

MIXED FINITE ELEMENT FORMULATION AND ERROR ESTIMATES BASED ON PROPER ORTHOGONAL DECOMPOSITION FOR THE NONSTATIONARY NAVIER–STOKES EQUATIONS*

ZHENDONG LUO[†], JING CHEN[‡], I. M. NAVON[§], AND XIAOZHONG YANG[†]

Abstract. In this paper, proper orthogonal decomposition (POD) is used for model reduction of mixed finite element (MFE) for the nonstationary Navier–Stokes equations and error estimates between a reference solution and the POD solution of reduced MFE formulation are derived. The basic idea of this reduction technique is that ensembles of data are first compiled from transient solutions computed equation system derived with the usual MFE method for the nonstationary Navier–Stokes equations or from physics system trajectories by drawing samples of experiments and interpolation (or data assimilation), and then the basis functions of the usual MFE method are substituted with the POD basis functions reconstructed by the elements of the ensemble to derive the POD-reduced MFE formulation for the nonstationary Navier–Stokes equations. It is shown by considering numerical simulation results obtained for the illustrating example of cavity flows that the error between POD solution of reduced MFE formulation and the reference solution is consistent with theoretical results. Moreover, it is also shown that this result validates the feasibility and efficiency of the POD method.

Key words. mixed finite element method, proper orthogonal decomposition, the nonstationary Navier–Stokes equations, error estimate

1. Introduction. The mixed finite element (MFE) method is one of the important approaches for solving systems of partial differential equations, for example, the nonstationary Navier–Stokes equations (see [1], [2], or [3]). However, the computational model for the fully discrete system of MFE solutions of the nonstationary Navier–Stokes equations yields very large systems that are computationally intensive. Thus, an important problem is how to simplify the computational load and save time-consuming calculations and resource demands in the actual computational process in a way that guarantees a sufficiently accurate and efficient numerical solution. Proper orthogonal decomposition (POD), also known as Karhunen–Loève expansions in signal analysis and pattern recognition (see [4]), or principal component analysis in statistics (see [5]), or the method of empirical orthogonal functions in geophysical fluid dynamics (see [6], [7]) or meteorology (see [8]), is a technique offering adequate approximation for representing fluid flow with reduced number of degrees of freedom, i.e., with lower dimensional models (see [9]), so as to alleviate the computational load

and provide CPU and memory requirements savings, and has found widespread applications in problems related to the approximation of large-scale models. Although the basic properties of the POD method are well established and studies have been conducted to evaluate the suitability of this technique for various fluid flows (see [10]–[12]), its applicability and limitations for reduced MFE formulation for the non-stationary Navier–Stokes equations are not well documented.

The POD method mainly provides a useful tool for efficiently approximating a large amount of data. The method essentially provides an orthogonal basis for representing the given data in a certain least squares optimal sense; that is, it provides a way to find optimal lower dimensional approximations of the given data. In addition to being optimal in a least squares sense, POD has the property that it uses a modal decomposition that is completely data dependent and does not assume any prior knowledge of the process used to generate the data. This property is advantageous in situations where a priori knowledge of the underlying process is insufficient to warrant a certain choice of basis. Combined with the Galerkin projection procedure, POD provides a powerful method for generating lower dimensional models of dynamical systems that have a very large or even infinite dimensional phase space. In many cases, the behavior of a dynamic system is governed by characteristics or related structures, even though the ensemble is formed by a large number of different instantaneous solutions. POD method can capture these temporal and spatial structures by applying a statistical analysis to the ensemble of data. In fluid dynamics, Lumley first employed the POD technique to capture the large eddy coherent structures in a turbulent boundary layer (see [13]); this technique was further extended in [14], where a link between the turbulent structure and dynamics of a chaotic system was investigated. In Holmes, Lumley, and Berkooz [9], the overall properties of POD are reviewed and extended to widen the applicability of the method. The method of snapshots was introduced by Sirovich [15], and is widely used in applications to reduce the order of POD eigenvalue problem. Examples of these are optimal flow control problems [16]–[18] and turbulence [9, 13, 14, 19, 20]. In many applications of POD, the method is used to generate basis functions for a reduced order model, which can simplify and provide quicker assessment of the major features of the fluid dynamics for the purpose of flow control as demonstrated by Ko et al. [18] or design optimization as shown by Ly and Tran [17]. This application is used in a variety of other physical applications, such as in [17], which demonstrates an effective use of POD for a chemical vapor deposition reactor. Some reduced order finite difference models and MFE formulations and error estimates based on POD for the upper tropical Pacific Ocean model (see [21]–[25]), as well as a finite difference scheme based on POD for the nonstationary Navier–Stokes equations (see [26]), have been derived. However, to the best of our knowledge, there are no published results addressing the use of POD to reduce the MFE formulation of the nonlinear nonstationary Navier–Stokes equations and provide estimates of the error between reference solution and the POD-reduced MFE solution.

In this paper, POD is used to reduce the MFE formulation for the nonstationary Navier–Stokes equations and to derive error estimates between reference solution and the POD-reduced MFE solution. It is shown by considering the results obtained for numerical simulations of cavity flows that the error between POD solution of reduced MFE formulation and reference solution is consistent with theoretically derived results. Moreover, it is also shown that this validates the feasibility and efficiency of the POD method. Though Kunisch and Volkwein have presented some Galerkin POD methods for parabolic problems and a general equation in fluid dynamics in [27], [28],

our method is different from their approaches, whose methods consist of Galerkin projection where the original variables are substituted for a linear combination of POD basis and the error estimates of the velocity field therein are only derived, their POD basis being generated with the solution of the physical system at all time instances. In particular, the velocity field is only approximated in [28], while both velocity and pressure fields are simultaneously approximated in our present method. While the singular value decomposition approach combined with POD methodology is used to treat the Burgers equation in [29] and the cavity flow problem in [12], the error estimates have not completely been derived, in particular, a reduced formulation of MFE for the nonstationary Navier–Stokes has not yet been derived up to now. Therefore, our method improves upon existing methods since our POD basis is generated with the solution of the physical system only at time instances which are both useful and of interest for us.

2. MFE approximation for the nonstationary Navier–Stokes equations and snapshots generate. Let $\Omega \subset R^2$ be a bounded, connected, and polygonal domain. Consider the following nonstationary Navier–Stokes equations.

Problem (I) Find $\mathbf{u} = (u_1, u_2)$, p such that, for $T > 0$,

$$(2.1) \quad \begin{cases} \mathbf{u}_t - \nu \Delta \mathbf{u} + (\mathbf{u} \cdot \nabla) \mathbf{u} + \nabla p = \mathbf{f} & \text{in } \Omega \times (0, T), \\ \operatorname{div} \mathbf{u} = 0 & \text{in } \Omega \times (0, T), \\ \mathbf{u}(x, y, t) = \boldsymbol{\varphi}(x, y, t) & \text{on } \partial\Omega \times (0, T), \\ \mathbf{u}(x, y, 0) = \boldsymbol{\varphi}(x, y, 0) & \text{in } \Omega, \end{cases}$$

where \mathbf{u} represents the velocity vector, p the pressure, ν the constant inverse Reynolds number, $\mathbf{f} = (f_1, f_2)$ the given body force, and $\boldsymbol{\varphi}(x, y, t)$ the given vector function. For the sake of convenience, without lost generality, we may as well suppose that $\boldsymbol{\varphi}(x, y, t)$ is a zero vector in the following theoretical analysis.

The Sobolev spaces used in this context are standard (see [30]). For example, for a bounded domain Ω , we denote by $H^m(\Omega)$ ($m \geq 0$) and $L^2(\Omega) = H^0(\Omega)$ the usual Sobolev spaces equipped with the seminorm and the norm, respectively,

$$|v|_{m,\Omega} = \left\{ \sum_{|\boldsymbol{\alpha}|=m} \int_{\Omega} |D^{\boldsymbol{\alpha}} v|^2 dx dy \right\}^{1/2} \quad \text{and} \quad \|v\|_{m,\Omega} = \left\{ \sum_{i=0}^m |v|_{i,\Omega}^2 \right\}^{1/2} \quad \forall v \in H^m(\Omega),$$

where $\boldsymbol{\alpha} = (\alpha_1, \alpha_2)$, α_1 and α_2 are two nonnegative integers, and $|\boldsymbol{\alpha}| = \alpha_1 + \alpha_2$. Especially, the subspace $H_0^1(\Omega)$ of $H^1(\Omega)$ is denoted by

$$H_0^1(\Omega) = \{v \in H^1(\Omega); u|_{\partial\Omega} = 0\}.$$

Note that $\|\cdot\|_1$ is equivalent to $|\cdot|_1$ in $H_0^1(\Omega)$. Let $L_0^2(\Omega) = \{q \in L^2(\Omega); \int_{\Omega} q dx dy = 0\}$, which is a subspace of $L^2(\Omega)$. It is necessary to introduce the Sobolev spaces dependent on time t in order to discuss the generalized solution for Problem (I). Let Φ be a Hilbert space. For all $T > 0$ and integer $n \geq 0$, for $t \in [0, T]$, define

$$H^n(0, T; \Phi) = \left\{ v(t) \in \Phi; \int_0^T \sum_{i=0}^n \left\| \frac{d^i}{dt^i} v(t) \right\|_{\Phi}^2 dt < \infty \right\},$$

which is endowed with the norm

$$\|v\|_{H^n(\Phi)} = \left[\sum_{i=0}^n \int_0^T \left\| \frac{d^i}{dt^i} v(t) \right\|_{\Phi}^2 dt \right]^{\frac{1}{2}} \quad \text{for } v \in H^n(\Phi),$$

where $\|\cdot\|_{\Phi}$ is the norm of space Φ . Especially, if $n = 0$,

$$\|v\|_{L^2(\Phi)} = \left(\int_0^T \|v(t)\|_{\Phi}^2 dt \right)^{\frac{1}{2}}.$$

And define

$$L^\infty(0, T; \Phi) = \left\{ v(t) \in \Phi; \operatorname{ess\,sup}_{0 \leq t \leq T} \|v(t)\|_{\Phi} < \infty \right\},$$

which is endowed with the norm

$$\|v\|_{L^\infty(\Phi)} = \operatorname{ess\,sup}_{0 \leq t \leq T} \|v(t)\|_{\Phi}.$$

The variational formulation for Problem (I) is written as:

Problem (II) Find $(\mathbf{u}, p) \in H^1(0, T; X) \times L^2(0, T; M)$ such that, for all $t \in (0, T)$,

$$(2.2) \quad \begin{cases} (\mathbf{u}_t, \mathbf{v}) + a(\mathbf{u}, \mathbf{v}) + a_1(\mathbf{u}, \mathbf{u}, \mathbf{v}) - b(p, \mathbf{v}) = (\mathbf{f}, \mathbf{v}) \quad \forall \mathbf{v} \in X, \\ b(q, \mathbf{u}) = 0 \quad \forall q \in M, \\ \mathbf{u}(x, 0) = \mathbf{0} \quad \text{in } \Omega, \end{cases}$$

where $X = H_0^1(\Omega)^2$, $M = L_0^2(\Omega)$, $a(\mathbf{u}, \mathbf{v}) = \nu \int_{\Omega} \nabla \mathbf{u} \cdot \nabla \mathbf{v} dx dy$, $a_1(\mathbf{u}, \mathbf{v}, \mathbf{w}) = \frac{1}{2} \int_{\Omega} \sum_{i,j=1}^2 [u_i \frac{\partial v_j}{\partial x_i} w_j - u_i \frac{\partial w_j}{\partial x_i} v_j] dx dy$ ($\mathbf{u}, \mathbf{v}, \mathbf{w} \in X$), and $b(q, \mathbf{v}) = \int_{\Omega} q \operatorname{div} \mathbf{v} dx dy$.

Throughout the paper, C indicates a positive constant which is possibly different at different occurrences, being independent of the spatial and temporal mesh sizes, but may depend on Ω , the Reynolds number, and other parameters introduced in this paper.

The following property for trilinear form $a_1(\cdot, \cdot, \cdot)$ is often used (see [1], [2], or [3]).

$$(2.3) \quad a_1(\mathbf{u}, \mathbf{v}, \mathbf{w}) = -a_1(\mathbf{u}, \mathbf{w}, \mathbf{v}), \quad a_1(\mathbf{u}, \mathbf{v}, \mathbf{v}) = 0 \quad \forall \mathbf{u}, \mathbf{v}, \mathbf{w} \in X.$$

The bilinear forms $a(\cdot, \cdot)$ and $b(\cdot, \cdot)$ have the following properties:

$$(2.4) \quad a(\mathbf{v}, \mathbf{v}) \geq \nu |\mathbf{v}|_1^2 \quad \forall \mathbf{v} \in H_0^1(\Omega)^2,$$

$$(2.5) \quad |a(\mathbf{u}, \mathbf{v})| \leq \nu |u|_1 |\mathbf{v}|_1 \quad \forall \mathbf{u}, \mathbf{v} \in H_0^1(\Omega)^2,$$

and

$$(2.6) \quad \sup_{\mathbf{v} \in H_0^1(\Omega)^2} \frac{b(q, \mathbf{v})}{|\mathbf{v}|_1} \geq \beta \|q\|_0 \quad \forall q \in L_0^2(\Omega),$$

where β is a positive constant. Define

$$(2.7) \quad N = \sup_{\mathbf{u}, \mathbf{v}, \mathbf{w} \in X} \frac{a_1(\mathbf{u}, \mathbf{v}, \mathbf{w})}{|\mathbf{u}|_1 |\mathbf{v}|_1 |\mathbf{w}|_1}; \quad \|\mathbf{f}\|_{-1} = \sup_{\mathbf{v} \in X} \frac{(\mathbf{f}, \mathbf{v})}{|\mathbf{v}|_1}.$$

The following result is classical (see [1], [2], or [3]).

THEOREM 2.1. *If $\mathbf{f} \in L^2(0, T; H^{-1}(\Omega)^2)$, then Problem (II) has at least a solution which, in addition, is unique provided that $\nu^{-2} N \|\mathbf{f}\|_{L^2(H^{-1})} < 1$, and there is the following prior estimate:*

$$\|\nabla \mathbf{u}\|_{L^2(L^2)} \leq \nu^{-1} \|\mathbf{f}\|_{L^2(H^{-1})} \equiv R, \quad \|\mathbf{u}\|_0 \leq \nu^{-1/2} \|\mathbf{f}\|_{L^2(H^{-1})} = R\nu^{-1/2}.$$

Let $\{\mathfrak{S}_h\}$ be a uniformly regular family of triangulation of $\bar{\Omega}$ (see [31], [32], or [33]), indexed by a parameter $h = \max_{K \in \mathfrak{S}_h} \{h_K; h_K = \text{diam}(K)\}$; i.e., there exists a constant C , independent of h , such that $h \leq Ch_K \forall K \in \mathfrak{S}_h$.

We introduce the following finite element spaces X_h and M_h of X and M , respectively. Let $X_h \subset X$ (which is at least the piecewise polynomial vector space of m th degree, where $m > 0$ is integer) and $M_h \subset M$ (which is the piecewise polynomial space of $(m-1)$ th degree). Write $\hat{X}_h = X_h \times M_h$.

We assume that (X_h, M_h) satisfies the following approximate properties: $\forall v \in H^{m+1}(\Omega)^2 \cap X$ and $\forall q \in M \cap H^m(\Omega)$,

$$(2.8) \quad \inf_{\mathbf{v}_h \in X_h} \|\nabla(\mathbf{v} - \mathbf{v}_h)\|_0 \leq Ch^m |\mathbf{v}|_{m+1}, \quad \inf_{q_h \in M_h} \|q - q_h\|_0 \leq Ch^m |q|_m,$$

together the so-called discrete LBB condition, i.e.,

$$(2.9) \quad \sup_{\mathbf{v}_h \in X_h} \frac{b(q_h, \mathbf{v}_h)}{\|\nabla \mathbf{v}_h\|_0} \geq \beta \|q_h\|_0 \quad \forall q_h \in M_h,$$

where β is a positive constant independent of h .

There are many spaces X_h and M_h satisfying the discrete LBB conditions (see [33]). Here, we provide some examples as follows.

Example 2.1. The first-order finite element space $X_h \times M_h$ can be taken as Bernardi–Fortin–Raugel’s element (see [33]), i.e.,

$$(2.10) \quad \begin{aligned} X_h &= \{\mathbf{v}_h \in X \cap C^0(\bar{\Omega})^2; \mathbf{v}_h|_K \in P_K \quad \forall K \in \mathfrak{S}_h\}, \\ M_h &= \{\varphi_h \in M; \varphi_h|_K \in P_0(K) \quad \forall K \in \mathfrak{S}_h\}, \end{aligned}$$

where $P_K = P_1(K)^2 \oplus \text{span}\{\mathbf{n}_i \prod_{j=1, j \neq i}^3 \lambda_{Kj}, i = 1, 2, 3\}$, \mathbf{n}_i are the unit normal vector to side F_i opposite the vertex A_i of triangle K , λ_{Ki} ’s are the barycenter coordinates corresponding to the vertex A_i ($i = 1, 2, 3$) on K (see [31], [32]), and $P_m(K)$ is the space of piecewise polynomials of degree m on K .

Example 2.2. The first-order finite element space $X_h \times M_h$ can also be taken as Mini’s element, i.e.,

$$(2.11) \quad \begin{aligned} X_h &= \{\mathbf{v}_h \in X \cap C^0(\Omega)^2; \mathbf{v}_h|_K \in P_K \quad \forall K \in \mathfrak{S}_h\}, \\ M_h &= \{q_h \in M \cap C^0(\Omega); q_h|_K \in P_1(K) \quad \forall K \in \mathfrak{S}_h\}, \end{aligned}$$

where $P_K = P_1(K)^2 \oplus \text{span}\{\lambda_{K1}\lambda_{K2}\lambda_{K3}\}^2$.

Example 2.3. The second-order finite element space $X_h \times M_h$ can be taken as

$$(2.12) \quad \begin{aligned} X_h &= \{\mathbf{v}_h \in X \cap C^0(\Omega)^2; \mathbf{v}_h|_K \in P_K \quad \forall K \in \mathfrak{S}_h\}, \\ M_h &= \{q_h \in M \cap C^0(\Omega); q_h|_K \in P_1(K) \quad \forall K \in \mathfrak{S}_h\}, \end{aligned}$$

where $P_K = P_2(K)^2 \oplus \text{span}\{\lambda_{K1}\lambda_{K2}\lambda_{K3}\}^2$.

Example 2.4. The third-order finite element space $X_h \times M_h$ can be taken as

$$(2.13) \quad \begin{aligned} X_h &= \{\mathbf{v}_h \in X \cap C^0(\Omega)^2; \mathbf{v}_h|_K \in P_K \quad \forall K \in \mathfrak{S}_h\}, \\ M_h &= \{q_h \in M \cap C^0(\Omega); q_h|_K \in P_2(K) \quad \forall K \in \mathfrak{S}_h\}, \end{aligned}$$

where $P_K = P_3(K)^2 \oplus \text{span}\{\lambda_{K1}\lambda_{K2}\lambda_{K3}\lambda_{Ki}, i = 1, 2, 3\}^2$.

It has been proved (see [33]) that, for the finite element space $X_h \times M_h$ in Examples 2.1–2.4, there exists a restriction operator $r_h: X \rightarrow X_h$ such that, for any $\mathbf{v} \in X$,

$$(2.14) \quad \begin{aligned} b(q_h, \mathbf{v} - r_h \mathbf{v}) &= 0 \quad \forall q_h \in M_h, \quad \|\nabla r_h \mathbf{v}\|_0 \leq C \|\nabla \mathbf{v}\|_0, \\ \|\nabla(\mathbf{v} - r_h \mathbf{v})\|_0 &\leq Ch^k |\mathbf{v}|_{k+1} \quad \text{if } \mathbf{v} \in H^{k+1}(\Omega)^2, \quad k = 1, 2, 3. \end{aligned}$$

The spaces $X_h \times M_h$ used throughout the next part in this paper mean those in Examples 2.1–2.4, which satisfy the discrete LBB condition (2.9) (see [33] for a more detailed proof).

In order to find a numerical solution for Problem (II), it is necessary to discretize Problem (II). We introduce a MFE approximation for the spatial variable and FDS (finite difference scheme) for the time derivative. Let L be the positive integer, denote the time step increment by $k = T/L$ (T being the total time), $t^{(n)} = nk$, $0 \leq n \leq L$; $(\mathbf{u}_h^n, p_h^n) \in X_h \times M_h$ the MFE approximation corresponding to $(u(t^{(n)}), p(t^{(n)})) \equiv (\mathbf{u}^n, p^n)$. Then, applying a semi-implicit Euler scheme for the time integration, the fully discrete MFE solution for Problem (I) may be written as:

Problem (III) Find $(\mathbf{u}_h^n, p_h^n) \in X_h \times M_h$ such that

$$(2.15) \quad \begin{cases} (\mathbf{u}_h^n, \mathbf{v}_h) + ka(\mathbf{u}_h^n, \mathbf{v}_h) + ka_1(\mathbf{u}_h^{n-1}, \mathbf{u}_h^n, \mathbf{v}_h) - kb(p_h^n, \mathbf{v}_h) \\ \quad = k(f^n, \mathbf{v}_h) + (\mathbf{u}_h^{n-1}, \mathbf{v}_h) \quad \forall \mathbf{v}_h \in X_h, \\ b(q_h, \mathbf{u}_h^n) = 0 \quad \forall q_h \in M_h, \\ \mathbf{u}_h^0 = \mathbf{0} \quad \text{in } \Omega, \end{cases}$$

where $1 \leq n \leq L$.

Put $A(\mathbf{u}_h^n, \mathbf{v}_h) = (\mathbf{u}_h^n, \mathbf{v}_h) + ka(\mathbf{u}_h^n, \mathbf{v}_h) + ka_1(\mathbf{u}_h^{n-1}, \mathbf{u}_h^n, \mathbf{v}_h)$. Since $A(\mathbf{u}_h^n, \mathbf{u}_h^n) = (\mathbf{u}_h^n, \mathbf{u}_h^n) + ka(\mathbf{u}_h^n, \mathbf{u}_h^n) + ka_1(\mathbf{u}_h^{n-1}, \mathbf{u}_h^n, \mathbf{u}_h^n) = \|\mathbf{u}_h^n\|_0 + k\nu \|\nabla \mathbf{u}_h^n\|_0$, $A(\cdot, \cdot)$ is coercive in $X_h \times X_h$. And $kb(\cdot, \cdot)$ also satisfies the discrete LBB condition in $X_h \times M_h$; therefore, by MFE theory (see [1], [32], or [33]), we obtain the following result.

THEOREM 2.2. *Under the assumptions (2.8), (2.9), if $\mathbf{f} \in H^{-1}(\Omega)^2$ satisfies $N \sum_{i=1}^n \|\mathbf{f}^i\|_{-1} < \nu^2$, then Problem (III) has a unique solution $(\mathbf{u}_h^n, p_h^n) \in X_h \times M_h$ and satisfies*

$$(2.16) \quad \|\mathbf{u}_h^n\|_0^2 + k\nu \sum_{i=1}^n \|\nabla \mathbf{u}_h^i\|_0^2 \leq k\nu^{-1} \sum_{i=1}^n \|\mathbf{f}^i\|_{-1}^2,$$

if $k = O(h^2)$,

$$(2.17) \quad \|\mathbf{u}^n - \mathbf{u}_h^n\|_0 + k^{1/2} \sum_{i=1}^n \|\nabla(\mathbf{u}^i - \mathbf{u}_h^i)\|_0 + k^{1/2} \sum_{i=1}^n \|p^i - p_h^i\|_0 \leq C(h^m + k),$$

where $(\mathbf{u}, p) \in [H_0^1(\Omega) \cap H^{m+1}(\Omega)]^2 \times [H^m(\Omega) \cap M]$ is the exact solution for the problem (I), C is a constant dependent on $|\mathbf{u}^n|_{m+1}$ and $|p^n|_m$, and $1 \leq n \leq L$.

If Reynolds number $Re = \nu^{-1}$, triangulation parameter h , finite element space $X_h \times M_h$, the time step increment k , and \mathbf{f} are given, by solving Problem (III), we can obtain a solution ensemble $\{u_{1h}^n, u_{2h}^n, p_h^n\}_{n=1}^L$ for Problem (III). Then we choose ℓ (for example, $\ell = 20$, or 30 , in general, $\ell \ll L$) instantaneous solutions $\mathbf{U}_i(x, y) = (u_{1h}^{n_i}, u_{2h}^{n_i}, p_h^{n_i})^T$ ($1 \leq n_1 < n_2 < \dots < n_\ell \leq L$) (which are useful and of interest for us) from the L group of solutions $(u_{1h}^n, u_{2h}^n, p_h^n)^T$ ($1 \leq n \leq L$) for Problem (III), which are referred to as snapshots.

3. A reduced MFE formulation based POD technique for the nonstationary Navier–Stokes equations. In this section, we use the POD technique to deal with the snapshots in section 2 and produce an optimal representation in an average sense.

Recall $\hat{X}_h = X_h \times M_h$. For $\mathbf{U}_i(x, y) = (u_{1h}^{n_i}, u_{2h}^{n_i}, p_h^{n_i})^T$ ($i = 1, 2, \dots, \ell$) in section 2, we set

$$(3.1) \quad \mathcal{V} = \text{span}\{\mathbf{U}_1, \mathbf{U}_2, \dots, \mathbf{U}_\ell\},$$

and refer to \mathcal{V} as the ensemble consisting of the snapshots $\{\mathbf{U}_i\}_{i=1}^\ell$, at least one of which is assumed to be nonzero. Let $\{\boldsymbol{\psi}_j\}_{j=1}^l$ denote an orthonormal basis of \mathcal{V} with $l = \dim \mathcal{V}$. Then each member of the ensemble can be expressed as

$$(3.2) \quad \mathbf{U}_i = \sum_{j=1}^l (\mathbf{U}_i, \boldsymbol{\psi}_j)_{\hat{X}} \boldsymbol{\psi}_j \quad \text{for } i = 1, 2, \dots, \ell,$$

where $(\mathbf{U}_i, \boldsymbol{\psi}_j)_{\hat{X}} \boldsymbol{\psi}_j = ((\nabla \mathbf{u}_h^{n_i}, \nabla \boldsymbol{\psi}_{u_j})_0 \boldsymbol{\psi}_{u_j}, (p_h^{n_i}, \boldsymbol{\psi}_{p_j})_0 \boldsymbol{\psi}_{p_j})$, $(\cdot, \cdot)_0$ is L^2 -inner product, and $\boldsymbol{\psi}_{u_j}$ and $\boldsymbol{\psi}_{p_j}$ are orthonormal bases corresponding to \mathbf{u} and p , respectively.

Since $\mathcal{V} = \text{span}\{\mathbf{U}_1, \mathbf{U}_2, \dots, \mathbf{U}_\ell\} = \text{span}\{\boldsymbol{\psi}_1, \boldsymbol{\psi}_2, \dots, \boldsymbol{\psi}_l\}$, $b(p_h^{n_i}, \mathbf{u}_h^{n_j}) = 0$ ($1 \leq i, j \leq \ell$) implies $b(\boldsymbol{\psi}_{p_i}, \boldsymbol{\psi}_{u_j}) = 0$ ($1 \leq i, j \leq l$).

DEFINITION 3.1. *The method of POD consists in finding the orthonormal basis such that for every d ($1 \leq d \leq l$) the mean square error between the elements \mathbf{U}_i ($1 \leq i \leq \ell$) and corresponding d th partial sum of (3.2) is minimized on average:*

$$(3.3) \quad \min_{\{\boldsymbol{\psi}_j\}_{j=1}^d} \frac{1}{\ell} \sum_{i=1}^{\ell} \left\| \mathbf{U}_i - \sum_{j=1}^d (\mathbf{U}_i, \boldsymbol{\psi}_j)_{\hat{X}} \boldsymbol{\psi}_j \right\|_{\hat{X}}^2$$

such that

$$(3.4) \quad (\boldsymbol{\psi}_i, \boldsymbol{\psi}_j)_{\hat{X}} = \delta_{ij} \quad \text{for } 1 \leq i \leq d, 1 \leq j \leq i,$$

where $\|\mathbf{U}_i\|_{\hat{X}} = [\|\nabla \mathbf{u}_h^{n_i}\|_0^2 + \|\nabla \mathbf{u}_{2h}^{n_i}\|_0^2 + \|p_h^{n_i}\|_0^2]^{\frac{1}{2}}$. A solution $\{\boldsymbol{\psi}_j\}_{j=1}^d$ of (3.3) and (3.4) is known as a POD basis of rank d .

We introduce the correlation matrix $\mathbf{K} = (K_{ij})_{\ell \times \ell} \in R^{\ell \times \ell}$ corresponding to the snapshots $\{\mathbf{U}_i\}_{i=1}^\ell$ by

$$(3.5) \quad K_{ij} = \frac{1}{\ell} (\mathbf{U}_i, \mathbf{U}_j)_{\hat{X}}.$$

The matrix \mathbf{K} is positive semidefinite and has rank l . The solutions of (3.3) and (3.4) can be found in [10], [15], or [28], for example.

PROPOSITION 3.2. *Let $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_l > 0$ denote the positive eigenvalues of \mathbf{K} and $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_l$ the associated orthonormal eigenvectors. Then a POD basis of rank $d \leq l$ is given by*

$$(3.6) \quad \boldsymbol{\psi}_i = \frac{1}{\sqrt{\lambda_i}} \sum_{j=1}^{\ell} (\mathbf{v}_i)_j \mathbf{U}_j,$$

where $(\mathbf{v}_i)_j$ denotes the j th component of the eigenvector \mathbf{v}_i . Furthermore, the following error formula holds:

$$(3.7) \quad \frac{1}{\ell} \sum_{i=1}^{\ell} \left\| \mathbf{U}_i - \sum_{j=1}^d (\mathbf{U}_i, \boldsymbol{\psi}_j)_{\hat{X}} \boldsymbol{\psi}_j \right\|_{\hat{X}}^2 = \sum_{j=d+1}^l \lambda_j.$$

Let $\mathcal{V}^d = \text{span}\{\boldsymbol{\psi}_1, \boldsymbol{\psi}_2, \dots, \boldsymbol{\psi}_d\}$ and $X^d \times M^d = \mathcal{V}^d$ with $X^d \subset X_h \subset X$ and $M^d \subset M_h \subset M$. Set the Ritz-projection $P^h: X \rightarrow X_h$ (if P^h is restricted to Ritz-projection from X_h to X^d , it is written as P^d) such that $P^h|_{X_h} = P^d: X_h \rightarrow X^d$ and $P^h: X \setminus X_h \rightarrow X_h \setminus X^d$ and L^2 -projection $\rho^d: M \rightarrow M^d$ denoted by, respectively,

$$(3.8) \quad a(P^h \mathbf{u}, \mathbf{v}_h) = a(\mathbf{u}, \mathbf{v}_h) \quad \forall \mathbf{v}_h \in X_h$$

and

$$(3.9) \quad (\rho^d p, q_d)_0 = (p, q_d)_0 \quad \forall q_d \in M^d,$$

where $\mathbf{u} \in X$ and $p \in M$. Due to (3.8) and (3.9) the linear operators P^h and ρ^d are well-defined and bounded:

$$(3.10) \quad \|\nabla(P^d \mathbf{u})\|_0 \leq \|\nabla \mathbf{u}\|_0, \quad \|\rho^d p\|_0 \leq \|p\|_0 \quad \forall \mathbf{u} \in X \text{ and } p \in M.$$

LEMMA 3.3. *For every d ($1 \leq d \leq l$) the projection operators P^d and ρ^d satisfy, respectively,*

$$(3.11) \quad \frac{1}{\ell} \sum_{i=1}^{\ell} \|\nabla(\mathbf{u}_h^{n_i} - P^d \mathbf{u}_h^{n_i})\|_0^2 \leq \sum_{j=d+1}^l \lambda_j,$$

$$(3.12) \quad \frac{1}{\ell} \sum_{i=1}^{\ell} \|\mathbf{u}_h^{n_i} - P^d \mathbf{u}_h^{n_i}\|_0^2 \leq Ch^2 \sum_{j=d+1}^l \lambda_j,$$

and

$$(3.13) \quad \frac{1}{\ell} \sum_{i=1}^{\ell} \|p_h^{n_i} - \rho^d p_h^{n_i}\|_0^2 \leq \sum_{j=d+1}^l \lambda_j,$$

where $\mathbf{u}_h^{n_i} = (u_{1h}^{n_i}, u_{2h}^{n_i})$ and $(u_{1h}^{n_i}, u_{2h}^{n_i}, p_h^{n_i})^T \in \mathcal{V}$.

Proof. For any $\mathbf{u} \in X$ we deduce from (3.8) that

$$\begin{aligned} \nu \|\nabla(\mathbf{u} - P^h \mathbf{u})\|_0^2 &= a(\mathbf{u} - P^h \mathbf{u}, \mathbf{u} - P^h \mathbf{u}) \\ &= a(\mathbf{u} - P^h \mathbf{u}, \mathbf{u} - \mathbf{v}_h) \\ &\leq \nu \|\nabla(\mathbf{u} - P^h \mathbf{u})\|_0 \|\nabla(\mathbf{u} - \mathbf{v}_h)\|_0 \quad \forall \mathbf{v}_h \in X_h. \end{aligned}$$

Therefore, we obtain that

$$(3.14) \quad \|\nabla(\mathbf{u} - P^h \mathbf{u})\|_0 \leq \|\nabla(\mathbf{u} - \mathbf{v}_h)\|_0 \quad \forall \mathbf{v}_h \in X_h.$$

If $\mathbf{u} = \mathbf{u}_h^{n_i}$, and P^h is restricted to Ritz-projection from X_h to X^d , i.e., $P^h \mathbf{u}_h^{n_i} = P^d \mathbf{u}_h^{n_i} \in X^d$, taking $\mathbf{v}_h = \sum_{j=1}^d (\mathbf{u}_h^{n_i}, \boldsymbol{\psi}_{u_j})_X \boldsymbol{\psi}_{u_j} \in X^d \subset X_h$ (where $\boldsymbol{\psi}_{u_j}$ is the component of $\boldsymbol{\psi}_j$ corresponding to \mathbf{u}) in (3.14), we can obtain (3.11) from (3.7).

In order to prove (3.12), we consider the following variational problem:

$$(3.15) \quad (\nabla \mathbf{w}, \nabla \mathbf{v}) = (\mathbf{u} - P^h \mathbf{u}, \mathbf{v}) \quad \forall \mathbf{v} \in X.$$

Thus, $\mathbf{w} \in [H_0^1(\Omega) \cap H^2(\Omega)]^2$ and satisfies $\|\mathbf{w}\|_2 \leq C \|\mathbf{u} - P^h \mathbf{u}\|_0$. Taking $\mathbf{v} = \mathbf{u} - P^h \mathbf{u}$ in (3.15), from (3.14) we obtain that

$$\begin{aligned} \|\mathbf{u} - P^h \mathbf{u}\|_0^2 &= (\nabla \mathbf{w}, \nabla(\mathbf{u} - P^h \mathbf{u})) \\ (3.16) \quad &= (\nabla(\mathbf{w} - \mathbf{w}_h), \nabla(\mathbf{u} - P^h \mathbf{u})) \\ &\leq \|\nabla(\mathbf{w} - \mathbf{w}_h)\|_0 \|\nabla(\mathbf{u} - P^d \mathbf{u})\|_0 \quad \forall \mathbf{w}_h \in X_h. \end{aligned}$$

Taking $\mathbf{w}_h = r_h \mathbf{w}$, from (2.14) and (3.16) we have

$$\begin{aligned} \|\mathbf{u} - P^h \mathbf{u}\|_0^2 &\leq Ch \|\mathbf{w}\|_2 \|\nabla(\mathbf{u} - P^h \mathbf{u})\|_0 \\ &\leq Ch \|\mathbf{u} - P^h \mathbf{u}\|_0 \|\nabla(\mathbf{u} - P^h \mathbf{u})\|_0. \end{aligned}$$

Thus, we obtain that

$$(3.17) \quad \|\mathbf{u} - P^h \mathbf{u}\|_0 \leq Ch \|\nabla(\mathbf{u} - P^h \mathbf{u})\|_0.$$

Therefore, if $\mathbf{u} = \mathbf{u}_h^{n_i}$ and P^h is restricted to Ritz-projection from X_h to X^d , i.e., $P^h \mathbf{u}_h^{n_i} = P^d \mathbf{u}_h^{n_i} \in X^d$, by (3.17) and (3.11) we obtain (3.12).

Using Hölder inequality and (3.9) can yield

$$\begin{aligned} \|p_h^{n_i} - \rho^d p_h^{n_i}\|_0^2 &= (p_h^{n_i} - \rho^d p_h^{n_i}, p_h^{n_i} - \rho^d p_h^{n_i}) \\ &= (p_h^{n_i} - \rho^d p_h^{n_i}, p_h^{n_i} - q_d) \\ &\leq \|p_h^{n_i} - \rho^d p_h^{n_i}\|_0 \|p_h^{n_i} - q_d\|_0 \quad \forall q_d \in M^d, \end{aligned}$$

and consequently,

$$(3.18) \quad \|p_h^{n_i} - \rho^d p_h^{n_i}\|_0 \leq \|p_h^{n_i} - q_d\|_0 \quad \forall q_d \in M^d.$$

Taking $q_d = \sum_{j=1}^d (p_h^{n_i}, \psi_{pj})_0 \psi_{pj}$ (where ψ_{pj} is the component of $\boldsymbol{\psi}_j$ corresponding to p) in (3.18), from (3.7) we can obtain (3.13), which completes the proof of Lemma 3.3. \square

Thus, using $\mathcal{V}^d = X^d \times M^d$, we can obtain the reduced formulation for Problem (III) as follows.

Problem (IV) Find $(\mathbf{u}_d^n, p_d^n) \in \mathcal{V}^d$ such that

$$(3.19) \quad \begin{cases} (\mathbf{u}_d^n, \mathbf{v}_d) + ka(\mathbf{u}_d^n, \mathbf{v}_d) + ka_1(\mathbf{u}_d^{n-1}, \mathbf{u}_d^n, \mathbf{v}_d) - kb(p_d^n, \mathbf{v}_d) \\ \quad = k(f^n, \mathbf{v}_d) + (\mathbf{u}_d^{n-1}, \mathbf{v}_d) \quad \forall \mathbf{v}_d \in X^d, \\ b(q_d, \mathbf{u}_d^n) = 0 \quad \forall q_d \in M^d, \\ \mathbf{u}_d^0 = \mathbf{0}, \end{cases}$$

where $1 \leq n \leq L$.

Remark 3.4. Problem (IV) is a reduced MFE formulation based on the POD technique for Problem (III), since it includes only $3d$ ($d \ll l \leq \ell \ll L$) degrees of freedom and is independent of the spatial grid scale h , while Problem (III) includes $3N_p + N_K \approx 5N_p$ for Mini's element of Example 2.2 (where N_p is the number of vertices in \mathfrak{S}_h and N_K the number of elements in \mathfrak{S}_h) and $3d \ll 5N_p$ (for example, in section 5, $d \leq 7$, while $N_p = 32 \times 32 = 1024$). The number of degrees of freedom of Example 2.1 is also approximately $5N_p$, but Example 2.3 and Example 2.4 are more. When one computes actual problems, one may obtain the ensemble of snapshots from physical system trajectories by drawing samples from experiments and interpolation (or data assimilation). For example, for weather forecast, one can use the previous weather prediction results to construct the ensemble of snapshots, and then restructure the POD basis for the ensemble of snapshots by above (3.3)–(3.6), and finally combine it with a Galerkin projection to derive a reduced order dynamical system; i.e., one needs only to solve the above Problem (IV), which has only $3d$ degrees of freedom,

but it is unnecessary to solve Problem (III). Thus, the forecast of future weather change can be quickly simulated, which is a result of major importance for real-life applications. Since the development and change of a large number of future nature phenomena are closely related to previous results (for example, weather change, biology anagenesis, and so on), using existing results as snapshots in order to structure POD basis, by solving corresponding PDEs, one may truly capture the laws of change of natural phenomena. Therefore, these POD methods provide useful and important applications.

4. Existence and error analysis of the solution of the reduced MFE formulation based on POD technique for the nonstationary Navier–Stokes equations. This section is devoted to discussing the existence and error estimates for Problem (IV).

We see from (3.6) that $\mathcal{V}^d = X^d \times M^d \subset \mathcal{V} \subset X_h \times M_h \subset X \times M$, where $X_h \times M_h$ is one of those spaces in Examples 2.1–2.4. Therefore, we have in the following result.

LEMMA 4.1. *There exists also an operator $r_d: X_h \rightarrow X^d$ such that, for all $\mathbf{u}_h \in X_h$,*

$$(4.1) \quad b(q_d, \mathbf{u}_h - r_d \mathbf{u}_h) = 0 \quad \forall q_d \in M^d, \quad \|\nabla r_d \mathbf{u}_h\|_0 \leq c \|\nabla \mathbf{u}_h\|_0,$$

and, for every d ($1 \leq d \leq l$),

$$(4.2) \quad \frac{1}{\ell} \sum_{i=1}^{\ell} \|\nabla(\mathbf{u}_h^{n_i} - r_d \mathbf{u}_h^{n_i})\|_0^2 \leq C \sum_{j=d+1}^l \lambda_j.$$

Proof. We use the Mini's and the second finite element as examples. Noting that for any $q_d \in M^d$ and $K \in \mathfrak{S}_h$, $\nabla q_d|_K \in P_0(K)$, using Green formula, we have

$$\begin{aligned} b(q_d, \mathbf{u}_h - r_d \mathbf{u}_h) &= - \int_{\Omega} \nabla q_d (\mathbf{u}_h - r_d \mathbf{u}_h) dx dy \\ &= - \sum_{K \in \mathfrak{S}_h} \nabla q_d|_K \int_K (\mathbf{u}_h - r_d \mathbf{u}_h) dx dy. \end{aligned}$$

Define r_d as follows:

$$(4.3) \quad r_d \mathbf{u}_h|_K = P^d \mathbf{u}_h|_K + \gamma_K \lambda_{K1} \lambda_{K2} \lambda_{K3} \quad \forall \mathbf{v}_h \in X_h \text{ and } K \in \mathfrak{S}_h,$$

where $\gamma_K = \int_K (\mathbf{u}_h - P^d \mathbf{u}_h) dx / \int_K \lambda_{K1} \lambda_{K2} \lambda_{K3} dx$. Thus, the first equality of (4.1) holds. Using (3.10)–(3.12) yields the inequality of (4.1). Then, if $\mathbf{u}_h = \mathbf{u}_h^{n_i}$, using (3.11)–(3.12), by simply computing we deduce (4.2). \square

Set

$$\begin{aligned} V &= \{\mathbf{v} \in X; b(q, \mathbf{v}) = 0 \quad \forall q \in M\}, \\ V_h &= \{\mathbf{v}_h \in X_h; b(q_h, \mathbf{v}_h) = 0 \quad \forall q_h \in M_h\}, \\ V^d &= \{\mathbf{v}_d \in X^d; b(q_d, \mathbf{v}_d) = 0 \quad \forall q_d \in M^d\}. \end{aligned}$$

Using dual principle and inequalities (3.11) and (3.12), we deduce the following result (see [1], [31]–[33]).

LEMMA 4.2. *There exists an operator $R_d: V \cup V_h \rightarrow V^d$ such that, for all $\mathbf{v} \in V \cup V_h$,*

$$(\mathbf{v} - R_d \mathbf{v}, \mathbf{v}_d) = 0 \quad \forall \mathbf{v}_d \in V^d, \quad \|\nabla R_d \mathbf{v}\|_0 \leq C \|\nabla \mathbf{v}\|_0,$$

and, for every d ($1 \leq d \leq l$),

$$(4.4) \quad \frac{1}{\ell} \sum_{i=1}^{\ell} \|\mathbf{u}_h^{n_i} - R_d \mathbf{u}_h^{n_i}\|_{-1}^2 \leq \frac{Ch^2}{\ell} \sum_{i=1}^{\ell} \|\nabla(\mathbf{u}_h^{n_i} - R_d \mathbf{u}_h^{n_i})\|_0^2 \leq Ch^2 \sum_{j=d+1}^l \lambda_j,$$

where $\|\cdot\|_{-1}$ denotes the normal of space $H^{-1}(\Omega)^2$ (see (2.7)).

We have the following result for the solution of Problem (IV).

THEOREM 4.3. *Under the hypotheses of Theorem 2.2, Problem (IV) has a unique solution $(\mathbf{u}_d^n, p_d^n) \in X^d \times M^d$ and satisfies*

$$(4.5) \quad \|\mathbf{u}_d^n\|_0^2 + k\nu \sum_{i=1}^n \|\nabla \mathbf{u}_d^i\|_0^2 \leq k\nu^{-1} \sum_{i=1}^n \|f^i\|_{-1}^2.$$

Proof. Using the same technique as the proof of Theorem 2.2, we could prove that Problem (IV) has a unique solution $(\mathbf{u}_d^n, p_d^n) \in X^d \times M^d$ and satisfies (4.5). \square

In the following theorem, error estimates of the solution for Problem (IV) are derived.

THEOREM 4.4. *Under the hypotheses of Theorem 2.2, if $h^2 = O(k)$, $k = O(\ell^{-2})$, snapshots are equably taken, and $\mathbf{f} \in H^{-1}(\Omega)^2$ satisfies $2\nu^{-2}N \sum_{i=1}^n \|\mathbf{f}^i\|_{-1} < 1$, then the error between the solution (\mathbf{u}_d^n, p_d^n) for Problem (IV) and the solution (\mathbf{u}_h^n, p_h^n) for Problem (III) has the following error estimates, for $n = 1, 2, \dots, L$,*

$$(4.6) \quad \begin{aligned} & \|\mathbf{u}_h^{n_i} - \mathbf{u}_d^{n_i}\|_0 + k^{1/2} \|p_h^{n_i} - p_d^{n_i}\|_0 + k^{1/2} \|\nabla(\mathbf{u}_h^{n_i} - \mathbf{u}_d^{n_i})\|_0 \\ & \leq C \left(k^{1/2} \sum_{j=d+1}^l \lambda_j \right)^{1/2}, \quad i = 1, 2, \dots, \ell; \\ & \|\mathbf{u}_h^n - \mathbf{u}_d^n\|_0 + k^{1/2} \|p_h^n - p_d^n\|_0 + k^{1/2} \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0 \\ & \leq Ck + C \left(k^{1/2} \sum_{j=d+1}^l \lambda_j \right)^{1/2}, \quad n \notin \{n_1, n_2, \dots, n_\ell\}. \end{aligned}$$

Proof. Subtracting Problem (IV) from Problem (III), taking $\mathbf{v}_h = \mathbf{v}_d \in X^d$ and $q_h = q_d \in M^d$, can yield

$$(4.7) \quad \begin{aligned} & (\mathbf{u}_h^n - \mathbf{u}_d^n, \mathbf{v}_d) + ka(\mathbf{u}_h^n - \mathbf{u}_d^n, \mathbf{v}_d) - kb(p_h^n - p_d^n, \mathbf{v}_d) + ka_1(\mathbf{u}_h^{n-1}, \mathbf{u}_h^n, \mathbf{v}_d) \\ & - ka_1(\mathbf{u}_d^{n-1}, \mathbf{u}_d^n, \mathbf{v}_d) = (\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1}, \mathbf{v}_d) \quad \forall \mathbf{v}_d \in X^d, \end{aligned}$$

$$(4.8) \quad b(q_d, \mathbf{u}_h^n - \mathbf{u}_d^n) = 0 \quad \forall q_d \in M^d,$$

$$(4.9) \quad \mathbf{u}_h^0 - \mathbf{u}_d^0 = \mathbf{0}.$$

We obtain, from (2.3), (2.7), Theorem 2.2, and Theorem 4.3, by Hölder inequality, that

$$(4.10) \quad \begin{aligned} & |a_1(\mathbf{u}_h^{n-1}, \mathbf{u}_h^n, \mathbf{v}_d) - a_1(\mathbf{u}_d^{n-1}, \mathbf{u}_d^n, \mathbf{v}_d)| \\ & = |a_1(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1}, \mathbf{u}_h^n, \mathbf{v}_d) + a_1(\mathbf{u}_d^{n-1}, \mathbf{u}_h^n - \mathbf{u}_d^n, \mathbf{v}_d)| \\ & \leq C[\|\nabla(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0 + \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0] \|\nabla \mathbf{v}_d\|_0, \end{aligned}$$

especially, if $\mathbf{v}_d = P^d \mathbf{u}_h^n - \mathbf{u}_d^n$, then

$$\begin{aligned}
& |a_1(\mathbf{u}_h^{n-1}, \mathbf{u}_h^n, P^d \mathbf{u}_h^n - \mathbf{u}_d^n) - a_1(\mathbf{u}_d^{n-1}, \mathbf{u}_d^n, P^d \mathbf{u}_h^n - \mathbf{u}_d^n)| \\
&= |a_1(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1}, \mathbf{u}_h^n, P^d \mathbf{u}_h^n - \mathbf{u}_d^n) + a_1(\mathbf{u}_d^{n-1}, \mathbf{u}_h^n - \mathbf{u}_d^n, P^d \mathbf{u}_h^n - \mathbf{u}_d^n)| \\
(4.11) \quad &= |a_1(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1}, \mathbf{u}_h^n, P^d \mathbf{u}_h^n - \mathbf{u}_h^n) + a_1(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1}, \mathbf{u}_h^n, \mathbf{u}_h^n - \mathbf{u}_d^n)| \\
&\quad + |a_1(\mathbf{u}_d^{n-1}, \mathbf{u}_h^n - \mathbf{u}_d^n, P^d \mathbf{u}_h^n - \mathbf{u}_h^n)| \\
&\leq C \|\nabla(\mathbf{u}_h^n - P^d \mathbf{u}_h^n)\|_0^2 + \varepsilon [\|\nabla(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0^2 + \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0^2] \\
&\quad + N \|\nabla \mathbf{u}_h^n\|_0 \|\nabla(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0 \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0,
\end{aligned}$$

where ε is a small positive constant which can be chosen arbitrarily.

Write $\bar{\partial}_t \mathbf{u}_h^n = [\mathbf{u}_h^n - \mathbf{u}_h^{n-1}]/k$ and note that $\bar{\partial}_t \mathbf{u}_d^n \in V^d$ and $\bar{\partial}_t R_d \mathbf{u}_h^n \in V^d$. From Lemma 4.2, (4.7), and (4.10), we have that

$$\begin{aligned}
& \|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t \mathbf{u}_d^n\|_{-1} \leq \|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t R_d \mathbf{u}_h^n\|_{-1} + \|\bar{\partial}_t R_d \mathbf{u}_h^n - \bar{\partial}_t \mathbf{u}_d^n\|_{-1} \\
&\leq \|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t R_d \mathbf{u}_h^n\|_{-1} + \sup_{\mathbf{v} \in V} \frac{(\bar{\partial}_t R_d \mathbf{u}_h^n - \bar{\partial}_t \mathbf{u}_d^n, \mathbf{v})}{\|\nabla \mathbf{v}\|_0} \\
&= \|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t R_d \mathbf{u}_h^n\|_{-1} + \sup_{\mathbf{v} \in V} \frac{(\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t \mathbf{u}_d^n, R_d \mathbf{v})}{\|\nabla \mathbf{v}\|_0} \\
(4.12) \quad &= \|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t R_d \mathbf{u}_h^n\|_{-1} + \sup_{\mathbf{v} \in V} \frac{1}{\|\nabla \mathbf{v}\|_0} [b(p_h^n - p_d^n, R_d \mathbf{v}) \\
&\quad - a(\mathbf{u}_h^n - \mathbf{u}_d^n, R_d \mathbf{v}) - a_1(\mathbf{u}_h^{n-1}, \mathbf{u}_h^n, R_d \mathbf{v}) + a_1(\mathbf{u}_d^{n-1}, \mathbf{u}_d^n, R_d \mathbf{v})] \\
&= \|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t R_d \mathbf{u}_h^n\|_{-1} + \sup_{\mathbf{v} \in V} \frac{1}{\|\nabla \mathbf{v}\|_0} [b(p_h^n - \rho^d p_h^n, R_d \mathbf{v}) \\
&\quad - a(\mathbf{u}_h^n - \mathbf{u}_d^n, R_d \mathbf{v}) - a_1(\mathbf{u}_h^{n-1}, \mathbf{u}_h^n, R_d \mathbf{v}) + a_1(\mathbf{u}_d^{n-1}, \mathbf{u}_d^n, R_d \mathbf{v})] \\
&\leq \|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t R_d \mathbf{u}_h^n\|_{-1} + C [\|p_h^n - \rho^d p_h^n\|_0 \\
&\quad + \|\nabla(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0 + \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0].
\end{aligned}$$

By using (2.9), (4.7), (4.10), (4.12), and Lemma 4.1, we have that

$$\begin{aligned}
& \beta \|\rho^d p_h^n - p_d^n\|_0 \leq \sup_{\mathbf{v}_h \in X_h} \frac{b(\rho^d p_h^n - p_d^n, \mathbf{v}_h)}{\|\nabla \mathbf{v}_h\|_0} = \sup_{\mathbf{v}_h \in X_h} \frac{b(p_h^n - p_d^n, r_d \mathbf{v}_h)}{\|\nabla \mathbf{v}_h\|_0} \\
&= \sup_{\mathbf{v}_h \in X_h} \frac{1}{\|\nabla \mathbf{v}_h\|_0} [(\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t \mathbf{u}_d^n, r_d \mathbf{v}_h) + a(\mathbf{u}_h^n - \mathbf{u}_d^n, r_d \mathbf{v}_h) \\
(4.13) \quad &\quad + a_1(\mathbf{u}_h^{n-1}, \mathbf{u}_h^n, r_d \mathbf{v}_h) - a_1(\mathbf{u}_d^{n-1}, \mathbf{u}_d^n, r_d \mathbf{v}_h)] \\
&\leq C [\|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t \mathbf{u}_d^n\|_{-1} + \|\nabla(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0 + \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0] \\
&\leq C [\|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t R_d \mathbf{u}_h^n\|_{-1} + \|p_h^n - \rho^d p_h^n\|_0 \\
&\quad + \|\nabla(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0 + \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0].
\end{aligned}$$

Thus, we obtain that

$$\begin{aligned}
(4.14) \quad & \|p_h^n - p_d^n\|_0 \leq \|p_h^n - \rho^d p_h^n\|_0 + \|\rho^d p_h^n - p_d^n\|_0 \leq C [\|\nabla(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0 \\
&\quad + \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0 + \|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t R_d \mathbf{u}_h^n\|_{-1} + \|p_h^n - \rho^d p_h^n\|_0].
\end{aligned}$$

Taking $\mathbf{v}_d = P^d \mathbf{u}_h^n - \mathbf{u}_d^n$ in (4.7), it follows from (4.8) that

$$\begin{aligned}
(4.15) \quad & (\mathbf{u}_h^n - \mathbf{u}_d^n, \mathbf{u}_h^n - \mathbf{u}_d^n) - (\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1}, \mathbf{u}_h^n - \mathbf{u}_d^n) + ka(\mathbf{u}_h^n - \mathbf{u}_d^n, \mathbf{u}_h^n - \mathbf{u}_d^n) \\
& = (\mathbf{u}_h^n - \mathbf{u}_d^n - (\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1}), \mathbf{u}_h^n - P^d \mathbf{u}_h^n) + ka(\mathbf{u}_h^n - P^d \mathbf{u}_h^n, \mathbf{u}_h^n - P^d \mathbf{u}_h^n) \\
& \quad + kb(p_h^n - \rho^d p_h^n, \mathbf{u}_h^n - \mathbf{u}_d^n) + kb(p_h^n - p_d^n, \mathbf{u}_h^n - P^d \mathbf{u}_h^n) \\
& \quad - ka_1(\mathbf{u}_h^{n-1}, \mathbf{u}_h^n, P^d \mathbf{u}_h^n - \mathbf{u}_d^n) + ka_1(\mathbf{u}_d^{n-1}, \mathbf{u}_d^n, P^d \mathbf{u}_h^n - \mathbf{u}_d^n).
\end{aligned}$$

Thus, noting that $a(a-b) = [a^2 - b^2 + (a-b)^2]/2$ (for $a \geq 0$ and $b \geq 0$), by (4.11), (4.14), Hölder inequality, Cauchy inequality, and Proposition 3.2, we obtain that

$$\begin{aligned}
(4.16) \quad & \frac{1}{2} [\|\mathbf{u}_h^n - \mathbf{u}_d^n\|_0^2 - \|\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1}\|_0^2 + \|\mathbf{u}_h^n - \mathbf{u}_d^n - (\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0^2] \\
& + \nu k \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0^2 \leq \frac{1}{2} \|\mathbf{u}_h^n - \mathbf{u}_d^n - (\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0^2 + \frac{1}{2} \|\mathbf{u}_h^n - P^d \mathbf{u}_h^n\|_0^2 \\
& + Ck \|\nabla(\mathbf{u}_h^n - P^d \mathbf{u}_h^n)\|_0^2 + Ck \|p_h^n - \rho^d p_h^n\|_0^2 + C \|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t R_d \mathbf{u}_h^n\|_{-1}^2 \\
& + (\varepsilon_1 + C\varepsilon_2 + \varepsilon)k [\|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0^2 + \|\nabla(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0^2] \\
& + \frac{1}{2} k [N^2 \gamma^{-1} \|\nabla \mathbf{u}_h^n\|_0^2 \|\nabla(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0^2 + \gamma \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0^2],
\end{aligned}$$

where ε_1 and ε_2 are two small positive constants which can be chosen arbitrarily. Taking $\varepsilon + \varepsilon_1 + C\varepsilon_2 = \nu/4$, it follows from (4.16) that

$$\begin{aligned}
(4.17) \quad & [\|\mathbf{u}_h^n - \mathbf{u}_d^n\|_0^2 - \|\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1}\|_0^2] + \nu k \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0^2 \\
& \leq \|\mathbf{u}_h^n - P^d \mathbf{u}_h^n\|_0^2 + Ck \|\nabla(\mathbf{u}_h^n - P^d \mathbf{u}_h^n)\|_0^2 + Ck \|p_h^n - \rho^d p_h^n\|_0^2 \\
& \quad + C \|\bar{\partial}_t \mathbf{u}_h^n - \bar{\partial}_t R_d \mathbf{u}_h^n\|_{-1}^2 + \frac{1}{2} k \gamma \|\nabla(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0^2 \\
& \quad + k N^2 \gamma^{-1} \|\nabla \mathbf{u}_h^n\|_0^2 \|\nabla(\mathbf{u}_h^{n-1} - \mathbf{u}_d^{n-1})\|_0^2, \quad 1 \leq n \leq L.
\end{aligned}$$

If $h^2 = O(k)$, $2\nu^{-2} N \sum_{j=1}^n \|\mathbf{f}^j\|_{-1} < 1$, $n = n_i$ ($i = 1, 2, \dots, \ell$), summing (4.17) from $n = n_1, n_2, \dots, n_i$ ($i = 1, 2, \dots, \ell$), let $n_0 = 0$, and noting that $\mathbf{u}_h^0 - \mathbf{u}_d^0 = \mathbf{0}$ and $\ell \leq L$, from Lemmas 3.3, 4.1, and 4.2, we obtain that

$$\begin{aligned}
(4.18) \quad & \|\mathbf{u}_h^{n_i} - \mathbf{u}_d^{n_i}\|_0^2 + \nu k \|\nabla(\mathbf{u}_h^{n_i} - \mathbf{u}_d^{n_i})\|_0^2 \leq C \sum_{j=1}^{n_i} \|\mathbf{u}_h^{n_j} - P^d \mathbf{u}_h^{n_j}\|_0^2 \\
& + Ck \sum_{j=1}^{n_i} [\|\nabla(\mathbf{u}_h^{n_j} - P^d \mathbf{u}_h^{n_j})\|_0^2 + \|p_h^{n_j} - \rho^d p_h^{n_j}\|_0^2] \\
& + C \sum_{j=1}^{n_i} [\|\mathbf{u}_h^{n_j} - R_d \mathbf{u}_h^{n_j}\|_{-1}^2 + \|\mathbf{u}_h^{n_{j-1}} - R_d \mathbf{u}_h^{n_{j-1}}\|_{-1}^2] \\
& \leq Ck \sum_{j=d+1}^l \lambda_j, \quad i = 1, 2, \dots, \ell.
\end{aligned}$$

Thus, we obtain that

$$(4.19) \quad \begin{aligned} & \|\mathbf{u}_h^{n_i} - \mathbf{u}_d^{n_i}\|_0 + (\nu k)^{1/2} \|\nabla(\mathbf{u}_h^{n_i} - \mathbf{u}_d^{n_i})\|_0 \\ & \leq C \left(k^{1/2} \sum_{j=d+1}^l \lambda_j \right)^{1/2}, \quad i = 1, 2, \dots, \ell. \end{aligned}$$

Combining (4.19) and (4.14), by Lemmas 3.3, 4.1, and 4.2, we obtain the first inequality of (4.6).

If $n \neq n_i$ ($i = 1, 2, \dots, \ell$), we may as well let $t^{(n)} \in (t^{(n_{i-1})}, t^{(n_i)})$ and $t^{(n)}$ be the nearest point to $t^{(n_i)}$. Expanding \mathbf{u}^n and p^n into Taylor series with respect to $t^{(n_i)}$ yields that

$$(4.20) \quad \begin{aligned} \mathbf{u}^n &= \mathbf{u}^{n_i} - \eta_i k \frac{\partial \mathbf{u}(\xi_1)}{\partial t}, \quad t^{(n)} \leq \xi_1 \leq t^{(n_i)}, \\ p^n &= p^{n_i} - \eta_i k \frac{\partial p(\xi_2)}{\partial t}, \quad t^{(n)} \leq \xi_2 \leq t^{(n_i)}, \end{aligned}$$

where η_i is the step number from $t^{(n)}$ to $t^{(n_i)}$. If $h^2 = O(k)$, $2\nu^{-2}N \sum_{j=1}^n \|\mathbf{f}^j\|_{-1} < 1$, $k = O(\ell^{-2})$, summing (4.17) for n_1, \dots, n_{i-1}, n , let $n_0 = 0$, and noting that $\mathbf{u}_h^0 - \mathbf{u}_d^0 = \mathbf{0}$, from Lemmas 4.1 and 4.2 and Lemma 3.3, we obtain that

$$(4.21) \quad \|\mathbf{u}_h^n - \mathbf{u}_d^n\|_0^2 + k\gamma \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0^2 \leq C\eta^2 k^3 + Ck^{1/2} \sum_{j=d+1}^l \lambda_j.$$

Since snapshots are equably taken, $\eta_i \leq L/(2\ell)$. If $k = O(\ell^{-2})$, we obtain that

$$(4.22) \quad \|\mathbf{u}_h^n - \mathbf{u}_d^n\|_0 + k^{1/2} \|\nabla(\mathbf{u}_h^n - \mathbf{u}_d^n)\|_0 \leq Ck + C \left(k^{1/2} \sum_{j=d+1}^l \lambda_j \right)^{1/2}.$$

Combining (4.22) and (4.14), by Lemmas 3.3, 4.1, and 4.2, we obtain the second inequality of (4.6). \square

Combining Theorem 2.2 and Theorem 4.4 yields the following result.

THEOREM 4.5. *Under Theorem 2.2 and Theorem 4.4 hypotheses, the error estimate between the solutions for Problem (II) and the solutions for the reduced order basic Problem (IV) is, for $n = 1, 2, \dots, L$, $m = 1, 2, 3$,*

$$(4.23) \quad \begin{aligned} & \|\mathbf{u}^n - \mathbf{u}_d^n\|_0 + k^{1/2} \|p^n - p_d^n\|_0 + k^{1/2} \|\nabla(\mathbf{u}^n - \mathbf{u}_d^n)\|_0 \\ & \leq Ck + Ch^m + C \left(k^{1/2} \sum_{j=d+1}^l \lambda_j \right)^{1/2}. \end{aligned}$$

Remark 4.6. Though the constants C in Theorems 4.4 and 4.5 are directly independent on k , they are indirectly dependent on L . Therefore, if $k \rightarrow 0$, that implies $L \rightarrow \infty$. The condition $k = O(\ell^{-2})$, which implies $L = O(\ell^2)$, in Theorem 4.4 shows the relation between the number ℓ of snapshots and the number L at all time instances. Therefore, it is unnecessary to take total transient solutions at all time instances $t^{(n)}$ as snapshots (see, for instance, in [27]–[29]). Theorems 4.4 and 4.5 have

FIG. 1. Physical model of the cavity flows: $t = 0$; i.e., $n = 0$ initial values on boundary.

presented the error estimates between the solution of the reduced MFE formulation Problem (IV) and the solution of usual MFE formulation Problem (III) and Problem (II), respectively. Since our methods employ some MFE solutions (\mathbf{u}_h^n, p_h^n) ($n = 1, 2, \dots, L$) for Problem (III) as assistant analysis, the error estimates in Theorem 4.5 are correlated to the spatial grid scale h and time step size k . However, when one computes actual problems, one may obtain the ensemble of snapshots from physical system trajectories by drawing samples from experiments and interpolation (or data assimilation). Therefore, the assistant (\mathbf{u}_h^n, p_h^n) ($n = 1, 2, \dots, L$) could be replaced with the interpolation functions of experimental and previous results, thus rendering it unnecessary to solve Problem (III), and requiring only to directly solve Problem (IV) such that Theorem 4.4 is satisfied.

5. Some numerical experiments. In this section, we present some numerical examples of the physical model of cavity flows for Mini's element and different Reynolds numbers by the reduced formulation Problem (IV), thus validating the feasibility and efficiency of the POD method.

Let the side length of the cavity be 1 (see Figure 1). We first divide the cavity into $32 \times 32 = 1024$ small squares with side length $\Delta x = \Delta y = \frac{1}{32}$, and then link the diagonal of the square to divide each square into two triangles in the same direction, which consists of triangularization \mathfrak{S}_h . Take time step increment as $k = 0.001$. Except that u_1 is equal to 1 on upper boundary, all other initial value, boundary values, and (f_1, f_2) are all taken as 0 (see Figure 1).

We obtain 20 values (i.e., snapshots) at time $t = 10, 20, 30, \dots, 200$ by solving the usual MFE formulation, i.e., Problem (III). It is shown by computing that eigenvalues satisfy $[k^{1/2} \sum_{i=7}^{20} \lambda_i]^{1/2} \leq 10^{-3}$. When $t = 200$, we obtain the solutions of the reduced formulation Problem (IV) based on the POD method of MFE depicted graphically in Figures 2 to 5 on the right-hand side employed six POD bases for $Re = 750$ and required six POD bases for $Re = 1500$, while the solutions obtained with usual MFE formulation Problem (III) are depicted graphically in Figures 2 to 5 on the left-hand side. (Since these figures are equal to solutions obtained with 20 bases, they are also referred to as the figures of the solution with full bases.)

Figure 6 shows the errors between solutions obtained with a different number of POD bases and solutions obtained with full bases. Comparing the usual MFE formulation Problem (III) with the reduced MFE formulation Problem (IV) containing six POD bases implementing 3000 times the numerical simulation computations, we

FIG. 2. When $Re = 750$, velocity stream line figure for usual MFE solutions (on left-hand side figure) and $d = 6$, the solution of the reduced MFE formulation (on right-hand side figure).

FIG. 3. When $Re = 1500$, velocity stream line figure for usual MFE solutions (on left-hand side figure) and $d = 6$, the solution of the reduced MFE formulation (on right-hand side figure).

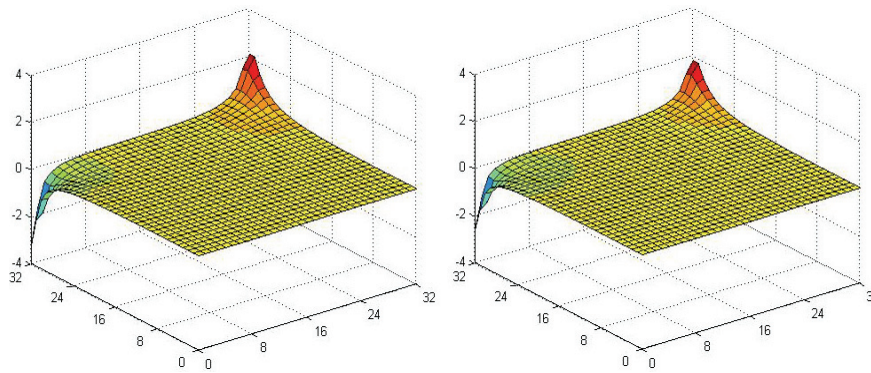

FIG. 4. When $Re = 750$, pressure figure for usual MFE solution (on left-hand side figure) and $d = 6$ solution of reduced MFE formulation (on right-hand side figure).

find that for usual MFE formulation Problem (III) the required CPU time is 6 minutes, while for the reduced MFE formulation Problem (IV) with 6 POD bases the corresponding time is only three seconds; i.e., the usual MFE formulation Problem (III) required a CPU time which is by a factor of 120 larger than that required by

FIG. 5. When $Re = 1500$, the pressure figure for usual MFE solution (on left-hand side figure) and $d = 6$ solution of reduced MFE formulation (on right-hand side figure).

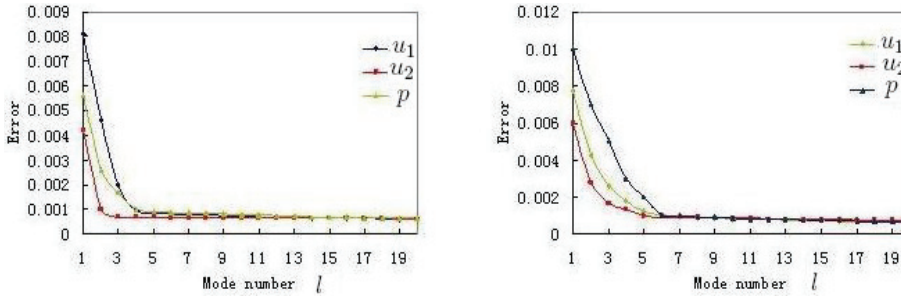

FIG. 6. Error for $Re = 750$ on left-hand side; error for $Re = 1500$ on right-hand side.

the reduced MFE formulation Problem (IV) with 6 POD bases, while the error between their respective solutions does not exceed 10^{-3} . It is also shown that finding the approximate solutions for the nonstationary Navier–Stokes equations with the reduced MFE formulation Problem (IV) is computationally very effective. The results for numerical examples are consistent with those obtained for the theoretical case.

6. Conclusions. In this paper, we have employed the POD technique to derive a reduced formulation for the nonstationary Navier–Stokes equations. We first reconstruct optimal orthogonal bases of ensembles of data which are compiled from transient solutions derived by using the usual MFE equation system, while in actual applications, one may obtain the ensemble of snapshots from physical system trajectories by drawing samples from experiments and interpolation (or data assimilation). For example, for weather forecast, one may use previous weather prediction results to construct the ensemble of snapshots to restructure the POD basis for the ensemble of snapshots by methods of the above section 3. We have also combined the optimal orthogonal bases with a Galerkin projection procedure, thus yielding a new reduced MFE formulation of lower dimensional order and of high accuracy for the nonstationary Navier–Stokes equations. We have then proceeded to derive error estimates between our reduced MFE approximate solutions and the usual MFE approximate solutions, and have shown, using numerical examples, that the error between the reduced MFE approximate solution and the usual MFE solution is consistent with the theoretical error results, thus validating both feasibility and efficiency

of our reduced MFE formulation. Future research work in this area will aim to extend the reduced MFE formulation, applying it to a realistic operational atmospheric numerical weather forecast system and to more complicated PDEs. We have shown both by theoretical analysis as well as by numerical examples that the reduced MFE formulation presented herein has extensive potential applications.

Though Kunisch and Volkwein have presented some Galerkin proper orthogonal decomposition methods for a general equation in fluid dynamics, i.e., for the nonstationary Navier–Stokes equations in [28], our method is different from their approaches, whose methods consist of Galerkin projection approaches where the original variables are substituted for linear combination of POD basis and the error estimates of the velocity field therein are only derived, their POD basis being generated with the solutions of the physical system at all time instances, while our POD basis is generated with only few solutions of the physical system which are useful and of interest for us. Especially, only the velocity field is approximated in [28], while both the velocity field and the pressure are all synchronously approximated in our present method, and error estimates of velocity field and pressure approximate solutions are also synchronously derived. Thus, our method appears to be more optimal than that in [28].

Acknowledgments. The authors thank all referees and Professor Karl Kunisch for their valued suggestions to this paper very much.

DATA APPROXIMATION USING SHAPE-PRESERVING PARAMETRIC SURFACES*

PAOLO COSTANTINI[†] AND FRANCESCA PELOSI[†]

Abstract. In this paper we present a new, composite, method for the construction of shape-preserving surfaces approximating a set of spatial data, obtained by combining together: a scheme for detecting the shape of the data, a new class of tensor-product splines, and a suitable linear least-squares strategy. This method is mainly conceived for the reconstruction of objects in reverse engineering.

Key words. approximation, parametric surfaces, tensor-product splines, shape preservation

1. Introduction. The construction of a mathematical model reproducing given objects plays an important role in many practical fields (medicine, geology, engineering, fine arts) essentially because it allows the possibility both of storing them in archives, databases, or electronic museum catalogs and of analyzing their physical, mechanical, aesthetic, etc., characteristics. Typically, such a construction is obtained computing a surface approximating a set of data points taken from the object itself; moreover, the measurements often involve a huge amount of data and are (very) accurate, so that the points furnish a good representation of the shape of the object.

It is clear that the surface must reproduce the main visual features (corners, ridges, patches with “visually uniform” curvature, etc.), and this requirement pushes our construction within the frame of the so-called *shape-preserving approximation*. It is worthwhile to recall that, despite its importance in practical applications and in contrast to the contiguous field of *shape-preserving interpolation*, shape-preserving approximation has not received a considerable attention. Indeed, the few available methods concern the construction of parametric curves and, to the best of our knowledge, only the paper [15] has been published on data approximation using parametric surfaces with shape constraints. The motivation is twofold: first, multivariate approximation is not an easy problem and becomes very hard when shape constraints are added,¹ and, second, it is intrinsically difficult to define the shape of the data and thus to properly set the shape constraints.

Suppose we are given a set of points $\{(t_\mu, \mathbf{P}_\mu), \mu = 0, \dots, M\}$ where $\mathbf{P}_\mu \in \mathbb{R}^d$, $d = 2, 3$, and $t_\mu \in \mathbb{R}$ is the associated value of the parameter. In order to better understand our strategy, consider for the moment the simpler and better known problem of constructing interpolating curves. A typical scheme is usually composed of the following steps. First we compute the piecewise linear curve interpolating the data points, and, second, we use it for extracting their geometric characteristics (e.g., discrete curvature and torsion). Then we construct an interpolating curve using some

¹Note that also for the much easier problem of *functional bivariate interpolation* there are few effective methods.

kind of *splines in tension*, that is, splines which depend on a set of *tension parameters* and which can be modified (stretched) so that their shape tends to the shape of the piecewise linear curve. In other words (a) we construct a reference curve, (b) define the shape of the data *as* the shape of the reference curve, and (c) construct an interpolating (smoother) curve which can reproduce as far as we want the shape of the reference curve.

The method we have recently proposed for the construction of shape-preserving approximating curves ([3],[4],[5]) follows essentially the above steps.

If we want to proceed as in (a) we need at first (a.1) to define a knot sequence in the parameter interval $[t_0, t_M]$, extracting from the parameter values $\{t_0, \dots, t_M\}$ a subsequence $\{u_0, \dots, u_m\}$ (typically $m \ll M$), and then (a.2) to construct a piecewise reference curve which gives a good reproduction of the shape of the data. For (a.1) we have used the so-called *zero moment approach* ([1] and references quoted therein, [18]; see also section 2), which provides an efficient tool for selecting the *significant* knots, where the data exhibit a change in the shape. Starting with our experiences on spatial shape-preserving interpolating curves, in [3] and [4] we used piecewise linear splines as reference curves, but we soon realized that they were not completely satisfactory for these purposes. Therefore, on the basis of experimental evidence (see, e.g., [5], Figure 3) we have used the space S_2^0 of C^0 piecewise quadratic splines for constructing the reference curve required in (a.2). We have then (b) defined the shape of the data as the shape of the selected reference curve and for (c) we have used a new spline space, isomorphic to the space S_4^2 of C^2 , four degree splines, which “tends” to S_2^0 for limit values of the tension parameters.

We remark that the advantages of using a curve from this new space instead of the (C^0) reference curve itself are in the possibility of locally modifying the shape and thus in reproducing either smooth sections or sharp corners of the underlying object.

The aim of the present paper is to describe a similar scheme for the construction of parametric surfaces, approximating a set of spatial data. Such surfaces are given by tensor product, variable degree polynomial splines, whose parameters are defined on rectangular grids of the form $\{u_0, \dots, u_m\} \otimes \{v_0, \dots, v_n\}$. The sections in which this paper is subdivided follow essentially the constructive steps given above.

More specifically, in the next one we present an algorithm for the selection of the knot lines, describe the construction of the reference surface, and define the shape of the data. We anticipate that the shape will be defined in terms of the *zero moment* of the reference surface. This choice (which does not involve the Gaussian curvature and only indirectly the mean curvature) is motivated by the good performance in detecting the shape of the data,² by the simplicity in the theoretical definition of the shape constraints, and in the acceptable complexity of their practical implementation. In order to avoid possible misunderstandings, we remark that the reference surface is given by a C^0 quadratic tensor-product spline, and we cannot expect the *classical* shape preserving properties of bilinear splines; therefore, in this paper (as well as in [5], which deals with approximating curves) there are no *standard* tension type theorems, which typically provide conditions for the elimination of extraneous oscillations. Indeed, our choice is motivated by the good flexibility of the biquadratic patches which gives a good reproduction of the changes in the shape of the data.

In section 3 we briefly recall some preliminary results, define the space of tensor-product variable degree splines together with their convergence properties, and then

²A graphical comparison of the *zero moments* with respect to the mean and Gaussian curvature for the approximating surface is given in Figures 9 and 10.

we present a global and a local algorithm for the construction of the final shape preserving surface.

In section 4 we report the graphical examples, and we close the paper with final comments, remarks, and anticipations of related works in section 5.

2. The shape of the data. In this section we want to define the *shape of the data*. Starting with the experimental observation that several data sets derived from profiles or sections of real objects are well represented by C^0 piecewise quadratic curves (see [5]), we develop the natural extension of this idea for surface data.

2.1. The zero moment analysis. We assume we are given a set of spatial data, together with the corresponding parameter values.³ In order to cover the main practical applications, we will consider data—taken from a function $\mathcal{P} = \mathcal{P}(t, r)$ —both with a tensor product topology

$$(2.1) \quad \mathcal{P} = \{(t_\mu, r_\nu, \mathbf{P}_{\mu,\nu}) : \mathbf{P}_{\mu,\nu} \in \mathbb{R}^3; \mu = 0, \dots, M; \nu = 0, \dots, N\}$$

or scattered

$$(2.2) \quad \mathcal{P} = \{(t_\mu, r_\mu, \mathbf{P}_\mu) : \mathbf{P}_\mu \in \mathbb{R}^3; \mu = 0, \dots, L\}.$$

In any case we assume that the parameter values are contained in a rectangular domain \mathcal{D} , where, setting $T := \{t_0, t_1, \dots\}$, $R := \{r_0, r_1, \dots\}$

$$\mathcal{D} = [\min(T), \max(T)] \times [\min(R), \max(R)].$$

As already said in the introduction, the first step of our construction is the detection of proper sequences of grid lines, taken in the parameter domain. In other words, we extract from the data parameters two subsequences of knots, $\mathcal{U} = \{u_0, \dots, u_m\}$, with $u_i = t_{\mu_i}$ and $\mathcal{V} = \{v_0, \dots, v_n\}$ with $v_j = r_{\nu_j}$ and subdivide \mathcal{D} using the rectangles

$$\mathcal{D}_{i,j} := [u_i, u_{i+1}] \times [r_j, r_{j+1}]$$

such that the corresponding subsets of points $\mathcal{P}_{i,j}$ define subregions of *uniform shape*.

In the following subsection we will also use \mathcal{U} and \mathcal{V} for defining the knot sequences of the tensor product splines.

The method we propose for such selection is based on some results on zero moments, described in [1]. First we briefly summarize the basic results of [1], and then we recall how to use them in order to select the knot sequences (for details see [17]).

Let $\mathbf{x} : \mathcal{T} \rightarrow \mathbb{R}^3$ be a parametric surface from the parameter manifold $\mathcal{T} \subset \mathbb{R}^2$. In accordance with [1], [18], we state the following.

DEFINITION 1. For any $(u, v) \in \mathcal{T}$ the zero moment of \mathbf{x} at (u, v) is given by the barycenter $\mathbf{M}_\epsilon^0(\mathbf{x}(u, v))$ of $\mathbf{x}(\mathcal{T}) \cap \Theta_\epsilon(\mathbf{x}(u, v))$:

$$(2.3) \quad \mathbf{M}_\epsilon^0(\mathbf{x}(u, v)) := \frac{1}{|\mathbf{x}(\mathcal{T}) \cap \Theta_\epsilon|} \int_{\mathcal{I}_\epsilon} \mathbf{x} \, dA,$$

where dA is the area element; $\Theta_\epsilon := \Theta_\epsilon(\mathbf{x}(u, v))$ is the Euclidean ball in \mathbb{R}^3 of radius ϵ , centered at $\mathbf{x}(u, v)$, and the domain of the integral is defined as $\mathcal{I}_\epsilon := \{(t, r) \in \mathcal{T} : \mathbf{x}(t, r) \in \Theta_\epsilon(\mathbf{x}(u, v))\}$.

³This heavy assumption will be discussed in section 5.

Using the zero moment we can define difference vector

$$(2.4) \quad \mathbf{n}_\epsilon(u, v; \mathbf{x}) := \mathbf{M}_\epsilon^0(\mathbf{x}(u, v)) - \mathbf{x}(u, v),$$

which will be called the ϵ -normal; the main result of [1] relates such a vector with the mean curvature of $\mathbf{x}(u, v)$ and the normal vector of the surface at (u, v) .

THEOREM 1. *Let $\mathbf{x} : \mathcal{T} \rightarrow \mathbb{R}^3$ be a regular parametric surface. For $(u, v) \in \mathcal{T}$ consider a ball of radius ϵ with center $\mathbf{x}(u, v)$. Then*

$$(2.5) \quad \mathbf{n}_\epsilon(u, v; \mathbf{x}) = -\epsilon^2 \frac{1}{6} H(u, v) \mathbf{n}(u, v) + o(\epsilon^2),$$

where $H(u, v)$ and $\mathbf{n}(u, v)$ are, respectively, the mean curvature and the normal vector of the surface \mathbf{x} at (u, v) .

From the above theorem we have that $\|\mathbf{n}_\epsilon(u, v; \mathbf{x})\|/\epsilon^2$ is proportional to the mean curvature $H(u, v)$, and thus it can be used to select corners or sharp changes in the shape of $\mathbf{x}(u, v)$. Moreover, since the vector $\mathbf{n}_\epsilon(u, v; \mathbf{x})$ lies parallel to the normal $\mathbf{n}(u, v)$, it gives information about convex or concave behaviors of $\mathbf{x}(u, v)$, in a neighborhood of (u, v) . In virtue of these considerations, $\mathbf{n}_\epsilon(u, v; \mathbf{x})$ will be called *local ϵ shape of \mathbf{x}* .

In view of the contents of the following sections, we remark that the ϵ -normal can be defined also at irregular points, still providing geometric information.

In order to select the sequences \mathcal{U} and \mathcal{V} of knots from the parameter values, we have to look for both sharp corners and changes in convexity of the data. We need two algorithms, respectively, Algorithm 1 for data of the forms (2.1) and Algorithm 2 for data of the form (2.2). Such algorithms are extremely important for the success of our method but also rather complicated and, in order to avoid interruptions in the reading of the paper, we have preferred to postpone their description until the final appendix. Here we limit ourselves to say that they are based on the discrete (and easier) counterpart of (2.3) studied in [17], namely

$$\mathbf{M}_\epsilon^0(\mathbf{P}_{\mu, \nu}) := \frac{1}{\text{card}(\Theta_\epsilon(\mathbf{P}_{\mu, \nu}))} \sum_{\mathbf{P}_{q, l} \in \text{wn}\Theta_\epsilon(\mathbf{P}_{\mu, \nu})} \mathbf{P}_{q, l}$$

in the case (2.1) or

$$\mathbf{M}_\epsilon^0(\mathbf{P}_\mu) := \frac{1}{\text{card}(\Theta_\epsilon(\mathbf{P}_\mu))} \sum_{\mathbf{P}_q \in \Theta_\epsilon(\mathbf{P}_\mu)} \mathbf{P}_q$$

in the case (2.2), and the changes of the corresponding *discrete ϵ -normals*

$$\mathbf{n}_\epsilon(\mathbf{P}_{\mu, \nu}) := \mathbf{M}_\epsilon^0(\mathbf{P}_{\mu, \nu}) - \mathbf{P}_{\mu, \nu} \quad \text{or} \quad \mathbf{n}_\epsilon(\mathbf{P}_\mu) := \mathbf{M}_\epsilon^0(\mathbf{P}_\mu) - \mathbf{P}_\mu$$

are compared with tolerances tol_{peak} and tol_{cc} for detecting, respectively, the peaks and the lines of convexity changes of the data points. Clearly, a good choice of the tolerances ϵ , tol_{peak} , and tol_{cc} is crucial for a suitable detection of the data subsets with *uniform shape*, as distinctly appears, for instance, in Figure 1.

2.2. The reference surface. For an arbitrary sequence of ordered knots $\{z_0, z_1, \dots, z_q\}$, let

$$\mathbf{S}_2^0[z_0, z_q] := \{\mathbf{s} : [z_0, z_l] \rightarrow \mathbb{R}^3 : \mathbf{s} \in C^0[z_0, z_l] \text{ s.t. } \mathbf{s}|_{[z_i, z_{i+1}]}\text{ has components in } \mathbb{P}_2 \text{ for } i = 0, \dots, q-1\},$$

FIG. 1. Influence of the input parameters on Algorithm 1: (a) Data points. (b) Gridlines and reference surface, large tol_{peak} . (c) Gridlines and reference surface, small tol_{peak} .

be the space of parametric C^0 , quadratic splines. We take the parameter sequences $\mathcal{U} = \{u_0, \dots, u_m\}$ and $\mathcal{V} = \{v_0, \dots, v_n\}$ given by the algorithms described in the previous subsection and form the tensor product space of C^0 biquadratic parametric splines

$$(2.6) \quad \mathbf{S}_{2,\mathcal{U}}^0 \otimes \mathbf{S}_{2,\mathcal{V}}^0 := \mathbf{S}_2^0[u_0, u_m] \otimes \mathbf{S}_2^0[v_0, v_n].$$

Let $\mathbf{f} : \mathcal{D} \mapsto \mathbb{R}^3$. We introduce the following semi-norm

$$(2.7) \quad |\mathbf{f}| := \sqrt{\sum_{\mu=0}^M \sum_{\nu=0}^N \|\mathbf{f}(t_\mu, r_\nu)\|_2^2} \quad \text{or} \quad |\mathbf{f}| := \sqrt{\sum_{\mu=0}^L \|\mathbf{f}(t_\mu, r_\mu)\|_2^2},$$

respectively, for the cases (2.1) or (2.2). Justified by practical applications (where we have many and well spread data), we assume the following property.

ASSUMPTION 1. *The semi-norm (2.7) is a norm for all the (finite dimensional) tensor-product spline spaces introduced in the present and in the following sections.*

Following the scheme proposed in [5] for spatial curves, we construct $\boldsymbol{\sigma}^* \in \mathbf{S}_{2,\mathcal{U}}^0 \otimes \mathbf{S}_{2,\mathcal{V}}^0$, the best approximation to data.

$$|\boldsymbol{\sigma}^* - \mathcal{P}| \leq |\boldsymbol{\sigma} - \mathcal{P}|, \quad \forall \boldsymbol{\sigma} \in \mathbf{S}_{2,\mathcal{U}}^0 \otimes \mathbf{S}_{2,\mathcal{V}}^0.$$

Remark 1. Since, obviously, the minimization of $|\boldsymbol{\sigma} - \mathcal{P}|$ is equivalent to that of $|\boldsymbol{\sigma} - \mathcal{P}|^2$, the computation of $\boldsymbol{\sigma}^*$ requires the solution of three independent discrete least squares problems for the three components of the surface.

We use $\boldsymbol{\sigma}^*$ for a comprehensive visual description of the data set; that is, we set the following definition.

DEFINITION 2. *The (local) shape of the data \mathcal{P} is given by $\mathbf{n}_\epsilon(u, v; \boldsymbol{\sigma}^*)$.*

We conclude this section by observing that the use of the *local ϵ shape* of $\boldsymbol{\sigma}^*$ has the advantage of being both simple and effective in the description of the data shape.

3. The tensor product spline spaces. In this section we want to define the tensor product space of *quartic-like* variable degree polynomial splines (VDPS for short) and analyze its main properties. We start recalling some basic facts on one-dimensional splines, referring for details to [2] and [5].

3.1. C^2 VDPS curves. Let $\mathcal{Z} = \{z_0, z_1, \dots, z_q\}$ be an ordered knot sequence, let $h_i := z_{i+1} - z_i$, $i = 0, \dots, q-1$, and let $\mathcal{K} = \{k_0, \dots, k_q\}$, $k_i \geq 4$ be a given sequence

of integers. In the following \mathcal{B}_j^ℓ will denote the j th ℓ -degree Bernstein polynomial and λ_j^ℓ the corresponding Bézier control net. In other words $\mathcal{B}_j^\ell = B^{(\ell)}\lambda_j^\ell$ where $B^{(\ell)}$ is the ℓ -degree Bernstein operator. For each interval $[z_i, z_{i+1}]$ we consider the five-dimensional polynomial space:

$$(3.1) \quad VP_{4,k_i,k_{i+1}} = \text{span} \{ (1-w)^{k_i}, \mathbb{P}_2, w^{k_{i+1}} \},$$

with $w = (z - z_i)/h_i$. Any $\phi_i \in VP_{4,k_i,k_{i+1}}$ can be expressed as

$$(3.2) \quad \phi_i(w) = e_i^-(1-w)^{k_i} + b_{i,0}^2 \mathcal{B}_0^2(w) + b_{i,1}^2 \mathcal{B}_1^2(w) + b_{i,2}^2 \mathcal{B}_2^2(w) + e_i^+ w^{k_{i+1}},$$

with $e_i^-, e_i^+, b_{i,0}^2 \in \mathbb{R}$. Note that the break points $\xi_{i,0}, \xi_{i,1}, \dots, \xi_{i,4}$ of the corresponding piecewise linear function

$$\lambda_i(w) = e_i^- \lambda_0^{k_i}(w) + b_{i,0}^2 \lambda_0^2(w) + b_{i,1}^2 \lambda_1^2(w) + b_{i,2}^2 \lambda_2^2(w) + e_i^+ \lambda_{k_{i+1}}^{k_{i+1}}(w)$$

are located at

$$\xi_{i,0} = z_i, \quad \xi_{i,1} = z_i + \frac{h_i}{k_i}, \quad \xi_{i,2} = z_i + \frac{h_i}{2}, \quad \xi_{i,3} = z_{i+1} - \frac{h_i}{k_{i+1}}, \quad \xi_{i,4} = z_{i+1}$$

and have values

$$\begin{aligned} \beta_{i,0} &= b_{i,0}^2 + e_i^-, \quad \beta_{i,1} = \left(1 - \frac{2}{k_i}\right) b_{i,0}^2 + \frac{2}{k_i} b_{i,1}^2, \quad \beta_{i,2} = b_{i,1}^2, \\ \beta_{i,3} &= \frac{2}{k_{i+1}} b_{i,1}^2 + \left(1 - \frac{2}{k_{i+1}}\right) b_{i,2}^2, \quad \beta_{i,4} = b_{i,2}^2 + e_i^+. \end{aligned}$$

For further references, we explicitly write the break points of λ_i :

$$(3.3) \quad \{(\xi_{i,0}, \beta_{i,0}), (\xi_{i,1}, \beta_{i,1}), (\xi_{i,2}, \beta_{i,2}), (\xi_{i,3}, \beta_{i,3}), (\xi_{i,4}, \beta_{i,4})\}.$$

Obviously $\phi_i \in \mathbb{P}_{\bar{k}}$ where $\bar{k} = \max\{k_i, k_{i+1}\}$; in [2], Theorem 2.1, the following result is given.

THEOREM 2. *The sequence $b_{i,0}^{\bar{k}}, \dots, b_{i,\bar{k}}^{\bar{k}}$ of control points of ϕ_i are obtained via repeated convex combinations of $\{\beta_{i,0}, \dots, \beta_{i,4}\}$.*

The convex combinations quoted in the theorem can be described by *degree elevation operators* (see [12]) and can be represented by a matrix (constructed as the product of the bidiagonal matrices describing each convex combination/degree elevation step), namely

$$(3.4) \quad \begin{bmatrix} b_{i,0}^{\bar{k}} \\ b_{i,1}^{\bar{k}} \\ \vdots \\ b_{i,\bar{k}}^{\bar{k}} \end{bmatrix} = A^{(\bar{k})} \begin{bmatrix} \beta_{i,0} \\ \beta_{i,1} \\ \vdots \\ \beta_{i,4} \end{bmatrix}; \quad A^{(\bar{k})} \in \mathbb{R}^{(\bar{k}+1) \times 5}.$$

Given the well-known properties of Bernstein polynomials, Theorem 2 says that ϕ_i lies in the convex hull of $\{\beta_{i,0}, \dots, \beta_{i,4}\}$ and satisfies the usual end tangent conditions.

Using (3.1) we easily define the space of C^2 *quartic-like* VDPS

$$VS_{4,\mathcal{K}}^2 = \{s \in C^2[z_0, z_q] \text{ s.t. } s(z) = \phi_i(w); \phi_i \in VP_{4,k_i,k_{i+1}}, z \in [z_i, z_{i+1}], w = (z - z_i)/h_i, i = 0, \dots, q-1\}.$$

FIG. 2. Some B-spline basis functions: N_i^S (solid), N_i^D (dashed) with $\mathcal{K} = \{4, 4, 4, 10, 10, 4, 4, 4\}$.

Let us take an extended knot sequence $z_{-2} < z_{-1} < z_0, z_q < z_{q+1} < z_{q+2}$, and an extended degree sequence $k_{-2} = k_{-1} = k_0, k_q = k_{q+1} = k_{q+2}$. In [5] it is shown that $VS_{4,\mathcal{K}}^2$ admits a stochastic and compactly supported B-spline-like basis, denoted by $\{N_{-1}^D, N_0^S, N_0^D, \dots, N_q^S, N_q^D\}$ (we have adopted this notation for relating this paper with the geometric construction described in [2], [5]; here it suffices to qualitatively say that the N_i^S and the N_i^D are related, respectively, to break and to internal points; see Figure 2). Note that, for $H \in \{S, D\}$, $N_i^H = N_i^H(\cdot; \mathcal{Z}, \mathcal{K})$. Figure 2 shows some B-spline basis functions. A spline curve in \mathbb{R}^3 can be constructed as

$$(3.5) \quad \mathbf{VS}_{4,\mathcal{K}}^2 = \{\mathbf{s} : [z_0, z_q] \rightarrow \mathbb{R}^3 \text{ s.t. has components in } VS_{4,\mathcal{K}}^2\},$$

and any spline curve $\mathbf{s} \in \mathbf{VS}_{4,\mathcal{K}}^2$ can be expressed as

$$(3.6) \quad \mathbf{s} = \sum_{i=0}^q \mathcal{L}_i^S N_i^S + \sum_{i=-1}^q \mathcal{L}_i^D N_i^D.$$

The points $\mathcal{L}_{-1}^D, \mathcal{L}_0^S, \mathcal{L}_0^D, \dots, \mathcal{L}_{q-1}^D, \mathcal{L}_q^S, \mathcal{L}_q^D$ are called *pseudo-de Boor control points* and play the same role as the classical control points for quartic splines. In particular, the control points $\{\beta_{i,0}, \dots, \beta_{i,4}\}$ of (3.3), corresponding to $\mathbf{s}|_{[z_i, z_{i+1}]}$, can be computed with some steps of a corner-cutting procedure (for details see [2]).

Remark 2. We easily see from (3.2) that the computational cost for the evaluation of ϕ_i is approximately the same as for a polynomial of \mathbb{P}_4 . This property is clearly inherited by the splines of \mathbf{VS} (and later by tensor product spline surfaces) which have a computational cost equivalent to that of quadratic splines in \mathbf{S}_4^2 .

3.2. C^2 VDPS surfaces. Given two extended sequences of knots

$$\mathcal{U} = \{u_{-2}, \dots, u_{m+2}\}, \quad \mathcal{V} = \{v_{-2}, \dots, v_{n+2}\}$$

and two extended sequences of degrees

$$\mathcal{K}^u = \{k_{-2}^u, \dots, k_{m+2}^u\}, \quad \mathcal{K}^v = \{k_{-2}^v, \dots, k_{n+2}^v\},$$

we consider the univariate spaces VS_{4,\mathcal{K}^u}^2 and VS_{4,\mathcal{K}^v}^2 as specified in the above subsection. The tensor-product space is given by

$$(3.7) \quad VS_{4,\mathcal{K}^u}^2 \otimes VS_{4,\mathcal{K}^v}^2 = \text{span} \left\{ \begin{aligned} &N_{i,j}^{DD}, \quad i = -1, \dots, m, \quad j = -1, \dots, n; \\ &N_{i,j}^{DS}, \quad i = -1, \dots, m, \quad j = 0, \dots, n; \\ &N_{i,j}^{SD}, \quad i = 0, \dots, m, \quad j = -1, \dots, n; \\ &N_{i,j}^{SS}, \quad i = 0, \dots, m, \quad j = 0, \dots, n \end{aligned} \right\},$$

where the basis functions are given by

$$\begin{aligned} N_{i,j}^{DD} &:= N_i^D(\cdot; \mathcal{U}, \mathcal{K}^u) N_j^D(\cdot; \mathcal{V}, \mathcal{K}^v), \quad N_{i,j}^{DS} := N_i^D(\cdot; \mathcal{U}, \mathcal{K}^u) N_j^S(\cdot; \mathcal{V}, \mathcal{K}^v), \\ N_{i,j}^{SD} &:= N_i^S(\cdot; \mathcal{U}, \mathcal{K}^u) N_j^D(\cdot; \mathcal{V}, \mathcal{K}^v), \quad N_{i,j}^{SS} := N_i^S(\cdot; \mathcal{U}, \mathcal{K}^u) N_j^S(\cdot; \mathcal{V}, \mathcal{K}^v). \end{aligned}$$

The plot of some tensor product basis functions is shown in Figure 3 for different degree sequences.

From Theorem 2 of [5], the following properties immediately hold:

- (a) $N_{i,j}^{DD}(u, v) > 0$ for $u \in (u_{i-1}, u_{i+2}) \times (v_{j-1}, v_{j+2})$ and $N_{i,j}^{DD}(u, v) = 0$ otherwise;
- $N_{i,j}^{DS}(u, v) > 0$ for $u \in (u_{i-1}, u_{i+2}) \times (v_{j-2}, v_{j+2})$ and $N_{i,j}^{DS}(u, v) = 0$ otherwise;
- $N_{i,j}^{SD}(u, v) > 0$ for $u \in (u_{i-2}, u_{i+2}) \times (v_{j-1}, v_{j+2})$ and $N_{i,j}^{SD}(u, v) = 0$ otherwise;
- $N_{i,j}^{SS}(u, v) > 0$ for $u \in (u_{i-2}, u_{i+2}) \times (v_{j-2}, v_{j+2})$ and $N_{i,j}^{SS}(u, v) = 0$ otherwise;
- (b) $\sum_{i=-1}^m \sum_{j=-1}^n N_{i,j}^{DD}(u, v) + \sum_{i=-1}^m \sum_{j=0}^n N_{i,j}^{DS}(u, v) + \sum_{i=0}^m \sum_{j=-1}^n N_{i,j}^{SD}(u, v) + \sum_{i=0}^m \sum_{j=0}^n N_{i,j}^{SS}(u, v) \equiv 1$
- (c) $N_{i,j}^{HH}(u, v)$ for $HH \in \{DD, DS, SD, SS\}$ is an element of the functional tensor product space (3.7).

Let $s \in VS_{4,\mathcal{K}^u}^2 \otimes VS_{4,\mathcal{K}^v}^2$. Obviously, $\phi_{i,j} := s|_{\mathcal{D}_{i,j}}$ is a bivariate polynomial in the tensor-product space obtained from (3.1), that is, $VP_{4,k_i^u, k_{i+1}^u} \otimes VP_{4,k_j^v, k_{j+1}^v}$. Following the notations of (3.2) and setting $\tilde{u} = (u - u_i)/(u_{i+1} - u_i)$, $\tilde{v} = (v - v_j)/(v_{j+1} - v_j)$ we have

$$\begin{aligned} VP_{4,k_i^u, k_{i+1}^u} \otimes VP_{4,k_j^v, k_{j+1}^v} &= \text{span} \left(\left\{ (1 - \tilde{u})^{k_i^u}, \mathcal{B}_0^2(\tilde{u}), \mathcal{B}_1^2(\tilde{u}), \mathcal{B}_2^2(\tilde{u}), \tilde{u}^{k_{i+1}^u} \right\} \right. \\ &\quad \left. \otimes \left\{ (1 - \tilde{v})^{k_j^v}, \mathcal{B}_0^2(\tilde{v}), \mathcal{B}_1^2(\tilde{v}), \mathcal{B}_2^2(\tilde{v}), \tilde{v}^{k_{j+1}^v} \right\} \right), \end{aligned}$$

and, recalling (3.3), $\phi_{i,j}$ admits a bivariate control polygon $\lambda_{i,j}$ defined by the control points

$$(3.8) \quad (\xi_{\mu,\nu}^{uv}, \beta_{\mu,\nu}^{uv}); \quad \xi_{\mu,\nu}^{uv} = \xi_{\mu}^u \xi_{\nu}^v, \quad \beta_{\mu,\nu}^{uv} \in \mathbb{R}, \quad \mu, \nu = 0, \dots, 4$$

The space of variable degree parametric surface is given by

$$(3.9) \quad \mathbf{VS}_{4,\mathcal{K}^u}^2 \otimes \mathbf{VS}_{4,\mathcal{K}^v}^2 := \{ \mathbf{s} : [u_0, u_m] \times [v_0, v_n] \mapsto \mathbb{R}^3 \text{ has component in (3.7)} \}$$

and any $\mathbf{s} \in \mathbf{VS}_{4,\mathcal{K}^u}^2 \otimes \mathbf{VS}_{4,\mathcal{K}^v}^2$ can be represented in the form

$$(3.10) \quad \begin{aligned} \mathbf{s} &= \sum_{i=-1}^m \sum_{j=-1}^n \mathcal{L}_{i,j}^{DD} N_{i,j}^{DD} + \sum_{i=-1}^m \sum_{j=0}^n \mathcal{L}_{i,j}^{DS} N_{i,j}^{DS} \\ &\quad + \sum_{i=0}^m \sum_{j=-1}^n \mathcal{L}_{i,j}^{SD} N_{i,j}^{SD} + \sum_{i=0}^m \sum_{j=0}^n \mathcal{L}_{i,j}^{SS} N_{i,j}^{SS}. \end{aligned}$$

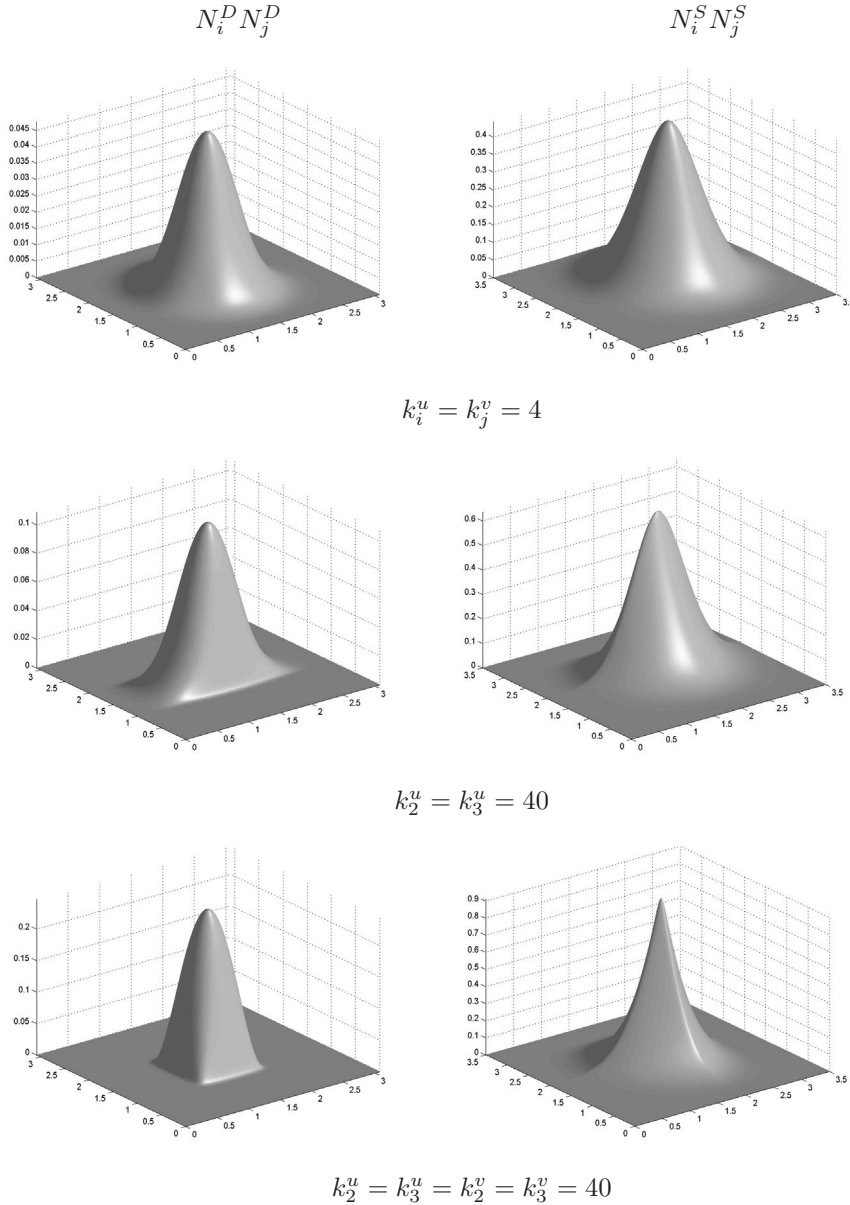

FIG. 3. Some tensor product B-spline basis functions with different degrees.

As a consequence of the properties of the basis functions, we have that the *pseudo-de Boor control net*, defined by the piecewise bilinear function interpolating the points $\mathcal{L}_{i,j}^{DD}$, $\mathcal{L}_{i,j}^{DS}$, $\mathcal{L}_{i,j}^{SD}$, and $\mathcal{L}_{i,j}^{SS}$ in (3.10), plays the role of the usual de Boor control net for C^2 quartic spline surface.

Remark 3. The basis functions $N_{i,j}^{HH}(u,v)$, $HH \in \{DD, DS, SD, SS\}$, tend to the corresponding basis elements of the space $\mathcal{S}_{2,u}^0 \otimes \mathcal{S}_{2,v}^0$ for limit values of the degrees. Despite the technical details, the convergence results of subsection 3.4 are essentially based on this property.

3.3. Boundary conditions. Given the rectangular shape of the parameter domain \mathcal{D} , the sections of the surface \mathbf{s} along the isoparametric lines $u = u_i$ and $v = v_j$ are VDPS spline curves from (3.5). This means that for each parametric lines of the form

$$\mathbf{s}(u, v_j), \quad j = 0, 1, \dots, n; \quad \mathbf{s}(u_i, v), \quad i = 0, 1, \dots, m,$$

we need to add suitable boundary conditions.

For open parametric lines, we consider restricted polynomial spaces at the first and last subintervals of the knot sequences of the form

$$VP_{4,k_1} = \text{span} \{ \mathbb{P}_2, w^{k_1} \}, \quad VP_{4,k_{q-1}} = \text{span} \{ (1-w)^{k_{q-1}}, \mathbb{P}_2 \},$$

and we construct the univariate space $\mathbf{VS}_{4,\mathcal{K},\text{open}}^2$ as

$$(3.11) \quad \mathbf{VS}_{4,\mathcal{K},\text{open}}^2 = \left\{ \mathbf{s} \in \mathbf{VS}_{4,\mathcal{K}}^2 : \mathbf{s}|_{[z_0, z_1]} \text{ and } \mathbf{s}|_{[z_{q-1}, z_q]} \right. \\ \left. \text{have components in } VP_{4,k_1} \text{ and } VP_{4,k_{q-1}} \right\},$$

so that $\dim(\mathbf{VS}_{4,\mathcal{K},\text{open}}^2) = \dim(\mathbf{S}_2^0)$. Also this space admits a B-spline basis, $\mathcal{N}_0^S, \mathcal{N}_0^D, \dots, \mathcal{N}_{q-1}^D, \mathcal{N}_q^S$, obtained with a slight modification of the scheme used for (3.5).

In the case of closed grid lines, we consider the univariate space $\mathbf{VS}_{4,\mathcal{K},\text{closed}}^2$ of the form

$$(3.12) \quad \mathbf{VS}_{4,\mathcal{K},\text{closed}}^2 = \left\{ \mathbf{s} \in \mathbf{VS}_{4,\mathcal{K}}^2 : \mathbf{s} = \sum_{i=0}^{q-1} \left(\mathcal{L}_i^S \mathcal{N}_i^S + \mathcal{L}_i^D \mathcal{N}_i^D \right) \right\},$$

where the basis functions \mathcal{N}_i^S and \mathcal{N}_i^D are obtained by imposing periodic extension of the boundary control points:

$$\begin{aligned} \mathcal{N}_0^S &:= N_0^S + N_q^S, & \mathcal{N}_i^S &:= N_i^S, & i &= 1, \dots, q-1, \\ \mathcal{N}_0^D &:= N_0^D + N_q^D, & \mathcal{N}_i^D &:= N_i^D, & i &= 1, \dots, q-2, \\ \mathcal{N}_{q-1}^D &:= N_{q-1}^D + N_{-1}^D. \end{aligned}$$

We limit ourselves to say that the properties of B-splines do not hold for the first and last group of the above functions and refer for details to [5].

Now, due to the tensor product structure, we can construct four different subspaces of $\mathbf{VS}_{4,\mathcal{K}^u}^2 \otimes \mathbf{VS}_{4,\mathcal{K}^v}^2$ in (3.9):

(I) The grid line curves $\mathbf{s}(u, v_j)$ and $\mathbf{s}(u_i, v)$ are open in both extreme knots, and then we form the tensor product space:

$$\mathbf{TVS}_{oo} := \mathbf{VS}_{4,\mathcal{K}^u,\text{open}}^2 \otimes \mathbf{VS}_{4,\mathcal{K}^v,\text{open}}^2,$$

where $\dim(\mathbf{TVS}_{oo}) = (2m+1)(2n+1)$. We can set

$$\begin{aligned} \mathbf{TVS}_{oo} = \text{span} \{ & \mathcal{N}_{i,j}^{DD}, \quad i = 0, \dots, m-1, \quad j = 0, \dots, n-1; \\ & \mathcal{N}_{i,j}^{DS}, \quad i = 0, \dots, m-1, \quad j = 0, \dots, n; \quad \mathcal{N}_{i,j}^{SD}, \quad i = 0, \dots, m, \quad j = 0, \dots, n-1; \\ & \mathcal{N}_{i,j}^{SS}, \quad i = 0, \dots, m, \quad j = 0, \dots, n \}. \end{aligned}$$

(II) The grid line curves $\mathbf{s}(u, v_j)$ are closed curves and $\mathbf{s}(u_i, v)$ are open, and then we form the tensor product space:

$$\mathbf{TVS}_{co} := \mathbf{VS}_{4,\mathcal{K}^u,\text{closed}}^2 \otimes \mathbf{VS}_{4,\mathcal{K}^v,\text{open}}^2,$$

where $\dim(\mathbf{TVS}_{co}) = 2m(2n + 1)$ and

$$\mathbf{TVS}_{co} = \text{span} \{ \mathcal{N}_{i,j}^{DD}, \mathcal{N}_{i,j}^{SD}, i = 0, \dots, m-1, j = 0, \dots, n-1; \\ \mathcal{N}_{i,j}^{DS}, \mathcal{N}_{i,j}^{SS}, i = 0, \dots, m-1, j = 0, \dots, n \}.$$

(III) The grid line curves $\mathbf{s}(u, v_j)$ are open and $\mathbf{s}(u_i, v)$ are closed, and then we form the tensor product space:

$$\mathbf{TVS}_{oc} := \mathbf{VS}_{4, \mathcal{K}^u, \text{open}}^2 \otimes \mathbf{VS}_{4, \mathcal{K}^v, \text{closed}}^2,$$

where $\dim(\mathbf{TVS}_{oc}) = 2n(2m + 1)$ and

$$\mathbf{TVS}_{oc} = \text{span} \{ \mathcal{N}_{i,j}^{DD}, \mathcal{N}_{i,j}^{DS}, i = 0, \dots, m-1, j = 0, \dots, n-1; \\ \mathcal{N}_{i,j}^{SD}, \mathcal{N}_{i,j}^{SS}, i = 0, \dots, m, j = 0, \dots, n-1 \}.$$

(IV) The grid line curves $\mathbf{s}(u, v_j)$ and $\mathbf{s}(u_i, v)$ are closed in both extreme knots, and then we form the tensor product space:

$$\mathbf{TVS}_{cc} := \mathbf{VS}_{4, \mathcal{K}^u, \text{closed}}^2 \otimes \mathbf{VS}_{4, \mathcal{K}^v, \text{closed}}^2,$$

where $\dim(\mathbf{TVS}_{cc}) = 4mn$ and we set

$$\mathbf{TVS}_{cc} = \text{span} \{ \mathcal{N}_{i,j}^{DD}, \mathcal{N}_{i,j}^{DS}, \mathcal{N}_{i,j}^{SD}, \mathcal{N}_{i,j}^{SS}, i = 0, \dots, m-1, j = 0, \dots, n-1 \}.$$

Note that type (II) is equivalent to impose that

$$\frac{\partial^{(r)}}{\partial u^{(r)}} \mathbf{s}(u, v)|_{(u_0, v)} = \frac{\partial^{(r)}}{\partial u^{(r)}} \mathbf{s}(u, v)|_{(u_m, v)},$$

and type (III) is equivalent to impose

$$\frac{\partial^{(r)}}{\partial v^{(r)}} \mathbf{s}(u, v)|_{(u, v_0)} = \frac{\partial^{(r)}}{\partial v^{(r)}} \mathbf{s}(u, v)|_{(u, v_n)}$$

for $r = 0, 1, 2$.

3.4. Convergence properties. It is clear from Definition (3.1) that, for limit values of the degrees k_i and k_{i+1} , the space $VP_{4, k_i, k_{i+1}}$ “tends” to the space \mathbb{P}_2 , that is, for any $\phi \in VP_{4, k_i, k_{i+1}}$, $\phi(w) = e_i^- (1-w)^{k_i} + b_{i,0}^2 \mathcal{B}_0^2(w) + b_{i,1}^2 \mathcal{B}_1^2(w) + b_{i,2}^2 \mathcal{B}_2^2(w) + e_i^+ w^{k_{i+1}}$, we have

$$\lim_{k_i, k_{i+1} \rightarrow \infty} \phi(w) = b_{i,0}^2 \mathcal{B}_0^2(w) + b_{i,1}^2 \mathcal{B}_1^2(w) + b_{i,2}^2 \mathcal{B}_2^2(w); \quad \forall w \in [a, b] \subset (z_i, z_{i+1}).$$

This property is clearly inherited by the spline space $VS_{4, \mathcal{K}}$ which, roughly speaking, “tends” to S_2^0 , the space of continuous quadratic splines. A first result is obtained as a straightforward consequence of Theorem 3 of [2].

THEOREM 3. *Let $\mathbf{s} \in \mathbf{TVS}_{xx}$, $xx \in \{oo, oc, co, cc\}$*

$$\mathbf{s}(u, v) = \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} \mathcal{L}_{i,j}^{DD} \mathcal{N}_{i,j}^{DD}(u, v) + \sum_{i=0}^{m-1} \sum_{j=0}^n \mathcal{L}_{i,j}^{DS} \mathcal{N}_{i,j}^{DS}(u, v) \\ + \sum_{i=0}^m \sum_{j=0}^{n-1} \mathcal{L}_{i,j}^{SD} \mathcal{N}_{i,j}^{SD}(u, v) + \sum_{i=0}^m \sum_{j=0}^n \mathcal{L}_{i,j}^{SS} \mathcal{N}_{i,j}^{SS}(u, v),$$

and let $\sigma_s \in \mathbf{S}_{2,\mathcal{U}}^0 \otimes \mathbf{S}_{2,\mathcal{V}}^0$ be defined by the control net $\mathcal{L}_{i,j}^{DD}, \mathcal{L}_{i,j}^{DS}, \mathcal{L}_{i,j}^{SD}$, and $\mathcal{L}_{i,j}^{SS}$ of s . Then, for all admissible indices, we have

$$\begin{aligned} \lim_{k_r^u, k_l^v, k_{l+1}^v \rightarrow \infty} s(u_r, v) &= \sigma_s(u_r, v), & v \in [v_l, v_{l+1}]; \\ \lim_{k_r^u, k_{r+1}^u, k_l^v \rightarrow \infty} s(u, v_l) &= \sigma_s(u, v_l), & u \in [u_r, u_{r+1}]; \end{aligned}$$

and

$$\lim_{k_r^u, k_{r+1}^u, k_l^v, k_{l+1}^v \rightarrow \infty} s(u, v) = \sigma_s(u, v), \quad (u, v) \in [u_r, u_{r+1}] \times [v_l, v_{l+1}].$$

The above theorem is not sufficient for our shape-preserving purposes. Let σ^* be our reference surface as defined in subsection 2.2 and let s^* be the best approximation in \mathbf{TVS}_{xx} ; that is,

$$|s^* - \mathcal{P}| \leq |s - \mathcal{P}|, \quad \forall s \in \mathbf{TVS}_{xx}.$$

Recalling Remark 1, we can easily state the following result.

THEOREM 4. *If $k_i^u, k_j^v \rightarrow \infty$; $i = 0, \dots, m$, $j = 0, \dots, n$, then*

$$|s^* - \sigma^*| \rightarrow 0.$$

Proof. For any $s \in \mathbf{TVS}_{xx}$ let us denote with σ_s the C^0 biquadratic spline surface in $\mathbf{S}_{2,\mathcal{U}}^0 \otimes \mathbf{S}_{2,\mathcal{V}}^0$ defined on the control net of s and, conversely, for any $\sigma \in \mathbf{S}_{2,\mathcal{U}}^0 \otimes \mathbf{S}_{2,\mathcal{V}}^0$ let us denote with s_σ the variable degree tensor product surface having the same control net as σ . Recalling the notations of subsection 3.2, let $\mathcal{K}_\ell^u = (k_{0,\ell}^u, \dots, k_{m,\ell}^u)$, $\mathcal{K}_\ell^v = (k_{0,\ell}^v, \dots, k_{n,\ell}^v)$ with $\lim_{\ell \rightarrow \infty} k_{i,\ell}^u = \lim_{\ell \rightarrow \infty} k_{j,\ell}^v = \infty$, all i, j , and let us denote $s = s(\mathcal{K}_\ell^u, \mathcal{K}_\ell^v)$. From Theorem 3 we have

$$\lim_{\ell \rightarrow \infty} |s^*(\mathcal{K}_\ell^u, \mathcal{K}_\ell^v) - \sigma_{s^*(\mathcal{K}_\ell^u, \mathcal{K}_\ell^v)}| = 0$$

and so $|s^*(\mathcal{K}_\ell^u, \mathcal{K}_\ell^v) - \sigma^*| \rightarrow 0$ if, and only if, $|\sigma_{s^*(\mathcal{K}_\ell^u, \mathcal{K}_\ell^v)} - \sigma^*| \rightarrow 0$.

Suppose that $|\sigma_{s^*(\mathcal{K}_\ell^u, \mathcal{K}_\ell^v)} - \sigma^*| \not\rightarrow 0$; then, for some subsequence $\{\mathcal{K}_{\ell(r)}^u, \mathcal{K}_{\ell(r)}^v\}$ and for a positive constant C , for sufficiently large r we have

$$|\sigma_{s^*(\mathcal{K}_{\ell(r)}^u, \mathcal{K}_{\ell(r)}^v)} - \sigma^*| \geq C.$$

We recall that the best approximations σ^* and $s^*(\mathcal{K}_{\ell(r)}^u, \mathcal{K}_{\ell(r)}^v)$ are unique; therefore we have $|\sigma_{s^*(\mathcal{K}_{\ell(r)}^u, \mathcal{K}_{\ell(r)}^v)} - \mathcal{P}| > |\sigma^* - \mathcal{P}|$ and for sufficiently large r , again by Theorem 3,

$$|s^*(\mathcal{K}_{\ell(r)}^u, \mathcal{K}_{\ell(r)}^v) - \mathcal{P}| > |\sigma_{s^*(\mathcal{K}_{\ell(r)}^u, \mathcal{K}_{\ell(r)}^v)} - \mathcal{P}|,$$

which leads to a contradiction. \square

We intend now to relate the convergence with shape properties. Using (2.3), (2.4), and Theorem 4 we have immediately the following result.

THEOREM 5. *If $k_i^u, k_j^v \rightarrow \infty$; $i = 0, \dots, m$, $j = 0, \dots, n$, then*

$$\mathbf{n}_\epsilon(u, v; s^*) \rightarrow \mathbf{n}_\epsilon(u, v; \sigma^*).$$

Recalling Definition 2 we can summarize the above property by saying that \mathbf{s}^* is *asymptotically shape-preserving*. The consequent shape-preserving criterium is formalized below (the notation is in accordance with Corollary 2).

COROLLARY 1. *Let $\delta_{i,j} > 0$, $i = 0, \dots, m$, $j = 0, \dots, n$. Then there exist threshold sequences $\tilde{\mathcal{K}}^u$, $\tilde{\mathcal{K}}^v$ such that for any $\mathcal{K}^u \geq \tilde{\mathcal{K}}^u$, $\mathcal{K}^v \geq \tilde{\mathcal{K}}^v$ (the inequalities hold componentwise), and for $(u, v) \in \mathcal{D}_{i,j}$*

$$(3.13) \quad \|\mathbf{n}_\epsilon(u, v; \mathbf{s}^*) - \mathbf{n}_\epsilon(u, v; \boldsymbol{\sigma}^*)\| \leq 2\delta_{i,j}.$$

However we note that its practical use requires extensive checks of the ϵ -normals associated to the progressive increases of the degree sequences. A weaker but cheaper criterium is given below.

Let $\mathbf{f}_{i,j}^* = \mathbf{s}_{|\mathcal{D}_{i,j}}^*$ and $\phi_{i,j}^* = \boldsymbol{\sigma}_{|\mathcal{D}_{i,j}}^*$ and let the corresponding control points (the 3D analogous of (3.8)) be denoted, respectively, by

$$(\boldsymbol{\xi}_{\mu,\nu}^{uv}, \boldsymbol{\beta}_{\mu,\nu}^{uv}(\mathbf{f}_{i,j}^*)), (\boldsymbol{\xi}_{\mu,\nu}^{uv}, \boldsymbol{\beta}_{\mu,\nu}^{uv}(\phi_{i,j}^*)); \mu, \nu = 0, \dots, 4.$$

LEMMA 1. *Let $\delta_{i,j} > 0$ and let $\|\boldsymbol{\beta}_{\mu,\nu}^{uv}(\mathbf{f}_{i,j}^*) - \boldsymbol{\beta}_{\mu,\nu}^{uv}(\phi_{i,j}^*)\| \leq \delta_{i,j}$; $\mu, \nu = 0, \dots, 4$. Then, for any $(u, v) \in \mathcal{D}_{i,j}$, $\|\mathbf{f}_{i,j}^*(u, v) - \phi_{i,j}^*(u, v)\| \leq \delta_{i,j}$.*

Proof. Let $\bar{k}^u = \max\{k_i^u, k_{i+1}^u\}$, $\bar{k}^v = \max\{k_j^v, k_{j+1}^v\}$, and let $B^{(\bar{k}^u)}$, $B^{(\bar{k}^v)}$ the Bernstein operators and $A^{(\bar{k}^u)}$, $A^{(\bar{k}^v)}$ the degree elevation convex combination operators (3.4). Obviously the components of $\phi_{i,j}^*$ belong to $VP_{4,k_i^u, k_{i+1}^u} \otimes VP_{4,k_j^v, k_{j+1}^v}$, and therefore we have (the matrix products apply componentwise)

$$\begin{aligned} \mathbf{f}_{i,j}^* - \phi_{i,j}^* &= B^{(\bar{k}^u)} A^{(\bar{k}^u)} \boldsymbol{\beta}^{uv}(\mathbf{f}_{i,j}^*) A^{(\bar{k}^v)T} B^{(\bar{k}^v)T} - B^{(\bar{k}^u)} A^{(\bar{k}^u)} \boldsymbol{\beta}^{uv}(\phi_{i,j}^*) A^{(\bar{k}^v)T} B^{(\bar{k}^v)T} \\ &= B^{(\bar{k}^u)} A^{(\bar{k}^u)} (\boldsymbol{\beta}^{uv}(\mathbf{f}_{i,j}^*) - \boldsymbol{\beta}^{uv}(\phi_{i,j}^*)) A^{(\bar{k}^v)T} B^{(\bar{k}^v)T}, \end{aligned}$$

where $\boldsymbol{\beta}^{uv}(\mathbf{f}_{i,j}^*)$ and $\boldsymbol{\beta}^{uv}(\phi_{i,j}^*)$ denote the matrices of control points. By the property of convex combination and of Bernstein operators we have, for any (u, v) ,

$$\|\mathbf{f}_{i,j}^*(u, v) - \phi_{i,j}^*(u, v)\| \leq \max_{\mu, \nu=0, \dots, 4} \|\boldsymbol{\beta}_{\mu,\nu}^{uv}(\mathbf{f}_{i,j}^*) - \boldsymbol{\beta}_{\mu,\nu}^{uv}(\phi_{i,j}^*)\| \leq \delta_{i,j}$$

which proves the claim. \square

For any $(u, v) \in \mathcal{D}_{i,j}$, we take the ϵ -balls $\Theta_\epsilon(\mathbf{f}_{i,j}^*(u, v))$ and $\Theta_\epsilon(\phi_{i,j}^*(u, v))$ and define the set

$$\begin{aligned} \overline{\mathcal{D}}_{i,j}(\epsilon; u, v) &:= \{(t, r) \in \mathcal{D}_{i,j} \text{ s.t. } \mathbf{f}_{i,j}^*(t, r) \in \Theta_\epsilon(\mathbf{f}_{i,j}^*(u, v)) \cap \Theta_\epsilon(\phi_{i,j}^*(u, v))\} \\ &\cap \{(t, r) \in \mathcal{D}_{i,j} \text{ s.t. } \phi_{i,j}^*(t, r) \in \Theta_\epsilon(\mathbf{f}_{i,j}^*(u, v)) \cap \Theta_\epsilon(\phi_{i,j}^*(u, v))\} \end{aligned}$$

and the *modified barycenters*

$$\begin{aligned} \overline{\mathbf{M}}_\epsilon^0(\mathbf{f}_{i,j}^*(u, v)) &:= \frac{1}{|\mathbf{f}_{i,j}^*(\overline{\mathcal{D}}_{i,j}(\epsilon; u, v))|} \int_{\overline{\mathcal{D}}_{i,j}(\epsilon; u, v)} \mathbf{f}_{i,j}^* dA, \\ \overline{\mathbf{M}}_\epsilon^0(\phi_{i,j}^*(u, v)) &:= \frac{1}{|\phi_{i,j}^*(\overline{\mathcal{D}}_{i,j}(\epsilon; u, v))|} \int_{\overline{\mathcal{D}}_{i,j}(\epsilon; u, v)} \phi_{i,j}^* dA. \end{aligned}$$

We make the assumption that the subsets $\overline{\mathcal{D}}_{i,j}(\epsilon; u, v)$ are nonempty and defer to Remark 4 its justification.

We have the following result.

LEMMA 2. Let $\delta_{i,j} > 0$ and let $\|\beta_{\mu,\nu}^{uv}(\mathbf{f}_{i,j}^*) - \beta_{\mu,\nu}^{uv}(\phi_{i,j}^*)\| \leq \delta_{i,j}$; $\mu, \nu = 0, \dots, 4$. Then, for any $(u, v) \in \mathcal{D}_{i,j}$

$$\left\| \overline{M}_\epsilon^0(\mathbf{f}_{i,j}^*(u, v)) - \overline{M}_\epsilon^0(\phi_{i,j}^*(u, v)) \right\| \leq \delta_{i,j}.$$

Proof. Let $q \in \mathbb{N}$, $q \geq k_i^u, k_{i+1}^u, k_j^v$, and k_{j+1}^v , and let $A^{(q)}$ be the degree elevation convex combination operator (3.4). Let $\lambda_{q,q}^{uv}(\mathbf{f}_{i,j}^*)$ and $\lambda_{q,q}^{uv}(\phi_{i,j}^*)$ be, respectively, the q -degree control nets of $\mathbf{f}_{i,j}^*$ and $\phi_{i,j}^*$. We recall that $\lambda_{q,q}^{uv}(\mathbf{f}_{i,j}^*)$ and $\lambda_{q,q}^{uv}(\phi_{i,j}^*)$ are continuous piecewise bilinear functions with knots at $\bar{u}_{i,\alpha} := u_i + \alpha(u_{i+1} - u_i)/q$, $\alpha = 0, \dots, q$, and $\bar{v}_{j,\gamma} := v_j + \gamma(v_{j+1} - v_j)/q$, $\gamma = 0, \dots, q$, and that

$$\lambda_{q,q}^{uv}(\mathbf{f}_{i,j}^*; \bar{u}_{i,\alpha}, \bar{v}_{j,\gamma}) = A^{(q)} \beta^{uv}(\mathbf{f}_{i,j}^*) A^{(q)T},$$

$$\lambda_{q,q}^{uv}(\phi_{i,j}^*; \bar{u}_{i,\alpha}, \bar{v}_{j,\gamma}) = A^{(q)} \beta^{uv}(\phi_{i,j}^*) A^{(q)T},$$

where $\beta^{uv}(\mathbf{f}_{i,j}^*)$ and $\beta^{uv}(\phi_{i,j}^*)$ denote the matrices of control points (the matrix products apply componentwise). Clearly we have

$$(3.14) \quad \left\| \lambda_{q,q}^{uv}(\mathbf{f}_{i,j}^*; \bar{u}_{i,\alpha}, \bar{v}_{j,\gamma}) - \lambda_{q,q}^{uv}(\phi_{i,j}^*; \bar{u}_{i,\alpha}, \bar{v}_{j,\gamma}) \right\| \leq \delta_{i,j}.$$

We also recall that

$$(3.15) \quad \lim_{q \rightarrow \infty} \lambda_{q,q}^{uv}(\mathbf{f}_{i,j}^*; u, v) = \mathbf{f}_{i,j}^*(u, v), \quad \lim_{q \rightarrow \infty} \lambda_{q,q}^{uv}(\phi_{i,j}^*; u, v) = \phi_{i,j}^*(u, v).$$

Now we set $R_{\alpha,\gamma} = [\bar{u}_{i,\alpha}, \bar{u}_{i,\alpha+1}] \times [\bar{v}_{j,\gamma}, \bar{v}_{j,\gamma+1}]$, which we use to define

$$\overline{\Delta}_{i,j}^{(q)}(\epsilon; u, v) := \left\{ \bigcup_{(\alpha,\gamma)} R_{\alpha,\gamma} \quad \text{s.t.} \quad \alpha, \gamma = 0, \dots, q-1; R_{\alpha,\gamma} \subset \overline{\mathcal{D}}_{i,j}(\epsilon; u, v) \right\}.$$

Note that $\overline{\Delta}_{i,j}^{(q)}(\epsilon; u, v) \subset \overline{\mathcal{D}}_{i,j}(\epsilon; u, v)$ and

$$(3.16) \quad \lim_{q \rightarrow \infty} \text{dist} \left(\overline{\Delta}_{i,j}^{(q)}(\epsilon; u, v), \overline{\mathcal{D}}_{i,j}(\epsilon; u, v) \right) = 0.$$

We observe that the values

$$\begin{aligned} \overline{M}_\epsilon^0(\lambda_{q,q}^{uv}(\mathbf{f}_{i,j}^*; u, v)) &:= \frac{1}{|\lambda_{q,q}^{uv}(\mathbf{f}_{i,j}^*; \overline{\Delta}_{i,j}^{(q)}(\epsilon; u, v))|} \int_{\overline{\Delta}_{i,j}^{(q)}(\epsilon; u, v)} \lambda_{q,q}^{uv}(\mathbf{f}_{i,j}^*) dA, \\ \overline{M}_\epsilon^0(\lambda_{q,q}^{uv}(\phi_{i,j}^*; u, v)) &:= \frac{1}{|\lambda_{q,q}^{uv}(\phi_{i,j}^*; \overline{\Delta}_{i,j}^{(q)}(\epsilon; u, v))|} \int_{\overline{\Delta}_{i,j}^{(q)}(\epsilon; u, v)} \lambda_{q,q}^{uv}(\phi_{i,j}^*) dA, \end{aligned}$$

can be computed, respectively, as an average of the points

$$\lambda_{q,q}^{uv}(\mathbf{f}_{i,j}^*; \bar{u}_{i,\alpha}, \bar{v}_{j,\gamma}), \lambda_{q,q}^{uv}(\phi_{i,j}^*; \bar{u}_{i,\alpha}, \bar{v}_{j,\gamma}); (\bar{u}_{i,\alpha}, \bar{v}_{j,\gamma}) \in \overline{\Delta}_{i,j}^{(q)}(\epsilon; u, v);$$

therefore, from (3.14) we have

$$\left\| \overline{M}_\epsilon^0(\lambda_{q,q}^{uv}(\mathbf{f}_{i,j}^*; u, v)) - \overline{M}_\epsilon^0(\lambda_{q,q}^{uv}(\phi_{i,j}^*; u, v)) \right\| \leq \delta_{i,j},$$

and the claim follows immediately from (3.15) and (3.16). \square

Let us define the *modified ϵ -normals*

$$(3.17) \quad \begin{aligned} \bar{\mathbf{n}}_\epsilon(u, v; \mathbf{f}_{i,j}^*) &:= \overline{\mathbf{M}}_\epsilon^0(\mathbf{f}_{i,j}^*(u, v)) - \mathbf{f}_{i,j}^*(u, v), \\ \bar{\mathbf{n}}_\epsilon(u, v; \phi_{i,j}^*) &:= \overline{\mathbf{M}}_\epsilon^0(\phi_{i,j}^*(u, v)) - \phi_{i,j}^*(u, v). \end{aligned}$$

From Lemmas 1 and 2 we have immediately the following results.

THEOREM 6. *Let $\delta_{i,j} > 0$ and let*

$$\|\beta_{\mu,\nu}^{uv}(\mathbf{f}_{i,j}^*) - \beta_{\mu,\nu}^{uv}(\phi_{i,j}^*)\|_\infty \leq \delta_{i,j}; \quad \mu, \nu = 0, \dots, 4.$$

Then, for any $(u, v) \in \mathcal{D}_{i,j}$

$$\|\bar{\mathbf{n}}_\epsilon(u, v; \mathbf{f}_{i,j}^*) - \bar{\mathbf{n}}_\epsilon(u, v; \phi_{i,j}^*)\|_\infty \leq 2\delta_{i,j}.$$

COROLLARY 2. *Let the values $\delta_{i,j} > 0$, $i = 0, \dots, m$, $j = 0, \dots, n$ be given. Then there exist threshold sequences $\tilde{\mathcal{K}}^u$ and $\tilde{\mathcal{K}}^v$ such that for any $\mathcal{K}^u \geq \tilde{\mathcal{K}}^u$, $\mathcal{K}^v \geq \tilde{\mathcal{K}}^v$ (the inequalities hold componentwise)*

$$(3.18) \quad \|\beta_{\mu,\nu}^{uv}(\mathbf{f}_{i,j}^*) - \beta_{\mu,\nu}^{uv}(\phi_{i,j}^*)\|_\infty \leq \delta_{i,j}; \quad \mu, \nu = 0, \dots, 4,$$

so that, for $(u, v) \in \mathcal{D}_{i,j}$,

$$\|\bar{\mathbf{n}}_\epsilon(u, v; \mathbf{f}_{i,j}^*) - \bar{\mathbf{n}}_\epsilon(u, v; \phi_{i,j}^*)\| \leq 2\delta_{i,j}.$$

We anticipate that in the schemes presented in the next section ϵ , which defines the radius of the ϵ -balls and the ϵ -normals, is a given input parameter and it is not adaptively changed during the execution of the algorithms. On the contrary, the algorithms modify the degree sequences, in order to fulfill the shape-preserving criteria.

Remark 4. From Theorem 4 and Lemma 1 we have that, for suitable sequences of the tolerances $\delta_{i,j}$ or, equivalently, for suitable sequences of the degrees, the center of the ϵ -balls $\Theta_\epsilon(\mathbf{f}_{i,j}^*(u, v))$ and $\Theta_\epsilon(\phi_{i,j}^*(u, v))$ are close enough to guarantee that $\overline{\mathcal{D}}_{i,j}(\epsilon; u, v) \neq \emptyset$.

Remark 5. Let

$$\mathcal{I}_{i,j}(\epsilon, \mathbf{f}_{i,j}^*; u, v) = \{(t, r) \in \mathcal{D}_{i,j} \text{ s.t. } \mathbf{f}_{i,j}^*(t, r) \in \Theta_\epsilon(\mathbf{f}_{i,j}^*(u, v))\},$$

$$\mathcal{I}_{i,j}(\epsilon, \phi_{i,j}^*; u, v) = \{(t, r) \in \mathcal{D}_{i,j} \text{ s.t. } \phi_{i,j}^*(t, r) \in \Theta_\epsilon(\phi_{i,j}^*(u, v))\}.$$

From Theorem 4 and Lemma 1 we have that, if $k_i^u, k_j^v \rightarrow \infty$, all i, j , then

$$\max \{ \text{dist}(\mathcal{I}_{i,j}(\epsilon, \mathbf{f}_{i,j}^*; u, v), \overline{\mathcal{D}}_{i,j}(\epsilon; u, v)), \text{dist}(\mathcal{I}_{i,j}(\epsilon, \phi_{i,j}^*; u, v), \overline{\mathcal{D}}_{i,j}(\epsilon; u, v)) \} \rightarrow 0.$$

Therefore, for the typical piecewise regular surfaces used in data approximation, (3.17) furnishes a good approximation of the corresponding ϵ -normals $\bar{\mathbf{n}}_\epsilon(u, v; \mathbf{f}_{i,j}^*)$ and $\bar{\mathbf{n}}_\epsilon(u, v; \phi_{i,j}^*)$ given in (2.4).

Remark 6. The implementation of (3.18) is much cheaper than (3.13) since it requires one only to check the distances of the Bézier control points of \mathbf{s}^* and σ^* .

Remark 7. In view of (2.5) we require that $\delta_{i,j} = o(\epsilon^2)$.

FIG. 4. *Example 1: (a) Data points. (b) Unconstrained approximation.*

3.5. The algorithms. The aim of this subsection is to propose two schemes for the effective construction of an approximating surface. We remark that simpler, unconstrained approximation methods are often inadequate for a good reproduction of the underlying object. Consider, for instance, the funnel data of Figure 4(a); the surface depicted in Figure 4(b) obtained using an unconstrained least square approximation in the space $\mathcal{S}_4^2 \otimes \mathcal{S}_4^2$ does not represent the main characteristics of the object.

The reader should compare this plot with Figure 5(d).

Global Algorithm

Let the data (2.1) or (2.2) and the real, positive numbers $\epsilon, \delta_{i,j}$ be given.

1. Compute the knot sequences \mathcal{U} and \mathcal{V} using Algorithm 1 or Algorithm 2 of section 6.
2. Compute σ^* as specified in subsection 2.1.
3. Set $k_i^u = 4, i = 0, \dots, m; k_j^v = 4, j = 0, \dots, n$.
4. Compute s^* as described in subsection 3.4.
5. While (3.13) or (3.18) is not satisfied
 - 5.1. Set $k_i^u = k_i^u + 1, i = 0, \dots, m; k_j^v = k_j^v + 1, j = 0, \dots, n$.
 - 5.2. Compute s^* as described in subsection 3.4.

This global algorithm produces an approximating surface s^* which is also shape preserving in the sense that its ϵ -normals or modified ϵ -normals agree in each $\mathcal{D}_{i,j}$ with those of the reference surface σ^* up to $2\delta_{i,j}$.

The main feature of such a global approach is in the convergence properties. On the other hand, its main drawback relies intrinsically in its global nature; a single, cumbersome, patch can force all the degrees to reach large values, and these in turn force the surface to have everywhere a nonsmooth and unpleasant appearance.

Therefore a local scheme, in which the only degrees related to the cumbersome patches of the data are increased, would be in some cases preferable. Unfortunately, in this case we cannot prove results similar to those of Corollaries 1 and 2. The very reason of this nonconvergence is that, even if $f_{i,j}^* = s_{|\mathcal{D}_{i,j}}^*$ tends to locally have a piecewise biquadratic shape when $k_i^u, k_{i+1}^u, k_j^v, k_{j+1}^v \rightarrow \infty$, it does not tend to $\phi_{i,j}^* = \sigma_{|\mathcal{D}_{i,j}}^*$. In other words, s^* belongs to a TVS space which does no more tend to the space of $\mathcal{S}_{2,\mathcal{U}}^0 \otimes \mathcal{S}_{2,\mathcal{V}}^0$. Therefore the best approximation taken from such a TVS can be, in general, far from σ^* .

We intend to show how it is possible to overcome this difficulty and obtain a local scheme, changing the linear least squares problem into a *weighted* linear least

FIG. 5. *Example 1: (a) Data points. (b) Selected gridlines. (c) Reference surface σ^* . (d) Shape-preserving approximation in TVS_{co} .*

squares problem (using basically the same idea proposed in [4]). The key fact is that we accept a compromise, obtaining the convergence at the price of a reduction in the approximation power. In order to force the spline to locally mimic σ^* when a local increase is applied, we work with an extension of the approximation problem. Let

$$\{w_{\bar{\mu}, \bar{\nu}}; \bar{\mu} = 0, \dots, 2m, \bar{\nu} = 0, \dots, 2n\}$$

be a sequence of positive weights. The basic idea is to push s^* towards σ^* , by inserting

$$\sigma^*(\gamma_{\bar{\mu}}, \zeta_{\bar{\nu}}); \bar{\mu} = 0, \dots, 2m, \bar{\nu} = 0, \dots, 2n$$

as weighted points in the approximation problem, with

$$\gamma_{2i} = u_i, \quad i = 0, \dots, m; \quad \gamma_{2i+1} = (u_{i+1} + u_i)/2, \quad i = 0, \dots, m-1$$

and

$$\zeta_{2j} = v_j, \quad j = 0, \dots, n; \quad \zeta_{2j+1} = (v_{j+1} + v_j)/2, \quad j = 0, \dots, n-1.$$

The points we are going to approximate are

$$\mathcal{Q} = \{(t_\mu r_\nu, \mathbf{P}_{\mu, \nu})\} \cup \{(\gamma_{\bar{\mu}}, \zeta_{\bar{\nu}}, \sigma^*(\gamma_{\bar{\mu}}, \zeta_{\bar{\nu}}))\}$$

in case (2.1) or

$$\mathcal{Q} = \{(t_\mu, r_\mu, \mathbf{P}_\mu)\} \cup \{(\gamma_{\bar{\mu}}, \zeta_{\bar{\nu}}, \boldsymbol{\sigma}^*(\gamma_{\bar{\mu}}, \zeta_{\bar{\nu}}))\}$$

in case (2.2). We take a modified semi-norm, given by

$$(3.19) \quad \langle \mathbf{f} \rangle := \sqrt{\sum_{\mu=0}^M \sum_{\nu=0}^N \|\mathbf{f}(t_\mu, r_\nu)\|_2^2 + \sum_{\bar{\mu}=0}^{2m} \sum_{\bar{\nu}=0}^{2n} w_{\bar{\mu}, \bar{\nu}} \|\mathbf{f}(\gamma_{\bar{\mu}}, \zeta_{\bar{\nu}})\|_2^2}$$

or by

$$(3.20) \quad \langle \mathbf{f} \rangle := \sqrt{\sum_{\mu=0}^L \|\mathbf{f}(t_\mu, r_\mu)\|_2^2 + \sum_{\bar{\mu}=0}^{2m} \sum_{\bar{\nu}=0}^{2n} w_{\bar{\mu}, \bar{\nu}} \|\mathbf{f}(\gamma_{\bar{\mu}}, \zeta_{\bar{\nu}})\|_2^2}.$$

We assume that the following property holds.

ASSUMPTION 2. *The semi-norm (3.19) or (3.20) is a norm for all the (finite dimensional) tensor-product spline spaces.*

We find $\mathbf{s}^* \in \mathbf{TVS}$, the best weighted least squares approximation:

$$\langle \mathbf{s}^* - \mathcal{Q} \rangle \leq \langle \mathbf{s} - \mathcal{Q} \rangle, \quad \forall \mathbf{s} \in \mathbf{TVS}.$$

Note that if $w_{\bar{\mu}, \bar{\nu}} = 0$, all $\bar{\mu}, \bar{\nu}$ we have the old approximation problem, and, for given $\bar{\mu}, \bar{\nu}$,

$$(3.21) \quad \lim_{w_{\bar{\mu}, \bar{\nu}} \rightarrow \infty} \mathbf{s}^*(\gamma_{\bar{\mu}}, \zeta_{\bar{\nu}}) = \boldsymbol{\sigma}^*(\gamma_{\bar{\mu}}, \zeta_{\bar{\nu}}).$$

We can use both the weights and the degrees to control the behavior of the surface in $\mathcal{D}_{i,j}$. Let

$$MN_{(i,j)} = \{(\bar{\mu}, \bar{\nu}) : \bar{\mu} = 2i, 2i+1, 2i+2, \bar{\nu} = 2j, 2j+1, 2j+2\}.$$

We have the following result, whose proof is a trivial consequence of Theorem 3 and (3.21).

THEOREM 7. *Let*

$$w_{\bar{\mu}, \bar{\nu}}, k_p^u, k_q^v \rightarrow \infty \quad \text{for } (\bar{\mu}, \bar{\nu}) \in MN_{(i,j)}, \quad p = i, i+1, \quad q = j, j+1,$$

and then

$$\mathbf{s}^*(u, v) \rightarrow \boldsymbol{\sigma}^*(u, v), \quad \forall (u, v) \in \mathcal{D}_{i,j}.$$

Now, we also have the following local versions of Corollaries 1 and 2.

COROLLARY 3. *Let $\delta_{i,j} > 0$. There exist threshold values $\tilde{w}_{\bar{\mu}, \bar{\nu}}$, \tilde{k}_p^u , and \tilde{k}_q^v with $(\bar{\mu}, \bar{\nu}) \in MN_{(i,j)}$, $p = i, i+1$, $q = j$, and $j+1$ such that for any $w_{\bar{\mu}, \bar{\nu}} \geq \tilde{w}_{\bar{\mu}, \bar{\nu}}$, $k_p^u \geq \tilde{k}_p^u$,*

and $k_q^v \geq \tilde{k}_q^v$, and for any $(u, v) \in \mathcal{D}_{i,j}$

$$(3.22) \quad \|\mathbf{n}_\epsilon(u, v; \mathbf{s}^*) - \mathbf{n}_\epsilon(u, v; \boldsymbol{\sigma}^*)\| \leq 2\delta_{i,j}.$$

COROLLARY 4. Let $\delta_{i,j} > 0$ be given. There exist threshold values $\tilde{w}_{\bar{\mu}, \bar{\nu}}$, \tilde{k}_p^u , and \tilde{k}_q^v with $(\bar{\mu}, \bar{\nu}) \in MN_{(i,j)}$, $p = i, i+1$, and $q = j, j+1$ such that for any $w_{\bar{\mu}, \bar{\nu}} \geq \tilde{w}_{\bar{\mu}, \bar{\nu}}$, $k_p^u \geq \tilde{k}_p^u$, and $k_q^v \geq \tilde{k}_q^v$

$$(3.23) \quad \|\beta_{\mu,\nu}^{uv}(\mathbf{f}_{i,j}^*) - \beta_{\mu,\nu}^{uv}(\boldsymbol{\phi}_{i,j}^*)\|_\infty \leq \delta_{i,j}; \quad \mu, \nu = 0, \dots, 4,$$

so that, for $(u, v) \in \mathcal{D}_{i,j}$,

$$\|\bar{\mathbf{n}}_\epsilon(u, v; \mathbf{f}_{i,j}^*) - \bar{\mathbf{n}}_\epsilon(u, v; \boldsymbol{\phi}_{i,j}^*)\| \leq 2\delta_{i,j}.$$

Clearly, the larger the weights, the more the approximation to the *true data* \mathcal{P} deteriorates, and we would like to keep the weights as small as possible while maintaining the “pleasantness” of the surface. Note that if we increase two consecutive degrees k_i^u, k_{i+1}^u (k_j^v, k_{j+1}^v) the effect spreads over the strip corresponding to $u_i \leq u \leq u_{i+1}$ ($v_j \leq v \leq v_{j+1}$), and if we increase the weights $w_{\mu,\nu}$ with $(\mu, \nu) \in MN^{(i,j)}$, the effect is local to $\mathcal{D}_{i,j}$.

A possible, simple strategy is described in the following algorithm.

Local Algorithm

Let the data (2.1) or (2.2) and the real, positive numbers ϵ , $\delta_{i,j}$, Δ_w be given.

1. Compute the knot sequences \mathcal{U} and \mathcal{V} using Algorithm 1 or Algorithm 2 of section 6.
2. Compute $\boldsymbol{\sigma}^*$ as specified in subsection 2.1.
3. Set $k_i^u = 4$, $i = 0, \dots, m$; $k_j^v = 4$, $j = 0, \dots, n$;
 $w_{\bar{\mu}, \bar{\nu}} = 0$, $\bar{\mu} = 0, \dots, 2m$, $\bar{\nu} = 0, \dots, 2n$.
4. Compute \mathbf{s}^* as described in subsection 3.4.
5. While (3.22) or (3.23) is not satisfied
 - 5.1. For all i, j compute
$$ERR_{i,j} = \max \left\{ \|\beta_{\alpha,\gamma}^{uv}(\mathbf{f}_{i,j}^*) - \beta_{\alpha,\gamma}^{uv}(\boldsymbol{\phi}_{i,j}^*)\|_\infty; \alpha, \gamma = 0, \dots, 4 \right\}.$$
 - 5.2. Find I, J such that $ERR_{I,J} \geq ERR_{i,j}$, all i, j .
 - 5.3. For $p = I, I+1$, $q = J, J+1$, $(\bar{\mu}, \bar{\nu}) \in MN_{(i,j)}$ set
 $k_p^u = k_p^u + 1$; $k_q^v = k_q^v + 1$; $w_{\bar{\mu}, \bar{\nu}} = w_{\bar{\mu}, \bar{\nu}} + \Delta_w$
 - 5.4. Compute \mathbf{s}^* as described in subsection 3.4.

Obviously, steps 5.2 and 5.3 could be modified to treat simultaneously more sub-rectangles (for instance, all $\mathcal{D}_{i,j}$ whose errors exceed a threshold value), thus reducing the computational cost required by instruction 5.4.

4. Graphical examples. In this section we want to discuss the practical applications of the theory developed in the previous sections with the aid of some graphical tests. As previously said in the introduction, our method is mainly conceived for applications in reverse engineering, where the surface is typically represented by well-identifiable patches with a clear geometric shape. Figures 5 and 6 are representative samples from this field. We have also added other additional examples using geological (Figure 7) and medical (Figure 8) data, which, being taken beyond the main field of applications,⁴ provide severe tests for our method. Indeed, if compared

⁴Geological data are often used as typical examples of fractal phenomena, in which a smooth representation could lead to erroneous interpretations.

FIG. 6. Example 2: (a) Data points. (b) Selected gridlines. (c) Reference surface σ^* . (d) Shape-preserving approximation in TVS_{co} . (e) Rotated biquadratic surface σ^* . (f) Rotated shape-preserving approximation s^* .

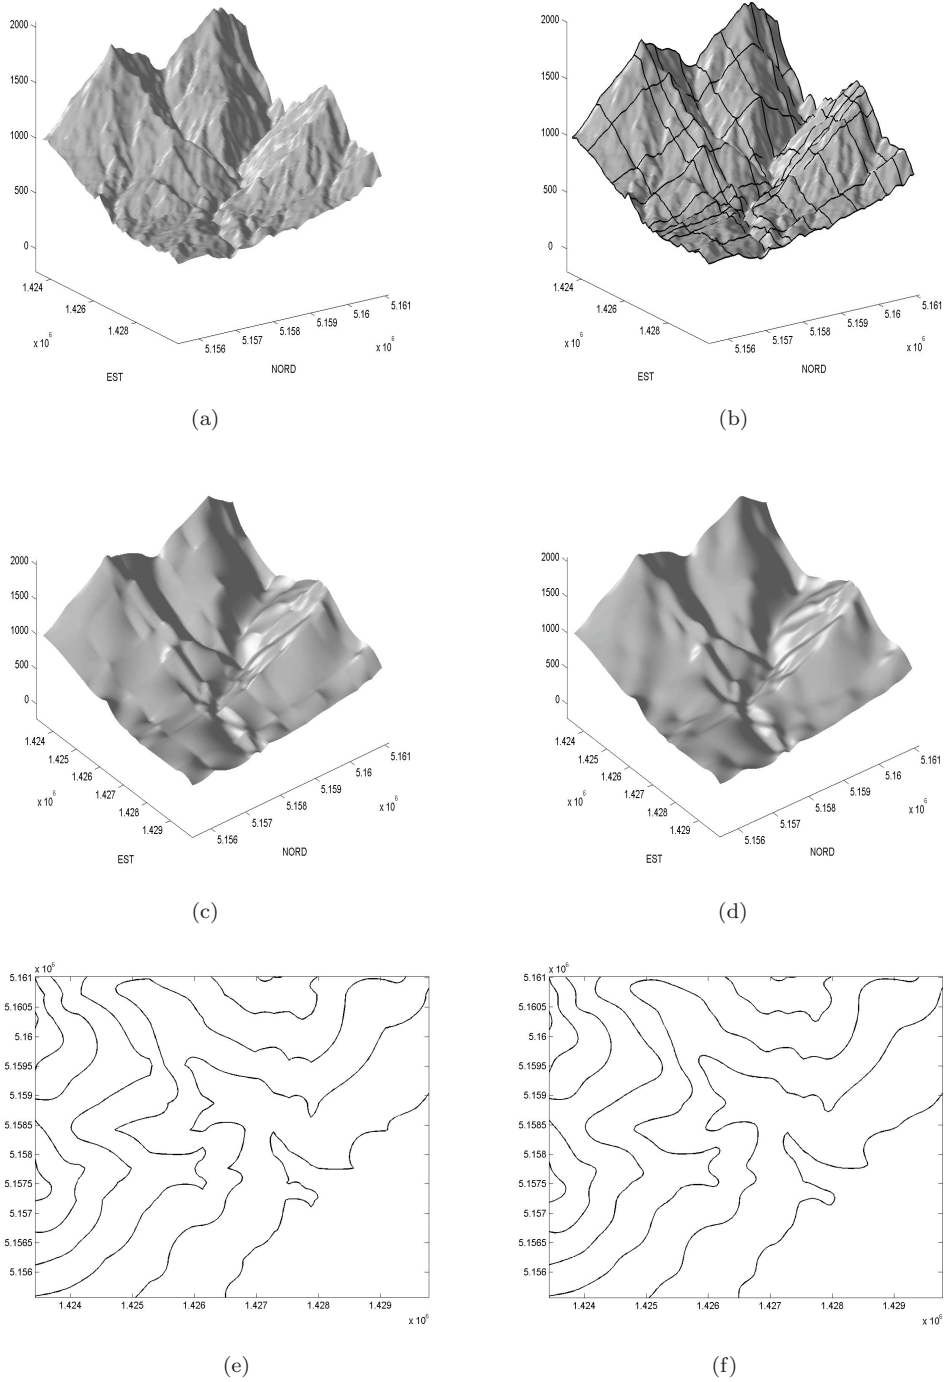

FIG. 7. Example 3: (a) Data surface. (b) Selected gridlines. (c) Reference surface σ^* . (d) Shape-preserving approximation $s^* \in TVSo$. (e) Contour plot of σ^* . (f) Contour plot of s^* .

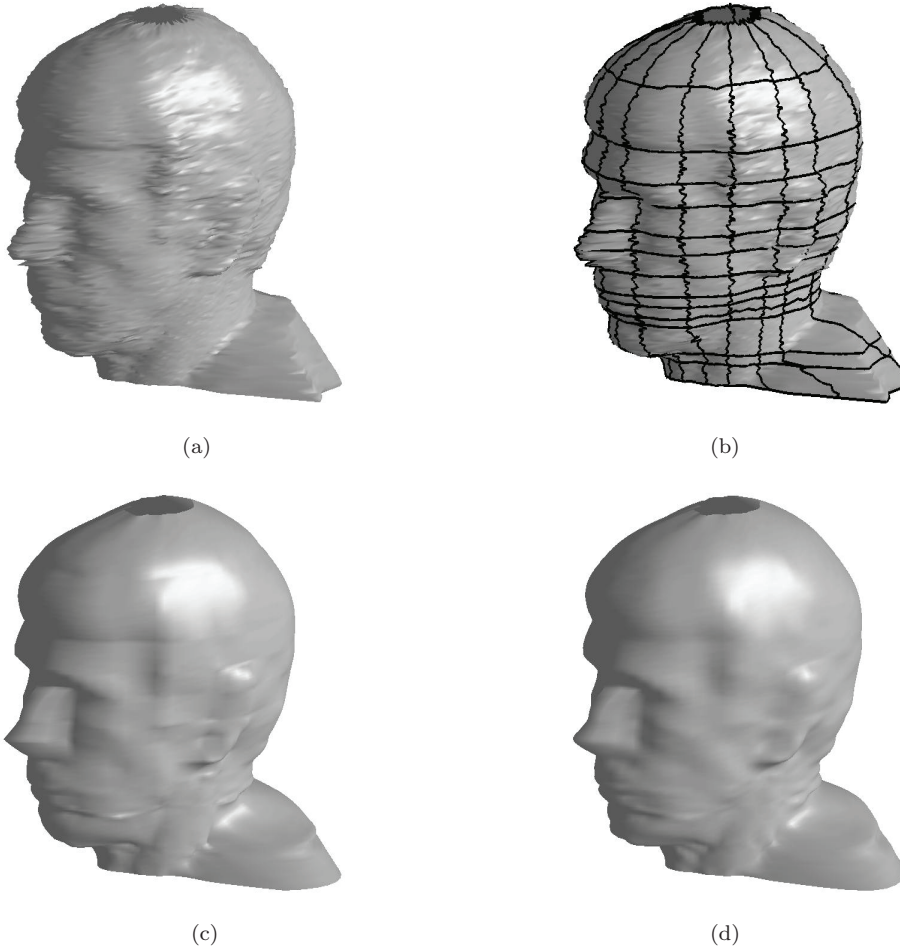

FIG. 8. *Example 4: (a) Data surface. (b) The selected gridlines. (c) Reference surface σ^* . (d) Shape-preserving approximation in $TV S_{co}$.*

with other pictures, Figures 7 and 8 are aesthetically poor. However, such kind of data are typically represented using a huge amount of (triangular) surface patches; here we intend to show that the shape of cumbersome data can be efficiently analyzed with the zero moment approach and that appreciably results in the representation of complex objects can be obtained with a single mathematical model composed of a (relatively) limited number of patches.

We conclude this section with a comparison of the zero-moments with the mean and Gaussian curvature. In Figure 9 the surface approximating the goblet data of Figure 6 has been enriched with some color maps. The first two rows show the normalized mean and Gaussian curvature. The last row shows the length of the normalized ϵ -normals, where the sign depends on the position with respect to the tangent plane. Figure 10 shows the normalized mean curvature, Gaussian curvature, and ϵ -normals as bivariate functions in the parameter domain. From this and similar examples we infer that, despite the inherent differences of the plots, the locations of the significant changes substantially agree. Therefore, the ϵ -normals seem to provide an effective tool both to analyze the data and to set up the shape constraints.

FIG. 9. Shape analysis of the “goblet” surface. Top: normalized mean curvature. Middle: normalized Gaussian curvature. Bottom: normalized length of ϵ -normals.

5. Conclusions. We have presented a new method for the construction of tensor-product parametric surfaces. Such a method, which, as far as we know, is the first one dealing with shape-preserving approximation of spatial data, is composed of three principal steps: a scheme for detecting the shape of the data, the application of a new class of tensor-product spline, and a suitable linear least-squares strategy, inserted in a global or in a local algorithm. Its main advantage relies in the possibility of

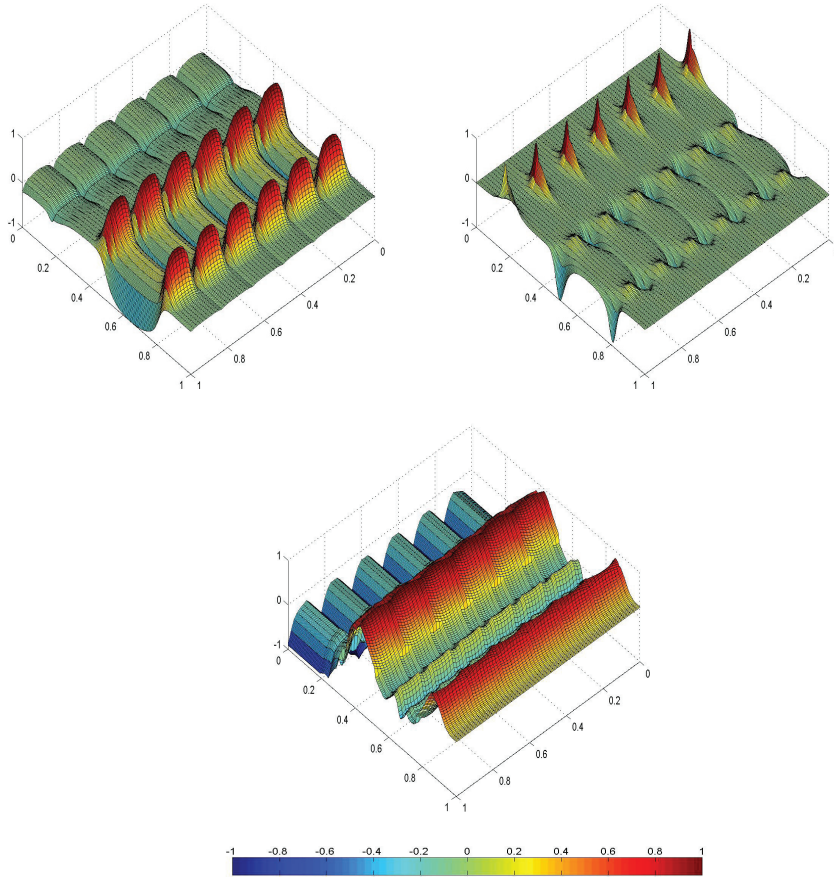

FIG. 10. Shape analysis of the “goblet surface”. In clockwise sense: normalized mean curvature, Gaussian curvature, and length of ϵ -normals represented as functions in the parameter domain.

using the same mathematical model (our variable degree polynomial spline spaces) for representing objects composed of patches with different shapes, and by sharp or smooth edges. The practical results, reported in the previous section, indicate that appreciable results are obtained at the price of limited computational expenses.

It is important to point out that in the tensor-product approximation all the points are uniformly treated. However, in practical applications it is common that some feature curves both summarize the shape of real objects and are crucial for understanding their physical properties. In other words, there are privileged subsets of the data points that form a network of fundamental grid lines and must be reproduced with much more accuracy than the remaining ones. In [6] is proposed a specific method based on surfaces defined via the Boolean sum of variable degree spline operators.

Several practical experiments, similar to those reported in Figures 7 and 8, suggest the opportunity of using spline surfaces on triangulations. This approach requires both the definition of new polynomials over triangular domains, approaching in the limit quadratic triangular elements, and the definition of the corresponding spline spaces. The zero-moment analysis must also be adapted to triangulations. These new results will be collected in a forthcoming paper.

It is worthwhile to point out that both in (2.1) or in (2.2) we have assumed to know the parameter values corresponding to the data points. It is well known that

the computation of the parameters, especially for arbitrary spatial data set, is a very difficult task. For more general applications, our algorithm should be integrated with some efficient tool, for instance, those proposed in [9], [10], and references therein.

We conclude this paper with some open questions.

The first one concerns a possible *adaptive strategy* for the zero-moment analysis. A crucial aspect is obviously in the size of ϵ : small values can detect useless details, and large values can ignore significant changes of the shape. Following the idea of adaptive quadrature rules, we could stop the process when we find no or few differences between the results of two zero-moment analysis obtained with, say, ϵ and $\epsilon/2$. Obviously, when necessary, this scheme could be separately applied and stopped to different subdivision levels, that is, to different subrectangles with decreasing area.

The second concerns the possible relations between ϵ -normals and the Bézier control points. It is well known that important consequences derive from the variation diminishing property, both for planar (see, e.g., [12]) and for spatial (see [11]) curves, and, in particular, that the geometric characteristics of the curve can be deduced from the discrete curvature and torsion of the control points. From a different point of view, we can say that there are some geometric properties which are invariant with respect to the refinement of the net⁵ and are thus inherited by the curve. Nothing similar occurs for parametric surfaces; the few results concerning the relations between the discrete geometry of the control points and the mean or Gaussian curvature of the surface are either very restrictive or very cumbersome (see, e.g., [8], [14], [16]). An investigation on the possible relations between the discrete ϵ -normals of the control points and the ϵ -normals of the final surface would therefore be very useful.

6. Appendix. Knot Selection: Algorithm 1.

Let the data (2.1) and the real positive numbers ϵ , tol_{peak} , and $\text{tol}_{\text{cc}} \in [0, 1]$ be given. The algorithm computes the knot sequences \mathcal{U} and \mathcal{V} .

1. Zero-moment computation. For each $(t_\mu, r_\nu, \mathbf{P}_{\mu,\nu}) \in \mathcal{P}$:

1.1 compute the barycenter $M_\epsilon^0(\mathbf{P}_{\mu,\nu})$ as

$$M_\epsilon^0(\mathbf{P}_{\mu,\nu}) := \frac{1}{\text{card}(\Theta_\epsilon(\mathbf{P}_{\mu,\nu}))} \sum_{\mathbf{P}_{q,l} \in \Theta_\epsilon(\mathbf{P}_{\mu,\nu})} \mathbf{P}_{q,l},$$

where $\Theta_\epsilon(\mathbf{P}_{\mu,\nu}) := \Theta_\epsilon(t_\mu, r_\nu, \mathbf{P}_{\mu,\nu})$ is the ball of radius ϵ centered at $(t_\mu, r_\nu, \mathbf{P}_{\mu,\nu})$;

1.2 compute the ϵ -normal, $\mathbf{n}_\epsilon(\mathbf{P}_{\mu,\nu}) := \mathbf{n}_\epsilon(t_\mu, r_\nu; \mathbf{P}_{\mu,\nu})$ as

$$\mathbf{n}_\epsilon(\mathbf{P}_{\mu,\nu}) := M_\epsilon^0(\mathbf{P}_{\mu,\nu}) - \mathbf{P}_{\mu,\nu}.$$

2. Peak selection

2.1 Find the points $(t_\mu, r_\nu, \mathbf{P}_{\mu,\nu}) \in \mathcal{P}$ such that

$$\|\mathbf{n}_\epsilon(\mathbf{P}_{\mu,\nu})\| = \max_{\mathbf{P}_{q,l} \in \Theta_{\epsilon/2}(\mathbf{P}_{\mu,\nu})} \{\|\mathbf{n}_\epsilon(\mathbf{P}_{q,l})\| : \|\mathbf{n}_\epsilon(\mathbf{P}_{q,l})\| > \epsilon^2 \text{tol}_{\text{peak}}\}.$$

2.2 $\mathcal{P}_{\text{peak}} \leftarrow \mathcal{P}_{\text{peak}} \cup \{(t_\mu, r_\nu, \mathbf{P}_{\mu,\nu})\}$.

⁵It is well known that the *degree elevation* or the (repeated) *de Casteljau* algorithms [12] produce finer and finer sets of control points converging to the Bézier curve.

3. Convexity change selection

3.1 For each $(t_\mu, r_\nu, \mathbf{P}_{\mu,\nu}) \in \mathcal{P}$ compute

$$\alpha_{\mu,\nu}^u := \frac{\mathbf{n}_\epsilon(\mathbf{P}_{\mu,\nu}) \cdot \mathbf{n}_\epsilon(\mathbf{P}_{\mu+1,\nu})}{\|\mathbf{n}_\epsilon(\mathbf{P}_{\mu,\nu})\| \|\mathbf{n}_\epsilon(\mathbf{P}_{\mu+1,\nu})\|}, \quad \alpha_{\mu,\nu}^v := \frac{\mathbf{n}_\epsilon(\mathbf{P}_{\mu,\nu}) \cdot \mathbf{n}_\epsilon(\mathbf{P}_{\mu,\nu+1})}{\|\mathbf{n}_\epsilon(\mathbf{P}_{\mu,\nu})\| \|\mathbf{n}_\epsilon(\mathbf{P}_{\mu,\nu+1})\|}.$$

3.2 Find the points $(t_\mu, r_\nu, \mathbf{P}_{\mu,\nu}) \in \mathcal{P}$ such that

$$\alpha_{\mu,\nu}^u = \min_{\mathbf{P}_{q,l} \in \Theta_{\epsilon/2}(\mathbf{P}_{\mu,\nu})} \{\alpha_{q,l}^u : \alpha_{q,l}^u < -\text{tol}_{\text{cc}}\}.$$

3.3 $\mathcal{P}_{\text{cc}}^u \leftarrow \mathcal{P}_{\text{cc}}^u \cup \{\mathbf{P}_{\mu,\nu}\}$.

3.4 Find the points $(t_\mu, r_\nu, \mathbf{P}_{\mu,\nu}) \in \mathcal{P}$ such that

$$\alpha_{\mu,\nu}^v = \min_{\mathbf{P}_{q,l} \in \Theta_{\epsilon/2}(\mathbf{P}_{\mu,\nu})} \{\alpha_{q,l}^v : \alpha_{q,l}^v < -\text{tol}_{\text{cc}}\}.$$

3.5 $\mathcal{P}_{\text{cc}}^v \leftarrow \mathcal{P}_{\text{cc}}^v \cup \{(t_\mu, r_\nu, \mathbf{P}_{\mu,\nu})\}$.

4. Grid-lines extraction

4.1 For each point $(t_\mu, r_\nu, \mathbf{P}_{\mu,\nu}) \in \mathcal{P}_{\text{peak}}$,

- $\mathcal{U} \leftarrow \mathcal{U} \cup \{t_\mu\}$,
- $\mathcal{V} \leftarrow \mathcal{V} \cup \{r_\nu\}$.

4.2 For each t_μ such that $(t_\mu, r_l, \mathbf{P}_{\mu,\nu}) \in \mathcal{P}_{\text{cc}}^u$, for some $l \in \{0, 1, \dots, M\}$

- compute the indicator $\mathcal{I}_\mu^{\text{cc}}$ as

$$\mathcal{I}_\mu^{\text{cc}} := \frac{\text{card}(\mathcal{C}_\mu^u)}{2(N+1)} + \frac{1}{2(N+1)} \sum_{l \in \mathcal{C}_\mu^u} |\alpha_{\mu,l}^u|,$$

where $\mathcal{C}_\mu^u = \{l : (t_\mu, r_l, \mathbf{P}_{\mu,l}) \in \mathcal{P}_{\text{cc}}^u\}$;

- if $\mathcal{I}_\mu^{\text{cc}} > \text{tol}_{\text{cc}}$, then $\mathcal{U} \leftarrow \mathcal{U} \cup \{t_\mu\}$.

4.3 For each r_ν such that $(t_q, r_\nu, \mathbf{P}_{\mu,\nu}) \in \mathcal{P}_{\text{cc}}^v$, for some $q \in \{0, 1, \dots, N\}$

- compute the indicator $\mathcal{J}_\nu^{\text{cc}}$ as

$$\mathcal{J}_\nu^{\text{cc}} := \frac{\text{card}(\mathcal{C}_\nu^v)}{2(M+1)} + \frac{1}{2(M+1)} \sum_{q \in \mathcal{C}_\nu^v} |\alpha_{q,\nu}^v|,$$

where $\mathcal{C}_\nu^v = \{q : (t_q, r_\nu, \mathbf{P}_{q,\nu}) \in \mathcal{P}_{\text{cc}}^v\}$;

- if $\mathcal{J}_\nu^{\text{cc}} > \text{tol}_{\text{cc}}$, then $\mathcal{V} \leftarrow \mathcal{V} \cup \{r_\nu\}$.

Knot Selection: Algorithm 2.

Let the data (2.2) and the real positive numbers ϵ , tol_{peak} , and $\text{tol}_{\text{cc}} \in [0, 1]$ be given.

The algorithm computes the knot sequences \mathcal{U} and \mathcal{V} .

1. **Zero-moment computation.** For each $(t_\mu, r_\mu, \mathbf{P}_\mu) \in \mathcal{P}$

1.1 Compute the barycenter $M_\epsilon^0(\mathbf{P}_\mu)$ as

$$M_\epsilon^0(\mathbf{P}_\mu) := \frac{1}{\text{card}(\Theta_\epsilon(\mathbf{P}_\mu))} \sum_{\mathbf{P}_q \in \Theta_\epsilon(\mathbf{P}_\mu)} \mathbf{P}_q,$$

where $\Theta_\epsilon(\mathbf{P}_\mu) := \Theta_\epsilon(t_\mu, r_\mu, \mathbf{P}_\mu)$ in the ball of radius ϵ centered at $(t_\mu, r_\mu, \mathbf{P}_\mu)$.

1.2 Compute the ϵ -normal, $\mathbf{n}_\epsilon(\mathbf{P}_\mu) := \mathbf{n}_\epsilon(t_\mu, r_\mu; \mathbf{P}_\mu)$ as

$$\mathbf{n}_\epsilon(\mathbf{P}_\mu) := M_\epsilon^0(\mathbf{P}_\mu) - \mathbf{P}_\mu.$$

2. Peak selection

2.1 Find the points $(t_\mu, r_\mu, \mathbf{P}_\mu) \in \mathcal{P}$ such that

$$\|\mathbf{n}_\epsilon(\mathbf{P}_\mu)\| = \max_{\mathbf{P}_q \in \Theta_{\epsilon/2}(\mathbf{P}_\mu)} \{ \|\mathbf{n}_\epsilon(\mathbf{P}_q)\| : \|\mathbf{n}_\epsilon(\mathbf{P}_q)\| > \epsilon^2 \text{tol}_{\text{peak}} \}.$$

2.2 $\mathcal{P}_{\text{peak}} \leftarrow \mathcal{P}_{\text{peak}} \cup \{(t_\mu, r_\mu, \mathbf{P}_\mu)\}$.

3. Convexity change selection

3.1 For each $(t_\mu, r_\mu, \mathbf{P}_\mu) \in \mathcal{P}$:

– find the set

$$\mathcal{C}_\mu := \left\{ q : \mathbf{P}_q \in \Theta_\epsilon(\mathbf{P}_\mu) \text{ and } \frac{\mathbf{n}_\epsilon(\mathbf{P}_\mu) \cdot \mathbf{n}_\epsilon(\mathbf{P}_q)}{\|\mathbf{n}_\epsilon(\mathbf{P}_\mu)\| \|\mathbf{n}_\epsilon(\mathbf{P}_q)\|} < -\text{tol}_{\text{cc}} \right\};$$

– compute the indicator of convexity change $\mathcal{F}_\mu^{\text{cc}}$ as

$$\mathcal{F}_\mu^{\text{cc}} = \frac{1}{2}(N_\mu + A_\mu),$$

where

$$N_\mu = \frac{\text{card}(\mathcal{C}_\mu)}{\text{card}(\Theta_\epsilon(\mathbf{P}_\mu))}, \quad A_\mu = \frac{\sum_{q: \mathbf{P}_q \in \mathcal{C}_\mu} (1 - d_q) \beta_q}{\sum_{q: \mathbf{P}_q \in \mathcal{C}_\mu} (1 - d_q)},$$

$$\beta_q = \frac{|\mathbf{n}_\epsilon(\mathbf{P}_\mu) \cdot \mathbf{n}_\epsilon(\mathbf{P}_q)|}{\|\mathbf{n}_\epsilon(\mathbf{P}_\mu)\| \|\mathbf{n}_\epsilon(\mathbf{P}_q)\|}, \quad d_q = \frac{\|\mathbf{P}_\mu - \mathbf{P}_q\|}{\epsilon}.$$

3.2 Find the points $(t_\mu, r_\mu, \mathbf{P}_\mu) \in \mathcal{P}$ such that

$$\mathcal{F}_\mu^{\text{cc}} = \max_{\mathbf{P}_q \in \Theta_{\epsilon/2}(\mathbf{P}_\mu)} \{ \mathcal{F}_q^{\text{cc}} : \mathcal{F}_q^{\text{cc}} > \text{tol}_{\text{cc}} \}.$$

3.3 $\mathcal{P}_{\text{cc}} \leftarrow \mathcal{P}_{\text{cc}} \cup \{(t_\mu, r_\mu, \mathbf{P}_\mu)\}$.

4. **Grid-lines extraction.** For each $\mathbf{P}_\mu \in \mathcal{P}_{\text{peak}} \cup \mathcal{P}_{\text{cc}}$,

– $\mathcal{U} \leftarrow \mathcal{U} \cup \{t_\mu\}$,

– $\mathcal{V} \leftarrow \mathcal{V} \cup \{r_\mu\}$.

In the above algorithms, after the computation of the zero-moments for discrete data (described at step 1), we look for sharp corners or *peaks*, in accordance with the magnitude of $\|\mathbf{n}_\epsilon(\mathbf{P}_{\mu,\nu})\|$ or $\|\mathbf{n}_\epsilon(\mathbf{P}_\mu)\|$ (step 2). Step 3 in Algorithms 1 and 2 describes the selection of convexity changes exploiting the different topology of data. For (2.1), with a tensor product topology of the data, we select *convexity changes* by considering the angles $\alpha_{\mu,\nu}^u, \alpha_{\mu,\nu}^v$ between consecutive ϵ -normals in u and v directions. Then we assign to each parametric line $u = t_\mu, \mu = 0, 1, \dots, M$ ($v = r_\nu, \nu = 0, 1, \dots, N$) an indicator $\mathcal{I}_\mu^{\text{cc}} \in [0, 1]$ ($\mathcal{I}_\nu^{\text{cc}} \in [0, 1]$) depending on the angles $\alpha_{\mu,l}^u, l = 0, 1, \dots, N$ ($\alpha_{q,\nu}^v, q = 0, 1, \dots, M$) and on the amount of convexity changes on such line. In order to select as knots the lines associated to the most significant changes in convexity, we choose the parameters with indicator $\mathcal{I}_\mu^{\text{cc}}$ or $\mathcal{I}_\nu^{\text{cc}}$ greater than a threshold tolerance (step 4 of Algorithm 1). For the sparse data (2.2), the indicator $\mathcal{F}_\mu^{\text{cc}}, \mu = 0, 1, \dots, M$, is a function of the angles between $\mathbf{n}_\epsilon(\mathbf{P}_\mu)$ and the ϵ -normals of all points contained in a ball centered at \mathbf{P}_μ and of the amount of convexity changes inside the ball. Again, great values of $\mathcal{F}_\mu^{\text{cc}} \in [0, 1]$ correspond to significant convexity changes. Both *peak* points and *convexity changes* are used in step 4 for the selection of the knot sequences \mathcal{U} and \mathcal{V} .

GEGENBAUER TAU METHODS WITH AND WITHOUT SPURIOUS EIGENVALUES*

MARIOS CHARALAMBIDES[†] AND FABIAN WALEFFE[‡]

Abstract. It is proven that a class of Gegenbauer tau approximations to a fourth order differential eigenvalue problem of a hydrodynamic type provides real, negative, and distinct eigenvalues, as is the case for the exact solutions. This class of Gegenbauer tau methods includes Chebyshev and Legendre Galerkin and “inviscid” Galerkin but does not include Chebyshev and Legendre tau. Rigorous and numerical results show that the results are sharp: positive or complex eigenvalues arise outside of this class. The widely used modified tau approach is proved to be equivalent to the Galerkin method.

Key words. spurious eigenvalues, Gegenbauer, spectrum, stable polynomials, positive pairs

1. Introduction. The Chebyshev tau method used by Orszag [17] to obtain exponentially accurate solutions of the Orr–Sommerfeld equation yields two eigenvalues with large positive real parts. Such eigenvalues also occur for the Stokes modes in a channel given by the fourth order differential equation

$$(1.1) \quad (D^2 - \alpha^2)^2 u = \lambda (D^2 - \alpha^2) u,$$

with the boundary conditions $u = Du = 0$ at $x = \pm 1$, where λ is the eigenvalue, $u = u(x)$ is the eigenfunction, $D = d/dx$, and α is a real wavenumber. The Stokes eigenvalues λ are real and negative as can be checked by multiplying (1.1) by u^* , the complex conjugate of $u(x)$, and by integrating by parts twice using the no-slip boundary conditions. In fact the Stokes spectrum has been known analytically since Rayleigh [7, section 26.1]. Yet, the Chebyshev tau method applied to (1.1) yields two eigenvalues with large positive real parts, for any order of approximation and for any numerical accuracy. Such eigenvalues are obviously *spurious* for (1.1). Gottlieb and Orszag [11, Chapter 13] introduced the eigenvalue problem

$$(1.2) \quad \begin{aligned} D^4 u &= \lambda D^2 u & \text{in } -1 \leq x \leq 1, \\ u &= Du = 0 & \text{at } x = \pm 1 \end{aligned}$$

as an even simpler one-dimensional (1D) model of incompressible fluid flow. This is the $\alpha \rightarrow 0$ limit of the eigenvalue problem (1.1) and of the Orr–Sommerfeld equation [17]. For any fixed α , problem (1.2) is also the asymptotic equation for large λ solutions of the Stokes and the Orr–Sommerfeld equations. The eigensolutions of (1.2) are known analytically. They consist of even modes $u(x) = 1 - \cos(n\pi x)/\cos(n\pi)$, with $\lambda = -n^2\pi^2$, and odd modes $u(x) = x - \sin(q_n x)/\sin(q_n)$, with $\lambda = -q_n^2$, where $q_n = \tan q_n$ so that $n\pi < q_n < (2n + 1)\pi/2 \forall$ integers $n > 0$. The key properties of

FIG. 1.1. Eigenvalues of a 3D steady state solution of the Navier–Stokes equations for plane Couette flow [21] computed with Chebyshev tau (left) and Chebyshev Galerkin (right) methods for identical resolutions (8773 modes after symmetry reductions. The solutions themselves are indistinguishable). Note the difference in horizontal scales. The Chebyshev tau method produces 274 eigenvalues with positive real parts, 273 of which are spurious. The Chebyshev Galerkin method returns only one positive eigenvalue, the physical one, equal to 0.03681 at Reynolds number 1000 [21, Figure 4].

these solutions are that the eigenvalues are *real*, *negative*, and *distinct*, and the even and odd mode eigenvalues interlace. These properties also hold for the Stokes modes, the solutions of (1.1) but not for the Orr–Sommerfeld modes.

The Chebyshev tau method provides spectrally accurate approximations to the lower magnitude eigenvalues, but it also yields two large positive eigenvalues for problems (1.1) and (1.2) [11, Table 13.1]. Those positive eigenvalues are clearly *spurious* since it is known that (1.1) and (1.2) should only have negative eigenvalues. The Chebyshev tau method yields two spurious eigenvalues for no-slip (i.e., clamped) boundary conditions $u = Du = 0$ at $x = \pm 1$ but none for the free-slip boundary conditions $u = D^2u = 0$ at $x = \pm 1$. The latter problem reduces to the second order problem $D^2v = \lambda v$, with $v(\pm 1) = 0$, for which a class of Jacobi and Gegenbauer tau methods has been proven to yield real, negative, and distinct eigenvalues [4, 5]. For mixed boundary conditions, e.g., $u(\pm 1) = Du(-1) = D^2u(1) = 0$, there is one spurious eigenvalue (this is a numerical observation).

For a 1D problem such as (1.1) or (1.2), the spurious eigenvalues are easy to recognize, and they appear as minor nuisances. Boyd [2, section 7.6] even questions the value of distinguishing between “spurious” and numerically inaccurate eigenvalues. However, in many applications, large *negative* eigenvalues are inconsequential, while “spurious” *positive* eigenvalues are very significant, and in higher dimensions, spurious eigenvalues are not as easy to pick out and set aside. In a recent application, three-dimensional (3D) *unstable* traveling wave solutions of the Navier–Stokes equations were calculated with both free-slip and no-slip boundary conditions, and anything in between, by Newton’s method [19, 20]. In that application, the Chebyshev tau method provides hundreds of spurious unstable eigenvalues, depending on the resolution and the exact type of boundary conditions, not all of which have very large magnitudes (Figure 1.1, left). A simple change in the *test* functions from Chebyshev polynomials $T_n(x)$ to $(1 - x^2)T_n(x)$ or $(1 - x^2)^2T_n(x)$ eliminates all of those spurious eigenvalues (Figure 1.1, right). This, and more, is proven below for the test problem (1.2) in the broader context of Gegenbauer tau methods, which include Chebyshev and Legendre tau and Chebyshev and Legendre Galerkin methods.

Another practical consequence of the spurious eigenvalues is that the Chebyshev tau method is unconditionally unstable when applied to the time-dependent version of (1.1) or (1.2), with $\partial/\partial t$ in place of λ . Such time-dependent problems appear as building blocks in the Navier–Stokes simulations of channel-type flows. Gottlieb and Orszag [11, p. 145] proposed a *modified tau* method for the time-dependent problems and proved that the modified method was stable for even solutions. The modified tau method (section 6) is a key idea behind several successful time integration schemes for the Navier–Stokes equations [3, section 7.3], [14]. The modified tau method amounts to using two more expansion polynomials for the fourth order differential operator on the left-hand sides of (1.2) and (1.1) than for the second order operator on the right hand sides. That modified tau method was adapted to eigenvalue problems by Gardner, Trogdon, and Douglass [8] and McFadden, Murray, and Boisvert [16]. McFadden, Murray, and Boisvert showed the equivalence between the modified Chebyshev tau method and the Chebyshev Galerkin method by direct calculation. Zebib [22] had given numerical evidence that the Galerkin method removed spurious eigenvalues. The modified tau method idea was adapted to the collocation formulation by Huang and Sloan [13].

A heuristic “explanation” for spurious eigenvalues is that there is a “mismatch” between the number of boundary conditions applied to the fourth order operator on the left-hand side of (1.2) and those applied to the second order operator on the right-hand side. That interpretation fits with the modified tau method, which uses two more polynomials for the fourth order operator than for the second order operator. However, it is incorrect, since, while the tau method for Chebyshev polynomials of the first kind $T_n(x)$ gives spurious eigenvalues, for instance, the tau method for Chebyshev polynomials of the second kind $U_n(x)$ does not.

All of these various methods are best seen in the context of the Gegenbauer class with residuals weighted by $W^{(\gamma)}(x) = (1 - x^2)^{\gamma-1/2}$ (section 2), where $\gamma = 0$ corresponds to Chebyshev and $\gamma = 1/2$ to Legendre polynomials. Dawkins, Dunbar, and Douglass [6] proved the existence of spurious positive eigenvalues for (1.2) when $\gamma < 1/2$. The proof is straightforward. For (1.2), the polynomial equation for $\mu = 1/\lambda$ can be derived explicitly (section 4). All coefficients of that polynomial are real and positive, except the constant term which is negative when $\gamma < 1/2$. Hence there is one real positive μ and a “spurious” positive eigenvalue when $\gamma < 1/2$ (details are given in section 5.2). For $\gamma = 1/2$, the Legendre tau case, the constant term is zero, and hence there is one $\mu = 0$ eigenvalue or a $\lambda = 1/\mu = \infty$ eigenvalue. Perturbation analysis shows that the $\lambda = \infty$ eigenvalues become very large positive eigenvalues for $\gamma < 1/2$ and very large negative eigenvalues for $\gamma > 1/2$. We provide a quicker derivation of those results in section 3. Dawkins, Dunbar, and Douglass’s results do not prove that there are no spurious eigenvalues for $\gamma > 1/2$ since there could be complex eigenvalues with positive real parts. In section 5, we prove that the Gegenbauer tau method applied to (1.2) provides eigenvalues that are *real*, *negative*, and *distinct* when $1/2 < \gamma \leq 7/2$. This provides a complete characterization of the Gegenbauer tau spectrum for problem (1.2). Numerical calculations confirm that the range $1/2 < \gamma \leq 7/2$ is sharp. Spurious positive eigenvalues exist for $\gamma < 1/2$ [6], and complex eigenvalues arise for $\gamma > 7/2$, for sufficiently high polynomial order. In section 6, we prove that the modified tau method is mathematically equivalent to the Galerkin approach.

Obviously, $\gamma = 1/2$ is a critical value for the weight function $(1 - x^2)^{\gamma-1/2}$. The boundaries $x = \pm 1$ have infinite weight for $\gamma < 1/2$ and zero weight for $\gamma > 1/2$, but we do not know a valid heuristic explanation for “spurious” eigenvalues beyond that observation, if one exists. Section 3 provides further insights into the nature of

the spurious eigenvalues and gives *some* support for the view that “spurious” and numerically inaccurate eigenvalues are related. In Figure 1.1, for *fixed resolution*, the 273 spurious eigenvalues for $\gamma = 0$ (Chebyshev tau) escape to $+\infty$ as $\gamma \nearrow 1/2$ (Legendre tau). They come back from $-\infty$ as γ increases beyond $1/2$. Thus there is indeed a connection between large positive eigenvalues and large negative eigenvalues, but whether we have “spurious” positive eigenvalues or inconsequential very negative eigenvalues is sharply controlled by γ , irrespective of the order of approximation n (see also (3.6)).

2. Tau and Galerkin methods.

DEFINITION 2.1. *A Gegenbauer tau method approximates the solution $u(x)$ of a differential equation in $-1 \leq x \leq 1$ by a polynomial of degree n , $u_n(x)$, that satisfies the m boundary conditions exactly. The remaining $n + 1 - m$ polynomial coefficients are determined by requiring that the residual be orthogonal to all polynomials of degree $n - m$ (or less) with respect to the Gegenbauer weight $W^{(\gamma)}(x) = (1 - x^2)^{\gamma-1/2}$, with $\gamma > -1/2$.*

For problem (1.2), the residual

$$(2.1) \quad R_{n-2}(x) \equiv \lambda D^2 u_n(x) - D^4 u_n(x)$$

is a polynomial of degree $n - 2$ in x . The polynomial approximation $u_n(x)$ is determined from the four boundary conditions $u_n(\pm 1) = Du_n(\pm 1) = 0$ and the requirement that $R_{n-2}(x)$ is orthogonal to *all* polynomials $q_{n-4}(x)$ of degree $n - 4$ or less with respect to the weight function $W^{(\gamma)}(x) = (1 - x^2)^{\gamma-1/2} \geq 0$ in the interval $(-1, 1)$

$$(2.2) \quad \int_{-1}^1 R_{n-2}(x) q_{n-4}(x) W^{(\gamma)}(x) dx = 0 \quad \forall q_{n-4}(x).$$

This provides $n - 3$ equations which, together with the four boundary conditions, yield $n + 1$ equations for the $n + 1$ undetermined coefficients in the polynomial approximation $u_n(x)$. For the Gegenbauer weight function $W^{(\gamma)}(x) = (1 - x^2)^{\gamma-1/2}$, the residual can be written explicitly as

$$(2.3) \quad R_{n-2}(x) = \tau_0 \lambda G_{n-2}^{(\gamma)}(x) + \tau_1 \lambda G_{n-3}^{(\gamma)}(x)$$

for some x -independent coefficients τ_0 and τ_1 , where $G_n^{(\gamma)}(x)$ is the Gegenbauer polynomial of degree n . This follows from orthogonality of the Gegenbauer polynomials in $-1 < x < 1$ with respect to the weight $(1 - x^2)^{\gamma-1/2}$, which implies the orthogonality of the Gegenbauer polynomial of degree k to *any* polynomial of degree $k - 1$ or less with respect to that weight function.

Gegenbauer (a.k.a. ultraspherical) polynomials are a special subclass of the Jacobi polynomials [1]. The latter are the most general class of polynomial solutions of a Sturm–Liouville eigenproblem that is singular at ± 1 , as required for faster-than-algebraic convergence [3]. Gegenbauer polynomials are the most general class of polynomials with the odd-even symmetry $G_n^{(\gamma)}(x) = (-1)^n G_n^{(\gamma)}(-x)$. This is a one-parameter family of polynomials, with the parameter $\gamma > -1/2$. Chebyshev polynomials correspond to $\gamma = 0$ and Legendre polynomials to $\gamma = 1/2$. We use a (slightly) nonstandard normalization of Gegenbauer polynomials since the standard normalization [1] is singular in the Chebyshev case. Some key properties of Gegenbauer polynomials used in this paper are given in Appendix A. Note that if $\lambda = 0$, then, from (2.1), the residual $R_{n-2}(x)$ must be a polynomial of degree $n - 4$ implying

that $\tau_0 = \tau_1 = 0$ in (2.3) and $D^4 u_n(x) = 0$ for all x in $(-1, 1)$. The boundary conditions $u_n(\pm 1) = Du_n(\pm 1) = 0$ then imply that $u_n(x) = 0$ for all x in $[-1, 1]$, the trivial solution. Hence we can assume that $\lambda \neq 0$ in the Gegenbauer tau method applied to (1.2). Following common usage [11, 3, 22, 16], we have the following definition.

DEFINITION 2.2. *The Gegenbauer Galerkin method approximates the solution $u(x)$ of a differential equation in $-1 \leq x \leq 1$ by a polynomial of degree n , $u_n(x)$, that satisfies the m boundary conditions exactly. The remaining $n+1-m$ polynomial coefficients are determined by imposing the fact that the residual be orthogonal to all polynomials of degree n (or less) that satisfy the homogeneous boundary conditions with respect to the Gegenbauer weight $W^{(\gamma)}(x) = (1-x^2)^{\gamma-1/2}$, with $\gamma > -1/2$.*

Strictly speaking, this a *Petrov-Galerkin* method since the test functions are not identical to the trial functions because of the Gegenbauer weight $(1-x^2)^{\gamma-1/2}$ [3].

For problem (1.2), $u_n(x)$ is determined from the boundary conditions $u_n(\pm 1) = Du_n(\pm 1) = 0$ and the orthogonality with respect to the weight $W^{(\gamma)}(x) = (1-x^2)^{\gamma-1/2}$ of the residual (2.1) to all polynomials of degree n that vanish together with their derivative at $x = \pm 1$. Such polynomials can be written as $(1-x^2)^2 q_{n-4}(x)$, where $q_{n-4}(x)$ is an arbitrary polynomial of degree $n-4$, and the weighted residual equations read

$$(2.4) \quad \int_{-1}^1 R_{n-2}(x) (1-x^2)^2 q_{n-4}(x) W^{(\gamma)}(x) dx = 0 \quad \forall q_{n-4}(x).$$

The Gegenbauer Galerkin method is therefore equivalent to the tau method for the weight $W^{(\gamma+2)}(x) = (1-x^2)^2 W^{(\gamma)}(x)$, and its residual has the explicit form

$$(2.5) \quad R_{n-2}(x) = \tau_0 \lambda G_{n-2}^{(\gamma+2)}(x) + \tau_1 \lambda G_{n-3}^{(\gamma+2)}(x).$$

So the *Chebyshev (or Legendre) Galerkin* method for clamped boundary conditions, $u_n(\pm 1) = Du_n(\pm 1) = 0$, is in fact a tau method for Chebyshev (or Legendre) polynomials of the *third kind* (proportional to the second derivative of Chebyshev (or Legendre) polynomials (A.5)). Since we consider a range of the Gegenbauer parameter γ , the Gegenbauer tau method also includes some Gegenbauer Galerkin methods.

This suggests an intermediate method where the test functions are polynomials that vanish at $x = \pm 1$ (inviscid boundary conditions only).

DEFINITION 2.3. *The Gegenbauer “inviscid Galerkin” method determines $u_n(x)$ from the four boundary conditions $u_n(\pm 1) = Du_n(\pm 1) = 0$ and the orthogonality of the residual to all polynomials of degree $n-2$ that vanish at $x = \pm 1$ with respect to the weight function $W^{(\gamma)}(x) = (1-x^2)^{\gamma-1/2}$.*

Such test polynomials can be written in the form $(1-x^2)q_{n-4}(x)$, where $q_{n-4}(x)$ is an arbitrary polynomial of degree $n-4$, and so the weighted residual equations read

$$(2.6) \quad \int_{-1}^1 R_{n-2}(x) (1-x^2) q_{n-4}(x) W^{(\gamma)}(x) dx = 0 \quad \forall q_{n-4}(x).$$

The *Gegenbauer inviscid Galerkin* method is therefore equivalent to the Gegenbauer tau method with weight $W^{(\gamma+1)}(x)$, and its residual for (1.2) is

$$(2.7) \quad R_{n-2}(x) = \tau_0 \lambda G_{n-2}^{(\gamma+1)}(x) + \tau_1 \lambda G_{n-3}^{(\gamma+1)}(x).$$

Thus the Chebyshev (or Legendre) inviscid Galerkin method is a tau method for Chebyshev (or Legendre) polynomials of the *second kind*. Since we consider a range of

the Gegenbauer parameter γ , the Gegenbauer tau method also includes some Gegenbauer inviscid Galerkin methods.

For completeness, we list the *collocation* approach, where $u_n(x)$ is determined from the boundary conditions $u_n(\pm 1) = Du_n(\pm 1) = 0$ and from enforcing $R_{n-2}(x_j) = 0$ at the $n - 3$ interior Gauss-Lobatto points x_j such that $DG_{n-2}(x_j) = 0$, $j = 1, \dots, n - 3$, [3, section 2.2]. The residual (2.1) has the form [10, equation (4.5)]

$$(2.8) \quad R_{n-2}(x) = (A + Bx) DG_{n-2}(x),$$

for some A and B independent of x . That residual can be written in several equivalent forms by using the properties of Gegenbauer polynomials (Appendix A). We do not have rigorous results for the collocation method.

3. Legendre and near-Legendre tau cases. Here we provide a quicker and more complete derivation of earlier results [6] about spurious eigenvalues for the Legendre and near-Legendre tau cases. This section provides a useful technical introduction to the problem, but it is not necessary to derive the main results of this paper. Dawkins, Dunbar, and Douglass [6], focusing only on even modes, use the monomial basis x^{2k} to derive an explicit form for the generalized eigenvalue problem $Aa = \lambda Ba$ for the Legendre tau method. In the monomial basis, the matrix A is upper triangular and nonsingular, and the matrix B is upper Hessenberg, but its first row is identically zero; hence there exists one infinite eigenvalue. A perturbation analysis is used to show that the infinite eigenvalue of the Legendre tau method becomes a large positive eigenvalue for the Gegenbauer tau methods with $\gamma < 1/2$ and a large negative eigenvalue for $\gamma > 1/2$.

In the Legendre tau method, the polynomial approximation $u_n(x)$ of degree n to problem (1.2) satisfies the four boundary conditions $u_n = Du_n = 0$ at $x = \pm 1$. Thus $u_n(x) = (1 - x^2)^2 p_{n-4}(x)$, and the polynomial $p_{n-4}(x)$ is determined from the weighted residual equation (2.2), with $\gamma = 1/2$ and $W^{(1/2)}(x) = 1$,

$$(3.1) \quad \int_{-1}^1 (\mu D^4 u_n - D^2 u_n) q_{n-4}(x) dx = 0 \quad \forall q_{n-4}(x).$$

The mathematical problem is fully specified, except for an arbitrary multiplicative constant for $u_n(x)$. Choosing various polynomial bases for $p_{n-4}(x)$ and $q_{n-4}(x)$ will lead to distinct matrix problems, but those problems are all similar to each other and provide exactly the same eigenvalues, in exact arithmetic.

We use the bases $G_l^{(5/2)}(x)$ for $p_{n-4}(x)$ and $G_k^{(1/2)}(x)$ for $q_{n-4}(x)$, with $k, l = 0, \dots, n - 4$, where $G_n^{(\gamma)}(x)$ is the Gegenbauer polynomial of degree n for index γ (see Appendix A, and recall that $G_k^{(1/2)}(x) = P_k(x)$ are Legendre polynomials). Thus we write $u_n(x) = \sum_{l=0}^{n-4} a_l (1 - x^2)^2 G_l^{(5/2)}(x)$ for some $n - 3$ coefficients a_l to be determined. The tau equation (3.1) provides the matrix eigenproblem $\mu Aa = Ba$ or $\mu \sum_{l=0}^{n-4} A(k, l) a_l = \sum_{l=0}^{n-4} B(k, l) a_l$ with

$$(3.2) \quad A(k, l) = \int_{-1}^1 D^4 \left[(1 - x^2)^2 G_l^{(5/2)}(x) \right] G_k^{(1/2)}(x) dx,$$

$$(3.3) \quad B(k, l) = \int_{-1}^1 D^2 \left[(1 - x^2)^2 G_l^{(5/2)}(x) \right] G_k^{(1/2)}(x) dx,$$

for $k, l = 0, \dots, n-4$. Using (B.1), these expressions simplify to

$$(3.4) \quad A(k, l) = \mathcal{C}_l \int_{-1}^1 \left[D^2 G_{l+2}^{(1/2)}(x) \right] G_k^{(1/2)}(x) dx,$$

$$(3.5) \quad B(k, l) = \mathcal{C}_l \int_{-1}^1 G_{l+2}^{(1/2)}(x) G_k^{(1/2)}(x) dx,$$

where $\mathcal{C}_l = \frac{1}{15}(l+1)(l+2)(l+3)(l+4)$.

Since the Legendre polynomials $G_n^{(1/2)}(x) = P_n(x)$ are orthogonal with respect to the unit weight, (3.5) yields that $B(k, l) \propto \delta_{k, l+2}$, where $\delta_{k, l+2}$ is the Kronecker delta so that $B(0, l) = B(1, l) = 0$, for all l , and B has nonzero elements only on the second subdiagonal. For $A(k, l)$, use (A.10) to express $D^2 G_{l+2}^{(1/2)}(x)$ as a linear combination of $G_l^{(1/2)}(x)$, $G_{l-2}^{(1/2)}(x)$, etc. Orthogonality of the Legendre polynomials $G_n^{(1/2)}(x)$ then implies that $A(k, l)$ is upper triangular with nonzero diagonal elements. Hence A is nonsingular, while the nullspace of B is two-dimensional. The eigenvalue problem $\mu Aa = Ba$ therefore has two $\mu = 0$ eigenvalues. Since the only nonzero elements of B consists of the subdiagonal $B(l+2, l)$, the two *right* eigenvectors corresponding to $\mu = 0$ are $a = [0, \dots, 0, 1]^T$ and $[0, \dots, 0, 1, 0]^T$, respectively. In other words,

$$(3.6) \quad u_n(x) = (1-x^2)^2 G_{n-4}^{(5/2)}(x) \quad \text{and} \quad u_n(x) = (1-x^2)^2 G_{n-5}^{(5/2)}(x)$$

satisfy the boundary conditions and the tau equation (3.1) with $\mu = 0 = 1/\lambda$, for all $n \geq 5$. One mode is even, and the other one is odd. Likewise, the *left* eigenvectors $b^T = [1, 0, \dots, 0]$ and $[0, 1, 0, \dots, 0]$ satisfy $\mu b^T A = b^T B$ with $\mu = 0$. These results are for the Legendre case, and $\mu = 0$ corresponds to $\lambda = 1/\mu = \infty$.

Now consider the Gegenbauer tau equations for $\gamma - 1/2 = \epsilon$ with $|\epsilon| \ll 1$, the near-Legendre case. The equation is (3.1) but with the extra weight factor $W^{(\gamma)}(x) = (1-x^2)^\epsilon$ inside the integral. We can figure out what happens to the $\mu = 0$ eigenvalues of the $\epsilon = 0$ Legendre case by perturbation. The matrices A and B and the left and right eigenvectors, denoted a and b , respectively, as well as the eigenvalue μ , now depend on ϵ . Let

$$(3.7) \quad A = A_0 + \epsilon A_1 + O(\epsilon^2), \quad B = B_0 + \epsilon B_1 + O(\epsilon^2),$$

$$(3.8) \quad a = a_0 + \epsilon a_1 + O(\epsilon^2), \quad b = b_0 + \epsilon b_1 + O(\epsilon^2),$$

$$(3.9) \quad \mu = \mu_0 + \epsilon \mu_1 + O(\epsilon^2),$$

where A_0 and B_0 are the matrices obtained above in (3.4) and (3.5) for $\epsilon = 0$, while a_0 and b_0^H are the corresponding right and left eigenvectors so that $\mu_0 A_0 a_0 = B_0 a_0$ and $\mu_0 b_0^H A_0 = b_0^H B_0$. Substituting these ϵ -expansions in the eigenvalue equation $\mu Aa = Ba$ and canceling out the zeroth order term, we obtain

$$(3.10) \quad \mu_1 A_0 a_0 + \mu_0 A_1 a_0 + \mu_0 A_0 a_1 = B_1 a_0 + B_0 a_1 + O(\epsilon).$$

Multiplying by b_0^H cancels out the $\mu_0 b_0^H A_0 a_1 = b_0^H B_0 a_1$ terms, so we obtain

$$(3.11) \quad \mu_1 = \frac{b_0^H B_1 a_0 - \mu_0 b_0^H A_1 a_0}{b_0^H A_0 a_0}.$$

This expression is general but simplifies further since we are interested in the perturbation of the zero eigenvalues $\mu_0 = 0$. This expression for μ_1 is quite simple since b_0 ,

a_0 , and A_0 are the zeroth order objects. All we need to compute when $\mu_0 = 0$ is the first order correction B_1 to the matrix B . But since a_0 and b_0 have only one nonzero component as given at the end of the previous paragraph, we need only to calculate two components of the B matrix. For n even, all that is needed are the first order corrections to $B(0, n-4)$ for the even mode and to $B(1, n-5)$ for the odd mode. For n odd, we need $B(0, n-5)$ for the even mode and $B(1, n-4)$ for the odd mode; however, since the even and odd modes decouple in this problem, it suffices to compute both the even and odd modes in only one case of n even or odd. The matrix elements in the $\epsilon \neq 0$ cases are still given by (3.4) and (3.5) but with the extra $(1-x^2)^\epsilon$ weight factor inside the integrals. Since $G_1^{(1/2)}(x) = x$ and $G_n^{(1/2)}(x) = P_n(x)$, the Legendre polynomial of degree n , we obtain

$$(3.12) \quad B(0, n-4) = C_{n-4} \int_{-1}^1 P_{n-2}(x) (1-x^2)^\epsilon dx = \epsilon B_1(0, n-4) + O(\epsilon^2),$$

$$(3.13) \quad B(1, n-5) = C_{n-5} \int_{-1}^1 x P_{n-3}(x) (1-x^2)^\epsilon dx = \epsilon B_1(1, n-5) + O(\epsilon^2),$$

with C_l as defined in (3.5). The integrals are readily evaluated, and details are provided in Appendix B. Using (B.2), (B.5), and (B.8), we obtain for the even mode (for n even) that

$$(3.14) \quad \mu_1 = \frac{B_1(0, n-4)}{A_0(0, n-4)} = \frac{-4}{(n-2)^2(n-1)^2}.$$

This matches the formula in Dawkins, Dunbar, and Douglass [6, p. 456] since their $2N = n-4$ and $2\nu - 1 = 2\epsilon$. Likewise using (B.7) and (B.9) for the odd mode (with n even) yields

$$(3.15) \quad \mu_1 = \frac{B_1(1, n-5)}{A_0(1, n-5)} = \frac{-4}{(n-4)^2(n-1)^2}.$$

Again if n is odd, then μ_1 for the even mode is given by (3.14) but with $n-1$ in lieu of n . Likewise for n odd, the odd mode is given by (3.15) with $n+1$ in lieu of n . Finally since $\lambda = 1/\mu$, the $\lambda = \infty$ eigenvalues in the Legendre tau case become $\lambda = 1/(\epsilon\mu_1 + O(\epsilon^2)) \sim 1/(\epsilon\mu_1)$ in the near-Legendre cases. From (3.14) and (3.15), these eigenvalues will be $O(n^4/\epsilon)$. Furthermore they will be positive when $\epsilon < 0$ (i.e., *spurious* when $\gamma < 1/2$) but negative when $\epsilon > 0$.

4. Characteristic polynomials. For the model problem (1.2), we can bypass the matrix eigenproblem of section 3 to directly derive the characteristic polynomial for the eigenvalues $\mu = 1/\lambda$. To do so, invert (2.1) to express the polynomial approximation $D^2 u_n(x)$ in terms of the residual $R_{n-2}(x)$

$$(4.1) \quad D^2 u_n(x) = \mu \sum_{k=0}^{\infty} \mu^k D^{2k} R_{n-2}(x),$$

where $\mu = 1/\lambda$. The inversion (4.1) follows from the application of the geometric (Neumann) series for $(1 - \mu D^2)^{-1} = \sum_{k=0}^{\infty} \mu^k D^{2k}$ which terminates since $R_{n-2}(x)$ is a polynomial. Thus $u_n(x)$ can be computed in terms of the unknown tau coefficients by double integration of (4.1) and the application of the boundary conditions. We can assume that $\lambda \neq 0$ because $\lambda = 0$ with $u_n(\pm 1) = Du_n(\pm 1) = 0$ necessarily

corresponds to the trivial solution $u_n(x) = 0 \forall x$ in $[-1, 1]$, as noted in the previous section.

The Gegenbauer polynomials are even in x for n even and odd for n odd (A.8). The symmetry of the differential equation (1.2) and of the Gegenbauer polynomials allows decoupling of the discrete problem into even and odd solutions. This parity reduction leads to simpler residuals and simpler forms for the corresponding characteristic polynomials. The residual in the parity-separated Gegenbauer case contains only one term

$$(4.2) \quad R_{n-2}(x) = \tau_0 \lambda G_{n-2}^{(\gamma)}(x),$$

instead of (2.3), where $G_n^{(\gamma)}(x)$ is the Gegenbauer polynomial of degree n with n even for even solutions and odd for odd solutions. Substituting (4.2) in (4.1) and renormalizing $u_n(x)$ by τ_0 gives

$$(4.3) \quad D^2 u_n(x) = \sum_{k=0}^{\infty} \mu^k D^{2k} G_{n-2}^{(\gamma)}(x).$$

For $\gamma > 1/2$, the identity (A.5) in the form $2\gamma G_{n-2}^{(\gamma)}(x) = DG_{n-1}^{(\gamma-1)}(x)$ can be used to write (4.3) in the form

$$(4.4) \quad D^2 u_n(x) = \frac{1}{2\gamma} \sum_{k=0}^{\infty} \mu^k D^{2k+1} G_{n-1}^{(\gamma-1)}(x),$$

which integrates to

$$(4.5) \quad Du_n(x) = \frac{1}{2\gamma} \sum_{k=0}^{\infty} \mu^k D^{2k} G_{n-1}^{(\gamma-1)}(x) + C,$$

where C is an arbitrary constant.

4.1. Even solutions. For even solutions $u_n(x) = u_n(-x)$, n is even and $Du_n(x)$ is odd so $C = 0$ in (4.5). The boundary condition $Du_n(1) = 0$ gives the characteristic equation for μ (for n even and $\gamma > 1/2$):

$$(4.6) \quad \sum_{k=0}^{\infty} \mu^k D^{2k} G_{n-1}^{(\gamma-1)}(1) = 0.$$

4.2. Odd solutions. For odd solutions, $u_n(x) = -u_n(-x)$, n is odd and the boundary condition $Du_n(1) = 0$ requires that

$$(4.7) \quad C = -\frac{1}{2\gamma} \sum_{k=0}^{\infty} \mu^k D^{2k} G_{n-1}^{(\gamma-1)}(1).$$

Substituting this C value in (4.5) and integrating gives

$$(4.8) \quad 2\gamma u_n(x) = \sum_{k=0}^{\infty} \mu^k D^{2k-1} G_{n-1}^{(\gamma-1)}(x) - x \sum_{k=0}^{\infty} \mu^k D^{2k} G_{n-1}^{(\gamma-1)}(1),$$

where we must define

$$(4.9) \quad D^{-1} G_{n-1}^{(\gamma-1)}(x) = \int_0^x G_{n-1}^{(\gamma-1)}(s) ds = \frac{G_n^{(\gamma-1)}(x) - G_{n-2}^{(\gamma-1)}(x)}{2(n + \gamma - 2)}$$

since $u_n(x)$ and n are odd, where we have used (A.10) to evaluate the integral and the symmetry (A.8) so that $G_n(0) = G_{n-2}(0) = 0$ for n odd. The boundary condition $u_n(1) = 0$ yields the characteristic polynomial equation (for n odd and $\gamma > 1/2$):

$$(4.10) \quad \sum_{k=0}^{\infty} \mu^k D^{2k-1} G_{n-1}^{(\gamma-1)}(1) - \sum_{k=0}^{\infty} \mu^k D^{2k} G_{n-1}^{(\gamma-1)}(1) = 0.$$

For $\gamma > 3/2$, we can use identity (A.5) in the form $2(\gamma-1)G_{n-1}^{(\gamma-1)}(x) = DG_n^{(\gamma-2)}(x)$ to write the characteristic equation (4.10) as

$$(4.11) \quad \sum_{k=0}^{\infty} \mu^k D^{2k} G_n^{(\gamma-2)}(1) - \sum_{k=0}^{\infty} \mu^k D^{2k+1} G_n^{(\gamma-2)}(1) = 0.$$

For $1/2 < \gamma \leq 3/2$, this cannot be used since $\gamma - 2 < -1/2$, but using (4.9) for the D^{-1} term in the first sum, the characteristic equation (4.10) can be written as

$$(4.12) \quad \mu \sum_{k=0}^{\infty} \mu^k D^{2k+1} G_{n-1}^{(\gamma-1)}(1) - \frac{G_{n-2}^{(\gamma-1)}(1) - G_n^{(\gamma-1)}(1)}{2(n+\gamma-2)} - \sum_{k=0}^{\infty} \mu^k D^{2k} G_{n-1}^{(\gamma-1)}(1) = 0.$$

5. Zeros of characteristic polynomials. Here we prove that the zeros of the characteristic polynomial equations (4.6) and (4.10) are real, negative, and distinct for $1/2 < \gamma \leq 7/2$. Some background material is needed.

5.1. Stable polynomials and the Hermite Biehler theorem. A polynomial $p(z)$ is *stable* if and only if all of its zeros have negative real parts. Stable polynomials can arise as characteristic polynomials of a numerical method applied to a differential equation as in [5] for $Du = \lambda u$, with $u(1) = 0$, and in other dynamical systems applications. The characterization of stable polynomials that is most useful here is given by [12], [18, p. 197].

THEOREM 5.1 (the Hermite Biehler theorem). *The real polynomial $p(z) = \Omega(z^2) + z\Theta(z^2)$ is stable if and only if $\Omega(\mu)$ and $\Theta(\mu)$ form a positive pair.*

DEFINITION 5.2. *Two real polynomials $\Omega(\mu)$ and $\Theta(\mu)$ of degree n and $n-1$ (or n), respectively, form a positive pair if*

(a) *the roots $\mu_1, \mu_2, \dots, \mu_n$ of $\Omega(\mu)$ and $\mu'_1, \mu'_2, \dots, \mu'_{n-1}$ (or $\mu'_1, \mu'_2, \dots, \mu'_n$) of $\Theta(\mu)$ are all distinct, real, and negative;*

(b) *the roots interlace as follows: $\mu_1 < \mu'_1 < \mu_2 < \dots < \mu'_{n-1} < \mu_n < 0$ (or $\mu'_1 < \mu_1 < \dots < \mu'_n < \mu_n < 0$);*

(c) *the highest coefficients of $\Omega(\mu)$ and $\Theta(\mu)$ are of like sign.*

We will use the following theorem about positive pairs [15, p. 198].

THEOREM 5.3. *Any nontrivial real linear combination of two polynomials of degree n (or n and $n-1$) with interlacing roots has real roots.*

(Since such a linear combination changes sign $n-1$ times along the real axis, it has $n-1$ real roots. Since it is a real polynomial of degree n , the remaining root is real also.)

5.2. Eigenvalues for even modes. In [5] and [4] we study the Gegenbauer tau method for $D^2u = \lambda u$, with $u(\pm 1) = 0$, which leads to the characteristic polynomial $\sum_{k=0}^{\infty} \mu^k D^{2k} G_n^{(\gamma)}(1)$. The derivation of that result is entirely similar to that in sections 2 and 4. The strategy to prove that the Gegenbauer tau method for that second order

problem has real, negative, and distinct roots is to show the stability of the polynomial

$$(5.1) \quad p(z) = \sum_{k=0}^n z^k D^k G_n^{(\gamma)}(1)$$

for $-1/2 < \gamma \leq 3/2$, then to use the Hermite Biehler theorem to deduce the following theorem.

THEOREM 5.4. *For $-1/2 < \gamma \leq 3/2$, the polynomials*

$$(5.2) \quad \Omega_n^{(\gamma)}(\mu) = \sum_{k=0}^{\infty} \mu^k D^{2k} G_n^{(\gamma)}(1) \quad \text{and} \quad \Theta_n^{(\gamma)}(\mu) = \sum_{k=0}^{\infty} \mu^k D^{2k+1} G_n^{(\gamma)}(1)$$

form a positive pair. From (A.5) this is equivalent to stating that the polynomials

$$(5.3) \quad \Omega_n^{(\gamma)}(\mu) = \sum_{k=0}^{\infty} \mu^k D^{2k} G_n^{(\gamma)}(1) \quad \text{and} \quad \Omega_{n-1}^{(\gamma+1)}(\mu) = \sum_{k=0}^{\infty} \mu^k D^{2k} G_{n-1}^{(\gamma+1)}(1)$$

also form a positive pair. Combining the γ and $\gamma+1$ ranges in (5.3) yields that $\Omega_n^{(\gamma)}(\mu)$ has real, negative, and distinct roots for $-1/2 < \gamma \leq 5/2$.

The stability of (5.1) is proven in [5, Theorem 1] for the broader class of Jacobi polynomials. The basic ideas of the proof are along the lines of Gottlieb [9] and Gottlieb and Lustman's work [10] on the stability of the Chebyshev collocation method for the first and second order operators.

For the fourth order problem (1.2), $D^4 u = \lambda D^2 u$, with $u(\pm 1) = Du(\pm 1) = 0$, the Gegenbauer tau method gives the characteristic polynomial (4.6) for even solutions. This is the polynomial $\Omega_{n-1}^{(\gamma-1)}(\mu)$ of (5.3) that appears for the second order problem [4, 5] and is known to have real, negative, and distinct eigenvalues for $-1/2 < \gamma - 1 \leq 5/2$, that is, for $1/2 < \gamma \leq 7/2$. Hence it follows directly from (4.6) and Theorem 5.4 that the Gegenbauer tau approximation for even solutions of problem (1.2), $D^4 u = \lambda D^2 u$, with $u(\pm 1) = Du(\pm 1) = 0$, has real, negative, and distinct eigenvalues for $1/2 < \gamma \leq 7/2$.

This result is sharp. For $\gamma > 7/2$ and sufficiently large n , our numerical computations show that the polynomial has a pair of complex eigenvalues. For $\gamma < 1/2$ the polynomial (4.6) has a real positive eigenvalue as first proven in [6]. The proof goes as follows. For $\gamma < 1/2$ we cannot use (4.5) since $\gamma - 1$ is below the range of definition of Gegenbauer polynomials (Appendix A). Instead, integrate (4.3) and use identity (A.10) to obtain $\int_0^1 G_{n-2}^{(\gamma)} dx = (G_{n-1}^{(\gamma)}(1) - G_{n-3}^{(\gamma)}(1))/(2(\gamma + n - 2))$ since $G_{n-1}(0) = G_{n-3}(0) = 0$ for n even (A.8). Using formula (A.11), one shows that $G_n^{(\gamma)}(1)$ increases with n if $\gamma > 1/2$ but decreases with n if $\gamma < 1/2$. Hence the constant term is negative for $\gamma < 1/2$, while all the other coefficients of the characteristic polynomial can be shown to be positive using (A.5) and (A.11). Therefore there is one real positive eigenvalue as proved in [6]. For $\gamma = 1/2$, the Legendre case, the constant term vanishes, and there is a $\mu = 0$ ($\lambda = \infty$) eigenvalue as established in section 3.

Remark 1. Exact even solutions of $D^4 u = \lambda D^2 u$, with $u(\pm 1) = Du(\pm 1) = 0$, obey $D^3 u = \lambda Du + C$, with $C = 0$, since $D^3 u$ and Du are odd. Thus even solution eigenvalues of (1.2) are equal to the eigenvalues for odd solutions of the second order problem $D^2 w = \lambda w$ with $w = 0$ at $x = \pm 1$, with $w = Du$. The Gegenbauer tau version of this property is that eigenvalues for even Gegenbauer tau solutions of (1.2) of order n (even) and index γ are equal to the eigenvalues for odd Gegenbauer tau solutions of $D^2 w = \lambda w$, $w(\pm 1) = 0$, of order $n - 1$ (odd) and index $\gamma - 1$. This follows directly from (4.6) and [4, 5].

5.3. Eigenvalues for odd modes. The reduction of the fourth order problem (1.2) to the second order problem does not hold for odd modes which have the characteristic equation (4.10). In fact, all previous theoretical work focused only on the even modes [6, 11]. The same general strategy as for the even case led us to prove the stability of a shifted version of polynomial (5.1).

THEOREM 5.5. *Let $G_n^{(\gamma)}(x)$ denote the nonstandard Gegenbauer polynomial of degree n as defined in Appendix A; then the polynomial*

$$(5.4) \quad p_n^{(\gamma)}(z) = \frac{G_{n-1}^{(\gamma)}(1) - G_{n+1}^{(\gamma)}(1)}{2(n + \gamma)} + \sum_{k=0}^n z^k D^k G_n^{(\gamma)}(1)$$

is stable for $-1/2 < \gamma \leq 1/2$.

The proof is elementary but technical; it is given in Appendix C. We also need the following simple lemma. This lemma will help us determine the sign of the coefficients of the characteristic polynomials.

LEMMA 5.6. *With $G_n^{(\gamma)}(x)$ as defined in Appendix A, the expression*

$$(5.5) \quad D^{k+1}G_n^{(\gamma)}(1) - D^k G_n^{(\gamma)}(1) \geq 0$$

for $k = 0, \dots, n-1$ and $\gamma > -1/2$.

Proof. From (A.13)

$$(5.6) \quad D^k G_n^{(\gamma)}(1) = \frac{2^{k-1} \Gamma(\gamma + k) \Gamma(n + 2\gamma + k)}{(n - k)! \Gamma(\gamma + 1) \Gamma(2\gamma + 2k)},$$

where $\Gamma(z)$ is the standard gamma function. For $k > 0$ and given that $\gamma > -1/2$, the sign of the above expression is positive since all individual terms are positive. In the $k = 0$ case, the sign of the expression is determined by the term $\frac{\Gamma(\gamma)}{\Gamma(2\gamma)}$ since all other terms are positive. If $-1/2 < \gamma < 0$, both numerator and denominator are negative, and thus their ratio is positive. If $\gamma > 0$, the two terms are positive, and thus again their ratio is positive. For $\gamma = 0$ a simple limiting argument shows positiveness again; in fact from (A.14), $G_n^{(0)}(1) = T_n(1)/n = 1/n$.

Taking the ratio $D^{k+1}G_n^{(\gamma)}(1)/D^k G_n^{(\gamma)}(1)$ and making some simplifications gives

$$(5.7) \quad \frac{D^{k+1}G_n^{(\gamma)}(1)}{D^k G_n^{(\gamma)}(1)} = \frac{(2\gamma + n + k)(n - k)}{(2\gamma + 2k + 1)}.$$

Since $k \leq n - 1$, then $2\gamma + 2k + 1 \leq 2\gamma + (n - 1) + k + 1 = 2\gamma + n + k$. Thus

$$(5.8) \quad \frac{D^{k+1}G_n^{(\gamma)}(1)}{D^k G_n^{(\gamma)}(1)} \geq 1, \quad k = 0, \dots, n - 1,$$

and since both derivatives are positive, the lemma follows. \square

We now have all of the tools to prove the following theorem.

THEOREM 5.7. *The Gegenbauer tau approximation to problem (1.2) has real, negative, and distinct eigenvalues for $1/2 < \gamma \leq 7/2$. This γ range is sharp, spurious positive eigenvalues exist for $\gamma < 1/2$, and complex eigenvalues arise for $7/2 < \gamma$.*

Proof. This has already been proven in section 5.2 for even solutions. For odd solutions, we need to consider two separate cases.

Case 1 ($3/2 < \gamma \leq 7/2$). The characteristic polynomial (4.11)

$$(5.9) \quad \sum_{k=0}^{\infty} \mu^k D^{2k} G_n^{(\gamma-2)}(1) - \sum_{k=0}^{\infty} \mu^k D^{2k+1} G_n^{(\gamma-2)}(1) = \Omega_n^{(\gamma-2)}(\mu) - \Theta_n^{(\gamma-2)}(\mu)$$

is a linear combination of the polynomials $\Omega_n^{(\gamma-2)}(\mu)$ and $\Theta_n^{(\gamma-2)}(\mu)$, which form a positive pair for $3/2 < \gamma \leq 7/2$, by Theorem 5.4. Therefore, by Theorem 5.3, this characteristic polynomial has real roots. Then, by Lemma 5.6, we deduce that all of its coefficients are of the same sign, and hence all of its roots must be negative.

Case 2 ($1/2 < \gamma \leq 3/2$). The polynomial

$$(5.10) \quad p_{n-1}^{(\gamma-1)}(z) = \Lambda(z^2) + z\Phi(z^2),$$

with $p_n^{(\gamma)}(z)$ as in Theorem 5.5, is stable for the desired range of parameters by Theorem 5.5, and so the Hermite Biehler theorem (Theorem 5.1) implies that the polynomials

$$(5.11) \quad \Lambda(\mu) = \frac{G_{n-2}^{(\gamma-1)}(1) - G_n^{(\gamma-1)}(1)}{2(n+\gamma-2)} + \sum_{k=0}^{\infty} \mu^k D^{2k} G_{n-1}^{(\gamma-1)}(1) \\ = \frac{G_{n-2}^{(\gamma-1)}(1) - G_n^{(\gamma-1)}(1)}{2(n+\gamma-2)} + \Omega_{n-1}^{(\gamma-1)}(\mu)$$

and

$$(5.12) \quad \Phi(\mu) = \sum_{k=0}^{\infty} \mu^k D^{2k+1} G_{n-1}^{(\gamma-1)}(1) = \Theta_{n-1}^{(\gamma-1)}(\mu)$$

form a positive pair, with $\Omega_n^{(\gamma)}(\mu)$ and $\Theta_n^{(\gamma)}(\mu)$ as defined in Theorem 5.4. Thus $\mu\Phi(\mu)$ and $\Lambda(\mu)$ have interlacing roots, and any real linear combination of the two must have real roots (Theorem 5.3). Now the characteristic polynomial (4.12) is in fact the linear combination $\mu\Phi(\mu) - \Lambda(\mu)$, so it has real roots. Its constant term is equal to

$$(5.13) \quad \frac{G_n^{(\gamma-1)}(1) - G_{n-2}^{(\gamma-1)}(1)}{2(n+\gamma-2)} - G_{n-1}^{(\gamma-1)}(1),$$

which is negative if $-1/2 < \gamma-1 \leq 1/2$, that is, $1/2 < \gamma \leq 3/2$, from (A.11). All other coefficients of the characteristic polynomial $\mu\Phi(\mu) - \Lambda(\mu)$ are negative by Lemma 5.6. Since all coefficients have the same sign and all roots are real, all of the roots must be negative. \square

6. Galerkin and modified tau methods. Our main Theorem 5.7 can be expressed in terms of the inviscid Galerkin and Galerkin methods since these methods are equivalent to Gegenbauer tau methods with index $\gamma+1$ and $\gamma+2$, respectively, as shown in section 2.

COROLLARY 6.1. *The Gegenbauer inviscid Galerkin approximation to problem (1.2) has real, negative, and distinct eigenvalues for $-1/2 < \gamma \leq 5/2$.*

COROLLARY 6.2. *The Gegenbauer Galerkin approximation to problem (1.2) has real negative eigenvalues for $-1/2 < \gamma \leq 3/2$.*

COROLLARY 6.3. *Since Chebyshev corresponds to $\gamma = 0$ and Legendre to $\gamma = 1/2$, the Chebyshev and Legendre tau approximations to problem (1.2) have spurious eigenvalues, but the Chebyshev and Legendre inviscid Galerkin ($\gamma = 1$ and $3/2$, respectively) and Galerkin ($\gamma = 2$ and $5/2$, respectively) approximations provide real, negative, and distinct eigenvalues.*

Finally, we prove that the modified tau method introduced by Gottlieb and Orszag [11] and developed by various authors [8, 16] is equivalent to the Galerkin method. McFadden, Murray, and Boisvert [16] have already shown the equivalence between the modified Chebyshev tau and the Chebyshev Galerkin methods. Our simpler proof generalizes their results to the Gegenbauer class of approximations.

The idea for the modified tau method, widely used for time marching, starts with the substitution $v(x) = D^2u(x)$. Problem (1.2) reads

$$(6.1) \quad D^2u = v, \quad D^2v = \lambda v, \quad \text{with } u = Du = 0 \text{ at } x = \pm 1.$$

If we approximate $u(x)$ by a polynomial of degree n , then $v = D^2u$ suggests that v should be a polynomial of degree $n - 2$; however, the modified tau method approximates both $u(x)$ and $v(x)$ by polynomials of degree n ,

$$(6.2) \quad \begin{aligned} u_n(x) &= \sum_{k=0}^n \hat{u}_k G_k^{(\gamma)}(x), & D^2u_n(x) &= \sum_{k=0}^{n-2} \hat{u}_k^{(2)} G_k^{(\gamma)}(x), \\ v_n(x) &= \sum_{k=0}^n \hat{v}_k G_k^{(\gamma)}(x), & D^2v_n(x) &= \sum_{k=0}^{n-2} \hat{v}_k^{(2)} G_k^{(\gamma)}(x), \end{aligned}$$

where the superscripts indicate the Gegenbauer coefficients of the corresponding derivatives. These can be expressed in terms of the Gegenbauer coefficients of the original function using (A.10) twice, as in the Chebyshev tau method [3, 17]. Hence there are $2n + 2$ coefficients to be determined, $\hat{u}_0, \dots, \hat{u}_n$ and $\hat{v}_0, \dots, \hat{v}_n$. In the modified tau method, these are determined by the four boundary conditions and the $2n - 2$ tau equations obtained from orthogonalizing the residuals of both equations $D^2u = v$ and $D^2v = \lambda v$ to the first $n - 1$ Gegenbauer polynomials $G_0^{(\gamma)}(x), \dots, G_{n-2}^{(\gamma)}(x)$ with respect to the Gegenbauer weight $(1 - x^2)^{\gamma-1/2}$. In terms of the expansions (6.2), these weighted residual equations have the simple form

$$(6.3) \quad \begin{aligned} \hat{u}_k^{(2)} &= \hat{v}_k, & 0 \leq k \leq n - 2, \\ \hat{v}_k^{(2)} &= \lambda \hat{v}_k, & 0 \leq k \leq n - 2. \end{aligned}$$

McFadden, Murray, and Boisvert [16] showed that the modified Chebyshev tau is equivalent to the Chebyshev Galerkin method for this particular problem. We provide a simpler proof for the general setting of Gegenbauer polynomials.

THEOREM 6.4. *The modified Gegenbauer tau method proposed in [11] is equivalent to the Gegenbauer Galerkin method for problem (1.2).*

Proof. Let the polynomial approximations and their derivatives be as in (6.2). Then the tau equations (6.3) are equivalent to the residual equations

$$(6.4) \quad \begin{aligned} v_n(x) - D^2u_n(x) &= \hat{v}_{n-1} G_{n-1}^{(\gamma)}(x) + \hat{v}_n G_n^{(\gamma)}(x), \\ (\lambda - D^2)v_n(x) &= \lambda \hat{v}_{n-1} G_{n-1}^{(\gamma)}(x) + \lambda \hat{v}_n G_n^{(\gamma)}(x). \end{aligned}$$

Combining the two yields

$$(6.5) \quad (\lambda - D^2) D^2 u_n(x) = \hat{v}_{n-1} D^2 G_{n-1}^{(\gamma)}(x) + \hat{v}_n D^2 G_n^{(\gamma)}(x), \quad u_n(\pm 1) = Du_n(\pm 1) = 0,$$

which using (A.5) is equivalent to

$$(6.6) \quad (\lambda - D^2) D^2 u_n(x) = \tau_0 \lambda G_{n-2}^{(\gamma+2)}(x) + \tau_1 \lambda G_{n-3}^{(\gamma+2)}(x), \quad u_n(\pm 1) = Du_n(\pm 1) = 0,$$

with $\hat{v}_n = 4\lambda(\gamma+1)(\gamma+2)\tau_0$ and $\hat{v}_{n-1} = 4\lambda(\gamma+1)(\gamma+2)\tau_1$. This is exactly the Gegenbauer Galerkin method as given in (2.5). \square

Since the modified Gegenbauer tau method is equivalent to the Galerkin method, the results in section 5 imply that the modified tau method for problem 1.2 has real and negative eigenvalues for $-1/2 < \gamma \leq 3/2$. This includes Chebyshev for $\gamma = 0$ and Legendre for $\gamma = 1/2$.

Appendix A. Gegenbauer (ultraspherical) polynomials. The Gegenbauer (a.k.a. ultraspherical) polynomials $C_n^{(\gamma)}(x)$, $\gamma > -1/2$, of degree n , are the Jacobi polynomials, with $\alpha = \beta = \gamma - 1/2$, up to normalization [1, 22.5.20]. They are symmetric (even for n even and odd for n odd) orthogonal polynomials with weight function $W^{(\gamma)}(x) = (1-x^2)^{\gamma-1/2}$. Since the standard normalization [1, 22.3.4] is singular for the Chebyshev case $\gamma = 0$, we use a nonstandard normalization that includes the Chebyshev case but preserves the simplicity of the Gegenbauer recurrences. Set

$$(A.1) \quad G_0^{(\gamma)}(x) := 1, \quad G_n^{(\gamma)}(x) := \frac{C_n^{(\gamma)}(x)}{2^\gamma}, \quad n \geq 1.$$

These Gegenbauer polynomials satisfy the orthogonality relationship

$$(A.2) \quad \int_{-1}^1 (1-x^2)^{\gamma-1/2} G_m^{(\gamma)} G_n^{(\gamma)} dx = \begin{cases} 0, & m \neq n, \\ h_n^\gamma, & m = n, \end{cases}$$

where [1, 22.2.3]

$$(A.3) \quad h_0^\gamma = \frac{\pi 2^{-2\gamma} \Gamma(2\gamma+1)}{\Gamma^2(\gamma+1)} \quad \text{and} \quad h_n^\gamma = \frac{\pi 2^{-1-2\gamma} \Gamma(n+2\gamma)}{(n+\gamma)n! \Gamma^2(\gamma+1)}, \quad n \geq 1.$$

The Sturm–Liouville form of the Gegenbauer equation for $G_n^{(\gamma)}(x)$ is

$$(A.4) \quad D \left[(1-x^2)^{\gamma+1/2} D G_n^{(\gamma)}(x) \right] = -n(n+2\gamma) (1-x^2)^{\gamma-1/2} G_n^{(\gamma)}(x).$$

They satisfy the derivative recurrence formula

$$(A.5) \quad \frac{d}{dx} G_{n+1}^{(\gamma)} = 2(\gamma+1) G_n^{(\gamma+1)}$$

(for $C_n^{(\gamma)}$ this is formula [2, A.57]), and their three-term recurrence takes the simple form

$$(A.6) \quad (n+1) G_{n+1}^{(\gamma)} = 2(n+\gamma)x G_n^{(\gamma)} - (n-1+2\gamma) G_{n-1}^{(\gamma)}, \quad n \geq 2,$$

with

$$(A.7) \quad G_0^{(\gamma)}(x) = 1, \quad G_1^{(\gamma)}(x) = x, \quad G_2^{(\gamma)} = (\gamma+1)x^2 - \frac{1}{2}.$$

These recurrences can be used to verify the odd-even symmetry of Gegenbauer polynomials [1, 22.4.2]

$$(A.8) \quad G_n^{(\gamma)}(x) = (-1)^n G_n^{(\gamma)}(-x).$$

Differentiating the recurrence (A.6) with respect to x and subtracting from the corresponding recurrence for $\gamma + 1$ using (A.5) yields [1, 22.7.23]

$$(A.9) \quad (n + \gamma)G_n^{(\gamma)} = (\gamma + 1) \left[G_n^{(\gamma+1)} - G_{n-2}^{(\gamma+1)} \right], \quad n \geq 3.$$

Combined with (A.5), this leads to the important derivative recurrence between Gegenbauer polynomials of same index γ

$$(A.10) \quad \begin{aligned} G_0^{(\gamma)}(x) &= DG_1^{(\gamma)}(x), \quad 2(1 + \gamma)G_1^{(\gamma)}(x) = DG_2^{(\gamma)}(x), \\ 2(n + \gamma)G_n^{(\gamma)} &= \frac{d}{dx} \left[G_{n+1}^{(\gamma)} - G_{n-1}^{(\gamma)} \right]. \end{aligned}$$

Evaluating the Gegenbauer polynomial at $x = 1$, we find [1, 22.4.2]

$$(A.11) \quad \begin{aligned} G_n^{(\gamma)}(1) &= \frac{1}{2\gamma} C_n^{(\gamma)}(1) = \frac{1}{2\gamma} \binom{2\gamma + n - 1}{n} = \frac{(2\gamma + n - 1)(2\gamma + n - 2) \cdots (2\gamma + 1)}{n!} \\ &= \frac{\Gamma(2\gamma + n)}{n! \Gamma(2\gamma + 1)} \end{aligned}$$

for $n \geq 2$, with $G_1^{(\gamma)}(1) = G_0^{(\gamma)}(1) = 1$, where $\Gamma(z)$ is the standard gamma function [1]. Note that $G_n^{(\gamma)}(1) > 0$ for $\gamma > -1/2$ and that it decreases with increasing n if $-1/2 < \gamma < 1/2$ but increases with n if $1/2 < \gamma$.

Now (A.5) gives

$$(A.12) \quad \frac{d^k G_n^{(\gamma)}}{dx^k}(x) = \frac{2^k \Gamma(\gamma + k + 1)}{\Gamma(\gamma + 1)} G_{n-k}^{(\gamma+k)}(x),$$

which coupled with (A.11) gives

$$(A.13) \quad \frac{d^k G_n^{(\gamma)}}{dx^k}(1) = \frac{2^{k-1} \Gamma(\gamma + k) \Gamma(n + 2\gamma + k)}{(n - k)! \Gamma(\gamma + 1) \Gamma(2\gamma + 2k)}, \quad n \geq 1.$$

Gegenbauer polynomials correspond to Chebyshev polynomials of the first kind $T_n(x)$ when $\gamma = 0$, to Legendre polynomials $P_n(x)$ for $\gamma = 1/2$, and to Chebyshev polynomials of the second kind $U_n(x)$ for $\gamma = 1$. For the nonstandard normalization,

$$(A.14) \quad G_n^{(0)}(x) = \frac{T_n(x)}{n}, \quad G_n^{(1/2)}(x) = P_n(x), \quad G_n^{(1)}(x) = \frac{U_n(x)}{2}.$$

Appendix B. Integrals and asymptotics. As shown in section 3, the tau equation (3.1) provides a matrix eigenproblem of the form $\mu Aa = Ba$. To reduce the coefficients $A(k, l)$ and $B(k, l)$ defined in (3.2) and (3.3) to the expressions (3.4) and

(3.5), respectively, use (A.4) and (A.5) repeatedly:

$$\begin{aligned}
\text{(B.1)} \quad D^2 \left[(1-x^2)^2 G_l^{(5/2)}(x) \right] &= \frac{1}{5} D^2 \left[(1-x^2)^2 D G_{l+1}^{(3/2)}(x) \right] \\
&= -\frac{1}{5} (l+1)(l+4) D \left[(1-x^2) G_{l+1}^{(3/2)}(x) \right] \\
&= -\frac{1}{15} (l+1)(l+4) D \left[(1-x^2) D G_{l+2}^{(1/2)}(x) \right] \\
&= \frac{1}{15} (l+1)(l+2)(l+3)(l+4) G_{l+2}^{(1/2)}(x) \\
&\equiv \mathcal{C}_l G_{l+2}^{(1/2)}(x).
\end{aligned}$$

For the perturbation analysis described in section 3, we need the first order corrections to $B(0, n-4)$ and to $B(1, n-5)$. From (3.12) and (3.13)

$$\text{(B.2)} \quad B_1(0, n-4) = \lim_{\epsilon \rightarrow 0} \frac{\mathcal{C}_{n-4}}{\epsilon} \int_{-1}^1 P_{n-2}(x) (1-x^2)^\epsilon dx,$$

$$\text{(B.3)} \quad B_1(1, n-5) = \lim_{\epsilon \rightarrow 0} \frac{\mathcal{C}_{n-5}}{\epsilon} \int_{-1}^1 x P_{n-3}(x) (1-x^2)^\epsilon dx.$$

To evaluate $\int_{-1}^1 P_n(x) (1-x^2)^\epsilon dx$ to $O(\epsilon)$ for $|\epsilon| \ll 1$ and n even, use (A.4) for $\gamma = 1/2$ and integration by parts to derive

$$\begin{aligned}
\text{(B.4)} \quad \int_{-1}^1 P_n(x) (1-x^2)^\epsilon dx &= \frac{-1}{n(n+1)} \int_{-1}^1 D \left[(1-x^2) D P_n \right] (1-x^2)^\epsilon dx \\
&= \frac{\epsilon}{n(n+1)} \int_{-1}^1 D P_n (1-x^2)^\epsilon (-2x) dx.
\end{aligned}$$

This integral is 0 if n is odd since $P_n(x) = (-1)^n P_n(-x)$. Since we have an ϵ prefactor, we can now set $\epsilon = 0$ in the integral and do the remaining integral by parts to obtain

$$\begin{aligned}
\text{(B.5)} \quad \int_{-1}^1 P_n(x) (1-x^2)^\epsilon dx &\sim \frac{-2\epsilon}{n(n+1)} \int_{-1}^1 x D P_n dx \\
&= \frac{-2\epsilon}{n(n+1)} \int_{-1}^1 (D(x P_n) - P_n) dx \\
&= \frac{-2\epsilon}{n(n+1)} (P_n(1) + P_n(-1)) = \frac{-4\epsilon}{n(n+1)}
\end{aligned}$$

for n even (0 for n odd as it should be).

For the integral in (B.3), use the recurrence (A.6) for $\gamma = 1/2$ to write $(2n-5)xP_{n-3}(x) = (n-2)P_{n-2}(x) + (n-3)P_{n-4}(x)$ and evaluate the resulting two integrals from (B.5). Hence, for n even,

$$\text{(B.6)} \quad B_1(0, n-4) \sim -\frac{4\mathcal{C}_{n-4}}{(n-2)(n-1)},$$

$$\text{(B.7)} \quad B_1(1, n-5) \sim -\frac{4\mathcal{C}_{n-5}}{(n-4)(n-1)}.$$

Now for $A_0(0, n-4)$, $A_0(1, n-5)$, and n even, we have

$$(B.8) \quad A_0(0, n-4) = \mathcal{C}_{n-4} \int_{-1}^1 D^2 P_{n-2}(x) dx = (n-2)(n-1)\mathcal{C}_{n-4},$$

$$(B.9) \quad A_0(1, n-5) = \mathcal{C}_{n-5} \int_{-1}^1 x D^2 P_{n-3}(x) dx = (n-4)(n-1)\mathcal{C}_{n-5}.$$

Appendix C. Proof of Theorem 5.5. Consider

$$(C.1) \quad f_n(x; z) = \sum_{k=0}^{\infty} z^k D^k G_n^{(\gamma)}(x) + K \left(G_n^{(\gamma)}(x) - G_{n+2}^{(\gamma)}(x) \right),$$

where z is a solution of $f_n(1; z) = 0$ and K is

$$(C.2) \quad K = \frac{\left(G_{n-1}^{(\gamma)}(1) - G_{n+1}^{(\gamma)}(1) \right)}{2(n+\gamma) \left(G_n^{(\gamma)}(1) - G_{n+2}^{(\gamma)}(1) \right)} = \dots = \frac{n+2}{2(n+\gamma+1)(n+2\gamma-1)},$$

where we have used (A.11). Note that $f_n(1; z) = p_n^{(\gamma)}(z)$ defined in Theorem 5.5. Taking the x -derivative of $f_n(x; z)$ and using (A.10), we find

$$(C.3) \quad \frac{df_n(x; z)}{dx} = \sum_{k=0}^{\infty} z^k D^{k+1} G_n^{(\gamma)}(x) - 2K(n+\gamma+1)G_{n+1}^{(\gamma)}(x).$$

Thus $f_n(x; z)$ satisfies the following differential equation,

$$(C.4) \quad f_n(x; z) - (1+K)G_n^{(\gamma)}(x) + KG_{n+2}^{(\gamma)}(x) = z \frac{df_n(x; z)}{dx} + z2K(n+\gamma+1)G_{n+1}^{(\gamma)}(x).$$

Multiplying by $(1+x) \frac{df_n^*(x; z)}{dx}$, integrating in the Gegenbauer norm, and adding the complex conjugate, we get

$$(C.5) \quad \int_{-1}^1 \frac{d|f_n|^2}{dx} (1+x)w(x)dx - (1+K) \left(\int_{-1}^1 (1+x) \frac{df_n^*}{dx} G_n^{(\gamma)}(x)w(x)dx + C.C. \right) \\ + K \left(\int_{-1}^1 (1+x) \frac{df_n^*}{dx} G_{n+2}^{(\gamma)}(x)w(x)dx + C.C. \right) = (z+z^*) \int_{-1}^1 \left| \frac{df_n}{dx} \right|^2 (1+x)w(x)dx \\ + \left(z2K(n+\gamma+1) \int_{-1}^1 (1+x) \frac{df_n^*}{dx} G_{n+1}^{(\gamma)}(x)w(x)dx + C.C. \right),$$

where $C.C.$ denotes the complex conjugate. To simplify (C.5) we need to compute four simple integrals:

$$(C.6) \quad \begin{aligned} I_1 &= \int_{-1}^1 \frac{d|f_n|^2}{dx} (1+x)w(x)dx, \\ J_0 &= \int_{-1}^1 (1+x) \frac{df_n^*}{dx} G_n^{(\gamma)}(x)w(x)dx, \\ J_1 &= \int_{-1}^1 (1+x) \frac{df_n^*}{dx} G_{n+1}^{(\gamma)}(x)w(x)dx, \\ J_2 &= \int_{-1}^1 (1+x) \frac{df_n^*}{dx} G_{n+2}^{(\gamma)}(x)w(x)dx. \end{aligned}$$

Using integration by parts, the first integral becomes

$$(C.7) \quad I_1 = \int_{-1}^1 \frac{d|f_n|^2}{dx} (1+x)w(x)dx = - \int_{-1}^1 |f_n|^2 (1-2\gamma x) \frac{w(x)}{1-x} dx.$$

Therefore, the integral is negative for $-1/2 < \gamma \leq 1/2$ since for this range of parameters $1-2\gamma x$ is positive.

For the calculation of the three other integrals, we are going to need the expressions

$$(C.8) \quad \frac{df_n}{dx} = \sum_{k=0}^{\infty} z^k D^{k+1} G_n^{(\gamma)}(x) - 2K(\gamma+n+1)G_{n+1}^{(\gamma)}(x),$$

$$(C.9) \quad = \mathcal{P}_{n-2}(x; z) + 2(\gamma+n-1)G_{n-1}^{(\gamma)}(x) - 2K(\gamma+n+1)G_{n+1}^{(\gamma)}(x),$$

$$(C.10) \quad = \mathcal{P}_{n-1}(x; z) - 2K(\gamma+n+1)G_{n+1}^{(\gamma)}(x),$$

where $\mathcal{P}_{n-2}(x; z)$ and $\mathcal{P}_{n-1}(x; z)$ are polynomials of degree $n-2$ and $n-1$, respectively.

With the use of (C.9) and the orthogonality of the Gegenbauer polynomials, we find

$$(C.11) \quad \begin{aligned} J_0 &= \int_{-1}^1 (1+x) \frac{df_n^*}{dx} G_n^{(\gamma)}(x) w(x) dx \\ &= 2(n-1+\gamma) \int_{-1}^1 x G_{n-1}^{(\gamma)}(x) G_n^{(\gamma)}(x) w(x) dx - 2K(n+1+\gamma) \\ &\quad \int_{-1}^1 x G_{n+1}^{(\gamma)}(x) G_n^{(\gamma)}(x) w(x) dx \\ &= n \int_{-1}^1 \left(G_n^{(\gamma)}(x) \right)^2 w(x) dx - K(n+\gamma+1) \frac{n+1}{n+\gamma} \int_{-1}^1 \left(G_{n+1}^{(\gamma)}(x) \right)^2 w(x) dx \\ &= nh_n^{(\gamma)} - K \frac{(n+\gamma+1)(n+1)}{n+\gamma} h_{n+1}^{(\gamma)}, \end{aligned}$$

where we have also used (A.5) and (A.6). In the same way, we compute

$$(C.12) \quad \begin{aligned} J_2 &= \int_{-1}^1 (1+x) \frac{df_n^*}{dx} G_{n+2}^{(\gamma)}(x) w(x) dx \\ &= -K \int_{-1}^1 2(n+\gamma+1)x G_{n+1}^{(\gamma)}(x) G_{n+2}^{(\gamma)}(x) w(x) dx \\ &= -K(n+2)h_{n+2}^{(\gamma)} \end{aligned}$$

and

$$(C.13) \quad \begin{aligned} J_1 &= \int_{-1}^1 (1+x) \frac{df_n^*}{dx} G_{n+1}^{(\gamma)}(x) w(x) dx \\ &= -2K(n+\gamma+1) \int_{-1}^1 (1+x) \left(G_{n+1}^{(\gamma)}(x) \right)^2 w(x) dx \\ &\quad - 2K(n+\gamma+1) \int_{-1}^1 \left(G_{n+1}^{(\gamma)}(x) \right)^2 w(x) dx \\ &= -2K(n+\gamma+1)h_{n+1}^{(\gamma)}. \end{aligned}$$

Thus (C.5) transforms to

$$(C.14) \quad - \int_{-1}^1 |f_n|^2 \frac{(1-2\gamma x)w(x)}{(1-x)} dx - 2(1+K) \left(nh_n^{(\gamma)} - K \frac{(n+\gamma+1)(n+1)}{n+\gamma} h_{n+1}^{(\gamma)} \right) - 2K^2(n+2)h_{n+2}^{(\gamma)} = (z+z^*) \left(\int_{-1}^1 \left| \frac{df_n}{dx} \right|^2 (1+x)w(x) dx - 4K^2(n+1+\gamma)^2 h_{n+1}^{(\gamma)} \right).$$

Our task is to show that the left-hand side of the above expression is negative, whereas the coefficient of the term $z+z^*$ on the right-hand side is positive. A simple calculation shows that

$$(C.15) \quad nh_n^{(\gamma)} - K \frac{(n+\gamma+1)(n+1)}{(n+\gamma)} h_{n+1}^{(\gamma)} = nh_n^{(\gamma)} - \frac{(n+1)(n+2)}{(n+\gamma)(n+2\gamma-1)} h_{n+1}^{(\gamma)} \\ = \frac{\pi 2^{-1-2\gamma} \Gamma(n+2\gamma)}{\gamma^2 \Gamma^2(\gamma) n! (n+\gamma)} \left(n - \frac{(n+2)(n+2\gamma)}{2(n-1+2\gamma)(n+1+\gamma)} \right) \\ \geq \frac{\pi 2^{-1-2\gamma} \Gamma(n+2\gamma)}{\gamma^2 \Gamma^2(\gamma) n! (n+\gamma)} \left(n - \frac{(n+2)(n+1)}{(n-2)(2n+1)} \right).$$

The last parenthesis is positive for $n \geq 3$.

For the right-hand side, we use the notation in (C.10) to get

$$(C.16) \quad \int_{-1}^1 \left| \frac{df_n}{dx} \right|^2 (1+x)w(x) dx - 4K^2(n+1+\gamma)^2 h_{n+1}^{(\gamma)} \\ = \int_{-1}^1 (1+x) \left(|\mathcal{P}_{n-1}(x; z)|^2 - 2K(n+1+\gamma)G_{n+1}^{(\gamma)}(x) (\mathcal{P}_{n-1}(x; z) + \mathcal{P}_{n-1}^*(x; z)) \right. \\ \left. + 4K^2(n+1+\gamma)^2 (G_{n+1}^{(\gamma)}(x))^2 \right) w(x) dx - 4K^2(n+1+\gamma)^2 h_{n+1}^{(\gamma)} \\ = \int_{-1}^1 (1+x) |\mathcal{P}_{n-1}(x; z)|^2 w(x) dx + 0 + 0 + 4K^2(n+1+\gamma)^2 h_{n+1}^{(\gamma)} - 4K^2(n+1+\gamma)^2 h_{n+1}^{(\gamma)} \\ = \int_{-1}^1 (1+x) |\mathcal{P}_{n-1}(x; z)|^2 w(x) dx > 0.$$

Thus (C.14) becomes

$$(C.17) \quad - \int_{-1}^1 |f_n|^2 \frac{(1-2\gamma x)w(x)}{(1-x)} dx - 2(1+K) \left(nh_n^{(\gamma)} - K \frac{(n+\gamma+1)(n+1)}{n+\gamma} h_{n+1}^{(\gamma)} \right) \\ - 2K^2(n+2)h_{n+2}^{(\gamma)} = (z+z^*) \int_{-1}^1 (1+x) |\mathcal{P}_{n-1}(x; z)|^2 w(x) dx,$$

and $\Re(z) < 0$.

For $n = 2$ we get the following characteristic polynomial:

$$(C.18) \quad f_2^{(\gamma)}(1; z) = \frac{2}{3}(\gamma+1)(3z^2 + 3z + 1),$$

whose zeros

$$(C.19) \quad z_1 = -\frac{1}{2} - \frac{\sqrt{3}i}{6}, \quad z_2 = -\frac{1}{2} + \frac{\sqrt{3}i}{6}$$

have negative real parts for any γ .

Acknowledgment. We thank Jue Wang for helpful calculations in the early stages of this work.

NUMERICAL ALGORITHM FOR CALCULATING THE GENERALIZED MITTAG-LEFFLER FUNCTION*

HANSJÖRG SEYBOLD[†] AND RUDOLF HILFER[‡]

Abstract. A numerical algorithm for calculating the generalized Mittag-Leffler $E_{\alpha,\beta}(z)$ function for arbitrary complex argument z and real parameters $\alpha > 0$ and $\beta \in \mathbb{R}$ is presented. The algorithm uses the Taylor series, the exponentially improved asymptotic series, and integral representations to obtain optimal stability and accuracy of the algorithm. Special care is applied to the limits of validity of the different schemes to avoid instabilities in the algorithm.

Key words. special functions of mathematical physics, fractional calculus, generalized Mittag-Leffler functions, numerical algorithms

DOI. 10.1137/070700280

1. Introduction. The (generalized) Mittag-Leffler function $E_{\alpha,\beta}(z)$ is an entire function with two parameters α and β . The function $E_{\alpha,1}(z)$ is named after Mittag-Leffler, who introduced it in 1903 in a publication on Laplace–Abel integrals [10, 11, 12]. Shortly after its introduction it was generalized by Wiman [21].

The generalized Mittag-Leffler function with a nonnegative argument is completely monotone if and only if $0 < \alpha \leq 1$, $\operatorname{Re}(\beta) \geq \alpha$ [18].

In the special case $\beta = 1$ and $0 < \alpha \leq 1$, complete monotonicity was already conjectured by Feller and later proved by Pollard in 1948 [2, 16]. Analytical investigations on the distribution of the zeros in the complex plane were published by Wiman [21, 22], and numerical results are given in [7, 19].

In recent years fractional calculus has become a popular topic in physics and engineering [8]. Fractional equations of motion are widely accepted for describing viscoelasticity and anomalous diffusion [5, 6, 8, 9, 24]. The generalized Mittag-Leffler function plays a central role in fractional calculus and its applications because it is closely related to the eigenfunction of the fractional derivative operator [8, 17]. Progress in this field requires the calculation of the exact numerical values of the generalized Mittag-Leffler function for arbitrary complex arguments and the study of its properties.

The Mittag-Leffler function shows very different behaviors in the complex plane with varying parameters α and β , so different approaches have to be used for different regions in the complex plane. We present a stable and robust numerical method based on recursion relations, exponentially improved asymptotics, and integral representations for calculating the generalized Mittag-Leffler function for real parameters $\alpha > 0$ and β and arbitrary complex argument z .

The article is organized as follows: First, we give an overview of the formulas used for the calculation in section 2 and introduce the partitioning of the complex plane in section 3. Then, we present the error estimates starting with the series expansions

(section 4). Finally, we discuss the numerical details of the algorithm in section 5 and present the results of extensive numerical calculations in the last section (section 6), comparing the speed and stability of the algorithm.

2. Overview. This section gives an overview of the numerical algorithm. The generalized Mittag-Leffler function is an entire function defined by the following power series:

$$(2.1) \quad E_{\alpha,\beta}(z) = \sum_{k=0}^{\infty} \frac{z^k}{\Gamma(\alpha k + \beta)}$$

for $z \in \mathbb{C}$, $\alpha > 0$, and $\beta \in \mathbb{R}$. If $|z| < 1$, finitely many terms of the power series are sufficient to approximate $E_{\alpha,\beta}(z)$ with arbitrary precision. The error estimates are given in section 4.

The case $\alpha \geq 1$ will be reduced to the case $\alpha < 1$ using the following recursion relation [2, 15]:

$$(2.2) \quad E_{\alpha,\beta}(z) = \frac{1}{2m+1} \sum_{h=-m}^m E_{\alpha/(2m+1),\beta} \left(z^{1/(2m+1)} e^{2\pi i h/(2m+1)} \right),$$

which is valid for all $\alpha, \beta \in \mathbb{R}$, $z \in \mathbb{C}$, and $m = [(\alpha - 1)/2] + 1$. Here $[x]$ denotes the largest integer less than or equal to x .

For large values $|z| \gg 1$ the exponentially improved asymptotic series with the Berry-type smoothing transition gives a fast approximation of the Mittag-Leffler function. If $|\arg(z)| > \pi\alpha$, the asymptotic series is given by [2]

$$(2.3) \quad E_{\alpha,\beta}(z) \sim - \sum_{k=1}^{\infty} \frac{z^{-k}}{\Gamma(\beta - \alpha k)},$$

while for $|\arg(z)| < \pi\alpha$ we find the following series:

$$(2.4) \quad E_{\alpha,\beta}(z) \sim \frac{1}{\alpha} z^{(1-\beta)/\alpha} e^{z^{1/\alpha}} - \sum_{k=1}^{\infty} \frac{z^{-k}}{\Gamma(\beta - \alpha k)}.$$

In the transition area around the Stokes lines $|\arg(z)| < \pi\alpha \pm \delta$, with $\delta < \pi\alpha/2$, we have the Berry-type smoothing given by

$$(2.5) \quad E_{\alpha,\beta}(z) \sim \frac{1}{2\alpha} z^{(1-\beta)/\alpha} e^{z^{1/\alpha}} \operatorname{erfc} \left(-c(\theta) \sqrt{|z|^{1/\alpha}/2} \right) - \sum_{k=1}^{\infty} \frac{z^{-k}}{\Gamma(\beta - \alpha k)}$$

around the lower Stokes line for $-3\pi\alpha/2 < \arg(z) < \pi\alpha/2$, where the parameter c is given by the relation $\frac{1}{2}c^2 = 1 + i\theta - e^{i\theta}$, with $\theta = \arg(z^{1/\alpha}) + \pi$ and the principle branch of c is chosen such that $c \approx \theta + \frac{i}{6}\theta^2 - \frac{1}{36}\theta^3$ for small θ [23]. Around the upper Stokes line $\pi\alpha/2 < \arg(z) < 3\pi\alpha/2$, one finds that

$$(2.6) \quad E_{\alpha,\beta}(z) \sim \frac{1}{2\alpha} z^{(1-\beta)/\alpha} e^{z^{1/\alpha}} \operatorname{erfc} \left(c(\theta) \sqrt{|z|^{1/\alpha}/2} \right) - \sum_{k=1}^{\infty} \frac{z^{-k}}{\Gamma(\beta - \alpha k)},$$

with $\frac{1}{2}c^2 = 1 + i\theta - e^{i\theta}$, $\theta = \arg(z^{1/\alpha}) - \pi$, and the same condition as before for small θ . This exponentially improved asymptotic series converges very rapidly for most values of $z \in \mathbb{C}$, with $|z| > 1$. The Stokes phenomenon and the Berry-type

smoothing for the Mittag-Leffler function have been investigated recently in [13, 23].

In an intermediate range $r_0 \leq |z| \leq r_1$ between the Taylor series and the asymptotic expansion, we use Wiman's integral representation [2, p. 210]

$$(2.7) \quad E_{\alpha,\beta}(z) = \frac{1}{2\pi i} \int_{\mathcal{C}} \frac{y^{\alpha-\beta} e^y}{y^\alpha - z} dy$$

for calculating $E_{\alpha,\beta}(z)$. The values r_0 where the Taylor series ends and r_1 where the asymptotic series starts will be specified later. The path of integration \mathcal{C} in the complex plane starts and ends at $-\infty$ and encircles the circular disc $|y| \leq |z|^{1/\alpha}$ in the positive sense. Equation (2.7) can be obtained by inserting the Hankel representation of the inverse Γ -function into the Taylor series and bending the contour in the complex plane.

3. Partitioning of the complex plane. In different regions of the complex plane the Mittag-Leffler function shows different kinds of behavior. Therefore different calculation schemes are needed for different regions. The following definitions are used to describe these regions. First,

$$(3.1) \quad \overline{\mathbb{D}(r)} = \{z \in \mathbb{C} : |z| \leq r\}$$

is the closure of the open disk $\mathbb{D}(r) = \{z \in \mathbb{C} : |z| < r\}$ of radius r centered at the origin. Next, we define the wedges

$$(3.2) \quad \mathbb{W}(\phi_1, \phi_2) = \{z \in \mathbb{C} : \phi_1 < |\arg(z)| < \phi_2\},$$

$$(3.3) \quad \overline{\mathbb{W}}(\phi_1, \phi_2) = \{z \in \mathbb{C} : \phi_1 \leq |\arg(z)| \leq \phi_2\},$$

where $\phi_2 - \phi_1$ is the opening angle measured in a positive sense and $\phi_1, \phi_2 \in (-\pi, \pi)$. On a disc

$$(3.4) \quad \mathbb{G}_0 = \overline{\mathbb{D}(r_0)}$$

of radius $r_0 < 1$, the Taylor series (2.1) gives a good approximation of the generalized Mittag-Leffler function. For the algorithm we choose $r_0 = 0.95$.

For large values of $|z| \in \mathbb{C}$ exponentially improved asymptotics can be used to calculate $E_{\alpha,\beta}(z)$. Equation (2.4) is used for z in

$$(3.5) \quad \mathbb{G}_1 = [\mathbb{C} \setminus \mathbb{D}(r_1)] \cap \mathbb{W}(-\pi\alpha + \delta, \pi\alpha - \delta)$$

and (2.3) for z in

$$(3.6) \quad \mathbb{G}_2 = [\mathbb{C} \setminus \mathbb{D}(r_1)] \cap \mathbb{W}(\pi\alpha + \tilde{\delta}, -\pi\alpha - \tilde{\delta}),$$

where $r_1 > r_0$ will be defined in (4.21) and δ and $\tilde{\delta}$ are numbers smaller than $\pi\alpha/2$. In the algorithm δ and $\tilde{\delta}$ are chosen to be

$$(3.7) \quad \delta = \pi\alpha/8 \quad \text{and} \quad \tilde{\delta} = \min\{\pi\alpha/8, (\pi + \pi\alpha)/2\}.$$

Close to the Stokes lines $|\arg(z)| = \pi\alpha$, the approximation scheme with the series (2.3) and (2.4) becomes unstable, so the Berry-type smoothed asymptotic series (2.6) is used in the area around the upper Stokes line

$$(3.8) \quad \mathbb{G}_3 = [\mathbb{C} \setminus \mathbb{D}(r_1)] \cap \overline{\mathbb{W}}(\pi\alpha - \delta, \pi\alpha + \tilde{\delta})$$

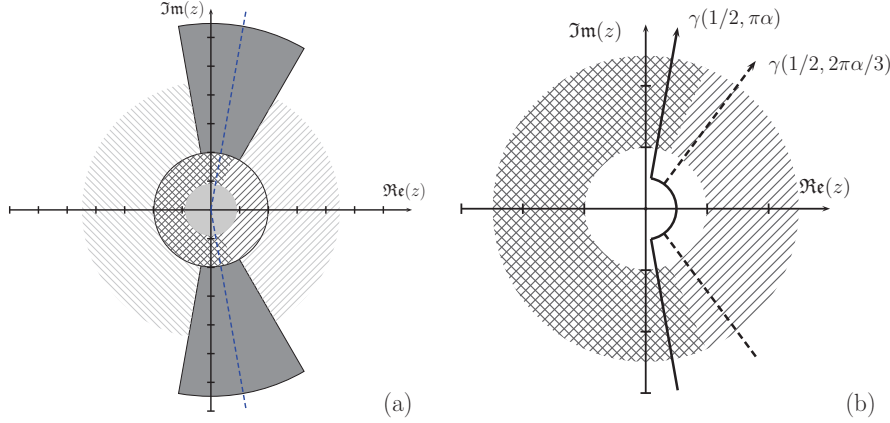

FIG. 1. Figure (a) shows the partitioning of the complex plane for calculating the generalized Mittag-Leffler function $E_{\alpha,\beta}(z)$. The thick dashed lines mark the Stokes line at $\arg(z) = \pm\pi\alpha$. In the central light gray region \mathbb{G}_0 , finitely many terms of the Taylor series (2.1) give a good approximation for the generalized Mittag-Leffler function. The black crosshatched region marks \mathbb{G}_6 (left) and the black hatched one \mathbb{G}_5 (right), where the integral representations (4.31), (4.32) and (4.25), (4.26), respectively, are used for the calculations. The asymptotic series (2.4) and (2.3) are used in the gray hatched regions \mathbb{G}_1 (left) and \mathbb{G}_2 (right). Berry-type smoothing is applied in the gray solid areas: (2.6) in the upper region \mathbb{G}_3 and (2.5) in the lower one \mathbb{G}_4 . In (b) the integration contours for the two cases $\vartheta = \pi\alpha$ (solid line) and $\vartheta = 2\pi\alpha/3$ (dashed line) are shown. While (4.25) and (4.26) are used in the crosshatched region corresponding to (\mathbb{G}_6) , (4.31) and (4.32) are used for the part where the hatching runs at 45° (\mathbb{G}_5).

and (2.5) close to the lower one

$$(3.9) \quad \mathbb{G}_4 = [\mathbb{C} \setminus \mathbb{D}(r_1)] \cap \overline{\mathbb{W}}(-\pi\alpha - \tilde{\delta}, -\pi\alpha + \delta).$$

In the transition area between the Taylor series and the asymptotic expansion, we make use of Hankel's integral representation for the generalized Mittag-Leffler function (2.7). We employ two different contour paths to avoid numerical problems which arise in other algorithms [4] when z is too close to the contour path. The two regions \mathbb{G}_5 and \mathbb{G}_6 are defined by

$$(3.10) \quad \mathbb{G}_5 = \mathbb{D}(r_1) \cap \overline{\mathbb{W}}(-5\pi\alpha/6, 5\pi\alpha/6) \setminus \mathbb{G}_0,$$

$$(3.11) \quad \mathbb{G}_6 = \mathbb{D}(r_1) \cap \mathbb{W}(5\pi\alpha/6, -5\pi\alpha/6) \setminus \mathbb{G}_0,$$

where $\overline{\mathbb{W}}(-5\pi\alpha/6, 5\pi\alpha/6)$ and $\mathbb{W}(5\pi\alpha/6, -5\pi\alpha/6)$ are defined as in (3.3) and (3.2), respectively. The different regions are shown in Figure 1.

4. Error estimates.

4.1. Taylor series. For $z \in \mathbb{G}_0$ finitely many terms of the Taylor series are sufficient to approximate the generalized Mittag-Leffler function for arbitrary $\alpha > 0$ and $\beta \in \mathbb{R}$. The maximum number of terms N taken into account is chosen such that the error

$$(4.1) \quad R_N(z) = \left| E_{\alpha,\beta}(z) - \sum_{k=0}^N \frac{z^k}{\Gamma(\alpha k + \beta)} \right| \leq \varepsilon$$

is smaller than a given accuracy ε .

THEOREM 4.1. Let $\varepsilon > 0$. If $|z| < 1$ and

$$(4.2) \quad N \geq \max \left\{ \left[(2 - \beta)/\alpha \right] + 1, \left[\frac{\ln(\varepsilon(1 - |z|))}{\ln(|z|)} \right] + 1 \right\},$$

then the error term $R_N(z) = \left| \sum_{k=N}^{\infty} \frac{z^k}{\Gamma(\alpha k + \beta)} \right|$ is smaller than the given accuracy ε .

We have $1/\Gamma(x) > 1$ for all $x > 2$. Setting $x = \alpha k + \beta$ one finds that $\frac{1}{\Gamma(\alpha N + \beta)} \leq 1$ for all $N \geq \left[\frac{(2 - \beta)}{\alpha} \right] + 1$, where $[a]$ is the smallest integer larger than a ; thus

$$(4.3) \quad R_N(z) = \left| \sum_{k=N}^{\infty} \frac{z^k}{\Gamma(\alpha k + \beta)} \right| \leq \left| \sum_{k=N}^{\infty} z^k \right| \leq \sum_{k=N}^{\infty} |z^k|.$$

Under the condition $|z| < 1$ the geometric series can be summed up, and one obtains together with (4.1) that

$$(4.4) \quad R_N(z) \leq \sum_{k=N}^{\infty} |z^k| = \frac{|z|^N}{1 - |z|} \stackrel{!}{\leq} \varepsilon \quad \text{and therefore} \quad N \geq \frac{\ln(\varepsilon(1 - |z|))}{\ln(|z|)}. \quad \square$$

For the algorithm we have chosen

$$(4.5) \quad M = \max \left\{ \left[\frac{(2 - \beta)}{\alpha} \right] + 1, \left[\frac{\ln(\varepsilon(1 - |z|))}{\ln(|z|)} \right] + 1 \right\}$$

for the maximum numbers of coefficients that have to be taken into account to reach an accuracy of ε .

4.2. Exponentially improved asymptotics. In this section we give an estimate of the error term of the asymptotic series. To apply the asymptotic series expansions for a given accuracy ε , two parameters have to be determined, which are the truncation point N of the series and a lower limit r_1 of $|z|$ such that the error is smaller than ε for $|z| > r_1$.

THEOREM 4.2. Let $\alpha \in (0, 1)$. For $N \approx \frac{1}{\alpha} |z|^{1/\alpha}$ and $|z| \geq (-2 \log \frac{\varepsilon}{C})^\alpha$ the estimate of the error term of the asymptotic series (2.3) and (2.4) fulfills the condition

$$(4.6) \quad R_N(z) = \left| E_{\alpha,\beta}(z) - \left(- \sum_{k=1}^{N-1} \frac{z^{-k}}{\Gamma(\beta - \alpha k)} \right) \right| \leq \varepsilon,$$

where C is a constant dependent only on α, β , and

$$(4.7) \quad R_N(z) = \frac{z^{N-1}}{2\pi i} \int_C \frac{t^{N\alpha - \beta} e^t}{t^\alpha - z} dt.$$

C is the classical Hankel contour, which runs along the positive real axis in the upper half-plane starting from $+\infty + i0$ encircling the origin and returning to $+\infty - i0$ along the positive real axis in the lower half-plane.

Without loss of generality we can assume that $\alpha N - \beta > -1$ by choosing N large enough. Then the circle can be shrunk to zero, and there remain two rays, above and below the cut of the complex plane along the negative real axis. Inserting $t = v e^{-\pi v}$ for the upper part of the contour and $t = v e^{\pi v}$ for the lower one, we obtain

$$(4.8) \quad R_N(z) = L_N(z) + U_N(z),$$

where

$$(4.9) \quad L_N(z) = e^{i\pi\beta} (z e^{i\pi\alpha})^{-N+1} \frac{1}{2\pi i} \int_0^\infty \frac{v^{\alpha N - \beta} e^{-v}}{v^\alpha - z e^{i\pi\alpha}} dv$$

and

$$(4.10) \quad U_N(z) = -e^{-i\pi\beta} (z e^{-i\pi\alpha})^{-N+1} \frac{1}{2\pi i} \int_0^\infty \frac{v^{\alpha N - \beta} e^{-v}}{v^\alpha - z e^{-i\pi\alpha}} dv$$

are the integrals along the upper and lower parts, respectively, of the remaining contour path. Following the arguments in [23] we obtain

$$(4.11) \quad U_N(z) \leq \frac{1}{2\pi \sin \alpha\pi} |z|^{-N} \Gamma(\alpha N - \beta + 1)$$

and similarly

$$(4.12) \quad L_N(z) \leq \frac{1}{2\pi \min\{\sin \alpha\pi, \sin \xi\}} |z|^{-N} \Gamma(\alpha N - \beta + 1),$$

where $\arg(z) \in (-\pi, -\pi\alpha - \xi)$ for $\xi > 0$. The angle ξ describes the distance of z to the Stokes line. Applying the argument of Boyd [1] yields

$$(4.13) \quad L_N(z) \leq C_1(\alpha, \beta) |z|^{-N} \Gamma(\alpha N - \beta + 1) \sqrt{N},$$

where C_1 now depends only on α and β . Combining (4.11) and (4.13) yields

$$(4.14) \quad R_N(z) \leq C_2(\alpha, \beta) |z|^{-N} \Gamma(\alpha N - \beta + 1) \sqrt{N},$$

where we used the fact that $N > 1$ and hence $\sqrt{N} > 1$.

To obtain an estimate for N and a minimal $|z|$, further approximations have to be applied. Using Stirling's formula for $R_N(z)$, (4.14) yields

$$(4.15) \quad \begin{aligned} R_N(z) &\leq C_2(\alpha, \beta) |z|^{-N} \Gamma(\alpha N - \beta + 1) \sqrt{N} \\ &= C_2(\alpha, \beta) |z|^{-N} (\alpha N - \beta) \Gamma(\alpha N - \beta) \sqrt{N} \\ &\leq C_3(\alpha, \beta) |z|^{-N} \sqrt{N} (\alpha N - \beta)^{(\alpha N - \beta + 3/2)} e^{-(\alpha N - \beta)}, \end{aligned}$$

with constant C_3 depending only on α and β . For $\beta \geq 0$ one has $(\alpha N - \beta) \leq \alpha N$. For $\beta < 0$ one obtains $(\alpha N - \beta)^\gamma \leq C'(\alpha N)^\gamma$ by applying the binomial series. Here γ was used as an abbreviation for $(\alpha N - \beta + 3/2)$. Combining these estimates with (4.15) we arrive at

$$(4.16) \quad R_N(z) \leq C_4(\alpha, \beta) (\alpha N)^{1-\beta} e^{N(-\alpha + \alpha \log(\alpha N) - \log |z|)},$$

where we applied the trivial identity $\sqrt{N} = (\alpha N)^{1/2} / \sqrt{\alpha}$ and C_4 absorbs all constants from the approximations. An optimal truncation should be obtained when

$$(4.17) \quad N \approx \frac{1}{\alpha} |z|^{1/\alpha},$$

which yields for real α and β

$$(4.18) \quad R_N(z) \leq C_4(\alpha, \beta)(\alpha N)^{1-\beta} e^{-N\alpha}.$$

Assuming that $|z| > 1$ yields $(|z|^{1/\alpha})^{1-\beta} \leq (|z|^{1/\alpha})^{|1-\beta|}$. Now we apply the inequality $x^y \leq (qy)^y e^{x/q}$, with $x, y, q > 0$ (see Theorem 4.4 below) for $q = 1/2$, $x = |z|^{1/\alpha}$, and $y = |1 - \beta|$. Thus the estimate

$$(4.19) \quad R_N(z) \leq C e^{-\frac{1}{2}|z|^{1/\alpha}}$$

holds for all α, β , and $|z| > 1$, where C is given by $C = C_4(\alpha, \beta)(1/2 \cdot |1 - \beta|)^{|1-\beta|}$. This can now be easily solved for $|z|$ to determine r_1 if we assume that the error $R_N(z)$ is smaller than a given error ε for $|z| > r_1$. Thus we obtain

$$(4.20) \quad |z| \geq r_1 = \left(-2 \log \frac{\varepsilon}{C}\right)^\alpha,$$

which yields the following conditions for the exponential asymptotics:

$$(4.21) \quad M = \left\lceil \frac{1}{\alpha} |z|^{1/\alpha} \right\rceil + 1, \quad r_1 = \left(-2 \log \frac{\varepsilon}{C}\right)^\alpha,$$

where $\lceil x \rceil$ is the smallest integer larger than x . The parameter M denotes the number of terms in the series that are taken into account to achieve the given accuracy. \square

Finally it is important to mention that the use of the Berry-type smoothing in the region close to the Stokes lines avoids numerical problems of the asymptotic series in the transition area between \mathbb{G}_2 (with (2.3)) and \mathbb{G}_3 (with (2.4)) and gives a much faster convergence due to the exponential corrections of the series.

4.3. Integral representation.

4.3.1. Basic formulas. For the area between the Taylor series and the exponentially improved asymptotics, Hankel's integral representation can be used for calculating the values of $E_{\alpha,\beta}(z)$. Another approach for calculating the Mittag-Leffler function was suggested in [4], but that algorithm neglects the numerical difficulties that arise for values of z close to the contour path. Also, it does not make use of the exponentially improved asymptotics and hence is much slower. We avoid the problems of [4] near the contour path by using two different integration formulas with different contours. In the following paragraph the integration formula will be derived from Hankel's integral representation by inserting the contour path into the definition, and the behavior of the integrands will be discussed. Finally we present the approximations and the error estimates of the integrals used in the numerical scheme.

We start from the classical Hankel representation of the generalized Mittag-Leffler function which is obtained by inserting the Hankel representation of the inverse Gamma function in the series expansion (2.1). The integral representation is given by [2, p. 210]

$$(4.22) \quad E_{\alpha,\beta}(z) = \frac{1}{2\pi i} \int_{\mathcal{C}} \frac{y^{\alpha-\beta} e^y}{y^\alpha - z} dy,$$

where the path of integration \mathcal{C} in the complex plane starts and ends at $-\infty$ and encircles the circular disc $|y| \leq |z|^{1/\alpha}$ in the positive sense.

Bending the contour in the complex plane and applying the Cauchy theorem, one obtains the following integral representation [21] for $0 < \alpha < 2$:

$$(4.23) \quad E_{\alpha,\beta}(z) = \frac{1}{2\pi i \alpha} \int_{\gamma(\varrho,\vartheta)} \frac{e^{\xi^{1/\alpha}} \xi^{\frac{1-\beta}{\alpha}}}{\xi - z} d\xi \quad \text{for } z \in G^{(-)}(\gamma),$$

$$(4.24) \quad E_{\alpha,\beta}(z) = \frac{1}{\alpha} z^{\frac{1-\beta}{\alpha}} \exp(z^{1/\alpha}) + \frac{1}{2\pi i \alpha} \int_{\gamma(\varrho,\vartheta)} \frac{e^{\xi^{1/\alpha}} \xi^{\frac{1-\beta}{\alpha}}}{\xi - z} d\xi \quad \text{for } z \in G^{(+)}(\gamma),$$

where the contour $\gamma(\varrho, \vartheta)$ starts at infinity in the lower half-plane, goes along a ray of $\arg(z) = -\vartheta$ towards the origin, encircles the origin with a circular arc of radius ϱ , and goes back to infinity in the upper half-plane along the ray $\arg(z) = +\vartheta$. Thus the complex plane is divided by the contour path in two parts, where $G^{(-)}(\gamma)$ and $G^{(+)}(\gamma)$ are the areas left and right of the contour path, respectively. Close to the contour path the numerical evaluation of the formulas (4.23) and (4.24) becomes inaccurate because of the singularity of the integral (4.23) at $r = |z|e^{\pm i\vartheta}$.

Combining formula (4.24) with $\vartheta = \pi\alpha$ and (4.23) with $\vartheta = 2\pi\alpha/3$, one can cover the whole complex plane. The regions $G^{(+)}(\pi\alpha)$ and $G^{(-)}(2\pi\alpha/3)$ have nonvanishing overlap. The overlap allows us to avoid the use of formulas (4.23) and (4.24) close to the contour path by choosing the partitioning described in section 3. The value of ϱ was set to 0.5 and thus lies in \mathbb{G}_1 , where the Taylor series is used for the calculation. Equation (4.24) is used with $\vartheta = \pi\alpha$ for $z \in \mathbb{G}_5$ and (4.23) with $\vartheta = 2\pi\alpha/3$ for $z \in \mathbb{G}_6$. When these integrals are evaluated, several cases arise. We distinguish the cases $\beta \leq 1$ and $\beta > 1$.

Let $z \in \mathbb{G}_5$. Summing up the different terms after inserting the parameterization of the contour path for $\vartheta = \pi\alpha$ and $\varepsilon = 1/2$ yields for $z \in G^{(+)}(\gamma)$ that

$$(4.25) \quad E_{\alpha,\beta}(z) = A(z; \alpha, \beta, 0) + \int_0^\infty B(r; \alpha, \beta, z, \pi\alpha) dr$$

for $\beta \leq 1$ and

$$(4.26) \quad E_{\alpha,\beta}(z) = A(z; \alpha, \beta, 0) + \int_{1/2}^\infty B(r; \alpha, \beta, z, \pi\alpha) dr + \int_{-\pi\alpha}^{\pi\alpha} C(\varphi; \alpha, \beta, z, 1/2) d\varphi$$

for $\beta > 1$, where the following abbreviations are used:

$$(4.27) \quad A(z; \alpha, \beta, x) = \frac{1}{\alpha} z^{(1-\beta)/\alpha} \exp\left[z^{1/\alpha} \cos(x/\alpha)\right],$$

$$(4.28) \quad B(r; \alpha, \beta, z, \phi) = \frac{1}{\pi} A(r; \alpha, \beta, \phi) \frac{r \sin[\omega(r, \phi, \alpha, \beta) - \phi] - z \sin[\omega(r, \phi, \alpha, \beta)]}{r^2 - 2rz \cos \phi + z^2},$$

$$(4.29) \quad C(\varphi; \alpha, \beta, z, \varrho) = \frac{\varrho}{2\pi} A(\varrho; \alpha, \beta, \varphi) \frac{\cos[\omega(\varrho, \varphi, \alpha, \beta)] + i \sin[\omega(\varrho, \varphi, \alpha, \beta)]}{\varrho(\cos \varphi + i \sin \varphi) - z},$$

$$(4.30) \quad \omega(x, y, \alpha, \beta) = x^{1/\alpha} \sin(y/\alpha) + y(1 + (1 - \beta)/\alpha).$$

In the case $\beta \leq 1$ we applied the limit $\varrho \rightarrow 0$. These equations are used to calculate $E_{\alpha,\beta}$ for $z \in \mathbb{G}_5$.

For $z \in \mathbb{G}_6$ we use a different contour with $\vartheta = 2\pi\alpha/3$. In this case the integral representations read

$$(4.31) \quad E_{\alpha,\beta}(z) = \int_0^\infty B(r; \alpha, \beta, z, 2\pi\alpha/3) dr, \quad \beta \leq 1,$$

$$(4.32) \quad E_{\alpha,\beta}(z) = \int_{1/2}^\infty B(r; \alpha, \beta, z, 2\pi\alpha/3) dr + \int_{-2\pi\alpha/3}^{2\pi\alpha/3} C(\varphi; \alpha, \beta, z, 1/2) d\varphi, \quad \beta > 1,$$

where the integrands have been defined in (4.27)–(4.30) above.

The integrand $C(\varphi; \alpha, \beta, z, \varrho)$ is oscillatory but bounded over the integration interval. Thus the integrals over C can be evaluated numerically using any appropriate quadrature formula. We use a robust adaptive 21-point Gauss–Kronrod scheme from the gnu scientific library (GSL) [3], which is based on the QUADPACK QAGS algorithm [14]. Other robust integration schemes such as the standard MATLAB Gauss–Lobatto scheme have also been used successfully. The integrals over $B(r; \alpha, \beta, z, \phi)$ involve unbounded intervals and have to be treated more carefully.

4.3.2. Integrands. As the integral representation is used only for $|z| > 0$, we assume z to be nonzero. It can be easily shown that the integrand $B(r; \alpha, \beta, z, \phi)$ in (4.28) behaves like $\mathcal{O}(r^{\frac{1-\beta}{\alpha}})$ for $r \rightarrow 0$ which yields to the following cases: For $\beta < 1 + \alpha$ the integrand $\int_a^\infty B(r; \alpha, \beta, z, \phi) dr$ is convergent in the limit $a \rightarrow 0$, but the integrand remains finite at $r = 0$ only for $\beta \leq 1$. Thus, for numerical integration the limit $a \rightarrow 0$ can be applied only in the case $\beta \leq 1$ in (4.31). For β exactly $1 + \alpha$ and $\phi = \pi\alpha$, the integrand can be further simplified and approaches a finite value in the limit $r \rightarrow 0$. The integrands for different cases of α and β are shown in Figure 2.

A special case in the integrand in (4.28) occurs when z lies on the contour line. Then the denominator becomes zero which causes problems in the numerical scheme. Although there are numerical algorithms for treating such integrands with singularities, it is much more accurate to avoid such a case if possible. In our case this has been done by choosing two different integral representations with different contour paths, so one can always be used in the case of z close to the contour of the other.

This also speeds up the algorithm because the integrand is smoother and the integration routine does not need to treat the singularities. The behavior of the integrand close to the contour path is shown in Figure 3.

4.3.3. Error estimates. Now we present the error estimates for the different integral formulas. The truncation points for the integrals over $B(r; \alpha, \beta, z, \phi)$ are determined such that the error $R(R_{\max}; \alpha, \beta, z, \phi)$ is smaller than a given accuracy ε .

For given $z \in \mathbb{G}_5$ (resp., $z \in \mathbb{G}_6$) and accuracy ε , we approximate the integrals by truncation. The error

$$(4.33) \quad R(R_{\max}; \alpha, \beta, z, \phi) \leq \left| \int_{R_{\max}}^\infty B(r; \alpha, \beta, z, \phi) dr \right| < \varepsilon$$

depends on the truncation point R_{\max} .

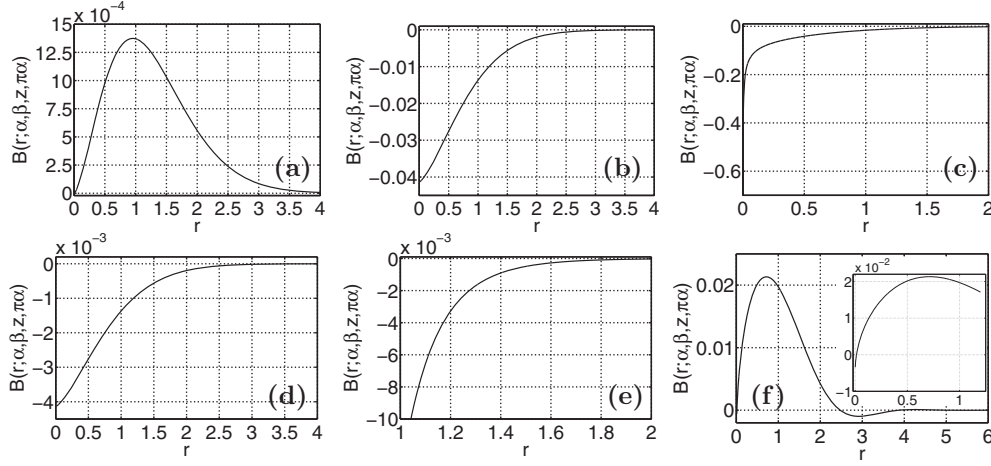

FIG. 2. (a)–(e) summarize the behavior of the integrand $B(r; \alpha, \beta, z, \phi)$ for different combinations of α and β , where $\phi = \pi\alpha$ and $z = 10$ are kept constant. (a) $\beta < 1$, $\beta < 1 + \alpha$: In this case the integral is convergent and the integrand approaches 0 for $r \rightarrow 0$. For the plot $\alpha = \beta = 2/3$ was chosen. (b) $\beta = 1$, $\beta < 1 + \alpha$: For $\beta = 1$ the integrand approaches a finite value in the limit $r \rightarrow 0$. The parameters for the figure are $\alpha = 2/3$ and $\beta = 1$. (c) $\beta > 1$, $\beta < 1 + \alpha$: If $\beta > 1$ but still smaller than $1 + \alpha$, the integral is still convergent but the integrand diverges in the limit $r \rightarrow 0$. The values for the plot have been chosen as $\alpha = 2/3$ and $\beta = 5/4$. (d) $\beta = 1 + \alpha$: This is a special case where the integrand approaches again a finite value in the limit $r \rightarrow 0$. The plot shows the integrand for $\alpha = 2/3$ and $\beta = 5/3$. (e) $\beta > 1 + \alpha$: For $\beta > 1 + \alpha$ the integrand diverges in the limit $r \rightarrow 0$ and the integral over $B(r; \alpha, \beta, z, \phi)$ does not converge anymore. (f) This figure shows the integrand $B(r; \alpha, \beta, z, \phi)$ for another value of $z = -10$ and $\phi = 2\pi\alpha/3$. The parameters α and β were chosen to be $\alpha = 2/3$ and $\beta = 1 + \alpha$. In this case the integrand does not approach a finite value in the limit $r \rightarrow 0$ as in the case $\phi = \pi\alpha$.

Inserting $\phi = \pi\alpha$ (resp., $\phi = 2\pi\alpha/3$) in $B(r; \alpha, \beta, z, \phi)$ one obtains, after simplifying the resulting terms,

$$(4.34) \quad B(r; \alpha, \beta, z, \pi\alpha) = \frac{1}{\pi\alpha} r^{(1-\beta)/\alpha} e^{-r^{1/\alpha}} \times \frac{r \sin[\pi(1-\beta)] - z \sin[\pi(1-\beta+\alpha)]}{r^2 - 2rz \cos \phi + z^2},$$

$$(4.35) \quad B(r; \alpha, \beta, z, 2\pi\alpha/3) = \frac{1}{\pi\alpha} r^{(1-\beta)/\alpha} e^{-(1/2)r^{1/\alpha}} \times \frac{r \sin[\omega(r, \frac{2\pi\alpha}{3}, \alpha, \beta) - \frac{2\pi\alpha}{3}] - z \sin[\omega(r, \frac{2\pi\alpha}{3}, \alpha, \beta)]}{r^2 - 2rz \cos \phi + z^2},$$

where $\omega(r, \frac{2\pi\alpha}{3}, \alpha, \beta) - \frac{2\pi\alpha}{3} = r^{1/\alpha} \frac{\sqrt{3}}{2} + \frac{2\pi}{3}(1-\beta)$ and $\omega(r, \frac{2\pi\alpha}{3}, \alpha, \beta) = r^{1/\alpha} \frac{\sqrt{3}}{2} + \frac{2\pi}{3}(\alpha + (1-\beta))$.

If we assume $r \geq 2|z|$, one finds for the denominator of (4.34) and (4.35) that

$$(4.36) \quad \frac{1}{|r^2 - 2rz \cos \phi + z^2|} = \frac{1}{r^2 \left| \frac{z}{r} - z_0 \right| \left| \frac{z}{r} - \bar{z}_0 \right|} \leq \frac{1}{r^2 \left(\left| \frac{z}{r} \right| - z_0 \right) \left(\left| \frac{z}{r} \right| - \bar{z}_0 \right)} \leq \frac{4}{r^2},$$

where ϕ is either $\pi\alpha$ or $2\pi\alpha/3$ and $z_0 = e^{i\phi}$.

As α, β, r , and ϕ are real numbers, one easily obtains

$$(4.37) \quad \left| \sin[\omega(r, \phi, \alpha, \beta) - \phi] - z \sin[\omega(r, \phi, \alpha, \beta)] \right| \leq \frac{3r}{2}$$

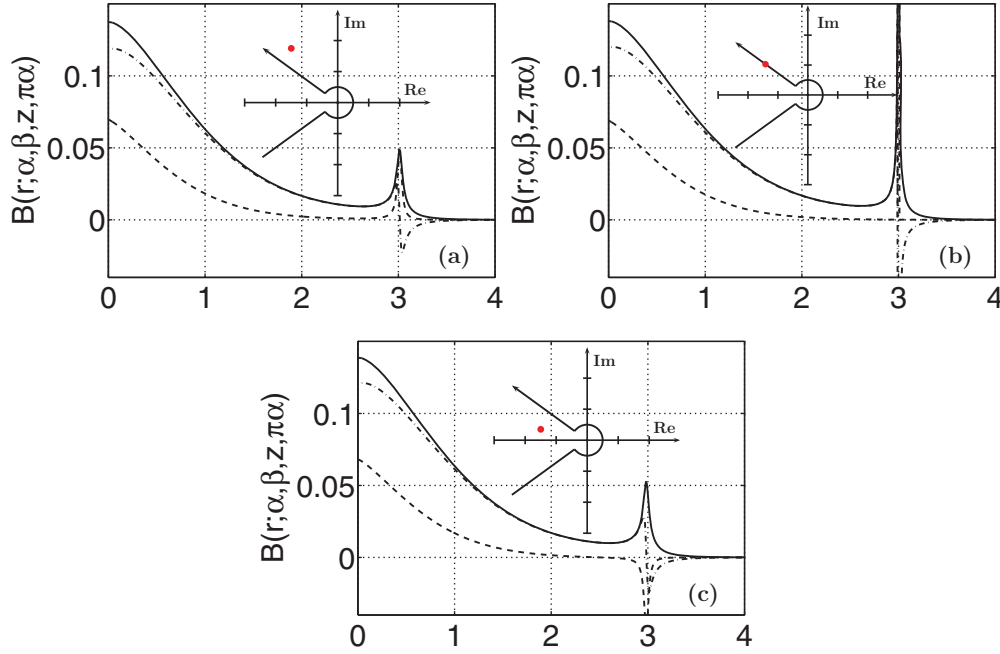

FIG. 3. The three plots show the divergence of the integrand $B(r; \alpha, \beta, z, \phi)$ close to the contour path. The real part is drawn with a dashed line and the imaginary part with a dashed-dotted line. The absolute value is marked with a black solid line. The parameters in the figures are $\alpha = 2/3$, $\beta = 1$, and $\phi = \pi\alpha$. (a) shows the integrand for z slightly above the contour path ($z = \exp(i\pi\alpha) + 0.03$), while in (c) the integrand is shown for slightly below ($z = \exp(i\pi\alpha) - 0.03$). The singularity is shown in (b) when z lies on the contour path. The insets show the contour path for the integration and the location of z relative to the contour path as a black dot.

for the numerator because in (4.36) r was assumed to be larger than $2|z|$. The angle ϕ is either $\pi\alpha$ or $2\pi\alpha/3$. Thus we obtain for the integrals

$$(4.38) \quad \left| \int_{R_{\max}}^{\infty} B(r; \alpha, \beta, z, \pi\alpha) dr \right| \leq \int_{R_{\max}}^{\infty} \frac{6}{\pi\alpha} r^{\frac{(1-\beta)}{\alpha}-1} e^{-r^{1/\alpha}} dr$$

$$\leq \frac{6}{\pi} \Gamma(1 - \beta, R_{\max}^{1/\alpha}),$$

$$(4.39) \quad \left| \int_{R_{\max}}^{\infty} B(r; \alpha, \beta, z, 2\pi\alpha/3) dr \right| \leq \int_{R_{\max}}^{\infty} \frac{6}{\pi\alpha} r^{\frac{(1-\beta)}{\alpha}-1} e^{-\frac{1}{2}r^{1/\alpha}} dr$$

$$\leq \frac{12}{2^{\beta}\pi} \Gamma\left(1 - \beta, \frac{1}{2}R_{\max}^{1/\alpha}\right)$$

after comparing with the definition of the incomplete gamma function. Now we apply the following two lemmas.

THEOREM 4.3 (lemma). *For the incomplete gamma function the following bounds hold:*

$$(4.40) \quad |\Gamma(1 - \beta, x)| \leq e^{-x} \quad \text{if } x \geq 1, \beta \geq 0,$$

$$(4.41) \quad |\Gamma(1 - \beta, x)| \leq (|\beta| + 2)x^{-\beta} e^{-x} \quad \text{if } x \geq |\beta| + 1, \beta < 0.$$

Proof. For $t \geq x \geq 1$ and $\beta \geq 0$ we have the inequality

$$(4.42) \quad t^{-\beta} e^{-t} \leq e^{-t},$$

and therefore

$$(4.43) \quad |\Gamma(1 - \beta, x)| \leq \int_x^\infty e^{-t} dt = e^{-x},$$

which proves the first inequality (4.40). For $\beta < 0$ we can find an $n \in \mathbb{N}$ such that

$$(4.44) \quad -(n + 1) \leq \beta < -n.$$

For $x > 0$ and $\beta < 0$ it holds that

$$(4.45) \quad \Gamma(1 - \beta, x) = x^{-\beta} e^{-x} \int_0^\infty e^{-u} (1 + (u/x))^{-\beta} du < x^{-\beta} e^{-x} \int_0^\infty e^{-u} (1 + (u/x))^N du,$$

where $N = |\beta| + 1$. This can be shown by using the binomial theorem for expanding $(1 + (u/x))^N$ and integrating (4.45) term by term:

$$(4.46) \quad \Gamma(1 - \beta, x) < x^{-\beta} e^{-x} \left(1 + \frac{N}{x} + N^2 x^2 + \dots + N^N x^N \right) < x^{-\beta} e^{-x} (N + 1),$$

where $x \geq N$ and $N + 1 \leq 2 - \beta$. This yields the second inequality of (4.41):

$$(4.47) \quad |\Gamma(1 - \beta, x)| \leq (|\beta| + 2)x^{-\beta} e^{-x}. \quad \square$$

THEOREM 4.4 (lemma). *The inequality*

$$(4.48) \quad x^y \leq (qy)^y e^{x/q}$$

holds for arbitrary $x, y, q > 0$.

Proof. Let $x = a \cdot y$ with $a > 0$. Then one can write (4.48) as $(ay)^y \leq (qy)^y e^{ay/q}$, which is equivalent to $a^y \leq q^y e^{ay/q}$. Dividing this by q^y and applying the logarithm on both sides yields $y \log(a/q) \leq y(a/q)$, which is the same as $\log(a/q) \leq (a/q)$ because $y > 0$. The last inequality is true because $\log(x) < x \forall x > 0$ and $a, q > 0$. \square

Using Theorem 4.3 with (4.38) (resp., (4.39)) and then applying Theorem 4.4 in the case $\beta < 0$, the following estimates for $\phi = \pi\alpha$ and $\phi = 2\pi\alpha/3$ are obtained:

$$(4.49) \quad R(R_{\max}; \alpha, \beta, z, \pi\alpha) \leq \begin{cases} \frac{6}{\pi} e^{-R_{\max}^{1/\alpha}}, & \beta \geq 0, R_{\max} \geq 1, \\ \frac{6}{\pi} (|\beta| + 2)(2|\beta|)^{|\beta|} e^{-\frac{1}{2}R_{\max}^{1/\alpha}}, & \beta < 0, R_{\max}^{1/\alpha} \geq |\beta| + 1, \end{cases}$$

$$(4.50) \quad R(R_{\max}; \alpha, \beta, z, 2\pi\alpha/3) \leq \begin{cases} \frac{12}{2^{\beta}\pi} e^{-\frac{1}{2}R_{\max}^{1/\alpha}}, & \beta \geq 0, R_{\max} \geq 1, \\ \frac{12}{2^{\beta}\pi} (|\beta| + 2)(4|\beta|)^{|\beta|} e^{-\frac{1}{4}R_{\max}^{1/\alpha}}, & \beta < 0, R_{\max}^{1/\alpha} \geq |\beta| + 1. \end{cases}$$

In the case $\phi = \pi\alpha$ we applied Theorem 4.4 with $x = R_{\max}^{1/\alpha}$, $y = -\beta$, and $q = 2$, whereas in the case $\phi = 2\pi\alpha/3$ Theorem 4.4 was used with the parameters $x = R_{\max}^{1/\alpha}$, $y = -\beta$, and $q = 4$.

Recalling that (4.36) requires $R_{\max} > 2|z|$ and solving (4.49) and (4.50) for the truncation point R_{\max} , one finds for $\phi = \pi\alpha$ that

$$(4.51) \quad R_{\max} \geq \begin{cases} \max \left\{ 1, 2|z|, \left(-\ln \frac{\pi\varepsilon}{6} \right)^\alpha \right\}, & \beta \geq 0, \\ \max \left\{ (|\beta| + 1)^\alpha, 2|z|, \left(-2 \ln \left(\frac{\pi\varepsilon}{6(|\beta| + 2)(2|\beta|)^{|\beta|}} \right) \right)^\alpha \right\} & \beta < 0 \end{cases}$$

while for $\phi = 2\pi\alpha/3$ we have

$$(4.52) \quad R_{\max} \geq \begin{cases} \max \left\{ 2^\alpha, 2|z|, \left(-2 \ln \frac{\pi 2^\beta \varepsilon}{12} \right)^\alpha \right\}, & \beta \geq 0, \\ \max \left\{ [2(|\beta| + 1)]^\alpha, 2|z|, \left[-4 \ln \frac{\pi 2^\beta \varepsilon}{12(|\beta| + 2)(4|\beta|)^{|\beta|}} \right]^\alpha \right\}, & \beta < 0. \end{cases}$$

5. Discussion of the algorithm. In this section we briefly summarize the algorithm and the different cases that have to be distinguished to calculate $E_{\alpha,\beta}$ for a given error ε . Also the numerical treatment of the constants and error terms is described and details of the algorithm are discussed.

For $|z| \leq 0.95$ the Taylor series (2.1) is used for all $\alpha > 0$ and $\beta \in \mathbb{R}$. We apply the recursion formula (2.2) in the case $\alpha > 1$. The maximum number of terms M in the Taylor series which are needed to achieve an accuracy of ε is given by (4.5). This number increases rapidly for $z \rightarrow 1$; thus the Taylor series becomes inefficient for the calculation of $E_{\alpha,\beta}$ if $z > 0.95$. Furthermore if M becomes very large, the calculation of the gamma function fails due to numerical overflows. This can be avoided by using the identity

$$(5.1) \quad z^k / \Gamma(\alpha k + \beta) = \exp(k \ln(z) - \ln \Gamma(\alpha k + \beta)),$$

which behaves in a more stable manner for large k and $|z|$ not too close to the origin, where the logarithm is singular. Thus for very small $|z| < 0.5$ we switch back to the definition (2.1). In this case only a few terms of the Taylor series are necessary to obtain good accuracy, so one does not have to worry about M . Also a real Lanczos approximation [3] of the reciprocal gamma function is used to avoid problems at the poles of $\Gamma(\alpha k + \beta)$ when β is smaller than 0.

The integral formulas are limited only by the floating arithmetic of the computer, where errors can accumulate due to the rounding errors of the numerical integration scheme.

Now if $|z| \geq r_1$, where r_1 is given by (4.21), the asymptotic formulas are used, where we distinguish between the two asymptotic formulas (2.3) in \mathbb{G}_1 (resp., (2.4) in \mathbb{G}_2) and the Berry-type smoothed regions \mathbb{G}_3 and \mathbb{G}_4 in an angle of $\pm\delta$ around the Stokes lines ((2.5) and (2.6)). In the algorithm we choose $\delta = \pi\alpha/8$ to avoid coming too close to the Stokes lines with (2.3) (resp., (2.4)). For $|\delta| \leq \pi\alpha/8$ the argument $\theta \in [-\pi/8, \pi/8]$ is sufficiently small that one can apply the approximation $c \approx \theta + \frac{1}{6}\theta^2 - \frac{1}{36}\theta^3$. Figure 4 shows a plot of $c(\theta)$. The error of the approximation is much smaller than 1×10^{-4} in the real part and 1×10^{-3} in the imaginary one so that this approximation in the exponent is negligible.

For large α ($\alpha \geq 8/9$) the angle $\pi\alpha + \delta$ would cross the negative real axis and produce a jump in θ ; thus we always make use of the normal asymptotic series in a

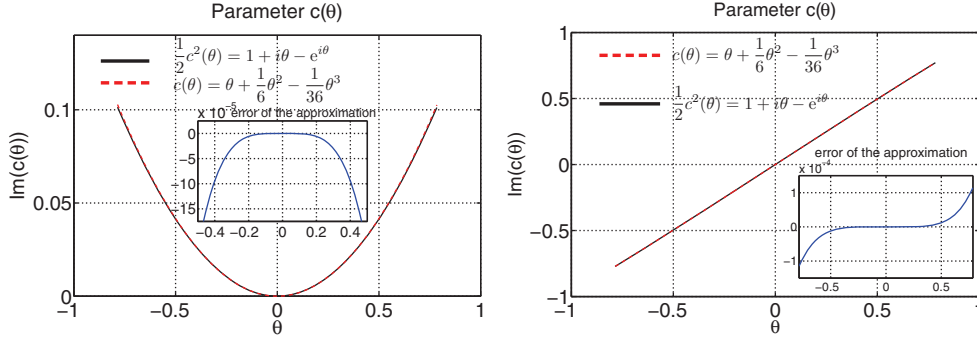

FIG. 4. The figures show the real (left) and imaginary part (right) of the parameter $c(\theta)$ of the Berry-type smoothed asymptotic series (2.5) (resp., (2.6)). The exact solution of $c(\theta)^2/2 = 1 + i\theta - e^{i\theta}$ is plotted as a black solid line, and the approximation $c \approx \theta + \frac{1}{6}\theta^2 - \frac{1}{36}\theta^3$ is marked with a dashed line. In the considered region of $\theta \in [-\pi/4, \pi/4]$ the difference between the two curves is negligible. The absolute error of the approximation is given in the inset plot.

wedge around the negative real axis, where the opening angle $\tilde{\delta}$ is between $\pi\alpha$ and π . More precisely $\tilde{\delta}$ is defined by $\tilde{\delta} = \min\{(\pi + \pi\alpha)/2, \delta\}$, where δ is the angle of the wedge around the Stokes line (cf. (3.7)). In the algorithm δ was chosen to be $\pi\alpha/8$.

Optimal truncation for the series should be achieved for M according to (4.21), which would mean that the number of necessary coefficients will increase with $\sim |z|^{1/\alpha}$. But for $z \rightarrow \infty$ the asymptotic series becomes better and better, so we apply an upper limit of $M < 100$ in the algorithm. This is also necessary to avoid overflows in the reciprocal gamma function for small negative values which reaches the floating point limit for about $\beta - \alpha k \approx 130$. As the term $z^{-k}/\Gamma(\beta - \alpha k)$ involves the multiplication of a very small number ($z^{-k} \ll 1$) with a very large number $1/\Gamma(\beta - \alpha k) \gg 1$, it is better to apply the $\exp - \log$ identity again for large k . In this case the calculation of $\log \Gamma(\beta - \alpha k)$ can fail due to the poles of the gamma function for negative integer values; thus we assume all terms to be zero for which $\beta - \alpha k$ is closer than 10^{-9} to a negative integer value.

In the algorithm the constant C in (4.19) is replaced with

$$(5.2) \quad C_0 = \frac{1}{2\pi} \left(\frac{1}{\sin \alpha\pi} + \frac{1}{\min\{\sin \alpha\pi, \sin \xi\}} \right) \approx \frac{1}{\pi \sin \pi\alpha},$$

obtained by combining (4.11) and (4.12). The choice to limit the constant C_0 on the Stokes line is supported analytically by the argument of Boyd [1, 23] that demands a smooth transition when crossing the Stokes line from one side to the other. Therefore the error cannot diverge when ξ goes to zero. Extensive numerical tests (see Table 2) and comparisons with the integral representations show that with (5.2) the relative errors between the asymptotic series and the integral representation are extremely small for $|z| \leq r_1 = (-2 \log(\varepsilon/C_0))^\alpha$. In practice the influence of the exact numerical value of C_0 is small as the constant appears inside a logarithm. In the Berry-type smoothed regions, the series (2.5) and (2.6) shows even better, namely, exponential convergence, than the normal series. Thus we can use the same estimate for r_1 as under optimal truncation.

FIG. 5. The two plots summarize the results of the error estimates of the integral representation. (a) shows the decay of the error term (4.38) of the integral representation for $\alpha = \beta = 2/3$ on a semilog scale. It decays faster than exponentially with R_{max} . (b) shows the dependence of the radius r_1 on the parameter α for a given tolerance $\varepsilon = 1e - 12$ using the formula $r_1 = (-2\log(\varepsilon/C_0))^\alpha = 14.16$, with C_0 given by (5.2). The radius r_1 determines from where on the asymptotic formula that is used to calculate $E_{\alpha,\beta}(z)$. The inset shows a semilogarithmic plot of the same region.

If $0.95 < |z| < r_1$, the integral formulas are used in \mathbb{G}_5 and \mathbb{G}_6 . For the error estimates we have to distinguish here $\beta > 1$ and $\beta \leq 1$, where the case $\beta \leq 1$ yields two further subcases $\beta \geq 0$ and $\beta < 0$. The contours for the integral formulas for the areas \mathbb{G}_5 and \mathbb{G}_6 have been chosen such that z will never come close to the contour of integration. A plot of the areas \mathbb{G}_5 and \mathbb{G}_6 with the two contour paths $\gamma(1/2, \pi\alpha)$ and $\gamma(1/2, 2\pi\alpha/3)$ is shown in Figure 1(b). Figure 5(a) shows a plot of the right-hand side of (4.38) versus R_{max} . One can see that the accuracy is extremely good even for rather small R_{max} . The estimates for R_{max} are given in (4.51) and (4.52).

The integrand in (4.29) is oscillatory. The amplitude of these oscillations is mainly determined by the prefactor in (4.27). For real argument $z \in \mathbb{R}$, the imaginary part of the integrand is antisymmetric in (4.27) with respect to the origin. This means that the integral over the imaginary part of (4.29) vanishes and does not have to be calculated. For the real part one can also make use of the symmetry and perform the integration over only half of the contour arc.

A detailed description of the behavior of the generalized Mittag-Leffler function in the complex plane and the investigation of the distribution of the zeros can be found in [7]. Two contour plots of $E_{\alpha,\beta}(z)$ are shown in Figure 6.

The algorithm has been implemented for complex z with real and imaginary parts in double precision. The parameters α and β are represented as real double variables. A separate function for real double z has also been implemented. In this case the integration routines make use of the symmetry of the integrand and the fact that $\text{Im}(E_{\alpha,\beta}(x)) = 0$. This speeds up the integration routine and improves the stability of the algorithm.

6. Numerical tests and speed analysis of the algorithm. Extensive numerical calculations of the algorithm were performed to test the stability and the validity range for the parameters $\alpha, \beta \in \mathbb{R}$ and the argument $z \in \mathbb{C}$. The results are summarized in this section.

By incorporating the asymptotic formula the algorithm has been much improved. Especially for large values of $|z|$ the asymptotic series are much faster and more stable than the integral formulas. For some representative values the differences are reported

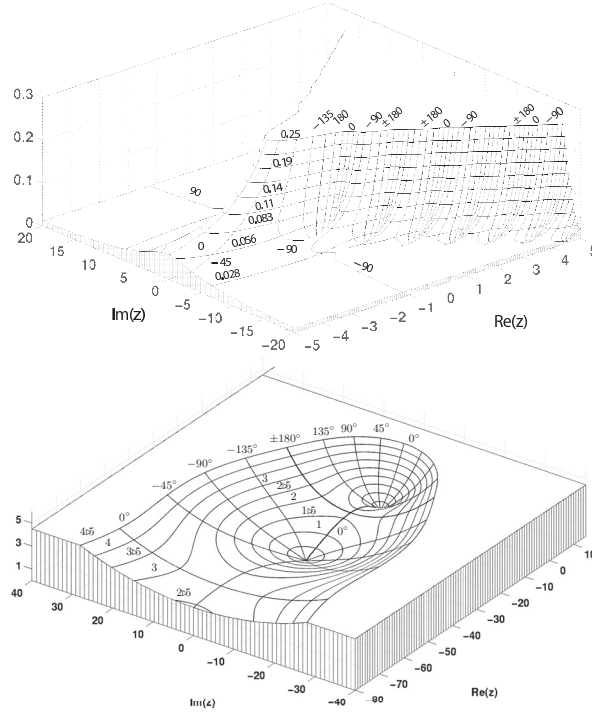

FIG. 6. The plots show the behavior of the Mittag-Leffler function $E_{\alpha,1}(z)$ in the complex plane for $\alpha = 0.8$ (top) and $\alpha = 2.25$ (bottom). In the three-dimensional plot the absolute value of the function is plotted with the contour lines on top. Furthermore, the contour lines of the argument are also marked.

in Table 1, where the speed of the integral routine is compared to the asymptotic formula in a range where both formulas can be used for the calculation. The speedup factor ranges typically between 20 and 40. Close to the Stokes lines the Berry-type smoothed formulas give a better approximation than the normal asymptotic series.

The convergence of the series is compared with the values obtained by the integral representation along rays with constant argument for $|z| \rightarrow \infty$. Good agreement and fast convergence is obtained in all sectors of the complex plane.

For very large values of $|z|$ the integral formula cannot be used due to rounding errors in the floating point arithmetic. Also the dependence on the parameters α and β is very important; for example, the amplitude equation (4.27) of the integrand $B(r; \alpha, \beta, z, \delta)$ in (4.28) behaves like $r^{(1-\beta)/\alpha}$. If this value becomes too large, the integration routines cannot achieve the required precision. An example of $B(r; \alpha, \beta, z, \delta)$ for different $\beta = 5, 10, 20$ is shown in Figure 7. Similar limitations hold for the integrand in (4.29), where the integrand oscillates with a higher and higher frequency while the value of the integral is close to zero (see Figure 8).

A comparison of the integral formula with the asymptotic series in a range around r_1 is shown in Figure 9. The range for which we still obtained reasonable results is summarized in Table 2. The tests were performed by calculating the values of $E_{\alpha,\beta}(z)$ on a rectangular grid with $\text{Re}_{\min} \leq \text{Re}(z) < \text{Re}_{\max}$ and $\text{Im}_{\min} \leq \text{Im}(z) < \text{Im}_{\max}$ with different lattice spacings. Furthermore the values of $E_{\alpha,\beta}$ are calculated along different rays from the origin covering the different areas of the partitioning (section 3) of the complex plane. For various combinations of α and β the range of validity with respect

TABLE 1

Comparison of the speedup for the calculation for $E_{\alpha,\beta}$ using the asymptotic series expansions. The tolerance ε is set to 10^{-16} . The last column indicates the equation used for the calculation of the asymptotic series. Each speedup factor is averaged over 100 calculations. All calculations were done using the complex algorithm.

FIG. 7. The figure shows the integrand $B(r; \alpha, \beta, z, 2\pi\alpha/3)$ for $\alpha = 0.2$ and different values of large $|\beta|$. The argument is set to $z = -5 \in \mathbb{G}_5$ (left). One can see how strongly the amplitude increases with increasing β . The oscillations are especially difficult to handle as the large positive parts of the integral cancel out with the large negative ones. The right figure shows the integrand $B(r; \alpha, \beta, z, 2\pi\alpha)$ in the case $z = 5 \in \mathbb{G}_6$ for the parameters $\beta = 28$ to $\beta = 30$. Note the values on the y-axis. In the inset the semilog plot of the absolute value of the integrand in the same range is shown.

to the argument z was determined for the integral representation and the asymptotic series. The upper limit $|z|_{\max}^{\text{int}}$ for which the integral representation is still valid is calculated as follows: Let $E_{\alpha,\beta}^{\text{int}}$ be the values of the Mittag-Leffler function calculated with the integral representation and $E_{\alpha,\beta}^{\text{asym}}$ those obtained from the asymptotic series. As for $|z| \rightarrow \infty$ the asymptotic series becomes more and more accurate; thus the difference $|E_{\alpha,\beta}^{\text{int}} - E_{\alpha,\beta}^{\text{asym}}|$ decreases until it increases again for $|z| > |z|_{\max}^{\text{int}}$ due to the fact that the integral representation becomes inaccurate. For given α and β the value reported in Table 2 is the minimum of all $|z|_{\max}^{\text{int}}$ obtained on the different rays covering all sectors of the partitioning described in section 3.

FIG. 8. The figure shows the integrand $C(\varphi; \alpha, \beta, z, \rho)$ in (4.29) for $\alpha = 0.9$ and different values of β (left). The same integrand but for $\alpha = 0.2$ is shown in the right figure. All other parameters are the same in both plots, where z was set to -5 and $\rho = 0.5$.

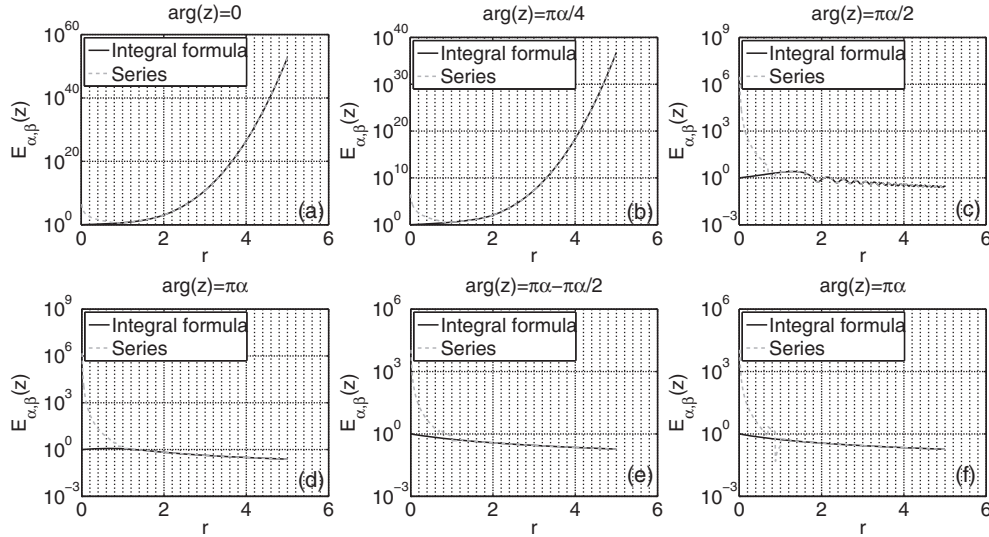

FIG. 9. The figures show the behavior of the Mittag-Leffler function in a range of $|z|$ around r_1 calculated with the asymptotic series (gray dashed line) and the integral formula (black solid line) for different arguments of z . Starting from (a) to (f) the arguments are (a) $\arg(z) = 0$, (b) $\arg(z) = \pi\alpha/4$, (c) $\arg(z) = \pi\alpha/2$, (d) $\arg(z) = \pi\alpha$, (e) $\arg(z) = \pi - \pi\alpha/4$, and (f) $\arg(z) = \pi$. The example is calculated for $\alpha = 1/3$, $\beta = 2$, and $\varepsilon = 10^{-10}$. The value of r_1 in this case is $r_1 = (-2 \log(\varepsilon/C))^\alpha = 3.53$.

In the case $|z| \rightarrow 0$ the asymptotic series becomes unstable. The lower bound $|z|_{\min}^{\text{asym}}$ of the asymptotic series is defined by the value of $|z|$ for which the relative error $\text{Err}_{\text{rel}} = |(E_{\alpha, \beta}^{\text{int}} - E_{\alpha, \beta}^{\text{asym}})/E_{\alpha, \beta}^{\text{int}}|$ exceeds 10^{-2} . The largest value of $|z|_{\min}^{\text{asym}}$ along the different rays is shown in Table 2.

For the parameters α and β we find that, in the range $0.05 < \alpha < 0.999$ and $-2 < \beta < 2$, the algorithm covers the whole complex plane up to machine precision in the asymptotic formula which is reached for positive values at $\text{Re}(z) \leq 1.5$ ($\alpha = 0.05$) and $|z| \leq 600$ ($\alpha = 0.999$) as the function grows like $1/\alpha \exp(x^{1/\alpha})$. For $\text{Re}(z) \rightarrow -\infty$ the limits are much larger. For a negative argument the function can be calculated at least for $\text{Re}(z) > -10^{50}$.

TABLE 2

Comparison of the asymptotic series and the integral formula for different combinations of α and β . The value $|z|_{\max}^{\text{int}}$ indicates when the integral formulas start to become inaccurate (see text). For $z < |z|_{\min}^{\text{asym}}$ the asymptotic formula begins to break down. This value is defined by the smallest number of $|z|$ for which the relative error is still smaller than 10^{-2} . The relative error is defined by $\text{Err}_{\text{rel}} = |(E_{\alpha,\beta}^{\text{int}} - E_{\alpha,\beta}^{\text{asym}})/E_{\alpha,\beta}^{\text{int}}|$, where $E_{\alpha,\beta}^{\text{int}}$ are the values of $E_{\alpha,\beta}$ obtained with the integral representation and $E_{\alpha,\beta}^{\text{asym}}$ are the values calculated with the series expansion. The numerical values of the relative error at the points $|z| = r_1$ are reported in the sixth column, where $r_1 = (-2 \log(\varepsilon/C_0))^\alpha$ is the lower radius for the asymptotic series. The value of ε is set to 10^{-11} , and C_0 is given by (5.2).

α	β	$ z _{\max}^{\text{int}}$	$ z _{\min}^{\text{asym}}$	r_1	Err_{rel} at r_1

0.9	-1	> 200	9.7702	34.2477	1.3282e - 10
0.9	-2/3	$ z _{\max} = 190.5 \pm 0.5$	8.5021	34.2477	4.6096e - 13
0.9	2/3	> 200	6.5593	34.2477	1.0505e - 11
0.9	1	> 200	6.3687	34.2477	6.1782e - 12
0.9	5/3	> 200	3.6252	34.2477	8.7930e - 14
0.9	10	> 200	5.9216	34.2477	6.6471e - 08

The limitations of large $|\beta|$ can be overcome using the following relation:

$$(6.1) \quad z^n E_{\alpha,\beta+n\alpha}(z) = \sum_{k=n}^{\infty} \frac{z^{n+k}}{\Gamma(\alpha(n+k) + \beta)} = E_{\alpha,\beta}(z) - \sum_{k=0}^n \frac{z^k}{\Gamma(\alpha k + \beta)}.$$

This extends the range of β to arbitrary large and small values.

7. Conclusion. A numerical algorithm for calculating the generalized Mittag-Leffler function for arbitrary real parameters $\alpha > 0$ and β was presented, and the error estimates have been calculated. Different representations have been used for different values of $z \in \mathbb{C}$ to obtain optimal stability and accuracy. The algorithm is not only fast, but it also eliminates numerical instabilities in other codes [4]. Furthermore the algorithm was extended using exponentially improved asymptotics. The Berry-type smoothing was used to avoid numerical instabilities close to the Stokes lines, where the asymptotic formulas fail. A great improvement in the speed and stability of the algorithm especially for large values of z has been achieved using the asymptotic series as presented in section 6. Furthermore the algorithm has been analyzed in detail, and

several numerical techniques have been discussed to improve the calculation. Finally, a detailed analysis of the numerical stability and validity of the algorithm is given. The algorithm is available as in C and as a MATLAB script for download [20].

Acknowledgments. The authors thank Julian Engel for useful discussions and performing extensive test runs with the algorithm. Furthermore, we want to thank the referees for their constructive criticism and useful hints.

DISCONTINUOUS DISCRETIZATION FOR LEAST-SQUARES FORMULATION OF SINGULARLY PERTURBED REACTION-DIFFUSION PROBLEMS IN ONE AND TWO DIMENSIONS*

RUNCHANG LIN[†]

Abstract. In this paper, we consider the singularly perturbed reaction-diffusion problem in one and two dimensions. The boundary value problem is decomposed into a first-order system to which a suitable weighted least-squares formulation is proposed. A robust, stable, and efficient approach is developed based on local discontinuous Galerkin (LDG) discretization for the weak form. Uniform error estimates are derived. Numerical examples are presented to illustrate the method and the theoretical results. Comparison studies are made between the proposed method and other methods.

Key words. least-squares methods, local discontinuous Galerkin methods, singular perturbation problems, reaction-diffusion problems

AMS subject classification. 65N30

DOI. 10.1137/070700267

1. Introduction. In this paper, we are concerned with the singularly perturbed reaction-diffusion problem

$$(1.1) \quad \begin{cases} -\epsilon^2 \Delta u + cu = f & \text{in } \Omega = (0, 1)^d, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $0 < \epsilon \ll 1$ is the perturbation parameter, c and f are continuous functions in $\bar{\Omega}$, $0 < c_0 \leq c \leq c_1$ in $\bar{\Omega}$ with two positive constants c_0 and c_1 , and $d = 1$ or 2 .

It is well known that exact solutions to singular perturbation problems (1.1) typically contain *layers*, which cause nonmonotonic numerical oscillations in the solutions from standard Galerkin finite element methods (FEMs). Stabilization techniques such as upwinding, Petrov–Galerkin, streamline diffusion, discontinuous Galerkin, and adaptive approximations have been developed to improve standard Galerkin methods. For an overview of these methods, we refer to the books by Miller, O’Riordan, and Shishkin [26], Morton [27], Roos, Stynes, and Tobiska [33], and the references therein. Nevertheless, singularly perturbed problems remain difficult to solve numerically.

The least-squares finite element method (LSFEM) is a general methodology, which is based on the minimization of the residuals in a least-squares sense. The method, for linear differential equations, leads to symmetric positive-definite algebraic systems which can be efficiently solved by iterative methods. Continuous LSFEMs have been applied to solve convection-reaction-diffusion problems; see, e.g., [4, 6, 8, 10, 11, 14, 16, 21, 22, 30, 31]. For more details on the theory of LSFEMs, we refer to the review paper of Bochev and Gunzburger [5] and the book by Jiang [20].

Although the least-squares method shows many attractive features, its use is restricted by several disadvantages [7, 10, 11]. In particular, comparing with the Galerkin method, the least-squares based weak formulation requires higher regularity

[†]Department of Mathematical and Physical Sciences, Texas A & M International University, Laredo, TX 78041-1900 (rlin@tamui.edu).

of finite element spaces. In addition, as we will illustrate in section 5, the standard least-squares method is inefficient for solving singularly perturbed problems, especially within and near the layers.

Discontinuous approximation spaces have been used to discretize least-squares formulations for solving a variety of problems, which can remove additional regularity requirement of the LSFEM. Cao and Gunzburger [12] used, for the first time in the literature, least-squares methods with discontinuous elements to treat interface problems. Gerritsma and Proot [17] derived a discontinuous least-squares spectral element method for a sample first order ordinary differential equation. Bensow and Larson applied discontinuous LSFEMs to elliptic problems [2] and div-curl problems [3] with boundary singularities. In all of these works, special least-squares functionals are proposed in discontinuous finite element spaces. On the other hand, the least-squares technique has also been used as a stabilizer of DG methods. For instance, Houston, Jensen, and Süli [19] investigated a general family of hp -discontinuous Galerkin FEMs with least-squares stabilization for symmetric systems of first-order partial differential equations.

Recently, the author proposed a discontinuously discretized LSFEM for 1D singularly perturbed reaction-diffusion problems with constant coefficients [24]. We hereby extend the method and develop a robust and stable numerical approach for more general singularly perturbed reaction-diffusion problems in 1D and 2D spaces. We will demonstrate the efficiency of our methods both theoretically and numerically. Numerical comparison studies between the proposed method and the local discontinuous Galerkin (LDG) method, the continuous LSFEM, and the discontinuous LSFEM indicate that the method is a promising alternative to existing schemes.

This paper is organized as follows. Section 2 introduces definitions and notations used in this paper. In section 3, we present the singularly perturbed problem and its least-squares variational formulation. The LDG method is utilized for the associated discrete problems. We prove coercivity of the bilinear forms in an associated energy norm. An adaptive method is also provided in this section to reduce computational cost. In section 4, a priori error estimate results are presented in one and two spatial dimensions. In section 5, numerical examples are given, which verify the theoretical results. Some comparisons of our method to other methods are included. Conclusions are drawn in section 6.

2. Notations. Throughout this paper, we shall use C to denote a generic positive constant which is independent of ϵ and the mesh used. Vectors and scalars are denoted by bold and plain letters, respectively.

We will denote the inner products in $L^2(\Omega)$ and product spaces of $L^2(\Omega)$ by (\cdot, \cdot) . For $1 \leq p \leq \infty$ and $s \geq 0$, we use the standard notation for the Sobolev space $W_p^s(\Omega)$ with the norm $\|\cdot\|_{W_p^s(\Omega)}$ and the seminorm $|\cdot|_{W_p^s(\Omega)}$. $H^s(\Omega)$ is used to stand for the space $W_2^s(\Omega)$, whose norm and seminorm are denoted by $\|\cdot\|_{s,\Omega}$ and $|\cdot|_{s,\Omega}$, respectively. When no confusion may arise, the measure Ω will be omitted from the above norm designations. We recall the space $H_0^1(\Omega)$ consisting of all functions in $H^1(\Omega)$ that vanish on the boundary $\partial\Omega$, and the space

$$H(\text{div}; \Omega) = \{\mathbf{q} \in [L^2(\Omega)]^d : \nabla \cdot \mathbf{q} \in L^2(\Omega)\}$$

with corresponding norm

$$\|\mathbf{q}\|_{H(\text{div}; \Omega)}^2 = \|\nabla \cdot \mathbf{q}\|_0^2 + \|\mathbf{q}\|_0^2.$$

Here, we denote also the norms on product spaces of $H^s(\Omega)$ by $\|\cdot\|_{s,\Omega}$, or simply $\|\cdot\|_s$, where there is no chance for ambiguity. We define further the vector function space

$$\mathbf{H}(\Omega) = H(\operatorname{div}; \Omega) \times H_0^1(\Omega)$$

with norms

$$\|\mathbf{v}\|_0^2 = \|\mathbf{q}\|_0^2 + \|v\|_0^2 \quad \text{and} \quad \|\mathbf{v}\|_{\mathbf{H}(\Omega)}^2 = \|\mathbf{q}\|_{H(\operatorname{div}; \Omega)}^2 + \|v\|_1^2,$$

where, and in the remainder of this paper, the vector valued functions \mathbf{u} , \mathbf{v} , and \mathbf{w} have components

$$\mathbf{u} = \begin{bmatrix} \mathbf{p} \\ u \end{bmatrix}, \quad \mathbf{v} = \begin{bmatrix} \mathbf{q} \\ v \end{bmatrix}, \quad \text{and} \quad \mathbf{w} = \begin{bmatrix} \mathbf{r} \\ w \end{bmatrix},$$

respectively, unless otherwise specified. As we shall see in section 3, \mathbf{p} , \mathbf{q} , and \mathbf{r} are vector functions of dimension d , which are corresponding to the gradients of u , v , and w , respectively.

Let u be a solution of (1.1). The following estimates hold (see, e.g., [34]):

$$\|u\|_s \leq \frac{C}{\epsilon^s} \|f\|_0$$

for $0 < \epsilon \leq 1$ and $s = 0, 1$, or 2 . These estimates are, in fact, sharp [35]. Thus the standard norm $\|u\|_1$ or $\|u\|_2$ does not provide an informative gauge when ϵ is small. It is natural to introduce the following ϵ -dependent norm in $H^1(\Omega)$ [33]:

$$\|v\|_{1,\epsilon}^2 = \epsilon^2 |v|_1^2 + \|v\|_0^2.$$

In addition, we present ϵ -dependent norms in $\mathbf{H}(\Omega)$ as

$$\begin{aligned} \|\mathbf{v}\|_{0,\epsilon}^2 &= \epsilon^2 \|\mathbf{q}\|_0^2 + \|v\|_0^2, \\ \|\mathbf{v}\|_{1,\epsilon}^2 &= \epsilon^4 \|\nabla \cdot \mathbf{q}\|_0^2 + \epsilon^2 |v|_1^2 + \|\mathbf{v}\|_{0,\epsilon}^2. \end{aligned}$$

Let $\mathcal{T}_h = \{\Omega_k\}_{k=1}^M$ be a shape regular triangulation on Ω with mesh size h . Let \mathcal{E} be the union of the boundaries of all elements Ω_k associated with the partition \mathcal{T}_h , and let $\mathcal{E}_{int} \subset \mathcal{E}$ be the set of all interior edges contained in Ω . Note that an anisotropic mesh (e.g., Shishkin mesh) will certainly improve numerical results, which, nevertheless, is not necessary.

We use the following broken Sobolev spaces:

$$H^s(\mathcal{T}_h) = \{v \in L^2(\Omega) : v|_{\Omega_k} \in H^s(\Omega_k), k = 1, \dots, M\},$$

where $H^s(\Omega_k)$ is the Sobolev space of order s on Ω_k , $s \geq 0$. The inner products and norms defined above can be taken over the elements Ω_k , which are denoted by $(\cdot, \cdot)_{\Omega_k}$ and $\|\cdot\|_{s,\Omega_k}$, respectively. For $v \in H^s(\mathcal{T}_h)$, we define its norms and seminorms as

$$(2.1) \quad \|v\|_s^2 = \sum_{k=1}^M \|v\|_{s,\Omega_k}^2, \quad |v|_s^2 = \sum_{k=1}^M |v|_{s,\Omega_k}^2,$$

$$(2.2) \quad \|v\|_{1,\epsilon}^2 = \sum_{k=1}^M \|v\|_{1,\epsilon,\Omega_k}^2,$$

where $s \geq 0$ and

$$\|v\|_{1,\epsilon,\Omega_k}^2 = \epsilon^2 \|v\|_{1,\Omega_k}^2 + \|v\|_{0,\Omega_k}^2.$$

We define also the space

$$\mathbf{H}(\mathcal{T}_h) = \{[\mathbf{q}, v]^T \in H(\operatorname{div}; \mathcal{T}_h) \times H^1(\mathcal{T}_h) : v|_{\partial\Omega} = 0\},$$

where

$$H(\operatorname{div}; \mathcal{T}_h) = \{\mathbf{q} \in [H^1(\mathcal{T}_h)]^d : \mathbf{q}|_{\Omega_k} \in [L^2(\Omega_k)]^d, \nabla \cdot \mathbf{q}|_{\Omega_k} \in L^2(\Omega_k)\}.$$

The inner products and norms in $\mathbf{H}(\mathcal{T}_h)$ can be defined analogously. In particular, for $\mathbf{v} \in \mathbf{H}(\mathcal{T}_h)$, we define

$$(2.3) \quad \|\mathbf{v}\|_{0,\epsilon}^2 = \sum_{k=1}^M \|\mathbf{v}\|_{0,\epsilon,\Omega_k}^2, \quad \|\mathbf{v}\|_{1,\epsilon}^2 = \sum_{k=1}^M \|\mathbf{v}\|_{1,\epsilon,\Omega_k}^2,$$

where

$$\begin{aligned} \|\mathbf{v}\|_{0,\epsilon,\Omega_k}^2 &= \epsilon^2 \|\mathbf{q}\|_{0,\Omega_k}^2 + \|v\|_{0,\Omega_k}^2, \\ \|\mathbf{v}\|_{1,\epsilon,\Omega_k}^2 &= \epsilon^4 \|\nabla \cdot \mathbf{q}\|_{0,\Omega_k}^2 + \epsilon^2 \|v\|_{1,\Omega_k}^2 + \|\mathbf{v}\|_{0,\epsilon,\Omega_k}^2. \end{aligned}$$

In (2.1)–(2.3), we use the same norm notations as in the continuous Sobolev spaces, which will cause no ambiguity.

For any element $\Omega_k \in \mathcal{T}_h$ and an edge $e \in \partial\Omega_k \cap \mathcal{E}_{int}$, let $\Omega_{k',e}$ be the unique element sharing e with Ω_k . Let $\mathbf{n}_{k,e}^+$ and $\mathbf{n}_{k,e}^-$ be the outward normal unit vectors of Ω_k and $\Omega_{k',e}$ to e , respectively. For $v \in H^1(\mathcal{T}_h)$, we denote $v_{k,e}^+$ and $v_{k,e}^-$, the interior and outer traces of v on e , with respect to Ω_k , respectively. Note that $v_{k,e}^-$ and $v_{k',e}^+$ are selfsame. Similarly, we can define traces $\mathbf{q}_{k,e}^+$ and $\mathbf{q}_{k,e}^-$ for $\mathbf{q} \in [H^1(\mathcal{T}_h)]^d$. As in [1], we define the *average* and *jump* of v and \mathbf{q} to element Ω_k across e by

$$\begin{aligned} \{v\}_{k,e} &= \frac{1}{2}(v_{k,e}^+ + v_{k,e}^-), & [[v]]_{k,e} &= v_{k,e}^+ \mathbf{n}_{k,e}^+ + v_{k,e}^- \mathbf{n}_{k,e}^-; \\ \{\mathbf{q}\}_{k,e} &= \frac{1}{2}(\mathbf{q}_{k,e}^+ + \mathbf{q}_{k,e}^-), & [[\mathbf{q}]]_{k,e} &= \mathbf{q}_{k,e}^+ \cdot \mathbf{n}_{k,e}^+ + \mathbf{q}_{k,e}^- \cdot \mathbf{n}_{k,e}^-. \end{aligned}$$

We denote v_k^+ , v_k^- , \mathbf{q}_k^+ , and \mathbf{q}_k^- , the interior and outer traces of v and \mathbf{q} , along $\partial\Omega_k$ with respect to Ω_k , respectively.

Finally, we define the finite element space associated with \mathcal{T}_h as

$$\mathbf{V}_h = [V^h]^d \times V_0^h \subset \mathbf{H}(\mathcal{T}_h),$$

where $V^h \subset H^1(\mathcal{T}_h)$ is the space of piecewise linear (1D and 2D) or bilinear (2D) polynomials allowing discontinuity along interelement edges, and V_0^h is the subspace of V^h , which consists of functions vanishing on the boundary $\partial\Omega$.

3. Least-squares finite element approximations. We rewrite (1.1) as the following system of first-order equations:

$$(3.1) \quad \begin{cases} \mathbf{p} - \nabla u = \mathbf{0} & \text{in } \Omega, \\ -\epsilon^2 \nabla \cdot \mathbf{p} + cu = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases}$$

For $\mathbf{u} \in \mathbf{H}(\Omega)$, define

$$A\mathbf{u} = \begin{bmatrix} \epsilon\sqrt{c_0}(\mathbf{p} - \nabla u) \\ -\epsilon^2\nabla \cdot \mathbf{p} + cu \end{bmatrix} \quad \text{and} \quad \mathbf{f} = \begin{bmatrix} \mathbf{0} \\ f \end{bmatrix}.$$

Notice that a weight $\epsilon\sqrt{c_0}$ is employed in the first component of $A\mathbf{u}$, where the same concerns as in the definitions of ϵ -dependent norms are reflected. Equation (3.1) can be written as

$$(3.2) \quad A\mathbf{u} = \mathbf{f} \quad \text{in } \Omega.$$

The homogenous boundary condition in (3.1) is satisfied since $\mathbf{u} \in \mathbf{H}(\Omega)$ implies $u \in H_0^1(\Omega)$. Note that problem (1.1) has a unique solution u in $H_0^1(\Omega) \cap H_{loc}^2(\Omega)$, which is, moreover, in $H_0^2(\Omega)$ when $\partial\Omega$ is sufficiently smooth [18]. We will assume from now on that problem (3.2) has a unique solution $\mathbf{u} \in \mathbf{H}(\Omega)$.

3.1. The least-squares formulation. Consider the least-squares functional \mathcal{J} in $\mathbf{H}(\Omega)$ defined by

$$\mathcal{J}(\mathbf{v}; f) = \|A\mathbf{v} - \mathbf{f}\|_0^2 = (A\mathbf{v} - \mathbf{f}, A\mathbf{v} - \mathbf{f}).$$

The least-squares method reads: find $\mathbf{u} \in \mathbf{H}(\Omega)$ such that

$$\mathcal{J}(\mathbf{u}; f) = \inf_{\mathbf{v} \in \mathbf{H}(\Omega)} \mathcal{J}(\mathbf{v}; f).$$

A necessary condition for \mathbf{u} to be a minimizer of the functional \mathcal{J} is that its first variation vanishes at \mathbf{u} , i.e.,

$$\lim_{t \rightarrow 0} \frac{d}{dt} \mathcal{J}(\mathbf{u} + t\mathbf{v}; f) = 2(A\mathbf{u} - \mathbf{f}, A\mathbf{v}) = 0 \quad \forall \mathbf{v} \in \mathbf{H}(\Omega).$$

The corresponding least-squares variational formulation for problem (1.1) thus follows: find $\mathbf{u} \in \mathbf{H}(\Omega)$ such that

$$(3.3) \quad B(\mathbf{u}, \mathbf{v}) = L(\mathbf{v}) \quad \forall \mathbf{v} \in \mathbf{H}(\Omega),$$

where the bilinear form $B : \mathbf{H}(\Omega) \times \mathbf{H}(\Omega) \rightarrow \mathbb{R}$ and linear functional $L : \mathbf{H}(\Omega) \rightarrow \mathbb{R}$ are defined as

$$(3.4) \quad B(\mathbf{w}, \mathbf{v}) = (A\mathbf{w}, A\mathbf{v}) = c_0\epsilon^2(\mathbf{r} - \nabla w, \mathbf{q} - \nabla v) + (-\epsilon^2\nabla \cdot \mathbf{r} + cw, -\epsilon^2\nabla \cdot \mathbf{q} + cv),$$

$$(3.5) \quad L(\mathbf{v}) = (\mathbf{f}, A\mathbf{v}) = (f, -\epsilon^2\nabla \cdot \mathbf{q} + cv)$$

for all $\mathbf{v}, \mathbf{w} \in \mathbf{H}(\Omega)$.

It is clear that the bilinear form $B(\cdot, \cdot)$ defined in (3.4) is symmetric. In addition, we have the following boundedness and coercivity results.

THEOREM 3.1. (i) *There exists a constant $C > 0$ independent of ϵ such that*

$$(3.6) \quad |B(\mathbf{w}, \mathbf{v})| \leq C\|\mathbf{w}\|_{1,\epsilon}\|\mathbf{v}\|_{1,\epsilon} \quad \forall \mathbf{v}, \mathbf{w} \in \mathbf{H}(\Omega).$$

(ii) *There exists a constant $\alpha > 0$ independent of ϵ such that*

$$(3.7) \quad B(\mathbf{v}, \mathbf{v}) \geq \alpha\|\mathbf{v}\|_{1,\epsilon}^2 \quad \forall \mathbf{v} \in \mathbf{H}(\Omega).$$

Proof. The boundedness property (3.6) is a direct consequence of the Cauchy-Schwartz and triangle inequalities.

We next prove the coercivity (3.7). From (3.4), one has

$$B(\mathbf{v}, \mathbf{v}) = c_0 \epsilon^2 \|\mathbf{q} - \nabla v\|_0^2 + \|\epsilon^2 \nabla \cdot \mathbf{q} + cv\|_0^2.$$

Using integration by parts and homogenous boundary conditions of v , we have

$$(3.8) \quad 2B(\mathbf{v}, \mathbf{v}) \geq \epsilon^4 \|\nabla \cdot \mathbf{q}\|_0^2 + \|cv\|_0^2 + c_0 \epsilon^2 \|\mathbf{q}\|_0^2 + c_0 \epsilon^2 \|\nabla v\|_0^2 + 2(\epsilon^2 \nabla \cdot \mathbf{q}, (c_0 - c)v).$$

Choose a constant $\delta = \frac{c_1}{c_0 + c_1}$. Then $0 < \delta < 1$. It follows that

$$(3.9) \quad \delta \epsilon^4 \|\nabla \cdot \mathbf{q}\|_0^2 + 2(\epsilon^2 \nabla \cdot \mathbf{q}, (c_0 - c)v) + \frac{1}{\delta} \|(c_0 - c)v\|_0^2 = \left\| \epsilon^2 \sqrt{\delta} \nabla \cdot \mathbf{q} + \frac{1}{\sqrt{\delta}} (c_0 - c)v \right\|_0^2 \geq 0.$$

By (3.8) and (3.9), we get

$$(3.10) \quad \begin{aligned} 2B(\mathbf{v}, \mathbf{v}) &\geq (1 - \delta) \epsilon^4 \|\nabla \cdot \mathbf{q}\|_0^2 + \|cv\|_0^2 - \frac{1}{\delta} \|(c_0 - c)v\|_0^2 + c_0 \epsilon^2 \|\mathbf{q}\|_0^2 + c_0 \epsilon^2 \|\nabla v\|_0^2 \\ &= (1 - \delta) \epsilon^4 \|\nabla \cdot \mathbf{q}\|_0^2 + \frac{1}{\delta} ((\delta c^2 - (c_0 - c)^2) v, v) + c_0 \epsilon^2 \|\mathbf{q}\|_0^2 + c_0 \epsilon^2 \|\nabla v\|_0^2. \end{aligned}$$

Note that

$$(\delta - 1)c + c_0 \geq -\frac{c_0}{c_0 + c_1} c_1 + c_0 = \frac{c_0^2}{c_0 + c_1}.$$

Hence

$$(3.11) \quad \delta c^2 - (c_0 - c)^2 = ((\delta - 1)c + c_0)c + c_0(c - c_0) \geq \frac{c_0^2}{c_0 + c_1} c \geq \frac{c_0^3}{c_0 + c_1}.$$

Finally, by (3.10) and (3.11), we arrive at

$$B(\mathbf{v}, \mathbf{v}) \geq \frac{1 - \delta}{2} \epsilon^4 \|\nabla \cdot \mathbf{q}\|_0^2 + \frac{c_0^3}{2c_1} \|v\|_0^2 + \frac{c_0}{2} \epsilon^2 \|\mathbf{q}\|_0^2 + \frac{c_0}{2} \epsilon^2 \|\nabla v\|_0^2,$$

which implies (3.7) by taking $\alpha = \min\{\frac{c_0}{2(c_0 + c_1)}, \frac{c_0^3}{2c_1}, \frac{c_0}{2}\}$. \square

The following result is a straightforward consequence of Theorem 3.1.

PROPOSITION 3.2. *The least-squares variational problem (3.3) is well posed.*

3.2. LDG discretization. We next discretize the least-squares formulation (3.3) with the LDG method [15]. Using integration by parts in each element, we get the LDG approximation for the least-squares variational formulation (3.3) as follows, by employing a process which will be referred to as the LDG-LS method in this paper. Find $\mathbf{u}_h = [\mathbf{p}_h, u_h]^T \in \mathbf{V}_h$ such that

$$(3.12) \quad B_h(\mathbf{u}_h, \mathbf{v}) = L_h(\mathbf{v}) \quad \forall \mathbf{v} \in \mathbf{V}_h,$$

where the bilinear form (or *primal form*) $B_h : \mathbf{H}(\mathcal{T}_h) \times \mathbf{H}(\mathcal{T}_h) \rightarrow \mathbb{R}$ and the linear form $L_h : \mathbf{H}(\mathcal{T}_h) \rightarrow \mathbb{R}$ are defined by

$$(3.13) \quad \begin{aligned} B_h(\mathbf{w}, \mathbf{v}) &= \sum_{k=1}^M \int_{\Omega_k} (c_0 \epsilon^2 \mathbf{r} \cdot \mathbf{q} + c_0 \epsilon^2 \nabla w \cdot \nabla v + \epsilon^4 \nabla \cdot \mathbf{r} \nabla \cdot \mathbf{q} + c^2 wv) \, dx \\ &+ \epsilon^2 \sum_{k=1}^M \int_{\Omega_k} (\mathbf{r} \cdot \nabla ((c - c_0)v) + (c_0 - c)w \nabla \cdot \mathbf{q}) \, dx \\ &- \epsilon^2 \sum_{k=1}^M \int_{\partial \Omega_k} (c_0 \widehat{w}_k \mathbf{q}_k^+ \cdot \mathbf{n}_k^+ + cv_k^+ \widehat{\mathbf{r}}_k \cdot \mathbf{n}_k^+) \, ds \end{aligned}$$

and

$$(3.14) \quad L_h(\mathbf{v}) = \sum_{k=1}^M (\mathbf{f}, A\mathbf{v})_{\Omega_k} = \sum_{k=1}^M (f, -\epsilon^2 \nabla \cdot \mathbf{q} + cv)_{\Omega_k}$$

for all $\mathbf{v}, \mathbf{w} \in \mathbf{H}(\mathcal{T}_h)$, respectively. In (3.13), \mathbf{n}_k^+ is the outward normal unit vector to $\partial\Omega_k$, \widehat{w} , and $\widehat{\mathbf{r}}$ are numerical fluxes defined by

$$(3.15) \quad \widehat{w}_{k,e} = \{w\}_{k,e} + [[w]]_{k,e} \cdot \boldsymbol{\lambda}_{k,e},$$

$$(3.16) \quad \widehat{\mathbf{r}}_{k,e} = \{\mathbf{r}\}_{k,e} + [[\mathbf{r}]]_{k,e} \boldsymbol{\mu}_{k,e}$$

on $e \in \mathcal{E}_{int}$ and by

$$(3.17) \quad \widehat{w}_{k,e} = w|_e,$$

$$(3.18) \quad \widehat{\mathbf{r}}_{k,e} = \mathbf{r}|_e$$

on $e \in \mathcal{E} \setminus \mathcal{E}_{int}$, where parameters $\boldsymbol{\lambda}$ and $\boldsymbol{\mu}$ are vector-valued functions. Note that \mathbf{V}_h does not need to be a subspace of $\mathbf{H}(\Omega)$. Our method is therefore nonconforming in this sense.

Remark 3.1. For continuous functions, the numerical fluxes defined in (3.15)–(3.18) are the restrictions of the corresponding functions on associated interelement edges. A straightforward computation shows that $B_h(\cdot, \cdot)$ coincides with $B(\cdot, \cdot)$ in $\mathbf{H}(\Omega) \times \mathbf{H}(\Omega)$.

Remark 3.2. To see the difference between the *discontinuous LSFEMs* in [2, 3, 17] and the LDG-LS method developed in this paper, we note that, for discontinuous LSFEMs in the papers cited, special least-squares functionals are defined on discontinuous spaces, which lead to symmetric weak forms from minimization of the corresponding functionals. The LDG-LS method, on the other hand, discretizes a standard least-squares functional with the LDG method, whose formulation is in general nonsymmetric.

Remark 3.3. If $\boldsymbol{\lambda}$ and $\boldsymbol{\mu}$ are properly selected, then $B_h(\cdot, \cdot)$ preserves many good properties of $B(\cdot, \cdot)$. For instance, letting $\boldsymbol{\lambda}_k = \mathbf{n}_k^+ / 2$ and $\boldsymbol{\mu}_k = \mathbf{n}_k^+ / 2$, it is easy to verify that $\widehat{w}_k = w_k^+$, $\widehat{\mathbf{r}}_k \cdot \mathbf{n}_k^+ = \mathbf{r}_k^+ \cdot \mathbf{n}_k^+$, and hence

$$B_h(\mathbf{w}, \mathbf{v}) = \sum_{k=1}^M (A\mathbf{w}, A\mathbf{v})_{\Omega_k},$$

which is symmetric.

Before considering the coercivity of $B_h(\cdot, \cdot)$, we recall the trace inequalities when $d = 2$. For $\mathbf{v} \in \mathbf{V}_h$, we have (see, e.g., [9])

$$(3.19) \quad \|v_k^+\|_{0, \partial\Omega_k} \leq C_1 h^{1/2} |v|_{1, \Omega_k},$$

$$(3.20) \quad \|\mathbf{q}_k^+\|_{0, \partial\Omega_k} \leq C_2 h^{-1/2} \|\mathbf{q}\|_{0, \Omega_k},$$

where $\|\cdot\|_{0, \partial\Omega_k}$ is the $H^0(\partial\Omega_k)$ norm, and C_1 and C_2 are fixed constants satisfying (3.19) and (3.20) for all k , respectively. Then we have the following results.

THEOREM 3.3. *Let $B_h(\cdot, \cdot)$ be the bilinear form defined in (3.13) with $\boldsymbol{\lambda}_k = \mathbf{0}$ and $\boldsymbol{\mu}_k = \mathbf{0}$.*

(i) *There exists a constant $C > 0$ independent of ϵ such that*

$$(3.21) \quad |B_h(\mathbf{w}, \mathbf{v})| \leq C \|\mathbf{w}\|_{1, \epsilon} \|\mathbf{v}\|_{1, \epsilon} \quad \forall \mathbf{v}, \mathbf{w} \in \mathbf{V}_h.$$

(ii) Assume that $\min\{\frac{c_0}{c_0+c_1}, \frac{c_0^3}{c_1^3}, c_0\} > (c_1 - c_0)C_1C_2$ when $d = 2$. There exists a constant $\alpha^* > 0$ independent of ϵ such that

$$(3.22) \quad B_h(\mathbf{v}, \mathbf{v}) \geq \alpha^* \|\mathbf{v}\|_{1,\epsilon}^2 \quad \forall \mathbf{v} \in \mathbf{V}_h.$$

Proof. We first prove the coercivity of $B_h(\cdot, \cdot)$. Comparing (3.4) and (3.13), we have

$$B_h(\mathbf{w}, \mathbf{v}) = \sum_{k=1}^M \left(B(\mathbf{w}, \mathbf{v})_k + \epsilon^2 \int_{\partial\Omega_k} (c_0(w_k^+ - \widehat{w}_k) \mathbf{q}_k^+ \cdot \mathbf{n}_k^+ + cv_k^+(\mathbf{r}_k^+ - \widehat{\mathbf{r}}_k) \cdot \mathbf{n}_k^+) ds \right)$$

for all $\mathbf{v}, \mathbf{w} \in \mathbf{V}_h$, where

$$B(\mathbf{w}, \mathbf{v})_k = (A\mathbf{w}, A\mathbf{v})_{\Omega_k}$$

is the restriction of $B(\mathbf{w}, \mathbf{v})$ to the element Ω_k . Since $\boldsymbol{\lambda}_k = \mathbf{0}$ and $\boldsymbol{\mu}_k = \mathbf{0}$, we get

$$B_h(\mathbf{w}, \mathbf{v}) = \sum_{k=1}^M \left(B(\mathbf{w}, \mathbf{v})_k + \epsilon^2 \int_{\partial\Omega_k} c_0(w_k^+ - \{w\}_k) \mathbf{q}_k^+ \cdot \mathbf{n}_k^+ ds + \epsilon^2 \int_{\partial\Omega_k} cv_k^+(\mathbf{r}_k^+ - \{\mathbf{r}\}_k) \cdot \mathbf{n}_k^+ ds \right).$$

It follows that

$$(3.23) \quad B_h(\mathbf{v}, \mathbf{v}) = \sum_{k=1}^M B(\mathbf{v}, \mathbf{v})_k + c_0\epsilon^2 \sum_{k=1}^M \sum_{e \in \mathcal{C}\partial\Omega_k} \int_e I_{\Omega_{k,e}} ds + \epsilon^2 \sum_{k=1}^M \sum_{e \in \mathcal{C}\partial\Omega_k} \int_e J_{\Omega_{k,e}} ds,$$

where $I_{\Omega_{k,e}}$ and $J_{\Omega_{k,e}}$ are the interior traces of $(v - \{v\})\mathbf{q} \cdot \mathbf{n}_k^+ + v(\mathbf{q} - \{\mathbf{q}\}) \cdot \mathbf{n}_k^+$ and $(c - c_0)v(\mathbf{q} - \{\mathbf{q}\}) \cdot \mathbf{n}_k^+$ on edge e with respect to Ω_k , respectively.

For any element Ω_k , if an edge $e \in \mathcal{E}_{int}$, then $v|_e = 0$ and $\{v\}|_e = 0$, and hence $I_{\Omega_{k,e}} = 0$ and $J_{\Omega_{k,e}} = 0$, which contribute 0 in the last two summations in (3.23). On the other hand, if the edge $e \in \mathcal{E}_{int}$, then there is another element $\Omega_{k',e}$ sharing e with Ω_k , and there are two terms associated with the edge in each double summation in (3.23). In particular,

$$(3.24) \quad \int_e I_{\Omega_{k,e}} ds = \int_e \left(\frac{1}{2}(v_{k,e}^+ - v_{k,e}^-) \mathbf{q}_{k,e}^+ \cdot \mathbf{n}_{k,e}^+ + \frac{1}{2}v_{k,e}^+ (\mathbf{q}_{k,e}^+ - \mathbf{q}_{k,e}^-) \cdot \mathbf{n}_{k,e}^+ \right) ds,$$

$$(3.25) \quad \int_e I_{\Omega_{k',e}} ds = \int_e \left(\frac{1}{2}(v_{k,e}^- - v_{k,e}^+) \mathbf{q}_{k,e}^- \cdot \mathbf{n}_{k,e}^- + \frac{1}{2}v_{k,e}^- (\mathbf{q}_{k,e}^- - \mathbf{q}_{k,e}^+) \cdot \mathbf{n}_{k,e}^- \right) ds.$$

Adding (3.24) and (3.25), we get

$$\int_e (I_{\Omega_{k,e}} + I_{\Omega_{k',e}}) ds = \int_e (v_{k,e}^+ \mathbf{q}_{k,e}^+ \cdot \mathbf{n}_{k,e}^+ + v_{k,e}^- \mathbf{q}_{k,e}^- \cdot \mathbf{n}_{k,e}^-) ds,$$

since $\mathbf{n}_{k,e}^+ + \mathbf{n}_{k,e}^- = \mathbf{0}$. We thus conclude that

$$\sum_{k=1}^M \sum_{e \in \mathcal{C}\partial\Omega_k} \int_e I_{\Omega_{k,e}} ds = \sum_{k=1}^M \int_{\partial\Omega_k} v_k^+ \mathbf{q}_k^+ \cdot \mathbf{n}_k^+ ds.$$

Similarly,

$$(3.26) \quad \int_e J_{\Omega_{k,e}} ds = \int_e \frac{1}{2} (c - c_0) v_{k,e}^+ (\mathbf{q}_{k,e}^+ - \mathbf{q}_{k,e}^-) \cdot \mathbf{n}_{k,e}^+ ds,$$

$$(3.27) \quad \int_e J_{\Omega_{k',e}} ds = \int_e \frac{1}{2} (c - c_0) v_{k,e}^- (\mathbf{q}_{k,e}^- - \mathbf{q}_{k,e}^+) \cdot \mathbf{n}_{k,e}^- ds.$$

By adding (3.26) and (3.27), we then have

$$\int_e (J_{\Omega_{k,e}} + J_{\Omega_{k',e}}) ds = \int_e (c - c_0) \{v\}_{k,e} [[\mathbf{q}]]_{k,e} ds,$$

and hence

$$\sum_{k=1}^M \sum_{e \subset \partial \Omega_k} \int_e J_{\Omega_{k,e}} ds = \sum_{k=1}^M \frac{1}{2} \int_{\partial \Omega_k} (c - c_0) \{v\}_k [[\mathbf{q}]]_k ds.$$

Therefore, (3.23) reads

$$(3.28) \quad B_h(\mathbf{v}, \mathbf{v}) = \sum_{k=1}^M R_k + \sum_{k=1}^M \frac{\epsilon^2}{2} \int_{\partial \Omega_k} (c - c_0) \{v\}_k [[\mathbf{q}]]_k ds,$$

where

$$R_k = B(\mathbf{v}, \mathbf{v})_k + c_0 \epsilon^2 \int_{\partial \Omega_k} v_k^+ \mathbf{q}_k^+ \cdot \mathbf{n}_k^+ ds.$$

Now, by Theorem 3.1, we have

$$(3.29) \quad R_k \geq \alpha \|\mathbf{v}\|_{1,\epsilon,\Omega_k}^2$$

for each element Ω_k , where $\alpha = \min\{\frac{c_0}{2(c_0+c_1)}, \frac{c_0^3}{2c_1}, \frac{c_0}{2}\}$. Consider the second summation in (3.28). When $d = 1$, a straightforward calculation shows that (see [24])

$$(3.30) \quad \sum_{k=1}^M \int_{\partial \Omega_k} (c - c_0) \{v\}_k [[\mathbf{q}]]_k ds = 0.$$

When $d = 2$, since the interior and outer traces of $\{v\}[[\mathbf{q}]]$ on each edge are equal, we may rearrange terms in the sum. Applying Cauchy–Schwartz inequality, it follows that

$$\begin{aligned} & \left| \sum_{k=1}^M \int_{\partial \Omega_k} (c - c_0) \{v\}_k [[\mathbf{q}]]_k ds \right| = 2 \left| \sum_{k=1}^M \int_{\partial \Omega_k} (c - c_0) v_k^+ \mathbf{q}_k^+ \cdot \mathbf{n}_k^+ ds \right| \\ & \leq 2(c_1 - c_0) \sum_{k=1}^M \|v_k^+\|_{0,\partial \Omega_k} \|\mathbf{q}_k^+ \cdot \mathbf{n}_k^+\|_{0,\partial \Omega_k} \leq 2(c_1 - c_0) \sum_{k=1}^M \|v_k^+\|_{0,\partial \Omega_k} \|\mathbf{q}_k^+\|_{0,\partial \Omega_k}. \end{aligned}$$

Using the trace inequalities (3.19) and (3.20), we obtain

$$(3.31) \quad \sum_{k=1}^M \frac{\epsilon^2}{2} \int_{\partial \Omega_k} (c - c_0) \{v\}_k [[\mathbf{q}]]_k ds \geq - \sum_{k=1}^M C_3 \epsilon^2 |v|_{1,\Omega_k} \|\mathbf{q}\|_{0,\Omega_k},$$

where $C_3 = (c_1 - c_0)C_1C_2$. From (3.29)–(3.31) we conclude that, when $d = 1$,

$$B_h(\mathbf{v}, \mathbf{v}) \geq \sum_{k=1}^M (\alpha \|\mathbf{v}\|_{1,\epsilon,\Omega_k}^2) \geq \alpha \|\mathbf{v}\|_{1,\epsilon}^2,$$

and when $d = 2$,

$$B_h(\mathbf{v}, \mathbf{v}) \geq \sum_{k=1}^M (\alpha \|\mathbf{v}\|_{1,\epsilon,\Omega_k}^2 - C_3 \epsilon^2 |v|_{1,\Omega_k} \|\mathbf{q}\|_{0,\Omega_k}) \geq (\alpha - C_3/2) \|\mathbf{v}\|_{1,\epsilon}^2.$$

The coercivity result follows with $\alpha^* = \alpha$ when $d = 1$ and $\alpha^* = \alpha - C_3/2$ when $d = 2$.

The boundedness (3.21) is a direct consequence of the Cauchy–Schwartz, triangle, and trace inequalities. \square

In addition, we have the following analogue of Proposition 3.2.

PROPOSITION 3.4. *Assume that the conditions of Theorem 3.3 are fulfilled. The LDG-LS approximation problem (3.12) is well posed.*

Remark 3.4. Note that the boundedness result (3.21), as well as (3.6), is in the more desirable norm $\|\cdot\|_{1,\epsilon}$, comparing with the results in only standard H^1 norm from some other classical FEMs [27, 33]. This inequality leads naturally to a Céa type error estimate and a uniform error estimate in the $\|\cdot\|_{1,\epsilon}$ norm, which will be presented in section 4.

Remark 3.5. $\boldsymbol{\lambda} = \mathbf{0}$ and $\boldsymbol{\mu} = \mathbf{0}$ are sufficient but not necessary conditions for the results of Theorem 3.3. In section 5, we provide numerical results with nonzero numerical flux parameters. Moreover, a proper selection of $\boldsymbol{\lambda}$ and $\boldsymbol{\mu}$ will produce numerical solutions of better quality. Our examples show that better computational results are obtained if $\boldsymbol{\lambda}$ and $\boldsymbol{\mu}$ are pointing toward the layers.

Remark 3.6. The LDG-LS method (3.12) is stable and robust with zero numerical flux parameters. In addition, if c is a constant function, then the assumption $\min\{\frac{c_0}{c_0+c_1}, \frac{c_0^3}{c_1}, c_0\} > (c_1 - c_0)C_1C_2$ for coercivity (3.22) is naturally true.

3.3. The hybrid adaptive method. We divide the solution domain Ω into two regions: the regular solution region Ω_C and the layer region Ω_D . In Ω_C the exact solution is smooth and the derivatives of the exact solution can be bounded by a constant that is independent of ϵ , where we may use continuous elements. In Ω_D the exact solution has large derivatives thus motivating the use of the discontinuous method in the region. Conforming with the triangulation \mathcal{T}_h , we may define $Z_D = \bigcup_{\Omega_k \cap \bar{\Omega}_D \neq \emptyset} \bar{\Omega}_k$, the region consisting of elements covering Ω_D , and $Z_C = \Omega \setminus Z_D$.

Let \mathbf{V}_h^* be a subspace of \mathbf{V}_h , such that the basis functions of \mathbf{V}_h^* are continuous in Z_C . The hybrid LDG/continuous least-squares (LDG/C-LS) FEM is: find $\mathbf{u}_h \in \mathbf{V}_h^*$ such that

$$(3.32) \quad B_h^*(\mathbf{u}_h, \mathbf{v}) = L_h(\mathbf{v}) \quad \forall \mathbf{v} \in \mathbf{V}_h^*,$$

where the bilinear form $B_h^* : \mathbf{V}_h^* \times \mathbf{V}_h^* \rightarrow \mathbb{R}$ is defined by

$$\begin{aligned} B_h^*(\mathbf{w}, \mathbf{v}) &= \sum_{k=1}^M \int_{\Omega_k} (c_0 \epsilon^2 \mathbf{r} \cdot \mathbf{q} + c_0 \epsilon^2 \nabla w \cdot \nabla v + \epsilon^4 \nabla \cdot \mathbf{r} \nabla \cdot \mathbf{q} + c^2 w v) \, d\mathbf{x} \\ &+ \epsilon^2 \sum_{k=1}^M \int_{\Omega_k} (\mathbf{r} \cdot \nabla((c - c_0)v) + (c_0 - c)w \nabla \cdot \mathbf{q}) \, d\mathbf{x} \\ &- \epsilon^2 \sum_{k=1}^M \int_{\partial\Omega_k} (c_0 \widehat{w}_k \mathbf{q}_k^+ \cdot \mathbf{n}_k^+ + c \widehat{\mathbf{x}}_k \cdot \mathbf{n}_k^+ v_k^+) \, ds \end{aligned}$$

for all $\mathbf{v}, \mathbf{w} \in \mathbf{V}_h^*$, the linear form L_h is given in (3.14), and the numerical fluxes are given in (3.15)–(3.18).

The continuous and discontinuous discretizations for the least-squares formulation (3.3) are naturally combined in the LDG/C-LS approximation (3.32), which saves the extra degrees of freedom required by the LDG-LS method. Moreover, the coercivity of B_h^* in the $\|\cdot\|_{1,\epsilon}$ norm and the well posedness of problem (3.32) can be verified. A computational comparison between the two methods is made in section 5.

4. Error estimates. In this section, we present some a priori error estimate results.

PROPOSITION 4.1. *The bilinear form $B_h(\cdot, \cdot)$ defined by (3.13) is consistent.*

Proof. Let $\mathbf{u} \in \mathbf{H}(\Omega)$ solve the problem (3.3). By the definitions (3.15)–(3.18), we have $\{u\}_{k,e} = u|_e$, $[[u]]_{k,e} = 0$, and $\{\mathbf{p}\}_{k,e} = \mathbf{p}|_e$ on all $e \in \mathcal{E}$; and $[[\mathbf{p}]]_{k,e} = \mathbf{0}$ on all $e \in \mathcal{E}_{int}$. Therefore, it follows that

$$B_h(\mathbf{u}, \mathbf{v}) = \sum_{k=1}^M B(\mathbf{u}, \mathbf{v})_k = \sum_{k=1}^M (\mathbf{f}, A\mathbf{v})_{\Omega_k} = L_h(\mathbf{v})$$

for all $\mathbf{v} \in \mathbf{V}_h$. The desired result thus follows. \square

Let \mathbf{u} and \mathbf{u}_h solve problems (3.3) and (3.12), respectively. It follows from Proposition 4.1 that $B_h(\cdot, \cdot)$ satisfies the Galerkin orthogonality

$$(4.1) \quad B_h(\mathbf{u} - \mathbf{u}_h, \mathbf{v}) = 0 \quad \forall \mathbf{v} \in \mathbf{V}_h.$$

We assume the numerical flux parameters $\boldsymbol{\lambda} = \mathbf{0}$ and $\boldsymbol{\mu} = \mathbf{0}$. Then, by Theorem 3.3 and (4.1), we have

$$\begin{aligned} \alpha^* \|\mathbf{u} - \mathbf{u}_h\|_{1,\epsilon}^2 &\leq B_h(\mathbf{u} - \mathbf{u}_h, \mathbf{u} - \mathbf{u}_h) \\ &= B_h(\mathbf{u} - \mathbf{u}_h, \mathbf{u} - \mathbf{v}) \leq C \|\mathbf{u} - \mathbf{u}_h\|_{1,\epsilon} \|\mathbf{u} - \mathbf{v}\|_{1,\epsilon} \end{aligned}$$

for all $\mathbf{v} \in \mathbf{V}_h$, which implies the following Céa type error estimate.

THEOREM 4.2. *Let \mathbf{u} and \mathbf{u}_h be solutions to (3.3) and (3.12), respectively. Assume that the conditions of Theorem 3.3 are fulfilled. Then*

$$(4.2) \quad \|\mathbf{u} - \mathbf{u}_h\|_{1,\epsilon} \leq C \inf_{\mathbf{v} \in \mathbf{V}_h} \|\mathbf{u} - \mathbf{v}\|_{1,\epsilon}.$$

Thus, the LDG-LS FEM is optimal in the ϵ -dependent norm. Consequently, we get the following a priori error estimate.

THEOREM 4.3. *Let \mathbf{u} and \mathbf{u}_h be solutions to (3.3) and (3.12), respectively. Assume that $u \in H^3(\Omega)$ and the conditions of Theorem 3.3 are fulfilled. Then*

$$(4.3) \quad \|\mathbf{u} - \mathbf{u}_h\|_{1,\epsilon} \leq Ch^{1/2}.$$

Proof. Let $I_h u$ and $I_h \mathbf{p}$ be the standard linear or bilinear finite element interpolation of u and \mathbf{p} (i.e., ∇u), respectively. Then, from approximation theory (e.g., [9]), we have

$$(4.4) \quad \begin{aligned} \|u - I_h u\|_{W_\infty^0(\Omega)} &\leq Ch|u|_{W_\infty^1(\Omega)}, \\ \|\mathbf{p} - I_h \mathbf{p}\|_{W_\infty^1(\Omega)} &\leq Ch|\mathbf{p}|_{W_\infty^2(\Omega)}, \end{aligned}$$

where C denotes a constant independent of the mesh size h .

By the coercivity of $B_h(\cdot, \cdot)$, we have

$$(4.5) \quad \begin{aligned} \alpha^* \|\mathbf{u} - I_h \mathbf{u}\|_{1,\epsilon}^2 &\leq B_h(\mathbf{u} - I_h \mathbf{u}, \mathbf{u} - I_h \mathbf{u}) \\ &= B(\mathbf{u} - I_h \mathbf{u}, \mathbf{u} - I_h \mathbf{u}) \\ &= (A(\mathbf{u} - I_h \mathbf{u}), A(\mathbf{u} - I_h \mathbf{u})), \end{aligned}$$

where the first identity is due to the fact that $\mathbf{u} - I_h \mathbf{u}$ is continuous in Ω (see Remark 3.1). Noting that the interpolation operator is linear, it follows that

$$A(\mathbf{u} - I_h \mathbf{u}) = A\mathbf{u} - AI_h \mathbf{u} = A\mathbf{u} - I_h A\mathbf{u} = \mathbf{f} - I_h \mathbf{f}.$$

By approximation theory, we have

$$(4.6) \quad \|f - I_h f\|_{W_\infty^0(\Omega)} \leq C|f|_{W_\infty^0(\Omega)}.$$

Using the estimates (4.4) and (4.6), we obtain

$$(4.7) \quad \begin{aligned} (A(\mathbf{u} - I_h \mathbf{u}), A(\mathbf{u} - I_h \mathbf{u})) &= (A(\mathbf{u} - I_h \mathbf{u}), \mathbf{f} - I_h \mathbf{f}) \\ &\leq Ch(\epsilon^2 |\mathbf{p}|_{W_\infty^2(\Omega)} + |u|_{W_\infty^1(\Omega)}) |f|_{W_\infty^0(\Omega)}. \end{aligned}$$

By (4.5) and (4.7), we get

$$(4.8) \quad \|\mathbf{u} - I_h \mathbf{u}\|_{1,\epsilon} \leq Ch^{1/2},$$

since u , and hence \mathbf{p} , is sufficiently smooth. The desired result follows immediately from Theorem 4.2 and (4.8) by selecting \mathbf{v} as $I_h \mathbf{u}$ in (4.2). \square

Remark 4.1. As shown in [10, 11], for second-order elliptic problems, the first-order system LSFEM has an optimal error estimate of $\mathcal{O}(h)$ in the H^1 norm. See also [5]. For singularly perturbed problems described in this paper, however, this optimal convergence rate cannot be achieved (cf. [33]).

Remark 4.2. In [36] and [28], uniform error estimates of $\mathcal{O}(h^{1/2})$ are obtained in an ϵ -dependent norm for singularly perturbed elliptic problems in 1D and 2D, respectively, by using exponentially fitted spline elements; cf. [33]. We obtain an estimate of the same order in Theorem 4.3. Our numerical examples show that this estimate is optimal.

Finally, by a standard procedure (see, e.g., [9]), we have the following maximum-norm error estimate, whose proof will not be included here.

THEOREM 4.4. *Let \mathbf{u} and \mathbf{u}_h be solutions to (3.3) and (3.12), respectively. Assume that conditions of Theorem 3.3 are fulfilled. Then*

$$(4.9) \quad \|u - u_h\|_{W_\infty^0(\Omega)} \leq Ch\|u\|_{W_\infty^1(\Omega)}.$$

FIG. 1. *Example 5.1: Numerical solutions by the LDG-LS method with different numerical fluxes.*

5. Numerical experiments. In this section we present three numerical examples to illustrate the theoretical results of the methods developed in section 3. The stiffness matrices and load vectors are analytically calculated. High order Gaussian quadrature rules are used to calculate the norms of numerical errors over the computational regions (including the layers), which hereby causes no competitive extra errors in numerical integration. In the following examples, if not otherwise specified, we set $\epsilon^2 = 10^{-8}$. Uniform meshes are used for all examples.

Example 5.1. Consider the reaction-diffusion equation

$$(5.1) \quad \begin{cases} -\epsilon^2 u''(x) + u(x) = x & \text{in } (0, 1), \\ u(0) = u(1) = 0. \end{cases}$$

The analytical solution to (5.1) is

$$u(x) = x - \frac{e^{(x-1)/\epsilon} - e^{-(x+1)/\epsilon}}{1 - e^{-2/\epsilon}},$$

which has a typical exponential boundary layer at $x = 1$ when $\epsilon \ll 1$.

We first inspect the impact of the numerical fluxes. In Figure 1, we present the computational results of the LDG-LS method with numerical flux parameters (i) $\lambda = \mu = 0$ and (ii) $\lambda = \mu = 1/2$ (toward the boundary layer), and mesh size $h = 1/32$ and $1/128$, respectively. The numerical solutions have two traces (one-sided limits) at each interior mesh point, which are denoted in Figure 1 by u^+ and u^- , respectively.

FIG. 2. Example 5.1: Convergence of the LDG-LS method with different numerical fluxes.

Figure 1 shows that the numerical results with (i) have oscillations. But those with (ii) have no oscillations even in quite a big mesh size. In addition, the jumps between u^+ and u^- are not visible. A more detailed investigation confirms that the jumps at the interior mesh points can be ignored when comparing them with other numerical errors.

Figure 2 shows log-log plots of numerical errors for the LDG-LS method with different numerical flux parameters, which are measured in the ϵ -dependent norm $\|\mathbf{u} - \mathbf{u}_h\|_{1,\epsilon}$ and the discrete maximum norm $\|u - u_h\|_{\max,h}$ at mesh points. Figure 2 confirms the estimates in Theorem 4.3. On the other hand, when selection (i) is used, the numerical results have first-order accuracy in the discrete maximum norm, as indicated in Theorem 4.4. When selection (ii) is used, the superconvergence phenomenon occurs. Superconvergence of singularly perturbed problems has been studied for continuous and discontinuous Galerkin methods; see, e.g., [23, 25, 32, 37, 38, 39]. In [13, 29], superconvergence results of LSFEM have been developed for second-order self-adjoint equations in 1D. Superconvergence analysis for least-squares methods in multidimensional nontensor product meshes is an ongoing research project.

Next, we compare the LDG-LS method with continuous LSFEMs, discontinuous LSFEMs, and DG methods. For comparison, we define a discontinuous least-squares functional in $\mathbf{H}(\mathcal{T}_h)$ as

$$\widehat{\mathcal{J}}(\mathbf{v}; f) = \sum_{k=1}^M \|A\mathbf{v} - \mathbf{f}\|_{0,\Omega_k}^2 + \sum_{k=1}^M \sum_{e \in \partial\Omega_K} \int_e ([v]_{k,e}^2 + \epsilon^2 [\mathbf{q}]_{k,e}^2) ds.$$

The corresponding FEM is referred to as *discontinuous LSFEM 1*. We also implemented the method proposed in [2], which is referred to as *discontinuous LSFEM*

FIG. 3. Example 5.1: Numerical solutions by different numerical methods.

TABLE 1

Example 5.1: Numerical errors $\|\mathbf{u} - \mathbf{u}_h\|_{1,\epsilon}$ by the LDG-LS method for different ϵ values.

$\epsilon^2 \setminus h$	1/16	1/32	1/64	1/128	Order of convergence
10^0	2.106547e-2	7.758647e-3	2.799855e-3	1.000096e-3	1.476201
10^{-2}	1.459560e-1	6.232572e-2	2.470814e-2	9.363776e-3	1.362641
10^{-4}	3.112819e-1	2.045051e-1	1.206056e-1	6.187578e-2	0.867373
10^{-6}	4.314102e-1	2.819504e-1	1.732858e-1	1.120847e-1	0.647382
10^{-8}	4.368976e-1	3.089476e-1	2.183285e-1	1.536840e-1	0.504225
10^{-10}	4.368963e-1	3.089774e-1	2.184881e-1	1.544961e-1	0.499952
10^{-12}	4.368963e-1	3.089773e-1	2.184879e-1	1.544957e-1	0.499954

2. All numerical computations are conducted in uniform meshes with $h = 1/32$ and $h = 1/128$, respectively. In Figure 3, we present the numerical results of these methods. Here $\lambda = \mu = 1/2$ are used for the LDG-LS method. For methods with discontinuous elements, the average of the numerical approximations is plotted. It is observed that the solutions by the DG method and the discontinuous LSFEM 1 illustrate the typical “over-shooting” phenomenon near the boundary layer, where the magnitude of the numerical heap does not decrease as the mesh size decreases. On the other hand, the standard LSFEM and the discontinuous LSFEM 2 smear out the boundary layer, whose numerical errors in the discrete maximum norm do not converge to 0, though the methods converge with order 1/2 in the ϵ -dependent norm. The LDG-LS method provides the best numerical solutions here.

Finally, Table 1 is used to test for numerical independence of the LDG-LS method on ϵ . Here zero numerical fluxes are used. It is observed that when a singular perturbation occurs, the error $\|\mathbf{u} - \mathbf{u}_h\|_{1,\epsilon}$ converges with rate 1/2, which is independent of ϵ , as indicated in Theorem 4.3. On the other hand, when the problem is not singularly perturbed, superconvergence is observed (e.g., as $\epsilon^2 = 1$ or 10^{-2}); cf. [10]. In fact, when $\epsilon = 1$, norms $\|\cdot\|_{1,\epsilon}$ and $\|\cdot\|_1$ are the same.

Example 5.2. Consider the reaction-diffusion equation

$$(5.2) \quad \begin{cases} -\epsilon^2 u''(x) + (2-x)u(x) = f & \text{in } (0,1), \\ u(0) = u(1) = 0, \end{cases}$$

where f is chosen properly such that the solution u to (5.2) is

$$u(x) = \left(1 - e^{-x/\epsilon}\right) \left(1 - e^{(x-1)/\epsilon}\right).$$

FIG. 4. Example 5.2: Numerical solutions by LDG-LS and LDG/C-LS methods ($h = 1/32$).

FIG. 5. Example 5.2: Convergence of LDG-LS and LDG/C-LS methods.

The exact solution has two boundary layers at $x = 0$ and 1 .

We compare the numerical solutions of the LDG-LS method and the LDG/C-LS method in this example. The numerical fluxes are first chosen toward the layers. In particular, for the LDG-LS scheme, we choose $\lambda = \mu = -1/2$ for elements located in $[0, 1/2]$ and $\lambda = \mu = 1/2$ for elements in $[1/2, 1]$. For the LDG/C-LS scheme, the numerical flux parameters are analogously chosen only for the first and last two elements, respectively, which contain the boundary layers. Recall that, in the case of this example, the LDG/C-LS method uses discontinuous basis functions only in two elements at each end, and uses continuous basis functions for the other elements. Analogous LDG-LS and LDG/C-LS schemes are developed with $\lambda = \mu = 0$ for comparison.

Figure 4 shows the numerical solutions by the two methods with different numerical fluxes in a uniform mesh ($h = 1/32$). When $\lambda = \mu = 0$, the LDG-LS solutions have oscillations in the entire region, while the LDG/C-LS solutions have only small

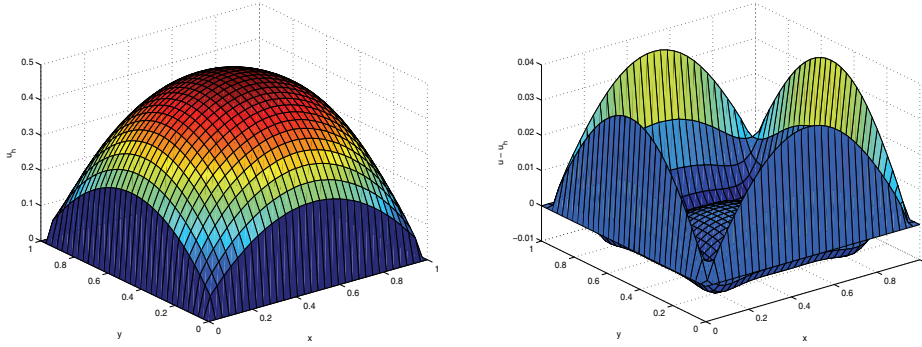

FIG. 6. Example 5.3: Numerical solutions and errors by the LDG/C-LS method ($h = 1/32$).

bumps near the boundary layers. On the other hand, solutions from both methods with $\lambda = \mu = \pm 1/2$ match the exact solutions very well. Figure 5 indicates that the convergence rates of the LDG-LS and LDG/C-LS methods are the same when identical numerical fluxes are applied, since the dominant error occurs near the boundary layers. Moreover, superconvergence is observed in the discrete maximum norm when the numerical flux parameters are $\pm 1/2$.

Note that the LDG/C-LS method produces an algebraic problem of about half the degrees of freedom as the LDG-LS method, which thus significantly reduces computational cost. This makes the method competitive with the standard DG or least-squares methods. Moreover, our numerical tests show that the resulting discrete problems by both methods have the same order condition numbers; in particular, $\mathcal{O}(h^{-2})$ condition numbers for the problem with nonsingular perturbation, and $\mathcal{O}(h^{-3})$ condition numbers for singularly perturbed cases.

Example 5.3. Consider the reaction-diffusion equation

$$(5.3) \quad \begin{cases} -\epsilon^2 \Delta u + 2u = f & \text{in } \Omega = (0, 1) \times (0, 1), \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where f is chosen properly such that the solution u to (5.3) is

$$u(x, y) = \left(1 - e^{-x/\epsilon}\right) \left(1 - e^{-(x-1)/\epsilon}\right) y(1-y) + x(1-x) \left(1 - e^{-y/\epsilon}\right) \left(1 - e^{-(y-1)/\epsilon}\right).$$

The exact solution has exponential layers on the boundary $\partial\Omega$.

We use bilinear LDG/C-LS elements on uniform meshes in this example. Discontinuous basis functions are used only in two layers of elements along the boundary, and continuous basis functions are used for the other elements. Here, we use $\lambda = \mu = \mathbf{0}$ for all discontinuous elements.

Figure 6 shows the numerical solutions u_h and the errors $u - u_h$ by the LDG/C-LS method when $h = 1/32$. Figure 7 is the log-log plot of the numerical errors of the LDG/C-LS method. The convergence rates are calculated based on the last three data points. The numerical results agree with the theoretical predictions in Theorems 4.3 and 4.4.

6. Conclusion. A singularly perturbed reaction-diffusion problem with homogeneous Dirichlet boundary conditions is considered in this paper, for which we developed a stable numerical approach based on LDG discretization of least-squares

FIG. 7. Example 5.3: Convergence of the LDG/C-LS method.

formulation, which needs no special treatments. The coercivity and boundedness of the bilinear forms have been proven, which leads to the well posedness of the methods. We prove a uniform optimal energy norm error estimate. A maximum-norm error estimate is also provided. A hybrid adaptive method is derived for efficiency reasons. Numerical examples are presented, which are in agreement with the theoretical results. Comparisons have been conducted numerically. In addition, some superconvergence results have been observed.

The proposed approach is innovative, requiring neither special treatments nor manually adjusted parameters. Comparing with the other methods, such as the LDG method and the continuous and discontinuous LSFEMs, our method is more robust and accurate in solving problems with singular perturbation. The hybrid method is competitive with the standard LDG method and LSFEM in the sense of computational cost. This paper provides an efficient alternative to numerical approaches for solving singularly perturbed reaction-diffusion problems.

It is our belief that an analogous approach can be developed for general singularly perturbed convection-diffusion problems, which is an ongoing research project.

Acknowledgments. The author thanks the anonymous referees and the editor, Dr. Pavel Bochev, for their constructive comments and suggestions, which greatly improved this article.

A POSTERIORI ERROR ESTIMATE AND ADAPTIVE MESH REFINEMENT FOR THE CELL-CENTERED FINITE VOLUME METHOD FOR ELLIPTIC BOUNDARY VALUE PROBLEMS*

CHRISTOPH ERATH[†] AND DIRK PRAETORIUS[‡]

Abstract. We extend a result of Nicaise [*SIAM J. Numer. Anal.*, 43 (2005), pp. 1481–1503] for the a posteriori error estimation of the cell-centered finite volume method for the numerical solution of elliptic problems. Having computed the piecewise constant finite volume solution u_h , we compute a Morley-type interpolant $\mathcal{I}u_h$. For the exact solution u , the energy error $\|\nabla_{\mathcal{T}}(u - \mathcal{I}u_h)\|_{L^2}$ can be controlled efficiently and reliably by a residual-based a posteriori error estimator η . The local contributions of η are used to steer an adaptive mesh-refining algorithm. A model example serves the Laplace equation in two dimensions with mixed Dirichlet–Neumann boundary conditions.

Key words. finite volume method, cell-centered method, diamond path, a posteriori error estimate, adaptive algorithm

1. Introduction. Throughout, $\Omega \subset \mathbb{R}^2$ is a bounded and connected domain with Lipschitz boundary $\Gamma := \partial\Omega$. We assume that Γ is divided into a closed Dirichlet boundary $\Gamma_D \subseteq \Gamma$ with positive surface measure and a Neumann boundary $\Gamma_N := \Gamma \setminus \Gamma_D$. We consider the elliptic model problem

$$(1.1) \quad -\Delta u = f \quad \text{in } \Omega$$

with mixed boundary conditions

$$(1.2) \quad u = u_D \quad \text{on } \Gamma_D \quad \text{and} \quad \partial u / \partial \mathbf{n} = g \quad \text{on } \Gamma_N.$$

Here $f \in L^2(\Omega)$, $u_D \in H^1(\Gamma_D)$, and $g \in L^2(\Gamma_N)$ are given data, and $L^2(\cdot)$ and $H^1(\cdot)$ denote the standard Lebesgue and Sobolev spaces equipped with the usual norms $\|\cdot\|_{L^2(\cdot)}$ and $\|\cdot\|_{H^1(\cdot)}$. The weak form of (1.1) reads as follows: Find $u \in H^1(\Omega)$ with $u|_{\Gamma_D} = u_D$ and

$$\int_{\Omega} \nabla u \cdot \nabla v \, dx = \int_{\Omega} f v \, dx + \int_{\Gamma_N} g v \, dx \quad \text{for all } v \in H_D^1(\Omega) := \{v \in H^1(\Omega) \mid v|_{\Gamma_D} = 0\}.$$

Recall that there is a unique solution u which we aim to approximate by a postprocessed finite volume scheme. For technical reasons, we assume that Γ_D as well as Γ_N are connected; see Theorem 5.1 below.

Let \mathcal{T} be a triangulation of Ω and \mathcal{E} the set of all edges of \mathcal{T} . Replacing the continuous diffusion flux $\int_E \partial u / \partial \mathbf{n}_E \, ds$ by a discrete diffusion flux $F_E^D(u_h)$, the cell-centered finite volume method provides a \mathcal{T} -elementwise constant approximation $u_h \in$

$\mathcal{P}_0(\mathcal{T})$ of u . The classical choice of $F_E^D(u_h)$ is based on the admissibility of the triangulation \mathcal{T} in the sense of [10]. However, locally refined meshes are usually not admissible. Another choice of $F_E^D(u_h)$ is the diamond path method, which has been mathematically analyzed in [6, 7] for rectangular meshes with a maximum of one hanging node per edge. Optimal order of convergence $\|u - u_h\|_{1,h} = \mathcal{O}(h)$ of the error with respect to a discrete H^1 -norm $\|\cdot\|_{1,h}$ holds under the regularity assumption $u \in H^2(\Omega)$, which is usually not met in practice.

We aim to provide a mathematical criterion for steering an adaptive mesh-refining algorithm to recover the optimal order of convergence $\mathcal{O}(N^{-1/2})$ with respect to the number $N = \#\mathcal{T}$ of elements. Following Nicaise [11], we introduce a Morley-type interpolant $\mathcal{I}u_h$ which belongs to a certain $H^1(\Omega)$ -nonconforming finite element space, the definition of which is a generalization of the definition in [11, section 5] to the case of hanging nodes and mixed boundary conditions. Roughly speaking, the analytical idea is to ensure that $\mathcal{I}u_h$ has enough orthogonality properties which can be used to adapt the well-known a posteriori error analysis from the context of the finite element method; see, e.g., [12, 1]. For each element $T \in \mathcal{T}$ with corresponding edges \mathcal{E}_T , we define the refinement indicators

$$\begin{aligned} \eta_T^2 := & h_T^2 \|f - f_T\|_{L^2(T)}^2 + \sum_{E \in \{E \in \mathcal{E}_E \mid E \subset \partial T\}} h_E \|\llbracket \nabla_{\mathcal{T}}(\mathcal{I}u_h) \rrbracket\|_{L^2(E)}^2 \\ & + \sum_{E \in \mathcal{E}_T \cap \mathcal{E}_N} h_E \left\| \frac{\partial(u - \mathcal{I}u_h)}{\partial \mathbf{n}_E} \right\|_{L^2(E)}^2 + \sum_{E \in \mathcal{E}_T \cap \mathcal{E}_D} h_E \left\| \frac{\partial(u - \mathcal{I}u_h)}{\partial \mathbf{t}_E} \right\|_{L^2(E)}^2. \end{aligned}$$

Here $\llbracket \cdot \rrbracket$ denotes the jump, \mathbf{n}_E and \mathbf{t}_E denote the normal and tangential vector on E , respectively, f_T denotes the piecewise integral mean of the volume term, and h_E is the length of the edge E . We prove that the corresponding error estimator

$$\eta := \left(\sum_{T \in \mathcal{T}} \eta_T^2 \right)^{1/2}$$

is reliable and efficient in the sense that

$$C_{\text{rel}}^{-1} \|\nabla_{\mathcal{T}}(u - \mathcal{I}u_h)\|_{L^2(\Omega)} \leq \eta \leq C_{\text{eff}} \left[\|\nabla_{\mathcal{T}}(u - \mathcal{I}u_h)\|_{L^2(\Omega)} + \|h(f - f_T)\|_{L^2(\Omega)} \right].$$

Here $\nabla_{\mathcal{T}}$ denotes the \mathcal{T} -piecewise gradient, and the constants $C_{\text{eff}}, C_{\text{rel}} > 0$ depend only on the shape of the elements in \mathcal{T} but not on f , the local mesh width h , or the number of elements. Moreover, the efficiency estimate holds even locally:

$$\eta_T \leq C_{\text{eff}} \left[\|\nabla_{\mathcal{T}}(u - \mathcal{I}u_h)\|_{L^2(\omega_T)} + \|h(f - f_T)\|_{L^2(\omega_T)} \right],$$

where ω_T denotes the patch of the element $T \in \mathcal{T}$.

The proof of the reliability makes use of the Helmholtz decomposition to deal with mixed boundary conditions. For the proof of the efficiency estimate, the non-avoidance of hanging nodes needs the extended definition of edge patches. We stress that [11] treats only the Dirichlet problem $\Gamma_D = \Gamma$ and that the a posteriori error analysis is restricted to the case of regular meshes. Therefore the definition of $\mathcal{I}u_h$ had to be substantially modified.

The content of this paper is organized as follows. In section 2, we introduce the notation that is used below. In particular, we define the concept of an *almost regular triangulation*, which allows the analytical error analysis in the case of certain hanging

nodes. Section 3 gives a short summary on the classical cell-centered finite volume method for our model problem. We recall the ideas of the diamond path, where emphasis is laid on the treatment of nodes $a \in \Gamma_N$ that lie on the Neumann boundary Γ_N . In section 4, we define the Morley interpolant and collect the orthogonality properties used for the error analysis. Reliability and efficiency of the error estimator η are then proven in section 5. Numerical experiments, found in section 6, confirm the theoretical results and conclude the work. In particular, we observe that the proposed strategy even recovers the optimal order of convergence with respect to the energy norm $\|u - u_h\|_{1,h}$.

2. Preliminaries and notation. In this section, we introduce the notation for the triangulations that are considered below. In particular, we define the so-called *almost regular* triangulation which allows certain hanging nodes.

2.1. Almost regular triangulation. Throughout, \mathcal{T} denotes a triangulation of Ω , where \mathcal{N} and \mathcal{E} are the corresponding set of nodes and edges, respectively. We assume that the elements $T \in \mathcal{T}$ are triangles or rectangles, either of which are nondegenerate. For $T \in \mathcal{T}$, $h_T := \text{diam}(T)$ denotes the Euclidean diameter and ϱ_T is the corresponding height; i.e., the volume of T is $|T| = h_T \varrho_T$ in the case of T being a rectangle and $|T| = h_T \varrho_T / 2$ in the case of T being a triangle. Moreover, for an edge $E \in \mathcal{E}$, we denote by h_E its length.

Nodes. In the following, we introduce a partition

$$\mathcal{N} = \mathcal{N}_D \cup \mathcal{N}_N \cup \mathcal{N}_H \cup \mathcal{N}_F$$

of \mathcal{N} into Dirichlet and Neumann nodes, hanging nodes, and free nodes, respectively: First, let $\mathcal{N}_D := \{a \in \mathcal{N} \mid a \in \Gamma_D\}$ (resp., $\mathcal{N}_N := \{a \in \mathcal{N} \mid a \in \Gamma_N\}$) be the set of all nodes that belong to the Dirichlet boundary (resp., Neumann boundary). A node $a \in \mathcal{N} \setminus (\mathcal{N}_D \cup \mathcal{N}_N)$ is a hanging node, provided that there are elements $T_1, T_2 \in \mathcal{T}$ such that $a \in T_1 \cap T_2$ is a node of T_1 but not of T_2 . Let \mathcal{N}_H be the set of all hanging nodes. Finally, the set of free nodes is $\mathcal{N}_F := \mathcal{N} \setminus (\mathcal{N}_D \cup \mathcal{N}_N \cup \mathcal{N}_H)$. For an element $T \in \mathcal{T}$, we denote with \mathcal{N}_T the set of nodes of T , i.e., $|\mathcal{N}_T| = 3$ for T being a triangle and $|\mathcal{N}_T| = 4$ for T being a rectangle, respectively.

Edges. For the edges, we introduce a partition

$$\mathcal{E} = \mathcal{E}_D \cup \mathcal{E}_N \cup \mathcal{E}_H \cup \mathcal{E}_E$$

into Dirichlet and Neumann edges, nonelementary edges, and interior elementary edges, respectively: First, we define $\mathcal{E}_D := \{E \in \mathcal{E} \mid E \subseteq \Gamma_D\}$ and $\mathcal{E}_N := \{E \in \mathcal{E} \mid E \subseteq \overline{\Gamma}_N\}$. Second, an interior edge $E \in \mathcal{E}$ is nonelementary if there are pairwise different nodes $x, y, z \in \mathcal{N}$ such that $E = \text{conv}\{x, y\}$ and $z \in E$; i.e., there is a hanging node z in the interior of E . The set of all nonelementary edges is denoted by \mathcal{E}_H . Contrarily, $\mathcal{E} \setminus \mathcal{E}_H$ denotes the set of all elementary edges, which is split into boundary edges $\mathcal{E}_D \cup \mathcal{E}_N$ and interior elementary edges $\mathcal{E}_E := \mathcal{E} \setminus (\mathcal{E}_H \cup \mathcal{E}_D \cup \mathcal{E}_N)$. Moreover, we define the set

$$\mathcal{E}_0 := \{E \in \mathcal{E}_E \mid \nexists E' \in \mathcal{E}_H \quad E \subsetneq E'\}$$

of all interior elementary edges which are not part of a nonelementary edge. Finally, for an element $T \in \mathcal{T}$, we denote with $\mathcal{E}_T \subset \mathcal{E}$ the set of all edges of T , i.e.,

$$\mathcal{E}_T := \{E \in \mathcal{E} \mid E \subseteq \partial T \quad \text{for all } E' \in \mathcal{E} \quad (E \subsetneq E' \Rightarrow E' \not\subseteq \partial T)\}.$$

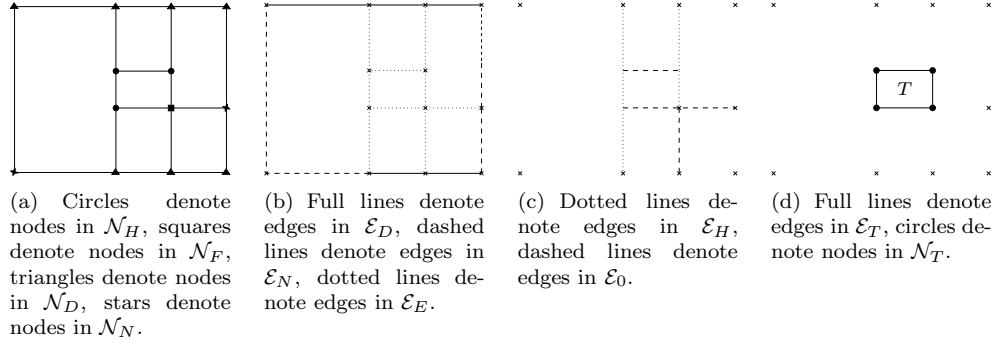

FIG. 2.1. The sets of edges and nodes for a simple (almost regular) triangulation, which consists of six rectangular elements.

Almost regular triangulations. We say that the triangulation \mathcal{T} is almost regular if the following hold:

- (i) the mixed boundary conditions are resolved; i.e., each edge $E \in \mathcal{E}$ with $E \cap \Gamma \neq \emptyset$ satisfies either $E \in \mathcal{E}_D$ or $E \in \mathcal{E}_N$;
- (ii) the intersection $T_1 \cap T_2$ of two elements $T_1, T_2 \in \mathcal{T}$ with $T_1 \neq T_2$ is either empty or a node or an edge;
- (iii) each nonelementary edge $E \in \mathcal{E}_H$ is the finite union of elementary edges; i.e., there are finitely many elementary edges $E_1, \dots, E_n \in \mathcal{E}_E$ such that $E = \bigcup_{i=1}^n E_i$.

With respect to regular triangulations in the sense of Ciarlet, the only difference is that in (ii) the intersection $T_1 \cap T_2$ may be, for instance, a node (or an edge) of T_1 but not of T_2 ; see Figure 2.1. However, in the case of $E := T_1 \cap T_2$ being an edge, (iii) implies that there holds at least either $E \in \mathcal{E}_{T_1}$ or $E \in \mathcal{E}_{T_2}$. From now on, we assume that all triangulations are at least almost regular (or even regular).

2.2. Normal and tangential vectors. For each edge $E \in \mathcal{E}$, we fix a normal vector \mathbf{n}_E as follows: For $E \in \mathcal{E}_D \cup \mathcal{E}_N$, let \mathbf{n}_E point outwards of Ω . For an edge $E \in \mathcal{E}_H$, there is a unique element $T \in \mathcal{T}$ with $E \in \mathcal{E}_T$, and we choose \mathbf{n}_E to point into T . For each elementary edge $E' \in \mathcal{E}_E$ with $E' \subset E$, we define $\mathbf{n}_{E'} := \mathbf{n}_E$. For the remaining edges, namely $E \in \mathcal{E}_0$, we may choose the orientation of \mathbf{n}_E arbitrarily.

In section 3, we shall use the following notational convention: For each elementary edge $E \in \mathcal{E}_E$, there are unique elements $T_{W,E}$ and $T_{E,E}$ such that $E \subseteq T_{W,E} \cap T_{E,E}$ and such that \mathbf{n}_E points from $T_{W,E}$ to $T_{E,E}$ (i.e., from west to east). For $E \in \mathcal{E}_D \cup \mathcal{E}_N$, there is a unique element $T_{W,E}$ with $E \subset \partial T_{W,E}$. If the edge E is clear from the context, we omit the additional subscript and simply write, e.g., $T_W = T_{W,E}$.

Moreover, for each element $T \in \mathcal{T}$ and an edge $E \in \mathcal{E}$ with $E \subset \partial T$, we define the sign

$$\sigma_{T,E} = \begin{cases} +1, & \text{provided } T = T_{W,E}, \\ -1 & \text{else;} \end{cases}$$

i.e., $\sigma_{T,E} \mathbf{n}_E$ is the outer normal vector $\mathbf{n}_T|_E$ of T restricted to the edge E .

Finally, the tangential vector \mathbf{t}_E of an edge $E \in \mathcal{E}$ is chosen orthogonal to \mathbf{n}_E in the mathematical positive sense. We note that $\sigma_{T,E} \mathbf{t}_E$ is the tangential vector $\mathbf{t}_T|_E$ of an element $T \in \mathcal{T}$ restricted to the edge E ; see Figure 2.2.

FIG. 2.2. The dashed lines show the a priori chosen normal vector \mathbf{n}_E (resp., tangential vector \mathbf{t}_E) on the edge E , whereas the full lines are the outer normal vector $\mathbf{n}_T|_E = \sigma_{T,E}\mathbf{n}_E$ of T (resp., $\mathbf{t}_T|_E = \sigma_{T,E}\mathbf{t}_E$) with respect to the edge E .

FIG. 2.3. The four patches introduced in section 2.3.

2.3. Patches. We recall the definition of the patches which are well known from finite element analysis. Additionally, we introduce the elementary patch of an edge which is needed for the handling of the hanging nodes in our a posteriori error analysis; see Figure 2.3.

Patch of a node. For $a \in \mathcal{N}$, the patch is given by

$$\omega_a = \bigcup_{T \in \tilde{\omega}_a} T, \quad \text{where } \tilde{\omega}_a := \{T \in \mathcal{T} \mid a \subseteq \partial T\}.$$

Patch of an edge. For an elementary edge $E \in \mathcal{E} \setminus \mathcal{E}_H$, the patch is given by

$$\omega_E := \bigcup_{T \in \tilde{\omega}_E} T, \quad \text{where } \tilde{\omega}_E := \{T \in \mathcal{T} \mid E \subseteq \partial T\}.$$

For a nonelementary edge $E \in \mathcal{E}_H$ and $E_1, \dots, E_n \in \mathcal{E}_E$ with $E = \bigcup_{i=1}^n E_i$, we define

$$\omega_E := \bigcup_{T \in \tilde{\omega}_E} T = \bigcup_{i=1}^n \omega_{E_i}, \quad \text{where } \tilde{\omega}_E := \bigcup_{i=1}^n \tilde{\omega}_{E_i}.$$

Elementary patch of an edge. Let us consider a nonelementary edge $E \in \mathcal{E}_H$ and $E_1, \dots, E_n \in \mathcal{E}_E$ with $E = \bigcup_{i=1}^n E_i$. Then there is a unique element $T_E \in \mathcal{T}$ with $E \in \mathcal{E}_{T_E}$. Moreover, there are unique elements $T_i \in \mathcal{T}$ such that $E_i \in \mathcal{E}_{T_i}$. We denote by $a_1, \dots, a_{n-1} \in \mathcal{N}_H$ the hanging nodes, which are on E . Moreover, let a_0 and a_n be the nodes of E . Without loss of generality, a_{i-1}, a_i are the nodes of E_i , i.e.,

$$E_i = \text{conv}\{a_{i-1}, a_i\}.$$

If $T_E = \text{conv}\{a_0, a_n, b\}$ is a triangle, we define triangles $\tilde{T}_i := \text{conv}\{a_{i-1}, a_i, b\}$ and note that

$$(2.1) \quad T_E = \bigcup_{i=1}^n \tilde{T}_i \quad \text{and} \quad \text{int}(\tilde{T}_i) \cap \text{int}(\tilde{T}_j) = \emptyset \quad \text{for } i \neq j,$$

where $\text{int}(\cdot)$ denotes the topological interior of a set. We stress that the triangles \tilde{T}_i cannot be elements of the triangulation \mathcal{T} . For T_E a rectangle, we can construct rectangles \tilde{T}_i with (2.1). For each of the elementary edges E_i , we may then define the elementary patch

$$\omega_{E_i}^* := T_i \cup \tilde{T}_i \quad \text{and} \quad \tilde{\omega}_{E_i}^* := \{T_i, \tilde{T}_i\}.$$

So far, we have defined the patch ω_E^* for all edges $E \in \mathcal{E}$ which are contained in a nonelementary edge. For the remaining edges $E \in \mathcal{E}$, we define $\omega_E^* := \omega_E$ and $\tilde{\omega}_E^* := \tilde{\omega}_E$.

Patch of an element. The patch of an element $T \in \mathcal{T}$ is defined by

$$\omega_T := \bigcup_{T' \in \tilde{\omega}_T} T', \quad \text{where} \quad \tilde{\omega}_T := \{T' \in \mathcal{T} \mid T \cap T' \in \mathcal{E}\}.$$

2.4. Jump terms. For $T \in \mathcal{T}$, $E \subseteq \partial T$, and $\varphi \in H^1(T)$, let $\varphi|_{E,T}$ denote the trace of φ on E . Now let $E \in \mathcal{E}_E$ be an interior elementary edge and T_E and T_W the unique elements with $E = T_E \cap T_W$. For a $\{T_E, T_W\}$ -piecewise H^1 function φ , the jump of φ on E is defined by

$$[[\varphi]]_E := \varphi|_{E,T_E} - \varphi|_{E,T_W}.$$

Note that $[[\varphi]]_E = 0$, provided $\varphi \in H^1(T_E \cup T_W)$. Moreover, for a $\{T_E, T_W\}$ -piecewise polynomial φ , the jump on E reads

$$[[\varphi]]_E(x) := \lim_{t \rightarrow 0_+} \varphi(x + t\mathbf{n}_E) - \lim_{t \rightarrow 0_+} \varphi(x - t\mathbf{n}_E) \quad \text{for all } x \in E.$$

For each nonelementary edge $E \in \mathcal{E}_H$, we define the jump $[[\varphi]]_E$ by

$$[[\varphi]]_E(x) := [[\varphi]]_{E_i}(x) \quad \text{for all } x \in E_i,$$

where $E = \bigcup_{i=1}^n E_i$ with $E_1, \dots, E_n \in \mathcal{E}_E$.

3. Cell-centered finite volume method. This section summarizes the discretization for the cell-centered finite volume method for our model problem. It especially points out the difference between the approximation of the diffusive flux on an admissible mesh and an almost regular mesh.

3.1. Discretization ansatz. We integrate the strong form (1.1) over a control volume $T \in \mathcal{T}$ and use the Gauss divergence theorem to obtain

$$\int_T f \, dx = - \int_T \Delta u \, dx = - \int_{\partial T} \frac{\partial u}{\partial \mathbf{n}_T} \, ds = - \sum_{E \in \mathcal{E}_T} \sigma_{T,E} \int_E \frac{\partial u}{\partial \mathbf{n}_E} \, ds \quad \text{for all } T \in \mathcal{T}.$$

With the diffusive flux $\Phi_E^D(u) = \int_E \partial u / \partial \mathbf{n}_E \, ds$, we get the so-called balance equation

$$(3.1) \quad - \sum_{E \in \mathcal{E}_T} \sigma_{T,E} \Phi_E^D(u) = \int_T f \, dx \quad \text{for all } T \in \mathcal{T}.$$

FIG. 3.1. The orthogonality condition for $E \in \mathcal{E}_E$ (left) (resp., $E \in \mathcal{E}_D$ (right)) for an admissible mesh in the sense of [10].

For the cell-centered finite volume method, one replaces the continuous diffusion flux $\Phi_E^D(u)$ by a discrete diffusion flux $F_E^D(u_h)$, which is discussed in section 3.2. Here $u_h \in \mathcal{P}_0(\mathcal{T})$ is a piecewise constant approximation of u , namely $u_T := u_h|_T \approx u(x_T)$, where x_T denotes the center of an element $T \in \mathcal{T}$. The discrete problem thus reads as follows: Find $u_h \in \mathcal{P}_0(\mathcal{T})$ such that

$$-\sum_{E \in \mathcal{E}_T} \sigma_{T,E} F_E^D(u_h) = \int_T f \, dx \quad \text{for all } T \in \mathcal{T}.$$

3.2. Discretization of diffusion flux. Note that $\Phi_E^D(u_h) = \int_E g \, ds$ is known for a Neumann edge $E \in \mathcal{E}_N$. One therefore defines

$$F_E^D(u_h) := \Phi_E^D(u_h) = \int_E g \, ds \quad \text{for } E \in \mathcal{E}_N.$$

Moreover, for a nonelementary edge with $E = \bigcup_{i=1}^n E_i$ and $E_i \in \mathcal{E}_E$, there holds $\Phi_E^D(u) = \sum_{i=1}^n \Phi_{E_i}^D(u)$, which leads to the definition

$$(3.2) \quad F_E^D(u_h) := \sum_{i=1}^n F_{E_i}^D(u_h) \quad \text{for all } E_1, \dots, E_n \in \mathcal{E}_E \quad \text{and} \quad E = \bigcup_{i=1}^n E_i \in \mathcal{E}_H.$$

Therefore, it remains only to define $F_E^D(u_h)$ for $E \in \mathcal{E}_E \cup \mathcal{E}_D$.

Admissible meshes. For an admissible mesh in the sense of [10, Definition 9.1], a first-order difference scheme leads to

$$(3.3) \quad \Phi_E^D(u) \approx F_E^D(u_h) := \begin{cases} \frac{u_{T_E} - u_{T_W}}{|x_{T_E} - x_{T_W}|} h_E & \text{if } E \in \mathcal{E}_E \text{ and } E = T_W \cap T_E, \\ \frac{u_{E_m} - u_{T_W}}{|x_{E_m} - x_{T_W}|} h_E & \text{if } E \in \mathcal{E}_D \text{ and } E = T_W \cap \Gamma_D, \end{cases}$$

with $u_{T_W} = u_h|_{T_W} \approx u(x_{T_W})$ and $u_{T_E} \approx u(x_{T_E})$ as well as for $E \in \mathcal{E}_D$, $u_{E_m} \approx u_D(x_{E_m})$.

The admissibility of the mesh \mathcal{T} allows one to choose the centers x_T for $T \in \mathcal{T}$ in a way that the edges $E = T_W \cap T_E$ for any $T_W, T_E \in \mathcal{T}$ are orthogonal to the directions $x_{T_E} - x_{T_W}$; see Figure 3.1. For general meshes, it is not possible to choose the centers x_T appropriately, and the approximation (3.3) is not consistent [10].

Remark 3.1. Even if a triangular mesh is admissible in the sense of [10, Definition 9.1], local mesh refinement is nontrivial: One has to guarantee that all angles are strictly less than $\pi/2$; i.e., one cannot avoid remeshing of the domain. For rectangular meshes, local mesh refinement cannot avoid hanging nodes. This, however, contradicts the admissibility condition.

FIG. 3.2. The different cases for calculating u_a with $a \in \mathcal{N}_N$ and $E_1, E_2 \in \mathcal{E}_N$.

Diamond path method. A possible choice of $F_E^D(u_h)$ for general meshes is the so-called *diamond path method*, which has been mathematically analyzed in [6, 7] for rectangular meshes with a maximum of one hanging node per edge. For each node $a \in \mathcal{N}$, we define

$$(3.4) \quad u_a = \begin{cases} \sum_{T \in \tilde{\omega}_a} \psi_T(a) u_T & \text{for all } a \in \mathcal{N}_F \cup \mathcal{N}_H, \\ u_D(a) & \text{for all } a \in \mathcal{N}_D, \\ \bar{u}_a + \bar{g}_a & \text{for all } a \in \mathcal{N}_N \end{cases}$$

for certain weights $\{\psi_T(a) \mid T \in \mathcal{T}, a \in \mathcal{N}_T\}$. For details on the computation of the weights, the reader is referred to [5, 6, 7, 9]. We stress that the computation can be done in linear complexity with respect to the number $\#\mathcal{T}$ of elements.

We remark only on the computation of \bar{u}_a and \bar{g}_a in the case of a Neumann node $a \in \mathcal{N}_N$; see Figure 3.2: Two edges $E_1, E_2 \in \mathcal{E}_N$ correspond to $a \in \mathcal{N}_N$ such that $\{a\} = E_1 \cap E_2$. Let \mathbf{n}_j denote the normal vector of E_j . In the case of $\#\tilde{\omega}_a > 1$, let $T_1, T_2 \in \tilde{\omega}_a$ with $T_1 \neq T_2$. We define x_a as the intersection of the line $\gamma_1(s) = a + s(\mathbf{n}_1 + \mathbf{n}_2)/2$ and the line $\gamma_2(t) = t(x_{T_1} - x_{T_2})$. Moreover, provided $\#\tilde{\omega}_a > 2$, we assume that $|x_a - a|$ is minimized over all pairs $T_1, T_2 \in \tilde{\omega}_a$. Then $\bar{u}_a \approx u(x_a)$ is interpolated linearly from u_{T_1} and u_{T_2} :

$$\bar{u}_a = \frac{u_{T_2} - u_{T_1}}{|x_{T_2} - x_{T_1}|} |x_a - x_{T_1}| + u_{T_1}.$$

For $\mathbf{n}_1 = \mathbf{n}_2$, we choose

$$\bar{g}_a = |x_a - a| \left(\frac{1}{|E_1|} \int_{E_1} g \, ds + \frac{1}{|E_2|} \int_{E_2} g \, ds \right) / 2,$$

and, finally, for $\mathbf{n}_1 \neq \mathbf{n}_2$, we choose

$$\bar{g}_a = \lambda \frac{1}{|E_1|} \int_{E_1} g \, ds + \mu \frac{1}{|E_2|} \int_{E_2} g \, ds,$$

where $\lambda, \mu \in \mathbb{R}$ are calculated from the linear equation $a - x_a = \lambda \mathbf{n}_1 + \mu \mathbf{n}_2$. In the case $\tilde{\omega}_a = \{T\}$, i.e., a is the node of only one element $T \in \mathcal{T}$, we choose $x_a = x_T$ and $\bar{u}_a = u_T$, whereas \bar{g}_a is computed as before.

Remark 3.2. Provided $x_a = a$, we obtain $a - x_a = 0$, $\lambda = \mu = 0$, and $\bar{g}_a = 0$.

With the notation from Figure 3.3, where x_{T_S} and x_{T_N} are the starting and end

FIG. 3.3. Diamond path with domain χ_E .

points of $E \in \mathcal{E}_E \cup \mathcal{E}_D$, we compute $F_E^D(u_h)$. For an elementary edge $E \in \mathcal{E}_E$,

$$(3.5) \quad F_E^D(u_h) := h_E \left(\frac{u_{T_E} - u_{T_W}}{d_E} - \alpha_E \frac{u_{T_N} - u_{T_S}}{h_E} \right)$$

$$\text{with} \quad \alpha_E = \frac{(x_{T_E} - x_{T_W}) \cdot \mathbf{t}_E}{(x_{T_E} - x_{T_W}) \cdot \mathbf{n}_E}, \quad d_E = (x_{T_E} - x_{T_W}) \cdot \mathbf{n}_E.$$

Here the additional unknowns u_{T_N} and u_{T_S} are located at the nodes x_{T_N} and x_{T_S} and are computed by (3.4). For a boundary edge $E \in \mathcal{E}_D$, we compute $F_E^D(u_h)$ by (3.5), where x_{T_E} is now replaced by the midpoint x_{E_m} of E and u_{T_E} becomes $u_D(x_{E_m})$.

4. Morley interpolant. Let $u_h \in \mathcal{P}_0(\mathcal{T})$ be the computed discrete solution. In this section, we define an interpolant $\mathcal{I}u_h$ which is appropriate for the a posteriori error analysis, the definition of which is an extension of the definition in [11, section 5] to the case of hanging nodes and Neumann nodes.

Triangular Morley element. Let $T = \text{conv}\{a_1, a_2, a_3\} \subset \mathbb{R}^2$ be a nondegenerate triangle with edges $E_j = \text{conv}\{a_j, a_{j+1}\}$, where $a_4 := a_1$. The standard Morley element $(T, \mathcal{P}_T, \Sigma_T)$ is given by $\mathcal{P}_T = \mathcal{P}_2$ and $\Sigma_T = (S_1, \dots, S_6)$, where

$$S_j(p) = p(a_j) \quad \text{and} \quad S_{j+3}(p) = \int_{E_j} \frac{\partial p}{\partial \mathbf{n}_{T, E_j}} ds \quad \text{for } j = 1, \dots, 3 \quad \text{and } p \in \mathcal{P}_2.$$

Note that $S_{j+3}(p) = h_{E_j} \partial p(m_j) / \partial \mathbf{n}_{T, E_j}$, where $m_j := (a_j + a_{j+1})/2$ denotes the midpoint of E_j , so that this definition is consistent with [2, section 8.3].

Rectangular Morley element. Let $T = \text{conv}\{a_1, a_2, a_3, a_4\} \subset \mathbb{R}^2$ be a nondegenerate rectangle with edges E_j . A Morley-type element $(T, \mathcal{P}_T, \Sigma_T)$ is then given by $\mathcal{P}_T = \mathcal{P}_2 \oplus \text{span}\{x^3 - 3xy^2, y^3 - 3yx^2\}$ and $\Sigma_T = (S_1, \dots, S_8)$, where

$$S_j(p) = p(a_j) \quad \text{and} \quad S_{j+4}(p) = \int_{E_j} \frac{\partial p}{\partial \mathbf{n}_{T, E_j}} ds \quad \text{for } j = 1, \dots, 4 \quad \text{and } p \in \mathcal{P}_T;$$

cf. [11, section 4.2]. Note that the polynomials $x^3 - 3xy^2$ and $y^3 - 3yx^2$, which enrich the ansatz space, are harmonic.

FIG. 4.1. An almost regular triangulation, where the elementwise and recursive computation of $\mathcal{I}u_h$ does not stop.

The Morley interpolant. In either of the cases, that T is a nondegenerate triangle or rectangle, the Morley element $(T, \mathcal{P}_T, \Sigma_T)$ is a nonconforming finite element. The Morley interpolant $\mathcal{I}u_h$ satisfies elementwise $(\mathcal{I}u_h)|_T \in \mathcal{P}_T$ for all $T \in \mathcal{T}$ defined by the following properties (4.1)–(4.3): For each free node $a \in \mathcal{N}_T \cap \mathcal{N}_F$, the value $\mathcal{I}u_h(a)$ satisfies

$$(4.1) \quad (\mathcal{I}u_h)|_T(a) = \sum_{T_a \in \tilde{\omega}_a} \psi_{T_a}(a) u_h|_{T_a},$$

where the weights $\psi_{T_a}(a)$ are the same as for the computation of u_h by the use of the diamond cell method. For each boundary node, the value $\mathcal{I}u_h(a)$ is prescribed:

$$(4.2) \quad (\mathcal{I}u_h)|_T(a) = \begin{cases} u_D(a) & \text{for } a \in \mathcal{N}_T \cap \mathcal{N}_D, \\ \bar{u}_a + \bar{g}_a & \text{for } a \in \mathcal{N}_T \cap \mathcal{N}_N, \end{cases}$$

where the calculation of \bar{u}_a and \bar{g}_a was discussed in section 3. For each hanging node $a \in \mathcal{N}_T \cap \mathcal{N}_H$, there holds

$$(4.3) \quad (\mathcal{I}u_h)|_T(a) = (\mathcal{I}u_h)|_{T_a}(a),$$

where $T_a \in \mathcal{T}$ is the unique element with $a \in \text{int}(E)$ for some (nonelementary) edge $E \in \mathcal{E}_{T_a}$. For each edge $E \in \mathcal{E}_T$, there holds

$$(4.4) \quad \int_E \frac{\partial(\mathcal{I}u_h)|_T}{\partial \mathbf{n}_E} ds = F_E^D(u_h),$$

where $F_E^D(u_h)$ is the numerical flux from section 3.2.

LEMMA 4.1. *The Morley interpolant $\mathcal{I}u_h$ is uniquely defined by (4.1)–(4.4). Moreover, $\mathcal{I}u_h$ is continuous in all nodes $a \in \mathcal{N}$ but not globally continuous in Ω .*

Proof. For an element $T \in \mathcal{T}$ without hanging nodes, i.e., $\mathcal{N}_T \cap \mathcal{N}_H = \emptyset$, the interpolant $(\mathcal{I}u_h)|_T$ is uniquely defined by (4.1)–(4.3) and (4.4) since $(T, \mathcal{P}_T, \Sigma_T)$ is a finite element. \square

Remark 4.1. The computation of $\mathcal{I}u_h$ can be performed by solving a large system of linear equations which is coupled through the hanging nodes. However, normally $\mathcal{I}u_h$ can be computed locally by solving a 6×6 (resp., 8×8) system for each element $T \in \mathcal{T}$. For an element $T \in \mathcal{T}$ without hanging nodes, the interpolant $(\mathcal{I}u_h)|_T$ is uniquely determined by (4.1)–(4.2) and (4.4). For an element with hanging nodes, we have to compute $(\mathcal{I}u_h)|_{T_a}$ first; cf. (4.3). This leads to a recursive algorithm. Figure 4.1 shows an almost regular triangulation, where the proposed recursion would not stop. Instead, one has to solve a global linear system to compute $\mathcal{I}u_h$.

Properties of Morley interpolant. From the definition of the discrete scheme and the property (4.3), we obtain an additional orthogonality property of $\mathcal{I}u_h$.

LEMMA 4.2. *The residual $R := f + \Delta(\mathcal{I}u_h)$ is L^2 -orthogonal to $\mathcal{P}_0(\mathcal{T})$, i.e.,*

$$(4.5) \quad \int_T (f + \Delta(\mathcal{I}u_h)) dx = 0 \quad \text{for all } T \in \mathcal{T}.$$

In particular, the residual satisfies $R = f - f_{\mathcal{T}}$.

Proof. From integration by parts and the definition of the balance equation (3.1), we infer

$$\int_T \Delta(\mathcal{I}u_h)|_T dx = \int_{\partial T} \frac{\partial(\mathcal{I}u_h)|_T}{\partial \mathbf{n}_T} ds = \sum_{E \in \mathcal{E}_T} \sigma_{T,E} F_E^D(u_h) = - \int_T f(x) dx,$$

where we have used (4.4) in the second equality. In particular, there holds $R_{\mathcal{T}}|_T := |T|^{-1} \int_T R dx = 0$. With $\Delta_{\mathcal{T}}(\mathcal{I}u_h) \in \mathcal{P}_0(\mathcal{T})$, we obtain $R = R - R_{\mathcal{T}} = f - f_{\mathcal{T}}$. \square

According to the definition of $\mathcal{I}u_h$ on the Dirichlet and Neumann boundaries, namely (4.2) and (4.3), we obtain corresponding orthogonalities.

LEMMA 4.3. *For boundary edges, there hold*

$$(4.6) \quad \int_E \frac{\partial(u - \mathcal{I}u_h)}{\partial \mathbf{t}_E} ds = 0 \quad \text{for all } E \in \mathcal{E}_D$$

as well as

$$(4.7) \quad \int_E \frac{\partial(u - \mathcal{I}u_h)}{\partial \mathbf{n}_E} ds = 0 \quad \text{for all } E \in \mathcal{E}_N.$$

Proof. For $E \in \mathcal{E}_D$, let a_S and a_N be the starting and end points of E , respectively. Then

$$\int_E \frac{\partial(u - \mathcal{I}u_h)}{\partial \mathbf{t}_E} ds = (u - \mathcal{I}u_h)(a_N) - (u - \mathcal{I}u_h)(a_S) = 0$$

by the use of (4.2). To prove (4.7), we use (4.4) and the definition of the finite volume scheme:

$$\int_E \frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} ds = F_E^D(u_h) = \int_E g ds,$$

where $g = \partial u / \partial \mathbf{n}$. \square

Finally, we note some orthogonality relations of the normal and tangential jumps of $\mathcal{I}u_h$ which again follow from (4.4) (in combination with (3.2)) and from the nodal values (4.1)–(4.3) of $\mathcal{I}u_h$.

LEMMA 4.4. *For the interior edges, there hold*

$$(4.8) \quad \int_E \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right] ds = 0 \quad \text{for all } E \in \mathcal{E}_0 \cup \mathcal{E}_H$$

as well as

$$(4.9) \quad \int_E \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] \right] ds = 0 \quad \text{for all } E \in \mathcal{E}_E.$$

Proof. We first prove (4.8) for $E \in \mathcal{E}_H$. There holds $E = \bigcup_{i=1}^n E_i$ with $E_1, \dots, E_n \in \mathcal{E}_E$, $E_i = T_{W_i} \cap T_E$ and \mathbf{n}_E shows from element T_{W_i} to T_E . Therefore, the definition (3.2) of the discrete flux on nonelementary edges implies

$$\begin{aligned} \int_E \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right] ds &= \int_E \frac{\partial(\mathcal{I}u_h)|_{T_E}}{\partial \mathbf{n}_E} ds - \sum_{i=1}^n \int_{E_i} \frac{\partial(\mathcal{I}u_h)|_{T_{W_i}}}{\partial \mathbf{n}_E} ds \\ &= F_E^D(u_h) - \sum_{i=1}^n F_{E_i}^D(u_h) = 0. \end{aligned}$$

For $E \in \mathcal{E}_0$, the proof of (4.8) works analogously with $n = 1$. To prove (4.9), let a_S and a_N be the starting and end points of $E \in \mathcal{E}_E$, respectively. Note that $[[\mathcal{I}u_h]]_E(a_N) = 0 = [[\mathcal{I}u_h]]_E(a_S)$ because of the continuity of $\mathcal{I}u_h$ in all nodes. Therefore,

$$\int_E \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] \right] ds = \int_{a_S}^{a_N} \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] \right] ds = [[\mathcal{I}u_h]]_E(a_N) - [[\mathcal{I}u_h]]_E(a_S) = 0,$$

which concludes the proof. \square

5. A posteriori error estimate. In this section, we provide a residual-based a posteriori error analysis for the error $u - \mathcal{I}u_h$, where \mathcal{I} denotes the Morley interpolant from section 4. The idea goes back to [11] and is now extended to almost regular triangulations and mixed boundary conditions. The mathematical techniques follow the a posteriori error analysis for nonconforming finite elements. Throughout, $\nabla_{\mathcal{T}}$ and $\Delta_{\mathcal{T}}$ denote the \mathcal{T} -piecewise gradient and Laplacian, respectively.

5.1. Residual-based error estimator. For each element $T \in \mathcal{T}$, we define the refinement indicator

$$\begin{aligned} \eta_T^2 &:= h_T^2 \|f - f_{\mathcal{T}}\|_{L^2(T)}^2 + \sum_{E \in \{E \in \mathcal{E}_E \mid E \subset \partial T\}} h_E^* \|[[\nabla_{\mathcal{T}}(\mathcal{I}u_h)]]\|_{L^2(E)}^2 \\ (5.1) \quad &+ \sum_{E \in \mathcal{E}_T \cap \mathcal{E}_N} h_E \left\| \frac{\partial(u - \mathcal{I}u_h)}{\partial \mathbf{n}_E} \right\|_{L^2(E)}^2 + \sum_{E \in \mathcal{E}_T \cap \mathcal{E}_D} h_E \left\| \frac{\partial(u - \mathcal{I}u_h)}{\partial \mathbf{t}_E} \right\|_{L^2(E)}^2. \end{aligned}$$

Here $f_{\mathcal{T}}$ denotes the \mathcal{T} -piecewise integral mean, i.e., $f_{\mathcal{T}}|_T := |T|^{-1} \int_T f dx$. Moreover, the length h_E^* of an edge $E \in \mathcal{E}_E$ is defined by

$$h_E^* := \begin{cases} h_{E'} & \text{if } E \subset E' \text{ for some } E' \in \mathcal{E}_H, \\ h_E & \text{else, i.e., } E \in \mathcal{E}_0. \end{cases}$$

The residual-based error estimator is then given by the ℓ_2 -sum $\eta = \left(\sum_{T \in \mathcal{T}} \eta_T^2 \right)^{1/2}$ of all refinement indicators. In the following sections, we prove that η is (up to terms of higher order) a lower and upper bound of the error $\|\nabla_{\mathcal{T}}(u - \mathcal{I}u_h)\|_{L^2(\Omega)}$ in the energy norm.

5.2. Reliability of error estimator.

THEOREM 5.1. *There is a constant $c_1 > 0$ which depends only on the shape of the elements in \mathcal{T} but neither on the size nor the number of elements such that*

$$\|\nabla_{\mathcal{T}}(u - \mathcal{I}u_h)\|_{L^2(\Omega)} \leq c_1 \left(\sum_{T \in \mathcal{T}} \eta_T^2 \right)^{1/2}.$$

Proof. To abbreviate notation, we use the symbol \lesssim if an estimate holds up to a multiplicative constant that depends only on the shape of the elements in \mathcal{T} . For $e := u - \mathcal{I}u_h$, the Helmholtz decomposition, e.g., from [4, Lemma 2.1], provides $v \in H^1(\Omega)$ and $w \in H^1(\Omega)$ such that

$$\nabla_{\mathcal{T}} e = \nabla v + \operatorname{curl} w \quad \text{and} \quad v|_{\Gamma_D} = 0 \quad \text{as well as} \quad \operatorname{curl} w \cdot \mathbf{n}|_{\Gamma_N} = 0.$$

Moreover, there holds

(5.2)

$$\|\nabla v\|_{L^2(\Omega)}^2 + \|\operatorname{curl} w\|_{L^2(\Omega)}^2 = \|\nabla_{\mathcal{T}} e\|_{L^2(\Omega)}^2 = \int_{\Omega} \nabla_{\mathcal{T}} e \cdot \nabla v \, dx + \int_{\Omega} \nabla_{\mathcal{T}} e \cdot \operatorname{curl} w \, dx.$$

Note that $0 = \operatorname{curl} w \cdot \mathbf{n} = \partial w / \partial \mathbf{t}$ on Γ_N . Since Γ_N is connected, we infer that w is constant on Γ_N . Subtracting a constant, we may therefore guarantee $w|_{\Gamma_N} = 0$. We now estimate the two addends on the right-hand side separately. The first term reads

$$\int_{\Omega} \nabla_{\mathcal{T}} e \cdot \nabla v \, dx = \sum_{T \in \mathcal{T}} \int_T Rv \, dx + \int_{\Gamma_N} gv \, ds - \sum_{T \in \mathcal{T}} \int_{\partial T} \frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_T} v \, ds$$

according to elementwise integration by parts and the definition of the residual $R := f + \Delta_{\mathcal{T}}(\mathcal{I}u_h)$. We now consider the sum over the boundary integrals, namely

$$\sum_{T \in \mathcal{T}} \int_{\partial T} \frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_T} v \, ds = \sum_{T \in \mathcal{T}} \sum_{E \in \mathcal{E}_T} \sigma_{T,E} \int_E \frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} v \, ds.$$

For $E \in \mathcal{E}_D$, the boundary integral vanishes due to $v|_{\Gamma_D} = 0$. The Neumann edges $E \in \mathcal{E}_N$ are combined with the boundary integral $\int_{\Gamma_N} g \, ds$. Each edge $E \in \mathcal{E}_0$ appears twice for associated elements T_W and T_E , respectively. The normal vectors $\sigma_{T_W,E} \mathbf{n}_E$ and $\sigma_{T_E,E} \mathbf{n}_E$ differ only in the sign so that we obtain the jump of the normal derivative on E . For a nonelementary edge $E \in \mathcal{E}_H$ with $E = \bigcup_{i=1}^n E_i$ and $E_i \in \mathcal{E}_E$, both E as well as the elementary edges E_i appear only once in the sum. Similarly to the prior arguments we are led to the jump of the normal derivative on E , where we make use of $\mathbf{n}_E = -\mathbf{n}_{E_i}$ for all $i = 1, \dots, n$. Altogether, we obtain

$$\begin{aligned} \int_{\Omega} \nabla_{\mathcal{T}} e \cdot \nabla v \, dx &= \sum_{T \in \mathcal{T}} \int_T Rv \, dx - \sum_{E \in \mathcal{E}_0 \cup \mathcal{E}_H} \int_E \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right] v \, ds \\ &\quad + \sum_{E \in \mathcal{E}_N} \int_E \left(g - \frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right) v \, ds \\ &= \sum_{T \in \mathcal{T}} \int_T R(v - v_T) \, dx - \sum_{E \in \mathcal{E}_0 \cup \mathcal{E}_H} \int_E \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right] (v - v_E) \, ds \\ &\quad + \sum_{E \in \mathcal{E}_N} \int_E \frac{\partial e}{\partial \mathbf{n}_E} (v - v_E) \, ds, \end{aligned}$$

where we have applied the orthogonalities (4.5), (4.7), and (4.8) for the integral means $v_T = |T|^{-1} \int_T v \, dx$ and $v_E := h_E^{-1} \int_E v \, ds$, respectively. We now apply the Cauchy inequality combined with a Poincaré inequality $\|v - v_T\|_{L^2(T)} \lesssim h_T \|\nabla v\|_{L^2(T)}$ for the

first sum and a trace inequality $\|v - v_E\|_{L^2(E)} \lesssim h_E^{1/2} \|\nabla v\|_{L^2(T_E)}$ for the remaining sums, where $T_E \in \mathcal{T}$ is an arbitrary element with $E \in \mathcal{E}_{T_E}$. This leads to

$$\begin{aligned}
\int_{\Omega} \nabla_{\mathcal{T}} e \cdot \nabla v \, dx &\lesssim \left(\sum_{T \in \mathcal{T}} h_T^2 \|R\|_{L^2(T)}^2 \right)^{1/2} \left(\sum_{T \in \mathcal{T}} \|\nabla v\|_{L^2(T)}^2 \right)^{1/2} \\
&\quad + \left(\sum_{E \in \mathcal{E}_0 \cup \mathcal{E}_H} h_E \left\| \left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right\|_{L^2(E)}^2 \right)^{1/2} \left(\sum_{E \in \mathcal{E}_0 \cup \mathcal{E}_H} \|\nabla v\|_{L^2(T_E)}^2 \right)^{1/2} \\
&\quad + \left(\sum_{E \in \mathcal{E}_N} h_E \left\| \frac{\partial e}{\partial \mathbf{n}_E} \right\|_{L^2(E)}^2 \right)^{1/2} \left(\sum_{E \in \mathcal{E}_N} \|\nabla v\|_{L^2(T_E)}^2 \right)^{1/2} \\
&\lesssim \left[\left(\sum_{T \in \mathcal{T}} h_T^2 \|R\|_{L^2(T)}^2 \right)^{1/2} + \left(\sum_{E \in \mathcal{E}_E} h_E^* \left\| \left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right\|_{L^2(E)}^2 \right)^{1/2} \right. \\
(5.3) \quad &\quad \left. + \left(\sum_{E \in \mathcal{E}_N} h_E \left\| \frac{\partial e}{\partial \mathbf{n}_E} \right\|_{L^2(E)}^2 \right)^{1/2} \right] \|\nabla v\|_{L^2(\Omega)}.
\end{aligned}$$

For the second integral in (5.2), we proceed in the same manner: Elementwise integration by parts yields

$$\int_{\Omega} \nabla_{\mathcal{T}} e \cdot \operatorname{curl} w \, dx = - \sum_{T \in \mathcal{T}} \int_{\partial T} \frac{\partial e}{\partial \mathbf{t}_T} w \, ds = - \sum_{T \in \mathcal{T}} \sum_{E \in \mathcal{E}_T \setminus \mathcal{E}_N} \sigma_{T,E} \int_E \frac{\partial e}{\partial \mathbf{t}_E} w \, ds,$$

since $w|_{\Gamma_N} = 0$. Treating the interior edges as before, we obtain

$$\sum_{T \in \mathcal{T}} \sum_{E \in \mathcal{E}_T} \sigma_{T,E} \int_E \frac{\partial e}{\partial \mathbf{t}_E} w \, ds = \sum_{E \in \mathcal{E}_E} \int_E \left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] w \, ds + \sum_{E \in \mathcal{E}_D} \int_E \frac{\partial e}{\partial \mathbf{t}_E} w \, ds,$$

where we have used that, for an interior edge E , the tangential jump of an H^1 -function vanishes, i.e., $[\partial u / \partial \mathbf{t}_E]_E = 0$. With the orthogonalities (4.9) and (4.6), we prove

$$\int_{\Omega} \nabla_{\mathcal{T}} e \cdot \operatorname{curl} w \, dx = - \sum_{E \in \mathcal{E}_E} \int_E \left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] (w - w_E) \, ds - \sum_{E \in \mathcal{E}_D} \int_E \frac{\partial e}{\partial \mathbf{t}_E} (w - w_E) \, ds$$

for the integral mean $w_E := h_E^{-1} \int_E w \, ds$. As before, the application of the Cauchy inequality and the trace inequality yields

$$\begin{aligned}
(5.4) \quad &\int_{\Omega} \nabla_{\mathcal{T}} e \cdot \operatorname{curl} w \, dx \\
&\lesssim \left[\sum_{E \in \mathcal{E}_E} h_E^* \left\| \left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] \right\|_{L^2(E)}^2 + \sum_{E \in \mathcal{E}_D} h_E \left\| \frac{\partial e}{\partial \mathbf{t}_E} \right\|_{L^2(E)}^2 \right]^{1/2} \|\nabla w\|_{L^2(\Omega)}.
\end{aligned}$$

If we finally combine (5.2)–(5.4), we prove

$$\begin{aligned}
\|\nabla_{\mathcal{T}} e\|_{L^2(\Omega)} &\lesssim \left[\sum_{T \in \mathcal{T}} h_T^2 \|R\|_{L^2(T)}^2 + \sum_{E \in \mathcal{E}_E} h_E^* \left\| \left[\nabla \mathcal{I}u_h \right] \right\|_{L^2(E)}^2 \right. \\
&\quad \left. + \sum_{E \in \mathcal{E}_N} h_E \left\| \frac{\partial e}{\partial \mathbf{n}_E} \right\|_{L^2(E)}^2 + \sum_{E \in \mathcal{E}_D} h_E \left\| \frac{\partial e}{\partial \mathbf{t}_E} \right\|_{L^2(E)}^2 \right]^{1/2},
\end{aligned}$$

FIG. 5.1. The different types of the edge-bubble functions on an almost regular triangulation.

where we have used that $\{\mathbf{t}_E, \mathbf{n}_E\}$ is an orthonormal basis of \mathbb{R}^2 and that $\|\nabla v\|_{L^2} \leq \|\nabla_{\mathcal{T}} e\|_{L^2}$ as well as $\|\nabla w\|_{L^2} = \|\operatorname{curl} w\|_{L^2} \leq \|\nabla_{\mathcal{T}} e\|_{L^2}$. This and $R = f - f_{\mathcal{T}}$ conclude the proof. \square

5.3. Local efficiency of error estimator. To prove the efficiency of the proposed error estimator, we need to control the constant $c_2 > 0$ in the estimate $h_E \leq h_E^* \leq c_2 h_E$ uniformly for all $E \in \mathcal{E}_E$.

THEOREM 5.2. *There is a constant $c_3 > 0$ which depends only on c_2 and the shape of the elements in \mathcal{T} but neither on the size nor the number of elements such that*

$$(5.5) \quad \eta_T^2 \leq c_3 (\|\nabla_{\mathcal{T}}(u - \mathcal{I}u_h)\|_{L^2(\omega_T)}^2 + h_T^2 \|f - f_{\mathcal{T}}\|_{L^2(\omega_T)}^2) \quad \text{for all } T \in \mathcal{T}.$$

The proof follows along the arguments of Verfürth [12] by use of appropriate bubble functions b_E (see Figure 5.1) and an edge lifting operator F_{ext} . The elementary edge patch ω_E^* is defined in a way that it belongs to a locally regular triangulation. For $E \in \mathcal{E}_E$, we may therefore adopt the notation of b_E and F_{ext} from the literature [12].

LEMMA 5.3. *For each edge $E \in \mathcal{E}_E \cup \mathcal{E}_D \cup \mathcal{E}_N$, there is a $\tilde{\omega}_E^*$ -piecewise polynomial bubble function $b_E \in H^1(\omega_E^*)$ with $0 \leq b_E \leq 1$ such that, for all $w \in \mathcal{P}_p(E)$, there holds*

$$(5.6) \quad c_4 \|w\|_{L^2(E)} \leq \|w b_E^{1/2}\|_{L^2(E)} \leq \|w\|_{L^2(E)}.$$

The constant $c_4 > 0$ depends only on the shape of the elements of \mathcal{T} and the polynomial degree p . Moreover, for $E \in \mathcal{E}_E$, the bubble function satisfies $b_E \in H_0^1(\omega_E^*)$, whereas for a boundary edge $E \in \mathcal{E}_D \cup \mathcal{E}_N$ there holds $b_E|_{\partial\omega_E^* \setminus E} = 0$.

LEMMA 5.4. *For each edge $E \in \mathcal{E}_E \cup \mathcal{E}_D \cup \mathcal{E}_N$, there is a lifting operator $F_{\text{ext}} : \mathcal{P}_p(E) \rightarrow H^1(\omega_E^*)$ such that $F_{\text{ext}}(w)|_E = w$, for $w \in \mathcal{P}_p(E)$, as well as*

$$(5.7) \quad c_5 h_E^{1/2} \|w\|_{L^2(E)} \leq \|F_{\text{ext}}(w) b_E\|_{L^2(\omega_E^*)} \leq c_6 h_E^{1/2} \|w\|_{L^2(E)}$$

and

$$(5.8) \quad \|\nabla(F_{\text{ext}}(w) b_E)\|_{L^2(\omega_E^*)} \leq c_7 h_E^{-1/2} \|w\|_{L^2(E)}.$$

The constants $c_5, c_6, c_7 > 0$ depend only on the shape of the elements in \mathcal{T} and the polynomial degree p . Here b_E denotes the bubble function from Lemma 5.3.

The proof of Theorem 5.2 is now split into four claims which dominate the different edge contributions of η_T^2 separately. Throughout the proofs, we adopt the foregoing notation for $e = u - \mathcal{I}u_h$, $R = f + \Delta_{\mathcal{T}}(\mathcal{I}u_h)$, and \lesssim .

CLAIM 1. *There holds $h_E \left\| \left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right\|_{L^2(E)}^2 \lesssim \|\nabla_{\mathcal{T}} e\|_{L^2(\omega_E^*)}^2 + h_E^2 \|R\|_{L^2(\omega_E^*)}^2$ for each $E \in \mathcal{E}_E$.*

Proof. We first stress that $u \in H^1(\Omega)$ implies $\left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E}\right]\right]_E = -\left[\left[\frac{\partial e}{\partial \mathbf{n}_E}\right]\right]_E$. With $b_E \in H_0^1(\omega_E^*)$ the corresponding edge-bubble function, (5.6) yields

$$\left\| \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right] \right\|_{L^2(E)}^2 \lesssim \int_E \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right]_E v \, ds \quad \text{with} \quad v := F_{\text{ext}} \left(\left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right]_E \right) b_E \in H_0^1(\omega_E^*).$$

We rewrite the right-hand side and use integration by parts to prove

$$\int_E \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right]_E v \, dx = - \sum_{T \in \tilde{\omega}_E^*} \int_{\partial T} \frac{\partial e}{\partial \mathbf{n}_T} v \, dy = - \sum_{T \in \tilde{\omega}_E^*} \left(\int_T \nabla e \cdot \nabla v \, dx - \int_T Rv \, dx \right).$$

With the help of (5.7)–(5.8), the Cauchy inequality proves

$$\left\| \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right] \right\|_{L^2(E)}^2 \lesssim (h_E^{-1} \|\nabla_{\mathcal{T}} e\|_{L^2(\omega_E^*)}^2 + h_E \|R\|_{L^2(\omega_E^*)}^2)^{1/2} \left\| \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{n}_E} \right] \right] \right\|_{L^2(E)}. \quad \square$$

CLAIM 2. *There holds $h_E \left\| \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] \right] \right\|_{L^2(E)}^2 \lesssim \|\nabla_{\mathcal{T}} e\|_{L^2(\omega_E^*)}^2$ for each $E \in \mathcal{E}_E$.*

Proof. With $b_E \in H_0^1(\omega_E^*)$ the corresponding edge-bubble function, we observe

$$\left\| \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] \right] \right\|_{L^2(E)}^2 \lesssim \int_E \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] \right]_E v \, ds \quad \text{with} \quad v := F_{\text{ext}} \left(\left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] \right]_E \right) b_E \in H_0^1(\omega_E^*).$$

As before, we rewrite the right-hand side and use integration by parts to prove

$$\int_E \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] \right]_E v \, ds = \sum_{T \in \tilde{\omega}_E^*} \int_{\partial T} \frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_T} v \, dx = - \sum_{T \in \tilde{\omega}_E^*} \int_T \nabla(\mathcal{I}u_h) \cdot \text{curl} \, v \, dx.$$

Together with $\int_{\omega_E^*} \nabla u \cdot \text{curl} \, v \, dx = 0$ and (5.8), we obtain

$$\left\| \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] \right] \right\|_{L^2(E)}^2 \lesssim \int_{\omega_E^*} \nabla_{\mathcal{T}} e \cdot \text{curl} \, v \, dx \lesssim h_E^{-1/2} \|\nabla_{\mathcal{T}} e\|_{L^2(\omega_E^*)} \left\| \left[\left[\frac{\partial(\mathcal{I}u_h)}{\partial \mathbf{t}_E} \right] \right] \right\|_{L^2(E)},$$

where we used $\|\text{curl} \, v\|_{L^2} = \|\nabla v\|_{L^2}$. \square

CLAIM 3. *For $E \in \mathcal{E}_D$, there holds $h_E \left\| \frac{\partial e}{\partial \mathbf{t}_E} \right\|_{L^2(E)}^2 \lesssim \|\nabla e\|_{L^2(T)}^2$.*

Proof. For $E \in \mathcal{E}_D$, there is a unique element $\omega_E = T \in \mathcal{T}$ with $E \in \mathcal{E}_T$. The corresponding edge-bubble function $b_E \in H^1(T)$ satisfies $b_E|_{\partial T \setminus E} = 0$. We consider $v := F_{\text{ext}}(\partial e / \partial \mathbf{t}_E) b_E \in H^1(T)$ and note that $v|_{\partial T \setminus E} = 0$ as well as $\mathbf{t}_T|_E = \mathbf{t}_E$. Therefore,

$$\left\| \frac{\partial e}{\partial \mathbf{t}_E} \right\|_{L^2(E)}^2 \lesssim \int_E \frac{\partial e}{\partial \mathbf{t}_E} v \, ds = - \int_T \nabla e \cdot \text{curl} \, v \, dx \leq h_E^{-1/2} \|\nabla e\|_{L^2(T)} \left\| \frac{\partial e}{\partial \mathbf{t}_E} \right\|_{L^2(E)},$$

where we finally used the Cauchy inequality together with (5.8). \square

CLAIM 4. *For $E \in \mathcal{E}_N$, there holds $h_E \left\| \frac{\partial e}{\partial \mathbf{n}_E} \right\|_{L^2(E)}^2 \lesssim \|\nabla e\|_{L^2(T)}^2 + h_E^2 \|R\|_{L^2(T)}^2$.*

Proof. As in Claim 3, let $T \in \mathcal{T}$ be the unique element with $\omega_E = T$ for a fixed edge $E \in \mathcal{E}_N$ and let $b_E \in H^1(T)$ be the associated edge bubble function. With $v := F_{\text{ext}}(\partial e / \partial \mathbf{n}_E) b_E \in H^1(T)$ and integration by parts, there holds

$$\left\| \frac{\partial e}{\partial \mathbf{n}_E} \right\|_{L^2(E)}^2 \lesssim \int_{\partial T} \frac{\partial e}{\partial \mathbf{n}_T} v \, ds = \int_T \nabla e \cdot \nabla v \, dx - \int_T Rv \, dx.$$

The proof now follows as in Claim 1. \square

Proof of Theorem 5.2. According to Claims 1 and 2, there holds

$$\begin{aligned} & \sum_{E \in \{E \in \mathcal{E}_E \mid E \subset \partial T\}} h_E^* \|\llbracket \nabla_{\mathcal{T}}(\mathcal{I}u_h) \rrbracket\|_{L^2(E)}^2 \\ & \lesssim \sum_{E \in \{E \in \mathcal{E}_E \mid E \subset \partial T\}} (\|\nabla_{\mathcal{T}} e\|_{L^2(\omega_E^*)}^2 + h_E^2 \|R\|_{L^2(\omega_E^*)}^2) \\ & \lesssim \|\nabla_{\mathcal{T}} e\|_{L^2(\omega_T)}^2 + h_E^2 \|R\|_{L^2(\omega_T)}^2. \end{aligned}$$

With Claim 3, there holds

$$\sum_{E \in \mathcal{E}_T \cap \mathcal{E}_D} h_E \left\| \frac{\partial e}{\partial \mathbf{t}_E} \right\|_{L^2(E)}^2 \lesssim \sum_{E \in \mathcal{E}_T \cap \mathcal{E}_D} \|\nabla e\|_{L^2(T)}^2 \leq 4 \|\nabla e\|_{L^2(T)}^2.$$

With Claim 4, there holds

$$\begin{aligned} \sum_{E \in \mathcal{E}_T \cap \mathcal{E}_N} h_E \left\| \frac{\partial e}{\partial \mathbf{n}_E} \right\|_{L^2(E)}^2 & \lesssim \sum_{E \in \mathcal{E}_T \cap \mathcal{E}_N} (\|\nabla e\|_{L^2(T)}^2 + h_E^2 \|R\|_{L^2(T)}^2) \\ & \leq 4(\|\nabla e\|_{L^2(T)}^2 + h_E^2 \|R\|_{L^2(T)}^2). \end{aligned}$$

Finally, this and $R = f - f_{\mathcal{T}}$ prove (5.5). \square

6. Numerical experiments. In this section, we study the accuracy of the derived a posteriori error estimate from section 5 as well as the performance of an adaptive mesh-refining algorithm which is steered by the local refinement indicators η_T from (5.1). All computations are done in MATLAB. Throughout, we run the following standard algorithm, where we use $\theta = 1$ for uniform and $\theta = 0.5$ for adaptive mesh refinement, respectively.

ALGORITHM 6.1. *Given an initial mesh $\mathcal{T}^{(0)}$, $k = 0$, and $0 \leq \theta \leq 1$, do the following:*

1. *Compute the discrete solution $u_h \in \mathcal{P}_0(\mathcal{T}^{(k)})$ for the current mesh $\mathcal{T}^{(k)} = \{T_1, \dots, T_N\}$.*
2. *Compute the Morley interpolant $\mathcal{I}u_h$.*
3. *Compute the refinement indicators η_{T_j} for all elements $T_j \in \mathcal{T}^{(k)}$.*
4. *Construct a minimal subset $\mathcal{M}^{(k)}$ of $\mathcal{T}^{(k)}$ such that*

$$(6.1) \quad \theta \sum_{T \in \mathcal{T}^{(k)}} \eta_T^2 \leq \sum_{T \in \mathcal{M}^{(k)}} \eta_T^2$$

and mark all elements in $\mathcal{M}^{(k)}$ for refinement.

5. *Refine at least all marked elements $T \in \mathcal{M}^{(k)}$ and generate a new mesh $\mathcal{T}^{(k+1)}$.*

6. *Update $k \mapsto k + 1$ and go to (1).*

Remark 6.1. The marking criterion (6.1) was introduced in [8] to prove convergence of an adaptive algorithm for some P1-FEM for the Laplace problem. Despite convergence, even the question of optimal convergence rates of the adaptive FEM based on residual error estimators is well understood; cf. the recent work [3] for a precise statement of optimality and the history of mathematical arguments.

FIG. 6.1. To bound the constant c_2 which enters the efficiency estimate of Theorem 5.2, we allow only one hanging node per edge: If in configuration (a) the element T_2 is marked for refinement, we mark element T_1 for refinement as well. This leads to configuration (c) instead of (b) after refinement.

FIG. 6.2. A priori computed weights ψ_T for the special mesh of squares with at most one hanging node per edge.

In all experiments, the initial mesh $\mathcal{T}^{(0)}$ is a uniform and regular triangulation, where all of the elements are either triangles or squares. In the case of triangular elements, we use a red-green-blue strategy to obtain $\mathcal{T}^{(k+1)}$ from $\mathcal{T}^{(k)}$; i.e., marked elements are uniformly refined, and the obtained mesh is regularized by a green-blue closure [12]. In the case of square elements, a marked element is uniformly refined, and we allow hanging nodes. However, we do some additional marking to ensure the following assumption.

Assumption 6.1. For all almost regular meshes consisting of squares, there is at most one step of refinement between two neighboring cells; see Figure 6.1.

Note that under this assumption, there are only seven possible geometrical configurations for triangulations with square elements. This allows the a priori computation of the weights $\psi_T(a)$ in (3.4) and (4.1) which is shown in Figure 6.2.

Throughout, we compute and compare the following numerical quantities for uniform and adaptive mesh refinement: First, we have the Morley error

$$E_{\mathcal{T}} := \|\nabla_{\mathcal{T}}(u - \mathcal{I}u_h)\|_{L^2(\Omega)},$$

FIG. 6.3. Domain $\Omega = (0, 1)^2$ as well as Dirichlet and Neumann boundary conditions in the example in section 6.1. The initial mesh $\mathcal{T}^{(0)}$ consists of four squares (left) and four triangles (right), respectively.

where \mathcal{I} denotes the Morley interpolant. Second, we have the corresponding residual-based error estimator

$$\eta := \left(\sum_{T \in \mathcal{T}} \eta_T^2 \right)^{1/2},$$

where η_T are the refinement indicators of (5.1). Finally, we have the discretization error in the discrete H^1 -norm

$$E_h := \|u - u_h\|_{1,h} := \left(\|u - u_h\|_{L^2(\Omega)}^2 + |u_{\mathcal{T}} - u_h|_{1,h}^2 \right)^{1/2},$$

where $u_{\mathcal{T}} \in \mathcal{P}_0(\mathcal{T})$ is the \mathcal{T} -piecewise integral mean of u , i.e., $u_{\mathcal{T}}|_T = |T|^{-1} \int_T u \, dx$, and where the discrete H^1 -seminorm is defined by

$$|v_h|_{1,h} = \left(\sum_{E \in \mathcal{E}_E \cup \mathcal{E}_D} \left| \frac{v_{T_E} - v_{T_W}}{d_E} \right|^2 h_E d_E \right)^{1/2}$$

for any \mathcal{T} -piecewise constant function $v_h \in \mathcal{P}_0(\mathcal{T})$. According to [7], the diamond path method satisfies $E_h = \mathcal{O}(h)$ with $h = \max_{T \in \mathcal{T}} h_T$, provided $u \in H^2(\Omega)$. We stress that this, however, is proven only for locally refined Cartesian meshes, i.e., meshes consisting of rectangular elements with at most one hanging node per edge. In the case of triangular meshes, the proof still seems to be open.

6.1. Example with smooth solution. We consider the Laplace problem (1.1) on the unit square $\Omega = (0, 1)^2$ with prescribed exact solution

$$(6.2) \quad u(x, y) = \sinh(\pi x) \cos(\pi y) \quad \text{for } (x, y) \in \Omega.$$

Note that u is smooth and satisfies $f := \Delta u = 0$ so that the data oscillation term $\|h(f - f_{\mathcal{T}})\|_{L^2(\Omega)}$ of the error estimator η vanishes. We consider mixed boundary conditions, where the Dirichlet and Neumann data on

$$(6.3) \quad \Gamma_D = \{1\} \times [0, 1] \cup [0, 1] \times \{1\} \quad \text{and} \quad \Gamma_N = (0, 1) \times \{0\} \cup \{0\} \times (0, 1)$$

are computed from the given exact solution. The initial mesh $\mathcal{T}^{(0)}$ consists of either four squares or four triangles; see Figure 6.3.

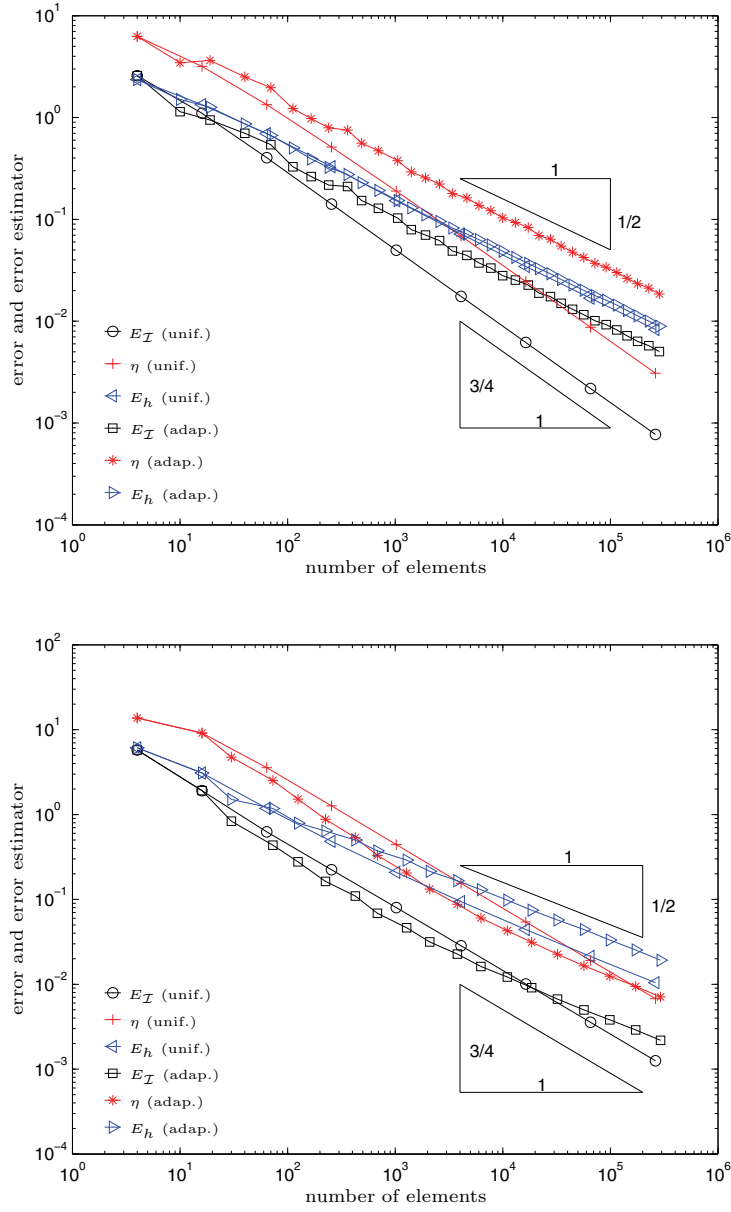

FIG. 6.4. Morley error $E_{\mathcal{I}} = \|\nabla_{\mathcal{T}}(u - \mathcal{I}u_h)\|_{L^2(\Omega)}$ and corresponding error estimator η as well as energy error $E_h = \|u - u_h\|_{1,h}$ in the example in section 6.1 for uniform and adaptive mesh refinement and triangulations consisting of squares (top) and triangles (bottom), respectively.

Figure 6.4 shows the curves of the errors $E_{\mathcal{I}} = \|\nabla_{\mathcal{T}}(u - \mathcal{I}u_h)\|_{L^2(\Omega)}$ and $E_h = \|u - u_h\|_{1,h}$ as well as the curve of the error estimator η with respect to uniform and adaptive mesh refinement. We plot the experimental results over the number of elements, where both axes are scaled logarithmically. Therefore, a straight line g with slope $-\alpha$ corresponds to a dependence $g = \mathcal{O}(N^{-\alpha})$, where $N = \#\mathcal{T}$ denotes

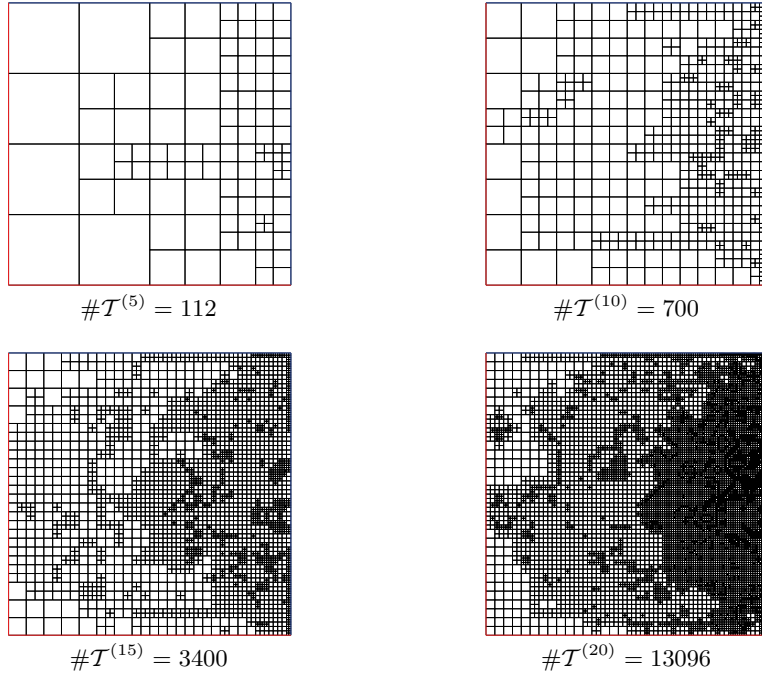

FIG. 6.5. Adaptively generated meshes $\mathcal{T}^{(k)}$ for $k = 5, 10, 15, 20$ with square elements in the example in section 6.1.

FIG. 6.6. \mathcal{T} -piecewise constant solutions u_h in the example in section 6.1 with respect to adaptively generated meshes $\mathcal{T}^{(8)}$ consisting of $\#\mathcal{T}^{(8)} = 361$ squares (left) and $\#\mathcal{T}^{(8)} = 1279$ triangles (right), respectively.

the number of elements. Note that, for uniform mesh refinement, the order $\mathcal{O}(N^{-\alpha})$ with respect to N corresponds to $\mathcal{O}(h^{2\alpha})$ with respect to the maximal mesh size $h := \max_{T \in \mathcal{T}} h_T$.

Because of $u \in H^2(\Omega)$, theory predicts the optimal order of convergence $E_h = \mathcal{O}(N^{-1/2})$ in the case of uniform mesh refinement and square elements. This is, in fact, observed. Moreover, in the case of square elements, the curves of E_h for uniform and adaptive mesh refinement almost coincide. However, the adaptive algorithm does not lead to uniformly refined meshes. Instead, the adaptive meshes plotted in Figure 6.5 show a certain refinement towards the edge $x = 1$ since the gradient of $u(x, y)$ is increasing with $x \rightarrow 1$ (see Figure 6.6), where we visualize some computed

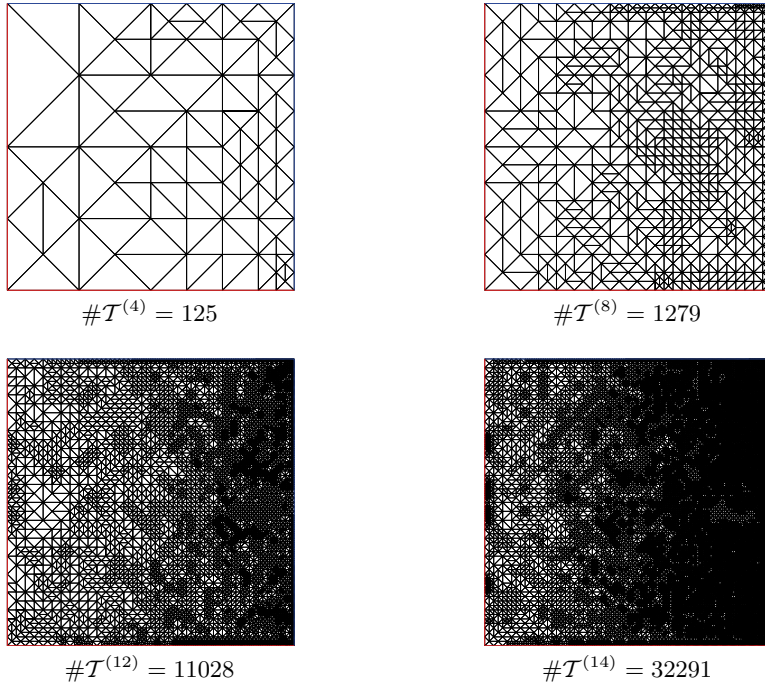

FIG. 6.7. *Adaptively generated meshes $\mathcal{T}^{(k)}$ for $k = 4, 8, 12, 14$ with triangular elements in the example in section 6.1.*

discrete solutions u_h . Although the Dirichlet and Neumann boundaries are not chosen symmetrically, the adaptive meshes appear to be almost symmetric with respect to the line $y = 1/2$, which corresponds to the symmetry $|\nabla u(x, 1/2 - y)| = |\nabla u(x, 1/2 + y)|$ of the exact solution.

For triangular elements, we observe the order $\mathcal{O}(N^{-1/2})$ for both uniform and adaptive mesh refinement. However, the absolute values of E_h are better in the case of uniform mesh refinement. As in the case of rectangular elements, we observe a certain refinement of the adaptively generated meshes towards the right edge $x = 1$ in Figure 6.7, and again they are almost symmetric related to the line $y = 1/2$.

For the Morley error $E_{\mathcal{T}}$ and uniform mesh refinement, we experimentally observe some superconvergence of order $3/4$ for both square and triangular elements in Figure 6.4. This superconvergence is destroyed by the use of adaptive mesh refinement, where we observe only a convergence order $1/2$. Independently of the mesh-refining strategy and the type of elements, we observe the theoretically predicted reliability and efficiency of the error estimator η : The curves of the Morley error $E_{\mathcal{T}}$ and the corresponding error estimator η are parallel up to a certain range.

6.2. Laplace problem with generic singularity. We consider the Laplace problem (1.1) on the L-shaped domain

$$(6.4) \quad \Omega = (-1, 1)^2 \setminus ([0, 1] \times [-1, 0])$$

FIG. 6.8. *L-shaped domain as well as Dirichlet and Neumann boundary conditions in the Laplace problem in section 6.2. The initial mesh $\mathcal{T}^{(0)}$ consists of 12 squares (left) and 12 triangles (right), respectively.*

as shown in Figure 6.8. The given exact solution is the harmonic function $u(x, y) = \text{Im}((x + iy)^{2/3})$ and reads in polar coordinates

$$u(x, y) = r^{2/3} \sin(2\varphi/3) \quad \text{with} \quad (x, y) = r(\cos \varphi, \sin \varphi).$$

Note that u has a generic singularity at the reentrant corner $(0, 0)$, which leads to $u \in H^{1+2/3-\varepsilon}(\Omega)$ for all $\varepsilon > 0$. Therefore, a conforming finite element method with polynomial ansatz space leads to convergence of order $\mathcal{O}(h^{2/3})$ for the finite element error in the H^1 -norm, where h denotes the uniform mesh size. This corresponds to order $\mathcal{O}(N^{-1/3})$ with respect to the number of elements.

For the numerical computation, we prescribe the exact Neumann and Dirichlet data, where

$$\Gamma_D = \Gamma \setminus \Gamma_N \quad \text{and} \quad \Gamma_N := \{0\} \times (-1, 0) \cup (0, 1) \times \{0\}.$$

The initial meshes as well as Γ_D and Γ_N are shown in Figure 6.8. Note that Γ_N includes the reentrant corner, where the normal derivative $\partial u / \partial \mathbf{n}$ is singular.

Figure 6.9 plots the experimental results for the energy error E_h as well as for the Morley error $E_{\mathcal{I}}$ and the corresponding error estimator η over the number of elements. For uniform mesh refinement, the energy error E_h converges with a suboptimal order slightly better than $\mathcal{O}(N^{-1/3})$ for square elements and $\mathcal{O}(N^{-1/3})$ for triangular elements. The proposed adaptive strategy regains the optimal order of convergence $\mathcal{O}(N^{-1/2})$.

As can be expected from the finite element method, the Morley error $E_{\mathcal{I}}$ decreases like $\mathcal{O}(N^{-1/3})$ for uniform mesh refinement. The adaptive algorithm leads to an improved order of convergence $\mathcal{O}(N^{-1/2})$. For both mesh-refining strategies as well as for square and triangular elements, the error estimator η is observed to be reliable and efficient. For a sequence of adaptively generated meshes for both square and triangular elements, see Figures 6.10 and 6.11, respectively.

6.3. Laplace problem with inhomogeneous right-hand side. Finally, we consider the Laplace problem (1.1) on the L-shaped domain (6.4) from the previous experiment. The exact solution is prescribed by $u(x, y) = \text{Im}((x + iy)^{2/3}) + (x^2 + y^2)^{3/2}$ and reads in polar coordinates

$$u(x, y) = r^{2/3} \sin(2\varphi/3) + r^3 \quad \text{with} \quad (x, y) = r(\cos \varphi, \sin \varphi).$$

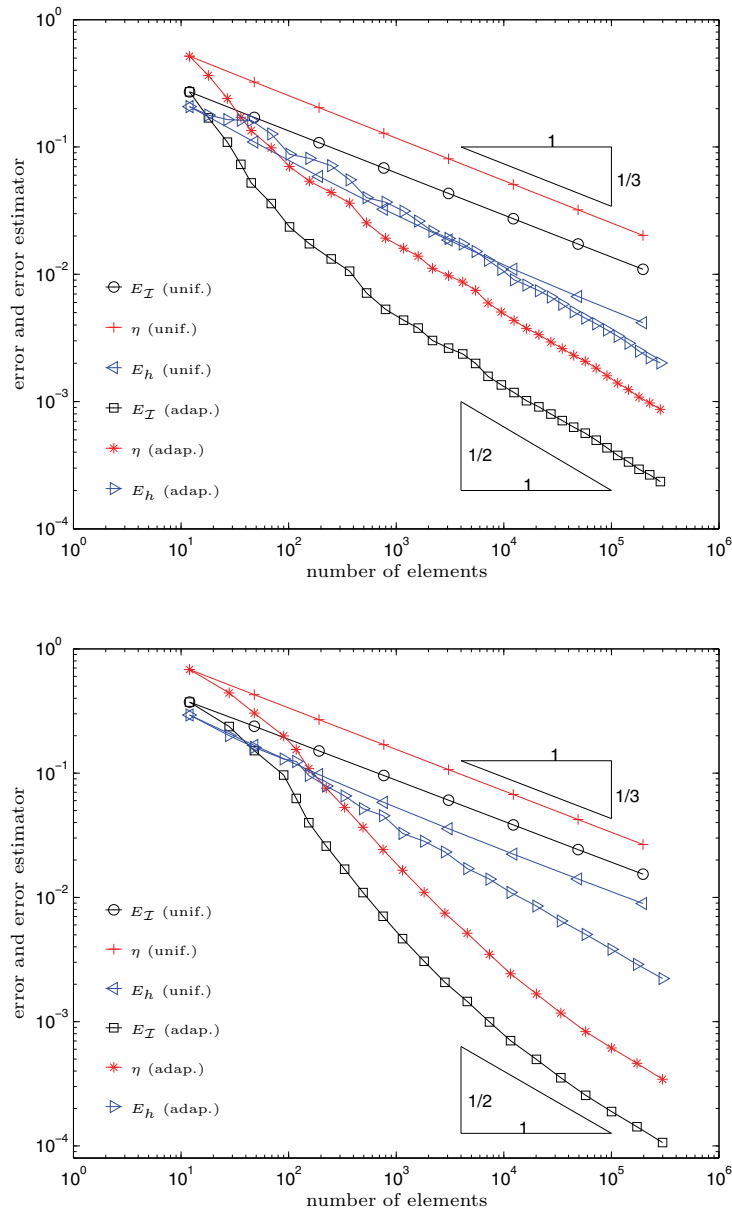

FIG. 6.9. Morley error $E_{\mathcal{I}} = \|\nabla_{\mathcal{T}}(u - \mathcal{I}u_h)\|_{L^2(\Omega)}$ and corresponding error estimator η as well as energy error $E_h = \|u - u_h\|_{1,h}$ in the Laplace problem in section 6.2 for uniform and adaptive mesh refinement and triangulations consisting of squares (top) and triangles (bottom), respectively.

Note that $f = -\Delta u$ reads $f(x, y) = -9(x^2 + y^2)^{1/2}$ (resp., $f(x, y) = -9r$) with respect to polar coordinates. We consider mixed boundary conditions with Γ_D and Γ_N as in the previous experiment. Figure 6.12 shows the numerical results of our computation. Despite a preasymptotic phase, where the f has to be resolved, we observe the same behavior as in the example in section 6.2.

A BDDC METHOD FOR MORTAR DISCRETIZATIONS USING A TRANSFORMATION OF BASIS*

HYEA HYUN KIM[†], MAKSYMILIAN DRYJA[‡], AND OLOF B. WIDLUND[§]

Abstract. A BDDC (balancing domain decomposition by constraints) method is developed for elliptic equations, with discontinuous coefficients, discretized by mortar finite element methods for geometrically nonconforming partitions in both two and three space dimensions. The coarse component of the preconditioner is defined in terms of one mortar constraint for each edge/face, which is the intersection of the boundaries of a pair of subdomains. A condition number bound of the form $C \max_i \{(1 + \log(H_i/h_i))^2\}$ is established under certain assumptions on the geometrically nonconforming subdomain partition in the three-dimensional case. Here H_i and h_i are the subdomain diameters and the mesh sizes, respectively. In the geometrically conforming case and the geometrically nonconforming cases in two dimensions, no assumptions on the subdomain partition are required. This BDDC preconditioner is also shown to be closely related to the Neumann–Dirichlet version of the FETI-DP algorithm. The results are illustrated by numerical experiments which confirm the theoretical results.

1. Introduction. This study concerns a scalable BDDC (balancing domain decomposition by constraints) method for solving linear systems arising from mortar finite element discretizations of elliptic problems with discontinuous coefficients. BDDC methods were first introduced by Dohrmann [5] as an alternative to and an improvement of the balancing Neumann–Neumann methods. These more recent methods use different and more flexible coarse finite element spaces which lead to sparser linear systems. Additionally, as in the dual-primal finite element tearing and interconnecting (FETI-DP) methods, all linear systems actually solved have symmetric, positive definite coefficient matrices.

The coarse basis functions are related to a relatively small set of continuity constraints, across the interface between the subdomains, which are enforced throughout the iteration. In the standard, conforming finite element case, these constraints are given in terms of common values at subdomain vertices and/or common values of averages computed over subdomain edges and/or faces. We will refer to these as *primal* constraints and the corresponding subspace as the primal space of displacements. We

note that the theory (and practice) of BDDC methods for conforming finite elements is by now quite well developed; see [23, 26, 25].

In a FETI-DP method, a linear system, formulated for a set of Lagrange multipliers, is solved after eliminating the displacement variables. The resulting linear system, in itself, contains a coarse problem, which also is directly related to the primal constraints discussed above, i.e., they are given by matching conditions on averages over edges/faces and/or by enforcing continuity of the solutions at vertices. Its preconditioner, on the other hand, is built only from subdomain problems, while for a BDDC method a linear system in the original degrees of freedom is solved in an iteration with a preconditioner that has both coarse and subdomain components. This appears to provide the BDDC methods with more flexibility, e.g., in allowing for the use of inexact coarse problems. Thus, for standard finite element problems an inexact coarse problem can be introduced by applying the BDDC method recursively to the coarse problem; see Tu [30, 29] and a recent conference paper by Mandel, Sousedík, and Dohrmann [27]. The use of inexact local problems for the BDDC preconditioners has also been considered by Li and Widlund [24]. We also note that Klawonn and Rheinbach [17] have developed and extensively tested algorithms which use inexact solvers for the coarse problem of FETI-DP methods.

There are a number of articles on solving the algebraic problems given by the mortar discretizations considered in this paper; see [32] and the literature cited therein. Most of them concern the simpler case of geometrically conforming partitioning of the original region Ω ; see, however, Achdou, Maday, and Widlund [1], where some iterative substructuring methods are developed and analyzed for problems in two dimensions in the geometrically nonconforming case, and Kim and Widlund [13], where an additive Schwarz method with overlap is designed and analyzed. Among the papers on the geometrically conforming case that are related to this paper, we mention [14, 12], where a Neumann–Dirichlet version of a FETI-DP method is analyzed. In [6], a FETI-DP method is considered, which is a generalization of a variant known for the standard conforming discretization. To the best of our knowledge, BDDC methods for the mortar discretization have not previously been discussed in the literature even for the geometrically conforming case.

A condition number bound of the form $C(1 + \log(H/h))^2$ was first given for the BDDC operator by Mandel and Dohrmann [26] for a standard conforming discretization. This bound is of the same quality as the FETI-DP methods. In fact, the BDDC methods have been shown to be closely related to the FETI-DP methods. Thus, Mandel, Dohrmann, and Tezaur [25] have shown that the eigenvalues of the FETI-DP and BDDC operators are the same except possibly for eigenvalues equal to 0 and 1. More recently, a new formulation of the BDDC method was given by Li and Widlund [23]. They introduced a change of variables as well as an average operator for the BDDC method closely related to the jump operator used in [19] in the analysis of FETI-DP methods. The change of variables greatly simplifies the analysis; it has also led to a successful and robust implementation of FETI-DP methods; see [16, 18]. We note that the idea of changing the variables for FETI-DP algorithms was discussed already in [20]. We also note that FETI-DP algorithms have also been implemented using enough point constraints to assure that there are no floating subdomains. In addition, *optional admissible* primal constraints (e.g., averages over edges or faces) are added to enhance the rate of convergence of the iterations; see [9]. These constraints are then handled by a separate set of Lagrange multipliers. We note that in our context, we often have no point constraints, and therefore this second approach cannot be used.

In this paper, we will describe a BDDC method for mortar discretizations, after

a brief introduction to mortar methods. We will use a change of variables, as in [23] and Klawonn and Widlund [21], which is related to the primal constraints over edges/faces. We will consider quite general geometrically nonconforming partitions, i.e., we will not make any assumptions that the intersection of the boundaries of a pair of subdomains is a full face, edge, or a subdomain vertex.

We will work with mortar methods without any continuity constraints at subdomain vertices. Our results are valid for the traditional mortar methods as well as the dual basis mortar methods first introduced by Wohlmuth [31, 32]. We propose a preconditioner with a certain matrix of weights D and obtain the condition number bound, $C \max_i \{(1 + \log(H_i/h_i))^2\}$, under some assumptions on the geometrically nonconforming subdomain partition in three dimensions. When the algorithm is applied to a geometrically conforming partition in three dimensions or a geometrically nonconforming partition in two dimensions, we obtain the same bound without any assumption on the partition. The subdomain partition can have interfaces that are narrow faces and our bounds can be established for such quite general cases. Section 4 is devoted to proving our condition number bound in terms of a bound of an average operator E_D in an appropriate norm.

In section 5, we show that our BDDC preconditioner is closely connected to the Neumann–Dirichlet preconditioner for the FETI-DP methods given in [14, 12]. Connections are established between the average and jump operators, and the spectra of the BDDC and FETI-DP methods are then shown to be the same except possibly for an eigenvalue equal to 1.

Results of numerical experiments are reported in the final section and show that the FETI-DP and BDDC methods perform well and very similarly when the same set of primal constraints is selected.

Throughout this paper, C denotes a generic constant that depends neither on the mesh parameters nor on the coefficients of the elliptic problems.

We note that this paper originated from two projects developed separately by the first and second authors; the contribution of the third began with a suggestion that a theory could be developed for the geometrically nonconforming case using tools similar to those of [23].

2. Finite element spaces and mortar matching constraints.

2.1. A model problem and the mortar methods. We consider a model elliptic problem in a polygonal/polyhedral domain $\Omega \subset \mathbb{R}^2$ (\mathbb{R}^3): find $u \in H_0^1(\Omega)$ such that

$$(2.1) \quad \int_{\Omega} \rho(x) \nabla u(x) \cdot \nabla v(x) \, dx = \int_{\Omega} f(x) v(x) \, dx \quad \forall v \in H_0^1(\Omega),$$

where $\rho(x) \geq \rho_0 > 0$ and $f(x) \in L^2(\Omega)$.

We partition Ω into disjoint polygonal/polyhedral subdomains

$$\bar{\Omega} = \bigcup_{i=1}^N \bar{\Omega}_i.$$

As previously noted, the partition can be geometrically nonconforming; see further discussion below. We assume that $\rho(x) = \rho_i$, $x \in \Omega_i$ for some positive constant ρ_i .

We denote by X_i the P_1 -conforming finite element space on a quasi-uniform triangulation of the subdomain Ω_i . The finite element meshes typically do not align

across subdomain interfaces. The trace space of X_i on $\partial\Omega_i$ is denoted by W_i . We will use the product spaces

$$X := \prod_{i=1}^N X_i, \quad W := \prod_{i=1}^N W_i.$$

For functions in these spaces, we will impose mortar matching conditions across the interfaces using suitable spaces of Lagrange multipliers. Some of these matching conditions will be enforced throughout the iteration; they are directly related to the primal subspace.

In a geometrically nonconforming partition, the intersection of the boundaries of neighboring subdomains may be only part of an edge/face of a subdomain. We define the entire interface by

$$\Gamma = \left(\bigcup_{ij} \partial\Omega_i \cap \partial\Omega_j \right) \setminus \partial\Omega.$$

Among the subdomain edges/faces, we select nonmortar (slave) edges/faces F_l such that

$$\bigcup_l \overline{F_l} = \overline{\Gamma}, \quad F_l \cap F_k = \emptyset, \quad l \neq k;$$

see Figure 1 for an example of the selection of the nonmortar edges. For the case when $\rho(x)$ are very different across the interface, it is beneficial to select the part with smaller ρ_i as the nonmortar; see Assumption 4.2.

Since the subdomain partition can be geometrically nonconforming, a single nonmortar edge/face $F_l \subset \partial\Omega_i$ may intersect the boundaries of several other subdomains Ω_j . This provides F_l with a partition

$$\overline{F_l} = \bigcup_j \overline{F_{ij}}, \quad F_{ij} = \partial\Omega_i \cap \partial\Omega_j;$$

see Figure 1 for the mortar counter parts of the nonmortar edge F_l . A dual or standard Lagrange multiplier space $M(F_l)$ is introduced for each nonmortar edge/face F_l . We require $M(F_l)$ to have the same dimension as the space

$$(2.2) \quad \mathring{W}(F_l) := W_i|_{F_l} \cap H_0^1(F_l),$$

FIG. 1. Nonmortar edges (black) and mortar edges (white) in a geometrically nonconforming partition.

that it is nonempty, and that it contains the constants. Constructions of such Lagrange multiplier spaces are given in [2, 3] using standard Lagrange multiplier spaces, and in [31, 32] using dual Lagrange multiplier spaces; see also [11].

For $(w_1, \dots, w_N) \in W$, $w_i \in W_i$, we define $\phi_l \in L^2(F_l)$ by $\phi_l = w_j$ on $F_{ij} \subset F_l$. The mortar matching condition for the geometrically nonconforming partition is given by

$$(2.3) \quad \int_{F_l} (w_i - \phi_l) \lambda \, ds = 0 \quad \forall \lambda \in M(F_l), \forall F_l.$$

The mortar finite element method for problem (2.1) amounts to approximating the solution of the continuous problem by a Galerkin method using the mortar finite element space

$$\widehat{X} := \{v \in X : v|_\Gamma \text{ satisfies the mortar matching condition (2.3)}\},$$

where $v|_\Gamma$ is the restriction of v to the interface Γ . We introduce the space \widehat{W} as the restriction of \widehat{X} to Γ ,

$$\widehat{W} := \left\{ w : w = v|_\Gamma \, \forall v \text{ in } \widehat{X} \right\}.$$

2.2. Finite element spaces and a change of variables. In this subsection, we introduce a change of variables for some of the unknowns in the space W . It is based on the primal constraints that will be specified for our BDDC method. In mortar discretizations, we may consider the following sets of primal constraints: vertex constraints; vertex and edge average constraints, or edge average constraints only, for two dimensions; and vertex constraints and face average constraints, or face average constraints only, for three dimensions. We note that vertex constraints are appropriate only for the first generation of the mortar methods, in which case the subdomain vertex values are constrained to be continuous. In order to reduce the number of primal constraints, we can also select only some edges/faces as primal. Such choices have been considered for the FETI-DP methods and conforming finite elements in [21], and for mortar finite elements in [15].

In our BDDC formulation, we will select primal constraints over edges/faces from the set of mortar matching constraints (2.3). We consider $\{\lambda_{ij,k}\}_k$, the basis functions of $M(F_l)$ that are supported in $\overline{F}_{ij} \subset \overline{F}_l$, and define

$$(2.4) \quad \lambda_{ij} = \sum_k \lambda_{ij,k}.$$

We assume that at least one such basis function $\lambda_{ij,k}$ exists for each F_{ij} .

We now introduce one primal constraint over each interface $F_{ij} \subset F_l$ and for all edges/faces F_l ,

$$(2.5) \quad \int_{F_{ij}} (w_i - w_j) \lambda_{ij} \, ds = 0,$$

and define

$$(2.6) \quad \widetilde{W} = \{w \in W : w \text{ satisfies the primal constraints (2.5)}\}.$$

We note that $\widehat{W} \subset \widetilde{W} \subset W$, where \widehat{W} is the restriction of \widehat{X} to Γ . For the case of a geometrically conforming partition, i.e., when each F_{ij} is a full edge/face of two subdomains, these constraints are edge/face average matching conditions because $\lambda_{ij} = 1$. In addition to these constraints, vertex constraints can be considered but only if the partition is geometrically conforming.

Throughout this paper, we use hats for functions and function spaces that satisfy all of the mortar matching conditions. We use tildes for functions and function spaces that satisfy only the primal constraints across the subdomain interface.

Following Li and Widlund [23], we now introduce a change of variables based on the primal constraints. We provide details for the two-dimensional case but note that this approach can be extended to the three-dimensional case without any difficulty.

We recall that $F_l \subset \partial\Omega_i$, denoted from now on by F , is a nonmortar edge/face and that $\{F_{ij}\}_j$ is a partition of F given by $F_{ij} = F \cap \partial\Omega_j$, a mortar edge/face of Ω_j . We denote by $\{v_k\}_{k=1}^L$ the values of the unknowns of $w_i \in W_i$ at the nodes on F_{ij} , with nodal basis functions that are supported in \overline{F}_{ij} , and by $\{\eta_k\}_{k=1}^p$ the other unknowns on \overline{F}_{ij} . We will now define a transformation that retains the unknowns $\{\eta_k\}_{k=1}^p$ and changes $\{v_k\}_{k=1}^L$ into $\{\xi_k\}_{k=1}^L$ as follows: we pick one unknown ξ_m among $\{\xi_k\}_{k=1}^L$ and build a transformation $T_{F_{ij}}$ so that

$$(2.7) \quad \begin{pmatrix} \eta \\ v \end{pmatrix} = T_{F_{ij}} \begin{pmatrix} \eta \\ \xi \end{pmatrix}, \quad \xi_m = \frac{\int_{F_{ij}} w_i \lambda_{ij} ds}{\int_{F_{ij}} \lambda_{ij} ds}.$$

Here η , v , and ξ denote vectors of the unknowns $\{\eta_k\}_{k=1}^p$, $\{v_k\}_{k=1}^L$, and $\{\xi_k\}_{k=1}^L$, respectively.

Let

$$A_{\eta_k} = \frac{\int_{F_{ij}} \phi_{\eta_k} \lambda_{ij} ds}{\int_{F_{ij}} \lambda_{ij} ds}, \quad A_{v_k} = \frac{\int_{F_{ij}} \phi_{v_k} \lambda_{ij} ds}{\int_{F_{ij}} \lambda_{ij} ds},$$

where ϕ_{η_k} and ϕ_{v_k} are the nodal basis functions of the unknowns η_k and v_k , respectively. To make the presentation simpler, we assume that $p = 2$, but what follows can be generalized to any p . We will use the following transformation $T_{F_{ij}}$:

$$\begin{pmatrix} \eta_1 \\ \eta_2 \\ v_1 \\ \vdots \\ v_{m-1} \\ v_m \\ v_{m+1} \\ \vdots \\ v_L \end{pmatrix} = T_{F_{ij}} \begin{pmatrix} \eta_1 \\ \eta_2 \\ \xi_1 \\ \vdots \\ \xi_{m-1} \\ \xi_m \\ \xi_{m+1} \\ \vdots \\ \xi_L \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ 0 & 1 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 & A & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & A & 0 & \cdots & 0 \\ c_1 & c_2 & r_1 & \cdots & r_{m-1} & A & r_{m+1} & \cdots & r_L \\ 0 & 0 & 0 & \cdots & 0 & A & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & A & 0 & \cdots & 1 \end{pmatrix}$$

$$\begin{pmatrix} \eta_1 \\ \eta_2 \\ \xi_1 \\ \vdots \\ \xi_{m-1} \\ \xi_m \\ \xi_{m+1} \\ \vdots \\ \xi_L \end{pmatrix} = A \begin{pmatrix} 0 \\ 0 \\ 1 \\ \vdots \\ \vdots \\ \vdots \\ \vdots \\ \vdots \\ \vdots \\ \vdots \\ \vdots \\ \vdots \\ 1 \end{pmatrix} \xi_m + \begin{pmatrix} \eta_1 \\ \eta_2 \\ \xi_1 \\ \vdots \\ \xi_{m-1} \\ \xi_0 \\ \xi_{m+1} \\ \vdots \\ \vdots \\ \vdots \\ \xi_L \end{pmatrix},$$

where

$$\xi_0 = c_1 \eta_1 + c_2 \eta_2 + r_1 \xi_1 + \cdots + r_{m-1} \xi_{m-1} + r_{m+1} \xi_{m+1} + \cdots + r_L \xi_L$$

and

$$A = \frac{\int_{F_{ij}} \lambda_{ij} ds}{\sum_{k=1}^L A_{v_k}}, \quad c_1 = -\frac{A_{\eta_1}}{A_{v_m}}, \quad c_2 = -\frac{A_{\eta_2}}{A_{v_m}}, \quad r_k = -\frac{A_{v_k}}{A_{v_m}}, \quad k \neq m.$$

We can then see that this transformation satisfies the (2.7) requirement. The transformation $T_{F_{ij}}$ can be applied to each face $F_{ij} \subset F$ independently, since it does not change any nodal values other than $\{v_k\}_{k=1}^L$, which are associated with the unknowns of the nodes interior to F_{ij} .

On the other side, the mortar side, of the interface F_{ij} , i.e., $F_{ij} \subset \partial\Omega_j$, we perform a change of basis to the unknowns in finite element space W_j . In this case, we introduce another set of unknowns $\{v_k\}_{k=1}^J$ and $\{\eta_k\}_{k=1}^p$. The unknowns $\{v_k\}_{k=1}^J$ are related to the nodes on F_{ij} with nodal basis functions, which belong to W_j and are supported in $\overline{F_{ij}}$. The unknowns $\{\eta_k\}_{k=1}^p$ are the remaining unknowns on F_{ij} . The transformation $T_{F_{ij}}$ is then defined for these unknowns similarly as for a nonmortar interface.

Using the transforms $T_{F_{ij}}$, we represent the Schur complement of the local stiffness and the mortar matching matrices, and the local force vector in the space of the new unknowns by

$$T^{(i)t} S^{(i)} T^{(i)}, \quad B^{(i)} T^{(i)}, \quad T^{(i)t} g^{(i)}.$$

Here $S^{(i)}$ is the reduced matrix obtained after eliminating all variables associated with only the subdomain Ω_i , and $T^{(i)}$ designates the transform of the original unknowns into the new unknowns of the subdomain boundary $\partial\Omega_i$. In the following, we will use the same notation, $S^{(i)}$, $B^{(i)}$, and $g^{(i)}$, for the matrices and vectors obtained after the change of unknowns, to simplify the notation. We will also use the notation W_i for the space of the new unknowns.

The unknowns ξ_m in (2.7), representing certain weighted averages over the edges, are the primal variables. Using the new variables, the space \widetilde{W} , defined in (2.6), can be represented as

$$(2.8) \quad \widetilde{W} = W_\Delta \oplus \widehat{W}_\Pi,$$

where W_Δ consists of the vectors of unknowns which are not primal unknowns, and \widetilde{W}_Π consists of the vectors of global, primal unknowns.

We now derive the matrix representation of the mortar matching condition (2.3) in the space \widetilde{W} of the new unknowns. The mortar matching condition (2.3) is redundant when enforced for the functions in the space \widetilde{W} . We recall that $\{\lambda_{ij,k}\}_k$ are the Lagrange multiplier basis elements supported in F_{ij} . To make the mortar matching condition nonredundant, we eliminate one basis element among $\{\lambda_{ij,k}\}_k$ for each $F_{ij} \subset F_l$, and we denote the reduced Lagrange multiplier space by $\overline{M}(F_l)$. The entire nonredundant Lagrange multiplier space is then defined as

$$\overline{M} = \prod_l \overline{M}(F_l).$$

The remaining nonprimal, mortar matching conditions of (2.3) are enforced using the reduced space $\overline{M}(F_l)$. In matrix form, this can be written as

$$(2.9) \quad B_\Delta w_\Delta + B_\Pi w_\Pi = 0.$$

The space W_Δ can be split into

$$W_\Delta = W_{\Delta,n} \oplus W_{\Delta,m},$$

where n and m denote unknowns in the interior of the nonmortar edges/faces and the remaining unknowns, respectively. The mortar matching conditions can then be written as

$$(2.10) \quad B_n w_n + B_m w_m + B_\Pi w_\Pi = 0.$$

Since these equations are obtained using only the nonredundant Lagrange multiplier space \overline{M} , the matrix B_n is invertible.

After a symmetric permutation, we can write the local Schur complement and the local Schur complement vector as

$$S^{(i)} = \begin{pmatrix} S_{\Delta\Delta}^{(i)} & S_{\Delta\Pi}^{(i)} \\ S_{\Pi\Delta}^{(i)} & S_{\Pi\Pi}^{(i)} \end{pmatrix}, \quad g^{(i)} = \begin{pmatrix} g_\Delta^{(i)} \\ g_\Pi^{(i)} \end{pmatrix},$$

and define a partially subassembled matrix and two vectors by

$$(2.11) \quad \tilde{S} = \begin{pmatrix} S_{\Delta\Delta} & S_{\Delta\Pi} \\ S_{\Pi\Delta} & S_{\Pi\Pi} \end{pmatrix}, \quad g_\Delta = \begin{pmatrix} g_\Delta^{(1)} \\ \vdots \\ g_\Delta^{(N)} \end{pmatrix}, \quad g_\Pi = \sum_{i=1}^N R_\Pi^{(i)t} g_\Pi^{(i)},$$

where

$$(2.12) \quad \begin{aligned} S_{\Delta\Delta} &= \text{diag}_{i=1}^N \left(S_{\Delta\Delta}^{(i)} \right), \\ S_{\Pi\Delta} &= \left(R_\Pi^{(1)t} S_{\Pi\Delta}^{(1)} \quad \cdots \quad R_\Pi^{(N)t} S_{\Pi\Delta}^{(N)} \right), \quad S_{\Delta\Pi} = S_{\Pi\Delta}^t, \\ S_{\Pi\Pi} &= \sum_{i=1}^N R_\Pi^{(i)t} S_{\Pi\Pi}^{(i)} R_\Pi^{(i)}. \end{aligned}$$

Here $R_\Pi^{(i)}$ is the restriction of the global primal unknowns to the subdomain primal unknowns. The matrix \tilde{S} is central to the description of our BDDC algorithm.

3. A BDDC method for the mortar discretizations. In this section, we will define a BDDC operator for the discrete elliptic problem described in section 2.1. We consider the same finite element space and subdomain partition as in section 2.1 and, as in section 2.2, we will work with the unknowns obtained after the change of variables.

Since the matrix B_n of (2.10) is invertible, we can solve for w_n ,

$$w_n = -B_n^{-1}(B_m w_m + B_\Pi w_\Pi).$$

We next define the matrix

$$(3.1) \quad R_\Gamma = \begin{pmatrix} -B_n^{-1}B_m & -B_n^{-1}B_\Pi \\ I & 0 \\ 0 & I \end{pmatrix},$$

which maps $(w_m^t, w_\Pi^t)^t$ into a vector $(w_n^t, w_m^t, w_\Pi^t)^t$ that satisfies the mortar matching condition (2.10). The mortar finite element space of section 2.1 can then be characterized as

$$\widehat{W} = \left\{ w \in \widetilde{W} : (w_n, w_m, w_\Pi) \text{ satisfies (2.10)} \right\}.$$

In the BDDC method, we work with the following discrete problem:

$$(3.2) \quad R_\Gamma^t \widetilde{S} R_\Gamma \begin{pmatrix} w_m \\ w_\Pi \end{pmatrix} = R_\Gamma^t \begin{pmatrix} g_m \\ g_\Pi \end{pmatrix},$$

where g_m is the component of the vector g_Δ in (2.11) not related to the nonmortar part.

Let us now define, with R_Γ given by (3.1),

$$(3.3) \quad R_{D,\Gamma} = D R_\Gamma = \begin{pmatrix} D_{nn} & & \\ & D_{mm} & \\ & & D_{\Pi\Pi} \end{pmatrix} R_\Gamma,$$

where the scaling matrices are selected to be

$$(3.4) \quad D_{nn} = 0, \quad D_{mm} = I, \quad D_{\Pi\Pi} = I.$$

We now propose the following preconditioner:

$$(3.5) \quad M^{-1} = R_{D,\Gamma}^t \widetilde{S}^{-1} R_{D,\Gamma}$$

for problem (3.2). Using the block Cholesky decomposition of \widetilde{S} as in Li and Widlund [23], we have

$$\widetilde{S}^{-1} = \begin{pmatrix} S_{\Delta\Delta}^{-1} & 0 \\ 0 & 0 \end{pmatrix} + \Psi^t F_{\Pi\Pi}^{-1} \Psi,$$

where

$$F_{\Pi\Pi} = \sum_{i=1}^N \left(R_\Pi^{(i)} \right)^t \left(S_{\Pi\Pi}^{(i)} - S_{\Pi\Delta}^{(i)} S_{\Delta\Delta}^{(i)-1} S_{\Delta\Pi}^{(i)} \right) R_\Pi^{(i)},$$

$$\Psi^t = R_\Pi^t - \sum_{i=1}^N \left(R_\Delta^{(i)} \right)^t \left(S_{\Delta\Delta}^{(i)} \right)^{-1} S_{\Delta\Pi}^{(i)} R_\Pi^{(i)}.$$

Here $R_{\Pi}^{(i)} : \widehat{W}_{\Pi} \rightarrow W_{\Pi}^{(i)}$ is the restriction of the global primal variables to those of the subdomain Ω_i , and $R_{\Pi}^t : \widehat{W}_{\Pi} \rightarrow W_{\Delta} \oplus \widehat{W}_{\Pi}$ and $(R_{\Delta}^{(i)})^t : W_{\Delta}^{(i)} \rightarrow W_{\Delta} \oplus \widehat{W}_{\Pi}$ provide extensions by zero. The columns of the matrix Ψ are coarse basis functions of minimal energy with the value 1 at one of the primal unknowns and vanishing at the other primal unknowns; see [5].

The BDDC operator of the problem, given in (3.2), with the preconditioner M^{-1} , given in (3.5), is then given by

$$(3.6) \quad B_{DDC} = R_{D,\Gamma}^t \widetilde{S}^{-1} R_{D,\Gamma} R_{\Gamma}^t \widetilde{S} R_{\Gamma}.$$

4. Condition number analysis using a bound on E_D . In this section, we will estimate the condition number of the BDDC operator by using the approach introduced in [22]. A bound for the average operator E_D in the \widetilde{S} -norm is central in the analysis; see below. For definitions of R_{Γ} and $R_{D,\Gamma}$, see (3.1) and (3.3), respectively. The operator E_D is defined by

$$(4.1) \quad E_D = R_{\Gamma} R_{D,\Gamma}^t.$$

In the following, we will show that the weight matrix D has been chosen so that

$$(P1) \quad R_{\Gamma}^t R_{D,\Gamma} = R_{D,\Gamma}^t R_{\Gamma} = I,$$

$$(P2) \quad |E_D w|_{\widetilde{S}}^2 \leq C \max_i \left\{ \left(1 + \log \frac{H_i}{h_i} \right)^2 \right\} |w|_{\widetilde{S}}^2.$$

Here $|w|_{\widetilde{S}}^2 = \langle \widetilde{S} w, w \rangle$. We then consider

$$R_{\Gamma}^t R_{D,\Gamma} \begin{pmatrix} w_m \\ w_{\Pi} \end{pmatrix} = \begin{pmatrix} -B_m^t (B_n^t)^{-1} D_{nm} z_n + D_{mm} w_m \\ -B_{\Pi}^t (B_n^t)^{-1} D_{n\Pi} z_n + D_{\Pi\Pi} w_{\Pi} \end{pmatrix},$$

where

$$z_n = -B_n^{-1} (B_m w_m + B_{\Pi} w_{\Pi}).$$

We recall the scaling factors of the weight matrix D in (3.4) and we can easily see that these weights give the (P1) property.

Remark 4.1. The weights above lead to an operator E_D of the form

$$E_D \begin{pmatrix} w_n \\ w_m \\ w_{\Pi} \end{pmatrix} = \begin{pmatrix} -B_n^{-1} (B_m w_m + B_{\Pi} w_{\Pi}) \\ w_m \\ w_{\Pi} \end{pmatrix}.$$

In contrast to the case of conforming finite elements, this does not involve any averaging across the interface. We will still call E_D the average operator, borrowing the name from the conforming case.

We will now show that the average operator E_D satisfies the (P2) property for the weight matrix D just given. As a preparation, we need to establish an estimate for the mortar projection of a function w in \widetilde{W} in the $H_{00}^{1/2}(F)$ -norm. For an edge/face $F \subset \partial\Omega_i$, the space $H_{00}^{1/2}(F)$ consists of the functions for which the zero extension to the whole boundary $\partial\Omega_i$ belongs to the Sobolev space $H^{1/2}(\partial\Omega_i)$. It is equipped with the norm

$$\|w\|_{H_{00}^{1/2}(F)}^2 = |w|_{H^{1/2}(F)}^2 + \int_F \frac{|w(x)|^2}{\text{dist}(x, \partial F)} ds(x).$$

This norm has the well-known property that

$$(4.2) \quad c|\tilde{w}|_{H^{1/2}(\partial\Omega_i)} \leq \|w\|_{H_0^{1/2}(F)} \leq C|\tilde{w}|_{H^{1/2}(\partial\Omega_i)},$$

where \tilde{w} is the zero extension of w to $\partial\Omega_i \setminus F$; see [10, Lemma 1.3.2.6].

We recall that a nonmortar edge/face F of $\partial\Omega_i$ is a union of mortar interfaces F_{ij} common to $\partial\Omega_i$ and $\partial\Omega_j$. We recall that ϕ is a function defined on F with $\phi = w_j$ on each $F_{ij} \subset F$, and with $w_j \in W_j$, the finite element space provided for $\partial\Omega_j$. We then have $\phi \in H^{1/2-\epsilon}(F)$ for any $\epsilon > 0$. Because of the slightly weaker regularity of the function ϕ , caused by the geometrically nonconforming partition, we have some difficulty obtaining the condition number bound with only two logarithmic factors for geometrically nonconforming partitions in three dimensions. We will overcome this difficulty by using an additional finite element space for the interface F_{ij} and an L^2 -projection onto this space. This will result in a condition number bound with two logarithmic factors under some assumptions on the geometry of the subdomain partition; see Assumption 4.3 below.

We also need the following assumption on the coefficients of the elliptic problem. We note that this assumption basically reflects a weakness of the mortar methods in the case of geometrically nonconforming partitions.

ASSUMPTION 4.2. *The coefficients satisfy*

$$\rho_i \leq C\rho_j,$$

where Ω_i and Ω_j correspond to the nonmortar and mortar side of the common set $F_{ij} = \partial\Omega_i \cap \partial\Omega_j$, respectively.

We also will use the following assumption.

ASSUMPTION 4.3. *A geometrically nonconforming partition $\{\Omega_i\}_i$ in three dimensions satisfies the following three assumptions.*

1. *The subdomains are polytopes.*
2. *A quasi-uniform triangulation, with a mesh size comparable to h_i , is possible for the interface F_{ij} .*
3. *Any subdomain has a diameter comparable to those of its neighbors.*

We recall that the finite element space $\mathring{W}(F)$, given in (2.2), and a Lagrange multiplier space $M(F)$ are provided for the nonmortar edge/face F . We now define the mortar projection.

DEFINITION 4.4. *The mortar projection $\pi_F : L^2(F) \rightarrow \mathring{W}(F)$ of the nonmortar edge/face F is defined by*

$$\int_F (v - \pi_F(v))\lambda \, ds = 0 \quad \forall \lambda \in M(F).$$

This mortar projection has been shown to be stable in the L^2 - and $H_0^{1/2}$ -norms in [3, 2, 32].

LEMMA 4.5. *Under Assumptions 4.2 and 4.3 and with $w = (w_1, \dots, w_N) \in \widetilde{W}$, we have*

$$\rho_i \|\pi_F(\phi - w_i)\|_{H_0^{1/2}(F)}^2 \leq C \left(1 + \log \frac{H_i}{h_i}\right)^2 \sum_{k \in I(F)} \langle S^{(k)} w_k, w_k \rangle.$$

Here $F \subset \partial\Omega_i$ is an edge/face, $\phi = w_j$ on $F_{ij} \subset F$, and $I(F)$ is the set of indices of the subdomains with boundaries that intersect F .

Proof. We will prove the result for a geometrically nonconforming partition in three dimensions under Assumption 4.3. In the case of a geometrically conforming partition in three dimensions and for any partition in two dimensions, the same result can be obtained straightforwardly without any assumption on the partition.

For each interface F_{ij} , we define a characteristic function $\chi_{ij} \in L^2(F)$ with the value 1 on F_{ij} and the value 0 on $F \setminus F_{ij}$. In addition, we introduce a quasi-uniform finite element space $U(F_{ij})$ on the interface F_{ij} with a mesh size comparable to h_i , that of the finite element space W_i of the subdomain Ω_i of the nonmortar side. The L^2 -projection onto $U(F_{ij})$ is denoted by Q_{ij} and it satisfies the following properties (see [4, Chapter II]: $\forall w \in H^{1/2}(F_{ij})$):

$$(4.3) \quad \|w - Q_{ij}w\|_{L^2(F_{ij})}^2 \leq Ch_i |w|_{H^{1/2}(F_{ij})}^2, \quad \|Q_{ij}w\|_{H^{1/2}(F_{ij})}^2 \leq C \|w\|_{H^{1/2}(F_{ij})}^2,$$

where the L^2 -term in the $H^{1/2}$ -norm is scaled by $1/|F_{ij}|$. Here $|F_{ij}|$ is the diameter of F_{ij} .

Then, on F , consider

$$\begin{aligned} w_i - \phi &= \sum_j \chi_{ij}(w_i - w_j) \\ &= \sum_j \chi_{ij}((w_i - c_{ij}) - (w_j - c_{ij})). \end{aligned}$$

Here c_{ij} denotes the common average value of w_i and w_j defined by

$$c_{ij} = \frac{\int_{F_{ij}} w_i \lambda_{ij} ds}{\int_{F_{ij}} \lambda_{ij} ds} = \frac{\int_{F_{ij}} w_j \lambda_{ij} ds}{\int_{F_{ij}} \lambda_{ij} ds},$$

where λ_{ij} are defined in (2.4); c_{ij} is closely related to the primal mortar matching condition (2.5).

It suffices to show that

$$(4.4) \quad \|\pi_F(\chi_{ij}(w_j - c_{ij}))\|_{H_0^{1/2}(F)}^2 \leq C \left(1 + \log \frac{H_i}{h_i}\right)^2 |w_j|_{H^{1/2}(\partial\Omega_j)}^2,$$

and to give a similar estimate for $w_i - c_{ij}$. We will prove (4.4) but leave out the estimate for $w_i - c_{ij}$, which is quite similar. The required estimate then follows from Assumption 4.2 and the fact that $|w_j|_{H^{1/2}(\partial\Omega_j)}^2$ is spectrally equivalent to $(1/\rho_j)\langle S^{(j)}w_j, w_j \rangle$.

Let

$$z = w_j - c_{ij}.$$

We decompose $Q_{ij}(z)$ into

$$(4.5) \quad Q_{ij}(z) = I_{F_{ij}}(Q_{ij}(z)) + I_{\partial F_{ij}}(Q_{ij}(z)),$$

where the first term is equal to $Q_{ij}(z)$ at all interior nodal points of F_{ij} and vanishes on ∂F_{ij} while the second term is equal to $Q_{ij}(z)$ at the nodal points of ∂F_{ij} and vanishes at the remaining nodal points of F_{ij} . We have

$$(4.6) \quad \begin{aligned} \|\pi_F(\chi_{ij}(w_j - c_{ij}))\|_{H_0^{1/2}(F)}^2 &= \|\pi_F(\chi_{ij}z)\|_{H_0^{1/2}(F)}^2 \\ &\leq 2\|\pi_F(\chi_{ij}(z - Q_{ij}(z)))\|_{H_0^{1/2}(F)}^2 \\ &\quad + 2\|\pi_F(\chi_{ij}Q_{ij}(z))\|_{H_0^{1/2}(F)}^2. \end{aligned}$$

The first term above is estimated by

$$\begin{aligned}
\|\pi_F(\chi_{ij}(z - Q_{ij}(z)))\|_{H_{00}^{1/2}(F)}^2 &\leq Ch_i^{-1} \|\chi_{ij}(z - Q_{ij}(z))\|_{L^2(F)}^2 \\
&= Ch_i^{-1} \|z - Q_{ij}(z)\|_{L^2(F_{ij})}^2 \\
&\leq C|z|_{H^{1/2}(F_{ij})}^2 \\
(4.7) \qquad \qquad \qquad &\leq C|w_j|_{H^{1/2}(\partial\Omega_j)}.
\end{aligned}$$

We have used an inverse inequality, the L^2 -stability of π_F , and the properties of $Q_{ij}(z)$ given in (4.3).

There remains for us to estimate the second term of (4.6). By Assumption 4.3, the subdomain interfaces F_{ij} are polygonal regions. For a geometrically nonconforming partition, the area of the interface F_{ij} might be comparable to that of F_j , the face of Ω_j such that $F_j \cap \partial\Omega_i = F_{ij}$. In the other case, when F_{ij} is only a small part of F_j , it could be a narrow strip, e.g., $[0, H] \times [0, \delta]$, or a rectangular region with its area comparable to $[0, \delta] \times [0, \delta]$, where δ is comparable to the mesh size h .

We will first consider the second term in (4.6) when the area of the interface F_{ij} is comparable to that of F_j . Using (4.5), we have

$$\begin{aligned}
\|\pi_F(\chi_{ij}Q_{ij}(z))\|_{H_{00}^{1/2}(F)}^2 &= \|\pi_F(\chi_{ij}(I_{F_{ij}}Q_{ij}(z) + I_{\partial F_{ij}}Q_{ij}(z)))\|_{H_{00}^{1/2}(F)}^2 \\
&\leq C \left(\|\tilde{I}_{F_{ij}}(Q_{ij}(z))\|_{H_{00}^{1/2}(F)}^2 + h_i^{-1} \|\tilde{I}_{\partial F_{ij}}Q_{ij}(z)\|_{L^2(F)}^2 \right) \\
(4.8) \qquad \qquad \qquad &\leq C \left(\|I_{F_{ij}}(Q_{ij}(z))\|_{H_{00}^{1/2}(F_{ij})}^2 + \|I_{\partial F_{ij}}Q_{ij}(z)\|_{L^2(\partial F_{ij})}^2 \right),
\end{aligned}$$

where $\tilde{I}_{F_{ij}}(v)$ and $\tilde{I}_{\partial F_{ij}}(v)$ are the extensions of $I_{F_{ij}}(v)$ and $I_{\partial F_{ij}}(v)$ by zero, respectively. Here, we have used an inverse inequality, the stability of π_F in the L^2 - and $H_{00}^{1/2}$ -norms, and the following inequalities:

$$\begin{aligned}
\|\tilde{I}_{F_{ij}}(Q_{ij}(z))\|_{H_{00}^{1/2}(F)} &\leq \|I_{F_{ij}}(Q_{ij}(z))\|_{H_{00}^{1/2}(F_{ij})}, \\
\|\tilde{I}_{\partial F_{ij}}Q_{ij}(z)\|_{L^2(F)}^2 &\leq Ch_i \|I_{\partial F_{ij}}Q_{ij}(z)\|_{L^2(\partial F_{ij})}^2.
\end{aligned}$$

By applying Lemmas 4.17, 4.19, and 4.24 of [28] to the terms of (4.8), and using (4.3) and the Poincaré inequality, we obtain

$$(4.9) \qquad \|\pi_F(\chi_{ij}Q_{ij}(z))\|_{H_{00}^{1/2}(F)}^2 \leq C \left(1 + \log \frac{H_{ij}}{h_i} \right)^2 |w_j|_{H^{1/2}(\partial\Omega_j)}^2,$$

where H_{ij} is the diameter of F_{ij} , which satisfies $H_{ij} \leq H_i$.

We now consider the second term in (4.6) for the case when F_{ij} is only a small part of F_j . Then,

$$\begin{aligned}
\|\pi_F(\chi_{ij}Q_{ij}(z))\|_{H_{00}^{1/2}(F)}^2 &\leq Ch_i^{-1} \|\pi_F(\chi_{ij}Q_{ij}(z))\|_{L^2(F)}^2 \\
&\leq Ch_i^{-1} \|z\|_{L^2(F_{ij})}^2 = Ch_i^{-1} \|w_j - c_{ij}\|_{L^2(F_{ij})}^2 \\
&\leq Ch_i^{-1} \|w_j\|_{L^2(F_{ij})}^2 \\
&\leq Ch_i^{-1} \delta (1 + \log(H_j/\delta)) \|w_j\|_{H^{1/2}(F_j)}^2 \\
(4.10) \qquad \qquad \qquad &\leq C (1 + \log(H_i/h_i)) |w_j|_{H^{1/2}(\partial\Omega_j)}^2.
\end{aligned}$$

Here we have used an inverse inequality, the stability of π_F and Q in the L^2 -norm, the inequality

$$\|c_{ij}\|_{L^2(F_{ij})}^2 \leq C \|w_j\|_{L^2(F_{ij})}^2,$$

Lemma 3.4 of Dryja and Widlund [7] for the fourth inequality, the Poincaré inequality in the last inequality, and that δ is comparable to the mesh size h_i . We note that we have only one log factor in this case.

Therefore, (4.6) combined with (4.7) and (4.9) or (4.10) proves the desired bound (4.4). \square

With the help of Lemma 4.5, we can establish property (P2) for the operator E_D .

LEMMA 4.6. *With Assumptions 4.2 and 4.3, the operator E_D satisfies*

$$|E_D w|_{\tilde{S}}^2 \leq C \max_i \left\{ \left(1 + \log \frac{H_i}{h_i} \right)^2 \right\} |w|_{\tilde{S}}^2 \quad \text{for any } w \in \widetilde{W},$$

where \tilde{S} is defined in (2.11).

Proof. Using the weight matrix D of (3.4), the average operator E_D , given by (4.1), satisfies

$$E_D \begin{pmatrix} w_n \\ w_m \\ w_\Pi \end{pmatrix} = \begin{pmatrix} w_n - B_n^{-1}(B_n w_n + B_m w_m + B_\Pi w_\Pi) \\ w_m \\ w_\Pi \end{pmatrix},$$

as in Remark 4.1. Here $w = (w_n, w_m, w_\Pi) \in \widetilde{W}$. Let

$$\widehat{w}_n = w_n - B_n^{-1}(B_n w_n + B_m w_m + B_\Pi w_\Pi),$$

and construct \widehat{w}_i by restricting the unknowns $(\widehat{w}_n, w_m, w_\Pi)$ to the subdomain Ω_i . Similarly, we construct w_i from (w_n, w_m, w_Π) . We note that (w_1, \dots, w_N) satisfies the primal constraints on the edges/faces. By definition, $\widehat{w} = (\widehat{w}_1, \dots, \widehat{w}_N) \in \widetilde{W}$; i.e., \widehat{w} satisfies all of the mortar matching conditions, and each \widehat{w}_i is of the form

$$\widehat{w}_i = w_i - \sum_{F \subset \partial\Omega_i} \widetilde{\pi}_F(w_i - \phi),$$

where F is a nonmortar edge/face of $\partial\Omega_i$, $\widetilde{\pi}_F(w_i - \phi)$ is the zero extension of $\pi_F(w_i - \phi)$ to all of $\partial\Omega_i \setminus F$, and $\phi = w_j$ on $F_{ij} := \partial\Omega_j \cap \partial\Omega_i \subset F$. We then obtain

$$\begin{aligned} |E_D w|_{\tilde{S}}^2 &= \sum_{i=1}^N \langle S^{(i)} \widehat{w}_i, \widehat{w}_i \rangle \\ &\leq C \sum_{i=1}^N \left(\langle S^{(i)} w_i, w_i \rangle + \sum_{F \subset \partial\Omega_i} \langle S^{(i)} \widetilde{\pi}_F(\phi - w_i), \widetilde{\pi}_F(\phi - w_i) \rangle \right) \\ &\leq C \left(\sum_{i=1}^N \langle S^{(i)} w_i, w_i \rangle + \sum_{i=1}^N \sum_{F \subset \partial\Omega_i} \rho_i \|\pi_F(\phi - w_i)\|_{H_{00}^{1/2}(F)}^2 \right) \\ &\leq C \max_i \left\{ \left(1 + \log \frac{H_i}{h_i} \right)^2 \right\} \sum_{i=1}^N \langle S^{(i)} w_i, w_i \rangle \\ &= C \max_i \left\{ \left(1 + \log \frac{H_i}{h_i} \right)^2 \right\} \langle \tilde{S} w, w \rangle. \end{aligned}$$

Here we have used that $\langle S^{(i)} w_i, w_i \rangle \simeq \rho_i |w_i|_{H^{1/2}(\partial\Omega_i)}^2$, the bounds in (4.2), and Lemma 4.5. \square

By using the properties (P1) and (P2), we can show the following condition number bound for the BDDC operator (3.6). A proof for a quite similar case is given in Li and Widlund [22] in their analysis of a BDDC method for the Stokes problem with conforming meshes. We do not include a proof, which would be almost identical to that of [22].

THEOREM 4.7. *With Assumptions 4.2 and 4.3, we have the condition number bound*

$$\kappa(B_{DDC}) \leq C \max_i \left\{ \left(1 + \log \frac{H_i}{h_i} \right)^2 \right\}.$$

Remark 4.8. For a geometrically nonconforming partition, the number of primal constraints tends to be larger than for a conforming partition if only edge/face constraints are used. We note that there are several previous studies which explore the possibility of selecting primal constraints for only some of the edges/faces; see [15, 21, 19].

5. A connection between the FETI-DP and BDDC methods. In this section, we will show that the BDDC method developed in the previous sections is closely connected to the FETI-DP method developed by the first author in [14, 15] and jointly with Lee in [12]. We will show that the two methods share the same spectra except possibly for an eigenvalue equal to 1.

As previously noted, a comparison of the spectra of the BDDC method to that of the FETI-DP method was made by Mandel, Dohrmann, and Tezaur [25] for conforming finite elements. They showed that the two algorithms have the same set of eigenvalues except possibly for eigenvalues equal to 1. A simpler proof of this fact was given more recently by Li and Widlund [23]. They formulated the BDDC operators, as well as the FETI-DP operators, using a change of variables and introducing certain projections and average operators. These projections and average operators provide an important connection between the FETI-DP and the BDDC operators.

We now formulate an FETI-DP operator after the same change of variables as in section 2.2. We then show that the FETI-DP operator has essentially the same spectrum as the BDDC operator by establishing several properties of the projections and average operators that were used by Li and Widlund [23].

After the change of variables, the linear system considered in the FETI-DP formulation is given by

$$(5.1) \quad \begin{pmatrix} S_{\Delta\Delta} & S_{\Delta\Pi} & B_{\Delta}^t \\ S_{\Pi\Delta} & S_{\Pi\Pi} & B_{\Pi}^t \\ B_{\Delta} & B_{\Pi} & 0 \end{pmatrix} \begin{pmatrix} u_{\Delta} \\ u_{\Pi} \\ \lambda \end{pmatrix} = \begin{pmatrix} g_{\Delta} \\ g_{\Pi} \\ 0 \end{pmatrix},$$

where the matrices $S_{\Delta\Delta}$, $S_{\Delta\Pi}$, $S_{\Pi\Delta}$, and $S_{\Pi\Pi}$ are defined in (2.12) and the matrices B_{Δ} and B_{Π} are obtained from the mortar matching condition (2.9). We recall that the subscripts Π and Δ stand for the unknowns or submatrices related to the primal variables and the remaining part, respectively, and that $\lambda \in \overline{M}$, the reduced, nonredundant Lagrange multiplier space.

After eliminating the unknowns u_{Δ} and u_{Π} , we obtain an equation for $\lambda \in \overline{M}$:

$$(5.2) \quad B_{\Gamma} \tilde{S}^{-1} B_{\Gamma}^t \lambda = d,$$

where

$$(5.3) \quad B_\Gamma = (B_\Delta \quad B_\Pi), \quad \tilde{S} = \begin{pmatrix} S_{\Delta\Delta} & S_{\Delta\Pi} \\ S_{\Pi\Delta} & S_{\Pi\Pi} \end{pmatrix},$$

and d is also the result of the Gaussian elimination.

We will now express the Neumann–Dirichlet preconditioner considered in [14, 15, 12] using the new unknowns. The Neumann–Dirichlet preconditioner M_{DP}^{-1} is defined by

$$(5.4) \quad \langle M_{DP}\lambda, \lambda \rangle = \max_{w_{\Delta,n} \in W_{\Delta,n}} \frac{\langle B_\Gamma \mathcal{E}(w_{\Delta,n}), \lambda \rangle^2}{\langle \tilde{S} \mathcal{E}(w_{\Delta,n}), \mathcal{E}(w_{\Delta,n}) \rangle},$$

where $\mathcal{E}(w_{\Delta,n})$ is the extension by zero of $w_{\Delta,n} \in W_{\Delta,n}$ to elements in the space $\widetilde{W} = W_{\Delta,n} \oplus W_{\Delta,m} \oplus \widehat{W}_\Pi$.

We recall that the matrix B_Δ is partitioned into

$$B_\Delta = (B_n \quad B_m),$$

where n denotes the columns of the nonmortar unknowns and m those that remain. The formula (5.4) can then be written as

$$(5.5) \quad \langle M_{DP}\lambda, \lambda \rangle = \max_{w_{\Delta,n} \in W_{\Delta,n}} \frac{\langle B_n w_{\Delta,n}, \lambda \rangle^2}{\langle S_{nn} w_{\Delta,n}, w_{\Delta,n} \rangle},$$

where S_{nn} is the submatrix of $S_{\Delta\Delta}$ in (5.1) corresponding to the nonmortar part. We see that $S_{nn} : W_{\Delta,n} \rightarrow W'_{\Delta,n}$ and $B_n^t : \overline{M} \rightarrow W'_{\Delta,n}$ are invertible. Here $W'_{\Delta,n}$ is the space dual to $W_{\Delta,n}$. The maximum in (5.5) occurs when $S_{nn} w_{\Delta,n} = B_n^t \lambda$, and hence it follows that

$$M_{DP}^{-1} = (B_n^t)^{-1} S_{nn} B_n^{-1}.$$

Furthermore, this matrix can be written as

$$(5.6) \quad M_{DP}^{-1} = B_{\Sigma,\Gamma}^{-1} \tilde{S} B_{\Sigma,\Gamma}^t,$$

where

$$B_{\Sigma,\Gamma}^t = \begin{pmatrix} \Sigma_{nn} & & \\ & \Sigma_{mm} & \\ & & \Sigma_{\Pi\Pi} \end{pmatrix} \begin{pmatrix} B_n^t \\ B_m^t \\ B_\Pi^t \end{pmatrix}$$

with the weights given by

$$\Sigma_{nn} = (B_n^t B_n)^{-1}, \quad \Sigma_{mm} = 0, \quad \Sigma_{\Pi\Pi} = 0.$$

Therefore, the FETI-DP operator with the Neumann–Dirichlet preconditioner M_{DP}^{-1} is given by

$$M_{DP}^{-1} F_{DP} = B_{\Sigma,\Gamma}^{-1} \tilde{S} B_{\Sigma,\Gamma}^t B_\Gamma \tilde{S}^{-1} B_\Gamma^t,$$

while the preconditioned BDDC operator is given by

$$B_{DDC} = R_{D,\Gamma}^t \tilde{S}^{-1} R_{D,\Gamma} R_\Gamma^t \tilde{S} R_\Gamma.$$

Let us now define the following jump and average operators:

$$P_\Sigma = B_{\Sigma,\Gamma}^t B_\Gamma, \quad E_D = R_\Gamma R_{D,\Gamma}^t.$$

The following results are provided in [23, section 5].

THEOREM 5.1. *Assume that P_Σ and E_D satisfy*

1. $E_D + P_\Sigma = I$,
2. $E_D^2 = E_D$, $P_\Sigma^2 = P_\Sigma$, and
3. $E_D P_\Sigma = P_\Sigma E_D = 0$.

Then the operators $M_{DP}^{-1} F_{DP}$ and B_{DDC} have the same eigenvalues except possibly for an eigenvalue equal to 1.

We will now show that the assumptions of Theorem 5.1 hold for the operators P_Σ and E_D . We recall the definition of the space of functions satisfying the primal constraints

$$\widetilde{W} = \left\{ (w_n^t, w_m^t, w_\Pi^t)^t : \forall w_n \in W_{\Delta,n}, w_m \in W_{\Delta,m}, w_\Pi \in \widehat{W}_\Pi \right\},$$

and the mortar finite element space

$$\widehat{W} = \{w \in \widetilde{W} : B_m w_m + B_\Pi w_\Pi + B_n w_n = 0\}.$$

We note that P_Σ and E_D are operators defined on the space \widetilde{W} .

LEMMA 5.2. *The operators P_Σ and E_D satisfy the assumptions of Theorem 5.1.*

Proof. From

$$\begin{aligned} \Sigma_{mm} &= 0, & \Sigma_{\Pi\Pi} &= 0, & \Sigma_{nn} &= (B_n^t B_n)^{-1}, \\ D_{mm} &= I, & D_{\Pi\Pi} &= I, & D_{nn} &= 0, \end{aligned}$$

we have

$$\begin{aligned} P_\Sigma w &= \begin{pmatrix} B_n^{-1}(B_m w_m + B_\Pi w_\Pi + B_n w_n) \\ 0 \\ 0 \end{pmatrix}, \\ E_D w &= \begin{pmatrix} -B_n^{-1}(B_m w_m + B_\Pi w_\Pi) \\ w_m \\ w_\Pi \end{pmatrix}. \end{aligned}$$

Hence,

$$(5.7) \quad E_D + P_\Sigma = I.$$

From $E_D w = w$ and $P_\Sigma w = 0$ for all $w \in \widehat{W}$, and from $\text{Range}(E_D) \subset \widehat{W}$, we obtain

$$(5.8) \quad E_D^2 = E_D, \quad P_\Sigma E_D = 0.$$

From (5.7), we have the identities

$$E_D(E_D + P_\Sigma) = E_D, \quad P_\Sigma(E_D + P_\Sigma) = P_\Sigma,$$

and combining them with (5.8), we obtain

$$E_D P_\Sigma = 0, \quad P_\Sigma^2 = P_\Sigma. \quad \square$$

Remark 5.3. Other FETI-DP preconditioners in two dimensions with different weights

$$\Sigma = \begin{pmatrix} \Sigma_{nn} & & \\ & \Sigma_{mm} & \\ & & \Sigma_{\Pi\Pi} \end{pmatrix},$$

with nonzero weights Σ_{mm} and Σ_{III} , have been developed and shown to give condition number bounds of the form

$$C \max_i \{ (1 + \log(H_i/h_i))^2 \}$$

for geometrically conforming partitions; see [8, 6]. We have not found any weight matrix D that results in $E_D + P_\Sigma = I$ for such a choice of Σ .

6. Numerical results. In this section, we present numerical results. We first compare the BDDC and the FETI-DP methods with the suggested preconditioners, for geometrically conforming cases, and we then illustrate the performance of our BDDC methods for some geometrically nonconforming partitions. We solve an elliptic problem with the exact solution $u(x, y) = \sin(\pi x)(1 - y)y$,

$$\begin{aligned} -\Delta u &= f \text{ in } \Omega, \\ u &= 0 \text{ on } \partial\Omega, \end{aligned}$$

where Ω is the unit square in \mathbb{R}^2 . The conjugate gradient iteration is halted when the ℓ_2 -norm of the relative residual has been reduced by a factor of 10^6 .

In the first series of experiments, the domain Ω is divided into uniform square subdomains, as in Figure 2, that are geometrically conforming. Common values at the subdomain vertices are selected as the primal constraints for this case. Each subdomain has either a nonuniform mesh or a uniform mesh with n nodes on each subdomain edge. The meshes do not match and have comparable mesh sizes across the interface as in Figure 2.

In Table 1, we show the performance of the two algorithms when Ω is partitioned into $N = 4 \times 4$ subdomains (see Figure 2) and with the local problem size n increasing. In this case, the upper and the right edges of each subdomain are selected to be nonmortar edges; see Figure 2. We provide the L^2 - and H^1 -errors between the exact solution and the solution of the iterative method, the number of conjugate gradient iterations, and the minimum and the maximum eigenvalues of the BDDC and the FETI-DP methods. For the H^1 -error, we use the broken H^1 -norm given by the subdomain partition. Table 2 shows the numerical results when we fix the local problem size to $n - 1 = 4$ and increase N , the number of subdomains to $N = 8 \times 8$, 16×16 , and 32×32 , and divide Ω into square subdomains in the same manner as for $N = 4 \times 4$. We observe that the two methods give the same L^2 - and H^1 -errors. The minimum eigenvalue of the BDDC operator is always equal to 1 while that of the

FETI-DP operator is greater than 1. The maximum eigenvalues of both operators are almost the same; the eigenvalues are estimated by using the parameters of the conjugate gradient iteration. We note that the minimum eigenvalue of the FETI-DP operator converges to 1 when the number of nodes increases; see Table 1. The two algorithms perform quite similarly with good scalability in terms of the local problem size and the number of subdomains.

We next illustrate the performance of the BDDC method for geometrically non-conforming partitions. We divide the unit square Ω into rectangular subdomains that are geometrically nonconforming. For a given N , we first divide Ω into N uniform vertical strips and then each strip into N or $N + 1$ rectangles, in succession; see Figure 3 for $N = 4$. Each subdomain has a uniform mesh with a number of nodes across the subdomain equal to n , $n + 2$, or $n + 4$; see Figure 3. We consider the case when the coefficient $\rho(x) = 1$ in Ω and the case when the coefficient $\rho(x)$ has jumps across the subdomain interfaces; i.e., $\rho(x) = \rho_i$, with different constants in different subdomains Ω_i . See Figure 3 for the distribution of the ρ_i with the values 1, 10, 100, and 1000 in a partition with $N = 4$, and for the selection of nonmortar and mortar edges which satisfies Assumption 4.2 with C less than 1. For the uniform case with $\rho(x) = 1$, we use the same selection of nonmortar and mortar edges. For a larger N , we copy the same pattern periodically. We run the BDDC method with increasing numbers of nodes in a fixed subdomain partition and with an increase of the number of subdomains with a fixed local problem size.

Table 3 presents the condition numbers and the number of iterations for both continuous and discontinuous $\rho(x)$. Since the subdomain partitions are geometrically nonconforming, we have chosen

$$\int_{F_{ij}} (v_i - v_j) \lambda_{ij} ds = 0$$

as the primal constraints for each face $F_{ij} = \partial\Omega_i \cap \partial\Omega_j$. Here λ_{ij} is the sum of the Lagrange multiplier basis functions that are supported in $\overline{F_{ij}}$. We observe good scalability in terms of the number of subdomains and the local problem size for both

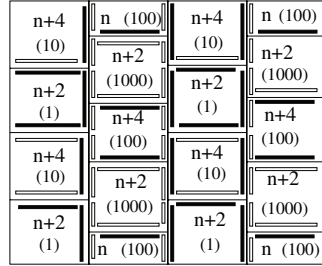

FIG. 3. A geometrically nonconforming partition with $N = 4$ and the number of nodes for each subdomain edge for a given n , and the values of ρ_i (in parentheses) in the jump coefficient case: nonmortar edges (black) and mortar edges (white) which satisfy Assumption 4.2 for the given ρ_i with C less than 1.

FIG. 4. Plot of the values, $\text{Cond}/(1 + \log n)^2$, with an increase of the local problem size, n , in a fixed geometrically nonconforming subdomain partition with $N = 4$; the dashed line is for the case $\rho(x) = 1$ and the solid line for the case with a jump coefficient ρ_i .

cases. In addition, the behavior of the condition number with an increase of the local problem size shows that the condition number bound $(1 + \log(H/h))^2$ appears to be optimal; see Figure 4.

ON PRESSURE APPROXIMATION VIA PROJECTION METHODS FOR NONSTATIONARY INCOMPRESSIBLE NAVIER–STOKES EQUATIONS*

ANDREAS PROHL†

Abstract. Projection methods are an efficient tool to approximate strong solutions of the incompressible Navier–Stokes equations. As a major deficiency, these methods often suffer from reduced accuracy for pressure iterates caused by nonphysical boundary data, going along with suboptimal error estimates for pressure iterates. We verify a rigorous bound for arising boundary layers in Chorin’s scheme under realistic regularity assumptions. In a second step, the new Chorin–Penalty method is proposed, where optimal rate of convergence for pressure iterates is shown.

Key words. Navier–Stokes equations, incompressible fluid, quasi-compressibility method, projection method

1. Introduction. Given an open bounded Lipschitz domain $\Omega \subset \mathbb{R}^d$, for $d = 2, 3$, and a time $T > 0$, we consider the time-dependent Navier–Stokes equations for incompressible, viscous ($\nu > 0$) Newtonian fluids,

$$(1.1) \quad \mathbf{u}_t - \nu \Delta \mathbf{u} + (\mathbf{u} \cdot \nabla) \mathbf{u} + \nabla p = \mathbf{f} \quad \text{in } \Omega_T := (0, T) \times \Omega,$$

$$(1.2) \quad \operatorname{div} \mathbf{u} = 0 \quad \text{in } \Omega_T,$$

$$(1.3) \quad \mathbf{u} = \mathbf{0} \quad \text{on } \partial\Omega_T := (0, T) \times \partial\Omega,$$

$$(1.4) \quad \mathbf{u}(0, \cdot) = \mathbf{u}_0 \quad \text{in } \Omega.$$

Here, $\mathbf{u} : \Omega_T \rightarrow \mathbb{R}^d$ denotes the velocity field, $p : \Omega_T \rightarrow \mathbb{R}$ the scalar pressure of vanishing mean value, i.e., $\int_{\Omega} p(\cdot, \mathbf{x}) \, d\mathbf{x} = 0$, and a given force $\mathbf{f} : \Omega_T \rightarrow \mathbb{R}^d$ is driving the fluid flow, with initial velocity field $\mathbf{u}_0 : \Omega \rightarrow \mathbb{R}^d$.

To construct and analyze numerical schemes for (1.1)–(1.4), we benefit from well-known analytical results for the given problem, which we recall here for the convenience of the reader. For this purpose, we introduce some notation: let $L^p(\Omega)$, $H^r(\Omega)$, and $H_0^r(\Omega)$, for $r \in \mathbb{N}$ be usual Lebesgue and Sobolev spaces, which are endowed with standard scalar products and induced norms $\|\cdot\|_{H^r}$. We recall that $H^{-1}(\Omega) = [H_0^1(\Omega)]^*$. Let $L_0^p(\Omega) \subset L^p(\Omega)$ be the space of functions, whose elements have vanishing integrals. Spaces of vector-valued functions will be indicated with bold-face letters, e.g., $\mathbf{H}_0^1(\Omega) = [H_0^1(\Omega)]^d$, for $d = 2, 3$. We make frequent use of the spaces

$$\mathbf{J}_0(\Omega) = \{\mathbf{v} \in \mathbf{L}^2(\Omega) : \operatorname{div} \mathbf{v} = 0 \text{ in } \Omega, \langle \mathbf{v}, \mathbf{n} \rangle = 0 \text{ on } \partial\Omega\},$$

$$\mathbf{J}_1(\Omega) = \{\mathbf{v} \in \mathbf{H}_0^1(\Omega) : \operatorname{div} \mathbf{v} = 0 \text{ in } \Omega\},$$

where $\langle \cdot, \cdot \rangle$ denotes the standard scalar product in \mathbb{R}^d , and $\mathbf{n}(\mathbf{x}) \in \mathbb{S}^{d-1}$ is the unit vector field pointing outside Ω . For a Banach space X , let $L^p(0, T; X)$, and $W^{m,p}(0, T; X)$ denote standard Bochner spaces.

†Mathematisches Institut, Universität Tübingen, Auf der Morgenstelle 10, D-72076 Tübingen, Germany (prohl@na.uni-tuebingen.de).

Let us recall the concept of weak solutions to (1.1)–(1.4), for $\mathbf{u}_0 \in \mathbf{J}_0(\Omega)$, and $\mathbf{f} \in L^2(0, T, \mathbf{J}_1^*(\Omega))$ from [20, Chapter 3]: A function $\mathbf{u} \in L^2(0, T; \mathbf{J}_1(\Omega)) \cap L^\infty(0, T; \mathbf{J}_0(\Omega))$ is called a weak solution of (1.1)–(1.4), if (1.1)–(1.2) hold in distributional sense, and boundary and initial data in (1.3) and (1.4) are attained. Moreover, we have the following further properties specific for dimensions $d = 2$ and $d = 3$:

- $d = 2$: weak solutions are unique, belong to $W^{1,2}(0, T; \mathbf{J}_1^*(\Omega))$, and hence to $C([0, T]; \mathbf{J}_0(\Omega))$, and satisfy for almost all $t \in [0, T]$ the energy identity (1.5)

$$\frac{1}{2} \|\mathbf{u}(t, \cdot)\|_{L^2}^2 + \nu \int_0^t \|\nabla \mathbf{u}(s, \cdot)\|_{L^2}^2 ds = \frac{1}{2} \|\mathbf{u}_0\|_{L^2}^2 + \int_0^t \langle \mathbf{f}(s, \cdot), \mathbf{u}(s, \cdot) \rangle_{\mathbf{J}_1^* \times \mathbf{J}_1} ds.$$

In addition, provided $\mathbf{u}_0 \in \mathbf{J}_1(\Omega)$, $\mathbf{f} \in L^2(0, T; \mathbf{J}_0(\Omega))$, and Ω has $C^{1,1}$ -boundary or is a convex polygonal domain, there holds

$$(\mathbf{u}, p) \in \left[L^2(0, T; \mathbf{H}^2(\Omega)) \cap C([0, T]; \mathbf{J}_1(\Omega)) \right] \times L^2(0, T; L_0^2(\Omega) \cap H^1(\Omega)).$$

- $d = 3$: weak solutions belong to $W^{1,4/3}(0, T; \mathbf{J}_1^*(\Omega))$, are weakly continuous mappings from $[0, T]$ to $\mathbf{J}_0(\Omega)$, and satisfy an inequality version of (1.5). They are locally strong, provided $\mathbf{u}_0 \in \mathbf{J}_1(\Omega)$, $\mathbf{f} \in L^2(0, T; \mathbf{J}_0(\Omega))$, and Ω has $C^{1,1}$ -boundary.

In below, we always suppose that the data of problems (1.1)–(1.4) satisfy

- (A1) (regularity of domain) The unique solution $\mathbf{w} \in \mathbf{J}_1(\Omega)$ of the stationary, incompressible Stokes problem $-\nu \Delta \mathbf{w} + \nabla \pi = \mathbf{g}$ in $\Omega \subset \mathbb{R}^d$ is already in $\mathbf{J}_1(\Omega) \cap \mathbf{H}^2(\Omega)$, provided $\mathbf{g} \in \mathbf{L}^2(\Omega)$, and satisfies $\|\mathbf{w}\|_{H^2} \leq C \|\mathbf{g}\|_{L^2}$.
- (A2) (regularity of data) For any $T > 0$, let $\mathbf{u}_0 \in \mathbf{J}_1(\Omega) \cap \mathbf{H}^2(\Omega)$, and $\mathbf{f} \in W^{2,\infty}(0, T; \mathbf{L}^2(\Omega))$.

In order to approximate weak solutions of (1.1)–(1.4) by using a general Galerkin method, one proper temporal discretization strategy is the implicit Euler method, where iterates satisfy the (damped) discrete energy law ($M > 0$); see, e.g., [20, Chapter 3],

$$(1.6) \quad \frac{1}{2} \|\mathbf{u}^M\|_{L^2}^2 + \frac{k^2}{2} \sum_{m=1}^M \|d_t \mathbf{u}^m\|_{L^2}^2 + \nu k \sum_{m=1}^M \|\nabla \mathbf{u}^m\|_{L^2}^2 = \frac{1}{2} \|\mathbf{u}_0\|_{L^2}^2 + k \sum_{m=1}^M \langle \mathbf{f}(t_m, \cdot), \mathbf{u}^m \rangle_{\mathbf{J}_1^* \times \mathbf{J}_1}.$$

Here, we denote $d_t \phi^{m+1} := \frac{1}{k} \{\phi^{m+1} - \phi^m\}$, where $k = t_{m+1} - t_m > 0$ is the time-step. For given $\mathbf{f} \in L^2(0, T; \mathbf{J}_0(\Omega))$, the uniform bound (1.6) is then the key to conclude (subsequence) convergence of iterates against weak solutions $\mathbf{u} : \Omega_T \rightarrow \mathbb{R}^d$ of (1.1)–(1.4), for $k \rightarrow 0$.

The practical disadvantage of implicit discretization strategies is the significant computational effort implied from the necessity to solve coupled nonlinear algebraic problems to determine (Galerkin approximations) (\mathbf{u}^m, p^m) at every time-step given by $1 \leq m \leq M$. As a consequence, splitting algorithms were developed to reduce complexity of actual computations; among them, and one of the first, is Chorin's projection method [2, 3, 19], where iterates for velocity field and pressure are independently obtained at every time-step. Below, let $\mathbf{f}^m := \mathbf{f}(t_m, \cdot)$, and suppose that $\mathbf{u}^0 \in \mathbf{J}_1(\Omega)$ is given.

ALGORITHM A. 1. Let $m \geq 0$. Given $\mathbf{u}^m \in \mathbf{J}_0(\Omega)$, find $\tilde{\mathbf{u}}^{m+1} \in \mathbf{H}_0^1(\Omega)$ that satisfies

$$(1.7) \quad \frac{1}{k} \{ \tilde{\mathbf{u}}^{m+1} - \mathbf{u}^m \} - \nu \Delta \tilde{\mathbf{u}}^{m+1} + (\mathbf{u}^m \cdot \nabla) \tilde{\mathbf{u}}^{m+1} = \mathbf{f}^{m+1} \quad \text{in } \Omega.$$

2. Given $\tilde{\mathbf{u}}^{m+1} \in \mathbf{H}_0^1(\Omega)$, compute $(\mathbf{u}^{m+1}, p^{m+1}) \in \mathbf{J}_0(\Omega) \times [L_0^2(\Omega) \cap H^1(\Omega)]$ from

$$(1.8) \quad \frac{1}{k} \{ \mathbf{u}^{m+1} - \tilde{\mathbf{u}}^{m+1} \} + \nabla p^{m+1} = \mathbf{0}, \quad \operatorname{div} \mathbf{u}^{m+1} = 0 \quad \text{in } \Omega,$$

$$(1.9) \quad \langle \mathbf{u}^{m+1}, \mathbf{n} \rangle = 0 \quad \text{on } \partial\Omega.$$

The latter step can be reformulated as a problem for the pressure function only,

$$(1.10) \quad -\Delta p^{m+1} = -\frac{1}{k} \operatorname{div} \tilde{\mathbf{u}}^{m+1} \quad \text{in } \Omega, \quad \partial_{\mathbf{n}} p^{m+1} = 0 \quad \text{on } \partial\Omega.$$

Hence, each step consists of (1.7), (1.10), and the algebraic update (1.8) to obtain $(\mathbf{u}^{m+1}, p^{m+1})$.

In order to understand error effects inherent to temporal discretization, and operator splitting in Chorin's scheme, we shift the index in (1.8) back, and add the equation to (1.7); together with (1.10), we obtain

$$(1.11) \quad d_t \tilde{\mathbf{u}}^{m+1} - \nu \Delta \tilde{\mathbf{u}}^{m+1} + (\mathbf{u}^m \cdot \nabla) \tilde{\mathbf{u}}^{m+1} + \nabla p^m = \mathbf{f}^{m+1} \quad \text{in } \Omega,$$

$$(1.12) \quad \operatorname{div} \tilde{\mathbf{u}}^{m+1} - k \Delta p^{m+1} = 0 \quad \text{in } \Omega,$$

$$(1.13) \quad \partial_{\mathbf{n}} p^{m+1} = 0 \quad \text{on } \partial\Omega.$$

We make the following crucial observations implied from Chorin's decoupling strategy, for every $0 \leq m \leq M$:

- (i) The velocity field $\tilde{\mathbf{u}}^{m+1} : \Omega \rightarrow \mathbb{R}^d$ is *not divergence-free* any more, but satisfies a "quasi-compressibility equation" (1.12), with a penalization parameter equal to the time-step, and a penalization term that requires $p^{m+1} \in [L_0^2(\Omega) \cap H^1(\Omega)]$.
- (ii) Iterates of the pressure satisfy a *homogeneous Neumann boundary condition*, which is in contrast to the pressure $p : \Omega_T \rightarrow \mathbb{R}$ that satisfies (1.1)–(1.4).
- (iii) The pressure iterate in (1.11) is used in an explicit fashion, which *rules out an immediate discrete energy law*, where test functions \mathbf{u}^{m+1} and p^{m+1} in (1.11) and (1.12) are used.

As a consequence of the lack of a discrete energy law, we need not hope to construct weak solutions of (1.1)–(1.4) as proper limits of iterates from Chorin's scheme (e.g., in the sense of weak subsequence convergence). Instead, given that strong solutions to (1.1)–(1.4) exist, we may exploit their improved regularity properties to establish convergence of iterates of Algorithm A at an optimal rate. As already mentioned, strong solutions exist globally in time in 2D, and local existence is known for $d = 3$.

The convergence analysis of Algorithm A has a long history, which started with first studies by Temam [19], and continued with a series of interesting works of Shen, and W. E & J.G. Liu (see, e.g., [17, 6] and [4, 5]), where solutions to (1.1)–(1.4) were assumed to be smooth. Unfortunately, solutions to (1.1)–(1.4) suffer a breakdown of regularity for $t \rightarrow 0$ even for smooth initial data, which is due to an incompatibility of (1.2) and the prescribed data [8], which restricts the applicability of these results. A major step towards getting optimal error estimates in the context of existing strong solutions has been done by Rannacher [16], where the different error effects in Chorin's

method as a semi-implicit pressure-stabilization method (1.11)–(1.13) were pointed out, leading to the following result which is first proved in [13, Theorem 6.1].

THEOREM 1.1. *Let $\{(\tilde{\mathbf{u}}^m, p^m)\}_{m=0}^M$ be the solution of Chorin’s method (1.7)–(1.9), and let (\mathbf{u}, p) be a strong solution of (1.1)–(1.4) up to $t_M = T$. Suppose that*

$$\|\mathbf{u}^0 - \mathbf{u}_0\|_{L^2} + \sqrt{k} \|\mathbf{u}^0 - \mathbf{u}_0\|_{H^1} \leq Ck.$$

For sufficiently small time-steps $k \leq k_0(T)$, there exists a constant $C = C(T) > 0$, such that

$$\begin{aligned} \text{(a)} \quad & \max_{1 \leq m \leq M} \left[\|\mathbf{u}(t_m, \cdot) - \tilde{\mathbf{u}}^m\|_{L^2} + \tau_m \|p(t_m, \cdot) - p^m\|_{H^{-1}} \right] \leq Ck, \\ \text{(b)} \quad & \max_{1 \leq m \leq M} \left[\|\mathbf{u}(t_m, \cdot) - \tilde{\mathbf{u}}^m\|_{H^1} + \sqrt{\tau_m} \|p(t_m, \cdot) - p^m\|_{L^2} \right] \leq C\sqrt{k}, \end{aligned}$$

where $\tau_m = \min\{1, t_m\}$.

Corresponding results hold for $\{\mathbf{u}^m\}_{m=1}^M \subset \mathbf{J}_0(\Omega)$ from Step 2 in Algorithm A, thanks to well-known stability properties of the Helmholtz projection $\mathbf{P}_{\mathbf{J}_0} : \mathbf{L}^2(\Omega) \rightarrow \mathbf{J}_0(\Omega)$; cf. [20].

The proof of Theorem 1.1 in [13] is split into three steps: in a first step, optimal error estimates for the implicit Euler discretization from [8] in the presence of strong solutions of (1.1)–(1.4) are recalled to control time-discretization effects. In a second step, a modified version of (1.11)–(1.13) is studied, where the pressure iterate p^m in (1.11) is shifted to p^{m+1} . We remark that this pressure-stabilization method is of its own interest, since it allows for more finite element pairings [9, 1], where otherwise the discrete LBB condition restricts stable finite element pairings. Optimal error estimates which control perturbation effects due to (1.12) and (1.13) are the key results of the analysis, and provide k -independent a priori bounds for velocity and pressure iterates in strong norms. The latter bounds are then necessary for an optimal error estimate between this auxiliary problem, and (1.11)–(1.13) in the last step, which closes the proof.

Remark 1.1. An extension of this result to a fully discrete (LLB-stable) finite element discretization of Algorithm A is easily possible in the proof in [13]. Moreover, the stabilization effect in Algorithm A allows for equal order finite elements which violate the discrete LBB condition for choices $k \geq Ch^2$ [9]; see [13] for further details.

These $L^2(\Omega)$ -error bounds show optimal convergence behavior for velocity fields computed from Algorithm A, and only suboptimal convergence behavior for pressure iterates, which become optimal in the negative norm $H^{-1}(\Omega) = [H_0^1(\Omega)]^*$. This observation reflects observed boundary layers in the computed pressure iterates, which are caused by the nonphysical boundary condition in (1.10). In [16], it is conjectured that the thickness of the boundary layer is of order $\mathcal{O}(\sqrt{k} |\log(k)|)$, and first order of convergence holds on compact subdomains $\Omega_\delta \Subset \Omega$, where $\text{dist}(\Omega_\delta, \partial\Omega) \geq \delta$, for $\delta = \sqrt{k} |\log(k)|$. The conjecture in [16] is based on a heuristic argument to control the error due to pressure stabilization in the case of the stationary Stokes problem: as has been pointed out above, the perturbation of the incompressibility constraint, and prescription of nonphysical boundary data for the pressure in Algorithm A are accounted for by considering a fully implicit version of (1.11)–(1.13), where the key is again to study the following stationary problem, with $\varepsilon = k$: Find $(\mathbf{u}^\varepsilon, p^\varepsilon) \in [\mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$ such that

$$(1.14) \quad -\nu \Delta \mathbf{u}^\varepsilon + \nabla p^\varepsilon = \mathbf{f}, \quad \text{div } \mathbf{u}^\varepsilon - \varepsilon \Delta p^\varepsilon = 0 \quad \text{in } \Omega,$$

$$(1.15) \quad \partial_{\mathbf{n}} p^\varepsilon = 0 \quad \text{on } \partial\Omega.$$

The following equations control errors $\mathbf{e} := \mathbf{u} - \mathbf{u}^\varepsilon$ and $\eta = p - p^\varepsilon$, where (\mathbf{u}, p) is the strong solution of the stationary incompressible Stokes problem,

$$(1.16) \quad -\nu \Delta \mathbf{e} + \nabla \eta = \mathbf{0}, \quad \operatorname{div} \mathbf{e} - \varepsilon \Delta \eta = -\varepsilon \Delta p \quad \text{in } \Omega,$$

$$(1.17) \quad \partial_{\mathbf{n}} \eta = \partial_{\mathbf{n}} p \quad \text{on } \partial \Omega.$$

Thanks to $\mathbf{e} = \frac{1}{\nu} \Delta_D^{-1} \nabla \eta$, the second identity in (1.16) may be replaced as an equation only for the pressure error $\eta : \Omega \rightarrow \mathbb{R}$, which involves a pseudo-differential operator of order zero, such that

$$(1.18) \quad \frac{1}{\nu} \operatorname{div} \Delta_D^{-1} \nabla \eta - \varepsilon \Delta \eta = -\varepsilon \Delta p \quad \text{in } \Omega, \quad \partial_{\mathbf{n}} \eta = \partial_{\mathbf{n}} p \quad \text{on } \partial \Omega.$$

Here, we denote $\boldsymbol{\psi} := \Delta_D^{-1} \mathbf{w}$ as the solution of $\Delta \boldsymbol{\psi} = \mathbf{w}$ in Ω , and $\boldsymbol{\psi} = \mathbf{0}$ on $\partial \Omega$. In [16], the operator $\operatorname{div} \Delta_D^{-1} \nabla$ is replaced by the identity operator, and the above control of boundary layers is then derived. Our first result in this work is a rigorous derivation of arising boundary layers caused by Chorin's method for existing strong solutions. We use the following notation, with $0 < \delta < \frac{1}{2} \operatorname{diam}(\Omega)$,

$$\Omega_\delta = \{ \mathbf{x} \in \Omega : \operatorname{dist}(\mathbf{x}, \partial \Omega) > \delta \} \Subset \Omega \subset \mathbb{R}^d.$$

THEOREM 1.2. *Suppose that (\mathbf{u}, p) is a strong solution of (1.1)–(1.4) up to time $t_M = T$, with $\mathbf{f} \in C([0, T]; \mathbf{L}^{2r}(\Omega))$, $r \geq 1$, and $\Omega \subset \mathbb{R}^d$ of class $C^{2,\alpha}$, for $0 < \alpha < 1$. Let $\{(\mathbf{u}^m, p^m)\}_{m=1}^M$ be iterates from Algorithm A. Let $\Omega_\delta \subset \mathbb{R}^d$, for $d = 2, 3$. For sufficiently small $k \leq k_0(T)$, and $r^{-1} + (r')^{-1} = 1$, there holds*

$$\begin{aligned} & \max_{1 \leq m \leq M} [\tau_m \|p(t_m, \cdot) - p^m\|_{L^2(\Omega_\delta)}] \\ & \leq C \sqrt{k} \left[\sqrt{k} + \left(\frac{\sqrt{k}}{2r'} \right)^{\frac{1}{2r'}} \|\mathbf{f}\|_{L^\infty(L^{2r})} + \exp\left(-\frac{\delta}{\sqrt{k}}\right) \right]. \end{aligned}$$

The result is verified in section 2, where the key observation is a corresponding bound for errors $\eta \in W^{1,2r}(\Omega)$ which solve (1.18); cf. Theorem 2.1. We remark that the error analysis is of independent interest to, e.g., control the quantitative behavior of errors close to the boundary for pressure stabilization methods [9], where $\varepsilon = \mathcal{O}(h^2)$.

Remark 1.2. 1. The decay property has first been studied by W. E and J.G. Liu in [4] via asymptotic analysis for a restricted model problem, where first order of convergence is established on compact subdomains.

2. Regularity of $\Omega \subset \mathbb{R}^d$ is required to use L^p -theory for strong solutions of the stationary incompressible Stokes problem; cf. [20, Prop. 2.2].

3. This result evidences a boundary layer of order $\delta = \sqrt{k} |\log(k)|$, with improved rate of convergence of almost $\frac{3}{4}$ on subdomains Ω_κ , $\kappa \geq \delta$.

Apparent boundary layers of the projection method cannot be accepted when accurate data for the pressure or the velocity gradient close to the boundary are needed; undesirable consequences include pollution effects to involved quantities in more complex fluid flow problems (e.g., physicochemical hydrodynamics, or magnetohydrodynamics) that cannot be avoided in general [14, 15]. Hence, it is necessary to develop projection methods of comparable computational effort that are exempted from this deficiency. In [13], the *Chorin–Uzawa scheme* ($\beta = 0$) is proposed that avoids this drawback of Chorin's projection method. Let $\beta \geq 0$. The

method again splits each iteration step into several substeps, and starts with initial data $(\mathbf{u}^0, \tilde{\mathbf{u}}^0, p^0, \tilde{p}^0) \in \mathbf{J}_1(\Omega) \times \mathbf{H}_0^1(\Omega) \times [L_0^2(\Omega)]^2$.

ALGORITHM B. 1. For $0 \leq m \leq M$, let $(\mathbf{u}^m, \tilde{\mathbf{u}}^m, p^m, \tilde{p}^m) \in \mathbf{J}_0(\Omega) \times \mathbf{H}_0^1(\Omega) \times [L_0^2(\Omega)]^2$ be given. Find $\tilde{\mathbf{u}}^{m+1} \in \mathbf{H}_0^1(\Omega)$ such that

$$(1.19) \quad \frac{1}{k} \{ \tilde{\mathbf{u}}^{m+1} - \mathbf{u}^m \} - \beta \nabla \operatorname{div} d_t \tilde{\mathbf{u}}^{m+1} - \nu \Delta \tilde{\mathbf{u}}^{m+1} + (\mathbf{u}^m \cdot \nabla) \tilde{\mathbf{u}}^{m+1} + \nabla \{ p^m - \tilde{p}^m \} = \mathbf{f}^{m+1} \quad \text{in } \Omega.$$

2. Find $(\mathbf{u}^{m+1}, \tilde{p}^{m+1}) \in \mathbf{J}_0(\Omega) \times L_0^2(\Omega)$ that solves

$$(1.20) \quad \frac{1}{k} \{ \mathbf{u}^{m+1} - \tilde{\mathbf{u}}^{m+1} \} + \nabla \tilde{p}^{m+1} = 0, \quad \operatorname{div} \mathbf{u}^{m+1} = 0 \quad \text{in } \Omega,$$

$$(1.21) \quad \langle \mathbf{u}^{m+1}, \mathbf{n} \rangle = 0 \quad \text{on } \partial\Omega.$$

3. Determine $p^{m+1} \in L_0^2(\Omega)$ from

$$(1.22) \quad p^{m+1} = p^m - \alpha \operatorname{div} \tilde{\mathbf{u}}^{m+1} \quad \text{in } \Omega, \quad 0 < \alpha < 1.$$

Again, (1.20) may be reformulated as a Poisson problem for the pressure $\tilde{p}^{m+1} : \Omega \rightarrow \mathbb{R}$.

Step 1 in Algorithm B leads to a coupled computation of components of the velocity field, which is due to the second term in (1.19), and which is the price we pay to better enforce the incompressibility constraint. However, other advantages of projection methods are still valid, since velocity and pressure iterates are computed independently.

By eliminating \tilde{p}^{m+1} from the scheme, we easily obtain the following reformulation of the Chorin–Uzawa method as a semiexplicit “artificial compressibility method” [20, 16, 13],

$$(1.23) \quad d_t \tilde{\mathbf{u}}^{m+1} - \beta \nabla \operatorname{div} d_t \tilde{\mathbf{u}}^{m+1} - \nu \Delta \tilde{\mathbf{u}}^{m+1} + (\mathbf{u}^m \cdot \nabla) \tilde{\mathbf{u}}^{m+1} + \nabla p^m = \mathbf{f}^{m+1} \quad \text{in } \Omega,$$

$$(1.24) \quad \operatorname{div} \tilde{\mathbf{u}}^{m+1} + \frac{k}{\alpha} d_t p^{m+1} = 0 \quad \text{in } \Omega,$$

$$(1.25) \quad \tilde{\mathbf{u}}^{m+1} = \mathbf{0} \quad \text{on } \partial\Omega.$$

Since no unphysical boundary conditions are involved any more, and motivated by numerical experiments in [13], we conjecture accurate approximations of the pressure up to the boundary $\partial\Omega$. In fact, the following result is taken from [13, Theorem 8.2].

THEOREM 1.3. Suppose that (\mathbf{u}, p) is a strong solution of (1.1)–(1.4). For $0 < t_{m_1} = \mathcal{O}(1)$, let initial data $\tilde{p}^{m_1} = 0$, and $(\mathbf{u}^{m_1}, \tilde{\mathbf{u}}^{m_1}, p^{m_1}) \in \mathbf{J}_0(\Omega) \times \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ are such that

$$(1.26) \quad \|\mathbf{u}^{m_1} - \mathbf{u}(t_{m_1}, \cdot)\|_{L^2} + \|\tilde{\mathbf{u}}^{m_1} - \mathbf{u}(t_{m_1}, \cdot)\|_{L^2} + \sqrt{k} \|p^{m_1} - p(t_{m_1}, \cdot)\|_{L^2} \leq Ck.$$

Then, iterates $\{(\tilde{\mathbf{u}}^m, p^m)\}_{m=m_1+1}^M$ solving (1.19)–(1.22), for $\beta = 0$, satisfy for $k \leq k_0(T)$,

$$(1.27) \quad \max_{m_1 \leq m \leq M} \left[\|\tilde{\mathbf{u}}^m - \mathbf{u}(t_m, \cdot)\|_{L^2} + \sqrt{k} \|p^m - p(t_m, \cdot)\|_{L^2} \right] + \left(k \sum_{m=m_1}^M \|\tilde{\mathbf{u}}^m - \mathbf{u}(t_m, \cdot)\|_{H^1}^2 \right)^{\frac{1}{2}} \leq C \left(1 + \log \frac{1}{k} \right) k.$$

The Chorin–Uzawa scheme suffers from the need of accurate initial data for the pressure function and additional regularity requirements for strong solutions of (1.1)–(1.4), and computational experiments are reported in [13] where rates of convergence deteriorate if one of the requirements is violated; see also the computational experiments reported in section 5. However, both drawbacks can be avoided, if stretched time-grids $m \mapsto k_m = \min\{mk_0^2, k_0\}$ are used throughout the calculation that refine near the origin to attribute a singular weight to iterates as $t \rightarrow 0$. Obviously, this strategy asymptotically requires the same computational costs; for further details on the *revised Chorin–Uzawa scheme*, we refer to [13, Chapter 10].

Despite this improvement over the original Chorin–Uzawa method, and improved rates of convergence for gradients of computed velocity fields $\{\nabla \mathbf{u}^m\}$, no improved error statements for pressure iterates over those of Theorem 1.3 are known so far. Our goal here is to construct a scheme that does so; for this purpose, we come back to Algorithm B, with positive β , and change (1.22) to

$$(1.28) \quad p^{m+1} = -\frac{1}{k} \operatorname{div} \tilde{\mathbf{u}}^{m+1}.$$

In the sequel, we refer to (1.19)–(1.21), (1.28) as the *Chorin–Penalty scheme*. The following result will be shown in section 3, which verifies optimal order of convergence for iterates $\{p^m\} \subset L_0^2(\Omega)$ of Algorithm B. As will be shown in section 3.3, choices $\beta \geq 1$ are sufficient to effectively account for the decoupling in the Chorin–Penalty scheme; see also Remarks 3.1 and 3.2 below.

THEOREM 1.4. *Suppose that initial data $(\mathbf{u}^0, \tilde{\mathbf{u}}^0, p^0, \tilde{p}^0) \in [\mathbf{H}_0^1(\Omega)]^2 \times [L_0^2(\Omega)]^2$ satisfy*

$$\|\mathbf{u}^0 - \mathbf{u}_0\|_{L^2} + \|\tilde{\mathbf{u}}^0 - \mathbf{u}_0\|_{L^2} \leq Ck, \quad \tilde{p}^0 = p^0 = 0.$$

Let $\{(\tilde{\mathbf{u}}^m, p^m)\}_{m=1}^M$ solve (1.19)–(1.21), (1.28), for $\beta \geq 1$, and let (\mathbf{u}, p) be strong solution to (1.1)–(1.4). There exists $C = C(T) > 0$, such that

$$\max_{1 \leq m \leq M} \left[\|\tilde{\mathbf{u}}^m - \mathbf{u}(t_m, \cdot)\|_{L^2} + \sqrt{\tau_m} \|\tilde{\mathbf{u}}^m - \mathbf{u}(t_m, \cdot)\|_{H^1} + \tau_m \|p^m - p(t_m, \cdot)\|_{L^2} \right] \leq Ck.$$

Remark 1.3. 1. The Chorin–Penalty method can be reformulated as a semi-explicit penalty method; see (3.1)–(3.2). This stationary quasi-compressibility method has been analyzed in [13, Chapter 3].

2. No additional regularity requirements for strong solutions of (1.1)–(1.4) are needed, and $p^0 \equiv \tilde{p}^0 \equiv 0$ is convenient.

Chorin’s original method is by no means the only existing projection method to solve (1.1)–(1.4): over the last four decades, many different further projection schemes have been developed, which use modified splitting strategies (e.g., the Gauge method; see, e.g., [5, 11, 12], modified boundary conditions for pressure iterates), or variants which use higher order temporal discretization, in combination with different projection (or quasi-compressibility) strategies. Recently, an interesting splitting strategy is proposed in [10] to implement boundary conditions consistently; however, the approach requires C^1 -finite elements for the velocity field, and to prove qualitative convergence (without rates) of iterates towards strong solutions of (1.1)–(1.4) requires bounded domains $\Omega \subset \mathbb{R}^d$ ($d = 2, 3$) with C^3 -boundary. Another strategy to avoid artificial boundary layers, and currently studied in the literature, are “velocity-correction methods” [7], where the error analysis requires accurate initial data for the pressure function (see discussion above). All these schemes share the goal to

TABLE 1.1

Comparison of different first-order projection methods: additional regularity requirements for strong solutions of (1.1)–(1.4) needed for convergence analysis are displayed in the first column. The subsequent two columns display convergence rates for different quantities, reflecting presence/absence of boundary layers. The last column indicates the corresponding quasi-compressibility method (QCM).

Method	additional requirements	$(k \sum_{m=1}^M \ \bar{\mathbf{u}}^m - \mathbf{u}(t_m, \cdot)\ _{H^1}^2)^{1/2}$	$\ p^M - p(t_M, \cdot)\ _{L^2}$	Related QCM
Chorin	no	$\leq C \sqrt{k}$	$\leq C \frac{1}{\sqrt{\tau_M}} \sqrt{k}$	pressure stabilization
Chorin–Uzawa	yes	$\leq C k$	$\leq C (1 + \log k) \sqrt{k}$	artificial compressibility
Chorin–Penalty	no	$\leq C k$	$\leq C \frac{1}{\tau_M} k$	penalty

circumvent the drawbacks of Chorin’s original projection scheme, and we refer to [6] for a review of the current state of the art. However, most numerical analyses of these schemes are based on the assumption that solutions of (1.1)–(1.4) are smooth, which leaves unclear whether these results apply to strong solutions which are known to exist. Hence, for general applicability, it is our goal in this work to validate the results discussed above on solid analytical grounds.

The remainder of this work is organized as follows: In section 2, we quantify arising boundary layers due to pressure-stabilization methods for the stationary Stokes problem in the context of strong solutions; see Theorem 2.1. Theorem 1.4 then follows from this result. The main results and properties for the Chorin–Penalty method (i.e., Algorithm B, for $\beta \geq 1$) are given and compared with other methods discussed above in Table 1.1; in section 3, we validate optimal convergence for pressure iterates to strong solutions of (1.1)–(1.4), as stated in Theorem 1.4. Comparative computational studies for Chorin, Chorin–Uzawa, and Chorin–Penalty schemes are reported in section 4. A conclusion is given in section 5.

2. Boundary layers in Chorin’s projection method. As is already discussed in the introduction, Chorin’s projection method, i.e., Algorithm A, suffers from marked boundary layers for the pressure error, which are bounded in Theorem 1.2. In this section, we verify this theorem by first studying a corresponding effect for strong solutions of the stationary, stabilized Stokes problem: For given $\mathbf{f} \in \mathbf{L}^2(\Omega)$, and $\varepsilon > 0$, find solutions $(\mathbf{u}^\varepsilon, p^\varepsilon) \in [\mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$ of $(\nu > 0)$

$$(2.1) \quad -\nu \Delta \mathbf{u}^\varepsilon + \nabla p^\varepsilon = \mathbf{f}, \quad \operatorname{div} \mathbf{u}^\varepsilon - \varepsilon \Delta p^\varepsilon = 0 \quad \text{in } \Omega,$$

$$(2.2) \quad \partial_{\mathbf{n}} p^\varepsilon = 0 \quad \text{on } \partial\Omega.$$

This problem is a perturbation of the incompressible Stokes equation, where strong solutions $(\mathbf{u}, p) \in [\mathbf{J}_1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$ solve $-\nu \Delta \mathbf{u} + \nabla p = \mathbf{f}$ in Ω . Below, we consider compactly contained subsets Ω_δ of Ω ,

$$\Omega_\delta = \{ \mathbf{x} \in \Omega : \operatorname{dist}(\mathbf{x}, \partial\Omega) > \delta \}, \quad \text{for } 0 < \delta < \frac{1}{2} \operatorname{diam}(\Omega).$$

THEOREM 2.1. *Let $\Omega \subset \mathbb{R}^d$, for $d \geq 2$, and $\mathbf{f} \in \mathbf{L}^2(\Omega)$, such that $\operatorname{div} \mathbf{f} \in L^2(\Omega)$. Suppose that (\mathbf{u}, p) is a strong solution of the stationary, incompressible Stokes equation in $\Omega \subset \mathbb{R}^d$, such that $p \in W^{1,2r}(\Omega)$, $r \geq 1$, and $(\mathbf{u}^\varepsilon, p^\varepsilon)$ is a strong solution*

of (2.1) and (2.2). There holds

$$\|p - p^\varepsilon\|_{L^2(\Omega_\delta)} \leq C\sqrt{\varepsilon\nu} \left[\sqrt{\varepsilon\nu} \|\Delta p\|_{L^2} + \left(\frac{\sqrt{\varepsilon\nu}}{2r'}\right)^{\frac{1}{2r'}} \|\nabla p\|_{L^{2r}} + \exp\left(-\frac{\delta}{\sqrt{\varepsilon\nu}}\right) \|\nabla p\|_{L^2} \right].$$

Proof. The equations for the error $(\mathbf{e}, \eta) := (\mathbf{u} - \mathbf{u}^\varepsilon, p - p^\varepsilon)$ are

$$(2.3) \quad \begin{aligned} -\nu\Delta\mathbf{e} + \nabla\eta &= \mathbf{0}, & \operatorname{div}\mathbf{e} - \varepsilon\Delta\eta &= -\varepsilon\Delta p & \text{in } \Omega, \\ \partial_{\mathbf{n}}\eta &= \partial_{\mathbf{n}}p & & & \text{on } \partial\Omega. \end{aligned}$$

Let

$$\sigma(\mathbf{x}) = \exp\left(-\frac{\delta}{\sqrt{\varepsilon\nu}}\right) \min\left[\exp\left(\frac{d(\mathbf{x})}{\sqrt{\varepsilon\nu}}\right), \exp\left(\frac{\delta}{\sqrt{\varepsilon\nu}}\right)\right], \quad \text{where } d(\mathbf{x}) = \operatorname{dist}(\mathbf{x}, \partial\Omega).$$

We employ a duality argument: Find $(\mathbf{w}, q) \in [\mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$, such that

$$(2.4) \quad -\nu\Delta\mathbf{w} + \nabla q = 0, \quad \operatorname{div}\mathbf{w} - \varepsilon\Delta q = \sigma\eta \quad \text{in } \Omega,$$

$$(2.5) \quad \partial_{\mathbf{n}}q = 0 \quad \text{on } \partial\Omega.$$

The following stability bound for solutions of (2.4) and (2.5) is easy to verify:

$$(2.6) \quad \frac{1}{\nu} \|q\|_{L^2}^2 + \nu \|\nabla\mathbf{w}\|_{L^2}^2 + \varepsilon \|\nabla q\|_{L^2}^2 \leq C\nu \|\sigma\eta\|_{L^2}^2.$$

By testing (2.4) with (\mathbf{e}, η) , and (2.3) with (\mathbf{w}, q) , we find

$$(2.7) \quad \begin{aligned} \|\sqrt{\sigma}\eta\|_{L^2}^2 &= \varepsilon(\nabla q, \nabla\eta) + (\operatorname{div}\mathbf{w}, \eta) - (\operatorname{div}\mathbf{e}, q) - \varepsilon(\nabla\eta, \nabla q) + \varepsilon(\nabla q, \nabla p) \\ &\quad - \nu(\nabla\mathbf{w}, \nabla\mathbf{e}) + (\operatorname{div}\mathbf{e}, q) + \nu(\nabla\mathbf{w}, \nabla\mathbf{e}) - (\operatorname{div}\mathbf{w}, \eta) \\ &= \varepsilon(\nabla p, \nabla q) = -\varepsilon(\Delta p, q) + \varepsilon\langle \partial_{\mathbf{n}}p, q \rangle_{\partial\Omega}. \end{aligned}$$

Since $\exp(-\frac{d(\mathbf{x})}{\sqrt{\varepsilon\nu}}) = 1$ on $\partial\Omega$, we further conclude for $\tilde{\sigma}(\mathbf{x}) = \max[\exp(-\frac{d(\mathbf{x})}{\sqrt{\varepsilon\nu}}), \exp(-\frac{\delta}{\sqrt{\varepsilon\nu}})]$,

$$(2.8) \quad \varepsilon\langle \partial_{\mathbf{n}}p, \tilde{\sigma}q \rangle_{\partial\Omega} = \varepsilon(\Delta p, \tilde{\sigma}q) + \varepsilon(\nabla p, \nabla(\tilde{\sigma}q)).$$

There remains to bound the last term in (2.8). By $|\nabla\tilde{\sigma}| \leq \frac{\tilde{\sigma}}{\sqrt{\varepsilon\nu}}$, we conclude

$$\begin{aligned} &\varepsilon(\nabla p, \tilde{\sigma}\nabla q) + \varepsilon(\nabla p, q\nabla\tilde{\sigma}) \\ &\leq C \left[\varepsilon\nu \|\tilde{\sigma}\nabla p\|_{L^2}^2 + \sqrt{\frac{\varepsilon}{\nu}} \int_{\mathcal{B}} |\nabla p| |q| \tilde{\sigma} \, d\mathbf{x} \right] + \frac{\varepsilon}{4\nu} \|\nabla q\|_{L^2}^2 \\ &\leq C\varepsilon\nu \left[\|\tilde{\sigma}\nabla p\|_{L^2(\Omega \setminus \mathcal{B})}^2 + 2\|\tilde{\sigma}\nabla p\|_{L^2(\mathcal{B})}^2 \right] + \frac{1}{4} \left[\frac{\varepsilon}{\nu} \|\nabla q\|_{L^2}^2 + \frac{1}{\nu^2} \|q\|_{L^2}^2 \right], \end{aligned}$$

where $\mathcal{B} := \operatorname{supp}|\nabla\tilde{\sigma}|$, which has d -dimensional Lebesgue measure $\mathcal{L}^d(\mathcal{B}) = \mathcal{O}(\delta)$. Hence,

$$\int_{\mathcal{B}} \exp\left(-\frac{d(\mathbf{x})}{\sqrt{\varepsilon\nu}}\right) \, d\mathbf{x} = \mathcal{O}(\sqrt{\varepsilon\nu}),$$

and we may conclude from (2.7), (2.6) as follows, for $r, r' \geq 1$, such that $\frac{1}{r} + \frac{1}{r'} = 1$,

$$\begin{aligned}
\|\sqrt{\sigma}\eta\|_{L^2} &\leq C\varepsilon\nu\|\Delta p\|_{L^2} \\
&\quad + C\sqrt{\varepsilon\nu}\left[\exp\left(-\frac{\delta}{\sqrt{\varepsilon\nu}}\right)\|\nabla p\|_{L^2(\Omega\setminus\mathcal{B})} + \|\exp\left(-\frac{d(\mathbf{x})}{\sqrt{\varepsilon\nu}}\right)\nabla p\|_{L^2(\mathcal{B})}\right] \\
&\leq C\varepsilon\nu\|\Delta p\|_{L^2} \\
&\quad + C\sqrt{\varepsilon\nu}\left[\exp\left(-\frac{\delta}{\sqrt{\varepsilon\nu}}\right)\|\nabla p\|_{L^2} + \|\nabla p\|_{2r}\left(\int_{\mathcal{B}}\exp\left(-\frac{2r'd(\mathbf{x})}{\sqrt{\varepsilon\nu}}\right)dx\right)^{\frac{1}{2r'}}\right] \\
&\leq C\varepsilon\nu\|\Delta p\|_{L^2} \\
&\quad + C\sqrt{\varepsilon\nu}\left[\exp\left(-\frac{\delta}{\sqrt{\varepsilon\nu}}\right)\|\nabla p\|_{L^2} + \left(\frac{\sqrt{\varepsilon\nu}}{2r'}\right)^{\frac{1}{2r'}}\|\nabla p\|_{L^{2r}}\right].
\end{aligned}$$

Thanks to $\|p\|_{L^2(\Omega_\delta)} \leq \|\sigma p\|_{L^2}$, this proves the assertion of the lemma. \square

Let $1 \leq r < \infty$. By [20, Prop. 2.2], solutions of the incompressible Stokes equation with $\mathbf{f} \in \mathbf{L}^{2r}(\Omega)$ are strong, and satisfy $(\mathbf{u}, p) \in \mathbf{W}^{2,2r}(\Omega) \times W^{1,2r}(\Omega)$, provided the open bounded set $\Omega \subset \mathbb{R}^d$ is of class $C^{2,\alpha}$, for $0 < \alpha < 1$. Then, for large values $r \rightarrow \infty$, the above lemma motivates an $L^2(\Omega_\delta)$ -error decay behavior for the pressure, which is almost order $\frac{3}{4}$ in the interior, and deteriorates to order $\frac{1}{2}$ if errors on a boundary layer of width $\delta = \sqrt{\nu\varepsilon}|\log(\nu\varepsilon)|$ are included.

We use Theorem 2.1 to show Theorem 1.2. As has already be pointed out in the introduction, an error analysis for Algorithm A to optimally bound time-discretization, perturbation, and decoupling error effects is split into three steps; the most critical step to bound arising errors is the one where the pressure stabilization effect is accounted for. As a consequence, we consider the following auxiliary problem: Let $\mathbf{u}_k^0 = \mathbf{u}_0$ be given. For every $0 \leq m \leq M$, find $(\mathbf{u}_k^{m+1}, p_k^{m+1}) \in [\mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$ such that

$$(2.9) \quad d_t \mathbf{u}_k^{m+1} - \nu \Delta \mathbf{u}_k^{m+1} + (\mathbf{P}_{\mathbf{J}_0} \mathbf{u}_k^m \cdot \nabla) \mathbf{u}_k^{m+1} + \nabla p_k^{m+1} = \mathbf{f}^{m+1} \quad \text{in } \Omega,$$

$$(2.10) \quad \operatorname{div} \mathbf{u}_k^{m+1} - k \Delta p_k^{m+1} = 0 \quad \text{in } \Omega,$$

$$(2.11) \quad \partial_{\mathbf{n}} p_k^{m+1} = 0 \quad \text{on } \partial\Omega.$$

The following uniform estimates for solutions $\{(\mathbf{v}^{m+1}, \pi^{m+1})\}_{m=0}^M \subset [\mathbf{J}_1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$ of (2.9) will be useful below; we refer to [16, 13] for a proof.

LEMMA 2.1. *Let (A1), (A2) be valid. Then, iterates $\{(\mathbf{v}^{m+1}, \pi^{m+1})\}_{m=0}^M \subset [\mathbf{J}_1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$ of (2.9) satisfy*

i) *the following uniform bounds for values $i \in \{0, 1, 2\}$, and $r \in \{1, 2, 3\}$,*

$$\max_{r \leq m \leq M} \left[\tau_{m-1}^{r-1+\frac{i}{2}} \|d_t^r \mathbf{v}^m\|_{W^{i,2}} \right] + \left(k \sum_{m=r}^M \tau_{m-1}^{[2(r-1)+i-1]_+} \|d_t^r \mathbf{v}^m\|_{W^{i,2}}^2 \right)^{1/2} \leq C,$$

where $[x]_+ := \max\{x, 0\}$. For values $i \in \{0, 1\}$, and $r \in \{1, 2, 3\}$, there holds

$$\max_{r+1 \leq m \leq M} \left[\tau_{m-1}^{r+\frac{i-1}{2}} \|d_t^r \pi^m\|_{W^{i,2}} \right] + \left(k \sum_{m=r+1}^M \tau_m^{2(r-1)+i} \|d_t^r \pi^m\|_{W^{i,2}}^2 \right)^{1/2} \leq C.$$

ii) the following error estimates, for (\mathbf{u}, p) , a strong solution of (1.1)–(1.4),

$$\begin{aligned} \max_{1 \leq m \leq M} [\|\mathbf{u}(t_m, \cdot) - \mathbf{v}^m\|_{L^2} + \sqrt{\tau_m} [\|p(t_m, \cdot) - \pi^m\|_{H^{-1}} \\ + \|\mathbf{u}(t_m, \cdot) - \mathbf{v}^m\|_{H^1}] + \tau_m \|p(t_m, \cdot) - \pi^m\|_{L^2}] \leq Ck. \end{aligned}$$

We are now in a position to sketch the proof of Theorem 1.2.

Proof. Step 1: consistency error. This error contribution in Algorithm A is accounted for by introducing the semi-implicit Euler scheme as a first auxiliary problem; then, Lemma 2.1 provides both optimal error estimates and stability results for the iterates.

Step 2: quasi-compressibility constraint. Problem (2.9)–(2.11) is the second auxiliary problem to account for error effects due to violating the incompressibility constraint; this is the step where we employ Theorem 2.1 by first considering the following quasi-stationary auxiliary problem, for every $0 \leq m \leq M$: Find $(\mathbf{U}_k^{m+1}, \Pi_k^{m+1}) \in [\mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$ such that

$$(2.12) \quad -\Delta \mathbf{U}_k^{m+1} + \nabla \Pi_k^{m+1} = \mathbf{F}^{m+1} \quad \text{in } \Omega,$$

$$(2.13) \quad \operatorname{div} \mathbf{U}_k^{m+1} - k \Delta \Pi_k^{m+1} = 0 \quad \text{in } \Omega,$$

$$(2.14) \quad \partial_{\mathbf{n}} \Pi_k^{m+1} = 0 \quad \text{in } \partial\Omega,$$

for $\mathbf{F}^{m+1} := \mathbf{f}^{m+1} - d_t \mathbf{v}^{m+1} - (\mathbf{v}^m \cdot \nabla) \mathbf{v}^{m+1}$, and where $\{(\mathbf{v}^{m+1}, \pi^{m+1})\}_{m=0}^M \subset [\mathbf{J}_1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$ solves (2.9). In order to apply Theorem 2.1, we need $\mathbf{F}^{m+1} \in \mathbf{L}^{2r}(\Omega)$ to apply [20, Prop. 2.2]. Thanks to the first result in Lemma 2.1, and Sobolev's inequality for $d = 2, 3$, we easily obtain uniform bounds for $\tau_{m+1} \|\mathbf{F}^{m+1}\|_{L^{2r}}$, with $1 \leq r < \infty$, and hence the right-hand side of (2.12)–(2.14),

$$\begin{aligned} & \|\pi^m - \Pi_k^m\|_{L^2(\Omega_\delta)} \\ & \leq C\sqrt{k\nu} \left[\sqrt{k\nu} \|\Delta \pi^m\|_{L^2} + \left(\frac{\sqrt{k\nu}}{2r'} \right)^{\frac{1}{2r'}} \|\pi^m\|_{W^{1,2r}} + \exp\left(-\frac{\delta}{\sqrt{k\nu}}\right) \|\pi^m\|_{W^{1,2}} \right], \end{aligned}$$

can be controlled uniformly if a time-weight τ_m is used. Next, we employ the bound

$$\max_{1 \leq m \leq M+1} \|\Pi_k^m - p_k^m\|_{L^2(\Omega)} \leq Ck,$$

which is already known from [13, section 6.2], and easily follows from the fact that both p_k^{m+1} and Π_k^{m+1} satisfy (2.13) and (2.14).

Step 3: splitting error. This step controls errors between solutions of systems (2.9)–(2.11) and (1.11)–(1.13). This error analysis leads to first-order estimates for all iterates in the considered norms; see [13, section 6.4] for a detailed analysis. \square

3. Algorithm B: The Chorin–Penalty projection method. In order to analyze the Chorin–Penalty scheme (1.19), (1.20), and (1.28), we use its reformulation as a semi-explicit penalty method,

$$(3.1) \quad \begin{aligned} d_t (\tilde{\mathbf{u}}_k^{m+1} - \beta \nabla \operatorname{div} \tilde{\mathbf{u}}_k^{m+1}) - \nu \Delta \tilde{\mathbf{u}}_k^{m+1} \\ + (\mathbf{P}_{\mathbf{J}_0} \tilde{\mathbf{u}}_k^m \cdot \nabla) \tilde{\mathbf{u}}_k^{m+1} + \nabla p_k^m = \mathbf{f}^{m+1} \quad \text{in } \Omega, \end{aligned}$$

$$(3.2) \quad \operatorname{div} \tilde{\mathbf{u}}_k^{m+1} + k p_k^{m+1} = 0 \quad \text{in } \Omega.$$

The main part of the subsequent analysis focuses on the fully implicit modification of (3.1),

$$(3.3) \quad d_t (\tilde{\mathbf{u}}_k^{m+1} - \beta \nabla \operatorname{div} \tilde{\mathbf{u}}_k^{m+1}) - \nu \Delta \tilde{\mathbf{u}}_k^{m+1} + (\mathbf{P}_{\mathbf{J}_0} \tilde{\mathbf{u}}_k^m \cdot \nabla) \tilde{\mathbf{u}}_k^{m+1} + \nabla q_k^{m+1} = \mathbf{f}^{m+1} \quad \text{in } \Omega,$$

and strong solutions $(\tilde{\mathbf{u}}_k^{m+1}, q_k^{m+1})_{m=0}^M \subset [\mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$, with $\tilde{\mathbf{u}}_k^0 = \mathbf{u}_0$. In the sequel, we use the sequence $\{(\mathbf{v}^{m+1}, \pi^{m+1})\}_{m=0}^M \subset [\mathbf{J}_1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$, with $\mathbf{v}^0 = \mathbf{u}_0$, which solves (2.9). We independently bound errors in (3.3) and (3.2), which are due to the perturbation of the incompressibility constraint in the linear case (section 3.1), from those which are introduced by the nonlinear term (section 3.2), as well as those due to the decoupling strategy in Algorithm B (section 3.3).

Remark 3.1. On putting $\varepsilon = k$, system (3.1)–(3.2) may be considered as a semi-implicit temporal discretization of $(\tilde{\beta} \geq 0)$

$$(3.4) \quad \mathbf{v}_t - \tilde{\beta} \nabla \operatorname{div} \mathbf{v}_t - \nu \Delta \mathbf{v} + (\mathbf{P}_{\mathbf{J}_0} \mathbf{v} \cdot \nabla) \mathbf{v} + \nabla \pi = \mathbf{f} \quad \text{in } \Omega_T,$$

$$(3.5) \quad \operatorname{div} \mathbf{v} + \varepsilon \pi = 0 \quad \text{in } \Omega_T,$$

together with $\mathbf{v}(0, \cdot) = \mathbf{u}_0$ on Ω . For $\tilde{\beta} = 0$, this formulation is known as a penalty method, which is studied in [18], and [13, section 3.2]. Hence, (3.4) is a modification thereof, which uses the additional term $-\tilde{\beta} \nabla \operatorname{div} \mathbf{v}_t$ to additionally enforce the incompressibility constraint for $\tilde{\beta} > 0$.

Another interpretation of system (3.1)–(3.2) for $\beta = 1$ comes from its reformulation

$$(3.6) \quad d_t \tilde{\mathbf{u}}_k^{m+1} - \frac{1}{k} \nabla \operatorname{div} \tilde{\mathbf{u}}_k^{m+1} - \nu \Delta \tilde{\mathbf{u}}_k^{m+1} + (\mathbf{P}_{\mathbf{J}_0} \tilde{\mathbf{u}}_k^m \cdot \nabla) \tilde{\mathbf{u}}_k^{m+1} = \mathbf{f}^{m+1}.$$

Hence, iterates $\{\tilde{\mathbf{u}}_k^m\}_m \subset \mathbf{H}_0^1(\Omega)$ from Algorithm B solve an implicit temporal discretization of the penalty formulation (3.4)–(3.5), with $\varepsilon = k$, and $\tilde{\beta} = 0$. Moreover, a discrete energy law similar to (1.6) holds for solutions of (3.6), which justifies (subsequence) convergence to weak solutions of (1.1)–(1.4) for $k \rightarrow 0$.

For $\beta \geq 1$, system (3.1)–(3.2) combines different stabilizing mechanisms to enforce the incompressibility constraint for $\beta \geq 1$ for iterates $\{\tilde{\mathbf{u}}_k^m\}$. Note that (3.6) is an implicit discretization which effectively describes iterates $\{\tilde{\mathbf{u}}_k^m\}$ in this case, and does not require one to prescribe initial data for the pressure; this is in contrast to Algorithm B, due to the (decoupling) projection step to obtain $\{\mathbf{u}^m\}_m \subset \mathbf{J}_0$.

3.1. Perturbation analysis for the penalized formulation (3.3), (3.2);

Part I: The linear case. Let $\mathbf{w}_k^0 = \mathbf{u}_0$. For every $0 \leq m \leq M$, let $(\mathbf{w}_k^{m+1}, b_k^{m+1}) \in [\mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$ be the strong solution of

$$(3.7) \quad d_t (\mathbf{w}_k^{m+1} - \beta \nabla \operatorname{div} \mathbf{w}_k^{m+1}) - \nu \Delta \mathbf{w}_k^{m+1} + \nabla b_k^{m+1} = \mathbf{F}^{m+1} \quad \text{in } \Omega,$$

$$(3.8) \quad \operatorname{div} \mathbf{w}_k^{m+1} + k b_k^{m+1} = 0 \quad \text{in } \Omega,$$

where $\mathbf{F}^{m+1} = \mathbf{f}^{m+1} - (\mathbf{v}^m \cdot \nabla) \mathbf{v}^{m+1}$, for every $0 \leq m \leq M$. By Lemma 2.1, we have

$$\max_{0 \leq m \leq M} [\|\mathbf{F}^{m+1}\|_{L^2} + \|d_t \mathbf{v}^{m+1}\|_{L^2}] \leq C.$$

Problem (3.7)–(3.8) is a semidiscretization in time of a penalized version of the nonstationary, incompressible Stokes equations. In order to verify optimal rates of convergence with respect to $k > 0$ towards strong solutions of the nonstationary, incompressible Stokes equations, we need to study the following auxiliary problem

first: For every $0 \leq m \leq M$, let $(\mathbf{W}_k^{m+1}, B_k^{m+1}) \in [\mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega)] \times [L_0^2(\Omega) \cap H^1(\Omega)]$ be the strong solution of

$$(3.9) \quad -\nu \Delta \mathbf{W}_k^{m+1} + \nabla B_k^{m+1} = \mathbf{F}^{m+1} - d_t \mathbf{v}^{m+1} \quad \text{in } \Omega,$$

$$(3.10) \quad \operatorname{div} \mathbf{W}_k^{m+1} + k B_k^{m+1} = 0 \quad \text{in } \Omega.$$

The following convergence properties have been shown in [13, section 3.2],

$$(3.11) \quad \|\mathbf{W}_k^m - \mathbf{v}^m\|_{H^1} + \|B_k^m - \pi^m\|_{L^2} \leq C k \|\pi^m\|_{L^2},$$

for every $1 \leq m \leq M$. By linearity of the problem (3.9)–(3.10), and Lemma 2.1, we easily obtain for $r \in \{1, 2, 3\}$,

$$(3.12) \quad \begin{aligned} & \max_{r \leq m \leq M} \tau_m^{r-1/2} [\|d_t^r (\mathbf{W}_k^m - \mathbf{v}^m)\|_{H^1} + \|d_t^r (B_k^m - \pi^m)\|_{L^2}] \\ & + \left(k \sum_{m=r}^M \tau_{m-1}^{2(r-1)} \|d_t^r (\mathbf{W}_k^m - \mathbf{v}^m)\|_{H^1}^2 \right)^{1/2} \leq C k. \end{aligned}$$

In the next step, we bound errors $(\mathbf{e}_k^{m+1}, \eta_k^{m+1}) := (\mathbf{w}_k^{m+1} - \mathbf{W}_k^{m+1}, b_k^{m+1} - B_k^{m+1})$ between solutions of (3.7)–(3.8) and (3.9)–(3.10). We have the following identities ($0 \leq m \leq M$),

$$(3.13) \quad d_t (\mathbf{e}_k^{m+1} - \beta \nabla \operatorname{div} \mathbf{e}_k^{m+1}) - \nu \Delta \mathbf{e}_k^{m+1} + \nabla \eta_k^{m+1} = (\operatorname{Id} - \beta \nabla \operatorname{div}) d_t (\mathbf{v}^{m+1} - \mathbf{W}_k^{m+1}),$$

$$(3.14) \quad \operatorname{div} \mathbf{e}_k^{m+1} + k \eta_k^{m+1} = 0,$$

with $\mathbf{e}_k^{m+1} = \mathbf{0}$ on $\partial\Omega$, and $\mathbf{e}_k^0 = \mathbf{0}$ on Ω . Let $\mathbf{W}_k^0 := \mathbf{u}^0$. By testing (3.13)–(3.14) with $(\mathbf{e}_k^{m+1}, \eta_k^{m+1})$, and using (3.12) we arrive at

$$(3.15) \quad \begin{aligned} & \frac{1}{2} \max_{1 \leq m \leq M} [\|\mathbf{e}_k^m\|_{L^2}^2 + \beta \|\operatorname{div} \mathbf{e}_k^m\|_{L^2}^2] + \frac{k^2}{2} \sum_{m=1}^M [\|d_t \mathbf{e}_k^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t \mathbf{e}_k^m\|_{L^2}^2] \\ & + k \sum_{m=1}^M [\nu \|\nabla \mathbf{e}_k^m\|_{L^2}^2 + k \|\eta_k^m\|_{L^2}^2] \leq C k^2. \end{aligned}$$

This result, together with (3.11), establishes optimal convergence behavior for the velocity field obtained from (3.7)–(3.8) in $\ell^\infty(0, t_M; \mathbf{L}^2)$.

In the next step, we want to verify error bounds for the velocity gradient in $\ell^\infty(0, t_M; \mathbf{L}^2)$. For this purpose, we make r times “discrete derivatives” of (3.13), test with $\tau_{m+1}^{2r} d_t^r \mathbf{e}_k^{m+1}$, $r \in \{1, 2\}$, and use (3.15) to find

$$(3.16) \quad \begin{aligned} & \max_{r \leq m \leq M} \tau_m^{2r} [\|d_t^r \mathbf{e}_k^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t^r \mathbf{e}_k^m\|_{L^2}^2] \\ & + k \sum_{m=r}^M \tau_m^{2r} [\nu \|\nabla d_t^r \mathbf{e}_k^m\|_{L^2}^2 + k \|d_t^r \eta_k^m\|_{L^2}^2] \\ & \leq C k^2 + C k \sum_{m=r}^M \tau_m^{2r-1} \left[\tau_m \|d_t^{r+1} (\mathbf{v}^m - \mathbf{W}_k^m)\|_{L^2}^2 \right. \\ & \left. + (\|d_t^r \mathbf{e}_k^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t^r \mathbf{e}_k^m\|_{L^2}^2) \right]. \end{aligned}$$

A similar argument, together with (3.15) leads to ($r \geq 1$)

$$\begin{aligned}
& k \sum_{m=r}^M \tau_m^{2r-1} \left[\|d_t^r \mathbf{e}_k^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t^r \mathbf{e}_k^m\|_{L^2}^2 \right] \\
& \quad + \max_{r \leq m \leq M} \tau_m^{2r-1} \left[\nu \|\nabla d_t^{r-1} \mathbf{e}_k^m\|_{L^2}^2 + k \|d_t^{r-1} \eta_k^m\|_{L^2}^2 \right] \\
(3.17) \quad & \leq C k^2 + C k \sum_{m=r}^M \left[\tau_m^{2r-1} \|d_t^r (\mathbf{v}^m - \mathbf{W}_k^m)\|_{L^2}^2 \right. \\
& \quad \left. + \tau_m^{2(r-1)} \left(\|\nabla d_t^{r-1} \mathbf{e}_k^m\|_{L^2}^2 + k \|d_t^{r-1} \eta_k^m\|_{L^2}^2 \right) \right].
\end{aligned}$$

We can now combine (3.16), (3.17), and use (3.15) to verify the following bound, for $r \in \{1, 2\}$,

$$\begin{aligned}
& \max_{r \leq m \leq M} \tau_m^{2r-1} \left[\tau_m \left[\|d_t^r \mathbf{e}_k^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t^r \mathbf{e}_k^m\|_{L^2}^2 \right] \right. \\
& \quad \left. + \nu \|\nabla d_t^{r-1} \mathbf{e}_k^m\|_{L^2}^2 + k \|d_t^{r-1} \eta_k^m\|_{L^2}^2 \right] \\
(3.18) \quad & + k \sum_{m=r}^M \tau_m^{2r-1} \left[\nu \tau_m \|\nabla d_t^r \mathbf{e}_k^m\|_{L^2}^2 \right. \\
& \quad \left. + \beta \|\operatorname{div} d_t^r \mathbf{e}_k^m\|_{L^2}^2 + k \tau_m \|d_t^r \eta_k^m\|_{L^2}^2 \right] \leq C k^2.
\end{aligned}$$

Then, Lemma 2.1, (3.11), (3.12), and a stability result for the *div*-operator yields to

$$(3.19) \quad \max_{0 \leq m \leq M} \left[\|\mathbf{u}(t_m, \cdot) - \mathbf{w}_k^m\|_{L^2} + \sqrt{\tau_m} \|\mathbf{u}(t_m, \cdot) - \mathbf{w}_k^m\|_{H^1} + \tau_m \|p(t_m, \cdot) - b_k^m\|_{L^2} \right] \leq C k,$$

with the latter result being a consequence of a stability result for the divergence operator.

3.2. Perturbation analysis for the penalized formulation (3.3), (3.2);

Part II: Extension to the nonlinear case. Because of (3.19), there remains to bound errors $(\boldsymbol{\xi}^{m+1}, \chi^{m+1}) := (\tilde{\mathbf{u}}_k^{m+1} - \mathbf{w}_k^{m+1}, q_k^{m+1} - b_k^{m+1})$ to estimate the error between strong solutions of (1.1)–(1.4), and (3.3), (3.2). We subtract the equations (3.7)–(3.8) of the linear auxiliary problem from the corresponding ones (3.3)–(3.2). For every $0 \leq m \leq M$, there holds

$$(3.20) \quad d_t (\boldsymbol{\xi}^{m+1} - \beta \nabla \operatorname{div} \boldsymbol{\xi}^{m+1}) - \nu \Delta \boldsymbol{\xi}^{m+1} + \nabla \chi^{m+1} = (\mathbf{v}^m \cdot \nabla) \mathbf{v}^{m+1} - (\mathbf{P}_{\mathbf{J}_0} \tilde{\mathbf{u}}_k^m \cdot \nabla) \tilde{\mathbf{u}}_k^{m+1},$$

$$(3.21) \quad \operatorname{div} \boldsymbol{\xi}^{m+1} + k \chi^{m+1} = 0.$$

We compute

$$\begin{aligned}
& -(\mathbf{v}^m \cdot \nabla) \mathbf{v}^{m+1} + (\mathbf{P}_{\mathbf{J}_0} \mathbf{u}_k^m \cdot \nabla) \mathbf{u}_k^{m+1} = (\mathbf{P}_{\mathbf{J}_0} \boldsymbol{\xi}^m \cdot \nabla) \mathbf{v}^{m+1} + (\mathbf{P}_{\mathbf{J}_0} \tilde{\mathbf{u}}_k^m \cdot \nabla) \boldsymbol{\xi}^{m+1} \\
& \quad - (\mathbf{P}_{\mathbf{J}_0} \tilde{\mathbf{u}}_k^m \cdot \nabla) (\mathbf{v}^{m+1} - \mathbf{w}_k^{m+1}) - (\mathbf{P}_{\mathbf{J}_0} (\mathbf{v}^m - \mathbf{w}_k^m) \cdot \nabla) \mathbf{v}^{m+1}.
\end{aligned}$$

This observation, the skew-symmetricity property $((\mathbf{P}_{\mathbf{J}_0} \boldsymbol{\phi} \cdot \nabla) \boldsymbol{\psi}, \boldsymbol{\psi}) = 0$ for $\boldsymbol{\psi} \in \mathbf{H}_0^1(\Omega)$, and the \mathbf{H}^1 -stability of $\mathbf{P}_{\mathbf{J}_0}$ then lead to

$$\begin{aligned}
& \frac{1}{2} \max_{1 \leq m \leq M} \left[\|\boldsymbol{\xi}^m\|_{L^2}^2 + \beta \|\operatorname{div} \boldsymbol{\xi}^m\|_{L^2}^2 \right] + \frac{k^2}{2} \sum_{m=1}^M \left[\|d_t \boldsymbol{\xi}^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t \boldsymbol{\xi}^m\|_{L^2}^2 \right] \\
& + k \sum_{m=1}^M \left[\frac{\nu}{2} \|\nabla \boldsymbol{\xi}^m\|_{L^2}^2 + k \|\chi^m\|_{L^2}^2 \right] \\
& \leq \left[\|\boldsymbol{\xi}^0\|_{L^2}^2 + \|\operatorname{div} \boldsymbol{\xi}^0\|_{L^2}^2 \right] + C k \sum_{m=1}^M \|\Delta \mathbf{v}^m\|_{L^2}^2 \left[\|\boldsymbol{\xi}^m\|_{L^2}^2 + \|\mathbf{v}^m - \mathbf{w}_k^m\|_{L^2}^2 \right] \\
& + \left| \left((\mathbf{P}_{\mathbf{J}_0} \tilde{\mathbf{u}}_k^{m-1} \cdot \nabla) (\mathbf{v}^m - \mathbf{w}_k^m), \boldsymbol{\xi}^m \right) \right| \\
& \leq C k^2 + k \sum_{m=1}^M \|\boldsymbol{\xi}^m\|_{L^2}^2 + k \sum_{m=1}^M \left[\|\nabla \boldsymbol{\xi}^{m-1}\|_{L^2} + \|\nabla (\mathbf{v}^{m-1} - \mathbf{w}_k^{m-1})\|_{L^2} \right] \\
& \quad \times \|\nabla (\mathbf{v}^m - \mathbf{w}_k^m)\|_{L^2} \|\boldsymbol{\xi}^m\|_{L^2}^{1/2} \|\nabla \boldsymbol{\xi}^m\|_{L^2}^{1/2} + k \sum_{m=1}^M \left[\|\boldsymbol{\xi}^m\|_{L^2}^2 + \|\mathbf{v}^m - \mathbf{w}_k^m\|_{L^2}^2 \right].
\end{aligned}$$

We use Lemma 2.1, ii), and (3.19) to conclude with the discrete Gronwall's inequality that

$$\begin{aligned}
& \max_{1 \leq m \leq M} \left[\|\boldsymbol{\xi}^m\|_{L^2}^2 + \beta \|\operatorname{div} \boldsymbol{\xi}^m\|_{L^2}^2 \right] + \frac{k^2}{2} \sum_{m=1}^M \left[\|d_t \boldsymbol{\xi}^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t \boldsymbol{\xi}^m\|_{L^2}^2 \right] \\
(3.22) \quad & + k \sum_{m=1}^M \left[\nu \|\nabla \boldsymbol{\xi}^m\|_{L^2}^2 + k \|\chi^m\|_{L^2}^2 \right] \leq C k^2.
\end{aligned}$$

Next, making “discrete time-derivatives” in (3.20), (3.21) with respect to time, and then test the system with $(\tau_{m+1}^2 d_t \boldsymbol{\xi}^{m+1}, \tau_{m+1}^2 d_t \chi_{m+1})$,

$$\begin{aligned}
& \max_{2 \leq m \leq M} \tau_m^2 \left[\|d_t \boldsymbol{\xi}^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t \boldsymbol{\xi}^m\|_{L^2}^2 \right] \\
& + k^2 \sum_{m=2}^M \tau_m^2 \left[\|d_t^2 \boldsymbol{\xi}^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t \boldsymbol{\xi}^m\|_{L^2}^2 \right] \\
(3.23) \quad & + k \sum_{m=2}^M \tau_m^2 \left[\nu \|\nabla d_t \boldsymbol{\xi}^m\|_{L^2}^2 + k \|d_t \chi^m\|_{L^2}^2 \right] \\
& \leq C k \sum_{m=2}^M \left[\tau_m^2 |(\text{NLT}_A^m, d_t \boldsymbol{\xi}^m)| + \tau_m \left(\|d_t \boldsymbol{\xi}^m\|_{L^2}^2 + \|\operatorname{div} d_t \boldsymbol{\xi}^m\|_{L^2}^2 \right) \right],
\end{aligned}$$

where

$$\begin{aligned}
\text{NLT}_A^{m+1} & = (\mathbf{P}_{\mathbf{J}_0} d_t \boldsymbol{\xi}^m \cdot \nabla) \mathbf{v}^{m+1} + (\mathbf{P}_{\mathbf{J}_0} \boldsymbol{\xi}^{m-1} \cdot \nabla) d_t \mathbf{v}^{m+1} + (\mathbf{P}_{\mathbf{J}_0} d_t \tilde{\mathbf{u}}_k^m \cdot \nabla) \boldsymbol{\xi}^{m+1} \\
(3.24) \quad & + (\mathbf{P}_{\mathbf{J}_0} \tilde{\mathbf{u}}_k^{m-1} \cdot \nabla) d_t \boldsymbol{\xi}^{m+1} - (\mathbf{P}_{\mathbf{J}_0} d_t \tilde{\mathbf{u}}_k^{m-1} \cdot \nabla) (\mathbf{v}^{m+1} - \mathbf{w}_k^{m+1}) \\
& - (\mathbf{P}_{\mathbf{J}_0} \tilde{\mathbf{u}}_k^{m-1} \cdot \nabla) d_t (\mathbf{v}^{m+1} - \mathbf{w}_k^{m+1}) \\
& - (\mathbf{P}_{\mathbf{J}_0} d_t (\mathbf{v}^m - \mathbf{w}_k^m) \cdot \nabla) \mathbf{v}^{m+1} - (\mathbf{P}_{\mathbf{J}_0} (\mathbf{v}^{m-1} - \mathbf{w}_k^{m-1}) \cdot \nabla) d_t \mathbf{v}^{m+1}.
\end{aligned}$$

Thanks to Lemma 2.1, i), the first two terms on the right-hand side of (3.24) in (3.23) can be easily controlled, as well as the fourth term. (Note that $\{d_t \tilde{\mathbf{u}}_k^{m+1}\}$ is uniformly bounded in $\ell^\infty(0, t_{M+1}; \mathbf{L}^2(\Omega))$.) By Lemma 2.1, i), and (3.18), the fifth, seventh, and eighth term on the right-hand side of (3.24) can be handled in a standard way. To bound the third and sixth term on the right-hand side of (3.24), we use the following reformulation:

$$(3.25) \quad \begin{aligned} (\mathbf{P}_{\mathbf{J}_0} d_t \tilde{\mathbf{u}}_k^m \cdot \nabla) \boldsymbol{\xi}^{m+1} &= (\mathbf{P}_{\mathbf{J}_0} d_t (\tilde{\mathbf{u}}_k^m - \mathbf{v}^m) \cdot \nabla) \boldsymbol{\xi}^{m+1} + (\mathbf{P}_{\mathbf{J}_0} d_t \mathbf{v}^m \cdot \nabla) \boldsymbol{\xi}^{m+1}, \\ (\mathbf{P}_{\mathbf{J}_0} \tilde{\mathbf{u}}_k^{m-1} \cdot \nabla) d_t (\mathbf{v}^{m+1} - \mathbf{w}_k^{m+1}) &= (\mathbf{P}_{\mathbf{J}_0} \boldsymbol{\xi}^{m-1} \cdot \nabla) d_t (\mathbf{v}^{m+1} - \mathbf{w}_k^{m+1}) \\ &+ (\mathbf{P}_{\mathbf{J}_0} \mathbf{w}_k^{m-1} \cdot \nabla) d_t (\mathbf{v}^{m+1} - \mathbf{w}_k^{m+1}). \end{aligned}$$

We use Lemma 2.1, i), (3.12), and (3.18) to obtain the uniform estimate

$$(3.26) \quad \max_{1 \leq m \leq M} \left[\|\nabla \mathbf{w}_k^m\|_{L^2} + \sqrt{\tau_m} \| \nabla d_t \mathbf{w}_k^m \|_{L^2} \right] \leq C.$$

By inserting these bounds in (3.23) yields to

$$(3.27) \quad \begin{aligned} &\max_{2 \leq m \leq M} \tau_m^2 \left[\|d_t \boldsymbol{\xi}^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t \boldsymbol{\xi}^m\|_{L^2}^2 \right] \\ &+ k^2 \sum_{m=2}^M \tau_m^2 \left[\|d_t^2 \boldsymbol{\xi}^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t^2 \boldsymbol{\xi}^m\|_{L^2}^2 \right] \\ &+ k \sum_{m=2}^M \tau_m^2 \left[\nu \|\nabla d_t \boldsymbol{\xi}^m\|_{L^2}^2 + k \|d_t \chi^m\|_{L^2}^2 \right] \\ &\leq C k^2 + k \sum_{m=2}^M \tau_m \left[\|d_t \boldsymbol{\xi}^m\|_{L^2}^2 + \|\operatorname{div} d_t \boldsymbol{\xi}^m\|_{L^2}^2 \right]. \end{aligned}$$

The last term in (3.27) can be controlled, if we test (3.20) by $d_t \boldsymbol{\xi}^{m+1}$ and the ‘‘discrete time-derivative’’ version of (3.21) by χ^{m+1} ,

$$(3.28) \quad \begin{aligned} &\|d_t \boldsymbol{\xi}^{m+1}\|_{L^2}^2 + \beta \|\operatorname{div} d_t \boldsymbol{\xi}^{m+1}\|_{L^2}^2 + \frac{\nu}{2} d_t \|\nabla \boldsymbol{\xi}^{m+1}\|_{L^2}^2 \\ &+ \frac{\nu k}{2} \|\nabla d_t \boldsymbol{\xi}^{m+1}\|_{L^2}^2 + \frac{k}{2} d_t \|\chi^{m+1}\|_{L^2}^2 + \frac{k^2}{2} \|d_t \chi^{m+1}\|_{L^2}^2 \\ &\leq C \left[\|\nabla \boldsymbol{\xi}^{m+1}\|_{L^2}^2 + \|\nabla (\mathbf{v}^m - \mathbf{w}_k^m)\|_{L^2}^2 \right] + \frac{C}{\delta \kappa} \|d_t \boldsymbol{\xi}^{m+1}\|_{L^2}^2 + \frac{\kappa}{\delta} \|\nabla d_t \boldsymbol{\xi}^{m+1}\|_{L^2}^2 \\ &+ \frac{\delta}{\tau_{m+1}^{1/2}} \|\nabla \mathbf{u}_k^m\|_{L^2}^2 \left[\|\nabla \boldsymbol{\xi}^{m+1}\|_{L^2}^2 + \|\nabla (\mathbf{v}^{m+1} - \mathbf{w}_k^{m+1})\|_{L^2}^2 \right], \end{aligned}$$

for $\delta, \kappa \geq 1$. If we choose $\kappa = \frac{1}{\sqrt{\delta}}$ and take δ sufficiently large, the last but one term can be absorbed on the left-hand side, and we obtain

$$\begin{aligned}
& k \sum_{m=1}^M \tau_m \left[\|d_t \boldsymbol{\xi}^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t \boldsymbol{\xi}^m\|_{L^2}^2 \right] \\
& + \max_{1 \leq m \leq M} \tau_m \left[\nu \|\nabla \boldsymbol{\xi}^m\|_{L^2}^2 + k \|\chi^m\|_{L^2}^2 \right] \\
(3.29) \quad & + k^2 \sum_{m=1}^M \left[\nu \tau_m \|\nabla d_t \boldsymbol{\xi}^m\|_{L^2}^2 + k \|d_t \chi^m\|_{L^2}^2 \right] \\
& \leq Ck \sum_{m=1}^M \left[\nu \|\nabla \boldsymbol{\xi}^m\|_{L^2}^2 + k \|\chi^m\|_{L^2}^2 + \nu \|\nabla(\mathbf{v}^m - \mathbf{w}_k^m)\|_{L^2}^2 \right. \\
& \quad \left. + \frac{\nu}{\delta^{3/2}} \tau_m^2 \|\nabla d_t \boldsymbol{\xi}^m\|_{L^2}^2 \right].
\end{aligned}$$

As a consequence, (3.29) and (3.27), in combination with a stability result for the divergence operator, give the desired bound

$$(3.30) \quad \max_{1 \leq m \leq M} \left[\|\mathbf{u}(t_m, \cdot) - \mathbf{u}_k^m\|_{L^2} + \sqrt{\tau_m} \|\mathbf{u}(t_m, \cdot) - \mathbf{u}_k^m\|_{H^1} + \tau_m \|p(t_m) - q_k^m\|_{L^2} \right] \leq Ck.$$

We finish this part with useful uniform bounds for $\{(\tilde{\mathbf{u}}_k^{m+1}, q_k^{m+1})\}_{m=0}^M$: make $r-1$ “discrete time-derivatives” in (3.3), (3.2), for $r \in \{1, 2\}$, and test with $\tau_{m+1}^{2(r-1)} d_t^r u_k^{m+1}$; in a second step, we make r “discrete time-derivatives,” and test with $\tau_{m+1}^{2r-1} d_t^r u_k^{m+1}$. A simple calculation then yields

$$\begin{aligned}
(3.31) \quad & \max_{r \leq m \leq M} \tau_m^{2r-1} \left[\|d_t^r \tilde{\mathbf{u}}_k^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t^r \tilde{\mathbf{u}}_k^m\|_{L^2}^2 \right] \\
& + k \sum_{m=r}^M \tau_m^{2(r-1)} \left[\|d_t^r \tilde{\mathbf{u}}_k^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t^r \tilde{\mathbf{u}}_k^m\|_{L^2}^2 \right] \\
& + k \sum_{m=r}^M \tau_m^{2r-1} \left[\nu \|\nabla d_t^r \tilde{\mathbf{u}}_k^m\|_{L^2}^2 + k \|d_t^r q_k^m\|_{L^2}^2 \right] \leq C,
\end{aligned}$$

thanks to (3.27) and (3.30). Also, we may use Lemma 2.1, i), (3.12), (3.16), and (3.27) together with (3.21) to find

$$(3.32) \quad \max_{1 \leq m \leq M} \left[\tau_m^2 \|d_t q_k^m\|^2 \right] + k \sum_{m=1}^M \tau_m \|d_t q_k^m\|^2 \leq C, \quad k^2 \sum_{m=2}^M \tau_m^2 \|d_t^2 q_k^m\|^2 \leq C.$$

3.3. Perturbation analysis for the Chorin–Penalty scheme (3.1)–(3.2): Transition from the penalty method to the projection method. In this section, let $\{(\mathbf{u}_k^{m+1}, q_k^{m+1})\}_{m=0}^M$ denote the solution of (3.3), (3.2), and $\{(\tilde{\mathbf{u}}_k^{m+1}, p_k^{m+1})\}_{m=0}^M$ solves (3.1)–(3.2)—where the latter is the reformulation of Algorithm B. The last step to verify Theorem 1.4 consists in bounding the error $(\mathbf{E}^m, \Pi^m) := (\mathbf{u}_k^m - \tilde{\mathbf{u}}_k^m, q_k^m - p_k^m)$,

which satisfies for every $1 \leq m \leq M$,

$$(3.33) \quad d_t(\mathbf{E}^m - \beta \nabla \operatorname{div} \mathbf{E}^m) - \nu \Delta \mathbf{E}^m + \nabla \Pi^{m-1} = -k \nabla d_t q_k^m - \mathcal{Q}(\mathbf{E}^m),$$

$$(3.34) \quad \operatorname{div} \mathbf{E}^m + k \Pi^m = 0,$$

with $\mathcal{Q}(\mathbf{E}^{m+1}) := (\mathbf{P}_{\mathbf{J}_0} \mathbf{E}^m \cdot \nabla) \mathbf{u}_k^{m+1} + (\mathbf{P}_{\mathbf{J}_0} [\mathbf{u}_k^m - \mathbf{E}^m] \cdot \nabla) \mathbf{E}^{m+1}$. In the next step, we test (3.33)–(3.34) with (\mathbf{E}^m, Π^m) ; for this purpose, we first calculate

$$(3.35) \quad \begin{aligned} (\nabla \Pi^{m-1}, \mathbf{E}^m) &= (\nabla \Pi^m, \mathbf{E}^m) - k (\nabla d_t \Pi^m, \mathbf{E}^m) \\ &= k \|\Pi^m\|_{L^2}^2 - k^2 (d_t \Pi^m, \Pi^m) \\ &\geq k \left[1 - \frac{2}{3} \right] \|\Pi^m\|_{L^2}^2 - \frac{3k^3}{8} \|d_t \Pi^m\|_{L^2}^2, \end{aligned}$$

and

$$k (\nabla d_t q_k^m, \mathbf{E}^m) = k^2 (d_t q_k^m, \Pi^m),$$

as well as

$$\begin{aligned} |(\mathcal{Q}(\mathbf{E}^m), \mathbf{E}^m)| &\leq C \|\mathbf{E}^{m-1}\|_{L^3} \|\nabla \mathbf{u}_k^m\|_{L^2} \|\mathbf{E}^m\|_{L^6} \\ &\leq C \|\mathbf{E}^{m-1}\|_{L^2}^{1/2} \|\nabla \mathbf{E}^{m-1}\|_{L^2}^{1/2} \|\nabla \mathbf{u}_k^m\|_{L^2} \|\nabla \mathbf{E}^m\|_{L^2}. \end{aligned}$$

Therefore, we arrive at the estimate

$$(3.36) \quad \begin{aligned} &\frac{1}{2} \max_{1 \leq m \leq M} \left[\|\mathbf{E}^m\|_{L^2}^2 + \beta \|\operatorname{div} \mathbf{E}^m\|_{L^2}^2 \right] \\ &\quad + \frac{k^2}{2} \sum_{m=1}^M \left[\|d_t \mathbf{E}^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t \mathbf{E}^m\|_{L^2}^2 \right] \\ &\quad + k \sum_{m=1}^M \left[\frac{\nu}{2} \|\nabla \mathbf{E}^m\|_{L^2}^2 + \left[\frac{1}{3} - \frac{1}{\delta} \right] k \|\Pi^m\|_{L^2}^2 \right] \\ &\leq k^4 \sum_{m=1}^M \left[\frac{3}{8} \|d_t \Pi^m\|_{L^2}^2 + C_\delta \|d_t q_k^m\|_{L^2}^2 \right] \\ &\quad + \frac{k}{\nu^3} \sum_{m=1}^M \|\mathbf{E}^m\|_{L^2}^2 \|\nabla \mathbf{u}_k^{m+1}\|_{L^2}^4, \quad \delta > 4. \end{aligned}$$

Thanks to (3.34), and $\beta \geq 1$, the first term on the right-hand side can be absorbed on the left-hand side. The second term can be bounded by $C k^2$, by means of (3.31) and (3.32).

To control the error for the pressure, we “make a time-derivative” of (3.33), test with $\tau_m^2 d_t \mathbf{E}^m$, and note (3.31), (3.32)₂.

$$\begin{aligned}
(3.37) \quad & \frac{1}{2} \max_{2 \leq m \leq M} \tau_m^2 \left[\|d_t \mathbf{E}^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t \mathbf{E}^m\|_{L^2}^2 \right] \\
& + \frac{k^2}{2} \sum_{m=2}^M \tau_m^2 \left[\|d_t^2 \mathbf{E}^m\|_{L^2}^2 + \left[\beta - \frac{3}{4} \right] \|\operatorname{div} d_t^2 \mathbf{E}^m\|_{L^2}^2 \right] \\
& + k \sum_{m=2}^M \tau_m^2 \left[\nu \|\nabla d_t \mathbf{E}^m\|_{L^2}^2 + \left[\frac{1}{3} - \frac{1}{\delta} \right] k \|d_t \Pi^m\|_{L^2}^2 \right] \\
& \leq Ck^2 + C_\delta k^4 \sum_{m=2}^M \tau_m^2 \|d_t^2 q_k^m\|_{L^2}^2 \\
& + k \sum_{m=2}^M \tau_m \left[\|d_t \mathbf{E}^m\|_{L^2}^2 + \beta \|\operatorname{div} d_t \mathbf{E}^m\|_{L^2}^2 \right] \\
& + k \sum_{m=2}^M \tau_m^2 |\operatorname{NLT}_B^m|.
\end{aligned}$$

Here, we used (3.34) to conclude that

$$\begin{aligned}
\tau_m^2 (\nabla d_t \Pi^{m-1}, d_t \mathbf{E}^m) &= \tau_m^2 (\nabla d_t \Pi^m, d_t \mathbf{E}^m) - k \tau_m^2 (\nabla d_t^2 \Pi^m, d_t \mathbf{E}^m) \\
&\geq k \tau_m^2 \|d_t \Pi^m\|_{L^2}^2 - k^2 \tau_m^2 (d_t^2 \Pi^m, d_t \Pi^m) \\
&\geq \left[1 - \frac{2}{3} \right] k \tau_m^2 \|d_t \Pi^m\|_{L^2}^2 - \frac{3}{8} k^3 \tau_m^2 \|d_t^2 \Pi^m\|_{L^2}^2 \\
&\geq \left[1 - \frac{2}{3} \right] k \tau_m^2 \|d_t \Pi^m\|_{L^2}^2 - \frac{3}{8} k \tau_m^2 \|\operatorname{div} d_t^2 \mathbf{E}^m\|_{L^2}^2.
\end{aligned}$$

We skip the detailed study of NLT_B^m , since it does not involve further difficulties superior to those detailed in subsection 3.2 at this place. The crucial term, however, is the last but one term on the right-hand side of (3.37).

For this purpose, we test (3.33) with $\tau_m d_t \mathbf{E}^m$. In a first step, we observe that

$$\begin{aligned}
\tau_m (\nabla \Pi^{m-1}, d_t \mathbf{E}^m) &= \tau_m (\nabla \Pi^m, d_t \mathbf{E}^m) + \tau_m k (d_t \Pi^m, \operatorname{div} d_t \mathbf{E}^m) \\
&\geq \frac{k}{2} \tau_m \left[d_t \|\Pi^m\|_{L^2}^2 + k \|d_t \Pi^m\|_{L^2}^2 \right] \\
&\quad - \frac{3}{4} \tau_m \|\operatorname{div} d_t \mathbf{E}^m\|_{L^2}^2 - \frac{k^2}{3} \tau_m \|d_t \Pi^m\|_{L^2}^2 \\
&= \frac{k}{2} d_t \left[\tau_m \|\Pi^m\|_{L^2}^2 \right] - \frac{k}{2} \|\Pi^{m-1}\|_{L^2}^2 \\
&\quad + \frac{k^2}{6} \tau_m \|d_t \Pi^m\|_{L^2}^2 - \frac{3}{4} \tau_m \|\operatorname{div} d_t \mathbf{E}^m\|_{L^2}^2,
\end{aligned}$$

as well as

$$\begin{aligned}
k \tau_m (\nabla d_t q_k^m, d_t \mathbf{E}^m) &= k^2 \tau_m (d_t \Pi^m, d_t q_k^m) \\
&\leq 3 \tau_m k^2 \|d_t q_k^m\|_{L^2}^2 + \frac{k^2}{12} \tau_m \|d_t \Pi^m\|_{L^2}^2.
\end{aligned}$$

By (3.31), (3.32), and (3.36), we then obtain

$$\begin{aligned}
 (3.38) \quad & k \sum_{m=1}^M \tau_m \left[\|d_t \mathbf{E}^m\|^2 + \left[\beta - \frac{3}{4} \right] \|\operatorname{div} d_t \mathbf{E}^m\|^2 \right] \\
 & + \frac{1}{2} \max_{1 \leq m \leq M} \tau_m \left[\nu \|\nabla \mathbf{E}^m\|^2 + k \|\Pi^m\|^2 \right] \\
 & + \frac{k^2}{12} \sum_{m=1}^M \tau_m \left[\|\nabla d_t \mathbf{E}^m\|^2 + k \|d_t \Pi^m\|^2 \right] \\
 & \leq C_\gamma k^2 + \frac{k}{\gamma^{3/2}} \sum_{m=1}^M \tau_m^2 \|\nabla d_t \mathbf{E}^m\|^2, \quad (\gamma > 1).
 \end{aligned}$$

We may now use (3.38) to control the last but one term on the right-hand side of (3.37); upon choosing $\gamma > 1$ sufficiently large, the last term in (3.38) may be absorbed by the corresponding term on the left-hand side of (3.37). A standard argumentation then establishes the bound $\max_{0 \leq m \leq M} \tau_m \|\Pi^m\| \leq C k$.

Together with (3.36) through (3.38) and the results from subsections 3.1 to 3.3, this settles the proof of Theorem 1.4.

Remark 3.2. Choosing $\beta \geq 0$ is sufficient to obtain all results in subsections 3.1 and 3.2. Values $\beta \geq 1$ are needed only in subsection 3.3 to properly deal with splitting errors in the Chorin–Penalty projection method; it is sufficient to justify the argument below inequality (3.36), where errors due to the splitting, and computed in (3.35), are absorbed by the term headed by β ; see also section 4 for computational evidence.

4. Computational experiments. We computationally compare Chorin’s method (Algorithm A) with its variants, i.e., Chorin–Uzawa method (Algorithm B, for $\alpha \in (0, 1)$) and Chorin–Penalty method ((1.19)–(1.21), (1.28), for $\beta \geq 1$). Our main focuses are

- (i) to compare possible boundary layers of $m \mapsto [p(t_m, \cdot) - p^m] \in L_0^2(\Omega)$, including their evolution in time,
- (ii) to compare possible transition layers caused by starting with initial pressure data p^0 for Chorin–Uzawa, and Chorin–Penalty scheme, where $\|p^0 - p(0, \cdot)\|_{L^2}$ is large, and
- (iii) to study convergence behavior of computed pressures for the Chorin–Uzawa and Chorin–Penalty methods, depending on different choices of α, β .

Example 1. Let $\Omega = (0, 1)^2 \subset \mathbb{R}^2$, and

$$\mathbf{u}(x, y, t) = \begin{pmatrix} x^2(1-x)^2(2y-6y^2+4y^3) \\ -y^2(1-y)^2(2x-6x^2+4x^3) \end{pmatrix}, \quad p(x, y, t) = \left(x^2 + y^2 - \frac{2}{3}\right)(1+t^2),$$

be the solution of the evolutionary Stokes problem; i.e., $\mathbf{f} : \Omega_T \rightarrow \mathbb{R}^2$ is computed from (1.1)–(1.4), where the nonlinear term in (1.1) is neglected. Let \mathcal{T}_h be an equidistant triangulation of Ω of mesh-size $h = 1/30$, and $k = 2^j/500$, $j = 0, 1, 2, \dots$, an equidistant time-step for the time interval $[0, 1]$. The LBB-stable MINI-Stokes element is used for spatial discretization of the three projection methods.

Snapshots for the pressure error in Figure 1 show marked boundary layers for the pressure (first line), as opposed to almost uniform errors for Chorin–Uzawa (middle line) and Chorin–Penalty (last line); comparative plots in the last line for corresponding L^2 -errors (before being dominated by errors due to spatial discretization) motivate that significant errors close to the boundary control the overall error in Chorin’s scheme. Corresponding profiles are obtained for plots of $m \mapsto \operatorname{div} \tilde{\mathbf{u}}^m$.

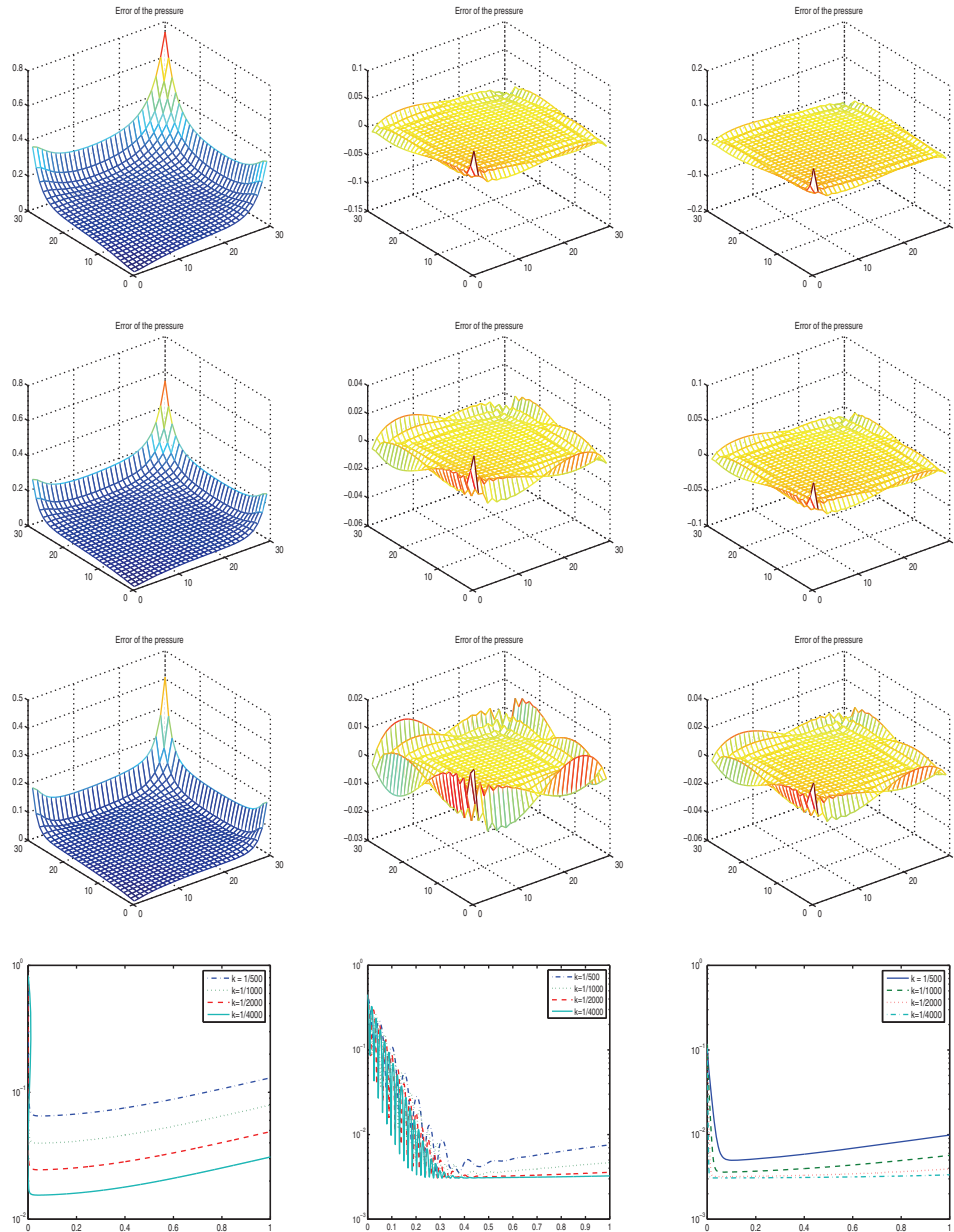

FIG. 1. Example 1: Errors of $p(t_m, \cdot) - p^m$ at time $t_m = 1$, for $k = 1/500$ (1st line), $k = 1/1000$ (2nd line), and $k = 1/2000$ (3rd line), and evolution plot of L^2 errors (4th line), for Chorin (left), Chorin-Uzawa (middle, $\alpha = 0,9$), and Chorin-Penalty (right, $\beta = 1.1$).

Both Chorin-Uzawa ($\alpha \in (0, 1)$) and Chorin-Penalty ($\beta \geq 1$) involve additional parameters; its dependence is studied in Figure 2, and failure of convergence of the Chorin-Penalty method is observed for some $\beta < 1$. The experiments suggest values $\alpha \approx 1$ and $\beta \approx 1$.

Over the last decade, different projection schemes have been developed and tested in academic examples, whose performance crucially relies on given initial functions

FIG. 2. Example 1: L^2 -errors of pressure at $t = 1$ for (i) Chorin–Uzawa with exact initial pressure, for different $\alpha \in (0, 1)$ (left). (ii) Chorin–Penalty for different $\beta \in (1, 100)$ (middle). (iii) Loss of convergence for Chorin–Penalty for $\beta < \frac{1}{2}$ (right). ($k = 1/500$).

FIG. 3. Example 1: Correct vs. noncorrect initial pressures for Chorin–Uzawa ($\alpha = 0.9$), and comparison with Chorin–Penalty ($\beta = 1.1$) for $k = 1/500$ (left), $k = 1/1000$ (middle), and $k = 1/2000$ (right).

$q \equiv p(0, \cdot)$; cf. [6] for further details. In fact, to compute pressure initial functions in general amounts to solve the following problem (for nonstationary Stokes)

$$\Delta q = \operatorname{div} \mathbf{f}(0, \cdot) \quad \text{in } \Omega, \quad \partial_{\mathbf{n}} q = [\mathbf{f}(0, \cdot) + \nu \Delta \mathbf{u}_0] \cdot \mathbf{n} \quad \text{on } \partial \Omega,$$

where optimal convergence for (finite element) approximations $q_h \approx q$ is not clear. In our case, choosing accurate data $p^0 \approx p(0, \cdot)$ for the Chorin–Uzawa method has been pointed out to be crucial in Theorem 1.3; in contrast, Chorin–Penalty is designed in order to avoid boundary layers for the pressure error in space, and also perform optimally for zero initial pressure data (Theorem 1.4). Figure 3 supports these theoretical results: we observe marked transition layers for Chorin–Uzawa in the case of “noncorrect” initial pressures, while L^2 -errors of the pressure in Chorin–Penalty are almost instantaneously reduced to spatial discretization errors.

5. Conclusion. In recent papers [11, 12], the authors stress the importance to construct and analyze practical projection methods under realistic regularity assumptions—which is also the guideline in this paper. Over the last decade, several projection methods are studied in the literature where (i) smooth solutions to (1.1)–(1.4) and (ii) accurate initial pressure data are assumed, leaving serious doubts on the applicability of these results to more realistic situations of incompatible data and limited solution’s regularity.

Projection methods are efficient methods to approximate strong solutions of the nonstationary incompressible Navier–Stokes equations; the most well-known example

is Chorin's method, which suffers from marked pressure error boundary layers. We give a first rigorous analysis of its structure in the case of existing strong solutions of (1.1)–(1.4) (Theorem 1.2). The new Chorin–Penalty method is proposed, and optimal (i.e., first-order) rate of convergence for the pressure is proved (Theorem 1.4), which reflects uniform, optimal convergence behavior up to the boundary. Comparative computational studies illustrate that the Chorin–Penalty method is exempted from the deficiencies of the Chorin method, in the way that no significant pressure errors arise close to the boundary.

Acknowledgment. The author is grateful to E. Carelli (Universität Tübingen) for providing the computational tests.

B-SERIES ANALYSIS OF STOCHASTIC RUNGE–KUTTA METHODS THAT USE AN ITERATIVE SCHEME TO COMPUTE THEIR INTERNAL STAGE VALUES*

KRISTIAN DEBRABANT[†] AND ANNE KVÆRNØ[‡]

Abstract. In recent years, implicit stochastic Runge–Kutta (SRK) methods have been developed both for strong and weak approximations. For these methods, the stage values are only given implicitly. However, in practice these implicit equations are solved by iterative schemes such as simple iteration, modified Newton iteration or full Newton iteration. We employ a unifying approach for the construction of stochastic B-series which is valid both for Itô- and Stratonovich-stochastic differential equations (SDEs) and applicable both for weak and strong convergence to analyze the order of the iterated Runge–Kutta method. Moreover, the analytical techniques applied in this paper can be of use in many other similar contexts.

Key words. stochastic Runge–Kutta method, composite method, stochastic differential equation, iterative scheme, order, internal stage values, Newton’s method, weak approximation, strong approximation, growth functions, stochastic B-series

1. Introduction. In many applications, e.g., in epidemiology and financial mathematics, taking stochastic effects into account when modeling dynamical systems often leads to stochastic differential equations (SDEs). Therefore, in recent years, the development of numerical methods for the approximation of SDEs has become a field of increasing interest; see, e.g., [16, 22] and references therein. Many stochastic schemes fall into the class of stochastic Runge–Kutta (SRK) methods. SRK methods have been studied both for strong approximation [1, 10, 11, 16], where one is interested in obtaining good pathwise solutions, and for weak approximation [8, 9, 16, 19, 21, 32], which focuses on the expectation of functionals of solutions. Order conditions for these methods are found by comparing series of the exact and the numerical solutions. In this paper, we will concentrate on the use of B-series and rooted trees. Such series are surprisingly general; as formal series they are independent of the choice of the stochastic integral, Itô or Stratonovich, or whether weak or strong convergence is considered. This is demonstrated in section 2. For solving SDEs which are stiff, implicit SRK methods have to be considered, which also has been done both for strong [4, 11, 12] and weak [7, 12, 17] approximation. For these methods, the stage values are only given implicitly. However, in practice these implicit equations are solved by iterative schemes like simple iteration or some kind of Newton iterations. For the numerical solution of ODEs such iterative schemes have been studied [13, 14], and it was shown that certain growth functions defined on trees give a precise description of the development of the iterations. Exactly the same growth functions apply to SRKs, as we prove in section 3. Only when these results

are interpreted in terms of the order of the overall scheme, we distinguish Itô from Stratonovich SDEs, weak from strong convergence. This is discussed in sections 4 and 5.

When considering strong convergence, it is difficult to implement fully implicit SRK methods in combination with Newton iterations due to the possible singularity of the numerical procedure. Therefore, various techniques have been developed to circumvent this problem [4]. One possibility is the use of so-called truncated random variables, which have finite distribution and can approximate the increment of Wiener processes to a chosen order [4, 23]. As the concrete choice of random variables in the numerical methods is not specified in this paper, all considerations are without any change also valid for SRK methods with such modified random variables.

Another possibility is to use composite methods [31], which are combinations of a semi-implicit SRK and an implicit SRK. Based on the results for conventional SRK methods, convergence results for iterated composite methods are given in section 6. Finally, in section 7 we present two numerical examples.

Let $(\Omega, \mathcal{A}, \mathcal{P})$ be a probability space. We denote by $(X(t))_{t \in I}$ the stochastic process which is the solution of either a d -dimensional Itô or Stratonovich SDE defined by

$$(1.1) \quad X(t) = x_0 + \int_{t_0}^t g_0(X(s)) ds + \sum_{l=1}^m \int_{t_0}^t g_l(X(s)) \star dW_l(s)$$

with an m -dimensional Wiener process $(W(t))_{t \geq 0}$ and $I = [t_0, T]$. The integral w.r.t. the Wiener process has to be interpreted either as Itô integral with $\star dW_l(s) = dW_l(s)$ or as Stratonovich integral with $\star dW_l(s) = \circ dW_l(s)$. We assume that the Borel-measurable coefficients $g_l : \mathbb{R}^d \rightarrow \mathbb{R}^d$ are sufficiently differentiable and satisfy a Lipschitz and a linear growth condition. For Stratonovich SDEs, we require in addition that the g_l are differentiable and that also the vectors $g'_l g_l$ satisfy a Lipschitz and a linear growth condition. Then the existence and uniqueness theorem [15] applies.

To simplify the presentation, we define $W_0(s) = s$, so that (1.1) can be written as

$$(1.2) \quad X(t) = x_0 + \sum_{l=0}^m \int_{t_0}^t g_l(X(s)) \star dW_l(s).$$

In the following we denote by Ξ a set of families of measurable mappings,

$$\Xi := \{ \{ \varphi(h) \}_{h \geq 0} : \varphi(h) : \Omega \rightarrow \mathbb{R} \text{ is } \mathcal{A} - \mathcal{B} \text{-measurable } \forall h \geq 0 \},$$

and by Ξ_0 the subset of Ξ defined by

$$\Xi_0 := \{ \{ \varphi(h) \}_{h \geq 0} \in \Xi : \varphi(0) \equiv 0 \}.$$

Let a discretization $I^h = \{t_0, t_1, \dots, t_N\}$ with $t_0 < t_1 < \dots < t_N = T$ of the time interval I with step sizes $h_n = t_{n+1} - t_n$ for $n = 0, 1, \dots, N-1$ be given. Now, we consider the general class of s -stage SRK methods given by $Y_0 = x_0$ and

$$(1.3a) \quad Y_{n+1} = Y_n + \sum_{l=0}^m \sum_{\nu=0}^M \left(z^{(l,\nu)\top} \otimes I_d \right) g_l \left(H^{(l,\nu)} \right)$$

for $n = 0, 1, \dots, N-1$ with $Y_n = Y(t_n)$, $t_n \in I^h$, $I_d \in \mathbb{R}^{d,d}$ the identity matrix, and

$$(1.3b) \quad H^{(l,\nu)} = \mathbb{1}_s \otimes Y_n + \sum_{r=0}^m \sum_{\mu=0}^M \left(Z^{(l,\nu)(r,\mu)} \otimes I_d \right) g_r \left(H^{(r,\mu)} \right)$$

for $l = 0, \dots, m$ and $\nu = 0, \dots, M$ with $\mathbf{1}_s = (1, \dots, 1)^\top \in \mathbb{R}^s$,

$$g_l \left(H^{(l,\nu)} \right) = \left(g_l \left(H_1^{(l,\nu)} \right)^\top, \dots, g_l \left(H_s^{(l,\nu)} \right)^\top \right)^\top$$

and

$$z^{(l,\nu)} \in \Xi_0^s, \quad Z^{(l,\nu)(r,\mu)} \in \Xi_0^{s,s}$$

for $l, r = 0, \dots, m$, $\mu, \nu = 0, \dots, M$.

The formulation (1.3) is a slight generalization of the class considered in [27] and includes the classes of SRK methods considered in [4, 11, 18, 20, 28, 29, 30] as well as the SRK methods considered in [12, 16, 25]. It defines a d -dimensional approximation process Y with $Y_n = Y(t_n)$.

Application of an iterative scheme yields

$$\begin{aligned} H_{k+1}^{(l,\nu)} &= \mathbf{1}_s \otimes Y_n + \sum_{r=0}^m \sum_{\mu=0}^M \left(Z^{(l,\nu)(r,\mu)} \otimes I_d \right) g_r \left(H_k^{(r,\mu)} \right) \\ &+ \sum_{r=0}^m \sum_{\mu=0}^M \left(Z^{(l,\nu)(r,\mu)} \otimes I_d \right) J_k^{(r,\mu)} \left(H_{k+1}^{(r,\mu)} - H_k^{(r,\mu)} \right), \end{aligned} \tag{1.4a}$$

$$Y_{n+1,k} = Y_n + \sum_{l=0}^m \sum_{\nu=0}^M \left(z^{(l,\nu)}^\top \otimes I_d \right) g_l \left(H_k^{(l,\nu)} \right) \tag{1.4b}$$

with some approximation $J_k^{(r,\mu)}$ to the Jacobian of $g_r(H_k^{(r,\mu)})$ and a predictor $H_0^{(l,\nu)}$. In the following we assume that (1.4a) can be solved uniquely at least for small enough h_n . We consider simple iterations with $J_k^{(r,\mu)} = 0$ (i.e., predictor-corrector methods), modified Newton iterations with $J_k^{(r,\mu)} = I_s \otimes g'_r(x_0)$, and full Newton iterations.

2. Some notation, definitions, and preliminary results. In this section we introduce some necessary notation and provide a few definitions and preliminary results that will be used later.

2.1. Convergence and consistency. Here we will give the definitions for both weak and strong convergence and results which relate convergence to consistency.

Let $C_P^l(\mathbb{R}^d, \mathbb{R}^{\hat{d}})$ denote the space of all $g \in C^l(\mathbb{R}^d, \mathbb{R}^{\hat{d}})$ fulfilling a polynomial growth condition [16].

DEFINITION 1. *A time discrete approximation $Y = (Y(t))_{t \in I^h}$ converges weakly with order p to X as $h \rightarrow 0$ at time $t \in I^h$ if for each $f \in C_P^{2(p+1)}(\mathbb{R}^d, \mathbb{R})$ there exist a constant C_f and a finite $\delta_0 > 0$ such that*

$$|\mathbb{E}(f(Y(t))) - \mathbb{E}(f(X(t)))| \leq C_f h^p$$

holds for each $h \in]0, \delta_0[$.

Now, let $le_f(h; t, x)$ be the weak local error of the method starting at the point (t, x) with respect to the functional f and step size h , i.e.,

$$le_f(h; t, x) = \mathbb{E} \left(f(Y(t+h)) - f(X(t+h)) \mid Y(t) = X(t) = x \right).$$

The following theorem due to Milstein [22], which holds also in the case of general one-step methods, shows that, as in the deterministic case, consistency implies convergence.

THEOREM 1. *Suppose the following conditions hold:*

- *The coefficients g_l are continuous, satisfy a Lipschitz condition, and belong to $C_P^{2(p+1)}(\mathbb{R}^d, \mathbb{R}^d)$ for $l = 0, \dots, m$. For Stratonovich SDEs, we require in addition that the g_l are differentiable and that also the vectors $g'_l g_l$ satisfy a Lipschitz condition and belong to $C_P^{2(p+1)}(\mathbb{R}^d, \mathbb{R}^d)$ for $l = 0, \dots, m$.*
- *For sufficiently large r (see, e.g., [22] for details) the moments $\mathbb{E}(\|Y(t_n)\|^{2r})$ exist for $t_n \in I^h$ and are uniformly bounded with respect to N and $n = 0, 1, \dots, N$.*
- *Assume that for all $f \in C_P^{2(p+1)}(\mathbb{R}^d, \mathbb{R})$ there exists a $K \in C_P^0(\mathbb{R}^d, \mathbb{R})$ such that*

$$|le_f(h; t, x)| \leq K(x) h^{p+1}$$

is valid for $x \in \mathbb{R}^d$ and $t, t+h \in I^h$, i.e., the approximation is weak consistent of order p .

Then the method (1.3) is convergent of order p in the sense of weak approximation.

Whereas weak approximation methods are used to estimate the expectation of functionals of the solution, strong approximation methods approach the solution pathwise.

DEFINITION 2. *A time discrete approximation $Y = (Y(t))_{t \in I^h}$ converges strongly, respectively, in the mean square with order p to X as $h \rightarrow 0$ at time $t \in I^h$ if there exists a constant C and a finite $\delta_0 > 0$ such that*

$$\mathbb{E} \|Y(t) - X(t)\| \leq C h^p, \quad \text{respectively,} \quad \sqrt{\mathbb{E}(\|Y(t) - X(t)\|^2)} \leq C h^p$$

holds for each $h \in]0, \delta_0[$.

In this article we will consider convergence in the mean square sense. But as by Jensen's inequality we have

$$(\mathbb{E} \|Y(t) - X(t)\|)^2 \leq \mathbb{E}(\|Y(t) - X(t)\|^2),$$

mean square convergence implies strong convergence of the same order.

Now, let $le^m(h; t, x)$ and $le^{ms}(h; t, x)$, respectively, be the mean and mean square local error, respectively, of the method starting at the point (t, x) with respect to the step size h ; i.e.,

$$\begin{aligned} le^m(h; t, x) &= \mathbb{E} (Y(t+h) - X(t+h) | Y(t) = X(t) = x), \\ le^{ms}(h; t, x) &= \sqrt{\mathbb{E} ((Y(t+h) - X(t+h))^2 | Y(t) = X(t) = x)}. \end{aligned}$$

The following theorem due to Milstein [22] which holds also in the case of general one step methods shows that in the mean square convergence case we obtain order p if the mean local error is consistent of order p and the mean square local error is consistent of order $p - \frac{1}{2}$.

THEOREM 2. *Suppose the following conditions hold:*

- *The coefficients g_l are continuous and satisfy a Lipschitz condition for $l = 0, \dots, m$, and $\mathbb{E}(\|X(t_0)\|^2) < \infty$. For Stratonovich SDEs, we require in addition that the g_l are differentiable and that also the vectors $g'_l g_l$ satisfy a Lipschitz condition.*
- *There exists a constant K independent of h such that*

$$\|le^m(h; t, x)\| \leq K \sqrt{1 + \|x\|^2} h^{p_1}, \quad le^{ms}(h; t, x) \leq K \sqrt{1 + \|x\|^2} h^{p+\frac{1}{2}}$$

with $p \geq 0$, $p_1 \geq p + 1$ is valid for $x \in \mathbb{R}^d$, and $t, t + h \in I^h$; i.e., the approximation is consistent in the mean of order $p_1 - 1 \geq p$ and in the mean square of order $p - \frac{1}{2}$.

Then the SRK method (1.3) is convergent of order p in the sense of mean square approximation.

For Stratonovich SDEs, this result is also obtained by Burrage and Burrage [2].

2.2. Stochastic B-series. In this section we will develop stochastic B-series for the solution of (1.2) as well as for the numerical solution given by (1.3). B-series for deterministic ODEs were introduced by Butcher [6]. Today such series appear as a fundamental tool to do local error analysis on a wide range of problems. B-series for SDEs have been developed by Burrage and Burrage [1, 2] to study strong convergence in the Stratonovich case, by Komori, Mitsui, and Sugiura [20] and Komori [18] to study weak convergence in the Stratonovich case, and by Rößler [26, 27] to study weak convergence in both the Itô and the Stratonovich case. However, the distinction between the Itô and the Stratonovich integrals depends only on the definition of the integrals, not on how the B-series are constructed. Similarly, the distinction between weak and strong convergence depends only on the definition of the local error. Thus, we find it convenient to present a uniform and self-contained theory for the construction of stochastic B-series. We will present results and proofs in a certain detail, since some intermediate results will be used in later sections.

Following the idea of Burrage and Burrage, we introduce the set of colored, rooted trees related to the SDE (1.1), as well as the elementary differentials associated with each of these trees.

DEFINITION 3 (trees). *The set of $m + 1$ -colored, rooted trees*

$$T = \{\emptyset\} \cup T_0 \cup T_1 \cup \dots \cup T_m$$

is recursively defined as follows:

(a) *The graph $\bullet_l = [\emptyset]_l$ with only one vertex of color l belongs to T_l .*

Let $\tau = [\tau_1, \tau_2, \dots, \tau_\kappa]_l$ be the tree formed by joining the subtrees $\tau_1, \tau_2, \dots, \tau_\kappa$ each by a single branch to a common root of color l .

(b) *If $\tau_1, \tau_2, \dots, \tau_\kappa \in T$, then $\tau = [\tau_1, \tau_2, \dots, \tau_\kappa]_l \in T_l$.*

Thus, T_l is the set of trees with an l -colored root, and T is the union of these sets.

DEFINITION 4 (elementary differentials). *For a tree $\tau \in T$ the elementary differential is a mapping $F(\tau) : \mathbb{R}^d \rightarrow \mathbb{R}^d$ defined recursively by*

- (a) $F(\emptyset)(x_0) = x_0$,
- (b) $F(\bullet_l)(x_0) = g_l(x_0)$,
- (c) *If $\tau = [\tau_1, \tau_2, \dots, \tau_\kappa]_l \in T_l$, then*

$$F(\tau)(x_0) = g_l^{(\kappa)}(x_0) (F(\tau_1)(x_0), F(\tau_2)(x_0), \dots, F(\tau_\kappa)(x_0)).$$

As will be shown in the following, both the exact and the numerical solutions, including the iterated solutions as we will see later, can formally be written in terms of B-series.

DEFINITION 5 (B-series). *Given a mapping $\phi : T \rightarrow \Xi$ satisfying*

$$\phi(\emptyset)(h) \equiv 1 \text{ and } \phi(\tau)(0) \equiv 0, \quad \forall \tau \in T \setminus \{\emptyset\}.$$

A (stochastic) B-series is then a formal series of the form

$$B(\phi, x_0; h) = \sum_{\tau \in T} \alpha(\tau) \cdot \phi(\tau)(h) \cdot F(\tau)(x_0),$$

where $\alpha : T \rightarrow \mathbb{Q}$ is given by

$$\alpha(\emptyset) = 1, \quad \alpha(\bullet_l) = 1, \quad \alpha(\tau = [\tau_1, \dots, \tau_\kappa]_l) = \frac{1}{r_1!r_2! \cdots r_q!} \prod_{j=1}^\kappa \alpha(\tau_j),$$

where r_1, r_2, \dots, r_q count equal trees among $\tau_1, \tau_2, \dots, \tau_\kappa$.

If $\phi : T \rightarrow \Xi^s$, then $B(\phi, x_0; h) = [B(\phi_1, x_0; h), \dots, B(\phi_s, x_0; h)]^\top$.

The next lemma proves that if $Y(h)$ can be written as a B-series, then $f(Y(h))$ can be written as a similar series, where the sum is taken over trees with a root of color f and subtrees in T . The lemma is fundamental for deriving B-series for the exact and the numerical solution. It will also be used for deriving weak convergence results.

LEMMA 3. *If $Y(h) = B(\phi, x_0; h)$ is some B-series and $f \in C^\infty(\mathbb{R}^d, \mathbb{R}^{\hat{d}})$, then $f(Y(h))$ can be written as a formal series of the form*

$$(2.1) \quad f(Y(h)) = \sum_{u \in U_f} \beta(u) \cdot \psi_\phi(u)(h) \cdot G(u)(x_0),$$

where U_f is a set of trees derived from T , by

- (a) $[\emptyset]_f \in U_f$, and if $\tau_1, \tau_2, \dots, \tau_\kappa \in T$, then $[\tau_1, \tau_2, \dots, \tau_\kappa]_f \in U_f$.
- (b) $G([\emptyset]_f)(x_0) = f(x_0)$ and $G(u = [\tau_1, \dots, \tau_\kappa]_f)(x_0) = f^{(\kappa)}(x_0)(F(\tau_1)(x_0), \dots, F(\tau_\kappa)(x_0))$.
- (c) $\beta([\emptyset]_f) = 1$ and $\beta(u = [\tau_1, \dots, \tau_\kappa]_f) = \frac{1}{r_1!r_2! \cdots r_q!} \prod_{j=1}^\kappa \alpha(\tau_j)$, where r_1, r_2, \dots, r_q count equal trees among $\tau_1, \tau_2, \dots, \tau_\kappa$.
- (d) $\psi_\phi([\emptyset]_f)(h) \equiv 1$ and $\psi_\phi(u = [\tau_1, \dots, \tau_\kappa]_f)(h) = \prod_{j=1}^\kappa \phi(\tau_j)(h)$.

Proof. Writing $Y(h)$ as a B-series, we have

$$\begin{aligned} f(Y(h)) &= f \left(\sum_{\tau \in T} \alpha(\tau) \cdot \phi(\tau)(h) \cdot F(\tau)(x_0) \right) \\ &= \sum_{\kappa=0}^\infty \frac{1}{\kappa!} f^{(\kappa)}(x_0) \left(\sum_{\tau \in T \setminus \{\emptyset\}} \alpha(\tau) \cdot \phi(\tau)(h) \cdot F(\tau)(x_0) \right)^\kappa \\ &= f(x_0) + \sum_{\kappa=1}^\infty \frac{1}{\kappa!} \sum_{\{\tau_1, \tau_2, \dots, \tau_\kappa\} \in T \setminus \{\emptyset\}} \frac{\kappa!}{r_1!r_2! \cdots r_q!} \\ &\quad \cdot \left(\prod_{j=1}^\kappa \alpha(\tau_j) \cdot \phi(\tau_j)(h) \right) f^{(\kappa)}(x_0)(F(\tau_1)(x_0), \dots, F(\tau_\kappa)(x_0)), \end{aligned}$$

where the last sum is taken over all possible unordered combinations of κ trees in T . For each set of trees $\tau_1, \tau_2, \dots, \tau_\kappa \in T$ we assign a $u = [\tau_1, \tau_2, \dots, \tau_\kappa]_f \in U_f$. The theorem is now proved by comparing term by term with (2.1). \square

Remark 1. For example, in the definition of weak convergence, just $f \in C_P^{2(p+1)}(\mathbb{R}^d, \mathbb{R})$ is required. Thus $f(Y(h))$ can be written only as a truncated B-series, with a remainder term. However, to simplify the presentation in the following we assume that all derivatives of f, g_0, \dots, g_l exist.

We will also need the following result.

LEMMA 4. *If $Y(h) = B(\phi_Y, x_0; h)$ and $Z(h) = B(\phi_Z, x_0; h)$ and $f \in C^\infty(\mathbb{R}^d, \mathbb{R}^{\hat{d}})$, then*

$$f'(Y(h))Z(h) = \sum_{u \in U_f} \beta(u) \cdot \Upsilon(u)(h) \cdot G(u)(x_0)$$

with

$$\Upsilon([\emptyset]_f)(h) \equiv 0, \quad \Upsilon([u = [\tau_1, \dots, \tau_\kappa]_f])(h) = \sum_{i=1}^{\kappa} \left(\prod_{\substack{j=1 \\ j \neq i}}^{\kappa} \phi_Y(\tau_j)(h) \right) \phi_Z(\tau_i)(h)$$

with $\beta(u)$ and $G(u)(x_0)$ given by Lemma 3. The proof is similar to the deterministic case (see [24]).

When Lemma 3 is applied to the functions g_l on the right-hand side of (1.2) we get the following result: If $Y(h) = B(\phi, x_0; h)$, then

$$(2.2) \quad g_l(Y(h)) = \sum_{\tau \in T_l} \alpha(\tau) \cdot \phi'_l(\tau)(h) \cdot F(\tau)(x_0)$$

in which

$$\phi'_l(\tau)(h) = \begin{cases} 1 & \text{if } \tau = \bullet_l, \\ \prod_{j=1}^{\kappa} \phi(\tau_j)(h) & \text{if } \tau = [\tau_1, \dots, \tau_\kappa]_l \in T_l. \end{cases}$$

THEOREM 5. *The solution $X(t_0 + h)$ of (1.2) can be written as a B-series $B(\varphi, x_0; h)$ with*

$$\varphi(\emptyset)(h) \equiv 1, \quad \varphi(\bullet_l)(h) = W_l(h), \quad \varphi(\tau = [\tau_1, \dots, \tau_\kappa]_l)(h) = \int_0^h \prod_{j=1}^{\kappa} \varphi(\tau_j)(s) \star dW_l(s).$$

Proof. Write the exact solution as some B-series $X(t_0 + h) = B(\varphi, x_0; h)$. By (2.2) the SDE (1.2) can be written as

$$\sum_{\tau \in T} \alpha(\tau) \cdot \varphi(\tau)(h) \cdot F(\tau)(x_0) = x_0 + \sum_{l=0}^m \sum_{\tau \in T_l} \alpha(\tau) \cdot \int_0^h \varphi'_l(\tau)(s) \star dW_l(s) \cdot F(\tau)(x_0).$$

Comparing term by term we get

$$\varphi(\emptyset)(h) \equiv 1, \quad \text{and} \quad \varphi(\tau)(h) = \int_0^h \varphi'(\tau)(s) \star dW_l(s) \quad \text{for } \tau \in T_l, \quad l = 0, 1, \dots, m.$$

The proof is completed by induction on τ . \square

The same result is given for the Stratonovich case in [2, 18], but it clearly also applies to the Itô case.

The definition of the order of the tree, $\rho(\tau)$, is motivated by the fact that $E W_l(h)^2 = h$ for $l \geq 1$ and $W_0(h) = h$.

DEFINITION 6 (order). *The order of a tree $\tau \in T$ is defined by*

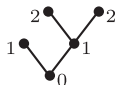

$$\rho(\emptyset) = 0, \quad \rho([\tau_1, \dots, \tau_\kappa]_f) = \sum_{i=1}^{\kappa} \rho(\tau_i)$$

and

$$\rho(\tau = [\tau_1, \dots, \tau_\kappa]_l) = \sum_{i=1}^{\kappa} \rho(\tau_i) + \begin{cases} 1 & \text{for } l = 0, \\ \frac{1}{2} & \text{otherwise.} \end{cases}$$

TABLE 2.1

Examples of trees and corresponding functions $\rho(\tau)$, $\alpha(\tau)$, and $\varphi(\tau)$. The integrals $\varphi(\tau)$ are also expressed in terms of multiple integrals $J_{(\dots)}$ for the Stratonovich (S) and $I_{(\dots)}$ for the Itô (I) cases; see [16] for their definition. In bracket notation, the trees will be written as \bullet_l , $[[\bullet_2]_0]_1$, $[\bullet_1, \bullet_1]_0$, and $[\bullet_1, [\bullet_2, \bullet_2]_1]_0$, respectively.

τ	$\rho(\tau)$	$\alpha(\tau)$	$\varphi(\tau)(h)$
\bullet_l	$\begin{cases} 1 & \text{if } l = 0 \\ \frac{1}{2} & \text{if } l \neq 0 \end{cases}$	1	$W_l(h) = \begin{cases} h & \text{if } l = 0 \\ J_{(l)} & \text{(S)} \\ I_{(l)} & \text{(I)} \end{cases}$
	2	1	$\int_0^h \int_0^{s_1} W_2(s_2) \star ds_2 \star dW_1(s_1) = \begin{cases} J_{(2,0,1)} & \text{(S)} \\ I_{(2,0,1)} & \text{(I)} \end{cases}$
	2	$\frac{1}{2}$	$\int_0^h W_1(s)^2 \star ds = \begin{cases} 2J_{(1,1,0)} & \text{(S)} \\ 2I_{(1,1,0)} + I_{(0,0)} & \text{(I)} \end{cases}$
	3	$\frac{1}{2}$	$\int_0^h W_1(s_1) (\int_0^{s_1} W_2(s_2)^2 \star dW_1(s_2)) \star ds_1$ $= \begin{cases} 4J_{(2,2,1,1,0)} + 2J_{(2,1,2,1,0)} + 2J_{(1,2,2,1,0)} & \text{(S)} \\ 4I_{(2,2,1,1,0)} + 2I_{(2,1,2,1,0)} + 2I_{(1,2,2,1,0)} \\ + 2I_{(0,1,1,0)} + 2I_{(2,2,0,0)} + I_{(1,0,1,0)} + I_{(0,0,0)} & \text{(I)} \end{cases}$

In Table 2.1 some trees and the corresponding values for the functions ρ , α , and φ are presented.

The following result is similar to results given in [1].

THEOREM 6. *If the coefficients $Z^{(l,\nu),(r,\mu)} \in \Xi_0^{s,s}$ and $z^{(l,\nu)} \in \Xi_0^s$, then the numerical solution Y_1 as well as the stage values can be written in terms of B-series*

$$H^{(l,\nu)} = B\left(\Phi^{(l,\nu)}, x_0; h\right), \quad Y_1 = B(\Phi, x_0; h)$$

for all l, ν , with

$$(2.3a) \quad \Phi^{(l,\nu)}(\emptyset)(h) \equiv \mathbb{1}_s, \quad \Phi^{(l,\nu)}(\bullet_r)(h) = \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \mathbb{1}_s,$$

$$(2.3b) \quad \Phi^{(l,\nu)}(\tau = [\tau_1, \dots, \tau_\kappa]_r)(h) = \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \prod_{j=1}^{\kappa} \Phi^{(r,\mu)}(\tau_j)(h)$$

and

$$(2.4a) \quad \Phi(\emptyset)(h) \equiv 1, \quad \Phi(\bullet_l)(h) = \sum_{\nu=0}^M z^{(l,\nu)} \mathbb{1}_s,$$

$$(2.4b) \quad \Phi(\tau = [\tau_1, \dots, \tau_\kappa]_l)(h) = \sum_{\nu=0}^M z^{(l,\nu)} \prod_{j=1}^{\kappa} \Phi^{(l,\nu)}(\tau_j)(h).$$

Proof. Write $H^{(l,\nu)}$ as a B-series, that is

$$H^{(l,\nu)} = \sum_{\tau \in T} \alpha(\tau) \left(\Phi^{(l,\nu)}(h) \otimes I_d \right) (\mathbb{1}_s \otimes F(\tau)(x_0)).$$

Use the definition of the method (1.3) together with (2.2) to obtain

$$H^{(l,\nu)} = \mathbb{1}_s \otimes x_0 + \sum_{r=0}^m \sum_{\mu=0}^M \sum_{\tau \in T_r} \alpha(\tau) \left(\left(Z^{(l,\nu)(r,\mu)} \cdot \left(\Phi^{(r,\mu)} \right)'_r(\tau)(h) \right) \otimes I_d \right) (\mathbb{1}_s \otimes F(\tau)(x_0))$$

with $(\Phi^{(r,\mu)})'_r(\tau)(h) = ((\Phi_1^{(r,\mu)})'_r(\tau)(h), \dots, (\Phi_s^{(r,\mu)})'_r(\tau)(h))^\top$. Comparing term-by-term gives the relations (2.3). The proof of (2.4) is similar. \square

To decide the weak order we will also need the B-series of the function f , evaluated at the exact and the numerical solution. From Theorem 5, Theorem 6, and Lemma 3 we obtain

$$f(X(t_0 + h)) = \sum_{u \in U_f} \beta(u) \cdot \psi_\varphi(u)(h) \cdot G(u)(x_0),$$

$$f(Y_1) = \sum_{u \in U_f} \beta(u) \cdot \psi_\Phi(u)(h) \cdot G(u)(x_0),$$

with

$$\psi_\varphi([\emptyset]_f)(h) \equiv 1, \quad \psi_\varphi(u = [\tau_1, \dots, \tau_\kappa]_f)(h) = \prod_{j=1}^\kappa \varphi(\tau_j)(h)$$

and

$$\psi_\Phi([\emptyset]_f)(h) \equiv 1, \quad \psi_\Phi(u = [\tau_1, \dots, \tau_\kappa]_f)(h) = \prod_{j=1}^\kappa \Phi(\tau_j)(h).$$

So, for the weak local error it follows

$$le_f(h; t, x) = \sum_{u \in U_f} \beta(u) \cdot \mathbb{E} [\psi_\Phi(u)(h) - \psi_\varphi(u)(h)] \cdot G(u)(x).$$

For the mean and mean square local error we obtain from Theorem 5 and Theorem 6,

$$le^{ms}(h; t, x) = \sqrt{\mathbb{E} \left(\sum_{\tau \in T} \alpha(\tau) \cdot (\Phi(\tau)(h) - \varphi(\tau)(h)) \cdot F(\tau)(x) \right)^2},$$

$$le^m(h; t, x) = \sum_{\tau \in T} \alpha(\tau) \cdot \mathbb{E} (\Phi(\tau)(h) - \varphi(\tau)(h)) \cdot F(\tau)(x).$$

With all the B-series in place, we can now present the order conditions for the weak and strong convergence for both the Itô and the Stratonovich case.¹ We have weak

¹As usual we assume that method (1.3) is constructed such that $E\psi_\varphi(u)(h) = \mathcal{O}(h^{\rho(u)}) \forall u \in U_f$ and $\varphi(\tau)(h) = \mathcal{O}(h^{\rho(\tau)}) \forall \tau \in T$, respectively, where especially in the latter expression the $\mathcal{O}(\cdot)$ -notation refers to the $L^2(\Omega)$ -norm and $h \rightarrow 0$. These conditions are fulfilled if for $i, j = 1, \dots, s$, $k \in \mathbb{N} = \{0, 1, \dots\}$ it holds that

$$(z_i^{(l,\nu)})^{2^k} = \begin{cases} \mathcal{O}(h^{(2^k)}) & l = 0 \\ \mathcal{O}(h^{(2^{k-1})}) & l > 0 \end{cases}, \quad (Z_{ij}^{(l,\nu)(r,\mu)})^{2^k} = \begin{cases} \mathcal{O}(h^{(2^k)}) & l = 0 \\ \mathcal{O}(h^{(2^{k-1})}) & l > 0 \end{cases}.$$

consistency of order p if and only if

$$(2.5) \quad \mathbb{E} \psi_{\Phi}(u)(h) = \mathbb{E} \psi_{\varphi}(u)(h) + \mathcal{O}(h^{p+1}) \quad \forall u \in U_f \text{ with } \rho(u) \leq p + \frac{1}{2},$$

where $\rho(u = [\tau_1, \dots, \tau_{\kappa}]_f) = \sum_{j=1}^{\kappa} \rho(\tau_j)$ ((2.5) slightly weakens conditions given in [27]), and mean square global order p if [4]

$$(2.6) \quad \Phi(\tau)(h) = \varphi(\tau)(h) + \mathcal{O}\left(h^{p+\frac{1}{2}}\right) \quad \forall \tau \in T \text{ with } \rho(\tau) \leq p,$$

$$(2.7) \quad \mathbb{E} \Phi(\tau)(h) = \mathbb{E} \varphi(\tau)(h) + \mathcal{O}(h^{p+1}) \quad \forall \tau \in T \text{ with } \rho(\tau) \leq p + \frac{1}{2}$$

and all elementary differentials $F(\tau)$ fulfill a linear growth condition. Instead of the last requirement it is also enough to claim that there exists a constant C such that $\|g'_j(y)\| \leq C \quad \forall y \in \mathbb{R}^m, j = 0, \dots, M$ (which implies the global Lipschitz condition) and all necessary partial derivatives exist [2].

3. B-series of the iterated solution and growth functions. In this section we will discuss how the iterated solution defined in (1.4) can be written in terms of B-series, that is,

$$H_k^{(l,\nu)} = B\left(\Phi_k^{(l,\nu)}, x_0; h\right) \quad \text{and} \quad Y_{1,k} = B(\Phi_k, x_0; h).$$

For notational convenience, in the following the h -dependency of the weight functions will be suppressed, so $\Phi(\tau)(h)$ will be written as $\Phi(\tau)$. Further, all results are valid for all $l = 0, \dots, m$ and $\nu = 0, \dots, M$.

Assume that the predictor can be written as a B-series,

$$H_0^{(l,\nu)} = B\left(\Phi_0^{(l,\nu)}, x_0; h\right),$$

satisfying $\Phi_0^{(l,\nu)}(\emptyset) = \mathbb{1}_s$ and $\Phi_0^{(l,\nu)}(\tau) = \mathcal{O}(h^{\rho(\tau)}) \forall \tau \in T$. The most common situation is the use of the trivial predictor $H^{(l,\nu)} = \mathbb{1}_s \otimes x_0$, for which $\Phi_0^{(l,\nu)}(\emptyset) = \mathbb{1}_s$ and $\Phi_0^{(l,\nu)}(\tau) = 0$ otherwise.

The iteration schemes we discuss here differ only in the choice of $J_k^{(r,\mu)}$ in (1.4). For all schemes, the following lemma applies. The proof follows directly from Lemma 3.

LEMMA 7. *If $H_k^{(l,\nu)} = B(\Phi_k^{(l,\nu)}, x_0; h)$, then $Y_{1,k} = B(\Phi_k, x_0; h)$ with*

$$\Phi_k(\emptyset) \equiv \mathbb{1}, \quad \Phi_k(\bullet_l) = \sum_{\nu=0}^M z^{(l,\nu)} \mathbb{1}_s, \quad \Phi_k(\tau = [\tau_1, \dots, \tau_{\kappa}]_l) = \sum_{\nu=0}^M z^{(l,\nu)} \prod_{j=1}^{\kappa} \Phi_k^{(l,\nu)}(\tau_j).$$

Further,

$$f(Y_{1,k}) = \sum_{u \in U_f} \beta(u) \cdot \psi_{\Phi_k}(u) \cdot G(u)(x_0)$$

with

$$\psi_{\Phi_k}([\emptyset]_f) = 1, \quad \psi_{\Phi_k}(u = [\tau_1, \dots, \tau_{\kappa}]_f) = \prod_{j=1}^{\kappa} \Phi_k(\tau_j),$$

where $\beta(u)$ and $G(u)(x_0)$ are given in Lemma 3.

$$\mathfrak{h}(\tau) = 3, \mathfrak{r}(\tau) = \mathfrak{d}(\tau) = 1; \quad \mathfrak{h}(\tau) = 4, \mathfrak{r}(\tau) = 3, \mathfrak{d}(\tau) = 2; \quad \mathfrak{h}(\tau) = \mathfrak{r}(\tau) = \mathfrak{d}(\tau) = 3$$

FIG. 3.1. Examples of trees and their growth functions for simple (\mathfrak{h}), modified Newton (\mathfrak{r}), and full Newton (\mathfrak{d}) iterations.

We are now ready to study each of the iteration schemes. In each case, we will first find the recurrence formula for $\Phi_k^{(l,\nu)}(\tau)$. From this we define a growth function $\mathfrak{g}(\tau)$.

DEFINITION 7 (growth function). A growth function $\mathfrak{g} : T \rightarrow \mathbb{N}$ is a function satisfying

$$(3.1) \quad \begin{aligned} \Phi_k^{(l,\nu)}(\tau) &= \Phi^{(l,\nu)}(\tau), \quad \forall \tau \in T, \quad \mathfrak{g}(\tau) \leq k \\ \Rightarrow \quad \Phi_{k+1}^{(l,\nu)}(\tau) &= \Phi^{(l,\nu)}(\tau), \quad \forall \tau \in T, \quad \mathfrak{g}(\tau) \leq k + 1, \end{aligned}$$

for all $k \geq 0$.

This result should be sharp in the sense that in general there exists $\tau \neq \emptyset$ with $\Phi_0^{(l,\nu)}(\tau) \neq \Phi^{(l,\nu)}(\tau)$ and $\Phi_k^{(l,\nu)}(\tau) \neq \Phi^{(l,\nu)}(\tau)$ when $k < \mathfrak{g}(\tau)$. From Lemma 7 we also have

$$(3.2) \quad \begin{aligned} \Phi_k(\tau) &= \Phi(\tau) & \forall \tau = [\tau_1, \dots, \tau_\kappa]_l \in T, & \quad \mathfrak{g}'(\tau) = \max_{j=1}^{\kappa} \mathfrak{g}(\tau_j) \leq k, \\ \psi_{\Phi_k}(u) &= \psi_{\Phi(\tau)} & \forall u = [\tau_1, \dots, \tau_\kappa]_f \in U_f, & \quad \mathfrak{g}'(u) = \max_{j=1}^{\kappa} \mathfrak{g}'(\tau_j) \leq k. \end{aligned}$$

The growth functions give a precise description of the development of the iterations. As we will see, the growth functions are exactly the same as in the deterministic case (see [13, 14]). However, to get applicable results, we will at the end need the relation between the growth functions and the order. Further, we will also take advantage of the fact that $E \Phi(\tau) = 0$ and $E \psi_{\Phi}(u) = 0$ for some trees. These aspects are discussed in the next sections. Examples of trees and the values of the growth functions for the three iteration schemes are given in Figure 3.1.

The simple iteration. Simple iterations are described by (1.4a) with $J_k^{(r,\mu)} = 0$, that is,

$$(3.3) \quad H_{k+1}^{(l,\nu)} = \mathbb{1}_s \otimes x_0 + \sum_{r=0}^m \sum_{\mu=0}^M \left(Z^{(l,\nu)(r,\mu)} \otimes I_d \right) g_r \left(H_k^{(r,\mu)} \right).$$

By (2.2) and Theorem 6 we easily get the next two results.

LEMMA 8. If $H_0^{(l,\nu)} = B(\Phi_0^{(l,\nu)}, x_0; h)$, then $H_k^{(l,\nu)} = B(\Phi_k^{(l,\nu)}, x_0; h)$, where

$$\Phi_{k+1}^{(l,\nu)}(\emptyset) \equiv \mathbb{1}_s, \quad \Phi_{k+1}^{(l,\nu)}(\tau = [\tau_1, \dots, \tau_\kappa]_r) = \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \prod_{j=1}^{\kappa} \Phi_k^{(r,\mu)}(\tau_j).$$

The corresponding growth function is given by

$$\mathfrak{h}(\emptyset) = 0, \quad \mathfrak{h}([\tau_1, \dots, \tau_\kappa]_l) = 1 + \max_{j=1}^{\kappa} \mathfrak{h}(\tau_j).$$

The function $\mathfrak{h}(\tau)$ is the height of τ , that is, the maximum number of nodes along one branch. The functions $\mathfrak{h}'(\tau)$ and $\mathfrak{h}'(u)$ are defined by (3.2), with \mathfrak{g} replaced by \mathfrak{h} .

The modified Newton iteration. In this subsection, we consider the modified Newton iteration (1.4a) with $J_k^{(r,\mu)} = I_s \otimes g'_r(x_0)$. The B-series for $H_k^{(l,\nu)}$ and the corresponding growth function can now be described by the following lemma.

LEMMA 9. *If $H_0^{(l,\nu)} = B(\Phi_0^{(l,\nu)}, x_0; h)$, then $H_k^{(l,\nu)} = B(\Phi_k^{(l,\nu)}, x_0; h)$ with*

$$(3.4) \quad \begin{aligned} \Phi_{k+1}^{(l,\nu)}(\emptyset) &\equiv \mathbb{1}_s, \\ \Phi_{k+1}^{(l,\nu)}(\tau) &= \begin{cases} \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \prod_{j=1}^{\kappa} \Phi_k^{(r,\mu)}(\tau_j) & \text{if } \tau = [\tau_1, \dots, \tau_\kappa]_r \in T \text{ and } \kappa \geq 2, \\ \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \Phi_{k+1}^{(r,\mu)}(\tau_1) & \text{if } \tau = [\tau_1]_r \in T. \end{cases} \end{aligned}$$

The corresponding growth function is given by

$$\mathfrak{r}(\emptyset) = 0, \quad \mathfrak{r}(\bullet_r) = 1, \quad \mathfrak{r}(\tau = [\tau_1, \dots, \tau_\kappa]_l) = \begin{cases} \mathfrak{r}(\tau_1) & \text{if } \kappa = 1, \\ 1 + \max_{j=1}^{\kappa} \mathfrak{r}(\tau_j) & \text{if } \kappa \geq 2. \end{cases}$$

The function $\mathfrak{r}(\tau)$ is one plus the maximum number of ramifications along any branch of the tree.

Proof. The iteration scheme (1.4a) can be rewritten in B-series notation as

$$(3.5) \quad \begin{aligned} \sum_{\tau \in T} \alpha(\tau) \cdot \Phi_{k+1}^{(l,\nu)}(\tau) \otimes F(\tau)(x_0) &= \mathbb{1} \otimes x_0 \\ + \sum_{r=0}^m \sum_{\tau \in T_r} \alpha(\tau) \cdot \left(\sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \left(\Phi_k^{(r,\mu)} \right)'_r(\tau) \right) \otimes F(\tau)(x_0) \\ + \sum_{r=0}^m \sum_{\tau_1 \in T_r} \alpha(\tau_1) \cdot \left(\sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \left(\Phi_{k+1}^{(r,\mu)}(\tau_1) - \Phi_k^{(r,\mu)}(\tau_1) \right) \right) \otimes (g'_r(x_0)F(\tau_1)(x_0)), \end{aligned}$$

where we have used (2.2). Clearly, $\Phi_{k+1}^{(l,\nu)}(\emptyset) \equiv \mathbb{1}_s$ for all $k \geq 0$ and

$$\Phi_{k+1}^{(l,\nu)}(\bullet_r) = \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \mathbb{1}_s,$$

proving the lemma for $\tau = \bullet_r = [\emptyset]_r$. Next, let $\tau = [\tau_1]_r$, where $\tau_1 \neq \emptyset$. Then $F(\tau)(x_0) = g'_r(x_0)F(\tau_1)$. Comparing equal terms on both sides of the equation, using $\alpha(\tau) = \alpha(\tau_1)$, we get

$$\Phi_{k+1}^{(l,\nu)}(\tau) = \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \left(\left(\Phi_k^{(r,\mu)} \right)'_r(\tau) + \Phi_{k+1}^{(r,\mu)}(\tau_1) - \Phi_k^{(r,\mu)}(\tau_1) \right).$$

Since $\left(\Phi_k^{(r,\mu)} \right)'_r(\tau) = \Phi_k^{(r,\mu)}(\tau_1)$ the lemma is proved for all $\tau = [\tau_1]_r$. For $\tau = [\tau_1, \dots, \tau_\kappa]_r$ with $\kappa \geq 2$ the last sum of (3.5) contributes nothing, thus

$$\Phi_{k+1}^{(l,\nu)}(\tau) = \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \left(\Phi_k^{(r,\mu)} \right)'_r(\tau),$$

which concludes the proof of (3.4).

The second statement of the lemma is obviously true for $\tau = \emptyset$. Let τ be any tree satisfying $\mathfrak{r}(\tau) \leq k + 1$. Then either $\tau = [\tau_1]_l$ with $\mathfrak{r}(\tau_1) \leq k + 1$ or $\tau = [\tau_1, \dots, \tau_\kappa]_l$ with $\kappa \geq 2$ and $\mathfrak{r}(\tau_i) \leq k$. In the latter case, we have by the hypothesis, by (3.4) and Theorem 6, that

$$\Phi_{k+1}^{(l,\nu)}(\tau) = \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \prod_{j=1}^{\kappa} \Phi^{(r,\mu)}(\tau_j) = \Phi^{(l,\nu)}(\tau).$$

In the first case, it follows easily by induction on τ that $\Phi_{k+1}^{(l,\nu)}(\tau) = \Phi^{(l,\nu)}(\tau)$ since $\Phi_{k+1}^{(l,\nu)}(\tau) = \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \Phi_{k+1}^{(r,\mu)}(\tau_1)$. \square

The full Newton iteration. In this subsection, we consider the full Newton iteration (1.4a) with

$$J_k^{(r,\mu)} = g_r' \left(H_k^{(r,\mu)} \right).$$

It follows that the B-series for $H_k^{(l,\nu)}$ and the corresponding growth function satisfy.

LEMMA 10. *If $H_0^{(l,\nu)} = B(\Phi_0^{(l,\nu)}, x_0; h)$, then $H_k^{(l,\nu)} = B(\Phi_k^{(l,\nu)}, x_0; h)$ with*

$$\begin{aligned} \Phi_{k+1}^{(l,\nu)}(\emptyset) &\equiv \mathbb{1}_s, \\ \Phi_{k+1}^{(l,\nu)}(\tau) &= \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \prod_{j=1}^{\kappa} \Phi_k^{(r,\mu)}(\tau_j) \\ &+ \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \sum_{i=1}^{\kappa} \left(\prod_{\substack{j=1 \\ j \neq i}}^{\kappa} \Phi_k^{(r,\mu)}(\tau_j) \right) \left(\Phi_{k+1}^{(r,\mu)}(\tau_i) - \Phi_k^{(r,\mu)}(\tau_i) \right), \end{aligned} \tag{3.6}$$

where $\tau = [\tau_1, \dots, \tau_\kappa]_r$ and the rightmost \prod is taken to be $\mathbb{1}_s$ if $\kappa = 1$. The corresponding growth function is given by

$$\begin{aligned} \mathfrak{d}(\emptyset) &= 0, & \mathfrak{d}(\bullet_l) &= 1, \\ \mathfrak{d}(\tau = [\tau_1, \dots, \tau_\kappa]_l) &= \begin{cases} \max_{j=1}^{\kappa} \mathfrak{d}(\tau_j) & \text{if } \gamma = 1, \\ \max_{j=1}^{\kappa} \mathfrak{d}(\tau_j) + 1 & \text{if } \gamma \geq 2, \end{cases} \end{aligned}$$

where γ is the number of subtrees in τ satisfying $\mathfrak{d}(\tau_i) = \max_{j=1}^{\kappa} \mathfrak{d}(\tau_j)$.

The function \mathfrak{d} is called the doubling index of τ .

Proof. Using (2.2) and Lemma 4 the scheme (1.4a) can be written as

$$\begin{aligned} \sum_{\tau \in \mathcal{T}} \alpha(\tau) \cdot \Phi_{k+1}^{(l,\nu)}(\tau) \otimes F(\tau)(x_0) &= \mathbb{1} \otimes x_0 \\ &+ \sum_{r=0}^m \sum_{\tau \in \mathcal{T}_r} \alpha(\tau) \cdot \left(\sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \left(\Phi_k^{(r,\mu)} \right)'_r(\tau) \right) \otimes F(\tau)(x_0) \\ &+ \sum_{r=0}^m \sum_{u \in \mathcal{U}_{g_r}} \beta(u) \cdot \left(\sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \Upsilon_k^{(r,\mu)}(u) \right) \otimes G(u)(x_0), \end{aligned} \tag{3.7}$$

where

$$\Upsilon_k^{(r,\mu)}(u = [\tau_1, \dots, \tau_\kappa]_{g_r}) = \sum_{i=1}^{\kappa} \left(\prod_{\substack{j=1 \\ j \neq i}}^{\kappa} \Phi_k^{(r,\mu)}(\tau_j) \right) \left(\Phi_{k+1}^{(r,\mu)}(\tau_i) - \Phi_k^{(r,\mu)}(\tau_i) \right).$$

From the definition of $F(\tau)$, $G(u = [\tau_1, \dots, \tau_\kappa]_{g_r})(x_0) = F(\tau = [\tau_1, \dots, \tau_\kappa]_r)(x_0)$. The sum over all $u \in U_{g_r}$ can be replaced by the sum over all $\tau \in T_r$, and the result is proved. Next, we will prove that $\mathfrak{d}(\tau)$ satisfies the implication (3.1) given in Definition 7. We will do so by induction on $n(\tau)$, the number of nodes in τ . Since \emptyset is the only tree satisfying $n(\tau) = 0$, and $\Phi_{k+1}^{(r,\mu)}(\emptyset) = \Phi^{(r,\mu)}(\emptyset) \equiv \mathbf{1}_s$, the conclusion of (3.1) is true for all $\tau \in T$ with $n(\tau) = 0$. Let $\bar{n} \geq 1$ and assume by the induction hypothesis that the conclusion of (3.1) holds for any tree satisfying $\mathfrak{d}(\tau) \leq k+1$ and $n(\tau) < \bar{n}$. We will show that $\Phi_{k+1}^{(r,\mu)}(\bar{\tau}) = \Phi^{(r,\mu)}(\bar{\tau})$ for all $\bar{\tau}$ satisfying $\mathfrak{d}(\bar{\tau}) \leq k+1$ and $n(\bar{\tau}) \leq \bar{n}$. Let $\bar{\tau} = [\tau_1, \dots, \tau_\kappa]_l$ where $n(\tau_j) < \bar{n}$ for $j = 1, \dots, \kappa$. Since $\mathfrak{d}(\bar{\tau}) \leq k+1$ there is at most one subtree τ_j satisfying $\mathfrak{d}(\tau_j) = k+1$, let us for simplicity assume this to be the last one. Thus $\mathfrak{d}(\tau_j) \leq k$ for $j = 1, \dots, \kappa-1$ and $\mathfrak{d}(\tau_\kappa) \leq k+1$. Consequently, $\Phi_k^{(r,\mu)}(\tau_j) = \Phi^{(r,\mu)}(\tau_j)$, $j = 1, \dots, \kappa-1$ by the hypothesis of (3.1), and $\Phi_{k+1}^{(r,\mu)}(\tau_j) = \Phi^{(r,\mu)}(\tau_j)$, $j = 1, \dots, \kappa$ by the induction hypothesis. By (3.6) and Theorem 6,

$$\begin{aligned} \Phi_{k+1}^{(l,\nu)}(\bar{\tau}) &= \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \prod_{j=1}^{\kappa} \Phi_k^{(r,\mu)}(\tau_j) \\ &\quad + \sum_{\mu=0}^M \sum_{i=1}^{\kappa} Z^{(l,\nu)(r,\mu)} \left(\prod_{\substack{j=1 \\ j \neq i}}^{\kappa} \Phi_k^{(r,\mu)}(\tau_j) \right) \left(\Phi_{k+1}^{(r,\mu)}(\tau_i) - \Phi_k^{(r,\mu)}(\tau_i) \right) \\ &= \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \left(\prod_{j=1}^{\kappa-1} \Phi_k^{(r,\mu)}(\tau_j) \right) \Phi_k^{(r,\mu)}(\tau_\kappa) \\ &\quad + \sum_{\mu=0}^M Z^{(l,\nu)(r,\mu)} \left(\prod_{j=1}^{\kappa-1} \Phi^{(r,\mu)}(\tau_j) \right) \left(\Phi^{(r,\mu)}(\tau_\kappa) - \Phi_k^{(r,\mu)}(\tau_\kappa) \right) \\ &= \Phi^{(l,\nu)}(\bar{\tau}), \end{aligned}$$

completing the induction proof. \square

4. General convergence results for iterated methods. Now we will relate the results of the previous section to the order of the overall scheme. In the following, we assume that the predictors satisfy the conditions

$$(4.1) \quad \begin{aligned} \Phi_0^{(l,\nu)}(\tau) &= \Phi^{(l,\nu)}(\tau) & \forall \tau \in T \text{ with } \mathfrak{g}(\tau) \leq \mathcal{G}_0, \\ \Phi_0^{(l,\nu)}(\tau) &\in \left\{ \Phi^{(l,\nu)}(\tau), 0 \right\} & \forall \tau \in T \text{ with } \mathfrak{g}(\tau) \leq \hat{\mathcal{G}}_0, \end{aligned}$$

where \mathcal{G}_0 and $\hat{\mathcal{G}}_0$ are chosen as large as possible. In particular, the trivial predictor satisfies $\mathcal{G}_0 = 0$ while $\hat{\mathcal{G}}_0 = \infty$. We assume further that in analogy to (3.1) we have

$$(4.2) \quad \begin{aligned} \Phi_k^{(l,\nu)}(\tau) &\in \left\{ \Phi^{(l,\nu)}(\tau), 0 \right\}, \quad \forall \tau \in T, \quad \mathfrak{g}(\tau) \leq k \\ \Rightarrow \quad \Phi_{k+1}^{(l,\nu)}(\tau) &\in \left\{ \Phi^{(l,\nu)}(\tau), 0 \right\}, \quad \forall \tau \in T, \quad \mathfrak{g}(\tau) \leq k+1, \end{aligned}$$

for all $k \geq 0$. By Lemmas 8, 9, and 10 this is guaranteed for the iteration schemes considered here.

It follows from (3.1), (3.2), and (4.2) that

$$(4.3) \quad \begin{aligned} \Phi_k(\tau) &= \Phi(\tau) & \forall \tau \in T \text{ with } \mathbf{g}'(\tau) \leq \mathcal{G}_0 + k, \\ \Phi_k(\tau) &\in \{\Phi(\tau), 0\} & \forall \tau \in T \text{ with } \mathbf{g}'(\tau) \leq \hat{\mathcal{G}}_0 + k \end{aligned}$$

as well as

$$(4.4) \quad \begin{aligned} \psi_{\Phi_k}(u) &= \psi_{\Phi}(u) & \forall u \in U_f \text{ with } \mathbf{g}'(u) \leq \mathcal{G}_0 + k, \\ \psi_{\Phi_k}(\tau) &\in \{\psi_{\Phi}(u), 0\} & \forall u \in U_f \text{ with } \mathbf{g}'(u) \leq \hat{\mathcal{G}}_0 + k. \end{aligned}$$

The next step is to establish the relation between the order and the growth function of a tree. We have chosen to do so by some maximum height functions, given by

$$(4.5) \quad \begin{aligned} \mathcal{G}_T(q) &= \max_{\tau \in T} \{\mathbf{g}'(\tau) : \rho(\tau) \leq q\}, & \mathcal{G}_{T,\varphi}(q) &= \max_{\tau \in T} \{\mathbf{g}'(\tau) : \mathbb{E} \varphi(\tau) \neq 0, \rho(\tau) \leq q\}, \\ \mathcal{G}_{U_f}(q) &= \max_{u \in U_f} \{\mathbf{g}'(u) : \rho(u) \leq q\}, & \mathcal{G}_{U_f,\psi_\varphi}(q) &= \max_{u \in U_f} \{\mathbf{g}'(u) : \mathbb{E} \psi_\varphi(u) \neq 0, \rho(u) \leq q\}. \end{aligned}$$

Note that the definition relates to the weights of the exact, not the numerical, solution. We are now ready to establish results on weak and strong convergence for the iterated solution.

Weak convergence. Let p be the weak order of the underlying scheme. The weak order of the iterated solution after k iterations is $\min(q_k, p)$ if

$$\mathbb{E} \psi_{\Phi_k}(u) = \mathbb{E} \psi_{\Phi}(u) \quad \forall u \in U_f, \quad \rho(u) \leq q_k + \frac{1}{2}.$$

If $q_k \leq p$ we can take advantage of the fact that $0 = \mathbb{E} \psi_\varphi(u) = \mathbb{E} \psi_{\Phi}(u) + \mathcal{O}(h^{p+1})$ for some u , and thereby relax the conditions to

$$(4.6) \quad \begin{aligned} \psi_{\Phi_k}(u) &= \psi_{\Phi}(u) & \forall u \in U_f \text{ with } \mathbb{E} \psi_\varphi(u) \neq 0, \\ \psi_{\Phi_k}(u) &\in \{\psi_{\Phi}(u), 0\} & \forall u \in U_f \text{ with } \mathbb{E} \psi_\varphi(u) = 0. \end{aligned}$$

By (4.4), this is fulfilled for all u of order $\rho(u) \leq \min(q_k, p)$ if

$$\mathcal{G}_{U_f,\Psi_\varphi} \left(q_k + \frac{1}{2} \right) \leq \mathcal{G}_0 + k \quad \text{and} \quad \mathcal{G}_{U_f} \left(q_k + \frac{1}{2} \right) \leq \hat{\mathcal{G}}_0 + k.$$

The results can then be summarized in the following theorem.

THEOREM 11. *The iterated method is of weak order $q_k \leq p$ after*

$$\max \left\{ \mathcal{G}_{U_f,\psi_\varphi} \left(q_k + \frac{1}{2} \right) - \mathcal{G}_0, \mathcal{G}_{U_f} \left(q_k + \frac{1}{2} \right) - \hat{\mathcal{G}}_0 \right\}$$

iterations.

Strong convergence. The strong convergence case can be treated similarly. Let p now be the mean square order of the underlying method. The iterated solution is of order $\min(p, q_k)$ if

$$(4.7) \quad \begin{aligned} \Phi_k(\tau) &= \Phi(\tau) & \forall \tau \in T \text{ with } \rho(\tau) \leq q_k, \\ \Phi_k(\tau) &= \Phi(\tau) & \forall \tau \in T \text{ with } \rho(\tau) = q_k + \frac{1}{2}, \quad \mathbb{E} \phi(\tau) \neq 0, \\ \Phi_k(\tau) &\in \{\Phi(\tau), 0\} & \forall \tau \in T \text{ with } \rho(\tau) = q_k + \frac{1}{2}, \quad \mathbb{E} \phi(\tau) = 0. \end{aligned}$$

According to (4.3) these are satisfied if all the conditions

$$\mathcal{G}_T(q_k) \leq \mathcal{G}_0 + k, \quad \mathcal{G}_T\left(q_k + \frac{1}{2}\right) \leq \hat{\mathcal{G}}_0 + k, \quad \text{and} \quad \mathcal{G}_{T,\varphi}\left(q_k + \frac{1}{2}\right) \leq \mathcal{G}_0 + k$$

are satisfied. We can summarize this by the following theorem.

THEOREM 12. *The iterated method is of mean square order $q_k \leq p$ after*

$$\max \left\{ \max \left\{ \mathcal{G}_T(q_k), \mathcal{G}_{T,\varphi}\left(q_k + \frac{1}{2}\right) \right\} - \mathcal{G}_0, \mathcal{G}_T\left(q_k + \frac{1}{2}\right) - \hat{\mathcal{G}}_0 \right\}$$

iterations.

5. Growth functions and order. In this section we will discuss the relation between the order of trees and the growth functions defined in section 3. Let us start with the following lemma.

LEMMA 13. *For $k \geq 1$,*

$$\begin{aligned} \mathfrak{h}'(\tau) = k &\Rightarrow \rho(\tau) \geq \frac{k}{2} + \frac{1}{2}, \\ \mathfrak{r}'(\tau) = k &\Rightarrow \rho(\tau) \geq k, \\ \mathfrak{d}'(\tau) = k &\Rightarrow \rho(\tau) \geq 2^{k-1}. \end{aligned}$$

The same result is valid for $\mathfrak{h}'(u)$, $\mathfrak{r}'(u)$, and $\mathfrak{g}'(u)$.

Proof. Let $\mathcal{T}_{\mathfrak{h},k}$, $\mathcal{T}_{\mathfrak{r},k}$, and $\mathcal{T}_{\mathfrak{d},k}$ be sets of trees of minimal order satisfying $\mathfrak{h}(\tau) = k \forall \tau \in \mathcal{T}_{\mathfrak{h},k}$, $\mathfrak{r}(\tau) = k \forall \tau \in \mathcal{T}_{\mathfrak{r},k}$, and $\mathfrak{d}(\tau) = k \forall \tau \in \mathcal{T}_{\mathfrak{d},k}$ (see Figure 5.1), and denote this minimal order by $\rho_{\mathfrak{h},k}$, $\rho_{\mathfrak{r},k}$ and $\rho_{\mathfrak{d},k}$. Minimal order trees are built up only by stochastic nodes. It follows immediately that $\mathcal{T}_{\mathfrak{h},1} = \mathcal{T}_{\mathfrak{r},1} = \mathcal{T}_{\mathfrak{d},1} = \{\bullet_l : l \geq 1\}$. Since $\rho(\bullet_l) = 1/2$ for $l \geq 1$, the results are proved for $k = 1$. It is easy to show by induction on k that

$$(5.1) \quad \begin{aligned} \mathcal{T}_{\mathfrak{h},k} &= \{[\tau]_l : \tau \in \mathcal{T}_{\mathfrak{h},k-1}, l \geq 1\}, & \rho_{\mathfrak{h},k} &= \rho_{\mathfrak{h},k-1} + \frac{1}{2} = \frac{k}{2}, \\ \mathcal{T}_{\mathfrak{r},k} &= \{[\bullet_{l_1}, \tau]_{l_2} : \tau \in \mathcal{T}_{\mathfrak{r},k-1}, l_1, l_2 \geq 1\}, & \rho_{\mathfrak{r},k} &= \rho_{\mathfrak{r},k-1} + 1 = k - \frac{1}{2}, \\ \mathcal{T}_{\mathfrak{d},k} &= \{[\tau_1, \tau_2]_l : \tau_1, \tau_2 \in \mathcal{T}_{\mathfrak{d},k-1}, l \geq 1\}, & \rho_{\mathfrak{d},k} &= 2\rho_{\mathfrak{d},k-1} + \frac{1}{2} = 2^{k-1} - \frac{1}{2}. \end{aligned}$$

For each \mathfrak{g} being either \mathfrak{h} , \mathfrak{r} , or \mathfrak{d} , the minimal order trees satisfying $\mathfrak{g}'(\tau'_{\mathfrak{g},k}) = k$, $\mathfrak{g}'(u_{\mathfrak{g},k}) = k$ are $\tau'_{\mathfrak{g},k} = [\tau_{\mathfrak{g},k}]_l$ with $\tau_{\mathfrak{g},k} \in \mathcal{T}_{\mathfrak{g},k}$ and $l \geq 1$, and $u_{\mathfrak{g},k} = [\tau'_{\mathfrak{g},k}]_f$. Both are of order $\rho(\tau_{\mathfrak{g},k}) + 1/2$. \square

Let $\mathcal{G}_T(q)$ and $\mathcal{G}_{U_f}(q)$ be defined by (4.5). Then the following corollary holds.

COROLLARY 14. *For $q \geq \frac{1}{2}$ we have*

$$\mathcal{G}_T(q) = \mathcal{G}_{U_f}(q) = \begin{cases} 2q - 1 & \text{for simple iterations,} \\ \lfloor q \rfloor & \text{for modified Newton iterations,} \\ \lfloor \log_2(q) \rfloor + 1 & \text{for full Newton iterations.} \end{cases}$$

FIG. 5.1. Minimal order trees with $\mathfrak{g}(\tau) = 3$. The sets $\mathcal{T}_{\mathfrak{g},3}$ consist of all such trees with only stochastic nodes.

Proof. The minimal order trees are also the maximum height/ramification number/doubling index trees, in the sense that as long as $\rho(\tau'_{\mathbf{g},k}) \leq q < \rho(\tau'_{\mathbf{g},k+1})$ there are no trees of order q for which the growth function can exceed k . \square

Let $T^S \subset T$ and $U_f^S \subset U_f$ be the set of trees with an even number of each kind of stochastic nodes. Further, let $T^I \subset T_0$ and $U_f^I \subset U_f$ be the set of trees constructed from the root $(\bullet_0$ or $\bullet_f)$, by a finite number of steps of the form:

- (i) add one deterministic node, or
- (ii) add two equal stochastic nodes, neither of them being a father of the other.

Clearly $T^I \subset T^S$ and $U_f^I \subset U_f^S$. From [5, 26] we have

$$(5.2) \quad \begin{aligned} \mathbb{E} \varphi(\tau) = 0 & \quad \text{if } \tau \notin \begin{cases} T^S & \text{in the Stratonovich case,} \\ T^I & \text{in the It\^o case,} \end{cases} \\ \mathbb{E} \psi_\varphi(u) = 0 & \quad \text{if } u \notin \begin{cases} U_f^S & \text{in the Stratonovich case,} \\ U_f^I & \text{in the It\^o case.} \end{cases} \end{aligned}$$

Considering only trees for which $\mathbb{E} \varphi$ or $\mathbb{E} \psi_\varphi$ are different from zero, we get the following lemma.

LEMMA 15. For $k \geq 1$,

$$\begin{aligned} \mathfrak{h}'(\tau) = k & \Rightarrow \rho(\tau) \geq \begin{cases} \lceil \frac{k+1}{2} \rceil & \text{if } \tau \in T^S, \\ k+1 & \text{if } \tau \in T^I, \end{cases} \\ \mathfrak{r}'(\tau) = k & \Rightarrow \rho(\tau) \geq \begin{cases} k & \text{if } \tau \in T^S, \\ k+1 & \text{if } \tau \in T^I, \end{cases} \\ \mathfrak{d}'(\tau) = k & \Rightarrow \rho(\tau) \geq \begin{cases} 2^{k-1} & \text{if } \tau \in T^S, \\ 2^{k-1} + 1 & \text{if } \tau \in T^I. \end{cases} \end{aligned}$$

This result is also valid for $\mathfrak{h}'(u)$, $\mathfrak{r}'(u)$, and $\mathfrak{g}'(u)$, with T replaced by U_f .

Proof. In the Stratonovich case, we consider only trees of integer order, which immediately gives the results. In the It\^o case, let $\tau_{\mathbf{g},k}$, $\tau'_{\mathbf{g},k}$ be the minimal order trees used in the proof of Lemma 13. Unfortunately $\tau'_{\mathbf{g},k}$ has a stochastic root, so $\tau'_{\mathbf{g},k} \notin T^I$, and there are no trees $\tau \in T^I$ of order $\rho(\tau_{\mathbf{g},k}) + 1/2$ satisfying $\mathfrak{g}'(\tau) = k$. When \mathbf{g} is either \mathfrak{r} or \mathfrak{d} then the tree $[\tau_{\mathbf{g}}, \bullet_l]_0 \in T^I$ if all the stochastic nodes are of color $l \geq 1$. The order of this tree is $\rho(\tau_{\mathbf{g}}) + 3/2$, proving the result for $\mathfrak{r}'(\tau)$ and $\mathfrak{d}'(\tau)$. Let $\hat{\tau}'_{\mathfrak{h},k} \in T^I$ be a tree of minimal order satisfying $\mathfrak{h}'(\hat{\tau}'_{\mathfrak{h},k}) = k$. Clearly, $\hat{\tau}'_{\mathfrak{h},1}$ can be either $[\bullet_0]_0$ or $[\bullet_l, \bullet_l]_0$ with $l \geq 1$, both of order 2. From the construction of trees in T^I it is clear that the height of the tree can be increased only by one for each order, thus $\rho(\hat{\tau}'_{\mathfrak{h},k}) = k + 1$. The result for U_f^I follows immediately. \square

Let $\mathcal{G}_{T,\varphi}(q)$ and $\mathcal{G}_{U_f,\psi_\varphi}(q)$ be given by (4.5). Then the analogue of Corollary 14 is as follows.

COROLLARY 16. For $q \geq \frac{1}{2}$ we have in the Stratonovich case

$$\mathcal{G}_{T,\varphi}(q) = \mathcal{G}_{U_f,\psi_\varphi}(q) = \begin{cases} \max\{0, 2\lfloor q \rfloor - 1\} & \text{for simple iterations,} \\ \lfloor q \rfloor & \text{for modified Newton iterations,} \\ \lfloor \log_2(q) \rfloor + 1 & \text{for full Newton iterations,} \end{cases}$$

TABLE 5.1

Number of iterations needed to achieve order p when using the simple, modified, or full Newton iteration scheme in the Itô or Stratonovich case for strong or weak approximation.

p	Stratonovich			Itô					
	Strong/weak appr.			Weak appr.			Strong appr.		
	simple	mod.	full	simple	mod.	full	simple	mod.	full
$\frac{1}{2}$	1	1	1	0	0	0	0	0	0
1	1	1	1	0	0	0	1	1	1
$1\frac{1}{2}$	3	2	2	1	1	1	2	1	1
2	3	2	2	1	1	1	3	2	2
$2\frac{1}{2}$	5	3	2	2	2	1	4	2	2
3	5	3	2	2	2	1	5	3	2

and in the Itô case

$$\mathcal{G}_{T,\varphi}(q) = \mathcal{G}_{U_f,\psi_\varphi}(q) = \begin{cases} \max\{0, \lfloor q \rfloor - 1\} & \text{for simple iterations,} \\ \max\{0, \lfloor q \rfloor - 1\} & \text{for modified Newton iterations,} \\ \max\{0, \lfloor \log_2(q) \rfloor\} & \text{for full Newton iterations.} \end{cases}$$

For the trivial predictor, Table 5.1 gives the number of iterations needed to achieve a certain order of convergence. The results concerning the Stratonovich case when considering strong approximation and using the simple iteration scheme were already obtained by Burrage and Tian [3] analyzing predictor corrector methods.

6. Convergence results for composite methods. Composite methods have been introduced by Tian and Burrage [31]. At each step either a semi-implicit Runge–Kutta method or an implicit Runge–Kutta method is used in order to obtain better stability properties, which results in the method

$$(6.1a) \quad \begin{aligned} Y_{n+1} = Y_n + \lambda_n \sum_{l=0}^m \sum_{\nu=0}^M \left(z^{(1,l,\nu)\top} \otimes I_d \right) g_l \left(H^{(1,l,\nu)} \right) \\ + (1 - \lambda_n) \sum_{l=0}^m \sum_{\nu=0}^M \left(z^{(2,l,\nu)\top} \otimes I_d \right) g_l \left(H^{(2,l,\nu)} \right) \end{aligned}$$

for $n = 0, 1, \dots, N - 1$, $t_n \in I^h$, $\lambda_n \in \{0, 1\}$ and

$$(6.1b) \quad H^{(j,l,\nu)} = \mathbb{1}_s \otimes Y_n + \sum_{r=0}^m \sum_{\mu=0}^M \left(Z^{(j,l,\nu)(r,\mu)} \otimes I_d \right) g_r \left(H^{(j,r,\mu)} \right), \quad j = 1, 2.$$

Here, the method coefficients with superscripts 1 are those of the implicit SRK and the method coefficients with superscripts 2 are those of the semi-implicit SRK. Let $\Phi^{(1)}$, $\Phi^{(2)}$ be the corresponding weight-functions and $\Phi_k^{(1)}$, $\Phi_k^{(2)}$ be the corresponding weight-functions of the iterated methods. Then the weight-function Φ of the composite method is given by $\Phi = \lambda_1 \Phi^{(1)} + (1 - \lambda_1) \Phi^{(2)}$, and similarly we have for the iterated method $\Phi_k = \lambda_1 \Phi_k^{(1)} + (1 - \lambda_1) \Phi_k^{(2)}$. It follows that the convergence conditions (4.6) and (4.7), respectively, are satisfied if and only if they are satisfied as well for the underlying implicit SRK as for the semi-implicit SRK. Thus, an iterated composite method has the same order as the original composite method, if in each step the number of iterations is chosen according to Theorem 11 and Theorem 12, respectively. For the trivial predictor, the number of iterations needed to achieve a certain order of convergence is again given by Table 5.1.

FIG. 7.1. Error of IPS applied to (7.1) without iteration, with one or two simple iterations, and with one modified Newton iteration (the last two results nearly coincide).

7. Numerical examples. In the following, we analyze numerically the order of convergence of three SRK methods in dependence on the kind and number of iterations. In each example, the solution is approximated with step sizes $2^{-8}, \dots, 2^{-12}$ and the sample average of $M = 20,000$ independent simulated realizations of the absolute error is calculated in order to estimate the expectation.

As a first example, we apply the drift implicit strong order 1.5 scheme due to Kloeden and Platen [16], implemented as a stiffly accurate SRK scheme with six stages and denoted by IPS; i.e., for one-dimensional Wiener processes

$$\begin{aligned}
 Y_{n+1} &= Y_n + \sum_{l=0}^1 \left(z^{(l)\top} \otimes I_d \right) g_l(H), & H &= \mathbf{1}_6 \otimes Y_n + \sum_{l=0}^1 \left(Z^{(l)} \otimes I_d \right) g_l(H), \\
 Z^{(0)} &= \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ h & 0 & 0 & 0 & 0 & 0 \\ h & 0 & 0 & 0 & 0 & 0 \\ h & 0 & 0 & 0 & 0 & 0 \\ h & 0 & 0 & 0 & 0 & 0 \\ \frac{h}{2} & a & -a & 0 & 0 & \frac{h}{2} \end{pmatrix}, & Z^{(1)} &= \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ \sqrt{h} & 0 & 0 & 0 & 0 & 0 \\ -\sqrt{h} & 0 & 0 & 0 & 0 & 0 \\ \sqrt{h} & \sqrt{h} & 0 & 0 & 0 & 0 \\ \sqrt{h} & -\sqrt{h} & 0 & 0 & 0 & 0 \\ I_{(1)} & b+c & b-c & d & -d & 0 \end{pmatrix}, \\
 z^{(0)} &= \left(\frac{h}{2}, a, -a, 0, 0, \frac{h}{2} \right)^\top, & z^{(1)} &= \left(I_{(1)}, b+c, b-c, d, -d, 0 \right)^\top, \\
 a &= \frac{I_{(1,0)} - \frac{1}{2}I_{(1)}h}{2\sqrt{h}}, & b &= \frac{I_{(0,1)}}{2h}, & c &= \frac{I_{(1,1)}}{2\sqrt{h}} - d, & d &= \frac{I_{(1,1,1)}}{2h},
 \end{aligned}$$

to the nonlinear SDE [16, 21]

$$(7.1) \quad dX(t) = \left(\frac{1}{2}X(t) + \sqrt{X(t)^2 + 1} \right) dt + \sqrt{X(t)^2 + 1} dW(t), \quad X(0) = 0,$$

on the time interval $I = [0, 1]$ with the solution $X(t) = \sinh(t + W(t))$.

The results at time $t = 1$ are presented in Figure 7.1, where the orders of convergence correspond to the slope of the regression lines. As predicted by Table 5.1 we observe strong order 0.5 without iteration, strong order 1.0 for one simple iteration, and strong order 1.5 for two simple or one modified Newton iteration.

As second example, we apply the diagonal implicit strong order 1.5 method DIRK4 which for one-dimensional Wiener processes is given by

$$Y_{n+1} = Y_n + \sum_{l=0}^1 \left(z^{(l)\top} \otimes I_d \right) g_l(H), \quad H = \mathbf{1}_3 \otimes Y_n + \sum_{l=0}^1 \left(Z^{(l)} \otimes I_d \right) g_l(H)$$

with coefficients²

$$\begin{aligned} z^0 &= h\alpha, & z^1 &= J_{(1)}\gamma^{(1)} + \frac{J_{(1,0)}}{h}\gamma^{(2)}, \\ Z^{(0)} &= hA, & Z^{(1)} &= J_{(1)}B^{(1)} + \frac{J_{(1,0)}}{h}B^{(2)} + \sqrt{h}B^{(3)}, \\ \alpha^\top &= (0.169775184, 0.297820839, 0.042159965, 0.490244012), \\ \gamma^{(1)\top} &= (-1.008751744, 0.285118644, 0.760818846, 0.962814254), \\ \gamma^{(2)\top} &= (1.507774621, 1.085932735, -1.458091242, -1.135616114), \\ A &= \begin{pmatrix} 0.240968725 & 0 & 0 & 0 \\ 0.167810317 & 0.160243373 & 0 & 0 \\ -0.002766912 & 0.473332751 & 0.178081733 & 0 \\ 0.415057712 & 0.115126049 & 0.020652745 & 0.130541130 \end{pmatrix}, \\ B_1 &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ -0.476890860 & 0 & 0 & 0 \\ 0.514160282 & 0.012424879 & 0 & 0 \\ -0.879966702 & 0.412866280 & 0.711524058 & 0 \end{pmatrix}, \\ B_2 &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 1.287951512 & 0 & 0 & 0 \\ 0.665416412 & -0.686930244 & 0 & 0 \\ 0.703868780 & 0.876627859 & -0.321270197 & 0 \end{pmatrix}, \\ B_3 &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0.568300129 & -0.568300129 & 0 & 0 \\ 1.614193125 & -0.618659748 & -0.995533377 & 0 \\ 0.660721631 & -0.714401673 & -0.896487337 & 0.950167380 \end{pmatrix} \end{aligned}$$

to the corresponding Stratonovich version of (7.1). This method is constructed such that the regularity of the linear system which has to be solved in each modified Newton iteration step does not depend directly on $J_{(1)}$ and $J_{(1,0)}$.

The results at time $t = 1$ are presented in Figure 7.2. As predicted by Table 5.1 we observe no convergence without iteration, strong order 1.0 for one or two simple iterations or one modified Newton iteration, and strong order 1.5 in the case of three simple iterations or two modified Newton iterations.

²For typographical reasons, we restrict ourselves to an accuracy of $5 \cdot 10^{-10}$. A 16-digits version of the coefficients can be obtained on request from the authors.

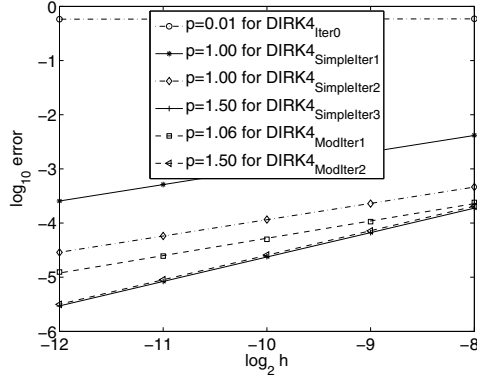

FIG. 7.2. Error of DIRK4 applied to the Stratonovich version of (7.1) without iteration, with one, two, or three simple iterations, and with one or two modified Newton iterations (the results for three simple iterations and two modified Newton iterations nearly coincide).

Finally, we apply the drift implicit strong order 1.0 scheme due to Kloeden and Platen [16], implemented as a stiffly accurate SRK scheme in the form

$$\begin{aligned}
 Y_{n+1} &= Y_n + \sum_{l=0}^m \sum_{\nu=0}^m \left(z^{(l,\nu)\top} \otimes I_d \right) g_l \left(H^{(\nu)} \right), \\
 H^{(\nu)} &= \mathbb{1}_2 \otimes Y_n + \sum_{l=0}^m \sum_{\mu=0}^m \left(Z^{(\nu)(l,\mu)} \otimes I_d \right) g_l \left(H^{(\mu)} \right), \quad \nu = 0, \dots, m, \\
 Z^{(0)(0,0)} &= \begin{pmatrix} 0 & 0 \\ \frac{h}{2} & \frac{h}{2} \end{pmatrix}, & Z^{(0)(0,\mu)} &= \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, & Z^{(0)(l,0)} &= \begin{pmatrix} 0 & 0 \\ I_{(l)} & 0 \end{pmatrix}, \\
 Z^{(0)(l,\mu)} &= \begin{pmatrix} 0 & 0 \\ -\frac{I_{(\mu,l)}}{\sqrt{h}} & \frac{I_{(\mu,l)}}{\sqrt{h}} \end{pmatrix}, & Z^{(j)(0,0)} &= \begin{pmatrix} 0 & 0 \\ h & 0 \end{pmatrix}, & Z^{(j)(l,l)} &= \begin{pmatrix} 0 & 0 \\ \sqrt{h} & 0 \end{pmatrix}, \\
 Z^{(j)(l,\mu)} &= \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} \text{ for } l \neq \mu, & z^{(0,0)} &= \left(\frac{h}{2}, \frac{h}{2} \right)^\top, & z^{(0,\mu)} &= (0, 0)^\top, \\
 z^{(l,0)} &= (I_{(l)}, 0)^\top, & z^{(l,\mu)} &= \left(-\frac{I_{(\mu,l)}}{\sqrt{h}}, \frac{I_{(\mu,l)}}{\sqrt{h}} \right)^\top, & j, l, \mu &= 1, \dots, m,
 \end{aligned}$$

and denoted by IPS10 to the following nonlinear problem of dimension two driven by two Wiener processes in which there is no commutativity between the driving terms,

$$\begin{aligned}
 dX_1(t) &= \left(\frac{1}{2}X_1(t) + \sqrt{X_1(t)^2 + X_2(t)^2 + 1} \right) dt + \sqrt{X_2(t)^2 + 1} dW_1(t) \\
 (7.2a) \quad &+ \cos X_1(t) dW_2(t),
 \end{aligned}$$

$$\begin{aligned}
 (7.2b) \quad dX_2(t) &= \left(\frac{1}{2}X_1(t) + \sqrt{X_2(t)^2 + 1} \right) dt + \sqrt{X_1(t)^2 + 1} dW_1(t) + \sin X_2(t) dW_2(t), \\
 (7.2c) \quad X(0) &= 0.
 \end{aligned}$$

As here we don't know the exact solution, to approximate it we use IPS10 with two modified Newton iterations and a step size ten times smaller than the actual step size. The multiple Itô integrals are approximated as described in [16]. The results at time

FIG. 7.3. Error of IPS10 applied to (7.2) without iteration, with one simple iteration and with one modified Newton iteration (the last two results nearly coincide).

$t = 1$ are presented in Figure 7.3. As predicted by Table 5.1 we observe strong order 0.5 without iteration and strong order 1.0 for one simple iteration or one modified Newton iteration.

8. Conclusion. For stochastic Runge–Kutta methods that use an iterative scheme to compute their internal stage values, we derived convergence results based on the order of the underlying Runge–Kutta method, the choice of the iteration method, the predictor, and the number of iterations. This was done by developing a unifying approach for the construction of stochastic B-series, which is valid both for Itô and Stratonovich-SDEs and can be used both for weak and strong convergence. We expect this to be useful also for the further development and analysis of stochastic Runge–Kutta type methods.

FINITE ELEMENT METHOD FOR THE SPACE AND TIME FRACTIONAL FOKKER–PLANCK EQUATION*

WEIHUA DENG[†]

Abstract. We develop the finite element method for the numerical resolution of the space and time fractional Fokker–Planck equation, which is an effective tool for describing a process with both traps and flights; the time fractional derivative of the equation is used to characterize the traps, and the flights are depicted by the space fractional derivative. The stability and error estimates are rigorously established, and we prove that the convergent order is $O(k^{2-\alpha} + h^\mu)$, where k is the time step size and h the space step size. Numerical computations are presented which demonstrate the effectiveness of the method and confirm the theoretical claims.

Key words. finite element method, fractional Fokker–Planck equation, Lévy flights, stability, convergence

DOI. 10.1137/080714130

1. Introduction. The use of fractional calculus to deal with engineering and physical problems has become increasingly popular in recent years [2, 7, 21, 33, 36]. The fractional approach has become a powerful modeling methodology; it is widely applied in material and mechanics, signal processing and systems identification, anomalous diffusion, control and robotics, wave propagation, turbulence, seepage in fractal media, friction modeling, etc. [2]. At the same time, more and more fractional dynamical appearances are disclosed, for instance, viscoelasticity [22], colored noise [31], boundary layer effects in ducts [39], electromagnetic waves [17], fractional kinetics [23, 41], electrode-electrolyte polarization [19], synchronization of chaos [10], and multidirectional multiscroll attractors [9]. When the fractional differential equations describe the asymptotic behavior of continuous time random walks, their solutions correspond to the Lévy walks. The advantage of the fractional model basically lies in the straightforward way of including external force terms and of calculating boundary value problems. The complexity of these equations comes from involving pseudodifferential operators that are nonlocal and have the character of history dependence and universal mutuality.

Anomalous diffusion is one of the most ubiquitous phenomena in nature, being observed in various fields of physics, for instance, transport of fluid in porous media, surface growth, diffusion of plasma, diffusion at liquid surfaces, and two-dimensional rotating flow [5, 16, 25, 38]. The processes of anomalous diffusion are various, including processes with infinite mean-square displacement and processes with distributed orders of fraction leading to the mean-square displacement for power laws with a time-dependent exponent; at the same time the most often arisen anomalous diffusion has the power law form $\langle x^2(t) \rangle - \langle x(t) \rangle^2 \sim k_\alpha t^\gamma$ of the mean-square displacement, deviating from the well-known property $\langle x^2(t) \rangle - \langle x(t) \rangle^2 \sim k_\alpha t$ of Brownian motion.

For Lévy flights, γ is larger than one (but typically smaller than two), which is called superdiffusion; $\gamma = 2$ corresponds to “ballistic” motion, for example, the particles of a bomb which is exploding, and it is called subdiffusion if γ is less than one, which in general corresponds to the divergence of microscopic time scales in random walk schemes, i.e., traps [5, 25, 34, 35, 38, 41]. A prominent characteristic feature of Lévy flights and traps is the probability distribution functions both on the step length for Lévy flights and on the waiting time between steps for traps that have a powerlike tail. There is no characteristic length or time scale in the case of flights or traps. Combining flights with traps is a more general way to describe an anomalous process. When a process has both flights and traps, then γ depends on the competition between flights and traps; that is, the process can be subdiffusion, superdiffusion, or normal diffusion (Brownian motion). Fractional derivatives play a key role in characterizing anomalous diffusion, including the space fractional Fokker–Planck (advection-dispersion) equation describing Lévy flights, the time fractional Fokker–Planck equation depicting traps, and the space and time fractional Fokker–Planck equation characterizing the competition between Lévy flights and traps [3, 4, 16, 18, 20, 23, 25, 28, 32, 34, 35, 38, 41].

The Fokker–Planck equation (named after Adriaan Fokker and Max Planck) describes the time evolution of the probability density function of the position and the velocity of a particle, which is one of the classical, widely used equations of statistical physics. For the numerical algorithms of the time fractional Fokker–Planck-type equation and the space fractional Fokker–Planck-type equation, there is already some progress covering the finite difference method, the finite element method, and some random approaches [11, 12, 13, 15, 18, 27, 28, 32, 40]. However, published papers on the numerical algorithm of the space and time fractional Fokker–Planck equation are very sparse. Using the Monte Carlo approach for this equation, Magdziarz and Weron [30] positively answer a question raised by Metzler and Klafter [34]: Can one see a competition between subdiffusion and Lévy flights in the framework of the fractional Fokker–Planck dynamics? Herein, we focus on developing the finite element method for the space and time fractional Fokker–Planck equation [30, 34, 35, 41], describing the competition between Lévy flights and traps under the influence of an external potential $U(x)$, given by

$$(1.1) \quad \frac{\partial}{\partial t} p(x, t) = {}_0D_t^{1-\alpha} \left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p(x, t),$$

where $p(x, t)$ is the probability density, prime stands for the derivative w.r.t. the space coordinate, κ_α denotes the anomalous diffusion coefficient with physical dimension $[\text{m}^\mu \text{s}^{-\alpha}]$, η_α represents the generalized friction coefficient possessing the dimension $[\text{kg s}^{\alpha-2}]$, $\alpha \in (0, 1)$, and $\mu \in (1, 2)$ throughout this paper. Here, the operators

$${}_0D_t^{1-\alpha} p(x, t) = \frac{1}{\Gamma(\alpha)} \frac{\partial}{\partial t} \int_0^t (t - \tau)^{\alpha-1} p(x, \tau) d\tau$$

and $\nabla^\mu = \frac{1}{2} {}_aD_x^\mu + \frac{1}{2} {}_xD_b^\mu$; ${}_aD_x^\mu$ and ${}_xD_b^\mu$ are the left and right Riemann–Liouville space fractional derivatives of order μ , respectively, described by

$${}_aD_x^\mu p(x, t) = D^2 {}_aD_x^{-(2-\mu)} p(x, t) = \frac{1}{\Gamma(2-\mu)} \frac{d^2}{dx^2} \int_a^x (x - \xi)^{1-\mu} p(\xi, t) d\xi$$

and

$${}_xD_b^\mu p(x, t) = (-D)^2 {}_xD_b^{-(2-\mu)} p(x, t) = \frac{1}{\Gamma(2-\mu)} \frac{d^2}{dx^2} \int_x^b (\xi - x)^{1-\mu} p(\xi, t) d\xi.$$

Letting ${}_0D_t^{\alpha-1}$ perform on both sides of (1.1) and according to the attributes of the Riemann–Liouville and the Caputo derivatives [11], we obtain the equivalent form of (1.1) as

$$(1.2) \quad D_*^\alpha p(x, t) = \left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p(x, t),$$

where D_*^α is the Caputo derivative and it is defined by

$$D_*^\alpha p(x, t) = \frac{1}{\Gamma(1-\alpha)} \int_0^t (t-\tau)^{-\alpha} \frac{\partial p(x, \tau)}{\partial \tau} d\tau.$$

There are several ways to discrete the time fractional derivative and speed its computation [8, 27, 29, 36]. Here we use the one provided by Lin and Xu in [27] to discrete the left-hand side time Caputo derivative and exploit the finite element method to approximate the right-hand side space fractional derivative. This approach based on the temporal backward differentiation and the spatial finite element method obtains estimates of $(2-\alpha)$ -order convergence in time and μ -order convergence in space. The time-stepping scheme is shown to be unconditionally stable. The numerical example is provided, and the real physical cases are simulated, which illustrate the effectiveness of the method and support the theoretical claims.

In section 2, we introduce the temporal discretization of (1.2) and the abstract setting, fractional derivative spaces, for the analysis of the finite element approximation of the space and time fractional Fokker–Planck equation. Section 3 is devoted to the stability analysis of the time-stepping scheme and the detailed error analysis of semidiscretization on time and of full discretization. In section 4, numerical experiments are carried out, and some of their results are compared with the exact solution. Some concluding remarks are given in the last section.

2. Preliminaries: Discretization of the Caputo derivative and the fractional derivative spaces. For the completeness of the paper, in this section we introduce the scheme to discretize the temporal Caputo derivative and the fractional derivative spaces; for more detailed discussions see [27] and [12, 13], respectively.

For the finite difference of the Caputo derivative, let $t_m := mk$, $m = 0, 1, \dots, M$, where $k := \frac{T}{M}$ is the time-step length, so we have the following formulation of the Caputo derivative [27]:

$$(2.1) \quad \begin{aligned} D_*^\alpha p(x, t_{m+1}) &= \frac{1}{\Gamma(1-\alpha)} \sum_{j=0}^m \int_{t_j}^{t_{j+1}} (t_{m+1}-\tau)^{-\alpha} \frac{\partial p(x, \tau)}{\partial \tau} d\tau \\ &= \frac{1}{\Gamma(1-\alpha)} \sum_{j=0}^m \frac{p(x, t_{j+1}) - p(x, t_j)}{k} \int_{t_j}^{t_{j+1}} \frac{d\tau}{(t_{m+1}-\tau)^\alpha} + r_k^{m+1} \\ &= \frac{1}{\Gamma(2-\alpha)} \sum_{j=0}^m \frac{p(x, t_{m+1-j}) - p(x, t_{m-j})}{k^\alpha} d_j + r_k^{m+1}, \end{aligned}$$

where $d_j = (j+1)^{1-\alpha} - j^{1-\alpha}$. Furthermore,

$$(2.2) \quad r_k^{m+1} \leq \tilde{c}_p k^{2-\alpha},$$

where \tilde{c}_p is a constant depending only on p . Let us define the discrete fractional

differential operator L_t^α by

$$L_t^\alpha p(x, t_{m+1}) := \frac{1}{\Gamma(2-\alpha)} \sum_{j=0}^m d_j \frac{p(x, t_{m+1-j}) - p(x, t_{m-j})}{k^\alpha}.$$

Then (2.1) reads

$$(2.3) \quad D_*^\alpha p(x, t_{m+1}) = L_t^\alpha p(x, t_{m+1}) + r_k^{m+1}.$$

In what follows, we introduce the left, right, and symmetric fractional derivative spaces.

DEFINITION 2.1 (left fractional derivative [12, 24, 37]). *Let q be a function defined on R , $\beta > 0$, n be the smallest integer greater than β ($n-1 \leq \beta < n$), and $\sigma = n - \beta$. Then the left fractional derivative of order β is defined to be*

$$\mathbf{D}^\beta q := D_{-\infty}^n D_x^{-\sigma} q(x) = \frac{1}{\Gamma(\sigma)} \frac{d^n}{dx^n} \int_{-\infty}^x (x-\xi)^{\sigma-1} q(\xi) d\xi.$$

DEFINITION 2.2 (right fractional derivative [12, 24, 37]). *Let q be a function defined on R , $\beta > 0$, n be the smallest integer greater than β ($n-1 \leq \beta < n$), and $\sigma = n - \beta$. Then the right fractional derivative of order β is defined to be*

$$\mathbf{D}^{\beta*} q := (-D)^n {}_x D_\infty^{-\sigma} q(x) = \frac{(-1)^n}{\Gamma(\sigma)} \frac{d^n}{dx^n} \int_x^\infty (\xi-x)^{\sigma-1} q(\xi) d\xi.$$

Note. If $\text{supp}(q) \subset (a, b)$, then $\mathbf{D}^\beta q = {}_a D_x^\beta q$ and $\mathbf{D}^{\beta*} q = {}_x D_b^\beta q$, where ${}_a D_x^\beta q$ and ${}_x D_b^\beta q$ are the left and right Riemann–Liouville fractional derivatives, respectively, of order β defined as

$${}_a D_x^\beta q = \frac{1}{\Gamma(\sigma)} \frac{d^n}{dx^n} \int_a^x (x-\xi)^{\sigma-1} q(\xi) d\xi$$

and

$${}_x D_b^\beta q = \frac{(-1)^n}{\Gamma(\sigma)} \frac{d^n}{dx^n} \int_x^b (\xi-x)^{\sigma-1} q(\xi) d\xi.$$

DEFINITION 2.3 (left fractional derivative space [12]). *Let $\beta > 0$. Define the seminorm*

$$|q|_{J_L^\beta(R)} := \|\mathbf{D}^\beta q\|_{L^2(R)}$$

and the norm

$$\|q\|_{J_L^\beta(R)} := \left(\|q\|_{L^2(R)}^2 + |q|_{J_L^\beta(R)}^2 \right)^{1/2},$$

and let $J_L^\beta(R)$ denote the closure of $C^\infty(R)$ with respect to $\|\cdot\|_{J_L^\beta(R)}$.

DEFINITION 2.4 (right fractional derivative space [12]). *Let $\beta > 0$. Define the seminorm*

$$|q|_{J_R^\beta(R)} := \|\mathbf{D}^{\beta*} q\|_{L^2(R)}$$

and the norm

$$\|q\|_{J_R^\beta(R)} := \left(\|q\|_{L^2(R)}^2 + |q|_{J_R^\beta(R)}^2 \right)^{1/2},$$

and let $J_R^\beta(R)$ denote the closure of $C^\infty(R)$ with respect to $\|\cdot\|_{J_R^\beta(R)}$.

DEFINITION 2.5 (symmetric fractional derivative space [12]). Let $\beta > 0$, $\beta \neq n - 1/2$, $n \in \mathbb{N}$. Define the seminorm

$$|q|_{J_S^\beta(R)} := \left| (\mathbf{D}^\beta q, \mathbf{D}^{\beta*} q)_{L^2(R)} \right|^{1/2}$$

and the norm

$$\|q\|_{J_S^\beta(R)} := \left(\|q\|_{L^2(R)}^2 + |q|_{J_S^\beta(R)}^2 \right)^{1/2},$$

and let $J_S^\beta(R)$ denote the closure of $C^\infty(R)$ with respect to $\|\cdot\|_{J_S^\beta(R)}$.

DEFINITION 2.6 (see [12]). Let $\beta > 0$. Define the seminorm

$$|q|_{H^\beta(R)} := \|\omega^{|\beta|} \hat{q}\|_{L^2(R)}$$

and the norm

$$(2.4) \quad \|q\|_{H^\beta(R)} := \left(\|q\|_{L^2(R)}^2 + |q|_{H^\beta(R)}^2 \right)^{1/2},$$

and let $H^\beta(R)$ denote the closure of $C^\infty(R)$ with respect to $\|\cdot\|_{H^\beta(R)}$.

Note. In this paper, instead of (2.4), we prefer to use

$$(2.5) \quad \|q\|_{H^\beta(R)} := \left(\|q\|_{L^2(R)}^2 + \alpha_0 \kappa_\alpha \left| \cos\left(\frac{\beta}{2}\pi\right) \right| |q|_{H^\beta(R)}^2 \right)^{1/2},$$

where $\alpha_0 = \Gamma(2 - \alpha)k^\alpha$; it is well known that these two definitions are equivalent [1].

LEMMA 2.7 (see [12]). Let $\beta > 0$ be given. Then

$$(2.6) \quad (\mathbf{D}^\beta q, \mathbf{D}^{\beta*} q) = \cos(\beta\pi) \|\mathbf{D}^\beta q\|_{L^2(R)}^2.$$

LEMMA 2.8 (see [12]). Let $\beta > 0$. The spaces $J_L^\beta(R)$, $J_R^\beta(R)$, and $H^\beta(R)$ are equivalent, with equivalent seminorms and norms; and in fact

$$|\cdot|_{J_L^\beta(R)} = |\cdot|_{J_R^\beta(R)} = |\cdot|_{H^\beta(R)},$$

in particular, when $\beta \neq n - 1/2$, $n \in \mathbb{N}$. The spaces $J_L^\beta(R)$ ($J_R^\beta(R)$ or $H^\beta(R)$) and $J_S^\beta(R)$ are equivalent, with equivalent seminorms and norms, and

$$|\cdot|_{J_S^\beta(R)} = |\cos(\beta\pi)| |\cdot|_{J_L^\beta(R)}.$$

DEFINITION 2.9 (see [12]). Define the spaces $J_L^\beta(\Omega)$, $J_R^\beta(\Omega)$, and $J_S^\beta(\Omega)$ as the closures of $C^\infty(\Omega)$ under their respective norms.

DEFINITION 2.10 (see [12]). Define the spaces $J_{L,0}^\beta(\Omega)$, $J_{R,0}^\beta(\Omega)$, and $J_{S,0}^\beta(\Omega)$ as the closures of $C_0^\infty(\Omega)$ under their respective norms.

LEMMA 2.11 (see [12]). *Let $\beta > 0$. Then the spaces $J_{L,0}^\beta(\Omega)$, $J_{R,0}^\beta(\Omega)$, and $H_0^\beta(\Omega)$ are equivalent. Also, if $\beta \neq n - \frac{1}{2}$, $n \in \mathbb{N}$, the seminorms and norms of $J_{L,0}^\beta(\Omega)$, $J_{R,0}^\beta(\Omega)$, and $H_0^\beta(\Omega)$ are equivalent, and $J_{S,0}^\beta(\Omega)$ and $J_{L,0}^\beta(\Omega)$ ($J_{R,0}^\beta(\Omega)$ or $H_0^\beta(\Omega)$) are equivalent with equivalent seminorms and norms.*

LEMMA 2.12 (fractional Poincaré–Friedrichs [12]). *For $q \in H_0^\beta(\Omega)$, we have*

$$\|q\|_{L^2(\Omega)} \leq c|q|_{H_0^\beta(\Omega)},$$

and for $0 < s < \beta$, $s \neq n - \frac{1}{2}$, $n \in \mathbb{N}$,

$$|q|_{H_0^s(\Omega)} \leq c|q|_{H_0^\beta(\Omega)}.$$

LEMMA 2.13. *The left and right Riemann–Liouville fractional integral operators are adjoint w.r.t. the $L^2(a, b)$ inner product, i.e.,*

$$\left({}_a D_x^{-\beta} p, q \right)_{L^2(a,b)} = \left(p, {}_x D_b^{-\beta} q \right)_{L^2(a,b)} \quad \forall \beta > 0,$$

where ${}_a D_x^{-\beta}$ and ${}_x D_b^{-\beta}$ are defined by

$${}_a D_x^{-\beta} p = \frac{1}{\Gamma(\beta)} \int_a^x (x - \xi)^{\beta-1} p(\xi) d\xi$$

and

$${}_x D_b^{-\beta} q = \frac{1}{\Gamma(\beta)} \int_x^b (\xi - x)^{\beta-1} q(\xi) d\xi.$$

Proof. Interchanging the order of integration leads to

$$\begin{aligned} \left({}_a D_x^{-\beta} p, q \right)_{L^2(a,b)} &= \frac{1}{\Gamma(\beta)} \int_a^b \int_a^x (x - \xi)^{\beta-1} p(\xi) q(x) d\xi dx \\ &= \frac{1}{\Gamma(\beta)} \int_a^b p(\xi) \int_\xi^b (x - \xi)^{\beta-1} q(x) dx d\xi \\ &= \left(p, {}_x D_b^{-\beta} q \right)_{L^2(a,b)}. \quad \square \end{aligned}$$

3. Variational formulation and finite element approximation. Letting $T > 0$, $\Omega = (a, b)$, rewriting (1.2), and making it subject to the given initial and boundary conditions, we have

$$(3.1) \quad D_*^\alpha p(x, t) = \left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p(x, t), \quad 0 < t \leq T, \quad x \in \Omega,$$

with initial and boundary conditions

$$(3.2) \quad p(x, 0) = g(x), \quad x \in \Omega,$$

$$(3.3) \quad p(a, t) = p(b, t) = 0, \quad 0 \leq t \leq T.$$

Because of (2.3), using $L_t^\alpha p(x, t_{m+1})$ as an approximation of $D_*^\alpha p(x, t_{m+1})$ leads to the following time-discrete scheme of (3.1):

$$(3.4) \quad L_t^\alpha p^{m+1}(x) = \left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p^{m+1}(x), \quad m = 0, 1, \dots, M-1,$$

where $p^{m+1}(x)$ is an approximation of $p(x, t_{m+1})$.

The scheme (3.4) can be recast as, with simplification by omitting the dependence of $p^{m+1}(x)$ on x ,

$$(3.5) \quad p^{m+1} - \alpha_0 \left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p^{m+1} = p^m - \sum_{j=0}^{m-1} d_{j+1} p^{m-j} + \sum_{j=1}^m d_j p^{m-j}.$$

For the first time step, that is, $m = 0$, the scheme simply reads

$$(3.6) \quad p^1 - \alpha_0 \left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p^1 = p^0,$$

and for the remaining steps, the equivalent form of (3.5) is

$$(3.7) \quad \begin{aligned} & p^{m+1} - \alpha_0 \left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p^{m+1} \\ &= (1 - d_1) p^m + \sum_{j=1}^{m-1} (d_j - d_{j+1}) p^{m-j} + d_m p^0, \quad m \geq 1. \end{aligned}$$

So the complete semidiscrete scheme of (3.1) is (3.6) and (3.7), together with the boundary conditions

$$(3.8) \quad p^{m+1}(a) = p^{m+1}(b) = 0, \quad m \geq 0,$$

and the initial condition

$$(3.9) \quad p^0(x) = g(x), \quad x \in \Omega.$$

The variational formulation of (3.7) subject to the boundary condition (3.8) reads as follows: Find $p^{m+1} \in H_0^{\frac{\mu}{2}}(\Omega)$ such that

$$(3.10) \quad \begin{aligned} & (p^{m+1}, q) - \alpha_0 \left(\left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p^{m+1}, q \right) \\ &= (1 - d_1)(p^m, q) + \sum_{j=1}^{m-1} (d_j - d_{j+1})(p^{m-j}, q) + d_m(p^0, q) \quad \forall q \in H_0^{\frac{\mu}{2}}(\Omega). \end{aligned}$$

3.1. Stability analysis and error estimates for the semidiscrete scheme.

In this subsection, we discuss the stability and error estimates for the weak time-discrete problem. First, let us introduce the denotation

$$B(p, q) := - \left(\left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p, q \right),$$

and we have the following lemma for $B(p, q)$.

LEMMA 3.1. *Let $U''(x) \leq 0$ for any $x \in \Omega$, $q \in H_0^{\frac{\mu}{2}}(\Omega)$. Then $B(q, q) \geq \kappa_\alpha |\cos(\frac{\mu}{2}\pi)| |q|_{H_0^{\frac{\mu}{2}}(\Omega)}^2$.*

Proof. To expand the expression, we obtain

$$\begin{aligned}
& B(q, q) \\
&= - \int_a^b \frac{U''(x)}{\eta_\alpha} q^2 dx - \int_a^b \frac{U'(x)}{\eta_\alpha} \frac{\partial q}{\partial x} q dx \\
&\quad - \frac{\kappa_\alpha}{2} \int_a^b \left(D_a^2 D_x^{-(2-\mu)} q \right) q dx - \frac{\kappa_\alpha}{2} \int_a^b \left(D_x^2 D_b^{-(2-\mu)} q \right) q dx \\
&= - \frac{1}{2} \int_a^b \frac{U''(x)}{\eta_\alpha} q^2 dx + \frac{\kappa_\alpha}{2} \left(\int_a^b \left({}_a D_x^{-(2-\mu)} Dq \right) Dq dx + \int_a^b \left({}_x D_b^{-(2-\mu)} Dq \right) Dq dx \right) \\
&\geq \frac{\kappa_\alpha}{2} \left(\int_a^b \left({}_a D_x^{-(2-\mu)} Dq \right) Dq dx + \int_a^b \left({}_x D_b^{-(2-\mu)} Dq \right) Dq dx \right) \\
&= \frac{\kappa_\alpha}{2} \left(\int_a^b \left({}_a D_x^{-(1-\frac{\mu}{2})} Dq \right) {}_x D_b^{-(1-\frac{\mu}{2})} Dq dx + \int_a^b \left({}_x D_b^{-(1-\frac{\mu}{2})} Dq \right) {}_a D_x^{-(1-\frac{\mu}{2})} Dq dx \right) \\
&= \kappa_\alpha \int_a^b \left({}_a D_x^{\frac{\mu}{2}} q \right) \cdot \left(-{}_x D_b^{\frac{\mu}{2}} q \right) dx \\
&= -\kappa_\alpha \cos\left(\frac{\mu}{2}\pi\right) |q|_{H_0^{\frac{\mu}{2}}(\Omega)}^2.
\end{aligned}$$

In the above calculations, Lemmas 2.7, 2.8, and 2.11 are used, and some of the properties of fractional operators [11, 26], such as ${}_a D_x^{-(2-\mu)} = {}_a D_x^{-(1-\frac{\mu}{2})} {}_a D_x^{-(1-\frac{\mu}{2})}$, ${}_a D_x^{-(2-\mu)} Dq = D_a D_x^{-(2-\mu)} q$, and ${}_x D_b^{-(2-\mu)} Dq = D_x D_b^{-(2-\mu)} q$, when $q \in H_0^{\frac{\mu}{2}}(\Omega)$, are also utilized. \square

The following theorem presents the stability results for the weak semidiscrete problem (3.10).

THEOREM 3.2. *Let $U''(x) \leq 0$ for any $x \in \Omega$. The weak semidiscrete scheme (3.10) is unconditionally stable in the sense that for any time-step length $k > 0$, it holds that*

$$\|p^{m+1}\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq \|p^0\|_{L^2}, \quad m = 0, 1, \dots, M-1.$$

Proof. The induction will be used to prove this theorem. When $m = 0$, we have

$$(p^1, q) - \alpha_0 \left(\left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p^1, q \right) = (p^0, q) \quad \forall q \in H_0^{\frac{\mu}{2}}(\Omega).$$

Taking $q = p^1$ and using (2.5) and Lemma 3.1, we obtain

$$\|p^1\|_{H_0^{\frac{\mu}{2}}(\Omega)}^2 \leq (p^0, p^1).$$

Applying the inequality $\|p^1\|_{L^2(\Omega)} \leq \|p^1\|_{H_0^{\frac{\mu}{2}}(\Omega)}$ and the Schwarz inequality, we attain immediately

$$\|p^1\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq \|p^0\|_{L^2(\Omega)}.$$

Assume we have proven

$$(3.11) \quad \|p^j\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq \|p^0\|_{L^2(\Omega)}, \quad j = 1, 2, \dots, m;$$

we will prove $\|p^{m+1}\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq \|p^0\|_{L^2(\Omega)}$. Letting $q = p^{m+1}$ in (3.10) gives

$$\begin{aligned} & (p^{m+1}, p^{m+1}) - \alpha_0 \left(\left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p^{m+1}, p^{m+1} \right) \\ &= (1 - d_1) (p^m, p^{m+1}) + \sum_{j=1}^{m-1} (d_j - d_{j+1}) (p^{m-j}, p^{m+1}) + d_m (p^0, p^{m+1}). \end{aligned}$$

Further using Lemma 3.1 and (3.11), we have

$$\begin{aligned} \|p^{m+1}\|_{H_0^{\frac{\mu}{2}}(\Omega)}^2 &\leq (1 - d_1) \|p^m\|_{L^2(\Omega)} \|p^{m+1}\|_{L^2(\Omega)} \\ &\quad + \sum_{j=1}^{m-1} (d_j - d_{j+1}) \|p^{m-j}\|_{L^2(\Omega)} \|p^{m+1}\|_{L^2(\Omega)} \\ &\quad + d_m \|p^0\|_{L^2(\Omega)} \|p^{m+1}\|_{L^2(\Omega)} \\ &\leq \left[(1 - d_1) + \sum_{j=1}^{m-1} (d_j - d_{j+1}) + d_m \right] \|p^0\|_{L^2(\Omega)} \|p^{m+1}\|_{H_0^{\frac{\mu}{2}}(\Omega)} \\ &= \|p^0\|_{L^2(\Omega)} \|p^{m+1}\|_{H_0^{\frac{\mu}{2}}(\Omega)}. \end{aligned}$$

Then we conclude

$$\|p^{m+1}\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq \|p^0\|_{L^2(\Omega)}. \quad \square$$

By virtue of (2.3), the weak semidiscrete scheme (3.10) is formally of $(2 - \alpha)$ -order accuracy. Now we carry out the rigorous error analysis. From now on, we denote by c (or $c(\alpha_0)$) if it depends on α_0 given in (2.5)) a generic constant which may not be the same at different occurrences.

THEOREM 3.3. *Let $U''(x) \leq 0$ for any $x \in \Omega$, p be the exact solution of (3.1)–(3.3), and $\{p^m\}_{m=0}^M$ be the solution of (3.10) with the boundary and initial conditions (3.8) and (3.9); then the error estimates are*

(1) when $0 < \alpha < 1$,

$$(3.12) \quad \|p(t_m) - p^m\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq c_{p,\alpha} T^\alpha k^{2-\alpha}, \quad m = 1, 2, \dots, M,$$

where $c_{p,\alpha} := c_p / (1 - \alpha)$, with constant c_p defined in (3.15);

(2) when $\alpha \rightarrow 1$,

$$(3.13) \quad \|p(t_m) - p^m\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq c_p T k, \quad m = 1, 2, \dots, M,$$

where c_p is defined in (3.15).

For the convenience of denotation in the proof, let us define the error term by

$$(3.14) \quad r^{m+1} := \alpha_0 r_k^{m+1};$$

then from (2.2) we have

$$(3.15) \quad |r^{m+1}| = \Gamma(2 - \alpha) k^\alpha |r_k^{m+1}| \leq \Gamma(2 - \alpha) \tilde{c}_p k^2 = c_p k^2.$$

Proof of Theorem 3.3. (1) The proof of the idea using the mathematical induction is similar to Theorem 3.2 of [27]. Let us first consider the case $0 \leq \alpha < 1$. We would like to prove the estimate

$$(3.16) \quad \|p(t_j) - p^j\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq c_p d_{j-1}^{-1} k^2, \quad j = 1, 2, \dots, M.$$

Denote $e^m = p(t_m) - p^m$. For $j = 1$, from (3.1), (3.6), and (3.15), we obtain the error equation

$$(3.17) \quad (e^1, q) - \alpha_0 \left(\left[\frac{\partial U'(x)}{\partial x} \frac{1}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] e^1, q \right) = (r^1, q) \quad \forall q \in H_0^{\frac{\mu}{2}}(\Omega).$$

Taking $q = e^1$ and using Lemma 3.1 yields

$$\|e^1\|_{H_0^{\frac{\mu}{2}}(\Omega)}^2 \leq \|r^1\|_{L^2(\Omega)} \|e^1\|_{L^2(\Omega)}.$$

This, together with (3.15), gives

$$\|p(t_1) - p^1\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq c_p d_0^{-1} k^2.$$

So, (3.16) is verified for the case $j = 1$. Suppose now that (3.16) holds for all $j = 1, 2, \dots, m$; we prove it holds also for $j = m + 1$.

Combining (3.1), (3.10), and (3.15) leads to

$$(3.18) \quad \begin{aligned} & (e^{m+1}, q) - \alpha_0 \left(\left[\frac{\partial U'(x)}{\partial x} \frac{1}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] e^{m+1}, q \right) \\ &= (1 - d_1)(e^m, q) + \sum_{j=1}^{m-1} (d_j - d_{j+1})(e^{m-j}, q) + (r^{m+1}, q) \quad \forall q \in H_0^{\frac{\mu}{2}}(\Omega). \end{aligned}$$

Taking $q = e^{m+1}$ in (3.18) and using Lemma 3.1 yields

$$\begin{aligned} \|e^{m+1}\|_{H_0^{\frac{\mu}{2}}(\Omega)}^2 &\leq (1 - d_1) \|e^m\|_{L^2(\Omega)} \|e^{m+1}\|_{L^2(\Omega)} \\ &\quad + \sum_{j=1}^{m-1} (d_j - d_{j+1}) \|e^{m-j}\|_{L^2(\Omega)} \|e^{m+1}\|_{L^2(\Omega)} \\ &\quad + \|r^{m+1}\|_{L^2(\Omega)} \|e^{m+1}\|_{L^2(\Omega)}. \end{aligned}$$

According to the induction assumption, we have

$$\begin{aligned} \|e^{m+1}\|_{H_0^{\frac{\mu}{2}}(\Omega)} &\leq \left((1 - d_1) d_{m-1}^{-1} + \sum_{j=1}^{m-1} (d_j - d_{j+1}) d_{m-j-1}^{-1} \right) c_p k^2 + c_p k^2 \\ &\leq \left((1 - d_1) + \sum_{j=1}^{m-1} (d_j - d_{j+1}) + d_m \right) c_p d_m^{-1} k^2 \\ &= c_p d_m^{-1} k^2. \end{aligned}$$

Therefore, the estimate (3.16) is proved.

A direct computation shows that $m^{-\alpha}d_{m-1}^{-1} = 1$ when $m = 1$, and $m^{-\alpha}d_{m-1}^{-1}$ increasingly tends to $\frac{1}{1-\alpha}$ as $1 < m \rightarrow +\infty$. Therefore,

$$(3.19) \quad m^{-\alpha}d_{m-1}^{-1} \leq \frac{1}{1-\alpha}, \quad m = 1, 2, \dots, M.$$

For all m such that $mk \leq T$, we obtain

$$\begin{aligned} \|p(t_m) - p^m\|_{H_0^{\frac{\mu}{2}}(\Omega)} &\leq c_p d_{m-1}^{-1} k^2 = c_p m^{-\alpha} d_{m-1}^{-1} m^\alpha k^2 \\ &\leq c_p \frac{1}{1-\alpha} (mk)^\alpha k^{2-\alpha} = c_{p,\alpha} T^\alpha k^{2-\alpha}. \end{aligned}$$

(2) Further consider the case $\alpha \rightarrow 1$. In this case, $c_{p,\alpha}$ tends to infinity as $\alpha \rightarrow 1$, so the estimate (3.12) has no meaning. We need an estimate of another form. The proof is similar to the procedure in case (1).

Noting the fact that $jk \leq T$ for all $j = 1, 2, \dots, M$, we want to prove

$$(3.20) \quad \|p(t_j) - p^j\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq c_p j k^2, \quad j = 1, 2, \dots, M.$$

When $j = 1$, the estimate holds from (3.16). Suppose now that (3.20) holds for $j = 1, 2, \dots, m$; we prove it also remains true for $j = m + 1$. Based on the induction assumption and the estimates of the right-hand side of the error equation, the details of which are omitted, we get

$$\|e^{m+1}\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq \left((1 - d_1) + \sum_{j=1}^{m-1} (d_j - d_{j+1}) + d_m \right) c_p (m+1) k^2 = c_p (m+1) k^2.$$

Then (3.20) holds, and (3.13) is proved. \square

3.2. Existence, uniqueness, and regularity of weak solutions for (3.10).

First, we further study the variational problem (3.10) for fixed m , where we suppose p^j , $j = 1, 2, \dots, m$, are known quantities and p^{m+1} is an unknown variable. We introduce the following denotations:

$$\begin{aligned} \tilde{B}(p^{m+1}, q) &:= (p^{m+1}, q) + \alpha_0 B(p^{m+1}, q), \\ f &:= (1 - d_1)p^m + \sum_{j=1}^{m-1} (d_j - d_{j+1})p^{m-j} + d_m p^0, \end{aligned}$$

and

$$\tilde{F}(q) := (f, q).$$

Then we can recast (3.10) as

$$(3.21) \quad \tilde{B}(p^{m+1}, q) = \tilde{F}(q) \quad \forall q \in H_0^{\frac{\mu}{2}}(\Omega).$$

We show that there exists a unique solution to (3.21). To do this, we need to establish the coercivity and continuity of $\tilde{B}(\cdot, \cdot)$.

LEMMA 3.4. *Let $U''(x) \leq 0$ for any $x \in \Omega$ and $q \in H_0^{\frac{\mu}{2}}(\Omega)$. The bilinear form $\tilde{B}(q, q) \geq \|q\|_{H_0^{\frac{\mu}{2}}(\Omega)}^2$; i.e., it is coercive over $H_0^{\frac{\mu}{2}}(\Omega)$.*

Proof. According to Lemma 3.1,

$$\begin{aligned}\tilde{B}(q, q) &= (q, q) + \alpha_0 B(q, q) \\ &\geq (q, q) + \alpha_0 \kappa_\alpha \left| \cos\left(\frac{\mu}{2}\pi\right) \right| \|q\|_{H_0^{\frac{\mu}{2}}(\Omega)}^2 \\ &= \|q\|_{H_0^{\frac{\mu}{2}}(\Omega)}^2.\end{aligned}$$

The proof is completed. \square

LEMMA 3.5. *The bilinear form $\tilde{B}(\cdot, \cdot)$ is continuous on $H_0^{\frac{\mu}{2}}(\Omega) \times H_0^{\frac{\mu}{2}}(\Omega)$; i.e., there exists a constant $c(\alpha_0)$ such that*

$$\left| \tilde{B}(p, q) \right| \leq c(\alpha_0) \|p\|_{H_0^{\frac{\mu}{2}}(\Omega)} \|q\|_{H_0^{\frac{\mu}{2}}(\Omega)} \quad \forall p, q \in H_0^{\frac{\mu}{2}}(\Omega).$$

Proof. From the definition of $|\tilde{B}(p, q)|$ we have

$$\begin{aligned}\left| \tilde{B}(p, q) \right| &= |(p, q) + \alpha_0 B(p, q)| \\ &= \left| (p, q) - \alpha_0 \int_a^b \frac{U''(x)}{\eta_\alpha} p q dx - \alpha_0 \int_a^b \frac{U'(x)}{\eta_\alpha} \frac{\partial p}{\partial x} q dx \right. \\ &\quad \left. - \alpha_0 \frac{\kappa_\alpha}{2} \int_a^b \left(D^2 {}_a D_x^{-(2-\mu)} p \right) q dx - \alpha_0 \frac{\kappa_\alpha}{2} \int_a^b \left(D^2 {}_x D_b^{-(2-\mu)} p \right) q dx \right| \\ &\leq |(p, q)| + \alpha_0 \left| \int_a^b \frac{U''(x)}{\eta_\alpha} p q dx \right| + \alpha_0 \left| \int_a^b \frac{U'(x)}{\eta_\alpha} \frac{\partial p}{\partial x} q dx \right| \\ &\quad + \alpha_0 \left| \frac{\kappa_\alpha}{2} \int_a^b (\mathbf{D}^\mu p) q dx \right| + \alpha_0 \left| \frac{\kappa_\alpha}{2} \int_a^b (\mathbf{D}^{\mu*} p) q dx \right|.\end{aligned}$$

Using the equivalence of norms, the fractional Poincaré–Friedrichs inequality, and Lemma 2.13,

$$\begin{aligned}\left| \int_a^b \frac{U'(x)}{\eta_\alpha} \frac{\partial p}{\partial x} q dx \right| &= \left| \int_a^b \mathbf{D}^{\frac{\mu}{2}} p \mathbf{D}^{(1-\frac{\mu}{2})*} \left(\frac{U'(x)}{\eta_\alpha} q \right) \right| \\ &\leq \|p\|_{J_{L,0}^{\frac{\mu}{2}}(\Omega)} \left| \frac{U'(x)}{\eta_\alpha} q \right|_{J_{R,0}^{1-\frac{\mu}{2}}(\Omega)} \\ &\leq c(\alpha_0) \|p\|_{H_0^{\frac{\mu}{2}}(\Omega)} \|q\|_{H_0^{\frac{\mu}{2}}(\Omega)}\end{aligned}$$

and

$$\begin{aligned}\left| \frac{\kappa_\alpha}{2} \int_a^b (\mathbf{D}^\mu p) q dx \right| &= \left| \frac{\kappa_\alpha}{2} \int_a^b \left(\mathbf{D}^{\frac{\mu}{2}} p \right) \mathbf{D}^{\frac{\mu}{2}*} q dx \right| \\ &\leq \frac{\kappa_\alpha}{2} \|p\|_{J_{L,0}^{\frac{\mu}{2}}(\Omega)} \|q\|_{J_{R,0}^{\frac{\mu}{2}}(\Omega)} \\ &\leq c(\alpha_0) \|p\|_{H_0^{\frac{\mu}{2}}(\Omega)} \|q\|_{H_0^{\frac{\mu}{2}}(\Omega)},\end{aligned}$$

and similarly

$$\left| \frac{\kappa_\alpha}{2} \int_a^b (\mathbf{D}^{\mu*} p) q dx \right| = \left| \frac{\kappa_\alpha}{2} \int_a^b (\mathbf{D}^{\frac{\mu}{2}*} p) \mathbf{D}^{\frac{\mu}{2}} q dx \right| \leq c(\alpha_0) \|p\|_{H_0^{\frac{\mu}{2}}(\Omega)} \|q\|_{H_0^{\frac{\mu}{2}}(\Omega)}.$$

Thus,

$$\begin{aligned} & \left| \tilde{B}(p, q) \right| \\ & \leq \|p\|_{L^2(\Omega)} \|q\|_{L^2(\Omega)} + \alpha_0 \left\| \frac{U''(x)}{\eta_\alpha} \right\|_\infty \|p\|_{L^2(\Omega)} \|q\|_{L^2(\Omega)} + c(\alpha_0) \|p\|_{H_0^{\frac{\mu}{2}}(\Omega)} \|q\|_{H_0^{\frac{\mu}{2}}(\Omega)} \\ & \leq c(\alpha_0) \|p\|_{H_0^{\frac{\mu}{2}}(\Omega)} \|q\|_{H_0^{\frac{\mu}{2}}(\Omega)}. \end{aligned}$$

The proof is completed. \square

LEMMA 3.6. *The linear functional $\tilde{F}(\cdot)$ is continuous over $H_0^{\frac{\mu}{2}}(\Omega)$.*

Proof. Using Theorem 3.2 and Minkowski's inequality leads to $f \in H_0^{-\frac{\mu}{2}}(\Omega) \subset H^{-\frac{\mu}{2}}(\Omega)$. Then the result of this lemma follows from

$$|\tilde{F}(q)| \leq \|f\|_{H^{-\frac{\mu}{2}}(\Omega)} \|q\|_{H^{\frac{\mu}{2}}(\Omega)}. \quad \square$$

According to Lemmas 3.4, 3.5, and 3.6, \tilde{B} and \tilde{F} satisfy the hypotheses of the Lax–Milgram theorem, and the solution p^{m+1} is bounded by f . So we have the following theorem.

THEOREM 3.7. *Let $U''(x) \leq 0$ for any $x \in \Omega$. There exists a unique solution $p^{m+1} \in H_0^{\frac{\mu}{2}}(\Omega)$ to (3.10) satisfying*

$$(3.22) \quad \|p^{m+1}\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq \|f\|_{H^{-\frac{\mu}{2}}(\Omega)}.$$

In order to establish the error estimate in the following subsection, we need to prove $\|p^{m+1}\|_{H_0^\mu(\Omega)} \leq \|f\|_{L^2(\Omega)}$. For the proof of this result, we need the following lemma.

LEMMA 3.8. *Let $U''(x) \leq 0$ for any $x \in \Omega$, $f \in L^2(\Omega)$, and p^{m+1} satisfy (3.7)–(3.9). If, in addition, for $\frac{\mu}{2} \leq s < 1$, $p^{m+1} \in H^s(\Omega) \cap H_0^{\frac{\mu}{2}}(\Omega)$ and satisfies*

$$(3.23) \quad \|p^{m+1}\|_{H^s(\Omega)} \leq c(\alpha_0) \|f\|_{L^2(\Omega)},$$

then $p^{m+1} \in H^{s+\frac{\mu}{2}-\frac{1}{2}}(\Omega)$ with estimate

$$(3.24) \quad \|p^{m+1}\|_{H^{s+\frac{\mu}{2}-\frac{1}{2}}(\Omega)} \leq c(\alpha_0) \|f\|_{L^2(\Omega)}.$$

Proof. Note that as $\frac{1}{2} < s < 1$, $0 < 2s - 1 < 1$, we can write

$$\mathbf{D}^{2s-1} p^{m+1} = {}_a D_x^{-\gamma} D p^{m+1}, \quad \text{with } \gamma = 2 - 2s.$$

Since p^{m+1} satisfies

$$\left(1 - \alpha_0 \frac{U''(x)}{\eta_\alpha}\right) p^{m+1} - \alpha_0 \left(\frac{U'(x)}{\eta_\alpha} \frac{\partial}{\partial x} + \frac{\kappa_\alpha}{2} \left(D^2 {}_a D_x^{-(2-\mu)} + D^2 {}_x D_b^{-(2-\mu)}\right)\right) p^{m+1} = f,$$

multiplying both sides by $\mathbf{D}^{2s-1} p^{m+1}$ and integrating over Ω , we have

$$\begin{aligned} & \frac{\alpha_0 \kappa_\alpha}{2} \left(\left(D^2 {}_a D_x^{-(2-\mu)} p^{m+1}, {}_a D_x^{-\gamma} D p^{m+1} \right) + \left(D^2 {}_x D_b^{-(2-\mu)} p^{m+1}, {}_a D_x^{-\gamma} D p^{m+1} \right) \right) \\ &= \left(\left(1 - \alpha_0 \frac{U''(x)}{\eta_\alpha} \right) p^{m+1}, {}_a D_x^{-\gamma} D p^{m+1} \right) + \alpha_0 \left(\frac{U'(x)}{\eta_\alpha} \frac{\partial p^{m+1}}{\partial x}, {}_a D_x^{-\gamma} D p^{m+1} \right) \\ & \quad - \left(f, {}_a D_x^{-\gamma} D p^{m+1} \right). \end{aligned}$$

First, we bound each of the terms on the right-hand side of the above equation. Using the Cauchy–Schwarz inequality and (3.23) leads to

$$\begin{aligned} \left| - \left(f, {}_a D_x^{-\gamma} D p^{m+1} \right) \right| &\leq \|f\|_{L^2(\Omega)} \left| P^{m+1} \right|_{J_L^{2s-1}(\Omega)} \\ &\leq c \|f\|_{L^2(\Omega)} \left| P^{m+1} \right|_{J_L^s(\Omega)}, \quad \text{since } 2s-1 < s, \\ &\leq c \|f\|_{L^2(\Omega)} \left| P^{m+1} \right|_{H^s(\Omega)} \\ &\leq c \|f\|_{L^2(\Omega)}. \end{aligned}$$

Because of Lemma 2.13, we have

$$\begin{aligned} & \left| \left(\frac{U'(x)}{\eta_\alpha} \frac{\partial p^{m+1}}{\partial x}, {}_a D_x^{-\gamma} D p^{m+1} \right) \right| \\ &= \left| \left({}_x D_b^{-\frac{\gamma}{2}} \left(\frac{U'(x)}{\eta_\alpha} \frac{\partial p^{m+1}}{\partial x} \right), {}_a D_x^{-\frac{\gamma}{2}} D p^{m+1} \right) \right| \\ &\leq \left\| {}_x D_b^{-\frac{\gamma}{2}} \left(\frac{U'(x)}{\eta_\alpha} \frac{\partial p^{m+1}}{\partial x} \right) \right\|_{L^2(\Omega)} \left\| {}_a D_x^{-\frac{\gamma}{2}} D p^{m+1} \right\|_{L^2(\Omega)} \\ &= \left\| {}_x D_b^{-\frac{\gamma}{2}} \left(D \left(\frac{U'(x)}{\eta_\alpha} p^{m+1} \right) - D \left(\frac{U'(x)}{\eta_\alpha} \right) p^{m+1} \right) \right\|_{L^2(\Omega)} \left\| {}_a D_x^{-\frac{\gamma}{2}} D p^{m+1} \right\|_{L^2(\Omega)} \\ &\leq \left(\left\| \mathbf{D}^{s*} \left(\frac{U'(x)}{\eta_\alpha} p^{m+1} \right) \right\|_{L^2(\Omega)} + \left\| D \left(\frac{U'(x)}{\eta_\alpha} \right) p^{m+1} \right\|_{L^2(\Omega)} \right) \left\| {}_a D_x^{-\frac{\gamma}{2}} D p^{m+1} \right\|_{L^2(\Omega)} \\ &\leq (c \|p^{m+1}\|_{H^s(\Omega)} + c \|p^{m+1}\|_{L^2(\Omega)}) \|p^{m+1}\|_{H^s(\Omega)} \\ &\leq c(\alpha_0) \|p^{m+1}\|_{H^s(\Omega)}. \end{aligned}$$

For the remaining term we have

$$\begin{aligned} \left| \left(\left(1 - \alpha_0 \frac{U''(x)}{\eta_\alpha} \right) p^{m+1}, {}_a D_x^{-\gamma} D p^{m+1} \right) \right| &\leq \left\| 1 - \alpha_0 \frac{U''(x)}{\eta_\alpha} \right\|_\infty \|p^{m+1}\|_{L^2(\Omega)} \left| p^{m+1} \right|_{J_L^{2s-1}(\Omega)} \\ &\leq c \|f\|_{L^2(\Omega)}. \end{aligned}$$

Further we bound the two terms of the left-hand side:

$$\begin{aligned}
& \left| \left(D^2 {}_a D_x^{-(2-\mu)} p^{m+1}, {}_a D_x^{-\gamma} D p^{m+1} \right) \right| \\
&= - \left(\mathbf{D}^{\mu-1} p^{m+1}, \mathbf{D}^{2s} p^{m+1} \right) \\
&= - \left(\mathbf{D}^{\mu-1} p^{m+1}, \mathbf{D}^{2s-\mu+1} \mathbf{D}^{\mu-1} p^{m+1} \right) \\
&= - \left(\mathbf{D}^{(s-\frac{\mu}{2}+\frac{1}{2})^*} \mathbf{D}^{\mu-1} p^{m+1}, \mathbf{D}^{s-\frac{\mu}{2}+\frac{1}{2}} \mathbf{D}^{\mu-1} p^{m+1} \right) \\
&= \left| \mathbf{D}^{\mu-1} p^{m+1} \right|_{J_s^{s-\frac{\mu}{2}+\frac{1}{2}}(\Omega)}^2 \\
&\geq c \left| \mathbf{D}^{\mu-1} p^{m+1} \right|_{J_L^{s-\frac{\mu}{2}+\frac{1}{2}}(\Omega)}^2 \\
&= c \left| p^{m+1} \right|_{J_L^{s+\frac{\mu}{2}-\frac{1}{2}}(\Omega)}^2.
\end{aligned}$$

Similarly, we obtain

$$\left| \left(D^2 {}_x D_b^{-(2-\mu)} p^{m+1}, {}_a D_x^{-\gamma} D p^{m+1} \right) \right| \geq c \left| p^{m+1} \right|_{J_R^{s+\frac{\mu}{2}-\frac{1}{2}}(\Omega)}^2.$$

Based on the above estimates and the equivalence of the spaces $J_L^{s+\frac{\mu}{2}-\frac{1}{2}}(\Omega)$, $J_R^{s+\frac{\mu}{2}-\frac{1}{2}}(\Omega)$, $H^{s+\frac{\mu}{2}-\frac{1}{2}}(\Omega)$, and $\left| p^{m+1} \right|_{L^2(\Omega)}^2 \leq c \left| p^{m+1} \right|_{J_R^{s+\frac{\mu}{2}-\frac{1}{2}}(\Omega)}^2$, the stated results follow. \square

THEOREM 3.9. *Let $U''(x) \leq 0$ for any $x \in \Omega$, $f \in L^2(\Omega)$, and p^{m+1} satisfy (3.7)–(3.9). Then $p^{m+1} \in H^\mu(\Omega)$ with*

$$(3.25) \quad \left\| p^{m+1} \right\|_{H^\mu(\Omega)} \leq c(\alpha_0) \|f\|_{L^2(\Omega)}, \quad \mu \neq \frac{3}{2},$$

$$(3.26) \quad \left\| p^{m+1} \right\|_{H^{\mu-\epsilon}(\Omega)} \leq c(\alpha_0) \|f\|_{L^2(\Omega)}, \quad \mu = \frac{3}{2}, \quad 0 < \epsilon < \frac{1}{2}.$$

Proof. First, we must establish an estimate for p^{m+1} in the H^1 norm. In order to do this, we repeatedly use Lemma 3.8 in an induction argument.

Suppose that $p^{m+1} \in H^{\frac{j\mu}{2}-\frac{j-1}{2}}(\Omega)$ for $j \in N$ such that $\frac{j\mu}{2} - \frac{j-1}{2} < 1$, with

$$\left\| p^{m+1} \right\|_{H^{\frac{j\mu}{2}-\frac{j-1}{2}}(\Omega)} \leq c(\alpha_0) \|f\|_{L^2(\Omega)}.$$

By Lemma 3.8, $p^{m+1} \in H^{\frac{(j+1)\mu}{2}-\frac{j}{2}}$ with

$$\left\| p^{m+1} \right\|_{H^{\frac{(j+1)\mu}{2}-\frac{j}{2}}(\Omega)} \leq c(\alpha_0) \|f\|_{L^2(\Omega)}.$$

For $j = 1$ we have that $p^{m+1} \in H_0^{\frac{\mu}{2}}(\Omega)$, so the initial step is valid. We repeat this process for $j = 1, j = 2, j = \dots$, until $j = K$, where

$$\frac{K\mu}{2} - \frac{K-1}{2} < 1 \quad \text{and} \quad \frac{(K+1)\mu}{2} - \frac{K}{2} \geq 1.$$

For this value of j , we have $p^{m+1} \in H_0^1(\Omega) \subset H^{\frac{(K+1)\mu}{2}-\frac{K}{2}}(\Omega)$ with the estimate

$$\left\| p^{m+1} \right\|_{H^1(\Omega)} \leq c(\alpha_0) \|f\|_{L^2(\Omega)}.$$

Now, multiplying both sides of (3.7) by $\mathbf{D}^\mu p^{m+1}$ and integrating over Ω , similar to the estimates in the proof of Lemma 3.8, we have

$$c(\alpha_0) \|p^{m+1}\|_{J_L^\mu(\Omega)}^2 + c(\alpha_0) \|p^{m+1}\|_{J_L^\mu(\Omega)} \|p^{m+1}\|_{J_R^\mu(\Omega)} \leq c(\alpha_0) \|f\|_{L^2(\Omega)} \|p^{m+1}\|_{J_L^\mu(\Omega)},$$

where the three $c(\alpha_0)$ terms generally are not equal.

When $\mu \neq \frac{3}{2}$, the three norms $J_L^\mu(\Omega)$, $J_R^\mu(\Omega)$, and $H^\mu(\Omega)$ are equivalent; then the stated result (3.25) follows. As $\mu = \frac{3}{2}$, because of the fact that $0 < \epsilon < \frac{1}{2}$, the following holds:

$$|p^{m+1}|_{H^{\mu-\epsilon}(\Omega)} \leq c |p^{m+1}|_{J_L^\mu(\Omega)} \quad \text{and} \quad |p^{m+1}|_{H^{\mu-\epsilon}(\Omega)} \leq c |p^{m+1}|_{J_R^\mu(\Omega)},$$

so the stated result (3.26) holds. \square

3.3. Finite element approximation and error estimates in the space and error estimates for full discretization. Denote $\{S_h\}$ to be a family of partitions of Ω with grid parameter h , and associated with S_h define the finite-dimensional subspace X_h to be the basis of the piecewise polynomials of order $n-1$, where $n \in \mathbb{N}$. Denote $I^h p^{m+1}$ to be the piecewise interpolation polynomial of p^{m+1} in S_h , being uniquely determined. We have the well-known approximation property.

LEMMA 3.10 (approximation property [6]). *Let $p^{m+1} \in H^l(\Omega)$, $0 < l \leq n$, and $0 \leq s \leq l$. Then there exists a constant $c(\alpha_0)$ depending on Ω such that*

$$(3.27) \quad \|p^{m+1} - I^h p^{m+1}\|_{H^s(\Omega)} \leq c(\alpha_0) h^{l-s} \|p^{m+1}\|_{H^l(\Omega)}.$$

Let \tilde{p}_h^{m+1} be the solution of the finite-dimensional variational problem

$$(3.28) \quad \tilde{B}(\tilde{p}_h^{m+1}, q_h) = \tilde{F}(q_h) \quad \forall q_h \in X_h.$$

We define the energy norm associated with (3.21) as

$$(3.29) \quad \|p^{m+1}\|_E := \tilde{B}(p^{m+1}, p^{m+1})^{\frac{1}{2}}.$$

According to Lemmas 3.4 and 3.5, we have the norm equivalence of $\|\cdot\|_E$ and $\|\cdot\|_{H_0^{\frac{\mu}{2}}(\Omega)}$.

THEOREM 3.11. *Let $U''(x) \leq 0$ for any $x \in \Omega$ and p^{m+1} be the solution to (3.21). There exists a unique solution to (3.28) satisfying the estimate*

$$(3.30) \quad \|p^{m+1} - \tilde{p}_h^{m+1}\|_E \leq c(\alpha_0) \inf_{q_h \in X_h} \|p^{m+1} - q_h\|_E \leq c(\alpha_0) \|p^{m+1} - I^h p^{m+1}\|_E.$$

Proof. Since X_h is a subset of the space $H_0^{\frac{\mu}{2}}(\Omega)$, (3.28) satisfies the hypothesis of the Lax–Milgram lemma over the finite-dimensional subspace. Then the existence and uniqueness hold for (3.28). The estimate (3.30) follows from Céa’s lemma. \square

Combining the previous results into an estimate for $p^{m+1} - \tilde{p}_h^{m+1}$ leads to the following corollary.

COROLLARY 3.12. *Let $U''(x) \leq 0$ for any $x \in \Omega$, $p^{m+1} \in H_0^{\frac{\mu}{2}}(\Omega) \cap H^l(\Omega)$ ($\frac{\mu}{2} \leq l \leq n$) solve (3.21), and \tilde{p}_h^{m+1} solve (3.28). Then there exists a constant $c(\alpha_0)$ such that*

$$(3.31) \quad \|p^{m+1} - \tilde{p}_h^{m+1}\|_{H_0^{\frac{\mu}{2}}(\Omega)} \leq c(\alpha_0) h^{l-\frac{\mu}{2}} \|p^{m+1}\|_{H^l(\Omega)}.$$

Applying the Aubin–Nitsche trick derives the convergence estimate in the L^2 norm.

THEOREM 3.13. *Let $U''(x) \leq 0$ for any $x \in \Omega$, $p^{m+1} \in H_0^{\frac{\mu}{2}}(\Omega) \cap H^l(\Omega)$ ($\frac{\mu}{2} \leq l \leq n$) solve (3.21), and \tilde{p}_h^{m+1} solve (3.28). Then there exists a constant $c(\alpha_0)$ such that*

$$(3.32) \quad \|p^{m+1} - \tilde{p}_h^{m+1}\|_{L^2(\Omega)} \leq c(\alpha_0)h^l \|p^{m+1}\|_{H^l(\Omega)}, \quad \mu \neq \frac{3}{2},$$

$$(3.33) \quad \|p^{m+1} - \tilde{p}_h^{m+1}\|_{L^2(\Omega)} \leq c(\alpha_0)h^{l-\epsilon} \|p^{m+1}\|_{H^l(\Omega)}, \quad \mu = \frac{3}{2}, \quad 0 < \epsilon < \frac{1}{2}.$$

Proof. Introduce the adjoint problem: Find $\omega \in H_0^{\frac{\mu}{2}}(\Omega)$ such that

$$(3.34) \quad \tilde{B}(\omega, q) = (p^{m+1} - \tilde{p}_h^{m+1}, q) \quad \forall q \in H_0^{\frac{\mu}{2}}(\Omega).$$

Theorem 3.9 implies that, for $\mu \neq \frac{3}{2}$, ω satisfies the regularity estimate

$$\|\omega\|_{H^\mu(\Omega)} \leq c(\alpha_0) \|p^{m+1} - \tilde{p}_h^{m+1}\|_{L^2(\Omega)}.$$

Substituting $q = p^{m+1} - \tilde{p}_h^{m+1}$ and using the Galerkin orthogonality, we obtain

$$\begin{aligned} \|p^{m+1} - \tilde{p}_h^{m+1}\|_{L^2(\Omega)}^2 &= \tilde{B}(\omega, p^{m+1} - \tilde{p}_h^{m+1}) \\ &= \tilde{B}(\omega - I^h\omega, p^{m+1} - \tilde{p}_h^{m+1}) \\ &\leq c(\alpha_0) \|\omega - I^h\omega\|_{H^{\frac{\mu}{2}}(\Omega)} \|p^{m+1} - \tilde{p}_h^{m+1}\|_{H^{\frac{\mu}{2}}(\Omega)} \\ &\leq c(\alpha_0)h^{\frac{\mu}{2}} \|\omega\|_{H^\mu(\Omega)} \|p^{m+1} - \tilde{p}_h^{m+1}\|_{H^{\frac{\mu}{2}}(\Omega)} \\ &\leq c(\alpha_0)h^{\frac{\mu}{2}} \|p^{m+1} - \tilde{p}_h^{m+1}\|_{L^2(\Omega)} \|p^{m+1} - \tilde{p}_h^{m+1}\|_{H^{\frac{\mu}{2}}(\Omega)}. \end{aligned}$$

Thus, we have the estimate

$$\|p^{m+1} - \tilde{p}_h^{m+1}\|_{L^2(\Omega)} \leq c(\alpha_0)h^{\frac{\mu}{2}} \|p^{m+1} - \tilde{p}_h^{m+1}\|_{H^{\frac{\mu}{2}}(\Omega)}.$$

Further applying (3.31), we get (3.32). Because of (3.26) in Theorem 3.9, we can similarly prove (3.33) with $\mu = \frac{3}{2}$. \square

Let p_h^j be the computational value at time t_j of full discretization; i.e., $\{p_h^j\}_{j=1}^M$ satisfy for all $q_h \in X_h$

$$(3.35) \quad \begin{aligned} &(p_h^{m+1}, q_h) - \alpha_0 \left(\left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p_h^{m+1}, q_h \right) \\ &= \left((1 - d_1)p_h^m + \sum_{j=1}^{m-1} (d_j - d_{j+1})p_h^{m-j} + d_m p_h^0, q_h \right). \end{aligned}$$

Now we aim at deriving the estimates for $\|p(t_m) - p_h^m\|_{H_0^{\frac{\mu}{2}}(\Omega)}$ and $\|p(t_m) - p_h^m\|_{L^2(\Omega)}$, being given in the following theorem.

THEOREM 3.14. *Let $U''(x) \leq 0$ for any $x \in \Omega$, p be the exact solution of (3.1)–(3.3), and $\{p_h^m\}_{m=0}^M$ be the solution of problem (3.35) with the initial condition $p_h^0 = I^h g$. Suppose $p \in H^1([0, T], H_0^{\frac{\mu}{2}}(\Omega) \cap H^l(\Omega))$ ($\frac{\mu}{2} \leq l \leq n$), then we have*

(1) when $0 < \alpha < 1$,

$$\begin{aligned} \|p(t_m) - p_h^m\|_{H^{\frac{\mu}{2}}(\Omega)} &\leq \frac{c_p T^\alpha}{1-\alpha} \left(k^{2-\alpha} + c(\alpha_0) k^{-\alpha} h^{l-\frac{\mu}{2}} \|p\|_{L^\infty(H^l(\Omega))} \right), \\ \|p(t_m) - p_h^m\|_{L^2(\Omega)} &\leq \frac{c_p T^\alpha}{1-\alpha} \left(k^{2-\alpha} + c(\alpha_0) k^{-\alpha} h^l \|p\|_{L^\infty(H^l(\Omega))} \right), \quad \mu \neq \frac{3}{2}, \\ \|p(t_m) - p_h^m\|_{L^2(\Omega)} &\leq \frac{c_p T^\alpha}{1-\alpha} \left(k^{2-\alpha} + c(\alpha_0) k^{-\alpha} h^{l-\epsilon} \|p\|_{L^\infty(H^l(\Omega))} \right), \quad \mu = \frac{3}{2}, \quad 0 < \epsilon < \frac{1}{2}; \end{aligned}$$

(2) when $\alpha \rightarrow 1$,

$$\begin{aligned} \|p(t_m) - p_h^m\|_{H^{\frac{\mu}{2}}(\Omega)} &\leq c_p T \left(k + c(\alpha_0) k^{-1} h^{l-\frac{\mu}{2}} \|p\|_{L^\infty(H^l(\Omega))} \right), \\ \|p(t_m) - p_h^m\|_{L^2(\Omega)} &\leq c_p T \left(k + c(\alpha_0) k^{-1} h^l \|p\|_{L^\infty(H^l(\Omega))} \right), \quad \mu \neq \frac{3}{2}, \\ \|p(t_m) - p_h^m\|_{L^2(\Omega)} &\leq c_p T \left(k + c(\alpha_0) k^{-1} h^{l-\epsilon} \|p\|_{L^\infty(H^l(\Omega))} \right), \quad \mu = \frac{3}{2}, \quad 0 < \epsilon < \frac{1}{2}, \end{aligned}$$

where c_p is given in (3.15).

Proof. From (2.3), (3.4), (3.5), and (3.14), we know that $\{p(t_j)\}_{j=1}^M$ satisfy $\forall q \in H_0^{\frac{\mu}{2}}(\Omega)$

$$\begin{aligned} (3.36) \quad & (p(t_{m+1}), q) - \alpha_0 \left(\left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] p(t_{m+1}), q \right) \\ &= \left((1-d_1)p(t_m) + \sum_{j=1}^{m-1} (d_j - d_{j+1})p(t_{m-j}) + d_m p(t_0), q \right) + (r^{m+1}, q). \end{aligned}$$

Let $\pi_h^{\frac{\mu}{2}}$ be the $H^{\frac{\mu}{2}}$ -orthogonal projection operator from $H_0^{\frac{\mu}{2}}$ to X_h , associated with the energy norm defined in (3.29), i.e., for all $q_h \in X_h$,

$$\begin{aligned} (3.37) \quad & \left(\pi_h^{\frac{\mu}{2}} p(t_{m+1}), q_h \right) - \alpha_0 \left(\left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] \pi_h^{\frac{\mu}{2}} p(t_{m+1}), q_h \right) \\ &= \left((1-d_1)p(t_m) + \sum_{j=1}^{m-1} (d_j - d_{j+1})p(t_{m-j}) + d_m p(t_0), q_h \right) + (r^{m+1}, q_h). \end{aligned}$$

Let $\tilde{e}_h^{m+1} = \pi_h^{\frac{\mu}{2}} p(t_{m+1}) - p_h^{m+1}$ and $e_h^{m+1} = p(t_{m+1}) - p_h^{m+1}$; by subtracting (3.35) from (3.37), we obtain

$$\begin{aligned} (3.38) \quad & (\tilde{e}_h^{m+1}, q_h) - \alpha_0 \left(\left[\frac{\partial}{\partial x} \frac{U'(x)}{\eta_\alpha} + \kappa_\alpha \nabla^\mu \right] \tilde{e}_h^{m+1}, q_h \right) \\ &= \left((1-d_1)e_h^m + \sum_{j=1}^{m-1} (d_j - d_{j+1})e_h^{m-j} + d_m e_h^0, q_h \right) + (r^{m+1}, q_h). \end{aligned}$$

Taking $q_h = \tilde{e}_h^{m+1}$ in (3.38) and using the triangular inequality $\|e_h^{m+1}\|_{H^{\frac{\mu}{2}}(\Omega)} \leq \|\tilde{e}_h^{m+1}\|_{H^{\frac{\mu}{2}}(\Omega)} + \|p(t_{m+1}) - \pi_h^{\frac{\mu}{2}} p(t_{m+1})\|_{H^{\frac{\mu}{2}}(\Omega)}$, from Corollary 3.12 we have

$$\begin{aligned}
(3.39) \quad & \|e_h^{m+1}\|_{H^{\frac{\mu}{2}}(\Omega)} \leq (1-d_1)\|e_h^m\|_{L^2(\Omega)} + \sum_{j=1}^{m-1} (d_j - d_{j+1})\|e_h^{m-j}\|_{L^2(\Omega)} \\
& + d_m \|e_h^0\|_{L^2(\Omega)} + \|r^{m+1}\|_{L^2(\Omega)} + \left\| p(t_{m+1}) - \pi_h^{\frac{\mu}{2}} p(t_{m+1}) \right\|_{H^{\frac{\mu}{2}}(\Omega)} \\
& \leq (1-d_1)\|e_h^m\|_{L^2(\Omega)} + \sum_{j=1}^{m-1} (d_j - d_{j+1})\|e_h^{m-j}\|_{L^2(\Omega)} \\
& + d_m \|e_h^0\|_{L^2(\Omega)} + c_p k^2 + c(\alpha_0) h^{l-\frac{\mu}{2}} \|p(t_{m+1})\|_{H^1(\Omega)}.
\end{aligned}$$

Similarly, taking $q_h = \tilde{e}_h^{m+1}$ in (3.38) and using the triangular inequality $\|e_h^{m+1}\|_{L^2(\Omega)} \leq \|\tilde{e}_h^{m+1}\|_{L^2(\Omega)} + \|p(t_{m+1}) - \pi_h^{\frac{\mu}{2}} p(t_{m+1})\|_{L^2(\Omega)}$ and $\|\tilde{e}_h^{m+1}\|_{L^2(\Omega)} \leq \|\tilde{e}_h^{m+1}\|_{H^{\frac{\mu}{2}}(\Omega)}$, from Theorem 3.13 we have

$$\begin{aligned}
(3.40) \quad & \|e_h^{m+1}\|_{L^2(\Omega)} \leq (1-d_1)\|e_h^m\|_{L^2(\Omega)} + \sum_{j=1}^{m-1} (d_j - d_{j+1}) \|e_h^{m-j}\|_{L^2(\Omega)} \\
& + d_m \|e_h^0\|_{L^2(\Omega)} + \|r^{m+1}\|_{L^2(\Omega)} + \left\| p(t_{m+1}) - \pi_h^{\frac{\mu}{2}} p(t_{m+1}) \right\|_{L^2(\Omega)} \\
& \leq (1-d_1)\|e_h^m\|_{L^2(\Omega)} + \sum_{j=1}^{m-1} (d_j - d_{j+1}) \|e_h^{m-j}\|_{L^2(\Omega)} \\
& + d_m \|e_h^0\|_{L^2(\Omega)} + c_p k^2 + c(\alpha_0) h^{\tilde{l}} \|p(t_{m+1})\|_{H^1(\Omega)},
\end{aligned}$$

where $\tilde{l} = l$ if $\mu \neq \frac{3}{2}$ and $\tilde{l} = l - \epsilon$, $0 < \epsilon < \frac{1}{2}$, if $\mu = \frac{3}{2}$.

It is at this point that we distinguish two cases for α ; from (3.39) and (3.40) the stated results are obtained by following the same lines as in Theorem 3.3, so the remaining details are omitted. \square

4. Numerical experiments and simulation of physical systems. In this section, we confirm the theoretical analysis by doing numerical computations with a smooth initial condition and then simulate the real physical cases with the δ distribution as the initial condition. The trial space used in the space finite element approximation is taken as X_h to be the basis with piecewise linear polynomials, i.e., $n = 2$.

In this paper, both the space and time derivatives of (3.1) are fractional. It is worth noting that fractional derivatives are nonlocal operators. Consequently, when approximating the space derivative, a sparse coefficient matrix [14], having the characteristic of using a finite element basis for the classical differential equation, does not occur. For the time derivative, because of its nonlocal property, we need to do a summation operation, the right-hand side of (3.35), in each time step. But it is possible to reduce the computational cost, since the fractional derivative has the short memory principle [8].

First, for confirming the theoretical prediction, we consider the problem (3.1)–(3.3) but, without loss of generality, add a force term $h(x, t)$ on the right-hand side of (3.1). Now the problem has the analytical solution

$$p(x, t) = t^2(x-a)^2(x-b)^2,$$

if taking

$$U(x) = 3x, \quad \kappa_\alpha = \eta_\alpha = 1.$$

TABLE 4.1

Experimental error results with fixed time step size $k = 0.0001$, $a = -2$, $b = -2$.

h	$\ p(T) - p_h^M\ _{L^2(\Omega)}$	Convergent rate
1/2	$3.077979 \cdot 10^{-2}$	
1/4	$9.020087 \cdot 10^{-3}$	1.77
1/8	$2.603326 \cdot 10^{-3}$	1.79

TABLE 4.2

Computational error results with fixed space step length $h = 0.05$, $a = -2$, $b = -2$.

k	$\ p(T) - p_h^M\ _{L^2(\Omega)}$	Convergent rate
1/10	$1.646337 \cdot 10^{-2}$	
1/20	$8.455413 \cdot 10^{-3}$	0.96
1/40	$4.270158 \cdot 10^{-3}$	0.99

It can be checked that the corresponding initial condition and force term are, respectively,

$$g(x) = 0,$$

$$\begin{aligned} h(x, t) = & \frac{2\Gamma(2)}{\Gamma(3-\alpha)} t^{2-\alpha} (x-a)^2 (x-b)^2 - 6t^2 ((x-a)(x-b))^2 + (x-a)^2 (x-b) \\ & - \frac{1}{2} t^2 \left(\frac{\Gamma(5)}{\Gamma(5-\mu)} ((x-a)^{4-\mu} + (b-x)^{4-\mu}) - 2(b-a) \frac{\Gamma(4)}{\Gamma(4-\mu)} ((x-a)^{3-\mu} \right. \\ & \left. + (b-x)^{3-\mu}) + (b-a)^2 \frac{\Gamma(3)}{\Gamma(3-\mu)} ((x-a)^{2-\mu} + (b-x)^{2-\mu}) \right). \end{aligned}$$

We compute the errors $\|p(T) - p_h^M\|_{L^2(\Omega)}$ at time $T = 1$, with space fractional order $\mu = 1.8$ and time fractional order $\alpha = 0.8$. In Table 4.1, with fixed time-step size, choosing different space step lengths leads to the experimental convergent rate in space. In Table 4.2, we fix space step size; using different time step lengths leads to the numerical convergent rate in time.

Further we simulate the real physical cases for (3.1)–(3.3) with absorbing boundary conditions and still taking $U(x) = 3x$, $\kappa_\alpha = \eta_\alpha = 1$, but using the δ distribution as the initial condition. The noteworthy features are the appearance of cusps when the time fractional order $\alpha \neq 1.0$, and the tail of the probability density function p decays as a power law when the space fractional order $\mu \neq 2.0$. See Figure 1, where $p(x, t|0, 0)$ is the unnormalized probability density at (x, t) starting from $t = 0$ with $\delta(x)$ as the initial distribution, and $a = -2$, $b = -2$, $k = 0.01$, and $h = 0.02$.

5. Conclusions. So far, it seems that no other published research takes into account the numerical method and detailed numerical error analysis for the space and time fractional partial differential equation, besides the stochastic approach used in [30]. In this paper, we have developed and analyzed an efficient numerical method for a partial differential equation with fractional derivatives in both space and time, the space and time fractional Fokker-Planck equation, which has a strong physical background, for example, characterizing the anomalous diffusion with both traps and flights. First, based on the properties of the Riemann-Liouville and Caputo derivatives, the formulation of the original equation is transformed. The time fractional derivative is discretized by using a backward differentiation, having $(2 - \alpha)$ -order accuracy.

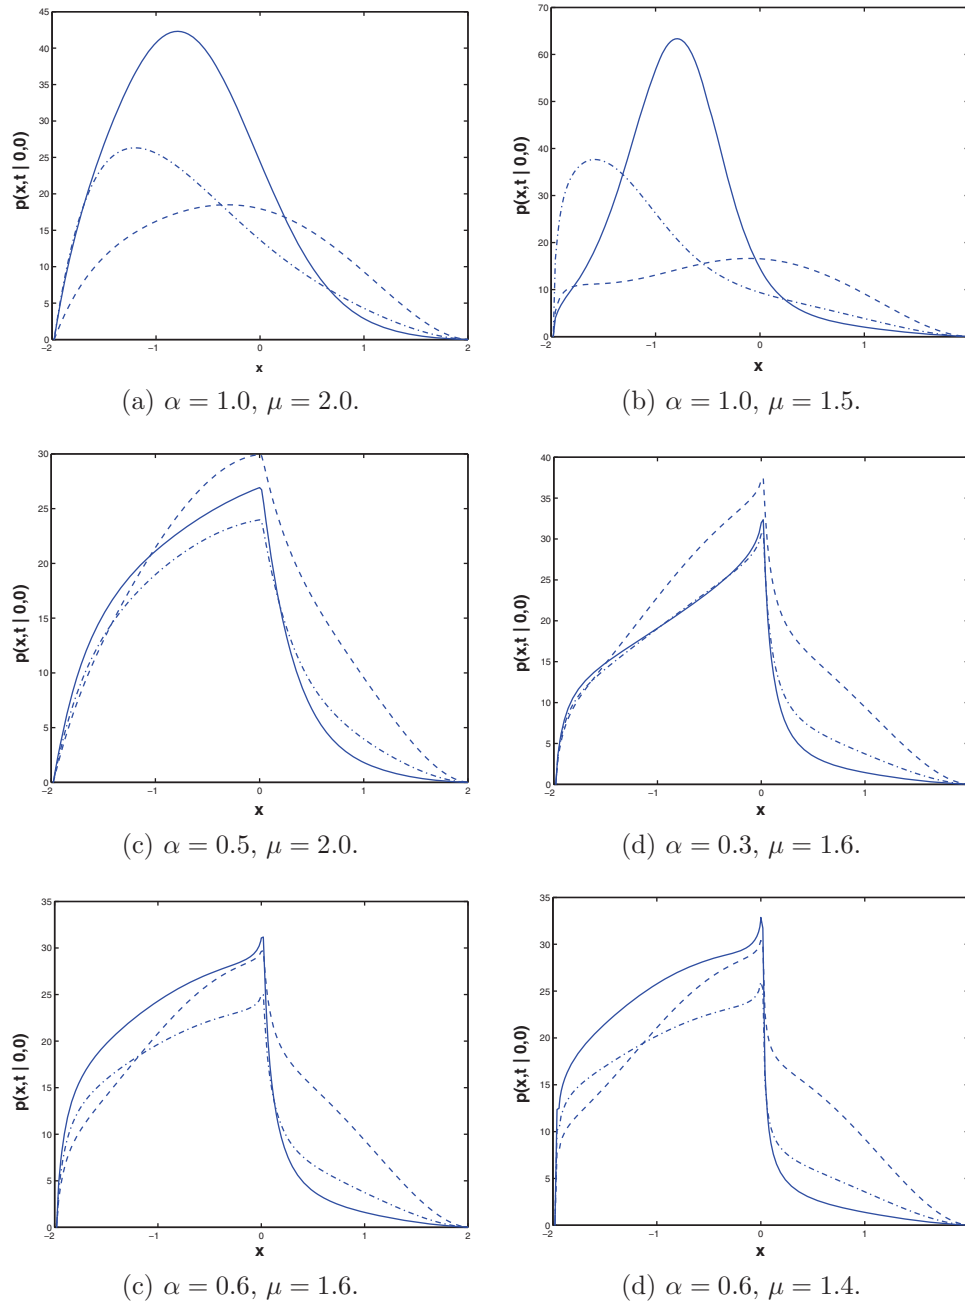

FIG. 1. The evolution of $p(x, t | 0, 0)$, where the solid line “—” stands for the solution when $t = 0.3$, the dashed-dotted line “-.” stands for the solution when $t = 0.6$, and the dashed line “--” stands for the solution when $t = 1.0$ ($p(x, t | 0, 0)$ is the unnormalized probability density at (x, t) starting from $t = 0$ with $\delta(x)$ as the initial distribution, and $a = -2$, $b = -2$, $k = 0.01$, and $h = 0.02$).

We then derived the variational formation of the semidiscrete scheme; its stability is rigorously proved. Use of the finite element method to approximate the space fractional derivative results in full discretization with μ -order convergence in space

and $(2 - \alpha)$ -order convergence in time. Our numerical experiments are in agreement with the theoretical analysis. The real physical cases are also simulated.

A key difference between fractional derivatives and the classical derivatives is that fractional derivatives are nonlocal operators. The matrix generated by finite element approximation in space is no longer sparse, and in the time direction, when advancing one step, we need to sum up all of the previous computed results' multiplied variational coefficients. So the computational cost, storage requirement, and time spent are expensive. Fortunately, although fractional derivatives have global dependence, they have the short memory principle. This principle works well for computing fractional ODEs [8]. Our future research along this direction is to investigate the effective ways of using the short memory principle for computing partial differential equations with both space and time fractional derivatives so as to reduce the computational cost.

RAPID SOLUTION OF THE WAVE EQUATION IN UNBOUNDED DOMAINS*

L. BANJAI[†] AND S. SAUTER[†]

Abstract. In this paper we propose and analyze a new, fast method for the numerical solution of time domain boundary integral formulations of the wave equation. We employ Lubich’s convolution quadrature method for the time discretization and a Galerkin boundary element method for the spatial discretization. The coefficient matrix of the arising system of linear equations is a triangular block Toeplitz matrix. Possible choices for solving the linear system arising from the above discretization include the use of fast Fourier transform (FFT) techniques and the use of data-sparse approximations. By using FFT techniques, the computational complexity can be reduced substantially while the storage cost remains unchanged and is, typically, high. Using data-sparse approximations, the gain is reversed; i.e., the computational cost is (approximately) unchanged while the storage cost is substantially reduced. The method proposed in this paper combines the advantages of these two approaches. First, the discrete convolution (related to the block Toeplitz system) is transformed into the (discrete) Fourier image, thereby arriving at a decoupled system of discretized Helmholtz equations with complex wave numbers. A fast data-sparse (e.g., fast multipole or panel-clustering) method can then be applied to the transformed system. Additionally, significant savings can be achieved if the boundary data are smooth and time-limited. In this case the right-hand sides of many of the Helmholtz problems are almost zero, and hence can be disregarded. Finally, the proposed method is inherently parallel. We analyze the stability and convergence of these methods, thereby deriving the choice of parameters that preserves the convergence rates of the unperturbed convolution quadrature. We also present numerical results which illustrate the predicted convergence behavior.

1. Introduction. Boundary value problems governed by the wave equation

$$\partial_t^2 u - \Delta u = f$$

arise in many physical applications such as electromagnetic wave propagation or the computation of transient acoustic waves. Since such problems are typically formulated in unbounded domains, the method of integral equations is an elegant tool for transforming this partial differential equation (PDE) into an integral equation on the bounded surface of the scatterer.

Although this approach goes back to the early 1960s (cf. [19]), the development of fast numerical methods for integral equations in the field of hyperbolic problems is still in its infancy compared to the multitude of fast methods for elliptic boundary integral equations (cf. [38] and references therein). Existing numerical discretization methods include collocation methods with some stabilization techniques (cf. [7], [8], [14], [15], [16], [33], [37]), and Laplace–Fourier methods coupled with Galerkin boundary elements in space (see [3], [12], [17], [20]). Numerical experiments can be found, e.g., in [21].

In [18] a fast version of the *marching-on-in-time* (MOT) method is presented which is based on a suitable plane wave expansion of the arising potential, which reduces the storage and computational costs.

We here employ the convolution quadrature method for the time discretization and a Galerkin boundary element method in space. The convolution quadrature method for the time discretization has been developed in [29], [30], [31], [32]. It provides a straightforward way to obtain a stable time stepping scheme using the Laplace transform of the kernel function. For applications to problems such as viscoelastic and poroelastic continua see [40], [41], [42].

The coefficient matrix in the arising system of linear equation is a block-triangular Toeplitz matrix consisting of N blocks of dimension $M \times M$, where N denotes the number of time steps and M is the number of spatial degrees of freedom. Due to the nonlocalness of the arising boundary integral operators, the $M \times M$ matrix blocks are densely populated.

In the literature, there exist (at least) two alternatives for solving this system efficiently. In [24], fast Fourier transform (FFT) techniques are employed, which make use of the Toeplitz structure of the system matrix, and the computational complexity is reduced to $\mathcal{O}(M^2 N \log^2 N)$, while the storage complexity stays at $\mathcal{O}(NM^2)$. In [23], [22], [28], the $M \times M$ block matrices are approximated by data-sparse representations based on a cutoff and panel-clustering strategy. This leads to a significant reduction of the storage complexity. The computational complexity is reduced compared to the $\mathcal{O}(N^2 M^2)$ cost of the naive approach but increased compared to the computational cost of the FFT approach.

Also the classical Galerkin discretization of the retarded boundary integral equation (see [3], [20]), leads to a block Toeplitz system matrix, where the matrix blocks are of size $M \times M$ and sparse. More precisely, the number of nonzero entries in the block Toeplitz matrix is, for piecewise constant boundary elements, of order $\mathcal{O}(M^2)$ and, for piecewise linear boundary elements, of order $\mathcal{O}(M^{2+\frac{1}{3}})$ for this approach. Here, the total cost for the computation of a full Galerkin approximation sums up to $\mathcal{O}(M^2 N)$ for piecewise constant boundary elements and to $\mathcal{O}(N^2 M^{3/2})$ for piecewise linear boundary elements. A drawback of this approach, however, is that the numerical quadrature for computing the coefficients of the system matrix has to be carried out on the intersections of the boundary element mesh with the discrete light cone. The stable handling of these intersections and the implementation is especially complicated for curved panels.

In this paper, we propose a new approach which combines the advantages of the FFT technique with the sparse approximation. We transfer the block Toeplitz system to the Fourier image by the discrete Fourier transform and then face the problem of computing approximate solutions of Helmholtz problems at different (complex) wave numbers. These Helmholtz problems are fully decoupled, and hence can be efficiently solved on parallel computers. Relatively standard, fast methods (e.g., fast multipole method, hierarchical matrices) for the solution of frequency domain scattering can effectively be applied to these problems; see [9], [35], and [5]. It may also be possible to further reduce the computational cost of assembling the matrices by using the techniques for multifrequency analysis described in [27], [44]. Further, we also show that if the boundary data are sufficiently smooth and compatible and of limited time duration, instead of N , only $\mathcal{O}(N^\epsilon)$, for any fixed $\epsilon > 0$, Helmholtz systems need to be solved. Our method is similar and shares some properties (the need to solve a series of elliptic problems and the intrinsic parallelizability) of certain methods for

parabolic equations; see [26], [43]. A related, interesting variation of the convolution quadrature for convolution kernels whose Laplace transform is sectorial can be found in [39].

2. Integral formulation of the wave equation. Let $\Omega \subset \mathbb{R}^3$ be a Lipschitz domain with boundary Γ ; typically, e.g., in scattering problems, Ω is an unbounded domain. In this paper, we present efficient methods for numerically solving the homogeneous wave equation

$$(2.1a) \quad \partial_t^2 u - \Delta u = 0 \quad \text{in } \Omega \times (0, T)$$

with initial conditions

$$(2.1b) \quad u(\cdot, 0) = \partial_t u(\cdot, 0) = 0 \quad \text{in } \Omega$$

and boundary conditions

$$(2.1c) \quad u = g \quad \text{on } \Gamma \times (0, T)$$

on a time interval $(0, T)$ for some $T > 0$. For its solution, we employ an ansatz as a *single layer potential*

$$(2.2) \quad u(x, t) = \int_0^t \int_{\Gamma} k(x - y, t - \tau) \phi(y, \tau) d\Gamma_y d\tau, \quad (x, t) \in \Omega \times (0, T),$$

where $k(z, t)$ is the fundamental solution of the wave equation,

$$(2.3) \quad k(z, t) = \frac{\delta(t - \|z\|)}{4\pi\|z\|},$$

with $\delta(t)$ being the Dirac delta distribution. The ansatz (2.2) satisfies the homogeneous equation (2.1a) and the initial conditions (2.1b). The extension $x \rightarrow \Gamma$ is continuous, and hence the unknown density ϕ in (2.2) is determined via the boundary conditions (2.1c), $u(x, t) = g(x, t)$. This results in the boundary integral equation for ϕ ,

$$(2.4) \quad \int_0^t \int_{\Gamma} k(x - y, t - \tau) \phi(y, \tau) d\Gamma_y d\tau = g(x, t) \quad \forall (x, t) \in \Gamma \times (0, T).$$

Existence and uniqueness results for the solution of the continuous problem are proved in [31] and [3, Prop. 3].

3. Numerical discretization.

3.1. Time discretization via convolution quadrature. For the time discretization, we employ the convolution quadrature approach which has been developed by Lubich in [29], [30], [31] and Lubich and Schneider in [32]. We do not recall the theoretical framework here but directly apply the approach to the wave equation. We make use of the following notation for the time convolution:

$$V(\partial_t)\phi := \int_0^t v(t - \tau)\phi(\tau)d\tau,$$

where V denotes the Laplace transform of the operator v ; for the reasons behind using this notation see [29]. Note that, for the retarded single layer potential (2.2),

v is a parameter-dependent integral operator, i.e., $(v(t - \tau)\phi(\tau))(x) = \int_{\Gamma} k(x - y, t - \tau)\phi(\tau, y)d\Gamma_y$ (where we write $\phi(\tau, y)$ for $(\phi(\tau))(y)$) and $V(s)$ is the Laplace transform of v given by (3.4).

To discretize the time convolution we split the time interval $[0, T]$ into $N + 1$ time steps of equal length $\Delta t = T/N$ and compute an approximate solution at the discrete time levels $t_n = n\Delta t$. The continuous convolution operator $V(\partial_t)$ at the discrete times t_n is replaced by the discrete convolution operator, for $n = 0, 1, \dots, N$,

$$(3.1) \quad (V(\partial_t^{\Delta t})\phi^{\Delta t})(t_n) := \sum_{j=0}^n \omega_{n-j}^{\Delta t}(V)\phi^{\Delta t}(t_j).$$

The convolution weights $\omega_n^{\Delta t}(V)$ are defined below (see (3.3)); whenever the underlying operator v , respectively, V , is clear from the context, we will write $\omega_n^{\Delta t}$. The time-discrete problem is given as follows: Find $\phi_j(\cdot) = \phi^{\Delta t}(\cdot, t_j)$, such that

$$(3.2) \quad \sum_{j=0}^n (\omega_{n-j}^{\Delta t}\phi_j)(x) = g_n(x), \quad n = 1, \dots, N, \quad x \in \Gamma,$$

where $g_n(x)$ is some approximation to $g(x, t_n)$, or $g(x, t_n)$ itself.

For the derivation, the general framework, and various applications, we refer the reader to [29], [30], [31], and for our concrete problem to [23]. If the time discretization is related to the unconditionally stable backward difference formula of second order (BDF2) scheme, the convolution weights $\omega_n^{\Delta t}$ are implicitly defined by

$$(3.3) \quad V\left(\frac{\gamma(\zeta)}{\Delta t}\right) = \sum_{n=0}^{\infty} \omega_n^{\Delta t}\zeta^n, \quad |\zeta| < 1.$$

Here, $V(s) : H^{-1/2}(\Gamma) \rightarrow H^{1/2}(\Gamma)$, $\text{Re } s > 0$, is the single layer potential for the Helmholtz operator $\Delta U - s^2U = 0$,

$$(3.4) \quad (V(s)\varphi)(x) = \int_{\Gamma} K(\|x - y\|, s)\varphi(y)d\Gamma_y, \quad \text{where } K(d, s) := \frac{e^{-sd}}{4\pi d}.$$

Note that K is the Laplace transform of the original time domain kernel function (2.3). The function $\gamma(\zeta)$ is the quotient of the generating polynomials of the BDF2 scheme and is given by

$$\gamma(\zeta) = \frac{1}{2}(\zeta^2 - 4\zeta + 3).$$

3.2. A decoupled system of Helmholtz problems. As recommended in [29, 31], the convolution weights $\omega_j^{\Delta t}$ can be numerically computed by applying the trapezoidal rule to its representation as a contour integral,

$$(3.5) \quad \omega_j^{\Delta t}(V) = \frac{1}{2\pi i} \oint_C \frac{V(\gamma(\zeta)/\Delta t)}{\zeta^{j+1}} d\zeta,$$

where C can be chosen as a circle centered at the origin of radius $\lambda < 1$. The approximate convolution weights are then given by the scaled inverse discrete Fourier transform

$$\omega_j^{\Delta t, \lambda}(V) := \frac{\lambda^{-j}}{N+1} \sum_{l=0}^N V(s_l)\zeta_{N+1}^{lj}, \quad \text{where } \zeta_{N+1} = e^{\frac{2\pi i}{N+1}}, \quad s_l = \frac{\gamma(\lambda\zeta_{N+1}^{-l})}{\Delta t}.$$

Let us extend the above two formulae to negative indices $j < 0$; note that this implies $\omega_j^{\Delta t} = 0$ for $j < 0$. As $N \rightarrow \infty$ or $\lambda \rightarrow 0$, we have $\omega_j^{\Delta t} - \omega_j^{\Delta t, \lambda} = \mathcal{O}(\lambda^{N+1})$, $j = -N, \dots, N$; see Proposition 5.4. By extending the sum in (3.1) to $j = N$ and substituting the approximate weights in (3.2), we obtain the following new system of equations for the new unknown $\phi^{\Delta t, \lambda}$:

$$(3.6) \quad \left(V(\partial_t^{\Delta t, \lambda}) \phi^{\Delta t, \lambda} \right) (t_n) := \sum_{j=0}^N \omega_{n-j}^{\Delta t, \lambda} (V) \phi_j^\lambda = g_n, \quad n = 0, 1, \dots, N.$$

The effect of the approximation on the difference between $\phi^{\Delta t, \lambda}$ and $\phi^{\Delta t}$ is discussed later. Substituting the definition of $\omega^{\Delta t, \lambda}$ in (3.6), we obtain the system of equations

$$(3.7) \quad \frac{\lambda^{-n}}{N+1} \sum_{l=0}^N \left(V(s_l) \hat{\phi}_l \right) (x) \zeta_{N+1}^{nl} = g_n(x), \quad n = 0, 1, \dots, N,$$

where

$$\hat{\phi}_l := \sum_{j=0}^N \lambda^j \phi_j^\lambda \zeta_{N+1}^{-lj}.$$

Note that the inverse transform is given by

$$(3.8) \quad \phi_l^\lambda = \frac{\lambda^{-l}}{N+1} \sum_{j=0}^N \hat{\phi}_j \zeta_{N+1}^{lj}.$$

Now, notice that, after multiplying by λ^n , applying the discrete Fourier transform with respect to n to both sides gives $N+1$ decoupled problems as follows:

$$(3.9) \quad \left(V(s_l) \hat{\phi}_l \right) (x) = \hat{g}_l(x) \quad \forall x \in \Gamma,$$

where

$$\hat{g}_l(x) = \sum_{n=0}^N \lambda^n g_n(x) \zeta_{N+1}^{-ln}.$$

We have thereby reduced the problem of solving numerically the wave equation to a system of Helmholtz problems with complex wave numbers s_l , $l = 0, 1, \dots, N$. An example of the range of frequencies is given in Figure 1.

Remark 3.1. An important remark to make here is that

$$V \left(\partial_t^{\Delta t, \lambda} \right) \phi^{\Delta t, \lambda} = g \quad \text{implies} \quad \phi^{\Delta t, \lambda} = V^{-1} \left(\partial_t^{\Delta t, \lambda} \right) g.$$

This can be seen by applying the scaled discrete inverse Fourier transform (see (3.8)) to

$$\hat{\phi}_l = V^{-1}(s_l) \hat{g}_l,$$

thereby obtaining

$$\phi_n^\lambda = \frac{\lambda^{-n}}{N+1} \sum_{l=0}^N \hat{\phi}_l \zeta_{N+1}^{nl} = \frac{\lambda^{-n}}{N+1} \sum_{l=0}^N V^{-1}(s_l) \hat{g}_l \zeta_{N+1}^{nl} = \sum_{j=0}^N \omega_{n-j}^{\Delta t, \lambda} (V^{-1}) g_j.$$

The last step is obtained from the definition of \hat{g}_l and $\omega_n^{\Delta t, \lambda} (V^{-1})$; see also (3.6) and (3.7). This fact will help us in obtaining optimal error and stability estimates.

FIG. 1. A range of complex frequencies for $N = 256$, $T = 2$, and $\lambda^N = 10^{-4}$. For this example it holds that $\text{Re } s_n > 4.6$, $n = 0, 1, \dots, N$.

3.3. Spatial discretization. Galerkin boundary element methods. In the previous section we derived the following semidiscrete problem: For $n = 0, 1, \dots, N$, find $\phi_n^\lambda \in H^{-1/2}(\Gamma)$ such that

$$(3.10) \quad \sum_{j=0}^N \omega_{n-j}^{\Delta t, \lambda} \phi_j^\lambda = g_n, \quad n = 0, 1, \dots, N.$$

We have further shown that the above system is equivalent to a system of decoupled Helmholtz equations

$$(3.11) \quad \left(V(s_l) \hat{\phi}_l \right) (x) = \hat{g}_l(x) \quad \forall x \in \Gamma.$$

In this paper we use a Galerkin boundary element method for the spatial discretization. Let \mathcal{G} be a regular (in the sense of Ciarlet [11]) boundary element mesh on Γ consisting of shape regular, possibly curved, triangles. For a triangle $\tau \in \mathcal{G}$, the (regular) pull-back to the reference triangle $\hat{\tau} := \text{conv} \left\{ \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \end{pmatrix} \right\}$ is denoted by $\chi_\tau : \hat{\tau} \rightarrow \tau$. The space of piecewise constant, discontinuous functions is

$$S_{-1,0} := \{ u \in L^\infty(\Gamma) \quad : \quad \forall \tau \in \mathcal{G} : u|_\tau \in \mathbb{P}_0 \},$$

and, alternatively, we consider the space of continuous, piecewise linear functions

$$S_{0,1} := \{ u \in C^0(\Gamma) \quad : \quad \forall \tau \in \mathcal{G} : (u \circ \chi_\tau)|_\tau \in \mathbb{P}_1 \}$$

for the space discretization. As a basis for $S_{-1,0}$, we choose the characteristic functions for the panels $\tau \in \mathcal{G}$, while the basis for $S_{0,1}$ consists of the standard hat functions, lifted to the surface Γ . The general notation is S for the boundary element space and $(b_m)_{m=1}^M$ for the basis. The mesh width is given by

$$h := \max_{\tau \in \mathcal{G}} h_\tau, \quad \text{where} \quad h_\tau := \text{diam}(\tau).$$

For the space-time discrete solution at time t_n we employ the ansatz

$$(3.12) \quad \phi_n^{h,\lambda}(y) = \sum_{m=1}^M \phi_{n,m} b_m(y),$$

where $(\phi_{n,m})_{m=1}^M \in \mathbb{R}^M$ are the nodal values of the discrete solution at time step t_n . Therefore, for the Helmholtz problems (3.11), the corresponding ansatz is

$$(3.13) \quad \hat{\phi}_l^h(y) = \sum_{m=1}^M \hat{\phi}_{l,m} b_m(y),$$

where the relationship between $\hat{\phi}_{l,m}$ and $\phi_{n,m}$ is given by $\hat{\phi}_{l,m} = \sum_{n=0}^N \lambda^n \phi_{n,m} \zeta_{N+1}^{ln}$.

To solve for the coefficients $\hat{\phi}_{l,m}$ we impose the integral equations (3.11) not pointwise but in a weak form as follows: Find $\hat{\phi}_l^h \in S$ of the form (3.13) such that

$$(3.14) \quad \sum_{m=1}^M \hat{\phi}_{l,m} \int_{\Gamma} \int_{\Gamma} K(\|x-y\|, s_l) b_m(y) b_k(x) d\Gamma_y d\Gamma_x = \int_{\Gamma} \hat{g}_l(x) b_k(x) d\Gamma_x,$$

for $l = 0, 1, \dots, N$, $k = 1, 2, \dots, M$. Note that this is equivalent to imposing (3.10) in a weak form in order to compute $\phi_n^{h,\lambda}$.

4. Algorithmic realization and sparse approximation. Applying the Galerkin boundary element method to the time-discrete equations (3.1) obtained by convolution quadrature results in a block-triangular, block Toeplitz system, where each block is a dense Galerkin boundary element matrix; see [31] and [22]. This block system can be solved by using FFT techniques (see [24]), with computational complexity of $\mathcal{O}(M^2 N \log^2 N)$ and a storage complexity of $\mathcal{O}(M^2 N)$. Alternatively (see [28]), one can approximate the block matrices \mathbf{A}_n by a cutoff strategy and panel-clustering and directly solve the system without the FFT. This reduces the storage cost significantly, while the computational complexity is $\mathcal{O}(M^2 N^{1+s})$, where the small value of s depends on the chosen discretization. By rewriting (3.1) as a system of decoupled Helmholtz problems, we are able to combine the advantages of both approaches.

We note that also the classical Galerkin discretization of the retarded boundary integral equation leads to a block Toeplitz system. Solving this system (see [3], [20]) nevertheless results in suboptimal, higher than linear, computational complexity.

4.1. Reduction of the number of Helmholtz problems to be solved. A closer look at the Helmholtz problems tells us that only half of the problems need to be solved. Since $\hat{\phi}_l$, \hat{g}_l , and s_l are discrete Fourier transforms of real data, we know that they are, for $l = 1, 2, \dots, \lfloor \frac{N}{2} + 1 \rfloor$, the complex conjugates of $\hat{\phi}_j$, \hat{g}_j , s_j , for $j = \lceil \frac{N}{2} + 2 \rceil, \dots, N + 1$; for the case of s_l see Figure 1. Most importantly, for us this means that

$$(4.1) \quad \hat{\phi}_{N+2-j} = \overline{\hat{\phi}_j}, \quad j = 1, 2, \dots, \left\lceil \frac{N}{2} + 1 \right\rceil.$$

Depending on the properties of the right-hand side g , it is possible to avoid the solution of a much larger number of Helmholtz problems without destroying the accuracy of the overall approximation. A particularly favorable case arises if g as a function of time can be extended to \mathbb{R} as a smooth function with support contained in $[0, T]$.

FIG. 2. We plot $\max_{\|x\|=1} |\hat{g}_n(x)|$ for $N = 256$, $T = 2$, $\lambda^N = 10^{-8}$, and where $g(x, t)$ is the Gaussian pulse given by (6.5). The solution to the n th Helmholtz problem, with n in the central plateau in the above plot, is accurately approximated by zero.

Let us assume that for some $x \in \Gamma$, $g(x, \cdot) \in C^\infty([0, T])$, and that

$$\partial_t^n g(x, 0) = \partial_t^n g(x, T) = 0 \quad \forall n \in \mathbb{N}_0.$$

Further, define $g_\lambda(x, t) := \lambda^{t/\Delta t} g(x, t)$. Then it is clear that $g_\lambda(x, \cdot) \in C^\infty([0, T])$ and that also all the partial derivatives with respect to time vanish at the end points of the time interval $[0, T]$. The reason for defining this function is that $\hat{g}_n(x)$ is an approximation of a Fourier coefficient of $g_\lambda(x, t)$, as we see next.

Let $g_\lambda(x, \cdot)$ be extended to the domain $[0, T + \Delta t]$ by zero (i.e., in a smooth way) and further extended to \mathbb{R} in a periodic way with period $T + \Delta t$. Let then

$$g_\lambda(x, t) = \sum_{j=-\infty}^{\infty} a_j e^{\frac{2\pi i j t}{T+\Delta t}}, \quad a_j = \frac{1}{T + \Delta t} \int_0^{T+\Delta t} g_\lambda(x, \tau) e^{\frac{-2\pi i j \tau}{T+\Delta t}} d\tau$$

be its Fourier expansion. Approximating the integral in the definition of the coefficients a_j by the trapezoidal rule, we obtain exactly the values $\frac{1}{N+1} \hat{g}_j(x)$, where, assuming N is even,

$$a_j \approx \frac{1}{N+1} \sum_{n=0}^N g_\lambda(x, t_n) e^{\frac{-2\pi i j n}{N+1}} = \frac{1}{N+1} \hat{g}_j(x) \quad \text{for } 0 \leq j \leq \frac{N}{2}.$$

See Figure 2 for an example of a right-hand side with the above properties and the decay of its Fourier coefficients. The solutions of Helmholtz problems with right-hand sides that are close to zero (i.e., all the right-hand sides on the central plateau in Figure 2) can be set to zero with no adverse affect on the accuracy of the overall method.

Remark 4.1. A right-hand side g with the above properties can be thought of as a smooth signal of finite durability. If g does not have these properties, it may still be possible to split the signal into a number of smooth and time-limited signals.

4.2. Data-sparse approximation. To find a solution to (3.9) we need to solve a number of dense linear systems, each of size $M \times M$. The cost of solving a single system by a direct method is $\mathcal{O}(M^3)$, and if a good preconditioner for an iterative method is available, this can be reduced to $\mathcal{O}(M^2)$. In both cases the storage costs are $\mathcal{O}(M^2)$. The cost of recovering the values $\phi_{j,m}$ from $\hat{\phi}_{l,m}$ is negligible since it can be done exactly (if we ignore errors due to finite precision arithmetic) and efficiently using the FFT in time $\mathcal{O}(MN \log N)$; see also Remark 5.11.

One possibility for reducing these costs is to use panel-clustering or fast multipole techniques. We explain the basic idea behind these methods.

Let A_n be the n th linear system to be solved in (3.9), i.e.,

$$(A_n)_{kj} = \int_{\Gamma} \int_{\Gamma} K(\|x - y\|, s_n) b_j(y) b_k(x) d\Gamma_y d\Gamma_x.$$

Further, we denote by \mathcal{I} the index set $\mathcal{I} := \{1, 2, \dots, M\}$, refer to subsets $\tau \subset \mathcal{I}$ as *clusters*, and define corresponding subsets of the boundary Γ by

$$\Gamma_{\tau} := \cup_{j \in \tau} \text{supp } b_j.$$

We call a pair of clusters $\tau \times \sigma$ a *block*. The corresponding block of the matrix A_n is then given by

$$(A_n|_{\tau \times \sigma})_{kj} = \begin{cases} (A_n)_{kj} & \text{if } k \in \tau \text{ and } j \in \sigma, \\ 0 & \text{otherwise.} \end{cases}$$

In the following definition, $B(c, r)$ denotes the ball centered at $c \in \mathbb{R}^3$ and radius $r > 0$.

DEFINITION 4.2. A block $b = \tau \times \sigma$ is said to be η -admissible, for some $\eta < 1$, if there exist $r_{\tau}, r_{\sigma} > 0$ and $c_{\tau}, c_{\sigma} \in \mathbb{R}^3$ such that

$$r_{\tau} + r_{\sigma} \leq \eta \|c_{\tau} - c_{\sigma}\| \quad \text{and} \quad \Gamma_{\tau} \subset B(c_{\tau}, r_{\tau}), \Gamma_{\sigma} \subset B(c_{\sigma}, r_{\sigma}).$$

For an admissible block, our goal is to find a *separable* approximation of the following fundamental solution:

$$(4.2) \quad K(\|x - y\|, s) \approx \sum_{l,k=1}^L u_k^{\tau}(x) s_{kl}^{\tau, \sigma} v_l^{\sigma}(y), \quad x \in \Gamma_{\tau}, y \in \Gamma_{\sigma}.$$

As indicated by the notation, we require that the basis functions $u_k^{\tau}(\cdot)$ (respectively, $v_l^{\sigma}(\cdot)$) depend only on the cluster τ (respectively, σ), and that the coefficients $s_{k,l}^b$ depend only on the block cluster $b = \tau \times \sigma$. Such an expansion allows us to approximate the block $A_n|_{\tau \times \sigma}$ of the matrix by a low rank matrix as follows:

$$(4.3) \quad A_n|_{\tau \times \sigma} \approx USV^{\top},$$

where

$$(4.4) \quad (U)_{kl} := \begin{cases} \int_{\Gamma_\tau} u_l^\tau(x) b_k(x) d\Gamma_x & \text{if } k \in \tau, l = 1, \dots, L, \\ 0 & \text{otherwise,} \end{cases}$$

$$(4.5) \quad (V)_{jl} := \begin{cases} \int_{\Gamma_\sigma} v_l^\sigma(y) b_j(y) d\Gamma_y & \text{if } j \in \sigma, l = 1, \dots, L, \\ 0 & \text{otherwise,} \end{cases}$$

and $(S)_{lm} := s_{lm}^{\tau, \sigma}$. Note that for $A_n|_{\tau \times \sigma}$ we need $O(|\tau||\sigma|)$ amount of storage, whereas for USV^\top we need $O(|\tau|L + |\sigma|L)$. If $L \ll \max\{|\tau|, |\sigma|\}$, it is significantly advantageous to use the low rank approximation of the block.

An extensive literature exists on the use of these methods to speed up the solution of the Helmholtz integral equations discretized by Galerkin boundary elements [2], [5], [13], [35], [36]. Most of this literature is, however, focused on the Helmholtz problem with a purely real wave number. For a purely real wave number the single layer potential representation is not always invertible; therefore certain stabilization methods need to be used. In our case the imaginary part of the wave number is strictly positive and we can use the single layer representation. The details of applying these “fast” methods to our case, together with algorithms and complexity estimates, will be given in a forthcoming paper. Here we investigate the effect of perturbations, due to the application of the fast methods, on the stability and accuracy. We assume that the kernel function $K(\cdot, s_l)$ in (3.9) is replaced by a separable approximation $K^{\text{pc}}(\cdot, s_l)$ such that

$$(4.6) \quad |K(d, s_l) - K^{\text{pc}}(d, s_l)| \leq \frac{\delta}{d} \quad \text{for some } \delta > 0.$$

The solution of the resulting perturbed system is denoted by $\hat{\phi}_{l,m}^{\text{pc}}$. To obtain a uniform approximation (4.6), the length of expansion L needs to depend both on the block cluster $b = \tau \times \sigma$ and on s_l . Typically L is chosen so that

$$(4.7) \quad L \geq C \left(\text{Re } s_l \|c_\tau - c_\sigma\| + \log \frac{1}{\delta} \right)^{d-1},$$

where C depends on the admissibility parameter η , and $d = 2, 3$ is the space dimension. Explicit and sharp estimates on the optimal choice of L are difficult to obtain, especially for complex wave numbers. In practice, one would estimate the error by a product of a Bessel function and a Hankel function; see, e.g., [1], [9]. Nevertheless, an important observation that can be made is that once L is greater than some threshold, the threshold depending on s_l , the convergence is exponential. This means that high accuracy can be obtained at little extra cost.

5. Error analysis. In the previous section we have introduced a method to reduce the numerical solution of the wave equation to a system of Helmholtz problems. We have also described two ways of reducing the cost of solving these systems by introducing further approximations. In this section we investigate the stability and convergence of both the basic method and the further approximations. This allows us to adjust the control parameters of these methods to the required accuracy in an optimal way.

Let the approximation to the unknown density $\phi(x, t_n)$ obtained by the pure Lubich’s method, i.e., with exact convolution weights, be given by $\phi_n^h \in S$. In [31] it is proved that if the data g are sufficiently smooth and compatible, then

$$(5.1) \quad \|\phi_n^h(\cdot) - \phi(\cdot, t_n)\|_{H^{-1/2}(\Gamma)} \leq C(\Delta t^2 + h^{m+3/2}),$$

where $m = 0$ for a piecewise constant basis and $m = 1$ for a piecewise linear basis. By “smooth and compatible” we mean that $g \in H_0^5([0, T]; H^{1/2}(\Gamma))$, where

$$H_0^r([0, T]; H^{1/2}(\Gamma)) := \left\{ g : \Gamma \times [0, T] \rightarrow \mathbb{R} : \text{there exists } g^* \in H^r(\mathbb{R}; H^{1/2}(\Gamma)) \right. \\ \left. \text{with } g = g^*|_{[0, T]} \text{ and } g^* \equiv 0 \text{ on } (-\infty, 0) \right\},$$

$$H^r(\mathbb{R}; H^{1/2}(\Gamma)) := \left\{ g : \Gamma \times \mathbb{R} \rightarrow \mathbb{R} : \int_{-\infty}^{\infty} (1 + |\omega|)^{2r} \|(\mathcal{F}g)(\cdot, \omega)\|_{H^{1/2}(\Gamma)}^2 d\omega < \infty \right\},$$

and \mathcal{F} denotes the integral Fourier transform with respect to the time variable $t \in \mathbb{R}$.

Our goal is to prove that the parameters in our method can be chosen so that convergence rates in (5.1) are preserved.

5.1. Errors due to the perturbation of $\omega_n^{\Delta t}$. Let $V_h(s) : S \rightarrow S$ be defined by

$$(V_h(s)\varphi, \psi)_{L^2(\Gamma)} := (V(s)\varphi, \psi)_{L^2(\Gamma)} \quad \forall \varphi, \psi \in S.$$

Whenever necessary, we will identify the inner product $(\cdot, \cdot)_{L^2(\Gamma)}$ with its extension to the dual pairing $H^{-1/2}(\Gamma) \times H^{1/2}(\Gamma)$. The solution by the convolution quadrature, i.e., with exact weights, is given by (see equation (5.5) in [31])

$$\phi^h = V_h^{-1}(\partial_t^{\Delta t})g^h,$$

whereas with the perturbed weights the solution is given by

$$\phi_n^{h, \lambda} = \left(V_h^{-1}(\partial_t^{\Delta t, \lambda})g^h \right)(t_n)$$

(see Remark 3.1), where $g^h \in S$ is the L^2 -projection of g on S as follows:

$$(g^h, \psi)_{L^2(\Gamma)} = (g, \psi)_{L^2(\Gamma)} \quad \forall \psi \in S.$$

For the remainder of the paper we will make use of the following notation:

$$(5.2) \quad \|\cdot\|_{+1} = \|\cdot\|_{H^{1/2}(\Gamma) \leftarrow H^{-1/2}(\Gamma)} \quad \text{and} \quad \|\cdot\|_{-1} = \|\cdot\|_{H^{-1/2}(\Gamma) \leftarrow H^{1/2}(\Gamma)}.$$

LEMMA 5.1. *Let $\text{Re } s \geq \sigma_0 > 0$. Then*

$$\|V_h^{-1}(s)\|_{-1} \leq \frac{C_{\text{stab}}}{\min(1, \sigma_0)} |s|^2.$$

Proof. The result follows immediately from the definition of $V_h(s)$ and the coercivity estimate for $V(s)$ as follows (see [3]):

$$\text{Re } (sV(s)\psi, \psi)_{L^2(\Gamma)} \geq C_{\text{stab}}^{-1} \frac{\min(1, \sigma_0)}{|s|} \|\psi\|_{H^{-1/2}(\Gamma)}^2. \quad \square$$

Remark 5.2. For $\omega \in \mathbb{R}$, there holds

$$\gamma(\lambda e^{i\omega}) = \frac{(\lambda + 3)(1 - \lambda) + 8(1 - \lambda)\lambda \sin^2 \frac{\omega}{2} + 8\lambda^2 \sin^4 \frac{\omega}{2}}{2} \\ - i\lambda \sin \omega \left(2(1 - \lambda) + \lambda \left(1 + 2 \sin^2 \frac{\omega}{2} \right) \right).$$

For the real part, we obtain the estimate

$$\operatorname{Re}(\gamma(\lambda e^{i\omega})/\Delta t) \geq \left(\frac{1-\lambda}{2} + 4\lambda^2 \sin^4 \frac{\omega}{2} \right) / \Delta t.$$

For $0 \leq \lambda < 1$, we have the uniform bound with respect to ω ,

$$\operatorname{Re} \frac{\gamma(\lambda e^{i\omega})}{\Delta t} \geq \operatorname{Re} \frac{\gamma(\lambda)}{\Delta t} = \frac{(3+\lambda)(1-\lambda)}{2\Delta t} \geq \frac{3(1-\lambda)}{2\Delta t}.$$

For the modulus, the (rough) upper estimate holds as follows:

$$\left| \frac{\gamma(\lambda e^{i\omega})}{\Delta t} \right| \leq \frac{C}{\Delta t} \quad \text{with} \quad C = 5^{3/2}.$$

LEMMA 5.3. *Let $W_h(s) := V_h^{-1}(s)/s^2$. Then,*

$$(5.3) \quad \|\omega_j^{\Delta t}(W_h)\|_{-1} \leq 2C_{\text{stab}}eT.$$

Further, for sufficiently smooth and compatible g , the identities

$$(5.4) \quad V_h^{-1}(\partial_t^{\Delta t})g = W_h(\partial_t^{\Delta t})((\partial_t^{\Delta t})^2g)$$

and, for $N \geq 4$,

$$(5.5) \quad V_h^{-1}(\partial_t^{\Delta t, \lambda})g = W_h(\partial_t^{\Delta t, \lambda})((\partial_t^{\Delta t})^2g),$$

hold, where $(\partial_t^{\Delta t})^2g$ denotes the twofold application of the multistep approximation, which in our case is the BDF2 scheme.

Proof. The bound for $\|\omega_j^{\Delta t}(W_h)\|_{-1}$ follows from the Cauchy estimate by choosing the circle with radius $e^{-\Delta t/T}$ as the integration contour in (3.5), Remark 5.2, and Lemma 5.1 as follows:

$$\begin{aligned} \|\omega_j^{\Delta t}(W_h)\|_{-1} &\leq e^{j\Delta t/T} \max_{\|z\|=1} \left\| W_h \left(\gamma(e^{-\Delta t/T}z)/\Delta t \right) \right\|_{-1} \\ &\leq \frac{C_{\text{stab}}}{\min(1, (1 - e^{-\Delta t/T})/(2\Delta t))} e^{j\Delta t/T} \leq 2C_{\text{stab}}Te^{j/N}. \end{aligned}$$

Applying the (scaled) inverse discrete Fourier transform to the identity $V_h^{-1}(s_l)\hat{g}_l = W_h(s_l)s_l^2\hat{g}_l$, we see that $V_h^{-1}(\partial_t^{\Delta t, \lambda})g^h = W_h(\partial_t^{\Delta t, \lambda})\widetilde{g}^h$, where

$$\widetilde{g}_n^h = \frac{\lambda^{-n}}{N+1} \sum_{l=0}^{N+1} \hat{g}_l^h s_l^2 \zeta_{N+1}^{ln}, \quad s_l = \frac{\gamma(\lambda \zeta_{N+1}^{-l})}{\Delta t}.$$

The inverse discrete Fourier transform of s_l^2 is

$$(5.6) \quad \frac{1}{N+1} \sum_{l=0}^{N+1} \left(\frac{\gamma(\lambda \zeta_{N+1}^{-l})}{\Delta t} \right)^2 \zeta_{N+1}^{lj} \approx \frac{\lambda^j}{2\pi i} \oint_C \frac{(\gamma(\lambda \zeta)/\Delta t)^2}{\zeta^{j+1}} d\zeta = \frac{\lambda^j}{\Delta t^2} \delta_j,$$

where

$$(\gamma(\zeta))^2 = \sum_{k=-\infty}^{\infty} \delta_k \zeta^k = \left(\frac{3}{2} - 2\zeta + \frac{1}{2}\zeta^2 \right)^2.$$

Since $(\gamma(\zeta))^2$ is a polynomial of order 4 and $N \geq 4$, the coefficients $\frac{\lambda^j}{\Delta t^2} \delta_j$ are reproduced exactly, without any quadrature error in (5.6). Therefore

$$\widetilde{g^h}_n = \frac{1}{\Delta t^2} \sum_{j=0}^n \delta_{n-j} g_j^h,$$

which is exactly the result of applying the BDF2 multistep method twice, where it is implicitly assumed that $g(t) = 0$ for $t \leq 0$. The result for $V_h^{-1}(\partial_t^{\Delta t})g^h$ is proved similarly, but with no restriction on N ; see also [31]. \square

PROPOSITION 5.4. *Let $0 < \lambda < 1$. Then*

$$\|V_h^{-1}(\partial_t^{\Delta t})g^h - V_h^{-1}(\partial_t^{\Delta t, \lambda})g^h\|_{H^{-1/2}(\Gamma)} \leq 2C_{\text{stab}}eT^2 \frac{\lambda^{N+1}}{1 - \lambda^{N+1}} \Delta t^{-1}.$$

Proof. Let $a_j := \lambda^j \omega_j^{\Delta t}(W_h)$, and let $\hat{a}_j := \lambda^j \omega_j^{\Delta t, \lambda}(W_h)$, $W_h(s) = V_h^{-1}(s)/s^2$. Then \hat{a}_j is the discrete Fourier transform approximation to a_j for $j = -N, \dots, N$ and (see [25])

$$\begin{aligned} \|a_j - \hat{a}_j\|_{-1} &= \left\| \sum_{l=1}^{\infty} a_{j+l(N+1)} + a_{j-l(N+1)} \right\|_{-1} \leq \sum_{l=1}^{\infty} \|a_{j+l(N+1)}\|_{-1} \\ &\leq \lambda^j \sum_{l=1}^{\infty} \lambda^{l(N+1)} \|\omega_{j+l(N+1)}^{\Delta t}\|_{-1} \leq 2C_{\text{stab}}eT\lambda^j \frac{\lambda^{N+1}}{1 - \lambda^{N+1}}, \end{aligned}$$

where we have used the bound (5.3). Therefore

$$\|\omega_j^{\Delta t}(W_h) - \omega_j^{\Delta t, \lambda}(W_h)\|_{-1} \leq 2C_{\text{stab}}T \frac{\lambda^{N+1}}{1 - \lambda^{N+1}},$$

and the result follows from the definition of the discrete convolution and identities (5.4) and (5.5). \square

THEOREM 5.5. *Let the exact solution $\phi(\cdot, t)$ be in $H^{m+1}(\Gamma)$ for any $t \in [0, T]$, data $g \in H_0^5([0, T]; H^{1/2}(\Gamma))$, $0 < \lambda < 1$, and let the boundary element space be $S = S_{m-1, m}$ for $m \in \{0, 1\}$. Then the discrete solution*

$$\phi_n^{h, \lambda} = \left(V_h^{-1}(\partial_t^{\Delta t, \lambda})g^h \right)(t_n)$$

satisfies the error estimate

$$\|\phi_n^{h, \lambda} - \phi(\cdot, t_n)\|_{H^{-1/2}(\Gamma)} \leq C_g \left(\frac{\lambda^{N+1}}{1 - \lambda^{N+1}} T^2 \Delta t^{-1} + \Delta t^2 + h^{m+3/2} \right),$$

where C_g depends on the right-hand side g , C_{stab} , and the time interval length T .

Proof. The result is a direct consequence of Proposition 5.4 and (5.1); see [31, Theorem 5.4]. \square

5.2. Error due to the perturbation of $V_h(s)$. We investigate the effect of perturbing $V_h(s)$, in particular the effect of approximate evaluation of the kernel $K(d, s)$ by separable expansions. If these perturbations could be chosen to be analytic in s , then a stability and error estimate from Lemma 5.5 in [31] could be used, in which there is no loss of powers of Δt . Unfortunately due to numerical stability issues

(see [5], [9], [34]), this is not the case for the problem at hand, i.e., different expansions need to be used for different values of s . Hence we will simply assume that

$$(5.7) \quad \|V_h^\varepsilon(s_l) - V_h(s_l)\|_{+1} \leq \varepsilon, \quad l = -N, -N+1, \dots, N-1, N,$$

and investigate how this perturbation affects the final solution.

LEMMA 5.6. *Let $\operatorname{Re} s > \sigma_0 > 0$ and $\varepsilon < \frac{1}{2}C_{\text{stab}}^{-1} \frac{\min(1, \sigma_0)}{|s|^2}$. Then $(V_h^\varepsilon(s))^{-1}$ is bounded and*

$$\|(V_h^\varepsilon(s))^{-1}\|_{-1} \leq 2C_{\text{stab}} \frac{|s|^2}{\min(1, \sigma_0)}.$$

Proof. Let us write

$$V_h^\varepsilon(s) = V_h(s) [I - V_h^{-1}(s)(V_h(s) - V_h^\varepsilon(s))].$$

From the estimate $\|V_h^{-1}(s)\|_{-1} \leq C_{\text{stab}}|s|^2/\min(1, \sigma_0)$ (see Lemma 5.1), we see that $\varepsilon < \frac{1}{2}C_{\text{stab}}^{-1} \min(1, \sigma_0)/|s|^2$ is sufficient for $(V_h^\varepsilon(s))^{-1}$ to exist and to be bounded as above. \square

LEMMA 5.7. *Let $\min_{l=0,1,\dots,N} \operatorname{Re} s_l > \sigma_0 > 0$ and $\varepsilon < \frac{1}{2}C_{\text{stab}} \frac{\min(1, \sigma_0)}{\max_{l=0,1,\dots,N} |s_l|^2}$. Then*

$$\|\omega_j^{\Delta t, \lambda}(Q_h) - \omega_j^{\Delta t, \lambda}(Q_h^\varepsilon)\|_{-1} \leq CT\lambda^{-j}\varepsilon\Delta t^{-1},$$

where

$$C = \left(\frac{C_{\text{stab}}}{\min(1, \sigma_0)} \right)^2, \quad Q_h(s) := \frac{V_h^{-1}(s)}{s^4}, \quad \text{and} \quad Q_h^\varepsilon(s) := \frac{(V_h^\varepsilon(s))^{-1}}{s^4}.$$

Proof. Using the fact that $Q_h^{-1}(s) = s^4 V_h(s)$, we obtain the bound

$$\|Q_h(s_l) - Q_h^\varepsilon(s_l)\|_{-1} = \|Q_h(s_l)(s_l^4 V_h^\varepsilon(s_l) - s_l^4 V_h(s_l))Q_h^\varepsilon(s_l)\|_{-1} \leq \left(\frac{C_{\text{stab}}}{\min(1, \sigma_0)} \right)^2 \varepsilon.$$

From this and the definition of the perturbed convolution weights, the result follows. \square

Let us define the solution of the ε -perturbed convolution equation by

$$\phi^{\lambda, h, \varepsilon} := (V_h^\varepsilon)^{-1}(\partial_t^{\Delta t, \lambda})g = Q_h^\varepsilon(\partial_t^{\Delta t, \lambda})((\partial_t^{\Delta t})^4 g)$$

and, as before,

$$\phi^{\lambda, h} := V_h^{-1}(\partial_t^{\Delta t, \lambda})g = Q_h(\partial_t^{\Delta t, \lambda})((\partial_t^{\Delta t})^4 g).$$

In the next result we estimate the difference between the two.

PROPOSITION 5.8. *Let $\min_{l=0,1,\dots,N} \operatorname{Re} s_l > \sigma_0 > 0$, let*

$$\varepsilon < \frac{1}{2}C_{\text{stab}} \frac{\min(1, \sigma_0)}{\max_{l=0,1,\dots,N} |s_l|^2},$$

and let the data g be sufficiently smooth and compatible. Then

$$\|\phi_n^{\lambda, h, \varepsilon} - \phi_n^{t, \lambda, h}\|_{H^{-1/2}(\Gamma)} \leq C\varepsilon T^2 \lambda^{-N} \Delta t^{-2},$$

with $C > 0$ as in Lemma 5.7.

Proof. The result is a direct consequence of the above lemma. \square

The above result, together with Remark 5.2, implies that to obtain optimal convergence it is sufficient to insure that $\varepsilon \leq C\lambda^N \Delta t^4$.

Let us now investigate the effect of perturbations on the kernel function $K(d, s)$. In order to do this, we assume

$$(5.8) \quad |K(\|x - y\|, s_l) - K^{pc}(\|x - y\|, s_l)| \leq \delta \frac{1}{\|x - y\|} \quad \forall x, y \in \Gamma$$

for $l = 0, 1, \dots, N$, and define the operator $V_h^{pc}(s) : S \rightarrow S$ by

$$(V_h^{pc}(s)\psi, \varphi)_{L^2(\Gamma)} = \int_{\Gamma} \int_{\Gamma} K^{pc}(\|x - y\|, s)\psi(y)\overline{\varphi(x)}d\Gamma_y d\Gamma_x.$$

PROPOSITION 5.9. *Let (5.8) hold. Then, there exists $C_0 > 0$ such that*

$$\|V_h^{pc}(s_l) - V_h(s_l)\|_{+1} \leq C_0 h^{-1} \delta.$$

Hence if $\delta \leq \frac{1}{2} C_0 C_{\text{stab}} h \frac{\min(1, \sigma_0)}{\max_l |s_l|^2} \leq Ch\Delta t^2$, the estimate

$$\|{}^{pc}\phi_n^{\lambda, h} - \phi_n^{\lambda, h}\|_{H^{-1/2}(\Gamma)} \leq C\delta T h^{-1} \lambda^{-N} \Delta t^{-2}$$

holds, where

$${}^{pc}\phi^{\lambda, h} = (V_h^{pc})^{-1} (\partial_t^{\Delta t, \lambda} g).$$

Proof. Let $\varphi \in S$. The well-known L^2 -continuity of the single layer potential for the Laplacian and a scaling inequality for boundary element functions lead to

$$\begin{aligned} & \| (V_h^{pc}(s_l) - V_h(s_l)) \varphi \|_{H^{1/2}(\Gamma)} \\ & \leq \delta \sup_{\substack{\psi \in S(\Gamma) \\ \|\psi\|_{H^{-1/2}(\Gamma)}=1}} \int_{\Gamma \times \Gamma} |\varphi(y)| |\psi(x)| \frac{1}{\|x - y\|} ds_x ds_y \\ & \leq C\delta \sup_{\substack{\psi \in S(\Gamma) \\ \|\psi\|_{H^{-1/2}(\Gamma)}=1}} \|\varphi\|_{L^2(\Gamma)} \|\psi\|_{L^2(\Gamma)} \leq Ch^{-1} \delta \|\varphi\|_{H^{-1/2}(\Gamma)}. \end{aligned}$$

The estimate of the error in the solution is then a direct consequence of Proposition 5.8 and Remark 5.2. \square

In the following result, the binary relation $A \lesssim B$ is used to denote the existence of a constant C independent of any discretization parameters such that $A \leq CB$. Further, $A \sim B$ implies $A \lesssim B$ and $B \lesssim A$.

COROLLARY 5.10. *Let the conditions of Theorem 5.5 be satisfied, let (5.8) hold, and let*

$$h^{m+3/2} \lesssim \Delta t^2, \quad \lambda^{N+1} \sim \Delta t^3, \quad \delta \lesssim \lambda^N h \Delta t^4 \lesssim h^{7m/2+25/4}.$$

Then the optimal rate of convergence is achieved,

$$\|{}^{pc}\phi_n^{\lambda, h} - \phi(\cdot, t_n)\|_{H^{-1/2}(\Gamma)} \leq C\Delta t^2,$$

where C depends on the data g .

Remark 5.11. According to the above result, λ should be chosen as $\lambda \sim \Delta t^{3/(N+1)} = e^{\frac{3}{N+1} \log \frac{T}{N}}$. Since the rounding errors, in the same manner as the errors due to panel-clustering, are magnified by λ^{-j} , λ should be chosen in the interval $\sqrt{\text{eps}} < \lambda^N < 1$, where eps is the machine accuracy. In IEEE double precision this is approximately 10^{-16} ; therefore the accuracy of the method is limited by the choice $\lambda > 10^{-8/N}$. This accuracy limit can, however, be improved if an n -trapezoidal rule is used to compute the weights $\omega_j^{\Delta t, \lambda}$ with $n = jN$, $j > 1$.

Remark 5.12. The condition on the accuracy of the panel-clustering approximation is rather stringent. However, since the convergence of the separable expansion is exponential for a large enough length of expansion L (see (4.7)), the computational costs of the panel-clustering method depend only logarithmically on the required accuracy. Therefore the overall computational cost is not significantly affected.

If we had assumed that $V_h^{\text{pc}}(s) - V_h(s)$ is analytic in s and could be bounded by $C|s|^2$, we could be obtained significantly better error estimates by using Lemma 5.5 in [31]. Unfortunately, due to the well-known numerical stability issues with the multipole expansions for the Helmholtz kernel [5], [9], [34], different types of expansions need to be used for different admissible blocks; the choice of the expansion depends on the wave number s_l and the size of the block. This restricts us from using the more favorable results of Lemma 5.5 in [31].

5.3. Error due to the reduction of the number of linear systems.

COROLLARY 5.13. *Let $0 \leq \lambda < 1$ and $\sigma_l = \text{Re } s_l$. Then*

$$\|\hat{\phi}_l^h\|_{H^{-1/2}(\Gamma)} \leq C_1(\Delta t)^{-2} \|\hat{g}_l\|_{H^{1/2}(\Gamma)},$$

where $C_1 = 5^3 \frac{C_{\text{stab}}}{\min(1, \sigma_l)}$.

Proof. The result is a direct consequence of Lemma 5.1 and Remark 5.2. □

Let $\mathbf{N}_z \subset \{0, 1, \dots, N\}$ determine the Helmholtz problems, the solution of which will be computed; the rest will be approximated by zero. Then we define the resulting approximation to $\phi^{h, \lambda}$ by

$$\emptyset \phi_n^{h, \lambda}(x) := \frac{\lambda^{-n}}{N+1} \sum_{l \in \mathbf{N}_z} \hat{\phi}_l^h(x) \zeta_{N+1}^{ln}.$$

COROLLARY 5.14. *Let $n \in \{0, 1, \dots, N\}$. If*

$$\max_{l \notin \mathbf{N}_z} \|\hat{g}_l\|_{H^{1/2}(\Gamma)} \leq C_1^{-1} \lambda^n (\Delta t)^4,$$

then we obtain optimal order convergence at time step t_n :

$$\|\emptyset \phi_n^{h, \lambda} - \phi_n^{h, \lambda}\|_{H^{-1/2}(\Gamma)} \leq \Delta t^2.$$

Proof. The proof follows directly from Corollary 5.13. □

Next we show that if the right-hand side is smooth and of finite duration, it is sufficient to solve only a few Helmholtz systems. Let us introduce the space of functions that are zero at both $t = 0$ and $t = T$ as follows:

$$H_{00}^r([0, T]; H^{1/2}(\Gamma)) := \left\{ g : \Gamma \times [0, T] \rightarrow \mathbb{R} : \text{there exists } g^* \in H^r(\mathbb{R}; H^{1/2}(\Gamma)) \right. \\ \left. \text{with } g = g^*|_{[0, T]} \text{ and } \text{supp } g^* \subset [0, T] \right\}.$$

THEOREM 5.15. *Let $g \in H_{00}^r([0, T]; H^{1/2}(\Gamma))$ for some $r \geq 3.5$, and let $\epsilon > 0$ be given. For any $N \in \mathbb{N}$ let $\lambda := \epsilon^{\frac{1}{N}}$. Then, \mathbf{N}_z can be chosen so that $\#\mathbf{N}_z \leq C\epsilon^{-\frac{1}{r+1/2}} N^{\frac{4}{r+1/2}}$ and the optimal order convergence is retained. The constant C depends on $r, (\log \epsilon)/T$, and g .*

Proof. Let $g_\lambda(x, t) := \lambda^{t/\Delta t} g(x, t) = \epsilon^{\frac{t}{T}} g(x, t) = e^{t \frac{\log \epsilon}{T}} g(x, t)$ on $t \in [0, T]$. Then we see that g_λ is independent of N and that $g_\lambda \in H_{00}^r([0, T]; H^{1/2}(\Gamma))$. Then for $\omega \in \mathbb{R}$, $\|(\mathcal{F}g_\lambda)(\cdot, \omega)\|_{H^{1/2}(\Gamma)} = o(|\omega|^{-r-1/2})$. Taking $\omega_j = 2\pi j/(T + \Delta t) = 2\pi jN/(T(N + 1))$, we define

$$a_j := \|(\mathcal{F}g_\lambda)(\cdot, \omega_j)\|_{H^{1/2}(\Gamma)} = o(j^{-r-1/2}), \quad j \in \mathbb{Z}.$$

Then using the aliasing formula (see [25]), we arrive at the following estimate for \hat{g}_n , $n = 1, \dots, N/2 - 1$:

$$\|\hat{g}_n\|_{H^{1/2}(\Gamma)} \leq a_n + \sum_{k>N/2} a_k = o(n^{-r-1/2} + N^{-r+1/2}) = o(n^{-r-1/2}).$$

The constants in the $o(\cdot)$ notation depend only on $r, (\log \epsilon)/T, \epsilon$, and g . The result now follows from Corollary 5.14. \square

6. Numerical experiments. In this section we present the results of numerical experiments. Except for one simple example, the experiments will be done in two dimensions. All the steps in the method remain the same in two dimensions, except that the fundamental solution for the wave equation is given by

$$(6.1) \quad k_{2D}(d, t) = \frac{H(t - d)}{2\pi\sqrt{t^2 - d^2}},$$

where H is the Heaviside function,

$$H(t) = \begin{cases} 0 & \text{for } t < 0, \\ 1 & \text{for } t > 0. \end{cases}$$

The Laplace transform $K_{2D}(d, s)$ is again the fundamental solution of the Helmholtz equation $\Delta U - s^2 U$ as follows:

$$(6.2) \quad K_{2D}(d, s) = \frac{i}{4} H_0^{(1)}(isd),$$

where $H_0^{(1)}(\cdot)$ is the zero order Hankel function of the first kind.

Let us consider the case of Γ being the unit ball in \mathbb{R}^2 or \mathbb{R}^3 and a right-hand side that is separable in the time and the spatial variables: $g(x, t) = g(t)e(x)$, where $e(x)$ is an eigenfunction of the single layer potential $V(s)$ with the eigenvalue $\lambda_l(s)$. In two dimensions the eigenfunctions are the complex exponentials $e^{il\theta}$ and $\lambda_l(s) = \frac{i\pi}{2} J_l(is)H_l(is)$, whereas in three dimensions these are the spherical harmonics $Y_l^m(\theta, \varphi)$ with $\lambda_l(s) = -sj_l(is)h_l(is)$; we have used the standard polar/spherical coordinates to describe the eigenfunctions. Here $J_l(\cdot)$ (respectively, $j_l(\cdot)$) are cylindrical (respectively, spherical) Bessel functions of order l , whereas $H_l^{(1)}(\cdot)$ (respectively, $h_l^{(1)}(\cdot)$) are the cylindrical (respectively, spherical) Hankel functions of the first kind and order l . The problem of finding the unknown density $\phi(x, t)$ can then be reduced to the single, time, dimension. This can be seen by replacing the fundamental solution k in the

single layer representation formula by the inverse Laplace transform of its Laplace transform K as follows:

$$\begin{aligned} g(t)e(x) &= \int_0^t \int_{\Gamma} k(t-\tau, \|x-y\|)\phi(\tau, x)d\Gamma_y d\tau \\ &= \frac{1}{2\pi i} \int_{\sigma-i\infty}^{\sigma+i\infty} \int_0^t e^{s\tau} \int_{\Gamma} K(s, \|x-y\|)\phi(t-\tau, y)d\Gamma_y d\tau ds \\ &= \frac{1}{2\pi i} \int_{\sigma-i\infty}^{\sigma+i\infty} \int_0^t e^{s\tau} (V(s)\phi(t-\tau, \cdot))(x) d\tau ds, \quad x \in \Gamma, \text{ for some } \sigma > 0. \end{aligned}$$

Therefore, we can use the ansatz $\phi(x, t) = \phi(t)e(x)$ to reduce the problem to finding $\phi(t)$ such that

$$g(t) = \frac{1}{2\pi i} \int_{\sigma-i\infty}^{\sigma+i\infty} \int_0^t e^{s\tau} \lambda_l(is)\phi(t-\tau) d\tau ds.$$

Hence we need to solve a convolution integral equation in one dimension as follows:

$$(6.3) \quad g(t) = \int_0^t \check{\lambda}_l(\tau)\phi(t-\tau) d\tau,$$

where $\check{\lambda}_l(\cdot)$ is the inverse Laplace transform of $\lambda_l(\cdot)$. The latter equation can then be solved by Lubich’s original method, which makes use of only $\lambda_l(\cdot)$ and not its inverse Laplace transform. The first few numerical examples will be of this type.

6.1. Radial solution of scattering by unit sphere. In this example we consider the three-dimensional case, $\Gamma = \mathbb{S}^2$. Let $g(x, t) = g(t)$ be constant for a fixed time t , i.e., $e(x) = 2\sqrt{\pi}Y_0^0 = 1$. In this particularly simple case it can be shown that

$$\phi(t) = 2g'(t), \quad t \in [0, 2].$$

The restriction to the interval $[0, 2]$ is a consequence of the fact that the diameter of the sphere is 2. For time $t > 2$ the expression for $\phi(t)$ is more complicated.

The right-hand side of the n th Helmholtz problem is a constant,

$$\hat{g}_n = \sum_{j=0}^N \lambda^j g(t_j) \zeta_{N+1}^{-nj},$$

and the solution of the Helmholtz problem is also a constant and is given by

$$\hat{\phi}_n = \frac{\hat{g}_n}{\lambda_0(s_n)}.$$

The approximation to the unknown density at time step t_n is given by

$$\phi_n := \frac{\lambda^{-n}}{N+1} \sum_{j=0}^N \hat{\phi}_j \zeta_{N+1}^{nj}.$$

If λ is chosen small enough, theoretical estimates predict the following behavior of the error:

$$\left(\sum_{n=0}^N \Delta t |\phi(t_n) - \phi_n|^2 \right)^{1/2} \leq C \Delta t^2.$$

TABLE 1

The results for scattering by unit sphere with $g(x, t) = \sin^5(t)$ and $\lambda = \Delta t^{3/N}$.

N	Error	Rate
4	1.44	-/-
8	0.45	1.68
16	0.12	1.90
32	0.032	1.94
64	0.0081	1.96
128	0.0020	1.99
256	0.00051	1.99
512	0.00013	2.00
1024	3.2×10^{-5}	2.00

One more detail needs to be fixed before the experiments can be started, namely, the choice of λ . Recall that λ needs to be chosen small enough to insure stability and accuracy (see Theorem 5.5) but also large enough to avoid numerical instability issues (see Remark 5.11). As suggested in Remark 5.11, we make the choice

$$(6.4) \quad \lambda = \max(\Delta t^{3/N}, \text{eps}^{\frac{1}{2N}}).$$

Numerical results for the scattering by unit sphere are given in Table 1 and show that our theoretical estimates are sharp for this example.

6.2. A nonradial example. In this example we consider the two-dimensional case. We pick the right-hand side to be $g(x, t) = h(t) \cos(l\theta)$, where for the space variable we use the polar coordinate system $r \in \mathbb{R}_{\geq 0}$, $\theta \in [0, 2\pi)$. Since $\cos(l\theta)$ is an eigenfunction of the single layer potential $V(s_n)$, the Helmholtz problems can be solved exactly. However, to investigate the effect of spatial discretization we solve the problems using the Galerkin method, and hence obtain an approximation $\phi^{h,\lambda}(t_n, \theta)$ of the unknown density. To investigate the error, we use the fact that $\phi(\theta, t) = \phi(t) \cos(l\theta)$ and solve with high accuracy for $\phi(t)$ by applying Lubich’s method to the one-dimensional problem (6.3). The error measure we use is the following:

$$\|\phi - \phi^{h,\lambda}\|_{-1/2,l^2} := \left(\sum_{n=0}^N \Delta t \|\phi(t_n) \cos(l\cdot) - \phi^{h,\lambda}(t_n, \cdot)\|_{H^{-1/2}(\Gamma)}^2 \right)^{1/2}.$$

The theory predicts the above error to be proportional to $h^{m+3/2} + \Delta t^2$, where $m = 0$ for the Galerkin basis of piecewise constant functions and $m = 1$ for the basis of piecewise linear functions. In all the experiments, we choose λ as in (6.4). To see if the spatial discretization has introduced significant errors, we compute the error obtained when the Helmholtz problems are solved exactly. The results are given in the following table:

N	4	8	16	32	64	128
$\ \phi - \phi^{h,\lambda}\ _{-1/2,l^2}$	0.61	0.24	0.077	0.022	0.0057	0.0015

Comparing these results to Tables 2 and 3, we see that the error due to the discretization in space is not significant.

6.3. Reduction of the number of systems. Let us now consider a signal that is smooth and of nearly limited time duration as follows:

$$(6.5) \quad g(\mathbf{r}, t) = \cos(5t - \mathbf{r} \cdot \alpha) \exp(-1.5(5t - \mathbf{r} \cdot \alpha - 5)^2), \quad \alpha = (1, 0).$$

TABLE 2

The results for scattering by the unit disk with $g(x, t) = \sin^5(t) \cos(3x)$ and the piecewise constant Galerkin basis $S = S_{-1,0}$. M is chosen so that $h^{3/2} \propto \Delta t^2$.

N	M	$\ \phi - \phi^{h,\lambda}\ _{-1/2,l^2}$	Rate
4	16	0.78	-/-
8	40	0.27	1.54
16	102	0.084	1.68
32	254	0.023	1.83
64	640	0.0062	1.93
128	1610	0.0016	1.98

TABLE 3

The results for scattering by the unit disk with $g(x, t) = \sin^5(t) \cos(3x)$ and the piecewise linear Galerkin basis $S = S_{0,1}$. M is chosen so that $h^{5/2} \propto \Delta t^2$.

N	M	$\ \phi - \phi^{h,\lambda}\ _{-1/2,l^2}$	Rate
4	22	0.66	-/-
8	40	0.26	1.34
16	68	0.082	1.67
32	116	0.023	1.84
64	204	0.0060	1.93
128	352	0.0015	1.99

TABLE 4

The results for scattering by the unit disk where the incoming wave is a Gaussian pulse and the piecewise linear Galerkin basis $S = S_{1,0}$ is used. The column $\#\mathbf{N}_z$ shows the number of Helmholtz problems actually solved.

N	$\#\mathbf{N}_z$	M	$\ \phi - \phi^{h,\lambda}\ _{-1/2,l^2}$	Rate
4	3	24	2.9	-/-
8	5	40	2.9	-0.03
16	9	68	1.4	1.09
32	17	116	0.42	1.70
64	24	204	0.11	1.92
128	24	352	0.028	1.98
256	24	612	0.0072	1.99

For such a Gaussian pulse our theory predicts that only $\mathcal{O}(N^\epsilon)$, for any fixed $\epsilon > 0$, Helmholtz systems need to be solved to obtain optimal convergence; see also Figure 2. The results for scattering by the unit disk and for piecewise-linear basis functions $S = S_{1,0}$ are given in Table 4. Since we approximate by zero only the solutions of those Helmholtz problems whose right-hand sides are zero almost to machine precision, the number of Helmholtz problems $\#\mathbf{N}_z$ is constant for large enough N . For this more complicated problem, for each N we have used as the reference solution the numerical solution using $2N$ steps in time and the corresponding number of nodes in the discretization in space.

7. Conclusion. We have described a method that requires the solution of a number of Helmholtz problems to obtain an approximate solution of the wave equation in an unbounded, homogeneous medium. We have proved stability and optimal convergence results for this approach. Further, we have indicated ways in which to efficiently solve the resulting system of Helmholtz problems. The stability and convergence results of the perturbations introduced by the efficient solvers have also been presented.

The fast methods we propose using are typically capable of computing a matrix-

vector product in almost linear time, i.e., $\mathcal{O}(M \log^a M)$, of a single dense $M \times M$ system arising from the discretization of the Helmholtz single layer potential. In order to solve efficiently the linear system by an iterative method requiring only matrix-vector multiplication, a good preconditioner is needed. The investigation of such a preconditioner is beyond the scope of this paper. With a preconditioned iterative solver we expect to obtain computational costs which scale linearly, up to logarithmic terms, with respect to the number of unknowns NM . An important observation is that in some cases only a few Helmholtz systems need to be solved. Although this does not change the overall complexity (the discrete Fourier transformation still requires $\mathcal{O}(MN \log N)$ operations), it can hugely reduce the absolute time for the computation. The storage costs will also scale linearly since at any one time only a single linear system representing the discretization of a Helmholtz problem needs to be stored. Since all the NM coefficients $\phi_{j,n}$ are stored, the storage costs are not better than linear. Crucially, since the Helmholtz problems to be solved are entirely decoupled, the proposed method is easily parallelizable.

These asymptotic estimates significantly improve both the storage and computational costs compared to the previously proposed approaches for the solution of the wave equation using the convolution quadrature discretization in time; see [24] and [22], [23], [28]. The asymptotic costs of the MOT method presented in [10], [18] are also almost linear in the number of degrees of freedom. Advantages of our method include the intrinsic parallel nature of the method, proven convergence and stability properties, and the relatively simple implementation details. In a forthcoming paper, algorithmic details for the data sparse approximations, a more in-depth asymptotic complexity analysis, and large-scale computational results will be presented.

Acknowledgments. We gratefully acknowledge the fruitful discussions with Ch. Lubich which led to significant improvements in the perturbation analysis.

A SEMI-IMPLICIT SCHEME FOR STATIONARY STATISTICAL PROPERTIES OF THE INFINITE PRANDTL NUMBER MODEL*

WENFANG (WENDY) CHENG[†] AND XIAOMING WANG[‡]

Abstract. We propose a semidiscrete in time semi-implicit numerical scheme for the infinite Prandtl model for convection. Besides the usual finite time convergence, this scheme enjoys the additional highly desirable feature that the stationary statistical properties of the scheme converge to those of the infinite Prandtl number model at vanishing time step. One of the key characteristics of the scheme is that it preserves the dissipativity of the infinite Prandtl number model uniformly in terms of the time step. So far as we know, this is the first rigorous result on convergence of stationary statistical properties of numerical schemes for infinite dimensional dissipative complex systems.

Key words. stationary statistical property, infinite Prandtl number model, uniformly dissipative scheme, Nusselt number

1. Introduction. Many dynamical systems arising in applications are dissipative complex systems in the sense that they possess a compact global attractor and the dynamics on the global attractor are complex/chaotic [39]. Well-known examples include the simple Lorenz 63 model, Lorenz 96 model, the Navier–Stokes equations at large Reynolds number or Grashoff number, the Boussinesq system for convection at large Rayleigh number, the Kuramoto–Sivashinsky equation at large spatial size, and many models for the atmosphere, ocean, weather, and climate, etc. The dynamics of these systems are typically very complex/chaotic with generic sensitive dependence on data. Therefore, it is hardly meaningful to discuss long time behavior of a single trajectory for this kind of complex system. Instead, we should study statistical properties of the system since they are physically much more relevant than single trajectories [33, 15, 31, 29]. If the system reaches some kind of stationary state, then the objects that characterize the stationary statistical properties are the invariant measures or stationary statistical solutions of the system.

With a given complex system, analytical exact expressions for statistical properties are extremely rare, just as exact solution formulas are rare for single trajectory. Therefore we naturally turn to numerical methods, especially with today’s powerful computers and ever advancing computational technologies. The natural question then is what kind of numerical schemes would provide good approximations for the stationary statistical properties.

In terms of trajectory approximations, we are not aware of any effective long time integrator for dissipative complex/chaotic systems in general unless the long time dynamics is trivial or the trajectory under approximation is stable [21, 17, 28]. It is not

at all clear whether those numerical methods that provide efficient and accurate approximations of the continuous complex dynamical system on a finite time interval are able to provide meaningful approximation for stationary statistical properties of the system since small errors (truncation and rounding) may accumulate and grow over a long time (think about the usual error estimates with a coefficient that grows exponentially in time due to the existence of chaotic behavior/positive Lyapunov exponent). Here we forego the idea of long time fidel approximation of any single trajectory, but ask if it is possible to approximate the mean or statistical properties faithfully. The numerical study of stationary statistical properties of complex system still is a very challenging task since it involves long time integration (so that the statistical averaging is computed utilizing time averaging under the assumption of ergodicity) and computation of a large number of trajectories (if no ergodicity is assumed).

We will demonstrate in this paper that a semidiscrete in time and semi-implicit scheme for the infinite Prandtl number model for convection is able to capture stationary statistical properties of the underlying infinite Prandtl number model. It seems that one of the key ingredients in the convergence of the stationary statistical properties is the *uniformly dissipativity* of the scheme; i.e., the scheme is dissipative uniformly with respect to the time step. Although this scheme may not approximate individual trajectory faithfully for a long time due to the accumulation of truncation and rounding errors and abundant instability/chaos, we will show that *stationary statistical properties characterized by the invariant measures (stationary statistical solutions) of the scheme converge to those of the continuous-in-time system*. This gives us strong evidence that these kinds of uniformly dissipative schemes are appropriate schemes in investigating statistics.

Although the idea of uniform dissipativity and convergence of stationary statistical properties is illustrated on the infinite Prandtl number model for convection and semidiscretization in time only, we believe that the methodology works for many more complex/chaotic dynamical systems [39] and fully discretized approximations. The key ingredients are uniform (in mesh size) dissipativity and finite time uniform convergence (see [48] for a somewhat general statement). The choice of the infinite Prandtl number model is both for its physical significance (see the next section) and for the sake of simplicity in exposition.

The idea of uniformly dissipative approximation for a dissipative dynamical system is a very natural one. Since the continuous-in-time dynamical system is dissipative (possess a global attractor), it is natural to consider numerical schemes that preserve the dissipativity in the sense that the solutions to the schemes should possess global attractors that are uniformly compact in some appropriate sense (say the union of the global attractors is precompact). These uniformly dissipative schemes are usually implicit in some way (to ensure long time stability) and therefore have not been very popular in practice so far. What we shall demonstrate below is that some of these uniformly dissipative schemes enjoy a highly desirable property in terms of approximating stationary statistical properties: the stationary statistical properties of the schemes converge to those of the continuous-in-time dynamical systems. We hope that our work will stimulate further study, both analytical and numerical, on approximating statistical properties of dissipative systems.

Earlier works on long time behavior of numerical schemes for dissipative systems mainly focused on the two-dimensional incompressible Navier–Stokes system and the Kuramoto–Sivashinsky equation (see [17, 22, 26, 36, 40, 13, 14, 25] among others) and the notion of long time stability or dissipativity. The uniform bound in the phase space and a finer/smaller space is called long time stability or dissipativity in

these works (some of the authors derived only uniform bound/long time stability in the phase space without other bounds that are necessary for ensuring the uniform dissipativity of the scheme). We prefer the term uniform dissipativity since long time stability could be misleading in the sense that it may imply the scheme is global in time, stable in one single phase space only, which is not sufficient to ensure the existence of the global attractor. Also, none of the authors discussed stationary statistical properties of their schemes. To the best of our knowledge, our work is the first in establishing the convergence of stationary statistical properties and therefore the usefulness of uniformly dissipative schemes in approximating stationary statistical properties. An announcement of the main results presented here can be found in [10].

The manuscript is organized as follows: we give an introduction in the first section; in section 2 we propose a semidiscrete (discrete in time) scheme for the infinite Prandtl number model and verify that it is uniformly dissipative and enjoys the property that the stationary statistical properties of the scheme converge to those of the continuous-in-time model; we then provide our conclusion and remarks in the third section.

2. A uniformly dissipative scheme for the infinite Prandtl number model.

2.1. The infinite Prandtl number model for convection. One of the fundamental systems in fluid dynamics is the *Boussinesq system for Rayleigh–Bénard convection*, which is a model for convection; i.e., fluid motion induced by differential heating under Boussinesq approximation [41, 16]. We assume that the fluids occupy the (nondimensionalized) region $\Omega = [0, L_x] \times [0, L_y] \times [0, 1]$ with periodicity imposed in the horizontal directions for simplicity.

The Boussinesq system exhibits extremely rich phenomena (see, for instance, [16, 41] and the recent reviews [4, 37]). In fact, the Boussinesq system is considered a fundamental paradigm for nonlinear dynamics including instabilities and bifurcations, pattern formation, chaotic dynamics, and fully developed turbulence [27]. On the other hand, we have very limited mathematical knowledge on the system. Therefore various physically relevant simplifications are highly desirable in order to make progress.

For fluids such as silicone oil or the earth’s mantle, the Prandtl number is large; therefore, we may formally set the Prandtl number to infinity in the nondimensional Boussinesq system, and we arrive at the following (see, for instance, [4, 6, 8, 18, 41] among others) *infinite Prandtl number model (nondimensional)*:

$$(2.1) \quad \nabla p = \Delta \mathbf{u} + Ra \mathbf{k}T, \quad \nabla \cdot \mathbf{u} = 0, \quad \mathbf{u}|_{z=0,1} = 0,$$

$$(2.2) \quad \frac{\partial T}{\partial t} + \mathbf{u} \cdot \nabla T = \Delta T, \quad T|_{z=0} = 1, T|_{z=1} = 0,$$

where \mathbf{u} is the Eulerian velocity of the fluid, p represents the kinematic pressure of the fluid, T is the temperature of the fluid, \mathbf{k} is a unit vector in the z direction, and Ra is the Rayleigh number measuring the ratio of differential heating over overall dissipation.

It is well known that for complex systems such as a convection system at large Rayleigh number where turbulent/chaotic behavior abounds (see, for instance, [6, 16, 27, 4, 37]), statistical properties for such systems are much more important and physically relevant than single trajectories [33, 15, 29, 31].

Although there have been extensive works on heat transport in Rayleigh–Bénard convection [1, 4, 6, 7, 18, 37, 23, 24], basic statistical properties of the system, such

as the heat transport in the vertical direction quantified by the Nusselt number and the mean velocity field, are not very well understood. On the other hand, the infinite Prandtl number model is much simpler than the Boussinesq system since the Navier–Stokes equations are replaced by the Stokes equations (and therefore the phase space is that of the temperature only). We also know that the statistics of the infinite Prandtl number model are close to those of the Boussinesq system at large Prandtl number [44, 45, 46]. Therefore it makes sense for us to study some fundamental statistical properties of convection utilizing the simple infinite Prandtl number model since we can generally expect to push to a physically more interesting higher Rayleigh number without sacrificing accuracy with the currently available computing resource.

In our case of infinite Prandtl number convection at large Rayleigh number, even the computation on order one time scale (diffusive time scale) is a challenge since it is in fact a long time integration in disguise. To see this, we can rewrite the infinite Prandtl number model as

$$(2.3) \quad \frac{\partial T}{\partial t} + Ra A^{-1}(\mathbf{k}T) \cdot \nabla T = \Delta T, \quad T|_{z=0} = 1, T|_{z=1} = 0,$$

where A denotes the Stokes operator with viscosity one and the associated boundary conditions. It is then apparent that this is an advection dominated problem (large Péclet number) for large Rayleigh number Ra . We divide both sides of the equation by Ra and introduce the fast time scale $\tau = Ra t$, for which we may rewrite the infinite Prandtl number model in the following alternative form with an order one advection term

$$(2.4) \quad \frac{\partial T}{\partial \tau} + A^{-1}(\mathbf{k}T) \cdot \nabla T = \frac{1}{Ra} \Delta T.$$

It appears that the leading order dynamics at large Rayleigh number is the nonlocal advection equation $\frac{\partial T}{\partial \tau} + A^{-1}(\mathbf{k}T) \cdot \nabla T = 0$. However, this is valid only on order one time scale for the fast time τ . What we are interested in is order one time scale for the diffusive time t , which means a long time for the fast time τ (of the order of Ra).

2.2. A semidiscrete in time scheme. In this subsection, we provide a specific semidiscrete in time convergent dissipative scheme for the infinite Prandtl number model. The scheme is semi-implicit and utilizes a background temperature profile. Indeed, consider a generic background temperature profile $\tau(z)$ which satisfies the nonhomogeneous Dirichlet boundary condition of T . We introduce the perturbative temperature field $\theta = T - \tau$. The exact form of the background profile τ to be used will be specified below. It is easy to see that θ satisfies the following equation:

$$(2.5) \quad \frac{\partial \theta}{\partial t} + Ra A^{-1}(\mathbf{k}\theta) \cdot \nabla \theta + Ra A^{-1}(\mathbf{k}\theta)_3 \tau'(z) = \Delta \theta + \tau''(z), \quad \theta|_{z=0,1} = 0,$$

and we are searching for a solution in the space $H_{0,per}^1$ (the subspace of H^1 with zero trace in the z direction and periodic in the horizontal directions). Here $A^{-1}(\mathbf{k}\theta)_3$ represents the third component (vertical velocity) of $A^{-1}(\mathbf{k}\theta)$.

The *semi-implicit semidiscrete in time scheme* that we propose is given by

$$(2.6) \quad \frac{\theta^{n+1} - \theta^n}{k} + Ra A^{-1}(\mathbf{k}\theta^n) \cdot \nabla \theta^{n+1} + Ra A^{-1}(\mathbf{k}\theta^{n+1})_3 \tau'(z) = \Delta \theta^{n+1} + \tau''(z),$$

where θ^n denotes the approximate solution at time kn where k is the time step. A more accurate notation would be θ_k^n to indicate the dependence on the time step k .

However, we will suppress the k dependence in the notion for simplicity except in the convergence proof.

Note that the scheme is linear although the PDE is nonlinear.

Also, we would arrive at a different scheme if we were to discretize in time first and then apply the translation/background profile (see (3.2) for the case of $\lambda = 0$).

Following the pioneering works of Constantin and Doering [7, 8], we set background temperature profile τ to be a locally smoothed (mollified) version of the following piecewise linear function:

$$(2.7) \quad \tau(z) = \begin{cases} 1 - \frac{z}{2\delta}, & 0 \leq z \leq \delta, \\ \frac{1}{2}, & \delta \leq z \leq 1 - \delta, \\ \frac{1-z}{2\delta}, & 1 - \delta \leq z \leq 1. \end{cases}$$

The choice of the parameter δ will be specified later.

We would like to remark here that the typical choice of τ being the conduction state $1 - z$ is not a good one. In fact, the linearized equation is unstable in this case [6] and the solutions (to the linearized problem) grow without bound for generic initial data. Therefore we have to utilize the nonlinear term (this is where the new background profile comes into the picture) to stabilize the whole system. It is also worthwhile to point out that boundary conditions play an important role in the stabilization process. For instance, if we choose $\tau = 1 - z$ (the pure conduction state) and utilize periodicity for the perturbative variables in all three directions (the so-called homogeneous Rayleigh–Bénard convection), then the nonlinear system is not stable [5] (look at solutions that are z independent).

2.3. Well-posedness. The well-posedness of the discrete scheme follows from the Lax–Milgram theorem [30].

The weak formulation of the scheme can be derived by multiplying the scheme (2.6) by a test function $\psi \in H_{0,per}^1$ and integrating by parts. The weak formulation of the discrete scheme can be rewritten into the form

$$(2.8) \quad B_n(\theta^{n+1}, \psi) = L_n(\psi),$$

where

$$(2.9) \quad B_n(\theta^{n+1}, \psi) = \left(\frac{1}{k} \theta^{n+1} + Ra A^{-1}(\mathbf{k}\theta^n) \cdot \nabla \theta^{n+1} + Ra A^{-1}(\mathbf{k}\theta^{n+1})_3 \tau' \right) + (\nabla \theta^{n+1}, \nabla \psi),$$

$$(2.10) \quad L_n(\psi) = - \left(\tau'(z), \frac{\partial \psi}{\partial z} \right) + \left(\frac{1}{k} \theta^n, \psi \right).$$

It is easy to see that B_n is a continuous bilinear form on $H_{0,per}^1 \times H_{0,per}^1$, and L_n is a continuous linear functional on $H_{0,per}^1$. We need only verify the coercivity for B_n in order to show the solvability thanks to the Lax–Milgram theorem.

For this purpose we notice that, thanks to the specific form of the background profile τ given in (2.7), the homogeneous boundary conditions for θ^{n+1} , $(A^{-1}(\mathbf{k}\theta^{n+1}))_3$, $\nabla(A^{-1}(\mathbf{k}\theta^{n+1}))_3$, elliptic regularity (for the Stokes operator), and Poincaré inequality

(three times), there exists a constant c_1 independent of k, n, Ra , such that

$$(2.11) \quad Ra \left| \int_{\Omega} \tau'(z)(A^{-1}(\mathbf{k}\theta^{n+1}))_3 \theta^{n+1} \right| \leq c_1 \delta^2 Ra \|\nabla \theta^{n+1}\|^2 \leq \frac{1}{4} \|\nabla \theta^{n+1}\|^2$$

provided that we choose¹

$$(2.12) \quad \delta = (4c_1 Ra)^{-\frac{1}{2}}.$$

Therefore

$$(2.13) \quad B_n(\theta^{n+1}, \theta^{n+1}) \geq \frac{1}{k} \|\theta^{n+1}\|^2 + \frac{3}{4} \|\nabla \theta^{n+1}\|^2$$

which proves the coercivity. Here and elsewhere $\|\theta\| = \sqrt{\int_{\Omega} |\theta|^2}$ denotes the spatial L^2 norm of θ , and $\|\theta\|_{\infty} = \text{esssup}_{\Omega} |\theta|$ denotes the spatial L^{∞} norm of θ .

This ends the proof of the well-posedness of the discrete scheme.

2.4. Uniform dissipativity. Next, we prove the uniform dissipativity. Here and below, the c_j s denote generic constants independent of k, n (but which may depend on the Rayleigh number).

We first derive a uniform bound in the L^2 space. For this purpose we take the inner product of the scheme with $\psi = \theta^{n+1}$ and utilize the identity $(a - b, a) = \frac{1}{2}(|a|^2 - |b|^2 + |a - b|^2)$ together with the estimate on the destabilizing term (2.11), and we have

$$\begin{aligned} & \frac{1}{2k} (\|\theta^{n+1}\|^2 - \|\theta^n\|^2 + \|\theta^{n+1} - \theta^n\|^2) + \|\nabla \theta^{n+1}\|^2 \\ & \leq \|\tau'\| \|\nabla \theta^{n+1}\| + Ra \left| \int_{\Omega} \tau'(z)(A^{-1}(\mathbf{k}\theta^{n+1}))_3 \theta^{n+1} \right| \\ & \leq \|\tau'\|^2 + \frac{1}{2} \|\nabla \theta^{n+1}\|^2. \end{aligned}$$

Therefore, there exists a constant c_2 such that

$$(2.14) \quad \frac{1}{k} (\|\theta^{n+1}\|^2 - \|\theta^n\|^2 + \|\theta^{n+1} - \theta^n\|^2) + \|\nabla \theta^{n+1}\|^2 \leq 2\|\tau'\|^2 \leq c_2 Ra^{\frac{1}{2}}$$

which further implies, thanks to the Poincaré inequality, that

$$(2.15) \quad (1 + k) \|\theta^{n+1}\|^2 \leq \|\theta^n\|^2 + c_2 k Ra^{\frac{1}{2}}.$$

This leads to, with the help of a simple iteration,

$$(2.16) \quad \|\theta^{n+1}\|^2 \leq (1 + k)^{-(n+1)} \|\theta_0\|^2 + c_2 Ra^{\frac{1}{2}}.$$

This is a uniform estimate in the L^2 space.

A byproduct of this estimate is that

$$(2.17) \quad \frac{1}{N} \sum_{n=0}^N \|\nabla \theta^{n+1}\|^2 \leq \frac{\|\theta_0\|^2}{kN} + c_2 Ra^{\frac{1}{2}},$$

which is a bound on the Nusselt number in this discretized case for large N (see the definition later for Nusselt number (2.58, 2.59)), and a bound in $L^2(H^1)$ for the scheme.

¹The choice of τ or δ given here is not optimal. A near optimal choice would be $\delta \sim Ra^{-\frac{1}{3}}$, but the control on the linear destabilizing term is much longer [8, 12, 46]. We use the simple one since the optimal bound is not our goal here.

We also have

$$(2.18) \quad \sum_{n=0}^N \|\theta^{n+1} - \theta^n\|^2 \leq \|\theta_0\|^2 + c_2 k N R a^{\frac{1}{2}}.$$

In order to obtain uniform estimates in H^1 , we take the inner product of the scheme with $\psi = -\Delta\theta^{n+1}$, and we have

$$\begin{aligned} & \frac{1}{2k} (\|\nabla\theta^{n+1}\|^2 - \|\nabla\theta^n\|^2 + \|\nabla(\theta^{n+1} - \theta^n)\|^2) + \|\Delta\theta^{n+1}\|^2 \\ & \leq \|\tau''\| \|\Delta\theta^{n+1}\| + Ra \|\tau'\| \|A^{-1}(\mathbf{k}\theta^{n+1})\|_{\infty} \|\Delta\theta^{n+1}\| \\ & \quad + Ra \|A^{-1}(\mathbf{k}\theta^n)\|_{\infty} \|\nabla\theta^{n+1}\| \|\Delta\theta^{n+1}\| \\ & \leq \|\tau''\| \|\Delta\theta^{n+1}\| + c_3 Ra \|\tau'\| \|\theta^{n+1}\| \|\Delta\theta^{n+1}\| + c_4 Ra \|\theta^n\| \|\theta^{n+1}\|^{\frac{1}{2}} \|\Delta\theta^{n+1}\|^{\frac{3}{2}} \\ & \leq \frac{1}{2} \|\Delta\theta^{n+1}\|^2 + c_5, \end{aligned}$$

where we have applied the regularity result for the Stokes operator, the Sobolev imbedding of H^2 into L^{∞} , interpolation inequality, the uniform L^2 estimate (2.16), and Hölder type inequality.

This implies that

$$(2.19) \quad (1+k)\|\nabla\theta^{n+1}\|^2 \leq \|\nabla\theta^n\|^2 + 2c_6 k,$$

which further implies, with the help of a simple iteration, that

$$(2.20) \quad \|\nabla\theta^{n+1}\|^2 \leq (1+k)^{-n} \|\nabla\theta^1\|^2 + 2c_6.$$

This is the desired uniform estimates in the H^1 space; i.e., there is a uniform in k bounded absorbing ball in H^1 which attracts all solutions with L^2 initial data.

Uniform estimates in Sobolev spaces with more derivatives can be derived just as in the case of a continuous-in-time system. Here we demonstrate that the H^2 norm of the solution is asymptotically uniformly bounded in time; i.e., there is an absorbing ball in H^2 which attracts all solutions with L^2 initial data uniformly for all k .

For this purpose we apply Δ to both sides of the scheme (2.6) and then multiply the scheme by $\Delta\theta^{n+1}$ and integrate over the domain. This leads to the following:

$$\begin{aligned} & \frac{1}{2k} (\|\Delta\theta^{n+1}\|^2 - \|\Delta\theta^n\|^2 + \|\Delta(\theta^{n+1} - \theta^n)\|^2) + \|\nabla\Delta\theta^{n+1}\|^2 \\ & \leq \|\tau^{(4)}\| \|\Delta\theta^{n+1}\| + Ra (\|\Delta(A^{-1}(\mathbf{k}\theta^n))\|_{L^6} \|\nabla\theta^{n+1}\|_{L^3} \\ & \quad + 2\|\nabla A^{-1}(\mathbf{k}\theta^n)\|_{L^{\infty}} \|\nabla^2\theta^{n+1}\|) \|\Delta\theta^{n+1}\| \\ & \quad + Ra (\|\Delta(A^{-1}(\mathbf{k}\theta^{n+1}))\| \|\tau'\|_{L^{\infty}} + 2\|\nabla(A^{-1}(\mathbf{k}\theta^{n+1}))\| \|\nabla\tau'\|_{L^{\infty}} \\ & \quad + \|A^{-1}(\mathbf{k}\theta^{n+1})\| \|\Delta\tau'\|_{L^{\infty}}) \|\Delta\theta^{n+1}\| \\ & \leq c_7 (\|\Delta\theta^{n+1}\| + \|\Delta\theta^{n+1}\|^2) \\ & \leq c_8 (\|\Delta\theta^{n+1}\| + \|\nabla\Delta\theta^{n+1}\| \|\nabla\theta^{n+1}\|) \\ & \leq \frac{1}{2} \|\nabla\Delta\theta^{n+1}\|^2 + c_9, \end{aligned}$$

where we have applied the identity $\int A^{-1}(\mathbf{k}\theta^n)\nabla\Delta\theta^{n+1}\Delta\theta^{n+1} = 0$, Hölder’s inequality, elliptic regularity, Sobolev imbedding, Cauchy–Schwarz, and interpolation inequality.

This leads to the inequality

$$(2.21) \quad (1+k)\|\Delta\theta^{n+1}\|^2 \leq \|\Delta\theta^n\|^2 + 2c_9k,$$

which further implies, with the help of a simple iteration,

$$(2.22) \quad \|\Delta\theta^{n+1}\|^2 \leq (1+k)^{-n+1}\|\Delta\theta^2\|^2 + 2c_9.$$

This is the desired uniform estimates in the H^2 space, i.e., there is a uniform in k bounded absorbing ball in H^2 which attracts all solutions with L^2 initial data.

To summarize, we have the following lemma.

LEMMA 1 (uniform bound/dissipativity). *There exists a constant c_9 independent of the time step k such that the scheme (2.6) possesses an absorbing ball in H^1 and H^2 with radius $2\sqrt{c_9}$ which attracts all bounded sets in L^2 .*

2.5. Consistency and convergence. Here we check the consistency first since this is what we need in the following.

Multiplying the scheme (2.6) by $k(\theta^{n+1} - \theta^n)$ and integrating over the domain we have

$$\begin{aligned} \|\theta^{n+1} - \theta^n\|^2 &\leq k \left\{ -\frac{1}{2}(\|\nabla\theta^{n+1}\|^2 - \|\nabla\theta^n\|^2 + \|\nabla(\theta^{n+1} - \theta^n)\|^2) \right. \\ &\quad + \|\tau'\| \|\nabla(\theta^{n+1} - \theta^n)\| + c_{10}\|\theta^n\|_\infty \|\nabla\theta^{n+1}\| \|\theta^{n+1} - \theta^n\| \\ &\quad \left. + c_{11}\|\theta^{n+1}\|_\infty \|\tau'\| \|\theta^{n+1} - \theta^n\| \right\} \\ &\leq k(c_{12} + c_{13}\|\theta^{n+1} - \theta^n\|), \end{aligned}$$

where we have applied the Cauchy–Schwarz inequality, Hölder’s inequality, elliptic regularity, and uniform bounds in H^1 (2.20).

This implies the following *consistency result*:

$$(2.23) \quad \|\theta^{n+1} - \theta^n\| \leq c_{14}k^{\frac{1}{2}},$$

provided that $\theta_0 \in H_{0,per}^1$.

If we assume $\theta_0 \in H_{0,per}^1 \cap H^2$, we may deduce from the scheme (2.6) and the uniform bound (2.22) the following stronger consistency result:

$$(2.24) \quad \|\theta^{n+1} - \theta^n\| \leq c_{15}k.$$

Next, we show that the solutions to the scheme converge to the solution of the infinite Prandtl number model in $L^2(0, T^*, L^2)$ for any given time $T^* > 0$ as $k \rightarrow 0$.

For this purpose, we rewrite the scheme (2.6) as

$$(2.25) \quad \begin{aligned} \frac{\partial \tilde{\theta}_k(t)}{\partial t} + Ra A^{-1}(\mathbf{k}\theta_k(t)) \cdot \nabla\theta_k(t+k) + Ra A^{-1}(\mathbf{k}\theta_k(t+k))_3\tau'(z) \\ = \Delta\theta_k(t+k) + \tau''(z), \end{aligned}$$

where

$$(2.26) \quad \theta_k(t) = \theta_k^n, \quad t \in [nk, (n+1)k),$$

$$(2.27) \quad \tilde{\theta}_k(t) = \theta_k^n + \frac{t - nk}{k}(\theta_k^{n+1} - \theta_k^n), \quad t \in [nk, (n+1)k).$$

The estimates (2.16, 2.17) imply that θ_k and $\tilde{\theta}_k$ are uniformly (in k) bounded in $L^\infty(0, T^*; L^2)$ and $L^2(0, T^*; H_{0,per}^1)$. Hence we have a subsequence, still denoted θ_k and $\tilde{\theta}_k$ and $\theta, \tilde{\theta} \in L^\infty(0, T^*; L^2) \cap L^2(0, T^*; H_{0,per}^1)$ such that

$$(2.28) \quad \theta_k \rightharpoonup \theta, \quad \text{weak } * \text{ in } L^\infty(0, T^*; L^2),$$

$$(2.29) \quad \theta_k \rightharpoonup \theta, \quad \text{weak in } L^2(0, T^*; H_{0,per}^1),$$

$$(2.30) \quad \tilde{\theta}_k \rightharpoonup \tilde{\theta}, \quad \text{weak } * \text{ in } L^\infty(0, T^*; L^2),$$

$$(2.31) \quad \tilde{\theta}_k \rightharpoonup \tilde{\theta}, \quad \text{weak in } L^2(0, T^*; H_{0,per}^1).$$

It is also easy to check, thanks to (2.18), for any $a < T^*$,

$$(2.32) \quad \int_0^{T^*-a} \|\theta_k(t+k) - \theta_k(t)\|^2 dt \leq c_{16}k,$$

$$(2.33) \quad \int_0^{T^*} \|\theta_k(t) - \tilde{\theta}_k(t)\|^2 dt \leq c_{17}k.$$

Therefore

$$(2.34) \quad \theta = \tilde{\theta},$$

$$(2.35) \quad \theta_k(\cdot + k) \rightharpoonup \theta, \quad \text{weak } * \text{ in } L^\infty(0, T^*; L^2),$$

$$(2.36) \quad \theta_k(\cdot + k) \rightharpoonup \theta, \quad \text{weak in } L^2(0, T^*; H_{0,per}^1).$$

Furthermore, thanks to a compactness theorem due to Témam ([38, Ch. 13, Theorem 13.3]), which states that a bounded set $\mathcal{G} \subset L^1(0, T^*; Y) \cap L^p(0, T^*; X)$, $p > 1$ with X, Y being two Banach spaces and the injection of Y into X being compact, and $\sup_{g \in \mathcal{G}} \int_0^{T^*-a} \|g(a+s) - g(s)\|_X^p ds \rightarrow 0$, as $a \rightarrow 0$, is necessarily precompact in $L^q(0, T^*; X) \forall q \in [1, p)$, there exists a sub-subsequence of $\tilde{\theta}_k$ which converges strongly in $L^q(0, T^*; L^2) \forall q \in [1, p)$. Indeed, testing the scheme (2.25) against a test function v and integrating from t to $t+a$, we have

$$(2.37) \quad \begin{aligned} & |(\tilde{\theta}_k(t+a) - \tilde{\theta}_k(t), v)| \\ & \leq \int_t^{t+a} \{ \|\nabla \theta_k(s+k)\| \|\nabla v\| \\ & \quad + \|\tau'\| \left\| \frac{\partial v}{\partial z} \right\| + Ra \|A^{-1}(\mathbf{k}\theta_k(s))\|_{L^\infty} \|\theta_k(s+k)\| \|\nabla v\| \\ & \quad + Ra \|A^{-1}(\mathbf{k}\theta_k(s+k))\|_3 \| \tau' \| \|v\| \} ds \\ & \leq c_{18} \|\nabla v\| a^{\frac{1}{2}}, \end{aligned}$$

where we have applied the regularity for the Stokes operator, Sobolev imbedding, Poincaré inequality, and the a priori estimates in $L^\infty(L^2)$ and $L^2(H^1)$ valid for L^2 initial data. Now set $v = \tilde{\theta}_k(t+a) - \tilde{\theta}_k(t)$ and utilize the $L^2(H^1)$ estimate on $\tilde{\theta}_k$. Then we have

$$(2.38) \quad \int_0^{T^*-a} \|\tilde{\theta}_k(t+a) - \tilde{\theta}_k(t)\|^2 \leq c_{19} a^{\frac{1}{2}}.$$

This implies the strong convergence by Témam’s compactness theorem.

Combining this strong convergence in $L^q(L^2)$, $q \in [1, 2)$ with the uniform $L^\infty(0, T^*; L^2)$ estimate, we conclude that the sub-subsequence in fact converges strongly in $L^q(0, T^*; L^2) \forall q \in [1, \infty)$. Hence we may summarize the a priori estimates as

$$(2.39) \quad \theta_k(\cdot), \theta_k(\cdot + k), \tilde{\theta}_k(\cdot), \tilde{\theta}_k(\cdot + k) \rightarrow \theta(\cdot), \text{ in } L^q(0, T^*; L^2) \forall q \in [1, \infty),$$

$$(2.40) \quad \theta_k(\cdot), \theta_k(\cdot + k), \tilde{\theta}_k(\cdot), \tilde{\theta}_k(\cdot + k) \rightharpoonup \theta(\cdot), \text{ weakly in } L^2(0, T^*; H_{0,per}^1).$$

Now for any $\phi \in H_{0,per}^1$ and $\psi \in C^1([0, T^*])$ with $\psi(T^*) = 0$, we can rewrite the scheme (2.25) in the following weak form:

$$(2.41) \quad \int_0^{T^*} \int_\Omega \left\{ -\tilde{\theta}_k(\mathbf{x}, t) \phi(\mathbf{x}) \psi'(t) + RaA^{-1}(\mathbf{k}\theta_k(\mathbf{x}, t)) \cdot \nabla \theta_k(\mathbf{x}, t+k) \phi(\mathbf{x}) \psi(t) \right. \\ \left. + RaA^{-1}(\mathbf{k}\theta_k(\mathbf{x}, t+k))_3 \tau'(z) \phi(\mathbf{x}) \psi(t) + \nabla \theta_k(\mathbf{x}, t+k) \cdot \nabla \phi(\mathbf{x}) \psi(t) \right. \\ \left. + \tau'(z) \frac{\partial}{\partial z} \phi(\mathbf{x}) \psi(t) \right\} d\mathbf{x} dt \\ = \int_\Omega \theta_0(\mathbf{x}) \phi(\mathbf{x}) \psi(0) d\mathbf{x}.$$

Utilizing the strong $L^q(L^2)$ convergence (2.39) and the weak $L^2(H_{0,per}^1)$ convergence (2.40) together with elliptic regularity, we can pass to the limit as $k \rightarrow 0$ and arrive at

$$(2.42) \quad \int_0^{T^*} \int_\Omega \left\{ -\theta \phi \psi' + RaA^{-1}(\mathbf{k}\theta) \cdot \nabla \theta \phi \psi + RaA^{-1}(\mathbf{k}\theta)_3 \tau' \phi \psi \right. \\ \left. + \nabla \theta \cdot \nabla \phi \psi + \tau' \frac{\partial}{\partial z} \phi \psi \right\} d\mathbf{x} dt = \int_\Omega \theta_0 \phi \psi(0),$$

which is exactly the weak form of the infinite Prandtl number model. Since the infinite Prandtl number model possesses a unique solution, θ must be the unique solution; hence, the whole sequence of θ_k and $\tilde{\theta}_k$ converges to θ as any subsequence has a sub-subsequence that converges to the same limit θ .

We summarize the result here as the following lemma.

LEMMA 2 (consistency and convergence). *For any given $T^* > 0$ and $\theta_0 \in L^2$, the solution to the numerical scheme (2.25) converges to the solution of the infinite Prandtl number model; i.e.,*

$$(2.43) \quad \theta_k(\cdot), \theta_k(\cdot + k), \tilde{\theta}_k(\cdot), \tilde{\theta}_k(\cdot + k) \rightarrow \theta(\cdot) \text{ in } L^q(0, T^*; L^2) \forall q \in [1, \infty),$$

$$(2.44) \quad \theta_k(\cdot), \theta_k(\cdot + k), \tilde{\theta}_k(\cdot), \tilde{\theta}_k(\cdot + k) \rightharpoonup \theta(\cdot) \text{ weakly in } L^2(0, T^*; H_{0,per}^1),$$

where θ is the unique solution to the infinite Prandtl number model.

Moreover, if $\theta_0 \in H_{0,per}^1 \cap H^2$, then there exists a generic constant c_{15} independent of k, n such that

$$(2.45) \quad \|\theta^{n+1} - \theta^n\| \leq c_{15}k.$$

We have established $L^q(L^2) \forall q < \infty$ convergence of the numerical scheme. Uniform in time convergence (on finite time interval, i.e., $L^\infty(0, T^*; L^2)$) of the scheme can be established as well if we assume all the compatibility conditions needed (so that the exact solution is smooth enough up to the initial time $t = 0$; see [38] for the case of Navier–Stokes equations). If no high order compatibility condition is assumed, then one can show the uniform in time convergence on any finite interval modulus an initial layer (see [20] for the case of Navier–Stokes equations). Uniform convergence without enough compatibility conditions is needed for the proof of convergence of the global attractors [48], but not required here and hence we skip the details.

2.6. Convergence of the stationary statistical properties. As we mentioned earlier, for complex systems with chaotic/turbulent behavior, statistical properties are much more important than individual trajectories. In fact it is essentially hopeless to try to find approximation schemes that possess the property that the approximate trajectory remain close to the “true” trajectory for all time due to abundant sensitive dependence on data and positive Lyapunov exponents.² Therefore, the natural question to ask is if stationary statistical properties are well approximated. These stationary statistical properties are characterized by stationary statistical solutions or invariant measures of the system. Hence the question that we ask here is if the invariant measures of the discrete time approximation approximate the invariant measures of the continuous-in-time infinite Prandtl number model.

We first observe that the numerical scheme (2.6) can be viewed as a *discrete time dynamical system* on the phase space L^2 with the notation

$$(2.46) \quad \theta^{n+1} = F_k(\theta^n).$$

Thanks to the well-posedness result, we see that F_k in fact maps L^2 into $H_{0,per}^1$, and F_k^2 maps L^2 into $H_{0,per}^1 \cap H^2$ by elliptic regularity. Moreover, the discrete dynamical system is uniformly (in k) dissipative thanks to the uniform H^1 estimate (2.20). Therefore, this dynamical system possesses a compact global attractor in H^1 which attracts all bounded sets in L^2 . This leads to the existence of invariant measures via a classical Krylov–Bogliubov argument [42, 15] for the numerical scheme (the discrete dynamical system).

We recall the definition of invariant measures.

DEFINITION 1 (invariant measures). *A Borel probability measure μ_k on L^2 is called an invariant measure for F_k if*

$$(2.47) \quad \int_{L^2} \Phi(F_k(\theta)) d\mu_k = \int_{L^2} \Phi(\theta) d\mu_k$$

for all bounded continuous test functional Φ .

The set of all invariant measures for F_k is denoted \mathcal{IM}_k .

²There is a notable exception when the system possesses an explicit hyperbolic structure for which numerical shadowing may be possible [35].

We also recall that a Borel probability measure μ on L^2 is an invariant measure, or stationary statistical solution, for the infinite Prandtl number model for convection if

1.

$$(2.48) \quad \int_{L^2} \|\nabla\theta\|^2 d\mu(\theta) < \infty,$$

2.

$$(2.49) \quad \int_{L^2} < -Ra A^{-1}(\mathbf{k}\theta) \cdot \nabla\theta - Ra A^{-1}(\mathbf{k}\theta)_3 \tau'(z) + \Delta\theta + \tau''(z), \Phi'(\theta) > d\mu(\theta) = 0$$

for any cylindrical test functional $\Phi(\theta) = \phi((\theta, w_1), \dots, (\theta, w_m))$, where ϕ is a C^1 function on R^m , $\{w_j, j \geq 1\}$ are the eigenfunctions of Δ which form an orthonormal basis for L^2 and $w_j \in H_{0,per}^1 \cap C^2 \forall j$, and $<, >$ denotes the $H^{-1}, H_{0,per}^1$ duality,

3.

$$(2.50) \quad \int_{L^2} \int_{\Omega} \{|\nabla\theta|^2 + Ra(A^{-1}(\mathbf{k}\theta))_3 \theta \tau' - \tau''\theta\} d\mathbf{x} d\mu(\theta) \leq 0.$$

The set of all stationary statistical solutions for the infinite Prandtl number model is denoted \mathcal{IM} .

Roughly speaking, the first condition says that the invariant measures are supported on the smaller and finer space of H^1 , the second condition is the differential form of the weak formulation of the invariance of the measure under the flow, and the third condition is a statistical version of the energy inequality.

Now let $\mu_k \in \mathcal{IM}_k$ be a sequence of invariant measures. Thanks to the uniform estimate in H^1 (2.20), we see that the support of μ_k is contained in a bounded ball in H^1 independent of k . Therefore, thanks to the Prokhorov compactness theorem and Rellich compactness theorem [3, 30], the sequence μ_k is weakly precompact in the set of all Borel probability measures on L^2 ; hence it must contain a weakly convergent subsequence (still denoted $\{\mu_k\}$) which converges to a Borel probability measure μ . Our goal is to show that μ must be an invariant measure of the infinite Prandtl number model.

The first condition in the definition is easily verified since the global attractors for the discrete dynamical systems are uniformly bounded in H^1 independent of the time step k , and the invariant measures are supported on the global attractor [15, 48].

In order to check the second condition, i.e., the differential form of the weak formulation of invariance, we let $\Phi(\theta) = \phi((\theta, w_1), \dots, (\theta, w_m)) = \phi(y_1, \dots, y_m)$ be a cylindrical test functional. Notice that

$$(2.51) \quad \Phi'(\theta) = \sum_{j=1}^m \frac{\partial}{\partial y_j} \phi((\theta, w_1), \dots, (\theta, w_m)) w_j.$$

Hence, denoting by $<, >$ the duality between H^{-1} and $H_{0,per}^1$, we have

$$\begin{aligned} & \int_{L^2} < -Ra A^{-1}(\mathbf{k}\theta) \cdot \nabla\theta - Ra A^{-1}(\mathbf{k}\theta)_3 \tau'(z) + \Delta\theta + \tau''(z), \Phi'(\theta) > d\mu(\theta) \\ &= \int_{L^2} < -Ra A^{-1}(\mathbf{k}\theta) \cdot \nabla\theta - Ra A^{-1}(\mathbf{k}\theta)_3 \tau'(z) \end{aligned}$$

$$\begin{aligned}
& +\Delta\theta + \tau''(z), \sum_{j=1}^m \frac{\partial\phi}{\partial y_j}((\theta, w_1), \dots, (\theta, w_m))w_j > d\mu(\theta) \\
& = \int_{L^2} \sum_{j=1}^m \frac{\partial\phi}{\partial y_j} \int_{\Omega} (Ra A^{-1}(\mathbf{k}\theta) \cdot \nabla w_j \theta - Ra A^{-1}(\mathbf{k}\theta)_3 \tau'(z)w_j \\
& \quad + \Delta w_j \theta + \tau''(z)w_j) d\mathbf{x} d\mu(\theta) \\
& = \lim_{k \rightarrow 0} \int_{L^2} \sum_{j=1}^m \frac{\partial\phi}{\partial y_j} \int_{\Omega} (Ra A^{-1}(\mathbf{k}\theta) \cdot \nabla w_j \theta - Ra A^{-1}(\mathbf{k}\theta)_3 \tau'(z)w_j \\
& \quad + \Delta w_j \theta + \tau''(z)w_j) d\mathbf{x} d\mu_k(\theta) \\
& = \lim_{k \rightarrow 0} \int_{L^2} \sum_{j=1}^m \frac{\partial\phi}{\partial y_j} \int_{\Omega} (Ra A^{-1}(\mathbf{k}\theta) \cdot \nabla w_j F_k(\theta) - Ra A^{-1}(\mathbf{k}F_k(\theta))_3 \tau'(z)w_j \\
& \quad + \Delta w_j F_k(\theta) + \tau''(z)w_j) d\mathbf{x} d\mu_k(\theta) \\
& = \lim_{k \rightarrow 0} \int_{L^2} \langle -Ra A^{-1}(\mathbf{k}\theta) \cdot \nabla F_k(\theta) - Ra A^{-1}(\mathbf{k}F_k(\theta))_3 \tau'(z) \\
& \quad + \Delta F_k(\theta) + \tau''(z), \Phi'(\theta) \rangle d\mu_k(\theta) \\
& = \lim_{k \rightarrow 0} \int_{L^2} \langle \frac{F_k(\theta) - \theta}{k}, \Phi'(\theta) \rangle d\mu_k(\theta) \\
& = \lim_{k \rightarrow 0} \int_{L^2} \frac{1}{k} (\Phi(F_k(\theta)) - \Phi(\theta)) d\mu_k(\theta) \\
& = 0,
\end{aligned}$$

where we have used the boundedness and continuity of $\frac{\partial\phi}{\partial y_j}$ on the union of the support of μ_k , the consistency estimate (2.24), the invariance of μ_k under F_k , and the following straightforward estimates valid on the union of the support of the μ_k s (uniformly bounded in $H_{0,per}^1 \cap H^2$):

$$\begin{aligned}
& \left| \int_{\Omega} A^{-1}(\mathbf{k}\theta) \cdot \nabla w_j (F_k(\theta) - \theta) d\mathbf{x} \right| \leq c \|F_k(\theta) - \theta\| = \mathcal{O}(k) \rightarrow 0, \\
& \left| \int_{\Omega} (A^{-1}(\mathbf{k}(F_k(\theta) - \theta)))_3 \tau'(z)w_j d\mathbf{x} \right| \leq c \|F_k(\theta) - \theta\| = \mathcal{O}(k) \rightarrow 0, \\
& \left| \int_{\Omega} \Delta w_j (F_k(\theta) - \theta) d\mathbf{x} \right| \leq c \|F_k(\theta) - \theta\| = \mathcal{O}(k) \rightarrow 0, \\
& \langle F_k(\theta) - \theta, \Phi'(\theta) \rangle = \Phi(F_k(\theta)) - \Phi(\theta) + \mathbf{o}(\|F_k(\theta) - \theta\|) \\
& \quad = \Phi(F_k(\theta)) - \Phi(\theta) + \mathbf{o}(k),
\end{aligned}$$

the weak convergence of μ_k to μ , the scheme, and the invariance of μ_k .

This proves the differential form of the weak invariance of μ under the infinite Prandtl number dynamics, i.e., 2 of Definition 1.

The energy type inequality 3 of Definition 1 can be verified easily as well. For this purpose, we first show that any invariant measure μ_k of the numerical scheme (2.6) must satisfy the same energy type estimate. The desired continuous one will be the limit as the time step approaches zero.

We first show that the invariant measures for F_k also satisfy the energy inequality. For this purpose we multiply the scheme (2.6) by θ^{n+1} and integrate over the domain, and we then have

$$\begin{aligned} & \frac{1}{2k}(\|\theta^{n+1}\|^2 - \|\theta^n\|^2 + \|\theta^{n+1} - \theta^n\|^2) + \|\nabla\theta^{n+1}\|^2 \\ & + \int_{\Omega} (-\tau''\theta^{n+1} + Ra \tau' A^{-1}(\mathbf{k}\theta^{n+1})_3\theta^{n+1}) = 0. \end{aligned}$$

This can be rewritten using the discrete dynamical system notation F_k as

$$(2.52) \quad \begin{aligned} & \frac{1}{2k}(\|F_k(\theta)\|^2 - \|\theta\|^2 + \|F_k(\theta) - \theta\|^2) + \|\nabla F_k(\theta)\|^2 \\ & + \int_{\Omega} (-\tau''F_k(\theta) + Ra \tau' A^{-1}(\mathbf{k}F_k(\theta))_3F_k(\theta)) = 0. \end{aligned}$$

Integrating this identity with respect to the invariant measure μ_k and utilizing the invariance of μ_k under F_k , we have

$$(2.53) \quad \begin{aligned} & \int_{L^2} \int_{\Omega} (|\nabla F_k(\theta)|^2 - \tau''F_k(\theta) + Ra \tau' A^{-1}(\mathbf{k}F_k(\theta))_3F_k(\theta)) d\mathbf{x} d\mu_k(\theta) \\ & = -\frac{1}{2k} \int_{L^2} \|F_k(\theta) - \theta\|^2 d\mu_k(\theta) \leq 0. \end{aligned}$$

Utilizing the invariance of μ_k under F_k again in the lower order terms we have

$$(2.54) \quad \int_{L^2} (\|\nabla F_k(\theta)\|^2 + \int_{\Omega} (-\tau''\theta + Ra \tau' (A^{-1}(\mathbf{k}\theta))_3\theta) d\mathbf{x}) d\mu_k(\theta) \leq 0.$$

Now we recall that the support of μ_k is uniformly bounded in H^1 and hence, since the w_j s are the eigenfunctions of Δ which form an orthonormal basis in L^2 , w_j also forms a complete orthogonal system in $H^1_{0,per}$ (with the inner product between f and g given by $\int_{\Omega} \nabla f \cdot \nabla g$),

$$\|\nabla F_k(\theta)\|^2 = \lim_{m \rightarrow \infty} \sum_{j=1}^m \frac{(\nabla F_k(\theta), \nabla w_j)^2}{\|\nabla w_j\|^2} = \lim_{m \rightarrow \infty} \sum_{j=1}^m \frac{(F_k(\theta), \Delta w_j)^2}{\|\nabla w_j\|^2}.$$

Therefore

$$(2.55) \quad \begin{aligned} \int_{L^2} \|\nabla F_k(\theta)\|^2 d\mu_k(\theta) &= \int_{L^2} \lim_{m \rightarrow \infty} \sum_{j=1}^m \frac{(F_k(\theta), \Delta w_j)^2}{\|\nabla w_j\|^2} d\mu_k(\theta) \\ &= \lim_{m \rightarrow \infty} \int_{L^2} \sum_{j=1}^m \frac{(F_k(\theta), \Delta w_j)^2}{\|\nabla w_j\|^2} d\mu_k(\theta) \\ &= \lim_{m \rightarrow \infty} \int_{L^2} \sum_{j=1}^m \frac{(\theta, \Delta w_j)^2}{\|\nabla w_j\|^2} d\mu_k(\theta) \\ &= \int_{L^2} \|\nabla\theta\|^2 d\mu_k(\theta), \end{aligned}$$

where we have used the uniform boundedness of $\|\nabla\theta\|$ and $\|\nabla F_k(\theta)\|$ on the support of μ_k , the Lebesgue dominated convergence theorem and the invariance of μ_k under F_k .

Hence we see that μ_k also satisfies the energy inequality, i.e.,

$$(2.56) \quad \int_{L^2} \int_{\Omega} (|\nabla\theta|^2 - \tau''\theta + Ra \tau'(A^{-1}(\mathbf{k}\theta))_3\theta) d\mu_k(\theta) \leq 0.$$

Next, we take the limit as k approaches zero. The last two terms in the discrete energy inequality above converge to the right limit by the very definition of weak convergence of μ_k to μ . As for the leading order quadratic term, we have

$$\begin{aligned} \int \|\nabla\theta\|^2 d\mu(\theta) &= \lim_{m \rightarrow \infty} \sum_{j=1}^m \int \frac{(\theta, \Delta w_j)^2}{\|\nabla w_j\|^2} d\mu(\theta) \\ &= \lim_{m \rightarrow \infty} \lim_{k \rightarrow 0} \sum_{j=1}^m \int \frac{(\theta, \Delta w_j)^2}{\|\nabla w_j\|^2} d\mu_k(\theta) \\ &\leq \liminf_{k \rightarrow 0} \sum_{j=1}^{\infty} \int \frac{(\theta, \Delta w_j)^2}{\|\nabla w_j\|^2} d\mu_k(\theta) \\ &= \liminf_{k \rightarrow 0} \int \|\nabla\theta\|^2 d\mu_k(\theta). \end{aligned}$$

This implies that

$$\begin{aligned} &\int_{L^2} \int_{\Omega} (|\nabla\theta|^2 - \tau''\theta + Ra \tau'(A^{-1}(\mathbf{k}\theta))_3\theta) d\mu(\theta) \\ &\leq \liminf_{k \rightarrow 0} \int \|\nabla\theta\|^2 d\mu_k(\theta) + \lim_{k \rightarrow 0} \int_{L^2} \int_{\Omega} (-\tau''\theta + Ra \tau'(A^{-1}(\mathbf{k}\theta))_3\theta) d\mu_k(\theta) \\ &\leq \liminf_{k \rightarrow 0} \int_{L^2} \int_{\Omega} (|\nabla\theta|^2 - \tau''\theta + Ra \tau'(A^{-1}(\mathbf{k}\theta))_3\theta) d\mu_k(\theta) \\ (2.57) &\leq 0. \end{aligned}$$

This completes the proof of the energy type inequality (3 in Definition 1) for the limit probability measure μ . Therefore we conclude that the limit μ must be an invariant measure of the infinite Prandtl number model.

Sometimes we impose a stronger version of the statistical energy inequality in the definition of stationary statistical solutions: we require that the statistical version of the energy inequality be true on any energy shells $e_1 \leq \|\theta\| \leq e_2$ instead of just one infinite shell from zero to infinity. Such a kind of energy inequalities is useful in some applications in the Navier–Stokes case (see, for instance, [15]). They can be verified with a little bit of extra work which involves approximating the finite difference by differentiation and utilizing the uniform in H^2 estimates (invariant measures are supported in a bounded ball in H^2). We shall supply details elsewhere. Likewise it is sometimes useful to have a stronger version of the invariance of μ under the continuous-in-time dynamics either as a straightforward pullback invariance or differential form of the weak invariance with a broader class of test functionals

that are bounded on bounded sets of L^2 , Fréchet differentiable for $\theta \in H^1_{0,per}$ with $\Phi'(\theta) \in H^1_{0,per}$, and the derivative is continuous and bounded as a function from $H^1_{0,per}$ to $H^1_{0,per}$. It can be shown that these variations yield the same definition just as in the case of two-dimensional Navier–Stokes equations [15].

Next, we turn our attention to one of the most important statistical quantities in convection: the heat transport in the vertical direction quantified by the Nusselt number. More specifically, we consider the limit of heat transport in the vertical direction; i.e., the Nusselt number, as the step size approaches zero. We first recall the definition of the *Nusselt number*.

DEFINITION 2 (Nusselt number). *For the infinite Prandtl number model, the nondimensional averaged heat transport in the vertical direction is defined as*

$$\begin{aligned}
 Nu &= \sup_{\theta_0 \in L^2} \limsup_{t \rightarrow \infty} \frac{1}{tL_xL_y} \int_0^t \int_{\Omega} |\nabla T(\mathbf{x}, s)|^2 \, d\mathbf{x}ds \\
 &= 1 + Ra \sup_{\theta_0 \in L^2} \limsup_{t \rightarrow \infty} \frac{1}{tL_xL_y} \int_0^t \int_{\Omega} A^{-1}(\mathbf{k}T(\mathbf{x}, s))_3 T(\mathbf{x}, s) \, d\mathbf{x}ds \\
 (2.58) \quad &= 1 + Ra \sup_{\theta_0 \in L^2} \limsup_{t \rightarrow \infty} \frac{1}{tL_xL_y} \int_0^t \int_{\Omega} A^{-1}(\mathbf{k}\theta(\mathbf{x}, s))_3 \theta(\mathbf{x}, s) \, d\mathbf{x}ds.
 \end{aligned}$$

Likewise, the nondimensional averaged heat transport in the vertical direction for the discrete in time scheme (2.6) is defined as

$$(2.59) \quad Nu_k = 1 + Ra \sup_{\theta_0 \in L^2} \limsup_{N \rightarrow \infty} \frac{1}{NL_xL_y} \sum_{n=1}^N \int_{\Omega} A^{-1}(\mathbf{k}\theta^n(\mathbf{x}))_3 \theta^n(\mathbf{x}) \, d\mathbf{x}.$$

It is well known that long time averages defined through Banach (generalized) limits are spatial averages with respect to appropriate invariant measures of the underlying dynamical system [2, 15, 42, 43, 47]. Moreover, for a given continuous test functional φ_0 (in the application here $\varphi_0(\theta) = 1 + \frac{Ra}{L_xL_y} \int_{\Omega} A^{-1}(\mathbf{k}\theta(\mathbf{x}))_3 \theta(\mathbf{x}) \, d\mathbf{x}$), and a particular trajectory (initial data), there exists a particular Banach limit, LIM_0 , so that $LIM_0 \frac{1}{T} \int_0^t \varphi_0(\theta(s)) \, ds = \limsup \frac{1}{T} \int_0^t \varphi_0(\theta(s)) \, ds$ [46, 47]. Therefore, when combined with the Prokhorov’s compactness theorem, we deduce the existence of an invariant measure $\mu_k \in \mathcal{IM}_k$ such that

$$(2.60) \quad Nu_k = 1 + \frac{Ra}{L_xL_y} \int_{L^2} \int_{\Omega} A^{-1}(\mathbf{k}\theta(\mathbf{x}))_3 \theta(\mathbf{x}) \, d\mathbf{x}d\mu_k.$$

Hence by the weak convergence result that we just proved, we see that for any sequence of Nu_k (and hence μ_k) there exists a subsequence (still denoted Nu_k and μ_k) and $\mu \in \mathcal{IM}$ such that

$$\begin{aligned}
 \lim_{k \rightarrow 0} Nu_k &= 1 + \frac{Ra}{L_xL_y} \lim_{k \rightarrow 0} \int_{L^2} \int_{\Omega} A^{-1}(\mathbf{k}\theta(\mathbf{x}))_3 \theta(\mathbf{x}) \, d\mathbf{x}d\mu_k \\
 &= 1 + \frac{Ra}{L_xL_y} \int_{L^2} \int_{\Omega} A^{-1}(\mathbf{k}\theta(\mathbf{x}))_3 \theta(\mathbf{x}) \, d\mathbf{x}d\mu \\
 &\leq 1 + \frac{Ra}{L_xL_y} \sup_{\nu \in \mathcal{IM}} \int_{L^2} \int_{\Omega} A^{-1}(\mathbf{k}\theta(\mathbf{x}))_3 \theta(\mathbf{x}) \, d\mathbf{x}d\nu \\
 (2.61) \quad &= 1 + \frac{Ra}{L_xL_y} \sup_{\theta_0 \in L^2} \lim_{t \rightarrow \infty} \frac{1}{tL_xL_y} \int_0^t \int_{\Omega} A^{-1}(\mathbf{k}\theta(\mathbf{x}, s))_3 \theta(\mathbf{x}, s) \, d\mathbf{x}ds,
 \end{aligned}$$

where we have used the weak convergence of μ_k to μ , the compactness of the set of all invariant measures due to Prokhorov's theorem and the a priori estimates, and the fact that extremal points of the set of invariant measures are ergodic (in the sense that phase space spatial average and time average are the same) [2, 43, 46].

To summarize, we have proved the following main result.

THEOREM 1 (convergence of stationary statistical properties). *Let μ_k be an arbitrary invariant measure of the numerical scheme (2.6) with time step k , i.e., $\mu_k \in \mathcal{IM}_k$, and let Nu_k be the Nusselt number characterizing the heat transport in the vertical direction for the scheme with time step k defined in (2.59). Then each subsequence of μ_k must contain a sub-subsequence (still denoted $\{\mu_k\}$) and an invariant measure μ of the infinite Prandtl number model so that μ_k weakly converges to μ ; i.e.,*

$$(2.62) \quad \mu_k \rightharpoonup \mu, k \rightarrow 0.$$

Moreover, the Nusselt number converges in an upper semicontinuous fashion in the sense that

$$(2.63) \quad \limsup_{k \rightarrow 0} Nu_k \leq Nu.$$

In particular, this implies that the convergent numerical schemes will not overestimate the Nusselt number asymptotically.

Notice that our asymptotic lower bound on the Nusselt number for the infinite Prandtl number model nicely complements the rigorous upper bound for the Nusselt number using a variational approach proposed by Constantin and Doering [7, 8].

3. Conclusions and remarks. Our main result clearly demonstrated the usefulness of the uniformly dissipative scheme that we proposed in terms of approximating stationary statistical properties of the infinite Prandtl number model for convection since the stationary statistical properties of the scheme converge to those of the continuous time model. To the best of our knowledge, this is the first rigorous result proving convergence of stationary statistical properties of numerical schemes to those of the continuous-in-time dynamical system under approximation. Our result may be viewed as a partial generalization of Lax's equivalence theorem in the sense that consistency and long time stability (uniform dissipativity) imply convergence of stationary statistical properties. We would like to emphasize that the methodology here can be applied to much more general dissipative systems (with chaotic behavior for relevance) although we have treated the infinite Prandtl number model only [48]. We hope that our work will stimulate further study on numerical schemes for approximating statistical properties of dissipative dynamical systems.

The convergence of the stationary statistical properties relies on the uniform bound in a space which is compactly embedded in the phase space (it is $H_{0,per}^1$ in the infinite Prandtl number case which is compactly imbedded in the phase space L^2 by Rellich's theorem). Simply having a uniform bound in the phase space may not imply the convergence of the statistical properties. (We could construct schemes that possess an absorbing ball in L^2 but not in H^1 .) Therefore, we would rather use the *uniformly dissipative* terminology instead of the *global in time stability* used by many other authors, which could mean uniform boundedness in the phase space only.

The convergence that we derived here is actually semiconvergence since different subsequences may converge to different invariant measures of the continuous-in-time dynamical system. There is no convergence rate either. This is perhaps the generic

picture in the sense that the result here is nearly optimal without additional assumption on the continuous dynamical system. One very useful physical assumption is the mixing of the continuous system. Indeed, if we assume that the continuous system is exponentially mixing with a rate of r [43], i.e., there is a physically relevant invariant measure μ so that

$$(3.1) \quad \left| \frac{1}{t} \int_0^t \Phi(\theta(\mathbf{x}, s)) ds - \int \Phi(\theta(\mathbf{x})) d\mu \right| \leq c \exp(-rt)$$

for all appropriate test functionals $\Phi(\theta)$ and almost all trajectories, then approximating a specific statistical quantity $\int \Phi(\theta(\mathbf{x})) d\mu$ becomes a finite time integration problem. Indeed, supposing the given tolerance level is 2ϵ , we first fix a time t so that $c \exp(-rt) \leq \epsilon$ (the time t is usually large for small mixing rate r). We then adjust our mesh size (small time step or mesh size) so that

$$\left| \frac{1}{t} \int_0^t \Phi(\theta(\mathbf{x}, s)) ds - \frac{1}{N} \sum_{n=1}^N \Phi(\theta^n) \right| \leq \epsilon,$$

where $Nk = t$ with k being the time step. Hence the infinite time approximation of a stationary statistical property becomes the problem of approximation on finite time interval $[0, t]$ for appropriate numerical schemes (say uniformly dissipative). This motivates us to work on higher order schemes so that the integration on $[0, t]$ can be calculated quickly.

Of course we do not have exponential mixing for generic dissipative complex/chaotic dynamical systems. One way to circumvent this difficulty is by considering noisy systems since our environment is intrinsically noisy. Exponential mixing can be verified for many dissipative systems with appropriate additive white noise [11, 49, 32, 29, 50]. Hence there is a strong incentive to generalize the notion of uniformly dissipative schemes to approximations of continuous-in-time stochastic dynamical systems (both SDE and SPDE; see [32] for the case of SDE and fully implicit approach). We will report results in this direction at another time.

The scheme that we presented here is not the only scheme that is able to capture stationary statistical properties of the underlying continuous system. The fully implicit backward Euler scheme is a uniformly dissipative scheme as one can readily verify. However, the backward Euler is nonlinear in the unknown and hence the computational cost at each time step is expected to be higher. There are other linear implicit uniformly dissipative schemes. For instance one may check that the following family of schemes is uniformly dissipative for $\lambda \in [0, 1]$:

$$(3.2) \quad \frac{\theta^{n+1} - \theta^n}{k} + Ra A^{-1}(\mathbf{k}\theta^n) \cdot \nabla \theta^{n+1} + Ra (A^{-1}(\mathbf{k}(\lambda\theta^{n+1} + (1 - \lambda)\theta^n)))_3 \tau'(z) = \Delta \theta^{n+1} + \tau''(z).$$

However, it seems that this family of schemes is uniformly dissipative under small time step restriction $k \leq \frac{1}{Ra^2}$. This kind of restriction may be expected since the linearly unstable modes grow as the Rayleigh number grows; hence the time step should reflect this through CFL condition. On the other hand, we observe that for the case of $\lambda = 0$, the scheme is the same as

$$\frac{T^{n+1} - T^n}{k} + Ra A^{-1}(\mathbf{k}T^n) \cdot \nabla T^{n+1} = \Delta T^{n+1},$$

whose inviscid part is stable (satisfies maximum principle). Hence if the viscous scheme is unstable, then the viscous term plays a destabilizing role. We also notice that the case with $\lambda = 0$ corresponds to discretization in time first followed by translation, as we mentioned in section 2.2.

It is also worthwhile to point out that at the time discretization only stage we should anticipate an implicit scheme due to the CFL condition.

An issue that we have not addressed here is spatial discretization. Since we have utilized the background temperature profile τ in our uniform dissipativity argument, it is expected that we need to resolve small scales within the background profile. A similar issue for the Navier–Stokes was investigated earlier [9]. We will report the details at another time.

Another issue that we have not addressed here is the behavior of the global attractors. We fully anticipate an upper semicontinuity result. The proof is a modification of the classical one [39, 34, 19] since we will not have uniform in time convergence of trajectories on finite time interval. In fact, we will have uniform in time convergence after a transitional period of time due to the fact that the points on the global attractors of the scheme may not satisfy high order compatibility condition for the infinite Prandtl number model and hence the solution may have an initial transitional layer (see [20] for the case of two-dimensional Navier–Stokes equations). We will report this at another time as well.

Acknowledgment. We acknowledge helpful conversations with Brian Ewald and Andy Majda.

A LAGUERRE–LEGENDRE SPECTRAL METHOD FOR THE STOKES PROBLEM IN A SEMI-INFINITE CHANNEL*

MEJDI AZAIEZ[†], JIE SHEN[‡], CHUANJU XU[§], AND QINGQU ZHUANG[§]

Abstract. A mixed spectral method is proposed and analyzed for the Stokes problem in a semi-infinite channel. The method is based on a generalized Galerkin approximation with Laguerre functions in the x direction and Legendre polynomials in the y direction. The well-posedness of this method is established by deriving a lower bound on the inf-sup constant. Numerical results indicate that the derived lower bound is sharp. Rigorous error analysis is also carried out.

Key words. Laguerre functions, Legendre polynomials, Stokes equations, inf-sup condition, error analysis, spectral method

1. Introduction. The Stokes problem plays an important role in fluid dynamics and in solid mechanics, and its numerical approximation has attracted much attention during the last three decades (see, for instance, [10, 5, 4] and the references therein). Most of these investigations have been concentrated on problems in bounded domains.

There is, however, a need to consider numerical approximations to the Stokes problem in unbounded domains. In particular, the flow in a channel and flow past a cylinder/sphere have important theoretical and practical applications. In most previous investigations for these problems, an artificial boundary is introduced, and an approximate boundary condition at the artificial boundary has to be used. The accuracy of these methods usually depends on how far downstream the artificial boundary is (cf. [17]). Therefore, even when high-order or spectral methods are applied for these problems, one can not achieve high-order or spectral accuracy for the original problem due to the approximation made to the “unknown” outflow boundary conditions.

We shall take a different approach in this paper. More precisely, we shall consider the problem directly in the unbounded domain without introducing an artificial boundary. In fact, many other problems in science and engineering are also set in unbounded domains, and there have been some investigations in using Laguerre polynomials/functions to approximate PDEs on semi-infinite intervals (see, among others, [8, 12, 18, 11, 15]). However, all these works are concerned with Poisson-type elliptic equations. To the best of our knowledge, no result is available for spectral methods to the Stokes problem in semi-infinite channels. Thus, results in this paper are the first of its kind and will play an important role for the numerical approximation of Stokes and Navier–Stokes equations in unbounded domains.

More precisely, we consider the Stokes equations in a semi-infinite channel and introduce a mixed formulation based on Laguerre functions in the x direction and Legendre polynomials in the y direction. It is worthwhile to emphasize that we use Laguerre functions instead of Laguerre polynomials because the latter behaves wildly at infinity and is not suitable for approximation to flows which are well-behaved at infinity (cf. [18]). The well-posedness of this mixed formulation relies on the verification of the so-called inf-sup condition (cf. [1, 6]). The main contribution of this paper is the derivation of a lower bound on the inf-sup constant. We shall also present numerical results which indicate that the derived lower bound is sharp.

The rest of the paper is organized as follows. In the next section, we introduce some notations, derive some useful inverse inequalities for Laguerre functions and Legendre polynomials, and present the mixed Laguerre–Legendre formulation for the Stokes problem. Section 3 is devoted to deriving a lower bound for the inf-sup constant. In section 4, we carry out a complete error analysis for the mixed Laguerre–Legendre approximation. Finally, we present some implementation details and numerical results in section 5.

2. Mixed Laguerre–Legendre approximation. We start by introducing some notations. Let $R^+ = (0, +\infty)$, $\Lambda = (-1, 1)$, $\Omega = R^+ \times \Lambda$, and $\Gamma = \partial\Omega$. Let $\omega > 0$ be a weight function on Ω ; we denote by $(u, v)_{\Omega, \omega} := \int_{\Omega} uv\omega d\Omega$ the inner product of $L^2_{\omega}(\Omega)$, whose norm is denoted by $\|\cdot\|_{\omega, \Omega}$. We use $H^m_{\omega}(\Omega)$ and $H^m_{0, \omega}(\Omega)$ to denote the usual weighted Sobolev spaces, with norm $\|\cdot\|_{m, \omega, \Omega}$. In cases where no confusion would arise, ω (if $\omega \equiv 1$) and Ω may be dropped from the notations. Let M and N be the discretization parameters in x and in y . We denote by c a generic positive constant independent of the discretization parameters, and we use the expression $A \lesssim B$ to mean that $A \leq cB$. Throughout this paper we will use boldface letters to denote vectors and vector functions for ease of reading.

Let $\mathcal{L}_k(x)$ be the Laguerre polynomial of degree k ; we denote the Laguerre function by

$$\hat{\mathcal{L}}_i(x) = \mathcal{L}_i(x)e^{-x/2}$$

and set

$$\mathbb{P}_M = \text{span}\{\mathcal{L}_i(x), i = 0, 1, \dots, M\}$$

and

$$\hat{\mathbb{P}}_M = \text{span}\{\hat{\mathcal{L}}_i(x), i = 0, 1, \dots, M\}.$$

We now recall some definitions and related results which will be used in what follows.

Let $\omega(x) = e^{-x}$, and let

$$L^2_{\omega}(R^+) := \left\{ v; ve^{-x/2} \in L^2(R^+) \right\} = \left\{ v; \int_0^{\infty} v^2 \omega dx < \infty \right\}.$$

The space $L^2_{\omega}(R^+)$ is endowed with the norm $\|\cdot\|_{0, \omega, R^+}$ (also denoted by $\|\cdot\|_{0, \omega}$ or $\|\cdot\|_{\omega}$ when there is no confusion), defined by

$$\|v\|_{0, \omega, R^+} = \left(\int_0^{\infty} v^2 \omega dx \right)^{1/2}.$$

Let π_M^x be the L_ω^2 -orthogonal projector from $L_\omega^2(R^+)$ into $\mathbb{P}_M(R^+)$ defined by

$$\int_0^\infty (v - \pi_M^x v) \phi_M \omega dx = 0, \quad \forall v \in L_\omega^2(R^+), \quad \phi_M \in \mathbb{P}_M(R^+).$$

The projector π_M^x can be characterized by the following expression:

$$(2.1) \quad \pi_M^x v(x) = \sum_{m=0}^M \alpha_m \mathcal{L}_m(x) \quad \forall v(x) = \sum_{m=0}^\infty \alpha_m \mathcal{L}_m(x).$$

We define the operator $\hat{\pi}_M^x$ from $L^2(R^+)$ into $\hat{\mathbb{P}}_M(R^+)$ by (cf. [18])

$$\hat{\pi}_M^x v(x) = e^{-x/2} \pi_M^x(v(x)e^{x/2}) \quad \forall v \in L^2(R^+).$$

It can be easily verified that

$$(2.2) \quad \int_0^\infty (\hat{\pi}_M^x v - v) \phi_M dx = \int_0^\infty \left(\pi_M^x(v(x)e^{x/2}) - v(x)e^{x/2} \right) e^{-x/2} \phi_M dx = 0 \quad \forall \phi_M \in \hat{\mathbb{P}}_M(R^+).$$

Consequently, $\hat{\pi}_M^x$ is the orthogonal projector from $L^2(R^+)$ into $\hat{\mathbb{P}}_M(R^+)$.

We now present several useful results. We start with an inverse inequality for Laguerre functions.

LEMMA 2.1. *For all $\phi_M \in \hat{\mathbb{P}}_M(R^+)$, we have*

$$\|\partial_x \phi_M\|_{0,R^+} \lesssim M \|\phi_M\|_{0,R^+}.$$

Proof. Let $\phi_M(x) = \sum_{k=0}^M \tilde{\phi}_k \hat{\mathcal{L}}_k(x)$. Then, $\|\phi_M\|_{0,R^+}^2 = \sum_{k=0}^M \tilde{\phi}_k^2$ and

$$\partial_x \phi_M(x) = \sum_{k=0}^M \tilde{\phi}_k \hat{\mathcal{L}}'_k(x) = \sum_{k=0}^M \tilde{\phi}_k \left(\mathcal{L}'_k(x) - \frac{1}{2} \mathcal{L}_k(x) \right) e^{-\frac{x}{2}}.$$

Hence, the desired result is a direct consequence of the above and the inverse inequality for Laguerre polynomials (cf. [4]). \square

We now denote by $\mathbb{P}_N(\Lambda)$ the space of polynomials of degree less than or equal to N in Λ , and let π_N^y be the standard L^2 -orthogonal projector from $L^2(\Lambda)$ into $\mathbb{P}_N(\Lambda)$.

LEMMA 2.2. *For all $\phi_N \in \mathbb{P}_N(\Lambda) \cap H_0^1(\Lambda)$, we have*

$$\|\phi_N\|_{0,\Lambda} \leq N^{1/2} \|\pi_{N-2}^y \phi_N\|_{0,\Lambda}.$$

Remark 2.1. A proof of the above result, with a constant in front of $N^{1/2}$, can be found in [3]. In fact, a more precise computation as in [3] shows that the constant can be bounded by one.

A similar result with respect to $\hat{\mathbb{P}}_M(R^+) \cap H_0^1(R^+)$ is as follows.

LEMMA 2.3. *For all $\phi_M \in \hat{\mathbb{P}}_M(R^+) \cap H_0^1(R^+)$, we have*

$$\|\phi_M\|_{0,R^+} \leq (M+1)^{1/2} \|\hat{\pi}_{M-1}^x \phi_M\|_{0,R^+}.$$

Proof. Writing ϕ_M in the form

$$\phi_M(x) = \sum_{m=0}^M \alpha_m \mathcal{L}_m(x) e^{-x/2},$$

we derive from (2.1) that

$$\hat{\pi}_{M-1}^x \phi_M(x) = e^{-x/2} \pi_{M-1}^x \left(\sum_{m=0}^M \alpha_m \mathcal{L}_m(x) \right) = e^{-x/2} \sum_{m=0}^{M-1} \alpha_m \mathcal{L}_m(x).$$

Hence,

$$\phi_M(x) = \hat{\pi}_{M-1}^x \phi_M(x) + \alpha_M \mathcal{L}_M(x) e^{-x/2},$$

and by using the orthogonality relation,

$$(2.3) \quad \|\phi_M\|_{0,R^+}^2 = \|\hat{\pi}_{M-1}^x \phi_M(x)\|_{0,R^+}^2 + \alpha_M^2 \int_0^\infty (\mathcal{L}_M(x) e^{-x/2})^2 dx.$$

Note that $\phi_M(0) = 0$ implies that

$$\alpha_0 + \alpha_1 + \dots + \alpha_M = 0,$$

from which

$$(2.4) \quad |\alpha_M| = |\alpha_0 + \dots + \alpha_{M-1}| \leq \left[\sum_{m=0}^{M-1} \alpha_m^2 \right]^{1/2} M^{1/2}.$$

Combining (2.3) and (2.4) gives

$$\|\phi_M\|_{0,R^+}^2 \leq \|\hat{\pi}_{M-1}^x \phi_M(x)\|_{0,R^+}^2 + M \sum_{m=0}^{M-1} \alpha_m^2 = (M+1) \|\hat{\pi}_{M-1}^x \phi_M(x)\|_{0,R^+}^2. \quad \square$$

Now we consider the mixed Laguerre–Legendre approximation. Let $\mathbb{P}_{M,N}(\Omega)$ be the space of all polynomials in Ω of degree $\leq M$ in the x direction and $\leq N$ in the y direction, i.e.,

$$\mathbb{P}_{M,N}(\Omega) := \text{span}\{\mathcal{L}_i(x)L_j(y), i = 0, 1, \dots, M; j = 0, 1, \dots, N\},$$

where $\mathcal{L}_i(x)$ and $L_j(y)$ are, respectively, Laguerre and Legendre polynomials of degree i and j , satisfying

$$\int_{-1}^1 \int_0^\infty \mathcal{L}_i(x)L_j(y)\mathcal{L}_m(x)L_n(y)e^{-x} dx dy = \frac{2}{2n+1} \delta_{im} \delta_{jn}.$$

We also define

$$\hat{\mathbb{P}}_{M,N}(\Omega) := \text{span}\{\hat{\mathcal{L}}_i(x)L_j(y), i = 0, 1, \dots, M; j = 0, 1, \dots, N\}.$$

Let us denote by \mathcal{N} the pair of parameters (M, N) and set

$$X_{\mathcal{N}} = H_0^1(\Omega)^2 \cap \hat{\mathbb{P}}_{M,N}(\Omega)^2, \quad M_{\mathcal{N}} = L^2(\Omega) \cap \hat{\mathbb{P}}_{M-1,N-2}(\Omega).$$

LEMMA 2.4. *For all $\psi \in H^2(\Omega) \cap H_0^1(\Omega)$, we have*

$$(2.5) \quad \|\psi\|_{2,\Omega}^2 \lesssim \left\| \frac{\partial^2 \psi}{\partial y^2} \right\|_{0,\Omega}^2 + \left\| \frac{\partial^2 \psi}{\partial x^2} \right\|_{0,\Omega}^2.$$

Proof. For all $\psi \in H^2(\Omega)$, with $\psi(x, \pm 1) = 0 \forall x \in (0, +\infty)$, we have

$$\begin{aligned} |\psi(x, y)|^2 &= \left| \int_{-1}^y \frac{\partial \psi(x, s)}{\partial s} ds \right|^2 \leq \int_{-1}^y \left(\frac{\partial \psi(x, s)}{\partial s} \right)^2 ds \int_{-1}^y ds \\ &\leq (y + 1) \int_{-1}^1 \left(\frac{\partial \psi(x, s)}{\partial s} \right)^2 ds. \end{aligned}$$

Therefore,

$$(2.6) \quad \int_{-1}^1 \psi^2(x, y) dy \leq \int_{-1}^1 (y + 1) dy \int_{-1}^1 \left(\frac{\partial \psi(x, s)}{\partial s} \right)^2 ds = 2 \int_{-1}^1 \left(\frac{\partial \psi(x, y)}{\partial y} \right)^2 dy.$$

As a consequence,

$$(2.7) \quad \begin{aligned} \|\psi\|_{0,\Omega}^2 &= \int_0^\infty \int_{-1}^1 \psi^2(x, y) dy dx \leq 2 \int_0^\infty \int_{-1}^1 \left(\frac{\partial \psi(x, y)}{\partial y} \right)^2 dy dx \\ &= 2 \left\| \frac{\partial \psi}{\partial y} \right\|_{0,\Omega}^2. \end{aligned}$$

Using (2.7), we find

$$\begin{aligned} \left\| \frac{\partial \psi}{\partial y} \right\|_{0,\Omega}^2 &= \int_0^\infty \int_{-1}^1 \left(\frac{\partial \psi}{\partial y} \right)^2 dy dx = - \int_0^\infty \int_{-1}^1 \frac{\partial^2 \psi}{\partial y^2} \psi dy dx \\ &\leq \left\| \frac{\partial^2 \psi}{\partial y^2} \right\|_{0,\Omega} \|\psi\|_{0,\Omega} \leq \sqrt{2} \left\| \frac{\partial^2 \psi}{\partial y^2} \right\|_{0,\Omega} \left\| \frac{\partial \psi}{\partial y} \right\|_{0,\Omega}, \end{aligned}$$

from which we derive

$$\left\| \frac{\partial \psi}{\partial y} \right\|_{0,\Omega}^2 \leq 2 \left\| \frac{\partial^2 \psi}{\partial y^2} \right\|_{0,\Omega}^2.$$

We then derive from (2.7) and the above that

$$(2.8) \quad \|\psi\|_{0,\Omega}^2 \leq 4 \left\| \frac{\partial^2 \psi}{\partial y^2} \right\|_{0,\Omega}^2.$$

On the other hand, applying (2.7) to $\frac{\partial \psi}{\partial x}$ with $\psi \in H_0^1(\Omega)$, we obtain

$$(2.9) \quad \left\| \frac{\partial \psi}{\partial x} \right\|_{0,\Omega}^2 \leq 2 \left\| \frac{\partial^2 \psi}{\partial y \partial x} \right\|_{0,\Omega}^2.$$

Furthermore, we have, for all $\psi \in H_0^1(\Omega)$,

$$(2.10) \quad 2 \left\| \frac{\partial^2 \psi}{\partial y \partial x} \right\|_{0,\Omega}^2 = 2 \int_{-1}^1 \int_0^\infty \left(\frac{\partial^2 \psi}{\partial x^2} \right) \left(\frac{\partial^2 \psi}{\partial y^2} \right) dx dy \leq \left\| \frac{\partial^2 \psi}{\partial x^2} \right\|_{0,\Omega}^2 + \left\| \frac{\partial^2 \psi}{\partial y^2} \right\|_{0,\Omega}^2.$$

Finally, combining the above inequalities leads to

$$\begin{aligned}
 \|\nabla\psi\|_{1,\Omega}^2 &= \left\| \frac{\partial\psi}{\partial x} \right\|_{1,\Omega}^2 + \left\| \frac{\partial\psi}{\partial y} \right\|_{1,\Omega}^2 \\
 &= \left\| \frac{\partial\psi}{\partial x} \right\|_{0,\Omega}^2 + \left| \frac{\partial\psi}{\partial x} \right|_{1,\Omega}^2 + \left\| \frac{\partial\psi}{\partial y} \right\|_{0,\Omega}^2 + \left| \frac{\partial\psi}{\partial y} \right|_{1,\Omega}^2 \\
 &= \int_{-1}^1 \int_0^\infty \left[\left(\frac{\partial\psi}{\partial x} \right)^2 + \left(\frac{\partial\psi}{\partial y} \right)^2 + \left(\frac{\partial^2\psi}{\partial x^2} \right)^2 + 2 \left(\frac{\partial^2\psi}{\partial x\partial y} \right)^2 + \left(\frac{\partial^2\psi}{\partial y^2} \right)^2 \right] dx dy \\
 &\leq \int_{-1}^1 \int_0^\infty \left[4 \left(\frac{\partial^2\psi}{\partial x\partial y} \right)^2 + \left(\frac{\partial^2\psi}{\partial x^2} \right)^2 + 3 \left(\frac{\partial^2\psi}{\partial y^2} \right)^2 \right] dx dy \\
 &\leq \int_{-1}^1 \int_0^\infty \left[3 \left(\frac{\partial^2\psi}{\partial x^2} \right)^2 + 5 \left(\frac{\partial^2\psi}{\partial y^2} \right)^2 \right] dx dy \\
 &= 3 \left\| \frac{\partial^2\psi}{\partial x^2} \right\|_{0,\Omega}^2 + 5 \left\| \frac{\partial^2\psi}{\partial y^2} \right\|_{0,\Omega}^2.
 \end{aligned}$$

This estimate, together with (2.7), yields (2.5). \square

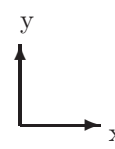

Now we set up the Stokes problem in a semi-infinite channel as depicted below:

(2.11)

Γ
 Ω
 Γ

Γ
 Γ

$\left\{ \begin{array}{l} -\Delta \mathbf{u} + \nabla p = \mathbf{f} \text{ in } \Omega, \\ \nabla \cdot \mathbf{u} = 0 \text{ in } \Omega, \\ \mathbf{u}|_\Gamma = 0, \\ \lim_{x \rightarrow \infty} \mathbf{u} = 0. \end{array} \right.$

Its weak formulation is as follows: Find $(\mathbf{u}, p) \in H_0^1(\Omega)^2 \times L^2(\Omega)$ such that

$$\begin{cases} (\nabla \mathbf{u}, \nabla \mathbf{v}) - (p, \nabla \cdot \mathbf{v}) = (\mathbf{f}, \mathbf{v}) \quad \forall \mathbf{v} \in H_0^1(\Omega)^2, \\ (q, \nabla \cdot \mathbf{u}) = 0 \quad \forall q \in L^2(\Omega). \end{cases}$$

Then, the mixed Laguerre–Legendre spectral approximation to (2.12) is as follows:

Find $\mathbf{u}_N \in X_N, p_N \in M_N$ such that

$$\begin{cases} (\nabla \mathbf{u}_N, \nabla \mathbf{v}_N)_N - (p_N, \nabla \cdot \mathbf{v}_N)_N = (\mathbf{f}, \mathbf{v}_N)_N \quad \forall \mathbf{v}_N \in X_N, \\ (q_N, \nabla \cdot \mathbf{u}_N)_N = 0 \quad \forall q_N \in M_N, \end{cases}$$

where the discrete inner product $(\cdot, \cdot)_N$ is defined by

$$(\phi, \psi)_N = \sum_{p=0}^M \sum_{q=0}^N \phi(\hat{\xi}_p, \xi_q) \psi(\hat{\xi}_p, \xi_q) \hat{\omega}_p \omega_q,$$

where $\{\hat{\xi}_p, \hat{\omega}_p\}_{p=0,1,\dots,N}$ are the Laguerre–Gauss–Radau points and the associated weights, such that the following quadrature rule holds:

$$\int_0^\infty \varphi(x) dx = \sum_{p=0}^M \varphi(\hat{\xi}_p) \hat{\omega}_p \quad \forall \varphi(x) \in \hat{\mathbb{P}}_{2M}(R^+);$$

$\{\xi_q, \omega_q\}_{q=0,1,\dots,N}$ are the Legendre–Gauss–Lobatto points and the associated weights, such that the following quadrature rule holds:

$$\int_{-1}^1 \varphi(y) dy = \sum_{q=0}^N \varphi(\xi_q) \omega_q, \quad \forall \varphi(y) \in \mathbb{P}_{2N-1}(\Lambda).$$

It is well known that, since the coercivity and continuity of the bilinear form $(\nabla \mathbf{w}_N, \nabla \mathbf{v}_N)_N$ and the continuity of the bilinear form $(\nabla \cdot \mathbf{v}_N, q_N)_N$ are evident, the well-posedness of the mixed formulation (2.13) relies on the so-called inf-sup condition [6]:

$$(2.14) \quad \inf_{q_N \in M_N} \sup_{\mathbf{v}_N \in X_N} \frac{-(\nabla \cdot \mathbf{v}_N, q_N)_N}{\|\mathbf{v}_N\|_{1,\Omega} \|q_N\|_{0,\Omega}} \geq \beta_N > 0,$$

where β_N is called the inf-sup constant. The next section is devoted to the estimation of this constant.

3. Estimation of the inf-sup constant. The main result in this section is what follows.

THEOREM 3.1.

$$(3.1) \quad \inf_{q_N \in M_N} \sup_{\mathbf{v}_N \in X_N} \frac{-(\nabla \cdot \mathbf{v}_N, q_N)_N}{\|\mathbf{v}_N\|_{1,\Omega} \|q_N\|_{0,\Omega}} \gtrsim \frac{1}{M}.$$

Remark 3.1. It is surprising that the inf-sup constant is independent of N , since it is well known that the inf-sup constant of the Legendre–Legendre $P_N^2 - P_{N-2}$ method in Λ^2 is of order $N^{-\frac{1}{2}}$ (see, for instance, [3]), and we have found numerically that in the Legendre–Legendre case in Λ^2 , the corresponding inf-sup constant behaves like $\max\{\frac{1}{\sqrt{M}}, \frac{1}{\sqrt{N}}\}$, where M, N are, respectively, the degrees of Legendre polynomials used in the x and y directions. However, our numerical results in section 5 indicate that the estimate (3.1) is sharp.

The proof of this result will be accomplished with a series of lemmas, which we present below. The confirmation of the result will be done by the numerical experiments carried out later.

LEMMA 3.1. *Given $q_N \in M_N$, the problem of finding $\psi_N \in H_0^1(\Omega) \cap \hat{\mathbb{P}}_{M,N}(\Omega)$ such that*

$$(3.2) \quad (\Delta \psi_N, r_N) = -(q_N, r_N) \quad \forall r_N \in M_N$$

admits a unique solution satisfying

$$(3.3) \quad \|\psi_N\|_{2,\Omega} \lesssim M \|q_N\|_{0,\Omega}.$$

Proof. Obviously, problem (3.2) defines a system with the number of unknowns equal to the number of equations, so the existence of such a function ψ_N is guaranteed by estimate (3.3), which we prove below.

By definition (3.2), we have

$$(\Delta \psi_N, r_1(x)r_2(y)) = -(q_N, r_1(x)r_2(y)), \quad \forall r_1 \in \hat{\mathbb{P}}_{M-1}(R^+), \quad \forall r_2 \in \mathbb{P}_{N-2}(\Lambda).$$

This implies

$$\begin{aligned} \int_0^\infty q_N(x, y) r_1(x) dx &= -\pi_{N-2}^y \int_0^\infty \Delta \psi_N(x, y) r_1(x) dx \\ &= -\int_0^\infty \pi_{N-2}^y (\Delta \psi_N(x, y)) r_1(x) dx \quad \forall r_1 \in \hat{\mathbb{P}}_{M-1}(R^+) \end{aligned}$$

and consequently

$$\begin{aligned} q_N(x, y) &= -\hat{\pi}_{M-1}^x \circ \pi_{N-2}^y (\Delta \psi_N(x, y)) = -\hat{\pi}_{M-1}^x \circ \pi_{N-2}^y \left(\frac{\partial^2 \psi_N}{\partial x^2} + \frac{\partial^2 \psi_N}{\partial y^2} \right) \\ &= -\hat{\pi}_{M-1}^x \circ \pi_{N-2}^y \frac{\partial^2 \psi_N}{\partial x^2} - \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial y^2} \\ &= -\pi_{N-2}^y \circ \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial x^2} - \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial y^2}. \end{aligned}$$

Hence,

$$\begin{aligned} \|q_N\|_{0,\Omega}^2 &= \left\| \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial y^2} \right\|_{0,\Omega}^2 + \left\| \pi_{N-2}^y \circ \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial x^2} \right\|_{0,\Omega}^2 \\ &\quad + 2 \int_{\Omega} \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial y^2} \pi_{N-2}^y \circ \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial x^2} \\ (3.4) \quad &= \left\| \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial y^2} \right\|_{0,\Omega}^2 + \left\| \pi_{N-2}^y \circ \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial x^2} \right\|_{0,\Omega}^2 + 2 \int_{\Omega} \frac{\partial^2 \psi_N}{\partial y^2} \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial x^2}. \end{aligned}$$

Observing that

$$(3.5) \quad \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial x^2} = \frac{\partial^2 \psi_N}{\partial x^2} - \frac{1}{4} (I - \hat{\pi}_{M-1}^x) \psi_N,$$

where I denotes the identity operator, then the last term in (3.4) can be rewritten as

$$\int_{\Omega} \frac{\partial^2 \psi_N}{\partial y^2} \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_N}{\partial x^2} = \int_{\Omega} \frac{\partial^2 \psi_N}{\partial y^2} \frac{\partial^2 \psi_N}{\partial x^2} - \frac{1}{4} \int_{\Omega} \frac{\partial^2 \psi_N}{\partial y^2} (I - \hat{\pi}_{M-1}^x) \psi_N.$$

For the first term on the right-hand side, we have, by integration by parts,

$$\int_{\Omega} \frac{\partial^2 \psi_N}{\partial y^2} \frac{\partial^2 \psi_N}{\partial x^2} = \int_{\Omega} \frac{\partial^2 \psi_N}{\partial x \partial y} \frac{\partial^2 \psi_N}{\partial x \partial y}.$$

To estimate the second term, we write

$$(3.6) \quad \psi_N = \sum_{m=0}^M \alpha_m(y) \mathcal{L}_m(x) e^{-x/2} \in H_0^1(\Omega) \cap \hat{\mathbb{P}}_{M,N}(\Omega).$$

Then, we have with $\alpha_m(y) \in \mathbb{P}_N^0(\Lambda)$, $m = 0, 1, \dots, M$, and by using the orthogonality of the Laguerre polynomials,

$$\begin{aligned} -\frac{1}{4} \int_{\Omega} \frac{\partial^2 \psi_N}{\partial y^2} (I - \hat{\pi}_{M-1}^x) \psi_N &= -\frac{1}{4} \int_{\Omega} \left[\sum_{m=0}^M \alpha_m''(y) \mathcal{L}_m(x) e^{-x/2} \right] \alpha_M(y) \mathcal{L}_M(x) e^{-x/2} \\ &= -\frac{1}{4} \sum_{m=0}^M \int_0^{\infty} \left(\int_{-1}^1 \alpha_m''(y) \alpha_M(y) dy \right) \mathcal{L}_m(x) \mathcal{L}_M(x) e^{-x} dx \\ &= -\frac{1}{4} \int_{-1}^1 \alpha_M''(y) \alpha_M(y) dy \\ &= \frac{1}{4} \int_{-1}^1 \alpha_M'(y) \alpha_M'(y) dy. \end{aligned}$$

Combining the above estimates leads to

$$(3.7) \quad \int_{\Omega} \frac{\partial^2 \psi_{\mathcal{N}}}{\partial y^2} \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_{\mathcal{N}}}{\partial x^2} = \int_{\Omega} \frac{\partial^2 \psi_{\mathcal{N}}}{\partial x \partial y} \frac{\partial^2 \psi_{\mathcal{N}}}{\partial x \partial y} + \frac{1}{4} \int_{-1}^1 \alpha'_M(y) \alpha'_M(y) dy.$$

Hence, by using (3.7) and Lemma 2.3 in (3.4), we obtain

$$(3.8) \quad \begin{aligned} \|q_{\mathcal{N}}\|_{0,\Omega}^2 &= \left\| \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_{\mathcal{N}}}{\partial y^2} \right\|_{0,\Omega}^2 + \left\| \pi_{N-2}^y \circ \hat{\pi}_{M-1}^x \frac{\partial^2 \psi_{\mathcal{N}}}{\partial x^2} \right\|_{0,\Omega}^2 \\ &\quad + 2 \int_{\Omega} \left(\frac{\partial^2 \psi_{\mathcal{N}}}{\partial x \partial y} \right)^2 dx dy + \frac{1}{2} \int_{-1}^1 (\alpha'_M(y))^2 dy \\ &\gtrsim M^{-1} \left\| \frac{\partial^2 \psi_{\mathcal{N}}}{\partial y^2} \right\|_{0,\Omega}^2 + \left\| \frac{\partial^2 \psi_{\mathcal{N}}}{\partial x \partial y} \right\|_{0,\Omega}^2. \end{aligned}$$

On the other hand, from the inverse inequality in the x direction (cf. Lemma 2.1) and the Poincaré inequality in the y direction, we have

$$\left\| \frac{\partial^2 \psi}{\partial x^2} \right\|_{0,\Omega} \lesssim M \left\| \frac{\partial \psi}{\partial x} \right\|_{0,\Omega} \lesssim M \left\| \frac{\partial^2 \psi}{\partial x \partial y} \right\|_{0,\Omega} \quad \forall \psi \in H_0^1(\Omega) \cap \hat{\mathbb{P}}_{M,N}(\Omega).$$

Using the above inequality and Lemma 2.4 in (3.8) gives

$$\begin{aligned} \|q_{\mathcal{N}}\|_{0,\Omega}^2 &\gtrsim M^{-1} \left\| \frac{\partial^2 \psi_{\mathcal{N}}}{\partial y^2} \right\|_{0,\Omega}^2 + M^{-2} \left\| \frac{\partial^2 \psi_{\mathcal{N}}}{\partial x^2} \right\|_{0,\Omega}^2 \\ &\gtrsim M^{-2} \|\psi_{\mathcal{N}}\|_{2,\Omega}^2. \end{aligned}$$

This leads to (3.3). \square

LEMMA 3.2. *For all $q_{\mathcal{N}} \in M_{\mathcal{N}}$, there exists $\mathbf{z}_{\mathcal{N}} \in (\hat{\mathbb{P}}_{M,N}(\Omega) \cap H_0^1(\Omega)) \times (\hat{\mathbb{P}}_{M,N+1}(\Omega) \cap H_0^1(\Omega))$ such that*

$$(\nabla \cdot \mathbf{z}_{\mathcal{N}}, r_{\mathcal{N}}) = -(q_{\mathcal{N}}, r_{\mathcal{N}}) \quad \forall r_{\mathcal{N}} \in M_{\mathcal{N}}$$

and

$$\|\mathbf{z}_{\mathcal{N}}\|_{1,\Omega} \lesssim M \|q_{\mathcal{N}}\|_{0,\Omega}.$$

Proof. For any $q_{\mathcal{N}} \in M_{\mathcal{N}}$, let $\psi_{\mathcal{N}}$ be defined by (3.2) and $\mathbf{w}_{\mathcal{N}} = \nabla \psi_{\mathcal{N}}$. Then, we have $\mathbf{w}_{\mathcal{N}} \in \hat{\mathbb{P}}_{M,N}(\Omega)^2$ satisfying

$$(3.9) \quad \begin{cases} (\nabla \cdot \mathbf{w}_{\mathcal{N}}, r_{\mathcal{N}}) = -(q_{\mathcal{N}}, r_{\mathcal{N}}) \quad \forall r_{\mathcal{N}} \in M_{\mathcal{N}}, \\ \mathbf{w}_{\mathcal{N}} \cdot \boldsymbol{\tau} = 0, \\ \|\mathbf{w}_{\mathcal{N}}\|_{1,\Omega} \lesssim M \|q_{\mathcal{N}}\|_{0,\Omega}, \end{cases}$$

where $\boldsymbol{\tau}$ is the unit tangent vector along $\partial\Omega$.

We now construct a lifting function $\phi_{\mathcal{N}} \in \hat{\mathbb{P}}_{M,N+1}(\Omega)$ such that

$$(3.10) \quad \begin{cases} \frac{\partial \phi_{\mathcal{N}}}{\partial \boldsymbol{\tau}} = -\mathbf{w}_{\mathcal{N}} \cdot \mathbf{n} \quad \text{on } \Gamma, \\ \frac{\partial \phi_{\mathcal{N}}}{\partial \mathbf{n}} = 0 \quad \text{on } \Gamma, \\ \|\phi_{\mathcal{N}}\|_{2,\Omega} \lesssim \|\mathbf{w}_{\mathcal{N}}\|_{1,\Omega}, \end{cases}$$

where \mathbf{n} is the outward normal to $\partial\Omega$. To this end, we define three functions on the boundaries $\Gamma_1 = \{(x, 1), 0 \leq x < \infty\}$, $\Gamma_2 = \{(0, y), -1 \leq y \leq 1\}$, $\Gamma_3 = \{(x, -1), 0 \leq x < \infty\}$, respectively, as follows:

$$\begin{aligned} b_{\mathcal{N}}^1(x, y) &= - \int_{\infty}^x (\mathbf{w}_{\mathcal{N}} \cdot \mathbf{n})(\sigma, y) d\sigma, \\ b_{\mathcal{N}}^2(x, y) &= b_{\mathcal{N}}^1(0, 1) - \int_1^y (\mathbf{w}_{\mathcal{N}} \cdot \mathbf{n})(x, \sigma) d\sigma, \\ b_{\mathcal{N}}^3(x, y) &= b_{\mathcal{N}}^2(0, -1) - \int_0^x (\mathbf{w}_{\mathcal{N}} \cdot \mathbf{n})(\sigma, y) d\sigma. \end{aligned}$$

Then, it can be easily verified that $b_{\mathcal{N}}^j$ ($j = 1, 2, 3$) satisfy the following continuity conditions:

$$\begin{aligned} b_{\mathcal{N}}^1(0, 1) &= b_{\mathcal{N}}^2(0, 1), \\ b_{\mathcal{N}}^2(0, -1) &= b_{\mathcal{N}}^3(0, -1), \\ \frac{\partial b_{\mathcal{N}}^1}{\partial \boldsymbol{\tau}}(0, 1) &= -\mathbf{w}_{\mathcal{N}} \cdot \mathbf{n}(0, 1) = 0 = \frac{\partial b_{\mathcal{N}}^2}{\partial \boldsymbol{\tau}}(0, 1), \\ \frac{\partial b_{\mathcal{N}}^2}{\partial \boldsymbol{\tau}}(0, -1) &= -\mathbf{w}_{\mathcal{N}} \cdot \mathbf{n}(0, -1) = 0 = \frac{\partial b_{\mathcal{N}}^3}{\partial \boldsymbol{\tau}}(0, -1), \\ \frac{\partial^2 b_{\mathcal{N}}^1}{\partial x \partial y}(0, 1) &= \frac{\partial^2 b_{\mathcal{N}}^2}{\partial x \partial y}(0, 1) = 0, \\ \frac{\partial^2 b_{\mathcal{N}}^2}{\partial x \partial y}(0, -1) &= \frac{\partial^2 b_{\mathcal{N}}^3}{\partial x \partial y}(0, -1) = 0. \end{aligned}$$

The above conditions, together with the fact that $b_{\mathcal{N}}^j \in \hat{\mathbb{P}}_{M, N+1}(\Omega)$ ($j = 1, 2, 3$), guarantee that there exists a $\phi_{\mathcal{N}} \in \hat{\mathbb{P}}_{M, N+1}(\Omega)$ satisfying (see [2])

$$(3.11) \quad \begin{cases} \phi_{\mathcal{N}} = b_{\mathcal{N}}^j & \text{on } \Gamma_j, \quad j = 1, 2, 3, \\ \frac{\partial \phi_{\mathcal{N}}}{\partial \mathbf{n}} = 0 & \text{on } \Gamma, \end{cases}$$

and

$$\|\phi_{\mathcal{N}}\|_{2, \Omega} \lesssim \sum_{j=1}^3 \|b_{\mathcal{N}}^j\|_{3/2, \Gamma} \lesssim \|\mathbf{w}_{\mathcal{N}} \cdot \mathbf{n}\|_{1/2, \Gamma} \lesssim \|\mathbf{w}_{\mathcal{N}}\|_{1, \Omega}.$$

Moreover, it is seen that the first equality of (3.11) implies

$$\frac{\partial \phi_{\mathcal{N}}}{\partial \boldsymbol{\tau}} = -\mathbf{w}_{\mathcal{N}} \cdot \mathbf{n} \quad \text{on } \Gamma.$$

This completes the construction of the lifting function $\phi_{\mathcal{N}}$. Now, let

$$\mathbf{z}_{\mathcal{N}} = \mathbf{w}_{\mathcal{N}} + \text{rot} \phi_{\mathcal{N}},$$

then $\mathbf{z}_{\mathcal{N}} \in \hat{\mathbb{P}}_{M, N}(\Omega) \times \hat{\mathbb{P}}_{M, N+1}(\Omega)$ and

$$\begin{aligned} \mathbf{z}_{\mathcal{N}} \cdot \mathbf{n}|_{\Gamma} &= \mathbf{w}_{\mathcal{N}} \cdot \mathbf{n} + \text{rot} \phi_{\mathcal{N}} \cdot \mathbf{n} = \mathbf{w}_{\mathcal{N}} \cdot \mathbf{n} + \frac{\partial \phi_{\mathcal{N}}}{\partial \boldsymbol{\tau}} = 0, \\ \mathbf{z}_{\mathcal{N}} \cdot \boldsymbol{\tau}|_{\Gamma} &= \mathbf{w}_{\mathcal{N}} \cdot \boldsymbol{\tau} + \text{rot} \phi_{\mathcal{N}} \cdot \boldsymbol{\tau} = \frac{\partial \phi_{\mathcal{N}}}{\partial \mathbf{n}} = 0, \end{aligned}$$

which means $\mathbf{z}_N \in (\hat{\mathbb{P}}_{M,N}(\Omega) \cap H_0^1(\Omega)) \times (\hat{\mathbb{P}}_{M,N+1}(\Omega) \cap H_0^1(\Omega))$. Moreover, we have

$$(\nabla \cdot \mathbf{z}_N, r_N) = (\nabla \cdot \mathbf{w}_N, r_N) + (\nabla \cdot \text{rot}\phi_N, r_N) = -(q_N, r_N) \quad \forall r_N \in M_N,$$

and, by (3.9) and the last inequality of (3.10),

$$(3.12) \quad \begin{aligned} \|\mathbf{z}_N\|_{1,\Omega} &= \|\mathbf{w}_N + \text{rot}\phi_N\|_{1,\Omega} \leq \|\mathbf{w}_N\|_{1,\Omega} + \|\text{rot}\phi_N\|_{1,\Omega} \\ &\lesssim \|\mathbf{w}_N\|_{1,\Omega} \lesssim M\|q_N\|_{0,\Omega}. \end{aligned}$$

The proof is complete. \square

LEMMA 3.3. *For all $q_N \in M_N$, there exists $\mathbf{v}_N \in X_N$ such that*

$$(\nabla \cdot \mathbf{v}_N, r_N) = -(q_N, r_N) \quad \forall r_N \in M_N$$

and

$$\|\mathbf{v}_N\|_{1,\Omega} \lesssim M\|q_N\|_{0,\Omega}.$$

Proof. For given q_N , let $\mathbf{z}_N := (z_N^{(1)}, z_N^{(2)}) \in (\hat{\mathbb{P}}_{M,N}(\Omega) \cap H_0^1(\Omega)) \times (\hat{\mathbb{P}}_{M,N+1}(\Omega) \cap H_0^1(\Omega))$ be a function associated to q_N in Lemma 3.2. Then, the second component of \mathbf{z}_N can be written under form

$$z_N^{(2)} = \sum_{i=2}^{N+1} \alpha_i(x) e^{-x/2} (L_i(y) - L_{i-2}(y)),$$

with $\alpha_i(x) \in \mathbb{P}_M(R^+) \cap H_0^1(R^+)$, $i = 2, \dots, M + 1$. We decompose $z_N^{(2)}$ into

$$z_N^{(2)} = \tilde{z}_N^{(2)} + \bar{z}_N^{(2)},$$

with

$$\begin{aligned} \tilde{z}_N^{(2)} &= \sum_{i=2}^N \alpha_i(x) e^{-x/2} (L_i(y) - L_{i-2}(y)), \\ \bar{z}_N^{(2)} &= \alpha_{N+1}(x) e^{-x/2} (L_{N+1}(y) - L_{N-1}(y)), \end{aligned}$$

and let

$$\mathbf{v}_N = \left(z_N^{(1)}, \tilde{z}_N^{(2)} \right).$$

Then, it is seen that $\mathbf{v}_N \in X_N$, moreover, for all $r_N \in M_N$, by using the orthogonality of the Legendre polynomials, we have

$$\begin{aligned} (\nabla \cdot \mathbf{v}_N, r_N) &= \left(\partial_x z_N^{(1)} + \partial_y \tilde{z}_N^{(2)}, r_N \right) \\ &= \left(\partial_x z_N^{(1)} + \partial_y \tilde{z}_N^{(2)}, r_N \right) - \left(\alpha_{N+1}(x) e^{-x/2} (L_{N+1}(y) - L_{N-1}(y)), \partial_y r_N \right) \\ &= \left(\partial_x z_N^{(1)} + \partial_y \tilde{z}_N^{(2)}, r_N \right) + \left(\alpha_{N+1}(x) e^{-x/2} \partial_y (L_{N+1}(y) - L_{N-1}(y)), r_N \right) \\ &= \left(\partial_x z_N^{(1)} + \partial_y z_N^{(2)}, r_N \right) \\ &= (\nabla \cdot \mathbf{z}_N, r_N) \\ &= -(q_N, r_N). \end{aligned}$$

It remains to prove $\|v_{\mathcal{N}}\|_{1,\Omega} \lesssim \|z_{\mathcal{N}}\|_{1,\Omega}$. Since $\tilde{z}_{\mathcal{N}}^{(2)} = z_{\mathcal{N}}^{(2)} - \bar{z}_{\mathcal{N}}^{(2)}$, we need only to prove $\|\bar{z}_{\mathcal{N}}^{(2)}\|_{1,\Omega} \lesssim \|z_{\mathcal{N}}^{(2)}\|_{1,\Omega}$. First, we have

$$\begin{aligned} \partial_x \bar{z}_{\mathcal{N}}^{(2)} &= \partial_x \left(\alpha_{N+1}(x)e^{-x/2} \right) (L_{N+1}(y) - L_{N-1}(y)), \\ \partial_x z_{\mathcal{N}}^{(2)} &= \sum_{i=2}^{N+1} \partial_x \left(\alpha_i(x)e^{-x/2} \right) (L_i(y) - L_{i-2}(y)) \\ &= \partial_x \left(\alpha_{N+1}(x)e^{-x/2} \right) L_{N+1}(y) + \partial_x \left(\alpha_N(x)e^{-x/2} \right) L_N(y) + \dots, \end{aligned}$$

thus

$$\begin{aligned} \left\| \partial_x z_{\mathcal{N}}^{(2)} \right\|_{0,\Omega}^2 &= \int_{-1}^1 \left[\int_0^\infty \left(\partial_x \left(\alpha_{N+1}(x)e^{-x/2} \right) \right)^2 dy \right] L_{N+1}(y)^2 dx + \dots \\ &\gtrsim \left\| \partial_x \left(\alpha_{N+1}(x)e^{-x/2} \right) \right\|_{0,R^+}^2 \frac{1}{N+1+1/2} \\ &\geq \frac{1}{6} \left| \alpha_{N+1}(x)e^{-x/2} \right|_{1,R^+}^2 \left(\frac{2}{2N+3} + \frac{2}{2N-1} \right) \\ &= \frac{1}{6} \left| \alpha_{N+1}(x)e^{-x/2} \right|_{1,R^+}^2 (\|L_{N+1}\|_{0,\Lambda}^2 + \|L_{N-1}\|_{0,\Lambda}^2) \\ &\gtrsim \left\| \partial_x \bar{z}_{\mathcal{N}}^{(2)} \right\|_{0,\Omega}^2. \end{aligned}$$

Similarly, we have

$$\left\| z_{\mathcal{N}}^{(2)} \right\|_{0,\Omega}^2 \gtrsim \left\| \bar{z}_{\mathcal{N}}^{(2)} \right\|_{0,\Omega}^2.$$

Second, from

$$\begin{aligned} \partial_y \bar{z}_{\mathcal{N}}^{(2)} &= \alpha_{N+1}(x)e^{-x/2} (L'_{N+1}(y) - L'_{N-1}(y)) = \alpha_{N+1}(x)e^{-x/2} (2N+1)L_N(y), \\ \partial_y z_{\mathcal{N}}^{(2)} &= \sum_{i=2}^{N+1} \alpha_i(x)e^{-x/2} (L'_i(y) - L'_{i-2}(y)) = \sum_{i=2}^{N+1} \alpha_i(x)e^{-x/2} (2i-1)L_{i-1}(y), \end{aligned}$$

we derive that

$$\begin{aligned} \left\| \partial_y z_{\mathcal{N}}^{(2)} \right\|_{0,\Omega}^2 &= \sum_{i=2}^{N+1} \left\| \alpha_i(x)e^{-x/2} \right\|_{0,R^+}^2 (2i-1)^2 \|L_{i-1}\|_{0,\Lambda}^2 \\ &\geq \left\| \alpha_{N+1}(x)e^{-x/2} \right\|_{0,R^+}^2 (2N+1)^2 \|L_N\|_{0,\Lambda}^2 \\ &= \left\| \partial_y \bar{z}_{\mathcal{N}}^{(2)} \right\|_{0,\Omega}^2. \end{aligned}$$

Combining all above estimations together gives

$$\left\| z_{\mathcal{N}}^{(2)} \right\|_{1,\Omega}^2 \gtrsim \left\| \bar{z}_{\mathcal{N}}^{(2)} \right\|_{1,\Omega}^2,$$

which yields

$$\left\| v_{\mathcal{N}}^{(2)} \right\|_{1,\Omega} = \left\| \tilde{z}_{\mathcal{N}}^{(2)} \right\|_{1,\Omega} = \left\| z_{\mathcal{N}}^{(2)} - \bar{z}_{\mathcal{N}}^{(2)} \right\|_{1,\Omega} \lesssim \left\| z_{\mathcal{N}}^{(2)} \right\|_{1,\Omega}.$$

This gives

$$\|\mathbf{v}_N\|_{1,\Omega} \lesssim \|\mathbf{z}_N\|_{1,\Omega} \lesssim M \|q_N\|_{0,\Omega}. \quad \square$$

Proof of Theorem 3.1. For all $q_N \in M_N$, let $\mathbf{v}_N \in X_N$ be the associated function given in Lemma 3.3, then

$$\begin{aligned} \frac{-(\nabla \cdot \mathbf{v}_N, q_N)_N}{\|\mathbf{v}_N\|_{1,\Omega} \|q_N\|_{0,\Omega}} &= \frac{-(\nabla \cdot \mathbf{v}_N, q_N)}{\|\mathbf{v}_N\|_{1,\Omega} \|q_N\|_{0,\Omega}} = \frac{(q_N, q_N)}{\|\mathbf{v}_N\|_{1,\Omega} \|q_N\|_{0,\Omega}} \\ &= \frac{\|q_N\|_{0,\Omega}}{\|\mathbf{v}_N\|_{1,\Omega}} \gtrsim \frac{1}{M}. \end{aligned}$$

This means (3.1) holds. \square

COROLLARY 3.1. For all $\mathbf{f} \in C^0(\Omega)^2$, problem (2.13) admits a unique solution (\mathbf{u}_N, p_N) satisfying

$$(3.13) \quad \|\mathbf{u}_N\|_{1,\Omega} + \frac{1}{M} \|p_N\|_{0,\Omega} \lesssim \|f\|_{L^\infty(\Omega)}.$$

Proof. First, it can be checked that, for each $\mathbf{u}_N \in X_N, \mathbf{v}_N \in X_N$,

$$\begin{aligned} |(\nabla \mathbf{u}_N, \nabla \mathbf{v}_N)_N| &\leq 3 \|\mathbf{u}_N\|_1 \|\mathbf{v}_N\|_1, \\ (\nabla \mathbf{v}_N, \nabla \mathbf{v}_N)_N &\geq |\mathbf{v}_N|_1^2 \geq \frac{1}{3} \|\mathbf{v}_N\|_1^2. \end{aligned}$$

Then, thanks to the above inequalities and (3.1), the well-posedness of problem (2.13) and stability estimate (3.13) are straightforward consequences of the abstract inf-sup theory (cf. [1, 6]). \square

4. Error estimation. We start with some notations and definitions which are needed in the following error analysis. Denote $\omega_r(x) = x^r e^{-x}$, $\hat{\omega}_r(x) = x^r$, and, in particular, we set $\omega(x) = \omega_0(x)$, $\hat{\omega}(x) = \hat{\omega}_0(x)$. Then, for any non-negative integer r , we define two Banach spaces

$$\begin{aligned} \hat{A}^r(R^+) &:= \{v; v \text{ is measurable on } R^+ \text{ and } \|v\|_{\hat{A}^r, R^+} < \infty\}, \\ A^r(R^+) &:= \{v; v \text{ is measurable on } R^+ \text{ and } \|v\|_{A^r, R^+} < \infty\}, \end{aligned}$$

equipped, respectively, with the following norms:

$$\begin{aligned} \|v\|_{\hat{A}^r, R^+} &= \left(\sum_{k=0}^r |v|_{\hat{A}^k, R^+}^2 \right)^{\frac{1}{2}}, \quad \text{with } |v|_{\hat{A}^k, R^+} = \|\partial_x^k v\|_{\omega_k, R^+} \quad \forall v \in \hat{A}^r(R^+), \\ \|v\|_{A^r, R^+} &= \left(\sum_{k=0}^r |v|_{A^k, R^+}^2 \right)^{\frac{1}{2}}, \quad \text{with } |v|_{A^k, R^+} = \|\partial_x^k v\|_{\hat{\omega}_k, R^+} \quad \forall v \in A^r(R^+). \end{aligned}$$

We now recall several approximation results. Let π_M^x and $\hat{\pi}_M^x$ be the projection operators defined in section 2.

LEMMA 4.1 (cf. [19]). For any $v \in \hat{A}^r(R^+)$ and integer $r \geq s \geq 0$,

$$(4.1) \quad \|v - \pi_M^x v\|_{\hat{A}^s, R^+} \lesssim M^{(s-r)/2} |v|_{\hat{A}^r, R^+}.$$

A direct consequence of Lemma 4.1 is that, for any integer $r \geq 0$, $v \in A^r(R^+)$,

$$(4.2) \quad \|v - \hat{\pi}_M^x v\|_{0, R^+} \lesssim M^{-r/2} |e^{x/2} v|_{\hat{A}^r, R^+}.$$

Denote $W_M = \{v \in \mathbb{P}_M(R^+); v(0) = 0\}$, and let $\pi_{1,M}^{x,0} : H_{0,\omega}^1(R^+) \rightarrow W_M$ be the $H_{0,\omega}^1(R^+)$ -orthogonal projection operator defined by

$$\int_0^\infty (\pi_{1,M}^{x,0} v)' \phi'_M \omega dx = \int_0^\infty v' \phi'_M \omega dx \quad \forall \phi_M \in W_M.$$

LEMMA 4.2. *If $v \in H_{0,\omega}^1(R^+)$, $\partial_x v \in \hat{A}^{r-1}(R^+)$, and integer $r \geq 1$, then*

$$\|v - \pi_{1,M}^{x,0} v\|_{1,\omega,R^+} \lesssim M^{\frac{1}{2}-\frac{r}{2}} |\partial_x v|_{\hat{A}^{r-1},R^+}.$$

Proof. Given $v \in H_{0,\omega}^1(R^+)$, let $v_M(z) = \int_0^z \pi_{M-1}^x \partial_x v(x) dx \quad \forall z \in R^+$, then $v_M \in W_M$ and $\partial_x v_M(x) = \pi_{M-1}^x(\partial_x v(x))$. Hence, by Lemma 2.2 of [11] and Lemma 4.1,

$$\begin{aligned} \|v - \pi_{1,M}^{x,0} v\|_{1,\omega,R^+} &\leq \|v - v_M\|_{1,\omega,R^+} \lesssim |v - v_M|_{1,\omega,R^+} \\ &= \|\partial_x v - \pi_{M-1}^x(\partial_x v)\|_{\omega,R^+} \lesssim M^{\frac{1}{2}-\frac{r}{2}} |\partial_x v|_{\hat{A}^{r-1},R^+}. \quad \square \end{aligned}$$

Now we set $\hat{W}_M = \{v e^{-x/2}; v \in W_M\}$ and define the projection operator $\hat{\pi}_{1,M}^{x,0}$ from $H_0^1(R^+)$ into \hat{W}_M by

$$\hat{\pi}_{1,M}^{x,0} v(x) := e^{-x/2} \pi_{1,M}^{x,0}(v(x) e^{x/2}) \quad \forall v \in H_0^1(R^+).$$

Then, it follows from Lemma 4.2 that, for $r \geq 1$,

$$(4.3) \quad \|v - \hat{\pi}_{1,M}^{x,0} v\|_{1,R^+} = \|v e^{x/2} - \pi_{1,M}^{x,0}(e^{x/2} v(x))\|_{1,\omega,R^+} \lesssim M^{\frac{1}{2}-\frac{r}{2}} |\partial_x(e^{x/2} v(x))|_{\hat{A}^{r-1},R^+}.$$

For $r \geq 1$, we introduce the space, suitable for analyzing the approximation properties of the Laguerre interpolation (cf. [19]),

$$B^r(R^+) := \{v; v \text{ is measurable on } R^+ \text{ and } \|v\|_{B^r,R^+} < \infty\},$$

with norm

$$\|v\|_{B^r,R^+} = \left(\sum_{k=1}^r \left\| x^{(r-1)/2} (x+1)^{1/2} \partial_x^k v \right\|_{0,R^+}^2 \right)^{1/2}.$$

Let I_M^x be the Laguerre–Gauss–Radau interpolation, and define $\hat{I}_M^x v(x) = e^{-x/2} I_M^x(e^{x/2} v(x))$; the following result is proved in [19].

LEMMA 4.3. *For any $v \in B^r(R^+)$, and $0 \leq \mu \leq 1 \leq r$,*

$$\begin{aligned} \|v - \hat{I}_M^x v\|_{\mu,R^+} &\lesssim (\ln M)^{1/2} M^{\mu+1/2-r/2} (|\partial_x v|_{\hat{A}^r,R^+} + |\partial_x(e^{x/2} v)|_{\hat{A}^{r-1},R^+}) \\ &\lesssim (\ln M)^{1/2} M^{\mu+1/2-r/2} \|v\|_{B^r,R^+}. \end{aligned}$$

Let $\pi_{1,N}^{y,0} : H_0^1(\Lambda) \rightarrow \mathbb{P}_N^0(\Lambda)$ be the $H_0^1(\Lambda)$ -orthogonal projector defined by

$$\int_{-1}^1 \partial_y(v - \pi_{1,N}^{y,0} v) \partial_y \phi dy = 0 \quad \forall \phi \in \mathbb{P}_N^0(\Lambda).$$

Then, it follows from [3] that, for all $s \geq 1$ and all $v \in H_0^1(\Lambda) \cap H^s(\Lambda)$, it holds that

$$(4.4) \quad \|v - \pi_{1,N}^{y,0} v\|_{k,\Lambda} \lesssim N^{k-s} \|v\|_{s,\Lambda}, \quad k = 0, 1.$$

We denote by $L^2(\Lambda, A^r(R^+))$ the space of the measurable functions $v : \Lambda \rightarrow A^r(R^+)$ such that

$$\|v\|_{A^r;0} := \left\{ \int_{\Lambda} \|v(\cdot, y)\|_{A^r, R^+}^2 dy \right\}^{\frac{1}{2}} < \infty.$$

Moreover, for any nonnegative integer s , we define

$$H^s(\Lambda, L^2(R^+)) := \left\{ v; \frac{\partial^j v}{\partial y^j} \in L^2(\Lambda, L^2(R^+)), 0 \leq j \leq s \right\}.$$

The norm of this space is given by

$$\|v\|_{0;s} = \left\{ \sum_{j=0}^s \left\| \frac{\partial^j v}{\partial y^j} \right\|_{0,\Omega}^2 \right\}^{\frac{1}{2}} = \left\{ \sum_{j=0}^s \left\| \frac{\partial^j v}{\partial y^j} \right\|_{0;0}^2 \right\}^{\frac{1}{2}}.$$

Now, for any nonnegative integer r and s , we define

$$A^{r;s}(\Omega) := H^s(\Lambda, L^2(R^+)) \cap L^2(\Lambda, A^r(R^+)),$$

with the following norm:

$$\|v\|_{A^{r;s}} = \left\{ \|v\|_{A^r;0}^2 + \|v\|_{0;s}^2 \right\}^{\frac{1}{2}} \quad \forall v \in A^{r;s}(\Omega).$$

We also define

$$\begin{aligned} \bar{B}^{r;s}(\Omega) &:= H^s(\Lambda, L^2(R^+)) \cap H^1(\Lambda, B^{r-1}(R^+)) \cap L^2(\Lambda, A^r(R^+)), \\ Y^{m;n}(\Omega) &:= H^n(\Lambda, L^2(R^+)) \cap H^1(\Lambda, A^{m-1}(R^+)) \cap H^{n-1}(\Lambda, H^1(R^+)) \\ &\quad \cap L^2(\Lambda, A^m(R^+)), \end{aligned}$$

equipped, respectively, with the following norms:

$$\begin{aligned} \|v\|_{\bar{B}^{r;s}} &= \left(\|v\|_{0;s}^2 + \|v\|_{B^{r-1};1}^2 + \|v\|_{A^r;0}^2 \right)^{\frac{1}{2}}, \\ \|v\|_{Y^{m;n}} &= \left(\|v\|_{0;n}^2 + \|v\|_{A^{m-1};1}^2 + \|v\|_{1;n-1}^2 + \|v\|_{A^m;0}^2 \right)^{\frac{1}{2}}. \end{aligned}$$

THEOREM 4.1. *If the solution (\mathbf{u}, p) of problem (2.12) satisfies $\mathbf{u} \in H_0^1(\Omega)^2 \cap Y^{m;n}(\Omega)^2 \cap C(\Omega)$, $p \in A^{m-1;n-1}(\Omega) \cap C(\Omega)$, $m \geq 1, n \geq 1$ and $\mathbf{f} \in \bar{B}^{r;s}(\Omega)^2 \cap C(\Omega)$, $r \geq 1, s \geq 1$, then the solution $(\mathbf{u}_{\mathcal{N}}, p_{\mathcal{N}})$ of (2.13) admits the following error estimates:*

$$\begin{aligned} \|\mathbf{u} - \mathbf{u}_{\mathcal{N}}\|_{1,\Omega} &\lesssim \left(M^{\frac{1}{2} - \frac{m}{2}} + N^{1-n} \right) (M \|\mathbf{u}\|_{Y^{m;n}} + \|p\|_{A^{m-1;n-1}}) \\ &\quad + \left((\ln M)^{\frac{1}{2}} M^{1 - \frac{r}{2}} + N^{-s} \right) \|\mathbf{f}\|_{\bar{B}^{r;s}}, \\ \|p - p_{\mathcal{N}}\|_{0,\Omega} &\lesssim M \left[\left(M^{\frac{1}{2} - \frac{m}{2}} + N^{1-n} \right) (M \|\mathbf{u}\|_{Y^{m;n}} + \|p\|_{A^{m-1;n-1}}) \right. \\ &\quad \left. + \left((\ln M)^{\frac{1}{2}} M^{1 - \frac{r}{2}} + N^{-s} \right) \|\mathbf{f}\|_{\bar{B}^{r;s}} \right]. \end{aligned}$$

Proof. Let

$$V_{\mathcal{N}} := \{\mathbf{v}_{\mathcal{N}} \in X_{\mathcal{N}}; (p_{\mathcal{N}}, \nabla \cdot \mathbf{v}_{\mathcal{N}})_{\mathcal{N}} = 0 \forall p_{\mathcal{N}} \in M_{\mathcal{N}}\}.$$

Then, for all $\mathbf{v}_{\mathcal{N}} \in X_{\mathcal{N}}, \mathbf{w}_{\mathcal{N}} \in V_{\mathcal{N}}$,

$$\begin{aligned} (\nabla \mathbf{w}_{\mathcal{N}}, \nabla \mathbf{v}_{\mathcal{N}}) - (\nabla \mathbf{w}_{\mathcal{N}}, \nabla \mathbf{v}_{\mathcal{N}})_{\mathcal{N}} &= (\nabla(\mathbf{w}_{\mathcal{N}} - \mathbf{u}), \nabla \mathbf{v}_{\mathcal{N}}) + (\nabla \mathbf{u}, \nabla \mathbf{v}_{\mathcal{N}}) \\ &\quad - (\nabla \mathbf{w}_{\mathcal{N}}, \nabla \mathbf{v}_{\mathcal{N}})_{\mathcal{N}} \\ &\lesssim (|\mathbf{u} - \mathbf{w}_{\mathcal{N}}|_{1,\Omega} + |\mathbf{u} - \hat{\pi}_{1,M}^{x,0} \pi_{1,N-1}^{y,0} \mathbf{u}|_{1,\Omega}) |\mathbf{v}_{\mathcal{N}}|_{1,\Omega} \\ &\quad + |\mathbf{w}_{\mathcal{N}} - \hat{\pi}_{1,M}^{x,0} \pi_{1,N-1}^{y,0} \mathbf{u}|_{1,\Omega} |\mathbf{v}_{\mathcal{N}}|_{1,\Omega} \\ &\lesssim (|\mathbf{u} - \mathbf{w}_{\mathcal{N}}|_{1,\Omega} + |\mathbf{u} - \hat{\pi}_{1,M}^{x,0} \pi_{1,N-1}^{y,0} \mathbf{u}|_{1,\Omega}) |\mathbf{v}_{\mathcal{N}}|_{1,\Omega}. \end{aligned}$$

This result, together with Theorem IV.2.5 and Remark IV.2.7 of [3], leads to

$$\begin{aligned} |\mathbf{u} - \mathbf{u}_{\mathcal{N}}|_{1,\Omega} &\lesssim \inf_{\mathbf{w}_{\mathcal{N}} \in V_{\mathcal{N}}} \left(|\mathbf{u} - \mathbf{w}_{\mathcal{N}}|_{1,\Omega} + \sup_{\mathbf{v}_{\mathcal{N}} \in X_{\mathcal{N}}} \frac{(\nabla \mathbf{w}_{\mathcal{N}}, \nabla \mathbf{v}_{\mathcal{N}}) - (\nabla \mathbf{w}_{\mathcal{N}}, \nabla \mathbf{v}_{\mathcal{N}})_{\mathcal{N}}}{|\mathbf{v}_{\mathcal{N}}|_{1,\Omega}} \right) \\ &\quad + \inf_{q_{\mathcal{N}} \in M_{\mathcal{N}}} \|p - q_{\mathcal{N}}\|_{0,\Omega} + \sup_{\mathbf{v}_{\mathcal{N}} \in X_{\mathcal{N}}} \frac{(\mathbf{f}, \mathbf{v}_{\mathcal{N}})_{\mathcal{N}} - (\mathbf{f}, \mathbf{v}_{\mathcal{N}})}{|\mathbf{v}_{\mathcal{N}}|_{1,\Omega}} \\ &\lesssim \inf_{\mathbf{w}_{\mathcal{N}} \in V_{\mathcal{N}}} |\mathbf{u} - \mathbf{w}_{\mathcal{N}}|_{1,\Omega} + |\mathbf{u} - \hat{\pi}_{1,M}^{x,0} \pi_{1,N-1}^{y,0} \mathbf{u}|_{1,\Omega} + \inf_{q_{\mathcal{N}} \in M_{\mathcal{N}}} \|p - q_{\mathcal{N}}\|_{0,\Omega} \\ &\quad + \sup_{\mathbf{v}_{\mathcal{N}} \in X_{\mathcal{N}}} \frac{(\mathbf{f}, \mathbf{v}_{\mathcal{N}})_{\mathcal{N}} - (\mathbf{f}, \mathbf{v}_{\mathcal{N}})}{|\mathbf{v}_{\mathcal{N}}|_{1,\Omega}} \\ &\lesssim M \inf_{\mathbf{v}_{\mathcal{N}} \in X_{\mathcal{N}}} |\mathbf{u} - \mathbf{v}_{\mathcal{N}}|_{1,\Omega} + |\mathbf{u} - \hat{\pi}_{1,M}^{x,0} \pi_{1,N-1}^{y,0} \mathbf{u}|_{1,\Omega} \\ &\quad + \inf_{q_{\mathcal{N}} \in M_{\mathcal{N}}} \|p - q_{\mathcal{N}}\|_{0,\Omega} + \sup_{\mathbf{v}_{\mathcal{N}} \in X_{\mathcal{N}}} \frac{(\mathbf{f}, \mathbf{v}_{\mathcal{N}})_{\mathcal{N}} - (\mathbf{f}, \mathbf{v}_{\mathcal{N}})}{|\mathbf{v}_{\mathcal{N}}|_{1,\Omega}}. \end{aligned}$$

And,

$$\begin{aligned} \|p - p_{\mathcal{N}}\|_{0,\Omega} &\lesssim M \left[|\mathbf{u} - \hat{\pi}_{1,M}^{x,0} \pi_{1,N-1}^{y,0} \mathbf{u}|_{1,\Omega} + \inf_{q_{\mathcal{N}} \in M_{\mathcal{N}}} \|p - q_{\mathcal{N}}\|_{0,\Omega} \right. \\ &\quad \left. + M \inf_{\mathbf{v}_{\mathcal{N}} \in X_{\mathcal{N}}} |\mathbf{u} - \mathbf{v}_{\mathcal{N}}|_{1,\Omega} + \sup_{\mathbf{v}_{\mathcal{N}} \in X_{\mathcal{N}}} \frac{(\mathbf{f}, \mathbf{v}_{\mathcal{N}})_{\mathcal{N}} - (\mathbf{f}, \mathbf{v}_{\mathcal{N}})}{|\mathbf{v}_{\mathcal{N}}|_{1,\Omega}} \right]. \end{aligned}$$

Now, for all $\mathbf{f}_{M,N-1} \in \hat{\mathbb{P}}_{M,N-1}(\Omega)^2$, we have

$$(\mathbf{f}, \mathbf{v}_{\mathcal{N}})_{\mathcal{N}} - (\mathbf{f}, \mathbf{v}_{\mathcal{N}}) \lesssim (\|\mathbf{f} - I_N^y \hat{I}_M^x \mathbf{f}\|_{0,\Omega} + \|\mathbf{f} - \mathbf{f}_{M,N-1}\|_{0,\Omega}) |\mathbf{v}_{\mathcal{N}}|_{1,\Omega}.$$

We know from the interpolation results of I_N^y and \hat{I}_M^x that

$$\begin{aligned} \|\mathbf{f} - I_N^y \hat{I}_M^x \mathbf{f}\|_{0,\Omega} &\leq \|\mathbf{f} - I_N^y \mathbf{f}\|_{0;0} + \|I_N^y (\mathbf{f} - \hat{I}_M^x \mathbf{f})\|_{0;0} \\ &\lesssim N^{-s} \|\mathbf{f}\|_{0;s} + \|\mathbf{f} - \hat{I}_M^x \mathbf{f}\|_{0;1} \\ &\lesssim N^{-s} \|\mathbf{f}\|_{0;s} + (\ln M)^{\frac{1}{2}} M^{1-\frac{s}{2}} \|\mathbf{f}\|_{B^{r-1;1}}. \end{aligned}$$

Furthermore,

$$\|\mathbf{f} - \mathbf{f}_{M,N-1}\|_{0,\Omega} \leq \|\mathbf{f} - \pi_{N-1}^y \circ \hat{\pi}_M^x \mathbf{f}\|_{0;0} \lesssim N^{-s} \|\mathbf{f}\|_{0;s} + M^{-\frac{s}{2}} \|\mathbf{f}\|_{A^r;0}.$$

Combining the above two inequalities, we get

$$(\mathbf{f}, \mathbf{v}_{\mathcal{N}})_{\mathcal{N}} - (\mathbf{f}, \mathbf{v}_{\mathcal{N}}) \lesssim \left((\ln M)^{\frac{1}{2}} M^{1-\frac{r}{2}} + N^{-s} \right) \|\mathbf{f}\|_{\bar{B}^{r;s}} |\mathbf{v}_{\mathcal{N}}|_{1,\Omega}.$$

Now we estimate $\inf_{\mathbf{v}_{\mathcal{N}} \in X_{\mathcal{N}}} |\mathbf{u} - \mathbf{v}_{\mathcal{N}}|_{1,\Omega}$. Since

$$|\mathbf{u} - \mathbf{v}_{\mathcal{N}}|_{1,\Omega} = \left\| \frac{\partial}{\partial x} (\mathbf{u} - \mathbf{v}_{\mathcal{N}}) \right\|_{0,\Omega} + \left\| \frac{\partial}{\partial y} (\mathbf{u} - \mathbf{v}_{\mathcal{N}}) \right\|_{0,\Omega},$$

by choosing $\mathbf{v}_{\mathcal{N}} = \hat{\pi}_{1,M}^{x,0} \pi_{1,N}^{y,0} \mathbf{u}$, we know from the approximation results of $\hat{\pi}_{1,M}^{x,0}$ and $\pi_{1,N}^{y,0}$ that

$$\begin{aligned} \left\| \frac{\partial}{\partial x} (\mathbf{u} - \mathbf{v}_{\mathcal{N}}) \right\|_{0,\Omega} &\leq \left\| \frac{\partial}{\partial x} (\mathbf{u} - \hat{\pi}_{1,M}^{x,0} \mathbf{u}) \right\|_{0,\Omega} + \left\| \frac{\partial}{\partial x} \hat{\pi}_{1,M}^{x,0} (\mathbf{u} - \pi_{1,N}^{y,0} \mathbf{u}) \right\|_{0,\Omega} \\ &\lesssim M^{\frac{1}{2}-\frac{m}{2}} |\partial_x (e^{x/2} \mathbf{u})|_{\hat{A}^{m-1;0}} + N^{1-n} \left\| \frac{\partial}{\partial x} \hat{\pi}_{1,M}^{x,0} \mathbf{u} \right\|_{0;n-1} \\ &\lesssim M^{\frac{1}{2}-\frac{m}{2}} \|\mathbf{u}\|_{A^{m;0}} + N^{1-n} \left\| \frac{\partial}{\partial x} (e^{x/2} \mathbf{u}) \right\|_{\omega_0;n-1} \\ &\lesssim M^{\frac{1}{2}-\frac{m}{2}} \|\mathbf{u}\|_{A^{m;0}} + N^{1-n} \|\mathbf{u}\|_{1;n-1}; \\ \left\| \frac{\partial}{\partial y} (\mathbf{u} - \mathbf{v}_{\mathcal{N}}) \right\|_{0,\Omega} &\leq \left\| \frac{\partial}{\partial y} (\mathbf{u} - \pi_{1,N}^{y,0} \mathbf{u}) \right\|_{0,\Omega} + \left\| \frac{\partial}{\partial y} \pi_{1,N}^{y,0} (\mathbf{u} - \hat{\pi}_{1,M}^{x,0} \mathbf{u}) \right\|_{0,\Omega} \\ &\lesssim N^{1-n} \|\mathbf{u}\|_{0;n} + M^{\frac{1}{2}-\frac{m}{2}} \left| e^{x/2} \frac{\partial}{\partial y} \pi_{1,N-1}^{y,0} \mathbf{u} \right|_{\hat{A}^{m-1;0}} \\ &\lesssim N^{1-n} \|\mathbf{u}\|_{0;n} + M^{\frac{1}{2}-\frac{m}{2}} \|\mathbf{u}\|_{A^{m-1;1}}. \end{aligned}$$

Combining the above two results leads to

$$\inf_{\mathbf{v}_{\mathcal{N}} \in X_{\mathcal{N}}} |\mathbf{u} - \mathbf{v}_{\mathcal{N}}|_{1,\Omega} \leq |\mathbf{u} - \hat{\pi}_{1,M}^{x,0} \pi_{1,N}^{y,0} \mathbf{u}|_{1,\Omega} \lesssim (M^{\frac{1}{2}-\frac{m}{2}} + N^{1-n}) \|\mathbf{u}\|_{Y^{m;n}}.$$

Similarly, we have

$$|\mathbf{u} - \hat{\pi}_{1,M}^{x,0} \pi_{1,N-1}^{y,0} \mathbf{u}|_{1,\Omega} \lesssim (M^{\frac{1}{2}-\frac{m}{2}} + N^{1-n}) \|\mathbf{u}\|_{Y^{m;n}}.$$

Now it remains to estimate $\inf_{q_{\mathcal{N}} \in M_{\mathcal{N}}} \|p - q_{\mathcal{N}}\|_{0,\Omega}$. By using the known properties of the projectors $\hat{\pi}_M^x$ and π_N^y in [16], it follows that

$$\begin{aligned} \inf_{q_{\mathcal{N}} \in M_{\mathcal{N}}} \|p - q_{\mathcal{N}}\|_{0,\Omega} &\leq \|p - \pi_{N-2}^y \circ \hat{\pi}_{M-1}^x p\|_{0;0} \\ &\lesssim (N-2)^{1-n} \|p\|_{0;n-1} + \|p - \hat{\pi}_{M-1}^x p\|_{0;0} \\ &\lesssim N^{1-n} \|p\|_{0;n-1} + M^{\frac{1}{2}-\frac{m}{2}} \|p\|_{A^{m-1;0}} \\ &\lesssim (M^{\frac{1}{2}-\frac{m}{2}} + N^{1-n}) \|p\|_{A^{m-1;n-1}}. \end{aligned}$$

As a direct consequence of the above estimates, we finally obtain

$$\begin{aligned} \|\mathbf{u} - \mathbf{u}_{\mathcal{N}}\|_{1,\Omega} &\lesssim (M^{\frac{1}{2}-\frac{m}{2}} + N^{1-n}) (M \|\mathbf{u}\|_{Y^{m;n}} + \|p\|_{A^{m-1;n-1}}) \\ &\quad + ((\ln M)^{\frac{1}{2}} M^{1-\frac{r}{2}} + N^{-s}) \|\mathbf{f}\|_{\bar{B}^{r;s}}, \\ \|p - p_{\mathcal{N}}\|_{0,\Omega} &\lesssim M \left[(M^{\frac{1}{2}-\frac{m}{2}} + N^{1-n}) (M \|\mathbf{u}\|_{Y^{m;n}} + \|p\|_{A^{m-1;n-1}}) \right. \\ &\quad \left. + ((\ln M)^{\frac{1}{2}} M^{1-\frac{r}{2}} + N^{-s}) \|\mathbf{f}\|_{\bar{B}^{r;s}} \right]. \quad \square \end{aligned}$$

5. Numerical results and discussions. We start with some implementation details. Let $\mathbf{u}_N = (u_N^1, u_N^2)^t$, and we write

$$u_N^r(x, y) = \sum_{j=1}^{N-1} \sum_{i=1}^M u_N^r(\hat{\xi}_i, \xi_j) \hat{h}_i(x) h_j(y), \quad r = 1, 2,$$

where $h_j \in \mathbb{P}_N(\Lambda)$ ($0 \leq j \leq N$) are the Legendre–Gauss–Lobatto interpolants satisfying $h_j(\xi_q) = \delta_{qj}$, while $\hat{h}_i \in \hat{\mathbb{P}}_M(R^+)$ ($0 \leq i \leq M$) are the Laguerre–Gauss–Radau interpolants satisfying $\hat{h}_i(\hat{\xi}_q) = \delta_{qi}$. We use $\underline{\mathbf{u}}_N$ to denote the vector consisting of the values of \mathbf{u}_N at the nodes $(\hat{\xi}_i, \xi_j)_{1 \leq i \leq M, 1 \leq j \leq N-1}$.

Similarly, we write

$$p_N(x, y) = \sum_{j=1}^{N-1} \sum_{i=1}^M p_N(\hat{\zeta}_i, \zeta_j) \hat{\ell}_i(x) \ell_j(y),$$

where $(\hat{\zeta}_i)_{1 \leq i \leq M}$ and $(\zeta_j)_{1 \leq j \leq N-1}$ are, respectively, the Laguerre–Gauss and Legendre–Gauss points, and $\ell_j \in \mathbb{P}_{N-2}(\Lambda)$ ($1 \leq j \leq N-1$) are the Legendre–Gauss interpolants satisfying $\ell_j(\xi_q) = \delta_{qj}$, while $\hat{\ell}_i \in \hat{\mathbb{P}}_{M-1}(R^+)$ ($1 \leq i \leq M$) are the Laguerre–Gauss interpolants satisfying $\hat{\ell}_i(\hat{\zeta}_q) = \delta_{qi}$. We use $\underline{\mathbf{p}}_N$ to denote the vector consisting of the values of p_N at the nodes $(\hat{\zeta}_i, \zeta_j)_{1 \leq i \leq M, 1 \leq j \leq N-1}$.

Inserting the expansions of \mathbf{u}_N and p_N into (2.13), the resulting set of algebraic equations can be written under a matrix form:

$$(5.1) \quad \mathbf{A}_N \underline{\mathbf{u}}_N + \mathbf{D}_N \underline{\mathbf{p}}_N = \mathbf{B}_N \underline{\mathbf{f}}_N,$$

$$(5.2) \quad \mathbf{D}_N^T \underline{\mathbf{u}}_N = 0,$$

where $\underline{\mathbf{f}}_N$ is a vector representation of the \mathbf{f} at the nodes $(\hat{\xi}_i, \xi_j)$. The matrices \mathbf{A}_N , \mathbf{D}_N , and \mathbf{B}_N are block-diagonal matrices with 2 blocks each. The blocks of \mathbf{A}_N are the discrete Laplace operators, and those of \mathbf{D}_N are associated to the different components of the discrete gradient operators, while blocks of \mathbf{B}_N are the mass matrices with respect to each component of \mathbf{f} .

Eliminating $\underline{\mathbf{u}}_N$ from (5.1)–(5.2), we obtain

$$(5.3) \quad \underbrace{\mathbf{D}_N^T \mathbf{A}_N^{-1} \mathbf{D}_N}_{\mathbf{S}_N} \underline{\mathbf{p}}_N = \mathbf{D}_N^T \mathbf{A}_N^{-1} \mathbf{B}_N \underline{\mathbf{f}}_N.$$

The matrix $\mathbf{S}_N := \mathbf{D}_N^T \mathbf{A}_N^{-1} \mathbf{D}_N$ is usually referred as the Uzawa matrix. A typical procedure for solving (5.1)–(5.2) is to first solve $\underline{\mathbf{p}}_N$ from (5.3) and then solve $\underline{\mathbf{u}}_N$ from the Poisson equation (5.1) with known $\underline{\mathbf{p}}_N$.

The Uzawa matrix is of dimension $M \times (N-1)$, full, symmetric, and semidefinite. A usual procedure is to use a preconditioned conjugate gradient procedure with the Gauss mass matrix $\tilde{\mathbf{B}}_N$ as a preconditioner [3, 7, 9, 14]. Each outer iteration requires the inversion of two Laplace operators (\mathbf{A}_N matrix), which can be carried out by the fast diagonalization method (see [13]). Hence, the efficiency of the method is dictated by the condition number κ_N of $\mathbf{B}_N^{-1} \mathbf{S}_N$. Another important consequence of the inf-sup constant is that $\kappa_N = \frac{1}{\beta_N^2}$ [14].

The first computational investigation is concerned with the sharpness of the lower bound on the inf-sup constant derived in section 3. In the left of Figure 1, we plot

FIG. 1. Left: inf-sup constant β_N vs. M in log-log scale; right: inf-sup constant β_N vs. N .

FIG. 2. Spectra of the Uzawa operator for three different values of N with $M = N$.

the variations of β_N versus (vs.) M in log-log scale for several N . We observe that β_N is independent of N while it decays as $\frac{1}{M}$. In the right of Figure 1, we plot the variations of β_N vs. N for several M . We observe that β_N remains to be constant as we vary N with M fixed. These results are fully consistent with Theorem 3.1, indicating that our estimate for the inf-sup constant is sharp.

In view of inverting the Uzawa operator, the knowledge of the eigenvalues' distribution of the matrix $\mathbf{B}_N^{-1}\mathbf{S}_N$ may help to design adapted preconditioners for (5.3). The efficiency of the iterating methods depends on how the preconditioners affect the eigenvalues of \mathbf{S}_N . In Figure 2 we plot all of the eigenvalues of $\tilde{\mathbf{B}}_N^{-1}\mathbf{S}_N$ for some values of $M = N \in \{12, 16, 24\}$.

The first feature of the spectra is the similarity of their distribution for different values of N with $M = N$. Another interesting aspect is a strong concentration of the eigenvalues around the largest value 1. It is known that this type of clustering is very advantageous for the conjugate gradient iteration since the contribution of the eigenspaces associated with a given multiple eigenvalue is resolved in only one iteration.

FIG. 3. The velocity (\circ) and pressure (\square) errors as a function of N with $M = N$: left, in L^2 norm; right, in L^∞ norm.

We now present some numerical tests to validate the error estimates. We consider the Stokes problem with the following analytical solution:

$$\mathbf{u} = \begin{pmatrix} \sin(x) \cos(y) e^{-x} \\ (\sin(x) - \cos(x)) \sin(y) e^{-x} \end{pmatrix}, \quad p = \cos(x) \cos(y) e^{-x}.$$

In Figure 3, we plot, in a semilogarithmic scale, the L^2 -velocity and the L^2 -pressure errors (top figure), and the L^∞ -velocity and the L^∞ -pressure errors (bottom figure) with respect to N with $M = N$. We observe that the errors converge exponentially, which is a typical behavior for spectral methods with analytical solutions.

Finally, in order to justify the use of compatible discrete velocity and pressure spaces, we show via a simple test that the equal-order velocity-pressure approximation $\mathbb{P}_{M,N}(\Omega)^2 \times \mathbb{P}_{M,N}(\Omega)$ is ill-posed. In Figure 4, we present the velocity and the pressure errors in the L^2 -norm as a function of N with $M = N$. Obviously the pressure fails to converge when the polynomial degree increases. The reason for this failure is that there are spurious pressure modes in the pressure space, similar to the well-known case of the Legendre–Legendre $P_N^2 - P_N$ method for the Stokes problem in a rectangular domain.

FIG. 4. The velocity and pressure errors as a function of $N(M = N)$ by the incompatible $\mathbb{P}_{M,N}(\Omega)^2 \times \mathbb{P}_{M,N}(\Omega)$ method.

In summary, we have presented a mixed Laguerre–Legendre spectral method for the Stokes problem on a semi-infinite channel. We established the well-posedness of this method by deriving a lower bound on the inf-sup constant and presented numerical results which indicated that the derived lower bound is sharp. We have also derived error estimates by using the inf-sup condition and the Laguerre and Legendre approximation properties.

OPTIMAL IMPORTANCE SAMPLING PARAMETER SEARCH FOR LÉVY PROCESSES VIA STOCHASTIC APPROXIMATION*

REIICHIRO KAWAI†

Abstract. The author proposes stochastic approximation methods of finding the optimal measure change by the exponential tilting for Lévy processes in Monte Carlo importance sampling variance reduction. In accordance with the structure of the underlying Lévy measure, either a constrained or unconstrained algorithm of the stochastic approximation is chosen. For both cases, the almost sure convergence to a unique stationary point is proved. Numerical examples are presented to illustrate the effectiveness of our method.

Key words. Esscher transform, Girsanov theorem, Monte Carlo simulation, infinitely divisible distribution, stochastic approximation algorithm, variance reduction

1. Introduction. The importance sampling method is aimed at reducing the variance of independently and identically distributed (i.i.d.) Monte Carlo summands by appropriately transforming the underlying probability measure, from which interested random variables or stochastic processes are generated, so as to put more weight on important events and less on undesirable ones. Due to its practical effectiveness, it has long been thought of as one of the most important variance reduction methods in the Monte Carlo simulation and has been intensively studied with a view towards a wide range of applications, such as mathematical finance, queueing theory, and sequential analysis, to mention just a few. For its principle with some numerical examples, see, for instance, section 4.6 of Glasserman [7].

In the importance sampling “variance” reduction, the optimal measure change means nothing but the one attaining the minimal variance of i.i.d. Monte Carlo summands. In the Gaussian framework, the Girsanov measure change is often indexed by a single parameter, that is, the drift parameter, and several attempts have been made to find its optimum. In financial applications, for example, Glasserman, Heidelberger, and Shahabuddin [6] propose an optimization procedure to find a nearly optimal measure change in pricing financial derivatives, while Su and Fu [14] and Arouna [1] apply the stochastic approximation so as to search for the root of the gradient of the Monte Carlo variance with respect to the measure change parameter.

The aim of the present work is to apply the idea of [1, 14] to Lévy processes without the Brownian motion, or equivalently after discretization, infinitely divisible laws without Gaussian component. In general, the measure change for Lévy processes involves every single jump, which forms the sample paths. (See section 33 of Sato [12] for details. For an importance sampling method with such intricate measure changes, see Kawai [8].) In this paper, we, however, restrict our attention to the simplest measure change, often called the Esscher transform, which has only to look at the terminal marginals. The Esscher transform is nothing but the well-known exponential

tilting of laws and is thus indexed by a single (multidimensional) parameter. As we will investigate later, a crucial difficulty in the case of Lévy processes without Gaussian component is that, depending on the structure of the underlying Lévy measure, the exponential tilting parameter might have to stay in a suitable compact set, while the drift parameter of the Gaussian distribution may be arbitrarily taken.

The rest of the paper is organized as follows. Section 2 recalls the Esscher transform and the principle of the importance sampling variance reduction, and constructs the basis of our analysis. In section 3, the almost sure convergence of the stochastic approximation is proved separately for the constrained and unconstrained algorithms, depending on the structure of the underlying Lévy measure. Section 4 illustrates the effectiveness of our method via numerical examples for both constrained and unconstrained stochastic approximation algorithms. Finally, section 5 concludes.

2. Preliminaries. Let us begin with some notations which will be used throughout the text. \mathbb{N} is the collection of all positive numbers, with $\mathbb{N}_0 := \{0\} \cup \mathbb{N}$. \mathbb{R}^d is the d -dimensional Euclidean space with the norm $\|\cdot\|$ and the inner product $\langle \cdot, \cdot \rangle$, $\mathbb{R}_0^d := \mathbb{R}^d \setminus \{0\}$ and $\mathcal{B}(\mathbb{R}_0^d)$ is the Borel σ -field of \mathbb{R}_0^d . $(\Omega, \mathcal{F}, \mathbb{P})$ is our underlying probability space. $\text{Leb}(\cdot)$ denotes the Lebesgue measure, while $\mathbb{P}|_{\mathcal{F}_t}$ is the restriction of a probability measure \mathbb{P} to the σ -field \mathcal{F}_t . Denote by ∇ the gradient, and by $\text{Hess}[\cdot]$ the Hessian matrix. The interval $(0, -1]$ is understood to be $[-1, 0)$. The expression $f(x) \sim g(x)$ means $f(x)/g(x)$ tends to 1. The identity in law is denoted by $\stackrel{L}{\sim}$. We say that a stochastic process $\{X_t : t \geq 0\}$ in \mathbb{R}^d is a Lévy process if it has independent and stationary increments, if it is continuous in probability, and if $X_0 = 0$, *a.s.* By the Lévy–Khinchine representation theorem, the characteristic function of its marginal law is uniquely given by

$$\mathbb{E} \left[e^{i\langle y, X_t \rangle} \right] = \exp \left[t \left(i\langle y, \gamma \rangle - \frac{1}{2} \langle y, Ay \rangle + \int_{\mathbb{R}_0^d} \left(e^{i\langle y, z \rangle} - 1 - i\langle y, z \rangle \mathbb{1}_{(0,1]}(\|z\|) \right) \nu(dz) \right) \right],$$

where $\gamma \in \mathbb{R}^d$, A is a symmetric nonnegative-definite $d \times d$ matrix, and ν is a Lévy measure on \mathbb{R}_0^d , that is, $\int_{\mathbb{R}_0^d} (\|z\|^2 \wedge 1) \nu(dz) < +\infty$. If the above holds, then we say that the Lévy process $\{X_t : t \geq 0\}$ is generated by the triplet (γ, A, ν) . *In this paper, we restrict our attention to pure-jump Lévy processes, that is, we set $A \equiv 0$ throughout. Moreover, we also assume that all components are nondegenerate.* A function $f : \mathbb{R}^d \mapsto [0, \infty)$ is said to be submultiplicative if there exists a positive constant a such that $f(x + y) \leq af(x)f(y)$ for $x, y \in \mathbb{R}^d$. Letting $c \in \mathbb{R}$, $\gamma \in \mathbb{R}^d$, and $b > 0$, if $f(x)$ is submultiplicative on \mathbb{R}^d , then $f(cx + \gamma)^b$ is submultiplicative, and the functions $\|x\| \vee 1$, $e^{\langle c, x \rangle}$ are submultiplicative, and a product of two submultiplicative functions is submultiplicative. We recall an important moment property of Lévy processes, which will be used often in what follows.

THEOREM 2.1 (Sato [12], Theorem 25.3). *Let f be a submultiplicative, locally bounded, measurable function on \mathbb{R}^d , and let $\{X_t : t \geq 0\}$ be a Lévy process in \mathbb{R}^d with Lévy measure ν . Then, $\mathbb{E}[f(X_t)]$ is finite for every $t > 0$ if and only if $\int_{\|z\|>1} f(z)\nu(dz) < +\infty$.*

2.1. Esscher transform. Among the density transformations of Lévy processes, there is a simple class ending up with looking only at the marginals, which is built via the exponential tilting. The class is often called the Esscher transform in mathematical finance and actuarial science. Let $\{X_t : t \geq 0\}$ be a Lévy process in \mathbb{R}^d generated by

$(\gamma, 0, \nu)$, and let $(\mathcal{F}_t)_{t \geq 0}$ be the natural filtration of $\{X_t : t \geq 0\}$. Define

$$\Lambda_1 := \left\{ \lambda \in \mathbb{R}^d : \mathbb{E}_{\mathbb{P}} \left[e^{\langle \lambda, X_1 \rangle} \right] < +\infty \right\} = \left\{ \lambda \in \mathbb{R}^d : \int_{\|z\| > 1} e^{\langle \lambda, z \rangle} \nu(dz) < +\infty \right\},$$

where the second equality holds by Theorem 2.1. We impose the condition $\text{Leb}(\Lambda_1) > 0$ throughout. Clearly, the set Λ_1 contains the origin and is convex. For $\lambda \in \Lambda_1$, we denote by φ the cumulant generating function of the marginal law at unit time of $\{X_t : t \geq 0\}$ under the probability measure \mathbb{P} ; that is, $\varphi(\lambda) := \ln \mathbb{E}_{\mathbb{P}}[e^{\langle \lambda, X_1 \rangle}]$. For ease in notation, we also write $\varphi_t(\lambda) := \ln \mathbb{E}_{\mathbb{P}}[e^{\langle \lambda, X_t \rangle}]$, $t > 0$, in view of

$$\varphi_t(\lambda) = \ln \mathbb{E}_{\mathbb{P}} \left[e^{\langle \lambda, X_t \rangle} \right] = t \ln \mathbb{E}_{\mathbb{P}} \left[e^{\langle \lambda, X_1 \rangle} \right] = t\varphi(\lambda),$$

where the second equality holds by the infinite divisibility of the marginal laws of Lévy processes. Note that $\varphi(\lambda)$ is continuous and $\nabla\varphi(\lambda)$ is well defined in $\lambda \in \Lambda_1$. Under the probability measure \mathbb{Q}_λ , where $\lambda \in \Lambda_1$ and which is defined via the Radon–Nikodym derivative, for every $t \in (0, +\infty)$,

$$\left. \frac{d\mathbb{Q}_\lambda}{d\mathbb{P}} \right|_{\mathcal{F}_t} = \frac{e^{\langle \lambda, X_t \rangle}}{\mathbb{E}_{\mathbb{P}} \left[e^{\langle \lambda, X_t \rangle} \right]} = e^{\langle \lambda, X_t \rangle - \varphi_t(\lambda)}, \quad \mathbb{P}\text{-a.s.},$$

the stochastic process $\{X_t : t \geq 0\}$ is again a Lévy process generated by $(\gamma_\lambda, 0, \nu_\lambda)$, where $\gamma_\lambda = \gamma + \int_{\|z\| \leq 1} z(\nu_\lambda - \nu)(dz)$, and

$$(2.1) \quad \nu_\lambda(dz) = e^{\langle \lambda, z \rangle} \nu(dz).$$

Then, the probability measures $\mathbb{P}|_{\mathcal{F}_t}$ and $\mathbb{Q}_\lambda|_{\mathcal{F}_t}$ are mutually absolutely continuous for every $t \in (0, +\infty)$. We also have $\mathbb{E}_{\mathbb{Q}_\lambda} [e^{-\langle \lambda, X_1 \rangle}] < +\infty$, and

$$\left. \frac{d\mathbb{P}}{d\mathbb{Q}_\lambda} \right|_{\mathcal{F}_t} = \left(\left. \frac{d\mathbb{Q}_\lambda}{d\mathbb{P}} \right|_{\mathcal{F}_t} \right)^{-1} = e^{-\langle \lambda, X_t \rangle + \varphi_t(\lambda)}, \quad \mathbb{Q}_\lambda\text{-a.s.}$$

For $t > 0$, let p be a probability density function on \mathbb{R}^d of the random vector X_t under \mathbb{P} , provided that it is well defined. Then, a density function p_λ of X_t under \mathbb{Q}_λ is given by

$$(2.2) \quad p_\lambda(x) = e^{\langle \lambda, x \rangle - \varphi_t(\lambda)} p(x), \quad x \in \mathbb{R}^d.$$

2.2. Importance sampling variance reduction. Suppose we are interested in evaluating

$$C := \mathbb{E}_{\mathbb{P}}[F(X)]$$

by Monte Carlo simulation, where $F(X) := F(\{X_t : t \in [0, T]\}) \in L^2(\Omega, \mathcal{F}_T, \mathbb{P})$, and assume $\mathbb{P}(F(X) \neq 0) > 0$. In view of the equality

$$\begin{aligned} \mathbb{E}_{\mathbb{P}}[F(X)] &= \mathbb{E}_{\mathbb{Q}_\lambda} \left[\left. \frac{d\mathbb{P}}{d\mathbb{Q}_\lambda} \right|_{\mathcal{F}_T} F(X) \right] \\ &= \mathbb{E}_{\mathbb{Q}_\lambda} \left[\left(\left. \frac{d\mathbb{Q}_\lambda}{d\mathbb{P}} \right|_{\mathcal{F}_T} \right)^{-1} F(X) \right] \\ &= \mathbb{E}_{\mathbb{Q}_\lambda} \left[e^{-\langle \lambda, X_T \rangle + \varphi_T(\lambda)} F(X) \right], \end{aligned}$$

define a set

$$\Lambda_2 := \Lambda_1 \cap \left\{ \lambda \in \mathbb{R}^d : \mathbb{E}_{\mathbb{P}} \left[e^{-\langle \lambda, X_T \rangle} F(X)^2 \right] < +\infty \right\},$$

and suppose that $\text{Leb}(\Lambda_2) > 0$. Let us now give a lemma, whose proof will be often adapted in what follows.

LEMMA 2.2. *The set Λ_2 is convex.*

Proof. For any $\lambda_1, \lambda_2 \in \Lambda_2$, and for any $m \in (0, 1)$ and $n = 1 - m$, the Hölder inequality gives

$$\mathbb{E}_{\mathbb{P}} \left[e^{-\langle m\lambda_1 + n\lambda_2, X_T \rangle} F(X)^2 \right] \leq \mathbb{E}_{\mathbb{P}} \left[e^{-\langle \lambda_1, X_T \rangle} F(X)^2 \right]^m \mathbb{E}_{\mathbb{P}} \left[e^{-\langle \lambda_2, X_T \rangle} F(X)^2 \right]^n < +\infty.$$

The claim then follows from the convexity of Λ_1 . \square

For $\lambda \in \Lambda_2$, the variance under the probability measure \mathbb{Q}_λ is given by

$$\begin{aligned} V(\lambda) &:= \mathbb{E}_{\mathbb{Q}_\lambda} \left[\left(\frac{d\mathbb{P}}{d\mathbb{Q}_\lambda} \Big|_{\mathcal{F}_T} \right)^2 F(X)^2 \right] - C^2 \\ &= \mathbb{E}_{\mathbb{P}} \left[\left(\frac{d\mathbb{Q}_\lambda}{d\mathbb{P}} \Big|_{\mathcal{F}_T} \right)^{-1} F(X)^2 \right] - C^2 \\ &= \mathbb{E}_{\mathbb{P}} \left[e^{-\langle \lambda, X_T \rangle + \varphi_T(\lambda)} F(X)^2 \right] - C^2. \end{aligned}$$

Define also a set

$$\Lambda_3 := \Lambda_2 \cap \left\{ \lambda \in \mathbb{R}^d : \mathbb{E}_{\mathbb{P}} \left[\|X_T\|^2 e^{-\langle \lambda, X_T \rangle} F(X)^2 \right] < +\infty \right\},$$

and assume that $\text{Leb}(\Lambda_3) > 0$.

PROPOSITION 2.3. *The set Λ_3 is convex and $V(\lambda)$ is strictly convex in $\lambda \in \Lambda_3$.*

Proof. The convexity of Λ_3 can be proved in a similar manner to the proof of Lemma 2.2.

Since $\lambda \in \Lambda_3$, by the Hölder inequality, we have

$$\mathbb{E}_{\mathbb{P}} \left[\|X_T\| e^{-\langle \lambda, X_T \rangle} F(X)^2 \right]^2 \leq \mathbb{E}_{\mathbb{P}} \left[e^{-\langle \lambda, X_T \rangle} F(X)^2 \right] \mathbb{E}_{\mathbb{P}} \left[\|X_T\|^2 e^{-\langle \lambda, X_T \rangle} F(X)^2 \right] < +\infty,$$

and thus with the help of the dominated convergence theorem, we obtain the gradient

$$\nabla V(\lambda) = \mathbb{E}_{\mathbb{P}} \left[(\nabla \varphi_T(\lambda) - X_T) e^{-\langle \lambda, X_T \rangle + \varphi_T(\lambda)} F(X)^2 \right],$$

and also the Hessian

$$\begin{aligned} \text{Hess}[V(\lambda)] &= \mathbb{E}_{\mathbb{P}} \left[\left(\text{Hess}[\varphi_T(\lambda)] + (\nabla \varphi_T(\lambda) - X_T)(\nabla \varphi_T(\lambda) - X_T)' \right) e^{-\langle \lambda, X_T \rangle + \varphi_T(\lambda)} F(X)^2 \right]. \end{aligned}$$

Then, we have for $y \in \mathbb{R}_0^d$,

$$\begin{aligned} y' \text{Hess}[V(\lambda)] y &= \mathbb{E}_{\mathbb{P}} \left[\left(y' \text{Hess}[\varphi_T(\lambda)] y + \langle y, \nabla \varphi_T(\lambda) - X_T \rangle^2 \right) e^{-\langle \lambda, X_T \rangle + \varphi_T(\lambda)} F(X)^2 \right] > 0, \end{aligned}$$

since $\text{Hess}[\varphi_T(\lambda)]$ reduces to the variance-covariance matrix of the random vector X_T under the probability measure \mathbb{Q}_λ , which is clearly positive definite. \square

Remark 2.4. The definition of the sets Λ_2 and Λ_3 is less intuitive and is of less practical use. We may instead give more intuitive definition in connection with the Lévy measure by giving up some part of its domain as

$$\Lambda'_2 = \left\{ \lambda \in \mathbb{R}^d : \int_{\|z\|>1} e^{-q\langle\lambda,z\rangle} \nu(dz) < +\infty, \mathbb{E}_{\mathbb{P}} [|F(X)|^{2p}] < +\infty, \frac{1}{p} + \frac{1}{q} = 1 \text{ for some } p > 1 \right\},$$

and

$$\Lambda'_3 = \left\{ \lambda \in \mathbb{R}^d : \int_{\|z\|>1} \|z\|^{2q} e^{-q\langle\lambda,z\rangle} \nu(dz) < +\infty, \mathbb{E}_{\mathbb{P}} [|F(X)|^{2p}] < +\infty, \frac{1}{p} + \frac{1}{q} = 1 \text{ for some } p > 1 \right\}.$$

It is easy to check that both Λ'_2 and Λ'_3 are convex, and that $\Lambda'_2 \subseteq \Lambda_2$, $\Lambda'_3 \subseteq \Lambda_3$, and $\Lambda'_3 \subseteq \Lambda'_2$. They are derived as follows. By the Hölder inequality, with $1/p + 1/q = 1$ for some $p > 1$ and for $k = 0, 2$,

$$\mathbb{E}_{\mathbb{P}} \left[\|X_T\|^k e^{-\langle\lambda,X_T\rangle} F(X)^2 \right] \leq \mathbb{E}_{\mathbb{P}} [|F(X)|^{2p}]^{1/p} \mathbb{E}_{\mathbb{P}} \left[\|X_T\|^{kq} e^{-q\langle\lambda,X_T\rangle} \right]^{1/q}.$$

By Theorem 2.1, the finiteness of the second expectation of the above right-hand side for each $k = 0, 2$ is equivalent to $\int_{\|z\|>1} \|z\|^{kq} e^{-q\langle\lambda,z\rangle} \nu(dz) < +\infty$ for corresponding k . This, with $k = 0$, asserts the definition of Λ_2 , while the definition of Λ_3 is verified with $k = 2$.

Meanwhile, as soon as $F(X)$ reduces to $f(X_T)$ with f being submultiplicative, the set Λ_3 is identical to

$$\left\{ \lambda \in \mathbb{R}^d : \int_{\|z\|>1} \left[e^{\langle\lambda,z\rangle} \vee \left(\|z\|^2 e^{-\langle\lambda,z\rangle} f(z)^2 \right) \right] \nu(dz) < +\infty \right\},$$

by Theorem 2.1.

3. Convergence of stochastic approximation algorithms. We begin with recalling the stochastic approximation algorithms. Let $\{X_{n,t} : t \in [0, T]\}_{n \in \mathbb{N}}$ be i.i.d. copies of the stochastic process $\{X_t : t \in [0, T]\}$. For ease in notation, we will write $X_n := X_{n,T}$ for $n \in \mathbb{N}$, and $F(X)_n := F(\{X_{n,t} : t \in [0, T]\})$. Let H be a connected set in \mathbb{R}^d with $\{0\} \in H$, and define a sequence $\{Y_n\}_{n \in \mathbb{N}}$ of random vectors in \mathbb{R}^d by

$$Y_{n+1} = (\nabla\varphi(\lambda_n) - X_{n+1}) e^{-\langle\lambda_n, X_{n+1}\rangle + \varphi(\lambda_n)} F(X)_{n+1}^2,$$

where $\lambda_0 \in H$, $\{\lambda_n\}_{n \in \mathbb{N}}$ is a sequence of random vectors in \mathbb{R}^d iteratively generated by

$$(3.1) \quad \lambda_{n+1} = \Pi_H [\lambda_n - \epsilon_n Y_{n+1}],$$

where Π_H is the projection onto the constraint set H and where $\{\epsilon_n\}_{n \in \mathbb{N}_0}$ is a sequence of positive constants satisfying

$$(3.2) \quad \sum_{n \in \mathbb{N}_0} \epsilon_n = +\infty, \quad \sum_{n \in \mathbb{N}_0} \epsilon_n^2 < +\infty.$$

Moreover, define the filtration $(\mathcal{G}_n)_{n \in \mathbb{N}_0}$ by $\mathcal{G}_n := \sigma(\{\lambda_k\}_{k \leq n}, \{X_k\}_{k \leq n})$.

In what follows, the term “the constrained algorithms” means the algorithms where the constraint set H in (3.1) is not \mathbb{R}^d and the sequence $\{\lambda_n\}_{n \in \mathbb{N}_0}$ is required to stay in the set, while by “the unconstrained algorithms,” we mean the ones whose constraint set H is extended to \mathbb{R}^d ; that is, the elements of $\{\lambda_n\}_{n \in \mathbb{N}_0}$ may be arbitrarily taken in \mathbb{R}^d .

Define a set

$$\Lambda_4 := \Lambda_1 \cap \left\{ \lambda \in \mathbb{R}^d : \mathbb{E}_{\mathbb{P}} \left[\|X_T\|^k e^{-2\langle \lambda, X_T \rangle} F(X)^4 \right] < +\infty, k = 0, 2 \right\}.$$

We will below see that the algorithm is unconstrained if $\Lambda_4 = \mathbb{R}^d$. It is, however, difficult to check whether or not that is the case, since the the operator F is involved. Meanwhile, to have an unconstrained algorithm, we need at least $\Lambda_4 \subseteq \Lambda_1 = \mathbb{R}^d$. In this sense, let us give a rough illustration of the situation in the following.

LEMMA 3.1. *If the Lévy measure ν has a compact support, then $\Lambda_1 = \mathbb{R}^d$. If $\int_{\|z\| > 1} e^{\|z\|^{1+\delta}} \nu(dz) < +\infty$ for some $\delta > 0$, then $\Lambda_1 = \mathbb{R}^d$.*

3.1. Constrained algorithms. The following proves the almost sure convergence of the constrained algorithms. Their gradient-based structure simplifies the argument.

THEOREM 3.2. *Assume that $\text{Leb}(\Lambda_4) \in (0, +\infty)$, and $\lambda_0 \in \Lambda_4$. Let H be a compact set such that $H \subseteq \Lambda_4$. Then, there exists $\lambda^* \in H$ such that the sequence $\{\lambda_n\}_{n \in \mathbb{N}_0}$ in (3.1) converges \mathbb{P} -a.s. to λ^* . Moreover, $V(\lambda^*) \leq V(0)$.*

Proof. First, note that $\mathbb{E}_{\mathbb{P}}[e^{-\langle \lambda, X_T \rangle} F(X)^2] < +\infty$ since $\mathbb{E}_{\mathbb{P}}[e^{-2\langle \lambda, X_T \rangle} F(X)^4] < +\infty$, and that by the Cauchy–Schwarz inequality,

$$\mathbb{E}_{\mathbb{P}} \left[\|X_T\|^2 e^{-\langle \lambda, X_T \rangle} F(X)^2 \right]^2 \leq \mathbb{E}_{\mathbb{P}} \left[\|X_T\|^2 \right] \mathbb{E}_{\mathbb{P}} \left[\|X_T\|^2 e^{-2\langle \lambda, X_T \rangle} F(X)^4 \right] < +\infty.$$

Hence, $\Lambda_4 \subseteq \Lambda_3$. The convexity of Λ_4 can be proved in a similar manner to the proof of Lemma 2.2. Moreover, we have

$$\begin{aligned} \mathbb{E}_{\mathbb{P}} \left[\|X_T\| e^{-2\langle \lambda, X_T \rangle} F(X)^4 \right]^2 \\ \leq \mathbb{E}_{\mathbb{P}} \left[e^{-2\langle \lambda, X_T \rangle} F(X)^4 \right] \mathbb{E}_{\mathbb{P}} \left[\|X_T\|^2 e^{-2\langle \lambda, X_T \rangle} F(X)^4 \right] < +\infty. \end{aligned}$$

Now, since

$$\sup_{n \in \mathbb{N}} \mathbb{E}_{\mathbb{P}} \left[\|Y_n\|^2 \right] \leq \sup_{\lambda \in H} \mathbb{E}_{\mathbb{P}} \left[\|\nabla \varphi_T(\lambda) - X_T\|^2 e^{-2\langle \lambda, X_T \rangle + 2\varphi_T(\lambda)} F(X)^4 \right],$$

and since $\|\nabla \varphi(\lambda)\| < +\infty$ and $\varphi(\lambda) < +\infty$, for $\lambda \in H$, the expectation of the above right-hand side is finite if and only if $\mathbb{E}_{\mathbb{P}}[\|X_T\|^k e^{-2\langle \lambda, X_T \rangle} F(X)^4] < +\infty$ for each $k = 0, 1, 2$. This proves $\sup_{n \in \mathbb{N}} \mathbb{E}_{\mathbb{P}}[\|Y_n\|^2] < +\infty$. Since Λ_4 is convex, it follows from Theorem 2.1 (p. 127) of Kushner and Yin [11] that the sequence $\{\lambda_n\}_{n \in \mathbb{N}_0}$ converges

\mathbb{P} -a.s. to a unique stationary point in H . The last claim holds by the strict convexity of V on H . \square

Remark 3.3. It is not clear whether or not there exists $\lambda \in H$ such that $\nabla V(\lambda) = 0$, and thus the above stationary point $\lambda^* \in H$ does not necessarily attain $\nabla V(\lambda^*) = 0$. If, however, there happens to exist $\lambda \in H$ such that $\nabla V(\lambda) = 0$, then $\nabla V(\lambda^*) = 0$ is guaranteed by the strict convexity of V on Λ_4 .

Remark 3.4. We may give some modifications of the set Λ_4 so that it looks more intuitive, as in Remark 3.3. If $F(X) = f(X_T)$ with f being submultiplicative, then Λ_4 can be rewritten as

$$\Lambda_4 = \left\{ \lambda \in \mathbb{R}^d : \int_{\|z\|>1} \left[e^{\langle \lambda, z \rangle} \vee \|z\|^2 e^{-2\langle \lambda, z \rangle} f(z)^4 \right] \nu(dz) < +\infty \right\}.$$

Otherwise, by the Hölder inequality,

$$\Lambda'_4 = \left\{ \lambda \in \mathbb{R}^d : \int_{\|z\|>1} \|z\|^{2q} e^{-2q\langle \lambda, z \rangle} \nu(dz) < +\infty, \mathbb{E}_{\mathbb{P}} [|F(X)|^{4p}] < +\infty, \frac{1}{p} + \frac{1}{q} = 1 \text{ for some } p > 1 \right\},$$

which is a convex subset of Λ_4 .

3.2. Unconstrained algorithms. We begin with the main result.

PROPOSITION 3.5. *If $\Lambda_4 = \mathbb{R}^d$ and if there exists $c > 0$ such that*

$$(3.3) \quad M := \inf_{\|y\|=1} \int_{\|z\|\leq c} \langle y, z \rangle^2 \mathbb{1}_{[0,+\infty)}(\langle y, z \rangle) \nu(dz) > 0,$$

then there exists a unique $\lambda^ \in \mathbb{R}^d$ such that $\nabla V(\lambda^*) = 0$.*

Remark 3.6. In most applications, Lévy processes are chosen to have independent components, each of which possesses small jumps in both positive and negative directions. Then, their Lévy measures are supported on all the axes of \mathbb{R}^d , that is,

$$\nu(dz_1, \dots, dz_d) = \sum_{k=1}^d \delta_0(dz_1) \cdots \delta_0(dz_{k-1}) \nu_k(dz_k) \delta_0(dz_{k+1}) \cdots \delta_0(dz_d),$$

for some Lévy measures $\{\nu_k\}_{k=1, \dots, d}$ on \mathbb{R}_0 . We then get

$$M = \inf_{\|y\|=1} \sum_{k=1}^d y_k^2 \int_{z_k \in (0, \text{sgn}(y_k)c]} z_k^2 \nu_k(dz_k) > 0.$$

In Example 4.2 below, we discretize the sample paths of Lévy processes with both positive and negative jumps on a finite time horizon into a few independent increments, and thus the condition (3.3) holds true.

Proof. By Proposition 2.3 with $\Lambda_3 \supseteq \Lambda_4 = \mathbb{R}^d$, it suffices to show that $\lim_{\|\lambda\| \uparrow +\infty} V(\lambda) = +\infty$. First, note that with a suitable $\gamma_c \in \mathbb{R}^d$,

$$\varphi(\lambda) - \langle \lambda, \gamma_c \rangle = \int_{\|z\|>c} \left(e^{\langle \lambda, z \rangle} - 1 \right) \nu(dz) + \int_{\|z\|\leq c} \left(e^{\langle \lambda, z \rangle} - 1 - \langle \lambda, z \rangle \right) \nu(dz).$$

The first component of the right-hand side above is bounded from below by $-\nu(\{z \in \mathbb{R}_0^d : \|z\| > c\})$ since $\Lambda_1 = \mathbb{R}^d$. For the second component, since $e^x - 1 - x \geq 0$, $x \in \mathbb{R}$, we have

$$\begin{aligned} & \int_{\|z\| \leq c} \left(e^{\langle \lambda, z \rangle} - 1 - \langle \lambda, z \rangle \right) \nu(dz) \\ & \geq \inf_{\|y\|=1} \int_{\|z\| \leq c} \left(e^{\|\lambda\| \langle y, z \rangle} - 1 - \|\lambda\| \langle y, z \rangle \right) \nu(dz) \\ & \geq \inf_{\|y\|=1} \int_{\|z\| \leq c} \left(e^{\|\lambda\| \langle y, z \rangle} - 1 - \|\lambda\| \langle y, z \rangle \right) \mathbb{1}_{[0, +\infty)}(\langle y, z \rangle) \nu(dz) \\ & \geq M \|\lambda\|^2. \end{aligned}$$

Therefore, we get

$$\begin{aligned} & \mathbb{E}_{\mathbb{P}} \left[e^{-\langle \lambda, X_T \rangle + \varphi_T(\lambda)} F(X)^2 \right] \\ & = e^{\varphi_T(\lambda) - T \langle \lambda, \gamma_c \rangle} \mathbb{E}_{\mathbb{P}} \left[e^{-\langle \lambda, X_T - T \gamma_c \rangle} F(X)^2 \right] \\ & \geq e^{\varphi_T(\lambda) - T \langle \lambda, \gamma_c \rangle} \mathbb{E}_{\mathbb{P}} \left[e^{-\|\lambda\| \|X_T - T \gamma_c\|} F(X)^2 \mathbb{1}(\|X_T - T \gamma_c\| \leq M \|\lambda\| / 2) \right] \\ & \geq e^{T(M \|\lambda\|^2 / 2 - \nu(\{z \in \mathbb{R}_0^d : \|z\| > c\}))} \mathbb{E}_{\mathbb{P}} \left[F(X)^2 \mathbb{1}(\|X_T - T \gamma_c\| \leq M \|\lambda\| / 2) \right], \end{aligned}$$

which explodes as $\|\lambda\| \uparrow +\infty$. This proves the claim. \square

The unconstrained algorithms often show a rough numerical behavior. This phenomenon is mainly due to the extremely fast growth of $\mathbb{E}_{\mathbb{P}}[\|\nabla \varphi_T(\lambda) - X_T\|^2 e^{-2\langle \lambda, X_T \rangle + 2\varphi_T(\lambda)} F(X)^4]$ with respect to $\|\lambda\|$. Alternatively, Chen, Guo and Gao [4] proposes a projection procedure. In essence, by forcing the iterates to stay in an increasing sequence of compact sets, the procedure avoids the explosion of the algorithm during the early stage. Meanwhile, we adapt the results of Chen and Zhu [3] and Delyon [5]. Let $\{H_n\}_{n \in \mathbb{N}_0}$ be an increasing sequence of compact sets such that $\cup_{n \in \mathbb{N}_0} H_n = \mathbb{R}^d$, and modify the algorithm (3.1) as

$$(3.4) \quad \lambda_{n+1} = \Pi_{H_{\sigma(n)}} [\lambda_n - \epsilon_n Y_{n+1}],$$

where $\sigma(n)$ counts the number of projections up to the n th step.

THEOREM 3.7. *Assume that $\Lambda_4 = \mathbb{R}^d$ and that there exists a unique λ^* such that $\nabla V(\lambda^*) = 0$. Then, the sequence $\{\lambda_n\}_{n \in \mathbb{N}_0}$ in (3.4) converges \mathbb{P} -a.s. to λ^* . Moreover, $\lim_{n \uparrow +\infty} \sigma(n) < +\infty$, \mathbb{P} -a.s.*

Proof. Let $m \in \mathbb{N}$ and define for $n \in \mathbb{N}_0$,

$$M_n := \sum_{k=0}^n \epsilon_k (Y_{k+1} - \mathbb{E}_{\mathbb{P}} [Y_{k+1} | \mathcal{G}_k]) \mathbb{1}(\|\lambda_k\| < m).$$

By Proposition 3.5 and the results in [3, 5], we are only to show that for each $m \in \mathbb{N}$, $\{M_n\}_{n \in \mathbb{N}_0}$ converges \mathbb{P} -a.s. Since the sequence $\{M_n\}_{n \in \mathbb{N}_0}$ is a martingale with respect to the filtration $(\mathcal{G}_n)_{n \in \mathbb{N}_0}$, it suffices to show that $\{M_n\}_{n \in \mathbb{N}_0}$ is a L^2 -martingale. To this end, for each $m \in \mathbb{N}$, we will show that, \mathbb{P} -a.s.,

$$\begin{aligned} & \sum_{n \in \mathbb{N}_0} \epsilon_n^2 \mathbb{E}_{\mathbb{P}} [\|Y_{n+1}\|^2 \mathbb{1}(\|\lambda_n\| \leq m) | \mathcal{G}_n] \\ & = \sum_{n \in \mathbb{N}_0} \epsilon_n^2 \mathbb{E}_{\mathbb{P}} \left[\|\nabla \varphi_T(\lambda_n) - X_T\|^2 e^{-2\langle \lambda_n, X_T \rangle + 2\varphi_T(\lambda_n)} F(X)^4 \mathbb{1}(\|\lambda_n\| \leq m) | \mathcal{G}_n \right] < +\infty. \end{aligned}$$

We begin with proving that for each $m \in \mathbb{N}$, the following four quantities are well defined:

$$\begin{aligned} C_1(m) &:= \sup_{\|\lambda\| \leq m} \left| \int_{\|z\| > 1} \left(e^{\langle \lambda, z \rangle} - 1 \right) \nu(dz) \right|, \\ C_2(m) &:= \sup_{\|\lambda\| \leq m} \left| \int_{\|z\| \leq 1} \left(e^{\langle \lambda, z \rangle} - 1 - \langle \lambda, z \rangle \right) \nu(dz) \right|, \\ C_3(m) &:= \sup_{\|\lambda\| \leq m} \int_{\|z\| > 1} \|z\| e^{\langle \lambda, z \rangle} \nu(dz), \\ C_4(m) &:= \sup_{\|\lambda\| \leq m} \int_{\|z\| \leq 1} \|z\| \left| e^{\langle \lambda, z \rangle} - 1 \right| \nu(dz). \end{aligned}$$

Clearly, $C_1(m)$ is finite since $\Lambda_1 = \mathbb{R}^d$ and $\nu(\{z \in \mathbb{R}_0^d : \|z\| > 1\}) < +\infty$, while the finiteness of $C_2(m)$ follows from $e^{\langle \lambda, z \rangle} - 1 - \langle \lambda, z \rangle \sim \langle \lambda, z \rangle^2 \leq \|\lambda\|^2 \|z\|^2$ as $\|z\| \downarrow 0$. For $C_3(m)$, the Hölder inequality gives the assertion, that is, with $1/p + 1/q = 1$ for some $p > 1$,

$$\int_{\|z\| > 1} \|z\| e^{\langle \lambda, z \rangle} \nu(dz) \leq \left[\int_{\|z\| > 1} \|z\|^p \nu(dz) \right]^{1/p} \left[\int_{\|z\| > 1} e^{q\langle \lambda, z \rangle} \nu(dz) \right]^{1/q} < +\infty,$$

again with the help of $\Lambda_1 = \mathbb{R}^d$. Finally, the finiteness of $C_4(m)$ holds by $\|z\| |e^{\langle \lambda, z \rangle} - 1| \sim \|z\| |\langle \lambda, z \rangle| \leq \|\lambda\| \|z\|^2$ as $\|z\| \downarrow 0$.

Let us now proceed to the main part of the proof. First, as previously, note that

$$\varphi(\lambda) - \langle \lambda, \gamma \rangle = \int_{\|z\| > 1} \left(e^{\langle \lambda, z \rangle} - 1 \right) \nu(dz) + \int_{\|z\| \leq 1} \left(e^{\langle \lambda, z \rangle} - 1 - \langle \lambda, z \rangle \right) \nu(dz).$$

Both the first and the second integrals of the right-hand side above are well defined due to the finiteness of $C_1(m)$ and $C_2(m)$, respectively. Hence, we get

$$|\varphi(\lambda) - \langle \lambda, \gamma \rangle| \leq C_1(m) + C_2(m) =: C_5(m).$$

Next, note that

$$\nabla (\varphi(\lambda) - \langle \lambda, \gamma \rangle) = \int_{\|z\| > 1} z e^{\langle \lambda, z \rangle} \nu(dz) + \int_{\|z\| \leq 1} z \left(e^{\langle \lambda, z \rangle} - 1 \right) \nu(dz),$$

where the passages to the gradient operator are verified by the finiteness of $C_3(m)$ and $C_4(m)$, and thus

$$\|\nabla (\varphi(\lambda) - \langle \lambda, \gamma \rangle)\| \leq C_3(m) + C_4(m) =: C_6(m).$$

In total, we get for each $m \in \mathbb{N}$,

$$\begin{aligned} &\mathbb{E}_{\mathbb{P}} \left[\|\nabla \varphi_T(\lambda) - X_T\|^2 e^{-2\langle \lambda, X_T \rangle + 2\varphi_T(\lambda)} F(X)^4 \mathbf{1}(\|\lambda\| \leq m) \mid \mathcal{G}_n \right] \\ &\leq \mathbb{E}_{\mathbb{P}} \left[(\|X_T - \gamma T\| + C_6(m)T)^2 e^{-2\langle \lambda, X_T - \gamma T \rangle + 2C_5(m)T} F(X)^4 \mathbf{1}(\|\lambda\| \leq m) \mid \mathcal{G}_n \right], \end{aligned}$$

which is bounded \mathbb{P} -a.s., since $\Lambda_4 = \mathbb{R}^d$. The proof is complete. \square

4. Numerical illustrations. In this section, we give two numerical examples, corresponding to the constrained algorithm and the unconstrained one. We will evaluate the efficiency of the importance sampling variance reduction by the ratio of variances (vratio), defined by

$$(\text{vratio}) := \frac{\text{Var}_{\mathbb{P}}(F(X))}{\text{Var}_{\mathbb{Q}_{\lambda_N}}((d\mathbb{P}/d\mathbb{Q}_{\lambda_N})F(X))}.$$

Example 4.1 (constrained algorithm). Let $X := (X^1, \dots, X^5)'$ be an infinitely divisible random vector with independent and identically distributed components under the probability measure \mathbb{P} , where the common Lévy measure ν on \mathbb{R}_0 for each component is of the Meixner type of Schoutens and Teugels [13]. It is characterized by three parameters (a, b, d) in the form

$$\nu(dz) = d \frac{\exp(bz/a)}{z \sinh(\pi z/a)} dz, \quad z \in \mathbb{R}_0,$$

where $a > 0$, $b \in (-\pi, \pi)$, and $d > 0$, while the probability density function p of X_1 is given in closed form by

$$(4.1) \quad p(x) = \frac{(2 \cos(b/2))^{2d}}{2a\pi\Gamma(2d)} e^{bx/a} \left| \Gamma\left(d + \frac{ix}{a}\right) \right|^2.$$

We can derive that

$$\Lambda_1 = \left\{ \lambda \in \mathbb{R} : \int_{|z|>1} e^{\lambda z} \nu(dz) < +\infty \right\}^5 = \left(\frac{-\pi - b}{a}, \frac{\pi - b}{a} \right)^5,$$

and that for $\lambda \in \Lambda_1$,

$$\varphi(\lambda) = \sum_{k=1}^5 2d \left[\ln \left(\cos \frac{b}{2} \right) - \ln \left(\cos \frac{b + a\lambda_k}{2} \right) \right],$$

and

$$\nabla \varphi(\lambda) = \left(2ad \tan \frac{b + a\lambda_1}{2}, \dots, 2ad \tan \frac{b + a\lambda_5}{2} \right)'.$$

Consider an Asian payoff

$$F(X) = \max \left[0, \frac{1}{5} \sum_{k=1}^5 S_0 e^{\sum_{i=1}^k X_i - k\varphi((1,0,0,0,0)')} - K \right].$$

For the condition $\mathbb{E}_{\mathbb{P}}[|F(X)|^{2p}] < +\infty$, it is sufficient to have $\int_{|z|>1} e^{2pz} \nu(dz) < +\infty$. With $p > 1$, we get $p \in (1, +\infty) \cap ((-\pi - b)/(2a), (\pi - b)/(2a))$, provided that $\pi - b > 2a$. Next, the condition $\int_{|z|>1} |z|^{2q} e^{-q\lambda z} \nu(dz) < +\infty$ yields $b/a - q\lambda \in (-\pi/a, \pi/a)$, and in view of the interval of q , we get

$$\Lambda'_2 = \Lambda_1 \cap \left(\frac{b - \pi}{a} \left(\left[1 - \frac{2a}{\pi - b} \right] \wedge 1 \right), \frac{b + \pi}{a} \left(\left[1 - \frac{2a}{\pi - b} \right] \wedge 1 \right) \right)^5,$$

provided that $\pi - b > 2a$. In a similar manner, we can prove $\Lambda'_3 = \Lambda'_2$ and

$$\Lambda'_4 = \Lambda_1 \cap \left(\frac{b - \pi}{2a} \left(\left[1 - \frac{4a}{\pi - b} \right] \wedge 1 \right), \frac{b + \pi}{2a} \left(\left[1 - \frac{4a}{\pi - b} \right] \wedge 1 \right) \right)^5,$$

provided that $\pi - b > 4a$.

We set the parameters of the Meixner distribution $(a, b, d) = (0.1, 0.0, 1.0)$, and thus an effective domain is approximately $\Lambda'_4 = (-13.707963, 13.707963)^5$. The constraint set H must be compact, so it is safe to set $H = [-13.70796, 13.70796]^5 \subset \Lambda'_4$. We generate $N = 1e + 5$ Monte Carlo runs with the full help of the closed form density function (4.1). With those runs, we perform the constrained algorithm (3.1) with $\epsilon_n = \alpha/(n + 1)$ and $\lambda_0 = \{0\}$. We examine three cases: the ATM case ($K = 100$), an OTM case ($K = 125$), and a deep OTM case ($K = 150$). The left figures in Figure 1 draw a sequence $\{\|\nabla V(\lambda_n)\|\}_{n \in \mathbb{N}_0}$ of the absolute gradient levels, which is “desired” to achieve $\lim_{n \uparrow +\infty} \|\nabla V(\lambda_n)\| = 0$, \mathbb{P} -*a.s.* (As pointed out in Remark 2.4, it is not clear whether or not the constraint set H contains λ^* such that $\nabla V(\lambda^*) = 0$.) The figures on the right present the convergence of the Monte Carlo estimate $\mathbb{E}_{\mathbb{P}}[F(X)]$ (MC) and that of the importance sampling Monte Carlo estimate $\mathbb{E}_{\mathbb{Q}_{\lambda_N}}[(d\mathbb{P}/d\mathbb{Q}_{\lambda_N})F(X)]$ (IS MC), of which λ_N is the exponential tilting parameter obtained after $N = 1e + 5$ of the stochastic approximation iterations, while the three vertical lines indicate $\tilde{C} := \mathbb{E}_{\mathbb{Q}_{\lambda_N}}[(d\mathbb{P}/d\mathbb{Q}_{\lambda_N})F(X)]$, $0.99\tilde{C}$ and $1.01\tilde{C}$.

The absolute gradient level tends to decrease as desired, and the resulting importance sampling succeeds in reducing the Monte Carlo variance. The absolute gradient level seems to have already converged to zero, while we have observed that a component of $\{\lambda_n\}_{n \in \mathbb{N}_0}$ seems to stay at the upper boundary ($= +13.70796$) in the ATM ($K = 100$) and in the OTM ($K = 125$). Those are delicate issues in the constrained algorithms.

Example 4.2 (unconstrained algorithm). Let $X := (X_1, \dots, X_5)'$ be an infinitely divisible random vector in \mathbb{R}^5 with independent and identically distributed components, whose common Lévy measure ν on \mathbb{R}_0 of each component is given in the form of the standard Gaussian density function,

$$\nu(dz) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2} dz.$$

Evidently, for each $\lambda \in \mathbb{R}$, $\int_{|z|>1} e^{\lambda z} \nu(dz) < +\infty$. Letting $\lambda := (\lambda_1, \dots, \lambda_5)'$, with the help of the independence of the components, we get $\Lambda_1 = \mathbb{R}^5$,

$$\varphi(\lambda) = \sum_{k=1}^5 \left(e^{\frac{1}{2}\lambda_k^2} - 1 \right),$$

and

$$\nabla \varphi(\lambda) = \left(\lambda_1 e^{\frac{1}{2}\lambda_1^2}, \dots, \lambda_5 e^{\frac{1}{2}\lambda_5^2} \right)'.$$

Due to the compound Poisson structure, the random vector under the probability measure \mathbb{P} can be generated via

$$X \stackrel{\mathcal{L}}{=} \left(\sum_{n=1}^{N_1} W_{1,n}, \dots, \sum_{n=1}^{N_5} W_{5,n} \right)',$$

The ATM (K=100) case with $\alpha = 5e+0$. The ratio is 5.063.

An OTM (K=125) case with $\alpha = 1e+3$. The ratio is 35.26.

A deep OTM (K=150) case with $\alpha = 1e+4$. The ratio is 60.67.

FIG. 1. Results for the constrained algorithm; $\{\|\nabla V(\lambda_n)\|\}_{n \in \mathbb{N}_0}$ (left figures), while $\mathbb{E}_{\mathbb{P}}[F(X)]$ (MC) and $\mathbb{E}_{\mathbb{Q}_{\lambda_N}}[(d\mathbb{P}/d\mathbb{Q}_{\lambda_N})F(X)]$ (IS MC) (right figures).

where $\{N_n\}_{n \leq 5}$ is a sequence of i.i.d. Poisson random variables with unit parameter and $\{W_{k,n}\}_{k \leq 5, n \in \mathbb{N}}$ is an i.i.d. standard Gaussian random array. In view of (2.1), the Lévy measure under the probability measure \mathbb{Q}_λ is given by

$$\nu_\lambda(dz) = e^{\lambda z} \nu(dz) = \frac{1}{\sqrt{2\pi}} e^{\frac{1}{2}\lambda^2} e^{-\frac{1}{2}(z-\lambda)^2} dz,$$

which is just like a drift shift of the Gaussian density by λ (up to the constant $e^{\frac{1}{2}\lambda^2}$). Hence, the random vector under the new probability measure \mathbb{Q}_λ can be generated

via the identity

$$(4.2) \quad \begin{aligned} X &\stackrel{\mathcal{L}}{=} \left(\sum_{n=1}^{N_1} (W_{1,n} + \lambda_1), \dots, \sum_{n=1}^{N_5} (W_{5,n} + \lambda_5) \right)' \\ &= \left(\sum_{n=1}^{N_1} W_{1,n} + \lambda_1 N_1, \dots, \sum_{n=1}^{N_5} W_{5,n} + \lambda_5 N_5 \right)', \end{aligned}$$

where $\{N_n\}_{n \leq 5}$ is now a sequence of i.i.d. Poisson random variables with parameter $e^{\frac{1}{2}\lambda^2}$ (≥ 1) and where $\{W_{k,n}\}_{k \leq 5, n \in \mathbb{N}}$ remains to be an i.i.d. standard Gaussian random array. For any $\lambda \in \mathbb{R}_0^d$, the componentwise variance tends to increase by factor $e^{\frac{1}{2}\lambda_k^2}$, since $\mathbb{E}_{\mathbb{Q}_\lambda}[\sum_{n=1}^{N_k} W_{k,n}] = \mathbb{E}_{\mathbb{Q}_\lambda}[N_k] \mathbb{E}_{\mathbb{Q}_\lambda}[W_{k,1}]$, while the drift shift λ_k is further accelerated by factor $e^{\frac{1}{2}\lambda_k^2}$ on average.

Consider a digital payoff

$$F(X) = \mathbf{1}(S_1 < 100 - K, S_2 > 100 + K, S_3 < 100 - K, S_4 > 100 + K, S_5 < 100 - K),$$

for a suitable K and where $S_n = 100 \exp[\sum_{k=1}^n X_k - n\varphi((1, 0, 0, 0, 0)')]$, $n \leq 5$. Since $|F(X)| \leq 1$, \mathbb{P} -a.s., we get $\Lambda_4 = \mathbb{R}^5$. We generate $N = 1e + 5$ Monte Carlo runs and perform the unconstrained algorithm (3.4) with $\epsilon_n := \alpha/(n + 1)$, $H_n := \{\lambda \in \mathbb{R}^d : \|\lambda\| \leq 10 \ln(100(n + 1))\}$, and $\lambda_0 := \{0\}$. We examine the three cases; $K = 5, 20$, and 40 . We present the results in Figure 2, where the three vertical lines in the right figures here indicate $\tilde{C} := \mathbb{E}_{\mathbb{Q}_{\lambda_N}}[(d\mathbb{P}/d\mathbb{Q}_{\lambda_N})F(X)]$, $0.98\tilde{C}$ and $1.02\tilde{C}$.

In similar to the results in Example 4.1, the algorithm reduces the absolute gradient level, and the resulting importance sampling succeeds in reducing the Monte Carlo variance. Unlike in the constrained algorithm case, we know that there exists a unique optimum λ^* which makes the absolute gradient level zero. It seems that the zero is fairly attained.

Remark 4.3. In the above numerical illustrations, we have chosen the Lévy measures of the Meixner type and of the Gaussian density. It is a clear reason of the choice that they are somewhat invariant with respect to the Esscher transform owing to the exponential component of their Lévy measure and thus remain very easy to generate in simulation even after the measure change. It should be mentioned here that from a computational point of view, Lévy measures without such an invariance property may not be a good candidate for simulation in our framework. However, this should not be a crucial drawback since most recent popular Lévy measures possess an exponential component, for instance, the Lévy measure of gamma processes.

5. Concluding remarks. In this paper, we have developed stochastic approximation methods of finding the optimal measure change for Lévy processes in Monte Carlo importance sampling variance reduction. Our analysis is valid on the basis of the restriction to the exponential tilting measure change, that is, limiting the density to a function the terminal value X_T . Nevertheless, our method should be applicable to a variety of applications since its principle is not specific to the structure of the Monte Carlo estimator itself. It may be of interest to extend to the intricate series representation setting of [8] by using characterizing parameters of the Lévy measure in the stochastic approximation procedure. Extensions to an optimal parameter search for the combined importance sampling and control variates variance

K=5 with $\alpha = 8e+2$. The ratio is 6.605.

K=20 with $\alpha = 1e+4$. The ratio is 11.75.

K=40 with $\alpha = 3e+4$. The ratio is 57.27.

FIG. 2. Results for the unconstrained algorithm; $\{\|\nabla V(\lambda_n)\|\}_{n \in \mathbb{N}_0}$ (left figures), while $\mathbb{E}_{\mathbb{P}}[F(X)]$ (MC) and $\mathbb{E}_{\mathbb{Q}_{\lambda_N}}[(d\mathbb{P}/d\mathbb{Q}_{\lambda_N})F(X)]$ (IS MC) (right figures).

reduction are studied using a two-time-scale version of the stochastic approximation algorithm in subsequent papers [9, 10].

Acknowledgments. The author is grateful to anonymous referees for a careful reading and various useful suggestions, and in particular for remarks which helped improve Proposition 3.5. Part of this work was done at Daiwa Securities SMBC Co. Ltd. The author would like to thank Tatsuya Toshida and the Financial Engineering team for their support and encouragement. This work is supported in part by JSPS Core-to-Core program. At last but not least, it is a great pleasure to express my appreciation to Arturo Kohatsu-Higa for stimulating discussions.

CONVERGENCE OF THE FORWARD EULER METHOD FOR NONCONVEX DIFFERENTIAL INCLUSIONS*

MATTIAS SANDBERG†

Abstract. The convergence of reachable sets for nonconvex differential inclusions is considered. When the right-hand side in the differential inclusion is a compact-valued, Lipschitz continuous set-valued function it is shown that the convergence in Hausdorff distance of reachable sets for a forward Euler discretization is linear in the time step.

Key words. differential inclusion, forward Euler, convergence order, convexification

1. Introduction. A natural method to approximate solutions to a differential inclusion is the forward Euler method. Before this method is described, some notation is introduced. We denote by B the closed unit ball in \mathbb{R}^d . The Minkowski sum of two nonempty sets $C, D \subset \mathbb{R}^d$, is defined by

$$C + D = \{c + d \mid c \in C \text{ and } d \in D\},$$

the multiplication by a scalar, $\lambda > 0$, by

$$\lambda C = \{\lambda c \mid c \in C\},$$

and the sum of an element $c \in \mathbb{R}^d$ and a set C by

$$c + C = \{c\} + C.$$

The Hausdorff distance is given by

$$\mathcal{H}(C, D) = \inf \{\lambda \geq 0 \mid C \subset D + \lambda B \text{ and } D \subset C + \lambda B\},$$

and the convex hull of a set C is denoted $\text{co}(C)$. The Euclidean norm is denoted $|\cdot|$. The differential inclusion to be studied is

$$(1.1) \quad \begin{aligned} x'(t) &\in F(x(t)), \\ x(0) &= x_0, \end{aligned}$$

where $x_0 \in \mathbb{R}^d$ is the starting position. The function F is *set-valued* $\mathbb{R}^d \rightsquigarrow \mathbb{R}^d$, i.e., for each $x \in \mathbb{R}^d$, $F(x)$ is a subset of \mathbb{R}^d . It is assumed that the images $F(x)$ are compact sets, uniformly bounded in the sense that

$$(1.2) \quad |y| \leq K \quad \text{for all } y \in \bigcup_{x \in \mathbb{R}^d} F(x),$$

†Centre of Mathematics for Applications, University of Oslo, P.O. Box 1053 Blindern, NO-0316 Oslo, Norway (mattias.sandberg@cma.uio.no).

and are Lipschitz continuous with respect to the Hausdorff distance:

$$(1.3) \quad \mathcal{H}(F(x), F(y)) \leq L|x - y| \quad \text{for all } x, y \in \mathbb{R}^d.$$

These assumptions are made for the sake of convenient notation, and could clearly be relaxed. We could, e.g., change the global Lipschitz continuity in (1.3) to local Lipschitz continuity, since, by the boundedness of F , the solutions to the differential inclusion remain in a bounded set in the finite time interval we will consider. It is also possible to treat the nonautonomous inclusion $x'(t) \in F(t, x(t))$ with the theory presented for the autonomous inclusion (1.1), if there is Lipschitz continuity in both space and time, i.e.,

$$(1.4) \quad \mathcal{H}(F(t, x), F(s, y)) \leq L(|t - s| + |x - y|).$$

This is done by introducing the variable $z = (t, x) \in \mathbb{R}^{d+1}$, which solves the inclusion

$$(1.5) \quad \begin{aligned} z' &\in \tilde{F}(z), \\ z(0) &= (0, x_0), \end{aligned}$$

where $\tilde{F}(z) = (1, F(z_1, z_s))$, and where z_1 is the first coordinate of the vector z and z_s is the vector containing the last d coordinates in z . Note that the inclusion (1.5) is autonomous in the variable z , with a right-hand side which by (1.4) is Lipschitz continuous with constant $\sqrt{2}L$.

By a solution to the differential inclusion in some interval, say $[0, T]$, we mean an absolutely continuous function $x : [0, T] \rightarrow \mathbb{R}^d$ such that (1.1) holds almost everywhere in $[0, T]$. General theory on differential inclusions can be found in [2, 3, 8]. This paper is about how well reachable sets of the differential inclusion can be approximated by reachable sets of a forward Euler discretization of it. The interval $[0, T]$ is split into N equal parts so that the step length is $\Delta t = T/N$. We shall consider solutions $\{\xi_n\}_{n=0}^N$ to the forward Euler discretized inclusion

$$(1.6) \quad \begin{aligned} \xi_{n+1} &\in \xi_n + \Delta t F(\xi_n), \quad n = 0, 1, \dots, N-1, \\ \xi_0 &= x_0. \end{aligned}$$

For convex differential inclusions, i.e., those where the function F is convex-valued, it has been shown in [9] that the forward Euler method converges with rate one. If the differential inclusion (1.1) is not convex, the relaxation theorem, restated in Theorem 2.2 (see also [2]), gives that its set of solutions is dense in the set of solutions to its convexified version, where $F(x)$ has been changed to the convex hull $\text{co}(F(x))$. Therefore, a straightforward way to approximate solutions of a nonconvex differential inclusion is to first convexify, and then to use the convergence result for the Euler method applied to convex differential inclusions, mentioned above. The new result presented here, in Theorem 2.5, is that the forward Euler method is convergent with rate one, even *without* the step of convexification.

The convergence result in Theorem 2.5 is weaker than the result for convex problems in [9] in two ways. First, the convergence is in the sense of the Hausdorff distance between reachable sets, to be explained in section 2, whereas the result for convex problems concerns convergence of entire solution paths. Second, the reachable sets to the forward Euler scheme are shown to be of the order $d^2\Delta t$ from the reachable sets to the original differential inclusion (1.1), measured in Hausdorff distance; i.e., there is a dependence on the dimension which is not present in the result for convex differential inclusions.

A benefit of using the forward Euler method directly, without convexifying, is that when applied to optimal control problems, the minimization in the approximating optimization problem might be over a finite set. The connection with optimal control is discussed further in section 2.1.

It will be shown that the Hausdorff distance between reachable sets for (1.1) and (1.6) is of the order Δt . When this is proved we use the fact that the forward Euler method for convex differential inclusions converges with rate one. The convexified variant of (1.6) is therefore also introduced:

$$(1.7) \quad \begin{aligned} \eta_{n+1} &\in \eta_n + \Delta t \operatorname{co}(F(\eta_n)), \quad n = 0, 1, \dots, N-1, \\ \eta_0 &= x_0. \end{aligned}$$

In this paper the forward Euler method for approximating differential inclusions is treated. This method is studied for convex problems in [1, 9, 13, 14]. For convex differential inclusions there are also other methods available; for surveys on such approximation methods, see [10, 15]. Under a condition of strong convexity, a Runge–Kutta-type scheme is shown to be convergent of order two in [18]. In [19] the second order convergence is established for linear differential inclusions that are convex, but not necessarily strongly convex.

2. The convergence result. Introduce the *reachable sets*

$$(2.1) \quad \begin{aligned} C_n &= \{x(n\Delta t) \mid x : [0, T] \rightarrow \mathbb{R}^d \text{ solution to (1.1)}\}, \\ D_n &= \{\xi_n \mid \{\xi_i\}_{i=0}^N \text{ solution to (1.6)}\}, \\ E_n &= \{\eta_n \mid \{\eta_i\}_{i=0}^N \text{ solution to (1.7)}\}. \end{aligned}$$

The main result is that the Hausdorff distance between the sets C_n and D_n is of the order Δt . The proof uses two previously known results, and a new one. Before stating these, a lemma about the Lipschitz continuity of $\operatorname{co}(F(x))$ is formulated.

LEMMA 2.1. *Let F be a function from \mathbb{R}^d into the compact subsets of \mathbb{R}^d which satisfies (1.3). Then*

$$\mathcal{H}(\operatorname{co}(F(x)), \operatorname{co}(F(y))) \leq L|x - y|.$$

Proof. This is a direct consequence of the fact that for any nonempty compact sets A and B in \mathbb{R}^d ,

$$\mathcal{H}(\operatorname{co}(A), \operatorname{co}(B)) \leq \mathcal{H}(A, B),$$

a fact which may be found in, e.g., [20]. \square

We now formulate the known results used in the proof of the convergence result for nonconvex differential inclusions in Theorem 2.5. The first is the relaxation theorem (see, e.g., [2]), which states that the set of solutions to the differential inclusion (1.1) is dense in the set of solutions to its convexified version, where $F(x)$ has been changed to $\operatorname{co}(F(x))$.

THEOREM 2.2. *Let F be a Lipschitz continuous function from \mathbb{R}^d into the nonempty compact subsets of \mathbb{R}^d . Let $y : [0, T] \rightarrow \mathbb{R}^d$ be a solution to*

$$y'(t) \in \operatorname{co}(F(y(t))), \quad y(0) = x_0.$$

Then for every positive ε , there exists a solution $x : [0, T] \rightarrow \mathbb{R}^d$ to (1.1) such that for all $t \in [0, T]$, $|x(t) - y(t)| \leq \varepsilon$.

The relaxation theorem makes it possible to move from the setting of nonconvex differential inclusions to the convex one. For convex differential inclusions it has been proved in [9] that the forward Euler method converges with rate one. The result in [9] is formulated in a slightly more general setting than here, but we give a version adapted to the present assumptions.

THEOREM 2.3. *Let F be a function from \mathbb{R}^d into the nonempty compact convex subsets of \mathbb{R}^d , which satisfies (1.2) and (1.3). For any solution $x : [0, T] \rightarrow \mathbb{R}^d$ to (1.1) there exists a solution $\{\xi_n\}_{n=0}^N$ to (1.6) such that*

$$(2.2) \quad \max_{0 \leq n \leq N} |x(n\Delta t) - \xi_n| \leq KLT e^{LT} \Delta t.$$

Moreover, for any solution $\{\xi_n\}_{n=0}^N$ to (1.6) there exists a solution $x : [0, T] \rightarrow \mathbb{R}^d$ to (1.1) such that (2.2) holds. Hence the sets C_n and D_n , defined in (2.1), satisfy

$$(2.3) \quad \max_{0 \leq n \leq N} \mathcal{H}(C_n, D_n) \leq KLT e^{LT} \Delta t.$$

Remark 2.4. Even though the constant in front of Δt in (2.2) and (2.3) does not occur explicitly in [9], it can be found by working through the proofs.

One method for approximation of (1.1) is to use a forward Euler scheme with a convexified right-hand side. Theorems 2.2 and 2.3 show that this method converges with order one. This paper, however, concerns the forward Euler scheme with the right-hand side unchanged. What remains to show in order to prove the desired convergence for this method is that the Hausdorff distance between the reachable sets to (1.6) and to (1.7) is of the order Δt . This is shown in section 3, but first we state the result for the forward Euler method for nonconvex differential inclusions.

THEOREM 2.5. *Let F be a function from \mathbb{R}^d into the nonempty compact subsets of \mathbb{R}^d which satisfies (1.2) and (1.3). Then the sets C_n and D_n , defined in (2.1), satisfy*

$$(2.4) \quad \max_{0 \leq n \leq N} \mathcal{H}(C_n, D_n) \leq (Ke^{LT}(Kd(d+1) + LT) + 2Kd)\Delta t.$$

Proof. Theorem 2.2 implies that

$$\bar{C}_n = \{y(n\Delta t) \mid y : [0, T] \rightarrow \mathbb{R}^d \text{ solves } y'(t) \in \text{co}(F(y(t))), y(0) = x_0\},$$

where the bar denotes set closure. Lemma 2.1 and Theorem 2.3 imply that

$$(2.5) \quad \max_{0 \leq n \leq N} \mathcal{H}(\bar{C}_n, E_n) \leq KLT e^{LT} \Delta t,$$

while Theorem 3.6 says that

$$(2.6) \quad \max_{0 \leq n \leq N} \mathcal{H}(D_n, E_n) \leq (Ke^{LT}d(d+1) + 2Kd)\Delta t.$$

Since $\mathcal{H}(C_n, D_n) = \mathcal{H}(\bar{C}_n, D_n)$, (2.4) follows by (2.5) and (2.6). \square

Let us compare Theorem 2.5 with other results regarding the convergence of the forward Euler method for differential inclusions. First, we note that the constant in front of Δt in (2.4) depends on the dimension d , while such explicit dependence on the dimension is not present in the estimate for convex differential inclusions in Theorem 2.3. Although this dependence on d might be weaker, it is not possible to avoid it completely. Consider, e.g., the case when F is constant and consists of the

FIG. 2.1. Part of the sets C_n (shaded) and D_n (dots), for some n , in two dimensions when $F = \{(0, 0), (1, 0), (0, 1)\}$. The closest distance between the dots is Δt , so the distance “center of square”—“corner of square” is $\frac{1}{2}\sqrt{2}\Delta t$, and hence $\mathcal{H}(C_n, D_n) = \frac{1}{2}\sqrt{2}\Delta t$. The analogous situation in dimension d gives $\mathcal{H}(C_n, D_n) = \frac{1}{2}\sqrt{d}\Delta t$.

unit vectors in the coordinate directions in \mathbb{R}^d , together with the zero vector. In this situation the Hausdorff distance between the sets C_n and D_n in Theorem 2.5 will be of the order $\sqrt{d}\Delta t$; see Figure 2.1. In [11] the same square root dependence on the dimension is shown to hold when the integral of a nonconvex set-valued function is approximated by Riemann sums.

In [12], equation (1.1) is considered with F a function from \mathbb{R}^d into the compact convex subsets of \mathbb{R}^d . The forward Euler approximation is however performed with the scheme

$$\begin{aligned}\xi_{n+1} &\in \xi_n + \Delta t G(\xi_n), \quad n = 0, 1, \dots, N-1, \\ \xi_0 &= x_0,\end{aligned}$$

where $G(x)$ is either $\partial F(x)$, the boundary points of $F(x)$, or $\text{ext}F(x)$, the set of extreme points of F . When $G(x) = \partial F(x)$, linear convergence is proved, while the result for $G(x) = \text{ext}F(x)$, assuming Lipschitz continuity of G , only is convergence of order $\sqrt{\Delta t}$. Theorem 2.5 covers the same situation if we let $\text{ext}F(x)$ in [12] be the F we are using in this paper. It improves the half-order convergence in [12] partially, since it proves linear convergence. The convergence in Theorem 2.5 is however of a weaker form as it gives convergence of the sets D_n to the sets C_n , for all n , while the result in [12] is of the same kind as in Theorem 2.3, i.e., convergence of approximating paths. The result in Theorem 2.5 is however what is needed in many applications. The relevance for optimal control is discussed in the following section.

2.1. Convergence of approximations in optimal control. We will consider the optimal control problem to minimize the functional

$$(2.7) \quad \int_0^T h(x(t), \alpha(t)) dt + g(x(T))$$

over all solutions to the equation

$$(2.8) \quad x'(t) = f(x(t), \alpha(t)), \quad x(0) = x_s,$$

where $\alpha : [0, T] \rightarrow D$ is the control variable. In order to be able to use the result in Theorem 2.5 to prove a convergence result for approximations of optimal control, the following result on equivalence between control problems and differential inclusions is needed. The theorem is taken from [2, Corollary 1, p. 91].

THEOREM 2.6. *Let $f : \mathbb{R}^d \times D \rightarrow \mathbb{R}^d$ be continuous where D is a compact separable metric space and assume that there exist a $T > 0$ and an absolutely continuous $x : [0, T] \rightarrow \mathbb{R}^d$ such that*

$$(2.9) \quad x'(t) \in \bigcup_{a \in D} f(x(t), a) \quad \text{for almost every } t \in [0, T].$$

Then there exists a Lebesgue measurable $\alpha : [0, T] \rightarrow D$ such that for almost every $t \in [0, T]$, (2.8) holds.

Remark 2.7. The theorem shows that every solution to the differential inclusion (2.9) is also a solution to the control equation (2.8) with a measurable control α . That every solution to (2.8) is a solution to (2.9) is obvious. Hence the solution sets to the control equation and the corresponding differential inclusion coincide.

With this duality between optimal control and differential inclusions, it is possible to use Theorem 2.5 to prove the following convergence result for the optimal value of the functional in (2.7).

THEOREM 2.8. *Let D and f satisfy the conditions in Theorem 2.6, and let $h : \mathbb{R}^d \times D \rightarrow \mathbb{R}$ be continuous. Let also f and h be such that the set-valued function $J : \mathbb{R}^{d+1} \rightsquigarrow \mathbb{R}^{d+1}$ defined by $J(y) = \bigcup_{a \in D} (f(x, a), h(x, a))$, where x is the vector consisting of the d first components in y , has compact values, and is uniformly bounded and uniformly Lipschitz continuous in \mathbb{R}^d . Let the function $g : \mathbb{R}^d \rightarrow \mathbb{R}$ be uniformly Lipschitz continuous. Furthermore, let x_s be an element in \mathbb{R}^d , let T be a positive real number, and split the interval $[0, T]$ into N equal parts of length $\Delta t = T/N$. Then*

$$|u - \bar{u}| = \mathcal{O}(\Delta t),$$

where the values u and \bar{u} are defined by

$$(2.10) \quad \begin{aligned} u = \inf \left\{ \int_0^T h(x(t), \alpha(t)) dt + g(x(T)) \mid \alpha : [0, T] \rightarrow D \text{ measurable,} \right. \\ \left. x : [0, T] \rightarrow \mathbb{R}^d \text{ measurable and satisfies (2.8) a.e. in } [0, T] \right\}, \\ \bar{u} = \inf \left\{ \Delta t \sum_0^{N-1} h(x_n, \alpha_n) + g(x_N) \mid \right. \\ \left. x_{n+1} = x_n + \Delta t f(x_n, \alpha_n), x_0 = x_s, \alpha_n \in D \text{ for all } 0 \leq n \leq N-1 \right\}. \end{aligned}$$

Remark 2.9. The conditions on the set-valued function J , appearing in the theorem, are satisfied, e.g., if the set D is a compact subset of a Euclidean space \mathbb{R}^n

(any n), and the functions f and h are uniformly bounded and uniformly Lipschitz continuous in $\mathbb{R}^d \times D$.

Proof. The value u can be written as

$$u = \inf \{ \tilde{g}(y(T)) \mid y : [0, T] \rightarrow \mathbb{R}^{d+1} \text{ measurable and} \\ y'(t) = p(y(t), \alpha(t)) \text{ a.e. } t \in [0, T], y(0) = (x_s, 0), \alpha : [0, T] \rightarrow D \text{ measurable} \},$$

where $p(y, a) = (f(x, a), h(x, a))$, $\tilde{g}(y) = g(x) + y_{d+1}$, and x and y_{d+1} are the d first components and the last component in y , respectively. The function p inherits the fact that it satisfies the conditions in Theorem 2.6 from f and h . Hence it is possible to express the value u in yet another way,

$$u = \inf \{ \tilde{g}(y(T)) \mid y : [0, T] \rightarrow \mathbb{R}^{d+1} \text{ measurable,} \\ y'(t) \in J(y(t)), \text{ a.e. } t \in [0, T], y(0) = (x_s, 0) \}.$$

Similarly, the value \bar{u} can be written as

$$\bar{u} = \inf \{ \tilde{g}(y_N) \mid y_{n+1} \in y_n + \Delta t J(y_n) \text{ for all } 0 \leq n \leq N - 1, y_0 = (x_s, 0) \}.$$

Pick an $\varepsilon > 0$ and let $z : [0, T] \rightarrow \mathbb{R}^{d+1}$ be an absolutely continuous function such that $z'(t) \in J(z(t))$ for a.e. $t \in [0, T]$, $z(0) = (x_s, 0)$, and such that $\tilde{g}(z(T)) \leq u + \varepsilon$.

As J satisfies the conditions in Theorem 2.5, it follows that there exists $\{z_n\}_0^N$ with $|z_N - z(T)| = \mathcal{O}(\Delta t)$ such that $z_{n+1} \in z_n + \Delta t J(z_n)$ for $0 \leq n \leq N$ and $z_0 = (x_s, 0)$. The terminal cost function \tilde{g} inherits Lipschitz continuity from g , and therefore $|\tilde{g}(z_N) - \tilde{g}(z(T))| = \mathcal{O}(\Delta t)$. Since $\bar{u} \leq \tilde{g}(z_N)$, it follows that there exists a constant C which is independent of Δt such that $\bar{u} - u \leq C\Delta t + \varepsilon$. As ε was arbitrary it may be removed from this expression. The relation $u - \bar{u} \leq C\Delta t$ is proved similarly. \square

In cases where the control set D is finite, the minimization in (2.10) is over a finite set, while convexification generally results in minimization over infinite sets.

The result in the theorem uses a minimization directly in the control variable. Another method for approximation of optimal control problems based on analysis of the underlying Hamilton–Jacobi equation can be found in [17]. General theory for optimal control problems can be found in [5, 6, 7, 8, 16].

3. Convexification of the forward Euler scheme. In order to be able to show that the distance between the solution sets to (1.6) and (1.7) is of the order Δt we introduce two set-valued maps. Let φ and ψ be functions from \mathbb{R}^d into the nonempty compact subsets of \mathbb{R}^d , defined by

$$\varphi(x) = x + \Delta t F(x), \\ \psi(x) = x + \Delta t \text{co}(F(x)).$$

If A is a subset of \mathbb{R}^d we define

$$\varphi(A) = \bigcup_{x \in A} \varphi(x),$$

and similarly for the set-valued maps ψ and F . The solution set to the forward Euler equation (1.6) is given by iterates of the function φ , while the solution set to (1.7) is given by iterates of ψ . We therefore introduce the notation

$$\varphi^n(x_0) = \underbrace{\varphi \circ \varphi \circ \dots \circ \varphi}_{n}(x_0),$$

and similarly for ψ .

It will be shown that

$$(3.1) \quad \max_{0 \leq n \leq N} \mathcal{H}(\varphi^n(x_0), \psi^n(x_0)) = \mathcal{O}(\Delta t).$$

Since we have the immediate inclusion

$$\varphi^n(x_0) \subset \psi^n(x_0),$$

this amounts to proving that

$$(3.2) \quad \psi^n(x_0) \subset \varphi^n(x_0) + \mathcal{O}(\Delta t)B \quad \text{for all } 0 \leq n \leq N.$$

When proving this, the Carathéodory theorem will play an important role.

THEOREM 3.1. *The convex hull of an arbitrary subset A of \mathbb{R}^d is given by*

$$\text{co}(A) = \left\{ \sum_{i=1}^{d+1} \lambda_i a_i \mid a_i \in A, \lambda_i \geq 0, \sum_{i=1}^{d+1} \lambda_i = 1 \right\}.$$

For a proof, see, e.g., [4].

The first step in establishing (3.2) is to show that

$$(3.3) \quad \psi^{d+1}(x_0) \approx \psi^d(\varphi(x_0)).$$

Theorem 3.2 shows that equality holds in (3.3) when F is constant.

THEOREM 3.2. *Let P be any nonempty subset of \mathbb{R}^d . For any integer $s \geq d$ it holds that*

$$(3.4) \quad (s + 1) \text{co}(P) = P + s \text{co}(P).$$

Proof. We begin by considering the case when P is a set containing $d + 1$ points,

$$P = \{p_i\}_{i=1}^{d+1},$$

which do not lie in a $(d - 1)$ -dimensional hyperplane; i.e., the dimension of $\text{co}(P)$ is d . To start with, (3.4) is shown with $s = d$. It holds that

$$P + d \text{co}(P) \subset (d + 1) \text{co}(P),$$

since

$$\text{co}(P + d \text{co}(P)) = \text{co}(P) + d \text{co}(P) = (d + 1) \text{co}(P).$$

It therefore remains to show that

$$(3.5) \quad P + d \text{co}(P) \supset (d + 1) \text{co}(P).$$

The polytope spanned by P is translated so that it is centered at the origin of \mathbb{R}^d ; i.e., it is assumed that

$$\sum_{i=1}^{d+1} p_i = 0.$$

Denote by Q a polytope spanned by $d + 1$ unit vectors, $\{q_i\}_{i=1}^{d+1}$, directed so that the angle between any two unit vectors is the same as the angle between any other two vectors and such that

$$\sum_{i=1}^{d+1} q_i = 0.$$

There exists a linear transformation $A : \mathbb{R}^d \rightarrow \mathbb{R}^d$ such that $A(\text{co}(P)) = Q$. It can be constructed by demanding that $Ap_i = q_i$, $i = 1, \dots, d$. Then also

$$Ap_{d+1} = A(-p_1 - p_2 - \dots - p_d) = -q_1 - q_2 - \dots - q_d = q_{d+1}.$$

All the sets $p_i + d \text{co}(P)$, $i = 1, \dots, d+1$ contain the zero vector. Furthermore, all these sets have d faces lying in the same planes as d faces of $(d+1) \text{co}(P)$. The remaining face of $p_i + d \text{co}(P)$ is parallel to the remaining face of $(d+1) \text{co}(P)$. Assume there exists a point $p \in (d+1) \text{co}(P)$ such that $p \notin P + d \text{co}(P)$. Denote by e_i the outward normal of the face of $A(p_i + d \text{co}(P))$ which contains the origin. It must then hold that

$$(3.6) \quad e_i \cdot Ap > 0, \quad i = 1, \dots, d+1.$$

Because of the symmetry, $\sum_{i=1}^{d+1} e_i = 0$, which contradicts (3.6). Hence (3.5) holds.

By this it easily follows that (3.4) holds also for $s > d$ in the situation where P contains $d + 1$ points and has a d -dimensional convex hull:

$$\begin{aligned} P + s \text{co}(P) &= P + d \text{co}(P) + (s - d) \text{co}(P) \\ &= (d + 1) \text{co}(P) + (s - d) \text{co}(P) = (s + 1) \text{co}(P). \end{aligned}$$

Now consider the case when P is any subset of \mathbb{R}^d such that $\text{co}(P)$ has dimension d . Denote by $\{P_d\}$ the set of all subsets of P with $d + 1$ elements, such that the dimension of $\text{co}(P_d)$ is d . By Carathéodory's theorem (Theorem 3.1) it then follows that

$$\text{co}(P) = \bigcup_{\{P_d\}} \text{co}(P_d).$$

With the result for sets containing $d + 1$ points already proved, we have that

$$(s + 1) \text{co}(P) = \bigcup_{\{P_d\}} (s + 1) \text{co}(P_d) = \bigcup_{\{P_d\}} (P_d + s \text{co}(P_d)) \subset P + s \text{co}(P).$$

As before, $P + s \text{co}(P) \subset (s + 1) \text{co}(P)$, since their convex hulls coincide. It therefore holds that $P + s \text{co}(P) = (s + 1) \text{co}(P)$.

It remains to show that (3.4) also holds when the dimension of $\text{co}(P)$ is lower than d . In this case there exists a vector $v \in \mathbb{R}^d$ such that $R \equiv v + P$ is contained in a linear subspace which also contains the origin. Consider the linear subspace of the dimension equal to the dimension of $\text{co}(P)$. By what has already been proved, (3.4) holds for the set R . This together with the fact that

$$\text{co}(R) = v + \text{co}(P)$$

implies that

$$v + P + s(v + \text{co}(P)) = (s + 1)(v + \text{co}(P)),$$

so that (3.4) holds also for P . \square

When F is not constant, equality does not hold in (3.3), but instead we have the following inclusion.

THEOREM 3.3.

$$(3.7) \quad \psi^{d+1}(x_0) \subset \psi^d(\varphi(x_0)) + KLd(d+1)\Delta t^2 B \quad \text{for any } x_0 \in \mathbb{R}^d.$$

Proof. By the definition of ψ , and by the simple fact that $F(\psi^i(x_0)) \supset F(x)$ for $x \in \psi^i(x_0)$, it follows that

$$(3.8) \quad \psi^{d+1}(x_0) \subset x_0 + \Delta t \operatorname{co}(F(x_0)) + \Delta t \operatorname{co}(F(\psi(x_0))) + \cdots + \Delta t \operatorname{co}(F(\psi^d(x_0))).$$

The boundedness of F implies

$$\mathcal{H}(\psi^i(x_0), x_0) \leq iKL\Delta t,$$

and by the Lipschitz continuity of $\operatorname{co}(F)$ (Lemma 2.1) it therefore holds that

$$\operatorname{co}(F(\psi^i(x_0))) \subset \operatorname{co}(F(x_0)) + iKL\Delta t B.$$

This fact in (3.8) yields

$$(3.9) \quad \begin{aligned} \psi^{d+1}(x_0) &\subset x_0 + (d+1)\Delta t \operatorname{co}(F(x_0)) + \sum_{i=1}^d iKL\Delta t^2 B \\ &= x_0 + (d+1)\Delta t \operatorname{co}(F(x_0)) + KL \frac{d(d+1)}{2} \Delta t^2 B \\ &= x_0 + \Delta t F(x_0) + d\Delta t \operatorname{co}(F(x_0)) + KL \frac{d(d+1)}{2} \Delta t^2 B, \end{aligned}$$

where the last equality follows by Theorem 3.2. Once again, the Lipschitz continuity of $\operatorname{co}(F)$ is used, so that

$$\operatorname{co}(F(x_0)) \subset \operatorname{co}(F(\psi^i(\varphi(x_0)))) + (i+1)KL\Delta t B.$$

This fact will be used to prove that

$$(3.10) \quad x_0 + \Delta t F(x_0) + d\Delta t \operatorname{co}(F(x_0)) \subset \psi^d(\varphi(x_0)) + KL \frac{d(d+1)}{2} \Delta t^2 B.$$

Let z be any element in $x_0 + \Delta t F(x_0) + d\Delta t \operatorname{co}(F(x_0))$. It then holds that

$$z = x_0 + \Delta t x_1 + \Delta t x_2 + \cdots + \Delta t x_{d+1},$$

where $x_1 \in F(x_0)$, and $x_2, \dots, x_{d+1} \in \operatorname{co}(F(x_0))$. Now let $\tilde{x}_1 = x_1$, let \tilde{x}_2 be the projection of x_2 on $\operatorname{co}(F(x_0 + \Delta t \tilde{x}_1))$ (i.e., the element in $\operatorname{co}(F(x_0 + \Delta t \tilde{x}_1))$ such that $d(x_2, \operatorname{co}(F(x_0 + \Delta t \tilde{x}_1))) = |\tilde{x}_2 - x_2|$), let \tilde{x}_3 be the projection of x_3 on $\operatorname{co}(F(x_0 + \Delta t \tilde{x}_1 + \Delta t \tilde{x}_2))$, and so on. The Lipschitz continuity of $\operatorname{co}(F)$ (Lemma 2.1) implies that

$$|\tilde{x}_i - x_i| \leq (i-1)KL\Delta t \quad \text{for } i = 2, \dots, d+1.$$

From this (3.10) follows, which together with (3.9) gives (3.7). \square

The next step to establish (3.2) is to show that

$$\psi^{d+n}(x_0) \subset \psi^d(\varphi^n(x_0)) + \mathcal{O}(\Delta t)B.$$

This is done in Theorems 3.4 and 3.5. The desired result, relation (3.2), follows from this and is given in Theorem 3.6.

THEOREM 3.4. *Assume that*

$$(3.11) \quad \psi^{d+n}(x_0) \subset \psi^d(\varphi^n(x_0)) + \varepsilon B.$$

Then

$$(3.12) \quad \psi^{d+n+1}(x_0) \subset \psi^d(\varphi^{n+1}(x_0)) + (KLd(d+1)\Delta t^2 + \varepsilon(1+L\Delta t))B.$$

Proof. By (3.11),

$$(3.13) \quad \psi^{d+n+1}(x_0) \subset \psi(\psi^d(\varphi^n(x_0)) + \varepsilon B).$$

Consider elements

$$\begin{aligned} z &\in \psi(\psi^d(\varphi^n(x_0)) + \varepsilon B), \\ x &\in \psi^d(\varphi^n(x_0)) + \varepsilon B \end{aligned}$$

such that $z \in x + \Delta t \operatorname{co}(F(x))$. Let x' be an element in $\psi^d(\varphi^n(x_0))$ such that $|x' - x| \leq \varepsilon$. The Lipschitz continuity of $\operatorname{co}(F)$ (Lemma 2.1) gives the inclusion

$$\operatorname{co}(F(x)) \subset \operatorname{co}(F(x')) + L\varepsilon B.$$

It therefore holds that

$$z \in x' + \Delta t \operatorname{co}(F(x')) + \varepsilon(1+L\Delta t)B = \psi(x') + \varepsilon(1+L\Delta t)B.$$

Hence,

$$\begin{aligned} \psi(\psi^d(\varphi^n(x_0)) + \varepsilon B) &\subset \psi^{d+1}(\varphi^n(x_0)) + \varepsilon(1+L\Delta t)B \\ &\subset \psi^d(\varphi^{n+1}(x_0)) + (KLd(d+1)\Delta t^2 + \varepsilon(1+L\Delta t))B, \end{aligned}$$

where the last inclusion follows from Theorem 3.3. Together with (3.13) this shows (3.12). \square

THEOREM 3.5. *For all $1 \leq n \leq N - d$ the following inclusion holds:*

$$(3.14) \quad \begin{aligned} \psi^{d+n}(x_0) &\subset \psi^d(\varphi^n(x_0)) + Ke^{LTn/N}d(d+1)\Delta tB \\ &\subset \psi^d(\varphi^n(x_0)) + Ke^{LT}d(d+1)\Delta tB. \end{aligned}$$

Proof. By Theorems 3.3 and 3.4 there are constants ε^n satisfying

$$(3.15) \quad \begin{aligned} \varepsilon^1 &= KLd(d+1)\Delta t^2, \\ \varepsilon^{n+1} &= KLd(d+1)\Delta t^2 + \varepsilon^n(1+L\Delta t) \quad \text{for } n \geq 1 \end{aligned}$$

such that

$$\psi^{d+n}(x_0) \subset \psi^d(\varphi^n(x_0)) + \varepsilon^n B.$$

By (3.15) the constants ε^n satisfy

$$\begin{aligned}\varepsilon^n &= K L d(d+1) \Delta t^2 \sum_{i=0}^{n-1} (1+L \Delta t)^i = K L d(d+1) \Delta t^2 \frac{(1+L \Delta t)^n - 1}{L \Delta t} \\ &= K((1+L \Delta t)^n - 1) d(d+1) \Delta t \leq K e^{L T n / N} d(d+1) \Delta t \\ &\leq K e^{L T} d(d+1) \Delta t,\end{aligned}$$

which proves (3.14). \square

THEOREM 3.6. *For all $0 \leq n \leq N$ the following inclusion holds:*

$$(3.16) \quad \psi^n(x_0) \subset \varphi^n(x_0) + (K e^{L T} d(d+1) + 2Kd) \Delta t B.$$

Hence the sets D_n and E_n , defined in (2.1), satisfy

$$\max_{0 \leq n \leq N} \mathcal{H}(D_n, E_n) \leq (K e^{L T} d(d+1) + 2Kd) \Delta t.$$

Proof. The bound (1.2) on the function F implies that for any $m \geq 1$

$$\varphi^d(\varphi^m(x_0)) \subset \varphi^m(x_0) + Kd \Delta t B \subset \varphi^{d+m}(x_0) + 2Kd \Delta t B.$$

Together with Theorem 3.5 this implies (3.16) when $n \geq d+1$. When $n \leq d$ it holds that

$$(3.17) \quad \psi^n(x_0) \subset \varphi^n(x_0) + 2Kn \Delta t B \subset \varphi^n(x_0) + 2Kd \Delta t B,$$

so (3.16) holds for all $0 \leq n \leq N$. \square

STABILITY PRESERVATION ANALYSIS FOR FREQUENCY-BASED METHODS IN NUMERICAL SIMULATION OF FRACTIONAL ORDER SYSTEMS*

MOHAMMAD SALEH TAVAZOEI[†], MOHAMMAD HAERI[†], SADEGH BOLOUKI[†], AND
MILAD SIAMI[†]

Abstract. In this paper, the frequency domain-based numerical methods for simulation of fractional order systems are studied in the sense of stability preservation. First, the stability boundary curve is exactly determined for these methods. Then, this boundary is analyzed and compared with an accurate (ideal) boundary in different frequency ranges. Also, the critical regions in which the stability does not preserve are determined. Finally, the analytical achievements are confirmed via some numerical illustrations.

Key words. fractional order system, frequency domain-based numerical method, fractional operator approximation, stability, stability boundary

1. Introduction. Fractional calculus as an extension of ordinary calculus is a mathematical topic with more than 300 years of history. Even though fractional calculus has a long history, its application to physics and engineering has attracted lots of attention only in the last few decades. It has been found that many real-world physical systems can be described by fractional differential equations. For instance, the fractional derivatives have been widely used in the mathematical modeling of viscoelastic materials [1, 2]. Some electromagnetic problems are described using fractional differentiation operators [3]. The anomalous diffusion phenomena in inhomogeneous media can be explained by noninteger derivative-based equations of diffusion [4, 5]. The RLC interconnect model of a transmission line is a fractional order model [6]. Heat conduction as a dynamical process can be more adequately modeled by fractional order models rather than their integer order counterparts [7]. In biology, it has been deduced that the membranes of the cells of a biological organism have fractional order electrical conductance [8] and then are classified in a group of noninteger order systems. In economy, it is known that some finance systems can display fractional order dynamics [9]. More examples from fractional order dynamics can be found in [10, 11] and references therein. Also, in recent years fractional order dynamic systems have been widely studied in the design and practice of control systems (for example, [12, 13, 14, 15, 16, 17]).

Although the integer order models can be considered as a special form of the more general fractional order models, there are basic differences between fractional order and integer order models. The main difference between them arises from an inherent attribute of fractional derivatives. In fact, the fractional derivatives are not local operators in opposition with integer derivatives that are local operators [11]. In other words, the fractional derivative of a function depends on its whole

past values. This property makes a fractional order model behave like a system with an “infinite memory” or “long memory.” Due to this property, simulation of these systems is more complicated [18]. Up to now, some analytic methods have been proposed to find numerical solution of the fractional differential equations (for example, [19, 20, 21, 22, 23, 24]). Since convergence, stability, and existence of bound for the estimation error have been proved for analytic methods, these direct methods are reliable and can be properly used for simulating fractional order systems. However, since the long memory behavior of these systems directly appears in the direct methods, simulation of fractional order systems via these methods sometimes requires a very long simulation time. Applying some ideas such as the short memory (fixed memory) principle and penalizing some forms of inaccuracy [11] may partly reduce the computational cost of time domain methods [25].

There is another popular way to simulate fractional order systems which is based on frequency domain approximation of fractional operators [26, 27, 28, 29, 30, 31, 32]. Simulation of a fractional order system by using rational approximation of the fractional operators consists of two steps as follows. First, the fractional order equation of the system is converted to the frequency domain, and the Laplace transform of the fractional integral operator is replaced by its integer order approximation. Then, the approximated equation in frequency domain is transformed back into the time domain. The resulted ordinary differential equation can now be numerically solved by applying the well-known numerical methods such as Runge–Kutta or the Adams–Bashforth–Moulton algorithm. Contrary to using direct methods, simulation of fractional order systems via using fractional operator approximation is simple, because, in this case, an ordinary differential system is simulated instead of the original fractional order system. But, unfortunately it has been shown that the results of simulations using the fractional operator approximation are not always reliable and the frequency-based numerical methods have some limitations in special cases [33, 34]. In this paper, a rigorous stability analysis is done to clear the problems arising from using frequency domain approximation in numerical simulations of fractional order systems. We show that this approximation can cause undesired changes in the stability. More precisely, stable systems may be converted to unstable approximated systems and vice versa.

This paper is organized as follows. Section 2 summarizes the basic concepts in the fractional calculus. Section 3 contains the main results of stability investigation for a frequency domain-based approximated system. Results of section 3 are numerically verified in section 4, and, finally, conclusions in section 5 close the paper.

2. Basic concepts. By extending the concept of integer order integral and derivative, the fractional integral and derivative have been defined. The definition of fractional integral is an outgrowth of the Cauchy formula for evaluating the integration. The q th order fractional integral of function $f(t)$ with respect to t is defined by [11]:

$$(1) \quad J^q f(t) = \frac{1}{\Gamma(q)} \int_0^t (t - \tau)^{q-1} f(\tau) d\tau,$$

where Γ is the Gamma function. Also, there are some definitions for fractional derivatives [11]. The Riemann–Liouville definition is the simplest and easiest definition to use. Based on this definition, the q th order fractional derivative of function $f(t)$ with respect to t and the terminal value 0 is given by

$$(2) \quad \frac{d^q f(t)}{dt^q} = \frac{1}{\Gamma(m - q)} \frac{d^m}{dt^m} \int_0^t (t - \tau)^{m-q-1} f(\tau) d\tau,$$

where m is the first integer larger than q , i.e., $m - 1 \leq q < m$. The Laplace transform of the Riemann–Liouville derivative is given as follows:

$$(3) \quad L \left\{ \frac{d^q f(t)}{dt^q} \right\} = s^q L\{f(t)\} - \sum_{k=0}^{m-1} s^k \frac{d^{q-k-1} f(0)}{dt^{q-k-1}}, \quad m - 1 < q \leq m.$$

Unfortunately, the Riemann–Liouville fractional derivative appears unsuitable to be treated by the Laplace transform technique in that it requires knowledge of the non-integer order derivatives of the function at $t = 0$. The mentioned problem does not exist in the Caputo definition of the fractional derivative. This definition of derivative, which is sometimes called a smooth fractional derivative, is described as

$$(4) \quad \frac{d^q f(t)}{dt^q} = \begin{cases} \frac{1}{\Gamma(m-q)} \int_0^t \frac{f^{(m)}(\tau)}{(t-\tau)^{q+1-m}} d\tau, & m - 1 < q \leq m, \\ \frac{d^m}{dt^m} f(t), & q = m, \end{cases}$$

where m is the first integer larger than q . The Laplace transform of the Caputo fractional derivative is

$$(5) \quad L \left\{ \frac{d^q f(t)}{dt^q} \right\} = s^q L\{f(t)\} - \sum_{k=0}^{m-1} s^{q-1-k} f^{(k)}(0), \quad m - 1 < q \leq m.$$

Contrary to the Riemann–Liouville fractional derivative, only integer order derivatives of function f appear in the Laplace transform of the Caputo fractional derivative. For zero initial conditions, (5) reduces to

$$(6) \quad L \left\{ \frac{d^q f(t)}{dt^q} \right\} = s^q L\{f(t)\}.$$

A fractional order linear time invariant system can be represented in the following state space form:

$$(7) \quad \begin{cases} \frac{d^q x}{dt^q} = Ax + Bu, \\ y = Cx, \end{cases}$$

where $x \in R^n$, $u \in R^m$, and $y \in R^p$ are states, inputs, and outputs vectors of the system and $A \in R^{n \times n}$, $B \in R^{n \times m}$, $C \in R^{p \times n}$, and q is the fractional commensurate order, respectively. Now, we state two stability theorems from the fractional calculus.

THEOREM 1 (see [35]). *The following autonomous system*

$$(8) \quad \frac{d^q x}{dt^q} = Ax, \quad x(0) = x_0,$$

where $0 < q \leq 1$, $x \in R^n$, and A is an $n \times n$ matrix is asymptotically stable if and only if $|\arg(\lambda)| > q\pi/2$ is satisfied for all eigenvalues (λ) of matrix A . Also, this system is stable if and only if $|\arg(\lambda)| \geq q\pi/2$ is satisfied for all eigenvalues (λ) of matrix A with those critical eigenvalues satisfying $|\arg(\lambda)| = q\pi/2$ have geometric multiplicity equal to algebraic multiplicity.

Theorem 1 can be proved by finding the solution of system (8) based on the eigenfunction of the smooth derivation operator for an eigenvalue and checking the

FIG. 1. Stability region of fractional order linear time invariant system with order $0 < q \leq 1$.

asymptotic behavior of this eigenfunction [35, 36]. The stable and unstable regions for $0 < q \leq 1$ is shown in Figure 1. In this paper, we will denote the stable and unstable regions for $0 < q \leq 1$ by C^{q-} and C^{q+} , respectively. Now, consider the following commensurate fractional order system:

$$(9) \quad \frac{d^q x}{dt^q} = f(x),$$

where $0 < q \leq 1$ and $x \in R^n$. The equilibrium points of system (9) are calculated by solving the following equation:

$$(10) \quad f(x) = 0.$$

THEOREM 2 (see [37]). *The equilibrium points of system (9) are locally asymptotically stable if all eigenvalues (λ) of the Jacobian matrix $J = \partial f / \partial x$ evaluated at the equilibrium points satisfy*

$$(11) \quad |\arg(\lambda)| > q\pi/2.$$

3. Analysis of frequency-based approximated model. There are many different methods to find frequency domain approximation of fractional operators (for example, see [38, 39, 40, 41, 42, 43]). In most of these methods, first a frequency range $[\omega_L, \omega_H]$ is chosen and then an integer order transfer function is determined to approximate the fractional operator in the selected frequency range. Suppose that the fractional integral operator $1/s^q$ is approximated by transfer function $G(s)$ in the given frequency range $[\omega_L, \omega_H]$:

$$(12) \quad \frac{1}{s^q} \stackrel{[\omega_L, \omega_H]}{\approx} G(s).$$

The main criticism that can be raised about using approximation in (12) in simulation of the fractional order system (9) is eliminating the inherent attribute of a fractional order system, i.e., omitting its long memory characteristics. In fact, the fractional integral operator $1/s^q$ is a nonlocal operator, whereas its approximation ($G(s)$) does not have this property. Hence, replacing $1/s^q$ by transfer function $G(s)$ causes the role of history to be ignored in simulation of the fractional order system (9).

Consequently, none of the simulations done via using frequency domain approximation of the fractional operators can preserve the long memory attribute of a fractional order system. Moreover, using approximation in (12) in simulation of the fractional order system (9) may cause some inaccuracies in the number and the location of fixed points. Fixed points of the original system are achieved by solving (10), whereas the fixed points of its frequency-based approximated model are solutions of the following equation:

$$(13) \quad f(x) = gx,$$

where g is the inverse of the steady state gain of the approximating filter $G(s)$ [34]. If the steady state gain of the approximating filter is infinite, fixed points of the approximated system and the fixed points of the original system are the same. Otherwise, the number and the location of fixed points of the original system and the approximated one may be different. In this section, our aim is to analyze stability of the approximated integer order system and compare it with that of the original fractional order system. First, the fractional order linear systems are considered and then the results of linear case are extended to a field of fractional order nonlinear systems.

3.1. Linear case. Suppose that the original system is a fractional order linear time invariant system described by

$$(14) \quad \frac{d^q x}{dt^q} = Ax,$$

where $x \in R^n$, $0 < q < 1$, and $A \in R^{n \times n}$. Also, without loss of generality, let the approximating filter $G(s)$ be strictly proper as described below:

$$(15) \quad G(s) = \frac{b_{m-1}s^{m-1} + \dots + b_1s + b_0}{s^m + a_{m-1}s^{m-1} + \dots + a_1s + a_0}.$$

The approximated model using the filter (15) is

$$(16) \quad \frac{d^m}{dt^m}x + (a_{m-1}I_n - b_{m-1}A)\frac{d^{m-1}}{dt^{m-1}}x + \dots + (a_1I_n - b_1A)\frac{d}{dt}x + (a_0I_n - b_0A)x = 0.$$

According to (13), the original system (14) and the approximated system (16) have the same fixed points if the inverse of the steady state gain of the approximating filter $G(s)$, i.e., a_0/b_0 , is not an eigenvalue of the matrix A . The high order descriptor system (16) can be realized by a first order state space model as

$$(17) \quad \dot{\tilde{x}} = M\tilde{x},$$

where

$$(18) \quad M = \begin{bmatrix} 0 & I_n & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & I_n \\ b_0A - a_0I_n & b_1A - a_1I_n & \dots & b_{m-1}A - a_{m-1}I_n \end{bmatrix}.$$

M is an $mn \times mn$ matrix and $\tilde{x} \in R^{mn}$ [34, 44]. The original system is asymptotically stable if and only if all eigenvalues of the matrix A are settled in stable region C^q (Figure 1), whereas the approximated system is asymptotically stable if and only if

$$(19) \quad \text{Re}(\text{eig}(M)) < 0.$$

In the following theorem, we state a property for eigenvalues of the matrix M .

THEOREM 3. *If the matrix A is diagonalizable in the complex field C , then eigenvalues of the matrix M defined by (18) depend only on the coefficients $a_0, \dots, a_{m-1}, b_0, \dots, b_{m-1}$ and eigenvalues of A .*

Proof. Since the matrix A is diagonalizable in the complex field C , there is a complex matrix Q such that $Q^{-1}AQ$ is a diagonal matrix with eigenvalues of A in its diagonal. Let us define

$$(20) \quad P = \begin{bmatrix} I_n & \cdots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & I_n & 0 \\ 0 & \cdots & 0 & Q \end{bmatrix},$$

where P is an $mn \times mn$ matrix. We have

$$(21) \quad P^{-1} = \begin{bmatrix} I_n & \cdots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & I_n & 0 \\ 0 & \cdots & 0 & Q^{-1} \end{bmatrix}.$$

Therefore,

$$(22) \quad P^{-1}MP = \begin{bmatrix} 0 & I_n & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & I_n \\ b_0(Q^{-1}AQ) - a_0I_n & b_1(Q^{-1}AQ) - a_1I_n & \cdots & b_{m-1}(Q^{-1}AQ) - a_{m-1}I_n \end{bmatrix}.$$

Since $Q^{-1}AQ$ depends only on the eigenvalues of A , eigenvalues of $P^{-1}MP$ depend only on the coefficients $a_0, \dots, a_{m-1}, b_0, \dots, b_{m-1}$ and eigenvalues of A . Also, M and $P^{-1}MP$ are similar matrices, and we know that similar matrices have the same set of eigenvalues. This completes the proof. \square

In the following theorem, we provide a more general property of eigenvalues of M . By this theorem, eigenvalues of M can be determined by solving an m -degree equation.

THEOREM 4. *μ is an eigenvalue of M if and only if there exists an eigenvalue of A , like λ , such that*

$$(23) \quad \mu^m - (b_{m-1}\lambda - a_{m-1})\mu^{m-1} - \cdots - (b_1\lambda - a_1)\mu - (b_0\lambda - a_0) = 0.$$

Proof. First, we prove the sufficiency of the condition. Let λ be an eigenvalue of A with corresponding eigenvector v , i.e.,

$$(24) \quad Av = \lambda v.$$

Suppose that $\mu = \mu_0$ is a solution of (23), i.e.,

$$(25) \quad \mu_0^m - (b_{m-1}\lambda - a_{m-1})\mu_0^{m-1} - \cdots - (b_1\lambda - a_1)\mu_0 - (b_0\lambda - a_0) = 0.$$

Define

$$(26) \quad w = \begin{bmatrix} v \\ \mu_0 v \\ \vdots \\ \mu_0^{m-1} v \end{bmatrix}.$$

We claim that $Mw = \mu_0 w$. First, note that

$$(27) \quad \begin{aligned} & [b_0 A - a_0 I_n \quad b_1 A - a_1 I_n \quad \cdots \quad b_{m-1} A - a_{m-1} I_n] w \\ &= (b_0 A - a_0 I_n) v + (b_1 A - a_1 I_n) \mu_0 v + \cdots + (b_{m-1} A - a_{m-1} I_n) \mu_0^{m-1} v \\ &= (b_0 + b_1 \mu_0 + \cdots + b_{m-1} \mu_0^{m-1}) A v - (a_0 + a_1 \mu_0 + \cdots + a_{m-1} \mu_0^{m-1}) v. \end{aligned}$$

Using (24) and (25), results in the above expression equal to

$$(28) \quad \begin{aligned} & (b_0 + b_1 \mu_0 + \cdots + b_{m-1} \mu_0^{m-1}) \lambda v - (a_0 + a_1 \mu_0 + \cdots + a_{m-1} \mu_0^{m-1}) v \\ &= [(b_0 \lambda - a_0) + (b_1 \lambda - a_1) \mu_0 + \cdots + (b_{m-1} \lambda - a_{m-1}) \mu_0^{m-1}] v \\ &= \mu_0^m v. \end{aligned}$$

Now, it is straightforward to verify that

$$(29) \quad \begin{aligned} Mw &= \begin{bmatrix} 0 & I_n & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & I_n \\ b_0 A - a_0 I_n & b_1 A - a_1 I_n & \cdots & b_{m-1} A - a_{m-1} I_n \end{bmatrix} \begin{bmatrix} \nu \\ \mu_0 \nu \\ \vdots \\ \mu_0^{m-1} \nu \end{bmatrix} \\ &= \begin{bmatrix} \mu_0 \nu \\ \mu_0^2 \nu \\ \vdots \\ \mu_0^m \nu \end{bmatrix} = \mu_0 w. \end{aligned}$$

Thus, the claim is proved. Therefore, μ_0 is an eigenvalue of M . Now, we prove the necessity of the condition given in Theorem 4. Let μ be an eigenvalue of M and w be the eigenvector of M corresponding to μ , i.e.,

$$(30) \quad Mw = \mu w.$$

We assume that

$$(31) \quad w = \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_m \end{bmatrix},$$

where v_i 's ($i = 1, 2, \dots, m$) are $n \times 1$ vectors. Hence,

$$(32) \quad Mw = \begin{bmatrix} 0 & I_n & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & I_n \\ b_0 A - a_0 I_n & b_1 A - a_1 I_n & \cdots & b_{m-1} A - a_{m-1} I_n \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_{m-1} \\ v_m \end{bmatrix} = \begin{bmatrix} v_2 \\ v_3 \\ \vdots \\ v_m \\ \nu \end{bmatrix},$$

where ν is an $n \times 1$ vector. According to (30) and (32), one finds $v_{i+1} = \mu v_i$ for $i = 1, 2, \dots, m-1$. Thus, $v_i = \mu^{i-1} v_1$ for $i = 1, 2, \dots, m$. Therefore,

$$(33) \quad w = \begin{bmatrix} v_1 \\ \mu v_1 \\ \vdots \\ \mu^{m-1} v_1 \end{bmatrix}.$$

From (32), we know that $\nu = \mu^m v_1$. On the other hand,

$$(34) \quad \begin{aligned} \nu &= [b_0 A - a_0 I_n \quad b_1 A - a_1 I_n \quad \cdots \quad b_{m-1} A - a_{m-1} I_n] w \\ &= (b_0 + b_1 \mu + \cdots + b_{m-1} \mu^{m-1}) Av_1 - (a_0 + a_1 \mu + \cdots + a_{m-1} \mu^{m-1}) v_1. \end{aligned}$$

Therefore,

$$(35) \quad (b_0 + b_1 \mu + \cdots + b_{m-1} \mu^{m-1}) Av_1 - (a_0 + a_1 \mu + \cdots + a_{m-1} \mu^{m-1}) v_1 = \mu^m v_1.$$

So,

$$(36) \quad Av_1 = \frac{\mu^m + a_{m-1} \mu^{m-1} + \cdots + a_1 \mu + a_0}{b_{m-1} \mu^{m-1} + \cdots + b_1 \mu + b_0} v_1.$$

Thus, the expression $(\mu^m + a_{m-1} \mu^{m-1} + \cdots + a_1 \mu + a_0)/(b_{m-1} \mu^{m-1} + \cdots + b_1 \mu + b_0)$ is an eigenvalue of A . In other words, the following relation holds for any eigenvalue λ_0 of A :

$$(37) \quad \lambda_0 = \frac{\mu^m + a_{m-1} \mu^{m-1} + \cdots + a_1 \mu + a_0}{b_{m-1} \mu^{m-1} + \cdots + b_1 \mu + b_0}.$$

Therefore,

$$(38) \quad \mu^m - (b_{m-1} \lambda_0 - a_{m-1}) \mu^{m-1} - \cdots - (b_1 \lambda_0 - a_1) \mu - (b_0 \lambda_0 - a_0) = 0,$$

and this closes the proof of Theorem 4. \square

According to (23), each eigenvalue of the matrix A converts to m eigenvalues in the approximated model, where m is the order of the approximating filter. Now, we want to find stable and unstable regions for the approximated model concerning the eigenvalues of A . The stable region for the approximated model is the region in which all m converted eigenvalues corresponding to each eigenvalue of A are stable. The rest of the complex plane forms an unstable region for the approximated model. Let $C_{G(s)}^{q-}$ and $C_{G(s)}^{q+}$, respectively, denote stable and unstable regions for the approximated model constructed by the approximating filter $G(s)$ as an approximation for operator $1/s^q$. Also, the phrase ‘‘stability boundary’’ indicates the boundary between $C_{G(s)}^{q-}$ and $C_{G(s)}^{q+}$. The ideal stability boundary is defined by $|\arg(z)| = q\pi/2$ as shown in Figure 1.

By Theorem 4, we know that if μ is an eigenvalue of M , then $(\mu^m + a_{m-1} \mu^{m-1} + \cdots + a_1 \mu + a_0)/(b_{m-1} \mu^{m-1} + \cdots + b_1 \mu + b_0)$ is an eigenvalue of A . Suppose that

$$(39) \quad H(s) = (G(s))^{-1} = \frac{s^m + a_{m-1} s^{m-1} + \cdots + a_1 s + a_0}{b_{m-1} s^{m-1} + \cdots + b_1 s + b_0}.$$

Now, we define the region D as follows:

$$(40) \quad D = \{H(s) | \operatorname{Re}(s) \geq 0\}.$$

Thus, the approximated system is stable if and only if A has no eigenvalue in D . Hence, the stability boundary of the approximated system is the following curve in the complex plane:

$$(41) \quad \gamma = \{H(j\omega) | -\infty < \omega < \infty\}.$$

Since γ is the stability boundary of the approximated system, it can precisely determine the stable region for the approximated system. In fact, the stability boundary is mapping of the vertical imaginary axis by relation $H(s) = 1/G(s)$. It is clear that the curve γ is symmetrical with respect to the horizontal real axis of the complex plane. Theorem 5 investigates the behavior of the curve γ when $\omega \rightarrow 0$.

THEOREM 5. *When ω is close enough to zero, the curve γ in the complex plane can be approximately determined by a horizontal parabola with the following equation:*

$$(42) \quad \operatorname{Re}(z) = A + B(\operatorname{Im}(z))^2,$$

where

$$(43) \quad A = a_0/b_0$$

and

$$(44) \quad B = \frac{(a_1b_1 + a_0b_2 - a_2b_0 - a_0b_1^2/b_0)}{(a_1 - a_0b_1/b_0)^2}.$$

Proof. We have

$$(45) \quad H(j\omega) = \frac{[a_0 - a_2\omega^2 + a_4\omega^4 - \dots] + j[a_1\omega - a_3\omega^3 + a_5\omega^5 - \dots]}{[b_0 - b_2\omega^2 + b_4\omega^4 - \dots] + j[b_1\omega - b_3\omega^3 + b_5\omega^5 - \dots]}.$$

Therefore,

$$(46) \quad \begin{aligned} &\operatorname{Re}(H(j\omega)) \\ &= \frac{[a_0 - a_2\omega^2 + \dots][b_0 - b_2\omega^2 + \dots] + [a_1\omega - a_3\omega^3 + \dots][b_1\omega - b_3\omega^3 + \dots]}{[b_0 - b_2\omega^2 + \dots]^2 + [b_1\omega - b_3\omega^3 + \dots]^2} \end{aligned}$$

and

$$(47) \quad \begin{aligned} &\operatorname{Im}(H(j\omega)) \\ &= \frac{[a_1\omega - a_3\omega^3 + \dots][b_0 - b_2\omega^2 + \dots] - [a_0 - a_2\omega^2 + \dots][b_1\omega - b_3\omega^3 + \dots]}{[b_0 - b_2\omega^2 + \dots]^2 + [b_1\omega - b_3\omega^3 + \dots]^2}. \end{aligned}$$

If $\omega \rightarrow 0$,

$$(48) \quad \begin{aligned} \operatorname{Re}(H(j\omega)) &\approx \frac{a_0b_0 + (a_1b_1 - a_0b_2 - a_2b_0)\omega^2}{b_0^2 + (b_1^2 - 2b_0b_2)\omega^2} \\ &\approx \frac{a_0}{b_0} + \frac{(a_1b_1 + a_0b_2 - a_2b_0 - a_0b_1^2/b_0)\omega^2}{b_0^2 + (b_1^2 - 2b_0b_2)\omega^2} \\ &\approx \frac{a_0}{b_0} + \frac{(a_1b_1 + a_0b_2 - a_2b_0 - a_0b_1^2/b_0)\omega^2}{b_0^2} \end{aligned}$$

and

$$(49) \quad \operatorname{Im}(H(j\omega)) \approx \frac{(a_1b_0 - a_0b_1)\omega}{b_0^2}.$$

Use of (48) and (49) results in (42). \square

FIG. 2. The stability boundary for low frequencies. The dashed lines indicate the actual stability boundary.

Figure 2 schematically shows the behavior of curve γ for low frequencies. According to this figure, it is clear that there is an area between sector $|\arg(z)| < q\pi/2$ and the parabola-like shape of boundary, which can be problematic in the sense of stability. In other words, if A has an unstable eigenvalue settled in this area, it converts to m stable eigenvalues in the approximated model. Thus, the original system may be unstable, whereas its approximation is stable. Now, we state another theorem to clear the behavior of curve γ when $\omega \rightarrow \infty$.

THEOREM 6. *If $b_{m-1} \neq 0$, when $\omega \rightarrow \infty$, the curve γ in the complex plane tends to the vertical line*

$$(50) \quad \operatorname{Re}(z) = \frac{\sum_{i=1}^{m-1} z_i - \sum_{i=1}^m p_i}{b_{m-1}},$$

where z_i ($i = 1, 2, \dots, m-1$) and p_i ($i = 1, 2, \dots, m$), respectively, denote zeros and poles of the approximating filter (15).

Proof. Since $G(s) = 1/H(s)$ is proper, $\lim_{\omega \rightarrow \infty} |H(j\omega)| = \infty$. Hence, it suffices to show that

$$(51) \quad \lim_{\omega \rightarrow \infty} \operatorname{Re}(H(j\omega)) = \frac{\sum_{i=1}^{m-1} z_i - \sum_{i=1}^m p_i}{b_{m-1}}.$$

If m is even ($m = 2k$, $k \in \mathbb{N}$),

$$(52) \quad H(j\omega) = \frac{[a_0 - a_2\omega^2 + \dots + (-1)^k a_{m-1}\omega^{m-1}] + j[a_1\omega - a_3\omega^3 + \dots + (-1)^{k-1} a_{m-1}\omega^{m-1}]}{[b_0 - b_2\omega^2 + \dots + (-1)^{k-1} b_{m-2}\omega^{m-2}] + j[b_1\omega - b_3\omega^3 + \dots + (-1)^{k-1} b_{m-1}\omega^{m-1}]},$$

and if m is odd ($m = 2k + 1$, $k \in \mathbb{N}$),

$$(53) \quad H(j\omega) = \frac{[a_0 - a_2\omega^2 + \dots + (-1)^k a_{m-1}\omega^{m-1}] + j[a_1\omega - a_3\omega^3 + \dots + (-1)^k \omega^m]}{[b_0 - b_2\omega^2 + \dots + (-1)^k b_{m-1}\omega^{m-1}] + j[b_1\omega - b_3\omega^3 + \dots + (-1)^{k-1} b_{m-2}\omega^{m-2}]}.$$

From (52) and (53),

$$(54) \quad \operatorname{Re}(H(j\omega)) = \frac{(a_{m-1}b_{m-1} - b_{m-2})\omega^{2m-2} + P_1(\omega)}{b_{m-1}^2\omega^{2m-2} + P_2(\omega)},$$

where $P_1(\omega)$ and $P_2(\omega)$ are polynomials with degrees less than $2m - 2$. So,

$$(55) \quad \lim_{\omega \rightarrow \infty} \operatorname{Re}(H(j\omega)) = \frac{a_{m-1}b_{m-1} - b_{m-2}}{b_{m-1}^2} = \frac{a_{m-1} - b_{m-2}/b_{m-1}}{b_{m-1}}.$$

We know that $a_{m-1} = -\sum_{i=1}^m p_i$ and $b_{m-2}/b_{m-1} = -\sum_{i=1}^{m-1} z_i$. This completes the proof. \square

The behavior of curve γ in low and high frequencies has been discussed in Theorems 5 and 6. Now, we want to analyze the behavior of curve γ in the intermediate frequencies. Suppose

$$(56) \quad \tilde{H}(s) = s^q,$$

where s belongs to the principal Riemann surface [45] and define curve $\tilde{\gamma}$ in the complex plane as follows:

$$(57) \quad \tilde{\gamma} = \{\tilde{H}(j\omega) \mid -\infty < \omega < \infty\}.$$

It is clear that the curve $\tilde{\gamma}$ is the boundary between C^{q-} and C^{q+} regions (ideal stability boundary). This means if we could use $1/s^q$ instead of $G(s)$ in numerical simulations, there is no problem in the sense of stability. We know $G(s)$ is an approximation for the fractional operator $1/s^q$ in the frequency range $[\omega_L, \omega_H]$. Suppose

$$(58) \quad \begin{aligned} \exists \varepsilon_0 > 0 : |G(j\omega)| &= \omega^{-q} + \varepsilon, & |\varepsilon| < \varepsilon_0, \\ \exists \delta_0 > 0 : \arg(G(j\omega)) &= -q\frac{\pi}{2} + \delta, & |\delta| < \delta_0 \end{aligned}$$

for $\omega_L < \omega < \omega_H$. From (58),

$$(59) \quad \frac{\operatorname{Im}(H(j\omega))}{\operatorname{Re}(H(j\omega))} = \tan\left(q\frac{\pi}{2} - \delta\right), \quad \omega_L < \omega < \omega_H.$$

If $\delta_0 < q\pi/2$, (59) results in

$$(60) \quad \tan\left(q\frac{\pi}{2} - \delta_0\right) < \frac{\operatorname{Im}(H(j\omega))}{\operatorname{Re}(H(j\omega))} < \tan\left(q\frac{\pi}{2} + \delta_0\right), \quad \omega_L < \omega < \omega_H.$$

The inequality (60) guarantees that the curve γ settle in the sector $|\arg(z) - q\pi/2| < \delta_0$. Therefore, the allowable phase error of approximating filter has a very effective role in the accuracy of the stability boundary, whereas in most approximation methods, the allowable magnitude error is considered as one of the determinable parameters [38, 39, 40]. Figure 3 schematically shows the behavior of curve γ for intermediate and high frequencies. According to this figure, it is obvious that if the matrix A has stable eigenvalues settled in the right side of vertical asymptote, the approximated system has at least one unstable eigenvalue. Thus, the original system may be stable, whereas its approximation is unstable.

FIG. 3. The stability boundary for intermediate and high frequencies. The dashed line indicates the actual stability boundary.

3.2. Nonlinear case. Suppose that the original system is a fractional order nonlinear time invariant system described by (9). According to Theorem 2, the fixed point of this system x_e (a solution of (10)) is asymptotically stable if

$$(61) \quad |\arg(\text{eig}(J))| > q\pi/2,$$

where

$$(62) \quad J = \frac{\partial f}{\partial x} \Big|_{x=x_e}.$$

Using the approximating filter (15), the approximated system is described by the following relation:

$$(63) \quad \frac{d^m}{dt^m}x + \dots + a_1 \frac{d}{dt}x + a_0x = b_{m-1} \frac{d^{m-1}}{dt^{m-1}}f(x) + \dots + b_1 \frac{d}{dt}f(x) + b_0f(x).$$

In [34], by using a generalization of Faa di Bruno’s formula [46], it has been shown that the fixed point of system (63) x_e^* (a solution of (13)) is asymptotically stable if

$$(64) \quad \text{Re}(\text{eig}(M^*)) < 0,$$

where

$$(65) \quad M^* = \begin{bmatrix} 0 & I_n & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & I_n \\ b_0J^* - a_0I_n & b_1J^* - a_1I_n & \dots & b_{m-1}J^* - a_{m-1}I_n \end{bmatrix}$$

and

$$(66) \quad J^* = \frac{\partial f}{\partial x} \Big|_{x=x_e^*}.$$

Results obtained in the previous part can be applied here for stability analysis of the equilibrium x_e^* . As in the previous case, eigenvalues of matrix M^* depend on eigenvalues of matrix J^* as well as the coefficients $a_0, \dots, a_{m-1}, b_0, \dots, b_{m-1}$ (Theorem 3). It should be noted that since the fixed point of original system x_e and the fixed point of the approximated system x_e^* are not equal, J^* is not necessarily equal to the original matrix J . However, if the steady state gain of the approximating filter (15) is

FIG. 4. Bode diagrams for transfer functions $G_1(s)$ (left) and $G_2(s)$ (right).

large enough, the fixed points of approximated system (63) are very close to the fixed points of the original system (9) [34].

4. Some numerical illustrations. In this section, results of the previous section are examined via numerical examples. Also, we analyze some wrong results reported in the literature and show that the negligence of authors in the limitations of the frequency domain methods has caused these mistakes. Table I of [26] has given approximations for $1/s^q$, with $q = 0.1 - 0.9$ in steps of 0.1. These approximations, obtained by trial and error, have maximum discrepancy of 2 dB from $\omega = 10^{-2}$ to 10^2 rad./sec. In this table, the integer order approximation of operator $1/s^{0.5}$ is given as

$$(67) \quad G_1(s) = \frac{15.97s^4 + 593.2s^3 + 1080s^2 + 135.4s + 1}{s^5 + 134.3s^4 + 1072s^3 + 543.4s^2 + 20.10s + 0.1259}.$$

Another integer order approximation for operator $1/s^{0.5}$ with maximum discrepancy of 2 dB from $\omega = 10^{-2}$ to 10^2 rad./sec. is given in Table 1 of [28]. This approximation, found by Charef’s method [39], is given as follows:

$$(68) \quad G_2(s) = \frac{15.8489(s + 0.03981)(s + 0.2512)(s + 1.585)(s + 10)(s + 63.1)}{(s + 0.01585)(s + 0.1)(s + 0.631)(s + 3.981)(s + 25.12)(s + 158.5)}.$$

Figure 4 shows the Bode diagrams for transfer functions $G_1(s)$ and $G_2(s)$. According to (41), curves $\gamma_1 = \{1/G_1(j\omega) | -\infty < \omega < \infty\}$ and $\gamma_2 = \{1/G_2(j\omega) | -\infty < \omega < \infty\}$ determine stability boundaries for the approximated systems constructed based on filters $G_1(s)$ and $G_2(s)$, respectively. The boundaries of low frequency range are illustrated in Figure 5(a). It is seen that the left side of the boundaries have a horizontal parabola-like shape which verifies Theorem 5. If the original system has an unstable eigenvalue settled between sector $|\arg(z)| < \pi/4$ and a parabola-like shape of boundaries, this eigenvalue is interpreted to stable eigenvalues in the approximated system. Consequently, results of the numerical simulation would not be reliable in this case. Figure 5(b) shows stability boundaries for intermediate frequencies. In these frequencies, the stability boundary of the approximating filter $G_2(s)$ is more consistent with the ideal boundary than the stability boundary of the approximating filter $G_1(s)$. The reason arises from accuracy of the approximation in the sense of phase. The phase of the approximating filter $G_2(s)$ is more accurate than the phase of the approximating

FIG. 5. Stability boundaries resulted from using approximating filters $G_1(s)$ (left) and $G_2(s)$ (right). (a): low frequencies, (b): intermediate frequencies. The dashed lines indicate the actual stability boundary.

FIG. 6. Stability boundaries resulted from using approximating filters $G_1(s)$ (left) and $G_2(s)$ (right). The dashed lines indicate the actual stability boundary.

filter $G_1(s)$ (Figure 4). Therefore, according to (60), this approximation preserves the stability boundary more accurately. Figure 6 shows the stability boundaries for a wide range of frequencies. The stability boundaries tend to vertical asymptotes obtained by (50). It is clear that if the original fractional order system has a stable eigenvalue in the right side of asymptotes, the approximated system has at least one unstable eigenvalue. Therefore, results of the numerical simulation in this case are not reliable. This fallacy has occurred in some papers. In the following, we debate about one of these mistakes. Existence of chaotic behavior has been reported for a fractional order Lu system based on numerical simulations in [29]. The fractional order Lu system is

described by

$$(69) \quad \begin{cases} \frac{d^q x}{dt^q} = a(y - x), \\ \frac{d^q y}{dt^q} = -xz + cy, \\ \frac{d^q z}{dt^q} = xy - bz. \end{cases}$$

For $bc > 0$, the Lu system has three equilibriums at

$$(70) \quad O = (0, 0, 0), \quad C^\pm = (\pm\sqrt{bc}, \pm\sqrt{bc}, c).$$

The Jacobian matrix of the system (69), evaluated at (x^*, y^*, z^*) , is

$$(71) \quad \begin{bmatrix} -a & a & 0 \\ -z^* & c & -x^* \\ y^* & x^* & -b \end{bmatrix}.$$

For instance, a chaotic attractor of the fractional order Lu system has been shown for parameter set $(a, b, c) = (26, 3, 28)$ and order $q = 0.5$ in [29]. For this parameter set, the fixed points and their corresponding eigenvalues are

$$\begin{aligned} O = (0, 0, 0) : & \quad \lambda_1 = -26, \quad \lambda_2 = 28, \quad \lambda_3 = -3, \\ O_{2,3} = (\pm 9.1652, \pm 9.1652, 28) : & \quad \lambda_1 = -15.0661, \quad \lambda_{2,3} = 7.0331 \pm j15.5067. \end{aligned}$$

The maximum fractional order q , for which the fixed points C^\pm remain unstable and consequently, the fractional order Lu system is susceptible to be chaotic, is about 0.73 [33]. Therefore, for $q = 0.5$ and parameter set $(a, b, c) = (26, 3, 28)$, the fixed points C^\pm are locally stable. This means the fractional order Lu system cannot be chaotic for parameter set $(a, b, c) = (26, 3, 28)$ and order $q = 0.5$. But why has the chaotic behavior been demonstrated in the numerical simulations of [29]? Numerical simulations in [29] have been performed based on the frequency domain approximations. The reference of this paper for frequency domain approximations is Table I of [26]. Similar to [29], we also used the approximating filter (67) to simulate the system (69) with the parameter set $(a, b, c) = (26, 3, 28)$ and order $q = 0.5$. The chaotic behavior was demonstrated in this case as well (Figure 7). By using approximating filter (67), the approximated system has three fixed points. From (13) and (71), these fixed points and their corresponding eigenvalues are

$$\begin{aligned} O = (0, 0, 0) : & \quad \lambda_1 = -26, \quad \lambda_2 = 28, \quad \lambda_3 = -3, \\ \tilde{O}_{2,3} = (\pm 9.3344, \pm 9.3796, 28.0091) : & \quad \lambda_1 = -15.2335, \quad \lambda_{2,3} = 7.1167 \pm j15.7336. \end{aligned}$$

All eigenvalues of fixed points $O_{2,3}$ are settled in region $C^{0.5-}$, but eigenvalues $\lambda_{2,3}$ of fixed points $\tilde{O}_{2,3}$ are not settled in $C_{G_1(s)}^-$ (Figure 8). Therefore, the fixed points $\tilde{O}_{2,3}$ of the approximated system are not stable and consequently, this system is capable to generate chaos. This inconsistency can be solved if one uses another approximating filter whose stability boundary is more coincident with the original stability boundary. Figure 8 shows a stability boundary of another approximating filter $G_3(s)$ for operator $1/s^{0.5}$ constructed by Charef's method [39] and has maximum discrepancy of 2 dB from $\omega = 10^{-3}$ to 10^3 rad./sec.

FIG. 7. Simulation results for Lu system with parameter set $(a, b, c) = (26, 3, 28)$ and order $q = 0.5$ (Simulation has been done by using approximating filter $G_1(s)$).

FIG. 8. Stability boundaries for $G_1(s)$ (left) and $G_3(s)$ (right). Locations of critical eigenvalues are highlighted by *. The dashed lines indicate the actual stability boundary.

(72)

$$G_3(s) = \frac{80.18s^8 + 1.51 \times 10^5 s^7 + 3.891 \times 10^7 s^6 + 1.555 \times 10^9 s^5 + 9.818 \times 10^9 s^4 + 9.813 \times 10^9 s^3 + 1.549 \times 10^9 s^2 + 3.793 \times 10^7 s + 1.271 \times 10^5}{s^9 + 4731s^8 + 3.062 \times 10^6 s^7 + 3.074 \times 10^8 s^6 + 4.875 \times 10^9 s^5 + 1.225 \times 10^{10} s^4 + 4.872 \times 10^9 s^3 + 3.062 \times 10^8 s^2 + 2.985 \times 10^6 s + 3981}$$

The above approximation does not change the stability of the fixed points of the original system. Thus, using it in the simulation of system (69) with the parameter set $(a, b, c) = (26, 3, 28)$ and order $q = 0.5$ does not lead to wrong consequences. The similar wrong results can be noticed in the numerical simulations of [30] and [31].

5. Conclusions. Before any conclusion can be made about the results of a performed numerical simulation, the reliability of the numerical method used in that simulation must be considered and checked. Hence, the reliability verification of numerical methods is of great importance. One of the basic points which should be considered in reliability verification of a numerical simulation is stability preserva-

tion. In fact, the original system and its simulated model must be similar in the sense of stability. In this paper, the stability preservation problem was investigated in one of the popular methods used in the simulation of fractional order systems. The method discussed in this paper is based on using integer order approximation of fractional operators. We found the “stability boundary” for this method and showed that the found boundary is not the same as the original boundary, and there are critical regions in which the stability can not preserve. Two types of inaccuracies can occur:

- The approximated model, obtained by frequency domain methods, is stable, whereas the original system is not actually stable.
- The original system is stable, but its frequency domain-based approximation is not stable.

Also, we showed that the second type of inaccuracies can lead to wrong results in detecting chaotic behaviors which are reported in some recent papers. Moreover, we found that the accuracy in the phase of integer order approximations has an undeniable role in the stability preservation of the frequency domain-based numerical methods. It should be noted that the methods available for finding integer order approximation of fractional order operators do not directly try to rectify the phase of the approximation.

L^1 -APPROXIMATION OF STATIONARY HAMILTON–JACOBI EQUATIONS*

JEAN-LUC GUERMOND[†] AND BOJAN POPOV[‡]

Abstract. We describe a nonlinear finite element technique to approximate the solutions of stationary Hamilton–Jacobi equations in two space dimensions using continuous finite elements of arbitrary degree. The method consists of minimizing a functional containing the L^1 -norm of the Hamiltonian plus a discrete entropy. It is shown that the approximate sequence converges to the unique viscosity solution under appropriate hypotheses on the Hamiltonian and the mesh family.

Key words. finite elements, best L^1 -approximation, viscosity solution, Hamilton–Jacobi equations

1. Introduction.

1.1. Formulation of the problem. Let Ω be an open, bounded, Lipschitz, and connected domain in \mathbb{R}^2 . We consider the stationary Hamilton–Jacobi equation

$$(1.1) \quad H(x, u, Du) = 0, \quad \text{a.e. } x \text{ in } \Omega, \quad u|_{\Gamma} = 0,$$

where Du denotes the gradient of u . We restrict ourselves to homogeneous boundary conditions to simplify the analysis. Nonhomogeneous boundary conditions can be accounted for by introducing appropriate continuous liftings provided the boundary data are compatible with our solution class; see (1.4)–(1.6).

The problem (1.1) has been extensively studied and is known to be particularly challenging in regard to the question of uniqueness. It turns out that adding a vanishing viscosity to the equation and passing to the limit usually leads to unique solutions under appropriate assumptions on the structure of the Hamiltonian H . We refer to Evans [10] for an introduction to this topic. Crandall and Lions [8] thoroughly characterized limit solutions by using the maximum principle and introducing the notions of subsolution and supersolution. They showed that the solution obtained by the vanishing viscosity limit is a subsolution and a supersolution. We refer to Barles [4] for additional details on this technique. When H is convex with respect to the gradient, Kruřkov [16] characterized the limit solution by proving that second finite differences satisfy a one-sided bound. This criteria has been significantly weakened by Lions and Souganidis [18]. It is the one-sided bound characterization of Lions and Souganidis that will be used in the present paper; see hypothesis (5.5).

The literature on the approximation of Hamilton–Jacobi equations is abundant; we refer to Sethian [19] for a thorough review. Most successful algorithms are based

on monotonicity and Lax–Friedrichs approximate Hamiltonians; see, e.g., Kao, Osher, and Tsai [15]. Monotonicity is at the core of most convergence proofs for low-order approximations; see, e.g., Crandall and Lions [9], Barles and Souganidis [5], and Abgrall [1, 2]. For higher-order approximations, limiters are typically used and monotonicity cannot be preserved. Convergence results are difficult to obtain. For instance, it is shown in [18] that MUSCL-like finite difference approximations converge to viscosity solutions. In the present paper we take a radically different point of view by formulating the discrete problem as a minimization in $L^1(\Omega)$. The motivation behind this approach is based on observations made in [11] that L^1 -minimization is capable of selecting viscosity solutions of transport equations equipped with ill-posed boundary conditions. This fact has indeed been proved in [13] in one space dimension. Numerical computations in [12] confirm that this is also the case for stationary one-dimensional Hamilton–Jacobi equations. Moreover, results from Lin and Tadmor [17] show that the L^1 -metric is appropriate for deriving error estimates for time-dependent Hamilton–Jacobi equations. This encouraged us to develop a research program in this direction, and the purpose of this paper is to report that indeed L^1 -minimization is a viable technique.

In the present paper we describe a nonlinear finite element technique for approximating viscosity solutions to (1.1) in two space dimensions using continuous finite elements of arbitrary degree. The method is based on the minimization over the finite element space of a functional containing the L^1 -norm of the Hamiltonian plus a discrete entropy. Under appropriate hypotheses on the Hamiltonian, it is shown that the algorithm converges to the unique viscosity solution. The main results of this paper are Theorems 4.5, 5.3, and 6.3.

The paper is organized as follows. In the rest of this section we introduce notation and structural hypotheses for (1.1). The discrete finite element setting, along with the minimization problem, is introduced in section 2. The existence of minimizers for the discrete problem is proved in section 3. The passage to the limit is done in section 4; i.e., it is shown in this section that the limit solution solves (1.1). The proof that the limit solution is indeed a viscosity solution is reported in section 5. Since the proof reported in section 5 is based on a hypothesis which we do not know how to verify on arbitrary grids (see (3.2)), we give an alternative proof in section 6 using a vertex-based entropy on Cartesian grids. The main argument in sections 5 and 6 consists of proving a one-sided bound.

1.2. Structure hypotheses. We make the following assumptions on the Hamiltonian:

$$(1.2) \quad \|p\| \leq c_s (|H(x, v, p)| + |v| + 1) \quad \forall (x, v, p) \in \Omega \times \mathbb{R} \times \mathbb{R}^2,$$

$$(1.3) \quad H(x, \cdot, \cdot) \in C^{0,1}(\overline{B_{\mathbb{R}}(0, R)} \times \overline{B_{\mathbb{R}^2}(0, R)}; \mathbb{R}) \quad \forall R > 0 \text{ uniformly in } x \in \Omega,$$

where $\|\cdot\|$ denotes the Euclidean norm in \mathbb{R}^2 . A typical example is the eikonal equation, $H(x, v, p) = |p| - 1$, or modified versions of this equation, say, $H(x, v, p) = v + F(|p|) - f(x)$, where F is a convex and f a bounded positive function.

DEFINITION 1.1. *A function u in $W^{1,\infty}(\Omega)$ is said to be q -semiconcave if there is a concave function $v_c \in W^{1,\infty}(\Omega)$ and a function $w \in W^{2,q}(\Omega)$ so that $u = v_c + w$.*

We assume that (1.1) has a unique viscosity solution u such that

$$(1.4) \quad u \in W^{1,\infty}(\overline{\Omega}),$$

$$(1.5) \quad u \text{ is } q\text{-semiconcave for some } q > 2,$$

$$(1.6) \quad Du \in \text{BV}(\Omega),$$

where we have set $W^{1,\infty}(\overline{\Omega}) := W^{1,\infty}(\Omega) \cap C^0(\overline{\Omega})$ and D is the gradient operator.

Remark 1.1. The class of problems we are working on is not empty. In particular, it is known that the unique viscosity solution to (1.1) satisfies the above hypotheses when the Hamiltonian is convex; see [16, 18].

Remark 1.2. Hypothesis (1.2) seems nonstandard. Typical hypotheses in the literature (see [4, p. 189]) consist of assuming H to be convex with respect to p and $H(x, v, p) \rightarrow +\infty$ when $|p| \rightarrow +\infty$. It can be shown that these two conditions (convexity plus growth at infinity) imply (1.2).

Remark 1.3. Recall that a function v in $W^{1,\infty}(\Omega)$ is usually called uniformly semiconcave in textbooks if and only if it can be decomposed into $v(x) = v_c(x) + c_v x^2$, where c_v is a nonnegative constant and v_c is concave and in $W^{1,\infty}(\Omega)$; see [10, p. 130]. Definition 1.1 is a slight generalization of semiconcavity.

Remark 1.4. When Ω can be finitely covered by open convex subsets, it can be shown that (1.4) and (1.5) imply (1.6). Actually, Definition 1.1 implies $u = v_c + w$, where $v_c \in W^{1,\infty}(\Omega)$, $w \in W^{2,q}(\Omega) \subset W^{2,1}(\Omega)$. Clearly $Dw \in W^{1,1}(\Omega) \subset \text{BV}(\Omega)$. It is also known that convex functions in $W^{1,\infty}(\Omega)$ have gradients in $\text{BV}(\Omega)$; see [3, Prop. 5.1, 7.11].

To be able to collectively refer to (1.4)–(1.6), we define

$$(1.7) \quad X = \{v \in W^{1,\infty}(\Omega); Dv \in \text{BV}(\Omega); v \text{ is } q\text{-semiconcave}\}$$

with the norm

$$(1.8) \quad \|v\|_X := \|v\|_{W^{1,\infty}(\Omega)} + \|Dv\|_{\text{BV}(\Omega)} + \inf_{v=v_c+w} \|w\|_{W^{2,q}(\Omega)}.$$

In the remainder of the paper c is a generic constant that does not depend on the mesh size and whose value may change at each occurrence. For any real number $r \geq 1$, we denote by r' the conjugate of r , i.e., $\frac{1}{r} + \frac{1}{r'} = 1$.

2. The discrete problem.

2.1. The meshes. Let $\{\mathcal{T}_h\}_{h>0}$ be a family of shape regular finite element meshes. For the sake of simplicity we assume that the mesh elements are triangles and the mesh family is quasi uniform. For each mesh \mathcal{T}_h , the subscript h refers to the maximum mesh size in the mesh. We denote by \mathcal{F}_h^i the set of mesh interfaces: F is a member of \mathcal{F}_h^i if and only if there are two elements $K_1(F)$, $K_2(F)$ in \mathcal{T}_h such that $F = K_1(F) \cap K_2(F)$. The intersection of two cells is either empty, a vertex, or an entire edge. For every function $v \in C^0(K_1(F)) \cup C^0(K_2(F))$, we denote

$$(2.1) \quad \forall x \in F, \quad \{v\}(x) = \frac{1}{2}(v|_{K_1(F)}(x) + v|_{K_2(F)}(x)).$$

DEFINITION 2.1 (see Figure 1). (1) *We call a chain a numbered collection of triangles $\Lambda = \{K_j\}_{1 \leq j \leq J}$ such that K_1 has one edge on Γ , K_j shares one edge with K_{j-1} and one edge with K_{j+1} for $1 < j < J$, and $K_i \neq K_j$ if $i \neq j$.*

FIG. 1. Illustration of the notation for the chain and path in Definition 2.1.

(2) The path associated with a chain $\Lambda = \{K_j\}_{1 \leq j \leq J}$ is the broken line traversing the chain in such a way that (i) it crosses K_j , $1 < j < J$, by connecting the two midpoints of the two interfaces that connect K_j to the chain; (ii) it connects the midpoint of the interface connecting K_1 to the chain and the midpoint of the face of K_1 that lies on Γ ; and (iii) it connects the midpoint of the interface connecting K_J to the chain and the midpoint of another arbitrary face of K_J .

Since the mesh family $\{\mathcal{T}_h\}_{h>0}$ is quasi uniform, the following property holds: For each mesh \mathcal{T}_h , there exists a collection of chains $\{\Lambda_l\}_{1 \leq l \leq L_h}$ such that every triangle in \mathcal{T}_h belongs to at least one chain (there are $L_h \in \mathbb{N}$ of those chains). Moreover, there is c independent of h such that

$$(2.2) \quad \text{card } \Lambda_l \leq ch^{-1}, \quad 1 \leq l \leq L_h,$$

$$(2.3) \quad L_h \leq ch^{-1}.$$

Let $k \geq 1$ be an integer and denote by \mathbb{P}_k the set of real-valued polynomials in \mathbb{R}^2 of total degree at most k . We introduce

$$(2.4) \quad X_h = \{v_h \in C^0(\bar{\Omega}); v_h|_K \in \mathbb{P}_k \ \forall K \in \mathcal{T}_h; v_h|_\Gamma = 0\},$$

$$(2.5) \quad X_{(h)} = X + X_h.$$

For every function v in $X_{(h)}$ we denote by $\lambda_+(v) : \mathcal{T}_h \rightarrow \mathbb{R}^+$ the mapping such that for every $x \in K \in \mathcal{T}_h$, $\lambda_+(v)(x)$ is the largest positive eigenvalue of the Hessian of v at x . Observe that Remark 1.3 implies that λ_+ is well defined on X ; that is, λ_+ is well defined on the space $X_{(h)}$.

Similarly, for every function v in $X_{(h)}$ we denote by $\{-\partial_n v\}_+ : \mathcal{F}_h^i \rightarrow \mathbb{R}^+$ the mapping such that for all $x \in F = K_1 \cap K_2 \in \mathcal{F}_h^i$,

$$\{-\partial_n v\}_+(x) = \left(-\frac{1}{2}(Dv|_{K_1}(x) \cdot n_1 + Dv|_{K_2}(x) \cdot n_2) \right)_+,$$

where n_1 and n_2 are the unit outward normals to K_1 and K_2 at x , respectively, and $(t)_+ := \frac{1}{2}(t + |t|)$ denotes the positive part of t for all $t \in \mathbb{R}$.

2.2. The discrete minimization problem. Let p_1 and p_2 be two fixed real numbers such that

$$(2.6) \quad 1 \leq p_1 \leq q \quad \text{and} \quad 1 \leq p_2 \leq q.$$

We now define the following functional $J_h : X_{(h)} \ni v \mapsto J_h(v) \in \mathbb{R}^+$ by

$$(2.7) \quad J_h(v) = \int_{\Omega} |H(x, v, Dv)| dx + h \sum_{K \in \mathcal{T}_h} \int_K [\lambda_+(v)]^{p_1} dx + h^{2-p_2} \sum_{F \in \mathcal{F}_h^i} \int_F \{-\partial_n v\}_+^{p_2} d\sigma.$$

For every function v in $X_{(h)}$ we refer to $H(x, v, Dv)$ as the residual. The two extra terms in the right-hand side above are referred to as the volume entropy and the interface entropy, respectively.

Remark 2.1. Whenever $v \in W^{1,\infty}(\Omega)$ is concave, the two entropy terms are zero; i.e., these two terms do not add extra viscosity. They act to prevent the occurrence of large positive second derivatives.

The discrete problem on which we shall henceforth focus our attention consists of the following minimization problem: Seek u_h in X_h such that

$$(2.8) \quad J_h(u_h) = \inf_{v_h \in X_h} J_h(v_h).$$

The goal of the rest of the paper is to show that minimizers exist for each mesh and every sequence of minimizers converges to the unique viscosity solution to (1.1).

3. Existence of minimizers. The goal of this section is to show the existence of (at least) one minimizer to problem (2.8). This is done by deriving a priori bounds and using a simple compactness argument.

3.1. Consistency. We start by deriving a consistency property. Since the mesh is quasi uniform, one can always construct a family of linear approximation operators on piecewise linear polynomials $\mathcal{I}_h : X \rightarrow X_h$ that are stable on $W^{1,\infty}(\Omega)$ and such that the following property holds:

$$(3.1) \quad \|v - \mathcal{I}_h v\|_{W^{1,1}(\Omega)} \leq ch \|Dv\|_{\text{BV}(\Omega)} \quad \forall v \in X.$$

This is a standard approximation property; for instance, the linear Clément operator [7, 6] satisfies this property (see also section 6.2 for a precise definition of the Clément approximation). It is also clear that for $p_2 = 1$ the Clément approximation (or any other reasonable approximation operator) satisfies

$$(3.2) \quad h^{2-p_2} \sum_{F \in \mathcal{F}_h^i} \int_F \{-\partial_n \mathcal{I}_h(u)\}_+^{p_2} d\sigma \leq c(\|u\|_X) h.$$

When $p_2 > 1$, (3.2) becomes a nontrivial property. In our previous paper [14], which deals with the one-dimensional case, we showed that the piecewise linear Lagrange interpolant of the exact solution satisfies (3.2) with $p_2 > 1$. Unfortunately, this argument does not hold in two space dimensions. To see this, assume that the gradient of u is discontinuous across a line L and the mesh family is such that $\mathcal{O}(h^{-1})$ cell interfaces cross L . Then the left-hand side of (3.2) is bounded from below and above by ch^{2-p_2} which is larger than ch unless $p_2 = 1$. In other words, (3.2) is hard to verify when $p_2 > 1$. Of course (3.2) can be shown to hold with $p_2 > 1$ if we are allowed to optimize or control the mesh. For instance, the Lagrange interpolant of u satisfies (3.2) with $p_2 > 1$ if the mesh family is such that no cell interface crosses the

lines across which the normal derivative of u is discontinuous; i.e., the mesh is aligned with the discontinuity lines of the gradient of u .

Henceforth we make the following assumption:

$$(3.3) \quad \left\{ \begin{array}{l} \text{If } p_2 > 1, \text{ there exists an approximation operator } \mathcal{I}_h \text{ such} \\ \text{that (3.1) and (3.2) hold simultaneously.} \end{array} \right.$$

The existence of such an operator (for $p_2 > 1$) is an open question when the mesh is not aligned with the discontinuities of the gradient of u . Note that the assumption is empty when $p_2 = 1$.

The following lemma is the first key step of the theory.

LEMMA 3.1. *Let u solve (1.1) and assume (3.3); then there is $c(u)$ independent of h such that*

$$(3.4) \quad J_h(\mathcal{I}_h u) \leq c(u) h.$$

Proof. (1) Since $\mathcal{I}_h u$ is piecewise linear, the restriction of the Hessian of $\mathcal{I}_h u$ to every mesh element is zero, i.e., $\lambda_+(\mathcal{I}_h u)|_K = 0$ for all $K \in \mathcal{T}_h$.

(2) Since \mathcal{I}_h is uniformly stable in $W^{1,\infty}(\Omega)$, there is $c \geq 0$, independent of h , such that $\|\mathcal{I}_h u\|_{W^{1,\infty}} \leq c \|u\|_{W^{1,\infty}}$. Let us set $R = c \|u\|_{W^{1,\infty}}$; then owing to (1.3), there is $c_R \geq 0$ such that for all $x \in \Omega$,

$$\begin{aligned} |H(x, \mathcal{I}_h u, D(\mathcal{I}_h u))| &= |H(x, \mathcal{I}_h u, D(\mathcal{I}_h u)) - H(x, u, Du)| \\ &\leq c_R (|\mathcal{I}_h u - u| + \|D(\mathcal{I}_h u - u)\|). \end{aligned}$$

Then together with (3.1), this implies

$$\int_{\Omega} |H(x, \mathcal{I}_h u, D(\mathcal{I}_h u))| \leq c_R \|\mathcal{I}_h u - u\|_{W^{1,1}} \leq c c_R h \|Du\|_{\text{BV}(\Omega)}.$$

(3) We now conclude by using (3.2) and collecting the above results:

$$J_h(\mathcal{I}_h u) \leq c(\|u\|_X) h \leq c' h.$$

This concludes the proof. \square

Remark 3.1. Note that it was critical to use the L^1 -norm of the residual to obtain (3.4). This is compatible with the fact that Du is in $\text{BV}(\Omega)$ only. Using any other L^p -norm would yield a suboptimal exponent on h .

3.2. The $W^{1,1}(\Omega) \cap L^\infty(\Omega)$ bound. Let $\alpha > 0$ be a positive real number. Define the set $S_{h,\alpha} = \{v_h \in X_h; \int_{\Omega} |H(x, v_h, Dv_h)| dx \leq \alpha h\}$. Using (3.4), we infer that $S_{h,c(u)}$ is not empty, i.e., $\mathcal{I}_h(u) \in S_{h,c(u)}$.

LEMMA 3.2. *Let $\alpha > 0$ and assume that $S_{h,\alpha}$ is not empty; then there is $c_0(\alpha) > 0$, independent of h , and $h_0 > 0$ such that*

$$(3.5) \quad \forall h < h_0, \quad \forall v_h \in S_{h,\alpha}, \quad \|v_h\|_{W^{1,1}} + \|v_h\|_{L^\infty} \leq c_0(\alpha).$$

Proof. Let Λ_l be a chain in the collection $\{\Lambda_l\}_{1 \leq l \leq L_h}$ (see Figure 1). Set $N_l = \text{card}(\Lambda_l)$, let v_h be a member of the nonempty set $S_{h,\alpha}$, and define

$$F_j^l = \sum_{i=1}^j \int_{K_i} \|Dv_h\| dx, \quad 1 \leq j \leq N_l.$$

Owing to (1.2), we infer

$$F_j^l \leq \sum_{i=1}^j \int_{K_i} c_s (|H(x, v_h, Dv_h)| dx + |v_h| + 1) dx.$$

Then using the fact that v_h is a member of $S_{h,\alpha}$ implies

$$F_j^l \leq \alpha c_s h + c_s N_l \max_{K \in \mathcal{T}_h} \text{meas}(K) + \sum_{i=1}^j c_s \int_{K_i} |v_h| dx.$$

In other words, using (2.2) together with $\max_{K \in \mathcal{T}_h} \text{meas}(K) \leq ch^2$, we infer

$$(3.6) \quad F_j^l \leq ch + c_s \sum_{i=1}^j \int_{K_i} |v_h| dx.$$

Let x_1, \dots, x_i be the points of the path traversing Λ_l such that $(x_m, x_{m+1}) = \Lambda_l \cap K_m$, $1 \leq m < N_l$ (see Figure 1). Denote $\tau_m = (x_{m+1} - x_m) / \|x_{m+1} - x_m\|$. Let us now consider a cell K_i , $1 \leq i \leq j$, and let y be an arbitrary point in K_i ; then the fundamental theorem of calculus implies

$$v_h(y) = v_h(x_1) + \sum_{m=1}^{i-1} \int_{x_m}^{x_{m+1}} \tau_m \cdot Dv_h(x) d\sigma + \int_{x_i}^y \frac{y - x_i}{\|y - x_i\|} \cdot Dv_h(x) d\sigma,$$

with the obvious convention if $i = 1$ or $y = x_i$. This in turn implies

$$|v_h(y)| \leq ch \sum_{m=1}^i \|Dv_h\|_{L^\infty(K_i)} \quad \forall y \in K_i.$$

Since $v_h|_{K_m}$ is a polynomial, the equivalence of norms on finite-dimensional normed spaces gives in two space dimensions

$$(3.7) \quad |v_h(y)| \leq ch^{-1} \sum_{m=1}^i \|Dv_h\|_{L^1(K_i)} = ch^{-1} F_i^l \quad \forall y \in K_i.$$

By integrating over K_i , we obtain

$$(3.8) \quad \int_{K_i} |v_h| dx \leq ch F_i^l.$$

By combining (3.6) and (3.8), we infer $F_j^l \leq ch + c'h \sum_{i=1}^j F_i^l$, which (provided h is small enough) immediately implies

$$F_j^l \leq \frac{ch}{1 - c'h} \left(1 + \frac{c'h}{1 - c'h}\right)^j.$$

Then, owing to (2.2) we have $j \leq N_l \leq ch^{-1}$, which in turn yields

$$F_j^l \leq ch,$$

which owing to (3.7) implies the desired L^∞ -bound on v_h .

We obtain the $W^{1,1}$ -bound by using the property saying that Ω can be covered with chains, i.e.,

$$\|Dv_h\|_{L^1(\Omega)} \leq \sum_{l=1}^{L_h} \sum_{K \in \Lambda_l} \|Dv_h\|_{L^1(K)} \leq c \sum_{l=1}^{L_h} F_l^{N_l} \leq chL_h \leq c,$$

which concludes the proof. \square

We are now in a position to prove the existence of a minimizer solving problem (2.8).

COROLLARY 3.3. *The discrete problem (2.8) has at least one minimizer u_h , and there is $c > 0$ independent of h such that*

$$(3.9) \quad J_h(u_h) \leq ch,$$

$$(3.10) \quad \|u_h\|_{W^{1,1}} + \|u_h\|_{L^\infty} \leq c.$$

Proof. Observe first that Lemma 3.1 implies that $S_{h,c(u)}$ is not empty, since $\mathcal{I}_h(u) \in S_{h,c(u)}$. Second, define $\mathcal{K}_h = \{v_h \in X_h; J_h(v_h) \leq J_h(\mathcal{I}_h u)\}$. Clearly $\mathcal{I}_h u$ is a member of \mathcal{K}_h . Moreover, owing to Lemma 3.1, for every v_h in \mathcal{K}_h ,

$$\int_{\Omega} |H(x, v_h, Dv_h)| dx \leq J_h(v_h) \leq J_h(\mathcal{I}_h u) \leq c(u) h.$$

That is, $\mathcal{K}_h \subset S_{h,c(u)}$. Lemma 3.2 implies that there is $c'(u)$ independent of h such that for all $v_h \in \mathcal{K}_h$, $\|v_h\|_{L^\infty} + \|v_h\|_{W^{1,1}} \leq c'(u)$. In other words, \mathcal{K}_h is uniformly bounded in $W^{1,1}(\Omega) \cap L^\infty(\Omega)$. Finite-dimensionality then implies that \mathcal{K}_h is compact. It is also clear that $J_h : \mathcal{K}_h \rightarrow \mathbb{R}$ is continuous in every norm (possibly not uniformly with respect to h). Then, there exists $u_h \in \mathcal{K}_h$ that minimizes J_h on \mathcal{K}_h . Since for every function v_h in $X_h \setminus \mathcal{K}_h$, $J_h(v_h)$ is larger than $J_h(\mathcal{I}_h u)$, we conclude that

$$\inf_{v_h \in X_h} J_h(v_h) = \inf_{v_h \in \mathcal{K}_h} J_h(v_h) = \min_{v_h \in \mathcal{K}_h} J_h(v_h) = J_h(u_h),$$

which concludes the proof. \square

Since in practice u_h might not be computed exactly or might be approximated to some extent by using some iterative process (the details of the process in question are irrelevant for our discussion), we now define the notion of an *almost minimizer*.

DEFINITION 3.1. *We say that a family of functions $\{v_h \in X_h\}_{h>0}$ is a sequence of almost minimizers for (1.1) if there is $c > 0$ such that for all $h > 0$,*

$$(3.11) \quad J_h(v_h) \leq ch.$$

It is clear that minimizers are almost minimizers, thus showing that the class of almost minimizers is not empty. Almost minimizers also satisfy the following uniform bound owing to Lemma 3.2:

$$(3.12) \quad \|v_h\|_{W^{1,1}} + \|v_h\|_{L^\infty} \leq c.$$

The rest of the paper consists of proving that sequences of almost minimizers for (1.1) converge to the viscosity solution of (1.1).

4. Passage to the limit. Henceforth $\{u_h \in X_h\}_{h>0}$ denotes a sequence of almost minimizers for (1.1) as defined above. We show in this section that sequences of almost minimizers for (1.1) converge to weak solutions of (1.1). The main result of this section is Theorem 4.5. That the limit solution is indeed the viscosity limit will be shown in sections 5 and 6 by proving a one-sided bound.

4.1. The $W^{1,\infty}(\overline{\Omega})$ -bound. We prove a $W^{1,\infty}(\overline{\Omega})$ -bound by using a regularization technique. Let $\rho : \mathbb{R}^2 \rightarrow \mathbb{R}^+$ be a positive kernel, i.e., ρ is compactly supported in $B_{\mathbb{R}^2}(0, 1)$ and $\int_{\mathbb{R}^2} \rho dx = 1$. We then define the sequence of mollifiers $\rho_\epsilon(x) = \rho(x/\epsilon)$ with

$$(4.1) \quad \epsilon = h^{1/2}.$$

This scaling is justified by the fact that $h\|\rho_\epsilon\|_{L^\infty} \leq c$, and this property is used in the proof of Lemma 4.1; see also Remark 4.1. Let us denote by \tilde{u}_h the extension of u_h to \mathbb{R}^2 by setting $u_h|_{\mathbb{R}^2 \setminus \Omega} = 0$. Since $u_h|_\Gamma = 0$, u_h is continuous and piecewise polynomial in $\overline{\Omega}$, this extension is $W^{1,\infty}$ -stable, i.e., $\|\tilde{u}_h\|_{W^{1,\infty}(\mathbb{R}^2)} \leq \|u_h\|_{W^{1,\infty}(\Omega)}$. We now define

$$(4.2) \quad u_{\epsilon,h} = \rho_\epsilon * \tilde{u}_h.$$

The main result of this section is the following lemma.

LEMMA 4.1. *There is a constant c , independent of h , such that*

$$\|u_{\epsilon,h}\|_{W^{1,\infty}(\overline{\Omega})} \leq c.$$

Proof. Let x be any point in \mathbb{R}^2 . We have

$$\begin{aligned} \|Du_{\epsilon,h}(x)\| &= \left| \int_{\mathbb{R}^2} \rho_\epsilon(x-y) D\tilde{u}_h(y) dy \right| \\ &\leq \int_{\Omega} \rho_\epsilon(x-y) \|D\tilde{u}_h(y)\| dy = \int_{\Omega} \rho_\epsilon(x-y) \|Du_h(y)\| dy \\ &\leq c_s \int_{\Omega} \rho_\epsilon(x-y) (|H(y, u_h(y), Du_h(y))| + |u_h(y)| + 1) dy \\ &\leq c_s \|\rho_\epsilon\|_{L^\infty(\Omega)} \int_{\Omega} |H(y, u_h(y), Du_h(y))| dy + (\|u_h\|_{L^\infty(\Omega)} + 1) \|\rho_\epsilon\|_{L^1(\Omega)}. \end{aligned}$$

The estimates (3.11) and (3.12) imply

$$\|Du_{\epsilon,h}(x)\| \leq c(h\|\rho_\epsilon\|_{L^\infty(\Omega)} + \|\rho_\epsilon\|_{L^1(\Omega)}).$$

Then the estimates $\|\rho_\epsilon\|_{L^\infty(\Omega)} \leq c\epsilon^{-2}$ and $\|\rho_\epsilon\|_{L^1(\Omega)} = 1$ along with the definition of ϵ (4.1) imply the desired result. \square

Remark 4.1. The above result generalizes to any space dimension d if estimates (3.11) and (3.12) hold and provided we take the scaling $\epsilon = h^{1/d}$.

4.2. The BV-bound on Du_h . We prove in this section an a priori bound on the BV-norm of Du_h . We start with a technical result concerning interface averages of the gradient of functions in X_h . Let (e_1, e_2) be the canonical basis of \mathbb{R}^2 .

LEMMA 4.2. *For all $v_h \in X_h$ and all $F \in \mathcal{F}_h^i$, the following holds:*

$$(4.3) \quad \{(n \cdot e_j) \partial_i v_h\}|_F = \{\partial_n v_h\}|_F (n_1 \cdot e_i)(n_1 \cdot e_j) = \{\partial_n v_h\}|_F (n_2 \cdot e_i)(n_2 \cdot e_j),$$

where n_1 (resp., n_2) is the unit outer normal of $K_1(F)$ on F (resp., $K_2(F)$ on F).

Proof. Let $\tau_1 := -\tau_2$ be one of the two unit vectors that are parallel to F (see Figure 2). Upon observing that $e_i = (n_1 \cdot e_i)n_1 + (\tau_1 \cdot e_i)\tau_1 = (n_2 \cdot e_i)n_2 + (\tau_2 \cdot e_i)\tau_2$,

FIG. 2. Illustration of the notation for Lemma 4.2.

$(n_1 \cdot e_i)(n_1 \cdot e_j) = (n_2 \cdot e_i)(n_2 \cdot e_j)$, and $(n_1 \cdot e_i)(\tau_1 \cdot e_j) = (n_2 \cdot e_i)(\tau_2 \cdot e_j)$, we infer

$$\begin{aligned}
 \{(n \cdot e_j) \partial_i v_h\} &= \frac{1}{2} ((n_1 \cdot e_j) \partial_i v_h|_{K_1} + (n_2 \cdot e_i) \partial_i v_h|_{K_2}) \\
 &= \frac{1}{2} ((n_1 \cdot e_j) (Dv_h|_{K_1}) \cdot ((n_1 \cdot e_i) n_1 + (\tau_1 \cdot e_i) \tau_1) \\
 &\quad + (n_2 \cdot e_j) (Dv_h|_{K_2}) \cdot ((n_2 \cdot e_i) n_2 + (\tau_2 \cdot e_i) \tau_2)) \\
 &= \{\partial_n v_h\} (n_1 \cdot e_i) (n_1 \cdot e_j) + \{\partial_\tau v_h\} (n_1 \cdot e_i) (\tau_1 \cdot e_j).
 \end{aligned}$$

Then, we conclude by observing that functions in X_h are continuous across interfaces, which implies $\{\partial_\tau v_h\} = 0$. \square

Another preliminary result consists of bounding the normal derivative of u_h at the boundary of the domain. This is achieved by means of the following lemma.

LEMMA 4.3. *There is c , independent of h , such that*

$$(4.4) \quad \int_{\Gamma} |\partial_n u_h| dx \leq c.$$

Proof. Let us denote by \mathcal{L}_h the layer of triangles that have at least one edge on Γ . Using an inverse inequality and (1.2), we deduce

$$\begin{aligned}
 \int_{\Gamma} |\partial_n u_h| dx &\leq c h^{-1} \sum_{K \in \mathcal{L}_h} \int_K \|Du_h\| dx \leq c h^{-1} \sum_{K \in \mathcal{L}_h} \int_K (|H(x, u_h, Du_h)| + |u_h| + 1) dx \\
 &\leq c h^{-1} \int_{\Omega} |H(x, u_h, Du_h)| dx + c h^{-1} \sum_{K \in \mathcal{L}_h} \int_K (|u_h| + 1) dx.
 \end{aligned}$$

Then we conclude using the estimates (3.11)–(3.12) together with the fact that $\sum_{K \in \mathcal{L}_h} \text{meas}(K) \leq ch$. \square

LEMMA 4.4. *There is c , independent of h , such that*

$$(4.5) \quad \|Du_h\|_{BV(\Omega)} \leq c.$$

Proof. Using (4.3) and the definition of the BV-seminorm implies

$$\begin{aligned} |Du_h|_{\text{BV}(\Omega)} &= \sum_{i,j=1}^2 \sup_{\substack{\phi \in C_0^\infty(\Omega) \\ \|\phi\|_{L^\infty} \leq 1}} \int_{\Omega} \partial_i u_h \partial_j \phi dx \\ &= \sum_{i,j=1}^2 \left(\sup_{\substack{\phi \in C_0^\infty(\Omega) \\ \|\phi\|_{L^\infty} \leq 1}} \sum_{K \in \mathcal{T}_h} \int_K -\partial_{ij} u_h \phi dx + \sum_{F \in \mathcal{F}_h^i} \int_F 2\{\partial_i u_h(n \cdot e_j)\} \phi ds \right) \\ &\leq \sum_{i,j=1}^2 \left(\sum_{K \in \mathcal{T}_h} \int_K |\partial_{ij} u_h| dx + \sum_{F \in \mathcal{F}_h^i} \int_F 2\{|\partial_n u_h|\} ds \right) \\ &\leq \sum_{K \in \mathcal{T}_h} \int_K (|\partial_{11} u_h| + |\partial_{22} u_h| + 2|\partial_{12} u_h|) dx + \sum_{F \in \mathcal{F}_h^i} \int_F 8\{|\partial_n u_h|\} ds. \end{aligned}$$

Now we use the relation $|x| = 2x_+ - x$ as follows:

$$\begin{aligned} |Du_h|_{\text{BV}(\Omega)} &\leq \sum_{K \in \mathcal{T}_h} \int_K (2((\partial_{11} u_h)_+ + (\partial_{22} u_h)_+) - \Delta u_h + 2|\partial_{12} u_h|) dx \\ &\quad + \sum_{F \in \mathcal{F}_h^i} \int_F (16\{|\partial_n u_h|\}_+ - 8\{|\partial_n u_h|\}) ds. \end{aligned}$$

Moreover, the definition of λ_+ implies that for all $x \in K$ and all $K \in \mathcal{T}_h$,

$$\begin{aligned} \max((\partial_{11} u_h)_+(x), (\partial_{22} u_h)_+(x)) &\leq \lambda_+(x), \\ |\partial_{12} u_h(x)| &\leq \lambda_+(x) - \frac{1}{2} \Delta u_h(x). \end{aligned}$$

Then,

$$\begin{aligned} |Du_h|_{\text{BV}(\Omega)} &\leq \sum_{K \in \mathcal{T}_h} \int_K (6\lambda_+ - 2\Delta u_h) dx + \sum_{K \in \mathcal{T}_h} \int_K 4\Delta u_h dx \\ &\quad + \sum_{F \in \mathcal{F}_h^i} \int_F (16\{|\partial_n u_h|\}_+) ds - \sum_{F \in \mathcal{F}_h^0} \int_F 4\partial_n u_h ds. \end{aligned}$$

Now we use $\Delta u_h \leq 2\lambda_+$ to derive

$$|Du_h|_{\text{BV}(\Omega)} \leq \sum_{K \in \mathcal{T}_h} \int_K 10\lambda_+ dx + \sum_{F \in \mathcal{F}_h^i} \int_F (16\{|\partial_n u_h|\}_+) ds + \int_{\Gamma} 4|\partial_n u_h| ds.$$

Let R_1 , R_2 , and R_3 be the three terms in the right-hand side of the above inequality.

We bound $R_1 + R_2$ as follows:

$$\begin{aligned} R_1 + R_2 &\leq c_1 \left(\sum_{K \in \mathcal{T}_h} \text{meas}(K) \right)^{1/p_1'} \left(\sum_{K \in \mathcal{T}_h} \int_K \lambda_+^{p_1} \right)^{1/p_1} \\ &\quad + c_2 \left(h^{\frac{p_2-1}{p_2} p_2'} \sum_{F \in \mathcal{F}_h^i} \text{meas}(F) \right)^{1/p_2'} \left(h^{1-p_2} \sum_{F \in \mathcal{F}_h^i} \int_F \{|\partial_n u_h|\}_+^{p_2} ds \right)^{1/p_2}. \end{aligned}$$

Then using the estimate on $J_h(u_h)$ in (3.11), we derive

$$R_1 + R_2 \leq c.$$

To conclude that R_3 is also bounded, we use the estimate (4.4). We conclude that $\|Du_h\|_{\text{BV}(\Omega)}$ is uniformly bounded by using the fact that Du_h is also uniformly bounded in $L^1(\Omega)$. \square

4.3. Convergence to a weak solution. We say that $v \in W^{1,\infty}(\overline{\Omega})$ is a weak solution to (1.1) if v solves (1.1) almost everywhere.

THEOREM 4.5. *Assume that (1.1) has a solution u in X and that the mesh family satisfies (3.3). Then the sequence of almost minimizers $\{u_h\}_{h>0}$ converges, up to subsequences, to a weak solution to (1.1).*

Proof. Owing to Corollary 3.3 and Lemma 4.4, the sequence $\{u_h\}_{h>0}$ is precompact in $W^{1,1}(\Omega)$. Let u be the limit, up to subsequences, of $\{u_h\}_{h>0}$ in $W^{1,1}(\Omega)$. We need to show that u is also in $W^{1,\infty}(\overline{\Omega})$. To see this, we observe that, up to subsequences again, $\{u_h\}_{h>0}$ and $\{u_{\epsilon,h}\}_{h>0}$ have the same limit in $W^{1,1}(\Omega)$ since

$$\|u_h - u_{\epsilon,h}\|_{W^{1,1}(\Omega)} \leq \|u_h - u\|_{W^{1,1}(\Omega)} + \|u - \rho_\epsilon * u\|_{W^{1,1}(\Omega)} + \|\rho_\epsilon * (u - u_h)\|_{W^{1,1}(\Omega)},$$

and the right-hand side goes to zero as $h \rightarrow 0$, owing to well-known properties of mollifiers, recalling that $\epsilon = h^{\frac{1}{2}}$. Moreover, the sequence $\{u_{\epsilon,h}\}_{h>0}$, being uniformly bounded in $W^{1,\infty}(\overline{\Omega}) \subset W^{1,\infty}(\Omega)$, converges in $W^{1,\infty}(\Omega)$ in the weak-* topology, up to subsequences. The uniqueness of limits implies that u is in $W^{1,\infty}(\Omega)$. The sequence $\{u_{\epsilon,h}\}_{h>0}$ being uniformly bounded in $W^{1,\infty}(\overline{\Omega})$ means that it is equicontinuous on $\overline{\Omega}$; as a result, the limit is continuous, i.e., $u \in C^0(\overline{\Omega})$. Combining the two above results implies $u \in W^{1,\infty}(\overline{\Omega}) = C^0(\overline{\Omega}) \cap W^{1,\infty}(\Omega)$.

We now prove that u is a weak solution to (1.1) by showing that $\|H(\cdot, u, Du)\|_{L^1(\Omega)} = 0$. Using that $u_h \rightarrow u$ in $W^{1,1}(\Omega)$, we conclude that, up to subsequences, $u_h \rightarrow u$ and $Du_h \rightarrow Du$ a.e. in Ω . Then, we can apply Egorov's theorem. Given $\epsilon' > 0$, there exists a set E with $\text{meas}(E) < \epsilon'$, such that the convergence of $u_h \rightarrow u$ on $\Omega \setminus E$ is uniform. Therefore, for every $\epsilon'', 1 \geq \epsilon'' > 0$, we can find $h(\epsilon'') > 0$ such that for every $h < h(\epsilon'')$,

$$|u_h(x) - u(x)| < \epsilon'' \quad \text{and} \quad \|Du_h(x) - Du(x)\| < \epsilon'' \quad \forall x \in \Omega \setminus E.$$

Note also that for every $x \in \Omega \setminus E$ and every $h < h(1)$, we have

$$\max(|u_h(x)|, |u(x)|, \|Du_h(x)\|, \|Du(x)\|) \leq R,$$

where $R := \|u\|_{W^{1,\infty}(\Omega)} + 1$. Hence, we can use the Lipschitz continuity of H to derive that there exists a value of $\epsilon'' > 0$ such that

$$(4.6) \quad |H(x, u, Du) - H(x, u_h, Du_h)| < \epsilon'$$

for every $x \in \Omega \setminus E$ and every $h < h(\epsilon'')$. Note that at this point the value of ϵ'' solely depends on ϵ' . We now split $\|H(\cdot, u, Du)\|_{L^1(\Omega)}$ in the following way:

$$(4.7) \quad \|H(\cdot, u, Du)\|_{L^1(\Omega)} = \|H(\cdot, u, Du)\|_{L^1(\Omega \setminus E)} + \|H(\cdot, u, Du)\|_{L^1(E)}.$$

We use that for every $R > 0$, $H(x, \cdot, \cdot)$ is Lipschitz continuous on $\overline{B_{\mathbb{R}}(0, R)} \times \overline{B_{\mathbb{R}^2}(0, R)}$ uniformly with respect to x to estimate

$$\|H(\cdot, u, Du)\|_{L^1(E)} \leq c \text{meas}(E) = c\epsilon'.$$

The other term in the right-hand side of (4.7) is estimated as follows:

$$\begin{aligned} & \|H(\cdot, u, Du)\|_{L^1(\Omega \setminus E)} \\ & \leq \|H(\cdot, u, Du) - H(\cdot, u_h, Du_h)\|_{L^1(\Omega \setminus E)} + \|H(\cdot, u_h, Du_h)\|_{L^1(\Omega \setminus E)} \\ & \leq \epsilon' \operatorname{meas}(\Omega \setminus E) + \|H(\cdot, u_h, Du_h)\|_{L^1(\Omega)} \\ & \leq c\epsilon' + ch, \end{aligned}$$

where we used (4.6) and (3.11) to derive the above inequality. As a result, for every $\epsilon' > 0$ and every $h < h(\epsilon')$,

$$\|H(\cdot, u, Du)\|_{L^1(\Omega)} \leq c(\epsilon' + h),$$

which means $\|H(\cdot, u, Du)\|_{L^1(\Omega)} = 0$. □

Remark 4.2. Recall that when $p_2 = 1$, hypothesis (3.3) is empty, i.e., Theorem 4.5 holds without any assumption on the mesh family other than that it is quasi uniform.

Now we have to address the question of whether this weak solution is indeed the viscosity solution.

5. One-sided bound. The goal of this section is to show that the algorithm described in this paper using the functional defined in (2.7) converges to the viscosity solution to (1.1) under the assumptions

$$(5.1) \quad p_1 > 2 \quad \text{and} \quad p_2 > 2.$$

Throughout section 5 we conjecture (3.3). That is, there exists an approximation operator \mathcal{I}_h satisfying (3.1) and (3.2) simultaneously for every mesh family. We have not been able to prove this statement for arbitrary meshes (unless the discontinuity lines of the gradient of u are aligned with the mesh). An alternative proof of convergence is reported in section 6 using a vertex-based entropy assuming that the mesh family is Cartesian and $p_1 = p_2 = 1$ so that the Clément interpolant always satisfies (3.1)–(3.2); i.e., the assumption (3.3) is empty.

Observe that if a function v is q -semiconcave, then there is $c > 0$ such that for all $\delta > 0$, all $\omega \subset \Omega$ so that $\omega + \delta e \subset \Omega$, and for every unit vector $e \in \mathbb{R}^2$, the following hold:

$$(5.2) \quad u(x + \delta e) - 2u(x) + u(x - \delta e) \leq c\delta^{2-\frac{2}{q}} \quad \forall x \in \omega,$$

$$(5.3) \quad \|(u(\cdot + \delta e) - 2u(\cdot) + u(\cdot - \delta e))_+\|_{L^q(\omega)} \leq c\delta^2.$$

Note that (5.2) implies that for every orthonormal basis of \mathbb{R}^2 , say (f_1, f_2) , every $\delta > 0$, every $\gamma \leq 1 - \frac{2}{q}$, and every $x \in \omega$, the following holds:

$$(5.4) \quad \Delta_\delta u(x) := \sum_{i=1}^2 u(x + \delta f_i) - 2u(x) + u(x - \delta f_i) \leq c\delta^{1+\gamma}.$$

To stay general in the remainder of the paper we make the following assumption:

$$(5.5) \quad \left\{ \begin{array}{l} \text{A weak solution } u \text{ to (1.1) is the unique viscosity solution if } u \in \\ W^{1,\infty}(\Omega) \text{ and there exist an orthonormal basis } (f_1, f_2) \text{ of } \mathbb{R}^2 \text{ and} \\ \gamma > 0 \text{ such that (5.4) is satisfied.} \end{array} \right.$$

FIG. 3. Illustration of the notation for Lemma 5.1.

This property is known to characterize viscosity solutions to stationary Hamilton–Jacobi equations with $H(x, u, Du) = u + F(Du)$, where $F : \mathbb{R}^2 \rightarrow \mathbb{R}$ is convex as shown by Lions and Souganidis [18, Thm. 2.6].

Throughout section 5 the orthonormal basis that we use is the canonical one (e_1, e_2) and the discrete Laplacian $\Delta_\delta u(x)$ is defined using this basis.

Let $x \in \Omega$ and $\delta > 0$ such that $B_{\mathbb{R}^2}(x, \delta) \subset \Omega$ and let us consider the square whose four vertices are $x - \delta e_1, x + \delta e_2, x + \delta e_1,$ and $x - \delta e_2$. This square is the union of the following four triangles:

$$\begin{aligned}
 E_1 &= x + \{(x_1, x_2) \in \mathbb{R}^2; x_1 \leq 0; x_2 \geq 0; x_1 - x_2 + \delta \geq 0\}, \\
 E_2 &= x + \{(x_1, x_2) \in \mathbb{R}^2; x_1 \geq 0; x_2 \geq 0; x_1 + x_2 - \delta \leq 0\}, \\
 E_3 &= x + \{(x_1, x_2) \in \mathbb{R}^2; x_1 \geq 0; x_2 \leq 0; x_1 - x_2 - \delta \leq 0\}, \\
 E_4 &= x + \{(x_1, x_2) \in \mathbb{R}^2; x_1 \leq 0; x_2 \leq 0; x_1 + x_2 + \delta \geq 0\}.
 \end{aligned}
 \tag{5.6}$$

The interior of E_i is henceforth denoted by $\dot{E}_i, i \in \{1, 2, 3, 4\}$. We also set

$$\begin{aligned}
 \Gamma_1 &= x + \{(x_1, 0) \in \mathbb{R}^2; -\delta \leq x_1 \leq 0\}, \\
 \Gamma_2 &= x + \{(0, x_2) \in \mathbb{R}^2; 0 \leq x_2 \leq \delta\}, \\
 \Gamma_3 &= x + \{(x_1, 0) \in \mathbb{R}^2; 0 \leq x_1 \leq \delta\}, \\
 \Gamma_4 &= x + \{(0, x_2) \in \mathbb{R}^2; -\delta \leq x_2 \leq 0\}.
 \end{aligned}
 \tag{5.7}$$

We now define the unit vectors $\tau_1 = 2^{-\frac{1}{2}}(e_1 + e_2), \tau_2 = 2^{-\frac{1}{2}}(e_1 - e_2), \tau_3 = \tau_1,$ and $\tau_4 = \tau_2$. See Figure 3.

We are now in a position to derive an integral representation of $\Delta_\delta u_h(x)$ over the square $E_1 \cup E_2 \cup E_3 \cup E_4$.

LEMMA 5.1. *The following holds for all $v_h \in X_h$ and all $x \in \Omega$ and $\delta > 0$ such that $B_{\mathbb{R}^2}(x, \delta) \subset \Omega$:*

$$(5.8) \quad \Delta_\delta v_h(x) = \sum_{l=1}^4 \sum_{\substack{K \in \mathcal{T}_h \\ K \cap E_l \neq \emptyset}} \int_{K \cap E_l} \partial_{\tau_l \tau_l} v_h + 2 \sum_{l=1}^4 \sum_{\substack{F \in \mathcal{F}_h^i \\ F \cap E_l \neq \emptyset}} \int_{F \cap E_l} \{-\partial_n v_h\}(\tau_l \cdot n)^2.$$

Proof. Consider first triangle E_1 . Upon integrating by parts two times and using Lemma 4.2 and the fact that $v_h \in C^0(\Omega)$, we infer the following:

$$\begin{aligned} 0 &= \int_{E_1} v_h \partial_{\tau_1 \tau_1}(1) dx = \sum_{\substack{K \in \mathcal{T}_h \\ K \cap E_1 \neq \emptyset}} \int_{K \cap E_1} v_h \partial_{\tau_1 \tau_1}(1) dx = \sum_{\substack{K \in \mathcal{T}_h \\ K \cap E_1 \neq \emptyset}} - \int_{K \cap E_1} \partial_{\tau_1} v_h \partial_{\tau_1}(1) dx \\ &= \sum_{\substack{K \in \mathcal{T}_h \\ K \cap E_1 \neq \emptyset}} \int_{K \cap E_1} \partial_{\tau_1 \tau_1} v_h dx - \int_{\partial(K \cap E_1)} (\tau_1 \cdot n) \partial_{\tau_1} v_h ds \\ &= \sum_{\substack{K \in \mathcal{T}_h \\ K \cap E_1 \neq \emptyset}} \int_{K \cap E_1} \partial_{\tau_1 \tau_1} v_h dx - \sum_{\substack{F \in \mathcal{F}_h^i \\ F \cap E_1 \neq \emptyset}} \int_{F \cap E_1} 2\{\partial_n v_h\}(\tau_1 \cdot n)^2 ds \\ &\quad + \frac{1}{2} \int_{\Gamma_1} \partial_1 v_h ds - \frac{1}{2} \int_{\Gamma_2} \partial_2 v_h ds - \int_{\Gamma_1} \partial_n v_h (\tau_1 \cdot n)^2 ds - \int_{\Gamma_2} \partial_n v_h (\tau_1 \cdot n)^2 ds. \end{aligned}$$

By proceeding similarly with the other triangles $E_2, E_3,$ and $E_4,$ and adding the four results, we obtain

$$\begin{aligned} & - \int_{\Gamma_1} \partial_1 v_h ds + \int_{\Gamma_2} \partial_2 v_h ds + \int_{\Gamma_3} \partial_1 v_h ds - \int_{\Gamma_4} \partial_2 v_h ds \\ &= \sum_{l=1}^4 \sum_{\substack{K \in \mathcal{T}_h \\ K \cap E_l \neq \emptyset}} \int_{K \cap E_l} \partial_{\tau_l \tau_l} v_h dx + 2 \sum_{l=1}^4 \sum_{\substack{F \in \mathcal{F}_h^i \\ F \cap E_l \neq \emptyset}} \int_{F \cap E_l} \{-\partial_n v_h\}(\tau_l \cdot n)^2. \end{aligned}$$

We conclude by observing that

$$\Delta_\delta v_h(x) = - \int_{\Gamma_1} \partial_1 v_h ds + \int_{\Gamma_2} \partial_2 v_h ds + \int_{\Gamma_3} \partial_1 v_h ds - \int_{\Gamma_4} \partial_2 v_h ds.$$

This concludes the proof. \square

We are now in a position to prove a one-sided bound similar to that in (5.5).

LEMMA 5.2. *For all sequences of almost minimizers for (2.8), say $\{u_h\}_{h>0},$ there exist $c > 0$ and $\gamma := \min(\frac{p_1-2}{p_1}, \frac{p_2-2}{p_2})$ such that for all $x \in \Omega$ and $\delta > h$ such that $B_{\mathbb{R}^2}(x, \delta) \subset \Omega,$ the following one-sided bound holds:*

$$(5.9) \quad \Delta_\delta u_h(x) \leq c\delta^{1+\gamma}.$$

Proof. Let us set $E := E_1 \cup E_2 \cup E_3 \cup E_4$. Using Lemma 5.1 together with the estimate (3.11), we infer

$$\begin{aligned} \Delta_\delta u_h(x) &\leq \sum_{K \in \mathcal{T}_h \cap E} \int_K \lambda_+(u_h) dx + 2 \sum_{F \in \mathcal{F}_h^i \cap E} \int_F \{-\partial_n u_h\}_+ ds \\ &\leq \left(\sum_{K \in \mathcal{T}_h \cap E} \text{meas } K \right)^{\frac{1}{p_1}} \left(\sum_{K \in \mathcal{T}_h} \int_K \lambda_+(u_h)^{p_1} dx \right)^{\frac{1}{p_1}} \\ &\quad + 2 \left(h^{\frac{p_2-1}{p_2} p_2'} \sum_{F \in \mathcal{F}_h^i \cap E} \text{meas } F \right)^{\frac{1}{p_2}} \left(h^{1-p_2} \sum_{F \in \mathcal{F}_h^i} \int_F \{-\partial_n u_h\}_+^{p_2} ds \right)^{\frac{1}{p_2}} \\ &\leq c \left(\delta^{\frac{2}{p_1}} + \delta^{\frac{2}{p_2}} \right), \end{aligned}$$

where we used $h \leq \delta$ in the last inequality. (We have bounded from above the number of cells in $\mathcal{T}_h \cap E$ and the number of interfaces in $\mathcal{F}_h^i \cap E$ by δ/h and this number cannot be less than 1.) We conclude by observing that $\frac{2}{p_i} = 1 + \frac{p_i-2}{p_i}$ and $p_i > 2$ for $i = 1, 2$. \square

THEOREM 5.3. *Let $u \in X$ be the unique solution to (1.1). Under the mesh assumption (3.3), the uniqueness assumption (5.5), and the restriction $p_1 > 2, p_2 > 2$, every sequence of almost minimizers converges to the unique viscosity solution to (1.1).*

Proof. Let $\{u_h\}_{h>0}$ be a sequence of almost minimizers. Let $\delta > 0$ and let $\Omega_\delta = \{x \in \Omega; B_{\mathbb{R}^2}(x, \delta) \subset \Omega\}$. Then owing to Lemma 5.9 the following holds for every $x \in \Omega_\delta$:

$$\Delta_\delta u_h(x) \leq c\delta^{1+\gamma}.$$

Since u_h converges strongly to u in L^1 , we infer that $u_h \rightarrow u$ a.e. in Ω_δ , that is,

$$\Delta_\delta u(x) \leq c\delta^{1+\gamma}, \quad \text{a.e. } x \text{ in } \Omega_\delta.$$

We then conclude that the above inequality holds for every $x \in \Omega_\delta$ since u is continuous. \square

Remark 5.1. Recall that whether hypothesis (3.3) holds for every quasi-uniform mesh family is an open question. It definitely holds on aligned meshes. We remove this assumption in the next section for uniform meshes by taking $p_2 = 1$ and adding an extra term in the entropy.

6. One-sided bound on uniform meshes. The goal of this section is to prove an analogue of Theorem 5.3 in the case $p_2 = 1$, i.e., the mesh assumption (3.3) is empty. For this purpose we assume that the mesh is uniform and add a vertex-centered entropy to the functional J_h . We prove the one-sided bound (5.5) using the orthonormal basis $\frac{1}{\sqrt{2}}(e_1 + e_2, e_1 - e_2)$.

6.1. The vertex-centered entropy. We henceforth assume that the mesh is uniform in the sense that the set of vertices is

$$(6.1) \quad \Omega_h := \{(sh, kh) \in \mathbb{R}^2; (s, k) \in I_h\} \subset \overline{\Omega},$$

where $\{I_h\}_{h>0}$ is a family of subsets of \mathbb{N}^2 . The set of interior vertices is denoted by $\dot{\Omega}_h$. The mesh cells are triangles whose edges are parallel to e_1, e_2 , or $e_1 + e_2$.

In order to understand how a vertex-centered entropy can be constructed, let us consider a point $x := (ih, jh) \in \Omega_h$ and $\delta > 0$ such that $x + B_h(0, \sqrt{2}\delta) \subset \Omega_h$, where $B_h(0, \mu) := \{(sh, kh) = z; (k, l) \in \mathbb{N}^2; \|z\| < \mu\}$. Assume for the time being that $\delta = nh$ with $n \geq 1$. We now define the following index sets

$$\begin{aligned}
 \Lambda_0 &= \{(s, k); |k - j| \leq n \text{ and } |s - i| \leq n\}, \\
 \Lambda_1 &= \{(s, k); 1 \leq k - j \leq n \text{ and } |s - i| \leq k - j - 1\}, \\
 \Lambda_2 &= \{(s, k); 1 \leq s - i \leq n \text{ and } |k - j| \leq s - i - 1\}, \\
 \Lambda_3 &= \{(s, k); 1 \leq j - k \leq n \text{ and } |s - i| \leq j - k - 1\}, \\
 \Lambda_4 &= \{(s, k); 1 \leq i - s \leq n \text{ and } |k - j| \leq i - s - 1\}, \\
 \Lambda_5 &= \{(s, k); 0 < |s - i| = |k - j| < n\}.
 \end{aligned}
 \tag{6.2}$$

Up to a $\pi/4$ rotation and an appropriate rescaling, the sets $\Lambda_m, m \in \{1, 2, 3, 4\}$ correspond to the triangles E_m defined in (5.6). The set Λ_0 corresponds to the square $E_1 \cup E_2 \cup E_3 \cup E_4$. The set Λ_5 corresponds to $\Gamma_1 \cup \Gamma_2 \cup \Gamma_3 \cup \Gamma_4$ minus the center and the four corners of the square (the Γ_m 's have been defined in (5.7)); see also Figure 3.

Let v be a member of X_h . To simplify notation we set $v_{s,k} := v(sh, kh)$. Now our goal is to find a discrete analogue of the integral representation (5.8) of the discrete Laplacian

$$\Delta_{\sqrt{2}\delta} u(x) = u_{i-n,j-n} + u_{i-n,j+n} + u_{i+n,j-n} + u_{i+n,j+n} - 4u_{i,j}.
 \tag{6.3}$$

Let $z = (sh, kh) \in \dot{\Omega}_h$ be an interior vertex. We introduce the following additional notation for the second-order directional finite differences at z :

$$D_1^2 v_{s,k} = u_{s-1,k} - 2u_{s,k} + u_{s+1,k}, \quad D_2^2 v_{s,k} = u_{s,k-1} - 2u_{s,k} + u_{s,k+1}.
 \tag{6.4}$$

Then the following discrete representation of $\Delta_{\sqrt{2}\delta} v(x)$ holds:

$$\begin{aligned}
 \Delta_{\sqrt{2}\delta} v(x) &= R_1(v, x, \delta) + D_1^2 v_{i,j} + D_2^2 v_{i,j} + \sum_{(s,k) \in \Lambda_1 \cup \Lambda_3} D_1^2 v_{s,k} + \sum_{(s,k) \in \Lambda_2 \cup \Lambda_4} D_2^2 v_{s,k} \\
 &+ \sum_{(s,k) \in \Lambda_5} \left(\frac{1}{2} D_1^2 v_{s,k} + \frac{1}{2} D_2^2 v_{s,k} \right),
 \end{aligned}
 \tag{6.5}$$

where the remainder $R_1(v, x, \delta)$ is defined by

$$\begin{aligned}
 2R_1(v, x, \delta) &= (v_{i-n+1,j+n} - v_{i-n,j+n}) + (v_{i-n,j+n-1} - v_{i-n,j+n}) \\
 &+ (v_{i+n-1,j+n} - v_{i+n,j+n}) + (v_{i+n,j+n-1} - v_{i+n,j+n}) \\
 &+ (v_{i+n-1,j-n} - v_{i+n,j-n}) + (v_{i+n,j-n+1} - v_{i+n,j-n}) \\
 &+ (v_{i-n+1,j-n} - v_{i-n,j-n}) + (v_{i-n,j-n+1} - v_{i-n,j-n}).
 \end{aligned}
 \tag{6.6}$$

We now define a vertex-centered entropy as follows:

$$E_h(v) := \sum_{(ih,jh) \in \dot{\Omega}_h} (D_1^2 v_{i,j})_+^{p_3} + (D_2^2 v_{i,j})_+^{p_3},
 \tag{6.7}$$

where

$$(6.8) \quad p_3 > 2.$$

We modify the functional J_h by setting $p_1 = p_2 = 1$ and by adding the vertex-centered entropy

$$(6.9) \quad J_h(v) = \int_{\Omega} |H(x, v, Dv)| dx + h \sum_{K \in \mathcal{T}_h} \int_K \lambda_+(v) dx + h \sum_{F \in \mathcal{F}_h^i} \int_F \{-\partial_n v\}_+ d\sigma + h^{3-2p_3} E_h(v),$$

and we henceforth denote by $\{u_h\}_{h>0}$ a sequence of almost minimizers for (2.8) using the above modified functional.

6.2. Consistency. The goal of this section is to show that, with the above choice of entropy, it is possible to construct an approximation of u , say $\mathcal{I}_h u$, that satisfies the estimate

$$(6.10) \quad J_h(\mathcal{I}_h u) \leq ch.$$

We make use of the Clément interpolation operator [7, 6] to this purpose. Let v be an arbitrary function in $L^1(\Omega)$. We define $\mathcal{I}_h(v)$ to be a piecewise linear function on the mesh \mathcal{T}_h as follows. Let a be any vertex of \mathcal{T}_h . If a is on Γ , we set $\mathcal{I}_h(v)(a) = 0$. If a is an interior vertex, we define Δ_a to be the set of all those triangles that have a as a vertex. We define $r(v) \in \mathbb{P}_1$ to the linear polynomial such that

$$(6.11) \quad \int_{\Delta_a} (r(v)(x) - v(x))q(x) dx = 0 \quad \forall q \in \mathbb{P}_1.$$

Then we set $\mathcal{I}_h(v)(a) = r(v)(a)$. The interpolant \mathcal{I}_h thus defined is $W^{1,\infty}$ -stable and there is $c > 0$ such that for all $m \in \{0, 1\}$, $k \in \{0, 1\}$, any number $p \geq 1$, and all $v \in W^{k+1,p}(\Omega) \cap W_0^{1,p}(\Omega)$ the following holds (see [6, 7]):

$$(6.12) \quad \|\mathcal{I}_h(v) - v\|_{W^{m,p}(\Omega)} \leq ch^{k+1-m} \|v\|_{W^{k+1,p}(\Omega)},$$

$$(6.13) \quad \left(\sum_{F \in \mathcal{F}_h^i} \|\mathcal{I}_h v - v\|_{W^{m,p}(F)}^p \right)^{1/p} \leq ch^{k+1-m-\frac{1}{p}} \|v\|_{W^{k+1,p}(\Omega)}.$$

LEMMA 6.1. *Under the above hypotheses and with the definition (6.9) of the functional J_h , there is c , uniform in h , such that the linear Clément interpolant of u , say $\mathcal{I}_h(u)$, satisfies*

$$(6.14) \quad J_h(\mathcal{I}_h(u)) \leq ch.$$

Proof. The $W^{1,\infty}$ -stability and the approximation property (6.12) with $m = p = k = 1$ of the Clément interpolant together with the assumption (1.3) yields $\|H(\cdot, \mathcal{I}_h(u), D\mathcal{I}_h(u))\|_{L^1(\Omega)} \leq ch$. Since $\mathcal{I}_h(u)$ is piecewise linear, the volume entropy in J_h involving $\lambda_+(\mathcal{I}_h(u))$ is zero. The q -semiconcavity of u implies $\{-\partial_n \mathcal{I}_h u\}_+ = \{-\partial_n(\mathcal{I}_h u - u)\}_+$ across every $F \in \mathcal{F}_h^i$, since the $W^{2,q}$ -component of u has a continuous gradient by embedding (recall that $q > 2$). This together with (6.13) (using $k = 1$,

$m = 0, p = 1$) yields that the interface entropy involving $\{-\partial_n \mathcal{I}_h u\}_+$ is bounded from above by ch .

Now we have to make sure that the vertex-centered entropy is appropriately controlled. Let $a \in \hat{\Omega}_h$ be an interior mesh vertex. Let us evaluate $r(u)$ at a as defined in (6.11). To do so, we expand $r(u)$ in the following manner:

$$r(u)(x) = \alpha + \beta \cdot (x - a),$$

where $\alpha \in \mathbb{R}$ and $\beta \in \mathbb{R}^2$ are yet to be determined. Since the mesh is structured, the following holds:

$$\int_{\Delta_a} (x - a) dx = 0.$$

This immediately implies

$$0 = \int_{\Delta_a} (r(u) - u) dx = |\Delta_a| \left(\alpha - \Delta_a^{-1} \int_{\Delta_a} u dx \right),$$

i.e., $r(u)(a) = \alpha = \frac{1}{|\Delta_a|} \int_{\Delta_a} u dx$.

Let i be an index in $\{1, 2\}$. Let us set $\Delta_a^+ = \Delta_a + he_i$ and $\Delta_a^- = \Delta_a - he_i$. Then, with obvious notation,

$$\begin{aligned} |\Delta_a| D_i^2 r(u)(a) &= \int_{\Delta_a^+} u(x) dx - 2 \int_{\Delta_a} u(x) dx + \int_{\Delta_a^-} u(x) dx \\ &= \int_{\Delta_a} (u(x + he_i) - 2u(x) + u(x - he_i)) dx \\ &= \int_{\Delta_a} D_i^2 u(x) dx. \end{aligned}$$

Now, using the q -semiconcavity hypothesis (1.5), we have $u = v_c + w$, where $v_c \in W^{1,\infty}(\Omega)$ is concave and $w \in W^{2,q}(\Omega)$. Then, using the concavity of v_c and the $W^{2,q}$ -regularity of w , infer

$$E(\mathcal{I}_h(u)) = E(\mathcal{I}_h(w)) \leq ch^{2p_3-2}.$$

This implies $h^{3-2p_3} E(\mathcal{I}_h(u)) \leq ch$. This completes the proof. \square

Lemma 6.1 means that the set of almost minimizers is not empty when using definition (6.9). No extra assumptions need to be made.

Remark 6.1. Note that the fact that the mesh is structured is a key argument in the proof of Lemma 6.1.

6.3. Convergence to the viscosity solution. Let $\delta \geq h$ be a real number that we assume for the time being to be a multiple of h , i.e., $\delta = nh$ with $n \geq 1$. Consider a point $x := (ih, jh) \in \Omega_h$ such that $x + B_h(0, \sqrt{2}\delta) \subset \Omega_h$.

LEMMA 6.2. *Under the above hypotheses, for all sequences of almost minimizers of (2.8), say $\{u_h\}_{h>0}$, there is c , independent of x, h , and δ , and there is $\gamma := 1 - \frac{2}{p_3} > 0$ so that*

$$(6.15) \quad \Delta_{\sqrt{2}\delta} u_h(x) \leq c\delta^{1+\gamma} + R_1(u_h, x, \delta).$$

Proof. From (6.5) we infer

$$\Delta_{\sqrt{2}\delta}u_h(x) \leq R_1(u_h, x, \delta) + \frac{5}{2} \sum_{(s,k) \in \Lambda_0} (D_1^2(u_h)_{s,k})_+ + \frac{5}{2} \sum_{(s,k) \in \Lambda_0} (D_2^2(u_h)_{s,k})_+.$$

Using Hölder’s inequality, this implies

$$\Delta_{\sqrt{2}\delta}u_h(x) \leq R_1(u_h, x, \delta) + \text{card}(\Lambda_0)^{\frac{1}{p_3}} (E_h(u_h))^{\frac{1}{p_3}},$$

where $\text{card}(\Lambda_0)$ is the cardinal number of Λ_0 . Clearly $\text{card}(\Lambda_0) \leq c(\delta/h)^2$. Moreover, since $\{u_h\}_{h>0}$ is a sequence of almost minimizers, it comes that $E_h(u_h) \leq ch^{2(p_3-1)}$. That is to say,

$$\Delta_{\sqrt{2}\delta}u_h(x) \leq R_1(u_h, x, \delta) + c\delta^{2/p_3}h^{-2/p_3}h^{2(p_3-1)/p_3} \leq R_1(u_h, x, \delta) + c\delta^{1+\gamma},$$

where $\gamma = 1 - 2/p_3 > 0$ since $p_3 > 2$. □

We now conclude the following theorem.

THEOREM 6.3. *Let $u \in X$ be the unique solution to (1.1). Consider the uniform mesh family defined by (6.1). Under the uniqueness assumption (5.5), and the restriction $p_3 > 2$, every sequence of almost minimizers for the functional (6.9) converges to the unique viscosity solution to (1.1).*

Proof. Let $\{u_h\}_{h>0}$ be a sequence of almost minimizers. Let x be a point in Ω . There exists δ_0 such that $B_{\mathbb{R}^2}(x, \delta_0) \subset \Omega$. Let δ be a fixed number in $(0, \delta_0/2\sqrt{2}]$ and let h be an arbitrary mesh size such that $h \leq \delta$.

Since the ratio δ/h may not be an integer and/or x is almost surely not a member of Ω_h , we define $n := \lfloor \delta/h \rfloor$, $i := \lfloor (x \cdot e_1)/h \rfloor$, and $j := \lfloor (x \cdot e_2)/h \rfloor$, where $\lfloor \cdot \rfloor$ is the floor function. Then we set $\bar{\delta} = nh$ and $\bar{x} = (ih, jh)$. Note that with our choice of parameters, \bar{z} is in Ω_h , where \bar{z} is either \bar{x} or $\bar{x} \pm \bar{\delta}e_1 \pm \bar{\delta}e_2$. These definitions imply

$$(6.16) \quad \Delta_{\sqrt{2}\delta}u_h(x) = \Delta_{\sqrt{2}\bar{\delta}}u_h(\bar{x}) + R_2(u_h, x, \delta),$$

where the remainder is defined by $R_2(u_h, x, \delta) := \Delta_{\sqrt{2}\delta}u_h(x) - \Delta_{\sqrt{2}\bar{\delta}}u_h(\bar{x})$.

Now we use the one-sided bound (6.15) from Lemma 6.2 to obtain

$$\Delta_{\sqrt{2}\delta}u_h(x) \leq c\bar{\delta}^{1+\gamma} + R_1(u_h, \bar{x}, \bar{\delta}) + R_2(u_h, x, \delta).$$

We conclude by passing to the limit on h . Clearly $\bar{\delta} \rightarrow \delta$. Since $u_h \rightarrow u$ a.e. in Ω , we infer $\Delta_{\sqrt{2}\delta}u_h(x) \rightarrow \Delta_{\sqrt{2}\delta}u(x)$ for a.e. x in Ω . Moreover, owing to Lemma 6.4, $R_1(u_h, \bar{x}, \bar{\delta}) \rightarrow 0$ and $R_2(u_h, x, \delta) \rightarrow 0$ for a.e. x in Ω . As a result,

$$\Delta_{\sqrt{2}\delta}u(x) \leq c\delta^{1+\gamma} \text{ for a.e. } x \in \Omega,$$

and the constant c does not depend on x . Since u is continuous, this implies that the inequality holds for every x in Ω and every δ such that $B_{\mathbb{R}^2}(x, \delta_0) \subset \Omega$. □

Remark 6.2. Recall that the class of stationary Hamilton–Jacobi equations defined by $H(x, u, Du) = u + F(Du)$, where $F : \mathbb{R}^2 \rightarrow \mathbb{R}$ is convex, has a unique viscosity solution characterized by (5.5); see [18, Thm. 2.6]. Moreover, it is known that the solution is ∞ -semiconcave under appropriate restrictions on the domain. In other words, Theorem 6.3 holds at least for the above class of Hamilton–Jacobi equations.

LEMMA 6.4. *Under the above hypotheses, $R_1(u_h, \bar{x}(x), \bar{\delta}) \rightarrow 0$ for a.e. $x \in \Omega$ and $R_2(u_h, x, \delta) \rightarrow 0$ for a.e. $x \in \Omega$.*

Proof. R_1 is composed of eight terms which have the generic form

$$r_h(\bar{x}, \bar{\delta}, h) := u_h(\bar{x} + s_1 \bar{\delta} e_{\pm} + s_2 h e_i) - u_h(\bar{x} + s_1 \bar{\delta} e_{\pm}),$$

where $e_{\pm} = e_1 \pm e_2$, $i \in \{1, 2\}$ and $s_1, s_2 \in \{-1, +1\}$. To avoid boundary issues, we extend r_h to \mathbb{R}^2 by replacing u_h by \tilde{u}_h ; the extension in question is denoted by \tilde{r}_h . We now evaluate the L^1 -norm of $\tilde{r}_h(\bar{x}(x), \bar{\delta}, h)$ as follows:

$$\begin{aligned} \|\tilde{r}_h(\bar{x}(\cdot), \bar{\delta}, h)\|_{L^1(\mathbb{R}^2)} &= \int_{\mathbb{R}^2} |\tilde{u}_h(\bar{x}(x) + s_1 \bar{\delta} e_{\pm} + s_2 h e_i) - \tilde{u}_h(\bar{x}(x) + s_1 \bar{\delta} e_{\pm})| dx \\ &= \int_{\mathbb{R}^2} |\tilde{u}_h(\bar{x}(x) + s_2 h e_i) - \tilde{u}_h(\bar{x}(x))| dx \\ &= h^2 \sum_{k,l=-\infty}^{+\infty} |\tilde{u}_h(x_{k,l} + s_2 h e_i) - \tilde{u}_h(x_{k,l})| \\ &= h^2 \sum_{k,l=-\infty}^{+\infty} \left| \int_{F_{k,l}} \partial_{e_i} \tilde{u}_h(y) dy \right|, \end{aligned}$$

where we have denoted $x_{k,l} = (kh, lh)$ and $F_{k,l}$ is the segment $(x_{k,l}, x_{k,l} + s_2 h e_i)$. Note that $F_{k,l}$ is equal to $(x_{k,l}, x_{(k+s_2),l})$ if $i = 1$ and $(x_{k,l}, x_{k,(l+s_2)})$ if $i = 2$. Let us denote by $\Delta_{x_{k,l}}$ the set of all those triangles that have $x_{k,l}$ as a vertex (there are six of those). Then a trace and an inverse inequality yield

$$\left| \int_{F_{k,l}} \partial_{e_i} \tilde{u}_h(y) dy \right| \leq ch^{-1} \sum_{K \in \Delta_{x_{k,l}}} \int_K \|D\tilde{u}_h\|_{L^1(K)}.$$

This then yields

$$\begin{aligned} \|\tilde{r}_h(\bar{x}(\cdot), \bar{\delta}, h)\|_{L^1(\mathbb{R}^2)} &\leq ch \sum_{k,l=-\infty}^{+\infty} \sum_{K \in \Delta_{x_{k,l}}} \int_K \|D\tilde{u}_h\|_{L^1(K)} \\ &\leq ch \|\tilde{u}_h\|_{W^{1,1}(\mathbb{R}^2)} \leq c' h \|u_h\|_{W^{1,1}(\Omega)}. \end{aligned}$$

This means $\tilde{r}_h(\bar{x}(\cdot), \bar{\delta}, h) \rightarrow 0$ in $L^1(\mathbb{R}^2)$, which immediately implies $r_h(\bar{x}(x), \bar{\delta}, h) \rightarrow 0$ for a.e. x in Ω .

For R_2 , we observe that R_2 is composed of five terms which have the generic form

$$r_h(x, \delta, h) := u_h(x + s\delta e_{\pm}) - u_h(\bar{x}(x) + s\bar{\delta} e_{\pm}),$$

where $s \in \{-1, 0, +1\}$. To avoid boundary issues, we again extend r_h to \mathbb{R}^2 by replacing u_h by \tilde{u}_h ; the extension in question is denoted by \tilde{r}_h . We now evaluate the

L^1 -norm of $\tilde{r}_h(x, \delta, h)$ as follows:

$$\begin{aligned} \|\tilde{r}_h(\cdot, \bar{\delta}, h)\|_{L^1(\mathbb{R}^2)} &= \int_{\mathbb{R}^2} |\tilde{u}_h(x + s\delta e_{\pm}) - \tilde{u}_h(\bar{x}(x) + s\bar{\delta}e_{\pm})| dx \\ &\leq \int_{\mathbb{R}^2} |\tilde{u}_h(x + s\delta e_{\pm}) - \tilde{u}_h(x + s\bar{\delta}e_{\pm})| dx \\ &\quad + \int_{\mathbb{R}^2} |\tilde{u}_h(x + s\bar{\delta}e_{\pm}) - \tilde{u}_h(\bar{x}(x) + s\bar{\delta}e_{\pm})| dx \\ &\leq \int_{\mathbb{R}^2} |\tilde{u}_h(x) - \tilde{u}_h(x + s(\bar{\delta} - \delta)e_{\pm})| dx \\ &\quad + \int_{\mathbb{R}^2} |\tilde{u}_h(x) - \tilde{u}_h(\bar{x}(x))| dx. \end{aligned}$$

Let r_1, r_2 be the two integrals in the right-hand side, respectively. For r_1 we have

$$\begin{aligned} r_1 &= \int_{\mathbb{R}^2} \left| \int_0^1 D\tilde{u}_h(x + \theta s(\bar{\delta} - \delta)e_{\pm}) \cdot (\bar{\delta} - \delta)e_{\pm} d\theta \right| dx \\ &\leq |\bar{\delta} - \delta| \int_0^1 \int_{\mathbb{R}^2} \|D\tilde{u}_h(x + \theta s(\bar{\delta} - \delta)e_{\pm})\| dx d\theta \leq h \|D\tilde{u}_h\|_{L^1(\mathbb{R}^2)} \\ &\leq ch \|u_h\|_{W^{1,1}(\Omega)}. \end{aligned}$$

For the second residual we have

$$r_2 = \sum_{k,l=-\infty}^{+\infty} \int_{S_{k,l}} |\tilde{u}_h(x) - \tilde{u}_h(x_{k,l})| dx,$$

where $x_{k,l} = (kh, lh)$ and $S_{k,l}$ is the square $(x_{k,l}, x_{k+1,l}) \times (x_{k,l}, x_{k,l+1})$. Then a trace inequality and an inverse inequality yields

$$\begin{aligned} r_2 &= \sum_{k,l=-\infty}^{+\infty} \int_{S_{k,l}} \left| \int_0^1 D\tilde{u}_h(x + \theta(x_{k,l} - x)) \cdot (x_{k,l} - x) d\theta \right| dx \\ &\leq ch^{-1} \sum_{k,l=-\infty}^{+\infty} \int_{S_{k,l}} \|D\tilde{u}_h\|_{L^1(S_{k,l})} \leq ch \sum_{k,l=-\infty}^{+\infty} \|D\tilde{u}_h\|_{L^1(S_{k,l})} \\ &\leq ch \|u_h\|_{W^{1,1}(\Omega)}. \end{aligned}$$

We then conclude as above. \square

7. Numerical experiments. A one-dimensional theory for the L^1 -approximation of stationary Hamilton–Jacobi equations is developed in [14], and efficient numerical algorithms are proposed and analyzed in [12].

The purpose of this section is to support our theory by reporting two-dimensional numerical experiments. Our goal is not to analyze or discuss the optimality of any given numerical strategy to solve (2.8) but to show that L^1 -minimizers are computable

FIG. 4. *Pentagon: Aligned unstructured mesh (left); nonaligned unstructured mesh (right).*

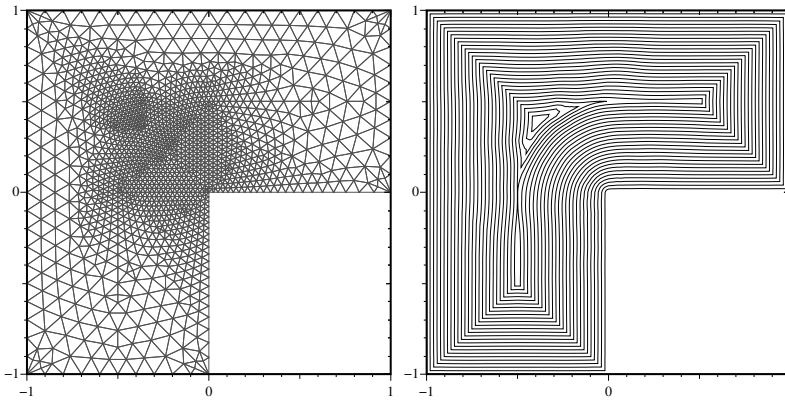

FIG. 5. *L-shaped domain: Unstructured mesh (left); iso-lines of approximate minimizer (right).*

and are very accurate nonoscillatory approximations to viscosity solutions of stationary two-dimensional Hamilton–Jacobi equations. We henceforth focus our attention on the eikonal equation, $\|Du\| = 1$, equipped with homogeneous Dirichlet boundary conditions. The computations are done using piecewise linear continuous finite elements. The entropy is defined using $p = 2$. The discrete problem (2.8) is solved by using an iterative regularization method described in [11]. In a few words, the algorithm consists of computing $\lim_{h \rightarrow 0} \lim_{\epsilon \rightarrow 0} \operatorname{argmin}_{v_h \in X_h} J_{h,\epsilon}(v_h)$. The functional $J_{h,\epsilon}(v_h)$ is a regularized version of $J_h(v_h)$, where the absolute value defining the L^1 -norm and the $(\cdot)_+$ function are replaced by $x \mapsto x^2/(|x| + \epsilon)$. The minimization problem is solved by using a Newton method. The number ϵ is used as a continuation parameter. The computation stops when $\epsilon = 1.10^{-5}$. The mesh size h is also used as a continuation parameter in the sense that the computation is done on three grids successively refined. The result on a coarse grid is used to initialize the solution on the next grid.

In the first example the domain Ω is a pentagon. The computation is done on two types of meshes. The first type is composed of meshes that are aligned with the discontinuities of the gradient and the second type consists of unstructured meshes. Typical results are reported in Figure 4. For both mesh types, we observe that the approximate L^1 -minimizer is similar to the Lagrange interpolant of the exact solution

on the same mesh. This is what we should expect intuitively. The L^1 -minimization process solves the equation in the region where the solution is smooth and simply ignores the PDE in the regions where the gradient of the exact solution is discontinuous. For more details we refer to [13, 14].

The second example is the eikonal equation on an L -shaped domain. The viscosity solution to this problem is in $W^{1,\infty}(\overline{\Omega})$ and is q semiconcave for every $q < 2$. This is a borderline case not covered by our theory (we a priori need $q > 2$). We nevertheless do the computations using $p = 2$ for the entropy. We show a mesh and the corresponding approximate minimizer in Figure 5. Once again, we observe that the solution is accurate. The iso-lines are not oscillating and are very sharp.

FAST MARCHING METHODS FOR STATIONARY HAMILTON–JACOBI EQUATIONS WITH AXIS-ALIGNED ANISOTROPY*

KEN ALTON[†] AND IAN M. MITCHELL[†]

Abstract. The fast marching method (FMM) has proved to be a very efficient algorithm for solving the isotropic Eikonal equation. Because it is a minor modification of Dijkstra’s algorithm for finding the shortest path through a discrete graph, FMM is also easy to implement. In this paper we describe a new class of Hamilton–Jacobi (HJ) PDEs with axis-aligned anisotropy which satisfy a causality condition for standard finite-difference schemes on orthogonal grids and can hence be solved using the FMM; the only modification required to the algorithm is in the local update equation for a node. This class of HJ PDEs has applications in anelliptic wave propagation and robotic path planning, and brief examples are included. Since our class of HJ PDEs and grids permit asymmetries, we also examine some methods of improving the efficiency of the local update that do not require symmetric grids and PDEs. Finally, we include explicit update formulas for variations of the Eikonal equation that use the Manhattan, Euclidean, and infinity norms on orthogonal grids of arbitrary dimension and with variable node spacing.

Key words. fast marching method, anisotropic optimal control, Hamilton–Jacobi equation, viscosity solution

1. Introduction. The fast marching method (FMM) [29, 23] has become a popular algorithm to use when solving the Dirichlet problem for an isotropic static Hamilton–Jacobi partial differential equation (HJ PDE), also known as the Eikonal equation $\|Du(x)\|_2 = c(x)$. FMM has proven to be particularly efficient in practice because it can approximately solve this problem in a single pass through the nodes of a grid. It is also straightforward to implement, requiring only a small modification of Dijkstra’s algorithm [9], which is a popular method for finding the shortest path through a graph.

While the isotropic case is the most common, there are applications which require the solution of anisotropic HJ PDEs. Unfortunately, FMM produces a correct approximation only under certain causality conditions on the values of nodes and their neighbors. This limitation has motivated the development of a more generally applicable version of FMM called ordered upwind methods (OUMs) [21] and also several recent works such as [31, 13, 19] on sweeping methods. However, OUMs are much more complex to implement than FMM, and sweeping methods can be much less efficient for problems with curved characteristics and practical grid sizes [12, 11].

Consequently, we have motivation to seek classes of anisotropic problems to which FMM might still be applied. One such class of problems was identified in [20] and includes the Eikonal equation where an energy norm replaces the standard Euclidean norm. In [3] we identified another such class of problems. Because its characteristics are minimum time paths to the boundary, the Eikonal equation has often been

proposed for robotic path planning; for example, see [15]. However, for some robots, using the Euclidean norm in this equation is inappropriate. Consider a robot arm, where each joint has its own motor. If each motor can rotate at some maximum speed independent of the action of the other motors, then the action of the whole arm is best bounded in an appropriately-scaled infinity norm. The corresponding Eikonal equation should use the dual Manhattan norm and is thus anisotropic. Other scenarios where such problems arise were considered in [3]—such as planning collision-free optimal paths for multiple robots—and experimental evidence suggested that FMM would be successful on these problems.

As a group, the anisotropy in these problems is axis-aligned. In this paper we describe a broader class of such axis-aligned problems (section 2) and demonstrate that FMM can be applied to approximate their solution on axis-aligned orthogonal grids without modification of the algorithm beyond the local update function for a single node (section 3). The examples (section 4) include an anelliptic wave propagation problem and a new multirobot scenario. In Appendix A, we propose some methods by which the local update's efficiency might be improved even if the grid and/or PDE lack symmetry. Lastly, in Appendix B, we provide analytic update formulas for the Eikonal equation with the $p = 1, 2,$ and ∞ norms on variably spaced orthogonal grids in any dimension.

Some proofs of theorems and experimental details have been omitted from this paper and may be found in [2].

1.1. The problem. The Dirichlet problem of a static HJ PDE is to find a function u such that

$$(1.1a) \quad H(x, Du(x)) = 0, \quad x \in \Omega,$$

$$(1.1b) \quad u(x) = g(x), \quad x \in \partial\Omega,$$

where $Du(x)$ is the gradient of u at x , $\Omega \subset \mathbb{R}^d$ is a bounded Lipschitz domain, and $\partial\Omega$ is the domain's boundary. In general, it is not possible to find a classical solution to the Dirichlet problem (1.1) where u is differentiable for all x , so we seek instead the viscosity solution [7], a unique weak solution which is continuous and almost everywhere differentiable.

To appreciate the difference between isotropic and anisotropic problems, it is useful to consider a control-theoretic formulation of the Hamiltonian

$$(1.2) \quad H(x, q) = \max_{a \in \mathcal{A}(x)} (-q \cdot a) - 1,$$

where a is an action and $\mathcal{A}(x) \subset \mathbb{R}^d$ is a compact, convex action set containing the origin in its interior. In an isotropic problem $\mathcal{A}(x)$ is a hypersphere centered on the origin for all x , although its radius may depend on x . In such a problem (1.2) reduces to

$$(1.3) \quad H(x, q) = \|q\|_2 - c(x),$$

where $c(x) = 1/r(x)$ and $r(x)$ is the radius of the hyperspherical $\mathcal{A}(x)$. In this case (1.1a) becomes the Eikonal equation. For an anisotropic problem, $\mathcal{A}(x)$ is not always an origin-centered hypersphere. Since not all Hamiltonians H fit the control-theoretic formulation, more generally, for an isotropic problem, the set of q solving $H(x, q) = 0$ is the surface of an origin-centered hypersphere. Several examples of anisotropic problems that do not fit this criterion are included in sections 2.2 and 4.

FIG. 1.1. Orthogonal grids combining discretizations $\underline{\Omega}$ and $\partial\Omega$. (a) boundary conditions are given around the outside of Ω . (b) boundary conditions are given on the inside of Ω .

1.2. The FMM. Since we typically cannot solve for the viscosity solution exactly, we compute an approximate solution \underline{u} on an axis-aligned orthogonal grid with nodes forming both a discretization $\underline{\Omega}$ of Ω , and a discretization $\partial\Omega$ of $\partial\Omega$; for example, see Figure 1.1. We take $\underline{\Omega}$ and $\partial\Omega$ to be disjoint sets. We allow any axis-aligned orthogonal grid, including those with node spacing that varies between dimensions and within a single dimension; the latter capability makes it easier to more accurately manage an irregular boundary [11]. It is important that the orthogonal grid and the Hamiltonian H are aligned to the same axis. What it means for H to be aligned to an axis is explained in section 2.

Let $\mathcal{N}(\underline{x})$ be the set of neighbors of node $\underline{x} \in \underline{\Omega}$. Whenever we refer to a simplex of a node \underline{x} , we mean a simplex specified by the node \underline{x} and d of its neighbors, each in a distinct dimension. Since we are restricted to orthogonal grids, each simplex of \underline{x} corresponds to a particular orthant.

Informally, we refer to $\underline{u}(\underline{x})$ as the value of node \underline{x} . In what follows, we may use \underline{u} to refer to either the values of the nodes in the operation or the output of FMM or to the solution of the discretized PDE (3.3). This ambiguity becomes less bothersome when we point out in Proposition 3.2 that the output of FMM is, in fact, the solution to (3.3).

Algorithm 1 outlines a simple dynamic programming algorithm. The algorithm can become either Dijkstra’s algorithm or FMM depending on the choice of the **Update** function. Consider, for example, the **Update** function in the context of optimal control, where we are computing the minimal cost over all possible paths. For Dijkstra’s algorithm, **Update** computes $\underline{u}(\underline{x}_0)$ as a simple minimization over the neighboring nodes of \underline{x}_0 of the path costs to \underline{x}_0 via each neighbor. For FMM, the **Update** function computes $\underline{u}(\underline{x}_0)$ as a minimization over the neighboring simplices of \underline{x}_0 of the minimum path costs to \underline{x}_0 via each simplex.

The **Update** function must satisfy a *causality* property in order for Algorithm 1 to terminate with a correct solution: **Update** must compute a node value $\underline{u}(\underline{x})$ based only on information from neighboring nodes with smaller values, so that \underline{u} is computed in increasing order of $\underline{u}(\underline{x})$ [28, 24]. In Dijkstra’s algorithm and FMM for a standard Euclidean norm Eikonal equation on an orthogonal grid, this property is automatic. A major contribution of this paper is to demonstrate that, for a class of static HJ PDEs with axis-aligned anisotropy, an **Update** function that is consistent with the PDE and satisfies the causality property can be defined, and thus FMM can be used.

While the **Update** function in Algorithm 1 is determined by the underlying equation which we seek to solve, it is assumed that its execution time is independent of

```

1 foreach  $\underline{x} \in \underline{\Omega}$  do  $\underline{u}(\underline{x}) \leftarrow \infty$ 
2 foreach  $\underline{x} \in \partial\underline{\Omega}$  do  $\underline{u}(\underline{x}) \leftarrow g(\underline{x})$

Algorithm 1: Dynamic Programming Algorithm.

grid resolution, and hence it does not affect the algorithm’s asymptotic complexity. The `Update` functions in this paper maintain this property. FMM is usually described as being $\mathcal{O}(n \log n)$, where $n = |\underline{\Omega}|$ is the number of grid points in the discretized domain. This complexity is derived by noting that each node is removed from \mathcal{Q} once by `ExtractMin` and, in the usual binary heap implementation of \mathcal{Q} , extraction of the minimum value node costs $\mathcal{O}(\log |\mathcal{Q}|) \leq \mathcal{O}(\log n)$. Note that the heap need only sort nodes with finite values. Because we restrict our modifications of Algorithm 1 to the `Update` function, all of the results here can be used with other versions of FMM; for example, the $\mathcal{O}(n)$ algorithm described in [30], which uses an untidy priority queue for \mathcal{Q} to reduce the cost of `ExtractMin` and hence the whole algorithm. However, for implementation simplicity, we have used the standard binary heap version of \mathcal{Q} in our experiments.

1.3. Related work. The first Dijkstra-like method for a first-order semi-Lagrangian discretization of the isotropic Eikonal PDE on an orthogonal grid was developed in [28]. The Dijkstra-like FMM was later independently developed in [23] for the first-order upwind Eulerian finite-difference discretization of the same Eikonal PDE. FMM was then extended to handle higher-order upwind discretizations on grids and unstructured meshes in \mathbb{R}^n and on manifolds [14, 25, 20]. In [24] it was shown that Dijkstra’s method on a uniform orthogonal grid produces the solution for the anisotropic maximum norm Eikonal equation. By solving an isotropic problem on a manifold and then projecting the solution into a subspace, FMM can solve certain anisotropic problems [20]; for example, (1.2) with a constant elliptic $\mathcal{A}(x) = \mathcal{A}$ can be solved by running isotropic FMM on an appropriately tilted planar manifold and then projecting away one dimension. Some anisotropic etching problems have also been solved using FMM [17].

The fact that correct operation of Dijkstra-like algorithms for approximating the Eikonal PDE requires the causality property that $\underline{u}(\underline{x})$ can be written only in terms of smaller values \underline{u} at neighboring nodes was stated in [28], but a reader might incorrectly infer from further comments in that paper that such algorithms would not work for any unstructured grid or anisotropic problem. That FMM is applicable for any consistent, orthogonal, causality satisfying, finite-difference discretization of a general static convex HJ PDE is stated in [24]; however, it is now understood that this criterion applies even more generally, since a Dijkstra-like method can be used to efficiently solve on a graph any nonlinear system of equations for which $\underline{u}(\underline{x})$ is dependent only on smaller values \underline{u} at neighboring nodes. A sufficient criterion (see section 2.1) under which FMM can be used for orthogonal, finite-difference discretizations of static HJ PDEs—now commonly referred to as “Osher’s criterion”—is widely attributed to an unpublished work by Osher and Helmsen, but the earliest published description seems

to be [17]. While it is stronger than the causality conditions described earlier, it is useful because it is stated as a condition on the analytic Hamiltonian instead of the equations created by the discretization. In this paper we likewise seek conditions under which FMM is applicable that are closer to the problem’s definition than the algorithm’s implementation.

OUMs [21, 22] can solve general convex anisotropic problems on unstructured grids with an asymptotic complexity only a constant factor (related to the degree of anisotropy) worse than FMM. FMM fails for these general problems because the neighboring simplex from which the characteristic approaches a node \underline{x}_0 may contain another node \underline{x} such that causality does not hold: $\underline{u}(\underline{x}_0) < \underline{u}(\underline{x})$. OUM avoids this difficulty by searching along the active front to find a set of neighboring nodes (which may not be direct neighbors of \underline{x}_0) whose values have been accepted, and then constructing a virtual simplex with these nodes from which to update $\underline{u}(\underline{x}_0)$. Although this search along the active front does not degrade the asymptotic complexity, it does significantly increase the computational cost in practice. This effect can be partially mitigated by using nontrivial data structures such as 2^d -trees to speed up the search.

An alternative to these single-pass (or label-setting) algorithms are the sweeping (or label-correcting) algorithms, which are often even simpler to implement than FMM. Sweeping algorithms are also capable of handling anisotropic and even non-convex problems. The simplest sweeping algorithm is to just iterate through the grid updating each node in a Gauss–Seidel (GS) fashion (so a new value for a node is used immediately in subsequent updates) until \underline{u} converges. GS converges quickly if the node update order is aligned with the characteristics of the solution, so better sweeping algorithms [8, 6, 31, 13, 19] alternate among a collection of static node orderings so that all possible characteristic directions will align with at least one ordering. It is argued in [31] that these methods achieve $\mathcal{O}(n)$ asymptotic complexity (assuming that the node orderings are already determined); however, unlike FMM and OUM, the constant depends on the problem. For practical grid resolutions on problems with curved characteristics, FMM does better despite the difference in asymptotic complexity [12, 11].

There are also a number of sweeping algorithms which use dynamic node orderings; for example [18, 5]. These algorithms attempt to approximate the optimal ordering generated by single-pass methods such as FMM without the overhead associated with managing an accurate queue. These methods have been demonstrated to be comparable to or better than single-pass methods for certain problems and grid resolutions [18, 5]. However, in general, these methods may need to revisit nodes multiple times.

Accurate robotic path planning is only required in cluttered environments where optimal paths—and hence the characteristics of the HJ PDE—are not straight. No alternative algorithm proposed approaches the simple implementation and guaranteed speed of FMM for these types of problems. Consequently, we set out in this paper to characterize another class of anisotropic HJ PDEs for which FMM will work and also to explore their efficient implementation. It should be noted that the update procedures discussed in this paper can be applied to any of the sweeping algorithms without modification.

2. Class of Hamiltonians. FMM can be extended to handle a class of axis-aligned anisotropic problems, defined by a restriction of the Hamiltonian H to that satisfying Properties 1 to 4. We let $q, \tilde{q} \in \mathbb{R}^d$ and make the following definitions.

DEFINITION 2.1. *Write $q \succeq \tilde{q}$ if $q_j \tilde{q}_j \geq 0$ and $|q_j| \geq |\tilde{q}_j|$, for $1 \leq j \leq d$.*

DEFINITION 2.2. Write $q \triangleright \tilde{q}$ if (i) $q \neq 0$ and (ii) $q_j \tilde{q}_j \geq 0$ and $|q_j| > |\tilde{q}_j|$ or $q_j = \tilde{q}_j = 0$, for $1 \leq j \leq d$.

The following properties are satisfied by H .

PROPERTY 1. H is continuous: $H \in C(\Omega \times \mathbb{R}^d)$.

PROPERTY 2. H is coercive: $H(x, q) \rightarrow \infty$ as $\|q\| \rightarrow \infty$ for all $x \in \Omega$.

PROPERTY 3. H is strictly compatible: $H(x, 0) < 0$ for all $x \in \Omega$.

PROPERTY 4. H is strictly one-sided monotone: If $q \triangleright \tilde{q}$, then $H(x, q) > H(x, \tilde{q})$.

We note that Properties 1, 2, and 3 are similar to some properties on the Hamiltonian in [5]. In this paper, we typically deal only with the `Update` function. For this reason, we usually consider a fixed $x \in \Omega$ and may write $H(q) = H(x, q)$ wherever no ambiguity results. When discussing properties of H , these are in reference to the q parameter. The source of the *axis-aligned* description of the problem class is the strict one-sided monotonicity property of H .

2.1. Connection to Osher’s criterion. Although there are earlier statements of the conditions on node values under which a Dijkstra-like algorithm can or cannot be used to solve the problem [28, 23], in this section we outline the connection between the properties described above and Osher’s criterion [17] because the latter directly provides a condition on the Hamiltonian rather than on the solution values. In section 3.3, we make the connection between Properties 1 to 4 and the earlier conditions.

Osher’s fast marching criterion is defined in [17, 27] as

$$q_j \frac{\partial H(x, q)}{\partial q_j} \geq 0$$

for $1 \leq j \leq d$. The authors state there that as long as this criterion is satisfied, a simple fast marching algorithm based on a one-sided upwind finite-difference discretization can be applied to solve the problem. However, we use Properties 1 to 4 instead of Osher’s criterion because Osher’s criterion requires H to be differentiable so that $D_q H(x, q)$ exists, but we are interested in potentially nondifferentiable H (e.g., see section 2.2). Note that strict one-sided monotonicity is applicable even when $D_q H(x, q)$ does not exist for all x .

Propositions 2.3, 2.4, and 2.5 explain the relationship between strict one-sided monotonicity of H (Property 4) and Osher’s criterion. Proposition 2.3 shows that Property 4 implies one-sided monotonicity (Property 5). Then, Proposition 2.4 shows that Property 5 is the same as Osher’s criterion as long as H is differentiable. Finally, Proposition 2.5 demonstrates that Property 5 with the addition of one-sided homogeneity (Property 6) implies Property 4.

PROPERTY 5. H is one-sided monotone: If $q \succeq \tilde{q}$, then $H(x, q) \geq H(x, \tilde{q})$.

PROPOSITION 2.3. Let H be continuous (Property 1). Then strict one-sided monotonicity of H (Property 4) implies one-sided monotonicity of H (Property 5).

Proof. Let H be strictly one-sided monotone. Let $q, \tilde{q} \in \mathbb{R}^d$ be such that $q \succeq \tilde{q}$. Let $r \in \{-1, 1\}^d$ be such that

$$r_j = \begin{cases} +1, & \text{if } q_j \geq 0, \\ -1, & \text{otherwise,} \end{cases}$$

and let $\epsilon > 0$. Note that $q + \epsilon r \triangleright \tilde{q}$ and thus we have $H(q + \epsilon r) > H(\tilde{q})$. By the continuity of H , we have

$$\lim_{\epsilon \rightarrow 0^+} H(q + \epsilon r) \geq H(\tilde{q})$$

and also

$$\lim_{\epsilon \rightarrow 0^+} H(q + \epsilon r) = H(q).$$

Therefore, $H(q) \geq H(\tilde{q})$. \square

PROPOSITION 2.4. *Let H be continuous (Property 1), and let $D_q H(q)$ exist for all $q \in \mathbb{R}^d$. Then the following conditions on H are equivalent:*

- (a) $q_j \frac{\partial H(q)}{\partial q_j} \geq 0$ for all j and $q \in \mathbb{R}^d$.
- (b) H is one-sided monotone (Property 5).

Proof. We begin by proving that (a) implies (b). Let $q, \tilde{q} \in \mathbb{R}^d$ be such that $q \succeq \tilde{q}$. If $q = \tilde{q}$, then $H(q) = H(\tilde{q})$. Otherwise, define the function $\bar{q} : [0, 1] \rightarrow \mathbb{R}^d$ such that $\bar{q}(t) = \tilde{q} + t(q - \tilde{q})$ to represent the line segment between \tilde{q} and q parameterized by $t \in [0, 1]$. Because $q \succeq \tilde{q}$ we have

$$(q - \tilde{q})_j \bar{q}_j(t) \geq 0$$

for $1 \leq j \leq d$ and for $t \in [0, 1]$. Thus, by condition (a), we have

$$(2.1) \quad (q - \tilde{q})_j \frac{\partial H(\bar{q}_j(t))}{\partial \bar{q}_j(t)} \geq 0$$

for $1 \leq j \leq d$ and for $t \in [0, 1]$. We know that

$$\begin{aligned} H(q) &= H(\tilde{q}) + \int_0^1 \frac{d\bar{q}(t)}{dt} \cdot D_q H(\bar{q}(t)) dt \\ &= H(\tilde{q}) + \int_0^1 (q - \tilde{q}) \cdot D_q H(\bar{q}(t)) dt \\ &= H(\tilde{q}) + \int_0^1 \sum_{i=1}^n (q - \tilde{q})_j \frac{\partial H(\bar{q}_j(t))}{\partial \bar{q}_j(t)} dt \\ &\geq H(\tilde{q}). \end{aligned}$$

The first equality follows from integrating the change in H along the line segment connecting \tilde{q} and q . The second equality is because the derivative $\frac{d\bar{q}(t)}{dt}$ is simply the vector $q - \tilde{q}$. The third equality breaks up the vector dot product into a sum of scalar products. The inequality results from (2.1) and the fact that an integral of a nonnegative function is nonnegative. Thus, for all q, \tilde{q} such that $q \succeq \tilde{q}$, including $q = \tilde{q}$, we have $H(q) \geq H(\tilde{q})$.

We now prove that (b) implies (a). Let $q \in \mathbb{R}^d$ and $1 \leq j \leq d$. Define the function $s : \mathbb{R} \rightarrow \{-1, +1\}$ such that

$$s(y) = \begin{cases} +1, & \text{if } y \geq 0, \\ -1, & \text{otherwise,} \end{cases}$$

let $\epsilon > 0$, and let e_j be the j th vector in the standard basis. Note that $q + \epsilon s(q_j)e_j \succeq q$ and thus by (b) we have $H(q + \epsilon s(q_j)e_j) - H(q) \geq 0$. Consequently, by the existence of $D_q H(q)$ for all $q \in \mathbb{R}^d$, we have

$$q_j \frac{\partial H(q)}{\partial q_j} = \lim_{\epsilon \rightarrow 0^+} q_j \frac{H(q + \epsilon s(q_j)e_j) - H(q)}{\epsilon s(q_j)} \geq 0. \quad \square$$

The following property is used to state Proposition 2.5.

PROPERTY 6. H is one-sided homogeneous: $H(tq) - H(0) = t(H(q) - H(0))$ for all $t \geq 0$ and $q \in \mathbb{R}^d$.

PROPOSITION 2.5. Let H satisfy Properties 1, 2, and 3, and let H be one-sided monotone (Property 5) and one-sided homogeneous (Property 6). Then H is strictly one-sided monotone (Property 4).

Proof. Let $q \triangleright \tilde{q}$. Then $q \supseteq \tilde{q}$ and $H(q) \geq H(\tilde{q})$ by one-sided monotonicity.

First consider the case $\tilde{q} = 0$. Assume $H(q) = H(\tilde{q}) = H(0)$. By the one-sided homogeneity of H ,

$$\lim_{t \rightarrow \infty} [H(tq) - H(0)] = \lim_{t \rightarrow \infty} [t(H(q) - H(0))] = 0.$$

But by the coercivity of H ,

$$\lim_{t \rightarrow \infty} [H(tq) - H(0)] = \infty,$$

since $\lim_{t \rightarrow \infty} \|tq\| = \infty$ and by compatibility $H(0) < 0$. Thus, we have a contradiction, and it must be that $H(q) > H(\tilde{q})$.

Second, consider the case where $\tilde{q} \neq 0$. Let $\mathcal{J} = \{j \mid |q_j| > |\tilde{q}_j|\}$. Note that by Definition 2.2 since $\tilde{q} \neq 0$, we have $\mathcal{J} \neq \emptyset$ and there exist $j \in \mathcal{J}$ such that $\tilde{q}_j \neq 0$. Define a scalar multiple of q :

$$\check{q} = tq = \left(\max_{j \in \mathcal{J}} \frac{|\tilde{q}_j|}{|q_j|} \right) q.$$

Since $|q_j| > |\tilde{q}_j|$, for all $j \in \mathcal{J}$, we have $0 < t < 1$. Furthermore, for $j \in \mathcal{J}$,

$$|\check{q}_j| = \left(\max_{j \in \mathcal{J}} \frac{|\tilde{q}_j|}{|q_j|} \right) |q_j| \geq |\tilde{q}_j|,$$

while for $j \notin \mathcal{J}$,

$$\check{q}_j = tq_j = 0 = \tilde{q}_j.$$

Consequently, $|\check{q}_j| \geq |\tilde{q}_j|$ for $1 \leq j \leq d$. Also, since $t > 0$, we have $\check{q}_j \tilde{q}_j = tq_j \tilde{q}_j \geq 0$ for $1 \leq j \leq d$. This implies, by one-sided monotonicity of H , that $H(\check{q}) \geq H(\tilde{q})$. Moreover, by one-sided homogeneity of H , $H(\check{q}) - H(0) = H(tq) - H(0) = t(H(q) - H(0))$. It follows that $H(q) - H(0) = (H(\check{q}) - H(0))/t > H(\tilde{q}) - H(0)$, since $0 < t < 1$ and $H(\check{q}) \geq H(0)$ by one-sided monotonicity. Therefore, $H(q) > H(\tilde{q}) \geq H(\tilde{q})$. \square

We impose strict one-sided monotonicity on H because it guarantees a unique solution to a first-order upwind finite-difference discretization of (1.1a), as shown in section 3.1. Simply imposing one-sided monotonicity on H or Osher's condition on differentiable H is not sufficient for a unique solution. However, Proposition 2.5 states that when H satisfies one-sided homogeneity in addition to one-sided monotonicity, then it also satisfies strict one-sided monotonicity, and there is a unique solution to the discretization. Moreover, by Propositions 2.4 and 2.5, when differentiable H satisfies one-sided homogeneity in addition to Osher's criterion, then H also satisfies strict one-sided monotonicity, and there is a unique solution to the discretization. Note that there exist conditions other than one-sided homogeneity, such as strict convexity, that in combination with Osher's criterion, result in strict one-sided monotonicity of H .

FIG. 2.1. Contour plots of $\|q\|_p$.

2.2. Example H functions. A Hamiltonian H that satisfies Properties 1 to 4 encompasses a fairly broad range of anisotropic problems. We consider examples of H that satisfy Properties 1 to 4. In particular, we look at the case

$$(2.2) \quad H(x, q) = G(x, q) - c(x),$$

where G is a p -norm or some variant and c is a positive cost. We must ensure that G is strictly one-sided monotone, which is not true of all norms.

The p -norm is a useful category of strictly one-sided monotone norms. Let a p -norm, $\|\cdot\|_p$, be defined by

$$\|q\|_p = \left(\sum_{j=1}^d |q_j|^p \right)^{1/p},$$

where $p \geq 1$. Commonly used p -norms, illustrated in Figure 2.1, are the Manhattan norm ($p = 1$), the Euclidean norm ($p = 2$), and the maximum norm ($p = \infty$). The following proposition is proved in [2].

PROPOSITION 2.6. $\|\cdot\|_p$ is strictly one-sided monotone.

Define a linearly-transformed p -norm $\|\cdot\|_{B,p}$ to be

$$\|q\|_{B,p} = \|Bq\|_p,$$

where $p \geq 1$ and B is a nonsingular $d \times d$ matrix. Note that B must be nonsingular so that $\|\cdot\|_{B,p}$ satisfies the properties of a norm such as definiteness and homogeneity. Such a norm is not strictly one-sided monotone in general. Figure 2.2(a) shows a simple example where a vector is rotated by $-\pi/4$ and scaled by 3 in the q_2 -axis before the Euclidean norm is taken; i.e.,

$$(2.3) \quad B = \begin{bmatrix} 1 & 0 \\ 0 & 3 \end{bmatrix} \begin{bmatrix} \cos(-\pi/4) & -\sin(-\pi/4) \\ \sin(-\pi/4) & \cos(-\pi/4) \end{bmatrix} = \begin{bmatrix} 1/\sqrt{2} & 1/\sqrt{2} \\ -3/\sqrt{2} & 3/\sqrt{2} \end{bmatrix}.$$

Let $q = (2, 2)^T$ and $\tilde{q} = (\sqrt{2}, 0)^T$. We have $q \succeq \tilde{q}$, but

$$\|Bq\|_2 = \left\| \begin{pmatrix} 2\sqrt{2} \\ 0 \end{pmatrix} \right\|_2 = \sqrt{8} < \sqrt{10} = \|(1, -3)^T\|_2 = \|B\tilde{q}\|_2.$$

FIG. 2.2. Contour plots of $\|Bq\|_p$. (a) is not strictly one-sided monotone: $p = 2$ and B is defined by (2.3). (b) is strictly one-sided monotone: $p = 1$ and B scales by 2 in the q_1 -axis.

Consequently, this particular linearly transformed p -norm is not strictly one-sided monotone. However, in this case an inverse transformation B^{-1} of the grid coordinates will result in a strictly one-sided monotone p -norm, while maintaining the grid's orthogonality. More generally, we conjecture that if the Hamiltonian is of the form $H(q) = \tilde{H}(Bq)$, where B is a rotation (which may be followed by scaling) and \tilde{H} satisfies Properties 1 to 4, a transformation of the grid coordinates by B^{-1} will result in a transformed H that also satisfies Properties 1 to 4, while maintaining the grid's orthogonality. More complex coordinate modifications might be possible, but we have not yet adequately investigated conditions or procedures.

A scaled p -norm (Figure 2.2(b)) is a special case of a linearly transformed p -norm. Such a norm scales the components of its argument before applying a p -norm by restricting B to be a nonsingular diagonal matrix. It is simple to show that a scaled p -norm is strictly one-sided monotone, considering Proposition 2.6.

A mixed p -norm is a recursive composition of p -norms, and it is strictly one-sided monotone. The following is an example (Figure 2.3(a)) of a mixed p -norm that takes the Euclidean norm of the first two components and then takes the Manhattan norm of the result and the last component:

$$(2.4) \quad \begin{aligned} \|q\| &= \|(\|(q_1, q_2)\|_2, q_3)\|_1 \\ &= \sqrt{(q_1)^2 + (q_2)^2} + |q_3|, \end{aligned}$$

where $q = (q_1, q_2, q_3)$. This particular norm was used as a G function in [3] for a simple two-robot coordinated optimal control problem.

Finally, the one-sidedness of Property 4 allows G to be asymmetric, which is not permitted for a norm. An example of such an asymmetric norm-like function is shown in Figure 2.3(b) and is given by

$$(2.5) \quad G(q) = \begin{cases} \|B_a q\|_\infty, & \text{if } q_1 \leq 0 \text{ and } q_2 \leq 0, \\ \|B_b q\|_1, & \text{if } q_1 \leq 0 \text{ and } q_2 > 0, \\ \|B_c q\|_2, & \text{if } q_1 > 0 \text{ and } q_2 \leq 0, \\ \|B_d q\|_2, & \text{if } q_1 > 0 \text{ and } q_2 > 0, \end{cases}$$

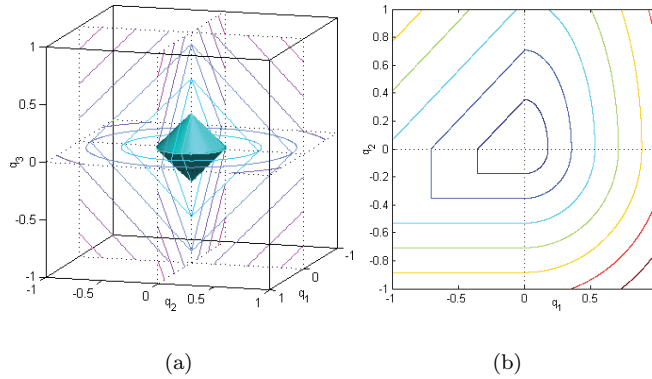

FIG. 2.3. Contour plots of $G(q)$. (a) mixed p -norm: G is defined by (2.4). (b) asymmetric norm-like function: G is defined by (2.5).

where

$$B_a = \begin{bmatrix} 1/2 & 0 \\ 0 & 1 \end{bmatrix} \quad B_b = \begin{bmatrix} 1/2 & 0 \\ 0 & 1/2 \end{bmatrix} \quad B_c = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad B_d = \begin{bmatrix} 1 & 0 \\ 0 & 1/2 \end{bmatrix}.$$

We solve the anisotropic problem characterized by (2.5) as well as an anelliptic wave propagation problem and a multirobot optimal path planning problem in section 4. Other examples of G functions which satisfy strict one-sided monotonicity are some polygonal norms such as axis aligned hexagonal or octagonal norms; however, we do not further investigate these options here.

3. FMM and the discretized problem. We define a discretized analogue of the Dirichlet problem (1.1). By describing the `Update` function in Algorithm 1, we also formalize the FMM algorithm. Finally, we examine important properties of the `Update` function.

We recall that the nodes in $\underline{\Omega}$ lie on an axis-aligned orthogonal grid. Let $\underline{x}_0 \in \underline{\Omega}$. The neighborhood of \underline{x}_0 is shown in Figure 3.1. Let \underline{x}_j^\pm be the neighbors of \underline{x}_0 in the $\pm e_j$ directions, e_j being the j th vector in the standard basis. The set of neighbors is

$$\mathcal{N}(\underline{x}_0) = \{\underline{x}_1^\pm, \underline{x}_2^\pm, \dots, \underline{x}_d^\pm\},$$

and the neighborhood vector is

$$N(\underline{x}_0) = (\underline{x}_0, \underline{x}_1^\pm, \underline{x}_2^\pm, \dots, \underline{x}_d^\pm).$$

Let $h_j^\pm = \pm \|\underline{x}_0 - \underline{x}_j^\pm\|$ be signed distances to the neighbors in the $\pm e_j$ directions. Let

$$\mathcal{S} = \{(s_1, s_2, \dots, s_d) \mid s_j \in \{-1, +1\}, 1 \leq j \leq d\}$$

such that $s \in \mathcal{S}$ represents one of the 2^d neighboring simplices of \underline{x}_0 . Note that we abuse notation by using $s_j \in \{-1, +1\}$ as a superscript indexing \underline{x}_j^\pm or h_j^\pm .

Let $B(\Omega)$ be the set of bounded functions on domain Ω . We define the numerical Hamiltonian $\underline{H} : \Omega^{1+2d} \times B(\Omega) \times \mathbb{R} \rightarrow \mathbb{R}$ as follows:

$$(3.1) \quad \underline{H}(N, \phi, \mu) = \max_{s \in \mathcal{S}} [H(\underline{x}_0, \underline{D}^s(N, \phi, \mu))],$$

FIG. 3.1. Neighborhood of \underline{x}_0 with $d = 2$.

where H is as defined in section 2 and

$$\underline{D}^s(N, \phi, \mu) = (\underline{D}_1^s(N, \phi, \mu), \underline{D}_2^s(N, \phi, \mu), \dots, \underline{D}_d^s(N, \phi, \mu))$$

is a first-order, upwind, finite-difference gradient approximation from the simplex represented by s ; that is,

$$(3.2) \quad \underline{D}_j^s(N, \phi, \mu) = \frac{\max(0, \mu - \phi(\underline{x}_j^{s_j}))}{-h_j^{s_j}}$$

for $1 \leq j \leq d$. Although \underline{H} is defined on domain $\Omega^{1+2d} \times B(\Omega) \times \mathbb{R}$, for FMM it will only be used on domain $\underline{\Omega}^{1+2d} \times B(\underline{\Omega}) \times \mathbb{R}$. The broader definition of domain is important for consistency [4]. The restriction of Ω^{1+2d} to $\underline{\Omega}^{1+2d}$ poses no problems to the definition of \underline{H} . Furthermore, to evaluate \underline{H} , ϕ need only be defined on \mathcal{N} , which is true of any function in $B(\underline{\Omega})$.

The discretized Dirichlet problem is to find a function $\underline{u} : (\underline{\Omega} \cup \partial\underline{\Omega}) \rightarrow \mathbb{R}$ such that

$$(3.3a) \quad \underline{H}(N(\underline{x}), \underline{u}, \underline{u}(\underline{x})) = 0, \quad \underline{x} \in \underline{\Omega},$$

$$(3.3b) \quad \underline{u}(\underline{x}) = g(\underline{x}), \quad \underline{x} \in \partial\underline{\Omega}.$$

DEFINITION 3.1. Let FMM be Algorithm 1 with the Update function defined as follows. A call to $\text{Update}(\underline{x}_0, \underline{u})$ returns the solution $\mu = \tilde{\mu}$ to

$$(3.4) \quad \underline{H}(N(\underline{x}_0), \underline{u}, \mu) = 0.$$

In this way it determines a node’s value $\underline{u}(\underline{x}_0) \leftarrow \tilde{\mu}$ given the values of its neighbors, $\underline{u}_j^\pm = \underline{u}(\underline{x}_j^\pm)$. When we are varying only μ , it will be convenient to write $\underline{H}(\mu) = \underline{H}(N, \phi, \mu)$ and $\underline{D}^s(\mu) = \underline{D}^s(N, \phi, \mu)$. For the lemmas and theorems stated below, we assume H satisfies Properties 1 to 4.

PROPOSITION 3.2. Let $\underline{u} : (\underline{\Omega} \cup \partial\underline{\Omega}) \rightarrow \mathbb{R}$ be the grid function after FMM terminates. Then \underline{u} is the unique solution of (3.3).

This proposition states that the grid function \underline{u} that results from running FMM solves the discretized problem (3.3). We use a method similar to those for isotropic FMM in [29, 23] to prove Proposition 3.2 in [2]. The causality of the Update function is essential so that FMM can be used to solve (3.3).

A method for proving the convergence of \underline{u} to the solution of (1.1) as the grid spacing goes to zero is presented in [4]. It is shown there that the consistency, monotonicity, and stability of the numerical scheme are sufficient for convergence. We closely follow the technique described in [4] to prove convergence in [2]. Also, uniqueness and monotonicity of the solution to (3.4) are useful for using numerical root finders to implement `Update`. We include proofs of uniqueness, monotonicity, and causality of the `Update` function below. For more details regarding convergence, including the proofs of consistency and stability, see [2].

3.1. Unique update. Let the minimum value of all neighbors of \underline{x}_0 be

$$(3.5) \quad \check{u} = \min_{\underline{x} \in \mathcal{N}(\underline{x}_0)} (\underline{u}(\underline{x})).$$

We show there is a unique solution $\mu = \tilde{\mu}$ to (3.4) such that $\tilde{\mu} > \check{u}$. First, we prove two useful lemmas.

LEMMA 3.3. *$\underline{H}(\mu)$ is strictly increasing on $\mu \geq \check{u}$.*

Proof. Let $\mu_a > \mu_b \geq \check{u}$. Let $s \in \mathcal{S}$ and $1 \leq j \leq d$. If $\mu_a > \underline{u}_j^{s_j}$, then $\underline{D}_j^s(\mu_a)\underline{D}_j^s(\mu_b) \geq 0$ and $|\underline{D}_j^s(\mu_a)| > |\underline{D}_j^s(\mu_b)|$. On the other hand, if $\mu_a \leq \underline{u}_j^{s_j}$, then $\underline{D}_j^s(\mu_a) = \underline{D}_j^s(\mu_b) = 0$. Also, there exists at least one $s \in \mathcal{S}$ and $1 \leq j \leq d$ such that $\underline{D}_j^s(\mu_a) \neq 0$, since $\mu_a > \check{u}$. For such s , $H(\underline{D}^s(\mu_a)) > H(\underline{D}^s(\mu_b))$, by strict one-sided monotonicity (Property 4). For all other s , $H(\underline{D}^s(\mu_a)) = H(\underline{D}^s(\mu_b)) = H(0)$. Therefore, by (3.1) $\underline{H}(\mu_a) > \underline{H}(\mu_b)$, so $\underline{H}(\mu)$ is strictly increasing on $\mu \geq \check{u}$. \square

LEMMA 3.4. *The numerical Hamiltonian $\underline{H}(\mu)$ satisfies the following:*

- (a) $\underline{H}(\mu) = H(0) < 0$ for $\mu \leq \check{u}$.
- (b) $\underline{H}(\mu) \rightarrow \infty$ as $\mu \rightarrow \infty$.
- (c) $\underline{H}(\mu)$ is nondecreasing on all μ .

Proof. If $\mu \leq \check{u}$, then by (3.2) and (3.5), we have $\underline{D}_j^s(\mu) = 0$ for all $s \in \mathcal{S}$, $1 \leq j \leq d$. By the strict compatibility of H , $H(\underline{D}^s(v_j)) = H(0) < 0$ for all s . By (3.1), we have $\underline{H}(\mu) = H(0) < 0$, for $\mu \leq \check{u}$, proving (a).

Let $s \in \mathcal{S}$ and $1 \leq j \leq d$. As $\mu \rightarrow \infty$, we have $\underline{D}_j^s(\mu) \rightarrow \infty$ and $\|\underline{D}^s(\mu)\| \rightarrow \infty$ for all $s \in \mathcal{S}$, $1 \leq j \leq d$. By the coercivity of H , as $\mu \rightarrow \infty$, we have $H(\underline{D}^s(\mu)) \rightarrow \infty$ for all $s \in \mathcal{S}$. By (3.1), we have $\underline{H}(\mu) \rightarrow \infty$ as $\mu \rightarrow \infty$, proving (b).

Because $\underline{H}(\mu)$ is constant on $\mu \leq \check{u}$ and by Lemma 3.3 increasing on $\mu \geq \check{u}$, $\underline{H}(\mu)$ is nondecreasing on all μ , proving (c). \square

THEOREM 3.5. *There exists a unique solution $\mu = \tilde{\mu}$ to $\underline{H}(\mu) = 0$ such that $\tilde{\mu} > \check{u}$.*

Proof. Each $\underline{D}_j^s(\mu)$ is continuous on μ . Furthermore, by the continuity of H , $H(\underline{D}^s(\mu))$ is continuous on μ for all s . Since \max is continuous, $\underline{H}(\mu)$ is continuous. By Lemma 3.4(a/b), $\underline{H}(\mu) < 0$ for $\mu \leq \check{u}$ and $\underline{H}(\mu) \rightarrow \infty$ as $\mu \rightarrow \infty$. Therefore, by the intermediate value theorem, there exists a solution $\mu = \tilde{\mu}$ to $\underline{H}(\mu) = 0$ such that $\check{u} < \tilde{\mu} < \infty$. Moreover, since \underline{H} is strictly increasing on $\mu \geq \check{u}$ by Lemma 3.3, the solution is unique. \square

Remark 1. We note that strict one-sided monotonicity (Property 4) of H is used to prove Lemma 3.3, and Lemma 3.3 is then used to show that the solution to $\underline{H}(\mu) = 0$ is unique. We might consider whether or not one-sided monotonicity (Property 5) of H is sufficient for a unique solution. However, Property 5 would not be sufficient to prove Lemma 3.3, and we would find that $\underline{H}(\mu)$ is only nondecreasing on $\mu \geq \check{u}$. A solution to $\underline{H}(\mu) = 0$ would still be guaranteed but not unique in this case. Analogously, for differentiable H , Osher’s criterion on H implies a solution that

may not be unique unless H satisfies some additional property, such as one-sided homogeneity (Property 6) or convexity.

3.2. Monotonicity. We show that \underline{H} and the `Update` function are monotone in the neighbor’s values. Monotonicity of \underline{H} requires that if none of the neighbor’s values decreases, the numerical Hamiltonian \underline{H} should not increase. Additionally, monotonicity of the `Update` function requires that if none of the neighbor’s values decreases, the solution to (3.4) should not decrease. Monotonicity is useful both for showing that FMM finds a unique solution and for proving convergence. We note that monotonicity does not require strict one-sided monotonicity of H , but rather one-sided monotonicity of H is sufficient.

THEOREM 3.6. *Let \underline{v} and \underline{u} be grid functions. Let $\underline{v}_j^\pm \geq \underline{u}_j^\pm$ for $1 \leq j \leq d$. Then for $\mu \in \mathbb{R}$, we have $\underline{H}(N, \underline{v}, \mu) \leq \underline{H}(N, \underline{u}, \mu)$. Furthermore, if $\mu = \mu_v$ is the unique solution to $\underline{H}(N, \underline{v}, \mu) = 0$ and $\mu = \mu_u$ is the unique solution to $\underline{H}(N, \underline{u}, \mu) = 0$, then $\mu_v \geq \mu_u$.*

Proof. Let $\mu \in \mathbb{R}$. We have $\underline{D}^s(N, \underline{u}, \mu) \supseteq \underline{D}^s(N, \underline{v}, \mu)$ for all $s \in \mathcal{S}$. Also, by Proposition 2.3, H satisfies one-sided monotonicity (Property 5). Thus,

$$H(\underline{D}^s(N, \underline{u}, \mu)) \geq H(\underline{D}^s(N, \underline{v}, \mu)) = 0$$

for all $s \in \mathcal{S}$. Consequently, $\underline{H}(N, \underline{u}, \mu) \geq \underline{H}(N, \underline{v}, \mu)$, proving the first claim.

To prove the second claim, we let μ_v and μ_u be as defined above. We note that $\underline{H}(N, \underline{u}, \mu_u) = 0 \geq \underline{H}(N, \underline{v}, \mu_u)$. By Lemma 3.4(c), $\underline{H}(N, \underline{v}, \mu)$ is nondecreasing on all μ , so in order that $\underline{H}(N, \underline{v}, \mu_v) = 0$, it must be that $\mu_v \geq \mu_u$. \square

3.3. Causality. We note that (3.3) defines a very large system of nonlinear equations, one equation for each node $\underline{x} \in \underline{\Omega}$. FMM can be used to solve this system very efficiently, if the solution $\mu = \tilde{\mu}$ to (3.4) is dependent only on neighbors with smaller values. This property represents a causal relationship between node values. There is an information flow from nodes with smaller values to those with larger values. The causal relationship is meant to mimic that of the PDE (1.1). The solution u of (1.1) is completely defined at x using only values of u from states that are backwards along the characteristic line that passes through x .

FMM exploits the causal property of \underline{H} by computing $\underline{u}(\underline{x})$ in increasing order in a single pass through the nodes. This causal property has been discussed as a requirement for Dijkstra-like single-pass methods in several works [28, 24, 26, 17, 22]. The following theorem states that \underline{H} and the `Update` function are causal. The `Update` function is considered causal if any change to the value of a neighboring node, such that both the new and old values are no smaller than the solution $\mu = \tilde{\mu}$ to $\underline{H}(N, \underline{u}, \mu) = 0$, has no effect on the solution.

THEOREM 3.7. *Let \underline{v} and \underline{u} be grid functions. Let*

$$\tilde{\mathcal{N}}(\underline{x}_0) = \{\underline{x} \in \mathcal{N}(\underline{x}_0) \mid \underline{v}(\underline{x}) \neq \underline{u}(\underline{x})\}.$$

Let

$$\tilde{w} = \begin{cases} \min_{\underline{x} \in \tilde{\mathcal{N}}(\underline{x}_0)} \min(\underline{v}(\underline{x}), \underline{u}(\underline{x})), & \text{if } \tilde{\mathcal{N}}(\underline{x}_0) \neq \emptyset, \\ +\infty, & \text{otherwise.} \end{cases}$$

Then $\underline{H}(N, \underline{v}, \mu) = \underline{H}(N, \underline{u}, \mu)$ for $\mu \leq \tilde{w}$.

Furthermore, let $\mu = \tilde{\mu}_u$ be the unique solution to $\underline{H}(N, \underline{u}, \mu) = 0$, and let $\mu = \tilde{\mu}_v$ be the unique solution to $\underline{H}(N, \underline{v}, \mu) = 0$. If $\tilde{\mu}_u \leq \tilde{w}$ or $\tilde{\mu}_v \leq \tilde{w}$, then $\tilde{\mu}_u = \tilde{\mu}_v$.

TABLE 4.1

Errors of approximate solution computed by FMM compared to exact solution of (1.1), where H is as in (2.2) and $G(Du(x)) = \|Du(x)\|_p$. The variables d , m , and n are the dimension, the number of nodes in each dimension, and the total number of nodes, respectively. Other variables are the spacing h between grid nodes, the \mathcal{L}_∞ -error e_∞ , the \mathcal{L}_∞ convergence rate r_∞ , the \mathcal{L}_1 -error e_1 , and the \mathcal{L}_1 convergence rate r_1 .

Proof. Let $\mu \leq \check{w}$. By (3.2) and the definition of \check{w} , we have $D_j^s(N, \underline{v}, \mu) = D_j^s(N, \underline{u}, \mu)$ for all $s \in \mathcal{S}$, $1 \leq j \leq d$. This implies that $\underline{H}(N, \underline{v}, \mu) = \underline{H}(N, \underline{u}, \mu)$, proving the first claim.

For the second claim, let $\tilde{\mu}_u$ and $\tilde{\mu}_v$ be as defined above. Let $\tilde{\mu}_u \leq \check{w}$. Then $\underline{H}(N, \underline{v}, \tilde{\mu}_u) = \underline{H}(N, \underline{u}, \tilde{\mu}_u) = 0$, so $\mu = \tilde{\mu}_u$ is a solution to $\underline{H}(N, \underline{v}, \mu) = 0$. By Theorem 3.5, this solution is unique. By a symmetric argument, if $\tilde{\mu}_v \leq \check{w}$, then $\mu = \tilde{\mu}_v$ is the unique solution to $\underline{H}(N, \underline{u}, \mu) = 0$. \square

4. Experiments. We conduct experiments to show numerical evidence that the result of FMM converges to the viscosity solution of (1.1), to demonstrate types of anisotropic problems that can be solved, and to determine the effectiveness of the node and simplex elimination techniques described in Appendix A. Throughout this section, the boundary conditions are $g(x) = 0$ for $x \in \partial\Omega$. For all experiments below, excluding that in section 4.4, we discretize $[-1, 1]^d$ such that there are m uniformly spaced nodes in each dimension, and we ensure that there is a node at the origin O .

4.1. Convergence study. We examine the difference between the solution to (3.3) and the solution to (1.1) for two simple Dirichlet problems. In particular, we look at how the absolute error changes as the grid spacing decreases toward zero. For the problems considered, $\Omega = [-1, 1]^d \setminus \{O\}$. We take H to have the form in (2.2), where $G(Du(x)) = \|Du(x)\|_p$ and $p = 1$ or $p = 2$. The boundary conditions are $g(O) = 0$. We use the analytic node value update equations provided in Appendix B.

Since there is a node at O , any error introduced is from the discretization of H and not from the discretization of the boundary condition. The approximation errors are summarized in Table 4.1.

4.2. Asymmetric anisotropic problem. For this anisotropic problem, H is as in (2.2), where G is defined by (2.5) (see Figure 2.3(b)). The domain is given by $\Omega = [-1, 1]^2 \setminus \{O\}$ and $\partial\Omega = \{O\}$. The cost is $c(x) = 1$, except in four rectangular regions shown in black in Figure 4.1, where $c(x) \gg 1$. In the `Update` function, we

FIG. 4.1. Contours of \underline{u} computed for the anisotropic problem where Hamiltonian H is as in (2.2) and G is as in (2.5). The black circle at $O = (0, 0)$ indicates $\partial\Omega$, and in the black rectangles $c(x) \gg 1$. In these regions, \underline{u} has purposefully not been computed.

analytically computed the solution to (3.4) using the equations for updating from a single simplex given in Appendix B. The number of nodes in each dimension is $m = 1281$. We plot the contours of \underline{u} computed by FMM in Figure 4.1. Note the asymmetric contours where the characteristics bend through gaps. The relationship between the shape of the contours of G in Figure 2.3(b) and those of \underline{u} is explained by the duality articulated in Proposition 2.7 of [1].

4.3. Anelliptic elastic wave propagation. As is done in [10], we consider elastic wave propagation in VTI media, which are transversely isotropic media with a vertical axis of symmetry. In particular, we wish to find the arrival times of quasi-longitudinal (quasi-P or qP) waves propagating in two dimensions from a point source at the origin O . We solve the anisotropic HJ PDE given by defining the Hamiltonian

$$(4.1) \quad H(q) = \frac{1}{2}(q_1^2 + q_2^2) \left\{ (a+l)q_1^2 + (c+l)q_2^2 + \sqrt{[(a-l)q_1^2 - (c-l)q_2^2]^2 + 4(f+l)^2 q_1^2 q_2^2} \right\} - 1.$$

This Hamiltonian is derived from the anisotropic Eikonal equation and the exact qP-wave phase velocity equation in [10]. The parameters $a = 14.47$, $l = 2.28$, $c = 9.57$, and $f = 4.51$ are taken from [10].

The Hamiltonian H and the approximate solution \underline{u} resulting from FMM are shown in Figure 4.2. We have not shown analytically that (4.1) satisfies strict one-sided monotonicity for some range of parameters. However, the level sets of H as shown in Figure 4.2(a) indicate that H is strictly one-sided monotone for the given parameters. Furthermore, the level sets of H indicate that H is convex and a computation of the derivative of H using the symbolic mathematics program Maple shows that H satisfies Osher's criterion for the given parameters. As a result, the analysis in this paper can be applied to the problem, and FMM can be used to compute the solution.

We used a grid of size 201×201 . In the `Update` function, we used the interval method to solve (3.4) numerically. We computed the maximum relative error of \underline{u} to be 0.0076 when compared to the travel-time computed with the group-velocity

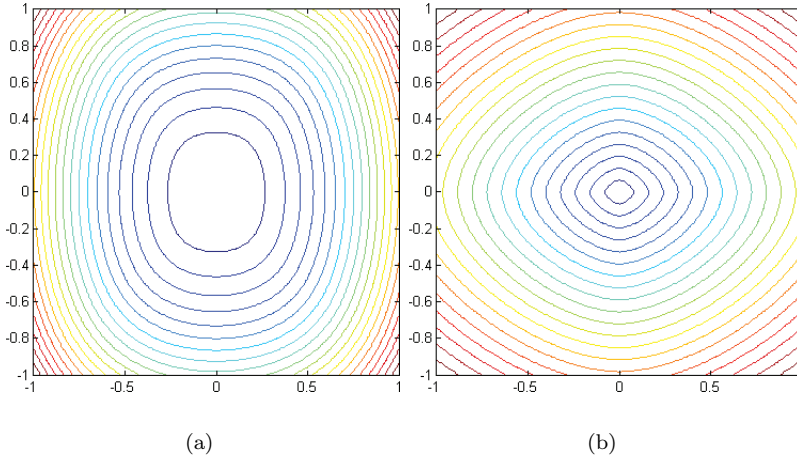

FIG. 4.2. Using FMM for computation of travel times of qP-waves in two-dimensional VTI media. (a) Contours of Hamiltonian H as given in (4.1). (b) Contours of approximate solution \underline{u} computed by FMM.

approximation for qP-waves presented in [10]. In turn, the group-velocity approximation is claimed to have a maximum error of about 0.003 when compared to the true solution.

4.4. Two robots. We consider the two-robot coordinated navigation problem illustrated in Figure 4.3. The circular robots are free to move independently in a two-dimensional plane but may not collide with each other or the obstacles (black region). Each may travel at a maximum speed of $1/c(x)$ in any direction. The robots attempt to achieve a joint goal state. This goal should be achieved in minimal time from any initial state in the domain without incurring collisions.

Let the state of the dark-colored robot be $(x_1, x_2) \in \mathbb{R}^2$ and the state of the light-colored robot be $(x_3, x_4) \in \mathbb{R}^2$ so that the combined state of the two robots is $(x_1, x_2, x_3, x_4) \in \mathbb{R}^4$. We define the control-theoretic action set

$$\mathcal{A}(x) = \{a \mid F(a) = \|(\|a_1, a_2\|_2, \|a_3, a_4\|_2)\|_\infty \leq 1/c(x)\}.$$

Proposition 2.7 of [1] states that we can use the dual of F to obtain

$$(4.2) \quad G(x, Du(x)) = \|(\|(\partial_1 u(x), \partial_2 u(x))\|_2, \|(\partial_3 u(x), \partial_4 u(x))\|_2)\|_1,$$

where $Du(x) = (\partial_1 u(x), \partial_2 u(x), \partial_3 u(x), \partial_4 u(x))$. Where x is a collision state, we set $c(x) \gg 1$. For all other states x , $c(x) = 1$.

We can compute \underline{u} using FMM since G is a mixed p -norm, and thus H satisfies Properties 1 to 4 (see section 2.2). The domain Ω is discretized using a uniform orthogonal grid of $(81 \times 21)^2$ nodes. The discretization of (4.2) is quartic in \underline{u}_0 , so it is difficult to solve analytically. However, Theorem 3.5 tells us that we can determine the solution to (3.4) uniquely. As a result, numerical root-finders can easily be used to compute this solution in the `Update` function. Once an approximation of u is generated by FMM, a gradient descent algorithm is used to find optimal paths [3, 2]. The optimal trajectories from a single starting condition are shown in Figure 4.3.

4.5. Efficient implementation. Appendix A describes three different methods for improving the efficiency of the `Update` function: symmetry, causality, and solution

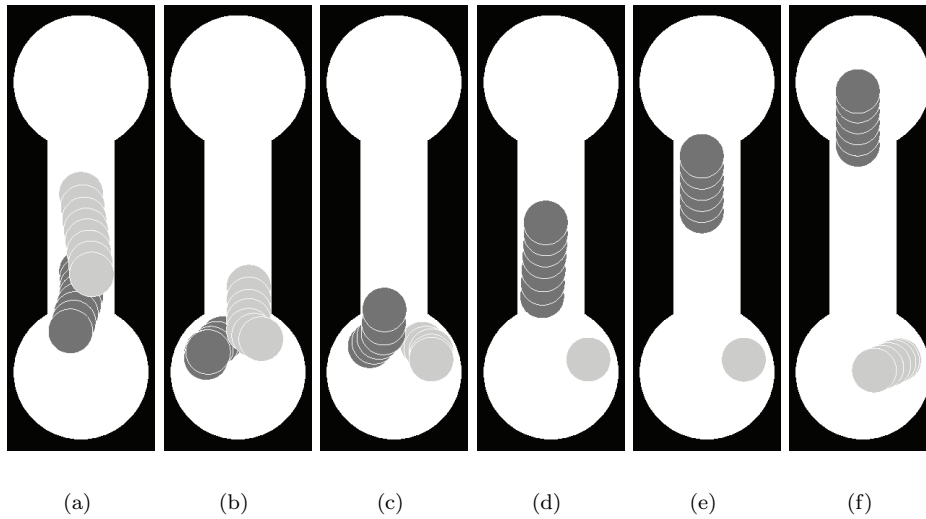

FIG. 4.3. *Two-robot coordinated optimal navigation problem. The joint goal is for the dark-colored robot to reach the center of the upper bulb and the light-colored robot to reach the center of the lower bulb. Black indicates an obstacle region. The sequence shows the robots achieving their joint goal without collision from a particular initial state. The solution of (1.1), where H is given by (2.2) and G is given by (4.2) allows quick determination of the optimal collision-free trajectories for both robots from any initial condition [3].*

elimination. Some of these methods are related to those found in [15, 31]. However, experimental results indicate that the efficiency gains from using these methods are not substantial for an already efficient implementation of FMM. In such an implementation the `Update` function computes only updates from those nodes that have already been extracted from \mathcal{Q} using the `ExtractMin` function. Also, only simplices that include the most-recently extracted node \underline{y} are considered in `Update`. Our experiments show that in many calls to `Update`, only a single simplex fits these criteria, and the fraction of updates for which only a single simplex fits the criteria grows as the grid is refined. For this reason, further techniques for eliminating nodes and simplices, such as those described in Appendix A, are largely ineffective.

However, for coarse grid resolutions and problems where characteristics intersect often, multiple simplices are considered by `Update` frequently enough that symmetry elimination, which is very cheap, significantly improves efficiency. In some cases, a node value update can be ignored altogether if the most-recently extracted node is eliminated by symmetry.

Despite the fact that the node and simplex elimination techniques described in Appendix A are useful only in limited circumstances, we include them for theoretical interest and because they may be applied in other algorithms, such as sweeping methods, that also require the `Update` function.

5. Conclusion. We have described a new class of static HJ PDEs with axis-aligned but potentially asymmetric anisotropy. Assuming Properties 1 to 4 of the Hamiltonian, we showed that uniqueness, monotonicity, and causality hold for a standard finite-difference discretization of these PDEs on an orthogonal grid, and so the FMM can be used to approximate their solution. In the appendix, we also demonstrate several methods for reducing the number of neighboring simplices which must

be considered when computing node updates, including novel methods which work when the PDE and/or grid are asymmetric. In future work, these results might be generalized to unstructured grids.

Appendix A. Efficient Implementation of Update. We discuss ways to improve the efficiency of the `Update` function, which calculates the unique solution $\mu = \tilde{\mu}$ to (3.4). We note that these improvements may be used for any type of solution method, including FMM and sweeping methods, as long as (3.4) is being solved. Some efficiency improvements are related to similar ideas specific to the isotropic Eikonal equation found in [15, 31].

Efficiency can be gained by determining which neighbors $\underline{x} \in \mathcal{N}(\underline{x}_0)$ have no influence on the solution and eliminating them from consideration. Let

$$\sigma = (\sigma_1, \sigma_2, \dots, \sigma_d),$$

where $\sigma_j \subseteq \{\pm 1\}$, indicate which $\underline{x} \in \mathcal{N}$ are considered in determining the solution $\mu = \tilde{\mu}$. Let \mathcal{N}_σ be the reduced set of neighbor nodes defined by σ . Let \mathcal{S}_σ be the set of neighboring simplices that can be formed by the neighbors in \mathcal{N}_σ . For example, in $d = 4$ dimensions, take

$$\sigma = (\emptyset, \{\pm 1\}, \{-1\}, \{\pm 1\}).$$

We have

$$\begin{aligned} \mathcal{N}_\sigma &= \{\underline{x}_2^\pm, \underline{x}_3^-, \underline{x}_4^\pm\} \quad \text{and} \\ \mathcal{S}_\sigma &= \{(0, -1, -1, -1), (0, +1, -1, -1), (0, -1, -1, +1), (0, +1, -1, +1)\}. \end{aligned}$$

Let $\underline{H}_\sigma(N, \phi, \mu) = \max_{s \in \mathcal{S}_\sigma} [H(\underline{x}_0, \underline{D}^s(N, \phi, \mu))]$ be the *reduced-neighbor numerical Hamiltonian*, a modification of (3.1) that considers only the neighbors and simplices indicated by σ . For $s \in \mathcal{S}_\sigma$ and $1 \leq j \leq d$, $s_j = 0$ indicates that $\underline{x}_j^{s_j}$ is not considered in computing the gradient approximation $D^s \underline{u}(\mu)$; that is, $\underline{D}_j^s(N, \phi, \mu) = 0$ if $s_j = 0$, and \underline{D}_j^s satisfies (3.2) otherwise.

To implement `Update`, we first reduce the set of considered neighbors and then solve

$$(A.1) \quad \underline{H}_\sigma(N(\underline{x}_0), \underline{u}, \mu) = 0$$

for $\mu = \tilde{\mu}$ to determine a node’s value $\underline{u}(\underline{x}_0)$. As in section 3, we may write $\underline{H}_\sigma(\mu) = \underline{H}_\sigma(N, \phi, \mu)$ and $\underline{D}^s(\mu) = \underline{D}^s(N, \phi, \mu)$, where no ambiguity results. Note that some properties of (A.1) are retained from (3.4) as long as at least one considered neighbor remains in σ . Let

$$\check{\underline{u}}_\sigma = \min_{\underline{x} \in \mathcal{N}_\sigma} (\underline{u}(\underline{x})).$$

PROPOSITION A.1 (analogue of Lemma 3.3). $\underline{H}_\sigma(\mu)$ is strictly increasing on $\mu \geq \check{\underline{u}}_\sigma$.

PROPOSITION A.2 (analogue of Lemma 3.4). The numerical Hamiltonian $\underline{H}_\sigma(\mu)$ satisfies the following:

- (a) $\underline{H}_\sigma(\mu) = H(0) < 0$ for $\mu \leq \check{\underline{u}}_\sigma$.
- (b) $\underline{H}_\sigma(\mu) \rightarrow \infty$ as $\mu \rightarrow \infty$.
- (c) $\underline{H}_\sigma(\mu)$ is nondecreasing on all μ .

PROPOSITION A.3 (analogue of Theorem 3.5). There exists a unique solution $\mu = \tilde{\mu}$ to $\underline{H}_\sigma(\mu) = 0$ such that $\tilde{\mu} > \check{\underline{u}}_\sigma$.

A.1. Symmetry. We show how the considered neighbors σ can be reduced by keeping only the neighbor with the smaller value of a pair of opposite neighbors in the j th dimension when (3.1) is symmetric in that dimension. This procedure is a generalization of those in [15, 31] to all axis-aligned anisotropic problems on unequally spaced grids. First, we introduce useful notation.

Let $q \in \mathbb{R}^d$. Let $T^i(q)$ be a reflection of q in the hyperplane orthogonal to the i th axis, such that

$$T_j^i(q) = \begin{cases} -q_j, & \text{if } j = i, \\ q_j, & \text{otherwise,} \end{cases}$$

for $1 \leq j \leq d$. Let Ψ_j indicate symmetry of (3.1) in the j th dimension, as follows:

$$\Psi_j = \begin{cases} 1, & \text{if } |h_j^-| = |h_j^+| \text{ and for all } q \in \mathbb{R}^d, H(q) = H(T^j(q)), \\ 0, & \text{otherwise.} \end{cases}$$

In other words, $\Psi_j = 1$ if and only if the grid spacing and H are symmetric in the j th dimension. The following theorem is proved in [2].

THEOREM A.4. *Let σ be such that $\sigma_j \subseteq \{\pm 1\}$ for $1 \leq j \leq d$. Let $\tilde{\sigma}$ be defined by*

$$\tilde{\sigma}_j = \begin{cases} \{-1\}, & \text{if } \sigma_j = \{\pm 1\}, \Psi_j = 1, \text{ and } \underline{u}_j^- \leq \underline{u}_j^+, \\ \{+1\}, & \text{if } \sigma_j = \{\pm 1\}, \Psi_j = 1, \text{ and } \underline{u}_j^- > \underline{u}_j^+, \\ \sigma_j, & \text{otherwise,} \end{cases}$$

for $1 \leq j \leq d$. Let $\mu = \mu_\sigma$ be the unique solution to $\underline{H}_\sigma(\mu) = 0$. Let $\mu = \mu_{\tilde{\sigma}}$ be the unique solution to $\underline{H}_{\tilde{\sigma}}(\mu) = 0$. Then $\mu_{\tilde{\sigma}} = \mu_\sigma$.

An implementation of the **Update** function can use the result obtained in Theorem A.4 to eliminate $\underline{x} \in \mathcal{N}$ from consideration in solving (A.1) by exploiting symmetries in (3.1). We call this *symmetry elimination*.

Remark 2. Theorem A.4 can be generalized to an asymmetric version. We let $1 \leq j \leq d$, and let $s_j, \tilde{s}_j \in \{\pm 1\}$ such that $s_j \neq \tilde{s}_j$. Node $\underline{x}_j^{s_j} \in \mathcal{N}$ may be eliminated from consideration if

- $|h_j^{\tilde{s}_j}| \leq |h_j^{s_j}|$;
- for all $q \in \mathbb{R}^d$ such that $s_j q_j \geq 0$, $H(q) \leq H(T^j(q))$;
- and $\underline{u}_j^{\tilde{s}_j} \leq \underline{u}_j^{s_j}$.

A.2. Causality. The causality of (3.1) can also be exploited to eliminate $\underline{x} \in \mathcal{N}_\sigma$ from consideration. This observation was used in two distinct but equivalent methods for analytically computing the **Update** from a single simplex to solve an isotropic Eikonal equation [15, 31]. We show with the following theorem that the condition $\underline{H}_\sigma(\underline{u}(\underline{x})) \geq 0$ can be checked to determine that a node \underline{x} is noncausal, i.e., that the solution $\mu = \mu_\sigma$ to (A.1) is not dependent on the node \underline{x} and its value $\underline{u}(\underline{x})$.

THEOREM A.5. *Let σ be such that $\sigma_j \subseteq \{\pm 1\}$ for $1 \leq j \leq d$. Pick any $s \in \mathcal{S}_\sigma$ and $i \in \{1, 2, \dots, d\}$ such that $s_i \neq 0$ and $\underline{H}_\sigma(\underline{u}_i^{s_i}) \geq 0$. Let $\tilde{\sigma}$ be defined by*

$$\tilde{\sigma}_j = \begin{cases} \sigma_j \setminus \{s_j\}, & \text{if } j = i, \\ \sigma_j, & \text{otherwise.} \end{cases}$$

Let $\mu = \mu_\sigma$ be the unique solution to $\underline{H}_\sigma(\mu) = 0$. Let $\mu = \mu_{\tilde{\sigma}}$ be the unique solution to $\underline{H}_{\tilde{\sigma}}(\mu) = 0$. Then $\mu_{\tilde{\sigma}} = \mu_\sigma$.

Proof. Let $\sigma, s, i, \tilde{\sigma}, \mu_\sigma,$ and $\mu_{\tilde{\sigma}}$ be as defined above. By Proposition A.2(c), $\underline{H}_\sigma(\mu)$ is nondecreasing. Since $\underline{H}_\sigma(\underline{u}_i^{s_i}) \geq 0 = \underline{H}_\sigma(\mu_\sigma)$, it must be that $\mu_\sigma \leq \underline{u}_i^{s_i}$. Note that $\underline{H}_{\tilde{\sigma}}(\mu)$ is identical to $\underline{H}_\sigma(\mu)$ except for $D_i^s \underline{u}(\mu)$, which is set to zero in $\underline{H}_{\tilde{\sigma}}(\mu)$. But for $\mu \leq \underline{u}_i^{s_i}$, we also have $D_i^s \underline{u}(\mu) = 0$ in $\underline{H}_\sigma(\mu)$. Consequently, $\underline{H}_{\tilde{\sigma}}(\mu) = \underline{H}_\sigma(\mu)$ for $\mu \leq \underline{u}_i^{s_i}$. In particular, $\underline{H}_{\tilde{\sigma}}(\mu_\sigma) = \underline{H}_\sigma(\mu_\sigma) = 0$. Therefore, $\mu_{\tilde{\sigma}} = \mu_\sigma$. \square

Theorem A.5 states that the unique solution μ to (A.1) does not change when a noncausal node is removed from σ . This node removal can be repeated until all noncausal nodes have been removed, and the solution $\mu = \mu_\sigma$ will remain unchanged. We call this *causality elimination*. A binary or linear search through sorted neighbors' values can be used to determine the largest node value that might be causal. Note that causality elimination does not require symmetry in (3.1). However, the test for noncausality requires an evaluation of \underline{H}_σ , which is more expensive than the comparison of two neighbors' values used for symmetry elimination.

A.3. Solution. After eliminating from consideration nodes in σ using symmetry and causality elimination, we can determine the solution $\mu = \tilde{\mu}$ to (A.1). Let

$$(A.2) \quad \tilde{\mu} = \min_{s \in \mathcal{S}_\sigma} (\mu_s),$$

where $\mu = \mu_s$ is the unique solution to

$$(A.3) \quad H(D^s \underline{u}(\mu)) = 0.$$

We show with the following proposition that, instead of solving (A.1) directly, we can solve (A.3) for each $s \in \mathcal{S}_\sigma$ and take the minimum such solution $\tilde{\mu}$. It can be shown that $H(D^s \underline{u}(\mu))$ is continuous and nondecreasing on μ and that (A.3) has a unique solution in an analogous but simpler manner as the proof of Theorem 3.5.

PROPOSITION A.6. *Let $\hat{\mu}$ be the unique solution to (A.1). Then $\hat{\mu} = \tilde{\mu}$.*

Proof. Let $\mu_s, \tilde{\mu},$ and $\hat{\mu}$ be as defined above. For any $s \in \mathcal{S}_\sigma$, we know $\mu_s \geq \tilde{\mu}$. Since $H(D^s \underline{u}(\mu))$ is nondecreasing on μ , it must be that $H(D^s \underline{u}(\mu)) \leq H(D^s \underline{u}(\mu_s)) = 0$ for all $\mu \leq \mu_s$. In particular, $H(D^s \underline{u}(\tilde{\mu})) \leq 0$. Furthermore, by the definition of $\tilde{\mu}$, there exists an $\tilde{s} \in \mathcal{S}_\sigma$ such that $H(D^{\tilde{s}} \underline{u}(\tilde{\mu})) = 0$. Consequently,

$$(A.4) \quad \underline{H}_\sigma(\tilde{\mu}) = \max_{s \in \mathcal{S}_\sigma} H(D^s \underline{u}(\tilde{\mu})) = 0.$$

Therefore, $\hat{\mu} = \tilde{\mu}$ solves (A.1), and it is a unique solution by Proposition A.3. \square

We further show that we may be able to determine $\tilde{\mu}$ without solving (A.3) for each $s \in \mathcal{S}_\sigma$. We demonstrate using the following proposition that if we have computed a solution $\mu = \mu_s$ of (A.3) for some $s \in \mathcal{S}_\sigma$, we can easily determine if $\mu_{\tilde{s}} \geq \mu_s$, where $\mu = \mu_{\tilde{s}}$ is the solution to $H(D^{\tilde{s}} \underline{u}(\mu)) = 0$ for some other $\tilde{s} \in \mathcal{S}_\sigma$. Note we do not necessarily need to compute $\mu_{\tilde{s}}$ to rule it out as a minimal solution.

PROPOSITION A.7. *Let $s \in \mathcal{S}_\sigma$ and $\tilde{s} \in \mathcal{S}_\sigma$. Let $\mu = \mu_s$ be the unique solution to $H(D^s \underline{u}(\mu)) = 0$ and $\mu = \mu_{\tilde{s}}$ be the unique solution to $H(D^{\tilde{s}} \underline{u}(\mu)) = 0$. Then $\mu_{\tilde{s}} < \mu_s$ if and only if $H(D^{\tilde{s}} \underline{u}(\mu_s)) > H(D^s \underline{u}(\mu_s))$.*

Proof. Let μ_s and $\mu_{\tilde{s}}$ be as defined above. If $H(D^{\tilde{s}} \underline{u}(\mu_s)) > H(D^s \underline{u}(\mu_s)) = 0$, then the unique solution $\mu = \mu_{\tilde{s}}$ to $H(D^{\tilde{s}} \underline{u}(\mu)) = 0$ must be such that $\mu_{\tilde{s}} < \mu_s$, since $H(D^{\tilde{s}} \underline{u}(\mu))$ is nondecreasing on μ . Similarly, if $H(D^{\tilde{s}} \underline{u}(\mu_s)) \leq H(D^s \underline{u}(\mu_s))$, then the unique solution $\mu = \mu_{\tilde{s}}$ to $H(D^{\tilde{s}} \underline{u}(\mu)) = 0$ must be such that $\mu_{\tilde{s}} \geq \mu_s$. \square

The result of Proposition A.7 can be used to eliminate simplices $s \in \mathcal{S}_\sigma$ for which solutions to (A.3) are irrelevant to the computation. We call this process *solution elimination*.

Appendix B. Analytic solutions. We provide analytic node value update equations for the cases where H is given by (2.2), where $G(Du(x)) = \|Du(x)\|_p$ and $p = 1$, $p = 2$, or $p = \infty$. In these cases, there is an exact solution to (3.4). For derivations of these equations, see [2]. The equation for $p = 2$ fixes some errors in the appendix of [16]. In [3] we demonstrated that these cases could be treated by FMM and are useful for robotic applications. However, here we generalize the update equations to any dimension and grid spacing.

Let (v_1, v_2, \dots, v_m) be the values of the neighboring nodes in the simplex $s \in \mathcal{S}_\sigma$ and (h_1, h_2, \dots, h_m) be the corresponding grid spacings. We are solving for μ . In order to use the analytic updates below, noncausal node values must already have been eliminated using causality elimination, so $\mu > \max_{1 \leq j \leq m} v_j$. However, in the case of the efficient implementation of FMM discussed in section 4.5, any nodes that would be removed from consideration by causality elimination could not already have been extracted from \mathcal{Q} , and so the analytic updates below can be applied directly.

The update formula for $p = 1$ is

$$\mu = \frac{\sum_j \left(\prod_{l \neq j} h_l \right) v_j + \prod_l h_l c}{\sum_j \prod_{l \neq j} h_l}.$$

The update formula for $p = 2$ is

$$\mu = \frac{\sum_j \left(\prod_{l \neq j} h_l^2 \right) v_j + \prod_l h_l \sqrt{\left(\sum_j \prod_{l \neq j} h_l^2 \right) c^2 - \sum_{j_1} \sum_{j_2 > j_1} \left(\prod_{l \neq j_1, j_2} h_l^2 \right) (v_{j_1} - v_{j_2})^2}}{\sum_j \prod_{l \neq j} h_l^2}.$$

The update formula for $p = \infty$ is

$$\mu = \min_j (v_j + h_j c).$$

The $p = \infty$ case is identical to the update formula for Dijkstra's algorithm for shortest path on a discrete graph.

Acknowledgments. We would like to thank Alexander Vladimirsky for enlightening discussions about FMM and OUM and Adam Oberman for discussions and insights regarding [4]. Furthermore, we wish to thank the reviewers for constructive and insightful comments.

NEW INTERIOR PENALTY DISCONTINUOUS GALERKIN METHODS FOR THE KELLER–SEGEL CHEMOTAXIS MODEL*

YEKATERINA EPSHTEYN[†] AND ALEXANDER KURGANOV[‡]

Abstract. We develop a family of new interior penalty discontinuous Galerkin methods for the Keller–Segel chemotaxis model. This model is described by a system of two nonlinear PDEs: a convection-diffusion equation for the cell density coupled with a reaction-diffusion equation for the chemoattractant concentration. It has been recently shown that the convective part of this system is of a mixed hyperbolic–elliptic-type, which may cause severe instabilities when the studied system is solved by straightforward numerical methods. Therefore, the first step in the derivation of our new methods is made by introducing the new variable for the gradient of the chemoattractant concentration and by reformulating the original Keller–Segel model in the form of a convection-diffusion-reaction system with a hyperbolic convective part. We then design interior penalty discontinuous Galerkin methods for the rewritten Keller–Segel system. Our methods employ the central-upwind numerical fluxes, originally developed in the context of finite-volume methods for hyperbolic systems of conservation laws. In this paper, we consider Cartesian grids and prove error estimates for the proposed high-order discontinuous Galerkin methods. Our proof is valid for pre-blow-up times since we assume boundedness of the exact solution. We also show that the blow-up time of the exact solution is bounded from above by the blow-up time of our numerical solution. In the numerical tests presented below, we demonstrate that the obtained numerical solutions have no negative values and are oscillation-free, even though no slope-limiting technique has been implemented.

1. Introduction. The goal of this work is to design new discontinuous Galerkin (DG) methods for the two-dimensional Keller–Segel chemotaxis model [13, 29, 30, 31, 36, 38]. The DG methods have recently become increasingly popular thanks to their attractive features such as local, elementwise mass conservation; flexibility to use high-order polynomial and nonpolynomial basis functions; ability to easily increase the order of approximation on each mesh element independently; ability to achieve almost an exponential convergence rate when smooth solutions are captured on appropriate meshes; block diagonal mass matrices, which are of great computational advantage if an explicit time integration is used; suitability for parallel computations due to (relatively) local data communications; applicability to problems with discontinuous coefficients and/or solutions. The DG methods have been successfully applied to a wide variety of problems ranging from solid mechanics to fluid mechanics (see, e.g., [3, 7, 14, 15, 17, 21, 23, 41] and references therein).

In this paper, we consider the most common formulation of the Keller–Segel system [13], which can be written in the dimensionless form as

$$(1.1) \quad \begin{cases} \rho_t + \nabla \cdot (\chi \rho \nabla c) = \Delta \rho, \\ c_t = \Delta c - c + \rho, \end{cases} \quad (x, y) \in \Omega, \quad t > 0,$$

subject to the Neumann boundary conditions:

$$\nabla \rho \cdot \mathbf{n} = \nabla c \cdot \mathbf{n} = 0, \quad (x, y) \in \partial\Omega.$$

Here, $\rho(x, y, t)$ is the cell density, $c(x, y, t)$ is the chemoattractant concentration, χ is a chemotactic sensitivity constant, Ω is a bounded domain in \mathbb{R}^2 , $\partial\Omega$ is its boundary, and \mathbf{n} is a unit normal vector.

It is well-known that solutions of this system may blow up in finite time; see, e.g., [27, 28] and references therein. This blow up represents a mathematical description of a cell concentration phenomenon that occurs in real biological systems; see, e.g., [1, 8, 10, 11, 16, 39].

Capturing blowing up solutions numerically is a challenging problem. Finite-volume [22] and finite element [35] methods have been proposed for a simpler version of the Keller–Segel model,

$$\begin{cases} \rho_t + \nabla \cdot (\chi \rho \nabla c) = \Delta \rho, \\ \Delta c - c + \rho = 0, \end{cases}$$

in which the equation for concentration c has been replaced by an elliptic equation using an assumption that the chemoattractant concentration c changes over much smaller time scales than the density ρ . A fractional step numerical method for a fully time-dependent chemotaxis system from [42] has been proposed in [43]. However, the operator-splitting approach may not be applicable when a convective part of the chemotaxis system is not hyperbolic, which is a generic situation for the original Keller–Segel model as it was shown in [12], where the finite-volume Godunov-type central-upwind scheme was derived for (1.1) and extended to some other chemotaxis and haptotaxis models.

The starting point in the derivation of the central-upwind scheme in [12] was rewriting the original system (1.1) in an equivalent form, in which the concentration equation is replaced with the corresponding equation for the gradient of c :

$$\begin{cases} \rho_t + \nabla \cdot (\chi \rho \mathbf{w}) = \Delta \rho, \\ \mathbf{w}_t - \nabla \rho = \Delta \mathbf{w} - \mathbf{w}, \end{cases} \quad \mathbf{w} \equiv (u, v) := \nabla c.$$

This form can be considered as a convection-diffusion-reaction system

$$(1.2) \quad \mathbf{U}_t + \mathbf{f}(\mathbf{U})_x + \mathbf{g}(\mathbf{U})_y = \Delta \mathbf{U} + \mathbf{r}(\mathbf{U}),$$

where $\mathbf{U} := (\rho, u, v)^T$, $\mathbf{f}(\mathbf{U}) := (\chi \rho u, -\rho, 0)^T$, $\mathbf{g}(\mathbf{U}) := (\chi \rho v, 0, -\rho)^T$, and $\mathbf{r}(\mathbf{U}) := (0, -u, -v)^T$. The system (1.2) is an appropriate form of the chemotaxis system if one wants to solve it numerically by a finite-volume method. Even though the convective part of the system (1.2) is not hyperbolic, some stability of the resulting central-upwind scheme was ensured by proving its positivity-preserving property; see [12].

A major disadvantage of the system (1.2) is a mixed type of its convective part. When a high-order numerical method is applied to (1.2), a switch from a hyperbolic

region to an elliptic one may cause severe instabilities in the numerical solution since the propagation speeds in the elliptic region are infinite. Therefore, in order to develop high-order DG methods for (1.1), we rewrite it in a different form, which is suitable for DG settings:

$$(1.3) \quad \rho_t + (\chi\rho u)_x + (\chi\rho v)_y = \Delta\rho,$$

$$(1.4) \quad c_t = \Delta c - c + \rho,$$

$$(1.5) \quad u = c_x,$$

$$(1.6) \quad v = c_y,$$

where the new unknowns $\rho, c, u,$ and v satisfy the following boundary conditions:

$$(1.7) \quad \nabla\rho \cdot \mathbf{n} = \nabla c \cdot \mathbf{n} = (u, v)^T \cdot \mathbf{n} = 0, \quad (x, y) \in \partial\Omega.$$

The new system (1.3)–(1.6) may also be considered as a system of convection-diffusion-reaction equations

$$(1.8) \quad k\mathbf{Q}_t + \mathbf{F}(\mathbf{Q})_x + \mathbf{G}(\mathbf{Q})_y = k\Delta\mathbf{Q} + \mathbf{R}(\mathbf{Q}),$$

where $\mathbf{Q} := (\rho, c, u, v)^T$, the fluxes are $\mathbf{F}(\mathbf{Q}) := (\chi\rho u, 0, -c, 0)^T$ and $\mathbf{G}(\mathbf{Q}) := (\chi\rho v, 0, 0, -c)^T$, the reaction term is $\mathbf{R}(\mathbf{Q}) := (0, \rho - c, -u, -v)$, the constant $k = 1$ in the first two equations in (1.8), and $k = 0$ in the third and the fourth equations there. As we show in section 3, the convective part of the system (1.8) is hyperbolic.

In this paper, we develop a family of high-order DG methods for the system (1.8). The proposed methods are based on three primal DG methods: the nonsymmetric interior penalty Galerkin (NIPG), the symmetric interior penalty Galerkin (SIPG), and the incomplete interior penalty Galerkin (IIPG) methods [4, 18, 19, 40]. The numerical fluxes in the proposed DG methods are the fluxes developed for the semidiscrete finite-volume central-upwind schemes in [33] (see also [32, 34] and references therein). These schemes belong to the family of nonoscillatory central schemes, which are highly accurate and efficient methods applicable to general multidimensional systems of conservation laws and related problems. Like other central fluxes, the central-upwind ones are obtained without using the (approximate) Riemann problem solver, which is unavailable for the system under consideration. At the same time, certain upwinding information—one-sided speeds of propagation—is incorporated into the central-upwind fluxes.

We consider Cartesian grids and prove the error estimates for the proposed high-order DG methods under the assumption of boundedness of the exact solution. We also show that the blow-up time of the exact solution is bounded from above by the blow-up time of the solution of our DG methods. In numerical tests presented in section 6, we demonstrate that the obtained numerical solutions have no negative values and are oscillation-free, even though no slope-limiting technique has been implemented. We also demonstrate a high order of numerical convergence, achieved even when the final computational time gets close to the blow-up time and the spiky structure of the solution is well-developed.

The paper is organized as follows. In section 2, we introduce our notations and assumptions and state some standard results. The new DG methods are presented in section 3. The consistency and error analysis of the proposed methods are established in sections 4 and 5; some technical details which are omitted from the proof can be found in [20]. Finally, in section 6, we perform several numerical experiments.

2. Assumptions, notations, and standard results. We denote by \mathcal{E}_h a nondegenerate quasi-uniform rectangular subdivision of the domain Ω (the quasi-uniformity requirement will be used only in section 5 for establishing the rate of convergence with respect to the polynomial degree). The maximum diameter over all mesh elements is denoted by h , and the set of the interior edges is denoted by Γ_h . To each edge e in Γ_h , we associate a unit normal vector $\mathbf{n}_e = (n_x, n_y)$. We assume that \mathbf{n}_e is directed from the element E^1 to E^2 , where E^1 denotes a certain element and E^2 denotes an element that has a common edge with the element E^1 and a larger index (this simplified element notation will be used throughout the paper). For a boundary edge, \mathbf{n}_e is chosen so that it coincides with the outward normal.

The discrete space of discontinuous piecewise polynomials of degree r is denoted by

$$\mathcal{W}_{r,h}(\mathcal{E}_h) = \{w \in L^2(\Omega) : \forall E \in \mathcal{E}_h, w|_E \in P_r(E)\},$$

where $P_r(E)$ is a space of polynomials of degree r over the element E . For any function $w \in \mathcal{W}_{r,h}$, we denote the jump and average operators over a given edge e by $[w]$ and $\{w\}$, respectively:

$$\begin{aligned} \text{for an interior edge } e = \partial E^1 \cap \partial E^2, \quad [w] &:= w_e^{E^1} - w_e^{E^2}, \quad \{w\} := 0.5w_e^{E^1} + 0.5w_e^{E^2}, \\ \text{for a boundary edge } e = \partial E^1 \cap \partial \Omega, \quad [w] &:= w_e^{E^1}, \quad \{w\} := w_e^{E^1}, \end{aligned}$$

where $w_e^{E^1}$ and $w_e^{E^2}$ are the corresponding polynomial approximations from the elements E^1 and E^2 , respectively. We also recall that the following identity between the jump and the average operators is satisfied:

$$(2.1) \quad [w_1 w_2] = \{w_1\}[w_2] + \{w_2\}[w_1].$$

For the finite-element subdivision \mathcal{E}_h , we define the broken Sobolev space

$$H^s(\mathcal{E}_h) = \{w \in L^2(\Omega) : w|_{E^j} \in H^s(E^j), j = 1, \dots, N_h\}$$

with the norms

$$\|w\|_{0,\Omega} = \left(\sum_{E \in \mathcal{E}_h} \|w\|_{0,E}^2 \right)^{\frac{1}{2}} \quad \text{and} \quad \|w\|_{s,\Omega} = \left(\sum_{E \in \mathcal{E}_h} \|w\|_{s,E}^2 \right)^{\frac{1}{2}}, \quad s > 0,$$

where $\|\cdot\|_{s,E}$ denotes the Sobolev s -norm over the element E .

We now recall some well-known facts that will be used in the error analysis in section 5. First, let us state some approximation properties and inequalities for the finite-element space.

LEMMA 2.1 (*hp approximation* [5, 6]). *Let $E \in \mathcal{E}_h$ and $\psi \in H^s(E)$, $s \geq 0$. Then there exist a positive constant C , independent of ψ, r , and h , and a sequence $\tilde{\psi}_r^h \in P_r(E)$, $r = 1, 2, \dots$, such that for any $q \in [0, s]$*

$$(2.2) \quad \left\| \psi - \tilde{\psi}_r^h \right\|_{q,E} \leq C \frac{h^{\mu-q}}{r^{s-q}} \|\psi\|_{s,E}, \quad \mu := \min(r+1, s).$$

LEMMA 2.2 (*trace inequalities* [2]). *Let $E \in \mathcal{E}_h$. Then for the trace operators γ_0 and γ_1 , there exists a constant C_t , independent of h , such that*

$$(2.3) \quad \forall w \in H^s(E), \quad s \geq 1, \quad \|\gamma_0 w\|_{0,e} \leq C_t h^{-\frac{1}{2}} \left(\|w\|_{0,E} + h \|\nabla w\|_{0,E} \right),$$

$$(2.4) \quad \forall w \in H^s(E), \quad s \geq 2, \quad \|\gamma_1 w\|_{0,e} \leq C_t h^{-\frac{1}{2}} \left(\|\nabla w\|_{0,E} + h \|\nabla^2 w\|_{0,E} \right),$$

where e is an edge of the element E .

LEMMA 2.3 (see [40]). *Let E be a mesh element with an edge e . Then there is a constant C_t , independent of h and r , such that*

$$(2.5) \quad \forall w \in P_r(E), \quad \|\gamma_0 w\|_{0,e} \leq C_t h^{-\frac{1}{2}} r \|w\|_{0,E}.$$

LEMMA 2.4 (see [4, 9]). *There exists a constant C , independent of h and r , such that*

$$\forall w \in \mathcal{W}_{r,h}(\mathcal{E}_h), \quad \|w\|_{0,\Omega}^2 \leq C \left(\sum_{E \in \mathcal{E}_h} \|\nabla w\|_{0,E}^2 + \sum_{e \in \Gamma_h} \frac{1}{|e|} \|[w]\|_{0,e}^2 \right)^{\frac{1}{2}},$$

where $|e|$ denotes the measure of e .

LEMMA 2.5 (inverse inequalities). *Let $E \in \mathcal{E}_h$ and $w \in P_r(E)$. Then there exists a constant C , independent of h and r , such that*

$$(2.6) \quad \|w\|_{L^\infty(E)} \leq Ch^{-1} r \|w\|_{0,E},$$

$$(2.7) \quad \|w\|_{1,E} \leq Ch^{-1} r \|w\|_{0,E}.$$

We also recall the following form of Gronwall’s lemma.

LEMMA 2.6 (Gronwall). *Let φ, ψ , and ϕ be continuous nonnegative functions defined on the interval $a \leq t \leq b$, and the function ϕ is nondecreasing. If $\varphi(t) + \psi(t) \leq \phi(t) + \int_a^t \varphi(s) ds$ for all $t \in [a, b]$, then $\varphi(t) + \psi(t) \leq e^{t-a} \phi(t)$.*

In the analysis below we also make the following assumptions:

- Ω is a rectangular domain with the boundary $\partial\Omega = \partial\Omega_{\text{ver}} \cup \partial\Omega_{\text{hor}}$, where $\partial\Omega_{\text{ver}}$ and $\partial\Omega_{\text{hor}}$ denote the vertical and horizontal pieces of the boundary $\partial\Omega$, respectively. We also split the set of interior edges Γ_h into two sets of vertical Γ_h^{ver} and horizontal Γ_h^{hor} edges, respectively.

- The degree of basis polynomials is $r \geq 2$, and the maximum diameter of the elements is $h < 1$ (the latter assumption is needed only for simplification of the error analysis).

3. Description of the numerical scheme. We consider the Keller–Segel system (1.8). First, notice that the Jacobians of \mathbf{F} and \mathbf{G} are

$$\frac{\partial \mathbf{F}}{\partial \mathbf{Q}} = \begin{pmatrix} \chi u & 0 & \chi \rho & 0 \\ 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \quad \text{and} \quad \frac{\partial \mathbf{G}}{\partial \mathbf{Q}} = \begin{pmatrix} \chi v & 0 & 0 & \chi \rho \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}$$

and their eigenvalues are

$$(3.1) \quad \lambda_1^{\mathbf{F}} = \chi u, \quad \lambda_2^{\mathbf{F}} = \lambda_3^{\mathbf{F}} = \lambda_4^{\mathbf{F}} = 0 \quad \text{and} \quad \lambda_1^{\mathbf{G}} = \chi v, \quad \lambda_2^{\mathbf{G}} = \lambda_3^{\mathbf{G}} = \lambda_4^{\mathbf{G}} = 0,$$

respectively. Hence, the convective part of (1.8) is hyperbolic. We now design semidiscrete interior penalty Galerkin methods for this system.

We assume that at any time level $t \in [0, T]$ the solution $(\rho, c, u, v)^T$ is approximated by (discontinuous) piecewise polynomials of the corresponding degrees r_ρ, r_c, r_u , and r_v , which satisfy the following relation:

$$(3.2) \quad \frac{r_{\max}}{r_{\min}} \leq a, \quad r_{\max} := \max\{r_\rho, r_c, r_u, r_v\}, \quad r_{\min} := \min\{r_\rho, r_c, r_u, r_v\},$$

where a is a constant independent of r_ρ, r_c, r_p , and r_q .

Our new DG methods are formulated as follows: find a continuous-in-time solution

$$(\rho^{\text{DG}}(\cdot, t), c^{\text{DG}}(\cdot, t), u^{\text{DG}}(\cdot, t), v^{\text{DG}}(\cdot, t)) \in \mathcal{W}_{r_\rho, h}^\rho \times \mathcal{W}_{r_c, h}^c \times \mathcal{W}_{r_u, h}^u \times \mathcal{W}_{r_v, h}^v$$

which satisfies the following weak formulation of the chemotaxis system (1.3)–(1.6):

$$\begin{aligned} & \int_{\Omega} \rho_t^{\text{DG}} w^\rho + \sum_{E \in \mathcal{E}_h} \int_E \nabla \rho^{\text{DG}} \nabla w^\rho - \sum_{e \in \Gamma_h} \int_e \{\nabla \rho^{\text{DG}} \cdot \mathbf{n}_e\} [w^\rho] \\ & + \varepsilon \sum_{e \in \Gamma_h} \int_e \{\nabla w^\rho \cdot \mathbf{n}_e\} [\rho^{\text{DG}}] \\ & + \sigma_\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \int_e [\rho^{\text{DG}}] [w^\rho] - \sum_{E \in \mathcal{E}_h} \int_E \chi \rho^{\text{DG}} u^{\text{DG}} (w^\rho)_x \\ & + \sum_{e \in \Gamma_h^{\text{ver}}} \int_e (\chi \rho^{\text{DG}} u^{\text{DG}})^* n_x [w^\rho] \\ (3.3) \quad & - \sum_{E \in \mathcal{E}_h} \int_E \chi \rho^{\text{DG}} v^{\text{DG}} (w^\rho)_y + \sum_{e \in \Gamma_h^{\text{hor}}} \int_e (\chi \rho^{\text{DG}} v^{\text{DG}})^* n_y [w^\rho] = 0, \end{aligned}$$

$$\begin{aligned} & \int_{\Omega} c_t^{\text{DG}} w^c + \sum_{E \in \mathcal{E}_h} \int_E \nabla c^{\text{DG}} \nabla w^c - \sum_{e \in \Gamma_h} \int_e \{\nabla c^{\text{DG}} \cdot \mathbf{n}_e\} [w^c] + \varepsilon \sum_{e \in \Gamma_h} \int_e \{\nabla w^c \cdot \mathbf{n}_e\} [c^{\text{DG}}] \\ (3.4) \quad & + \sigma_c \sum_{e \in \Gamma_h} \frac{r_c^2}{|e|} \int_e [c^{\text{DG}}] [w^c] + \int_{\Omega} c^{\text{DG}} w^c - \int_{\Omega} \rho^{\text{DG}} w^c = 0, \end{aligned}$$

$$\begin{aligned} & \int_{\Omega} u^{\text{DG}} w^u + \sum_{E \in \mathcal{E}_h} \int_E c^{\text{DG}} (w^u)_x + \sum_{e \in \Gamma_h^{\text{ver}}} \int_e (-c^{\text{DG}})_u^* n_x [w^u] \\ (3.5) \quad & - \sum_{e \in \partial\Omega_{\text{ver}}} \int_e c^{\text{DG}} n_x w^u + \sigma_u \sum_{e \in \Gamma_h \cup \partial\Omega_{\text{ver}}} \frac{r_u^2}{|e|} \int_e [u^{\text{DG}}] [w^u] = 0, \end{aligned}$$

$$\begin{aligned} & \int_{\Omega} v^{\text{DG}} w^v + \sum_{E \in \mathcal{E}_h} \int_E c^{\text{DG}} (w^v)_y + \sum_{e \in \Gamma_h^{\text{hor}}} \int_e (-c^{\text{DG}})_v^* n_y [w^v] \\ (3.6) \quad & - \sum_{e \in \partial\Omega_{\text{hor}}} \int_e c^{\text{DG}} n_y w^v + \sigma_v \sum_{e \in \Gamma_h \cup \partial\Omega_{\text{hor}}} \frac{r_v^2}{|e|} \int_e [v^{\text{DG}}] [w^v] = 0, \end{aligned}$$

with the initial conditions

$$\begin{aligned} (3.7) \quad & \int_{\Omega} \rho^{\text{DG}}(\cdot, 0) w^\rho = \int_{\Omega} \rho(\cdot, 0) w^\rho, \quad \int_{\Omega} c^{\text{DG}}(\cdot, 0) w^c = \int_{\Omega} c(\cdot, 0) w^c, \\ & \int_{\Omega} u^{\text{DG}}(\cdot, 0) w^u = \int_{\Omega} u(\cdot, 0) w^u, \quad \int_{\Omega} v^{\text{DG}}(\cdot, 0) w^v = \int_{\Omega} v(\cdot, 0) w^v. \end{aligned}$$

Here, $(w^\rho, w^c, w^u, w^v) \in \mathcal{W}_{r_\rho, h}^\rho \times \mathcal{W}_{r_c, h}^c \times \mathcal{W}_{r_u, h}^u \times \mathcal{W}_{r_v, h}^v$ are the test functions, and $\sigma_\rho, \sigma_c, \sigma_u$, and σ_v are real positive penalty parameters. The parameter ε is equal to either $-1, 0$, or 1 ; these values of ε correspond to the SIPG, IIPG, or NIPG method, respectively.

To approximate the convective terms in (3.3) and (3.5)–(3.6), we use the central-upwind fluxes from [33]:

$$\begin{aligned}
 (\chi\rho^{\text{DG}}u^{\text{DG}})^* &= \frac{a^{\text{out}}(\chi\rho^{\text{DG}}u^{\text{DG}})_e^{E^1} - a^{\text{in}}(\chi\rho^{\text{DG}}u^{\text{DG}})_e^{E^2}}{a^{\text{out}} - a^{\text{in}}} - \frac{a^{\text{out}}a^{\text{in}}}{a^{\text{out}} - a^{\text{in}}} [\rho^{\text{DG}}], \\
 (\chi\rho^{\text{DG}}v^{\text{DG}})^* &= \frac{b^{\text{out}}(\chi\rho^{\text{DG}}v^{\text{DG}})_e^{E^1} - b^{\text{in}}(\chi\rho^{\text{DG}}v^{\text{DG}})_e^{E^2}}{b^{\text{out}} - b^{\text{in}}} - \frac{b^{\text{out}}b^{\text{in}}}{b^{\text{out}} - b^{\text{in}}} [\rho^{\text{DG}}], \\
 (-c^{\text{DG}})_u^* &= -\frac{a^{\text{out}}(c^{\text{DG}})_e^{E^1} - a^{\text{in}}(c^{\text{DG}})_e^{E^2}}{a^{\text{out}} - a^{\text{in}}} - \frac{a^{\text{out}}a^{\text{in}}}{a^{\text{out}} - a^{\text{in}}} [u^{\text{DG}}], \\
 (-c^{\text{DG}})_v^* &= -\frac{b^{\text{out}}(c^{\text{DG}})_e^{E^1} - b^{\text{in}}(c^{\text{DG}})_e^{E^2}}{b^{\text{out}} - b^{\text{in}}} - \frac{b^{\text{out}}b^{\text{in}}}{b^{\text{out}} - b^{\text{in}}} [v^{\text{DG}}].
 \end{aligned}
 \tag{3.8}$$

Here, a^{out} , a^{in} , b^{out} , and b^{in} are the one-sided local speeds in the x - and y -directions. Since the convective part of the system (1.3)–(1.6) is hyperbolic, these speeds can be estimated using the largest and the smallest eigenvalues of the Jacobian $\frac{\partial \mathbf{F}}{\partial \mathbf{Q}}$ and $\frac{\partial \mathbf{G}}{\partial \mathbf{Q}}$ (see (3.1)):

$$\begin{aligned}
 a^{\text{out}} &= \max\left((\chi u^{\text{DG}})_e^{E^1}, (\chi u^{\text{DG}})_e^{E^2}, 0\right), & a^{\text{in}} &= \min\left((\chi u^{\text{DG}})_e^{E^1}, (\chi u^{\text{DG}})_e^{E^2}, 0\right), \\
 b^{\text{out}} &= \max\left((\chi v^{\text{DG}})_e^{E^1}, (\chi v^{\text{DG}})_e^{E^2}, 0\right), & b^{\text{in}} &= \min\left((\chi v^{\text{DG}})_e^{E^1}, (\chi v^{\text{DG}})_e^{E^2}, 0\right).
 \end{aligned}
 \tag{3.9}$$

Remark. If $a^{\text{out}} - a^{\text{in}} = 0$ at a certain element edge e , we set

$$\begin{aligned}
 (\chi\rho^{\text{DG}}u^{\text{DG}})^* &= \frac{(\chi\rho^{\text{DG}}u^{\text{DG}})_e^{E^1} + (\chi\rho^{\text{DG}}u^{\text{DG}})_e^{E^2}}{2}, & (-c^{\text{DG}})_u^* &= -\frac{(c^{\text{DG}})_e^{E^1} + (c^{\text{DG}})_e^{E^2}}{2}, \\
 (\chi\rho^{\text{DG}}v^{\text{DG}})^* &= \frac{(\chi\rho^{\text{DG}}v^{\text{DG}})_e^{E^1} + (\chi\rho^{\text{DG}}v^{\text{DG}})_e^{E^2}}{2}, & (-c^{\text{DG}})_v^* &= -\frac{(c^{\text{DG}})_e^{E^1} + (c^{\text{DG}})_e^{E^2}}{2}
 \end{aligned}$$

there. Notice that in any case the following inequalities are satisfied:

$$\frac{a^{\text{out}}}{a^{\text{out}} - a^{\text{in}}} \leq 1, \quad \frac{-a^{\text{in}}}{a^{\text{out}} - a^{\text{in}}} \leq 1, \quad \frac{b^{\text{out}}}{b^{\text{out}} - b^{\text{in}}} \leq 1, \quad \text{and} \quad \frac{-b^{\text{in}}}{b^{\text{out}} - b^{\text{in}}} \leq 1.
 \tag{3.10}$$

From now on we will assume that $a^{\text{out}} - a^{\text{in}} > 0$ and $b^{\text{out}} - b^{\text{in}} > 0$ throughout the computational domain.

4. Consistency of the numerical scheme. In this section, we show that the proposed DG methods (3.3)–(3.6) are strongly consistent with the Keller–Segel system (1.3)–(1.6).

LEMMA 4.1. *If the solution of (1.3)–(1.6) is sufficiently regular, namely, if $(\rho, c) \in H^1([0, T]) \cap H^2(\mathcal{E}_h)$ and $(u, v) \in L^2([0, T]) \cap H^2(\mathcal{E}_h)$, then it satisfies the formulation (3.3)–(3.6).*

Proof. We first multiply (1.3) by $w^\rho \in \mathcal{W}_{r_\rho, h}^\rho$ and integrate by parts on one element E to obtain

$$\begin{aligned}
 \int_E \rho_t w^\rho + \int_E \nabla \rho \nabla w^\rho - \int_{\partial E} \nabla \rho \cdot \mathbf{n}_e w^\rho - \int_E \chi \rho u (w^\rho)_x + \int_{\partial E} \chi \rho u n_x w^\rho \\
 - \int_E \chi \rho v (w^\rho)_y + \int_{\partial E} \chi \rho v n_y w^\rho = 0.
 \end{aligned}
 \tag{4.1}$$

Notice that the continuity of ρ and u implies that at the edge e , $\rho_e^{E^1} = \rho_e^{E^2}$ and $(\chi\rho u)_e^{E^1} = (\chi\rho u)_e^{E^2}$. Therefore, $[\rho] = 0$ and

$$\begin{aligned} \{\chi\rho u\} &= \frac{1}{2}(\chi\rho u)_e^{E^1} + \frac{1}{2}(\chi\rho u)_e^{E^2} = (\chi\rho u)_e^{E^1} = \frac{a^{\text{out}} - a^{\text{in}}}{a^{\text{out}} - a^{\text{in}}}(\chi\rho u)_e^{E^1} \\ &= \frac{a^{\text{out}}}{a^{\text{out}} - a^{\text{in}}}(\chi\rho u)_e^{E^1} - \frac{a^{\text{in}}}{a^{\text{out}} - a^{\text{in}}}(\chi\rho u)_e^{E^2} \\ &= \frac{a^{\text{out}}(\chi\rho u)_e^{E^1} - a^{\text{in}}(\chi\rho u)_e^{E^2}}{a^{\text{out}} - a^{\text{in}}} = (\chi\rho u)^*. \end{aligned}$$

Summing now (4.1) over all elements $E \in \mathcal{E}_h$, using the jump-average identity (2.1), adding the penalty terms $\varepsilon \sum_{e \in \Gamma_h} \int_e \{\nabla w^\rho \cdot \mathbf{n}_e\}[\rho]$ and $\sigma_\rho \sum_{e \in \Gamma_h} \frac{r_e^2}{|e|} \int_e [\rho][w^\rho]$, and using the Neumann boundary conditions (1.7), we obtain that the solution of the system (1.3)–(1.6) satisfies (3.3). A similar procedure can be applied to show that the solution of (1.3)–(1.6) satisfies (3.4)–(3.6) as well. This concludes the consistency proof. \square

5. Error analysis. In this section, we prove the existence and show the convergence of the numerical solution using Schauder’s fixed point theorem [25].

In the analysis below, we will assume that the exact solution of the system (1.3)–(1.6) is sufficiently regular for $t \leq T$, where T is a pre-blow-up time. In particular we will assume that

$$(5.1) \quad (\rho, c, u, v) \in H^{s_1}([0, T]) \cap H^{s_2}(\Omega), \quad s_1 > 3/2, \quad s_2 \geq 3,$$

which is needed for the h -analysis (convergence rate with respect to the mesh size), or

$$(5.2) \quad (\rho, c, u, v) \in H^{s_1}([0, T]) \cap H^{s_2}(\Omega), \quad s_1 > 3/2, \quad s_2 \geq 5,$$

which is needed for the r -analysis (convergence rate with respect to the polynomial degree). Notice that these assumptions are reasonable since classical solutions of the Keller–Segel system (1.1) are regular (before the blow-up time), provided the initial data are sufficiently smooth; see [27] and references therein.

We denote by $\tilde{\rho}, \tilde{c}, \tilde{u}$, and \tilde{v} the piecewise polynomial interpolants of the exact solution components ρ, c, u , and v of the Keller–Segel system (1.3)–(1.6) and assume that these interpolants satisfy the approximation property (2.2). We then use the idea similar to [37] and define the following subset of the broken Sobolev space:

$$\begin{aligned} S = \left\{ (\phi^\rho, \phi^c, \phi^u, \phi^v) \in L^2([0, T]) \cap L^\infty([0, T]) \cap \mathcal{W}_{r_\rho, h}^\rho \times \mathcal{W}_{r_c, h}^c \times \mathcal{W}_{r_u, h}^u \times \mathcal{W}_{r_v, h}^v : \right. \\ \sup_{t \in [0, T]} \|\phi^\rho - \tilde{\rho}\|_{0, \Omega}^2 + \int_0^T \left(\|\nabla(\phi^\rho - \tilde{\rho})\|_{0, \Omega}^2 + \sum_{e \in \Gamma_h} \frac{r_e^2}{|e|} \|[(\phi^\rho - \tilde{\rho})]\|_{0, e}^2 \right) \leq C_\rho \mathcal{E}_1, \\ \sup_{t \in [0, T]} \|\phi^c - \tilde{c}\|_{0, \Omega}^2 + \int_0^T \left(\|\nabla(\phi^c - \tilde{c})\|_{0, \Omega}^2 + \sum_{e \in \Gamma_h} \frac{r_e^2}{|e|} \|[(\phi^c - \tilde{c})]\|_{0, e}^2 \right) \leq C_c \mathcal{E}_1, \\ \sup_{[0, T]} \|\phi^u - \tilde{u}\|_{0, \Omega} \leq \mathcal{E}_2, \quad \int_0^T \left(\|\phi^u - \tilde{u}\|_{0, \Omega}^2 + \sum_{e \in \Gamma_h} \frac{r_e^2}{|e|} \|[(\phi^u - \tilde{u})]\|_{0, e}^2 \right) \leq C_u \mathcal{E}_1, \\ \left. \sup_{[0, T]} \|\phi^v - \tilde{v}\|_{0, \Omega} \leq \mathcal{E}_2, \quad \int_0^T \left(\|\phi^v - \tilde{v}\|_{0, \Omega}^2 + \sum_{e \in \Gamma_h} \frac{r_e^2}{|e|} \|[(\phi^v - \tilde{v})]\|_{0, e}^2 \right) \leq C_v \mathcal{E}_1 \right\}, \end{aligned}$$

where

$$(5.3) \quad \mathcal{E}_1 := \sum_{\alpha \in \{\rho, c, u, v\}} \frac{h^{2 \min(r_\alpha + 1, s_\alpha) - 2}}{r_\alpha^{2s_\alpha - 4}}, \quad \mathcal{E}_2 := Ch \left(\frac{1}{r_\rho} + \frac{1}{r_c} + \frac{1}{r_u} + \frac{1}{r_v} \right),$$

$C, C_\rho, C_c, C_u,$ and C_v are positive constants (which will be defined later) independent of h and the polynomial degrees (r_ρ, r_c, r_u, r_v) , and the parameters $s_\rho, s_c, s_u,$ and s_v denote the regularity of the corresponding components of the exact solution. Clearly the subset S is a closed convex subset of the broken Sobolev space, and it is not empty since it contains the element $(\tilde{\rho}, \tilde{c}, \tilde{u}, \tilde{v})$. We first show that the functions in S are bounded.

LEMMA 5.1. *For any $(\phi^\rho, \phi^c, \phi^u, \phi^v) \in S$, there exist positive constants $M_\rho, M_c, M_u,$ and M_v , independent of $h, r_\rho, r_c, r_u,$ and r_v , such that*

$$(5.4) \quad \sup_{t \in [0, T]} \|\phi^\alpha\|_{\infty, \Omega} \leq M_\alpha, \quad \alpha \in \{\rho, c, u, v\}.$$

Proof. From the definition of the subset S , we have $\sup_{t \in [0, T]} \|\phi^\rho - \tilde{\rho}\|_{0, \Omega}^2 \leq C_\rho \mathcal{E}_1$ and hence $\sup_{t \in [0, T]} \|\phi^\rho - \tilde{\rho}\|_{0, \Omega} \leq M \frac{h}{r_{\min}}$. Using the inverse inequality (2.6), we obtain

$$\sup_{t \in [0, T]} \|\phi^\rho - \tilde{\rho}\|_{\infty, \Omega} \leq M_1 r_\rho h^{-1} \sup_{t \in [0, T]} \|\phi^\rho - \tilde{\rho}\|_{0, \Omega} \leq \frac{r_{\max}}{r_{\min}} M^* \leq M.$$

This estimate implies that $\sup_{t \in [0, T]} \|\phi^\rho\|_{\infty, \Omega} \leq M + \sup_{[0, T]} \|\tilde{\rho}\|_{\infty, \Omega}$, which, together with the hp approximation property (see Lemma 2.1), yields the bound (5.4) for $\alpha = \rho$. The estimates for $\alpha = c, u,$ and v are obtained in a similar manner. \square

We now define the solution operator A on S as follows:

$$\forall (\phi^\rho, \phi^c, \phi^u, \phi^v) \in S, \quad A(\phi^\rho, \phi^c, \phi^u, \phi^v) = (\phi_L^\rho, \phi_L^c, \phi_L^u, \phi_L^v),$$

where the initial conditions are $(\phi_L^{\rho, 0}, \phi_L^{c, 0}, \phi_L^{u, 0}, \phi_L^{v, 0}) = (\tilde{\rho}^0, \tilde{c}^0, \tilde{u}^0, \tilde{v}^0)$ and the functions

$$\begin{aligned} \phi_L^\rho &\in \mathcal{W}_{r_\rho, h, t}^\rho := H^s([0, T]) \cap \mathcal{W}_{r_\rho, h}^\rho, & \phi_L^c &\in \mathcal{W}_{r_c, h, t}^c := H^s([0, T]) \cap \mathcal{W}_{r_c, h}^c, & s > 3/2, \\ \phi_L^\alpha &\in \mathcal{W}_{r_\alpha, h, t}^\alpha := L^2([0, T]) \cap L^\infty([0, T]) \cap \mathcal{W}_{r_\alpha, h}^\alpha, & \alpha &\in \{u, v\}, \end{aligned}$$

are such that

$$(5.5) \quad \begin{aligned} &\int_\Omega (\phi_L^\rho)_t w^\rho + \sum_{E \in \mathcal{E}_h} \int_E \nabla(\phi_L^\rho) \nabla w^\rho - \sum_{e \in \Gamma_h} \int_e \{\nabla \phi_L^\rho \cdot \mathbf{n}_e\} [w^\rho] + \varepsilon \sum_{e \in \Gamma_h} \int_e \{\nabla w^\rho \cdot \mathbf{n}_e\} [\phi_L^\rho] \\ &+ \sigma_\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \int_e [\phi_L^\rho] [w^\rho] - \sum_{E \in \mathcal{E}_h} \int_E \chi \phi_L^\rho \phi^u (w^\rho)_x + \sum_{e \in \Gamma_h^{\text{ver}}} \int_e (\chi \phi_L^\rho \phi^u)^* n_x [w^\rho] \\ &- \sum_{E \in \mathcal{E}_h} \int_E \chi \phi_L^\rho \phi^v (w^\rho)_y + \sum_{e \in \Gamma_h^{\text{hor}}} \int_e (\chi \phi_L^\rho \phi^v)^* n_y [w^\rho] = 0 \quad \forall w^\rho \in \mathcal{W}_{r_\rho, h}^\rho, \end{aligned}$$

$$(5.6) \quad \begin{aligned} &\int_\Omega (\phi_L^c)_t w^c + \sum_{E \in \mathcal{E}_h} \int_E \nabla(\phi_L^c) \nabla w^c - \sum_{e \in \Gamma_h} \int_e \{\nabla \phi_L^c \cdot \mathbf{n}_e\} [w^c] + \varepsilon \sum_{e \in \Gamma_h} \int_e \{\nabla w^c \cdot \mathbf{n}_e\} [\phi_L^c] \\ &+ \sigma_c \sum_{e \in \Gamma_h} \frac{r_c^2}{|e|} \int_e [\phi_L^c] [w^c] + \int_\Omega \phi_L^c w^c - \int_\Omega \phi_L^\rho w^c = 0 \quad \forall w^c \in \mathcal{W}_{r_c, h}^c, \end{aligned}$$

$$\begin{aligned}
 & \int_{\Omega} \phi_L^u w^u + \sum_{E \in \mathcal{E}_h} \int_E \phi_L^c (w^u)_x + \sum_{e \in \Gamma_h^{\text{ver}}} \int_e (-\phi_L^c)_u^* n_x [w^u] - \sum_{e \in \partial\Omega_{\text{ver}}} \int_e \phi_L^c n_x w^u \\
 (5.7) \quad & + \sigma_u \sum_{e \in \Gamma_h \cup \partial\Omega_{\text{ver}}} \frac{r_u^2}{|e|} \int_e [\phi_L^u] [w^u] = 0 \quad \forall w^u \in \mathcal{W}_{r_u, h}^u,
 \end{aligned}$$

$$\begin{aligned}
 & \int_{\Omega} \phi_L^v w^v + \sum_{E \in \mathcal{E}_h} \int_E \phi_L^c (w^v)_y + \sum_{e \in \Gamma_h^{\text{hor}}} \int_e (-\phi_L^c)_v^* n_y [w^v] - \sum_{e \in \partial\Omega_{\text{hor}}} \int_e \phi_L^c n_y w^v \\
 (5.8) \quad & + \sigma_v \sum_{e \in \Gamma_h \cup \partial\Omega_{\text{hor}}} \frac{r_v^2}{|e|} \int_e [\phi_L^v] [w^v] = 0 \quad \forall w^v \in \mathcal{W}_{r_v, h}^v.
 \end{aligned}$$

As before, the central-upwind numerical fluxes are utilized in (5.5)–(5.8):

$$\begin{aligned}
 (\chi \phi_L^\rho \phi^u)^* &= \frac{a_L^{\text{out}} (\chi \phi_L^\rho \phi^u)_e^{E^1} - a_L^{\text{in}} (\chi \phi_L^\rho \phi^u)_e^{E^2}}{a_L^{\text{out}} - a_L^{\text{in}}} - \frac{a_L^{\text{out}} a_L^{\text{in}}}{a_L^{\text{out}} - a_L^{\text{in}}} [\phi_L^\rho], \\
 (\chi \phi_L^\rho \phi^v)^* &= \frac{b_L^{\text{out}} (\chi \phi_L^\rho \phi^v)_e^{E^1} - b_L^{\text{in}} (\chi \phi_L^\rho \phi^v)_e^{E^2}}{b_L^{\text{out}} - b_L^{\text{in}}} - \frac{b_L^{\text{out}} b_L^{\text{in}}}{b_L^{\text{out}} - b_L^{\text{in}}} [\phi_L^\rho], \\
 (-\phi_L^c)_u^* &= -\frac{a_L^{\text{out}} (\phi_L^c)_e^{E^1} - a_L^{\text{in}} (\phi_L^c)_e^{E^2}}{a_L^{\text{out}} - a_L^{\text{in}}} - \frac{a_L^{\text{out}} a_L^{\text{in}}}{a_L^{\text{out}} - a_L^{\text{in}}} [\phi_L^u], \\
 (-\phi_L^c)_v^* &= -\frac{b_L^{\text{out}} (\phi_L^c)_e^{E^1} - b_L^{\text{in}} (\phi_L^c)_e^{E^2}}{b_L^{\text{out}} - b_L^{\text{in}}} - \frac{b_L^{\text{out}} b_L^{\text{in}}}{b_L^{\text{out}} - b_L^{\text{in}}} [\phi_L^v],
 \end{aligned}
 \tag{5.9}$$

where the one-sided local speeds are

$$\begin{aligned}
 a_L^{\text{out}} &:= \max \left((\chi \phi^u)_e^{E^1}, (\chi \phi^u)_e^{E^2}, 0 \right), \quad a_L^{\text{in}} := \min \left((\chi \phi^u)_e^{E^1}, (\chi \phi^u)_e^{E^2}, 0 \right), \\
 b_L^{\text{out}} &:= \max \left((\chi \phi^v)_e^{E^1}, (\chi \phi^v)_e^{E^2}, 0 \right), \quad b_L^{\text{in}} := \min \left((\chi \phi^v)_e^{E^1}, (\chi \phi^v)_e^{E^2}, 0 \right).
 \end{aligned}
 \tag{5.10}$$

Notice that the inequalities similar to (3.10),

$$(5.11) \quad \frac{a_L^{\text{out}}}{a_L^{\text{out}} - a_L^{\text{in}}} \leq 1, \quad \frac{-a_L^{\text{in}}}{a_L^{\text{out}} - a_L^{\text{in}}} \leq 1, \quad \frac{b_L^{\text{out}}}{b_L^{\text{out}} - b_L^{\text{in}}} \leq 1, \quad \text{and} \quad \frac{-b_L^{\text{in}}}{b_L^{\text{out}} - b_L^{\text{in}}} \leq 1,$$

which are needed in our convergence proof, are satisfied for the local speeds defined in (5.10) as well (for simplicity, we assume that $a^{\text{out}} - a^{\text{in}} \neq 0$ and $b^{\text{out}} - b^{\text{in}} \neq 0$ throughout the computational domain).

We now show that the operator A is well-defined by proving the existence and uniqueness of $(\phi_L^\rho, \phi_L^c, \phi_L^u, \phi_L^v)$.

LEMMA 5.2. *There exists a unique solution $(\phi_L^\rho, \phi_L^c, \phi_L^u, \phi_L^v) \in \mathcal{W}_{r_\rho, h, t}^\rho \times \mathcal{W}_{r_c, h, t}^c \times \mathcal{W}_{r_u, h, t}^u \times \mathcal{W}_{r_v, h, t}^v$ of (5.5)–(5.8).*

Proof. First, notice that (5.5)–(5.6) can be rewritten as the explicit linear differential equations for ϕ_L^ρ and ϕ_L^c . Hence, there exists a unique solution $(\phi_L^\rho, \phi_L^c) \in \mathcal{W}_{r_\rho, h, t}^\rho \times \mathcal{W}_{r_c, h, t}^c$.

Equations (5.7)–(5.8) can be rewritten as

$$\begin{aligned}
 \int_{\Omega} \phi_L^u w^u + \sigma_u \sum_{e \in \Gamma_h \cup \partial\Omega_{\text{ver}}} \frac{r_u^2}{|e|} \int_e [\phi_L^u][w^u] &= - \sum_{E \in \mathcal{E}_h} \int_E \phi_L^c (w^u)_x - \sum_{e \in \Gamma_h^{\text{ver}}} \int_e (-\phi_L^c)_u^* n_x [w^u] \\
 (5.12) \qquad \qquad \qquad &+ \sum_{e \in \partial\Omega_{\text{ver}}} \int_e \phi_L^c n_x w^u \quad \forall w^u \in \mathcal{W}_{r_u, h}^u,
 \end{aligned}$$

$$\begin{aligned}
 \int_{\Omega} \phi_L^v w^v + \sigma_v \sum_{e \in \Gamma_h \cup \partial\Omega_{\text{hor}}} \frac{r_v^2}{|e|} \int_e [\phi_L^v][w^v] &= - \sum_{E \in \mathcal{E}_h} \int_E \phi_L^c (w^v)_y - \sum_{e \in \Gamma_h^{\text{hor}}} \int_e (-\phi_L^c)_v^* n_y [w^v] \\
 (5.13) \qquad \qquad \qquad &+ \sum_{e \in \partial\Omega_{\text{hor}}} \int_e \phi_L^c n_y w^v \quad \forall w^v \in \mathcal{W}_{r_v, h}^v.
 \end{aligned}$$

The bilinear form on the left-hand side (LHS) of (5.12) is coercive since for all $\varphi \in \mathcal{W}_{r_u, h}^u$, $\int_{\Omega} \varphi \varphi + \sigma_u \sum_{e \in \Gamma_h \cup \partial\Omega_{\text{ver}}} \frac{r_u^2}{|e|} \int_e [\varphi][\varphi] \geq \|\varphi\|_{0, \Omega}^2$. It is also continuous on $\mathcal{W}_{r_u, h}^u \times \mathcal{W}_{r_u, h}^u$, while the linear form on the right-hand side (RHS) of (5.12) is continuous on $\mathcal{W}_{r_u, h}^u$. Hence, there exists a unique solution of (5.12). The same argument is true for (5.13). This concludes the proof of the lemma. \square

Our next goal is to show that the operator A maps S into itself and that A is compact. By the second Shauder fixed-point theorem [25], this will imply that the nonlinear mapping $(\phi^\rho, \phi^c, \phi^u, \phi^v) \in S \rightarrow A(\phi^\rho, \phi^c, \phi^u, \phi^v)$ has a fixed point denoted by $(\rho^{\text{DG}}, c^{\text{DG}}, u^{\text{DG}}, v^{\text{DG}})$.

THEOREM 5.3. *Let the solution of (1.3)–(1.6) satisfy the assumption (5.1). Then for any $(\phi^\rho, \phi^c, \phi^u, \phi^v) \in S$, $A(\phi^\rho, \phi^c, \phi^u, \phi^v) \in S$.*

Proof. Let $(\phi^\rho, \phi^c, \phi^u, \phi^v) \in S$ and $(\phi_L^\rho, \phi_L^c, \phi_L^u, \phi_L^v) = A(\phi^\rho, \phi^c, \phi^u, \phi^v)$. We introduce the following notation:

$$\begin{aligned}
 (5.14) \qquad \tau^\rho &:= \phi_L^\rho - \tilde{\rho}, & \xi^\rho &:= \rho - \tilde{\rho}, & \tau^c &:= \phi_L^c - \tilde{c}, & \xi^c &:= c - \tilde{c}, \\
 \tau^u &:= \phi_L^u - \tilde{u}, & \xi^u &:= u - \tilde{u}, & \tau^v &:= \phi_L^v - \tilde{v}, & \xi^v &:= v - \tilde{v}.
 \end{aligned}$$

It follows from the consistency Lemma 4.1 that the exact solution of (1.3)–(1.6) satisfies not only (3.3) but also the similar equation

$$\begin{aligned}
 \int_{\Omega} \rho_t w^\rho + \sum_{E \in \mathcal{E}_h} \int_E \nabla \rho \nabla w^\rho - \sum_{e \in \Gamma_h} \int_e \{\nabla \rho \cdot \mathbf{n}_e\} [w^\rho] + \varepsilon \sum_{e \in \Gamma_h} \int_e \{\nabla w^\rho \cdot \mathbf{n}_e\} [\rho] \\
 + \sigma_\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \int_e [\rho][w^\rho] - \sum_{E \in \mathcal{E}_h} \int_E \chi \rho u (w^\rho)_x + \sum_{e \in \Gamma_h^{\text{ver}}} \int_e (\chi \rho u)^{**} n_x [w^\rho] \\
 (5.15) \qquad \qquad \qquad - \sum_{E \in \mathcal{E}_h} \int_E \chi \rho v (w^\rho)_y + \sum_{e \in \Gamma_h^{\text{hor}}} \int_e (\chi \rho v)^{**} n_y [w^\rho] = 0,
 \end{aligned}$$

where

$$\begin{aligned}
 (\chi \rho u)^{**} &:= \frac{a_L^{\text{out}} (\chi \rho u)_e^{E^1} - a_L^{\text{in}} (\chi \rho u)_e^{E^2}}{a_L^{\text{out}} - a_L^{\text{in}}} - \frac{a_L^{\text{out}} a_L^{\text{in}}}{a_L^{\text{out}} - a_L^{\text{in}}} [\rho], \\
 (\chi \rho v)^{**} &:= \frac{b_L^{\text{out}} (\chi \rho v)_e^{E^1} - b_L^{\text{in}} (\chi \rho v)_e^{E^2}}{b_L^{\text{out}} - b_L^{\text{in}}} - \frac{b_L^{\text{out}} b_L^{\text{in}}}{b_L^{\text{out}} - b_L^{\text{in}}} [\rho]
 \end{aligned}$$

and the local speeds a_L^{out} , a_L^{in} , b_L^{out} , and b_L^{in} are given by (5.10). Using (5.14), (5.15) can be rewritten as

$$\begin{aligned}
 & \int_{\Omega} \tilde{\rho}_t w^\rho + \sum_{E \in \mathcal{E}_h} \int_E \nabla \tilde{\rho} \nabla w^\rho - \sum_{e \in \Gamma_h} \int_e \{\nabla \tilde{\rho} \cdot \mathbf{n}_e\} [w^\rho] + \varepsilon \sum_{e \in \Gamma_h} \int_e \{\nabla w^\rho \cdot \mathbf{n}_e\} [\tilde{\rho}] \\
 & + \sigma_\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \int_e [\tilde{\rho}] [w^\rho] - \sum_{E \in \mathcal{E}_h} \int_E \chi \tilde{\rho} \phi^u (w^\rho)_x + \sum_{e \in \Gamma_h^{\text{ver}}} \int_e (\chi \rho u)^{**} n_x [w^\rho] \\
 & - \sum_{E \in \mathcal{E}_h} \int_E \chi \tilde{\rho} \phi^v (w^\rho)_y + \sum_{e \in \Gamma_h^{\text{hor}}} \int_e (\chi \rho v)^{**} n_y [w^\rho] \\
 & = - \int_{\Omega} \xi_t^\rho w^\rho - \sum_{E \in \mathcal{E}_h} \int_E \nabla \xi^\rho \nabla w^\rho + \sum_{e \in \Gamma_h} \int_e \{\nabla \xi^\rho \cdot \mathbf{n}_e\} [w^\rho] \\
 & \quad - \varepsilon \sum_{e \in \Gamma_h} \int_e \{\nabla w^\rho \cdot \mathbf{n}_e\} [\xi^\rho] \\
 & \quad - \sigma_\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \int_e [\xi^\rho] [w^\rho] + \sum_{E \in \mathcal{E}_h} \int_E \chi \xi^\rho u (w^\rho)_x - \sum_{E \in \mathcal{E}_h} \int_E \chi \tilde{\rho} (\phi^u - u) (w^\rho)_x \\
 (5.16) \quad & + \sum_{E \in \mathcal{E}_h} \int_E \chi \xi^\rho v (w^\rho)_y - \sum_{E \in \mathcal{E}_h} \int_E \chi \tilde{\rho} (\phi^v - v) (w^\rho)_y.
 \end{aligned}$$

Subtracting (5.16) from (5.5) and choosing $w^\rho = \tau^\rho$, we obtain

$$\begin{aligned}
 & \frac{1}{2} \frac{d}{dt} \left(\|\tau^\rho\|_{0,\Omega}^2 \right) + \|\nabla \tau^\rho\|_{0,\Omega}^2 + \sigma_\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|\tau^\rho\|_{0,e}^2 \\
 & = (1 - \varepsilon) \sum_{e \in \Gamma_h} \int_e \{\nabla \tau^\rho \cdot \mathbf{n}_e\} [\tau^\rho] + \sum_{E \in \mathcal{E}_h} \int_E \chi \tau^\rho \phi^u (\tau^\rho)_x \\
 & \quad - \sum_{e \in \Gamma_h^{\text{ver}}} \int_e ((\chi \phi_L^\rho \phi^u)^* - (\chi \rho u)^{**}) n_x [\tau^\rho] + \sum_{E \in \mathcal{E}_h} \int_E \chi \tau^\rho \phi^v (\tau^\rho)_y \\
 & \quad - \sum_{e \in \Gamma_h^{\text{hor}}} \int_e ((\chi \phi_L^\rho \phi^v)^* - (\chi \rho v)^{**}) n_y [\tau^\rho] + \int_{\Omega} \xi_t^\rho \tau^\rho \\
 & \quad + \sum_{E \in \mathcal{E}_h} \int_E \nabla \xi^\rho \nabla \tau^\rho - \sum_{e \in \Gamma_h} \int_e \{\nabla \xi^\rho \cdot \mathbf{n}_e\} [\tau^\rho] + \varepsilon \sum_{e \in \Gamma_h} \int_e \{\nabla \tau^\rho \cdot \mathbf{n}_e\} [\xi^\rho] \\
 & \quad + \sigma_\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \int_e [\xi^\rho] [\tau^\rho] - \sum_{E \in \mathcal{E}_h} \int_E \chi \xi^\rho u (\tau^\rho)_x - \sum_{E \in \mathcal{E}_h} \int_E \chi \xi^\rho v (\tau^\rho)_y \\
 (5.17) \quad & + \sum_{E \in \mathcal{E}_h} \int_E \chi \tilde{\rho} (\phi^u - u) (\tau^\rho)_x + \sum_{E \in \mathcal{E}_h} \int_E \chi \tilde{\rho} (\phi^v - v) (\tau^\rho)_y =: T_1^\rho + T_2^\rho + \dots + T_{14}^\rho.
 \end{aligned}$$

Next, we bound each term on the RHS of (5.17) using standard DG techniques. The quantities ε_i in the estimates below are positive real numbers, which will be defined later.

We begin with the first term on the RHS of (5.17). The Cauchy–Schwarz inequality yields

$$|T_1^\rho| \leq (1 - \varepsilon) \sum_{e \in \Gamma_h} \|\{\nabla \tau^\rho\}\|_{0,e} \|\tau^\rho\|_{0,e}.$$

As before, we denote by E^1 and E^2 the two elements sharing the edge e . Then, using the inequality (2.5), we obtain

$$\begin{aligned} \sum_{e \in \Gamma_h} \|\{\nabla \tau^\rho\}\|_{0,e} \|\tau^\rho\|_{0,e} &\leq \sum_{e \in \Gamma_h} \frac{1}{2} \left(\left\| (\nabla \tau^\rho)_e^{E^1} \right\|_{0,e} + \left\| (\nabla \tau^\rho)_e^{E^2} \right\|_{0,e} \right) \|\tau^\rho\|_{0,e} \\ &\leq \frac{C_t r_\rho}{2\sqrt{h}} \sum_{e \in \Gamma_h} \left(\|\nabla \tau^\rho\|_{0,E^1} + \|\nabla \tau^\rho\|_{0,E^2} \right) \|\tau^\rho\|_{0,e}, \end{aligned}$$

and hence, using the fact that $|e| \leq \sqrt{h}$, we end up with the following bound on T_1^ρ :

$$|T_1^\rho| \leq \varepsilon_1^\rho \sum_{E \in \mathcal{E}_h} \|\nabla \tau^\rho\|_{0,E}^2 + C_1^\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|\tau^\rho\|_{0,e}^2 = \varepsilon_1^\rho \|\nabla \tau^\rho\|_{0,\Omega}^2 + C_1^\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|\tau^\rho\|_{0,e}^2. \quad (5.18)$$

Consider now the second term on the RHS of (5.17). From Lemma 5.1 we know that ϕ^u is a bounded function, and hence T_2^ρ can be bounded as follows:

$$(5.19) \quad |T_2^\rho| \leq \varepsilon_2^\rho \sum_{E \in \mathcal{E}_h} \|(\tau^\rho)_x\|_{0,E}^2 + C_2^\rho \|\tau^\rho\|_{0,\Omega}^2 \leq \varepsilon_2^\rho \|(\tau^\rho)_x\|_{0,\Omega}^2 + C_2^\rho \|\tau^\rho\|_{0,\Omega}^2.$$

Next, we bound the third term on the RHS of (5.17) as

$$\begin{aligned} |T_3^\rho| &\leq \sum_{e \in \Gamma_h^{\text{ver}}} \left(\left| \int_e \frac{a_L^{\text{out}}}{a_L^{\text{out}} - a_L^{\text{in}}} \left((\chi \phi_L^\rho \phi^u)_e^{E^1} - (\chi \rho u)_e^{E^1} \right) n_x[\tau^\rho] \right| \right. \\ &\quad + \left| \int_e \frac{-a_L^{\text{in}}}{a_L^{\text{out}} - a_L^{\text{in}}} \left((\chi \phi_L^\rho \phi^u)_e^{E^2} - (\chi \rho u)_e^{E^2} \right) n_x[\tau^\rho] \right| \\ (5.20) \quad &\quad \left. + \left| \int_e \frac{-a_L^{\text{in}} a_L^{\text{out}}}{a_L^{\text{out}} - a_L^{\text{in}}} [\phi_L^\rho - \rho] n_x[\tau^\rho] \right| \right) =: \text{I} + \text{II} + \text{III}. \end{aligned}$$

Using (5.11) and (5.14), the first term on the RHS of (5.20) can be estimated by

$$\begin{aligned} \text{I} &\leq \chi \sum_{e \in \Gamma_h^{\text{ver}}} \left| \int_e \left((\phi_L^\rho \phi^u)_e^{E^1} - (\rho u)_e^{E^1} \right) n_x[\tau^\rho] \right| \\ &\leq \chi \sum_{e \in \Gamma_h^{\text{ver}}} \left(\left| \int_e (\tau^\rho \phi^u)_e^{E^1} n_x[\tau^\rho] \right| + \left| \int_e (\xi^\rho \phi^u)_e^{E^1} n_x[\tau^\rho] \right| \right. \\ &\quad \left. + \left| \int_e ((\phi^u - \tilde{u})\rho)_e^{E^1} n_x[\tau^\rho] \right| + \left| \int_e (\xi^u \rho)_e^{E^1} n_x[\tau^\rho] \right| \right) =: \tilde{\text{I}}. \end{aligned}$$

We now use the Cauchy–Schwarz inequality, the trace inequality (2.3), the inequality (2.5), the assumption (3.2), the approximation inequality (2.2), and the bound on ϕ^u from Lemma 5.1 to obtain the bound on $\tilde{\text{I}}$:

$$\tilde{\text{I}} \leq \frac{1}{2} \|\tau^\rho\|_{0,\Omega}^2 + K \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|\tau^\rho\|_{0,e}^2 + C^* \sum_{\alpha=\rho,u} \frac{h^{2 \min(r_\alpha+1, s_\alpha)}}{r_\alpha^{2s_\alpha}} + C^{**} \|\phi^u - \tilde{u}\|_{0,\Omega}^2.$$

A similar bound can be derived for the second term II on the RHS of (5.20). To estimate the last term on the RHS of (5.20), we first use (5.14) and the definition of

the one-sided local speeds (5.10) to obtain

$$\text{III} \leq C \sum_{e \in \Gamma_h^{\text{ver}}} \left(\|[\tau^\rho]\|_{0,e}^2 + \left| \int_e [\xi^\rho][\tau^\rho] \right| \right) := \widetilde{\text{III}}.$$

Then, using the Cauchy–Schwarz inequality, the trace inequality (2.3), and the approximation inequality (2.2), we bound $\widetilde{\text{III}}$ as follows:

$$\widetilde{\text{III}} \leq \left(\frac{K_1 h}{r_\rho^2} + K_2 \right) \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|[\tau^\rho]\|_{0,e}^2 + C \frac{h^{2 \min(r_\rho+1, s_\rho)}}{r_\rho^{2s_\rho}}.$$

Combining the above bounds on I, II, and III, we arrive at

$$|T_3^\rho| \leq \|\tau^\rho\|_{0,\Omega}^2 + C_3^\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|[\tau^\rho]\|_{0,e}^2 + C^* \sum_{\alpha \in \{\rho, u\}} \frac{h^{2 \min(r_\alpha+1, s_\alpha)}}{r_\alpha^{2s_\alpha}} + C^{**} \|\phi^u - \tilde{u}\|_{0,\Omega}^2. \tag{5.21}$$

The terms T_4^ρ and T_5^ρ are bounded in the same way as the terms T_2^ρ and T_3^ρ , respectively, and the bounds are

$$|T_4^\rho| \leq \varepsilon_2^\rho \|(\tau^\rho)_y\|_{0,\Omega}^2 + C_4^\rho \|\tau^\rho\|_{0,\Omega}^2 \tag{5.22}$$

and

$$|T_5^\rho| \leq \|\tau^\rho\|_{0,\Omega}^2 + C_5^\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|[\tau^\rho]\|_{0,e}^2 + C^* \sum_{\alpha \in \{\rho, v\}} \frac{h^{2 \min(r_\alpha+1, s_\alpha)}}{r_\alpha^{2s_\alpha}} + C^{**} \|\phi^v - \tilde{v}\|_{0,\Omega}^2. \tag{5.23}$$

The term T_6^ρ is bounded using the Cauchy–Schwarz inequality and the approximation inequality (2.2):

$$|T_6^\rho| \leq \|\tau^\rho\|_{0,\Omega}^2 + C^* \frac{h^{2 \min(r_\rho+1, s_\rho)}}{r_\rho^{2s_\rho}}. \tag{5.24}$$

Using the Cauchy–Schwarz inequality, Young’s inequality, and the approximation inequality (2.2) for ρ , we obtain the following bound for the term T_7^ρ :

$$|T_7^\rho| \leq \varepsilon_7^\rho \|\nabla \tau^\rho\|_{0,\Omega}^2 + C^* \frac{h^{2 \min(r_\rho+1, s_\rho)-2}}{r_\rho^{2s_\rho-2}}. \tag{5.25}$$

The term T_8^ρ is bounded using the Cauchy–Schwarz inequality, the trace inequality (2.4), and the approximation inequality (2.2):

$$|T_8^\rho| \leq C_8^\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|[\tau^\rho]\|_{0,e}^2 + C^* \frac{h^{2 \min(r_\rho+1, s_\rho)-2}}{r_\rho^{2s_\rho-2}}. \tag{5.26}$$

To bound the term T_9^ρ , we use the trace inequality (2.5), inequality (2.3), the Cauchy–Schwarz inequality, and Young’s inequality:

$$|T_9^\rho| \leq \varepsilon_9^\rho \|\nabla \tau^\rho\|_{0,\Omega}^2 + C^* \frac{h^{2 \min(r_\rho+1, s_\rho)-2}}{r_\rho^{2s_\rho-4}}. \tag{5.27}$$

Similarly, we bound the term T_{10}^ρ by

$$(5.28) \quad |T_{10}^\rho| \leq C_{10}^\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|[\tau^\rho]\|_{0,e}^2 + C^* \frac{h^{2 \min(r_\rho+1, s_\rho)-2}}{r_\rho^{2s_\rho-4}}.$$

For the terms T_{11}^ρ and T_{12}^ρ , we use our assumption on the smoothness of the exact solution together with the Cauchy–Schwarz inequality and the approximation inequality (2.2) to obtain the following bounds:

$$(5.29) \quad |T_{11}^\rho| \leq \varepsilon_{11}^\rho \|(\tau^\rho)_x\|_{0,\Omega}^2 + C^* \frac{h^{2 \min(r_\rho+1, s_\rho)}}{r_\rho^{2s_\rho}}, \quad |T_{12}^\rho| \leq \varepsilon_{11}^\rho \|(\tau^\rho)_y\|_{0,\Omega}^2 + C^* \frac{h^{2 \min(r_\rho+1, s_\rho)}}{r_\rho^{2s_\rho}}.$$

Consider now the term T_{13}^ρ . We first use (5.14) to obtain

$$|T_{13}^\rho| \leq C \sum_{E \in \mathcal{E}_h} \left(\left| \int_E (\phi^u - \tilde{u})(\tau^\rho)_x \right| + \left| \int_E \xi^u(\tau^\rho)_x \right| \right).$$

Then we apply the Cauchy–Schwarz inequality and the approximation inequality (2.2), which result in

$$(5.30) \quad |T_{13}^\rho| \leq \varepsilon_{13}^\rho \|(\tau^\rho)_x\|_{0,\Omega}^2 + C^* \frac{h^{2 \min(r_u+1, s_u)}}{r_u^{2s_u}} + C^{**} \|\phi^u - \tilde{u}\|_{0,\Omega}^2.$$

The bound on the term T_{14}^ρ is obtained in the same way as the bound on T_{13}^ρ :

$$(5.31) \quad |T_{14}^\rho| \leq \varepsilon_{13}^\rho \|(\tau^\rho)_y\|_{0,\Omega}^2 + C^* \frac{h^{2 \min(r_v+1, s_v)}}{r_v^{2s_v}} + C^{**} \|\phi^v - \tilde{v}\|_{0,\Omega}^2.$$

Finally, we plug the estimates (5.18)–(5.19) and (5.21)–(5.31) into (5.17) and use the assumption that $h < 1$ to obtain

$$(5.32) \quad \begin{aligned} & \frac{1}{2} \frac{d}{dt} \|\tau^\rho\|_{0,\Omega}^2 + (1 - \varepsilon_1^\rho - \varepsilon_2^\rho - \varepsilon_7^\rho - \varepsilon_9^\rho - \varepsilon_{11}^\rho - \varepsilon_{13}^\rho) \|\nabla \tau^\rho\|_{0,\Omega}^2 \\ & + (\sigma_\rho - C_1^\rho - C_3^\rho - C_5^\rho - C_8^\rho - C_{10}^\rho) \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|[\tau^\rho]\|_{0,e}^2 \leq (3 + C_2^\rho + C_4^\rho) \|\tau^\rho\|_{0,\Omega}^2 \\ & + C_\rho^* \left(\frac{h^{2 \min(r_\rho+1, s_\rho)-2}}{r_\rho^{2s_\rho-4}} + \sum_{\alpha \in \{u,v\}} \frac{h^{2 \min(r_\alpha+1, s_\alpha)}}{r_\alpha^{2s_\alpha}} \right) + C^{**} \sum_{\alpha \in \{u,v\}} (\|\phi^\alpha - \tilde{\alpha}\|_{0,\Omega}^2). \end{aligned}$$

We now choose ε_i^ρ and the penalty parameter σ_ρ so that the coefficients of $\|\nabla \tau^\rho\|_{0,\Omega}^2$ and $\sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|[\tau^\rho]\|_{0,e}^2$ on the LHS of (5.32) are equal to 1/2. We then multiply (5.32) by 2 and integrate it in time from 0 to t . Taking into account that $(\phi^u, \phi^v) \in S$ and using the fact that $\tau^0 = 0$, we obtain

$$(5.33) \quad \|\tau^\rho\|_{0,\Omega}^2 + \int_0^t \left(\|\nabla \tau^\rho\|_{0,\Omega}^2 + \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|[\tau^\rho]\|_{0,e}^2 \right) \leq \tilde{C}^\rho \int_0^t \|\tau^\rho\|_{0,\Omega}^2 + C^{uv} \mathcal{E}_1.$$

Next, we apply Gronwall's Lemma 2.6 and take the supremum with respect to t of both sides of (5.33):

$$(5.34) \quad \sup_{[0,T]} \|\tau^\rho\|_{0,\Omega}^2 + \int_0^T \left(\|\nabla \tau^\rho\|_{0,\Omega}^2 + \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|[\tau^\rho]\|_{0,e}^2 \right) \leq C^I \mathcal{E}_1,$$

where \mathcal{E}_1 is given in (5.3) and C^I is a constant that depends on $\|\rho\|_{(L^\infty([0,T]);H^2(\Omega))}$, $\|\rho_t\|_{(L^\infty([0,T]);L^2(\Omega))}$, $\|u\|_{(L^\infty([0,T]);L^2(\Omega))}$, $\|v\|_{(L^\infty([0,T]);L^2(\Omega))}$, and T only.

According to the definition of the broken Sobolev space S given on p. 393, the estimate (5.34) implies that $\phi_L^\rho \in S$. Using similar techniques, it can be shown that $(\phi_L^c, \phi_L^u, \phi_L^v) \in S$ as well (see [20] for the detailed proof). Therefore, we have shown that $A(S) \subset S$, and the proof of Theorem 5.3 is now complete. \square

Let us recall that our goal is to show that the operator A has a fixed point. Equipped with Theorem 5.3, it remained to prove that A is compact. To this end, we need to show that A is continuous and equicontinuous.

LEMMA 5.4. *The operator A is continuous and equicontinuous.*

Proof. We consider the sequence $\{(\phi_n^\rho, \phi_n^c, \phi_n^u, \phi_n^v)\}$ and assume that

$$\sup_{t \in [0, T]} (\|(\phi_n^\rho, \phi_n^c, \phi_n^u, \phi_n^v) - (\phi^\rho, \phi^c, \phi^u, \phi^v)\|_S) \rightarrow 0 \quad \text{as } n \rightarrow \infty.$$

Let

$$(5.35) \quad (\phi_{L,n}^\rho, \phi_{L,n}^c, \phi_{L,n}^u, \phi_{L,n}^v) = A(\phi_n^\rho, \phi_n^c, \phi_n^u, \phi_n^v)$$

and

$$(5.36) \quad (\phi_L^\rho, \phi_L^c, \phi_L^u, \phi_L^v) = A(\phi^\rho, \phi^c, \phi^u, \phi^v)$$

be two solutions of (5.5)–(5.8). We denote by $(\widehat{\phi}_L^\rho, \widehat{\phi}_L^c, \widehat{\phi}_L^u, \widehat{\phi}_L^v)$ the difference between these two solutions (note that $(\widehat{\phi}_L^{\rho,0}, \widehat{\phi}_L^{c,0}, \widehat{\phi}_L^{u,0}, \widehat{\phi}_L^{v,0}) = (0, 0, 0, 0)$), subtract (5.36) from (5.35), and choose the test function in the resulting equation for ρ to be $w^\rho = \widehat{\phi}_L^\rho$. This yields

$$\begin{aligned} & \frac{1}{2} \frac{d}{dt} \|\widehat{\phi}_L^\rho\|_{0,\Omega}^2 + \|\widehat{\nabla} \widehat{\phi}_L^\rho\|_{0,\Omega}^2 + \sigma_\rho \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|\llbracket \widehat{\phi}_L^\rho \rrbracket\|_{0,e}^2 \\ &= (1 - \varepsilon) \sum_{e \in \Gamma_h} \int_e \{ \widehat{\nabla} \widehat{\phi}_L^\rho \cdot \mathbf{n}_e \} \llbracket \widehat{\phi}_L^\rho \rrbracket + \sum_{E \in \mathcal{E}_h} \int_E \chi \widehat{\phi}_L^\rho \phi^u (\widehat{\phi}_L^\rho)_x \\ & \quad + \sum_{E \in \mathcal{E}_h} \int_E \chi \phi_{L,n}^\rho (\phi_n^u - \phi^u) (\widehat{\phi}_L^\rho)_x \\ & \quad - \sum_{e \in \Gamma_h^{\text{ver}}} \int_e (\chi \widehat{\phi}_L^\rho \phi^u)^* n_x \llbracket \widehat{\phi}_L^\rho \rrbracket + \sum_{e \in \Gamma_h^{\text{ver}}} \int_e ((\chi \phi_{L,n}^\rho \phi^u)^* - (\chi \phi_{L,n}^\rho \phi_n^u)^*) n_x \llbracket \widehat{\phi}_L^\rho \rrbracket \\ & \quad + \sum_{E \in \mathcal{E}_h} \int_E \chi \widehat{\phi}_L^\rho \phi^v (\widehat{\phi}_L^\rho)_y + \sum_{E \in \mathcal{E}_h} \int_E \chi \phi_{L,n}^\rho (\phi_n^v - \phi^v) (\widehat{\phi}_L^\rho)_y \\ & \quad - \sum_{e \in \Gamma_h^{\text{hor}}} \int_e (\chi \widehat{\phi}_L^\rho \phi^v)^* n_y \llbracket \widehat{\phi}_L^\rho \rrbracket \\ (5.37) \quad & + \sum_{e \in \Gamma_h^{\text{hor}}} \int_e ((\chi \phi_{L,n}^\rho \phi^v)^* - (\chi \phi_{L,n}^\rho \phi_n^v)^*) n_y \llbracket \widehat{\phi}_L^\rho \rrbracket =: R_1 + R_2 + \dots + R_9. \end{aligned}$$

We now bound each term on the RHS of (5.37).

The term R_1 can be bounded using the Cauchy–Schwarz inequality, Young’s inequality, and the inequality (2.5):

$$(5.38) \quad |R_1| \leq \frac{1}{6} \|\widehat{\nabla} \widehat{\phi}_L^\rho\|_{0,\Omega}^2 + C_1 \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \|\llbracket \widehat{\phi}_L^\rho \rrbracket\|_{0,e}^2.$$

Next, applying the Cauchy–Schwarz and Young’s inequalities and using the boundness of $\|\phi^u\|_{\infty,\Omega}$, established in Lemma 5.1, we obtain the following bound on R_2 :

$$(5.39) \quad |R_2| \leq \frac{1}{6} \left\| \left(\widehat{\phi}_L^\rho \right)_x \right\|_{0,\Omega}^2 + C_2 \left\| \widehat{\phi}_L^\rho \right\|_{0,\Omega}^2.$$

Using the Cauchy–Schwarz and Young’s inequalities and the fact that $\phi_{L,n}^\rho \in S$, we bound the term R_3 by

$$(5.40) \quad |R_3| \leq \frac{1}{6} \left\| \left(\widehat{\phi}_L^\rho \right)_x \right\|_{0,\Omega}^2 + C_3 \|\phi_n^u - \phi^u\|_{0,\Omega}^2.$$

We then use the Cauchy–Schwarz inequality, the inequality (2.5), and the first numerical flux formula in (5.9) to estimate R_4 :

$$(5.41) \quad |R_4| \leq \left\| \widehat{\phi}_L^\rho \right\|_{0,\Omega}^2 + C_4 \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \left\| \left[\widehat{\phi}_L^\rho \right] \right\|_{0,e}^2.$$

We now consider the term R_5 . It follows from formulas (5.9)–(5.10) that the numerical fluxes $(\chi \phi_{L,n}^\rho \phi^u)^*$ are the composition of the continuous functions with respect to the variables $(\phi^u)_e^{E^1}$ and $(\phi^u)_e^{E^2}$. Hence, we can apply the Cauchy–Schwarz inequality and the inequality (2.5) to R_5 so that it is bounded by

$$(5.42) \quad |R_5| \leq \|(\chi \phi_{L,n}^\rho \phi^u)^* - (\chi \phi_{L,n}^\rho \phi_n^u)^*\|_{0,\Omega}^2 + C_5 \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \left\| \left[\widehat{\phi}_L^\rho \right] \right\|_{0,e}^2.$$

The terms R_6 , R_7 , R_8 , and R_9 are similar to the terms R_2 , R_3 , R_4 , and R_5 estimated in (5.39), (5.40), (5.41), and (5.42), respectively. Therefore, we obtain

$$(5.43) \quad |R_6| \leq \frac{1}{6} \left\| \left(\widehat{\phi}_L^\rho \right)_y \right\|_{0,\Omega}^2 + C_6 \left\| \widehat{\phi}_L^\rho \right\|_{0,\Omega}^2,$$

$$(5.44) \quad |R_7| \leq \frac{1}{6} \left\| \left(\widehat{\phi}_L^\rho \right)_y \right\|_{0,\Omega}^2 + C_7 \|\phi_n^v - \phi^v\|_{0,\Omega}^2,$$

$$(5.45) \quad |R_8| \leq \left\| \widehat{\phi}_L^\rho \right\|_{0,\Omega}^2 + C_8 \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \left\| \left[\widehat{\phi}_L^\rho \right] \right\|_{0,e}^2,$$

$$(5.46) \quad |R_9| \leq \|(\chi \phi_{L,n}^\rho \phi^v)^* - (\chi \phi_{L,n}^\rho \phi_n^v)^*\|_{0,\Omega}^2 + C_9 \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \left\| \left[\widehat{\phi}_L^\rho \right] \right\|_{0,e}^2.$$

Substituting the estimates (5.38)–(5.46) into (5.37) yields

$$\begin{aligned} & \frac{1}{2} \frac{d}{dt} \left\| \widehat{\phi}_L^\rho \right\|_{0,\Omega}^2 + \frac{1}{2} \left\| \nabla \widehat{\phi}_L^\rho \right\|_{0,\Omega}^2 + (\sigma_\rho - C) \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \left\| \left[\widehat{\phi}_L^\rho \right] \right\|_{0,e}^2 \leq C^* \left\| \widehat{\phi}_L^\rho \right\|_{0,\Omega}^2 \\ & + C^{**} \sum_{\alpha \in \{u,v\}} \left(\|\phi_n^\alpha - \phi^\alpha\|_{0,\Omega}^2 + \|(\chi \phi_{L,n}^\rho \phi^\alpha)^* - (\chi \phi_{L,n}^\rho \phi_n^\alpha)^*\|_{0,\Omega}^2 \right), \end{aligned}$$

where the penalty parameter σ_ρ is chosen sufficiently large so that the coefficient $(\sigma_\rho - C)$ is nonnegative.

We now integrate the latter inequality with respect to time from 0 to t and apply Gronwall's Lemma 2.6 to obtain

$$\begin{aligned} & \left\| \widehat{\phi}_L^\rho \right\|_{0,\Omega}^2 + \int_0^t \left(\left\| \nabla \widehat{\phi}_L^\rho \right\|_{0,\Omega}^2 + (\sigma_\rho - C) \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \left\| [\widehat{\phi}_L^\rho] \right\|_{0,e}^2 \right) dt \leq M \left(\left\| \phi_L^{\rho,0} \right\|_{0,\Omega}^2 \right. \\ & \left. + \sum_{\alpha \in \{u,v\}} \int_0^t \left(\left\| \phi_n^\alpha - \phi^\alpha \right\|_{0,\Omega}^2 + \left\| (\chi \phi_{L,n}^\rho \phi^\alpha)^* - (\chi \phi_{L,n}^\rho \phi_n^\alpha)^* \right\|_{0,\Omega}^2 \right) \right). \end{aligned}$$

Finally, taking the supremum over t and since $\widehat{\phi}_L^{\rho,0} = 0$, we arrive at

$$\begin{aligned} & \sup_{t \in [0,T]} \left\| \widehat{\phi}_L^\rho \right\|_{0,\Omega}^2 + \int_0^T \left(\left\| \nabla \widehat{\phi}_L^\rho \right\|_{0,\Omega}^2 + \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \left\| [\widehat{\phi}_L^\rho] \right\|_{0,e}^2 \right) dt \\ & \leq M^* \sum_{\alpha \in \{u,v\}} \int_0^T \left(\left\| \phi_n^\alpha - \phi^\alpha \right\|_{0,\Omega}^2 + \left\| (\chi \phi_{L,n}^\rho \phi^\alpha)^* - (\chi \phi_{L,n}^\rho \phi_n^\alpha)^* \right\|_{0,\Omega}^2 \right) dt. \end{aligned}$$

This inequality together with the similar inequalities for $\widehat{\phi}^c$, $\widehat{\phi}^u$, and $\widehat{\phi}^v$, which can be obtained in an analogous way, imply continuity of the operator A .

Applying similar techniques to the difference $(\overline{\phi}_L^\rho, \overline{\phi}_L^c, \overline{\phi}_L^u, \overline{\phi}_L^v) := (\phi_L^\rho, \phi_L^c, \phi_L^u, \phi_L^v)(t_1, x_1, y_1) - (\phi_L^\rho, \phi_L^c, \phi_L^u, \phi_L^v)(t_2, x_2, y_2)$ and using the fact that $(\phi^u, \phi^v) \in S$, one can show that the operator A is equicontinuous. \square

Equipped with Lemma 5.4, we conclude that the operator A is compact. Hence, by the second Schauder fixed-point theorem [25], it has at least one fixed point $(\rho^{\text{DG}}, c^{\text{DG}}, u^{\text{DG}}, v^{\text{DG}})$, which is the DG solution of (3.3)–(3.6). For this solution, we establish the convergence rate results, stated in the following theorem.

THEOREM 5.5 ($L^2(H^1)$ - and $L^\infty(L^2)$ -error estimates). *Let the solution of the Keller–Segel system (1.3)–(1.6) satisfy the smoothness assumption (5.2). If the penalty parameters σ_ρ , σ_c , σ_u , and σ_v in the DG method (3.3)–(3.9) are sufficiently large and $r_{\min} \geq 2$, then there exist constants C_ρ and C_c , independent of h , r_ρ , r_c , r_u , and r_v , such that the following two error estimates hold:*

$$\begin{aligned} & \left\| \rho^{\text{DG}} - \rho \right\|_{L^\infty([0,T];L^2(\Omega))} + \left\| \nabla (\rho^{\text{DG}} - \rho) \right\|_{L^2([0,T];L^2(\Omega))} \\ & \quad + \left(\int_0^T \sum_{e \in \Gamma_h} \frac{r_\rho^2}{|e|} \left\| [\rho^{\text{DG}} - \rho] \right\|_{0,e}^2 \right)^{\frac{1}{2}} \leq C_\rho E, \\ & \left\| c^{\text{DG}} - c \right\|_{L^\infty([0,T];L^2(\Omega))} + \left\| \nabla (c^{\text{DG}} - c) \right\|_{L^2([0,T];L^2(\Omega))} \\ & \quad + \left(\int_0^T \sum_{e \in \Gamma_h} \frac{r_c^2}{|e|} \left\| [c^{\text{DG}} - c] \right\|_{0,e}^2 \right)^{\frac{1}{2}} \leq C_c E, \end{aligned}$$

where

$$E := \sum_{\alpha \in \{\rho, c, u, v\}} \frac{h^{\min(r_\alpha+1, s_\alpha)-1}}{r_\alpha^{s_\alpha-2}}.$$

Proof. The result follows from the definition of space S , the fact that the DG solution is a fixed point of the compact operator A (defined above), the hp approximation Lemma 2.1, and the triangle inequality. \square

Remark. The obtained error estimates are h -optimal but only suboptimal for r .

Finally, equipped with the results established in Theorem 5.5, we obtain the following bound for the blow-up time of the exact solution of the Keller–Segel system.

THEOREM 5.6. *Let us denote by t_b the blow-up time of the exact solution of the Keller–Segel system (1.1) and by t_b^{DG} the blow-up time of the DG solution of (3.3)–(3.9). Then $t_b \leq t_b^{\text{DG}}$.*

Proof. The solution ρ of the Keller–Segel model blows up if $\|\rho\|_{L^\infty(\Omega)}$ becomes unbounded in either finite or infinite time (see, e.g., [27, 28]). Therefore, in order to prove the theorem we need to establish an L^∞ -error bound.

From Theorem 5.5 we have the following L^2 -error bound: $\|\rho^{\text{DG}} - \rho\|_{L^2(\Omega)} \leq C_\rho E$, and hence from (2.6) we obtain $\|\rho^{\text{DG}} - \rho\|_{L^\infty(\Omega)} \leq C_\rho E_1$, which, in turn, implies that $\|\rho^{\text{DG}}\|_{L^\infty(\Omega)} \leq \|\rho\|_{L^\infty(\Omega)} + C_\rho E_1$, where $E_1 := \sum_{\alpha \in \{\rho, c, u, v\}} \frac{h^{\min(r_\alpha + 1, s_\alpha) - 2}}{r_\alpha^{s_\alpha - 3}}$. From the last estimate the statement of the theorem follows. \square

6. Numerical example. In this section, we demonstrate the performance of the proposed DG method. In all of our numerical experiments, we have used the third-order strong stability-preserving Runge–Kutta method for the time discretization [24]. No slope-limiting technique has been implemented. The values of the penalty parameters used are $\sigma_\rho = \sigma_c = 1$ and $\sigma_u = \sigma_v = 0.01$. We note that no instabilities have been observed when the latter two parameters were taken as zero; however, since our convergence proof requires σ_u and σ_v to be positive, we show only the results obtained with positive σ_u and σ_v , which are almost identical to the ones obtained with $\sigma_u = \sigma_v = 0$.

We consider the initial boundary value problem for the Keller–Segel system in the square domain $[-\frac{1}{2}, \frac{1}{2}] \times [-\frac{1}{2}, \frac{1}{2}]$. We take the chemotactic sensitivity $\chi = 1$ and the bell-shaped initial data

$$\rho(x, y, 0) = 1200e^{-120(x^2+y^2)}, \quad c(x, y, 0) = 600e^{-60(x^2+y^2)}.$$

According to the results in [26], both components ρ and c of the solution are expected to blow up at the origin in finite time. This situation is especially challenging since capturing the blowing up solution with shrinking support is extremely hard.

In Figures 6.1–6.4, we plot the logarithmically scaled density $\ln(1 + \rho^{\text{DG}})$ computed at different times on two different uniform grids with $h = 1/51$ (Figures 6.1 and 6.3) and $h = 1/101$ (Figures 6.2 and 6.4). The results shown in Figures 6.1–6.2 have been obtained with quadratic polynomials (i.e., $r_\rho = r_c = r_u = r_v = r = 2$), while the solution shown in Figures 6.3–6.4 have been computed with the help of cubic polynomials (i.e., $r_\rho = r_c = r_u = r_v = r = 3$).

Numerical convergence of the scheme is verified by refining the mesh and by increasing the polynomial degree. As one can see, the computed solutions are in very good agreement at the smaller times ($t = 1.46 \cdot 10^{-5}$, $2.99 \cdot 10^{-5}$, and $6.03 \cdot 10^{-5}$). However, at time close to the blow-up time ($t = 1.21 \cdot 10^{-4}$) the maximum value of ρ^{DG} grows, while its support shrinks, and no mesh-refinement convergence is observed: the numerical solution keeps increasing when the mesh is refined. Using Theorem 5.6, we can conclude that in this example the blow-up time of the exact solution is less than or equal to the blow-up time of the DG solution, which is approximately $t_b^{\text{DG}} \approx 1.21 \cdot 10^{-4}$.

We note that even though no slope-limiting or any other positivity-preserving techniques have been implemented, the computed solutions have never developed negative values and are oscillation-free.

Finally, we check the numerical order of the convergence of the proposed DG method. We first consider the smooth solution at a very small time $t = 1.0 \cdot 10^{-7}$

FIG. 6.1. $h = 1/51, r = 2$. Logarithmically scaled density computed at $t = 1.46 \cdot 10^{-5}$ (top left), $t = 2.99 \cdot 10^{-5}$ (top right), $t = 6.03 \cdot 10^{-5}$ (bottom left), and $t = 1.21 \cdot 10^{-4} \approx t_b^{\text{DG}}$ (bottom right).

FIG. 6.2. The same as in Figure 6.1 but with $h = 1/101, r = 2$.

and test the convergence with respect to the mesh size h for the fixed $r = 2$ (piecewise quadratic polynomials). Since the exact solution for the Keller–Segel system is unavailable, we compute the reference solution by the proposed DG method on a fine mesh with $h = 1/128$ and using the fifth-order ($r = 5$) piecewise polynomials. We then use the obtained reference solution to compute the relative L^2 - and relative H^1 -errors. These errors are presented in Table 6.1. From this table, one can see that the solution numerically converges to the reference solution with the (optimal) second order in the H^1 -norm which confirms the theoretical results predicted by our convergence analysis. Moreover, the achieved third order of convergence in the L^2 -norm is optimal for quadratic piecewise polynomials.

FIG. 6.3. *The same as in Figures 6.1–6.2 but with $h = 1/51, r = 3$.*

FIG. 6.4. *The same as in Figures 6.1–6.3 but with $h = 1/101, r = 3$.*

We then test the convergence of the proposed DG method with respect to the degree r of piecewise polynomials for the fixed $h = 1/32$. The obtained results, reported in Table 6.2, show that the error decreases almost exponentially when the polynomial degree increases (this is a typical situation when DG methods capture smooth solutions).

We also compute the L^2 -errors with respect to the reference solution for the solutions plotted on Figures 6.1 and 6.2 at times $t = 2.99 \cdot 10^{-5}$ and $t = 6.03 \cdot 10^{-5}$. These times are close to the blow-up time, and the solutions develop a pick at the origin. The obtained errors are reported in Table 6.3. As one can see, even for the spiky solutions, the convergence rate is very high though it, as expected, deteriorates as t approaches t_b^{DG} .

TABLE 6.1
Relative errors as functions of the mesh size h ; $r = 2$ is fixed.

h	L^2 -error	Rate	H^1 -error	Rate
1/4	3.0578	–	1.5591	–
1/8	1.0290	1.6	1.2348	0.35
1/16	0.0796	3.7	0.5206	1.3
1/32	0.0075	3.4	0.0937	2.5
1/64	0.0006	3.6	0.0157	2.6

TABLE 6.2
Relative errors as functions of the piecewise polynomial degree r ; $h = 1/32$ is fixed.

GALERKIN FINITE ELEMENT METHODS WITH SYMMETRIC PRESSURE STABILIZATION FOR THE TRANSIENT STOKES EQUATIONS: STABILITY AND CONVERGENCE ANALYSIS*

ERIK BURMAN[†] AND MIGUEL A. FERNÁNDEZ[‡]

Abstract. We consider the stability and convergence analysis of pressure stabilized finite element approximations of the transient Stokes equation. The analysis is valid for a class of symmetric pressure stabilization operators, but also for standard, inf-sup stable, velocity/pressure spaces without stabilization. Provided the initial data are chosen as a specific (method-dependent) Ritz-projection, we get unconditional stability and optimal convergence for both pressure and velocity approximations, in natural norms. For arbitrary interpolations of the initial data, a condition between the space and time discretization parameters has to be verified in order to guarantee pressure stability.

Key words. transient Stokes equations, finite element methods, symmetric pressure stabilization, time discretization, Ritz-projection

1. Introduction. In this paper we consider stabilized finite element methods for the transient Stokes problem. For methods of standard pressure stabilized Petrov–Galerkin (PSPG) or Galerkin least squares (GLS) type, the analysis of time-discretization schemes is a difficult issue, unless a space-time approach is applied with a discontinuous Galerkin discretization in time. Indeed, for standard finite difference type time discretizations, the finite difference term must be included in the stabilization operator to ensure consistency (see, e.g., [11, 23]). It has been shown in [3] that even for first order backward difference (BDF1) schemes this perturbs the stability of the numerical scheme when the time step is small, unless the following condition between the space mesh size and the time step is verified:

$$(1.1) \quad \delta t \geq Ch^2,$$

where δt denotes the time step and h the space discretization parameter. For higher order schemes, such as Crank–Nicholson or second order backward differencing, the strongly consistent scheme appears to be unstable (see, e.g., [1]). Similar initial time-step instabilities were observed in [19] for the algebraic (static) subscale stabilization scheme applied to the Navier–Stokes equations, and they were cured by including time dependent subscales.

Our goal in this work is to consider a fairly large class of pressure stabilization methods and show that convergence of velocities and pressures, for the transient Stokes problem, can be obtained without conditions on the space- and time-discretization parameters (like (1.1)), provided the initial data are chosen as a specific (method-dependent) Ritz-projection (see, e.g., [33, 34]) onto a space of discretely *divergence-free* functions. *Discretely divergence-free* should here be interpreted

in the sense of the stabilized method. If, on the other hand, the initial data are chosen as some interpolant that does not conserve the discrete divergence-free character, the condition

$$(1.2) \quad \delta t \geq \tilde{C}h^{2k},$$

with k the polynomial degree of the velocity approximation space, has to be respected in order to avoid pressure oscillations in the transient solution for small times.

Although the stability conditions (1.1) and (1.2) are similar, their natures are different. As mentioned above, if (1.2) fails to be satisfied, pressure instabilities appear when dealing with nondiscrete divergence-free initial velocity approximation, but they are not related to the structure of the pressure stabilization. For residual-based stabilization methods (PSPG, GLS, etc.) on the other hand, the finite difference/pressure coupling of the stabilization perturbs the coercivity of the discrete pressure operator (see [3]) unless condition (1.1) is satisfied (irrespective of the divergence-free character of the initial velocity approximation).

The analysis carried out in this paper is valid not only for pressure stabilization operators that are symmetric and weakly consistent but also for standard methods using inf-sup stable velocity/pressure pairs, but it does not apply to residual-based pressure stabilizations (PSPG, GLS, etc.). In particular, space and time discretizations commute (i.e., lead to the same fully discrete scheme) for the methods we analyze.

We prove unconditional stability of velocities and pressures and optimal convergence (in natural norms) when the initial data are chosen as a certain Ritz-type projection. In the case when a standard interpolation of the initial data is applied, an *inverse parabolic Courant–Friedrich–Lewy (CFL)-type* condition must be respected in order to maintain pressure stability for small time steps. We give the full analysis only for the backward difference formula of order one, and we indicate how the analysis changes in the case of second order approximations in time. Indeed, any \mathcal{A} -stable implicit scheme is expected to yield optimal performance.

The remainder of the paper is organized as follows. In the next section we introduce the problem under consideration and some useful notation. The space- and time-discretized formulations are introduced in section 3. In subsection 3.1, the space discretization is formulated using a general framework; we also discuss how some known pressure stabilized finite element methods enter this setting. The time discretization is performed in subsection 3.2 using the first order backward difference (BDF1), Crank–Nicholson, and second order backward difference (BDF2) schemes. Section 4 is devoted to the stability analysis of the resulting fully discrete formulations. The convergence analysis for the BDF1 scheme is carried out in section 5. We illustrate the theoretical results with some numerical experiments in section 6, using interior penalty stabilization of the gradient jumps. Finally, some conclusions are given in section 7.

2. Problem setting. Let Ω be a domain in \mathbb{R}^d ($d = 2$ or 3) with a polyhedral boundary $\partial\Omega$. For $T > 0$ we consider the problem of solving, for $\mathbf{u} : \Omega \times (0, T) \rightarrow \mathbb{R}^d$ and $p : \Omega \times (0, T) \rightarrow \mathbb{R}$, the following time-dependent Stokes problem:

$$(2.1) \quad \begin{cases} \partial_t \mathbf{u} - \nu \Delta \mathbf{u} + \nabla p = \mathbf{f} & \text{in } \Omega \times (0, T), \\ \nabla \cdot \mathbf{u} = 0 & \text{in } \Omega \times (0, T), \\ \mathbf{u} = \mathbf{0} & \text{on } \partial\Omega \times (0, T), \\ \mathbf{u}(\cdot, 0) = \mathbf{u}_0 & \text{in } \Omega. \end{cases}$$

Here, $\mathbf{f} : \Omega \times (0, T) \rightarrow \mathbb{R}$ stands for the source term, $\mathbf{u}_0 : \Omega \rightarrow \mathbb{R}^d$ for the initial velocity, and $\nu > 0$ for a given constant viscosity. In order to introduce a variational setting for (2.1) we consider the following standard velocity and pressure spaces:

$$V \stackrel{\text{def}}{=} [H_0^1(\Omega)]^d, \quad H \stackrel{\text{def}}{=} [L^2(\Omega)]^d, \quad Q \stackrel{\text{def}}{=} L_0^2(\Omega),$$

normed with

$$\|\mathbf{v}\|_H \stackrel{\text{def}}{=} (\mathbf{v}, \mathbf{v})^{\frac{1}{2}}, \quad \|\mathbf{v}\|_V \stackrel{\text{def}}{=} \|\nu^{\frac{1}{2}} \nabla \mathbf{v}\|_H, \quad \|q\|_Q \stackrel{\text{def}}{=} \|\nu^{-\frac{1}{2}} q\|_H,$$

where (\cdot, \cdot) denotes the standard L^2 -inner product in Ω .

Problem (2.1) can be formulated in weak form as follows: For all $t > 0$, find $\mathbf{u}(t) \in V$ and $p(t) \in Q$ such that

$$(2.2) \quad \begin{cases} (\partial_t \mathbf{u}, \mathbf{v}) + a(\mathbf{u}, \mathbf{v}) + b(p, \mathbf{v}) = (\mathbf{f}, \mathbf{v}) & \text{a.e. in } (0, T), \\ b(q, \mathbf{u}) = 0 & \text{a.e. in } (0, T), \\ \mathbf{u}(\cdot, 0) = \mathbf{u}_0 & \text{a.e. in } \Omega \end{cases}$$

for all $\mathbf{v} \in V$, $q \in Q$ and with

$$a(\mathbf{u}, \mathbf{v}) \stackrel{\text{def}}{=} (\nu \nabla \mathbf{u}, \nabla \mathbf{v}), \quad b(p, \mathbf{v}) \stackrel{\text{def}}{=} -(p, \nabla \cdot \mathbf{v}).$$

From these definitions, the following classical coercivity and continuity estimates hold:

$$(2.3) \quad a(\mathbf{v}, \mathbf{v}) \geq \|\mathbf{v}\|_V^2, \quad a(\mathbf{u}, \mathbf{v}) \leq \|\mathbf{u}\|_V \|\mathbf{v}\|_V, \quad b(\mathbf{v}, q) \leq \|\mathbf{v}\|_V \|q\|_Q$$

for all $\mathbf{u}, \mathbf{v} \in V$ and $q \in Q$. It is known (see, e.g., [22]) that if $\mathbf{f} \in C^0([0, T]; H)$ and that $\mathbf{u}_0 \in V \cap H_0(\text{div}; \Omega)$, problem (2.2) admits a unique solution (\mathbf{u}, p) in $L^2(0, T; V) \times L^2(0, T; Q)$ with $\partial_t \mathbf{u} \in L^2(0, T; V')$.

Throughout this paper, C stands for a generic positive constant independent of the physical and discretization parameters.

3. Space and time discretization. In this section we discretize problem (2.2) with respect to the space and time variables. Symmetric pressure stabilized finite elements are used for the space discretization (subsection 3.1), and some known \mathcal{A} -stable schemes are used for the time discretization (subsection 3.2).

3.1. Space semidiscretization: Symmetric pressure stabilized formulations. Let $\{\mathcal{T}_h\}_{0 < h \leq 1}$ denote a shape-regular family of triangulations of the domain Ω . For each triangulation \mathcal{T}_h , the subscript $h \in (0, 1]$ refers to the level of refinement of the triangulation, which is defined by

$$h \stackrel{\text{def}}{=} \max_{K \in \mathcal{T}_h} h_K,$$

with h_K the diameter of K . In order to simplify the analysis, we assume that the family of triangulations $\{\mathcal{T}_h\}_{0 < h \leq 1}$ is quasi uniform. For more precise information on the constraint on the mesh, we refer the reader to the analysis of the various finite element methods in the steady case; see subsection 3.1.1.

In this paper, we let X_h^k and M_h^l denote, respectively, the standard spaces of continuous and (possibly) discontinuous piecewise polynomial functions of degree $k \geq 1$ and $l \geq 0$ ($k - 1 \leq l \leq k$),

$$X_h^k \stackrel{\text{def}}{=} \{v_h \in C^0(\bar{\Omega}) : v_h|_K \in \mathbb{P}_k(K) \quad \forall K \in \mathcal{T}_h\},$$

$$M_h^l \stackrel{\text{def}}{=} \{q_h \in L^2(\Omega) : q_h|_K \in \mathbb{P}_l(K) \quad \forall K \in \mathcal{T}_h\}.$$

For the approximated velocities, we will use the space $[V_h^k]^d \stackrel{\text{def}}{=} [X_h^k \cap H_0^1(\Omega)]^d$, and for the pressure, we will use either $Q_h^l \stackrel{\text{def}}{=} M_h^l \cap L_0^2(\Omega)$ or $Q_h^l \stackrel{\text{def}}{=} M_h^l \cap L_0^2(\Omega) \cap C^0(\overline{\Omega})$. In order to stabilize the pressure we introduce a bilinear form $j : Q_h \times Q_h \rightarrow \mathbb{R}$ satisfying the following properties:

- Symmetry:

$$(3.1) \quad j(p_h, q_h) = j(q_h, p_h) \quad \forall p_h, q_h \in Q_h^l;$$

- continuity:

$$(3.2) \quad |j(p_h, q_h)| \leq j(p_h, p_h)^{\frac{1}{2}} j(q_h, q_h)^{\frac{1}{2}} \leq C \|p_h\|_Q \|q_h\|_Q \quad \forall p_h, q_h \in Q_h^l;$$

- weak consistency:

$$(3.3) \quad j(\Pi_h^l q, \Pi_h^l q)^{\frac{1}{2}} \leq C \frac{h^{s_p}}{\nu} \|q\|_{s_p, \Omega} \quad \forall q \in H^s(\Omega),$$

with $s_p \stackrel{\text{def}}{=} \min\{s, \tilde{l}, l + 1\}$, $\tilde{l} \geq 1$, denoting the order of weak consistency of the stabilization operator, and $\Pi_h^l : Q \rightarrow Q_h^l$ a given projection operator such that

$$(3.4) \quad \|q - \Pi_h^l q\|_Q \leq \frac{C}{\nu^{\frac{1}{2}}} h^{l+1} \|q\|_{l+1, \Omega}$$

for all $q \in H^{l+1}(\Omega)$.

Finally, we assume that there exists a projection operator $\mathcal{I}_h^k : V \rightarrow V_h^k$ satisfying the following approximation properties:

$$(3.5) \quad \|\mathbf{v} - \mathcal{I}_h^k \mathbf{v}\|_H + h\nu^{-\frac{1}{2}} \|\mathbf{v} - \mathcal{I}_h^k \mathbf{v}\|_V \leq C_{\mathcal{I}} h^{r_u} \|\mathbf{v}\|_{r_u, \Omega},$$

$$(3.6) \quad |b(q_h, \mathbf{v} - \mathcal{I}_h^k \mathbf{v})| \leq C j(q_h, q_h)^{\frac{1}{2}} \left(\nu^{\frac{1}{2}} \|h^{-1}(\mathbf{v} - \mathcal{I}_h^k \mathbf{v})\|_H + \|\mathbf{v} - \mathcal{I}_h^k \mathbf{v}\|_V \right)$$

for all $\mathbf{v} \in [H^r(\Omega)]^d$, $r_u = \min\{r, k + 1\}$, and $(q_h, \mathbf{v}_h) \in Q_h^l \times [V_h^k]^d$.

Our space semidiscretized scheme reads as follows: For all $t \in (0, T)$, find $(\mathbf{u}_h(t), p_h(t)) \in [V_h^k]^d \times Q_h^l$ such that

$$(3.7) \quad \begin{aligned} (\partial_t \mathbf{u}_h, \mathbf{v}_h) + a(\mathbf{u}_h, \mathbf{v}_h) + b(p_h, \mathbf{v}_h) - b(q_h, \mathbf{u}_h) + j(p_h, q_h) &= (\mathbf{f}, \mathbf{v}_h), \\ \mathbf{u}_h(0) &= \mathbf{u}_h^0, \end{aligned}$$

for all $(\mathbf{v}_h, q_h) \in [V_h^k]^d \times Q_h^l$ and with \mathbf{u}_h^0 a suitable approximation of \mathbf{u}_0 in $[V_h^k]^d$.

The following modified inf-sup condition states the stability of the discrete pressures in (3.7).

LEMMA 3.1. *There exists two constants $C, \beta > 0$, independent of h and ν , such that*

$$(3.8) \quad \sup_{\mathbf{v}_h \in [V_h^k]^d} \frac{|b(q_h, \mathbf{v}_h)|}{\|\mathbf{v}_h\|_V} + C j(q_h, q_h)^{\frac{1}{2}} \geq \beta \|q_h\|_Q$$

for all $q_h \in Q_h^l$.

Proof. Let $q_h \in Q_h^l$; from [25, Corollary 2.4] and (3.5) there exists $\mathbf{v}_q \in H_0^1(\Omega)$ such that $\nabla \cdot \mathbf{v}_q = \nu^{-1} q_h$ and

$$(3.9) \quad \|\mathcal{I}_h^k \mathbf{v}_q\|_V \leq C \|\mathbf{v}_q\|_V \leq C \|q_h\|_Q.$$

On the other hand, using (3.6), we have

$$\begin{aligned} \|q_h\|_Q^2 &= b(q_h, \mathbf{v}_q) \\ &= b(q_h, \mathbf{v}_q - \mathcal{I}_h^k \mathbf{v}_q) + b(q_h, \mathcal{I}_h^k \mathbf{v}_q) \\ &\leq Cj(q_h, q_h)^{\frac{1}{2}} \left(\|\nu^{\frac{1}{2}} h^{-1}(\mathbf{v} - \mathcal{I}_h^k \mathbf{v})\|_H + \|\mathbf{v} - \mathcal{I}_h^k \mathbf{v}\|_V \right) + b(q_h, \mathcal{I}_h^k \mathbf{v}_q) \\ &\leq Cj(q_h, q_h)^{\frac{1}{2}} \|q_h\|_Q + b(q_h, \mathcal{I}_h^k \mathbf{v}_q). \end{aligned}$$

We conclude the proof by dividing this last inequality by $\|\mathcal{I}_h^k \mathbf{v}_q\|_V$ and using (3.9). \square

The above lemma ensures the well-posedness of problem (3.7). This is stated in the following theorem.

THEOREM 3.2. *The discrete problem (3.7) with $\mathbf{u}_h^0 \in V_{h,k}^{\text{div}} \stackrel{\text{def}}{=} \{\mathbf{v}_h \in V_j^k : b(q_h, \mathbf{v}_h) = 0 \text{ for all } q_h \in Q_h \cap \text{Ker } j\}$ has a unique solution $(\mathbf{u}_h, p_h) \in C^1((0, T]; [V_h^k]^d) \times C^0((0, T]; Q_h^k)$.*

To facilitate the analysis we introduce the following (mesh-dependent) seminorm, which is a norm for the velocity and a seminorm for the pressure:

$$(3.10) \quad \|(\mathbf{v}_h, q_h)\|_h^2 \stackrel{\text{def}}{=} \|\mathbf{v}_h\|_V^2 + j(q_h, q_h).$$

Remark 3.3. If the velocity/pressure finite element pair V_h^k/Q_h^k is inf-sup stable, we can take $j(\cdot, \cdot) \stackrel{\text{def}}{=} 0$ in (3.7), as usual. Obviously, this choice is compatible with hypothesis (3.1)–(3.3) so that the results of this paper still apply. In particular, the relation (3.8) becomes the standard inf-sup condition between V_h^k and Q_h^k .

3.1.1. Examples. In this section we will review some of the most well-known pressure projection stabilization methods and discuss how they enter the abstract framework of the previous subsection. For detailed results on analysis for the respective methods, we refer the reader to the references considering the stationary case.

Recently, several different weakly consistent symmetric pressure stabilized finite element methods have been proposed. These methods take their origin from the works of Silvester [32] and Codina and Blasco [17]. Further developments include the work by Becker and Braack [2] on local projection schemes; the extension of the interior penalty method, using penalization of gradient jumps, to the case of pressure stabilization by Burman and Hansbo [14]; and the interpretation of these methods as minimal stabilization procedures by Brezzi and Fortin [9]. Similar approaches have been advocated in Dohrmann and Bochev in [21], and a review of the analysis (with special focus on discontinuous pressure spaces and the Darcy problem) is given in [12].

The main idea underpinning all these methods is that, when using a velocity-pressure space pair $V_h \times Q_h$, the inf-sup stability constraint on the spaces may be relaxed by the addition of an operator penalizing the difference between the discrete pressure variable and its projection onto a subspace $\tilde{Q}_h \subset Q_h$, such that $V_h \times \tilde{Q}_h$ is inf-sup stable. The penalization may either act directly on the pressure, as in [21, 12], or on the gradient of the pressure, as in [2, 18, 14]. Generally speaking, the pressure approximation properties of the numerical scheme will be given by \tilde{Q}_h , expressed in the weak consistency satisfied by the penalty operator. For the Oseen’s problem, some of these methods may be extended to include high Reynolds number effects (see, e.g., [13, 6, 16]). The advantages and disadvantages of symmetric weakly consistent pressure stabilization methods compared to GLS or PSPG approaches is discussed in a recent review paper [7].

The methods of Brezzi and Pitkäranta, Silvester, and Dohrmann and Bochev. The original pressure stabilized finite element method was proposed by Brezzi and Pitkäranta in [10]. Here, the velocity and pressure discrete spaces are chosen as the standard finite element space of piecewise affine continuous functions, $[V_h^1]^d \times Q_h^1$. The operator $j(\cdot, \cdot)$ is given by

$$(3.11) \quad j(p_h, q_h) = \left(\frac{h^2}{\nu} \nabla p_h, \nabla q_h \right).$$

A variant of this method was recently proposed by Dohrmann and Bochev in [21], using an equivalent stabilization operator, namely,

$$(3.12) \quad j(p_h, q_h) = \left(\frac{1}{\nu} (I - \pi_0) p_h, (I - \pi_0) q_h \right),$$

where $\pi_0 : Q \rightarrow Q_h^0$ denotes the (elementwise) projection onto piecewise constants. Property (3.6) is verified after an integration by parts, with \mathcal{I}_h^1 simply the Scott–Zhang interpolant onto $[V_h^1]^d$ (see, e.g., [31, 22]),

$$\begin{aligned} b(q_h, \mathbf{v} - \mathcal{I}_h^1 \mathbf{v}) &= (\nabla q_h, \mathbf{v} - \mathcal{I}_h^1 \mathbf{v}) \\ &\leq j(q_h, q_h)^{\frac{1}{2}} \left(h^{-1} \nu^{\frac{1}{2}} \|\mathbf{v} - \mathcal{I}_h^1 \mathbf{v}\|_H + \|\mathbf{v} - \mathcal{I}_h^1 \mathbf{v}\|_V \right). \end{aligned}$$

One readily verifies that (3.2) and (3.3) hold. Moreover, in both cases (3.11) and (3.12), the weak consistency property holds (with $\tilde{l} = 1$),

$$j(\Pi_h^1 p, \Pi_h^1 p)^{\frac{1}{2}} \leq \frac{C}{\nu^{\frac{1}{2}}} h \|p\|_{1,\Omega},$$

with Π_h^1 being, for instance, the L^2 -projection onto Q_h^1 (we could use instead the Clément [15] or Scott–Zhang interpolants). Indeed, for (3.11) we apply the H^1 -stability of the L^2 -projection (see, e.g., [22, 20, 8, 5]), whereas for (3.12) we add and subtract suitable terms (p and $\pi_0 p$) and use the approximation properties of π_0 and Π_h^1 (see, e.g., [22]). As a result, our analysis for the time discretization is valid.

Another low order scheme, covered by the analysis, is the method which consists of using piecewise affine continuous velocities and elementwise constants pressures, $[V_h^1]^d \times Q_h^0$; see, e.g., [27]. Stability is obtained by the addition of the jump over element faces of the discontinuous pressure, namely,

$$j(p_h, q_h) = \sum_{K \in \mathcal{T}_h} \int_{\partial K \setminus \partial \Omega} \frac{h}{\nu} \llbracket p_h \rrbracket \llbracket q_h \rrbracket.$$

Here, $\llbracket q_h \rrbracket$ denotes the jump of q_h over the interelement boundary, defined by

$$\llbracket q_h \rrbracket(\mathbf{x}) \stackrel{\text{def}}{=} \lim_{\epsilon \rightarrow 0} (q_h(\mathbf{x} + \epsilon \mathbf{n}) - q_h(\mathbf{x} - \epsilon \mathbf{n})) \quad \forall \mathbf{x} \in F,$$

with \mathbf{n} standing for a fixed, but arbitrary, normal to the internal face F . In this case, (3.6) is obtained after an integration by parts in the term $b(q_h, \mathbf{v} - \mathcal{I}_h^1 \mathbf{v})$ and an elementwise trace inequality (see, e.g., [22]),

$$\begin{aligned} b(q_h, \mathbf{v} - \mathcal{I}_h^1 \mathbf{v}) &= - \sum_K \int_{\partial K \setminus \partial \Omega} \llbracket q_h \rrbracket (\mathbf{v} - \mathcal{I}_h^1 \mathbf{v}) \cdot \mathbf{n} \\ &\leq j(q_h, q_h)^{\frac{1}{2}} \left(h^{-1} \nu^{\frac{1}{2}} \|\mathbf{v} - \mathcal{I}_h^1 \mathbf{v}\|_H + \|\mathbf{v} - \mathcal{I}_h^1 \mathbf{v}\|_V \right). \end{aligned}$$

In addition, by taking, for instance, Π_h^0 as the L^2 -projection onto Q_h^0 , using an elementwise trace inequality and the approximation properties of Π_h^0 (see, e.g., [22]), one also easily shows that the weak consistency property holds,

$$j(\Pi_h^0 p, \Pi_h^0 p)^{\frac{1}{2}} = j((I - \Pi_h^0)p, (I - \Pi_h^0)p)^{\frac{1}{2}} \leq \frac{C}{\nu^{\frac{1}{2}}} h \|p\|_{1,\Omega},$$

and hence $\tilde{l} = 1$.

For details on the cases of stabilization of the pressure jumps only in macroelements, or the generalization to higher order finite element spaces of the Taylor–Hood family with discontinuous pressures, we refer the reader to [12].

Orthogonal subscale stabilization. The orthogonal subscale stabilization was proposed by Codina and Blasco in [17]. Equal order ($k = l \geq 1$) continuous approximation spaces are used for the velocities and the pressures.

Here the main idea is to penalize the difference between the pressure gradient and its projection onto the finite element space. This imposes the introduction of an auxiliary variable for the projection since it may not be localized and is given only implicitly. Hence, the stabilization operator is given by

$$j(p_h, q_h) = \left(\frac{h^2}{\nu} (\nabla p_h - \pi_h^k \nabla p_h), \nabla q_h \right),$$

where $\pi_h^k : [L^2(\Omega)]^d \rightarrow [V_h^k]^d$ stands for the L^2 -projection onto $[V_h^k]^d$, which is given as the solution of the (global) problem

$$(\pi_h^k \nabla p_h, \boldsymbol{\xi}_h) = (\nabla p_h, \boldsymbol{\xi}_h) \quad \forall \boldsymbol{\xi}_h \in [V_h^k]^d.$$

One may readily show that (3.2) and (3.3) hold. Disregarding for simplicity the boundary conditions, the projection operator $\mathcal{I}_h^k = \pi_h^k$ of (3.6) is here chosen also as the L^2 -projection onto $[V_h^k]^d$. This can be justified if boundary conditions are imposed weakly, for instance, using Nitsche’s method (see [29, 24]), and V_h^k includes the degrees of freedom on the boundary. Indeed, then we have

$$\begin{aligned} b(q_h, \mathbf{v} - \mathcal{I}_h^k \mathbf{v}) &= (\nabla q_h - \pi_h^k \nabla q_h, \mathbf{v} - \mathcal{I}_h^k \mathbf{v}) \\ (3.13) \quad &\leq j(q_h, q_h)^{\frac{1}{2}} \left(h^{-1} \nu^{\frac{1}{2}} \|\mathbf{v} - \mathcal{I}_h^k \mathbf{v}\|_H + \|\mathbf{v} - \mathcal{I}_h^k \mathbf{v}\|_V \right). \end{aligned}$$

Finally, by taking $\Pi_h^k : Q \rightarrow Q_h^k$ as the L^2 -projection onto Q_h^k , adding and subtracting suitable terms (∇p and $\pi_h^k \nabla p$), and using the approximation properties of π_h^k and Π_h^k (see, e.g., [22]), one readily verifies the weak consistency

$$j(\Pi_h^k p, \Pi_h^k p)^{\frac{1}{2}} = \frac{h}{\nu^{\frac{1}{2}}} \|(I - \pi_h^k) \nabla \Pi_h^k p\|_{0,\Omega} \leq \frac{C}{\nu^{\frac{1}{2}}} h^{s_p} \|p\|_{s_p,\Omega},$$

for all $p \in H^s(\Omega)$ and with $s_p = \min\{k + 1, s\}$. In particular, $\tilde{l} = l = k$. The above analysis is hence valid also in this case (with some modifications of a technical nature due to the weakly imposed boundary conditions).

Local projection stabilization. In the local projection stabilization proposed in [2], stability is obtained by penalizing the projection of the gradient onto piecewise discontinuous functions defined on patches consisting of several elements, obtained by

using hierarchic meshes, or by penalizing the gradient of the difference of the pressure and its projection on polynomials of lower polynomial order. The construction relies on the inf-sup stability of a velocity/pressure pair typically of mini-element character or of the Taylor–Hood family. Similar ideas were advocated in [21]. The stabilization operator is written as

$$j(p_h, q_h) = \sum_{\tilde{K}} \left(\frac{h^2}{\nu} \kappa \nabla p_h, \kappa \nabla q_h \right),$$

where κ is the so-called *fluctuation operator* defined as $\kappa \stackrel{\text{def}}{=} I - \tilde{\pi}_h$, where $\tilde{\pi}_h$ denotes a *local* projection operator onto either a polynomial of order k on a macropatch consisting of three triangles (or four quadrilaterals) or a polynomial of order $k - 1$ on the element. One may show that (3.6), (3.2), and (3.3) hold (for details on the construction of \mathcal{I}_h^k , see [2, 6], and for general conditions on the finite element spaces and stabilization operators, see [28]). In the case when we consider the projection $\tilde{\pi}_h$ onto polynomials of order $k - 1$, the stabilization operator may be written as

$$(3.14) \quad j(p_h, q_h) = \sum_{\tilde{K}} \left(\frac{h^2}{\nu} \nabla(\kappa p_h), \nabla(\kappa q_h) \right),$$

or, equivalently, following [21], as

$$j(p_h, q_h) = \sum_{\tilde{K}} \left(\frac{1}{\nu} \kappa p_h, \kappa q_h \right).$$

In these latter cases, condition (3.6) is obtained by choosing \mathcal{I}_h^k as the Fortin interpolation operator associated with $[V_h^k]^d \times \tilde{Q}_h$, where \tilde{Q}_h is the space of continuous piecewise polynomial functions of order $k - 1$. Clearly, we then have

$$\begin{aligned} b(q_h, \mathbf{v} - \mathcal{I}_h^k \mathbf{v}) &= b(\kappa q_h, \mathbf{v} - \mathcal{I}_h^k \mathbf{v}) \\ &\leq j(q_h, q_h)^{\frac{1}{2}} \left(h^{-1} \nu^{\frac{1}{2}} \|\mathbf{v} - \mathcal{I}_h^k \mathbf{v}\|_H + \|\mathbf{v} - \mathcal{I}_h^k \mathbf{v}\|_V \right), \end{aligned}$$

since $b(\tilde{q}_h, \mathbf{v} - \mathcal{I}_h^k \mathbf{v}) = 0$ for all $\tilde{q}_h \in \tilde{Q}_h$. The form (3.14) is treated in a similar fashion after an integration by parts. On the other hand, by taking $\Pi_h^l : Q \rightarrow Q_h^l$ as the L^2 -projection operator onto Q_h^l and using approximation properties of Π_h^l and $\tilde{\pi}_h$, we have

$$\begin{aligned} j(\Pi_h^l p, \Pi_h^l p)^{\frac{1}{2}} &\leq j((I - \Pi_h^l)p, (I - \Pi_h^l)p)^{\frac{1}{2}} + j(p, p)^{\frac{1}{2}} \\ &\leq \frac{C}{\nu^{\frac{1}{2}}} h^{s_p} \|p\|_{s_p, \Omega} \quad \forall p \in H^s(\Omega), \end{aligned}$$

where $s_p = \min\{\tilde{l}, s, l + 1\}$ and $\tilde{l} - 1$ denotes the polynomial order of the space on which the local projection is taken. Clearly, if we project on polynomials of order $k - 1$, the stabilization operator loses one order in the weak consistency; however, the estimates remain optimal since we expect the velocities to be one order more regular than the pressure.

Continuous interior penalty (CIP) stabilization. The CIP stabilization for the stationary Stokes problem was proposed in [14] and generalized to Oseen’s problem in [13]. It uses equal order continuous approximation spaces for velocities and pressures ($k = l \geq 1$) and relies on the fact that the component of the pressure gradient orthogonal to the finite element space may be controlled by the gradient jumps using an interpolation estimate between discrete spaces. Indeed, it was shown in [13] that the following inequality holds:

$$(3.15) \quad \|h(\nabla p_h - \tilde{i}\nabla p_h)\|_H^2 \leq \sum_{K \in \mathcal{T}_h} \int_{\partial K \setminus \partial \Omega} h_K^3 \llbracket \nabla p_h \cdot \mathbf{n} \rrbracket^2$$

for a certain Clément-type quasi-interpolation operator \tilde{i} . This motivates the use of the pressure stabilization operator

$$j(p_h, q_h) = \sum_{K \in \mathcal{T}_h} \int_{\partial K \setminus \partial \Omega} \frac{h^3}{\nu} \llbracket \nabla p_h \cdot \mathbf{n} \rrbracket \llbracket \nabla q_h \cdot \mathbf{n} \rrbracket.$$

Clearly (3.2) and (3.3) are verified in this case. Moreover, (3.6) may be shown to hold if \mathcal{I}_h^k is chosen to be the L^2 -projection onto $[V_h^k]^d$ and boundary conditions are imposed weakly [13]. To show the inequality we combine (3.13) with (3.15). Finally, by taking Π_h^k as the L^2 -projection onto Q_h^k , since $\llbracket \mathcal{C}_h^k \nabla p \rrbracket = \mathbf{0}$ (with \mathcal{C}_h^k the Clément interpolant onto $[X_h^k]^d$), using an elementwise trace inequality, adding and subtracting ∇p , and using the approximation properties of \mathcal{C}_h^k and Π_h^k , one readily verifies (see [13, Lemma 4.7]) the weak consistency

$$\begin{aligned} j(\Pi_h^k p, \Pi_h^k p)^{\frac{1}{2}} &\leq C \frac{h}{\nu^{\frac{1}{2}}} \|\nabla \Pi_h^k p - \mathcal{C}_h^k \nabla p\|_{0,\Omega} \\ &\leq \frac{C}{\nu^{\frac{1}{2}}} h^{s_p} \|p\|_{s_p,\Omega} \quad \forall p \in H^s(\Omega), \end{aligned}$$

with $s_p = \min\{k + 1, s\}$, so that $\tilde{l} = l = k$.

We refer the reader to [13] for the details on the technical issue related to the weak imposition of the boundary conditions using Nitsche’s method.

3.1.2. The Ritz-projection operator. For the purpose of the stability and convergence analysis below we introduce the Ritz-projection operator

$$S_h^{k,l} : [H^1(\Omega)]^d \times L^2(\Omega) \longrightarrow V_h^k \times Q_h^l.$$

For each $(\mathbf{u}, p) \in [H^1(\Omega)]^d \times L^2(\Omega)$, the projection $S_h^{k,l}(\mathbf{u}, p) \stackrel{\text{def}}{=} (P_h^k(\mathbf{u}, p), R_h^l(\mathbf{u}, p)) \in [V_h^k]^d \times Q_h^l$ is defined as the unique solution of

$$(3.16) \quad \begin{cases} a(P_h^k(\mathbf{u}, p), \mathbf{v}_h) + b(R_h^l(\mathbf{u}, p), \mathbf{v}_h) = a(\mathbf{u}, \mathbf{v}_h) + b(p, \mathbf{v}_h), \\ -b(q_h, P_h^k(\mathbf{u}, p)) + j(R_h^l(\mathbf{u}, p), q_h) = 0 \end{cases}$$

for all $(\mathbf{v}_h, q_h) \in [V_h^k]^d \times Q_h^l$.

Problem (3.16) is well-posed thanks to the inf-sup condition (3.8); in particular, we have the following a priori stability estimate:

$$(3.17) \quad \|(P_h^k(\mathbf{u}, p), R_h^l(\mathbf{u}, p))\|_h^2 \leq C (\|\mathbf{u}\|_V^2 + \|p\|_Q^2),$$

with $C > 0$ a constant independent of h and ν .

Finally, we have the following approximation result.

LEMMA 3.4. *Let $(\mathbf{u}, p) \in C^1([0, T], [H^r(\Omega) \cap H_0^1(\Omega)]^d \cap H_0(\text{div}; \Omega) \times H^s(\Omega))$ with $r \geq 2$ and $s \geq 1$. The following error estimate for the projection $S_h^{k,l}$ holds with $\alpha = 0, 1$:*

$$\begin{aligned} \|(\partial_t^\alpha(\mathbf{u} - P_h^k(\mathbf{u}, p)), \partial_t^\alpha R_h^l(\mathbf{u}, p))\|_h &\leq C \left(\nu^{\frac{1}{2}} h^{r_u-1} \|\partial_t^\alpha \mathbf{u}\|_{r_u, \Omega} + \nu^{-\frac{1}{2}} h^{s_p} \|\partial_t^\alpha p\|_{s_p, \Omega} \right), \\ \|p - R_h^l(\mathbf{u}, p)\|_Q &\leq C \left(\nu^{\frac{1}{2}} h^{r_u-1} \|\mathbf{u}\|_{r_u, \Omega} + \nu^{-\frac{1}{2}} h^{s_p} \|p\|_{s_p, \Omega} \right) \end{aligned}$$

for all $t \in [0, T]$ and with $r_u \stackrel{\text{def}}{=} \min\{r, k+1\}$ and $s_p \stackrel{\text{def}}{=} \min\{s, \tilde{l}, l+1\}$, and $C > 0$ independent of ν and h . Moreover, provided the domain Ω is sufficiently smooth and, if $\tilde{l} \geq 1$, there also holds

$$(3.18) \quad \|\partial_t^\alpha(\mathbf{u} - P_h^k(\mathbf{u}, p))\|_H \leq Ch \|(\partial_t^\alpha(\mathbf{u} - P_h^k(\mathbf{u}, p)), \partial_t^\alpha R_h^l p)\|_h.$$

Proof. For simplicity we here use the notation $\mathbf{u}_h \stackrel{\text{def}}{=} P_h^k(\mathbf{u}, p)$ and $p_h \stackrel{\text{def}}{=} R_h^l(\mathbf{u}, p)$. From (3.10), the V -coercivity of $a(\cdot, \cdot)$ (see (2.3)), and the orthogonality provided by (3.16), we have

$$\begin{aligned} \|(\mathbf{u}_h - \mathcal{I}_h^k \mathbf{u}, p_h - \Pi_h^l p)\|_h^2 &= a(\mathbf{u} - \mathcal{I}_h^k \mathbf{u}, \mathbf{u}_h - \mathcal{I}_h^k \mathbf{u}) + b(p - \Pi_h^l p, \mathbf{u}_h - \mathcal{I}_h^k \mathbf{u}) \\ &\quad + b(p_h - \Pi_h^l p, \mathbf{u} - \mathcal{I}_h^k \mathbf{u}) + j(\Pi_h^l p, p_h - \Pi_h^l p). \end{aligned}$$

Finally, using (2.3) and (3.6), we have that

$$\begin{aligned} \|(\mathbf{u}_h - \mathcal{I}_h^k \mathbf{u}, p_h - \Pi_h^l p)\|_h^2 &\leq (\|\mathbf{u} - \mathcal{I}_h^k \mathbf{u}\|_V + \|p - \Pi_h^l p\|_Q) \|\mathbf{u}_h - \mathcal{I}_h^k \mathbf{u}\|_V \\ &\quad + C \left(\nu^{\frac{1}{2}} \|h^{-1}(\mathbf{u} - \mathcal{I}_h^k \mathbf{u})\|_H + \|\mathbf{u} - \mathcal{I}_h^k \mathbf{u}\|_V + j(\Pi_h^l p, \Pi_h^l p)^{\frac{1}{2}} \right) j(p_h - \Pi_h^l p, p_h - \Pi_h^l p)^{\frac{1}{2}}. \end{aligned}$$

We obtain the estimation for the velocity ($\alpha = 0$) using the approximation properties of \mathcal{I}_h^k and Π_h^l (see (3.5) and (3.4)) and the weak consistency (3.3) of the stabilizing term $j(\cdot, \cdot)$. The convergence for the time derivative ($\alpha = 1$) is obtained in a similar fashion after the time derivation of (3.16).

For the pressure estimate, we use the generalized inf-sup condition (3.8) and the orthogonality provided by (3.16). We then have

$$\begin{aligned} &\beta \|\Pi_h^l p - p_h\|_Q \\ &\leq \sup_{\mathbf{v}_h \in [V_h^k]^d} \frac{b(\Pi_h^l p - p_h, \mathbf{v}_h)}{\|\mathbf{v}_h\|_V} + C j(\Pi_h^l p - p_h, \Pi_h^l p - p_h)^{\frac{1}{2}} \\ &\leq \sup_{\mathbf{v}_h \in [V_h^k]^d} \frac{b(\Pi_h^k p - p, \mathbf{v}_h) - a(\mathbf{u} - \mathbf{u}_h, \mathbf{v}_h)}{\|\mathbf{v}_h\|_V} + C j(\Pi_h^l p - p_h, \Pi_h^l p - p_h)^{\frac{1}{2}}. \end{aligned}$$

We conclude by using the continuity of $a(\cdot, \cdot)$ and $b(\cdot, \cdot)$, approximability, the weak consistency of $j(\cdot, \cdot)$, and the previous error estimate. For a proof of the optimality in the H -norm, see, e.g., [13, Theorem 4.14]. \square

3.2. Fully discrete formulation: Time discretization. In this subsection we discretize (3.7) with respect to the time variable. To this end, we will use some known \mathcal{A} -stable time discretization schemes for ODEs.

Let $N \in \mathbb{N}^*$ be given. We consider a uniform partition $\{[t_n, t_{n+1}]\}_{0 \leq n \leq N-1}$, with $t_n \stackrel{\text{def}}{=} n\delta t$, of the time interval of interest $[0, T]$ with time-step size $\delta t \stackrel{\text{def}}{=} T/N$. The discrete pair (\mathbf{u}_h^n, p_h^n) stands for an approximation of $(\mathbf{u}(t_n), p(t_n))$ in $[V_h^k]^d \times Q_h^l$.

First order backward difference formula (BDF1). By introducing the first order backward difference quotient

$$\bar{D}u_h^{n+1} \stackrel{\text{def}}{=} \frac{u_h^{n+1} - u_h^n}{\delta t},$$

our first fully discrete scheme reads as follows: For $0 \leq n \leq N-1$, find $(\mathbf{u}_h^{n+1}, p_h^{n+1}) \in [V_h^k]^d \times Q_h^l$ such that

$$(3.19) \quad (\bar{D}\mathbf{u}_h^{n+1}, \mathbf{v}_h) + a(\mathbf{u}_h^{n+1}, \mathbf{v}_h) + b(p_h^{n+1}, \mathbf{v}_h) - b(q_h, \mathbf{u}_h^{n+1}) \\ + j(p_h^{n+1}, q_h) = (\mathbf{f}(t_{n+1}), \mathbf{v}_h)$$

for all $(\mathbf{v}_h, q_h) \in V_h^k \times Q_h^l$ and with \mathbf{u}_h^0 a suitable approximation of \mathbf{u}_0 in $[V_h^k]^d$.

Crank–Nicholson scheme. Let us consider now the scheme given by the following: For $0 \leq n \leq N-1$, find $(\mathbf{u}_h^{n+1}, p_h^{n+\frac{1}{2}}) \in [V_h^k]^d \times Q_h^l$ such that

$$(3.20) \quad (\bar{D}\mathbf{u}_h^{n+1}, \mathbf{v}_h) + a(\mathbf{u}_h^{n+\frac{1}{2}}, \mathbf{v}_h) + b(p_h^{n+\frac{1}{2}}, \mathbf{v}_h) - b(q_h, \mathbf{u}_h^{n+\frac{1}{2}}) \\ + j(p_h^{n+\frac{1}{2}}, q_h) = (\mathbf{f}^{n+\frac{1}{2}}, \mathbf{v}_h)$$

for all $(\mathbf{v}_h, q_h) \in [V_h^k]^d \times Q_h^l$, where $\mathbf{u}_h^{n+\frac{1}{2}} \stackrel{\text{def}}{=} \frac{1}{2}(\mathbf{u}_h^{n+1} + \mathbf{u}_h^n)$ and \mathbf{u}_h^0 is a suitable approximation of \mathbf{u}_0 in $[V_h^k]^d$.

Remark 3.5. Note that (3.20) uniquely determines \mathbf{u}_h^{n+1} , since \mathbf{u}_h^0 is given. For the pressure, however, neither p_h^{n+1} nor p_h^n is used in (3.20). Therefore, by working with $p_h^{n+\frac{1}{2}}$ as the pressure variable, we do not need to provide an initial condition for the pressure. On the other hand, we do not have an approximation of p_h^{n+1} unless one is constructed by extrapolation.

Second order backward difference (BDF2). Finally, by considering the second order backward difference quotient

$$\tilde{D}\mathbf{u}^{n+1} \stackrel{\text{def}}{=} \frac{1}{2\delta t}(3\mathbf{u}_h^{n+1} - 4\mathbf{u}_h^n + \mathbf{u}_h^{n-1}),$$

we obtain the following BDF2 scheme: For $1 \leq n \leq N-1$, find $(\mathbf{u}_h^{n+1}, p_h^{n+1}) \in [V_h^k]^d \times Q_h^l$ such that

$$(3.21) \quad (\tilde{D}\mathbf{u}_h^{n+1}, \mathbf{v}_h) + a(\mathbf{u}_h^{n+1}, \mathbf{v}_h) + b(p_h^{n+1}, \mathbf{v}_h) - b(q_h, \mathbf{u}_h^{n+1}) \\ + j(p_h^{n+1}, q_h) = (\mathbf{f}^{n+1}, \mathbf{v}_h)$$

for all $(\mathbf{v}_h, q_h) \in [V_h^k]^d \times Q_h^l$ and $(\mathbf{u}_h^1, p_h^1) \in [V_h^k]^d \times Q_h^l$ given by the first step of backward Euler scheme (3.19).

4. Stability. In this section we analyze the stability properties of the fully discrete schemes introduced in subsection 3.2. For the sake of simplicity, full details will be given only for the backward scheme (3.19). Nevertheless, in subsection 4.2, we will discuss how the results extend to the second order time-stepping schemes Crank–Nicholson and BDF2.

4.1. First order \mathcal{A} -stable scheme. The next result provides the unconditional stability of the velocity. It also provides a uniform estimate for the pressure, in terms of the discrete velocity time derivative. Theorem 4.2 points out the role of the initial velocity approximation on the stability of the velocity time derivative approximations. Finally, Corollary 4.3 states the (conditional or unconditional) stability of the pressure, depending on the choice of the initial velocity approximation.

THEOREM 4.1. *Let \mathbf{u}_h^0 be a given H -stable approximation of \mathbf{u}_0 in $[V_h^k]^d$, and let $\{(\mathbf{u}_h^n, p_h^n)\}_{n=1}^N$ be the solution of the fully discrete problem (3.19). The following estimate holds for $1 \leq n \leq N$:*

$$(4.1) \quad \begin{aligned} & \|\mathbf{u}_h^n\|_H^2 + \sum_{m=0}^{n-1} \delta t \|(\mathbf{u}_h^{m+1}, p_h^{m+1})\|_h^2 \leq C \|\mathbf{u}_0\|_H^2 + \frac{C_P^2}{\nu} \sum_{m=0}^{n-1} \delta t \|\mathbf{f}(t_{m+1})\|_H^2, \\ & \sum_{m=0}^{n-1} \delta t \|p_h^{m+1}\|_Q^2 \\ & \leq \frac{C}{\beta^2} \sum_{m=0}^{n-1} \delta t \left(\|(\mathbf{u}_h^{m+1}, p_h^{m+1})\|_h^2 + \nu^{-1} \|\bar{D}\mathbf{u}_h^{m+1}\|_H^2 + \nu^{-1} \|\mathbf{f}(t_{m+1})\|_H^2 \right), \end{aligned}$$

with $C_P > 0$ the Poincaré constant.

Proof. Taking $\mathbf{v}_h = \mathbf{u}_h^{n+1}$ and $q_h = p_h^{n+1}$ in (3.19), using the coercivity of the bilinear form, the Cauchy–Schwarz inequality, and the Poincaré inequality, we have

$$(4.2) \quad (\bar{D}\mathbf{u}_h^{n+1}, \mathbf{u}_h^{n+1}) + \frac{1}{2} \|(\mathbf{u}_h^{n+1}, p_h^{n+1})\|_h^2 \leq \frac{C_P^2}{2\nu} \|\mathbf{f}(t_{n+1})\|_H^2.$$

Now, recalling that

$$(4.3) \quad (\bar{D}\mathbf{u}_h^{n+1}, \mathbf{u}_h^{n+1}) = \frac{1}{2} \bar{D} \|\mathbf{u}_h^{n+1}\|_H^2 + \frac{1}{2\delta t} \|\mathbf{u}_h^{n+1} - \mathbf{u}_h^n\|_H^2,$$

we have

$$\bar{D} \|\mathbf{u}_h^{n+1}\|_H^2 + \|(\mathbf{u}_h^{n+1}, p_h^{n+1})\|_h^2 \leq \frac{C_P^2}{\nu} \|\mathbf{f}(t_{n+1})\|_H^2,$$

leading to, after summation over $0 \leq m \leq n-1$,

$$\|\mathbf{u}_h^n\|_H^2 + \sum_{m=0}^{n-1} \delta t \|(\mathbf{u}_h^{m+1}, p_h^{m+1})\|_h^2 \leq \|\mathbf{u}_h^0\|_H^2 + \frac{C_P^2}{\nu} \sum_{m=0}^{n-1} \delta t \|\mathbf{f}(t_{m+1})\|_H^2.$$

For the pressure estimate, from (3.8), (3.19) (with $q_h = 0$) and the Poincaré inequality, we have

$$\beta \|p_h^{n+1}\|_Q \leq C \left(\|(\mathbf{u}_h^{n+1}, p_h^{n+1})\|_h + \nu^{-\frac{1}{2}} \|\bar{D}\mathbf{u}_h^{n+1}\|_H + \nu^{-\frac{1}{2}} \|\mathbf{f}(t_{n+1})\|_H \right),$$

which completes the proof. \square

The next theorem states some a priori estimates of the approximations of the velocity time derivative.

THEOREM 4.2. *Let $\{(\mathbf{u}_h^n, p_h^n)\}_{n=1}^N$ be the solution of the fully discrete problem (3.19).*

- *If $\mathbf{u}_0 \in [H^1(\Omega)]^d$ and $\mathbf{u}_h^0 = P_h^k(\mathbf{u}_0, 0)$, the following estimate holds for $1 \leq n \leq N$:*

$$(4.4) \quad \sum_{m=0}^{n-1} \delta t \|\bar{D}\mathbf{u}_h^{m+1}\|_H^2 + \|(\mathbf{u}_h^n, p_h^n)\|_h^2 \leq C \left(\|\mathbf{u}_0\|_V^2 + \sum_{m=0}^{n-1} \delta t \|\mathbf{f}(t_{m+1})\|_H^2 \right).$$

- *If $\mathbf{u}_0 \in [H^r(\Omega) \cap H_0^1(\Omega)]^d \cap H_0(\text{div}; \Omega)$, $r \geq 2$, and $\mathbf{u}_h^0 = \mathcal{I}_h^k \mathbf{u}_0$, the following estimate holds for $1 \leq n \leq N$:*

$$(4.5) \quad \sum_{m=0}^{n-1} \delta t \|\bar{D}\mathbf{u}_h^{m+1}\|_H^2 + \|(\mathbf{u}_h^n, p_h^n)\|_h^2 \leq C \left(\|\mathbf{u}_0\|_V^2 + \nu h^{2(r_u-1)} \|p_h^1\|_Q^2 + \|\mathbf{u}_0\|_{r_u, \Omega}^2 + \sum_{m=0}^{n-1} \delta t \|\mathbf{f}(t_{m+1})\|_H^2 \right),$$

with $r_u \stackrel{\text{def}}{=} \min\{k+1, r\}$.

Proof. For $0 \leq n \leq N-1$, by taking $\mathbf{v}_h = \bar{D}\mathbf{u}_h^{n+1}$ and $q_h = 0$ in (3.19) and using the Cauchy–Schwarz inequality, we have

$$(4.6) \quad \frac{1}{2} \|\bar{D}\mathbf{u}_h^{n+1}\|_H^2 + a(\mathbf{u}_h^{n+1}, \bar{D}\mathbf{u}_h^{n+1}) + b(p_h^{n+1}, \bar{D}\mathbf{u}_h^{n+1}) = \frac{1}{2} \|\mathbf{f}(t_{n+1})\|_H^2.$$

On the other hand, for $1 \leq n \leq N-1$, testing (3.19) at the time levels n and $n+1$ with $\mathbf{v}_h = \mathbf{0}$ and $q_h = p_h^{n+1}$, we have

$$(4.7) \quad \begin{aligned} b(p_h^{n+1}, \mathbf{u}_h^{n+1}) &= j(p_h^{n+1}, p_h^{n+1}), \\ b(p_h^{n+1}, \mathbf{u}_h^n) &= j(p_h^n, p_h^{n+1}). \end{aligned}$$

Therefore, by subtracting these equalities and using the bilinearity of $j(\cdot, \cdot)$, we obtain

$$(4.8) \quad b(p_h^{n+1}, \bar{D}\mathbf{u}_h^{n+1}) = j(\bar{D}p_h^{n+1}, p_h^{n+1})$$

for $1 \leq n \leq N-1$. It then follows from (4.6) that

$$(4.9) \quad \frac{1}{2} \|\bar{D}\mathbf{u}_h^{n+1}\|_H^2 + a(\mathbf{u}_h^{n+1}, \bar{D}\mathbf{u}_h^{n+1}) + j(p_h^{n+1}, \bar{D}p_h^{n+1}) \leq \frac{1}{2} \|\mathbf{f}(t_{n+1})\|_H^2.$$

On the other hand, using the symmetry and bilinearity of $a(\cdot, \cdot)$ and $j(\cdot, \cdot)$, we have

$$\begin{aligned} a(\mathbf{u}_h^{n+1}, \bar{D}\mathbf{u}_h^{n+1}) &= \frac{1}{2} \bar{D}a(\mathbf{u}_h^{n+1}, \mathbf{u}_h^{n+1}) + \frac{\delta t}{2} a(\bar{D}\mathbf{u}_h^{n+1}, \bar{D}\mathbf{u}_h^{n+1}), \\ j(p_h^{n+1}, \bar{D}p_h^{n+1}) &= \frac{1}{2} \bar{D}j(p_h^{n+1}, p_h^{n+1}) + \frac{\delta t}{2} j(\bar{D}p_h^{n+1}, \bar{D}p_h^{n+1}). \end{aligned}$$

Hence,

$$\|\bar{D}\mathbf{u}_h^{n+1}\|_H^2 + \bar{D}(a(\mathbf{u}_h^{n+1}, \mathbf{u}_h^{n+1}) + j(p_h^{n+1}, p_h^{n+1})) \leq \|\mathbf{f}(t_{n+1})\|_H^2$$

for $1 \leq n \leq N - 1$. After multiplication by δt and summation over $1 \leq m \leq n - 1$, it follows that

$$(4.10) \quad \sum_{m=1}^{n-1} \delta t \|\bar{D}\mathbf{u}_h^{m+1}\|_H^2 + \|(\mathbf{u}_h^n, p_h^n)\|_h^2 \leq \|(\mathbf{u}_h^1, p_h^1)\|_h^2 + \sum_{m=1}^{n-1} \delta t \|\mathbf{f}(t_{m+1})\|_H^2.$$

In order to highlight the impact of the initial velocity approximation on the stability of the time derivative, we consider now the first time level ($n = 0$) of (3.19). By testing with $\mathbf{v}_h = \bar{D}\mathbf{u}_h^1$, $q_h = 0$, after multiplication by $2\delta t$ and using the symmetry and bilinearity of $a(\cdot, \cdot)$, we get

$$(4.11) \quad \delta t \|\bar{D}\mathbf{u}_h^1\|_H^2 + a(\mathbf{u}_h^1, \mathbf{u}_h^1) - a(\mathbf{u}_h^0, \mathbf{u}_h^0) + 2\delta t b(p_h^1, \bar{D}\mathbf{u}_h^1) \leq \delta t \|\mathbf{f}(t_1)\|_H^2.$$

If the initial velocity approximation is given in terms of the Ritz-projection, $\mathbf{u}_h^0 = P_h^k(\mathbf{u}_0, 0)$ with $\mathbf{u}_0 \in [H^1(\Omega)]^d$, by setting $p_h^0 \stackrel{\text{def}}{=} R_h^l(\mathbf{u}_0, 0)$ it follows that (4.7) also holds for $n = 0$. Therefore,

$$(4.12) \quad b(p_h^1, \bar{D}\mathbf{u}_h^1) = j(\bar{D}p_h^1, p_h^1).$$

Thus, from the symmetry and bilinearity of $j(\cdot, \cdot)$ and (4.11), we have

$$(4.13) \quad \delta t \|\bar{D}\mathbf{u}_h^1\|_H^2 + \|(\mathbf{u}_h^1, p_h^1)\|_h^2 \leq \|(\mathbf{u}_h^0, p_h^0)\|_h^2 + \delta t \|\mathbf{f}(t_1)\|_H^2.$$

Estimate (4.4) is obtained by adding this last inequality to (4.10) and using the stability of the Ritz-projection (3.17), $\|(\mathbf{u}_h^0, p_h^0)\|_h^2 \leq C\|\mathbf{u}_0\|_V^2$.

If the initial velocity approximation is given in terms of a general interpolant, $\mathbf{u}_h^0 = \mathcal{I}_h^k \mathbf{u}_0$ with $\mathbf{u}_0 \in [H^r(\Omega) \cap H_0^1(\Omega)]^d \cap H_0(\text{div}; \Omega)$, equality (4.12) does not hold in general. Instead, we can use an approximation argument to obtain

$$(4.14) \quad \begin{aligned} b(p_h^1, \bar{D}\mathbf{u}_h^1) &= \frac{1}{\delta t} (j(p_h^1, p_h^1) - (p_h^1, \nabla \cdot (\mathcal{I}_h^k \mathbf{u}_0 - \mathbf{u}_0))) \\ &\geq \frac{1}{\delta t} j(p_h^1, p_h^1) - \frac{C_{\mathcal{I}}}{\delta t} (\nu h^{2(r_u-1)} \|p_h^1\|_Q^2 + \|\mathbf{u}_0\|_{r_u, \Omega}^2), \end{aligned}$$

with $r_u \stackrel{\text{def}}{=} \min\{k + 1, r\}$. As a result, from (4.11) it follows that

$$\delta t \|\bar{D}\mathbf{u}_h^1\|_H^2 + \|(\mathbf{u}_h^1, p_h^1)\|_h^2 \leq a(\mathbf{u}_h^0, \mathbf{u}_h^0) + C_{\mathcal{I}} (\nu h^{2(r_u-1)} \|p_h^1\|_Q^2 + \|\mathbf{u}_0\|_{r_u, \Omega}^2) + \delta t \|\mathbf{f}(t_1)\|_H^2.$$

We conclude the proof by adding this equality to (4.10) and using the stability of the Ritz-projection. \square

The next corollary solves the problem of the stability of the pressures by combining the results of Theorems 4.1 and 4.2.

COROLLARY 4.3. *Let $\{(\mathbf{u}_h^n, p_h^n)\}_{n=1}^N$ be the solution of the fully discrete problem (3.19). Then*

- if $\mathbf{u}_0 \in [H^1(\Omega)]^d$ and $\mathbf{u}_h^0 = P_h^k(\mathbf{u}_0, 0)$, the following estimate holds for $1 \leq n \leq N$:

$$(4.15) \quad \begin{aligned} \sum_{m=0}^{n-1} \delta t \|p_h^{m+1}\|_Q^2 &\leq \frac{C}{\beta^2 \nu} \|\mathbf{u}_0\|_V^2 \\ &+ \frac{C}{\beta^2} \sum_{m=0}^{n-1} \delta t \left(\|(\mathbf{u}_h^{m+1}, p_h^{m+1})\|_h^2 + \nu^{-1} \|\mathbf{f}(t_{m+1})\|_H^2 \right). \end{aligned}$$

- if $\mathbf{u}_0 \in [H^r(\Omega) \cap H_0^1(\Omega)]^d \cap H_0(\text{div}; \Omega)$, $r \geq 2$, $\mathbf{u}_h^0 = \mathcal{I}_h^k \mathbf{u}_0$, and

$$(4.16) \quad \frac{2C_{\mathcal{I}}}{\beta^2} h^{2(r_{\mathbf{u}}-1)} \leq \delta t,$$

the following estimate holds for $1 \leq n \leq N$:

$$(4.17) \quad \sum_{m=0}^{n-1} \delta t \|p_h^{m+1}\|_Q^2 \leq \frac{C}{\beta^2 \nu} (\|\mathbf{u}_0\|_V^2 + \|\mathbf{u}_0\|_{r_{\mathbf{u}}, \Omega}^2) \\ + \frac{C}{\beta^2} \sum_{m=0}^{n-1} \delta t \left(\|(\mathbf{u}_h^{m+1}, p_h^{m+1})\|_h^2 + \nu^{-1} \|\mathbf{f}(t_{m+1})\|_H^2 \right),$$

with $r_{\mathbf{u}} \stackrel{\text{def}}{=} \min\{k+1, r\}$.

Proof. Estimate (4.17) is a direct consequence of Theorem 4.1 and estimate (4.4). On the other hand, from Theorem 4.1 and estimate (4.5), we have

$$\left(\beta^2 \delta t - C_{\mathcal{I}} h^{2(r_{\mathbf{u}}-1)} \right) \|p_h^1\|_Q^2 + \beta^2 \sum_{m=1}^{n-1} \delta t \|p_h^{m+1}\|_Q^2 \\ \leq \frac{C}{\nu} (\|\mathbf{u}_0\|_V^2 + \|\mathbf{u}_0\|_{r_{\mathbf{u}}, \Omega}^2) + C \sum_{m=0}^{n-1} \delta t \left(\|(\mathbf{u}_h^{m+1}, p_h^{m+1})\|_h^2 + \nu^{-1} \|\mathbf{f}(t_{m+1})\|_H^2 \right),$$

which combined with the stability condition (4.16) leads to (4.17). \square

A few observations are now in order. Corollary 4.3 states the unconditional stability of the pressure provided the initial velocity approximation \mathbf{u}_h^0 is given in terms of the Ritz-projection operator (3.16). In the general case, i.e., whenever \mathbf{u}_h^0 does not satisfy a discrete divergence-free condition (as \mathbf{u}_h^1 does), only conditional stability can be guaranteed. As a matter of fact, from the stability condition (4.16), pressure instabilities are expected for very small time steps. This issue will be illustrated by numerical experiments in section 6.

Finally, let us mention that residual-based stabilization methods, such as PSPG and GLS, combined with finite difference time discretization schemes, are known to give rise to pressure instabilities in the small time-step limit; see [3, 19]. Indeed, it has been shown in [3] that the finite difference/pressure coupling of the stabilization perturbs the coercivity of the discrete pressure operator unless a condition of the type

$$(4.18) \quad Ch^2 \leq \delta t$$

is satisfied. It is worth emphasizing that, although the stability conditions (4.18) and (4.16) are somehow similar, their natures are different. Actually, the instabilities anticipated by Corollary 4.3 are related to the discrete divergence-free character of the initial velocity approximation, but not to the structure of the pressure stabilization $j(\cdot, \cdot)$.

4.2. Second order \mathcal{A} -stable schemes. In this subsection we discuss how the results of Theorems 4.1 and 4.2 and Corollary 4.3 extend to the second order time-stepping schemes Crank–Nicholson and BDF2.

Crank–Nicholson. The following theorem summarizes the resulting stability estimates.

THEOREM 4.4. *Let \mathbf{u}_h^0 be a given H -stable approximation of \mathbf{u}_0 in $[V_h^k]^d$, and let $\{(\mathbf{u}_h^n, p_h^n)\}_{n=1}^N$ be the solution of the discrete scheme (3.20). Then the following estimate holds for $1 \leq n \leq N$:*

$$\|\mathbf{u}_h^n\|_H^2 + \sum_{m=0}^{n-1} \delta t \|(\mathbf{u}_h^{m+\frac{1}{2}}, p_h^{m+\frac{1}{2}})\|_h^2 \leq C \|\mathbf{u}_0\|_H^2 + \frac{C_P^2}{\nu} \sum_{m=0}^{n-1} \delta t \|\mathbf{f}(t_{m+\frac{1}{2}})\|_H^2.$$

Moreover, if $\mathbf{u}_0 \in [H^1(\Omega)]^d$ and $\mathbf{u}_h^0 = P_h^k(\mathbf{u}_0, 0)$, the following estimate holds for $1 \leq n \leq N$:

$$\sum_{m=0}^{n-1} \delta t \|p_h^{m+\frac{1}{2}}\|_Q^2 \leq \frac{C}{\beta^2 \nu} \|\mathbf{u}_0\|_V^2 + \frac{C}{\beta^2} \sum_{m=0}^{n-1} \delta t \left(\|(\mathbf{u}_h^{m+\frac{1}{2}}, p_h^{m+\frac{1}{2}})\|_h^2 + \nu^{-1} \|\mathbf{f}(t_{m+\frac{1}{2}})\|_H^2 \right).$$

On the other hand, if $\mathbf{u}_0 \in [H^r(\Omega) \cap H_0^1(\Omega)]^d \cap H_0(\operatorname{div}; \Omega)$, $r \geq 2$, $\mathbf{u}_h^0 = \mathcal{I}_h^k \mathbf{u}_0$, and the stability condition (4.16) is satisfied, the following estimate holds for $1 \leq n \leq N$:

$$\begin{aligned} \sum_{m=0}^{n-1} \delta t \|p_h^{m+\frac{1}{2}}\|_Q^2 &\leq \frac{C}{\beta^2 \nu} (\|\mathbf{u}_0\|_V^2 + \|\mathbf{u}_0\|_{r_u, \Omega}^2) \\ &\quad + \frac{C}{\beta^2} \sum_{m=0}^{n-1} \delta t \left(\|(\mathbf{u}_h^{m+\frac{1}{2}}, p_h^{m+\frac{1}{2}})\|_h^2 + \nu^{-1} \|\mathbf{f}(t_{m+\frac{1}{2}})\|_H^2 \right). \end{aligned}$$

Proof. The first estimate, corresponding to Theorem 4.1, holds by taking $\mathbf{v}_h = \mathbf{u}_h^{n+\frac{1}{2}}$ and $q_h = p_h^{n+\frac{1}{2}}$ in (3.20).

The pressure estimate requires an a priori bound of the discrete velocity time derivative. As in Theorem 4.2, such an estimate can be obtained by taking $\mathbf{v}_h = \bar{D}\mathbf{u}_h^{n+1}$ and $q_h = 0$ in (3.20) for $0 \leq n \leq N-1$. The main difference, with respect to the proof of Theorem 4.2, arises in the treatment of the coupling term $b(p_h^{n+\frac{1}{2}}, \bar{D}\mathbf{u}_h^{n+1})$. Indeed, in the Crank–Nicholson scheme incompressibility is enforced on $\mathbf{u}_h^{n+\frac{1}{2}}$ instead of \mathbf{u}_h^{n+1} . We first note that, since

$$\mathbf{u}_h^{n+1} - \mathbf{u}_h^n = 2 \left(\mathbf{u}_h^{n+\frac{1}{2}} - \mathbf{u}_h^n \right), \quad \mathbf{u}_h^n = 2\mathbf{u}_h^{n-1+\frac{1}{2}} - \mathbf{u}_h^{n-1},$$

we have

$$\mathbf{u}_h^{n+1} - \mathbf{u}_h^n = 2\mathbf{u}_h^{n+\frac{1}{2}} + 4 \sum_{l=1}^n (-1)^l \mathbf{u}_h^{n-l+\frac{1}{2}} - (-1)^n 2\mathbf{u}_h^0$$

for $0 \leq n \leq N-1$. Therefore, from (3.20) and using the bilinearity of $j(\cdot, \cdot)$, we get

$$\begin{aligned} (4.19) \quad b(p_h^{n+\frac{1}{2}}, \mathbf{u}_h^{n+1} - \mathbf{u}_h^n) &= j \left(2p_h^{n+\frac{1}{2}} + 4 \sum_{l=1}^n (-1)^l p_h^{n-l+\frac{1}{2}}, p_h^{n+\frac{1}{2}} \right) \\ &\quad - 2(-1)^n b(p_h^{n+\frac{1}{2}}, \mathbf{u}_h^0). \end{aligned}$$

On the other hand, for $0 \leq n \leq N - 1$, we introduce the following change of variables (or extrapolation):

$$\frac{1}{2} (p_h^{n+1} + p_h^n) \stackrel{\text{def}}{=} p_h^{n+\frac{1}{2}},$$

with $p_h^0 \in Q_h^l$ to be specified later on. By inserting this expression into (4.19), we obtain

$$(4.20) \quad \begin{aligned} b(p_h^{n+\frac{1}{2}}, \mathbf{u}_h^{n+1} - \mathbf{u}_h^n) &= j(p_h^{n+1} - p_h^n, p_h^{n+\frac{1}{2}}) \\ &+ 2(-1)^n \left[j(p_h^0, p_h^{n+\frac{1}{2}}) - b(p_h^{n+\frac{1}{2}}, \mathbf{u}_h^0) \right]. \end{aligned}$$

If $\mathbf{u}_h^0 = P_h^k(\mathbf{u}_0, 0)$ and we choose $p_h^0 \stackrel{\text{def}}{=} R_h^l(\mathbf{u}_0, 0)$, from (3.16)₂ it follows that the last term in (4.20) cancels. Thus, we have

$$\begin{aligned} b(p_h^{n+\frac{1}{2}}, \bar{D}\mathbf{u}_h^{n+1}) &= j(\bar{D}p_h^{n+1}, p_h^{n+\frac{1}{2}}) \\ &= \frac{1}{2} \bar{D}j(p_h^{n+1}, p_h^{n+1}), \end{aligned}$$

which corresponds to the Crank–Nicholson counterpart of (4.8).

Finally, when the initial velocity approximation is given in terms of a general interpolant, $\mathbf{u}_h^0 = \mathcal{I}_h^k \mathbf{u}_0$ with $\mathbf{u}_0 \in [H^r(\Omega) \cap H_0^1(\Omega)]^d \cap H_0(\text{div}; \Omega)$, we take $p_h^0 \stackrel{\text{def}}{=} 0$. Therefore, from (4.20) and using an approximation argument (as in (4.14)), we get

$$(4.21) \quad \begin{aligned} b(p_h^{n+\frac{1}{2}}, \bar{D}\mathbf{u}_h^{n+1}) &= \frac{1}{2} \bar{D}j(p_h^{n+1}, p_h^{n+1}) - \frac{2}{\delta t} (-1)^n b(p_h^{n+\frac{1}{2}}, \mathbf{u}_h^0) \\ &\geq \frac{1}{2} \bar{D}j(p_h^{n+1}, p_h^{n+1}) \\ &\quad - \frac{2C_{\mathcal{I}}}{\delta t} \left(\nu h^{2(r_u-1)} \|p_h^{n+\frac{1}{2}}\|_Q^2 + \|\mathbf{u}_0\|_{r_u, \Omega}^2 \right), \end{aligned}$$

which leads to the stability condition (4.16). The rest of the proof follows with minor modifications. \square

Remark 4.5. By comparing the proofs of Corollary 4.3 and the previous theorem, we can notice that, if the initial velocity approximation is not discretely divergence free, the stability condition (4.16) has to be satisfied at each time level when using the Crank–Nicholson scheme (due to (4.21)), whereas for the backward Euler scheme that condition is needed only at the first time step (thanks to (4.8) and (4.14)).

BDF2. The following theorem summarizes the resulting stability estimates.

THEOREM 4.6. *Let \mathbf{u}_h^0 be a given H -stable approximation of \mathbf{u}_0 in $[V_h^k]^d$, let (u_h^1, p_h^1) be the corresponding first time step of the backward Euler scheme (3.19), and let $\{(\mathbf{u}_h^n, p_h^n)\}_{n=2}^N$ be the solution of the discrete scheme (3.21). Then, the following estimate holds for $2 \leq n \leq N$:*

$$\|\mathbf{u}_h^n\|_H^2 + 2 \sum_{m=1}^{n-1} \delta t \|(\mathbf{u}_h^{m+1}, p_h^{m+1})\|_h^2 \leq C (\|\mathbf{u}_0\|_H^2 + \|\mathbf{u}_h^1\|_H^2) + \frac{2C_{\text{P}}^2}{\nu} \sum_{m=1}^{n-1} \delta t \|\mathbf{f}(t_{m+1})\|_H^2.$$

Moreover, if $\mathbf{u}_0 \in [H^1(\Omega)]^d$ and $\mathbf{u}_h^0 = P_h^k(\mathbf{u}_0, 0)$, the following estimate holds for $2 \leq n \leq N$:

$$\begin{aligned} \sum_{m=1}^{n-1} \delta t \|p_h^{m+1}\|_Q^2 &\leq \frac{C}{\beta^2 \nu} \left(\|\mathbf{u}_0\|_V^2 + \|(\mathbf{u}_h^1, p_h^1)\|_h^2 \right) \\ &\quad + \frac{C}{\beta^2} \sum_{m=1}^{n-1} \delta t \left(\|(\mathbf{u}_h^{m+1}, p_h^{m+1})\|_h^2 + \nu^{-1} \|\mathbf{f}(t_{m+1})\|_H^2 \right). \end{aligned}$$

On the other hand, if $\mathbf{u}_0 \in [H^r(\Omega) \cap H_0^1(\Omega)]^d \cap H_0(\operatorname{div}; \Omega)$, $r \geq 2$, $\mathbf{u}_h^0 = \mathcal{I}_h^k \mathbf{u}_0$, and the stability condition (4.16) is satisfied, the following estimate holds for $2 \leq n \leq N$:

$$\begin{aligned} \sum_{m=1}^{n-1} \delta t \|p_h^{m+1}\|_Q^2 &\leq \frac{C}{\beta^2 \nu} \left(\|\mathbf{u}_0\|_V^2 + \|\mathbf{u}_0\|_{r, \Omega}^2 + \|(\mathbf{u}_h^1, p_h^1)\|_h^2 \right) \\ &\quad + \frac{C}{\beta^2} \sum_{m=1}^{n-1} \delta t \left(\|(\mathbf{u}_h^{m+1}, p_h^{m+1})\|_h^2 + \nu^{-1} \|\mathbf{f}(t_{m+1})\|_H^2 \right). \end{aligned}$$

Proof. The first estimate, corresponding to Theorem 4.1, holds by taking $\mathbf{v}_h = \mathbf{u}_h^{n+1}$ and $q_h = p_h^{n+1}$ in (3.21) and applying the standard identity

$$(4.22) \quad (3a - 4b + c)a = \frac{1}{2} [a^2 - b^2 + (2a - b)^2 - (2b - c)^2 + (a - 2b + c)^2],$$

which provides the numerical dissipation of the BDF2 scheme.

Since the pressure estimate is here based on the control of the time derivative, $\tilde{D}\mathbf{u}_h^{n+1}$, we take $\mathbf{v}_h = \tilde{D}\mathbf{u}_h^{n+1}$ and $q_h = 0$ in (3.21). In particular, for the coupling term $b(p_h^{n+1}, \tilde{D}\mathbf{u}_h^{n+1})$, using (3.21) and (4.22), we have

$$(4.23) \quad \begin{aligned} b(p_h^{n+1}, \tilde{D}\mathbf{u}_h^{n+1}) &= j(\tilde{D}p_h^{n+1}, p_h^{n+1}) \\ &\geq \frac{1}{4} \bar{D} (j(p_h^{n+1}, p_h^{n+1}) + j(2p_h^{n+1} - p_h^n, 2p_h^{n+1} - p_h^n)) \end{aligned}$$

for $2 \leq n \leq N - 1$, which corresponds to the BDF2 counterpart of (4.8). On the other hand, for $n = 1$, from (3.21) and (3.19), we obtain

$$(4.24) \quad b(p_h^2, \tilde{D}\mathbf{u}_h^2) = \frac{1}{2\delta t} (3j(p_h^2, p_h^2) - 4j(p_h^1, p_h^2) + b(p_h^2, \mathbf{u}_h^0)).$$

If the initial velocity approximation is given in terms of the Ritz-projection, $\mathbf{u}_h^0 = P_h^k(\mathbf{u}_0, 0)$, it follows that $b(p_h^2, \mathbf{u}_h^0) = j(p_h^0, p_h^2)$, with $p_h^0 \stackrel{\text{def}}{=} R_h^l(\mathbf{u}_0, 0)$. Thus, (4.24) reduces to

$$b(p_h^2, \tilde{D}\mathbf{u}_h^2) = j(\tilde{D}p_h^2, p_h^2),$$

so that (4.23) holds true also for $n = 1$.

Finally, if the initial velocity approximation is given in terms of a general interpolant, $\mathbf{u}_h^0 = \mathcal{I}_h^k \mathbf{u}_0$, we apply an approximation argument (as in (4.14)). Hence,

from (4.24)

(4.25)

$$b\left(p_h^2, \tilde{D}\mathbf{u}_h^2\right) \geq \frac{1}{2\delta t} \left[3j(p_h^2, p_h^2) - 4j(p_h^1, p_h^1) - C_{\mathcal{I}} \left(\nu h^{2(r_{\mathbf{u}}-1)} \|p_h^2\|_Q^2 + \|\mathbf{u}_0\|_{r_{\mathbf{u}}, \Omega}^2 \right) \right],$$

which is the BDF2 counterpart of (4.14) and leads to the stability condition (4.16). The rest of the proof follows with minor modifications. \square

Remark 4.7. A bound for the backward Euler initialization terms $\|\mathbf{u}_h^1\|_H$ and $\|(\mathbf{u}_h^1, p_h^1)\|_h$, appearing in the above estimates, is provided by Theorems 4.1 and 4.2 with $n = 1$.

Remark 4.8. When the initial velocity approximation is not discretely divergence free, the stability condition (4.16) has to be satisfied twice when using BDF2, at the first time step (according to (4.25)) and at the backward Euler initialization (see Theorem 4.2).

5. Convergence. In this section we provide optimal convergence error estimates for the discrete formulation (3.19), the backward Euler scheme.

Theorem 5.2 concerns the convergence for the velocity and gives an estimate for the pressure in terms of the error in the velocity time derivative. Theorem 5.3 answers the question of optimal convergence of the pressure by providing an optimal error estimate for the time derivative, provided the exact pressure is smooth. Finally, Theorem 5.4 provides an improved $L^\infty((0, T), H)$ estimate that justifies the initialization of the BDF2 scheme with a backward Euler step.

The following result expresses the modified Galerkin orthogonality in terms of the consistency error in space and time.

LEMMA 5.1 (consistency error). *Let (\mathbf{u}, p) be the solution of (2.1) and let $\{(\mathbf{u}_h^n, p_h^n)\}_{0 \leq n \leq N}$ be the solution of (3.19). Assume that $\mathbf{u} \in C^0([0, T]; V) \cap C^1((0, T]; H)$, and let $p \in C^0((0, T]; Q)$. Then, for $0 \leq n \leq N - 1$, there holds*

$$\begin{aligned} & (\bar{D}\mathbf{u}(t_{n+1}) - \bar{D}\mathbf{u}_h^{n+1}, \mathbf{v}_h) + a(\mathbf{u}(t_{n+1}) - \mathbf{u}_h^{n+1}, \mathbf{v}_h) + b(p(t_{n+1}) - p_h^{n+1}, \mathbf{v}_h) \\ & - b(q_h, \mathbf{u}(t_{n+1}) - \mathbf{u}_h^{n+1}) = j(p_h^{n+1}, q_h) + (\bar{D}\mathbf{u}(t_{n+1}) - \partial_t \mathbf{u}(t_{n+1}), \mathbf{v}_h) \end{aligned}$$

for all $(\mathbf{v}_h, q_h) \in [V_h^k]^d \times Q_h^l$.

THEOREM 5.2. *Assume that $\mathbf{u} \in H^1(0, T; [H^r(\Omega)]^d) \cap H^2(0, T; [L^2(\Omega)]^d)$ and $p \in C^0((0, T]; H^s(\Omega))$ with $r \geq 2$ and $s \geq 1$, and set $\mathbf{u}_h^0 \in [V_h^k]^d$ as a given approximation of \mathbf{u}_0 . Then the following estimate holds for $1 \leq n \leq N$:*

$$\begin{aligned} \|\mathbf{u}_h^n - \mathbf{u}(t_n)\|_H^2 &+ \sum_{m=0}^{n-1} \delta t \|(\mathbf{u}_h^{m+1} - \mathbf{u}(t_{m+1}), p_h^{m+1})\|_h^2 \leq \|\mathcal{I}_h^k \mathbf{u}_0 - \mathbf{u}_h^0\|_H^2 \\ &+ Ch^{2r_{\mathbf{u}}} \left(\|\mathbf{u}\|_{C^0([t_1, t_n]; H^{r_{\mathbf{u}}}(\Omega))}^2 + \nu^{-1} \|\partial_t \mathbf{u}\|_{L^2(0, t_n; H^{r_{\mathbf{u}}}(\Omega))}^2 \right) \\ &+ C \left(\frac{\delta t^2}{\nu} \|\partial_{tt} \mathbf{u}\|_{L^2(0, t_n; H)}^2 + \frac{h^{2s_p}}{\nu} t_n \|p\|_{C^0([t_1, t_n]; H^{s_p}(\Omega))}^2 \right. \\ &\quad \left. + \nu h^{2(r_{\mathbf{u}}-1)} t_n \|\mathbf{u}\|_{C^0([t_1, t_n]; H^{r_{\mathbf{u}}}(\Omega))}^2 \right), \end{aligned}$$

$$\begin{aligned} \sum_{m=0}^{n-1} \delta t \|p_h^{m+1} - p(t_{m+1})\|_Q^2 &\leq C \left(1 + \frac{1}{\beta^2}\right) \frac{h^{2s_p}}{\nu} t_n \|p\|_{C^0([t_1, t_n]; H^{s_p}(\Omega))}^2 \\ &+ \frac{C}{\beta^2} \sum_{m=0}^{n-1} \delta t \left(\|(\mathbf{u}_h^{m+1} - \mathbf{u}(t_{m+1}), p_h^{m+1})\|_h^2 + \nu^{-1} \|\partial_t \mathbf{u}(t_{m+1}) - \bar{D}\mathbf{u}_h^{m+1}\|_H^2 \right), \end{aligned}$$

with $C > 0$ a positive constant independent of h , δt , and ν .

Proof. The error estimate for the velocity follows standard energy arguments, and for the pressure we use the modified inf-sup condition (3.8). We start by decomposing the velocity and pressure error using, respectively, the projections \mathcal{I}_h^k and Π_h^l . This yields

$$\begin{aligned} \mathbf{u}(t_{n+1}) - \mathbf{u}_h^{n+1} &= \underbrace{\mathbf{u}(t_{n+1}) - \mathcal{I}_h^k \mathbf{u}(t_{n+1})}_{\boldsymbol{\theta}_\pi^{n+1}} + \underbrace{\mathcal{I}_h^k \mathbf{u}(t_{n+1}) - \mathbf{u}_h^{n+1}}_{\boldsymbol{\theta}_h^{n+1}} = \boldsymbol{\theta}_\pi^{n+1} + \boldsymbol{\theta}_h^{n+1}, \\ (5.1) \quad p(t_{n+1}) - p_h^{n+1} &= \underbrace{p(t_{n+1}) - \Pi_h^l p(t_{n+1})}_{y_\pi^{n+1}} + \underbrace{\Pi_h^l p(t_{n+1}) - p_h^{n+1}}_{y_h^{n+1}} = y_\pi^{n+1} + y_h^{n+1}. \end{aligned}$$

The first term $\boldsymbol{\theta}_\pi^{n+1}$ can be bounded using approximation (3.5). In order to estimate $\boldsymbol{\theta}_h^{n+1}$ we first note, using (4.3) and the coercivity of the bilinear form $a(\cdot, \cdot) + j(\cdot, \cdot)$,

$$\begin{aligned} (5.2) \quad \frac{1}{2} \bar{D} \|\boldsymbol{\theta}_h^{n+1}\|_H^2 + \|(\boldsymbol{\theta}_h^{n+1}, y_h^{n+1})\|_h^2 &\leq (\bar{D}\boldsymbol{\theta}_h^{n+1}, \boldsymbol{\theta}_h^{n+1}) + \|(\boldsymbol{\theta}_h^{n+1}, y_h^{n+1})\|_h^2 \\ &\leq \underbrace{(\bar{D}\boldsymbol{\theta}_h^{n+1}, \boldsymbol{\theta}_h^{n+1}) + a(\boldsymbol{\theta}_h^{n+1}, \boldsymbol{\theta}_h^{n+1}) + b(y_h^{n+1}, \boldsymbol{\theta}_h^{n+1}) - b(y_h^{n+1}, \boldsymbol{\theta}_h^{n+1}) + j(y_h^{n+1}, y_h^{n+1})}_{T_1^{n+1}}. \end{aligned}$$

In addition, using (5.1) we have

$$\begin{aligned} T_1^{n+1} &= -(\bar{D}\boldsymbol{\theta}_\pi^{n+1}, \boldsymbol{\theta}_h^{n+1}) - a(\boldsymbol{\theta}_\pi^{n+1}, \boldsymbol{\theta}_h^{n+1}) + j(\Pi_h^l p(t_{n+1}), y_h^{n+1}) - b(y_\pi^{n+1}, \boldsymbol{\theta}_h^{n+1}) \\ &\quad + b(y_h^{n+1}, \boldsymbol{\theta}_\pi^{n+1}) + (\bar{D}\mathbf{u}(t_{n+1}) - \bar{D}\mathbf{u}_h^{n+1}, \boldsymbol{\theta}_h^{n+1}) + a(\mathbf{u}(t_{n+1}) - \mathbf{u}_h^{n+1}, \boldsymbol{\theta}_h^{n+1}) \\ &\quad + b(p(t_{n+1}) - p_h^{n+1}, \boldsymbol{\theta}_h^{n+1}) - b(y_h^{n+1}, \mathbf{u}(t_{n+1}) - \mathbf{u}_h^{n+1}) - j(p_h^{n+1}, y_h^{n+1}). \end{aligned}$$

By the modified Galerkin orthogonality (Lemma 5.1), this expression reduces to

$$\begin{aligned} (5.3) \quad T_1^{n+1} &= -(\bar{D}\boldsymbol{\theta}_\pi^{n+1}, \boldsymbol{\theta}_h^{n+1}) + (\bar{D}\mathbf{u}(t_{n+1}) - \partial_t \mathbf{u}(t_{n+1}), \boldsymbol{\theta}_h^{n+1}) \\ &\quad - a(\boldsymbol{\theta}_\pi^{n+1}, \boldsymbol{\theta}_h^{n+1}) + j(\Pi_h^l p(t_{n+1}), y_h^{n+1}) - b(y_\pi^{n+1}, \boldsymbol{\theta}_h^{n+1}) + b(y_h^{n+1}, \boldsymbol{\theta}_\pi^{n+1}). \end{aligned}$$

Now, using the Cauchy–Schwarz and the Poincaré inequalities and (3.6), we have

$$\begin{aligned} (5.4) \quad T_1^{n+1} &\leq \underbrace{\left(\|\bar{D}\mathbf{u}(t_{n+1}) - \partial_t \mathbf{u}(t_{n+1})\|_H + \|\bar{D}\boldsymbol{\theta}_\pi^{n+1}\|_H \right)}_{T_2^{n+1}} \frac{C_P}{\nu^{\frac{1}{2}}} \|(\boldsymbol{\theta}_h^{n+1}, y_h^{n+1})\| \\ &\quad + \left(\|\boldsymbol{\theta}_\pi^{n+1}\|_V + \|y_\pi^{n+1}\|_Q + \nu^{\frac{1}{2}} \|h^{-1} \boldsymbol{\theta}_\pi^{n+1}\|_H \right. \\ &\quad \left. + j(\Pi_h^l p(t_{n+1}), \Pi_h^l p(t_{n+1}))^{\frac{1}{2}} \right) \|(\boldsymbol{\theta}_h^{n+1}, y_h^{n+1})\|. \end{aligned}$$

The term T_2^{n+1} can be treated, in a standard way (see, e.g., [30]), using a Taylor expansion and the Cauchy–Schwarz inequality, which yields

$$(5.5) \quad \begin{aligned} T_2^{n+1} &\leq \frac{1}{\delta t} \int_{t_n}^{t_{n+1}} (\delta t \|\partial_{tt} \mathbf{u}(s)\|_H + \|\partial_t \boldsymbol{\theta}_\pi(s)\|_H) ds \\ &\leq \delta t^{\frac{1}{2}} \|\partial_{tt} \mathbf{u}(s)\|_{L^2((t_n, t_{n+1}); H)} + \delta t^{-\frac{1}{2}} \|\partial_t \boldsymbol{\theta}_\pi\|_{L^2((t_n, t_{n+1}); H)}. \end{aligned}$$

Thus, from (5.4), using Young’s inequality, it follows that

$$\begin{aligned} T_1^{n+1} &\leq \frac{1}{2} \|(\boldsymbol{\theta}_h^{n+1}, y_h^{n+1})\|_h^2 \\ &\quad + C \left[\frac{C_P^2}{\nu} \left(\delta t \|\partial_{tt} \mathbf{u}\|_{L^2((t_n, t_{n+1}); H)}^2 + \delta t^{-1} \|\partial_t \boldsymbol{\theta}_\pi\|_{L^2((t_n, t_{n+1}); H)}^2 \right) \right. \\ &\quad \left. + \|\boldsymbol{\theta}_\pi^{n+1}\|_V^2 + \|y_\pi^{n+1}\|_Q^2 + \nu \|h^{-1} \boldsymbol{\theta}_\pi^{n+1}\|_H^2 + j(\Pi_h^l p(t_{n+1}), \Pi_h^l p(t_{n+1})) \right]. \end{aligned}$$

By inserting this expression into (5.2), multiplying the resulting expression by $2\delta t$, and summing over $0 \leq m \leq n-1$, we obtain

$$\begin{aligned} &\|\boldsymbol{\theta}_h^n\|_H^2 + \sum_{m=0}^{n-1} \delta t \|(\boldsymbol{\theta}_h^{m+1}, y_h^{m+1})\|_h^2 \\ &\leq \|\boldsymbol{\theta}_h^0\|_H^2 + C \left[\delta t^2 \nu^{-1} \|\partial_{tt} \mathbf{u}\|_{L^2(0, t_n; H)}^2 + \nu^{-1} \|\partial_t \boldsymbol{\theta}_\pi\|_{L^2(0, t_n; H)}^2 \right. \\ &\quad \left. + \sum_{m=0}^{n-1} \delta t \left(\|\boldsymbol{\theta}_\pi^{m+1}\|_V^2 + \|y_\pi^{m+1}\|_Q^2 + \nu \|h^{-1} \boldsymbol{\theta}_\pi^{m+1}\|_H^2 + j(\Pi_h^l p(t_{m+1}), \Pi_h^l p(t_{m+1})) \right) \right]. \end{aligned}$$

Finally, the velocity error estimate is obtained using approximation (3.5) and the consistency of the pressure stabilization (3.3), which yields

$$\begin{aligned} &\|\boldsymbol{\theta}_h^n\|_H^2 + \sum_{m=0}^{n-1} \delta t \|(\boldsymbol{\theta}_h^{m+1}, y_h^{m+1})\|_h^2 \leq \|\boldsymbol{\theta}_h^0\|_H^2 \\ &\quad + C \left[\frac{\delta t^2}{\nu} \|\partial_{tt} \mathbf{u}\|_{L^2(0, t_n; H)}^2 + \frac{h^{2r_u}}{\nu} \|\partial_t \mathbf{u}\|_{L^2(0, t_n; H^{r_u}(\Omega))}^2 \right. \\ &\quad \left. + \nu h^{2(r_u-1)} \sum_{m=0}^{n-1} \delta t \|\mathbf{u}(t_{m+1})\|_{r_u, \Omega}^2 + \frac{h^{2s_p}}{\nu} \sum_{m=0}^{n-1} \delta t \|p(t_{m+1})\|_{s_p, \Omega}^2 \right]. \end{aligned}$$

For the pressure error estimate we first note that, from (5.1), it suffices to control $\|y_h^{n+1}\|_{0, \Omega}$. To this end, we use the modified inf-sup condition (3.8):

$$(5.6) \quad \beta \|y_h^{n+1}\|_Q \leq \sup_{\mathbf{v}_h \in [V_h^k]^d} \frac{|b(y_h^{n+1}, \mathbf{v}_h)|}{\|\mathbf{v}_h\|_V} + C j(y_h^{n+1}, y_h^{n+1})^{\frac{1}{2}}.$$

From (5.1) we get

$$b(y_h^{n+1}, \mathbf{v}_h) = -b(y_\pi^{n+1}, \mathbf{v}_h) + b(p(t_{n+1}) - p_h^{n+1}, \mathbf{v}_h).$$

The first term can be bounded, using the continuity of $b(\cdot, \cdot)$ (see (2.3)), which yields

$$b(y_\pi^{n+1}, \mathbf{v}_h) \leq \|y_\pi^{n+1}\|_Q \|\mathbf{v}_h\|_V.$$

On the other hand, using the modified Galerkin orthogonality (Lemma 5.1 with $q_h = 0$) we have

$$\begin{aligned} & b(p(t_{n+1}) - p_h^{n+1}, \mathbf{v}_h) \\ &= -a(\mathbf{u}(t_{n+1}) - \mathbf{u}_h^{n+1}, \mathbf{v}_h) - (\partial_t \mathbf{u}(t_{n+1}) - \bar{D}\mathbf{u}_h^{n+1}, \mathbf{v}_h) \\ &\leq C \|(\mathbf{u}(t_{n+1}) - \mathbf{u}_h^{n+1}, 0)\|_h \|\mathbf{v}_h\|_V + \|\partial_t \mathbf{u}(t_{n+1}) - \bar{D}\mathbf{u}_h^{n+1}\|_H \|\mathbf{v}_h\|_H. \end{aligned}$$

As a result, from the above estimations we have

$$\beta \|y_h^{n+1}\|_Q \leq C (\|y_\pi^{n+1}\|_Q + \|(\mathbf{u}(t_{n+1}) - \mathbf{u}_h^{n+1}, y_h^{n+1})\|_h) + \frac{C_P}{\nu^{\frac{1}{2}}} \|\partial_t \mathbf{u}(t_{n+1}) - \bar{D}\mathbf{u}_h^{n+1}\|_H.$$

Therefore,

$$\begin{aligned} \beta^2 \sum_{m=0}^{n-1} \delta t \|y_h^{m+1}\|_Q^2 &\leq C \sum_{m=0}^{n-1} \delta t \left(\|y_\pi^{m+1}\|_Q^2 + \|(\mathbf{u}(t_{m+1}) - \mathbf{u}_h^{m+1}, y_h^{m+1})\|_h^2 \right. \\ &\quad \left. + \nu^{-1} \|\partial_t \mathbf{u}(t_{m+1}) - \bar{D}\mathbf{u}_h^{m+1}\|_H^2 \right), \end{aligned}$$

and we conclude using approximation and the error estimate for the velocity. \square

We solve the problem of the pressure convergence by providing an error estimate for the time derivative of the velocity.

THEOREM 5.3. *Under the assumptions of Theorem 5.2, assuming that $p \in C^0([0, T]; H^s(\Omega))$, $\mathbf{u}_0 \in V \cap H_0(\text{div}; \Omega)$, and $\mathbf{u}_h^0 \stackrel{\text{def}}{=} P_h^k(\mathbf{u}_0, 0)$, for $1 \leq n \leq N$ we have*

$$\begin{aligned} & \sum_{m=0}^{n-1} \delta t \|\bar{D}\mathbf{u}_h^{m+1} - \partial_t \mathbf{u}(t_{m+1})\|_H^2 + \|(P_h^k(\mathbf{u}(t_n), p(t_n)) - \mathbf{u}_h^n, R_h^l(\mathbf{u}(t_n), p(t_n)) - p_h^n)\|_h^2 \\ & \leq C \left(\delta t^2 \|\partial_t \mathbf{u}\|_{L^2(0, T; H)}^2 + h^{2r_u} \|\partial_t \mathbf{u}\|_{L^2(0, T; H^{r_u}(\Omega))}^2 \right) + C \frac{h^{2s_p}}{\nu} \|p(0)\|_{s_p, \Omega}^2. \end{aligned}$$

Proof. In order to provide an optimal error estimate, we decompose the error in terms of the Ritz-projection operator (3.16) as follows:

(5.7)

$$\begin{aligned} \mathbf{u}(t_{n+1}) - \mathbf{u}_h^{n+1} &= \underbrace{\mathbf{u}(t_{n+1}) - P_h^k(\mathbf{u}(t_{n+1}), p(t_{n+1}))}_{\boldsymbol{\theta}_\pi^{n+1}} + \underbrace{P_h^k(\mathbf{u}(t_{n+1}), p(t_{n+1})) - \mathbf{u}_h^{n+1}}_{\boldsymbol{\theta}_h^{n+1}} \\ &= \boldsymbol{\theta}_\pi^{n+1} + \boldsymbol{\theta}_h^{n+1}, \\ p(t_{n+1}) - p_h^{n+1} &= \underbrace{p(t_{n+1}) - R_h^l(\mathbf{u}(t_{n+1}), p(t_{n+1}))}_{y_\pi^{n+1}} + \underbrace{R_h^l(\mathbf{u}(t_{n+1}), p(t_{n+1})) - p_h^{n+1}}_{y_h^{n+1}} \\ &= y_\pi^{n+1} + y_h^{n+1}. \end{aligned}$$

Using the triangle inequality, we then have

$$(5.8) \quad \sum_{m=0}^{n-1} \delta t \|\partial_t \mathbf{u}(t_{m+1}) - \bar{D}\mathbf{u}_h^{m+1}\|_H^2 \\ \leq C \sum_{m=0}^{n-1} \delta t (\|\partial_t \mathbf{u}(t_{m+1}) - \bar{D}\mathbf{u}(t_{m+1})\|_H^2 + \|\bar{D}\boldsymbol{\theta}_\pi^{m+1}\|_H^2 + \|\bar{D}\boldsymbol{\theta}_h^{m+1}\|_H^2).$$

For the first term, we proceed as in (5.5) using a Taylor expansion, which yields

$$\|\partial_t \mathbf{u}(t_{n+1}) - \bar{D}\mathbf{u}(t_{n+1})\|_H \leq \delta t^{\frac{1}{2}} \|\partial_{tt} \mathbf{u}(s)\|_{L^2((t_n, t_{n+1}); H)}.$$

For the second term, we have

$$(5.9) \quad \|\bar{D}\boldsymbol{\theta}_\pi^{n+1}\|_H = \frac{1}{\delta t} \int_{t_n}^{t_{n+1}} \|\partial_t \boldsymbol{\theta}_\pi(s)\|_H ds \leq \delta t^{-\frac{1}{2}} \|\partial_t \boldsymbol{\theta}_\pi\|_{L^2((t_n, t_{n+1}); H)}.$$

Finally, for the third term we use the modified Galerkin orthogonality (Lemma 5.1 with $q_h = 0$) and the definition of the Ritz-projection (3.16) to obtain

$$\begin{aligned} & \|\bar{D}\boldsymbol{\theta}_h^{n+1}\|_H^2 + a(\boldsymbol{\theta}_h^{n+1}, \bar{D}\boldsymbol{\theta}_h^{n+1}) + b(y_h^{n+1}, \bar{D}\boldsymbol{\theta}_h^{n+1}) \\ &= -(\bar{D}\boldsymbol{\theta}_\pi^{n+1}, \bar{D}\boldsymbol{\theta}_h^{n+1}) - a(\boldsymbol{\theta}_\pi^{n+1}, \bar{D}\boldsymbol{\theta}_h^{n+1}) \\ & \quad - b(y_\pi^{n+1}, \bar{D}\boldsymbol{\theta}_h^{n+1}) + (\bar{D}\mathbf{u}(t_{n+1}) - \partial_t \mathbf{u}(t_{n+1}), \bar{D}\boldsymbol{\theta}_h^{n+1}) \\ &= -(\bar{D}\boldsymbol{\theta}_\pi^{n+1}, \bar{D}\boldsymbol{\theta}_h^{n+1}) + (\bar{D}\mathbf{u}(t_{n+1}) - \partial_t \mathbf{u}(t_{n+1}), \bar{D}\boldsymbol{\theta}_h^{n+1}). \end{aligned}$$

Young's inequality yields

$$\begin{aligned} & \frac{1}{2} \|\bar{D}\boldsymbol{\theta}_h^{n+1}\|_H^2 + a(\boldsymbol{\theta}_h^{n+1}, \bar{D}\boldsymbol{\theta}_h^{n+1}) + b(y_h^{n+1}, \bar{D}\boldsymbol{\theta}_h^{n+1}) \\ & \leq C (\|\bar{D}\boldsymbol{\theta}_\pi^{n+1}\|_H^2 + \|\bar{D}\mathbf{u}(t_{n+1}) - \partial_t \mathbf{u}(t_{n+1})\|_H^2). \end{aligned}$$

In addition, for $0 \leq n \leq N$, testing (3.16) at the time level n with $\mathbf{v}_h = \mathbf{0}$, we have

$$(5.10) \quad b(q_h, P_h^k(\mathbf{u}(t_n), p(t_n))) = j(R_h^l(\mathbf{u}(t_n), p(t_n)), q_h).$$

On the other hand, for $1 \leq n \leq N$, testing (3.19) at the time level n with $\mathbf{v}_h = \mathbf{0}$ and since, by definition, $\mathbf{u}_h^0 \stackrel{\text{def}}{=} P_h^k(\mathbf{u}_0, 0)$, we have

$$(5.11) \quad b(q_h, \mathbf{u}_h^n) = j(p_h^n, q_h)$$

for all $q_h \in Q_h^l$ and $0 \leq n \leq N$ and where we have defined $p_h^0 \stackrel{\text{def}}{=} R_h^l(\mathbf{u}_0, 0)$. As a result, from (5.10)–(5.11), we have

$$b(q_h, \boldsymbol{\theta}_h^n) = j(y_h^n, q_h)$$

for all $q_h \in Q_h^l$ and $0 \leq n \leq N$. We therefore have, for $0 \leq n \leq N-1$,

$$b(y_h^{n+1}, \bar{D}\boldsymbol{\theta}_h^{n+1}) = j(\bar{D}y_h^{n+1}, y_h^{n+1}).$$

On the other hand, using the symmetry of a and j , we have

$$\begin{aligned} a(\boldsymbol{\theta}_h^{n+1}, \bar{D}\boldsymbol{\theta}_h^{n+1}) &= \frac{1}{2}\bar{D}a(\boldsymbol{\theta}_h^{n+1}, \boldsymbol{\theta}_h^{n+1}) + \frac{\delta t}{2}a(\bar{D}\boldsymbol{\theta}_h^{n+1}, \bar{D}\boldsymbol{\theta}_h^{n+1}), \\ j(y_h^{n+1}, \bar{D}y_h^{n+1}) &= \frac{1}{2}\bar{D}j(y_h^{n+1}, y_h^{n+1}) + \frac{\delta t}{2}j(\bar{D}y_h^{n+1}, \bar{D}y_h^{n+1}), \end{aligned}$$

so that

$$\begin{aligned} \frac{1}{2}\|\bar{D}\boldsymbol{\theta}_h^{n+1}\|_H^2 + \frac{1}{2}\bar{D}(a(\boldsymbol{\theta}_h^{n+1}, \boldsymbol{\theta}_h^{n+1}) + j(y_h^{n+1}, y_h^{n+1})) \\ \leq \|\bar{D}\boldsymbol{\theta}_\pi^{n+1}\|_H^2 + \|\bar{D}\mathbf{u}(t_{n+1}) - \partial_t\mathbf{u}(t_{n+1})\|_H^2. \end{aligned}$$

Thus, after multiplication by $2\delta t$ and summation over $0 \leq n \leq N - 1$, we have

$$\begin{aligned} (5.12) \quad \sum_{m=0}^{n-1} \delta t \|\bar{D}\boldsymbol{\theta}_h^{m+1}\|_H^2 + \|\boldsymbol{\theta}_h^n, y_h^n\|_h^2 \\ \leq \|\boldsymbol{\theta}_h^0, y_h^0\|_h^2 + C \sum_{m=0}^{n-1} \delta t (\|\bar{D}\boldsymbol{\theta}_\pi^{m+1}\|_H^2 + \|\bar{D}\mathbf{u}(t_{m+1}) - \partial_t\mathbf{u}(t_{m+1})\|_H^2). \end{aligned}$$

For the initial terms, we use the linearity of the Ritz-projection and its approximation properties (Lemma 3.4) to obtain

$$\begin{aligned} \|\boldsymbol{\theta}_h^0, y_h^0\|_h^2 &= \|(P_h^k(\mathbf{0}, p(0)), R_h^l(\mathbf{0}, p(0)))\|_h^2 \\ &\leq \frac{C}{\nu} h^{2s_p} \|p(0)\|_{s_p, \Omega}^2. \end{aligned}$$

Therefore, using (5.9) and (5.5), we have

$$\sum_{m=0}^{n-1} \delta t \|\bar{D}\boldsymbol{\theta}_h^{m+1}\|_H^2 + \|\boldsymbol{\theta}_h^n, y_h^n\|_h^2 \leq C \left(\frac{h^{2s_p}}{\nu} \|p(0)\|_{s_p, \Omega}^2 + \delta t^2 \|\partial_{tt}\mathbf{u}\|_{L^2(0, t_n; H)}^2 \right)$$

for $1 \leq n \leq N$. \square

Finally, for completeness, we here give a result of optimal convergence in the $L^\infty((0, T), H)$ -norm. For this we assume that the domain Ω is such that the optimal convergence in the H -norm holds for the Ritz-projection (see Lemma 3.4). This result is of importance since it shows that the initialization of the BDF2 method using one BDF1 step is justified (i.e., we keep error optimality in time).

THEOREM 5.4. *Assume that the domain Ω is sufficiently smooth so that the H -estimate (3.18) holds. Assume also that $\mathbf{u} \in H^1(0, T; [H_{\mathbf{u}}^r(\Omega)]^d) \cap H^2(0, T; [L^2(\Omega)]^d)$, $p \in C^0([0, T]; H^{s_p}(\Omega))$ with $r_{\mathbf{u}} \geq 2$, $s_p \geq 1$, $\mathbf{u}_0 \in V \cap H_0(\text{div}; \Omega)$, and $\mathbf{u}_h^0 \stackrel{\text{def}}{=} P_h^k(\mathbf{u}_0, 0)$. Then the following estimate holds for $1 \leq n \leq N$:*

$$\begin{aligned} \|\mathbf{u}(t_n) - \mathbf{u}_h^n\|_H \leq \frac{C}{\nu^{\frac{1}{2}}} \left(h^{r_{\mathbf{u}}} \|\mathbf{u}_0\|_{r_{\mathbf{u}}, \Omega} + h^{s_p+1} \|p(0)\|_{s_p, \Omega} \right. \\ \left. + h^{r_{\mathbf{u}}} \|\partial_t\mathbf{u}\|_{L^1(0, t_n; H^{r_{\mathbf{u}}}(\Omega))} + \delta t \|\partial_{tt}\mathbf{u}\|_{L^1(0, t_n; H)} \right). \end{aligned}$$

Proof. Since the proof is similar to that of Theorem 5.3 and we will give only the outline. Let $\boldsymbol{\theta}_h^{n+1}$ and y_h^{n+1} be defined as in (5.7). From (5.2) and (5.3), it follows that

$$(\bar{D}\boldsymbol{\theta}_h^{n+1}, \boldsymbol{\theta}_h^{n+1}) \leq -(\bar{D}\boldsymbol{\theta}_\pi^{n+1}, \boldsymbol{\theta}_h^{n+1}) + (\bar{D}\mathbf{u}(t_{n+1}) - \partial_t \mathbf{u}(t_{n+1}), \boldsymbol{\theta}_h^{n+1}).$$

Applying now the Cauchy–Schwarz inequality, we have

$$\|\boldsymbol{\theta}_h^{n+1}\|_H \leq \|\boldsymbol{\theta}_h^n\|_H + \delta t (\|\bar{D}\boldsymbol{\theta}_\pi^{n+1}\|_H + \|\bar{D}\mathbf{u}(t_{n+1}) - \partial_t \mathbf{u}(t_{n+1})\|_H),$$

and by summation over n , we get

$$\|\boldsymbol{\theta}_h^n\|_H \leq \|\boldsymbol{\theta}_h^0\|_H + \sum_{m=0}^{n-1} \delta t (\|\bar{D}\boldsymbol{\theta}_\pi^{m+1}\|_H + \|\bar{D}\mathbf{u}(t_{m+1}) - \partial_t \mathbf{u}(t_{m+1})\|_H)$$

for $1 \leq n \leq N$. The first term in the right-hand side can be estimated using Lemma 3.4 since, by definition,

$$(5.13) \quad \boldsymbol{\theta}_h^0 = P_h^k(\mathbf{u}(0), p(0)) - \mathbf{u}_h^0 = P_h^k(\mathbf{u}_0, p(0)) - P_h^k(\mathbf{u}_0, 0) = P_h^k(\mathbf{0}, p(0)).$$

Finally, for the finite difference consistency terms we use a standard argument (see, e.g., [34, Theorem 1.5, page 14]). \square

Remark 5.5. From (5.13), one could pretend to initialize the time-stepping procedure with $\mathbf{u}_h^0 = P_h^k(\mathbf{u}_0, p(0))$ (as in [33], for instance). In practice, however, the initial pressure is unknown, so that the choice $\mathbf{u}_h^0 = P_h^k(\mathbf{u}_0, 0)$ is more convenient. Lemma 3.4 shows that we can preserve optimality while keeping this choice (see also [4]).

Remark 5.6. Note that the above convergence proofs use only stability, Galerkin orthogonality, and the truncation error of the finite difference time approximation scheme. Hence the extension to the second order Crank–Nicholson or BDF2 scheme is straightforward. In particular we recall that the estimate of Theorem 5.4 shows that the initialization using one BDF1 step does not make the convergence deteriorate, provided the solution is sufficiently smooth under the first time step. Indeed, for smooth solutions we expect $\|\partial_{tt}\mathbf{u}\|_{L^1(0, \delta t; H)}$ to be $O(\delta t)$, and hence the global convergence will be second order in spite of the initial low order perturbation.

6. Numerical experiments. In this section we will consider some numerical examples using the CIP stabilization, described in subsection 3.1.1. We present computations demonstrating the optimal convergence using finite element spaces consisting of quadratic functions, for the space discretization, BDF1, BDF2, and the Crank–Nicholson scheme for the time discretization. We also verify numerically that, for small time steps, the pressure is unstable for initial data that are not discretely divergence free. All computations have been performed using FreeFem++ [26].

6.1. Convergence rate in time. We consider problem (2.1) in two dimensions, $\Omega = [0, 1] \times [0, 1]$ and $T = 1$, with nonhomogeneous boundary conditions. The right-hand side \mathbf{f} and the boundary and initial data are chosen in order to ensure that the exact solution is given by

$$\mathbf{u}(x, y, t) = g(t) \begin{pmatrix} \sin(\pi x - 0.7) \sin(\pi y + 0.2) \\ \cos(\pi x - 0.7) \cos(\pi y + 0.2) \end{pmatrix},$$

$$p(x, y, t) = g(t) (\sin(x) \cos(y) + (\cos(1) - 1) \sin(1)),$$

with $g(t) = 1 + t^5 + e^{-\frac{t}{10}} + \sin(t)$.

In order to illustrate the convergence rate in time of the discrete solution, we have used quadratic approximations in space and a mesh parameter $h = 0.01$. In this case, the stability condition (4.16) is always satisfied for the range of time steps considered. Thus, the choice of the Lagrange interpolant or of the Ritz-projection as approximation of the initial velocity give similar results.

In Figures 1(a)–(c) we report the convergences of the errors for the velocities ($\|\cdot\|_{L^\infty(0,T;L^2(\Omega))}$) and the pressures ($\|\cdot\|_{L^2(0,T;L^2(\Omega))}$) for the BDF1, Crank–Nicholson, and BDF2 schemes. In all the numerical examples, both the velocities and the pressures converge at the optimal rate ($O(\delta t)$ for BDF1 and $O(\delta t^2)$ for Crank–Nicholson and BDF2). The BDF2 scheme was initialized using one step of BDF1.

6.2. Behavior in the small time-step limit. In this subsection we illustrate the impact of the initial velocity approximation on the approximate pressures for small time steps. For nondiscrete divergence-free initial approximations, a pressure instability is predicted by Corollary 4.3 unless condition (4.16) is satisfied. In other words, pressure instabilities are expected for very small time steps.

We consider problem (2.1) in two dimensions and with nonhomogeneous boundary conditions. We set $\Omega = [0, 1] \times [0, 1]$, and the right-hand side \mathbf{f} and the boundary data are chosen in order to ensure that the exact (steady) solution is given by

$$\mathbf{u}(x, y, t) = \begin{pmatrix} \sin(\pi x - 0.7) \sin(\pi y + 0.2) \\ \cos(\pi x - 0.7) \cos(\pi y + 0.2) \end{pmatrix},$$

$$p(x, y, t) = \sin x \cos y + (\cos(1) - 1) \sin(1).$$

This numerical experiment is, in some degree, motivated by the work reported in [3] (see also [19]), where pressure instabilities, of a different nature, are illustrated for pressure stabilizations involving residuals of the PDEs (e.g., PSPG and GLS). Indeed, the time derivative involved in the residual perturbs the coercivity of the space semidiscrete operator, which leads to pressure instabilities for (sufficiently) small time steps (see [3]). Let us emphasize that, according to section 4, such instabilities do not appear here, in particular since the CIP pressure stabilization (and the other examples of subsection 3.1.1) are consistent without introducing the time derivative.

For different initial velocity approximations, we compare the behavior of the error in the pressure after one time step of the backward Euler scheme, i.e.,

$$\delta t^{\frac{1}{2}} \|p(t_1) - p_h^1\|_Q.$$

We choose the initial data either as the Lagrange interpolant, $\mathbf{u}_h^0 = I_h^k \mathbf{u}_0$, or as the Ritz-projection, $\mathbf{u}_h^0 = P_h^k(\mathbf{u}_0, 0)$.

In Figure 2 we have reported the convergence history (in space) of the pressure error, at the first time step, using $\mathbb{P}_1/\mathbb{P}_1$ finite elements for different time step sizes. The pressure instability for small time steps is illustrated in Figure 4(a), where the initial velocity approximation is given in terms of the Lagrange interpolant. Indeed, we can observe that the pressure error has the right convergence rate in space, but it grows when the time step is decreased. On the other hand, as shown in Figure 4(b), the instability is eliminated when the initial velocity approximation is provided by the Ritz-projection, as stated in Corollary 4.3. In this case the error remains bounded (dominated by the space discretization) while reducing the time-step size.

(b) Crank-Nicholson

(c) BDF2 scheme

FIG. 1. Convergence history in time: $\mathbb{P}_2/\mathbb{P}_2$ CIP stabilized finite elements.

Similar results are found with $\mathbb{P}_2/\mathbb{P}_2$ finite elements, as shown in Figure 3. In particular, we can notice, from Figures 2(a) and 3(a), that for quadratic approximations the pressure instability shows up only for very small time steps. As a matter of fact, condition (4.16) is less restrictive for quadratic than for affine velocity approximations of smooth initial data. Finally, some pressure contours are reported in

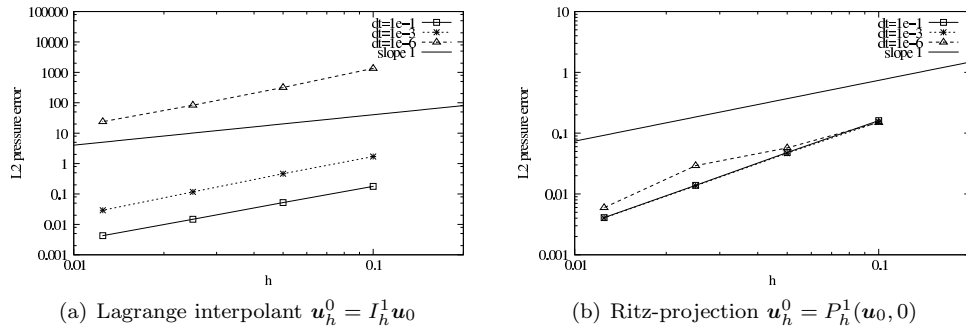

FIG. 2. Convergence history: $\mathbb{P}_1/\mathbb{P}_1$ finite elements.

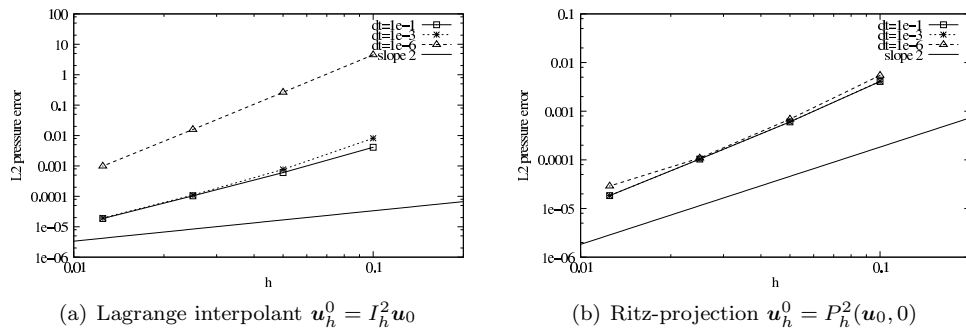

FIG. 3. Convergence history: $\mathbb{P}_2/\mathbb{P}_2$ finite elements.

FIG. 4. Pressure contour lines with $\mathbb{P}_2/\mathbb{P}_2$ finite elements in a 40×40 mesh: $\mathbf{u}_h^0 = I_h^2 \mathbf{u}_0$.

Figure 4 for the Lagrange interpolation, and in Figure 5 for the Ritz-projection. The pressure degradation is clearly visible in Figure 4, whereas with the Ritz-projection initialization (Figure 5) the pressure remains unconditionally stable.

7. Conclusion. In this paper we have proved unconditional stability and optimal error estimates, in natural norms, for pressure stabilized finite element approximations of the transient Stokes problem. It should be noted that the extension of

FIG. 5. Pressure contour lines with $\mathbb{P}_2/\mathbb{P}_2$ finite elements in a 40×40 mesh: $\mathbf{u}_h^0 = P_h^2(\mathbf{u}_0, 0)$.

the present results to mixed formulations of the Poisson problem is straightforward. We have shown that for small initial time steps the use of a pressure stabilization dependent Ritz-projection, for the initial data, is essential to avoid pressure instabilities, unless a condition between time and space discretization parameters is satisfied. From the analysis, we also conclude that a second order scheme (e.g., BDF2) can be initialized (without optimality loss) using a first step with BDF1, *provided* that the Ritz-projection (3.16) is used for the initial data.

It is interesting to note that for low order elements the weakly consistent stabilization operators still yield optimal convergence in time when used with a second order scheme. However, in the case when streamline upwind Petrov–Galerkin (SUPG)-type stabilization is used for the convective term, the convergence order in time will be lost unless full consistency is guaranteed in the stabilization term. This is why SUPG-type stabilizations prompt space time finite element formulations with discontinuous approximation in time.

Some of the methods described in subsection 3.1.1, on the other hand, may be extended to the case of Oseen’s equations, handling all Reynolds numbers, by applying the same type of stabilizing term for the convection (see [13, 6, 16, 7] for details).

LOCALIZED LINEAR POLYNOMIAL OPERATORS AND QUADRATURE FORMULAS ON THE SPHERE*

Q. T. LE GIA[†] AND H. N. MHASKAR[‡]

Abstract. The purpose of this paper is to construct universal, auto-adaptive, localized, linear, polynomial (-valued) operators based on scattered data on the (hyper) sphere \mathbb{S}^q ($q \geq 2$). The approximation and localization properties of our operators are studied theoretically in deterministic as well as probabilistic settings. Numerical experiments are presented to demonstrate their superiority over traditional least squares and discrete Fourier projection polynomial approximations. An essential ingredient in our construction is the construction of quadrature formulas based on scattered data, exact for integrating spherical polynomials of (moderately) high degree. Our formulas are based on scattered sites; i.e., in contrast to such well-known formulas as Driscoll–Healy formulas, we need not choose the location of the sites in any particular manner. While the previous attempts to construct such formulas have yielded formulas exact for spherical polynomials of degree at most 18, we are able to construct formulas exact for spherical polynomials of degree 178.

Key words. quadrature formulas, localized kernels, polynomial quasi interpolation, learning theory on the sphere

1. Introduction. The problem of approximation of functions on the sphere arises in almost all applications involving modeling of data collected on the surface of the earth. More recent applications such as manifold matching and neural networks have led to the approximation of functions on the unit sphere \mathbb{S}^q embedded in the Euclidean space \mathbb{R}^{q+1} for integers $q \geq 3$ as well. Various applications in learning theory, meteorology, cosmology, and geophysics require analysis of *scattered data* collected on the sphere [9, 7, 8]. This means that the data is of the form $\{(\xi, f(\xi))\}$ for some unknown function $f : \mathbb{S}^q \rightarrow \mathbb{R}$, where one has no control on the choice of the sites ξ .

There are many methods to model such data: spherical splines, radial basis functions (called zonal function networks in this context), etc. However, the most traditional method is to approximate by spherical polynomials, i.e., restrictions of algebraic polynomials in $q+1$ variables to \mathbb{S}^q . Apart from tradition, some important advantages of polynomials are that they are eigenfunctions of many pseudodifferential operators which arise in practical applications and that they are infinitely smooth. Unlike in the case of spline approximation with a given degree of the piecewise component polynomials, global polynomial approximation does not exhibit a saturation property [2, section 2, Chapter 11]; i.e., for an arbitrary sequence $\delta_n \downarrow 0$, it is possible to find a continuous function on the sphere, not itself a polynomial, which can be approximated by spherical polynomials of degree at most n uniformly within δ_n , $n \geq 1$. In [21, 19], we have shown how a good polynomial approximation also yields a good zonal function

network approximation. In [20], we have shown that the approximation spaces determined by zonal function network approximation are the same as those determined by polynomial approximations.

To illustrate the issues to be discussed in this paper, we consider an example in the case $q = 1$ or, equivalently, the case of 2π -periodic functions on the real line. In this discussion only, let $f(x) = |\cos x|^{1/4}$, $x \in \mathbb{R}$. In Figure 1 (left), we show the log-plot of the absolute errors between f and its (trigonometric) Fourier projection of order 31, where the Fourier coefficients are estimated by a 128 point DFT. In Figure 1 (right), we show a similar log-plot where the Fourier projection is replaced by a suitable summability operator (described more precisely in (3.1)), yielding again a trigonometric polynomial of order 31. It is clear that our summability operator is far more localized than the Fourier projection; i.e., the error in approximation decreases more rapidly as one goes away from the singularities at $\pi/2$ and $3\pi/2$. The maximum error on $[3\pi/4, 5\pi/4]$ is 0.0103 for the projection, and 0.0028 for our operator. Out of the 2048 points considered for the test, the error by the summability operator is less than 10^{-3} at 38.96% points, the corresponding percentage for the projection is only 4.88%. In contrast to free-knot spline approximation, our summability operator is universal; i.e., its construction (convolution with a kernel) does not require any a priori knowledge about the location of singularities of the target function. It yields a single, globally defined trigonometric polynomial, computed using global data. Nevertheless, it is auto-adaptive, in the sense that the error in approximation on different subintervals adjusts itself according to the smoothness of the target function on these subintervals. In [24, 25], we have given a very detailed analysis of the approximation properties of these operators in the case $q = 1$.

FIG. 1. The log-plot of the absolute error between the function $f(x) = |\cos x|^{1/2}$ and its Fourier projection of order 31 (left). The log-plot of the absolute error between the function f and its trigonometric polynomial approximation obtained by our summability operator (right). The numbers on the x axis are in multiples of π ; the actual absolute errors are 10^y .

Our computation based on a 128 point DFT implies that the values of the function are available at 128 equidistant points. If only scattered data is available, the following method is often used (especially in the context of approximation on the sphere) to estimate the values needed for the DFT. For each point ξ , we consider the nearest point of the form $2\pi k/128$ and imagine that the value of f at this point is $f(\xi)$, taking averages in the case of multiplicities and interpolating in the case of gaps. If we use our summability operator, estimating the Fourier coefficients in this way, then the maximum error on $[3\pi/4, 5\pi/4]$ is 0.0357, and the proportion of points where the

error is less than 10^{-3} is 7.08%. It is clear that a careful construction of quadrature formulas is essential to obtaining good approximation results.

The purpose of this paper is to construct universal, auto-adaptive, localized, linear, polynomial (ℓ^p -valued) operators based on scattered data on \mathbb{S}^q ($q \geq 2$) and to analyze their approximation properties. An essential ingredient in our construction is the construction of quadrature formulas based on scattered data, exact for integrating spherical polynomials of (moderately) high degree, and satisfying certain technical conditions known as the Marcinkiewicz–Zygmund (M–Z) conditions. Our construction is different from the usual construction of quadrature formulas (designs) studied in numerical analysis, where one has a choice of the placement of nodes. In [22, 23], we proved the existence of such quadrature formulas for scattered data. However, previous efforts to compute such formulas did not yield exactness beyond degree 18 polynomials. This was a severe limitation on the practical applications of our theoretical constructions. We will show that a very simple idea of solving a system of equations involving a Gram matrix yields surprisingly good results, in particular, quadrature formulas exact for integrating polynomials of degree as high as 178. Gram matrices are typically ill conditioned. However, we will show both theoretically and numerically that the ones which we use are, in fact, very well conditioned. We will introduce another algorithm of theoretical interest to compute data dependent orthogonal polynomials and use these to compute the quadrature formulas in a memory efficient manner. To the best of our knowledge, this is the first effort to extend the univariate constructions in Gautschi’s book [11] to a multivariate setting. Considering that computation of classical spherical harmonics is a very delicate task, requiring many tricks based on the special function properties of these polynomials for a stable computation, it is not expected that our computation of data dependent orthogonal polynomials with no such special function properties would be stable. In describing this algorithm, we hope to stimulate further research in this interesting direction. We note that even if this algorithm is not as stable for high degrees as the other algorithm, it yields satisfactory quadrature formulas exact for integrating polynomials of degree 32. Most importantly, our newfound ability to compute quadrature formulas for moderately high degrees allows us to offer our operators as a viable, practical method of approximation, even superior to the commonly used methods of least squares and Fourier projection as far as localized approximation is concerned.

An additional problem is when the available values of the target function are noisy. One may assume that the noise is an additive random variable with mean zero. It is also routine in learning theory to assume that the random variables have a bounded range. This assumption is usually satisfied with a high probability even if the random variables do not actually have a bounded range. However, one does not typically know the actual distribution of these random variables. We obtain probabilistic estimates in this setting on the global and local approximations by our operators. To underline the practical utility of our operators, we use them for modeling the MAGSAT data supplied to us by Dr. Thorsten Maier, obtaining results comparable to those obtained by other techniques.

In section 2, we review certain facts about spherical polynomials, the existence of quadrature formulas to integrate these, a few properties of the quadrature weights, and certain polynomial kernels which we will need throughout the paper. In section 3, we study the approximation properties of the linear polynomial operators. The new results here are Theorems 3.1 and 3.2. The first parts of these theorems were proved essentially in [18], but were not stated in the form given here. In order to apply these

operators in practice, one needs quadrature formulas exact for high degree spherical polynomials. Explicit algorithms to construct such formulas are described in section 4. The new results in this section are Theorems 4.1 and 4.2. Numerical results are presented in section 5, and the proofs of all new results are given in section 6.

2. Background. In this section, we review some known results regarding spherical polynomials and localized polynomial kernels.

2.1. Spherical polynomials. Let $q \geq 1$ be an integer, \mathbb{S}^q be the unit sphere embedded in the Euclidean space \mathbb{R}^{q+1} (i.e., $\mathbb{S}^q := \{(x_1, \dots, x_{q+1}) \in \mathbb{R}^{q+1} : \sum_{k=1}^{q+1} x_k^2 = 1\}$), and μ_q be its Lebesgue surface measure, normalized so that $\mu_q(\mathbb{S}^q) = 1$. The surface area of \mathbb{S}^q is $\frac{2\pi^{(q+1)/2}}{\Gamma((q+1)/2)}$. For $\delta > 0$, a spherical cap with radius δ and center $\mathbf{x}_0 \in \mathbb{S}^q$ is defined by

$$\mathbb{S}_\delta^q(\mathbf{x}_0) := \{\mathbf{x} \in \mathbb{S}^q : \arccos(\mathbf{x} \cdot \mathbf{x}_0) \leq \delta\}.$$

If $1 \leq p \leq \infty$, and $f : \mathbb{S}^q \rightarrow \mathbb{R}$ is measurable, we write

$$\|f\|_p := \begin{cases} \left\{ \int_{\mathbb{S}^q} |f(\mathbf{x})|^p d\mu_q(\mathbf{x}) \right\}^{1/p} & \text{if } 1 \leq p < \infty, \\ \text{ess sup}_{\mathbf{x} \in \mathbb{S}^q} |f(\mathbf{x})| & \text{if } p = \infty. \end{cases}$$

The space of all Lebesgue measurable functions on \mathbb{S}^q such that $\|f\|_p < \infty$ will be denoted by L^p , with the usual convention that two functions are considered equal as elements of this space if they are equal almost everywhere. The symbol $C(\mathbb{S}^q)$ denotes the class of all continuous, real-valued functions on \mathbb{S}^q , equipped with the norm $\|\circ\|_\infty$.

For a real number $x \geq 0$, let Π_x^q denote the class of all spherical polynomials of degree at most x . (This is the same as the class Π_n^q , where n is the largest integer not exceeding x . However, our extension of the notation allows us, for example, to use the simpler notation $\Pi_{n/2}^q$ rather than the more cumbersome notation $\Pi_{\lfloor n/2 \rfloor}^q$.) For a fixed integer $\ell \geq 0$, the restriction to \mathbb{S}^q of a homogeneous harmonic polynomial of exact degree ℓ is called a spherical harmonic of degree ℓ . Most of the following information is based on [26], [33, section IV.2], and [5, Chapter XI], although we use a different notation. The class of all spherical harmonics of degree ℓ will be denoted by \mathbf{H}_ℓ^q . The spaces \mathbf{H}_ℓ^q are mutually orthogonal relative to the inner product of L^2 . For any integer $n \geq 0$, we have $\Pi_n^q = \bigoplus_{\ell=0}^n \mathbf{H}_\ell^q$. The dimension of \mathbf{H}_ℓ^q is given by

$$(2.1) \quad d_\ell^q := \dim \mathbf{H}_\ell^q = \begin{cases} \frac{2\ell + q - 1}{\ell + q - 1} \binom{\ell + q - 1}{\ell} & \text{if } \ell \geq 1, \\ 1 & \text{if } \ell = 0 \end{cases}$$

and that of Π_n^q is $\sum_{\ell=0}^n d_\ell^q = d_n^{q+1}$. Furthermore, $L^2 = L^2\text{-closure}\{\bigoplus_{\ell=0}^\infty \mathbf{H}_\ell^q\}$. Hence, if we choose an orthonormal basis $\{Y_{\ell,k} : k = 1, \dots, d_\ell^q\}$ for each \mathbf{H}_ℓ^q , then the set $\{Y_{\ell,k} : \ell = 0, 1, \dots \text{ and } k = 1, \dots, d_\ell^q\}$ is a complete orthonormal basis for L^2 . One has the well-known addition formula [26] and [5, Chapter XI, Theorem 4]:

$$(2.2) \quad \sum_{k=1}^{d_\ell^q} Y_{\ell,k}(\mathbf{x}) Y_{\ell,k}(\zeta) = \frac{2^{q-1} \Gamma(q/2)^2}{\Gamma(q)} p_\ell(1) p_\ell(\mathbf{x} \cdot \zeta), \quad \ell = 0, 1, \dots,$$

where $p_\ell := p_\ell^{(q/2-1, q/2-1)}$ is the orthonormalized Jacobi polynomial with positive leading coefficient

$$\int_{-1}^1 p_\ell(t)p_k(t)(1-t^2)^{q/2-1}dt = \begin{cases} 1 & \text{if } \ell = k, \\ 0 & \text{otherwise.} \end{cases}$$

In particular, for $\mathbf{x} \in \mathbb{S}^q$, $\ell = 0, 1, \dots$,

$$(2.3) \quad \sum_{k=1}^{d_\ell^q} Y_{\ell,k}^2(\mathbf{x}) = \frac{2^{q-1}\Gamma(q/2)^2}{\Gamma(q)} p_\ell(1)^2 = \int_{\mathbb{S}^q} \sum_{k=1}^{d_\ell^q} Y_{\ell,k}^2(\zeta) d\mu_q(\zeta) = d_\ell^q.$$

2.2. Localized polynomial kernels. Let $h : [0, \infty) \rightarrow \mathbb{R}$ be a compactly supported function, and let $t > 0$. We define for $u \in \mathbb{R}$

$$(2.4) \quad \Phi_t(h; u) := \frac{2^{q-1}\Gamma(q/2)^2}{\Gamma(q)} \sum_{\ell=0}^\infty h\left(\frac{\ell}{t}\right) p_\ell(1)p_\ell(u)$$

and define $\Phi_t(h; u) = 0$ if $t \leq 0$.

In what follows, we adopt the following convention regarding constants. The letters c, c_1, \dots will denote generic, positive constants depending only on the dimension q and other fixed quantities in the discussion such as the function h , the different norms involved in the formula, etc. Their value will be different at different occurrences, even within the same formula. The symbol $A \sim B$ will mean $cA \leq B \leq c_1A$.

The following proposition summarizes some of the important properties of the kernels defined in (2.4).

PROPOSITION 2.1. *Let $S \geq q$ be an integer, $h : [0, \infty) \rightarrow \mathbb{R}$ be an S times iterated integral of a function of bounded variation, $h(x) = 1$ for $x \in [0, 1/2]$, $h(x) = 0$ for $x > 1$, and h be nonincreasing. Let $\mathbf{x} \in \mathbb{S}^q$. We have, for every integer $n \geq 0$, $\Phi_n(h; \circ \cdot \mathbf{x}) \in \Pi_n^q$ and*

$$(2.5) \quad \int \Phi_n(h; \mathbf{x} \cdot \zeta) P(\zeta) d\mu_q(\zeta) = P(\mathbf{x}), \quad P \in \Pi_{n/2}.$$

Further,

$$(2.6) \quad \begin{aligned} & \sup_{n \geq 1, \zeta \in \mathbb{S}^q} \int |\Phi_n(h; \zeta \cdot \xi)| d\mu_q(\xi) = \sup_{n \geq 1} \int |\Phi_n(h; \mathbf{x} \cdot \xi)| d\mu_q(\xi) \\ & = \frac{2\pi^{q/2}}{\Gamma(q/2)} \sup_{n \geq 1} \int_{-1}^1 |\Phi_n(h; u)| (1-u^2)^{q/2-1} du < \infty, \\ & \int |\Phi_n(h; \mathbf{x} \cdot \xi)|^2 d\mu_q(\xi) = \frac{2\pi^{q/2}}{\Gamma(q/2)} \int_{-1}^1 |\Phi_n(h; u)|^2 (1-u^2)^{q/2-1} du \\ (2.7) \quad & \sim n^q \sim \max_{\xi \in \mathbb{S}^q} |\Phi_n(h; \mathbf{x} \cdot \xi)| = |\Phi_n(h; 1)|, \end{aligned}$$

and for every $\xi \in \mathbb{S}^q$, $\xi \neq \mathbf{x}$,

$$(2.8) \quad |\Phi_n(h; \mathbf{x} \cdot \xi)| \leq cn^q \begin{cases} (n\sqrt{1-\mathbf{x} \cdot \xi})^{1/2-q/2-S} & \text{if } 0 \leq \mathbf{x} \cdot \xi < 1, \\ n^{-S} & \text{if } -1 \leq \mathbf{x} \cdot \xi < 0. \end{cases}$$

Except for (2.7), all parts of Proposition 2.1 have been proved and verified repeatedly in [17, 18, 12, 19]. We will sketch a proof of this proposition, mainly to reconcile notation.

Proof of Proposition 2.1. Equation (2.5) and the first two equations in (2.6) are clear. The last estimate in (2.6) follows from [17, Lemma 4.6] with the following choice of the parameters there: $\alpha = \beta = q/2 - 1$, $h_\nu = h(\nu/n)$, where we observe that by a repeated application of the mean value theorem,

$$\sum_{\nu=0}^{\infty} (\nu + 1)^s |\Delta^r h(\nu/n)| \leq cn^{s-r+1}, \quad s \in \mathbb{R}, r, n = 1, 2, \dots,$$

where Δ^r is the r th order forward difference applied with respect to ν . Similarly, the estimate (2.8) follows from [17, Lemma 4.10] with the same parameters as above, S in place of K in [17], and $y = \mathbf{x} \cdot \xi$ (cf. the appendix in [12]). We prove (2.7). The first equation is a consequence of the rotation invariance of μ_q . In view of the addition formula (2.2),

$$(2.9) \quad \Phi_n(h; \mathbf{x} \cdot \xi) = \sum_{\ell=0}^n h \left(\frac{\ell}{n} \right) \sum_{k=1}^{d_\ell^q} Y_{\ell,k}(\mathbf{x}) Y_{\ell,k}(\xi).$$

It follows, using (2.3) and the facts that $h(\ell/n) = 1$ for $\ell \leq n/2$ and $0 \leq h(t) \leq 1$ for $t \in [0, \infty)$, that

$$\int \Phi_n(h; \mathbf{x} \cdot \xi)^2 d\mu_q(\xi) = \sum_{\ell=0}^n h \left(\frac{\ell}{n} \right)^2 \sum_{k=1}^{d_\ell^q} Y_{\ell,k}(\mathbf{x})^2 = \sum_{\ell=0}^n h \left(\frac{\ell}{n} \right)^2 d_\ell^q \sim n^q.$$

Similarly, using the Schwarz inequality, (2.2), (2.3), and the fact that $h(\ell/n) \geq 0$,

$$\begin{aligned} \Phi_n(h; 1) &= |\Phi_n(h; \mathbf{x} \cdot \mathbf{x})| \leq \sup_{\xi \in \mathbb{S}^q} |\Phi_n(h; \mathbf{x} \cdot \xi)| \\ &\leq \sum_{\ell=0}^n h \left(\frac{\ell}{n} \right) \left\{ \sum_{k=1}^{d_\ell^q} Y_{\ell,k}(\mathbf{x})^2 \right\}^{1/2} \left\{ \sum_{k=1}^{d_\ell^q} Y_{\ell,k}(\xi)^2 \right\}^{1/2} = \sum_{\ell=0}^n h \left(\frac{\ell}{n} \right) d_\ell^q = \Phi_n(h; 1). \end{aligned}$$

Since $d_\ell^q \sim \ell^{q-1}$, $0 \leq h(\ell/n) \leq 1$, and $h(\ell/n) = 1$ for $\ell \leq n/2$, the above two estimates lead to (2.7). \square

In the remainder of this paper, h will denote a fixed function satisfying the conditions of Proposition 2.1.

2.3. Quadrature formulas. Let \mathcal{C} be a finite set of distinct points on \mathbb{S}^q . A quadrature formula based on \mathcal{C} has the form $\mathcal{Q}(f) = \sum_{\xi \in \mathcal{C}} w_\xi f(\xi)$, where w_ξ , $\xi \in \mathcal{C}$, are real numbers. For integer $n \geq 0$, the formula is exact for degree n if $\mathcal{Q}(P) = \int_{\mathbb{S}^q} P d\mu_q$ for all $P \in \Pi_n^q$. It is not difficult to verify that if $\mathcal{Q}_n(f) = \sum w_{\xi_n} f(\xi_n)$ is a sequence of quadrature formulas, with \mathcal{Q}_n being exact with degree n , then $\mathcal{Q}_n(f) \rightarrow \int f d\mu_q$ for every continuous function f on \mathbb{S}^q if and only if $\sum |w_{\xi_n}| \leq c$, with c being independent of n . In what follows, we will assume tacitly that \mathcal{C} is one of the members of a nested sequence of finite subsets of \mathbb{S}^q , whose union is dense in \mathbb{S}^q . All the constants may depend upon the whole sequence, but not on any individual member of this sequence. Thus, a formula \mathcal{Q} will be called a bounded variation

formula if $\sum_{\xi \in \mathcal{C}} |w_\xi| \leq c$, with the understanding that this is an abbreviation for the concept described above with a sequence of quadrature formulas.

DEFINITION 2.1. *Let $m \geq 0$ be an integer. The set \mathcal{C} admits an M-Z quadrature of order m if there exist weights w_ξ such that*

$$(2.10) \quad \int_{\mathbb{S}^q} P(\mathbf{x}) d\mu_q(\mathbf{x}) = \sum_{\xi \in \mathcal{C}} w_\xi P(\xi), \quad P \in \Pi_{2m}^q,$$

and

$$(2.11) \quad \left(\sum_{\xi \in \mathcal{C}} |w_\xi| |P(\xi)|^p \right)^{1/p} \leq c \|P\|_p, \quad P \in \Pi_{2m}^q, \quad 1 \leq p < \infty.$$

The weights w_ξ will be called M-Z weights of order m . The condition (2.11) will be referred to as the M-Z condition.

If \mathcal{C} admits an M-Z quadrature of order m , and $\{w_\xi\}$ are the weights involved, it is clear from using (2.11) with the polynomial identically equal to 1 in place of P that $\sum_{\xi \in \mathcal{C}} |w_\xi| \leq c$. Further, if $\zeta \in \mathcal{C}$, then applying (2.11) with $p = 2$ and $\Phi_m(h; \zeta \cdot \circ)$ in place of P , we obtain for M-Z weights of order m :

$$|w_\zeta| \Phi_m(h; 1)^2 \leq \sum_{\xi \in \mathcal{C}} |w_\xi| \Phi_m(h; \zeta \cdot \xi)^2 \leq c \int \Phi_m(h; \zeta \cdot \mathbf{x})^2 d\mu_q(\mathbf{x}).$$

The estimate (2.7) now implies that for all M-Z weights $\{w_\xi\}$ of order m ,

$$(2.12) \quad |w_\xi| \leq cm^{-q}, \quad \xi \in \mathcal{C}.$$

In [22, 23], we proved that every finite set $\mathcal{C} \subset \mathbb{S}^q$ admits an M-Z quadrature with an order depending upon how dense the set \mathcal{C} is. This density is measured in terms of the mesh norm. The mesh norm of \mathcal{C} with respect to a subset $K \subseteq \mathbb{S}^q$ is defined to be

$$(2.13) \quad \delta_{\mathcal{C}}(K) := \sup_{\mathbf{x} \in K} \text{dist}(\mathbf{x}, \mathcal{C}).$$

The following theorem summarizes the quadrature formula given in [22, 23].

THEOREM 2.1. *There exists a constant α_q with the following property. Let \mathcal{C} be a finite set of distinct points on \mathbb{S}^q , and let m be an integer with $m \leq \alpha_q (\delta_{\mathcal{C}}(\mathbb{S}^q))^{-1}$. Then \mathcal{C} admits an M-Z quadrature of order m , and the set $\{w_\xi\}$ of M-Z weights may be chosen to satisfy*

$$(2.14) \quad |\{\xi : w_\xi \neq 0\}| \sim m^q \sim \dim(\Pi_{2m}^q).$$

3. Polynomial operators. For $t > 0$, $f \in L^1$, we define the summability operator σ_t^* by the formula

$$(3.1) \quad \begin{aligned} \sigma_t^*(h; f, \mathbf{x}) &= \int_{\mathbb{S}^q} f(\zeta) \Phi_t(h; \mathbf{x} \cdot \zeta) d\mu_q(\zeta) \\ &= \sum_{\ell=0}^{\infty} h \left(\frac{\ell}{t} \right) \sum_{k=1}^{d_\ell^q} \hat{f}(\ell, k) Y_{\ell, k}(\mathbf{x}), \quad \mathbf{x} \in \mathbb{S}^q. \end{aligned}$$

(It is convenient, and customary in approximation theory, to use the notation $\sigma_t^*(h; f, \mathbf{x})$ rather than $\sigma_t^*(h; f)(\mathbf{x})$.) Although we defined the operator for L^1 to underline the fact that it is a universal operator, we will be interested only in its restriction to $C(\mathbb{S}^q)$. If $f : \mathbb{S}^q \rightarrow \mathbb{R}$ is a continuous function, the degree of approximation of f from Π_x^q is defined by

$$E_x(f) = \inf_{P \in \Pi_x^q} \|f - P\|_\infty.$$

It is well known [16, 18] that, for all integers $n \geq 1$ and $f \in C(\mathbb{S}^q)$,

$$(3.2) \quad E_n(f) \leq \|f - \sigma_n^*(h; f)\|_\infty \leq cE_{n/2}(f).$$

Following [18], we now define a discretized version of these operators.

If $\mathcal{C} \subset \mathbb{S}^q$ is a finite set and $\mathbf{W} = \{w_\xi\}_{\xi \in \mathcal{C}}$ and $\mathbf{Z} = \{z_\xi\}_{\xi \in \mathcal{C}}$ are sets of real numbers, we define the polynomial operator

$$(3.3) \quad \sigma_t(\mathcal{C}, \mathbf{W}; h; \mathbf{Z}, \mathbf{x}) := \sum_{\xi \in \mathcal{C}} w_\xi z_\xi \Phi_t(h; \mathbf{x} \cdot \xi), \quad t \in \mathbb{R}, \mathbf{x} \in \mathbb{S}^q.$$

If $f : \mathbb{S}^q \rightarrow \mathbb{R}$ and $z_\xi = f(\xi)$, $\xi \in \mathcal{C}$, we will write $\sigma_t(\mathcal{C}, \mathbf{W}; h; f, \mathbf{x})$ in place of $\sigma_t(\mathcal{C}, \mathbf{W}; h; \mathbf{Z}, \mathbf{x})$. In [18], we denoted these operators by $\sigma_t(\nu; h, f)$, where ν is the measure that associates the mass w_ξ with $\xi \in \mathcal{C}$. In this paper, we prefer to use the slightly expanded notation as in (3.3). If $n \geq 1$ is an integer, $\mathcal{C} \subset \mathbb{S}^q$ is a finite set that admits an M–Z quadrature of order n , and \mathbf{W} is the set of the corresponding M–Z weights, then it is shown in [18, Proposition 4.1] that

$$(3.4) \quad E_n(f) \leq \|f - \sigma_n(\mathcal{C}, \mathbf{W}; h; f)\|_\infty \leq cE_{n/2}(f), \quad f \in C(\mathbb{S}^q).$$

In this paper, we will be especially interested in the approximation of functions in the class \mathbb{W}_r , $r > 0$, composed of functions $f \in C(\mathbb{S}^q)$ for which $E_n(f) = \mathcal{O}(n^{-r})$, $n \geq 1$. A complete characterization of the classes \mathbb{W}_r in terms of such constructive properties of its members as the number of partial derivatives and their moduli of smoothness is well known [27, 16]. In view of (3.2), $f \in \mathbb{W}_r$ if and only if

$$\|f\|_{\mathbb{W}_r} := \|f\|_\infty + \sup_{n \geq 1} 2^{nr} \|\sigma_{2n}^*(h; f) - \sigma_{2n-1}^*(h; f)\|_\infty < \infty.$$

In practical applications, the data is contaminated with noise. Therefore, we wish to examine the behavior of our operators based on data of the form $\{(\xi, f(\xi) + \epsilon_\xi)\}$, where ϵ_ξ are independent random variables with unknown probability distributions, each with mean 0. If the range of these random variables is not bounded, one can still assume that the probability of the variables going out of a sufficiently large interval is small. Hence, it is customary in learning theory to assume that the variables ϵ_ξ have a bounded range, so that one may use certain technical inequalities of probability theory known as Bennett’s inequalities; see the proof of Lemma 6.2 below.

In the statements of the theorems below, we use three parameters. The symbol M denotes the number of points in the data set; we assume that the set admits an M–Z quadrature of order m , and the degree n of the polynomial approximant $\sigma_n(\mathcal{C}, \mathbf{W}; h; f)$ is determined in terms of m . For theoretical considerations where one is not concerned about the actual numerical constructions of the quadrature weights, one can imagine a data set \mathcal{C} with $M := |\mathcal{C}| \sim \delta_{\mathcal{C}}(\mathbb{S}^q)^{-q}$ and assume that the weights \mathbf{W} are as guaranteed by Theorem 2.1. If so, then we can take $M \sim m^q \sim \delta_{\mathcal{C}}(\mathbb{S}^q)^{-q}$ in

the discussion in this section. For example, the estimates (3.7) and (3.8) below can then be expressed in terms of the number of samples, respectively, as follows:

$$(3.5) \quad \|f - \sigma_n(\mathcal{C}, \mathbf{W}; h; f)\|_\infty \leq cM^{-r/q}, \quad \text{with some } n \sim M^{1/q},$$

and

$$(3.6) \quad \text{Prob} \left(\|\sigma_n(\mathcal{C}, \mathbf{W}; h; \mathbf{Z}) - f\|_\infty \geq c_1 \frac{(\log M)^c}{M^{r/(q+2r)}} \right) \leq c_2 M^{-c},$$

with some $n \sim (M/\log M)^{1/(2r+q)}$.

THEOREM 3.1. *Suppose that $m \geq 1$ is an integer and $\mathcal{C} = \{\xi_j\}_{j=1}^M$ admits an M -Z quadrature of order m , and let \mathbf{W} be the corresponding quadrature weights. Let $r > 0$, $f \in \mathbb{W}_r$, $\|f\|_{\mathbb{W}_r} = 1$.*

(a) *For integer $n \leq m$, we have*

$$(3.7) \quad \|f - \sigma_n(\mathcal{C}, \mathbf{W}; h; f)\|_\infty \leq cn^{-r}.$$

(b) *For $j = 1, \dots, M$, let ϵ_j be independent random variables with mean 0 and range $[-1, 1]$, and let $\mathbf{Z} = \{\epsilon_j + f(\xi_j)\}$. If $A > 0$ and $n \geq 1$ is the greatest integer with $(A+q)n^{2r+q} \log n \leq c_3 m^q$, $n \leq m$, then*

$$(3.8) \quad \text{Prob} \left(\|\sigma_n(\mathcal{C}, \mathbf{W}; h; \mathbf{Z}) - f\|_\infty \geq c_1 n^{-r} \right) \leq c_2 n^{-A}.$$

Here, the constants c_1, c_2, c_3 are independent of the distribution of the variables ϵ_j .

We now turn our attention to local approximation by our operators. In what follows, if $K \subseteq \mathbb{S}^q$, $f: K \rightarrow \mathbb{R}$, then $\|f\|_{\infty, K} := \sup_{\mathbf{x} \in K} |f(\mathbf{x})|$. If $\mathbf{x}_0 \in \mathbb{S}^q$, a function f is defined to be r -smooth at \mathbf{x}_0 if there is a spherical cap $\mathbb{S}_\delta^q(\mathbf{x}_0)$ such that $f\phi \in \mathbb{W}_r$ for every infinitely differentiable function ϕ supported on $\mathbb{S}_\delta^q(\mathbf{x}_0)$. We have proved in [18, Theorem 3.3] that f is r -smooth at a point \mathbf{x}_0 if and only if there is a cap $\mathbb{S}_\delta^q(\mathbf{x}_0)$ such that

$$\|\sigma_{2^n}^*(h; f) - \sigma_{2^{n-1}}^*(h; f)\|_{\infty, \mathbb{S}_\delta^q(\mathbf{x}_0)} = \mathcal{O}(2^{-nr}).$$

Accordingly, if K is a spherical cap, we may define the class $\mathbb{W}_r(K)$ as consisting of $f \in C(\mathbb{S}^q)$, for which

$$\|f\|_{\mathbb{W}_r(K)} := \|f\|_\infty + \sup_{n \geq 1} 2^{nr} \|\sigma_{2^n}^*(h; f) - \sigma_{2^{n-1}}^*(h; f)\|_{\infty, K} < \infty.$$

THEOREM 3.2. *Suppose that $m \geq 1$ is an integer and $\mathcal{C} = \{\xi_j\}_{j=1}^M$ admits an M -Z quadrature of order m , and let \mathbf{W} be the corresponding quadrature weights. Let $0 < r \leq S - q$, $K' \subset K$ be concentric spherical caps, $f \in C(\mathbb{S}^q)$, and $\|f\|_{\mathbb{W}_r(K)} = 1$.*

(a) *For integer n , $1 \leq n \leq m$,*

$$(3.9) \quad \|f - \sigma_n(\mathcal{C}, \mathbf{W}; h; f)\|_{\infty, K'} \leq cn^{-r}.$$

(b) *For $j = 1, \dots, M$, let ϵ_j be independent random variables with mean 0 and range contained in $[-1, 1]$, and let $\mathbf{Z} = \{\epsilon_j + f(\xi_j)\}$. If $A > 0$ and $n \geq 1$ is the greatest integer with $(A+q)n^{2r+q} \log n \leq c_3 m^q$, $n \leq m$, then*

$$(3.10) \quad \text{Prob} \left(\|\sigma_n(\mathcal{C}, \mathbf{W}; h; \mathbf{Z}) - f\|_{\infty, K'} \geq c_1 n^{-r} \right) \leq c_2 n^{-A}.$$

Here, the constants c_1, c_2, c_3 are independent of the distribution of the variables ϵ_j .

4. Construction of quadrature formulas. In this section, we describe two algorithms to obtain bounded variation quadrature formulas associated with a given finite set of points $\mathcal{C} \subset \mathbb{S}^q$. Both of these constructions can be described in a very general setting. Since this also simplifies the notation and ideas considerably by avoiding the use of real and imaginary parts of a doubly indexed polynomial $Y_{\ell,k}$, we will describe the algorithms in this generality.

Let Ω be a nonempty set; μ be a probability measure on Ω ; $\mathcal{C} \subset \Omega$, y_1, y_2, \dots , be a complete orthonormal basis for $L^2(\Omega, \mu)$, where $y_1 \equiv 1$; and V_k denote the span of y_1, \dots, y_k . Let ν be another measure on Ω , and $\langle \circ, \circ \rangle$ denote the inner product of $L^2(\Omega, \nu)$. For an integer $N \geq 1$, the Gram matrix G_N is an $N \times N$ matrix, defined by $(G_N)_{\ell,k} = \langle y_\ell, y_k \rangle = (G_N)_{k,\ell}$, $1 \leq k, \ell \leq N$. We wish to find a weight function W on Ω such that $\int_\Omega P d\mu = \int_\Omega PW d\nu$ for all $P \in V_N$ for an integer N for which G_N is positive definite.

For the applications to the case of quadrature formulas for the sphere, $\Omega = \mathbb{S}^q$, $\mu = \mu_q$, and y_k 's are the orthogonal spherical harmonics, arranged in a sequence, so that $y_1 \equiv 1$, and all polynomials of lower degree are listed before those of a higher degree. To include all polynomials in Π_n^q , we need $N = d_n^{q+1}$. There are many possibilities for defining the measure ν . The simplest is the measure ν^{MC} that associates the mass $1/|\mathcal{C}|$ with each point of \mathcal{C} . A more sophisticated way to define the measure ν is the following. We obtain a partition of \mathbb{S}^q into a dyadic triangulation such that each triangle contains at least one point of \mathcal{C} . We choose only one point in each triangle and, hence, assume that each triangle contains exactly one point of \mathcal{C} . We define the measure ν^{TR} to be the measure that associates with each $\xi \in \mathcal{C}$ the area of the triangle containing ξ .

One of the simplest ideas for computing the quadrature weights is the following. Let N be an integer for which G_N is positive definite. If $P = \sum_{j=1}^N a_j y_j$, then $\int_\Omega P d\mu = a_1$. Also, the vector $\mathbf{a} = (a_1, \dots, a_N)^T$ satisfies the matrix equation

$$G_N \mathbf{a} = (\langle P, y_1 \rangle, \dots, \langle P, y_N \rangle)^T,$$

so that

$$(4.1) \quad \int_\Omega P d\mu = \sum_{k=1}^N (G_N)_{1,k}^{-1} \langle P, y_k \rangle = \left\langle P, \sum_k (G_N)_{1,k}^{-1} y_k \right\rangle.$$

In the setting of the sphere, this gives the following quadrature formula:

$$(4.2) \quad \int_{\mathbb{S}^q} P d\mu_q = \sum_{\xi \in \mathcal{C}} P(\xi) \left\{ \nu(\{\xi\}) \sum_{k=1}^N (G_N)_{1,k}^{-1} y_k(\xi) \right\} =: \sum_{\xi \in \mathcal{C}} w_\xi^{LSQ} P(\xi).$$

We formulate this as the following algorithm.

ALGORITHM LSQ.

Input: The matrix $Y = (y_k(\xi))$, $k = 1, \dots, N$ (optional), and the vector $\mathbf{v} = (\nu(\{\xi\}))$.

1. Solve $Y \text{diag}(\mathbf{v}) Y^T \mathbf{b} = (1, 0, \dots, 0)^T$.
2. Return $w_\xi^{LSQ} = \nu(\{\xi\}) \sum_{k=1}^N b_k y_k(\xi)$.

We observe that $G_N = Y \text{diag}(\mathbf{v}) Y^T$. It is clear that the matrix G_N is always positive semidefinite; the assumption that it is positive definite is equivalent to the assumption that no nonzero element of V_N vanishes identically on \mathcal{C} . If \mathcal{C} and $\{\nu(\{\xi\})\}$

satisfy the M–Z inequalities, Theorem 4.1 shows that G_N is well conditioned. Assuming that the matrix Y is input, the time to compute G_N is $\mathcal{O}(N^2|\mathcal{C}|)$, and the space requirement is $\mathcal{O}(N^2)$. (In the case of the sphere \mathbb{S}^q , we need $N = d_n^{q+1} = \mathcal{O}(n^q)$ to compute formulas exact for degree n .) The vector \mathbf{b} in step 1 can be found using such iterative methods as the conjugate residual method. We refer the reader to [6] for a more detailed analysis of this method. Using this approach, the matrix Y and G_N need not be stored or precomputed, but the product of the matrix G_N with an arbitrary residual vector \mathbf{r} needs to be computed. This observation results in a substantial savings in the time and memory complexity of the algorithm when the results are desired only within a given accuracy. For the unit sphere \mathbb{S}^2 , when $N = (n + 1)^2$, the product $G_N \mathbf{r} = Y \text{diag}(\mathbf{v}) Y^T \mathbf{r}$ can be computed within an accuracy ϵ using a recent algorithm of Keiner [14] using $\mathcal{O}(n^2(\log n)^2 + \log(1/\epsilon)|\mathcal{C}|)$ operations, where ϵ is the accuracy of the method.

One way to interpret this algorithm is the following. Let $f : \mathbb{S}^q \rightarrow \mathbb{R}$, and P be the solution to the least squares problem

$$P = \arg \min \{ \langle f - Q, f - Q \rangle : Q \in V_N \}.$$

If \mathbf{f} is the vector $(\langle f, y_j \rangle)$, then $P = \sum_j (G_N^{-1} \mathbf{f})_j y_j$. The quadrature formula with weights w_ξ^{LSQ} thus offers $\int_{\mathbb{S}^q} P d\mu_q$ as the approximation to $\int_{\mathbb{S}^q} f d\mu_q$. The weights w_ξ^{LSQ} also satisfy a least squares property among all the possible quadrature formulas, as shown in Lemma 6.1(a). We summarize some of the properties of the weights w_ξ^{LSQ} in the following theorem.

THEOREM 4.1. *Let $n \geq 1$ be an integer, $N = d_n^{q+1}$, \mathcal{C} be a finite set of points on \mathbb{S}^q , and ν be a measure supported on \mathcal{C} . Let $v_\xi := \nu(\{\xi\})$, $\xi \in \mathcal{C}$, and*

$$(4.3) \quad c_1 \|P\|_p \leq \left\{ \sum_{\xi \in \mathcal{C}} v_\xi |P(\xi)|^p \right\}^{1/p} \leq c_2 \|P\|_p, \quad P \in \Pi_n^q, \quad 1 \leq p \leq \infty.$$

(a) *For the Gram matrix G_N , the lowest eigenvalue is $\geq c_1^2$, and the largest eigenvalue is $\leq c_2^2$, where c_1, c_2 are the constants in (4.3) with $p = 2$. In particular, G_N is positive definite. Moreover, $\sum_{\xi \in \mathcal{C}} |w_\xi^{LSQ}| \leq c$.*

(b) *If*

$$(4.4) \quad \left| \int P^2 d\nu - \int P^2 d\mu_q \right| \leq \frac{c}{n^q} \int P^2 d\mu_q, \quad P \in \Pi_n^q,$$

then $|w_\xi^{LSQ}| \leq cv_\xi$, $\xi \in \mathcal{C}$. In particular, the weights $\{w_\xi^{LSQ}\}$ satisfy the M–Z condition.

(c) *Let $M \geq 1$ be an integer, \mathcal{C} be an independent random sample of M points chosen from the distribution μ_q , and $A, \eta > 0$. Let $v_\xi = 1/M$, $\xi \in \mathcal{C}$. There exists a constant $c = c(A)$ such that if $n \geq 2$ is an integer with $M \geq cn^q \log n / \eta^2$, then*

$$(4.5) \quad \text{Prob} \left(\left| \int P^2 d\nu - \int P^2 d\mu_q \right| \geq \eta \int P^2 d\mu_q, \quad P \in \Pi_n^q \right) \leq c_1 n^{-A}.$$

In particular, if $M \geq cn^{3q} \log n$, then condition (4.4) is satisfied with probability exceeding $1 - c_1 n^{-A}$.

One disadvantage of Algorithm LSQ is that one needs to know the value of N in advance. We now describe an idea which has the potential to avoid this problem. In

the case when Ω is a subset of a Euclidean space and the y_j 's are polynomials, with y_1 denoting the constant polynomial, one can construct a system $\{t_k\}$ of orthonormalized polynomials with respect to ν using recurrence relations. Recurrence relations for orthogonal polynomials in several variables have been discussed in detail by Dunkl and Xu [4, Chapter 3]. In contrast to the viewpoint in [4], we may depend upon a specific enumeration but require the recurrence relation to have a specific form described in Theorem 4.2 below. This form allows us to generalize the ideas in Gautschi's book [11, Chapter 2] in our context.

To describe our ideas in general, let $\Omega \subset \mathbb{R}^{q+1}$, u_1, u_2, \dots , be an enumeration of the monomials in $q + 1$ variables, so that u_1 is the monomial identically equal to 1, the restrictions of u_k 's to Ω are linearly independent, all lower degree polynomials are listed before the higher degree ones, and $V_k = \text{span} \{u_1, \dots, u_k\}$. It is not difficult to see that, for every integer $k \geq 1$, there is a minimal index $p(k)$ such that there exists a monomial \tilde{f}_k of degree 1 with

$$(4.6) \quad \tilde{f}_k u_{p(k)} = u_{k+1}, \quad k = 1, 2, \dots$$

We now let, for each $k = 1, 2, \dots$, $\{y_1, \dots, y_k\}$ be a basis for V_k orthonormal with respect to μ , $N \geq 1$ be an integer for which the Gram matrix G_N is positive definite, and, for each $k = 1, \dots, N$, $\{t_1, \dots, t_k\}$ be a basis for V_k orthonormal with respect to ν . Clearly, any polynomial $P \in V_N$ can be written in the form

$$P(\mathbf{x}) = \int P(\zeta) \sum_k t_k(\mathbf{x}) t_k(\zeta) d\nu(\zeta),$$

and, consequently, one gets the "quadrature formula"

$$(4.7) \quad \int P(\mathbf{x}) d\mu(\mathbf{x}) = \int P(\zeta) \left\{ \sum_k \left(\int t_k(\mathbf{x}) d\mu(\mathbf{x}) \right) t_k(\zeta) \right\} d\nu(\zeta).$$

In this discussion only, let $t_k =: \sum_j c_{k,j} y_j$, and let the matrix $(c_{k,j})$ be denoted by C . The condition that t_1, \dots, t_N is an orthonormal system with respect to ν is equivalent to the condition that $CG_N C^T = I$, where I is the $N \times N$ identity matrix. Hence, $G_N^{-1} = C^T C$. Moreover, $\int t_k d\mu = c_{k,1}$ for $k = 1, \dots, N$, and, hence, we conclude that

$$\sum_k \left(\int t_k(\mathbf{x}) d\mu(\mathbf{x}) \right) t_k = \sum_j \sum_k c_{k,1} c_{k,j} y_j = \sum_j (G_N^{-1})_{1,j} y_j.$$

Thus, the quadrature weights in (4.7) are the same as those in (4.1).

First, we summarize the various recurrence relations in Theorem 4.2, although we will not use all of them. We will denote the (total) degree of u_k by D_k , and observe that D_k is also the degree of y_k and t_k , $D_j \leq j$, and $D_{p(k)} = D_{k+1} - 1$.

THEOREM 4.2. *There exist real numbers $s_{k,j}$, $\tilde{r}_{k,j}$, $A_k \geq 0$, and a linear polynomial f_k such that*

$$(4.8) \quad f_k y_{p(k)} = y_{k+1} - \sum_{\substack{D_{k+1}-2 \leq D_j \leq D_k \\ j \leq k}} \tilde{r}_{k,j} y_j, \quad f_k t_{p(k)} = A_k t_{k+1} - \sum_{\substack{D_{k+1}-2 \leq D_j \leq D_k \\ j \leq k}} s_{k,j} t_j.$$

More generally, if P is any linear polynomial, there exist real numbers $r_{k,j}(P)$ such that

$$(4.9) \quad P y_k = \sum_{D_k-1 \leq D_j \leq D_k+1} r_{k,j}(P) y_j.$$

We have $t_k = \sum_j c_{k,j} y_j$, where

$$(4.10) \quad A_k C_{k+1, \ell} = \left\{ \sum_{D_\ell - 1 \leq D_m \leq D_{\ell+1}} r_{\ell, m}(f_k) c_{p(k), m} + \sum_{D_{k+1} - 2 \leq D_j \leq D_k} s_{k, j} c_{j, \ell} \right\}.$$

In the context of the sphere \mathbb{S}^q , we will compute t_k 's using (4.8) and compute $\int t_k d\mu_q$ using a known quadrature formula. The resulting algorithm, Algorithm REC, in the context of the sphere is summarized below. This algorithm is similar to the Stieltjes method in Gautschi's book [11, section 2.2]. Even though it is feasible to carry out the algorithm for as large an N as the data allow and to find this value of N during run time, it is still desirable from the point of view of numerical stability to limit the largest N from the outset. Accordingly, in describing the following algorithm, we stipulate that the quadrature formula is to be computed to be exact only for polynomials in V_N for the largest possible $N \leq L$ for some integer $L \geq 1$. We assume further that we know another quadrature formula (for example, the Driscoll–Healy formula [3]) exact for polynomials in V_L :

$$(4.11) \quad \sum_{\zeta \in \mathcal{C}^*} \lambda_\zeta P(\zeta) = \int P d\mu_q, \quad P \in V_L.$$

ALGORITHM REC.

Input: An integer L ; the sequence $p(k)$, $k = 1, \dots, L$; sets \mathcal{C} , \mathcal{C}^* ; weights $(\lambda_\zeta)_{\zeta \in \mathcal{C}^*}$ so that (4.11) holds; the values $\{y_j(\xi)\}_{\xi \in \mathcal{C}}$, $\{y_j(\zeta)\}_{\zeta \in \mathcal{C}^*}$ for $j = 1, 2, 3, 4$; and the values $f_k(\xi)$, $f_k(\zeta)$, $k = 1, \dots, L$.

1. Using the Gram–Schmidt procedure, initialize t_1, t_2, t_3, t_4 , for points in both \mathcal{C} and \mathcal{C}^* , and initialize $N = 4$.
2. For $k = 1, \dots, 4$, let $\gamma_k = \sum_{\zeta \in \mathcal{C}^*} \lambda_\zeta t_k(\zeta)$.
3. For each $\xi \in \mathcal{C}$, initialize $w_\xi = \sum_{k=1}^4 \gamma_k t_k(\xi)$.
4. For $k = 4, 5, \dots$ (so that the degrees are at least 0 for all polynomials entering in the recursions) and while $N \leq L$, repeat steps 5–8 below.
5. For j with $D_{k+1} - 2 \leq D_j \leq D_k$, set

$$s_{k, j} = \langle f_k t_{p(k)}, t_j \rangle.$$

6. Define T_{k+1} by

$$T_{k+1} = f_k t_{p(k)} - \sum_{D_{k+1} - 2 \leq D_j \leq D_k} s_{k, j} t_j$$

for points in both \mathcal{C} and \mathcal{C}^* . If $I_{k+1} = \langle T_{k+1}, T_{k+1} \rangle = 0$, then stop and set $N = k$. Otherwise, define $t_{k+1} = T_{k+1} / I_{k+1}^{1/2}$.

7. Set $\gamma_{k+1} = \sum_{\zeta \in \mathcal{C}^*} \lambda_\zeta t_{k+1}(\zeta)$.
8. For each $\xi \in \mathcal{C}$, $w_\xi = w_\xi + \gamma_{k+1} t_{k+1}(\xi)$, $k = k + 1$, $N = N + 1$.

In the case of the sphere \mathbb{S}^q , we take $L = d_{\tilde{n}}^{q+1}$ for some integer $\tilde{n} \geq 1$. The number of j 's with $D_{k+1} - 2 \leq D_j \leq D_k$, $1 \leq j, k \leq L$, is $\mathcal{O}(\tilde{n}^{q-1})$. In this discussion only, let $M = |\mathcal{C}| + |\mathcal{C}^*|$. Consequently, steps 5 and 6 require $\mathcal{O}(M\tilde{n}^{q-1})$ operations. Since the remaining two steps in the loop take $\mathcal{O}(M)$ operations, the loop starting at step 4 requires $\mathcal{O}(M\tilde{n}^{2q-1})$ operations. Finally, we observe that in implementing the above algorithm, one need not keep the whole matrix $t_k(\xi)$; only the rows corresponding to three degrees are required in any step. In particular, the memory requirement of this algorithm is $\mathcal{O}(M\tilde{n}^{q-1})$.

5. Numerical experiments. The objective of this section is to demonstrate and supplement the theoretical results presented in sections 3 and 4.

Our first set of experiments illustrates Algorithms LSQ and REC. The experiments were conducted over a long period of time, many of them long before we started to write the paper. Hence, the normalizations for the spherical polynomials $Y_{\ell,k}$ in Tables 1 and 2 are somewhat different from those in the rest of the paper. This is reflected in the sum of the absolute values of the weights, but has no effect on the various results other than scaling.

First, we report on Algorithm LSQ. Each of the experiments in this case was repeated 30 times with data sets chosen randomly from the distribution μ_2 on \mathbb{S}^2 . To test our algorithms, we computed the computed Gram matrix G^{COM} given by

$$G_{\ell,m}^{COM} = \sum_{\xi \in \mathcal{C}} w_{\xi}^{LSQ} y_{\ell}(\xi) y_m(\xi), \quad \ell, m < \lfloor n/2 \rfloor.$$

The average maximum matrix norm of the difference between G^{COM} and the identity matrix of the same size indicates the error of the quadrature formulas. The results are shown in Table 1. Based on these results we conjecture that in order to obtain stable quadrature formulas (i.e., with small condition number for the original Gram matrix G_N) exact for degree $n \geq 1$, one has to use at most $4d_n^{q+1}$ uniformly distributed points. In contrast, the theoretical guarantee in Theorem 4.1(c) requires $\mathcal{O}(n^{3q} \log n)$ points.

TABLE 1

The statistics for the experiments with Algorithm LSQ. $M = |\mathcal{C}|$; $n - 2$ is the degree of spherical polynomials for which exact quadrature formulas were computed; $N = n^2$; pos stands for the number of positive weights; and $\kappa(G_N)$, λ_{\min} , and λ_{\max} are the condition number, the maximum eigenvalue, and the minimum eigenvalue of the matrix G_N , respectively.

As can be seen from the table, for a fixed degree n , the condition number $\kappa(G_N)$ decreases as the number of points increases. For $n > 140$ and various sets of randomly generated points on the sphere, we do not obtain good numerical results. This might be due to a defect in the built-in numerical procedures used by MATLAB in computing the spherical harmonics of high degree at values close to -1 or 1 . The situation was much better for the dyadic points, i.e., the centers of the dyadic triangles.

For dyadic points on the sphere, the best result we obtained so far is $n = 178$ with 131072 points. As a further verification of this quadrature, we considered the following data. The data is constructed using coefficients $\{a_{\ell,k}\}$ for spherical polynomials up to degree 90, taken from model MF4 used for modeling the lithospheric field. The model, based on CHAMP satellite data, is computed by geophysicists at

GeoForschungsZentrum Potsdam in Germany. We use those coefficients to construct the samples of a function $f = \sum_{\ell,k} a_{\ell,k} Y_{\ell,k}$ at the centers of $8 * 4^7$ dyadic triangles. We then use our precomputed quadrature based at these centers which can integrate spherical polynomials up to degree 178 to compute the Fourier coefficients $\widehat{a}_{\ell,k}$. The maximum difference between the vector $\{\widehat{a}_{\ell,k}\}$ and the vector $\{a_{\ell,k}\}$ was found to be $6.66 * 10^{-15}$.

Next, we considered Algorithm REC. In the context of spherical polynomials, the recurrence relations have to be chosen very carefully using the special function properties of the spherical harmonics $Y_{\ell,k}$ in order to get stable results [29]. In the present situation, the polynomials t_k have no special structure. Therefore, it turns out that Algorithm REC is not very stable for high degrees. However, when we took the centers of 8192 dyadic triangles as the quadrature nodes and used the measure ν^{TR} as the starting measure, then we were able to obtain satisfactory quadrature formulas for degree 32. We note an interesting feature here that all the weights obtained by this algorithm are positive. These results are summarized in Table 2.

TABLE 2
Quadrature constructed using REC on 8192 dyadic points.

n	Error	$\min(w_\xi)$	$\max(w_\xi)$	$\sum w_\xi$
16	$4.196643 * 10^{-14}$	$5.181468 * 10^{-4}$	$2.538441 * 10^{-3}$	12.56637
22	$5.302425 * 10^{-13}$	$5.175583 * 10^{-4}$	$2.543318 * 10^{-3}$	12.56637
32	$9.240386 * 10^{-11}$	$5.154855 * 10^{-4}$	$2.544376 * 10^{-3}$	12.56637
42	$4.434868 * 10^{-8}$	$5.086157 * 10^{-4}$	$2.544141 * 10^{-3}$	12.56637
44	$2.320896 * 10^{-5}$	$5.094771 * 10^{-4}$	$2.562948 * 10^{-3}$	12.56638

Our second set of experiments demonstrates the local approximation properties of the operators $\sigma_n(\mathcal{C}, \mathbf{W}; h)$ for a smooth function h . For this purpose, we consider the following benchmark functions (5.1), considered by various authors [32, 31, 15, 10]. Using the notation $\mathbf{x} = (x_1, x_2, x_3)$, the functions are defined by

$$\begin{aligned}
 g_1(\mathbf{x}) &= (x_1 - 0.9)_+^{3/4} + (x_3 - 0.9)_+^{3/4}, \\
 g_2(\mathbf{x}) &= [0.01 - (x_1^2 + x_2^2 + (x_3 - 1)^2)]_+ + \exp(x_1 + x_2 + x_3), \\
 g_3(\mathbf{x}) &= 1/(101 - 100x_3), \\
 g_4(\mathbf{x}) &= 1/(|x_1| + |x_2| + |x_3|), \\
 g_5(\mathbf{x}) &= \begin{cases} \cos^2\left(\frac{3\pi}{2}\text{dist}(\mathbf{x}, \mathbf{x}_0)\right) & \text{if } \text{dist}(\mathbf{x}, \mathbf{x}_0) < 1/3, \\ 0 & \text{if } \text{dist}(\mathbf{x}, \mathbf{x}_0) \geq 1/3, \end{cases}
 \end{aligned}$$

(5.1) where $\mathbf{x}_0 = (-1/2, -1/2, 1/\sqrt{2})$.

In order to define the function h , we recall first that the B spline B_m of order m is defined recursively [1, p. 131] by

$$(5.2) \quad B_m(x) := \begin{cases} 1 & \text{if } m = 1, 0 < x \leq 1, \\ 0 & \text{if } m = 1, x \in \mathbb{R} \setminus (0, 1], \\ \frac{x}{m-1} B_{m-1}(x) + \frac{m-x}{m-1} B_{m-1}(x-1) & \text{if } m > 1, x \in \mathbb{R}. \end{cases}$$

The function B_m is an $m-1$ times iterated integral of a function of bounded variation. We will choose h to be

$$(5.3) \quad h_m(x) = \sum_{k=-m}^m B_m(2mx - k),$$

for different values of m , in order to illustrate the effect of the smoothness of h_m on the quality of local approximation. If $m \geq 3$, the function h_m satisfies the conditions in Proposition 2.1 with $S = m - 1$. We note that the discretized Fourier projection operator $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_1)$ has been called the hyperinterpolation operator [30].

One example of the localization properties of our operators is given in Table 3, where we show the error in approximation of g_1 on the whole sphere and on the cap $K = \mathbb{S}_{0.4510}^2((-1/\sqrt{2}, 0, -1/\sqrt{2}))$. The operators were constructed using the Driscoll–Healy quadrature formulas [3] based on $4(n+1)^2$ points, exact for integrating polynomials of degree $2n$. The maximum error on the whole sphere, given in columns 2 and 3, is estimated by the error at 10000 randomly chosen points; the maximum error on the cap, given in columns 4 and 5, is estimated by the error at 1000 randomly chosen points on the cap. It is clear that even though the maximum error on the whole sphere is slightly better for the (discretized) Fourier projection than for our summability operator, the singularities of g_1 continue to dominate the error in the Fourier projection on a cap away from these singularities; the performance of our summability operator is far superior.

TABLE 3

$S2errh1 = \max_{\mathbf{x} \in \mathbb{S}^2} |g_1(\mathbf{x}) - \sigma_n(\mathcal{C}, \mathbf{W}; h_1, g_1, \mathbf{x})|$, $S2errh5 = \max_{\mathbf{x} \in \mathbb{S}^2} |g_1(\mathbf{x}) - \sigma_n(\mathcal{C}, \mathbf{W}; h_5, g_1, \mathbf{x})|$,
 $Kerrh1 = \max_{\mathbf{x} \in K} |g_1(\mathbf{x}) - \sigma_n(\mathcal{C}, \mathbf{W}; h_1, g_1, \mathbf{x})|$, $Kerrh5 = \max_{\mathbf{x} \in K} |g_1(\mathbf{x}) - \sigma_n(\mathcal{C}, \mathbf{W}; h_5, g_1, \mathbf{x})|$,
 and $(\mathcal{C}, \mathbf{W})$ are given by the Driscoll–Healy formulas.

n	$S2errh1$	$S2errh5$	$Kerrh1$	$Kerrh5$
63	0.0097	0.0112	$3.4351 * 10^{-4}$	$6.5926 * 10^{-7}$
127	0.0044	0.0055	$8.0596 * 10^{-5}$	$6.5240 * 10^{-8}$
255	0.0033	0.0038	$1.4170 * 10^{-5}$	$1.1816 * 10^{-8}$

Theorem 3.2 points out another way to demonstrate the superior localization of our summability operator without a priori knowledge of the locations of the singularities. Since each of the test functions is infinitely differentiable on large caps of different sizes, Theorem 3.2 suggests that the more localized the method, the greater the probability that the approximation error would be smaller than a given number. To demonstrate also how our ability to construct quadrature formulas based on scattered data helps us to analyze the approximation properties of our summability operators, we took for the set \mathcal{C} a randomly generated sample of 65536 points. For these points, the weights \mathbf{W} computed by Algorithm LSQ yield a quadrature formula exact for integrating spherical polynomials of degree 126. We compared three approximation methods, the least squares approximation from Π_{63}^2 , the approximation given by the operator $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_1)$, and the approximation given by $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_5)$. For each function, we computed the absolute value of the difference between the approximate value computed by each of the three methods and the true value of the function at 20000 randomly chosen points on the sphere. The percentage of points where the value of this difference is less than 10^{-x} is reported in Table 4 for $x = 2 : 10$. It is very obvious that $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_5)$ gives a performance far superior to those of the other methods, due to its localization properties.

TABLE 4

Percentages of error less than 10^{-x} for different functions: $S1 =$ error with $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_1)$, $LS =$ least squares, $S5 =$ error with $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_5)$. For example, for the function g_3 , $S5$ was less than 10^{-7} for 82.22% of the 20000 randomly selected points, while $S1$ (respectively, LS) was less than 10^{-7} for 1.26% (respectively, 1.49%) points.

TABLE 5

Percentages of error less than 10^{-x} for $\epsilon = 0.01$, $S1 =$ error with $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_1)$, $LS =$ least squares, $S5 =$ error with $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_5)$. The random noise in the left half comes from the uniform distribution in $[-\epsilon, \epsilon]$; that in the right half is from the normal distribution with mean 0 and standard deviation ϵ .

$x \rightarrow$	5	4	3	2	3.0	2.75	2.5	2.25
$S1$	0.05	0.635	9.93	97.45	0	7.97	92.75	100.00
LS	0	0	0	100	0	0.04	30.93	99.07
$S5$	0.085	1.015	10.03	97.49	0.24	51.97	99.87	100.00

Next, we illustrate the stability of our operators under noise. Since our operators are linear operators, we assume for this part of the study that the target function f is the zero function contaminated either by uniform random noise in the range $[-\epsilon, \epsilon]$ or by a normally distributed random variable with mean 0 and standard deviation ϵ . We let \mathcal{C} be a set of 65536 random points and computed corresponding weights \mathbf{W} that integrate exactly polynomial up to degree 126. These were used in calculating $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_1)$ and $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_5)$ at each point of a test data set consisting of 20000 random samples from the distribution μ_2 . For each value of $\epsilon = 0.1; 0.01; 0.001; 0.0001$, the experiment was repeated 50 times, and the errors were then averaged over the number of repetitions. The percentage of points at which the absolute computed value was less than 10^{-x} is reported in Table 5 in the case when $\epsilon = 0.01$. The results for the other values of ϵ were consistent with the linearity of the operator. We observe that in each case, both $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_1)$ and $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_5)$ yield better results than the least squares approximation, while $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_5)$ is slightly superior to $\sigma_{63}(\mathcal{C}, \mathbf{W}; h_1)$.

Finally, we used our operator $\sigma_{22}(\mathcal{C}, \mathbf{W}; h_7)$ with the MAGSAT data. Our purpose here was only to test how our methods work on “real life” data. This data, kindly supplied to us by Dr. Thorsten Maier, measures the magnetic field of the earth in nano-Tesla as a vector field. It was derived from vectorial MAGSAT morning data that has been processed by Nils Olsen of the Danish Space Research Institute. The measurements are averaged on a longitude-latitude grid with $\Delta\phi = 4^\circ$ and $\Delta\theta = 2^\circ$ in geomagnetic coordinates. The radial variations of the MAGSAT satellite have

FIG. 2. From left to right: The original data, its reconstruction using $\sigma_{22}(\mathcal{C}, \mathbf{W}; h_7)$, and the error in the approximation, $|\sigma_{22}(\mathcal{C}, \mathbf{W}; h_7) - y|$.

been neglected in the data set and, therefore, prior to the averaging process, the GSFC(12/83) reference potential model has been subtracted. The data results from one month of measurements, centered at March 21, 1980. We extract the east-west component of the vectorial data as a scalar-valued function on the sphere. In total, there are 8190 data sites. A quadrature of degree 44 was computed based on those sites. Figure 2 shows the original data, its reconstruction using $\sigma_{22}(\mathcal{C}, \mathbf{W}; h_7)$, and the error in the approximation, $|\sigma_{22}(\mathcal{C}, \mathbf{W}; h_7) - y|$, as a map in the longitude-latitude plane. As can be seen from the figures, the reconstruction preserves the key features of the original data.

6. Proofs. In the interest of organization, we will prove the various new results in the paper in the following order. We will prove Theorem 4.2 first, since its proof does not require any preparation. We will then use Proposition 2.1 to prove Theorems 3.1(a) and 3.2(a). Next, we will prove Lemma 6.1 and use it to prove parts (a) and (b) of Theorem 4.1. The remaining results involve probabilities. We prove Lemma 6.2 next, estimating the probability that the supremum norm of a sum of random spherical polynomials exceeds a given number. This lemma will be used immediately to prove Theorem 4.1(c). Finally, we will prove Theorems 3.1(b) and 3.2(b).

Proof of Theorem 4.2. It is convenient to prove (4.9) first. Since Py_k is a polynomial of degree $D_k + 1$, there exist real numbers $r_{k,j}(P)$ such that

$$Py_k = \sum_{D_j \leq D_k + 1} r_{k,j}(P)y_j.$$

Since the system $\{y_k\}$ is orthonormal with respect to μ ,

$$r_{k,j}(P) = \int_{\Omega} P y_k y_j d\mu.$$

If $D_j < D_k - 1$, then the degree of $P y_j$ is less than D_k . Because of the lexicographic ordering where lower degree polynomials appear before the higher degree ones, this implies that $P y_j \in V_{k-1}$. Since y_k is orthogonal to V_{k-1} , it follows that $r_{j,k}(P) = 0$ if $D_j < D_k - 1$. This completes the proof of (4.9).

We observe that $y_{p(k)} \in \text{span}\{u_1, \dots, u_{p(k)}\}$. Thus, there exists a constant α such that $\alpha y_{p(k)} - u_{p(k)} \in V_{p(k)-1}$. Thus, $\alpha \tilde{f}_k y_{p(k)} - \tilde{f}_k u_{p(k)} = \alpha \tilde{f}_k y_{p(k)} - u_{k+1}$ is a linear combination of terms of the form $\tilde{f}_k u_j$, $1 \leq j \leq p(k) - 1$. Since $p(k)$ is the minimal index for which there exists a monomial \tilde{f}_k with $\tilde{f}_k u_{p(k)} \in V_{k+1}$, each of the terms $\tilde{f}_k u_j$, $1 \leq j \leq p(k) - 1$, is in V_k . It follows that $\alpha \tilde{f}_k y_{p(k)} - u_{k+1} \in V_k$. Again, there exists a constant α' such that $\alpha' u_{k+1} - y_{k+1} \in V_k$. Therefore, writing $f_k = \alpha \alpha' \tilde{f}_k$, we conclude that $f_k y_{p(k)} - y_{k+1} = \alpha' (\alpha \tilde{f}_k y_{p(k)} - u_{k+1}) + \alpha' u_{k+1} - y_{k+1} \in V_k$; i.e., $f_k y_{p(k)} = y_{k+1} - \sum_{D_j \leq D_k} \tilde{r}_{k,j} y_j$. The first equation in (4.8) is now proved in view of (4.9), applied with $p(k)$ in place of k and the fact that $D_{p(k)} = D_{k+1} - 1$. We note that f_k is a constant multiple of the monomial \tilde{f}_k . The second equation in (4.8) is proved in the same way.

Using the second equation in (4.8) and (4.9), we obtain from the definition of $c_{k,j}$'s that

$$\begin{aligned} A_k c_{k+1,\ell} &= A_k \int_{\Omega} t_{k+1} y_{\ell} d\mu \\ &= \int_{\Omega} f_k t_{p(k)} y_{\ell} d\mu + \sum_{D_{k+1}-2 \leq D_j \leq D_k} s_{k,j} \int_{\Omega} t_j y_{\ell} d\mu \\ &= \sum_{D_{\ell}-1 \leq D_m \leq D_{\ell}+1} r_{\ell,m}(f_k) \int_{\Omega} t_{p(k)} y_m d\mu + \sum_{D_{k+1}-2 \leq D_j \leq D_k} s_{k,j} c_{j,\ell} \\ &= \sum_{D_{\ell}-1 \leq D_m \leq D_{\ell}+1} r_{\ell,m}(f_k) c_{p(k),m} + \sum_{D_{k+1}-2 \leq D_j \leq D_k} s_{k,j} c_{j,\ell}. \end{aligned}$$

This proves (4.10). \square

Next, we use Proposition 2.1 to prove Theorems 3.1(a) and 3.2(a).

Proof of Theorem 3.1(a). To prove part (a), we assume without loss of generality that $n \geq 8$, and let $\ell \geq 1$ be the largest integer with $2^{\ell+2} \leq n$. In view of (3.4),

$$\begin{aligned} \|f - \sigma_n^*(\mathcal{C}, \mathbf{W}; h; f)\|_{\infty} &\leq c E_{n/2}(f) \leq c E_{2^{\ell+1}}(f) \leq c \|f - \sigma_{2^{\ell+1}}^*(h; f)\|_{\infty} \\ &\leq c \sum_{k=\ell+1}^{\infty} \|\sigma_{2^{k+1}}^*(h; f) - \sigma_{2^k}^*(h; f)\|_{\infty} \leq c 2^{-r\ell} \leq c n^{-r}. \end{aligned}$$

This proves part (a). \square

Proof of Theorem 3.2(a). Let K'' be a spherical cap, concentric with K , K' , and having radius equal to the average of the radii of K , K' . Let ψ be a fixed C^{∞} function that is equal to 1 on K'' and equal to 0 outside of K . Without loss of generality, we

can assume that $n \geq 8$, and let $\ell \geq 1$ be the largest integer such that $2^{\ell+2} \leq n$. The direct theorem of approximation theory (cf. [27]) implies that there exists $P \in \Pi_{2^\ell}^q$ such that

$$\|\psi - P\|_\infty \leq c2^{-\ell S}.$$

Therefore, using the definition of $\|f\|_{\mathbb{W}_r(K)}$, we conclude that

$$\begin{aligned} E_{2^{\ell+1}}(f\psi) &\leq \|f\psi - P\sigma_{2^\ell}^*(h; f)\|_\infty \leq \|(f - \sigma_{2^\ell}^*(h; f))\psi\|_\infty + \|(\psi - P)\sigma_{2^\ell}^*(h; f)\|_\infty \\ &\leq c\{\|f - \sigma_{2^\ell}^*(h; f)\|_{\infty, K} + 2^{-nS}\|f\|_\infty\} \\ &\leq c\left\{\sum_{k=\ell+1}^\infty \|\sigma_{2^{k+1}}^*(h; f) - \sigma_{2^k}^*(h; f)\|_{\infty, K} + 2^{-nS}\|f\|_\infty\right\} \leq c2^{-r\ell}. \end{aligned}$$

In view of (3.4),

$$\begin{aligned} \|f - \sigma_n(\mathcal{C}, \mathbf{W}; h; f\psi)\|_{\infty, K'} &= \|f\psi - \sigma_n(\mathcal{C}, \mathbf{W}; h; f\psi)\|_{\infty, K'} \\ &\leq \|f\psi - \sigma_n(\mathcal{C}, \mathbf{W}; h; f\psi)\|_\infty \\ (6.1) \qquad \qquad \qquad &\leq cE_{n/2}(f\psi) \leq E_{2^{\ell+1}}(f\psi) \leq c2^{-r\ell} \leq cn^{-r}. \end{aligned}$$

Since $1 - \psi(\zeta) = 0$ for $\zeta \in K''$, we can use (2.8) to deduce that, for $\mathbf{x} \in K'$,

$$\begin{aligned} |\sigma_n(\mathcal{C}, \mathbf{W}; h; (1 - \psi)f, \mathbf{x})| &= \left| \sum_{\xi \in \mathcal{C} \setminus K''} w_\xi f(\xi)(1 - \psi(\xi))\Phi_n(h; \mathbf{x} \cdot \xi) \right| \\ &\leq \frac{c(K, K', K'')}{n^{S-q}} \|(1 - \psi)f\|_\infty \sum_{\xi \in \mathcal{C}} |w_\xi| \leq \frac{c(K, K', K'')}{n^{S-q}}. \end{aligned}$$

Together with (6.1) and the fact that $r \leq S - q$, this implies (3.9). □

Next, we prove Lemma 6.1, describing certain extremal properties for the weights w_ξ^{LSQ} . These will be used in the proof of parts (a) and (b) of Theorem 4.1.

LEMMA 6.1. *Let $n \geq 1$ be an integer, $N = d_n^{q+1}$, \mathcal{C} be a finite set of points on \mathbb{S}^q , and ν be a measure supported on \mathcal{C} . Let $v_\xi := \nu(\{\xi\})$, $\xi \in \mathcal{C}$.*

(a) *If the Gram matrix is positive definite, then the weights w_ξ^{LSQ} are solutions of the extremal problem to minimize $\sum_{\xi \in \mathcal{C}} w_\xi^2/v_\xi$ subject to the conditions that $\sum_{\xi \in \mathcal{C}} w_\xi y_\ell(\xi) = \delta_{1,\ell}$.*

(b) *If (4.3) holds, there exist real numbers W_ξ , $\xi \in \mathcal{C}$, such that $|W_\xi| \leq v_\xi$ for $\xi \in \mathcal{C}$ and $\sum_{\xi \in \mathcal{C}} W_\xi P(\xi) = \int P d\mu_q$ for all $P \in \Pi_n^q$.*

Proof. In this proof, we will write G in place of G_N . The Lagrange multiplier method for solving the minimization problem sets up parameters λ_ℓ and minimizes

$$\sum_{\xi \in \mathcal{C}} w_\xi^2/v_\xi - 2 \sum_\ell \lambda_\ell \left(\sum_\xi w_\xi y_\ell(\xi) - \delta_{1,\ell} \right).$$

Setting the gradient (with respect to w_ξ) equal to 0, we get $w_\xi = v_\xi \sum_\ell \lambda_\ell y_\ell(\xi)$. Writing, in this proof only, $Q = \sum_\ell \lambda_\ell y_\ell$, we see that $w_\xi = v_\xi Q(\xi)$. Substituting back

in the linear constraints, this reduces to $\sum_{\xi \in \mathcal{C}} v_\xi Q(\xi) y_\ell(\xi) = \delta_{1,\ell}$. These conditions determine Q uniquely; indeed, $Q = \sum_j G_{1,j}^{-1} y_j$. This proves part (a).

Part (b) is proved essentially in [22, 23], but since it is not stated in this manner, we sketch a proof again. During this proof, different constants will retain their values. Let $M = |\mathcal{C}|$, \mathbb{R}^M be equipped with the norm $\|\mathbf{r}\| = \sum_{\xi \in \mathcal{C}} v_\xi |r_\xi|$. In this proof only, let \mathcal{S} be the operator defined on Π_n^q by $\mathcal{S}(P) = (P(\xi))_{\xi \in \mathcal{C}} \in \mathbb{R}^M$, and let \mathbb{V} be the range of \mathcal{S} . The estimate

$$(6.2) \quad \int |P| d\mu_q \leq c_1 \sum_{\xi \in \mathcal{C}} v_\xi |P(\xi)|$$

implies that the operator $\mathcal{S} : \Pi_n^q \rightarrow \mathbb{V}$ is invertible. We may now define a linear functional on \mathbb{V} by

$$x^*(\mathbf{r}) = \int \mathcal{S}^{-1}(\mathbf{r}) d\mu_q, \quad \mathbf{r} \in \mathbb{V}.$$

It is clear from (6.2) that the norm of x^* is bounded above by c_1 . The Hahn–Banach theorem yields a norm-preserving extension of this functional to the whole space \mathbb{R}^M . Identifying this functional with the vector $(W_\xi)_{\xi \in \mathcal{C}}$, the extension property implies that $\sum_{\xi \in \mathcal{C}} W_\xi P(\xi) = \int P d\mu_q$ for all $P \in \Pi_n^q$, while the norm preservation property implies that $|W_\xi| \leq c_1 v_\xi$ for $\xi \in \mathcal{C}$. \square

Proof of Theorem 4.1(a), (b). Let $N = d_n^{q+1}$, $\mathbf{r} \in \mathbb{R}^N$, and $P = \sum_\ell r_\ell y_\ell$. In this proof only, we write G in place of G_N . Then

$$\mathbf{r}^T G \mathbf{r} = \sum_{\ell, m} r_\ell \left\{ \sum_{\xi \in \mathcal{C}} v_\xi y_\ell(\xi) y_m(\xi) \right\} r_m = \sum_{\xi \in \mathcal{C}} v_\xi P(\xi)^2,$$

and $\mathbf{r}^T \mathbf{r} = \|P\|_2^2$.

Therefore, (4.3) with $p = 2$ implies that $c_1^2 \mathbf{r}^T \mathbf{r} \leq \mathbf{r}^T G \mathbf{r} \leq c_2^2 \mathbf{r}^T \mathbf{r}$ for all $\mathbf{r} \in \mathbb{R}^N$. The statements about the eigenvalues of G are an immediate consequence of the Raleigh–Ritz theorem [13, Theorem 4.2.2]. Using Lemma 6.1(b), we obtain weights W_ξ such that $\sum_{\xi \in \mathcal{C}} W_\xi y_\ell(\xi) = \delta_{1,\ell}$, $\ell = 1, \dots, N$, and $|W_\xi| \leq c v_\xi$, $\xi \in \mathcal{C}$. During the remainder of this proof, we write $w_\xi = w_\xi^{LSQ}$. In view of Lemma 6.1(a), we have

$$\sum_{\xi \in \mathcal{C}} |w_\xi| \leq \left\{ \sum_{\xi} v_\xi \right\}^{1/2} \left\{ \sum_{\xi \in \mathcal{C}} \frac{w_\xi^2}{v_\xi} \right\}^{1/2} \leq \left\{ \sum_{\xi} v_\xi \right\}^{1/2} \left\{ \sum_{\xi \in \mathcal{C}} \frac{W_\xi^2}{v_\xi} \right\}^{1/2} \leq c \sum_{\xi \in \mathcal{C}} v_\xi \leq c_1.$$

This completes the proof of part (a).

In order to prove part (b), we adopt the following notation during this proof only. Let I denote the $N \times N$ identity matrix. For any $N \times N$ matrix H , let $\|H\|$ denote $\sup \|H\mathbf{r}\|$, $\|\mathbf{r}\| = 1$, $\mathbf{r} \in \mathbb{R}^N$. We note that $\|H\|$ is the largest singular value of H . If H is a symmetric, positive definite matrix, then it is also the largest eigenvalue of H , and, moreover, $|\mathbf{r}_1^T H \mathbf{r}_2| \leq \|H\| \|\mathbf{r}_1\| \|\mathbf{r}_2\|$, $\mathbf{r}_1, \mathbf{r}_2 \in \mathbb{R}^N$. Using (4.4), it is easy to conclude using the Raleigh–Ritz theorem that $\|G - I\| \leq cn^{-q}$, $\|G^{-1}\| \leq c$, and, hence,

$$\|G^{-1} - I\| = \|G^{-1}(I - G)\| \leq c \|G^{-1}\| \|G - I\| \leq cn^{-q}.$$

Let $\mathbf{y}(\mathbf{x})$ denote the vector $(y_1(\mathbf{x}), \dots, y_N(\mathbf{x}))^T$ for $\mathbf{x} \in \mathbb{S}^q$. In view of the addition formula, $\|\mathbf{y}(\mathbf{x})\|^2$ is independent of \mathbf{x} , and, hence,

$$\|\mathbf{y}(\mathbf{x})\|^2 = \int_{\mathbb{S}^q} \sum_{j=1}^N y_j(\mathbf{x})^2 d\mu_q(\mathbf{x}) = d_n^{q+1} \leq cn^q, \quad \mathbf{x} \in \mathbb{S}^q.$$

Consequently, we have

$$\begin{aligned} \frac{|w_\xi^{LSQ}|}{v_\xi} &= \left| \int \mathbf{y}(\mathbf{x})^T G^{-1} \mathbf{y}(\xi) d\mu_q(\mathbf{x}) \right| \\ &\leq \left| \int \mathbf{y}(\mathbf{x})^T (G^{-1} - I) \mathbf{y}(\xi) d\mu_q(\mathbf{x}) \right| + \left| \int \mathbf{y}(\mathbf{x})^T \mathbf{y}(\xi) d\mu_q(\mathbf{x}) \right| \\ &\leq \|G^{-1} - I\| \int \|\mathbf{y}(\mathbf{x})\| \|\mathbf{y}(\xi)\| d\mu_q + |(1, 0, \dots, 0)^T \mathbf{y}(\xi)| \leq cn^{-q} n^q + c \leq c. \end{aligned}$$

This completes the proof of part (b). \square

The proof of the remaining new results in the paper are based on the following lemma, which gives a recipe for estimating the probabilities involving polynomial-valued random variables.

LEMMA 6.2. *Let $n, M \geq 1$ be integers, let $\{\omega_j\}_{j=1}^M$ be independent random variables, and, for $j = 1, \dots, M$, let $Z_j = Z(\omega_j, \circ) \in \Pi_n^q$ have mean equal to 0 according to ω_j . Let $B, R > 0$, $\max_{1 \leq j \leq M, \mathbf{x} \in \mathbb{S}^q} |Z_j(\mathbf{x})| \leq Rn^q$, and the sum of the variances of Z_j be bounded by Bn^q uniformly on \mathbb{S}^q . If $A > 0$ and $12R^2(A + q)n^q \log n \leq B$, then*

$$(6.3) \quad \text{Prob} \left(\left\| \sum_{j=1}^M Z_j \right\|_\infty \geq \sqrt{12B(A + q)n^q \log n} \right) \leq c_1 n^{-A}.$$

Here, the positive constant c_1 is independent of M and the distributions of ω_j .

Proof. The proof depends upon Bennett's inequality [28, p. 192]. In this proof only, we adopt a slightly different meaning for the symbols L, V, η . Let L, V, η be positive numbers, and let $X_j, j = 1, \dots, M$, be independent random variables. According to Bennett's inequality, if the mean of each X_j is 0, the range of each X_j is a subset of $[-L, L]$, and V exceeds the sum of the variances of X_j , then, for $\eta > 0$,

$$(6.4) \quad \text{Prob} \left(\left| \sum_{j=1}^M X_j \right| \geq \eta \right) \leq 2 \exp \left(-\frac{V}{L^2} g \left(\frac{L\eta}{V} \right) \right),$$

where, in this proof only, $g(t) := (1+t) \log(1+t) - t$. We observe that $g(t) = \int_0^t \int_0^u (1+w)^{-1} dw du$. Therefore, if $0 \leq t \leq 1/2$, then for $0 \leq w \leq u \leq t$, $(1+w)^{-1} \geq 2/3$ and hence, $g(t) \geq t^2/3$. Consequently, if $L\eta \leq V/2$, then

$$(6.5) \quad \text{Prob} \left(\left| \sum_{j=1}^M X_j \right| \geq \eta \right) \leq 2 \exp \left(\frac{-\eta^2}{(3V)} \right).$$

Now, let $\mathbf{x} \in \mathbb{S}^q$. We apply (6.5) with $Z_j(\mathbf{x})$ in place of X_j , Rn^q in place of L , Bn^q in place of V , and $\eta = \sqrt{3B(A + q)n^q \log n}$. Our condition on n ensures that

$L\eta/V \leq 1/2$ with these choices. Therefore,

$$(6.6) \quad \text{Prob} \left(\left| \sum_{j=1}^M Z_j(\mathbf{x}) \right| \geq \sqrt{3B(A+q)n^q \log n} \right) \leq 2n^{-A-q}.$$

Next, in the proof only, let $P^* = \sum_{j=1}^M Z_j$, $\mathbf{x}^* \in \mathbb{S}^q$ be chosen so that $|P^*(\mathbf{x}^*)| = \|P^*\|_\infty$, and let $\mathcal{C} \subset \mathbb{S}^q$ be chosen so that $|\mathcal{C}| \sim cn^q$ and $\delta_{\mathcal{C}}(\mathbb{S}^q) \leq 1/(2n)$. Then we may find $\xi^* \in \mathcal{C}$ such that $\text{dist}(\mathbf{x}^*, \xi^*) \leq 1/(2n)$. Since $P^* \in \Pi_n^q$, its restriction to the great circle through \mathbf{x}^* and ξ^* is a trigonometric polynomial of order at most n . In view of the Bernstein inequality for these polynomials [2, Chapter 4, inequality (1.1)],

$$|P^*(\xi^*) - P^*(\mathbf{x}^*)| \leq n\|P^*\|_\infty \text{dist}(\xi^*, \mathbf{x}^*) \leq (1/2)|P^*(\mathbf{x}^*)|.$$

We deduce that

$$\left\| \sum_{j=1}^M Z_j \right\|_\infty \leq 2 \max_{\mathbf{x} \in \mathcal{C}} \left| \sum_{j=1}^M Z_j(\mathbf{x}) \right|.$$

Therefore, the event $\|\sum_{j=1}^M Z_j\|_\infty \geq 2\sqrt{3B(A+q)n^q \log n}$ is a subset of the union of the $|\mathcal{C}|$ events $|\sum_{j=1}^M Z_j(\mathbf{x})| \geq \sqrt{3B(A+q)n^q \log n}$, $\mathbf{x} \in \mathcal{C}$. Hence, the estimate (6.6) implies (6.3) with $c_1 = 2c$. \square

We are now in a position to prove Theorem 4.1(c).

Proof of Theorem 4.1(c). Let $\mathbf{x} \in \mathbb{S}^q$. In this proof only, let $Z_\xi = \Phi_{4n}(h; \mathbf{x} \cdot \xi) - \int \Phi_{4n}(h; \mathbf{x} \cdot \zeta) d\mu_q(\zeta)$. Then the mean of each Z_ξ is 0, and its variance can be estimated by

$$\int Z_\xi^2 d\mu_q(\xi) \leq \int (\Phi_{4n}(h; \mathbf{x} \cdot \xi))^2 d\mu_q(\xi) \leq cn^q.$$

Finally, $|Z_\xi| \leq cn^q$ for each ξ . Hence, we may use Lemma 6.2, with cM in place of B and c in place of R , to conclude that

$$\text{Prob} \left(\sup_{\mathbf{x} \in \mathbb{S}^q} \left| \frac{1}{M} \sum_{\xi \in \mathcal{C}} \Phi_{4n}(h; \mathbf{x} \cdot \xi) - \int \Phi_{4n}(h; \mathbf{x} \cdot \zeta) d\mu_q(\zeta) \right| \geq c_2 \sqrt{\frac{n^q \log n}{M}} \right) \leq cn^{-A}$$

and, with $M \geq cn^q \log n / \eta^2$,

$$\text{Prob} \left(\sup_{\mathbf{x} \in \mathbb{S}^q} \left| \frac{1}{M} \sum_{\xi \in \mathcal{C}} \Phi_{4n}(h; \mathbf{x} \cdot \xi) - \int \Phi_{4n}(h; \mathbf{x} \cdot \zeta) d\mu_q(\zeta) \right| \geq \eta \right) \leq cn^{-A}.$$

Since any $P \in \Pi_{2n}^q$ can be written in the form

$$P(\zeta) = \int P(\mathbf{x}) \Phi_{4n}(h; \mathbf{x} \cdot \zeta) d\mu_q(\mathbf{x}),$$

we see that, with probability exceeding $1 - cn^{-A}$,

$$\begin{aligned}
 & \left| \frac{1}{M} \sum_{\xi \in \mathcal{C}} P(\xi) - \int P(\zeta) d\mu_q(\zeta) \right| \\
 &= \left| \frac{1}{M} \sum_{\xi \in \mathcal{C}} \int P(\mathbf{x}) \Phi_{4n}(h; \xi \cdot \mathbf{x}) d\mu_q(\mathbf{x}) \right. \\
 &\quad \left. - \int \int P(\mathbf{x}) \Phi_{4n}(h; \mathbf{x} \cdot \zeta) d\mu_q(\mathbf{x}) d\mu_q(\zeta) \right| \\
 &\leq \int |P(\mathbf{x})| \left| \frac{1}{M} \sum_{\xi \in \mathcal{C}} \Phi_{4n}(h; \xi \cdot \mathbf{x}) - \int \Phi_{4n}(h; \mathbf{x} \cdot \zeta) d\mu_q(\zeta) \right| d\mu_q(\mathbf{x}) \\
 &\leq \eta \int |P(\mathbf{x})| d\mu_q(\mathbf{x}).
 \end{aligned}$$

For $P \in \Pi_n^q$, we may now apply this estimate with $P^2 \in \Pi_{2n}^q$. \square

Another immediate consequence of Lemma 6.2 is the following lemma, describing the probabilistic behavior of the operator $\sigma_n(\mathcal{C}, \mathbf{W}; h)$.

LEMMA 6.3. *Suppose that $m \geq 1$ is an integer and that $\mathcal{C} = \{\xi_j\}_{j=1}^M$ admits an M-Z quadrature of order m , and let \mathbf{W} be the corresponding quadrature weights. Let $R, V > 0$, and, for $j = 1, \dots, M$, let ϵ_j be independent random variables with mean 0, variance not exceeding V , and range $[-R, R]$. Let $g \in C(\mathbb{S}^q)$, $\|g\|_\infty \leq 1$, and $\mathbf{E} = \{\epsilon_j g(\xi_j)\}_{\xi_j \in \mathcal{C}}$. Then, for integer $n \geq 1$ with $(R^2/V)(A + q)n^q \log n \leq c_3 m^q$,*

$$(6.7) \quad \text{Prob} \left(\|\sigma_n(\mathcal{C}, \mathbf{W}; h; \mathbf{E})\|_\infty \geq c_1 \sqrt{\frac{V(A + q)n^q \log n}{m^q}} \right) \leq c_2 n^{-A}.$$

Here the positive constants c_1, c_2, c_3 depend only on q but not on M and the distributions of ϵ_j .

Proof. In this proof only, if $\xi = \xi_j \in \mathcal{C}$, we will write ϵ_ξ for ϵ_j and w_ξ for the weight in \mathbf{W} corresponding to ξ . We use Lemma 6.2 with $E_\xi = m^q w_\xi \epsilon_\xi g(\xi) \Phi_n(h; \xi \cdot \circ)$, $\xi \in \mathcal{C}$. We note that the random variable ω_j in Lemma 6.2 is ϵ_ξ in this case. It is clear that the mean of each E_ξ is 0. Since (2.12) implies that $|w_\xi| \leq cm^{-q}$, (2.7) shows that $\|E_\xi\|_\infty \leq cRn^q$. Moreover, for any $\mathbf{x} \in \mathbb{S}^q$, the variance of $E_\xi(\mathbf{x})$ does not exceed $Vm^{2q} w_\xi^2 \Phi_n(h; \xi \cdot \mathbf{x})^2$. In view of the fact that w_ξ are M-Z quadrature weights, (2.12) and (2.7) imply that

$$\begin{aligned}
 \sum_{\xi \in \mathcal{C}} m^{2q} w_\xi^2 \Phi_n(h; \xi \cdot \mathbf{x})^2 &\leq cm^q \sum_{\xi \in \mathcal{C}} |w_\xi| \Phi_n^2(h; \xi \cdot \mathbf{x}) \\
 &\leq cm^q \int_{\mathbb{S}^q} \Phi_n^2(h; \zeta \cdot \mathbf{x}) d\mu_q(\zeta) \leq cm^q n^q.
 \end{aligned}$$

Thus, we may choose B in Lemma 6.2 to be cVm^q . The estimate (6.7) now follows as a simple consequence of (6.3). \square

We are now in a position to prove the probabilistic assertions of Theorems 3.1 and 3.2.

Proof of Theorem 3.1(b). To prove part (b), we use Lemma 6.3 with $g \equiv 1$. Since the range of ϵ_j 's is contained in $[-1, 1]$, we can take $R = V = 1$ and obtain from (6.7) that

$$\text{Prob} \left(\|\sigma_n(\mathcal{C}, \mathbf{W}; h; \mathbf{E})\|_\infty \geq c_4 \sqrt{\frac{(A+q)n^q \log n}{m^q}} \right) \leq c_2 n^{-A}.$$

The choice of n with an appropriate c_3 ensures that $(A+q)n^q \log n / m^q \leq n^{-2r}$. Therefore,

$$\text{Prob} (\|\sigma_n(\mathcal{C}, \mathbf{W}; h; \mathbf{E})\|_\infty \geq c_4 n^{-r}) \leq c_2 n^{-A}.$$

The estimate (3.8) is now clear in view of (3.4) and the linearity of the operators $\sigma_n(\mathcal{C}, \mathbf{W}; h)$. \square

Proof of Theorem 3.2(b). We apply Lemma 6.3 again with $g \equiv 1$. As before, we may choose $R = V = 1$. The choice of n with an appropriate c_3 ensures that $(A+q)n^q \log n / m^q \leq n^{-2r}$. Therefore, (6.7) with these choices implies that

$$\text{Prob} (\|\sigma_n(\mathcal{C}, \mathbf{W}; h; \mathbf{E})\|_\infty \geq c_4 n^{-r}) \leq c_2 n^{-A}.$$

Together with inequality (3.9) and the linearity of the operators $\sigma_n(\mathcal{C}, \mathbf{W}; h)$, this leads to (3.10). \square

7. Conclusion. We have described a construction of linear operators yielding spherical polynomial approximations based on scattered data on a Euclidean sphere. While the operators can be defined for arbitrary continuous functions on the sphere, without any a priori knowledge about the location and nature of its singularities, they are auto-adaptive in the sense that the approximation properties of these globally defined polynomials adapt themselves on the different parts of the sphere according to the smoothness of the target function on these parts. While the theoretical properties of these operators and their localization were studied in [18], a bottleneck in their numerical construction was the construction of quadrature formulas based on scattered data, exact for integrating moderately high degree spherical polynomials. Until now, it has been possible only to compute quadrature formulas exact for at most degree 18 polynomials. We show that a simple construction involving a Gram matrix is surprisingly well conditioned, and yields the necessary quadrature rules, up to degree 178. Using these newly constructed quadrature formulas, we are able to demonstrate that our constructions yield approximation properties superior to those of more traditional techniques of least squares and Fourier projection, in the sense that the presence of singularities in some parts of the sphere affects the degree of approximation by our operators on other parts far less than in the case of these other traditional techniques. We give probabilistic estimates on the local and global degrees of approximation by our operators in the presence of noise and demonstrate its use in the modeling of a “real life” data set. We also describe a theoretical algorithm for construction of data dependent multivariate orthogonal polynomials and their use in the construction of quadrature formulas, analogous to the univariate algorithms in Gautschi’s book [11].

Acknowledgments. This paper is a result of a long process, involving discussions with a number of mathematicians. In particular, it is our pleasure to acknowledge the support and encouragement of Mahadevan Ganesh, Thorsten Maier, Volker Michel, Dominik Michel, Ian Sloan, and Joe Ward. We are also grateful to the two referees and Fred Hickernell for their many useful suggestions for the improvement of the first draft of this paper.

ON THE INTERPOLATION ERROR ESTIMATES FOR \mathcal{Q}_1 QUADRILATERAL FINITE ELEMENTS*

SHIPENG MAO[†], SERGE NICAISE[‡], AND ZHONG-CI SHI[†]

Abstract. In this paper, we study the relation between the error estimate of the bilinear interpolation on a general quadrilateral and the geometric characters of the quadrilateral. Some explicit bounds of the interpolation error are obtained based on some sharp estimates of the integral over $\frac{1}{|J|^{p-1}}$ for $1 \leq p \leq \infty$ on the reference element, where J is the Jacobian of the nonaffine mapping. This allows us to introduce weak geometric conditions (depending on p) leading to interpolation error estimates in the $W^{1,p}$ norm, for any $p \in [1, \infty)$, which can be regarded as a generalization of the *regular decomposition property* (RDP) condition introduced in [G. Acosta and R. G. Durán, *SIAM J. Numer. Anal.*, 38 (2000), pp. 1073–1088] for $p = 2$ and new RDP conditions (NRDP) for $p \neq 2$. We avoid the use of the reference family elements, which allows us to extend the results to a larger class of elements and to introduce the NRDP condition in a more unified way. As far as we know, the mesh condition presented in this paper is weaker than any other mesh conditions proposed in the literature for any p with $1 \leq p \leq \infty$.

Key words. error estimates, quadrilateral elements, isoparametric finite elements, maximal angle condition

AMS subject classifications. 65N30, 65N15

DOI. 10.1137/070700486

1. Introduction. Quadrilateral finite elements, particularly low order quadrilateral elements, are widely used in engineering computations due to their flexibility and simplicity. However, numerical accuracy cannot be achieved over arbitrary quadrilateral meshes, and certain geometric conditions are indispensable to guarantee the optimal convergence error estimates. It is known that the \mathcal{Q}_1 quadrilateral finite element is one of the most widely used quadrilateral elements. In order to obtain its optimal interpolation error, many mesh conditions have been introduced in the literature; let us give a review of them.

Denoting by \mathcal{Q} the Lagrange interpolation operator and using the standard notation for Sobolev spaces (cf. [11]), the first interpolation error estimate for the operator \mathcal{Q} goes back to Ciarlet and Raviart in [14], where the regular quadrilateral is supposed to satisfy

$$(1.1) \quad h_K / \bar{h}_K \leq \mu_1$$

and

$$(1.2) \quad |\cos \theta_K| \leq \mu_2 < 1$$

for all angles θ_K of the quadrilateral K ; here h_K is the diameter of K , and \bar{h}_K is the length of the shortest side of K . Under the above so-called nondegenerate condition,

Ciarlet and Raviart proved the following interpolation error estimate:

$$(1.3) \quad |u - \mathcal{Q}u|_{1,K} \leq Ch_K |u|_{2,K}.$$

On the other hand, error estimates for degenerate elements have attracted much attention since the works by Babuška and Aziz [9] and by Jamet [19]; interested readers are also referred to the works [5, 7, 8, 12, 13, 15, 17, 18, 21, 23, 24, 22, 32], the book [6] by Apel, the ICM report [16] by Durán, and the references therein. For triangular elements, the constant C in the estimate (1.3) depends only on the maximal angle of the element. For quadrilaterals, the situation may be different since the maximal angle condition is not necessary due to [20]. In such a case, the term “degenerate” is used in the following two situations: one refers to elements which are close to a triangle, while the other refers to narrow elements or anisotropic elements; interested readers are referred to Jamet [20] for the first case and to Ženíšek and Vanmaele [29, 30] and Apel [5] for the second.

In the first case, Jamet [20] considered a quadrilateral that can degenerate into a regular triangle and proved the error estimate (1.3) under the condition that there exists a constant σ such that

$$h_K/\rho_K \leq \sigma,$$

where ρ_K denotes the diameter of the maximum circle contained in quadrilateral K .

In view of this result, one may believe that the maximal angle condition is not necessary for the optimal interpolation error of the \mathcal{Q}_1 Lagrange interpolation operator. Recently, Acosta and Durán [2] made a great contribution in this regard and obtained the optimal interpolation error of \mathcal{Q}_1 interpolation under the regular decomposition property (RDP) condition (cf. the definition in section 2), which states that, if we divide the quadrilateral into two triangles by one diagonal, the ratio of the length of the other diagonal to that of the first is bounded, and both of the divided triangles satisfy the maximal angle condition. The above RDP condition is so weak that almost all of the degenerate quadrilateral conditions proposed before fall into this scope. Furthermore, the authors of [2] assert that this condition is necessary and state it as an open problem in the conclusion of their paper. For related papers concerning this assertion, we refer the reader to [25, 26, 31]. More recently, interpolation error estimates have been extended to the L^p setting; more precisely, the estimate

$$|u - \mathcal{Q}u|_{1,p,K} \leq Ch_K |u|_{2,p,K}$$

was proved by Acosta and Monzón [4] in the case $1 \leq p < 3$. In addition, the authors of [4] introduced the *double angle condition* (DAC), which is indeed equivalent to (1.2), and showed that this condition is a sufficient condition for the optimal interpolation error in the $W^{1,p}$ norm with $p \geq 3$. Though the DAC condition is much stronger than the RDP condition, so far, it is the weakest mesh condition for the optimal interpolation error in the $W^{1,p}$ norm with $p \geq 3$. One of the key techniques employed in [2] and [4] is to introduce an appropriate affine change of variables, which reduces the problem to a reference family of elements.

In this paper, we revisit the optimal error estimates of \mathcal{Q}_1 isoparametric Lagrange interpolation for degenerate quadrilaterals. Our motivation comes from the observation that, if we divide the quadrilateral into two triangles by the longer diagonal, when the two triangles have comparable areas, we should impose the maximal angle condition for both triangles. Otherwise, we may need to impose the maximal angle condition only for the big triangle T_1 , and because the error on the small triangle

T_3 contributes little to the interpolation error on the global quadrilateral, its maximal angle may become very large as $\frac{|T_3|}{|T_1|}$ approaches zero. Based on this observation, we introduce a generalized RDP condition which involves the ratio between the area of the two divided triangles in the mesh condition and show that under this generalized RDP condition the estimate (1.3) is valid. The interpolation error of \mathcal{Q}_1 Lagrange interpolation in the $W^{1,p}$ norm with $1 \leq p \leq \infty$ is proved in the same spirit. More precisely, we have found the weakest known geometric condition on a quadrilateral K (that depends on p) such that

$$(1.4) \quad |u - \mathcal{Q}u|_{1,p,K} \leq Ch_K |u|_{2,p,K}, \quad p \in [1, \infty),$$

holds. One of the key points in the proof of this estimate is to bound the integral

$$\int_{\widehat{K}} \frac{1}{|J|^{p-1}},$$

where J is the Jacobian of the mapping sending the reference element \widehat{K} to K . It turns out that to obtain such a bound, the cases $p \in [1, 2)$, $p = 2$, $p \in (2, 3)$, $p \in [3, \frac{7}{2}]$, $p \in (\frac{7}{2}, 4]$, and $p > 4$ have to be distinguished, leading to different geometric hypotheses. Note that, for $p \geq 3$, the proposed condition is much weaker than the DAC condition proposed in [4]. The technique developed in this paper is a combination of those in [2] and [20].

The rest of the paper is organized as follows. In section 2, we present our motivation for the geometric condition by revisiting a simple example considered in [2], and based on some observations we propose our generalized RDP (GRDP) condition for the optimal H^1 interpolation error. In section 3, following the techniques developed in [2] and [20], we prove the optimal interpolation error in the H^1 norm for the \mathcal{Q}_1 quadrilateral finite element. In section 4, we prove the above-mentioned technical bounds for different values of p . Then in section 5 we introduce our different geometric conditions depending on the values of $p \geq 1$ in the above-mentioned intervals and prove the interpolation error estimate (1.4) for all $p \geq 1$.

2. The generalized regular decomposition property. In this section, we will introduce a mesh condition that is sufficient for (1.3). This can be regarded as a generalization of the *regular decomposition property* presented by Acosta and Durán in [2].

We will adopt the following notation. Let K be a general quadrilateral with its vertices M_1, M_2, M_3, M_4 enumerated in counterclockwise order. In order to define the isoparametric elements on K , if $\widehat{K} = [0, 1]^2$ denotes the reference element, then there exists a bijective mapping $F_K : \widehat{K} \rightarrow K$ which is defined as

$$(2.1) \quad M = F_K(\widehat{M}) = \sum_{i=1}^4 M_i \widehat{\phi}_i(\xi, \eta) \quad \forall \widehat{M} = (\xi, \eta) \in \widehat{K},$$

where $\widehat{\phi}_i$ is the bilinear basis function associated with the vertex \widehat{M}_i , i.e., $\widehat{\phi}_i(\widehat{M}_j) = \delta_i^j, i = 1, 2, 3, 4$ and $j = 1, 2, 3, 4$.

Let the basis functions on the general quadrilateral K be defined as $\phi_i(M) = \widehat{\phi}_i(\widehat{M}) = \widehat{\phi}_i(F_K^{-1}(M))$ for any point $M \in K$. Then the \mathcal{Q}_1 isoparametric interpolation operator is defined by

$$\mathcal{Q}u(M) = \widehat{\mathcal{Q}}\widehat{u}(\widehat{M}) \quad \text{for any point } M \in K,$$

and $\widehat{\mathcal{Q}}$ is the bilinear Lagrange interpolation operator on \widehat{K} .

There are several mesh conditions in the literature that lead to (1.3). Among them, the RDP condition proposed by Acosta and Durán in [2] is the weakest. It is defined as follows.

DEFINITION 2.1. *A quadrilateral or a triangle verifies the maximal angle condition (MAC) with constant $\psi < \pi$, or $MAC(\psi)$, if the interior angles of K are less than or equal to ψ .*

DEFINITION 2.2. *Let K be a convex quadrilateral. We say that K satisfies the regular decomposition property with constants $N \in \mathbb{R}_+$ and $0 < \psi < \pi$, or $RDP(N, \psi)$, if we can divide K into two triangles along one of its diagonals, always called d_1 , the other being denoted by d_2 in such a way that $|d_2|/|d_1| \leq N$ and both triangles satisfy $MAC(\psi)$.*

In order to motivate our mesh condition introduced below, we first analyze the following examples. Let $K = K(a, b, \tilde{a}, \tilde{b})$ be the convex quadrilateral with vertices $M_1 = (0, 0), M_2 = (a, 0), M_3 = (\tilde{a}, \tilde{b}), M_4 = (0, b)$. Consider the case $K(1, a, a, a)$ (cf. the left-hand side of Figure 2.1) and take $u = x^2$. Straightforward computations show that

$$\left\| \frac{\partial(u - \mathcal{Q}u)}{\partial y} \right\|_{0,K}^2 \geq Ca \ln(a^{-1}) \quad \text{and} \quad |u|_{2,K}^2 \leq Ca.$$

Then the constant on the right-hand side of (1.3) cannot be bounded when a approaches zero. This is just the counterexample given in [2].

FIG. 2.1.

If we consider the case $K(1, a, a^s, a)$ with $s > 1$ (the right-hand side of Figure 2.1), we have

$$\left\| \frac{\partial(u - \mathcal{Q}u)}{\partial y} \right\|_{0,K}^2 \leq Ca^{2s-1} \ln(a^{-1}), \quad |u|_{2,K}^2 \geq Ca.$$

However, in this case the error constant

$$\frac{\left\| \frac{\partial(u - \mathcal{Q}u)}{\partial y} \right\|_{0,K}^2}{|u|_{2,K}^2} \leq Ca^{2s-2} \ln(a^{-1})$$

can be bounded with a constant independent of a . Both cases do not satisfy the RDP condition since the MAC of $\triangle M_2 M_3 M_4$ is violated if we divide the quadrilateral by the diagonal $M_2 M_4$.

What is the difference between these two examples? One reasonable interpretation is that for $s > 1$ the ratio $\frac{|\triangle M_2 M_3 M_4|}{|\triangle M_1 M_2 M_4|} = a^s$ for $K(1, a, a^s, a)$ is much smaller than the

FIG. 2.2. A general convex quadrilateral K .

ratio for $K(1, a, a, a)$. This suggests relaxing the MAC on $\triangle M_2M_3M_4$ because the error on $\triangle M_2M_3M_4$ contributes less compared to that on $\triangle M_2M_1M_4$.

Based on these considerations, we introduce the following geometric condition, which can be regarded as a GRDP condition and in section 3 will be proved to be sufficient for the optimal interpolation error estimate for the \mathcal{Q}_1 Lagrange interpolation.

DEFINITION 2.3. *Let K be a convex quadrilateral (illustrated by Figure 2.2). We say that K satisfies the generalized regular decomposition property with constant $N \in \mathbb{R}_+$ and $0 < \psi < \pi$, or $GRDP(N, \psi)$, if we can divide K into two triangles along one of its diagonals, always called d_1 , in such a way that the big triangle satisfies $MAC(\psi)$ and that*

$$(2.2) \quad \frac{h_K}{|d_1| \sin \alpha} \left(\frac{|T_3|}{|T_1|} \ln \frac{|T_1|}{|T_3|} \right)^{\frac{1}{2}} \leq N,$$

where the big triangle will always be called T_1 , the other is denoted by T_3 , h_K denotes the diameter of the quadrilateral K , and α is the maximal angle of T_3 .

Remark 2.4. Noticing that the term $\frac{|T_3|}{|T_1|} = \frac{|a_3|}{|a_1|}$, where $a_3 = d_2 \cap T_3$ and $a_1 = d_2 \cap T_1$ denote the two parts of the diagonal d_2 divided by the diagonal d_1 , the condition (2.2) can be easily checked in practical computations; in particular, if we choose the longest diagonal for d_1 , the condition (2.2) becomes $\frac{1}{\sin \alpha} \left(\frac{|a_3|}{|a_1|} \ln \frac{|a_1|}{|a_3|} \right)^{\frac{1}{2}} \leq N$ since the big triangle satisfies $MAC(\psi)$. Note that the above constant N is a generic constant and may be different from that in (2.2).

Remark 2.5. It is easy to see that if a quadrilateral K satisfies the RDP condition, then it also satisfies the GRDP condition. However, the converse is not true, as shown by the example $K(1, a, a^s, a)$ with $s > 2$. Note that the elements $K(1, a, a^s, a)$ do not satisfy the RDP condition if $s > 1$, while they satisfy the GRDP condition if and only if $s > 2$.

Remark 2.6. In fact, if one divides the quadrilateral into two triangles by the longest diagonal and if the small triangle is much smaller compared to the big one, then the quadrilateral K is almost degenerated into the big triangle, and the MAC of the small triangle should be relaxed under the control of $\frac{|T_3|}{|T_1|}$ because the error on T_3 contributes little to the interpolation error on the global quadrilateral. This is just our motivation for the presentation of the GRDP condition.

Remark 2.7. Let us finish this section by showing that for some particular examples the condition in Definition 2.3 that the big triangle satisfy the MAC is necessary. Indeed, consider the family of quadrilaterals Q_α of vertices $M_1 = (-1 + \cos \alpha, -\sin \alpha)$, $M_2 = (1, 0)$, $M_3 = (1 - \cos \alpha, \sin \alpha)$, and $M_4 = (-1, 0)$, with the parameter $\alpha \in (\frac{\pi}{2}, \pi)$; see Figure 2.3. Since the angles at M_2 and M_4 are larger than α , any triangle obtained

FIG. 2.3. The quadrilateral Q_α .

by subdividing Q_α by one diagonal does not satisfy $\text{MAC}(\psi)$ for some $\psi < \pi$ independent on α . If we consider $u(x, y) = x^2$, we directly see that

$$|u|_{2, Q_\alpha} = 2|Q_\alpha|^{1/2}.$$

On the other hand, by using the affine transformation that maps Q_α into the reference \hat{K} , we check that

$$\begin{aligned} |u - \mathcal{Q}u|_{1, Q_\alpha}^2 &\geq \left| \frac{\partial}{\partial y}(u - \mathcal{Q}u) \right|_{0, Q_\alpha}^2 = \left| \frac{\partial \mathcal{Q}u}{\partial y} \right|_{0, Q_\alpha}^2 \\ &\geq \frac{|Q_\alpha|}{4(\sin \alpha)^2} \int_{\hat{K}} (2 \cos \alpha \eta + 2(1 - \cos \alpha)\xi + (1 - \cos \alpha)^2) d\xi d\eta. \end{aligned}$$

As α goes to π , we see that

$$\int_{\hat{K}} (2 \cos \alpha \eta + 2(1 - \cos \alpha)\xi + (1 - \cos \alpha)^2) d\xi d\eta \rightarrow \int_{\hat{K}} (-2\eta + 4\xi + 4) d\xi d\eta = C^2 > 0.$$

Hence there exists $\beta_0 > 0$ small enough such that for all $\alpha \in (\pi - \beta_0, \pi)$

$$\int_{\hat{K}} (2 \cos \alpha \eta + 2(1 - \cos \alpha)\xi + (1 - \cos \alpha)^2) d\xi d\eta \geq \frac{C^2}{2}.$$

This finally shows that for all $\alpha \in (\pi - \beta_0, \pi)$ one has

$$\frac{|u - \mathcal{Q}u|_{1, Q_\alpha}}{|u|_{2, Q_\alpha}} \geq \frac{C}{4 \sin \alpha},$$

and hence the ratio $\frac{|u - \mathcal{Q}u|_{1, Q_\alpha}}{|u|_{2, Q_\alpha}}$ goes to infinity as α tends to π .

3. Interpolation error estimate in H^1 for \mathcal{Q}_1 elements. In this section, we shall prove the optimal order error estimate for \mathcal{Q}_1 Lagrange elements satisfying the GRDP condition by following the idea from [2] and [20]. Let Π be the conforming P_1 Lagrange interpolation operator on the big triangle T_1 ; i.e., Πu is the linear function which admits the same values with the function u at the three vertices M_1, M_2 , and M_4 . Then we have

$$|u - \mathcal{Q}u|_{1, K} \leq |\Pi u - \mathcal{Q}u|_{1, K} + |u - \Pi u|_{1, K}.$$

Because $\Pi u - \mathcal{Q}u$ belongs to the isoparametric finite element space and vanishes at M_1, M_2 , and M_4 , it follows that

$$(\Pi u - \mathcal{Q}u)(x) = (\Pi u - u)(M_3)\phi_3(x),$$

where ϕ_3 is the basis function corresponding to M_3 . Hence we obtain

$$(3.1) \quad |u - \mathcal{Q}u|_{1,K} \leq |(\Pi u - u)(M_3)| |\phi_3|_{1,K} + |u - \Pi u|_{1,K}.$$

The goal of the rest of this section is to estimate the two terms of the right-hand side of (3.1). We first give an estimate for the term $|\phi_3|_{1,K}$ following the idea developed in [20] and leave the terms $|(\Pi u - u)(M_3)|$ and $|u - \Pi u|_{1,K}$ for the end.

In order to estimate $|\phi_3|_{1,K}$, we start with a new bound for the term $\int_{\hat{K}} \frac{1}{|J|} d\xi d\eta$, where J is the Jacobian of the mapping F_K .

LEMMA 3.1. *Let K be a general convex quadrilateral with consecutive vertices M_1, M_2, M_3 , and M_4 (cf. Figure 2.2). Let θ be the angle of the two diagonals M_1M_3 (denoted by d_2) and M_2M_4 (denoted by d_1), and let O be the point at which they intersect. Let $a_i = |OM_i|$ with $a_i > 0$ for $i = 1, 2, 4$ and $a_3 \geq 0$. Let α, s be the maximal angle and the shortest edge of the triangle T_3 , respectively. Without loss of generality, we can assume that $M_3M_4 = s$. Then we have*

$$(3.2) \quad \int_{\hat{K}} \frac{1}{|J|} d\xi d\eta < \frac{4}{|d_1||s| \sin \alpha} \frac{|T_3|}{|T_1|} \left(2 + \ln \frac{|T_1|}{|T_3|} \right).$$

Proof. Let $(O\tilde{x}, O\tilde{y})$ be two auxiliary axes oriented along the vectors M_1M_3 and M_2M_4 . Let \tilde{J} be the Jacobian of the affine mapping $(\xi, \eta) \rightarrow (\tilde{x}, \tilde{y})$ and let J_1 be the Jacobian of the affine mapping $(\tilde{x}, \tilde{y}) \rightarrow (x, y)$. Then we have $J = \tilde{J}J_1$ with $|J_1| = \sin \theta$. It follows from (2.1) that

$$\begin{cases} \tilde{x} = -(1 - \xi)(1 - \eta)a_1 + \xi\eta a_3, \\ \tilde{y} = -\xi(1 - \eta)a_2 + (1 - \xi)\eta a_4. \end{cases}$$

First we assume that $a_2 \geq a_4$. It is easy to see that

$$\begin{aligned} \tilde{J} &= a_2a_3\xi + a_3a_4\eta + a_1a_4(1 - \xi) + a_1a_2(1 - \eta) \\ &\geq a_2a_3\xi + a_1a_2(1 - \eta) \geq 0. \end{aligned}$$

Then we can derive that

$$\begin{aligned} \int_{\hat{K}} \frac{1}{|\tilde{J}|} d\xi d\eta &\leq \int_{\hat{K}} \frac{1}{a_2a_3\xi + a_1a_2(1 - \eta)} d\xi d\eta \\ &= \frac{1}{a_2a_3} \int_0^1 \ln \left(1 + \frac{a_3}{a_1(1 - \eta)} \right) d\eta \\ &= \frac{1}{a_2a_3} \left(\int_0^{\frac{a_3}{a_1}} + \int_{\frac{a_3}{a_1}}^1 \right) \ln \left(1 + \frac{a_3}{a_1t} \right) dt \\ &< \frac{1}{a_2a_3} \left(\int_0^{\frac{a_3}{a_1}} \sqrt{\frac{a_3}{a_1t}} dt + \int_{\frac{a_3}{a_1}}^1 \frac{a_3}{a_1t} dt \right) \\ &= \frac{1}{a_1a_2} \left(2 - \ln \frac{a_3}{a_1} \right), \end{aligned}$$

where we have used the inequalities $\ln(1+x) < \sqrt{x}$ for all $x \in [1, \infty)$ and $\ln(1+x) < x$ for all $x \in [\frac{a_3}{a_1}, 1]$.

On the other hand, an application of the sin theorem in the triangle M_3OM_4 yields

$$(3.3) \quad \sin \theta = \frac{\sin \angle M_2M_4M_3|s|}{a_3}.$$

Furthermore, it can be easily proved that $\sin \angle M_2M_4M_3 \geq \frac{1}{2} \sin \alpha$. Indeed, if $\alpha = \angle M_2M_4M_3$, the assertion is obvious; otherwise, $\alpha = \angle M_2M_3M_4$, and then

$$\sin \angle M_2M_4M_3 = \sin(\angle M_2M_4M_3 + \angle M_4M_2M_3) \leq 2 \sin \angle M_2M_4M_3$$

because $\angle M_4M_2M_3 \leq \angle M_2M_4M_3$. Therefore,

$$\int_{\widehat{K}} \frac{1}{|J|} d\xi d\eta < \frac{2}{a_2|s| \sin \alpha} \frac{a_3}{a_1} \left(2 - \ln \frac{a_3}{a_1} \right),$$

together with the fact that $\frac{a_3}{a_1} = \frac{|T_3|}{|T_1|}$ and $a_2 \geq \frac{1}{2}|d_1|$, implies (3.2).

In the case $a_2 < a_4$, we just use the inequality $\tilde{J} \geq a_3a_4\eta + a_1a_4(1 - \xi)$ and prove the assertion by the same argument. \square

LEMMA 3.2. *Let K be a general convex quadrilateral with the same hypotheses as Lemma 3.1. Then we have*

$$(3.4) \quad \left| \phi_3 \right|_{1,K} \leq \frac{8h_K}{(|d_1||s| \sin \alpha)^{\frac{1}{2}}} \left(\frac{|T_3|}{|T_1|} \left(2 + \ln \frac{|T_1|}{|T_3|} \right) \right)^{\frac{1}{2}}.$$

Proof. By Lemma 2.2 in [20], we have

$$\left| \phi_3 \right|_{1,K} \leq 4h_K \left(\int_{\widehat{K}} \frac{1}{|J|} d\xi d\eta \right)^{\frac{1}{2}} \left| \widehat{\phi}_3 \right|_{1,\infty,\widehat{K}}.$$

The conclusion follows from Lemma 3.1 and the fact that $|\widehat{\phi}_3|_{1,\infty,\widehat{K}} = 1$. \square

Remark 3.3. As mentioned in [2], the error estimate of the term $|\phi_3|_{1,K}$ is the most technical one. It is estimated therein by introducing an appropriate affine change of variables that reduces the problem to a reference family of elements. Here we did not adopt the technique developed in [2] because we have not imposed the MAC on the small triangle. Meanwhile, the estimate of $|\phi_3|_{1,K}$ in [2] (see Lemma 4.6 of [2]) can be easily recovered under the assumption that $\frac{|d_2|}{|d_1|}$ is bounded.

Remark 3.4. Note that (3.4) gives a sharp estimate of the term $|\phi_3|_{1,K}$ up to a generic constant. In fact, one can just consider the example of the quadrilateral $K(1, b, a, b)$ under the assumption $0 < a, b \ll 1$. Some immediate calculations yield

$$\begin{aligned} \left| \phi_3 \right|_{1,K} &\geq \left\| \frac{\partial \phi_3}{\partial y} \right\|_{0,K} \geq C \frac{1}{\sqrt{b(1-a)}} \left(\ln \frac{1}{a} \right)^{\frac{1}{2}} \\ &\geq C \frac{h_K}{(|d_1||s| \sin \alpha)^{\frac{1}{2}}} \left(\frac{|T_3|}{|T_1|} \left(2 + \ln \frac{|T_1|}{|T_3|} \right) \right)^{\frac{1}{2}} \end{aligned}$$

since $|s| = a$, $\sin \alpha > b$, and $\frac{|T_3|}{|T_1|} = a$.

The next lemma gives an estimate for $|(u - \Pi u)(M_3)|$.

LEMMA 3.5. *Let K be a general convex quadrilateral; then we have*

$$(3.5) \quad |(u - \Pi u)(M_3)| \leq \left(\frac{4|s|}{|d_1| \sin \alpha} \right)^{\frac{1}{2}} \left\{ |u - \Pi u|_{1,T_3} + h_K |u|_{2,T_3} \right\}.$$

Proof. The proof is just the same as that of Lemma 4.2 in [2], which exploited a trace theorem with a sharp dependence of the constant given by [28]; we therefore omit it here. \square

Remark 3.6. The result of Lemma 3.5 gives a sharp estimate up to a generic constant. Consider the example of the quadrilateral $K(1, b, a, b)$ under the assumption $0 < a, b \ll 1$ and the function $u(x, y) = x^2$. We then see that $\Pi u = x$ and therefore

$$|(\Pi u - u)(M_3)| = a(1 - a) \geq C \left(\frac{|s|}{|d_1| \sin \alpha} \right)^{\frac{1}{2}} \left\{ |u - \Pi u|_{1,T_3} + h_K |u|_{2,T_3} \right\}$$

since $|s| = a$, $\sin \alpha > b$, and $|u - \Pi u|_{1,T_3} + h_K |u|_{2,T_3} \leq \sqrt{ab}$.

It remains to bound the term $|u - \Pi u|_{1,K}$. This is the goal of the following lemma.

FIG. 3.1.

LEMMA 3.7. *Let K be a general convex quadrilateral and Π be the linear Lagrange interpolation operator defined on T_1 ; then*

$$(3.6) \quad |u - \Pi u|_{1,K} \leq \frac{4}{\sin \gamma} \left(1 + \frac{2}{\pi} \right) \left(\frac{2|K|}{|T_1|} \right)^{\frac{1}{2}} h_K |u|_{2,K},$$

where γ is the maximal angle of T_1 .

Proof. Without loss of generality, we can assume that $\angle M_1 M_3 M_2 = \gamma$ is the maximal angle of T_1 and adopt the notation of Figure 3.1. Let v_1, v_2 be the directions of the edges l_1 and l_2 , respectively. Then we have

$$|u - \Pi u|_{1,K} \leq \frac{1}{\sin \gamma} \left(\|\nabla(u - \Pi u) \cdot v_1\|_{0,K} + \|\nabla(u - \Pi u) \cdot v_2\|_{0,K} \right).$$

Consider $A = \nabla(u - \Pi u) \cdot v_1 = \frac{\partial(u - \Pi u)}{\partial v_1}$, and let A_K be the mean value of A on K . The well-known Poincaré inequality gives

$$(3.7) \quad \|A - A_K\|_{0,K} \leq \frac{h_K}{\pi} |A|_{1,K}.$$

Note that for a general convex domain the constant in the above Poincaré inequality can be taken explicitly and independent of its shape (i.e., it depends only on its diameter). However, the original proof in [27] contains a mistake, and recently [10] gives a corrected proof; fortunately, the optimal constant $\frac{1}{\pi}$ in the Poincaré inequality remains valid.

Now we bound $\|A_K\|_{0,K}$ following an idea from [2]. By the sharp trace theorem of [28], the Cauchy–Schwarz inequality, and the fact that $\int_{l_1} A dv_1 = 0$, we have

$$\begin{aligned} \|A_K\|_{0,K} &= |K|^{\frac{1}{2}} |A_K| = \frac{|K|^{\frac{1}{2}}}{|l_1|} \left| \int_{l_1} (A - A_K) dv_1 \right| \\ &\leq \left(\frac{2|K|}{|T_1|} \right)^{\frac{1}{2}} \left(\|A - A_K\|_{0,K} + h_K |A|_{1,K} \right), \end{aligned}$$

which, together with (3.7), gives

$$\|\nabla(u - \Pi u) \cdot v_1\|_{0,K} \leq \left(1 + \frac{2}{\pi} \right) \left(\frac{2|K|}{|T_1|} \right)^{\frac{1}{2}} h_K |u|_{2,K}.$$

The term $\|\nabla(u - \Pi u) \cdot v_2\|_{0,K}$ is estimated similarly, and the proof of the lemma follows. \square

Collecting all of the above lemmas, we can obtain the main theorem of this section, which gives the optimal error estimate in the H^1 norm for convex quadrilaterals.

THEOREM 3.8. *Let K be a convex quadrilateral satisfying $GRDP(N, \psi)$; then we have*

$$(3.8) \quad |u - \mathcal{Q}u|_{1,K} \leq Ch_K |u|_{2,K},$$

with $C > 0$ depending only on N and ψ .

Proof. A combination of (3.4) and (3.5) yields

$$\begin{aligned} |(\Pi u - u)(M_3)| |\phi_3|_{1,K} &\leq \frac{16h_K}{|d_1| \sin \alpha} \left(\frac{|T_3|}{|T_1|} \left(2 + \ln \frac{|T_1|}{|T_3|} \right) \right)^{\frac{1}{2}} \\ &\quad \times \left\{ |u - \Pi u|_{1,T_3} + h_K |u|_{2,T_3} \right\}, \end{aligned}$$

which, together with (3.1) and (3.6), gives

$$\begin{aligned} |u - \mathcal{Q}u|_{1,K} &\leq \left\{ \frac{32h_K}{|d_1| \sin \alpha} \left(\frac{|T_3|}{|T_1|} \left(2 + \ln \frac{|T_1|}{|T_3|} \right) \right)^{\frac{1}{2}} + 1 \right\} \\ (3.9) \quad &\quad \times \frac{4}{\sin \gamma} \left(1 + \frac{2}{\pi} \left(\frac{2|K|}{|T_1|} \right)^{\frac{1}{2}} \right) h_K |u|_{2,K}. \end{aligned}$$

Since T_1 satisfies the MAC and $|T_1| \geq \frac{1}{2}|K|$, (3.8) follows from the assumption (2.2) and (3.9). \square

Remark 3.9. In fact, (3.9) gives an explicit error bound for the bilinear interpolation operator. If the two divided triangles have comparable areas, i.e., $\frac{|T_3|}{|T_1|} = O(1)$, then the results of [2] can be recovered from (3.9) with the RDP condition. Otherwise, if the quadrilateral is nearly degenerated into the triangle T_1 , i.e., $\frac{|T_3|}{|T_1|} \rightarrow 0$, we can see that the interpolation error of the \mathcal{Q}_1 element is dominated by that of the P_1 Lagrange interpolation operator on T_1 . Obviously, this is a quite reasonable conclusion. This reinforces the fact that the MAC imposed on T_1 cannot be relaxed

because it is also a necessary condition for the optimal interpolation error of the P_1 Lagrange interpolation operator (cf. [6, 9]).

Remark 3.10. One may ask whether the GRDP condition is necessary in the sense that, given a family of elements that does not satisfy the GRDP condition, the interpolation error estimate (3.8) cannot be uniformly bounded. Indeed we have already shown in Remark 2.7 that the MAC on the biggest triangle seems to be necessary. In its full generality we cannot hope to show that (2.2) is also necessary. From Remarks 3.4 and 3.6 we present a family of quadrilaterals that satisfies the MAC but not the condition (2.2) and for which the interpolation error estimate (3.8) is not uniformly satisfied. In that sense our condition (2.2) is almost necessary. For that purpose, we take the example from Remark 3.4 and the function $u(x, y) = x^2$. We then see that $\Pi u(x, y) = x$ and therefore

$$(\Pi u - u)(M_3) = a(1 - a), \quad |u|_{2,K} \leq C\sqrt{b}.$$

By the triangular inequality, we then have

$$|u - \mathcal{Q}u|_{1,K} \geq |(\Pi u - u)(M_3)| |\phi_3|_{1,K} - |u - \Pi u|_{1,K}.$$

Hence by Lemma 3.7, we have

$$\begin{aligned} \frac{|u - \mathcal{Q}u|_{1,K}}{h_K |u|_{2,K}} &\geq \frac{|(\Pi u - u)(M_3)| |\phi_3|_{1,K}}{h_K |u|_{2,K}} - \frac{|u - \Pi u|_{1,K}}{h_K |u|_{2,K}} \\ &\geq C_1 \frac{a\sqrt{|\ln a|}}{b} - C_2 \end{aligned}$$

for some positive constants C_1, C_2 independent on a and b . By choosing $b = a|\ln a|^\alpha$, with $\alpha \geq 0$, the above right-hand side tends to infinity for $a \rightarrow 0$ and therefore (3.8) is not uniformly satisfied. Furthermore, we easily check that this family of quadrilaterals satisfies the MAC but not the condition (2.2). In our proof of (3.8), the point where we make an overestimation is when we use the estimates $\|u - \Pi u\|_{1,T_3} \leq \|u - \Pi u\|_{1,K}$ and $|u|_{2,T_3} \leq |u|_{2,K}$. In many cases (for instance, in the case $a = b^2$), the right-hand sides are much larger than the corresponding left-hand sides.

4. Some technical bounds. Until now, we have studied the interpolation error estimate of the \mathcal{Q}_1 element in the H^1 norm. In this section and the next, we will extend our mesh condition for the error estimate in $W^{1,p}$ for $p \geq 1$. As suggested by section 3, the key point is to estimate $\frac{|\phi_3|_{1,p,K}}{h_K}$. But noticing that $|\frac{\partial \phi_3}{\partial x}| \leq \frac{2h_K}{|J|}$, $|\frac{\partial \phi_3}{\partial y}| \leq \frac{2h_K}{|J|}$, we have

$$(4.1) \quad |\phi_3|_{1,p,K} \leq 4h_K \left(\int_{\hat{K}} \frac{1}{|J|^{p-1}} d\xi d\eta \right)^{\frac{1}{p}},$$

and we are reduced to estimating the quantity

$$\int_{\hat{K}} \frac{1}{|J|^{p-1}} d\xi d\eta.$$

The remainder of this section is devoted to finding an explicit bound of this quantity for different values of p .

Let us start with the case $1 \leq p < 3$.

LEMMA 4.1. *Let K be a general convex quadrilateral; then we have*

$$(4.2) \quad \int_{\widehat{K}} \frac{1}{|J|^{p-1}} d\xi d\eta < \frac{4^{p-1}}{(2-p)(|d_1||s|\sin\alpha)^{p-1}} \left(\frac{|T_3|}{|T_1|}\right)^{p-1} \quad \text{for } p \in [1, 2),$$

$$(4.3) \quad \int_{\widehat{K}} \frac{1}{|J|^{p-1}} d\xi d\eta < \frac{4^{p-1}}{(p-2)(3-p)(|d_1||s|\sin\alpha)^{p-1}} \left(\frac{|T_3|}{|T_1|}\right)^{p-1} \quad \text{for } p \in (2, 3).$$

Proof. We adopt the notation introduced in Lemma 3.1. By direct computations, if $a_2 \geq a_4$, we can derive

$$\begin{aligned} \int_{\widehat{K}} \frac{1}{|\tilde{J}|^{p-1}} d\xi d\eta &\leq \int_{\widehat{K}} \frac{1}{(a_2 a_3 \xi + a_1 a_2 (1-\eta))^{p-1}} d\xi d\eta \\ &= \frac{1}{(2-p)(a_1 a_2)^{p-1}} \int_0^1 \left(\left(1 + \frac{a_3}{a_1} \xi\right)^{2-p} - \xi^{2-p} \right) d\xi \\ &= \frac{1}{(2-p)(3-p)a_1^{p-2} a_2^{p-1} a_3} \left(\left(1 + \frac{a_3}{a_1}\right)^{3-p} - \left(\frac{a_3}{a_1}\right)^{3-p} - 1 \right). \end{aligned}$$

If $p \in [1, 2)$, it can be easily proved that $(1+x)^{3-p} < 1 + (3-p)x + x^{3-p}$ for all $x \in (0, 1]$. Then we have

$$\int_{\widehat{K}} \frac{1}{|\tilde{J}|^{p-1}} d\xi d\eta < \frac{1}{(2-p)a_1^{p-1} a_2^{p-1}}.$$

Recalling that $|J| = |\tilde{J}| \sin\theta$ and (3.3), we get

$$\int_{\widehat{K}} \frac{1}{|J|^{p-1}} d\xi d\eta < \frac{4^{p-1}}{(2-p)(|d_1||s|\sin\alpha)^{p-1}} \left(\frac{a_3}{a_1}\right)^{p-1},$$

which implies (4.2).

Otherwise, if $p \in (2, 3)$, we have

$$\begin{aligned} \int_{\widehat{K}} \frac{1}{|\tilde{J}|^{p-1}} d\xi d\eta &\leq \frac{1}{(2-p)(a_2 a_3)^{p-1}} \int_0^1 \left(\left(1 + \frac{a_1}{a_3}(1-\eta)\right)^{2-p} - \left(\frac{a_1}{a_3}(1-\eta)\right)^{2-p} \right) d\eta \\ &= \frac{1}{(p-2)(3-p)a_3^{p-2} a_2^{p-1} a_1} \left(\left(\frac{a_1}{a_3}\right)^{3-p} + 1 - \left(1 + \frac{a_1}{a_3}\right)^{3-p} \right). \end{aligned}$$

On the other hand, we directly see that

$$(1+x)^{3-p} \geq x^{3-p} \quad \forall x > 0.$$

Then we have

$$\int_{\widehat{K}} \frac{1}{|\tilde{J}|^{p-1}} d\xi d\eta < \frac{1}{(p-2)(3-p)a_3^{p-2} a_2^{p-1} a_1}$$

and

$$\int_{\widehat{K}} \frac{1}{|J|^{p-1}} d\xi d\eta < \frac{4^{p-1}}{(p-2)(3-p)(|d_1||s|\sin\alpha)^{p-1}} \frac{a_3}{a_1},$$

which implies (4.3).

The case $a_2 < a_4$ is treated similarly. The proof is complete. \square

Remark 4.2. Comparing the upper bounds in (4.2), (4.3) with the one from (3.2), we can make the following conclusions: the right-hand sides of (4.2) and (4.3) are not valid for $p = 2$. Hence it is reasonable to have added a log factor in (3.2). Indeed, in the proof of Lemma 4.1, passing to the limit $p \rightarrow 2$ in the estimates of $\int_{\hat{K}} \frac{1}{|\tilde{J}|^{p-1}} d\xi d\eta$, we can show that

$$\begin{aligned} \int_{\hat{K}} \frac{1}{|\tilde{J}|} d\xi d\eta &= \lim_{p \rightarrow 2} \int_{\hat{K}} \frac{1}{|\tilde{J}|^{p-1}} d\xi d\eta \\ &\leq \lim_{p \rightarrow 2} \frac{1}{(p-2)(3-p)a_3^{p-2}a_2^{p-1}a_1} \left(\left(\frac{a_1}{a_3}\right)^{3-p} + 1 - \left(1 + \frac{a_1}{a_3}\right)^{3-p} \right) \\ &= \frac{1}{a_1 a_2} \left(\frac{a_1}{a_3} \ln \frac{a_1}{a_3} - \left(1 + \frac{a_1}{a_3}\right) \ln \left(1 + \frac{a_1}{a_3}\right) \right). \end{aligned}$$

This leads to (2.2) because $\left(\frac{a_1}{a_3} \ln \frac{a_1}{a_3} - \left(1 + \frac{a_1}{a_3}\right) \ln \left(1 + \frac{a_1}{a_3}\right)\right) \leq 2 + \ln \frac{a_1}{a_3}$.

On the other hand, the right-hand side of (4.3) is not valid for the critical point $p = 3$, so it is natural to make another analysis of the bound for $p \geq 3$. This will be discussed below.

Remark 4.3. When p approaches 2, the estimate (4.2) can be improved in order to avoid a blowup. In fact, for $p < 2$, $|\phi_3|_{1,p,K}$ can be bounded directly from (3.2). Indeed, taking into account $\frac{1}{p-1} > 1$ and applying Hölder’s inequality in the right-hand side of (4.1), it holds that

$$\begin{aligned} |\phi_3|_{1,p,K} &\leq 4h_K \left(\int_{\hat{K}} \frac{1}{|\tilde{J}|} d\xi d\eta \right)^{1-\frac{1}{p}} \\ &\leq \frac{4^{1+\frac{1}{p}} h_K}{(|d_1| |s| \sin \alpha)^{1-\frac{1}{p}}} \left(\frac{|T_3|}{|T_1|} \right)^{1-\frac{1}{p}} \left(2 + \ln \frac{|T_1|}{|T_3|} \right)^{1-\frac{1}{p}}. \end{aligned}$$

Let us proceed with the case $p \geq 3$.

LEMMA 4.4. *Let K be a general convex quadrilateral, and let $T_i = \triangle M_{i-1} M_i M_{i+1}$, $i = 1, 2, 3, 4$, with $M_{i\pm 4} = M_i$. Without loss of generality we may assume that $|T_3| = \min_{i=1,3} |T_i|$, $|T_4| = \min_{i=2,4} |T_i|$. Then we have*

$$(4.4) \quad \int_{\hat{K}} \frac{1}{|\tilde{J}|^{p-1}} d\xi d\eta \leq \frac{2^{1+\frac{1}{p}} M^{1-\frac{3}{p}+\frac{1}{2p}}}{|T_1|^{\frac{1}{p}} |T_3|^{1-\frac{2}{p}}} \quad \text{for } p \in \left[3, \frac{7}{2} \right],$$

$$(4.5) \quad \int_{\hat{K}} \frac{1}{|\tilde{J}|^{p-1}} d\xi d\eta \leq \frac{2^{1+\frac{2}{p}} M^{\frac{1}{p}}}{(p-2)^{\frac{1}{p}} |T_1|^{\frac{1}{p}} |T_3|^{1-\frac{2}{p}}} \quad \text{for } p \in \left(\frac{7}{2}, 4 \right],$$

$$(4.6) \quad \int_{\hat{K}} \frac{1}{|\tilde{J}|^{p-1}} d\xi d\eta < \frac{(p-3)^{\frac{1}{p}} 2^{1+\frac{2}{p}} M^{1-\frac{3}{p}}}{(p-2)^{\frac{1}{p}} |T_1|^{\frac{1}{p}} |T_3|^{1-\frac{2}{p}}} \quad \text{for } p > 4,$$

where $M = \max\{1, \frac{|T_3|}{|T_4|}\}$.

Proof. First consider the case $p = 3$. In view of the results in Lemma 3.1, we have

$$J = \tilde{J}J_1 = 2(|T_1| + (|T_2| - |T_1|)\xi + (|T_4| - |T_1|)\eta).$$

Noticing the fact

$$|T_1| + |T_3| = |T_2| + |T_4| = |K|,$$

we can derive that

$$\begin{aligned} \int_{\widehat{K}} \frac{1}{|J|^2} d\xi d\eta &= \frac{1}{4} \int_{\widehat{K}} \frac{1}{(|T_1| + (|T_2| - |T_1|)\xi + (|T_4| - |T_1|)\eta)^2} d\xi d\eta \\ &= \frac{1}{4(|T_1| - |T_2|)} \int_0^1 \left(\frac{1}{|T_2| + (|T_4| - |T_1|)\eta} - \frac{1}{|T_1| + (|T_4| - |T_1|)\eta} \right) d\eta \\ &= \frac{1}{4(|T_1| - |T_2|)(|T_4| - |T_1|)} \ln \frac{|T_1||T_3|}{|T_2||T_4|} \\ &= \frac{1}{4(|T_1||T_3| - |T_2||T_4|)} \ln \frac{|T_1||T_3|}{|T_2||T_4|}. \end{aligned}$$

Now let us discuss the above result. If $|T_3| \leq |T_4|$, then we have

$$(4.7) \quad |T_1| \geq |T_2| \quad \text{and} \quad |T_1||T_3| \leq |T_2||T_4|,$$

which implies

$$(4.8) \quad \int_{\widehat{K}} \frac{1}{|J|^2} d\xi d\eta \leq \frac{1}{4|T_1||T_3|},$$

where we have used the inequality $\frac{\ln x}{1-\frac{x}{2}} \leq 1$ for all $x \in (0, 1]$.

On the other hand, if $|T_3| > |T_4|$, then

$$(4.9) \quad |T_2| > |T_1| \quad \text{and} \quad |T_1||T_3| > |T_2||T_4|;$$

thus we can derive

$$\begin{aligned} \int_{\widehat{K}} \frac{1}{|J|^2} d\xi d\eta &= \frac{1}{4(|T_1||T_3| - |T_2||T_4|)} \ln \left(1 + \frac{|T_1||T_3| - |T_2||T_4|}{|T_2||T_4|} \right) \\ &\leq \frac{1}{4(\sqrt{|T_1||T_3|} + \sqrt{|T_2||T_4|})\sqrt{|T_2||T_4|}} \\ (4.10) \quad &< \frac{1}{4\sqrt{|T_1||T_3||T_2||T_4|}} < \frac{1}{4|T_1||T_3|} \left(\frac{|T_3|}{|T_4|} \right)^{\frac{1}{2}}, \end{aligned}$$

where we have used the inequality $\ln(1+x) \leq \sqrt{x}$ for all $x \in (0, \infty)$.

Then a combination of (4.8), (4.10), and (4.1) gives (4.4) for the case $p = 3$.

For $p \in (3, \frac{7}{2}]$, we write

$$\begin{aligned} \int_{\widehat{K}} \frac{1}{|J|^{p-1}} d\xi d\eta &= \int_{\widehat{K}} \frac{1}{|J|^{p-3}} \frac{1}{|J|^2} d\xi d\eta \\ &\leq \left(\frac{M}{2|T_3|} \right)^{p-3} \int_{\widehat{K}} \frac{1}{|J|^2} d\xi d\eta, \end{aligned}$$

where $M = \max\{1, \frac{|T_3|}{|T_4|}\}$, since we notice that

$$\min_{\widehat{K}} |J| = 2 \min\{|T_1|, |T_2|, |T_3|, |T_4|\} = 2 \min\{|T_3|, |T_4|\} = \frac{2|T_3|}{M}.$$

By the estimate (4.8) and (4.10), we deduce that

$$\int_{\widehat{K}} \frac{1}{|J|^{p-1}} d\xi d\eta \leq \left(\frac{M}{2|T_3|}\right)^{p-3} \frac{M^{\frac{1}{2}}}{4|T_1||T_3|}.$$

This estimate yields

$$\left|\phi_3\right|_{1,p,K} \leq \frac{2^{1+\frac{1}{p}} h_K}{|T_1|^{\frac{1}{p}} |T_3|^{1-\frac{2}{p}}} M^{1-\frac{3}{p}+\frac{1}{2p}}.$$

Now we come to the case $\frac{7}{2} < p$. An immediate computation gives that

$$\begin{aligned} \int_{\widehat{K}} \frac{1}{|J|^{p-1}} d\xi d\eta &= \frac{1}{(2-p)2^{p-1}(|T_2| - |T_1|)} \left(\int_0^1 \left(\frac{1}{|T_2| + (|T_4| - |T_1|)\eta} \right)^{2-p} d\eta \right. \\ &\quad \left. - \int_0^1 \left(\frac{1}{|T_1| + (|T_4| - |T_1|)\eta} \right)^{2-p} d\eta \right) \\ (4.11) \quad &= \frac{|T_1|^{3-p} + |T_3|^{3-p} - |T_2|^{3-p} - |T_4|^{3-p}}{(p-2)(p-3)2^{p-1}(|T_1| - |T_2|)(|T_1| - |T_4|)}. \end{aligned}$$

If $|T_3| > |T_4|$, using (4.9) and the fact that $|T_2| - |T_1| = |T_3| - |T_4|$, and by applying Cauchy's mean value theorem repeatedly, we have

$$\begin{aligned} &|T_1|^{3-p} + |T_3|^{3-p} - |T_2|^{3-p} - |T_4|^{3-p} \\ &= \frac{(|T_2||T_4|)^{p-3}(|T_1|^{p-3} + |T_3|^{p-3}) - (|T_1||T_3|)^{p-3}(|T_2|^{p-3} + |T_4|^{p-3})}{|T_1|^{p-3}|T_2|^{p-3}|T_3|^{p-3}|T_4|^{p-3}} \\ &= \frac{(|T_2||T_4|)^{p-3}(|T_1|^{p-3} + |T_3|^{p-3} - |T_2|^{p-3} - |T_4|^{p-3})}{|T_1|^{p-3}|T_2|^{p-3}|T_3|^{p-3}|T_4|^{p-3}} \\ &\quad + \frac{((|T_2||T_4|)^{p-3} - (|T_1||T_3|)^{p-3})(|T_2|^{p-3} + |T_4|^{p-3})}{|T_1|^{p-3}|T_2|^{p-3}|T_3|^{p-3}|T_4|^{p-3}} \\ &= \frac{(p-3)(|T_2||T_4|)^{p-3}(m_{34}^{p-4} - m_{12}^{p-4})(|T_2| - |T_1|)}{|T_1|^{p-3}|T_2|^{p-3}|T_3|^{p-3}|T_4|^{p-3}} \\ &\quad + \frac{(p-3)(|T_2||T_4| - |T_1||T_3|)m_{1324}^{p-4}(|T_2|^{p-3} + |T_4|^{p-3})}{|T_1|^{p-3}|T_2|^{p-3}|T_3|^{p-3}|T_4|^{p-3}} \\ &= \frac{(p-3)(p-4)(|T_2||T_4|)^{p-3}m_{1234}^{p-5}(m_{12} - m_{34})(|T_1| - |T_2|)}{|T_1|^{p-3}|T_2|^{p-3}|T_3|^{p-3}|T_4|^{p-3}} \\ (4.12) \quad &\quad + \frac{(p-3)(|T_1| - |T_2|)(|T_1| - |T_4|)m_{1324}^{p-4}(|T_2|^{p-3} + |T_4|^{p-3})}{|T_1|^{p-3}|T_2|^{p-3}|T_3|^{p-3}|T_4|^{p-3}}; \end{aligned}$$

here the constants $m_{12}, m_{34}, m_{1324}, m_{1234}$ are constants produced by the mean value theorem that satisfy $|T_1| \leq m_{12} \leq |T_2|, |T_4| \leq m_{34} \leq |T_3|, |T_2||T_4| \leq m_{1324} \leq |T_1||T_3|,$ and $|T_{34}| \leq m_{1234} \leq |T_{12}|.$

Since, for $\frac{7}{2} < p \leq 4,$ we have

$$(p - 4)(|T_2||T_4|)^{p-3}m_{1234}^{p-5}(m_{12} - m_{34}) \leq 0$$

and

$$m_{1324}^{p-4} \leq (|T_2||T_4|)^{p-4},$$

by (4.11) and (4.12), it holds that

$$\begin{aligned} \int_{\hat{K}} \frac{1}{|J|^{p-1}} d\xi d\eta &\leq \frac{|T_4|^{p-4}|T_2|^{2p-7}}{(p - 2)2^{p-2}|T_1|^{p-3}|T_2|^{p-3}|T_3|^{p-3}|T_4|^{p-3}} \\ (4.13) \qquad \qquad \qquad &= \frac{1}{(p - 2)2^{p-2}|T_1||T_3|^{p-2}} \frac{|T_3|}{|T_4|}. \end{aligned}$$

When $p > 4,$ further noticing that

$$\begin{aligned} |T_4|^{p-3}m_{1234}^{p-5} &\leq \begin{cases} |T_4|^{2p-8}, & 4 < p \leq 5, \\ |T_2|^{p-5}|T_4|^{p-3}, & p > 5, \end{cases} \\ &\leq (|T_1||T_3|)^{p-4} \end{aligned}$$

and

$$m_{12} - m_{34} \leq |T_2| - |T_4| \leq 2(|T_1| - |T_4|),$$

we can derive

$$\begin{aligned} \int_{\hat{K}} \frac{1}{|J|^{p-1}} d\xi d\eta &\leq \frac{(p - 3)(|T_1||T_3|)^{p-4}|T_2|^{p-3}}{(p - 2)2^{p-2}|T_1|^{p-3}|T_2|^{p-3}|T_3|^{p-3}|T_4|^{p-3}} \\ (4.14) \qquad \qquad \qquad &\leq \frac{(p - 3)}{(p - 2)2^{p-2}|T_1||T_3|^{p-2}} \left(\frac{|T_3|}{|T_4|} \right)^{p-3}. \end{aligned}$$

In the case $|T_3| \leq |T_4|,$ we proved similarly that (4.13) and (4.14) hold by (4.7). This yields (4.5) and (4.6). \square

Remark 4.5. The technique developed in Lemma 4.4 renders the continuity of the upper bounds at the turning points $p = 3, \frac{7}{2}, 4.$

5. Interpolation error estimates in $W^{1,p}.$ According to the bounds from the previous section, we can make the following definition.

DEFINITION 5.1. *Let K be a convex quadrilateral. We say that K satisfies the new RDP with constants $N \in \mathbb{R}_+, 0 < \psi < \pi,$ and $p \in [1, \infty) \setminus \{2\},$ or NRDP(N, ψ, p), if we can divide K into two triangles along one of its diagonals, always called $d_1,$ in such a way that the big triangle satisfies MAC(ψ) and that*

$$(5.1) \qquad \frac{h_K}{(2 - p)^{\frac{1}{p}}|d_1| \sin \alpha} \left(\frac{|T_3|}{|T_1|} \right)^{1 - \frac{1}{p}} \leq N \quad \text{for } p \in [1, 2),$$

$$(5.2) \quad \frac{h_K}{(p-2)^{\frac{1}{p}}(3-p)^{\frac{1}{p}}|d_1|\sin\alpha} \left(\frac{|T_3|}{|T_1|}\right)^{\frac{1}{p}} \leq N \quad \text{for } p \in (2, 3),$$

$$(5.3) \quad \frac{h_K M^{1-\frac{3}{p}+\frac{1}{2p}}}{|d_1|\sin\alpha} \left(\frac{|T_3|}{|T_1|}\right)^{\frac{1}{p}} \leq N \quad \text{for } p \in \left[3, \frac{7}{2}\right],$$

$$(5.4) \quad \frac{h_K M^{\frac{1}{p}}}{|d_1|\sin\alpha} \left(\frac{|T_3|}{|T_1|}\right)^{\frac{1}{p}} \leq N \quad \text{for } p \in \left(\frac{7}{2}, 4\right],$$

$$(5.5) \quad \frac{h_K M^{1-\frac{3}{p}}}{|d_1|\sin\alpha} \left(\frac{|T_3|}{|T_1|}\right)^{\frac{1}{p}} \leq N \quad \text{for } p > 4,$$

where the big triangle will always be called T_1 , the other is called T_3 , h_K denotes the diameter of the quadrilateral K , α denotes the maximal angle of T_3 , and s denotes the smallest edge of T_3 .

Remark 5.2. In view of Remark 4.3, when $p < 2$, the condition (5.1) could be replaced by

$$\frac{h_K}{|d_1|\sin\alpha} \left(\frac{|T_3|}{|T_1|} \ln \frac{|T_1|}{|T_3|}\right)^{1-\frac{1}{p}} \leq N.$$

This condition is more advantageous than (5.1) for p close to 2, while it is the converse for p far from 2.

We first state an estimate for $|(u - \Pi u)(M_3)|$, which follows from the proof of Lemma 5.2 of [4].

LEMMA 5.3. *Let K be a general convex quadrilateral and Π be the linear Lagrange interpolation operator defined on T_1 ; then*

$$(5.6) \quad |(u - \Pi u)(M_3)| \leq \left(\frac{2^p |s|^{p-1}}{|d_1|\sin\alpha}\right)^{\frac{1}{p}} \left\{ |u - \Pi u|_{1,p,T_3} + h_K |u|_{2,p,T_3} \right\}, \quad p \geq 1.$$

Remark 5.4. Since K is convex, it is well known that the Poincaré inequality holds for general $p \geq 1$; i.e., there exists a constant C_p depending only on p such that

$$(5.7) \quad \|v\|_{0,p,K} \leq C_p h |v|_{1,p,K}$$

for any $v \in W^{1,p}(K)$ with vanishing average on K .

Now we are in a position to bound the term $|u - \Pi u|_{1,p,K}$.

LEMMA 5.5. *Let K be a general convex quadrilateral and Π be the linear Lagrange interpolation operator defined on T_1 ; then*

$$|u - \Pi u|_{1,p,K} \leq (1 + 2C_p) \frac{2^{2-\frac{1}{p}}}{\sin\gamma} \left(\frac{|K|}{|T_1|}\right)^{\frac{1}{p}} h_K |u|_{2,p,K},$$

where γ is the maximal angle of T_1 .

Proof. The proof is just a combination of the arguments of Lemma 3.7 in section 3 (using here (5.7)) and of Lemma 5.3 of [4]. \square

Now we come to the main theorem of this section.

THEOREM 5.6. *Let K be a convex quadrilateral satisfying NRDP(N, ψ, p) with $p \in [1, \infty) \setminus \{2\}$; then we have*

$$(5.8) \quad |u - \mathcal{Q}u|_{1,p,K} \leq Ch_K |u|_{2,p,K},$$

with $C > 0$ depending only on N, p , and ψ .

Proof. A combination of (4.1), Definition 5.1, and (5.6) yields

$$|(\Pi u - u)(M_3)| |\phi_3|_{1,p,K} \leq C_p N \left\{ |u - \Pi u|_{1,p,T_3} + h_K |u|_{2,p,T_3} \right\},$$

where $C_p > 0$ depends only on p .

Now invoking Lemma 5.5, we get

$$\begin{aligned} |u - \mathcal{Q}u|_{1,p,K} &\leq |(\Pi u - u)(M_3)| |\phi_3|_{1,p,K} + |u - \Pi u|_{1,p,K} \\ &\leq \kappa(K, p) C'_p h_K |u|_{2,p,K}, \end{aligned}$$

where $C'_p > 0$ depends only on p and $\kappa(K, p)$ is defined by

$$\kappa(K, p) = N + (1 + C_p N) \frac{1}{\sin \gamma} \left(\frac{|K|}{|T_1|} \right)^{\frac{1}{p}}.$$

Hence we will obtain (5.8) if $\kappa(K, p)$ is bounded uniformly. By the definition of T_1 implying that $|K| \leq 2|T_1|$, we have

$$\left(\frac{|K|}{|T_1|} \right)^{\frac{1}{p}} \leq 2^p.$$

We therefore conclude by using the assumption on γ from Definition 5.1. □

Let us finish our paper by comparing our geometrical conditions with the *double angle condition* (DAC) introduced in [4], which we recall here.

DEFINITION 5.7. *Let K be a convex quadrilateral. We say that K satisfies the DAC with constants ψ_m, ψ_M , or $DAC(\psi_m, \psi_M)$, if the interior angles ω of K verify $0 < \psi_m \leq \omega \leq \psi_M < \pi$.*

Obviously, the above $DAC(\psi_m, \psi_M)$ is equivalent to (1.2). In [4], the authors proved that it is a sufficient condition for the optimal error estimate in $W^{1,p}$ with $p \geq 3$ and showed that the restriction on the maximal angle cannot be relaxed by some counterexamples. In fact, the $DAC(\psi_m, \psi_M)$ is a quite strong geometric condition, and the following elementary implications hold:

$$DAC(\psi_m, \psi_M) \implies MAC(\psi_M) \implies RDP(N, \psi_M) \implies GRDP(N, \psi_M).$$

One can see that the above NRDP condition for $p \geq 3$ is much weaker than the DAC. In fact, if the quadrilateral K satisfies $DAC(\psi_m, \psi_M)$, it can be easily proved that $\frac{|T_3|}{|T_4|} \leq C(\psi_m, \psi_M)$ and $d_1 = O(h_K)$; hence there exists a constant $N = N(\psi_m, \psi_M)$ such that K satisfies $NRDP(N(\psi_m, \psi_M), \psi_M, p)$ for all $p \geq 3$.

If K satisfies $\frac{|T_3|}{|T_4|} \leq C$ which is satisfied in many cases, the above NRDP condition for $p \geq 3$ is even weaker than the RDP condition. However, there are some examples such that K satisfies the RDP condition but not the above NRDP condition for $p \geq 3$, e.g., $K(1, 1, s, s)$ with $s \rightarrow \frac{1}{2}$ (cf. Figure 5.1), which is employed as a counterexample in [4]. In this sense we may say that our NRDP conditions for $p \geq 3$ are as weak as the RDP condition.

If K satisfies $\frac{|T_3|}{|T_4|} \rightarrow \infty$, the quadrilateral K is almost degenerated into the triangle T_2 . In such a case, the constant of the interpolation error in the $W^{1,p}$ norm ($p > 3$) may not be bounded even if K satisfies the RDP condition. This can be partly

FIG. 5.1. $K(1, 1, s, s)$.

interpreted by the fact that $\max\{1, \frac{|T_3|}{|T_4|}\}$ appears as a factor in our NRDP condition. Taking $K(1, 1, s, s)$ with $s \rightarrow \frac{1}{2}$ (see Figure 5.1) as an example, if one chooses d_1 to divide K into two triangles, K does satisfy the RDP condition, but (5.8) does not hold because $\frac{|T_3|}{|T_4|} \rightarrow \infty$, which violates the NRDP condition for $p \geq 3$.

6. Conclusion. Interpolation error estimates of the finite elements play an important role in the finite element literature. In this paper, we have introduced a generalized RDP (GRDP) condition for $p = 2$ and new RDP (NRDP) conditions for $p \neq 2$, which permit us to prove some interpolation error estimates in the $W^{1,p}$ norm with $1 \leq p < \infty$ for the \mathcal{Q}_1 isoparametric finite elements. As far as we know, our NRDP conditions presented here are weaker than any other mesh conditions proposed in the literature for the same p with $1 \leq p < \infty$.

The results of this paper are valid only for bilinear elements, and it seems difficult to extend them to higher order Lagrange quadrilateral elements or other quadrilateral elements, e.g., mixed elements and nonconforming elements. Some preliminary results for some mixed elements and nonconforming elements are already obtained and will be investigated in our future work.

Acknowledgments. We warmly thank the referees for their helpful remarks that allowed us to considerably improve the presentation of our results. We also would like to thank Professor Thomas Apel, Professor Roland Becker, and Professor Ricardo Durán for some useful discussions.

REHABILITATION OF THE LOWEST-ORDER RAVIART–THOMAS ELEMENT ON QUADRILATERAL GRIDS*

PAVEL B. BOCHEV[†] AND DENIS RIDZAL[‡]

Abstract. A recent study [D. N. Arnold, D. Boffi, and R. S. Falk, *SIAM J. Numer. Anal.*, 42 (2005), pp. 2429–2451] reveals that convergence of finite element methods using $H(\operatorname{div}, \Omega)$ -compatible finite element spaces deteriorates on nonaffine quadrilateral grids. This phenomena is particularly troublesome for the lowest-order Raviart–Thomas elements, because it implies loss of convergence in some norms for finite element solutions of mixed and least-squares methods. In this paper we propose reformulation of finite element methods, based on the natural mimetic divergence operator [M. Shashkov, *Conservative Finite Difference Methods on General Grids*, CRC Press, Boca Raton, FL, 1996], which restores the order of convergence. Reformulations of mixed Galerkin and least-squares methods for the Darcy equation illustrate our approach. We prove that reformulated methods converge optimally with respect to a norm involving the mimetic divergence operator. Furthermore, we prove that standard and reformulated versions of the mixed Galerkin method lead to *identical* linear systems, but the two versions of the least-squares method are veritably different. The surprising conclusion is that the degradation of convergence in the mixed method on nonaffine quadrilateral grids is superficial, and that the lowest-order Raviart–Thomas elements are safe to use in this method. However, the breakdown in the least-squares method is real, and there one should use our proposed reformulation.

Key words. Raviart–Thomas, quadrilateral, mixed methods, least-squares methods, mimetic methods

1. Introduction. We consider finite element solution of the elliptic boundary value problem

$$(1.1) \quad \begin{cases} \nabla \cdot \mathbf{u} + \sigma \Theta_0 p = f, & \text{in } \Omega \quad \text{and} \quad p = 0 \quad \text{on } \Gamma_D, \\ \nabla p + \Theta_1^{-1} \mathbf{u} = 0, & \mathbf{n} \cdot \mathbf{u} = 0 \quad \text{on } \Gamma_N, \end{cases}$$

where $\Omega \subset \mathbb{R}^2$ has a Lipschitz-continuous boundary $\partial\Omega = \Gamma_D \cup \Gamma_N$, \mathbf{n} is the unit outward normal to $\partial\Omega$, Θ_1 is a symmetric tensor, Θ_0 is a real valued function, and σ is a nondimensional parameter that is either 0 or 1. Regarding Θ_1 and Θ_0 , we will assume that there exists a constant $\alpha > 0$ such that for every $\mathbf{x} \in \Omega$ and $\boldsymbol{\xi} \in \mathbb{R}^2$,

$$(1.2) \quad \frac{1}{\alpha} \boldsymbol{\xi}^T \boldsymbol{\xi} \leq \boldsymbol{\xi}^T \Theta_1(\mathbf{x}) \boldsymbol{\xi} \leq \alpha \boldsymbol{\xi}^T \boldsymbol{\xi} \quad \text{and} \quad \frac{1}{\alpha} \leq \Theta_0(\mathbf{x}) \leq \alpha.$$

The equations (1.1) are often called the Darcy problem and provide a simplified model of a single phase flow in porous media. In this context, p is the pressure, \mathbf{u} is the

Darcy velocity, and Θ_1 is the permeability tensor divided by the viscosity. The use of this first-order system as a basis for a finite element method stems from the fact that in porous media flow the vector variable \mathbf{u} is more important than the pressure p . In such cases numerical methods that compute accurate, locally conservative velocity approximations are favored.

Two such methods are the mixed Galerkin method [11] and the locally conservative least-squares method [7, 8, 13]. The main focus of this paper will be on implementations of these two methods with the lowest-order quadrilateral Raviart–Thomas elements (RT_0) [19, 11]. Several reasons motivate our interest in these elements. Quadrilateral grids are widely used in the petroleum industry for porous media flow simulations and there are connections between conservative finite difference methods for (1.1) and mixed methods implemented with the lowest-order $H(\text{div}, \Omega)$ -compatible spaces; see [1, 5, 22] and the references therein. Our study is also prompted by the recent work of Arnold, Boffi, and Falk [4], whose paper asserts that the accuracy of $H(\text{div}, \Omega)$ -conforming finite element spaces deteriorates on nonaffine quadrilateral grids, which in turn leads to reduced orders of convergence in finite element methods. Arnold, Boffi, and Falk [4] support this assertion by examples that show reduced convergence in $H(\text{div}, \Omega)$ of the vector variable in the mixed method, and examples which suggest that in the least-squares method loss of accuracy also spreads to pressure approximations.

These examples are particularly damning for low-order elements because for them the degradation of accuracy in the methods takes the form of a total loss of convergence in some norms for one or both variables. The main goal of this paper is to restore confidence in RT_0 elements and show that with some simple modifications in the finite element methods they can be safely used on general, shape-regular, but not necessarily affine quadrilateral grids.

The proposed reformulation of the mixed and least-squares methods is motivated by mimetic finite difference methods [20]. A mimetic discretization of (1.1) uses the so-called *natural mimetic* divergence, DIV , and *derived* gradient, $\overline{\text{GRAD}}$, operators; see [15, 16]. Of particular interest to us is DIV , which is constructed using the coordinate-invariant definition [2, p. 188]

$$(1.3) \quad \nabla \cdot \mathbf{u}(\mathbf{x}) = \lim_{\kappa \ni \mathbf{x}; \mu(\kappa) \rightarrow 0} \frac{\int_{\partial \kappa} \mathbf{u} \cdot \mathbf{n} \, dS}{\mu(\kappa)}$$

of the divergence operator.¹ The result is a discrete operator² that maps face-based values (the fluxes of \mathbf{u}) onto cell-based constants. Because DIV acts on the same set of degrees of freedom as used to define the lowest-order Raviart–Thomas space, its action can be extended to that space in a natural way. This is the key to our *mimetic* reformulation of finite element methods, in which the main idea is to

¹In this definition κ is a bounded region and $\mu(\kappa)$ denotes its measure. The mimetic approximation of $\nabla \cdot \mathbf{u}$ on an element κ , belonging to a finite element partition \mathcal{T}_h of Ω , is defined by the right-hand side in this formula, assuming that \mathbf{u} and \mathbf{n} are constant on the faces of κ .

²For brevity we call this operator “natural divergence.”

replace³ the analytic divergence $\nabla \cdot$ by the natural divergence DIV .

A somewhat unexpected byproduct of our analysis is a theorem which shows that the mimetic reformulation of the mixed method is actually equivalent to its standard version, in the sense that the two methods generate identical linear algebraic systems with identical solutions. Since in the mimetic reformulation $\text{DIV}(\mathbf{u}^h)$ converges to the divergence of the exact solution, it follows that the same must be true for the solution of the standard mixed method. In other words, the flux degrees of freedom in the mixed Galerkin solution do contain accurate information about the divergence of the exact solution. The reason $\nabla \cdot$ fails to recover this information on nonaffine quads is that it acts on the flux data *indirectly* via basis functions defined by the Piola transform, which makes the result dependent upon the element shape.⁴ In contrast, DIV is able to always recover accurate divergence approximation because it acts *directly* on the flux degrees of freedom, which makes its action independent of the element shape. It follows that the loss of convergence in the mixed method is superficial and that this method can be safely used on nonaffine quadrilateral grids.

Unlike the mixed method, mimetic reformulation of the least-squares method turns out to be veritably different from its standard finite element realization, and the loss of convergence in this method, reported in [4], is genuine. We refine the conclusions of [4] by showing that for Darcy problems that include a “reaction” term ($\sigma = 1$) the loss of accuracy does not spread to the pressure approximation. However, the “information content” of the velocity approximation is ruined, and using DIV in lieu of $\nabla \cdot$ to extract divergence information does not help much. Thus, the breakdown in the least-squares method is real, and for general quadrilateral grids one should use our proposed reformulation.

This paper is organized as follows. Section 2 reviews notation and definitions of finite element spaces. Section 3 discusses the natural divergence operator, its properties, and extension to the lowest-order Raviart–Thomas elements. Section 4 presents mimetic reformulations of mixed and least-squares methods. Section 5 contains analyses of these methods. Numerical results are collected in section 6.

2. Notation and quotation of results. For $p > 0$, $H^p(\Omega)$ denotes the Sobolev space of order p with norm and inner product denoted by $\|\cdot\|_p$ and $(\cdot, \cdot)_p$, respectively. When $p = 0$, we use the standard notation $L^2(\Omega)$. The symbol $|\cdot|_k$, $0 \leq k \leq p$, denotes the k th seminorm on $H^p(\Omega)$, while $H_D^1(\Omega)$ is the subspace of $H^1(\Omega)$ consisting of all functions that vanish on Γ_D . The set $H(\text{div}, \Omega) = \{\mathbf{u} \in (L^2(\Omega))^2 \mid \nabla \cdot \mathbf{u} \in L^2(\Omega)\}$ and its subset $H_N(\text{div}, \Omega) = \{\mathbf{v} \in H(\text{div}, \Omega) \mid \mathbf{v} \cdot \mathbf{n} = 0 \text{ on } \Gamma_N\}$ are Hilbert spaces when equipped with the graph norm $\|\mathbf{u}\|_{\text{div}} = (\|\mathbf{u}\|_0^2 + \|\nabla \cdot \mathbf{u}\|_0^2)^{1/2}$.

Throughout this paper \mathcal{T}_h is a partition of Ω into convex quadrilateral elements κ , \mathcal{N}_h is the set of nodes \mathbf{x}_i in \mathcal{T}_h , and \mathcal{F}_h is the set of oriented faces \mathbf{f}_i in \mathcal{T}_h . A face is oriented by choosing a unit normal $\mathbf{n}_{\mathbf{f}}$, and an element is oriented by choosing a unit normal \mathbf{n}_{κ} to its boundary $\partial\kappa$. By default, all elements are oriented as sources

³A perfectly valid alternative solution is to divide each element into two affine triangles and simply use an RT_0 space on triangles [17]. Nonetheless, quadrilateral elements may still be favored for the following reasons. When a quadrilateral grid is transformed into a triangular one by the above procedure, the number of faces increases by a number equal to the number of elements in the original mesh. Because in the RT_0 space each face is associated with a degree of freedom, this means that the size of the discretized problem will also increase by the same number without formally increasing its accuracy. Second, for problems with advection, quadrilateral grids are easier to align with the flow, which reduces the amount of artificial numerical diffusion.

⁴This is also the reason why formal finite element analysis fails to recognize that the mixed Galerkin solution does contain accurate divergence information.

so that \mathbf{n}_κ is the outer unit normal to $\partial\kappa$.

We assume that the elements in \mathcal{T}_h satisfy the usual conditions required of finite element partitions; see [12, pp. 38–51]. In what follows we restrict our attention to shape-regular partitions \mathcal{T}_h where each κ is a bilinear image of the reference square $\hat{\kappa} = [-1, 1]^2$. We recall that for such partitions there exists a positive α such that

$$(2.1) \quad \frac{1}{\alpha} \mu(\kappa) \leq \| \det D\Phi_\kappa \|_{\infty, \hat{\kappa}} \leq \alpha \mu(\kappa) \quad \forall \kappa \in \mathcal{T}_h;$$

see [14, p. 105]. In (2.1) $D\Phi_\kappa(\hat{\mathbf{x}})$ is the derivative of the bilinear function $\Phi_\kappa(\hat{\mathbf{x}})$ that maps $\hat{\kappa}$ to a given quadrilateral κ . When the range of Φ_κ is clear from the context we will skip the subscript κ . There also hold (see [14, p. 105])

$$(2.2) \quad \det D\Phi_\kappa(\hat{\mathbf{x}}) > 0 \quad \forall \hat{\mathbf{x}} \in \hat{\kappa} \quad \text{and} \quad \mu(\kappa) = \det D\Phi_\kappa(0, 0) \mu(\hat{\kappa}).$$

The first property follows from the convexity of each κ .

$P_{qr}(V)$ denotes polynomial functions on a region $V \subset \mathfrak{R}^2$, whose degree in x and y does not exceed q and r , respectively. Thus, $P_{00}(V)$ is the set of constant polynomials on V ; P_{11} is the set of bilinear polynomials on V ; and so on.

Since our focus is on low-order methods, for the mixed Galerkin method we consider pressure approximations by the piecewise constant space

$$(2.3) \quad Q_0 = \{ p^h \in L^2(\Omega) \mid p^h|_\kappa \in P_{00}(\kappa) \quad \forall \kappa \in \mathcal{T}_h \}$$

and velocity approximations by the lowest-order Raviart–Thomas space

$$(2.4) \quad RT_0 = \{ \mathbf{u}^h \in H(\text{div}, \Omega) \mid \mathbf{u}^h|_\kappa = \mathcal{P}_\kappa \circ \hat{\mathbf{u}}^h; \quad \hat{\mathbf{u}}^h \in P_{10}(\hat{\kappa}) \times P_{01}(\hat{\kappa}) \quad \forall \kappa \in \mathcal{T}_h \},$$

where $\mathcal{P}_\kappa = \det(D\Phi(\hat{\mathbf{x}}))^{-1} D\Phi(\hat{\mathbf{x}})$ is the Piola transform; see [11, p. 97]. The least-squares method uses the same space for the velocity, and the C^0 Lagrangian space

$$(2.5) \quad Q_1 = \{ p^h \in C^0(\bar{\Omega}); p^h|_\kappa = \hat{p} \circ \Phi_\kappa^{-1}; \quad \hat{p} \in P_{11}(\hat{\kappa}) \quad \forall \kappa \in \mathcal{T}_h \}$$

for the pressure approximation.

Finite element spaces are restricted by boundary conditions. RT_0^N is the subspace of RT_0 such that $\mathbf{u}^h \cdot \mathbf{n} = 0$ on Γ_N , and Q_1^D is the subspace of Q_1 such that $p^h = 0$ on Γ_D . No boundary conditions are imposed on Q_0 .

Remark 1. The mapping Φ_κ is affine if and only if κ is a parallelogram. Therefore, in general, RT_0 and Q_1 are not piecewise polynomial spaces.

The unisolvent set of Q_0 consists of the element averages

$$(2.6) \quad \Lambda(Q_0) = \left\{ l_\kappa \mid l_\kappa(p) = \int_\kappa p dx; \quad \kappa \in \mathcal{T}_h \right\},$$

the unisolvent set of Q_1 is given by the nodal values

$$(2.7) \quad \Lambda(Q_1) = \left\{ l_x \mid l_x(p) = \int_\Omega \delta(\mathbf{x}) p dx; \quad \mathbf{x} \in \mathcal{N}_h \right\},$$

and the unisolvent set for RT_0 is the average flux across element faces

$$(2.8) \quad \Lambda(RT_0) = \left\{ l_f \mid l_f(\mathbf{v}) = \int_f \mathbf{v} \cdot \mathbf{n} dS; \quad \mathbf{f} \in \mathcal{F}_h \right\}.$$

The symbols $\{p_\kappa\}$, $\{p_x\}$, and $\{\mathbf{u}_f\}$ stand for the basis sets of Q_0 , Q_1 , and RT_0 , which are dual to (2.6), (2.7), and (2.8), respectively; see [12, 11] for further details.

\mathcal{I}_{Q_0} , \mathcal{I}_{Q_1} , and \mathcal{I}_{RT_0} are the interpolation operators into Q_0 , Q_1 , and RT_0 induced by the degrees of freedom in (2.6)–(2.8). Domains of \mathcal{I}_{Q_1} and \mathcal{I}_{RT_0} consist of those functions in $H^1(\Omega)$ and $H(\text{div}, \Omega)$ for which the functionals in (2.7) and (2.8) are meaningful. For the domain of \mathcal{I}_{RT_0} we will use the space

$$(2.9) \quad W(\Omega) = \{\mathbf{u} \in (L^s(\Omega))^2 \mid \nabla \cdot \mathbf{u} \in L^2(\Omega); \quad s > 2\}.$$

With this choice \mathcal{I}_{RT_0} is uniformly bounded as an operator $W \mapsto RT_0$ (see [11, p. 125]):

$$(2.10) \quad \|\mathcal{I}\mathbf{u}\|_{\text{div}} \leq C\|\mathbf{u}\|_W.$$

When the range of the interpolation operator is clear from this type of argument we skip the space designation and simply write \mathcal{I} .

Approximation properties of interpolation operators are as follows. The L^2 projection \mathcal{I}_{Q_0} is first-order accurate (see [14, p. 108]):

$$(2.11) \quad \|p - \mathcal{I}_{Q_0}p\|_0 \leq Ch\|p\|_1 \quad \forall p \in H^1(\Omega).$$

On shape-regular quadrilateral grids \mathcal{I}_{RT_0} is first-order⁵ accurate in L^2 :

$$(2.12) \quad \|\mathbf{u} - \mathcal{I}_{RT_0}\mathbf{u}\|_0 \leq Ch\|\mathbf{u}\|_1 \quad \forall \mathbf{u} \in H^1(\Omega)^2;$$

see [4, Theorem 4.1]. The nodal interpolant \mathcal{I}_{Q_1} satisfies the error bound

$$(2.13) \quad \|p - \mathcal{I}_{Q_1}p\|_0 + h\|\nabla(p - \mathcal{I}_{Q_1}p)\|_0 \leq Ch\|p\|_2 \quad \forall p \in H^2(\Omega);$$

see [14, p. 107] and [3]. The next lemma states an important property of the divergence operator that will be needed later.

LEMMA 2.1. *Divergence is a surjective mapping $H_N(\text{div}, \Omega) \cap W(\Omega) \mapsto L^2(\Omega)$ with a continuous lifting from $L^2(\Omega)$ into $H_N(\text{div}, \Omega) \cap W(\Omega)$; that is, for every $q \in L^2(\Omega)$ there exists $\mathbf{u}_q \in H_N(\text{div}, \Omega) \cap W(\Omega)$ such that*

$$(2.14) \quad q = \nabla \cdot \mathbf{u}_q \quad \text{and} \quad \|\mathbf{u}_q\|_W \leq C\|q\|_0.$$

For details we refer the reader to [11, p. 136].

3. Extension of DIV to RT_0 . Definition of the natural divergence DIV is based on the coordinate-independent characterization of $\nabla \cdot \mathbf{u}$ in (1.3), applied to each cell $\kappa \in \mathcal{T}_h$. Let \mathcal{F}_h^* and \mathcal{T}_h^* denote the duals of \mathcal{F}_h and \mathcal{T}_h , i.e., collections of real numbers $\{F_f\}$, $\{K_\kappa\}$ associated with the oriented faces and cells in the mesh. Clearly, \mathcal{F}_h^* and \mathcal{T}_h^* are isomorphic⁶ to RT_0 and Q_0 , respectively; therefore, we denote their elements by the same symbols.

The natural divergence is a mapping $\text{DIV} : \mathcal{F}_h^* \mapsto \mathcal{T}_h^*$ defined by

$$(3.1) \quad \text{DIV}(\mathbf{u}^h)|_\kappa = \frac{1}{\mu(\kappa)} \sum_{f \in \mathcal{F}_h(\kappa)} \sigma_f F_f \quad \forall \kappa \in \mathcal{T}_h,$$

⁵On nonaffine grids the divergence error of Raviart–Thomas spaces drops by one order. As a result, $\nabla \cdot \mathcal{I}_{RT_0}(\mathbf{u})$ does not converge to $\nabla \cdot \mathbf{u}$; see [4, Theorem 4.2]. However, as we shall see, the natural divergence of the interpolant is first-order accurate.

⁶This is the key reason why many conservative finite difference methods for (1.1) can be related to low-order implementations of the mixed method—both types of schemes share the same set of degrees of freedom.

where $\mathbf{u}^h \in \mathcal{F}_h^*$, $\mathcal{F}_h(\kappa)$ is the set of oriented faces of κ and

$$\sigma_{\mathbf{f}} = \begin{cases} 1 & \text{if } \mathbf{n}_{\mathbf{f}} = \mathbf{n}_{\kappa}, \\ -1 & \text{if } \mathbf{n}_{\mathbf{f}} = -\mathbf{n}_{\kappa}. \end{cases}$$

Note that $F_{\mathbf{f}}$ are also the degrees of freedom that define vector fields in RT_0 :

$$\mathbf{u}^h = \sum_{\mathbf{f} \in \mathcal{F}_h} F_{\mathbf{f}} \mathbf{u}_{\mathbf{f}} \quad \forall \mathbf{u}^h \in RT_0.$$

Therefore, the action of DIV can be extended to RT_0 vector fields by simply adopting formula (3.1) to compute the discrete divergence of $\mathbf{u}^h \in RT_0$. This defines an operator $\text{DIV} : RT_0 \mapsto Q_0$ which we will use to reformulate mixed and least-squares methods. It is easy to see that for the basis $\{\mathbf{u}_{\mathbf{f}}\}$ of RT_0 ,

$$(3.2) \quad \text{DIV}(\mathbf{u}_{\mathbf{f}}) = \frac{\sigma_{\mathbf{f}}}{\mu(\kappa)} \quad \forall \mathbf{f} \in \mathcal{F}_h.$$

The next lemma states an important property of the natural divergence.

LEMMA 3.1. *The natural divergence DIV has a pointwise Commuting Diagram Property (CDP)*

$$(3.3) \quad \begin{array}{ccc} W(\Omega) & \xrightarrow{\nabla \cdot} & L^2(\Omega) \\ \mathcal{I}_{RT_0} \downarrow & & \downarrow \mathcal{I}_{Q_0} \\ RT_0 & \xrightarrow{\text{DIV}} & Q_0 \end{array}$$

Proof. We need to prove that $\text{DIV}(\mathcal{I}_{RT_0} \mathbf{u}) = \mathcal{I}_{Q_0}(\nabla \cdot \mathbf{u})$ for all $\mathbf{u} \in W(\Omega)$. From definition (3.1) and equation (3.2) it follows that

$$\text{DIV}(\mathcal{I}_{RT_0} \mathbf{u})|_{\kappa} = \text{DIV} \sum_{\mathbf{f} \in \mathcal{F}_h(\kappa)} F_{\mathbf{f}} \mathbf{u}_{\mathbf{f}} = \frac{1}{\mu(\kappa)} \sum_{\mathbf{f} \in \mathcal{F}_h(\kappa)} \sigma_{\mathbf{f}} F_{\mathbf{f}}.$$

On the other hand, from (2.6) and the divergence theorem

$$\mathcal{I}_{Q_0}(\nabla \cdot \mathbf{u})|_{\kappa} = \frac{1}{\mu(\kappa)} \int_{\kappa} \nabla \cdot \mathbf{u} \, dx = \frac{1}{\mu(\kappa)} \int_{\partial\kappa} \mathbf{u} \cdot \mathbf{n} \, dS = \frac{1}{\mu(\kappa)} \sum_{\mathbf{f} \in \mathcal{F}_h(\kappa)} \int_{\mathbf{f}} \mathbf{u} \cdot \mathbf{n} \, dS.$$

CDP follows from the identity

$$\int_{\mathbf{f}} \mathbf{u} \cdot \mathbf{n} \, dS = \sigma_{\mathbf{f}} F_{\mathbf{f}}. \quad \square$$

A discrete version of Lemma 2.1 holds for the natural divergence.

LEMMA 3.2. *The natural divergence is a surjective mapping $RT_0 \mapsto Q_0$ with a continuous lifting from Q_0 into RT_0 ; that is, for every $q^h \in Q_0$ there exists $\mathbf{u}_q^h \in RT_0$ such that*

$$(3.4) \quad q^h = \text{DIV}(\mathbf{u}_q^h) \quad \text{and} \quad \|\mathbf{u}_q^h\|_0 + \|\text{DIV}(\mathbf{u}_q^h)\|_0 \leq C \|q^h\|_0.$$

Proof. To show that DIV is surjective we use CDP and the fact that analytic divergence is a surjective mapping $W(\Omega) \mapsto L^2(\Omega)$ (Lemma 2.1). Any $q^h \in Q_0$ is also

in $L^2(\Omega)$, and so there exists $\mathbf{u}_q \in H_N(\text{div}, \Omega) \cap W(\Omega)$ such that $\nabla \cdot \mathbf{u}_q = q^h$. Let $\mathbf{u}_q^h = \mathcal{I}_{RT_0}(\mathbf{u}_q)$. From CDP it follows that $\text{DIV}(\mathbf{u}_q^h) = \mathcal{I}_{Q_0}(\nabla \cdot \mathbf{u}_q) = \mathcal{I}_{Q_0}(q^h) = q^h$.

Because by construction $\text{DIV}(\mathbf{u}_q^h) = q^h$, to prove that the lifting of DIV from Q_0 into RT_0 is continuous it suffices to show that $\|\mathbf{u}_q^h\|_0 = \|\mathcal{I}_{RT_0}(\mathbf{u}_q)\|_0 \leq \|q^h\|_0$. Using (2.10) (uniform boundedness of \mathcal{I}_{RT_0}) and (2.14) in Lemma 2.1, we see that

$$\|\mathcal{I}_{RT_0}(\mathbf{u}_q)\|_0 \leq \|\mathcal{I}_{RT_0}(\mathbf{u}_q)\|_{\text{div}} \leq C\|\mathbf{u}_q\|_W \leq C\|q^h\|_0.$$

This proves the lemma. \square

Remark 2. According to Lemma 2.1, $\nabla \cdot$ is surjection $H_N(\text{div}, \Omega) \mapsto L^2(\Omega)$. In the mixed method the domain and the range of this operator are approximated by RT_0 and Q_0 elements, respectively. However, on nonaffine quadrilateral grids, $\nabla \cdot RT_0 \neq Q_0$, and the surjective property connecting the domain and the range of $\nabla \cdot$ is lost.⁷ By replacing the analytic divergence by DIV , surjectivity is restored. As a result, if RT_0 is to approximate the domain of the divergence and Q_0 its range, then the approximation of $\nabla \cdot$, which is compatible with its surjective property, is given by DIV rather than $\nabla \cdot$. In other words, DIV provides a better approximation of $\nabla \cdot$ on RT_0 than the usual finite element practice of restricting the analytic operator to the finite element space. This fact validates the mimetic reformulation strategy presented in the next two sections.

Remark 3. The surjective property of DIV , and its lack thereof in $\nabla \cdot$, is a direct consequence of the way these operators act on the flux degrees of freedom. As we have already noted in section 1, DIV operates directly on these degrees of freedom, whereas the action of $\nabla \cdot$ is indirect via basis functions defined by the Piola transform. As a result, the divergence approximation computed by DIV depends only on the flux data and not on the element shape.

The following two lemmas will prove useful later.

LEMMA 3.3. *For every $\mathbf{u}^h \in RT_0$ there holds*

$$(3.5) \quad \int_{\kappa} \nabla \cdot \mathbf{u}^h \, dx = \int_{\kappa} \text{DIV}(\mathbf{u}^h) \, dx, \quad \kappa \in \mathcal{T}_h.$$

Proof. It is enough to show (3.5) for a basis function \mathbf{u}_f associated with a face $f \in \partial\kappa$. Using (3.2) and the definition of the basis functions,

$$\int_{\kappa} \text{DIV}(\mathbf{u}_f) \, dx = \frac{\sigma_f}{\mu(\kappa)} \int_{\kappa} dx = \sigma_f = \int_{\partial\kappa} \mathbf{n} \cdot \mathbf{u}_f \, dS = \int_{\kappa} \nabla \cdot \mathbf{u}_f \, dx. \quad \square$$

LEMMA 3.4. *Assume that \mathcal{T}_h is shape-regular. There is a positive constant C_D such that*

$$(3.6) \quad \|\nabla \cdot \mathbf{u}^h\|_0 \leq C_D \|\text{DIV}(\mathbf{u}^h)\|_0.$$

Proof. It suffices to show (3.6) for one element κ and one basis function \mathbf{u}_f with $f \in \partial\kappa$. After changing variables and noting that the Jacobian is positive (see (2.2)),

$$\|\nabla \cdot \mathbf{u}_f\|_{0,\kappa}^2 = \int_{\kappa} (\nabla \cdot \mathbf{u}_f)(\nabla \cdot \mathbf{u}_f) \, dx = \int_{\hat{\kappa}} (\nabla_{\hat{\mathbf{x}}} \cdot \hat{\mathbf{u}}_f)(\nabla_{\hat{\mathbf{x}}} \cdot \hat{\mathbf{u}}_f)(\det D\Phi)^{-1} \, d\hat{x},$$

⁷The reason why stability of the mixed method is not ruined on such grids is that the following weak CDP holds for $\nabla \cdot$: $\mathcal{I}_{Q_0}(\nabla \cdot \mathcal{I}_{RT_0}(\mathbf{u})) = \mathcal{I}_{Q_0}(\nabla \cdot \mathbf{u})$, i.e.,

$$\int_{\Omega} q^h \nabla \cdot \mathbf{u} \, dx = \int_{\Omega} q^h \nabla \cdot \mathcal{I}_{RT_0}(\mathbf{u}) \, dx.$$

According to Fortin’s lemma this is enough for the inf-sup condition to hold; see [11, p. 138].

where $\hat{\mathbf{f}}$ is one of the faces of the reference element $\hat{\kappa}$. From (2.4) and (2.8) it follows that

$$\hat{\mathbf{u}}_{\hat{\mathbf{f}}} = \frac{1}{4} \begin{bmatrix} 1 \pm x \\ 0 \end{bmatrix} \quad \text{or} \quad \hat{\mathbf{u}}_{\hat{\mathbf{f}}} = \frac{1}{4} \begin{bmatrix} 0 \\ 1 \pm y \end{bmatrix}, \quad \text{and} \quad \nabla_{\hat{\mathbf{x}}} \cdot \hat{\mathbf{u}}_{\hat{\mathbf{f}}} = 1/4.$$

Using the mean value theorem, the lower bound in (2.1), (3.2), and $\mu(\hat{\kappa}) = 4$, we have

$$\|\nabla \cdot \mathbf{u}_{\mathbf{f}}\|_{0,\kappa}^2 = \frac{1}{16} \int_{\hat{\kappa}} (\det D\Phi)^{-1} d\hat{x} = \frac{\mu(\hat{\kappa})}{16 \det D\Phi(\hat{x}^*)} \leq \frac{\alpha\mu(\hat{\kappa})}{16\mu(\kappa)} = \frac{\alpha}{4} \|\text{DIV}(\mathbf{u}_{\mathbf{f}})\|_{0,\kappa}^2.$$

Thus, (3.6) holds with $C_D = \alpha/4$. \square

4. Mimetic reformulation of finite element methods. We begin with a brief summary of the standard mixed method [11] and the locally conservative least-squares method [8]. For further information about related least-squares methods, we refer the reader to [6, 13, 7] and the references cited therein.

4.1. Standard methods. The standard mixed finite element method for (1.1) solves the following variational problem: seek $\mathbf{u}^h \in RT_0^N$ and $p^h \in Q_0$ such that

$$(4.1) \quad \begin{cases} \int_{\Omega} \mathbf{u}^h \Theta_1^{-1} \mathbf{v}^h dx - \int_{\Omega} p^h \nabla \cdot \mathbf{v}^h dx = 0 & \forall \mathbf{v}^h \in RT_0^N, \\ \int_{\Omega} \nabla \cdot \mathbf{u}^h q^h dx + \sigma \int_{\Omega} p^h \Theta_0 q^h dx = \int_{\Omega} f q^h dx & \forall q^h \in Q_0. \end{cases}$$

The second method in our study is a compatible least-squares method for (1.1). In this method the finite element approximation is determined by seeking the minimizer of the least-squares quadratic functional

$$(4.2) \quad J(p^h, \mathbf{u}^h; f) = \|\Theta_0^{-1/2}(\nabla \cdot \mathbf{u}^h + \sigma \Theta_0 p^h - f)\|_0^2 + \|\Theta_1^{1/2}(\nabla p^h + \Theta_1^{-1} \mathbf{u}^h)\|_0^2$$

in $U^h = Q_1^D \times RT_0^N$. The standard finite element implementation of this method solves the following variational equation: seek $\{p^h, \mathbf{u}^h\} \in Q_1^D \times RT_0^N$ such that

$$(4.3) \quad \begin{cases} \int_{\Omega} (\nabla p^h + \Theta_1^{-1} \mathbf{u}^h) \Theta_1 (\nabla q^h + \Theta_1^{-1} \mathbf{v}^h) dx \\ \quad + \int_{\Omega} (\nabla \cdot \mathbf{u}^h + \sigma \Theta_0 p^h) \Theta_0^{-1} (\nabla \cdot \mathbf{v}^h + \sigma \Theta_0 q^h) dx \\ = \int_{\Omega} f \Theta_0^{-1} (\nabla \cdot \mathbf{v}^h + \sigma \Theta_0 q^h) dx & \forall q^h \in Q_1^D, \forall \mathbf{v}^h \in RT_0^N. \end{cases}$$

The following theorem from [8] provides additional information about the standard least-squares method. Specifically, it asserts that (4.3) is locally conservative.

THEOREM 4.1. *Assume that the reaction term is present in (1.1), i.e., $\sigma = 1$. Then, the least-squares equation (4.3) decouples into independent problems for the velocity: seek $\mathbf{u}^h \in RT_0^N$ such that*

$$(4.4) \quad \int_{\Omega} \mathbf{u}^h \Theta^{-1} \mathbf{v}^h dx + \int_{\Omega} \nabla \cdot \mathbf{u}^h \Theta_0^{-1} \nabla \cdot \mathbf{v}^h dx = \int_{\Omega} f \Theta_0^{-1} \nabla \cdot \mathbf{v}^h dx \quad \forall \mathbf{v}^h \in RT_0^N;$$

and the pressure: seek $p^h \in Q_1^D$ such that

$$(4.5) \quad \int_{\Omega} \nabla p^h \Theta_1 \nabla q^h dx + \int_{\Omega} p^h \Theta_0 q^h dx = \int_{\Omega} f q^h dx \quad \forall q^h \in Q_1^D.$$

If the grid is such that the analytic divergence is a surjective map $RT_0 \mapsto Q_0$, then the solution of the weak problem (4.4) coincides with the velocity approximation in the mixed method (4.1).

For proof of this theorem we refer the reader to [8]. On the positive side, Theorem 4.1 implies that for problems with a reaction term the deterioration of accuracy should not spread to the pressure approximation. This follows from the fact that (4.5) defines the Ritz–Galerkin method for (1.1) which retains optimal orders of convergence on general quadrilateral grids; see [12].

On the negative side, for nonaffine quadrilateral elements the analytic divergence does not map RT_0 onto Q_0 (see Remark 2), and so the solution of (4.4) will not coincide with the velocity approximation in the mixed method. Considering that Theorem 5.1 will show that the mixed method produces accurate velocities, this spells potential trouble for the least-squares velocity.

Of course, in the absence of a reaction term ($\sigma = 0$), the least-squares equation remains coupled. In this case we can expect deterioration of accuracy in both variables. Numerical tests in [4] confirm this conjecture. Section 6 will provide further computational evidence to corroborate these conclusions.

4.2. Reformulated methods. We obtain mimetic reformulations of (4.1) and (4.3) by swapping the analytic divergence with DIV . The reformulated mixed method is as follows: seek $\mathbf{u}^h \in RT_0^N$ and $p^h \in Q_0$ such that

$$(4.6) \quad \begin{cases} \int_{\Omega} \mathbf{u}^h \Theta_1^{-1} \mathbf{v}^h \, dx - \int_{\Omega} p^h \text{DIV}(\mathbf{v}^h) \, dx = 0 & \forall \mathbf{v}^h \in RT_0^N, \\ \int_{\Omega} \text{DIV}(\mathbf{u}^h) q^h \, dx + \sigma \int_{\Omega} p^h \Theta_0 q^h \, dx = \int_{\Omega} f q^h \, dx & \forall q^h \in Q_0. \end{cases}$$

We make the usual identifications:

$$a^h(\mathbf{u}^h, \mathbf{v}^h) = \int_{\Omega} \mathbf{u}^h \Theta_1^{-1} \mathbf{v}^h \, dx \quad \text{and} \quad b^h(\mathbf{u}^h, p^h) = \int_{\Omega} p^h \text{DIV}(\mathbf{u}^h) \, dx.$$

Note that $a^h(\cdot, \cdot)$ and $b^h(\cdot, \cdot)$ are defined only for finite element functions.

The method for reformulation of the least-squares method is as follows: seek $\{p^h, \mathbf{u}^h\} \in Q_1^D \times RT_0^N$ such that

$$(4.7) \quad \begin{cases} \int_{\Omega} (\nabla p^h + \Theta_1^{-1} \mathbf{u}^h) \Theta_1 (\nabla q^h + \Theta_1^{-1} \mathbf{v}^h) \, dx \\ \quad + \int_{\Omega} (\text{DIV}(\mathbf{u}^h) + \sigma \Theta_0 p^h) \Theta_0^{-1} (\text{DIV}(\mathbf{v}^h) + \sigma \Theta_0 q^h) \, dx \\ = \int_{\Omega} f \Theta_0^{-1} (\text{DIV}(\mathbf{v}^h) + \sigma \Theta_0 q^h) \, dx & \forall q^h \in Q_1^D, \forall \mathbf{v}^h \in RT_0^N. \end{cases}$$

Remark 4. An existing finite element program for the standard mixed or the least-squares method can be trivially converted to its mimetic reformulation by changing just a few lines of code. From (3.1), (2.2), and $\mu(\hat{\kappa}) = 4$, it follows that

$$\text{DIV}(\mathbf{u}_f)|_{\kappa} = \frac{\sigma f}{\mu(\kappa)} = \frac{\sigma f}{4 \det(D\Phi(0, 0))}.$$

As a result, the conversion to mimetic reformulations amounts to replacing multiple calls to the function that computes $\nabla \cdot \mathbf{u}_f(\mathbf{x})$ at quadrature points, along with the

computation of $\det D\Phi$ at those points, by a single call to compute $\det(D\Phi(0,0))$ combined with a few Boolean operations related to the orientation choice σ_f .

Remark 5. An alternative approach that also restores the first-order convergence in the divergence error has been proposed in [21]. The idea is to “correct” the standard RT_0 basis on $\hat{\kappa}$ so that the basis functions on any $\kappa \in \mathcal{T}_h$ have constant divergence. Correction is affected by adding a vector field defined with the help of $\det D\Phi_\kappa$ which makes the reference basis dependent upon the elements in \mathcal{T}_h . This should be contrasted with our approach, where the definition of the RT_0 basis on $\hat{\kappa}$ is unchanged and remains independent of $\kappa \in \mathcal{T}_h$; instead one changes the definition of the divergence operator on κ . Connection between a mixed method implemented with the modified RT_0 space and a mimetic finite difference scheme for (1.1) is shown in [10].

5. Properties of reformulated methods. This section examines stability and convergence of the reformulated methods. We begin with the analysis of the reformulated mixed method.

5.1. The mixed method. The following theorem shows that (4.1) and (4.6) are equivalent.

THEOREM 5.1. *The standard mixed method (4.1) and its mimetic reformulation (4.6) give rise to identical linear systems of equations for the unknown coefficients of $\mathbf{u}^h \in RT_0^N$ and $p^h \in Q_0$; i.e., their solutions coincide.*

Proof. The mixed problem (4.1) and its mimetic reformulation (4.6) reduce to the linear systems of equations

$$\begin{bmatrix} \mathbf{M}_u & \mathbf{D}^T \\ \mathbf{D} & \mathbf{M}_p \end{bmatrix} \begin{bmatrix} \vec{\mathbf{u}} \\ \vec{p} \end{bmatrix} = \begin{bmatrix} \vec{0} \\ \vec{f} \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} \mathbf{M}_u & \tilde{\mathbf{D}}^T \\ \tilde{\mathbf{D}} & \mathbf{M}_p \end{bmatrix} \begin{bmatrix} \vec{\mathbf{u}} \\ \vec{p} \end{bmatrix} = \begin{bmatrix} \vec{0} \\ \vec{f} \end{bmatrix},$$

respectively, for the unknown coefficients $\vec{\mathbf{u}}, \vec{p}$ of \mathbf{u}^h and p^h . Here \mathbf{M}_u and \mathbf{M}_p are the consistent mass matrices for RT_0 and Q_0 finite element spaces, respectively. The matrices \mathbf{D} and $\tilde{\mathbf{D}}$ are given by their respective entries

$$\mathbf{D}_{f,\kappa} = \int_{\Omega} p_{\kappa} \nabla \cdot \mathbf{u}_f \, dx \quad \text{and} \quad \tilde{\mathbf{D}}_{f,\kappa} = \int_{\Omega} p_{\kappa} \text{DIV}(\mathbf{u}_f) \, dx, \quad \mathbf{f} \in \mathcal{F}_h, \kappa \in \mathcal{T}_h.$$

The theorem will follow if we can show that $\mathbf{D}_{f,\kappa} = \tilde{\mathbf{D}}_{f,\kappa}$. Let κ be fixed and \mathbf{f} be one of its faces. The basis function $p_{\kappa} = 1/\mu(\kappa)$ is constant on κ and $p_{\kappa} = 0$ on all other elements. Therefore, using (3.5) from Lemma 3.3 it follows that

$$\begin{aligned} \mathbf{D}_{f,\kappa} &= \int_{\Omega} p_{\kappa} \nabla \cdot \mathbf{u}_f \, dx = \frac{1}{\mu(\kappa)} \int_{\kappa} \nabla \cdot \mathbf{u}_f \, dx \\ &= \frac{1}{\mu(\kappa)} \int_{\kappa} \text{DIV}(\mathbf{u}_f) \, dx = \int_{\Omega} p_{\kappa} \text{DIV}(\mathbf{u}_f) \, dx = \tilde{\mathbf{D}}_{f,\kappa}. \quad \square \end{aligned}$$

Remark 6. Boffi brought to our attention a similar equivalence result [9] for two modifications of a primal finite element method for Maxwell’s eigenvalue problem⁸ defined by using a local L^2 projection and reduced integration, respectively. From (3.3) in Lemma 3.1 $\text{DIV}(\mathbf{u}^h) = \mathcal{I}_{Q_0}(\nabla \cdot \mathbf{u}^h)$ for all $\mathbf{u}^h \in RT_0$, from which it follows that the first approach of [9] is equivalent to our mimetic reformulation.

⁸Finite element solution of this problem in two dimensions requires “rotated” RT elements, which suffer from the same accuracy problems as standard RT elements on nonaffine quadrilateral grids.

In light of this theorem we could in principle skip a formal stability analysis of the reformulated mixed method because we already know that the discrete system in the standard mixed method is well behaved. However, a separate stability proof for (4.6) will be very convenient for the error estimates in which we will work with the discrete norm $\|\mathbf{u}^h\|_{\text{DIV}} = (\|\mathbf{u}^h\|_0^2 + \|\text{DIV}(\mathbf{u}^h)\|_0^2)^{1/2}$. The proofs are stated for the case $\sigma = 0$. The extension to $\sigma = 1$ is straightforward.

LEMMA 5.2. *Let $Z^h = \{\mathbf{u}^h \in RT_0 \mid \text{DIV}(\mathbf{u}^h) = 0\}$ denote the null-space of DIV . The form $a^h(\cdot, \cdot)$ is coercive on $Z^h \times Z^h$:*

$$(5.1) \quad C_a \|\mathbf{v}^h\|^2 \leq a^h(\mathbf{v}^h, \mathbf{v}^h) \quad \forall \mathbf{v}^h \in Z^h.$$

The form $b^h(\cdot, \cdot)$ satisfies a discrete inf-sup condition:

$$(5.2) \quad \sup_{\mathbf{v}^h \in RT_0} \frac{b^h(\mathbf{v}^h, p^h)}{\|\mathbf{v}^h\|_{\text{DIV}}} \geq C_b \|p^h\|_0 \quad \forall p^h \in Q_0.$$

Proof. The first statement is a direct consequence of the definition of Z^h and condition (1.2) on the tensor Θ_1 . To prove the inf-sup condition we proceed as follows. Let $p^h \in Q_0$ be arbitrary. From Lemma 3.2 we know that there exists a $\mathbf{u}_p^h \in RT_0$ such that (3.4) holds. Therefore,

$$\sup_{\mathbf{v}^h \in RT_0} \frac{b^h(\mathbf{v}^h, p^h)}{\|\mathbf{v}^h\|_{\text{DIV}}} \geq \frac{b^h(\mathbf{u}_p^h, p^h)}{\|\mathbf{u}_p^h\|_{\text{DIV}}} \geq \frac{\|p^h\|_0^2}{\|\mathbf{u}_p^h\|_{\text{DIV}}} \geq C \|p^h\|_0. \quad \square$$

Lemma 5.2 directly implies the following stability result.

THEOREM 5.3. *Define the discrete bilinear operator*

$$Q^h(\mathbf{u}^h, p^h; \mathbf{v}^h, q^h) = a^h(\mathbf{u}^h, \mathbf{v}^h) - b^h(\mathbf{v}^h, p^h) + b^h(\mathbf{u}^h, q^h).$$

There exists a positive constant C_Q such that

$$(5.3) \quad \sup_{(\mathbf{v}^h, q^h) \in RT_0^N \times Q_0} \frac{Q^h(\mathbf{u}^h, p^h; \mathbf{v}^h, q^h)}{\|\mathbf{v}^h\|_{\text{DIV}} + \|q^h\|_0} \geq C_Q (\|\mathbf{u}^h\|_{\text{DIV}} + \|p^h\|_0).$$

We can now prove optimal error estimates for (4.6).

THEOREM 5.4. *Assume that (2.1) holds for the finite element partition \mathcal{T}_h and that the exact solution of (1.1) is such that $p \in H_D^1(\Omega)$ and $\mathbf{u} \in H_N(\text{div}, \Omega) \cap (H^2(\Omega))^2$. Solution of the reformulated mixed problem (4.6) satisfies the error bound*

$$(5.4) \quad \|\nabla \cdot \mathbf{u} - \text{DIV}(\mathbf{u}^h)\|_0 + \|\mathbf{u} - \mathbf{u}^h\|_0 + \|p - p^h\|_0 \leq Ch (\|\mathbf{u}\|_2 + \|p\|_1).$$

Proof. To avoid tedious technical details, we limit the proof to the case $\Theta_1 = \mathbb{I}$. We begin by splitting the left-hand side in (5.4) into interpolation error and discrete error:

$$\begin{aligned} & \|\nabla \cdot \mathbf{u} - \text{DIV}(\mathbf{u}^h)\|_0 + \|\mathbf{u} - \mathbf{u}^h\|_0 + \|p - p^h\|_0 \\ & \leq (\|\nabla \cdot \mathbf{u} - \text{DIV}\mathcal{I}(\mathbf{u})\|_0 + \|\mathbf{u} - \mathcal{I}\mathbf{u}\|_0 + \|p - \mathcal{I}p\|_0) \\ & \quad + (\|\text{DIV}\mathcal{I}(\mathbf{u}) - \text{DIV}(\mathbf{u}^h)\|_0 + \|\mathcal{I}\mathbf{u} - \mathbf{u}^h\|_0 + \|\mathcal{I}p - p^h\|_0) = E_{\mathcal{I}} + E_h. \end{aligned}$$

The next step is to estimate the discrete error E_h in terms of the interpolation error $E_{\mathcal{I}}$. We make use of the fact that for $(\mathbf{v}^h, q^h) \in RT_0^N \times Q_0$,

$$(5.5) \quad \int_{\Omega} \mathbf{u}^h \mathbf{v}^h \, dx - \int_{\Omega} p^h \text{DIV}(\mathbf{v}^h) \, dx = 0 = \int_{\Omega} \mathbf{u} \mathbf{v}^h \, dx - \int_{\Omega} p \nabla \cdot \mathbf{v}^h \, dx$$

and

$$(5.6) \quad \int_{\Omega} q^h \operatorname{DIV}(\mathbf{u}^h) dx = \int_{\Omega} f q^h dx = \int_{\Omega} q^h \nabla \cdot \mathbf{u} dx.$$

For brevity we switch to inner product notation. Adding and subtracting $\mathcal{I}\mathbf{u}$ and $\mathcal{I}p$ in (5.5), we obtain

$$(\mathbf{u} - \mathcal{I}\mathbf{u}, \mathbf{v}^h) + (\mathcal{I}\mathbf{u} - \mathbf{u}^h, \mathbf{v}^h) - (p - \mathcal{I}p, \nabla \cdot \mathbf{v}^h) - (\mathcal{I}p, \nabla \cdot \mathbf{v}^h) + (p^h, \operatorname{DIV}(\mathbf{v}^h)) = 0.$$

As $\mathcal{I}p$ is constant, by Lemma (3.3) we can replace $(\mathcal{I}p, \nabla \cdot \mathbf{v}^h)$ by $(\mathcal{I}p, \operatorname{DIV}(\mathbf{v}^h))$; thus

$$(5.7) \quad (\mathbf{u}^h - \mathcal{I}\mathbf{u}, \mathbf{v}^h) + (\mathcal{I}p - p^h, \operatorname{DIV}(\mathbf{v}^h)) = (\mathbf{u} - \mathcal{I}\mathbf{u}, \mathbf{v}^h) + (\mathcal{I}p - p, \nabla \cdot \mathbf{v}^h).$$

Adding and subtracting $\mathcal{I}(\nabla \cdot \mathbf{u})$ in (5.6) yields

$$(\nabla \cdot \mathbf{u} - \mathcal{I}(\nabla \cdot \mathbf{u}), q^h) + (\mathcal{I}(\nabla \cdot \mathbf{u}) - \operatorname{DIV}(\mathbf{u}^h), q^h) = 0.$$

Using CDP, we obtain

$$(5.8) \quad (\operatorname{DIV}(\mathbf{u}^h - \mathcal{I}\mathbf{u}), q^h) = (\nabla \cdot \mathbf{u} - \operatorname{DIV}(\mathcal{I}\mathbf{u}), q^h).$$

Substituting $(\mathbf{u}^h - \mathcal{I}\mathbf{u}, \mathcal{I}p - p^h)$ into the inf-sup result (5.3), we get

$$\begin{aligned} Q^h(\mathbf{u}^h - \mathcal{I}\mathbf{u}, \mathcal{I}p - p^h; \mathbf{v}^h, q^h) \\ \geq C_Q (\|\mathbf{u}^h - \mathcal{I}\mathbf{u}\|_0 + \|\operatorname{DIV}(\mathbf{u}^h - \mathcal{I}\mathbf{u})\|_0 + \|p^h - \mathcal{I}p\|_0) \\ \times (\|\mathbf{v}^h\|_0 + \|\operatorname{DIV}(\mathbf{v}^h)\|_0 + \|q^h\|_0). \end{aligned}$$

On the other hand, due to the definition of Q^h , (5.7), (5.8), Cauchy inequalities, and Lemma 3.4,

$$\begin{aligned} Q^h(\mathbf{u}^h - \mathcal{I}\mathbf{u}, \mathcal{I}p - p^h; \mathbf{v}^h, q^h) \\ = (\mathbf{u} - \mathcal{I}\mathbf{u}, \mathbf{v}^h) + (\mathcal{I}p - p, \nabla \cdot \mathbf{v}^h) + (\nabla \cdot \mathbf{u} - \operatorname{DIV}(\mathcal{I}\mathbf{u}), q^h) \\ \leq (\|\mathbf{u} - \mathcal{I}\mathbf{u}\|_0 + \|p - \mathcal{I}p\|_0 + \|\nabla \cdot \mathbf{u} - \operatorname{DIV}(\mathcal{I}\mathbf{u})\|_0) \\ \times (\|\mathbf{v}^h\|_0 + C_D \|\operatorname{DIV}(\mathbf{v}^h)\|_0 + \|q^h\|_0) \end{aligned}$$

for a positive constant C_D . It is safe to assume $C_D \geq 1$ (without loss of generality), and thus $(\|\mathbf{v}^h\|_0 + C_D \|\operatorname{DIV}(\mathbf{v}^h)\|_0 + \|q^h\|_0) \leq C_D (\|\mathbf{v}^h\|_0 + \|\operatorname{DIV}(\mathbf{v}^h)\|_0 + \|q^h\|_0)$, which, combined with the previous two estimates of Q^h , yields

$$\begin{aligned} E_h &= \|\mathbf{u}^h - \mathcal{I}\mathbf{u}\|_0 + \|\operatorname{DIV}(\mathbf{u}^h - \mathcal{I}\mathbf{u})\|_0 + \|p^h - \mathcal{I}p\|_0 \\ &\leq \frac{C_D}{C_Q} (\|\mathbf{u} - \mathcal{I}\mathbf{u}\|_0 + \|p - \mathcal{I}p\|_0 + \|\nabla \cdot \mathbf{u} - \operatorname{DIV}(\mathcal{I}\mathbf{u})\|_0) = \frac{C_D}{C_Q} E_{\mathcal{I}}. \end{aligned}$$

Therefore,

$$(5.9) \quad \|\nabla \cdot \mathbf{u} - \operatorname{DIV}(\mathbf{u}^h)\|_0 + \|\mathbf{u} - \mathbf{u}^h\|_0 + \|p - p^h\|_0 \leq \left(1 + \frac{C_D}{C_Q}\right) E_{\mathcal{I}}.$$

The remainder of the proof follows from CDP, (2.11), and (2.12). We have

$$\|\nabla \cdot \mathbf{u} - \text{DIV}(\mathcal{I}\mathbf{u})\|_0 = \|\nabla \cdot \mathbf{u} - \mathcal{I}(\nabla \cdot \mathbf{u})\|_0 \leq Ch\|\nabla \cdot \mathbf{u}\|_1$$

and

$$\|\mathbf{u} - \mathcal{I}\mathbf{u}\|_0 + \|p - \mathcal{I}p\|_0 \leq Ch(\|\mathbf{u}\|_1 + \|p\|_1);$$

i.e.,

$$E_{\mathcal{I}} \leq Ch(\|\nabla \cdot \mathbf{u}\|_1 + \|\mathbf{u}\|_1 + \|p\|_1) \leq Ch(\|\mathbf{u}\|_2 + \|p\|_1),$$

which establishes (5.4). \square

Remark 7. The presence of the constant C_D in (5.9) indicates that the size of the approximation error is directly related to assumption (2.1) on the shape-regularity of the finite element partition \mathcal{T}_h .

5.2. The least-squares method. It is easy to see that the equivalence result of Theorem 5.1 cannot be extended to the least-squares method. To convince ourselves that the mimetic reformulation (4.7) of this method is genuinely different from its standard version (4.3) let us examine the term

$$\int_{\Omega} (\text{DIV}(\mathbf{u}^h) + \sigma\Theta_0 p^h)\Theta_0^{-1}(\text{DIV}(\mathbf{v}^h) + \sigma\Theta_0 q^h)dx$$

from (4.7). It is clear that, for the same reasons as stated in Remark 2, on a nonaffine quadrilateral element,

$$\int_{\Omega} \text{DIV}(\mathbf{u}^h)\Theta_0^{-1}\text{DIV}(\mathbf{v}^h)dx \neq \int_{\Omega} \nabla \cdot \mathbf{u}^h\Theta_0^{-1}\nabla \cdot \mathbf{v}^h dx.$$

The cross terms also do not match because in the least-squares method $p^h \in Q_1$ is not constant and cannot be pulled out of the integral as in Theorem 5.1. Thus,

$$\int_{\Omega} q^h\text{DIV}(\mathbf{u}^h)dx \neq \int_{\Omega} q^h\nabla \cdot \mathbf{u}^h dx.$$

Another difference between the two versions of the least-squares method is that the splitting in Theorem 4.1 does not extend to the mimetic reformulation (4.7). This would require the discrete Green's identity

$$\int_{\Omega} p^h\text{DIV}(\mathbf{u}^h) dx + \int_{\Omega} \mathbf{u}^h\nabla p^h dx = 0 \quad \forall \mathbf{u}^h \in RT_0^N, \quad \forall p^h \in Q_1^D,$$

which in general does not hold. Therefore, velocity computed by (4.7) is not locally conservative in the sense described in [8]. This can be fixed by using the flux-correction procedure defined in [8].

The following theorem asserts stability of the reformulated least-squares method.

THEOREM 5.5. *Assume that (2.1) holds. There is a positive constant C such that*

$$(5.10) \quad \begin{aligned} & C(\|\text{DIV}(\mathbf{u}^h)\|_0 + \|\mathbf{u}^h\|_0 + \|p^h\|_1) \\ & \leq \|\Theta_0^{-1/2}(\text{DIV}(\mathbf{u}^h) + \Theta_0 p^h)\|_0 + \|\Theta_1^{1/2}(\nabla p^h + \Theta_1^{-1}\mathbf{u}^h)\|_0 \end{aligned}$$

for every $\mathbf{u}^h \in RT_0^N$ and $p^h \in Q_1^D$.

Proof. To avoid simple but tedious technical details, we state the proof for $\Theta_1 = \mathbb{I}$ and $\Theta_0 = 1$. In this case, the right-hand side in (5.10) expands into

$$\begin{aligned} \|\text{DIV}(\mathbf{u}^h) + p^h\|_0^2 + \|\nabla p^h + \mathbf{u}^h\|_0^2 &= 2 \left(\int_{\Omega} p^h \text{DIV}(\mathbf{u}^h) dx + \int_{\Omega} \mathbf{u}^h \nabla p^h dx \right) \\ &+ \|\mathbf{u}^h\|_0^2 + \|\text{DIV}(\mathbf{u}^h)\|_0^2 + \|p^h\|_0^2 + \|\nabla p^h\|_0^2. \end{aligned}$$

We switch to inner product notation. Adding and subtracting the projection of p^h onto Q_0 , using Green's identity, (3.5) in Lemma 3.3, and Cauchy's inequality, we get

$$\begin{aligned} &(\text{DIV}(\mathbf{u}^h), p^h) + (\nabla p^h, \mathbf{u}^h) \\ &= (\text{DIV}(\mathbf{u}^h), p^h - \mathcal{I}_{Q_0} p^h) + (\text{DIV}(\mathbf{u}^h), \mathcal{I}_{Q_0} p^h) - (\nabla \cdot \mathbf{u}^h, p^h) \\ &= (\text{DIV}(\mathbf{u}^h), p^h - \mathcal{I}_{Q_0} p^h) + (\nabla \cdot \mathbf{u}^h, \mathcal{I}_{Q_0} p^h - p^h) \\ &\leq \|\text{DIV}(\mathbf{u}^h)\|_0 \|p^h - \mathcal{I}_{Q_0} p^h\|_0 + \|\nabla \cdot \mathbf{u}^h\|_0 \|p^h - \mathcal{I}_{Q_0} p^h\|_0. \end{aligned}$$

Using (3.6) from Lemma 3.4, the approximation result (2.11), and the inequality $2ab \leq a^2 + b^2$, we get

$$\begin{aligned} &2((\text{DIV}(\mathbf{u}^h), p^h) + (\nabla p^h, \mathbf{u}^h)) \\ &\leq 2(1 + C_D)Ch \|\text{DIV}(\mathbf{u}^h)\|_0 \|\nabla p^h\|_0 \leq (1 + C_D)Ch (\|\text{DIV}(\mathbf{u}^h)\|_0^2 + \|\nabla p^h\|_0^2). \end{aligned}$$

As a result, for sufficiently small h ,

$$\begin{aligned} &\|\text{DIV}(\mathbf{u}^h) + p^h\|_0^2 + \|\nabla p^h + \mathbf{u}^h\|_0^2 \\ &\geq (1 - (1 + C_D)Ch) (\|\mathbf{u}^h\|_0^2 + \|\text{DIV}(\mathbf{u}^h)\|_0^2 + \|p^h\|_0^2 + \|\nabla p^h\|_0^2) \\ &\geq \frac{1}{2} (\|\mathbf{u}^h\|_0^2 + \|\text{DIV}(\mathbf{u}^h)\|_0^2 + \|p^h\|_1^2). \quad \square \end{aligned}$$

Theorem 5.5 in conjunction with the Lax–Milgram lemma implies that the reformulated least-squares problem has a unique solution. Using this theorem, we can also prove optimal error estimates for the solution of (4.7).

THEOREM 5.6. *Assume that (2.1) holds for the finite element partition \mathcal{T}_h and that the exact solution of (1.1) is such that $p \in H_D^1(\Omega) \cap H^2(\Omega)$ and $\mathbf{u} \in H_N(\text{div}, \Omega) \cap (H^2(\Omega))^2$. Solution of the reformulated least-squares problem (4.7) satisfies the error bound*

$$(5.11) \quad \|\nabla \cdot \mathbf{u} - \text{DIV}(\mathbf{u}^h)\|_0 + \|\mathbf{u} - \mathbf{u}^h\|_0 + \|p - p^h\|_1 \leq Ch (\|p\|_2 + \|\mathbf{u}\|_2).$$

Proof. For clarity we state the proof using the same setting as in the proof of Theorem 5.5. We begin by splitting the left-hand side in (5.11) into interpolation error and discrete error:

$$\begin{aligned} &\|\nabla \cdot \mathbf{u} - \text{DIV}(\mathbf{u}^h)\|_0 + \|\mathbf{u} - \mathbf{u}^h\|_0 + \|p - p^h\|_1 \\ &\leq (\|\nabla \cdot \mathbf{u} - \text{DIV}\mathcal{I}(\mathbf{u})\|_0 + \|\mathbf{u} - \mathcal{I}\mathbf{u}\|_0 + \|p - \mathcal{I}p\|_1) \\ &\quad + (\|\text{DIV}\mathcal{I}(\mathbf{u}) - \text{DIV}(\mathbf{u}^h)\|_0 + \|\mathcal{I}\mathbf{u} - \mathbf{u}^h\|_0 + \|\mathcal{I}p - p^h\|_1) = E_{\mathcal{I}} + E_h. \end{aligned}$$

The next step is to estimate E_h in terms of the interpolation error. For this purpose, we use that $f = \nabla \cdot \mathbf{u} + p$ and $0 = \nabla p + \mathbf{u}$ to write (4.7) as

$$\begin{aligned} & (\text{DIV}(\mathbf{u}^h) + p^h, \text{DIV}(\mathbf{v}^h) + q^h) + (\nabla p^h + \mathbf{u}^h, \nabla q^h + \mathbf{v}^h) \\ &= (\nabla \cdot \mathbf{u} + p, \text{DIV}(\mathbf{v}^h) + q^h) + (\nabla p + \mathbf{u}, \nabla q^h + \mathbf{v}^h). \end{aligned}$$

Subtracting the interpolants of p and \mathbf{u} from both sides of this identity and using Cauchy’s inequality gives

$$\begin{aligned} & (\text{DIV}(\mathbf{u}^h - \mathcal{I}\mathbf{u}) + p^h - \mathcal{I}p, \text{DIV}(\mathbf{v}^h) + q^h) + (\nabla(p^h - \mathcal{I}p) + \mathbf{u}^h - \mathcal{I}\mathbf{u}, \nabla q^h + \mathbf{v}^h) \\ &= (\nabla \cdot \mathbf{u} - \text{DIV}(\mathcal{I}\mathbf{u}) + p - \mathcal{I}p, \text{DIV}(\mathbf{v}^h) + q^h) + (\nabla(p - \mathcal{I}p) + \mathbf{u} - \mathcal{I}\mathbf{u}, \nabla q^h + \mathbf{v}^h) \\ &\leq C(\|\nabla \cdot \mathbf{u} - \text{DIV}(\mathcal{I}\mathbf{u})\|_0 + \|\mathbf{u} - \mathcal{I}\mathbf{u}\|_0 + \|p - \mathcal{I}p\|_1) (\|\text{DIV}(\mathbf{v}^h)\|_0 + \|\mathbf{v}^h\|_0 + \|q^h\|_1) \\ &\leq CE_{\mathcal{I}} \times (\|\text{DIV}(\mathbf{v}^h)\|_0 + \|\mathbf{v}^h\|_0 + \|q^h\|_1). \end{aligned}$$

Then we set $\mathbf{v}^h = \mathbf{u}^h - \mathcal{I}\mathbf{u}$ and $q^h = p^h - \mathcal{I}p$ and use the stability bound (5.10):

$$\begin{aligned} E_h^2 &\leq C (\text{DIV}(\mathbf{u}^h - \mathcal{I}\mathbf{u}) + p^h - \mathcal{I}p, \text{DIV}(\mathbf{u}^h - \mathcal{I}\mathbf{u}) + p^h - \mathcal{I}p) \\ &\quad + (\nabla(p^h - \mathcal{I}p) + \mathbf{u}^h - \mathcal{I}\mathbf{u}, \nabla(p^h - \mathcal{I}p) + \mathbf{u}^h - \mathcal{I}\mathbf{u}) \leq CE_{\mathcal{I}} \times E_h. \end{aligned}$$

Therefore, $E_h \leq CE_{\mathcal{I}}$ and

$$\|\nabla \cdot \mathbf{u} - \text{DIV}(\mathbf{u}^h)\|_0 + \|\mathbf{u} - \mathbf{u}^h\|_0 + \|p - p^h\|_1 \leq (1 + C)E_{\mathcal{I}}.$$

To complete the proof we estimate $E_{\mathcal{I}}$ as follows. Using CDP (3.3) and (2.11),

$$\|\nabla \cdot \mathbf{u} - \text{DIV}\mathcal{I}(\mathbf{u})\|_0 = \|\nabla \cdot \mathbf{u} - \mathcal{I}(\nabla \cdot \mathbf{u})\|_0 \leq Ch\|\nabla \cdot \mathbf{u}\|_1,$$

while from (2.12) and (2.13) we have that

$$\|\mathbf{u} - \mathcal{I}\mathbf{u}\|_0 + \|p - \mathcal{I}p\|_1 \leq Ch(\|\mathbf{u}\|_1 + \|p\|_2).$$

Therefore,

$$E_{\mathcal{I}} \leq Ch(\|p\|_2 + \|\mathbf{u}\|_2).$$

This establishes (5.11). \square

6. Numerical results. Computational experiments in this section illustrate the properties of standard and reformulated finite element methods using three different partitions of $\Omega = [0, 1]^2$ into quadrilateral elements; see Figure 6.1. We refer to the leftmost partition in this figure as the “trapezoidal grid.” This grid was used by Arnold, Boffi, and Falk [4] to demonstrate loss of accuracy in div-conforming elements and is characterized by a high degree of “nonaffinity.” The middle partition corresponds to a randomly perturbed⁹ uniform grid which provides a more realistic

⁹This grid was suggested by one of the anonymous referees and is defined as follows. We start with a uniform partition of Ω into square elements with side lengths h and draw a circle of radius $h/4$ around each node. All internal nodes are then randomly repositioned inside these circles, corner nodes are held fixed, and the rest of the nodes on the boundary are moved randomly along the sides of Ω within $\pm h/4$ of their original locations.

FIG. 6.1. *Quadrilateral grids used in the computational experiments. From left to right: Trapezoidal grid [4], randomly perturbed grid, and sinusoidal grid [18].*

example of a highly nonaffine quadrilateral grid. The rightmost partition in Figure 6.1 provides an example of a smooth nonorthogonal grid¹⁰ which may become quite distorted while retaining “near-affinity” of most of its quadrilateral elements. This grid is used to underscore the fact that the root cause for the loss of convergence is nonaffinity of the grid rather than the level of its distortion.

We show that on the first two partitions, i.e., on trapezoidal and random grids,

- the natural divergence of the velocity approximation in the standard mixed method is first-order accurate; i.e., it is optimally accurate;
- the deterioration of accuracy in the least-squares method does not spread to the pressure approximation if the reaction term is present; however, the velocity approximation is worse than in the mixed method;
- without the reaction term, the deterioration of accuracy affects all variables in the least-squares method;
- the mimetic reformulation of the least-squares method solves all of these problems and yields optimally accurate pressure and velocity approximations.

As far as the last partition is concerned, we show that thanks to the almost affine nature of the sinusoidal grid there is virtually no degradation of accuracy in mixed and least-squares methods.

The linear systems are assembled using 2×2 Gauss quadrature and solved “exactly” using direct solvers. The order of convergence study solves (1.1) with $\Gamma_N = \emptyset$,

$$\Theta_1 = \begin{bmatrix} \exp((x+y)/2) & \sin(2\pi x) \\ \sin(2\pi x) & \exp((x/2+y)/2) \end{bmatrix}, \quad \Theta_0 = 1,$$

and the right-hand side and boundary data generated from the manufactured solution

$$p = -\exp(x) \sin(y), \quad \text{and} \quad \mathbf{u} = -\Theta_1 \nabla p.$$

Orders of convergence are estimated using data on 33×33 , 65×65 , and 129×129 grids with 1024, 4096, and 16384 elements, respectively.

The maximum anisotropy of Θ_1 is attained at the top right corner of Ω and equals $4 \exp(3/2) \approx 18$. The nonconstant full tensor permeability is used only in order to

¹⁰The nodal positions in this grid are defined by

$$x(\xi, \eta, t) = \xi + \alpha(t) \sin(2\pi\xi) \sin(2\pi\eta) \quad \text{and} \quad y(\xi, \eta, t) = \eta + \alpha(t) \sin(2\pi\xi) \sin(2\pi\eta),$$

respectively, where $\alpha(t) \leq 0.1$ and t is a real parameter between 0 and 1; see [18]. The grid shown in Figure 6.1 corresponds to $t = 0.5$ and $\alpha(t) = t/5$.

make the tests more “realistic” and is not necessary to elicit the loss of convergence in the two standard methods. The latter can be observed even in the trivial case of $\Theta_1 = \mathbf{I}$, where \mathbf{I} is a 2×2 unit matrix; see [4].

The mixed method and its reformulation. The presence of the reaction term in (1.1) or lack thereof does not affect the overall behavior of the computed error. For brevity, results without this term ($\sigma = 0$) are omitted. Error data and estimated convergence rates for (4.1) and its mimetic reformulation (4.6) on trapezoidal and randomly perturbed grids are summarized in Tables 6.1–6.2. The tables show identical¹¹ errors for both versions of the mixed method, which confirms the assertion of

¹¹To avoid data variations caused by the randomness of the grid, for each grid size the two methods were run on the same instance of the random mesh.

Theorem 5.1 that their solutions coincide.

As predicted by Theorem 5.1, when the divergence error of the velocity approximation is measured *directly* by DIV instead of *indirectly* by $\nabla \cdot$, the order of convergence improves to 1. This validates our assertion that the loss of convergence in the mixed method is superficial rather than real. It follows that a standard implementation of this method with the lowest-order Raviart–Thomas element is safe to use on general quadrilateral grids, as long as one remembers to extract the divergence information using DIV.

Table 6.3 shows error data and estimated convergence rates for the standard mixed method on the sinusoidal grid. Owing to the fact that this grid is nearly affine, the rates of convergence measured by using the analytic and the mimetic divergence operators are identical despite the small variations in their values.

The least-squares method and its reformulation. Theorem 4.1 suggests that the reaction term could be very important for the standard least-squares method. This turns out to be the case. Tables 6.4–6.5 show error data for (4.3) and (4.7) with the term ($\sigma = 1$) on trapezoidal and randomly perturbed grids, respectively. For the velocity in the standard method on both grids we see a reduced order of convergence in the L^2 -norm and an almost complete loss of convergence in the divergence error. It is worth pointing out that using DIV to extract the divergence information from the standard least-squares solution does not help much. Nevertheless, the order of convergence in the divergence error is somewhat improved.

As predicted by Theorem 4.1, when the reaction term is present the loss of accuracy does not spread to the pressure approximation in the standard method. Tables 6.4–6.5 show the expected second- and first-order convergence for the L^2 - and H^1 -seminorm errors of this variable, respectively.

In the absence of the reaction term, the standard least-squares method fares much worse. Tables 6.6–6.7 show that the loss of accuracy on trapezoidal and randomly perturbed grids when $\sigma = 0$ affects both variables. We see that, without the reaction term, the L^2 order of convergence of the pressure is completely ruined, and the H^1 -seminorm error is severely reduced. These results are consistent with the numerical data on trapezoidal grids presented in [4] and confirm that, unlike in the mixed method, the loss of accuracy in the least-squares method is real. Inclusion of the reaction term helps to stem the deterioration of the pressure approximation, but, as

	$\sigma = 1$	0.179E-01	0.896E-02	0.448E-02	1.000
$\ \mathbf{u} - \mathbf{u}^h\ _0$	$\sigma = 0$	0.638E-01	0.318E-01	0.159E-01	1.001
	$\sigma = 1$	0.638E-01	0.318E-01	0.159E-01	1.001
$\ \nabla \cdot \mathbf{u} - \nabla \cdot \mathbf{u}^h\ _0$	$\sigma = 0$	0.576E+00	0.288E+00	0.144E+00	1.000
	$\sigma = 1$	0.576E+00	0.288E+00	0.144E+00	1.000
$\ \nabla \cdot \mathbf{u} - \text{DIV}(\mathbf{u}^h)\ _0$	$\sigma = 0$	0.541E+00	0.271E+00	0.135E+00	1.000
	$\sigma = 1$	0.541E+00	0.271E+00	0.135E+00	1.000

As expected, the mimetic reformulation of the least-squares method completely eliminates these problems. From the data in Tables 6.4–6.7 we see that the reformulation restores the optimal order of convergence for all variables regardless of whether or not the reaction terms are included.

Finally, Table 6.8 shows error and convergence data for the standard least-squares method on sinusoidal grids. We see that despite the highly distorted nature of this grid, the fact that most of its elements remain close to affine quads is enough to restore convergence rates for all variables.

7. Conclusions. The mimetic reformulation proposed in this paper is a simple yet effective approach to restoring convergence of finite element methods that employ the lowest-order quadrilateral Raviart–Thomas elements.

By proving that the reformulation of the mixed method is equivalent to its standard version, we establish that the loss of convergence in this method is benign and can be avoided by using DIV to compute the divergence of the velocity approximation.

Our results also show that the deterioration of accuracy in the least-squares method is real. For problems with a reaction term it is confined to the velocity approximation, but without this term, the loss of convergence spreads to both variables. The mimetic reformulation of the least-squares method mitigates convergence problems and should be used whenever computations with this method involve nonaffine quadrilateral grids.

Acknowledgment. We thank the anonymous referees for several suggestions that helped to improve this paper and prompted us to include more informative numerical examples and data.

LOW ORDER DISCONTINUOUS GALERKIN METHODS FOR SECOND ORDER ELLIPTIC PROBLEMS*

E. BURMAN[†] AND B. STAMM[‡]

Abstract. We consider DG-methods for second order scalar elliptic problems using piecewise affine approximation in two or three space dimensions. We prove that both the symmetric and the nonsymmetric versions of the DG-method have regular system matrices without penalization of the interelement solution jumps provided boundary conditions are imposed in a certain weak manner. Optimal convergence is proved for sufficiently regular meshes and data. We then propose a DG-method using piecewise affine functions enriched with quadratic bubbles. Using this space we prove optimal convergence in the energy norm for both a symmetric and nonsymmetric DG-method without stabilization. All of these proposed methods share the feature that they conserve mass locally independent of the penalty parameter.

Key words. discontinuous Galerkin, elliptic equation, Crouzeix–Raviart approximation, interior penalty, local mass conservation

AMS subject classifications. 65M160, 65M15

DOI. 10.1137/070685105

1. Introduction. The discontinuous Galerkin (DG) method for $(2n)$ th order elliptic problems was introduced by Baker [2] with special focus on the fourth order case. In parallel, the interior penalty method of Douglas and Dupont for second order elliptic problems [9] led to the symmetric interior penalty DG-method (SIPG-method) proposed by Wheeler [15] and Arnold [1]. In the SIPG-method, a penalty term on the solution jumps between adjacent elements and has to be introduced to ensure coercivity of the bilinear form.

In the nineties, Babuska, Baumann, and Oden proposed a nonsymmetric method for elliptic problems with a less stiff penalty term [12] (NIPG). The DG-methods for second order elliptic problems have been further analyzed in the works by Girault, Rivière, and Wheeler [13] and Larson and Niklasson [11]. In these papers the authors proved that in the nonsymmetric case, when using high order polynomial approximation, optimal convergence can be obtained without any penalization of the solution jumps. In a recent paper, Brezzi and Marini [6] showed that enriching the piecewise affine discontinuous finite element space by some nonconforming quadratic bubbles yields a space which is the smallest one for which the nonsymmetric version converges optimally without interior penalty.

For a review of discontinuous Galerkin methods for elliptic problems, we refer the reader to Arnold [1], and for a review of stabilization mechanisms in discontinuous Galerkin methods, we refer the reader to Brezzi et al. [5].

One of the advantages of the DG-method is that it has enhanced local conservation compared to the continuous Galerkin method. However, only in the case of the

nonsymmetric DG-method, without penalization of the solution jumps, is the conservation independent of the stabilization parameter. The nonsymmetric formulation, however, is not adjoint consistent and one may not analyze L^2 -convergence using the Nitsche trick.

In this paper we discuss the relation between stabilization, existence of discrete solution, and optimal convergence, in the case of scalar second order elliptic problems. The aim is to design a low order DG-method that

1. has optimal convergence in the DG-energy norm (including both the broken H^1 semi-norm and the solution jumps over element faces) and the L^2 -norm,
2. is locally massconservative independently of the penalty parameter.

We will show that for the symmetric DG-method the only thing required to guarantee the existence of a solution to the discrete system is to impose boundary conditions in the same way as for the Crouzeix–Raviart nonconforming finite elements. No interelement penalization of the solution jumps is needed. Under some assumptions on the mesh and on the data, optimal convergence is obtained as well. Indeed, the condition is either that the mesh is uniform in the asymptotic limit and that the right-hand side is smooth enough or that the mesh satisfies a certain macroelement property.

If these conditions are not satisfied, then the convergence of the solution jumps can be perturbed by the appearance of a checkerboard mode that vanishes too slowly in the absence of interior penalty. We exemplify the checkerboard mode numerically and show how it is quenched by penalization.

To reduce the constraints on the mesh we enrich the space with quadratic nonconforming bubble functions. These stabilizing bubbles eliminate the checkerboard mode. We prove optimal convergence in the energy norm without stabilization both in the symmetric and nonsymmetric case. In the symmetric case we obtain additionally optimal convergence in the L^2 -norm. In both cases the analysis relies on a discrete inf-sup condition drawing from earlier ideas on minimal stabilization for DG-methods in [8, 7, 10, 11].

2. The problem setting. Let Ω be an open, bounded, and convex polygon (polyhedron in three space dimensions) in \mathbb{R}^d , $d = 2, 3$, with outer unit normal n . Let \mathcal{K} be a subdivision of $\Omega \subset \mathbb{R}^d$ into nonoverlapping d -simplices κ . An element $\kappa \in \mathcal{K}$ is assumed to be an closed set. We consider the following elliptic problem with homogeneous Dirichlet boundary conditions.

Find $u : \Omega \rightarrow \mathbb{R}$ such that

$$(2.1) \quad \begin{cases} -\nabla \cdot \sigma \nabla u = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $f \in L^2(\Omega)$ and with a diffusion coefficient that is piecewise constant on each element $\sigma(x)|_\kappa = \sigma_\kappa \in \mathbb{R}$ for all $\kappa \in \mathcal{K}$ and $\sigma(x) > \sigma_0 > 0$. We assume that there exists a constant $\rho > 0$ such that $\sigma|_{\kappa_1} \leq \rho \sigma|_{\kappa_2}$ for any two elements satisfying $\partial\kappa_1 \cap \partial\kappa_2 \neq \emptyset$. The fact that the boundary conditions are of homogeneous Dirichlet type is not a limitation of the presented methods but rather to avoid technical details.

Let \mathcal{F}_i denote the set of interior faces ($(d - 1)$ -manifolds) of the mesh; i.e., the set of faces that are not included in the boundary $\partial\Omega$. The set \mathcal{F}_e denotes the faces that are included in $\partial\Omega$ and defines $\mathcal{F} = \mathcal{F}_i \cup \mathcal{F}_e$. Note that for an element $\kappa \in \mathcal{K}$, $\mathcal{F}(\kappa)$ denotes the set of faces of κ . Furthermore, denote by Γ the skeleton of the mesh, i.e., the set of points belonging to faces, $\Gamma = \{x \in \overline{\Omega} : \exists F \in \mathcal{F} \text{ s.t. } x \in F\}$.

Assume that \mathcal{K} is shape-regular, does not contain any hanging node, and covers $\overline{\Omega}$ exactly. Suppose that each $\kappa \in \mathcal{K}$ is an affine image of the reference element $\hat{\kappa}$; i.e., for each element κ there exists an affine transformation $T_\kappa : \hat{\kappa} \rightarrow \kappa$. For an element $\kappa \in \mathcal{K}$, h_κ denotes its diameter. Set $h = \max_{\kappa \in \mathcal{K}} h_\kappa$, and let \tilde{h}, \tilde{m} be the functions such that $\tilde{h}|_\kappa = h_\kappa$ (resp., $\tilde{m}|_\kappa = \text{meas}_d(\kappa)$). We will say that a family of subdivisions $\{\mathcal{K}\}_h$ is asymptotically ζ -uniform with some $\zeta > 0$ if there exists a constant $c > 0$ such that for every mesh \mathcal{K} and every $F \in \mathcal{F}_i$ there holds $|\tilde{m}|_{\kappa_1} - \tilde{m}|_{\kappa_2}| \leq c \text{meas}_{d-1}(F)^\zeta \min(\tilde{m}|_{\kappa_1}, \tilde{m}|_{\kappa_2})$, where $F = \partial\kappa_1 \cap \partial\kappa_2$ with $\kappa_1, \kappa_2 \in \mathcal{K}$.

For a face $F \in \mathcal{F}$, h_F denotes its diameter, and let \tilde{h}_F be the function such that $\tilde{h}_F|_F = h_F$.

For a nonempty subdomain $R \subset \Omega$ or $R \subset \Gamma$, $(\cdot, \cdot)_R$ denotes the $L^2(R)$ -scalar product, $\|\cdot\|_R = (\cdot, \cdot)_R^{1/2}$ the corresponding norm, and $\|\cdot\|_{s,R}$ the $H^s(R)$ -norm. The elementwise counterparts will be distinguished using the discrete partition as subscript, for example $(\cdot, \cdot)_\mathcal{K} = \sum_{\kappa \in \mathcal{K}} (\cdot, \cdot)_\kappa$. For $s \geq 1$, let $H^s(\mathcal{K})$ be the space of piecewise Sobolev H^s -functions and denote its norm by $\|\cdot\|_{s,\mathcal{K}}$.

For $v \in H^1(\mathcal{K})$, $\tau \in [H^1(\mathcal{K})]^d$ and an interior face $F = \kappa_1 \cap \kappa_2 \in \mathcal{F}_i$, where κ_1 and κ_2 are two distinct elements of \mathcal{K} with respective outer unit normals n_1 and n_2 , define the jump and average by

$$\begin{aligned} [v] &= (v|_{\kappa_1} n_1 + v|_{\kappa_2} n_2), & \{v\} &= \frac{1}{2} (v|_{\kappa_1} + v|_{\kappa_2}), \\ [\tau] &= (\tau|_{\kappa_1} \cdot n_1 + \tau|_{\kappa_2} \cdot n_2), & \{\tau\} &= \frac{1}{2} (\tau|_{\kappa_1} + \tau|_{\kappa_2}). \end{aligned}$$

Additionally we define on each face $F \in \mathcal{F}$ the unit normal n_F in an arbitrary but fixed manner.

On outer faces $F = \partial\kappa \cap \partial\Omega \in \mathcal{F}_e$, for some $\kappa \in \mathcal{K}$ with outer unit normal n , the jump and the average are defined as $[v] = v|_F n$ and $\{v\} = v|_F$ (resp., $[\tau] = \tau|_F \cdot n$ and $\{\tau\} = \tau|_F$). The projection of $\{v\}$ and $[v]$ onto the space of facewise constant functions are denoted by $\overline{\{v\}} \in \mathbb{R}$ and $\overline{[v]} \in \mathbb{R}^d$ and defined by

$$\int_F \overline{\{v\}} \, ds = \int_F \{v\} \, ds \quad \text{and} \quad \int_F \overline{[v]} \, ds = \int_F [v] \, ds$$

for all $F \in \mathcal{F}$.

The shape-regularity implies that there exists a constant $c > 0$ independent of the mesh size h such that on any face $F \in \mathcal{F}$,

$$h_F \leq \{\tilde{h}\} \leq c h_F.$$

In this paper $c > 0$ denotes a generic constant and can change at each occurrence, while an indexed constant stays fixed. Any constant is independent of the mesh size h but not necessarily of σ .

3. Finite element spaces. We will consider two low order finite element spaces, the space of piecewise affine discontinuous functions, and the space of piecewise affine discontinuous functions enriched with nonconforming quadratic bubbles. We show that every function in the former space can be written as a sum of a midpoint continuous function (in the Crouzeix–Raviart space) and a “midpoint discontinuous” function in a space that will be specified later. The motivation for this decomposition is that such a choice of basis in the symmetric DG-bilinear form results in a block diagonal matrix, and hence the continuous and the discontinuous contributions may be analyzed separately.

Define the piecewise affine discontinuous finite element space by

$$V_h^1 = \{v_h \in L^2(\Omega) : v_h|_\kappa \in \mathbb{P}_1(\kappa) \forall \kappa \in \mathcal{K}\}.$$

Then, introduce the enriched space

$$V_h^b = V_h^1 \oplus V^b,$$

with

$$V^b = \{v \in L^2(\Omega) : v(x)|_\kappa = \alpha_\kappa x \cdot x, \text{ where } \alpha_\kappa \in \mathbb{R}\},$$

where $x = (x_1, \dots, x_d)$ denotes the physical variables. Observe that V_h^b is the space introduced by Brezzi and Marini in [6]. Additionally, we define

$$V_{h,0}^1 = \left\{ v_h \in V_h^1 : \int_F v_h ds = 0 \forall F \in \mathcal{F}_e \right\},$$

the space of piecewise affine elements where the homogeneous Dirichlet boundary conditions are imposed on the midpoints of each exterior face.

3.1. Splitting of the finite element space $V_{h,0}^1$. The idea is to split $V_{h,0}^1$ into a midpoint continuous space, the Crouzeix–Raviart space, and a midpoint discontinuous space, similar to what was proposed in the one-dimensional case in [10]. Recall the definition of the Crouzeix–Raviart space

$$V^C = \left\{ v_h \in V_{h,0}^1 : \int_F [v_h] ds = 0 \forall F \in \mathcal{F}_i \right\}.$$

Its “midpoint discontinuous” counterpart is defined by

$$V^D = \left\{ v_h \in V_{h,0}^1 : \int_F \{v_h\} ds = 0 \forall F \in \mathcal{F}_i \right\}.$$

Denote by N_{int} the number of interior faces of the mesh \mathcal{K} . Let us denote $\{\phi_i^c\}_{i=1}^{N_{int}}$, the Crouzeix–Raviart basis defined such that

$$\int_{F_j} \{\phi_i^c\} ds = \delta_{i,j} \text{meas}_{d-1}(F_i) \quad \forall 1 \leq i, j \leq N_{int}.$$

This defines a basis for the space V^C . Denote by $x_F \in F$ the midpoint of $F \in \mathcal{F}$ for a one-dimensional face and the barycenter (which coincides with the Gauss point) of F for a two-dimensional face. Recall that the midpoint integration rule on F is exactly of order two in the one-dimensional case and of order one in the two-dimensional case. Thus $v_c \in V^C$ is midpoint continuous, i.e.,

$$[v_c](x_F) = \frac{1}{\text{meas}_{d-1}(F)} \int_F [v_c] ds = 0 \quad \forall F \in \mathcal{F},$$

in two and three space dimensions. Now, let us define a basis for the space V^D . For each face $F_i \in \mathcal{F}_i$ consider the basis function ϕ_i^d defined by

$$\phi_i^d = \frac{1}{2} \phi_i^c \frac{\nabla \phi_i^c \cdot n_{F_i}}{|\nabla \phi_i^c \cdot n_{F_i}|}$$

with n_{F_i} a fixed but arbitrary unit normal associated to the face F_i . It is easy to verify that $\phi_i^d \in V^D$ and that

$$\int_{F_j} [\phi_i^d] \cdot n_{F_j} ds = \delta_{i,j} \text{meas}_{d-1}(F_i) \quad \forall F_i \in \mathcal{F}.$$

Now we are ready to prove the following lemma.

LEMMA 3.1. *The splitting of $V_{h,0}^1$ into V^C and V^D is a direct sum; i.e., $V_{h,0}^1 = V^C \oplus V^D$. Any function v_h in $V_{h,0}^1$ can be written as*

$$v_h(x) = \sum_{i=1}^{N_{int}} c_i \phi_i^c(x) + d_i \phi_i^d(x),$$

where $c_i = \frac{1}{\text{meas}_{d-1}(F_i)} \int_{F_i} \{v_h\} ds$ and $d_i = \frac{1}{\text{meas}_{d-1}(F_i)} \int_{F_i} [v_h] \cdot n_{F_i} ds$.

Remark 3.2. Note that, for $v \in H^1(\Omega)$ the function

$$(3.1) \quad i_c v(x) = \sum_{i=1}^{N_{int}} c_i \phi_i^c(x)$$

with $c_i = \frac{1}{\text{meas}_{d-1}(F_i)} \int_{F_i} v ds$ is the Crouzeix–Raviart interpolant and has optimal approximation properties.

Proof. First, assume that $v_h \in V^C \cap V^D$ and show that $v_h \equiv 0$. This is an immediate consequence of the properties of V^C and V^D . One may then show that $V^C \oplus V^D$ covers $V_{h,0}^1$ entirely. This is easily proven by taking $v_h \in V_{h,0}^1$ and defining $w_h \in V^C \oplus V^D$ by

$$w_h(x) = \sum_{i=1}^{N_{int}} c_i \phi_i^c(x) + d_i \phi_i^d(x)$$

with $c_i = \frac{1}{\text{meas}_{d-1}(F_i)} \int_{F_i} \{v_h\} ds$ and $d_i = \frac{1}{\text{meas}_{d-1}(F_i)} \int_{F_i} [v_h] \cdot n_{F_i} ds$. Using the properties of the basis functions $\{\phi_i^c\}_{i=1}^{N_{int}}$ and $\{\phi_i^d\}_{i=1}^{N_{int}}$ it follows that $w_h \equiv v_h$. \square

LEMMA 3.3 (asymptotic L^2 -orthogonality between V^C and V^D). *Assume that the mesh is asymptotically ζ -uniform with some $\zeta > 0$, then the spaces V^C and V^D satisfy the following weak L^2 -orthogonality property: there exists a constant $c > 0$ independent of h , such that*

$$|(v_c, v_d)_\mathcal{K}| \leq ch^\zeta \|v_c\|_\mathcal{K} \|v_d\|_\mathcal{K} + r(d) \|\tilde{h} \nabla v_c\|_\mathcal{K} \|\tilde{h} \nabla v_d\|_\mathcal{K} \quad \forall v_c \in V^C, v_d \in V^D,$$

where $r(2) = 0$ and $r(3) = c$.

Proof. In the two-dimensional case we can proceed as follows. Take $v_c \in V^C$ and $v_d \in V^D$ and develop

$$(3.2) \quad |(v_c, v_d)_\mathcal{K}| = \left| \sum_{\kappa \in \mathcal{K}} (v_c, v_d)_\kappa \right| = \frac{1}{3} \left| \sum_{\kappa \in \mathcal{K}} \sum_{F \in \mathcal{F}(\kappa)} \tilde{m}|_\kappa v_c(x_F) v_d(x_F) \right|$$

with numerical integration on κ using the midpoints/barycenters of its faces as integration points (x_F denotes the midpoint/barycenter of the face F). This numerical

integration on κ is exact of order 2 in the two-dimensional case but not in the three-dimensional one. Since $v_c(x_F) = v_d(x_F) = 0$ for exterior faces $F \in \mathcal{F}_e$ and since v_c is midpoint continuous we can rearrange the sum

$$|(v_c, v_d)_\mathcal{K}| = \frac{2}{3} \left| \sum_{F \in \mathcal{F}_i} v_c(x_F) \{ \tilde{m} v_d \}(x_F) \right|.$$

Using the equality $\{wv\} = \{w\}\{v\} + \frac{1}{4}[w] \cdot [v]$ and the fact that $\{v_d\}(x_F) = 0$ for all interior faces yields

$$|(v_c, v_d)_\mathcal{K}| \leq c \sum_{F \in \mathcal{F}_i} |v_c(x_F)| |[\tilde{m}](x_F) \cdot n_F| |[v_d](x_F) \cdot n_F|.$$

The regularity assumption on the mesh implies that $|[\tilde{m}] \cdot n_F| \leq ch_F^\zeta \{ \tilde{m} \}$ with $\zeta > 0$, and since $\frac{1}{2}|[v_d](x_F) \cdot n_F| = |v_d|_{\kappa_i}(x_F)|$, for $i = 1, 2$, we can rearrange the sum again,

$$|(v_c, v_d)_\mathcal{K}| \leq ch^\zeta \sum_{\kappa \in \mathcal{K}} (|v_c|, |v_d|)_\kappa \leq ch^\zeta \|v_c\|_\mathcal{K} \|v_d\|_\mathcal{K}.$$

In the three-dimensional case, since the numerical integration is no longer of order two, we introduce the local midpoint interpolation $i_h^\kappa : H^2(\kappa) \rightarrow \mathbb{P}_1(\kappa)$ for each element $\kappa \in \mathcal{K}$ by $i_h^\kappa v(x_F) = v(x_F)$ for all $F \in \mathcal{F}(\kappa)$. Then using the triangle inequality yields

$$(3.3) \quad |(v_c, v_d)_\mathcal{K}| \leq \left| \sum_{\kappa \in \mathcal{K}} \int_\kappa i_h^\kappa(v_c v_d) dx \right| + \left| \sum_{\kappa \in \mathcal{K}} \int_\kappa (v_c v_d - i_h^\kappa(v_c v_d)) dx \right|.$$

The first term of the right-hand side of (3.3) can be developed as in (3.2) since now for the local midpoint interpolation i_h^κ the above defined numerical integration rule is exact. For the second term of the right-hand side of (3.3), one can show using standard interpolation results that

$$\left| \sum_{\kappa \in \mathcal{K}} \int_\kappa (v_c v_d - i_h^\kappa(v_c v_d)) dx \right| \leq c \|\tilde{h} \nabla v_c\|_\mathcal{K} \|\tilde{h} \nabla v_d\|_\mathcal{K}. \quad \square$$

3.2. Properties of the enriched space V_h^b . The motivation for the particular form of the enriched space is given in the following lemma. The key idea is that the gradient of a function in V_h^b restricted to an element is locally in the Raviart–Thomas space. Let RT_0 denote the space of Raviart–Thomas elements of order zero.

LEMMA 3.4. *For all $w_h \in V_h^b$ there holds*

$$\nabla w_h|_\kappa \in RT_0(\kappa),$$

and for all $r_h \in RT_0(\kappa)$ there exists $w_h \in V_h^b$ such that $\nabla w_h|_\kappa = r_h$ for all $\kappa \in \mathcal{K}$.

Proof. Let $w_h \in V_h^b$, restricting w_h to an arbitrary element κ we can write

$$w_h|_\kappa(x) = \alpha x \cdot x + \beta \cdot x + \gamma,$$

where $\alpha, \gamma \in \mathbb{R}$ and $\beta \in \mathbb{R}^d$ are the local degrees of freedom. Then

$$\nabla w_h|_\kappa(x) = 2\alpha x + \beta.$$

To show that this function lies in the Raviart–Thomas finite element space we have to map it on the reference element using the *Piola* transformation. But let us first introduce the *affine* transformation T_κ between the reference element $\hat{\kappa}$ defined by its vertices $a_i = e_i$ for $i = 1, \dots, d$ and $a_{d+1} = \mathcal{O}$ and the physical element κ . The vectors e_i denote the unit vectors corresponding to the i th coordinate. The affine transformation may be written as

$$T_\kappa(\hat{x}) = J_\kappa \hat{x} + t_\kappa,$$

where $\hat{x} = (\hat{x}_1, \dots, \hat{x}_d)^\top \in \hat{\kappa}$ denotes the variable in the reference element. Then we denote by ψ_κ the Piola transformation between the physical element and the reference element defined by

$$\psi_\kappa(v)(\hat{x}) = |J_\kappa| J_\kappa^{-1} v(T_\kappa(\hat{x})).$$

Thus

$$\psi_\kappa(\nabla w_h|_\kappa)(\hat{x}) = |J_\kappa| J_\kappa^{-1} (2\alpha T_\kappa(\hat{x}) + \beta) = |J_\kappa| (2\alpha \hat{x} + J_\kappa^{-1}(\beta + 2\alpha t_\kappa)),$$

and this function is clearly an element of the Raviart–Thomas finite element space on the reference element.

On the other hand if $r_h \in RT_0$, then $\psi_\kappa \circ r_h|_\kappa$ is of the form

$$\psi_\kappa(r_h|_\kappa)(\hat{x}) = a\hat{x} + b,$$

where $a \in \mathbb{R}$ and $b = (b_1, \dots, b_d)^\top \in \mathbb{R}^d$. Thus

$$r_h|_\kappa(x) = \frac{1}{|J_\kappa|} (ax + J_\kappa b - t_\kappa).$$

Defining locally,

$$w_h|_\kappa(x) = \frac{1}{|J_\kappa|} \left(\frac{a}{2} x \cdot x + (J_\kappa b - t_\kappa) \cdot x \right)$$

yields that

$$\nabla w_h|_\kappa(x) = r_h|_\kappa(x). \quad \square$$

4. Poincaré inequalities. The analysis of the model problem (2.1) relies on the Poincaré inequality. In this section we state the Poincaré inequalities that hold for the two spaces V^C and V^D , separately. Then we prove a stronger Poincaré inequality for the space V^D under some assumptions on the mesh.

LEMMA 4.1. *There is a constant $c > 0$ independent of h such that for all $v_h \in V_h^b$ there holds*

$$c \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} [v_h]\|_{\mathcal{F}}^2 \leq \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[v_h]}\|_{\mathcal{F}}^2 + \|\sigma^{\frac{1}{2}} \nabla v_h\|_{\mathcal{K}}^2,$$

where $\omega|_F = \max(\sigma|_{\kappa_1}, \sigma|_{\kappa_2})$ for $F = \partial\kappa_1 \cap \partial\kappa_2$.

Proof. The proof is completed immediately by the approximation properties of the average jump, a discrete trace inequality, and the bounded variation of σ over faces. \square

COROLLARY 4.2. *The following Poincaré inequality for broken H^1 -spaces holds for all $v_h \in V_h^b$:*

$$c \|\sigma^{\frac{1}{2}} v_h\|_{\mathcal{K}}^2 \leq \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[v_h]}\|_{\mathcal{F}}^2 + \|\sigma^{\frac{1}{2}} \nabla v_h\|_{\mathcal{K}}^2.$$

Proof. An immediate consequence of the previous lemma and the Poincaré inequality is

$$(4.1) \quad c \|\sigma^{\frac{1}{2}} v_h\|_{\mathcal{K}}^2 \leq \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} [v_h]\|_{\mathcal{F}}^2 + \|\sigma^{\frac{1}{2}} \nabla v_h\|_{\mathcal{K}}^2$$

proved by Brenner [3]. \square

PROPOSITION 4.3 (Poincaré inequality for V^C). *There exists a constant $c > 0$ depending only on Ω such that, for all $h < 1$,*

$$\forall v_c \in V^C, \quad c \|v_c\|_{\mathcal{K}} \leq \|\nabla v_c\|_{\mathcal{K}}.$$

Proof. See Temam [14] for the proof. \square

PROPOSITION 4.4 (Poincaré inequality for V^D). *There exists a constant $c > 0$ depending only on Ω such that, for all $h < 1$,*

$$\forall v_d \in V^D, \quad c \|v_d\|_{\mathcal{K}} \leq \|\nabla v_d\|_{\mathcal{K}}.$$

Proof. Let $v_d \in V^D$ be fixed. Then, define the splitting of Ω into two parts \mathcal{K}_1 and \mathcal{K}_2 by

$$\begin{aligned} \mathcal{K}_1 &= \{\kappa \in \mathcal{K} : \exists x \in \kappa \text{ s.t. } v_d(x) = 0\}, \\ \mathcal{K}_2 &= \{\kappa \in \mathcal{K} : v_d(x) \neq 0 \forall x \in \kappa\}. \end{aligned}$$

First, prove the inequality for the region \mathcal{K}_1 . Fix an element $\kappa_1 \in \mathcal{K}_1$ and define

$$Z(\kappa_1) = \{x \in \kappa_1 : v_d(x) = 0\}.$$

Since $v_d|_{\kappa_1} \in \mathbb{P}_1(\kappa_1)$ we may write

$$v_d(x) = \nabla v_d \cdot (x - x^*) \quad \text{with } x^* \in Z(\kappa_1).$$

Thus we conclude immediately that

$$(4.2) \quad \|v_d\|_{\mathcal{K}_1} \leq \|\tilde{h} \nabla v_d\|_{\mathcal{K}_1}.$$

Second, split \mathcal{K}_2 in maximal subsets $\{\mathcal{K}_2^j\}_{j=1}^m$ in order that each

$$\Omega_2^j = \left(\overset{\circ}{\bigcup}_{\kappa \in \mathcal{K}_2^j} \kappa \right)$$

is connected. Fix a subset \mathcal{K}_2^j and observe that $|v_d|$ is midpoint continuous on interior faces of \mathcal{K}_2^j . In consequence, $|v_d|$ lies in the Crouzeix–Raviart space over the domain Ω_2^j , and we may proceed analogously to the proof of Proposition 4.3. Details are left to the reader. \square

In case the mesh has a certain macroelement structure we may prove a stronger Poincaré inequality for the space V^D .

PROPOSITION 4.5 (strong Poincaré inequality for V^D). *Let \mathcal{K} be a mesh. Assume that there exists a coarse mesh \mathcal{T} covering $\bar{\Omega}$ such that each macroelement (d -simplex) $T \in \mathcal{T}$ contains exactly $d+1$ elements $\kappa_1, \dots, \kappa_{d+1}$ of \mathcal{K} and such that $\kappa_i \cap \kappa_j \cap \overset{\circ}{T} \neq \emptyset$ for all $1 \leq i, j \leq d+1$. Then the following inequality holds:*

$$\forall v_d \in V^D, \quad c \|v_d\|_{\mathcal{K}} \leq \|\tilde{h} \nabla v_d\|_{\mathcal{K}}.$$

FIG. 1. Illustration of the macroelement argument of Lemma 4.5. The “+” and “-” signs refer to the sign of v_d at the midpoints of the faces.

Proof. Let $v_d \in V^D$ and fix an element $\kappa \in \mathcal{K}$. If there exists $x^* \in \kappa$ such that $v_d(x^*) = 0$, then we conclude analogous to (4.2) that

$$\|v_d\|_\kappa \leq \|h_\kappa \nabla v_d\|_\kappa.$$

Otherwise there exists in the same macroelement $T \in \mathcal{T}$ a neighbor element $\kappa' \in \mathcal{K}$ such that there exists $x^* \in \kappa'$ with $v_d(x^*) = 0$. Indeed assume that $v_d(x) \neq 0$ for all $x \in T$. Observe that v_d changes sign in the midpoint of each face since it lies in V^D and hence $\int_F \{v_d\} = 0$. Consider all three elements of T in two dimensions and an arbitrary selection of three elements containing κ' in three dimensions. The solution changes sign over each face. However, in the three elements the sign has to change four times. Hence it has to change sign within one element, which leads to a contradiction. See the illustration in Figure 1. Thus there exists at least one element $\kappa^* \in \mathcal{K}$ of the macroelement T such that there exists a point $x^* \in \kappa^*$ with $v_d(x^*) = 0$. Since $\kappa \cap \kappa^* \neq \emptyset$, we conclude that

$$\|v_d\|_\kappa \leq c \|h_\kappa \nabla v_d\|_\kappa. \quad \square$$

Remark 4.6. Observe that the above defined macroelement property is sufficient but not necessary for the strong Poincaré inequality to hold. The sufficient and necessary condition on the mesh is: For each element $\kappa \in \mathcal{K}$ there exists a path in an h -neighborhood of κ , starting and ending at κ , passing an odd number of faces.

5. Discontinuous Galerkin methods. Define the following bilinear form:

$$(5.1) \quad a_s(u_h, v_h) = (\sigma \nabla u_h, \nabla v_h)_\mathcal{K} - (\{\sigma \nabla u_h\}, [v_h])_\mathcal{F} - s (\{\sigma \nabla v_h\}, [u_h])_\mathcal{F}$$

for $s \in \{-1, 1\}$ and the stabilization term

$$j(u_h, v_h) = (\omega \tilde{h}_\mathcal{F}^{-1} \overline{[u_h]}, \overline{[v_h]})_{\mathcal{F}_i},$$

where $\omega|_F = \max(\sigma|_{\kappa_1}, \sigma|_{\kappa_2})$ for $F = \partial\kappa_1 \cap \partial\kappa_2$. Note that we only penalize the average value of the jumps in the spirit of Lemma 4.1. Let us define two methods to approximate the solution of (2.1).

Reduced interior penalty (RIP-) method. Find $u_h^1 \in V_{h,0}^1$ such that

$$(5.2) \quad a_s(u_h^1, v_h) + \gamma j(u_h^1, v_h) = (f, v_h)_\mathcal{K} \quad \forall v_h \in V_{h,0}^1,$$

for some $\gamma \in \mathbb{R}$ and $s \in \{-1, 1\}$.

Bubble stabilized discontinuous Galerkin (BSDG-) method. Find $u_h^b \in V_h^b$ such that, with $s \in \{-1, 1\}$,

$$(5.3) \quad a_s(u_h^b, v_h) = (f, v_h)_{\mathcal{K}} \quad \forall v_h \in V_h^b.$$

Remark 5.1 (local mass conservation property). The solutions u_h^1, u_h^b of (5.2) (resp., (5.3)) satisfy

$$\begin{aligned} - \int_{\partial\kappa} \{\sigma \nabla u_h^1\} \cdot n_\kappa \, ds + \gamma \int_{\partial\kappa} \omega \tilde{h}_{\mathcal{F}}^{-1} [\overline{u_h^1}] \cdot n_\kappa \, ds &= \int_\kappa f \, dx, \\ - \int_{\partial\kappa} \{\sigma \nabla u_h^b\} \cdot n_\kappa \, ds &= \int_\kappa f \, dx. \end{aligned}$$

LEMMA 5.2 (consistency of methods). *If the exact solution u of problem (2.1) satisfies $u \in H^2(\Omega)$, then the formulations defined by (5.2) and (5.3) are consistent (and adjoint consistent if the bilinear form is symmetric). Moreover, the following Galerkin orthogonalities hold:*

$$\begin{aligned} a_s(u - u_h^1, v_h) + \gamma j(u - u_h^1, v_h) &= 0 & \forall v_h \in V_{h,0}^1, \\ a_s(u - u_h^b, v_h) &= 0 & \forall v_h \in V_h^b, \end{aligned}$$

where $u_h^1 \in V_{h,0}^1$ and $u_h^b \in V_h^b$ denote the discrete solutions of (5.2) (resp., (5.3)).

Proof. Since $u \in H^2(\Omega)$ and the form $a_s(\cdot, \cdot)$ coincides with the SIPG formulation for $s = 1$ (resp., NIPG for $s = -1$) it is consistent. Moreover, for $s = 1$ the method is adjoint consistent. Observe that for $u \in H^1(\Omega)$ there holds

$$j(u, v_h) = (\omega \tilde{h}_{\mathcal{F}}^{-1} [\overline{u}], [\overline{v_h}])_{\mathcal{F}_i} = 0. \quad \square$$

6. Analysis of the RIP-method. For the analysis it is useful to introduce the following norms:

$$\begin{aligned} \|v\|^2 &= \|\sigma^{\frac{1}{2}} \nabla v\|_{\mathcal{K}}^2 + \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} [v]\|_{\mathcal{F}}^2, \\ \|w\|_c^2 &= \|\sigma^{\frac{1}{2}} \nabla w\|_{\mathcal{K}}^2 + \|\tilde{h}_{\mathcal{F}}^{\frac{1}{2}} \{\sigma \nabla w\}\|_{\mathcal{F}_i}^2 \end{aligned}$$

for all $v \in H^1(\mathcal{K})$, $w \in H^2(\mathcal{K})$. We have the following standard approximability results that we state without proof.

LEMMA 6.1 (approximability in V^C). *Let $u \in H^\beta(\Omega)$, with $\beta \in \{1, 2\}$, and $i_c u \in V^C$ denote the Crouzeix–Raviart-interpolant of u onto V^C defined by (3.1), then there holds*

$$(6.1) \quad \|u - i_c u\|_{\mathcal{K}} \leq c h^\beta \|u\|_{\beta, \mathcal{K}}.$$

If $u \in H^2(\Omega)$, then

$$(6.2) \quad \| \|u - i_c u\| \| \leq c h \|u\|_{2, \mathcal{K}},$$

$$(6.3) \quad \| \|u - i_c u\|_c \| \leq c h \|u\|_{2, \mathcal{K}}.$$

6.1. Stability. In this section we will use the orthogonality properties of V^C and V^D to obtain coercivity results for the unstabilized method also. These results ensure the existence of the discrete solution.

LEMMA 6.2 (orthogonality relations). *The bilinear forms $a_s(\cdot, \cdot)$ and $j(\cdot, \cdot)$ satisfy the following orthogonality relations:*

$$\begin{aligned} a_s(v_c, v_d) &= 0 & \forall v_c \in V^C, \forall v_d \in V^D, \\ a_s(v_d, v_c) &= (1-s)(\sigma \nabla v_d, \nabla v_c)_\mathcal{K} & \forall v_c \in V^C, \forall v_d \in V^D, \\ j(v_c, v_d) &= j(v_d, v_c) = 0 & \forall v_c \in V^C, \forall v_d \in V^D. \end{aligned}$$

Remark 6.3. The spaces V^C and V^D are orthogonal with respect to the symmetric bilinear form $a_1(\cdot, \cdot)$.

Proof. Let $v_c \in V^C$ and $v_d \in V^D$. Since $\int_F [v_c] ds = 0$ for all interior faces $F \in \mathcal{F}_i$, it follows directly that

$$j(v_c, v_d) = j(v_d, v_c) = 0,$$

and that

$$a_s(v_c, v_d) = (\sigma \nabla v_c, \nabla v_d)_\mathcal{K} - (\{\sigma \nabla v_c\}, [v_d])_{\mathcal{F}_i}.$$

An integration by parts yields

$$a_s(v_c, v_d) = -(\nabla \cdot \sigma \nabla v_c, v_d)_\mathcal{K} + ([\sigma \nabla v_c], \{v_d\})_{\mathcal{F}} = 0,$$

since $\int_F \{v_d\} ds = 0$ for all faces $F \in \mathcal{F}$ and $\nabla \cdot \sigma \nabla v_c|_\kappa = 0$ for all $\kappa \in \mathcal{K}$. Analogously we prove that

$$a_s(v_d, v_c) = (\sigma \nabla v_d, \nabla v_c)_\mathcal{K} - s(\{\sigma \nabla v_c\}, [v_d])_{\mathcal{F}_i} = (1-s)(\sigma \nabla v_d, \nabla v_c)_\mathcal{K}. \quad \square$$

LEMMA 6.4. *The bilinear forms $a_s(\cdot, \cdot)$ and $j(\cdot, \cdot)$ satisfy the following relations:*

$$\begin{aligned} a_s(u_c, v_c) &= (\sigma \nabla u_c, \nabla v_c)_\mathcal{K} & \forall u_c, v_c \in V^C, \\ a_s(u_d, v_d) &= -s(\sigma \nabla u_d, \nabla v_d)_\mathcal{K} & \forall u_d, v_d \in V^D, \\ j(u_c, v_c) &= 0 & \forall u_c, v_c \in V^C. \end{aligned}$$

Proof. The proof is similar to the one of Lemma 6.2 and uses the properties of the spaces V^C and V^D . \square

LEMMA 6.5 (splitting of the RIP-method). *The first method defined by (5.2) is equivalent to: Find $u_c \in V^C$, $u_d \in V^D$ such that*

$$(6.4) \quad (\sigma \nabla u_c, \nabla v_c)_\mathcal{K} + (1-s)(\sigma \nabla u_d, \nabla v_c)_\mathcal{K} = (f, v_c)_\mathcal{K} \quad \forall v_c \in V^C,$$

$$(6.5) \quad -s(\sigma \nabla u_d, \nabla v_d)_\mathcal{K} + \gamma(\omega \tilde{h}_{\mathcal{F}}^{-1} [\overline{u_d}], \overline{[v_d]})_{\mathcal{F}_i} = (f, v_d)_\mathcal{K} \quad \forall v_d \in V^D.$$

Remark 6.6. Observe that for $s = 1$, (6.4) is the Crouzeix–Raviart method for problem (2.1). As a consequence the stability and convergence analysis is known. It follows that the midpoint continuous part of u_h is independent of the parameter γ .

Moreover, note that (6.5) is independent of (6.4). Hence we can solve first for the discontinuous field u_d and then for the continuous field u_c also in the case $s = -1$.

Proof. Let $v_h \in V_{h,0}^1$. Since $V_{h,0}^1 = V^C \oplus V^D$ we can write $v_h = v_c + v_d$ with $v_c \in V^C$ and $v_d \in V^D$. Analogously we can write $u_h^1 = u_c + u_d$. Testing in (5.2) with v_c and v_d separately yields the problem: Find $u_c \in V^C$ and $u_d \in V^D$ such that

$$\begin{aligned} a_s(u_c + u_d, v_c) + \gamma j(u_c + u_d, v_c) &= (f, v_c)_K & \forall v_c \in V^C, \\ a_s(u_c + u_d, v_d) + \gamma j(u_c + u_d, v_d) &= (f, v_d)_K & \forall v_d \in V^D. \end{aligned}$$

Applying Lemma 6.2 leads directly to: Find $u_c \in V^C$ and $u_d \in V^D$ such that

$$(6.6) \quad a_s(u_c + u_d, v_c) = (f, v_c)_K \quad \forall v_c \in V^C,$$

$$(6.7) \quad a_s(u_d, v_d) + \gamma j(u_d, v_d) = (f, v_d)_K \quad \forall v_d \in V^D.$$

Note that the equivalences between the problems (6.6) and (6.4) (resp., (6.7) and (6.5)) follow directly from Lemma 6.4. \square

LEMMA 6.7 (coercivity of the RIP-method). *A unique solution to the discrete problem (6.5) exists for all $s\gamma \leq 0$ and $s\gamma > C_{stab}$, where $C_{stab} > 0$ is a certain constant independent of h . Moreover, the following coercivity bound holds:*

$$C(\gamma) \| \|u_d\| \|^2 \leq |a_s(u_d, u_d) + \gamma j(u_d, u_d)|,$$

where

$$C(\gamma) = \begin{cases} c \min(1, |\gamma|) & \text{if } s\gamma < 0, \\ c(\gamma - C_{stab}) & \text{if } s\gamma > C_{stab}. \end{cases}$$

On general meshes for $\gamma = 0$ there holds

$$c \|\sigma^{\frac{1}{2}} u_d\|_K^2 \leq |a_s(u_d, u_d)|.$$

On meshes described in Proposition 4.5 there holds, for $\gamma = 0$,

$$(6.8) \quad c \| \|u_d\| \|^2 \leq |a_s(u_d, u_d)|.$$

Proof. Let us prove first the regularity of (6.5) for $s\gamma < 0$. Observe, using Lemma 4.1, that

$$\begin{aligned} c \min(1, |\gamma|) \| \|u_d\| \|^2 &\leq \|\sigma^{\frac{1}{2}} \nabla u_d\|_K^2 + |\gamma| \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_d]}\|_{\mathcal{F}_i}^2 = -s a_s(u_d, u_d) + |\gamma| j(u_d, u_d) \\ &= |a_s(u_d, u_d) + \gamma j(u_d, u_d)| \end{aligned}$$

since $\|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_d]}\|_{\mathcal{F}_e}^2 = 0$.

For $s\gamma > 0$ observe that using the inverse and trace inequalities yields

$$\| \|u_d\| \|^2 = \|\sigma^{\frac{1}{2}} \nabla u_d\|_K^2 + \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} [u_d]\|_{\mathcal{F}}^2 \leq c \|\tilde{h}^{-1} \sigma^{\frac{1}{2}} u_d\|_K^2.$$

On the other hand, by norm equivalence on discrete spaces there exists a constant $c_\star > 0$, independent of the mesh size h , such that

$$\|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_d]}\|_{\mathcal{F}_i}^2 \geq c_\star \|\tilde{h}^{-1} \sigma^{\frac{1}{2}} u_d\|_K^2,$$

since $\omega|_F \geq \sigma|_{\kappa_i}$, $i = 1, 2$, for $F = \partial\kappa_1 \cap \partial\kappa_2$. Thus, using the inverse inequality with constant c_{ie} yields

$$\begin{aligned} |a_s(u_d, u_d) + \gamma j(u_d, u_d)| &\geq -\|\sigma^{\frac{1}{2}} \nabla u_d\|_{\mathcal{K}}^2 + s\gamma \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_d]}\|_{\mathcal{F}_i}^2 \\ &\geq (s\gamma c_\star - c_{ie}) \|\tilde{h}^{-1} \sigma^{\frac{1}{2}} u_d\|_{\mathcal{K}}^2. \end{aligned}$$

Observe that coercivity holds under the assumption that $s\gamma = |\gamma| > \frac{c_{ie}}{c_\star} =: C_{stab}$.

For $\gamma = 0$ on general meshes observe that

$$c \|\sigma^{\frac{1}{2}} u_d\|_{\mathcal{K}}^2 = \|\sigma^{\frac{1}{2}} \nabla u_d\|_{\mathcal{K}}^2 = -s a_s(u_d, u_d) = |a_s(u_d, u_d)|$$

using the Poincaré inequality noted in Proposition 4.4.

For $\gamma = 0$ on meshes described in Proposition 4.5, we have

$$\begin{aligned} \|u_d\|^2 &= \|\sigma^{\frac{1}{2}} \nabla u_d\|_{\mathcal{K}}^2 + \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} [u_d]\|_{\mathcal{F}}^2 \leq \|\sigma^{\frac{1}{2}} \nabla u_d\|_{\mathcal{K}}^2 + c \|\tilde{h}^{-1} \sigma^{\frac{1}{2}} u_d\|_{\mathcal{K}}^2 \\ &\leq c \|\sigma^{\frac{1}{2}} \nabla u_d\|_{\mathcal{K}}^2 = c |a_s(u_d, u_d)| \end{aligned}$$

using the trace inequality and the strong Poincaré inequality noted in Proposition 4.5. \square

6.2. Convergence. We will now address the question of optimal convergence for different values of the stabilization parameter. In the case where the stabilization parameter is set to zero, the lack of continuity of the bilinear form may perturb convergence. However, if the mesh has the macroelement structure of Proposition 4.5 optimal convergence is recovered.

THEOREM 6.8. *Let $u \in H^2(\Omega)$ be the solution of (2.1), and let u_h^1 be the solution of (5.2) with $s\gamma < 0$, $s\gamma > C_{stab}$, or $\gamma = 0$ on the meshes defined in Proposition 4.5, then there holds*

$$\|u - u_h^1\| \leq ch \|u\|_{2,\mathcal{K}}.$$

Remark 6.9. On general meshes, in the particular case $\gamma = 0$, this theorem is no longer valid. In this case an optimal convergence result can be shown under some restrictive regularity assumptions on f and the mesh; see Theorem 6.10.

Proof. First, note that for the bilinear form $a_s(\cdot, \cdot)$ the following continuity holds for all $w \in H_0^1(\Omega)$, $w_c \in V^C$, and $v_h \in V_h^1$ by the Cauchy–Schwarz inequality:

$$(6.9) \quad a_s(w - w_c, v_h) \leq \|w - w_c\|_c \|v_h\|.$$

1. Since $u_h^1 = u_c + u_d$ decomposes the error in two midpoint-continuous parts and one midpoint-discontinuous part,

$$(6.10) \quad \|u - u_h^1\| \leq \|u - i_c u\| + \|u_c - i_c u\| + \|u_d\|.$$

2. Observe that by Lemmas 6.4, 5.2, and 6.2 and (6.9),

$$\begin{aligned} \|u_c - i_c u\|^2 &= a_s(u_c - i_c u, u_c - i_c u) = a_s(u - i_c u - u_d, u_c - i_c u) \\ &\leq c (\|u - i_c u\|_c + \|u_d\|) \|u_c - i_c u\|, \end{aligned}$$

since $u_c - i_c u + u - u_h^1 = u - i_c u - u_d$ and $a_s(u - u_h^1, i_c u - u_c) = 0$. Thus

$$(6.11) \quad \|u - u_h^1\| \leq c (\|u - i_c u\| + \|u - i_c u\|_c + \|u_d\|).$$

3. Use Lemma 6.1 to bound the first two terms of the right-hand side of (6.11),

$$\| \|u - i_c u\| \| + \| \|u - i_c u\|_c \leq ch \|u\|_{2,\mathcal{K}}.$$

4. For the third term of (6.11) use the coercivity noted in Lemma 6.7,

$$\| \|u_d\| \|^2 \leq \frac{c}{C(\gamma)} |a_s(u_d, u_d) + \gamma j(u_d, u_d)|.$$

In the particular case $\gamma = 0$, the constant $C(0)$ denotes the constant of (6.8).

5. Use the consistency of the bilinear form noted in Lemma 5.2,

$$\| \|u_d\| \|^2 \leq \frac{c}{C(\gamma)} |a_s(u - u_c, u_d)|,$$

since $u_d + u - u_h^1 = u - u_c$ and $a_s(u - u_h^1, u_d) - \gamma j(u_h^1, u_d) = 0$.

6. Conclude by applying the continuity (6.9) and the approximation result (6.3) that

$$\| \|u - u_h^1\| \| \leq ch \|u\|_{2,\mathcal{K}}. \quad \square$$

Under some restrictions we can show optimal convergence also in the particular case of $\gamma = 0$ for the symmetric version on meshes without the macroelement property.

THEOREM 6.10. *Let $u \in H^2(\Omega)$ be the solution of (2.1), and let u_h^1 be the solution of (5.2) with $s = 1$ and $\gamma = 0$. Assume that $f \in H^\beta(\Omega)$, with $\beta \in \{1, 2\}$, and that the mesh is asymptotically ζ -uniform with some $\zeta > 0$, then there holds*

$$\| \sigma^{\frac{1}{2}} \nabla(u - u_h^1) \|_{\mathcal{K}} \leq c(h \|u\|_{2,\mathcal{K}} + (h^\zeta + r(d) h^2) \|f\|_{1,\mathcal{K}} + h^\beta \|f\|_{\beta,\mathcal{K}}),$$

where $r(2) = 0$ and $r(3) = c$.

Proof. Using the triangle inequality we can split

$$\| \sigma^{\frac{1}{2}} \nabla(u - u_h^1) \|_{\mathcal{K}} \leq \| \sigma^{\frac{1}{2}} \nabla(u - u_c) \|_{\mathcal{K}} + \| \sigma^{\frac{1}{2}} \nabla u_d \|_{\mathcal{K}}.$$

Since we only consider the symmetric version ($s = 1$), u_c is the standard Crouzeix–Raviart solution, and the first term of the right-hand side of the previous equation can be bounded by

$$\| \sigma^{\frac{1}{2}} \nabla(u - u_c) \|_{\mathcal{K}} \leq ch \|u\|_{2,\mathcal{K}}.$$

From (6.5) we can write

$$(6.12) \quad \| \sigma^{\frac{1}{2}} \nabla u_d \|^2 = |(f, u_d)_{\mathcal{K}}| \leq |(f - i_c f, u_d)_{\mathcal{K}}| + |(i_c f, u_d)_{\mathcal{K}}|,$$

where i_c is the Crouzeix–Raviart interpolant introduced in Remark 3.2. The first term of the right-hand side of (6.12) can be bounded by

$$(6.13) \quad |(f - i_c f, u_d)_{\mathcal{K}}| \leq \|f - i_c f\|_{\mathcal{K}} \|u_d\|_{\mathcal{K}} \leq ch^\beta \|f\|_{\beta,\mathcal{K}} \| \sigma^{\frac{1}{2}} \nabla u_d \|_{\mathcal{K}}$$

by optimal approximation properties of the Crouzeix–Raviart interpolant and by the Poincaré inequality for V^D noted in Proposition 4.4.

For the second term of the right-hand side of (6.12), we use Lemma 3.3, the Poincaré inequality for V^D , Proposition 4.4, and the stability of the Crouzeix–Raviart interpolant $\|i_c f\|_{\mathcal{K}} \leq \|f\|_{1,\mathcal{K}}$ (resp., $\|\nabla i_c f\|_{\mathcal{K}} \leq \|f\|_{1,\mathcal{K}}$):

$$(6.14) \quad \begin{aligned} |(i_c f, u_d)_{\mathcal{K}}| &\leq c(h^\zeta \|i_c f\|_{\mathcal{K}} \|u_d\|_{\mathcal{K}} + r(d) h^2 \|\nabla i_c f\|_{\mathcal{K}} \| \sigma^{\frac{1}{2}} \nabla u_d \|_{\mathcal{K}}) \\ &\leq c(h^\zeta + r(d) h^2) \|f\|_{1,\mathcal{K}} \| \sigma^{\frac{1}{2}} \nabla u_d \|_{\mathcal{K}}. \end{aligned}$$

Combining (6.13) and (6.14) completes the proof. \square

Remark 6.11. If $\beta = 2$ and $\zeta = 2$, then optimal convergence can be shown in the triple norm $\|\cdot\|$ since in this case

$$\|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} [u_d]\|_{\mathcal{F}}^2 \leq c \|\tilde{h}^{-1} \nabla u_d\|_{\mathcal{K}} \leq ch \|f\|_{2,\mathcal{K}}.$$

Remark 6.12. Observe that on uniform meshes the convergence is only limited by the regularity of f .

We will now show that we have optimal L^2 -convergence for the symmetric version thanks to the adjoint consistency. For the nonsymmetric version, the L^2 -convergence rate depends on the regularity of the mesh and the right-hand side, as pointed out in [10] in the one-dimensional case.

THEOREM 6.13. *Let $u \in H^2(\Omega)$ with $\|u\|_{2,\mathcal{K}} \leq c \|f\|_{\mathcal{K}}$ be the solution of (2.1), and let u_h^1 be the solution of (5.2) with $s\gamma < 0$, $s\gamma > C_{stab}$, or $\gamma = 0$ on meshes as described in Proposition 4.5, then the following hold.*

(a) *If $s = 1$, then*

$$\|u - u_h^1\|_{\mathcal{K}} \leq ch^2 \|u\|_{2,\mathcal{K}}.$$

(b) *If $s = -1$, assuming that $f \in H^\beta(\Omega)$, with $\beta \in \{1, 2\}$, and that the mesh is asymptotically ζ -uniform with some $\zeta > 0$, then*

$$\|u - u_h^1\|_{\mathcal{K}} \leq c(h^2 \|u\|_{2,\mathcal{K}} + (h^\zeta + r(d)h^2) \|f\|_{1,\mathcal{K}} + h^\beta \|f\|_{\beta,\mathcal{K}}),$$

where $r(2) = 0$ and $r(3) = c$.

Proof. Let $e = u - u_h$ and consider the dual problem: Find $\phi \in H_0^1(\Omega)$ such that

$$(\sigma \nabla \phi, \nabla z)_{\mathcal{K}} = (e, z)_{\mathcal{K}} \quad \forall z \in H_0^1(\Omega).$$

Under the regularity assumptions on u we have $\|\phi\|_{1,\mathcal{K}} \leq c \|e\|_{\mathcal{K}}$ and $\|\phi\|_{2,\mathcal{K}} \leq c \|e\|_{\mathcal{K}}$. It follows that

$$-(\nabla \cdot \sigma \nabla \phi, z)_{\mathcal{K}} = (e, z)_{\mathcal{K}} \quad \forall z \in L^2(\Omega).$$

Then we have by the dual consistency of Lemma 5.2,

$$\begin{aligned} \|e\|_{\mathcal{K}}^2 &= a_1(e, \phi) = a_s(e, \phi) + (s - 1)(\{\sigma \nabla \phi\}, [e])_{\mathcal{F}} \\ &= a_s(e, \phi - i_c \phi) - (s - 1)(\{\sigma \nabla \phi\}, \overline{[u_d]})_{\mathcal{F}_i} - (s - 1)(\{\sigma \nabla(\phi - i_c \phi)\}, [e] - \overline{[e]})_{\mathcal{F}}. \end{aligned}$$

First, observe that using the Cauchy–Schwarz inequality, the trace inequality for nondiscrete functions, and the approximation properties of the DG-solution, Theorem 6.8, (resp., the interpolation property of the Crouzeix–Raviart interpolant from (6.2)), implies that

$$\begin{aligned} a_s(e, \phi - i_c \phi) &\leq c \left(\|e\|^2 + \|\tilde{h}_{\mathcal{F}}^{\frac{1}{2}} \{\sigma \nabla e\}\|_{\mathcal{F}}^2 \right)^{\frac{1}{2}} \left(\|\phi - i_c \phi\|^2 + \|\tilde{h}_{\mathcal{F}}^{\frac{1}{2}} \{\sigma \nabla(\phi - i_c \phi)\}\|_{\mathcal{F}}^2 \right)^{\frac{1}{2}} \\ &\leq c \left(\|e\|^2 + h^2 \|u\|_{2,\mathcal{K}}^2 \right)^{\frac{1}{2}} \left(\|\phi - i_c \phi\|^2 + h^2 \|\phi\|_{2,\mathcal{K}}^2 \right)^{\frac{1}{2}} \\ &\leq ch^2 \|u\|_{2,\mathcal{K}} \|\phi\|_{2,\mathcal{K}} \leq ch^2 \|u\|_{2,\mathcal{K}} \|e\|_{\mathcal{K}}. \end{aligned}$$

Second, observe that

$$\begin{aligned} (\{\sigma \nabla \phi\}, \overline{[u_d]})_{\mathcal{F}_i} &\leq c \|\tilde{h}_{\mathcal{F}}^{\frac{1}{2}} \{\sigma \nabla \phi\}\|_{\mathcal{F}} \|\tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \omega^{\frac{1}{2}} [u_d]\|_{\mathcal{F}} \leq c \|\phi\|_{1,\mathcal{K}}^{\frac{1}{2}} \|\phi\|_{2,\mathcal{K}}^{\frac{1}{2}} \|u_d\| \\ &\leq c \|e\|_{\mathcal{K}} \|u_d\| \end{aligned}$$

using a multiplicative trace inequality, see [4], and third, applying the approximability of the average jump and the trace inequality for nondiscrete functions yields

$$\begin{aligned} (\{\sigma \nabla \phi - \sigma \nabla i_c \phi\}, [e] - \overline{[e]})_{\mathcal{F}} &\leq c \|\tilde{h}_{\mathcal{F}}^{\frac{1}{2}} \{\sigma \nabla (\phi - i_c \phi)\}\|_{\mathcal{F}} \|\tilde{h}_{\mathcal{F}}^{\frac{1}{2}} [\nabla e]_t\|_{\mathcal{F}} \\ &\leq c (\|\nabla (\phi - i_c \phi)\|_{\mathcal{K}} + h \|\phi\|_{2,\mathcal{K}}) (\|e\| + h \|u\|_{2,\mathcal{K}}) \\ &\leq c h^2 \|\phi\|_{2,\mathcal{K}} \|u\|_{2,\mathcal{K}} \leq c h^2 \|e\|_{\mathcal{K}} \|u\|_{2,\mathcal{K}}, \end{aligned}$$

where $[\nabla e]_t$ denotes the tangential jump defined by $[\nabla e]_t|_F = \nabla e|_{\kappa_1} \times n_1 + \nabla e|_{\kappa_2} \times n_2$ for $F = \partial \kappa_1 \cap \partial \kappa_2 \in \mathcal{F}$. We conclude that

$$\|e\|_{\mathcal{K}} \leq c h^2 \|u\|_{2,\mathcal{K}} + c |s - 1| (\|u_d\| + h^2 \|u\|_{2,\mathcal{K}}).$$

For the symmetric case the result follows immediately since $|s - 1| = 0$.

Consider now the nonsymmetric case for which $s = -1$. By the coercivity noted in Lemma 6.7, it follows that

$$C(\gamma) \| \|u_d\| \|^2 \leq |a_{-1}(u_d, u_d) + \gamma j(u_d, u_d)| = |(f, u_d)_{\mathcal{K}}|.$$

Using Lemma 3.3, (6.1), and the stability of the Crouzeix–Raviart interpolant, we may conclude that

$$\begin{aligned} C(\gamma) \| \|u_d\| \|^2 &\leq |(f - i_c f, u_d)_{\mathcal{K}}| + |(i_c f, u_d)_{\mathcal{K}}| \\ &\leq (\|f - i_c f\|_{\mathcal{K}} + c h^\zeta \|i_c f\|_{\mathcal{K}}) \|u_d\|_{\mathcal{K}} + r(d) h^2 \|\nabla i_c f\|_{\mathcal{K}} \|\nabla u_d\|_{\mathcal{K}} \\ &\leq (c h^\beta \|f\|_{\beta,\mathcal{K}} + c (h^\zeta + r(d) h^2) \|f\|_{1,\mathcal{K}}) \| \|u_d\| \|. \quad \square \end{aligned}$$

Remark 6.14. For $\gamma = 0$, in the particular case of Remark 6.11 optimal convergence in the L^2 -norm can be shown also on regular meshes without the macroelement property. The details are left to the reader.

6.3. Numerical tests. Observe that the only difference between the standard SIPG/NIPG-method and the RIP-method is that in the latter case the stabilization term is composed by the facewise L^2 -projection of order 0 of the jumps. From an implementational viewpoint this can be realized by reducing the order of the quadrature formula for the numerical integration on the faces; i.e., applying the midpoint integration rules for the computation of the stabilization term.

6.3.1. Test problems. Let us briefly present the test problems used for the numerical tests.

(i) *Problem with smooth solution.* We consider problem (2.1) with $\sigma = 1$ and $f(x, y) = 2(2 - x^2 - y^2)$ on the square $\Omega = (-1, 1)^2$. The analytic exact solution is given by $u(x, y) = (x^2 - 1)(y^2 - 1) \in C^\infty(\overline{\Omega})$. A sequence of unstructured meshes is considered.

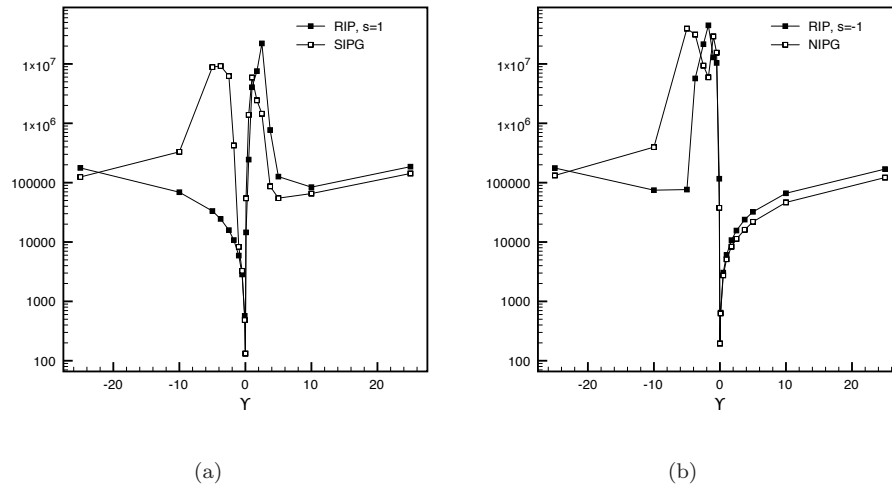

FIG. 2. Comparison of the condition number of the matrices corresponding to the symmetric version (a) and nonsymmetric version (b) of the RIP-method and the SIPG- (a), respectively, NIPG-method (b) for the test problem (i) with smooth solution.

(ii) *Problem with irregular solution.* Now choose the following L -shaped domain: $\Omega = ([-1, 1] \times [-1, 0] \cup [0, 1]^2)^\circ$. We consider problem (2.1) with $\sigma = 1$ and $f \equiv 0$ and nonhomogeneous boundary conditions such that the solution is

$$u(x, y) = (x^2 + y^2)^{\frac{1}{3}} \sin\left(\frac{2}{3} \arctan_*\left(\frac{x}{y}\right)\right),$$

where \arctan_* is chosen in such a manner that it is a continuous function at points with $y = 0$. One can prove that $u \notin H^2(\Omega)$. Therefore Theorems 6.8, 6.13, 7.4, and 7.5 are no longer valid. A sequence of unstructured meshes is considered.

(iii) *Problem with checkerboard mode.* We consider problem (2.1) with $\sigma = 1$ and $f(x, y) = -1 + 2\chi_{x>y}$, where χ denotes the characteristic function on the square $\Omega = (-1, 1)^2$. A sequence of structured meshes is considered.

6.3.2. Robustness with respect to the stabilization parameter. Let us consider the test problem (i) with smooth solution. We compare the robustness of the symmetric RIP-method with the SIPG-method; respectively, the nonsymmetric RIP-method with the NIPG-method.

In Figure 2 we give comparisons of the condition number of the corresponding matrices. We define the condition number of a square matrix (not necessarily symmetric positive definite) as the ratio of the largest singular value of the matrix to the smallest one. Since the continuous and the discontinuous part of the approximation decouples for our formulation, we may also consider negative values of the penalization parameter. One readily verifies from the graphics that the approximate solution degenerates for values of the stability parameter that do not satisfy the hypothesis $s\gamma \leq 0$ or $s\gamma > C_{stab}$ given in Lemma 6.7. Observe in particular for the symmetric methods that the RIP-method is stable for negative stabilization parameters whereas the SIPG-method is not, which is due to the fact that the stabilization in the former case affects only the discontinuous subspace.

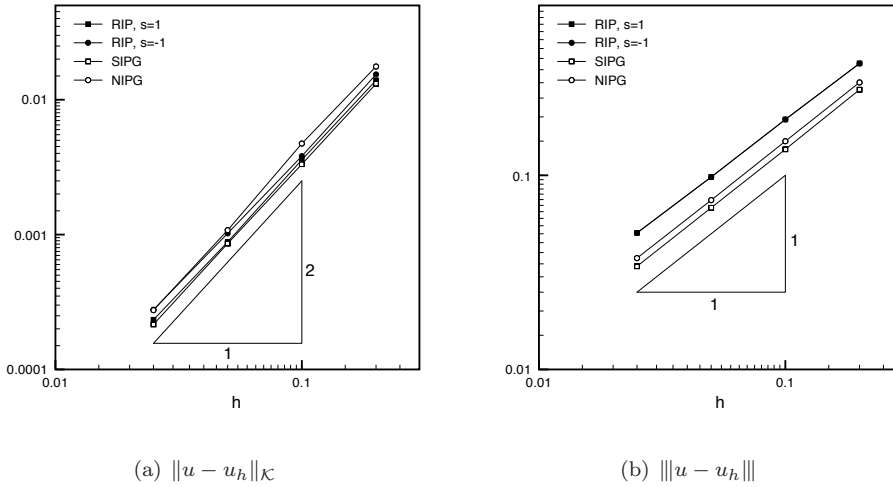

FIG. 3. L^2 -error (a) and energy-error (b) for h -refinement for the test problem (i) with smooth solution using stabilization parameters $\gamma = 0$ for the RIP-method, $\gamma = 10$ for the SIPG-method, and $\gamma = 1$ for the NIPG-method.

FIG. 4. L^2 -error (a) and energy-error (b) for h -refinement for the test problem (ii) with irregular solution using stabilization parameters $\gamma = 0$ for the RIP-method, $\gamma = 10$ for the SIPG-method, and $\gamma = 1$ for the NIPG-method.

6.3.3. Convergence. The convergence rates of the RIP-method with stabilization parameter $\gamma = 0$ are compared to those of the standard SIPG- and NIPG-method once for the problem (i) with regular solution and once for the problem (ii) with irregular solution.

Note that in several plots the curves of two different methods may have exactly the same error and the two curves are indistinguishable.

Figure 3 shows the optimal convergence rates of the error in the approximations of the solution of the smooth problem measured in the L^2 - and energy-norm. The

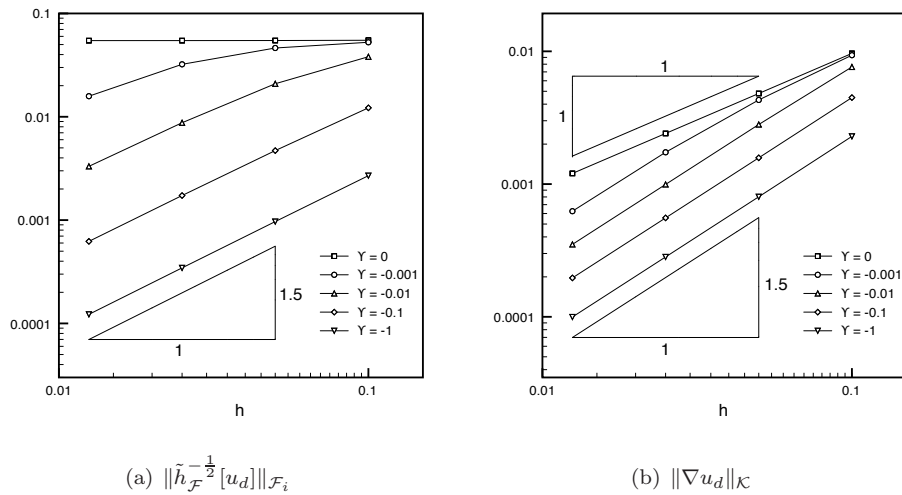

FIG. 5. Different norms of the discontinuous field u_d of the RIP-method for h -refinement and for different stabilization parameters γ for the test problem (ii).

symmetric versions have slightly better convergence rates in the L^2 -norm, which can be justified by Theorem 6.13.

Figure 4 shows the accuracy of the methods when solving the problem with an irregular solution. The SIPG-method has a smaller L^2 -error than the other methods; however, the convergence rates are the same.

The test problem (iii) is chosen so as to give rise to a checkerboard mode in the discontinuous field. The convergence of the jump term for different values of the stabilization parameter is given in Figure 5(a), and the convergence of the broken H^1 seminorm of u_d is given in Figure 5(b). Clearly the broken H^1 seminorm of u_d converges for the case without stabilization even though u_d does not converge in the norm $\|\cdot\|$ including the jumps. This lack of convergence of the interelement jumps is caused by the checkerboard mode in the field u_d . In Figure 6 we give plots of the u_d field for various values of the penalization parameter γ . This clearly illustrates how the penalization localizes the perturbation caused by the discontinuous data, and hence enhances convergence for $\gamma \neq 0$.

7. Analysis of the BSDG-method. In the previous section we saw that for the unstabilized symmetric DG-method the appearance of a checkerboard mode for rough data destroyed convergence of the solution jumps. Optimal convergence is recovered if the mesh has a certain macroelement structure. In the framework of the BSDG-method this structure is replaced by a bubble enrichment of the space. The motivation for the DG-method using the enriched space is to obtain local mass conservation independent of the stabilization parameter for a low order DG-method while keeping optimal convergence properties in the general case.

7.1. Projection. In order to prove stability of the method we first need to define the following projection.

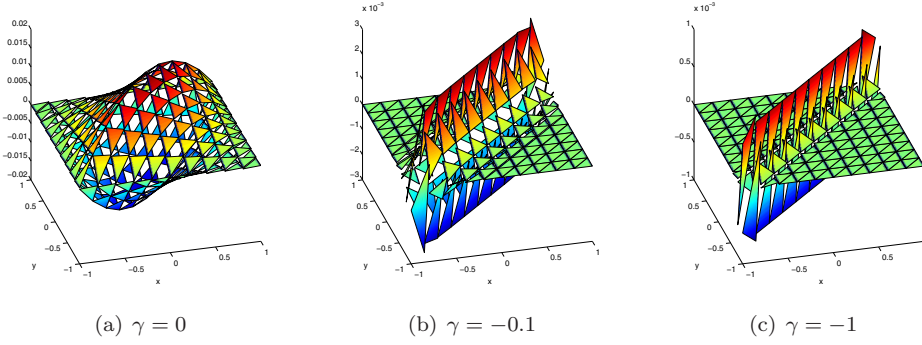

FIG. 6. The discontinuous field u_d of the RIP-method computed using different values of the stabilization parameter for the test problem (ii) generating a checkerboard mode.

LEMMA 7.1 (interpolant). Let $u_h \in V_h^b$ be a fixed function. Then there exists a unique $w_h \in V_h^b$ such that

$$(7.1) \quad \int_{\kappa} w_h \, dx = 0 \quad \forall \kappa \in \mathcal{K},$$

$$(7.2) \quad \{\sigma \nabla w_h\}|_F \cdot n_F = -s\omega h_F^{-1} \overline{[u_h]}|_F \cdot n_F \quad \forall F \in \mathcal{F},$$

$$(7.3) \quad \overline{[w_h]}|_F = 0 \quad \forall F \in \mathcal{F}_i.$$

In addition the following a priori estimate holds:

$$(7.4) \quad \|\sigma^{\frac{1}{2}} \nabla w_h\|_{\mathcal{K}} \leq c \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_h]}\|_{\mathcal{F}},$$

where $\omega = \max(\sigma|_{\kappa_1}, \sigma|_{\kappa_2})$ for $F = \partial\kappa_1 \cap \partial\kappa_2$.

Proof. Let us first observe that the number of conditions on the projection is equal to the number of unknowns. The dimension of the finite element space V_h^b is $(d+2)N_{el}$, where N_{el} denotes the number of elements in the mesh. On the other hand condition (7.1) enforces N_{el} constraints whereas conditions (7.2) and (7.3) demand $N_f + N_{int}$ constraints where N_f and N_{int} denote the number of the number of faces, respectively, the number of interior faces of the mesh. Observing that $N_f + N_{int} = (d+1)N_{el}$ implies directly a square linear system to determine the projection, let us now establish the a priori estimate

$$(7.5) \quad \|\sigma^{\frac{1}{2}} \nabla w_h\|_{\mathcal{K}} \leq c \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_h]}\|_{\mathcal{F}}.$$

Since w_h has zero mean over each element, it satisfies the following strong Poincaré inequality:

$$(7.6) \quad \|\sigma^{\frac{1}{2}} w_h\|_{\mathcal{K}} \leq c \|\tilde{h} \sigma^{\frac{1}{2}} \nabla w_h\|_{\mathcal{K}}.$$

Hence, using a trace inequality yields

$$(7.7) \quad \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[w_h]}\|_{\mathcal{F}}^2 \leq c \|\sigma^{\frac{1}{2}} \tilde{h}^{-1} w_h\|_{\mathcal{K}}^2 \leq c \|\sigma^{\frac{1}{2}} \nabla w_h\|_{\mathcal{K}}^2.$$

Moreover, integrating by parts and using the properties of w_h , it follows that

$$\begin{aligned} \|\sigma^{\frac{1}{2}}\nabla w_h\|_{\mathcal{K}}^2 &= -\underbrace{(\nabla \cdot \sigma \nabla w_h, w_h)_{\mathcal{K}}}_{=0} + \underbrace{(\{\sigma \nabla w_h\}, [w_h])_{\mathcal{F}}}_{=0} + \underbrace{([\sigma \nabla w_h], \{w_h\})_{\mathcal{F}_i}}_{=0} \\ &= -s(\omega \tilde{h}_{\mathcal{F}}^{-1} \overline{[u_h]}, [w_h])_{\mathcal{F}} \leq \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_h]}\|_{\mathcal{F}} \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} [w_h]\|_{\mathcal{F}} \end{aligned}$$

since $\{\sigma \nabla w_h\}|_{F \cdot n_F}$ and $[\sigma \nabla w_h]|_F$ are constant along each face $F \in \mathcal{F}$; see Lemma 3.4. Applying further (7.7) proves (7.4):

$$\|\sigma^{\frac{1}{2}}\nabla w_h\|_{\mathcal{K}} \leq c \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_h]}\|_{\mathcal{F}}.$$

Since we consider a square linear system, existence and uniqueness of a solution of the linear system are equivalent. Uniqueness follows by the a priori estimate. \square

COROLLARY 7.2. *Let $u_h \in V_h^b$ be a fixed function. Then there exists a unique $y_h \in V_h^b$ such that*

$$\begin{aligned} \int_{\kappa} y_h \, dx &= \int_{\kappa} (f - \nabla \cdot \sigma \nabla u_h) \, dx && \forall \kappa \in \mathcal{K}, \\ \{\sigma \nabla y_h\}|_{F \cdot n_F} &= -s\omega h_F^{-1} \overline{[u_h]}|_{F \cdot n_F} && \forall F \in \mathcal{F}, \\ \overline{\{y_h\}}|_F &= [\sigma \nabla u_h]|_F && \forall F \in \mathcal{F}_i. \end{aligned}$$

Proof. Since the matrix associated to the above defined projection w_h has zero kernel, y_h exists and is unique. \square

7.2. Stability. Although we do not explicitly penalize the solution jumps, control of the solution jumps in the energy-norm is recovered by an inf-sup argument as shown in this section.

THEOREM 7.3 (discrete inf-sup condition). *There exists a constant $c > 0$ independent of h such that for all $u_h \in V_h^b$ there holds*

$$c \| \|u_h\| \| \leq \sup_{v_h \in V_h^b} \frac{a_s(u_h, v_h)}{\| \|v_h\| \|}$$

for $s \in \{-1, 1\}$.

Proof. Let us prove this theorem in four steps.

Step 1. First, we take $v_h = u_h$ in a standard fashion

$$(7.8) \quad a_s(u_h, u_h) = \|\sigma^{\frac{1}{2}}\nabla u_h\|_{\mathcal{K}}^2 - (1+s)(\{\sigma \nabla u_h\}, \overline{[u_h]})_{\mathcal{F}}$$

since $\{\sigma \nabla u_h\}|_{F \cdot n_F}$ is constant along each face $F \in \mathcal{F}$. Applying a trace inequality and the inverse inequality for the second term of the right-hand side of (7.8) followed by an arithmetic-geometric inequality, there exists a constant $c_u > 0$ independent on the mesh size h such that

$$(7.9) \quad a_s(u_h, u_h) \geq \frac{1}{2} \|\sigma^{\frac{1}{2}}\nabla u_h\|_{\mathcal{K}}^2 - c_u(1+s)^2 \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_h]}\|_{\mathcal{F}}^2.$$

Step 2. Second, by Lemma 7.1 there exists $w_h \in V_h^b$ such that

1. $\int_{\kappa} w_h \, dx = 0 \forall \kappa \in \mathcal{K}$,
2. $\{\sigma \nabla w_h\} \cdot n_F = -s\omega h_F^{-1} \overline{[u_h]} \cdot n_F$ on each face $F \in \mathcal{F}$,

3. $\int_F \{w_h\} = 0$ on each face $F \in \mathcal{F}_i$.

An immediate consequence is that

$$\begin{aligned} a_s(u_h, w_h) &= -(\nabla \cdot \sigma \nabla u_h, w_h)_{\mathcal{K}} + ([\sigma \nabla u_h], \{w_h\})_{\mathcal{F}_i} - s(\{\sigma \nabla w_h\}, [u_h])_{\mathcal{F}} \\ (7.10) \quad &= \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_h]}\|_{\mathcal{F}}^2. \end{aligned}$$

Step 3. Combining the results (7.9) and (7.10), we may take

$$v_h = u_h + \left(\frac{1}{2} + c_u(1 + s)^2\right)w_h$$

to obtain

$$a_s(u_h, v_h) \leq \frac{1}{2} (\|\sigma^{\frac{1}{2}} \nabla u_h\|_{\mathcal{K}}^2 + \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_h]}\|_{\mathcal{F}}^2) \leq c \|u_h\|^2$$

by Lemma 4.1.

Step 4. To conclude, it remains to show that there exists $c > 0$ independent of h such that

$$\|v_h\| \leq c \|u_h\|.$$

This follows by straightforward estimation,

$$\|v_h\| = \|u_h + cw_h\| \leq \|u_h\| + c \|w_h\|.$$

Consider the second term of the right-hand side,

$$\|w_h\|^2 = \|\sigma^{\frac{1}{2}} \nabla w_h\|_{\mathcal{K}}^2 + \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} [w_h]\|_{\mathcal{F}}^2 = I_1 + I_2.$$

It follows by (7.4) that

$$I_1 \leq c \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_h]}\|_{\mathcal{F}}^2 \leq c \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} [u_h]\|_{\mathcal{F}}^2,$$

and by the trace inequality, the strong Poincaré inequality (7.6), and by (7.4) that

$$I_2 \leq c \|\sigma^{\frac{1}{2}} \tilde{h}^{-1} w_h\|_{\mathcal{K}}^2 \leq c \|\sigma^{\frac{1}{2}} \nabla w_h\|_{\mathcal{K}}^2 \leq c \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_h]}\|_{\mathcal{F}}^2 \leq c \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} [u_h]\|_{\mathcal{F}}^2. \quad \square$$

7.3. Convergence. Using the previously derived inf-sup condition optimal convergence is proved in a standard fashion.

THEOREM 7.4. *Let $u \in H^2(\Omega)$ be the solution of (2.1) and u_h^b the solution of (5.3). Then there holds*

$$\|u - u_h^b\| \leq ch \|u\|_{2, \mathcal{K}}.$$

Proof. First, note that for the bilinear form $a_s(\cdot, \cdot)$ the following continuity holds for all $v \in H^1(\Omega)$, $v_c \in V^C$, and $v_h \in V_h^b$ by Cauchy–Schwarz and trace inequalities

$$(7.11) \quad a_s(v - v_c, v_h) \leq \|v - v_c\|_c \|v_h\|.$$

1. Decompose the error in a weakly continuous and a discrete part

$$\|u - u_h^b\| \leq \|u - i_c u\| + \|i_c u - u_h^b\|.$$

Recall that i_c denotes the Crouzeix–Raviart interpolant onto V^C and observe that the convergence of the continuous part follows by Lemma 6.1.

2. Use the inf-sup condition on the discrete part and the consistency of the bilinear form (Lemma 5.2)

$$c \|i_c u - u_h^b\| \leq \sup_{v_h \in V_h^b} \frac{a_s(i_c u - u_h^b, v_h)}{\|v_h\|} \leq \sup_{v_h \in V_h^b} \frac{a_s(i_c u - u, v_h)}{\|v_h\|}.$$

3. Conclude by applying the continuity (7.11) and the approximation result of Lemma 6.1 that

$$\|u - u_h^1\| \leq ch \|u\|_{2, \mathcal{K}}.$$

Finally, using Lemma 4.1 and Corollary 4.2 proves the result. \square

The following optimal L^2 -convergence for the symmetric version may readily be proved for the symmetric version of the BSDG-method thanks to the adjoint consistency.

THEOREM 7.5. *Let $u \in H^2(\Omega)$ with $\|u\|_{2, \mathcal{K}} \leq c \|f\|_{\mathcal{K}}$ be the solution of (2.1) and u_h^b the solution of (5.3) with $s = 1$, then there holds*

$$\|u - u_h^b\|_{\mathcal{K}} \leq c h^2 \|u\|_{2, \mathcal{K}}.$$

Additionally, this method has some interesting properties as pointed out in the following remark.

Remark 7.6. Let $u_h^b \in V_h^b$ be the solution of (5.3). If the right-hand side f is elementwise constant, then there holds

$$\|\nabla \cdot \sigma \nabla u_h^b - f\|_{\mathcal{K}}^2 + \|[\sigma \nabla u_h^b]\|_{\mathcal{F}_i}^2 + \|\omega^{\frac{1}{2}} \tilde{h}_{\mathcal{F}}^{-\frac{1}{2}} \overline{[u_h^b]}\|_{\mathcal{F}}^2 = 0.$$

Indeed, choosing the function y_h defined in Corollary 7.2 in (5.3) and applying an integration by parts leads to the result. As a consequence, since the flux $\sigma \nabla u_h^b$ is continuous across faces, the solution u_h^b satisfies the following local mass conservation property:

$$-\int_{\partial \kappa} \sigma \nabla u_h^b \cdot n_{\kappa} ds = \int_{\kappa} f dx.$$

7.4. Numerical tests. We consider the same three test problems as in section 6.3.1 and give the convergence rates for those test problems. Note that in the case of the BSDG-method the local mass conservation property is satisfied independently of the stabilization parameter. We get optimal convergence of the error in the L^2 - and energy-norms, and similar convergence curves as for the SIPG- and NIPG-methods for the case of smooth exact solution (Figure 7). When the solution presents a singularity (Figure 8) we once again observe a larger constant for the BSDG-method than for the SIPG-method, in particular in the L^2 -norm. For the test problem (ii) we compare the error of the jumps of the solution of the RIP-method using various stabilization parameters and the same error of BSDG-method (Figure 9). As predicted by Theorem 7.4 the solution of BSDG-method shows optimal convergence also in this case. Hence the checkerboard mode is not present in the solution.

8. Conclusion. In this paper we discussed low order discontinuous Galerkin methods for second order scalar elliptic problems in two and three space dimensions. The main results are given in the following points.

FIG. 7. L^2 -error (a) and energy-error (b) for h -refinement for the test problem (ii) with smooth solution. For the SIPG- and NIPG-methods a stabilization parameter of $\gamma = 10$, respectively, $\gamma = 1$ is chosen.

FIG. 8. L^2 -error (a) and energy-error (b) for h -refinement for the test problem (i) with irregular solution. For the SIPG- and NIPG-methods a stabilization parameter of $\gamma = 10$, respectively, $\gamma = 1$ is chosen.

(i) Midpoint imposition of Dirichlet boundary conditions is sufficient to assure existence of a discrete solution for the symmetric DG-formulation using piecewise affine approximation (no interior stabilization is needed).

(ii) The symmetric version of RIP-method without stabilization has optimal convergence in the energy-norm and in the L^2 -norm provided the meshes and data are sufficiently regular or satisfy the macroelement property of Proposition 4.5.

(iii) For irregular data and general meshes a checkerboard mode destroys convergence for the unstabilized DG-method when using piecewise affine approximations.

(iv) Enriching the space with nonconforming quadratic bubbles leads to a DG-method where the symmetric and nonsymmetric versions are stable without stabilization and optimally convergent in the energy-norm. Moreover, the methods are locally

(a) $\|\tilde{h}^{-\frac{1}{2}}[u_h]\|_{\mathcal{F}}$

FIG. 9. Error of the jumps $\|\tilde{h}^{-\frac{1}{2}}[u_h]\|_{\mathcal{F}}$ of the BSDG-method compared to the RIP-method for h -refinement and the test problem (ii).

mass conservative independently of the penalty parameter.

(v) The symmetric DG-method on the enriched space has additionally optimal convergence in the L^2 -norm.

The aim of this work was to construct a symmetric DG-method that enjoys optimal convergence and local mass conservation independently of the penalty parameter. This goal has been realized in the framework of low order approximation in the symmetric version of the BSDG-method (see (5.3)) or, in the symmetric version of the RIP-method with $\gamma = 0$ on meshes having the macroelement property of Lemma 4.5.

Acknowledgments. The authors thank the anonymous reviewers for their comments that helped improve this manuscript.

CONVERGENCE ANALYSIS OF AN ADAPTIVE INTERIOR PENALTY DISCONTINUOUS GALERKIN METHOD*

R. H. W. HOPPE[†], G. KANSCHAT[‡], AND T. WARBURTON[§]

Abstract. We study the convergence of an adaptive interior penalty discontinuous Galerkin (IPDG) method for a two-dimensional model second order elliptic boundary value problem. Based on a residual-type a posteriori error estimator, we prove that after each refinement step of the adaptive scheme we achieve a guaranteed reduction of the global discretization error in the mesh-dependent energy norm associated with the IPDG method. In contrast to recent work on adaptive IPDG methods [O. Karakashian and F. Pascal, *Convergence of Adaptive Discontinuous Galerkin Approximations of Second-order Elliptic Problems*, preprint, University of Tennessee, Knoxville, TN, 2007], the convergence analysis does not require multiple interior nodes for refined elements of the triangulation. In fact, it will be shown that bisection of the elements is sufficient. The main ingredients of the proof of the error reduction property are the reliability and a perturbed discrete local efficiency of the estimator, a bulk criterion that takes care of a proper selection of edges and elements for refinement, and a perturbed Galerkin orthogonality property with respect to the energy inner product. The results of numerical experiments are given to illustrate the performance of the adaptive method.

Key words. discontinuous Galerkin, adaptive methods, interior penalty, error estimates

1. Introduction. During the past decade, discontinuous Galerkin (DG) methods have emerged as a powerful algorithmic tool in the numerical solution of boundary and initial boundary value problems for partial differential equations (PDE) (cf., e.g., [15, 17] and the references therein). For second order elliptic problems, one may distinguish between primal schemes and mixed methods. Primal schemes rely on augmenting the elliptic operator by an appropriate penalization of the discontinuous nodal shape functions. On the other hand, in mixed methods the second order PDE is reformulated as a system of first order PDEs for which suitable numerical fluxes are designed. The most prominent primal schemes are interior penalty discontinuous Galerkin (IPDG) methods, whereas a widely used class of mixed techniques is given by the local discontinuous Galerkin (LDG) methods. Both IPDG and LDG methods have been intensively studied with regard to an a priori error analysis in terms of error estimates for the global discretization error (see, e.g., [2, 3, 12, 26]).

The a posteriori analysis of finite element methods (FEM) is in some state of maturity, as documented by a series of monographs that have been published in recent years [1, 4, 6, 19, 32, 37]. As far as DG methods are concerned, a posteriori error estimators have been developed and analyzed for elliptic problems in H^1 in [7, 25, 27, 33, 34], for elliptic problems in $H(\text{curl})$ in [22, 23], and for the Stokes problem in [24].

In this paper, we will be concerned with a convergence analysis of an adaptive IPDG method in the sense that for a two-dimensional (2D) second order elliptic model problem we will prove guaranteed error reduction with respect to the mesh-dependent energy norm. We note that for standard conforming P1 approximations of elliptic problems the convergence analysis of adaptive finite element methods (AFEM) has been initiated in [5] and further studied in [18, 29, 30, 31], whereas the issue of optimal order of convergence has been addressed in [8] and [36]. Nonstandard finite element techniques such as mixed and nonconforming methods and edge element discretizations of Maxwell’s equations have been recently investigated in [9, 10, 11]. In the recent paper [28], a convergence analysis of symmetric IPDG methods has been provided. In contrast to [28], our analysis does not require multiple interior nodes for refined elements of the triangulation. In fact, we show that it suffices to refine by bisection.

The paper is organized as follows: In section 2, we briefly introduce the IPDG method. Section 3 describes the adaptive loop consisting of the basic steps SOLVE, ESTIMATE, MARK, and REFINE and states the main convergence result. Section 4 recalls the reliability of the estimator from [27] and establishes a perturbed discrete local efficiency, whereas section 5 is devoted to the proof of the error reduction property. Finally, section 6 contains a documentation of the results of numerical experiments that illustrate the performance of the adaptive IPDG (AIPDG).

2. The IPDG method. We assume $\Omega \subset \mathbb{R}^2$ to be a bounded, polygonal domain with boundary $\Gamma = \partial\Omega, \Gamma = \Gamma_D \cup \Gamma_N, \Gamma_D \cap \Gamma_N = \emptyset$. We adopt standard notation from Sobolev space theory and refer to $(\cdot, \cdot)_{k,D}$ and $\|\cdot\|_{k,D}, k \in \mathbb{N}_0, D \subseteq \Omega$, as the $H^k(D)$ -inner product and associated norm, respectively.

As a model problem, for given $f \in L^2(\Omega), u^D \in H^{1/2}(\Gamma_D), u^N \in L^2(\Gamma_N)$, we consider Poisson’s equation with inhomogeneous Dirichlet and Neumann boundary data

$$\begin{aligned} (2.1a) \quad & -\Delta u = f \quad \text{in } \Omega, \\ (2.1b) \quad & u = u^D \quad \text{on } \Gamma_D, \\ (2.1c) \quad & \partial_{n_{\Gamma_N}} u = u^N \quad \text{on } \Gamma_N, \end{aligned}$$

whose variational formulation amounts to the computation of a solution $u \in V := \{v \in H^1(\Omega) \mid v|_{\Gamma_D} = u^D\}$ such that

$$(2.2) \quad a(u, v) = (f, v)_\Omega + \langle u^N, v \rangle_{\Gamma_N}, \quad v \in H_{0,\Gamma_D}^1(\Omega),$$

where $a(u, v) := \int_\Omega \nabla u \cdot \nabla v dx$.

For the DG approximation of (2.2), we further assume that $\mathcal{T}_H(\Omega)$ is a simplicial triangulation of Ω which aligns with Γ_D, Γ_N on the boundary Γ . For $D \subseteq \bar{\Omega}$, we denote by $|D|$ the volume of D and by $\Pi_p(D), p \in \mathbb{N}_0$, the linear space of polynomials of degree p on D , and we refer to $\mathcal{N}_H(D), \mathcal{E}_H(D)$, and $\mathcal{T}_H(D)$ as the sets of vertices, edges, and elements, respectively, in D . For $T \in \mathcal{T}_H(\Omega)$, h_T stands for the diameter of T , whereas for $E \in \mathcal{E}_H(\bar{\Omega})$, we denote by h_E the length of E . Moreover, for an interior edge $E \in \mathcal{E}_H(\Omega)$ such that $E = T_+ \cap T_-, T_\pm \in \mathcal{T}_H(\Omega)$, we refer to $\omega_E := T_+ \cup T_-$ as the patch formed by the union of the elements sharing E as a common edge. Finally, for a function $g \in L^2(D), D \subset \bar{\Omega}$, the quantity \hat{g}_D stands for the integral mean of g with respect to D , i.e., $\hat{g}_D := |D|^{-1} \int_D g dx$.

We define the product space $V_H := \prod_{T \in \mathcal{T}_H(\Omega)} \Pi_p(T)$, $p \in \mathbb{N}$, and introduce the bilinear form $a_H(\cdot, \cdot) : V_H \times V_H \rightarrow \mathbb{R}$ according to

$$(2.3) \quad a_H(u_H, v_H) := \sum_{T \in \mathcal{T}_H(\Omega)} (\nabla u_H, \nabla v_H)_T \\ - \sum_{E \in \mathcal{E}_H(\bar{\Omega})} \left((\{\partial_{n_E} u_H\}, [v_H])_E + ([u_H]_E, \{\partial_{n_E} v_H\})_E \right) \\ + \alpha \sum_{E \in \mathcal{E}_H(\bar{\Omega})} h_E^{-1} ([u_H]_E, [v_H]_E)_E,$$

where the normal vector on E points from T_+ to T_- and with $v_H^\pm := v_H|_{T_\pm}$ on E ,

$$\begin{aligned} [v_H]_E &:= v_H^+ - v_H^-, & E \in \mathcal{E}_H(\Omega), \\ [v_H]_E &:= v_H|_E, & E \in \mathcal{E}_H(\Gamma), \\ \{v_H\}_E &:= \frac{1}{2} (v_H^+ + v_H^-), & E \in \mathcal{E}_H(\Omega), \\ \{v_H\}_E &:= v_H|_E, & E \in \mathcal{E}_H(\Gamma), \end{aligned}$$

and $\alpha > 0$ stands for a properly chosen penalization parameter.

Then, the interior penalty method in its symmetric formulation amounts to the computation of $u_H \in V_H$ such that

$$(2.4) \quad a_H(u_H, v_H) = \ell(v_H), \quad v_H \in V_H,$$

where

$$(2.5) \quad \ell(v_H) := (f, v_H)_\Omega + (u^N, v_H)_{\Gamma_N} - \sum_{E \subset \Gamma_D} (u^D, \partial_n v_H - \alpha h_E^{-1} v_H)_E.$$

On V_H , we introduce the mesh-dependent H^1 -norm

$$(2.6) \quad \|v_H\|_{1,H,\Omega} := \left(\sum_{T \in \mathcal{T}_H(\Omega)} \|\nabla v_H\|_T^2 + \sum_{E \in \mathcal{E}_H(\bar{\Omega})} (h_E \|\{\partial_{n_E} v_H\}\|_E^2 + h_E^{-1} \|[v_H]\|_E^2) \right)^{1/2}.$$

As has been shown in [27], the bilinear form $a_H(\cdot, \cdot)$ is bounded

$$(2.7) \quad |a_H(u_H, v_H)| \leq (1 + \alpha) \|u_H\|_{1,H,\Omega} \|v_H\|_{1,H,\Omega}, \quad u_H, v_H \in V_H,$$

and for sufficiently large α coercive with respect to the $\|\cdot\|_{1,H,\Omega}$ -norm, i.e., there exist positive constants α_{min} and γ such that for $\alpha \geq \alpha_{min}$

$$(2.8) \quad |a_H(v_H, v_H)| \geq \gamma \|v_H\|_{1,H,\Omega}^2, \quad v_H \in V_H.$$

It follows from (2.7) and (2.8) that for $\alpha \geq \alpha_{min}$ the IPDG (2.4) admits a unique

solution $u_H \in V_H$. Moreover, for such α the mesh-dependent energy norm

$$(2.9) \quad |||v_H|||_{H,\Omega} := a_H(v_H, v_H)^{1/2}, \quad v_H \in V_H,$$

is equivalent to the $\|\cdot\|_{1,H,\Omega}$ -norm

$$(2.10) \quad \gamma \|v_H\|_{1,H,\Omega}^2 \leq |||v_H|||_{H,\Omega}^2 \leq (1 + \alpha) \|v_H\|_{1,H,\Omega}^2, \quad v_H \in V_H.$$

For a subset $D_H \subset \mathcal{T}_H(\Omega)$ of the triangulation, $\|\cdot\|_{1,H,D_H}$ and $|||\cdot|||_{H,D_H}$ are defined analogously.

Remark 2.1. We have chosen the 2D model problem (2.1a)–(2.1c) to focus on the essential ingredients for the proof of the error reduction property and not to overload the convergence analysis with too many technicalities. Using the tools from [29], we think that the results can be extended to more general elliptic differential operators, thus including advection-diffusion problems. We further believe that the ideas presented in this paper can be also adopted to hybridized DG methods [16] where the number of degrees of freedom is comparable to standard finite element discretizations.

3. The adaptive loop and the main convergence result. An adaptive FEM for the IPDG (2.4) consists of successive loops of the following sequence:

$$(3.1) \quad \text{SOLVE} \rightarrow \text{ESTIMATE} \rightarrow \text{MARK} \rightarrow \text{REFINE}.$$

Here, SOLVE stands for the numerical solution of (2.4) with respect to the given triangulation $\mathcal{T}_H(\Omega)$. We remark that for this purpose efficient preconditioned iterative solvers have been developed, analyzed, and implemented (cf., e.g., [20, 21, 25]).

The following residual-type a posteriori error estimator η_H has been introduced and analyzed in [27]:

$$(3.2) \quad \eta_H^2 := \sum_{T \in \mathcal{T}_H(\Omega)} \eta_T^2 + \sum_{E \in \mathcal{E}_H(\Omega)} \eta_E^2.$$

Here, η_T stands for the element residual

$$(3.3) \quad \eta_T := h_T \|f + \Delta u_H\|_T, \quad T \in \mathcal{T}_H(\Omega).$$

On the other hand, η_E summarizes the edge residuals

$$(3.4) \quad \eta_E^2 := \eta_{E,1}^2 + \eta_{E,2}^2 + \eta_{E,N}^2 + \eta_{E,D}^2$$

given by

$$(3.5a) \quad \eta_{E,1} := h_E^{1/2} \|[\partial_{n_E} u_H]\|_E, \quad E \in \mathcal{E}_H(\Omega),$$

$$(3.5b) \quad \eta_{E,2} := h_E^{-1/2} \|[u_H]\|_E, \quad E \in \mathcal{E}_H(\Omega),$$

$$(3.5c) \quad \eta_{E,N} := h_E^{1/2} \|u^N - \partial_{n_E} u_H\|_E, \quad E \in \mathcal{E}_H(\Gamma_N),$$

$$(3.5d) \quad \eta_{E,D} := h_E^{-1/2} \|u^D - u_H\|_E, \quad E \in \mathcal{E}_H(\Gamma_D).$$

The convergence analysis further invokes the data oscillations

$$(3.6) \quad \text{osc}_H^2 := \text{osc}_H^2(f) + \text{osc}_H^2(u^D) + \text{osc}_H^2(u^N),$$

where

$$(3.7a) \quad \text{osc}_H^2(f) := \sum_{T \in \mathcal{T}_H(\Omega)} \text{osc}_T^2(f),$$

$$\text{osc}_T(f) := h_T \|f - \hat{f}_T\|_T,$$

$$(3.7b) \quad \text{osc}_H^2(u^D) := \sum_{E \in \mathcal{E}_H(\Gamma_D)} \text{osc}_E^2(u^D),$$

$$\text{osc}_E(u^D) := h_E^{-1/2} \|u^D - \hat{u}_E^D\|_E,$$

$$(3.7c) \quad \text{osc}_H^2(u^N) := \sum_{E \in \mathcal{E}_H(\Gamma_N)} \text{osc}_E^2(u^N),$$

$$\text{osc}_E(u^N) := h_E^{1/2} \|u^N - \hat{u}_E^N\|_E.$$

In the step MARK of the adaptive loop, given a universal constant $0 < \Theta \leq 1$, we choose subsets $\mathcal{M}_T \subset \mathcal{T}_H(\Omega)$ and $\mathcal{M}_E \subset \mathcal{M}_H(\bar{\Omega})$ such that the following bulk criterion is satisfied:

$$(3.8a) \quad \Theta \sum_{T \in \mathcal{T}_H(\Omega)} \eta_T^2 \leq \sum_{T \in \mathcal{M}_T} \eta_T^2,$$

$$(3.8b) \quad \Theta \sum_{E \in \mathcal{E}_H(\bar{\Omega})} \eta_E^2 \leq \sum_{E \in \mathcal{M}_E} \eta_E^2.$$

The bulk criterion can be realized by a greedy algorithm.

As far as the data oscillations are concerned, for simplicity we assume that the set \mathcal{M}_T selected by (3.8a) is already rich enough such that there exists a constant $0 \leq \rho_2 < 1$ such that

$$(3.9) \quad \text{osc}_h^2 \leq \rho_2 \text{osc}_H^2.$$

We note that the data oscillations may be included in the bulk criterion as well to guarantee (3.9). We refer to [30, 31] for details.

The refinement strategy in the final step REFINE of the adaptive loop is as follows: If an element $T \in \mathcal{T}_H(\Omega)$ has been marked for refinement, it will be refined by longest edge bisection. If an edge $E \in \mathcal{E}_H(\Omega)$, $E = T^+ \cap T^-$ (resp., $E \in \mathcal{T}_H(\Gamma)$, $E = \partial T \cap \Gamma$) has been marked, the triangles T^\pm (resp., the triangle T) will be refined by bisection. We note that this refinement is different from that used in [28] where the refinement of a triangle requires multiple interior nodes based on subsequent regular refinements.

The main result of this paper is a guaranteed error reduction of the global discretization error measured in the mesh-dependent energy norm associated with the IPDG method.

THEOREM 3.1. *Let $u \in V$ be the solution of (2.2), and suppose that $u_H \in V_H$ and $u_h \in V_h$ are the solutions of IPDG (2.4) with respect to the triangulation $\mathcal{T}_H(\Omega)$ and the adaptively refined triangulation $\mathcal{T}_h(\Omega)$ generated according to the refinement rules described before. Assume that (3.9) holds true. Then, for sufficiently large penalization parameter α there exist positive constants $\rho_1 < 1$ and C which depend*

only on α, Θ and the shape regularity of the triangulations such that for $e_H := u - u_H$ and $e_h := u - u_h$ there holds

$$(3.10) \quad \begin{pmatrix} a_h(e_h, e_h) \\ \text{osc}_h^2 \end{pmatrix} \leq \begin{pmatrix} \rho_1 & C \\ 0 & \rho_2 \end{pmatrix} \begin{pmatrix} a_H(e_H, e_H) \\ \text{osc}_H^2 \end{pmatrix}.$$

The proof of Theorem 3.1 will be given in section 5 based on the reliability and a perturbed discrete local efficiency of the estimator (3.2), which will be studied in the following section.

4. Reliability and perturbed discrete local efficiency. The reliability of the residual-type a posteriori error estimator (3.2) has been established in [27] using standard techniques from AFEM [37]. Here, we prove that it is also locally efficient in a relaxed way. We will derive the main lemmas for the case of the newest edge bisection [13, 14, 35].

THEOREM 4.1. *Let $u \in V$ and $u_H \in V_H$ be the solution of (2.2) and its IPDG approximation (2.4), and let η_H and osc_H be the residual error estimator and the data oscillations as given by (3.2) and (3.6), respectively. Then, for $e_H := u - u_H$ there holds*

$$(4.1) \quad a_H(e_H, e_H) \lesssim \eta_H^2.$$

Discrete local efficiency means that up to data oscillations the local contributions of the estimator can be bounded from above by the energy norm of the difference between the fine mesh and coarse mesh approximations on a refined triangle and the patch ω_E associated with a refined edge, respectively [18, 30]. In the framework of the IPDG approximations under consideration, we can prove only a perturbed discrete local efficiency in the sense that the upper bounds involve additional quantities in terms of the fine mesh approximation. In particular, the following result holds true.

THEOREM 4.2. *Let $u \in V$ and $u_H \in V_H, u_h \in V_h$, be the solution of (2.2) and its IPDG approximations (2.4) with respect to $\mathcal{T}_H(\Omega)$ and $\mathcal{T}_h(\Omega)$, respectively. Moreover, let η_H and osc_H be the residual error estimator (3.2) and the data oscillations (3.6), respectively. Then, there holds*

$$(4.2) \quad \begin{aligned} \sum_{T \in \mathcal{M}_T} \eta_T^2 + \sum_{E \in \mathcal{M}_E} \eta_E^2 &\lesssim a_h(u_h - u_H, u_h - u_H) \\ &+ \alpha \sum_{E' \in \mathcal{E}_h(\mathcal{M}_E \setminus \Gamma_D)} h_{E'}^{-1} \| [u_h] \|_{E'}^2 \\ &+ \alpha \sum_{E' \in \mathcal{E}_h(\mathcal{M}_E \cap \Gamma_D)} h_{E'}^{-1} \| u^D - u_h \|_{E'}^2 + \text{osc}_H^2. \end{aligned}$$

Proof. The proof of (4.2) follows by collecting the estimates from the subsequent series of lemmas. \square

LEMMA 4.3. *Let $T \in \mathcal{T}_H(\Omega)$ be a refined triangle such that $T = T_+ \cup T_-, T_{\pm} \in \mathcal{T}_h(\Omega)$. Then, there holds*

$$(4.3) \quad \begin{aligned} h_T^2 \| f + \Delta u_H \|_T^2 &\lesssim a_h|_T(u_h - u_H, u_h - u_H) + \text{osc}_T^2(f) \\ &+ \alpha \sum_{E \in \mathcal{E}_H(\partial T \cap \Omega)} \eta_{E,2}^2 + \alpha \sum_{E \in \mathcal{E}_H(\partial T \cap \Gamma_D)} \eta_{E,D}^2 + \sum_{E \in \mathcal{E}_H(\partial T \cap \Gamma_N)} \text{osc}_E^2(u^N). \end{aligned}$$

Proof. We denote by $CR_p(\Omega; \mathcal{T}_h(\Omega))$, $p \in \mathbb{N}$, the nonconforming Crouzeix–Raviart finite element space, where $v_h|_{T'} \in \Pi_p(T')$, $T' \in \mathcal{T}_h(\Omega)$, is uniquely determined by the degrees of freedom

$$\begin{aligned} \int_E v_h q_E ds, \quad q_E \in \Pi_{p-1}(E), \quad E \in \mathcal{E}_h(T'), \\ \int_T v_h q_{T'} dx, \quad q_{T'} \in \Pi_{p-3}(T') \quad (p \geq 3). \end{aligned}$$

We choose $\varphi_h \in V_h$ with $\varphi_h|_{T_\pm} \in \Pi_p(T_\pm)$ and $\varphi_h|_{T'} \equiv 0$, $T' \in \mathcal{T}_h(\Omega) \setminus \{T\}$, such that

$$(4.4a) \quad h_{T_\pm}^2 \left\| \hat{f}_T + \Delta u_H \right\|_{T_\pm}^2 = \left(\hat{f}_T + \Delta u_H, \varphi_h \right)_{T_\pm},$$

$$(4.4b) \quad \|\varphi_h\|_{T_\pm}^2 \lesssim h_{T_\pm}^4 \left\| \hat{f}_T + \Delta u_H \right\|_{T_\pm}^2,$$

$$(4.4c) \quad (q_h, \varphi_h)_E = 0, \quad q_h \in \Pi_{p-1}(E), \quad E \in \mathcal{E}_h(\partial T).$$

In particular, in the case $p \leq 2$ we choose φ_h as a linear combination of the basis functions associated with the interior edge $E \in \mathcal{E}_h(\text{int}(T))$, whereas for $p \geq 3$ we choose φ_h as a linear combination of the basis functions associated with $\text{int}(T_\pm)$. Using (4.4a), Green’s formula, and setting $T_1 := T_+$, $T_2 := T_-$, we obtain

$$(4.5) \quad h_T^2 \left\| \hat{f}_T + \Delta u_H \right\|_T^2 = \sum_{i=1}^2 \left(\hat{f}_T + \Delta u_H, \varphi_h \right)_{T_i} \\ = \sum_{i=1}^2 \left(-(\nabla u_H, \nabla \varphi_h)_{T_i} + (f, \varphi_h)_{T_i} + \left(\hat{f}_T - f, \varphi_h \right)_{T_i} \right),$$

where we have used that due to (4.4c) for $T \in \mathcal{T}_H$ there holds

$$(4.6a) \quad (\partial_{n_E} u_H, \varphi_h)_E = 0, \quad E \in \mathcal{E}_h(\partial T), \quad p \geq 1,$$

$$(4.6b) \quad (\partial_{n_E} u_H, [\varphi_h])_E = 0, \quad E \in \mathcal{E}_h(\text{int}(T)), \quad p \geq 1.$$

On the other hand, φ_h is an admissible test function in the fine grid equation (2.4) whence

$$(4.7) \quad \sum_{i=1}^2 \left((\nabla u_h, \nabla \varphi_h)_{T_i} - (f, \varphi_h)_{T_i} \right) \\ + \sum_{E \in \mathcal{E}_h(\partial T \cap \Gamma_D)} (u^D, \partial_{n_E} \varphi_h - \alpha h_E^{-1} \varphi_h)_E \\ - \sum_{E \in \mathcal{E}_h(\partial T \cap \Gamma_N)} (u^N, \varphi_h)_E \\ - \sum_{E \in \mathcal{E}_h(T)} \left((\{\partial_{n_E} u_h\}, [\varphi_h])_E + ([u_h], \{\partial_{n_E} \varphi_h\})_E \right) \\ + \alpha \sum_{E \in \mathcal{E}_h(T)} h_E^{-1} ([u_h], [\varphi_h])_E = 0.$$

Adding (4.5) and (4.7) and observing again (4.6a)–(4.6b) as well as $[u_H] = 0$ on $E \in \mathcal{E}_h(\text{int}(T))$, it follows that

$$\begin{aligned}
 (4.8) \quad & h_T^2 \left\| \hat{f}_T + \Delta u_H \right\|_T^2 \\
 &= \sum_{i=1}^2 \left((\nabla(u_h - u_H), \nabla \varphi_h)_{T_i} + \left(\hat{f}_T - f, \varphi_h \right)_{T_i} \right) \\
 &\quad - \sum_{E \in \mathcal{E}_h(T)} \left((\{\partial_{n_E}(u_h - u_H)\}, [\varphi_h])_E \right. \\
 &\quad \quad \left. + ([u_h - u_H], \{\partial_{n_E} \varphi_h\})_E \right) \\
 &\quad - \sum_{E \in \mathcal{E}_h(\partial T \cap \Omega)} ([u_H], \{\partial_{n_E} \varphi_h\})_E \\
 &\quad + \sum_{E \in \mathcal{E}_h(\partial T \cap \Gamma_D)} (u^D - u_H, \partial_{n_E} \varphi_h - \alpha h_E^{-1} \varphi_h)_E \\
 &\quad - \sum_{E \in \mathcal{E}_h(\partial T \cap \Gamma_N)} (u^N - \hat{u}_E^N, \varphi_h)_E \\
 &\quad + \alpha \sum_{E \in \mathcal{E}_h(T)} h_E^{-1} ([u_h - u_H], [\varphi_h])_E \\
 &\quad + \alpha \sum_{E \in \mathcal{E}_h(\partial T \setminus \Gamma_D)} h_E^{-1} ([u_H], [\varphi_h])_E.
 \end{aligned}$$

In view of (4.4b), the inverse inequality and the trace inequalities imply that for $1 \leq i \leq 4$

$$(4.9a) \quad \|\nabla \varphi_h\|_{T_i}^2 \lesssim h_{T_i}^2 \|\hat{f}_T + \Delta u_H\|_{T_i}^2,$$

$$(4.9b) \quad \|\varphi_h\|_E^2 \lesssim h_E^3 \|\hat{f}_T + \Delta u_H\|_{T_i}^2, \quad E \in \mathcal{E}_h(\partial T_i),$$

$$(4.9c) \quad \|\{\partial_{n_E} \varphi_h\}\|_E^2 \lesssim h_E \|\hat{f}_T + \Delta u_H\|_{T_i}^2, \quad E \in \mathcal{E}_h(\partial T_i).$$

Then, using (4.4b) and (4.9a)–(4.9c), straightforward estimation of the terms on the right-hand side in (4.8) gives the assertion. \square

LEMMA 4.4. *Let $E \in \mathcal{E}_H(\Omega)$, $E = T_+ \cap E_-$, $T_\pm \in \mathcal{T}_H(\Omega)$, be a refined edge and $\omega_E := T_+ \cup T_-$. Then, there holds*

$$\begin{aligned}
 (4.10) \quad & h_E \|\{\partial_{n_E} u_H\}\|_E^2 \lesssim \sum_{T_\pm \in \mathcal{T}_H(\omega_E)} \eta_{T_\pm}^2 + \alpha \sum_{E' \in \mathcal{E}_H(\omega_E \cap \Omega)} \eta_{E',2}^2 \\
 & + \alpha \sum_{E \in \mathcal{E}_H(\partial \omega_E \cap \Gamma_D)} \eta_{E',D}^2 + \sum_{E \in \mathcal{E}_H(\partial \omega_E \cap \Gamma_N)} \text{osc}_{E'}^2(u^N).
 \end{aligned}$$

For a refined edge $E \in \mathcal{E}_H(\Gamma_N)$ with $E = \partial T \cap \Gamma_N$, $T \in \mathcal{T}_H(\Omega)$, we have

$$(4.11) \quad h_E \|u^N - \partial_{n_E} u_H\|_E^2 \lesssim \eta_T^2 + \alpha \sum_{E' \in \mathcal{E}_H(T \cap \Omega)} \eta_{E',2}^2.$$

Proof. For the proof of (4.10) let us assume that $E = T_+ \cap T_-$, $T_\pm \in \mathcal{T}_H(\Omega)$. We choose $\varphi_H \in CR_p(\Omega; \mathcal{T}_H(\Omega))$ as a linear combination of the basis functions associated

with the edge E such that

$$(4.12a) \quad h_E \|[\partial_{n_E} u_H]\|_E^2 = ([\partial_{n_E} u_H], \varphi_H)_E,$$

$$(4.12b) \quad \|\varphi_H\|_{T_\pm} \lesssim h_E^{3/2} \|[\partial_{n_E} u_H]\|_E,$$

$$(4.12c) \quad (q_{E'}, \varphi_H)_{E'} = 0, \quad q_{E'} \in \Pi_{p-1}(E')$$

for any edge E' . Using the definition of $\partial_{n_E} u_H$, it follows that

$$(4.13) \quad \begin{aligned} & ([\partial_{n_E} u_H], \varphi_H)_E \\ &= (\nu_E^+ \cdot \nabla u_H^+, \varphi_H)_E + (\nu_E^- \cdot \nabla u_H^-, \varphi_H)_E. \end{aligned}$$

By Green's formula, we find

$$(4.14) \quad \begin{aligned} & (\nabla u_H, \nabla \varphi_H)_{T_\pm} \\ &= -(\Delta u_H, \varphi_H)_{T_\pm} + \sum_{E' \in \mathcal{E}_H(\partial T_\pm)} (\partial_{n_{E'}} u_H, \varphi_H)_{E'}. \end{aligned}$$

By (4.12c) we have

$$(4.15) \quad (\partial_{n_{E'}} u_H, \varphi_H)_{E'} = 0, \quad E' \in \mathcal{E}_H(\partial \omega_E),$$

whence

$$(4.16) \quad \begin{aligned} & h_E \|[\partial_{n_E} u_H]\|_E^2 \\ &= ([\partial_{n_E} u_H], \varphi_H)_E = (\nabla u_H, \nabla \varphi_H)_{\omega_E} + (\Delta u_H, \varphi_H)_{\omega_E}. \end{aligned}$$

On the other hand, since φ_H is an admissible test function in (2.4), we have

$$(4.17) \quad \begin{aligned} & (\nabla u_H, \nabla \varphi_H)_{\omega_E} = (f, \varphi_H)_{\omega_E} + \sum_{E' \in \mathcal{E}_H(\partial \omega_E \cap \Gamma_N)} (u^N, \varphi_H)_{E'} \\ & - \sum_{E' \in \mathcal{E}_H(\partial \omega_E \cap \Gamma_D)} (u^D, \partial_{n_{E'}} \varphi_H - \alpha h_{E'}^{-1} \varphi_H)_{E'} \\ & + \sum_{E' \in \mathcal{E}_H(\omega_E)} ([u_H], \{\partial_{n_{E'}} \varphi_H\})_{E'} - \alpha \sum_{E' \in \mathcal{E}_H(\partial \omega_E)} h_{E'}^{-1} ([u_H], [\varphi_H])_{E'}, \end{aligned}$$

where we have used (4.15) and (4.12c) on E . Combining (4.16) and (4.17) results in

$$(4.18) \quad \begin{aligned} & h_E \|[\partial_{n_E} u_H]\|_E^2 = (f + \Delta u_H, \varphi_H)_{\omega_E} \\ & + \sum_{E' \in \mathcal{E}_H(\omega_E \setminus \Gamma_D)} ([u_H], \{\partial_{n_{E'}} \varphi_H\})_{E'} \\ & - \alpha \sum_{E' \in \mathcal{E}_H(\partial \omega_E \setminus \Gamma_D)} h_{E'}^{-1} ([u_H], [\varphi_H])_{E'} \\ & + \sum_{E' \in \mathcal{E}_H(\partial \omega_E \cap \Gamma_N)} (u^N - \hat{u}_{E'}^N, \varphi_H)_{E'} \\ & - \sum_{E' \in \mathcal{E}_H(\partial \omega_E \cap \Gamma_D)} (u^D - u_H, \partial_{n_{E'}} \varphi_H - \alpha h_{E'}^{-1} \varphi_H)_{E'}. \end{aligned}$$

Observing (4.12b), the trace inequalities yield

$$(4.19a) \quad \|\varphi_H\|_{E'} \lesssim h_E \|[\partial_{n_E} u_H]\|_E, \quad E' \in \mathcal{E}_H(\partial \omega_E),$$

$$(4.19b) \quad \|[\partial_{n_{E'}} \varphi_H]\|_{E'} \lesssim \|[\partial_{n_E} u_H]\|_E, \quad E' \in \mathcal{E}_H(\partial \omega_E).$$

Taking advantage of (4.12b), (4.19a), and (4.19b), the assertion can be deduced by straightforward estimation of the terms on the right-hand side in (4.18). The proof of (4.11) follows by similar arguments. \square

LEMMA 4.5. *Let $E \in \mathcal{E}_H(\Omega)$, $E = T_+ \cap T_-$, $T_\pm \in \mathcal{T}_H(\Omega)$, be a refined edge and $\omega_E := T_+ \cup T_-$. Then, there holds*

$$(4.20) \quad \alpha h_E^{-1} \|[u_H]|_E\|_E^2 \lesssim a_h|_{\omega_E}(u_h - u_H, u_h - u_H) + \alpha \sum_{E' \in \mathcal{E}_h(E)} h_{E'}^{-1} \|[u_h]|_{E'}^2.$$

Likewise, if $E \in \mathcal{E}_H(\Gamma_D)$ is a refined edge such that $E = \partial T \cap \Gamma_D$, $T \in \mathcal{T}_H(\Omega)$, there holds

$$(4.21) \quad \alpha h_E^{-1} \|u^D - u_H\|_E^2 \lesssim a_h|_T(u_h - u_H, u_h - u_H) + \alpha \sum_{E' \in \mathcal{E}_h(E)} h_{E'}^{-1} \|u^D - u_h\|_{E'}^2 + \text{osc}_E^2(u^D).$$

Proof. For the proof of (4.20), choose $\psi_H^\pm \in CR_p(\Omega; \mathcal{T}_H(\Omega))$ with $\text{supp}(\psi_H^\pm) = T_\pm$ as a linear combination of basis functions associated with E such that

$$(4.22a) \quad ([u_H], \psi_H^\pm)_E = \pm \frac{1}{2} \|[u_H]|_E\|_E^2,$$

$$(4.22b) \quad \|\psi_H^\pm\|_{T_\pm} \lesssim h_E^{1/2} \|[u_H]|_E\|_E.$$

We define $\varphi_H \in V_H$ by $\varphi_H|_{T_\pm} = \psi_H^\pm$ and $\varphi_H|_T \equiv 0$, $T \in \mathcal{T}_H(\Omega) \setminus \{\omega_E\}$. Then, it follows from (4.22a) that

$$(4.23) \quad \alpha h_E^{-1} \|[u_H]|_E\|_E^2 = \alpha h_E^{-1} ([u_H], [\varphi_H])_E.$$

Since φ_H is an admissible test function in (2.4), we have

$$(4.24) \quad \begin{aligned} & \alpha h_E^{-1} ([u_H], [\varphi_H])_E = \\ & - (\nabla u_H, \nabla \varphi_H)_{\omega_E} + (f, \varphi_H)_{\omega_E} \\ & + \sum_{E' \in \mathcal{E}_H(\partial \omega_E \cup \{E\})} (\{\partial_{n_{E'}} u_H\}, [\varphi_H])_{E'} \\ & + \sum_{E' \in \mathcal{E}_H(\partial \omega_E) \cup \{E\}} ([u_H], \{\partial_{n_{E'}} \varphi_H\})_{E'} \\ & - \alpha \sum_{E' \in \mathcal{E}_H(\partial \omega_E)} h_{E'}^{-1} ([u_H], [\varphi_H])_{E'} \\ & + \sum_{E' \in \mathcal{E}_H(\partial \omega_E \cap \Gamma_N)} (u^N, \varphi_H)_{E'} \\ & - \alpha \sum_{E' \in \mathcal{E}_H(\partial \omega_E \cap \Gamma_D)} (u^D, \partial_{n_{E'}} \varphi_H - \alpha h_{E'}^{-1} \varphi_H)_{E'}. \end{aligned}$$

On the other hand, $(\varphi_H|_{T'})_{T' \in \mathcal{T}_h(\Omega)}$ is an admissible test function in the fine grid

equation (2.4). Hence, observing $[\varphi_H] = 0$ and $[u_H] = 0$ on $E' \in \mathcal{E}_h(\text{int}(T_\pm))$, we get

$$\begin{aligned}
 (4.25) \quad 0 &= (\nabla u_h, \nabla \varphi_H)_{\omega_E} - (f, \varphi_H)_{\omega_E} \\
 &\quad - \sum_{E' \in \mathcal{E}_h(\partial\omega_E \cup \{E\})} (\{\partial_{n_{E'}} u_h\}, [\varphi_H])_{E'} \\
 &\quad - \sum_{E' \in \mathcal{E}_h(\partial\omega_E \cup \{E\})} ([u_h], \{\partial_{n_{E'}} \varphi_H\})_{E'} \\
 &\quad - \sum_{E' \in \mathcal{E}_h(\text{int}(\omega_E) \setminus \{E\})} ([u_h - u_H], \{\partial_{n_{E'}} \varphi_H\})_{E'} \\
 &\quad + \alpha \sum_{E' \in \mathcal{E}_h(\partial\omega_E \cup \{E\})} h_{E'}^{-1} ([u_h], [\varphi_H])_{E'} \\
 &\quad - \sum_{E' \in \mathcal{E}_h(\partial\omega_E \cap \Gamma_N)} (u^N, \varphi_H)_{E'} \\
 &\quad + \alpha \sum_{E' \in \mathcal{E}_h(\partial\omega_E \cap \Gamma_D)} (u^D, \partial_{n_{E'}} \varphi_H - \alpha h_{E'}^{-1} \varphi_H)_{E'}.
 \end{aligned}$$

In view of (4.22b), the inverse inequality and the trace inequalities imply

$$(4.26a) \quad \|\nabla \psi_H^\pm\|_{T_\pm} \lesssim h_E^{-1/2} \|[u_H]\|_E,$$

$$(4.26b) \quad \|\psi_H^\pm\|_{E'} \lesssim \|[u_H]\|_E, \quad E' \in \mathcal{E}_H(\omega_E),$$

$$(4.26c) \quad \|\partial_{n_{E'}} \psi_H^\pm\|_{E'} \lesssim h_E^{-1} \|[u_H]\|_E, \quad E' \in \mathcal{E}_H(\omega_E).$$

Combining (4.24) and (4.25) and using (4.22b) and (4.26a)–(4.26c), straightforward estimation gives the assertion. The proof of (4.21) can be established similarly. \square

Remark 4.6. The proof of the perturbed discrete local efficiency is carried out under the assumption of geometrically conforming meshes. However, the fact that in Lemmas 4.4 and 4.5 the admissible test functions for the fine grid equation are chosen as linear combinations of the coarse grid Crouzeix–Raviart basis functions allows the handling of hanging nodes as well.

5. Proof of the error reduction property. In the convergence analysis of standard FEMs [18, 30], the proof of the error reduction property makes essential use of Galerkin orthogonality which in the framework of IPDG reads as follows:

$$(5.1) \quad a_h(u_h - u_H, u_h - u_H) = a_h(e_H, e_H) - a_h(e_h, e_h).$$

However, we measure the error e_H with respect to the mesh-dependent energy norm $a_H(\cdot, \cdot)$ associated with the coarse mesh $\mathcal{T}_H(\Omega)$, and, hence, (5.1) cannot be used directly. It is known from the convergence analysis of adaptive nonconforming finite elements [10] or of mixed finite elements [11] that in the absence of Galerkin orthogonality convergence can be established provided some sort of perturbed Galerkin orthogonality holds true. For the IPDG under consideration, we can rewrite (5.1) according to

$$(5.2) \quad a_h(u_h - u_H, u_h - u_H) = (1 + \delta_{h,H}(e_H)) a_H(e_H, e_H) - a_h(e_h, e_h),$$

where in the case $a_H(e_H, e_H) \neq 0$ the perturbation term $\delta_{h,H}(e_H)$ is given by

$$(5.3) \quad \delta_{h,H}(e_H) := \frac{a_h(e_H, e_H) - a_H(e_H, e_H)}{a_H(e_H, e_H)}.$$

We would be able to conclude, if we can show that $\delta_{h,H}(e_H)$ can be made sufficiently small.

LEMMA 5.1 (perturbed Galerkin orthogonality). *There exists a positive constant C_1 depending only on the local geometry of the triangulations such that for the perturbation term $\delta_{h,H}(e_H)$ there holds*

$$(5.4) \quad \delta_{h,H}(e_H) \leq \frac{C_1}{\alpha}.$$

Proof. Following the reasoning in [28, Proposition 4.1], we can easily show

$$a_h(e_H, e_H) \leq a_H(e_H, e_H) + c_1 \alpha \left(\sum_{E \in \mathcal{E}_H(\Omega)} h_E^{-1} \| [u_H] \|_E^2 + \sum_{E \in \mathcal{E}_H(\Gamma_D)} h_E^{-1} \| u^D - u_H \|_E^2 \right),$$

where $c_1 > 0$ is a constant depending only on the local geometry of the triangulations. On the other hand, the local efficiency of the residual estimator (cf. [27]) tells us that there exists another positive constant c_2 which also depends only on the local geometry of the triangulations such that

$$(5.5) \quad \sum_{E \in \mathcal{E}_H(\Omega)} h_E^{-1} \| [u_H] \|_E^2 + \sum_{E \in \mathcal{E}_H(\Gamma_D)} h_E^{-1} \| u^D - u_H \|_E^2 \leq \frac{c_2}{\alpha^2} a_H(e_H, e_H).$$

Combining the two preceding estimates allows us to conclude with $C_1 := c_1 c_2$. \square

Proof of Theorem 3.1. The reliability, the bulk criterion, and the discrete local efficiency infer the existence of a positive constant C_2 depending only on γ, Θ , and the local geometry of the triangulations such that

$$a_H(e_H, e_H) \leq C_2 \left(a_h(u_h - u_H, u_h - u_H) + \text{osc}_H^2 + \alpha \sum_{E \in \mathcal{E}_h(\Omega)} h_E^{-1} \| [u_h] \|_E^2 + \alpha \sum_{E \in \mathcal{E}_h(\Gamma_D)} h_E^{-1} \| u_D - u_h \|_E^2 \right).$$

Using (5.2), (5.4), and (5.5) with h instead of H , we obtain the existence of a positive constant C_3 such that

$$a_H(e_H, e_H) \leq C_2 \left(1 + \frac{2C_1}{\alpha} \right) a_H(e_H, e_H) - \left(C_2 - \frac{C_3}{\alpha} \right) a_h(e_h, e_h) + C_2 \text{osc}_H^2,$$

from which we deduce

$$a_h(e_h, e_h) \leq \left(C_2 - \frac{C_3}{\alpha}\right)^{-1} \left[\left(\left(1 + \frac{2C_1}{\alpha}\right) C_2 - 1 \right) a_H(e_H, e_H) + C_2 \operatorname{osc}_H^2 \right].$$

For $\alpha > 2C_1C_2 + C_3$, the error reduction property (3.10) results with $\rho_1 := (C_2 - \frac{C_3}{\alpha})^{-1}((1 + \frac{2C_1}{\alpha})C_2 - 1) < 1$. \square

Remark 5.2. We note that $a_h(\cdot, \cdot)$ is not coercive on the energy space. However, it can be shown (cf. Proposition 4.2 in [28]) that $\|e_h\|_{1,h,\Omega}^2 \lesssim a_h(e_h, e_h)$.

Remark 5.3. The coefficients $C_i, 1 \leq i \leq 3$, depend on the local geometry of the triangulations which is determined by the initial coarse triangulation and the refinement process. Moreover, C_2 depends on γ in (2.8) and on $0 < \Theta \leq 1$ in (3.8a) and (3.8b). For an appropriate initial triangulation, we can expect $C_i = O(1), 1 \leq i \leq 3$, so that the requirement $\alpha > C_1C_2 + C_3$ results in values of α of approximately the same magnitude as required for the coercivity of the mesh-dependent bilinear forms. This is confirmed by the numerical results in section 6.

6. Computational results. In the following numerical experiments, we used the bisection algorithm, for all test cases, derived from the *AFEM@Matlab* implementation [14].

We verify the suitability of our theoretical results using standard test cases (see [10]). They are studies of the behavior of the algorithm in the case of the standard singularities induced by a reentrant corner of the domain. The right-hand side is chosen to be zero, and, therefore, data oscillations are present only on the boundary edges not adjacent to the singularity, where values of the analytical solutions are prescribed. The penalty parameter α has been chosen according to $\alpha = 15(p + 1)^2$ as dictated by the coercivity requirement (2.8) (cf. also Remark 5.3).

First, we study the L-shaped domain with Dirichlet data $u^D = 0$ on the two edges adjacent to the reentrant corner and Neumann data on the remaining boundary. The refinement parameter is chosen as $\Theta = 0.6$. Table 6.1 shows a decline of the energy norm for this case by a factor of about 2/3 in each refinement step. This factor is only slightly better for quartic shape functions, confirming that the reduction rate depends mostly on Θ . Nevertheless, the meshes for P_4 are growing much slower, and in both cases we obtain the optimal approximation rates in terms of N_{dof} , namely, $N_{\text{dof}}^{-1/2}$ and N_{dof}^{-2} . Data oscillation occurs only at the outer boundary and is negligible in this case.

FIG. 6.1. Error versus number of degrees of freedom for the slit domain, quartic polynomials.

Next, we study the higher singularity of the slit domain. Here, Dirichlet boundary conditions are used on the whole boundary. Table 6.2 shows that for $\Theta = 0.4$ we obtain again constant error reduction rates.

The solution in this example is highly singular, and we expect that at least for higher order polynomials the refinement should be very local. Indeed, Figure 6.1 shows that the parameter Θ must be chosen carefully in order to obtain the optimal approximation with respect to the degrees of freedom, confirming results from [36] for standard AFEM. Only the very small value of $\Theta = 0.1$ is able to reproduce the optimal convergence order of N^{-2} . Figure 6.2 shows that this corresponds asymptotically to adding only 1/16 of the current number of cells in each step.

Even with the small size of $\Theta = 0.1$, the optimal N -term approximation rate is obtained only after several thousand degrees of freedom. Comparing Figures 6.1 and 6.2, we note that this corresponds to the fact that the bulk criterion refines much faster than the asymptotic rate in its initialization phase. On the other hand, this fast refinement allows the method to reach the asymptotic regime in only about 10 steps. Figure 6.3 shows that the refinement for $\Theta = 0.1$ is much more concentrated

FIG. 6.2. Development of mesh sizes during adaptive refinement, quartic polynomials.

FIG. 6.3. Meshes for the slit domain, polynomial degree 4, $\Theta = 0.4$ (left) and $\Theta = 0.1$ (right).

at the central singularity, while $\Theta = 0.4$ puts more weight in reducing the boundary projection errors.

MODELING OF THERMALLY ASSISTED MAGNETODYNAMICS*

LUBOMÍR BAÑAS[†], ANDREAS PROHL[‡], AND MARIÁN SLODIČKA[§]

Abstract. Thermomagnetic recording uses local heating of ferromagnetic media to locally decrease coercivity and change saturation magnetization of the material and alleviate magnetization reversal. A modified Landau–Lifshitz equation is proposed as a phenomenological model to allow for changes in magnetization magnitude and is studied both analytically and numerically.

Key words. temperature dependent Landau–Lifshitz equation, full-discretization, numerical analysis, convergence

1. Introduction. The application of thermal energy to enable recording on extremely high anisotropy magnetic media at room temperature is a viable means of extending the density of stored information on hard disk drives; cf. [14, 20, 21, 23]. In order to guarantee long-term data/magnetic regions thermal stability, a usable signal-to-noise ratio has to exist to find, follow, and read the smallest bits. Stability depends on material properties like saturation magnetization $\tilde{M}_s = \tilde{M}_s(\tau)$ and uniaxial magnetocrystalline anisotropy $\tilde{K} = \tilde{K}(\tau)$, where both (in magnitude) monotonically drop towards zero as the material temperature τ is increased toward the Curie temperature τ_C —the temperature where thermal energy overcomes electronic exchange forces in ferromagnets and produces a randomizing effect, leading to total disorder, and hence zero saturation magnetization; cf. Figure 1. Thermomagnetic recording uses local heating close to or above Curie temperature of the ferromagnetic medium during recording to locally decrease $K(\tau)$ to thus lower the energy barrier for reversal, and allow one to write data at available magnetic fields from recording heads. The written bits rapidly freeze during the cooling process and are stable at room temperature. Throughout this process in ferromagnetic films with tailored anisotropy, saturation magnetization behavior, and Curie temperature (see, e.g., [28], [21]), the heat deposition should be minimum and concentrated at the recording site, with optimized heating profile and cooling rate [20], to avoid lost of neighboring information and damage of ferromagnetic material at peak cycling temperatures; see Figure 1.

Isothermal gyromagnetic dynamics of single magnetic moment particles are described by the Landau–Lifshitz (LL) equation: Let $M_s(t, \mathbf{x}) \equiv \tilde{M}_s(\tau(t, \mathbf{x}))$ for $(t, \mathbf{x}) \in \Omega_T$. Given $\mathbf{m}(0, \cdot) = \mathbf{m}_0$, for $|\mathbf{m}_0| = M_s \geq 0$, solve

$$(1.1) \quad \mathbf{m}_t = -\gamma \mathbf{m} \times \mathbf{h}_{\text{eff}} - \gamma \delta \frac{\mathbf{m}}{M_s} \times (\mathbf{m} \times \mathbf{h}_{\text{eff}}) \quad \text{in } \Omega_T := (0, T) \times \Omega,$$

FIG. 1. (a) *thermally assisted magnetic recording*, (b) *temperature-dependent saturation magnetization \tilde{M}_s resp. anisotropy \tilde{K}* (dotted), and (c) *precession of magnetization*.

with the first term on the right-hand side representing magnetic moment precession (with gyromagnetic ratio $\gamma > 0$), and the second term on the right-hand side describing damping of the moment motion (with damping coefficient $\delta > 0$). Here, $\mathbf{h}_{\text{eff}} = -D\mathcal{E}(\mathbf{m})$ is the effective field, with Landau energy

$$(1.2) \quad \mathcal{E}(\mathbf{m}) = \alpha \int_{\Omega} |\nabla \mathbf{m}|^2 \, d\mathbf{x} + \int_{\Omega} \varphi(\mathbf{m}) \, d\mathbf{x} + \frac{\mu_0}{2} \int_{\mathbb{R}^n} |\nabla u|^2 \, d\mathbf{x} - \mu_0 \int_{\Omega} \langle \mathbf{h}_{\text{ext}}, \mathbf{m} \rangle \, d\mathbf{x},$$

which ensembles exchange, anisotropy, magnetostatic, and Zeeman's energy, respectively. Here, α denotes the exchange constant and μ_0 stands for the vacuum permeability. For uniaxial anisotropy with easy axis $\mathbf{e} \in \mathbb{S}^2$, it is common to choose $\varphi(\mathbf{m}) = K |\langle \mathbf{m}, \mathbf{e}_{\perp} \rangle|^2$, with $\tilde{K}(t, \mathbf{x}) \equiv K(\tau(t, \mathbf{x})) \geq 0$ for all $(t, \mathbf{x}) \in \Omega_T$ introduced before; see [19] for a recent survey.

Precessional motion of magnetization is based on quantum mechanics, where the mean value \mathbf{s}_{aver} of the spin operator $\mathbf{s} \in \mathbb{S}^2$ evolves according to Schrödinger's equation

$$\frac{d}{dt} \mathbf{s}_{\text{aver}} = -\frac{\gamma}{\mu_0} \mathbf{s}_{\text{aver}} \times \mathbf{b},$$

with magnetic induction $\mathbf{b} = \mu_0 \mathbf{h}_{\text{eff}}$; if the magnetization $\mathbf{m} : \Omega_T \rightarrow \mathbb{R}^3$ is understood to be the dipole of spins per unit volume, we arrive at

$$(1.3) \quad \mathbf{m}_t = -\gamma \mathbf{m} \times \mathbf{h}_{\text{eff}}.$$

Experimental evidence suggests an additional damping term to be responsible for alignment of magnetization with the applied field \mathbf{h}_{eff} , which is the reason for the additional damping term in (1.2) introduced by Landau and Lifshitz. An important feature of both (1.1) and (1.3) is conservation of length of initial magnetization; i.e., $\frac{1}{2} \frac{d}{dt} |\mathbf{m}|^2 = 0$ almost everywhere in Ω_T . Later on, Gilbert augmented \mathbf{h}_{eff} by an Ohmic dissipation term, by inserting the modified $\tilde{\mathbf{h}}_{\text{eff}} = \mathbf{h}_{\text{eff}} - \beta \mathbf{m}_t$ into (1.3). For different constants, this Landau–Lifshitz–Gilbert equation can again be restated in the form (1.1); see [1, 8, 9, 13, 15, 25] and [2, 3, 4, 5, 6, 7, 10, 12, 15, 18, 19, 22] for further details. Despite the model's success, the underlying physics of damping behavior is still not clear to rigorously justify the corresponding term in (LL); moreover, the saturation magnetization $\tilde{M}_s = \tilde{M}_s(\tau)$ varies for changing temperature, for which Landau proposes the following phenomenological power-law behavior for all $\tau < \tau_C$,

$$(1.4) \quad \tilde{M}_s(\tau) = \tilde{M}_0 \left(1 - \frac{\tau}{\tau_C}\right)^{\beta},$$

where the exponent $\beta > 0$ is found by experimental or theoretical evidence. This law agrees very well with experimental observations away from τ_C .

In this work, we propose and study an extended Landau–Lifshitz equation allowing for changes in the saturation magnetization. The subsequent modified Landau–Lifshitz model uses mutual orthogonality of \mathbf{m} , $\mathbf{m} \times \mathbf{h}_{\text{eff}}$, and $\mathbf{m} \times (\mathbf{m} \times \mathbf{h}_{\text{eff}})$, for every $(t, \mathbf{x}) \in \Omega_T$, to describe temperature-dependent gyroscopic precession: For a given $0 < M_s \in C^2(\Omega_T)$ solve (with $\mathbf{h}_{\text{eff}} = \Delta \mathbf{m}$)

$$(1.5) \quad \mathbf{m}_t = \kappa \mathbf{m} - \gamma \mathbf{m} \times \mathbf{h}_{\text{eff}} - \gamma \delta \frac{\mathbf{m}}{M_s} \times (\mathbf{m} \times \mathbf{h}_{\text{eff}}) \quad \text{in } \Omega_T,$$

$$(1.6) \quad \partial_{\mathbf{n}} \mathbf{m} = 0 \quad \text{on } \partial \Omega_T := \partial \Omega \times [0, T],$$

$$(1.7) \quad \mathbf{m}(0, \cdot) = \mathbf{m}_0 \quad \text{in } \Omega.$$

Let $\kappa(t, \mathbf{x}) \equiv \tilde{\kappa}(\tau(t, \mathbf{x}), \tau_t(t, \mathbf{x}))$, for all $(t, \mathbf{x}) \in \Omega_T$, which is chosen in such a way that $|\mathbf{m}(t, \mathbf{x})| = M_s(t, \mathbf{x})$ holds in Ω_T . We make the following assumptions: $\tilde{\kappa} \in C^2([0, \tau_C) \times \mathbb{R})$ satisfies

1. $\tilde{\kappa}(\tau, \tau_t) = 0$ for $\tau_t = 0$,
2. $\tilde{\kappa}(\tau, \tau_t) \leq 0$ for $\tau_t \geq 0$, and $\tilde{\kappa}(\tau, \tau_t) > 0$ for $\tau_t < 0$.

A scalar multiplication of (1.5) by \mathbf{m} yields to

$$(1.8) \quad \frac{d}{dt} M_s^2 = 2\kappa M_s^2 \quad \text{in } \Omega_T.$$

For a given temperature distribution $\tau : \Omega_T \rightarrow \mathbb{R}^+$, we obtain by the chain rule,

$$(1.9) \quad \tilde{\kappa}(\tau, \tau_t) = \frac{\tau_t}{2} \frac{d}{d\tau} \ln \left[\tilde{M}_s(\tau) \right]^2 = \tau_t \frac{d}{d\tau} \ln \tilde{M}_s(\tau),$$

which satisfies the above requirements (1) and (2). Shrinking, extension, and conservation of magnetization saturation by means of heating, cooling, as well as thermal equilibrium as further effects may then be described by (1.9), once $M_s \in C^2([0, \tau_C])$ is provided, which is either by experiment or theory (e.g., mean field theory). For $0 \leq t_1 \leq t_2 \leq T$ we compute

$$(1.10) \quad \tilde{M}_s^2(\tau(t_2, \cdot)) = \tilde{M}_s^2(\tau(t_1, \cdot)) \exp \left(-2 \int_{t_1}^{t_2} \tilde{\kappa}(\tau(s, \cdot), \tau_t(s, \cdot)) \, ds \right) \quad \text{in } \Omega.$$

In passing, a possible explicit dependence of $\tilde{\kappa}$ on M_s may also be assumed, which seems advantageous in a neighborhood of τ_C . Moreover, if we adopt the phenomenological power-law (1.4), then the relation (1.9) will take the form

$$(1.11) \quad \tilde{\kappa}(\tau, \tau_t) = -\frac{\tau_t \beta}{\tau_C - \tau}.$$

In the literature, to verify solvability of (1.1) is often based on the reformulation in Landau–Lifshitz–Gilbert form, which exploits the property $|\mathbf{m}| = \text{const}$ almost everywhere in Ω_T . In the present case, the target for solutions of (1.5)–(1.6) depends on $(t, \mathbf{x}) \in \Omega_T$, and the authors are not aware of any analytical studies where the target of solutions is allowed to (smoothly) vary in space-time. Our first contribution in this work is to verify the existence of locally strong (section 3) and globally weak (section 5) solutions, for $\Omega \subset \mathbb{R}^d$, $d = 2, 3$ a bounded Lipschitz domain. While the first result uses abstract results, where locally strong solutions are constructed as proper

limits of a sequence of smooth solutions, whose existence follows from general inverse function theorem (here, we follow [26, 27], and [18], where (LL) with $M_s \equiv \text{const}$ is studied), weak solutions are constructed as proper limits of iterates of a practical discretization in space-time (see Scheme B).

From a numerical viewpoint, to construct convergent, fully practical numerical schemes (including discretization in time and space, numerical integration, and a simple fixed point scheme to solve arising nonlinear algebraic problems), where iterates respect the constraint $|\mathbf{m}| = M_s > 0$ in a proper sense is a nontrivial endeavor. Over the last decade, projection strategies have been shown to converge in the context of (locally existing) strong solutions for (LL), where $M_s \equiv \text{const}$, and optimal convergence rates have been verified in this case [22]. Unfortunately, convergence of these methods in the case of only weak solutions is still not clear; it is only recently that space-time discretizations of (LL) and for $M_s = \text{const}$ were found, where iterates satisfy $|\mathbf{M}^j| = \text{const}$ at all nodes of the triangulation ($0 \leq j \leq J$), and construct weak solutions in the limit when all discretization parameters tend to zero. Interestingly, both ansatzes use different formulations of the problem in the continuous setting, leading to different schemes, numerical analysis, and properties as indicated.

The present case of $0 < M_s \equiv M_s(t, \mathbf{x})$ makes the construction of stable, convergent discretizations, which satisfy $|\mathbf{M}^j| = M_s > 0$ even only at mesh-points challenging ($0 \leq j \leq J$). More specifically, we study two discretizations of (1.5)–(1.7), which are also based on two formulations (1.5)–(1.7), and (5.1), (1.6)–(1.7) of the problem, which are equivalent for strong solutions:

- Scheme A: At the end of each iterative step, vectors are projected to the sphere of a given radius $M_s = M_s(t_j, \mathbf{z})$, for every $1 \leq j \leq J$, and every node of the mesh $\mathbf{z} \in \mathcal{N}_h$. The scheme is based on a reformulation of (1.5) in the form (3.1). Iterates converge to (locally existing) strong solutions of (1.5)–(1.7) at optimal rates.
- Scheme B: The scheme is a discretization in space-time of (5.1), (1.6)–(1.7), which uses trapezoidal rule, reduced integration (in space), and discrete Laplacian. Its motivation comes from (LL) with $M_s = \text{const}$, where conservation of the “sphere-constraint” at mesh-points $\mathbf{z} \in \mathcal{N}_h$, and convergence to weak solutions is known [6, 7]. As will be shown in section 5, $M_s = M_s(t_j, \mathbf{z})$ at nodes $\mathbf{z} \in \mathcal{N}_h$ holds only approximately, but is attained in the limit of vanishing discretization parameters. Iterates are shown to converge to weak solutions of (the reformulation) (5.1), (1.6)–(1.7).

Sections 3 and 4 briefly recall arguments to verify corresponding results on locally existing strong solutions for $M_s = \text{const}$ from [18, 10], and on optimal rates of convergence for iterates of a projection method (Scheme A) [22, 12]. Main results are stated in section 5, where weak solutions to (5.1), (1.6)–(1.7) are constructed as proper limits of iterates of Scheme B. The paper closes with section 7, where 2D computational academic and applied examples compare Schemes A and B, and evidence interesting dynamics for the new model of targets varying in space-time for (LL). Benchmark problems from [29] are adopted and studied for the case of smoothly varying spheres in space-time, and comparative studies using Schemes A and B are discussed.

2. Preliminaries. Throughout this paper we assume that \mathcal{T}_h is a quasiuniform triangulation of the polygonal or polyhedral bounded Lipschitz domain $\Omega \subset \mathbb{R}^d$ into triangles or tetrahedra of maximal diameter h for $d = 2$ or $d = 3$, respectively. We let $V_h \subset W^{1,2}(\Omega)$ denote the lowest order finite element space on \mathcal{T}_h ; i.e., $\phi_h \in V_h$ if and only if $\phi_h \in C(\bar{\Omega})$ and $\phi_h|_K$ is affine for each $K \in \mathcal{T}_h$. Given the set of all nodes

(or vertexes) \mathcal{N}_h in \mathcal{T}_h and letting $\{\varphi_{\mathbf{z}} : \mathbf{z} \in \mathcal{N}_h\}$ denote the nodal basis in V_h , we define the nodal interpolation operator $\mathcal{I}_h : C(\overline{\Omega}) \rightarrow V_h$ by $\mathcal{I}_h \psi := \sum_{\mathbf{z} \in \mathcal{N}_h} \psi(\mathbf{z}) \varphi_{\mathbf{z}}$, for $\psi \in C(\overline{\Omega})$, and $P_h : L^2(\Omega) \rightarrow V_h$ the $L^2(\Omega)$ -projection. We use boldface notation to indicate vectorial quantities, like $\mathbf{V}_h = [V_h]^3$, for example. We write $(\mathbf{f}, \mathbf{g}) = \int_{\Omega} \langle \mathbf{f}, \mathbf{g} \rangle \, d\mathbf{x}$ for $\mathbf{f}, \mathbf{g} \in L^2(\Omega, \mathbb{R}^3)$ and abbreviate $\|\mathbf{f}\| = \|\mathbf{f}\|_{L^2(\Omega)}$. For functions $\mathbf{f}, \mathbf{g} \in C(\overline{\Omega}, \mathbb{R}^3)$ a discrete inner product is defined by

$$(2.1) \quad (\mathbf{f}, \mathbf{g})_h := \int_{\Omega} \mathcal{I}_h[\langle \mathbf{f}, \mathbf{g} \rangle] \, d\mathbf{x} = \sum_{\mathbf{z} \in \mathcal{N}_h} \beta_{\mathbf{z}} \langle \mathbf{f}(\mathbf{z}), \mathbf{g}(\mathbf{z}) \rangle,$$

where $\beta_{\mathbf{z}} = \int_{\Omega} \varphi_{\mathbf{z}} \, d\mathbf{x}$ for all $\mathbf{z} \in \mathcal{N}_h$; we define $\|\boldsymbol{\psi}\|_h^2 := (\boldsymbol{\psi}, \boldsymbol{\psi})_h$. We remark that there holds

$$(2.2) \quad \|\boldsymbol{\psi}\| \leq \|\boldsymbol{\psi}\|_h \leq (d+2)^{1/2} \|\boldsymbol{\psi}\| \quad \forall \boldsymbol{\psi} \in \mathbf{V}_h.$$

Basic interpolation estimates yield (cf., e.g., [7]) that

$$(2.3) \quad |(\boldsymbol{\phi}, \boldsymbol{\psi})_h - (\boldsymbol{\phi}, \boldsymbol{\psi})| \leq Ch \|\boldsymbol{\phi}\| \|\nabla \boldsymbol{\psi}\| \quad \forall \boldsymbol{\phi}, \boldsymbol{\psi} \in \mathbf{V}_h,$$

where here and throughout this paper $C > 0$ denotes a (h, k) -independent generic constant, which may change from place to place. We define a discrete Laplace operator $\tilde{\Delta}_h : W^{1,2}(\Omega, \mathbb{R}^3) \rightarrow \mathbf{V}_h$ by requiring

$$\left(-\tilde{\Delta}_h \boldsymbol{\phi}, \boldsymbol{\chi}\right)_h = (\nabla \boldsymbol{\phi}, \nabla \boldsymbol{\chi}) \quad \forall \boldsymbol{\chi} \in \mathbf{V}_h.$$

We note that there exists a constant $c_1 > 0$ such that for all $\boldsymbol{\phi} \in \mathbf{V}_h$ there holds (cf. [6])

$$(2.4) \quad \|\tilde{\Delta}_h \boldsymbol{\phi}\|_h \leq c_1 h^{-2} \|\boldsymbol{\phi}\|_h \quad \text{and} \quad \|\tilde{\Delta}_h \boldsymbol{\phi}\|_{L^\infty} \leq c_1 h^{-2} \|\boldsymbol{\phi}\|_{L^\infty}.$$

Given a time-step size $k > 0$ and a sequence $\{\varphi^j\}_{j \geq 0}$ in some vector space X , we set

$$d_t \varphi^{j+1} := k^{-1} (\varphi^{j+1} - \varphi^j) \quad \text{and} \quad \varphi^{j+1/2} := \frac{\varphi^j + \varphi^{j+1}}{2},$$

for $j \geq 0$. Note that there holds $\langle d_t \varphi^{j+1}, \varphi^{j+1/2} \rangle_X = \frac{1}{2} d_t \|\varphi^{j+1}\|_X^2$, if X is a Hilbert space. Finally, we recall some elementary properties of vector products: Let $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3, \mathbf{a}_4 \in \mathbb{R}^3$ there holds

$$(2.5) \quad \begin{aligned} \langle \mathbf{a}_1 \times \mathbf{a}_2, \mathbf{a}_3 \rangle &= -\langle \mathbf{a}_2, \mathbf{a}_1 \times \mathbf{a}_3 \rangle, \\ \mathbf{a}_1 \times (\mathbf{a}_2 \times \mathbf{a}_3) &= \langle \mathbf{a}_1, \mathbf{a}_3 \rangle \mathbf{a}_2 - \langle \mathbf{a}_1, \mathbf{a}_2 \rangle \mathbf{a}_3, \\ \langle \mathbf{a}_1 \times \mathbf{a}_2, \mathbf{a}_3 \times \mathbf{a}_4 \rangle &= \langle \mathbf{a}_1, \mathbf{a}_3 \rangle \langle \mathbf{a}_2, \mathbf{a}_4 \rangle - \langle \mathbf{a}_2, \mathbf{a}_3 \rangle \langle \mathbf{a}_1, \mathbf{a}_4 \rangle. \end{aligned}$$

3. Local existence of strong solutions for (1.5)–(1.7). We start with a reformulation of (1.5)–(1.7). For a given $0 < M_s \in L^\infty(0, T; W^{2,2}(\Omega))$, solve

$$(3.1) \quad \mathbf{m}_t - \gamma \delta M_s \Delta \mathbf{m} - \kappa \mathbf{m} = \frac{\gamma \delta}{M_s} |\nabla \mathbf{m}|^2 \mathbf{m} - \frac{\gamma \delta}{2M_s} (\Delta M_s^2) \mathbf{m} - \gamma \mathbf{m} \times \Delta \mathbf{m},$$

together with (1.6), (1.7), where $|\mathbf{m}_0| = M_s(0, \cdot)$. In the following, for given $T > 0$ we call $\mathbf{m} \in C([0, T]; W^{1,2}(\Omega, \mathbb{R}^3)) \cap L^2(0, T; W^{2,2}(\Omega, \mathbb{R}^3))$ that solves (1.5) in

distributional sense, and (1.6)–(1.7), a strong solution to (1.5)–(1.7). We use the same notion for (3.1), (1.6)–(1.7) below.

LEMMA 3.1. *Let $0 < M_s \in L^\infty(0, T; W^{2,2}(\Omega))$ be given, with $\partial_n M_s = 0$ on $\partial\Omega_T$. The function $\mathbf{m} : \Omega_T \rightarrow \mathbb{R}^3$ is a strong solution of (1.5)–(1.7) if and only if it is a strong solution to (3.1), (1.6)–(1.7).*

Proof. We use the vector cross product formula (2.5)₂ and (1.5), and $|\mathbf{m}|^2 = M_s^2$ in Ω_T to obtain

$$\begin{aligned} \mathbf{m} \times (\mathbf{m} \times \Delta \mathbf{m}) &= \langle \mathbf{m}, \Delta \mathbf{m} \rangle \mathbf{m} - |\mathbf{m}|^2 \Delta \mathbf{m} \\ (3.2) \qquad \qquad \qquad &= -|\nabla \mathbf{m}|^2 \mathbf{m} + \frac{1}{2} (\Delta M_s^2) \mathbf{m} - M_s^2 \Delta \mathbf{m}. \end{aligned}$$

Inserting this identity into (1.5) proves that a strong solution $\mathbf{m} : \Omega_T \rightarrow \mathbb{R}^3$ of (1.5)–(1.7) solves (3.1) in a distributional sense, satisfying (1.6)–(1.7).

Let now $\mathbf{m} : \Omega_T \rightarrow \mathbb{R}^3$ be a strong solution to (3.1), (1.6)–(1.7). Setting $W(t, \mathbf{x}) = |\mathbf{m}(t, \mathbf{x})|^2$, and observing

$$W_t = 2\langle \mathbf{m}, \mathbf{m}_t \rangle, \quad \nabla W = 2\langle \mathbf{m}, \nabla \mathbf{m} \rangle, \quad \Delta W = 2\langle \mathbf{m}, \Delta \mathbf{m} \rangle + 2|\nabla \mathbf{m}|^2,$$

implies a.e. in Ω_T ,

$$W_t - \gamma \delta M_s \Delta W - 2\kappa W = \frac{2\gamma \delta}{M_s} |\nabla \mathbf{m}|^2 (W - M_s^2) - \frac{\gamma \delta}{M_s} (\Delta M_s^2) W.$$

Setting $Z = W - M_s^2$ leads to

$$Z_t - \gamma \delta M_s \Delta Z - 2\kappa Z = (2\kappa M_s^2 - \partial_t M_s^2) + \frac{\gamma \delta}{M_s} [2|\nabla \mathbf{m}|^2 - (\Delta M_s^2)] Z.$$

The first bracket on the right-hand side vanishes, owing to (1.8). Multiplying with Z in L^2 sense, and observing that $\partial_n Z = 0$ on $\partial\Omega_T$ gives

$$\left(\frac{Z_t}{M_s}, Z \right) + \gamma \delta \|\nabla Z\|^2 = \left(\frac{2\kappa}{M_s} + \frac{2\gamma \delta}{M_s^2} |\nabla \mathbf{m}|^2 - \frac{\gamma \delta}{M_s^2} (\Delta M_s^2), Z^2 \right).$$

Owing to $c_1 > M_s > 0$, rearranging terms then leads to

$$\frac{d}{dt} \|Z\|^2 + \|\nabla Z\|^2 \leq \tilde{C} \|Z\|^2,$$

for some finite $0 \leq \tilde{C} \equiv \tilde{C}(|\nabla \mathbf{m}|, |(\Delta M_s^2)|)$. Integration in time, observing $Z(0, \cdot) = 0$, and Gronwall’s inequality then shows that $Z \equiv 0$ in Ω_T . \square

In order to verify existence of strong solutions to (3.1), (1.6)–(1.7), we either suppose smallness of initial energies $E(\mathbf{m}_0) \equiv \frac{1}{2} \|\nabla \mathbf{m}_0\|^2$ to conclude global existence of strong solutions, or local existence for bounded initial energies. The following arguments are taken from [18, 26], and [27, section 1.4], and are mostly sketched, in case their elaboration can be taken from these references on a line-by-line basis. First, we verify a priori bounds, under the assumption that smooth solutions $\mathbf{m} : \Omega_T \rightarrow \mathbb{R}^3$ of (3.1) exist.

LEMMA 3.2. *Let $T > 0$. There exists a constant $0 < C = C(M_s, \gamma, \delta) < \infty$ such that for any smooth solution to (3.1), (1.6)–(1.7) there holds for all $0 \leq t \leq T$,*

$$\frac{\delta^2}{2(1 + \delta^2)} \int_0^t \|\mathbf{m}_t(s, \cdot)\|^2 ds + \frac{\gamma \delta}{2} E(\mathbf{m}(t, \cdot)) \leq C(1 + E(\mathbf{m}_0)).$$

Proof. Multiply (3.1) by \mathbf{m}_t and integrate over $[0, T] \times \Omega$. We compute

$$\begin{aligned}
 -(M_s \Delta \mathbf{m}, \mathbf{m}_t) &= \frac{1}{2} \frac{d}{dt} (M_s, |\nabla \mathbf{m}|^2) - \frac{1}{2} (\partial_t M_s, |\nabla \mathbf{m}|^2) + (\nabla M_s^\top \nabla \mathbf{m}, \mathbf{m}_t), \\
 2(\kappa \mathbf{m}, \mathbf{m}_t) &= \frac{d}{dt} (\kappa, M_s^2) - (\partial_t \kappa, M_s^2), \\
 (3.3) \quad \left(\frac{|\nabla \mathbf{m}|^2}{2M_s}, \partial_t M_s^2 \right) &= (|\nabla \mathbf{m}|^2, \partial_t M_s), \\
 \left(\frac{\Delta M_s^2}{4M_s}, \partial_t M_s^2 \right) &= \frac{1}{2} (\Delta M_s^2, \partial_t M_s).
 \end{aligned}$$

Next, we bound $|(\mathbf{m} \times \Delta \mathbf{m}, \mathbf{m}_t)|$: take the cross product of (3.1) with \mathbf{m} , and use (3.2) to obtain

$$\begin{aligned}
 \mathbf{m} \times \mathbf{m}_t &= \gamma \delta M_s \mathbf{m} \times \Delta \mathbf{m} - \gamma \mathbf{m} \times (\mathbf{m} \times \Delta \mathbf{m}) \\
 (3.4) \quad &= \gamma \delta M_s \mathbf{m} \times \Delta \mathbf{m} + \gamma M_s^2 \Delta \mathbf{m} - \frac{\gamma}{2} (\Delta M_s^2) \mathbf{m} + \gamma |\nabla \mathbf{m}|^2 \mathbf{m} \\
 &= \gamma M_s \left(\delta + \frac{1}{\delta} \right) \mathbf{m} \times \Delta \mathbf{m} - \frac{M_s}{\delta} \kappa \mathbf{m} + \frac{M_s}{\delta} \mathbf{m}_t.
 \end{aligned}$$

Multiplying this equation with $\frac{\delta}{M_s} \mathbf{m}_t$ leads to

$$0 = \gamma (\delta^2 + 1) (\mathbf{m} \times \Delta \mathbf{m}, \mathbf{m}_t) - \frac{1}{2} (M_s \kappa, \partial_t M_s) + \|\mathbf{m}_t\|^2,$$

and hence

$$\gamma \int_0^T |(\mathbf{m} \times \Delta \mathbf{m}, \mathbf{m}_t)| \, ds \leq C + \frac{1}{1 + \delta^2} \|\mathbf{m}_t\|^2.$$

Putting things together, we arrive at

$$\begin{aligned}
 \frac{1}{2} \left(1 - \frac{1}{1 + \delta^2} \right) \int_0^T \|\mathbf{m}_t(s, \cdot)\|^2 \, ds &+ \frac{\gamma \delta}{2} (M_s(T, \cdot) |\nabla \mathbf{m}(T, \cdot)|^2) \\
 &\leq \frac{\gamma \delta}{2} (M_s(0, \cdot) |\nabla \mathbf{m}(0, \cdot)|^2) + \tilde{C}_1 \int_0^T [|\nabla \mathbf{m}(s, \cdot)|^2] \, ds + \tilde{C}_2,
 \end{aligned}$$

for some positive, bounded

$$\tilde{C}_1 \equiv \tilde{C}_2 (\|M_s\|_{W^{1,\infty}(\Omega_T)}, \delta), \quad \tilde{C}_2 \equiv \tilde{C}_2 (\|M_s\|_{W^{2,\infty}(\Omega_T)}).$$

The assertion of the lemma then follows from applying Gronwall’s inequality. \square

In the sequel, we limit ourselves to $\Omega \subset \mathbb{R}^2$. Let $E(\mathbf{m}; \omega) = \int_\omega |\nabla \mathbf{m}|^2 \, d\mathbf{y}$, for $\omega \subset \Omega$, and $B_R(\mathbf{x}) \subset \mathbb{R}^2$ be a ball around $\mathbf{x} \in \mathbb{R}^2$ of radius $R > 0$. The following technical lemma holds for functions from $L^\infty(0, T; W^{1,2}(\Omega, \mathbb{R}^3)) \cap L^2(0, T; W^{2,2}(\Omega, \mathbb{R}^3))$, and is taken from [27, p. 274]; see also [18, Lemma 3.1].

LEMMA 3.3. *Let $T > 0$. There exist bounded, positive constants $C, R_0 > 0$ such that for any $\varphi \in L^\infty(0, T; W^{1,2}(\Omega, \mathbb{R}^3)) \cap L^2(0, T; W^{2,2}(\Omega, \mathbb{R}^3))$, and any $R \in (0, R_0]$ there holds*

$$\begin{aligned}
 &\int_0^T \|\nabla \varphi(s, \cdot)\|_{L^4}^4 \, ds \\
 &\leq C \left(\operatorname{ess\,sup}_{(t,\mathbf{x}) \in \Omega_T} \int_{B_R(\mathbf{x})} |\nabla \varphi(t, \cdot)|^2 \, d\mathbf{x} \right) \left(\int_0^T \|\nabla^2 \varphi\|^2 \, dt + R^{-2} \int_0^T \|\nabla \varphi(s, \cdot)\|^2 \, ds \right).
 \end{aligned}$$

Like in [26, Lemma 1.5], local energies at a fixed time can be controlled in terms of those at earlier times. The proof on the subsequent lemma uses Lemma 3.2 and localizes the argumentation around (3.4). A proof for (3.1) for $M_s = \text{const}$ is given in [18, Lemma 3.4], and can easily be adopted to the present case.

LEMMA 3.4. *Let $T > 0$. There exists a constant $C \equiv C(M_s, \gamma, \delta) > 0$ such that for any smooth solution of (3.1), any $R \in (0, R_0]$, and any $(t, \mathbf{x}) \in \Omega_T$ there holds the estimate*

$$E(\mathbf{m}(t, \cdot); B_R(\mathbf{x}_0)) \leq E(\mathbf{m}_0; B_{2R}(\mathbf{x}_0)) + C \frac{t}{R^2} (1 + E(\mathbf{m}_0)).$$

We can now follow the general argumentation from [26, p. 274], which we include for the convenience of the reader: For $\mathbf{m}_0 \in W^{1,2}(\Omega, \mathbb{R}^3)$ and any given $\varepsilon_0 > 0$, let $R_0 > 0$ be the maximal number such that

$$\sup_{\mathbf{x}_0 \in \Omega} E(\mathbf{m}_0; B_{2R_0}(\mathbf{x}_0)) < \varepsilon_0,$$

and let $T_0 > 0$ be the number such that any smooth solution $\mathbf{m} : \Omega_T \rightarrow \mathbb{R}^3$ of (3.1) taking initial value $\mathbf{m}_0 : \Omega \rightarrow \mathbb{R}^3$ satisfies

$$\sup_{\mathbf{x}_0 \in \Omega} \sup_{0 \leq t \leq T_0} E(\mathbf{m}(t, \cdot); B_{R_0}(\mathbf{x}_0)) < 2\varepsilon_0.$$

Note that in view of Lemma 3.4, we may let $T_0 = \frac{\varepsilon_0 R_0^2}{CE(\mathbf{m}_0)}$. Let $\{\phi_i\}$ be smooth cut-off functions subordinate to a cover of $\Omega \subset \mathbb{R}^2$ by balls $B_{2R_0}(\mathbf{x}_i)$ with finite overlap, and such that $0 \leq \phi_i \leq 1$, and $|\nabla \phi_i| \leq \frac{2}{R_1}$, such that $\sum_i \phi_i^2 = 1$. We may then compute

$$\begin{aligned} \|\nabla \mathbf{m}(t, \cdot)\|_{L^4}^4 &= \sum_i \int_{\Omega} |\nabla \mathbf{m}(t, \cdot)|^4 \phi_i^2 \, d\mathbf{x} \\ (3.5) \quad &\leq C \sup_i E(\mathbf{m}(t, \cdot); B_{2R_0}(\mathbf{x}_i)) \left(\int_{\Omega} |\nabla^2 \mathbf{m}(t, \cdot)|^2 \, d\mathbf{x} + R_0^{-2} E(\mathbf{m}_0) \right) \\ &\leq C\varepsilon_0 \left(\int_{\Omega} |\nabla^2 \mathbf{m}(t, \cdot)|^2 \, d\mathbf{x} + R_0^{-2} E(\mathbf{m}_0) \right). \end{aligned}$$

We are now in a position to verify the following bound.

LEMMA 3.5. *For sufficiently small $\varepsilon_0 > 0$, and any $R \in (0, R_0]$, there exists $T_0 > 0$ such that an existing smooth solution of (3.1) satisfies*

$$\int_0^t \|\nabla^2 \mathbf{m}(s, \cdot)\|^2 \, ds \leq C (E(\mathbf{m}_0) + 1) \left(1 + \frac{t}{R^2}\right) \quad \forall 0 \leq t \leq T_0.$$

Proof. Multiply (3.1) with $-\Delta \mathbf{m}$ to find

$$\frac{1}{2} \frac{d}{dt} \|\nabla \mathbf{m}\|^2 + \frac{\gamma \delta}{2} \|\sqrt{M_s} \Delta \mathbf{m}\|^2 \leq C (1 + \|\nabla \mathbf{m}\|^2 + |(\nabla \kappa \otimes \mathbf{m}, \nabla \mathbf{m})| + \|\nabla \mathbf{m}\|_{L^4}^4).$$

For sufficiently small $\varepsilon_0 > 0$, by (3.5) we can control the last term on the right-hand side by the second one on the left-hand side. Integration in time and Lemma 3.2 then yields the assertion. \square

Summing up, for sufficiently small $\varepsilon_0 > 0$ we have locally in time bounds for $\mathbf{m} : \Omega_{T_0} \rightarrow \mathbb{R}^3$ in

$$V(\Omega_{T_0}; \mathbb{R}^3) := \left\{ \varphi : \Omega_{T_0} \rightarrow \mathbb{R}^3 : \text{ess sup}_{0 \leq t \leq T_0} E(\varphi) + \int_0^{T_0} \|\nabla^2 \varphi(s, \cdot)\|^2 + \|\varphi_t(s, \cdot)\|^2 ds < \infty \right\}.$$

Then it is not difficult to verify uniqueness of smooth solutions $\mathbf{m} : \Omega_T \rightarrow \mathbb{R}^3$ to (3.1), (1.6)–(1.7) from these bounds; see [18, Theorem 3.9] for the simplified case $M_s \equiv 1$.

In order to prove the local existence in time of smooth solutions to (3.1), (1.6)–(1.7), we may then exploit strong parabolicity of our problem and follow the arguments given in [18, Theorem 3.12 and Lemma 3.10] for $M_s \equiv \text{const}$. Let us note that all results from [18] are valid for an equation of the type

$$\partial_t \mathbf{u} + \mathbf{u} \times \Delta \mathbf{u} + \mathbf{u} \times (\mathbf{u} \times \Delta \mathbf{u}) = \mathbf{0}.$$

Our equation (3.1) represents a slight modification of this by adding an additional term of the type \mathbf{u} , due to variable M_s . This can be handled in an easier way than other terms (note that other terms contain derivatives) and therefore we skip unnecessary details. According to [18, Theorem 3.13], we may say that:

THEOREM 3.1. *Let $\mathbf{m}_0 : \Omega \rightarrow \mathbb{R}^3$ be a smooth map and $0 < M_s \in L^\infty(0, T; W^{2,2}(\Omega))$. There exists $T_0 > 0$, and a unique, smooth mapping $\mathbf{m} : \Omega_{T_0} \rightarrow \mathbb{R}^3$ solving (3.1), (1.6)–(1.7). Let $\ell \in \mathbb{N}$, and $\mathbf{m}_{0,\ell} \in C^\infty(\Omega, \mathbb{R}^3)$ be such that*

$$\sup_{(t, \mathbf{x}_0) \in \Omega_{T_0}} E(\mathbf{m}_\ell(t, \cdot); B_R(\mathbf{x}_0)) \leq \varepsilon_0 \quad \forall R \in (0, R_0],$$

for any $\varepsilon_0 > 0$, with $\mathbf{m}_{0\ell} \rightarrow \mathbf{m}_0$ in $W^{1,2}(\Omega, \mathbb{R}^3)$ for $\ell \rightarrow \infty$. For every $\ell \in \mathbb{N}$, let $\mathbf{m}_\ell : \Omega_{T_0} \rightarrow \mathbb{R}^3$ be the smooth, unique local solution to (3.1), (1.6) starting from $\mathbf{m}_{0\ell}$. Similar to [18, Lemma 3.7], a consequence from Lemmas 3.2 and 3.5, and the Aubin–Lions lemma, there holds for $\ell \rightarrow \infty$,

$$(3.6) \quad \begin{aligned} \partial_t \mathbf{m}_\ell &\rightharpoonup \partial_t \mathbf{m} && \text{in } L^2(0, T_0; L^2(\Omega, \mathbb{R}^3)), \\ \Delta \mathbf{m}_\ell &\rightharpoonup \Delta \mathbf{m} && \text{in } L^2(0, T_0; L^2(\Omega, \mathbb{R}^3)), \\ \mathbf{m}_\ell &\rightarrow \mathbf{m} && \text{in } L^2(0, T_0; W^{1,2}(\Omega, \mathbb{R}^3)) \cap C([0, T_0]; L^2(\Omega, \mathbb{R}^3)). \end{aligned}$$

Take any smooth vector field ϕ and any $t \in (0, T_0)$. The solution \mathbf{m}_ℓ to (3.1) satisfies

$$\begin{aligned} &(\mathbf{m}_\ell(t) - \mathbf{m}_{0\ell}, \phi) - \gamma\delta \int_0^t (M_s \Delta \mathbf{m}_\ell, \phi) - \kappa \int_0^t (\mathbf{m}_\ell, \phi) \\ &= \int_0^t \left(\frac{\gamma\delta}{M_s} |\nabla \mathbf{m}_\ell|^2 \mathbf{m}_\ell, \phi \right) - \int_0^t \left(\frac{\gamma\delta}{2M_s} (\Delta M_s^2) \mathbf{m}_\ell, \phi \right) - \gamma \int_0^t (\mathbf{m}_\ell \times \Delta \mathbf{m}_\ell, \phi). \end{aligned}$$

Using (3.6) and recalling that a product of a weak and a strong convergent sequence is strongly convergent, we can pass to the limit for $\ell \rightarrow \infty$ and we get

$$\begin{aligned} &(\mathbf{m}(t) - \mathbf{m}(0), \phi) - \gamma\delta \int_0^t (M_s \Delta \mathbf{m}, \phi) - \kappa \int_0^t (\mathbf{m}, \phi) \\ &= \int_0^t \left(\frac{\gamma\delta}{M_s} |\nabla \mathbf{m}|^2 \mathbf{m}, \phi \right) - \int_0^t \left(\frac{\gamma\delta}{2M_s} (\Delta M_s^2) \mathbf{m}, \phi \right) - \gamma \int_0^t (\mathbf{m} \times \Delta \mathbf{m}, \phi). \end{aligned}$$

Differentiating this with respect to the time variable we see that $\mathbf{m} \in V(\Omega_{T_0}, \mathbb{R}^3)$ may be identified to be a strong solution of (3.1), (1.6)–(1.7) for $t \in (0, T_0)$. Hence we verified:

THEOREM 3.2. *Let $\mathbf{m}_0 \in W^{1,2}(\Omega, \mathbb{R}^3)$, $0 < M_s \in L^\infty(0, T; W^{2,2}(\Omega))$ be given. Then there exists a unique, local in time strong solution to (3.1), (1.6)–(1.7), which—by Lemma 3.1—is also a local in time strong solution to (1.5)–(1.7).*

According to the imbedding $W^{2,2}(\Omega) \subset C(\bar{\Omega})$ and the assumption $0 < M_s \in L^\infty(0, T; W^{2,2}(\Omega))$, we see that M_s always remains strictly positive. There arises a natural question: what will happen if $M_s \rightarrow 0$? The constants obtained from a priori estimates depend on M_s in such a way that they blow up if $M_s \rightarrow 0$. Therefore we do not allow M_s to vanish.

4. Convergence with optimal rates for Scheme A. A space-time discretization of (3.1) may produce iterates $\{\mathbf{M}^j\} \subset \mathbf{V}_h$, with $|\mathbf{M}^j(\mathbf{z})| \neq M_s(t_j, \mathbf{z})$ for $1 \leq j \leq J$ and $\mathbf{z} \in \mathcal{N}_h$. This is the motivation for the following projection scheme, which adopts the corresponding one for $M_s = \text{const}$ in [22, p. 139] to the present case.

Scheme A: Let $\mathbf{M}^0 \equiv \tilde{\mathbf{M}}^0 \in \mathbf{V}_h$. 1. For $j = 1, 2, \dots, J - 1$ find $\mathbf{M}^j \in \mathbf{V}_h$ such that for all $\Phi \in \mathbf{V}_h$ there holds

$$\begin{aligned} & \frac{1}{k} \left(\tilde{\mathbf{M}}^j - \mathbf{M}^{j-1}, \Phi \right)_h + \gamma \delta \left(M_s(t_j, \cdot) \nabla \tilde{\mathbf{M}}^j, \nabla \Phi \right) = \gamma \delta \left(\nabla \tilde{\mathbf{M}}^j, \nabla M_s(t_j, \cdot) \otimes \Phi \right) \\ & + \left(\left[\frac{\gamma \delta}{M_s(t_j, \cdot)} \left(|\nabla \tilde{\mathbf{M}}^{j-1}|^2 - \frac{1}{2} \Delta M_s^2(t_j, \cdot) \right) + \kappa(t_j, \cdot) \right] \tilde{\mathbf{M}}^j, \Phi \right) \\ & + \gamma \left(\tilde{\mathbf{M}}^{j-1} \times \nabla \tilde{\mathbf{M}}^j, \nabla \Phi \right). \end{aligned}$$

2. Compute $\mathbf{M}^j \in \mathbf{V}_h$ according to

$$\mathbf{M}^j(\mathbf{z}) = M_s(t_j, \mathbf{z}) \frac{\tilde{\mathbf{M}}^j(\mathbf{z})}{|\tilde{\mathbf{M}}^j(\mathbf{z})|} \quad \forall \mathbf{z} \in \mathcal{N}_h.$$

If we combine both steps, we obtain the following equation for iterates $\tilde{\mathbf{M}}^j : \Omega \rightarrow \mathbb{R}^3$,

$$\begin{aligned} & (d_t \tilde{\mathbf{M}}^j, \Phi)_h + \gamma \delta \left(M_s(t_j, \cdot) \nabla \tilde{\mathbf{M}}^j, \nabla \Phi \right) = \gamma \delta \left(\nabla \tilde{\mathbf{M}}^j, \nabla M_s(t_j, \cdot) \otimes \Phi \right) \\ (4.1) \quad & - \frac{1}{k} \left(\left[1 - \frac{M_s(t_{j-1}, \cdot)}{|\tilde{\mathbf{M}}^{j-1}|} \right] \tilde{\mathbf{M}}^{j-1}, \Phi \right)_h + \left(\left[\frac{\gamma \delta}{M_s(t_j, \cdot)} \left(|\nabla \tilde{\mathbf{M}}^{j-1}|^2 \right. \right. \right. \\ & \left. \left. \left. - \frac{1}{2} \Delta M_s^2(t_j, \cdot) \right) + \kappa(t_j, \cdot) \right] \tilde{\mathbf{M}}^j, \Phi \right) + \gamma \left(\tilde{\mathbf{M}}^{j-1} \times \nabla \tilde{\mathbf{M}}^j, \nabla \Phi \right) \quad \forall \Phi \in \mathbf{V}_h. \end{aligned}$$

As is now evident from the leading term in the second line, the projection method may be regarded as a semi-explicit penalization method. The following result asserts optimal convergence rates for solutions of Scheme A. Its proof uses an inductive argument, which has been developed in [22, Chapter 4] ($d = 2$), and used in [12] ($d = 3$) for the case $M_s = \text{const}$; we skip a proof of the following.

THEOREM 4.1. *Let $t_J \leq T_0$, where $[0, T_0)$ is the interval, where a strong solution to (3.1), (1.6)–(1.7) exists. For $k \leq k_0(T_0, M_s, \gamma \delta)$ sufficiently small, solutions $\{\tilde{\mathbf{M}}^j\}_{j=1}^J$ of Scheme A exist. Suppose that $\|\mathbf{M}^0 - \mathbf{m}_0\|_{W^{1,2}} \leq C(k + h)$. There exists*

a constant $C > 0$ independent from $k, h \geq 0$, such that

$$(4.2) \quad \max_{1 \leq j \leq J} \|\mathbf{M}(t_j, \cdot) - \tilde{\mathbf{M}}^j\|_{L^2} + \left(k \sum_{j=1}^J \|\mathbf{M}(t_j, \cdot) - \tilde{\mathbf{M}}^j\|_{W^{1,2}}^2 \right)^{1/2} \leq C(k + h).$$

Moreover, there holds

$$(4.3) \quad \max_{1 \leq j \leq J} \|M_s(t_j, \cdot) - |\tilde{\mathbf{M}}^j|\|_{L^2} \leq C(k + h).$$

Remark 4.1 (Extension of results to 3D). Let $\Omega \subset \mathbb{R}^3$. Carbou and Fabrie [10] have proved the local existence of a regular solution of (1.1), (1.6)–(1.7) (for $\mathbf{h}_{\text{eff}} = \Delta \mathbf{m}$) in the case $M_s = \text{const}$. For variable, strictly positive $M_s \in C^2(\overline{\Omega}_T)$, we may proceed accordingly then to generalize their result to 3D.

5. Construction of weak solutions. Scheme B. Let $\Omega \subset \mathbb{R}^3$. We consider a reformulation of (1.5), which has been proposed by Gilbert for the case $M_s = \text{const}$; cf. [19]. As in (3.4), we take the cross product of (3.1) with \mathbf{m} , and hence restate (1.5) (with $\mathbf{h}_{\text{eff}} = \Delta \mathbf{m}$) as

$$(5.1) \quad \mathbf{m}_t = \kappa \mathbf{m} - \gamma (1 + \delta^2) \mathbf{m} \times \Delta \mathbf{m} + \delta \frac{\mathbf{m}}{M_s} \times \mathbf{m}_t.$$

We introduce the notion of weak solutions of (5.1), (1.6)–(1.7), which generalizes strong solutions introduced in section 3. Let $\kappa \in C^1(\Omega_T)$.

DEFINITION 5.1. Let $\mathbf{m}_0 \in L^\infty(\Omega, \mathbb{R}^3) \cap W^{1,2}(\Omega, \mathbb{R}^3)$, such that $|\mathbf{m}_0(\cdot)| = M_s(0, \cdot)$ almost everywhere in Ω . A function $\mathbf{m} : \Omega_T \rightarrow \mathbb{R}^3$ is called a weak solution of (5.1), (1.6)–(1.7) if

- (1) $\partial_t \mathbf{m} \in L^2(\Omega_T, \mathbb{R}^3)$, and $\mathbf{m} \in L^\infty(0, T; W^{1,2}(\Omega, \mathbb{R}^3))$, with $\mathbf{m}(0, \cdot) = \mathbf{m}_0$ in the sense of traces,
- (2) $|\mathbf{m}| \in L^\infty(\Omega_T)$, and satisfies (1.8) almost everywhere in Ω_T ,
- (3) for all $\phi \in C^\infty(\overline{\Omega}_T, \mathbb{R}^3)$, there holds

$$(5.2) \quad \int_{\Omega_T} \left[\langle \mathbf{m}_t, \phi \rangle - \kappa \langle \mathbf{m}, \phi \rangle - \frac{\delta}{M_s} \langle \mathbf{m} \times \mathbf{m}_t, \phi \rangle - \gamma (1 + \delta^2) \langle \mathbf{m} \times \nabla \mathbf{m}, \nabla \phi \rangle \right] dx dt = 0.$$

In the remainder of this section, we verify existence of weak solutions of (5.1), (1.6)–(1.7), by using a practical finite-element based scheme.

Scheme B: Let $\kappa \in C(\overline{\Omega}_T)$ and $\mathbf{M}^0 \in \mathbf{V}_h$. For $j = 0, 1, 2, \dots, J - 1$ find $\mathbf{M}^{j+1} \in \mathbf{V}_h$ such that for all $\Phi \in \mathbf{V}_h$ there holds

$$\begin{aligned} & (d_t \mathbf{M}^{j+1}, \Phi)_h - \left(\kappa_{j+1} \mathbf{M}^{j+1/2}, \Phi \right)_h - \delta \left(\frac{\mathbf{M}^j}{M_s^{j+1/2}} \times d_t \mathbf{M}^{j+1}, \Phi \right)_h \\ & = -\gamma (1 + \delta^2) \left(\mathbf{M}^{j+1/2} \times \tilde{\Delta}_h \mathbf{M}^{j+1/2}, \Phi \right)_h. \end{aligned}$$

Remark 5.1. 1. The linear second term in Scheme B is motivated from the identity

$$\mathbf{M}^j \times d_t \mathbf{M}^{j+1} = \left(\mathbf{M}^{j+1/2} - \frac{k}{2} d_t \mathbf{M}^{j+1} \right) \times d_t \mathbf{M}^{j+1} = \mathbf{M}^{j+1/2} \times d_t \mathbf{M}^{j+1}.$$

2. As is detailed in [6] for the case $M_s \equiv \text{const}$, solutions to Scheme B satisfy a perturbed version of a discretization of (3.1), which is due to the competition of local

and nonlocal aspects in fully discrete finite-element based discretizations of (3.1) and (5.1), respectively. First, we verify the existence of solutions to Scheme B.

LEMMA 5.1. *Let $T > 0$, $\kappa \in C(\overline{\Omega}_T)$, $J + 1 = \lceil T/k \rceil$, and $\mathbf{M}^0 \in \mathbf{V}_h$ be given. Then, for a sufficiently small $k \leq k_0(T)$, there exists $\{\mathbf{M}^{j+1}\}_{j=0}^J \subset \mathbf{V}_h$, which solves Scheme B.*

Proof. Let $\mathbf{M}^j \in \mathbf{V}_h$ be given. We define a continuous functional $\mathbf{F} : \mathbf{V}_h \rightarrow \mathbf{V}_h$ by setting for $\mathbf{W} \in \mathbf{V}_h$

$$\mathbf{F}(\mathbf{W}) = \frac{2}{k} \{ \mathbf{W} - \mathbf{M}^j \} - \mathcal{I}_h \left[\kappa_{j+1} \mathbf{W} + \frac{2\delta}{kM_s^{j+1/2}} \mathbf{W} \right. \\ \left. \times \left[\mathbf{W} - \mathbf{M}^j \right] - \gamma(1 + \delta^2) \mathbf{W} \times \tilde{\Delta}_h \mathbf{W} \right].$$

For $k^{-1} > \max_{\Omega_T} \kappa$, and all $\mathbf{W} \in \mathbf{V}_h$ such that $(1 - k \max_{\Omega_T} \kappa) \|\mathbf{W}\|_h \geq \|\mathbf{M}^j\|$, we have

$$\begin{aligned} (\mathbf{F}(\mathbf{W}), \mathbf{W})_h &= \frac{2}{k} \left(\|\mathbf{W}\|_h^2 - (\mathbf{M}^j, \mathbf{W})_h \right) - \left(\kappa(t_{j+1}, \cdot) \mathbf{W}, \mathbf{W} \right)_h \\ &\geq \frac{2}{k} \|\mathbf{W}\|_h \left((1 - k \max_{\Omega_T} \kappa) \|\mathbf{W}\|_h - \|\mathbf{M}^j\|_h \right) \\ &\geq 0. \end{aligned}$$

Hence, Brouwer’s fixed point theorem (see also Evans [17, p. 493]) implies the existence of $\mathbf{W}^* \in \mathbf{V}_h$ such that $\mathbf{F}(\mathbf{W}^*) = 0$. Then, $\mathbf{M}^{j+1} := 2\mathbf{W}^* - \mathbf{M}^j$ solves (5.3). \square

We study stability properties of discrete solutions from Scheme B. This is established in the next lemmas.

LEMMA 5.2. *Let the assumptions of Lemma 5.1 be fulfilled, and $\kappa \in C^2(\Omega_T)$. Then*

- (i) $\max_{\mathbf{z} \in \mathcal{N}_h} \max_{0 \leq j \leq J+1} |\mathbf{M}^j(\mathbf{z})|^2 + \max_{\mathbf{z} \in \mathcal{N}_h} \max_{1 \leq j \leq J+1} |d_t |\mathbf{M}^j(\mathbf{z})|^2| \leq C,$
- (ii) $\|\nabla \mathbf{M}^{j+1}\|^2 + k \sum_{j=0}^J \frac{\delta}{1 + \delta^2} \|d_t \mathbf{M}^{j+1}\|_h^2 \leq C,$
- (iii) $k \sum_{j=0}^J \|\mathbf{M}^{j+1/2} \times \tilde{\Delta}_h \mathbf{M}^{j+1/2}\|_h^2 \leq C,$

where $C \equiv C(t_J, \gamma, \delta, M_s)$.

Proof. To verify assertion (i), choose $\Phi = \mathbf{M}^{j+1/2}(\mathbf{z})\varphi_{\mathbf{z}}$ for Scheme B, and observe Remark 5.1 to find

$$(5.3) \quad d_t |\mathbf{M}^{j+1}(\mathbf{z})|^2 = 2\kappa(t_{j+1}, \mathbf{z}) |\mathbf{M}^{j+1/2}(\mathbf{z})|^2 \\ \leq C \left(|\mathbf{M}^{j+1}(\mathbf{z})|^2 + |\mathbf{M}^j(\mathbf{z})|^2 \right).$$

Summation of (5.3) over j followed by an application of the discrete version of Gronwall’s lemma yields to

$$\max_{\mathbf{z} \in \mathcal{N}_h} \max_{0 \leq j \leq J+1} |\mathbf{M}^j(\mathbf{z})|^2 \leq C.$$

The rest of assertion (i) now follows from the last inequality and (5.3).

In order to verify (ii), we first choose $\Phi = -\tilde{\Delta}_h \mathbf{M}^{j+1/2}$. We obtain

$$\begin{aligned} & -(\kappa(t_{j+1}, \cdot) \mathbf{M}^{j+1/2}, -\tilde{\Delta}_h \mathbf{M}^{j+1/2})_h = -(\mathcal{I}_h[\kappa(t_{j+1}, \cdot) \mathbf{M}^{j+1/2}], \tilde{\Delta}_h \mathbf{M}^{j+1/2})_h - I \\ & \geq -C \|\kappa(t_{j+1}, \cdot)\|_{C(\bar{\Omega})} \|\nabla \mathbf{M}^{j+1/2}\|^2 \\ & - \left| (\mathbf{M}^{j+1/2} \otimes \nabla \kappa(t_{j+1}, \cdot), \nabla \mathbf{M}^{j+1/2}) \right| - I + II, \end{aligned}$$

with error terms I, II , which can be controlled by standard interpolation estimates, using $\nabla^2 \mathbf{M}^{j+1/2}|_K = 0$, for all $K \in \mathcal{T}_h$,

$$\begin{aligned} I & := \left([\mathbf{Id} - \mathcal{I}_h](\kappa(t_{j+1}, \cdot) \mathbf{M}^{j+1/2}), \tilde{\Delta}_h \mathbf{M}^{j+1/2} \right)_h \\ & \leq Ch^2 \|\kappa(t_{j+1}, \cdot)\|_{C^2(\Omega)} \|\mathbf{M}^{j+1/2}\|_{W^{1,2}(\Omega)} \|\Delta_h \mathbf{M}^{j+1/2}\|, \\ II & := \left(\nabla[\mathbf{Id} - \mathcal{I}_h](\kappa(t_{j+1}, \cdot) \mathbf{M}^{j+1/2}), \nabla \mathbf{M}^{j+1/2} \right) \\ & \leq Ch \|\kappa(t_{j+1}, \cdot)\|_{C^2(\Omega)} \|\mathbf{M}^{j+1/2}\|_{W^{1,2}(\Omega)}^2. \end{aligned}$$

Putting things together, by inverse estimate we find for some $C \equiv C(\kappa, \gamma, \delta) > 0$,

$$(5.4) \quad \frac{1}{2} d_t \|\nabla \mathbf{M}^{j+1}\|^2 \leq C(1+h) \|\nabla \mathbf{M}^{j+1}\|^2 - \delta \left(\frac{\mathbf{M}^j}{M_s^{j+1/2}} \times d_t \mathbf{M}^{j+1}, \tilde{\Delta}_h \mathbf{M}^{j+1/2} \right)_h.$$

Choosing $\Phi = \mathcal{I}_h \left[\frac{d_t \mathbf{M}^{j+1}}{M_s^{j+1/2}} \right]$ in Scheme B yields

$$\begin{aligned} \frac{\delta}{\gamma(1+\delta^2)} \left\| \frac{d_t \mathbf{M}^{j+1}}{\sqrt{M_s^{j+1/2}}} \right\|_h^2 & = \frac{\delta}{\gamma(1+\delta^2)} \left(\kappa(t_{j+1}, \cdot) \frac{\mathbf{M}^{j+1/2}}{M_s^{j+1/2}}, d_t \mathbf{M}^{j+1} \right)_h \\ & - \delta \left(\frac{\mathbf{M}^{j+1/2}}{M_s^{j+1/2}} \times \tilde{\Delta}_h \mathbf{M}^{j+1/2}, d_t \mathbf{M}^{j+1} \right)_h. \end{aligned}$$

Now, adding (5.4) to this relation, thanks to Remark 5.1 and Young's inequality, we find

$$d_t \|\nabla \mathbf{M}^{j+1}\|^2 + \frac{\delta}{\gamma(1+\delta^2)} \left\| \frac{d_t \mathbf{M}^{j+1}}{\sqrt{M_s^{j+1/2}}} \right\|_h^2 \leq C(1+h) \left(1 + \|\nabla \mathbf{M}^{j+1}\|^2 \right).$$

We employ discrete Gronwall's inequality, and assertion (ii) follows. Assertion (iii) is now an immediate consequence from Scheme B. \square

Note that (5.3) is the discrete version of property (1.8) for solutions of Scheme A at every node $\mathbf{z} \in \mathcal{N}_h$; hence, we can only expect that $|\mathbf{M}^j(\mathbf{z})|^2 \approx M_s^2(t_j, \mathbf{z})$, for all $1 \leq j \leq J$, and all $\mathbf{z} \in \mathcal{N}_h$.

DEFINITION 5.2. For $(t, \mathbf{x}) \in [t_j, t_{j+1}) \times \Omega$ we define

$$\begin{aligned} \mathcal{M}_{k,h}(t, \mathbf{x}) & := \frac{t-t_j}{k} \mathbf{M}^{j+1}(\mathbf{x}) + \frac{t_{j+1}-t}{k} \mathbf{M}^j(\mathbf{x}) = \mathbf{M}^j(\mathbf{x}) + (t-t_j) d_t \mathbf{M}^{j+1}(\mathbf{x}), \\ \mathcal{M}_{k,h}^-(t, \mathbf{x}) & := \mathbf{M}^j(\mathbf{x}), \quad \mathcal{M}_{k,h}^+(t, \mathbf{x}) := \mathbf{M}^{j+1}(\mathbf{x}), \quad \overline{\mathcal{M}}_{k,h}(t, \mathbf{x}) := \mathbf{M}^{j+1/2}(\mathbf{x}). \end{aligned}$$

For almost every $T' > 0$, assertion (ii) of Lemma 5.2 may be rewritten as

$$(5.5) \quad \|\nabla \mathcal{M}_{k,h}^+(T', \cdot)\|_{L^2}^2 + \frac{\delta}{1+\delta^2} \int_0^{T'} \|(\mathcal{M}_{k,h})_t(s, \cdot)\|_h^2 dt \leq C.$$

This bound yields the existence of some $\mathbf{m} \in W^{1,2}(\Omega_T, \mathbb{R}^3)$, which is the weak limit (as $k, h \rightarrow 0$) of a subsequence $\{\mathbf{M}_{k,h}\}$ such that

$$(5.6) \quad \begin{aligned} \mathcal{M}_{k,h} &\rightharpoonup \mathbf{m} && \text{in } W^{1,2}(\Omega_T, \mathbb{R}^3), \\ \nabla \mathcal{M}_{k,h}^+, \nabla \mathcal{M}_{k,h}^-, \nabla \overline{\mathcal{M}}_{k,h} &\rightharpoonup \nabla \mathbf{m} && \text{in } L^2(\Omega_T, \mathbb{R}^3), \\ \mathcal{M}_{k,h}^-, \mathcal{M}_{k,h}^+, \overline{\mathcal{M}} &\rightarrow \mathbf{m} && \text{in } L^2(\Omega_T, \mathbb{R}^3), \end{aligned}$$

where we use the Aubin–Lions compactness result to obtain (5.6)₃. Dropping the index $\{k, h\}$ on $\mathcal{M}_{k,h}$, Scheme B may be rewritten in the following form: taking $\Phi(t, \cdot) := \mathcal{I}_h \phi(t, \cdot)$ for $\phi \in C^\infty(\Omega_T, \mathbb{R}^3)$ there holds

$$(5.7) \quad \int_0^T \left[(\mathcal{M}_t, \Phi)_h - (\kappa^+ \overline{\mathcal{M}}, \Phi)_h - \delta \left(\mathcal{M}^- \times \frac{\mathcal{M}_t}{M_s}, \Phi \right)_h + \gamma (1 + \delta^2) \left(\overline{\mathcal{M}} \times \tilde{\Delta}_h \overline{\mathcal{M}}, \Phi \right)_h \right] dt = 0.$$

THEOREM 5.1. *Suppose that the assumptions of Lemma 5.2 are valid, and*

$$\mathbf{M}^0 \rightarrow \mathbf{m}_0 \quad \text{in } W^{1,2}(\Omega, \mathbb{R}^3), \quad \text{and} \quad |\mathbf{M}^0(\mathbf{z})| \rightarrow M_s(0, \mathbf{z}) \quad \forall \mathbf{z} \in \mathcal{N}_h \quad (h \rightarrow 0).$$

For $k, h \rightarrow 0$ there exists $\mathbf{m} \in W^{1,2}(\Omega_T, \mathbb{R}^3)$ such that iterates $\{\mathcal{M}_{k,h}\}$ of Scheme B subconverge to \mathbf{m} in $W^{1,2}(\Omega_T, \mathbb{R}^3)$, and \mathbf{m} is a weak solution to (5.1), (1.6)–(1.7).

Remark 5.2. It is not known if iterates of Scheme B converge at optimal rates to (locally existing) strong solutions of (1.5)–(1.7): this shortcoming reflects the known, but seemingly confusing situation even in the simpler case $M_s = \text{const}$ in [6, 7], where (a simplified version of) Scheme B was developed to construct weak solutions in the limit, but where convergence with rates in the presence of existing strong solutions is still an open problem.

Proof. Step 1. Verification of (i), (iii) of Definition 5.1. Effects of reduced integration need to be controlled by using (2.3): For almost all $t \in (0, T)$, we have

$$|(\mathcal{M}_t, \Phi) - (\mathcal{M}_t, \Phi)_h| \leq Ch \|\mathcal{M}_t\|_{L^2(\Omega)} \|\nabla \Phi\|_{L^2(\Omega)}.$$

This bound, and (5.5), together with standard Lagrange interpolation results yields to

$$(5.8) \quad \int_0^T (\mathcal{M}_t, \Phi)_h dt \rightarrow \int_0^T (\mathbf{m}_t, \phi) dt \quad (k, h \rightarrow 0).$$

In a similar fashion, we obtain

$$(5.9) \quad \int_0^T (\kappa^+ \overline{\mathcal{M}}, \Phi)_h dt \rightarrow \int_0^T (\kappa \mathbf{m}, \phi) dt \quad (k, h \rightarrow 0).$$

The convergence

$$(5.10) \quad \int_0^T \left(\frac{\overline{\mathcal{M}}}{M_s} \times \mathcal{M}_t, \Phi \right)_h dt \rightarrow \int_0^T \left(\frac{\mathbf{m}}{M_s} \times \mathbf{m}_t, \phi \right) dt \quad (k, h \rightarrow 0)$$

again uses (2.3), (5.5), and Lemma (5.2), (i) to control effects due to reduced integration, and (5.6)₃ together with (5.6)₂.

The last term in (5.7) requires a more detailed study. We write

$$\begin{aligned}
 - \left(\overline{\mathcal{M}} \times \tilde{\Delta}_h \overline{\mathcal{M}}, \Phi \right)_h &= \left(\overline{\mathcal{M}} \times \Phi, \tilde{\Delta}_h \overline{\mathcal{M}} \right)_h = \left([\text{Id} - \mathcal{I}_h] \left(\overline{\mathcal{M}} \times \Phi \right), \tilde{\Delta}_h \overline{\mathcal{M}} \right)_h \\
 + \left(\nabla [\text{Id} - \mathcal{I}_h] \left(\overline{\mathcal{M}} \times \Phi \right), \nabla \overline{\mathcal{M}} \right) &- \left(\nabla \left[\overline{\mathcal{M}} \times \Phi \right], \nabla \overline{\mathcal{M}} \right) =: I + II - III.
 \end{aligned}$$

Control of I uses the bound $\|\tilde{\Delta}_h \Psi\| \leq Ch^{-1} \|\nabla \Psi\|_{L^2}$, and estimates of nodal interpolation,

$$\begin{aligned}
 I &\leq Ch^2 h^{-1} \sum_{K \in \mathcal{T}} \|D^2(\overline{\mathcal{M}} \times \Phi)\|_{L^2(K)} \|\nabla \overline{\mathcal{M}}\|_{L^2(K)} \\
 &\leq Ch \|\nabla \overline{\mathcal{M}}\| \|\Phi\|_{C^2} \|\nabla \overline{\mathcal{M}}\|.
 \end{aligned}$$

Similarly, we obtain

$$II \leq Ch \sum_{K \in \mathcal{T}} \|D^2(\overline{\mathcal{M}} \times \Phi)\|_{L^2(K)} \|\nabla \overline{\mathcal{M}}\|_{L^2(K)} \leq Ch \|\nabla \overline{\mathcal{M}}\| \|\Phi\|_{C^2} \|\nabla \overline{\mathcal{M}}\|.$$

For the third term, we use the vector identity $\langle \nabla \mathbf{a}, \nabla[\mathbf{a} \times \mathbf{b}] \rangle = \langle \nabla \mathbf{a}, \mathbf{a} \times \nabla \mathbf{b} \rangle$, for $\mathbf{a}, \mathbf{b} \in W^{1,2}(\Omega, \mathbb{R}^3)$ to verify

$$III = \left(\nabla \left[\overline{\mathcal{M}} \times \Phi \right], \nabla \overline{\mathcal{M}} \right) = \left(\overline{\mathcal{M}} \times \nabla \Phi, \nabla \overline{\mathcal{M}} \right).$$

Putting things together then yields

$$\begin{aligned}
 (5.11) \quad \int_0^T \left(\overline{\mathcal{M}} \times \tilde{\Delta}_h \overline{\mathcal{M}}, \Phi \right)_h ds &\rightarrow - \int_0^T (\mathbf{m} \times \nabla \phi, \nabla \mathbf{m}) dt \\
 &= - \int_0^T (\nabla[\mathbf{m} \times \phi], \nabla \phi) ds \quad (k, h \rightarrow 0).
 \end{aligned}$$

We may now insert (5.8)–(5.11) into (5.7) to validate (ii) of Definition 5.1 for $\mathbf{m} : \Omega_T \rightarrow \mathbb{R}^3$.

Step 2. Verification of (ii) of Definition 5.1. The function $|\mathbf{m}|$ solves

$$(5.12) \quad \frac{d}{dt} |\mathbf{m}|^2 = 2\kappa |\mathbf{m}|^2 \quad \text{a.e. in } \Omega_T.$$

Its verification is split into two parts:

A) *Verification of (5.12) for $\mathbf{z} \in \mathcal{N}_h$.* For all $t \in [t_{m-1}, t_m)$, there hold

$$(5.13) \quad |\mathcal{M}_{k,h}(t, \mathbf{z})|^2 = |\mathcal{M}_{k,h}^-(t, \mathbf{z})|^2 + 2(t - t_{m-1})\kappa^+(t, \mathbf{z}) |\overline{\mathcal{M}}_{k,h}(t, \mathbf{z})|^2 \quad \forall \mathbf{z} \in \mathcal{N}_h,$$

$$(5.14) \quad |\mathcal{M}_{k,h}(t, \mathbf{x})|^2 = \left| \sum_{\mathbf{z}_i \in \mathcal{N}_h \cap \overline{K}} \mathcal{M}_{k,h}(t, \mathbf{z}_i) \varphi_{\mathbf{z}_i}(\mathbf{x}) \right|^2 \quad \forall \mathbf{x} \in K.$$

For every $\mathbf{z} \in \mathcal{N}_h$, consider $\{|\mathcal{M}_{k,h}(\cdot, \mathbf{z})|^2\}_k$. Let $0 \leq s \leq t \leq T$ such that $t \in$

$[t_{m-1}, t_m]$, and $s \in [t_{j-1}, t_j]$, for some $t_j \leq t_m$. Then

$$\begin{aligned}
 & |\mathcal{M}_{k,h}(t, \mathbf{z})|^2 - |\mathcal{M}_{k,h}(s, \mathbf{z})|^2 = |\mathcal{M}_{k,h}(t, \mathbf{z})|^2 - |\mathbf{M}^{m-1}(\mathbf{z})|^2 \\
 & \quad + \sum_{\ell=j}^{m-1} \{ |\mathbf{M}^\ell(\mathbf{z})|^2 - |\mathbf{M}^{\ell-1}(\mathbf{z})|^2 \} + |\mathbf{M}^{j-1}(\mathbf{z})|^2 - |\mathcal{M}_{k,h}(s, \mathbf{z})|^2 \\
 (5.15) \quad & = 2(t - t_{m-1}) \left(\kappa|_{[t_{m-1}, t_m]} \right)^+ (\mathbf{z}) |\overline{\mathbf{M}}_{k,h}(t, \mathbf{z})|^2 + 2k \sum_{\ell=j}^{k-1} \kappa(t_\ell, \mathbf{z}) |\mathbf{M}^{\ell-1/2}(\mathbf{z})|^2 \\
 & \quad + 2(t_{j-1} - s) \left(\kappa|_{[t_{j-1}, t_j]} \right)^+ (\mathbf{z}) |\overline{\mathbf{M}}_{k,h}(s, \mathbf{z})|^2,
 \end{aligned}$$

and uniform (Lipschitz-)equicontinuity of $\{|\mathcal{M}_{k,h}(\cdot, \mathbf{z})|^2\}_k$, for every $\mathbf{z} \in \mathcal{N}_h$ then follows from the computation

$$\begin{aligned}
 & \| |\mathcal{M}_{k,h}(t, \mathbf{z})|^2 - |\mathcal{M}_{k,h}(s, \mathbf{z})|^2 \|_{C([0, T])} \leq C \{ (t - t_{m-1}) + (t_{m-1} - t_j) + (t_j - s) \} \\
 (5.16) \quad & \leq C |t - s| \quad \forall \mathbf{z} \in \mathcal{N}_h.
 \end{aligned}$$

By the Arzela–Ascoli theorem, for every $\mathbf{z} \in \mathcal{N}_h$ there exist a subsequence $\{|\mathcal{M}_{k,h}(\cdot, \mathbf{z})|^2\}_k$, and $\chi^2(\cdot, \mathbf{z}) \in C([0, T])$, such that for $k \rightarrow 0$,

$$\max_{\mathbf{z} \in \mathcal{N}_h} \max_{t \in [0, T]} \left| |\mathcal{M}_{k,h}(t, \mathbf{z})|^2 - \chi^2(t, \mathbf{z}) \right| \rightarrow 0.$$

We need to verify that $t \mapsto \chi^2(t, \mathbf{z})$ solves (1.8), for all $\mathbf{z} \in \mathcal{N}_h$. Let $t \in [t_{m-1}, t_m]$. By construction, there holds

$$\begin{aligned}
 & |\mathcal{M}_{k,h}(t, \mathbf{z})|^2 = |\mathbf{M}^0(\mathbf{z})|^2 + 2 \int_{t_{m-1}}^t \left\{ \kappa^+(s, \mathbf{z}) |\mathbf{M}^{m-1/2}(\mathbf{z})|^2 - \kappa(s, \mathbf{z}) |\mathcal{M}_{k,h}(s, \mathbf{z})|^2 \right\} ds \\
 (5.17) \quad & + 2 \sum_{\ell=1}^{m-1} \int_{t_{\ell-1}}^{t_\ell} \left\{ \kappa^+(s, \mathbf{z}) |\mathbf{M}^{\ell-1/2}(\mathbf{z})|^2 - \kappa(s, \mathbf{z}) |\mathcal{M}_{k,h}(s, \mathbf{z})|^2 \right\} ds \\
 & + 2 \int_0^t \kappa(s, \mathbf{z}) |\mathcal{M}_{k,h}(s, \mathbf{z})|^2 ds.
 \end{aligned}$$

By uniform equicontinuity of $\{|\mathcal{M}_{k,h}(\cdot, \mathbf{z})|^2\}_k$, Lipschitz continuity of $t \mapsto \kappa(t, \mathbf{z})$, for every $\mathbf{z} \in \mathcal{N}_h$, and parallelogram identity together with the bound of Lemma 5.1, (iii) to conclude for all $\varepsilon > 0$, and sufficiently small $k = k(\varepsilon)$,

$$\sum_{\ell=1}^m \int_{t_{\ell-1}}^{t_\ell} \left| \kappa^+(s, \mathbf{z}) |\mathbf{M}^{\ell-1/2}(\mathbf{z})|^2 - \kappa(s, \mathbf{z}) |\mathcal{M}_{k,h}(s, \mathbf{z})|^2 \right| ds \leq \varepsilon.$$

Together with uniform convergence of $|\mathcal{M}_{k,h}(\cdot, \mathbf{z})|^2 \rightarrow \chi^2(\cdot, \mathbf{z})$ ($k \rightarrow 0$) on $[0, T]$, (1.8) holds for the limit $\chi^2(\cdot, \mathbf{z})$, for every $\mathbf{z} \in \mathcal{N}_h$.

B) *Verification of (5.12) for almost all $(t, \mathbf{x}) \in \Omega_T$.* Let $\mathbf{x} \in \overline{K} = \text{conv}(\mathbf{z}_1, \dots, \mathbf{z}_4)$, and fix one $\mathbf{z}_* = \min_i \{ |\mathbf{z}_i - \mathbf{x}| \}$. There exist $\xi_* \equiv \xi_*(\mathbf{x}, \mathbf{z}_*) \in \mathbb{S}^2$, and $0 \leq h_*(\mathbf{x}, \mathbf{z}_*) < h$, such that $\mathcal{M}_{k,h}(t, \mathbf{x}) = \mathcal{M}_{k,h}(t, \mathbf{z}_*) + h_* \nabla \mathcal{M}_{k,h}(t, \cdot) \xi_*$ owing $\nabla \mathcal{M}_{k,h}(t, \cdot)|_K = \text{const.}$, and

$$(5.18) \quad |\mathcal{M}_{k,h}(t, \mathbf{x})|^2 = |\mathcal{M}_{k,h}(t, \mathbf{z}_*)|^2 + 2h_* \left\langle \mathcal{M}_{k,h}(t, \mathbf{z}_*), \nabla \mathcal{M}_{k,h}(t, \cdot) \xi_* \right\rangle + h_*^2 |\nabla \mathcal{M}_{k,h}(t, \cdot) \xi_*|^2.$$

For the leading term on the right-hand side, we have (5.13). Therefore, we modify argument (5.17) in the way that instead of adding and subtracting $\int_0^t \kappa(s, \mathbf{z}) |\mathcal{M}_{k,h}(s, \mathbf{z})|^2 ds$ on the right-hand side, we choose $\pm \int_0^t \kappa(s, \mathbf{x}) |\mathcal{M}_{k,h}(s, \mathbf{x})|^2 ds$. For all $\mathbf{x} \in \Omega$, there holds

$$\begin{aligned}
 & |\mathcal{M}_{k,h}(t, \mathbf{x})|^2 - |\mathbf{M}^0(\mathbf{x})|^2 - 2 \int_0^t \kappa(s, \mathbf{x}) |\mathcal{M}_{k,h}(s, \mathbf{x})|^2 ds \\
 &= [|\mathbf{M}^0(\mathbf{z}_*)|^2 - |\mathbf{M}^0(\mathbf{x})|^2] + 2 \int_{t_{m-1}}^t \left\{ \kappa^+(s, \mathbf{z}) [|\overline{\mathcal{M}}_{k,h}(s, \mathbf{z})|^2 \right. \\
 &\quad \left. - |\mathcal{M}_{k,h}(s, \mathbf{x})|^2] - [\kappa(s, \mathbf{x}) - \kappa^+(s, \mathbf{z})] |\mathcal{M}_{k,h}(s, \mathbf{x})|^2 \right\} ds \\
 (5.19) \quad &+ 2 \sum_{\ell=1}^{m-1} \int_{t_{\ell-1}}^{t_\ell} \left\{ \kappa^+(s, \mathbf{z}) |\overline{\mathcal{M}}_{k,h}(s, \mathbf{z})|^2 - \kappa(s, \mathbf{x}) |\mathcal{M}_{k,h}(s, \mathbf{x})|^2 \right\} ds \\
 &+ 2h_* \langle \mathcal{M}_{k,h}(t, \mathbf{z}_*), \nabla \mathcal{M}_{k,h}(t, \cdot) \xi_* \rangle + h_*^2 |\nabla \mathcal{M}_{k,h}(t, \cdot) \xi_*|^2 \\
 &\leq Ch_* \left[\|\nabla \mathbf{M}^0\|_{L^\infty} \max_{\mathbf{z}_i \in \mathcal{N}_h \cap \overline{K}} |\mathbf{M}^0(\mathbf{z}_i)| + \|\kappa\|_{L^\infty(\Omega_T)} \|\mathcal{M}_{k,h}\|_{L^\infty(\Omega_T)} \right. \\
 &\quad \left. \int_{t_{m-1}}^t |\nabla \overline{\mathcal{M}}_{k,h}(s, \cdot)| ds \right] \\
 &+ (k+h) \|\kappa\|_{W^{1,\infty}(\Omega_T)} \|\mathcal{M}_{k,h}\|_{L^\infty(\Omega_T)}^2 + Ck \|\mathcal{M}_{k,h}\|_{L^\infty(\Omega_T)} \\
 &\quad \int_{t_{m-1}}^t |\partial_t \mathcal{M}_{k,h}(s, \mathbf{x})| ds \\
 &+ Ch \|\mathcal{M}_{k,h}\|_{L^\infty(\Omega_T)} \|\nabla \mathcal{M}_{k,h}(t, \cdot)\|_{L^\infty(\Omega)} + h^2 \|\nabla \mathcal{M}_{k,h}(t, \cdot)\|_{L^\infty(\Omega)}^2,
 \end{aligned}$$

where we use binomial formula, differentiability, and boundedness of $\kappa : \Omega_T \rightarrow \mathbb{R}$, the estimate

$$\|\mathcal{M}_{k,h}^+ - \mathcal{M}_{k,h}\| + \|\overline{\mathcal{M}}_{k,h} - \mathcal{M}_{k,h}\| \leq 2k \|\partial_t \mathcal{M}_{k,h}\|,$$

and Lemma 5.2. Integration over Ω_T of (5.19) then leads to

$$\int_{\Omega_T} \left| |\mathcal{M}_{k,h}(s, \mathbf{x})|^2 - |\mathbf{M}^0(\mathbf{x})|^2 - 2 \int_0^s \kappa(\tilde{s}, \mathbf{x}) |\mathcal{M}_{k,h}(\tilde{s}, \mathbf{x})|^2 d\tilde{s} \right| dx ds \rightarrow 0 \quad (k, h \rightarrow 0).$$

Because of binomial formula and (5.6)₂, we may pass to limits in every term, which verifies (1.8) almost everywhere in Ω_T for $\mathbf{m} : \Omega_T \rightarrow \mathbb{R}^3$. \square

6. Solution of the nonlinear system in Scheme B. We use a simple fixed-point iterative algorithm to solve the nonlinear system in each step of Scheme B. Similar fixed-point algorithms were employed in the context of the LLG and Maxwell-LLG equations; see [5, 6]. We solve the nonlinear system for $\mathbf{W}_h := \mathbf{M}_h^{j+1/2}$. The time derivative $d_t \mathbf{m}_h^{j+1}$ is replaced by $\frac{2}{k} (\mathbf{W}_h - \mathbf{M}_h^j)$. After linearization of the nonlinear term $(\mathbf{W}_h \times \tilde{\Delta}_h \mathbf{W}_h, \Phi)_h$ and using the identity $\mathbf{M}_h^j \times d_t \mathbf{M}_h^{j+1} = -\frac{2}{k} \mathbf{M}_h^{j+1/2} \times \mathbf{M}_h^j$, we obtain the following algorithm.

ALGORITHM 6.1. Set $\mathbf{W}_h^0 := \mathbf{M}_h^j$ and $\ell := 0$.

(i) Compute $\mathbf{W}_h^{\ell+1} \in \mathbf{V}_h$ such that for all $\Phi \in \mathbf{V}_h$ there holds

$$(6.1) \quad \frac{2}{k} (\mathbf{W}_h^{\ell+1}, \Phi)_h - (\kappa^{j+1} \mathbf{W}_h^{\ell+1}, \Phi)_h - \frac{2\delta}{k} \left(\frac{\mathbf{M}_h^j}{M_s^{j+1/2}} \times \mathbf{W}_h^{\ell+1}, \Phi \right)_h + \gamma(1 + \delta^2) \left(\mathbf{W}_h^{\ell+1} \times \tilde{\Delta}_h \mathbf{W}_h^\ell, \Phi \right)_h = \frac{2}{k} \left(\mathbf{M}_h^j, \Phi \right)_h.$$

(ii) For fixed $\varepsilon > 0$, stop and set $\mathbf{M}_h^{j+1} := 2\mathbf{W}_h^{\ell+1} - \mathbf{M}_h^j$, once

$$(6.2) \quad \|\mathbf{W}_h^{\ell+1} - \mathbf{W}_h^\ell\|_h \leq \varepsilon.$$

(iii) Set $\ell := \ell + 1$ and go to (i).

We give a condition, which is sufficient for convergence for every $1 \leq j \leq J$.

LEMMA 6.1. Suppose that $\|\mathbf{M}_h^j\|_{L^\infty} \leq C_0$. For all $\ell \geq 0$ there exists a unique solution to (6.1). Further, there holds

$$(6.3) \quad \|\mathbf{W}_h^{\ell+1} - \mathbf{W}_h^\ell\|_h \leq \Theta \|\mathbf{W}_h^\ell - \mathbf{W}_h^{\ell-1}\|_h,$$

with $\Theta < 1$ provided that $k < \frac{(2-k\|\kappa^{j+1}\|_{L^\infty})h^2}{\gamma(1+\delta^2)C_0C}$ is sufficiently small, where $C > 0$ only depends on the geometry of the mesh. For given $\mathbf{M}_h^j \in \mathbf{V}_h$ such that $|\mathbf{M}_h^j(\mathbf{z})| = M_s(t_j, \mathbf{z})$ for all $\mathbf{z} \in \mathcal{N}_h$, by Banach fixed point theorem, the contraction property (6.3) then implies the existence of a unique $\mathbf{M}_h^{j+1} \in \mathbf{V}_h$, which solves Scheme B.

Proof. In order to prove the existence of $\mathbf{W}_h^{\ell+1} \in \mathbf{V}_h$ for $\ell \geq 0$ it suffices to show that the bilinear form $a : \mathbf{V}_h \times \mathbf{V}_h \rightarrow \mathbb{R}$ defined by the left-hand side of (6.1) is positive definite. In order to do so, we set $\Phi = \mathbf{W}_h^{\ell+1}$ in (6.1), and use the properties of κ to obtain for $k < 2/\|\kappa^{j+1}\|_{L^\infty}$,

$$a(\mathbf{W}_h^{\ell+1}, \mathbf{W}_h^{\ell+1}) \geq \left(\frac{2}{k} - \|\kappa^{j+1}\|_{L^\infty} \right) \|\mathbf{W}_h^{\ell+1}\|_h^2 > 0.$$

Next, we choose $\Phi = \mathbf{W}_h^{\ell+1}(\mathbf{z})\varphi_{\mathbf{z}}$ in (6.1) and get (for sufficiently small k)

$$(6.4) \quad |\mathbf{W}_h^{\ell+1}(\mathbf{z})| \leq \frac{2}{(2-k\|\kappa\|_{L^\infty})} |\mathbf{M}_h^j(\mathbf{z})| \quad (\ell \geq 0).$$

Finally, we subtract two subsequent iterations of (6.1), set $\Phi = \mathbf{e}_h^{\ell+1} := \mathbf{W}_h^{\ell+1} - \mathbf{W}_h^\ell$, and use (6.4) together with $\|\tilde{\Delta}_h \mathbf{e}_h^\ell\|_{L^2} \leq Ch^{-2}\|\mathbf{e}_h^\ell\|_h$ to conclude

$$\begin{aligned} \left(\frac{2-k\|\kappa^{j+1}\|_{L^\infty}}{k} \right) \|\mathbf{e}_h^{\ell+1}\|_h^2 &\leq \gamma(1 + \delta^2) \left(\mathbf{W}_h^{\ell+1} \times \tilde{\Delta}_h \mathbf{e}_h^\ell, \mathbf{e}_h^{\ell+1} \right)_h \\ &\leq \gamma(1 + \delta^2) Ch^{-2} \|\mathbf{W}_h^{\ell+1}\|_{L^\infty} \|\mathbf{e}_h^\ell\|_h \|\mathbf{e}_h^{\ell+1}\|_h \\ &\leq \gamma(1 + \delta^2) C_0 Ch^{-2} \|\mathbf{e}_h^\ell\|_h \|\mathbf{e}_h^{\ell+1}\|_h; \end{aligned}$$

i.e., the algorithm converges for k such that $\frac{\gamma(1+\delta^2)C_0C}{(2-k\|\kappa^{j+1}\|_{L^\infty})} \frac{k}{h^2} < 1$. \square

7. Computational experiments. We study temperature effects on the discrete finite-time blow-up problem suggested in [6]. Our computational code was built on the finite element package ALBERT [24].

FIG. 2. Detail of the magnetization near the blow-up time (left). $M_s \equiv 1$: Plot of $t_j \mapsto E(\mathbf{M}_h^j)$, and $t_j \mapsto \|\nabla \mathbf{M}_h^j\|_{L^\infty}$ for Schemes A,B ($h = \frac{1}{16}, h = \frac{1}{32}, h = \frac{1}{64}$) (right).

For $\Omega = (0, 1)^2$, let $\mathbf{m}^0 : \Omega \rightarrow \mathbb{S}^2$ be defined by

$$\mathbf{m}^0(\mathbf{x}) = \begin{cases} (0, 0, -M_s(\mathbf{x})) & \text{for } |\mathbf{x}^*| \leq 1/2 \\ M_s(\mathbf{x}) (2\mathbf{x}^* A, A^2 - |\mathbf{x}^*|^2) / (A^2 + |\mathbf{x}^*|^2) & \text{for } |\mathbf{x}^*| \geq 1/2 \end{cases}$$

with $\mathbf{x}^* = (x_1 - 0.5, x_2 - 0.5)$, $\mathbf{x} = (x_1, x_2) \in \Omega$, and $A = (1 - 2|\mathbf{x}^*|)^4/4$. We set $\mathbf{M}_h^0 = I^h \mathbf{m}^0$. The above choice with $M_s \equiv 1$ leads to discrete finite-time blow-up of the solution with singularity at $\mathbf{x} = (0.5, 0.5)$ as reported in [6]. Shortly before the blow-up takes part, the magnetization vector at $\mathbf{x} = (0.5, 0.5)$ points in the $(0, 0, 1)$ direction, with all the surrounding vectors pointing antiparallel, i.e., in the $(0, 0, -1)$ direction; see Figure 2 (left) for detail of the magnetization at $\mathbf{x} = (0.5, 0.5)$ near the blow-up time. For comparison, we display the evolution of the discrete energy, and $\|\nabla \mathbf{M}_h\|_{L^\infty}$ in Figure 2 (right), respectively, for different values of h .

The computational domain Ω was partitioned into uniform squares with side h , each square subdivided into four equal triangles.

For the evolution of the saturation magnetization M_s we adopt the law (1.4) with $\beta = 0.5$, and the function κ given in (1.11). Further we set $\alpha = \delta = \gamma = 1$, $\tau_C = 1$ in all our computations.

For Scheme B, we choose the time step using the following formula $k = 0.0256 h^2$. Given the mesh parameter h we set $\varepsilon = 4 \times 10^{-12} h^2$ in (6.2). With the former choice of the parameter ε the fixed-point iterations in (6.1) always converged after at most 14 iterations with average iteration count of about 5. We were able to use time steps independent of h with the projection scheme (Scheme A) (cf. [4]). The presented results for the projection scheme are computed with $k = 10^{-4}$ for $h = 1/16, 1/32$. For $h = 1/64$, in order to obtain results that are in better agreement with the corresponding results computed by the Scheme B, we take $k = 2.5 \times 10^{-5}$ for the projection scheme.

Example 7.1. The first example demonstrates the effects of constant in time, varying in space temperature $\tau \equiv \tau(\mathbf{x})$. The temperature is defined as

$$\tau(\mathbf{x}) = 0.99 e^{B|\mathbf{x}^*|^2}.$$

We take $B = -25$. The saturation magnetization $M_s(\mathbf{x})$ is now space dependent with values in the interval $[0.1, 1]$.

The discrete energy and $t_j \mapsto \|\nabla \mathbf{M}_h^j\|_{L^\infty}$ are displayed for both Schemes A and B, in Figure 3 (left) and Figure 3 (right), respectively. The discrete energy decreases monotonically for both methods.

FIG. 3. Example 7.1: Plot of $t_j \mapsto E(\mathbf{M}_h^j)$ for Schemes A,B ($h = \frac{1}{16}, \frac{1}{32}, \frac{1}{64}$) (left). Example 7.1: Plot of $t_j \mapsto E(\mathbf{M}_h^j)$ for Schemes A,B ($h = \frac{1}{16}, \frac{1}{32}, \frac{1}{64}$) (right).

FIG. 4. Example 7.1: Magnetization at times $t = 0, 0.0068, 0.033, 0.073, 0.076, 0.1$ (from left to right, from top to bottom).

Snapshots of the magnetization at different time levels computed by the Scheme A can be found in Figure 4; the vectors are colored according to the modulus of the magnetization.

Note that the constraint $|\mathbf{M}_h^j(\mathbf{z})| = M_s(\mathbf{z})$ for \mathbf{M}_h^j computed by Scheme B was satisfied up to the error of the iterative algebraic solver for all nodes $\mathbf{z} \in \mathcal{N}_h$.

Example 7.2. We study the influence of a space-time varying $M_s(t, \mathbf{x})$ on the evolution of the blow-up example. The temperature profile is defined as

$$\tau(t, \mathbf{x}) = \begin{cases} 0.99 e^{B|\mathbf{x}^*|^2} e^{A_1(t-t_{\max})^2} & t < t_{\max}, \\ 0.99 e^{B|\mathbf{x}^*|^2} e^{A_2(t-t_{\max})^2} & t > t_{\max}, \end{cases}$$

with $B = -25$, $A_1 = -100000$, $A_2 = -10000$, and $t_{\max} = 0.02$. The temperature attains its maximum at time $t = t_{\max}$.

The results for both Schemes A and B are displayed in Figure 5 (left) and (right), respectively. In the case of time varying M_s , the monotonic decrease of the discrete energy is not to be expected as can be seen from the graphs. The results are similar for both methods. The effects of the temperature on the magnetization cause a slight delay of the blow-up for $h = 1/16, 1/32$, when compared to $M_s \equiv 1$ (Figure 2 (right)). The difference is quite significant for $h = 1/64$, when the blow-up occurs earlier than in the case of constant M_s .

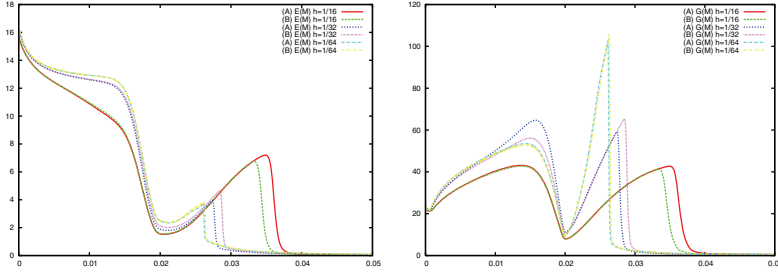

FIG. 5. *Example 7.2: Plot of $t_j \mapsto E(\mathbf{M}_h^j)$ for Schemes A,B ($h = \frac{1}{16}, \frac{1}{32}, \frac{1}{64}$) (left). Example 7.2: Plot of $t_j \mapsto \|\nabla \mathbf{M}_h^j\|_{L^\infty}$ for Schemes A,B ($h = \frac{1}{16}, \frac{1}{32}, \frac{1}{64}$) (right).*

FIG. 6. *Example 7.2: Magnetization at times $t = 0, 0.0135, 0.02, 0.0345, 0.0356, 0.05$ (from left to right, from top to bottom).*

FIG. 7. *Example 7.2: Plot of $t_j \mapsto \max_{\mathbf{z} \in \mathcal{N}_h} \|\mathbf{M}_h^j(\mathbf{z}) - M_s(t_j, \mathbf{z})\|$ for Scheme B ($h = \frac{1}{16}, h = \frac{1}{32}, h = \frac{1}{64}$) (left). Example 7.3: The evolution of M_y^{avg} with and without temperature effects (right).*

Snapshots of the magnetization at different time levels computed by the Scheme A can be found in Figure 6; the vectors are colored according to the modulus of the magnetization.

In the case of time-varying M_s , Scheme B no longer satisfies the constraint $\|\mathbf{M}_h^j(\mathbf{z})\| = M_s(t_j, \mathbf{z})$. This is because of the time integration error due to the discretization of the function κ in time and the nonconsistency of (5.3) with (1.10). In Figure 7 (left) we depict the deviation in the magnitude of the magnetization from

the prescribed values; i.e., $\max_{\mathbf{z} \in \mathcal{N}_h} \|\mathbf{M}_h^j(\mathbf{z}) - M_s(t_j, \mathbf{z})\|$. We observe that the error decreases with decreasing time step.

Example 7.3. The following example is to demonstrate the combined effects of a constant applied magnetic field and temperature on the evolution of the magnetization; i.e., we consider equation (1.1) with $\mathbf{h}_{eff} = \mathbf{h}_{app} + \Delta \mathbf{m}$.

Assume that the temperature solves the linear heat equation,

$$(7.1) \quad \begin{aligned} \tau_t - K \Delta \tau &= f & \text{in} & \quad \Omega, \\ \partial_{\mathbf{n}} \tau &= 0 & \text{on} & \quad \partial \Omega_T, \\ \tau(0, \mathbf{x}) &= \tau_0(\mathbf{x}), \end{aligned}$$

where $f \equiv f(t, \mathbf{x})$ is a prescribed function to represent the heating source (e.g., a laser beam) and $K > 0$ is a constant, which depends on the thermal conductivity, the density, and the heat capacity of the material. We take the initial condition $\tau_0 \equiv 0$, $\alpha \equiv 1$, and f as follows:

$$f(t, \mathbf{x}) = \begin{cases} \begin{cases} 1 & |\mathbf{x}^*| < 0.5, \\ 0, & \text{elsewhere,} \end{cases} & t \leq 0.04 \\ 0 & t > 0.04. \end{cases}$$

After we heat the domain we apply for short time a constant magnetic field in the direction of the y -axes. This is represented by the constant vector field \mathbf{h}_{app} which is defined as

$$\mathbf{h}_{app}(t) = \begin{cases} (0, 10, 0) & \text{for } 0.04 \leq t \leq 0.06, \\ (0, 0, 0) & \text{for } t < 0.04 \text{ or } t > 0.06. \end{cases}$$

We compute the temperature from (7.1) by using backward Euler discretization in time, and standard H^1 -conforming linear finite elements in space. We denote the computed temperature at time t_j by $\tau_h^j(\cdot) \approx \tau(t_j, \cdot)$.

This example was computed using Scheme B, since the projection scheme involves to evaluate ΔM_s , which is not directly available when solving (7.1) by linear finite elements. The extension of Scheme B to the case $\mathbf{h}_{eff} = \mathbf{h}_{app} + \Delta \mathbf{m}$ is straightforward since \mathbf{h}_{app} is a constant vector field. The coefficient κ_{j+1} in Scheme B was computed in the following way:

$$\kappa_{j+1} = -\frac{\beta}{k} \left(\frac{\tau_h^{j+1} - \tau_h^j}{\tau_C - \tau_h^{j+1}} \right),$$

i.e., we use $(\tau_h)_t(t_{j+1}, \cdot) \approx \frac{\tau_h^{j+1} - \tau_h^j}{k}$.

We study the influence of the applied magnetic field \mathbf{h} on the evolution of the magnetization. For this purpose we define the function

$$(7.2) \quad M_y^{avg} = \frac{1}{\#\mathcal{N}_h} \sum_{\mathbf{z} \in \mathcal{N}_h} \frac{[\mathbf{M}_h(\mathbf{z})]_y}{|\mathbf{M}_h(\mathbf{z})|},$$

with $\mathbf{M}_h = ([\mathbf{M}_h]_x, [\mathbf{M}_h]_y, [\mathbf{M}_h]_z)$. The quantity $M_y^{avg} \in [-M_s, M_s]$ represents the “relative alignment” of the magnetization in the direction of the applied field; i.e., the greater the effect of the applied field on the magnetization is, the greater is the value of M_y^{avg} .

We display the time evolution of M_y^{avg} in Figure 7 (right) for the problem with temperature effects, and for $M_s \equiv 1$. The results indicate that the applied magnetic

FIG. 8. Example 7.4: The evolution of M_y^{avg} with and without temperature effects.

field has greater effects on the evolution of the magnetization when temperature is taken into account.

Example 7.4. The last example illustrates the effect of temperature on the magnetization switching by a constant applied field in materials with high anisotropy. We take

$$\mathbf{h}_{eff} = K(\mathbf{m} \cdot \mathbf{p})\mathbf{p} + \mathbf{h}_{app} + \Delta\mathbf{m},$$

where K is the anisotropy constant and $\mathbf{p} = \mathbf{e}_\perp$ is a unit vector of anisotropy direction (with $\mathbf{e} \in \mathbb{S}^2$ the easy axis). The temperature is uniform in space and only varies in time as

$$\tau(t) = \begin{cases} 0.9999 e^{-10000(t-0.04)^2} & t < 0.04, \\ 0.9999 & t > 0.04. \end{cases}$$

We take $K = -1000$ and $\mathbf{p} = (1, 0, 0)$. The choice of $K < 0$ results in an in-plane anisotropy; i.e., at the steady state magnetization lies in the plane perpendicular to the vector \mathbf{p} , in the present case the yz -plane. The magnetization is initially aligned in the y -direction, i.e.,

$$\mathbf{m}_0 = (0, 1, 0).$$

At time $t = 0.04$, after the temperature attains its maximum, a constant magnetic field is applied for a period of time, in order to switch the magnetization to the opposite direction. This is modeled by the following choice of \mathbf{h}_{app} :

$$\mathbf{h}_{app}(t) = \begin{cases} (20, -20, 0) & 0.04 < t < 0.3, \\ (0, 0, 0) & \text{elsewhere.} \end{cases}$$

The example was computed using the Scheme B. The fixed-point algorithm (6.1) is adopted to include the additional anisotropy term; this is done by simply adding the linearized term $\gamma(1 + \delta^2)\mathbf{W}_h^{l+1} \times [K(\mathbf{W}_h^l \cdot \mathbf{p})\mathbf{p}]$ to the left-hand side of (6.1).

In Figure 8 we display the graphs of the computed evolutions of M_y^{avg} from (7.2) for the case with temperature effects and with constant $M_s = 1$. We observe that the applied field \mathbf{h}_{app} has no effect on the magnetization for the problem with constant M_s . On the other hand, when the effects of the temperature are included, the magnetization is reversed to the $(0, -1, 0)$ direction. The computed results support the physical observations from magnetic recording applications that lower strength of the magnetic field is needed for writing if local heating is employed. The practical need for lower writing fields leads to potential improvements in the storage density, faster writing times, and higher reliability of magnetic storage; cf. [21].

Acknowledgment. The project started when A.P. visited Ghent University in February 2006, and was finished when L.B. and M.S. visited Universität Tübingen in April and July 2007, respectively. The hospitality of the hosting institutes is gratefully acknowledged. L.B. was supported by the EPSRC grant EP/C548973/1 and M.S. was supported by the BOF/GOA-project no. 01G00607, Ghent University, Belgium.

LOCAL ANISOTROPIC INTERPOLATION ERROR ESTIMATES BASED ON DIRECTIONAL DERIVATIVES ALONG EDGES*

U. HETMANIUK[†] AND P. KNUPP[†]

Abstract. We present new local anisotropic error estimates for the Lagrangian finite element interpolation. The bounds apply to affine equivalent elements and use information from directional derivatives of the function to interpolate along a set of adjacent edges. These new bounds do not require any geometric limitation but may vary, in some cases, with the node ordering. Several existing results are recovered from the new bounds. Examples compare the asymptotic behavior of the new and existing bounds when the diameter of the element goes to zero. For some elements with small or large angles, our new bound exhibits the same asymptotic behavior as the norm of the interpolation error while existing results do not have the correct asymptotic behavior.

Key words. affine equivalent elements, anisotropic estimates, finite element interpolation error, Lagrange interpolation

1. Introduction. Interpolation operators, which associate a function v with a function in the finite element space, are key components for the analysis of the finite element method. In particular, measuring the interpolation error is a crucial step to prove the convergence of the finite element method.

For nodal Lagrangian finite elements, the first bounds of the interpolation error appeared in the 1970s. These early estimates focused on bounding seminorms of the interpolation error over one element K with shape and size characteristics of K and with the norm of a Fréchet derivative for the function v . Examples are given by Babuška and Aziz [2], Ciarlet [8], Jamet [14], Zlámal [18], and in the references cited therein. Such bounds are called isotropic as they treat equally the partial derivatives of v .

However, engineering applications often generate solutions with different scales of variations along different directions. For these problems, it is important to derive bounds, called anisotropic bounds, which take into account these variations. Early works studied the relation between the error when approximating a quadratic function by a linear polynomial and the geometric characteristics of a simplex (see, for example, Nadler [15, 16] and Rippa [17]). For the nodal Lagrangian linear interpolation, Berzins [4] derived an exact expression for the L^2 -norm of the linear interpolation error on a tetrahedron in terms of directional derivatives along the edges. Bank and Smith [3] studied the $W^{1,2}$ seminorm of the linear interpolation error on a triangle. For convex quadratic functions, D’Azevedo and Simpson [9] and Chen [7] derived similar expressions for, respectively, the L^∞ -norm on a triangle and the L^p -norm on a simplex.

For an arbitrary function v , Apel [1] studied local anisotropic interpolation error estimates that treat distinctly partial derivatives of v along coordinate directions.

Unfortunately, his results require a priori geometric limitations on the element: a limitation on the maximum angle and a coordinate system condition. For triangles, this coordinate system condition limits the angle between the longest side and the x_1 -axis. Chen, Sun, and Xu [6] presented optimal linear interpolation error estimates in L^p -norm for simplicial meshes that satisfy a geometric assumption; i.e., they are quasi-uniform under a metric based on the Hessian of v . Formaggia and Perotto [10], Georgoulis, Hall, and Houston [12], and Huang [13] presented local anisotropic bounds that do not require any geometric limitation. However, for right-angled triangles with a small angle or for rectangles with a large aspect ratio, their estimates do not have the correct asymptotic behavior when the element diameter goes to zero.

Therefore, the goal of this paper is to present new local anisotropic bounds that do not require any geometric limitation and to assess their asymptotic behavior when the diameter of the element goes to zero. We develop our results for affine equivalent elements and for Lagrangian finite elements. Section 2 describes the notations used in this paper. Section 3 presents the new bounds and their proof. Finally, in section 4, we compare the new estimates with existing results and we assess the asymptotic behavior of these bounds when the diameter of the element goes to zero.

2. Notation. Throughout this paper, we adopt the following notations.

- \mathbb{R} is the set of real numbers.
- $d = 2$ or 3 denotes the space dimension.
- (x_1, \dots, x_d) denotes a global Cartesian coordinate system and the vectors $(\mathbf{e}_1, \dots, \mathbf{e}_d)$ are the associated unit basis vectors.
- \mathbf{x} the vector position in \mathbb{R}^d .
- For each integer $k \geq 0$, \mathbb{P}_k is the space of polynomials of degree smaller than k in (x_1, \dots, x_d) . \mathbb{Q}_k is the space of all polynomials of degree smaller than k with respect to each one of the d variables (x_1, \dots, x_d) .
- For any integer $m > 0$, $\alpha = (\alpha_1, \dots, \alpha_m)$ is a multi-index where each index α_i belongs to $\{1, 2, \dots, d\}$. I_m is the set of multi-indices $\{1, 2, \dots, d\}^m$.
- For any smooth function v defined in a domain $\Omega \subset \mathbb{R}^d$, Dv denotes the first Fréchet derivative and $D^m v$ the Fréchet derivative of order m . $D^m v \cdot (\mathbf{w}_1, \dots, \mathbf{w}_m)$ is the partial derivative of order m in the direction of the m vectors $\mathbf{w}_1, \dots, \mathbf{w}_m$ and, at a point $\mathbf{x} \in \Omega$, its value is denoted $D^m v(\mathbf{x}) \cdot (\mathbf{w}_1, \dots, \mathbf{w}_m)$.
- For $1 \leq p < \infty$, $L^p(\Omega)$ is the Sobolev space of real functions whose p -power is integrable over Ω . Each space $L^p(\Omega)$ is endowed with the usual norm, denoted $\|v\|_{0,p,\Omega}$. $L^\infty(\Omega)$ is the Sobolev space of essentially bounded real functions. We denote by $\|v\|_{0,\infty,\Omega}$ the usual norm in $L^\infty(\Omega)$.
- For $m > 0$ and $1 \leq p \leq \infty$, the spaces $W^{m,p}(\Omega)$ contain functions whose weak derivatives up to order m are in $L^p(\Omega)$. Each space $W^{m,p}(\Omega)$ is endowed with the norm $\|v\|_{m,p,\Omega}$ defined by

$$\left(\int_{\Omega} |v(\mathbf{x})|^p + \sum_{j=1}^m \sum_{\alpha \in I_j} |D^j v(\mathbf{x}) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_j})|^p d\mathbf{x} \right)^{\frac{1}{p}} \quad \text{for } 1 \leq p < \infty$$

and, when $p = \infty$,

$$\max \left(\sup_{\mathbf{x} \in \Omega} |v(\mathbf{x})|, \max_{1 \leq j \leq m} \max_{\alpha \in I_j} \sup_{\mathbf{x} \in \Omega} |D^j v(\mathbf{x}) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_j})| \right).$$

- For $m > 0$, we will also use the seminorm $|v|_{m,p,\Omega}$ defined by

$$\left(\sum_{\alpha \in I_m} \int_{\Omega} |D^{\alpha} v(\mathbf{x}) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m})|^p d\mathbf{x} \right)^{1/p} \quad \text{for } 1 \leq p < \infty$$

and, when $p = \infty$,

$$\max_{\alpha \in I_m} \sup_{\mathbf{x} \in \Omega} |D^{\alpha} v(\mathbf{x}) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m})|.$$

- The letter C is used to denote a generic positive constant.

We consider the element \hat{K} to be either

- the unit right triangle: $\{(x_1, x_2) \in \mathbb{R}^2 \mid 0 \leq x_1 \leq 1, 0 \leq x_2 \leq 1 - x_1\}$,
- the unit square: $\{(x_1, x_2) \in \mathbb{R}^2 \mid 0 \leq x_1 \leq 1, 0 \leq x_2 \leq 1\}$,
- the unit right tetrahedron: $\{(x_1, x_2, x_3) \in \mathbb{R}^3 \mid 0 \leq x_1 \leq 1, 0 \leq x_2 \leq 1 - x_1, 0 \leq x_3 \leq 1 - x_1 - x_2\}$,
- the unit cube: $\{(x_1, x_2, x_3) \in \mathbb{R}^3 \mid 0 \leq x_1 \leq 1, 0 \leq x_2 \leq 1, 0 \leq x_3 \leq 1\}$.

We introduce now the Lagrangian finite element $(\hat{K}, \hat{\mathcal{P}}, \hat{\mathcal{N}})$ such that

$$\begin{aligned} \hat{\mathcal{P}} &= \begin{cases} \mathbb{P}_k & \text{when } \hat{K} \text{ is a simplex} \\ \mathbb{Q}_k & \text{when } \hat{K} \text{ is a square or a cube} \end{cases} \\ \hat{\mathcal{N}} &= \left\{ \hat{N}_{i,\hat{K}}, 1 \leq i \leq n \mid \hat{N}_{i,\hat{K}}(\hat{v}) = \hat{v}(\hat{\mathbf{x}}_i) \right\}, \end{aligned}$$

where $(\hat{\mathbf{x}}_i)_{1 \leq i \leq n}$ is the classical set of nodes for \hat{K} . k defines the polynomial degree of the shape functions $(\hat{\phi}_{i,\hat{K}})_{1 \leq i \leq n}$. For any smooth function \hat{v} defined on \hat{K} , its nodal interpolant is defined by

$$(2.1) \quad \hat{\Pi} \hat{v} = \sum_{i=1}^n \hat{N}_{i,\hat{K}}(\hat{v}) \hat{\phi}_{i,\hat{K}}.$$

Given an invertible matrix \mathbf{A} of size d and a vector \mathbf{a} of length d , we define the affine-equivalent Lagrangian finite element $(K, \mathcal{P}, \mathcal{N})$, where the element K satisfies

$$(2.2) \quad K = \left\{ \mathbf{x} \in \mathbb{R}^d \mid \mathbf{x} = \mathbf{A}\hat{\mathbf{x}} + \mathbf{a}, \forall \hat{\mathbf{x}} \in \hat{K} \right\}.$$

Following the classical approach (see, for example, Ciarlet [8, section 2.3]), we introduce, for any smooth function v defined on K , its nodal interpolant

$$(2.3) \quad \Pi v = \sum_{i=1}^n N_{i,K}(v) \phi_{i,K}.$$

In the remainder of this document, any smooth function v defined on K is associated with a smooth function \hat{v} on \hat{K} , such that

$$\hat{v}(\hat{\mathbf{x}}) = v(\mathbf{A}\hat{\mathbf{x}} + \mathbf{a}).$$

3. New local anisotropic bounds. In this section, we derive the new local anisotropic bounds on one element. On an affine-equivalent element K , let $(\mathbf{b}_j)_{1 \leq j \leq d}$ denote a basis of \mathbb{R}^d composed of adjacent edge vectors of K . Several choices of basis are available. For instance, each vertex of a simplex is associated to a different basis.

A different ordering of edges results also in a different basis. For our new results, a different basis may result in a different anisotropic bound. So we will comment on the behavior of the upper bound when using different choices of adjacent edges.

First, the result on the L^q -norm of the interpolation error is stated. Its proof is given in section 3.1.

THEOREM 3.1. *Let v be a function on K belonging to $W^{l,p}(K)$. The integral index l and the real numbers p and q satisfy*

$$(3.1) \quad 1 \leq p, q \leq \infty, \quad 0 \leq l \leq k + 1.$$

We assume that the continuous embeddings hold

$$(3.2) \quad W^{l,p}(K) \hookrightarrow \mathcal{C}(K) \quad \text{and} \quad W^{l,p}(K) \hookrightarrow L^q(K)$$

Let Π be the nodal interpolation (2.3) to the finite element space with polynomials of degree k . Under these assumptions, the following anisotropic bounds hold. When p is finite, we have

$$(3.3) \quad \|v - \Pi v\|_{0,q,K} \leq C |K|^{\frac{1}{q} - \frac{1}{p}} \left[\sum_{\beta \in I_l} \int_K |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_l})|^p dx \right]^{\frac{1}{p}}.$$

When $p = \infty$, we have

$$(3.4) \quad \|v - \Pi v\|_{0,q,K} \leq C |K|^{\frac{1}{q}} \max_{\beta \in I_l} \left[\sup_{\mathbf{x} \in K} |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_l})| \right].$$

The constants C depend only on \hat{K} , l , p , q , and d .

The final bound is a simple reformulation of existing results from Ciarlet [8], Apel [1], Formaggia and Perotto [11], and Huang [13]. However, this formulation highlights the importance of directional derivatives along edges of the element. The constraint (3.2) is classical when working with the Lagrangian interpolation operator (see Ciarlet [8, Theorem 3.1.5] or Apel [1, section 2.1.1]). Besides the affine-equivalent assumption on K , this theorem does not require further geometric assumption on K . When using different choices of adjacent edges, the resulting upper bounds have the same asymptotic behavior when the diameter of K goes to zero.

Then, norms of partial derivatives of the interpolation error are bounded. The result is proved in section 3.2.

THEOREM 3.2. *Let $m > 0$ and α be in I_m . Let v be a continuous function belonging to $W^{l,p}(K)$, where $1 \leq p \leq \infty$ and $1 \leq l \leq k + 1$. Let $1 \leq q \leq \infty$, such that $W^{l-m,p}(K)$ has a continuous embedding into $L^q(K)$ and the following constraints are satisfied:*

$$(3.5a) \quad l > m \quad \text{when } \alpha \in \{\{1\}^m, \{2\}^m\} \quad \text{when } K \subset \mathbb{R}^2$$

$$(3.5b) \quad \begin{cases} l > m & \text{when } \alpha \in \{\{1, 2\}^m, \{1, 3\}^m, \{2, 3\}^m\} \\ p > 2 & \text{when } m = l - 1 \text{ and } \alpha \in \{\{1\}^m, \{2\}^m, \{3\}^m\} \end{cases} \quad \text{when } K \subset \mathbb{R}^3.$$

Let Π be the nodal interpolation (2.3) to the finite element space with polynomials of degree k . Let \mathbf{B} denote the matrix whose columns are the edge vectors $(\mathbf{b}_j)_{1 \leq j \leq d}$. The entries of matrix \mathbf{B}^{-1} are denoted $B_{i,j}^{(-1)}$.

Under these assumptions, the following anisotropic bounds hold. When p is finite, we have

$$(3.6) \quad \|D^m(v - \Pi v) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m})\|_{0,q,K} \leq C |K|^{\frac{1}{q} - \frac{1}{p}} \left\{ \sum_{j_1, \dots, j_m=1}^d |B_{j_1, \alpha_1}^{(-1)}|^q \dots |B_{j_m, \alpha_m}^{(-1)}|^q \left[\sum_{\beta \in I_{l-m}} \int_K |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})|^p d\mathbf{x} \right]^{\frac{q}{p}} \right\}^{\frac{1}{q}}.$$

When $p = \infty$, we have

$$(3.7) \quad \|D^m(v - \Pi v) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m})\|_{0,q,K} \leq C |K|^{\frac{1}{q}} \left\{ \sum_{j_1, \dots, j_m=1}^d |B_{j_1, \alpha_1}^{(-1)}|^q \dots |B_{j_m, \alpha_m}^{(-1)}|^q \max_{\beta \in I_{l-m}} \left[\sup_{\mathbf{x} \in K} |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})| \right]^q \right\}^{\frac{1}{q}}.$$

The constants C depend only on \hat{K} , l , m , p , q , and d .

Besides the affine-equivalent assumption on K , Theorem 3.2 does not require further geometric assumption on K . The constraints (3.5) are explained in the proof. When choosing a different ordering of the adjacent edges, the resulting upper bounds will be unchanged. When using different choices of adjacent edges or different node numbering, the resulting upper bounds may have different asymptotic behaviors when the diameter of K goes to zero. Such an example will be presented in section 4.

3.1. Proof of Theorem 3.1. We give the proof when p and q are finite. The other cases are proved in a similar fashion. The proof technique is classical and consists of deriving estimates on \hat{K} and of applying an affine coordinate transformation between K and \hat{K} . First, we recall bounds on \hat{K} in the following lemma.

LEMMA 3.3. *Let \hat{v} be a function on \hat{K} belonging to $W^{l,p}(\hat{K})$. The integral index l and the real numbers p and q satisfy*

$$(3.8) \quad 1 \leq p, q \leq \infty, \quad 0 \leq l \leq k + 1.$$

We assume that the continuous embeddings hold

$$(3.9) \quad W^{l,p}(\hat{K}) \hookrightarrow C(\hat{K}) \quad \text{and} \quad W^{l,p}(\hat{K}) \hookrightarrow L^q(\hat{K}).$$

Then the following bound holds:

$$(3.10) \quad \|\hat{v} - \hat{\Pi}\hat{v}\|_{0,q,\hat{K}} \leq C |\hat{v}|_{l,p,\hat{K}},$$

where the constant C depends only on l , p , q , and \hat{K} .

The proof for this lemma is given in Ciarlet [8, section 3.1] and Apel [1, Chapter 2]. We recall that the element \hat{K} is either the unit right triangle, the unit square, the unit right tetrahedron, or the unit cube. The constraints (3.2) are equivalent to the constraints (3.9). \mathbf{B} denotes the matrix whose columns are the edge vectors $(\mathbf{b}_j)_{1 \leq j \leq d}$. \mathbf{B} is the Jacobian matrix of an affine map between \hat{K} and K .

When q is finite, we have

$$\begin{aligned} \|v - \Pi v\|_{0,q,K} &= \left(\int_K |(v - \Pi v)(\mathbf{x})|^q d\mathbf{x} \right)^{\frac{1}{q}} \\ &= \left(\int_{\hat{K}} |(\hat{v} - \hat{\Pi} \hat{v})(\hat{\mathbf{x}})|^q |\det \mathbf{B}| d\hat{\mathbf{x}} \right)^{\frac{1}{q}} \\ &\leq C |\det \mathbf{B}|^{\frac{1}{q}} \left(\sum_{\beta \in I_l} \int_{\hat{K}} |D^\beta \hat{v}(\hat{\mathbf{x}}) \cdot (\mathbf{e}_{\beta_1}, \dots, \mathbf{e}_{\beta_l})|^p d\hat{\mathbf{x}} \right)^{\frac{1}{p}}, \end{aligned}$$

where we have used the result of Lemma 3.3. Using the differentiation rule for composition of functions (see Ciarlet [8, p. 118]), we note that

$$D^l \hat{v}(\hat{\mathbf{x}}) \cdot (\mathbf{e}_{\beta_1}, \dots, \mathbf{e}_{\beta_l}) = D^l v(\mathbf{x}) \cdot (\mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_l}).$$

Consequently, we obtain

$$\|v - \Pi v\|_{0,q,\hat{K}} \leq C |\det \mathbf{B}|^{\frac{1}{q}} \left(\sum_{\beta \in I_l} \int_K |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_l})|^p |\det \mathbf{B}^{-1}| d\mathbf{x} \right)^{\frac{1}{p}},$$

and conclude by using the relation

$$|\det \mathbf{B}| = |K| / |\hat{K}|.$$

3.2. Proof of Theorem 3.2. We give the proof when p and q are finite. The other cases are proved in a similar fashion. As previously, we start with local anisotropic bounds on \hat{K} and, then, apply an affine coordinate transformation between K and \hat{K} .

LEMMA 3.4. *Let α be in I_m and \hat{v} be a continuous function on \hat{K} satisfying $D^m \hat{v} \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m}) \in W^{l-m,p}(\hat{K})$. The indices l, m , and p satisfy*

$$(3.11) \quad 1 \leq p \leq \infty, \quad l, m \in \mathbb{N}, \quad 0 < m \leq l \leq k + 1,$$

and the constraints defined by

$$(3.12a) \quad l > m \quad \text{when } \alpha \in \{\{1\}^m, \{2\}^m\} \quad \text{when } \hat{K} \subset \mathbb{R}^2$$

$$(3.12b) \quad \begin{cases} l > m & \text{when } \alpha \in \{\{1, 2\}^m, \{1, 3\}^m, \{2, 3\}^m\} \\ p > 2 & \text{when } m = l - 1 \text{ and } \alpha \in \{\{1\}^m, \{2\}^m, \{3\}^m\} \end{cases} \quad \text{when } \hat{K} \subset \mathbb{R}^3.$$

For $1 \leq q \leq \infty$, such that $W^{l-m,p}(\hat{K})$ has a continuous embedding into $L^q(\hat{K})$, the following bound holds:

$$(3.13) \quad \left\| D^m(\hat{v} - \hat{\Pi} \hat{v}) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m}) \right\|_{0,q,\hat{K}} \leq C |D^m \hat{v} \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m})|_{l-m,p,\hat{K}},$$

where the constant C depends only on l, m, p, q , and \hat{K} .

These bounds were proved by Apel [1] (see Lemmas 2.4, 2.6, 2.10, and 2.18, respectively, for triangles, tetrahedra, quadrilaterals, and hexahedrals). We emphasize that these bounds are on \hat{K} and that \hat{K} is either the unit right triangle, the unit square, the unit right tetrahedron, or the unit cube. In his book, Apel comments about the necessity of the constraints (3.12) to derive anisotropic bounds on \hat{K} . The constraints (3.5) match the constraints (3.12).

We represent the vectors \mathbf{e}_j in the basis of edge vectors $(\mathbf{b}_i)_{1 \leq i \leq d}$,

$$\mathbf{e}_j = \sum_{i=1}^d B_{i,j}^{(-1)} \mathbf{b}_i,$$

where the coefficients $B_{i,j}^{(-1)}$ are the entries of matrix \mathbf{B}^{-1} .

When q is finite, we have

$$\begin{aligned} & \|D^m(v - \Pi v) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m})\|_{0,q,K} \\ &= \left(\int_K \left| \sum_{j_1, \dots, j_m=1}^d B_{j_1, \alpha_1}^{(-1)} \dots B_{j_m, \alpha_m}^{(-1)} D^m(v - \Pi v)(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}) \right|^q d\mathbf{x} \right)^{\frac{1}{q}}. \end{aligned}$$

We recall the generalized mean inequality for a set of real positive numbers $(a_i)_{1 \leq i \leq N}$:

$$\left(\sum_{i=1}^N a_i \right)^q \leq N^{q-1} \left(\sum_{i=1}^N a_i^q \right).$$

Consequently, there exists a constant $C = d^{\frac{m(q-1)}{q}}$ such that

$$\begin{aligned} & \|D^m(v - \Pi v) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m})\|_{0,q,K} \\ & \leq C \left(\sum_{j_1, \dots, j_m=1}^d |B_{j_1, \alpha_1}^{(-1)}|^q \dots |B_{j_m, \alpha_m}^{(-1)}|^q \int_K |D^m(v - \Pi v)(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m})|^q d\mathbf{x} \right)^{\frac{1}{q}}. \end{aligned}$$

The differentiation rule for composition of functions gives

$$D^m(v - \Pi v)(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}) = D^m(\hat{v} - \hat{\Pi}\hat{v})(\hat{\mathbf{x}}) \cdot (\mathbf{e}_{j_1}, \dots, \mathbf{e}_{j_m}).$$

Using a change of variables, we obtain

$$\begin{aligned} & \|D^m(v - \Pi v) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m})\|_{0,q,K} \leq C |\det \mathbf{B}|^{\frac{1}{q}} \\ & \left(\sum_{j_1, \dots, j_m=1}^d |B_{j_1, \alpha_1}^{(-1)}|^q \dots |B_{j_m, \alpha_m}^{(-1)}|^q \int_K |D^m(\hat{v} - \hat{\Pi}\hat{v})(\hat{\mathbf{x}}) \cdot (\mathbf{e}_{j_1}, \dots, \mathbf{e}_{j_m})|^q d\mathbf{x} \right)^{\frac{1}{q}}. \end{aligned}$$

The result of Lemma 3.4 now implies

$$\begin{aligned} & \|D^m(v - \Pi v) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m})\|_{0,q,K} \leq C |\det \mathbf{B}|^{\frac{1}{q}} \\ & \left(\sum_{j_1, \dots, j_m=1}^d |B_{j_1, \alpha_1}^{(-1)}|^q \dots |B_{j_m, \alpha_m}^{(-1)}|^q |D^m \hat{v} \cdot (\mathbf{e}_{j_1}, \dots, \mathbf{e}_{j_m})|_{l-m,p,\hat{K}}^q \right)^{\frac{1}{q}}. \end{aligned}$$

The seminorm,

$$|D^m \hat{v} \cdot (\mathbf{e}_{j_1}, \dots, \mathbf{e}_{j_m})|_{l-m,p,\hat{K}}^q = \left(\sum_{\beta \in I_{l-m}} \int_{\hat{K}} |D^m \hat{v}(\hat{\mathbf{x}}) \cdot (\mathbf{e}_{j_1}, \dots, \mathbf{e}_{j_m}, \mathbf{e}_{\beta_1}, \dots, \mathbf{e}_{\beta_{l-m}})|^p d\hat{\mathbf{x}} \right)^{\frac{q}{p}},$$

becomes, after a change of variables,

$$|D^m \hat{v} \cdot (\mathbf{e}_{j_1}, \dots, \mathbf{e}_{j_m})|_{l-m,p,\hat{K}}^q = |\det \mathbf{B}|^{-\frac{q}{p}} \left(\sum_{\beta \in I_{l-m}} \int_K |D^m v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})|^p d\mathbf{x} \right)^{\frac{q}{p}}.$$

We conclude as previously

$$\begin{aligned} & \|D^m(v - \Pi v) \cdot (\mathbf{e}_{\alpha_1}, \dots, \mathbf{e}_{\alpha_m})\|_{0,q,K} \\ & \leq C |K|^{\frac{1}{q} - \frac{1}{p}} \left\{ \sum_{j_1, \dots, j_m=1}^d |B_{j_1, \alpha_1}^{(-1)}|^q \dots |B_{j_m, \alpha_m}^{(-1)}|^q \right. \\ & \left. \left[\sum_{\beta \in I_{l-m}} \int_K |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})|^p d\mathbf{x} \right]^{\frac{q}{p}} \right\}^{\frac{1}{q}}. \end{aligned}$$

Lemma 3.4 was proved only when \hat{K} is the unit right triangle, the unit square, the unit right tetrahedron, or the unit cube. We were not able to generalize Lemma 3.4 to the unit equilateral triangle or the unit equilateral tetrahedron. As the unit right triangle and tetrahedron are not invariant with respect to node numbering, the resulting bound on the affine-equivalent element K may vary with respect to node numbering. Further work would be required to guarantee such an invariance on simplices or to characterize the basis $(\mathbf{b}_j)_{1 \leq j \leq d}$ giving the sharpest upper bound.

3.3. Expression for particular cases. In this section, we write the new estimates for the $W^{m,q}$ seminorm and for square integrable functions. In particular, we present the expression for the L^2 -norm and for the $W^{1,2}$ seminorm.

Expression for the $W^{m,q}$ seminorm. We bound the $W^{m,q}$ seminorm by combining the results of Theorem 3.2 for all the partial derivatives of order m .

COROLLARY 3.5. *Let v be a continuous function belonging to $W^{l,p}(K)$, where $1 \leq p \leq \infty$ and $1 \leq l \leq k + 1$. Let $0 < m < l$ and $1 \leq q \leq \infty$, such that $W^{l-m,p}(K)$ has a continuous embedding into $L^q(K)$ and the following constraints are satisfied:*

(3.14a) $p > 2$ if $l = 1$ when $K \subset \mathbb{R}^2$,

(3.14b) $p > 2$ if $m = l - 1$ when $K \subset \mathbb{R}^3$.

Under these assumptions, the following anisotropic bounds hold. When p is finite, we have

$$(3.15) \quad |v - \Pi v|_{m,q,K} \leq C |K|^{\frac{1}{q} - \frac{1}{p}} \left\{ \sum_{\alpha \in I_m} \sum_{j_1, \dots, j_m=1}^d \left| B_{j_1, \alpha_1}^{(-1)} \right|^q \cdots \left| B_{j_m, \alpha_m}^{(-1)} \right|^q \left[\sum_{\beta \in I_{l-m}} \int_K |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})|^p d\mathbf{x} \right]^{\frac{q}{p}} \right\}^{\frac{1}{q}}.$$

When $p = \infty$, we have

$$(3.16) \quad |v - \Pi v|_{m,q,K} \leq C |K|^{\frac{1}{q}} \left\{ \sum_{\alpha \in I_m} \sum_{j_1, \dots, j_m=1}^d \left| B_{j_1, \alpha_1}^{(-1)} \right|^q \cdots \left| B_{j_m, \alpha_m}^{(-1)} \right|^q \max_{\beta \in I_{l-m}} \left[\sup_{\mathbf{x} \in K} |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})| \right]^q \right\}^{\frac{1}{q}}.$$

The constants C depend only on \hat{K} , l , m , p , q , and d .

The proof consists of summing the bounds (3.6) for all the multi-indices α belonging to I_m and of combining all the associated constraints (3.5).

Expression for the L^2 -norm in \mathbb{R}^2 . For the L^2 -norm, we set $m = 0$, $p = q = 2$, and $l = 2$. We have for any continuous function v belonging to $W^{2,2}(K)$:

$$(3.17) \quad \|v - \Pi v\|_{0,2,K}^2 \leq C \left(\int_K |D^2 v(\mathbf{x}) \cdot (\mathbf{b}_1, \mathbf{b}_1)|^2 d\mathbf{x} + \int_K |D^2 v(\mathbf{x}) \cdot (\mathbf{b}_2, \mathbf{b}_2)|^2 d\mathbf{x} + 2 \int_K |D^2 v(\mathbf{x}) \cdot (\mathbf{b}_1, \mathbf{b}_2)|^2 d\mathbf{x} \right).$$

In matrix notation, the bound becomes

$$\|v - \Pi v\|_{0,2,K}^2 \leq C \int_K \|\mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B}\|_F^2 d\mathbf{x},$$

where $D^2 v(\mathbf{x})$ denotes the Hessian matrix for v and $\|\cdot\|_F$ is the Frobenius norm. We note that the formula in matrix notation also holds in \mathbb{R}^3 . This anisotropic bound is well known and appeared, for instance, in the case of simplices, in Formaggia and Perotto [11] and in Huang [13].

Expression for the $W^{1,2}$ seminorm in \mathbb{R}^2 . For the $W^{1,2}$ seminorm, we set $m = 1$, $p = q = 2$, and $l = 2$. For any continuous function v in $W^{2,2}(K)$, we have

$$\begin{aligned} & |v - \Pi v|_{1,2,K}^2 \\ & \leq C \left[\left(\left| B_{1,1}^{(-1)} \right|^2 + \left| B_{1,2}^{(-1)} \right|^2 \right) \left(\int_K |D^2 v(\mathbf{x}) \cdot (\mathbf{b}_1, \mathbf{b}_1)|^2 d\mathbf{x} + \int_K |D^2 v(\mathbf{x}) \cdot (\mathbf{b}_1, \mathbf{b}_2)|^2 d\mathbf{x} \right) \right. \\ & \left. + \left(\left| B_{2,1}^{(-1)} \right|^2 + \left| B_{2,2}^{(-1)} \right|^2 \right) \left(\int_K |D^2 v(\mathbf{x}) \cdot (\mathbf{b}_2, \mathbf{b}_1)|^2 d\mathbf{x} + \int_K |D^2 v(\mathbf{x}) \cdot (\mathbf{b}_2, \mathbf{b}_2)|^2 d\mathbf{x} \right) \right]. \end{aligned}$$

In matrix notation, the bound becomes

$$(3.18) \quad |v - \Pi v|_{1,2,K}^2 \leq C \int_K \left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B} \right\|_F^2 dx,$$

where $\|\mathbf{B}^{-1}(1, \cdot)\|_2$ is the 2-norm for the first row vector of \mathbf{B}^{-1} .

4. Applications. In this section, the new bounds are compared to existing results. First, we derive existing results as upper bounds of our new bounds. This derivation indicates that our new bounds are, at worst, equivalent to existing results. Then, for some elements with small or large angles, we compare the asymptotic behavior of the new bounds with the behavior of the existing results, when the diameter of the element goes to zero. For these simple cases, our new bound exhibits the same asymptotic behavior as the norm of the interpolation error while existing results do not have the correct asymptotic behavior. This difference indicates that our new bounds are not equivalent to existing results and, in some cases, the new bounds are strictly sharper than the existing results of Ciarlet [8], Formaggia and Perotto [10], Georgoulis et al. [12], and Huang [13].

4.1. Recovering existing results. In this section, we recover, from Theorem 3.2, local bounds on K derived by Jamet [14], Formaggia and Perotto [11], and Apel [1].

Result of Jamet [14] on triangles. For triangular elements, Jamet proved

$$(4.1) \quad |v - \Pi v|_{m,p,K} \leq C \frac{h^{k+1-m}}{(\cos \theta)^m} |v|_{k+1,p,K},$$

where h is the diameter of K and θ is half the largest angle of triangle K . We will show that we can recover Jamet’s result from (3.15).

First we recall the decomposition of \mathbf{e}_j :

$$\mathbf{e}_j = \sum_{i=1}^2 B_{i,j}^{(-1)} \mathbf{b}_i = \sum_{i=1}^2 B_{i,j}^{(-1)} \|\mathbf{b}_i\|_2 \frac{\mathbf{b}_i}{\|\mathbf{b}_i\|_2}.$$

Using Lemma 2.4 of Jamet [14], we have

$$(4.2) \quad \sum_{j=1}^2 \left| B_{j,i}^{(-1)} \right| \|\mathbf{b}_j\|_2 \leq \frac{1}{\cos \theta}.$$

We recall also

$$(4.3) \quad \max_{1 \leq i \leq 2} \|\mathbf{b}_i\|_2 \leq \|\mathbf{B}\|_F \leq C \frac{h}{\hat{\rho}},$$

where $\hat{\rho}$ is the inner radius for the reference element \hat{K} . For a finite value of $p = q$ and for $l = k + 1$, we describe how to recover Jamet’s result from (3.15):

$$|v - \Pi v|_{m,p,K} \leq C \left[\sum_{\alpha \in I_m} \sum_{j_1, \dots, j_m=1}^2 \left| B_{j_1, \alpha_1}^{(-1)} \right|^p \cdots \left| B_{j_m, \alpha_m}^{(-1)} \right|^p \sum_{\beta \in I_{k+1-m}} \int_K |D^{k+1} v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{k+1-m}})|^p dx \right]^{\frac{1}{p}}.$$

We now incorporate (4.3) and normalize the edge vectors:

$$|v - \Pi v|_{m,p,K} \leq C \frac{h^{k+1-m}}{\hat{\rho}^{k+1-m}} \left[\sum_{\alpha \in I_m} \sum_{j_1, \dots, j_m=1}^2 \left| B_{j_1, \alpha_1}^{(-1)} \right|^p \|\mathbf{b}_{j_1}\|_2^p \cdots \left| B_{j_m, \alpha_m}^{(-1)} \right|^p \|\mathbf{b}_{j_m}\|_2^p \right. \\ \left. \sum_{\beta \in I_{k+1-m}} \int_K \left| D^{k+1} v(\mathbf{x}) \cdot \left(\frac{\mathbf{b}_{j_1}}{\|\mathbf{b}_{j_1}\|_2}, \dots, \frac{\mathbf{b}_{j_m}}{\|\mathbf{b}_{j_m}\|_2}, \frac{\mathbf{b}_{\beta_1}}{\|\mathbf{b}_{\beta_1}\|_2}, \dots, \frac{\mathbf{b}_{\beta_{k+1-m}}}{\|\mathbf{b}_{\beta_{k+1-m}}\|_2} \right) \right|^p d\mathbf{x} \right]^{\frac{1}{p}}.$$

We can bound the integral term by $C |v|_{k+1,p,K}^p$:

$$|v - \Pi v|_{m,p,K} \leq C \frac{h^{k+1-m}}{\hat{\rho}^{k+1-m}} |v|_{k+1,p,K} \left[\sum_{\alpha \in I_m} \sum_{j_1, \dots, j_m=1}^2 \left| B_{j_1, \alpha_1}^{(-1)} \right|^p \|\mathbf{b}_{j_1}\|_2^p \cdots \left| B_{j_m, \alpha_m}^{(-1)} \right|^p \|\mathbf{b}_{j_m}\|_2^p \right]^{\frac{1}{p}}.$$

With the result (4.2), we conclude

$$|v - \Pi v|_{m,p,K} \leq C \left[\sum_{\alpha \in I_m} \sum_{j_1, \dots, j_m=1}^2 \left| B_{j_1, \alpha_1}^{(-1)} \right|^p \cdots \left| B_{j_m, \alpha_m}^{(-1)} \right|^p \right. \\ \left. \sum_{\beta \in I_{k+1-m}} \int_K \left| D^{k+1} v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{k+1-m}}) \right|^p d\mathbf{x} \right]^{\frac{1}{p}} \\ \leq \frac{C}{(\cos \theta)^m} \frac{h^{k+1-m}}{\hat{\rho}^{k+1-m}} |v|_{k+1,p,K},$$

where the constants C depend only on \hat{K} , k , m , and p . This bound is isotropic as it does not distinguish the partial derivatives of v .

Bound of Formaggia and Perotto [11, Lemma 2] for smooth functions in \mathbb{R}^2 . For smooth functions ($v \in W^{2,2}(K)$), their result bounds the $W^{1,2}$ seminorm of the error for piecewise linear elements on triangles. For piecewise linear interpolation in \mathbb{R}^2 , our result writes as follows:

$$(4.4) \quad |v - \Pi v|_{1,2,K}^2 \leq C \int_K \left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B} \right\|_F^2 d\mathbf{x}.$$

We have

$$\left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B} \right\|_F^2 \leq \|\mathbf{B}^{-1}\|_F^2 \|\mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B}\|_F^2.$$

For any 2×2 matrix \mathbf{B} ,

$$(4.5) \quad \|\mathbf{B}^{-1}\|_F^2 \leq 2 \|\mathbf{B}^{-1}\|_2^2.$$

Consequently, we obtain

$$|v - \Pi v|_{1,2,K}^2 \leq C \|\mathbf{B}^{-1}\|_2^2 \int_K \|\mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B}\|_F^2 d\mathbf{x}.$$

We introduce the singular decomposition of $\mathbf{B} = \mathbf{R}\mathbf{\Sigma}\mathbf{P}^T$ where \mathbf{R} and \mathbf{P} are orthogonal matrices associated with the left and right singular vectors. $\mathbf{\Sigma}$ is a diagonal matrix containing the singular values. The column vectors of \mathbf{R} and \mathbf{P} are written

$$\mathbf{R} = [\mathbf{r}_1, \mathbf{r}_2] \quad \text{and} \quad \mathbf{P} = [\mathbf{p}_1, \mathbf{p}_2].$$

We remark that $\mathbf{B}\mathbf{r}_i = \sigma_i\mathbf{p}_i$.

The Frobenius norm being invariant by rotation, we now write

$$|v - \Pi v|_{1,2,K}^2 \leq C \|\mathbf{B}^{-1}\|_2^2 \int_K \|\mathbf{\Sigma}\mathbf{R}^T D^2 v(\mathbf{x})\mathbf{R}\mathbf{\Sigma}\|_F^2 dx,$$

which is exactly the estimate of Formaggia and Perotto [11, Lemma 2]. This derivation shows also that we have

$$\begin{aligned} |v - \Pi v|_{1,2,K}^2 &\leq C \int_K \left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x})\mathbf{B} \right\|_F^2 dx \\ &\leq C \|\mathbf{B}^{-1}\|_2^2 \int_K \|\mathbf{\Sigma}\mathbf{R}^T D^2 v(\mathbf{x})\mathbf{R}\mathbf{\Sigma}\|_F^2 dx. \end{aligned}$$

Georgoulis et al. [12] proved recently an extension for the result of Formaggia and Perotto to quadrilaterals in the $W^{m,2}$ spaces. We will show in the following section that these bounds do not have the correct asymptotic behavior when K is a right-angled triangle with a small angle or a rectangle with large aspect ratio and the diameter of K goes to zero.

Bounds of Apel [1, Theorem 2.1] on a triangle. Without any loss of generality, we restrict the derivation to a triangle K and finite values for p and q . We denote by h_1 the length of the longest edge and by $h_2 = |\det \mathbf{B}|/h_1$ the thickness. We assume that the element K satisfies a maximal angle condition; i.e., all the interior angles of K are uniformly bounded by a constant $\theta_* < \pi$, and a coordinate system condition; i.e., the angle γ between the longest edge and the x_1 -axis is bounded by $|\sin \gamma| \leq Ch_2/h_1$. Under these assumptions, Apel [1, Lemma 2.5] proved that

$$(4.6) \quad |B_{i,j}| \leq C \min(h_i, h_j) \quad \text{and} \quad |B_{i,j}^{(-1)}| \leq C \min(h_i^{-1}, h_j^{-1}),$$

where the constants C do not depend on K .

The new bound of Theorem 3.2 writes as follows:

$$\begin{aligned} |v - \Pi v|_{m,q,K} &\leq C |\det \mathbf{B}|^{\frac{1}{q} - \frac{1}{p}} \left\{ \sum_{\alpha \in I_m} \sum_{j_1, \dots, j_m=1}^d |B_{j_1, \alpha_1}^{(-1)}|^q \cdots |B_{j_m, \alpha_m}^{(-1)}|^q \right. \\ &\quad \left. \left[\sum_{\beta \in I_{l-m}} \int_K |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})|^p dx \right]^{\frac{q}{p}} \right\}^{\frac{1}{q}}. \end{aligned}$$

Using (4.6), we have

$$|B_{j_1, \alpha_1}^{(-1)}|^q \cdots |B_{j_m, \alpha_m}^{(-1)}|^q \leq C \left(\prod_{i=1}^m h_{j_i}^{-1} \right)^q.$$

When we represent an edge vector \mathbf{b}_{j_i} in the basis of $(\mathbf{e}_k)_{1 \leq k \leq d}$, we have

$$\begin{aligned} & D^l v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}}) \\ &= \sum_{k_1, \dots, k_m=1}^d B_{k_1, j_1} \cdots B_{k_m, j_m} D^l v(\mathbf{x}) \cdot (\mathbf{e}_{k_1}, \dots, \mathbf{e}_{k_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}}) \end{aligned}$$

and, consequently,

$$\begin{aligned} & |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})| \\ & \leq C \left(\prod_{i=1}^m h_{j_i} \right) \sum_{k_1, \dots, k_m=1}^d |D^l v(\mathbf{x}) \cdot (\mathbf{e}_{k_1}, \dots, \mathbf{e}_{k_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})|. \end{aligned}$$

As v is a smooth function, we can change the order of derivatives in the right-hand side to obtain

$$\begin{aligned} & \int_K |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})|^p d\mathbf{x} \\ & \leq C \left(\prod_{i=1}^m h_{j_i} \right) |D^{l-m} v \cdot (\mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})|_{m,p,K}^p. \end{aligned}$$

The bound on the seminorm becomes now

$$|v - \Pi v|_{m,q,K} \leq C |\det \mathbf{B}|^{\frac{1}{q} - \frac{1}{p}} \left[\sum_{\beta \in I_{l-m}} |D^{l-m} v \cdot (\mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})|_{m,p,K}^p \right]^{\frac{1}{p}}.$$

Therefore, we obtain

$$\begin{aligned} (4.7) \quad & |v - \Pi v|_{m,q,K} \\ & \leq C |\det \mathbf{B}|^{\frac{1}{q} - \frac{1}{p}} \left[\sum_{s \in I_{l-m}} \left(\prod_{i=1}^{l-m} h_{s_i}^p \right) |D^{l-m} v \cdot (\mathbf{e}_{s_1}, \dots, \mathbf{e}_{s_{l-m}})|_{m,p,K}^p \right]^{\frac{1}{p}}, \end{aligned}$$

which corresponds to the estimate of Apel [1, Theorem 2.1]. This derivation shows that, when assuming the maximal angle condition and the coordinate system condition on K , we have

$$\begin{aligned} & |v - \Pi v|_{m,q,K} \leq C |\det \mathbf{B}|^{\frac{1}{q} - \frac{1}{p}} \left\{ \sum_{\alpha \in I_m} \sum_{j_1, \dots, j_m=1}^d |B_{j_1, \alpha_1}^{(-1)}|^q \cdots |B_{j_m, \alpha_m}^{(-1)}|^q \right. \\ & \quad \left. \left[\sum_{\beta \in I_{l-m}} \int_K |D^l v(\mathbf{x}) \cdot (\mathbf{b}_{j_1}, \dots, \mathbf{b}_{j_m}, \mathbf{b}_{\beta_1}, \dots, \mathbf{b}_{\beta_{l-m}})|^p d\mathbf{x} \right]^{\frac{q}{p}} \right\}^{\frac{1}{q}} \\ & \leq C |\det \mathbf{B}|^{\frac{1}{q} - \frac{1}{p}} \left[\sum_{s \in I_{l-m}} \left(\prod_{i=1}^{l-m} h_{s_i}^p \right) |D^{l-m} v \cdot (\mathbf{e}_{s_1}, \dots, \mathbf{e}_{s_{l-m}})|_{m,p,K}^p \right]^{\frac{1}{p}}. \end{aligned}$$

The estimates of Apel [1, Theorem 2.1] and of Theorem 3.2 start from the same bound on the element \hat{K} . We recall that the bounds on \hat{K} in Lemma 3.4 do not require further geometric assumption. After exploiting the affine transformation between K and \hat{K} , the estimates of Apel and of Theorem 3.2 differ on the physical element K . Apel uses, in the right-hand side, partial derivatives along the coordinate axis direction. To bound the affine transformations from K to \hat{K} and from \hat{K} to K with (4.6), Apel requires geometric limitations on the element K : a maximum angle condition and a coordinate system condition. On the other hand, the bounds in this paper emphasize directional derivatives of the function along adjacent edges. They do not require further geometric assumption on K . These new bounds use element-related directions which are more appropriate for mesh adaptation techniques.

4.2. Behavior with small and large angles. In this section, we study the behavior of our bounds when small or large angles are present. We focus on elements in \mathbb{R}^2 , but the comments hold also for elements in \mathbb{R}^3 .

4.2.1. Right-angled triangle with a small angle. Let us consider the triangle

$$K = \{(x_1, x_2) \in \mathbb{R}^2 \mid 0 < x_1 < h \text{ and } 0 < x_2 < h^{\beta-1}(h - x_1)\},$$

where h is a real positive number, smaller than 1, that will converge to 0. β is a real positive number greater than 1. This triangle exhibits a small angle at the node $(h, 0)$ and two angles close to $\pi/2$ at the other nodes. We choose the matrix \mathbf{B} for the affine map to be

$$\mathbf{B} = \begin{bmatrix} h & 0 \\ 0 & h^\beta \end{bmatrix}.$$

Suppose we want to approximate the function $v(x_1, x_2) = x_1^2$. The nodal interpolant with \mathbb{P}_1 functions is $\Pi v(x_1, x_2) = hx_1$. The $W^{1,2}$ seminorm of the interpolation error satisfies

$$(4.8) \quad |v - \Pi v|_{1,2,K} = \left(\int_K |\nabla v - \nabla \Pi v|^2 \right)^{1/2} = \frac{1}{\sqrt{6}} h^{\frac{3+\beta}{2}}.$$

As the function v depends only on the variable x_1 , we have

$$\mathbf{B}^T D^2 v \mathbf{B} = \begin{bmatrix} 2h^2 & 0 \\ 0 & 0 \end{bmatrix}.$$

So the upper bound for the $W^{1,2}$ seminorm becomes

$$\left(\int_K \left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B} \right\|_F^2 dx \right)^{\frac{1}{2}} = \sqrt{2} h^{\frac{3+\beta}{2}},$$

which has the correct asymptotic behavior when h goes to zero.

Ciarlet [8, Theorem 3.1.2], Formaggia and Perotto [10, Proposition 2.1], and Huang [13, Lemma 2.1] use, as a starting point for their estimates, the following isotropic bound:

$$(4.9) \quad |v - \Pi v|_{1,2,K} \leq C \sqrt{\det \mathbf{B}} \|\mathbf{B}^{-1}\|_2 \left| \hat{v} - \hat{\Pi} \hat{v} \right|_{1,2,\hat{K}}.$$

We will show that this bound does not have the correct asymptotic behavior when the diameter of K goes to zero. On the reference triangle, we have

$$\hat{v}(\hat{x}_1, \hat{x}_2) = h^2 \hat{x}_1^2 \quad \text{and} \quad \left| \hat{v} - \hat{\Pi} \hat{v} \right|_{1,2,\hat{K}} = \frac{h^2}{\sqrt{6}}.$$

So the bound (4.9) becomes

$$\sqrt{\det \mathbf{B}} \|\mathbf{B}^{-1}\|_2 \left| \hat{v} - \hat{\Pi} \hat{v} \right|_{1,2,\hat{K}} = h^{\frac{1+\beta}{2}} h^{-\beta} \frac{h^2}{\sqrt{6}} = \frac{1}{\sqrt{6}} h^{\frac{5-\beta}{2}}.$$

The upper bound (4.9) is not sharp because of the term $\|\mathbf{B}^{-1}\|_2$. The isotropic estimate (4.9) can even explode to infinity when $\beta > 5$ while the interpolation error converges to zero. As the asymptotic behavior of (4.9) is not correct, the derived bounds of Ciarlet [8], Formaggia and Perotto [10], and Huang [13] will not have the correct asymptotic behavior. For this particular element and this choice of basis $(\mathbf{b}_j)_{1 \leq j \leq d}$, our new bound is sharper than the three existing results of Ciarlet [8], Formaggia and Perotto [10], and Huang [13].

Effect of node numbering. For this triangle, we can define three different matrices \mathbf{B} when we assume that the edges \mathbf{b}_1 and \mathbf{b}_2 are ordered counter-clockwise. We will assess the effect of these different matrices on the upper bound for $|v - \Pi v|_{1,2,K}$.

If we choose the matrix \mathbf{B} to be

$$\mathbf{B} = \begin{bmatrix} h & 0 \\ 0 & h^\beta \end{bmatrix},$$

the previous analysis shows that the upper bound has the correct asymptotic behavior. When the matrix \mathbf{B} is

$$\mathbf{B} = \begin{bmatrix} 0 & h \\ -h^\beta & -h^\beta \end{bmatrix},$$

the same conclusion holds. However, when we choose

$$\mathbf{B} = \begin{bmatrix} -h & -h \\ h^\beta & 0 \end{bmatrix},$$

the upper bound becomes

$$\left(\int_K \left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B} \right\|_F^2 d\mathbf{x} \right)^{\frac{1}{2}} = \sqrt{4h^{3+\beta} + 8h^{5-\beta}},$$

which does not have the correct asymptotic behavior when h goes to zero. This example illustrates that the bound (3.6) is not invariant with the numbering of vertices. We expect that the same conclusion holds for tetrahedra. Finally, we note that the upper bound (4.9) gives in all three cases the wrong asymptotic behavior when h goes to zero.

4.2.2. Rectangle with a large aspect ratio. Let us consider the rectangle

$$K = \{(x_1, x_2) \in \mathbb{R}^2 \mid 0 < x_1 < h \text{ and } 0 < x_2 < h^\beta\},$$

where h is a real positive number, smaller than 1, that will converge to 0. β is a real positive number greater than 1. We choose the matrix \mathbf{B} for the affine map to be

$$\mathbf{B} = \begin{bmatrix} h & 0 \\ 0 & h^\beta \end{bmatrix}.$$

We want to approximate the function $v(x_1, x_2) = x_1^2$. The nodal interpolant with \mathbb{Q}_1 functions is $\Pi v(x_1, x_2) = hx_1$. The $W^{1,2}$ seminorm of the interpolation error satisfies

$$(4.10) \quad |v - \Pi v|_{1,2,K} = \left(\int_K |\nabla v - \nabla \Pi v|^2 \right)^{1/2} = \frac{1}{\sqrt{3}} h^{\frac{3+\beta}{2}}.$$

We remark that

$$|v|_{2,2,K} = 2h^{\frac{1+\beta}{2}} \text{ and } |v - \Pi v|_{1,2,K} = \frac{h}{2\sqrt{3}} |v|_{2,2,K}.$$

Similarly to section 4.2.1, we can show that the upper bound for the $W^{1,2}$ seminorm is

$$\left(\int_K \left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B} \right\|_F^2 dx \right)^{\frac{1}{2}} = 2h^{\frac{3+\beta}{2}},$$

which has the correct asymptotic behavior when h goes to zero. However, the isotropic bound (4.9) satisfies

$$\sqrt{\det \mathbf{B}} \|\mathbf{B}^{-1}\|_2 |\hat{v} - \hat{\Pi} \hat{v}|_{1,2,\hat{K}} = h^{\frac{1+\beta}{2}} h^{-\beta} \frac{h^2}{\sqrt{6}} = \frac{1}{\sqrt{6}} h^{\frac{5-\beta}{2}},$$

which does not exhibit the correct asymptotic behavior when h goes to zero. For rectangular elements, Georgoulis et al. [12] and Huang [13] use the isotropic bound (4.9) as a starting point for their estimates. As the asymptotic behavior of (4.9) is not correct, the derived bounds of Georgoulis et al. [12] and Huang [13] will not have the correct asymptotic behavior. For this particular element, our new bound is sharper than the existing results of Georgoulis et al. [12] and Huang [13]. Mesh adaptation techniques based on (4.9) or on derived bounds could result in overmeshing.

Effect of node numbering. For this rectangle, we can define four different matrices \mathbf{B} when we assume that the edges \mathbf{b}_1 and \mathbf{b}_2 are ordered counter-clockwise. Here, the upper bound for $|v - \Pi v|_{1,2,K}$ remains unchanged for all the matrices. Indeed, for a rectangle or a parallelogram, the edge directions remain the same. In the upper bounds, making different choices of adjacent edges result in permuting the same terms, which will not change the asymptotic behavior of the upper bound. The same remark holds for parallelepipeds. Finally, we note that the upper bound (4.9) gives in all four cases the wrong asymptotic behavior when h goes to zero.

4.2.3. Rotating triangle with a large angle. We consider a rotating triangle K_α with vertices $(-\cos \alpha/2, -\sin \alpha/2)$, $(\cos \alpha/2, \sin \alpha/2)$, and $(-h \sin \alpha, h \cos \alpha)$. h is a real positive number that will go to 0. This triangle exhibits a large angle at the third vertex $(-h \sin \alpha, h \cos \alpha)$. We choose the matrix \mathbf{B} for the affine map to be

$$\mathbf{B} = \begin{bmatrix} \cos \alpha & -h \sin \alpha + \frac{\cos \alpha}{2} \\ \sin \alpha & h \cos \alpha + \frac{\sin \alpha}{2} \end{bmatrix}.$$

The shape functions are

$$\begin{aligned} \phi_{1,K_\alpha}(x_1, x_2) &= \frac{1}{2} - \left(\cos \alpha - \frac{\sin \alpha}{2h} \right) x_1 - \left(\sin \alpha + \frac{\cos \alpha}{2h} \right) x_2, \\ \phi_{2,K_\alpha}(x_1, x_2) &= \frac{1}{2} + \left(\cos \alpha + \frac{\sin \alpha}{2h} \right) x_1 + \left(\sin \alpha - \frac{\cos \alpha}{2h} \right) x_2, \\ \phi_{3,K_\alpha}(x_1, x_2) &= -\frac{\sin \alpha}{h} x_1 + \frac{\cos \alpha}{h} x_2. \end{aligned}$$

We want to approximate the function $v(x_1, x_2) = x_1^2$. The nodal interpolant with \mathbb{P}_1 functions is

$$\begin{aligned} \Pi v(x_1, x_2) &= \frac{1}{4} \cos^2 \alpha [\phi_{1,K_\alpha}(x_1, x_2) + \phi_{2,K_\alpha}(x_1, x_2)] + h^2 \sin^2 \alpha \phi_{3,K_\alpha}(x_1, x_2), \\ \Pi v(x_1, x_2) &= \frac{1}{4} \cos^2 \alpha - x_1 \left(h \sin^3 \alpha - \frac{\cos^2 \alpha \sin \alpha}{4h} \right) + x_2 \left(h \cos \alpha \sin^2 \alpha - \frac{\cos^3 \alpha}{4h} \right). \end{aligned}$$

We have the following integrals:

$$\begin{aligned} \int_{K_\alpha} \left[\frac{\partial}{\partial x_1} (v - \Pi v) \right]^2 &= h^3 \left(\frac{1}{3} \sin^2 \alpha - \frac{2}{3} \sin^4 \alpha + \frac{1}{2} \sin^6 \alpha \right) \\ &\quad + \frac{h}{12} (\cos^2 \alpha + 2 \cos^2 \alpha \sin^2 \alpha - 3 \cos^2 \alpha \sin^4 \alpha) + \frac{\cos^4 \alpha \sin^2 \alpha}{32h} \end{aligned}$$

and

$$\int_{K_\alpha} \left[\frac{\partial}{\partial x_2} (v - \Pi v) \right]^2 = \frac{\cos^6 \alpha}{32h} - \frac{h}{4} \cos^4 \alpha \sin^2 \alpha + \frac{h^3}{2} \cos^2 \alpha \sin^4 \alpha.$$

For $\alpha = 0$, the $W^{1,2}$ seminorm of the interpolation error is

$$|v - \Pi v|_{1,2,K_0} = \sqrt{\frac{h}{12} + \frac{1}{32h}}.$$

The interpolation error becomes unbounded when h goes to zero. This example was introduced by Babuška and Aziz [2] to justify that all interior angles of a triangle should be bounded away from π . The upper bound (3.18) becomes

$$\left(\int_{K_0} \left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B} \right\|_F^2 d\mathbf{x} \right)^{\frac{1}{2}} = \sqrt{\frac{5h}{2} + \frac{5}{4h}},$$

which has the correct asymptotic behavior when h goes to zero. We can also bound separately the partial derivative in x_1

$$\int_{K_0} \left[\frac{\partial}{\partial x_1} (v - \Pi v) \right]^2 \leq C \int_{K_0} \left\| \begin{bmatrix} |B_{1,1}^{(-1)}| & 0 \\ 0 & |B_{2,1}^{(-1)}| \end{bmatrix} \mathbf{B}^T D^2 v \mathbf{B} \right\|_F^2 = \frac{5Ch}{2},$$

which has the correct asymptotic behavior. The upper bound for the partial derivative in x_2 has also the correct asymptotic behavior.

For $\alpha = \pi/2$, the $W^{1,2}$ seminorm of the interpolation error is

$$|v - \Pi v|_{1,2,K_{\pi/2}} = \sqrt{\frac{h^3}{6}}.$$

Here the interpolation error converges to 0 when h goes to zero even though a large angle is present in the triangle $K_{\pi/2}$. This example illustrates the importance of the element orientation with respect to the function v . When studying the linear interpolation error for quadratic functions, Cao [5] highlighted also the importance of the element orientation with respect to the function when a large angle is present in the triangle.

The upper bound (3.18) becomes

$$\left(\int_{K_{\pi/2}} \left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B} \right\|_F^2 dx \right)^{\frac{1}{2}} = \sqrt{2} h^{\frac{3}{2}},$$

which has the correct asymptotic behavior when h goes to zero. We can also bound separately the partial derivatives in x_1

$$\int_{K_{\pi/2}} \left[\frac{\partial}{\partial x_1} (v - \Pi v) \right]^2 \leq C \int_{K_{\pi/2}} \left\| \begin{bmatrix} |B_{1,1}^{(-1)}| & 0 \\ 0 & |B_{2,1}^{(-1)}| \end{bmatrix} \mathbf{B}^T D^2 v \mathbf{B} \right\|_F^2 = 2Ch^3,$$

and in x_2

$$\int_{K_{\pi/2}} \left[\frac{\partial}{\partial x_2} (v - \Pi v) \right]^2 \leq C \int_{K_{\pi/2}} \left\| \begin{bmatrix} |B_{1,2}^{(-1)}| & 0 \\ 0 & |B_{2,2}^{(-1)}| \end{bmatrix} \mathbf{B}^T D^2 v \mathbf{B} \right\|_F^2 = 0.$$

Both upper bounds have the correct asymptotic behavior when h goes to zero.

Effect of node numbering. For this example, we can define three different matrices \mathbf{B} when we assume that the edges \mathbf{b}_1 and \mathbf{b}_2 are ordered counter-clockwise.

When α is 0 and if we choose the matrix \mathbf{B} to be

$$\mathbf{B} = \begin{bmatrix} 1 & \frac{1}{2} \\ 0 & h \end{bmatrix} \quad \text{or} \quad \mathbf{B} = \begin{bmatrix} -\frac{1}{2} & -1 \\ h & 0 \end{bmatrix},$$

the upper bound remains unchanged and it has the correct asymptotic behavior. When $\alpha = 0$ and the matrix \mathbf{B} is

$$\mathbf{B} = \begin{bmatrix} -\frac{1}{2} & \frac{1}{2} \\ -h & -h \end{bmatrix},$$

the upper bound becomes

$$\left(\int_{K_0} \left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B} \right\|_F^2 dx \right)^{\frac{1}{2}} = \sqrt{\frac{h}{2} + \frac{1}{8h}},$$

which still has the correct asymptotic behavior when h goes to zero.

The same conclusion holds when $\alpha = \pi/2$. For this example, the bound (3.18) keeps the same asymptotic behavior.

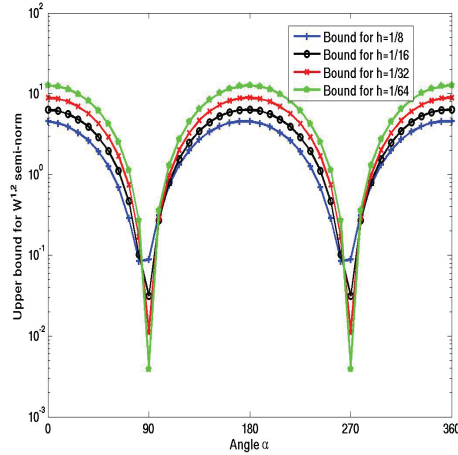

FIG. 4.1. Behavior of upper bound (3.18) for different heights.

Effect of α . Finally, in Figure 4.1, we present the behavior of the upper bound (3.18) as a function of α for several heights h . The upper bound increases when h goes to zero except when α is equal to $\pi/2$ and $3\pi/2$. This final example shows that the upper bound (3.18) reproduces the correct asymptotic behavior for every angle α . Therefore, the validity of (3.18) is not subject to a limitation on the angle between the largest edge and the x_1 -axis.

4.2.4. Parallelogram with two large angles. Let us consider the parallelogram

$$K = \left\{ (x_1, x_2) \in \mathbb{R}^2 \mid -\frac{1}{2} < x_1 < \frac{1}{2} \text{ and } |x_2| < h(1 - 2|x_1|) \right\},$$

where h is a real positive number, smaller than 1, that will converge to 0. This parallelogram exhibits two large angles at the nodes $(0, -h)$ and $(0, h)$ and two small angles at the other vertices. We choose the matrix \mathbf{B} for the affine map to be

$$\mathbf{B} = \begin{bmatrix} \frac{1}{2} & -\frac{1}{2} \\ h & h \end{bmatrix}.$$

We want to approximate the function $v(x_1, x_2) = x_1^2$. The nodal interpolant with \mathbb{Q}_1 functions is

$$\Pi v(x_1, x_2) = \frac{1}{4} \left[2x_1^2 - \frac{x_2^2}{2h^2} + \frac{1}{2} \right].$$

The $W^{1,2}$ seminorm of the interpolation error satisfies

$$(4.12) \quad |v - \Pi v|_{1,2,K} = \left(\int_K |\nabla v - \nabla \Pi v|^2 \right)^{1/2} = \sqrt{\frac{h}{24} + \frac{1}{96h}}.$$

The upper bound for the $W^{1,2}$ seminorm is

$$\left(\int_K \left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B} \right\|_F^2 dx \right)^{\frac{1}{2}} = \sqrt{h + \frac{1}{4h}},$$

which has the correct asymptotic behavior when h goes to zero.

We want to approximate the function $v(x_1, x_2) = x_2^2$. The nodal interpolant with \mathbb{Q}_1 functions is

$$\Pi v(x_1, x_2) = h^2 \left[-2x_1^2 + \frac{x_2^2}{2h^2} + \frac{1}{2} \right].$$

The $W^{1,2}$ seminorm of the interpolation error satisfies

$$(4.13) \quad |v - \Pi v|_{1,2,K} = \left(\int_K |\nabla v - \nabla \Pi v|^2 \right)^{1/2} = \sqrt{\frac{2h^5}{3} + \frac{h^3}{6}}.$$

The upper bound for the $W^{1,2}$ seminorm is

$$\left(\int_K \left\| \begin{bmatrix} \|\mathbf{B}^{-1}(1, \cdot)\|_2 & 0 \\ 0 & \|\mathbf{B}^{-1}(2, \cdot)\|_2 \end{bmatrix} \mathbf{B}^T D^2 v(\mathbf{x}) \mathbf{B} \right\|_F^2 dx \right)^{\frac{1}{2}} = \sqrt{4h^3 + 16h^5},$$

which has also the correct asymptotic behavior when h goes to zero.

When two large angles are present in a parallelogram, this example illustrates the importance of the element orientation with respect to the function v . In both cases, the upper bound (3.18) has the correct asymptotic behavior.

5. Conclusion. We have presented new anisotropic error estimates for the Lagrangian finite element interpolation on affine equivalent elements. The bounds use information from the directional derivatives of the function to interpolate along adjacent edges. Besides the affine equivalent assumption on K , these local estimates do not require further geometric assumption. For simplices, the asymptotic behavior of the bounds, when the diameter of the element goes to zero, may vary with the choice of node ordering. However, for parallelograms and parallelepipeds, the asymptotic behavior does not vary with the choice of node ordering. Finally, we showed that existing results can be derived from our new bounds. For some simple cases, the new bounds are sharper than some existing results.

POSTPROCESSING FINITE-ELEMENT METHODS FOR THE NAVIER–STOKES EQUATIONS: THE FULLY DISCRETE CASE*

JAVIER DE FRUTOS[†], BOSCO GARCÍA-ARCHILLA[‡], AND JULIA NOVO[§]

Abstract. An accuracy-enhancing postprocessing technique for finite-element discretizations of the Navier–Stokes equations is analyzed. The technique had been previously analyzed only for semidiscretizations, and fully discrete methods are addressed in the present paper. We show that the increased spatial accuracy of the postprocessing procedure is not affected by the errors arising from any convergent time-stepping procedure. Further refined bounds are obtained when the time-stepping procedure is either the backward Euler method or the two-step backward differentiation formula.

Key words. Navier–Stokes equations, mixed finite-element methods, time-stepping methods, optimal regularity, error estimates, backward Euler method, two-step BDF

1. Introduction. The purpose of the present paper is to study a postprocessing technique for fully discrete mixed finite-element (MFE) methods for the incompressible Navier–Stokes equations

$$(1.1) \quad u_t - \Delta u + (u \cdot \nabla)u + \nabla p = f,$$

$$(1.2) \quad \operatorname{div}(u) = 0,$$

in a bounded domain $\Omega \subset \mathbb{R}^d$ ($d = 2, 3$) with smooth boundary subject to homogeneous Dirichlet boundary conditions $u = 0$ on $\partial\Omega$. In (1.1), u is the velocity field, p the pressure, and f a given force field. We assume that the fluid density and viscosity have been normalized by an adequate change of scale in space and time.

For semidiscrete MFE methods the postprocessing technique has been studied in [2, 3, 18] and is as follows. In order to approximate the solution u and p corresponding to a given initial condition

$$(1.3) \quad u(\cdot, 0) = u_0,$$

at a time $t \in (0, T]$, $T > 0$, consider first standard MFE approximations u_h and p_h to the velocity and pressure, respectively, solutions at time $t \in (0, T]$ of the corresponding discretization of (1.1)–(1.3). Then compute MFE approximations \tilde{u}_h and \tilde{p}_h to the

solution \tilde{u} and \tilde{p} of the following Stokes problem,

$$(1.4) \quad -\Delta \tilde{u} + \nabla \tilde{p} = f - \frac{d}{dt}u_h - (u_h \cdot \nabla)u_h \quad \text{in } \Omega,$$

$$(1.5) \quad \operatorname{div}(\tilde{u})=0 \quad \text{in } \Omega,$$

$$(1.6) \quad \tilde{u} = 0 \quad \text{on } \partial\Omega.$$

The MFE on this postprocessing step can be either the same MFE over a finer grid or a higher-order MFE over the same grid. In [2, 18] it is shown that if the errors in the velocity (in the H^1 norm) and the pressure of the standard MFE approximations u_h and p_h are $O(t^{-(r-2)/2}h^{r-1})$, $r = 2, 3, 4$, for $t \in (0, T]$, then those of the postprocessed approximations \tilde{u}_h and \tilde{p}_h are $O(t^{-(r-1)/2}h^r |\log(h)|)$, that is, an $O(h |\log(h)|)$ improvement with respect the standard MFE error bound (see precise statement on Theorem 2.2 below), and if $r \geq 3$ (finite elements of degree at least two), the $O(h |\log(h)|)$ improvement is also obtained in the L^2 norm of the velocity.

In practice, however, the finite-element approximations u_h and p_h can rarely be computed exactly, and one has to compute approximations $U_h^{(n)} \approx u_h(t_n)$ and $P_h^{(n)} \approx p_h(t_n)$ at some time levels $0 = t_0 < t_1 \cdots < t_N = T$, by means of a time integrator. Consequently, instead of the postprocessed approximations $\tilde{u}_h(t_n)$ and $\tilde{p}_h(t_n)$, one obtains $\tilde{U}_h^{(n)}$ and $\tilde{P}_h^{(n)}$ as solutions of a system similar to (1.4)–(1.6) but with u_h on the right-hand side of (1.4) replaced by $U_h^{(n)}$ and \dot{u}_h replaced by an appropriate approximation $d_t^*U_h^{(n)}$.

In the present paper we analyze the errors $u(t_n) - \tilde{U}_h^{(n)}$ and $p(t_n) - \tilde{P}_h^{(n)}$. We show that, if any convergent time stepping procedure is used to integrate the standard MFE approximation, then the error of the fully discrete postprocessed approximation, $u(t_n) - \tilde{U}_h^{(n)}$, is that of the semidiscrete postprocessed approximation $u(t_n) - \tilde{u}_h$ plus a term \tilde{e}_n whose norm is proportional to that of the time-discretization error $e_n = u_h(t_n) - U_h^{(n)}$ of the MFE method, and, furthermore, we show $\tilde{e}_n = e_n$ plus higher-order terms for two particular time integration methods, the backward Euler method and the two-step backward differentiation formula (BDF) [9] (see also [25, section III.1]). We remark that the fact that \tilde{e}_n is asymptotically equivalent to e_n has proved its relevance when developing a posteriori error estimators for dissipative problems [17] (see also [15, 16]). To prove $\tilde{e}_n \approx e_n$ we perform first a careful error analysis of the backward Euler method and the two-step BDF. This allows us to obtain error estimates for the pressure that improve by a factor of the time step k those in the literature [10, 34].

It must be noticed that the backward Euler method and the two-step BDF are the only G-stable methods (see, e.g., [26, section V.6]) in the BDF family of methods. G-stability makes it easier the use of energy methods in the analysis, and this has proved crucial in obtaining our error bounds. At present we ignore if error bounds similar to that obtained in the present paper can be obtained without resource to energy methods, so that error bounds for higher-order methods in the BDF family of methods can be proved.

The analysis of fully discrete postprocessed methods may be less trivial than it may seem at first sight, since although many results for postprocessed semidiscrete methods can be found in the literature (see next paragraph) as well as numerical experiments (carried out with fully discrete methods) showing an increase in accuracy similar to that theoretically predicted in semidiscrete methods [3, 11, 14, 12, 20, 22], the only analysis of postprocessed fully discrete methods is that by Yan [44]. There, for a semilinear parabolic equation of the type $u_t - \Delta u = F(u)$, Δ being the Laplacian

operator and F a smooth and bounded function, the postprocess of a finite-element (FE) approximation when integrated in time with the backward Euler method with fixed stepsize k is analyzed (higher-order time-stepping methods are also considered, but only for linear homogeneous parabolic equations). Error estimates are obtained where an $O(k(1 + h^2))$ term is added to the bounds previously obtained for the postprocessed semidiscrete approximation. It must be remarked, though, that in [44] no attempt is made to analyze methods for equations with convective terms. In fact, in [44], it is stated that “It is not quite clear how it is possible to generalize our method to deal with a nonlinear convection term”. This is precisely what we do in the present paper.

The postprocess technique considered here was first developed for spectral methods in [20, 21]. Later it was extended to methods based on Chebyshev and Legendre polynomials [11], spectral element methods [12, 13], and finite element methods [22, 14]. In these works, numerical experiments show that, if the postprocessed approximation is computed at the final time T , the postprocessed method is computationally more efficient than the method to which it is applied. Similar results are obtained in the numerical experiments in [2, 3] for MFE methods. Due to this better practical performance, the postprocessing technique has been applied to the study of nonlinear shell vibrations [37], as well as to stochastic differential parabolic equations [38]. Also, it has been effectively applied to reduce the order of practical engineering problems modeled by nonlinear differential systems [42, 43].

The postprocess technique can be seen as a two-level method, where the postprocessed (or fine-mesh) approximations \tilde{u}_h and \tilde{p}_h are an improvement of the previously computed (coarse mesh) approximations u_h and p_h . Recent research on two-level finite-element methods for the transient Navier–Stokes equations can be found in [23, 27, 28, 40] (see also [30, 29, 36, 39] for spectral discretizations), where the fully nonlinear problem is dealt with on the coarse mesh, and a linear problem is solved on the fine mesh.

The rest of the paper is as follows. In section 2 we introduce some standard material and the methods to be studied. In section 3 we analyze the fully discrete postprocessed method. In section 4 we prove some technical results and, finally, section 5 is devoted to analyze the time discretization errors of the MFE approximation when integrated with the backward Euler method or the two-step BDF.

2. Preliminaries and notations.

2.1. The continuous solution. We will assume that Ω is a bounded domain in \mathbb{R}^d , $d = 2, 3$, of class \mathcal{C}^m , for $m \geq 2$, and we consider the Hilbert spaces

$$\begin{aligned} H &= \{u \in L^2(\Omega)^d \mid \operatorname{div}(u) = 0, u \cdot n|_{\partial\Omega} = 0\}, \\ V &= \{u \in H_0^1(\Omega)^d \mid \operatorname{div}(u) = 0\}, \end{aligned}$$

endowed with the inner product of $L^2(\Omega)^d$ and $H_0^1(\Omega)^d$, respectively. For $l \geq 0$ integer and $1 \leq q \leq \infty$, we consider the standard Sobolev spaces, $W^{l,q}(\Omega)^d$, of functions with derivatives up to order l in $L^q(\Omega)$, and $H^l(\Omega)^d = W^{l,2}(\Omega)^d$. We will denote by $\|\cdot\|_l$ the norm in $H^l(\Omega)^d$, and $\|\cdot\|_{-l}$ will represent the norm of its dual space. We consider also the quotient spaces $H^l(\Omega)/\mathbb{R}$ with norm $\|p\|_{H^l/\mathbb{R}} = \inf\{\|p + c\|_l \mid c \in \mathbb{R}\}$.

Let $\Pi : L^2(\Omega)^d \longrightarrow H$ be the $L^2(\Omega)^d$ projection onto H . We denote by A the Stokes operator on Ω :

$$A : \mathcal{D}(A) \subset H \longrightarrow H, \quad A = -\Pi\Delta, \quad \mathcal{D}(A) = H^2(\Omega)^d \cap V.$$

Applying Leray’s projector to (1.1), the equations can be written in the form

$$u_t + Au + B(u, u) = \Pi f \quad \text{in } \Omega,$$

where $B(u, v) = \Pi(u \cdot \nabla)v$ for u, v in $H_0^1(\Omega)^d$.

We shall use the trilinear form $b(\cdot, \cdot, \cdot)$ defined by

$$b(u, v, w) = (F(u, v), w) \quad \forall u, v, w \in H_0^1(\Omega)^d,$$

where

$$F(u, v) = (u \cdot \nabla)v + \frac{1}{2}(\nabla \cdot u)v \quad \forall u, v \in H_0^1(\Omega)^d.$$

It is straightforward to verify that b enjoys the skew-symmetry property

$$(2.1) \quad b(u, v, w) = -b(u, w, v) \quad \forall u, v, w \in H_0^1(\Omega)^d.$$

Let us observe that $B(u, v) = \Pi F(u, v)$ for $u \in V, v \in H_0^1(\Omega)^d$.

We shall assume that u is a strong solution up to time $t = T$, so that

$$(2.2) \quad \|u(t)\|_1 \leq M_1, \quad \|u(t)\|_2 \leq M_2, \quad 0 \leq t \leq T,$$

for some constants M_1 and M_2 . We shall also assume that there exists another constant \tilde{M}_2 such that

$$(2.3) \quad \|f\|_1 + \|f_t\|_1 + \|f_{tt}\|_1 \leq \tilde{M}_2, \quad 0 \leq t \leq T.$$

Let us observe, however, that if for $k \geq 2$

$$\sup_{0 \leq t \leq T} \|\partial_t^{\lfloor k/2 \rfloor} f\|_{k-1-2\lfloor k/2 \rfloor} + \sum_{j=0}^{\lfloor (k-2)/2 \rfloor} \sup_{0 \leq t \leq T} \|\partial_t^j f\|_{k-2j-2} < +\infty,$$

and if Ω is of class C^k , then, according to Theorems 2.4 and 2.5 in [32], there exist positive constants M_k and K_k such that the following bounds hold:

$$(2.4) \quad \|u(t)\|_k + \|u_t(t)\|_{k-2} + \|p(t)\|_{H^{k-1}/\mathbb{R}} \leq M_k \tau(t)^{1-k/2},$$

$$(2.5) \quad \int_0^t \sigma_{k-3}(s) (\|u(s)\|_k^2 + \|u_s(s)\|_{k-2}^2 + \|p(s)\|_{H^{k-1}/\mathbb{R}}^2 + \|p_s(s)\|_{H^{k-3}/\mathbb{R}}^2) ds \leq K_k^2,$$

where $\tau(t) = \min(t, 1)$ and $\sigma_n = e^{-\alpha(t-s)}\tau^n(s)$ for some $\alpha > 0$. Observe that for $t \leq T < \infty$, we can take $\tau(t) = t$ and $\sigma_n(s) = s^n$. For simplicity, we will take these values of τ and σ_n .

We note that although the results in the present paper require only (2.2) and (2.3) to hold, those in [18] that we summarize in section 2.3 require that for $r = 3, 4$, (2.4)–(2.5) hold for $k = r + 2$.

2.2. The spatial discretization. Let $\mathcal{T}_h = (\tau_i^h, \phi_i^h)_{i \in I_h}, h > 0$ be a family of partitions of suitable domains Ω_h , where h is the maximum diameter of the elements $\tau_i^h \in \mathcal{T}_h$, and ϕ_i^h are the mappings of the reference simplex τ_0 onto τ_i^h . We restrict ourselves to quasi-uniform and regular meshes \mathcal{T}_h .

Let $r \geq 3$, we consider the finite-element spaces

$$S_{h,r} = \left\{ \chi_h \in \mathcal{C}(\bar{\Omega}_h) \mid \chi_h|_{\tau_i^h} \circ \phi_i^h \in P^{r-1}(\tau_0) \right\} \subset H^1(\Omega_h), \quad S_{h,r}^0 = S_{h,r} \cap H_0^1(\Omega_h),$$

where $P^{r-1}(\tau_0)$ denotes the space of polynomials of degree at most $r - 1$ on τ_0 . Since we are assuming that the meshes are quasi-uniform, the following inverse inequality holds for each $v_h \in (S_{h,r}^0)^d$ (see, e.g., [7, Theorem 3.2.6])

$$(2.6) \quad \|v_h\|_{W^{m,q}(\tau)^d} \leq Ch^{l-m-d(\frac{1}{q'}-\frac{1}{q})} \|v_h\|_{W^{l,q'}(\tau)^d},$$

where $0 \leq l \leq m \leq 1$, $1 \leq q' \leq q \leq \infty$, and τ is an element in the partition \mathcal{T}_h .

We shall denote by $(X_{h,r}, Q_{h,r-1})$ the so-called Hood–Taylor element [5, 35], when $r \geq 3$, where

$$X_{h,r} = (S_{h,r}^0)^d, \quad Q_{h,r-1} = S_{h,r-1} \cap L^2(\Omega_h)/\mathbb{R}, \quad r \geq 3,$$

and the so-called mini-element [6] when $r = 2$, where $Q_{h,1} = S_{h,2} \cap L^2(\Omega_h)/\mathbb{R}$, and $X_{h,2} = (S_{h,2}^0)^d \oplus \mathbb{B}_h$. Here, \mathbb{B}_h is spanned by the bubble functions b_τ , $\tau \in \mathcal{T}_h$, defined by $b_\tau(x) = (d + 1)^{d+1} \lambda_1(x) \cdots \lambda_{d+1}(x)$, if $x \in \tau$ and 0 elsewhere, where $\lambda_1(x), \dots, \lambda_{d+1}(x)$ denote the barycentric coordinates of x . For these elements a uniform inf-sup condition is satisfied (see [5]), that is, there exists a constant $\beta > 0$ independent of the mesh grid size h such that

$$(2.7) \quad \inf_{q_h \in Q_{h,r-1}} \sup_{v_h \in X_{h,r}} \frac{(q_h, \nabla \cdot v_h)}{\|v_h\|_1 \|q_h\|_{L^2/\mathbb{R}}} \geq \beta.$$

The approximate velocity belongs to the discretely divergence-free space

$$V_{h,r} = X_{h,r} \cap \{ \chi_h \in H_0^1(\Omega_h)^d \mid (q_h, \nabla \cdot \chi_h) = 0 \quad \forall q_h \in Q_{h,r-1} \},$$

which is not a subspace of V . We shall frequently write V_h instead of $V_{h,r}$ whenever the value of r plays no particular role.

Let $\Pi_h : L^2(\Omega)^d \rightarrow V_{h,r}$ be the discrete Leray’s projection defined by

$$(\Pi_h u, \chi_h) = (u, \chi_h) \quad \forall \chi_h \in V_{h,r}.$$

We will use the following well-known bounds

$$(2.8) \quad \|(I - \Pi_h)u\|_j \leq Ch^{l-j} \|u\|_l, \quad 1 \leq l \leq 2, \quad j = 0, 1.$$

We will denote by $A_h : V_h \rightarrow V_h$ the discrete Stokes operator defined by

$$(\nabla v_h, \nabla \phi_h) = (A_h v_h, \phi_h) = \left(A_h^{1/2} v_h, A_h^{1/2} \phi_h \right) \quad \forall v_h, \phi_h \in V_h.$$

Let $(u, p) \in (H^2(\Omega)^d \cap V) \times (H^1(\Omega)/\mathbb{R})$ be the solution of a Stokes problem with right-hand side g , we will denote by $s_h = S_h(u) \in V_h$ the so-called Stokes projection (see [33]) defined as the velocity component of solution of the following Stokes problem: find $(s_h, q_h) \in (X_{h,r}, Q_{h,r-1})$ such that

$$(2.9) \quad (\nabla s_h, \nabla \phi_h) + (\nabla q_h, \phi_h) = (g, \phi_h) \quad \forall \phi_h \in X_{h,r},$$

$$(2.10) \quad (\nabla \cdot s_h, \psi_h) = 0 \quad \forall \psi_h \in Q_{h,r-1}.$$

Obviously, $s_h = S_h(u)$. The following bound holds for $2 \leq l \leq r$:

$$(2.11) \quad \|u - s_h\|_0 + h \|u - s_h\|_1 \leq Ch^l (\|u\|_l + \|p\|_{H^{l-1}/\mathbb{R}}).$$

The proof of (2.11) for $\Omega = \Omega_h$ can be found in [33]. For the general case, Ω_h must be such that the value of $\delta(h) = \max_{x \in \partial\Omega_h} \text{dist}(x, \partial\Omega)$ satisfies

$$(2.12) \quad \delta(h) = O\left(h^{2(r-1)}\right).$$

This can be achieved if, for example, $\partial\Omega$ is piecewise of class $\mathcal{C}^{2(r-1)}$, and superparametric approximation at the boundary is used [1]. Under the same conditions, the bound for the pressure is [24]

$$(2.13) \quad \|p - q_h\|_{L^2/\mathbb{R}} \leq C_\beta h^{l-1} (\|u\|_l + \|p\|_{H^{l-1}/\mathbb{R}}),$$

where the constant C_β depends on the constant β in the inf-sup condition (2.7).

In the sequel we will apply the above estimates to the particular case in which (u, p) is the solution of the Navier–Stokes problem (1.1)–(1.3). In that case s_h is the discrete velocity in problem (2.9)–(2.10) with $g = f - u_t - (u \cdot \nabla u)$. Note that the temporal variable t appears here merely as a parameter and then, taking the time derivative, the error bounds (2.11) and (2.13) can also be applied to the time derivative of s_h changing u, p by u_t, p_t , respectively.

Since we are assuming that Ω is of class \mathcal{C}^m and $m \geq 2$, from (2.11) and standard bounds for the Stokes problem [1, 19], we deduce that

$$(2.14) \quad \|(A^{-1}\Pi - A_h^{-1}\Pi_h) f\|_j \leq Ch^{2-j} \|f\|_0 \quad \forall f \in L^2(\Omega)^d, \quad j = 0, 1.$$

In our analysis we shall frequently use the following relation, which is a consequence of (2.14) and the fact that any $f_h \in V_h$ vanishes on $\partial\Omega$. For some $c \geq 1$,

$$(2.15) \quad \frac{1}{c} \|A_h^{s/2} f_h\|_0 \leq \|f_h\|_s \leq c \|A_h^{s/2} f_h\|_0 \quad \forall f_h \in V_h, \quad s = 1, -1.$$

Finally, we will use the following inequalities whose proof can be obtained applying [32, Lemma 4.4]

$$(2.16) \quad \|v_h\|_\infty \leq C \|A_h v_h\|_0 \quad \forall v_h \in V_h,$$

$$(2.17) \quad \|\nabla v_h\|_{L^3} \leq C \|\nabla v_h\|_0^{1/2} \|A_h v_h\|_0^{1/2} \quad \forall v_h \in V_h.$$

We consider the finite-element approximation (u_h, p_h) to (u, p) , solution of (1.1)–(1.3). That is, given $u_h(0) = \Pi_h u_0$, we compute $u_h(t) \in X_{h,r}$ and $p_h(t) \in Q_{h,r-1}$, $t \in (0, T]$, satisfying

$$(2.18) \quad (\dot{u}_h, \phi_h) + (\nabla u_h, \nabla \phi_h) + b(u_h, u_h, \phi_h) + (\nabla p_h, \phi_h) = (f, \phi_h) \quad \forall \phi_h \in X_{h,r},$$

$$(2.19) \quad (\nabla \cdot u_h, \psi_h) = 0 \quad \forall \psi_h \in Q_{h,r-1}.$$

For convenience, we rewrite this problem in the following way,

$$(2.20) \quad \dot{u}_h + A_h u_h + B_h(u_h, u_h) = \Pi_h f, \quad u_h(0) = \Pi_h u_0,$$

where $B_h(u, v) = \Pi_h F(u, v)$.

For $r = 2, 3, 4, 5$, provided that (2.11)–(2.13) hold for $l \leq r$, and (2.4)–(2.5) hold for $k = r$, then we have

$$(2.21) \quad \|u(t) - u_h(t)\|_0 + h \|u(t) - u_h(t)\|_1 \leq C \frac{h^r}{t^{(r-2)/2}}, \quad 0 \leq t \leq T,$$

(see, e.g., [18, 32, 33]), and also,

$$(2.22) \quad \|p(t) - p_h(t)\|_{L^2/\mathbb{R}} \leq C \frac{h^{r-1}}{t^{(r'-2)/2}}, \quad 0 \leq t \leq T,$$

where $r' = r$ if $r \leq 4$ and $r' = r + 1$ if $r = 5$. Results in [18] hold for h sufficiently small. In the rest of the paper we assume h to be small enough for (2.21)–(2.22) to hold.

Observe that from (2.21) and (2.2) it follows that $\|u_h(t)\|_1$ is bounded for $0 \leq t \leq T$. However, further bounds for $u_h(t)$ will be needed in the present paper, so we recall the following result, which, since we are considering finite times $0 < T < +\infty$, it is a rewriting of [34, Proposition 3.2].

PROPOSITION 2.1. *Let the forcing term f in (1.1) satisfy (2.3). Then, there exists a constant $\tilde{M}_3 > 0$, depending only on \tilde{M}_2 , $\|A_h u_h(0)\|_0$ and $\sup_{0 \leq t \leq T} \|u_h(t)\|_1$, such that the following bounds hold for $0 \leq t \leq T$:*

$$(2.23) \quad F_{0,2}(t) \equiv \|A_h u_h(t)\|_0^2 \leq \tilde{M}_3^2,$$

$$(2.24) \quad F_{1,r}(t) \equiv t^r \|A_h^{r/2} \dot{u}_h(t)\|_0^2 \leq \tilde{M}_3^2, \quad r = 0, 1, 2,$$

$$(2.25) \quad F_{2,r}(t) \equiv t^{r+2} \|A_h^{r/2} \ddot{u}_h(t)\|_0^2 \leq \tilde{M}_3^2, \quad r = -1, 0, 1,$$

$$(2.26) \quad I_{1,r}(t) \equiv \int_0^t s^{r-1} \|A_h^{r/2} \dot{u}_h(s)\|_0^2 ds \leq \tilde{M}_3^2, \quad r = 1, 2,$$

$$(2.27) \quad I_{2,r}(t) \equiv \int_0^t s^{r+1} \|A_h^{r/2} \ddot{u}_h(s)\|_0^2 ds \leq \tilde{M}_3^2, \quad r = -1, 0, 1.$$

2.3. The postprocessed method. This method obtains for any $t \in (0, T]$ an improved approximation by solving the following discrete Stokes problem: find $(\tilde{u}_h(t), \tilde{p}_h(t)) \in (\tilde{X}, \tilde{Q})$ satisfying

$$(2.28) \quad \begin{aligned} (\nabla \tilde{u}_h(t), \nabla \tilde{\phi}) + (\nabla \tilde{p}_h(t), \tilde{\phi}) &= (f, \tilde{\phi}) - b(u_h(t), u_h(t), \tilde{\phi}) \\ &\quad - (\dot{u}_h(t), \tilde{\phi}) \quad \forall \tilde{\phi} \in \tilde{X}, \end{aligned}$$

$$(2.29) \quad (\nabla \cdot \tilde{u}_h(t), \tilde{\psi}) = 0 \quad \forall \tilde{\psi} \in \tilde{Q},$$

where (\tilde{X}, \tilde{Q}) is either:

- (a) The same-order MFE over a finer grid. That is, for $h' < h$, we choose $(\tilde{X}, \tilde{Q}) = (X_{h',r}, Q_{h',r-1})$.
- (b) A higher-order MFE over the same grid. In this case we choose $(\tilde{X}, \tilde{Q}) = (X_{h,r+1}, Q_{h,r})$.

In both cases, we will denote by \tilde{V} the corresponding discretely divergence-free space that can be either $\tilde{V} = V_{h',r}$ or $\tilde{V} = V_{h,r+1}$ depending on the selection of the postprocessing space. The discrete orthogonal projection into \tilde{V} will be denoted by $\tilde{\Pi}_h$, and we will represent by \tilde{A}_h the discrete Stokes operator acting on functions in \tilde{V} . Notice then that from (2.28) it follows that $\tilde{u}_h(t) \in \tilde{V}$ and it satisfies

$$(2.30) \quad \tilde{A}_h \tilde{u}_h(t) = \tilde{\Pi}_h (f - F(u_h(t), u_h(t)) - \dot{u}_h(t)).$$

In [18] the following result is proved.

THEOREM 2.2. *Let (u, p) be the solution of (1.1)–(1.3) and for $r = 3, 4$, let (2.4)–(2.5) hold with $k = r + 2$ and let (2.11) hold for $2 \leq l \leq r$. Then, there exists a*

positive constant C such that the postprocessed MFE approximation to u , \tilde{u}_h satisfies the following bounds for $r = 3, 4$ and $t \in (0, T]$:

(i) if the postprocessing element is $(\tilde{X}, \tilde{Q}) = (X_{h',r}, Q_{h',r-1})$, then

$$(2.31) \quad \|u(t) - \tilde{u}_h(t)\|_j \leq \frac{C}{t^{(r-2)/2}}(h')^{r-j} + \frac{C}{t^{(r-1)/2}}h^{r+1-j}|\log(h)|, \quad j = 0, 1,$$

$$(2.32) \quad \|p(t) - \tilde{p}_h(t)\|_{L^2/\mathbb{R}} \leq \frac{C}{t^{(r-2)/2}}(h')^{r-1} + \frac{C}{t^{(r-1)/2}}h^r|\log(h)|,$$

(ii) if the postprocessing element is $(\tilde{X}, \tilde{Q}) = (X_{h,r+1}, Q_{h,r})$, then

$$(2.33) \quad \|u(t) - \tilde{u}_h(t)\|_j \leq \frac{C}{t^{(r-1)/2}}h^{r+1-j}|\log(h)|, \quad j = 0, 1,$$

$$(2.34) \quad \|p(t) - \tilde{p}_h(t)\|_{L^2/\mathbb{R}} \leq \frac{C}{t^{(r-1)/2}}h^r|\log(h)|.$$

Since the constant C depends on the type of element used, the result is stated for a particular kind of MFE methods, but it applies to any kind of MFE method satisfying the *LBB* condition (2.7), the approximation properties (2.11)–(2.13), as well as negative norm estimates, that is,

$$\|u - s_h\|_{-m} \leq Ch^{l+\min(m,r-2)}(\|u\|_l + \|p\|_{H^{l-1}/\mathbb{R}})$$

for $m = 1, 2$ and $1 \leq l \leq r$. For these negative norm estimates to hold, it is necessary on the one hand that Ω is of class C^{2+m} , and, on the other hand, that $X_{h,r} \subset H_0^1(\Omega)^d$, so that $X_{h,r}$ consists of continuous functions vanishing on $\partial\Omega$ (i.e., discontinuous elements are excluded).

As pointed out in [18, Remark 4.2], with a much simpler analysis than that needed to prove Theorem 2.2, together with results in [2], the previous result applies to the so-called mini element ($r = 2$) but excluding the case $j = 0$ (L^2 errors) in (2.31) and (2.33).

3. Analysis of fully discrete postprocessed methods.

3.1. The general case. As mentioned in the Introduction, in practice, it is hardly ever possible to compute the MFE approximation exactly, and, instead, some time-stepping procedure must be used to approximate the solution of (2.18)–(2.19). Hence, for some time levels $0 = t_0 < t_1 < \dots < t_N = T$, approximations $U_h^{(n)} \approx u_h(t_n)$ and $P_h^{(n)} \approx p_h(t_n)$ are obtained. Then, given an approximation $d_t^*U_h^{(n)}$ to $\dot{u}_h(t_n)$, the fully discrete postprocessed approximation $(\tilde{U}_h^{(n)}, \tilde{P}_h^{(n)})$ is obtained as the solution of the following Stokes problem:

$$(3.1) \quad \left(\nabla \tilde{U}_h^{(n)}, \nabla \tilde{\phi} \right) + \left(\nabla \tilde{P}_h^{(n)}, \tilde{\phi} \right) = \left(f, \tilde{\phi} \right) - b \left(U_h^{(n)}, U_h^{(n)}, \tilde{\phi} \right) - \left(d_t^* U_h^{(n)}, \tilde{\phi} \right) \quad \forall \tilde{\phi} \in \tilde{X},$$

$$(3.2) \quad \left(\nabla \cdot \tilde{U}_h^{(n)}, \tilde{\psi} \right) = 0 \quad \forall \tilde{\psi} \in \tilde{Q},$$

where (\tilde{X}, \tilde{Q}) is as in (2.28)–(2.29). Notice then that $\tilde{U}_h^{(n)} \in \tilde{V}$ and it satisfies

$$(3.3) \quad \tilde{A}_h \tilde{U}_h^{(n)} = \tilde{\Pi}_h \left(f - F \left(U_h^{(n)}, U_h^{(n)} \right) - d_t^* U_h^{(n)} \right).$$

For reasons already analyzed in [17] and confirmed in the arguments that follow, we propose

$$(3.4) \quad d_t^* U_h^{(n)} = \Pi_h f - A_h U_h^{(n)} - B_h \left(U_h^{(n)}, U_h^{(n)} \right)$$

as an adequate approximation to the time derivative $\dot{u}_h(t_n)$, which is very convenient from the practical point of view.

We decompose the errors $u(t) - \tilde{U}_h^{(n)}$ and $p(t) - \tilde{P}_h^{(n)}$ as follows,

$$(3.5) \quad u(t) - \tilde{U}_h^{(n)} = (u(t) - \tilde{u}_h(t_n)) + \tilde{e}_n,$$

$$(3.6) \quad p(t_n) - \tilde{P}_h^{(n)} = (p(t_n) - \tilde{p}_h(t_n)) + \tilde{\pi}_n,$$

where $\tilde{e}_n = \tilde{u}_h(t_n) - \tilde{U}_h^{(n)}$ and $\tilde{\pi}_n = \tilde{p}_h(t_n) - \tilde{P}_h^{(n)}$ are the temporal errors of the fully discrete postprocessed approximation $(\tilde{U}_h^{(n)}, \tilde{P}_h^{(n)})$. The first terms on the right-hand sides of (3.5)–(3.6) are the errors of the (semidiscrete) postprocessed approximation whose size is estimated in Theorem 2.2. In the present section we analyze the time discretization errors \tilde{e}_n and $\tilde{\pi}_n$.

To estimate the size of \tilde{e}_n and $\tilde{\pi}_n$, we bound them in terms of

$$e_n = u_h(t_n) - U_h^{(n)},$$

the temporal error of the MFE approximation. We do this for any time-stepping procedure satisfying the following assumption

$$(3.7) \quad \lim_{k \rightarrow 0} \max_{0 \leq n \leq N} \|e_n\|_0 = 0, \quad \text{and} \quad \limsup_{k \rightarrow 0} \max_{0 \leq n \leq N} \|e_n\|_1 = O(1),$$

where $k = \max\{t_n - t_{n-1} \mid 1 \leq n \leq N\}$. Bounds for $\|e_n\|_0$ and $\|e_n\|_1$ of size $O(k^2/t_n)$ and $O(k/t_n^{1/2})$, respectively, have been proven for the Crank–Nicolson method in [34] (see also [41]). The arguments in [10] can be adapted to show that, for the two-step BDF, $\|e_n\|_j \leq Ck^{2-j}/t_n$, for $2 \leq n \leq N$, $j = 0, 1$ (although in section 5 we shall obtain sharper bounds of $\|e_n\|_1$). For problems in two spatial dimensions, bounds for a variety of methods can be found in the literature (see a summary in [31]).

In the arguments in the present section we use the following inequalities [34, (3.7)] which hold for all $v_h, w_h \in V_h$ and $\phi \in H_0^1(\Omega)^d$:

$$(3.8) \quad |b(v_h, v_h, \phi)| \leq c \|v_h\|_1^{3/2} \|A_h v_h\|_0^{1/2} \|\phi\|_0,$$

$$(3.9) \quad |b(v_h, w_h, \phi)| + |b(w_h, v_h, \phi)| \leq c \|v_h\|_1 \|A_h w_h\|_0 \|\phi\|_0,$$

$$(3.10) \quad |b(v_h, w_h, \phi)| + |b(w_h, v_h, \phi)| \leq \|v_h\|_1 \|w_h\|_1 \|\phi\|_1.$$

PROPOSITION 3.1. *Let (2.11) hold for $l = 2$. Then, there exists a positive constant $C = C(\max_{0 \leq t \leq T} \|A_h u_h(t)\|_0)$ such that*

$$(3.11) \quad \|\tilde{e}_n - e_n\|_j \leq Ch^{2-j} (\|e_n\|_1 + \|e_n\|_1^3 + \|A_h e_n\|_0), \quad j = 0, 1, \quad 1 \leq n \leq N,$$

$$(3.12) \quad \|\tilde{\pi}_n\|_{L^2(\Omega)/\mathbb{R}} \leq C(\|\tilde{e}_n\|_1 + \|e_n\|_1 + \|e_n\|_1^2), \quad 1 \leq n \leq N.$$

Proof. From (3.4) and (2.20) it follows that

$$(3.13) \quad \dot{u}_h(t_n) - d_t^* U_h^{(n)} = -A_h e_n + \Pi_h \left(F \left(U_h^{(n)}, U_h^{(n)} \right) - F(u_h(t_n), u_h(t_n)) \right),$$

so that subtracting (3.3) from (2.30) and multiplying by \tilde{A}_h^{-1} we get

$$(3.14) \quad \tilde{e}_n = -\tilde{A}_h^{-1}\tilde{\Pi}_h(I - \Pi_h)g + \tilde{A}_h^{-1}\tilde{\Pi}_h A_h e_n,$$

where $g = F(u_h(t_n), u_h(t_n)) - F(U_h^{(n)}, U_h^{(n)})$. By writing

$$\tilde{A}_h^{-1}\tilde{\Pi}_h A_h e_n = e_n + \left(\tilde{A}_h^{-1}\tilde{\Pi}_h - A_h^{-1}\right) A_h e_n,$$

and applying (2.14) we get

$$(3.15) \quad \|\tilde{e}_n - e_n\|_j \leq \left\| \tilde{A}_h^{-1}\tilde{\Pi}_h(I - \Pi_h)g \right\|_j + Ch^{2-j}\|A_h e_n\|_0, \quad j = 0, 1.$$

Similarly, for g we write

$$(3.16) \quad \tilde{A}_h^{-1}\tilde{\Pi}_h(I - \Pi_h)g = \left(\tilde{A}_h^{-1}\tilde{\Pi}_h - A^{-1}\Pi\right)(I - \Pi_h)g + A^{-1}\Pi(I - \Pi_h)g.$$

In order to bound the first term on the right-hand side above we first apply (2.14), and then we observe that $\|(I - \Pi_h)g\|_0 \leq \|g\|_0$. For the second term on the right-hand side of (3.16), we may use a simple duality argument and (2.8), so that we have $\|\tilde{A}_h^{-1}\tilde{\Pi}_h(I - \Pi_h)g\|_j \leq Ch^{2-j}\|g\|_0$. Now, by writing g as

$$(3.17) \quad g = F(e_n, u_h(t_n)) + F(u_h(t_n), e_n) - F(e_n, e_n),$$

a duality argument and (3.8)–(3.9) show that

$$\left\| \tilde{A}_h^{-1}\tilde{\Pi}_h(I - \Pi_h)g \right\|_j \leq Ch^{2-j} \left(\|A_h u_h(t_n)\|_0 \|e_n\|_1 + \|e_n\|_1^{3/2} \|A_h e_n\|_0^{1/2} \right).$$

Applying Hölder’s inequality to the last term on the right-hand side above, the bound (3.11) follows from (3.14) and (3.15).

For the pressure, subtracting (3.1) from (2.28) and recalling (3.13) we have

$$\left(\tilde{\pi}_n, \nabla \cdot \tilde{\phi}\right) = \left(\nabla \tilde{e}_n, \nabla \tilde{\phi}\right) + \left(g, \tilde{\phi}\right) + \left(\dot{u}_h - d_t^* U_h^{(n)}, \tilde{\phi}\right),$$

for all $\tilde{\phi} \in \tilde{X}$, where g is as in (3.17). Then, thanks to the inf-sup condition (2.7), we have

$$\|\tilde{\pi}_n\|_{L^2(\Omega)/\mathbb{R}} \leq C \left(\|\tilde{e}_n\|_1 + \sup_{\tilde{\phi} \in \tilde{X}} \frac{|(g, \tilde{\phi})|}{\|\tilde{\phi}\|_1} + \left\| \dot{u}_h(t_n) - d_t^* U_h^{(n)} \right\|_{-1} \right).$$

Taking into account the expression of g in (3.17) and applying (3.10) it follows that

$$\|\tilde{\pi}_n\|_{L^2(\Omega)/\mathbb{R}} \leq C \left(\|\tilde{e}_n\|_1 + \|e_n\|_1 (\|u_h(t_n)\|_1 + \|e_n\|_1) + \left\| \dot{u}_h - d_t^* U_h^{(n)} \right\|_{-1} \right),$$

so that (3.12) follows by applying Lemma 3.2 below, (2.15), and using the fact that $\|u_h(t_n)\|_1 \leq C\|A_h u_h(t_n)\|_0$. \square

LEMMA 3.2. *Under the hypotheses of Proposition 3.1, there exists a constant $C = C(\max_{0 \leq t \leq T} \|u_h(t)\|_1) > 0$ such that the following bound holds for $1 \leq n \leq N$:*

$$(3.18) \quad \left\| \dot{u}_h - d_t^* U_h^{(n)} \right\|_{-1} \leq C \left\| A_h^{1/2} e_n \right\|_0 \left(1 + \|A_h^{1/2} e_n\|_0 \right).$$

Proof. Since $\dot{u}_h - d_t^* U_h^{(n)} \in V_h$, we have

$$\left\| \dot{u}_h - d_t^* U_h^{(n)} \right\|_{-1} \leq C \left\| A_h^{-1/2} \left(\dot{u}_h - d_t^* U_h^{(n)} \right) \right\|_0,$$

due to (2.15). Thus, in view of (3.13), the lemma is proved if for

$$g = F(u_h(t_n), u_h(t_n)) - F \left(U_h^{(n)}, U_h^{(n)} \right),$$

we show that $\|A_h^{-1/2} \Pi_h g\|_0$ can be bounded by the right-hand side of (3.18). If we write g as in (3.17), a simple duality argument, (3.10), and the equivalence (2.15) show that, indeed,

$$\left\| A_h^{-1/2} \Pi_h g \right\|_0 \leq C \|e_n\|_1 (\|u_h(t_n)\|_1 + \|e_n\|_1).$$

Since according to (2.15), $\|e_n\|_1$ and $\|A_h^{1/2} e_n\|_0$ are equivalent, then the result follows. \square

Since we are assuming that the meshes are quasiuniform and, hence, both (2.6) and (2.15) hold, we have $Ch^{2-j} \|A_h e_n\|_0 \leq C \|e_n\|_j$ and $Ch \|e_n\|_1 \leq C \|e_n\|_0$. Thus, from (3.11)–(3.12) and (3.7) the following result follows.

THEOREM 3.3. *Let (2.11) hold for $l = 2$ and let (2.3) hold. Then there exists a positive constant C depending on $\max\{F_{2,0}(t) \mid 0 \leq t \leq T\}$, such that if the errors $e_n = u_h(t_n) - U_h^{(n)}$, $1 \leq n \leq N$ of any approximation $U_h^{(n)} \approx u_h(t_n)$ for $0 = t_0 < \dots < t_N$ satisfy (3.7), then the (fully discrete) postprocessed approximations $(\tilde{U}_h^{(n)}, \tilde{P}_h^{(n)})$ solution of (3.1)–(3.2) satisfy*

$$(3.19) \quad \left\| \tilde{u}_h(t_n) - \tilde{U}_h^{(n)} \right\|_j \leq C \left\| u_h(t_n) - U_h^{(n)} \right\|_j, \quad 1 \leq n \leq N, \quad j = 0, 1,$$

$$(3.20) \quad \left\| \tilde{p}_h(t_n) - \tilde{P}_h^{(n)} \right\|_{L^2(\Omega)/\mathbb{R}} \leq C \left\| u_h(t_n) - U_h^{(n)} \right\|_1, \quad 1 \leq n \leq N,$$

for k sufficiently small, where $(\tilde{u}_h(t_n), \tilde{p}_h(t_n))$ is the (semidiscrete) postprocessed approximation defined in (2.28)–(2.29).

3.2. The case of the BDF. Better estimates than (3.19) can be obtained when $\|A_h e_n\|_0$ can be shown to decay with k at the same rate as $\|e_n\|_0$. As mentioned in the introduction this will be shown to be the case of two (fixed time-step) time integration procedures in section 5: the backward Euler method and the two-step BDF [9] (see also [25, section III.1]). We describe them now.

For $N \geq 2$ integer, we fix $k = \Delta t = T/N$, and we denote $t_n = nk$, $n = 0, 1, \dots, N$. For a sequence $(y_n)_{n=0}^N$ we denote

$$Dy_n = y_n - y_{n-1}, \quad n = 1, 2, \dots, N.$$

Given $U_h^{(0)} = u_h(0)$, a sequence $(U_h^{(n)}, P_h^{(n)})$ of approximations to $(u_h(t_n), p_h(t_n))$, $n = 1, \dots, N$, is obtained by means of the following recurrence relation:

$$(3.21) \quad \left(d_t U_h^{(n)}, \phi_h \right) + \left(\nabla U_h^{(n)}, \nabla \phi_h \right) + b \left(U_h^{(n)}, U_h^{(n)}, \phi_h \right) - \left(P_h^{(n)}, \nabla \cdot \phi_h \right) = (f, \phi_h) \quad \forall \phi_h \in X_{h,r},$$

$$(3.22) \quad \left(\nabla \cdot U_h^{(n)}, \psi_h \right) = 0, \quad \forall \psi_h \in Q_{h,r-1},$$

where $d_t = k^{-1}D$ in the case of the backward Euler method and $d_t = k^{-1}(D + \frac{1}{2}D^2)$ for the two-step BDF. In this last case, a second starting value $U_h^{(1)}$ is needed. In the present paper, we will always assume that $U_h^{(1)}$ is obtained by one step of the backward Euler method. Also, for both the backward Euler and the two-step BDF, we assume that $U_h^{(0)} = u_h(0)$, which is usually the case in practical situations.

In order to cope for the minor differences between the two methods, we set

$$(3.23) \quad l_0 = \begin{cases} 1, & \text{for the backward Euler method,} \\ 2, & \text{for the two-step BDF.} \end{cases}$$

Under these conditions, we show in Lemma 5.2 and Theorems 5.4 and 5.7 in section 5 that the errors e_n of these two time integration procedures satisfy that

$$(3.24) \quad \|e_n\|_0 + t_n \|A_h e_n\|_0 \leq C_{l_0} \frac{k^{l_0}}{t_n^{l_0-1}}, \quad 1 \leq n \leq N,$$

for a certain constants C_1 and C_2 . These are, respectively, the terms between parentheses in (5.23) and (5.33) below, which as Proposition 2.1 above and Lemma 4.3 below show, can be bounded for $T > 0$ fixed. Thus, from Proposition 3.1 and (3.24) the following result follows readily.

THEOREM 3.4. *Under the hypotheses of Proposition 3.1, let the approximations $U_h^{(n)}$, $n = 1, \dots, N$ be obtained by either the backward Euler method or the two-step BDF under the conditions stated above. Then, there exist positive constants $C'_l = C(C_l)$, for $l = 1, 2$, and k' , such that for $k < k'$ the temporal errors \tilde{e}_n of the fully discrete postprocessed approximation satisfy that $\tilde{e}_n = e_n + r_n$, and*

$$\|r_n\|_j \leq C'_{l_0} h^{2-j} \frac{k^{l_0}}{t_n^{l_0}}, \quad j = 0, 1, \quad 1 \leq n \leq N.$$

We remark that a consequence of the above result is that for these two methods the temporal errors of the postprocessed and MFE approximations are asymptotically the same as $h \rightarrow 0$. This allows to use the difference $\gamma_h^{(n)} = \tilde{U}_h^{(n)} - U_h^{(n)}$ as an a posteriori error estimator of the spatial error of the MFE approximation, since, as shown in [15, 16, 17], its size is that of $u(t) - u_h(t)$ so long as the spatial and temporal errors are not too unbalanced.

We also remark that at a price of lengthening the already long and elaborate analysis in the present paper, variable stepsizes could have been considered following ideas in [4], but, for the sake of simplicity we consider only fixed stepsize in the analysis that follows.

4. Technical results.

4.1. Inequalities for the nonlinear term. We now obtain several estimates for the quadratic form $B_h(v, w) = \Pi_h F(u, v)$ that will be frequently used in our analysis. We start by proving an auxiliary result.

LEMMA 4.1. *Let (2.11) hold for $l = 2$. Then, the following bound holds for any f_h, g_h , and ψ_h in V_h :*

$$(4.1) \quad |b(f_h, g_h, \psi_h)| + |b(g_h, f_h, \psi_h)| \leq C \|A_h f_h\|_0 \|A_h^{-1/2} g_h\|_0 \|A_h \psi_h\|_0.$$

Proof. To prove this bound we will use the following identity,

$$I = A^{-1} \Pi A_h + (A_h^{-1} - A^{-1} \Pi) A_h.$$

It will be applied to either f_h or ψ_h whenever any of their derivatives appears in the expressions of $b(f_h, g_h, \psi_h)$ and $b(g_h, f_h, \psi_h)$. We deal first with the second term on the left-hand side of (4.1). Integrating by parts we may write

$$\begin{aligned} b(g_h, f_h, \psi_h) &= \frac{1}{2}((g_h \cdot \nabla)f_h, \psi_h) - \frac{1}{2}((g_h \cdot \nabla)\psi_h, f_h) \\ &= \frac{1}{2}((g_h \cdot \nabla)A^{-1}\Pi A_h f_h, \psi_h) - \frac{1}{2}((g_h \cdot \nabla)A^{-1}\Pi A_h \psi_h, f_h) \\ &\quad + \frac{1}{2}((g_h \cdot \nabla)(A_h^{-1} - A^{-1}\Pi)A_h f_h, \psi_h) \\ &\quad - \frac{1}{2}((g_h \cdot \nabla)(A_h^{-1} - A^{-1}\Pi)A_h \psi_h, f_h). \end{aligned}$$

Using (2.14) with $j = 1$ and (2.16), the last two terms on the right-hand side above can be bounded by

$$Ch(\|A_h f_h\|_0 \|\psi_h\|_\infty + \|A_h \psi_h\|_0 \|f_h\|_\infty) \|g_h\|_0 \leq Ch \|A_h f_h\|_0 \|A_h \psi_h\|_0 \|g_h\|_0.$$

By writing $\|g_h\|_0 \leq \|A_h^{1/2}\|_0 \|A_h^{-1/2} g_h\|_0 \leq Ch^{-1} \|A_h^{-1/2} g_h\|_0$, we thus have

$$(4.2) \quad \begin{aligned} |b_h(g_h, f_h, \psi_h)| &\leq \frac{1}{2} |((g_h \cdot \nabla)A^{-1}\Pi A_h f_h, \psi_h)| + \frac{1}{2} |((g_h \cdot \nabla)A^{-1}\Pi A_h \psi_h, f_h)| \\ &\quad + C \|A_h f_h\|_0 \|A_h \psi_h\|_0 \left\| A_h^{-1/2} g_h \right\|_0. \end{aligned}$$

Now, applying Hölder's inequality it easily follows that

$$\begin{aligned} |((g_h \cdot \nabla)A^{-1}\Pi f_h, \psi_h)| &\leq \\ &C \|g_h\|_{-1} (\|A^{-1}\Pi A_h f_h\|_2 \|\psi_h\|_\infty + \|\nabla A^{-1}\Pi A_h f_h\|_{L^6} \|\nabla \psi_h\|_{L^3}), \end{aligned}$$

so that, applying (2.16)–(2.17) and regularity estimates for the Stokes problem, and standard Sobolev's inequalities we have

$$(4.3) \quad |((g_h \cdot \nabla)A^{-1}\Pi f_h, \psi_h)| \leq C \|g_h\|_{-1} \|A_h f_h\|_0 \|A_h \psi_h\|_0.$$

Also, arguing similarly, $|((g_h \cdot \nabla)A^{-1}\Pi A_h \psi_h, f_h)| \leq C \|g_h\|_{-1} \|A_h f_h\|_0 \|A_h \psi_h\|_0$, so that from (4.2) and (4.3) it follows that

$$|b(g_h, f_h, \psi_h)| \leq C \left(\|g_h\|_{-1} + \left\| A_h^{-1/2} g_h \right\|_0 \right) \|A_h f_h\|_0 \|A_h \psi_h\|_0.$$

Now, recalling the equivalence (2.15) we have

$$(4.4) \quad |b(g_h, f_h, \psi_h)| \leq C \left\| A_h^{-1/2} g_h \right\|_0 \|A_h f_h\|_0 \|A_h \psi_h\|_0.$$

For the second term on the left-hand side of (4.1), thanks to (2.1) we may write

$$\begin{aligned} |b(f_h, g_h, \psi_h)| &\leq |((f_h \cdot \nabla)A^{-1}\Pi A_h \psi_h, g_h)| + |((\nabla \cdot A^{-1}\Pi A_h f_h) \psi_h, g_h)| \\ &\quad + |((f_h \cdot \nabla)(A_h^{-1} - A^{-1}\Pi)A_h \psi_h, g_h)| \\ &\quad + |((\nabla \cdot (A_h^{-1} - A^{-1}\Pi)A_h f_h) \psi_h, g_h)|, \end{aligned}$$

so that

$$\begin{aligned} |b(f_h, g_h, \psi_h)| &\leq (\|(f_h \cdot \nabla)A^{-1}\Pi A_h \psi_h\|_1 + \|(\nabla \cdot A^{-1}\Pi A_h f_h) \psi_h\|_1) \|g_h\|_{-1} \\ &\quad + Ch \|A_h f_h\|_0 \|A_h \psi_h\|_0 \|g_h\|_0. \end{aligned}$$

Then, recalling that $\|g_h\|_0 \leq Ch^{-1}\|A_h^{-1/2}g_h\|_0$ and (2.15), arguments like those used from (4.2) to (4.4) also show that

$$|b_h(f_h, g_h, \psi_h)| \leq C\|A_h^{-1/2}g_h\|_0\|A_h f_h\|_0\|A_h \psi_h\|_0,$$

so that, in view of (4.4), the proof of (4.1) is finished. \square

LEMMA 4.2. *Under the conditions of Lemma 4.1, there exists a constant $C > 0$ such that the following bounds hold for $v_h, w_h \in V_h$*

$$(4.5) \quad \left\|A_h^{j/2}B_h(v_h, w_h)\right\|_0 + \left\|A_h^{j/2}B_h(w_h, v_h)\right\|_0 \leq C\left\|A_h^{(j+1)/2}v_h\right\|_0\|A_h w_h\|_0,$$

for $j = -2, -1, 0, 1$, and

$$(4.6) \quad \|B_h(v_h, v_h)\|_0 \leq C\|v_h\|_1^{3/2}\|A_h v_h\|_0^{1/2},$$

$$(4.7) \quad \|A_h^{-1}B_h(v_h, v_h)\|_0 \leq C\|v_h\|_0\|v_h\|_1.$$

Proof. The cases $j = -1, 0$ in (4.5) as well as (4.6) are easily deduced from the fact that for every $v_h \in V_h$, $\|A_h^{1/2}v_h\|_0 = \|\nabla v_h\|_0$, (2.16), and from standard bounds (e.g., (3.8), [34, (3.7)]).

If we denote $f_h = w_h$, $g_h = v_h$, and, for $\phi_h \in V_h$ $\psi_h = A_h^{-1}\phi_h$, case $j = -2$ in (4.5) is a direct consequence of standard duality arguments and (4.1). Also, arguing by duality the bound (4.7) is a straightforward consequence of well-known bounds for the trilinear form b (e.g., [34, (3.7)]).

Finally, for the case $j = 1$ in (4.5), we argue by duality. For $\phi_h \in V_h$, thanks to (2.1), we have

$$b(v_h, w_h, A_h^{1/2}\phi_h) + b(w_h, v_h, A_h^{1/2}\phi_h) = -b(v_h, A_h^{1/2}\phi_h, w_h) - b(w_h, A_h^{1/2}\phi_h, v_h),$$

so that, by denoting $g_h = A_h^{1/2}\phi_h$, the case $j = 1$ in (4.5) is a direct consequence of (4.1). \square

4.2. Further a priori estimates for the finite-element solution. We maintain the notation tacitly introduced in Proposition 2.1,

$$F_{l,r} = t^{r+2(l-1)}\left\|A_h^{r/2}\frac{d^l}{ds^l}u_h(t)\right\|_0^2, \quad \text{and} \quad I_{l,r} = \int_0^t s^{r+2l-3}\left\|A_h^{r/2}\frac{d^l}{ds^l}u_h(t)\right\|_0^2 ds.$$

LEMMA 4.3. *Under the conditions of Proposition 2.1, there exists a positive constant \tilde{M}_4 such that for $0 \leq t \leq T$ the following bounds hold:*

$$(4.8) \quad F_{2,-2}(t) = \|A_h^{-1}\ddot{u}_h(t)\|_0 \leq \tilde{M}_4,$$

$$(4.9) \quad I_{3,-3}(t) = \int_0^t \left\|A_h^{-3/2}\ddot{\ddot{u}}_h(s)\right\|_0^2 ds \leq \tilde{M}_4,$$

$$(4.10) \quad I_{2,2}(t) = \int_0^t s^3 \|A_h \ddot{u}_h(s)\|_0^2 ds \leq \tilde{M}_4,$$

$$(4.11) \quad I_{3,-1}(t) = \int_0^t s^2 \left\|A_h^{-1/2}\ddot{\ddot{u}}_h(s)\right\|_0^2 ds \leq \tilde{M}_4,$$

$$(4.12) \quad I_{3,1}(t) + F_{2,2}(t) = \int_0^t s^4 \left\|A_h^{1/2}\ddot{\ddot{u}}_h(s)\right\|_0^2 ds + t^4 \|A_h \ddot{u}_h(t)\|_0^2 \leq \tilde{M}_4.$$

Proof. Taking derivatives with respect to t in (2.20) and multiplying by A_h^{-1} we have

$$A_h^{-1}\ddot{u}_h = A_h^{-1}\Pi_h f_t - \dot{u}_h - A_h^{-1}(B_h(\dot{u}_h, u_h) + B_h(u_h, \dot{u}_h)).$$

Applying Lemma 4.2 we have

$$\|A_h^{-1}(B_h(\dot{u}_h, u_h) + B_h(u_h, \dot{u}_h))\|_0 \leq C\|A_h u_h\|_0 \|A_h^{-1/2}\dot{u}_h\|_0 \leq C\|A_h u_h\|_0 \|\dot{u}_h\|_0,$$

so that (4.8) follows from (2.3), (2.23), and (2.24) with $r = 0$.

We now prove (4.9). Taking derivatives twice with respect to t in (2.20) and multiplying by $A_h^{-3/2}$ we have

$$(4.13) \quad A_h^{-3/2}\ddot{u}_h = A_h^{-3/2}\Pi_h f_{tt} - A_h^{-1/2}\ddot{u}_h - A_h^{-3/2}\frac{d^2}{dt^2}B_h(u_h, u_h).$$

Taking into account that for $v_h \in V_h$, we have $\|A_h^{-3/2}v_h\|_0 \leq C\|A_h^{-1}v_h\|_0$, and that

$$(4.14) \quad \frac{d^2}{dt^2}B_h(u_h, u_h) = B_h(\ddot{u}_h, u_h) + 2B_h(\dot{u}_h, \dot{u}_h) + B_h(u_h, \ddot{u}_h),$$

then, applying the bound (4.5) for $j = -2$ with $v_h = \ddot{u}_h$, and $w_h = u_h$, on the one hand, and, on the other, (4.7) with $v_h = \dot{u}_h$, it follows

$$\left\|A_h^{-3/2}\frac{d^2}{dt^2}B_h(u_h, u_h)\right\|_0 \leq C\|A_h u_h\|_0 \left\|A_h^{-1/2}\ddot{u}_h\right\|_0 + \|\dot{u}_h\|_0 \|\dot{u}_h\|_1,$$

so that the bound (4.9) follows from (4.13), (2.3), and the fact that $A_h^{-3/2}$ is bounded independently of h , together with (2.23), (2.24) with $r = 0$, (2.26) with $r = 1$, and (2.27) with $r = -1$.

We now prove (4.10). Taking derivatives twice with respect to t in (2.18) and then setting $\phi = t^3 A_h \ddot{u}_h$, we have

$$\frac{1}{2}t^3 \frac{d}{dt} \left\|A_h^{1/2}\ddot{u}_h\right\|_0^2 + t^3 \|A_h \ddot{u}_h\|_0^2 = t^3 \left(f_{tt} - \frac{d^2}{dt^2}B_h(u_h, u_h), A_h \ddot{u}_h \right).$$

Since $|(f_{tt} - \frac{d^2}{dt^2}B_h(u_h, u_h), A_h \ddot{u}_h)| \leq \|f_{tt}\|_0^2 + \|\frac{d^2}{dt^2}B_h(u_h, u_h)\|_0^2 + \frac{1}{2}\|A_h \ddot{u}_h\|_0^2$, it follows that

$$(4.15) \quad \frac{d}{dt} \left(t^3 \|A_h^{1/2}\ddot{u}_h\|_0^2 \right) + t^3 \|A_h \ddot{u}_h\|_0^2 \leq 2t^3 \|f_{tt}\|_0^2 \left\| \frac{d^2}{dt^2}B_h(u_h, u_h) \right\|_0^2 + 3t^2 \left\| A_h^{1/2}\ddot{u}_h \right\|_0^2.$$

Now recall (4.14) and apply (4.5) with $v_h = \ddot{u}_h$, and $w_h = u_h$, on the one hand, and, on the other, (4.6) with $v_h = \dot{u}_h$ to get

$$\left\| \frac{d^2}{dt^2}B_h(u_h, u_h) \right\|_0 \leq C \left(\|A_h u_h\|_0 \|A_h^{1/2}\ddot{u}_h\|_0 + \|A_h^{1/2}\dot{u}_h\|_0^{3/2} \|A_h \dot{u}_h\|_0^{1/2} \right),$$

so that, in view of (2.23)–(2.25) it follows that

$$(4.16) \quad t^3 \left\| \frac{d^2}{dt^2}B_h(u_h, u_h) \right\|_0^2 \leq C \left(1 + t^{1/2} \right) \tilde{M}_3^4.$$

Integrating with respect to t in (4.15) and taking into account (2.3), (2.25) with $r = 1$, and (4.16), the bound (4.10) follows.

To prove (4.12), we take derivatives twice with respect to t in (2.18) and then we set $\phi = t^4 A_h \ddot{u}_h$, so that

$$t^4 \left\| A_h^{1/2} \ddot{u}_h \right\|_0^2 + \frac{1}{2} t^4 \frac{d}{dt} \|A_h \dot{u}_h\|_0^2 = t^4 \left(f_{tt} - \frac{d^2}{dt^2} B_h(u_h, u_h), A_h \ddot{u}_h \right),$$

and, since $\|A_h^{1/2} \Pi_h f_{tt}\|_0 \leq C \|f_{tt}\|_1$,

$$(4.17) \quad t^4 \left\| A_h^{1/2} \ddot{u}_h \right\|_0^2 + \frac{d}{dt} (t^4 \|A_h \dot{u}_h\|_0^2) \leq 4t^3 \|A_h \dot{u}_h\|_0^2 + 2t^4 \left(C^2 \|f_{tt}\|_1^2 + \left\| A_h^{1/2} \frac{d^2}{dt^2} B_h(u_h, u_h) \right\|_0^2 \right).$$

Applying (4.5) to bound the third term on the right-hand side above we have

$$(4.18) \quad t^4 \left\| A_h^{1/2} \frac{d^2}{dt^2} B_h(u_h, u_h) \right\|_0^2 \leq C t^4 (\|A_h u_h\|_0^2 \|A_h \dot{u}_h\|_0^2 + \|A_h \dot{u}_h\|_0^4) \leq C t \tilde{K} (1 + \tilde{M}_4^2) (t^3 \|A_h \dot{u}_h\|_0^2 + t \|A_h \dot{u}_h\|_0^2),$$

the last inequality being a consequence of (2.23) and (2.24) with $r = 2$. Thus, integrating with respect to t in (4.17) and applying (2.3), (2.26) with $r = 2$, (4.18), and (4.10), the bound (4.12) follows.

Finally, since standard spectral theory of positive self-adjoint operators shows that $\|A_h^{-1/2} \ddot{u}_h\|_0^2 \leq \|A_h^{-3/2} \ddot{u}_h\|_0 \|A_h^{1/2} \ddot{u}_h\|_0$, by applying Hölder's inequality the bound (4.11) follows from (4.9) and (4.12). \square

5. Error estimates. In this section we obtain error estimates for the temporal errors e_n of the two BDF described in section 3.2, the backward Euler method and the two-step formula (3.21)–(3.22), for which, an equivalent formulation is

$$(5.1) \quad d_t U_h^{(n)} = -A_h U_h^{(n)} - B_h(U_h^{(n)}, U_h^{(n)}) + \Pi_h f(t_n), \quad l_0 \leq n \leq N.$$

We remark that although higher regularity was required in section 2.3, in what follows it is only required that Ω is of class C^2 and that (2.11)–(2.13) hold for $l = 2$.

A simple calculation shows that for a sequence $(y_n)_{n=0}^N$ in V_h ,

$$(5.2) \quad \sum_{j=l}^n (y_j, D y_j) = \frac{1}{2} \|y_n\|_0^2 - \frac{1}{2} \|y_{l-1}\|_0^2 + \frac{1}{2} \sum_{j=l}^n \|D y_j\|_0^2, \quad 1 \leq l \leq n \leq N,$$

and, for $2 \leq l \leq n \leq N$, (see, e.g., [10, (2.4b)])

$$(5.3) \quad \sum_{j=l}^n \left(y_j, \left(D + \frac{1}{2} D^2 \right) y_j \right) = \frac{1}{4} \|y_n\|_0^2 + \frac{1}{4} \|y_n + D y_n\|_0^2 + \frac{1}{4} \sum_{j=l}^n \|D^2 y_j\|_0^2 - \frac{1}{4} \|y_{l-1}\|_0^2 - \frac{1}{4} \|y_{l-1} + D y_{l-1}\|_0^2.$$

As mentioned in section 3.2, we shall assume that $e_0 = 0$ although in some of the previous lemmas this condition will not be required. It must be noticed that $e_0 = 0$ is not a serious restriction, since, on the one hand, it is usually satisfied in practice, and, on the other hand, were it not satisfied, there are standard ways to show that the effect of $e_0 \neq 0$ decays exponentially with time.

The finite-element approximation u_h to the velocity satisfies

$$(5.4) \quad d_t u_h(t_n) + A_h u_h(t_n) + B_h(u_h(t_n), u_h(t_n)) - \Pi_h f(t_n) = \tau_n,$$

where

$$(5.5) \quad \tau_n = d_t u_h(t_n) - \dot{u}_h(t_n) = \frac{1}{k} \int_{t_{n-1}}^{t_n} (t - t_{n-1}) \ddot{u}_h(t) dt, \quad n = 1, 2, \dots, N,$$

for the backward Euler method, and, for the two-step BDF,

$$(5.6) \quad \tau_n = \frac{1}{k} \int_{t_{n-2}}^{t_n} \left(2(t - t_{n-1})_+ - \frac{1}{2}(t - t_{n-2}) \right) \ddot{u}_h(t) dt,$$

where for $x \in \mathbb{R}$, $x_+ = \max(x, 0)$, and, also,

$$(5.7) \quad \tau_n = \frac{1}{2k} \int_{t_{n-2}}^{t_n} \left(2(t - t_{n-1})_+^2 - \frac{1}{2}(t - t_{n-2})^2 \right) \frac{d^3}{dt^3} u_h(t) dt.$$

Subtracting (5.1) from (5.4), we obtain that the temporal error e_n satisfies

$$(5.8) \quad d_t e_n + A_h e_n + B_h(e_n, u_h(t_n)) + B(U_h^{(n)}, e_n) = \tau_n, \quad n = 2, 3, \dots, N.$$

We shall now prove a result valid for both the backward Euler method and the two-step BDF.

LEMMA 5.1. *Fix $T > 0$ and $M > 0$. Then, there exist positive constants k_0 and C , such that for any $k \leq k_0$ with $Nk = T$, and any four sequences $(Y_n)_{n=0}^N$, $(V_n)_{n=0}^N$, $(W_n)_{n=0}^N$, and $(g_n)_{n=0}^N$ in V_h satisfying*

$$(5.9) \quad \max(\|A_h V_n\|, \|A_h W_n\|) \leq M, \quad n = 0, 1, \dots, N,$$

and

$$(5.10) \quad d_t Y_i + A_h Y_i + B_h(Y_i, V_i) + B_h(W_i, Y_i) = g_i, \quad i = l_0, \dots, N,$$

where l_0 is the value defined in (3.23), the following bound holds for $n = l_0, \dots, N$, and $j = -2, -1, 0, 1, 2$.

$$(5.11) \quad \begin{aligned} & \left\| A_h^{j/2} Y_n \right\|_0^2 + k \sum_{i=l_0}^n \left\| A_h^{(j+1)/2} Y_i \right\|_0^2 \\ & \leq C^2 \left(\left\| A_h^{j/2} Y_0 \right\|_0^2 + (l_0 - 1) \left\| A_h^{j/2} Y_1 \right\|_0^2 + k \sum_{i=l_0}^n \left\| A_h^{(j-1)/2} g_i \right\|_0^2 \right). \end{aligned}$$

When $j = 0$, condition (5.9) can be relaxed to $\|A_h V_n\| \leq M$, for $n = 0, 1, \dots, N$.

Proof. Take inner product with $A^j Y_i$ in (5.10) so that we have

$$(5.12) \quad \left(d_t A_h^{j/2} Y_i, A_h^{j/2} Y_i \right) + \left\| A_h^{(j+1)/2} Y_i \right\|_0^2 \leq \left| \left(Z_i, A_h^j Y_i \right) \right| + \left| \left(A_h^{(j-1)/2} g_i, A_h^{(j+1)/2} Y_i \right) \right|,$$

where

$$(5.13) \quad Z_i = B(Y_i, V_i) + B(W_i, Y_i).$$

Applying Hölder's inequality to the last term on the right-hand side of (5.12) and rearranging terms we have

$$(5.14) \quad \left(d_t A_h^{j/2} Y_i, A_h^{j/2} Y_i \right) + \frac{1}{2} \left\| A_h^{(j+1)/2} Y_i \right\|_0^2 \leq \left| \left(Z_i, A_h^j Y_i \right) \right| + \frac{1}{2} \left\| A_h^{(j-1)/2} g_i \right\|_0^2.$$

For $j > -2$, we write $(Z_i, A_h^j Y_i) = (A_h^{(j-1)/2} Z_i, A_h^{(j+1)/2} Y_i)$, so that applying Hölder's inequality and Lemma 4.2 with V_i and W_i taking the role of v_h and w_h in (4.5), and recalling (5.9) we have

$$(5.15) \quad \begin{aligned} \left| \left(Z_i, A_h^j Y_i \right) \right| &\leq \left\| A_h^{(j-1)/2} Z_i \right\|_0^2 + \frac{1}{4} \left\| A_h^{(j+1)/2} Y_i \right\|_0^2 \\ &\leq C^2 M^2 \left\| A_h^{j/2} Y_i \right\|_0^2 + \frac{1}{4} \left\| A_h^{(j+1)/2} Y_i \right\|_0^2. \end{aligned}$$

Notice that when $j = 0$, due to the skew-symmetry property (2.1) of the trilinear form b we have $|(Z_i, Y_i)| = |b(Y_i, V_i, Y_i)|$, so that only $\|A_h V_i\|_0 \leq M$ is necessary for (5.15) to hold; that is, no condition on $A_h W_i$ is required. For $j = 2$, on the other hand, we write $(Z_i, A_h^2 Y_i) = (A_h^{j/2} Z_i, A_h^{j/2} Y_i)$, so that arguing similarly we have

$$(5.16) \quad \begin{aligned} \left| \left(Z_i, A_h^{-2} Y_i \right) \right| &\leq \left\| A_h^{-1} Z_i \right\|_0 \left\| A_h^{-1} Y_i \right\|_0 \leq C M \left\| A_h^{-1/2} Y_i \right\|_0 \left\| A_h^{-1} Y_i \right\|_0 \\ &\leq C^2 M^2 \left\| A_h^{-1} Y_i \right\|_0^2 + \frac{1}{4} \left\| A_h^{-1/2} Y_i \right\|_0^2. \end{aligned}$$

In all cases, then, from (5.14) it follows that for an appropriate constant $C_0 > 0$

$$\left(d_t A_h^{j/2} Y_i, A_h^{j/2} Y_i \right) + \frac{1}{4} \left\| A_h^{(j+1)/2} Y_i \right\|_0^2 \leq C_0^2 M^2 \left\| A_h^{j/2} Y_i \right\|_0^2 + \frac{1}{2} \left\| A_h^{(j-1)/2} g_i \right\|_0^2,$$

so that multiplying this inequality by k and summing from l_0 to n , and recalling (5.2–5.3), after some rearrangements we can write

$$(5.17) \quad \begin{aligned} \frac{1}{2l_0} \left\| A_h^{j/2} Y_n \right\|_0^2 + \frac{k}{4} \sum_{i=l_0}^n \left\| A_h^{(j+1)/2} Y_i \right\|_0^2 \\ \leq \frac{1}{2l_0} \left(\left\| A_h^{j/2} Y_{l_0-1} \right\|_0^2 + (l_0 - 1) \left\| A_h^{j/2} (Y_{l_0-1} + DY_{l_0-1}) \right\|_0^2 \right) \\ + C_0^2 M^2 k \sum_{i=l_0}^n \left\| A_h^{j/2} Y_i \right\|_0^2 + \frac{k}{2} \sum_{i=l_0}^n \left\| A_h^{(j-1)/2} g_i \right\|_0^2. \end{aligned}$$

A simple calculation shows that

$$\left\| A_h^{j/2} Y_1 \right\|_0^2 + \left\| A_h^{j/2} (Y_1 + DY_1) \right\|_0^2 \leq 7 \left\| A_h^{j/2} Y_1 \right\|_0^2 + 3 \left\| A_h^{j/2} Y_0 \right\|_0^2,$$

so that multiplying by $2l_0$ in (5.17) and taking into account that $2l_0/4 \leq 1$, for an appropriate constant C' we may write

$$\begin{aligned} \left\| A_h^{j/2} Y_n \right\|_0^2 + k \sum_{i=l_0}^n \left\| A_h^{(j+1)/2} Y_i \right\|_0^2 &\leq 2l_0 C_0^2 M^2 k \sum_{i=l_0}^n \left\| A_h^{j/2} Y_i \right\|_0^2 \\ &+ C' \left(\left\| A_h^{j/2} Y_0 \right\|_0^2 + (l_0 - 1) \left\| A_h^{j/2} Y_1 \right\|_0^2 + k \sum_{i=l_0}^n \left\| A_h^{(j-1)/2} g_i \right\|_0^2 \right). \end{aligned}$$

Now, for k sufficiently small so that $2l_0 C_0^2 M^2 k < 1/2$, applying a standard discrete Gronwall lemma (e.g., [34, Lemma 5.1]) we have that (5.11) holds, with C^2 being $C' \exp(4l_0 C_0^2 M^2 T)$. \square

LEMMA 5.2. *Let (2.11) hold for $l = 2$. Then, there exist positive constants k_0 and c_1 such that the errors e_n satisfy the following bound for $1 \leq n \leq N$, $k \leq k_0$:*

$$(5.18) \quad E_n \equiv \|e_n\|_0^2 + k \sum_{i=l_0}^n \left\| A_h^{1/2} e_i \right\|_0^2 \leq c_1^2 (\|e_0\|_0^2 + (l_0 - 1)\|e_1\|_0^2 + k^2 I_{2,-1}(t_n)).$$

Proof. We apply Lemma 5.1 to (5.8) in the case where $j = 0$ and $Y_i = e_i$, $V_i = u_h(t_i)$, and $W_i = U_h^{(i)}$. Observe that since we are in the case $j = 0$, only one of the two sequences $(A_h u_h(t_i))_{i=0}^N$, $(A_h U_h^{(i)})_{i=0}^N$ has to be bounded, and, in the present case, the first one is bounded according to (2.23). Thus, we have

$$(5.19) \quad \|e_n\|_0^2 + k \sum_{i=l_0}^n \left\| A_h^{1/2} e_i \right\|_0^2 \leq C^2 \left(\|e_0\|_0^2 + (l_0 - 1)\|e_1\|_0^2 + k \sum_{i=1}^n \left\| A_h^{-1/2} \tau_j \right\|_0^2 \right).$$

Now, applying Hölder’s inequality to the right-hand side of (5.5) we have

$$\begin{aligned} k \left\| A_h^{-1/2} \tau_j \right\|_0^2 &\leq \frac{1}{k} \int_{t_{j-1}}^{t_j} (t - t_{j-1})^2 dt \int_{t_{j-1}}^{t_j} \left\| A_h^{-1/2} \ddot{u}_h(t) \right\|_0^2 dt \\ &= \frac{k^2}{3} \int_{t_{j-1}}^{t_j} \left\| A_h^{-1/2} \ddot{u}_h(t) \right\|_0^2 dt. \end{aligned}$$

Similarly, for the two-step BDF, applying Hölder’s inequality to the right-hand side of (5.6) we have

$$\begin{aligned} k \left\| A_h^{-1/2} \tau_n \right\|_0^2 &\leq \frac{1}{4k} \int_{t_{n-2}}^{t_n} (4(t - t_{n-1})_+ - (t - t_{n-2}))^2 dt \int_{t_{n-2}}^{t_n} \left\| A_h^{-1/2} \ddot{u}_h(t) \right\|_0^2 dt \\ &\leq \frac{5}{3} k^2 \int_{t_{n-2}}^{t_n} \left\| A_h^{-1/2} \ddot{u}_h(t) \right\|_0^2 dt. \end{aligned}$$

Thus, the statement of the lemma follows from (5.19). \square

The previous result allows us to deduce a bound for $\|A_h e_n\|_0$ in the following lemma. The values of $I_{2,-1}$, $I_{2,0}$ are those of Proposition 2.1.

LEMMA 5.3. *Under the conditions of Lemma 5.2, there exist positive constants \tilde{k}_0 and \tilde{c}_0 such that if $e_0 = 0$ and, in the case of the two-step BDF, also $U_h^{(1)}$ is given by the backward Euler method, the following bound holds for $k \leq \tilde{k}_0$ and $n = 1, 2, \dots, N$:*

$$(5.20) \quad \|A_h e_n\|_0 \leq \tilde{c}_0 J_n,$$

where $J_n = (I_{2,-1}(t_n) + I_{2,0}(t_n))^{1/2}$.

Proof. If $e_0 = 0$, from (5.18) for the Euler method (for which $l_0 = 1$) it follows that

$$(5.21) \quad \|e_n\|_0 \leq c'k(I_{2,-1}(t_n))^{1/2} \leq c'kJ_n, \quad n = 1, 2, \dots, N$$

for $c' = c_1$. In the case of the two-step BDF, if $U_h^{(1)}$ is obtained by the backward Euler method, if we allow for a larger value of c' , it is clear that (5.21) also holds.

Furthermore, it is immediate to check that $\|d_t e_n\|_0 \leq 2l_0 k^{-1} \max_{0 \leq i \leq l_0} \|e_n\|_0$, so that, in view of (5.21), from (5.8) it follows that

$$\|A_h e_n\|_0 \leq c''J_n + \left\| B_h(e_n, u_h(t_n)) + B(U_h^{(n)}, e_n) \right\|_0 + \|\tau_n\|_0,$$

for some constant $c'' > 0$. For the Euler method, recalling the expression of τ_n in (5.5) we can write

$$\|\tau_n\|_0^2 = \left\| \frac{1}{k} \int_{t_{n-1}}^{t_n} (t - t_{n-1}) \ddot{u}_h \, dt \right\|_0^2 \leq \frac{1}{k^2} \int_{t_{n-1}}^{t_n} \frac{(t - t_{n-1})^2}{t} \, dt \int_{t_{n-1}}^{t_n} t \|\ddot{u}_h\|_0^2 \, dt.$$

A simple calculation shows that the first factor on the right-hand side above can be bounded by $k/t_n \leq 1$ for $n = 1, 2, \dots, N$. Furthermore, a similar bound can be also obtained in the case of the two-step BDF. Thus, we have

$$\|A_h e_n\|_0 \leq c'''J_n + \left\| B_h(e_n, u_h(t_n)) + B(U_h^{(n)}, e_n) \right\|_0,$$

for an appropriate constant $c''' > 0$. Finally,

$$\left\| B_h(e_n, u_h(t_n)) + B(U_h^{(n)}, e_n) \right\|_0 = \|B_h(e_n, u_h(t_n)) + B(u_h(t_n), e_n) - B_h(e_n, e_n)\|_0.$$

Applying (4.5) and (4.6) we get

$$\|A_h e_n\|_0 \leq c'''J_n + C \left\| A_h^{1/2} e_n \right\|_0 \|A_h u_h\|_0 + C \left\| A_h^{1/2} e_n \right\|_0^{3/2} \|A_h e_n\|_0^{1/2},$$

and, thus,

$$\frac{1}{2} \|A_h e_n\|_0 \leq c'''J_n + C \left\| A_h^{1/2} e_n \right\|_0 \|A_h u_h\|_0 + \frac{1}{2} C^2 \left\| A_h^{1/2} e_n \right\|_0^3.$$

Since $\|A_h u_h\|_0$ is bounded (recall Proposition 2.1) and, arguing as in (5.21), we have $\|A_h^{1/2} e_n\|_0 \leq c_1(kI_{2,-1}(t_n))^{1/2}$, the bound (5.20) follows for k sufficiently small. \square

Remark 5.1. Observe that from the previous lemma and Proposition 2.1 it follows that $\|A_h U_h^{(n)}\|_0 \leq c\tilde{M}_3$ where $c = 1 + \tilde{c}_0\sqrt{2}$. Thus, as long as $e_0 = 0$ and, in case of the two-step BDF, also $U_h^{(1)}$ is given by the Euler method, we may apply Lemma 5.1 for $j \neq 0$, with V_n and W_n replaced by $u_h(t_n)$ and $U_h^{(n)}$, respectively.

We now study the errors $A_h t_n e_n$. We deal first with the backward Euler method. Observe that $D(t_n e_n) = t_n D e_n + k e_{n-1}$, so that multiplying by t_n in (5.8), after some rearrangements we get

$$(5.22) \quad d_t(t_n e_n) + A_h(t_n e_n) + B_h(t_n e_n, u_h) + B_h(U_h^{(n)}, t_n e_n) = e_{n-1} + t_n \tau_n.$$

We have the following result.

THEOREM 5.4. *Let (2.11) hold for $l = 2$. Then, there exist positive constants k_2 and c_2 such that for $k \leq k_2$, if $e_0 = 0$ the errors $\epsilon_n = t_n e_n$ satisfy*

$$(5.23) \quad \left(\|A_h \epsilon_n\|_0^2 + k \sum_{i=1}^n \left\| A_h^{3/2} \epsilon_i \right\|_0^2 \right)^{1/2} \leq c_2 k (I_{2,-1}(t_n) + I_{2,1}(t_n))^{1/2}, \quad 1 \leq n \leq N.$$

Proof. Applying Lemma 5.1 with $j = 2$ to (5.22) we have

$$\|A_h \epsilon_n\|_0^2 + k \sum_{i=1}^n \left\| A_h^{3/2} \epsilon_i \right\|_0^2 \leq c \left(k \sum_{i=1}^{n-1} \left\| A_h^{1/2} e_i \right\|_0^2 + k \sum_{i=1}^n \left\| t_i A_h^{1/2} \tau_i \right\|_0^2 \right).$$

The first term on the right-hand side above is bounded Lemma 5.2 by $c_1^2 k^2 I_{2,-1}(t_n)$. For the second one we notice that

$$k \left\| t_i A_h^{1/2} \tau_i \right\|_0^2 = k \left\| \frac{t_i}{k} \int_{t_{i-1}}^{t_i} \frac{t - t_{i-1}}{t} t A_h^{1/2} \ddot{u}_h(t) dt \right\|_0^2,$$

so that, for $i \geq 2$ since $t_i/t \leq t_i/t_{i-1} \leq 2$, if $t \in (t_{i-1}, t_i)$, we may bound $k \|t_i A_h^{1/2} \tau_i\|_0^2$ by

$$\frac{4}{k} \int_{t_{i-1}}^{t_i} (t - t_{i-1})^2 dt \int_{t_{i-1}}^{t_i} t^2 \left\| A_h^{1/2} \ddot{u}_h(t) \right\|_0^2 dt \leq \frac{4k^2}{3} \int_{t_{i-1}}^{t_i} t^2 \left\| A_h^{1/2} \ddot{u}_h(t) \right\|_0^2 dt,$$

and, for $i = 1$, since $t_1/k = 1$, and $(t - t_0)/t = 1$, we may bound $k \|t_i A_h^{1/2} \tau_i\|_0^2$ by

$$k \int_{t_{i-1}}^{t_i} dt \int_{t_{i-1}}^{t_i} t^2 \left\| A_h^{1/2} \ddot{u}_h(t) \right\|_0^2 dt \leq k^2 \int_{t_{i-1}}^{t_i} t^2 \left\| A_h^{1/2} \ddot{u}_h(t) \right\|_0^2 dt.$$

Thus, (5.23) follows. \square

LEMMA 5.5. *Under the conditions of Lemma 5.2, there exist positive constants k'_0 and c'_1 such that for $k \leq k'_0$, if $e_0 = 0$, in the backward Euler method e_1 satisfies*

$$(5.24) \quad \left\| A_h^{-1} e_1 \right\|_0^2 + k \left\| A_h^{-1/2} e_1 \right\|_0^2 \leq c'_1 k^4 G_1,$$

where $G_1 = \max_{0 \leq s \leq k} F_{2,-2}(s)$.

Proof. We take inner product with $2k A_h^{-2} e_1$ in (5.8) for $n = 1$, and recalling (5.2) and taking into account that $e_0 = 0$, after some rearrangements we have

$$(5.25) \quad \left\| A_h^{-1} e_1 \right\|_0^2 + 2k \left\| A_h^{-1/2} e_1 \right\|_0^2 \leq 2k |(Z_1, A_h^{-2} e_1)| + 2k |(A_h^{-1} \tau_1, A_h^{-1} e_1)|,$$

where Z_1 is as in (5.13) but with Y_1 , V_1 , and W_1 replaced by e_1 , $u_h(t_1)$, and $U_h^{(1)}$, respectively. Thus, arguing as in (5.16)

$$\left(1 - 2k C^2 \tilde{M}_3^2 \right) \left\| A_h^{-1} e_1 \right\|_0^2 + \frac{3}{2} k \left\| A_h^{-1/2} e_1 \right\|_0^2 \leq 2k |(A_h^{-1} \tau_1, A_h^{-1} e_1)|,$$

so that taking into account that

$$2k |(A_h^{-1} e_1, A_h^{-1} \tau_1)| \leq \left\| A_h^{-1} e_1 \right\|_0^2 / 2 + k^2 \left\| A_h^{-1} \tau_1 \right\|_0^2,$$

from (5.25) it follows that

$$(5.26) \quad \left(\frac{1}{2} - 2kC^2\tilde{M}_3^2\right) \|A_h^{-1}e_1\|^2 + \frac{3}{2}k \|A_h^{-1/2}e_1\|_0^2 \leq k^2 \|A_h^{-1}\tau_1\|_0^2.$$

Recalling the expression of τ_n in (5.5) we can write

$$\|A_h^{-1}\tau_1\|_0^2 \leq \max_{0 \leq t \leq t_1} \|A_h^{-1}\ddot{u}_h(t)\|_0^2 \left(\frac{1}{k} \int_0^k t \, dt\right)^2 = \frac{k^2}{4} \max_{0 \leq t \leq t_1} \|A_h^{-1}\ddot{u}_h(t)\|_0^2,$$

we then have that (5.24) follows from (5.26) provided that k is sufficiently small. \square

LEMMA 5.6. *Under the conditions of Lemma 5.2, let $e_0 = 0$ and let $U_h^{(1)}$ be given by the backward Euler method. Then, there exist positive constants k_0 and c_1 such that the errors e_n of the two-step BDF satisfy*

$$(5.27) \quad E'_n \equiv \|A_h^{-1}e_n\|_0^2 + k \sum_{j=2}^n \|A_h^{-1/2}e_j\|_0^2 \leq c_1k^4(G_1 + I_{3,-3}(t_n)), \quad 2 \leq n \leq N,$$

where G_1 is given after (5.24).

Proof. In view of the comments in Remark 5.1, we can apply Lemma 5.1 with $j = -2$ to (5.8), so that, recalling that $e_0 = 0$, we have

$$(5.28) \quad \|A_h^{-1}e_n\|^2 + k \sum_{i=2}^n \|A_h^{-1/2}e_i\|_0^2 \leq c \left(\|A_h^{-1}e_1\|_0^2 + k \sum_{j=2}^n \|A_h^{-3/2}\tau_j\|_0^2 \right).$$

Notice that, as we showed in Lemma 5.5, the first term on the right-hand side above is bounded by $c_1k^4G_1$. For the second term on the right-hand side of (5.28), in view of (5.7) a simple calculation shows that

$$k \|A_h^{-3/2}\tau_j\|_0^2 \leq Ck^4 \int_{t_{n-2}}^{t_n} \left\| A_h^{-3/2} \frac{d^3 u_h(s)}{ds^3} \right\|_0^2 ds.$$

Thus, (5.27) follows. \square

For any two sequences $(y_n)_{n=0}^\infty$ and $(z_n)_{n=0}^\infty$, it is easy to check that $D(y_n z_n) = y_n D z_n + z_{n-1} D y_n$, for $n = 1, 2, \dots$, and, also,

$$D^2(y_n z_n) = y_n D^2 z_n + 2 D y_n D z_{n-1} + z_{n-2} D^2 y_n.$$

Thus, for the two-step BDF, multiplying (5.8) by t_n and t_n^2 and rearranging terms, for $j = 2, 3, \dots, N$, we have

$$(5.29) \quad \begin{aligned} d_t(t_n e_n) + A_h t_n e_n + B_h(u_h(t_n), t_n e_n) \\ - t_n B(U_h^{(n)}, t_n e_n) = t_n \tau_n + (e_{n-1} + D e_{n-1}), \end{aligned}$$

and

$$(5.30) \quad d_t(t_n^2 e_n) + A_h t_n^2 e_n + B_h(t_n^2 e_n, u_h(t_n)) - B(U_h^{(n)}, t_n^2 e_n) = t_n^2 \tau_j + \sigma_{n-1},$$

where

$$(5.31) \quad \sigma_{n-1} = (t_n + t_{n-1})(e_{n-1} + D e_{n-1}) + k e_{n-2}.$$

THEOREM 5.7. *Under the conditions of Theorem 5.4, there exist positive constants k_1 and c_2 such that for $k \leq k_1$ if $e_0 = 0$ and $U_h^{(1)}$ be given by the backward Euler method, the errors $\epsilon_n = t_n e_n$ and $\epsilon'_n = t_n^2 e_n$ of the two-step BDF satisfy the following bounds for $2 \leq n \leq N$:*

$$(5.32) \quad \mathcal{E}_n \equiv \left(\|\epsilon_n\|_0^2 + k \sum_{i=2}^n \|A_h^{1/2} \epsilon_i\|_0^2 \right)^{\frac{1}{2}} \leq c_2 k^2 (H_1 + I(t_n))^{\frac{1}{2}},$$

$$(5.33) \quad \mathcal{E}'_n \equiv \left(\|A_h \epsilon'_n\|_0^2 + k \sum_{i=2}^n \|A_h^{3/2} \epsilon'_i\|_0^2 \right)^{\frac{1}{2}} \leq c_2 k^2 (H_1 + I(t_n) + J_1^2 + I_{3,1}(t_n))^{1/2},$$

where J_1 is given after (5.20), $H_1 = I_{2,-1}(t_1) + G_1$, where G_1 is given after (5.24), and $I(t) = I_{3,-1}(t) + I_{3,-3}(t)$.

Proof. To prove (5.32) we apply Lemma 5.1 with $j = 0$ to (5.29), so that taking into account that $e_0 = 0$ we have

$$(5.34) \quad \|\epsilon_n\|_0^2 + k \sum_{j=2}^n \|A_h^{1/2} \epsilon_j\|_0^2 \leq c \left(\|\epsilon_1\|_0^2 + k \sum_{i=1}^{n-1} \|A_h^{-1/2} (e_i + De_i)\|_0^2 + k \sum_{i=2}^n \|t_i A_h^{-1/2} \tau_i\|_0^2 \right).$$

Notice that since $e_i + De_i = 2e_i - e_{i-1}$, the second term on the right-hand side above can be bounded by $7k \sum_{i=1}^{n-1} \|A_h^{-1/2} e_i\|_0^2$, a quantity that has already been bounded in Lemma 5.6. Also, by writing

$$t_i \tau_i = \frac{t_i}{2k} \int_{t_{i-2}}^{t_i} \frac{1}{t} \left(2(t - t_{i-1})_+^2 - \frac{1}{2}(t - t_{i-2})^2 \right) t \frac{d^3}{dt^3} u_h(t) dt,$$

and noticing that $t_i/t_{i-2} \leq 3$ for $i \geq 3$, and $t_2/k \leq 2$, a straightforward calculation shows that

$$(5.35) \quad k \|A_h^{-1/2} t_i \tau_j\|_0^2 \leq C k^4 \int_{t_{i-2}}^{t_i} t^2 \|A_h^{-1/2} \ddot{u}_h(t)\|_0^2 dt, \quad j = 2, \dots, N.$$

Finally, noticing that $\|\epsilon_1\|_0^2 = k^2 \|e_1\|_0^2$ and recalling Lemma 5.2, we have that (5.32) follows from (5.34) and (5.35).

To prove (5.33) we apply Lemma 5.1 with $j = 2$ to (5.30) to get

$$(5.36) \quad \|A_h \epsilon'_n\|_0^2 + k \sum_{j=2}^n \|A_h^{3/2} \epsilon'_j\|_0^2 \leq c \left(\|A_h \epsilon'_1\|_0^2 + k \sum_{i=1}^{n-1} \|A_h^{1/2} \sigma_i\|_0^2 + k \sum_{i=2}^n \|t_i^2 A_h^{1/2} \tau_i\|_0^2 \right).$$

For the first term on the right-hand side above, in view of Lemma 5.3 we can write

$$(5.37) \quad \|A_h \epsilon'_1\|_0 = k^2 \|A_h e_1\| \leq k^2 \tilde{c}_0 J_1.$$

For the second term on the right-hand side of (5.36), we first recall the expression of σ_i in (5.31) and then we notice that for $i \geq 1$ we have that $k \leq t_i$, $t_{i+2}/t_i \leq 3$ and $t_{i+1}/t_i \leq 2$, so that, recalling that $e_0 = 0$, for an appropriate constant $C > 0$ we may write

$$(5.38) \quad k \sum_{i=1}^{n-1} \|A_h^{1/2} \sigma_i\|_0^2 \leq C \left(k \|A_h^{1/2} \epsilon_1\|_0^2 + k \sum_{i=2}^{n-1} \|A_h^{1/2} \epsilon_i\|_0^2 \right) \leq C \left(k^3 \|A_h^{1/2} e_1\|_0^2 + \mathcal{E}_n^2 \right),$$

\mathcal{E}_n being the quantity in (5.32). Also, by writing

$$t_i^2 \tau_i = \frac{t_i^2}{2k} \int_{t_{i-2}}^{t_i} \frac{1}{t^2} \left(2(t - t_{i-1})_+^2 - \frac{1}{2}(t - t_{i-2})^2 \right) t^2 \frac{d^3}{dt^3} u_h(t) dt,$$

and noticing that $t_i^2/t_{i-2}^2 \leq 9$ for $i \geq 3$, and $t_2^2/k \leq 4k$, we get

$$(5.39) \quad k \left\| A_h^{1/2} t_i^2 \tau_i \right\|_0^2 \leq C k^4 \int_{t_{i-2}}^{t_i} t^4 \left\| A_h^{1/2} \ddot{u}_h(t) \right\|_0^2 dt, \quad j = 2, \dots, N.$$

Thus, (5.33) follows from (5.36), (5.37), (5.38), (5.32), (5.18), and (5.39). \square

Although not strictly necessary for the analysis of the postprocessed approximation, for the sake of completeness we include an error bound for the pressure. We first notice that as a consequence of the LBB condition (2.7) we have that the error $\pi_n = p_h(t_n) - P_h^{(n)}$ satisfies

$$\|\pi_n\|_{L^2(\Omega)/\mathbb{R}} \leq \frac{1}{\beta} \sup_{\phi_h \in X_{h,r}} \frac{|(\pi_n, \nabla \cdot \phi_h)|}{\|\phi_h\|_1}.$$

Furthermore subtracting (3.21) from (2.18), we have

$$(\pi_n, \nabla \cdot \phi_h) = \left(\dot{u}_h - d_t U_h^{(n)}, \phi_h \right) + (\nabla e_n, \nabla \phi_h) + b(e_n, u_h, \phi_h) + b\left(U_h^{(n)}, e_n, \phi_h \right)$$

for all $\phi_h \in X_{h,r}$. Using standard bounds for the trilinear form b (e.g., [34, (3.7)]) we can write

$$(5.40) \quad \|\pi_n\|_{L^2(\Omega)/\mathbb{R}} \leq C \left(\|e_n\|_1 + \left\| \dot{u}_h - d_t U_h^{(n)} \right\|_{-1} \right).$$

Recalling the expression of $d_t^* U_h^{(n)}$ in (3.4), we see that $\dot{u}_h - d_t U_h^{(n)} = \dot{u}_h - d_t^* U_h^{(n)}$, so that applying Lemma 3.2 and taking into account the equivalence (2.15) between $\|e_n\|_1$ and $\|A_h^{1/2} e_n\|_0$, we have $\|\pi_n\|_{L^2(\Omega)/\mathbb{R}} \leq C \|A_h^{1/2} e_n\|_0$. Since using standard spectral theory of positive self-adjoint operators it is straightforward to show that $\|A_h^{1/2} e_n\|_0 \leq C \|e_n\|_0^{1/2} \|A_h e_n\|_0^{1/2}$, applying Lemma 5.2 and Theorem 5.4 in the case of the backward Euler method, and Theorem 5.7 in the case of the two-step BDF, we conclude the following result.

THEOREM 5.8. *Under the conditions of Theorem 5.4, there exist positive constants k_3 and c_4 such that if $e_0 = 0$ and $U_h^{(1)}$ is obtained by the backward Euler method, the following bound holds for $k < k_3$ and for $n = l_0, \dots, N$: For the backward Euler method,*

$$\left\| p_h(t_n) - P_h^{(n)} \right\|_{L^2(\Omega)/\mathbb{R}} \leq c_4 C_1^{1/2} \frac{k}{t_n^{1/2}},$$

where $C_1 = (I_{2,-1}(I_{2,-1} + I_{2,1}))^{1/2}$, and, for the two-step BDF,

$$\left\| p_h(t_n) - P_h^{(n)} \right\|_{L^2(\Omega)/\mathbb{R}} \leq c_4 C_2^{1/2} \frac{k^2}{t_n^{3/2}},$$

where C_2 is the product of the quantities between parentheses on the right-hand sides of (5.32) and (5.33).

A BOUNDED ARTIFICIAL VISCOSITY LARGE EDDY SIMULATION MODEL*

JEFF BORGGAARD[†], TRAIAN ILIESCU[‡], AND JOHN PAUL ROOP[§]

Abstract. In this paper, we present a rigorous numerical analysis for a bounded artificial viscosity model ($\tau = \mu\delta^\sigma a(\delta\|\nabla^s \mathbf{u}\|_F)\nabla^s \mathbf{u}$) for the numerical simulation of turbulent flows. In practice, the commonly used Smagorinsky model ($\tau = (c_s\delta)^2\|\nabla^s \mathbf{u}\|_F \nabla^s \mathbf{u}$) is overly dissipative and yields unphysical results. To date, several methods for “clipping” the Smagorinsky viscosity have proven useful in improving the physical characteristics of the simulated flow. However, such heuristic strategies strongly rely upon a priori knowledge of the flow regime. The bounded artificial viscosity model relies on a highly nonlinear, but monotone and smooth, semilinear elliptic form for the artificial viscosity. For this model, we have introduced a variational computational strategy, provided finite element error convergence estimates, and included several computational examples indicating its improvement on the overly diffusive Smagorinsky model.

1. Introduction. Turbulence is central to many important applications. Direct numerical simulation is not feasible for the foreseeable future in many of these applications. Indeed, Kolmogorov’s 1941 theory (K-41) of homogeneous, isotropic turbulence predicts that small scales exist down to $O(Re^{-3/4})$, where $Re > 0$ is the Reynolds number. Thus, in order to capture all scales on a mesh, we need a mesh-size $h \sim Re^{-3/4}$ and consequently (in three-dimensional (3D) case) $N \sim Re^{9/4}$ mesh points.

Large eddy simulation (LES) is one of the most successful approaches in the numerical simulation of turbulent flows. LES seeks to calculate the large, energetic structures (the large eddies) in a turbulent flow. The large structures are defined by convolving the flow variables with a rapidly decaying spatial filter g_δ . To derive equations for $\bar{\mathbf{u}}$, the large eddy flow structure, we convolve the Navier–Stokes equations (NSE) with $g_\delta(\mathbf{x})$. The resulting system is not closed, since it involves both \mathbf{u} and $\bar{\mathbf{u}}$. The tensor $\boldsymbol{\tau}(\mathbf{u}, \mathbf{u}) = \overline{\mathbf{u}\mathbf{u}^T} - \bar{\mathbf{u}}\bar{\mathbf{u}}^T$ is often called the subgrid-scale stress (SGS) tensor. Thus, the closure problem in LES is to model the SGS tensor $\boldsymbol{\tau}(\mathbf{u}, \mathbf{u})$.

The simplest and most commonly used approach to the closure problem is the eddy viscosity (EV) model. EV models are motivated by the idea that the global effect of the SGS stress tensor $\boldsymbol{\tau}(\mathbf{u}, \mathbf{u})$, in the mean, is to transfer energy from resolved to

FIG. 1.1. The amount of artificial viscosity introduced by the Smagorinsky and the bounded AV models against $\|\delta \nabla^s \bar{\mathbf{u}}\|_F$.

unresolved scales through inertial interactions [4, 45]:

$$\nabla \cdot \boldsymbol{\tau}(\mathbf{u}, \mathbf{u}) \approx -\nabla \cdot (\nu_T \nabla^s \bar{\mathbf{u}}) + \text{terms incorporated into } \bar{p},$$

where $\nabla^s \bar{\mathbf{u}}$ is the deformation tensor and $\nu_T \geq 0$ is the “turbulent viscosity coefficient.” The most common EV model is known in LES as the *Smagorinsky model* [32, 33, 36, 47, 51] in which

$$(1.1) \quad \nu_T = \nu_{\text{Smag}}(\bar{\mathbf{u}}, \delta) := (c_s \delta)^2 \|\nabla^s \bar{\mathbf{u}}\|_F.$$

Although the Smagorinsky model is easy to implement, is stable, and replicates energy dissipation rates, it is quite inaccurate for many problems. Probably the most common complaint for the Smagorinsky model (1.1) is that it is *too dissipative*. The reason is clearly illustrated in Figure 1.1: for large values of the deformation tensor $\nabla^s \bar{\mathbf{u}}$, the Smagorinsky model introduces an unbounded amount of artificial viscosity (AV). This behavior is manifest in practical computations of flows displaying large velocity deformation tensors, such as wall-bounded flows. For example, in turbulent channel flows and pipe flows [4], the Smagorinsky model yields unphysical results.

Different approaches have been devised to cope with this limitation: the “clipping procedure” [2, 8, 20, 31, 52], the van Driest damping [4, 26, 27, 50], the *Ri*-dependent Smagorinsky model [11, 15, 38, 44, 46, 48] (where *Ri* is the Richardson number, the square of the ratio of the buoyancy frequency, and the vertical shear), the dynamic SGS model [19], and the Lagrangian dynamic SGS model [39, 41]. All of these approaches target the same deficiency of the Smagorinsky model—its *overly diffusive character*.

In this paper, we consider a *bounded AV model* for the numerical simulation of turbulent flows with high velocity deformation tensors. The bounded AV model has a *general* form: it can be used to reduce the overly dissipative nature of the Smagorinsky model without massive a priori knowledge of the flow regime. The bounded AV model reads

$$(1.2) \quad \nu_T = \mu \delta^\sigma a(\delta \|\nabla^s \bar{\mathbf{u}}\|_F) \nabla^s \bar{\mathbf{u}},$$

where $a(\cdot)$ is a general function whose graph resembles that in Figure 1.1.

The bounded AV model was proposed in [28] as an alternative to the Smagorinsky model and yielded improved results for convection-dominated convection-diffusion problems. In this paper, we analyze and test the bounded AV model (1.2) in the numerical simulation of incompressible fluid flows.

The paper is organized as follows: In section 2, we discuss the commonly used EV models. We note the benefits and limitations of heuristic procedures in which a “clipping” of the Smagorinsky AV is performed and present (1.2) as a viable alternative to such strategies. In section 3, we provide the variational setting for which the NSE with (1.2) is solved and introduce the necessary notation. In section 4, we present some stability results for the variational solution to NSE with (1.2), which are generalizations of Leray’s inequality for the usual Navier–Stokes system. In section 5, we prove an error estimate for the semidiscrete finite element approximation of the NSE with (1.2). In section 6, we discuss the Newton approximation scheme as applied to the NSE with the bounded AV term (1.2). Finally, in section 7, we include finite element calculations for NSE with (1.2), which both support the theoretical error estimate of section 5 and show that the bounded AV model (1.2) yields better results than the Smagorinsky model (1.1) in the numerical simulation of turbulent flow in a 3D square duct. We provide both sequential computations for an academic vortex decay problem and parallel computations for a 3D square duct flow, using the Virginia Tech large eddy simulator (ViTLES).

2. Large eddy simulation. LES is a natural computational idea: when a numerical mesh is so coarse that the problem data and solution fluctuate significantly inside each mesh cell, it is reasonable to replace the problem data by mesh cell averages of that data and define an approximate solution that represents a mesh cell average of the true solution. Thus, if δ is the mesh cell width, then we should not seek to approximate the pointwise fluid velocity $\mathbf{u}(\mathbf{x}, t)$ but rather some mesh cell average $\bar{\mathbf{u}}(\mathbf{x}, t)$. The simplest such average is given by the convolution of the velocity \mathbf{u} with a rapidly decaying spatial filter $g_\delta(\mathbf{x})$ such as the sharp cut-off, box (top hat), Gaussian, or differential filters.

The essential idea of LES is the following: Pick a spatial filter $g_\delta(\mathbf{x})$ and define $\bar{\mathbf{u}}(\mathbf{x}, t) := (g_\delta * \mathbf{u})(\mathbf{x}, t)$. Derive appropriate equations for $\bar{\mathbf{u}}$ by convolving the NSE with the spatial filter. Solve the closure problem. Impose accurate boundary conditions for $\bar{\mathbf{u}}$. Then discretize the resulting continuum model and solve it. Generally, such an averaging suppresses any fluctuations in \mathbf{u} below $O(\delta)$ and preserves those on scales larger than $O(\delta)$. In many flows, the portion of the flow that must be modeled $\mathbf{u}' := \mathbf{u} - \bar{\mathbf{u}}$ is small relative to the portion that is calculated $\bar{\mathbf{u}}$. Models in LES tend to be both simple and accurate, and the overall computational cost is comparable to that of computing an (unreliable, underrefined) solution of the NSE on the same mesh.

For an incompressible fluid, the nondimensionalized form of the NSE is

$$(2.1) \quad \mathbf{u}_t - Re^{-1} \Delta \mathbf{u} + (\mathbf{u} \cdot \nabla) \mathbf{u} + \nabla p = \mathbf{f}, \quad \text{in } \Omega \times (0, T),$$

$$(2.2) \quad \nabla \cdot \mathbf{u} = 0, \quad \text{in } \Omega \times (0, T),$$

$$(2.3) \quad \mathbf{u} = 0, \quad \text{on } \partial\Omega \times (0, T),$$

where $\Omega \subset \mathbb{R}^d$, $d = 2, 3$ is the flow domain, T is the final time, \mathbf{u} is the velocity, p is the pressure, and $Re := UL/\nu$ is the Reynolds number, defined as the ratio between the product of a characteristic length-scale L and a characteristic velocity U , and the kinematic viscosity ν .

To derive equations for $\bar{\mathbf{u}}$, we convolve the NSE with the chosen filter function $g_\delta(\mathbf{x})$. Using the fact that (for constant $\delta > 0$ and in the absence of boundaries) filtering commutes with differentiation gives the space-filtered NSE:

$$(2.4) \quad \bar{\mathbf{u}}_t - Re^{-1}\Delta\bar{\mathbf{u}} + \nabla \cdot (\bar{\mathbf{u}}\bar{\mathbf{u}}^T) + \nabla\bar{p} = -\nabla \cdot \boldsymbol{\tau}(\mathbf{u}, \mathbf{u}) + \bar{\mathbf{f}} \quad \text{in } \Omega \times (0, T),$$

$$(2.5) \quad \nabla \cdot \bar{\mathbf{u}} = 0 \quad \text{in } \Omega \times (0, T).$$

This system is not closed, since it involves both \mathbf{u} and $\bar{\mathbf{u}}$. The tensor $\boldsymbol{\tau}(\mathbf{u}, \mathbf{u}) = \overline{\mathbf{u}\mathbf{u}^T} - \bar{\mathbf{u}}\bar{\mathbf{u}}^T$ or $\tau_{ij}(\mathbf{u}, \mathbf{u}) = \overline{u_i u_j} - \bar{u}_i \bar{u}_j$ is often called the SGS tensor. Thus, the closure problem in LES is to model the SGS tensor $\boldsymbol{\tau}(\mathbf{u}, \mathbf{u})$, i.e., to specify a tensor $\mathcal{S} = \mathcal{S}(\bar{\mathbf{u}}, \bar{\mathbf{u}})$ to replace $\boldsymbol{\tau}(\mathbf{u}, \mathbf{u})$ in (2.4).

2.1. Eddy viscosity models. The most popular approach to the closure problem is the EV model, which is motivated by the idea that the global effect of $\boldsymbol{\tau}(\mathbf{u}, \mathbf{u})$, in the mean, is to transfer energy from resolved to unresolved scales through inertial interactions. EV models are motivated by Kolmogorov’s K-41 theory ([4, 45]), and, in particular, by the *energy cascade*. The essence of the energy cascade (see [43]) is that kinetic energy enters the turbulent flow at the largest scales of motion, and is then transferred by inviscid processes to smaller and smaller scales, until it is eventually dissipated through viscous effects. Thus, the action of $\boldsymbol{\tau}(\mathbf{u}, \mathbf{u})$ is thought of as having a dissipative effect on the mean flow: the scales uncaptured on the numerical mesh (above the cutoff wavenumber k_c) should dissipate energy from the large scales (below the cutoff wavenumber k_c).

Boussinesq [5] first formulated the *EV/Boussinesq hypothesis* based upon an analogy between the interaction of small eddies and the perfectly elastic collision of molecules (e.g., molecular viscosity or heat): “*Turbulent fluctuations are dissipative in the mean.*” The mathematical realization is the model

$$\nabla \cdot \boldsymbol{\tau}(\mathbf{u}, \mathbf{u}) \approx -\nabla \cdot (\nu_T \nabla^s \bar{\mathbf{u}}) + \text{terms incorporated into } \bar{p},$$

where $\nabla^s \bar{\mathbf{u}} := (\nabla \bar{\mathbf{u}} + \nabla \bar{\mathbf{u}}^T)/2$ is the deformation tensor of $\bar{\mathbf{u}}$ and $\nu_T \geq 0$ is the “turbulent viscosity coefficient.” The modeling problem then reduces to determining one parameter: the turbulent viscosity coefficient $\nu_T(\bar{\mathbf{u}}, \delta)$.

2.2. The Smagorinsky model. The most common EV model is known in LES as the Smagorinsky model, in which

$$(2.6) \quad \nu_T = \nu_{\text{Smag}}(\bar{\mathbf{u}}, \delta) := (c_s \delta)^2 \|\nabla^s \bar{\mathbf{u}}\|_F,$$

where δ is the filter radius, c_s is the Smagorinsky constant, and $\|\sigma\|_F := \sqrt{\sum_{i,j=1}^d |\sigma_{ij}|^2}$ is the Frobenius norm of the tensor σ . This model was studied in [51] as a nonlinear AV in gas dynamics and in [47] for geophysical flow calculations. A complete mathematical theory for partial differential equations involving this term was constructed by Ladyžhenskaya [32, 33].

The Smagorinsky model (1.1) where $c_s \sim 0.17$ [36] seems to be a universal answer in LES. It is easy to implement, stable, and (under “optimistic” assumptions) it replicates energy dissipation rates. Unfortunately, it can be also quite inaccurate for many problems.

The most successful form of the Smagorinsky model is the *dynamic* SGS model of [19], in which c_s is chosen locally in space and time, $c_s = c_s(\mathbf{x}, t)$. An essential improvement is that the dynamic SGS model introduces *backscatter*, the inverse transfer of energy from small scales to large scales [27, 4]. A yet improved version of the dynamic SGS model is the *Lagrangian dynamic* SGS model of [39, 41].

2.3. The overly diffusive character of the Smagorinsky model. Whether simplistic or more involved, all these approaches target the same deficiency of the Smagorinsky model—its overly diffusive character. This negative feature of the Smagorinsky model is clearly illustrated by the schematic in Figure 1.1. Plotting the amount of AV introduced by the Smagorinsky model against $\|\delta \nabla^s \bar{\mathbf{u}}\|_F$, we obtain a linear profile: Indeed, (1.1) can be rewritten as

$$(2.7) \quad \nu_T = \nu_{\text{Smag}}(\bar{\mathbf{u}}, \delta) = c_s^2 \delta \|\delta \nabla^s \bar{\mathbf{u}}\|_F,$$

which yields a linear profile for ν_T (if δ is held constant). In smooth regions of the flow, where the deformation tensor is relatively small ($\|\nabla^s \bar{\mathbf{u}}\|_F \leq O(1/\delta)$), the Smagorinsky model will introduce a moderate amount of AV ($\nu_T \leq O(\delta)$). In those regions of the flow where the deformation tensor is large ($\|\nabla^s \bar{\mathbf{u}}\|_F \geq O(1/\delta^2)$, for example), the Smagorinsky model will introduce an *unphysical* amount of AV ($\nu_T \sim O(1)$).

The overly diffusive feature of the Smagorinsky model is manifested in practical computations of flows displaying a large deformation tensor, such as wall-bounded flows. Indeed, for turbulent channel flows and pipe flows, because the velocity deformation tensor is very large near the solid wall, the Smagorinsky model introduces an unphysical amount of AV. Similarly, in stratified flows with large shear (and thus large deformation tensors), the Smagorinsky model introduces an unphysical amount of AV in the vertical direction.

There have been numerous modifications of the Smagorinsky model, all trying to attenuate its overly diffusive character. The simplest such approach is the “clipping procedure”

$$(2.8) \quad \nu_T = \nu_{\text{Smag}}^{\text{clipping}}(\bar{\mathbf{u}}, \delta) := \min\{\nu_{\text{Smag}}(\bar{\mathbf{u}}, \delta), C\},$$

where C is a user-defined constant [2, 8, 20, 31, 52].

A more involved approach for wall-bounded flows (such as channel and pipe flows) is the van Driest damping [4, 26, 27, 50], in which

$$(2.9) \quad \nu_T = \nu_{\text{Smag}}^{VD}(\bar{\mathbf{u}}, \delta) := \left[\left(1 - e^{-\frac{y^+}{25}} \right) \right] \nu_{\text{Smag}}(\bar{\mathbf{u}}, \delta),$$

where y^+ is the nondimensionalized distance to the wall (see Chapter 12 in [4] for more details). The main improvement over the ad hoc clipping procedure (2.8) is that the damping function in (2.9) is chosen so that the resulting flow satisfies the turbulent boundary layer theory [4].

In stratified flows, the Smagorinsky model is used with a damping function in the vertical direction [11, 15, 38, 44, 46, 48]:

$$(2.10) \quad \nu_T^z = \nu_{\text{Smag}}^{Ri}(\bar{\mathbf{u}}, \delta) := \sqrt{1 - \frac{Ri}{Ri_c}} \nu_{\text{Smag}}(\bar{\mathbf{u}}, \delta),$$

where Ri is the Richardson number, the square of the ratio of the buoyancy frequency and the vertical shear, and Ri_c is a critical Richardson number (a popular choice is $Ri_c \sim 0.25$) [40, 44].

2.4. The bounded AV model. In this paper, we consider the bounded AV model, a general, mathematically sound alternative to the Smagorinsky model. The bounded AV model reads

$$(2.11) \quad \nu_T = \mu \delta^\sigma a(\delta \|\nabla^s \bar{\mathbf{u}}\|_F) \nabla^s \bar{\mathbf{u}},$$

where $a(\cdot)$ is a general function whose graph resembles that in Figure 1.1. This new model, proposed in [28] for convection-diffusion problems, is a clear improvement over the Smagorinsky model. Indeed, in the flow regions with large velocity deformation tensors, the bounded AV model introduces a *bounded* amount of AV, just enough to spread the solution onto the computational mesh. This is in clear contrast with the Smagorinsky model, which introduces an unbounded amount of AV, thus being overly dissipative. The improvement of the bounded AV model over the Smagorinsky model is clearly supported by the numerical simulation of a turbulent flow in a 3D square duct in section 7.

Another distinct advantage of the bounded AV model over other modifications of the Smagorinsky model is that, when appropriately chosen, the bounded AV term represents a monotonic semilinear operator. This property allows for existence and uniqueness results for the finite element approximation as well as the error estimates presented herein. It is important to note that the results of this paper are more straightforward for the bounded AV model than for the previously mentioned heuristic AV bounding techniques, as the bounded AV model translates more readily into the mathematical framework established for the NSE.

The bounded AV model is general. Indeed, the function $a(\cdot)$ in (1.2) is just required to be bounded and monotonically increasing (see Figure 1.1). Thus, the bounded AV model clearly includes the ad hoc “clipped” Smagorinsky model (2.8) as a particular case. Although the bounded AV model does not directly include the Smagorinsky model with van Driest damping (2.9) ($a(\cdot)$ must be monotonically increasing) or the *Ri*-dependent Smagorinsky model (2.10) ($a(\cdot)$ depends on $\nabla^s \mathbf{u}$, whereas (2.10) depends on $\frac{\partial \mathbf{u}}{\partial z}$), it is certainly related to these two models, targeting the overly diffusive character of the Smagorinsky model. Note that while models (2.9) and (2.10) are tailored for specific flows (wall-bounded and stratified, respectively), the bounded AV model is not restricted to any particular type of flow. Of course, the function $a(\cdot)$ should be optimized for each particular flow setting in which the bounded AV model is used. To this end, extensive a priori and a posteriori testing [4] should be carried out for each such flow setting.

It was shown in [28] that the bounded AV model yields a clear improvement over the Smagorinsky model in the numerical simulation of convection-dominated convection-diffusion problems with sharp transition layers. In this paper, we show that the bounded AV model is a dramatic improvement over the Smagorinsky model in the numerical simulation of a turbulent flow in a 3D square duct.

There are numerous challenges in the numerical analysis of LES, where the study of classic topics such as consistency, stability, and convergence of the LES discretization are still at an initial stage. Only the first few steps along these lines have been made, some of which are presented in the exquisite monograph of John [30]. A thorough numerical analysis for the finite element implementation of the Smagorinsky model has been presented in [12, 13]. Further studies have been presented in [29, 34].

In this paper, we present a rigorous numerical analysis for the finite element implementation of the bounded AV model:

$$\begin{aligned}
 (2.12) \quad & \mathbf{w}_t - Re^{-1} \Delta \mathbf{w} - \nabla \cdot (\mu \delta^\sigma a(\delta \|\nabla^s \mathbf{w}\|_F) \nabla^s \mathbf{w}) \\
 & + (\mathbf{w} \cdot \nabla) \mathbf{w} - \nabla q = \bar{\mathbf{f}} \quad \text{in } \Omega \times (0, T), \\
 (2.13) \quad & \nabla \cdot \mathbf{w} = 0 \quad \text{in } \Omega \times (0, T), \\
 (2.14) \quad & \mathbf{w} = 0 \quad \text{on } \partial\Omega \times (0, T).
 \end{aligned}$$

We also illustrate our error estimates with numerical simulations, using the bounded

AV model for the 3D square duct turbulent flow and the two-dimensional (2D) vortex decay problem.

Remark 2.1. The numerical analysis presented herein is concerned with the *numerical error* (i.e., $\mathbf{w} - \mathbf{w}_h$) associated with the bounded AV model, and not the *modeling error* (i.e., $\bar{\mathbf{u}} - \mathbf{w}$) associated with the proposed EV model.

3. The variational formulation. In this section, we develop the variational formulation for (2.12)–(2.14). We will denote the usual Sobolev spaces [1] by $W^{m,p}(\Omega)$, with norms $\|\cdot\|_{W^{m,p}}$ and seminorms $|\cdot|_{W^{m,p}}$, and set $H^m(\Omega) := W^{m,2}(\Omega)$ and $L^p(\Omega) := W^{0,p}(\Omega)$. In what follows, we will denote $\|\cdot\|$ and (\cdot, \cdot) the norm and inner product for $L^2(\Omega)$, and $\|\cdot\|_m$ the norm for $H^m(\Omega)$. The vector spaces and vector functions will be indicated by boldface type letters.

Specifically, we use the following function spaces for the variational formulation:

$$\begin{aligned} \text{Velocity space : } \mathbf{X} &:= \mathbf{H}_0^1(\Omega) := \{ \mathbf{v} \in \mathbf{H}^1(\Omega) : \mathbf{v} = 0 \text{ on } \partial\Omega \}, \\ \text{Pressure space : } Q &:= L_0^2(\Omega) := \left\{ q \in L^2(\Omega) : \int_{\Omega} q \, dx = 0 \right\}. \end{aligned}$$

The velocity and pressure spaces \mathbf{X} and Q satisfy the inf-sup condition [21]

$$(3.1) \quad \inf_{\lambda \in Q} \sup_{\mathbf{v} \in \mathbf{X}} \frac{(\lambda, \nabla \cdot \mathbf{v})}{\|\lambda\| \|\mathbf{v}\|_1} \geq \beta > 0.$$

The inf-sup condition (3.1), in turn, implies that the space of weakly divergence-free functions \mathbf{V} :

$$(3.2) \quad \mathbf{V} := \{ \mathbf{v} \in \mathbf{X} : (\lambda, \nabla \cdot \mathbf{v}) = 0, \forall \lambda \in Q \}$$

is a well-defined, nontrivial, closed subspace of \mathbf{X} [21].

The variational formulation of (2.12)–(2.14) proceeds in the usual manner. Multiplying (2.12) and (2.13) by a velocity (\mathbf{v}) and pressure (λ) test function, respectively, integrating over Ω , and integrating by parts (using the fact that $\mathbf{v} = 0$ on $\partial\Omega$), we obtain

$$(3.3) \quad (\mathbf{w}_t, \mathbf{v}) + A(\mathbf{w}, \mathbf{v}) + B(\mathbf{w}, \mathbf{w}, \mathbf{v}) + C(\mathbf{w}, \mathbf{w}, \mathbf{v}) - (q, \nabla \cdot \mathbf{v}) = (\bar{\mathbf{f}}, \mathbf{v}), \quad \forall \mathbf{v} \in \mathbf{X}, \quad t \in [0, T],$$

$$(3.4) \quad (\nabla \cdot \mathbf{w}, \lambda) = 0, \quad \forall \lambda \in Q, \quad t \in [0, T],$$

where the bilinear form $A(\cdot, \cdot)$ is defined by

$$A(\mathbf{w}, \mathbf{v}) := Re^{-1} (\nabla \mathbf{w}, \nabla \mathbf{v})$$

and the trilinear forms $B(\cdot, \cdot, \cdot)$ and $C(\cdot, \cdot, \cdot)$ are defined by

$$\begin{aligned} B(\mathbf{u}, \mathbf{v}, \mathbf{w}) &:= \mu \delta^\sigma (a(\delta \|\nabla \mathbf{u}\|_F) \nabla \mathbf{v}, \nabla \mathbf{w}), \\ C(\mathbf{u}, \mathbf{v}, \mathbf{w}) &:= \frac{1}{2} (\mathbf{u} \cdot \nabla \mathbf{v}, \mathbf{w}) - \frac{1}{2} (\mathbf{u} \cdot \nabla \mathbf{w}, \mathbf{v}). \end{aligned}$$

It is a simple index calculation to check that, for $\mathbf{v} \in \mathbf{X}$, $\mathbf{w} \in \mathbf{V}$, $(\mathbf{w} \cdot \nabla \mathbf{w}, \mathbf{v}) = C(\mathbf{w}, \mathbf{w}, \mathbf{v})$.

Remark 3.1. Although the bounded AV model (2.12)–(2.14) depends on $\nabla^s \mathbf{w}$, for clarity we will replace $\nabla^s \mathbf{w}$ by $\nabla \mathbf{w}$. The same numerical analysis can be carried out with the $\nabla^s \mathbf{w}$ by using Korn’s inequalities, which relate the L^p -norms of the deformation tensor $\nabla^s \mathbf{w}$ to the same norms of the gradient $\nabla \mathbf{w}$ for $1 < p < \infty$ [16, 29].

3.1. Finite element spaces. Let $\Omega \subset \mathbb{R}^d$, ($d = 2, 3$) be a polygonal domain, and let T_h denote a triangulation of Ω made up of triangles (in \mathbb{R}^2) or tetrahedra (in \mathbb{R}^3). Thus, the computational domain is defined by

$$\Omega = \bigcup K, \quad K \in T_h.$$

We also assume that for a particular triangulation T_h of Ω , there exist positive constants c_1, c_2 such that

$$c_1 h \leq h_K \leq c_2 \rho_K,$$

where h_K is the diameter of K , ρ_K is the diameter of the greatest ball (sphere) included in K , and $h = \max_{K \in T_h} h_K$. Let $P_k(A)$ denote the space of polynomials on a subdomain A of degree no greater than k . We define the conforming finite element spaces associated with the velocity and pressure spaces as follows:

$$(3.5) \quad \mathbf{X}_h := \{ \mathbf{v}_h \in \mathbf{X} \cap C(\overline{\Omega})^d : \mathbf{v}_h|_K \in P_k(K), \forall K \in T_h \},$$

$$(3.6) \quad Q_h := \{ \lambda_h \in Q \cap C(\overline{\Omega}) : \lambda_h|_K \in P_l(K), \forall K \in T_h \},$$

where $C(\overline{\Omega})$ denotes the set of continuous functions on the closure of Ω . Analogous to the continuous inf-sup condition, the spaces \mathbf{X}_h, Q_h satisfy the *discrete* inf-sup condition [14, 21]

$$(3.7) \quad \inf_{\lambda_h \in Q_h} \sup_{\mathbf{v}_h \in \mathbf{X}_h} \frac{(\lambda_h, \nabla \cdot \mathbf{v}_h)}{\|\lambda_h\| \|\mathbf{v}_h\|_1} \geq \beta > 0.$$

The *discrete* inf-sup condition (3.7), in turn, implies that the space of weakly divergence-free functions \mathbf{V}_h

$$(3.8) \quad \mathbf{V}_h := \{ \mathbf{v}_h \in \mathbf{X}_h : (\lambda_h, \nabla \cdot \mathbf{v}_h) = 0, \forall \lambda_h \in Q_h \}$$

is a well-defined, nontrivial, closed subspace of \mathbf{X}_h [14, 21, 22].

We assume that the finite element spaces \mathbf{X}_h, Q_h satisfy the usual approximation properties [6, 21]: For $(\mathbf{w}, \lambda) \in \mathbf{H}^{k+1}(\Omega) \times H^{l+1}(\Omega)$, there exist interpolants $(I_h \mathbf{w}, I_h \lambda) \in \mathbf{X}_h \times Q_h$ satisfying [6, 21]

$$(3.9) \quad \|\mathbf{w} - I_h \mathbf{w}\| \leq C_I h^{k+1} |\mathbf{w}|_{\mathbf{H}^{k+1}},$$

$$(3.10) \quad \|\mathbf{w} - I_h \mathbf{w}\|_1 \leq C_I h^k |\mathbf{w}|_{\mathbf{H}^{k+1}},$$

$$(3.11) \quad \|\lambda - I_h \lambda\| \leq C_I h^{l+1} |\lambda|_{H^{l+1}}.$$

From [6], we have the following useful results concerning interpolation.

LEMMA 3.1. *Let $\{T_h\}$ ($0 < h \leq 1$) denote a quasi-uniform family of subdivisions of a polyhedral domain $\Omega \subset \mathbb{R}^d$. Let (\hat{K}, P, N) be a reference finite element such that $P \subset W^{l,p}(\hat{K}) \cap W^{m,q}(\hat{K})$, where $1 \leq p, q \leq \infty$, and $0 \leq m \leq l$. For $K \in T_h$, let (K, P_K, N_K) be the affine equivalent element and*

$$V_h := \left\{ v : v \text{ is measurable and } v|_K \in P_K, \forall K \in T_h \right\}.$$

Then there exists $C = C(l, p, q)$ such that

$$(3.12) \quad \left[\sum_{K \in T_h} \|v\|_{W^{l,p}(K)}^p \right]^{1/p} \leq C h^{m-l+\min(0, \frac{d}{p}-\frac{d}{q})} \left[\sum_{K \in T_h} \|v\|_{W^{m,q}(K)}^q \right]^{1/q}.$$

4. Stability results. In this section, we prove some stability results concerning the variational problem (3.3)–(3.4), as well as its semidiscrete finite element approximation. Useful in the following analysis are the following three lemmas.

LEMMA 4.1 (monotonicity of $B(\cdot, \cdot, \cdot)$ [28]). *For $\mathbf{u}, \mathbf{v} \in \mathbf{X}$, and the function $a(\cdot)$ satisfying*

$$0 \leq a(x) \leq 1, \quad a'(x) \geq 0, \quad \forall x \in [0, \infty),$$

we have

$$B(\mathbf{u}, \mathbf{u}, \mathbf{u} - \mathbf{v}) - B(\mathbf{v}, \mathbf{v}, \mathbf{u} - \mathbf{v}) \geq 0.$$

Proof. Consider the functional $I : \mathbf{X} \rightarrow \mathbb{R}$, defined by

$$I(\mathbf{U}) := \int_{\Omega} A(\|\nabla \mathbf{U}\|_F) \, d\mathbf{x},$$

where the function $A : [0, \infty) \rightarrow \mathbb{R}$ is defined by

$$A(x) := \int_0^x t a(t) dt.$$

First, note that

$$dI(\mathbf{U}, \mathbf{V}) = \int_{\Omega} A'(\|\nabla \mathbf{U}\|_F) \frac{\nabla \mathbf{U}}{\|\nabla \mathbf{U}\|_F} \nabla \mathbf{V} \, d\mathbf{x} = \int_{\Omega} a(\|\nabla \mathbf{U}\|_F) \nabla \mathbf{U} \nabla \mathbf{V} \, d\mathbf{x},$$

where $dI(\mathbf{U}, \mathbf{V})$ is the Gâteaux derivative of I at \mathbf{U} in the direction of \mathbf{V} .

Therefore, setting $\mathbf{U}_1 := \delta \mathbf{u}$, $\mathbf{U}_2 := \delta \mathbf{v}$, and $\mathbf{V} := \mathbf{U}_1 - \mathbf{U}_2$, we have

$$(4.1) \quad B(\mathbf{u}, \mathbf{u}, \mathbf{u} - \mathbf{v}) - B(\mathbf{v}, \mathbf{v}, \mathbf{u} - \mathbf{v}) = \frac{\mu \delta^\sigma}{\delta^2} (dI(\mathbf{U}_1, \mathbf{V}) - dI(\mathbf{U}_2, \mathbf{V})).$$

However, we can rewrite this expression as

$$\begin{aligned} dI(\mathbf{U}_1, \mathbf{V}) - dI(\mathbf{U}_2, \mathbf{V}) &= \int_0^1 \frac{d}{dt} dI(\mathbf{U}_2 + t(\mathbf{U}_1 - \mathbf{U}_2), \mathbf{V}) \, dt \\ &= \int_0^1 \frac{d}{dt} \int_{\Omega} a(\|\nabla(\mathbf{U}_2 + t(\mathbf{U}_1 - \mathbf{U}_2))\|_F) \nabla(\mathbf{U}_2 + t(\mathbf{U}_1 - \mathbf{U}_2)) \nabla \mathbf{V} \, d\mathbf{x} \, dt \\ &= \int_0^1 \int_{\Omega} a'(\|\nabla(\mathbf{U}_2 + t(\mathbf{U}_1 - \mathbf{U}_2))\|_F) \frac{\nabla(\mathbf{U}_2 + t(\mathbf{U}_1 - \mathbf{U}_2)) \nabla \mathbf{V}}{\|\nabla(\mathbf{U}_2 + t(\mathbf{U}_1 - \mathbf{U}_2)) \nabla \mathbf{V}\|_F} \\ &\quad \nabla(\mathbf{U}_2 + t(\mathbf{U}_1 - \mathbf{U}_2)) \nabla \mathbf{V} \, d\mathbf{x} \, dt \\ (4.2) \quad &+ \int_0^1 \int_{\Omega} a(\|\nabla(\mathbf{U}_2 + t(\mathbf{U}_1 - \mathbf{U}_2))\|_F) \|\nabla \mathbf{V}\|_F^2 \, d\mathbf{x} \, dt. \end{aligned}$$

As $a(x), a'(x) \geq 0$, it is clear that the expression in (4.2) is nonnegative. Finally, using (4.1), we obtain the stated result. \square

Remark 4.1. Notice that Lemma 4.1 states that the bounded AV operator $B(\cdot, \cdot, \cdot)$ is monotone but not strongly monotone. The Smagorinsky AV operator

$$B^{Smag}(\mathbf{u}, \mathbf{v}, \mathbf{w}) := ((c_s \delta)^2 \|\nabla^s \mathbf{u}\|_F \nabla^s \mathbf{v}, \nabla^s \mathbf{w}),$$

on the other hand, is strongly monotone [13, 29, 34]. Indeed, $\forall \mathbf{u}, \mathbf{v} \in \mathbf{W}^{1,3}(\Omega)$,

$$B^{Smag}(\mathbf{u}, \mathbf{u}, \mathbf{u} - \mathbf{v}) - B^{Smag}(\mathbf{v}, \mathbf{v}, \mathbf{u} - \mathbf{v}) \geq C \delta^2 \|\nabla^s(\mathbf{u} - \mathbf{v})\|_{L^3}^3.$$

Therefore, the error estimate we prove in Theorem 5.1 for the bounded AV model assumes higher regularity for the solution \mathbf{w} ($\mathbf{w} \in L^4(0, T; \mathbf{W}^{1,\infty}(\Omega))$) than the regularity for \mathbf{w} assumed for the Smagorinsky model [29] ($\mathbf{w} \in L^2(0, T; \mathbf{W}^{1,\infty}(\Omega))$).

LEMMA 4.2. For $\mathbf{u}_1, \mathbf{u}_2, \mathbf{v}, \mathbf{w} \in \mathbf{X}$, and the function $a(\cdot)$ satisfying

$$0 \leq a(x) \leq 1, \quad 0 \leq a'(x) \leq M_a, \quad \forall x \in [0, \infty),$$

we have

$$(4.3) \quad |B(\mathbf{u}_1, \mathbf{v}, \mathbf{w}) - B(\mathbf{u}_2, \mathbf{v}, \mathbf{w})| \leq M_a \mu \delta^{\sigma+1} (\|\nabla \mathbf{u}_1 - \nabla \mathbf{u}_2\|_F \|\nabla \mathbf{v}\|_F, \|\nabla \mathbf{w}\|_F)$$

and

$$(4.4) \quad |B(\mathbf{u}_1, \mathbf{v}, \mathbf{w})| \leq M_a \mu \delta^{\sigma+1} (\|\nabla \mathbf{u}_1\|_F \|\nabla \mathbf{v}\|_F, \|\nabla \mathbf{w}\|_F).$$

Proof. Without loss of generality, we assume that $\|\nabla \mathbf{u}_1\|_F \geq \|\nabla \mathbf{u}_2\|_F$. Immediately, we have

$$(4.5) \quad |B(\mathbf{u}_1, \mathbf{v}, \mathbf{w}) - B(\mathbf{u}_2, \mathbf{v}, \mathbf{w})| = \mu \delta^\sigma |(a(\delta \|\nabla \mathbf{u}_1\|_F) - a(\delta \|\nabla \mathbf{u}_2\|_F)) \nabla \mathbf{v}, \nabla \mathbf{w}|.$$

Now, by the mean value theorem, there exists $c_a \in [\delta \|\nabla \mathbf{u}_2\|_F, \delta \|\nabla \mathbf{u}_1\|_F]$ such that

$$a(\delta \|\nabla \mathbf{u}_1\|_F) - a(\delta \|\nabla \mathbf{u}_2\|_F) = a'(c_a) \delta (\|\nabla \mathbf{u}_1\|_F - \|\nabla \mathbf{u}_2\|_F).$$

Combining this with the reverse triangle inequality $||x| - |y|| \leq |x - y|$, we have

$$(4.6) \quad |a(\delta \|\nabla \mathbf{u}_1\|_F) - a(\delta \|\nabla \mathbf{u}_2\|_F)| \leq a'(c_a) \delta \|\nabla \mathbf{u}_1 - \nabla \mathbf{u}_2\|_F.$$

Finally, substituting (4.6) into (4.5) and noting that $a'(c_a) \leq M_a$, we obtain (4.3). The result (4.4) follows directly. \square

Remark 4.2. Again, the bounded AV operator $B(\cdot, \cdot, \cdot)$ satisfies a weaker inequality than the Smagorinsky AV operator $B^{Smag}(\cdot, \cdot, \cdot)$ [13, 29, 34].

LEMMA 4.3 (Leray’s inequality for the bounded AV model). A solution of (3.3)–(3.4) satisfies

$$\frac{1}{2} \|\mathbf{w}(t)\|^2 + \int_0^t Re^{-1} \|\nabla \mathbf{w}\|^2 ds \leq \frac{1}{2} \|\mathbf{w}(0)\|^2 + \int_0^t (\mathbf{f}, \mathbf{w}) ds \quad \forall t \in [0, T].$$

Proof. The stated result follows by setting $\mathbf{v} = \mathbf{w}$ and $\lambda = q$ in (3.3) and (3.4), noting that

$$B(\mathbf{w}, \mathbf{w}, \mathbf{w}) \geq 0, \quad C(\mathbf{w}, \mathbf{w}, \mathbf{w}) = 0,$$

and integrating from 0 to t . \square

We now define the semidiscrete approximation as the solution of (3.3)–(3.4) restricted to the finite element spaces \mathbf{X}_h, Q_h .

DEFINITION 4.4 (The semidiscrete approximation). The semidiscrete approximation is defined to be an element $(\mathbf{w}_h, q_h) \in C(0, T; \mathbf{X}_h) \cap C(0, T; Q_h)$ such that

$$(4.7) \quad (\mathbf{w}_{h,t}, \mathbf{v}_h) + A(\mathbf{w}_h, \mathbf{v}_h) + B(\mathbf{w}_h, \mathbf{w}_h, \mathbf{v}_h) + C(\mathbf{w}_h, \mathbf{w}_h, \mathbf{v}_h) - (q_h, \nabla \cdot \mathbf{v}_h) = (\bar{\mathbf{f}}, \mathbf{v}_h), \quad \forall \mathbf{v}_h \in \mathbf{X}_h, \quad t \in [0, T],$$

$$(4.8) \quad (\nabla \cdot \mathbf{w}_h, \lambda_h) = 0, \quad \forall \lambda_h \in Q_h, \quad t \in [0, T].$$

We immediately obtain the following two lemmas.

LEMMA 4.5 (Leray's inequality for \mathbf{w}_h). *A solution of (4.7)–(4.8) satisfies*

$$\frac{1}{2} \|\mathbf{w}_h(t)\|^2 + \int_0^t Re^{-1} \|\nabla \mathbf{w}_h\|^2 ds \leq \frac{1}{2} \|\mathbf{w}_h(0)\|^2 + \int_0^t (\overline{\mathbf{f}}, \mathbf{w}_h) ds.$$

Proof. Setting $\mathbf{v}_h = \mathbf{w}_h$ and $\lambda_h = q_h$ in (4.7)–(4.8), we immediately have

$$(4.9) \quad \frac{1}{2} \frac{d}{dt} \|\mathbf{w}_h(t)\|^2 + Re^{-1} \|\nabla \mathbf{w}_h\|^2 \leq (\overline{\mathbf{f}}, \mathbf{w}_h).$$

Integrating from 0 to t thus yields the stated result. \square

LEMMA 4.6 (Stability of \mathbf{w}_h). *A solution \mathbf{w}_h of (4.7)–(4.8) satisfies*

$$(4.10) \quad \begin{aligned} \|\mathbf{w}_h(t)\|^2 + Re^{-1} C(\Omega) \int_0^t \|\mathbf{w}_h\|_{\mathbf{H}^1}^2 ds \\ \leq \|\mathbf{w}_h(0)\|^2 + \frac{Re}{C(\Omega)} \int_0^t \|\overline{\mathbf{f}}\|_{\mathbf{H}^{-1}}^2 ds \end{aligned}$$

and

$$(4.11) \quad \begin{aligned} \|\mathbf{w}_h(t)\|^2 + 2Re^{-1} \int_0^t e^{t-s} \|\nabla \mathbf{w}_h\|^2 ds \\ \leq e^t \|\mathbf{w}_h(0)\|^2 + \int_0^t e^{t-s} \|\overline{\mathbf{f}}\|^2 ds, \end{aligned}$$

where $C(\Omega)$ denotes a generic constant depending on Ω .

Proof. By using the Cauchy–Schwarz and Young's inequalities, we have

$$(4.12) \quad (\overline{\mathbf{f}}, \mathbf{w}_h) \leq \frac{\varepsilon}{2} \|\mathbf{w}_h\|_{\mathbf{H}^1}^2 + \frac{1}{2\varepsilon} \|\overline{\mathbf{f}}\|_{\mathbf{H}^{-1}}^2.$$

By using Poincaré's inequality [17], we get

$$(4.13) \quad Re^{-1} C(\Omega) \|\mathbf{w}_h\|_{\mathbf{H}^1}^2 \leq Re^{-1} \|\nabla \mathbf{w}_h\|^2.$$

Inserting (4.12) with $\varepsilon := Re^{-1} C(\Omega)$ and (4.13) in (4.9), we obtain

$$(4.14) \quad \frac{1}{2} \frac{d}{dt} \|\mathbf{w}_h\|^2 + \frac{Re^{-1} C(\Omega)}{2} \|\mathbf{w}_h\|_{\mathbf{H}^1}^2 \leq \frac{Re}{2C(\Omega)} \|\overline{\mathbf{f}}\|_{\mathbf{H}^{-1}}^2.$$

By integrating (4.14) from 0 to t , we get (4.10).

By using the Cauchy–Schwarz and Young's inequalities, we have

$$(4.15) \quad (\overline{\mathbf{f}}, \mathbf{w}_h) \leq \frac{1}{2} \|\mathbf{w}_h\|^2 + \frac{1}{2} \|\overline{\mathbf{f}}\|^2.$$

By using (4.15) in (4.9), we obtain

$$\frac{1}{2} \frac{d}{dt} \|\mathbf{w}_h\|^2 - \frac{1}{2} \|\mathbf{w}_h\|^2 + Re^{-1} \|\nabla \mathbf{w}_h\|^2 \leq \frac{1}{2} \|\overline{\mathbf{f}}\|^2.$$

The positivity of the exponential implies

$$e^{-s} \left(\frac{d}{ds} \|\mathbf{w}_h\|^2 - \|\mathbf{w}_h\|^2 + 2Re^{-1} \|\nabla \mathbf{w}_h\|^2 \right) \leq e^{-s} \|\overline{\mathbf{f}}\|^2.$$

By integrating from 0 to $t < T$ and then multiplying by e^t , we get (4.11). \square

LEMMA 4.7 (Existence of (\mathbf{w}_h, q_h)). *There exists a solution (\mathbf{w}_h, q_h) of the semidiscrete approximation (4.7)–(4.8).*

Proof. Since $\dim(\mathbf{X}_h) < \infty$ and any possible solution (\mathbf{w}_h, q_h) satisfies the a priori stability estimates in Lemma 4.6, Schauder’s fixed point theorem [35] implies existence of a solution (\mathbf{w}_h, q_h) of the semidiscrete approximation (4.7)–(4.8). \square

REMARK 4.3 (Uniqueness of (\mathbf{w}_h, q_h)). The uniqueness of the solution (\mathbf{w}_h, q_h) of the semidiscrete approximation (4.7)–(4.8) would follow by using a general argument: Assume that there exist two distinct solutions $(\mathbf{w}_{1h}, q_{1h})$ and $(\mathbf{w}_{2h}, q_{2h})$ of (4.7)–(4.8); subtract (4.7)–(4.8) corresponding to the two solutions; use the coercivity of the operators in the error equation to obtain inequalities of the form $\|\mathbf{w}_{1h} - \mathbf{w}_{2h}\| \leq 0$ and $\|q_{1h} - q_{2h}\| \leq 0$.

This approach, however, fails for (4.7)–(4.8) because of the nonlinear term $C(\cdot, \cdot, \cdot)$ and the bounded AV operator $B(\cdot, \cdot, \cdot)$ is just monotone and *not* strongly monotone (see Lemma 4.1).

Note that when $\delta \rightarrow 0$, the bounded AV operator $B(\cdot, \cdot, \cdot)$ becomes strongly monotone (see Remark 4.1), which could, in turn, allow us to prove the uniqueness of (\mathbf{w}_h, q_h) .

5. An a priori error estimate. In order to prove an a priori error estimate for the semidiscrete approximation (\mathbf{w}_h, q_h) , we will assume that the solution to the continuous problem satisfies $\mathbf{w} \in L^4(0, T; \mathbf{W}^{1,\infty}(\Omega))$.

THEOREM 5.1. *Assume that the system (3.3)–(3.4) has a solution $(\mathbf{w}, q) \in \mathbf{X} \times Q$ which satisfies*

$$(5.1) \quad \mathbf{w} \in L^4(0, T; \mathbf{W}^{1,\infty}(\Omega)).$$

Then, there exist generic constants C and $C_1(\mathbf{w})$ independent of Re , such that the error $\mathbf{w} - \mathbf{w}_h$ satisfies for $T > 0$

$$(5.2) \quad \begin{aligned} & \|\mathbf{w} - \mathbf{w}_h\|_{L^\infty(0,T;L^2)}^2 + Re^{-1} \|\nabla(\mathbf{w} - \mathbf{w}_h)\|_{L^2(0,T;L^2)}^2 \\ & \leq C \exp(C_1(\mathbf{w})) \|(\mathbf{w} - \mathbf{w}_h)(\mathbf{x}, 0)\|^2 \\ & \quad + C \inf_{\tilde{\mathbf{w}} \in \mathbf{V}_h, \lambda_h \in Q_h} \mathcal{F}(\mathbf{w} - \tilde{\mathbf{w}}, q - \lambda_h, \delta, Re), \end{aligned}$$

where

$$\begin{aligned} & \mathcal{F}(\mathbf{w} - \tilde{\mathbf{w}}, q - \lambda_h, \delta, Re) \\ := & \|\mathbf{w} - \tilde{\mathbf{w}}\|_{L^\infty(0,T;L^2)}^2 + Re^{-1} \|\nabla(\mathbf{w} - \tilde{\mathbf{w}})\|_{L^2(0,T;L^2)}^2 \\ & + \exp(C_1(\mathbf{w})) \left[\|(\mathbf{w} - \tilde{\mathbf{w}})_t\|_{L^2(0,T;L^2)}^2 \right. \\ & + \|\mathbf{w} - \tilde{\mathbf{w}}\|_{L^2(0,T;L^2)}^2 + \|\nabla(\mathbf{w} - \tilde{\mathbf{w}})\|_{L^2(0,T;L^2)}^2 \\ & \left. + \|\nabla(\mathbf{w} - \tilde{\mathbf{w}})\|_{L^4(0,T;L^2)}^2 + \|q - \lambda_h\|_{L^2(0,T;L^2)}^2 \right]. \end{aligned}$$

Proof. First note that, for standard piecewise polynomial finite element spaces, it is known that the L^p -projection of a function in $L^p, p \geq 2$, is in L^p itself, and the L^2 -projection operator is stable in $L^p, 2 \leq p \leq \infty$ [9].

Let the error in \mathbf{w} be denoted by $\mathbf{e} := \mathbf{w} - \mathbf{w}_h$, and $\tilde{\mathbf{w}}$ denote a stable approximation of \mathbf{w} in \mathbf{V}_h , for example, the L^2 -projection under the conditions of [9].

The error \mathbf{e} is decomposed as

$$(5.3) \quad \mathbf{e} = (\mathbf{w} - \tilde{\mathbf{w}}) + (\tilde{\mathbf{w}} - \mathbf{w}_h) := \boldsymbol{\eta} + \boldsymbol{\phi}_h,$$

where $\boldsymbol{\eta} := \mathbf{w} - \tilde{\mathbf{w}}$ and $\boldsymbol{\phi}_h := \tilde{\mathbf{w}} - \mathbf{w}_h \in \mathbf{V}_h$. By subtracting (4.7) from (3.3) and using that $\mathbf{w} \in \mathbf{V}$, we obtain an error equation

$$(5.4) \quad (\mathbf{e}_t, \mathbf{v}_h) + A(\mathbf{e}, \mathbf{v}_h) + [B(\mathbf{w}, \mathbf{w}, \mathbf{v}_h) - B(\mathbf{w}_h, \mathbf{w}_h, \mathbf{v}_h)] \\ + [C(\mathbf{w}, \mathbf{w}, \mathbf{v}_h) - C(\mathbf{w}_h, \mathbf{w}_h, \mathbf{v}_h)] - (q - \lambda_h, \nabla \cdot \mathbf{v}_h) = 0 \quad \forall (\mathbf{v}_h, \lambda_h) \in \mathbf{V}_h \times Q_h.$$

By adding and subtracting terms and setting $\mathbf{v}_h := \boldsymbol{\phi}_h$, (5.4) becomes

$$(5.5) \quad (\boldsymbol{\phi}_{h,t}, \boldsymbol{\phi}_h) + A(\boldsymbol{\phi}_h, \boldsymbol{\phi}_h) + [B(\tilde{\mathbf{w}}, \tilde{\mathbf{w}}, \boldsymbol{\phi}_h) - B(\mathbf{w}_h, \mathbf{w}_h, \boldsymbol{\phi}_h)] \\ = -(\boldsymbol{\eta}_t, \boldsymbol{\phi}_h) - A(\boldsymbol{\eta}, \boldsymbol{\phi}_h) - [B(\mathbf{w}, \mathbf{w}, \boldsymbol{\phi}_h) - B(\tilde{\mathbf{w}}, \tilde{\mathbf{w}}, \boldsymbol{\phi}_h)] \\ - [C(\mathbf{w}, \mathbf{w}, \boldsymbol{\phi}_h) - C(\mathbf{w}_h, \mathbf{w}_h, \boldsymbol{\phi}_h)] + (q - \lambda_h, \nabla \cdot \boldsymbol{\phi}_h).$$

By using the monotonicity of $B(\cdot, \cdot, \cdot)$ (Lemma 4.1), we have

$$B(\tilde{\mathbf{w}}, \tilde{\mathbf{w}}, \boldsymbol{\phi}_h) - B(\mathbf{w}_h, \mathbf{w}_h, \boldsymbol{\phi}_h) \geq 0.$$

Thus, the left-hand side of (5.5) can be bounded from below as follows:

$$(5.6) \quad (\boldsymbol{\phi}_{h,t}, \boldsymbol{\phi}_h) + A(\boldsymbol{\phi}_h, \boldsymbol{\phi}_h) + [B(\tilde{\mathbf{w}}, \tilde{\mathbf{w}}, \boldsymbol{\phi}_h) - B(\mathbf{w}_h, \mathbf{w}_h, \boldsymbol{\phi}_h)] \geq \frac{1}{2} \frac{d}{dt} \|\boldsymbol{\phi}_h\|^2 + Re^{-1} \|\nabla \boldsymbol{\phi}_h\|^2.$$

We now start bounding from above the five terms on the right-hand side of (5.5). By using the Cauchy–Schwarz and Young’s inequalities, we obtain

$$(5.7) \quad -(\boldsymbol{\eta}_t, \boldsymbol{\phi}_h) \leq |(\boldsymbol{\eta}_t, \boldsymbol{\phi}_h)| \leq \frac{1}{2} \|\boldsymbol{\phi}_h\|^2 + \frac{1}{2} \|\boldsymbol{\eta}_t\|^2,$$

$$(5.8) \quad -A(\boldsymbol{\eta}, \boldsymbol{\phi}_h) \leq |A(\boldsymbol{\eta}, \boldsymbol{\phi}_h)| \leq Re^{-1} \varepsilon_1 \|\nabla \boldsymbol{\phi}_h\|^2 + \frac{Re^{-1}}{4\varepsilon_1} \|\nabla \boldsymbol{\eta}\|^2.$$

By adding and subtracting terms and using Lemma 4.2, we get

$$(5.9) \quad B(\mathbf{w}, \mathbf{w}, \boldsymbol{\phi}_h) - B(\tilde{\mathbf{w}}, \tilde{\mathbf{w}}, \boldsymbol{\phi}_h) \leq |B(\mathbf{w}, \mathbf{w}, \boldsymbol{\phi}_h) - B(\tilde{\mathbf{w}}, \tilde{\mathbf{w}}, \boldsymbol{\phi}_h)| \\ \leq |B(\mathbf{w}, \mathbf{w}, \boldsymbol{\phi}_h) - B(\tilde{\mathbf{w}}, \mathbf{w}, \boldsymbol{\phi}_h)| + |B(\tilde{\mathbf{w}}, \mathbf{w}, \boldsymbol{\phi}_h) - B(\tilde{\mathbf{w}}, \tilde{\mathbf{w}}, \boldsymbol{\phi}_h)| \\ \leq M_a \mu \delta^{\sigma+1} (\|\nabla \boldsymbol{\eta}\|_F \|\nabla \mathbf{w}\|_F, \|\nabla \boldsymbol{\phi}_h\|_F) \\ + M_a \mu \delta^{\sigma+1} (\|\nabla \tilde{\mathbf{w}}\|_F \|\nabla \boldsymbol{\eta}\|_F, \|\nabla \boldsymbol{\phi}_h\|_F).$$

Note that the stability estimates in [9] imply

$$(5.10) \quad \|\nabla \tilde{\mathbf{w}}\|_{L^\infty} \leq \tilde{C} \|\nabla \mathbf{w}\|_{L^\infty}.$$

Thus,

$$(5.11) \quad B(\mathbf{w}, \mathbf{w}, \boldsymbol{\phi}_h) - B(\tilde{\mathbf{w}}, \tilde{\mathbf{w}}, \boldsymbol{\phi}_h) \\ \leq M_a \mu \delta^{\sigma+1} \|\nabla \mathbf{w}\|_{L^\infty} \|\nabla \boldsymbol{\eta}\| \|\nabla \boldsymbol{\phi}_h\| + M_a \mu \delta^{\sigma+1} \tilde{C} \|\nabla \mathbf{w}\|_{L^\infty} \|\nabla \boldsymbol{\eta}\| \|\nabla \boldsymbol{\phi}_h\| \\ \leq C \left(M_a, \mu, \delta, \sigma, \tilde{C} \right) \frac{1}{4\varepsilon_2} \|\nabla \mathbf{w}\|_{L^\infty}^2 \|\nabla \boldsymbol{\eta}\|^2 + \varepsilon_2 \|\nabla \boldsymbol{\phi}_h\|^2.$$

By adding and subtracting terms, we obtain

$$\begin{aligned}
 & C(\mathbf{w}, \mathbf{w}, \phi_h) - C(\mathbf{w}_h, \mathbf{w}_h, \phi_h) \\
 & \leq |C(\mathbf{w}, \mathbf{w}, \phi_h) - C(\mathbf{w}, \mathbf{w}_h, \phi_h)| + |C(\mathbf{w}, \mathbf{w}_h, \phi_h) - C(\mathbf{w}_h, \mathbf{w}_h, \phi_h)| \\
 & = |C(\mathbf{w}, \boldsymbol{\eta} + \phi_h, \phi_h)| + |C(\boldsymbol{\eta} + \phi_h, \mathbf{w}_h, \phi_h)| \\
 & \quad \left(\text{since } C(\boldsymbol{\eta} + \phi_h, \tilde{\mathbf{w}} - \mathbf{w}_h, \phi_h) = C(\boldsymbol{\eta} + \phi_h, \phi_h, \phi_h) = 0 \right) \\
 & = |C(\mathbf{w}, \boldsymbol{\eta}, \phi_h)| + |C(\boldsymbol{\eta} + \phi_h, \tilde{\mathbf{w}}, \phi_h)| \\
 & = |(\mathbf{w} \cdot \nabla \boldsymbol{\eta}, \phi_h)| + |(\boldsymbol{\eta} \cdot \nabla \tilde{\mathbf{w}}, \phi_h)| + |(\phi_h \cdot \nabla \tilde{\mathbf{w}}, \phi_h)| \\
 & \leq \left(\frac{1}{2} \|\nabla \boldsymbol{\eta}\|^2 + \frac{1}{2} \|\mathbf{w}\|_{L^\infty}^2 \|\phi_h\|^2 \right) \\
 (5.12) \quad & + \left(\frac{1}{2} \|\boldsymbol{\eta}\|^2 + \frac{1}{2} \|\nabla \tilde{\mathbf{w}}\|_{L^\infty}^2 \|\phi_h\|^2 \right) + (\|\nabla \tilde{\mathbf{w}}\|_{L^\infty} \|\phi_h\|^2).
 \end{aligned}$$

By using the Cauchy–Schwarz and Young’s inequalities, we obtain

$$(5.13) \quad (q - \lambda_h, \nabla \cdot \phi_h) \leq |(q - \lambda_h, \nabla \cdot \phi_h)| \leq \varepsilon_3 \|\nabla \phi_h\|^2 + \frac{1}{4\varepsilon_3} \|q - \lambda_h\|^2.$$

Inserting estimates (5.6)–(5.13) into (5.5) and picking $\varepsilon_1 := 1/6$, $\varepsilon_2 := Re^{-1}/6$, $\varepsilon_3 := Re^{-1}/6$, we get

$$\begin{aligned}
 & \frac{1}{2} \frac{d}{dt} \|\phi_h\|^2 + \frac{Re^{-1}}{2} \|\nabla \phi_h\|^2 \\
 & \leq \left(\frac{1}{2} + \frac{6}{4} Re^{-1} + \frac{6}{4} Re C(M_a, \mu, \delta, \sigma, \tilde{C}) \|\nabla \mathbf{w}\|_{L^\infty}^2 \right) \|\nabla \boldsymbol{\eta}\|^2 \\
 & \quad + \frac{1}{2} \|\boldsymbol{\eta}_t\|^2 + \frac{1}{2} \|\boldsymbol{\eta}\|^2 + \frac{6}{4} Re \|q - \lambda_h\|^2 \\
 (5.14) \quad & + \left(\frac{1}{2} + \frac{1}{2} \|\mathbf{w}\|_{L^\infty}^2 + \frac{\tilde{C}^2}{2} \|\nabla \mathbf{w}\|_{L^\infty}^2 + \tilde{C} \|\nabla \mathbf{w}\|_{L^\infty} \right) \|\phi_h\|^2.
 \end{aligned}$$

In order to apply Gronwall’s lemma, we need

$$\begin{aligned}
 b(t) & := \left(\frac{1}{2} + \frac{1}{2} \|\mathbf{w}\|_{L^\infty}^2 + \frac{\tilde{C}^2}{2} \|\nabla \mathbf{w}\|_{L^\infty}^2 + \tilde{C} \|\nabla \mathbf{w}\|_{L^\infty} \right) \\
 (5.15) \quad & \in L^1(0, T).
 \end{aligned}$$

This follows immediately from the hypothesis ($\mathbf{w} \in L^4(0, T; \mathbf{W}^{1,\infty}(\Omega))$).

Hiding all constants in generic C ’s, Gronwall’s lemma now implies, for almost all $t \in [0, T]$, that

$$\begin{aligned}
 & \|\phi_h(\mathbf{x}, t)\|^2 + Re^{-1} \|\nabla \phi_h\|_{L^2(0,t;L^2)}^2 \\
 & \leq C \exp(\|b(t)\|_{L^1(0,t)}) \|\phi_h(\mathbf{x}, 0)\|^2 \\
 & \quad + C \exp(\|b(t)\|_{L^1(0,t)}) \left[\|\boldsymbol{\eta}_t\|_{L^2(0,t;L^2)}^2 + \|\boldsymbol{\eta}\|_{L^2(0,t;L^2)}^2 \right. \\
 & \quad + (1 + 3Re^{-1}) \|\nabla \boldsymbol{\eta}\|_{L^2(0,t;L^2)}^2 + C(M_a, \mu, \delta, \sigma, \tilde{C}) \int_0^t 3Re \|\nabla \mathbf{w}\|_{L^\infty}^2 \|\nabla \boldsymbol{\eta}\|^2 ds \\
 (5.16) \quad & \left. + 3Re \|q - \lambda_h\|^2 \right].
 \end{aligned}$$

By using the Cauchy–Schwarz inequality in $L^2(0, t), t \in [0, T]$, and the hypothesis ($\mathbf{w} \in L^4(0, T; \mathbf{W}^{1,\infty}(\Omega))$), we get

$$(5.17) \quad \int_0^t \|\nabla \mathbf{w}\|_{L^\infty}^2 \|\nabla \boldsymbol{\eta}\|^2 ds \leq \|\nabla \mathbf{w}\|_{L^4(0,t;L^\infty)}^2 \|\nabla \boldsymbol{\eta}\|_{L^4(0,t;L^2)}^2.$$

We apply now the essential supremum over $t \in [0, T]$ on both sides of inequality (5.16). By using the triangle inequality, the error estimate in the theorem now follows. \square

Remark 5.1. The error estimate in Theorem 5.1 is not uniform in Re , as the error estimate for the Smagorinsky model (Theorem 4.2 in [29]). The reason is that our bounded AV operator $B(\cdot, \cdot, \cdot)$ is just monotone (Lemma 4.1) and not strongly monotone as the Smagorinsky AV operator in [29].

Remark 5.2. The regularity of \mathbf{w} ($\mathbf{w} \in L^4(0, T; \mathbf{W}^{1,\infty}(\Omega))$) assumed in Theorem 5.1 is higher than the regularity of \mathbf{w} assumed in the error estimate for the Smagorinsky model in [29] ($\mathbf{w} \in L^2(0, T; \mathbf{W}^{1,\infty}(\Omega))$). Again, the reason is that our bounded AV operator $B(\cdot, \cdot, \cdot)$ is just monotone (Lemma 4.1), whereas the Smagorinsky AV operator is strongly monotone.

Remark 5.3. The multiplicative constant $C_1(\mathbf{w}) := \exp(\|b(t)\|_{L^1(0,T)})$ in the error estimate in Theorem 5.1 does not depend on Re .

COROLLARY 5.2. *Assuming $\mathbb{P}_k/\mathbb{P}_{k-1}$ velocity pressure discretization (i.e., choosing $l := k - 1$ in (3.6)), the order of convergence of*

$$(5.18) \quad \|\mathbf{w} - \mathbf{w}_h\|_{L^\infty(0,T;L^2)} \text{ is } O(h^k),$$

$$(5.19) \quad \|\mathbf{w} - \mathbf{w}_h\|_{L^2(0,T;H^1)} \text{ is } O(h^k).$$

Proof. The proof is an immediate consequence of Theorem 5.1 and the approximation properties of the interpolation (3.9)–(3.11). \square

6. Newton approximation scheme for the bounded AV model. In this section, we discuss the Newton approximation scheme as applied to the NSE with the bounded AV term (1.2). The analysis in this section is especially relevant to the numerical discretization of the vortex decay problem used in section 7.2.1. Note that approximate solutions $(\mathbf{u}_h, p_h) \in \mathbf{X}_h \times Q_h$ for the NSE with the bounded AV term (1.2) must satisfy a nonlinear system of ordinary differential equations. In this section, we derive the Newton approximation scheme for the semidiscrete variational problem, and note that, in practice, one would apply a Newton iteration at each time step for a fully discrete approximation.

It is a straightforward calculation to show that the Gâteaux derivative for the bounded AV term considered in this paper satisfies the following.

THEOREM 6.1. *Suppose that the function $a(\cdot) : \mathbb{R} \rightarrow \mathbb{R}$ is analytic, and define the (continuous) map $\mathcal{G}_1 : \mathbf{X}_h \rightarrow \mathbf{X}_h$ as*

$$\langle \mathcal{G}_1[\mathbf{u}], \mathbf{v} \rangle := (a(\|\nabla \mathbf{u}\|_F) \nabla \mathbf{u}, \nabla \mathbf{v}).$$

Then the Gâteaux derivative in the direction of \mathbf{u} evaluated at \mathbf{w} , denoted as $\mathcal{J}_\mathbf{u} \mathcal{G}_1[\mathbf{w}]$, is equal to

$$\langle \mathcal{J}_\mathbf{u} \mathcal{G}_1[\mathbf{w}], \mathbf{v} \rangle = (a(\|\nabla \mathbf{w}\|_F) \nabla \mathbf{w}, \nabla \mathbf{v}) + \left(\frac{a'(\|\nabla \mathbf{w}\|_F)}{\|\nabla \mathbf{w}\|_F} [\nabla \mathbf{u} : \nabla \mathbf{w}] \nabla \mathbf{u}, \nabla \mathbf{v} \right).$$

COROLLARY 6.2. *Suppose that the function $a(\cdot) : \mathbb{R} \rightarrow \mathbb{R}$ is analytic, and define the (continuous) map $\mathcal{G}_2 : \mathbf{X}_h \rightarrow \mathbf{X}_h$ as*

$$\langle \mathcal{G}_2[\mathbf{u}], \mathbf{v} \rangle := (a(\delta \|\nabla \mathbf{u}\|_F) \nabla \mathbf{u}, \nabla \mathbf{v}).$$

Then the Gâteaux derivative in the direction of \mathbf{u} evaluated at \mathbf{w} , denoted as $\mathcal{J}_{\mathbf{u}} \mathcal{G}_2[\mathbf{w}]$, is equal to

$$\langle \mathcal{J}_{\mathbf{u}} \mathcal{G}_2[\mathbf{w}], \mathbf{v} \rangle = (a(\|\delta \nabla \mathbf{u}\|_F) \nabla \mathbf{w}, \nabla \mathbf{v}) + \delta \left(\frac{a'(\|\delta \nabla \mathbf{u}\|_F)}{\|\nabla \mathbf{u}\|_F} [\nabla \mathbf{u} : \nabla \mathbf{w}] \nabla \mathbf{u}, \nabla \mathbf{v} \right).$$

We now consider the semidiscrete approximation $(\mathbf{u}_h, p_h) \in \mathbf{X}_h \times Q_h$, which solves the NSE with the bounded AV term (1.2). For notational simplicity, we drop the “ h ” subscripts from \mathbf{u} and p . Define the (continuous) map $\mathcal{G} : \mathbf{X}_h \times Q_h \rightarrow \mathbf{X}_h \times Q_h$ as

$$\begin{aligned} \langle \mathcal{G}[\mathbf{u}, p], (\mathbf{v}, q) \rangle &:= (\mathbf{u}_t, \mathbf{v}) + Re^{-1} (\nabla \mathbf{u}, \nabla \mathbf{v}) + \mu \delta^\sigma (a(\delta \|\nabla \mathbf{u}\|_F) \nabla \mathbf{u}, \nabla \mathbf{v}) \\ &\quad + (\mathbf{u} \cdot \nabla \mathbf{u}, \mathbf{v}) - (p, \nabla \cdot \mathbf{v}) + (q, \nabla \cdot \mathbf{u}) - (\mathbf{f}, \mathbf{v}). \end{aligned}$$

Therefore, we immediately have that the Gâteaux derivative of \mathcal{G} in the direction of (\mathbf{u}, p) , evaluated at (\mathbf{w}, r) , is given by

$$\begin{aligned} \langle \mathcal{J}_{(\mathbf{u}, p)} \mathcal{G}[\mathbf{w}, r], (\mathbf{v}, q) \rangle &= (\mathbf{w}_t, \mathbf{v}) + Re^{-1} (\nabla \mathbf{w}, \nabla \mathbf{v}) + \mu \delta^\sigma (a(\delta \|\nabla \mathbf{u}\|_F) \nabla \mathbf{w}, \nabla \mathbf{v}) \\ &\quad + \mu \delta^{\sigma+1} \left(\frac{a'(\delta \|\nabla \mathbf{u}\|_F)}{\|\nabla \mathbf{u}\|_F} [\nabla \mathbf{u} : \nabla \mathbf{w}] \nabla \mathbf{u}, \nabla \mathbf{v} \right) \\ &\quad + (\mathbf{u} \cdot \nabla \mathbf{w}, \mathbf{v}) + (\mathbf{w} \cdot \nabla \mathbf{u}, \mathbf{v}) \\ &\quad - (r, \nabla \cdot \mathbf{v}) + (q, \nabla \cdot \mathbf{w}) - (\mathbf{f}, \mathbf{v}). \end{aligned}$$

Now, substituting this formula for $\langle \mathcal{J}_{(\mathbf{u}, p)} \mathcal{G}[\mathbf{w}, r], (\mathbf{v}, q) \rangle$ into the Newton iteration system

$$\langle \mathcal{J}_{(\mathbf{u}^{(n-1)}, p^{(n-1)})} \mathcal{G}[\mathbf{u}^{(n)} - \mathbf{u}^{(n-1)}, p^{(n)} - p^{(n-1)}], (\mathbf{v}, q) \rangle = - \langle \mathcal{G}[\mathbf{u}^{(n-1)}, p^{(n-1)}], (\mathbf{v}, q) \rangle,$$

we obtain the Newton iteration scheme

$$\begin{aligned} &(\mathbf{u}_t^{(n)}, \mathbf{v}) + Re^{-1} (\nabla \mathbf{u}^{(n)}, \nabla \mathbf{v}) + \mu \delta^\sigma (a(\delta \|\nabla \mathbf{u}^{(n-1)}\|_F) \nabla \mathbf{u}^{(n)}, \nabla \mathbf{v}) \\ (6.1) \quad &+ \mu \delta^{\sigma+1} \left(\frac{a'(\delta \|\nabla \mathbf{u}^{(n-1)}\|_F)}{\|\nabla \mathbf{u}^{(n-1)}\|_F} [\nabla \mathbf{u}^{(n-1)} : \nabla \mathbf{u}^{(n)}] \nabla \mathbf{u}^{(n-1)}, \nabla \mathbf{v} \right) \\ &+ (\mathbf{u}^{(n-1)} \cdot \nabla \mathbf{u}^{(n)}, \mathbf{v}) + (\mathbf{u}^{(n)} \cdot \nabla \mathbf{u}^{(n-1)}, \mathbf{v}) - (p^{(n)}, \nabla \cdot \mathbf{v}) + (q, \nabla \cdot \mathbf{u}^{(n)}) \\ &= (\mathbf{f}, \mathbf{v}) + \mu \delta^{\sigma+1} (a'(\delta \|\nabla \mathbf{u}^{(n-1)}\|_F) \|\nabla \mathbf{u}^{(n-1)}\|_F \nabla \mathbf{u}^{(n-1)}, \nabla \mathbf{v}) \\ &+ (\mathbf{u}^{(n-1)} \cdot \nabla \mathbf{u}^{(n-1)}, \mathbf{v}) \end{aligned}$$

$\forall (\mathbf{v}, q) \in \mathbf{X}_h \times Q_h$.

Remark 6.1. Given an initial $(\mathbf{u}^{(0)}, p^{(0)}) \in \mathbf{X}_h \times Q_h$, the existence of a solution $(\mathbf{u}^{(n)}, p^{(n)}) \in \mathbf{X}_h \times Q_h \forall n = 1, 2, \dots$ to (6.1) follows by using the same arguments as in section 4 (Lemmas 4.6 and 4.7). Since the system (6.1), however, is linear, we can easily prove (by using the properties of $a(\cdot)$) that the solution $(\mathbf{u}^{(n)}, p^{(n)})$ is also unique.

7. Numerical results. In this section, we present numerical results that illustrate the benefits of the bounded AV model (2.12)–(2.14). We begin with a numerical simulation of turbulent flow in a 3D square duct, comparing the bounded AV model and Smagorinsky model with a direct numerical simulation (DNS) of the flow (section 7.1). This is followed with a careful mesh-refinement study that supports the theoretical error estimates shown above (section 7.2).

FIG. 7.1. Computational domain for the turbulent flow in a 3D square duct.

7.1. Turbulent flow in a 3D square duct. To demonstrate the improvement of the bounded AV model over the Smagorinsky model for a wall-bounded flow, we consider the numerical simulation of a turbulent flow in a 3D square duct. This test problem is often employed in the validation of LES models, e.g., [18, 24, 25, 37]. For our demonstration, we use the same parameters used in [24, 25] for their DNS simulation.

We performed a posteriori testing of the LES models, comparing coarser discretizations of the bounded AV model and the Smagorinsky model to a DNS in the *same geometry*, with the *same level of discretization*, and the *same Reynolds number* (based on the bulk velocity) as in [24]. In particular, we used the same geometry, illustrated in Figure 7.1, where $\Omega = (-D/2, D/2) \times (-D/2, D/2) \times (0, L) \subset \mathbb{R}^3$, with $D = 1$ and $L = 6.4$. The grid point distributions in the x - and y -directions also follow [24]:

$$(7.1) \quad x_j = -\frac{1}{2} + \frac{1}{2}(b-1) \left[\frac{a^{2j/N_x} - 1}{a^{(2j/N_x - 1)} + 1} \right], \quad j = 0, 1, \dots, N_x - 1,$$

where $a = \frac{b+1}{b-1}$, N_x is the number of grid points in the x -direction, and $b = 1.1$ is a stretching parameter. We use a similar distribution for the y -direction. In the z -direction, we used a uniform grid point distribution

$$(7.2) \quad z_j = j \frac{L}{N_z - 1}, \quad j = 0, 1, \dots, N_z,$$

where N_z is number of grid points in the z -direction.

- For the benchmark DNS, we used similar discretization levels as used for the DNS in [24]:

$$N_x \times N_y \times N_z = 97 \times 97 \times 145$$

yielding 3.6 million degrees of freedom. This is about 50% finer in the z -direction.

- For the two LES simulations (bounded AV and Smagorinsky), we used the coarser discretization:

$$N_x \times N_y \times N_z = 25 \times 25 \times 97$$

yielding 0.14 million degrees of freedom.

Note that the LES runs were performed on meshes that employed roughly 4 times fewer nodes in the wall normal directions. This is typical in the a posteriori testing of LES models (e.g., LES of a turbulent channel flow [26]).

For all three numerical simulations (DNS, Smagorinsky, and bounded AV models), we used the following boundary conditions: no-slip ($\mathbf{u} = 0$) on the walls, stress-free, “do-nothing” boundary conditions at the outlet ($z = 6.4$)

$$(7.3) \quad (-p\mathbf{I} + 2 Re^{-1} \nabla^s \mathbf{u}) \cdot \mathbf{n} = 0,$$

and Dirichlet boundary conditions at the inlet. The inflow profile is

$$(7.4) \quad u(x, y, z = 0, t) = 0,$$

$$(7.5) \quad v(x, y, z = 0, t) = 0,$$

$$(7.6) \quad w(x, y, z = 0, t) = C_1 \frac{2}{\pi} \arctan \left[C_2 \left(\frac{1}{2} - \max\{|x|, |y|\} \right) \right],$$

where $C_2 = 100$ and $C_1 = \frac{\pi}{2 \arctan(C_2/2)} \approx 1.01$. The constant C_2 controls the steepness of the inflow profile near the walls, whereas the constant C_1 was chosen to yield a centerline streamwise velocity of 1.

The initial conditions were obtained from the inflow conditions $\mathbf{u}(x, y, z, 0) = \mathbf{u}(x, y, z = 0, t)$ for $(x, y, z) \subset \Omega$. The initial pressure was obtained by substituting the initial conditions into the momentum equations, integrating in z , and using (7.3) at $(x = 0, y = 0)$ to determine the integration constant.

The inflow velocity (7.4)–(7.6) was used to compute the bulk velocity u_B :

$$(7.7) \quad u_B = \frac{1}{\text{area}(\Omega_{cs})} \int_{\Omega_{cs}} u(x, y, z, t) dV,$$

where Ω_{cs} is the cross-section of the computational domain at the inlet. Formulas (7.4)–(7.6) and the values of C_1 and C_2 immediately yield the bulk velocity

$$(7.8) \quad u_B \approx 0.9.$$

We define the Reynolds number based on the bulk velocity in the usual way [24, 25]:

$$(7.9) \quad Re_B := \frac{u_B D}{\nu},$$

where ν is the kinematic viscosity. Thus, in order to achieve the Re_B used in [24]

$$(7.10) \quad Re_B = 10,320,$$

we used the following value for the kinematic viscosity ν :

$$(7.11) \quad \nu = \frac{u_B D}{Re_B} \approx 8.7207 \times 10^{-5}.$$

A time dependent forcing function in the z -direction

$$f_z(x, y, z = 0, t) = \begin{cases} 0.1 \sin(20t) \cos(10\pi x) \cos(10\pi y), & 0 < t < 1, \\ 0, & t \geq 1, \end{cases}$$

was used to induce the flow transition to turbulence.

The flow was integrated in time up to the final time $T = 14.5$ with a time step $\Delta T = 0.02$, which is similar to that used in [24]. Since the centerline streamwise velocity has magnitude 1, this allows a particle in the center to travel the entire length of the 3D square duct 2.25 times. Each DNS run was performed on 48 nodes of SystemX (www.arc.vt.edu) for two CPU weeks. The high computational cost associated with the DNS runs has restricted the final time to the value presented above. The numerical results presented below represent instantaneous results and not time and spatial averages. We emphasize, however, that the qualitative behavior of the numerical simulations is representative for the entire duration of the numerical simulation and not only for the particular instantaneous time frame that we present.

The numerical simulations in this section have been carried out with the ViTLES (see Appendix A for a detailed description of the algorithm and computational implementation). We used a small penalty parameter $\varepsilon = 10^{-4}$ in the penalty method to compute the pressure. The nonlinear system at each time step was solved with a Newton iteration up to a Euclidean norm of the residual vector less than 10^{-8} .

For the Smagorinsky model, we chose a filter radius $\delta = 0.01$ and the Smagorinsky constant $c_s = 0.17$, which is a popular choice in the literature. For the bounded AV model, we chose the parameters $\mu \sim 0.4$ and $\sigma = 1$. The function $a(\cdot)$ was chosen to resemble that in Figure 1.1:

$$(7.12) \quad a(\delta \|\nabla^s \mathbf{u}\|_F) := -0.02 + \frac{1}{1 + 49 e^{-5.7\delta \|\nabla^s \mathbf{u}\|_F}}.$$

Remark 7.1. This is exactly the function that was chosen in [28] for a *completely different setting* (a rotating pulse for the convection-diffusion equation). Therefore, this choice is *not optimal* for our present setting (the 3D square duct turbulent flow). Further testing is needed to find the optimal values. We thus emphasize that we compare the Smagorinsky model with tuned parameters with the bounded AV model with nonoptimized parameters.

Figure 7.2 presents numerical approximations for the pressure (p) for the following cases (with the given pressure ranges): (i) the DNS ($p \in [-.003, .124]$); (ii) the Smagorinsky model (1.1) ($p \in [-.018, .710]$); and (iii) the bounded AV model (1.2) ($p \in [-.005, .160]$). Note that the pressure loss for the bounded AV model is more consistent with the DNS. The larger pressure loss observed in the Smagorinsky model is indicative of the overly diffusive nature of this model. A larger pressure drop is required to overcome the diffusion and maintain the inflow velocity.

Remark 7.2. The results obtained in the numerical simulation of turbulent flow in a 3D square duct are encouraging. They do, however, represent just a first step in a thorough validation of the bounded AV model. Testing in other settings, such as turbulent channel flow simulations [4], is needed. Furthermore, improved versions of the Smagorinsky model (such as the use of the van Driest damping (2.9)) should be used in the comparison with the bounded AV model. In this case, however, optimized parameters in the bounded AV model (such as the function $a(\cdot)$) should be employed to allow for a fair comparison with the optimized version of the Smagorinsky model.

7.2. Mesh-refinement study. In this section, we present a careful mesh-refinement study supporting the error estimates in Theorem 5.1 for the bounded AV model (1.2).

7.2.1. The 2D vortex decay problem. In this section, we present numerical results for the bounded AV model applied to the vortex decay problem of Chorin [7, 49]. A similar study for the vortex decay problem using the Smagorinsky model was

FIG. 7.2. 3D square duct flow, vertical cross-section. The pressure distribution (top to bottom): DNS (first), Smagorinsky (second), and bounded AV (third).

presented in [29]. For the vortex decay problem, we define the domain $\Omega = (0, 1)^2 \subset \mathbb{R}^2$ and specify

$$\begin{aligned}
 (7.13) \quad u_1 &:= -\cos(n\pi x) \sin(n\pi y) \exp(-2n^2\pi^2 t/\tau), \\
 u_2 &:= \sin(n\pi x) \cos(n\pi y) \exp(-2n^2\pi^2 t/\tau), \\
 p &:= -\frac{1}{4}(\cos(2n\pi x) + \cos(2n\pi y)) \exp(-4n^2\pi^2 t/\tau).
 \end{aligned}$$

Note that for $\tau := Re^{-1}$, the set (u_1, u_2, p) solves the time-dependent NSE with the appropriate (time-dependent, Dirichlet) boundary conditions. For our purposes, we take (7.13) as the solution to (2.12)–(2.14) and illustrate two points: that the spatial semidiscretization error estimates (5.18)–(5.19) in Corollary 5.2 are satisfied and that the estimates are bounded uniformly with respect to the Reynolds number.

TABLE 7.1
Finite element convergence estimates for the vortex decay problem.

h	$\ \mathbf{w} - \mathbf{w}_h\ _{L^\infty(0,T;L^2)}$	rate	$\ \mathbf{w} - \mathbf{w}_h\ _{L^2(0,T;L^2)}$	rate	$\ \mathbf{w} - \mathbf{w}_h\ _{L^2(0,T;H^1)}$	rate
1/8	$4.020927 \cdot 10^{-1}$		$4.936365 \cdot 10^{-1}$		$1.560773 \cdot 10^1$	
1/16	$3.103567 \cdot 10^{-2}$	3.70	$3.952673 \cdot 10^{-2}$	3.64	$2.886625 \cdot 10^0$	2.43
1/24	$5.534371 \cdot 10^{-3}$	4.25	$7.594030 \cdot 10^{-3}$	4.07	$1.096755 \cdot 10^0$	2.39
1/32	$1.822532 \cdot 10^{-3}$	3.86	$2.418206 \cdot 10^{-3}$	3.98	$5.182457 \cdot 10^{-1}$	2.61
1/40	$7.778230 \cdot 10^{-4}$	3.82	$1.018835 \cdot 10^{-3}$	3.87	$2.870239 \cdot 10^{-1}$	2.65
1/48	$4.227375 \cdot 10^{-4}$	3.34	$5.138958 \cdot 10^{-4}$	3.75	$1.763596 \cdot 10^{-1}$	2.68
1/56	$2.567581 \cdot 10^{-4}$	3.26	$2.907396 \cdot 10^{-4}$	3.70	$1.166515 \cdot 10^{-1}$	2.68
1/64	$1.645877 \cdot 10^{-4}$	3.33	$1.779283 \cdot 10^{-4}$	3.68	$8.151033 \cdot 10^{-2}$	2.68
1/72	$1.102856 \cdot 10^{-4}$	3.40	$1.154125 \cdot 10^{-4}$	3.68	$5.940966 \cdot 10^{-2}$	2.69

Accordingly, we specify the following parameters:

$$\begin{aligned}
 Re &:= 10^{10}, \\
 \tau &:= 1000, \\
 \text{final time } T &:= 2, \\
 \text{filter radius } \delta &:= 0.1, \\
 \mu = c_s^2 &:= 0.17^2, \\
 \Delta t &:= 0.01.
 \end{aligned}$$

For our calculations, we assume $n = 3$, i.e., a 3×3 array of vortices and study the finite element convergence rates for fixed $\delta := 0.1$ as $h \rightarrow 0$. For the spatial discretization, we take the Taylor–Hood finite element pair and implement the Newton iteration scheme as described in section 6. For the temporal discretization, we use the Crank–Nicolson scheme. As indicated in Table 7.1, the spatial semidiscretization errors are of order 3 in the spatial L^2 norm and 2 in the spatial H^1 norm. Thus, for this test problem, we obtain superconvergence in both norms (see Corollary 5.2). Also, note that these estimates are *independent* of the selected Reynolds number, as we have taken a relatively high value for Re and a relatively high value for Δt .

Appendix A. The Virginia Tech large eddy simulator (ViTLES). In this paper, we have used *ViTLES*, a *parallel, finite element* computational platform for the numerical validation of CFD and LES models. In what follows, we briefly describe the algorithm around which ViTLES is developed. More details can be found at <http://icam.vt.edu/ViTLES>.

For spatial discretization, the computational domain is decomposed in a collection of nonoverlapping triangles (in 2D) or tetrahedra (in 3D). We employ the traditional Taylor–Hood finite element pair (continuous quadratic velocities and continuous linear pressures), which satisfies the discrete inf-sup (LBB_h) condition [6].

For time discretization, we employ the second-order accurate, unconditionally stable Crank–Nicolson scheme [10].

We also employ the penalty method [10, 22, 42], in which the incompressibility constraint $\nabla \cdot \mathbf{u} = 0$ in the NSE (2.1)–(2.3) is relaxed by setting

$$(A.1) \quad \varepsilon p_\varepsilon + \nabla \cdot \mathbf{u}_\varepsilon = 0,$$

where ε is a small parameter. In our computations, we used $\varepsilon = 0.0001$. As $\varepsilon \rightarrow 0$, the solution of the penalized problem converges to that of the unpenalized problem [22].

We employ a Newton iteration scheme for solving the nonlinear system at each time step. The scheme implemented in ViTLES explicitly constructs finite difference approximations of the Jacobians rather than calculating the actual Jacobian matrix.

ViTLES is written on top of PETSc (the portable, extensible toolkit for scientific computing) developed at Argonne National Laboratory [3]. ViTLES makes use of the message passing interface (MPI), the LINPACK library, and the basic linear algebra subprograms (BLAS) library. We have also used ADIC, the automatic differentiation tool [23], to compute Jacobians. Tecplot (<http://www.tecplot.com/>) was used to visualize the numerical results.

Acknowledgments. We thank the two anonymous referees whose comments and suggestions have greatly improved the paper. We also acknowledge computer time on System X (www.arc.vt.edu/arc/SystemX) and a cluster obtained through the NSF scientific computing research environments for the mathematical sciences (SCREMS) program (NSF grant DMS-0322852).

SUPERCONVERGENCE OF SOME PROJECTION APPROXIMATIONS FOR WEAKLY SINGULAR INTEGRAL EQUATIONS USING GENERAL GRIDS*

ANDREY AMOSOV[†], MARIO AHUES[‡], AND ALAIN LARGILLIER[‡]

Abstract. This paper deals with superconvergence phenomena in general grids when projection-based approximations are used for solving Fredholm integral equations of the second kind with weakly singular kernels. Four variants of the Galerkin method are considered. They are the classical Galerkin method, the iterated Galerkin method, the Kantorovich method, and the iterated Kantorovich method. It is proved that the iterated Kantorovich approximation exhibits the best superconvergence rate if the right-hand side of the integral equation is nonsmooth. All error estimates are derived for an arbitrary grid without any uniformity or quasi-uniformity condition on it, and are formulated in terms of the data without any additional assumption on the solution. Numerical examples concern the equation governing transfer of photons in stellar atmospheres. The numerical results illustrate the fact that the error estimates proposed in the different theorems are quite sharp, and confirm the superiority of the iterated Kantorovich scheme.

Key words. projections, grids, superconvergence, weak singularity

AMS subject classifications. 65R20, 65B99, 65J10

DOI. 10.1137/070685464

1. Introduction. It is well known that some variants of the Galerkin approximation can be superconvergent in the sense that convergence to the solution is faster than the convergence to it of its own projection.

We recall that in a Hilbert space H , if π^h is a family of orthogonal projections pointwise convergent to the identity operator I and if T is a compact operator for which 1 is not an eigenvalue, then the operator $T^h := \pi^h T$ gives the Galerkin approximation φ^h to $\varphi = T\varphi + f$ as $\varphi^h = (I - T^h)^{-1} \pi^h f$ for all $f \in H$, where the inverses $(I - T^h)^{-1}$ exist and are uniformly bounded in the operator norm; i.e., $\|(I - T^h)^{-1}\| \leq c$ for some constant c independent of h , for sufficiently small h . The identity

$$\varphi^h - \varphi = (I - T^h)^{-1} \pi^h (I - T)\varphi - (I - T^h)^{-1} (I - T^h)\varphi = (I - T^h)^{-1} (\pi^h - I)\varphi$$

shows that

$$\|(I - \pi^h)\varphi\| \leq \|\varphi - \varphi^h\| \leq c \|(I - \pi^h)\varphi\|,$$

so the Galerkin approximation φ^h converges to the solution φ as slow as the projection of φ onto the range of π^h converges to φ .

For integral equations the phenomenon of superconvergence of some variants of the Galerkin approximation has been studied since 1976 (cf. [16], [17], [18], [11], [12], [4], [19], [6], [23], [20], [15], [24], [9], and references therein).

In this paper we study superconvergence results on three other projection methods for solving weakly singular integral equations of the form

$$(1) \quad \varphi(\tau) = \varpi_0 \int_0^{\tau_*} \mathcal{E}(|\tau - \tau'|)\varphi(\tau') d\tau' + f(\tau), \quad \tau \in J :=]0, \tau_*[,$$

where φ is the unknown.

The phenomenon of superconvergence is studied here following the properties of the Banach space X , which may be $L^p(J)$, $C(\overline{J})$, $BV(\overline{J})$, or $W^{1,p}(J)$, in which the equation is settled. In all the spaces, the discretization procedure is the weakest one we can conceive in the Lebesgue space L^1 , namely, projection techniques based on piecewise constant functions. We are particularly interested in the case in which ϖ_0 is close to 1 from below, and τ_* is much bigger than 1. For instance, in Astrophysics, typical values may be $\varpi_0 = 0.9999$ and $\tau_* = 10^6$.

2. Description of the methods and formulation of some results. We assume that the kernel \mathcal{E} is a positive decreasing function defined on $\mathbb{R}^+ :=]0, +\infty[$, such that $\mathcal{E}(0^+) = +\infty$ (that is why (1) is called singular), $\mathcal{E} \in L^r(\mathbb{R})$ for all $r \in [1, \infty[$ (that is why (1) is only weakly singular), and

$$(2) \quad \|\mathcal{E}\|_{L^1(\mathbb{R}^+)} \leq 1/2.$$

We suppose that ϖ_0 is a fixed real number in $]0, 1[$, and that $f \in L^p(J)$ for some $p \in [1, \infty]$.

The heat transfer integral equation

$$(3) \quad \varphi(\tau) = \frac{\varpi_0}{2} \int_0^{\tau_*} E_1(|\tau - \tau'|)\varphi(\tau') d\tau' + f(\tau), \quad \tau \in J,$$

widely used for mathematical modelling in Astrophysics (cf. [3], [5], [10], and [22]), is an important example of (1), where

$$E_1(\tau) := \int_0^1 \mu^{-1} e^{-\tau/\mu} d\mu, \quad \tau > 0,$$

is the exponential-integral function of order 1. Usually, in Astrophysics, τ_* , called the optical depth, is a very large number, and ϖ_0 , called the albedo, may be very close to 1. So it is important to find accurate estimates of the error which are independent of τ_* but depend on ϖ_0 in an explicit form.

Let us define the integral operator

$$(\Lambda\varphi)(\tau) := \int_0^{\tau_*} \mathcal{E}(|\tau - \tau'|)\varphi(\tau') d\tau', \quad \varphi \in X, \quad \tau \in [0, \tau_*],$$

where $X \subseteq L^1(J)$ is a suitable Banach space, and rewrite (1) as follows.

For a given $f \in X$, find $\varphi \in X$ such that

$$(4) \quad \varphi = \varpi_0 \Lambda\varphi + f.$$

Different choices of X will be made precise throughout the paper.

For integers p and q such that $p \leq q$, we denote by $\llbracket p, q \rrbracket$ the set of all integers j such that $p \leq j \leq q$.

In order to compute approximate solutions to (4), we consider the following numerical process:

Let $J^h := \{\tau_j : j \in \llbracket 0, n \rrbracket\}$ be a finite set of $n + 1$ points in $[0, \tau_*]$ such that

$$0 = \tau_0 < \tau_1 < \dots < \tau_{n-1} < \tau_n = \tau_*.$$

Set

$$(5) \quad h_i := \tau_i - \tau_{i-1}, \quad i \in \llbracket 1, n \rrbracket, \quad h_{\max} := \max_{i \in \llbracket 1, n \rrbracket} h_i, \quad h := (h_1, h_2, \dots, h_n),$$

$$(6) \quad J_{i-1/2} := [\tau_{i-1}, \tau_i[, \quad i \in \llbracket 1, n \rrbracket.$$

Let $S_{1/2}^h(J)$ be the following space of piecewise constant functions:

$$S_{1/2}^h(J) := \{f : f(\tau) = f_{i-1/2} \quad \text{for all } i \in \llbracket 1, n \rrbracket, \text{ and all } \tau \in J_{i-1/2}\}.$$

Let $\pi^h : L^p(J) \rightarrow L^p(J)$ be the bounded projection defined, for all $\varphi \in L^p(J)$, as follows:

For each $i \in \llbracket 1, n \rrbracket$ and all $\tau \in J_{i-1/2}$,

$$(7) \quad (\pi^h \varphi)(\tau) := \frac{1}{h_i} \int_{\tau_{i-1}}^{\tau_i} \varphi(\tau') d\tau'.$$

It is clear that the range of π^h is equal to $S_{1/2}^h(J)$.

We shall deal with four different projection approximations based on π^h :

The first one is the well-known classical Galerkin approximation φ^h which solves

$$(8) \quad \varphi^h = \varpi_0 \pi^h \Lambda \varphi^h + \pi^h f.$$

We observe that $\varphi^h \in S_{1/2}^h(J)$. Since $\pi^h \Lambda$ is a finite rank operator, φ^h may be computed with the help of the solution of an auxiliary system of linear algebraic equations (cf. [2]). Moreover, in this particular case, the coefficient matrix of the linear system is self-adjoint and positive definite with respect to the inner product

$$\langle \varphi^h, \psi^h \rangle = \sum_{i=1}^n \varphi_{i-1/2}^h \psi_{i-1/2}^h h_i$$

defined in $S_{1/2}^h(J) \times S_{1/2}^h(J)$.

The second approximation is the iterated Galerkin approximation $\overline{\varphi}^h$ [21], also called Sloan approximation, which solves

$$(9) \quad \overline{\varphi}^h = \varpi_0 \Lambda \pi^h \overline{\varphi}^h + f.$$

$\overline{\varphi}^h$ may be computed in the following way: Apply π^h to (9) and note that $\pi^h \overline{\varphi}^h = \varphi^h$, the Galerkin approximation. Hence

$$\overline{\varphi}^h = \varpi_0 \Lambda \varphi^h + f.$$

It is well known (cf. [16], [19], [4], [6], [7], [23]) that the iterated Galerkin method has a higher order of convergence than the Galerkin method itself.

The third one, called Kantorovich approximation, is based on *Kantorovich regularization* (cf. [8]) of (4):

$$(10) \quad y = \varpi_0 \Lambda y + \Lambda f.$$

The Kantorovich approximation is defined to be the solution of

$$(11) \quad \tilde{\varphi}^h = \varpi_0 \pi^h \Lambda \tilde{\varphi}^h + f.$$

To solve (11), set $y := \Lambda \varphi$, $y^h := \pi^h \Lambda \tilde{\varphi}^h$ and note that

$$\varphi = \varpi_0 y + f, \quad \tilde{\varphi}^h = \varpi_0 y^h + f,$$

and that y solves (10) while y^h solves

$$y^h = \varpi_0 \pi^h \Lambda y^h + \pi^h \Lambda f.$$

So $y^h \in S_{1/2}^h(J)$ is the Galerkin approximation to (10).

This method was considered in [11], [12], [13], [15], [20]. Since it approximates $y = \Lambda \varphi$, this method is appropriate if $\Lambda \varphi$ is more smooth than φ .

The fourth approximation is the iterated Kantorovich approximation (cf. [20], [14]) defined to be the solution of

$$(12) \quad \hat{\varphi}^h = \varpi_0 \Lambda \pi^h \hat{\varphi}^h + f + \varpi_0 \Lambda (I - \pi^h) f.$$

As it is quoted in [20], to compute $\hat{\varphi}^h$ we may find the Sloan approximation \bar{y}^h to (10),

$$\bar{y}^h = \varpi_0 \Lambda \pi^h \bar{y}^h + \Lambda f,$$

and then use the fact that $\hat{\varphi}^h = \varpi_0 \bar{y}^h + f$.

Remark 1. Note that $\hat{\varphi}^h - \varphi = \varpi_0 (y^h - y)$ and $\tilde{\varphi}^h - \varphi = \varpi_0 (\bar{y}^h - y)$. So for estimating the errors of Kantorovich and iterated Kantorovich approximations, we may apply the estimates we have obtained for the error of Galerkin and Sloan approximations but to (10) with right-hand side Λf instead of f and with solution $y = \Lambda \varphi$ instead of φ .

Remark 2. We recall that the classical Galerkin approximation $\varphi^h \in S_{1/2}^h(J)$ is defined by reducing to zero the projection of the residual onto the finite dimensional approximating subspace $S_{1/2}^h(J)$, the range of π^h :

$$\pi^h (\varphi^h - \varpi_0 \pi^h \Lambda \varphi^h - f) = 0.$$

Another Galerkin-type approximation ψ^h can be built as the solution of

$$\psi^h = \varpi_0 \pi^h \Lambda \pi^h \psi^h + f.$$

In this case, f is kept as it is and no projection acts on it. Obviously, $\varphi^h = \pi^h \psi^h$, but in general, φ^h and ψ^h do not coincide. However, if f belongs to the range of π^h , i.e., if $\pi^h f = f$, then not only $\psi^h = \varphi^h$ but $\tilde{\varphi}^h = \varphi^h$ too, and hence the iterated Galerkin approximation and the iterated Kantorovich approximation coincide: $\hat{\varphi}^h = \tilde{\varphi}^h$.

Throughout this paper, p , q , and s are real numbers in $[1, \infty]$ such that $p \leq q$, and

$$(13) \quad 1/s = 1 - 1/p + 1/q.$$

Note that $s \in [1, \infty]$, $s = 1$ if $p = q$ and that $s = \infty$ means that $p = 1$ and $q = \infty$.

Let

$$\gamma_0 := \frac{1}{1 - \varpi_0}, \quad \gamma_1 := \frac{\varpi_0}{1 - \varpi_0}, \quad M_p := 2^{1/p} \|\mathcal{E}\|_{L^p(\mathbb{R}^+)}.$$

Let $C^0(\overline{J})$ denote the space of all continuous functions on \overline{J} , $BV(\overline{J})$ the space of functions with bounded variation, and $W^{1,p}(J)$ the classical Sobolev space, with respective norms

$$\begin{aligned} \|f\|_{C^0} &:= \max_{\tau \in \overline{J}} |f(\tau)|, & \|f\|_{BV} &:= \operatorname{var} f + \gamma_1 \sup_{\tau \in \overline{J}} |f(\tau)|, \\ \|f\|_{W^{1,p}} &:= \|Df\|_{L^p} + 2^{1-1/p} M_p \gamma_1 \|f\|_{C^0}. \end{aligned}$$

Here and later $Df = f'$.

Let us formulate the error estimates which are proved in this paper in the case of the heat transfer equation (3).

These errors will be denoted by

$$\varepsilon^h := \varphi^h - \varphi, \quad \overline{\varepsilon}^h := \overline{\varphi}^h - \varphi, \quad \tilde{\varepsilon}^h := \tilde{\varphi}^h - \varphi, \quad \widehat{\varepsilon}^h := \widehat{\varphi}^h - \varphi.$$

Remark 3. All error estimates are derived for an arbitrary grid without any uniformity or quasi-uniformity condition on it, and are formulated in the terms of the data without any additional assumption on the solution. All the error bounds are independent of τ_* and depend on ϖ_0 through γ_0 and γ_1 .

THEOREM 1. *Assume that $\mathcal{E} = \frac{1}{2}E_1$, $f \in L^p(J)$, and $1 \leq p \leq q \leq \infty$. The following estimates hold as $h_{\max} \rightarrow 0$:*

$$\begin{aligned} \|\pi^h \varepsilon^h\|_{L^q} &\leq \gamma_0 \gamma_1 h_{\max}^{1-1/p+1/q} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{L^p} \quad \text{for } s < \infty, \\ \|\overline{\varepsilon}^h\|_{L^q} &\leq \gamma_0 \gamma_1 h_{\max}^{1-1/p+1/q} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{L^p} \quad \text{for } s < \infty, \\ \|\pi^h \tilde{\varepsilon}^h\|_{L^q} &\leq \gamma_1^2 h_{\max}^{2-1/p+1/q} \ln^2 \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{L^p}, \\ \|\widehat{\varepsilon}^h\|_{L^q} &\leq \gamma_0 \gamma_1 h_{\max}^{1-1/p+1/q} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{L^p} \quad \text{for } s < \infty, \\ \|\widehat{\varepsilon}^h\|_{L^q} &\leq \gamma_1^2 h_{\max}^{2-1/p+1/q} \ln^2 \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{L^p}. \end{aligned}$$

As a corollary

$$\begin{aligned} \|\pi^h \varepsilon^h\|_{L^p} &\leq \gamma_0 \gamma_1 h_{\max} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{L^p}, \\ \|\overline{\varepsilon}^h\|_{L^p} &\leq \gamma_0 \gamma_1 h_{\max} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{L^p}, \\ \|\pi^h \tilde{\varepsilon}^h\|_{L^p} &\leq \gamma_1^2 h_{\max}^2 \ln^2 \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{L^p}, \\ \|\widehat{\varepsilon}^h\|_{L^p} &\leq \gamma_0 \gamma_1 h_{\max} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{L^p}, \\ \|\widehat{\varepsilon}^h\|_{L^p} &\leq \gamma_1^2 h_{\max}^2 \ln^2 \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{L^p}. \end{aligned}$$

As we see, when $f \in L^p(J)$, then the iterated Galerkin method and the Kantorovich method have the same accuracy. The iterated Kantorovich method is appreciably more accurate.

THEOREM 2. Assume that $\mathcal{E} = \frac{1}{2}E_1$, $f \in BV(\overline{J})$, and $1 \leq q \leq \infty$. The following estimates hold as $h_{\max} \rightarrow 0$:

$$\begin{aligned} \|\pi^h \varepsilon^h\|_{L^q} &\leq \gamma_0 \gamma_1 h_{\max}^{1+1/q} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{BV}, \\ \|\varepsilon^h\|_{L^q} &\leq \gamma_0^2 h_{\max}^{1/q} \|f\|_{BV}, \\ \|\overline{\varepsilon}^h\|_{L^q} &\leq \gamma_0 \gamma_1 h_{\max}^{1+1/q} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{BV}, \\ \|\pi^h \widehat{\varepsilon}^h\|_{L^q} &\leq \gamma_1^2 h_{\max}^2 \ln \frac{1}{h_{\max}} (1 + o(1)) \|\Lambda f\|_{W^{1,q}} \quad \text{for } q < \infty, \\ \|\widehat{\varepsilon}^h\|_{L^q} &\leq \gamma_0 \gamma_1 h_{\max} \|\Lambda f\|_{W^{1,q}} \quad \text{for } q < \infty, \\ \|\widehat{\varepsilon}^h\|_{L^q} &\leq \gamma_1^2 h_{\max}^2 \ln \frac{1}{h_{\max}} (1 + o(1)) \|\Lambda f\|_{W^{1,q}} \quad \text{for } q < \infty, \end{aligned}$$

The following estimates hold too:

$$\begin{aligned} \|\pi^h \varepsilon^h\|_{BV} &\leq 3\gamma_0 \gamma_1 h_{\max} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{BV}, \\ \|\overline{\varepsilon}^h\|_{W^{1,1}} &\leq 3\gamma_0 \gamma_1 h_{\max} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{BV}, \\ \|\pi^h \widehat{\varepsilon}^h\|_{BV} &\leq 3\gamma_0 \gamma_1 h_{\max} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{BV}, \\ \|\widehat{\varepsilon}^h\|_{W^{1,1}} &\leq 3\gamma_0 \gamma_1 h_{\max} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{BV}. \end{aligned}$$

Theorem 2 shows that, when $f \in BV(\overline{J})$, then the iterated Galerkin method is more accurate than the Kantorovich method. The iterated Kantorovich method keeps an advantage.

THEOREM 3. Assume that $\mathcal{E} = \frac{1}{2}E_1$, $f \in W^{1,p}(J)$ for some $p \in [1, \infty[$, and $p \leq q \leq \infty$. The following estimates hold as $h_{\max} \rightarrow 0$:

$$\begin{aligned} \|\pi^h \varepsilon^h\|_{L^q} &\leq \gamma_0 \gamma_1 h_{\max}^{2-1/p+1/q} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{W^{1,p}}, \\ \|\varepsilon^h\|_{L^q} &\leq \gamma_0^2 h_{\max}^{1-1/p+1/q} \|f\|_{W^{1,p}}, \\ \|\overline{\varepsilon}^h\|_{L^q} &\leq \gamma_0 \gamma_1 h_{\max}^{2-1/p+1/q} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{W^{1,p}}. \end{aligned}$$

As a corollary

$$\begin{aligned} \|\pi^h \varepsilon^h\|_{L^p} &\leq \gamma_0 \gamma_1 h_{\max} \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{W^{1,p}}, \\ \|\varepsilon^h\|_{L^p} &\leq \gamma_0^2 h_{\max} \|f\|_{W^{1,p}}, \\ \|\overline{\varepsilon}^h\|_{L^p} &\leq \gamma_0 \gamma_1 h_{\max}^2 \ln \frac{1}{h_{\max}} (1 + o(1)) \|f\|_{W^{1,p}}. \end{aligned}$$

Theorems 2 and 3 show us that, when $f \in W^{1,p}(J)$, $p \in [1, \infty[$, then the classical Galerkin method has almost the same accuracy as the Kantorovich method, and the iterated Galerkin method has almost the same accuracy as the iterated Kantorovich method.

Theorems 1–3 follow from Theorem 11 and Theorem 14 because E_1 satisfies the following properties:

1. $E_1 \in W^{1,r}(\delta, \infty)$ for all $\delta > 0$ and $r \in [1, \infty[$,
2. $DE_1(t) = o(t^{-1}E_1(t))$ as $t \rightarrow 0^+$,
3. $E_1(t) = \ln \frac{1}{t}(1 + o(1))$ as $t \rightarrow 0^+$ (cf. [1]).

Remark 4. It is proved in section 3 that, if $f \in BV(\overline{J})$, then $\Lambda f \in BV(\overline{J})$, $\Lambda f \in W^{1,q}(J)$ for all $q \in [1, \infty[$, and

$$\begin{aligned} \|\Lambda f\|_{BV(\overline{J})} &\leq \operatorname{var}_{\overline{J}} f + \gamma_0 \sup_{\tau \in \overline{J}} |f(\tau)|, \\ \|\Lambda f\|_{W^{1,q}} &\leq M_q \left(\operatorname{var}_{\overline{J}} f + 2^{1-1/q} \gamma_0 \sup_{\tau \in \overline{J}} |f(\tau)| \right). \end{aligned}$$

It is proved also that, if $f \in W^{1,p}(J)$ for some $p \in [1, \infty[$, then $\Lambda f \in W^{1,q}(J)$ for all $q \in [p, \infty[$, and

$$\|\Lambda f\|_{W^{1,q}} \leq M_s \|Df\|_{L^p} + 2^{1-1/q} \gamma_0 M_q \|f\|_{C^0(\overline{J})}.$$

Remark 5. The Kantorovich approach has no sense if $f \in W^{1,\infty}(J)$ is such that $f(0) \neq 0$ or $f(\tau_*) \neq 0$. It follows from formula (21) that in that case $\Lambda f \notin W^{1,\infty}(J)$, and, as a corollary, $\Lambda \varphi \notin W^{1,\infty}(J)$. So the iterated Galerkin method should be preferred if f belongs to $W^{1,\infty}(J)$ or if it is smoother than that.

3. Some properties of the solution. We use the notations

$$\begin{aligned} (\varphi, \psi) &:= \int_0^{\tau_*} \varphi(\tau) \psi(\tau) d\tau, \\ \mathcal{E}_*(\tau) &:= \mathcal{E}(\tau_* - \tau). \end{aligned}$$

Let $f \in L^p(J)$, and $\mathcal{E} \in L^r(\mathbb{R}^+)$ for all $r \in [1, \infty[$.

In this section, h denotes a strictly positive real number. We introduce differences

$$\Delta_h f(\tau) := f(\tau + h) - f(\tau), \quad \Delta_{-h} f(\tau) := f(\tau - h) - f(\tau),$$

and the modulus of continuity of the kernel \mathcal{E} :

$$\omega_r(\mathcal{E}, h) := \sup_{0 < \delta \leq h} \|\Delta_\delta \mathcal{E}(\cdot)\|_{L^r(\mathbb{R})},$$

that is to say

$$\omega_r(\mathcal{E}, h) = \sup_{0 < \delta \leq h} \left(\int_{\mathbb{R}} |\mathcal{E}(|\tau + \delta|) - \mathcal{E}(|\tau|)|^r d\tau \right)^{1/r}.$$

LEMMA 1. *Let $s \neq \infty$. Then Λ is a bounded linear operator from $L^p(J)$ into $L^q(J)$, and the following estimates hold:*

(14) $\|\Lambda\|_{L^p \rightarrow L^q} \leq M_s,$

(15) $\|\Delta_h \Lambda\|_{L^p \rightarrow L^q} \leq \omega_s(\mathcal{E}, h).$

Proof. For $p \in [1, \infty[$ and by Hölder inequality,

$$\begin{aligned} |\Lambda f(\tau)|^p &\leq \left(\int_0^{\tau_*} \mathcal{E}(|\tau - \tau'|) |f(\tau')| d\tau' \right)^p \\ &= \left(\int_0^{\tau_*} \mathcal{E}(|\tau - \tau'|)^{s(1-1/p)} \mathcal{E}(|\tau - \tau'|)^{s/q} |f(\tau')| d\tau' \right)^p \\ &\leq \left[\int_0^{\tau_*} \mathcal{E}(|\tau - \tau'|)^s d\tau' \right]^{p-1} \int_0^{\tau_*} \mathcal{E}(|\tau - \tau'|)^{sp/q} |f(\tau')|^p d\tau' \\ &\leq M_s^{s(p-1)} \int_0^{\tau_*} \mathcal{E}(|\tau - \tau'|)^{sp/q} |f(\tau')|^p d\tau', \end{aligned}$$

and similarly

$$\begin{aligned} |\Delta_h \Lambda f(\tau)|^p &= \left| \int_0^{\tau_*} \Delta_h \mathcal{E}(|\tau - \tau'|) f(\tau') d\tau' \right|^p \\ &\leq \omega_s(\mathcal{E}, h)^{s(p-1)} \int_0^{\tau_*} |\Delta_h \mathcal{E}(|\tau - \tau'|)|^{sp/q} |f(\tau')|^p d\tau'. \end{aligned}$$

If $q = \infty$ these estimates immediately imply inequalities (14), (15).

If $q < \infty$, then by generalized Minkowski inequality we get

$$\begin{aligned} \|\Lambda f\|_{L^q}^p &\leq M_s^{s(p-1)} \left\| \int_0^{\tau_*} \mathcal{E}(|\cdot - \tau'|)^{sp/q} |f(\tau')|^p d\tau' \right\|_{L^{q/p}} \\ &\leq M_s^{s(p-1)} \int_0^{\tau_*} \|\mathcal{E}(|\cdot - \tau'|)^{sp/q}\|_{L^{q/p}} |f(\tau')|^p d\tau' \\ &= M_s^{s(p-1)} \int_0^{\tau_*} \|\mathcal{E}(|\cdot - \tau'|)\|_{L^s}^{sp/q} |f(\tau')|^p d\tau' \leq M_s^p \|f\|_{L^p}^p, \end{aligned}$$

and

$$\begin{aligned} \|\Delta_h \Lambda f\|_{L^q}^p &\leq \omega_s(\mathcal{E}, h)^{s(p-1)} \left\| \int_0^{\tau_*} |\Delta_h \mathcal{E}(|\cdot - \tau'|)|^{sp/q} |f(\tau')|^p d\tau' \right\|_{L^{q/p}} \\ &\leq \omega_s(\mathcal{E}, h)^{s(p-1)} \int_0^{\tau_*} \|\Delta_h \mathcal{E}(|\cdot - \tau'|)^{sp/q}\|_{L^{q/p}} |f(\tau')|^p d\tau' \\ &= \omega_s(\mathcal{E}, h)^{s(p-1)} \int_0^{\tau_*} \|\Delta_h \mathcal{E}(|\cdot - \tau'|)\|_{L^s}^{sp/q} |f(\tau')|^p d\tau' \leq \omega_s(\mathcal{E}, h)^p \|f\|_{L^p}^p. \end{aligned}$$

If $p = q = \infty$, then

$$|\Lambda f(\tau)| \leq \int_0^{\tau_*} \mathcal{E}(|\tau - \tau'|) d\tau' \|f\|_{L^\infty} \leq M_1 \|f\|_{L^\infty}, \quad |\Delta_h \Lambda f(\tau)| \leq \omega_1(\mathcal{E}, h) \|f\|_{L^\infty}.$$

The proof is complete. \square

COROLLARY 1. *The following estimate holds for all $p \in [1, \infty[$:*

$$(16) \quad \|\Lambda\|_{L^p \rightarrow L^p} \leq M_1 = 1.$$

COROLLARY 2. *If $1 < p \leq \infty$, then Λ is a bounded linear operator from $L^p(J)$ into $C^0(\overline{J})$.*

THEOREM 4. *If $f \in L^p(J)$ for some $p \in [1, \infty]$, then there exists a unique solution $\varphi \in L^p(J)$ of (1) and*

$$(17) \quad \|\varphi\|_{L^p} \leq \gamma_0 \|f\|_{L^p}.$$

If $f \in C^0(\bar{J})$, then $\varphi \in C^0(\bar{J})$ and

$$(18) \quad \|\varphi\|_{C^0} \leq \gamma_0 \|f\|_{C^0}.$$

Proof. It follows from (16) and the Banach Fixed Point Theorem. \square

LEMMA 2. *Assume that $\varphi, y \in L^1(J)$ and $h^{-1}\Delta_h\varphi \rightarrow y$ in $L^1_{loc}(J)$ as $h \rightarrow 0$. Then $\varphi \in W^{1,1}(J)$ and $D\varphi = y$.*

Proof. It is easy to see that, if h is a sufficiently small number, then

$$(h^{-1}\Delta_h\varphi, \psi) = (\varphi, h^{-1}\Delta_{-h}\psi) \quad \text{for all } \psi \in C_0^\infty(\bar{J}).$$

After a limit transition we get

$$(y, \psi) = -(\varphi, D\psi) \quad \text{for all } \psi \in C_0^\infty(\bar{J}).$$

This means that $y = D\varphi$. \square

THEOREM 5. *If $f \in W^{1,p}(J)$ for some $p \in [1, \infty[$, then $\varphi \in W^{1,p}(J)$ and*

$$(19) \quad D\varphi = \varpi_0 \Lambda D\varphi + \varpi_0 \varphi(0) \mathcal{E} - \varpi_0 \varphi(\tau_*) \mathcal{E}_* + Df \text{ in } J,$$

$$(20) \quad \|D\varphi\|_{L^p} \leq \gamma_0 \|f\|_{W^{1,p}}.$$

Proof. Let $h \in]0, \tau_*[$ and $\tau \in J_h :=]0, \tau_* - h[$. It follows from (1) that

$$\begin{aligned} \Delta_h\varphi(\tau) &= \varpi_0 \int_0^{\tau_*} \Delta_h \mathcal{E}(|\tau - \tau'|) \varphi(\tau') d\tau' + \Delta_h f(\tau) \\ &= \varpi_0 \int_0^{\tau_*-h} \mathcal{E}(|\tau - \tau'|) \Delta_h \varphi(\tau') d\tau' + \varpi_0 \int_0^h \mathcal{E}(|\tau + h - \tau'|) \varphi(\tau') d\tau' \\ &\quad - \varpi_0 \int_{\tau_*-h}^{\tau_*} \mathcal{E}(|\tau - \tau'|) \varphi(\tau') d\tau' + \Delta_h f(\tau). \end{aligned}$$

Hence the function $y^h := h^{-1}\Delta_h\varphi$ solves

$$y^h(\tau) = \varpi_0 \int_0^{\tau_*-h} \mathcal{E}(|\tau - \tau'|) y^h(\tau') d\tau' + \psi^h(\tau) \quad \text{for all } \tau \in J_h,$$

where

$$\begin{aligned} \psi^h(\tau) &:= \varpi_0 h^{-1} \int_0^h \mathcal{E}(|\tau + h - \tau'|) \varphi(\tau') d\tau' - \varpi_0 h^{-1} \int_{\tau_*-h}^{\tau_*} \mathcal{E}(|\tau - \tau'|) \varphi(\tau') d\tau' + h^{-1} \Delta_h f(\tau). \end{aligned}$$

Note that

$$\begin{aligned} &\|h^{-1} \int_0^h \mathcal{E}(|\cdot + h - \tau'|) \varphi(\tau') d\tau' - \varphi(0) \mathcal{E}(\cdot)\|_{L^1} \\ &\leq h^{-1} \int_0^h \|\mathcal{E}(|\cdot + h - \tau'|)\|_{L^1} |\varphi(\tau') - \varphi(0)| d\tau' \\ &\quad + h^{-1} \int_0^h \|\mathcal{E}(|\cdot + h - \tau'|) - \mathcal{E}(|\cdot|)\|_{L^1} d\tau' |\varphi(0)| \\ &\leq h^{-1} \int_0^h |\varphi(\tau') - \varphi(0)| d\tau' + \omega_1(\mathcal{E}, h) |\varphi(0)|, \end{aligned}$$

which tends to 0 as $h \rightarrow 0$.

Similarly,

$$\left\| h^{-1} \int_{\tau_*-h}^{\tau_*} \mathcal{E}(|\cdot - \tau'|) \varphi(\tau') d\tau' - \varphi(\tau_*) \mathcal{E}_*(\cdot) \right\|_{L^1} \rightarrow 0 \quad \text{as } h \rightarrow 0.$$

But $Df \in L^p(J)$ and hence $\|h^{-1} \Delta_h f - Df\|_{L^p(J_h)} \rightarrow 0$ as $h \rightarrow 0$. Thus, $\|\psi^h - \psi\|_{L^1(J_h)} \rightarrow 0$, where

$$\psi := \varpi_0 \varphi(0) \mathcal{E} - \varpi_0 \varphi(\tau_*) \mathcal{E}_* + Df \in L^p(J).$$

Let $y \in L^p(J)$ be a solution of the equation

$$y(\tau) = \varpi_0 \int_0^{\tau_*} \mathcal{E}(|\tau - \tau'|) y(\tau') d\tau' + \psi(\tau), \quad \tau \in J.$$

Applying Theorem 3 to this equation we get

$$\|y\|_{L^p} \leq \gamma_0 \|\psi\|_{L^p} \leq 2\gamma_1 \|\mathcal{E}\|_{L^p} \|\varphi\|_{C^0} + \gamma_0 \|Df\|_{L^p} \leq \gamma_0 \|f\|_{W^{1,p}}.$$

Considering $z^h := y^h - y$ as a solution of equation

$$z^h(\tau) = \varpi_0 \int_0^{\tau_*-h} \mathcal{E}(|\tau - \tau'|) z^h(\tau') d\tau' + g^h(\tau), \quad \tau \in J_h,$$

where

$$g^h(\tau) := \psi^h(\tau) - \psi(\tau) + \varpi_0 \int_{\tau_*-h}^{\tau_*} \mathcal{E}(|\tau - \tau'|) y(\tau') d\tau',$$

we get the estimate

$$\|y^h - y\|_{L^1(J_h)} \leq \gamma_0 \left[\|\psi^h - \psi\|_{L^1(J_h)} + \varpi_0 \int_{\tau_*-h}^{\tau_*} \|\mathcal{E}(|\cdot - \tau'|)\|_{L^1} |y(\tau')| d\tau' \right],$$

which tends to 0 as $h \rightarrow 0$. So $h^{-1} \varphi_h \rightarrow y$ in $L^1_{\text{loc}}(J)$ and, from Lemma 2, $y = D\varphi$. \square

LEMMA 3. If $f \in W^{1,p}(J)$ for some $p \in [1, \infty[$, then $\Lambda f \in W^{1,q}(J)$ for all $q \in [p, \infty[$, and

$$(21) \quad D\Lambda f = \Lambda Df + f(0) \mathcal{E} - f(\tau_*) \mathcal{E}_*,$$

$$(22) \quad \|D\Lambda f\|_{L^q} \leq M_s \|Df\|_{L^p} + 2^{1-1/q} M_q \|f\|_{C^0}.$$

Proof. As in the proof of Theorem 5

$$\begin{aligned} h^{-1} \Delta_h \Lambda f(\tau) &= \int_0^{\tau_*-h} \mathcal{E}(|\tau - \tau'|) h^{-1} \Delta_h f(\tau') d\tau' + h^{-1} \int_0^h \mathcal{E}(|\tau + h - \tau'|) f(\tau') d\tau' \\ &- h^{-1} \int_{\tau_*-h}^{\tau_*} \mathcal{E}(|\tau - \tau'|) f(\tau') d\tau' \rightarrow \int_0^{\tau_*} \mathcal{E}(|\tau - \tau'|) Df(\tau') d\tau' + f(0) \mathcal{E}(\tau) - f(\tau_*) \mathcal{E}_*(\tau) \end{aligned}$$

in $L^1_{\text{loc}}(J)$. So (21) is true. Inequality (22) follows from (21). \square

LEMMA 4. If $f \in BV(\overline{J})$, then $\Lambda f \in W^{1,p}(J)$ for all $p \in [1, \infty[$ and

$$(23) \quad \|D\Lambda f\|_{L^p} \leq M_p \left(\text{var}_{\overline{J}} f + 2^{1-1/p} \sup_{\tau \in \overline{J}} |f(\tau)| \right).$$

Proof. Put $f(\tau) := f(\tau_*)$ for $\tau > \tau_*$. Consider the average function

$$(24) \quad f_\delta(\tau) := \delta^{-1} \int_0^\delta f(\tau + \tau') d\tau'.$$

It is well known that $f_\delta \in W^{1,\infty}(J)$ and that, for all $p \in [1, \infty[$, $f_\delta \rightarrow f$ in $L^p(J)$ as $\delta \rightarrow 0$. Also,

$$(25) \quad \|Df_\delta\|_{L^1} \leq \text{var}_{\bar{J}} f, \quad \|f_\delta\|_{C^0} \leq \sup_{\tau \in \bar{J}} |f(\tau)|.$$

It follows from Lemma 3 that

$$\|D\Lambda f_\delta\|_{L^p} \leq M_p \left(\text{var}_{\bar{J}} f + 2^{1-1/p} \sup_{\tau \in \bar{J}} |f(\tau)| \right) \quad \text{for all } p \in [1, \infty[.$$

If $p \in]1, \infty[$ this inequality implies that there exists $D\Lambda f \in L^p(J)$ and inequality (23) holds. For $p = 1$ the inequality may be justified by a limiting process as $p \rightarrow 1$. \square

THEOREM 6. *Let $f \in BV(\bar{J})$. Then there exists a function $\varphi \in BV(\bar{J})$ satisfying (4) for all $\tau \in \bar{J}$ and*

$$(26) \quad \text{var}_{\bar{J}} \varphi \leq \gamma_0 \|f\|_{BV},$$

$$(27) \quad \sup_{\tau \in \bar{J}} |\varphi(\tau)| \leq \gamma_0 \sup_{\tau \in \bar{J}} |f(\tau)|.$$

Proof. As $f \in BV(\bar{J}) \subset L^\infty(J)$, there exists a solution $\varphi \in L^\infty(J)$ for which $\Lambda\varphi \in C^0(\bar{J})$ and (4) is satisfied almost everywhere. Putting $\varphi_* := \varpi_0 \Lambda\varphi + f$, we note that this function is equivalent to φ and $\varphi_* = \varpi_0 \Lambda\varphi_* + f$ for all $\tau \in \bar{J}$. We will consider this special solution of (4) and will denote it by φ again.

It is evident that function φ is bounded. It follows from (4) that

$$\sup_{\tau \in \bar{J}} |\varphi(\tau)| \leq \varpi_0 \sup_{\tau \in \bar{J}} |\varphi(\tau)| + \sup_{\tau \in \bar{J}} |f(\tau)|.$$

So (27) holds.

Now put $\varphi(\tau) := \varphi(0)$ for $\tau < 0$ and $\varphi(\tau) := \varphi(\tau_*)$ for $\tau > \tau_*$. Let

$$V_N := \max_{M \in \llbracket 1, N \rrbracket} \left[\sup_{0 = \tau_0 < \tau_1 < \dots < \tau_M = \tau_*} \sum_{i=0}^{M-1} |\varphi(\tau_{i+1}) - \varphi(\tau_i)| \right].$$

Note that $V_N < \infty$ and that

$$V_N = \max_{M \in \llbracket 1, N \rrbracket} \left[\sup_{-\infty < \tau_0 < \tau_1 < \dots < \tau_M < \infty} \sum_{i=0}^{M-1} |\varphi(\tau_{i+1}) - \varphi(\tau_i)| \right].$$

It follows from (4) that

$$\begin{aligned} \varphi(\tau_{i+1}) - \varphi(\tau_i) &= \varpi_0 \int_{\mathbb{R}} \mathcal{E}(|\tau|) (\varphi(\tau + \tau_{i+1}) - \varphi(\tau + \tau_i)) d\tau \\ &\quad + \varpi_0 \int_{-\tau_{i+1}}^{-\tau_i} \mathcal{E}(|\tau|) d\tau \varphi(0) - \varpi_0 \int_{\tau_* - \tau_{i+1}}^{\tau_* - \tau_i} \mathcal{E}(|\tau|) d\tau \varphi(\tau_*) \\ &\quad + f(\tau_{i+1}) - f(\tau_i). \end{aligned}$$

So

$$\begin{aligned} \sum_{i=0}^{M-1} |\varphi(\tau_{i+1}) - \varphi(\tau_i)| &\leq \varpi_0 \int_{\mathbb{R}} \mathcal{E}(|\tau|) \sum_{i=0}^{M-1} |\varphi(t + \tau_{i+1}) - \varphi(t + \tau_i)| \, dt \\ &+ \varpi_0 \int_{-\tau_*}^0 \mathcal{E}(|\tau|) \, d\tau |\varphi(0)| + \varpi_0 \int_0^{\tau_*} \mathcal{E}(\tau) \, d\tau |\varphi(\tau_*)| + \sum_{i=0}^{M-1} |f(\tau_{i+1}) - f(\tau_i)| \\ &\leq \varpi_0 V_N + \varpi_0 \sup_{\tau \in \bar{J}} |\varphi(\tau)| + \operatorname{var}_{\bar{J}} f \leq \varpi_0 V_N + \gamma_1 \sup_{\tau \in \bar{J}} |f(\tau)| + \operatorname{var}_{\bar{J}} f. \end{aligned}$$

As a consequence $V_N \leq \varpi_0 V_N + \|f\|_{BV}$ and $V_N \leq \gamma_0 \|f\|_{BV}$. The last inequality implies (26). \square

COROLLARY 3. *If $\Lambda f \in BV(\bar{J})$, then $\Lambda\varphi \in BV(\bar{J})$ and*

$$(28) \quad \operatorname{var}_{\bar{J}} \Lambda\varphi \leq \gamma_0 \|\Lambda f\|_{BV},$$

$$(29) \quad \sup_{\tau \in \bar{J}} |\Lambda\varphi(\tau)| \leq \gamma_0 \sup_{\tau \in \bar{J}} |\Lambda f(\tau)|.$$

To prove Corollary 3 we remind that $y = \Lambda\varphi$ solves (10).

4. Some subsidiary results. In this section we will consider some properties of operators π^h and $I - \pi^h$. We come back to the general notations of the paper, introduced in section 2. In addition, $p' \in [1, \infty]$ will denote the conjugate of $p \in [1, \infty]$ in the sense that $1/p + 1/p' = 1$.

It is evident that $(\pi^h)^2 = \pi^h$. So π^h and $I - \pi^h$ are projections from $L^p(J)$ into $L^p(J)$. It is easy to see that for all $p \in [1, \infty]$ we have

$$\|\pi^h\|_{L^p \rightarrow L^p} = 1.$$

Moreover, π^h has this self-adjoint-like property:

$$(\pi^h \varphi, \psi) = (\varphi, \pi^h \psi) \quad \text{for all } \varphi \in L^p(J), \psi \in L^{p'}(J).$$

Let $f \in L^p(J)$, $\mathcal{E} \in L^r(\mathbb{R}^+)$ for all $r \in [1, \infty[$, and $\alpha \in]0, 1[$. We introduce the following difference operator Δ_α^h and two moduli of continuity, all three associated with the grid J^h :

$$\begin{aligned} \Delta_\alpha^h f(\tau) &:= \begin{cases} \Delta_{\alpha h_i} f(\tau) & \text{for all } \tau \in [\tau_{i-1}, \tau_i - \alpha h_i], \\ 0 & \text{for all } \tau \in]\tau_i - \alpha h_i, \tau_i[, \end{cases} \quad i \in \llbracket 1, n \rrbracket, \\ \omega_p(f, J^h) &:= \begin{cases} 2^{1/p} \left[\int_0^1 \|\Delta_\alpha^h f\|_{L^p(J)}^p \, d\alpha \right]^{1/p} & \text{for all } p \in [1, \infty[, \\ \max_{i \in \llbracket 1, n \rrbracket} \operatorname{esssup}_{(\tau, \tau') \in [\tau_{i-1}, \tau_i]^2} |f(\tau) - f(\tau')| & \text{for } p = \infty, \end{cases} \\ \bar{\omega}_r(\mathcal{E}, J^h) &:= \sup_{0 < \tau' < \tau_*} \omega_r(\mathcal{E}(|\cdot - \tau'|), J^h) \\ &= 2^{1/r} \sup_{0 < \tau' < \tau_*} \left[\int_0^1 \|\Delta_\alpha^h \mathcal{E}(|\cdot - \tau'|)\|_{L^r}^r \, d\alpha \right]^{1/r} \quad \text{for all } r \in [1, \infty[. \end{aligned}$$

LEMMA 5. *The following estimates hold:*

$$(30) \quad \|(I - \pi^h) f\|_{L^p} \leq \omega_p(f, J^h) \quad \text{for all } f \in L^p(J),$$

$$(31) \quad \|(I - \pi^h) f\|_{L^q} \leq h_{\max}^{1/q} \operatorname{var}_{\bar{J}} f \quad \text{for all } f \in BV(\bar{J}),$$

$$(32) \quad \|(I - \pi^h) f\|_{L^q} \leq h_{\max}^{1/s} \|Df\|_{L^p} \quad \text{for all } f \in W^{1,p}(J).$$

Proof. Let $f \in L^p(J)$. It follows from (7) that, for all $i \in \llbracket 1, n \rrbracket$ and $\tau \in J_{i-1/2}$,

$$(33) \quad (I - \pi^h) f(\tau) = \frac{1}{h_i} \int_{\tau_{i-1}}^{\tau_i} (f(\tau) - f(\tau')) d\tau'.$$

If $p < \infty$, then

$$\begin{aligned} & \int_{\tau_{i-1}}^{\tau_i} |(I - \pi^h) f(\tau)|^p d\tau \leq \int_{\tau_{i-1}}^{\tau_i} \left[\frac{1}{h_i} \int_{\tau_{i-1}}^{\tau_i} |f(\tau') - f(\tau)| d\tau' \right]^p d\tau \\ & \leq \frac{1}{h_i} \int_{\tau_{i-1}}^{\tau_i} \left[\int_{\tau_{i-1}}^{\tau_i} |f(\tau') - f(\tau)|^p d\tau' \right] d\tau = \frac{2}{h_i} \int_{\tau_{i-1}}^{\tau_i} \left[\int_{\tau}^{\tau_i} |f(\tau') - f(\tau)|^p d\tau' \right] d\tau \\ & = 2 \int_{\tau_{i-1}}^{\tau_i} \left[\int_0^{(\tau_i - \tau)/h_i} |f(\tau + \alpha h_i) - f(\tau)|^p d\alpha \right] d\tau = 2 \int_0^1 \left[\int_{\tau_{i-1}}^{\tau_i - \alpha h_i} |\Delta_{\alpha h_i} f(\tau)|^p d\tau \right] d\alpha. \end{aligned}$$

As a consequence

$$\|(I - \pi^h) f\|_{L^p}^p \leq 2 \sum_{i=1}^n \int_0^1 \left[\int_{\tau_{i-1}}^{\tau_i - \alpha h_i} |\Delta_{\alpha h_i} f(\tau)|^p d\tau \right] d\alpha = \omega_p(f, J^h)^p.$$

In the case $p = \infty$ the estimate is evident.

Let $f \in BV(J)$. It follows from (33) that, for all $i \in \llbracket 1, n \rrbracket$,

$$\sup_{\tau \in [\tau_{i-1}, \tau_i[} |(I - \pi^h) f(\tau)| \leq \operatorname{var}_{[\tau_{i-1}, \tau_i]} f,$$

so

$$\|(I - \pi^h) f\|_{L^\infty} \leq \frac{\operatorname{var} f}{J},$$

and if $q < \infty$, then

$$\|(I - \pi^h) f\|_{L^q}^q = \sum_{i=1}^n \|(I - \pi^h) f\|_{L^q(\tau_{i-1}, \tau_i)}^q \leq \sum_{i=1}^n h_i \left(\operatorname{var}_{[\tau_{i-1}, \tau_i]} f \right)^q \leq h_{\max} \left(\frac{\operatorname{var} f}{J} \right)^q.$$

Let $f \in W^{1,p}(J)$. It follows from (33) that, for all $i \in \llbracket 1, n \rrbracket$,

$$\sup_{\tau \in [\tau_{i-1}, \tau_i]} |(I - \pi^h) f(\tau)| \leq \|Df\|_{L^1(\tau_{i-1}, \tau_i)} \leq h_i^{1-1/p} \|Df\|_{L^p(\tau_{i-1}, \tau_i)}.$$

If $q = \infty$, then (32) is evident. If $q < \infty$, then

$$\begin{aligned} \|(I - \pi^h) f\|_{L^q(J)}^q &= \sum_{i=1}^n \|(I - \pi^h) f\|_{L^q(\tau_{i-1}, \tau_i)}^q \\ &\leq \sum_{i=1}^n h_i^{q-q/p+1} \|Df\|_{L^p(\tau_{i-1}, \tau_i)}^q \\ &\leq h_{\max}^{q-q/p+1} \|Df\|_{L^p}^q. \end{aligned}$$

The proof is complete. \square

LEMMA 6. Let $g \in L^1(0, 1)$ be a positive nonincreasing function. Then $g(t) = o(t^{-1})$ as $t \rightarrow 0^+$.

Proof. Otherwise there exist a number $c_0 > 0$ and a sequence $(t_k)_{k=1}^\infty$ in $]0, 1[$ such that $\lim_{k \rightarrow \infty} t_k = 0$, $t_{k+1} < t_k/2$, and $g(t_k) \geq c_0 t_k^{-1}$ for all $k \geq 1$. So

$$\int_0^1 g(t) dt \geq \sum_{k=1}^\infty g(t_k)t_k(1 - t_{k+1}/t_k) \geq c_0 \sum_{k=1}^\infty (1 - t_{k+1}/t_k) \geq \sum_{k=1}^\infty 1/2 = +\infty.$$

This contradiction proves the lemma. \square

COROLLARY 4. $\mathcal{E}^r(t) = o(t^{-1})$ as $t \rightarrow 0^+$ for all $r \in [1, \infty[$.

LEMMA 7. If

$$(34) \quad \mathcal{E} \in W^{1,r}(\delta, \infty) \quad \text{for all } \delta > 0 \text{ and all } r \in [1, \infty[,$$

then

$$\omega_r(\mathcal{E}, \eta) \leq \sup_{0 < \delta \leq \eta} 4^{1/r} \left(\int_0^{\delta/2} \mathcal{E}(\tau)^r d\tau + \delta^r \int_{\delta/2}^\infty |D\mathcal{E}(\tau)|^r d\tau \right)^{1/r} \quad \text{for all } r \in]1, \infty[.$$

(35)

If in addition

$$(36) \quad D\mathcal{E}(\tau) = o(\tau^{-1}\mathcal{E}(\tau)) \quad \text{as } \tau \rightarrow 0^+,$$

then, for all $r \in [1, \infty[$,

$$(37) \quad \omega_r(\mathcal{E}, \eta) \leq 2^{1/r} \eta^{1/r} \mathcal{E}(\eta/2)(1 + o(1)) \quad \text{as } \eta \rightarrow 0^+.$$

Proof. Note that

$$\begin{aligned} & \int_{-\infty}^\infty |\mathcal{E}(|\tau + \delta|) - \mathcal{E}(|\tau|)|^r d\tau = 2 \int_0^\infty |\mathcal{E}(\tau + \delta/2) - \mathcal{E}(\tau - \delta/2)|^r d\tau \\ & \leq 2 \int_0^{\delta/2} \mathcal{E}(|\tau - \delta/2|)^r d\tau + 2 \int_{\delta/2}^\delta \mathcal{E}(|\tau - \delta/2|)^r d\tau + 2 \int_\delta^\infty (\mathcal{E}(\tau - \delta/2) - \mathcal{E}(\tau + \delta/2))^r d\tau \\ & \leq 4 \int_0^{\delta/2} \mathcal{E}(\tau)^r d\tau + 2 \int_{\delta/2}^\infty (\mathcal{E}(\tau) - \mathcal{E}(\tau + \delta))^r d\tau \\ & \leq 4 \int_0^{\delta/2} \mathcal{E}(\tau)^r d\tau + 2 \int_{\delta/2}^\infty \left[\int_\tau^{\tau+\delta} |D\mathcal{E}(\tau')| d\tau' \right]^r d\tau \\ & \leq 4 \int_0^{\delta/2} \mathcal{E}(\tau)^r d\tau + 2\delta^{r-1} \int_{\delta/2}^\infty \left[\int_\tau^{\tau+\delta} |D\mathcal{E}(\tau')|^r d\tau' \right] d\tau \\ & \leq 4 \int_0^{\delta/2} \mathcal{E}(\tau)^r d\tau + 2\delta^r \int_{\delta/2}^\infty |D\mathcal{E}(\tau)|^r d\tau. \end{aligned}$$

So (35) holds.

To prove (37) we note that $\delta \mathcal{E}^r(\delta/2) \rightarrow 0$ as $\delta \rightarrow 0^+$. (See Corollary 4.) By our assumptions and the L'Hospital rule,

$$\begin{aligned} \lim_{\delta \rightarrow 0^+} \frac{2 \int_0^{\delta/2} \mathcal{E}^r(\tau) d\tau}{\delta \mathcal{E}^r(\delta/2)} &= \lim_{\delta \rightarrow 0^+} \frac{\mathcal{E}^r(\delta/2)}{\mathcal{E}^r(\delta/2) + (r/2)\delta \mathcal{E}^{r-1}(\delta/2) D\mathcal{E}(\delta/2)} = 1, \\ \lim_{\delta \rightarrow 0^+} \frac{\delta^r \int_{\delta/2}^{\infty} |D\mathcal{E}(\tau)|^r d\tau}{\delta \mathcal{E}^r(\delta/2)} &= \lim_{\delta \rightarrow 0^+} \frac{\int_{\delta/2}^{\infty} |D\mathcal{E}(\tau)|^r d\tau}{\delta^{1-r} \mathcal{E}^r(\delta/2)} \\ &= \lim_{\delta \rightarrow 0^+} \frac{-|D\mathcal{E}(\delta/2)|^r/2}{(1-r)\delta^{-r} \mathcal{E}^r(\delta/2) + (r/2)\delta^{1-r} \mathcal{E}^{r-1}(\delta/2) D\mathcal{E}(\delta/2)} = 0. \end{aligned}$$

So (37) follows from (35). \square

Remark 6. We do not need the assumption (34) to prove that

$$\omega_1(\mathcal{E}, \eta) \leq 4 \int_0^{\eta/2} \mathcal{E}(\tau) d\tau.$$

Proof. In fact,

$$\begin{aligned} &\int_{-\infty}^{\infty} |\mathcal{E}(|\tau + \delta|) - \mathcal{E}(|\tau|)| d\tau = \int_{-\infty}^{\infty} |\mathcal{E}(|\tau + \delta/2|) - \mathcal{E}(|\tau - \delta/2|)| d\tau \\ &= 2 \int_0^{\infty} |\mathcal{E}(|\tau + \delta/2|) - \mathcal{E}(|\tau - \delta/2|)| d\tau = 2 \int_0^{\infty} (\mathcal{E}(|\tau - \delta/2|) - \mathcal{E}(|\tau + \delta/2|)) d\tau \\ &= 2 \int_{-\delta/2}^{\infty} \mathcal{E}(|\tau|) d\tau - 2 \int_{\delta/2}^{\infty} \mathcal{E}(|t|) dt = 4 \int_0^{\delta/2} \mathcal{E}(\tau) d\tau. \end{aligned}$$

The proof is complete. \square

LEMMA 8. *If \mathcal{E} satisfies (34), then*

$$(38) \quad \bar{\omega}_r(\mathcal{E}, J^h) \leq 4^{1/r} \left[\int_0^{h_{\max}/2} \mathcal{E}(\tau)^r d\tau + h_{\max}^r \int_{h_{\max}/2}^{\infty} |D\mathcal{E}(\tau)|^r d\tau \right]^{1/r}.$$

If in addition \mathcal{E} satisfies (36), then

$$(39) \quad \bar{\omega}_r(\mathcal{E}, J^h) \leq 2^{1/r} h_{\max}^{1/r} \mathcal{E}(h_{\max}/2) (1 + o(1)) \quad \text{as } h_{\max} \rightarrow 0^+.$$

Proof. Note that

$$\bar{\omega}_r(\mathcal{E}, J^h)^r = 2 \sup_{0 < \tau' < \tau_*} \sum_{i=1}^n \int_0^1 \left[\int_{t_{i-1}}^{t_i - \alpha h_i} |\mathcal{E}(|\tau + \alpha h_i|) - \mathcal{E}(|\tau|)|^r d\tau \right] d\alpha,$$

where $t_i := \tau_i - \tau'$ for all $i \in \llbracket 0, n \rrbracket$.

Let us estimate

$$\begin{aligned} I_i &:= \int_0^1 \left[\int_{t_{i-1}}^{t_i - \alpha h_i} |\mathcal{E}(|\tau + \alpha h_i|) - \mathcal{E}(|\tau|)|^r d\tau \right] d\alpha \\ &= \int_{t_{i-1}}^{t_i} \left[\int_0^{(t_i - \tau)/h_i} |\mathcal{E}(|\tau + \alpha h_i|) - \mathcal{E}(|\tau|)|^r d\alpha \right] d\tau. \end{aligned}$$

If $-h_{\max}/2 \leq t_{i-1} < t_i \leq h_{\max}/2$, then

$$\begin{aligned} I_i &\leq \int_0^1 \left[\int_{t_{i-1}}^{t_i - \alpha h_i} (\mathcal{E}(|\tau + \alpha h_i|)^r + \mathcal{E}(|\tau|)^r) d\tau \right] d\alpha \\ &= \int_0^1 \left[\int_{t_{i-1} + \alpha h_i}^{t_i} \mathcal{E}(|\tau|)^r d\tau \right] d\alpha + \int_0^1 \left[\int_{t_{i-1}}^{t_i - \alpha h_i} \mathcal{E}(|\tau|)^r d\tau \right] d\alpha \\ &= \int_{t_{i-1}}^{t_i} \frac{\tau - t_{i-1}}{h_i} \mathcal{E}(|\tau|)^r d\tau + \int_{t_{i-1}}^{t_i} \frac{t_i - \tau}{h_i} \mathcal{E}(|\tau|)^r d\tau = \int_{t_{i-1}}^{t_i} \mathcal{E}(|\tau|)^r d\tau. \end{aligned}$$

Let $t_{i-1} < 0 < h_{\max}/2 < t_i$. Note that $0 < -t_{i-1} < h_{\max}/2$ and

$$|\mathcal{E}(|\tau + \alpha h_i|) - \mathcal{E}(|\tau|)| \leq \begin{cases} \mathcal{E}(|\tau + \alpha h_i|) & \text{for } \tau \in (t_{i-1}, -\alpha h_i/2), \\ \mathcal{E}(|\tau|) & \text{for } \tau \in [-\alpha h_i/2, h_{\max}/2], \\ \mathcal{E}(h_{\max}/2) - \mathcal{E}(t_i) & \text{for } \tau \in (h_{\max}/2, t_i - \alpha h_i). \end{cases}$$

So

$$\begin{aligned} I_i &\leq \int_{t_{i-1}}^0 \left[\int_0^{-2\tau/h_i} \mathcal{E}(|\tau + \alpha h_i|)^r d\alpha \right] d\tau + \int_{t_{i-1}}^0 \left[\int_{-2\tau/h_i}^{(t_i - \tau)/h_i} \mathcal{E}(|\tau|)^r d\alpha \right] d\tau \\ &\quad + \int_0^{h_{\max}/2} \left[\int_0^{(t_i - \tau)/h_i} \mathcal{E}(|\tau|)^r d\alpha \right] d\tau + h_i \left| \int_{h_{\max}/2}^{t_i} D\mathcal{E}(\tau) d\tau \right|^r \\ &= \int_{t_{i-1}}^0 \left[\int_0^{(\tau - t_{i-1})/h_i} \mathcal{E}(|\tau|)^r d\alpha \right] d\tau + \int_0^{-t_{i-1}} \left[\int_{2\tau/h_i}^{(\tau - t_{i-1})/h_i} \mathcal{E}(|\tau|)^r d\alpha \right] d\tau \\ &\quad + \int_{t_{i-1}}^0 \frac{t_i + \tau}{h_i} \mathcal{E}(|\tau|)^r d\tau + \int_0^{h_{\max}/2} \frac{t_i - \tau}{h_i} \mathcal{E}(|\tau|)^r d\tau + h_i \left| \int_{h_{\max}/2}^{t_i} D\mathcal{E}(\tau) d\tau \right|^r \\ &\leq \int_{t_{i-1}}^0 \left(1 + \frac{2\tau}{h_i} \right) \mathcal{E}(|\tau|)^r d\tau + \int_0^{-t_{i-1}} \mathcal{E}(|\tau|)^r d\tau + \int_{-t_{i-1}}^{h_{\max}/2} \frac{t_i - \tau}{h_i} \mathcal{E}(|\tau|)^r d\tau \\ &\quad + h_{\max} \left| \int_{h_{\max}/2}^{t_i} D\mathcal{E}(\tau) d\tau \right|^r \leq \int_{t_{i-1}}^{h_{\max}/2} \mathcal{E}(|\tau|)^r d\tau + h_{\max}^r \int_{h_{\max}/2}^{t_i} |D\mathcal{E}(\tau)|^r d\tau. \end{aligned}$$

If $t_{i-1} \leq -h_{\max}/2 < 0 < t_i$, then in an analogous manner

$$I_i \leq \int_{-h_{\max}/2}^{t_i} \mathcal{E}(|\tau|)^r d\tau + h_{\max}^r \int_{t_{i-1}}^{-h_{\max}/2} |D\mathcal{E}(\tau)|^r d\tau.$$

If $0 \leq t_{i-1} \leq h_{\max}/2 < t_i$, then

$$\begin{aligned} I_i &\leq \int_{t_{i-1}}^{h_{\max}/2} \mathcal{E}(\tau)^r d\tau + \int_{h_{\max}/2}^{t_i} (\mathcal{E}(\tau) - \mathcal{E}(t_i))^r d\tau \\ &\leq \int_{t_{i-1}}^{h_{\max}/2} \mathcal{E}(\tau)^r d\tau + h_i^r \int_{h_{\max}/2}^{t_i} |D\mathcal{E}(\tau)|^r d\tau. \end{aligned}$$

In an analogous way if $t_{i-1} < -h_{\max}/2 \leq t_i \leq 0$, then

$$I_i \leq h_i^r \int_{t_{i-1}}^{-h_{\max}/2} |D\mathcal{E}(\tau)|^r d\tau + \int_{-h_{\max}/2}^{t_i} \mathcal{E}(|\tau|)^r d\tau.$$

If $h_{\max}/2 \leq t_{i-1}$, then
