APPROXIMATION BOUNDS FOR QUADRATIC OPTIMIZATION WITH HOMOGENEOUS QUADRATIC CONSTRAINTS*

ZHI-QUAN LUO†, NICHOLAS D. SIDIROPOULOS‡, PAUL TSENG§, AND SHUZHONG ZHANG¶

Abstract. We consider the NP-hard problem of finding a minimum norm vector in n-dimensional real or complex Euclidean space, subject to m concave homogeneous quadratic constraints. We show that a semidefinite programming (SDP) relaxation for this nonconvex quadratically constrained quadratic program (QP) provides an $O(m^2)$ approximation in the real case and an $O(m)$ approximation in the complex case. Moreover, we show that these bounds are tight up to a constant factor. When the Hessian of each constraint function is of rank 1 (namely, outer products of some given so-called steering vectors) and the phase spread of the entries of these steering vectors are bounded away from $\pi/2$, we establish a certain "constant factor" approximation (depending on the phase spread but independent of m and n) for both the SDP relaxation and a convex QP restriction of the original NP-hard problem. Finally, we consider a related problem of finding a maximum norm vector subject to m convex homogeneous quadratic constraints. We show that an SDP relaxation for this nonconvex QP provides an $O(1/\ln(m))$ approximation, which is analogous to a result of Nemirovski et al. [*Math. Program.*, 86 (1999), pp. 463–473] for the real case.

Key words. semidefinite programming relaxation, nonconvex quadratic optimization, approximation bound

1. Introduction.

Consider the quadratic optimization problem with concave homogeneous quadratic constraints:

$$\begin{array}{rll} v_{\rm qp} := \min & \|z\|^2 & \\ \text{subject to (s.t.)} & \displaystyle\sum_{\ell\in\mathcal{I}_i} |h_\ell^H z|^2 \ge 1, & i=1,\dots,m, \\ & z\in\mathbb{F}^n, & \end{array} \tag{1}$$

where $\mathbb{F}$ is either $\mathbb{R}$ or $\mathbb{C}$, $\|\cdot\|$ denotes the Euclidean norm in $\mathbb{F}^n$, $m \ge 1$, each h_ℓ is a given vector in $\mathbb{F}^n$, and $\mathcal{I}_1,\dots,\mathcal{I}_m$ are nonempty, mutually disjoint index sets satisfying $\mathcal{I}_1 \cup \cdots \cup \mathcal{I}_m = \{1,\dots,M\}$. Throughout, the superscript H will denote the complex Hermitian transpose, i.e., for $z = x + \mathbf{i}y$, where $x, y \in \mathbb{R}^n$ and $\mathbf{i}^2 = -1$, $z^H = x^T - \mathbf{i}y^T$. Geometrically, problem (1) corresponds to finding a least norm vector

in a region defined by the intersection of the exteriors of m cocentered ellipsoids. If the vectors $h_1, \ldots, h_M$ are linearly independent, then M equals the sum of the ranks of the matrices defining these m ellipsoids. Notice that the problem (1) is easily solved for the case of $n = 1$, so we assume $n \geq 2$.

We assume that $\sum_{\ell \in \mathcal{I}_i} \|h_\ell\| \neq 0$ for all i, which is clearly a necessary condition for (1) to be feasible. This is also a sufficient condition (since $\bigcup_{i=1}^m \{z \mid \sum_{\ell \in \mathcal{I}_i} |h_\ell^H z|^2 = 0\}$ is a finite union of proper subspaces of $\mathbb{F}^n$, so its complement is nonempty and any point in its complement can be scaled to be feasible for (1)). Thus, problem (1) always has an optimal solution (not unique) since its objective function is coercive and continuous, and its feasible set is nonempty and closed. Notice, however, that the feasible set of (1) is typically nonconvex and disconnected, with an exponential number of connected components exhibiting little symmetry. This is in contrast to the quadratic problems with convex feasible set but nonconvex objective function considered in [13, 14, 22]. Furthermore, unlike the class of quadratic problems studied in [1, 7, 8, 15, 16, 21, 23, 24, 25, 26], the constraint functions in (1) do not depend on $z_1^2, \ldots, z_n^2$ only.

Our interest in the nonconvex quadratic program (QP) (1) is motivated by the transmit beamforming problem for multicasting applications [20] and by the wireless sensor network localization problem [6]. In the transmit beamforming problem, a transmitter utilizes an array of n transmitting antennas to broadcast information within its service area to m radio receivers, with receiver $i \in \{1, \ldots, m\}$ equipped with $|\mathcal{I}_i|$ receiving antennas. Let h_ℓ, $\ell \in \mathcal{I}_i$, denote the $n \times 1$ complex *steering vector* modeling propagation loss and phase shift from the transmitting antennas to the ℓth receiving antenna of receiver i. Assuming that each receiver performs spatially matched filtering/maximum ratio combining, which is the optimal combining strategy under standard mild assumptions, then the constraint

$$\sum_{\ell \in \mathcal{I}_i} |h_\ell^H z|^2 \geq 1$$

models the requirement that the total received signal power at receiver i must be above a given threshold (normalized to 1). This constraint is also equivalent to a signal-to-noise ratio (SNR) condition commonly used in data communication. Thus, to minimize the total transmit power subject to individual SNR requirements (one at each receiver), we are led to the QP (1). In the special case where each radio receiver is equipped with a single receiving antenna, the problem reduces to [20]

$$\begin{array}{ll} \min & \|z\|^2 \\ \text{s.t.} & |h_\ell^H z|^2 \geq 1, \quad \ell = 1, \ldots, m, \\ & z \in \mathbb{F}^n. \end{array} \tag{2}$$

This problem is a special case of (1), whereby each ellipsoid lies in $\mathbb{F}^n$ and the corresponding matrix has rank 1.

In this paper, we first show that the nonconvex QP (2) is NP-hard in either the real or the complex case, which further implies the NP-hardness of the general problem (1). Then, we consider a semidefinite programming (SDP) *relaxation* of (1) and a convex QP *restriction* of (2) and study their worst-case performance. In particular, let $v_{\rm sdp}$, $v_{\rm cqp}$, and $v_{\rm qp}$ denote the optimal values of the SDP relaxation, the convex QP restriction, and the original QP (1), respectively. We establish a performance ratio of $v_{\rm qp}/v_{\rm sdp} = O(m^2)$ for the SDP relaxation in the real case, and we give an example showing that this bound is tight up to a constant factor. Similarly, we establish a

performance ratio of $\upsilon_{\rm qp}/\upsilon_{\rm sdp} = O(m)$ in the complex case, and we give an example showing the tightness of this bound. We further show that in the case when the phase spread of the entries of $h_1, \ldots, h_M$ is bounded away from $\pi/2$, the performance ratios $\upsilon_{\rm qp}/\upsilon_{\rm sdp}$ and $\upsilon_{\rm cqp}/\upsilon_{\rm qp}$ for the SDP relaxation and the convex QP restriction, respectively, are independent of m and n.

In recent years, there have been extensive studies of the performance of SDP relaxations for nonconvex QP. However, to our knowledge, this is the first performance analysis of SDP relaxation for QP with concave quadratic constraints. Our proof techniques also extend to a maximization version of the QP (1) with convex homogeneous quadratic constraints. In particular, we give a simple proof of a result analogous to one of Nemirovski et al. [14] (also see [13, Theorem 4.7]) for the real case, namely, the SDP relaxation for this nonconvex QP has a performance ratio of $O(1/\ln(m))$.

2. NP-hardness. In this section, we show that the nonconvex QP (1) is NP-hard in general. First, we notice that, by a linear transformation if necessary, the problem

$$\begin{array}{lll} \text{minimize} & z^H Q z & \\ \text{s.t.} & |z_\ell| \geq 1, & \ell = 1, \ldots, n, \\ & z \in \mathbb{F}^n, & \end{array} \tag{3}$$

is a special case of (1), where $Q \in \mathbb{F}^{n\times n}$ is a Hermitian positive definite matrix (i.e., $Q \succ 0$), and z_ℓ denotes the ℓth component of z. Hence, it suffices to establish the NP-hardness of (3). To this end, we consider a reduction from the NP-complete partition problem: Given positive integers $a_1,\ a_2,\ \ldots,\ a_N$, decide whether there exists a subset $\mathcal{I}$ of $\{1, \ldots, N\}$ satisfying

$$\sum_{\ell\in\mathcal{I}} a_\ell = \frac{1}{2}\sum_{\ell=1}^{N} a_\ell. \tag{4}$$

Our reductions differ for the real and complex cases. As will be seen, the NP-hardness proof in the complex case[1] is more intricate than in the real case.

2.1. The real case. We consider the real case of $\mathbb{F} = \mathbb{R}$. Let $n := N$ and

$$\begin{aligned} a &:= (a_1, \ldots, a_N)^T, \\ Q &:= aa^T + I_n \ \succ\ 0, \end{aligned}$$

where I_n denotes the $n \times n$ identity matrix.

We show that a subset $\mathcal{I}$ satisfying (4) exists if and only if the optimization problem (3) has a minimum value of n. Since

$$z^T Q z = |a^T z|^2 + \sum_{\ell=1}^{n} |z_\ell|^2 \geq n \quad \text{ whenever } \ |z_\ell| \geq 1 \ \forall\ \ell,\ z \in \mathbb{R}^n,$$

we see that (3) has a minimum value of n if and only if there exists a $z \in \mathbb{R}^n$ satisfying

$$a^T z = 0, \quad |z_\ell| = 1 \ \ \forall\ \ell.$$

The above condition is equivalent to the existence of a subset $\mathcal{I}$ satisfying (4), with the correspondence $\mathcal{I} = \{\ell \mid z_\ell = 1\}$. This completes the proof.

[1] This NP-hardness proof was first presented in an appendix of [20] and is included here for completeness; also see [26, Proposition 3.5] for a related proof.

2.2. The complex case. We consider the complex case of $\mathbb{F} = \mathbb{C}$. Let $n := 2N + 1$ and

$$\begin{aligned} a &:= (a_1, \ldots, a_N)^T, \\ A &:= \begin{pmatrix} I_N & I_N & -e_N \\ a^T & 0_N^T & -\frac{1}{2}a^T e_N \end{pmatrix}, \\ Q &:= A^T A + I_n \succ 0, \end{aligned}$$

where e_N denotes the N-dimensional vector of ones, 0_N denotes the N-dimensional vector of zeros, and I_n and I_N are identity matrices of sizes $n \times n$ and $N \times N$, respectively.

We show that a subset $\mathcal{I}$ satisfying (4) exists if and only if the optimization problem (3) has a minimum value of n. Since

$$z^H Q z = \|Az\|^2 + \sum_{\ell=1}^{n} |z_\ell|^2 \geq n \quad \text{whenever } |z_\ell| \geq 1 \ \forall\, \ell,\ z \in \mathbb{C}^n,$$

we see that (3) has a minimum value of n if and only if there exists a $z \in \mathbb{C}^n$ satisfying

$$Az = 0, \quad |z_\ell| = 1 \ \ \forall\, \ell.$$

Expanding $Az = 0$ gives the following set of linear equations:

$$0 = z_\ell + z_{N+\ell} - z_n, \quad \ell = 1, \ldots, N, \tag{5}$$

$$0 = \sum_{\ell=1}^{N} a_\ell z_\ell - \frac{1}{2}\left(\sum_{\ell=1}^{N} a_\ell\right) z_n. \tag{6}$$

For $\ell = 1, \ldots, 2N$, since $|z_\ell| = |z_n| = 1$ so that $z_\ell / z_n = e^{\mathbf{i}\theta_\ell}$ for some $\theta_\ell \in [0, 2\pi)$, we can rewrite (5) as

$$\begin{array}{rcll} \cos\theta_\ell + \cos\theta_{N+\ell} & = & 1, & \\ \sin\theta_\ell + \sin\theta_{N+\ell} & = & 0, & \ell = 1, \ldots, N. \end{array}$$

These equations imply that $\theta_\ell \in \{-\pi/3, \pi/3\}$ for all $\ell \neq n$. In fact, these equations further imply that $\cos\theta_\ell = \cos\theta_{N+\ell} = 1/2$ for $\ell = 1, \ldots, N$, so that

$$\mathrm{Re}\left(\sum_{\ell=1}^{N} a_\ell \frac{z_\ell}{z_n} - \frac{1}{2}\left(\sum_{\ell=1}^{N} a_\ell\right)\right) = 0.$$

Therefore, (6) is satisfied if and only if

$$\mathrm{Im}\left(\sum_{\ell=1}^{N} a_\ell \frac{z_\ell}{z_n} - \frac{1}{2}\left(\sum_{\ell=1}^{N} a_\ell\right)\right) = \mathrm{Im}\left(\sum_{\ell=1}^{N} a_\ell \frac{z_\ell}{z_n}\right) = 0,$$

which is further equivalent to the existence of a subset $\mathcal{I}$ satisfying (4), with the correspondence $\mathcal{I} = \{\ell \mid \theta_\ell = \pi/3\}$. This completes the proof.

3. Performance analysis of SDP relaxation. In this section, we study the performance of an SDP relaxation of (2). Let

$$H_i := \sum_{\ell \in \mathcal{I}_i} h_\ell h_\ell^H, \quad i = 1, \ldots, m.$$

The well-known SDP relaxation of (1) [11, 19] is

$$\begin{array}{rcll} \upsilon_{\text{sdp}} & := & \min & \text{Tr}(Z) \\ & & \text{s.t.} & \text{Tr}(H_i Z) \geq 1, \quad i = 1, \ldots, m, \\ & & & Z \succeq 0, \quad Z \in \mathbb{F}^{n \times n} \text{ is Hermitian.} \end{array} \tag{7}$$

An optimal solution of the SDP relaxation (7) can be computed efficiently using, say, interior-point methods; see [18] and references therein.

Clearly $\upsilon_{\text{sdp}} \leq \upsilon_{\text{qp}}$. We are interested in upper bounds for the relaxation performance of the form

$$\upsilon_{\text{qp}} \leq C \upsilon_{\text{sdp}},$$

where $C \geq 1$. Since we assume $H_i \neq 0$ for all i, it is easily checked that (7) has an optimal solution, which we denote by Z^*.

3.1. General steering vectors: The real case. We consider the real case of $\mathbb{F} = \mathbb{R}$. Upon obtaining an optimal solution Z^* of (7), we construct a feasible solution of (1) using the following randomization procedure:

1. Generate a random vector $\xi \in \mathbb{R}^n$ from the real-valued normal distribution $N(0, Z^*)$.
2. Let $z^*(\xi) = \xi / \min_{1 \leq i \leq m} \sqrt{\xi^T H_i \xi}$.

We will use $z^*(\xi)$ to analyze the performance of the SDP relaxation. Similar procedures have been used for related problems [1, 3, 4, 5, 14]. First, we need to develop two lemmas. The first lemma estimates the left-tail of the distribution of a convex quadratic form of a Gaussian random vector.

LEMMA 1. *Let $H \in \mathbb{R}^{n \times n}$, $Z \in \mathbb{R}^{n \times n}$ be two symmetric positive semidefinite matrices (i.e., $H \succeq 0$, $Z \succeq 0$). Suppose $\xi \in \mathbb{R}^n$ is a random vector generated from the real-valued normal distribution $N(0, Z)$. Then, for any $\gamma > 0$,*

$$\text{Prob}\left(\xi^T H \xi < \gamma E(\xi^T H \xi)\right) \leq \max\left\{\sqrt{\gamma}, \frac{2(\bar{r} - 1)\gamma}{\pi - 2}\right\}, \tag{8}$$

where $\bar{r} := \min\{\text{rank}(H), \text{rank}(Z)\}$.

Proof. Since the covariance matrix $Z \succeq 0$ has rank $r := \text{rank}(Z)$, we can write $Z = UU^T$, for some $U \in \mathbb{R}^{n \times r}$ satisfying $U^T Z U = I_r$. Let $\bar{\xi} := Q^T U^T \xi \in \mathbb{R}^r$, where $Q \in \mathbb{R}^{r \times r}$ is an orthogonal matrix corresponding to the eigen-decomposition of the matrix

$$U^T H U = Q \Lambda Q^T$$

for some diagonal matrix $\Lambda = \text{diag}\{\lambda_1, \lambda_2, \ldots, \lambda_r\}$ with $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_r \geq 0$. Since $U^T H U$ has rank at most $\bar{r}$, we have $\lambda_i = 0$ for all $i > \bar{r}$. It is readily checked

that $\bar{\xi}$ has the normal distribution $N(0, I_r)$. Moreover, ξ is statistically identical to $UQ\bar{\xi}$, so that $\xi^T H\xi$ is statistically identical to

$$\bar{\xi}^T Q^T U^T HUQ\bar{\xi} = \bar{\xi}^T \Lambda \bar{\xi} = \sum_{i=1}^{\bar{r}} \lambda_i |\bar{\xi}_i|^2.$$

Then we have

$$\begin{aligned}\text{Prob}\left(\xi^T H\xi < \gamma E(\xi^T H\xi)\right) &= \text{Prob}\left(\sum_{i=1}^{\bar{r}} \lambda_i |\bar{\xi}_i|^2 < \gamma E\left(\sum_{i=1}^{\bar{r}} \lambda_i |\bar{\xi}_i|^2\right)\right) \\ &= \text{Prob}\left(\sum_{i=1}^{\bar{r}} \lambda_i |\bar{\xi}_i|^2 < \gamma \sum_{i=1}^{\bar{r}} \lambda_i\right).\end{aligned}$$

If $\lambda_1 = 0$, then this probability is zero, which proves (8). Thus, we will assume that $\lambda_1 > 0$. Let $\bar{\lambda}_i := \lambda_i/(\lambda_1 + \cdots + \lambda_{\bar{r}})$ for $i = 1, \ldots, \bar{r}$. Clearly, we have

$$\bar{\lambda}_1 + \cdots + \bar{\lambda}_{\bar{r}} = 1, \quad \bar{\lambda}_1 \geq \bar{\lambda}_2 \geq \cdots \geq \bar{\lambda}_{\bar{r}} \geq 0.$$

We consider two cases. First, suppose $\bar{\lambda}_1 \geq \alpha$, where $0 < \alpha < 1$. Then, we can bound the above probability as follows:

$$\begin{aligned}\text{Prob}\left(\xi^T H\xi < \gamma E(\xi^T H\xi)\right) &= \text{Prob}\left(\sum_{i=1}^{\bar{r}} \bar{\lambda}_i |\bar{\xi}_i|^2 < \gamma\right) \\ &\leq \text{Prob}\left(\bar{\lambda}_1 |\bar{\xi}_1|^2 < \gamma\right) \\ &\leq \text{Prob}\left(|\bar{\xi}_1|^2 < \gamma/\alpha\right) \\ &\leq \sqrt{\frac{2\gamma}{\pi\alpha}},\end{aligned} \tag{9}$$

where the last step is due to the fact that $\bar{\xi}_1$ is a real-valued zero mean Gaussian random variable with unit variance.

In the second case, we have $\bar{\lambda}_1 < \alpha$, so that

$$\bar{\lambda}_2 + \cdots + \bar{\lambda}_{\bar{r}} = 1 - \bar{\lambda}_1 > 1 - \alpha.$$

This further implies $(\bar{r} - 1)\bar{\lambda}_2 \geq \bar{\lambda}_2 + \cdots + \bar{\lambda}_{\bar{r}} > 1 - \alpha$. Hence

$$\bar{\lambda}_1 \geq \bar{\lambda}_2 > \frac{1-\alpha}{\bar{r}-1}.$$

Using this bound, we obtain the following probability estimate:

$$\begin{aligned}\text{Prob}\left(\xi^T H\xi < \gamma E(\xi^T H\xi)\right) &= \text{Prob}\left(\sum_{i=1}^{\bar{r}} \bar{\lambda}_i |\bar{\xi}_i|^2 < \gamma\right) \\ &\leq \text{Prob}\left(\bar{\lambda}_1 |\bar{\xi}_1|^2 < \gamma,\ \bar{\lambda}_2 |\bar{\xi}_2|^2 < \gamma\right) \\ &= \text{Prob}\left(\bar{\lambda}_1 |\bar{\xi}_1|^2 < \gamma\right) \cdot \text{Prob}\left(\bar{\lambda}_2 |\bar{\xi}_2|^2 < \gamma\right) \\ &\leq \sqrt{\frac{2\gamma}{\pi\bar{\lambda}_1}} \cdot \sqrt{\frac{2\gamma}{\pi\bar{\lambda}_2}} \\ &\leq \frac{2(\bar{r}-1)\gamma}{\pi(1-\alpha)}.\end{aligned} \tag{10}$$

Combining the estimates for the above two cases and setting $\alpha = 2/\pi$, we immediately obtain the desired bound (8). ∎

LEMMA 2. *Let $\mathbb{F} = \mathbb{R}$. Let $Z^* \succeq 0$ be a feasible solution of* (7) *and let $z^*(\xi)$ be generated by the randomization procedure described earlier. Then, with probability* 1, *$z^*(\xi)$ is well defined and feasible for* (1). *Moreover, for every $\gamma > 0$ and $\mu > 0$,*

(11)
$$\text{Prob}\left(\min_{1\le i\le m} \xi^T H_i \xi \ge \gamma,\ \|\xi\|^2 \le \mu \text{Tr}(Z^*)\right) \ge 1 - m \cdot \max\left\{\sqrt{\gamma}, \frac{2(r-1)\gamma}{\pi - 2}\right\} - \frac{1}{\mu},$$

where $r := \text{rank}(Z^*)$.

Proof. Since $Z^* \succeq 0$ is feasible for (7), it follows that $\text{Tr}(H_i Z^*) \ge 1$ for all $i = 1, \ldots, m$. Since $E(\xi^T H_i \xi) = \text{Tr}(H_i Z^*) \ge 1$ and the density of $\xi^T H_i \xi$ is absolutely continuous, the probability of $\xi^T H_i \xi = 0$ is zero, implying that $z^*(\xi)$ is well defined with probability 1. The feasibility of $z^*(\xi)$ is easily verified.

To prove (11), we first note that $E(\xi\xi^T) = Z^*$. Thus, for any $\gamma > 0$ and $\mu > 0$,

$$\begin{aligned}
&\text{Prob}\left(\min_{1\le i\le m} \xi^T H_i \xi \ge \gamma,\ \|\xi\|^2 \le \mu \text{Tr}(Z^*)\right) \\
&\quad = \text{Prob}\left(\xi^T H_i \xi \ge \gamma\ \forall\, i = 1, \ldots, m \ \text{ and } \ \|\xi\|^2 \le \mu \text{Tr}(Z^*)\right) \\
&\quad \ge \text{Prob}\left(\xi^T H_i \xi \ge \gamma \text{Tr}(H_i Z^*)\ \forall\, i = 1, \ldots, m \ \text{ and } \ \|\xi\|^2 \le \mu \text{Tr}(Z^*)\right) \\
&\quad = \text{Prob}\left(\xi^T H_i \xi \ge \gamma E(\xi^T H_i \xi)\ \forall\, i = 1, \ldots, m \ \text{ and } \ \|\xi\|^2 \le \mu E(\|\xi\|^2)\right) \\
&\quad = 1 - \text{Prob}\left(\xi^T H_i \xi < \gamma E(\xi^T H_i \xi) \text{ for some } i \text{ or } \|\xi\|^2 > \mu E(\|\xi\|^2)\right) \\
&\quad \ge 1 - \sum_{i=1}^m \text{Prob}\left(\xi^T H_i \xi < \gamma E(\xi^T H_i \xi)\right) - \text{Prob}\left(\|\xi\|^2 > \mu E(\|\xi\|^2)\right) \\
&\quad > 1 - m \cdot \max\left\{\sqrt{\gamma}, \frac{2(r-1)\gamma}{\pi - 2}\right\} - \frac{1}{\mu},
\end{aligned}$$

where the last step uses Lemma 1 as well as Markov's inequality:

$$\text{Prob}\left(\|\xi\|^2 > \mu E(\|\xi\|^2)\right) \le \frac{1}{\mu}.$$

This completes the proof. ∎

We now use Lemma 2 to bound the performance of the SDP relaxation.

THEOREM 1. *Let $\mathbb{F} = \mathbb{R}$. For the QP* (1) *and its SDP relaxation* (7), *we have $\upsilon_{\text{qp}} = \upsilon_{\text{sdp}}$ if $m \le 2$, and otherwise*

$$\upsilon_{\text{qp}} \le \frac{27m^2}{\pi} \upsilon_{\text{sdp}}.$$

Proof. By applying a suitable rank reduction procedure if necessary, we can assume that the rank r of the optimal SDP solution Z^* satisfies $r(r+1)/2 \le m$; see, e.g., [17]. Thus $r < \sqrt{2m}$. If $m \le 2$, then $r = 1$, implying that $Z^* = z^*(z^*)^T$ for some $z^* \in \mathbb{R}^n$, and it is readily seen that z^* is an optimal solution of (1), so that $\upsilon_{\text{qp}} = \upsilon_{\text{sdp}}$. Otherwise, we apply the randomization procedure to Z^*. We also choose

$$\mu = 3, \quad \gamma = \frac{\pi}{4m^2}\left(1 - \frac{1}{\mu}\right)^2 = \frac{\pi}{9m^2}.$$

Then, it is easily verified using $r < \sqrt{2m}$ that

$$\sqrt{\gamma} \geq \frac{2(r-1)\gamma}{\pi - 2} \quad \forall\ m = 1, 2, \ldots .$$

Plugging these choices of γ and μ into (11), we see that there is a positive probability (independent of problem size) of at least

$$1 - m\sqrt{\gamma} - \frac{1}{\mu} = 1 - \frac{\sqrt{\pi}}{3} - \frac{1}{3} = 0.0758\ldots$$

that ξ generated by the randomization procedure satisfies

$$\min_{1 \leq i \leq m} \xi^T H_i \xi \geq \frac{\pi}{9m^2} \quad \text{and} \quad \|\xi\|^2 \leq 3\,\mathrm{Tr}(Z^*).$$

Let ξ be any vector satisfying these two conditions.[2] Then, $z^*(\xi)$ is feasible for (1), so that

$$\upsilon_{\mathrm{qp}} \leq \|z^*(\xi)\|^2 = \frac{\|\xi\|^2}{\min_i \xi^T H_i \xi} \leq \frac{3\,\mathrm{Tr}(Z^*)}{(\pi/9m^2)} = \frac{27m^2}{\pi}\,\upsilon_{\mathrm{sdp}},$$

where the last equality uses $\mathrm{Tr}(Z^*) = \upsilon_{\mathrm{sdp}}$. □

In the above proof, other choices of μ can also be used, but the resulting bound seems not as sharp. Theorem 1 suggests that the worst-case performance of the SDP relaxation deteriorates quadratically with the number of quadratic constraints. Below we give an example demonstrating that this bound is in fact tight up to a constant factor.

Example 1. For any $m \geq 2$ and $n \geq 2$, consider a special instance of (2), corresponding to (1) with $|\mathcal{I}_i| = 1$ (i.e., each H_i has rank 1), whereby

$$h_\ell = \left(\cos\left(\frac{\ell\pi}{m}\right), \sin\left(\frac{\ell\pi}{m}\right), 0, \ldots, 0\right)^T, \qquad \ell = 1, \ldots, m.$$

Let $z^* = (z_1^*, \ldots, z_n^*)^T \in \mathbb{R}^n$ be an optimal solution of (2) corresponding to the above choice of steering vectors h_ℓ. We can write

$$(z_1^*, z_2^*) = \rho(\cos\theta, \sin\theta) \quad \text{for some } \theta \in [0, 2\pi).$$

Since $\{\ell\pi/m,\ \ell = 1, \ldots, m\}$ is uniformly spaced on $[0, \pi)$, there must exist an integer ℓ such that

$$\text{either} \quad \left|\theta - \frac{\ell\pi}{m} - \frac{\pi}{2}\right| \leq \frac{\pi}{2m} \quad \text{or} \quad \left|\theta - \frac{\ell\pi}{m} + \frac{\pi}{2}\right| \leq \frac{\pi}{2m}.$$

For simplicity, we assume the first case. (The second case can be treated similarly.) Since the last $(n-2)$ entries of h_ℓ are zero, it is readily checked that

$$|h_\ell^T z^*| = \rho\left|\cos\left(\theta - \frac{\ell\pi}{m}\right)\right| = \rho\left|\sin\left(\theta - \frac{\ell\pi}{m} - \frac{\pi}{2}\right)\right| \leq \rho\left|\sin\left(\frac{\pi}{2m}\right)\right| \leq \frac{\rho\pi}{2m}.$$

[2] The probability that no such ξ is generated after N independent trials is at most $(1-0.0758..)^N$, which for $N = 100$ equals 0.000375.. Thus, such ξ requires relatively few trials to generate.

Since z^* satisfies the constraint $|h_\ell^T z^*| \geq 1$, it follows that

$$\|z^*\| \geq \rho \geq \frac{2m|h_\ell^T z^*|}{\pi} \geq \frac{2m}{\pi},$$

implying

$$\upsilon_{\rm qp} = \|z^*\|^2 \geq \frac{4m^2}{\pi^2}.$$

On the other hand, the positive semidefinite matrix

$$Z^* = \mathrm{diag}\{1, 1, 0, \ldots, 0\}$$

is feasible for the SDP relaxation (7), and it has an objective value of $\mathrm{Tr}(Z^*) = 2$. Thus, for this instance, we have

$$\upsilon_{\rm qp} \geq \frac{2m^2}{\pi^2}\, \upsilon_{\rm sdp}.$$

The preceding example and Theorem 1 show that the SDP relaxation (7) can be weak if the number of quadratic constraints is large, especially when the steering vectors h_ℓ are in a certain sense "uniformly distributed" in space.

3.2. General steering vectors: The complex case. We consider the complex case of $\mathbb{F} = \mathbb{C}$. We will show that the performance ratio of the SDP relaxation (7) improves to $O(m)$ in the complex case (as opposed to $O(m^2)$ in the real case). Similar to the real case, upon obtaining an optimal solution Z^* of (7), we construct a feasible solution of (1) using the following randomization procedure:

1. Generate a random vector $\xi \in \mathbb{C}^n$ from the *complex-valued* normal distribution $N_c(0, Z^*)$ [2, 26].
2. Let $z^*(\xi) = \xi / \min_{1\leq i\leq m} \sqrt{\xi^H H_i \xi}$.

Most of the ensuing performance analysis is similar to that of the real case. In particular, we will also need the following two lemmas analogous to Lemmas 1 and 2.

LEMMA 3. *Let $H \in \mathbb{C}^{n\times n}$, $Z \in \mathbb{C}^{n\times n}$ be two Hermitian positive semidefinite matrices (i.e., $H \succeq 0$, $Z \succeq 0$). Suppose $\xi \in \mathbb{C}^n$ is a random vector generated from the complex-valued normal distribution $N_c(0, Z)$. Then, for any $\gamma > 0$,*

$$\mathrm{Prob}\left(\xi^H H\xi < \gamma E(\xi^H H\xi)\right) \leq \max\left\{\frac{4}{3}\gamma, 16(\bar{r}-1)^2\gamma^2\right\}, \tag{12}$$

where $\bar{r} := \min\{\mathrm{rank}(H), \mathrm{rank}(Z)\}$.

Proof. We follow the same notations and proof as for Lemma 1, except for two blanket changes:

$$\begin{array}{rcl} \text{matrix transpose} & \rightarrow & \text{Hermitian transpose}, \\ \text{orthogonal matrix} & \rightarrow & \text{unitary matrix}. \end{array}$$

Also, $\bar{\xi}$ has the complex-valued normal distribution $N_c(0, I_r)$. With these changes, we consider the same two cases: $\bar{\lambda}_1 \geq \alpha$ and $\bar{\lambda}_1 < \alpha$, where $0 < \alpha < 1$. In the first case, we have similar to (9) that

$$\mathrm{Prob}\left(\xi^H H\xi < \gamma E(\xi^H H\xi)\right) \leq \mathrm{Prob}\left(|\bar{\xi}_1|^2 < \gamma/\alpha\right). \tag{13}$$

Recall that the density function of a complex-valued circular normal random variable $u \sim N_c(0, \sigma^2)$, where σ is the standard deviation, is

$$\frac{1}{\pi\sigma^2} e^{-\frac{|u|^2}{\sigma^2}} \quad \forall\ u \in \mathbb{C}.$$

In polar coordinates, the density function can be written as

$$f(\rho, \theta) = \frac{\rho}{\pi\sigma^2} e^{-\frac{\rho^2}{\sigma^2}} \quad \forall\ \rho \in [0, +\infty),\ \theta \in [0, 2\pi).$$

In fact, a complex-valued normal distribution can be viewed as a joint distribution of its modulus and its argument, with the following particular properties: (1) the modulus and argument are independently distributed; (2) the argument is uniformly distributed over $[0, 2\pi)$; (3) the modulus follows a Weibull distribution with density

$$f(\rho) = \begin{cases} \frac{2\rho}{\sigma^2} e^{-\frac{\rho^2}{\sigma^2}} & \text{if } \rho \geq 0; \\ 0 & \text{if } \rho < 0, \end{cases}$$

and distribution function

$$\text{Prob}\{|u| \leq t\} = 1 - e^{-\frac{t^2}{\sigma^2}}. \tag{14}$$

Since $\bar{\xi}_1 \sim N_c(0, 1)$, substituting this into (13) yields

$$\text{Prob}\left(\xi^H H\xi < \gamma E(\xi^H H\xi)\right) \leq \text{Prob}\left(|\bar{\xi}_1|^2 < \gamma/\alpha\right) \leq 1 - e^{-\gamma/\alpha} \leq \gamma/\alpha,$$

where the last inequality uses the convexity of the exponential function.

In the second case of $\bar{\lambda}_1 < \alpha$, we have similar to (10) that

$$\begin{aligned} \text{Prob}\left(\xi^H H\xi < \gamma E(\xi^H H\xi)\right) &\leq \text{Prob}\left(\bar{\lambda}_1|\bar{\xi}_1|^2 < \gamma\right) \cdot \text{Prob}\left(\bar{\lambda}_2|\bar{\xi}_2|^2 < \gamma\right) \\ &= (1 - e^{-\gamma/\bar{\lambda}_1})(1 - e^{-\gamma/\bar{\lambda}_2}) \\ &\leq \frac{\gamma^2}{\bar{\lambda}_1\bar{\lambda}_2} \\ &\leq \frac{(\bar{r} - 1)^2\gamma^2}{(1 - \alpha)^2}, \end{aligned}$$

where the last step uses the fact that $\bar{\lambda}_1 \geq \bar{\lambda}_2 \geq (1 - \alpha)/(\bar{r} - 1)$. Combining the estimates for the above two cases and setting $\alpha = 3/4$, we immediately obtain the desired bound (12). □

LEMMA 4. *Let $\mathbb{F} = \mathbb{C}$. Let $Z^* \succeq 0$ be a feasible solution of (7) and let $z^*(\xi)$ be generated by the randomization procedure described earlier. Then, with probability 1, $z^*(\xi)$ is well defined and feasible for (1). Moreover, for every $\gamma > 0$ and $\mu > 0$,*

$$\text{Prob}\left(\min_{1 \leq i \leq m} \xi^H H_i \xi \geq \gamma,\ \|\xi\|^2 \leq \mu \text{Tr}(Z^*)\right) \geq 1 - m \cdot \max\left\{\frac{4}{3}\gamma, 16(r-1)^2\gamma^2\right\} - \frac{1}{\mu},$$

where $r := \text{rank}(Z^*)$.

Proof. The proof is mostly the same as that for the real case (see Lemma 2). In particular, for any $\gamma > 0$ and $\mu > 0$, we still have

$$\begin{aligned} &\text{Prob}\left(\min_{1 \leq i \leq m} \xi^H H_i \xi \geq \gamma,\ \|\xi\|^2 \leq \mu \text{Tr}(Z^*)\right) \\ &\quad \geq 1 - \sum_{i=1}^{m} \text{Prob}\left(\xi^H H_i \xi < \gamma E(\xi^H H_i \xi)\right) - \text{Prob}\left(\|\xi\|^2 > \mu E(\|\xi\|^2)\right). \end{aligned}$$

Therefore, we can invoke Lemma 3 to obtain

$$\begin{aligned}
&\mathrm{Prob}\left(\min_{1\le i\le m} \xi^H H_i \xi \ge \gamma,\ \|\xi\|^2 \le \mu \mathrm{Tr}(Z^*)\right) \\
&\quad \ge 1 - m\cdot\max\left\{\frac{4}{3}\gamma, 16(r-1)^2\gamma^2\right\} - \mathrm{Prob}\left(\|\xi\|^2 > \mu E(\|\xi\|^2)\right) \\
&\quad \ge 1 - m\cdot\max\left\{\frac{4}{3}\gamma, 16(r-1)^2\gamma^2\right\} - \frac{1}{\mu},
\end{aligned}$$

which completes the proof. □

THEOREM 2. *Let $\mathbb{F} = \mathbb{C}$. For the QP* (1) *and its SDP relaxation* (7)*, we have $v_{\mathrm{sdp}} = v_{\mathrm{qp}}$ if $m \le 3$ and otherwise*

$$v_{\mathrm{qp}} \le 8m \cdot v_{\mathrm{sdp}}.$$

Proof. By applying a suitable rank reduction procedure if necessary, we can assume that the rank r of the optimal SDP solution Z^* satisfies $r = 1$ if $m \le 3$ and $r \le \sqrt{m}$ if $m \ge 4$; see [9, section 5]. Thus, if $m \le 3$, then $Z^* = z^*(z^*)^H$ for some $z^* \in \mathbb{C}^n$ and it is readily seen that z^* is an optimal solution of (1), so that $v_{\mathrm{sdp}} = v_{\mathrm{qp}}$. Otherwise, we apply the randomization procedure to Z^*. By choosing $\mu = 2$ and $\gamma = \frac{1}{4m}$, it is easily verified using $r \le \sqrt{m}$ that

$$\frac{4}{3}\gamma \ge 16(r-1)^2\gamma^2 \quad \forall\ m = 1, 2, \ldots .$$

Therefore, it follows from Lemma 4 that

$$\mathrm{Prob}\left\{\min_{1\le i\le m} \xi^H H_i \xi \ge \gamma,\ \|\xi\|^2 \le \mu \mathrm{Tr}(Z^*)\right\} \ge 1 - m\frac{4}{3}\gamma - \frac{1}{\mu} = \frac{1}{6}.$$

Then, similar to the proof of Theorem 1, we obtain that with probability of at least 1/6, $z^*(\xi)$ is a feasible solution of (1) and $v_{\mathrm{qp}} \le \|z^*(\xi)\|^2 \le 8m \cdot v_{\mathrm{sdp}}$.[3] □

The proof of Theorem 2 shows that by repeating the randomization procedure, the probability of generating a feasible solution with a performance ratio no more than $8m$ approaches 1 exponentially fast (independent of problem size). Alternatively, a derandomization technique from theoretical computer science can perhaps convert the above randomization procedure into a polynomial-time deterministic algorithm [12]; also see [14].

Theorem 2 shows that the worst-case performance of SDP relaxation deteriorates *linearly* with the number of quadratic constraints. This contrasts with the *quadratic* rate of deterioration in the real case (see Theorem 1). Thus, the SDP relaxation can yield better performance in the complex case. This is in the same spirit as the recent results in [26] which showed that the quality of SDP relaxation improves by a constant factor for certain quadratic *maximization* problems when the space is changed from $\mathbb{R}^n$ to $\mathbb{C}^n$. Below we give an example demonstrating that this approximation bound is tight up to a constant factor.

Example 2. For any $m \ge 2$ and $n \ge 2$, let $K = \lceil \sqrt{m} \rceil$ (so $K \ge 2$). Consider a special instance of (2), corresponding to (1) with $|\mathcal{I}_i| = 1$ (i.e., each H_i has rank 1),

[3] The probability that no such ξ is generated after N independent trials is at most $(5/6)^N$, which for $N = 30$ equals 0.00421.. Thus, such ξ requires relatively few trials to generate.

whereby

$$h_\ell = \left(\cos\frac{j\pi}{K}, \sin\frac{j\pi}{K} e^{\mathbf{i}\frac{2k\pi}{K}}, 0, \ldots, 0\right)^T \quad \text{with} \;\; \ell = jK - K + k, \qquad j,k = 1,\ldots,K.$$

Hence there are K^2 complex rank-1 constraints. Let $z^* = (z_1^*, \ldots, z_n^*)^T \in \mathbb{C}^n$ be an optimal solution of (2) corresponding to the above choice of $\lceil\sqrt{m}\rceil^2$ steering vectors h_ℓ. By a phase rotation if necessary, we can without loss of generality assume that z_1^* is real and write

$$(z_1^*, z_2^*) = \rho(\cos\theta, \sin\theta e^{\mathbf{i}\psi}) \quad \text{for some } \theta, \psi \in [0, 2\pi).$$

Since $\{2k\pi/K,\ k = 1,\ldots,K\}$ and $\{j\pi/K,\ j = 1,\ldots,K\}$ are uniformly spaced in $[0, 2\pi)$ and $[0, \pi)$, respectively, there must exist integers j and k such that

$$\left|\psi - \frac{2k\pi}{K}\right| \le \frac{\pi}{K} \quad \text{and} \quad \text{either } \left|\theta - \frac{j\pi}{K} - \frac{\pi}{2}\right| \le \frac{\pi}{2K} \text{ or } \left|\theta - \frac{j\pi}{K} + \frac{\pi}{2}\right| \le \frac{\pi}{2K}.$$

Without loss of generality, we assume

$$\left|\theta - \frac{j\pi}{K} - \frac{\pi}{2}\right| \le \frac{\pi}{2K}.$$

Since the last $(n-2)$ entries of each h_ℓ are zero, it is readily seen that for $\ell = jK-K+k$,

$$\begin{aligned}
\left|\mathrm{Re}(h_\ell^H z^*)\right| &= \rho\left|\cos\theta\cos\frac{j\pi}{K} + \sin\theta\sin\frac{j\pi}{K}\cos\left(\psi - \frac{2k\pi}{K}\right)\right| \\
&= \rho\left|\cos\left(\theta - \frac{j\pi}{K}\right) + \sin\theta\sin\frac{j\pi}{K}\left(\cos\left(\psi - \frac{2k\pi}{K}\right) - 1\right)\right| \\
&= \rho\left|\sin\left(\theta - \frac{j\pi}{K} - \frac{\pi}{2}\right) - 2\sin\theta\sin\frac{j\pi}{K}\sin^2\left(\frac{K\psi - 2k\pi}{2K}\right)\right| \\
&\le \rho\left|\sin\frac{\pi}{2K}\right| + 2\rho\sin^2\frac{\pi}{2K} \\
&\le \frac{\rho\pi}{2K} + \frac{\rho\pi^2}{2K^2}.
\end{aligned}$$

In addition, we have

$$\begin{aligned}
\left|\mathrm{Im}(h_\ell^H z^*)\right| &= \rho\left|\sin\theta\sin\frac{j\pi}{K}\sin\left(\psi - \frac{2k\pi}{K}\right)\right| \\
&\le \rho\left|\sin\left(\psi - \frac{2k\pi}{K}\right)\right| \\
&\le \rho\left|\psi - \frac{2k\pi}{K}\right| \le \frac{\rho\pi}{K}.
\end{aligned}$$

Combining the above two bounds, we obtain

$$\left|h_\ell^H z^*\right| \le \left|\mathrm{Re}(h_\ell^H z^*)\right| + \left|\mathrm{Im}(h_\ell^H z^*)\right| \le \frac{3\rho\pi}{2K} + \frac{\rho\pi^2}{2K^2}.$$

Since z^* satisfies the constraint $|h_\ell^H z^*| \ge 1$, it follows that

$$\|z^*\| \ge \rho \ge \frac{2K^2|h_\ell^H z^*|}{\pi(3K+\pi)} \ge \frac{2K^2}{\pi(3K+\pi)},$$

implying

$$v_{\rm qp} = \|z^*\|^2 \geq \frac{4K^4}{\pi^2(3K+\pi)^2} = \frac{4\lceil\sqrt{m}\rceil^4}{\pi^2(3\lceil\sqrt{m}\rceil+\pi)^2}.$$

On the other hand, the positive semidefinite matrix

$$Z^* = \mathrm{diag}\{1, 1, 0, \ldots, 0\}$$

is feasible for the SDP relaxation (7), and it has an objective value of $\mathrm{Tr}(Z^*) = 2$. Thus, for this instance, we have

$$v_{\rm qp} \geq \frac{2\lceil\sqrt{m}\rceil^4}{\pi^2(3\lceil\sqrt{m}\rceil+\pi)^2}\ v_{\rm sdp} \geq \frac{2m}{\pi^2(3+\pi/2)^2}\ v_{\rm sdp}.$$

The preceding example and Theorem 2 show that the SDP relaxation (7) can be weak if the number of quadratic constraints is large, especially when the steering vectors h_ℓ are in a certain sense uniformly distributed in space. In the next subsection, we will tighten the approximation bound in Theorem 2 by considering special cases where the steering vectors are not too spread out in space.

3.3. Specially configured steering vectors: The complex case. We consider the complex case of $\mathbb{F} = \mathbb{C}$. Let Z^* be any optimal solution of (7). Since Z^* is feasible for (7), $Z^* \neq 0$. Then

$$Z^* = \sum_{k=1}^{r} w_k w_k^H \tag{15}$$

for some nonzero $w_k \in \mathbb{C}^n$, where $r := \mathrm{rank}(Z^*) \geq 1$. By decomposing $w_k = u_k + v_k$, with $u_k \in \mathrm{span}\{h_1, \ldots, h_M\}$ and $v_k \in \mathrm{span}\{h_1, \ldots, h_M\}^\perp$, it is easily checked that $\tilde{Z} := \sum_{k=1}^r u_k u_k^H$ is feasible for (7) and

$$\langle I, Z^*\rangle = \sum_{k=1}^{r} \|u_k + v_k\|^2 = \sum_{k=1}^{r}(\|u_k\|^2 + \|v_k\|^2) = \langle I, \tilde{Z}\rangle + \sum_{k=1}^{r}\|v_k\|^2.$$

This implies $v_k = 0$ for all k, so that

$$w_k \in \mathrm{span}\{h_1, \ldots, h_M\}. \tag{16}$$

Below we show that the SDP relaxation (7) provides a *constant factor approximation* to the QP (1) when the phase spread of the entries of h_ℓ is bounded away from $\pi/2$.

THEOREM 3. *Suppose that*

$$h_\ell = \sum_{i=1}^{p} \beta_{i\ell} g_i \quad \forall\ \ell = 1, \ldots, M \tag{17}$$

for some $p \geq 1$, $\beta_{i\ell} \in \mathbb{C}$, and $g_i \in \mathbb{C}^n$ such that $\|g_i\| = 1$ and $g_i^H g_j = 0$ for all $i \neq j$. Then the following results hold:

(a) *If $\mathrm{Re}(\beta_{i\ell}^H \beta_{j\ell}) > 0$ whenever $\beta_{i\ell}^H \beta_{j\ell} \neq 0$, then $v_{\rm qp} \leq C v_{\rm sdp}$, where*

$$C := \max_{i,j,\ell\ |\ \beta_{i\ell}^H\beta_{j\ell}\neq 0} \left(1 + \frac{|\mathrm{Im}(\beta_{i\ell}^H\beta_{j\ell})|^2}{|\mathrm{Re}(\beta_{i\ell}^H\beta_{j\ell})|^2}\right)^{1/2}. \tag{18}$$

(b) *If* $\beta_{i\ell} = |\beta_{i\ell}|e^{\mathbf{i}\phi_{i\ell}}$, *where*

$$\phi_{i\ell} \in [\bar{\phi}_\ell - \phi, \bar{\phi}_\ell + \phi] \quad \forall\, i, \ell \ \text{ for some } 0 \le \phi < \frac{\pi}{4} \text{ and some } \bar{\phi}_\ell \in \mathbb{R}, \tag{19}$$

then $\mathrm{Re}(\beta_{i\ell}^H \beta_{j\ell}) > 0$ *whenever* $\beta_{i\ell}^H \beta_{j\ell} \neq 0$, *and* C *given by* (18) *satisfies*

$$C \le \frac{1}{\cos(2\phi)}. \tag{20}$$

Proof. (a) By (16), we have $w_k = \sum_{i=1}^p \alpha_{ki} g_i$ for some $\alpha_{ki} \in \mathbb{C}$. This together with (15) yields

$$\begin{aligned}\langle I, Z^* \rangle = \sum_{k=1}^r \|w_k\|^2 \ &= \ \sum_{k=1}^r \left\| \sum_{i=1}^p \alpha_{ki} g_i \right\|^2 \\ &= \sum_{k=1}^r \sum_{i=1}^p |\alpha_{ki}|^2 \ = \ \sum_{i=1}^p \lambda_i^2,\end{aligned}$$

where the third equality uses the orthonormal properties of $g_1, \ldots, g_p$, and the last equality uses $\lambda_i := \left(\sum_{k=1}^r |\alpha_{ki}|^2\right)^{1/2} = \|(\alpha_{ki})_{k=1}^r\|$.

Let $z^* := \sum_{i=1}^p \lambda_i g_i$. Then, the orthonormal properties of $g_1, \ldots, g_p$ yield

$$\|z^*\|^2 = \left\| \sum_{i=1}^p \lambda_i g_i \right\|^2 = \sum_{i=1}^p \lambda_i^2 = \langle I, Z^* \rangle = \upsilon_{\rm sdp}. \tag{21}$$

Moreover, for each $\ell \in \{1, \ldots, M\}$, we obtain from (15) that

$$\begin{aligned}\langle h_\ell h_\ell^H, Z^* \rangle &= \sum_{k=1}^r \langle h_\ell h_\ell^H, w_k w_k^H \rangle = \sum_{k=1}^r |h_\ell^H w_k|^2 \\ &= \sum_{k=1}^r \left| \sum_{i=1}^p \alpha_{ki} h_\ell^H g_i \right|^2 = \sum_{k=1}^r \left| \sum_{i=1}^p \alpha_{ki} \beta_{i\ell} \right|^2 \\ &= \mathrm{Re}\left(\sum_{k=1}^r \sum_{i=1}^p \sum_{j=1}^p \alpha_{ki}^H \alpha_{kj} \beta_{i\ell}^H \beta_{j\ell} \right) = \mathrm{Re}\left(\sum_{i=1}^p \sum_{j=1}^p \beta_{i\ell}^H \beta_{j\ell} \sum_{k=1}^r \alpha_{ki}^H \alpha_{kj} \right) \\ &= \sum_{i=1}^p \sum_{j=1}^p \mathrm{Re}\left(\beta_{i\ell}^H \beta_{j\ell} \sum_{k=1}^r \alpha_{ki}^H \alpha_{kj} \right) \\ &\le \sum_{i=1}^p \sum_{j=1}^p \left| \beta_{i\ell}^H \beta_{j\ell} \right| \left| \sum_{k=1}^r \alpha_{ki}^H \alpha_{kj} \right| \le \sum_{i=1}^p \sum_{j=1}^p \left| \beta_{i\ell}^H \beta_{j\ell} \right| \|(\alpha_{ki})_{k=1}^r\| \|(\alpha_{kj})_{k=1}^r\| \\ &= \sum_{i=1}^p \sum_{j=1}^p \left| \beta_{i\ell}^H \beta_{j\ell} \right| \lambda_i \lambda_j,\end{aligned}$$

where the fourth equality uses (17) and the orthonormal properties of $g_1, \ldots, g_p$; the last inequality is due to the Cauchy–Schwarz inequality. Then, it follows that

$$\begin{aligned}\langle h_\ell h_\ell^H, Z^* \rangle &\le \sum_{i=1}^p \sum_{j=1}^p \left(|\mathrm{Re}(\beta_{i\ell}^H \beta_{j\ell})|^2 + |\mathrm{Im}(\beta_{i\ell}^H \beta_{j\ell})|^2 \right)^{1/2} \lambda_i \lambda_j \\ &= \sum_{i=1}^p \sum_{j=1}^p \left| \mathrm{Re}(\beta_{i\ell}^H \beta_{j\ell}) \right| \left(1 + \frac{|\mathrm{Im}(\beta_{i\ell}^H \beta_{j\ell})|^2}{|\mathrm{Re}(\beta_{i\ell}^H \beta_{j\ell})|^2} \right)^{1/2} \lambda_i \lambda_j \\ &\le \sum_{i=1}^p \sum_{j=1}^p \left| \mathrm{Re}(\beta_{i\ell}^H \beta_{j\ell}) \right| C \lambda_i \lambda_j \\ &= \sum_{i=1}^p \sum_{j=1}^p \mathrm{Re}(\beta_{i\ell}^H \beta_{j\ell}) C \lambda_i \lambda_j,\end{aligned}$$

where the summation in the second step is taken over i, j with $\beta_{i\ell}^H \beta_{j\ell} \neq 0$, the third step is due to (18), and the last step is due to the assumption that $\mathrm{Re}(\beta_{i\ell}^H \beta_{j\ell}) > 0$ whenever $\beta_{i\ell}^H \beta_{j\ell} \neq 0$. Also, we have from (17) and the orthonormal properties of $g_1, \ldots, g_p$ that

$$|h_\ell^H z^*|^2 = \left\| \sum_{i=1}^p \lambda_i h_\ell^H g_i \right\|^2 = \left\| \sum_{i=1}^p \lambda_i \beta_{i\ell} \right\|^2 = \sum_{i=1}^p \sum_{j=1}^p \lambda_i \lambda_j \mathrm{Re}(\beta_{i\ell}^H \beta_{j\ell}).$$

Comparing the above two displayed equations, we see that

$$\langle h_\ell h_\ell^H, Z^* \rangle \le C |h_\ell^H z^*|^2, \quad \ell = 1, \ldots, M.$$

Since Z^* is feasible for (7), this shows that $\sqrt{C} z^*$ is feasible for (1), which further implies

$$v_{\mathrm{qp}} \le \left\| \sqrt{C} z^* \right\|^2 = C \|z^*\|^2 = C v_{\mathrm{sdp}}.$$

This proves the desired result.

(b) The condition (19) implies that $|\phi_{i\ell} - \phi_{j\ell}| \le 2\phi < \pi/2$. In other words, the phase angle spread of the entries of each $\beta_\ell = (\beta_{1\ell}, \beta_{2\ell}, \ldots, \beta_{n\ell})^T$ is no more than 2ϕ. This further implies that

$$\cos(\phi_{i\ell} - \phi_{j\ell}) \ge \cos(2\phi) \quad \forall\, i, j, \ell. \tag{22}$$

We have

$$\begin{aligned}\beta_{i\ell}^H \beta_{j\ell} &= |\beta_{i\ell}| e^{-\mathbf{i}\phi_{i\ell}} |\beta_{j\ell}| e^{\mathbf{i}\phi_{j\ell}} \\ &= |\beta_{i\ell}||\beta_{j\ell}| e^{\mathbf{i}(\phi_{j\ell} - \phi_{i\ell})} \\ &= |\beta_{i\ell}||\beta_{j\ell}| (\cos(\phi_{j\ell} - \phi_{i\ell}) + \mathbf{i} \sin(\phi_{j\ell} - \phi_{i\ell})).\end{aligned}$$

Since $|\phi_{i\ell} - \phi_{j\ell}| < \pi/2$ so that $\cos(\phi_{j\ell} - \phi_{i\ell}) > 0$, we see that $\mathrm{Re}(\beta_{i\ell}^H \beta_{j\ell}) > 0$ whenever $\beta_{i\ell}^H \beta_{j\ell} \neq 0$. Then

$$\left(1 + \frac{|\mathrm{Im}(\beta_{i\ell}^H \beta_{j\ell})|^2}{|\mathrm{Re}(\beta_{i\ell}^H \beta_{j\ell})|^2} \right)^{1/2} \le \left(1 + \tan^2(\phi_{j\ell} - \phi_{i\ell}) \right)^{1/2} = \frac{1}{\cos(\phi_{j\ell} - \phi_{i\ell})} \le \frac{1}{\cos(2\phi)},$$

where the last step uses (22). Using this in (18) completes the proof. ∎

In Theorem 3(b), we can more generally consider $\beta_{i\ell}$ of the form $\beta_{i\ell} = \omega_{i\ell} e^{\mathbf{i}\phi_{i\ell}}(1 + \mathbf{i}\theta_{i\ell})$, where $\omega_{i\ell} \geq 0$, $\alpha_{i\ell}$ satisfies (19), and

$$|\theta_{j\ell} - \theta_{i\ell}| \leq \sigma |1 + \theta_{i\ell}\theta_{j\ell}| \quad \forall\, i, j, \ell \ \text{ for some } \sigma \geq 0 \text{ with } \tan(2\phi)\sigma < 1. \tag{23}$$

Then the proof of Theorem 3(b) can be extended to show the following upper bound on C given by (18):

$$C \leq \frac{1}{\cos(2\phi)} \cdot \frac{\sqrt{1+\sigma^2}}{1 - \tan(2\phi)\sigma}. \tag{24}$$

However, this generalization is superficial as we can also derive (24) from (20) by rewriting $\beta_{i\ell}$ as

$$\beta_{i\ell} = |\beta_{i\ell}| e^{\mathbf{i}\tilde{\phi}_{i\ell}} \quad \text{with} \quad \tilde{\phi}_{i\ell} = \phi_{i\ell} + \tan^{-1}(\theta_{i\ell}).$$

Then, applying (20) yields $C \geq \cos(2\tilde{\phi})$, where $\tilde{\phi} = \max_{i,j,\ell} |\tilde{\phi}_{i\ell} - \tilde{\phi}_{j\ell}|/2$. Using trigonometric identity, it can be shown that $\cos(2\tilde{\phi})$ equals the right-hand side of (24) with $\sigma = \max_{\{i,j,\ell \ \mid \ \theta_{i\ell}\theta_{j\ell} \neq -1\}} |\theta_{j\ell} - \theta_{i\ell}|/|1 + \theta_{i\ell}\theta_{j\ell}|$.

Notice that Theorem 3(b) implies that if $\phi = 0$, then the SDP relaxation (7) is tight for the quadratically constrained QP (1) with $\mathbb{F} = \mathbb{C}$. Such is the case when all components of h_ℓ, $\ell = 1, \ldots, M$, are real and nonnegative.

4. A convex QP restriction. In this subsection, we consider a convex quadratic programming *restriction* of (2) in the complex case of $\mathbb{F} = \mathbb{C}$ and analyze its approximation bound. Let us write h_ℓ (the channel steering vector) as

$$h_\ell = (\ldots, |h_{j\ell}| e^{\mathbf{i}\phi_{j\ell}}, \ldots)_{j=1,\ldots,n}^T.$$

For any $\bar{\phi}_j \in [0, 2\pi)$, $j = 1, \ldots, n$, and any $\phi \in (0, \pi/2)$, define the four corresponding index subsets

$$\begin{aligned}
J_\ell^1 &:= \{j \mid \phi_{j\ell} \in [\bar{\phi}_j - \phi, \bar{\phi}_j + \phi]\},\\
J_\ell^2 &:= \{j \mid \phi_{j\ell} \in [\bar{\phi}_j - \phi + \pi/2, \bar{\phi}_j + \phi + \pi/2]\},\\
J_\ell^3 &:= \{j \mid \phi_{j\ell} \in [\bar{\phi}_j - \phi + \pi, \bar{\phi}_j + \phi + \pi]\},\\
J_\ell^4 &:= \{j \mid \phi_{j\ell} \in [\bar{\phi}_j - \phi + 3\pi/2, \bar{\phi}_j + \phi + 3\pi/2]\}
\end{aligned}$$

for $\ell = 1, \ldots, M$. The above four subsets are pairwise disjoint if and only if $\phi < \pi/4$ and are collectively exhaustive if and only if $\phi \geq \pi/4$. Choose an index subset J with the property that

$$\text{for each } \ell, \text{ at least one of } J_\ell^1,\ J_\ell^2,\ J_\ell^3,\ J_\ell^4 \text{ contains } J.$$

Of course, $J = \emptyset$ is always allowable, but we should choose J maximally since our approximation bound will depend on the ratio $n/|J|$ (see Theorem 4). Partition the constraint set index $\{1, \ldots, M\}$ into four subsets K^1, K^2, K^3, K^4 such that

$$J \subseteq J_\ell^k \quad \forall\, \ell \in K^k,\ k = 1,2,3,4.$$

Consider the following convex QP restriction of (2) corresponding to K^1, K^2, K^3, K^4:

$$\begin{array}{rcll} \upsilon_{\rm cqp} & := & \min & \|z\|^2 \\ & & \text{s.t.} & \mathrm{Re}(h_\ell^H z) \geq 1 \quad \forall\, \ell \in K^1, \\ & & & -\mathrm{Im}(h_\ell^H z) \geq 1 \quad \forall\, \ell \in K^2, \\ & & & -\mathrm{Re}(h_\ell^H z) \geq 1 \quad \forall\, \ell \in K^3, \\ & & & \mathrm{Im}(h_\ell^H z) \geq 1 \quad \forall\, \ell \in K^4. \end{array} \tag{25}$$

The above problem is a restriction of (2) because for any $z \in \mathbb{C}$,

$$\begin{aligned} |z| &\geq \max\{|\mathrm{Re}(z)|, |\mathrm{Im}(z)|\} \\ &= \max\{\mathrm{Re}(z), \mathrm{Im}(z), -\mathrm{Re}(z), -\mathrm{Im}(z)\}. \end{aligned}$$

If $J \neq \emptyset$ and $(\dots, h_{j\ell}, \dots)_{j\in J} \neq 0$ for $\ell = 1, \dots, M$, then (25) is feasible and hence has an optimal solution. Since (25) is a restriction of (2), $\upsilon_{\rm qp} \leq \upsilon_{\rm cqp}$. We have the following approximation bound.

THEOREM 4. *Suppose that $J \neq \emptyset$ and (25) is feasible. Then*

$$\upsilon_{\rm cqp} \leq \upsilon_{\rm qp}\ \frac{N}{\cos^2\phi} \max_{k=1,\dots,N} \left(\max_{j\in\hat{J}_k} \frac{\bar{\eta}_j}{\underline{\eta}_{\pi_k(j)}} \right)^2,$$

where $N := \lceil n/|J| \rceil$, $\bar{\eta}_j := \max_\ell |h_{j\ell}|$, $\underline{\eta}_j := \min_{\ell | h_{j\ell} \neq 0} |h_{j\ell}|$, $\hat{J}_1, \dots, \hat{J}_N$, is any partition of $\{1, \dots, n\}$ satisfying $|\hat{J}_k| \leq |J|$ for $k = 1, \dots, N$ and π_k is any injective mapping from $\hat{J}_k$ to J.

Proof. By making the substitution

$$z_j^{\rm new} \leftarrow z_j e^{\mathbf{i}\bar{\phi}_j},$$

we can without loss of generality assume that $\bar{\phi}_j = 0$ for all j and ℓ.

Let z^* denote an optimal solution of (2) and write

$$z^* = (\dots, r_j e^{\mathbf{i}\beta_j}, \dots)_{j=1,\dots,n}^T$$

with $r_j \geq 0$. Then, for any ℓ, we have from $|h_{j\ell}| \leq \bar{\eta}_j$ for all j that

$$1 \leq |h_\ell^H z^*| \leq r := \sum_{j=1}^n r_j \bar{\eta}_j.$$

Also, we have

$$\upsilon_{\rm qp} = \|z^*\|^2 = \sum_{j=1}^n r_j^2.$$

Define

$$R_k := \left(\sum_{j\in\hat{J}_k} r_j^2 \right)^{1/2}, \qquad S_k := \sum_{j\in\hat{J}_k} r_j \bar{\eta}_j.$$

Then

$$1 \le r = \sum_{k=1}^{N} S_k, \qquad v_{\rm qp} = \sum_{k=1}^{N} R_k^2.$$

Without loss of generality, assume that $R_1/S_1 = \min_k R_k/S_k$. Then, using the fact that

$$\min_k \frac{|x_k|}{|y_k|} \le \sqrt{N}\frac{\|x\|_2}{\|y\|_1}$$

for any $x, y \in \mathbb{R}^N$ with $y \neq 0$,[4] we see from the above relations that

$$\begin{aligned}\frac{R_1}{S_1} &\le \frac{R_1}{S_1} r \\ &\le \sqrt{N}\frac{\sqrt{v_{\rm qp}}}{r} r \\ &= \sqrt{N}\sqrt{v_{\rm qp}}.\end{aligned}$$

Since $|\hat{J}_1| \le |J|$, there is an injective mapping π from $\hat{J}_1$ to J. Let $\omega := \min_{j\in\hat{J}_1} \underline{\eta}_{\pi(j)}/\bar{\eta}_j$. Define the vector $\bar{z} \in \mathbb{C}^n$ by

$$\bar{z}_j := \begin{cases} r_{\pi^{-1}(j)}/(S_1\omega\cos\phi) & \text{if } j \in \pi(\hat{J}_1); \\ 0 & \text{else.}\end{cases}$$

Then,

$$\|\bar{z}\|^2 = \frac{R_1^2}{S_1^2\omega^2\cos^2\phi} \le \frac{N v_{\rm qp}}{\omega^2\cos^2\phi}.$$

Moreover, for each $\ell \in K^1$, since $\pi(\hat{J}_1) \subseteq J \subseteq J_\ell^1$, we have

$$\begin{aligned}\mathrm{Re}\left(h_\ell^H \bar{z}\right) &= \mathrm{Re}\left(\sum_{j\in\pi(\hat{J}_1)} h_{j\ell}^H \bar{z}_j\right) \\ &= \frac{1}{S_1\omega\cos\phi}\mathrm{Re}\left(\sum_{j\in\pi(\hat{J}_1)} r_{\pi^{-1}(j)}|h_{j\ell}|e^{-\mathbf{i}\phi_{j\ell}}\right) \\ &= \frac{1}{S_1\omega\cos\phi}\sum_{j\in\pi(\hat{J}_1)} r_{\pi^{-1}(j)}|h_{j\ell}|\cos\phi_{j\ell} \\ &\ge \frac{1}{S_1\omega\cos\phi}\sum_{j\in\pi(\hat{J}_1)} r_{\pi^{-1}(j)}\underline{\eta}_j\cos\phi \\ &= \frac{1}{S_1\omega}\sum_{j\in\hat{J}_1} r_j\bar{\eta}_j\,\frac{\underline{\eta}_{\pi(j)}}{\bar{\eta}_j} \\ &\ge \frac{1}{S_1\omega}\sum_{j\in\hat{J}_1} r_j\bar{\eta}_j\cdot\min_{j\in\hat{J}_1}\frac{\underline{\eta}_{\pi(j)}}{\bar{\eta}_j} \\ &= 1,\end{aligned}$$

[4] *Proof.* Suppose the contrary, so that for some $x, y \in \mathbb{R}^N$ with $y \neq 0$, we have $|x_k|/|y_k| > \sqrt{N}\|x\|_2/\|y\|_1$ for all k. Then, multiplying both sides by $|y_k|$ and summing over k yields $\|x\|_1 > \sqrt{N}\|x\|_2$, contradicting properties of 1- and 2-norms.

where the first inequality uses $|h_{j\ell}| \geq \underline{\eta}_j$ and $\phi_{j\ell} \in [-\phi, \phi]$ for $j \in J_\ell^1$. Since $\bar{z}_j = 0$ for $j \notin J_\ell^1$, this shows that $\bar{z}$ satisfies the first set of constraints in (25). A similar reasoning shows that $\bar{z}$ satisfies the remaining three sets of constraints in (25). □

Notice that the $\bar{z}$ constructed in the proof of Theorem 4 is feasible for the further restriction of (25) whereby $z_j = 0$ for all $j \notin J$. This further restricted problem has the same (worst-case) approximation bound specified in Theorem 4.

Let us compare the two approximation bounds in Theorems 3 and 4. First, the required assumptions are different. On the one hand, the bound in Theorem 3 does not depend on $|h_{j\ell}|$, while the bound in Theorem 4 does. On the other hand, Theorem 3 requires that the bounded angular spread

$$|\phi_{j\ell} - \phi_{i\ell}| \leq 2\phi \quad \forall\, j, \ell \tag{26}$$

for some $\phi < \pi/4$, while Theorem 4 allows $\phi < \pi/2$ and requires only the condition (26) for all $1 \leq \ell \leq M$ and $j \in J$, where J is a preselected index set. Thus, the bounded angular spread condition required in Theorem 3 corresponds exactly to $|J| = n$. Thus, the assumptions required in the two theorems do not imply one another. Second, the two performance ratios are also different. Naturally, the final performance ratio in Theorem 4 depends on the choice of J through the ratio $|J|/n$, so a large J is preferred. In the event that the assumptions of both theorems are satisfied and let us assume for simplicity that $\bar{\eta}_j = \underline{\eta}_j$ for all j, then $|J| = n$ and $\phi < \pi/4$, in which case Theorem 4 gives a performance ratio of $1/\cos^2\phi$ while Theorem 3 gives $1/\cos(2\phi)$. Since $\cos(2\phi) = \cos^2\phi - \sin^2\phi \leq \cos^2\phi$, we have $1/\cos(2\phi) \geq 1/\cos^2\phi$, showing that Theorem 4 gives a tighter approximation bound. However, this does not mean Theorem 4 is stronger than Theorem 3 since the two theorems hold under different assumptions in general.

We can specialize Theorem 4 to a typical situation in transmit beamforming. Consider a uniform linear transmit antenna array consisting of n elements, and let us assume that the M receivers are in a sector area from the far field and the propagation is line-of-sight. By reciprocity, each steering vector h_ℓ will be Vandermonde with generator $e^{-\mathbf{i}2\pi\frac{d}{\lambda}\sin\theta_\ell}$ (see, e.g., [10]), where d is the interantenna spacing, λ is the wavelength, and θ_ℓ is the angle of arrival of the ℓth receiving antenna. In a sector of approximately 60 degrees about the array broadside, we will have $|\theta_\ell| \leq \pi/3$. Suppose that $d/\lambda = 1/2$. Then the steering vector corresponding to the ℓth receiving antenna will have the form

$$h_\ell = (\ldots, e^{-\mathbf{i}(j-1)\pi\sin\theta_\ell}, \ldots)_{j=1,\ldots,n}^T.$$

In this case, we have that $\phi_{j\ell} = (j-1)\pi\sin\theta_\ell$ and $|h_{j\ell}| = 1$ for all j and ℓ. We can take, e.g.,

$$\bar{\phi}_j = 0, \quad \phi = \bar{j}\pi \max_\ell |\sin\theta_\ell|, \quad J = \{1, \ldots, \bar{j}+1\},$$

where $\bar{j} := \lfloor 1/\max_\ell |\sin\theta_\ell| \rfloor$. Thus, the assumptions of Theorem 4 are satisfied. Moreover, since $|\theta_\ell| \leq \pi/3$ for all ℓ, it follows that $|J| = \bar{j} + 1 \geq 2$. If n is not large, say, $n \leq 8$, then Theorem 4 gives a performance ratio of $n/(|J|\cos^2\phi) \leq 16$.

More generally, if we can choose the partition $\hat{J}_1, \ldots, \hat{J}_N$ and the mapping π_k in Theorem 4 such that

$$(\dots,\bar{\eta}_j,\dots)_{j\in\hat{J}_k} = (\dots,\underline{\eta}_{\pi_k(j)},\dots)_{j\in J} \quad \forall\, k,$$

then the performance ratio in Theorem 4 simplifies to $N/\cos^2\phi$. In particular, this holds when $|h_{j\ell}| = \eta > 0$ for all j and ℓ or when $J = \{1,\dots,n\}$ (so that $N = 1$) and $|h_{j\ell}|$ is independent of ℓ for all j, and, more generally, when the channel coefficients periodically repeat their magnitudes. In general, we should choose the partition $\hat{J}_1,\dots,\hat{J}_N$ and the mapping π_k to make the performance ratio in Theorem 4 small. For example, if $J = \hat{J}_1 = \{1,2\}$ and $\bar{\eta}_1 = 100$, $\bar{\eta}_2 = 10$, $\underline{\eta}_1 = 1$, $\underline{\eta}_2 = 10$, then $\pi_1(1) = 2, \pi_1(2) = 1$ is the better choice.

5. Homogeneous QP in maximization form. Let us now consider the following complex norm maximization problem with convex homogeneous quadratic constraints:

$$\begin{array}{rll} v_{\rm qp} := \max & \|z\|^2 & \\ \text{s.t.} & \displaystyle\sum_{\ell\in\mathcal{I}_i} |h_\ell^H z|^2 \le 1, & i = 1,\dots,m, \\ & z\in\mathbb{C}^n, & \end{array} \tag{27}$$

where $h_\ell \in \mathbb{C}^n$.

To motivate this problem, consider the problem of designing an intercept beamformer[5] capable of suppressing signals impinging on the receiving antenna array from irrelevant or hostile emitters, e.g., jammers, whose steering vectors (spatial signatures, or "footprints") have been previously estimated, while achieving as high gain as possible for all other transmissions. The jammer suppression capability is captured in the constraints of (27), and $|\mathcal{I}_i| > 1$ covers the case where a jammer employs more than one transmit antenna. The maximization of the objective $\|z\|^2$ can be motivated as follows. In intercept applications, the steering vector of the emitter of interest, h, is a priori unknown and is naturally modeled as random. A pertinent optimization objective is then the average beamformer output power, measured by $E[|h^H z|^2]$. Under the assumption that the entries of h are uncorrelated and have equal average power, it follows that $E[|h^H z|^2]$ is proportional to $\|z\|^2$, which is often referred to as the beamformer's *white noise gain*.

Similar to (1), we let

$$H_i := \sum_{\ell\in\mathcal{I}_i}^{m} h_\ell h_\ell^H$$

and consider the natural SDP relaxation of (27):

$$\begin{array}{rll} v_{\rm sdp} := \max & \mathrm{Tr}(Z) & \\ \text{s.t.} & \mathrm{Tr}(H_i Z) \le 1, & i = 1,\dots,m, \\ & Z \succeq 0, & Z \text{ is complex and Hermitian.} \end{array} \tag{28}$$

We are interested in lower bounds for the relaxation performance of the form

$$v_{\rm qp} \ge C\; v_{\rm sdp},$$

where $0 < C \le 1$. It is easily checked that (28) has an optimal solution.

Let Z^* be an optimal solution of (28). We will analyze the performance of the SDP relaxation using the following randomization procedure:

[5]Note that here we are talking about a receive beamformer, as opposed to our earlier motivating discussion of transmit beamformer design.

1. Generate a random vector $\xi \in \mathbb{C}^n$ from the *complex-valued* normal distribution $N_c(0, Z^*)$.
2. Let $z^*(\xi) = \xi / \max_{1 \le i \le m} \sqrt{\xi^H H_i \xi}$.

First, we need the following lemma analogous to Lemmas 1 and 3.

LEMMA 5. *Let $H \in \mathbb{C}^{n \times n}$, $Z \in \mathbb{C}^{n \times n}$ be two Hermitian positive semidefinite matrices (i.e., $H \succeq 0$, $Z \succeq 0$). Suppose $\xi \in \mathbb{C}^n$ is a random vector generated from the complex-valued normal distribution $N_c(0, Z)$. Then, for any $\gamma > 0$,*

$$\text{Prob}\left(\xi^H H \xi > \gamma E(\xi^H H \xi)\right) \le \bar{r}\ e^{-\gamma}, \tag{29}$$

where $\bar{r} := \min\{\text{rank}(H), \text{rank}(Z)\}$.

Proof. If $H = 0$, then (29) is trivially true. Suppose $H \neq 0$. Then, as in the proof of Lemma 1, we have

$$\text{Prob}\left(\xi^H H \xi > \gamma E(\xi^H H \xi)\right) = \text{Prob}\left(\sum_{i=1}^{\bar{r}} \bar{\lambda}_i |\bar{\xi}_i|^2 > \gamma\right),$$

where $\bar{\lambda}_1 \ge \bar{\lambda}_2 \ge \cdots \ge \bar{\lambda}_{\bar{r}} \ge 0$ satisfy $\bar{\lambda}_1 + \cdots + \bar{\lambda}_{\bar{r}} = 1$ and each $\bar{\xi}_i \in \mathbb{C}$ has the complex-valued normal distribution $N_c(0, 1)$. Then

$$\begin{aligned}
\text{Prob}\left(\xi^H H \xi > \gamma E(\xi^H H \xi)\right) &\le \text{Prob}\left(|\bar{\xi}_1|^2 > \gamma \text{ or } |\bar{\xi}_2|^2 > \gamma \text{ or } \cdots \text{ or } |\bar{\xi}_{\bar{r}}|^2 > \gamma\right) \\
&\le \sum_{i=1}^{\bar{r}} \text{Prob}\left(|\bar{\xi}_i|^2 > \gamma\right) \\
&= \bar{r}\ e^{-\gamma},
\end{aligned}$$

where the last step uses (14). □

THEOREM 5. *For the complex QP* (27) *and its SDP relaxation* (28)*, we have $v_{\text{sdp}} = v_{\text{qp}}$ if $m \le 3$ and otherwise*

$$v_{\text{qp}} \ge \frac{1}{4 \ln(100K)} v_{\text{sdp}},$$

where $K := \sum_{i=1}^m \min\{\text{rank}(H_i), \sqrt{m}\}$.

Proof. By applying a suitable rank reduction procedure if necessary, we can assume that the rank r of the optimal SDP solution Z^* satisfies $r = 1$ if $m \le 3$ and $r \le \sqrt{m}$ if $m \ge 4$; see [9, section 5]. Thus, if $m \le 3$, then $Z^* = z^*(z^*)^H$ for some $z^* \in \mathbb{C}^n$ and it is readily seen that z^* is an optimal solution of (27), so that $v_{\text{sdp}} = v_{\text{qp}}$. Otherwise, we apply the randomization procedure to Z^*. By using Lemma 5, we have, for any $\gamma > 0$ and $\mu > 0$,

$$\begin{aligned}
&\text{Prob}\left(\max_{1 \le i \le m} \xi^H H_i \xi \le \gamma,\ \|\xi\|^2 \ge \mu \text{Tr}(Z^*)\right) \\
&\ge 1 - \sum_{i=1}^m \text{Prob}\left(\xi^H H_i \xi > \gamma E(\xi^H H_i \xi)\right) - \text{Prob}\left(\|\xi\|^2 < \mu \text{Tr}(Z^*)\right) \\
&\ge 1 - K e^{-\gamma} - \text{Prob}\left(\|\xi\|^2 < \mu \text{Tr}(Z^*)\right), \qquad (30)
\end{aligned}$$

where the last step uses $r \le \sqrt{m}$.

Let

$$\eta_j := \begin{cases} |\xi_j|^2/Z^*_{jj} & \text{if } Z^*_{jj} > 0; \\ 0 & \text{if } Z^*_{jj} = 0, \end{cases} \quad j = 1, \ldots, n.$$

For simplicity, let us assume that $Z^*_{jj} > 0$ for all $j = 1, \ldots, n$. Since $\xi_j \sim N_c(0, Z^*_{jj})$, as we discussed in subsection 3.2, $|\xi_j|$ follows a Weibull distribution with variance Z^*_{jj} (see (14)), and therefore

$$\text{Prob}\,(\eta_j \leq t) = 1 - e^{-t} \quad \forall\, t \in [0, \infty).$$

Hence,

$$E(\eta_j) = \int_0^\infty te^{-t}dt = 1, \quad E(\eta_j^2) = \int_0^\infty t^2 e^{-t}dt = 2, \quad \text{Var}(\eta_j) = 1.$$

Moreover,

$$E(|\eta_j - E(\eta_j)|) = \int_0^1 (1-t)e^{-t}dt + \int_1^\infty (t-1)e^{-t}dt = \frac{2}{e}.$$

Let us denote $\lambda_j = Z^*_{jj}/\text{Tr}(Z^*)$, $j = 1, \ldots, n$, and $\eta := \sum_{j=1}^n \lambda_j \eta_j$. We have $E(\eta) = 1$ and

$$E(|\eta - E(\eta)|) = E\left(\left|\sum_{j=1}^n \lambda_j(\eta_j - E(\eta_j))\right|\right) \leq \sum_{j=1}^n \lambda_j E(|\eta_j - E(\eta_j)|) = \frac{2}{e}.$$

Since, by Markov's inequality,

$$\text{Prob}\,(|\eta - E(\eta)| > \alpha) \leq \frac{E(|\eta - E(\eta)|)}{\alpha} \leq \frac{2}{\alpha e} \quad \forall\, \alpha > 0,$$

we have

$$\begin{aligned} \text{Prob}\left(\|\xi\|^2 < \mu \text{Tr}(Z^*)\right) &= \text{Prob}\,(\eta < \mu) \\ &\leq \text{Prob}\,(|\eta - E(\eta)| > 1 - \mu) \\ &\leq \frac{2}{e(1-\mu)} \quad \forall\, \mu \in (0,1). \end{aligned}$$

Substituting the above inequality into (30), we obtain

$$\text{Prob}\left(\max_{1\leq i\leq m} \xi^H H_i \xi \leq \gamma,\ \|\xi\|^2 \geq \mu \text{Tr}(Z^*)\right) > 1 - \text{Ke}^{-\gamma} - \frac{2}{e(1-\mu)} \quad \forall\, \mu \in (0,1).$$

Setting $\mu = 1/4$ and $\gamma = \ln(100K)$ yields a positive right-hand side of 0.00898.., which then proves the desired bound. □

The above proof technique also applies to the real case, i.e., $h_\ell \in \mathbb{R}^n$ and $z \in \mathbb{R}^n$. The main difference is that $\xi \sim N(0, Z^*)$, so that $|\bar{\xi}_i|^2$ in the proof of Lemma 5 and η_j in the proof of Theorem 5 both follow a χ^2 distribution with one degree of freedom. Then

$$\text{Prob}\left(|\bar{\xi}_i|^2 > \gamma\right) = \int_{\sqrt{\gamma}}^\infty \frac{e^{-t^2/2}}{\sqrt{2\pi}}dt \leq \int_{\sqrt{\gamma}}^\infty \frac{e^{-\gamma t/2}}{\sqrt{2\pi}}dt = \sqrt{\frac{2}{\pi\gamma}}e^{-\gamma/2} \quad \forall\, \gamma > 0,$$

$E(\eta_j) = 1$, and

$$\begin{aligned} E|\eta_j - E(\eta_j)| &= \int_0^\infty \frac{e^{-t/2}}{\sqrt{2\pi t}}|t-1|dt \\ &= \frac{1}{\sqrt{2\pi}}\int_0^1 \frac{e^{-t/2}}{\sqrt{t}}dt - \frac{1}{\sqrt{2\pi}}\int_0^1 \sqrt{t}e^{-t/2}dt \\ &\quad + \frac{1}{\sqrt{2\pi}}\int_1^\infty \sqrt{t}e^{-t/2}dt - \frac{1}{\sqrt{2\pi}}\int_1^\infty \frac{e^{-t/2}}{\sqrt{t}}dt \\ &= \frac{4}{\sqrt{2\pi e}} < 0.968, \end{aligned}$$

where in the last step we used integration by parts on the first and the fourth terms. This yields the analogous bound that for any $\gamma \geq 1$ and $\mu \in (0,1)$,

$$\begin{aligned} \text{Prob}\left(\max_{1\leq i\leq m} \xi^T H_i \xi \leq \gamma,\ \|\xi\|^2 \geq \mu \text{Tr}(Z^*)\right) &> 1 - K\sqrt{\frac{2}{\pi\gamma}}e^{-\gamma/2} - \frac{0.968}{1-\mu} \\ &> 1 - Ke^{-\gamma/2} - \frac{0.968}{1-\mu}, \end{aligned}$$

where $K := \sum_{i=1}^m \min\{\text{rank}(H_i), \sqrt{2m}\}$. Setting $\mu = 0.01$ and $\gamma = 2\ln(50K)$ yields a positive right-hand side of 0.0022... This in turn shows that $v_{\text{sdp}} = v_{\text{qp}}$ if $m \leq 2$ (see the proof of Theorem 1) and otherwise

$$v_{\text{qp}} \geq \frac{1}{200\ln(50K)} v_{\text{sdp}}.$$

We note that, in the real case, a sharper bound of

$$v_{\text{qp}} \geq \frac{1}{2\ln(2m\mu)} v_{\text{sdp}},$$

where $\mu := \min\{m, \max_i \text{rank}(H_i)\}$, was shown by Nemirovski et al. [14] (also see [13, Theorem 4.7]), although the above proof seems simpler. Also, an example in [14] shows that the $O(1/\ln m)$ bound is tight (up to a constant factor) in the worst case. This example readily extends to the complex case by identifying $\mathbb{C}^n$ with $\mathbb{R}^{2n}$ and observing that $|h_\ell^H z| \geq |\text{Re}(h_\ell)^T \text{Re}(z) + \text{Im}(h_\ell)^T \text{Im}(z)|$ for any $h_\ell, z \in \mathbb{C}^n$. Thus, in the complex case, the $O(1/\ln m)$ bound is also tight (up to a constant factor).

6. Discussion. In this paper, we have analyzed the worst-case performance of SDP relaxation and convex restriction for a class of NP-hard quadratic optimization problems with homogeneous quadratic constraints. Our analysis is motivated by important emerging applications in transmit beamforming for physical layer multicasting and sensor localization in wireless sensor networks. Our generalization (1) of the basic problem in [20] is useful, for it shows that the same convex approximation approaches and bounds hold in the case where each multicast receiver is equipped with multiple antennas. This scenario is becoming more pertinent with the emergence of small and cheap multiantenna mobile terminals. Furthermore, our consideration of the related homogeneous QP maximization problem has direct application to the design of jam-resilient intercept beamformers. In addition to these timely topics, more traditional signal processing design problems can be cast in the same mathematical framework; see [20] for further discussions.

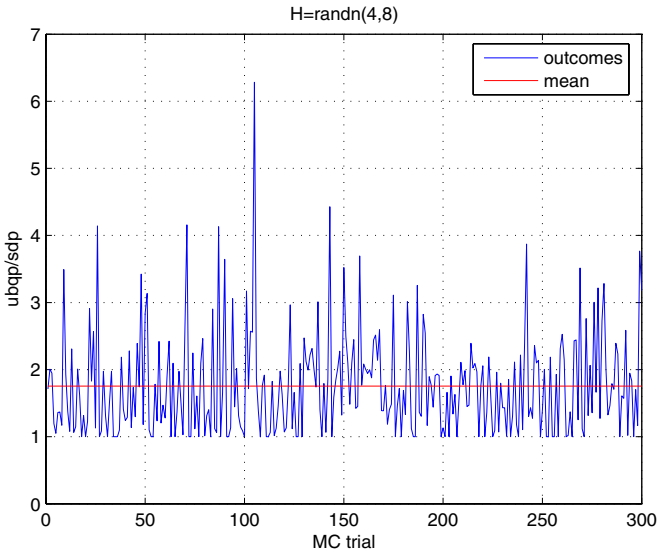

FIG. 1. *Upper bound on* $\frac{v_{\rm qp}}{v_{\rm sdp}}$ *for* $m = 8$, $n = 4$, 300 *realizations of real Gaussian i.i.d. steering vector entries, solution constrained to be real.*

While theoretical worst-case analysis is very useful, empirical analysis of the ratio $\frac{v_{\rm qp}}{v_{\rm sdp}}$ through simulations with randomly generated steering vectors $\{h_\ell\}$ is often equally important. In the context of transmit beamforming for multicasting [20] for the case $|\mathcal{I}_i| = 1$ for all i (single receiving antenna per subscriber node), simulations have provided the following insights:

- For moderate values of m, n (e.g., $m = 24$, $n = 8$), and independent and identically distributed (i.i.d.) complex-valued circular Gaussian (i.i.d. Rayleigh) entries of the steering vectors $\{h_\ell\}$, the average value of $\frac{v_{\rm qp}}{v_{\rm sdp}}$ is under 3—much lower than the worst-case value predicted by our analysis.
- In all generated instances where all steering vectors have positive real and imaginary parts, the ratio $\frac{v_{\rm qp}}{v_{\rm sdp}}$ equals one (with error below 10^{-8}). This is better than what our worst-case analysis predicts for limited phase spread (see Theorem 3).
- In experiments with measured VDSL channel data, for which the steering vectors follow a correlated log-normal distribution, $\frac{v_{\rm qp}}{v_{\rm sdp}} = 1$ in over 50% of instances.
- Our analysis shows that the worst-case performance ratio $\frac{v_{\rm qp}}{v_{\rm sdp}}$ is smaller in the complex case than in the real case ($O(m)$ versus $O(m^2)$). Moreover, this remains true with high probability when $v_{\rm qp}$ is replaced by its upper bound

$$v_{\rm ubqp} := \min_{k=1,\ldots,N} \|z^*(\xi^k)\|^2,$$

where $\xi^1, \ldots, \xi^N$ are generated by N independent trials of the randomization procedure (see subsections 3.1 and 3.2) and N is taken sufficiently large. In our simulation, we used $N = 30nm$. Figure 1 shows our simulation results

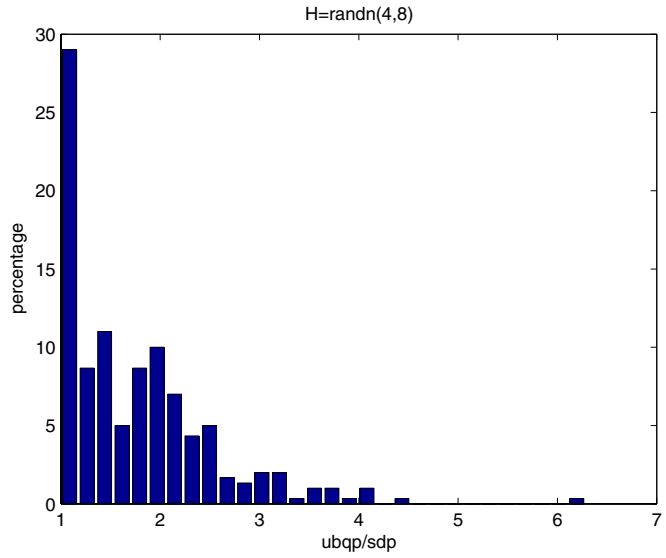

FIG. 2. *Histogram of the outcomes in Figure* 1.

for the real Gaussian case.[6] It plots $\frac{v_{\text{ubqp}}}{v_{\text{sdp}}}$ for 300 independent realizations of i.i.d. real-valued Gaussian steering vector entries for $m = 8$, $n = 4$. Figure 2 plots the corresponding histogram. Figures 3 and 4 show the corresponding results for i.i.d. complex-valued circular Gaussian steering vector entries.[7] Both the mean and the maximum of the upper bound $\frac{v_{\text{ubqp}}}{v_{\text{sdp}}}$ are lower in the complex case. The simulations indicate that SDP approximation is better in the complex case not only in the worst case but also on average.

The above empirical (worst-case and average-case) analysis complements our theoretical worst-case analysis of the performance of SDP relaxation for the class of problems considered herein.

Finally, we remark that our worst-case analysis of SDP performance is based on the assumption that the homogeneous quadratic constraints are concave (see (1)). Can we extend this analysis to general homogeneous quadratic constraints? The following example in $\mathbb{R}^2$ suggests that this is not possible.

Example 3. For any $L > 0$, consider the quadratic optimization problem with homogeneous quadratic constraints:

$$\begin{array}{ll} \min & \|z\|^2 \\ \text{s.t.} & z_2^2 \geq 1, \quad z_1^2 - L z_1 z_2 \geq 1, \quad z_1^2 + L z_1 z_2 \geq 1, \\ & z \in \mathbb{R}^2. \end{array} \tag{31}$$

The last two constraints imply $z_1^2 \geq L|z_1||z_2| + 1$ which, together with the first constraint $z_2^2 \geq 1$, yield $z_1^2 \geq L|z_1| + 1$ or, equivalently, $|z_1| \geq (L + \sqrt{L^2+4})/2$. So the optimal value of (31) is at least $1 + (L + \sqrt{L^2+4})^2/4$ (and in fact is equal to this).

[6]Here the SDP solution is constrained to be real-valued, and real Gaussian randomization is used.

[7]Here the SDP solutions are complex-valued, and complex Gaussian randomization is used.

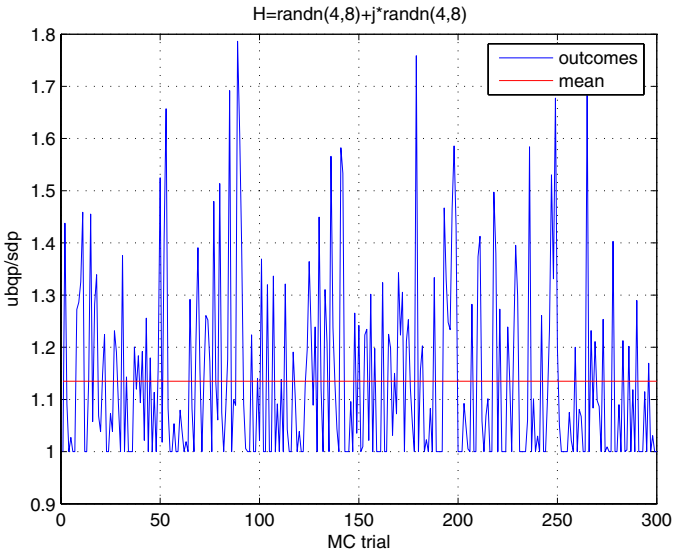

FIG. 3. *Upper bound on* $\frac{v_{\rm qp}}{v_{\rm sdp}}$ *for* $m = 8$, $n = 4$, 300 *realizations of complex Gaussian i.i.d. steering vector entries.*

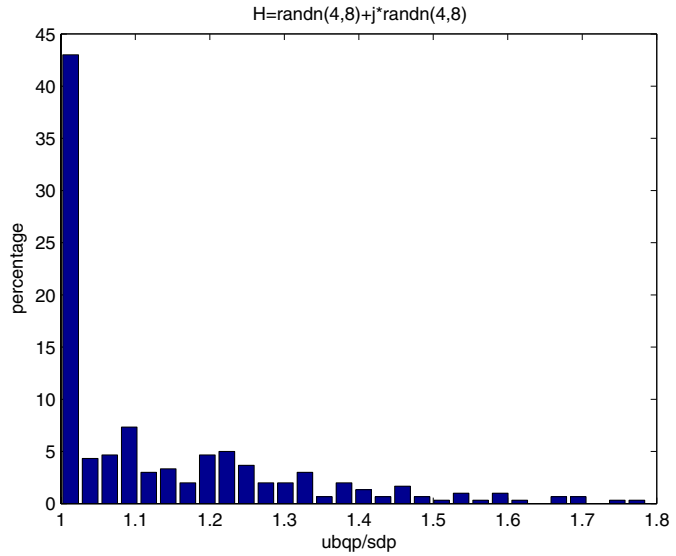

FIG. 4. *Histogram of the outcomes in Figure* 3.

The natural SDP relaxation of (31) is

$$\begin{array}{ll} \min & Z_{11} + Z_{22} \\ \text{s.t.} & Z_{22} \geq 1, \quad Z_{11} - LZ_{12} \geq 1, \quad Z_{11} + LZ_{12} \geq 1, \\ & Z \succeq 0. \end{array}$$

Clearly, $Z = I_2$ is a feasible solution (and, in fact, an optimal solution) of this SDP, with an objective value of 2. Therefore, the SDP performance ratio for this example is at least $1/2 + (L + \sqrt{L^2+4})^2/8$, which can be arbitrarily large.

A CONVERGENT INCREMENTAL GRADIENT METHOD WITH A CONSTANT STEP SIZE*

DORON BLATT†, ALFRED O. HERO‡, AND HILLEL GAUCHMAN§

Abstract. An incremental aggregated gradient method for minimizing a sum of continuously differentiable functions is presented. The method requires a single gradient evaluation per iteration and uses a constant step size. For the case that the gradient is bounded and Lipschitz continuous, we show that the method visits infinitely often regions in which the gradient is small. Under certain unimodality assumptions, global convergence is established. In the quadratic case, a global linear rate of convergence is shown. The method is applied to distributed optimization problems arising in wireless sensor networks, and numerical experiments compare the new method with other incremental gradient methods.

1. Introduction.

Consider the unconstrained optimization problem

$$\text{minimize} \qquad f(x) = \sum_{l=1}^{L} f_l(x), \quad x \in \mathbb{R}^p, \tag{1.1}$$

where $\mathbb{R}^p$ is the p-dimensional Euclidean space, and $f_l : \mathbb{R}^p \to \mathbb{R}$ are continuously differentiable scalar functions on $\mathbb{R}^p$. Our interest in this problem stems from optimization problems arising in wireless sensor networks (see, e.g., [9, 33, 36, 37, 38]), in which $f_l(x)$ corresponds to the data collected by the lth sensor in the network. This problem also arises in neural network training, in which $f_l(x)$ corresponds to the lth training data set (see, e.g., [7, 17, 18, 27, 28, 26]).

The iterative method proposed and analyzed in this paper for solving (1.1), which we call the *incremental aggregated gradient* (IAG) method, generates a sequence $\{x^k\}_{k\geq 1}$ as follows. Given L arbitrary initial points $x^1, x^2, \ldots, x^L$, an aggregated gradient, denoted by d^L, is defined as $\sum_{l=1}^{L} \nabla f_l(x^l)$. Possible initializations are discussed in section 3. For $k \geq L$,

$$x^{k+1} = x^k - \mu \frac{1}{L} d^k, \tag{1.2}$$

$$d^{k+1} = d^k - \nabla f_{(k+1)_L}(x^{k+1-L}) + \nabla f_{(k+1)_L}(x^{k+1}), \tag{1.3}$$

where μ is a positive constant step size chosen small enough to ensure convergence, $(k)_L$ denotes k modulo L with representative class $\{1, 2, \ldots, L\}$, and the factor $1/L$ is explicitly included to make the approximate descent direction $\frac{1}{L}d^k$ comparable in magnitude to the one used in the standard incremental gradient method to be discussed below. Thus, at every iteration a new point x^{k+1} is generated according to the direction of the aggregated gradient d^k. Then only one of the gradient summands $\nabla f_{(k+1)_L}(x^{k+1})$ is computed to replace the previously computed $\nabla f_{(k+1)_L}(x^{k+1-L})$. Note that for $k \geq L$ the IAG iteration (1.2)–(1.3) is equivalent to

$$x^{k+1} = x^k - \mu \frac{1}{L} \sum_{l=0}^{L-1} \nabla f_{(k-l)_L}(x^{k-l}). \tag{1.4}$$

The IAG method is related to the large class of incremental gradient methods that has been studied extensively in the literature [8, 17, 18, 19, 21, 25, 26, 28, 44] (see also [22, 32] and the references therein for incremental subgradient methods for nondifferentiable convex optimization). The standard incremental gradient method updates x^k according to

$$x^{k+1} = x^k - \mu(k) \nabla f_{(k)_L}(x^k), \tag{1.5}$$

where $\mu(k)$ is a positive step size, possibly depending on k. Therefore, it is seen that the principal difference between the two methods is that the standard incremental gradient method uses only one of the components in order to generate an approximate descent direction, whereas the IAG method uses the average of the L previously computed gradients. This property leads to convergence of the IAG method for fixed and sufficiently small positive step size μ. This is in contrast to the standard incremental gradient method, whose convergence requires that the step size sequence $\mu(k)$ converge to zero.

Incremental gradient methods can be motivated by the observation that when the iterates are far from the eventual limit, the evaluation of a single gradient component is sufficient for generating an approximate descent direction. Hence, these methods lead to a significant reduction in the amount of required computations per iteration (see, e.g., [6, sect. 1.5.2] and the discussion in [5]). The drawback of these methods, when using a constant step size, is that the iterates converge to a limit cycle and oscillate around a stationary point [25], unless restrictions of the type $\nabla f_l(x) = 0$, $l = 1, \ldots, L$, whenever $\nabla f(x) = 0$ are imposed [44]. Convergence for a diminishing step size has been established by a number of authors under different conditions [8, 17, 18, 21, 25, 26, 28, 44]. However, a diminishing step size usually leads to slow convergence near the eventual limit and requires exhaustive experimentation to determine how rapidly the step size must decrease in order to prevent scenarios in which the step size becomes too small when the iterates are far from the eventual limit (e.g., determining the constants a and b in step sizes of the form $\mu(k) = a/(k + b)$).

A hybrid between the steepest descent method and the incremental gradient method was studied in [5]. The hybrid method starts as an incremental gradient method and gradually becomes the steepest descent. This method requires a tuning parameter, which controls the transition between the two methods, to gradually increase with k to ensure convergence. When the tuning parameter increases sufficiently fast with the number of iterations, it is shown that the rate of convergence is linear. However, the question of determining the rate of transition between the two methods still remains. For any fixed value of the tuning parameter, the hybrid method con-

verges to a limit cycle, unless a diminishing step size is used, similar to the standard incremental gradient method.

The choice of the aggregated gradient d^k (1.3) for generating an approximate descent direction was mentioned in [18] in the context of adaptive step size methods, which require repeated evaluations of either the complete objective function $f(x)$ or its gradient. This requirement renders the methods proposed in [18] inapplicable to problems in sensor networks of interest to us or any other applications which require decentralized implementation, as will be explained in section 3. In addition, as noted in [46], if $\nabla f_l(x)$, $l = 1, \ldots, L$, are not necessarily zero whenever $\nabla f(x) = 0$, the step size tends to zero, resulting in slow convergence.

The IAG method is closely related to Tseng's incremental gradient with momentum term [46], which is an incremental generalization of Polyak's heavy-ball method [34, p. 65] (also called the steepest descent with momentum term [7, p. 104]). Rewriting Tseng's method's update rule as

$$x^{k+1} = x^k - \mu(k) \sum_{l=0}^{k} \zeta^l \nabla f_{(k-l)_L}(x^{k-l}),$$

we see from (1.4) that the IAG method is a variation of this method with a truncated sum, $\zeta = 1$, and a constant step size. Similar to [18], the step size adaptation rule that leads to convergence in [46] requires repeated evaluations of the complete objective function $f(x)$ and its gradient. Hence, this method cannot be implemented in a distributed manner either. Furthermore, a linear convergence rate is established only under a certain growth property on the functions' gradients, which requires $\nabla f_l(x) = 0$, $l = 1, \ldots, L$, whenever $\nabla f(x) = 0$.

In contrast to the available methods, the IAG method has all four of the following properties: (a) it evaluates a single gradient per iteration, (b) it uses a constant step size, (c) it is convergent (Proposition 2.7), and (d) it has a global linear convergence rate for quadratic objective $f(x)$ (Proposition 2.8).

Finally, we note that the IAG method is reminiscent of other methods in various optimization problems, such as the incremental version of the Gauss–Newton method or the extended Kalman filter [2, 4, 15, 30], the distributed EM algorithm for maximum likelihood estimation [31, 33], the ordered subset and incremental optimization transfer for image reconstruction [1, 3, 10], and iterative methods for the convex feasibility problem [11, 12].

2. Convergence analysis. In this section we present convergence proofs for two different function classes: (I) restricted Lipschitz and (II) quadratic. Under a Lipschitz condition and a bounded gradient assumption on $f_l(x)$, $l = 1, \ldots, L$ (Assumptions 1 and 2), we obtain an upper bound on the limit inferior of $||\nabla f(x^k)||$, which depends linearly on the step size μ. By imposing additional restrictions on the function $f(x)$ (Assumptions 3 and 4), we prove pointwise convergence of the method. There are many functions that satisfy Assumptions 1–4. However, one important case does not satisfy these assumptions. This is the case when $f(x)$ and $f_l(x)$ are quadratic functions on $\mathbb{R}^p$. For this important case we provide a completely different convergence proof and show in addition that the convergence rate is globally linear.

For later reference, it will be useful to write (1.4) in a form known as the "gradient

method with errors" [8]:

$$x^{k+1} = x^k - \mu\frac{1}{L}\left[\sum_{l=0}^{L-1}\nabla f_{(k-l)_L}(x^k) + \sum_{l=0}^{L-1}\nabla f_{(k-l)_L}(x^{k-l}) - \sum_{l=0}^{L-1}\nabla f_{(k-l)_L}(x^k)\right]$$

$$= x^k - \mu\frac{1}{L}\left[\nabla f(x^k) + h^k\right], \tag{2.1}$$

where

$$h^k = \sum_{l=1}^{L-1}\left[\nabla f_{(k-l)_L}(x^{k-l}) - \nabla f_{(k-l)_L}(x^k)\right]$$

is the error term in the calculation of the gradient at x^k. Also note that for all $k \geq 2L$ and $1 \leq l \leq L$,

$$x^{k-l} - x^k = \mu\frac{1}{L}\left(d^{k-1} + d^{k-2} + \cdots + d^{k-l}\right).$$

2.1. Case I.

Assumption 1. $\nabla f_l(x)$, $l = 1, \ldots, L$, satisfy a Lipschitz condition in $\mathbb{R}^p$; i.e., there is a positive number M_1 such that for all $x, \overline{x} \in \mathbb{R}^p$, $||\nabla f_l(x) - \nabla f_l(\overline{x})|| \leq M_1||x - \overline{x}||$, $l = 1, \ldots, L$.

Assumption 1 implies that $\nabla f(x)$ also satisfies a Lipschitz condition; that is, for all $x, \overline{x} \in \mathbb{R}^p$, $||\nabla f(x) - \nabla f(\overline{x})|| \leq M_2||x - \overline{x}||$, where $M_2 = LM_1$.

Assumption 2. There exists a positive number M_3 such that for all $x \in \mathbb{R}^p$, $||\nabla f_l(x)|| \leq M_3$, $l = 1, \ldots, L$.

Assumption 2 implies that for all $x \in \mathbb{R}^p$, $||\nabla f(x)|| \leq M_4$, where $M_4 = LM_3$.

LEMMA 2.1. *Let $\{s_k\}_{k\geq 1}$ be a sequence of nonnegative real numbers satisfying for some fixed integer $L > 1$ and all $k \geq L$*

$$s_k \leq cQ(s_{k-1}, s_{k-2}, \ldots, s_{k-L+1}) + M,$$

where $0 < c < 1$, M is nonnegative, and $Q(s_{k-1}, s_{k-2}, \ldots, s_{k-L+1})$ is a linear form in the variables $s_{k-1}, s_{k-2}, \ldots, s_{k-L+1}$, whose coefficients are nonnegative and the sum of the coefficients equals one. Then $\limsup_{k\to\infty} s_k \leq \frac{M}{1-c}$.

Proof. Define the sequence $\{w_k\}_{k\geq 1}$ by $w_k = s_k$ for $1 \leq k \leq L-1$ and

$$w_k = cQ(w_{k-1}, w_{k-2}, \ldots, w_{k-L+1}) + M$$

for $k \geq L$. Since $s_k \leq w_k$ for all k, if $\lim_{k\to\infty} w_k = \frac{M}{1-c}$, then

$$\limsup_{k\to\infty} s_k \leq \limsup_{k\to\infty} w_k = \lim_{k\to\infty} w_k = \frac{M}{1-c}.$$

To show that $\lim_{k\to\infty} w_k = \frac{M}{1-c}$, define the sequence $\{v_k\}_{k\geq 1}$ by $v_k = s_k - \frac{M}{1-c}$ for $1 \leq k \leq L-1$ and

$$v_k = cQ(v_{k-1}, v_{k-2}, \ldots, v_{k-L+1})$$

for $k \geq L$. By this construction,

$$w_L = cQ\left(\frac{M}{1-c} + v_{L-1}, \frac{M}{1-c} + v_{L-2}, \ldots, \frac{M}{1-c} + v_1\right) + M$$

$$= c\frac{M}{1-c} + cQ(v_{L-1}, v_{L-2}, \ldots, v_1) + M = \frac{M}{1-c} + v_L,$$

and, by induction, $w_k = \frac{M}{1-c} + v_k$ for all $k > L$. Therefore, if $\lim_{k\to\infty} v_k = 0$, then $\lim_{k\to\infty} w_k = \frac{M}{1-c}$. To show that $\lim_{k\to\infty} v_k = 0$, set $A = \max\{|v_1|, |v_2|, \ldots, |v_{L-1}|\}$. Hence,

$$|v_L| = c|Q(v_{L-1}, v_{L-2}, \ldots, v_1)| \leq cQ(|v_{L-1}|, |v_{L-2}|, \ldots, |v_1|) \leq cA.$$

Similarly, $|v_{L+1}| \leq cA$, and in general $|v_k| \leq cA$ for all $k \geq L$. Consider now v_{2L}. Since $\max\{|v_{2L-1}|, |v_{2L-2}|, \ldots, |v_{L+1}|\} \leq cA$, we have

$$|v_{2L}| = c|Q(v_{2L-1}, v_{2L-2}, \ldots, v_{L+1})| \leq cQ(|v_{2L-1}|, |v_{2L-2}|, \ldots, |v_{L+1}|) \leq c^2 A,$$

and in general $|v_k| \leq c^2 A$ for all $k \geq 2L$. Similarly, we obtain $|v_k| \leq c^n L$ for all $k \geq nL$. Since $0 < c < 1$, we have $\lim_{n\to\infty} c^n = 0$, and therefore $\lim_{k\to\infty} v_k = 0$. □

Remark 1. Lemma 2.1 can also be proven using concepts from dynamical systems. The sequence w_k is the output of an autoregressive linear system

$$w_k = c\sum_{l=1}^{L-1} \alpha_k w_{k-l} + Mu(k-L),$$

where $u(k)$ is the unit step function which equals one when $k \geq 0$ and zero otherwise, with initial condition $w_k = s_k$ for $1 \leq k \leq L-1$. Since the coefficients of the linear form are all positive and sum to one, and $0 < c < 1$, it is possible to show that the system is stable (bounded input bounded output) and the steady state response is $\frac{M}{1-c}$ [35], i.e., $\lim_{k\to\infty} w_k = \frac{M}{1-c}$.

LEMMA 2.2. *Under Assumption* 1, *if* $||\nabla f(x^k)|| > \frac{||h^k||}{1-2\mu M_1}$, *and* $0 < 1-2\mu M_1 < 1$, *then* $f(x^k) > f(x^{k+1})$.

Proof. Assume that $||\nabla f(x^k)|| > \frac{||h^k||}{1-2\mu M_1}$. Then

$$\begin{aligned} ||d^k||^2 = ||\nabla f(x^k) + h^k||^2 &\leq 2||\nabla f(x^k)||^2 + 2||h^k||^2 \\ &< 2||\nabla f(x^k)||^2 + 2\frac{||h^k||^2}{1-2\mu M_1} < 4||\nabla f(x^k)||^2. \end{aligned}$$

By [6, Prop. A.24], if Assumption 1 holds, then

$$f(x+y) - f(x) \leq y'\nabla f(x) + \frac{1}{2}M_2||y||^2.$$

Hence

$$\begin{aligned} f(x^k) - f(x^{k+1}) &= f(x^k) - f\left(x^k - \mu\frac{1}{L}d^k\right) \\ &\geq \mu\frac{1}{L}d^{k\prime}\nabla f(x^k) - \frac{1}{2}M_2\mu^2\frac{1}{L^2}||d^k||^2 \\ &> \mu\frac{1}{L}(\nabla f(x^k) + h^k)'\nabla f(x^k) - \frac{1}{2}M_2\mu^2\frac{1}{L^2}4||\nabla f(x^k)||^2 \\ &= \mu\frac{1}{L}||\nabla f(x^k)||^2 + \mu\frac{1}{L}h^{k\prime}\nabla f(x^k) - 2M_2\mu^2\frac{1}{L^2}||\nabla f(x^k)||^2 \\ &\geq \mu\frac{1}{L}||\nabla f(x^k)||^2 - \mu\frac{1}{L}||h^k|| \cdot ||\nabla f(x^k)|| - 2M_2\mu^2\frac{1}{L^2}||\nabla f(x^k)||^2 \\ &= \frac{\mu}{L}||\nabla f(x^k)||(1-2\mu M_1)\left(||\nabla f(x^k)|| - \frac{||h^k||}{1-2\mu M_1}\right) \\ &> 0. \end{aligned}$$

□

LEMMA 2.3. *Set $\delta_0 = \mu M_2 M_3$. Under Assumptions 1 and 2, if $\mu M_2 < 1$, there exists K such that for all $k > K$, $||h^k|| < \delta_0$.*

Proof.

$$\begin{aligned}
||h^k|| &\leq \sum_{l=1}^{L-1} ||\nabla f_{(k-l)_L}(x^{k-l}) - \nabla f_{(k-l)_L}(x^k)|| \\
&\leq M_1 \sum_{l=1}^{L-1} ||x^{k-l} - x^k|| \\
&= \mu M_1 \frac{1}{L} \sum_{l=1}^{L-1} ||d^{k-1} + d^{k-2} + \cdots + d^{k-l}|| \\
&\leq \mu M_1 \frac{1}{L} \sum_{l=1}^{L-1} \left(||d^{k-1}|| + ||d^{k-2}|| + \cdots + ||d^{k-l}|| \right) \\
&= \mu M_1 \frac{1}{L} \left[(L-1)||d^{k-1}|| + (L-2)||d^{k-2}|| + \cdots + ||d^{k-L+1}|| \right] \\
&= \mu M_1 \frac{1}{L} \frac{L(L-1)}{2} \left[\frac{(L-1)||d^{k-1}|| + (L-2)||d^{k-2}|| + \cdots + ||d^{k-L+1}||}{L(L-1)/2} \right] \\
&= \mu M_1 \frac{L-1}{2} Q(||d^{k-1}||, ||d^{k-2}||, \ldots, ||d^{k-L+1}||),
\end{aligned}$$

where $Q(||d^{k-1}||, ||d^{k-2}||, \ldots, ||d^{k-L+1}||)$ is a linear form in the variables $||d^{k-1}||$, $||d^{k-2}||, \ldots, ||d^{k-L+1}||$ whose coefficients, $\frac{L-1}{L(L-1)/2}, \frac{L-2}{L(L-1)/2}, \ldots, \frac{1}{L(L-1)/2}$, sum to one. Next, we use $||d^k|| = ||\nabla f(x^k) + h^k|| \leq ||\nabla f(x^k)|| + ||h^k||$ to obtain

$$\begin{aligned}
||h^k|| &\leq \mu M_1 \frac{L-1}{2} Q(||h^{k-1}||, ||h^{k-2}||, \ldots, ||h^{k-L+1}||) \\
&\quad + \mu M_1 \frac{L-1}{2} Q(||\nabla f(x^{k-1})||, ||\nabla f(x^{k-2})||, \ldots, ||\nabla f(x^{k-L+1})||) \\
&\leq \mu M_1 \frac{L-1}{2} Q(||h^{k-1}||, ||h^{k-2}||, \ldots, ||h^{k-L+1}||) + \mu M_1 \frac{L-1}{2} M_3 \\
&< \mu \frac{M_2}{2} Q(||h^{k-1}||, ||h^{k-2}||, \ldots, ||h^{k-L+1}||) + \mu \frac{M_2}{2} M_3,
\end{aligned}$$

where Assumption 2 was used in the second to last inequality. Hence, by Lemma 2.1, since $0 < \mu \frac{M_2}{2} < 1/2$, $\limsup_{k\to\infty} ||h^k|| \leq \frac{\mu \frac{M_2}{2} M_3}{1 - \mu \frac{M_2}{2}}$. By using $\mu \frac{M_2}{2} < 1/2$, we obtain $\limsup_{k\to\infty} ||h^k|| < \mu M_2 M_3$ and the lemma follows. ∎

PROPOSITION 2.4. *Under Assumptions 1 and 2, if $f(x)$ is bounded from below and $\mu \max\{2M_1, M_2\} < 1$, then*

$$\liminf_{k\to\infty} ||\nabla f(x^k)|| \leq \frac{2M_2 M_3}{1 - 2\mu M_1} \mu.$$

Proof. The proof is similar to the proof of Theorem 2.1 in [44]. ∎

Next, by imposing two additional assumptions, we prove that the IAG method converges with a constant step size to the minimum point of $f(x)$.

Assumption 3. $f(x)$ has a unique global minimum at x^*. The Hessian $\nabla^2 f(x)$ is continuous and positive definite at x^*.

Assumption 4. For any sequence $\{t^k\}_{k=1}^{\infty}$ in $\mathbb{R}^p$, if $\lim_{k\to\infty} f(t^k) = f(x^*)$ or $\lim_{k\to\infty} ||\nabla f(t^k)|| = 0$, then $\lim_{k\to\infty} t^k = x^*$.

There is an equivalent form of Assumption 4: For each neighborhood $\mathcal{U}$ of x^* there exists $\eta > 0$ such that if $f(x) - f(x^*) < \eta$ or $||\nabla f(x)|| < \eta$, then $x \in \mathcal{U}$.

Remark 2. Assumptions 3 and 4 are stronger than the assumptions usually made on $f(x)$ in the literature (see [8] for a summary of the available convergence proofs and the assumptions they require). However, our results hold for a constant step size and do not require that $\nabla f_l(x) = 0$, $l = 1, \ldots, L$, whenever $\nabla f(x) = 0$. In addition, note that there are nonconvex functions that satisfy Assumption 4. However, if $f(x)$ is strictly convex and takes a minimum in the interior of its domain ($\mathbb{R}^p$), then Assumption 4 is automatically satisfied. In particular, if $f(x)$ satisfies Assumption 3 and is strictly convex, then Assumption 4 is satisfied. In fact, the implication $\lim_{k\to\infty} f(t^k) = f(x^*) \Rightarrow \lim_{k\to\infty} t^k = x^*$ is the statement of Corollary 27.2.2 from [41]. The implication $\lim_{k\to\infty} ||\nabla f(t^k)|| = 0 \Rightarrow \lim_{k\to\infty} t^k = x^*$ can be obtained as follows: Consider the function $\nabla f : \mathbb{R}^p \to \mathbb{R}^p$. The derivative $(\nabla f)'$ of this function is the Hessian $\nabla^2 f$. Since $f(x)$ satisfies Assumption 3 and is strictly convex, $\det(\nabla f)' \neq 0$. Therefore, by the inverse function theorem, there are open neighborhoods V of $x^* \in \mathbb{R}^p$ and W of $0 \in \mathbb{R}^p$ such that $\nabla f : V \to W$ has a continuous inverse $\gamma : W \to V$. Let $\{t^k\}_{k=1}^{\infty}$ be a sequence such that $\lim_{k\to\infty} ||\nabla f(t^k)|| = 0$. Then there exists k_0 such that $\nabla f(t^k) \in W$ for all $k \geq k_0$. By Theorem B on page 99 in [40], since $f(x)$ is strictly convex, ∇f is one-to-one; i.e., if $x \neq y$, then $\nabla f(x) \neq \nabla f(y)$. It follows that $t^k \in V$ for all $k \geq k_0$. Now we have

$$\begin{aligned}\lim_{k\to\infty} t^k &= \lim_{k\to\infty} \gamma\left(\nabla f(t^k)\right) \\ &= \gamma\left(\lim_{k\to\infty} \nabla f(t^k)\right) \\ &= \gamma(0) = x^*.\end{aligned}$$

Remark 3. Unimodal functions which are convex in the neighborhood of their minimum and have bounded gradient are common in robust estimation [20]. An example of a robust estimation objective function that satisfies Assumptions 1–4 is given in section 4.1. Another important function which satisfies Assumptions 1–4 is the objective function minimized by the LogitBoost algorithm [16] (or adaptive logistic regression). To explain the components which are used to construct this objective function we include a short description (taken from [14]) of the supervised learning problem, and in particular, the problem of combining weak features. Let $\{z_l, y_l\}_{l=1}^{L}$ be a set of training examples, where each instance z_l takes values in an instance domain $\mathcal{Z}$, and each y_l, called the label, takes values in $\{-1, +1\}$. Given a set of p real-valued functions on $\mathcal{Z}$, $h_1, h_2, \ldots, h_p$ called features, the goal is to find a vector $x \in \mathbb{R}^p$ for which the sign of $g_x(z_l) = \sum_{i=1}^{p} x_i h_i(z_l)$ is a good predictor of y_l for $l = 1, \ldots, L$. Let M be the $L \times p$ matrix whose (l, i) element is $h_i(z_l)$. The objective function $f(x) : \mathbb{R}^p \to \mathbb{R}$ minimized by the LogitBoost algorithm [14] is given by

$$f(x) = \sum_{l=1}^{L} \log\left[1 + \exp\left(-y_l [Mx]_l\right)\right], \tag{2.2}$$

where $[Mx]_l$ is the lth element of the vector Mx. It can be motivated as being a convex surrogate to the nonconvex and nondifferentiable $0-1$ loss function

$$f(x) = \sum_{l=1}^{L} I(g_x(z_l)y_l \leq 0),$$

which is the number of labels that are not predicted correctly by the sign of $g_x(z_l)$, or through the maximum likelihood method for estimating the conditional probability of y_l given z_l. It is shown below that in the nonseparable case, i.e., when there exists no value of x for which $\operatorname{sign}(g_x(z_l)) = y_l$, for $l = 1, \ldots, L$, and when the features are linearly independent on the training set, i.e., $\operatorname{rank} M = p$, the function $f(x)$ (2.2) satisfies Assumptions 1–4:

$$\frac{\partial}{\partial x_j} \log\left[1 + \exp\left(-y_l[Mx]_l\right)\right] = \frac{\exp\left(-y_l[Mx]_l\right)}{1 + \exp\left(-y_l[Mx]_l\right)} \left(-y_l h_j(z_l)\right) \leq |h_j(z_l)|.$$

Hence Assumption 2 holds:

$$\begin{aligned}\frac{\partial^2}{\partial x_j \partial x_k} \log\left[1 + \exp\left(-y_l[Mx]_l\right)\right] &= \frac{\exp\left(-y_l[Mx]_l\right)}{\left[1 + \exp\left(-y_l[Mx]_l\right)\right]^2} h_j(z_l)h_k(z_l) \\ &\leq |h_j(z_l)h_k(z_l)|.\end{aligned}$$

Hence Assumption 1 holds. Let $d_l(x) = \exp\left(-y_l[Mx]_l\right) / \left[1 + \exp\left(-y_l[Mx]_l\right)\right]^2 > 0$. Then

$$\frac{\partial^2 f(x)}{\partial x_j \partial x_k} = \sum_{l=1}^{L} d_l(x) M_{lj} M_{lk}.$$

To show that $\nabla f(x)$ is positive definite for all x, consider $\zeta^T \nabla f(x) \zeta$ for some vector $\zeta \in \mathbb{R}^p$:

$$\zeta^T \nabla f(x) \zeta = \sum_{j,k=1}^{p} \sum_{l=1}^{L} d_l(x) M_{lk} M_{lj} \zeta_k \zeta_j = \sum_{l=1}^{L} d_l(x) \left([M\zeta]_l\right)^2 \geq 0$$

with equality if and only if $\zeta = 0$, by the assumption that $\operatorname{rank} M = p$. Hence the function $f(x)$ is strictly convex. Assume the training set $\{z_l, y_l\}_{l=1}^{L}$ is nonseparable with respect to the features $h_1, h_2, \ldots, h_p$; i.e., for every x there exists at least one l for which $y_l[Mx]_l < 0$. For any given $x \neq 0$ let $I_1(x) = \{l : y_l[Mx]_l < 0\}$, $I_2(x) = \{l : y_l[Mx]_l = 0\}$, and $I_3(x) = \{l : y_l[Mx]_l > 0\}$, and note that $I_1(x)$ is nonempty by assumption. For a positive scalar c, we can write $f(cx)$ as the sum of three summations:

$$\begin{aligned}f(cx) = &\sum_{l \in I_1(x)} \log\left\{1 + \exp\left[-cy_l \sum_{i=1}^{p} x_i h_i(z_l)\right]\right\} \\ &+ \sum_{l \in I_2(x)} \log 2 \\ &+ \sum_{l \in I_3(x)} \log\left\{1 + \exp\left[-cy_l \sum_{i=1}^{p} x_i h_i(z_l)\right]\right\}.\end{aligned}$$

When $c \to \infty$,

$$\sum_{l \in I_1(x)} \log \left\{ 1 + \exp \left[-cy_l \sum_{i=1}^{p} x_i h_i(z_l) \right] \right\} \to \infty$$

and

$$\sum_{l \in I_3(x)} \log \left\{ 1 + \exp \left[-cy_l \sum_{i=1}^{p} x_i h_i(z_l) \right] \right\} \to 0.$$

Therefore, $\lim_{c \to \infty} f(cx) = \infty$ for all $x \neq 0$. This implies that $f(x)$ has no directions of recession. A direction of recession is a nonzero vector x^1 such that $f(x^2 + cx^1)$ is a nonincreasing function of the scalar c for every choice of vector x^2. Hence by Theorem 27.1(d) in [41, p. 265] the minimum set of $f(x)$ is nonempty. The minimum is unique by the strict convexity of $f(x)$. Therefore, Assumption 3 is also satisfied, and the strict convexity, together with Assumption 3, implies Assumption 4 as well.

The following lemma is well known.

LEMMA 2.5. *Under Assumption* 3, *there exists a neighborhood* $\mathcal{U}$ *of* x^* *and positive constants* A_1, A_2, B_1, B_2 *such that for all* $x \in \mathcal{U}$,

$$A_1 ||x - x^*||^2 \leq f(x) - f(x^*) \leq B_1 ||x - x^*||^2, \tag{2.3}$$

$$A_2 ||x - x^*||^2 \leq ||\nabla f(x)||^2 \leq B_2 ||x - x^*||^2. \tag{2.4}$$

Let $\mathcal{U}$ be a neighborhood of x^* for which inequalities (2.3) and (2.4) hold. By Assumption 4 there exists $\eta > 0$ such that $x \in \mathcal{U}$ if $f(x) - f(x^*) < \eta$ or $||\nabla f(x)|| < \eta$.

LEMMA 2.6. *Set* $M_5 = \max\{3\sqrt{\frac{B_1 B_2}{A_1 A_2}}, \frac{2}{1-2\mu M_1}\}$ *and* $\lambda = \mu M_2 M_5$. *Under Assumptions* 1, 3, *and* 4, *if there exist positive numbers* n_1 *and* δ *such that* $||h^k|| < \delta$ *for every* $k \geq n_1$, $3\delta < \eta$, $\frac{9B_1}{A_2}\delta^2 < \eta$, *and* $9\mu M_1 < 1$, *then*

(i) *there exists a number* k_1 *such that* $||\nabla f(x^k)|| < M_5\delta$ *and* $||d^k|| < 2M_5\delta$ *for every* $k \geq k_1$, *and*

(ii) *there exists a number* n_2 *such that* $||h^k|| < \lambda\delta$ *for every* $k \geq n_2$.

Proof. First, we show that there exists k such that $k \geq n_1$ and $||\nabla f(x^k)|| < \frac{2\delta}{1-2\mu M_1}$. In fact, if $||\nabla f(x^k)|| \geq \frac{2\delta}{1-2\mu M_1}$ for all $k \geq n_1$, then $||\nabla f(x^k)|| > \frac{2||h^k||}{1-2\mu M_1} \geq \frac{||h^k||}{1-2\mu M_1}$ for all $k \geq n_1$. By Lemma 2.2, the sequence $\{f(x^k)\}_{k=n_1}^{\infty}$is decreasing. Since it is bounded from below by $f(x^*)$, there exists $\lim_{k \to \infty} f(x^k)$. By replacing δ_0 with δ and $\max\{K_1, K_2\}$ with n_1 at the last argument of the proof of Proposition 2.4, we obtain a contradiction.

Let k_1 be the smallest natural number such that $k_1 \geq n_1$ and $||\nabla f(x^{k_1})|| \leq \frac{2\delta}{1-2\mu M_1}$. Without loss of generality, assume there exists k_2, the smallest natural number such that $k_2 > k_1$ and $||\nabla f(x^{k_2})|| > \frac{2\delta}{1-2\mu M_1}$. Let k_3 be the smallest natural number such that $k_3 > k_2$ and $||\nabla f(x^{k_3})|| \leq \frac{2\delta}{1-2\mu M_1}$. Let k_4 be the smallest natural number such that $k_4 > k_3$ and $||\nabla f(x^{k_4})|| > \frac{2\delta}{1-2\mu M_1}$. We define $k_5, k_6, \ldots$ in a similar manner.

For every natural m,

$$||d^{k_{2m}-1}|| \leq ||\nabla f(x^{k_{2m}-1})|| + ||h^{k_{2m}-1}|| \leq \frac{2\delta}{1-2\mu M_1} + \delta \leq \frac{3\delta}{1-2\mu M_1},$$

$$||x^{k_{2m}} - x^{k_{2m}-1}|| = \mu \frac{1}{L} ||d^{k_{2m}-1}|| \leq \frac{3\mu/L}{1-2\mu M_1}\delta,$$

and

$$\begin{aligned}||\nabla f(x^{k_{2m}})|| &\leq ||\nabla f(x^{k_{2m}}) - \nabla f(x^{k_{2m}-1})|| + ||\nabla f(x^{k_{2m}-1})|| \\ &\leq M_2||x^{k_{2m}} - x^{k_{2m}-1}|| + \frac{2\delta}{1-2\mu M_1} \\ &\leq M_2\frac{3\mu/L}{1-2\mu M_1}\delta + \frac{2}{1-2\mu M_1}\delta \\ &= \frac{2+3\mu M_1}{1-2\mu M_1}\delta < 3\delta,\end{aligned}$$

where we used $\mu < \frac{1}{9M_1}$ to obtain the last inequality.

Since $||\nabla f(x^{k_{2m}})|| < 3\delta < \eta$, $x^{k_{2m}} \in \mathcal{U}$, and we can use Lemma 2.5. We obtain

$$f(x^{k_{2m}}) - f(x^*) \leq B_1||x^{k_{2m}} - x^*|| \leq \frac{B_1}{A_2}||\nabla f(x^{k_{2m}})||^2 < \frac{B_1}{A_2}9\delta^2.$$

Let k be such that $k_{2m} \leq k < k_{2m+1}$. Then, by Lemma 2.2,

$$f(x^k) - f(x^*) < f(x^{k_{2m}}) - f(x^*) < 9\frac{B_1}{A_2}\delta^2.$$

Since $f(x^k) - f(x^*) < 9\frac{B_1}{A_2}\delta^2 < \eta$, $x^k \in \mathcal{U}$, and we can use Lemma 2.5. We obtain

$$||\nabla f(x^k)||^2 \leq B_2||x^k - x^*||^2 \leq \frac{B_2}{A_1}\left[f(x^k) - f(x^*)\right] < 9\frac{B_1B_2}{A_1A_2}\delta^2.$$

Thus, if k satisfies $k_{2m} \leq k < k_{2m+1}$, we have $||\nabla f(x^k)|| < 3\sqrt{\frac{B_1B_2}{A_1A_2}}\delta$. If k satisfies $k_{2m-1} \leq k < k_{2m}$, we have $||\nabla f(x^k)|| < \frac{2}{1-2\mu M_1}\delta$. Therefore for each $k \geq k_1$, $||\nabla f(x^k)|| < M_5\delta$, and therefore

$$||d^k|| \leq ||\nabla f(x^k)|| + ||h^k|| \leq M_5\delta + \delta < 2M_5\delta.$$

Thus, if $k \geq k_1$, we have

$$\begin{aligned}||\nabla f(x^k)|| &< M_5\delta, \\ ||d^k|| &< 2M_5\delta.\end{aligned} \tag{2.5}$$

This proves the first part of the lemma.

To prove the second part, we take $n_2 = k_1 + L - 1$. If $k \geq n_2$, then not only x^k but also $L-1$ previous terms of the sequence $\{x^k\}$ satisfy inequalities (2.5). Therefore, by following the steps in the proof of Proposition 2.4, we have for $k \geq n_2$

$$\begin{aligned}||h^k|| &\leq \mu M_1\frac{1}{L}\sum_{l=1}^{L-1}\left(||d^{k-1}|| + ||d^{k-2}|| + \cdots + ||d^{k-l}||\right) \\ &< \mu M_1\frac{1}{L}2M_5\delta\sum_{l=1}^{L-1}\sum_{m=1}^{l}1 = \mu M_1\frac{1}{L}2M_5\delta\frac{L(L-1)}{2} \\ &< \mu M_2M_5\delta = \lambda\delta.\end{aligned}$$

Thus $||h^k|| < \lambda\delta$. This proves the second part of Lemma 2.6. ∎

Remark 4. A direct result of Lemma 2.6 is that under Assumptions 1–4, $||h^k|| \to 0$ is a sufficient condition for the convergence of x^k, generated by any gradient method with errors (2.1), to x^*.

PROPOSITION 2.7. *Under Assumptions* 1, 2, 3, *and* 4, *if* $\mu < \min\{\frac{1}{9M_1}, \frac{1}{M_2M_5}, \frac{\eta}{3M_1M_3}, \frac{1}{3M_2M_3}\sqrt{\frac{A_2\eta}{B_1}}\}$, *then* $\lim_{k\to\infty} x^k = x^*$.

Proof. We prove Proposition 2.7 by repeated use of Lemma 2.6. We start with $\delta = \delta_0$. By applying Lemma 2.3, there exists K such that for all $k > K$, $||h^k|| < \delta_0$. After applying Lemma 2.6 r times we get a number n_r such that $||h^k|| < \delta_0\lambda^r$, $||\nabla f(x^k)|| < M_5\delta_0\lambda^r$, and $||d^k|| < 2M_5\delta_0\lambda^r$ for $k \geq n_r$. The inequality $\mu < \frac{1}{M_2M_5}$ is equivalent to $0 < \lambda < 1$. Hence, $\lim_{k\to\infty} ||h^k|| = 0$, $\lim_{k\to\infty} ||d^k|| = 0$, and $\lim_{k\to\infty} ||\nabla f(x^k)|| = 0$, and by Assumption 4, $\lim_{k\to\infty} x^k = x^*$.

Note that the inequality $\mu < \frac{1}{9M_1}$ was used in the proof of Lemma 2.6, and the inequalities $\mu < \frac{\eta}{3M_2M_3}$ and $\mu < \frac{1}{3M_2M_3}\sqrt{\frac{A_2\eta}{B_1}}$ are equivalent to $3\delta_0 < \eta$ and $\frac{9B_1}{A_2}\delta_0^2 < \eta$, respectively. ∎

2.2. Case II: Quadratic case. In [25] it is shown that when applied to the objective function

$$f(x) = \frac{1}{2}(x - c_1)^2 + \frac{1}{2}(x - c_2)^2,$$

the standard incremental gradient method with a constant step size

$$x^{k+1} = x^k - \mu\nabla f_{(k)_L}(x^k)$$

converges to a limit cycle with limit points

$$x_1^*(\mu) = \frac{(1-\mu)c_1 + c_2}{2-\mu}, \qquad x_2^*(\mu) = \frac{(1-\mu)c_2 + c_1}{2-\mu}$$

whenever $0 < \mu < 1$. When implementing the IAG method one obtains

$$\begin{aligned} x^{k+1} &= x^k - \frac{\mu}{2}\left[\left(x^k - c_{(k)_2}\right) + \left(x^{k-1} - c_{(k-1)_2}\right)\right] \\ &= x^k - \frac{\mu}{2}\left[x^k + x^{k-1} - (c_1 + c_2)\right]. \end{aligned}$$

Subtracting $x^* = (c_1 + c_2)/2$, the unique minimum of $f(x)$, from both sides and denoting the error at the kth iteration by $e^k = x^k - x^*$ lead to the following error form:

$$e^{k+1} = e^k - \frac{\mu}{2}\left[e^k + e^{k-1}\right].$$

The characteristic polynomial of this linear system is $\lambda^2 - (1 - \mu/2)\lambda + \mu/2$, and it is easy to show that the roots of this polynomial are inside the unit circle whenever $0 < \mu < 2$. Hence, when $0 < \mu < 2$, $e^k \to 0$; i.e., x^k converges to the unique minimum, in contrast to the standard incremental gradient method.

More generally, suppose that the functions f_l, $l = 1, \ldots, L$, have the following form:

$$f_l(x) = \frac{1}{2}x'Q_lx - c_l'x, \quad l = 1, \ldots, L, \tag{2.6}$$

where Q_l are given symmetric matrices, c_l are given vectors, and $\sum_{l=1}^{L} Q_l$ is positive definite. Under this assumption, the function $f(x) = \sum_{l=1}^{L} f_l(x)$ is strictly convex, having its minimum point at

$$x^* = \left(\sum_{l=1}^{L} Q_l\right)^{-1} \sum_{l=1}^{L} c_l, \tag{2.7}$$

and x^* is the only stationary point of $f(x)$.

PROPOSITION 2.8. *For sufficiently small μ, $\lim_{k\to\infty} x^k = x^*$, and the rate of convergence of the IAG method* (1.4) *is linear.*

Proof. Plugging (2.6) into (1.4), the IAG method becomes

$$x^{k+1} = x^k - \mu\left[\sum_{l=0}^{L-1} Q_{(k-l)_L} x^{k-l} - c_{(k-l)_L}\right] = x^k - \mu \sum_{l=0}^{L-1} Q_{(k-l)_L} x^{k-l} + \mu c,$$

where $c = \sum_{l=1}^{L} c_l$, and the factor $\frac{1}{L}$ was absorbed into μ to simplify the notation. Subtracting x^* (2.7) from both sides and adding and subtracting x^* inside the parentheses, we obtain

$$x^{k+1} - x^* = x^k - x^* - \mu \sum_{l=0}^{L-1} Q_{(k-l)_L}(x^{k-l} - x^* + x^*) + \mu c.$$

Denoting the error at the kth iteration by $e^k = x^k - x^*$ and the substitution of (2.7) for x^* lead to the following error form:

$$e^{k+1} = e^k - \mu \sum_{l=0}^{L-1} Q_{(k-l)_L} e^{k-l}.$$

This relation between a new error and the previous errors can be seen as a periodically time varying linear system. To analyze its stability, which will lead to the convergence result, it is useful to consider L iterations as one iteration [29]. This can be seen as downsampling the original system by a factor of L, which leads to a time invariant system of a lower sampling rate. Without loss of generality, consider the case where $k = NL$ for some integer N; i.e., $k+1$ corresponds to the first iteration of a new cycle. In this case we have

$$\begin{aligned} e^{k+1} &= e^k - \mu \sum_{l=0}^{L-1} Q_{(k-l)_L} e^{k-l} = e^k - \mu \begin{bmatrix} Q_L & Q_{L-1} & Q_{L-2} & \dots & Q_1 \end{bmatrix} \overline{e}^k \\ &= \begin{bmatrix} I_p - \mu Q_L & -\mu Q_{L-1} & -\mu Q_{L-2} & \dots & -\mu Q_1 \end{bmatrix} \overline{e}^k, \end{aligned}$$

where I_p is the $p \times p$ identity matrix and

$$\overline{e}^k = \begin{bmatrix} e^k \\ e^{k-1} \\ \vdots \\ e^{k-L+1} \end{bmatrix}.$$

Similarly,

$$\begin{aligned} e^{k+2} &= e^{k+1} - \mu \sum_{l=0}^{L-1} Q_{(k+1-l)L} e^{k+1-l} \\ &= e^{k+1} - \mu \begin{bmatrix} Q_1 & Q_L & Q_{L-1} & \dots & Q_2 \end{bmatrix} \overline{e}^{k+1} \\ &= \begin{bmatrix} I_p - \mu Q_1 & -\mu Q_L & -\mu Q_{L-1} & \dots & -\mu Q_2 \end{bmatrix} \overline{e}^{k+1}, \end{aligned}$$

and finally

$$\begin{aligned} e^{k+L} &= e^{k+L-1} - \mu \sum_{l=0}^{L-1} Q_{(k+L-1-l)L} e^{k+L-1-l} \\ &= e^{k+L-1} - \mu \begin{bmatrix} Q_{L-1} & Q_{L-2} & Q_{L-3} & \dots & Q_L \end{bmatrix} \overline{e}^{k+L-1} \\ &= \begin{bmatrix} I_p - \mu Q_{L-1} & -\mu Q_{L-2} & -\mu Q_{L-3} & \dots & -\mu Q_L \end{bmatrix} \overline{e}^{k+L-1}. \end{aligned}$$

This leads to the relation

$$\overline{e}^{k+L} = M_L \overline{e}^{k+L-1},$$

where

$$M_L = \begin{bmatrix} I_p - \mu Q_{L-1} & -\mu Q_{L-2} & \dots & -\mu Q_1 & -\mu Q_L \\ I_p & 0_p & \dots & 0_p & 0_p \\ 0_p & I_p & \dots & 0_p & 0_p \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0_p & 0_p & \dots & I_p & 0_p \end{bmatrix},$$

where 0_p denotes the $p \times p$ zero matrix. Taking another step we have

$$\overline{e}^{k+L} = M_L M_{L-1} \overline{e}^{k+L-2},$$

where

$$M_{L-1} = \begin{bmatrix} I_p - \mu Q_{L-2} & -\mu Q_{L-3} & \dots & -\mu Q_L & -\mu Q_{L-1} \\ I_p & 0_p & \dots & 0_p & 0_p \\ 0_p & I_p & \dots & 0_p & 0_p \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0_p & 0_p & \dots & I_p & 0_p \end{bmatrix},$$

and finally, by induction,

$$\overline{e}^{k+L} = M_L M_{L-1} \dots M_1 \overline{e}^{k},$$

where

$$M_1 = \begin{bmatrix} I_p - \mu Q_L & -\mu Q_{L-1} & \dots & -\mu Q_2 & -\mu Q_1 \\ I_p & 0_p & \dots & 0_p & 0_p \\ 0_p & I_p & \dots & 0_p & 0_p \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0_p & 0_p & \dots & I_p & 0_p \end{bmatrix}.$$

Denoting $M = M_L M_{L-1} \dots M_1$, we have $\overline{e}^{k+L} = M\overline{e}^k$, and in general $\overline{e}^{k+nL} = M^n\overline{e}^k$. Therefore, if for sufficiently small $\mu > 0$ the eigenvalues of M are inside the unit circle, then $\lim_{n\to\infty} \overline{e}^{k+nL} = 0_{pL\times 1}$, where $0_{pL\times 1}$ is a $pL \times 1$ zero vector; i.e., the method converges to the minimum of the function $f(x)$ and the convergence rate is linear.

To prove that the eigenvalues of M are inside the unit circle, set

$$A = \begin{bmatrix} I_p & 0_p & \dots & 0_p & 0_p \\ I_p & 0_p & \dots & 0_p & 0_p \\ 0_p & I_p & \dots & 0_p & 0_p \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0_p & 0_p & \dots & I_p & 0_p \end{bmatrix}$$

and

$$B_k = \begin{bmatrix} Q_{(k-1)_L} & Q_{(k-2)_L} & \dots & Q_{(k+1)_L} & Q_k \\ 0_p & 0_p & \dots & 0_p & 0_p \\ 0_p & 0_p & \dots & 0_p & 0_p \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0_p & 0_p & \dots & 0_p & 0_p \end{bmatrix}, \quad k = 1, \dots, L,$$

so that $M_k = A - \mu B_k$ and $M = (A - \mu B_L)(A - \mu B_{L-1}) \dots (A - \mu B_1)$. Hence,

$$M = A^L - \mu\big(B_L A^{L-1} + A B_{L-1} A^{L-2} + A^2 B_{L-2} A^{L-3} + \cdots + A^{L-2} B_2 A + A^{L-1} B_1\big) + \mu^2 C(\mu),$$

where $C(\mu)$ is an $Lp \times Lp$ matrix whose elements are polynomials in μ.

Note that premultiplying a matrix by A will duplicate the first row of $p\times p$ matrices and will shift the rest of the rows down, discarding the last p rows. Postmultiplying by A will add the second column of $p \times p$ matrices to the first one and will shift the rest of the columns to the left, inserting a block of $p \times p$ zero matrices to the last column. It follows that

$$A^L = \begin{bmatrix} I_p & 0_p & \dots & 0_p & 0_p \\ I_p & 0_p & \dots & 0_p & 0_p \\ I_p & 0_p & \dots & 0_p & 0_p \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ I_p & 0_p & \dots & 0_p & 0_p \end{bmatrix}$$

and

$$A^{L-k} B^k A^{k-1} = \begin{bmatrix} W_1(k) & 0_{(L-k+1)p\times(k-1)p} \\ 0_{(k-1)p\times(L-k+1)p} & 0_{(k-1)p\times(k-1)p} \end{bmatrix},$$

where $W_1(k)$ is a $(L-k+1)p \times (L-k+1)p$ matrix whose elements are

$$W_1(k) = \begin{bmatrix} \sum_{l=0}^{k-1} Q_{(l)_L} & Q_{L-1} & \dots & Q_k \\ \vdots & \vdots & & \vdots \\ \sum_{l=0}^{k-1} Q_{(l)_L} & Q_{L-1} & \dots & Q_k \end{bmatrix}.$$

Therefore, the characteristic polynomial $F(\mu,\lambda)$ of M is

$$F(\mu,\lambda)=\det\left(M-\lambda I_{Lp}\right)=\det\left(A^L-\mu\sum_{k=1}^{L}A^{L-k}B^kA^{k-1}-\lambda I_{Lp}+\mu^2C(\mu)\right).$$

The first p columns of $\left(A^L-\mu\sum_{k=1}^{L}A^{L-k}B^kA^{k-1}-\lambda I_{Lp}+\mu^2C(\mu)\right)$ are

$$\begin{bmatrix}(1-\lambda)I_p-\mu\left[LQ_L+(L-1)Q_1+\cdots+Q_{L-1}\right]+\mu^2C_{11}\\ I_p-\mu\left[(L-1)Q_L+(L-2)Q_1+\cdots+Q_{L-2}\right]+\mu^2C_{21}\\ I_p-\mu\left[(L-2)Q_L+(L-3)Q_1+\cdots+Q_{L-3}\right]+\mu^2C_{31}\\ \vdots\\ I_p-\mu\left(2Q_L+Q_1\right)+\mu^2C_{L-1\,1}\\ I_p-\mu Q_L+\mu^2C_{L1}\end{bmatrix},$$

the second p columns are

$$\begin{bmatrix}-(L-1)\mu Q_{L-1}+\mu^2C_{12}\\ -(L-1)\mu Q_{L-1}-\lambda I_p+\mu^2C_{22}\\ -(L-2)\mu Q_{L-1}+\mu^2C_{32}\\ \vdots\\ -2\mu Q_{L-1}+\mu^2C_{L-1\,2}\\ -\mu Q_{L-1}+\mu^2C_{L2}\end{bmatrix},$$

the next $(L-3)p$ columns are

$$\begin{bmatrix}-(L-2)\mu Q_{L-2}+\mu^2C_{13} & \dots & -2\mu Q_2+\mu^2C_{1\,L-1}\\ -(L-2)\mu Q_{L-2}+\mu^2C_{23} & \dots & -2\mu Q_2+\mu^2C_{2\,L-1}\\ -(L-2)\mu Q_{L-2}-\lambda I_p+\mu^2C_{33} & \dots & -2\mu Q_2+\mu^2C_{3\,L-1}\\ \vdots & & \vdots\\ -2\mu Q_{L-2}+\mu^2C_{L-1\,3} & \dots & -2\mu Q_2-\lambda I_p+\mu^2C_{L-1\,L-1}\\ -\mu Q_{L-2}+\mu^2C_{L3} & \dots & -\mu Q_2+\mu^2C_{L\,L-1}\end{bmatrix},$$

and the last p columns are

$$\begin{bmatrix}-\mu Q_1+\mu^2C_{1L}\\ -\mu Q_1+\mu^2C_{2L}\\ -\mu Q_1+\mu^2C_{3L}\\ \vdots\\ -\mu Q_1+\mu^2C_{L-1\,L}\\ -\mu Q_1-\lambda I_p+\mu^2C_{LL}\end{bmatrix},$$

where C_{ij}, $i,j=1,\dots,L$, are $p\times p$ matrices whose entries are polynomials in μ.

It is easy to see that if $\mu=0$, then $F(0,\lambda)=(-1)^{Lp}\lambda^{Lp-p}(\lambda-1)^p$. Hence, if $\mu=0$, we have an eigenvalue 0 of multiplicity $Lp-p$ and an eigenvalue 1 of multiplicity p. If μ is close enough to zero, the 0-eigenvalues will be close to the origin and therefore inside the unit circle. We need to prove that for sufficiently small positive μ, all the 1-eigenvalues will be inside the unit circle. Let $\lambda=\lambda(\mu)$ be a smooth function expressing the dependence of one of the 1-eigenvalues on μ. We will prove that $\frac{\mathrm{d}\lambda}{\mathrm{d}\mu}(0^+)<0$. It will be enough for our purposes, since it will show that the

trajectory $\lambda = \lambda(\mu)$ is entering the unit circle, and hence $\lambda(\mu)$ is inside the unit circle for sufficiently small positive μ.

By the definition of $\lambda(\mu)$, $\lambda(0+) = 1$ and $F(\mu, \lambda(\mu)) = 0$ for all μ. It follows that

$$\frac{\mathrm{d}^p F(\mu, \lambda(\mu))}{\mathrm{d}\mu^p} = 0. \tag{2.8}$$

To calculate the left-hand side of (2.8), we use the formula for the derivative of a determinant [23]. Note that substituting $\mu = 0$ and $\lambda = 1$ into each of the first p rows of the matrix $M - \lambda I_{Lp}$ leads to a row in which all of the entries are zeros, and therefore the determinant has a zero value. Therefore the only nonzero terms in $\frac{\mathrm{d}^p F(\mu,\lambda(\mu))}{\mathrm{d}\mu^p}$ after substituting $\mu = 0$ and $\lambda = 1$ (more precisely, taking $\mu \to 0^+$) are the terms with the first derivatives in the first p rows (there are $p!$ such terms). Hence taking the pth derivative is reduced to taking the first derivative of each of the first p rows. Substituting $\lambda = 1$ and $\mu \to 0^+$ we obtain

$$\frac{\mathrm{d}^p F(\mu, \lambda(\mu))}{\mathrm{d}\mu^p} = p! \det \begin{bmatrix} W_2 & W_3 \\ W_4 & -I_{(L-1)p\times(L-1)p} \end{bmatrix} = 0,$$

where $W_2 = -\lambda'(0^+) I_p - \sum_{k=0}^{L-1} (L-k) Q_{(k)_L}$,

$$W_3 = \begin{bmatrix} -(L-1)Q_{L-1} & -(L-2)Q_{L-2} & \dots & -2Q_2 & -Q_1 \end{bmatrix},$$

and $W_4 = [I_p\, I_p \dots I_p]^T$. Add all columns of $p \times p$ matrices to the first column of $p \times p$ matrices to obtain

$$\det \begin{bmatrix} W_5 & W_3 \\ 0_{(L-1)p\times p} & -I_{(L-1)p\times(L-1)p} \end{bmatrix} = 0,$$

where $W_5 = -\lambda'(0^+) I_p - L \sum_{k=1}^{L} Q_k$. Calculating the last determinant gives

$$\det \left[L \sum_{k=1}^{L} Q_k + \lambda'(0^+) I_p \right] = 0.$$

The last equation shows that $-\lambda'(0^+)$ is an eigenvalue of the matrix $L \sum_{k=1}^{L} Q_k$. Since $L \sum_{k=1}^{L} Q_k$ is positive definite, $-\lambda'(0^+) > 0$, and therefore $\lambda'(0^+) < 0$. This proves that for sufficiently small $\mu > 0$ the eigenvalues of the matrix M are strictly inside the unit circle, and hence the sequence x^k converges to x^*, and the convergence rate is linear. ∎

3. Initialization and distributed implementation. As mentioned in section 1, the IAG method is initiated with L points, $x^1, x^2, \dots, x^L$. Possible initialization strategies include setting $x^1 = x^2 = \cdots = x^L$ or generating the initial points using a single cycle of the standard incremental gradient method (1.5). Another possibility is the following. Given x^1, compute $d^1 = \nabla f_1(x^1)$. Then, for $1 \le k \le L-1$,

$$\begin{aligned} x^{k+1} &= x^k - \mu \frac{1}{k} d^k, \\ dkk + 1 &= d^k + \nabla f_{(k+1)_L}(x^{k+1}). \end{aligned} \tag{3.1}$$

Therefore, after $L-1$ iterations we obtain $x^1, \dots, x^L$ and $d^L = \sum_{l=1}^{L} \nabla f_l(x^l)$.

The key feature of the IAG method that makes it suitable for wireless sensor networks applications is that it can be implemented in a distributed manner. Consider a distributed system of L processors enumerated over $1, 2, \ldots, L$, each of which has access to one of the functions $f_l(x)$. The initialization (3.1) begins with x^1 at processor 1. Then processor 1 sets $d^1 = \nabla f_1(x^1)$ and transmits x^1 and d^1 to processor 2. Upon receiving x^{k-1} and d^{k-1} from processor $k-1$, processor k calculates x^k and d^k according to (3.1) and transmits them to processor $k+1$. The initialization phase is completed when processor L, upon receiving x^{L-1} and d^{L-1} from processor $L-1$, computes x^L and d^L according to (3.1) and transmits them to processor 1.

Once the initialization phase is completed, the algorithm progresses in a cyclic manner. Upon receiving x^{k-1} and d^{k-1} from processor $(k-1)_L$, processor $(k)_L$ computes x^k and d^k according to (1.2) and (1.3), respectively, and transmits them to processor $(k+1)_L$. Note that $\nabla f_{(k)_L}(x^{k-L})$ in (1.3) is available at processor $(k)_L$, since it was the last gradient computed at that processor. Therefore, the only gradient computation at processor $(k)_L$ is $\nabla f_{(k)_L}(x^k)$. At no phase of the algorithm do the processors share information regarding the complete function $f(x)$ or its gradient $\nabla f(x)$.

4. Application to wireless sensor networks. There are two motivations to use the IAG method: (a) reduced computational burden due to the evaluation of a single gradient per iteration compared to L gradients required for the steepest descent method; and (b) the possibility of a distributed implementation of the method in which each component has access to one of the functions $f_l(x)$. The second item has been shown to be very useful in the context of wireless sensor networks [38]. Wireless sensor networks provide means for efficient large scale monitoring of large areas [45]. Often the ultimate goal is to estimate certain parameters based on measurements that the sensors collect, giving rise to an optimization problem. If measurements from distinct sensors are modelled as statistically independent, the estimation problem takes the form of (1.1), where $f_l(x)$ is indexed by the measurements available at sensor l (see, e.g., [9, 33, 36, 37] and the references therein). When transmitting the complete set of data to a central processor is impractical due to bandwidth and power constraints, the IAG method can be implemented in a distributed manner as described in section 3. In the following sections we consider two such estimation problems.

4.1. Robust estimation. One of the benefits of a wireless sensor network is the ability to deploy a large number of low cost sensors to densely monitor a certain area [45]. Because low cost sensors have limited reliability, the system must be designed to be robust to the possibility of individual sensor failures. In estimation tasks, this means that some of the sensors will contribute unreliable measurements, namely outliers. In [36] the authors suggest the use of robust statistics to alleviate the influence of outliers in the data (see [20] or, specifically in the context of optimization, [34, p. 347]). The robust statistics framework uses objective functions that give less weight to outliers. A common objective function used to this end is the function "Fair" [39, p. 110], given by

$$g(x) = c^2 \left[\frac{|x|}{c} - \log\left(1 + \frac{|x|}{c}\right) \right]. \tag{4.1}$$

Following [36] we simulate a sensor network for measuring pollution levels and assume that a certain percentage of the sensors are damaged and provide unreliable measurements. Each sensor collects a single noisy measurement of the pollution level,

and the estimate of the average pollution level is found by minimizing the objective function defined by

$$f(x) = \sum_{l=1}^{L} f_l(x), \tag{4.2}$$

where $x \in \mathbb{R}$, and

$$f_l(x) = \frac{1}{L} g(x - y_l),$$

where y_l is the measurement collected by sensor l. There were $L = 50$ sensors in the simulation. To reflect the possibility of faulty sensors, half of the samples were generated according to a Gaussian distribution with mean $m_1 = 10$ and unit variance ($\sigma_1^2 = 1$), and the other half were generated according to a Gaussian distribution with mean $m_2 = 10$ and ten times higher variance ($\sigma_2^2 = 10$). The coefficient c in (4.1) was chosen to be 10.

For positive x, the first derivative of $g(x)$ is $\frac{x}{1+x/c}$, and for negative x it is $\frac{x}{1-x/c}$. Hence, $g'(0+) = g'(0-) = 0$. The continuity of $g(x)$ implies then that it is differentiable at zero despite the term $|x|$. Therefore, the first derivative of $g(x)$ is $\frac{x}{1+|x|/c}$, it is continuous, and it is bounded by c. Considering positive and negative x's separately also shows that $g''(0+) = g''(0-) = 1$ and that, in general, the second derivative of $g(x)$ is $\frac{1}{(1+|x|/c)^2}$, which is bounded by 1. Hence both Assumptions 1 and 2 hold. In addition, since $\frac{1}{(1+|x|/c)^2}$ is strictly positive, $g(x)$ is strictly convex, and therefore $f(x)$ is strictly convex as well. Since both $\lim_{x\to\infty} f(x)$ and $\lim_{x\to-\infty} f(x)$ diverge to ∞, $f(x)$ has no directions of recession, and therefore, by Theorem 27.1(d) in [41, p. 265], the minimum set of $f(x)$ is nonempty. The minimum is unique by the strict convexity of $f(x)$. Since $g''(x)$ is continuous and positive everywhere, Assumption 3 is satisfied. The strict convexity of $f(x)$ implies that Assumption 4 holds as well (see Remark 2).

Both the standard incremental gradient method (1.5) with a constant step size $\mu(k) = \mu$ (abbreviated as IG in the figures) and the IAG method with the initialization (3.1) were implemented with several choices of step size μ. The initial point x^1 was set to 0. In Figure 4.1 the trajectories of the two methods are presented. The solid straight line corresponds to the minimum point x^*. It is seen that when the step size is sufficiently small, IAG increases more rapidly towards x^* than the standard incremental gradient in the early iterations. Furthermore, as predicted by the theory, IAG converges to the true limit, whereas the incremental gradient method converges to a limit cycle. For a larger step size the IAG method overshoots due to its heavy ball characteristic (1.4). When the step size is too large, the IAG method no longer converges, but the incremental gradient method still converges to a limit cycle. We have observed this behavior for other values of the parameters $m_1, m_2, \sigma_1^2, \sigma_2^2, c$ as well.

We also compared the IAG method with the incremental gradient method with a diminishing step size, with Bertsekas' hybrid method [5], and with Tseng's incremental gradient with momentum [46] in terms of number of iterations to convergence. To optimize the performance of the incremental gradient method with a diminishing step size, a relatively large constant step size $\mu = 0.2$ is used until convergence to a limit cycle is detected, and then the diminishing step size is $\mu(k) = .2\mu/(\widetilde{k} - k)$, where $\widetilde{k}$ is the first iteration in which a limit cycle is detected. Convergence to a limit cycle is declared when $|x^k - x^{k-L}| < .01$ for k a multiple of L. To describe the parameters

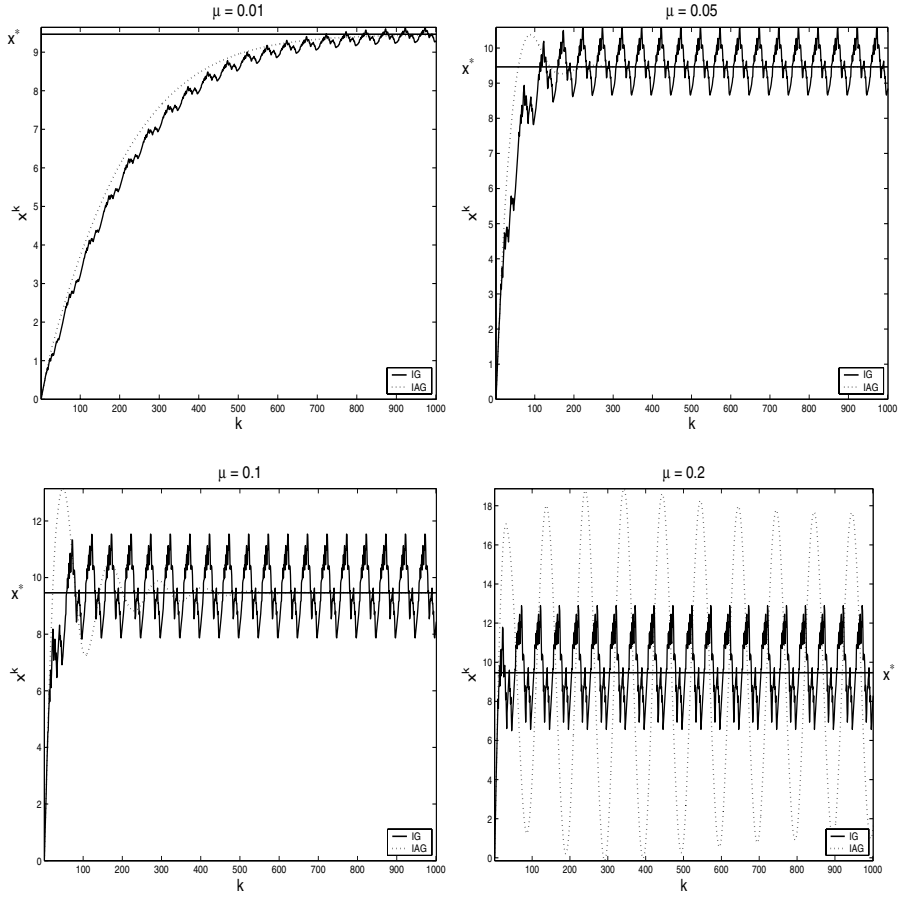

FIG. 4.1. *Trajectories taken by the IG and IAG methods for the robust "Fair" estimation problem.*

used in the hybrid method, we switch to the notation in [5]. We set $\gamma = 0.05$ and $\alpha(\mu)$ as defined in equation (47) in [5], with $\phi(\mu) = \zeta(1-\mu)$, where $\zeta = 2.5$. The transition parameter μ is kept at zero; i.e., the iterates are identical to the incremental gradient method until convergence to a limit cycle is detected as described above. Once a limit cycle is detected, μ is updated after every cycle according to $\mu := 1.5\mu + 0.3$, i.e., $\widehat{n} = 1$. These parameters seemed to optimize the performance of the hybrid method. The parameters of the incremental gradient with momentum term were set according to the recommendation in [46], which seemed to optimize the performance of the method in our application as well. In particular, we set $\epsilon_0 = 1$, $\epsilon_1 = \epsilon_2 = 0.00001$, $\epsilon_3 = 1000$, $\eta = 1.5 f(x_1^0) + 100$, $\rho = \infty$, $\omega = 0.5$, $\zeta = 0.8$, and $\lambda_1 + \lambda_2 + \cdots + \lambda_m = 1$. For the IAG method we set $\mu = 0.05$. The convergence point was specified to be the first iteration for which all subsequent iterations satisfy $|x^k - x^*| < \epsilon$. Since the IAG and the hybrid methods outperform the incremental gradient method with a diminishing step size and the incremental gradient with momentum term by a large margin, ϵ was specified to be 0.01 for the IAG and the hybrid method and 0.1 for the incremental gradient method with a diminishing step size and the incremental gradient with momentum term. The average number of iterations until convergence and its standard deviation were estimated from 100 Monte Carlo simulations and are summarized in Table 4.1.

TABLE 4.1
Number of iterations to convergence.

	IAG $\epsilon = 0.01$	Hybrid $\epsilon = 0.01$	IG diminishing step size $\epsilon = 0.1$	IG momentum term $\epsilon = 0.1$
Mean	290	589	601	2063
Std	23	135	258	919

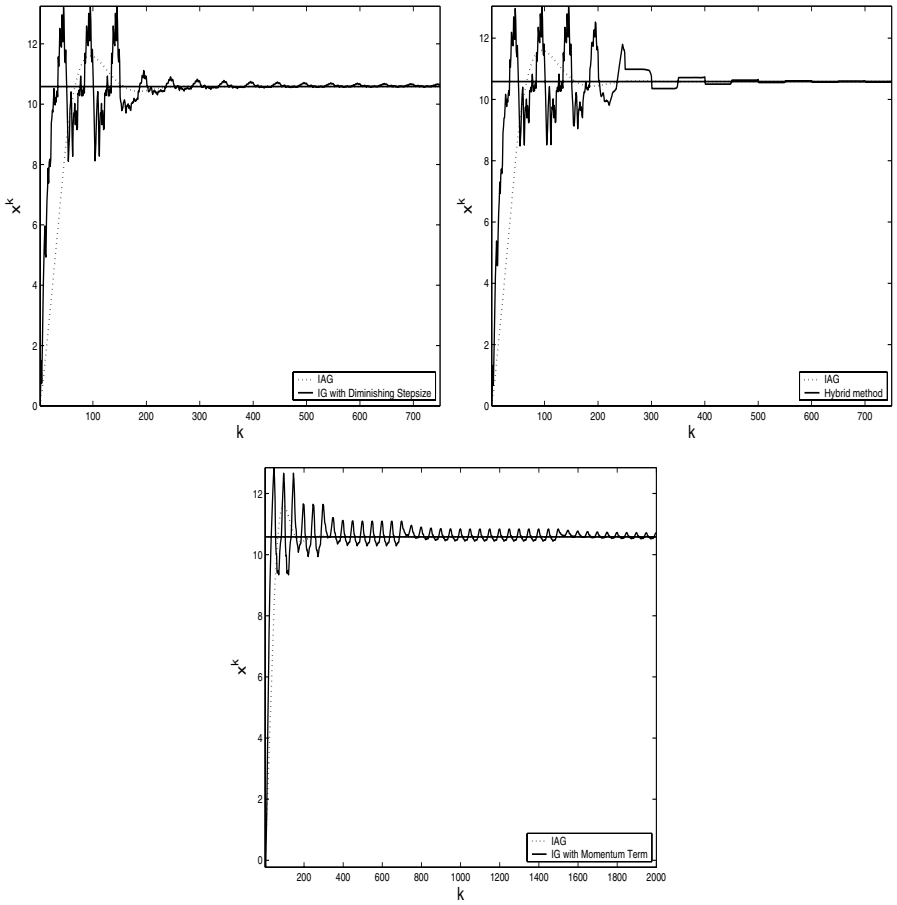

FIG. 4.2. *IAG compared to IG with diminishing step size, to the hybrid method, and to IG with momentum term.*

The trajectory taken by the different methods in one of these simulations is presented in Figure 4.2. It is seen that for this application, the IAG method performs best. Further experimentation is required to make more general conclusions.

4.2. Source localization. This section presents a simulation of a sensor network for localizing a source that emits acoustic waves. L sensors are distributed on the perimeter of a field at known spatial locations, denoted r_l, $l = 1, \ldots, L$, where $r_l \in \mathbb{R}^2$. Each sensor collects a noisy measurement of the acoustic signal transmitted by the source, denoted y_l, at an unknown location x. Based on a far-field assumption and an isotropic acoustic wave propagation model [13, 24, 36, 42, 43], the problem of estimation of source location can be formulated as a nonlinear least squares problem.

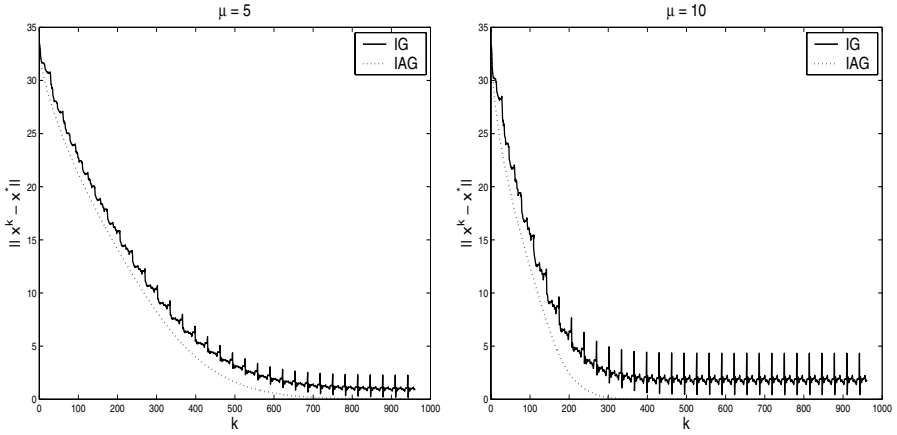

FIG. 4.3. *Distance of IG and IAG iterates to the optimal solution x^* for source localization problem.*

The objective function is again of the form (4.2), but now

$$f_l(x) = \left(y_l - g(||r_l - x||^2)\right)^2, \tag{4.3}$$

$x \in \mathbb{R}^2$, and

$$g(z) = \begin{cases} A/z & : \quad z \geq A/\epsilon, \\ 2\epsilon - \epsilon^2 z/A & : \quad z < A/\epsilon. \end{cases} \tag{4.4}$$

In (4.3) $g(\cdot)$ models the received signal strength as a function of the squared distance. In (4.4) A is a known constant characterizing the source's signal strength. For $z \geq A/\epsilon$ (far-field source), the source's signal strength has isotropic attenuation as an inverse function of the squared distance, while for $z < A/\epsilon$ (near-field source), the attenuation is linear in the squared distance. It is easy to see that Assumptions 1 and 2 are satisfied, and therefore Proposition 2.4 holds. Clearly, since $f(x)$ is multimodal in this case, Assumptions 3 and 4 cannot hold. However, it was observed in our experiments that when the source is sufficiently distant from the sensors, the objective function has a single minimum inside the observed field (see Figure 4.4 for a contour plot of the objective function) and, when initiated not too far from the minimum point, the IAG method has good convergence properties. This suggests the possible application of the IAG method under weaker assumptions than those considered in this paper and motivates further investigation into its properties.

In the numerical experiment, $L = 32$ sensors are distributed equidistantly on the perimeter of a 100×100 field. The source is located at the point $[60, 60]$ and emits a signal with strength $A = 1000$. The sensors' noisy measurements were generated according to a Gaussian distribution with a mean equal to the true signal power and unit variance. Both the incremental gradient method with a constant step size and the IAG method with the initialization (3.1) were initiated at the point $[40, 40]$. The error term $||x^k - x^*||$ as a function of the iteration number is presented in Figure 4.3 for two choices of step size. The actual path taken by the methods for step size $\mu = 10$ is presented in Figure 4.4, where the asterisk denotes the true minimum point of the objective function. It is seen that, as the theory predicts, the incremental

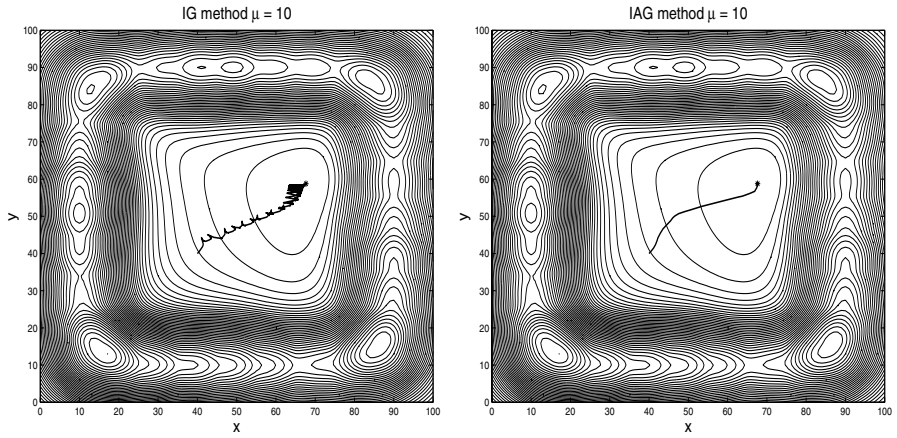

FIG. 4.4. *Path taken by the IG and IAG methods for source localization problem.*

gradient method exhibits oscillations near the eventual limit, whereas the IAG method converges to the minimum. In this scenario, the IAG method outperforms the IG method at early iterations as well.

ON THE RELATIONSHIP BETWEEN THE CONVERGENCE RATES OF ITERATIVE AND CONTINUOUS PROCESSES*

RAPHAEL HAUSER† AND JELENA NEDIĆ†

Abstract. Considering iterative sequences that arise when approximate solutions x_k to a numerical problem are updated by $x_{k+1} = x_k + v(x_k)$, where v is a differentiable vector field, we derive necessary and sufficient conditions for such discrete processes to converge to a stationary point of v at different Q-rates in terms of a similar notion of fast convergence for the corresponding continuous processes.

Key words. Q-convergence, superlinear convergence, nonlinear analysis, unconstrained optimization, root finding

1. Introduction.

In this paper we study sequences $(x_k)_{\mathbb{N}_0}$ which, given a starting point x_0, consist of points that are iteratively related to one another via the rule

$$x_{k+1} = x_k + v(x_k), \tag{1.1}$$

where $v : D \subseteq \mathbb{R}^n \to \mathbb{R}^n$ is a differentiable vector field with Jacobian $J = \mathrm{D}v$, and where D is a convex open domain. We are interested in the situation where x_k converges to a stationary point x^* of v, i.e., a point where $v(x^*) = 0$. Sequences of the form (1.1) appear in many areas of numerical analysis where an approximate solution x_k is iteratively improved, notably in unconstrained optimization and in zero-finding problems. One of the major objectives in designing iterative schemes of this kind is to ensure that they converge at a provably fast rate to a point x^* which represents a solution of interest. The concept of fast convergence used in this paper is that of *uniform* Q-convergence. Related but not entirely equivalent notions of Q-convergence have been discussed in the literature; see, e.g., [5].

DEFINITION 1.1. *We say that the process* (1.1) *converges to* x^* *uniformly at Q-convergence rate* $q > 1$ *in the ball* $\mathrm{B}_\rho(x^*)$ *if there exists* $\beta > 0$ *such that*

$$\|x + v(x) - x^*\| \le \beta \|x - x^*\|^q \tag{1.2}$$

for all $x \in \mathrm{B}_\rho(x^*)$*, where* $\|\cdot\|$ *denotes the Euclidean norm.*

Setting $\tilde{\rho} := \min(\rho, \beta^{\frac{1}{q-1}})$, another way to express this is that if the sequence $(x_k)_{\mathbb{N}}$ ever enters the ball $\mathrm{B}_{\tilde{\rho}}(x^*)$, then it converges to x^*, and each iteration starting from within the ball improves the accuracy of x_k as an approximation of x^* to about q times as many correct digits as beforehand. The constant β is called the *convergence factor*. For example, the well-known Kantorovich theorem [3] shows that Newton's method

for zero-solving converges Q-quadratically under standard regularity assumptions. A weaker notion of fast convergence is the following.

DEFINITION 1.2. *We say that the process* (1.1) *converges uniformly Q-superlinearly to* x^* *if*

$$\lim_{x \to x^*} \frac{\|x + v(x) - x^*\|}{\|x - x^*\|} = 0. \tag{1.3}$$

That is, asymptotically, each iteration adds more than any fixed number of additional correct digits to the current approximation of x^*.

Let us briefly comment on the notation used in this paper. All identity matrices are denoted by I, irrespective of their dimension. We write S^{n-1} for the set of unit vectors $\{x \in \mathbb{R}^n : \|x\| = 1\}$ in $\mathbb{R}^n$. This is a standard notation that accounts for the fact that the sphere S^{n-1} is a $(n-1)$-dimensional manifold. Another standard notation, already used, is to write $B_\delta(x) := \{y \in \mathbb{R}^n : \|y - x\| < \delta\}$ for the open Euclidean ball of radius δ in $\mathbb{R}^n$. We denote inner products by $\langle \cdot, \cdot \rangle$ and use $\cdot$ for scalar multiplication instead where it helps improve the readability of the text. If x is a nonzero vector in $\mathbb{R}^n$, we write $\mathfrak{n}(x) := \|x\|^{-1} \cdot x$ for its normalization.

1.1. Overview. The discrete dynamical system (1.1) has a continuous analogue obtained when damping with an infinitesimal step size is applied. The associated flow is defined by

$$\frac{\partial}{\partial t}\varphi(x,t) = v(\varphi(x,t)), \qquad \varphi(x,0) = x. \tag{1.4}$$

In other words, in the continuous process one chooses a starting point x and follows the flux line $t \mapsto \varphi(x,t)$, obtained by integrating the ODE (1.4) to a limit point $x^* = \lim_{t\to\infty} \varphi(x,t)$. Note that the *flow-conservation property*

$$\varphi(x, t+\tau) = \varphi\big(\varphi(x,t), \tau\big) \tag{1.5}$$

holds for all x, t, and τ for which both sides are well defined.

The main goal of this paper is to investigate the notion of Q-convergence for the discrete process (1.1) via a new notion of fast convergence for the associated continuous process (1.4). This is done in section 3, where we define the notions of exponential and p-exponential convergence for (1.4) and show that they are equivalent to uniform Q-superlinear and Q-convergence of rate $p+1$ for (1.1); see Theorem 3.4.

Our results shed new light on the well-established notion of Q-convergence, as exponential convergence has an easy geometric interpretation in terms of the flux lines of (1.4): not only do these have to converge to x^* exponentially fast in t, but also does a rotational component have to die out sufficiently quickly.

It is often observed that continuous dynamical systems are easier to analyze than discrete ones. Useful applications of Theorem 3.4 as an analytic tool derive from this observation. We illustrate this in section 5, where we discuss an example of a vector field $v(x)$ with the property that none of the rescaled vector fields $\lambda(x)v(x)$ leads to a discrete process (1.1) with a faster Q-convergence rate than the process corresponding to $v(x)$. In this context $\lambda(x)$ can be chosen as an arbitrary positive differentiable scalar function. This observation is relevant in unconstrained optimization, as it shows that a line search cannot be expected to speed up the asymptotic convergence rate of a search direction field.

Continuous methods for solving zero-finding and optimization problems have been proposed by various authors; see, e.g., [1, 2] for relevant ideas and references. To avoid

any confusion, we point out that our paper is not intended as a direct contribution to this discussion. Instead, our focus is on understanding convergence rates alone and on deriving a useful observation in the context of unconstrained optimization.

To prepare the analysis of our main result in section 3, an exact characterization of the vector fields that make the process (1.1) converge fast under either notion of uniform Q-convergence is given in section 2: Theorem 2.3 shows that when the Jacobian $J(x)$ is sufficiently smooth at x^*, then the process (1.1) converges at a quantifiable Q-convergence rate if and only if $v(x^*) = 0$ and $J(x^*) = -\mathrm{I}$. This result is also interesting in its own right.

2. Fast convergence of the discrete process. In this section we consider the discrete dynamical system (1.1). We will see that uniform Q-superlinear convergence and uniform Q-convergence at a given rate are characterized by the differential properties of $v(x)$ in a neighborhood of x^*.

Let $p > 0$. Recall that the tensor field $J(x)$ is said to be *p-Hölder continuous at* x^* if there exist constants $\alpha > 0$ and $\varrho > 0$ such that

$$\|J(x) - J(x^*)\| \leq \alpha \|x - x^*\|^p \tag{2.1}$$

for all $x \in \mathrm{B}_\varrho(x^*)$.

LEMMA 2.1. *Let J be continuous at x^*, $v(x^*) = 0$, and $J(x^*) = -\mathrm{I}$. Then* (1.1) *converges uniformly Q-superlinearly to x^*. If J is furthermore p-Hölder continuous at x^* then* (1.1) *converges uniformly at the Q-convergence rate $p+1$ in a neighborhood of x^*.*

Proof. Using $v(x^*) = 0$, we find that for all $x \in D$,

$$\begin{aligned}\lim_{x\to x^*} \frac{\|x + v(x) - x^*\|}{\|x - x^*\|} &= \lim_{x\to x^*} \frac{\left\| \left(\mathrm{I} + \int_0^1 J(x^* + t(x - x^*))dt \right)(x - x^*) \right\|}{\|x - x^*\|} \\ &\leq \lim_{x\to x^*} \left\| \mathrm{I} + \int_0^1 J(x^* + t(x - x^*))dt \right\| = 0,\end{aligned}$$

where the last equality follows from the continuity of J at x^*. This shows the first claim. The second claim is established as follows:

$$\begin{aligned}\|x + v(x) - x^*\| &= \left\| \left(\mathrm{I} + \int_0^1 J(x^* + t(x - x^*))dt \right)(x - x^*) \right\| \\ &\leq \left\| \mathrm{I} + \int_0^1 J(x^* + t(x - x^*))dt \right\| \cdot \|x - x^*\| \\ &\leq \int_0^1 \alpha t^p \|x - x^*\|^p dt \cdot \|x - x^*\| = \frac{\alpha}{p+1} \cdot \|x - x^*\|^{p+1}. \qquad \square\end{aligned}$$

We remark that Lemma 2.1 is a minor adaptation of a special case of Theorem 10.1.6 [4] by Ortega and Rheinboldt, which says that if $G : D \subset \mathbb{R}^n \to \mathbb{R}^n$ has a fixed point $x^* \in D$ at which it is F-differentiable with $G'(x^*) = 0$, then x^* is a point of attraction of the process $x_{k+1} := G(x_k)$, and furthermore, if $G(x)$ is p-Hölder continuous at x^*, then the process converges at order p. In the context of Lemma 2.1 one can choose $G(x) = x + v(x)$, so that the criterion $G'(x^*) = 0$ becomes $\mathrm{I} + J(x^*) = 0$ and the fixed-point criterion $G(x^*) = x^*$ becomes $x^* = x^* + v(x^*)$. Furthermore, p-Hölder continuity of $G(x)$ at x^* means the existence of a constant $\beta > 0$ such that

$$\|x + v(x) - x^*\| = \|G(x) - G(x^*)\| \leq \beta \|x - x^*\|^p \tag{2.2}$$

in a neighborhood of x^*, which is in fact nothing but the definition of uniform Q-convergence of order p; see Definition 1.1. Thus, Theorem 10.1.6 in [4] applies to more general maps under weaker differentiability assumptions than Lemma 2.1, but by making the assumption (2.2), order-p convergence is a forgone conclusion in the specific case that is of interest here.

We are now going to prove a partial inverse of Lemma 2.1.

LEMMA 2.2. *If* (1.1) *converges uniformly Q-superlinearly to* x^**, then* $v(x^*) = 0$ *and* $J(x^*) = -\mathrm{I}$.

Proof. Equation (1.3) implies that for all $\varepsilon > 0$ there exists $\delta_\varepsilon > 0$ such that $x \in \mathrm{B}_{\delta_\varepsilon}(x^*)$ implies

$$\|x + v(x) - x^*\| \le \varepsilon \|x - x^*\|. \tag{2.3}$$

Taking limits $x \to x^*$ on both sides and using the continuity of v, we obtain $\|v(x^*)\| \le 0$, which shows that $v(x^*) = 0$. Next, let $z \in \mathrm{S}^{n-1}$ and consider the sequence $(x_n)_{\mathbb{N}}$ defined by $x_n = x^* + z/n$. Then (1.3) and $v(x^*) = 0$ show that

$$\|\big(\mathrm{I} + J(x^*)\big)z\| = \lim_{n\to\infty} \frac{\|x_n - x^* + v(x_n) - v(x^*)\|}{\|x_n - x^*\|} = 0.$$

But this shows that $J(x^*)z = -z$, and since z was an arbitrary unit vector, it follows that $J(x^*) = -\mathrm{I}$. ∎

It thus emerges that if continuity or Hölder continuity of J at x^* is given, then the two preceding lemmas yield the following exact characterization of fast convergence.

THEOREM 2.3. *If* J *is continuous at* x^**, then* (1.1) *converges to* x^* *uniformly Q-superlinearly if and only if* $v(x^*) = 0$ *and* $J(x^*) = -\mathrm{I}$. *If* J *is p-Hölder continuous at* x^**, then* (1.1) *converges uniformly at the Q-convergence rate* $p+1$ *in a neighborhood of* x^* *if and only if* $v(x^*) = 0$ *and* $J(x^*) = -\mathrm{I}$.

Proof. Observe that Q-convergence at a rate $p + 1 > 1$ implies Q-superlinear convergence. Everything else follows directly from Lemmas 2.1 and 2.2. ∎

Note that Theorem 2.3 shows that the only difference between Q-superlinear convergence and convergence at Q-rates $p + 1 > 1$ consists in the smoothness of the Jacobian of v in a neighborhood of x^*.

3. Fast convergence of the continuous process. In this section we introduce notions of fast convergence for the continuous dynamical system (1.4) which we will show to be equivalent to uniform Q-superlinear convergence and uniform Q-convergence of rate $p + 1$, respectively, of the discrete system (1.1).

The following property of differential inequalities is well known; see, e.g., [6].

LEMMA 3.1. *Let* $\frac{d}{dt}y(t) = g(t, y(t))$, $y(0) = y_0$, $t \ge 0$, *where* $g \in C(\mathbb{R}_+, \mathbb{R})$ *and* $y \in C^1(\mathbb{R}_+, \mathbb{R})$, *and let* $\frac{d}{dt}z(t) \lessgtr g(t, z(t))$, $z(0) = y_0$, $t \ge 0$. *If* $g(t, x)$ *is monotone increasing in* x *or of the form* $g(t, x) = h(t)$ *or* $g(t, x) = h(t)x$, *then* $z(t) \lessgtr y(t)$ *for all* $t \ge 0$.

We will be interested in the normalized vector

$$\mathfrak{n}(\varphi(x,t) - x^*) := \frac{\varphi(x,t) - x^*}{\|\varphi(x,t) - x^*\|} \in \mathrm{S}^{n-1} := \big\{x \in \mathbb{R}^n : \|x\| = 1\big\}$$

and the speed $\|\frac{\partial}{\partial t}\mathfrak{n}(\varphi(x,t) - x^*)\|$ which we will call the *angular speed* and which can be interpreted as the absolute angle traversed by the flux line $\varphi(x,t)$ with respect to x^* per unit time.

LEMMA 3.2. *For $\varphi(x,t)$ as defined by (1.4) it is true that*

$$\frac{\partial}{\partial t}\mathfrak{n}(\varphi(x,t)-x^*) = \frac{(\mathrm{I}-P(x,t))\,v(\varphi(x,t))}{\|\varphi(x,t)-x^*\|}, \tag{3.1}$$

where $P(x,t)$ denotes the orthogonal projection of $\mathbb{R}^n$ onto $\operatorname{span}\{\varphi(x,t)-x^*\}$.

Proof. The proof is a straightforward calculation. ∎

DEFINITION 3.3. *Let $v : D \to \mathbb{R}$ be a differentiable vector field with Jacobian J and let $x^* \in D$ be a stationary point of v, that is, $v(x^*) = 0$. We say that the continuous dynamical system (1.4) defined by v converges* exponentially *to x^* if for all $\varepsilon \in (0,1)$ there exists $\rho_\varepsilon > 0$ such that $x \in \mathrm{B}_{\rho_\varepsilon}(x^*) \setminus \{x^*\}$ and $t \geq 0$ imply*

$$\mathrm{e}^{-(1+\varepsilon)t}\,\|x-x^*\| \leq \|\varphi(x,t)-x^*\| \leq \mathrm{e}^{-(1-\varepsilon)t}\,\|x-x^*\|, \tag{3.2}$$

$$\left\|\frac{\partial}{\partial t}\mathfrak{n}(\varphi(x,t)-x^*)\right\| \leq \varepsilon. \tag{3.3}$$

We say that (1.4) converges p-exponentially to x^* if (3.2) holds and there exist constants $\xi > 0$ and $\gamma > 0$ such that $\rho_\varepsilon > \xi\varepsilon^{1/p}$ for all ε small enough and

$$\left\|\frac{\partial}{\partial t}\mathfrak{n}(\varphi(x,t)-x^*)\right\| \leq \gamma\,\mathrm{e}^{-(1-\varepsilon)pt}\,\|x-x^*\|^p \tag{3.4}$$

for all $x \in \mathrm{B}_{\rho_\varepsilon}(x^*)$ and $t \geq 0$.

Our goal now is to establish the following equivalence that constitutes the main result of this paper. Note that in contrast to Theorem 2.3, this theorem does not make any assumptions on the Hölder continuity of J at x^*.

THEOREM 3.4. *The notion of exponential convergence of the continuous dynamical system (1.4) is equivalent to the notion of uniform Q-superlinear convergence of the discrete system (1.1). Likewise, the notion of p-exponential convergence of (1.4) is equivalent to the notion of uniform Q-convergence of rate $p+1$.*

Proof. The proof follows immediately from Lemmas 3.5 and 3.6. ∎

LEMMA 3.5. *If (1.1) converges uniformly Q-superlinearly to x^*, then (1.4) converges exponentially to x^*. Moreover, if (1.1) converges uniformly at Q-convergence rate $p+1 > 1$, then (1.4) converges p-exponentially.*

Proof. Let δ_ε be chosen as in the proof of Lemma 2.2 and let $\varepsilon \in (0,1)$. If $\varphi(x,t) \in \mathrm{B}_{\delta_\varepsilon}(x^*)$, then (2.3) applied to $\varphi(x,t)$ (in the role of x) yields

$$\begin{aligned}\frac{\partial}{\partial t}\Big\|\varphi(x,t)-x^*\Big\| &= \big\langle v\big(\varphi(x,t)\big), \mathfrak{n}\big(\varphi(x,t)-x^*\big)\big\rangle \\ &\overset{(2.3)}{\leq} -(1-\varepsilon)\|\varphi(x,t)-x^*\| < 0.\end{aligned} \tag{3.5}$$

We now claim that

$$x \in \mathrm{B}_{\delta_\varepsilon}(x^*) \Rightarrow \varphi(x,t) \in \mathrm{B}_{\delta_\varepsilon}(x^*) \qquad \forall t \geq 0. \tag{3.6}$$

Indeed, if the contrary holds, then there exists $\tau > 0$ such that $\varphi(x,\tau) \in \partial\,\mathrm{B}_{\delta_\varepsilon}(x^*)$ and $\varphi(x,t) \in \mathrm{B}_{\delta_\varepsilon}(x^*)$ for all $t \in [0,\tau)$. But this leads to

$$\delta_\varepsilon = \|\varphi(x,\tau)-x^*\| = \|x-x^*\| + \int_0^\tau \frac{\partial}{\partial t}\Big|_{t=\theta}\|\varphi(x,t)-x^*\|\,d\theta < \delta_\varepsilon + \int_0^\tau 0\,d\theta,$$

which is a contradiction showing that (3.6) holds true, as claimed. It follows from (3.6) that $x \in \mathrm{B}_{\delta_\varepsilon}(x^*)$ implies (3.5) for all $t \geq 0$. Now let

$$R(x,t) := \frac{v\big(\varphi(x,t)\big) + \varphi(x,t) - x^*}{\|\varphi(x,t) - x^*\|}.$$

By the definition of δ_ε, $\varphi(x,t) \in \mathrm{B}_{\delta_\varepsilon}(x^*)$ implies

$$\|R(x,t)\| = \frac{\big\|\varphi(x,t) + v\big(\varphi(x,t)\big) - x^*\big\|}{\big\|\varphi(x,t) - x^*\|} < \varepsilon. \tag{3.7}$$

By (3.6), (3.7) thus holds true for all $t \geq 0$ when $x \in \mathrm{B}_{\delta_\varepsilon}(x^*)$, and then

$$\begin{aligned}\frac{\partial}{\partial t}\|\varphi(x,t) - x^*\| &= \big\langle v(\varphi(x,t)), \mathfrak{n}(\varphi(x,t) - x^*)\big\rangle \\ &= \big(-1 + \big\langle R(x,t), \mathfrak{n}(\varphi(x,t) - x^*)\big\rangle\big)\ \|\varphi(x,t) - x^*\| \\ &\overset{(3.7)}{\geq} -(1+\varepsilon)\|\varphi(x,t) - x^*\|.\end{aligned}$$

The combination of the last inequality with (3.5) establishes that if $x \in \mathrm{B}_{\delta_\varepsilon}(x^*)$, then

$$-(1+\varepsilon)\|\varphi(x,t) - x^*\| \leq \frac{\partial}{\partial t}\Big\|\varphi(x,t) - x^*\Big\| \leq -(1-\varepsilon)\|\varphi(x,t) - x^*\| \quad \forall t \geq 0. \tag{3.8}$$

Furthermore, for $x \in \mathrm{B}_{\delta_\varepsilon}(x^*)$ we have

$$\begin{aligned}\Big\|\frac{\partial}{\partial t}\mathfrak{n}\big(\varphi(x,t) - x^*\big)\Big\| &= \frac{\big\|v(\varphi(x,t)) - \frac{\partial}{\partial t}\|\varphi(x,t) - x^*\| \cdot \mathfrak{n}(\varphi(x,t) - x^*)\big\|}{\|\varphi(x,t) - x^*\|} \\ = \frac{\big\|v(\varphi(x,t)) + \varphi(x,t) - x^* - \big(\varphi(x,t) - x^* + \frac{\partial}{\partial t}\|\varphi(x,t) - x^*\| \cdot \mathfrak{n}(\varphi(x,t) - x^*)\big)\big\|}{\|\varphi(x,t) - x^*\|} &\qquad (3.9) \\ \leq \|R(x,t)\| + \frac{\big|\|\varphi(x,t) - x^*\| + \frac{\partial}{\partial t}\|\varphi(x,t) - x^*\|\big|}{\|\varphi(x,t) - x^*\|} \\ \overset{(3.7),(3.8)}{\leq} \varepsilon + \varepsilon. &\qquad (3.10)\end{aligned}$$

Equations (3.8), (3.10), and Lemma 3.1 therefore show that (3.2) and (3.3) hold with $\rho_\varepsilon = \delta_{\varepsilon/2}$ for all $\varepsilon \in (0,1)$. This settles the first claim of the lemma.

For the purposes of proving the second claim, let β and ρ be chosen as in (1.2), and note that if (1.2) holds, then by the same arguments as above the inequality (3.8) can be strengthened to

$$\begin{aligned}&-(1+\beta\|\varphi(x,t) - x^*\|^p)\|\varphi(x,t) - x^*\| \\ &\qquad \leq \frac{\partial}{\partial t}\Big\|\varphi(x,t) - x^*\Big\| \\ &\qquad\qquad \leq -(1-\beta\|\varphi(x,t) - x^*\|^p)\|\varphi(x,t) - x^*\|\end{aligned} \tag{3.11}$$

for $x \in \mathrm{B}_r(x^*)$ and $t \geq 0$, where $r = \min\{(\beta)^{-1/p}, \rho\}$ now ensures that if $x \in \mathrm{B}_r(x^*)$, then $\varphi(x,t) \in \mathrm{B}_r(x^*)$ for all $t \geq 0$. It follows from (3.11) that for $r_\varepsilon = \min\{(\varepsilon/\beta)^{1/p}, r\} = \min\{(\varepsilon/\beta)^{1/p}, \rho\}$, $x \in \mathrm{B}_{r_\varepsilon}(x^*)$, and $t \geq 0$, it is the case that

$$-(1+\varepsilon)\|\varphi(x,t) - x^*\| \leq \frac{\partial}{\partial t}\|\varphi(x,t) - x^*\| \leq -(1-\varepsilon)\|\varphi(x,t) - x^*\|.$$

Lemma 3.1 therefore shows that (3.2) holds with $\rho_\varepsilon = r_\varepsilon$. Furthermore, if (1.2) holds, then $x \in \mathrm{B}_{r_\varepsilon}(x^*)$ implies $\varphi(x,t) \in \mathrm{B}_{r_\varepsilon}(x^*) \subset \mathrm{B}_\rho(x^*)$ for all $t \geq 0$ and then

$$\|R(x,t)\| \leq \beta \|\varphi(x,t) - x^*\|^p.$$

Equations (3.11), (3.10), and (3.2) therefore show that (3.4) holds with $\gamma = 2\beta$. ∎

LEMMA 3.6. *If* (1.4) *converges exponentially to* x^**, then* (1.1) *converges uniformly Q-superlinearly to* x^**. Moreover, if* (1.4) *converges p-exponentially, then* (1.1) *converges uniformly at Q-convergence rate* $p+1$*.*

Proof. Let ρ_ε be as in Definition 3.3. Suppose that $\frac{\partial}{\partial t}\|\varphi(x,t_0) - x^*\| > -\|\varphi(x,t_0) - x^*\|(1-\varepsilon)$ for some $x \in \mathrm{B}_{\rho_\varepsilon}(x^*)$ and $t_0 > 0$. By continuity there exists $\delta > 0$ such that

$$\frac{\partial}{\partial t}\|\varphi(x,t) - x^*\| > -\|\varphi(x,t) - x^*\|(1-\varepsilon)$$

for all $t \in [t_0, t_0+\delta]$. By Lemma 3.1 we then have

$$\|\varphi(x,t) - x^*\| > \|\varphi(x,t_0) - x^*\| \, \mathrm{e}^{-(1-\varepsilon)t}$$

for $t \in [t_0, t_0+\delta]$, contradicting the upper bound in (3.2) when $\varphi(x,t_0)$ is used in place of x. This and a similar argument using the lower bound in (3.2) show that

$$-\|\varphi(x,t) - x^*\|(1+\varepsilon) \leq \frac{\partial}{\partial t}\|\varphi(x,t) - x^*\| \leq -\|\varphi(x,t) - x^*\|(1-\varepsilon)$$

for all $t \geq 0$ and $x \in \mathrm{B}_{\rho_\varepsilon}(x^*)$, and hence,

$$\begin{aligned} &\big\|P(x,t)\big(v(\varphi(x,t)) + \varphi(x,t) - x^*\big)\big\| \\ &\qquad = \left|\frac{\partial}{\partial t}\|\varphi(x,t) - x^*\| + \|\varphi(x,t) - x^*\|\right| \\ &\qquad \leq \varepsilon\|\varphi(x,t) - x^*\|. \end{aligned} \tag{3.12}$$

On the other hand, (3.1) and (3.3) show that for all $t \geq 0$ and $x \in \mathrm{B}_{\rho_\varepsilon}(x^*)$,

$$\begin{aligned} &\big\|(\mathrm{I} - P(x,t))\big(v(\varphi(x,t)) + \varphi(x,t) - x^*\big)\big\| \\ &\qquad = \Big\|\frac{\partial}{\partial t}\mathfrak{n}(\varphi(x,t) - x^*)\Big\| \cdot \|\varphi(x,t) - x^*\| \\ &\qquad \leq \varepsilon\|\varphi(x,t) - x^*\|. \end{aligned} \tag{3.13}$$

Inequalities (3.12) and (3.13) finally show that

$$\begin{aligned} &\frac{\big\|x + v(x) - x^*\big\|}{\|x - x^*\|} = \frac{\big\|v\big(\varphi(x,0)\big) + \varphi(x,0) - x^*\big\|}{\|\varphi(x,0) - x^*\|} \\ &\leq \frac{\big\|P(x,0)\big(v(\varphi(x,0)) + \varphi(x,0) - x^*\big)\big\|}{\|\varphi(x,0) - x^*\|} + \frac{\big\|\big(\mathrm{I} - P(x,0)\big)\big(v(\varphi(x,0)) + \varphi(x,0) - x^*\big)\big\|}{\|\varphi(x,0) - x^*\|} \\ &\leq 2\varepsilon \end{aligned} \tag{3.14}$$

for all $x \in \mathrm{B}_{\rho_\varepsilon}(x^*)$. Since this holds true for any $\varepsilon > 0$, we find that (1.3) holds, showing the first claim. If (1.4) converges p-exponentially, then the estimate (3.13) improves to

$$\Big\|\frac{\partial}{\partial t}\mathfrak{n}(\varphi(x,t) - x^*)\Big\| \cdot \|\varphi(x,t) - x^*\| \leq \gamma\|x - x^*\|^{p+1} \, \mathrm{e}^{-(1-\varepsilon)(p+1)t},$$

which leads to the inequality

$$\big\|(\mathrm{I}-P(x,0))\big(v(\varphi(x,0))+\varphi(x,0)-x^*\big)\big\| \le \gamma\|x-x^*\|^{p+1}. \tag{3.15}$$

Likewise, the estimate (3.12) improves, because there exists $\delta > 0$ such that for all $x \in \mathrm{B}_\delta(x^*)$ we have $x \in \mathrm{B}_{\rho_\varepsilon}(x^*)$ for some $\varepsilon \le \xi^{-p}\|x-x^*\|^p$. But then (3.2) shows that for $t \ge 0$,

$$\mathrm{e}^{-(1+\xi^{-p}\|x-x^*\|^p)t}\,\|x-x^*\| \le \|\varphi(x,t)-x^*\| \le \mathrm{e}^{-(1-\xi^{-p}\|x-x^*\|^p)t}\,\|x-x^*\|,$$

and by a similar argument as used above,

$$-\big(1+\xi^{-p}\|x-x^*\|^p\big)\|\varphi(x,t)-x^*\| \le \frac{\partial}{\partial t}\|\varphi(x,t)-x^*\| \le -\big(1-\xi^{-p}\|x-x^*\|^p\big)\|\varphi(x,t)-x^*\|$$

for all $t \ge 0$ and $x \in \mathrm{B}_\delta(x^*)$, so that

$$\left|\frac{\partial}{\partial t}\|\varphi(x,0)-x^*\| + \|\varphi(x,0)-x^*\|\right| \le \xi^{-p}\|x-x^*\|^{p+1}.$$

Using this in (3.12), we obtain

$$\big\|P(x,0)\big(v(\varphi(x,0))+\varphi(x,0)-x^*\big)\big\| \le \xi^{-p}\|x-x^*\|^{p+1}. \tag{3.16}$$

Finally, substituting (3.15) and (3.16) in (3.14), we obtain (1.2) with $\beta = \gamma+\xi^{-p}$ and $q = p$, and hence the second claim is true. □

4. Implications for the Newton process. The notion of exponential convergence shows that Q-convergence of the discrete process (1.1) corresponding to a vector field $v(x)$ is essentially due to two factors: the associated continuous flow $\varphi(x,t)$ converges exponentially fast to x^*, and the angular speed of $\varphi(x,t)$ relative to x^* decays to zero at a fast-enough rate. An important condition is that these rates must occur in neighborhoods of x^* that are not too small. Theorem 3.4 thus sets a geometric paradigm for constructing a vector field $v(x)$ such that the process (1.1) is attractive to x^* and converges fast. Let us now comment on the extent to which the Newton–Raphson approach satisfies this paradigm.

In Theorem 10.2.2 of [4], Ortega and Rheinboldt showed that if $f : D \to \mathbb{R}^n$, $x^* \in D \subset \mathbb{R}^n$, is such that $f(x^*) = 0$ and f' is p-Hölder continuous and nonsingular at x^*, then the Newton process converges to x^* at order at least $p+1$.

By linking the notion of uniform Q-convergence of order $p+1$ with the concept of p-exponential convergence, Theorem 3.4 can be used to derive an alternative proof that explains this phenomenon geometrically in the case where f is k times continuously differentiable for some $k > p \ge 1$: p-Hölder continuity of f' then implies that $p \in \mathbb{N}$ and $f''(x^*), \dots, f^{(p)}(x^*) = 0$ so that the Taylor developments of f, f', and f'' around x^* are of the form

$$f(x) = f'(x^*)[x-x^*] + f^{(p+1)}(x^*)[x-x^*,\dots,x-x^*] + o\left(\|x-x^*\|^{p+1}\right), \tag{4.1}$$

$$f'(x) = f'(x^*) + f^{(p+1)}(x^*)[x-x^*,\dots,x-x^*;\cdot] + o\left(\|x-x^*\|^{p}\right), \tag{4.2}$$

$$f''(x) = f^{(p+1)}(x^*)[x-x^*,\dots,x-x^*;\cdot,\cdot] + o\left(\|x-x^*\|^{p-1}\right). \tag{4.3}$$

Therefore,

$$\begin{aligned} v(x) &= -(f'(x))^{-1} f(x) \\ &= -\left(f'(x^*) + \mathscr{O}(\|x-x^*\|^p)\right)^{-1} \left(f'(x^*)(x-x^*) + \mathscr{O}(\|x-x^*\|^{p+1})\right) \\ &= -\left(f'(x^*)^{-1} + \mathscr{O}(\|x-x^*\|^p)\right) \left(f'(x^*)(x-x^*) + \mathscr{O}(\|x-x^*\|^{p+1})\right) \\ &= x^* - x + \mathscr{O}(\|x-x^*\|^{p+1}). \end{aligned} \tag{4.4}$$

Thus, multiplying the vector field $f(x)$ with $-(f'(x))^{-1}$ produces a new vector field $v(x)$ that asymptotically looks like the radial vector field $r(x) := x^* - x$ in the sense that

$$v(x) = r(x) + o(\|x-x^*\|). \tag{4.5}$$

This is exactly the condition needed to make the associated flux $\varphi(x,t)$ converge exponentially to x^*: (4.5) implies that for every $\varepsilon > 0$ there exists $\rho_\varepsilon > 0$ such that for all $x \in \mathrm{B}_{\rho_\varepsilon}(x^*)$,

$$\|v(x) - (x^* - x)\| \leq \varepsilon \|x - x^*\|. \tag{4.6}$$

Therefore,

$$\begin{aligned} \frac{\partial}{\partial t}\|\varphi(x,t)-x^*\| &= \|\varphi(x,t)-x^*\|^{-1} \left\langle \frac{\partial}{\partial t}\varphi(x,t), \varphi(x,t)-x^* \right\rangle \\ &= \langle v(\varphi(x,t)), \mathfrak{n}(\varphi(x,t)-x^*)\rangle \\ &\leq -\|\varphi(x,t)-x^*\| \cdot (1-\varepsilon), \end{aligned}$$

and likewise,

$$\frac{\partial}{\partial t}\|\varphi(x,t)-x^*\| \geq -\|\varphi(x,t)-x^*\| \cdot (1+\varepsilon).$$

Invoking Lemma 3.1, we find (3.2). Furthermore, by Lemma 3.2,

$$\left\| \frac{\partial}{\partial t}\mathfrak{n}(\varphi(x,t)-x^*) \right\| = \frac{\left\| \big(\mathrm{I} - P(\varphi(x,t))\big) v(\varphi(x,t)) \right\|}{\|\varphi(x,t)-x^*\|} \leq \varepsilon,$$

where the last inequality follows from $P(\varphi(x,t))(\varphi(x,t)-x^*) = \varphi(x,t)-x^*$ and (4.6). Therefore, (3.3) holds as required.

In order to furthermore achieve p-exponential convergence, the "rotational speed" $\frac{\partial}{\partial t}\mathfrak{n}(\varphi(x,t)-x^*)$ needs to decay uniformly and fast enough. But if $f'(x)$ is p-Hölder continuous, then

$$\begin{aligned} \frac{\partial}{\partial t}\Big|_{t=0} \mathfrak{n}(\varphi(x,t)-x^*) &\overset{(3.1)}{=} \frac{(\mathrm{I}-P(x,0))\, v(x)}{\|x-x^*\|} \\ &\overset{(4.4)}{=} (\mathrm{I}-P(x,0)) \left(\frac{x-x^* + \mathscr{O}(\|x-x^*\|^{p+1})}{\|x-x^*\|} \right) \\ &= \mathscr{O}(\|x-x^*\|^p), \end{aligned}$$

where we used $(\mathrm{I}-P(x,0))(x-x^*) = 0$. This shows that the rotational component dies out at the required rate (3.4).

5. Q-convergence rates for rescaled vector fields. The question naturally arises as to whether a rescaled vector field $\lambda(x)v(x)$ for some scalar function $\lambda : D \to \mathbb{R}_+$ has a faster Q-convergence rate than $v(x)$. Such rescaling is routinely used in unconstrained optimization, where search-direction-based descent methods are combined with line-searches. It turns out that in the general case the Q-convergence rate cannot be arbitrarily increased by such a rescaling, that is, there exist vector fields $v \in C^1(D, \mathbb{R}^n)$ for which there exists a bound $\bar{q} > 0$ such that for all positive scalar functions $\lambda \in C^1(D, \mathbb{R}_+)$ the vector field $\lambda(x)v(x)$ has a Q-convergence rate no faster than $\bar{q}$. Indeed, the vector field of Example 5.1 has this property, as shown in Theorem 5.3.

We believe that the existence of a finite $\bar{q}$ is in fact typical in the sense that arbitrarily fast convergence rates can be achieved only for a thin set of vector fields, where thin has to be appropriately defined. For the moment, rather than developing such a theory here, we content ourselves with answering the more modest question regarding the existence of vector fields with finite $\bar{q}$.

Example 5.1. Let $g(t) := \mathrm{e}^{-t}\,\mathrm{e}^{-1/t}$. Then the vector field

$$v(x) := \begin{cases} 0 & \text{if } x = 0, \\ -x & \text{if } x \in \mathrm{S}^1 = \partial\,\mathrm{B}_1(0), \\ -\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + g'\left(-\ln\|x\|\right)\begin{bmatrix} -x_2 \\ x_1 \end{bmatrix} & \text{if } x \in \mathrm{B}_1(0) \setminus \{0\} \end{cases}$$

is continuously differentiable on the closed unit ball $\overline{\mathrm{B}_1(0)}$, and furthermore we have $J(0) = -\,\mathrm{I}$, that is, $v(x)$ satisfies the conditions of Lemma 2.1 for superlinear convergence of the process (1.1) to the stationary point $x^* = 0$.

It is easily checked by taking the partial derivative with respect to t that for $y \in \mathrm{S}^1$, the flux line through y defined by the vector field $v(x)$ defined in Example 5.1 is given by

$$\varphi(y,t) = \mathrm{e}^{-t}\begin{bmatrix} y_1 & -y_2 \\ y_2 & y_1 \end{bmatrix}\begin{bmatrix} \cos g(t) \\ \sin g(t) \end{bmatrix}. \tag{5.1}$$

We also observe that $\varphi(U_\theta y, t) = U_\theta \varphi(y,t)$ holds for all rotations

$$U_\theta = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix};$$

see Figure 5.1. Since $\lim_{t\to\infty}\varphi(y,t) = 0$ for all $y \in \mathrm{S}^1$, this rotational invariance implies that for all $x \in \mathrm{B}_1(0)$ there exists $y^{[x]} \in \mathrm{S}^1$ such that

$$\varphi(x,t) = \mathrm{e}^{-t}\,\|x\|\begin{bmatrix} y_1^{[x]} & -y_2^{[x]} \\ y_2^{[x]} & y_1^{[x]} \end{bmatrix}\begin{bmatrix} \cos g(t - \ln\|x\|) \\ \sin g(t - \ln\|x\|) \end{bmatrix}.$$

To find $y^{[x]}$, it suffices to integrate the flow in reverse direction starting from x until the flux line crosses S^1. This crossing happens in finite time because of (5.1) and the flow-conservation property (1.5). It is also easy to check that

$$\left\| \frac{\partial}{\partial t}\mathfrak{n}(\varphi(x,t)) \right\| = \left| g'\left(t - \ln\|x\|\right) \right|, \tag{5.2}$$

$$\|\varphi(x,t)\| = \mathrm{e}^{-t}\,\|x\| \tag{5.3}$$

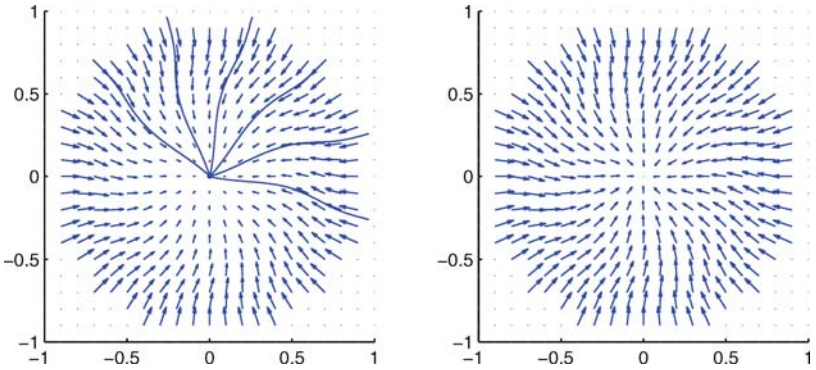

FIG. 5.1. *The figure on the left shows the vector field of Example* 5.1 *and a few of its flux lines, while the figure on the right shows a rescaling of the same vector field, here* $w(x) = v(x)/\sqrt{\|x\|}$.

for all $t \geq 0$ and $x \in \mathrm{B}_1(0)$.

LEMMA 5.2. *For the vector field* $v(x)$ *constructed in Example* 5.1 *we have*

$$\bar{q} := \sup\{q : \text{the process (1.1) defined by } v(x) \text{ is unif. Q-conv. with rate } q\} < +\infty.$$

Proof. It suffices to show that the process (1.1) is uniformly Q-convergent at rate 2 but not 3. By Theorem 3.4 this is equivalent to showing that the continuous process (3) converges 1-exponentially to $x^* = 0$ but not 2-exponentially. Note that

$$\|\varphi(x,t)\| = \mathrm{e}^{-t}\ \|x\|.$$

To satisfy (3.2), ρ_ε can thus be chosen arbitrarily in $(0,1)$, for example, $\rho_\varepsilon = \mathrm{e}^{-1}$, so that $\rho_\varepsilon \geq \varepsilon = 1 \cdot \varepsilon^{1/1}$ for all $\varepsilon \leq \mathrm{e}^{-1}$, as required for the claim of 1-exponential convergence. Furthermore, we have

$$\begin{aligned} \left\| \frac{\partial}{\partial t} \mathfrak{n}\left(\varphi(x,t) - x^*\right) \right\| &= |g'\left(t - \ln\|x\|\right)\| \\ &= \|x\| \cdot \mathrm{e}^{\frac{1}{\ln\|x\| - t}} \cdot \left| 1 - \frac{1}{(t - \ln\|x\|)^2} \right| \cdot \mathrm{e}^{-t} \end{aligned} \tag{5.4}$$

for all $t \geq 0$, and since $x \in \mathrm{B}_{\mathrm{e}^{-1}}(0)$ implies

$$\mathrm{e}^{\frac{1}{\ln\|x\| - t}} \cdot \left| 1 - \frac{1}{(t - \ln\|x\|)^2} \right| \leq 1,$$

we find that (3.4) holds with $p = 1$ and $\gamma = 1$. This establishes the claimed 1-exponential convergence. On the other hand, if 2-exponential convergence were to hold, then

$$\left\| \frac{\partial}{\partial t} \mathfrak{n}\left(\varphi(x,t)\right) \right\| \leq \gamma \cdot \|x\|^2 \cdot \mathrm{e}^{-2(1-\varepsilon)t}$$

would have to be true for some fixed γ and for all $t \geq 0$, $x \in \mathrm{B}_{\xi\varepsilon^{1/p}}(0)$, and $\varepsilon \in (0,1)$ for some appropriately chosen $\xi > 0$. By virtue of (5.4), we thus need

$$\mathrm{e}^{\frac{1}{\ln\|x\| - t}} \cdot \left| 1 - \frac{1}{(t - \ln\|x\|)^2} \right| \leq \gamma \cdot \|x\| \cdot \mathrm{e}^{-t + 2\varepsilon t}$$

to hold for all $t \geq 0$ and $x \in \mathrm{B}_{\rho_\varepsilon}(0)$. But since the left-hand side tends to 1 when $t \to \infty$ while the right-hand side converges to zero when $\varepsilon < 1/2$, this cannot be achieved for any fixed γ. ∎

We are now ready to show that a rescaling of the vector field $v(x)$ from Example 5.1 cannot speed up the Q-convergence rate of the process (1.1).

THEOREM 5.3. *Let $v(x)$ and $\bar{q}$ be as in Lemma 5.2, let $\lambda \in C^1(\mathbb{R}^2, \mathbb{R}_+)$ be a positive scalar function and consider the vector field $w(x) = \lambda(x)v(x)$. Then*

$$\sup\{q : \textit{the process } (1.1) \textit{ defined by } w(x) \textit{ is unif. Q-conv. with rate } q\} \leq \bar{q}.$$

Proof. Let $\bar{p} = \bar{q} - 1$. It suffices to show that for $p > \bar{p}$ the process (1.1) $w(x)$ is not Q-convergent with rate $p+1$. If the contrary holds for some choice of $\lambda(x)$, then the flux $\psi(x,t)$ associated with $w(x)$ converges p-exponentially to the origin, that is, there exist constants $\xi > 0$, $\gamma_p > 0$ such that for all $\varepsilon > 0$ small enough there exists $\rho_\varepsilon > \xi\varepsilon^{1/p}$ with the property that for all $x \in \mathrm{B}_{\rho_\varepsilon}(0)$ and $t \geq 0$,

$$\mathrm{e}^{-(1+\varepsilon)t}\,\|x\| \leq \|\psi(x,t)\| \leq \mathrm{e}^{-(1-\varepsilon)t}\,\|x\|, \tag{5.5}$$

$$\left\| \frac{\partial}{\partial t}\mathfrak{n}(\psi(x,t)) \right\| \leq \gamma_p \|x\|^p\,\mathrm{e}^{-(1-\varepsilon)pt}\,. \tag{5.6}$$

On the other hand, $\varphi(x,t)$ does not converge p-exponentially, and since (5.3) holds for all $x \in \mathrm{B}_1(0)$, this must be because for $0 < \varepsilon \ll 1$ there exists $z_\varepsilon \in \mathrm{B}_{\rho_\varepsilon}(0)$ and $T \geq 0$ such that

$$\frac{\gamma_p}{1-\varepsilon}\|z_\varepsilon\|^p\,\mathrm{e}^{-(1-\varepsilon)pT} < \left|g'\left(T - \ln\|z_\varepsilon\|\right)\right|.$$

Replacing z_ε by $\varphi(z_\varepsilon, T)$, it is easy to see that we may assume without loss of generality that $T = 0$, and then by continuity there exist constants $\delta, \tau > 0$ such that

$$\frac{\gamma_p}{1-\varepsilon}\|z_\varepsilon\|^p\,\mathrm{e}^{-(1-\varepsilon)pt} < \left|g'\left(t - \ln\|z_\varepsilon\|\right)\right|(1-\delta) \tag{5.7}$$

for all $t \in [0, \tau)$. Now let $s(t)$ be defined by the ODE

$$\frac{d}{dt}s(t) = \lambda\big(\varphi(z_\varepsilon, t)\big), \qquad s(0) = 0.$$

Since $\lambda > 0$, $s(t)$ is a monotone increasing reparameterization of t constructed so that $\psi(z_\varepsilon, t) = \varphi\big(z_\varepsilon, s(t)\big)$. Using the chain rule, we find

$$\begin{aligned}\left\| \frac{\partial}{\partial t}\mathfrak{n}(\psi(z_\varepsilon,t)) \right\| &= \left|\frac{d}{dt}s(t)\right| \cdot \left\| \frac{\partial}{\partial s}\mathfrak{n}(\varphi(z_\varepsilon,s)) \right\| \\ &\overset{(5.2)}{=} \frac{d}{dt}s(t) \cdot \left|g'\left(s(t) - \ln\|z_\varepsilon\|\right)\right|,\end{aligned}$$

and using (5.6)) and (5.7) we obtain that

$$\begin{aligned}\frac{d}{dt}s(t) \cdot \frac{\gamma_p}{1-\varepsilon}\,\|z_\varepsilon\|^p\,\mathrm{e}^{-(1-\varepsilon)p\,s(t)} &< \frac{d}{dt}s(t) \cdot \left|g'\left(s(t) - \ln\|z_\varepsilon\|\right)\right|\,(1-\delta) \\ &\leq \gamma_p\,\|z_\varepsilon\|^p\,\mathrm{e}^{-(1-\varepsilon)pt}\,(1-\delta)\end{aligned}$$

holds for every $t \in [0, s^{-1}(\tau))$, that is,

$$\frac{d}{dt}\left(s(t)-t\right) < \frac{\gamma_p \left\|z_\varepsilon\right\|^p \, \mathrm{e}^{-(1-\varepsilon)pt}\,(1-\delta)}{\frac{\gamma_p}{1-\varepsilon}\left\|z_\varepsilon\right\|^p \, \mathrm{e}^{-(1-\varepsilon)p\,s(t)}} - 1 = (1-\varepsilon)\,(1-\delta)\,\mathrm{e}^{(1-\varepsilon)p\,(s(t)-t)} - 1.$$

Note that the right-hand side is monotone increasing in $s(t)-t$. Therefore, we can apply Lemma 3.1 to find that

$$s(t) - t < -\frac{\ln\left[(1-\varepsilon)(1-\delta) + (\varepsilon+\delta-\varepsilon\delta)\,\mathrm{e}^{(1-\varepsilon)pt}\right]}{(1-\varepsilon)p}$$

holds for small positive t. Since

$$\ln\left[(1-\varepsilon)(1-\delta) + (\varepsilon+\delta-\varepsilon\delta)\,\mathrm{e}^{(1-\varepsilon)pt}\right] = (\varepsilon+\delta-\varepsilon\delta)(1-\varepsilon)pt + \mathscr{O}(t^2),$$

it follows that

$$s(t) - t < -\varepsilon t \tag{5.8}$$

for small positive t. On the other hand, (5.3) and (5.5) imply

$$\mathrm{e}^{-s(t)}\left\|z_\varepsilon\right\| = \left\|\varphi(z_\varepsilon, s(t))\right\| = \left\|\psi(z_\varepsilon, t)\right\| \le \mathrm{e}^{-(1-\varepsilon)t}\left\|z_\varepsilon\right\|,$$

and hence, $-\varepsilon t \le s(t) - t$ for small positive t. Since this contradicts (5.8), it follows that our claim is true. ∎

Acknowledgments. The authors would like to thank the three referees and the associate editor for extremely helpful feedback and valuable suggestions for improving the paper.

AN INTERIOR-POINT TRUST-REGION ALGORITHM FOR GENERAL SYMMETRIC CONE PROGRAMMING*

YE LU† AND YA-XIANG YUAN‡

Abstract. An interior-point trust-region algorithm is proposed for minimizing a general (nonconvex) quadratic objective function in the intersection of a symmetric cone and an affine subspace. The algorithm uses a trust-region model to ensure descent on a suitable merit function. Global first-order and second-order convergence results are proved. Numerical results are presented.

Key words. interior-point algorithm, trust-region subproblem, symmetric cone

1. Introduction. In the last two decades, interior-point algorithms for convex programming have been developed quite well in both theory and practice. However, research on interior-point algorithms for nonconvex programming is still very active, as nonconvex problems are considerably more difficult. We mention here some of the recent works. For semidefinite relaxations, see Zhang [33] and Ye and Zhang [31]; for line search based algorithms, see Absil and Tits [1] and Bakry et al. [3], Forsgren and Gill [12], Gay, Overton, and Wright [13], Tits et al. [25], Vanderbei and Shanno [27], and Wächter [28]. By contrast, for trust-region-type interior-point algorithms, Ye [29] developed an affine scaling algorithm for indefinite quadratic programming by solving sequential trust-region subproblems. Global first-order and second-order convergence results were proved, and later enhanced by Sun [24] for the convex case. The idea of affine scaling can be traced back to Dikin [8]. An affine-scaling potential-reduction interior-point trust-region algorithm was developed for the indefinite quadratic programming in Ye [30, section 9]. Recently, in Faybusovich and Lu [11], Ye's algorithm has been extended to the minimization of a quadratic function in the intersection of a symmetric cone and an affine subspace. In this paper, we call such a problem symmetric cone programming and develop an affine-scaling primal barrier interior-point trust-region algorithm to solve it. Since the class of symmetric cones contains the positive orthant in R^n, the second-order cone, and the cone of positive semidefinite symmetric matrices, our approach solves a large class of optimization problems. In the trust-region literature, we refer the reader to Conn, Gould, and Toint [6, section 13] for a primal barrier algorithm and Conn et al. [7] for a primal-dual algorithm. Under the theoretical framework of their work, we bring the properties of ϑ-*normal barrier* and symmetric cone into our analysis. By doing so, we show that the primal barrier algorithm developed in Conn, Gould, and Toint [6] can be extended to solve symmetric cone programming. Although our algorithm still provides the mechanism to declare the iteration unsuccessful if feasibility is not achieved, it does not contain an explicit

constraint on the step calculation (see constraint (13.2.1) in Conn, Gould, and Toint [6, p. 499] and the constraint (13.3.1) of the algorithm in Conn, Gould, and Toint [6, p. 505]). This makes our algorithm theoretically somewhat simpler, although its practical merit remains to be investigated. Moreover, we establish inequality (4.22) in section 4 of this paper to explicitly estimate the convergence of the algorithm. This is quite remarkable, since our analysis does not require any convexity assumptions.

This paper is organized as follows. In section 2, we present some concepts and results of the symmetric cone and *ϑ-normal barrier* in the theory of interior-point methods. In section 3, we formulate the first-order and second-order optimality conditions for our optimization problem. In section 4, we present a convergence analysis for our interior-point trust-region algorithm. The techniques of proofs in Lemmas 4.3–4.6 essentially follow from Conn, Gould, and Toint [6, section 13], together with the applications of the properties of the *ϑ-normal barrier*. In section 5, our algorithm is used to solve the large-scale trust-region subproblem. In section 6, we apply our algorithm to a class of quadratic programs and discuss some further implementation issues. Concluding remarks and recommendations are presented in section 7.

2. Symmetric cone and ϑ-normal barrier. In this section we introduce some concepts and relevant results which will be used in the following sections.

Nesterov and Nemirovskii [18] developed the concept of *ϑ-normal barrier*, which has become one of the most important tools for the analysis of interior-point methods. It is also an essential tool in our analysis. We assume that K is a convex cone in a finite-dimensional real vector space E. Let K° be the interior of K. The definition of *ϑ-normal barrier* is given as follows.

DEFINITION 2.1. *Let $F : K^\circ \to R$ be a C^3-smooth strictly convex function such that F is a barrier for K (i.e., $F(x) \to \infty$ as $x \in K^\circ$ approaches the boundary of K), and there exists $\vartheta \geq 1$ such that for each $t > 0$,*

$$F(tx) = F(x) - \vartheta \ln(t) \tag{2.1}$$

and

$$| F^{'''}(x)[h,h,h] | \leq 2 \langle F^{''}(x)h, h\rangle^{3/2} \tag{2.2}$$

for all $x \in K^\circ$ and for all $h \in E$. Then F is called a ϑ-normal barrier for K and ϑ is called barrier parameter of F.

In principle, every convex cone admits a *ϑ-normal barrier* (see Nesterov and Nemirovskii [18, section 4]). But, in this paper we consider only a special kind of convex cone, called a symmetric cone. As a regular convex cone K in a finite-dimensional real vector space E endowed with an inner product $\langle\ \rangle$, the dual of K is defined as

$$K^* = \{y \in E \mid \langle x, y\rangle \geq 0\ \forall x \in E\}.$$

We define $Aut(K)$ to be the set of automorphisms of the convex cone K, that is, $AK = K$ for any $A \in Aut(K)$. The following is the definition of symmetric cone.

DEFINITION 2.2. *A convex cone K is called homogeneous if $Aut(K)$ is transitive on K°; that is, given any pair of points $x, s \in K^\circ$ there exists $A \in Aut(K)$ such that $Ax = s$. The cone K is said to be self-dual if there is an inner product such that $K^* = K$. K is said to be symmetric if it is homogeneous and self-dual.*

The following important cones are special symmetric cones.

The positive orthant. The simplest symmetric cone is the positive orthant

$$R^n_{++} = \{x \mid x > 0, x \in R^n\} = R_{++} \oplus \cdots \oplus R_{++}, \tag{2.3}$$

which is the direct sum of n copies of R_{++}. $F(x) = -\sum_{i=1}^{n} \ln x_i$ is a *ϑ-normal barrier* for R^n_{++} with $\vartheta = n$.

The second-order cone. This is the cone defined by

$$SOC := \left\{ x \in R^n : \sum_{i=1}^{n-1} x_i^2 \le x_n^2 \text{ and } x_n \ge 0 \right\}. \tag{2.4}$$

The function $F(x) = -\ln(x_n^2 - \sum_{i=1}^{n-1} x_i^2)$ is a *ϑ-normal barrier* for the second-order cone SOC with $\vartheta = 2$.

The cone of positive semidefinite matrices. This is the cone of all positive semidefinite matrices

$$S_+^{n\times n} = \{X \mid X \in R^{n\times n}, \quad X \text{ positive semidefinite}\}. \tag{2.5}$$

$F(X) = -\ln\det(X)$ is a *ϑ-normal barrier* for $S_+^{n\times n}$ with $\vartheta = n$.

Let $F''(x)$ denote the Hessian of *ϑ-normal barrier* $F(x)$. The strictly convex assumption of $F(x)$ implies that $F''(x)$ is positive definite for every $x \in K^\circ$. Thus, $\|v\|_x = \langle v, F''(x)v\rangle^{\frac{1}{2}}$ is a norm on E induced by $F''(x)$. Let $B_x(y, r)$ denote the open ball of radius r centered at y, where the radius is measured with respect to $\| \ \|_x$. This ball is called the Dikin ball. The following lemmas are very crucial for the analysis of our algorithm in the next sections.

LEMMA 2.1. *Assume $F(x)$ is a ϑ-normal barrier for K; then for all $x \in K^\circ$ we have $B_x(x, 1) \subseteq K^\circ$.*

LEMMA 2.2. *Assume $F(x)$ is a ϑ-normal barrier for K, $x \in K^\circ$, and $y \in B_x(x, 1)$; then*

$$\left| F(y) - F(x) - \langle F'(x), y - x\rangle - \frac{\langle y - x, F''(x)(y - x)\rangle}{2} \right| \le \frac{\|y - x\|_x^3}{3(1 - \|y - x\|_x)}. \tag{2.6}$$

LEMMA 2.3. *Let F be a ϑ-normal barrier for K; then*

$$F''(x)^{-1}F'(x) = -x, \tag{2.7}$$

$$\langle -F'(x), x\rangle = \vartheta. \tag{2.8}$$

LEMMA 2.4. *If K is a symmetric cone and F is a ϑ-normal barrier for K, then $F''(x)$ is a linear automorphism of K for each $x \in K^\circ$.*

The proofs of the above lemmas can be found in Chapter 2 of Renegar [20].

Lemma 2.1 tells us the ball of radius 1 measured by $\|.\|_x$ is always contained in K°. Lemma 2.2 shows that at least locally, the quadratic approximation is very good for the *ϑ-normal barrier* F. Lemma 2.3 plays an important role in our proof of Lemma 4.1 in section 4. Lemma 2.4 is a special property of the symmetric cone, which is one of the reasons why in this paper we focus on the symmetric cones instead of general cones.

3. Optimality conditions. In this section, we formulate the first-order and second-order optimality conditions of our optimization problem:

We consider the following optimization problem:

$$\min \quad q(x) = \frac{1}{2}\langle x, Qx\rangle + \langle c, x\rangle \tag{3.1}$$

$$\text{subject to} \quad Ax = b, \tag{3.2}$$

$$x \in K. \tag{3.3}$$

Here $Q : E \mapsto E$ is a symmetric linear operator, $c \in E$. $A : E \mapsto R^m$ is a linear operator and $b \in R^m$. K is a symmetric cone. We assume that our feasible set $\digamma_p = \{x \in E | Ax = b, x \in K\}$ is bounded and has relative interior. The following theorem is the first-order optimality condition for our optimization problem. For a proof, see, e.g., Bonnans and Shapiro [5] or Faybusovich and Lu [11].

THEOREM 3.1 (first-order optimality condition). *If x^* is a locally minimal solution of* (3.1)–(3.3), *then there exists $s \in K^*(= K)$ such that $Qx^* + c - s \in R(A^*)$ and $\langle x^*, s\rangle = 0$; here $R(A^*)$ is the range of A^* and $A^* : R^m \mapsto E$ is the adjoint of A.*

Assume x is a point in our feasible set $\digamma_p = \{x \in E | Ax = b, x \in K\}$; there must be a unique face $\digamma_x$ of $\digamma_p$ such that x is a relative interior point of $\digamma_x$. We denote $Aff(\digamma_x)$ to be the affine space generated by $\digamma_x$ and V_x to be the vector space such that $Aff(\digamma_x) = V_x + x$. Now we are ready to formulate the second-order optimality condition.

THEOREM 3.2 (second-order optimality condition). *If x^* is a locally minimal solution of* (3.1)–(3.3), *$\digamma_{x^*}$ is the unique face of the feasible set $\digamma_p$ such that x^* is one of its relative interior points, and $V_{x^*} = Aff(\digamma_{x^*}) - x^*$, then Q is positive semidefinite over V_{x^*}.*

Proof. For all $d \in V_{x^*}$, because x^* is a relative interior of $\digamma_{x^*}$, we know $x^* + td \in \digamma_{x^*}$, provided that $|t|$ is sufficiently small. Hence, there exists a $\epsilon > 0$ such that

$$q(x^* + td) - q(x^*) = t\langle Qx^* + c, d\rangle + \frac{t^2}{2}\langle d, Qd\rangle \geq 0 \tag{3.4}$$

as long as $|t| \leq \epsilon$, due to the fact that x^* is a local minimim. The above inequality implies that

$$\langle Qx^* + c, d\rangle = 0, \qquad \langle d, Qd\rangle \geq 0. \tag{3.5}$$

This completes our proof. ∎

If $x \in K^\circ$, it is obvious that $V_x = \{x \in E | Ax = 0\}$. If $x \in \partial K$, the matter becomes much more complicated. But fortunately, we can get some very helpful results in the case of symmetric cones.

If $K = R^n_{++}$ and $x' \in \partial K$, it can be shown that $V_{x'} = \{x \in R^n | Ax = 0, x_j = 0, j \in I\}$, where $I = \{j | x'_j = 0\}$. We know that $F(x) = -\sum_{i=1}^n \ln x_i$ is a *ϑ-normal barrier* for R^n_{++}. Therefore, $F''(x')^{-\frac{1}{2}} = \mathrm{diag}\{x'_1, x'_2, \ldots, x'_n\}$, and consequently $V_{x'} = \{F''(x')^{-\frac{1}{2}} x | AF''(x')^{-\frac{1}{2}} x = 0, , x \in R^n\}$.

If $K = S^{n\times n}_+$, we know $F(X) = -\ln\det(X)$ is a *ϑ-normal barrier* for $S^{n\times n}_+$. Now let $A' \in \partial K$, and $\mathrm{rank}(A') = r < n$. Then $F''(A')^{-\frac{1}{2}} X = A'^{\frac{1}{2}} X A'^{\frac{1}{2}}$. We set $V = \{A'^{\frac{1}{2}} X A'^{\frac{1}{2}} | AA'^{\frac{1}{2}} X A'^{\frac{1}{2}} = 0, X \in S^{n\times n}\}$; just as with the positive orthant case, it holds that $V_{A'} = V$. The following theorem tells us that this property actually holds for all symmetric cones. We will prove this theorem in the appendix.

THEOREM 3.3. *Assume K is a symmetric cone in a finite-dimensional real Euclidean space E and $F(x)$ is the ϑ-normal barrier for K. If $x^* \in K$, then $V_{x^*} = \{F''(x^*)^{-\frac{1}{2}} x | AF''(x^*)^{-\frac{1}{2}} x = 0, x \in E\}$.*

We want to mention that $F''(x^*)^{-\frac{1}{2}}$ is well defined on the boundary of the cone, since it is the quadratic representation of x^* in Jordan algebra. This theorem immediately implies the following corollary, which is extremely important to prove that any limit point of the iterate generated by our algorithm satisfies the second-order optimality condition.

COROLLARY 3.1. *Assume K is a symmetric cone in our optimization problem (3.1)–(3.3); then Q is positive semidefinite on V_{x^*} if and only if the linear operator $F''(x^*)^{-\frac{1}{2}}QF''(x^*)^{-\frac{1}{2}}$ is positive semidefinite on $\{x|AF''(x^*)^{-\frac{1}{2}}x = 0, x \in E\}$.*

4. Interior-point trust-region algorithm. In this section, we present our interior-point trust-region algorithm for solving (3.1)–(3.3). Global first-order and second-order convergence results are proved.

We assume $F(x)$ is the *ϑ-normal barrier* for the symmetric cone K and define the merit function as

$$f_{\eta_k}(x) = q(x) + \frac{1}{\eta_k}F(x). \tag{4.1}$$

In the inner iterations, $f_{\eta_k}(x)$ is decreased for a fixed η_k, while η_k is increased to positive infinity in outer iterations. From Lemma 2.1, for any $x_{k,j} \in K^\circ$ and $d \in E$, we have that $x_{k,j} + d \in K^\circ$, provided that $\|F''(x_{k,j})^{\frac{1}{2}}d\| \le \alpha_{k,j} < 1$. It follows from Lemma 2.2 that

$$\begin{aligned} F(x_{k,j}+d) - F(x_{k,j}) &\le \langle F'(x_{k,j}), d\rangle + \frac{\langle d, F''(x_{k,j})d\rangle}{2} + \frac{\|d\|^3_{x_{k,j}}}{3(1-\|d\|_{x_{k,j}})} \\ &\le \langle F'(x_{k,j}), d\rangle + \frac{\langle d, F''(x_{k,j})d\rangle}{2} + \frac{\alpha^3_{k,j}}{3(1-\alpha_{k,j})}. \end{aligned} \tag{4.2}$$

Therefore, we get

$$\begin{aligned} f_{\eta_k}(x_{k,j}+d) - f_{\eta_k}(x_{k,j}) \le{}& \frac{\langle d, (Q + \frac{1}{\eta_k}F''(x_{k,j}))d\rangle}{2} \\ &+ \left\langle Qx_{k,j} + c + \frac{1}{\eta_k}F'(x_{k,j}), d\right\rangle + \frac{\alpha^3_{k,j}}{3(1-\alpha_{k,j})\eta_k}. \end{aligned} \tag{4.3}$$

From the above relation, it is obvious that in order to decrease $f_{\eta_k}(x)$, we can try to minimize its upper bound given in the right-hand side of the above inequality. This leads to the following subproblem:

$$\min \frac{1}{2}\left\langle d, \left(Q + \frac{1}{\eta_k}F''(x_{k,j})\right)d\right\rangle + \left\langle Qx_{k,j} + c + \frac{1}{\eta_k}F'(x_{k,j}), d\right\rangle = m_{k,j}(d) \tag{4.4}$$

$$\text{subject to} \quad Ad = 0, \tag{4.5}$$

$$\|F''(x_{k,j})^{\frac{1}{2}}d\|^2 \le \alpha^2_{k,j}. \tag{4.6}$$

Define

$$Q_{k,j} = F''(x_{k,j})^{-\frac{1}{2}}QF''(x_{k,j})^{-\frac{1}{2}} + \frac{1}{\eta_k}I, \tag{4.7}$$

$$c_{k,j} = F''(x_{k,j})^{-\frac{1}{2}}\left(Qx_{k,j} + c + \frac{1}{\eta_k}F'(x_{k,j})\right), \tag{4.8}$$

$$A_{k,j} = AF''(x_{k,j})^{-\frac{1}{2}}, \tag{4.9}$$

and using the transformation

$$d' = F''(x_{k,j})^{\frac{1}{2}}d, \tag{4.10}$$

equations (4.4)–(4.6) can be rewritten as

$$\min q'_{k,j}(d') = \frac{1}{2}\langle d', Q_{k,j}d'\rangle + \langle c_{k,j}, d'\rangle \tag{4.11}$$

$$\text{subject to} \qquad A_{k,j}d' = 0, \tag{4.12}$$

$$\|d'\|^2 \le \alpha_{k,j}^2. \tag{4.13}$$

Instead of solving (4.11)–(4.13) exactly, we need only compute an approximate solution $d'_{k,j}$ satisfying the following two inequalities:

$$q'_{k,j}(d'_{k,j}) \le -\theta\|p_{k,j}\| \min\left\{\frac{\|p_{k,j}\|}{\beta_{k,j}}, \alpha_{k,j}\right\} \tag{4.14}$$

and

$$q'_{k,j}(d'_{k,j}) \le \theta\lambda_{k,j}\min\{\lambda_{k,j}^2, \alpha_{k,j}^2\}, \tag{4.15}$$

where $\theta \in (0, \frac{1}{2})$, $\beta_{k,j} = 1 + \|Q_{k,j}\|$, $p_{k,j}$ is the projection of $c_{k,j}$ onto the null space of $A_{k,j}$, and $\lambda_{k,j}$ is the least eigenvalue of $(N_{k,j})^* Q_{k,j} N_{k,j}$, $N_{k,j}$ being an orthonormal basis spanning the null space of $A_{k,j}$. We can see that inequality (4.15) makes sense only when $\lambda_{k,j} < 0$. The two conditions (4.14) and (4.15) are common in trust-region methods. Inequality (4.14) can be obtained at the Cauchy point and inequality (4.15) can be obtained when the negative curvature is exploited. Projected conjugate gradient/Lanczos-like methods are able to produce such a step at a reasonable cost (see Gould et al. [14]).

Once $d'_{k,j}$ is computed, we obtain the trial step

$$d_{k,j} = F''(x_{k,j})^{-\frac{1}{2}} d'_{k,j} \tag{4.16}$$

and define the predicted reduction in the merit function (4.1) by

$$Pred_{k,j} = m_{k,j}(0) - m_{k,j}(d_{k,j}) = -q'_{k,j}(d'_{k,j}). \tag{4.17}$$

The feasible set is denoted by $F_p = \{x \in E | Ax = b, x \in K\}$. Now we are ready to present our algorithm.

ALGORITHM 4.1 (an interior-point trust-region algorithm).

Step 0 **Initialization.** *An initial point $x_{0,0} \in ri\{F_p\}$, an initial trust-region radius $\alpha_{0,0} \in (0,1)$, and an initial parameter $\eta_0 > 0$ are given. The constants η'_1, η'_2, γ_1, and γ_2 are also given and satisfy $0 < \eta'_1 \le \eta'_2 < 1$ and $0 < \gamma_1 \le \gamma_2 < 1$. Two tolerance numbers $\epsilon_1, \epsilon_2 \in (0,1)$ are given. Set $k = 0$ and $j = 0$.*

Step 1 **Test inner iteration termination.** *If $\eta_k\|p_{k,j}\| < \epsilon_1$ and $\eta_k\lambda_{k,j} > -\epsilon_2$, set $x_{k+1,0} = x_{k,j}$ and go to Step* 5.

Step 2 **Step calculation.** *Solve* (4.11)–(4.13) *to obtain $d'_{k,j}$, which satisfies* (4.14) *and* (4.15)*, and set $d_{k,j}$ by* (4.16).

Step 3 **Acceptance of the trial point.** *If $x_{k,j} + d_{k,j} \notin ri\{F_p\}$, set $\rho_{k,j} = -\infty, x_{k,j+1} = x_{k,j}$ and go to Step* 4*; otherwise compute the ratio*

$$\rho_{k,j} = \frac{f_{\eta_k}(x_{k,j}) - f_{\eta_k}(x_{k,j} + d_{k,j})}{Pred_{k,j}}. \tag{4.18}$$

Let

$$x_{k,j+1} = \begin{cases} x_{k,j} + d_{k,j} & \text{if } \rho_{k,j} \geq \eta_1', \\ x_{k,j} & \text{otherwise.} \end{cases} \tag{4.19}$$

Step 4 **Trust-region radius update.** *If* $\rho_{k,j} \geq \eta_2'$, *set* $\alpha_{k,j+1} \in [\alpha_{k,j}, \infty)$; *if* $\rho_{k,j} \geq \eta_1'$, *set* $\alpha_{k,j+1} \in [\gamma_2 \alpha_{k,j}, \alpha_{k,j}]$; *if* $\rho_{k,j} < \eta_1'$, *set* $\alpha_{k,j+1} \in [\gamma_1 \alpha_{k,j}, \gamma_2 \alpha_{k,j}]$; *increase* j *by* 1 *and go to Step* 1.

Step 5 **Update parameter** η. *Choose* $\eta_{k+1} > \eta_k$ *in such a way as to ensure that* $\eta_k \to +\infty$ *when* $k \to +\infty$. *Increase* k *by* 1 *and go to Step* 1.

We want to mention that from Lemma 2.1, our trail point will always stay inside the feasible set if we keep $\alpha_{k,j}$ less than 1. However, we believe that our current mechanism can make the algorithm more efficient without keeping $\alpha_{k,j}$ less than 1. Although it allows the feasibility to not be achieved, sufficient descent of the merit function can be achieved in a successful step. Just like the usual notation in the trust-region literature, if $\rho_{k,j} \geq \eta_2'$, we call this iteration very successful; if $\rho_{k,j} \geq \eta_1'$, we call this iteration successful; if $\rho_{k,j} < \eta_1'$, we call this iteration a failure. Since $p_{k,j}$ is the projection of $c_{k,j}$ onto the null space of $A_{k,j}$, there exists a vector $y \in R^m$ such that

$$p_{k,j} = c_{k,j} - (A_{k,j})^* y. \tag{4.20}$$

LEMMA 4.1. *Let* $p_{k,j}$ *be given by* (4.20) *and*

$$s_{k,j} = Q x_{k,j} + c - A^* y; \tag{4.21}$$

if $\eta_k \|p_{k,j}\| < 1$, *then* $s_{k,j} \in K^\circ$ *and*

$$\langle x_{k,j}, s_{k,j} \rangle \leq \frac{1}{\eta_k}(\sqrt{\vartheta} + \vartheta). \tag{4.22}$$

Proof. It follows from (4.20) that

$$\begin{aligned} p_{k,j} = c_{k,j} - (A_{k,j})^* y &= F''(x_{k,j})^{-\frac{1}{2}} Q x_{k,j} + F''(x_{k,j})^{-\frac{1}{2}} c \\ &\quad + \frac{1}{\eta_k} F''(x_{k,j})^{-\frac{1}{2}} F'(x_{k,j}) - (A F''(x_{k,j})^{-\frac{1}{2}})^* y \\ &= F''(x_{k,j})^{-\frac{1}{2}} s_{k,j} + \frac{1}{\eta_k} F''(x_{k,j})^{-\frac{1}{2}} F'(x_{k,j}). \end{aligned} \tag{4.23}$$

Therefore, the above relation and our assumption $\eta_k \|p_{k,j}\| < 1$ imply that

$$\begin{aligned} \|F''(x_{k,j})^{-\frac{1}{2}}(\eta_k s_{k,j} + F'(x_{k,j}))\| &= \|F''(x_{k,j})^{\frac{1}{2}}(F''(x_{k,j})^{-1} \eta_k s_{k,j} - x_{k,j})\| \\ &< 1. \end{aligned} \tag{4.24}$$

Here the last equality follows from Lemma 2.3. Then from Lemma 2.1, we know that $F''(x_{k,j})^{-1} \eta_k s_{k,j} \in K^\circ$. It follows from Lemma 2.4 that $\eta_k s_{k,j} \in K^\circ$, and consequently $s_{k,j} \in K^\circ$.

It follows from (4.23) that $s_{k,j} = \frac{1}{\eta_k}(F''(x_{k,j})^{\frac{1}{2}}(\eta_k p_{k,j}) - F'(x_{k,j}))$. Consequently, we have that

$$\begin{aligned}
\langle x_{k,j}, s_{k,j}\rangle &= \frac{1}{\eta_k}(\langle F''(x_{k,j})^{\frac{1}{2}} x_{k,j}, \eta_k p_{k,j}\rangle + \langle x_{k,j}, -F'(x_{k,j})\rangle) \\
&\le \frac{1}{\eta_k}(\|F''(x_{k,j})^{\frac{1}{2}} x_{k,j}\|\|\eta_k p_{k,j}\| + \langle x_{k,j}, -F'(x_{k,j})\rangle) \\
&\le \frac{1}{\eta_k}(\langle x_{k,j}, F''(x_{k,j}) x_{k,j}\rangle^{\frac{1}{2}} + \langle x_{k,j}, -F'(x_{k,j})\rangle) \\
&= \frac{1}{\eta_k}(\langle x_{k,j}, -F'(x_{k,j})\rangle^{\frac{1}{2}} + \langle x_{k,j}, -F'(x_{k,j})\rangle) \\
&= \frac{1}{\eta_k}(\sqrt{\vartheta} + \vartheta). \qquad (4.25)
\end{aligned}$$

The last two equalities follow from Lemma 2.3. □

This convergence estimate is remarkable, considering the problem is nonconvex. We can achieve this mainly due to the special properties of the *ϑ-normal barrier*. From this estimate, we can see that the barrier parameter ϑ determines the complexity of our problem, which coincides with its role in the interior-point algorithm for convex programming.

For the rest of this section, we will show that the stop rule for the inner iterations can be satisfied in finitely many iterations. First, the following two lemmas are indispensable for our analysis.

LEMMA 4.2. (a) *The map $x \mapsto F''(x)^{-\frac{1}{2}}$ is continuous on the feasible set $\mathcal{F}_p$.*

(b) *There is a constant $C > 0$, such that $\|F''(x)^{-\frac{1}{2}}\| \le C$ for any $x \in \mathcal{F}_p$.*

For the positive orthant case, $F''(x)^{-\frac{1}{2}} = X = \mathrm{diag}\{x_1, x_2, \ldots, x_n\}$, and for the cone of semidefinite matrices, $F''(X)^{-\frac{1}{2}}\xi = X^{\frac{1}{2}}\xi X^{\frac{1}{2}}$. Therefore, part (a) is obviously true for these two cases. For the general symmetric cone, it is still true from the Jordan algebra point of view. We will give an explanation in the appendix. Part (b) follows immediately form part (a) and our assumption that $\mathcal{F}_p$ is bounded.

LEMMA 4.3. *There exists a positive constant C' such that if*

$$\alpha_{k,j} \le \min\left\{\frac{(1-\eta_2')\theta\eta_k\|p_{k,j}\|}{1+(1-\eta_2')\theta\eta_k\|p_{k,j}\|}, \frac{\|p_{k,j\|}}{C'}\right\}, \qquad (4.26)$$

then the iteration $\{k, j\}$ is very successful and $\alpha_{k,j+1} \ge \alpha_{k,j}$.

Proof. Let $C' = 1 + C^2\|Q\|$, where C is defined as in Lemma 4.2. It follows from the definition of $\beta_{k,j}$ and the last lemma that

$$\beta_{k,j} = 1 + \|Q_{k,j}\| \le C'. \qquad (4.27)$$

Therefore, when $\alpha_{k,j} \le \frac{\|p_{k,j}\|}{C'}$, the inequality (4.14) becomes

$$q'(d'_{k,j}) \le -\theta\|p_{k,j}\|\alpha_{k,j}. \qquad (4.28)$$

Inequality $\alpha_{k,j} \le \frac{(1-\eta_2')\theta\eta_k\|p_{k,j}\|}{1+(1-\eta_2')\theta\eta_k\|p_{k,j}\|} < 1$ ensures that $x_{k,j} + d_{k,j} \in ri\{\mathcal{F}_p\}$. It follows

from inequalities (4.3) and (4.28) that

$$|\rho_{k,j}-1| = \left|\frac{f_{\eta_k}(x_{k,j}) - f_{\eta_k}(x_{k,j}+d_{k,j}) + m_{k,j}(d_{k,j})}{Pred_{k,j}}\right| \le \frac{\frac{(\alpha_{k,j})^3}{3(1-\alpha_{k,j})}}{\theta\alpha_{k,j}\eta_k\|p_{k,j}\|}$$

$$< \frac{\frac{\alpha_{k,j}}{1-\alpha_{k,j}}}{\theta\eta_k\|p_{k,j}\|} \le 1-\eta_2'. \tag{4.29}$$

Therefore, $-(\rho_{k,j}-1) \le |\rho_{k,j}-1| \le 1-\eta_2'$, and we can see that $\rho_{k,j} \ge \eta_2'$. Consequently, the iteration is very successful and $\alpha_{k,j+1} \ge \alpha_{k,j}$. □

LEMMA 4.4. *If $\eta_k\|p_{k,j}\| \ge \epsilon$ for some constant $\epsilon \in (0, \alpha_{k,0})$ and all j, then*

$$\alpha_{k,j} \ge \min\left\{\frac{\gamma_1(1-\eta_2')\theta\epsilon}{1+(1-\eta_2')\theta\epsilon}, \frac{\gamma_1\epsilon}{C'\eta_k}\right\} \tag{4.30}$$

holds for all j.

Proof. It is easy to see that (4.30) holds for $j=0$ as $\alpha_{k,0} > \epsilon$. Assume that the j is the first integer such that $\alpha_{k,j+1} < \min\{\frac{\gamma_1(1-\eta_2')\epsilon}{1+(1-\eta_2')\epsilon}, \frac{\gamma_1\epsilon}{C'\eta_k}\}$; from the update of the trust-region radius, we know $\gamma_1\alpha_{k,j} \le \alpha_{k,j+1}$, and hence

$$\alpha_{k,j} < \min\left\{\frac{(1-\eta_2')\theta\epsilon}{1+(1-\eta_2')\theta\epsilon}, \frac{\epsilon}{C'\eta_k}\right\}$$

$$< \min\left\{\frac{(1-\eta_2')\theta\eta_k\|p_{k,j}\|}{1+(1-\eta_2')\theta\eta_k\|p_{k,j}\|}, \frac{\|p_{k,j\|}}{C'}\right\}. \tag{4.31}$$

From the above inequality and the last lemma, we have that $\alpha_{k,j+1} \ge \alpha_{k,j}$, which contradicts the assumption that $\alpha_{k,j+1}$ is the first trust-region radius violating (4.30). The contradiction shows that the lemma is true. □

Now we are ready to prove that the first part of the stopping rule, i.e., $\eta_k\|p_{k,j}\| < \epsilon_1$, can be satisfied in finitely many iterations.

LEMMA 4.5. (a) *If there are only finitely many successful iterations in each inner algorithm, then $x_{k,j} = x^*$ and $\|p_{k,j}\| = \|p(x^*)\| = 0$ for all sufficiently large j.*

(b) $\liminf_{j\to\infty} \eta_k\|p_{k,j}\| = 0$.

(c) $\lim_{j\to\infty} \eta_k\|p_{k,j}\| = 0$.

Proof. (a) The mechanism of the algorithm ensures that $x^* = x_{k,j_0} = x_{k,j}$ for all $j > j_0$, where $\{k, j_0\}$ is the index of the last successful iterate. Since all iterations are unsuccessful for sufficiently large j, we know $\alpha_{k,j}$ will converge to zero. If $\|p(x^*)\| = \|p_{k,j_0}\| > 0$, Lemma 4.4 implies that $\alpha_{k,j}$ will be bounded from zero. This contradiction shows that $\|p_{k,j_0}\|$ has to be zero.

(b) For the purpose of deriving contradiction, we assume that for all j, $\eta_k\|p_{k,j}\| \ge \epsilon$ for some $\epsilon > 0$. From Lemma 4.4 we know that $\alpha_{k,j} \ge \min\{\frac{\gamma_1(1-\eta_2)\theta\epsilon}{1+(1-\eta_2)\theta\epsilon}, \frac{\gamma_1\epsilon}{C'\eta_k}\}$ for all j. We consider all successful iterations $\{k, j\}$; then

$$f_{\eta_k}(x_{k,j}) - f_{\eta_k}(x_{k,j}+d_{x_{k,j}}) \ge \eta_1' Pred_{k,j}$$

$$\ge \eta_1'\theta\|p_{k,j}\| \min\left\{\frac{\|p_{k,j}\|}{\beta_{k,j}}, \alpha_{k,j}\right\}; \tag{4.32}$$

here the last inequality follows by inequality (4.14). From the above analysis, we know $\eta_1'\theta\|p_{k,j}\| \min\{\frac{\|p_{k,j}\|}{\beta_{k,j}}, \alpha_{k,j}\} \ge \sigma > 0$; here σ is some positive constant number

that is independent of j. If we have infinitely many successful iterations, the difference between $f_{\eta_k}(x_{k,0})$ and $f_{\eta_k}(x_{k,j})$ will be unbounded when $j \to +\infty$. This contradicts the assumption that $f_{\eta_k}(x)$ is bounded from below on the feasible set. Hence, we conclude that $\liminf_{j\to\infty} \eta_k \|p_{k,j}\| = 0$.

(c) For the purpose of deriving a contradiction, assume there is a subsequence of successful iterations $\{x_{k,j_i}\}$ such that $\eta_k\|p_{k,j_i}\| \geq 2\epsilon$ for some $\epsilon > 0$ and for all $\{j_i\}$. Our part (b) ensures the existence for each $\{j_i\}$ of a first successful iteration $l_i = l(j_i) > j_i$ such that $\eta_k\|p_{k,l_i}\| < \epsilon$. We thus obtain another subsequence of successful iterations $\{l_i\}$ such that $\eta_k\|p_{k,j}\| \geq \epsilon$ for $j_i \leq j < l_i$ and $\eta_k\|p_{k,l_i}\| < \epsilon$. Define $\kappa = \{j \in S | j_i \leq j < l_i\}$; here S indicates the successful iterations. For $j \in \kappa$, from inequality (4.32) we have

$$\begin{aligned} f_{\eta_k}(x_{k,j}) - f_{\eta_k}(x_{k,j+1}) &\geq \eta_1'\theta\|p_{k,j}\| \min\left\{\frac{\|p_{k,j}\|}{\beta_{k,j}}, \alpha_{k,j}\right\} \\ &\geq \eta_1'\theta\frac{\epsilon}{\eta_k}\min\left\{\frac{\epsilon}{\eta_k\beta_{k,j}}, \alpha_{k,j}\right\}. \end{aligned} \tag{4.33}$$

Since the sequence $f_{\eta_k}(x_{k,j})$ is monotonically decreasing and bounded from below, it is convergent. Therefore, the left-hand side of (4.33) must tend to zero when j tends to infinity. This gives that $\lim_{j\to\infty, j\in\kappa} \alpha_{k,j} = 0$. As a consequence, the second term dominates the minimum in (4.33) and we obtain that for $j \in \kappa$ sufficiently large,

$$\alpha_{k,j} \leq \frac{2\eta_k(f_{\eta_k}(x_{k,j}) - f_{\eta_k}(x_{k,j+1}))}{\eta_1'\theta\epsilon}. \tag{4.34}$$

We then deduce from this bound that, for i sufficiently large,

$$\begin{aligned} \|x_{k,j_i} - x_{k,l_i}\| &\leq \sum_{j=j_i, j\in\kappa}^{l_i-1} \|d_{x_{k,j}}\| = \sum_{j=j_i, j\in\kappa}^{l_i-1} \|F''(x_{k,j})^{-\frac{1}{2}} d'_{x_{k,j}}\| \\ &\leq \sum_{j=j_i, j\in\kappa}^{l_i-1} \|F''(x_{k,j})^{-\frac{1}{2}}\| \|d'_{x_{k,j}}\| \leq \sum_{j=j_i, j\in\kappa}^{l_i-1} C\alpha_{k,j} \\ &\leq C \sum_{j=j_i, j\in\kappa}^{l_i-1} \frac{2\eta_k(f_{\eta_k}(x_{k,j}) - f_{\eta_k}(x_{k,j+1}))}{\eta_1'\theta\epsilon} \\ &= \frac{2C\eta_k(f_{\eta_k}(x_{k,j_i}) - f_{\eta_k}(x_{k,l_i}))}{\eta_1'\theta\epsilon}. \end{aligned} \tag{4.35}$$

Here the third inequality follows from part (b) of Lemma 4.2, and the fourth inequality follows from inequality (4.34). Because $f_{\eta_k}(x_{k,j})$ is monotonically decreasing for j and bounded from below, it is convergent. Consequently, $f_{\eta_k}(x_{k,j_i}) - f_{\eta_k}(x_{k,l_i})$ tends to zero when $i \to +\infty$. We therefore obtain that $\|x_{k,j_i} - x_{k,l_i}\|$ tends to zero when $i \to +\infty$. Without loss of generality, we can assume x^* to be the common limit point of sequences $\{x_{k,j_i}\}_{i=1}^{\infty}$ and $\{x_{k,l_i}\}_{i=1}^{\infty}$. Since the sequences of our algorithm make the value of $f_{\eta_k}(x)$ decrease, the limit point x^* must be in the interior of the feasible set F_p. We know

$$\|p_{k,j_i} - p_{k,l_i}\| \leq \|p_{k,j_i} - p(x^*)\| + \|p(x^*) - p_{k,l_i}\|. \tag{4.36}$$

From part (a) of Lemma 4.2, we know that $c_{k,j}$ is continuous for x. Since $p_{k,j}$ is the projection of $c_{k,j}$ over the null space of $A_{k,j}$, $p_{k,j}$ is also continuous for x. Therefore, the right-hand side of inequality (4.36) will converge to zero when i tends to infinity. But, on the other hand, we know $\eta_k\|p_{k,j_i} - p_{k,l_i}\| \geq \eta_k\|p_{k,j_i}\| - \eta_k\|p_{k,l_i}\| \geq \epsilon$. Therefore, we get a contradiction, which means our initial assumption that $\eta_k\|p_{k,j}\|$ does not converge to zero cannot be true. This completes our proof. ∎

Now we prove that the second part of the stop rule, $\eta_k\lambda_{k,j} > -\epsilon_2$, can also be satisfied in finitely many iterations.

LEMMA 4.6. *For every fixed k, $\limsup_{j\to\infty} \lambda_{k,j} \geq 0$.*

Proof. For the purpose of deriving a contradiction, we assume that $\lambda_{k,j} \leq \lambda_*$ for some $\lambda_* < 0$ and all j. From inequality (4.15) we know that

$$Pred_{k,j} = -q'(d'_{x_{k,j}}) \geq -\theta\lambda_{k,j}\min\{\lambda_{k,j}^2, \alpha_{k,j}^2\} \geq -\theta\lambda_*\min\{\lambda_*^2, \alpha_{k,j}^2\}. \tag{4.37}$$

Therefore, we get

$$|\rho_{k,j} - 1| = \left|\frac{f_{\eta_k}(x_{k,j}) - f_{\eta_k}(x_{k,j} + d_{k,j}) + m_{k,j}(d_{k,j})}{Pred_{k,j}}\right| \leq \frac{\frac{(\alpha_{k,j})^3}{3(1-\alpha_{k,j})}}{-\eta_k\theta\lambda_*\min\{\lambda_*^2, \alpha_{k,j}^2\}}. \tag{4.38}$$

From this inequality, there exists a constant $\delta_1 > 0$ such that if $\alpha_{k,j} < \delta_1$, then $|\rho_{k,j} - 1| \leq 1 - \eta_2'$, that is, $\rho_{k,j} \geq \eta_2'$, which means this iteration is very successful and $\alpha_{k,j+1} \geq \alpha_{k,j}$. Now we assume $\{k, j_0\}$ is the first iteration such that $\alpha_{k,j_0} \leq \delta_1$; then from our above analysis, we know that $\alpha_{k,j} \geq \min\{\gamma_1\delta_1, \alpha_{k,j_0}\} := \delta_2$ for all $j \geq j_0$. Consequently,

$$\begin{aligned} f_{\eta_k}(x_{k,j}) - f_{\eta_k}(x_{k,j} + d_{x_{k,j}}) &\geq \eta_1' Pred_{k,j} \geq -\eta_1'\theta\lambda_*\min\{\lambda_*^2, \alpha_{k,j}^2\} \\ &\geq -\eta_1'\theta\lambda_*\min\{\lambda_*^2, \delta_2^2\} > 0 \end{aligned} \tag{4.39}$$

whenever $\{k, j\}$ is successful. If there are infinitely many successful iterations after $\{k, j_0\}$, (4.39) contradicts the fact that $f_{\eta_k}(x)$ is bounded from below. If there are finitely many successful iterations, the mechanism of our algorithm ensures that $\alpha_{k,j}$ converges to zero. But it again contradicts $\alpha_{k,j} \geq \min\{\gamma_1\delta_1, \alpha_{k,j_0}\} := \delta_2$ for all $j \geq j_0$. Hence our original assumption that there exists $\lambda_* < 0$ such that for all j, $\lambda_{k,j} \leq \lambda_*$ cannot be true. This completes the proof. ∎

From Lemma 4.6 and part (c) of Lemma 4.5, it is obvious that the stopping rule of our inner algorithm can be satisfied in finite many iterations.

THEOREM 4.1. *For every fixed η_k, Step 1 through Step 4 can be terminated in finitely many iterations.*

Finally, we can derive that any limit point of the sequences our algorithm generates satisfies both the first-order and the second-order optimality conditions.

THEOREM 4.2. *Assume x^* is any limit point of the sequences $\{x_{k,0}\}_{k=0}^{\infty}$ our algorithm generates; then x^* satisfies both the first-order and the second-order optimality conditions for our problem* (3.1)–(3.3).

Proof. We assume that $s_{k+1,0}$ is defined by (4.21). From Lemma 4.1, we know

$$\langle x_{k+1,0}, s_{k+1,0}\rangle \leq \frac{1}{\eta_k}(\vartheta + \sqrt{\vartheta}). \tag{4.40}$$

The above inequality implies that $\eta_k \to \infty$ as $k \to \infty$. Hence, any limit point of the sequences $\{x_{k,0}\}_{k=0}^{\infty}$ must satisfy the first-order optimality condition. Moreover, we know that

$$\lambda_{k+1,0} \geq \frac{-\epsilon_2}{\eta_k}, \tag{4.41}$$

which implies that

$$\liminf_{k\to\infty} \lambda_{k,0} \geq 0. \tag{4.42}$$

The above inequality, the definition of $\lambda_{k,j}$, and our continuity assumption show that $F''(x^*)^{-\frac{1}{2}} Q F''(x^*)^{-\frac{1}{2}}$ is positive semidefinite on the vector space $\{x | AF''(x^*)^{-\frac{1}{2}} x = 0, x \in E\}$. From Corollary 3.1, we know x^* satisfies the second-order optimality condition. □

5. Solve the large-scale trust-region subproblem. In this section, we show how to use our algorithm to solve the trust-region subproblem exactly and approximately. Numerical results are presented.

Consider the following standard trust-region subproblem:

$$\min \quad q(x) = \frac{1}{2}\langle x, Qx\rangle + \langle c, x\rangle \tag{5.1}$$

$$\text{subject to} \quad \|x\| \leq \Delta, \tag{5.2}$$

where $\|.\|$ is the ℓ_2-norm. By introducing a new variable x_{n+1}, we can transform this problem into the following nonlinear second-order cone programming:

$$\min \quad q(x) = \frac{1}{2}\langle x, Qx\rangle + \langle c, x\rangle \tag{5.3}$$

$$\text{subject to} \quad x_{n+1} = \Delta, \tag{5.4}$$

$$\sum_{i=1}^{n} x_i^2 \leq x_{n+1}^2. \tag{5.5}$$

Obviously, this is a special symmetric cone programming with $A = (0 \cdots 0, 1)$ and $K = \{x \in R^{n+1} : \sum_{i=1}^{n} x_i^2 \leq x_{n+1}^2 \text{ and } x_{n+1} \geq 0\}$. If we want to use Algorithm 4.1 to solve (5.3)–(5.5), we need to choose a method of solving (4.11)–(4.13). Since we are interested in solving large-scale problems, this motivates us to choose the methods that rely only on matrix-vector product. The first method in this class is the Steihaug–Toint truncated conjugate gradient method, which is due to Toint [26] and Steihaug [23]. And the adaptation to handle additional affine constraints can be found in Gould, Hribar, and Nocedal [15]. Here we give the version of the algorithm for solving (4.11)–(4.13).

ALGORITHM 5.1 (the Steihaug–Toint method with affine constraints).

Step 0 **Initialization.** *For fixed* $\{k, j\}$ *in* (4.11)–(4.13), *let* $d'_0 = 0$, $g_0 = c_{k,j}$, $v_0 = P_{A_{k,j}} c_{k,j}$, *and* $p_0 = -v_0$. *For* $h = 0, 1, \ldots$ *until convergence, perform the iteration.*

Step 1 **Check the negative curvature.** *Set* $\kappa_h = \langle p_h, Q_{k,j} p_h\rangle$. *If* $\kappa_h \leq 0$, *compute* σ_h *as the positive root of* $\|d'_h + \sigma p_h\| = \alpha_{k,j}$, *set* $d'_{h+1} = d'_h + \sigma_h p_h$, *and stop. End if*

Step 2 **Check the boundary constraints.** *Set* $\beta_h = \langle g_h, v_h\rangle/\kappa_h$. *If* $\|d'_h + \beta_h p_h\| \geq \alpha_{k,j}$, *compute* σ_h *as the positive root of* $\|d'_h + \sigma p_h\| = \alpha_{k,j}$, *set* $d'_{h+1} = d'_h + \sigma_h p_h$, *and stop. End if*

Step 3 **Perform the conjugate gradient step.** *Set* $d'_{h+1} = d'_h + \beta_h p_h$, $g_{h+1} = g_h + \beta_h Q_{k,j} p_h$, $v_{h+1} = P_{A_{k,j}} g_{h+1}$, *and* $p_{h+1} = -v_{h+1} + \frac{\langle g_{h+1}, v_{h+1}\rangle}{\langle g_h, v_h\rangle} p_h$.

Here $P_{A_{k,j}}$ is the projection onto the null space of $A_{k,j}$.

There are several advantages of this algorithm:

(1) It requires only matrix-vector product.
(2) It usually terminates very fast.
(3) It is applicable to problems with affine constraints.
(4) If the objective function is convex, the computed approximation solution gives at least half of the optimal reduction (Yuan [32]).

This Steihaug–Toint method is basically unconcerned with the trust region until it blunders into its boundary and stops. This is rather unfortunate, particularly, as considerable experience has shown that this frequently happens during the first few iterations when a negative curvature is present, causing the following disadvantages to the algorithm:

(A) Even if the problem is convex, optimal solution cannot be expected, except when the solution lies interior to the trust region.
(B) If it blunders into the boundary or a negative curvature is present too early, the approximate solution is not very good.
(C) It cannot handle the hard case.
(D) Optimal solution for the nonconvex problem is normally impossible for this algorithm.

Can we remove these disadvantages of Algorithm 5.1 while retaining its advantages? The answer is yes. After transforming (5.1)–(5.2) into (5.3)–(5.5), we use Algorithm 4.1 to solve it. In each iteration we use the Steihaug–Toint conjugate gradient method to solve (4.11)–(4.13). Since we basically repeat using Algorithm 5.1 in each iteration, we can keep all the advantages of Algorithm 5.1 as long as the number of iterations is not too big. It turns out that the number of iterations is very reasonable from the numerical results presented in this section. What can we achieve by doing this? We can get at least a first-order critical point of (5.3)–(5.5). This gives an optimal solution of (5.1)–(5.2) if Q is positive semidefinite. Thus we have removed (A). Algorithm 5.1 sometimes cannot give us a good approximate solution because it hits the boundary too early. By adding a ϑ-norm barrier to the quadratic model, we can prevent the iterates to reach the boundary too soon. This idea can give us a much better approximate solution, which is verified by the numerical results in this section. Therefore, we have removed (B). We know that Algorithm 5.1 cannot handle the hard case. If $c = 0$ and Q is indefinite, the method will terminate at $d' = 0$ with no decrease in the model. This cannot happen in our new framework. For Algorithm 4.1, a first-order critical point is always ensured even if the problem is in the hard case. Therefore, we have removed (C). Moreover, Algorithm 4.1 can be improved to find the optimal solution of (5.1)–(5.2) for all the cases, including the nonconvex case and the hard case. We first need the following lemma, which is well known in the trust-region literature.

LEMMA 5.1. *Any global minimizer* x^* *of* (5.1)–(5.2) *satisfies the equation*

$$(Q + \mu^* I)x^* = -c; \tag{5.6}$$

here $Q + \mu^* I$ *is positive semidefinite,* $\mu^* \geq 0$, *and* $\mu^*(\|x^*\| - \Delta) = 0$.

For a proof, see, e.g., Section 7.2 of Conn, Gould, and Toint [6].

The following algorithm removes (D).

ALGORITHM 5.2 (an algorithm for optimal solution).

Step 0 **Make Q positive semidefinite** *Find s, the smallest eigenvalue of Q and v, its corresponding eigenvector. If $s < 0$, set $Q = Q - sI$, end if.*

Step 1 **Solve new model.** *Use Algorithm* 4.1 *to solve* (5.3)–(5.5) *with Q positive semidefinite to get solution x_0.*

Step 2 **Go back to original model.** *If $s \geq 0$, set $x = x_0$, end if. If $s < 0$ and $\|x_0\| = \Delta$, set $x = x_0$, end if. If $s < 0$ and $\|x_0\| < \Delta$, set $x = x_0 + \sigma v$, σ is chosen so that $\|x_0 + \sigma v\| = \Delta$, end if.*

We claim that x is an optimal solution of (5.1)–(5.2). If $s \geq 0$, it is obvious. If $s < 0$ and $\|x_0\| = \Delta$, it follows from the fact that x_0 is an optimal solution of the new model with Q positive semidefinite and Lemma 5.1. If $s < 0$ and $\|x_0\| < \Delta$, $\mu^* = 0$ in (5.6) of Lemma 5.1 and consequently $Qx_0 = -c$ for the new convex Q. And since $Qv = 0$ for the new Q, $Qx = Q(x_0 + \sigma v) = -c$. From Lemma 5.1, we know that x is an optimal solution of (5.1)–(5.2). Therefore, we have removed all the disadvantages of the Steihaug–Toint method, while our algorithms mainly rely on the conjugate gradient method. For finding the optimal solution of the problem when it is nonconvex, we need to compute the least eigenvalue. However, those eigenvalue-based algorithms like those of Sorensen [22], Rojas, Santos, and Sorensen [21], and Rendl and Wolkowicz [19] require computing sequences of least eigenvalues, while we compute the least eigenvalue only once. As pointed out to us by a referee, Griffin and Gill [16] independently applied a truncated conjugate gradient algorithm to a shifted quadratic function to solve the trust-region subproblem.

We need to mention two implementation techniques when we use Algorithm 5.1 to solve (4.11)–(4.13) in each iteration.

We can see that the main computation in this algorithm is the product of the matrix $Q_{k,j}$ with a vector. In practice, we do not form $Q_{k,j}$ explicitly because it is expensive and destroys the sparse structure of Q. Since $Q_{k,j} = F''(x_{k,j})^{-\frac{1}{2}} Q F''(x_{k,j})^{-\frac{1}{2}} + \frac{1}{\eta_k} I$, we need to compute the product of the matrix $F''(x_{k,j})^{-\frac{1}{2}}$ with a vector, which can be done efficiently. For $F(x) = -\ln(x_{n+1}^2 - \sum_{i=1}^n x_i^2)$, $F''(x)^{-1}$ and $F''(x)^{-\frac{1}{2}}$ have the following explicit forms:

$$F''(x)^{-1} = \frac{1}{2}\begin{bmatrix} (x_{n+1}^2 - y^T y)I + 2yy^T & 2x_{n+1}y \\ 2x_{n+1}y^T & x_{n+1}^2 + y^T y \end{bmatrix}, \tag{5.7}$$

$$F''(x)^{-\frac{1}{2}} = \frac{\sqrt{2}}{2}\begin{bmatrix} \sqrt{x_{n+1}^2 - y^T y}I + \frac{yy^T}{\sqrt{x_{n+1}^2 - y^T y} + x_{n+1}} & y \\ y^T & x_{n+1} \end{bmatrix}, \tag{5.8}$$

where $y = (x_1 \dots x_n)^T$. For more details about the second-order cone and its barrier, see, e.g., Alizadeh and Goldfarb [2] or Faybusovich and Tsuchiya [10].

The first technique is that we do not have to formulate $F''(x)^{-\frac{1}{2}}$ explicitly for computing the product of the matrix $F''(x_{k,j})^{-\frac{1}{2}}$ with a vector. Since $yy^T u = \langle y, u\rangle y$ for any vector $u \in R^n$, the computation needs only $O(n)$ arithmetic operations.

The second technique is for the projection $P_{A_{k,j}}$. For any vector $u \in R^{n+1}$,

$$\begin{aligned} P_{A_{k,j}} u &= u - A_{k,j}^T (A_{k,j} A_{k,j}^T)^{-1} A_{k,j} u \\ &= u - F''(x_{k,j})^{-\frac{1}{2}} A^T (A F''(x_{k,j})^{-1} A^T)^{-1} A F''(x_{k,j})^{-\frac{1}{2}} u. \end{aligned} \tag{5.9}$$

Because $A = (0 \dots 0, 1)$, $AF''(x_{k,j})^{-1}A^T$ is just the $(n+1, n+1)$ entry of $F''(x_{k,j})^{-1}$. The only thing left is to compute the product of $F''(x_{k,j})^{-\frac{1}{2}}$ with a vector, which has been taken care of by $O(n)$ arithmetic operations.

By the above two techniques, each iteration of our algorithm takes hardly more extra work than the Steihaug–Toint truncated conjugate gradient method.

When applying Algorithm 4.1 to (5.3)–(5.5), we change the stopping rule for the inner iterations to make the algorithm more efficient. We remind the reader that there are two conditions of our stopping rule: (a) $\eta_k \|p_{k,j}\| < \epsilon_1$ and (b) $\eta_k \lambda_{k,j} > -\epsilon_2$ for some $\epsilon_1, \epsilon_2 \in (0, 1)$. We ignore condition (b), since a first-order critical point is good enough for our purpose. For condition (a), we need to change it a little because it is independent of whether or not optimality is nearly achieved. In practice, we directly follow the definition of the first-order optimality condition. If $x_{k,j}$ is a first-order critical point, $s_{k,j} = Qx_{k,j} + c - A^*y$ should be inside the second-order cone for some y. In our case $A = (0 \dots 0, 1)$ and all of the entries in the last row of Q are zeros. Therefore, we set $y = -\|Qx_{k,j} + c\|$ such that $s_{k,j}$ is inside the second-order cone. Then we stop the inner iteration as soon as we find $x_{k,j}$ such that $\langle x_{k,j}, s_{k,j} \rangle \le \frac{\epsilon}{\eta_k}$ for some constant ϵ. Lemma 4.1 suggests that $\epsilon = \sqrt{\vartheta} + \vartheta$ is a good choice. For the second-order cone, $\vartheta = 2$. From our practical experience, it works very well for convex problems. In the nonconvex case, it seems that this stopping rule works for some problems but not all of them, which remains to be investigated. The algorithm is halted as soon as $x_{k,j}$ is found such that $\langle x_{k,j}, s_{k,j} \rangle \le 10^{-4}$. In Algorithm 4.1, $\eta_1' = 0.05$ and $\eta_2' = 0.9$ are used and the trust region is updated according to the usual rule. If $\rho_{k,j} \ge \eta_2'$, set $\alpha_{k,j+1} = \max(\alpha_{k,j}, 2\|d_{k,j}'\|)$; if $\rho_{k,j} \in [\eta_1', \eta_2')$, set $\alpha_{k,j+1} = \alpha_{k,j}$; if $\rho_{k,j} < \eta_1'$, set $\alpha_{k,j+1} = \frac{1}{2}\alpha_{k,j}$. The initial value of parameter η is set to be $\frac{1}{\Delta}$ and is updated by $\eta_{k+1} = 10\eta_k$. In each iteration, the Steihaug–Toint conjugate gradient method (Algorithm 5.1) is stopped as soon as $\|v_h\| \le 10^{-\frac{3}{2}}\|v_0\|$ if it does not hit the boundary and negative curvature is not present before that. We decide not to put an upper bound on the number of Steihaug–Toint iterations, which is denoted by h in Algorithm 5.1. In this way, for the convex problems, we will be able to know the number of iterations our algorithm needs to get an optimal solution if we solve each trust-region subproblem approximately, which is measured by $\|v_h\| \le 10^{-\frac{3}{2}}\|v_0\|$.

The algorithms are tested in MATLAB 7.0 on a Linux system. We run our experiments on a Gateway computer with a Pentium IV 3.2G processor and 1G RAM. We compare our results with a software called "Newtrust4b" based on Rendel and Wolkowicz [19]. We choose "Newtrust4b" because it is one of the best software packages for finding the optimal solution of the trust-region subproblem and because it is also implemented in MATLAB code. For the test problems, Q and c are randomly generated with entries uniformly distributed on (0,1). We set the trust-region radius $\Delta = 1$. For different radiuses, the computation time and the number of iterations may vary, but they vary reasonably. In Tables 1–5, n is the dimension of the problems, d is the density of Q; i.e., Q has $d * n^2$ nonzero entries. The data in those columns under the algorithms' names is the computational time by seconds. Sometimes, the MATLAB timing is dependent on the CPU load. Our timings have been averaged to eliminate this dependency. And *its* is the number of iterations of our algorithm. ST *its* is the total number of Steihaug–Toint iterations used during the whole computation. From Algorithm 5.1, we can see that the dominating cost of each Steihaug–Toint iteration is the product of $Q_{k,j}$ and p_h. Therefore, ST *its* gives us the total number of the matrix-vector products used by our algorithm. We first test some convex problems. To make the problem convex, we let $Q = Q - sI$ if s, the least eigenvalue of

Q, is negative. In this way, the problem is convex and nearly singular. To show that our algorithm can handle the singular problems, we set $Q = \left[\begin{smallmatrix} Q & 0 \\ 0 & 0 \end{smallmatrix}\right]$ to make it even more singular. Now the dimension of Q is $n + 1$, and so is c. Since the problems are convex, Algorithm 4.1 gives us optimal solutions.

We can see that Algorithm 4.1 outperforms Newtrust4b for the convex singular problems. The success of Algorithm 4.1 in this case is a good basis for Algorithm 5.2. If the problem is nonconvex or if we do not know whether or not our problem is convex, we have to use Algorithm 5.2 to get an optimal solution. The following two groups of results show us the performance of Algorithm 5.2.

We can see that Algorithm 5.2 is competitive with Newtrust4b in both sparse and dense cases. The eigenvalue time is the computational time cost by computing the least eigenvalue of Q in Algorithm 5.2, which becomes dominant when the problem becomes large. Fortunately, we have reduced this part to the minimum level in Algorithm 5.2 (we need only compute the least eigenvalue once for all). Moreover, the number of iterations and ST iterations of our algorithm is independent of the dimension of the problems.

So far, we have been focusing on finding the optimal solution of the trust-region subproblem. But if the problem is nonconvex, Algorithm 4.1 can deliver us only an approximate solution. How good is Algorithm 4.1 for nonconvex problems? From our practical experience, we have to say that the performance of Algorithm 4.1 on finding an approximate solution for nonconvex problems is not as stable as its performance on finding exact solution for convex problems. This is reflected by the fact that the convergence is sensitive to the inner iteration stopping rule. The inner iteration stopping rule, $\langle x_{k,j}, s_{k,j}\rangle \le \frac{\sqrt{\vartheta}+\vartheta}{\eta_k}$, works for some of our testing problems but not for all of them. For those test problems where Algorithm 4.1 has good performance, the number of iterations is around 40. For those test problems where Algorithm 4.1 has bad performance, the number of iterations can reach over 100. The change of stopping rule of inner iteration (like from $\langle x_{k,j}, s_{k,j}\rangle \le \frac{\sqrt{\vartheta}+\vartheta}{\eta_k}$ to $\langle x_{k,j}, s_{k,j}\rangle \le \frac{1}{\eta_k}$) can significantly affect the performance of the algorithm on the same test problem. This phenomenon remains to be investigated. On the positive side, even for the problems where Algorithm 4.1 has bad performance, the convergence slows down only when η_k

becomes large and our solution is close to the optimal solution. Here we give a group of examples to show that Algorithm 4.1 can deliver us a good approximate solution at a relatively low cost. For each of these problems, we first use Algorithm 5.2 to get an optimal solution and consequently the best possible reduction. Then we use Algorithm 4.1 to solve it and stop the algorithm when 90% of the optimal reduction is achieved. Q is randomly generated with entries uniformly distributed on (0,1). We have check that Q is indefinite. To show the performance of our algorithm on the singular problems, we set $Q = \left[\begin{smallmatrix} Q & 0 \\ 0 & 0 \end{smallmatrix}\right]$. Therefore, the actual dimension of Q in Table 4 is $n + 1$.

We can see that after a few Steihaug–Toint iterations, Algorithm 4.1 can deliver us a good approximate solution. Therefore, we have achieved our goal of improving the solution quality of the Steihaug–Toint method while keeping its computational advantages.

In summary, techniques developed in this section give us two algorithms for solving the trust-region subproblem. Algorithm 5.2 gives us an optimal solution for both convex and nonconvex problems. Algorithm 4.1 gives us a good approximate solution for nonconvex problems and an optimal solution for convex problems.

6. Further numerical results and implementation issues. In this section, we discuss some implementation issues for solving general symmetric cone programming. We also present some numerical results of solving a class of quadratic programming.

To solve the general symmetric cone programming, we have to handle three basic implementation issues. The first issue is to find a starting point in our feasible set. This feasible set has been well studied in the interior-point algorithm literature. We can use the same technique to find a feasible starting point for our problem. The second issue is to handle affine constraints. This requires us either to solve the normal equations or to project iterates onto the null space of $A_{k,j}$. Gould, Hribar, and Nocedal [15] is a good reference for handling this issue. The third issue is about preconditioning. We recall that $Q_{k,j} = F''(x_{k,j})^{-\frac{1}{2}} Q F''(x_{k,j})^{-\frac{1}{2}} + \frac{1}{\eta_k} I$. When we are getting close to the optimal solution, η_k is getting large, and consequently the right part $\frac{1}{\eta_k} I$ is about to disappear. At the same time, the iterate $x_{k,j}$ is getting close

TABLE 5
Q is positive definite with density d = 1.

n	its	ST its	Algorithm 4.1

5000	70	671	109

to the boundary. Therefore, $F''(x_{k,j})^{-\frac{1}{2}}$ becomes nearly singular, which can make the condition number of $Q_{k,j}$ large. As we know, the convergence behavior of the conjugate gradient method is strongly dependent on the conditioning of $Q_{k,j}$. Therefore, the appropriate preconditioning technique is necessary to make the algorithm efficient.

Handling these implementation issues is beyond the scope of this paper. However, to see how our algorithm performs on solving problems other than the trust-region subproblem, we present some numerical results for a class of quadratic programming, which is minimization of a strictly convex quadratic objective function over the positive orthant. This problem is bounded from below. We use the vector e with every entry 1 as our starting point. Q is randomly generated with entries uniformly distributed on (0,1). We make the problem convex by letting $Q = Q + (-s + 1)I$ if s, the least eigenvalue of Q, is negative. c is randomly generated with entries uniformly distributed on $(-1, 0)$. In this way, the problem will have nontrivial solution. In each step, the conjugate gradient method is stopped if the iterate hits the boundary or $\|g_h\| \leq 10^{-3/2}\|g_0\|$. The inner iteration is stopped when we find $x_{k,j}$ such that $s_{k,j} = Qx_{k,j} + c$ belongs to positive orthant and $\langle x_{k,j}, s_{k,j}\rangle \leq \frac{n+\sqrt{n}}{\eta_k}$. The algorithm is halted as soon as $x_{k,j}$ is found such that $\langle x_{k,j}, s_{k,j}\rangle \leq 10^{-4}$. All other implementation techniques are similar to those we discussed in section 5. The following is a group of results.

The number of iterations as well as the total number of Steihaug–Toint iterations are independent of the dimension of problems, which makes our algorithm have practical potential for solving large-scale problems. One practical observation we want to mention is that the computational time of reducing $\langle x_{k,j}, s_{k,j}\rangle$ from 10^{-3} to 10^{-4} is even more than the computational time of reducing it from the starting value to 10^{-3}. This is caused by the fact that the convergence of the conjugate gradient algorithm considerably slows down when the iterate is close to optimal solution and consequently the boundary, which agrees with our theoretical analysis above. Therefore, appropriate preconditioning is indispensable to make the algorithm more efficient. Since it has been shown in section 5 that Algorithm 4.1 works well for solving the singular problems, an alternative way is to use it to solve the trust-region subproblem when the iterate is close to the boundary of the positive orthant. Which way is better remains to be investigated.

7. Concluding remarks. In this paper, we have shown that combining the techniques developed in trust-region literature (especially Conn, Gould, and Toint [6]) with those techniques in interior-point method literature can be very powerful both in theoretical analysis and practical implementation. For further theoretical research, Lu and Yuan [17] have recently proved that the complexity of an interior-point trust-region algorithm for convex programming is polynomial time. On the practical side, the numerical results presented in this paper show that our algorithm

has practical potential. But a lot more work needs to be done to turn this method into a practical software package for solving general symmetric cone programming.

Appendix. In this appendix, we describe the face $V_{A'}$ for the semidefinite case. We use the Jordan algebra technique to prove Theorem 3.3 and give an explanation why Lemma 4.2 holds for general symmetric cone.

If $K = S_+^{n\times n}$, we know $F(X) = -\ln\det(X)$ is a *ϑ-normal barrier* for $S_+^{n\times n}$. Let $A' \in \partial K$, and $\operatorname{rank}(A') = r < n$; then $F''(A')^{-\frac{1}{2}}X = A'^{\frac{1}{2}}XA'^{\frac{1}{2}}$. We set $V = \{A'^{\frac{1}{2}}XA'^{\frac{1}{2}} | AA'^{\frac{1}{2}}XA'^{\frac{1}{2}} = 0, X \in S^{n\times n}\}$. In section 3, we have claimed that $V_{A'} = V$. Now we give a proof.

Proof. First, we need to characterize $V_{A'}$. Since A' is a semidefinite matrix, then we can find an orthogonal matrix U, such that $U^{-1}A'U = D$, where $D = \operatorname{diag}\{\lambda_1, \ldots, \lambda_r, 0, \ldots, 0\}$ with $\lambda_i > 0$, $i = 1, \ldots, r$.

Let $C = \operatorname{diag}\{0, \ldots, 0, 1, \ldots, 1\}$ be the matrix whose first r diagonal entries are 0 and the last $n - r$ diagonal entries are 1, and let $Q' = UCU^{-1}$. Then Q' is a nonzero positive semidefinite matrix and $\langle Q', A'\rangle = \langle UCU^{-1}, UDU^{-1}\rangle = \langle C, D\rangle = 0$. Furthermore, for any positive semidefinite $n \times n$ matrix X, $\langle Q', X\rangle \geq 0$. Therefore, the hyperplane $H = \{X \in S^{n\times n} | \langle Q', X\rangle = 0\}$ isolates $S_+^{n\times n}$ and contains A'. We claim that

$$\digamma_{A'} = \{X \in S_+^{n\times n} | AX = b, \langle Q', X\rangle = 0\}.$$

To see that A' is a relative interior point of $\digamma_{A'}$, we need only show that A' is an interior point of $\digamma = \{X \in S_+^{n\times n} | \langle Q', X\rangle = 0\}$. The map $X \mapsto Y = U^{-1}XU$ is a nondegenerate linear transform which maps $S_+^{n\times n}$ onto itself, maps Q' onto C, and maps A' onto D. Then $\digamma$ is mapped onto $\digamma' = \{Y \in S_+^{n\times n} | \langle C, Y\rangle = 0\}$. Clearly, Y must have the last $n - r$ rows and last $n - r$ columns be 0. The upper left $r \times r$ submatrix Y' of Y can be arbitrary positive semidefinite matrix, $Y = \left(\begin{smallmatrix} Y' & 0 \\ 0 & 0 \end{smallmatrix}\right)$. It is easy to see that $\digamma'$ contains D in its interior. Since $Y \mapsto X = UYU^{-1}$ is a nondegenerate linear transform, which maps D onto A' and $\digamma'$ onto $\digamma$, then A' is an interior point of $\digamma$. Therefore A' is a relative interior point of $\digamma_{A'}$. Then

$$V_{A'} = \{X \in S^{n\times n} | AX = 0, \langle Q', X\rangle = 0\}.$$

To show that $V_{A'} = V$, we need only verify that

$$V' = \{A'^{\frac{1}{2}}XA^{\frac{1}{2}} | X \in S_+^{n\times n}\} = \digamma = \{X \in S_+^{n\times n} | \langle Q', X\rangle = 0\}.$$

For all $F \in \digamma$, since $\digamma = U\digamma' U^{-1}$,

$$F = U \begin{pmatrix} Y' & 0 \\ 0 & 0 \end{pmatrix} U^{-1}$$

for some $r \times r$ positive semidefinite matrix Y'. Let

$$X = U \begin{pmatrix} D'Y'D' & 0 \\ 0 & 0 \end{pmatrix} U^{-1};$$

here $D' = \operatorname{diag}\{\sqrt{\lambda_1}, \ldots, \sqrt{\lambda_r}\}^{-1}, \lambda_i > 0, i = 1, \ldots, r$ are the eigenvalues of A'. Then

$$A'^{\frac{1}{2}}XA'^{\frac{1}{2}} = \left(U\operatorname{diag}\{\sqrt{\lambda_1}, \ldots, \sqrt{\lambda_r}, 0, \ldots, 0\}U^{-1}\right)\left(U\begin{pmatrix} D'Y'D' & 0 \\ 0 & 0 \end{pmatrix}U^{-1}\right),$$

$$\left(U\mathrm{diag}\{\sqrt{\lambda_1},\ldots,\sqrt{\lambda_r},0,\ldots,0\}U^{-1}\right) = U\begin{pmatrix} Y^{'} & 0 \\ 0 & 0 \end{pmatrix}U^{-1} = F.$$

We conclude that $\digamma \subset V'$. It is easy to see that $\dim(\digamma) = \dim(V') = \frac{r(r+1)}{2}$, and we get $\digamma = V'$. Therefore,

$$\{X \in S^{n\times n} | \langle Q', X\rangle = 0\} = Aff(\digamma) = Aff(V') = \{A'^{\frac{1}{2}} X A'^{\frac{1}{2}} | X \in S^{n\times n}\},$$

which implies that

$$V_{A'} = V = \{F''(A')^{-\frac{1}{2}} X | AF''(A')^{-\frac{1}{2}} X = 0, X \in S^{n\times n}\}.$$

Before we prove Theorem 3.3, we introduce some notation of Jordan algebra. Since every symmetric cone K can be realized as a cone of squares in an appropriated Euclidean algebra (see Faraut and Koranyi [9] for details), we can use the Jordan algebra technique to prove Theorem 3.3.

Let V be an Euclidean Jordan algebra and Ω be a cone of invertible squares in V. We define $\langle x, y\rangle = \mathrm{tr}(x \circ y)$ as the canonical scalar product in V. Let $F(x) = -\log\det(x)$, $x \in \Omega$. Then $F''(x) = P(x)^{-1}$; here $F''(x)$ is the Hession of F evaluated at $x \in \Omega$ with respect to the canonical scalar product $\langle , \rangle$. $P(x)$ is the quadratic representation of x. We assume $\mathrm{rank}(V) = r$. When x is on the boundary $\partial\Omega$ of Ω, $\mathrm{rank}(x) = j < r$.

In the following, we fix a Jordan frame $c_1, \ldots, c_r$ and denote $e_j = c_1 + \cdots + c_j$, $V^{(j)} = V(e_j, 1)$. We denote by Ω^j the symmetric cone associated with the subspace $V^{(j)}$, i.e., the interior relative to $V^{(j)}$. Then $\Omega_j \subset \partial\Omega$. The following lemma characterizes the boundary of symmetric cone. For a proof, see Proposition IV.3.1 in Faraut and Koranyi [9].

LEMMA A.1. *For x in $\overline{\Omega}$ the following properties are equivalent:*

(a) *The rank of x is j.*
(b) *$x \in k\Omega^j$ for some k in $K = G \cap O(V)$; here G is the connected component of the identity in $G(\Omega)$ and $G(\Omega)$ denotes the set of automorphisms of Ω.*
(c) *The rank of $P(x)$ is equal to the dimension of $V^{(j)}$.*

Now we assume $x^* \in \overline{\Omega}$ and $\mathrm{rank}(x^*) = j$. From Lemma A.1, we know that $x^* \in k\Omega^j$ for some k in K. It can be verified that $V_{x^*} = kV^{(j)}$. Now we are ready to prove Theorem 3.3.

Proof of Theorem 3.3. From the above analysis, we need only prove $P(x^*)^{\frac{1}{2}} V = kV^{(j)}$. Since $P(x^*)$ is a positive semidefinite linear operator, $P(x^*)^{\frac{1}{2}} V = P(x^*)V$. Therefore we need only prove $P(x^*)V = kV^{(j)}$. From part (b) of Lemma A.1, we know $x^* = k\sum_{i=1}^{j} \lambda_i c_i = kP(a)e_j$, with $a = \sum_{i=1}^{j} \sqrt{\lambda_i} c_i + \sum_{i=j+1}^{r} c_i$. Then $P(x^*) = p(kP(a)e_j) = kP(P(a)e_j)k^* = kP(a)P(e_j)P(a)k^*$; here the second equality follows by Proposition III.5.2 in Faraut and Koranyi [9] and the last equality follows by Proposition II.3.3 in Faraut and Koranyi [9]. Since $P(e_j)$ is the orthogonal projection onto $V^{(j)}$ and $P(a)$ maps $V^{(j)}$ onto $V^{(j)}$, it is easy to see that $P(x^*)V \subset kV^{(j)}$. Since from part (c) of Lemma A.1, we know $\mathrm{rank}(P(x^*)) = \mathrm{rank}(V^{(j)}) = \mathrm{rank}(kV^{(j)})$, we conclude that $P(x^*)V = kV^{(j)}$. We complete the proof. □

Part (a) of Lemma 4.2 holds only because $F''(x^*)^{-\frac{1}{2}} = P(x^*)^{\frac{1}{2}}$ and $P(x^*)$ is the quadratic representation of x^*.

Acknowledgments. The first author would like to thank his advisor, Andrew Sommese, at Notre Dame for his help and support, and Professor Faybusovich for his guidance in the interior-point methods. Professor Yinyu Ye read this paper carefully

and gave some sincere advice; we appreciate his support and encouragement. We would like to thank Mr. Dong Yang for his help in the implementation of our algorithm. We are grateful to the associate editor and the referees for their precious comments.

COMPUTING THE STABILITY NUMBER OF A GRAPH VIA LINEAR AND SEMIDEFINITE PROGRAMMING*

JAVIER PEÑA†, JUAN VERA‡, AND LUIS F. ZULUAGA§

Abstract. We study certain linear and semidefinite programming lifting approximation schemes for computing the stability number of a graph. Our work is based on and refines de Klerk and Pasechnik's approach to approximating the stability number via copositive programming [*SIAM J. Optim.*, 12 (2002), pp. 875–892]. We provide a *closed-form* expression for the values computed by the linear programming approximations. We also show that the *exact* value of the stability number $\alpha(G)$ is attained by the semidefinite approximation of order $\alpha(G) - 1$ as long as $\alpha(G) \leq 6$. Our results reveal some sharp differences between the linear and the semidefinite approximations. For instance, the value of the linear programming approximation of any order is strictly larger than $\alpha(G)$ whenever $\alpha(G) > 1$.

Key words. stability number, copositivity, polynomials, lifting procedures

1. Introduction.

The maximum stable set problem is a central problem in combinatorial optimization and has been the subject of extensive study. The survey by Bomze et al. [2] gives an overview of a variety of approaches to the maximum clique problem, which is equivalent to the maximum stable set problem. In addition to being a classical NP-hard problem, the maximum stable set is among the provably hardest combinatorial problems to approximate [7, 8].

The maximum stable set problem has a straightforward 0–1 integer programming formulation and hence is a natural candidate for application of integer programming. Indeed, lift-and-project approaches provide interesting insight into this problem. For instance, the lift-and-project procedures of Balas, Ceria, and Cornuéjols [1] and of Lovász and Schrijver [12] give relaxations of the stable set polytope that already satisfy a number of valid inequalities. Furthermore, the repeated lift-and-project procedures of Balas, Ceria, and Cornuéjols and of Lovász and Schrijver yield a *finite* sequence of increasingly tighter relaxations of the stable set polytope. Indeed, for a graph G with stability number $\alpha(G)$, the Lovász and Schrijver linear lifting procedure yields the stable set polytope if it is applied $n - \alpha(G) - 1$ times. The stronger Lovász and Schrijver semidefinite lifting procedure yields the stable set polytope when applied $\alpha(G)$ times.

Using a different mathematical programming formulation of the stable set problem, de Klerk and Pasechnik [4] proposed two alternative approximation schemes to $\alpha(G)$. Their approach is based on a characterization of $\alpha(G)$ via copositive programming (cf. (2)) combined with a successive approximation procedure for the copositive

cone inspired by the work of Parrilo [14]. More specifically, de Klerk and Pasechnik [4] define two sequences of cones $\mathcal{K}_n^0 \subseteq \mathcal{K}_n^1 \subseteq \cdots$ and $\mathcal{C}_n^0 \subseteq \mathcal{C}_n^1 \subseteq \cdots$ that converge to the n-dimensional copositive cone $\mathcal{C}_n$ and define $\vartheta^{(r)}(G)$ and $\zeta^{(r)}(G)$ as the upper bounds on $\alpha(G)$ obtained by replacing the copositive cone $\mathcal{C}_n$ by $\mathcal{K}_n^r$ and $\mathcal{C}_n^r$, respectively. Each $\vartheta^{(r)}(G)$ can be computed via semidefinite programming, and each $\zeta^{(r)}(G)$ can be computed via linear programming. De Klerk and Pasechnik establish several properties of the approximations $\vartheta^{(r)}(G)$ and $\zeta^{(r)}(G)$. They show that $\vartheta^{(0)}(\cdot)$ coincides with Schrijver's ϑ'-function. They also show that $\vartheta^{(1)}(\cdot) = \alpha(\cdot)$ for odd cycles and complements of triangle-free graphs. In addition, they prove that the approximations $\zeta^{(r)}(G)$ satisfy $\lfloor \zeta^{(r)}(G) \rfloor = \alpha(G)$ as long as $r \geq \alpha(G)^2$ and $\zeta^{(r)}(G) < \infty$ only if $r \geq \alpha(G) - 1$.

We refine the results of de Klerk and Pasechnik concerning the approximations $\zeta^{(r)}(G)$ and $\vartheta^{(r)}(G)$ to the stability number $\alpha(G)$. We derive a closed-form expression for $\zeta^{(r)}(G)$ in terms of r and $\alpha(G)$ (Theorem 1). The closed-form expression readily yields several interesting properties of $\zeta^{(r)}(G)$ (Corollaries 2, 3, and 4).

We also define a third sequence of cones $\mathcal{Q}_n^0 \subseteq \mathcal{Q}_n^1 \subseteq \cdots$ that converges to $\mathcal{C}_n$ with $\mathcal{C}_n^r \subseteq \mathcal{Q}_n^r \subseteq \mathcal{K}_n^r$, $r = 0, 1, \ldots$. This in turn yields a third sequence of approximations $\nu^{(r)}(G)$ to $\alpha(G)$ with $\vartheta^{(r)}(G) \leq \nu^{(r)}(G) \leq \zeta^{(r)}(G)$. Like $\vartheta^{(r)}(G)$, each $\nu^{(r)}(G)$ can be computed via semidefinite programming. The approximations $\nu^{(r)}(\cdot)$ satisfy an interesting recursive inequality (Theorem 6). Such inequality implies $\nu^{(r)}(G) = \alpha(G)$ as long as $r \geq \alpha(G) - 1$ for $\alpha(G) \leq 6$ (Corollary 7). In particular, the latter gives a partial solution to a conjecture of de Klerk and Pasechnik [4, Conjecture 5.1].

Our results reveal some sharp differences between the two approximation schemes $\zeta^{(r)}(G)$ and $\nu^{(r)}(G)$. For instance, $\zeta^{(r)}(G) \downarrow \alpha(G)$, but $\zeta^{(r)}(G) > \alpha(G)$ for all r whenever $\alpha(G) > 1$ (Corollary 2). Furthermore, as it was previously established by de Klerk and Pasechnik, $\zeta^{(r)}(G) = \infty$ for $r < \alpha(G) - 1$ (Corollary 3). By contrast, $\nu^{(r)}(G) \leq \chi(\overline{G}) \leq n$ for all r (Proposition 14), where $\chi(\overline{G})$ denotes the chromatic number of the complement of G.

It is interesting to note that our results guarantee the convergence of $\zeta^{(r)}(G)$ and $\nu^{(r)}(G)$ to $\alpha(G)$ *without* relying on the convergence of $\mathcal{Q}_n^r$ and $\mathcal{C}_n^r$ to the copositive cone $\mathcal{C}_n$ (Corollary 2).

The paper is organized as follows. In section 2 we introduce the basic terminology and notation. In section 3 we present the closed-form expression for $\zeta^{(r)}(\cdot)$ and discuss some of its consequences. In section 4 we discuss the successive approximations $\nu^{(r)}(\cdot)$. Finally in section 5 we specialize some of our results to three special classes of graphs, namely, the graphs whose stability number coincides with the chromatic number of their complement, the cycles, and the complements of cycles.

During the completion of this paper, we learned about the related independent work by Gvozdenović and Laurent [6]. Gvozdenović and Laurent studied some properties of the approximations $\vartheta^{(r)}(G)$. In particular, they establish a connection with the approximations obtained by applying Lasserre's lift-and-project procedure [9, 10] and also give a partial solution to [4, Conjecture 5.1] that is slightly stronger than ours.

2. Preliminaries. Throughout the paper $G = (V, E)$ will denote a loopless undirected graph with vertex set $V = \{1, \ldots, n\}$. A subset $S \subseteq V$ is *stable* if $\{i, j\} \notin E$ for all $i, j \in S$. The *stability number* $\alpha(G)$ is the cardinality of a stable set of maximum size in G.

Let $\mathbb{S}^n$ denote the space of symmetric $n \times n$ matrices. The *positive semidefinite cone* $\mathbb{S}_+^n \subseteq \mathbb{S}^n$ is

$$\mathbb{S}_+^n := \{X \in \mathbb{S}^n : u^{\mathrm{T}} X u \geq 0 \text{ for all } u \in \mathbb{R}^n\}.$$

Following the usual convention in the semidefinite programming literature, we will write $X \succeq 0$ as shorthand for $X \in \mathbb{S}^n_+$. In addition, we will write $X \geq 0$ to indicate that every entry of X is nonnegative.

The *copositive cone* $\mathcal{C}_n \subseteq \mathbb{S}^n$ is

$$\mathcal{C}_n := \{X \in \mathbb{S}^n : u^{\mathrm{T}} X u \geq 0 \ \text{ for all } \ u \in \mathbb{R}^n_+\}.$$

Throughout the paper $A(G) \in \mathbb{S}^n$ will denote the *adjacency* matrix of the graph G; i.e., the (i,j) entry of $A(G)$ is 1 if $\{i,j\} \in E$ and it is 0 otherwise. Also, e will denote the vector of all ones, and I will denote the identity matrix, whose dimensions will be clear from the context.

Our work relies on the following inequality, which can be easily verified:

$$\alpha(G) \leq \inf\{\lambda : \lambda(I + A(G)) - ee^{\mathrm{T}} \in \mathcal{C}_n\}. \tag{1}$$

De Klerk and Pasechnik showed that indeed the following stronger identity holds [4, Corollary 2.4]:

$$\alpha(G) = \min\{\lambda : \lambda(I + A(G)) - ee^{\mathrm{T}} \in \mathcal{C}_n\}. \tag{2}$$

It is easy to see that $\{P + N : P, N \in \mathbb{S}^n,\ P \succeq 0,\ N \geq 0\} \subseteq \mathcal{C}_n$. Furthermore, it is known [5] that this inclusion is strict for $n \geq 5$. There is not a simple description of the copositive cone, and in fact the problem of deciding if a matrix is copositive is known to be NP-hard [13]. A way of addressing this difficulty was proposed by Parrilo [14]. For a given symmetric matrix $M \in \mathbb{S}^n$, consider the four degree form (homogeneous polynomial)

$$P_M(x) := \sum_{i=1}^{n} \sum_{j=1}^{n} M_{ij} x_i^2 x_j^2.$$

Observe that M is copositive if and only if $P_M(x) \geq 0$ for all $x \in \mathbb{R}^n$.

Parrilo proposed the following *sum-of-squares* (sos) approximation scheme for the copositive cone: Define the cone $\mathcal{K}^r_n \subseteq \mathcal{C}_n$ as

$$\mathcal{K}^r_n := \left\{ M \in \mathbb{S}^n : \left(\sum_{i=1}^{n} x_i^2 \right)^r P_M(x) \text{ is a sos} \right\}. \tag{3}$$

It is easy to see that the sos condition can be recast in terms of linear matrix inequalities (LMI). Therefore, membership in each $\mathcal{K}^r_n$ can be phrased in terms of LMI. In particular, Parrilo showed that $M \in \mathcal{K}^0_n$ if and only if $M = P + N$ for $P \succeq 0$, $N \geq 0$. Parrilo also showed that $M \in \mathcal{K}^1_n$ if the following system of LMI has a solution:

$$\begin{aligned} M - \Lambda^i &\succeq 0, && i = 1, \ldots, n, \\ \Lambda^i_{ii} &= 0, && i = 1, \ldots, n, \\ \Lambda^i_{jj} + \Lambda^j_{ji} + \Lambda^j_{ij} &= 0, && i \neq j, \\ \Lambda^i_{jk} + \Lambda^j_{ik} + \Lambda^k_{ij} &\geq 0, && i, j, k \ \text{ all different.} \end{aligned} \tag{4}$$

Bomze and de Klerk [3] showed that indeed $M \in \mathcal{K}^1_n$ if and only if (4) has a solution.

De Klerk and Pasechnik define

$$\vartheta^{(r)}(G) := \min\{\lambda : \lambda(I + A(G)) - ee^{\mathrm{T}} \in \mathcal{K}^r_n\}.$$

Since each $\mathcal{K}_n^r$ can be defined in terms of LMI, the approximation $\vartheta^{(r)}(G)$ can be computed via semidefinite programming.

De Klerk and Pasechnik also define the cone $\mathcal{C}_n^r \subseteq \mathcal{C}_n$ as

$$\mathcal{C}_n^r := \left\{ P \in \mathbb{S}^n : \left(\sum_{i=1}^n x_i\right)^r x^{\mathrm{T}} P x \text{ has nonnegative coefficients} \right\},$$

and

$$\zeta^{(r)}(G) := \min\{\lambda : \lambda(I + A(G)) - ee^{\mathrm{T}} \in \mathcal{C}_n^r\}.$$

It is easy to see that $\mathcal{C}_n^r \subseteq \mathcal{K}_n^r \subseteq \mathcal{C}_n$ so $\alpha(G) \leq \vartheta^{(r)}(G) \leq \zeta^{(r)}(G)$. Furthermore, since each $\mathcal{C}_n^r$ is polyhedral, the approximation $\zeta^{(r)}(G)$ can be computed via linear programming. De Klerk and Pasechnik [4] established the following interesting properties of $\vartheta^{(r)}(\cdot)$ and $\zeta^{(r)}(\cdot)$: The function $\vartheta^{(0)}(\cdot)$ coincides with Schrijver's ϑ'-function, and $\vartheta^{(1)}(\cdot) = \alpha(\cdot)$ for odd cycles and complements of triangle-free graphs. They also proved that $\lfloor \zeta^{(r)}(G) \rfloor = \alpha(G)$ for $r \geq \alpha(G)^2$ and $\zeta^{(r)}(G) < \infty$ only if $r \geq \alpha(G) - 1$.

3. Linear programming approximations. From the above definition of the linear approximation $\zeta^{(r)}(G)$, the fact that $\mathcal{C}_n^0 \subseteq \mathcal{C}_n^1 \subseteq \cdots \subseteq \mathcal{C}_n$, and (1), it follows that

$$\zeta^{(0)}(G) \geq \zeta^{(1)}(G) \geq \cdots \geq \alpha(G).$$

Theorem 1 below gives a closed-form expression for $\zeta^{(r)}(G)$ in terms of r and $\alpha(G)$.

Throughout this section, the binomial coefficient $\binom{a}{2}$ is to be understood as $\frac{a(a-1)}{2}$ for any nonnegative integer a. In particular, $\binom{a}{2} = 0$ for $a = 0$ and $a = 1$. Also, by convention $a/0 = +\infty$ for $a > 0$.

THEOREM 1. *Assume $r + 2 = u\alpha(G) + v$, where u, v are nonnegative integers with $v < \alpha(G)$. Then*

$$\zeta^{(r)}(G) = \frac{\binom{r+2}{2}}{\binom{u}{2}\alpha(G) + vu}.$$

COROLLARY 2. *$\zeta^{(r)}(G) \downarrow \alpha(G)$. Furthermore, if $\alpha(G) > 1$, then $\zeta^{(r)}(G) > \alpha(G)$ for all nonnegative integers r.*

Proof. To simplify notation write α as a shorthand for $\alpha(G)$. Let u, v be nonnegative integers such that $r + 2 = u\alpha + v$ and $v < \alpha$. Then for $\epsilon \geq 0$

$$(\alpha + \epsilon)\left(\binom{u}{2}\alpha + vu\right) - \binom{r+2}{2} = \frac{u\alpha(1 + \epsilon u - \epsilon - \alpha) + v(2\epsilon u - v + 1)}{2}. \tag{5}$$

Let $\epsilon > 0$ be given. Then from (5) it follows that for r sufficiently large

$$(\alpha + \epsilon)\left(\binom{u}{2}\alpha + vu\right) > \binom{r+2}{2}.$$

Thus Theorem 1 yields $\limsup_{r\to\infty} \zeta^{(r)}(G) \leq \alpha(G)$. Since $\zeta^{(r)}(G) \geq \alpha(G)$ for all r, then indeed $\lim_{r\to\infty} \zeta^{(r)}(G) = \alpha(G)$.

For the second part, just observe that for $\epsilon = 0$ and $\alpha > 1$ the right-hand side of (5) is negative. Thus again Theorem 1 yields $\zeta^{(r)}(G) > \alpha(G)$ whenever $\alpha(G) > 1$. ∎

From Theorem 1, we can also recover two key properties of $\zeta^{(r)}(G)$ due to de Klerk and Pasechnik [4]. The following two corollaries are slight refinements of [4, Theorem 4.2] and [4, Theorem 4.1], respectively.

COROLLARY 3. *$\zeta^{(r)}(G) < \infty$ if and only if $r \geq \alpha(G) - 1$.*

Proof. By Theorem 1, $\zeta^{(r)}(G) = \infty$ if and only if $\binom{u}{2}\alpha(G) + vu = 0$. The latter occurs if and only if $u = 0$ or $u = 1$ and $v = 0$, i.e., if and only if $r + 2 \leq \alpha(G)$. ∎

COROLLARY 4. *$\lfloor \zeta^{(r)}(G) \rfloor = \alpha(G)$ if and only if $r \geq \alpha(G)^2 - 1$.*

Proof. To simplify notation write α as a shorthand for $\alpha(G)$. Since $\zeta^{(r)}(G) \geq \alpha$, it follows that $\lfloor \zeta^{(r)}(G) \rfloor = \alpha$ if and only if $\zeta^{(r)}(G) < \alpha + 1$. Since $\zeta^{(r)}(G)$ is nonincreasing in r, it suffices to show that

$$\zeta^{(\alpha^2-2)}(G) = \alpha + 1 \quad \text{and} \quad \zeta^{(\alpha^2-1)}(G) < \alpha + 1.$$

But this readily follows from Theorem 1. ∎

The proof of Theorem 1 relies on Lemma 5, which gives a bound on the number of edges of any induced subgraph of $G = (V, E)$. Given a graph G and $S \subseteq V$, let $E_G[S]$ be the set of edges of G with both endpoints in S.

LEMMA 5. *Let $G = (V, E)$ be a graph, and assume $S \subseteq V$. Let u, v be nonnegative integers such that $|S| = u\alpha(G) + v$ and $v < \alpha(G)$. Then $|E_G[S]| \geq \binom{u}{2}\alpha(G) + vu$.*

Proof. Proceed by induction on u. The result is trivial for $u = 0$. Thus assume $|S| \geq \alpha(G)$. Let I be a maximal stable subset of S, and let $S_1 = S \setminus I$. Since I is stable, $|I| \leq \alpha(G)$ and $|S_1| \geq |S| - \alpha(G) = (u-1)\alpha(G) + v$. Furthermore, since I is maximal in S, every vertex in S_1 is connected to some vertex in I. Therefore there are at least $|S_1|$ edges between S_1 and I. Then

$$|E_G[S]| \geq |S_1| + |E_G[S_1]| \geq |S| - \alpha(G) + |E_G[S_1]|.$$

But by induction hypothesis $|E_G[S_1]| \geq \binom{u-1}{2}\alpha(G) + v(u-1)$. Therefore

$$|E_G[S]| \geq |S| - \alpha(G) + \binom{u-1}{2}\alpha(G) + v(u-1) = \binom{u}{2}\alpha(G) + vu. \qquad \blacksquare$$

In the proof below we use the following convenient notation: For a positive integer d, we write $[d]$ as shorthand for the set $\{1, \ldots, d\}$. Also, K_r denotes the complete graph with r vertices.

Proof of Theorem 1. Let $B := I + A(G)$. For any $1 \leq i < j \leq r + 2$ we have

$$\left(\sum_{k=1}^{n} x_k\right)^r x^{\mathrm{T}}(\lambda B - ee^{\mathrm{T}})x = \sum_{s \in [n]^{r+2}} (\lambda B_{s_i,s_j} - 1)x_{s_1} \ldots x_{s_{r+2}}.$$

Thus, adding over all possible pairs (i, j) with $1 \leq i < j \leq r + 2$, we get

$$\begin{aligned}\left(\sum_{k=1}^{n} x_k\right)^r x^{\mathrm{T}}(\lambda B - ee^{\mathrm{T}})x &= \sum_{s \in [n]^{r+2}} \left(\frac{\lambda}{\binom{r+2}{2}} \sum_{1 \leq i < j \leq r+2} B_{s_i,s_j} - 1\right) x_{s_1} \ldots x_{s_{r+2}} \\ &= \sum_{1 \leq s_1 \leq \cdots \leq s_{r+2} \leq n} perm(s) \left(\frac{\lambda}{\binom{r+2}{2}} \sum_{1 \leq i < j \leq r+2} B_{s_i,s_j} - 1\right) x_{s_1} \ldots x_{s_{r+2}},\end{aligned}$$

where $perm(s)$ is the number of different permutations of $s = (s_1, \ldots, s_{r+2})$.

Therefore

$$\zeta^{(r)}(G) \leq \lambda \Leftrightarrow \lambda \sum_{1\leq i<j\leq r+2} B_{s_i,s_j} \geq \binom{r+2}{2} \text{ for all } s \in [n]^{r+2}. \tag{6}$$

Fix $s \in [n]^{r+2}$. Let $H = K_{r+2} \times G$, i.e., the strong product of the graphs K_{r+2} and G. Let $S = \{(i, s_i) : i = 1, \ldots, r+2\} \subseteq V(H)$. Notice that

$$B_{s_i,s_j} = 1 \Leftrightarrow \{s_i, s_j\} \in E(G) \text{ or } s_i = s_j \Leftrightarrow \{(i, s_i), (j, s_j)\} \in E(H).$$

Hence $\sum_{1\leq i<j\leq r+2} B_{s_i,s_j} = |E_H[S]|$. Since $\alpha(H) = \alpha(G)$, Lemma 5 yields

$$\sum_{1\leq i<j\leq r+2} B_{s_i,s_j} \geq \binom{u}{2}\alpha(G) + vu.$$

This can be done for each $s \in [n]^{r+2}$. Hence it follows from (6) that

$$\zeta^{(r)}(G) \leq \frac{\binom{r+2}{2}}{\binom{u}{2}\alpha(G) + vu}.$$

On the other hand, assume $\{v_1, \ldots, v_{\alpha(G)}\}$ is a maximal stable set in G. Define $s \in [n]^{r+2}$ by putting $s_{k\alpha(G)+l} = v_l$ for $k = 0, 1, \ldots, u-1$ and $l = 1, \ldots, \alpha(G)$ and for $k = u$ and $l = 1, \ldots, v$. Then

$$B_{s_i,s_j} = 1 \Leftrightarrow i \equiv j \mod (\alpha(G)),$$

and consequently

$$\sum_{1\leq i<j\leq r+2} B_{s_i,s_j} = \binom{u+1}{2}v + \binom{u}{2}(\alpha(G) - v) = \binom{u}{2}\alpha(G) + vu.$$

Therefore, again from (6) it follows that $\zeta^{(r)}(G) \geq \binom{r+2}{2}/\left(\binom{u}{2}\alpha(G) + vu\right)$. ∎

4. Semidefinite programming approximations. Define the sequences of cones $\mathcal{E}_n^r \subseteq \mathbb{R}[x_1, \ldots, x_n]$, $\mathcal{Q}_n^r \subseteq \mathbb{S}^n$, $r = 0, 1, \ldots$, as follows. For $r = 0, 1, \ldots$ let

$$\mathcal{E}_n^r := \left\{ \sum_{\beta\in\mathbb{N}^n,\, |\beta|=r} x^\beta x^{\mathrm{T}}(P_\beta + N_\beta)x : P_\beta, N_\beta \in \mathbb{S}^n,\, P_\beta \succeq 0,\, N_\beta \geq 0 \right\}, \tag{7}$$

where for a given $\beta \in \mathbb{N}^n$, $|\beta| := \beta_1 + \cdots + \beta_n$ and $x^\beta := x_1^{\beta_1} \ldots x_n^{\beta_n}$. Also let

$$\mathcal{Q}_n^r := \left\{ B \in \mathbb{S}^n : \left(\sum_{i=1}^n x_i\right)^r x^{\mathrm{T}} B x \in \mathcal{E}_n^r \right\}. \tag{8}$$

Notice that $\mathcal{E}_n^r$ contains all homogeneous polynomials of degree $r+2$ with nonnegative coefficients. Therefore, by (8), we have $\mathcal{C}_n^r \subseteq \mathcal{Q}_n^r$, $r = 0, 1, 2, \ldots$.

4.1. LMI description of $\mathcal{Q}_n^r$. From (7) and (8) it follows that membership in $\mathcal{Q}_n^r$ can be written in terms of an LMI in the matrix variables $P_\beta, N_\beta \in \mathbb{S}^n$, $P_\beta \succeq 0$, $N_\beta \geq 0$. This involves $2\binom{n+r-1}{r} = 2|\{\beta \in \mathbb{N}^n,\ |\beta| = r\}|$ matrices of size $n \times n$. More precisely, $M \in \mathcal{Q}_n^r$ if and only if there exist $P_\beta, N_\beta \in \mathbb{S}^n$, $P_\beta \succeq 0$, $N_\beta \geq 0$ such that

$$\sum_{\beta \in \mathbb{N}^n,\, |\beta| = r} x^\beta x^{\mathrm{T}} M x = \sum_{\beta \in \mathbb{N}^n,\, |\beta| = r} x^\beta x^{\mathrm{T}} (P_\beta + N_\beta) x. \tag{9}$$

Notice that the equality in (9) is equivalent to the equality of the coefficients of the two polynomials appearing in each side of the expression. Since each coefficient is a linear combination of the entries of the involved matrices, the equality in (9) is a linear system of equations in the entries of matrix M and the matrices P_β, N_β.

Notice that (9) can be written as

$$\sum_{\beta \in \mathbb{N}^n,\, |\beta| = r} x^\beta x^{\mathrm{T}} M x \preceq \sum_{\beta \in \mathbb{N}^n,\, |\beta| = r} x^\beta x^{\mathrm{T}} P_\beta x \tag{10}$$

involving only the $\binom{n+r-1}{r}$ matrix variables $P_\beta \in \mathbb{S}_+^n$. Here we use the sign "$\preceq$" to indicate that the vector of coefficients of the polynomial in the left-hand side is componentwise less than or equal to the vector of coefficients of the polynomial in the right-hand side. Furthermore, by grouping identical monomials, (10) can be written in the following slightly more concise form involving fewer matrix variables $P_\beta \in \mathbb{S}_+^n$:

$$\sum_{\beta \in \mathbb{N}^n,\, |\beta| = r} x^\beta x^{\mathrm{T}} M x \preceq \sum_{\substack{\beta \in \mathbb{N}^n,\, |\beta| = r \\ \beta_1 \leq \beta_2 \leq \cdots \leq \beta_r}} x^\beta x^{\mathrm{T}} P_\beta x. \tag{11}$$

The condition (11) is a linear system of inequalities in the entries of M and P_β. It states that the vector of coefficients in the left-hand side, which is a linear combination of entries of M, should be componentwise less than or equal to the vector of coefficients in the right-hand side, which is a linear combination of the entries of the matrices P_β.

It is insightful to compare the cones $\mathcal{Q}_n^r$ and $\mathcal{K}_n^r$. To that end, we note that by [17, Proposition 9] a homogeneous polynomial $p(x)$ of degree $r+2$ satisfies the condition

$$p(x_1^2, \ldots, x_n^2) \text{ is a sos}$$

if and only if

$$p(x) \in \mathcal{F}_n^r := \left\{ \sum_{\beta \in \mathbb{N}^n, |\beta| \leq r+2} x^\beta q_\beta(x) : q_\beta(x) \text{ is a sos} \right\}. \tag{12}$$

Hence the set $\mathcal{K}_n^r$ defined by (3) can also be described as

$$\mathcal{K}_n^r = \left\{ B \in \mathbb{S}^n : \left(\sum_{i=1}^n x_i \right)^r x^{\mathrm{T}} B x \in \mathcal{F}_n^r \right\}. \tag{13}$$

From (7) and (12) it follows that $\mathcal{E}_n^0 = \mathcal{F}_n^0$, $\mathcal{E}_n^1 = \mathcal{F}_n^1$, and $\mathcal{E}_n^r \subseteq \mathcal{F}_n^r$, $r = 2, \ldots$. Therefore from (8) and (13) we get $\mathcal{Q}_n^0 = \mathcal{K}_n^0$, $\mathcal{Q}_n^1 = \mathcal{K}_r^1$, and $\mathcal{Q}_n^r \subseteq \mathcal{K}_n^r$, $r = 2, \ldots$. In

addition, via a standard limiting argument it follows that each cone $\mathcal{Q}_n^r$ is closed. It should be noted that the identities $\mathcal{E}_n^0 = \mathcal{F}_n^0$, $\mathcal{E}_n^1 = \mathcal{F}_n^1$ were first derived (in a slightly different form) by Parrilo [14].

As it is now well documented (see, e.g., [9, 14, 17]), the sos condition can be written as an LMI. Specifically, by letting $x^{[d]}$ denote the vector of monomials of degree d, it follows that a $2d$-degree homogeneous polynomial $q(x)$ is sos if and only if there exists $P \in \mathbb{S}_+^{\binom{n+d-1}{d}}$ such that

$$q(x) = (x^{[d]})^{\mathrm{T}} P x^{[d]}.$$

It thus follows that membership in $\mathcal{K}_n^r$ can be written as an LMI. More precisely, from (12) it follows that $M \in \mathcal{K}_n^r$ if and only if for $k = 0, 1, \ldots, \lfloor \frac{r+2}{2} \rfloor$ there exist $P_{k,\beta} \in \mathbb{S}_+^{\binom{n+k-1}{k}}$ such that

$$\sum_{\beta \in \mathbb{N}^n,\, |\beta| = r} x^\beta x^{\mathrm{T}} M x = \sum_{k=0}^{\lfloor \frac{r+2}{2} \rfloor} \sum_{\beta \in \mathbb{N}^n,\, |\beta| = r+2-2k} x^\beta (x^{[k]})^{\mathrm{T}} P_{k,\beta} x^{[k]}. \tag{14}$$

Again by grouping identical monomials, (14) can be written in the following slightly more concise form:

$$\sum_{\beta \in \mathbb{N}^n,\, |\beta| = r} x^\beta x^{\mathrm{T}} M x \preceq \sum_{k=1}^{\lfloor \frac{r+2}{2} \rfloor} \sum_{\substack{\beta \in \mathbb{N}^n,\, |\beta| = r+2-2k \\ \beta_1 \le \beta_2 \le \cdots \le \beta_{r+2-2k}}} x^\beta (x^{[k]})^{\mathrm{T}} P_{k,\beta} x^{[k]}. \tag{15}$$

For $r \geq 2$ the LMI description (11) involves a substantially lower number of matrix variables than (15). To illustrate the difference, consider the case $r = 4$. We have $M \in \mathcal{Q}_n^4$ if and only if there exist $P_{ijk\ell} \in \mathbb{S}_+^n$ such that

$$\left(\sum_{i=1}^n x_i \right)^4 x^{\mathrm{T}} M x \preceq \sum_{1 \le i \le j \le k \le \ell \le n} x_i x_j x_k x_\ell \, x^{\mathrm{T}} P_{ijk\ell} x.$$

On the other hand, $M \in \mathcal{K}_n^4$ if and only if there exist $P_{ijk\ell} \in \mathbb{S}_+^n$, $P_{ij} \in \mathbb{S}_+^{\binom{n+1}{2}}$, and $P \in \mathbb{S}_+^{\binom{n+2}{3}}$ such that

$$\left(\sum_{i=1}^n x_i \right)^4 x^{\mathrm{T}} M x \preceq \sum_{1 \le i \le j \le k \le \ell \le n} x_i x_j x_k x_\ell \, x^{\mathrm{T}} P_{ijk\ell} x + \sum_{1 \le i \le j \le n} x_i x_j (x^{[2]})^{\mathrm{T}} P_{ij} x^{[2]} + (x^{[3]})^{\mathrm{T}} P x^{[3]}.$$

4.2. New semidefinite programming approximations to $\alpha(G)$. In analogy to $\zeta^{(r)}(G)$ and $\vartheta^{(r)}(G)$ we define

$$\nu^{(r)}(G) := \min\{\lambda : \lambda(I + A(G)) - ee^{\mathrm{T}} \in \mathcal{Q}_n^r\}. \tag{16}$$

We note that the above minimum is indeed always attained. This follows by applying the same conic duality argument used in [4, section 4]: Both (16) and its dual

are strictly feasible. Notice also that as $\vartheta^{(r)}(G)$, the approximation $\nu^{(r)}(G)$ can be computed via semidefinite programming. The semidefinite program that computes $\nu^{(r)}(G)$ involves only $n \times n$ matrices because the LMI description (11) of $\mathcal{Q}_n^r$ uses $n \times n$ matrices only. By contrast, the LMI description (15) of $\mathcal{K}_n^r$ uses the same number of $n \times n$ matrices in addition to some matrices of size $\binom{n+1}{2} \times \binom{n+1}{2}$, some matrices of size $\binom{n+2}{3} \times \binom{n+2}{3}$, and so on. Henceforth, the semidefinite program that computes $\nu^{(r)}(G)$ is simpler than the one that computes $\vartheta^{(r)}(G)$. Some `matlab` code that constructs the relevant semidefinite programs for $\nu^{(r)}(G)$ and $\vartheta^{(r)}(G)$ in `SeDuMi` format [16] is available at http://www.andrew.cmu.edu/user/jfp/alpha.html. We have used this code for the numerical experiments discussed in section 5.

Observe that $\nu^{(r)}(G) \geq \vartheta^{(r)}(G)$ because $\mathcal{Q}_n^r \subseteq \mathcal{K}_n^r$. Furthermore, the examples in section 5 show that for $r \geq 2$ there are graphs G such that $\nu^{(r)}(G) > \vartheta^{(r)}(G)$.

Since $\mathcal{Q}_n^0 \subseteq \mathcal{Q}_n^1 \subseteq \cdots \subseteq \mathcal{C}_n$ and $\mathcal{C}_n^r \subseteq \mathcal{Q}_n^r$, Corollary 2 implies that

$$\nu^{(r)}(G) \downarrow \alpha(G).$$

Corollary 7 below shows that indeed $\nu^{(r)}(G) = \alpha(G)$ for $r \geq \alpha(G) - 1$ as long as $\alpha(G) \leq 6$.

Given $v \in \{1, \ldots, n\}$ let $v^\perp$ be the union of the neighborhood of v with itself, i.e., $v^\perp := \{j : \{v, j\} \in E\} \cup \{v\}$. Given a set $S \subseteq V$ let $S^\perp := \bigcup_{v \in S} v^\perp$. Let $G \setminus S^\perp$ denote the induced subgraph of G with vertex set $V \setminus S^\perp$, i.e., the graph with vertex set $V \setminus S^\perp$ and edge set $\{\{i, j\} \in E : i, j \in V \setminus S^\perp\}$.

Observe that $\alpha(G)$ satisfies the following relationship as long as $\alpha(G) > r$:

$$\alpha(G) = r + \max_{S \subseteq V \text{ stable}, |S| = r} \alpha(G \setminus S^\perp).$$

The approximations $\nu^{(r)}(\cdot)$ in turn satisfy the related inequality in Theorem 6 below. We note that Theorem 6 generalizes [4, Theorem 5.3].

THEOREM 6. *For $r = 1, 2, 3$ and $\alpha(G) > r$,*

$$\nu^{(r)}(G) \leq r + \max_{S \subseteq V \text{ stable}, |S| = r} \nu^{(0)}(G \setminus S^\perp).$$

Furthermore, the above inequality also holds for $r = 4, 5$ if $\alpha(G) \leq 6$.

COROLLARY 7. *If $r \geq \alpha(G) - 1$ and $\alpha(G) \leq 6$, then $\nu^{(r)}(G) = \alpha(G)$.*

Proof. Since $\nu^{(r)}(G) \downarrow \alpha(G)$ it suffices to show that $\nu^{(\alpha(G)-1)}(G) \leq \alpha(G)$ as long as $\alpha(G) \leq 6$. By Theorem 6 applied to $r = \alpha(G) - 1$ we have

$$\nu^{(\alpha(G)-1)}(G) \leq \alpha(G) - 1 + \max_{S \subseteq V \text{ stable}, |S| = \alpha(G)-1} \nu^{(0)}(G \setminus S^\perp). \tag{17}$$

Notice that $\nu^{(0)}(K) = 1 = \alpha(K)$ for every complete graph K. Notice also that, for each stable set $S \subseteq V$ with $|S| = \alpha(G) - 1$, the subgraph $G \setminus S^\perp$ is a complete graph, and thus $\nu^{(0)}(G \setminus S^\perp) = 1$. Therefore (17) yields

$$\nu^{(\alpha(G)-1)}(G) \leq \alpha(G) - 1 + 1 = \alpha(G). \qquad \square$$

Since $\mathcal{Q}_n^r \subseteq \mathcal{K}_n^r \subseteq \mathcal{C}_n$, we have $\alpha(G) \leq \vartheta^{(r)}(G) \leq \nu^{(r)}(G)$. Thus Corollary 7 yields $\vartheta^{(\alpha(G)-1)}(G) = \alpha(G)$ for $\alpha(G) \leq 6$. This gives a partial solution to [4, Conjecture 5.1].

The proof technique of Theorem 6 also yields the following interesting result.

THEOREM 8. *Let $u \in V$ be such that $u^\perp$ induces a clique in G. Then for $r = 1, 2, 3$ and $\alpha(G) > r$,*

$$\nu^{(r-1)}(G) \leq r + \max_{S \subseteq V \text{ stable}, |S|=r,\, u \in S} \nu^{(0)}(G \setminus S^\perp).$$

Furthermore, the above inequality also holds for $r = 4, 5$ if $\alpha(G) \leq 6$.

Theorems 6 and 8 follow from Lemmas 10 and 11 below, which are interesting on their own. Before stating these lemmas, we introduce some convenient notation: We will write B as shorthand for $I + A(G)$. For $S \subseteq V$ we will write $S^{\complement}$ to denote $V \setminus S^\perp$ and $B_{S^{\complement}}$ to denote $I + A(G \setminus S^\perp)$. Observe that $B_{S^{\complement}}$ is precisely the submatrix of B obtained by deleting the rows and columns indexed by $S^\perp$. For a given vector of variables $x = (x_1, \ldots, x_n)$ we will write Σ_S as shorthand for $\sum_{i \in S} x_i$ and x_S to denote the vector of variables indexed by the elements of S. Finally, given two homogeneous polynomials $p(x), q(x)$ of degree $2 + r$, we write $p(x) \sqsupseteq q(x)$ to indicate that $p(x) - q(x) \in \mathcal{E}_n^r$.

In what follows we use the recursive characterization of $\mathcal{E}_n^r$ given in Proposition 9.

PROPOSITION 9. *For all $r > 0$,*

$$\mathcal{E}_n^r = \left\{ \sum_{i=1}^n x_i p_i(x) : p_i(x) \in \mathcal{E}_n^{r-1},\ i = 1, \ldots, n \right\}.$$

Proof. The inclusion "$\supseteq$" is immediate. The inclusion "$\subseteq$" follows by induction on r using the following identity:

$$\begin{aligned}
\sum_{\beta \in \mathbb{N}^n,\, |\beta|=r} x^\beta x^{\mathrm{T}} B_\beta\, x &= \sum_{\beta \in \mathbb{N}^n,\, |\beta|=r} \frac{1}{r} \sum_{i=1}^n \beta_i x^\beta x^{\mathrm{T}} B_\beta\, x \\
&= \sum_{\beta \in \mathbb{N}^n,\, |\beta|=r} \frac{1}{r} \sum_{i=1}^n \beta_i x_i x^{\beta - e_i} x^{\mathrm{T}} B_\beta\, x \\
&= \frac{1}{r} \sum_{i=1}^n x_i \sum_{\beta \in \mathbb{N}^n,\, |\beta|=r} \beta_i x^{\beta - e_i} x^{\mathrm{T}} B_\beta\, x \\
&= \frac{1}{r} \sum_{i=1}^n x_i \sum_{\beta \in \mathbb{N}^n,\, |\beta|=r,\, \beta_i \geq 1} \beta_i x^{\beta - e_i} x^{\mathrm{T}} B_\beta\, x \\
&= \frac{1}{r} \sum_{i=1}^n x_i \sum_{\gamma \in \mathbb{N}^n,\, |\gamma|=r-1} (\gamma_i + 1) x^\gamma x^{\mathrm{T}} B_{\gamma + e_i}\, x,
\end{aligned}$$

where $e_i \in \mathbb{N}^n$ denotes the vector with 1 in the ith coordinate and 0 in all the other coordinates. ∎

LEMMA 10. *For $\lambda > 1$*

$$\sum_{v \in V} x_v x^{\mathrm{T}} (\lambda B - e e^{\mathrm{T}}) x \sqsupseteq \sum_{v \in V} x_v P_v(x),$$

where

$$P_v(x) = \frac{1}{\lambda - 1} \left((\lambda - 1)\Sigma_{v^\perp} - \Sigma_{v^{\complement}} \right)^2 + \frac{\lambda}{\lambda - 1} x_{v^{\complement}}^{\mathrm{T}} \left((\lambda - 1) B_{v^{\complement}} - e e^{\mathrm{T}} \right) x_{v^{\complement}}.$$

Lemma 11 below can be seen as an extension of Lemma 10. First we introduce one more piece of notation. Assume $\lambda > k$ and $v_1, \dots, v_k \in V$ are such that $v_{j+1} \in \{v_1, \dots, v_j\}^{\underline{c}}$ for $j = 1, \dots, k-1$. Put $\vec{v} := \{v_1, \dots, v_k\}$, and define

$$p_{\vec{v}}(x) = \frac{\lambda^{k-2}}{2(\lambda-1)(\lambda-2)\cdots(\lambda-k)}\Big((\lambda-k+1)\left((\lambda-k)\Sigma_{\vec{v}^\perp} - k\Sigma_{\vec{v}^{\underline{c}}}\right)^2 + 2\lambda^2 x_{\vec{v}^{\underline{c}}}^{\mathrm{T}}\left((\lambda-k)B_{\vec{v}^{\underline{c}}} - ee^{\mathrm{T}}\right)x_{\vec{v}^{\underline{c}}}\Big).$$

In the statement of Lemma 11 below we also use the following convenient notation: Given $\vec{v} = \{v_1, \dots, v_k\}$ as above and $w \in \vec{v}^{\underline{c}}$ we write $\vec{v}, w$ to denote the set $\{v_1, \dots, v_k, w\}$.

LEMMA 11. *Assume $\lambda > k+1$ and $v_1, \dots, v_k \in V$ are such that $v_{j+1} \in \{v_1, \dots, v_j\}^{\underline{c}}$ for $j = 1, \dots, k-1$ and $\{v_1, \dots, v_k\}^{\underline{c}} \neq \emptyset$. If $k = 1, 2$ or if $k = 3, 4$ and $\lambda \leq 6$, then*

$$\Sigma_V p_{\vec{v}}(x) \sqsupseteq \sum_{w \in \vec{v}^{\underline{c}}} x_w p_{\vec{v},w}(x).$$

Proof of Theorem 6. Put

$$t = \max_{S \subseteq V \text{ stable}, |S| = r} \nu^{(0)}(G \setminus S^\perp).$$

Then for any stable set $\vec{v} := \{v_1, \dots, v_r\}$ of size r we have $\nu^{(0)}(G \setminus \vec{v}^\perp) \leq t$, i.e., $x_{\vec{v}^{\underline{c}}}^{\mathrm{T}}(tB_{\vec{v}^{\underline{c}}} - ee^{\mathrm{T}})x_{\vec{v}^{\underline{c}}} \in \mathcal{E}_n^0$. Therefore, for $\lambda := t + r$ we have $p_{\vec{v}}(x) \in \mathcal{E}_n^0$. In addition, observe that for each $v \in V$ the polynomial $P_v(x)$ defined in Lemma 10 satisfies

$$P_v(x) = p_v(x) + \frac{1}{2(\lambda-1)}\left((\lambda-1)\Sigma_{v^\perp} - \Sigma_{v^{\underline{c}}}\right)^2 \sqsupseteq p_v(x).$$

Hence from Lemmas 10 and 11 it follows that

$$\left(\sum_{v \in V} x_v\right)^r x^{\mathrm{T}}(\lambda B - ee^{\mathrm{T}})x \sqsupseteq \sum_{v_1 \in V} x_{v_1} \sum_{v_2 \in v_1^{\underline{c}}} x_{v_2} \cdots \sum_{v_r \in \{v_1, \dots, v_{r-1}\}^{\underline{c}}} x_{v_r} p_{\vec{v}}(x) \in \mathcal{E}_n^r$$

and so

$$\nu^{(r)}(G) \leq \lambda = r + t = r + \max_{S \subseteq V \text{ stable}, |S| = r} \nu^{(0)}(G \setminus S^\perp). \qquad \square$$

Proof of Theorem 8. If $u \in V$ is such that $u^\perp$ induces a clique in G, then

$$\begin{aligned} x^{\mathrm{T}}(\lambda B - ee^{\mathrm{T}})x &\sqsupseteq \lambda\left(\Sigma_{u^\perp}^2 + x_{u^{\underline{c}}}^{\mathrm{T}} B_{u^{\underline{c}}} x_{u^{\underline{c}}}\right) - \Sigma_V^2 \\ &= \lambda\left(\Sigma_{u^\perp}^2 + x_{u^{\underline{c}}}^{\mathrm{T}} B_{u^{\underline{c}}} x_{u^{\underline{c}}}\right) - \left(\Sigma_{u^\perp} + \Sigma_{u^{\underline{c}}}\right)^2 \\ &= (\lambda-1)\Sigma_{u^\perp}^2 - 2\Sigma_{u^\perp}\Sigma_{u^{\underline{c}}} + \tfrac{1}{\lambda-1}\Sigma_{u^{\underline{c}}}^2 + \lambda x_{u^{\underline{c}}}^{\mathrm{T}} B_{u^{\underline{c}}} x_{u^{\underline{c}}} - \tfrac{\lambda}{\lambda-1}\Sigma_{u^{\underline{c}}}^2 \\ &= P_u(x) \\ &\sqsupseteq p_u(x). \end{aligned}$$

Hence by taking $v_1 := u$, we can modify the last step in the proof of Theorem 6 to

$$\left(\sum_{v \in V} x_v\right)^{r-1} x^{\mathrm{T}}(\lambda B - ee^{\mathrm{T}})x \sqsupseteq \sum_{v_2 \in v_1^{\underline{c}}} x_{v_2} \cdots \sum_{v_r \in \{v_1, \dots, v_{r-1}\}^{\underline{c}}} x_{v_r} p_{\vec{v}}(x) \in \mathcal{E}_n^{r-1},$$

as long as $\lambda := r + t$, where

$$t := \max_{S \subseteq V \text{ stable } |S|=r,\, u \in S} \nu^{(0)}(G \setminus S^{\perp}).$$

Hence we obtain

$$\nu^{(r-1)}(G) \leq \lambda = r + t = r + \max_{S \subseteq V \text{ stable } |S|=r,\, u \in S} \nu^{(0)}(G \setminus S^{\perp}). \qquad \square$$

We conclude this section with the proofs of Lemmas 10 and 11. The proof of Lemma 10 relies on the following lemma.

LEMMA 12.

$$\sum_{v \in V} x_v \Sigma_{v^{\perp}} \Sigma_{v^{\subseteq}} \sqsupseteq \sum_{v \in V} x_v x_{v^{\subseteq}}^{\mathrm{T}} B_{v^{\subseteq}} x_{v^{\subseteq}}.$$

Proof.

$$\begin{aligned}
\sum_{v \in V} x_v \Sigma_{v^{\perp}} \Sigma_{v^{\subseteq}} &= \sum_{v \in V} \sum_{u \in v^{\subseteq}} x_u x_v \Sigma_{v^{\perp}} \\
&= \sum_{u \in V} \sum_{v \in u^{\subseteq}} x_u x_v \Sigma_{v^{\perp}} \\
&\sqsupseteq \sum_{u \in V} x_u \sum_{v \in u^{\subseteq}} x_v \sum_{w \in v^{\perp} \cap u^{\subseteq}} x_w \\
&= \sum_{u \in V} x_u x_{u^{\subseteq}}^{\mathrm{T}} B_{u^{\subseteq}} x_{u^{\subseteq}}. \qquad \square
\end{aligned}$$

The proofs below also rely on the following observation.

Observation 13. $x^{\mathrm{T}}(\lambda B - ee^{\mathrm{T}})x = \sum_{v \in V} x_v((\lambda - 1)\Sigma_{v^{\perp}} - \Sigma_{v^{\subseteq}})$.

Proof of Lemma 10. From Observation 13 and Lemma 12 it follows that

$$\begin{aligned}
\sum_{v \in V} x_v x^{\mathrm{T}} \left(\lambda B - ee^{\mathrm{T}}\right) x &= \sum_{v \in V} x_v((\lambda - 1)\Sigma_{v^{\perp}} - \Sigma_{v^{\subseteq}})\Sigma_V \\
&= \sum_{v \in V} x_v \left(\frac{1}{\lambda - 1} \left((\lambda - 1)\Sigma_{v^{\perp}} - \Sigma_{v^{\subseteq}}\right)^2 + \frac{\lambda}{\lambda - 1} \left((\lambda - 1)\Sigma_{v^{\perp}} - \Sigma_{v^{\subseteq}}\right) \Sigma_{v^{\subseteq}} \right) \\
&\sqsupseteq \sum_{v \in V} x_v \left(\frac{1}{\lambda - 1} \left((\lambda - 1)\Sigma_{v^{\perp}} - \Sigma_{v^{\subseteq}}\right)^2 + \frac{\lambda}{\lambda - 1} x_{v^{\subseteq}}^{\mathrm{T}} \left((\lambda - 1)B_{v^{\subseteq}} - ee^{\mathrm{T}}\right) x_{v^{\subseteq}} \right) \\
&= \sum_{v \in V} x_v P_v(x). \qquad \square
\end{aligned}$$

Proof of Lemma 11. Put

$$C := \frac{\lambda^{k-2}}{2(\lambda - 1)(\lambda - 2) \cdots (\lambda - k)}.$$

By dropping some terms and the fact that $\Sigma_V = \Sigma_{\vec{v}^{\subseteq}} + \Sigma_{\vec{v}^{\perp}}$, it follows that

$$\begin{aligned}
\Sigma_V p_{\vec{v}}(x) \sqsupseteq C \Big(& (\lambda - k + 1)\Sigma_{\vec{v}^{\subseteq}} \left((\lambda - k)\Sigma_{\vec{v}^{\perp}} - k\Sigma_{\vec{v}^{\subseteq}}\right)^2 \\
& + 2\lambda^2 \Sigma_{\vec{v}^{\subseteq}} x_{\vec{v}^{\subseteq}}^{\mathrm{T}} \left((\lambda - k)B_{\vec{v}^{\subseteq}} - ee^{\mathrm{T}}\right) x_{\vec{v}^{\subseteq}} \\
& + 2\lambda^2 \Sigma_{\vec{v}^{\perp}} x_{\vec{v}^{\subseteq}}^{\mathrm{T}} \left((\lambda - k)B_{\vec{v}^{\subseteq}} - ee^{\mathrm{T}}\right) x_{\vec{v}^{\subseteq}} \Big).
\end{aligned}$$

To simplify notation, put $\ell := \lambda - k$. Then the latter inequality can be rewritten as

$$\begin{aligned}\Sigma_V p_{\vec{v}}(x) \sqsupseteq C\Big(& (\ell+1)\Sigma_{\vec{v}^{\subseteq}} \left(\ell\, \Sigma_{\vec{v}^{\perp}} - k\Sigma_{\vec{v}^{\subseteq}}\right)^2 \\ & + \; 2\lambda^2 \Sigma_{\vec{v}^{\subseteq}} x_{\vec{v}^{\subseteq}}^{\mathrm{T}} \left(\ell\, B_{\vec{v}^{\subseteq}} - ee^{\mathrm{T}}\right) x_{\vec{v}^{\subseteq}} \\ & + \; 2\lambda^2 \Sigma_{\vec{v}^{\perp}} x_{\vec{v}^{\subseteq}}^{\mathrm{T}} \left(\ell\, B_{\vec{v}^{\subseteq}} - ee^{\mathrm{T}}\right) x_{\vec{v}^{\subseteq}} \Big).\end{aligned} \tag{18}$$

By Observation 13 (applied to the graph $G := G \setminus \vec{v}^{\perp}$ and $\lambda := \ell$) and the fact that $\Sigma_{\vec{v}^{\perp}} = \frac{1}{\ell}\left(\ell\, \Sigma_{\vec{v}^{\perp}} - k\Sigma_{\vec{v}^{\subseteq}}\right) + \frac{k}{\ell}\Sigma_{\vec{v}^{\subseteq}}$, we can rewrite $\Sigma_{\vec{v}^{\perp}} x_{\vec{v}^{\subseteq}}^{\mathrm{T}} \left(\ell\, B_{\vec{v}^{\subseteq}} - ee^{\mathrm{T}}\right) x_{\vec{v}^{\subseteq}}$ as

$$\frac{1}{\ell} \sum_{w \in \vec{v}^{\subseteq}} x_w \left(\ell\, \Sigma_{\vec{v}^{\perp}} - k\Sigma_{\vec{v}^{\subseteq}}\right) \left((\ell-1)\Sigma_{w^{\perp} \cap \vec{v}^{\subseteq}} - \Sigma_{\{\vec{v},w\}^{\subseteq}}\right) + \frac{k}{\ell}\Sigma_{\vec{v}^{\subseteq}} x_{\vec{v}^{\subseteq}}^{\mathrm{T}} \left(\ell\, B_{\vec{v}^{\subseteq}} - ee^{\mathrm{T}}\right) x_{\vec{v}^{\subseteq}}.$$

Thus from (18) we get

$$\Sigma_V p_{\vec{v}}(x) \sqsupseteq C \sum_{w \in \vec{v}^{\subseteq}} x_w Q_{\vec{v},w}(x), \tag{19}$$

where

$$\begin{aligned} Q_{\vec{v},w}(x) = & (\ell+1)\left(\ell\, \Sigma_{\vec{v}^{\perp}} - k\Sigma_{\vec{v}^{\subseteq}}\right)^2 \\ & + \; \tfrac{2\lambda^3}{\ell} x_{\vec{v}^{\subseteq}}^{\mathrm{T}} \left(\ell\, B_{\vec{v}^{\subseteq}} - ee^{\mathrm{T}}\right) x_{\vec{v}^{\subseteq}} \\ & + \; \tfrac{2\lambda^2}{\ell} \left(\ell\, \Sigma_{\vec{v}^{\perp}} - k\Sigma_{\vec{v}^{\subseteq}}\right) \left((\ell-1)\Sigma_{w^{\perp} \cap \vec{v}^{\subseteq}} - \Sigma_{\{\vec{v},w\}^{\subseteq}}\right). \end{aligned}$$

By Lemma 10 (applied to the graph $G := G \setminus \vec{v}^{\perp}$ and $\lambda := \ell$), it follows that

$$\sum_{w \in \vec{v}^{\subseteq}} x_w Q_{\vec{v},w}(x) \sqsupseteq \sum_{w \in \vec{v}^{\subseteq}} x_w q_{\vec{v},w}(x), \tag{20}$$

where

$$\begin{aligned} q_{\vec{v},w}(x) = & (\ell+1)\left(\ell\, \Sigma_{\vec{v}^{\perp}} - k\Sigma_{\vec{v}^{\subseteq}}\right)^2 \\ & + \; \tfrac{2\lambda^3}{\ell(\ell-1)} \left((\ell-1)\, \Sigma_{w^{\perp} \cap \vec{v}^{\subseteq}} - \Sigma_{\{\vec{v},w\}^{\subseteq}}\right)^2 \\ & + \; \tfrac{2\lambda^3}{\ell-1} x_{\{\vec{v},w\}^{\subseteq}}^{\mathrm{T}} \left((\ell-1)B_{\{\vec{v},w\}^{\subseteq}} - ee^{\mathrm{T}}\right) x_{\{\vec{v},w\}^{\subseteq}} \\ & + \; \tfrac{2\lambda^2}{\ell} \left(\ell\, \Sigma_{\vec{v}^{\perp}} - k\Sigma_{\vec{v}^{\subseteq}}\right) \left((\ell-1)\Sigma_{w^{\perp} \cap \vec{v}^{\subseteq}} - \Sigma_{\{\vec{v},w\}^{\subseteq}}\right). \end{aligned}$$

Using some algebraic manipulations and the fact that $\ell = \lambda - k$, we can rewrite $q_{\vec{v},w}(x)$ as

$$\begin{aligned} q_{\vec{v},w}(x) = & \tfrac{\lambda(\ell-1)}{\ell} \left(\ell\, \Sigma_{\vec{v}^{\perp}} - k\Sigma_{\vec{v}^{\subseteq}} + \tfrac{\lambda}{\ell-1} \left((\ell-1)\Sigma_{w^{\perp} \cap \vec{v}^{\subseteq}} - \Sigma_{\{\vec{v},w\}^{\subseteq}}\right)\right)^2 \\ & + \; \tfrac{\lambda(2-k)+k^2-k}{\ell} \left(\ell\, \Sigma_{\vec{v}^{\perp}} - k\Sigma_{\vec{v}^{\subseteq}}\right)^2 \\ & + \; \tfrac{\lambda^3}{\ell(\ell-1)} \left((\ell-1)\Sigma_{w^{\perp} \cap \vec{v}^{\subseteq}} - \Sigma_{\{\vec{v},w\}^{\subseteq}}\right)^2 \\ & + \; \tfrac{2\lambda^3}{\ell-1} x_{\{\vec{v},w\}^{\subseteq}}^{\mathrm{T}} \left((\ell-1)B_{\{\vec{v},w\}^{\subseteq}} - ee^{\mathrm{T}}\right) x_{\{\vec{v},w\}^{\subseteq}}. \end{aligned} \tag{21}$$

Since $\Sigma_{\vec{v}^{\subseteq}} = \Sigma_{(w^{\perp} \cap \vec{v}^{\subseteq}) \cup \{\vec{v},w\}^{\subseteq}} = \Sigma_{w^{\perp} \cap \vec{v}^{\subseteq}} + \Sigma_{\{\vec{v},w\}^{\subseteq}}$, it follows that

$$\begin{aligned} & \left(\ell\, \Sigma_{\vec{v}^{\perp}} - k\Sigma_{\vec{v}^{\subseteq}} + \tfrac{\lambda}{\ell-1} \left((\ell-1)\Sigma_{w^{\perp} \cap \vec{v}^{\subseteq}} - \Sigma_{\{\vec{v},w\}^{\subseteq}}\right)\right)^2 = \\ & \qquad \left(\ell\, \Sigma_{\vec{v}^{\perp}} + (\lambda-k)\Sigma_{w^{\perp} \cap \vec{v}^{\subseteq}} - \tfrac{k\ell+\lambda-k}{\ell-1}\Sigma_{\{\vec{v},w\}^{\subseteq}}\right)^2 = \\ & \qquad\qquad \left(\ell\, \Sigma_{\{\vec{v},w\}^{\perp}} - \tfrac{(k+1)\ell}{\ell-1}\Sigma_{\{\vec{v},w\}^{\subseteq}}\right)^2. \end{aligned} \tag{22}$$

The last step holds because $\ell = \lambda - k$ and $\Sigma_{\{\vec{v},w\}^{\perp}} = \Sigma_{\vec{v}^{\perp}} + \Sigma_{w^{\perp} \cap \vec{v}^{\subseteq}}$.

Since $\lambda > k+1$, it follows that $\lambda(2-k)+k^2-k \geq 0$ if $k = 1, 2$, or if $k = 3, 4$ and $\lambda \leq 6$. Thus by dropping the second and third terms in (21) and using (22), we get

$$
\begin{aligned}
q_{\vec{v},w}(x) &\sqsupseteq \tfrac{\lambda(\ell-1)}{\ell}\left(\ell\,\Sigma_{\{\vec{v},w\}^\perp} - \tfrac{(k+1)\ell}{\ell-1}\Sigma_{\{\vec{v},w\}^{\subseteq}}\right)^2 \\
&\quad + \tfrac{2\lambda^3}{\ell-1}x^{\mathrm{T}}_{\{\vec{v},w\}^{\subseteq}}\left((\ell-1)B_{\{\vec{v},w\}^{\subseteq}} - ee^{\mathrm{T}}\right)x_{\{\vec{v},w\}^{\subseteq}} \\
&= \tfrac{\lambda\ell}{\ell-1}\left((\ell-1)\Sigma_{\{\vec{v},w\}^\perp} - (k+1)\Sigma_{\{\vec{v},w\}^{\subseteq}}\right)^2 \\
&\quad + \tfrac{2\lambda^3}{\ell-1}x^{\mathrm{T}}_{\{\vec{v},w\}^{\subseteq}}\left((\ell-1)B_{\{\vec{v},w\}^{\subseteq}} - ee^{\mathrm{T}}\right)x_{\{\vec{v},w\}^{\subseteq}} \\
&= \tfrac{\lambda(\lambda-k)}{\lambda-k-1}\left((\lambda-k-1)\Sigma_{\{\vec{v},w\}^\perp} - (k+1)\Sigma_{\{\vec{v},w\}^{\subseteq}}\right)^2 \qquad (23)\\
&\quad + \tfrac{2\lambda^3}{\lambda-k-1}x^{\mathrm{T}}_{\{\vec{v},w\}^{\subseteq}}\left((\lambda-k-1)B_{\{\vec{v},w\}^{\subseteq}} - ee^{\mathrm{T}}\right)x_{\{\vec{v},w\}^{\subseteq}} \\
&= \tfrac{\lambda}{\lambda-k-1}\Big((\lambda-k)\left((\lambda-k-1)\Sigma_{\{\vec{v},w\}^\perp} - (k+1)\Sigma_{\{\vec{v},w\}^{\subseteq}}\right)^2 \\
&\qquad\qquad + 2\lambda^2 x^{\mathrm{T}}_{\{\vec{v},w\}^{\subseteq}}\left((\lambda-k-1)B_{\{\vec{v},w\}^{\subseteq}} - ee^{\mathrm{T}}\right)x_{\{\vec{v},w\}^{\subseteq}}\Big) \\
&= \tfrac{p_{\vec{v},w}(x)}{C}.
\end{aligned}
$$

Combining (19), (20), and (23) we get

$$\Sigma_V p_{\vec{v}}(x) \sqsupseteq \sum_{w\in\vec{v}^{\subseteq}} x_w p_{\vec{v},w}(x). \qquad \square$$

5. Some special classes of graphs. Recall that the *chromatic number* $\chi(G)$ of a graph $G = (V, E)$ is the minimum number of colors required to color the vertices of G so that for all $\{i, j\} \in E$ the vertices i and j have different colors. Recall also that the *complement* $\overline{G}$ of $G = (V, E)$ is the graph with the same vertex set V and set of edges $\{\{i, j\} : \{i, j\} \notin E\}$.

We next discuss in further detail three important classes of graphs: the class of graphs G with $\alpha(G) = \chi(\overline{G})$, the cycles C_n, and their complements $\overline{C}_n$. For the first class of graphs, Corollary 15 below shows that $\nu^{(0)}(\cdot) = \alpha(\cdot)$. This readily applies to even cycles and their complements. By contrast, $\nu^{(0)}(\cdot) > \alpha(\cdot)$ for odd cycles and their complements. Furthermore, for these classes of graphs, the identities in Examples 19 and 21 show that $\nu^{(1)}(\cdot) = \alpha(\cdot)$.

5.1. Graphs G with $\chi(\overline{G}) = \alpha(G)$. Proposition 14 below gives a succinct proof of the inequality $\nu^{(0)}(G) \leq \chi(\overline{G})$. We note that this inequality also follows from putting together the Lovász sandwich theorem [11], the identity $\nu^{(0)}(G) = \vartheta^{(0)}(G) = \vartheta'(G)$ due to de Klerk and Pasechnik [4], and the inequality $\vartheta'(G) \leq \vartheta(G)$ due to Schrijver [15]. Here $\vartheta'(\cdot)$ and $\vartheta(\cdot)$ are, respectively, Schrijver's ϑ' function [15] and Lovász ϑ function [11]. However, the proof below is direct and provides an interesting constructive procedure. This procedure will allow us to derive the identities in Examples 17, 18, and 19.

PROPOSITION 14. $\nu^{(0)}(G) \leq \chi(\overline{G})$.

Proof. To simplify notation, we shall write χ as shorthand for $\chi(\overline{G})$. Fix a coloring of $\overline{G}$ with χ colors, and let V_j be the set of vertices colored with color j for $j = 1, \ldots, \chi$. Since each V_j is a clique in G,

$$x^{\mathrm{T}}(I + A(G))x = \sum_{j=1}^{\chi}\left(\sum_{i\in V_j} x_i\right)^2 + q(x) \qquad (24)$$

for some quadratic form $q(x)$ with nonnegative coefficients.

On the other hand,

$$\chi \cdot \sum_{j=1}^{\chi} \left(\sum_{i \in V_j} x_i \right)^2 - \left(\sum_{i \in V} x_i \right)^2 = \sum_{1 \le j < k \le \chi} \left(\sum_{i \in V_j} x_i - \sum_{i \in V_k} x_i \right)^2. \tag{25}$$

From (24) and (25) we get

$$x^{\mathrm{T}} \left(\chi \cdot (I + A(G)) - ee^{\mathrm{T}} \right) x = \sum_{1 \le j < k \le \chi} \left(\sum_{i \in V_j} x_i - \sum_{i \in V_k} x_i \right)^2 + \chi \cdot q(x).$$

Thus $\chi \cdot (I + A(G)) - ee^{\mathrm{T}} \in \mathcal{Q}_n^0$, and consequently $\nu^{(0)}(G) \le \chi(\overline{G})$. □

COROLLARY 15. *If $\alpha(G) = \chi(\overline{G})$, then $\nu^{(0)}(G) = \alpha(G)$.*

From Corollary 15, it readily follows that $\nu^{(0)}(C_n) = \alpha(C_n)$ and $\nu^{(0)}(\overline{C}_n) = \alpha(\overline{C}_n)$ for n even or $n = 3$. By contrast, we next show that $\nu^{(0)}(C_n) > \alpha(C_n) = \nu^{(1)}(C_n)$ and $\nu^{(0)}(\overline{C}_n) > \alpha(\overline{C}_n) = \nu^{(1)}(\overline{C}_n)$ for $n \ge 5$ and odd.

5.2. Odd cycles. For ease of notation, throughout this section the arithmetic operations in the indices below are meant to be performed modulo $2m + 1$, i.e., $1 + 2m + 1 = 1$, $3 + 2m = 2$, etc.

PROPOSITION 16. *Assume $m \ge 2$. Then $\nu^{(0)}(C_{2m+1}) > m = \alpha(C_{2m+1})$.*

Proof. Assume $\nu^{(0)}(C_{2m+1}) = m$. Then $m(I + A(C_{2m+1})) - ee^{\mathrm{T}} \in \mathcal{Q}_n^0$, i.e.,

$$m(I + A(C_{2m+1})) - ee^{\mathrm{T}} = RR + N$$

for some $R, N \in \mathbb{S}^n$ with $N \ge 0$. Let R_j denote the jth column of R. It follows that for any stable set $S \subseteq V$ of size m

$$0 = \left\| \sum_{j \in S} R_j \right\|^2 + \sum_{i,j \in S} N_{ij} \ge \left\| \sum_{j \in S} R_j \right\|^2,$$

and thus $\sum_{j \in S} R_j = 0$. Taking the stable sets $S = \{j, j+3, j+5, \ldots, j+2m-1\}$ and $S' = \{j+1, j+3, j+5, \ldots, j+2m-1\}$, we get $0 = R_j + \sum_{k=1}^{m-1} R_{j+2k+1} = R_{j+1} + \sum_{k=1}^{m-1} R_{j+2k+1}$ and so $R_j = R_{j+1}$ for all j. Applying this to $j = 1, 2, \ldots, 2m+1$, we conclude that $R = 0$. But this yields $m(I + A(C_{2m+1})) - ee^{\mathrm{T}} = N \ge 0$, which is clearly a contradiction. □

Examples 17, 18, and 19 below show that $m(I + A(C_{2m+1})) - ee^{\mathrm{T}} \in \mathcal{Q}_n^1$ for every odd cycle C_{2m+1} with $m \ge 2$. This in particular yields $\nu^{(1)}(C_{2m+1}) = m = \alpha(C_{2m+1})$. The identities in Examples 17, 18, and 19 follow from specializing the proofs of Theorem 6 and Proposition 14 to odd and even cycles, respectively. We note that the identity in Example 17 had been derived by Parrilo [14, Chapter 5].

Example 17. Let $p(x_1, x_2, x_3, x_4, x_5) = (x_1 + x_2 + x_5 - x_3 - x_4)^2 + 4x_2x_3$. Then

$$\sum_{i=1}^{5} x_i x^{\mathrm{T}} \left(2(I + A(C_5)) - ee^{\mathrm{T}} \right) x = \sum_{i=1}^{5} x_i p(x_i, x_{i+1}, x_{i+2}, x_{i+3}, x_{i+4}).$$

Example 18. Let

$$p(x_1, \ldots, x_7) = 2 \left(x_1 + x_2 + x_7 - \frac{1}{2}(x_3 + x_4 + x_5 + x_6) \right)^2 + \frac{3}{2}(x_3 + x_4 - x_5 - x_6)^2 + 6(x_2x_3 + x_4x_5).$$

Then

$$\sum_{i=1}^{7} x_i x^{\mathrm{T}} \left(3(I + A(C_7)) - ee^{\mathrm{T}}\right) x = \sum_{i=1}^{7} x_i p(x_i, x_{i+1}, \ldots, x_{i+6}).$$

Example 19. Assume $m \geq 2$. Let

$$\begin{aligned} p(x) = (m-1) &\left(x_1 + x_2 + x_{2m+1} - \frac{1}{m-1} \sum_{k=3}^{2m} x_k \right)^2 \\ &+ \frac{m}{m-1} \sum_{1 \leq i < j \leq m-1} \left(x_{2i+1} + x_{2i+2} - x_{2j+1} - x_{2j+2}\right)^2 \\ &+ 2m \sum_{i=1}^{m-1} x_{2i} x_{2i+1}. \end{aligned}$$

Then

$$\sum_{i=1}^{2m+1} x_i x^{\mathrm{T}} \left(m(I + A(C_{2m+1})) - ee^{\mathrm{T}}\right) x = \sum_{i=1}^{2m+1} x_i p(x_i, x_{i+1}, \ldots, x_{i+2m}).$$

5.3. Complements of odd cycles. The following proposition is proven with an argument similar (but simpler) to that used in the proof of Proposition 16.

PROPOSITION 20. *Assume $m \geq 2$. Then $\nu^{(0)}(\overline{C}_{2m+1}) > 2 = \alpha(\overline{C}_{2m+1})$.*

Example 21 below shows that $2(I + A(\overline{C}_{2m+1})) - ee^{\mathrm{T}} \in \mathcal{Q}_n^1$ for every $\overline{C}_{2m+1}$, which in turn yields $\nu^{(1)}(\overline{C}_{2m+1}) = 2 = \alpha(\overline{C}_{2m+1})$. The identity in Example 21 follows from specializing the proof of Theorem 6 to complements of odd cycles.

Example 21. Assume $m \geq 2$. Let

$$p(x) = \left(x_1 - x_2 - x_{2m+1} + \sum_{k=3}^{2m} x_k \right)^2 + 4x_2 \sum_{k=4}^{2m} x_k.$$

Then

$$\sum_{i=1}^{2m+1} x_i x^{\mathrm{T}} \left(2(I + A(\overline{C}_{2m+1})) - ee^{\mathrm{T}}\right) x = \sum_{i=1}^{2m+1} x_i p(x_i, x_{i+1}, \ldots, x_{i+2m}).$$

5.4. The smallest graphs G such that $\nu^{(\alpha(G)-2)}(G) > \alpha(G)$ for $\alpha(G) = 2, 3, 4, 5$. The examples below show that the result in Corollary 7 concerning the attainment of $\alpha(G)$ is tight on r. Furthermore, the graphs in these examples are the smallest possible. Several of these examples rely on numerical computations for $\nu^{(r)}(G)$. These numerical results were obtained by solving the semidefinite programming formulations using `SeDuMi` [16], with a precision of at least `1E-8`.

From Theorem 6 and Proposition 16 it follows that C_5 is the smallest (with fewest vertices) graph G such that $\nu^{(0)}(G) > \alpha(G)$. In addition, again by Theorem 6

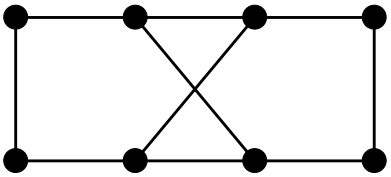
$$\nu^{(1)}(G) \leq 1 + \max_{v \in V} \nu^{(0)}(G \setminus v^{\perp}). \tag{26}$$

Furthermore, if some vertex $u \in V$ is such that $\deg(u) = 0$ or 1, then $u^{\perp}$ induces a clique in G, and Theorem 8 yields

$$\nu^{(1)}(G) \leq 2 + \max_{v \in u^{\subseteq}} \nu^{(0)}(G \setminus \{u, v\}^{\perp}). \tag{27}$$

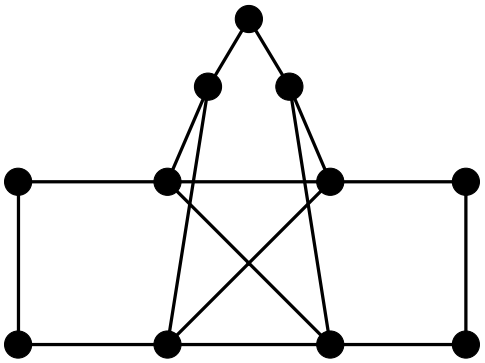
From (26) and (27) and the fact that C_5 is the smallest graph G such that $\nu^{(0)}(G) > \alpha(G)$, it follows that $\nu^{(1)}(G) = \alpha(G)$ if G has at most seven vertices and $\alpha(G) = 3$.

Now consider the following graph G_8:



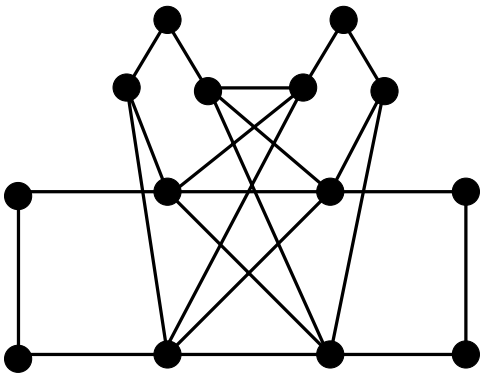
We have $\nu^{(1)}(G_8) = 3.043276 > 3 = \alpha(G_8)$. Furthermore, it is easy to show that if G' is another graph with eight vertices such that $\nu^{(1)}(G') > \alpha(G')$, then the vertices of G' can be numbered so that $E(G_8) \subseteq E(G')$. Thus G_8 is the smallest graph G such that $\nu^{(1)}(G) > \alpha(G) = 3$.

We can extend the above reasoning further. Again, from observations above, it follows that $\nu^{(2)}(G) = \alpha(G)$ if G has at most ten vertices and $\alpha(G) = 4$. Consider the following graph G_{11}:



We have $\nu^{(2)}(G_{11}) = 4.011111 > 4 = \alpha(G_{11})$.

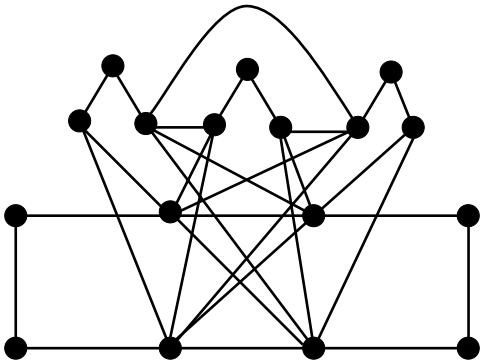
We can go yet one step further. Again, from observations above, it follows that $\nu^{(3)}(G) = \alpha(G)$ if G has at most 13 vertices and $\alpha(G) = 5$. Now Consider the following graph G_{14}:



We have $\nu^{(3)}(G_{14}) = 5.004886 > 5 = \alpha(G_{14})$.

It is interesting to note that (up to the a numerical accuracy of `1E-8`) both $\vartheta^{(2)}(G_{11}) = \alpha(G_{11})$ and $\vartheta^{(2)}(G_{14}) = \alpha(G_{14})$. So in general $\nu^{(r)}(\cdot) > \vartheta^{(r)}(\cdot)$ for $r > 1$ even though $\nu^{(r)}(\cdot) = \vartheta^{(r)}(\cdot)$ for $r = 0, 1$.

We conjecture that the general construction suggested above gives graphs G with $\alpha(G) = r$ and $\nu^{(r-2)}(G) > r$ for any r. For example, for $r = 4$ consider the following graph G_{17}:



It should be the case that $\nu^{(4)}(G_{17}) > \alpha(G_{17})$. Unfortunately the semidefinite program involved in the calculation of $\nu^{(4)}(G_{17})$ is beyond our current computational capabilities. For this graph we did find that $\vartheta^{(2)}(G_{17}) = 6.000475 > 6 = \alpha(G_{17})$. To this date this is the smallest explicit example of a graph G with $\vartheta^{(2)}(G) > \alpha(G)$.

Acknowledgment. We thank the anonymous referees whose helpful suggestions substantially improved the paper.

APPROXIMATE GAUSS–NEWTON METHODS FOR NONLINEAR LEAST SQUARES PROBLEMS*

S. GRATTON†, A. S. LAWLESS‡, AND N. K. NICHOLS‡

Abstract. The Gauss–Newton algorithm is an iterative method regularly used for solving nonlinear least squares problems. It is particularly well suited to the treatment of very large scale variational data assimilation problems that arise in atmosphere and ocean forecasting. The procedure consists of a sequence of linear least squares approximations to the nonlinear problem, each of which is solved by an "inner" direct or iterative process. In comparison with Newton's method and its variants, the algorithm is attractive because it does not require the evaluation of second-order derivatives in the Hessian of the objective function. In practice the exact Gauss–Newton method is too expensive to apply operationally in meteorological forecasting, and various approximations are made in order to reduce computational costs and to solve the problems in real time. Here we investigate the effects on the convergence of the Gauss–Newton method of two types of approximation used commonly in data assimilation. First, we examine "truncated" Gauss–Newton methods where the inner linear least squares problem is not solved exactly, and second, we examine "perturbed" Gauss–Newton methods where the true linearized inner problem is approximated by a simplified, or perturbed, linear least squares problem. We give conditions ensuring that the truncated and perturbed Gauss–Newton methods converge and also derive rates of convergence for the iterations. The results are illustrated by a simple numerical example. A practical application to the problem of data assimilation in a typical meteorological system is presented.

Key words. nonlinear least squares problems, approximate Gauss–Newton methods, variational data assimilation

DOI. 10.1137/050624935

1. Introduction.

The Gauss–Newton (GN) method is a well-known iterative technique used regularly for solving the nonlinear least squares problem (NLSP)

$$\min_x \phi(x) = \frac{1}{2} \|f(x)\|_2^2, \tag{1}$$

where x is an n-dimensional real vector and f is an m-dimensional real vector function of x [20].

Problems of this form arise commonly from applications in optimal control and filtering and in data fitting. As a simple example, if we are given m observed data (t_i, y_i) that we wish to fit with a model $S(x,t)$, determined by a vector x of n parameters, and if we define the ith component of $f(x)$ to be $f_i(x) = S(x,t_i) - y_i$, then the solution to the NLSP (1) gives the best model fit to the data in the sense of the minimum sum of square errors. The choice of norm is often justified by statistical considerations [22].

Recently, very large inverse problems of this type arising in *data assimilation* for numerical weather, ocean, and climate prediction and for other applications in the environmental sciences have attracted considerable attention [11, 6, 18, 19, 14].

In data assimilation a set of observed data is matched to the solution of a discrete dynamical model of a physical system over a period of time. The aim is to provide a "best" estimate of the current state of the system to enable accurate forecasts to be made of the future system behavior. Operationally the incremental four-dimensional variational data assimilation technique (4D-Var) is now used in many meteorological forecasting centers [6]. Recently it has been established that this method corresponds to a GN procedure [14, 15].

The GN method consists of solving a sequence of linearized least squares approximations to the nonlinear (NLSP) problem, each of which can be solved efficiently by an "inner" direct or iterative process. In comparison with Newton's method and its variants, the GN method for solving the NLSP is attractive because it does not require computation or estimation of the second derivatives of the function $f(x)$ and hence is numerically more efficient.

In practice, particularly for the very large problems arising in data assimilation, approximations are made within the GN process in order to reduce computational costs. The effects of these approximations on the convergence of the method need to be understood. Here we investigate the effects of two types of approximation used commonly in data assimilation: First, we examine "truncated" GN (TGN) methods where the inner linear least squares problem is not solved exactly, and second, we examine "perturbed" GN (PGN) methods where the true linearized inner problem is approximated by a simplified, or perturbed, linear least squares problem. We give conditions ensuring that the truncated and perturbed GN methods converge and also derive rates of convergence for the iterations.

In the next section we state the problem in detail, together with our assumptions, and define the GN algorithm. We also present some basic theory for the exact method. The truncated and perturbed algorithms that are to be investigated are then defined. In the following sections theoretical convergence results are established for the approximate GN methods. Two different approaches are used to derive the theory. First, we apply extensions of the results of [20, 8] for inexact Newton (IN) methods to the approximate GN methods in order to obtain general convergence theorems. We then derive more restricted results using the approach of [9]. The restricted results also provide estimates for the rates of convergence of the methods. Conditions for linear, superlinear, and quadratic convergence are noted. Numerical results demonstrating and validating the theory are presented. Finally, in the remaining sections, an application to a practical problem arising in data assimilation is described, and the conclusions are summarized.

2. GN method.

We begin by introducing the GN method and reviewing briefly some results on the convergence of the method. We then define the truncated and perturbed approximate GN methods that will be examined in subsequent sections.

2.1. Statement of the algorithm.

We consider the NLSP defined in (1), where we assume that

A0. $f : \mathbb{R}^n \mapsto \mathbb{R}^m$ is a nonlinear twice continuously Fréchet differentiable function.

We denote the Jacobian of the function f by $J(x) \equiv f'(x)$. The gradient and Hessian of $\phi(x)$ are then given by

$$\nabla\phi(x) = J(x)^T f(x), \tag{2}$$

$$\nabla^2\phi(x) = J(x)^T J(x) + Q(x), \tag{3}$$

where $Q(x)$ denotes the second-order terms

$$Q(x) = \sum_{i=1}^{m} f_i(x) \nabla^2 f_i(x). \tag{4}$$

The following additional assumptions are made in order to establish the theory:

A1. There exists $x^* \in \mathbb{R}^n$ such that $J(x^*)^T f(x^*) = 0$;

A2. The Jacobian matrix $J(x^*)$ at x^* has full rank n.

Finding the stationary points of ϕ is equivalent to solving the gradient equation

$$F(x) \equiv \nabla \phi(x) = J(x)^T f(x) = 0. \tag{5}$$

Techniques for treating the NLSP can thus be derived from methods for solving this nonlinear algebraic system.

A common method for solving nonlinear equations of form (5) and hence for solving the NLSP (1) is Newton's method [20, section 10.2]. This method requires the full Hessian matrix (3) of function ϕ. For many large scale problems, the second-order terms $Q(x)$ of the Hessian are, however, impracticable to calculate and, in order to make the procedure more efficient, Newton's method is approximated by ignoring these terms. The resulting iterative method is known as the GN algorithm [20, section 8.5] and is defined as follows.

ALGORITHM GN ALGORITHM.

Step 0. Choose an initial $x_0 \in \mathbb{R}^n$.

Step 1. Repeat until convergence:

Step 1.1. Solve $J(x_k)^T J(x_k) s_k = -J(x_k)^T f(x_k)$.

Step 1.2. Set $x_{k+1} = x_k + s_k$.

Remarks. We note that at each iteration, Step 1.1 of the method corresponds to solving the linearized least squares problem

$$\min_s \frac{1}{2} \left\| J(x_k) s + f(x_k) \right\|_2^2. \tag{6}$$

We note also that the GN method can be written as a fixed-point iteration of the form

$$x_{k+1} = G(x_k), \tag{7}$$

where $G(x) \equiv x - J^+(x) f(x)$ and $J^+(x) \equiv (J(x)^T J(x))^{-1} J(x)^T$ denotes the Moore–Penrose pseudoinverse of $J(x)$.

2.2. Convergence of the exact GN method. Sufficient conditions for the convergence of the GN method are known in the case where the normal equations for the linearized least squares problem (6) are solved *exactly* in Step 1.1 at each iteration. We now recall some existing results.

We introduce the notation $\rho(A)$ to indicate the spectral radius of an $n \times n$ matrix A, and we define

$$\varrho = \rho\left(\left(J(x^*)^T J(x^*) \right)^{-1} Q(x^*) \right). \tag{8}$$

The following theorem on local convergence of the GN method then holds.

THEOREM 1 (Ortega and Rheinboldt [20, Theorem 10.1.3]). *Let assumptions* A0, A1, *and* A2 *hold. If* $\varrho < 1$, *then the GN iteration converges locally to* x^*; *that is, there*

exists $\varepsilon > 0$ *such that the sequence* $\{x_k\}$ *generated by the GN algorithm converges to* x^* *for all* $x_0 \in \mathcal{D} \equiv \{x \mid \|x - x^*\|_2 < \varepsilon\}$.

Theorem 1 has a geometrical interpretation as described in [23] (see also [2, section 9.2.2]). We denote by $\mathcal{S}$ the surface in $\mathbb{R}^m$ given by the parametric representation $y = f(x)$, $x \in \mathbb{R}^n$, and we let M be the point on $\mathcal{S}$ with coordinates $f(x^*)$, taking O as the origin of the coordinate system. The vector OM is orthogonal to the plane tangent to the surface $\mathcal{S}$ through M.

THEOREM 2 (Wedin [23]). *Suppose that the assumptions of Theorem* 1 *hold and that* $f(x^*)$ *is nonzero. Then*

$$\varrho = \|f(x^*)\|_2 \chi, \tag{9}$$

where χ *is the maximal principal curvature of the surface* $\mathcal{S}$ *at point* M *with respect to the normal direction* $w^* = f(x^*)/\|f(x^*)\|_2$.

In the *zero residual* case, where $f(x^*) = 0$, the relation (9) continues to hold. In this case the origin O lies on the surface $\mathcal{S}$ and χ denotes the maximal principal curvature of $\mathcal{S}$ with respect to the direction normal to the tangent surface at O. Since we then have $Q(x^*) = 0$ and hence $\varrho = 0$, the result still holds.

For the GN method to converge it is therefore sufficient for the maximal principal curvature χ of the surface $\mathcal{S}$ at the point $f(x^*)$ to satisfy $1/\chi > \|f(x^*)\|_2$. This condition holds if and only if $\nabla^2\phi(x^*)$ is positive definite at x^* and ensures that x^* is a local minimizer of the objective function ϕ [2, section 9.1.2]. The relation (9) implies that the convergence condition of Theorem 1 is invariant under transformation of the NLSP by a local diffeomorphism, since the quantity $\|f(x^*)\|_2 \chi$ has this property [23].

The proofs of these results depend on theory for stationary fixed point iteration processes [20]. The theory ensures local convergence at a linear rate. Additional, but more restrictive, conditions for local convergence are given in [9]. Conditions giving higher-order rates of convergence can be deduced from this theory. The GN method can also be treated as an IN method [21, 8, 3, 4]. Results of these types will be discussed further in sections 4 and 5.

We remark that the GN method may not be locally convergent in some cases [9]. Nevertheless, approximate GN methods are used widely in practice for solving the very large NLSP problems arising in data assimilation. The approximations are designed to make the algorithm more computationally efficient. Our aim here is to investigate the effects of these approximations on the convergence of the GN algorithm and to establish conditions for the local convergence of the approximate methods, given that conditions hold for the exact GN method to be locally convergent.

3. Approximate GN algorithms. A serious difficulty associated with the use of the GN method in large scale applications, such as data assimilation, is that the linearized least squares problem (6) is computationally too expensive to solve exactly in Step 1.1 of the algorithm at each iteration. The dimensions of the normal matrix equations to be solved in Step 1.1 are often so great that the system coefficients cannot be stored in core memory, even in factored form. Therefore, in order to solve the full nonlinear problem efficiently, in real forecasting time, approximations must be made within the GN procedure.

Two types of approximation are commonly applied. First, the linearized least squares problem (6) is solved only approximately by an inner iteration method that is truncated before full accuracy is reached. We refer to this approximate algorithm as the TGN method. Second, the linearized least squares problem in Step 1.1 is replaced by an approximate, simplified or perturbed, linear problem that can be solved more

efficiently in the inner loop. We refer to this algorithm as the PGN method. Here we examine both of these approximate GN methods and also the combined truncated perturbed GN (TPGN) method, where both approximations are applied. In the next subsections we define these procedures explicitly, and in sections 4 and 5 we analyze the convergence of the approximate methods.

3.1. TGN method. At each outer iteration k of the GN method, we solve the normal equations

$$J(x_k)^T J(x_k) s = -J(x_k)^T f(x_k) \tag{10}$$

for the linearized least squares problem (6) using an iterative procedure. Intuitively, when x_k is far from x^* and the function f is nonlinear, it is not worth solving (10) to high accuracy. A natural stopping criterion for the iterative process is where the relative residual satisfies

$$\left\| J(x_k)^T J(x_k) s_k + J(x_k)^T f(x_k) \right\|_2 / \left\| J(x_k)^T f(x_k) \right\|_2 \leq \beta_k. \tag{11}$$

Here s_k denotes the current estimate of the solution of (10), and β_k is a specified tolerance. For this reason we define the TGN algorithm as follows.

Algorithm TGN algorithm.

Step 0. Choose an initial $x_0 \in \mathbb{R}^n$.

Step 1. Repeat until convergence:

Step 1.1. Find s_k such that
$(J(x_k)^T J(x_k)) s_k = -J(x_k)^T f(x_k) + r_k$
with $\|r_k\|_2 \leq \beta_k \left\| J(x_k)^T f(x_k) \right\|_2$.

Step 1.2. Update $x_{k+1} = x_k + s_k$.

The tolerances β_k, $k = 0, 1, 2 \ldots$, must be chosen to ensure convergence of the procedure to the optimal x^* of the NLSP (1). Conditions guaranteeing convergence of the TGN method are presented in sections 4 and 5.

3.2. PGN method. For some applications it is desirable to apply a PGN method in which the true Jacobian J is replaced by an approximation $\tilde{J}$; this is practical, for example, in cases where a perturbed Jacobian is much easier or computationally less expensive to calculate. We therefore define the PGN method as follows.

Algorithm PGN algorithm.

Step 0. Choose an initial $x_0 \in \mathbb{R}^n$.

Step 1. Repeat until convergence:

Step 1.1. Solve $\tilde{J}(x_k)^T \tilde{J}(x_k) s_k = -\tilde{J}(x_k)^T f(x_k)$.

Step 1.2. Set $x_{k+1} = x_k + s_k$.

We emphasize that in Step 1.1 of the PGN algorithm only the Jacobian is approximated and not the nonlinear function $f(x_k)$. The approximate Jacobian, $\tilde{J}(x)$, is assumed to be continuously Fréchet differentiable.

In applications to data assimilation the approximate Jacobian is derived from an approximate linearization of the discrete nonlinear model equations, and hence the perturbed Jacobian approximates the same underlying dynamical system as the exact Jacobian and has similar properties. The assumptions made here and in sections 4.4–4.6 on the perturbed Jacobian are therefore regarded as reasonable. The derivation of the perturbed Jacobian for a practical data assimilation problem is shown in section 7.

In order to interpret the PGN iteration, it is convenient to define the function

$$\tilde{F}(x) = \tilde{J}(x)^T f(x) \tag{12}$$

and to write its first derivative in the form

$$\tilde{F}'(x) = \tilde{J}(x)^T J(x) + \tilde{Q}(x), \tag{13}$$

where $J(x)$ is the Jacobian of the function $f(x)$ and $\tilde{Q}(x)$ represents second-order terms arising from the derivative of $\tilde{J}(x)$. Then the PGN algorithm can be considered as an iterative method for finding a solution $\tilde{x}^*$ to the nonlinear equation

$$\tilde{F}(x) = 0. \tag{14}$$

We remark that, just as the GN method can be regarded as an IN method for solving the gradient equation (5), the PGN method can be treated as an IN method for solving the perturbed gradient equation (14). In the PGN method, the second-order term in the derivative $\tilde{F}'$ is ignored and the first-order term is now approximated, allowing the iteration to be written as a sequence of linear least squares problems.

For the zero residual NLSP, where $f(x^*) = 0$, the solution x^* of the problem satisfies (14) and so the fixed point $\tilde{x}^* = x^*$ of the PGN procedure is also a fixed point of the exact GN iteration. Similarly, if $f(x^*)$ lies in the null space of $\tilde{J}(x^*)$, then (14) is satisfied by x^* and the fixed point of the PGN method is again a fixed point of the exact GN method. In general, the fixed point of the PGN method will not be the same as that of the GN algorithm. We might expect, however, that if $\tilde{J}$ is close to J, then the solution $\tilde{x}^*$ of (14) will be close to the solution x^* of the true gradient equation (5).

In sections 4 and 5 we give conditions for the PGN method to converge locally, and in section 4 we also examine the distance between the fixed points of the two algorithms.

3.3. TPGN method. In the PGN method, we solve the normal equations in Step 1.1 of the algorithm at each outer iteration k by applying an iterative method to the perturbed linear least squares problem

$$\min_s \frac{1}{2} \left\| \tilde{J}(x_k)s + f(x_k) \right\|_2^2. \tag{15}$$

To improve the efficiency of the PGN procedure, the iteration is truncated before full accuracy is reached. The iterations are halted where the relative residual satisfies

$$\left\| \tilde{J}(x_k)^T \tilde{J}(x_k)s_k + \tilde{J}(x_k)^T f(x_k) \right\|_2 / \left\| \tilde{J}(x_k)^T f(x_k) \right\|_2 \leq \beta_k. \tag{16}$$

Here s_k is the current estimate of the solution of (15), and β_k is a specified tolerance. This procedure is referred to as the TPGN method and is defined as follows.

ALGORITHM TPGN ALGORITHM.

Step 0. Choose an initial $x_0 \in \mathbb{R}^n$.

Step 1. Repeat until convergence:

Step 1.1. Find s_k such that

$$\tilde{J}(x_k)^T \tilde{J}(x_k)s_k = -\tilde{J}(x_k)^T f(x_k) + r_k$$

$$\text{with } \|r_k\|_2 \leq \beta_k \left\| \tilde{J}(x_k)^T f(x_k) \right\|_2.$$

Step 1.2. Update $x_{k+1} = x_k + s_k$.

The tolerances β_k, $k = 0, 1, 2 \ldots$, must be chosen to ensure convergence of the procedure to the optimal $\tilde{x}^*$ of the perturbed gradient equation (14). Conditions guaranteeing local convergence of the TPGN method are presented in sections 4 and 5.

4. Convergence of approximate GN methods I. We now derive sufficient conditions for the convergence of the truncated and perturbed GN methods. The theory is based on two different approaches. In this section we present results based on theory for IN methods found in [8] and [3]. In the subsequent section we extend the arguments of [9] for exact GN methods to the approximate truncated and perturbed methods. The aim is to establish conditions for the convergence of the approximate methods, given that conditions hold for the exact method to converge.

We begin by introducing the theory for IN methods. This theory is applied to the exact GN method to obtain a new convergence condition. Criteria for the convergence of the truncated and perturbed methods are then derived using these results.

4.1. IN methods. The IN method for solving the NLSP problem (1), as defined in [8], is given as follows.

ALGORITHM IN ALGORITHM.

Step 0. Choose an initial $x_0 \in \mathbb{R}^n$.

Step 1. Repeat until convergence:

Step 1.1. Solve $\nabla^2\phi(x_k)s_k = -\nabla\phi(x_k) + \tilde{r}_k$.

Step 1.2. Set $x_{k+1} = x_k + s_k$.

In Step 1.1 the residual errors $\tilde{r}_k$ measure the amount by which the calculated solution s_k fails to satisfy the exact Newton method at each iteration. It is assumed that the relative sizes of these residuals are bounded by a nonnegative forcing sequence $\{\eta_k\}$ such that for each iteration

$$\frac{\|\tilde{r}_k\|_2}{\|\nabla\phi(x_k)\|_2} \leq \eta_k. \tag{17}$$

Conditions for the convergence of the IN algorithm are established in the following theorem.

THEOREM 3 (Dembo, Eisenstat, and Steihaug [8]). *Let assumptions* A0, A1, *and* A2 *hold, and let* $\nabla^2\phi(x^*)$ *be nonsingular. Assume* $0 \leq \eta_k \leq \hat{\eta} < t < 1$. *Then there exists* $\varepsilon > 0$ *such that, if* $\|x_0 - x^*\|_2 \leq \varepsilon$, *the sequence of IN iterates* $\{x_k\}$ *satisfying* (17) *converges to* x^*. *Moreover, the convergence is linear in the sense that*

$$\| x_{k+1} - x^* \|_* \leq t \| x_k - x^* \|_*, \tag{18}$$

where $\| y \|_* = \left\|\nabla^2\phi(x^*)y\right\|_2$.

In [3] Theorem 3 is applied to obtain more general results in which the Jacobian and Hessian matrices are perturbed on each iteration of the Newton method. Here we adopt similar techniques to derive results for the approximate GN methods based on theory for the IN methods.

4.2. GN as an IN method. We first establish novel sufficient conditions for the exact GN method to converge by treating it as an IN method.

THEOREM 4. *Let assumptions* A0, A1, *and* A2 *hold, and let* $\nabla^2\phi(x^*)$ *be nonsingular. Assume* $0 \leq \hat{\eta} < 1$. *Then there exists* $\varepsilon > 0$ *such that, if* $\|x_0 - x^*\|_2 \leq \varepsilon$ *and if*

$$\left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2 \leq \eta_k \leq \hat{\eta} \quad \text{for} \quad k = 0, 1, \ldots, \tag{19}$$

the sequence of GN iterates $\{x_k\}$ *converges to* x^*.

Proof of Theorem 4. We can write the GN method as an IN method by setting

$$\begin{aligned} \tilde{r}_k &= \nabla\phi(x_k) - \nabla^2\phi(x_k)(J(x_k)^T J(x_k))^{-1}\nabla\phi(x_k) \\ &= (I - \nabla^2\phi(x_k)(J(x_k)^T J(x_k))^{-1})\nabla\phi(x_k). \end{aligned} \tag{20}$$

Then, using (3), we have

$$\begin{aligned} \|\tilde{r}_k\|_2 &= \left\|(I - \nabla^2\phi(x_k)(J(x_k)^T J(x_k))^{-1})\nabla\phi(x_k)\right\|_2 \\ &\leq \left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2 \|\nabla\phi(x_k)\|_2 . \end{aligned} \tag{21}$$

By Theorem 3, a sufficient condition for local convergence is therefore

$$\left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2 \leq \eta_k \leq \hat{\eta}, \quad k = 0, 1, \ldots . \qquad \square \tag{22}$$

The convergence condition derived in this theorem is more restrictive than that obtained in Theorem 1, which requires a bound only on the spectral radius of the matrix $Q(x)(J(x)^T J(x))^{-1}$ at the fixed point $x = x^*$ rather than on its norm at each iterate x_k. The technique used in the proof of Theorem 4 is, however, more readily extended to the case of the approximate GN iterations and enables qualitative information on the conditions needed for convergence to be established. This approach also provides a practical test of convergence for the approximate methods (see [17]).

4.3. Convergence of the TGN method (I). We now give a theorem that provides sufficient conditions for the convergence of the TGN method. It is assumed that the residuals in the TGN method are bounded such that

$$\|r_k\|_2 \leq \beta_k \|\nabla\phi(x_k)\|_2 , \tag{23}$$

where $\{\beta_k\}$ is a nonnegative forcing sequence. The theorem is established by considering the algorithm as an IN method, as in the proof of Theorem 4.

THEOREM 5. *Let assumptions* A0, A1, *and* A2 *hold, and let* $\nabla^2\phi(x^*)$ *be nonsingular. Assume that* $0 \leq \hat{\beta} < 1$, *and select* β_k, $k = 0, 1, \ldots$, *such that*

$$0 \leq \beta_k \leq \frac{\hat{\beta} - \left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2}{1 + \left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2}, \quad k = 0, 1, \ldots . \tag{24}$$

Then there exists $\varepsilon > 0$ *such that, if* $\|x_0 - x^*\|_2 \leq \varepsilon$, *the sequence of TGN iterates* $\{x_k\}$ *satisfying* (23) *converges to* x^*.

Proof of Theorem 5. We can write the TGN method as an IN method by setting

$$\tilde{r}_k = \nabla\phi(x_k) - \nabla^2\phi(x_k)(J(x_k)^T J(x_k))^{-1}\nabla\phi(x_k) + \nabla^2\phi(x_k)(J(x_k)^T J(x_k))^{-1} r_k. \tag{25}$$

Then we have

$$\begin{aligned} \|\tilde{r}_k\|_2 &\leq \left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2 \|\nabla\phi(x_k)\|_2 + \left\|I + Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2 \|r_k\|_2 \\ &\leq \left(\left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2 + \beta_k(1 + \left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2)\right) \|\nabla\phi(x_k)\|_2 \\ &\leq \left(\left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2 + (\hat{\beta} - \left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2)\right) \|\nabla\phi(x_k)\|_2 \\ &\leq \hat{\beta} \|\nabla\phi(x_k)\|_2 . \end{aligned} \tag{26}$$

Local convergence then follows from Theorem 3. $\square$

Since $\beta_k \geq 0$ is necessary, we require that $\left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2 \leq \hat{\beta} < 1$. This is just the sufficient condition given by Theorem 4 for the exact GN method to converge.

We remark also that the more highly nonlinear the problem is, the larger the norm $\left\|Q(x_k)(J(x_k)^T J(x_k))^{-1}\right\|_2$ will be and hence the smaller the limit on β_k will be. The inner iteration of the TGN method must then be solved more accurately to ensure convergence of the algorithm.

4.4. Convergence of the PGN method (I). Next we present sufficient conditions for the PGN method to converge. The theorem is established by considering the PGN method as an IN method for solving the perturbed gradient equation (14). We make the assumptions:

A1′. There exists $\tilde{x}^* \in \mathbb{R}^n$ such that $\tilde{F}(\tilde{x}^*) \equiv \tilde{J}(\tilde{x}^*)^T f(\tilde{x}^*) = 0$;

A2′. The matrix $\tilde{J}(\tilde{x}^*)$ at $\tilde{x}^*$ has full rank n.

We then obtain the theorem.

THEOREM 6. *Let assumptions* A0, A1′, *and* A2′ *hold, and let* $\tilde{F}'(\tilde{x}^*) \equiv \tilde{J}(\tilde{x}^*)^T J(\tilde{x}^*) + \tilde{Q}(\tilde{x}^*)$ *be nonsingular. Assume* $0 \le \hat{\eta} < 1$. *Then there exists* $\varepsilon > 0$ *such that, if* $\|x_0 - \tilde{x}^*\|_2 \le \varepsilon$ *and if*

$$\left\| I - (\tilde{J}(x_k)^T J(x_k) + \tilde{Q}(x_k))(\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1} \right\|_2 \le \eta_k \le \hat{\eta}, \quad k = 0, 1, \ldots, \tag{27}$$

the sequence of perturbed GN iterates $\{x_k\}$ *converges to* $\tilde{x}^*$.

Proof of Theorem 6. We can write the PGN method as an IN method by setting

$$\tilde{r}_k = \tilde{J}(x_k)^T f(x_k) - (\tilde{J}(x_k)^T J(x_k) + \tilde{Q}(x_k))(\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1} \tilde{J}(x_k)^T f(x_k) \tag{28}$$

$$= (I - (\tilde{J}(x_k)^T J(x_k) + \tilde{Q}(x_k))(\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1}) \tilde{J}(x_k)^T f(x_k). \tag{29}$$

Then, provided the condition (27) holds, we have

$$\|\tilde{r}_k\|_2 \le \hat{\eta} \left\| \tilde{J}(x_k)^T f(x_k) \right\|_2, \tag{30}$$

and by Theorem 3 local convergence is guaranteed. ∎

The theorem gives explicit conditions on the perturbed Jacobian $\tilde{J}$ that are sufficient to guarantee the convergence of the PGN method. The requirement is that $\tilde{J}(x)^T \tilde{J}(x)$ should be a good approximation to the derivative $\tilde{F}'(x) = \tilde{J}(x)^T J(x) + \tilde{Q}(x)$ of the perturbed gradient equation (14).

4.5. Fixed point of the PGN method. We now consider how close the solution $\tilde{x}^*$ of the perturbed gradient equation (14) is to the solution x^* of the original NLSP. To answer this question we treat the GN method as a stationary fixed-point iteration of the form (7).

We assume that the GN iteration converges locally to x^* for all x_0 in an open convex set $\mathcal{D}$ containing x^* (defined as in Theorem 1) and that $G(x)$ satisfies

$$\|G(x) - G(x^*)\|_2 \le \nu \|x - x^*\|_2 \quad \forall\, x \in \mathcal{D} \ \text{ with } \ \nu < 1, \tag{31}$$

where $G(x)$ is as given in section 2.1. Then we have the following theorem, which bounds the distance between the solutions of the exact and perturbed iterations.

THEOREM 7. *Let assumptions* A0, A1, A2, A1′, *and* A2′ *hold, and assume* $\varrho < 1$. *Let* (31) *be satisfied. Also let* $\tilde{x}^* \in \mathcal{D}$, *and assume* $J(\tilde{x}^*)$ *is of full rank. Then*

$$\|\tilde{x}^* - x^*\|_2 \le \frac{1}{1-\nu} \left\| (\tilde{J}^+(\tilde{x}^*) - J^+(\tilde{x}^*)) f(\tilde{x}^*) \right\|_2. \tag{32}$$

Proof of Theorem 7. We define $\tilde{G}(x) = x - \tilde{J}^+(x) f(x)$. Then $\tilde{x}^* = \tilde{G}(\tilde{x}^*)$, and we have

$$\begin{aligned} \|\tilde{x}^* - x^*\|_2 &= \left\| \tilde{G}(\tilde{x}^*) - G(x^*) \right\|_2 \\ &\le \left\| \tilde{G}(\tilde{x}^*) - G(\tilde{x}^*) \right\|_2 + \|G(\tilde{x}^*) - G(x^*)\|_2 \\ &\le \nu \|\tilde{x}^* - x^*\|_2 + \left\| \tilde{G}(\tilde{x}^*) - G(\tilde{x}^*) \right\|_2. \end{aligned}$$

Hence, we obtain

$$\begin{aligned}\|\tilde{x}^* - x^*\|_2 &\le \frac{1}{1-\nu}\left\|\tilde{G}(\tilde{x}^*) - G(\tilde{x}^*)\right\|_2 \\ &\le \frac{1}{1-\nu}\left\|(\tilde{J}^+(\tilde{x}^*) - J^+(\tilde{x}^*))f(\tilde{x}^*)\right\|_2. \qquad \square\end{aligned}$$

The theorem shows that the distance between x^* and $\tilde{x}^*$ is bounded in terms of the distance between the pseudoinverses of $\tilde{J}$ and J at $\tilde{x}^*$ and will be small if these are close together. The theorem also implies, from (14), that the bound given in (32) equals $\|J^+(\tilde{x}^*)f(\tilde{x}^*)\|_2/(1-\nu)$, which is proportional to the residual in the true gradient equation (5) evaluated at the solution $\tilde{x}^*$ of the perturbed gradient equation (14).

A different approach to the convergence of the perturbed fixed point iteration can be found in [20, Theorem 12.2.5]. This approach shows essentially that if the GN method converges, then the PGN iterates eventually lie in a small region around x^* of radius $\delta/(1-\nu)$, where δ bounds the distance $\|\tilde{G}(x) - G(x)\|_2$ over all $x \in \mathcal{D}$. This theory does not establish convergence of the perturbed method, but the theory for the distance between the fixed points of the GN and PGN methods presented here is consistent with these results.

4.6. Convergence of the TPGN method (I). We now examine the convergence of the approximate GN method where the Jacobian is perturbed and the inner linear least squares problem is not solved exactly. The residuals in the inner normal equations at each outer iteration are assumed to be bounded such that

$$\|r_k\|_2 \le \beta_k \left\|\tilde{J}(x_k)^T f(x_k)\right\|_2, \tag{33}$$

where $\{\beta_k\}$ is a nonnegative forcing sequence. Sufficient conditions for the convergence of this TPGN method are given by the next theorem.

THEOREM 8. *Let assumptions* A0, A1′, *and* A2′ *hold, and let* $\tilde{F}'(\tilde{x}^*) \equiv \tilde{J}(\tilde{x}^*)^T J(\tilde{x}^*) + \tilde{Q}(\tilde{x}^*)$ *be nonsingular. Assume that* $0 \le \hat{\beta} < 1$, *and select* β_k, $k = 0, 1, \ldots,$ *such that*

$$0 \le \beta_k \le \frac{\hat{\beta} - \left\|I - (\tilde{J}(x_k)^T J(x_k) + \tilde{Q}(x_k))(\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1}\right\|_2}{\left\|(\tilde{J}(x_k)^T J(x_k) + \tilde{Q}(x_k))(\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1}\right\|_2}. \tag{34}$$

Then there exists $\varepsilon > 0$ *such that, if* $\|x_0 - \tilde{x}^*\|_2 \le \varepsilon$, *the sequence of PGN iterates* $\{x_k\}$ *satisfying* (33) *converges to* $\tilde{x}^*$.

Proof of Theorem 8. We can write TPGN in the same form as IN by setting

$$\begin{aligned}\tilde{r}_k = {} & (I - (\tilde{J}(x_k)^T J(x_k) + \tilde{Q}(x_k))(\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1})\tilde{J}(x_k)^T f(x_k) \\ & + (\tilde{J}(x_k)^T J(x_k) + \tilde{Q}(x_k))(\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1} r_k.\end{aligned} \tag{35}$$

Then, provided the condition (33) holds, we have

$$\|\tilde{r}_k\|_2 \le \hat{\beta}\left\|\tilde{J}(x_k)^T f(x_k)\right\|_2, \tag{36}$$

and by Theorem 3 local convergence is guaranteed. $\square$

We remark that in order to ensure $\beta_k \geq 0$ we also require that

$$\left\| I - (\tilde{J}(x_k)^T J(x_k) + \tilde{Q}(x_k))(\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1} \right\|_2 \leq \hat{\beta} < 1,$$

which is simply the sufficient condition found in Theorem 6 for the PGN method to converge.

4.7. Summary. In this section we have established theory ensuring local linear convergence of the GN, the TGN, the PGN, and the TPGN methods based on the theory of [8] for IN methods. Numerical examples illustrating the results for the three approximate GN methods are shown in section 6, and a practical application to data assimilation is presented in section 7. In the next section we derive additional convergence conditions for these methods based on the theory of [9] for exact GN methods.

5. Convergence of approximate GN methods II. We now derive conditions for the convergence of the approximate GN methods by extending the results of [9] for the exact GN method. These results are more restrictive than those given in section 4 but provide more precise estimates of the rates of convergence of the methods. Conditions for linear, superlinear, and quadratic convergence are established.

5.1. Sufficient conditions for the exact GN method. We begin by recalling the sufficient conditions of [9] for local convergence of the GN iterates to a stationary point x^* of the NLSP.

THEOREM 9 (Dennis and Schnabel [9, Theorem 10.2.1]). *Let assumptions* A0, A1, *and* A2 *hold, and let λ be the smallest eigenvalue of the matrix $J(x^*)^T J(x^*)$. Suppose that there exists an open convex set $\mathcal{D}$ containing x^* such that*

(i) *$J(x)$ is Lipschitz continuous in $\mathcal{D}$ with a Lipschitz constant equal to γ;*
(ii) *$\|J(x)\|_2 \leq \alpha$ for all $x \in \mathcal{D}$;*
(iii) *there exists $\sigma \geq 0$ such that $\left\|(J(x) - J(x^*))^T f(x^*)\right\|_2 \leq \sigma \|x - x^*\|_2$ for all $x \in \mathcal{D}$;*
(iv) *$\sigma < \lambda$.*

Let c be such that $1 < c < \lambda/\sigma$. Then there exists $\varepsilon > 0$ such that, if $\|x_0 - x^*\|_2 < \varepsilon$, the iterates $\{x_k\}$ generated by the GN algorithm converge to x^*. Additionally, the following inequality holds:

$$\|x_{k+1} - x^*\|_2 \leq \frac{c\sigma}{\lambda} \|x_k - x^*\|_2 + \frac{c\alpha\gamma}{2\lambda} \|x_k - x^*\|_2^2 . \tag{37}$$

The constant σ may be regarded as an approximation to the norm of the second-order terms $\|Q(x^*)\|_2$ and is a combined measure of the nonlinearity of the problem and the size of the residual [9, section 10.2]. The theorem shows that the convergence of the GN method is quadratic in the case $\sigma = 0$. This holds, for example, for the zero-residual problem where $f(x^*) = 0$.

The sufficient conditions given by Theorem 9 for the local convergence of the GN method are more restrictive than those given in Theorem 1. We demonstrate this as follows.

THEOREM 10. *If the assumptions of Theorem* 9 *hold, then $\varrho < 1$.*

Proof of Theorem 10. By Taylor expansion of the map $x \mapsto J(x)^T f(x^*)$ with respect to x, we find

$$J(x)^T f(x^*) = Q(x^*)(x - x^*) + \|x - x^*\|_2 \, \Theta(x - x^*), \tag{38}$$

with $\lim_{h\to 0}\Theta(h) = 0$. We denote $f(x^*)$, $J(x^*)$, and $Q(x^*)$ by f^*, J^*, and Q^*, respectively. Then multiplying (38) by $(J^{*T}J^*)^{-1}$ on the left yields

$$(J^{*T}J^*)^{-1}J(x)^T f^* = (J^{*T}J^*)^{-1}Q^*(x-x^*) + \|x-x^*\|_2\,\Theta_1(x-x^*), \tag{39}$$

with $\lim_{h\to 0}\Theta_1(h) = 0$. We let v be the right singular vector associated with the largest singular value of $(J^{*T}J^*)^{-1}Q^*$ and let $x_\epsilon = x^* + \epsilon v$ for $\epsilon > 0$. Substituting x_ϵ for x in (39) and rearranging the terms of the equality then gives us

$$\epsilon(J^{*T}J^*)^{-1}Q^*v = (J^{*T}J^*)^{-1}J(x_\epsilon)^T f^* - \epsilon\Theta_1(\epsilon v). \tag{40}$$

By the assumptions of Theorem 9, we have $\left\|J(x_\epsilon)^T f^*\right\|_2 \le \sigma\epsilon$ for ϵ sufficiently small, and therefore

$$\left\|(J^{*T}J^*)^{-1}J(x_\epsilon)^T f^*\right\|_2 \le \left\|(J^{*T}J^*)^{-1}\right\|_2 \sigma\epsilon = \epsilon\sigma/\lambda. \tag{41}$$

Taking norms in (40) and letting ϵ tend to 0 then yields

$$\left\|(J^{*T}J^*)^{-1}Q^*\right\|_2 \le \sigma/\lambda. \tag{42}$$

Since

$$\varrho \le \left\|(J^{*T}J^*)^{-1}Q^*\right\|_2, \tag{43}$$

we obtain $\varrho \le \sigma/\lambda$. Therefore, if $\sigma < \lambda$, then $\varrho < 1$. □

The conditions of Theorem 9 ensure that the conditions of Theorem 1 hold and that the exact GN method converges, but the conditions of Theorem 1 are weaker than those of Theorem 9. Since the quantity $\sigma > \|Q(x^*)\|_2$ can be made arbitrarily close to $\|Q(x^*)\|_2$ in a sufficiently small neighborhood of x^*, the condition $\sigma < \lambda$ can be achieved only if $\|Q(x^*)\|_2 \left\|(J(x^*)^T J(x^*)^T)^{-1}\right\|_2 < 1$, which is a stronger requirement than that of Theorem 1 for convergence (see [12]).

We now extend the theory of Theorem 9 to the approximate GN methods. The results are not as general as those of section 4 but allow the rates of convergence of the methods to be determined.

5.2. Convergence of the TGN method (II). By an extension of Theorem 9, we now establish alternative conditions for the TGN method to converge. We assume, as previously, that the residuals in the TGN method are bounded such that

$$\|r_k\|_2 \le \beta_k \left\|J(x_k)^T f(x_k)\right\|_2, \tag{44}$$

where $\{\beta_k\}$ is a nonnegative forcing sequence.

THEOREM 11. *Let the conditions of Theorem* 9 *hold, and let* c *be such that* $1 < c < \lambda/\sigma$. *Select* β_k, $k = 0, 1, \ldots$, *to satisfy*

$$0 \le \beta_k \le \hat{\beta} < \frac{\lambda - c\sigma}{c(\sigma + \alpha^2)}, \quad k = 0, 1, \ldots. \tag{45}$$

Then there exists $\varepsilon > 0$ *such that, if* $\|x_0 - x^*\|_2 < \varepsilon$, *the sequence of TGN iterates* $\{x_k\}$ *satisfying* (44) *converges to* x^*. *Additionally, the following inequality holds:*

$$\|x_{k+1} - x^*\|_2 \le \frac{c}{\lambda}(\sigma + \beta_k(\sigma + \alpha^2))\,\|x_k - x^*\|_2 + C\,\|x_k - x^*\|_2^2, \tag{46}$$

where $C = \frac{c\alpha\gamma}{2\lambda}(1 + \hat{\beta})$.

Proof of Theorem 11. The proof is by induction. Let $k = 0$, and denote by J_0, f_0, J^*, and f^* the quantities $J(x_0)$, $f(x_0)$, $J(x^*)$, and $f(x^*)$, respectively. From the proof of Theorem 9 (see [9, Theorem 10.2.1]), there exists a positive quantity ε_1 such that, if $\|x_0 - x^*\|_2 < \varepsilon_1$, then $x_0 \in \mathcal{D}$, $J_0^T J_0$ is nonsingular, $\left\|(J_0^T J_0)^{-1}\right\|_2 \leq c/\lambda$, and

$$\left\|x_0 - (J_0^T J_0)^{-1} J_0^T f_0 - x^*\right\|_2 \leq \frac{c\sigma}{\lambda} \|x_0 - x^*\|_2 + \frac{c\alpha\gamma}{2\lambda} \|x_0 - x^*\|_2^2 . \tag{47}$$

Let

$$\varepsilon = \min\left\{\varepsilon_1, \frac{\lambda - c(\sigma + \hat{\beta}(\sigma + \alpha^2))}{c\alpha\gamma(1 + \hat{\beta})}\right\}, \tag{48}$$

where $\lambda - c(\sigma + \hat{\beta}(\sigma + \alpha^2)) > 0$ by (45).

We start from

$$\left\|J_0^T f_0\right\|_2 = \left\|J_0^T f^* + J_0^T (J_0(x_0 - x^*) + f_0 - f^*) - J_0^T J_0 (x_0 - x^*)\right\|_2 \tag{49}$$

and bound successively each term in the norm. From the definitions of σ and α in Theorem 9, we have $\left\|J_0^T f^*\right\|_2 \leq \sigma \|x_0 - x^*\|_2$ and $\left\|J_0^T J_0 (x_0 - x^*)\right\|_2 \leq \alpha^2 \|x_0 - x^*\|_2$. From [9, Lemma 4.1.12] and the Lipschitz continuity of J_0, we also have

$$\|J_0(x_0 - x^*) + f^* - f_0\|_2 \leq \frac{\gamma}{2} \|x_0 - x^*\|_2^2 . \tag{50}$$

Using the triangular inequality then shows that

$$\left\|J_0^T f_0\right\|_2 \leq (\sigma + \alpha^2) \|x_0 - x^*\|_2 + \frac{\alpha\gamma}{2} \|x_0 - x^*\|_2^2 . \tag{51}$$

Gathering the partial results (47) and (51), we obtain

$$\begin{aligned}
\|x_1 - x^*\|_2 &= \left\|x_0 - (J_0^T J_0)^{-1} J_0^T f_0 + (J_0^T J_0)^{-1} r_0 - x^*\right\|_2 \\
&\leq \left\|x_0 - (J_0^T J_0)^{-1} J_0^T f_0 - x^*\right\|_2 + \|r_0\|_2 \left\|(J_0^T J_0)^{-1}\right\|_2 \\
&\leq \left\|x_0 - (J_0^T J_0)^{-1} J_0^T f_0 - x^*\right\|_2 + \beta_0 \left\|(J_0^T J_0)^{-1}\right\|_2 \left\|J_0^T f_0\right\|_2 \\
&\leq \frac{c}{\lambda}(\sigma + \beta_0(\sigma + \alpha^2)) \|x_0 - x^*\|_2 + C \|x_0 - x^*\|_2^2 , \qquad (52)
\end{aligned}$$

where $C = c\alpha\gamma(1+\hat{\beta})/(2\lambda)$, which proves (46) in the case $k = 0$. Since $\|x_0 - x^*\|_2 < \varepsilon$ is assumed initially, it follows from (45) and (48) that

$$\|x_1 - x^*\|_2 \leq \left(\frac{c}{\lambda}(\sigma + \hat{\beta}(\sigma + \alpha^2)) + C\varepsilon\right) \|x_0 - x^*\|_2 \leq K \|x_0 - x^*\|_2 < \|x_0 - x^*\|_2 , \tag{53}$$

where $K = (\lambda + c(\sigma + \hat{\beta}(\sigma + \alpha^2)))/(2\lambda) < 1$. The convergence is then established by repeating the argument for $k = 1, 2, \ldots$. ∎

The theorem shows that to ensure the convergence of the TGN method, the relative residuals in the solution of the inner linear least square problem must be bounded in terms of the parameters σ, λ, and α. The theorem also establishes the rates of convergence of the method in various cases. These cases are discussed in section 5.5.

We remark that the convergence of the TGN method can be established under weaker conditions than we give here, as proved in [10]. Only linear rates of convergence can be derived under the weaker conditions, however, whereas quadratic rates of convergence can be shown in certain cases under the assumptions made here (see section 5.5).

5.3. Convergence of the PGN method (II). In the next theorem we consider the PGN iteration where an approximate Jacobian $\tilde{J}$ is used instead of J.

THEOREM 12. *Let the conditions of Theorem* 9 *hold, and let* $\tilde{J}(x)$ *be an approximation to* $J(x)$. *Let* c *be such that* $1 < c < \lambda/\sigma$. *Assume that*

$$0 \le \hat{\eta} < \frac{\lambda - c\sigma}{c(\sigma + \alpha^2)}. \tag{54}$$

Then there exists $\varepsilon > 0$ *such that, if* $\|x_0 - x^*\|_2 < \varepsilon$ *and if*

$$\left\| J(x_k)^T J(x_k) \left(J^+(x_k) - \tilde{J}^+(x_k) \right) f(x_k) \right\|_2 / \left\| J(x_k)^T f(x_k) \right\|_2 \le \eta_k \le \hat{\eta}, \quad k = 0, 1, \ldots, \tag{55}$$

the sequence of PGN iterates $\{x_k\}$ *converge to* x^*. *Additionally, the following inequality holds:*

$$\|x_{k+1} - x^*\|_2 \le \frac{c}{\lambda}(\sigma + \eta_k(\sigma + \alpha^2)) \|x_k - x^*\|_2 + C \|x_k - x^*\|_2^2, \tag{56}$$

where $C = c\alpha\gamma(1 + \hat{\eta})/(2\lambda)$.

Proof of Theorem 12. The PGN iteration takes the form $x_{k+1} = x_k + s_k$, where $s_k = -\tilde{J}^+(x_k) f(x_k)$. Therefore, using the notation of Theorem 11, we may consider the PGN method as a TGN method with the residual defined by

$$r_k = J(x_k)^T J(x_k) s_k + J(x_k)^T f(x_k) = J(x_k)^T J(x_k)(J^+(x_k) - \tilde{J}^+(x_k)) f(x_k).$$

The conclusion then follows directly from Theorem 11. ∎

We remark that Theorem 12 establishes the convergence of the PGN method to the fixed point x^* of the *exact* GN method. At the fixed point, the perturbed Jacobian $\tilde{J}$ must, therefore, be such that $\tilde{J}(x^*)^T f(x^*) = 0$ in order to be able to satisfy the conditions of the theorem; that is, at the fixed point x^* the null space of $\tilde{J}(x^*)^T$ must contain $f(x^*)$. In contrast the convergence results of Theorem 6 require only that a point $\tilde{x}^*$ exists such that $\tilde{J}(\tilde{x}^*)^T f(\tilde{x}^*) = 0$ and $\tilde{J}(\tilde{x}^*)$ is full rank.

5.4. Convergence of the TPGN method (II). In the following theorem we consider the TPGN iteration where an approximate Jacobian $\tilde{J}$ is used and the inner linear least squares problem (15) is not solved exactly on each outer step. The residuals in the inner normal equations at each outer iteration are assumed to be bounded such that

$$\|r_k\|_2 \le \beta_k \left\| \tilde{J}(x_k)^T f(x_k) \right\|_2, \tag{57}$$

where $\{\beta_k\}$ is a nonnegative forcing sequence. Sufficient conditions for the TPGN method to converge are then given as follows.

THEOREM 13. *Let the conditions of Theorem* 9 *hold, and let* $\tilde{J}(x)$ *be an approximation to* $J(x)$. *Let* c *be such that* $1 < c < \lambda/\sigma$. *Assume that* $\eta_k \le \hat{\eta} < (\lambda - c\sigma)/(c(\sigma + \alpha^2))$, *and select* $\beta_k, k = 0, 1, \ldots,$ *such that*

$$\begin{aligned} 0 \;\le\; \beta_k \le \Big(& \eta_k \left\| J(x_k)^T f(x_k) \right\|_2 - \left\| J(x_k)^T J(x_k)(J^+(x_k) - \tilde{J}^+(x_k)) f(x_k) \right\|_2 \Big) \\ & \cdot \Big(\left\| J(x_k)^T J(x_k)(\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1} \right\|_2 \left\| \tilde{J}(x_k)^T f(x_k) \right\|_2 \Big)^{-1} \end{aligned} \tag{58}$$

for $k = 0, 1, \ldots$. *Then there exists* $\varepsilon > 0$ *such that, if* $\|x_0 - x^*\|_2 < \varepsilon$, *the sequence of PGN iterates* $\{x_k\}$ *satisfying* (57) *converges to* x^*. *Additionally, the following inequality holds:*

$$\|x_{k+1} - x^*\|_2 \leq \frac{c}{\lambda}(\sigma + \eta_k(\sigma + \alpha^2)) \|x_k - x^*\|_2 + C \|x_k - x^*\|_2^2, \tag{59}$$

where $C = c\alpha\gamma(1 + \hat{\eta})/(2\lambda)$.

Proof of Theorem 13. The TPGN iteration takes the form $x_{k+1} = x_k + s_k$, where $s_k = -\tilde{J}^+(x_k)f(x_k) + (\tilde{J}(x_k)^T\tilde{J}(x_k))^{-1}r_k$. Therefore, using the notation of Theorem 11, we may consider the TPGN method as a TGN method with the residual defined as

$$\tilde{r}_k = J(x_k)^T J(x_k)(J^+(x_k) - \tilde{J}^+(x_k))f(x_k) + J(x_k)^T J(x_k)(\tilde{J}(x_k)^T\tilde{J}(x_k))^{-1}r_k. \tag{60}$$

Then, provided the condition (57) holds, we have

$$\begin{aligned} \|\tilde{r}_k\|_2 &\leq \left\|J(x_k)^T J(x_k)(J^+(x_k) - \tilde{J}^+(x_k))f(x_k)\right\|_2 \\ &\quad + \left\|J(x_k)^T J(x_k)(\tilde{J}(x_k)^T\tilde{J}(x_k))^{-1}\right\|_2 \beta_k \left\|\tilde{J}(x_k)^T f(x_k)\right\|_2 \\ &\leq \eta_k \left\|J(x_k)^T f(x_k)\right\|_2. \end{aligned} \tag{61}$$

The conclusion then follows from Theorem 11. ∎

We remark that to ensure $\beta_k \geq 0$ we require that the relation given by equation (55) holds. This is simply the condition of Theorem 12 that guarantees the convergence of the PGN method in the case where the inner loop is solved exactly without truncation.

Theorem 13 gives conditions for the TPGN method to converge to the fixed point x^* of the *exact* GN method and is therefore more restrictive than the theorem developed in section 4. Here the allowable form of the perturbed Jacobian is constrained to satisfy $\tilde{J}(x^*)^T f(x^*) = J(x^*)^T f(x^*) = 0$ in order that the conditions of the theorem may be met. The theorem does, however, establish that the method converges with rates of convergence higher than linear in certain cases. These cases are discussed in the next section.

5.5. Rates of convergence of the approximate GN methods. From Theorems 11, 12, and 13, the expected convergence rates of the approximate GN methods may be established for various cases. The convergence rates are shown in (46), (56), and (59) for the TGN, the PGN, and the TPGN methods, respectively. These rates are dependent on the parameters σ, λ, and α, defined as in Theorem 9, and can be contrasted directly with the convergence rates of the exact GN method, given by (37). We observe the following.

1. *Linear convergence.* The theorems show that in general if the GN, TGN, PGN, and TPGN methods converge, then they converge linearly. In comparison with the exact GN algorithm, we see that the price paid for the inaccurate solution of the linear least squares problem in the inner step of the approximate methods is a degradation of the local linear rate of convergence.
2. *Superlinear convergence.* As previously noted, if $\sigma = 0$, which holds, for example, in the zero-residual case where $f(x^*) = 0$, the convergence of the exact GN method is quadratic [9, Corollary 10.2.2]. In this same case, if $\sigma = 0$ and if the forcing sequence $\{\beta_k\}$ satisfies $\lim_{k\to+\infty} \beta_k = 0$, then the convergence

rates of the approximate TGN and TPGN methods are superlinear. For the PGN method to converge superlinearly in this case, the sequence $\{\eta_k\}$ must satisfy $\lim_{k\to+\infty} \eta_k = 0$.

3. *Quadratic convergence.* From the proof of Theorem 11, we see that the convergence of the TGN method is quadratic if $\sigma = 0$ and if the normal equation residual is such that

$$\|r_k\|_2 \equiv \left\|J(x_k)^T J(x_k) s_k + J(x_k)^T f(x_k)\right\|_2 \leq C_1 \left\|J(x_k)^T f(x_k)\right\|_2^2$$

for some positive constant C_1. Similarly, in the case $\sigma = 0$, the PGN method converges quadratically if

$$\left\|J(x_k)^T J(x_k) \left(J^+(x_k) - \tilde{J}^+(x_k)\right) f(x_k)\right\|_2 \leq C_2 \left\|J(x_k)^T f(x_k)\right\|_2^2,$$

as does the TPGN method in this case if

$$\left\|(J(x_k)^T J(x_k))((J^+(x_k) - \tilde{J}^+(x_k))f(x_k) + (\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1} r_k)\right\|_2 \leq C_3 \left\|J(x_k)^T f(x_k)\right\|_2^2$$

for positive constants C_2, C_3.

4. *Effect of nonlinearity.* Since $\lambda - c\sigma > 0$, we also see from the theorems that the allowable upper bound on the truncation decreases as σ increases. Since σ is a combined measure of the nonlinearity and the residual size in the problem, we see therefore that, in order to guarantee convergence of the approximate methods, the inner linearized equation must be solved more accurately when the problem is highly nonlinear or when there is a large residual at the optimal.

In section 6 we give numerical results demonstrating the convergence behavior of the approximate GN methods. The rates of convergence of the approximate methods are also illustrated for various cases.

5.6. Summary. In this section we have established theory ensuring local convergence of the GN, the TGN, the PGN, and the TPGN methods based on the theory of [9] for exact GN methods. The conditions for convergence derived in this section are less general than those of section 4 but enable the rates of convergence to be established. Numerical examples illustrating the results for the three approximate GN methods are shown in the next section, and in section 7 an application to a practical problem in data assimilation is presented.

6. Numerical example. We examine the theoretical results of sections 4 and 5 using a simple data assimilation problem from [13, Chapter 4]. The aim is to fit the solution of a discrete dynamical model to observations of the model state at two points in time. The system dynamics are described by the ordinary differential equation

$$\frac{dz}{dt} = z^2, \tag{62}$$

where $z = z(t)$. A second-order Runge–Kutta scheme is applied to the continuous equation to give the discrete nonlinear model

$$x^{n+1} = x^n + (x^n)^2 \Delta t + (x^n)^3 \Delta t^2 + \frac{1}{2}(x^n)^4 \Delta t^3, \tag{63}$$

where Δt denotes the model time step and $x^n \approx z(t_n)$ at time $t_n = n\Delta t$. The data assimilation problem is then defined to be

$$\min_{x^0} \phi(x) = \frac{1}{2}(x^0 - y^0)^2 + \frac{1}{2}(x^1 - y^1)^2 \tag{64}$$

subject to (63), where $y^0,\ y^1$ are values of observed data at times $t_0,\ t_1$, respectively. This is a NLSP of the form (1) with

$$f = \begin{pmatrix} x^0 - y^0 \\ x^1 - y^1 \end{pmatrix}. \tag{65}$$

The Jacobian of f is given by

$$J(x^0) = \begin{pmatrix} 1 \\ 1 + 2x^0\Delta t + 3(x^0)^2\Delta t^2 + 2(x^0)^3\Delta t^3 \end{pmatrix}, \tag{66}$$

and the second-order terms of the Hessian are

$$Q(x^0) = \left(x^0 + (x^0)^2\Delta t + (x^0)^3\Delta t^2 + \tfrac{1}{2}(x^0)^4\Delta t^3 - y^1\right)(2\Delta t + 6x^0\Delta t^2 + 6(x^0)^2\Delta t^3). \tag{67}$$

We use this example to test the convergence theory for the approximate GN methods. In the experiments we set the true value of x^0 to -2.5 and begin the iteration with an initial estimate of -2.3 for x^0. The observations are generated by solving the discrete numerical model (63) with the true initial state. The time step is set to $\Delta t = 0.5$. The algorithms are considered to have converged when the difference between two successive iterates is less than 10^{-12}, and we restrict the maximum number of iterations to 1000. We first test the convergence of the TGN algorithm.

6.1. TGN method: Numerical results. The exact GN method is easy to apply to this simple example since we can solve the inner step directly at each iteration. In order to test the theory for the TGN algorithm, we apply an error to the exact GN step and solve instead the approximate equation

$$J(x_k^0)^T J(x_k^0) s_k = -J(x_k^0)^T f(x_k^0) + r_k, \tag{68}$$

where on each iteration we select the size of the residual r_k. We choose

$$r_k = \epsilon \left(\frac{\hat{\beta} - |Q(x_k^0)(J(x_k^0)^T J(x_k^0))^{-1}|}{1 + |Q(x_k^0)(J(x_k^0)^T J(x_k^0))^{-1}|} \right) |\nabla \phi(x_k^0)|, \tag{69}$$

with ϵ a specified parameter and $\hat{\beta} = 0.999$. From Theorem 5 we expect the algorithm to converge to the correct solution for values of ϵ less than 1. In Table 1 we show the results of the iterative process for various levels of truncation. The first and second columns of the table give the values of ϵ chosen for the truncation and the number of iterations taken to reach convergence. The third and fourth columns show the differences between the iterated and true solutions and the gradient of the objective function at the iterated solution, which should be 0 if the true minimum has been reached.

For $\epsilon = 0$ (the exact GN method) the exact solution is found in 5 iterations. As the value of ϵ is increased, the number of iterations to reach convergence also increases. At $\epsilon = 0.95$ the number of iterations needed to achieve convergence is 401, but even for this large truncation, the correct solution to the NLSP is attained, as seen from

the size of the error and gradient values. For a value of $\epsilon = 1.0$ the algorithm fails to converge within 1000 iterations. For values of ϵ greater than 1, the algorithm also converges, but the solution is not correct. With $\epsilon = 1.05$, for example, the stopping criterion is satisfied after 431 iterations, but the final gradient is now of the order 10^{-2}, indicating that a true minimum has not been found. Thus from these results it appears that the bound on the truncation proposed in Theorem 5 is precise. For truncations less than this bound we converge to the correct solution of the NLSP but not for truncations above this bound.

We note that, for this example, if the observations are perfect, then we have a zero-residual NLSP problem. In order to test the theory when this is not the case, we consider an example where the observational data contains errors, as generally occurs in practice. We add an error of 5% to observation y^0 and subtract an error of 5% from observation y^1. The true solution is then calculated by applying the full Newton method to the problem, giving the value $x^0 = -2.5938$ in 7 iterations. (The accuracy of this result is checked by ensuring that the gradient is 0 at the solution.) The convergence results for this test case are shown in Table 2, where the third column is now the difference between the iterated TGN solution and the solution calculated using the exact Newton method.

We see a similar pattern of behavior to that in the perfect observation (zero-residual) case. For all values of ϵ less than 1 the TGN algorithm converges to the same solution as the exact Newton method, but the number of iterations required for

convergence increases as ϵ increases. Where $\epsilon = 1$, the method now converges within the iteration limit to the optimal found by the Newton method. The procedure also converges for values of ϵ greater than 1, but the solution is no longer correct. In these cases the size of the gradient indicates that a minimum has not been found.

6.2. PGN method: Numerical results. In data assimilation, a perturbed Jacobian is often derived by replacing the linearized discrete dynamical model by a simplified discrete form of the linearized continuous system. In this test case we generate a perturbed Jacobian in the same way, following the example of [13]. The linearization of the continuous nonlinear equation (62) is written

$$\frac{d(\delta z)}{dt} = 2z(\delta z), \tag{70}$$

where $\delta z(t)$ is a perturbation around a state $z(t)$ that satisfies the nonlinear equation (62). Applying the second-order Runge–Kutta scheme to this equation gives

$$(\delta x)^{n+1} = \left(1 + 2x^n\Delta t + 3(x^n)^2\Delta t^2 + 3(x^n)^3\Delta t^3 + \tfrac{5}{2}(x^n)^4\Delta t^4 + (x^n)^5\Delta t^5\right)(\delta x)^n, \tag{71}$$

where $(\delta x)^n \approx \delta z(t_n)$ at time $t_n = n\Delta t$ and $x^n \approx z(t_n)$ satisfies the discrete nonlinear model (63). The perturbed Jacobian for this example thus becomes

$$\tilde{J}(x^0) = \begin{pmatrix} 1 \\ 1 + 2x^0\Delta t + 3(x^0)^2\Delta t^2 + 3(x^0)^3\Delta t^3 + \frac{5}{2}(x^0)^4\Delta t^4 + (x^0)^5\Delta t^5 \end{pmatrix}. \tag{72}$$

Using this perturbed Jacobian we apply the PGN algorithm to our example and test whether the sufficient condition (27) for convergence is satisfied on each iteration. For this example the second-order terms $\tilde{Q}$ are given by

$$\begin{aligned}\tilde{Q}(x^0) = &\left(x^0 + (x^0)^2\Delta t + (x^0)^3\Delta t^2 + \tfrac{1}{2}(x^0)^4\Delta t^3 - y^1\right) \\ &\cdot (2\Delta t + 6x^0\Delta t^2 + 9(x^0)^2\Delta t^3 + 10(x^0)^3\Delta t^4 + 5(x^0)^4\Delta t^5).\end{aligned} \tag{73}$$

In the case where we have perfect observations, condition (27) is satisfied on each iteration, and the PGN method converges to the true solution in 27 iterations. When error is added to the observations, as in the previous section, the PGN method converges in 21 iterations, and again, the condition for convergence is always satisfied. Now, however, the NLSP problem is no longer a zero-residual problem, and the fixed points of the GN and PGN methods are no longer the same. The converged solutions differ in the norm by 0.05389, which is within the minimum upper bound $\|J^+(\tilde{x}^*)f(\tilde{x}^*)\|_2 = 0.05425$ on the error (with $\nu = 0$) given by Theorem 7.

In order to examine a case in which the sufficient condition (27) is not satisfied on each iteration, we change the time step to $\Delta t = 0.6$, keeping all other parameters of the problem the same. With this time step the perturbed linear model has significantly different characteristics from the exact linear model (see [13]). The Jacobians J and $\tilde{J}$ are therefore also very different, as are the second derivative matrices Q and $\tilde{Q}$, which are dependent here upon the observations. For perfect observations (zero-residual problem), the PGN iterations converge to the same solution as the exact GN and Newton procedures in 36 iterations (compared with 10 and 7 iterations for the GN and Newton methods, respectively). The condition for convergence of the PGN method is satisfied on each iteration, with the maximum value of the left-hand side of (27) reaching 0.709. In the case where there are errors in the observed values,

TABLE 3
Imperfect observations, inexact Jacobian.

1.25	23	2.085381e+00	2.283791e+00

however, the perturbed problem is no longer close to the NLSP, and the condition for convergence of the PGN method fails on every second iteration. As anticipated in this case, the PGN method fails to converge, even after 1000 iterations. By comparison, the exact GN algorithm, using the true Jacobian, converges in 8 iterations to the same solution of the NLSP as that obtained by Newton's method. This example illustrates the effects of approximations on the convergence properties of the GN method and demonstrates the limits on the convergence of the PGN method as established by the theory of sections 4 and 5.

6.3. TPGN method: Numerical results. Finally in this section we consider the case in which the PGN method is also truncated. Following the same method as in the previous two sections, we solve on each iteration the approximate equation

$$\tilde{J}(x_k^0)^T \tilde{J}(x_k^0) s_k = -\tilde{J}(x_k^0)^T f(x_k^0) + r_k, \tag{74}$$

where we select the residual r_k. We choose

$$r_k = \epsilon \left(\frac{\hat{\beta} - |1 - (\tilde{J}(x_k)^T J(x_k) + \tilde{Q}(x_k))(\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1}|}{|(\tilde{J}(x_k)^T J(x_k) + \tilde{Q}(x_k))(\tilde{J}(x_k)^T \tilde{J}(x_k))^{-1}|} \right) |\nabla \phi(x_k^0)|, \tag{75}$$

where ϵ is a specified parameter and $\hat{\beta} = 0.999$. The other data are as before, with errors added to the observations. From Theorem 8 we expect the method to converge for values of $\epsilon < 1$. The true solution is calculated by applying the exact Newton method to the perturbed problem, giving a result in 5 iterations of $x^0 = -2.6477$. In Table 3 we present the convergence results for the TPGN method using various levels of truncation. The third column now shows the difference between the TPGN solution and the exact Newton method applied to the perturbed problem, and the fourth column gives the residual in the perturbed equation (14). We find that, as expected from the theory, the TPGN algorithm converges to the correct solution for values of $\epsilon < 1$. For values of $\epsilon > 1$ the algorithm converges to an incorrect solution. Thus it appears that the bound derived in Theorem 8 is robust.

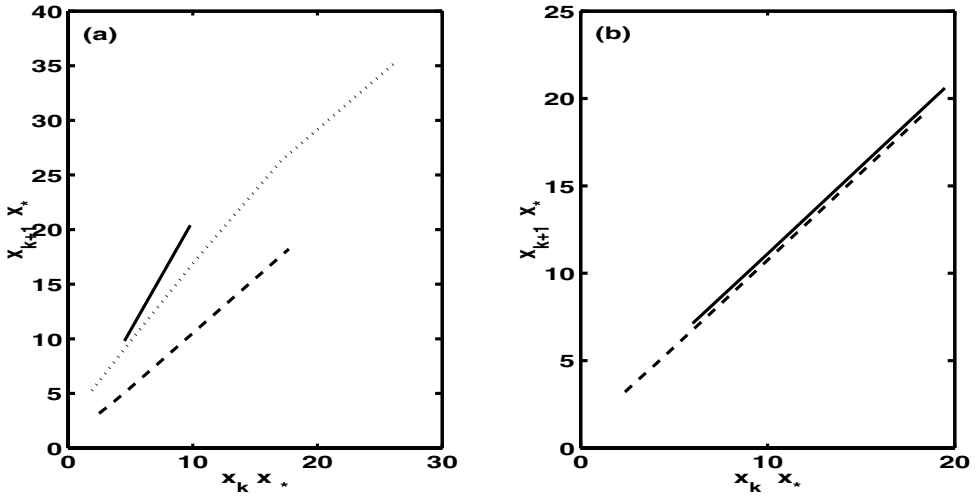

FIG. 1. *Convergence rates for the cases of* (a) *an exact Jacobian and* (b) *a perturbed Jacobian for the zero-residual case. The solid line is for no truncation; the dashed line is for constant truncation; and the dotted line in plot* (a) *is for variable truncation.*

6.4. Rates of convergence. Finally we test numerically the convergence rates derived in section 5. We examine the zero-residual problem for the numerical example with perfect observations. The convergence is measured in terms of the norms of the errors on each iteration. If the convergence is of order p, then

$$\| x_{k+1} - x^* \|_2 = K \| x_k - x^* \|_2^p \quad \text{for some constant } K, \tag{76}$$

where x^* is the exact fixed point. The plot of $|\log(\| x_{k+1} - x^* \|_2)|$ against $|\log(\| x_k - x^* \|_2)|$ will therefore have slope p.

In Figure 1(a) we plot this slope for the case where the exact Jacobian is used. Three curves are shown corresponding to the exact GN method, the TGN method with constant truncation, and the TGN method with $\beta_k \to 0$. From the theory of section 5 we expect the rates of the convergence for these cases to be quadratic, linear, and superlinear. We find that this is the case. For the exact GN method the slope of the line in the figure is 1.97, and for the TGN method it is 0.98. For the case in which the truncation tends to 0, the slope is 0.96 on the upper part of the line, which corresponds to the initial iterations, but steepens to 1.5 on the lower part of the line, demonstrating the superlinear nature of the convergence.

In Figure 1(b) the slope is plotted for the case where the perturbed Jacobian is used. We show the convergence for the PGN method with no truncation and the TPGN method with constant truncation. From the previous theory we expect both of these to have linear convergence. The numerical results show that this is the case, with both lines in the figure having a slope of one.

We conclude from these studies that the theoretical results of sections 4 and 5 predict the convergence behavior of the approximate GN methods reliably and robustly.

7. Application to data assimilation. We now consider the application of the approximate GN theory to a more realistic problem in atmosphere and ocean data assimilation. In the technique of 4D-Var the aim is to find an initial state x_0 at time

t_0 such that the distance between the trajectory of the numerical model of the system initiated from state x_0 and a set of observations of the system at times $t_i, i = 0, \ldots, N$, is minimized. In practice other constraints may also be added to the system so as to ensure, for example, that the state x_0 lies close to an a priori estimate. These constraints are not needed, however, in order to illustrate the theory developed here. We therefore express the 4D-Var problem in the form

$$\min_{x_0} \mathcal{J}[x_0] = \frac{1}{2} \sum_{i=0}^{N} (H_i[x_i] - y_i)^T R_i^{-1} (H_i[x_i] - y_i) \tag{77}$$

subject to $x_i = S(t_i, t_0, x_0)$, where S is the solution operator of the discrete nonlinear model, H_i is an operator that maps the model state into the p_i-dimensional vector of observations y_i at time t_i, and R_i is a weighting matrix given by the error covariance matrix of the observations at time t_i. This is an NLSP of the form (1) with

$$f(x_0) = - \begin{pmatrix} R_0^{1/2}(H_0[x_0] - y_0) \\ \vdots \\ R_N^{1/2}(H_N[x_N] - y_N) \end{pmatrix}, \tag{78}$$

where we note that the definition of $f(x_0)$ implicitly involves the nonlinear model operators $S(t_i, t_0, x_0)$ for calculating the states of the system x_i at the different observation times. In atmospheric data assimilation the size of the state vector x is very large, of order 10^7–10^8, and so efficient methods for minimizing (77) must be found. A common implementation of 4D-Var is the incremental formulation of [6], which minimizes a series of linear approximations to (77). Recently we have shown this to be equivalent to applying a GN method to the nonlinear problem (77) [14, 15].

7.1. Model problem. To illustrate the theory we examine a 4D-Var assimilation problem for a simplified model of fluid flow over an obstacle. The system is described by the one-dimensional nonlinear shallow water equations in the absence of rotation given by

$$\frac{\mathrm{D}u}{\mathrm{Dt}} + \frac{\partial \phi}{\partial \xi} = -g \frac{\partial \bar{h}}{\partial \xi}, \tag{79}$$

$$\frac{\mathrm{D}(\ln \phi)}{\mathrm{Dt}} + \frac{\partial u}{\partial \xi} = 0, \tag{80}$$

with

$$\frac{\mathrm{D}}{\mathrm{Dt}} = \frac{\partial}{\partial t} + u \frac{\partial}{\partial \xi}. \tag{81}$$

In these equations u is the wind velocity; $\phi = gh$ is the geopotential, where g is the gravitational constant; $h > 0$ is the height of the fluid above the topography; and $\bar{h}$ is the height of the underlying topography. We define the problem on a spatial domain $\xi \in [0, L]$ with periodic boundary conditions. The system is discretized using a two-time-level semi-implicit semi-Lagrangian integration scheme, as described in [16]. This is a similar numerical scheme to that commonly used in operational weather forecasting models (see, for example, [5, 7]).

We note that to apply the GN method to (77) we require the Jacobian of the function f, which includes the linearization of the discrete nonlinear model operator

S. This linear operator is known as the tangent linear model and is usually found by a direct linearization of the discrete nonlinear model, using the procedure of automatic differentiation [1]. An alternative method of generating the linear model is first to linearize the continuous nonlinear equations (79) and (80) and then to discretize the resulting linear equations. This is the method that the UK Met Office has used to develop the linear model for their operational assimilation scheme [18]. In general this method will usually give a discrete model that is not the exact linearization of the discrete nonlinear model. Thus when this model is used within the GN iteration, we have only an approximate Jacobian $\tilde{J}$. The theory for the PGN method then applies.

To demonstrate this technique with the shallow water model, we let $\delta u(\xi, t)$, $\delta\phi(\xi, t)$ denote perturbations around states $\bar{u}(\xi, t)$, $\bar{\phi}(\xi, t)$ that satisfy the nonlinear equations. Then substituting into (79) and (80) gives the linearized equations

$$\frac{\mathrm{D}(\delta u)}{\mathrm{Dt}} + (\delta u)\frac{\partial \bar{u}}{\partial \xi} + \frac{\partial(\delta\phi)}{\partial \xi} = 0, \tag{82}$$

$$\frac{\mathrm{D}}{\mathrm{Dt}}\Big(\frac{\delta\phi}{\bar{\phi}}\Big) + (\delta u)\frac{\partial(\ln\bar{\phi})}{\partial \xi} + \frac{\partial(\delta u)}{\partial \xi} = 0, \tag{83}$$

where

$$\frac{\mathrm{D}}{\mathrm{Dt}} = \frac{\partial}{\partial t} + \bar{u}\frac{\partial}{\partial \xi} \tag{84}$$

is the material derivative defined with the linearization state wind $\bar{u}$. These equations are discretized using a semi-implicit semi-Lagrangian scheme, similar to that used in the full nonlinear model. Full details of the resulting numerical scheme are given in [16], where it is also shown that this scheme is different from that of the tangent linear model.

To solve the inner step of the GN method, a conjugate gradient iterative minimization is applied to the exact or perturbed linear least squares problem (6) or (15). The gradient directions are determined using the adjoints of the discrete linear model equations. We note that, in the case where the inexact linear model is used, this procedure generates the perturbed gradient $\tilde{J}(x)^T f(x)$, as required by the iteration method, rather than the exact gradient $J(x)^T f(x)$.

The inner iteration is stopped when the relative residual, defined as in (11) or (16), falls below a specified tolerance. If the minimization is stopped before full convergence, then the theory derived in sections 4 and 5 for the convergence of the TGN or TPGN method applies. For a complex model such as this, it is not possible to calculate the tolerances on the residuals required by the theory. The convergence results do, however, provide a theoretical basis for a practical inner loop stopping criterion that leads to smoother convergence of the outer loops and more efficient algorithms for solving the data assimilation problem, as described in [17]. Suitable tolerances are found experimentally, and the inner loop is stopped when the relative change in the gradient of the linear least squares problem, which is equal to the relative residual, is below the selected tolerance.

We perform idealized assimilation experiments in which the observations are generated by the nonlinear model, starting from a known initial state that we define to give the truth. These observations are then used in the assimilation, which is started from an incorrect prior estimate of the state. Further details of the implementation of the assimilation scheme can be found in [14]. Assimilation experiments are performed

with the exact linear model (and hence exact Jacobian) and with the inexact linear model (perturbed Jacobian). We consider the cases of both perfect observations, which imply a zero-residual problem, and observations with random Gaussian error added, which lead to a nonzero residual. We see that in practice the convergence behavior of the approximate GN methods is as predicted by the theory established in sections 4 and 5.

7.2. Numerical results. For the numerical experiments we consider a periodic domain of 200 grid points with a spacing of $\Delta\xi = 0.01$ m, so that $\xi \in [0\text{ m}, 2\text{ m}]$. In the center of the domain we define an idealized mountain by the formula

$$\bar{h}(\xi) = \bar{h}_c \left(1 - \frac{\xi^2}{a^2}\right) \quad \text{for} \quad 0 < |\xi| < a \tag{85}$$

and $\bar{h}(\xi) = 0$, otherwise, where we choose $\bar{h}_c = 0.05$ m and a is taken to be $40\Delta\xi = 0.4$ m. The gravitational constant g is set to be 10 ms^{-2}, and the model time step is 9.2×10^{-3} s.

Idealized observations of both u and ϕ are taken at every spatial grid point ξ_j, $j = 1, \ldots, 200$, over a time window of 50 steps. This gives a state vector of dimension $n = 400$ with $p_i = 400$ observations of the states at all grid points at times t_i, $i = 0, \ldots, 50$. The function f is thus of dimension $m = 20400$. The observations are assimilated using the GN or PGN method, starting from an incorrect prior estimate, which is generated by adding a phase shift of 0.5 m to the true initial state. The outer iteration is stopped when the norm of the gradient or the perturbed gradient, defined as in (5) or (12), respectively, is less than a given tolerance. The tolerance is set to 0.005 in the case of perfect observations and to 0.05 in the case where random errors have been added to the observations.

The inner minimization loop is stopped when the relative change in the gradient of the linear least squares problem falls below tolerances of 0.1 and 0.9. For a tolerance of 0.1 we find that the inner loop is fully converged and choosing a value several orders of magnitude lower than this does not change the convergence of the GN or PGN iterations. Thus we can consider this case as the method without truncation. The value of 0.9 on the other hand corresponds to a severely truncated method. In the zero-residual case for the exact Jacobian, we also perform a variable truncation experiment in which the truncation tolerance is initially set to 0.9 but is halved on each new GN iteration.

We consider first the case where we have exact observations of the true solution, so that the NLSP has a zero residual. In Figure 2 we plot the values of the nonlinear cost function (77) and the gradient, or perturbed gradient, for each iterative procedure. We observe that the fastest convergence is obtained when using the exact Jacobian with no truncation, as we expect from the theory. When the truncation level is increased, then the convergence rate slows down. (We remark that as the tolerance level is increased, however, less work is needed per iteration.) From Figure 2 we see also that if the tolerance tends to 0 as the iterations proceed, then the convergence rate increases. This behavior is expected from the theory, which predicts superlinear convergence in this case.

When the perturbed Jacobian is used, the convergence rate is found to be the same or slightly slower than when using the exact Jacobian, depending on whether truncation is applied or not. In general for the perturbed Jacobian with no truncation, this rate is faster than we would expect from the theory, which predicts only linear convergence. As we showed in section 5.5, however, the PGN method can converge

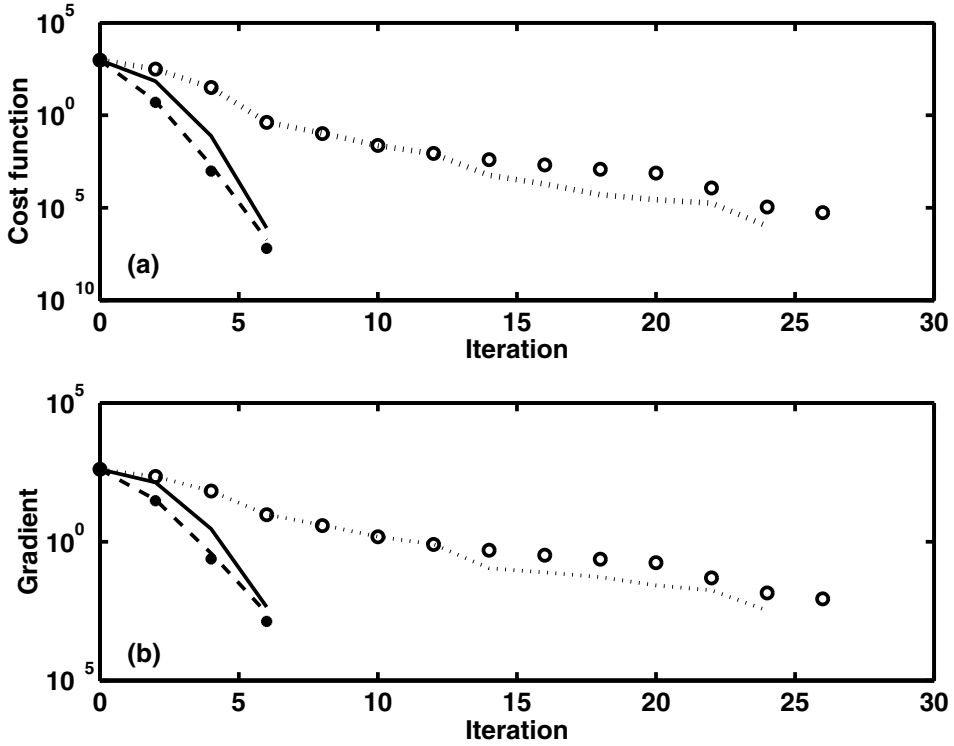

FIG. 2. *Convergence of the* (a) *cost function and* (b) *gradient, or perturbed gradient, for the perfect observation case. The different lines are for the exact Jacobian with no truncation (dashed line), with truncation (dotted line), and with variable truncation (solid line). The symbols indicate the convergence for the perturbed Jacobian with no truncation (solid dots) and with truncation (circles).*

quadratically for the zero-residual problem if the perturbed and exact Jacobians are close to each other. This can explain the fast convergence with the inexact Jacobian in this case.

For the experiments with imperfect observations, the observational errors for u and ϕ are taken from a Gaussian distribution, with standard deviations equal to 5% of the mean value of each field. The rates of convergence for these experiments are shown in Figure 3. In this case the solution does not fit the observations exactly, and we have a nonzero-residual problem. The fixed points of the exact GN and the PGN iterations are not the same now and differ in the norm by 0.01425. This difference is within the minimum upper bound $\|J^+(\tilde{x}^*)f(\tilde{x}^*)\|_2 = 0.01608$ on the error (with $\nu = 0$) predicted by Theorem 7.

For the nonzero-residual problem we expect linear convergence for all cases and so we do not show a variable truncation run. If we examine the convergence for the exact Jacobian, we again find that, where truncation is used on the inner minimization, the convergence rate slows down in comparison with the case where the inner problem is solved exactly. However, the difference is less marked than in the zero-residual case. This is as expected from Theorem 11, which predicts linear convergence for both of these cases, but with the rate constant increasing with the degree of truncation. When the inexact Jacobian is used we see that, as for the perfect observation case, the convergence is very close to that using the exact Jacobian.

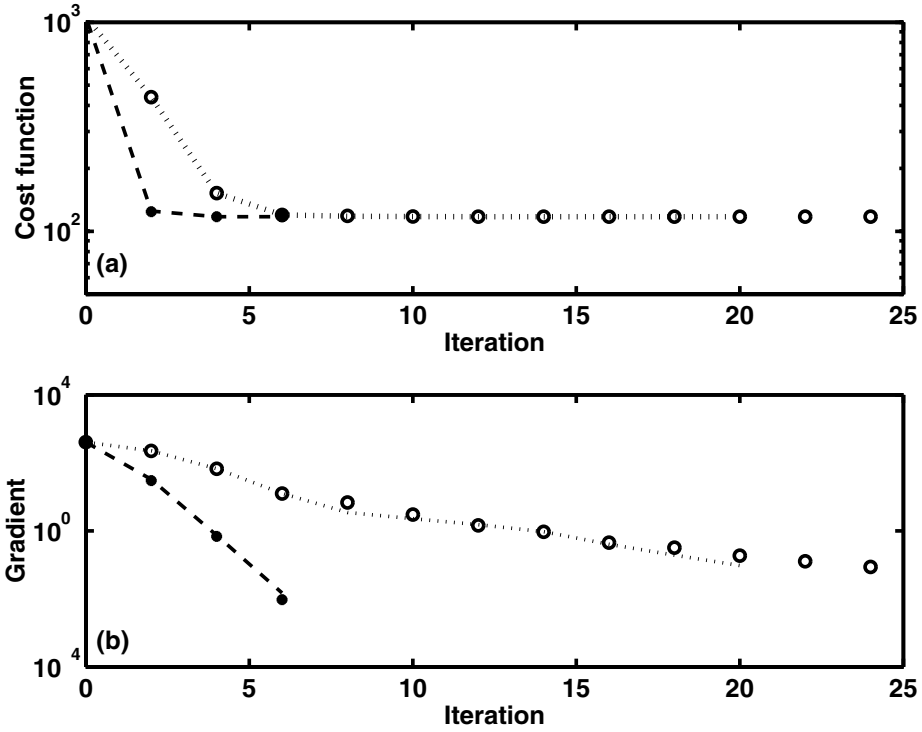

FIG. 3. *Convergence of the* (a) *cost function and* (b) *gradient, or perturbed gradient, for the imperfect observation case. The lines are for the exact Jacobian with no truncation (dashed line) and with truncation (dotted line). The symbols indicate the convergence for the perturbed Jacobian with no truncation (solid dots) and with truncation (circles).*

8. Conclusions. We have described here three approximate GN methods, the TGN, the PGN, and the TPGN methods, for solving the NLSP. We have derived conditions for the local linear convergence of these approximate methods by treating them as IN methods, following the theory of [8]. Additional, more restricted, convergence results have been derived for the approximate methods by extending the theory of [9] for the exact GN method. Through this approach, higher-order rates of convergence have been established for the approximate methods. We remark that many of these results could be generalized to hold under weaker assumptions than we have made here. The theory for IN methods could also be applied to give results on higher convergence rates for the approximate methods (see [4] and [8]).

In practice the approximate GN methods are used to treat very large data assimilation problems arising in atmosphere and ocean modeling and prediction. The convergence properties of these algorithms have not previously been investigated. Here we have established sufficient conditions for convergence to hold, allowing the approximate methods to be used operationally with confidence. By a simple numerical example we have shown that the bounds established by the theory are precise, in a certain sense, and that the approximate methods are convergent if the conditions of the theory hold. We have also demonstrated the application of the theory to a data assimilation problem for a typical model of a meteorological system.

REPRESENTATION OF SETS OF LATTICE POINTS*

RAYMOND HEMMECKE† AND ROBERT WEISMANTEL†

Abstract. Original algorithmic approaches in integer programming rely on the availability of different representations for all the lattice points in the feasible region. We present three results that are applicable to fairly general sets of lattice points and characterize a nonnegative integer linear representation.

Key words. integral generating set, Hilbert basis, representation, lattice, optimality certificate

AMS subject classification. 90C10

DOI. 10.1137/040616474

1. Introduction.

A fundamental theorem for the theory of linear integer optimization states that for every rational polyhedral cone C there exists a finite subset H of the set of integer points in C such that every integer point in C can be represented as a nonnegative linear integer combination of elements in H. This result follows from the work of Gordan [3]; see also [7, 8]. It has applications in many scenarios for linear integer programming. In particular, it is important for

- proving finiteness results in cutting plane theory [7],
- showing the existence of totally dual integral systems of linear diophantine systems [2],
- deriving optimality conditions for linear integer optimization problems [4],
- designing integer simplex type methods based on reformulation techniques [5].

In this paper it is our goal to extend this result to general sets of lattice points. Here, and throughout the paper, $\mathbb{Z}_+$ denotes the nonnegative integer numbers. For a set $P \subseteq \mathbb{R}^n$ we denote by

$$\text{recCone}(P) := \{\delta \in \mathbb{R}^n : \exists x \in P \text{ such that } x + \lambda\delta \in P \text{ for all } \lambda \geq 0\}$$

the recession cone of P. Moreover, for $S \subseteq \mathbb{Z}^n$, we call $T \subseteq S$ an *integral generating set* of S if for every $s \in S$ there exists a finite (integer) linear combination $s = \sum \alpha_i t_i$ with $t_i \in T$ and $\alpha_i \in \mathbb{Z}_+$.

It follows immediately that not every set S has a finite integral generating set. The following general result establishes necessary and sufficient conditions for a given rational polyhedral cone $C = \text{cone}(V)$ such that a finite nonnegative integer representation of S with elements in $S \cup C$ is possible.

The result can be used to determine a minimal number of vectors V that have to be added to a given set S to guarantee the existence of an integral generating set of S.

THEOREM 1.1.

(a) *Let $S \subseteq \mathbb{Z}^n$, and let $C = \operatorname{cone}(v_1, \ldots, v_m) \subseteq \mathbb{R}^n$ be a rational polyhedral cone. Then there exists a polytope $Q \subseteq \mathbb{R}^n$ with $S \subseteq Q + C$ if and only if there exists a finite set $H \subseteq S$ such that every $s \in S$ can be written as*

$$s = h + \sum_{j=1}^{m} \alpha_j v_j$$

for some $h \in H$ and with $\alpha_j \in \mathbb{Z}_+$, $j = 1 \ldots, m$.

(b) *Every nonempty set $S \subseteq \mathbb{Z}^n$ possesses a finite integral generating set if and only if the following two conditions hold:*
   - *The recession cone* $\operatorname{recCone}(\operatorname{conv}(S))$ *of* $\operatorname{conv}(S)$ *is a rational polyhedral cone.*
   - $\operatorname{recCone}(\operatorname{conv}(S)) \setminus \operatorname{conv}(S)$ *contains only finitely many lattice points.*

As a consequence of Theorem 1.1, we recover a few nice and well-known facts.

COROLLARY 1.2 (Giles and Pulleyblank [2]). *For every nonempty rational polyhedron $P \subseteq \mathbb{R}^n$, there exist a rational polytope $Q \subseteq \mathbb{R}^n$ and a rational polyhedral cone $C \subseteq \mathbb{R}^n$ such that $P \cap \mathbb{Z}^n = (Q \cap \mathbb{Z}^n) + (C \cap \mathbb{Z}^n)$.*

Proof. By Weyl's theorem, every rational polyhedron P can be written as the Minkowski sum of a polytope Q and the recession cone C of P. Thus, $S = P \cap \mathbb{Z}^n \subseteq Q + C$. From the first part of Theorem 1.1 we now get a desired representation $S = P \cap \mathbb{Z}^n = (\operatorname{conv}(H) \cap \mathbb{Z}^n) + (C \cap \mathbb{Z}^n)$. ∎

COROLLARY 1.3 (Jeroslow [6]). *A monoid $M \subseteq \mathbb{Z}^n$ has a finite (integral) generating set if and only if $C = \operatorname{cone}(M)$ is a rational polyhedral cone.*

Proof. If $C = \operatorname{cone}(M)$ is a rational polyhedral cone, then there exist finitely many elements $v_1, \ldots, v_m \in M$ that generate C. Therefore, we have $M \subseteq \{0\} + \operatorname{cone}(v_1, \ldots, v_m)$ and consequently, by the first part of Theorem 1.1, there exists a finite generating set $H \cup \{v_1, \ldots, v_m\}$ for M. The reverse direction is trivial, since any basis of M forms a generating set for $C = \operatorname{cone}(M)$. If the basis is finite, C is a rational polyhedral cone. ∎

As a generalization of Jeroslow's theorem one obtains the following statement, in which we do not assume a structure on the set S of lattice points.

COROLLARY 1.4. *Let $S \subseteq \mathbb{Z}^n$ be any set of lattice points in $\mathbb{Z}^n$. Then the following statements are equivalent:*

(1) *S has a finite integral generating set.*
(2) *$\operatorname{cone}(S)$ has a finite integral generating set.*
(3) *$\operatorname{conv}(S)$ has a finite integral generating set.*

Proof. (1) ⇔ (2): It is easy to see that S has a finite integral generating set if and only if the monoid generated by S has a finite integral generating set. The result follows now from Corollary 1.3 and by the fact that a polyhedral cone C possesses a finite integral generating set (Hilbert basis) if and only if C is rational [2].

(1) ⇒ (3): Let $V \subseteq S$ be a finite integral generating set for S. Then $\operatorname{cone}(S) = \operatorname{cone}(V)$ is a rational polyhedral cone and $\operatorname{conv}(S) \subseteq \{0\} + \operatorname{cone}(S) = \{0\} + \operatorname{cone}(V)$. Now, part (a) of Theorem 1.1 implies that there is some finite set $H \subseteq \operatorname{conv}(S) \cap \mathbb{Z}^n$ such that $H \cup V$ forms a finite integral generating set of $\operatorname{conv}(S)$.

(3) ⇒ (2): Let $V \subseteq \operatorname{conv}(S)$ be a finite integral generating set of $\operatorname{conv}(S)$. Then we conclude that $\operatorname{cone}(S) = \operatorname{cone}(\operatorname{conv}(S)) = \operatorname{cone}(V)$ is a rational polyhedral cone and thus possesses a finite integral generating set. ∎

Part (b) of Theorem 1.1 is an extension of the following result by using the equivalence (1) ⇔ (3) of Corollary 1.4.

COROLLARY 1.5 (Bertsimas and Weismantel [1]). *For $A \in \mathbb{Z}^{d\times n}$ and $b \in \mathbb{Z}^d$, define the sets $P = \{x \in \mathbb{R}^n_+ : Ax \le b\}$, $S = P \cap \mathbb{Z}^n$, and $C = \{x \in \mathbb{R}^n_+ : Ax \le 0\}$. If S is not empty, there exists a finite integral generating set of S if and only if S contains all but finitely many integer points in $C \cap \mathbb{Z}^n$.*

Theorem 1.1 allows us to classify arbitrary sets $S \subseteq \mathbb{Z}^n$ according to the minimum number of vectors $v_1, \dots, v_r \in \mathbb{Z}^n$ *not* in S such that $\text{cone}(S \cup \{v_1, \dots, v_r\})$ is a rational polyhedral cone. We call this number the polyhedral defect of $\text{cone}(S)$ or simply of S. Note that the polyhedral defect is always between 0 and $n+1$, since $n+1$ is the conic dimension of $\mathbb{R}^n$. Sets S have a polyhedral defect of 0 if and only if $\text{cone}(S)$ is rational and polyhedral.

It is an interesting open question to characterize all those sets $S \subseteq \mathbb{Z}^n$ that have a given polyhedral defect. As a subproblem, we would find it interesting to devise an algorithm that determines the polyhedral defect for sets $S = P \cap \mathbb{Z}^n$, where P is a given rational polyhedron.

If S is the set of integer points in a semialgebraic set, then Theorem 1.1 can be applied only if we know a polytope Q and a rational polyhedral cone C with $S \subseteq Q + C$. It is, however, a nontrivial task to determine such a cone C generated only by a minimal number of generators not belonging to S. This raises the question of whether there exist other representations for $x \in S$ of the kind

$$x = s_x + v_x,$$

where $s_x \in S$ and $v_x \in V$, where V is not necessarily of the form

$$V = \left\{ v \in \mathbb{Z}^n : v = \sum_{i=1}^{m} \alpha_i v_i, \alpha_i \in \mathbb{Z}_+, i = i, \dots, m \right\}$$

as in Theorem 1.1.

For a quite general family of semialgebraic sets, such a representation is possible. Interestingly, when the semialgebraic set describes a rational polyhedral cone, our proof recovers finiteness of a Hilbert basis.

THEOREM 1.6. *Let $\mathcal{C} := \{x \in \mathbb{R}^n : \exists y \ge 0$ with $x = g(y)\}$ be a semialgebraic set, where $g : \mathbb{R}^d \to \mathbb{R}^n$ is a vector of polynomial functions that map integer vectors to integers. There exist two vectors of polynomial functions $g_l, g_u : \mathbb{R}^n \to \mathbb{R}^n$ with $\text{maxdeg}(g_l), \text{maxdeg}(g_u) < \text{maxdeg}(g)$ such that for every point $x \in S = \mathcal{C} \cap \mathbb{Z}^n$ there exist a $\lambda \in \mathbb{Z}^d_+$ and a point $v_x \in \mathbb{Z}^n$ satisfying $x = g(\lambda) + v_x$ and $g_l(\lambda) \le v_x \le g_u(\lambda)$.*

2. Proofs of main theorems.

Proof of Theorem 1.1. If there exists a finite set $H \subseteq S$ such that every $s \in S$ can be written as

$$s = h + \sum_{j=1}^{m} \alpha_j v_j$$

for some $h \in H$ and with $\alpha_j \in \mathbb{Z}_+$, $j = 1 \dots, m$, then we have $S \subseteq \text{conv}(H) + C$.

It remains to show that given a polytope $Q \subseteq \mathbb{R}^n$ with $S \subseteq Q + C$, there exists a representation as desired.

First, note that $S \subseteq Q + C$ implies

$$S \subseteq \bigcup_{q \in Q \cap \mathbb{Z}^n} (q + C).$$

Next, let us triangulate C into (finitely many!) rational simplicial cones $C_1, \ldots, C_l$. Note that we can and do choose such a triangulation for which the generators of the cones C_i are also among the generators $v_1, \ldots, v_m$ of C. Then

$$S \subseteq \bigcup_{q \in Q \cap \mathbb{Z}^n} \bigcup_{i=1}^{l} (q + C_i).$$

We now construct a desired representation for each of the sets $(q + C_i) \cap S$. Without loss of generality, we assume $C_i = \operatorname{cone}(v_1, \ldots, v_r)$ (otherwise relabel the v_i). Consider the parallelepiped

$$F_i = \left\{ \sum_{j=1}^{r} \alpha_j v_j : 0 \leq \alpha_1, \ldots, \alpha_r < 1 \right\}.$$

As F_i is bounded, F_i contains only finitely many lattice points $\{f_1, \ldots, f_t\}$ in $\mathbb{Z}^n$. Moreover, $(q + C_i) \cap \mathbb{Z}^n$ is the disjoint union of the following t sets $F_{i,1}, \ldots, F_{i,t}$ with

$$F_{i,j} = \left\{ q + f_{i,j} + \sum_{k=1}^{r} \alpha_k v_k : \alpha_1, \ldots, \alpha_r \in \mathbb{Z}_+ \right\}.$$

Thus, it suffices to construct a desired representation for each of the sets $F_{i,j} \cap S$. If $q + f_{i,j} \in S$, we have already found a desired representation of the points $F_{i,j} \cap S$. Thus assume on the contrary that $q + f_{i,j} \notin S$. We construct now a finite set $H_{i,j} \subseteq S$ such that every $s \in F_{i,j} \cap S$ can be written as

$$s = h + \sum_{j=1}^{r} \alpha_j v_j$$

for some $h \in H_{i,j}$ and with $\alpha_j \in \mathbb{Z}_+$, $j = 1 \ldots, m$, as desired.

As C_i is a simplicial cone, each point in $F_{i,j}$ has a unique representation as $q + f_{i,j} + \sum_{k=1}^{r} \alpha_k v_k$, implying that there is a one-to-one correspondences $\phi_{i,j}$ between $F_{i,j}$ and $\mathbb{Z}_+^r$ given by

$$\phi_{i,j}\left(q + f_{i,j} + \sum_{k=1}^{r} \alpha_k v_k \right) = (\alpha_1, \ldots, \alpha_r).$$

Consider the set $\phi_{i,j}(F_{i,j} \cap S) \subseteq \mathbb{Z}_+^r$. By the Gordan–Dickson lemma [3], there are only finitely many points $\{g_1, \ldots, g_p\}$ that are minimal with respect to the partial ordering $\leq$ defined on $\mathbb{Z}_+^r$. Let $H_{i,j} = \{\phi_{i,j}^{(-1)}(g_1), \ldots, \phi_{i,j}^{(-1)}(g_p)\} \subseteq S$. Thus, for every element $s \in F_{i,j} \cap S$ there exists some $g \in \{g_1, \ldots, g_p\}$ with $g \leq \phi_{i,j}(s)$, implying that $s = \phi_{i,j}^{(-1)}(g) + \sum_{k=1}^{r} \alpha_k v_k$ for $\phi_{i,j}^{(-1)}(g) \in H_{i,j}$ and $\alpha_k = (\phi_{i,j}(s) - g)^{(k)} \in \mathbb{Z}_+$, $k = 1, \ldots, r$. □

Proof of Theorem 1.6. Choose any $x \in S := \mathcal{C} \cap \mathbb{Z}^n$. Then $x = g(y)$ for some $y \in \mathbb{R}_+^n$. Now define $\lambda := \lfloor y \rfloor$ componentwise and let $v_x = x - g(\lambda)$ and $h = y - \lambda$. We will now construct functions $g_l : \mathbb{R}^n \to \mathbb{R}^n$ and $g_u : \mathbb{R}^n \to \mathbb{R}^n$, with the desired properties.

Let $D = \operatorname{maxdeg}(g)$. By multivariate Taylor expansion, we get for $j = 1, \ldots, n$

$$x^{(j)} = g^{(j)}(\lambda + h) = g^{(j)}(\lambda) + \sum_{i=1}^{D} \frac{1}{i!} \cdot \sum_{\substack{\alpha \in \mathbb{Z}_+^n : \\ \|\alpha\|_1 = i}} \frac{\mathrm{d}g^{(j)}(\lambda)}{\mathrm{d}x^{\alpha}} \cdot h^{\alpha}.$$

Therefore,

$$v_x^{(j)} = x^{(j)} - g^{(j)}(\lambda) = \sum_{i=1}^{D} \frac{1}{i!} \cdot \sum_{\substack{\alpha \in \mathbb{Z}_+^n : \\ \|\alpha\|_1 = i}} \frac{\mathrm{d}g^{(j)}(\lambda)}{\mathrm{d}x^\alpha} \cdot h^\alpha.$$

Note that $\operatorname{maxdeg}(\frac{\mathrm{d}g^{(j)}}{\mathrm{d}x^\alpha}) < \operatorname{maxdeg}(g)$ and that $0 \le h < 1$ by construction.

This sum is a polynomial in λ and h; that is, it is a sum of terms $c_{\alpha,\beta}\lambda^\alpha h^\beta$. Since all $\lambda \ge 0$ we can use $0 \le h_i < 1$, for all i, to bound the expression $c_{\alpha,\beta}\lambda^\alpha h^\beta$ by

$$0 \le c_{\alpha,\beta}\lambda^\alpha h^\beta < c_{\alpha,\beta}\lambda^\alpha$$

if $c_{\alpha,\beta} > 0$ and by

$$c_{\alpha,\beta}\lambda^\alpha < c_{\alpha,\beta}\lambda^\alpha h^\beta \le 0$$

if $c_{\alpha,\beta} < 0$. Putting now

$$g_l^{(j)}(\lambda) := \sum_{\alpha,\beta : c_{\alpha,\beta} < 0} c_{\alpha,\beta}\lambda^\alpha \quad \text{and} \quad g_u^{(j)}(\lambda) := \sum_{\alpha,\beta : c_{\alpha,\beta} > 0} c_{\alpha,\beta}\lambda^\alpha$$

we have

$$g_l^{(j)}(\lambda) \le v_x^{(j)} \le g_u^{(j)}(\lambda)$$

by construction. Moreover, again by construction, the degree of $g_l^{(j)}$ and of $g_u^{(j)}$ is strictly less than the degree of $g^{(j)}$. □

Acknowledgments. The authors wish to thank Jesus De Loera and an anonymous referee for many helpful comments. We express our thanks to Peter Malkin for pointing out [6].

MONGE PROPERTY AND BOUNDING MULTIVARIATE PROBABILITY DISTRIBUTION FUNCTIONS WITH GIVEN MARGINALS AND COVARIANCES*

XIAOLING HOU† AND ANDRÁS PRÉKOPA†

Abstract. Multivariate probability distributions with given marginals are considered, along with linear functionals, to be minimized or maximized, acting on them. The functionals are supposed to satisfy the Monge or inverse Monge or some higher order convexity property, and they may be only partially known. Existing results in connection with Monge arrays are reformulated and extended in terms of linear programming dual feasible bases. Lower and upper bounds are given for the optimum value as well as for unknown coefficients of the objective function, based on the knowledge of some dual feasible bases and corresponding objective function coefficients. In the two- and three-dimensional cases dual feasible bases are obtained for the problem, where not only the univariate marginals but also the covariances of the pairs of random variables are known.

Key words. distributions with given marginals, transportation problem, Monge arrays, bounding expectations under incomplete information

1. Introduction.

In this paper we consider multivariate (or multidimensional) discrete probability distributions with given marginals, along with special linear functionals, to be minimized or maximized, acting on them. In other words, we consider multidimensional transportation problems with special objective functions, where the sum of the marginal values is equal to 1. In the two- and three-dimensional cases we also look at distributions, where not only the marginals but also the covariances of the random variables involved are prescribed.

About the objective functions we assume that they enjoy the Monge or inverse Monge or some discrete higher order convexity property.

There is a considerable literature on the Monge property and its use in optimization and other fields of applied mathematics. The papers by Burkard, Klinz, and Rudolf [3] and Burkard [2] provide us with an overview of its history and the most important results. For basic results in connection with multivariate discrete higher order convexity, see Prékopa [6, 7] and Mádi-Nagy and Prékopa [5].

The purpose of this paper is the following. First, we reformulate the Monge and inverse Monge properties in terms of dual feasible bases of the transportation problem and obtain further results for them. Second, we give lower and upper bounds for the optimum value based on the knowledge of the univariate marginals and the covariances of pairs of bivariate marginals. The results for the latter case concern the two- and three-dimensional transportation problems. Third, we look at partially known objective functions and give lower and upper bounds for the unknown entries of the coefficient array. The bounds are based on the knowledge of the univariate marginals in the general d-dimensional case and on additional knowledge of the covariances in the two- and three-dimensional cases.

†RUTCOR, Rutgers University, 640 Bartholomew Rd., Piscataway, NJ 08854 (xhou@rutcor.rutgers.edu, prekopa@rutcor.rutgers.edu). The work of the first author was supported by the DIMACS Winter 2004 and Summer 2005 Research Program.

The d-dimensional ($d \geq 2$) transportation problem is the following (linear program) LP:

$$
\begin{array}{ll}
\min(\max) & \sum_{i_1,\ldots,i_d} c(i_1,\ldots,i_d)x(i_1,\ldots,i_d) \\
\text{subject to} & \sum_{i_1,\ldots,i_d,i_k=i} x(i_1,\ldots,i_d) = a_k(i) \\
& \text{for all } \; i = 1,\ldots,n_k, \quad k = 1,\ldots,d, \\
& x(i_1,\ldots,i_d) \geq 0, \\
& \text{for all } \; i_k = 1,\ldots,n_k, \quad k = 1,\ldots,d.
\end{array} \tag{1}
$$

Let $\mathbf{A} = (\{\mathbf{a}(i_1,\ldots,i_d)\})$, $\mathbf{b} = (a_1(1),\ldots,a_1(n_1),\ldots,a_d(1),\ldots,a_d(n_d))^T$, $\mathbf{c} = (\{c(i_1,\ldots,i_d)\})$, $\mathbf{x} = (\{x(i_1,\ldots,i_d)\})$ be the coefficient matrix, the right-hand-side vector, the vector of the objective function coefficients, and the decision vector, respectively. Then problem (1) can be written as $\min(\max)\mathbf{c}^T\mathbf{x}$, subject to $\mathbf{A}\mathbf{x} = \mathbf{b}$, $\mathbf{x} \geq 0$. We assume that the above vectors and components are arranged in such a way that $(i_1,\ldots,i_d)$ follow the lexicographic order starting with the smallest. In what follows, the d-tuples $(i_1,\ldots,i_d)$ will be referred to as cells, and their collection will be called a transportation tableau.

If in problem (1) we have the relation $\sum_{i=1}^{n_1} a_1(i) = \cdots = \sum_{i=1}^{n_d} a_d(i) = 1$, then $\{x(i_1,\ldots,i_d)\}$ is a multivariate probability distribution, where its univariate marginals are prescribed. Problem (1) can then be reformulated in such a way that we minimize or maximize the expectation of $c(X_1,\ldots,X_d)$, where $X_1,\ldots,X_d$ are random variables with given distributions, $P(X_k = i) = a_k(i)$, $i = 1,\ldots,n_k$, $k = 1,\ldots,d$. Note that $\{1,\ldots,n_k\}$ serves as the support of X_k, $k = 1,\ldots,d$, but the solution of problem (1) does not depend on the choices of these sets.

In what follows we assume that the sum of each set of marginal values is equal to 1. Our results, however, generalize in a trivial way for the case where the sum of the marginal values is not 1.

A d-dimensional $n_1 \times \cdots \times n_d$ array $\mathbf{c} = \{c(i_1,\ldots,i_d)\}$ is called a *Monge array* if for all entries $c(i_1,\ldots,i_d)$ and $c(j_1,\ldots,j_d)$, $1 \leq i_k, j_k \leq n_k$, $1 \leq k \leq d$, we have

$$
c(s_1,\ldots,s_d) + c(t_1,\ldots,t_d) \leq c(i_1,\ldots,i_d) + c(j_1,\ldots,j_d), \tag{2}
$$

where for all $1 \leq k \leq d$, $s_k = \min\{i_k, j_k\}$, $t_k = \max\{i_k, j_k\}$. If (2) holds strictly for all $(s_1,\ldots,s_d) \neq (i_1,\ldots,i_d)$ and $(s_1,\ldots,s_d) \neq (j_1,\ldots,j_d)$, then we say that $\mathbf{c}$ is a *strict Monge array*. If the above inequalities are reversed, then $\mathbf{c}$ is called an *inverse Monge array* or a *strict inverse Monge array*.

To define discrete higher order convexity, let $Z_j = \{z_{j0},\ldots,z_{jn_j}\}$, $j = 1,\ldots,d$, be distinct element finite sets, and $f(z)$, $z \in Z = Z_1 \times \cdots \times Z_d$, a multivariate discrete function. Take a subset of Z,

$$
Z_{I_1,\ldots,I_d} = \{z_{1i}, i \in I_1\} \times \cdots \times \{z_{di}, i \in I_d\} = Z_{I_1} \times \cdots \times Z_{I_d},
$$

where $|I_j| = k_j + 1$, $k_j \leq n_j$, $j = 1,\ldots,d$. The $(k_1,\ldots,k_d)$*-order divided difference*, corresponding to $Z_{I_1,\ldots,I_d}$, will be designated by $[z_{1i}, i \in I_1; \ldots; z_{di}, i \in I_d; f]$. The sum $k_1 + \cdots + k_d$ is called its *total order*. We call the discrete function $(k_1,\ldots,k_d)$-order convex if all sequences in all $Z_1,\ldots,Z_d$ are increasing and all $(k_1,\ldots,k_d)$-order divided differences are nonnegative.

Our presentation is based, to a large extent, on linear programming theory. In this respect we use the notations and definitions presented in Prékopa [6].

We also introduce the concept of an ordered sequence for the columns of matrix $\mathbf{A}$ in problem (1). The collection of columns $\{\mathbf{a}(i_1,\ldots,i_d), (i_1,\ldots,i_d) \in I\}$ is called

an *ordered sequence* if I has the following form:

$$\begin{aligned} I = \{&(1,\dots,1,1),\dots,(1,\dots,1,i_{d,1}),\dots,(1,\dots,i_{d-1,1},i_{d,1}),\\ &\dots,(i_{1,1},\dots,i_{d-1,1},i_{d,1}),\dots,(i_{1,n-1},\dots,i_{d-1,n-1},i_{d,n-1}),\\ &\dots,(i_{1,n-1},\dots,i_{d-1,n-1},i_{d,n}),\dots,(i_{1,n-1},\dots,i_{d-1,n},i_{d,n}),\\ &\dots,(i_{1,n},\dots,i_{d-1,n},i_{d,n})\}, \end{aligned}$$

where $1 \le i_{k,1} \le \cdots \le i_{k,n-1} \le i_{k,n} = n_k$ for all $1 \le k \le d$. In what follows, the terms *ordered sequence* and *basis* for the columns of $\mathbf{A}$ will briefly be referred to as ordered *sequence* and *basis*, respectively. It is easy to see that the following assertion holds true: any ordered sequence forms a basis.

When $d = 2$ in problem (1), we call the collection of columns $\{\mathbf{a}_{ij},\ (i,j) \in J\}$ an *inverse ordered sequence* if J has the following form:

$$\begin{aligned} J = \{&(1,n-j_0),\dots,(1,n-j_1),(2,n-j_1),\dots,(2,n-j_2),\\ &\dots,(m,n-j_{m-1}),\dots,(m,n-j_m)\}, \end{aligned}$$

where $0 = j_0 \le j_1 \le j_2 \le \cdots \le j_{m-1} \le j_m = n-1$. The following assertion holds true: any inverse ordered sequence forms a basis.

An ordered (inverse ordered) sequence is a chain (antichain) in the partially ordered set of the cells.

The further parts of the paper are organized as follows. Section 2 is devoted to the study of the bivariate and multivariate cases. Existing results in connection with Monge and distribution arrays are reformulated and extended in terms of dual feasibility of bases. Bounds on the expectation and the unknown components of $\mathbf{c}$ are obtained under the condition that the univariate marginals of the random vector are known. In section 3 a new algorithm called $(GREEDY\ DUAL)_d$ for solving the d-dimensional transportation problem is presented. In section 4 the bivariate case is considered, where, in addition to the knowledge of the marginal distributions, we assume the knowledge of the covariance of the two random variables involved. We give bounds for the same values as before. In section 5 we present similar results for the three-dimensional case. Finally, some applications and illustrative examples are given in section 6.

2. Monge property and dual feasible bases. In this section we establish relationship between ordered sequences and dual feasible bases in the d-dimensional problem (1), and between the inverse ordered sequences and the dual feasible bases in the two-dimensional problem (1).

First, we present the relationship between ordered sequences and the dual feasible bases in the d-dimensional problem (1). To prove our results we recall three theorems from linear programming. For a proof of the first one, see Prékopa [6, Theorem 5]; the second one can be derived from Theorem 3 of the same paper.

THEOREM 2.1. *If problem* (1) *has a primal feasible solution and a finite optimum, then there exists a primal feasible basis that is also dual feasible.*

THEOREM 2.2. *If in problem* (1) B *is a nondegenerate optimal basis, then* $\mathbf{B}$ *is dual feasible.*

Bein et al. [1] extended the two-dimensional greedy algorithm $GREEDY_2$, due to Hoffman [4], to the d-dimensional greedy algorithm $GREEDY_d$ and proved the following theorem.

THEOREM 2.3 (see Bein et al. [1]). *Given a particular d-dimensional* $n_1 \times \cdots \times n_d$ *cost array* $\mathbf{c}$*, the algorithm* $GREEDY_d$ *solves the corresponding d-dimensional transportation problem for any* $\mathbf{b}$ *if and only if* $\mathbf{c}$ *is Monge.*

For the d-dimensional minimization problem (1), we prove two theorems.

THEOREM 2.4. *In the minimization problem* (1)*, any ordered sequence forms a dual feasible basis if and only if* $\mathbf{c}$ *satisfies the Monge property.*

Proof. For the proof of the "if" direction, assume that $\mathbf{c}$ is Monge. For any given ordered sequence write positive numbers in its cells, and call what comes out on the right-hand side (r.h.s.) $\mathbf{b}$. For this $\mathbf{b}$ the algorithm $GREEDY_d$ produces the same ordered sequence. By Theorem 2.3 this ordered sequence is a primal nondegenerate optimal basis to the problem. By Theorem 2.2, this ordered sequence is dual feasible.

For the proof of the "only if" direction, assume that any ordered sequence forms a dual feasible basis. Then for any $\mathbf{b}$ the algorithm $GREEDY_d$ solves the problem optimally, because the algorithm $GREEDY_d$ produces an ordered sequence. Thus, by Theorem 2.3, $\mathbf{c}$ is Monge. □

To prove the next theorem we need the dual of the minimization problem (1) that is given as follows:

$$\begin{aligned} \max \quad & \textstyle\sum_{k=1}^{d} \sum_{i_k=1}^{n_k} a_k(i_k) w_k(i_k) \\ \text{subject to} \quad & \\ & w_1(i_1) + \cdots + w_d(i_d) \le c(i_1, \ldots, i_d) \\ & \text{for all} \quad i_k = 1, \ldots, n_k, \quad k = 1, \ldots, d. \end{aligned}$$

THEOREM 2.5. *If, in the minimization problem* (1)*,* $\mathbf{c}$ *satisfies the strict Monge property, then any dual feasible basis is dual nondegenerate and forms an ordered sequence.*

Proof. Suppose that $\mathbf{c}$ satisfies the strict Monge property and that $\mathbf{B}$ is a dual feasible basis. First, assume that the vectors of $\mathbf{B}$ do not form an ordered sequence. Then there must exist vectors $\mathbf{a}(i_1, \ldots, i_d)$ and $\mathbf{a}(j_1, \ldots, j_d)$ in $\mathbf{B}$ such that if $s_k = \min\{i_k, j_k\}$, $t_k = \max\{i_k, j_k\}$, then $(s_1, \ldots, s_d) \neq (i_1, \ldots, i_d)$, $(s_1, \ldots, s_d) \neq (j_1, \ldots, j_d)$. Let $w_k(i_k)$, $i_k = 1, \ldots, n_k$, $k = 1, \ldots, d$, be the components of the dual vector corresponding to $\mathbf{B}$. Then

$$\begin{aligned} c(i_1, \ldots, i_d) &= w_1(i_1) + \cdots + w_d(i_d), \\ c(j_1, \ldots, j_d) &= w_1(j_1) + \cdots + w_d(j_d), \\ c(s_1, \ldots, s_d) &\ge w_1(s_1) + \cdots + w_d(s_d), \\ c(t_1, \ldots, t_d) &\ge w_1(t_1) + \cdots + w_d(t_d). \end{aligned} \tag{3}$$

Since

$$\begin{aligned} w_1(i_1) + \cdots + w_d(i_d) + w_1(j_1) + \cdots + w_d(j_d) & \\ = w_1(s_1) + \cdots + w_d(s_d) + w_1(t_1) + \cdots + w_d(t_d), & \end{aligned} \tag{4}$$

we have the relation

$$c(s_1, \ldots, s_d) + c(t_1, \ldots, t_d) \ge c(i_1, \ldots, i_d) + c(j_1, \ldots, j_d).$$

This contradicts the strict Monge property, so any dual feasible basis must be an ordered sequence.

TABLE 1
"min (max)" means minimization (maximization) problem (1)*, "o.s." means ordered sequence, and "d.f.b." means dual feasible basis.*

	d-dimensional min (max)
Any o.s. forms a d.f.b.	*iff* **c** is (inverse) Monge
Any d.f.b. forms an o.s.	*if* **c** is strict (inverse) Monge

TABLE 2
"i.o.s." means inverse ordered sequence.

	two-dimensional max (min)
Any i.o.s. forms a d.f.b.	*iff* **c** is (inverse) Monge
Any d.f.b. forms an i.o.s.	*if* **c** is strict (inverse) Monge

Second, suppose that the vector $\mathbf{a}(i_1, \ldots, i_d)$ is nonbasic. Since $\mathbf{B}$ forms an ordered sequence, we can find a basic vector $\mathbf{a}(j_1, \ldots, j_d)$ in $\mathbf{B}$ such that if $s_k = \min\{i_k, j_k\}$, $t_k = \max\{i_k, j_k\}$, then $(s_1, \ldots, s_d) \neq (i_1, \ldots, i_d)$, $(s_1, \ldots, s_d) \neq (j_1, \ldots, j_d)$. It is easy to see that the last three equations in (3) and the one in (4) hold true. Because of the strict Monge property, we have the following relations:

$$\begin{aligned} c(i_1, \ldots, i_d) + c(j_1, \ldots, j_d) &> c(s_1, \ldots, s_d) + c(t_1, \ldots, t_d) \\ &\geq w_1(s_1) + \cdots + w_d(s_d) + w_1(t_1) + \cdots + w_d(t_d) \\ &= w_1(i_1) + \cdots + w_d(i_d) + w_1(j_1) + \cdots + w_d(j_d). \end{aligned}$$

So

$$c(i_1, \ldots, i_d) > w_1(i_1) + \cdots + w_d(i_d).$$

Therefore $\mathbf{B}$ is dual nondegenerate. □

From these two theorems, we can easily get the similar results for the d-dimensional maximization problem (1). We summarize all these results in Table 1.

In the two-dimensional case let $c'_{ij} = c_{(m-i+1)j}$, $\mathbf{a}'_{ij} = \mathbf{a}_{(m-i+1)j}$. Then $\mathbf{c} = (c_{ij})$ is an inverse Monge array if and only if $\mathbf{c}' = (c'_{ij}) = (c_{(m-i+1)j})$ is a Monge array. $\{\mathbf{a}_{ij},\ (i,j) \in J\}$ is an inverse ordered sequence of $\mathbf{A}$ if and only if $\{\mathbf{a}'_{ij},\ (i,j) \in J\}$ is an ordered sequence of $\mathbf{A}' = (\mathbf{a}'_{ij})$. Thus, for the two-dimensional problem (1) we obtain the relationship between the inverse ordered sequences and the dual feasible bases given in Table 2.

If $\mathbf{c}$ is Monge in the three-dimensional maximization problem (1), then we have the following theorem.

THEOREM 2.6. *Consider the three-dimensional maximization problem* (1)*. If* $\mathbf{c}$ *is Monge, then each of the following sequences of vectors forms a dual feasible basis:*

$$\begin{aligned} (S'_1)\quad & \{\mathbf{a}_{i11}, i = 1, \ldots, n_1, \mathbf{a}_{1j1}, j = 2, \ldots, n_2, \mathbf{a}_{11k}, k = 2, \ldots, n_3\}, \\ (S'_2)\quad & \{\mathbf{a}_{in_2n_3}, i = 1, \ldots, n_1, \mathbf{a}_{n_1jn_3}, j = 1, \ldots, n_2 - 1, \\ & \quad \mathbf{a}_{n_1n_2k}, k = 1, \ldots, n_3 - 1\}. \end{aligned}$$

3. The (*GREEDY DUAL*)$_d$ algorithm. In addition to the $GREEDY_d$ algorithm a dual algorithm can also be constructed to solve the d-dimensional transportation problem with a Monge array in the objective function.

Consider an ordered sequence, and single out from it those cells which are "turning points" in the sequence of cells. Let us call them *pivot cells*. Thus, if in the ordered

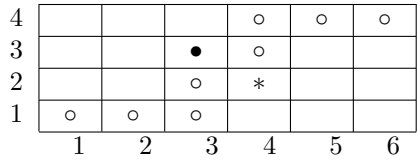

FIG. 1. *"○" means basic cell, "●" means the leaving (entering) cell, and "∗" means the entering (leaving) cell.*

sequence we have one of the following consecutive cells,

$$(\dots, i-1, \dots, j, \dots)\ (\dots, i, \dots, j, \dots)\ (\dots, i, \dots, j+1, \dots), \tag{5}$$

$$(\dots, i, \dots, j-1, \dots)\ (\dots, i, \dots, j, \dots)\ (\dots, i+1, \dots, j, \dots), \tag{6}$$

where the elements represented by dots remains unchanged, then the cell $(\dots, i, \dots, j, \dots)$ is a pivot cell. The algorithm can be described as follows.

Step 0. Choose arbitrarily an ordered sequence. By Theorem 2.4 it represents a dual feasible basis. Compute the corresponding basic solution.

Step 1. Check whether the basic components of the basic solution are nonnegative. In view of the constraints in problem (1) only pivot cells may contain negative entries; thus it is enough to check the entries in the pivot cells. If all pivot entries are nonnegative, then stop; optimal basis and optimal solution have been found.

Step 2. Choose arbitrarily a pivot cell that contains a negative entry, and let it leave the basis.

Step 3. If the leaving cell is the second one in (5) (in (6)), then let the cell $(\dots, i-1, \dots, j+1, \dots)$ (the cell $(\dots, i+1, \dots, j-1, \dots)$) enter the basis.

Step 4. Compute the basic solution $\mathbf{x}'$ corresponding to the new basis. In the case of (5) we have

$$x'_{(\dots,i-1,\dots,j,\dots)} = x_{(\dots,i-1,\dots,j,\dots)} + x_{(\dots,i,\dots,j,\dots)} x'_{(\dots,i,\dots,j,\dots)} = 0,$$
$$x'_{(\dots,i,\dots,j+1,\dots)} = x_{(\dots,i,\dots,j+1,\dots)} + x_{(\dots,i,\dots,j,\dots)} x'_{(\dots,i-1,\dots,j+1,\dots)} = -x_{(\dots,i,\dots,j,\dots)}.$$

All other $\mathbf{x}'$ components remain unchanged. The basic solution for the case of (6) can be obtained similarly. Go to Step 1.

Figure 1 provides an illustration of the leaving and entering cells.

With straightforward modification in the above algorithm we can create one to solve the problem with an inverse Monge array.

The above algorithm does not depend on $\mathbf{c}$ as long as it is Monge. Since all dual feasible bases are nondegenerate if $\mathbf{c}$ has the strict Monge property, it follows that the algorithm terminates in a finite number of steps.

4. The use of covariance in the two-dimensional case. In this section we consider the following problem:

$$\begin{aligned} &\min(\max) && \textstyle\sum_{i=1}^{m}\sum_{j=1}^{n} c_{ij}x_{ij} \\ &\text{subject to} \\ &&& \textstyle\sum_{j=1}^{n} x_{ij} = a_i, \quad i = 1, \dots, m, \\ &&& \textstyle\sum_{i=1}^{m} x_{ij} = b_j, \quad j = 1, \dots, n, \\ &&& \textstyle\sum_{i=1}^{m}\sum_{j=1}^{n} y_i z_j x_{ij} = d, \\ &&& x_{ij} \geq 0, \quad i = 1, \dots, m, \quad j = 1, \dots, n. \end{aligned} \tag{7}$$

We have in mind a pair of discrete random variables, Y, Z, with supports $\{y_i\}$, $\{z_j\}$, respectively, where the univariate marginal distributions as well as $E(YZ)$ are prescribed but the joint distribution of Y and Z is not specified otherwise. Since the marginal distributions determine $E(Y)$ and $E(Z)$, to prescribe $E(YZ)$ is the same as to prescribe $Cov(Y,Z) = E(YZ) - E(Y)E(Z)$. Since we can write c_{ij} in the form $c_{ij} = c(y_i, z_j)$, it follows that c is a function of the random vector (y, z), and if we plug in the random variables Y, Z, it becomes a function of (Y, Z). Thus, the optimum values of problem (7) provide us with the best possible lower and upper bounds for $E(c(Y,Z))$ under the given conditions.

Problem (7) can be written in the following matrix form: $\min(\max)\mathbf{c}^T\mathbf{x}$, subject to $\overline{\mathbf{A}}\mathbf{x} = \overline{\mathbf{b}}$, $\mathbf{x} \geq 0$, where $\overline{\mathbf{A}} = (\overline{\mathbf{a}}_{ij})$, $\overline{\mathbf{a}}_{ij} = \mathbf{e}_i + \mathbf{e}_{m+j} + y_i z_j \mathbf{e}_{m+n+1}$, $i = 1, \ldots, m$, $j = 1, \ldots, n$; $\mathbf{e}_i$, $\mathbf{e}_{m+j}$, and $\mathbf{e}_{m+n+1}$ are unit vectors in $\mathbf{E}^{m+n+1}$ with ones in the ith, $(m+j)$th, and $(m+n+1)$th positions, respectively; and $\overline{\mathbf{b}} = (\mathbf{b}^T, d)^T$.

THEOREM 4.1. *Consider the minimization problem* (7)*, and assume that* $\{y_i\}$ *is strictly increasing,* $\{z_j\}$ *is strictly decreasing, and the* (1,2)*-order and* (2,1)*-order divided differences of* $c(y_i, z_j)$ *are nonnegative. Then* $B_1 = \{\overline{\mathbf{a}}_{i1}, i = 1, \ldots, m, \overline{\mathbf{a}}_{mj}, j = 2, \ldots, n, \overline{\mathbf{a}}_{1n}\}$ *forms a dual feasible basis of the columns of* $\overline{\mathbf{A}}$*.*

Proof. First, let us show that B_1 forms a basis of the columns of $\overline{\mathbf{A}}$. It is easy to see that the rank of $\overline{\mathbf{A}}$ is $m+n$, and there are $m+n$ vectors in B_1. To show the linear independence of the $m+n$ vectors in B_1, consider the linear combination of the vectors of B_1:

$$\begin{aligned}
&\sum_{i=1}^{m} \lambda_{i1}\overline{\mathbf{a}}_{i1} + \sum_{j=2}^{n} \lambda_{mj}\overline{\mathbf{a}}_{mj} + \lambda_{1n}\overline{\mathbf{a}}_{1n} \\
&\quad = \sum_{i=1}^{m} \lambda_{i1}(\mathbf{e}_i + \mathbf{e}_{m+1} + y_i z_1 \mathbf{e}_{m+n+1}) + \sum_{j=2}^{n} \lambda_{mj}(\mathbf{e}_m + \mathbf{e}_{m+j} + y_m z_j \mathbf{e}_{m+n+1}) \\
&\qquad + \lambda_{1n}(\mathbf{e}_1 + \mathbf{e}_{m+n} + y_1 z_n \mathbf{e}_{m+n+1}) \\
&\quad = (\lambda_{11} + \lambda_{1n})\mathbf{e}_1 + \sum_{i=2}^{m-1} \lambda_{i1}\mathbf{e}_i + \left(\sum_{j=1}^{n} \lambda_{mj}\right)\mathbf{e}_m + \left(\sum_{i=1}^{m} \lambda_{i1}\right)\mathbf{e}_{m+1} + \sum_{j=2}^{n-1} \lambda_{mj}\mathbf{e}_{m+j} \\
&\qquad + (\lambda_{mn} + \lambda_{1n})\mathbf{e}_{m+n} + \left(\sum_{i=1}^{m} \lambda_{i1} y_i z_1 + \sum_{j=2}^{n} \lambda_{mj} y_m z_j + \lambda_{1n} y_1 z_n\right)\mathbf{e}_{m+n+1}.
\end{aligned}$$

If it equals 0, then, by the linear independence of the unit vectors, it follows that all λ's must be 0.

Secondly, let us show that this basis is dual feasible. For any nonbasic vector $\overline{\mathbf{a}}_{ij}$, $1 \leq i < m$, $1 < j \leq n$, we have the equations

$$\begin{aligned}
\overline{\mathbf{a}}_{ij} - \overline{\mathbf{a}}_{i1} + \overline{\mathbf{a}}_{m1} - \overline{\mathbf{a}}_{mj} &= (y_i - y_m)(z_j - z_1)\mathbf{e}_{m+n+1} \\
\overline{\mathbf{a}}_{ij} - \overline{\mathbf{a}}_{i1} + \overline{\mathbf{a}}_{11} - \overline{\mathbf{a}}_{1n} + \overline{\mathbf{a}}_{mn} - \overline{\mathbf{a}}_{mj} & \\
= [(y_i - y_m)(z_j - z_1) - (y_1 - y_m)(z_n - z_1)]\mathbf{e}_{m+n+1}. &
\end{aligned}$$

From here we derive the expression of $\overline{\mathbf{a}}_{\mathbf{ij}}$ as the following linear combination of the basic vectors:

$$\begin{aligned}
\overline{\mathbf{a}}_{ij} = &\frac{(y_1 - y_m)(z_1 - z_n) - (y_i - y_m)(z_1 - z_j)}{(y_1 - y_m)(z_1 - z_n)}(\overline{\mathbf{a}}_{i1} - \overline{\mathbf{a}}_{m1} + \overline{\mathbf{a}}_{mj}) \\
&- \frac{(y_i - y_m)(z_1 - z_j)}{(y_1 - y_m)(z_1 - z_n)}(\overline{\mathbf{a}}_{11} - \overline{\mathbf{a}}_{1n} + \overline{\mathbf{a}}_{mn} - \overline{\mathbf{a}}_{mj} - \overline{\mathbf{a}}_{i1}).
\end{aligned}$$

We have to prove that

$$\frac{(y_1-y_m)(z_1-z_n)-(y_i-y_m)(z_1-z_j)}{(y_1-y_m)(z_1-z_n)}(c_{i1}-c_{m1}+c_{mj})$$
$$-\frac{(y_i-y_m)(z_1-z_j)}{(y_1-y_m)(z_1-z_n)}(c_{11}-c_{1n}+c_{mn}-c_{mj}-c_{i1})-c_{ij}\le 0,$$

or, equivalently,

$$(c_{i1}-c_{m1}+c_{mj}-c_{ij})\le\frac{(y_i-y_m)(z_1-z_j)}{(y_1-y_m)(z_1-z_n)}(c_{11}-c_{m1}+c_{mn}-c_{1n}). \tag{8}$$

Since $(y_i-y_m)(z_1-z_j)<0$, the above inequality is equivalent to

$$\frac{c_{i1}-c_{m1}-c_{ij}+c_{mj}}{(y_i-y_m)(z_1-z_j)}\ge\frac{c_{11}-c_{m1}-c_{1n}+c_{mn}}{(y_1-y_m)(z_1-z_n)}.$$

We have assumed that the (1,2)-order and (2,1)-order divided differences of $c(y_i,z_j)$ are nonnegative. The nonnegativity of the (1,2)-order divided difference implies

$$\frac{\frac{c_{11}-c_{m1}-c_{1n}+c_{mn}}{(y_1-y_m)(z_1-z_n)}-\frac{c_{11}-c_{m1}-c_{1j}+c_{mj}}{(y_1-y_m)(z_1-z_j)}}{z_n-z_j}\ge 0.$$

Similarly, the nonnegativity of (2,1)-order divided difference gives

$$\frac{\frac{c_{11}-c_{m1}-c_{1j}+c_{mj}}{(y_1-y_m)(z_1-z_j)}-\frac{c_{i1}-c_{m1}-c_{ij}+c_{mj}}{(y_i-y_m)(z_1-z_j)}}{y_1-y_i}\ge 0.$$

Since both z_n-z_j and y_1-y_i are negative, the above two inequalities imply

$$\frac{c_{i1}-c_{m1}-c_{ij}+c_{mj}}{(y_i-y_m)(z_1-z_j)}\ge\frac{c_{11}-c_{m1}-c_{1j}+c_{mj}}{(y_1-y_m)(z_1-z_j)}\ge\frac{c_{11}-c_{m1}-c_{1n}+c_{mn}}{(y_1-y_m)(z_1-z_n)}.$$

This completes the proof. □

If we use the reasoning in the proof of Theorem 4.1, we can obtain a variety of dual feasible bases for problem (7), under different conditions. Let $B_2=\{\bar{\mathbf{a}}_{in}, i=1,\dots,m,\bar{\mathbf{a}}_{1j}, j=1,\dots,n-1,\bar{\mathbf{a}}_{m1}\}$, $B_3=\{\bar{\mathbf{a}}_{i1}, i=1,\dots,m,\bar{\mathbf{a}}_{1j}, j=2,\dots,n,\bar{\mathbf{a}}_{mn}\}$, $B_4=\{\bar{\mathbf{a}}_{in}, i=1,\dots,m,\bar{\mathbf{a}}_{mj}, j=1,\dots,n-1,\bar{\mathbf{a}}_{11}\}$. The cells corresponding to the vectors in B_1, B_2, B_3 and B_4 are designated by **boldface** points in Figure 2.

We summarize all the results for the minimization (maximization) problem (7) in Table 3.

5. The use of covariances in the three-dimensional case. In this section we consider the following three-dimensional problem:

$$\begin{array}{ll}
\min(\max) & \sum_{i=1}^{n_1}\sum_{j=1}^{n_2}\sum_{k=1}^{n_3} c_{ijk}x_{ijk}\\
\text{subject to} & \\
& \sum_{j=1}^{n_2}\sum_{k=1}^{n_3} x_{ijk}=a_i,\quad i=1,\dots,n_1,\\

This problem can be interpreted in such a way that, given the supports $\{y_i\}$, $\{z_j\}$, $\{w_k\}$, the univariate marginals $\{a_i\}$, $\{b_j\}$, $\{c_k\}$, and the covariances of all pairs of three random variables Y, Z, W, we want to find the best possible lower and upper bounds for $E(c(Y,Z,W))$, where $c(y_i,z_j,w_k)=c_{ijk}$ for all i,j,k. Problem (9) can be written in the compact form $\min(\max)\mathbf{c}^T\mathbf{x}$, subject to $\overline{\mathbf{A}}\mathbf{x}=\overline{\mathbf{b}}$, $\mathbf{x}\geq 0$, where

$\overline{\mathbf{A}} = (\overline{\mathbf{a}}_{ijk})$, $\overline{\mathbf{a}}_{ijk} = \mathbf{e}_i + \mathbf{e}_{n_1+j} + \mathbf{e}_{n_1+n_2+k} + y_i z_j \mathbf{e}_{n_1+n_2+n_3+1} + z_j w_k \mathbf{e}_{n_1+n_2+n_3+2} + y_i w_k \mathbf{e}_{n_1+n_2+n_3+3}$, $i = 1, \ldots, n_1$, $j = 1, \ldots, n_2$, $k = 1, \ldots, n_3$; $\mathbf{e}_l$, $1 \le l \le n_1+n_1+n_3+3$, is the unit vector in $\mathbf{E}^{n_1+n_2+n_3+3}$ with one in the lth position; and $\overline{\mathbf{b}} = (\mathbf{b}^T, \mathbf{d}^T)^T$, $\mathbf{d} = (d_1, d_2, d_3)^T$.

Let $\overline{S}_1 = \{\overline{\mathbf{a}}_{i11}, i = 1, \ldots, n_1, \overline{\mathbf{a}}_{n_1 j 1}, j = 2, \ldots, n_2, \overline{\mathbf{a}}_{n_1 n_2 k}, k = 2, \ldots, n_3\}$. We prove the following result.

THEOREM 5.1. *Consider the minimization problem* (9). *If y_i, z_j, and w_k are strictly increasing; all $(1,2,0)$-order, $(1,0,2)$-order, $(0,1,2)$-order divided differences of $c(y_i, z_j, w_k)$ are nonnegative; and all $(2,1,0)$-order, $(2,0,1)$-order, $(0,2,1)$-order, and $(1,1,1)$-order divided differences of $c(y_i, z_j, w_k)$ are nonpositive, then $\overline{S}_1 \cup \{\overline{\mathbf{a}}_{n_1 1 n_3}, \overline{\mathbf{a}}_{1 n_2 1}, \overline{\mathbf{a}}_{11 n_3}\}$ forms a dual feasible basis of the columns of $\overline{\mathbf{A}}$.*

Proof. Similarly with Theorem 4.1 we can show that the vectors of the sequence $\overline{S}_1$ supplemented by the vectors $\overline{\mathbf{a}}_{n_1 1 n_3}$, $\overline{\mathbf{a}}_{1 n_2 1}$, and $\overline{\mathbf{a}}_{11 n_3}$ form a basis of the columns of $\overline{\mathbf{A}}$.

Now let us show that this basis is dual feasible. Assume that all $\{y_i\}$, $\{z_j\}$, and $\{w_k\}$ sequences are strictly increasing. For any nonbasic vector $\overline{\mathbf{a}}_{ijk}$, $1 \le i \le n_1$, $1 \le j \le n_2$, $1 \le k \le n_3$, we have the following four equations:

$$\begin{aligned} &\overline{\mathbf{a}}_{ijk} - \overline{\mathbf{a}}_{i11} + \overline{\mathbf{a}}_{n_1 11} - \overline{\mathbf{a}}_{n_1 j 1} + \overline{\mathbf{a}}_{n_1 n_2 1} - \overline{\mathbf{a}}_{n_1 n_2 k} \\ &\quad = \begin{pmatrix} \mathbf{0} \\ (y_i - y_{n_1})(z_j - z_1) \\ (z_j - z_{n_2})(w_k - w_1) \\ (y_i - y_{n_1})(w_k - w_1) \end{pmatrix}, \end{aligned} \tag{10}$$

$$\begin{aligned} &\overline{\mathbf{a}}_{ijk} - \overline{\mathbf{a}}_{i11} + \overline{\mathbf{a}}_{n_1 11} - \overline{\mathbf{a}}_{n_1 n_2 k} + \overline{\mathbf{a}}_{n_1 n_2 n_3} - \overline{\mathbf{a}}_{n_1 1 n_3} + \overline{\mathbf{a}}_{n_1 11} - \overline{\mathbf{a}}_{n_1 j 1} \\ &\quad = \begin{pmatrix} \mathbf{0} \\ (y_i - y_{n_1})(z_j - z_1) \\ (z_j - z_{n_2})(w_k - w_1) - (z_1 - z_{n_2})(w_{n_3} - w_1) \\ (y_i - y_{n_1})(w_k - w_1) \end{pmatrix}, \end{aligned} \tag{11}$$

$$\begin{aligned} &\overline{\mathbf{a}}_{ijk} - \overline{\mathbf{a}}_{n_1 j 1} + \overline{\mathbf{a}}_{n_1 n_2 1} - \overline{\mathbf{a}}_{n_1 n_2 k} + \overline{\mathbf{a}}_{n_1 1 n_3} - \overline{\mathbf{a}}_{11 n_3} + \overline{\mathbf{a}}_{111} - \overline{\mathbf{a}}_{i11} \\ &\quad = \begin{pmatrix} \mathbf{0} \\ (y_i - y_{n_1})(z_j - z_1) \\ (z_j - z_{n_2})(w_k - w_1) \\ (y_i - y_{n_1})(w_k - w_1) - (y_1 - y_{n_1})(w_{n_3} - w_1) \end{pmatrix}, \end{aligned} \tag{12}$$

$$\begin{aligned} &\overline{\mathbf{a}}_{ijk} - \overline{\mathbf{a}}_{i11} + \overline{\mathbf{a}}_{111} - \overline{\mathbf{a}}_{1 n_2 1} + \overline{\mathbf{a}}_{n_1 n_2 1} - \overline{\mathbf{a}}_{n_1 j 1} + \overline{\mathbf{a}}_{n_1 n_2 1} - \overline{\mathbf{a}}_{n_1 n_2 k} \\ &\quad = \begin{pmatrix} \mathbf{0} \\ (y_i - y_{n_1})(z_j - z_1) - (y_1 - y_{n_1})(z_{n_2} - z_1) \\ (z_j - z_{n_2})(w_k - w_1) \\ (y_i - y_{n_1})(w_k - w_1) \end{pmatrix}, \end{aligned} \tag{13}$$

where $\mathbf{0}$ is a zero vector in $\mathbf{R}^{n_1+n_2+n_3}$. For simplicity, let

$$\begin{aligned} A_1 &= (y_i - y_{n_1})(z_j - z_1), & A_2 &= (z_j - z_{n_2})(w_k - w_1), \\ A_3 &= (y_i - y_{n_1})(w_k - w_1), & B_1 &= (y_1 - y_{n_1})(z_{n_2} - z_1), \\ B_2 &= (z_1 - z_{n_2})(w_{n_3} - w_1), & B_3 &= (y_1 - y_{n_1})(w_{n_3} - w_1), \end{aligned}$$

$$\mathbf{a}_{12} = \begin{pmatrix} \mathbf{0} \\ A_1 \\ A_2 \\ 0 \end{pmatrix}, \quad \mathbf{a}_{13} = \begin{pmatrix} \mathbf{0} \\ A_1 \\ 0 \\ A_3 \end{pmatrix}, \quad \mathbf{a}_{23} = \begin{pmatrix} \mathbf{0} \\ 0 \\ A_2 \\ A_3 \end{pmatrix}.$$

From (10) and (11) we obtain

$$\frac{A_2 - B_2}{A_2}(\overline{\mathbf{a}}_{ijk} - \overline{\mathbf{a}}_{i11} + \overline{\mathbf{a}}_{n_1 11} - \overline{\mathbf{a}}_{n_1 j1} + \overline{\mathbf{a}}_{n_1 n_2 1} - \overline{\mathbf{a}}_{n_1 n_2 k} - \mathbf{a}_{13})$$
$$= \overline{\mathbf{a}}_{ijk} - \overline{\mathbf{a}}_{i11} + \overline{\mathbf{a}}_{n_1 11} - \overline{\mathbf{a}}_{n_1 n_2 k} + \overline{\mathbf{a}}_{n_1 n_2 n_3} - \overline{\mathbf{a}}_{n_1 1 n_3} + \overline{\mathbf{a}}_{n_1 11} - \overline{\mathbf{a}}_{n_1 j1} - \mathbf{a}_{13}.$$

Thus,

$$\begin{aligned}\overline{\mathbf{a}}_{ijk} &= (\overline{\mathbf{a}}_{i11} - \overline{\mathbf{a}}_{n_1 11} + \overline{\mathbf{a}}_{n_1 j1} - \overline{\mathbf{a}}_{n_1 n_2 1} + \overline{\mathbf{a}}_{n_1 n_2 k} + \mathbf{a}_{13}) \\ &\quad - \frac{A_2}{B_2}(\overline{\mathbf{a}}_{n_1 n_2 n_3} - \overline{\mathbf{a}}_{n_1 1 n_3} + \overline{\mathbf{a}}_{n_1 11} - \overline{\mathbf{a}}_{n_1 n_2 1}). \qquad (14)\end{aligned}$$

Equations (10) and (12) imply

$$\begin{aligned}\overline{\mathbf{a}}_{ijk} &= (\overline{\mathbf{a}}_{i11} - \overline{\mathbf{a}}_{n_1 11} + \overline{\mathbf{a}}_{n_1 j1} - \overline{\mathbf{a}}_{n_1 n_2 1} + \overline{\mathbf{a}}_{n_1 n_2 k} + \mathbf{a}_{12}) \\ &\quad - \frac{A_3}{B_3}(\overline{\mathbf{a}}_{n_1 1 n_3} - \overline{\mathbf{a}}_{11 n_3} + \overline{\mathbf{a}}_{111} - \overline{\mathbf{a}}_{n_1 11}). \qquad (15)\end{aligned}$$

Similarly, equations (10) and (13) imply

$$\begin{aligned}\overline{\mathbf{a}}_{ijk} &= (\overline{\mathbf{a}}_{i11} - \overline{\mathbf{a}}_{n_1 11} + \overline{\mathbf{a}}_{n_1 j1} - \overline{\mathbf{a}}_{n_1 n_2 1} + \overline{\mathbf{a}}_{n_1 n_2 k} + \mathbf{a}_{23}) \\ &\quad - \frac{A_1}{B_1}(\overline{\mathbf{a}}_{111} - \overline{\mathbf{a}}_{1 n_2 1} + \overline{\mathbf{a}}_{n_1 n_2 1} - \overline{\mathbf{a}}_{n_1 11}). \qquad (16)\end{aligned}$$

Finally, from the definitions of $\mathbf{a}_{13}$, $\mathbf{a}_{12}$, $\mathbf{a}_{23}$, and (10), we derive the relation

$$\mathbf{a}_{13} + \mathbf{a}_{12} + \mathbf{a}_{23} = 2(\overline{\mathbf{a}}_{ijk} - \overline{\mathbf{a}}_{i11} + \overline{\mathbf{a}}_{n_1 11} - \overline{\mathbf{a}}_{n_1 j1} + \overline{\mathbf{a}}_{n_1 n_2 1} - \overline{\mathbf{a}}_{n_1 n_2 k}).$$

If we add (14), (15), and (16), we obtain

$$\begin{aligned}\overline{\mathbf{a}}_{ijk} &= \overline{\mathbf{a}}_{i11} - \overline{\mathbf{a}}_{n_1 11} + \overline{\mathbf{a}}_{n_1 j1} - \overline{\mathbf{a}}_{n_1 n_2 1} + \overline{\mathbf{a}}_{n_1 n_2 k} \\ &\quad - \frac{A_2}{B_2}(\overline{\mathbf{a}}_{n_1 n_2 n_3} - \overline{\mathbf{a}}_{n_1 1 n_3} + \overline{\mathbf{a}}_{n_1 11} - \overline{\mathbf{a}}_{n_1 n_2 1}) \\ &\quad - \frac{A_3}{B_3}(\overline{\mathbf{a}}_{n_1 1 n_3} - \overline{\mathbf{a}}_{11 n_3} + \overline{\mathbf{a}}_{111} - \overline{\mathbf{a}}_{n_1 11}) \\ &\quad - \frac{A_1}{B_1}(\overline{\mathbf{a}}_{111} - \overline{\mathbf{a}}_{1 n_2 1} + \overline{\mathbf{a}}_{n_1 n_2 1} - \overline{\mathbf{a}}_{n_1 11}).\end{aligned}$$

To prove the dual feasibility we need to prove that

$$\begin{aligned}&c_{i11} - c_{n_1 11} + c_{n_1 j1} - c_{n_1 n_2 1} + c_{n_1 n_2 k} \\ &- \frac{A_2}{B_2}(c_{n_1 n_2 n_3} - c_{n_1 1 n_3} + c_{n_1 11} - c_{n_1 n_2 1}) \\ &- \frac{A_3}{B_3}(c_{n_1 1 n_3} - c_{11 n_3} + c_{111} - c_{n_1 11}) \\ &- \frac{A_1}{B_1}(c_{111} - c_{1 n_2 1} + c_{n_1 n_2 1} - c_{n_1 11}) - c_{ijk} \le 0,\end{aligned}$$

or, equivalently,

$$\begin{aligned}&(c_{i11} - c_{n_1 11} + c_{n_1 j1} - c_{ij1}) + (c_{ij1} - c_{n_1 j1} + c_{n_1 jk} - c_{ijk}) \\ &\quad + (c_{n_1 j1} - c_{n_1 n_2 1} + c_{n_1 n_2 k} - c_{n_1 jk}) \\ &\quad \le \frac{A_2}{B_2}(c_{n_1 n_2 n_3} - c_{n_1 1 n_3} + c_{n_1 11} - c_{n_1 n_2 1}) \qquad (17) \\ &\quad + \frac{A_3}{B_3}(c_{n_1 1 n_3} - c_{11 n_3} + c_{111} - c_{n_1 11}) + \frac{A_1}{B_1}(c_{111} - c_{1 n_2 1} + c_{n_1 n_2 1} - c_{n_1 11}).\end{aligned}$$

If we fix one of the i, j, k subscripts in c_{ijk}, then, in view of Theorem 4.1 and the results in Table 3, (8) will hold for the remaining two subscripts. Thus we can obtain the following inequalities:

$$c_{i11} - c_{n_1 11} + c_{n_1 j1} - c_{ij1} \le \frac{A_1}{B_1}(c_{111} - c_{1n_2 1} + c_{n_1 n_2 1} - c_{n_1 11}), \tag{18}$$

$$c_{n_1 j1} - c_{n_1 n_2 1} + c_{n_1 n_2 k} - c_{n_1 jk} \le \frac{A_2}{B_2}(c_{n_1 n_2 n_3} - c_{n_1 1 n_3} + c_{n_1 11} - c_{n_1 n_2 1}), \tag{19}$$

$$c_{ij1} - c_{n_1 j1} + c_{n_1 jk} - c_{ijk} \le \frac{A_3}{B_3}(c_{n_1 j n_3} - c_{1 j n_3} + c_{1j1} - c_{n_1 j1}). \tag{20}$$

Also, from the nonpositivity of the (1,1,1)-order divided difference of $c(y_i, z_j, w_k)$, we obtain

$$\frac{\frac{c_{111} - c_{n_1 11} - c_{11n_3} + c_{n_1 1 n_3}}{(y_1 - y_{n_1})(w_1 - w_{n_3})} - \frac{c_{1j1} - c_{n_1 j1} - c_{1jn_3} + c_{n_1 jn_3}}{(y_1 - y_{n_1})(w_1 - w_{n_3})}}{(z_1 - z_j)} \le 0,$$

where $z_1 - z_j < 0$, $y_1 - y_{n_1} < 0$, $w_1 - w_{n_3} < 0$. This implies

$$c_{1j1} - c_{n_1 j1} - c_{1jn_3} + c_{n_1 jn_3} \le c_{111} - c_{n_1 11} - c_{11n_3} + c_{n_1 1 n_3}. \tag{21}$$

By (20), (21), and the inequality $\frac{A_3}{B_3} > 0$, we have

$$c_{ij1} - c_{n_1 j1} + c_{n_1 jk} - c_{ijk} \le \frac{A_3}{B_3}(c_{111} - c_{n_1 11} - c_{11n_3} + c_{n_1 1 n_3}). \tag{22}$$

If we add (18), (19), and (22), we obtain (17). Thus the basis is dual feasible. □

By a similar proof we can obtain the following theorem.

THEOREM 5.2. *Under the same conditions as in Theorem* 5.1*, except that* $(1,1,1)$*-order divided differences of* $c(y_i, z_j, w_k)$ *are nonnegative, the vectors in* $\overline{S}_1 \cup \{\overline{\mathbf{a}}_{n_1 1 n_3}, \overline{\mathbf{a}}_{1 n_2 1}, \overline{\mathbf{a}}_{1 n_2 n_3}\}$ *form a dual feasible basis of the columns of* $\overline{\mathbf{A}}$*.*

Let

$$\begin{aligned}
\overline{S}_2 &= \{\overline{\mathbf{a}}_{i11}, i = 1, \ldots, n_1, \overline{\mathbf{a}}_{n_1 1k}, k = 2, \ldots, n_3, \overline{\mathbf{a}}_{n_1 jn_3}, j = 2, \ldots, n_2\},\\
\overline{S}_3 &= \{\overline{\mathbf{a}}_{1j1}, j = 1, \ldots, n_2, \overline{\mathbf{a}}_{in_2 1}, i = 2, \ldots, n_1, \overline{\mathbf{a}}_{n_1 n_2 k}, k = 2, \ldots, n_3\},\\
\overline{S}_4 &= \{\overline{\mathbf{a}}_{1j1}, j = 1, \ldots, n_2, \overline{\mathbf{a}}_{1n_2 k}, k = 2, \ldots, n_3, \overline{\mathbf{a}}_{in_2 n_3}, i = 2, \ldots, n_1\},\\
\overline{S}_5 &= \{\overline{\mathbf{a}}_{11k}, k = 1, \ldots, n_3, \overline{\mathbf{a}}_{i1n_3}, i = 2, \ldots, n_1, \overline{\mathbf{a}}_{n_1 jn_3}, j = 2, \ldots, n_2\},\\
\overline{S}_6 &= \{\overline{\mathbf{a}}_{11k}, k = 1, \ldots, n_3, \overline{\mathbf{a}}_{1jn_3}, j = 2, \ldots, n_2, \overline{\mathbf{a}}_{in_2 n_3}, i = 2, \ldots, n_1\},\\
\overline{S'}_1 &= \{\overline{\mathbf{a}}_{i11}, i = 1, \ldots, n_1, \overline{\mathbf{a}}_{1j1}, j = 2, \ldots, n_2, \overline{\mathbf{a}}_{11k}, k = 2, \ldots, n_3\},\\
\overline{S'}_2 &= \{\overline{\mathbf{a}}_{in_2 n_3}, i = 1, \ldots, n_1, \overline{\mathbf{a}}_{n_1 jn_3}, j = 1, \ldots, n_2 - 1,\\
&\qquad \overline{\mathbf{a}}_{n_1 n_2 k}, k = 1, \ldots, n_3 - 1\}.
\end{aligned}$$

The vectors of $\overline{S}_i$, $i = 1, \ldots, 6$, $\overline{S'}_1$, and $\overline{S'}_2$ are illustrated in Figure 3. They are represented by the lattice points of the boldface lines.

\overline{S'}_{13} &= \overline{S'}_1 \cup \{\overline{\mathbf{a}}_{n_1 n_2 1}, \overline{\mathbf{a}}_{n_1 n_2 n_3}, \overline{\mathbf{a}}_{1 n_2 n_3}\},\\
\overline{S'}_{14} &= \overline{S'}_1 \cup \{\overline{\mathbf{a}}_{n_1 n_2 n_3}, \overline{\mathbf{a}}_{n_1 1 n_3}, \overline{\mathbf{a}}_{1 n_2 n_3}\}.
\end{aligned}$$

These sets can be dual feasible bases of the three-dimensional problem (9) under different conditions. We present some results in Table 4.

There are, however, cases other than those presented in Table 4. We summarize the results for them in Table 5.

6. Applications and illustrative examples. Monge and inverse Monge arrays come up in many practical applications. In this section we present three more applications which, at the same time, illustrate the ways we can use the results of the present paper.

6.1. Bounding unknown entries in partially known arrays. Any dual feasible basis in an LP may serve for bounding and approximation of unknown components of the coefficient vector of the objective function. If $\mathbf{B}_1$ ($\mathbf{B}_2$) is a dual feasible basis in a minimization (maximization) problem such that $\mathbf{c}_{\mathbf{B}_1}$ ($\mathbf{c}_{\mathbf{B}_2}$) is known, then we have the bound for any unknown c_k:

$$\mathbf{y}_{\mathbf{B}_1}^T \mathbf{a}_k \leq c_k (\leq \mathbf{y}_{\mathbf{B}_2}^T \mathbf{a}_k), \tag{23}$$

where $\mathbf{y}_{\mathbf{B}_i}$ is the solution of the equation $\mathbf{y}_{\mathbf{B}_i}^T \mathbf{B}_i = \mathbf{c}_{\mathbf{B}_i}^T$, $i = 1, 2$.

In section 2 we presented dual feasible bases for problem (1) with Monge arrays in the objective function. Each dual feasible basis gives us a lower (upper) bound. Thus, we have created a method for bounding the entries of the above-mentioned arrays if they are only partially known. If both the lower and upper bounds can be given for c_k and the bounds are close, then they may be used for the approximation of that value.

We can improve on the bounds if we take further dual feasible bases, compute the lower (upper) bounds to the unknown c_{ij} values with each of them, and then take the best lower (upper) bounds obtained that way. One way to get further dual feasible bases is to use the $(GREEDY\ DUAL)_d$ algorithm. We make subsequent steps until the algorithm stops either because a primal feasible basis has been found or because the objective function coefficient corresponding to the entering vector is unknown. Then we take the best bound so far as our final (lower or upper) bound.

Any distribution array is a Monge array, and the entries of a distribution array are values of a probability distribution function. Hence, the methodology of sections 2 and 3 provides us with a methodology for bounding and approximation of unknown values of a multivariate discrete probability distribution function.

Example 6.1. We look at problem (1) where the values of partially known Monge array $\mathbf{c}$ and a_i, b_j are given in the Table 6. First we choose the initial dual feasible basis of the minimization problem as

$$L_1 = \{\mathbf{a}_{11}, \mathbf{a}_{12}, \mathbf{a}_{22}, \mathbf{a}_{23}, \mathbf{a}_{33}, \mathbf{a}_{34}, \mathbf{a}_{35}, \mathbf{a}_{36}, \mathbf{a}_{46}\}.$$

The $(GREEDY\ DUAL)_2$ algorithm provides us with the optimal basis in one step by substituting $\mathbf{a}_{24}$ for $\mathbf{a}_{33}$. By the use of the two dual feasible bases encountered in the algorithm, we have obtained the following final lower bounds:

$$c_{13} \geq 11, \quad c_{14} \geq 9, \quad c_{15} \geq 5, \quad c_{16} \geq 8, \quad c_{21} \geq 14, \quad c_{25} \geq 11, \quad c_{26} \geq 14,$$
$$c_{31} \geq 13, \quad c_{32} \geq 15, \quad c_{41} \geq 14, \quad c_{42} \geq 16, \quad c_{43} \geq 17, \quad c_{44} \geq 14, \quad c_{45} \geq 10.$$

$a_3 = \frac{39}{93}$	c_{31}	c_{32}	$c_{33} = 16$	$c_{34} = 13$	$c_{35} = 9$	$c_{36} = 12$
$a_2 = \frac{22}{93}$	c_{21}	$c_{22} = 16$	$c_{23} = 17$	$c_{24} = 15$	c_{25}	c_{26}
$a_1 = \frac{18}{93}$	$c_{11} = 8$	$c_{12} = 10$	c_{13}	c_{14}	c_{15}	c_{16}
	$b_1 = \frac{10}{93}$	$b_2 = \frac{11}{93}$	$b_3 = \frac{13}{93}$	$b_4 = \frac{20}{93}$	$b_5 = \frac{24}{93}$	$b_6 = \frac{15}{93}$

TABLE 7
Values of c_{ij} for Example 6.2.

$c_{41} = 0.17$	$c_{42} = 0.34$	$c_{43} = 0.53$	$c_{44} = 0.68$	$c_{45} = 0.81$	$c_{46} = 1.00$
$c_{31} = 0.12$	$c_{32} = 0.23$	$c_{33} = 0.36$	$c_{34} = 0.47$	$c_{35} = 0.57$	$c_{36} = 0.72$
$c_{21} = 0.07$	$c_{22} = 0.14$	$c_{23} = 0.23$	$c_{24} = 0.30$	$c_{25} = 0.37$	$c_{26} = 0.49$
$c_{11} = 0.02$	$c_{12} = 0.05$	$c_{13} = 0.09$	$c_{14} = 0.12$	$c_{15} = 0.16$	$c_{16} = 0.22$

6.2. Bounding a probability $P(\mathbf{X_1} \leq \mathbf{X_2})$. Let $\mathbf{X}_1$, $\mathbf{X}_2$ be two independent random vectors with the same discrete support set. Suppose that the probability distribution of $\mathbf{X}_1$ is fully known but the distribution of $\mathbf{X}_2$ is only partially known. We may know all univariate marginal distributions of the components of $\mathbf{X}_2$ and, if $d = 2$ or 3, all covariances of the pairs. Then we can give lower and upper bounds for $P(\mathbf{X}_1 \leq \mathbf{X}_2)$. Each lower or upper bound is based on a dual feasible basis. Any dual feasible basis that we have presented in sections 2–5 provides us with a bound. If the basis is both primal and dual feasible, then the bound is sharp, and no better bound can be given based on the available information. If only the marginals are known, then the $(GREEDY\ DUAL)_d$ algorithm provides us with the sharp bound. If, however, the covariances are also known, then the dual algorithm can be used to obtain the sharp bounds. The dual feasible bases presented in section 2, 4, 5 can serve as initial bases.

Example 6.2. Suppose that the two-dimensional random vectors $\mathbf{X}_1 = (Y_1, Z_1)$ and $\mathbf{X}_2 = (Y_2, Z_2)$ can take on the values (y_i, z_j), $i = 1, \ldots, 4$, $j = 1, \ldots, 6$, where

$$y_1 = 1, \quad y_2 = 3, \quad y_3 = 4, \quad y_4 = 5,$$
$$z_1 = 18, \quad z_2 = 11, \quad z_3 = 6, \quad z_4 = 3, \quad z_5 = 2, \quad z_6 = 1.$$

The values $c_{ij} = F_{\mathbf{X}_1}(y_i, z_j)$ are given in Table 7.

The distribution of $\mathbf{X}_2$ is not completely known; we know only the univariate marginal distributions $P(Y_2 = y_i) = a_i$, $P(Z_2 = z_j) = b_j$ that are given as follows:

$$a_1 = 0.19, \quad a_2 = 0.24, \quad a_3 = 0.42, \quad a_4 = 0.15,$$
$$b_1 = 0.11, \quad b_2 = 0.12, \quad b_3 = 0.14, \quad b_4 = 0.21, \quad b_5 = 0.26, \quad b_6 = 0.16. \tag{24}$$

Since

$$P(\mathbf{X}_1 \leq \mathbf{X}_2) = E[P(\mathbf{X}_1 \leq \mathbf{X}_2 | \mathbf{X}_2)] = \sum_{i=1}^{4} \sum_{j=1}^{6} c_{ij} F_{\mathbf{X}_2}(y_i, z_j),$$

the lower and upper bounds for $P(\mathbf{X}_1 \leq \mathbf{X}_2)$ can be obtained by application of $(GREEDY\ DUAL)_2$ with the a_i, b_j, and c_{ij} values presented in (24) and Table 7. The inverse Monge property of the array c_{ij} allowed us the choice of an initial dual feasible basis for the minimization problem and one for the maximization problem. The obtained bounds for $P(\mathbf{X}_1 \leq \mathbf{X}_2)$ are as follows:

$$0.3232 \leq P(\mathbf{X}_1 \leq \mathbf{X}_2) \leq 0.4381.$$

We can improve on these bounds if the covariance of Y_2, Z_2 is also known. Assume that this covariance equals -5.003. Since

$$E[Y_2] = \sum_{i=1}^{4} y_i a_i = 3.34, \qquad E[Z_2] = \sum_{j=1}^{6} z_j b_j = 5.45,$$

it follows that

$$E[Y_2Z_2] = \sum_{i=1}^{4}\sum_{j=1}^{6} y_i z_j P_{X_2}(y_i, z_j) = \mathrm{Cov}(Y_2, Z_2) + E[Y_2]E[Z_2]$$
$$= -5.003 + (3.34)(5.45) = 13.2.$$

The new bounds can be obtained by the solutions of the minimization and maximization problems (7) by the use of a dual method with 13.2 on the r.h.s. of the last constraint.

The $c(y_i, z_j) = c_{ij}$ has nonnegative (1,2)-order and nonpositive (2,1)-order divided differences; thus we could choose initial dual feasible bases for those problems by the use of Table 3. Then the application of the dual method for both problems gives us the improved bounds as follows:

$$0.4084 \le P(X_1 \le X_2) \le 0.4337.$$

6.3. The Wasserstein distance of two probability distributions. The Wasserstein distance between the probability distributions μ and ν, defined in R^n, is the value

$$W(\mu, \nu) = \inf_{\pi \in \Pi} \sqrt{\int\int \frac{1}{2} d(x, y)^2 d\pi(x, y)}, \tag{25}$$

where Π is the set of all probability distributions in $R^n \times R^n$ with marginals μ and ν, respectively; i.e., if $\pi \in \Pi$, then $\pi(\circ \times R^n) = \mu$, $\pi(R^n \times \circ) = \nu$, and $d(x, y)$ is the Euclidean distance between x and y.

Let $n = 1$ and μ, ν be the discrete distributions with supports $\{y_1, \ldots, y_m\}$, $\{z_1, \ldots, z_n\}$ and corresponding probabilities $\{a_i\}$, $\{b_j\}$, respectively. Then

$$\begin{aligned} W^2(\mu, \nu) = \quad & \min \quad \textstyle\sum_{i=1}^{m}\sum_{j=1}^{n} \frac{1}{2}(y_i - z_j)^2 x_{ij} \\ & \text{subject to} \\ & \textstyle\sum_{j=1}^{n} x_{ij} = a_i, \quad i = 1, \ldots, m, \\ & \textstyle\sum_{i=1}^{m} x_{ij} = b_j, \quad j = 1, \ldots, n, \\ & x_{ij} \ge 0, \quad i = 1, \ldots, m, \quad j = 1, \ldots, n. \end{aligned} \tag{26}$$

Assume that both $\{y_i\}$ and $\{z_j\}$ are increasing sequences. It is easy to see that the array

$$c_{ij} = \frac{1}{2}(y_i - z_j)^2, \quad i = 1, \ldots, m, \quad j = 1, \ldots, n,$$

has the Monge property (its $(1, 1)$-order divided difference is constant, equal to -1).

By Theorem 2.1 the objective function value, corresponding to any ordered sequence of the minimization transportation problem, is a lower bound on $W^2(\mu, \nu)$. That ordered sequence, which is also primal feasible, provides us with the exact value of $W^2(\mu, \nu)$.

7. Conclusions. We have reformulated some basic results, and obtained them in connection with Monge and inverse Monge arrays, in terms of dual feasible bases in the multidimensional transportation problem. We have also obtained general results in connection with the structures of dual feasible bases in the two- and three-dimensional

cases, where the constraints of the transportation problems are supplemented by covariance constraints.

Our results allow for creating lower and upper bounds for unknown entries in partially known Monge and inverse Monge arrays. We have also shown how the results can be used to obtain lower and upper bounds for the expectation of a function of a discrete random vector, where the values of this function form a Monge or inverse Monge array and the univariate marginal distributions of the random vector are known. In the two- and three-dimensional cases we have obtained improved bounds under the condition that the covariances of the pairs of the random variables are also known. In this case the coefficient array of the objective function is supposed to have some special higher order convexity property.

We have presented three applications of the results of the paper. The first one provides us with bounds for unknown entries in a Monge array. The second one gives bounds for the probability that one random vector dominates another one. In the third one we obtain bounds for the Wasserstein distance between two discrete probability distributions.

SECOND-ORDER CONE PROGRAMMING RELAXATION OF SENSOR NETWORK LOCALIZATION*

PAUL TSENG†

In memory of Jos Sturm

Abstract. The sensor network localization problem has been much studied. Recently Biswas and Ye proposed a semidefinite programming (SDP) relaxation of this problem which has various nice properties and for which a number of solution methods have been proposed. Here, we study a second-order cone programming (SOCP) relaxation of this problem, motivated by its simpler structure and its potential to be solved faster than SDP. We show that the SOCP relaxation, though weaker than the SDP relaxation, has nice properties that make it useful as a problem preprocessor. In particular, sensors that are uniquely positioned among interior solutions of the SOCP relaxation are accurate up to the square root of the distance error. Thus, these sensors, which are easily identified, are accurately positioned. In our numerical simulation, the interior solution found can accurately position up to 80–90% of the sensors. We also propose a smoothing coordinate gradient descent method for finding an interior solution that is faster than an interior-point method.

Key words. sensor network localization, semidefinite program, second-order cone program, approximation algorithm, error bound

1. Introduction.

A problem that has received considerable attention is that of ad hoc wireless sensor network localization [3, 10, 11, 16, 17, 22, 28, 30, 31]. The basic version of this problem can be described as follows:

> There are n distinct points in $\Re^d$ ($d \geq 1$). We know the Cartesian coordinates of the last $n-m$ points ("anchors") $x_{m+1}, \ldots, x_n$ and the Euclidean distance $d_{ij} > 0$ between "neighboring" points i and j for $(i,j) \in \mathcal{A}$, where $\mathcal{A} \subseteq (\{1,\ldots,n\} \times \{1,\ldots,m\}) \cup (\{1,\ldots,m\} \times \{1,\ldots,n\})$.[1] We wish to estimate the Cartesian coordinates of the first m points ("sensors").

Typically, $d = 2$ and two points are neighbors if the distance between them is below some threshold (the radio range). In variants of this problem, the distances may be non-Euclidean [30] or may have measurement errors, and there may be additional constraints on the unknown points [16]. This problem is closely related to distance geometry problems arising in the determination of protein structure [8, 24] and to graph rigidity [1, 17, 31].

It is known that the sensor network localization problem is NP-hard in general [29]; see also the remark in [24]. A proof for $d = 1$ is by reduction from the set partition problem, which is readily generalized to $d > 1$. Additional studies are given in [3, 28]. Thus, efforts have been directed at solving this problem approximately. A method based on second-order cone programming (SOCP) relaxation was proposed in [16]. In the case where the anchors lie on the "perimeter," a distributed relaxation

†Department of Mathematics, University of Washington, Seattle, WA 98195-4350 (tseng@math.washington.edu).

[1]The set $\mathcal{A}$ is undirected in the sense that $(i,j) = (j,i)$ and $d_{ij} = d_{ji}$ for all $(i,j) \in \mathcal{A}$.

method was proposed in [28]. The performances of these methods were tested through simulations.

Recently, Biswas and Ye proposed an approach to sensor network localization based on semidefinite programming (SDP) relaxation [10, 11]. In this approach, the problem is formulated as the following nonconvex minimization problem:

$$\upsilon_{\text{opt}} \stackrel{\text{def}}{=} \min_{x_1,\ldots,x_m} \sum_{(i,j)\in\mathcal{A}} |\|x_i - x_j\|^2 - d_{ij}^2|, \tag{1}$$

where $\|\cdot\|$ denotes the Euclidean norm. Introduce

$$X \stackrel{\text{def}}{=} [x_1 \ \cdots \ x_m], \quad A \stackrel{\text{def}}{=} [x_{m+1} \ \cdots \ x_n].$$

Then, for each $(i,j) \in \mathcal{A}$,

$$\begin{aligned}
\|x_i - x_j\|^2 &= (x_i - x_j)^T (x_i - x_j) \\
&= (e_i - e_j)^T \begin{bmatrix} X^T \\ A^T \end{bmatrix} \begin{bmatrix} X & A \end{bmatrix} (e_i - e_j) \\
&= b_{ij}^T \begin{bmatrix} X^T \\ I_d \end{bmatrix} \begin{bmatrix} X & I_d \end{bmatrix} b_{ij} \\
&= \left\langle b_{ij} b_{ij}^T, \begin{bmatrix} X^T X & X^T \\ X & I_d \end{bmatrix} \right\rangle_F,
\end{aligned}$$

where e_i is the ith coordinate vector in $\Re^n$ and $b_{ij} \stackrel{\text{def}}{=} \left[\begin{smallmatrix} I_m & 0 \\ 0 & A \end{smallmatrix}\right] (e_i - e_j)$. Throughout, I_k is the $k \times k$ identity matrix and $\langle A, B\rangle_F \stackrel{\text{def}}{=} \text{trace}[AB]$ for any symmetric real matrices A, B of the same dimension. It is not difficult to see that

$$\begin{bmatrix} Y & X^T \\ X & I_d \end{bmatrix} \succeq 0 \text{ has rank } d \quad \Longleftrightarrow \quad Y = X^T X.^2$$

Thus (1) may be reformulated as

$$\begin{aligned}
\upsilon_{\text{opt}} = \ & \min_{Z} \sum_{(i,j)\in\mathcal{A}} \left|\left\langle b_{ij} b_{ij}^T, Z\right\rangle_F - d_{ij}^2\right| \\
& \text{s.t. } [Z_{ij}]_{i,j\geq n-d} = I_d, \ Z \succeq 0, \ \text{rank}\, Z = d.
\end{aligned} \tag{2}$$

Relaxing the rank-d constraint yields the convex problem

$$\begin{aligned}
\upsilon_{\text{sdp}} \stackrel{\text{def}}{=} \ & \min_{Z} \sum_{(i,j)\in\mathcal{A}} \left|\left\langle b_{ij} b_{ij}^T, Z\right\rangle_F - d_{ij}^2\right| \\
& \text{s.t. } [Z_{ij}]_{i,j\geq n-d} = I_d, \ Z \succeq 0,
\end{aligned} \tag{3}$$

which is an SDP. In particular, by introducing slack variables, this can be written in the standard conic form

$$\begin{aligned}
\min \quad & \sum_{(i,j)\in\mathcal{A}} u_{ij} + v_{ij} \\
\text{s.t.} \quad & \left\langle b_{ij} b_{ij}^T, Z\right\rangle_F - u_{ij} + v_{ij} = d_{ij}^2 \quad \forall (i,j) \in \mathcal{A}, \\
& [Z_{ij}]_{i,j\geq n-d} = I_d, \\
& u_{ij} \geq 0, \ v_{ij} \geq 0 \quad \forall (i,j) \in \mathcal{A}, \ Z \succeq 0,
\end{aligned} \tag{4}$$

[2] In general, $\left[\begin{smallmatrix} u \\ v \end{smallmatrix}\right] \in \text{Null}\left[\begin{smallmatrix} Y & X^T \\ X & I_d \end{smallmatrix}\right]$ if and only if $u \in \text{Null}(Y - X^T X)$, $v = -Xu$.

which has $(m+d)(m+d+1)/2+2|\mathcal{A}|$ variables and $|\mathcal{A}|+d(d+1)/2$ equality constraints. Here $|\mathcal{A}|$ denotes the cardinality of $\mathcal{A}$. In sensor network localization, $|\mathcal{A}| = \Omega(m)$ and $d = 2$ so that (4) has $\Omega(m^2)$ variables and $\Omega(m)$ equality constraints. Properties of the SDP relaxation and its solutions are studied in [10, 31].[3] As noted in [11], the SDP relaxation can be solved by existing SDP solvers for $m \leq 100$ but not for much larger m. Thus, a distributed (domain decomposition) method is proposed to solve larger SDP relaxations. In [22], to further improve the speed and accuracy, the distributed SDP method is terminated early and then a gradient search method is used to locally refine the approximate solution. Simulation results show that this method can more quickly and accurately position most sensors, even in the presence of distance errors.

The challenge in solving the SDP relaxation motivates us to consider SOCP relaxation, first studied by Doherty, Pister, and El Ghaoui [16], since SOCP can be solved to a much larger size than SDP [2, 27]. In fact, there has been little study of SOCP relaxation, compared to SDP relaxation, for nonconvex optimization. Besides [16], which presented models and simulation results with SOCP relaxations of sensor network localization (assuming no distance error), Kim and Kojima [20] and Kim, Kojima, and Yamashita [21] studied SOCP relaxations of certain special classes of SDP and quadratic optimization problems, but their results do not apply to sensor network localization. Here, we present a study, both theoretical and numerical, of the SOCP relaxation of the sensor network localization problem (1), allowing for distance errors. In particular, we show that an interior solution of the SOCP relaxation can be used to accurately position a high percentage of the sensors.[4] To motivate the SOCP relaxation, we reformulate (1) as

$$\begin{aligned} v_{\rm opt} = \quad & \min_{x_1,\ldots,x_m,y_{ij}} \sum_{(i,j)\in\mathcal{A}} |y_{ij} - d_{ij}^2| \\ & \text{s.t.} \;\; y_{ij} = \|x_i - x_j\|^2 \;\; \forall (i,j) \in \mathcal{A}. \end{aligned} \tag{5}$$

Relaxing the equality constraints to "$\geq$" inequality constraints yields the convex problem

$$\begin{aligned} v_{\rm socp} \stackrel{\rm def}{=} \quad & \min_{x_1,\ldots,x_m,y_{ij}} \sum_{(i,j)\in\mathcal{A}} |y_{ij} - d_{ij}^2| \\ & \text{s.t.} \;\; y_{ij} \geq \|x_i - x_j\|^2 \quad \forall (i,j) \in \mathcal{A}, \end{aligned} \tag{6}$$

which is an SOCP. In particular, by noting that $y_{ij} \geq d_{ij}^2$ in any solution of (6) and introducing slack variables, this can be written in the standard conic form

$$\begin{aligned} \min \quad & \sum_{(i,j)\in\mathcal{A}} u_{ij} \\ \text{s.t.} \quad & x_i - x_j - w_{ij} = 0 \quad \forall (i,j) \in \mathcal{A}, \\ & y_{ij} - u_{ij} = d_{ij}^2 \quad \forall (i,j) \in Z\mathcal{A}, \\ & \alpha_{ij} = \tfrac{1}{2} \quad \forall (i,j) \in \mathcal{A}, \\ & u_{ij} \geq 0, \; (\alpha_{ij}, y_{ij}, w_{ij}) \in \text{Rcone}^{d+2} \quad \forall (i,j) \in \mathcal{A}, \end{aligned} \tag{7}$$

where $\text{Rcone}^{d+2} \stackrel{\rm def}{=} \{(\alpha, y, w) \in \Re \times \Re \times \Re^d : 2\alpha y \geq \|w\|^2\}$ [32]. This is an SOCP since

[3] Throughout, "solution" of an optimization problem means a global optimal solution.

[4] Throughout, "interior solution" means an element in the relative interior of the optimal solution set.

$$y \geq \|w\|^2 \iff \left(y+\frac{1}{4}\right)^2 \geq \left(y-\frac{1}{4}\right)^2 + \|w\|^2 \iff y+\frac{1}{4} \geq \left\|\left(y-\frac{1}{4}, w\right)\right\|$$

(see [4, p. 88] or [25, p. 221]). The SOCP (7) has $(d+3)|\mathcal{A}|+md$ variables and $(d+2)|\mathcal{A}|$ equality constraints. In sensor network localization, $|\mathcal{A}| = \Omega(m)$ and $d = 2$, so that (7) has $\Omega(m)$ variables and $\Omega(m)$ equality constraints. Thus, the SOCP relaxation has smaller size than the SDP relaxation.

How good an approximation is the SOCP relaxation? Can it be efficiently solved? We will show that the SOCP relaxation is always weaker than the SDP relaxation and that any interior solution of the SOCP relaxation (which can be found by, say, an interior-point method) will accurately position (up to square root distance error) those sensors that are uniquely positioned; see Propositions 3.1, 7.1, and 7.2. Moreover, the aforementioned sensors (which lie in the convex hull of the anchors) can be easily identified; see Propositions 5.1 and 6.2. In our simulations, described in section 9, up to 80–90% of the sensors are accurately positioned using this technique. Thus, the SOCP relaxation can act as a useful preprocessor by accurately positioning most of the sensors, thus greatly reducing the problem size. The remaining sensors can be positioned by other means, such as SDP relaxation. In section 8, we propose a smoothing coordinate gradient descent (SCGD) method that computes an interior solution of the SOCP relaxation faster than an interior-point method. In sections 10 and 11, we present a mixed SDP-SOCP relaxation of (1), which can flexibly mediate between strength of relaxation and problem size, and discuss alternative problem formulations. In particular, other objective functions can be used in (1), for which SOCP relaxation may be more "natural" than SDP relaxation. However, changing the objective function of (1) changes its solution. Here we consider (1) so to better compare with the existing SDP relaxation approach (Propositions 3.1 and 4.1) and to introduce the mixed SDP-SOCP relaxation. In addition, the SOCP relaxation is a useful problem preprocessor even if it is weaker than SDP relaxation.

Throughout, $\Re^n$ denotes the space of n-dimensional real column vectors (sometimes written horizontally for convenience), $\mathcal{S}^n$ denotes the space of $n \times n$ real symmetric matrices, and ^{T} denotes transpose. For $A \in \Re^{m\times n}$, A_{ij} denotes the (i,j)th entry of A. For $A, B \in \mathcal{S}^n$, $A \succeq B$ means $A - B$ is positive semidefinite. "conv" means the convex hull.

2. An illustrative example. To understand properties of SDP and SOCP relaxations, it is instructive to look at an example. Consider the following example of Ye, with $d = 2$, $n = 3$, $m = 1$, and

$$x_2 = (-1, 0), \quad x_3 = (1, 0), \quad d_{12} = d_{13} = 2.$$

The optimization problem (1) is

$$\min_{x_1=(\alpha,\beta)\in\Re^2} \quad |(1-\alpha)^2 + \beta^2 - 4| + |(-1-\alpha)^2 + \beta^2 - 4|.$$

It has two solutions at $x_1 = (0, \sqrt{3})$, $x_1 = (0, -\sqrt{3})$; see Figure 1.

The SDP relaxation (3) is

$$\begin{array}{ll} \min\limits_{\substack{x_1=(\alpha,\beta)\in\Re^2\\ y\in\Re}} & |y - 2\alpha - 3| + |y + 2\alpha - 3| \\ \text{s.t.} & \begin{bmatrix} y & \alpha & \beta \\ \alpha & 1 & 0 \\ \beta & 0 & 1 \end{bmatrix} \succeq 0. \end{array}$$

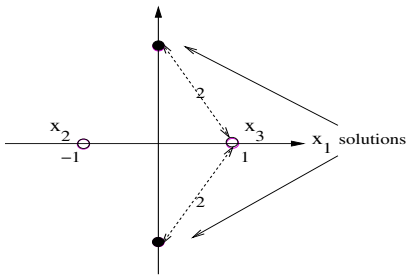

FIG. 1. *The localization problem has two solutions at* $(0, \pm\sqrt{3})$.

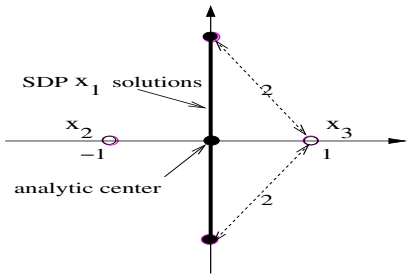

FIG. 2. *The SDP relaxation has the entire line segment as its* x_1*-solution set.*

Its solutions have the form $y = 3$ and x_1 is any point on the line segment joining $(0, -\sqrt{3})$ and $(0, \sqrt{3})$. If we solve the corresponding SDP (4) by an interior-point method, then it will find the solution that maximizes the barrier (see [25, p. 235], [4, p. 384])

$$\det \begin{bmatrix} 3 & 0 & \beta \\ 0 & 1 & 0 \\ \beta & 0 & 1 \end{bmatrix} = 3 - \beta^2.$$

The maximum is attained at $\beta = 0$. The corresponding x_1-solution $(0, 0)$ is the analytic center of the SDP solution set; see Figure 2.

The SOCP relaxation (6) is

$$\begin{array}{ll} \min\limits_{\substack{x_1=(\alpha,\beta)\in\Re^2 \\ y,z\in\Re}} & |y-4| + |z-4| \\ \text{s.t.} & y \geq (\alpha-1)^2 + \beta^2, \\ & z \geq (\alpha+1)^2 + \beta^2. \end{array}$$

Its solutions have the form $y = z = 4$ and x_1 is any point in the intersection of the two disks of radius 2 and centered at $(-1, 0)$ and $(1, 0)$. If we solve the corresponding SOCP (7) by an interior-point method, then it will find the solution that maximizes the barrier (see [25, p. 223], [4, p. 384], and also section 6)

$$\log(4 - (\alpha-1)^2 - \beta^2) + \log(4 - (\alpha+1)^2 - \beta^2).$$

This maximization is attained at $\alpha = \beta = 0$. The corresponding x_1-solution $(0, 0)$ is the analytic center of the SOCP solution set; see Figure 3. In general, finding the

analytic center may be more efficient and accurate than the bounding approach suggested in [16], which entails solving an SOCP $2d$ times with different linear objective functions.

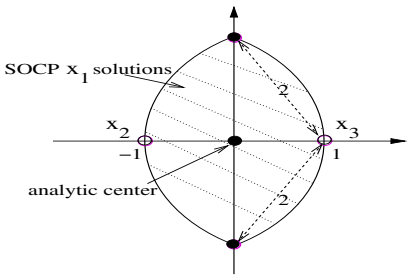

FIG. 3. *The SOCP relaxation has the intersection of two disks as its x_1-solution set.*

From the above example, we make the following observations:

- The SDP x_1-solution set is contained in the SOCP x_1-solution set.
- The analytic center of the SOCP x_1-solution set lies in the convex hull of its neighbors x_2 and x_3.

We will now study in more generality these observed properties of the SDP and SOCP relaxations.

3. Properties of SDP and SOCP relaxations. We show below that the SDP $(x_1, \ldots, x_m)$-solution set is contained in the SOCP $(x_1, \ldots, x_m)$-solution set, so that the SOCP relaxation is weaker than the SDP relaxation.

PROPOSITION 3.1. *If $Z = \left[\begin{smallmatrix} Y & X^T \\ X & I_d \end{smallmatrix}\right]$ is feasible for the SDP relaxation* (3)*, then*

$$x_i = i\text{th column of } X, \quad i = 1, \ldots, m,$$
$$y_{ij} = \begin{cases} Y_{ii} - 2Y_{ij} + Y_{jj} & \text{if } (i,j) \in \mathcal{A},\ i < j \le m; \\ \|x_i\|^2 - 2x_i^T x_j + Y_{jj} & \text{if } (i,j) \in \mathcal{A},\ j \le m < i, \end{cases}$$

is feasible for the SOCP relaxation (6) *with the same objective function value.*

Proof. Since Z is feasible for (3), we have $Z \succeq 0$, so that $Y - X^T X \succeq 0$. Then any 2×2 principal submatrix of $Y - X^T X$ is positive semidefinite, so that, for any $(i,j) \in \mathcal{A}$ with $i < j \le m$,

$$\begin{bmatrix} Y_{ii} - \|x_i\|^2 & Y_{ij} - x_i^T x_j \\ Y_{ij} - x_i^T x_j & Y_{jj} - \|x_j\|^2 \end{bmatrix} \succeq 0,$$

implying that

$$Y_{ii} \ge \|x_i\|^2, \quad Y_{jj} \ge \|x_j\|^2, \quad (Y_{ii} - \|x_i\|^2)(Y_{jj} - \|x_j\|^2) \ge (Y_{ij} - x_i^T x_j)^2. \tag{8}$$

For any $a \ge 0$, $b \ge 0$, $ab \ge c^2$, we have $(a+b)^2 = 4ab + (a-b)^2 \ge 4c^2$ and hence $a + b \ge 2|c|$. Thus (8) implies

$$Y_{ii} - \|x_i\|^2 + Y_{jj} - \|x_j\|^2 \ge 2|Y_{ij} - x_i^T x_j| \ge 2(Y_{ij} - x_i^T x_j).$$

Hence

$$y_{ij} = Y_{ii} - 2Y_{ij} + Y_{jj} \ge \|x_i\|^2 - 2x_i^T x_j + \|x_j\|^2 = \|x_i - x_j\|^2.$$

Similarly, any diagonal entry of $Y - X^T X$ is nonnegative, so that, for any $(i,j) \in \mathcal{A}$ with $j \le m < i$, $Y_{jj} - \|x_j\|^2 \ge 0$ and hence

$$y_{ij} = \|x_i\|^2 - 2x_i^T x_j + Y_{jj} \ge \|x_i\|^2 - 2x_i^T x_j + \|x_j\|^2 = \|x_i - x_j\|^2.$$

Thus $x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ is feasible for (6).

Last, we have from the definition of b_{ij} and y_{ij} that

$$\begin{aligned}
&\sum_{(i,j)\in\mathcal{A}} \left|\left\langle b_{ij} b_{ij}^T, Z\right\rangle_F - d_{ij}^2\right| \\
&= \sum_{\substack{i<j\le m \\ (i,j)\in\mathcal{A}}} |Y_{ii} - 2Y_{ij} + Y_{jj} - d_{ij}^2| + \sum_{\substack{j\le m<i \\ (i,j)\in\mathcal{A}}} |\|x_i\|^2 - 2x_i^T x_j + Y_{jj} - d_{ij}^2| \\
&= \sum_{\substack{i<j\le m \\ (i,j)\in\mathcal{A}}} |y_{ij} - d_{ij}^2| + \sum_{\substack{j\le m<i \\ (i,j)\in\mathcal{A}}} |y_{ij} - d_{ij}^2|.
\end{aligned}$$

Thus, Z and $x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ have the same objective function value for (3) and (6), respectively. □

Proposition 3.1 shows that (i) $v_{\text{SDP}} \ge v_{\text{SOCP}}$ and (ii) if $v_{\text{SDP}} = v_{\text{SOCP}}$, then the set of SDP solutions is contained in the set of SOCP solutions when projected onto the $x_1, \ldots, x_m$-space.

It is well known that the solution set of (3) is closed and convex, and the same is true of (6). An interior solution can be found by, say, applying an interior-point method to (4) and (7). We will see that such an interior solution has desirable properties for identifying sensors that are accurately positioned.

When solving SDP or SOCP by an interior-point method, the solution set must be bounded. It is readily seen that the solution set of (3) is bounded if and only if the solution set of (4) is bounded. Similarly, the solution set of (6) is bounded if and only if the solution set of (7) is bounded. In [31, Proposition 1], it is shown in the case of $v_{\text{opt}} = 0$ (i.e., no distance error) that the solution set of (3) is bounded if the following assumption holds.

ASSUMPTION 1. *Each connected component of the graph* $\mathcal{G} \stackrel{\text{def}}{=} (\{1, \ldots, n\}, \mathcal{A})$ *contains an anchor index.*

It is not difficult to see that this remains true when $v_{\text{opt}} > 0$ and that the converse also holds. Similarly, it is readily shown that the set of solutions of (6) is bounded if and only if Assumption 1 holds. This is summarized in the following lemma.

LEMMA 3.2. (a) *The solution set of* (3) *is bounded if and only if Assumption* 1 *holds.*

(b) *The solution set of* (6) *is bounded if and only if Assumption* 1 *holds.*

Assumption 1 is reasonable since if a connected component of $\mathcal{G}$ does not contain an anchor index, then the corresponding sensors cannot be accurately positioned. In the absence of an anchor (i.e., $m = n$), as arises in protein structure prediction, the solution set is unbounded and, in particular, each solution can be rotated and translated to yield another solution. In [8], an optimization formulation is proposed to remove the translation factor and ensure a bounded solution set (assuming no distance error) and an extension of the distributed SDP method in [11] is proposed, in which points in overlapping "subconfigurations" are further rotated and translated to match closely on the overlap.

4. Interior solution of the SDP relaxation. Let $Z = \left[\begin{smallmatrix} Y & X^T \\ X & I_d \end{smallmatrix}\right]$ be any solution of the SDP relaxation (3). Biswas and Ye introduced the notion of individual traces of Z, defined by

$$\mathrm{tr}_i[Z] \stackrel{\mathrm{def}}{=} Y_{ii} - \|x_i\|^2, \quad i = 1, \ldots, m,$$

where x_i is the ith column of X. Since $Z \succeq 0$ so that $Y - X^T X \succeq 0$, we have

$$\mathrm{tr}_i[Z] \geq 0, \quad i = 1, \ldots, m.$$

These individual traces were given a probabilistic interpretation in [10, section 4] as the variance of random points $\tilde{x}_i$ with $\mathrm{E}[\tilde{x}_i] = x_i$ and $\mathrm{E}[\tilde{x}_i^T \tilde{x}_j] = Y_{ij}$. In [11, section 2], they were used to evaluate the accuracy of the estimated positions x_i, $i = 1, \ldots, m$, with smaller trace indicating higher accuracy. So and Ye [31, Theorem 2] proved in the case of $\upsilon_{\mathrm{sdp}} = 0$ that the sensors are "uniquely localizable" if and only if, for any interior solution Z (equivalently, Z is a solution of maximum rank), all individual traces of Z are zero, i.e., $Y = X^T X$.

The following proposition provides some justification for using individual traces to evaluate accuracy of computed sensor positions. It shows that, for any interior solution of (3), if the ith trace is zero, then the ith sensor is uniquely positioned by the SDP relaxation (and hence is correctly positioned when $\upsilon_{\mathrm{sdp}} = 0$). This result gives a local generalization of the "if" direction in [31, Theorem 2] that is analogous to [31, Theorem 4].

PROPOSITION 4.1. *Let $Z = \left[\begin{smallmatrix} Y & X^T \\ X & I_d \end{smallmatrix}\right]$ be an interior solution of* (3)*. For each $i \in \{1, \ldots, m\}$, if $\mathrm{tr}_i[Z] = 0$, then x_i is invariant over all solutions of* (3)*, where x_i is the ith column of X. Moreover, $Y_{JJ} - X_J^T X_J = 0$, where $J \stackrel{\mathrm{def}}{=} \{i \leq m : \mathrm{tr}_i[Z] = 0\}$, Y_{JJ} is the principal submatrix of Y indexed by J, and X_J is submatrix of X comprising the columns indexed by J.*

Proof. Consider any solution Z' of (3). Since Z is an interior solution, then

$$Z^1 \stackrel{\mathrm{def}}{=} Z + \epsilon(Z' - Z), \quad Z^2 \stackrel{\mathrm{def}}{=} Z - \epsilon(Z' - Z)$$

are both solutions of (3) for any sufficiently small $\epsilon > 0$. Write them in the forms

$$Z^1 = \begin{bmatrix} Y^1 & (X^1)^T \\ X^1 & I_d \end{bmatrix} \quad \text{and} \quad Z^2 = \begin{bmatrix} Y^2 & (X^2)^T \\ X^2 & I_d \end{bmatrix}.$$

Since $Z = (Z^1 + Z^2)/2$, this implies that, for any $i \in \{1, \ldots, m\}$,

$$\begin{aligned} \mathrm{tr}_i[Z] &= \mathrm{tr}_i[(Z^1 + Z^2)/2] \\ &= (Y_{ii}^1 + Y_{ii}^2)/2 - \|(x_i^1 + x_i^2)/2\|^2 \\ &= (Y_{ii}^1 + Y_{ii}^2)/2 - \big(\|x_i^1\|^2 + \|x_i^2\|^2 - \|x_i^1 - x_i^2\|^2/2\big)/2 \\ &= (\mathrm{tr}_i[Z^1] + \mathrm{tr}_i[Z^2])/2 + \|x_i^1 - x_i^2\|^2/4, \end{aligned}$$

where x_i^1, x_i^2 are the ith columns of X^1, X^2, respectively. Since $\mathrm{tr}_i[Z^1] \geq 0$ and $\mathrm{tr}_i[Z^2] \geq 0$, if $\mathrm{tr}_i[Z] = 0$, then $x_i^1 = x_i^2$ and hence $x_i' = x_i$.

Since $Y - X^T X \succeq 0$, we have $Y_{JJ} - X_J^T X_J \succeq 0$. Since $0 = \mathrm{tr}_i[Z] = [Y - X^T X]_{ii}$ for all $i \in J$ so that $Y_{JJ} - X_J^T X_J$ has zero diagonals, this implies $Y_{JJ} - X_J^T X_J = 0$. ∎

Proposition 4.1 shows that any interior solution identifies some subset of sensors that are uniquely positioned by the SDP relaxation. It is an open question whether

the converse of Proposition 4.1 holds, i.e., if Z is an interior solution of (3) and $\mathrm{tr}_i[Z] > 0$, then x_i is not invariant over all solutions of (3). We will prove in section 5 an analogous result for the SOCP relaxation (6).

When an interior-point method is used to solve the SDP relaxation (4), it will find not only an interior solution, but an interior solution that maximizes the nonzero traces in some sense. Using such a solution should make the zero-trace test more robust under computation errors. A rigorous study of this topic requires knowledge of the asymptotic behavior of the central path for SDP, which is not fully understood; see [26] and references therein. On the other hand, the simpler structure of the SOCP relaxation (7) makes possible such a study, as we will do in section 5.

5. Interior solution of the SOCP relaxation. Since the SOCP is a convex minimization problem, there exists a maximal subset of constraints that are tight/active at every solution. In particular, there exists a unique $\mathcal{B} \subseteq \mathcal{A}$ such that

$$\|x_i - x_j\|^2 = y_{ij} \ \forall \text{ solutions } x_1, \ldots, x_m, (y_{ij})_{(i,j)\in\mathcal{A}} \text{ of (6)} \quad \Longleftrightarrow \quad (i,j) \in \mathcal{B}. \tag{9}$$

Any solution that satisfies strictly the remaining constraints of (6) lies in the relative interior of the solution set; i.e., it is an interior solution.

In what follows, we denote the set of neighbors of $i \in \{1, \ldots, m\}$ relative to any $\mathcal{B} \subseteq \mathcal{A}$ by

$$N_{\mathcal{B}}(i) \stackrel{\text{def}}{=} \{j \in \{1, \ldots, n\} \ : \ (i,j) \in \mathcal{B}\}.$$

Also,

$$M_{\mathcal{B}} \stackrel{\text{def}}{=} \{i \in \{1, \ldots, m\} \ : \ N_{\mathcal{B}}(i) \neq \emptyset\}.$$

The next result is key for identifying those sensors that are uniquely positioned by the SOCP relaxation.

PROPOSITION 5.1. *Let $x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ be any interior solution of* (6). *Let $\mathcal{B}$ be given by* (9). *The following results hold.*

(a) *For each $i \in M_{\mathcal{B}}$,*

$$x_i \in \mathrm{conv}\,\{x_j\}_{j\in N_{\mathcal{B}}(i)}\,. \tag{10}$$

(b) *Each connected component of the graph $G_{\mathcal{B}} \stackrel{\text{def}}{=} (M_{\mathcal{B}} \cup \{m+1, \ldots, n\}, \mathcal{B})$ contains an anchor index $i \in \{m+1, \ldots, n\}$.*

(c) *For each $i \in \{1, \ldots, m\}$, x_i is invariant over all solutions of* (6) *if and only if $i \in M_{\mathcal{B}}$.*

Proof. (a) We argue by contradiction. Suppose that (10) fails to hold for some $i \in M_{\mathcal{B}}$. Let p_i denote the nearest-point projection of x_i onto $\mathrm{conv}\,\{x_j\}_{j\in N_{\mathcal{B}}(i)}$. Then, $p_i \neq x_i$ and, for each $j \in N_{\mathcal{B}}(i)$, we have $(x_i - p_i)^T(p_i - x_j) \geq 0$, implying

$$\begin{aligned}\|x_i - x_j\|^2 &= \|x_i - p_i + p_i - x_j\|^2 \\ &= \|x_i - p_i\|^2 + \|p_i - x_j\|^2 + 2(x_i - p_i)^T(p_i - x_j) \\ &> \|p_i - x_j\|^2.\end{aligned}$$

For $\epsilon \in (0,1)$, let

$$x_i^\epsilon = (1-\epsilon)x_i + \epsilon p_i.$$

Since $\|x_i - x_j\|^2 = y_{ij}$ for all $j \in N_{\mathcal{B}}(i)$ and $\|x_i - x_j\|^2 < y_{ij}$ for all $j \in N_{\mathcal{A}\setminus\mathcal{B}}(i)$, the convexity and continuity of $\|\cdot\|^2$ yield that

$$\|x_i^\epsilon - x_j\|^2 < y_{ij} \quad \forall j \in N_{\mathcal{A}}(i),$$

for all ϵ sufficiently small. Thus, replacing x_i by x_i^ϵ yields another solution of (6), and it satisfies strictly the constraints corresponding to $j \in N_{\mathcal{B}}(i)$. This contradicts the assumption that $x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ is an interior solution.

(b) Choose any $\bar{i} \in M_{\mathcal{B}}$ and initialize $\bar{M} \leftarrow \{\bar{i}\}$. Then, whenever there is an $i \in \bar{M} \cap M_{\mathcal{B}}$ with $N_{\mathcal{B}}(i) \not\subseteq \bar{M}$, we add $N_{\mathcal{B}}(i)$ to $\bar{M}$, i.e., $\bar{M} \leftarrow \bar{M} \cup N_{\mathcal{B}}(i)$, until no such i exists. Since, for each $i \in M_{\mathcal{B}}$, each $j \in N_{\mathcal{B}}(i)$ either indexes an anchor or else belongs to $M_{\mathcal{B}}$ (since $N_{\mathcal{B}}(j) \neq \emptyset$), we see that $\bar{M} \subseteq M_{\mathcal{B}} \cup \{m+1, \ldots, n\}$. Moreover, for each $i \in \bar{M} \cap M_{\mathcal{B}}$, we have $N_{\mathcal{B}}(i) \subseteq \bar{M}$ and, by (a), (10) holds, so that

$$x_i \in \operatorname{conv}\{x_j\}_{j\in N_{\mathcal{B}}(i)} \subseteq \operatorname{conv}\{x_j\}_{j\in\bar{M}},$$

implying that x_i is not an extreme point of $\{x_j\}_{j\in\bar{M}}$. Thus, all extreme points of $\operatorname{conv}\{x_j\}_{j\in\bar{M}}$ are anchors. Let

$$\bar{\mathcal{A}} = \{(i,j) \ : \ i \in \bar{M} \cap M_{\mathcal{B}},\ j \in N_{\mathcal{B}}(i)\}.$$

Then $(\bar{M}, \bar{\mathcal{A}})$ is a connected subgraph of $G_{\mathcal{B}}$, and it contains an anchor index; see Figure 4 for an illustrative example. Thus the connected component of $G_{\mathcal{B}}$ that contains this subgraph contains an anchor index. Since the choice of $\bar{i} \in M_{\mathcal{B}}$ was arbitrary, this shows that every connected component of $G_{\mathcal{B}}$ contains an anchor index.

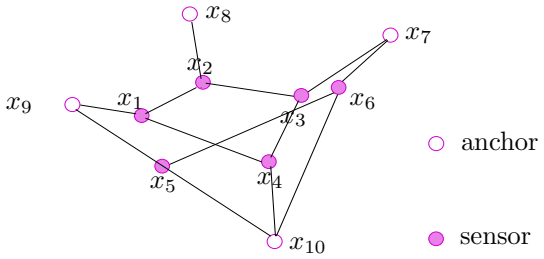

FIG. 4. *In this example, $\mathcal{B}$ is shown as lines and $M_{\mathcal{B}} = \{1, 2, \ldots, 6\}$. For $\bar{i} \in \{1,2,3,4\}$, we have $\bar{M} = \{1,2,3,4,7,8,9,10\}$, $\bar{\mathcal{A}} = \{(1,2),(1,4),(1,9),(2,3),(2,8),(3,7),(3,4),(4,10)\}$. For $\bar{i} \in \{5,6\}$, we have $\bar{M} = \{5,6,7,9,10\}$, $\bar{\mathcal{A}} = \{(5,6),(5,9),(5,10),(6,7),(6,10)\}$.*

(c) If $x'_1, \ldots, x'_m$, $(y'_{ij})_{(i,j)\in\mathcal{A}}$ is any solution of (6), then for each $(i,j) \in \mathcal{B}$,

$$\|x'_i - x'_j\|^2 = y'_{ij}$$

(with $x'_i = x_i$ for $i > m$). Combining this with $\|x_i - x_j\|^2 = y_{ij}$ yields

$$\frac{y_{ij} + y'_{ij}}{2} = \left\| \frac{x_i - x_j}{2} + \frac{x'_i - x'_j}{2} \right\|^2 + \left\| \frac{x_i - x_j}{2} - \frac{x'_i - x'_j}{2} \right\|^2. \tag{11}$$

Since the solution set of (6) is convex, so that $\frac{1}{2}(x_1 + x'_1), \ldots, \frac{1}{2}(x_m + x'_m)$, $(\frac{1}{2}(y_{ij} + y'_{ij}))_{(i,j)\in\mathcal{A}}$ also forms a solution, $(i,j) \in \mathcal{B}$ implies that the rightmost term in (11) must be zero. This in turn implies that

$$x'_i - x'_j = x_i - x_j.$$

Thus, for each $(i,j) \in \mathcal{B}$ there exists $\Delta_{ij} \in \Re^d$ such that

$$x'_i - x'_j = \Delta_{ij} \quad \begin{array}{l} \forall \text{ solutions } x'_1, \ldots, x'_m, (y'_{ij})_{(i,j)\in\mathcal{A}} \\ \text{of (6) (with } x'_i = x_i \text{ for } i > m). \end{array} \tag{12}$$

Let $(\bar{M}, \bar{\mathcal{B}})$ be any connected component of $G_{\mathcal{B}}$. By (b), there exists $i \in \bar{M} \cap \{m+1, \ldots, n\}$, i.e., x_i is an anchor. For each $j \in N_{\bar{\mathcal{B}}}(i)$, we have $(i,j) \in \mathcal{B}$ so that (12) implies

$$x_i - x'_j = \Delta_{ij} = x_i - x_j$$

for all solutions $x'_1, \ldots, x'_m$, $(y'_{ij})_{(i,j)\in\mathcal{A}}$ of (6). Hence $x'_j = x_j$. Since $j \in \bar{M}$, we can repeat the above argument with j in place of i and so on. This yields $x'_j = x_j$ for all $j \in \bar{M}$. Since the choice of the connected component was arbitrary, this shows that $x'_j = x_j$ for all $j \in M_{\mathcal{B}}$.

If $i \le m$ and $i \notin M_{\mathcal{B}}$, then $N_{\mathcal{B}}(i) = \emptyset$. This implies

$$\|x_i - x_j\|^2 < y_{ij} \quad \forall j \in N_{\mathcal{A}}(i).$$

Then, we can perturb x_i and obtain another solution $x'_1, \ldots, x'_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ of (6) with $x'_i \neq x_i$. □

As a corollary of Proposition 5.1(c), we have that the solution of (6) is unique if and only if each connected component of the graph $(\{1, \ldots, n\}, \mathcal{B})$ contains an anchor index (i.e., $M_{\mathcal{B}} = \{1, \ldots, m\}$).

Proposition 5.1 shows that those points x_i with $i \in M_{\mathcal{B}}$ have the following three properties: (i) they satisfy (10), (ii) $\|x_i - x_j\|^2 = y_{ij}$ for all $j \in N_{\mathcal{B}}(i)$, and (iii) their positions are uniquely determined by the anchors $x_{m+1}, \ldots, x_n$ and $(y_{ij})_{(i,j)\in\mathcal{B}}$. Might the first two properties (i), (ii) imply property (iii)? This question is related to graph rigidity and uniqueness of graph realizability. However, the following example in Figure 5, suggested by Connelly [15], shows that this is not true. The outer three points are anchors, the edges of $\mathcal{B}$ are as shown, and the inner three points (sensors) form a triangle that can be twisted slightly clockwise or counterclockwise to be in two different positions, both of which have properties (i) and (ii).

FIG. 5. *An example in* $\Re^2$ *of nonunique sensor positions satisfying* (10) *and preserving distances.*

6. Analytic center solution of the SOCP relaxation. As mentioned in section 2, when we solve (7) using an interior-point method, the method will generally find not only an interior solution, but an analytic center of the solution set. We study this in more depth below. We first need the following lemma to relate the solutions of (6) and (7).

LEMMA 6.1. $(y_{ij})_{(i,j)\in\mathcal{A}}$ *is invariant over all solutions of* (6).

Proof. Let $\mathcal{B}$ be given by (9). Suppose we have two solutions of (6): $x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ and $x'_1, \ldots, x'_m$, $(y'_{ij})_{(i,j)\in\mathcal{A}}$. Then, for each $(i,j) \in \mathcal{B}$, $y_{ij} = \|x_i - x_j\|^2$ and $y'_{ij} = \|x'_i - x'_j\|^2$ (with $x'_i = x_i$ for $i > m$), so that

$$\frac{y_{ij} + y'_{ij}}{2} = \left\| \frac{x_i - x_j}{2} + \frac{x'_i - x'_j}{2} \right\|^2 + \left\| \frac{x_i - x_j}{2} - \frac{x'_i - x'_j}{2} \right\|^2.$$

Since the solution set is convex so that $\frac{1}{2}(x_1 + x'_1), \ldots, \frac{1}{2}(x_m + x'_m)$, $(\frac{1}{2}(y_{ij} + y'_{ij}))_{(i,j)\in\mathcal{A}}$ also forms a solution of (6), the rightmost term must be zero, i.e., $x_i - x_j = x'_i - x'_j$. Thus $y_{ij} = y'_{ij}$.

For each $(i,j) \in \mathcal{A}\backslash\mathcal{B}$, we have $y_{ij} > \|x_i - x_j\|^2$ for all interior solutions $x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ of (6), implying $y_{ij} = d_{ij}^2$. (If $y_{ij} \neq d_{ij}^2$, then y_{ij} can be perturbed to decrease $|y_{ij} - d_{ij}^2|$ and hence decrease the objective function value.) Taking closure yields that $y_{ij} = d_{ij}^2$ for all solutions $x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ of (6) so that y_{ij} is unique. ∎

By using Lemma 6.1, we see that $(u_{ij})_{(i,j)\in\mathcal{A}}$ is invariant over all solutions of (7). Then, under Assumption 1, the limiting point of the central path for (7) would be an interior solution of (7) that maximizes (see [25, p. 223], [4, p. 384])

$$\sum_{(i,j)\in\mathcal{A}\backslash\mathcal{B}} \log\left(\left(y_{ij} + \frac{1}{4} \right)^2 - \left\| \left(y_{ij} - \frac{1}{4}, w_{ij} \right) \right\|^2 \right) = \sum_{(i,j)\in\mathcal{A}\backslash\mathcal{B}} \log\left(y_{ij} - \|x_i - x_j\|^2 \right).$$

Accordingly, we define an *analytic center solution* of (6) to be an interior solution of (6) that maximizes

$$\sum_{(i,j)\in\mathcal{A}\backslash\mathcal{B}} \log\left(y_{ij} - \|x_i - x_j\|^2 \right) \tag{13}$$

over all interior solutions. Thus, an analytic center solution in some sense maximizes the slacks $y_{ij} - \|x_i - x_j\|^2$ for all inactive constraints $(i,j) \in \mathcal{A} \setminus \mathcal{B}$. Its existence is guaranteed by Assumption 1. It is unique because of Proposition 5.1(c) and that, by Lemma 6.1 and the strict concavity of $\log(y_{ij} - \|\cdot\|^2)$, $x_i - x_j$ is unique for all $(i,j) \in \mathcal{A} \setminus \mathcal{B}$. This is the interior solution that a log-barrier interior-point method will likely find. If a barrier method based on a different barrier function is used to solve (7), then the interior solution found need not be the analytic center.

The next proposition verifies one of our observations from the example in section 2. This is further illustrated in Figure 7.

PROPOSITION 6.2. *If $x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ is the analytic center solution of (6), then*

$$x_i \in \operatorname{conv}\{x_j\}_{j\in N_{\mathcal{A}}(i)}, \quad i = 1, \ldots, m.$$

Proof. We argue by contradiction. Suppose there exists $i \in \{1, \ldots, m\}$ such that

$$x_i \notin \operatorname{conv}\{x_j\}_{j\in N_{\mathcal{A}}(i)}.$$

Let p_i denote the nearest-point projection of x_i onto this convex hull. Then, as in the proof of Proposition 5.1(a), we have

$$\|p_i - x_j\|^2 < \|x_i - x_j\|^2 \quad \forall j \in N_{\mathcal{A}}(i).$$

Thus, replacing x_i by p_i would yield another interior solution of (6). Moreover, if $(i,j) \in \mathcal{A} \setminus \mathcal{B}$, then $y_{ij} - \|p_i - x_j\|^2 > y_{ij} - \|x_i - x_j\|^2 > 0$, so that

$$\log\left(y_{ij} - \|p_i - x_j\|^2\right) \; > \; \log\left(y_{ij} - \|x_i - x_j\|^2\right).$$

Summing these inequalities yields

$$\sum_{j \in N_{\mathcal{A}\setminus\mathcal{B}}(i)} \log\left(y_{ij} - \|p_i - x_j\|^2\right) > \sum_{j \in N_{\mathcal{A}\setminus\mathcal{B}}(i)} \log\left(y_{ij} - \|x_i - x_j\|^2\right).$$

This contradicts our assumption that $x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ is the analytic center solution of (6). □

It is an open question whether a result analogous to Lemma 6.1 holds for the SDP relaxation (3); namely, is $\left(\langle b_{ij} b_{ij}^T, Z\rangle_F\right)_{(i,j)\in\mathcal{A}}$ invariant over all solutions of (3)? There does not appear to be a result analogous to Proposition 6.2 for SDP relaxation. In particular, (3) need not have any solution satisfying the convex hull condition of Proposition 6.2; see an example in Figure 1(a) of [31].

7. Error analysis for the SOCP relaxation. In practice, the distance d_{ij} has measurement error, i.e.,

$$d_{ij}^2 = \bar{y}_{ij} + \delta_{ij} \quad \forall (i,j) \in \mathcal{A},$$

where $\delta_{ij} \in \Re$ and $\bar{y}_{ij} = \|x_i^{\text{true}} - x_j^{\text{true}}\|^2$ for some $x_1^{\text{true}}, \ldots, x_m^{\text{true}}$ representing the true positions of the sensors, and with $x_i^{\text{true}} = x_i$ for $i > m$. What is the corresponding error in the solution of (6)? We study this question in this section.

In what follows, we denote for simplicity $x = (x_1, \ldots, x_m) \in \Re^d \times \cdots \times \Re^d$ and

$$q_{ij}(x) \stackrel{\text{def}}{=} \|x_i - x_j\|^2 - \bar{y}_{ij} \quad \forall (i,j) \in \mathcal{A}. \tag{14}$$

Also,

$$\Xi \stackrel{\text{def}}{=} \{x : q_{ij}(x) \le 0 \;\; \forall \; (i,j) \in \mathcal{A}\}. \tag{15}$$

Then Ξ contains the true solution $x^{\text{true}} = (x_1^{\text{true}}, \ldots, x_m^{\text{true}})$. By the convexity of q_{ij}, Ξ is a convex set and there exists $\bar{\mathcal{B}} \subseteq \mathcal{A}$ such that

$$q_{ij}(x) = 0 \; \forall x \in \Xi \quad \Longleftrightarrow \quad (i,j) \in \bar{\mathcal{B}}.$$

Since x^{true}, $(\bar{y}_{ij})_{(i,j)\in\mathcal{A}}$ is feasible for (6), any solution $x = (x_1, \ldots, x_m)$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ of (6) satisfies

$$\sum_{(i,j)\in\mathcal{A}} |y_{ij} - d_{ij}^2| \le \sum_{(i,j)\in\mathcal{A}} |\bar{y}_{ij} - d_{ij}^2| = \sum_{(i,j)\in\mathcal{A}} |\delta_{ij}|. \tag{16}$$

Since $\|x_i - x_j\|^2 \le y_{ij}$ so that $q_{ij}(x) \le y_{ij} - \bar{y}_{ij}$, this yields

$$\begin{aligned}
\sum_{(i,j)\in\mathcal{A}} q_{ij}(x)_+ &\le \sum_{(i,j)\in\mathcal{A}} (y_{ij} - \bar{y}_{ij})_+ \\
&\le \sum_{(i,j)\in\mathcal{A}} |y_{ij} - \bar{y}_{ij}| \\
&\le \sum_{(i,j)\in\mathcal{A}} (|y_{ij} - d_{ij}^2| + |d_{ij}^2 - \bar{y}_{ij}|) \\
&\le 2 \sum_{(i,j)\in\mathcal{A}} |\delta_{ij}|, \qquad (17)
\end{aligned}$$

where $\alpha_+ \stackrel{\text{def}}{=} \max\{0, \alpha\}$.

Using Proposition 5.1, we show below that if the distance error is small so the right-hand side of (17) is small, then $(x_i)_{i\in M_{\mathcal{B}}}$ in a solution of (6) has small error (in fact, proportional to the square root of distance error), where $\mathcal{B}$ is given by (9); see Propositions 7.1 and 7.2. Moreover, we can find $\mathcal{B}$ from an interior solution of (6); see also section 9. Although there exist sensitivity analysis results for convex quadratic inequalities of the form (15), the results either make the restrictive assumption that Ξ has nonempty interior [23] or prove a much weaker result that the solution error is proportional to the $2^{|\mathcal{A}|+1}$th root of the distance error [33]; see discussions following Corollary 7.3. Existing sensitivity analysis results for general nonlinear programs make technical assumptions that either do not hold or are difficult to verify for (15); see, e.g., [12, sections 5.2, 5.3].

For any $\mathcal{B} \subseteq \mathcal{A}$,

$$\Xi_{\mathcal{B}} \stackrel{\text{def}}{=} \{x \in \Xi \ : \ q_{ij}(x) = 0 \ \forall (i,j) \in \mathcal{B}\}.$$

For any nonempty closed subset Ξ' of Ξ, let

$$\operatorname{dist}((x_1 \ldots, x_m), \Xi') \stackrel{\text{def}}{=} \min_{(\bar{x}_1,\ldots,\bar{x}_m)\in\Xi'} \max_{i=1,\ldots,m} \|x_i - \bar{x}_i\|.$$

PROPOSITION 7.1. (a) *For each $\epsilon > 0$, there exists a scalar $\delta > 0$ such that*

$$\Xi_{\mathcal{B}} \neq \emptyset \qquad \textit{and} \qquad \operatorname{dist}(x, \Xi_{\mathcal{B}}) \leq \epsilon$$

whenever $\mathcal{B}$ satisfies (9), *$x = (x_1, \ldots, x_m)$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ is a solution of* (6), *and $\sum_{(i,j)\in\mathcal{A}} |\delta_{ij}| \leq \delta$.*

(b) *There exists an $\bar{\epsilon} > 0$ such that, for each $0 < \epsilon < \bar{\epsilon}$, there exists a scalar $\delta > 0$ such that*

$$\mathcal{B} \subseteq \bar{\mathcal{B}} \qquad \textit{and} \qquad \|x_i - x_i^{\text{true}}\| \leq \epsilon \quad \forall i \in M_{\mathcal{B}},$$

whenever $\mathcal{B}$ satisfies (9), *$x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ is a solution of* (6), *and $\sum_{(i,j)\in\mathcal{A}} |\delta_{ij}| \leq \delta$.*

Proof. (a) Fix any $\epsilon > 0$. If the desired δ does not exist, there would exist $(\delta_{ij}^t)_{(i,j)\in\mathcal{A}}$, $t = 1, 2, \ldots$, with $\sum_{(i,j)\in\mathcal{A}} |\delta_{ij}^t| \to 0$, and a $\mathcal{B} \subseteq \mathcal{A}$ satisfying (9) with $d_{ij}^2 = \bar{y}_{ij} + \delta_{ij}^t$ for $(i,j) \in \mathcal{A}$ in (6), $t = 1, 2, \ldots$. In addition, for each $t = 1, 2, \ldots$, there would exist a solution $x^t = (x_1^t, \ldots, x_m^t)$, $y^t = (y_{ij}^t)_{(i,j)\in\mathcal{A}}$, of (6) with $d_{ij}^2 = \bar{y}_{ij} + \delta_{ij}^t$, and yet either the set $\Xi_{\mathcal{B}}$ is empty or $\operatorname{dist}(x^t, \Xi_{\mathcal{B}}) > \epsilon$ for all t.

We see from (16) that $\{y_{ij}^t\} \to \bar{y}_{ij}$ for all $(i,j) \in \mathcal{A}$. Also, we can assume without loss of generality that $\{x^t\}$ is bounded.[5] By passing to a subsequence if necessary, we assume that $\{x^t\}$ converges to some $\bar{x} = (\bar{x}_1, \ldots, \bar{x}_m)$. By (17),

$$\sum_{(i,j)\in\mathcal{A}} q_{ij}(x^t)_+ \leq 2 \sum_{(i,j)\in\mathcal{A}} |\delta_{ij}^t|, \quad t = 1, 2, \ldots.$$

[5] Consider any connected component $\mathcal{C}$ of the graph $\mathcal{G} = (\{1, \ldots, n\}, \mathcal{A})$. If $\mathcal{C}$ contains an anchor index, then $\{x_i^t\}$ is bounded for all $i \leq m$ in $\mathcal{C}$. If $\mathcal{C}$ does not contain an anchor index, then it can be seen that $\{\|x_i^t - x_j^t\|\}$ is bounded for all i and j in $\mathcal{C}$, so we can translate x_i^t for all i in $\mathcal{C}$ by the same displacement (thus preserving the distances between them) so that one of them is at the origin.

This yields in the limit $\sum_{(i,j)\in\mathcal{A}} q_{ij}(\bar{x})_+ \le 0$, implying $\bar{x} \in \Xi$. Since $\mathcal{B}$ satisfies (9) with $d_{ij}^2 = \bar{y}_{ij} + \delta_{ij}^t$ for $(i,j) \in \mathcal{A}$ in (6), we also have

$$\|x_i^t - x_j^t\|^2 = y_{ij}^t \quad \forall (i,j) \in \mathcal{B},\ t = 1,2,\ldots \quad (\text{with } x_i^t = x_i\ \forall i > m).$$

This yields in the limit

$$\|\bar{x}_i - \bar{x}_j\|^2 = \bar{y}_{ij} \quad \forall (i,j) \in \mathcal{B} \quad (\text{with } \bar{x}_i = x_i\ \forall i > m),$$

implying $\bar{x} \in \Xi_{\mathcal{B}}$. Moreover $\max_{i=1,\ldots,m} \|x_i^t - \bar{x}_i\| \to 0$. This contradicts $\Xi_{\mathcal{B}} = \emptyset$ or $\operatorname{dist}(x^t, \Xi_{\mathcal{B}}) > \epsilon$ for all t.

(b) Since each q_{ij} is convex, Ξ has an interior solution, i.e., $x' = (x_1', \ldots, x_m') \in \Xi$ satisfying

$$\|x_i' - x_j'\|^2 < \bar{y}_{ij} \quad \forall (i,j) \in \mathcal{A} \setminus \bar{\mathcal{B}}, \tag{18}$$

where we let $x_i' = x_i$ for $i > m$.

By (a), for any $\epsilon > 0$, there exists $\delta > 0$ such that, for any interior solution $x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ of (6) with $\sum_{(i,j)\in\mathcal{A}} |\delta_{ij}| \le \delta$, there exists $\bar{x} = (\bar{x}_1, \ldots, \bar{x}_m) \in \Xi_{\mathcal{B}}$ with $\max_{i=1,\ldots,m} \|x_i - \bar{x}_i\| \le \epsilon$, where $\mathcal{B}$ satisfies (9). Let

$$\begin{aligned} d_i &= \bar{x}_i - x_i, \quad i = 1, \ldots, n, \\ d_i' &= x_i' - \bar{x}_i, \quad i = 1, \ldots, n, \end{aligned}$$

with $\bar{x}_i = x_i$ for $i > m$. Since $\bar{x}$ and x' are both in Ξ, we have $\|\bar{x}_i - \bar{x}_j\|^2 = \|x_i' - x_j'\|^2$ for all $(i,j) \in \bar{\mathcal{B}}$, which yields (also see the proof of Lemma 6.1)

$$d_i' - d_j' = 0 \quad \forall (i,j) \in \bar{\mathcal{B}}. \tag{19}$$

For each $(i,j) \in \mathcal{B}$, we have

$$\|x_i' - x_j'\|^2 = \bar{y}_{ij} - s_{ij}$$

for some $s_{ij} \ge 0$, or, equivalently,

$$\|d_i' - d_j' + \bar{x}_i - \bar{x}_j\|^2 = \|\bar{x}_i - \bar{x}_j\|^2 - s_{ij}.$$

Expanding the quadratics yields

$$2(\bar{x}_i - \bar{x}_j)^T (d_i' - d_j') = -\|d_i' - d_j'\|^2 - s_{ij}$$

or, equivalently,

$$\begin{aligned} 2(x_i - x_j)^T (d_i' - d_j') &= -\|d_i' - d_j'\|^2 - s_{ij} - 2(d_i - d_j)^T (d_i' - d_j') \\ &\le -\|d_i' - d_j'\|^2 - s_{ij} + 2\|d_i - d_j\|\|d_i' - d_j'\|. \end{aligned}$$

Since $s_{ij} \ge 0$, this implies that

$$(x_i - x_j)^T (d_i' - d_j') < 0 \quad \text{whenever} \quad \|d_i - d_j\| < \|d_i' - d_j'\|/2. \tag{20}$$

Let us choose

$$\epsilon < \frac{1}{4} \min_{(i,j)\in\mathcal{A}\setminus\bar{\mathcal{B}}} \{\sqrt{\bar{y}_{ij}} - \|x_i' - x_j'\|\}, \tag{21}$$

where the right-hand side is positive by (18). For each $(i,j) \in \mathcal{B}$ with $d'_i - d'_j \neq 0$, we have from (19) that $(i,j) \notin \bar{\mathcal{B}}$. Then, by using $\|d_i\| \leq \epsilon$ and (21), we have

$$\|d_i - d_j\| \leq 2\epsilon < \frac{\sqrt{\bar{y}_{ij}} - \|x'_i - x'_j\|}{2} \leq \frac{\|d'_i - d'_j\|}{2},$$

where the last inequality follows from

$$\|d'_i - d'_j\| = \|x'_i - x'_j - (\bar{x}_i - \bar{x}_j)\| \geq \|\bar{x}_i - \bar{x}_j\| - \|x'_i - x'_j\| = \sqrt{\bar{y}_{ij}} - \|x'_i - x'_j\|.$$

Then, by (20), $(x_i - x_j)^T(d'_i - d'_j) < 0$. Thus, for each $(i,j) \in \mathcal{B}$ and for all $\alpha > 0$ sufficiently small, we have

$$\|(x_i + \alpha d'_i) - (x_j + \alpha d'_j)\|^2 \begin{cases} < \|x_i - x_j\|^2 = y_{ij} & \text{if } d'_i - d'_j \neq 0; \\ = \|x_i - x_j\|^2 = y_{ij} & \text{if } d'_i - d'_j = 0. \end{cases}$$

Also, for each $(i,j) \in \mathcal{A} \setminus \mathcal{B}$, since $\|x_i - x_j\|^2 < y_{ij}$, we have

$$\|(x_i + \alpha d'_i) - (x_j + \alpha d'_j)\|^2 < y_{ij}$$

for all $\alpha > 0$ sufficiently small. Thus, if $d'_i - d'_j \neq 0$ for some $(i,j) \in \mathcal{B}$, this would contradict the definition of $\mathcal{B}$. Hence $d'_i - d'_j = 0$ for all $(i,j) \in \mathcal{B}$. This in turn implies

$$\|x'_i - x'_j\|^2 = \|\bar{x}_i - \bar{x}_j\|^2 = \bar{y}_{ij} \quad \forall (i,j) \in \mathcal{B}.$$

Hence (18) yields that $\mathcal{B} \subseteq \bar{\mathcal{B}}$.

Since $\bar{x} \in \Xi$, by applying Proposition 5.1(c) we have

$$\bar{x}_i = x_i^{\text{true}} \quad \forall i \in M_{\bar{\mathcal{B}}}.$$

Since $\mathcal{B} \subseteq \bar{\mathcal{B}}$, $M_{\mathcal{B}} \subseteq M_{\bar{\mathcal{B}}}$. Thus

$$\|x_i - x_i^{\text{true}}\| = \|x_i - \bar{x}_i\| \leq \epsilon \quad \forall i \in M_{\mathcal{B}}. \qquad \square$$

From the proof of Proposition 7.1(b) we see that we can take $\bar{\epsilon}$ to be the right-hand side of (21), maximized over all $(x'_1, \ldots, x'_m) \in \Xi$. Proposition 7.1(b) says that if the distance error is not too large, then the error in the position of those sensors indexed by $M_{\mathcal{B}}$ is also not too large. However, it does not say how fast the position error grows with the distance error. We show below that the position error grows at most like the square root of the distance error.

We say that $\mathcal{B} \subseteq \bar{\mathcal{B}}$ is *active with respect to* $\mathcal{M} \subseteq \{1, \ldots, m\}$ if

$$q_{ij}(x) \leq 0 \ \ \forall (i,j) \in \mathcal{B}, \ \ x_i = x_i^{\text{true}} \ \ \forall i \notin \mathcal{M} \quad \Longrightarrow \quad q_{ij}(x) = 0 \ \ \forall (i,j) \in \mathcal{B}.$$

We say that $\mathcal{B}$ is *minimally active with respect to* $\mathcal{M}$ if there is no proper subset of $\mathcal{B}$ that is active with respect to $\mathcal{M}$.

PROPOSITION 7.2. *There exists a constant $K > 0$ such that*

$$\max_{i \in M_{\bar{\mathcal{B}}}} \|x_i - x_i^{\text{true}}\| \leq K \max_{(i,j) \in \bar{\mathcal{B}}} q_{ij}(x)_+^{1/2} \quad \forall x = (x_1, \ldots, x_m).$$

Proof. If $\bar{\mathcal{B}} = \emptyset$, then our proof is complete. Otherwise, by its definition, $\bar{\mathcal{B}}$ is active with respect to $\{1, \ldots, m\}$. Then, there exists nonempty $\mathcal{B}_1 \subseteq \bar{\mathcal{B}}$ that is

minimally active with respect to $\{1,\ldots,m\}$. By using Gordan's theorem as in the proof of [33, Theorem 3.1], there exist $\lambda_{ij} > 0$, $(i,j) \in \mathcal{B}_1$, satisfying

$$\sum_{(i,j)\in\mathcal{B}_1} \nabla q_{ij}(x^{\text{true}})\lambda_{ij} = 0.^6 \tag{22}$$

Fix any $x = (x_1,\ldots,x_m)$. For each $(i,j) \in \mathcal{B}_1$, we have from $q_{ij}(x^{\text{true}}) = 0$ that

$$q_{ij}(x) = \nabla q_{ij}(x^{\text{true}})^T(x - x^{\text{true}}) + \|x_i - x_j - (x_i^{\text{true}} - x_j^{\text{true}})\|^2.$$

Multiplying both sides by λ_{ij} and summing over all $(i,j) \in \mathcal{B}_1$ and using (22) yield

$$\sum_{(i,j)\in\mathcal{B}_1} q_{ij}(x)\lambda_{ij} = \sum_{(i,j)\in\mathcal{B}_1} \|x_i - x_j - (x_i^{\text{true}} - x_j^{\text{true}})\|^2\lambda_{ij}.$$

Thus

$$\|x_i - x_j - (x_i^{\text{true}} - x_j^{\text{true}})\|^2\lambda_{ij} \le \sum_{(i,j)\in\mathcal{B}_1} \lambda_{ij} \cdot \max_{(i,j)\in\mathcal{B}_1} q_{ij}(x)_+ \quad \forall (i,j) \in \mathcal{B}_1.$$

This in turn implies

$$\|x_i - x_j - (x_i^{\text{true}} - x_j^{\text{true}})\| \le C_1 \max_{(i,j)\in\mathcal{B}_1} q_{ij}(x)_+^{1/2} \quad \forall (i,j) \in \mathcal{B}_1, \tag{23}$$

where

$$C_1 \stackrel{\text{def}}{=} \left(\frac{\sum_{(i,j)\in\mathcal{B}_1}\lambda_{ij}}{\min_{(i,j)\in\mathcal{B}_1}\lambda_{ij}}\right)^{1/2}.$$

We can then apply Proposition 5.1(b) with d_{ij}, $\mathcal{A}$, $\mathcal{B}$, $\{1,\ldots,m\}$ replaced by, respectively, $\sqrt{\bar{y}_{ij}}$, $\mathcal{B}_1$, $\mathcal{B}_1$, $\mathcal{M}_1 \stackrel{\text{def}}{=} \{i \in \{1,\ldots,m\} : N_{\mathcal{B}_1}(i) \neq \emptyset\} = M_{\mathcal{B}_1}$. This yields that each connected component of the graph $\mathcal{G}_1 \stackrel{\text{def}}{=} (\mathcal{M}_1 \cup \{m+1,\ldots,n\}, \mathcal{B}_1)$ contains an anchor index $j \in \{m+1,\ldots,n\}$. (In fact, this graph is connected since $\mathcal{B}_1$ is minimally active with respect to $\mathcal{M}_1$.) Then, for each $i \in N_{\mathcal{B}_1}(j)$, we have from (23) and $x_j = x_j^{\text{true}}$ that

$$\|x_i - x_i^{\text{true}}\| \le C_1 \max_{(i,j)\in\mathcal{B}_1} q_{ij}(x)_+^{1/2}.$$

Continuing this argument with each neighbor of i in $\mathcal{G}_1$, and so on, we obtain that

$$\|x_i - x_i^{\text{true}}\| \le C_1 D_1 \max_{(i,j)\in\mathcal{B}_1} q_{ij}(x)_+^{1/2} \quad \forall i \in \mathcal{M}_1, \tag{24}$$

[6] Why? Since $\mathcal{B}_1$ is active with respect to $\{1,\ldots,m\}$ and $q_{ij}(x^{\text{true}}) = 0$ for all $(i,j) \in \mathcal{B}_1$, the linear system $\nabla q_{ij}(x^{\text{true}})^T d < 0$, $(i,j) \in \mathcal{B}_1$, is infeasible. By Gordan's theorem [13, p. 23], there exist $\lambda_{ij} \ge 0$ for $(i,j) \in \mathcal{B}_1$, not all zero, satisfying (22). Let $\hat{\mathcal{B}}_1 \stackrel{\text{def}}{=} \{(i,j) \in \mathcal{B}_1 : \lambda_{ij} > 0\}$. By Gordan's theorem again, the linear system $\nabla q_{ij}(x^{\text{true}})^T d < 0$, $(i,j) \in \hat{\mathcal{B}}_1$, is infeasible. If $\hat{\mathcal{B}}_1 \neq \mathcal{B}_1$, then the quadratic system $q_{ij}(x) < 0$, $(i,j) \in \hat{\mathcal{B}}_1$, would be feasible. (Otherwise there would exist a nonempty $\tilde{\mathcal{B}}_1 \subseteq \hat{\mathcal{B}}_1$ such that $q_{ij}(x) = 0$, $(i,j) \in \tilde{\mathcal{B}}_1$, whenever $q_{ij}(x) \le 0$, $(i,j) \in \hat{\mathcal{B}}_1$. Choose $\tilde{\mathcal{B}}_1$ to be maximal. Then $\tilde{\mathcal{B}}_1$ would be active with respect to $\{1,\ldots,m\}$, contradicting $\mathcal{B}_1$ being minimally active with respect to $\{1,\ldots,m\}$.) Then the linear system $\nabla q_{ij}(x^{\text{true}})^T d < 0$, $(i,j) \in \hat{\mathcal{B}}_1$, would be feasible, which is a contradiction. Thus $\hat{\mathcal{B}}_1 = \mathcal{B}_1$.

where $D_1 \stackrel{\text{def}}{=} \max_{i\in\mathcal{M}_1} \min_{j\notin\mathcal{M}_1}$(minimum number of edges in a path between i and j in $\mathcal{G}_1$).

If $\bar{\mathcal{B}} = \mathcal{B}_1$, then our proof is complete. Otherwise, $\bar{\mathcal{B}} \setminus \mathcal{B}_1$ is active with respect to $\{1,\dots,m\} \setminus \mathcal{M}_1$. Then, there exists nonempty $\mathcal{B}_2 \subseteq \bar{\mathcal{B}} \setminus \mathcal{B}_1$ that is minimally active with respect to $\{1,\dots,m\} \setminus \mathcal{M}_1$. Repeating the above argument, we obtain that

$$\|x_i - x_j - (x_i^{\text{true}} - x_j^{\text{true}})\| \le C_2 \max_{(i,j)\in\mathcal{B}_2} q_{ij}(x)_+^{1/2} \quad \forall (i,j) \in \mathcal{B}_2, \tag{25}$$

with C_2 defined analogously as C_1 and with $x_i = x_i^{\text{true}}$ for $i \in \mathcal{M}_1$. We can then apply Proposition 5.1(b) with d_{ij}, $\mathcal{A}$, $\mathcal{B}$, $\{1,\dots,m\}$ replaced by, respectively, $\sqrt{\bar{y}_{ij}}$, $\mathcal{B}_2$, $\mathcal{B}_2$, $\mathcal{M}_2 \stackrel{\text{def}}{=} \{i \in \{1,\dots,m\} \setminus \mathcal{M}_1 : N_{\mathcal{B}_2}(i) \neq \emptyset\}$. This yields that each connected component of the graph $\mathcal{G}_2 \stackrel{\text{def}}{=} (\mathcal{M}_1 \cup \mathcal{M}_2 \cup \{m+1,\dots,n\}, \mathcal{B}_2)$ contains a node $j \in \mathcal{M}_1 \cup \{m+1,\dots,n\}$. Then, for each $i \in N_{\mathcal{B}_2}(j)$, we have from (25) and (24) that

$$\|x_i - x_i^{\text{true}}\| \le C_1 D_1 \max_{(i,j)\in\mathcal{B}_1} q_{ij}(x)_+^{1/2} + C_2 \max_{(i,j)\in\mathcal{B}_2} q_{ij}(x)_+^{1/2}.$$

Continuing this argument with each neighbor of i in $\mathcal{G}_2$, and so on, we obtain that

$$\|x_i - x_i^{\text{true}}\| \le C_1 D_1 \max_{(i,j)\in\mathcal{B}_1} q_{ij}(x)_+^{1/2} + C_2 D_2 \max_{(i,j)\in\mathcal{B}_2} q_{ij}(x)_+^{1/2} \quad \forall i \in \mathcal{M}_2,$$

with D_2 defined analogously as D_1.

Continuing the above argument inductively completes the proof. □

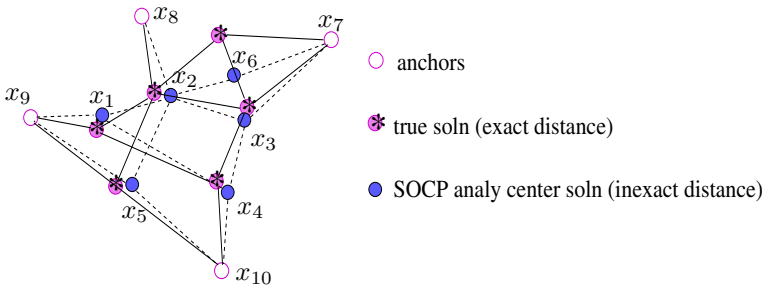

FIG. 6. *In this example,* $\mathcal{M}_1 = \{1,2,3,4\}$, $\mathcal{B}_1 = \{(1,2),(1,4),(1,9),(2,3),(2,8),(3,7),(3,4),(4,10)\}$, $\mathcal{M}_2 = \{5\}$, $\mathcal{B}_2 = \{(5,2),(5,9),(5,10)\}$, *and* $\bar{\mathcal{B}} = \mathcal{B}_1 \cup \mathcal{B}_2$. *Removing a point indexed by* $\mathcal{M}_1$ *affects points indexed by* $\mathcal{M}_2$ *but not conversely.*

The proof of Proposition 7.2 shows that the points indexed by $\mathcal{M}_1$, which are the sensors "nearest" to the anchors, are the least sensitive to distance measurement errors. An important (and intuitively reasonable) result shown by Proposition 7.2 is that the errors affect the sensor positions additively as they percolate to $\mathcal{M}_2$, and so on; see Figure 6 for an illustrative example.

COROLLARY 7.3. *There exists a constant* $L > 0$ *such that*

$$\operatorname{dist}(x,\Xi) \le L \max_{(i,j)\in\mathcal{A}\setminus\bar{\mathcal{B}}} q_{ij}(x)_+ + LK \max_{(i,j)\in\bar{\mathcal{B}}} q_{ij}(x)_+^{1/2} \quad \forall x = (x_1,\dots,x_m),$$

where K *is defined as in Proposition* 7.2.

Proof. Consider the system of convex quadratic inequalities and linear equations in $x = (x_1,\dots,x_m)$:

$$q_{ij}(x) \le 0 \ \ \forall (i,j) \in \mathcal{A} \setminus \bar{\mathcal{B}}, \qquad x_i = x_i^{\text{true}} \ \ \forall i \in M_{\bar{\mathcal{B}}}.$$

By applying Proposition 5.1(c) with d_{ij} replaced by $\sqrt{\bar{y}_{ij}}$, we see that Ξ equals the solution set of this system. Moreover, each interior solution of Ξ satisfies the quadratic inequalities strictly. Thus, applying a result of Luo and Luo [23], there exists $L > 0$ such that

$$\mathrm{dist}(x, \Xi) \le L \max_{(i,j)\in\mathcal{A}\setminus\bar{\mathcal{B}}} q_{ij}(x)_+ + L \max_{i\in M_{\bar{\mathcal{B}}}} \|x_i - x_i^{\text{true}}\| \quad \forall x = (x_1, \ldots, x_m).$$

Using Proposition 7.2 to bound the second term on the right-hand side completes the proof. □

The error bound in Corollary 7.3 sharpens the Hölderian error bound of Wang and Pang [33] for general convex quadratic inequalities. In particular, a direct application of the result in [33] yields the existence of $\tau > 0$ and integer $\ell \le |\mathcal{A}| + 1$ such that

$$\mathrm{dist}(x, \Xi) \le \kappa \max_{(i,j)\in\mathcal{A}} \left(q_{ij}(x)_+ + q_{ij}(x)_+^{1/2^\ell} \right) \quad \forall x = (x_1, \ldots, x_m).$$

An example in [33] shows that, for general convex quadratic functions q_{ij}, $\ell = |\mathcal{A}|$ is possible. Corollary 7.3 in effect shows that we can take $\ell = 1$ in the special case where each q_{ij} has the form (14). It is an open question whether the active set index $\bar{\mathcal{B}}$ can be identified using the Lipschitzian error bound. The difficulty lies in that $\bar{y}_{ij}$ is unknown, so that $q_{ij}(x)$ cannot be directly evaluated.

Last, we show that the x-component of the analytic center solution of (6) converges to the analytic center solution of Ξ as the distance error goes to zero.

PROPOSITION 7.4. *Under Assumption* 1, *let* $x^c = (x_1^c, \ldots, x_m^c)$, $(y_{ij}^c)_{(i,j)\in\mathcal{A}}$ *be the analytic center solution of* (6). *As* $\sum_{(i,j)\in\mathcal{A}} |\delta_{ij}| \to 0$, x^c *converges to the analytic center* $\bar{x}^c = (\bar{x}_1^c, \ldots, \bar{x}_m^c)$ *of* Ξ.

Proof. For $i = 1, \ldots, m$, let

$$\tilde{x}_i \stackrel{\text{def}}{=} \begin{cases} x_i^c & \text{if } i \in M_{\bar{\mathcal{B}}}; \\ \bar{x}_i^c & \text{if } i \notin M_{\bar{\mathcal{B}}}. \end{cases}$$

By $\bar{x}^c \in \Xi$ and Proposition 7.2, we have $\bar{x}_i^c = x_i^{\text{true}}$ for all $i \in M_{\bar{\mathcal{B}}}$. Let

$$\rho \stackrel{\text{def}}{=} - \max_{(i,j)\in\mathcal{A}\setminus\bar{\mathcal{B}}} q_{ij}(\bar{x}^c) > 0. \tag{26}$$

Suppose $\sum_{(i,j)\in\mathcal{A}} |\delta_{ij}| \le \delta$ for some $\delta > 0$. By (16), (17), and Proposition 7.2, we have

$$\max_{(i,j)\in\mathcal{A}} |y_{ij}^c - \bar{y}_{ij}| \le \delta, \qquad \max_{i\in M_{\bar{\mathcal{B}}}} \|x_i^c - \bar{x}_i^c\| \le K\sqrt{2\delta}. \tag{27}$$

For each $(i, j) \in \mathcal{A}$, consider the following three cases: (i) If $i \in M_{\bar{\mathcal{B}}}$ and $j \in M_{\bar{\mathcal{B}}}$, then

$$\|\tilde{x}_i - \tilde{x}_j\|^2 = \|x_i^c - x_j^c\|^2 \le y_{ij}^c.$$

(ii) If $i \notin M_{\bar{\mathcal{B}}}$ and $j \notin M_{\bar{\mathcal{B}}}$, then $(i, j) \notin \bar{\mathcal{B}}$ and hence (26), (27) yield

$$\|\tilde{x}_i - \tilde{x}_j\|^2 = \|\bar{x}_i^c - \bar{x}_j^c\|^2 \le \bar{y}_{ij} - \rho \le y_{ij}^c + \delta - \rho.$$

(iii) If $i \in M_{\bar{\mathcal{B}}}$ and $j \notin M_{\bar{\mathcal{B}}}$, then $(i,j) \notin \bar{\mathcal{B}}$ and hence (26), (27) yield

$$\begin{aligned}\|\tilde{x}_i - \tilde{x}_j\|^2 &= \|x_i^c - \bar{x}_j^c\|^2 \\ &\le (\|x_i^c - \bar{x}_i^c\| + \|\bar{x}_i^c - \bar{x}_j^c\|)^2 \\ &\le (K\sqrt{2\delta} + \|\bar{x}_i^c - \bar{x}_j^c\|)^2 \\ &\le 2K^2\delta + 2K\sqrt{2\delta}\sqrt{\bar{y}_{ij}} + \bar{y}_{ij} - \rho \\ &\le 2K^2\delta + 2K\sqrt{2\delta}\sqrt{\bar{y}_{ij}} + y_{ij}^c + \delta - \rho.\end{aligned}$$

Notice that $(i,j) = (j,i)$, so the case of $i \notin M_{\bar{\mathcal{B}}}$ and $j \in M_{\bar{\mathcal{B}}}$ is covered by case (iii). Since $x^c = (x_1^c, \ldots, x_m^c)$, $(y_{ij}^c)_{(i,j)\in\mathcal{A}}$ is a solution of (6) and $\rho > 0$, the above analysis shows that, for δ sufficiently small, $\tilde{x}_1, \ldots, \tilde{x}_m$, $(y_{ij}^c)_{(i,j)\in\mathcal{A}}$ is an interior solution of (6). Since $x^c = (x_1^c, \ldots, x_m^c)$, $(y_{ij}^c)_{(i,j)\in\mathcal{A}}$ is the analytic center solution of (6), this implies

$$\sum_{(i,j)\in\mathcal{A}\setminus\mathcal{B}} \log\left(y_{ij}^c - \|x_i^c - x_j^c\|^2\right) \ge \sum_{(i,j)\in\mathcal{A}\setminus\mathcal{B}} \log\left(y_{ij}^c - \|\tilde{x}_i - \tilde{x}_j\|^2\right),$$

where $\mathcal{B}$ satisfies (9) (with $x_i^c = \tilde{x}_i = x_i$ for $i > m$). By Proposition 7.1(b), we have $\mathcal{B} \subseteq \bar{\mathcal{B}}$ for δ sufficiently small. For $(i,j) \in \bar{\mathcal{B}}$, since $i \in M_{\bar{\mathcal{B}}}$ and $j \in M_{\bar{\mathcal{B}}}$, we have $\|\tilde{x}_i - \tilde{x}_j\|^2 = \|x_i^c - x_j^c\|^2$. Thus we further have

$$\sum_{(i,j)\in\mathcal{A}\setminus\bar{\mathcal{B}}} \log\left(y_{ij}^c - \|x_i^c - x_j^c\|^2\right) \ge \sum_{(i,j)\in\mathcal{A}\setminus\bar{\mathcal{B}}} \log\left(y_{ij}^c - \|\tilde{x}_i - \tilde{x}_j\|^2\right).$$

Taking $\delta \to 0$, we have from (27) that $y_{ij}^c \to \bar{y}_{ij}$ for all $(i,j) \in \mathcal{A}\setminus\bar{\mathcal{B}}$ and $\tilde{x}_i = x_i^c \to \bar{x}_i^c$ for all $i \in M_{\bar{\mathcal{B}}}$. Also, $\tilde{x}_i = \bar{x}_i^c$ for all $i \notin M_{\bar{\mathcal{B}}}$. Thus, we obtain in the limit that any cluster point $\bar{x} = (\bar{x}_1, \ldots, \bar{x}_m)$ of x^c (which exists since x^c is uniformly bounded by Assumption 1) belongs to Ξ (using (17) and Corollary 7.3) and satisfies

$$\sum_{(i,j)\in\mathcal{A}\setminus\bar{\mathcal{B}}} \log\left(\bar{y}_{ij} - \|\bar{x}_i - \bar{x}_j\|^2\right) \ge \sum_{(i,j)\in\mathcal{A}\setminus\bar{\mathcal{B}}} \log\left(\bar{y}_{ij} - \|\bar{x}_i^c - \bar{x}_j^c\|^2\right)$$

(with $\bar{x}_i = \bar{x}_i^c = x_i$ for $i > m$). This shows that $\bar{x}$ is an analytic center of Ξ, so that in fact $\bar{x} = \bar{x}^c$. □

It is an open question whether the results of this section extend to the SDP relaxation (3).

8. Methods for solving the SOCP relaxation. We saw in previous sections that the SOCP relaxation (6), though weaker than the SDP relaxation (3), has the advantage of a smaller problem size and its interior solutions are useful for identifying sensors that are accurately positioned. What method would best solve (6) and, in particular, find an interior solution? A primal-dual interior-point method can find an analytic center solution of SOCP with good accuracy. However, as we will see in section 9, applying an interior-point method directly to (7) can be slow, due to the large size of the SOCP. We tried adapting the distributed SDP method of Biswas and Ye [11] to the SOCP relaxation. However, possibly due to the weaker SOCP relaxation, the resulting distributed SOCP method was not satisfactory. Further studies are needed. Below we describe a third method, based on smoothing and (block) coordinate gradient descent, which can find an interior solution faster, as we will see in section 9. This method has the nice feature that its computations easily distribute over many processors in parallel.

First, we observe that, for any $d \in \Re$,

$$\min_{y \geq z} |y - d^2| = [z - d^2]_+ \quad \forall z \in \Re,$$

where $[t]_+ = \max\{0, t\}$. Thus, we can rewrite the SOCP relaxation (6) as the unconstrained optimization problem

$$v_{\text{socp}} = \min_{x_1,\ldots,x_m} \sum_{(i,j)\in\mathcal{A}} [\|x_i - x_j\|^2 - d_{ij}^2]_+. \tag{28}$$

The objective function is convex, but nonsmooth due to the term $\max\{0, \cdot\}$. It is well known in the context of complementarity problems that a smoothing approach can be effective in handling this type of nonsmoothness; see [14, 18] and references therein. In particular, for any function $h : \Re \to \Re$ that is smooth and convex and satisfies $\lim_{t\to-\infty} h(t) = \lim_{t\to\infty} h(t) - t = 0$, we have that

$$\lim_{\mu\downarrow 0} \mu h(t/\mu) \;=\; [t]_+.$$

Thus, for $\mu > 0$ and small, we have $\mu h(t/\mu) \approx [t]_+$. In our numerical tests, we use a popular choice of h due to Chen, Harker, Kanzow, and Smale:

$$h(t) = ((t^2 + 4)^{1/2} + t)/2.$$

Thus, the nonsmooth problem (28) is approximated by the smooth problem, parameterized by $\mu > 0$:

$$\min_{x_1,\ldots,x_m} \sum_{(i,j)\in\mathcal{A}} \mu h\left(\frac{\|x_i - x_j\|^2 - d_{ij}^2}{\mu}\right). \tag{29}$$

For each $\mu > 0$, the objective function is smooth and convex and, as $\mu \to 0$, any cluster point of the solution of (29) is a solution of (28).

Since we wish to find an interior solution, following the interior-point approach, we add a log-barrier term and consider

$$\min_{y\geq z} |y - d^2| - \mu \log(y - z) = [z + \mu - d^2]_+ - \mu \log\left(\mu + [d^2 - z - \mu]_+\right) \quad \forall z \in \Re.$$

This is a convex function of z. Upon smoothing $[\cdot]_+$ by $\mu h(\cdot/\mu)$, we obtain the corresponding smooth barrier problem:

$$\min_{x=(x_1,\ldots,x_m)} f_\mu(x) \;\stackrel{\text{def}}{=}\; \sum_{(i,j)\in\mathcal{A}} \mu h\left(\frac{t_{ij}}{\mu}\right) - \mu \log\left(1 + h\left(\frac{-t_{ij}}{\mu}\right)\right)_{t_{ij}=\|x_i-x_j\|^2+\mu-d_{ij}^2}. \tag{30}$$

Here, for simplicity, we used the same parameter μ for the log-barrier and the smoothing function. Notice that the objective function f_μ is partially separable, being a sum of functions each of which depends only on the difference of neighboring points. This suggests that a block-coordinate descent approach may be efficient for solving (30), whereby at each iteration the objective function f_μ is minimized with respect to x_i, for some $i \in \{1, \ldots, m\}$, while the other points are held fixed at their current value. Since exact minimization is expensive, the minimization is done only inexactly. In

particular, we minimize a quadratic approximation of f_μ with respect to x_i to generate the descent direction d_i and then minimize f_μ inexactly along d_i using an Armijo stepsize rule [6]. We decrease μ whenever $\|\nabla f_\mu(x)\|$ is small relative to μ. The method, which we refer to as the smoothing coordinate gradient descent (SCGD) method, is described more precisely below.

0. Initialize $\mu > 0$ and $x = (x_1, \ldots, x_m)$. Choose $\mu^{\text{final}} > 0$ and a continuous function $\psi : (0, \infty) \to (0, \infty)$ satisfying $\lim_{\mu \downarrow 0} \psi(\mu) = 0$. Choose stepsize parameters $0 < \beta < 1$, $0 < \sigma < \frac{1}{2}$. Go to step 1.
1. If there exists an $i \in \{1, \ldots, m\}$ satisfying $\|\nabla_{x_i} f_\mu(x)\| > \psi(\mu)$, then set

$$d_i = -[H_i]^{-1} \nabla_{x_i} f_\mu(x),$$

update

$$x_i^{\text{new}} = x_i + \alpha d_i,$$

and repeat step 1, where $H_i \in \Re^{d \times d}$ is a user-chosen symmetric positive definite matrix, and α is the largest element of $\{1, \beta, (\beta)^2, \ldots\}$ satisfying

$$f_\mu(x_1, \ldots, x_i + \alpha d_i, \ldots, x_m) \leq f_\mu(x) - \alpha \sigma d_i^T \nabla_{x_i} f_\mu(x).$$

Otherwise, go to step 2.
2. If $\mu \leq \mu^{\text{final}}$, then stop. Otherwise decrease μ, and return to step 1.

The SCGD method is highly parallelizable since updating x_i requires knowledge of only neighboring points $\{x_j\}_{j \in N_{\mathcal{A}}(i)}$, so nonneighbors can update their positions simultaneously. Thus the computation can be distributed over the sensors, with each sensor communicating with its neighbors only.

In our current implementation of the SCGD method, we choose

$$H_i = \nabla^2_{x_i x_i} f_\mu(x),$$

which can be verified to be positive definite. Both $\nabla_{x_i} f_\mu(x)$ and H_i can be efficiently evaluated using network data structure for $\mathcal{G}$.

9. Numerical simulation results. In this section, we present simulation results based on the SOCP relaxations (6) and (7). Following Biswas and Ye [10, 11], we generate the true positions of the points $x_1^{\text{true}}, \ldots, x_n^{\text{true}}$ independently according to a uniform distribution on the unit square $[-.5, .5]^2$, and set $m = 0.9n$ (i.e., 10% of the points are anchors), $\mathcal{A} = \{(i, j) : \|x_i^{\text{true}} - x_j^{\text{true}}\| < \textit{radiorange}\}$, and

$$d_{ij} = \|x_i^{\text{true}} - x_j^{\text{true}}\| \cdot |1 + \epsilon_{ij} \cdot \textit{noisyfactor}| \quad \forall (i, j) \in \mathcal{A},$$

where ϵ_{ij} is a random variable representing measurement noise, and *radiorange* $\in (0, 1)$, *noisyfactor* $\in [0, 1]$. Similar to [10, 11], each ϵ_{ij} is normally distributed, and we use the parameter values of *noisyfactor* $= 0, .001, .01$ and *radiorange* $= .06$ for $n = 1000, 2000$, *radiorange* $= .035$ for $n = 4000$[7]; see Table 1.

We wrote two codes to compute an interior solution of the SOCP relaxation (6). The first code is written in MATLAB and calls SeDuMi (Version 1.05) by Jos Sturm [32], a C implementation of a predictor-corrector primal-dual interior-point method

[7] Other noise models can also be used. We use the model from [10, 11] to facilitate comparison with previous work.

TABLE 1
Input parameters for the test problems and the corresponding SOCP (7) *dimensions.* (*radiorange* $= .06$ *for* $n = 1000, 2000$, *radiorange* $= .035$ *for* $n = 4000$.)

for solving SDP/SOCP, to find an interior solution of (7).[8] The second code is written in FORTRAN 77 and implements the SCGD method described in section 8, whereby we initialize $\mu = 10^{-5}$, and $x_i = x_i^{\text{true}} + \Delta_i$, with the components of Δ_i randomly generated from the square $[-.2, .2]^2$. We choose

$$\mu^{\text{final}} = 10^{-9}, \quad \psi(\mu) = \max\{10\mu, 10^{-7}\}, \quad \beta = 0.5, \quad \sigma = 0.1.$$

We choose i in step 1 in a cyclic order, and we decrease μ by a factor of 10 in step 2. These choices were made with little experimentation. Conceivably the performance can be improved with more judicious choices (e.g., replacing the cyclic order by a queue, as in the Bellman–Ford method for shortest path [5, section 2.4]).

For the interior solution $x_1, \ldots, x_m$, $(y_{ij})_{(i,j)\in\mathcal{A}}$ found, the position of the ith sensor is judged to be uniquely positioned (using Propositions 7.1 and 7.2) if there exists a $j \in N_{\mathcal{A}}(i)$ satisfying

$$\left| \|x_i - x_j\|^2 - y_{ij} \right| \le 10^{-7} d_{ij}$$

(with $x_i = x_i^{\text{true}}$ for $i > m$). In what follows, m_{up} is the number of sensors that are judged to be uniquely positioned by this test. To check the accuracy of these sensors, we compute the maximum error between their computed positions and their true positions:

$$err_{\text{up}} = \max_{i \text{ is uniquely positioned}} \|x_i - x_i^{\text{true}}\|.$$

For comparison, we also compute the maximum error between computed positions and true positions of all sensors:

$$err = \max_{i=1,\ldots,m} \|x_i - x_i^{\text{true}}\|.$$

Table 2 reports the iteration count, cpu time, the final SOCP objective value, m_{up}, err_{up}, err for the two codes. We see from Table 2 that SCGD is consistently faster than SeDuMi, though it uses more iterations. SCGD is more sensitive to *noisyfactor* than SeDuMi. We do not have a good explanation for this yet. On the other hand, the

[8] We also tried a new version 1.1 of SeDuMi, maintained by the Advanced Optimization Laboratory at McMaster University, but it gave wrong answers on our SOCP problems.

TABLE 2

Times to solve SOCP relaxation and accuracy of sensors judged to be uniquely positioned. cpu times are in minutes on an HP DL360 workstation, running MATLAB (Version 7.0) and Gnu F-77 compiler (Version 3.2.57) under Red Hat Linux 3.5.

cpu times for SCGD are still high on problems with higher distance errors. These times can conceivably be further reduced by fine tuning the algorithm parameters and/or distributing the computations over multiple processors. This is a topic for future research. One idea would be to adapt the approach in [22] by terminating the SOCP method early and then applying a local descent method to the original problem (1) to refine the solution. Or we can find new methods to solve the SOCP (6), as is discussed in section 12.

We also see from Table 2 that $err_{\rm up}$ is much smaller than err and decreases with *noisyfactor*, which corroborates Propositions 7.1 and 7.2. For the larger problems 4–9, $m_{\rm up}$ is large (80–90% of m), showing that a large number of sensors are accurately positioned (with error $err_{\rm up}$) by the interior solutions found. Of course, $m_{\rm up}$ depends on *radiorange* also. If *radiorange* is small, so the graph $\mathcal{G}$ has low connectivity, then $m_{\rm up}$ would be small.

The true sensor positions and the computed positions for problems 1 and 3 are shown in Figure 7. Notice the close match of sensors whose true positions lie in the convex hull of "nearby" anchors. The positions are least accurate on the boundary, as we expect. The computed position of each sensor lies in the convex hull of its neighbors, corroborating Proposition 6.2.

At the suggestion of a referee, we also compare the SOCP solutions with solutions of the SDP (3) when n, m are small, *noisyfactor* is large, and ϵ_{ij}'s have different distributions. In particular, we apply SeDuMi to compute a solution $Z = \left[\begin{smallmatrix} Y & X^T \\ X & I_d \end{smallmatrix}\right]$ of the SDP (4), which is likely to be the analytic center solution, and extract the sensor positions $X = [x_1 \ \cdots \ x_m]$. To compare with existing work, we follow a recent study by Biswas et al. [9] of an SDP solution under noisy distance measurements and choose $n = 64$, $m = 60$, *radiorange* $= 0.3$, with 4 anchors at $(\pm.45, \pm.45)$. We also choose *noisyfactor* $\in \{0.1, 0.2\}$ and choose ϵ_{ij}'s to be (i) normally distributed, (ii) uniformly distributed on $[-\sqrt{3}, \sqrt{3}]$, or (iii) distributed as an additive-Gaussian which, with probability $\frac{1}{2}$, is normally distributed with mean 1 (otherwise with mean -1). Thus ϵ_{ij} has mean 0 and variance 1. Table 3 reports the final objective value for SDP and SOCP, as well as

$$err_{\rm rms} = \sum_{i=1}^{m} \|x_i - x_i^{\rm true}\|^2$$

and $m_{\rm up}$, $err_{\rm up}$ for SOCP.

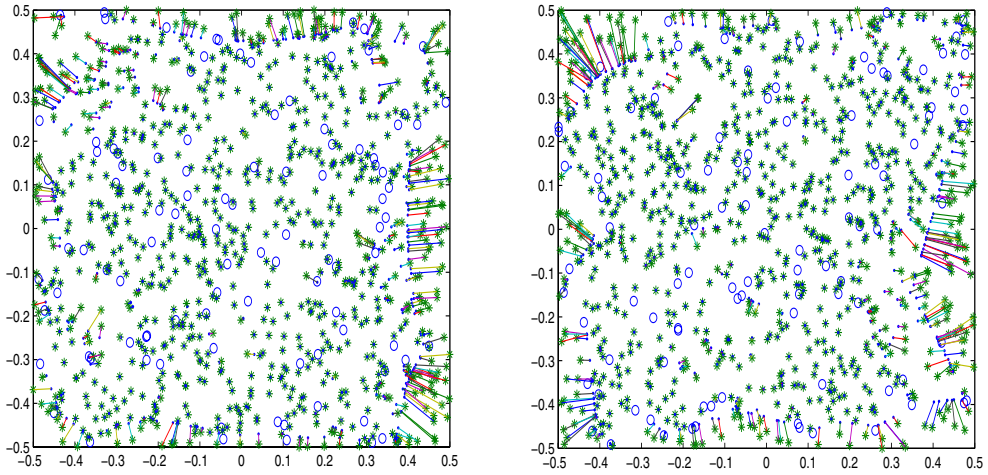

FIG. 7. *The left figure shows the anchors ("∘") and the analytic center solution found by SCGD for problem* 1 *(*$n = 1000$*). Each sensor position found ("·") is joined to its true position ("∗") by a line. The right figure shows the same information for problem* 3.

TABLE 3
Comparing analytic center solutions of SDP and SOCP for smaller problems and more noisy distance measurements.

		SOCP	**SDP**
Noise Pdf	*noisyfactor*	**obj**/$err_{\rm rms}$/$m_{\rm up}$/$err_{\rm up}$	**obj**/$err_{\rm rms}$
Normal	.1	.28/.24/52/.10	1.78/.06
	.2	.43/.48/48/.17	2.82/.23
Uniform	.1	.09/.41/30/.07	.88/.13
	.2	.24/.29/41/.11	2.26/.16
Additive-	.1	.34/.63/42/.17	2.30/.41
Gaussian	.2	.82/.71/52/.22	3.86/.50

We see from Table 3 that objective value is higher and $err_{\rm rms}$ is lower for the SDP solution than for the SOCP solution, corroborating Proposition 3.1. The $err_{\rm rms}$ is higher for both SDP and SOCP solutions under additive Gaussian noise. We do not yet have a good explanation for this. Figures 8–10 display the SDP solutions and SOCP solutions for the case of *noisyfactor* $= .2$. These results suggest that, for small randomly generated problems where the points are irregularly spaced, SDP (3) is much more preferable than SOCP (6). This situation could change with alternative problem formulations (see section 11), so further studies would be needed. In general, SOCP relaxation and mixed SDP-SOCP relaxation (see next section) seem most useful for larger problems where SDP relaxation is expensive to solve. Also, the SCGD method for solving (6) can be implemented in a highly distributed manner, with each sensor communicating with its neighbors only; see discussions at the end of section 8. This may help to reduce communication and synchronization delays among sensors in practice.

10. A mixed SDP-SOCP relaxation. Instead of an SDP or an SOCP relaxation, we can more generally consider a mixed SDP-SOCP relaxation of (1). Let $\mathcal{N}$

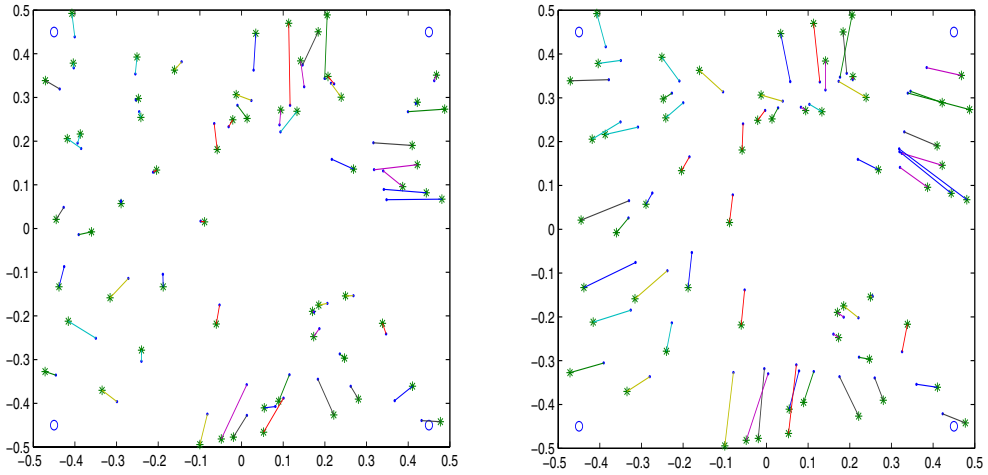

FIG. 8. *The left figure shows the anchors ("∘") and the analytic center solution of SDP found by SeDuMi for normally distributed noise and noisyfactor = .2 (row 2 of Table 3). Each sensor position found ("·") is joined to its true position ("∗") by a line. The right figure shows the same information for the analytic center solution of SOCP found by SCGD.*

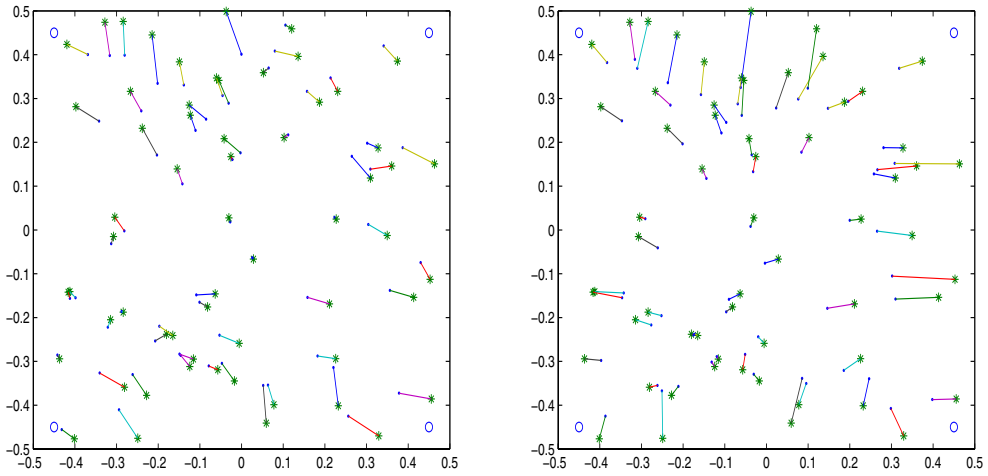

FIG. 9. *This figure is analogous to Figure 8, but for uniformly distributed noise and noisyfactor = .2 (row 4 of Table 3).*

be any subset of $\{1, \ldots, m\}$. By renumbering the points if necessary, we assume that

$$\mathcal{N} = \{\hat{m} + 1, \ldots, m\},$$

with $0 \leq \hat{m} \leq m$. Let

$$\hat{\mathcal{A}} \stackrel{\text{def}}{=} \{(i, j) \in \mathcal{A} \ : \ i \in \mathcal{N} \text{ or } j \in \mathcal{N}\}.$$

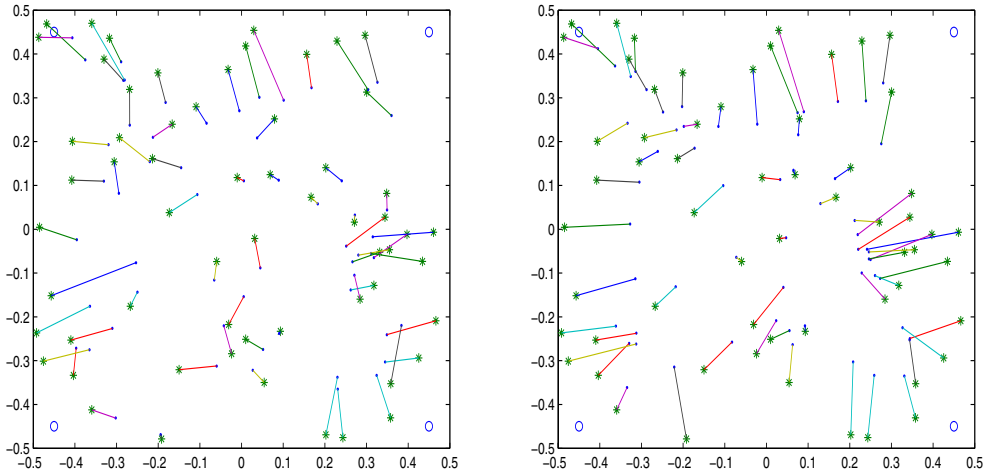

FIG. 10. *This figure is analogous to Figure* 8*, but for additive Gaussian noise and noisyfactor* = .2 *(row* 6 *of Table* 3*).*

Then the mixed SDP-SOCP relaxation associated with $\mathcal{N}$ is

$$\begin{aligned} \min_{x_1,\ldots,x_m,y_{ij},Z} \quad & \sum_{(i,j)\in\mathcal{A}\setminus\hat{\mathcal{A}}} \left|\left\langle \hat{b}_{ij}\hat{b}_{ij}^T, Z\right\rangle_F - d_{ij}^2\right| + \sum_{(i,j)\in\hat{\mathcal{A}}} |y_{ij} - d_{ij}^2| \\ \text{s.t.} \quad & [Z_{ij}]_{i,j\geq n-d} = I_d, \quad Z \succeq 0, \\ & [Z_{ij}]_{i\geq n-d, j\leq \hat{m}} = [x_1 \ \cdots \ x_{\hat{m}}], \\ & y_{ij} \geq \|x_i - x_j\|^2 \quad \forall (i,j)\in\hat{\mathcal{A}}, \end{aligned}$$

where $\hat{b}_{ij} \overset{\text{def}}{=} \left[\begin{smallmatrix} I_{\hat{m}} & 0 & 0 \\ 0 & 0 & A \end{smallmatrix}\right](e_i - e_j)$. Notice that $Z \in \mathcal{S}^{d+\hat{m}}$. This relaxation reduces to the SDP relaxation (3) if $\hat{\mathcal{A}} = \emptyset$ and reduces to the SOCP relaxation (6) if $\hat{\mathcal{A}} = \mathcal{A}$.

Such a mixed SDP-SOCP relaxation mediates between approximation accuracy and solution efficiency. In particular, Propositions 5.1 and 6.2 suggest putting into $\hat{\mathcal{A}}$ those pairs $(i,j) \in \mathcal{A}$ of sensors that are estimated to lie in the convex hull of their neighbors. Can the results in sections 4–7 be extended to the mixed SDP-SOCP relaxation? Can we design efficient methods to find interior solutions? These are topics for future research.

11. Variants of the basic problem. If "sum" is replaced by "max," then (1) becomes

$$\min_{x_1,\ldots,x_m} \quad \max_{(i,j)\in\mathcal{A}} |\|x_i - x_j\|^2 - d_{ij}^2|, \tag{31}$$

and the SDP relaxation (3) and SOCP relaxation (6) change accordingly. In general, if the objective function is a convex piecewise linear/quadratic function of $\|x_i - x_j\|^2$, $(i,j) \in \mathcal{A}$, then both an SDP relaxation and an SOCP relaxation can be analogously formulated. If the distances are not squared, then (1) becomes

$$\min_{x_1,\ldots,x_m} \sum_{(i,j)\in\mathcal{A}} |\|x_i - x_j\| - d_{ij}|. \tag{32}$$

If the distances d_{ij} are exact (i.e., $\upsilon_{\text{opt}} = 0$), then (32) is equivalent to (1). In general, (32) puts a smaller penalty on large deviation from d_{ij} and has different solutions from (1). We leave the choice of the objective function to the modeler.

For (32), an SOCP relaxation, which seems more natural than an SDP relaxation, is

$$\begin{aligned} &\min_{x_1,\ldots,x_m,y_{ij}} \sum_{(i,j)\in\mathcal{A}} |y_{ij} - d_{ij}| \\ &\text{s.t.} \quad y_{ij} \geq \|x_i - x_j\| \quad \forall (i,j) \in \mathcal{A}. \end{aligned} \tag{33}$$

By noting that $y_{ij} \geq d_{ij}$ in any solution of (33), we can write this in the standard conic form

$$\begin{aligned} \min \quad & \sum_{(i,j)\in\mathcal{A}} u_{ij} \\ \text{s.t.} \quad & x_i - x_j - w_{ij} = 0 \quad \forall (i,j) \in \mathcal{A}, \\ & y_{ij} - u_{ij} = d_{ij} \quad \forall (i,j) \in \mathcal{A}, \\ & u_{ij} \geq 0, \ (y_{ij}, w_{ij}) \in \text{Qcone}^{d+1} \quad \forall (i,j) \in \mathcal{A}, \end{aligned} \tag{34}$$

where $\text{Qcone}^{d+1} \stackrel{\text{def}}{=} \{(y,w) \in \Re \times \Re^d : y \geq \|w\|\}$ [32]. This SOCP has a smaller size than (7). In general, if the objective function is a convex piecewise linear/quadratic function of $\|x_i - x_j\|$, $(i,j) \in \mathcal{A}$, then an SOCP relaxation can be analogously formulated. Other variants of (1) involve replacing the Euclidean (ℓ_2) distance by, say, rectilinear (ℓ_1) distance or ℓ_∞ distance.

When $\upsilon_{\text{opt}} = 0$, (33) is equivalent to (6) and, moreover, they have the same analytic center solution.

12. Future directions. There are many directions for future research. For example, can our results for (1) be extended to other variants such as (31) and (32)? How do these variants compare under different distance noise distributions? What about additional constraints as discussed in [16] or replacing the 2-norm by a p-norm ($1 \leq p \leq \infty$)? Can our analysis of the SOCP relaxation (6) be extended to the mixed SDP-SOCP relaxation of section 10? Can finite termination of the SCGD method be proved? Finally, the SOCP relaxation (28) may be interpreted as the Lagrangian dual of a d-commodity convex network flow problem. For $d = 1$, this can be solved very efficiently using an ϵ-relaxation method [5, 7, 19]. Can this method be extended to $d \geq 2$, thus speeding up the solution time of the SOCP relaxation?

Acknowledgments. The author thanks Yinyu Ye for motivating the topic of this paper. He also thanks two anonymous referees for their helpful comments and suggestions.

APPROXIMATING K-MEANS-TYPE CLUSTERING VIA SEMIDEFINITE PROGRAMMING*

JIMING PENG† AND YU WEI‡

Abstract. One of the fundamental clustering problems is to assign n points into k clusters based on minimal sum-of-squared distances (MSSC), which is known to be NP-hard. In this paper, by using matrix arguments, we first model MSSC as a so-called 0-1 semidefinite programming (SDP) problem. We show that our 0-1 SDP model provides a unified framework for several clustering approaches such as normalized k-cut and spectral clustering. Moreover, the 0-1 SDP model allows us to solve the underlying problem approximately via the linear programming and SDP relaxations. Second, we consider the issue of how to extract a feasible solution of the original 0-1 SDP model from the optimal solution of the relaxed SDP problem. By using principal component analysis, we develop a rounding procedure to construct a feasible partitioning from a solution of the relaxed problem. In our rounding procedure, we need to solve a K-means clustering problem in $\Re^{k-1}$, which can be done in $O(n^{k^2-2k+2})$ time. In case of biclustering, the running time of our rounding procedure can be reduced to $O(n \log n)$. We show that our algorithm provides a 2-approximate solution to the original problem. Promising numerical results for biclustering based on our new method are reported.

1. Introduction.

In general, clustering involves partitioning a given data set into subsets based on the closeness or similarity among the data. Clustering is one of the major issues in data mining and machine learning with many applications arising from different disciplines including text retrieval, pattern recognition, and web mining [19, 23].

There are many kinds of clustering problems and algorithms, resulting from various choices of measurements used in the model to measure the similarity/dissimilarity among entities in a data set. For a comprehensive introduction to the topic, we refer the reader to the books [19, 23], and for more recent results, see survey papers [9] and [20].

Among various criteria in clustering, the minimum sum-of-squared Euclidean distance (MSSC) from each entity to its assigned cluster center is the most intuitive and broadly used. In the present paper, we are particularly interested in the partitioning procedure for MSSC. A well-known method to deal with this problem is the classical K-means [28]. To describe the algorithm, let us go into a bit more detail.

Given a set S of n points in a d-dimensional Euclidean space,[1] denoted by

$$S = \{\mathbf{s}_i = (s_{i1}, \ldots, s_{id})^T \in \mathbf{R}^d, \quad i = 1, \ldots, n\},$$

the task of a partitional MSSC is to find an assignment of the n points into k disjoint clusters $\mathcal{S} = (S_1, \ldots, S_k)$ centered at cluster centers $\mathbf{c}_j\,(j = 1, \ldots, k)$ such that the total sum-of-squared Euclidean distances from each point $\mathbf{s}_i$ to its assigned cluster centroid $\mathbf{c}_i$

$$f(S, \mathcal{S}) = \sum_{j=1}^{k} \sum_{i=1}^{|S_j|} \left\| \mathbf{s}_i^{(j)} - \mathbf{c}_j \right\|^2$$

is minimized. Here $|S_j|$ is the number of points in S_j, and $\mathbf{s}_i^{(j)}$ is the ith point in S_j. Note that if the cluster centers are known, then the function $f(S, \mathcal{S})$ achieves its minimum when each point is assigned to its closest cluster center. Therefore, MSSC can be described by the following bilevel programming problem (see, for instance, [4, 30]):

$$\min_{\mathbf{c}_1, \ldots, \mathbf{c}_k} \sum_{i=1}^{n} \min\{\|\mathbf{s}_i - \mathbf{c}_1\|^2, \ldots, \|\mathbf{s}_i - \mathbf{c}_k\|^2\}. \tag{1}$$

Geometrically speaking, assigning each point to the nearest center fits into a framework called the *Voronoi program*, and the resulting partition is named the *Voronoi partition*. On the other hand, if the points in cluster S_j are fixed, then the function

$$f(S_j, \mathcal{S}_j) = \sum_{i=1}^{|S_j|} \left\| \mathbf{s}_i^{(j)} - \mathbf{c}_j \right\|^2$$

is minimized when

$$\mathbf{c}_j = \frac{1}{|S_j|} \sum_{i=1}^{|S_j|} \mathbf{s}_i^{(j)}.$$

The classical K-means algorithm [28], based on the above two observations, is described as follows.

K-means clustering algorithm.

(1) Randomly generate k cluster centers in a domain containing all the points,
(2) Assign each point to the closest cluster center,
(3) Recompute the cluster centers using the current cluster memberships,
(4) If a convergence criterion is met, stop; Otherwise go to step 2.

In spite of its popularity, the above simple procedure is very sensitive to the initial choice of the starting points and could not find the global solution in terms of its objective in general.

Another way to model MSSC works as follows. Let $X = [x_{ij}] \in \Re^{n \times k}$ be the assignment matrix defined by

$$x_{ij} = \begin{cases} 1 & \text{if } \mathbf{s}_i \text{ is assigned to } S_j; \\ 0 & \text{otherwise.} \end{cases}$$

[1] In the present paper, we always assume that $n \geq k > 1$, because otherwise the underlying clustering problem becomes trivial.

As a consequence, the cluster center of the cluster S_j, as the mean of all the points in the cluster, is defined by

$$\mathbf{c}_j = \frac{\sum_{l=1}^{n} x_{lj}\mathbf{s}_l}{\sum_{l=1}^{n} x_{lj}}.$$

Using this fact, we can represent (1) as

$$\min_{x_{ij}} \sum_{j=1}^{k}\sum_{i=1}^{n} x_{ij} \left\| \mathbf{s}_i - \frac{\sum_{l=1}^{n} x_{lj}\mathbf{s}_l}{\sum_{l=1}^{n} x_{lj}} \right\|^2 \tag{2}$$

$$\text{s.t.} \sum_{j=1}^{k} x_{ij} = 1 \ (i = 1, \ldots, n), \tag{3}$$

$$\sum_{i=1}^{n} x_{ij} \geq 1 \ (j = 1, \ldots, k), \tag{4}$$

$$x_{ij} \in \{0, 1\} \ (i = 1, \ldots, n;\ j = 1, \cdots, k). \tag{5}$$

The constraint (3) ensures that each point $\mathbf{s}_i$ is assigned to one and only one cluster, and constraint (4) ensures that there are exactly k clusters. This is a mixed integer programming problem with a nonlinear objective function [14], which is NP-hard. The problem has two difficulties. First, the constraints are discrete. Second, the objective is nonlinear and nonconvex. Both difficulties make MSSC extremely hard to solve.

Many different approaches have been proposed for attacking (2) both in the communities of machine learning and optimization [1, 14, 8]. Most methods are heuristics that can locate only a good local solution and not the exact global solution for (2). Only a few works are dedicated to the exact algorithm for (2) as listed in the references of [8]. In particular, by using the notion of *Voronoi partitions*, Inaba, Katoh, and Imai [18] showed that the exact solution of (2) can be located in $O(n^{kd+1})$ time. Due to its high complexity, the algorithm can be applied only to small data sets. In the special case $k = 2$, Hansen, Jaumard, and Mladenović [15] provided an algorithm running in $O(n^{d+1} \log n)$ time, where d is the dimension of the space to which the entities belong. Promising numerical results are reported for data sets in low dimensions.

Approximation methods provide a useful approach for solving (2). There are several ways to approximate (2). For example, Hasegawa et al. [16] proposed to select the k points from the present data set and then run the classical K-means for the selected centers. If we try all possible combinations of the k starting centers and output the best solution as the final one, then we can obtain a 2-approximately optimal solution for (2) in $O(n^{k+1})$ time [16]. In [33], Mutousek proposed a geometric approximation method that can find a $(1 + \epsilon)$ approximately optimal solution for (2) in $O(dn \log^k n)$ time, where the constant hidden in the big-O notation depends polynomially on ϵ^{-1}. Though theoretically efficient, so far no numerical results have been reported based on Matousek's algorithm. More recently, Kumar, Sabharwal, and Sen [25] proposed a linear time $O(2^{\epsilon^{-O(1)}} nd)$ algorithm for K-means clustering based on random sampling techniques and showed that their algorithm can find a $(1 + \epsilon)$ approximation with a certain probability. Only theoretical analysis based on the probabilistic model is presented, however. For more results on approximation algorithms for K-means clustering based on randomization techniques, we refer the reader to [25] and the references therein.

An efficient way of approximation is to attack the original problem (typically NP-hard) by solving a relaxed polynomially solvable problem. This has been well studied in the field of optimization, in particular, in the areas of combinatorial optimization and semidefinite programming (SDP) [10]. We noted that recently, Xing and Jordan [44] considered the SDP relaxation for the so-called normalized k-cut spectral clustering.

In the present paper, we mainly focus on developing approximation methods for (2) based on SDP relaxation. A crucial step in relaxing (2) is to rewrite the objective in (2) as a simple convex function of matrix argument that can be tackled easily, while the constraint set still enjoys certain geometric properties. This idea was possibly first suggested in [12], where the authors owed the idea to an anonymous referee. However, the authors of [12] did not explore the idea in depth to design any usable algorithm. A similar effort was made in [45], where the authors rewrote the objective in (2) as a convex quadratic function in which the argument is an $n \times k$ orthonormal matrix.

One major contribution of the present paper is the introduction of a new optimization model (0-1 SDP), which follows the same stream as in [12, 45]. However, different from the approach in [45], where the authors used only a quadratic objective and simple spectral relaxation, we elaborate more on how to characterize (2) exactly by means of matrix arguments. In particular, we show that MSSC can be modeled as the so-called 0-1 SDP, which can be further relaxed to polynomially solvable linear programming (LP) and SDP. Our model provides novel avenues not only for solving MSSC, but also for solving clustering problems based on some other criteria. For example, the K-means clustering in the kernel space and the clustering problem based on normalized cuts can also be embedded into our model. Moreover, by slightly changing the constraints in the 0-1 SDP model, we can attack clustering problems with constraints, e.g., the so-called balanced clustering.

The second major contribution of the present work is the development of an efficient approximation algorithm for the 0-1 SDP model, especially for biclustering. For this purpose, we first relax the 0-1 SDP model by removing some constraints so that the relaxed problem can be solved by using singular value decomposition (SVD) of the underlying coefficient matrix. Then we introduce a rounding procedure to extract a feasible solution for the original 0-1 model. In our rounding procedure, we need to solve the K-means clustering problem in $\Re^{k-1}$, which can be done in $O(n^{k^2-2k+2})$ time. We show that our algorithm provides a 2-approximate solution to the original K-means clustering.

Our algorithm uses an idea similar to the so-called spectral clustering [7, 45, 34], where the SVD of the coefficient matrix is employed to calculate the eigenvectors corresponding to the first k largest eigenvalues of the coefficient matrix, and these eigenvectors are further used to formulate a new data set in a lower dimension for which the classical K-means clustering is performed. A similar idea has been adopted in the principal components analysis (PCA) [22, 5]. In particular, Drineas et al. [7] proposed to solve the K-means clustering problem in $\Re^k$ whose solution can be found in $O(n^{k^2+1})$ time and showed that their method can provide a 2-approximate solution to the original K-means clustering problem.[2] For the classical K-means clustering, our algorithm can be viewed as a slight improvement over the algorithm in [7]. As we

[2]It should be pointed out that although the algorithm in [7] enjoys some nice properties, the high complexity in solving the subproblem might prevent it from practical efficiency when dealing with large-scale data sets. For example, for the biclustering problem with a data set with $n = 10^4$, the running time of the algorithm in [7] will reach a formidable $O(10^{20})$.

shall see later in our discussion, the only difference between the two algorithms in [7] and that in the present paper lies in how the 0-1 SDP model is relaxed.

It should be mentioned that for the cases with $k \geq 3$, the complexity of our algorithm is not as good as that of the algorithms in [16, 33]. However, in the case of biclustering ($k = 2$, which is still NP-hard), the global solution to the subproblem in our algorithm can be found in $O(n \log n)$ time. This implies that, for the classical K-means clustering problems with $k = 2$ and $d << n$, the complexity of our algorithm reduces to $O(n \log n)$. Although the theoretical complexity of our algorithm is only slightly better than that of the algorithm in [33], our algorithm is practically much simpler and allows us to efficiently solve large-scale biclustering problems in many applications with guaranteed quality.

Besides the above-mentioned contributions, our algorithm also provides a useful tool for solving several new clustering problems such as the balanced K-means clustering for which no approximation algorithms have been reported in the literature. The algorithm is particularly helpful for solving clustering problems arising from text mining where the data is typically in very high dimension ($n << d$) since the original data is only used to calculate the coefficient matrix.

The paper is organized as follows. In section 2, we show that MSSC can be modelled as a 0-1 SDP, which allows convex relaxation such as SDP and LP. In section 3, we consider approximation algorithms for solving our 0-1 SDP model. We propose to use PCA to reduce the dimension of the problem, and then perform K-means clustering in the lower dimension. The approximate ratio between the obtained solution and the global solution of the original K-means clustering is estimated in section 4. In section 5, we report some preliminary numerical tests, and finally we close the paper by a few concluding remarks.

2. 0-1 SDP for clustering problems. In this section, we establish the equivalence between several clustering scenarios and the 0-1 SDP model. The section has three parts. In the first part, we briefly describe SDP and 0-1 SDP. In the second part, we establish the equivalence between MSSC and the 0-1 SDP model. In the last part, we explore the interrelation between the 0-1 SDP model and other K-means-type clustering problems.

2.1. 0-1 semidefinite programming. In general, SDP refers to the problem of minimizing (or maximizing) a linear function over the intersection of a polyhedron and the cone of symmetric and positive semidefinite matrices. The canonical SDP takes the following form:

$$(\text{SDP}) \begin{cases} \min & \text{Tr}(WZ) \\ \text{s.t.} & \text{Tr}(B_i Z) = b_i \quad \text{for } i = 1, \ldots, m, \\ & Z \succeq 0. \end{cases}$$

Here $\text{Tr}(M)$ denotes the trace of the matrix M, and $Z \succeq 0$ means that Z is positive semidefinite. If we replace the constraint $Z \succeq 0$ by the requirement that $Z^2 = Z$ and $Z = Z^T$, then we end up with the following problem:

$$(\text{0-1 SDP}) \begin{cases} \min & \text{Tr}(WZ) \\ \text{s.t.} & \text{Tr}(B_i Z) = b_i \quad \text{for } i = 1, \ldots, m, \\ & Z^2 = Z, Z = Z^T. \end{cases}$$

We call it 0-1 SDP owing to the similarity of the constraint $Z^2 = Z$ to the classical 0-1 requirement in integer programming.

2.2. Equivalence of MSSC to 0-1 SDP. In this subsection we give the 0-1 SDP model of MSSC, which was first established in [36]. However, for completeness, we still give a detailed description of the reformulation process.

By rearranging the items in the objective of (2), we have

$$f(S,\mathcal{S}) = \sum_{i=1}^{n} \|\mathbf{s}_i\|^2 \left(\sum_{j=1}^{k} x_{ij}\right) - \sum_{j=1}^{k} \frac{\left\|\sum_{i=1}^{n} x_{ij}\mathbf{s}_i\right\|^2}{\sum_{i=1}^{n} x_{ij}} = \mathrm{Tr}\big(W_S W_S^T\big) - \sum_{j=1}^{k} \frac{\left\|\sum_{i=1}^{n} x_{ij}\mathbf{s}_i\right\|^2}{\sum_{i=1}^{n} x_{ij}}, \tag{6}$$

where $W_S \in \Re^{n\times d}$ denotes the matrix whose ith row is $\mathbf{s}_i^T$. Since X is an assignment matrix, we have

$$X^T X = \mathrm{diag}\left(\sum_{i=1}^{n} x_{i1}^2, \ldots, \sum_{i=1}^{n} x_{ik}^2\right) = \mathrm{diag}\left(\sum_{i=1}^{n} x_{i1}, \ldots, \sum_{i=1}^{n} x_{ik}\right).$$

Let

$$Z := [z_{ij}] = X(X^T X)^{-1} X^T;$$

we can write (6) as $\mathrm{Tr}\big(W_S W_S^T (I - Z)\big) = \mathrm{Tr}\big(W_S^T W_S\big) - \mathrm{Tr}\big(W_S^T W_S Z\big)$. Obviously Z is a projection matrix satisfying $Z^2 = Z$ with nonnegative elements. For any integer m, let e^m be the vector in $\Re^m$ with all entries equal to 1. We can write the constraint (3) as

$$Xe^k = e^n.$$

It follows immediately that

$$Ze^n = ZXe^k = Xe^k = e^n.$$

Moreover, the trace of Z should equal to k, the number of clusters, i.e.,

$$\mathrm{Tr}(Z) = k.$$

Therefore, we have the following 0-1 SDP model for MSSC:

$$\begin{aligned} \min & \mathrm{Tr}\big(W_S W_S^T (I - Z)\big) \\ & Ze = e, \mathrm{Tr}(Z) = k, \\ & Z \geq 0, Z = Z^T, Z^2 = Z. \end{aligned} \tag{7}$$

Here $Z \geq 0$ means the componentwise inequality, and the constraints $Z^T = Z$ and $Z^2 = Z$ imply that Z is an orthogonal projection matrix.

The following result from [36] established the equivalence between the 0-1 SDP model (7) and MSSC.

THEOREM 2.1. *Solving the* 0–1 *SDP problem* (7) *is equivalent to finding a global solution of the integer programming problem* (2).

It is worthwhile comparing the two objective functions in (7) and (2). First, the objective function in (7) is linear while the constraint in (7) is still nonlinear. The most difficult part in the constraint of (7) is the requirement that $Z^2 = Z$. Several relaxations of problem (7) will be discussed in the next section.

2.3. 0-1 SDP reformulation for other clustering approaches. In this subsection, we show that the 0-1 SDP can also be used for other clustering approaches based on other measurements. Let us consider the more general 0-1 SDP model for clustering,

$$\begin{aligned} \min & \mathrm{Tr}(W(I-Z)) \\ & Ze = e, \mathrm{Tr}(Z) = k, \\ & Z \geq 0, Z^2 = Z, Z = Z^T, \end{aligned} \tag{8}$$

where W is the so-called affinity matrix whose entries represent the similarities or closeness among the entities in the data set. In the MSSC model, we use the geometric distance between two points to characterize the similarity between them. In this case, we have $W_{ij} = \mathbf{s}_i^T \mathbf{s}_j$. However, we can also use a general function $\phi(\mathbf{s}_i, \mathbf{s}_j)$ to describe the similarity relationship between $\mathbf{s}_i$ and $\mathbf{s}_j$. For example, let us choose

$$W_{ij} = \phi(\mathbf{s}_i, \mathbf{s}_j) = \exp^{-\frac{\|\mathbf{s}_i - \mathbf{s}_j\|^2}{\sigma}}, \quad \sigma > 0. \tag{9}$$

This leads to the so-called K-means clustering in the kernel space. In order to apply the classical K-means algorithm to (8), we can first use the singular eigenvalue decomposition method to decompose the matrix W into the product of two matrices, i.e., $W = U^T U$. In this case, each column of U can be cast as a point in a suitable space. Then, we can apply the classical K-means method for the MSSC model to solving problem (8). This is exactly the procedure that the recently proposed spectral clustering follows [2, 34, 43, 44]. However, we now have a new interpretation for spectral clustering, i.e., a variant of MSSC in a different kernel space. It is worthwhile mentioning that certain variants of K-means can be adapted to solve (8) directly without using the SVD of the affinity matrix.

We note that recently, the normalized cut and spectral clustering have attracted a lot of attention in the machine learning community, and many interesting results about these two approaches have been reported [13, 31, 34, 40, 43, 44, 45]. In particular, Zha et al. [45] discussed the links between spectral relaxation and K-means clustering. Similar ideas were also used in [34]. An SDP relaxation for the normalized k-cut problem was discussed in [44]. For completeness, we next describe briefly how the normalized cut problem can be embedded into the 0-1 SDP model. Let us first recall the exact model for the normalized k-cut problem [44]. Let W be the affinity matrix defined by (9) and X be the assignment matrix in the set $\mathcal{F}_k$ defined by

$$\mathcal{F}_k = \{X : Xe^k = e^n, x_{ij} \in \{0, 1\}\}.$$

Let $d = We^n$ and $D = \mathrm{diag}\,(d)$. The exact model for the normalized k-cut problem in [44] can be rewritten as

$$\max_{X \in \mathcal{F}_k} \mathrm{Tr}\big((X^T D X)^{-1} X^T W X\big). \tag{10}$$

If we define

$$Z = D^{\frac{1}{2}} X (X^T D X)^{-1} X^T D^{\frac{1}{2}},$$

then we have

$$Z^2 = Z, Z^T = Z, Z \geq 0, Z d^{\frac{1}{2}} = d^{\frac{1}{2}}.$$

Following a similar process as in the proof of Theorem 2.1, we can show that the model (10) is equivalent to the following 0-1 SDP:

$$\begin{aligned} \min & \mathrm{Tr}\Big(D^{-\frac{1}{2}} W D^{-\frac{1}{2}} (I - Z)\Big) \\ & Z d^{\frac{1}{2}} = d^{\frac{1}{2}}, \mathrm{Tr}(Z) = k, \\ & Z \geq 0, Z^2 = Z, Z = Z^T. \end{aligned} \tag{11}$$

The only difference between (8) and (11) is the introduction of the scaling matrix D.

Besides the above-mentioned cases, the 0-1 SDP model can also be applied to the so-called balanced clustering [3], where the number of entities in every cluster is restricted. One special case of balanced clustering is requiring the number of entities in every cluster to be equal to or larger than a prescribed quantity, i.e., $|C_i| \geq \tilde{n}$. It is straightforward to see that such a problem can be modeled as a 0-1 SDP by adding the constraint $Z_{ii} \leq \frac{1}{\tilde{n}}$ to (8), which leads to the following problem:

$$\begin{aligned} \min & \mathrm{Tr}(W(I - Z)) \\ & Z_{ii} \leq \frac{1}{\tilde{n}}, \quad i = 1, \ldots, n, \\ & Ze = e, \mathrm{Tr}(Z) = k, \\ & Z \geq 0, Z^2 = Z, Z = Z^T. \end{aligned} \tag{12}$$

3. Approximation algorithms for solving 0-1 SDP. In this section we discuss how to solve the 0-1 SDP model for clustering. For simplification of our discussion, we restrict ourselves to the model (8) with a positive semidefinite matrix W. This assumption is satisfied in the MSSC model as well as in the so-called kernel K-means clustering, where the kernel matrix is defined by (9) or some other kernel function. It is worthwhile mentioning that although we restrict our discussion to (8), with minimal effort our results can be extended to (11) as well.

The section consists of two parts. In the first subsection, we give a general introduction to algorithms for solving (8). In the second part, we introduce a new approximation method for (8).

3.1. Algorithms for 0-1 SDP. In this subsection, we discuss various algorithms for solving the 0-1 SDP model (8). From an algorithm design viewpoint, we can categorize all the algorithms for (8) into two groups. The first group consists of the so-called feasible iterative algorithms, where all the generated iterates are feasible for problem (8) and the objective function value decreases step by step until some termination criterion is reached. The classical K-means algorithm described in the introduction can be interpreted as a special feasible iterative scheme for attacking (8). It is also easy to see that many variants of the K-means algorithm, such as the variants proposed in [17, 21], can also be interpreted as specific iterative schemes for (8).

The second group of algorithms for (8) consists of approximation algorithms that are based on LP/SDP relaxation. We start with a general procedure for those algorithms.

Approximation Algorithm Based on Relaxation.

Step 1. Choose a relaxation model for (7),

Step 2. Solve the relaxed problem for an approximate solution,

Step 3. Use a rounding procedure to extract a feasible solution to (7) from the approximate solution.

Various relaxations and rounding procedures have been proposed for solving (8) in the literature. For example, in [36], Peng and Xia considered a relaxation of (8) based on linear programming and a rounding procedure was also proposed in that work. Xing and Jordan [44] considered an SDP relaxation for the normalized cut problem and proposed a rounding procedure based on the SVD of the solution Z of the relaxed problem, i.e., $Z = U^T U$. In their approach, every row of U^T is cast as a point in the new space, and then the weighted K-means clustering is performed over the new set of points in $\Re^k$. Similar works for spectral clustering can also be found in [13, 31, 34, 43, 45], where the SVD of the underlying matrix W is used and a K-means-type clustering based on the eigenvectors of W is performed. In the above-mentioned works, the solutions obtained from the weighted K-means algorithm for the original problem and that based on the eigenvectors of W has been compared, and simple theoretical bounds have been derived based on the eigenvalues of W.

The idea of using the SVD of the underlying matrix W is natural in the so-called PCA [22]. In [5], the link between PCA and K-means clustering was also explored and simple bounds were derived. In particular, Drineas et al. [7] proposed using PCA to reduce the dimension of the input data, and then performing K-means clustering in the reduced subspace $\Re^k$. They proved that their algorithm can provide a 2-approximation solution to the clustering problem in the original input space.

We note that in [40], Shi and Malik used the eigenvector of a projection matrix of W (not W itself) onto a subspace to construct a feasible partitioning for the original problem. In this paper, we follow a similar idea as that in [40]. We first use SVD to obtain the $k-1$ eigenvectors corresponding to the first $k-1$ largest eigenvalues of a projection matrix of W, and then perform K-means clustering in $\Re^{k-1}$. This allows us to improve the complexity of the algorithm for solving the subproblem in the reduced space. As we shall see later, such a rounding procedure can also provide a 2-approximation solution to the original problem.

3.2. A new approximation method. In this subsection, we describe our SDP-based approximation method for (8). We start our discussion on various relaxation forms for (8).

First, recall that in (8), the argument Z is stipulated to be a projection matrix, i.e., $Z^2 = Z$ and $Z = Z^T$. This implies that the matrix Z is a positive semidefinite matrix whose eigenvalues are either 0 or 1. A straightforward relaxation to (8) is replacing the requirement $Z^2 = Z$ by the relaxed condition

$$I \succeq Z \succeq 0.$$

Note that in (8), we further stipulate that all the entries of Z are nonnegative, and the sum of each row (or each column) of Z equals to 1. This means all the eigenvalues of Z are less than or equal to 1. In this circumstance, the constraint $Z \preceq I$ becomes superfluous and can be removed. Therefore, we obtain the following SDP relaxation[3]:

$$\begin{aligned} \min & \mathrm{Tr}(W(I-Z)) \\ & Ze = e, \mathrm{Tr}(Z) = k, \\ & Z \geq 0, Z \succeq 0. \end{aligned} \tag{13}$$

The above problem is feasible and bounded below. We can apply many existing optimization solvers such as interior-point methods to solve (13). It is known that an

[3]In [44], the constraint $Ze = e$ in (8) is replaced by $Zd = d$, where d is a positive scaling vector associated with the affinity matrix.

approximate solution to (13) can be found in polynomial time. However, we would like to point out here that although there exist theoretically polynomial algorithms for solving (13), most of the present optimization solvers are unable to handle the problem in large size efficiently.

Another interesting relaxation to (8) is to further relax (13) by dropping some constraints. For example, if we remove the nonnegative requirement on the elements of Z, then we obtain the following simple SDP problem[4]:

$$\begin{aligned} \min & \mathrm{Tr}(W(I-Z)) \\ & Ze = e, \mathrm{Tr}(Z) = k, \\ & I \succeq Z \succeq 0. \end{aligned} \tag{14}$$

In what follows we discuss how to solve (14). Note that if Z is a feasible solution for (14), then we have

$$\frac{1}{\sqrt{n}} Ze = \frac{1}{\sqrt{n}} e,$$

which implies $\frac{1}{\sqrt{n}} e$ is an eigenvector of Z corresponding to its largest eigenvalue 1. For any feasible solution of (14), let us define

$$Z_1 = Z - \frac{1}{n} ee^T.$$

It is easy to see that

$$Z_1 = \left(I - \frac{1}{n} ee^T\right) Z = \left(I - \frac{1}{n} ee^T\right) Z \left(I - \frac{1}{n} ee^T\right); \tag{15}$$

i.e., Z_1 represents the projection of the matrix Z onto the null subspace of e. Moreover, it is easy to verify that

$$\mathrm{Tr}(Z_1) = \mathrm{Tr}(Z) - 1 = k - 1.$$

Let W_1 denote the projection of the matrix W onto the null space of e, i.e.,

$$W_1 = \left(I - \frac{1}{n} ee^T\right) W \left(I - \frac{1}{n} ee^T\right). \tag{16}$$

Then, we can reduce (14) to

$$\begin{aligned} \min & \mathrm{Tr}(W_1(I - Z_1)) \\ & \mathrm{Tr}(Z_1) = k - 1, \\ & I \succeq Z_1 \succeq 0. \end{aligned} \tag{17}$$

Let $\lambda_1, \ldots, \lambda_{n-1}$ be the eigenvalues of the matrix W_1 listed in the order of decreasing values. The optimal solution of (17) can be achieved if and only if [35]

$$\mathrm{Tr}(W_1 Z_1) = \sum_{i=1}^{k-1} \lambda_i.$$

[4]We point out that in [7], the authors considered a relaxation of the K-means clustering based on projection matrices of rank k. This relaxation is equivalent to simply removing the nonnegativity requirement on the elements of Z and the constraint $Ze = e$. In such a case, solving the relaxed problem in [7] reduces to the standard PCA.

This gives us an easy way to solve (17) and correspondingly (14). The algorithmic scheme for solving (14) can be described as follows.

Relaxation Algorithm 1.

Step 1. Calculate the projection W_1 via (16);

Step 2. Use the SVD method to compute the first $k-1$ largest eigenvalues of the matrix W_1 and their corresponding eigenvectors $v^1, \ldots, v^{k-1}$,

Step 3. Set

$$Z = \frac{1}{n} ee^T + \sum_{i=1}^{k-1} v^i v^{i^T}.$$

From our above discussion, we immediately have the following theorem.

THEOREM 3.1. *Let Z^* be the global optimal solution of* (8)*, and $\lambda_1, \ldots, \lambda_{k-1}$ be the first largest eigenvalues of the matrix W_1. Then we have*

$$\mathrm{Tr}(W(I - Z^*)) \geq \mathrm{Tr}(W) - \frac{1}{n} e^T W e - \sum_{i=1}^{k-1} \lambda_i.$$

It is of interest to discuss briefly the computational cost of the relaxation algorithm 1. In general, to compute the projection matrix W_1, we need $O(n^2)$ operations in total. Typically, performing the SVD for W_1 requires $O(n^3)$ time. If we use the power method or some other iterative methods [11] to compute the eigenvectors corresponding to the first $k-1$ largest eigenvalues of W_1, then the overall computational cost can be reduced to $O(kn^2)$. It should be mentioned that for the classical K-means clustering, we do not even need to compute the matrices W and W_1 explicitly. Recall that in case of the classical K-means clustering, we have $W = W_s W_S^T$. It is straightforward to see that for calculating W_1, we can first perform a simple normalization for the data set $s_i = s_i - \bar{s}$, where $\bar{s}$ is the geometric center of the whole data set. Correspondingly, the task in Step 2 of the relaxation algorithm can be realized by performing the SVD on the new coefficient matrix $W_{\bar{S}}$ for the normalized data set, which can be done in $O(\min\{n,d\}^3 + \min\{n,d\}nd)$ time.[5] If $d << n$ (this is true for data sets in many applications), the computational cost involved in the relaxation algorithm is linear in n.

We point out that if $k = 2$, then Step 2 in the above algorithm uses the eigenvector corresponding to the largest eigenvalue of W_1. A similar relaxation was used by Shi and Malik [40] (see also [43]) for image segmentation where the normalized cut problem with $k = 2$ was discussed. Similar bounds for the normalized cut problem and spectral clustering can also be found in [34, 5].

Note that solving the relaxed problem (14) cannot provide a solution to the original problem (8). In what follows we propose a rounding procedure to extract a feasible solution for (8) from a solution of the relaxed problem (14). Our rounding procedure follows a similar vein as the rounding procedure in [7]. Let us denote $V = (\sqrt{\lambda_1} v^1, \ldots, \sqrt{\lambda_{k-1}} v^{k-1}) \in \Re^{n \times (k-1)}$ the solution matrix obtained from the relaxation algorithm, Algorithm 1. We can cast each row of V as a point in $\Re^{k-1}$, and thus we obtain a data set of n points in $\Re^{k-1}$, i.e., $\mathcal{V} = \{v_1, \ldots, v_n\}$. Then we perform

[5] To see this, let us first consider the case $d < n$. We can perform the SVD for the matrix $W_{\bar{S}}^T W_{\bar{S}} = V^T \mathrm{diag}\{\lambda_1, \ldots, \lambda_d\} V$, which takes $O(d^3)$ time. Then we can get the eigenvalues and their corresponding eigenvectors of $W_{\bar{S}}$ from the product $W_{\bar{S}} V$. The whole process takes only $O(d^3 + d^2 n)$ operations. The case for $d \geq n$ follows similarly.

the classical K-means clustering for the new reduced data set $\mathcal{V}$. From Theorem 2.1, this is equivalent to solving the following 0-1 SDP problem:

$$\begin{aligned} \min & \mathrm{Tr}\left((I-Z)\sum_{i=1}^{k-1}\lambda_i v^i (v^i)^T\right) \\ & Ze = e, \mathrm{Tr}(Z) = k, \\ & Z \geq 0, Z^2 = Z, Z = Z^T. \end{aligned} \tag{18}$$

For constrained K-means clustering, we need to solve the following subproblem:

$$\begin{aligned} \min & \mathrm{Tr}\left((I-Z)\sum_{i=1}^{k-1}\lambda_i v^i (v^i)^T\right) \\ & Z_{ii} \geq \frac{1}{\tilde{n}} \quad i = 1, \ldots, n, \\ & Ze = e, \mathrm{Tr}(Z) = k, \\ & Z \geq 0, Z^2 = Z, Z = Z^T. \end{aligned} \tag{19}$$

Finally, we partition all the entities in the original space based on the clustering on $\mathcal{V}$; i.e., the entities s_i, s_j belong to the same cluster if and only if v_i, v_j are in the same cluster.

The whole algorithm can be described as follows.

Approximation Algorithm 2.

Step 1. Calculate the projection of the matrix W onto the null space of e, i.e.,

$$W_1 = \left(I - \frac{1}{n}ee^T\right) W \left(I - \frac{1}{n}ee^T\right);$$

Step 2. Use the SVD method to compute the first $k-1$ largest eigenvalues of the matrix W_1 and their corresponding eigenvectors $v^1, \ldots, v^{k-1}$;

Step 3. Solve problem (18) (or (19)) for (constrained) K-means clustering;

Step 4. Assign all the entities in $\mathcal{S}$ based on the assignment obtained from Step 3.

Before closing this section, we discuss the complexity of Algorithm 2. We can resort to the exact algorithm in [7] or the algorithm in [18][6] to solve problem (18). According to Theorem 5 of [18], the algorithm takes $O(n^{(k-1)^2})$ time to find the global solution of the subproblem in Step 3 of Algorithm 2, which improves the running time when the same procedure is applied to solve the subproblem in [7]. This is because the working space in our algorithm is one dimension less than the space in [7]. In case of biclustering, the improvement is substantial since we can use our refined K-means described in the next section. For general kernel K-means clustering or spectral clustering, the overall complexity becomes $O(kn^2+n^{(k-1)^2})$. For the classical K-means clustering, the overall complexity is $O(\min\{n,d\}^3 + \min\{n,d\}mn + n^{(k-1)^2})$. In case of $k = 2$ and $d << n$, then the complexity of Algorithm 2 reduces to $O(n \log n)$. Since our algorithm uses only SVD and the constant in the big-O notation is very small, the algorithm for biclustering is very efficient and can be implemented easily. Because

[6]We point out that both works [7] and [18] employed the same technique for the MSSC model. However, in the present work, we cite only the results from [18] because the estimation of the complexity in [7] is not precise [6].

biclustering is the basis of the so-called divisive hierarchical clustering, our results are applicable to clustering methods based on divisive approaches.

We also point out that it is possible to use some approximation algorithm to solve the reduced problem in Algorithm 2. For example, if we apply the algorithm in [16] to the reduced problem, then we can find a 2-approximation to the reduced problem in $O(n^{k+1})$ time. From Theorem 4.1, we can immediately conclude that the obtained solution is a 4-approximation to the original problem. Note that the quality of the solution we have now is worse than what was obtained by applying the algorithm in [16] directly to the original data set. However, when $d \geq n$, the complexity of the algorithm in [16] goes up $O(n^{k+2})$. This implies that the complexity of the new approximation algorithm is better than the direct algorithm in [16] for scenarios like the kernel K-means clustering, spectral clustering, or problems from text mining where $d \geq n$.

4. Estimation of the approximate solution. In this section, we estimate the approximation solution provided by our algorithm. We first consider the case for the classical K-means clustering. It should be pointed out that in [7], Drineas et al. considered a similar algorithm based on the SVD of W and showed that their algorithm can provide a 2-approximation solution to the original K-means clustering. However, since the working subspace in our algorithm is different from that in [7], a new analysis is necessary to investigate the approximation ratio of the solution of Algorithm 2.

We first discuss the case of biclustering. One reason for this is that for biclustering, the subproblem involved in Step 3 of Algorithm 2 is in $\Re$. In such a case, the task in Step 3 of Algorithm 2 reduces to partitioning the data set $\mathcal{V} = \{v_i \in \Re, i = 1, \ldots, n\}$ into two clusters based on the MSSC model. Therefore, we can refer to the following refined K-means clustering in one dimension.

Refined K-means in One Dimension.

Step 0. Input the data set $\mathcal{V} = \{v_1, v_2, \ldots, v_n\}$;

Step 1. Sort the sequence so that

$$v_{i_1} \geq v_{i_2} \cdots \geq v_{i_n},$$

where $\{i_1, \ldots, i_n\}$ is a permutation of the index set $\{1, \ldots, n\}$;

Step 2. For $l = 1$ to n, set

$$C_1^l = \{v_{i_1}, \ldots, v_{i_l}\}, C_2^l = \{v_{i_{l+1}}, \ldots, v_{i_n}\},$$

and calculate the objective function

$$f(C_1^l, C_2^l) = \sum_{v_i \in C_1^l} \left(v_i - \frac{1}{l} \sum_{v_i \in C_1^l} v_i \right)^2 + \sum_{v_i \in C_2^l} \left(v_i - \frac{1}{n-l} \sum_{v_i \in C_2^l} v_i \right)^2$$

based on the partition (C_1^l, C_2^l);

Step 3. Find the optimal partition (C_1^*, C_2^*) such that

$$(C_1^*, C_2^*) = \arg \min_{l \in \{1, \ldots, n\}} f(C_1^l, C_2^l),$$

and output it as the final solution.

The above algorithm is similar to the algorithm in [15] for divisive k-clustering in low dimension. It is straightforward to see that for biclustering problems in $\Re$ based

on the MSSC model, the above procedure can find the global solution in $O(n \log n)$ time.

If $k \geq 3$, then we can use some existing exact algorithms in the literature for K-means clustering such as the algorithms in [7, 18] to solve the subproblem (18).

We next progress to estimate the approximation ratio of the solution of Algorithm 2. Let Z^* be a global solution to (8), and $\bar{Z}$ is the solution provided by Algorithm 2. Let us define

$$U = \frac{1}{n} ee^T + \sum_{i=1}^{k-1} v^i (v^i)^T. \tag{20}$$

It follows that

$$\mathrm{Tr}\left((I - U) \sum_{i=1}^{k-1} v^i (v^i)^T \right) = 0; \tag{21}$$

$$\mathrm{Tr}\left(U \sum_{i=k}^{n-1} v^i (v^i)^T \right) = 0. \tag{22}$$

From Theorem 3.1, we have

$$\mathrm{Tr}(W(I - Z^*)) \geq \mathrm{Tr}(W(I - U)). \tag{23}$$

It follows that

$$\mathrm{Tr}\big(W(I - \bar{Z})\big) = \mathrm{Tr}\big(W(I - U + U - \bar{Z})\big) \leq \mathrm{Tr}(W(I - Z^*)) + \mathrm{Tr}\big(W(U - \bar{Z})\big).$$

The above relation implies that if

$$\mathrm{Tr}\big(W(U - \bar{Z})\big) \leq \mathrm{Tr}(W(I - Z^*)), \tag{24}$$

then

$$\mathrm{Tr}\big(W(I - \bar{Z})\big) \leq 2\mathrm{Tr}(W(I - Z^*));$$

i.e., in the worst case, the solution provided by Algorithm 2 is a 2-approximation to the original K-means clustering.

In what follows we prove (24), which can be equivalently stated as

$$\mathrm{Tr}\big(W(I - Z^* + \bar{Z} - U)\big) \geq 0. \tag{25}$$

By the choices of $Z^*, \bar{Z}$, and U, it is easy to verify

$$(I - Z^* + \bar{Z} - U)e = 0, \tag{26}$$

$$\left(I - \frac{ee^T}{n}\right)(I - Z^* + \bar{Z} - U) = \left(I - \frac{ee^T}{n}\right)(I - Z^* + \bar{Z} - U)\left(I - \frac{ee^T}{n}\right). \tag{27}$$

It follows immediately that

$$\begin{aligned}
\mathrm{Tr}\big(W(I-Z^*+\bar{Z}-U)\big) &= \frac{1}{n}\mathrm{Tr}\big(W(I-Z^*+\bar{Z}-U)ee^T\big)+\mathrm{Tr}\big(W_1(I-Z^*+\bar{Z}-U)\big)\\
&= \mathrm{Tr}\left((I-Z^*+\bar{Z}-U)\sum_{i=1}^{n-1}\lambda_i v^i(v^i)^T\right)\\
&= \mathrm{Tr}\left((I-Z^*+\bar{Z}-U)\sum_{i=1}^{k-1}\lambda_i v^i(v^i)^T)\right)\\
&\quad +\mathrm{Tr}\left((I-Z^*+\bar{Z}-U)\sum_{i=k}^{n-1}\lambda_i v^i(v^i)^T\right)\\
&= \mathrm{Tr}\left((\bar{Z}-Z^*)\sum_{i=1}^{k-1}\lambda_i v^i(v^i)^T)\right)+Tr\left(I-Z^*+\bar{Z})\sum_{i=k}^{n-1}\right.\\
&\quad \left.\lambda_i v^i(v^i)^T\right)\\
&\geq \mathrm{Tr}\left((\bar{Z}-Z^*)\sum_{i=1}^{k-1}\lambda_i v^i(v^i)^T)\right),
\end{aligned}$$

where the last equality is given by (21) and (22), and the last inequality is implied by the fact that the matrix $I-Z^*+\bar{Z}$ is positive semidefinite. Recall that $\bar{Z}$ is the global solution of subproblem (18) and Z^* is only a feasible solution of (18); we therefore have

$$\mathrm{Tr}\left((\bar{Z}-Z^*)\sum_{i=1}^{k-1}\lambda_i v^i(v^i)^T)\right)\geq 0,$$

which further implies (24).

Now we are ready to state the main result in this section, which follows immediately from (23) and (24).

THEOREM 4.1. *Suppose that Z^* is a global solution to problem* (8) *and $\bar{Z}$ is the solution provided by Algorithm* 2*. Then, we have*

$$\mathrm{Tr}\big(W(I-\bar{Z})\big)\leq 2\mathrm{Tr}(W(I-Z^*)).$$

In what follows we estimate the approximation ratio of Algorithm 2 for constrained K-means clustering. It is worthwhile mentioning that in such a case, no polynomial algorithm has been reported in the literature to find a global solution of subproblem (19). However, suppose a global solution to (19) can be located; then by following a similar chain of reasoning as in the proof of Theorem 4.1, we can prove the following result.

THEOREM 4.2. *Suppose that Z^* is a global solution to problem* (12) *and $\bar{Z}$ is the solution provided by Algorithm* 2*. Then, we have*

$$\mathrm{Tr}\big(W(I-\bar{Z})\big)\leq 2\mathrm{Tr}(W(I-Z^*)).$$

5. Numerical experiments. To test the new algorithm, we have done some preliminary numerical experiments on several data sets from the UCI Machine Learning Repository[7] and internet newsgroups. All the experiments are done by using

[7] http://www.ics.uci.edu/~mlearn/MLRepository.html

TABLE 5.1
Results on three UCI data sets.

Data set	Stage 1	Stage 2	Global opt.
Soybean	404.4593	404.4593	404.4593

Spam e-mail	$9.43479784e+08$	$9.43479784e+08$	$9.43479784e+08$

MATLAB on a personal computer with a Pentium 4 1700 MHz Processor and a 256M memory. The power method is applied for calculating the largest eigenvalue and eigenvector for the matrix [11].

It should be mentioned that although the subproblem (18) can be solved by using the procedure in [7], the running time of the procedure is clearly too much for a reasonably large data set. Due to this fact, in our experiments, we restrict ourselves only to biclustering ($k = 2$).

We mention that in the following tables, we concentrate mainly on the quality of the obtained solutions. This is due to the fact that our tests are on biclustering problems. Based on our theoretical analysis, our algorithm enjoys the best complexity for the underlying problems compared with the algorithms in [16] and [36]. Even for the largest test problem (e-mail spam database) in this work, our algorithm takes less than one second to find the solution, while such a problem cannot be handled by using the LP relaxation in [36] because of the huge number (n^3) of constraints introduced in the LP model.[8]

Data sets from the UCI machine learning repository.

- *Soybean data set (small).* See also [32]. This data set has 47 points in $\Re^{35}$.
- *The Späth's postal zones.* This data set is from [41] about the post zones in Bavaria. It has 89 points in $\Re^3$.
- *Spam e-mail database.* Created by M. Hopkins et al. from Hewlett–Packard Labs. It has 4601 in $\Re^{57}$. For purposes of clustering, we have removed the last boolean attribute which indicates whether the e-mail was considered spam or not.

In our experiments, we use a two-phase strategy. After we obtain the partition of the data sets from Approximation Algorithm 2, we use the classical K-means to further improve the partition. In other words, we use Algorithm 2 only as a starting strategy for K-means clustering. In the following tables, we list the solutions from both phase 1 and phase 2.

Since, for the first two data sets, the global optimum has already been reported in [36] by using a linear programming model in the case of $K = 2$, we list it in the Global opt. column as a reference. The global solution for the third data set has been reported in [37]. The numerical results for general biclustering are summarized in Table 5.1. As one can see from the table, for the test problems, the solutions from stage 1 match the global solution.

Numerical results for balanced biclustering. We also test our algorithm for balanced biclustering. To find a global solution to balanced biclustering, we adapt the

[8] In one of our recent works [38], we also compared the algorithm in [16] with the so-called Q-means developed in [38] and our preliminary tests indicated that the Q-means algorithm outperformed the algorithm in [16]. For example, for the Email spam database under the same computational environment as in the present work, the Q-means took more than 300 seconds while the algorithm in [16] took more than half an hour to find a solution [38].

TABLE 5.2
Results for balanced biclustering.

LP model in [36] slightly to incorporate balanced constraints. The solution obtained from the LP model gives us a lower bound for the global optimum of the balanced biclustering. We also pointed out that for the third data set, its relatively large size prevents us from the use of the LP model due to the enormous amount $O(n^3)$ of constraints involved in the model. In such a case, we list the result from [38], which is derived by a so-called Q-means heuristic for the same data and same balanced constraint.

In the experiments for the last two data sets, we require that each cluster have at least $n/3$ entities. For the soybean data set, we require that each cluster have at least 22 entities. This is because the data set itself is fairly balanced already (the optimal biclustering has a $(20, 27)$ distribution). Table 5.2 summarizes the results.

From the above tables we can see that the solution from phase 1 is very close to the solution from phase 2. In all the cases, the solution from phase 2 matches the global solution of the underlying problem.

Internet newsgroups. Text mining has been popular in document analysis, search engine, and knowledge discovery in a large volume of text data. We have also performed experiments on newsgroup articles submitted to 20 newsgroups.[9] This data set has also been used in [5, 13, 45], where a similar framework to ours was used to solve the problem. The algorithm we use is still the two-phase heuristic which was introduced in the last section.

This data set consists of about 20,000 articles (e-mail messages) evenly distributed among the 20 newsgroups. We list the name of the newsgroups together with the associated group labels.

Before constructing the word-document matrices, we perform the preprocessing by using the *bow* toolkit, a preprocessor similar to what was employed in [5, 13, 45]. In particular, we use the tokenization option such that the UseNet headers are stripped, since the headers include the name of the correct newsgroup, and we also

[9]The news group data together with the bow toolkit for preprocessing can be downloaded from http://www-2.cs.cmu.edu/afs/cs/project/theo-11/www/naive-bayes.html.

TABLE 5.4

apply stemming [27]. Afterward, we apply the standard tf.idf weighting scheme and normalize each document vector to have unit Euclidean length. Finally, we conduct feature selection where 500 words are selected according to the mutual information between words and documents in an unsupervised manner.

In our experiment, we choose 50 random document vectors from each of two newsgroups. This implies that for each test, we have a data set with 100 points in $\Re^{500}$. Then we apply our approximation algorithm to the problem. The results are summarized in Table 5.3. Note that, since the global optima are not known for these data sets, we use the linear programming relaxation model proposed in [36] to get a lower bound on the global optimum. More specifically, we implement the LP relaxation model (14) in [36] using package CPLEX 7.1 with AMPL interface on an IBM RS-6000; by solving this LP problem, we can obtain a lower bound for the global optimum solution. Apparently, if the solution obtained from the LP relaxation equals to the solution provided by our two-phase heuristic, then it must be a global optimal solution of the original problem. The numerical results for the internet newsgroups are summarized in Table 5.4.

From the above experiments, we can conclude that our deterministic two-phase heuristic performs very well on these data sets and it finds the global optimum for most of these data sets.

6. Conclusions. In this paper, we reformulated the classical MSSC as a 0-1 SDP. Our new model not only provides a unified framework for several existing clustering approaches, but also opens new avenues for clustering. An approximation method based on the SDP relaxation and PCA has been proposed to attack the underlying 0-1 SDP. It is shown that in the worst case, our method can provide a 2-approximate solution to the original classical or constrained K-means clustering. Preliminary numerical tests indicate that our algorithm can always find a global solution for biclustering.

Several important issues regarding the new framework remain open. First, for general $k \geq 3$, although subproblem (18) can be solved by using some exact algorithms in the literature [7, 18], its complexity is still exponential in k. This makes the algorithm impractical for relatively large data sets. Second, the current model can deal with only a simple case of constrained K-means clustering. The issue of how to deal with general constrained K-means clustering still remains open. More study is needed to address these questions.

Acknowledgments. The authors would like to thank Dr. Y. Xia, Prof. F. Rendl, and Prof. K. C. Toh for their useful advice in the preparation of this paper.

DECOMPOSITION-BASED INTERIOR POINT METHODS FOR TWO-STAGE STOCHASTIC SEMIDEFINITE PROGRAMMING*

SANJAY MEHROTRA† AND M. GÖKHAN ÖZEVIN‡

Abstract. We introduce two-stage stochastic semidefinite programs with recourse and present an interior point algorithm for solving these problems using Bender's decomposition. This decomposition algorithm and its analysis extend Zhao's results [*Math. Program.*, 90 (2001), pp. 507–536] for stochastic linear programs. The convergence results are proved by showing that the logarithmic barrier associated with the recourse function of two-stage stochastic semidefinite programs with recourse is a strongly self-concordant barrier on the first stage solutions. The short-step variant of the algorithm requires $O(\sqrt{p+Kr}\ln\mu^0/\epsilon)$ Newton iterations to follow the first stage central path from a starting value of the barrier parameter μ^0 to a terminating value ϵ. The long-step variant requires $O((p+Kr)\ln\mu^0/\epsilon)$ damped Newton iterations. The calculation of the gradient and Hessian of the recourse function and the first stage Newton direction decomposes across the second stage scenarios.

1. Introduction.

We introduce and study the two-stage stochastic semidefinite programming (TSSDP) problem with recourse in the dual standard form:

$$\begin{aligned} \max \quad & \eta(x) := c^T x + \varrho(x) \\ \text{s.t.} \quad & Ax + s = b, \\ & s \in \mathcal{K}^p, \end{aligned} \tag{1.1}$$

where

$$\varrho(x) := E[\varrho^{\tilde{\xi}}(x)] \tag{1.2}$$

and

$$\begin{aligned} \varrho^{\xi}(x) := \max \quad & {d^{\xi}}^T y^{\xi} \\ \text{s.t.} \quad & W^{\xi} y^{\xi} + s^{\xi} = h^{\xi} - T^{\xi} x, \\ & s^{\xi} \in \mathcal{K}^r. \end{aligned} \tag{1.3}$$

In the first stage problem (1.1), $x \in \mathbb{R}^n$ and $s \in \mathbb{R}^{p^2}$ are decision variables. A is a $p^2 \times n$ matrix with n linearly independent columns that are obtained by vectorization of n symmetric real $p \times p$ matrices and $b \in \mathbb{R}^{p^2}$. We have chosen this form of TSSDP

*Received by the editors January 5, 2005; accepted for publication (in revised form) September 12, 2006; published electronically March 19, 2007. for notational convenience in the analysis of this paper. By $S := \mathbf{mat}(s)$ we denote the $\nu \times \nu$ matrix whose (i,j)th element is the $((j-1)\nu+i)$th element of a vector $s \in \mathbb{R}^{\nu^2}$. We use $\mathbf{vec}(S)$ to denote a vector whose $((j-1)\nu+i)$th element is the (i,j)th element of a matrix S. The cone $\mathcal{K}^\nu := \{\mathbf{vec}(S) \mid S \in \mathbb{R}^{\nu\times\nu} \text{is symmetric positive semidefinite}\}$ is the cone of vectors obtained from the vectorization of symmetric positive semidefinite matrices. $\mathcal{K}^\nu_+$ is used to describe the cone generated by positive definite matrices.

Randomness in the second stage is governed by the random variable $\tilde{\xi}$. We assume that the support Ξ of $\tilde{\xi}$ is discrete and finite. $E[\cdot]$ in (1.2) represents the expectation. For each realization ξ of $\tilde{\xi}$, $y^\xi \in \mathbb{R}^m$ and $s^\xi \in \mathbb{R}^{r^2}$ are decision variables. $h^\xi \in \mathbb{R}^{r^2}$ and T^ξ is a $r^2 \times n$ matrix with n linearly independent columns that are obtained by vectorization of n symmetric real $r \times r$ matrices. Similarly, W^ξ is a $r^2 \times m$ matrix with m linearly independent columns that are obtained by vectorization of m symmetric real $r \times r$ matrices. Under suitable assumptions (see section 2), $\varrho^\xi(x)$ is finite and well defined for all feasible first stage solutions (x,s). $\varrho(x)$ is called the recourse function.

The TSSDP problem is a natural generalization of a semidefinite programming problem [14] to its two-stage stochastic programming counterpart. Problems where objective and constraints are defined by convex quadratic inequalities or second order cone inequalities are special cases. The linear-quadratic model introduced by Rockafellar and Wets [11] is also a special case. In general, we can write the explicit extensive formulation of these problems as a large-scale semidefinite program. We can then solve this extensive formulation directly, particularly by using primal-dual interior point methods, exploiting its special structure through efficient matrix factorization schemes [3, 4, 5]. However, the focus of this paper is in developing decomposition-based interior point methods for TSSDP in the spirit of Bender's decomposition.

Optimal dual solutions of second stage problems are used in the evaluation of the gradient and Hessian of the recourse function, which is central to the algorithm. In practice, we can calculate the gradient and Hessian information approximately. This view of the algorithm has several potential advantages since it does not require explicit knowledge of all the scenarios and associated variables in the algorithm up front. First, the scenarios can be added as the algorithm progresses. This has the potential for speeding up the algorithm in its early stages. Mehrotra and Özevin [7] provide evidence for this benefit. Second, if computations for some of the scenarios fail due to unreliability of available computational resources, one may still be able to proceed with the algorithm. This allows for implementations in a distributed computing environment where some of the computing nodes may not be reliable.

In general, the recourse function $\varrho(x)$ is not differentiable with respect to x everywhere. The decomposition approaches either use the nonsmooth optimization techniques [1, 2, 13], or use techniques to smooth this function [11, 12]. Given the success of interior point methods, it is logical to investigate whether decomposition-based interior point algorithms are possible for stochastic programming problems. Zhao [15] developed an interior decomposition algorithm for linear two-stage stochastic programs by regularizing the second stage problem with a log barrier. In particular, he showed that the log barrier associated with the recourse function of two-stage stochastic linear programs behaves as a strongly self-concordant barrier (see Nesterov and Nemirovskii [8] and Renegar [10]) on the first stage solutions. Mehrotra and Ozevin [6] extended Zhao's analysis for two-stage stochastic convex quadratic programs. In this paper we show that the recourse function is also strongly self-concordant for TSSDP. This allows us to give a Benders decomposition-based linearly convergent interior point algorithm for TSSDP. The convergence analysis of this paper provides

the conceptual framework for a more practical algorithm developed and implemented in [7].

This paper is organized as follows. In section 2 we give barrier problem formulations and our assumptions. In section 3 we show that the barrier recourse function comprises a self-concordant family. In section 4 we present short- and long-step variants of an interior point decomposition algorithm and state the convergence results. Proofs of these convergence theorems are given in section 5.

We use the following additional notation. For any strictly positive vector x in $\mathbb{R}^n$, we define $x^{-1} := (x_1^{-1}, \ldots, x_n^{-1})^T$. An identity matrix of appropriate dimension is denoted by I. Throughout this paper we use "∇","∇^2","∇^3" to denote the gradient, Hessian, and the third order derivative with respect to x, and a " $'$ " for the derivative with respect to a single variables other than x. For example,

$$[\{\nabla^2 f(\mu, x)\}']_{i,j} = \frac{\partial}{\partial \mu}\left(\frac{\partial^2 f(\mu, x)}{\partial x_i \partial x_j}\right).$$

"∇" is also used to denote the Jacobian of a vector function. $A \otimes B$ represents the Kronecker product of matrices A and B. The Kronecker product satisfies relationship $[A \otimes B][C \otimes D] = [AC \otimes BD]$, assuming that the number of rows in A and B equals the number of columns in C and D. Also, $(A \otimes B)\mathbf{vec}(C) = \mathbf{vec}(BCA^T)$.

2. Problem formulation and assumptions. Let the random variable $\tilde{\xi}$ have a finite discrete support $\Xi = \{\xi^1, \ldots, \xi^K\}$ with probabilities $\{\pi^1, \ldots, \pi^K\}$. For simplicity of notation we define $\varrho^i(x) := \varrho^{\xi^i}(x)$, $T^i := T^{\xi^i}$, $W^i := W^{\xi^i}$, $h^i := h^{\xi^i}$, $y^i := y^{\xi^i}$, and $d^i := \pi^i d^{\xi^i}$. The problem (1.1)–(1.3) is rewritten as

$$\begin{aligned} \max \quad & \eta(x) := c^T x + \varrho(x) \\ \text{s.t.} \quad & Ax + s = b, \\ & s \in \mathcal{K}^p, \end{aligned} \tag{2.1}$$

where

$$\varrho(x) := \sum_{i=1}^{K} \varrho^i(x), \tag{2.2}$$

and for $i = 1, \ldots, K$,

$$\begin{aligned} \varrho^i(x) := \max \quad & {d^i}^T y^i \\ \text{s.t.} \quad & W^i y^i + s^i = h^i - T^i x, \\ & s^i \in \mathcal{K}^r. \end{aligned} \tag{2.3}$$

Let γ and λ^i be the first and second stage dual multipliers. The dual of (2.3) is

$$\begin{aligned} \min \quad & (h^i - T^i x)^T \lambda^i \\ \text{s.t.} \quad & {W^i}^T \lambda^i = d^i, \\ & \lambda^i \in \mathcal{K}^r. \end{aligned} \tag{2.4}$$

Here $s^i \in \mathbb{R}^{r^2}$, $W^i \in \mathbb{R}^{r^2 \times m}$, and h^i, T^i is data of appropriate dimensions.

Let us define the following feasibility sets:

$$\mathcal{F}^i(x) := \{y^i \mid W^i y^i + s^i = h^i - T^i x,\ s^i \in \mathcal{K}^r\}, \qquad \mathcal{F}_1^i := \{x \mid \mathcal{F}^i(x) \neq \emptyset\},$$
$$\mathcal{F}_1 := \cap_{i=1}^K \mathcal{F}_1^i, \qquad \mathcal{F}_0 := \mathcal{F}_1 \cap \{x \mid Ax + s = b,\ s \in \mathcal{K}^p\}, \text{ and}$$
$$\mathcal{F} := \{(x, s, \gamma) \times (y^1, s^1, \lambda^1, \ldots, y^K, s^K, \lambda^K) \mid Ax + s = b, s \in \mathcal{K}^p; W^i y^i + s^i = h^i - T^i x,$$
$$s^i \in \mathcal{K}^r; {W^i}^T \lambda^i = d^i, \lambda^i \in \mathcal{K}^r, \text{ for } i = 1, \ldots, K;\ A^T\gamma + \textstyle\sum_{i=1}^K {T^i}^T \lambda^i = c\}.$$

We make the following assumptions:

A1. The set $\mathcal{F}$ is not empty, is bounded, and has a nonempty relative interior.

A2. Matrices A and W^i have full column rank.

Assumption A1 requires that primal and dual feasible sets of the explicit deterministic equivalent formulation of (2.1)–(2.3) have nonempty interiors. In particular, it assumes strong duality (see, for example, Ramana, Tunçel, and Wolkowicz [9]) for first and second stage semidefinite programs. This assumption also ensures that the recourse function $\varrho(x) : \mathcal{F} \to \mathbb{R}$ is finite and well defined. In practice this assumption can be ensured by introducing artificial variables. Assumption A2 is for convenience.

Consider the following log-barrier decomposition problem

$$\begin{aligned} \max \quad & \eta(\mu, x) := c^T x + \rho(\mu, x) + \mu \ln\det S \\ \text{s.t.} \quad & Ax + s = b, \\ & s \in \mathcal{K}^p, \end{aligned} \tag{2.5}$$

where

$$\rho(\mu, x) := \sum_{i=1}^K \rho^i(\mu, x) \tag{2.6}$$

and for $i = 1, \ldots, K$

$$\begin{aligned} \rho^i(\mu, x) := \max \quad & {d^i}^T y^i + \mu \ln\det S^i \\ \text{s.t.} \quad & W^i y^i + s^i = h^i - T^i x, \\ & s^i \in \mathcal{K}^r. \end{aligned} \tag{2.7}$$

The log-barrier problem associated with the dual (2.4) is given by

$$\begin{aligned} \min \quad & (h^i - T^i x)^T \lambda^i - \mu \ln\det \Lambda^i \\ \text{s.t.} \quad & {W^i}^T \lambda^i = d^i, \\ & \lambda^i \in \mathcal{K}^r. \end{aligned} \tag{2.8}$$

Note that, for a given $\mu > 0$, the log-barrier recourse function $\rho(\mu, x) < \infty$ iff $x \in \mathcal{F}_1$. Hence, it describes the interior of $\mathcal{F}_0$ implicitly. Assumption A1 implies that problems (2.5) and (2.7)–(2.10) have a unique solution. Since the objective in problems (2.7) and (2.8), is respectively, concave and convex function, (y^i, s^i) and λ^i are optimal solutions to (2.7) and (2.8), respectively, iff they satisfy the following optimality conditions:

$$\begin{aligned} & {W^i}^T \lambda^i = d^i, \\ & W^i y^i + s^i = h^i - T^i x, \\ & S^i \Lambda^i = \mu I, \\ & \lambda^i, s^i \in \mathcal{K}_+^r, \end{aligned} \tag{2.9}$$

where $\Lambda^i = \mathbf{mat}(\lambda^i)$. Throughout this paper we denote the optimal solution of the first stage problem (2.5) by $x(\mu)$, and the solutions of the optimality conditions (2.9) for a given $x \in \mathcal{F}_1$ by $(y^i(\mu,x), s^i(\mu,x), \lambda^i(\mu,x))$. The optimal solutions of (2.5)–(2.7) and those of the log-barrier problem

$$\begin{aligned} \max \quad & c^T x + \sum_{i=1}^{K} {d^i}^T y^i + \mu \ln\det S + \mu \sum_{i=1}^{K} \ln\det S^i \\ \text{s.t.} \quad & Ax + s = b, \\ & W^i y^i + s^i = h^i - T^i x, \quad i = 1,\dots,K, \\ & s \in \mathcal{K}^p,\ s^i \in \mathcal{K}^r, \quad i = 1,\dots,K, \end{aligned} \tag{2.10}$$

associated with the extensive formulation of (2.1)–(2.3) have the following relationship.

PROPOSITION 2.1. *For a given $\mu > 0$, if $(x(\mu), s(\mu); y^1(\mu), s^1(\mu), \dots, y^K(\mu), s^K(\mu))$ is the optimal solution of* (2.10)*, then $(x(\mu), s(\mu))$ is the optimal solution of* (2.5)*, and $(y^1(\mu), s^1(\mu), \dots, y^K(\mu), s^K(\mu))$ are the optimal solutions of subproblems* (2.7) *for the given μ and $x = x(\mu)$. Conversely, if for a given μ, $(x(\mu), s(\mu))$ is the optimal solution of* (2.5) *and $(y^1(\mu), s^1(\mu), \dots, y^K(\mu), s^K(\mu))$ are the optimal solutions of* (2.7) *with $x = x(\mu)$, then $(x(\mu), s(\mu) y^1(\mu), s^1(\mu), \dots, y^K(\mu), s^K(\mu))$ is the optimal solution of* (2.10).

3. The self-concordance properties of the log-barrier recourse.

3.1. Computation of $\nabla\eta(\mu,x)$ and $\nabla^2\eta(\mu,x)$. From (2.9) we can show that the optimal objective values of primal and dual barrier problems (2.7)–(2.8) differ by a constant term, in particular

$$\rho^i(\mu,x) = (h^i - T^i x)\lambda^i(\mu,x) - \mu \ln\det \Lambda^i(\mu,x) + r\mu(1 - \ln\mu). \tag{3.1}$$

In order to compute $\nabla\eta(\mu,x)$ and $\nabla^2\eta(\mu,x)$ we need to determine the derivative of $\lambda^i(\mu,x)$ with respect to x. Let $(y^i, \lambda^i, s^i) := (y^i(\mu,x), \lambda^i(\mu,x), s^i(\mu,x))$. Differentiating (2.9) with respect to x, we obtain

$$\begin{aligned} {W^i}^T \nabla\lambda^i &= 0, \\ W^i \nabla y^i + \nabla s^i &= -T^i, \\ (I \otimes S^i)\nabla\lambda^i + (\Lambda^i \otimes I)\nabla s^i &= 0. \end{aligned} \tag{3.2}$$

Solving the system (3.2), we get

$$\begin{aligned} \nabla y^i &= -{R^i}^{-1} {W^i}^T {Q^i}^2 T^i, \\ \nabla\lambda^i &= Q^i P^i Q^i T^i, \\ \nabla s^i &= -{Q^i}^{-1} P^i Q^i T^i, \end{aligned} \tag{3.3}$$

where

$$Q^i := Q^i(\mu,x) = (\Lambda^i \otimes {S^i}^{-1})^{1/2}, \qquad R^i := R^i(\mu,x) = {W^i}^T {Q^i}^2 W^i \tag{3.4}$$

$$\text{and} \quad P^i := P^i(\mu,x) = I - Q^i W^i {R^i}^{-1} {W^i}^T Q^i. \tag{3.5}$$

Now differentiating (3.1) and using the optimality conditions (2.9) and (3.3), we can verify that

$$\nabla\rho^i(\mu,x) = -{T^i}^T\lambda^i(\mu,x) \quad \text{and} \quad \nabla^2\rho^i(\mu,x) = -{T^i}^T\nabla\lambda^i(\mu,x). \tag{3.6}$$

Hence,

$$\nabla\eta(\mu,x) = c - \sum_{i=1}^{K} {T^i}^T\lambda^i(\mu,x) - \mu A^T s^{-1}, \tag{3.7}$$

$$\nabla^2\eta(\mu,x) = -\sum_{i=1}^{K} {T^i}^T\nabla\lambda^i(\mu,x) - \mu A^T(S^{-1}\otimes S^{-1})A. \tag{3.8}$$

Then, substituting for $\nabla\lambda_i$ in (3.8), we get

$$\nabla^2\eta(\mu,x) = -\sum_{i=1}^{K} {T^i}^T Q^i P^i Q^i T^i - \mu A^T(S^{-1}\otimes S^{-1})A. \tag{3.9}$$

3.2. Self-concordance of the recourse function. The following definition of self-concordant functions was introduced by Nesterov and Nemirovskii [8].

DEFINITION 3.1 (Nesterov and Nemirovskii [8]). *Let $\mathcal{E}$ be a finite-dimensional real vector space, $\mathcal{Q}$ be an open nonempty convex subset of $\mathcal{E}$, and $f : \mathcal{Q} \to \mathbb{R}$ be a function, $\alpha > 0$. f is called α-self-concordant on $\mathcal{Q}$ with the parameter value α if $f \in C^3$ is a convex function on $\mathcal{Q}$, and, for all $x \in \mathcal{Q}$ and $h \in \mathcal{E}$, the following inequality holds:*

$$|\nabla^3 f(x)[h,h,h]| \le 2\alpha^{-1/2}(\nabla^2 f(x)[h,h])^{3/2}.$$

An α-self-concordant on $\mathcal{Q}$ function f is called strongly α-self-concordant on $\mathcal{Q}$ if $f(x^i)$ tends to infinity along every sequence $\{x^i \in \mathcal{Q}\}$ converging to a boundary point of $\mathcal{Q}$.

We now show that recourse function $\rho(\mu,x)$ behaves as a strongly self-concordant barrier on $\mathcal{F}_1$.

LEMMA 3.1. *For any fixed $\mu > 0$, $\rho^i(\mu,\cdot)$ is strongly μ-self-concordant on $\mathcal{F}_1^i, i = 1,\dots,K$.*

Proof. For any $\mu > 0$, $d \in \mathbb{R}^n$, and $\bar{x} \in \{x \mid \rho^i(x) < \infty\}$ we define the univariate function

$$\Phi^i(t) := \nabla^2\rho^i(\mu,\bar{x}+td)[d,d].$$

Note that $\Phi^i(0)' = \nabla^3\rho^i(\mu,\bar{x})[d,d,d]$. Along every sequence $\{x^j \in \mathcal{F}_1^i\}$ converging to the boundary of $\mathcal{F}_1^i$, $\rho^i(\mu,x^j)$ tends to infinity. To prove this lemma it suffices to show that

$$|\Phi^i(0)'| \le \frac{2}{\sqrt{\mu}}|\Phi^i(0)|^{3/2}.$$

Let $(\lambda^i(t), P^i(t), s^i(t), Q^i(t), R^i(t)) := (\lambda^i(\mu,\bar{x}+td), P^i(\mu,\bar{x}+td), s^i(\mu,\bar{x}+td), Q^i(\mu,\bar{x}+td), R^i(\mu,\bar{x}+td))$. We define $u^i(t) := P^i(t)Q^i(t)T^i(t)d$. The argument "$(t)$" is dropped when considering all of these variables and their derivatives at $t = 0$, e.g., $u' := u'(0)$. Note that $\Phi^i(0) = -{u^i}^T u^i = -\|u^i\|^2$ and thus $|\Phi^i(0)'| = |2{u^i}^T {u^i}'|$.

The first equality below follows from using (3.4)–(3.5). The second equality is derived by using derivatives by parts. The third equality uses ${R^i}' = {W^i}^T[Q^i{Q^i}' + {Q^i}'Q^i]W^i$.

We have

$$\begin{aligned}
u^{i\prime} &= [Q^i - Q^i W^i R^{i^{-1}} W^i Q^{i^2}]' T^i d \\
&= [Q^{i\prime} - Q^{i\prime} W^i R^{i^{-1}} W^i Q^{i^2} + Q^i W^i R^{i^{-1}} R^{i\prime} R^{i^{-1}} W^i Q^{i^2} \\
&\qquad - Q^i W^i R^{i^{-1}} W^i (Q^i Q^{i\prime} + Q^{i\prime} Q^i)] T^i d \\
&= [Q^{i\prime}(I - W^i R^{i^{-1}} W^i Q^{i^2}) - Q^i W^i R^{i^{-1}} W^i (Q^i Q^{i\prime} + Q^{i\prime} Q^i) \\
&\qquad (I - W^i R^{i^{-1}} W^i Q^{i^2})] T^i d \\
&= [(Q^{i\prime} - Q^i W^i R^{i^{-1}} W^i (Q^i Q^{i\prime} + Q^{i\prime} Q^i))](I - W^i R^{i^{-1}} W^i Q^{i^2}) T^i d \\
&= [(Q^{i\prime} - Q^i W^i R^{i^{-1}} W^i (Q^i Q^{i\prime} + Q^{i\prime} Q^i))] Q^{i^{-1}} u^i \\
&\qquad \text{(noting that } (I - W^i R^{i^{-1}} W^i Q^{i^2}) T^i d = Q^{i^{-1}} u^i). \qquad (3.10)
\end{aligned}$$

Observing that ${u^i}^T Q^i W^i = 0$, from (3.10) we get

$$\begin{aligned}
|\Phi^i(0)'| &= |2{u^i}^T u^{i\prime}| = |2{u^i}^T Q^{i\prime} Q^{i^{-1}} u^i| \\
&= |{u^i}^T (Q^{i\prime} Q^{i^{-1}} + Q^{i^{-1}} Q^{i\prime}) u^i| \qquad \text{(since } Q^i, Q^{i\prime} \text{are symmetric matrices)} \\
&= |{u^i}^T Q^{i^{-1}} (Q^i Q^{i\prime} + Q^{i\prime} Q^i) Q^{i^{-1}} u^i| = |{u^i}^T Q^{i^{-1}} ({Q^i}^2)' Q^{i^{-1}} u^i|. \qquad (3.11)
\end{aligned}$$

We let $\nabla\lambda^i := \nabla\lambda^i(\mu, \bar{x})$ and $\lambda^{i\prime} := \frac{\partial \lambda^i(\mu, \bar{x}+td)}{\partial t}\big|_{t=0} = \nabla\lambda_i d$. Note that from (3.4) we have

$$\begin{aligned}
({Q^i}^2)' &= (\Lambda^i \otimes S^{i^{-1}})' = \mu^{-1}(\Lambda^i \otimes \Lambda^i)' = \mu^{-1}(\Lambda^i \otimes \Lambda^{i\prime} + \Lambda^{i\prime} \otimes \Lambda^i) \\
&\qquad \text{(since } \Lambda^{i\prime} = \mathbf{mat}(\nabla\lambda^i d)) \\
&= \mu^{-1}(\Lambda^i \otimes \mathbf{mat}(\nabla\lambda^i d) + \mathbf{mat}(\nabla\lambda^i d) \otimes \Lambda^i). \qquad (3.12)
\end{aligned}$$

Combining (3.11), (3.12), and using (3.4), we obtain

$$\begin{aligned}
|\Phi^i(0)'| &= |{u^i}^T (\Lambda^{i^{-1/2}} \otimes \Lambda^{i^{-1/2}}) \\
&\qquad [(\Lambda^i \otimes \mathbf{mat}(\nabla\lambda^i d) + \mathbf{mat}(\nabla\lambda^i d) \otimes \Lambda^i)](\Lambda^{i^{-1/2}} \otimes \Lambda^{i^{-1/2}}) u^i| \\
&= |{u^i}^T [I \otimes (\Lambda^{i^{-1/2}} \mathbf{mat}(\nabla\lambda^i d) \Lambda^{i^{-1/2}}) + (\Lambda^{i^{-1/2}} \mathbf{mat}(\nabla\lambda^i d) \Lambda^{i^{-1/2}}) \otimes I] u^i| \\
&\le 2\|u^i\|_2^2 \, \|\mathbf{vec}(\Lambda^{i^{-1/2}} \mathbf{mat}(\nabla\lambda^i d) \Lambda^{i^{-1/2}})\|_2 \\
&= 2\|u^i\|_2^2 \, \|(\Lambda^{i^{-1/2}} \otimes \Lambda^{i^{-1/2}})(\nabla\lambda^i d)\|_2 \\
&= 2\mu^{-1/2}\|u^i\|_2^2 \, \|Q^{i^{-1}} \nabla\lambda^i d\|_2 \qquad \text{(noting that } Q^{i^{-1}} = \sqrt{\mu}(\Lambda^{i^{-1/2}} \otimes \Lambda^{i^{-1/2}})) \\
&= 2\mu^{-1/2}\|u^i\|_2^3 \qquad \text{(noting that } Q^{i^{-1}} \nabla\lambda^i d = u^i) \\
&= 2\mu^{-1/2}|\Phi^i(0)|^{3/2} \qquad \text{(since } |\Phi^i(0)| = \|u^i\|_2^2). \qquad (3.13)
\end{aligned}$$

□

We have the following corollary.

COROLLARY 3.1. *The recourse function $\rho(\mu, x)$ is a μ-self-concordant barrier on $\mathcal{F}_1$, and the first stage objective function $\eta(\mu, x) := c^T x + \rho(\mu, x) + \mu \ln\det S$ is a strongly μ-self-concordant barrier on $\mathcal{F}_0$.*

Proof. It is easy to verify that $\mu \ln\det S$ is a strongly μ-self-concordant barrier on $\{x | Ax + s = b, s \in \mathcal{K}^p\}$. The corollary follows from Proposition 2.1.1(ii) in [8]. □

3.3. Parameters of the self-concordant family. The self-concordant family with appropriate parameters is defined in Nesterov and Nemirovskii [8]. They showed that, given such a family, the parameters defining the family allow us to relate the rate at which the barrier parameter μ is varied and the number of Newton steps required to maintain the proximity to the central path. Below is the definition of a strongly self-concordant family adapted to the current setting from the original definition in Nesterov and Nemirovskii [8]. These conditions might look rather technical; nevertheless they simplify our convergence analysis and the accompanying proofs in what follows and explicitly reveal some essential properties of the log-barrier recourse function $\rho(\mu, x)$. They allow us to invoke the interior point convergence theory developed by Nesterov and Nemirovskii [8].

DEFINITION 3.2. *The family of functions* $\{\eta(\mu,\cdot) : \mu > 0\}$ *is strongly self-concordant on* $\mathcal{F}_0$ *with parameter functions* $\alpha(\mu)$, $\gamma(\mu)$, $\nu(\mu)$, $\xi(\mu)$, *and* $\sigma(\mu)$ *if the following six conditions are satisfied:*

C1. $\eta(\mu, x)$ *is concave in* x, *continuous in* $(\mu, x) \in \mathbb{R}_{++} \times \mathcal{F}_0$, *and has three derivatives in* x, *continuous in* $(\mu, x) \in \mathbb{R}_{++} \times \mathcal{F}_0$.

C2. $\nabla\eta(\mu, x)$ *and* $\nabla^2\eta(\mu, x)$ *are continuously differentiable in* μ.

C3. *For any* $\mu \in \mathbb{R}_{++}$, $\eta(\mu, x)$ *is strongly* $\alpha(\mu)$*-self-concordant on* $\mathcal{F}_0$.

C4. *The parameter functions* $\alpha(\mu)$, $\gamma(\mu)$, $\xi(\mu)$, *and* $\sigma(\mu)$ *are continuous positive scalar functions on* $\mu \in \mathbb{R}_{++}$.

C5. *For every* $(\mu, x) \in \mathbb{R}_{++} \times \mathcal{F}_0$ *and* $h \in \mathbb{R}^n$,

$$|\{\nabla\eta(\mu,x)h\}' - \{\ln\nu(\mu)\}'\{\nabla\eta(\mu,x)h\}| \le \xi(\mu)\alpha(\mu)^{1/2}(-h^T\nabla^2\eta(\mu,x)h)^{1/2}.$$

C6. *For every* $(\mu, x) \in \mathbb{R}_{++} \times \mathcal{F}_0$ *and* $h \in \mathbb{R}^n$,

$$|\{h^T\nabla^2\eta(\mu,x)h\}' - \{\ln\gamma(\mu)\}'h^T\nabla^2\eta(\mu,x)h| \le -2\sigma(\mu)h^T\nabla^2\eta(\mu,x)h.$$

We refer the reader to Nesterov and Nemirovskii [8] for the original definition of self-concordant families and their properties. The essence of the above definition is in conditions C5 and C6.

THEOREM 3.1. *The family of functions* $\eta : \mathbb{R}_{++} \times \mathcal{F} \mapsto \mathbb{R}$ *is a strongly self-concordant family with parameters* $\alpha(\mu) = \mu$, $\gamma(\mu) = \nu(\mu) = 1$, $\xi(\mu) = \frac{\sqrt{p+Kr}}{\mu}$, *and* $\sigma(\mu) = \frac{\sqrt{r}}{2\mu}$.

Proof. It is easy to verify that conditions C1–C4 of Definition 3.2 hold. Lemmas 3.2 and 3.3 below show that C5 and C6 are satisfied. □

In Lemmas 3.2 and 3.3 we bound the changes of $\nabla\eta(\mu, x)$ and $\nabla^2\eta(\mu, x)$ as the barrier parameter μ changes. This requires us to calculate the derivatives of $(y^i(\mu, x), \lambda^i(\mu, x), s^i(\mu, x))$ with respect to μ. This derivative is represented by $(y^{i\prime}, \lambda^{i\prime}, s^{i\prime})$. Differentiating (2.9) with respect to μ, we get

$$\begin{aligned} W^{iT}\lambda^{i\prime} &= 0, \\ W^i y^{i\prime} + s^{i\prime} &= 0, \\ (I \otimes S^i)\lambda^{i\prime} + (\Lambda^i \otimes I)s^{i\prime} &= \mathbf{vec}(I). \end{aligned} \tag{3.14}$$

Solving (3.14), we obtain

$$\begin{aligned} y^{i\prime} &= -R^{i-1}W^{iT}s^{i-1}, \\ \lambda^{i\prime} &= \frac{1}{\sqrt{\mu}}Q^iP^i\mathbf{vec}(I), \\ s^{i\prime} &= W^iR^{i-1}W^{iT}s^{i-1}. \end{aligned} \tag{3.15}$$

LEMMA 3.2. *For any $\mu > 0$, $x \in \mathcal{F}_0$, and $h \in \mathbb{R}^n$ we have*

$$|\{\nabla\eta(\mu,x)^T h\}'| \le \left[\frac{-(p+Kr)}{\mu} h^T \nabla^2\eta(\mu,x)^T h\right]^{1/2}.$$

Proof. Differentiating (3.7) with respect to μ and applying (3.15), we get

$$\begin{aligned}\{\nabla\eta(\mu,x)\}' &= -\frac{1}{\sqrt{\mu}}\sum_{i=1}^{K} {T^i}^T Q^i P^i \mathbf{vec}(I) - A^T s^{-1} \\ &= -\frac{1}{\sqrt{\mu}}\sum_{i=1}^{K} {T^i}^T Q^i P^i \mathbf{vec}(I) - A^T(S^{-1/2}\otimes S^{-1/2})\mathbf{vec}(I).\end{aligned}$$

We define

$$B := \left[\frac{1}{\sqrt{\mu}}{T^1}^T Q^1 P^1,\ \ldots,\ \frac{1}{\sqrt{\mu}}{T^K}^T Q^K P^K,\ A^T(S^{-1/2}\otimes S^{-1/2})\right],$$

and let z be a (p^2+Kr^2)-dimensional vector defined by $z := [\mathbf{vec}(I_r),\ldots,\ \mathbf{vec}(I_r), \mathbf{vec}(I_p)]$. We can write

$$\{\nabla\eta(\mu,x)\}' = -Bz. \tag{3.16}$$

Note that $BB^T = \frac{1}{\mu}\sum_{i=1}^{K} {T^i}^T Q^i P^i Q^i T^i + A^T(S^{-1}\otimes S^{-1})A = -\frac{1}{\mu}\nabla^2\eta(\mu,x)$. Now we have

$$-\{\nabla\eta(\mu,x)^T\}'[\nabla^2\eta(\mu,x)]^{-1}\{\nabla\eta(\mu,x)\}' = \frac{1}{\mu}z^T B^T[BB^T]^{-1}Bz \le \frac{1}{\mu}z^T z = \frac{1}{\mu}(p+Kr). \tag{3.17}$$

Now by using norm inequalities and (3.17), it follows that

$$\begin{aligned}|\{\nabla\eta(\mu,x)^T h\}'| &\le \left[-\{\nabla\eta(\mu,x)^T\}'[\nabla^2\eta(\mu,x)]^{-1}\{\nabla\eta(\mu,x)\}'\right]^{1/2}\left[-h^T\nabla^2\eta(\mu,x)h\right]^{1/2} \\ &\le \left[\frac{-(p+Kr)}{\mu}h^T\nabla^2\eta(\mu,x)h\right]^{1/2}. \qquad \square\end{aligned}$$

LEMMA 3.3. *For any $\mu > 0$, $x \in \mathcal{F}^0$ and $h \in \mathbb{R}^n$ we have*

$$|\{h^T\nabla^2\eta(\mu,x)h\}'| \le -\frac{\sqrt{r}}{\mu}h^T\nabla^2\eta(\mu,x)h.$$

Proof. We fix $h \in \mathbb{R}^n$ and let $(\lambda^i, P^i, s^i, Q^i, R^i) := (\lambda^i(\mu,x), P^i(\mu,x), s^i(\mu,x), Q^i(\mu,x), R^i(\mu,x))$. Let us define $u^i := P^i Q^i T^i h$. We have

$$h^T\nabla^2\eta(\mu,x)h = -\sum_{i=1}^{K}{u^i}^T u^i - \mu h^T A^T(S^{-1}\otimes S^{-1})Ah.$$

Following the steps in Lemma 3.1 leading up to (3.11) and the definition of $\eta(\mu,x)$, we have

$$\{h^T\nabla^2\eta(\mu,x)h\}' = -\sum_{i=1}^{K}{u^i}^T {Q^i}^{-1}({Q^i}^2)'{Q^i}^{-1}u^i - h^T A^T(S^{-1}\otimes S^{-1})Ah. \tag{3.18}$$

From (3.15), the definition of Q^i from (3.4), $S^i\Lambda^i = \mu I$, and using $S^i\Lambda^{i\prime} + \Lambda^i S^{i\prime} = I$, $\Lambda^{i^{-1}} = \mu^{-1}S^i$, it follows that

$$\begin{aligned}
&u^{i^T}Q^{i^{-1}}(Q^{i^2})'Q^{i^{-1}}u^i \\
&\quad = u^{i^T}(I \otimes \Lambda^{i^{-1/2}}\Lambda^{i\prime}\Lambda^{i^{-1/2}} - S^{i^{-1/2}}S^{i\prime}S^{i^{-1/2}} \otimes I)u^i \\
&\quad = \mu^{-1}u^{i^T}(I \otimes I - \mu(S^{i^{-1/2}}S^{i\prime}S^{i^{-1/2}} \otimes I + I \otimes S^{i^{-1/2}}S^{i\prime}S^{i^{-1/2}}))u^i \\
&\quad \le \frac{\|u^i\|_2^2}{\mu}\|\mathbf{vec}(I) - 2\mu(S^{i^{-1/2}} \otimes S^{i^{-1/2}})s^{i\prime}\|_2 \\
&\quad = \frac{\|u^i\|_2^2}{\mu}\|\mathbf{vec}(I) - 2\mu(S^{i^{-1/2}} \otimes S^{i^{-1/2}})W^iR^{i^{-1}}W^{i^T}s^{i^{-1}}\|_2 \\
&\quad = \frac{\|u^i\|_2^2}{\mu}\|(I - 2P^i)\mathbf{vec}(I)\|_2 \\
&\quad \le \frac{\sqrt{r}}{\mu}\|u^i\|_2^2 \qquad (\text{since } I - 2P \preceq I, \|(I - 2P^i)\|_2 \le 1). \qquad (3.19)
\end{aligned}$$

From (3.18) and (3.19), we obtain for any $h \in R^n$

$$|\{h^T\nabla^2\eta(\mu,x)h\}'| \le \frac{\sqrt{r}}{\mu}\sum_{i=1}^K u^{i^T}u^i + h^TA^T(S^{-1}\otimes S^{-1})Ah = -\frac{\sqrt{r}}{\mu}h^T\nabla^2\eta(\mu,x)h. \qquad \square$$

4. Interior point decomposition algorithms for TSSDP. Once it is established that the family of functions $\{\eta(\mu,\cdot) : \mu > 0\}$ is strongly self-concordant, the development of primal path following interior point methods is straightforward. These methods reduce μ by a factor at each iteration and seek to approximate the minimizer $x(\mu)$ for each μ by taking one or more Newton steps. The novelty of the algorithm in the context of TSSDP is in computing the Newton direction from the solutions of the decomposed second stage problems. As μ varies, the minimizers $x(\mu)$ form the central path. By tracing the central path as $\mu \to 0$, this procedure will generate a strictly feasible ϵ-solution to (2.5).

For a given μ the optimality condition for the problem (2.5) is

$$\nabla\eta(\mu, x(\mu)) = 0. \qquad (4.1)$$

Hence, at a feasible point x the Newton direction is given by

$$\Delta x = -[\nabla^2\eta(\mu,x)]^{-1}\nabla\eta(\mu,x). \qquad (4.2)$$

Note that although problems (2.5)–(2.7) and (2.10) share the same central path, the associated Newton directions are not identical and lead to different ways of path following. A conceptual primal path following algorithm is given below.

THE DECOMPOSITION ALGORITHM. Here $\beta > 0, \gamma \in (0,1)$ and $\theta > 0$ are suitable scalars. We make their values more precise in Theorems 4.1 and 4.2. The desired precision ϵ, an initial point $x^0 \in \mathcal{F}_0$, and μ^0 are given as inputs.

Initialization. $x = x^0$; $\mu = \mu^0$.

Step 1 (Newton or damped Newton iterations).

1.1. For all i solve the optimality conditions (2.9) to find $(y^i(\mu,x), s^i, \lambda^i(\mu,x))$.

1.2. Compute the Newton direction Δx from (4.2).

1.3. Let $\delta(\mu,x)=\sqrt{-\frac{1}{\mu}\Delta x^T\nabla^2\eta(\mu,x)\Delta x}$. If $\delta\le\beta$, go to Step 2.

1.4. Set $x=x+\theta\Delta x$ and go to Step 1.1.

Step 2 (termination check). If $\mu\le\epsilon$, stop; otherwise set $\mu=\gamma\mu$ and go to Step 1.1.

In the above algorithm we assume that we can find exact solutions of the optimality conditions (2.9). This assumption considerably simplifies the complexity analysis. In a practical implementation of this algorithm (such as the one in [7]) we use approximate solutions of the optimality conditions (2.9) to construct the Newton direction (4.2).

Theorems 4.1 and 4.2 give two standard complexity results for the generic primal interior point method. In the short-step version of the algorithm, barrier parameter μ is decreased by a factor $1-\sigma/\sqrt{n+m}$ ($\sigma>0$) in each iteration.

An iteration of the short-step algorithm is performed as follows. At the beginning of iteration k, x^k is close to the central path; i.e., $\delta(\mu^k,x^k)\le\beta$. After reducing the parameter from μ^k to $\mu^{k+1}=\gamma\mu^k$, we will have $\delta(\mu^{k+1},x^k)\le 2\beta$. Then a Newton step with step size $\theta=1$ is taken, resulting in a new point x^{k+1} with $\delta(\mu^{k+1},x^{k+1})\le\beta$. We have the following theorem.

THEOREM 4.1. *Let μ^0 be the initial barrier parameter, $\epsilon>0$ the stopping criterion, and $\beta=(2-\sqrt{3})/2$. If the starting point x^0 is sufficiently close to the central path, i.e., $\delta(\mu^0,x^0)\le\beta$, then the short-step algorithm reduces the barrier parameter μ at a linear rate and terminates within $O(\sqrt{p+Kr}\ln\mu^0/\epsilon)$ executions of Steps* 1.1–1.4 *in Algorithm* 1.

Proof. For the proof, see section 5.1. ∎

In the long-step version we decrease the barrier parameter μ by an arbitrary constant factor $\lambda\in(0,1)$. This has a potential for much faster progress; however, several damped Newton steps might be needed for restoring the proximity to the central path. We have the following theorem.

THEOREM 4.2. *Let μ^0 be the initial barrier parameter, $\epsilon>0$ be the stopping criterion, and $\beta=1/6$. If the starting point x^0 is sufficiently close to the central path, i.e., $\delta(\mu^0,x^0)\le\beta$, then the long-step algorithm reduces the barrier parameter μ at a linear rate and terminates within $O((p+Kr)\ln\mu^0/\epsilon)$ executions of Steps* 1.1–1.4 *in Algorithm* 1.

Proof. For the proof, see section 5.2. ∎

5. Convergence proof for short- and long-step algorithms. Part (i) of the following proposition follows directly from the definition of self-concordance and is due to Nesterov and Nemirovskii [8, Theorem 2.1.1]. Part (ii) is a corollary of part (i) and is given in Zhao [15] without a proof.

PROPOSITION 5.1. *For any $\mu>0$, $x\in\mathcal{F}^0$, and Δx computed from* (4.2), *let $\delta:=\sqrt{-\frac{1}{\mu}\Delta x^T\nabla^2\eta(\mu,x)\Delta x}$. Then, for $\delta<1$, $\tau\in[0,1]$, and any $h\in\mathbb{R}^n$ we have*

$$\text{(i)}\quad -(1-\tau\delta)^2h^T\nabla^2\eta(\mu,x)h\le -h^T\nabla^2\eta(\mu,x+\tau\Delta x)h\le -(1-\tau\delta)^{-2}h^T\nabla^2\eta(\mu,x)h,$$

$$\text{(ii)}\quad |h_1^T[\nabla^2\eta(\mu,x+\tau\Delta x)-\nabla^2\eta(\mu,x)]h_2|\le[(1-\tau\delta)^{-2}-1]\sqrt{-h_1^T\nabla^2\eta(\mu,x)h_1}\sqrt{-h_2^T\nabla^2\eta(\mu,x)h_2}.$$

For the estimation of the number of Newton steps needed for recentering we use two different merit functions to measure the progress of Newton iterates. We use $\delta(\mu,x)$ for the short-step algorithm and the first stage objective $\eta(\mu,x)$ for the long-

step algorithm. The following lemma is due to Theorem 2.2.3 in [8] and describes the behavior of the Newton method as applied to $\eta(\mu, \cdot)$.

LEMMA 5.1. *Let $\mu > 0$ and $x \in \mathcal{F}^0$, Δx be the Newton direction calculated at x from (4.2); $\delta := \delta(\mu, x) = \sqrt{-\frac{1}{\mu}\Delta x^T \nabla^2 \eta(\mu, x)\Delta x}$, $x^+ = x + \Delta x$, Δx^+ be the Newton direction calculated at x^+; and $\delta(\mu, x^+) := \sqrt{-\frac{1}{\mu}\Delta x^{+T} \nabla^2 \eta(\mu, x^+)\Delta x^+}$. Then,*

(i) *if $\delta < 2 - \sqrt{3}$, then*

$$\delta(\mu, x^+) \leq \left(\frac{\delta}{1-\delta}\right)^2 \leq \frac{\delta}{2};$$

(ii) *if $\delta \geq 2 - \sqrt{3}$, then*

$$\eta(\mu, x) - \eta(\mu, x + \overline{\theta}\Delta x) \geq \mu[\delta - \ln(1+\delta)],$$

for $\overline{\theta} = (1+\delta)^{-1}$.

5.1. Complexity of the short-step algorithm. We now show that in this version of the algorithm a single Newton step is sufficient for recentering after updating the barrier parameter μ. To this end we make use of Theorem 3.1.1 in [8], which is restated for the present context in the next proposition.

PROPOSITION 5.2. *Let $\varphi_\kappa(\eta; \mu, \mu^+) := \left(\frac{1+r}{2} + \frac{\sqrt{p+Kr}}{\kappa}\right) \ln \gamma^{-1}$. Assume that $\delta(\mu, x) < \kappa$ and $\mu^+ := \gamma\mu$ satisfies*

$$\varphi_\kappa(\eta; \mu, \mu^+) \leq 1 - \frac{\delta(\mu, x)}{\kappa}.$$

Then $\delta(\mu^+, x) < \kappa$.

LEMMA 5.2. *Let $\mu^+ = \gamma\mu$, where $\gamma = 1 - \sigma/\sqrt{p+Kr}$ and $\sigma \leq 0.1$. Furthermore let $\beta = (2-\sqrt{3})/2$. If $\delta(\mu, x) \leq \beta$, then $\delta(\mu^+, x) \leq 2\beta$.*

Proof. Let $\kappa = 2\beta = 2 - \sqrt{3}$. It is easy to verify that with $\sigma \leq 0.1$, μ^+ satisfies

$$\begin{aligned}\varphi_\kappa(\eta; \mu, \mu^+) &= \left(\frac{1+r}{2} + \frac{\sqrt{p+Kr}}{\kappa}\right) \ln(1 - \sigma/\sqrt{p+Kr})^{-1} \\ &\leq \frac{1}{2} \leq 1 - \frac{\delta(\mu, x)}{\kappa}.\end{aligned}$$

Now Proposition 5.2 implies

$$\delta(\mu^+, x) \leq \kappa = 2\beta. \qquad \square$$

From Lemmas 5.1 and 5.2 it is clear that we can reduce μ by the factor $\gamma = 1 - \sigma/\sqrt{p+Kr}$, $\sigma < 0.1$, at each iteration and that a single Newton step is sufficient to restore proximity to the central path. Hence, Theorem 4.1 follows.

5.2. Complexity of the long-step algorithm. For the analysis of the long-step algorithm we use η as the merit function since the iterates generated by the less conservative long-step algorithm may violate the condition, $\delta < 2 - \sqrt{3}$, required in part (i) of Lemma 5.1. Our analysis follows the steps in Zhao [15].

Assume that we have a point x^{k-1} sufficiently close to $x(\mu^{k-1})$. Next we reduce the barrier parameter from μ^{k-1} to $\mu^k = \gamma\mu^{k-1}$, where $\gamma \in (0, 1)$. While searching for a point x^k that is sufficiently close to $x(\mu^k)$, the long-step algorithm generates a

finite sequence of points (inner iterates) $p^1, \ldots, p^N \in \mathcal{F}_0$, and we finally set $x^k = p^N$. We need to determine an upper bound on N, the number of Newton iterations needed for recentering. Let

$$\phi(\mu, x) := \eta(\mu, x(\mu)) - \eta(\mu, x).$$

The next lemma gives upper bounds on $\phi(\mu^{k-1}, x)$ and $\phi'(\mu^{k-1}, x)$, respectively, for any $\mu > 0$ and $x \in \mathcal{F}_0$. They facilitate us bounding $\phi(\mu^k, x)$.

LEMMA 5.3. *Let $\mu > 0$ and $x \in \mathcal{F}_0$. We denote $\tilde{\Delta}x := x(\mu) - x$ and define*

$$\tilde{\delta}(\mu, x) := \sqrt{-\frac{1}{\mu}\tilde{\Delta}x^T \nabla^2 \eta(\mu, x)\tilde{\Delta}x}.$$

For any $\mu > 0$ and $x \in \mathcal{F}_0$, if $\tilde{\delta} < 1$, then

$$\phi(\mu, x) \le \mu \left[\frac{\tilde{\delta}}{1-\tilde{\delta}} + \ln(1-\tilde{\delta})\right], \tag{5.1}$$

$$|\phi'(\mu, x)| \le -\sqrt{p + Kr}\ln(1-\tilde{\delta}). \tag{5.2}$$

Proof.

$$\phi(\mu, x) = \eta(\mu, x(\mu)) - \eta(\mu, x) = \int_0^1 \nabla\eta(\mu, x + \tau\tilde{\Delta}x)^T \tilde{\Delta}x d\tau.$$

Since $x(\mu)$ is the optimal solution of (2.5), it satisfies the optimality conditions (4.1). Hence,

$$\begin{aligned}
\phi(\mu, x) &= \int_0^1 \int_0^\tau \tilde{\Delta}x^T \nabla^2 \eta(\mu, x + \alpha\tilde{\Delta}x)\tilde{\Delta}x d\alpha d\tau \\
&\le \int_0^1 \int_0^\tau \frac{\mu\tilde{\delta}^2}{(1-\alpha\tilde{\delta})^2} d\alpha d\tau \qquad \text{(using Proposition 5.1 (i))} \\
&= \mu \left[\frac{\tilde{\delta}}{1-\tilde{\delta}} + \ln(1-\tilde{\delta})\right]. \qquad (5.3)
\end{aligned}$$

This proves (5.1). Now, for any $\mu > 0$, by applying the chain rule and using (4.1) we have

$$\begin{aligned}
\phi'(\mu, x) &= \eta'(\mu, x(\mu)) - \eta'(\mu, x) + \nabla\eta(\mu, x(\mu))^T x'(\mu) \\
&= \eta'(\mu, x(\mu)) - \eta'(\mu, x). \qquad (5.4)
\end{aligned}$$

From (5.4), applying the mean-value theorem, we obtain

$$\begin{aligned}
|\phi'(\mu, x)| &= \left| \int_0^1 \{\nabla\eta(\mu, x + \tau\tilde{\Delta}x)^T\}' \tilde{\Delta}x \, d\tau \right| \\
&\le \int_0^1 \left[-\tilde{\Delta}x^T \nabla^2 \eta(\mu, x + \tau\tilde{\Delta}x)\tilde{\Delta}x\right]^{1/2} \\
&\quad \left[-\{\nabla\eta(\mu, x + \tau\tilde{\Delta}x)^T\}'[\nabla^2\eta(\mu, x + \tau\tilde{\Delta}x)]^{-1}\{\nabla\eta(\mu, x + \tau\tilde{\Delta}x)^T\}'\right]^{1/2} d\tau. \qquad (5.5)
\end{aligned}$$

From (5.5), and using (3.17) from the proof of Lemma 3.2 and Proposition 5.1(i), we get

$$|\phi'(\mu,x)| \le \int_0^1 \frac{\sqrt{-\tilde{\Delta}x^T\nabla^2\eta(\mu,x)\tilde{\Delta}x}}{1-\tilde{\delta}+\tau\tilde{\delta}}\sqrt{\frac{p+Kr}{\mu}}\,d\tau$$
$$\le \int_0^1 \frac{\sqrt{\mu}\tilde{\delta}}{1-\tilde{\delta}+\tau\tilde{\delta}}\sqrt{\frac{p+Kr}{\mu}}\,d\tau = -\sqrt{p+Kr}\ln(1-\tilde{\delta}). \qquad \square$$

LEMMA 5.4. *Let $\mu > 0$ and $x \in \mathcal{F}_0$ be such that $\tilde{\delta} < 1$, where $\tilde{\delta}$ is defined in Lemma 5.3. Let $\mu^+ = \gamma\mu$ with $\gamma \in (0,1)$. Then,*

$$\eta(\mu^+, x(\mu^+)) - \eta(\mu^+, x) \le O(p+Kr)\mu^+.$$

Proof. By differentiating (5.4) with respect to μ, we obtain

$$\phi''(\mu,x) = \eta''(\mu,x(\mu)) + \nabla\eta'(\mu,x(\mu))^T x'(\mu) - \eta''(\mu,x). \tag{5.6}$$

Now we will bound the two terms on the right-hand side of (5.6) separately. From the definition of $\eta(\mu,x)$ in (2.5) we see that for $\mu > 0$ and $x \in \mathcal{F}_0$, $\eta''(\mu,x) = \sum_{i=1}^K \rho^{i\prime\prime}(\mu,x)$. Differentiating $\rho^i(\mu,x)$ and using (3.15), we obtain

$$\begin{aligned}\rho^{i\prime}(\mu,x) &= d^{i^T}y^{i\prime} + \ln\det S^i + \mu s^{i^{-T}}s^{i\prime}\\ &= \ln\det S^i + (-d^i + W^{i^T}\lambda^i)^T R^{i^{-1}} W^{i^T} s^{i^{-1}}\\ &= \ln\det S^i. \end{aligned} \tag{5.7}$$

Differentiating (5.7) once more and using (3.15) for $\mu > 0$ and $x \in \mathcal{F}_0$, we get

$$\rho^{i\prime\prime}(\mu,x) = s^{i^{-T}}s^{i\prime} = s^{i^{-T}}W^i R^{i^{-1}} W^{i^T} s^{i^{-1}} = s^{i^{-T}}Q^{i^{-1}}P^i Q^{i^{-1}} s^{i^{-1}}.$$

Since P^i in (3.5) is an orthogonal projection matrix $\rho^{i\prime\prime}(\mu,x) \ge 0$, hence $\eta(\mu,x)$ is a convex function in μ. We also have

$$\rho^{i\prime\prime}(\mu,x(\mu)) \le s^{i^{-T}}Q^{i^{-2}}s^{i^{-1}} = s^{i^{-T}}\lambda^{i^{-1}} = \frac{r}{\mu}$$

and thus

$$\eta''(\mu,x(\mu)) \le \frac{Kr}{\mu}. \tag{5.8}$$

Differentiating the optimality condition of the first stage problem (2.5), we observe

$$x(\mu)' = -[\nabla^2\eta(\mu,x(\mu))]^{-1}\nabla\eta'(\mu,x(\mu)). \tag{5.9}$$

Hence, we have

$$\begin{aligned}\nabla\eta'(\mu,x(\mu))^T x'(\mu) &= -\nabla\eta'(\mu,x(\mu))^T[\nabla^2\eta(\mu,x(\mu))]^{-1}\nabla\eta'(\mu,x(\mu))\\ &\le \mu^{-1}(p+Kr).\end{aligned} \tag{5.10}$$

In the last inequality we used (3.17), which is valid for any $\mu > 0$ and $x \in \mathcal{F}_0$. Combining (5.8), (5.10), and using $\eta''(\mu,x) > 0$, we have

$$\phi''(\mu,x) \le \mu^{-1}(p+2Kr). \tag{5.11}$$

Now in view of Lemma 5.3 and (5.11), we have

$$\begin{aligned}\phi(\mu^+,x) &= \phi(\mu,x)+\phi'(\mu,x)(\mu^+-\mu)+\int_\mu^{\mu^+}\int_\mu^\tau \phi''(\nu,x)\ d\nu\ d\tau\\ &\le \mu\left[\frac{\tilde\delta}{1-\tilde\delta}+\ln(1-\tilde\delta)\right]-\sqrt{p+Kr}\ln(1-\tilde\delta)(\mu-\mu^+)\\ &\quad +(p+2Kr)\int_\mu^{\mu^+}\int_\mu^\tau \nu^{-1}\ d\nu\ d\tau\\ &\le \mu\left[\frac{\tilde\delta}{1-\tilde\delta}+\ln(1-\tilde\delta)\right]-\sqrt{p+Kr}\ln(1-\tilde\delta)(\mu-\mu^+)\\ &\quad +(p+2Kr)\ln\gamma^{-1}\ (\mu-\mu^+).\end{aligned}\tag{5.12}$$

Since γ and $\tilde\delta$ are absolute constants, and given the fact that $\eta(\mu,x)$ is a strictly convex function in μ (implying $\eta''(\mu,x)>0$), we have a proof of this lemma. ∎

Note that Lemmas 5.3 and 5.4 require $\tilde\delta$ to be less than one. However, we cannot evaluate $\tilde\delta$ since we do not explicitly know the points $x(\mu)$ forming the central path. Nonetheless we can evaluate δ and $\tilde\delta$ in proportion to δ, as shown in the following lemma.

LEMMA 5.5. *For any given $\mu>0$, $x\in\mathcal{F}_0$, let Δx be the Newton direction defined in (4.2) and $\tilde\Delta x := x-x(\mu)$. We denote*

$$\delta:=\delta(\mu,x)=\sqrt{-\frac{1}{\mu}\Delta x^T\nabla^2\eta(\mu,x)\Delta x}\quad\text{and}\quad \tilde\delta:=\tilde\delta(\mu,x)=\sqrt{-\frac{1}{\mu}\tilde\Delta x^T\nabla^2\eta(\mu,x)\tilde\Delta x}.$$

If $\delta\le 1/6$, then

$$\frac{2}{3}\delta\le\tilde\delta\le 2\delta.\tag{5.13}$$

Proof. Let $H:=\nabla^2\eta(\mu,x)$, $g:=\nabla\eta(\mu,x)$. We denote $\overline{g}:=g+H\tilde\Delta x$. Note that

$$\tilde\Delta x=-\Delta x+H^{-1}\overline{g}.\tag{5.14}$$

By applying the triangle inequality to (5.14), we obtain

$$\tilde\delta\le\delta+\sqrt{-\frac{1}{\mu}\overline{g}^TH^{-1}\overline{g}}.\tag{5.15}$$

It is straightforward to verify that

$$-\overline{g}H^{-1}\overline{g}=\max\{h^THh-2h^T\overline{g}\mid h\in\mathbb{R}^n\}.$$

Now in consideration of Proposition 5.1(ii), we have

$$\begin{aligned}-h^T\overline{g} &= -\int_0^1 h^T[\nabla^2\eta(\mu,x)-\nabla^2\eta(\mu,x-(1-\tau)\tilde\Delta x)]\tilde\Delta x d\tau\\ &\le \int_0^1[(1-(1-\tau)\tilde\delta)^{-2}-1]d\tau\ \sqrt{-\tilde\Delta x^TH\tilde\Delta x}\sqrt{-h^THh}\\ &= \frac{\sqrt{\mu}\tilde\delta^2}{1-\tilde\delta}\sqrt{-h^THh}.\end{aligned}$$

Hence,

$$-\overline{g}H^{-1}\overline{g} \le \max\left\{ h^T Hh + \frac{2\sqrt{\mu}\tilde{\delta}^2}{1-\tilde{\delta}}\sqrt{-h^T Hh} \mid h \in \mathbb{R}^n \right\}$$

$$= \frac{\mu\tilde{\delta}^4}{(1-\tilde{\delta})^2}. \tag{5.16}$$

Combining (5.15) and (5.16), we obtain

$$\tilde{\delta} \le \delta + \frac{\tilde{\delta}^2}{(1-\tilde{\delta})}. \tag{5.17}$$

When $\delta \le \frac{1}{6}$, the quadratic inequality (5.17) implies $\tilde{\delta} \le 2\delta$. The condition $\delta \le \frac{1}{6}$ is eventually reached, since the inner iterations of the long-step algorithm converge.

From (5.15), exchanging positions of Δx and $\tilde{\Delta} x$ and following the above steps, we obtain $\delta \le \tilde{\delta} + \frac{\tilde{\delta}^2}{(1-\delta)}$, which in turn implies $\delta \le \frac{3}{2}\tilde{\delta}$, since $\tilde{\delta} \le 2\delta \le \frac{1}{3}$. ∎

Lemma 5.1 implies that each inner iteration decreases the value of η by at least $\mu[\delta - \ln(1+\delta)]$. Therefore, in view of Lemmas 5.1 and 5.4 after reducing μ by a factor $\gamma \in (0,1)$, at most $O(p + Kr)$ Newton iterations are needed for recentering. In the long-step version of our algorithm we need to update the barrier parameter μ no more than $O(\ln \mu^0/\epsilon)$ times.

Theorem 4.2 follows from Lemma 5.1(ii), Lemma 5.4, and Lemma 5.5.

6. Concluding remarks. We have described and analyzed short- and long-step interior point decomposition algorithms that follow the primal central trajectory of the first stage problem. At each iteration, these algorithms generate gradient and Hessian information for the first stage problem using optimal dual solutions of the second stage barrier problems and then update the primal first stage solution taking a step along the Newton direction. Although this framework is attractive from the decomposition point of view, it has several limitations that need further work to develop practical implementations. These include (i) generating a good starting point, (ii) development of a practical first stage step length selection procedure, (iii) a practical strategy for reducing μ in our context, (iv) adaptive addition of scenarios, (v) computation of approximate solutions of the second stage problems, and (vi) a proper choice of ϵ to terminate the algorithm. These issues are addressed in a companion computational paper [7].

Acknowledgement. We would like to thank two anonymous referees, whose careful reading of the first draft of this paper resulted in several improvements and corrections.

A COPOSITIVE PROGRAMMING APPROACH TO GRAPH PARTITIONING*

JANEZ POVH† AND FRANZ RENDL‡

Abstract. We consider 3-partitioning the vertices of a graph into sets S_1, S_2, and S_3 of specified cardinalities, such that the total weight of all edges joining S_1 and S_2 is minimized. This problem is closely related to several NP-hard problems like determining the bandwidth or finding a vertex separator in a graph. We show that this problem can be formulated as a linear program over the cone of completely positive matrices, leading in a natural way to semidefinite relaxations of the problem. We show in particular that the spectral relaxation introduced by Helmberg et al. (1995) can equivalently be formulated as a semidefinite program. Finally we propose a tightened version of this semidefinite program and show on some small instances that this new bound is a significant improvement over the spectral bound.

Key words. semidefinite programming, copositive programming, graph partitioning problem, bandwidth problem, vertex separator problem

1. Introduction.

We consider the following partition problem on graphs, and we denote it as the MIN-CUT problem (MCP). Let $G = (V, E)$ be an undirected graph on n vertices, given by its (weighted) adjacency matrix $A \geq 0$, so $a_{ij} > 0$ implies the edge $(ij) \in E(G)$ with weight a_{ij}. For given integers m_1, m_2, and m_3 summing to n, we are interested in the following NP-complete problem: find subsets S_1, S_2, and S_3 of $V(G)$ with cardinalities m_1, m_2, and m_3, respectively, such that the total weight of edges between S_1 and S_2 is minimal. More formally, let (S_1, S_2, S_3) be a partition of V with $|S_i| = m_i$ for $i = 1, 2, 3$. The total weight of edges between sets S_1 and S_2 will be denoted as $\mathrm{cut}(S_1, S_2)$. Hence

$$\mathrm{cut}(S_1, S_2) = \sum_{i \in S_1,\, j \in S_2} a_{ij}.$$

We define the MCP as the following optimization problem:

$$\text{(MCP)} \qquad \begin{array}{rl} \min & \mathrm{cut}(S_1, S_2) \\ \text{such that} & (S_1, S_2, S_3) \text{ partitions } V(G) \\ & \text{and } |S_i| = m_i,\ i = 1, 2, 3. \end{array}$$

The optimal value of this problem will be denoted as OPT_{MC}.

REMARK 1. *If $m_1 = 0$ or $m_2 = 0$, then the MCP is trivial: $OPT_{MC} = 0$. Therefore, we assume from now on that $1 \leq m_1 \leq m_2$. If $m_3 = 0$, $m_1 = \lfloor \frac{n}{2} \rfloor$, and $m_2 = \lceil \frac{n}{2} \rceil$, we get the NP-complete bisection problem as a special case (see [7]).*

The MCP by itself may seem like an artificial optimization problem. It can however serve as a powerful tool to solve some fundamental graph optimization problems. It is connected to the (balanced) vertex separator problem, where the objective is to find a minimal subset of $V(G)$, whose removal disconnects the graph into two subgraphs of roughly equal size. If $OPT_{MC} = 0$, then the graph G underlying A has a *vertex separator* of size m_3 and its connectivity is at most m_3 (see [10] for more details). On the other hand, if $OPT_{MC} > 0$, then the *bandwidth* of the matrix A is at least $m_3 + 1$ (see [10]). The ability to solve (or at least approximate) the MCP therefore has strong impact on these graph problems. The MCP is a special instance of more general graph partitioning problems, where one is interested in a partition of $V(G)$ into k disjoint subsets $S_1, \ldots, S_k$ with cardinalities $m_1 \leq m_2 \leq \cdots \leq m_k$, $\sum_i m_i = |V(G)|$, such that the total weight of edges between some subsets is minimized. A survey on the graph partitioning problem and related problems is given in [13]. Graph partitioning, bandwidth minimization, and vertex separator problems appear in a wide range of applications, from numerical linear algebra to floor planning and analysis of bottlenecks in communication networks. In parallel computing, partitioning the set of tasks among processors in order to minimize the communication between processors is another instance of a graph partitioning problem. A comprehensive survey with results in this area up to 1995 is contained in [1]. Formulating the partitions using vertex variables leads to a quadratic cost function with linear and quadratic constraints in binary variables; see (1)–(5) below. Maintaining the orthogonality condition (2) leads to spectral relaxations based on the Hoffman–Wielandt inequality; see [10, 17]. In [10, 17], these relaxations are investigated for the MCP. The quality of this approach has also been studied in [8]. The spectral relaxation of the MCP from [10] is attractive because of the closed form optimal solution; see (15) in section 3 below. The drawback of this model however is that further refinements, like adding sign constraints, make it intractable. It is the purpose of the present paper to overcome these difficulties, and extend and strengthen the spectral approach. Here are our main contributions.

(i) We first formulate the MCP as a linear program over the cone of completely positive matrices; see section 2. This does not make the problem tractable, since linear optimization over this cone is NP-hard [14], but suggests a new family of tractable relaxations, which we get by approximating the copositive constraint with a tractable one, for example, by using the hierarchy of cones, suggested by Parrilo [15], which approximates the cone of completely positive matrices arbitrarily close.

(ii) The conic formulation of the MCP leads to various semidefinite programming (SDP) relaxations of increasing complexity and strength. In section 3 we show that the spectral model from [10] corresponds to a specific semidefinite program, obtained by approximating the cone of completely positive matrices by the cone of positive semidefinite matrices. The proof of this result is rather involved, and we break it down into several smaller steps. It is given in section 4. As in [10] we provide a closed form solution of this semidefinite program (subsection 4.3).

(iii) Finally, we investigate further tightenings of the SDP relaxation in section 5. This opens the way to powerful new approximations of the bandwidth and vertex separator problems. We provide some preliminary computational results which clearly indicate the potential of the new relaxations.

We point out that similar results have been shown recently for other combinatorial optimization problems. De Klerk and Pasechnik [11] have shown that computing the stability number of a graph is equivalent to solving a copositive program. Anstreicher and Wolkowicz [2] have shown that the spectral relaxation of the quadratic assignment

problem can equivalently be formulated as a semidefinite program. SDP also turned out to be a useful tool to get tractable relaxations for the graph partitioning problem (see [19]) and the vertex separator problem (see [6]). Finally, de Sousa and Balas have recently proposed an integer linear programming approach combined with a branch and cut algorithm to get minimal balanced vertex separators; see [18].

1.1. Notation. We denote the ith standard unit vector by e_i, while the vector of all ones is $u_n \in R^n$ (or u if dimension n is obvious). The square matrix of all ones is J_n (or J) and the identity matrix is $I = (\delta_{ij})$. We set $E_{ij} = e_i e_j^T$ and its symmetrization is $B_{ij} = \frac{1}{2}(E_{ij} + E_{ji})$. In this paper we consider the following sets of matrices. The vector space of real symmetric $n \times n$ matrices is denoted by $\mathcal{S}_n = \{X \in R^{n\times n} \colon X = X^T\}$. The cone of $n \times n$ positive semidefinite matrices is $\mathcal{S}_n^+ = \{X \in \mathcal{S}_n \colon y^T X y \geq 0 \ \forall y \in R^n\}$. The cone of $n \times n$ copositive matrices is denoted by $\mathcal{C}_n = \{X \in \mathcal{S}_n \colon y^T X y \geq 0 \ \forall y \in R_+^n\}$, the cone of $n \times n$ completely positive matrices is $\mathcal{C}_n^* = \{X = \sum_{i=1}^k y_i y_i^T,\ k \geq 1,\ y_i \in R_+^n \ \forall i = 1, \ldots, k\}$, and the cone of $n \times n$ symmetric nonnegative matrices is $\mathcal{N}_n = \{X \in \mathcal{S}_n \colon x_{ij} \geq 0 \ \forall i, j\}$. We also use $X \succeq 0$ for $X \in \mathcal{S}_n^+$ and $X \geq 0$ for an elementwise nonnegative matrix. A linear program over $\mathcal{S}_n^+$ is called a semidefinite program, while a linear program over $\mathcal{C}_n$ or $\mathcal{C}_n^*$ is called a copositive program.

The sign $\otimes$ stands for Kronecker product, while the matrices V_i and W_j denote $V_i = e_i u_3^T \in R^{3\times 3}$, $W_j = e_j u_n^T \in R^{n\times n}$, $1 \leq i \leq 3$, $1 \leq j \leq n$. When we consider a matrix $X \in R^{m\times n}$ as a vector from R^{mn}, we write this vector as $\mathrm{vec}(X)$ or x. The $\langle \cdot, \cdot \rangle$ denote the standard scalar product. For $u, v \in R^n$ we have $\langle u, v \rangle = u^T v$ and for $X, Y \in R^{m\times n}$ we have $\langle X, Y \rangle = \mathrm{trace}(X^T Y)$. For matrix columns and rows we will use MATLAB notation; hence $X(i,:)$ and $X(:,i)$ will stand for the ith row and column, respectively. If $a \in R^n$, then $\mathrm{Diag}(a)$ is an $n \times n$ diagonal matrix with a on the main diagonal. When P is the name of the optimization problem then OPT_P denotes its optimal value.

2. The MCP as a conic linear program. We first use the partition formulation of the MCP to express the MCP as a quadratic program in nonnegative variables. Following [10] we represent partitions (S_1, S_2, S_3) of $V(G)$ by $n \times 3$ matrices X, where

$$x_{ij} = \begin{cases} 1 & \text{if} \quad i \in S_j, \\ 0 & \text{if} \quad i \notin S_j. \end{cases}$$

It will also be useful to identify columns of X directly; hence we denote the ith column of X by x_i. Using X, we can easily express $\mathrm{cut}(S_1, S_2)$ as

$$\mathrm{cut}(S_1, S_2) = x_1^T A x_2 = \frac{1}{2}\langle X, AXB \rangle, \tag{1}$$

where

$$B = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

In [17] it is shown that an $n \times 3$ matrix X represents a partition of $V(G)$ into subsets S_1, S_2, and S_3 of prescribed sizes $m = (m_1, m_2, m_3)^T$ if and only if X satisfies the following relations:

$$X^T X = \mathrm{Diag}(m) =: M, \tag{2}$$

$$Xu_3 = u_n, \tag{3}$$

$$X \geq 0. \tag{4}$$

Note in particular that the constraint

$$X^T u_n = m, \tag{5}$$

asking that each partition block has the right number of elements, is implied by these conditions. The set of all $n \times 3$ matrices, representing some partition of $V(G)$ into sets of cardinalities, specified by m, will be denoted by $\mathcal{F}$. Using the above characterization of such partition matrices, we have

$$\mathcal{F} = \{X \in R^{n\times 3};\ X \text{ satisfies (2)–(4)}\}.$$

The MCP can equivalently be written as a quadratic program:

$$(MC_{QP}) \qquad \min\ \tfrac{1}{2}\langle X,\, AXB\rangle \text{ such that } X \in \mathcal{F}.$$

This problem has a nonconvex objective function, defined over a finite set. Our main goal in this section is to transform this problem into an equivalent linear program over the cone of completely positive matrices. We do this by expressing the linear constraints in an appropriate way as quadratic ones. Then we linearize the resulting quadratic terms. Specifically, we consider the following equations in the variable $X \in R^{n\times 3}$:

$$(e_i^T X u_3)^2 = \left(\sum_k X_{ik}\right)^2 = 1,\ 1 \leq i \leq n, \tag{6}$$

$$(u_n^T X e_j)(e_i^T X u_3) = \left(\sum_k X_{kj}\right)\left(\sum_k X_{ik}\right) = m_j,\ 1 \leq i \leq n,\ 1 \leq j \leq 3, \tag{7}$$

$$(u_n^T X e_i)(u_n^T X e_j) = \left(\sum_k X_{ki}\right)\left(\sum_k X_{kj}\right) = m_i m_j,\ 1 \leq i \leq j \leq 3. \tag{8}$$

Equations (6) are obtained by squaring the equations from (3). The equations (7) are obtained by elementwise multiplication of (3) and (5). The last set of equations is obtained from pairwise multiplication of (5). Clearly, any $X \in \mathcal{F}$ will satisfy (6)–(8). Using the Kronecker product and the property $\mathrm{vec}(PXQ) = (Q^T \otimes P)\,\mathrm{vec}(X)$ we get

$$\langle X,\, PXQ\rangle = \mathrm{vec}(X)^T\,\mathrm{vec}(PXQ) = x^T(Q^T \otimes P)x = \langle Q^T \otimes P,\, xx^T\rangle.$$

This helps us to reformulate the constraints (6)–(8) as follows:

$$\left\{\begin{array}{rcccl} (e_i^T X u_3)^2 & = & \langle X,\, e_i e_i^T X u_3 u_3^T\rangle & = & \langle J_3 \otimes E_{ii},\, xx^T\rangle, \\ (u_n^T X e_i)(e_j^T X u_3) & = & \langle X,\, u_n e_j^T X u_3 e_i^T\rangle & = & \langle V_i \otimes W_j^T,\, xx^T\rangle, \\ (u_n^T X e_i)(u_n^T X e_j) & = & \langle X,\, u_n u_n^T X e_j e_i^T\rangle & = & \langle E_{ij} \otimes J_n,\, xx^T\rangle. \end{array}\right. \tag{9}$$

In the last term we may replace E_{ij} with B_{ij}, since xx^T is symmetric. Similarly, we can rewrite the $(i,\, j)$th component on the left-hand side of (2) as

$$e_i^T X^T X e_j \quad = \quad \langle Xe_i,\, Xe_j\rangle \quad = \quad \langle X,\, XE_{ji}\rangle \quad = \quad \langle E_{ij} \otimes I,\, xx^T\rangle.$$

Let us now introduce $Y = xx^T$. Then MC_{QP} can be equivalently formulated as follows:

$$\begin{aligned} \min \quad & \frac{1}{2}\langle B^T \otimes A, Y\rangle \\ & \langle B_{ij} \otimes I, Y\rangle = m_i\delta_{ij}, \quad 1 \le i \le j \le 3, \qquad (10)\\ \text{s. t.} \quad & \langle J_3 \otimes E_{ii}, Y\rangle = 1, \quad 1 \le i \le n, \qquad (11)\\ & \langle V_i \otimes W_j^T, Y\rangle = m_i, \quad 1 \le i \le 3,\ 1 \le j \le n, \qquad (12)\\ & \langle B_{ij} \otimes J_n, Y\rangle = m_i m_j, \quad 1 \le i \le j \le 3, \qquad (13)\\ & Y = xx^T, \quad x \in R_+^{3n}. \end{aligned}$$

To see that this optimization problem is equivalent to MC_{QP}, we note that for any X feasible for MC_{QP}, we can take $x = \mathrm{vec}(X)$ to get a feasible $Y = xx^T$ for this problem with the same objective value and vice versa. The above problem has linear objective, linear constraints, and the quadratic equation, coupling Y and x. As a final simplification, we replace the constraints $Y = xx^T$ and $x \ge 0$ by $Y \in \mathcal{C}_{3n}^*$. The new optimization problem, which is a copositive program, will be denoted by MC_{CP}:

$$(MC_{CP}) \qquad \min \frac{1}{2}\langle B^T \otimes A, Y\rangle \text{ such that } Y \in \mathcal{C}_{3n}^* \text{ satisfies (10)–(13).}$$

The following theorem explains the relation between the feasible sets of MC_{QP} and MC_{CP}.

THEOREM 1.

$$\begin{aligned} &\mathrm{CONV}\{xx^T;\ x \in R_+^{3n},\ xx^T \textit{ feasible for } (10)\text{–}(13)\} \\ &= \{Y \in \mathcal{C}_{3n}^*;\ Y \textit{ feasible for } (10)\text{–}(13)\}. \end{aligned}$$

Proof. The "$\subseteq$" inclusion is obvious. To show inclusion in the other direction, we have to prove that for any $Y \in \mathcal{C}_{3n}^*$, feasible for MC_{CP}, there exist finitely many vectors $y^1, y^2, \ldots \in R_+^{3n}$ and numbers $\lambda_k \in [0, 1]$ with $\sum_k \lambda_k = 1$ such that $y^k(y^k)^T$ are feasible for constraints (10)–(13) and $Y = \sum_k \lambda_k y^k(y^k)^T$. Let $Y \in \mathcal{C}_{3n}^*$. From the definition of the cone $\mathcal{C}_{3n}^*$ follows that there exist finitely many nonzero vectors $x^k \in R_+^{3n}$ such that $Y = \sum_k x^k(x^k)^T$. We can treat x^k as a vector representation of some matrix $X^k \in R^{n\times 3}$; therefore we will index the components of each x^k with two indices: $x^k = (x_{ij}^k)$, $i = 1, \ldots, n$ and $j = 1, 2, 3$ (components $x_{:1}^k$ are the first n components of x^k—the first "column" of x^k, etc.). Let us first fix i and j ($1 \le i \le n$, $1 \le j \le 3$). If we denote with $r_k = \sum_{s=1}^3 x_{is}^k$ the sum of the "ith row" of x^k and with $c_k = \sum_{s=1}^n x_{sj}^k$ the sum of the "jth column" of x^k, then we can rewrite the constraints (11)–(13) using (6)–(9) as

$$\textstyle\sum_k r_k^2 \;=\; 1,\ \sum_k r_k c_k \;=\; m_j,\ \sum_k c_k^2 \;=\; m_j^2.$$

The Cauchy inequality, applied to vectors $v_1 = (r_1, r_2, \ldots)$ and $v_2 = (c_1, c_2, \ldots)$, implies $r_k = c_k/m_j$, or equivalently

$$\sum_s x_{is}^k = \frac{\sum_s x_{sj}^k}{m_j}, \quad k = 1, 2, \ldots. \qquad (14)$$

Since this is true for all i and j, we can see that the numbers $\sum_s x_{sj}^k/m_j$ are equal for all j. This means that in any vector x^k the sum of any "row" is equal to the sum

of column j divided by m_j for all $j = 1, 2, 3$. Therefore we may take without loss of generality $j = 1$ and define $\alpha_k = \sum_s x^k_{s1}/m_1$. Since none of x^k is zero we have $\alpha_k > 0$ for all k, and we may define $\lambda_k = \alpha_k^2 = (\sum_s x^k_{s1})^2/m_1^2$ and $y^k = x^k/\alpha_k$. From (13) we get

$$\sum_k \lambda_k = \frac{1}{m_1^2} \sum_k \Big(\sum_s x^k_{s1} \Big)^2 = 1.$$

Equation (14) implies that $y^k(y^k)^T$ are feasible for (11)–(13) and $Y = \sum_k \lambda_k y^k (y^k)^T$. To finish the proof it remains to show that $y^k(y^k)^T$ is feasible for (10) for all k. Indeed, if there exist $i \neq j$ and k such that $\langle B_{ij} \otimes I,\, y^k(y^k)^T \rangle > 0$, then because of nonnegativity of y^k we have $\langle B_{ij} \otimes I,\, Y \rangle > 0$, but this is a contradiction to the feasibility of Y. In particular, this means that in each "row" of y^k there is only one nonzero component, which must be equal to 1 because of feasibility for (11). Hence y^k is a 0–1 vector. This implies together with (13) that $\langle E_{ii} \otimes I,\, y^k(y^k)^T \rangle = \sum_s (y^k_{si})^2 = \sum_s y^k_{si} = m_i$; hence $y^k(y^k)^T$ is feasible for (10), too. □

The feasible set of MC_{CP} is therefore a polytope, spanned by the rank 1 matrices of type xx^T, where x is a vector representation of matrix X, feasible for MC_{QP}. Since MC_{CP} is a linear program, it has a rank 1 optimal solution; hence $OPT_{CP} \geq OPT_{QP}$. The opposite direction is obvious; hence we have the following corollary.

COROLLARY 2. *Problems MC_{QP} and MC_{CP} have the same optimal value; therefore the MCP can be equivalently formulated as a linear program in completely positive matrices.*

REMARK 2. *This copositive representation again confirms the importance of copositive programming in combinatorial optimization which was revealed by de Klerk and Pasechnik* [11]*, who proved that computing the stability number of a graph is equivalent to solving a copositive program and then presented a hierarchy of positive semidefinite relaxations, which follow from this approach and are strongly connected with the ϑ-function.*

3. The spectral relaxation as a semidefinite program. Helmberg et al. have derived in [10] a lower bound for OPT_{MC} which is easy to compute. They have omitted the nonnegativity constraint (4) in MC_{QP} and added constraint (5), yielding the problem

$$OPT_{HW} \quad = \quad \min \ \tfrac{1}{2}\langle X,\, \hat{A}XB \rangle \ \text{ such that } X \text{ satisfies (2), (3), and (5).}$$

In the above formulation we introduced $\hat{A} = A + D$ with $D = \frac{s(A)}{n} I - \mathrm{Diag}(r(A))$ and $s(A) = u^T A u$, $r(A) = Au$. This is a quadratic problem defined over a nonconvex set described by linear and quadratic equations. If we replace in the models MC_{QP} and MC_{CP} matrix A with $\hat{A}$, then the optimal values of these models do not change, since matrix XBX^T in the model MC_{QP} has only zeros on the main diagonal and similarly any feasible matrix Y in model MC_{CP} has only zeros on the main diagonals of off-diagonal blocks, as follows from (10) and complete positiveness of Y. Therefore $OPT_{MC} \geq OPT_{HW}$. Helmberg et al. [10] have in fact shown that OPT_{HW} has the explicit form

$$OPT_{HW} = -\frac{1}{2}\mu_2\lambda_2 - \frac{1}{2}\mu_1\lambda_n, \tag{15}$$

where λ_2 and λ_n are second smallest and the largest Laplacian eigenvalues of the graph G (i.e., the eigenvalues of matrix $L = \mathrm{Diag}(r(A)) - A = \frac{s(A)}{n} I - \hat{A}$) and $\mu_1 \geq \mu_2$ are defined as

$$\mu_{1,2} = \frac{1}{n}\Big(-m_1 m_2 \pm \sqrt{m_1 m_2 (n-m_1)(n-m_2)}\Big). \tag{16}$$

The key tool to get this result was the Hoffman–Wielandt inequality [9] combined with a projection technique for partitioning the nodes of a graph from [17]. It is an attractive feature of this bound that the closed form solution (15) is quite easy to compute, as it involves only the computation of the extreme Laplacian eigenvalues. On the other hand, the relaxation OPT_{HW}, as described above, does not permit the inclusion of further constraints, like, for instance, $X \geq 0$, without losing tractability. One of the main motivations for the current research was in fact the search for a new equivalent formulation of OPT_{HW} which is suitable for further tractable refinements. We now propose such a refinement. As already mentioned, we do not change the optimal value by replacing A with $\hat{A}$ in the models MC_{QP} and MC_{CP}. Let us consider the model, obtained from MC_{CP} by this replacement and relaxing the constraint $Y \in \mathcal{C}^*_{3n}$ to $Y \in \mathcal{S}^+_{3n}$. We will denote it by MC_{SDP} and its optimal value by OPT_{SDP}. Hence

$$\begin{array}{lrll} & OPT_{SDP} & = & \min \quad \frac{1}{2}\langle B^T \otimes \hat{A},\, Y\rangle \\ (MC_{SDP}) & & & \text{s. t.} \quad Y \in \mathcal{S}^+_{3n} \\ & & & \qquad\quad Y \text{ satisfies (10)–(13).} \end{array}$$

In the next section we will show that the value OPT_{SDP} is equal to OPT_{HW}. First we have the easy part.

LEMMA 3.

$$OPT_{HW} \geq OPT_{SDP}.$$

Proof. If X satisfies (2), (3), and (5), then X satisfies constraints (2) and (6)–(8). The matrix $Y = xx^T$ satisfies (10)–(13) and is in $\mathcal{S}^+_{3n}$ hence is feasible for MC_{SDP}. Since $\frac{1}{2}\langle X,\, \hat{A}XB\rangle = \frac{1}{2}\langle B^T \otimes \hat{A},\, Y\rangle$, the lemma follows. ∎

The main result of this section is the following theorem.

THEOREM 4.

$$OPT_{HW} = OPT_{SDP}.$$

From Lemma 3 it follows that we need to prove that $OPT_{HW} \leq OPT_{SDP}$. Our proof of this result is rather involved and consists of two major steps. In the first step we reformulate the semidefinite program MC_{SDP} in a new coordinate system, obtained by diagonalizing the cost matrix $B^T \otimes \hat{A}$. This is the content of subsection 4.1, which ends with the main result of the first step, i.e., with the semidefinite program (18). The second part of the proof is more subtle. We extract a subproblem of (18) by leaving out some constraints and projecting the feasible set to a proper hyperplane. In subsection 4.2 we show that this subproblem, denoted by MC_{SDPa}, in fact captures the essential part of MC_{SDP}, and its optimal solution OPT_{SDPa} satisfies $OPT_{SDP} \geq OPT_{SDPa} \geq OPT_{HW}$. This closes the chain of inequalities and the proof is finished.

4. Proof of Theorem 4.

4.1. Diagonalization of the cost matrix. Let $\frac{1}{2}\hat{A} = PSP^T$, $B = QTQ^T$, where P and Q are orthonormal matrices whose columns are eigenvectors of $\frac{1}{2}\hat{A}$ and B, respectively, and S, T are diagonal matrices with eigenvalues on the diagonal. We

take the factorizations where the eigenvalues are in nondecreasing order; hence we have

$$Q = \frac{1}{2}\begin{bmatrix} -\sqrt{2} & 0 & \sqrt{2} \\ \sqrt{2} & 0 & \sqrt{2} \\ 0 & 2 & 0 \end{bmatrix}, \; T = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

If we denote with $\ell_i = s_{ii}$, then from $\hat{A} = \frac{s(A)}{n} I - L$ (see the beginning of the previous section) follows $\ell_i = \frac{s(A)}{2n} - \frac{\lambda_{n-i+1}(L)}{2}$, in particular $\ell_1 = \frac{s(A)}{2n} - \frac{\lambda_n(L)}{2}$ and $\ell_n = \frac{s(A)}{2n}$. We choose P in such a way that the last column of P is equal to $u/\sqrt{n}$. This can be done since u is an eigenvector of $\hat{A}$ corresponding to the largest eigenvalue of $\hat{A}$. In the following lemmas we investigate what happens if we substitute in the model MC_{SDP} the matrix variable Y with matrix variable Z, which are related by

$$Y = (Q \otimes P)\, Z\, (Q \otimes P)^T. \tag{17}$$

This substitution simplifies the objective function, which becomes $\langle T \otimes S,\, Z\rangle$; hence only diagonal elements of Z will determine the objective value. If $Y \in \mathcal{S}^+_{3n}$, then the new matrix variable Z is from $\mathcal{S}^+_{3n}$, too. We will often for the sake of simplicity write matrix Z as a block matrix: $Z = [Z^{ij}]_{1\le i,j\le 3}$, where $Z^{ij} \in R^{n\times n}$. This actually means that

$$Z = \sum_{1\le i,j\le 3} E_{ij} \otimes Z^{ij} = \begin{bmatrix} Z^{11} & Z^{12} & Z^{13} \\ Z^{21} & Z^{22} & Z^{23} \\ Z^{31} & Z^{32} & Z^{33} \end{bmatrix}.$$

We will denote with Z^{ij}_{kl} the (k,l)th component of matrix Z^{ij}.

LEMMA 5. *Let $Y, Z \in \mathcal{S}_{3n}$ satisfy* (17). *The matrix Y satisfies constraint* (13) *if and only if the matrix Z satisfies*

$$Z^{ij}_{nn} = f_{ij},\; 1 \le i \le j \le 3, \tag{13a}$$

where matrix $F = (f_{ij}) \in \mathcal{S}^+_3$ is as follows:

$$F = \frac{1}{2n}\begin{bmatrix} m_2 - m_1 \\ \sqrt{2}m_3 \\ m_2 + m_1 \end{bmatrix} \cdot \begin{bmatrix} m_2 - m_1 \\ \sqrt{2}m_3 \\ m_2 + m_1 \end{bmatrix}^T.$$

Proof. Here we use the fact that $P(:,n) = u/\sqrt{n}$. Constraint (13) becomes $\langle (Q^T B_{ij} Q) \otimes (P^T J_n P),\, Z\rangle = m_i m_j$. Since all columns of P are orthogonal, we have $P^T J_n P = P^T W_n^T = nE_{nn}$. We also get matrices $\tilde{B}_{ij} := Q^T B_{ij} Q$:

$$\begin{aligned}
\tilde{B}_{11} &= \tfrac{1}{2}\begin{bmatrix} 1 & 0 & -1 \\ 0 & 0 & 0 \\ -1 & 0 & 1 \end{bmatrix}, & \tilde{B}_{12} &= \tfrac{1}{2}\begin{bmatrix} -1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \\
\tilde{B}_{13} &= \tfrac{\sqrt{2}}{4}\begin{bmatrix} 0 & -1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}, & \tilde{B}_{22} &= \tfrac{1}{2}\begin{bmatrix} 1 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 1 \end{bmatrix}, \\
\tilde{B}_{23} &= \tfrac{\sqrt{2}}{4}\begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}, & \tilde{B}_{33} &= \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}.
\end{aligned}$$

Therefore we get $\langle B_{11} \otimes J_n,\, Y\rangle = n\langle \tilde{B}_{11} \otimes E_{nn},\, Z\rangle = \frac{n}{2}(Z^{11}_{nn} - 2Z^{13}_{nn} + Z^{33}_{nn})$. Equation $\langle B_{11} \otimes J_n,\, Y\rangle = m_1^2$ is thus equivalent to

$$Z^{11}_{nn} - 2Z^{13}_{nn} + Z^{33}_{nn} = \frac{2m_1^2}{n}.$$

Similarly, we rewrite the other equations from constraint (13) into

$$\begin{aligned} -Z^{11}_{nn} + Z^{33}_{nn} &= \tfrac{2m_1m_2}{n}, & -Z^{12}_{nn} + Z^{23}_{nn} &= \tfrac{\sqrt{2}m_1m_3}{n},\\ Z^{11}_{nn} + 2Z^{13}_{nn} + Z^{33}_{nn} &= \tfrac{2m_2^2}{n}, & Z^{12}_{nn} + Z^{23}_{nn} &= \tfrac{\sqrt{2}m_2m_3}{n},\\ Z^{22}_{nn} &= \tfrac{m_3^2}{n}. \end{aligned}$$

The solution of this system of six linear equations in six variables is $Z^{ij}_{nn} = f_{ij}$. ∎

LEMMA 6. *Let $Y, Z \in \mathcal{S}_{3n}$ satisfy* (17). *The matrix Y satisfies constraint* (10) *if and only if the matrix Z satisfies constraint*

$$\operatorname{trace}(Z^{ij}) = h_{ij},\ 1 \le i \le j \le 3, \tag{10a}$$

where matrix $H = (h_{ij}) \in \mathcal{S}_3$ is defined as

$$H = \frac{1}{2}\begin{bmatrix} m_1 + m_2 & 0 & m_2 - m_1 \\ 0 & 2m_3 & 0 \\ m_2 - m_1 & 0 & m_1 + m_2 \end{bmatrix}.$$

Proof. From $P^T I\, P = I$ follows $\langle B_{ij} \otimes I,\, Y\rangle = \langle \tilde{B}_{ij} \otimes I,\, Z\rangle$. If $i = j = 1$, then $\langle \tilde{B}_{11} \otimes I,\, Z\rangle = (\operatorname{trace}(Z^{11}) - 2\operatorname{trace}(Z^{13}) + \operatorname{trace}(Z^{33}))/2$, so the first equation from (10) could be rewritten as

$$\frac{1}{2}\Big(\operatorname{trace}(Z^{11}) - 2\operatorname{trace}(Z^{13}) + \operatorname{trace}(Z^{33})\Big) = m_1.$$

Similarly, we get the other five linear equations in six variables $\operatorname{trace}(Z^{ij})$. The unique solution is given by $\operatorname{trace}(Z^{ij}) = h_{ij}$, $1 \le i \le j \le 3$. ∎

LEMMA 7. *Let $Y, Z \in \mathcal{S}_{3n}$ satisfy* (17).

(a) *The matrix Y satisfies constraint* (11) *if and only if the matrix Z satisfies the constraint*

$$\big\langle U \otimes P(i,:)^T P(i,:),\, Z\big\rangle = 1,\ 1 \le i \le n, \tag{11a}$$

where

$$U = Q^T J_3 Q = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & \sqrt{2} \\ 0 & \sqrt{2} & 2 \end{bmatrix}.$$

(b) *The matrix Y satisfies constraint* (12) *if and only if the matrix Z satisfies the constraint*

$$\langle \tilde{V}_i \otimes (e_n \cdot P(j,:)),\, Z\rangle = \frac{m_i}{\sqrt{n}},\ 1 \le i \le 3,\ 1 \le j \le n, \tag{12a}$$

where $\tilde{V}_i = Q^T V_i Q$.

Proof. (a) This statement follows immediately from $P^T E_{ii} P = P(i,:)^T P(i,:)$.

(b) After the substitution the left-hand side of constraint (12) becomes $\langle (Q^T V_i Q) \otimes (P^T W_j^T P),\, Z\rangle = m_i$. A short calculation shows

$$\tilde{V}_1 \;=\; \tfrac{1}{2}\begin{bmatrix} 0 & -\sqrt{2} & -2 \\ 0 & 0 & 0 \\ 0 & \sqrt{2} & 2 \end{bmatrix}, \quad \tilde{V}_2 \;=\; \tfrac{1}{2}\begin{bmatrix} 0 & \sqrt{2} & 2 \\ 0 & 0 & 0 \\ 0 & \sqrt{2} & 2 \end{bmatrix}, \quad \tilde{V}_3 \;=\; \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & \sqrt{2} \\ 0 & 0 & 0 \end{bmatrix}.$$

The term $P^T W_j^T P$ simplifies because of the choice of the last column of P into $\sqrt{n} E_{nj} P = \sqrt{n} e_n e_j^T P = \sqrt{n} e_n P(j,:)$. ∎

By introducing the set

$$\mathcal{G} = \{Z \in \mathcal{S}^+_{3n},\ Z \text{ satisfies constraints (10a), (11a), (12a), and (13a)}\},$$

we can see that the problem MC_{SDP} is equivalent to the problem

$$\min \langle T \otimes S,\, Z\rangle \ \text{ such that } Z \in \mathcal{G}, \tag{18}$$

since for any feasible solution Y for MC_{SDP} we can find a solution $Z \in \mathcal{G}$ via (17) with the same value of the objective value and vice versa. It should be noted that the cost function in (18) simplifies to $\langle T \otimes S,\, Z\rangle = \sum_{i=1}^n \ell_i (Z_{ii}^{33} - Z_{ii}^{11})$.

4.2. A block-diagonal subproblem. The semidefinite program (18) is still quite complicated. Since Lemmas 5–7 show that feasibility for constraints (10a)–(13a) is mostly determined with the diagonal entries of blocks Z^{ij}, we are going to study the following semidefinite program, which we obtain by keeping in the program (18) only constraints (10a) and (13a) and ignoring all nondiagonal components in any block Z^{ij}. We also omit blocks Z^{2i} and Z^{i2}, $i = 1, 2, 3$, since they do not contribute to the cost function.

$$(MC_{SDPa}) \qquad \begin{array}{lrcl} \min & \sum_{i=1}^{n-1} \ell_i (r_i - p_i) + \ell_n (f_{33} - f_{11}) & & \\ \text{s. t.} & \sum_{i=1}^{n-1} p_i & = & h_{11} - f_{11} := b_1, \\ & \sum_{i=1}^{n-1} r_i & = & h_{33} - f_{33} := b_2, \\ & \sum_{i=1}^{n-1} q_i & = & h_{13} - f_{13} := b_3, \\ & U_i & = & \begin{bmatrix} p_i & q_i \\ q_i & r_i \end{bmatrix} \succeq 0. \end{array}$$

The constants b_i are

$$b_1 \;=\; \frac{4m_1m_2 + m_1m_3 + m_2m_3}{2n}, \quad b_2 \;=\; \frac{(m_1+m_2)m_3}{2n}, \quad \text{and} \quad b_3 \;=\; \frac{(m_2-m_1)m_3}{2n}.$$

In the following lemma we compare the optimal values of MC_{SDP} and MC_{SDPa}.

LEMMA 8.

$$OPT_{SDP} \geq OPT_{SDPa}.$$

Proof. We will show that any feasible solution for (18) implies a feasible solution for MC_{SDPa}. Let $Z = [Z^{ij}]$ be a feasible solution for (18) and let us define $p_i = Z_{ii}^{11}$, $r_i = Z_{ii}^{33}$, and $q_i = Z_{ii}^{13}$ for $1 \leq i \leq n-1$. From Lemmas 5 and 6 follows $\sum_{i=1}^{n-1} p_i = \text{trace}(Z^{11}) - Z_{nn}^{11} = b_1$, and hence p_i are feasible for the first equation in MC_{SDPa}. Similarly we can show that the other two constraints are satisfied and

that the matrices $U_i = \left[\begin{smallmatrix} p_i & q_i \\ q_i & r_i \end{smallmatrix}\right]$ are positive semidefinite, following from $Z \succeq 0$. The objective value of the MC_{SDPa} is exactly $\sum_{i=1}^{n} \ell_i(Z_{ii}^{11} - Z_{ii}^{33}) = \langle T \otimes S, Z\rangle$; hence the lemma follows. □

Here is the dual semidefinite program for MC_{SDPa}:

$$\begin{aligned} & \max \quad b_1y_1 + b_2y_2 + 2b_3y_3 + \ell_n(f_{33} - f_{11}) \\ (DMC_{SDPa}) \qquad & \text{s. t.} \quad V_i = \begin{bmatrix} -\ell_i - y_1 & -y_3 \\ -y_3 & \ell_i - y_2 \end{bmatrix} \succeq 0, \quad 1 \le i \le n-1. \end{aligned}$$

First let us introduce the number

$$\delta = \frac{2m_1m_2 + m_1m_3 + m_2m_3}{2\sqrt{m_1m_2(n-m_1)(n-m_2)}} = \frac{m_1(n-m_1) + m_2(n-m_2)}{2\sqrt{m_1m_2(n-m_1)(n-m_2)}}.$$

This number is well defined in view of Remark 1. Note also that δ is of the form

$$\frac{1}{2}\left(u + \frac{1}{u}\right) \text{ with } u = \sqrt{\frac{m_1(n-m_1)}{m_2(n-m_2)}} > 0.$$

Therefore $\delta \ge 1$. The next lemma allows us to finish the proof of Theorem 4. We need the following simple observation for its proof.

PROPOSITION 9. *If $a + b = c + d$ and $|a - b| \le |c - d|$, then $ab \ge cd$.*

Proof. We can write $(a-b)^2 = (a+b)^2 - 4ab$ and $(c-d)^2 = (c+d)^2 - 4cd$. Using the assumptions of the proposition we get $(a+b)^2 - 4ab \ge (c+d)^2 - 4cd$ and the result follows. □

LEMMA 10. *The numbers*

$$\begin{aligned} y_1 &= -\frac{\ell_1 + \ell_{n-1}}{2} - \frac{\delta}{2}(\ell_{n-1} - \ell_1), \\ y_2 &= \frac{\ell_1 + \ell_{n-1}}{2} - \frac{\delta}{2}(\ell_{n-1} - \ell_1), \\ y_3 &= \sqrt{(-\ell_1 - y_1)(\ell_1 - y_2)} \end{aligned}$$

form an optimal solution for the dual problem DMC_{SDPa} with objective value equal to OPT_{HW}.

Proof. First note that $\delta \ge 1$ implies $y_1 \le -\ell_{n-1}$ and $y_2 \le \ell_1$. This shows that in the definition of y_3 we take the square root of a nonnegative number; hence y_3 is well defined. To see that $V_i \succeq 0$, we first note that the numbers ℓ_i are in nondecreasing order; therefore $-\ell_i - y_1 \ge 0$, $\ell_i - y_2 \ge 0$. Using that $y_2 = y_1 + \ell_1 + \ell_{n-1}$ we get $y_3^2 = (-\ell_1 - y_1)(\ell_1 - y_2) = (-\ell_{n-1} - y_1)(\ell_{n-1} - y_2)$ and $(-\ell_i - y_1) + (\ell_i - y_2) = -y_1 - y_2 = \delta(\ell_{n-1} - \ell_1)$. Since $|(-\ell_i - y_1) - (\ell_i - y_2)| = |\ell_1 + \ell_{n-1} - 2\ell_i| \le |\ell_{n-1} - \ell_1| = |(-\ell_1 - y_1) - (\ell_1 - y_2)|$, we get by Proposition 9

$$(-\ell_i - y_1)(\ell_i - y_2) \ge (-\ell_1 - y_1)(\ell_1 - y_2) = (-\ell_{n-1} - y_1)(\ell_{n-1} - y_2) = y_3^2;$$

hence $\det(V_i) \ge 0$ and positive semidefiniteness of V_i follows. Second we will show the optimality of (y_1, y_2, y_3). It is sufficient to prove that

$$b_1y_1 + b_2y_2 + 2b_3y_3 + \ell_n(f_{33} - f_{11}) = -\frac{1}{2}\mu_2\lambda_2 - \frac{1}{2}\mu_1\lambda_n = OPT_{HW},$$

since from Lemmas 3 and 8 and the weak duality property we know that the optimal value of DMC_{SDPa} is at most $OPT_{SDP} \le OPT_{HW}$. Using the fact that

$\ell_1 = \frac{s(A)}{2n} - \frac{\lambda_n}{2}$, $\ell_{n-1} = \frac{s(A)}{2n} - \frac{\lambda_2}{2}$, and $\ell_n(f_{33} - f_{11}) = \frac{s(A)m_1m_2}{n^2}$, it remains to show that

$$b_1y_1 + b_2y_2 + 2b_3y_3 = \mu_2\ell_{n-1} + \mu_1\ell_1.$$

One can derive that

$$y_3 = \sqrt{(-\ell_1 - y_1)(\ell_1 - y_2)} = \frac{\ell_{n-1}-\ell_1}{2}\sqrt{\delta^2 - 1} = \frac{m_3(m_2-m_1)(\ell_{n-1}-\ell_1)}{4\sqrt{m_1m_2(n-m_1)(n-m_2)}}$$

and show

$$\begin{aligned} b_1y_1 + b_2y_2 + 2b_3y_3 &= \frac{\ell_1}{2}(\delta(b_1+b_2) - b_1 + b_2 - 2b_3\frac{m_3(m_2-m_1)}{2\sqrt{m_1m_2(n-m_1)(n-m_2)}}) \\ &\quad - \frac{\ell_{n-1}}{2}(\delta(b_1+b_2) + b_1 - b_2 - 2b_3\frac{m_3(m_2-m_1)}{2\sqrt{m_1m_2(n-m_1)(n-m_2)}}) \\ &= \mu_1\ell_1 + \mu_2\ell_{n-1}. \end{aligned}$$

Checking the last equality involves tedious but straightforward algebraic manipulation. □

Proof of Theorem 4. From Lemmas 3, 8, and 10 and the weak duality property for semidefinite program MC_{SDPa} follows

$$OPT_{HW} \geq OPT_{SDP} \geq OPT_{SDPa} \geq OPT_{DSDPa} = OPT_{HW};$$

hence equality holds throughout. □

4.3. Reconstructing the optimal solution of the problem MC_{SDP}. Once we know the optimal solution of the dual problem DMC_{SDPa}, we can reconstruct the optimal solution of MC_{SDP} by tracing the procedure from the previous subsection and using the structural information about the feasible set $\mathcal{G}$. We will first compute the optimal solution of MC_{SDPa} from the optimal solution of MC_{DSDPa} and then will extend it to the optimal solution of MC_{SDP}. Let $U^* = \mathrm{diag}(U_1, \ldots, U_{n-1})$ be the optimal solution of MC_{SDPa} and (y_1, y_2, y_3) the optimal solution for DMC_{SDPa} from Lemma 8. We define matrix $V^* = \mathrm{diag}(V_1, \ldots, V_{n-1})$ with

$$V_i = \begin{bmatrix} -\ell_i - y_1 & -y_3 \\ -y_3 & \ell_i - y_2 \end{bmatrix}, \quad 1 \leq i \leq n-1. \tag{19}$$

From the feasibility of (y_1, y_2, y_3) it follows that $V_i \succeq 0$ and any matrix V_i is in fact the dual matrix to U_i for $1 \leq i \leq n-1$. Since V^* is actually optimal for DMC_{SDPa}, the strong duality property implies $\langle U_i, V_i \rangle = 0$ for $1 \leq i \leq n-1$. Suppose first that $\ell_1 < \ell_{n-1}$ and V_1 and V_{n-1} are the only singular matrices in V^* (hence V_1 and V_{n-1} are rank one matrices). Let

$$U_1 = \begin{bmatrix} p_1 & q_1 \\ q_1 & r_1 \end{bmatrix}, \; U_{n-1} = \begin{bmatrix} p_2 & q_2 \\ q_2 & r_2 \end{bmatrix}, \; V_1 = \begin{bmatrix} v_1 & z_1 \\ z_1 & w_1 \end{bmatrix}, \text{ and } V_{n-1} = \begin{bmatrix} v_2 & z_2 \\ z_2 & w_2 \end{bmatrix}.$$

Using (19) we see that $v_1 = -\ell_1 - y_1$, $z_1 = -y_3$, $w_1 = \ell_1 - y_2$, etc. From the strong duality property it follows that $U_2, U_3, \ldots, U_{n-2}$ are zero matrices and U_1, U_{n-1} are singular. Since U_1, U_{n-1}, V_1, and V_{n-1} are singular, the following must be true:

$$\begin{aligned} z_1^2 &= v_1w_1, \quad z_2^2 = v_2w_2, \\ q_1^2 &= p_1r_1, \quad q_2^2 = p_2r_2. \end{aligned}$$

Together with the strong duality property $\langle U_1, V_1\rangle = p_1v_1 + 2q_1z_1 + r_1w_1 = 0$ this implies that

$$\frac{p_1v_1 + r_1w_1}{2} = |q_1z_1| = \sqrt{p_1v_1r_1w_1}.$$

From the arithmetic-geometric inequality it follows that $p_1v_1 = r_1w_1$ and similarly $p_2v_2 = r_2w_2$. Components of U_1 and U_{n-1} must also satisfy linear constraints from MC_{SDPa}: $p_1 + p_2 = b_1$, $r_1 + r_2 = b_2$, and $q_1 + q_2 = b_3$. All these equations uniquely determine the components of U_1 and U_{n-1} as

$$\begin{array}{cccccccccc} p_1 & = & \alpha w_1, & q_1 & = & -\alpha z_1, & r_1 & = & \alpha v_1, \\ p_2 & = & \beta w_2, & q_2 & = & -\beta z_2, & r_2 & = & \beta v_2, \end{array} \tag{20}$$

where

$$\begin{array}{rcccc} \alpha & = & \frac{b_2w_2 - b_1v_2}{v_1w_2 - v_2w_1} = \frac{-m_1m_2 + \sqrt{m_1m_2(n-m_1)(n-m_2)}}{(\ell_{n-1} - \ell_1)n} & = & \frac{\mu_1}{\ell_{n-1} - \ell_1}, \\ \beta & = & \frac{b_1v_1 - b_2w_1}{v_1w_2 - v_2w_1} = \frac{m_1m_2 + \sqrt{m_1m_2(n-m_1)(n-m_2)}}{(\ell_{n-1} - \ell_1)n} & = & -\frac{\mu_2}{\ell_{n-1} - \ell_1}. \end{array}$$

If we have $\ell_1 < \ell_{n-1}$ and there exists $1 < i < n-1$ such that V_i is a rank one matrix, then the matrix $U^* = \mathrm{diag}(U_1, \ldots, U_{n-1})$, where $U_2, \ldots, U_{n-2}$ are zero matrices and components of U_1 and U_{n-1} are those from (20), is still the (nonunique) optimal solution of MC_{SDPa}. The last case is that $\ell_1 = \ell_{n-1}$. In this case we cannot use U_1 and U_{n-1}, defined with (20), because α and β are not defined. We will find the optimal solution of MC_{SDPa} directly. Let us define U_1 and U_{n-1} with

$$p_1 = p_2 = \frac{b_1}{2}, \quad r_1 = r_2 = \frac{b_2}{2}, \quad q_1 = q_2 = \frac{b_3}{2}, \tag{21}$$

and let U_i be zero matrices for $2 \le i \le n-2$. The matrix $U = \mathrm{Diag}(U_1, \ldots, U_{n-1})$ is feasible for MC_{SDPa} and $\sum_{i=1}^{n-1} \ell_i(r_i - p_i) + \ell_n(f_{33} - f_{11}) = \ell_1(b_2 - b_1) + \ell_n(f_{33} - f_{11}) = -\frac{2m_1m_2\ell_1}{n} + \frac{s(A)m_1m_2}{n^2} = OPT_{HW}$; hence U is optimal for MC_{SDPa}. However, the MCP is trivial if $\ell_1 = \ell_{n-1}$, since in this case the underlying graph is the complete graph K_n. Let us introduce the matrices

$$Z_1 = \begin{bmatrix} p_1 & -\sqrt{2}q_1 & q_1 \\ -\sqrt{2}q_1 & 2r_1 & -\sqrt{2}r_1 \\ q_1 & -\sqrt{2}r_1 & r_1 \end{bmatrix}, \; Z_{n-1} = \begin{bmatrix} p_2 & -\sqrt{2}q_2 & q_2 \\ -\sqrt{2}q_2 & 2r_2 & -\sqrt{2}r_2 \\ q_2 & -\sqrt{2}r_2 & r_2 \end{bmatrix},$$

and $Z_n = F$, where $F \in \mathcal{S}_3^+$ is from Lemma 5, and p_i, r_i, and q_i are either from (20) or from (21).

PROPOSITION 11. *The matrix*

$$Z^* = Z_1 \otimes E_{11} + Z_{n-1} \otimes E_{n-1,n-1} + Z_n \otimes E_{nn} \tag{22}$$

is the optimal solution for (18) *and the matrix*

$$Y^* = (Q \otimes P)\, Z^*\, (Q \otimes P)^T$$

is the optimal solution for MC_{SDP}.

Proof. The structure of Z^* for the case $n = 3$ can be seen in Figure 1. From the construction of Z^*, Theorem 4, and Proposition 10 follows that $\langle T \otimes S, Z^*\rangle = \ell_1(r_1 - p_1) + \ell_{n-1}(r_2 - p_2) + \ell_n(f_{33} - f_{11}) = OPT_{HW} = OPT_{SDP}$; hence Z^* gives the optimal value of (18). Therefore it remains to show that Z^* is feasible for the problem (18). Positive semidefiniteness of Z^* follows from positive semidefiniteness

$$Z^* = \left[\begin{array}{ccc|ccc|ccc}
p_1 & 0 & 0 & -\sqrt{2}q_1 & 0 & 0 & q_1 & 0 & 0 \\
0 & p_2 & 0 & 0 & -\sqrt{2}q_2 & 0 & 0 & q_2 & 0 \\
0 & 0 & f_{11} & 0 & 0 & f_{12} & 0 & 0 & f_{13} \\
\hline
-\sqrt{2}q_1 & 0 & 0 & 2r_1 & 0 & 0 & -\sqrt{2}r_1 & 0 & 0 \\
0 & -\sqrt{2}q_2 & 0 & 0 & 2r_2 & 0 & 0 & -\sqrt{2}r_2 & 0 \\
0 & 0 & f_{12} & 0 & 0 & f_{22} & 0 & 0 & f_{23} \\
\hline
q_1 & 0 & 0 & -\sqrt{2}r_1 & 0 & 0 & r_1 & 0 & 0 \\
0 & q_2 & 0 & 0 & -\sqrt{2}r_2 & 0 & 0 & r_2 & 0 \\
0 & 0 & f_{13} & 0 & 0 & f_{23} & 0 & 0 & f_{33}
\end{array}\right]$$

FIG. 1. *Structure of Z^* for $n = 3$.*

of matrices U_1, U_{n-1}, and F. Feasibility for the constraints (10a) and (13a) follows immediately from the feasibility of U_1 and U_{n-1} for the problem MC_{SDPa} and the structure of Z^*.

To check the feasibility for (11a) we need to compute for all $1 \le i \le n$

$$\begin{aligned}
\left\langle U \otimes P(i,:)^T P(i,:),\, Z^* \right\rangle &= P(i,n)^2(f_{22} + 2\sqrt{2}f_{23} + 2f_{33}) \\
&\quad + (P(i,1)^2 + P(i,n-1)^2)(2r_1 + 2r_2 - 4r_1 - 4r_2 + 2r_1 + 2r_2) \\
&= (f_{22} + 2\sqrt{2}f_{23} + 2f_{33})/n \;+\; 0 \;=\; 1,
\end{aligned}$$

so Z^* is feasible for (11a). The last constraint (12a) reduces for $i = 1$ and arbitrary $1 \le j \le n$ to

$$\begin{aligned}
\langle \tilde{V}_1 \otimes e_n P(j,:),\, Z^* \rangle &= \frac{P(j,n)}{2}\left(-\sqrt{2}f_{12} - 2f_{13} + \sqrt{2}f_{23} + 2f_{33}\right) \\
&= \frac{1}{2\sqrt{n}} 2m_1 \;=\; \frac{m_1}{\sqrt{n}}.
\end{aligned}$$

Similarly, we check the feasibility for (12a) for $i = 2, 3$. Once we know that Z^* is optimal for (18), the optimality of Y^* follows from Lemmas 5–7 and the fact that $\langle T \otimes S,\, Z^* \rangle = \frac{1}{2}\langle B \otimes \hat{A},\, Y^* \rangle$. □

A simple implication of Proposition 11 is the following closed form formula for the optimal solution of the semidefinite program MC_{SDP}:

$$\begin{aligned}
Y^* = (Q \otimes P)\, Z^*\, (Q \otimes P)^T &= (QZ_1Q^T) \otimes (P(:,1)P(:,1)^T) \\
&\quad + (QZ_{n-1}Q^T) \otimes (P(:,n-1)P(:,n-1)^T) + \frac{1}{n}(QZ_nQ^T) \otimes J_n.
\end{aligned} \tag{23}$$

We can see that for any graph and fixed m, Y^* is completely determined by (y_1, y_2, y_3) from Lemma 8 and hence with the first and the second to last eigenvalues of $\hat{A}$ and corresponding eigenvectors, which are determined by the second and the last eigenvalues of the graph Laplacian (λ_2 and λ_n) and corresponding eigenvectors.

5. A new family of relaxations for the MCP. In the previous section we have seen that relaxing the constraint $Y \in \mathcal{C}^*_{3n}$ in model MC_{CP} to $Y \in \mathcal{S}^+_{3n}$ leads to the lower bound OPT_{HW}. To get a better lower bound it is therefore natural to use a (tractable) set $\mathcal{K}$ with $\mathcal{C}^*_{3n} \subset \mathcal{K} \subset \mathcal{S}^+_{3n}$. Specifically, let $OPT_{\mathcal{K}}$ be defined by

$$OPT_{\mathcal{K}} = \min \frac{1}{2}\langle B^T \otimes \hat{A},\, Y \rangle \text{ such that } Y \in \mathcal{K} \text{ and } Y \text{ satisfies (10)–(13)};$$

then $OPT_{MC} \ge OPT_{\mathcal{K}} \ge OPT_{HW}$. A simple (and tractable) candidate for the set $\mathcal{K}$ is $\mathcal{K}_0 = \mathcal{S}^+_{3n} \cap \mathcal{N}_{3n}$. This is actually the first member in the hierarchy of cones introduced by Parrilo in [15] and used also by de Klerk and Pasechnik in their work

about the stability number in [11]. We may also replace it with any other member of this hierarchy, but already the second cone $\mathcal{K}_1$ leads to a very expensive semidefinite program. $OPT_{\mathcal{K}_0}$ is already quite expensive, since each sign constraint contributes one linear equation and one slack variable and we have approximately $9n^2/2$ of them. We get cheaper models if we take for $\mathcal{K}$ the cone

$$\mathcal{K}_0^a = \{X \in \mathcal{S}_{3n}^+,\ \mathcal{Z}(X) = 0, \text{ and } X_{ij}^{12} \geq 0 \text{ for any } (i,j) \text{ with } a_{ij} > 0\},$$

where $\mathcal{Z}(X) = 0$ means that all diagonal entries in all nondiagonal blocks must be zero, which corresponds to componentwise orthogonality of columns of partition matrices. Taking the last cone makes sense, since the matrix $B^T \otimes \hat{A}$ in the model MC_{CP} is nonzero only in those positions of $(1,2)$th and $(2,1)$th blocks, where $a_{ij} > 0$, and the constraint $\mathcal{Z}(X) = 0$ is satisfied by any feasible solution for MC_{CP}. Table 1 shows numerical results, which we obtained by optimizing over the cones $\mathcal{K}_0$ and $\mathcal{K}_0^a$. Table 1 contains computational results on small graphs: $P_6 \times P_4$ is the product of two paths, i.e., a 6×4 grid graph, $K_{6,9}$ is the complete bipartite graph on 15 nodes, and rand(15, 0.5) is a random graph on 15 nodes with edge density 0.5. We partition them in several different ways, given by m in column 2. The vectors m are exactly those for which $m_2/2 \leq m_1 \leq m_2$ and m_3 fixed (later we will see that this is useful when considering the balanced vertex separators of a graph). For all these graphs except the random graph we can determine OPT_{MC} by inspection; see column 3. The last three columns contain the original bound OPT_{HW} from [10] and improvements obtained by optimizing over the cones $\mathcal{K}_0$ and $\mathcal{K}_0^a$.

TABLE 1
MCP and the relaxations on some small graphs.

Graph	m_1, m_2, m_3	OPT_{MC}	OPT_{HW}	$OPT_{\mathcal{K}_0}$	$OPT_{\mathcal{K}_0^a}$
$P_6 \times P_4$	7 14 3	1	-3.36	0.26	0.00
$P_6 \times P_4$	8 13 3	1	-3.32	0.22	0.00
$P_6 \times P_4$	9 12 3	1	-3.31	0.15	0.00
$P_6 \times P_4$	10 11 3	1	-3.29	0.10	0.00
$P_6 \times P_4$	8 14 2	2	-1.88	1.12	0.00
$P_6 \times P_4$	9 13 2	2	-1.84	1.09	0.00
$P_6 \times P_4$	10 12 2	2	-1.81	0.94	0.05
$P_6 \times P_4$	11 11 2	2	-1.80	0.85	0.06
rand(15, 0.5)	5 6 4	7	0.19	6.65	6.07
$K_{6,9}$	4 6 5	4	2.18	4.00	3.61
$K_{6,9}$	5 5 5	5	2.50	4.79	3.99
$K_{6,9}$	4 7 4	8	4.71	8.00	6.87
$K_{6,9}$	5 6 4	9	5.41	8.99	7.75

While the relaxation over $\mathcal{K}_0$ provides a substantial improvement as compared to OPT_{HW}, this bound is also rather expensive: we need to solve a semidefinite program in matrices of order $3n$ with approximately $9n^2/2$ additional constraints. Looking at $OPT_{\mathcal{K}_0^a}$ we see that this relaxation is slightly weaker than $OPT_{\mathcal{K}_0}$ but is less expensive since it includes only approximately $m = |E|$ additional constraints, if E is the edge set of the graph. When it is positive, then it is significantly better than OPT_{HW}. We note that $OPT_{\mathcal{K}_0}$ rounded up gives the exact value OPT_{MC} in almost all cases.

To explore the potential of our approach, we also generated some bigger instances with up to 100 nodes. We generated random graphs with edge probability p (g50.1, g50.4, g100) and also random graphs where the entries in the (1,2) block of size (m_1, m_2) are chosen with probability $q < p$. This should result in "easier" instances, as the partition $S_1 = \{1, \ldots, m_1\}$, $S_2 = \{m_1+1, \ldots, m_1+m_2\}$ has a smaller expected

TABLE 2

	35 35 30	107	12.5	84.7	43

number of edges (g50.2, g50.3). In Table 2 we provide some specifics about these graphs.

For these graphs the computation of the relaxation over $\mathcal{K}_0$ is beyond the possibilities of our computing facilities. The simpler relaxation over $\mathcal{K}_0^a$ can still be calculated rather easily. In Table 3 we summarize the results. The column labeled ubd gives an upper bound on OPT_{MC}, obtained by a simulated annealing heuristic. Then we compare $OPT_{\mathcal{K}_0^a}$ to the spectral bound OPT_{HW}. We partition the graphs in several ways, indicated by the vector m. We note also here that the new relaxation provides a substantial improvement over the original spectral bound, which in case of negative values does not give any relevant information at all. Further, more detailed, computational experiments will be reported elsewhere; see the dissertation [16].

6. Advances to the bandwidth and the vertex separator problem. For a graph G on n vertices we define a labeling of vertices as a bijection $\Phi\colon V = \{v_1, \ldots, v_n\} \to \{1, 2, \ldots, n\}$. The labeling bandwidth $\sigma_\infty(G, \Phi)$ of the labeling Φ is the maximal difference over all graph edges:

$$\sigma_\infty(G, \Phi) := \max_{(i,j)\in E} |\Phi(v_i) - \Phi(v_j)|.$$

The bandwidth of a graph G is the minimum of the labeling bandwidth over all labelings:

$$\sigma_\infty(G) := \min_{\Phi} \sigma_\infty(G, \Phi).$$

The bandwidth problem is an NP-hard problem and remains NP-hard even if the graph G is a tree with maximal degree at most 3 or a caterpillar with hairlength ≤ 3. Even approximating the bandwidth is an extremely difficult task. Blache et al. have

shown that there is no polynomial time algorithm with an approximation ratio smaller than 1.5 unless P = NP (for more results about the bandwidth problem and its complexity see [3, 4, 5, 12]). In [10] several lower bounds for σ_∞ have been established for an unweighted graph, using Laplacian eigenvalues of the graph. The basic tool the authors used was showing that $OPT_{MC} > 0$. If this is the case, then $\sigma_\infty(G) \geq m_3 + 1$. This is generalized in the following proposition.

PROPOSITION 12. *Let G be an undirected and unweighted graph. If for some $m = (m_1, m_2, m_3)$ it holds that $OPT_{MC} \geq \alpha > 0$, then*

$$\sigma_\infty(G) \geq \max\{m_3 + 1,\, m_3 + \lceil\sqrt{2\alpha}\rceil - 1\}.$$

Proof. Let Φ be the optimal labeling of G. We may assume that the vertices of G are initially labeled such that Φ is identity, i.e., $\Phi(i) = i$. Let (S_1, S_2, S_3) be a partition of $V(G)$, defined by $S_1 = \{1, \ldots, m_1\}$ and $S_2 = \{m_1 + m_3 + 1, \ldots, n\}$, Δ the maximal difference of end numbers over all edges, connecting sets S_1 and S_2, and $\delta = \Delta - m_3$. We have $\delta \geq 1$ since $OPT_{MC} > 0$. The only vertices from S_1 that might have a neighbor in S_2 are $m_1 - \delta + 1, \ldots, m_1$, since otherwise the difference of end vertices is greater than Δ. The same argument implies that the vertex m_1 has δ neighbors at most in S_2 , the vertex $m_1 - 1$ has $\delta - 1$ neighbors at most, etc. The last vertex $m_1 - \delta + 1$ has 1 neighbor at most in S_2. The number of edges between S_1 and S_2 is therefore $\delta + (\delta - 1) + \cdots + 1 = \delta(\delta + 1)/2$ at most; hence we get the inequality $\delta(\delta + 1) \geq 2\alpha$, which implies $\delta \geq \lceil\sqrt{2\alpha}\rceil - 1$. Since we also know that $\delta \geq 1$, the proposition follows from $\sigma_\infty(G) \geq \Delta$. □

Table 4 demonstrates the tightness of this lower bound on the graph instances from Table 1. The third column contains the bandwidth of the graph (for graphs $P_m \times P_n$ and $K_{m,n}$ we can compute it using the closed form formula, e.g., $\sigma_\infty(P_m \times P_n) = \min\{m, n\}$). In the fourth column we have α, the lower bound for OPT_{MC}, obtained by rounding up the best $OPT_{\mathcal{K}_0}$ from Table 1, and the last column shows the lower bound for $\sigma_\infty(G)$ from Proposition 12. We can see that we might get good information about the bandwidth using a good lower bound for the OPT_{MC}, and this is very important according to the complexity hardness of the bandwidth problem.

TABLE 4
Lower bounds for bandwidth for the graphs from Table 1.

Graph	m_3	$\sigma_\infty(G)$	α	$m_3 + \lceil\sqrt{2\alpha}\rceil - 1$
$P_6 \times P_4$	3	4	1	4
$P_6 \times P_4$	2	4	2	3
rand(15, 0.5)	4	10	7	7
$K_{6,9}$	5	10	5	8
$K_{6,9}$	4	10	9	8

Finally, we also compare the lower bound on the bandwidth from [10], which is based on the spectral bound OPT_{HW}, and the bound from Proposition 12 on the graphs from Table 2. The results in Table 5 show again that the new model provides a significant improvement over the spectral bound.

A set $S_3 \subset V$ is a vertex separator if removing these vertices disconnects the graph. It is a balanced vertex separator if the resulting graph has two components of sizes between $s/3$ and $2s/3$, where $s = |V| - |S_3|$. Helmberg et al. have derived in [10] several lower bounds on the size of a minimal vertex separator. They have used the fact that if $OPT_{MC} = 0$ then $OPT_{HW} \leq 0$ and from this have derived lower bounds on the size of the vertex separator. By using the fact that for fixed m_3 is OPT_{HW}

TABLE 5
Lower bounds on the bandwidth for the graphs from Table 2.

Graph	Bound from [10]	Proposition 12
g50.1	9	19
g50.2	9	18
g50.3	5	16
g50.4	5	8
g100	33	43

maximal if m_1 and m_2 are equal (or differs by 1 if $n - m_3$ is an odd number) they have extended the result to balanced vertex separators. The optimal values $OPT_{\mathcal{K}}$ for $\mathcal{K}$ as above give information about the vertex separators only if they are positive, since in this case we know that the graph does not have a vertex separator of size m_3 whose removal divides the graph vertices into sets of sizes m_1 and m_2. Table 1 shows that on the test instances we always detected the nonexistence of the appropriate vertex separator. However, since in general the value $OPT_{\mathcal{K}}$ does not monotonically change with the difference $|m_1 - m_2|$ as is the case for OPT_{HW}, we can get the information about the balanced vertex separator only by checking all possible pairs $m_2/2 \leq m_1 \leq m_2$ with $m_1 + m_2 = n - m_3$. This might be time consuming so it is worth trying to change the model MC_{CP} in order to include the balanced cardinality constraint and then relaxing this model. We have already done some promising steps and the results appear in [16].

7. Conclusions. We have shown that the MCP can be formulated as a linear program over the cone of completely positive matrices of order $3n \times 3n$. Replacing the cone of completely positive matrices with any cone for which we are able to solve the separation problem gives a tractable approximate model. We have analyzed the relaxation, obtained by using the cone of positive semidefinite matrices, and we showed that this model gives the eigenvalue lower bound, originally found by Helmberg et al. in [10]. We provided the closed form solution of this relaxation and showed that it is determined with the second and the largest eigenvalues of graph Laplacian and corresponding eigenvectors. We also proposed some other relaxations, using the hierarchy of cones, proposed by Parrilo in [15]. Numerical results in section 5 show that the lower bounds, obtained this way, may be very tight. At this point we want to emphasize that our approach may be easily extended to a general graph partitioning problem. We finished with the study of the impact that the new results have on approximation of some other combinatorial problems. A reasonable good lower bound for the bandwidth problem may be obtained this way as well as the certificate that the graph does not have a separator of specified size, whose removal disconnects the graph into two sets of prescribed sizes. A preliminary study in modeling the balanced vertex separator problem by copositive programming has also been done and the results together with an extension to the general graph partitioning problem will be reported elsewhere; see also the dissertation [16].

Acknowledgments. We thank two anonymous referees for several suggestions to improve an earlier version of the paper.

A BUNDLE METHOD FOR A CLASS OF BILEVEL NONSMOOTH CONVEX MINIMIZATION PROBLEMS*

MIKHAIL V. SOLODOV†

Abstract. We consider the bilevel problem of minimizing a nonsmooth convex function over the set of minimizers of another nonsmooth convex function. Standard convex constrained optimization is a particular case in this framework, corresponding to taking the lower level function as a penalty of the feasible set. We develop an explicit bundle-type algorithm for solving the bilevel problem, where each iteration consists of making one descent step for a weighted sum of the upper and lower level functions, after which the weight can be updated immediately. Convergence is shown under very mild assumptions. We note that in the case of standard constrained optimization, the method does not require iterative solution of any penalization subproblems—not even approximately—and does not assume any regularity of constraints (e.g., the Slater condition). We also present some computational experiments for minimizing a nonsmooth convex function over a set defined by linear complementarity constraints.

Key words. bilevel optimization, convex optimization, nonsmooth optimization, bundle methods, penalty methods

1. Introduction.

We consider a class of *bilevel problems* of the form

$$\begin{array}{ll} \text{minimize} & f_1(x) \\ \text{subject to} & x \in S_2 = \arg\min\{f_2(x) \mid x \in \Re^n\}, \end{array} \tag{1.1}$$

where $f_1 : \Re^n \to \Re$ and $f_2 : \Re^n \to \Re$ are convex functions, in general nondifferentiable.

The above is a special case of the *mathematical program with generalized equation (or equilibrium) constraint* [20, 7], which is

$$\begin{array}{ll} \text{minimize} & f_1(x) \\ \text{subject to} & x \in \{x \in \Re^n \mid 0 \in T(x)\}, \end{array}$$

where T is a set-valued mapping from $\Re^n$ to the subsets of $\Re^n$. The bilevel problem (1.1) is obtained by setting $T(x) = \partial f_2(x)$, $x \in \Re^n$. In the formulation of the problem considered here, there is only one (decision) variable $x \in \Re^n$, and we are interested in identifying specific solutions of the inclusion $0 \in T(x)$ (equivalently, of the lower level minimization problem in (1.1)); see [7]. Problems of the form of (1.1) are also sometimes referred to as *hierarchical optimization*; see, e.g., [12, 4].

Note that, as a special case, (1.1) contains the standard convex constrained optimization problem

$$\begin{array}{ll} \text{minimize} & f_1(x) \\ \text{subject to} & g_i(x) \le 0, \quad i = 1, \ldots, m, \end{array} \tag{1.2}$$

where $g : \Re^n \to \Re^m$ is a (nonsmooth) convex function. Indeed, (1.2) is obtained from (1.1) by taking $f_2(x) = p(x)$, where $p : \Re^n \to \Re_+$ is some penalty of the constraints, e.g.,

$$f_2(x) = p(x) = \sum_{i=1}^{m} \max\{0,\, g_i(x)\}. \tag{1.3}$$

In this paper, we show that the bilevel problem (1.1) can be solved by a properly designed (proximal) bundle method [15, 11, 3], iteratively applied to the parametrized family of functions

$$F_\sigma(x) = \sigma f_1(x) + f_2(x), \quad \sigma > 0, \tag{1.4}$$

where σ varies along the iterations. Specifically, if $x^k \in \Re^n$ is the current iterate and $\sigma_k > 0$ is the current parameter, it is enough to make *just one* descent step for F_{σ_k} from the point x^k, after which the parameter σ_k can be immediately updated. We emphasize that at no iteration is the function F_{σ_k} minimized to any prescribed precision. Once the descent condition is achieved, the parameter can be updated immediately and we can start working with the new function $F_{\sigma_{k+1}}$. For convergence of the resulting algorithm to the solution set of (1.1), parameters $\{\sigma_k\}$ should be chosen is such a way that

$$\lim_{k\to\infty} \sigma_k = 0, \quad \sum_{k=0}^{\infty} \sigma_k = +\infty. \tag{1.5}$$

The requirement that σ_k must tend to zero is natural and indispensable, as can be seen from the case of standard optimization (1.2). To this end, it is interesting to comment on the relation between our method and the classical penalty approximation scheme [8, 23]. The penalty scheme consists of solving a sequence of unconstrained subproblems

$$\text{minimize } F_\sigma(x), \quad x \in \Re^n, \tag{1.6}$$

where F_σ is given by (1.4) with f_2 being a penalty term p, such as (1.3). (In the literature, it is more common to minimize $\sigma^{-1}F_\sigma(x) = f_1(x) + \sigma^{-1}p(x)$, but the resulting subproblem is clearly equivalent to (1.6).) As is well known, under mild assumptions optimal paths of solutions $x(\sigma)$ of penalized problems (1.6) tend to the solution set of (1.2) as $\sigma \to 0$. We emphasize that the requirement that penalty parameters should tend to zero is, in general, indispensable. To guarantee that a solution of (1.6) is a solution of the original problem (1.2) for some *fixed* $\sigma > 0$ (i.e., exactness of the penalty function), some regularity assumptions on constraints are needed (e.g., see [3, section 14.4]). No assumptions of this type are made in this paper. The fundamental issue is approximating $x(\sigma_k)$ for some sequence of parameters $\sigma_k \to 0$. It is clear that approximating $x(\sigma_k)$ with precision is computationally impractical. It is therefore attractive to trace the optimal path in a loose (and computationally cheap) manner, while still safeguarding convergence. In a sense, this is what our method does: instead of solving subproblems (1.6) to some prescribed accuracy, it makes just one descent step for F_{σ_k} from the current iterate x^k and immediately updates the parameter. We emphasize that this results in meaningful progress (and ultimately produces iterates converging to solutions of the problem) for arbitrary points x^k, and not just for points close to the optimal path, i.e., points close to $x(\sigma_k)$.

We therefore obtain an implementable algorithm for tracing optimal paths of penalty schemes.

We next discuss the relationship of our algorithm to the existing literature. For the bilevel setting of (1.1), we believe that our proposal is the first method which is completely *explicit*. In some ways, it is related to [4], where a proximal point method for (1.1) has been considered, and (1.5) is referred to as *slow control*. However, as any proximal method, the method of [4] is *implicit*: it requires solving nontrivial subproblems of minimizing regularizations of functions F_{σ_k} at every iteration, even if approximately. By contrast, the method proposed in this paper is completely explicit: each iteration is a serious (or descent) step for the current F_{σ_k}, constructed by a finite number of null steps in a way which is essentially standard in nonsmooth optimization.

The special case of standard optimization deserves some further comments. We next discuss bundle methods applicable to problems with nonlinear constraints, such as (1.2) above. When the problem admits exact penalization, one can solve the equivalent unconstrained problem of minimizing the exact penalty function; see [14, 18]. However, as already mentioned above, exact penalization requires regularity assumptions on constraints, such as the Slater condition (existence of some $x \in \Re^n$ such that $g_i(x) < 0$ for all $i = 1, \ldots, m$). We stress that no assumptions of this type are needed for our method. For example, our method is applicable to minimizing a nonsmooth function subject to (monotone linear) complementarity constraints

$$(Qx + q)_i \geq 0, \quad x_i \geq 0, \quad x_i(Qx + q)_i = 0, \quad i = 1, \ldots, n,$$

where Q is an $n \times n$ positive semidefinite matrix. Those constraints can be modeled in the form (1.2) as

$$-Qx - q \leq 0, \quad -x \leq 0, \quad \langle Qx + q, x \rangle \leq 0.$$

Complementarity constraints do not satisfy constraint qualifications, no matter how they are modeled, which makes this class of problems particularly difficult. We shall come back to problems with complementarity constraints in section 4, where some computational experiments are presented.

The methods in [21, 22] and [15, Chap. 5] do not use penalization but enforce feasibility of every serious iteration. In particular, they require a feasible starting point, which is a difficult computational task (in the case of nonlinear constraints). In addition, regularity of constraints is still needed for convergence. Bundle methods which do not use penalty functions and do not enforce feasibility are [19, 9, 24, 13]. The methods in [24, 13] share one feature in common with the one proposed here: they apply bundle techniques to a dynamically changing objective function, except that the function is different (underlying [24, 13] is the so-called *improvement function*, which goes back to [21, 15, 1]). The methods of [24, 13] require the Slater condition, while those in [19, 9] do not. However, [19, 9] (as well as [21, 17, 18]) need a priori boundedness assumptions on the iterates to prove convergence. For our method, we assume only that the solution set of the problem is bounded.

For the standard optimization setting (1.2), this paper is also somewhat related to [5], where interior penalty schemes are coupled with continuous-time steepest descent to produce a family of paths converging to a solution set. However, concrete numerical schemes in [5] arise from *implicit* discretization and, thus, result in implicit proximal-point iterations, just as in [4]. Nevertheless, it was conjectured in [5] that an economic algorithm performing a single iteration of some descent method for each value of σ_k could be enough to generate a sequence of iterates converging to a solution of the

problem. This is what the presented method does, although we use exterior rather than interior penalties and consider the more general nonsmooth setting (as well as the more general bilevel setting). A related explicit descent scheme for the smooth case has been developed in [25].

Our notation is quite standard. By $\langle x, y\rangle$ we denote the inner product of x and y, and by $\|\cdot\|$ the associated norm, where the space is always clear from the context. For a convex function $f : \Re^n \to \Re$, its ε-subdifferential at the point $x \in \Re^n$ is denoted by $\partial_\varepsilon f(x) = \{g \in \Re^n \mid f(y) \geq f(x) + \langle g, y - x\rangle - \varepsilon \text{ for all } y \in \Re^n\}$, where $\varepsilon \in \Re_+$. Then the subdifferential of f at x is given by $\partial f(x) = \partial_0 f(x)$. If S is a closed convex set in $\Re^n$, then $P_S(x)$ stands for the orthogonal projection of the point $x \in \Re^n$ onto S, and $\operatorname{dist}(x, S) = \|x - P_S(x)\|$ is the distance from x to S.

2. The algorithm. As already outlined above, the conceptual idea of the algorithm is quite simple. If $x^k \in \Re^n$ is the current approximation to a solution of (1.1) and $\sigma_k > 0$ is the current parameter defining the function F_{σ_k} in (1.4), an iteration of the method consists of making a descent step for F_{σ_k} relative to its value at x^k. After this, the value of σ_k can be changed immediately. Since the function F_{σ_k} is nonsmooth, the computationally implementable way to construct a descent step is the bundle technique [15, 11, 3]. We next introduce the notation necessary for stating our algorithm.

Bundle methods keep memory of the past in a *bundle* of information. Let x^k be the current approximation to a solution and let y^i, $i = 1, \ldots, \ell - 1$, be all the points that have been produced by the method so far, including the ones which have not been accepted as satisfactory (so-called "null steps"). Generally, $\{x^k\}$ is a particular subsequence of $\{y^i\}$. For an iteration index ℓ, we shall denote by $k(\ell)$ the index of the last iteration preceding the iteration ℓ at which x^k and σ_k have been modified. Whenever k and ℓ appear in the same expression, we mean that $k = k(\ell)$.

Let us denote the function and subgradient values of f_1 at the points y^i, $i = 1, \ldots, \ell - 1$, by $f_1^i = f_1(y^i)$, $g_1^i \in \partial f_1(y^i)$, and similarly for f_2. Since $(\sigma_k g_1^i + g_2^i) \in \partial F_{\sigma_k}(y^i)$, this information can be used to define a cutting-planes approximation Ψ_ℓ of the function F_{σ_k}, as follows:

$$\begin{aligned}\Psi_\ell(y) &:= \max_{i<\ell} \left\{\sigma_k f_1^i + f_2^i + \langle \sigma_k g_1^i + g_2^i, y - y^i\rangle\right\} \\ &= \sigma_k f_1(x^k) + f_2(x^k) \\ &\quad + \max_{i<\ell} \left\{-(\sigma_k e_1^{k,i} + e_2^{k,i}) + \langle \sigma_k g_1^i + g_2^i, y - x^k\rangle\right\}, \end{aligned} \tag{2.1}$$

where the second expression is centered at x^k and uses the linearization errors at y^i with respect to x^k:

$$e_p^{k,i} := f_p(x^k) - f_p^i - \langle g_p^i, x^k - y^i\rangle \geq 0, \quad p = 1, 2. \tag{2.2}$$

We note that the second representation of Ψ_ℓ in (2.1) is better suited for implementations, due to lower storage requirements. As is readily seen from the definition of ε-subgradients, it holds that

$$g_p^i \in \partial_{e_p^{k,i}} f_p(x^k), \quad p = 1, 2, \tag{2.3}$$

and

$$(\sigma_k g_1^i + g_2^i) \in \partial_{(\sigma_k e_1^{k,i} + e_2^{k,i})} F_{\sigma_k}(x^k). \tag{2.4}$$

The linearization errors in (2.2) have to be properly updated every time x^k changes.

Choosing a proximal parameter $\mu_\ell > 0$, we generate the next candidate point y^ℓ by solving a quadratic programming (QP) reformulation of the problem

$$\min_{y\in\Re^n}\left\{\Psi_\ell(y)+\frac{1}{2}\mu_\ell\|y-x^k\|^2\right\}. \tag{2.5}$$

We note that the resulting quadratic program possesses a certain special structure, for which efficient software has been developed [16, 10]. The iterate y^ℓ is considered good enough when $F_{\sigma_k}(y^\ell)$ is sufficiently smaller than $F_{\sigma_k}(x^k)$ (the so-called "serious step"; this will be made precise later). If y^ℓ is acceptable, then we set $x^{k+1} := y^\ell$, choose new σ_{k+1}, and proceed to construct a descent step for $F_{\sigma_{k+1}}$. Otherwise, a so-called "null step" is declared and the procedure continues for F_{σ_k}, using the enhanced approximation $\Psi_{\ell+1}$.

In order for the basic idea outlined above to be practical, some important details have to be incorporated into the design of the method, as discussed next.

The number of constraints in the QP reformulation of (2.5) is precisely the number of elements in the bundle. Obviously, one has to keep this number computationally manageable. Thus, the bundle has to be *compressed* whenever the number of elements reaches some chosen bound. Reducing the bundle amounts to replacing the cutting-planes model (2.1) with another function, defined with a smaller number of cutting planes, which we shall still denote by Ψ_ℓ. This has to be done without impairing convergence of the algorithm. For this purpose, the so-called *aggregate function* is fundamental [3, Chap. 9], which we shall introduce in what follows.

It is convenient to split the information kept at iteration ℓ into two separate parts. One is the "oracle" bundle containing subgradient values at (some of!) points y^i, $i = 1, \ldots, \ell-1$, and the associated linearization errors (recall (2.3) and (2.2)):

$$\mathcal{B}_\ell^{oracle} \subset \bigcup_{i<\ell}\left\{\left(e_p^{k,i}\in\Re_+, g_p^i\in\partial_{e_p^{k,i}} f_p(x^k),\ p=1,2\right)\right\}.$$

Note that here, the bundle $\mathcal{B}_\ell^{oracle}$ is not required to contain information at all the previous points (this is reflected by the use of the inclusion, rather than equation, in the definition above). The other part is the "aggregate" bundle, obtained from solutions of the QP subproblems. This bundle contains certain special ε-subgradients at x^k, to be introduced in Lemma 2.1 below. For now, we formally set

$$\mathcal{B}_\ell^{agg} \subset \bigcup_{i<\ell}\left\{\left(\hat\varepsilon_p^{k,i}\in\Re_+, \hat g_p^i\in\partial_{\hat\varepsilon_p^{k,i}} f_p(x^k),\ p=1,2\right)\right\},$$

without specifying how exactly those objects are obtained. Note that here there may no longer exist any previous point y^i, $i<\ell$, for which $\hat g_p^i \in \partial f_p(y^i)$, $p = 1, 2$.

The information in $\mathcal{B}_\ell^{oracle}$ and $\mathcal{B}_\ell^{agg}$ defines a cutting-planes approximation of F_{σ_k} given by

$$\begin{aligned}\Psi_\ell(y) = {}& \sigma_k f_1(x^k) + f_2(x^k)\\ &+\max\left\{\max_{i\in\mathcal{B}_\ell^{oracle}}\left\{-(\sigma_k e_1^{k,i}+e_2^{k,i})+\langle\sigma_k g_1^i+g_2^i, y-x^k\rangle\right\},\right.\\ &\left.\max_{i\in\mathcal{B}_\ell^{agg}}\left\{-(\sigma_k\hat\varepsilon_1^{k,i}+\hat\varepsilon_2^{k,i})+\langle\sigma_k\hat g_1^i+\hat g_2^i, y-x^k\rangle\right\}\right\},\end{aligned} \tag{2.6}$$

where by $i \in \mathcal{B}_\ell^{oracle}$ we mean that there exists an element in the set $\mathcal{B}_\ell^{oracle}$ indexed by i; and similarly for $\mathcal{B}_\ell^{agg}$. Although this notation is formally improper (the bundles are not sets of indices), it does not lead to any confusion while simplifying the formulas.

We next discuss properties of the solution of QP subproblem (2.5) with Ψ_ℓ given by (2.6). The following characterization is an adaptation of [3, Lemma 9.8] for our setting.

LEMMA 2.1. *For the unique solution y^ℓ of (2.5) with Ψ_ℓ given by (2.6), it holds that*

(i) $y^\ell = x^k - \frac{1}{\mu_\ell}(\sigma_k \hat{g}_1^\ell + \hat{g}_2^\ell)$;
(ii) $\hat{g}_p^\ell = \sum_{i \in \mathcal{B}_\ell^{oracle}} \lambda_i^\ell g_p^i + \sum_{i \in \mathcal{B}_\ell^{agg}} \hat{\lambda}_i^\ell \hat{g}_p^i$, $p = 1, 2$,
where $\lambda^\ell \geq 0$, $\hat{\lambda}^\ell \geq 0$ and $\sum_{i \in \mathcal{B}_\ell^{oracle}} \lambda_i^\ell + \sum_{i \in \mathcal{B}_\ell^{agg}} \hat{\lambda}_i^\ell = 1$;
(iii) $(\sigma_k \hat{g}_1^\ell + \hat{g}_2^\ell) \in \partial \Psi_\ell(y^\ell)$;
(iv) $\hat{g}_p^\ell \in \partial_{\hat{\varepsilon}_p^{k,\ell}} f_p(x^k)$, *where* $\hat{\varepsilon}_p^{k,\ell} = \sum_{i \in \mathcal{B}_\ell^{oracle}} \lambda_i^\ell e_p^{k,i} + \sum_{i \in \mathcal{B}_\ell^{agg}} \hat{\lambda}_i^\ell \hat{\varepsilon}_p^{k,i}$, $p = 1, 2$;
(v) $(\sigma_k \hat{g}_1^\ell + \hat{g}_2^\ell) = \hat{g}^\ell \in \partial_{\hat{\varepsilon}^{k,\ell}} F_{\sigma_k}(x^k)$, *where* $\hat{\varepsilon}^{k,\ell} = \sigma_k \hat{\varepsilon}_1^{k,\ell} + \hat{\varepsilon}_2^{k,\ell}$;
(vi) $\hat{\varepsilon}^{k,\ell} = F_{\sigma_k}(x^k) - \Psi_\ell(y^\ell) - \frac{1}{\mu_\ell}\|\hat{g}^\ell\|^2 \geq 0$.

Proof. The assertions can be verified following the analysis in [3, Lemma 9.8], and taking into account the special structure of the function F_{σ_k} and of its approximation Ψ_ℓ. We omit the details. □

We note that λ^ℓ and $\hat{\lambda}^\ell$ in Lemma 2.1 are the Lagrange multipliers associated with y^ℓ in the quadratic program reformulation of (2.5) (or the problem variables, if one solves the dual of this quadratic program, as in [16]). In any case, λ^ℓ and $\hat{\lambda}^\ell$ are available as part of the solution to (2.5). The quantities $\hat{g}_p^\ell$, $\hat{\varepsilon}_p^{k,\ell}$, $p = 1, 2$, defined in Lemma 2.1 are precisely the ones that appear in the definition of $\mathcal{B}_\ell^{agg}$ (except that $\mathcal{B}_\ell^{agg}$ contains information computed at iterations previous to the ℓth; at the first iteration we formally set $\mathcal{B}_\ell^{agg} = \emptyset$). We are now ready to introduce the aggregate function, already mentioned above:

$$l_{k,\ell}(y) := \sigma_k f_1(x^k) + f_2(x^k) - (\sigma_k \hat{\varepsilon}_1^{k,\ell} + \hat{\varepsilon}_2^{k,\ell}) + \langle \sigma_k \hat{g}_1^\ell + \hat{g}_2^\ell, y - x^k \rangle,$$

where

$$\hat{g}_p^\ell \in \partial_{\hat{\varepsilon}_p^{k,\ell}} f_p(x^k), \quad p = 1, 2, \tag{2.7}$$

and consequently,

$$(\sigma_k \hat{g}_1^\ell + \hat{g}_2^\ell) \in \partial_{(\sigma_k \hat{\varepsilon}_1^{k,\ell} + \hat{\varepsilon}_2^{k,\ell})} F_{\sigma_k}(x^k). \tag{2.8}$$

As already noted above, this function is defined directly from the quantities available after solving (2.5).

As pointed out in [6, eqs. (4.7)–(4.9)], to guarantee that a bundle technique would be able to construct a descent step for F_{σ_k} with respect to its value at x^k (assuming x^k is not a minimizer of F_{σ_k}) one can actually use any cutting-planes models Ψ_ℓ satisfying (for all $y \in \Re^n$) the following three conditions:

$$\begin{aligned} \Psi_\ell(y) &\leq F_{\sigma_k}(y) && \text{for all } \ell \geq 1 \text{ and all } k, \\ l_{k,\ell}(y) &\leq \Psi_{\ell+1}(y) && \text{for those } \ell \text{ for which } y^\ell \text{ is a null step}, \\ \sigma_k f_1^\ell + f_2^\ell + \langle \sigma_k g_1^\ell + g_2^\ell, y - y^\ell \rangle &\leq \Psi_{\ell+1}(y) && \text{for those } \ell \text{ for which } y^\ell \text{ is a null step}. \end{aligned}$$

The last two conditions mean that when defining the new bundles, it is enough for $\mathcal{B}_{\ell+1}^{oracle}$ to contain the cutting plane computed at the new point y^ℓ (i.e., the subgradients g_1^ℓ, g_2^ℓ, and the associated linearization errors $e_1^{k,\ell}$, $e_2^{k,\ell}$) and for $\mathcal{B}_{\ell+1}^{agg}$ to contain

the last aggregate function $l_{k,\ell}$ (i.e., the ε-subgradients $\hat{g}_1^\ell$, $\hat{g}_2^\ell$, and the associated $\hat{\varepsilon}_1^{k,\ell}$, $\hat{\varepsilon}_2^{k,\ell}$). In particular, at any iteration, the bundle can contain as few elements as we wish (as long as the two specified above are included). This fact is crucial for effective control of the size of subproblems (2.5). Finally, to make sure that the first condition above holds for all k, the linearization and aggregate errors have to be properly updated every time x^k changes to x^{k+1} (in particular, to ensure the key relations (2.4) and (2.8)). As is readily seen, the following formulas do the job:

(2.9)
$$e_p^{k+1,i} = e_p^{k,i} + f_p(x^{k+1}) - f_p(x^k) + \langle g_p^i, x^k - x^{k+1}\rangle, \quad p = 1,2, \text{ for } i \in \mathcal{B}_{\ell+1}^{oracle},$$
$$\hat{\varepsilon}_p^{k+1,i} = \hat{\varepsilon}_p^{k,i} + f_p(x^{k+1}) - f_p(x^k) + \langle \hat{g}_p^i, x^k - x^{k+1}\rangle, \quad p = 1,2, \text{ for } i \in \mathcal{B}_{\ell+1}^{agg}.$$

We are now ready to formally state the algorithm.

ALGORITHM 2.1 (bilevel bundle method).

Step 0. `Initialization.`
Choose parameter $m \in (0,1)$ *and an integer* $|\mathcal{B}|_{max} \geq 2$.
Choose $x^0 \in \Re^n$ *and* $\sigma_0 > 0$, $\beta_0 > 0$. *Set* $y^0 := x^0$ *and compute* f_p^0, g_p^0, $p = 1,2$. *Set* $k = 0$, $\ell = 1$, $e_p^{0,0} := 0$, $p = 1,2$. *Define the starting bundles* $\mathcal{B}_1^{oracle} := \{(e_p^{0,0}, g_p^0,\ p = 1,2)\}$ *and* $\mathcal{B}_1^{agg} := \emptyset$.

Step 1. `QP subproblem.`
Choose $\mu_\ell > 0$ *and compute* y^ℓ *as the solution of* (2.5), *where* Ψ_ℓ *is defined by* (2.6). *Compute*

$$\hat{g}^\ell = \mu_\ell(x^k - y^\ell), \quad \hat{\varepsilon}^{k,\ell} = F_{\sigma_k}(x^k) - \Psi_\ell(y^\ell) - \frac{1}{\mu_\ell}\|\hat{g}^\ell\|^2, \quad \delta_\ell = \hat{\varepsilon}^{k,\ell} + \frac{1}{2\mu_\ell}\|\hat{g}^\ell\|^2.$$

Compute f_p^ℓ, g_p^ℓ, $p = 1,2$. *Compute* $e_p^{k,\ell}$, $p = 1,2$, *using* (2.2) *written with* $i = \ell$.

Step 2. `Descent test.` *If*

$$F_{\sigma_k}(y^\ell) \leq F_{\sigma_k}(x^k) - m\delta_\ell, \tag{2.10}$$

then declare a serious step. *Otherwise, declare a* null step.

Step 3. `Bundle management.`
Set $\mathcal{B}_{\ell+1}^{oracle} := \mathcal{B}_\ell^{oracle}$ *and* $\mathcal{B}_{\ell+1}^{agg} := \mathcal{B}_\ell^{agg}$. *If the bundle has reached the maximum size (i.e., if* $|\mathcal{B}_{\ell+1}^{oracle} \cup \mathcal{B}_{\ell+1}^{agg}| = |\mathcal{B}|_{max}$*), then delete at least two elements from* $\mathcal{B}_{\ell+1}^{oracle} \cup \mathcal{B}_{\ell+1}^{agg}$ *and append the aggregate information* $(\hat{\varepsilon}_p^{\ell,k}, \hat{g}_p^\ell,\ p = 1,2)$ *to* $\mathcal{B}_{\ell+1}^{agg}$.
In any case, append $(e_p^{k,\ell}, g_p^\ell,\ p = 1,2)$ *to* $\mathcal{B}_{\ell+1}^{oracle}$.

Step 4. *If* `Descent test` *was satisfied,*
set $x^{k+1} = y^\ell$ *and choose* $0 < \sigma_{k+1} \leq \sigma_k$ *and* $0 < \beta_{k+1} \leq \beta_k$.
Update the linearization and aggregate errors using (2.9).
Set $k = k + 1$ *and go to Step* 5.
If

$$\max\{\hat{\varepsilon}^{k,\ell}, \|\hat{g}^\ell\|\} \leq \beta_k\sigma_k, \tag{2.11}$$

choose $0 < \sigma_{k+1} < \sigma_k$ *and* $0 < \beta_{k+1} < \beta_k$.
Set $x^{k+1} = x^k$, $k = k + 1$ *and go to Step* 5.

Step 5. *Set* $\ell = \ell + 1$ *and go to Step* 1.

The role of checking condition (2.11) is to detect the situation when the point x^k happens to be a minimizer of the function F_{σ_k} (or is almost a minimizer; recall Lemma 2.1(v)). If it is so, we immediately update the parameter σ_k. This is reasonable, since we are not interested in minimizing F_{σ_k}. The case of x^k being a minimizer of F_{σ_k}, however, is very unlikely to occur, since for no iteration k the function F_{σ_k} is being minimized with any prescribed precision. This is also confirmed by our numerical experiments in section 4, where we ignored the safeguard (2.11) in our implementation.

The algorithm does not have an overall stopping test. In the unconstrained case, a reliable stopping test is one of the important advantages of bundle methods (as compared, for example, to subgradient methods). However, lack of a stopping test in our setting cannot be considered to be a drawback of the algorithm. Indeed, a bilevel problem does not admit an explicit optimality condition. Actually, the same is in general already true for constrained optimization without a regularity assumption on the constraints (except for some special cases, of course). As a result, there is no explicit way to measure violation/satisfaction of optimality in (1.1), and, consequently, lack of a stopping test is inherent in the nature of the problem.

We note that there is certain freedom in updating or not updating the parameter σ_k after every iteration. While our goal is to show that we can update it after a single descent step, note that, in principle, we are not obliged to do so ($\sigma_{k+1} = \sigma_k$ is allowed, unless (2.11) holds; in the latter case, x^k almost minimizes F_{σ_k} and it does not make sense to insist on further descent for this function). For convergence, it would be required that σ_k not go to zero too fast, in the sense of condition (1.5) stated above. In the case of the standard optimization problem (1.2), this condition allows a natural interpretation. In order to be able to trace the optimal penalty path $x(\sigma)$ with such a relaxed precision (making just one descent step for each penalized subproblem (1.6)), we should not be jumping too far from the target $x(\sigma_k)$ on the path to the next target $x(\sigma_{k+1})$ as we move along. On the other hand, if σ_k is kept constant over a few descent iterations, this allows for a more rapid change in the parameter for the next iteration, while still guaranteeing the second condition in (1.5). This is intuitively reasonable: if we get closer to the optimal path, then the target can be moved further. In our numerical experiments in section 4, we have used the simplest generic choice of $\sigma_k = \sigma_0/(k+1)$. We have experimented with some other options (for example, keeping the parameter unchanged for some iterations), but found that this does not make much difference (for our test problems). We shall discuss this further in section 4.

3. Convergence analysis. In our convergence analysis, we assume that the objective function f_1 is bounded below; i.e.,

$$-\infty < \bar{f}_1 = \inf\{f_1(x) \mid x \in \Re^n\}.$$

Since we also assume that the problem is solvable, the function f_2 is automatically bounded below, and we define

$$-\infty < \bar{f}_2 = \min\{f_2(x) \mid x \in \Re^n\}.$$

For the subsequent analysis, it is convenient to think of Algorithm 2.1 as "applied" to the shifted function

$$F_\sigma(x) = \sigma(f_1(x) - \bar{f}_1) + (f_2(x) - \bar{f}_2), \tag{3.1}$$

instead of the function F_σ given by (1.4), as stated originally. We can do this because Algorithm 2.1 would generate the same iterates whether F_σ were given by (3.1) or

(1.4). Indeed, the two functions have the same subgradients and the same difference for function values at any two points. Hence, the cutting-planes models (2.6) for the two functions would differ by a constant term (not dependent on y). This means that solutions y^ℓ of QP subproblems (2.5) would be the same, as well as the quantities $\hat{g}^\ell$ and $\hat{\varepsilon}^{k,\ell}$, which are defined by those solutions. Therefore, the relations in (2.10) and (2.11), which are guiding the algorithm, also do not change. From now on, we consider that the method is "applied" to function F_σ defined by (3.1) (even though the function from (1.4) is used in reality, of course). This is convenient for the subsequent analysis and should not lead to any confusion.

We proceed to prove convergence of the algorithm.

PROPOSITION 3.1. *Let f_1 and f_2 be convex functions.*

If for consecutive null steps it holds that $\bar{\mu} \geq \mu_{\ell+1} \geq \mu_\ell > 0$, then Algorithm 2.1 *is well defined and either* (2.10) *or* (2.11) *(or both) hold infinitely often. In particular, the parameter σ_k is updated infinitely often.*

Proof. Let k be any iteration index and consider the sequence of null steps applied to the current (fixed over those null steps) function F_{σ_k}. By properties of standard bundle methods (e.g., [3, Thm. 9.15]), it holds that either the descent test (2.10) is satisfied after a finite number of null steps, or x^k is a minimizer of F_{σ_k}. In the latter case, it further holds that $\delta_\ell \to 0$ as $\ell \to \infty$. Hence, $\hat{g}^\ell \to 0$ and $\hat{\varepsilon}^{k,\ell} \to 0$ as $\ell \to \infty$. This means that the condition (2.11) would be satisfied after a finite number of null steps.

We have therefore established that either (2.10) or (2.11) is guaranteed to be satisfied after a finite number of null steps. This shows that the method is well defined and updates σ_k infinitely often. □

We next prove that the generated sequence $\{x^k\}$ is bounded and its accumulation points are feasible for problem (1.1).

PROPOSITION 3.2. *Let f_1 and f_2 be convex functions such that f_1 is bounded below on $\Re^n$ and the solution set S_1 of problem* (1.1) *is nonempty and bounded.*

Suppose that $\bar{\mu} \geq \mu_\ell \geq \hat{\mu} > 0$ for all iterations ℓ, that $\mu_{\ell+1} \geq \mu_\ell$ on consecutive null steps, and that $\sigma_k \to 0$ as $k \to \infty$.

Then any sequence $\{x^k\}$ generated by Algorithm 2.1 *is bounded and all its accumulation points are feasible for problem* (1.1); *i.e., they belong to S_2.*

Proof. If the serious step descent test (2.10) is satisfied only a finite number of times, it is readily seen that there exists some iteration index k_0 such that $x^k = x^{k_0}$ for all $k \geq k_0$ (because x^k is changed only at serious steps, i.e., when (2.10) holds). Hence, in this case $\{x^k\}$ is trivially bounded.

Assume now that (2.10) is satisfied infinitely often. In what follows, we consider the subsequence of indices k at which (2.10) holds, i.e., at which x^k changes. But to simplify the notation, we shall not introduce this subsequence explicitly. Here, we can simply disregard all the iterations at which x^k remained fixed. We can do this within the current analysis of boundedness of $\{x^k\}$, because those iterations merely changed σ_k (and the only assumption for the latter used below is that it should be nonincreasing—the property which holds for any subsequence of $\{\sigma_k\}$ by the construction of the method).

For each k, let $\ell(k)$ be the index ℓ for which (2.10) was satisfied (in particular, $x^{k+1} = y^{\ell(k)}$). By (2.10), it holds that

$$\begin{aligned} m\delta_{\ell(k)} &\leq F_{\sigma_k}(x^k) - F_{\sigma_k}(x^{k+1}) \\ &= \sigma_k(f_1(x^k) - \bar{f}_1) - \sigma_k(f_1(x^{k+1}) - \bar{f}_1) \\ &\quad + (f_2(x^k) - \bar{f}_2) - (f_2(x^{k+1}) - \bar{f}_2). \end{aligned}$$

Summing up the latter inequalities for $k = 0, \dots, k_1$, we obtain that

$$\begin{aligned} m\sum_{k=0}^{k_1}\delta_{\ell(k)} &\le \sigma_0(f_1(x^0)-\bar f_1) + \sum_{k=0}^{k_1-1}(\sigma_{k+1}-\sigma_k)(f_1(x^{k+1})-\bar f_1) \\ &\quad - \sigma_{k_1}(f_1(x^{k_1+1})-\bar f_1) + (f_2(x^0)-\bar f_2) - (f_2(x^{k_1+1})-\bar f_2) \\ &\le \sigma_0(f_1(x^0)-\bar f_1) + (f_2(x^0)-\bar f_2), \end{aligned}$$

where we have used the facts that, for all k, $f_1(x^k) \ge \bar f_1$, $f_2(x^k) \ge \bar f_2$, and $0 < \sigma_{k+1} \le \sigma_k$. Letting $k_1 \to \infty$, we conclude that

$$\sum_{k=0}^{\infty}\delta_{\ell(k)} \le m^{-1}(\sigma_0(f_1(x^0)-\bar f_1) + (f_2(x^0)-\bar f_2)) < +\infty. \tag{3.2}$$

In particular,

$$\delta_{\ell(k)} \to 0 \quad \text{as } k \to \infty. \tag{3.3}$$

Take any $\bar x \in S_1 \ne \emptyset$. Using Lemma 2.1(i), we obtain that

$$\begin{aligned} \|x^{k+1}-\bar x\|^2 &= \|x^k-\bar x\|^2 - \frac{2}{\mu_{\ell(k)}}\langle \hat g^{\ell(k)}, x^k-\bar x\rangle + \frac{1}{\mu_{\ell(k)}^2}\|\hat g^{\ell(k)}\|^2 \\ &\le \|x^k-\bar x\|^2 + \frac{2}{\mu_{\ell(k)}}\left(F_{\sigma_k}(\bar x) - F_{\sigma_k}(x^k) + \hat\varepsilon^{k,\ell(k)} + \frac{1}{2\mu_{\ell(k)}}\|\hat g^{\ell(k)}\|^2\right) \\ &= \|x^k-\bar x\|^2 + \frac{2}{\mu_{\ell(k)}}\delta_{\ell(k)} \\ &\quad + \frac{2}{\mu_{\ell(k)}}\left(\sigma_k(f_1(\bar x)-f_1(x^k)) + f_2(\bar x) - f_2(x^k)\right) \\ &\le \|x^k-\bar x\|^2 + \frac{2}{\mu_{\ell(k)}}\delta_{\ell(k)} + \frac{2\sigma_k}{\mu_{\ell(k)}}\left(f_1(\bar x)-f_1(x^k)\right), \end{aligned} \tag{3.4}$$

where the first inequality is by Lemma 2.1(v), and the last is by the fact that $f_2(\bar x) \le f_2(x^k)$, since $\bar x \in S_1 \subset S_2$.

We next consider separately the following two possible cases:

Case 1. There exists k_2 such that $f_1(\bar x) \le f_1(x^k)$ for all $k \ge k_2$.

Case 2. For each k, there exists $k_3 \ge k$ such that $f_1(\bar x) > f_1(x^{k_3})$.

Case 1. For $k \ge k_2$, we obtain from (3.4) that

$$\|x^{k+1}-\bar x\|^2 \le \|x^k-\bar x\|^2 + \frac{2}{\hat\mu}\delta_{\ell(k)}. \tag{3.5}$$

Recalling (3.2), we conclude that $\{\|x^k-\bar x\|^2\}$ converges (see, e.g., [23, Lem. 2, p. 44]). Hence, $\{x^k\}$ is bounded.

Case 2. For each k, define

$$i_k = \max\{i \le k \mid f_1(\bar x) > f_1(x^i)\}.$$

In the case under consideration, it holds that $i_k \to \infty$ when $k \to \infty$.

We first show that $\{x^{i_k}\}$ is bounded. Observe that

$$\begin{aligned} S_1 &= \{x \in S_2 \mid f_1(x) \le f_1(\bar x)\} \\ &= \{x \in \Re^n \mid \max\{f_2(x)-\bar f_2, f_1(x)-f_1(\bar x)\} \le 0\}. \end{aligned}$$

By assumption, the set S_1 is nonempty and bounded. Therefore, the convex function

$$\phi : \Re^n \to \Re, \quad \phi(x) = \max\{f_2(x) - \bar{f}_2, f_1(x) - f_1(\bar{x})\}$$

has a particular level set $\{x \in \Re^n \mid \phi(x) \leq 0\}$ which is nonempty and bounded. It follows that all level sets of ϕ are bounded (see, e.g., [2, Prop. 2.3.1]), i.e.,

$$L_\phi(c) = \{x \in \Re^n \mid \phi(x) \leq c\}$$

is bounded for any $c \in \Re$.

Since $f_1(x) - \bar{f}_1 \geq 0$ for all $x \in \Re^n$ and $0 < \sigma_{k+1} \leq \sigma_k$, it holds that

$$F_{\sigma_{k+1}}(x) \leq F_{\sigma_k}(x) \qquad \text{for all } x \in \Re^n.$$

Hence,

$$0 \leq F_{\sigma_{k+1}}(x^{k+1}) \leq F_{\sigma_k}(x^{k+1}) \leq F_{\sigma_k}(x^k),$$

where the third inequality follows from (2.10). The above relations show that $\{F_{\sigma_k}(x^k)\}$ is nonincreasing and bounded below. Hence, it converges. It then easily follows that $\{f_2(x^k) - \bar{f}_2\}$ is bounded (because both terms in $F_{\sigma_k}(x^k) = \sigma_k(f_1(x^k) - \bar{f}_1) + (f_2(x^k) - \bar{f}_2)$ are nonnegative).

Fix any $c \geq 0$ such that $f_2(x^k) - \bar{f}_2 \leq c$ for all k. Since $f_1(x^{i_k}) - f_1(\bar{x}) < 0 \leq c$ (by the definition of the index i_k), we have that $x^{i_k} \in L_\phi(c)$, which is a bounded set. This shows that $\{x^{i_k}\}$ is bounded.

By the definition of i_k, it further holds that

$$f_1(\bar{x}) \leq f_1(x^i), \quad i = i_k + 1, \ldots, k \quad (\text{if } k > i_k).$$

Hence, from (3.4), we have that

$$\|x^{i+1} - \bar{x}\|^2 \leq \|x^i - \bar{x}\|^2 + \frac{2}{\hat{\mu}}\delta_{\ell(i)}, \quad i = i_k + 1, \ldots, k.$$

Therefore, for any k, it holds that

$$\begin{aligned} \|x^k - \bar{x}\|^2 &\leq \|x^{i_k} - \bar{x}\|^2 + \frac{2}{\hat{\mu}} \sum_{i=i_k+1}^{k-1} \delta_{\ell(i)} \\ &\leq \|x^{i_k} - \bar{x}\|^2 + \frac{2}{\hat{\mu}} \sum_{i=i_k+1}^{\infty} \delta_{\ell(i)}. \end{aligned} \tag{3.6}$$

Recalling that $i_k \to \infty$, by (3.2) we have that

$$\sum_{i=i_k+1}^{\infty} \delta_{\ell(i)} \to 0 \quad \text{as } k \to \infty. \tag{3.7}$$

Taking also into account the boundedness of $\{x^{i_k}\}$, the relation (3.6) implies that the whole sequence $\{x^k\}$ is bounded.

We next show that all accumulation points of $\{x^k\}$ belong to S_2. For each k, either (2.10) or (2.11) holds. Regardless of whether both conditions hold infinitely often or only one does, it is easy to see that

$$\hat{g}^{\ell(k)} \to 0 \quad \text{and} \quad \hat{\varepsilon}^{k,\ell(k)} \to 0 \quad \text{as } k \to \infty, \tag{3.8}$$

where (3.3) is used if (2.10) holds infinitely often, and (2.11) is used directly.

Let $x \in \Re^n$ be arbitrary but fixed. By Lemma 2.1(v),

$$\sigma_k f_1(x) + f_2(x) \geq \sigma_k f_1(x^k) + f_2(x^k) + \langle \hat{g}^{\ell(k)}, x - x^k \rangle - \hat{\varepsilon}^{k,\ell(k)}. \tag{3.9}$$

Let x^∞ be any accumulation point of $\{x^k\}$. Using boundedness of $\{x^k\}$, the continuity of f_1 and f_2, the fact that $\sigma_k \to 0$ and (3.8), and passing onto the limit in (3.9) along the subsequence which converges to x^∞, we obtain that $f_2(x) \geq f_2(x^\infty)$, where $x \in \Re^n$ is arbitrary. Hence, $x^\infty \in S_2$. □

The rest of the proof is done separately for the following two cases: the number of serious steps when (2.10) is satisfied is either infinite or finite.

THEOREM 3.3. *Let f_1 and f_2 be convex functions such that f_1 is bounded below on $\Re^n$ and the solution set S_1 of problem* (1.1) *is nonempty and bounded.*

Suppose that $\bar{\mu} \geq \mu_\ell \geq \hat{\mu} > 0$ for all iterations ℓ, and that $\mu_{\ell+1} \geq \mu_\ell$ on consecutive null steps.

If serious step descent test (2.10) *is satisfied an infinite number of times and we choose $\{\sigma_k\}$ according to* (1.5) *and $\{\beta_k\} \to 0$ as $k \to \infty$, then $\operatorname{dist}(x^k, S_1) \to 0$ as $k \to \infty$, and all accumulation points of $\{x^k\}$ are solutions of* (1.1).

Proof. Take any $\bar{x} \in S_1$. We again consider separately the two possible cases introduced in the proof of Proposition 3.2:

Case 1. There exists k_2 such that $f_1(\bar{x}) \leq f_1(x^k)$ for all $k \geq k_2$.

Case 2. For each k, there exists $k_3 \geq k$ such that $f_1(\bar{x}) > f_1(x^{k_3})$.

Case 2. Recalling that $i_k = \max\{i \leq k \mid f_1(\bar{x}) > f_1(x^i)\}$ so that $f_1(x^{i_k}) < f_1(\bar{x})$, by the continuity of f_1 it holds that $f_1(x^\infty) \leq f_1(\bar{x})$ for any accumulation point x^∞ of $\{x^{i_k}\}$. Since all accumulation points of $\{x^k\}$ belong to S_2 (as established in Proposition 3.2), it must be the case that all accumulation points of $\{x^{i_k}\}$ are solutions of the problem. In particular,

$$\operatorname{dist}(x^{i_k}, S_1) \to 0 \quad \text{as } k \to \infty. \tag{3.10}$$

For each k, define $\bar{x}^k = P_{S_1}(x^{i_k})$. Using (3.6) with $\bar{x} = \bar{x}^k$ gives

$$\begin{aligned} \operatorname{dist}(x^k, S_1)^2 &\leq \|x^k - \bar{x}^k\|^2 \\ &\leq \operatorname{dist}(x^{i_k}, S_1)^2 + \frac{2}{\hat{\mu}} \sum_{i=i_k+1}^{\infty} \delta_{\ell(i)}. \end{aligned}$$

Passing onto the limit in the latter relation as $k \to \infty$, and using (3.7) and (3.10), we obtain that $\operatorname{dist}(x^k, S_1) \to 0$.

Case 1. As has been shown in Proposition 3.2, in this case the sequence $\{\|x^k - \bar{x}\|\}$ converges for any $\bar{x} \in S_1$. Therefore, if we establish that $\{x^k\}$ has an accumulation point $x^\infty \in S_1$, it would immediately follow that $\{\|x^k - x^\infty\|\} \to 0$; i.e., the whole sequence $\{x^k\}$ converges to $x^\infty \in S_1$.

Suppose first that (2.11) is satisfied only a finite number of times. Suppose further that there is no accumulation point of $\{x^k\}$ which solves (1.1). Since, by Proposition 3.2, all accumulation points are feasible for (1.1), the second assumption means that $\liminf_{k\to\infty} f_1(x^k) > f_1(\bar{x})$, where $\bar{x} \in S_1$. In particular, there exists $t > 0$ such that

$f_1(\bar{x}) \le f_1(x^k) - t$ for all $k \ge k_4$. We then obtain from (3.4) that for $k > k_4$, it holds that

$$\begin{aligned}\|x^{k+1} - \bar{x}\|^2 &\le \|x^k - \bar{x}\|^2 + \frac{2}{\hat{\mu}}\delta_{\ell(k)} - \frac{2t}{\bar{\mu}}\sigma_k \\ &\le \|x^{k_4} - \bar{x}\|^2 + \frac{2}{\hat{\mu}}\sum_{i=k_4-1}^{k}\delta_{\ell(i)} - \frac{2t}{\bar{\mu}}\sum_{i=k_4-1}^{k}\sigma_i.\end{aligned}$$

Passing onto the limit when $k \to \infty$ in the latter relation, we obtain

$$\frac{2t}{\bar{\mu}}\sum_{i=k_4-1}^{\infty}\sigma_i \le \|x^{k_4} - \bar{x}\|^2 + \frac{2}{\hat{\mu}}\sum_{i=k_4-1}^{\infty}\delta_{\ell(i)},$$

which is a contradiction, due to (3.2) and (1.5). Hence, $\liminf_{k\to\infty} f_1(x^k) = f_1(\bar{x})$. Since $\{x^k\}$ is bounded, it must have an accumulation point x^∞ such that $f_1(x^\infty) = f_1(\bar{x})$. As $x^\infty \in S_2$, this means that $x^\infty \in S_1$.

Finally, suppose that (2.11) is satisfied an infinite number of times. Consider the subsequence of indices k for which (2.11) holds (we shall not specify it explicitly) and let $\ell(k)$ denote the associated index ℓ in (2.11). We have that

$$\max\{\sigma_k^{-1}\hat{\varepsilon}^{k,\ell(k)}\,,\,\sigma_k^{-1}\|\hat{g}^{\ell(k)}\|\} \le \beta_k, \quad \beta_k \to 0. \tag{3.11}$$

Taking any $x \in S_2$ and using Lemma 2.1(v), we have that

$$\sigma_k f_1(x) + f_2(x) \ge \sigma_k f_1(x^k) + f_2(x^k) + \langle \hat{g}^{\ell(k)}, x - x^k\rangle - \hat{\varepsilon}^{k,\ell(k)}.$$

Since $f_2(x) \le f_2(x^k)$ for any $x \in S_2$, we obtain

$$f_1(x) \ge f_1(x^k) + \langle \sigma_k^{-1}\hat{g}^{\ell(k)}, x - x^k\rangle - \sigma_k^{-1}\hat{\varepsilon}^{k,\ell(k)}. \tag{3.12}$$

Hence, passing onto the limit in (3.12) as $k \to \infty$ along some subsequence converging to x^∞ and taking into account (3.11), we conclude that $f_1(x) \ge f_1(x^\infty)$ for any $x \in S_2$. Therefore, $x^\infty \in S_1$ also in this case, which concludes the proof. □

It remains to consider the case of a finite number of serious steps in Algorithm 2.1. As already discussed above, this is rather unlikely to occur. Actually, as the next result shows, it can happen only if we hit an exact solution of the problem, which is generally an exceptional situation.

THEOREM 3.4. *Let f_1 and f_2 be convex functions such that f_1 is bounded below on $\Re^n$ and the solution set S_1 of problem (1.1) is nonempty and bounded.*

Suppose that $\bar{\mu} \ge \mu_\ell \ge \hat{\mu} > 0$ for all iterations ℓ, and that $\mu_{\ell+1} \ge \mu_\ell$ on consecutive null steps.

If the serious step descent test (2.10) is satisfied a finite number of times and we choose $\{\sigma_k\} \to 0$ and $\{\beta_k\} \to 0$ as $k \to \infty$, then there exists an iteration index k_0 such that $x^k = x^{k_0}$ for all $k \ge k_0$ and $x^{k_0} \in S_1$.

Proof. Since x^k is changed only when (2.10) holds, it is readily seen that $x^k = x^{k_0}$ for all $k \ge k_0$. By Proposition 3.2, we have that $x^{k_0} \in S_2$.

By Proposition 3.1, we have that for all $k \ge k_0$, σ_k is updated when (2.11) holds. For each k, let $\ell(k)$ denote the index ℓ for which (2.11) is satisfied. We have that

$$\max\{\sigma_k^{-1}\hat{\varepsilon}^{k,\ell(k)}\,,\,\sigma_k^{-1}\|\hat{g}^{\ell(k)}\|\} \le \beta_k, \quad \beta_k \to 0. \tag{3.13}$$

Taking any $x \in S_2$ and using Lemma 2.1(v), we have that

$$\sigma_k f_1(x) + f_2(x) \geq \sigma_k f_1(x^{k_0}) + f_2(x^{k_0}) + \langle \hat{g}^{\ell(k)}, x - x^{k_0} \rangle - \hat{\varepsilon}^{k,\ell(k)}.$$

Since $f_2(x) = f_2(x^{k_0})$ for any $x \in S_2$, we obtain

$$f_1(x) \geq f_1(x^{k_0}) + \langle \sigma_k^{-1} \hat{g}^{\ell(k)}, x - x^{k_0} \rangle - \sigma_k^{-1} \hat{\varepsilon}^{k,\ell(k)}. \tag{3.14}$$

Hence, passing onto the limit in (3.14) as $k \to \infty$ and taking into account (3.13), we conclude that $f_1(x) \geq f_1(x^{k_0})$ for any $x \in S_2$. Therefore, $x^{k_0} \in S_1$, as claimed. ∎

4. Computational experiments. In this section, we report on some numerical experiments for the problem of minimizing a piecewise quadratic convex function over a set defined by monotone linear complementarity constraints. Specifically, we consider the problem

$$\begin{array}{ll} \text{minimize} & \max_{j=1,\ldots,l}\{\langle A^j x, x\rangle + \langle b^j, x\rangle + c^j\} \\ \text{subject to} & Qx + q \geq 0,\ x \geq 0,\ \langle x, Qx + q\rangle \leq 0, \end{array} \tag{4.1}$$

where Q and A^j, $j = 1, \ldots, l$, are $n \times n$ positive semidefinite matrices; q and b^j, $j = 1, \ldots, l$, are vectors in $\Re^n$; and $c^j \in \Re$, $j = 1, \ldots, l$. This problem is converted to the setting of the paper by choosing

$$f_1(x) = \max_{j=1,\ldots,l}\{\langle A^j x, x\rangle + \langle b^j, x\rangle + c^j\},$$

$$f_2(x) = \sum_{i=1}^{n} \max\{-x_i, 0\} + \sum_{i=1}^{n} \max\{-(Qx+q)_i, 0\} + \max\{\langle Qx + q, x\rangle, 0\}.$$

The code is written in MATLAB, essentially by making modifications to a more-or-less standard unconstrained proximal bundle code. Runs are performed under MATLAB Version 7.0.0.19901 (R14). The test problems were constructed by first generating a feasible point $\bar{x}$ of (4.1), and then a function f_1 for which $\bar{x}$ is optimal. Details are presented next.

The process starts with defining an $n \times n$ positive semidefinite matrix Q of rank $r < n$, whose entries are uniformly distributed in the interval $[-5, 5]$. We next generate a point $\bar{x}$, with each coordinate having equal probability of being zero or being uniformly distributed in $[0, 5]$. Finally, we define $q = -Q\bar{x} + \bar{y}$, where a coordinate of $\bar{y}$ is zero if the corresponding coordinate of $\bar{x}$ is positive, while other coordinates of $\bar{y}$ have equal probability of being zero or uniformly generated from $[0, 5]$. As can be easily seen, such $\bar{x}$ is a feasible point for problem (4.1). It does not satisfy strict complementarity and, typically, is not an isolated feasible point (here, it is important that Q is a degenerate matrix). Obviously, $\bar{x}$ is an unconstrained minimizer of the function f_2, i.e., $\bar{x} \in S_2$.

Next, we construct a function f_1 such that $\bar{x}$ is a minimizer of f_1 over S_2. As the constraints in (4.1) do not satisfy a constraint qualification, we can only overestimate the tangent cone $T_{S_2}(\bar{x})$ to S_2 at $\bar{x}$, which gives underestimation of its dual:

$$(T_{S_2}(\bar{x}))^* \supset K = \operatorname{cone}\left(\{-e^i \mid \bar{x}_i = 0\} \cup \{-Q_i \mid \bar{y}_i = 0\} \cup \{q + (Q + Q^\top)\bar{x}\}\right), \tag{4.2}$$

where e^i is the ith element of the canonical basis of $\Re^n$, Q_i is the ith row of the matrix Q, and $\operatorname{cone}(X)$ stands for the conic hull of the set X in $\Re^n$.

We shall construct the needed function f_1 by defining antigradients of pieces of f_1 active at $\bar{x}$ as some elements belonging to the right-hand side of (4.2). This would guarantee the optimality condition

$$0 \in \partial f_1(\bar{x}) + (T_{S_2}(\bar{x}))^*, \tag{4.3}$$

even though the set $(T_{S_2}(\bar{x}))^*$ is not fully known. First, we generate symmetric $n \times n$ positive semidefinite matrices A^j, $j = 1, \ldots, l$, with random entries distributed in $[-5, 5]$. Choosing the number $l_0 \leq l$ of pieces of f_1 active at $\bar{x}$, we next define

$$b^j = -2A^j\bar{x} - u^j, \;\; u^j \in K, \quad j = 1, \ldots, l_0,$$

where elements u^j of K are generated by taking random coefficients in $[0, 1]$ for all vectors in the right-hand side of (4.2). The elements b^j, $j = l_0+1, \ldots, l$, are generated randomly.

It remains to make sure that the first l_0 pieces in the definition of f_1 are active at $\bar{x}$. To this end, we compute

$$\bar{c} = 5 + \max_{j=1,\ldots,l}\{\langle A^j\bar{x}, \bar{x}\rangle + \langle b^j, \bar{x}\rangle\},$$

and set

$$c^j = \bar{c} - \langle A^j\bar{x}, \bar{x}\rangle - \langle b^j, \bar{x}\rangle, \quad j = 1, \ldots, l_0,$$

$$c^j = 0, \quad j = l_0 + 1, \ldots, l.$$

It can be seen that for the point $\bar{x}$, the maximum in the definition of f_1 is attained for indices $j = 1, \ldots, l_0$, and that $f_1(\bar{x}) = \bar{c}$. By the previous constructions, we have that (4.3) holds, and thus $\bar{x}$ is a solution of (4.1). Furthermore, the optimal value of this problem is $\bar{c}$.

Our code is a slightly simplified version of Algorithm 2.1, in particular in the following two details. First, instead of an aggregation technique to control the bundle, we use simple selection of active pieces; i.e., after every iteration we discard those cutting planes which correspond to zero multipliers in the solution of the QP subproblem. Second, we ignore the safeguard (2.11) that detects when the current point x^k is almost a minimizer of F_{σ_k}, and so σ_k needs to be reduced (even if a serious step has not yet been constructed). As already discussed above, since at no iteration F_{σ_k} is being minimized to any specific precision, this situation is unlikely to occur prematurely if σ_k is updated after each serious step. This intuition was confirmed by our experiments. We observed that optimality is achieved only asymptotically, and so the standard bundle stopping test,

$$\hat{\varepsilon}^{k,\ell} \leq t_1 \quad \text{and} \quad \|\hat{g}^\ell\|^2 \leq t_2, \tag{4.4}$$

can be used without any harm. But, of course, one has to be aware that this stopping test cannot be fully reliable in our setting. In our experiments, we set $t_1 = 10^{-2}$ and $t_2 = 10^{-4}$, as it is often difficult to get more precision from a nondifferentiable optimization code in a simple MATLAB implementation. We start with $x^0 = (2, \ldots, 2)$, and set $m = 10^{-1}$ in the descent test (2.10). The proximal parameter μ_ℓ in (2.5) is changed at serious steps only by the safeguarded version of the *reversal quasi-Newton* scalar update; see [3, section 9.3.3]. More precisely,

$$\mu_{k+1} = \min\left\{c_1, \max\{\tilde{\mu}_{k+1}, c_2\}\right\},$$

TABLE 4.1
Summary of numerical experiments.

	Convergence (out of 20)		"Failures" (out of 20)	
$n = 5$	18 cases	38.3 oracle calls	2 cases	100 oracle calls
$\operatorname{rank} Q = 4$	$R_1 = 2.2 * 10^{-5}$	$R_2 = 1.2 * 10^{-5}$	$R_1 = 4.1 * 10^{-4}$	$R_2 = 2.2 * 10^{-4}$
$n = 5$	19 cases	32.2 oracle calls	1 case	100 oracle calls
$\operatorname{rank} Q = 2$	$R_1 = 6.2 * 10^{-4}$	$R_2 = 8.1 * 10^{-5}$	$R_1 = 3.2 * 10^{-4}$	$R_2 = 1.1 * 10^{-5}$
$n = 10$	12 cases	109.5 oracle calls	8 cases	200 oracle calls
$\operatorname{rank} Q = 8$	$R_1 = 2.8 * 10^{-5}$	$R_2 = 1.4 * 10^{-5}$	$R_1 = 2.2 * 10^{-4}$	$R_2 = 3.3 * 10^{-5}$
$n = 10$	14 cases	89.9 oracle calls	6 cases	200 oracle calls
$\operatorname{rank} Q = 5$	$R_1 = 3.7 * 10^{-4}$	$R_2 = 4.2 * 10^{-5}$	$R_1 = 7.2 * 10^{-4}$	$R_2 = 5.3 * 10^{-4}$
$n = 10$	16 cases	60.6 oracle calls	4 cases	200 oracle calls
$\operatorname{rank} Q = 2$	$R_1 = 9.8 * 10^{-4}$	$R_2 = 5.4 * 10^{-6}$	$R_1 = 2 * 10^{-3}$	$R_2 = 3.1 * 10^{-6}$

where $\tilde{\mu}_{k+1}$ is the value prescribed by [3, section 9.3.3], and $c_1 = 10$, $c_2 = 10^{-1}$. Subproblems (2.5) are solved by applying the MATLAB QP routine `qp.m` to the dual formulation of (2.5).

For updating the weight parameter, we use the simple generic choice

$$\sigma_k = \sigma_0/(k+1). \tag{4.5}$$

For lower dimensions (say, $n = 5$), when fewer iterations are expected, we start with $\sigma_0 = 10$. For higher dimensions (say, $n = 10$), when more iterations are typically needed, we start with $\sigma_0 = 20$. We have experimented with other possibilities, like keeping σ_k fixed over some number of serious steps, as well as with some more involved strategies. While improvements are possible, at this time we did not find them significant enough, with respect to the simple (4.5), to warrant their description. Generally, our experiments are intended for merely verifying that the proposed algorithm works and in a reasonable way. We did not spend much time on tuning various parameters to obtain an efficient code. To achieve this, as a first step, one should dispense with the generic `qp.m` MATLAB QP solver, which is known to be problematic (and was observed to be a limitation for our experiments as well). Instead, some good specialized solver (e.g., based on [16, 10]) has to be employed.

Our results are summarized in Table 4.1. We report on problems of dimensions $n = 5$ and $n = 10$, with various degrees of degeneracy of matrix Q, i.e., for different values of rank $Q = r < n$. Note that the number of constraints in (4.1) is $2n + 1$. For each pair of n and r the results are averaged over 20 runs. For all the problems, $l = 5$ and $l_0 = 3$; i.e., f_1 is defined by a maximum of five quadratic functions, with three of them being active at $\bar{x}$. We found that moderate variations of l and l_0 do not change much of the average behavior of the method. We thus keep them fixed in our report, to simplify the table. We report the number of times (out of 20 runs) that convergence had been declared according to the stopping rule (4.4), and the number of times this did not happen (declared as a failure) after a maximum allowed number of calls to the oracle (i.e., evaluations of f_1, f_2, and of their subgradients). In the case of $n = 5$, the maximal number of oracle calls is 100, and in the case of $n = 10$, it is 200. For both outcomes, we report the average number of oracle calls at termination (which is redundant in the case of failures) and the average of the relative accuracies achieved with respect to the optimal value $\bar{c}$ of problem (4.1) and of the (in)feasibility measure (the optimal value of f_1, which is zero). Specifically, in Table 4.1, we denote

$$R_1 = |(f_1(x^k) - \bar{c})/(f_1(x^0) - \bar{c})|, \quad R_2 = f_2(x^k)/f_2(x^0),$$

where x^k is the last serious iterate before termination.

We note that even in the cases of "failure" the method actually makes reasonable progress to the solution of the problem, as evidenced by the values of R_1 and R_2 in Table 4.1. We believe that a more careful implementation, including a better QP solver, should improve the accuracy (especially in higher dimensions) and eliminate "failures" of nonsatisfaction of the stopping rule (4.4). To this end, we observed that in most cases, the values of R_1 and R_2 (which measure actual proximity to solution) are very satisfactory, and close to those reported at termination, well before the stopping rule (4.4) is activated or the maximum number of oracle calls is reached. To some extent, this is quite normal for bundle methods, as they have to generate enough information in order to "recognize" optimality of the current point. For example, even starting with $x^0 = \bar{x}$, about 20 oracle calls were required in our experiments before the method stopped according to (4.4). But in some cases, even when the values in the stopping test (4.4) are already quite close to the required tolerances relatively early, it proves difficult to get more precision and satisfy (4.4). As already stated, we believe that the QP solver used in our implementation is likely the main reason we are not able to progress to higher accuracy with respect to stopping test (4.4). In any case, we believe that Table 4.1 shows reasonable behavior of Algorithm 2.1, even in our simple implementation, on problems with complementarity constraints (which is a difficult class of problems). Finally, we observe that degeneracy of the matrix Q defining complementarity constraints is not a problem for our algorithm at all. Actually, problems with higher degeneracy of Q appear even easier to solve. We conjecture that the reason for this is that, in the case of high degeneracy of Q, the feasible set of (4.1) is larger and the function f_2 is easier to minimize. This may make the overall problem easier to deal with in our setting.

5. Concluding remarks. We have presented a bundle method for solving a nonsmooth convex bilevel problem, which includes standard nonsmooth constrained optimization as a special case. The attractive feature of the method is that it is completely explicit. In particular, it does not require an iterative solution (not even approximate) of any optimization subproblems with general structure. Moreover, in the case of optimization, no constraint qualifications are required for convergence.

Acknowledgment. The author thanks Claudia Sagastizábal for her MATLAB unconstrained bundle code, which served as the basis for the implementation of Algorithm 2.1.

A UNILATERALLY CONSTRAINED QUADRATIC MINIMIZATION WITH ADAPTIVE FINITE ELEMENTS*

KUNIBERT G. SIEBERT† AND ANDREAS VEESER‡

Abstract. We consider obstacle problems where a quadratic functional associated with the Laplacian is minimized in the set of functions above a possibly discontinuous and thin but piecewise affine obstacle. In order to approximate minimum point and value, we propose an adaptive algorithm that relies on minima with respect to admissible linear finite element functions and on an a posteriori estimator for the error in the minimum value. It is proven that the generated sequence of approximate minima converges to the exact one. Furthermore, our numerical results in two and three dimensions indicate that the convergence rate with respect to the number of degrees of freedom is optimal in that it coincides with the one of nonlinear or adaptive approximation.

Key words. unilaterally constrained minimization, obstacle problems, contact problems, thin obstacles, adaptive finite elements, conforming methods, a posteriori error estimates, convergence of adaptive algorithms, optimal convergence rate, full contact

1. Introduction and outline.

The solutions of infinite-dimensional minimization problems are in general not computable. In order to get computable approximations, one usually replaces the infinite-dimensional feasible set by a finite-dimensional, or discrete, one. For an important class of minimizations, this can be done with the help of finite elements. Of course, the error of such an approximate minimum is then affected by the choice of the discrete feasible set. There are two ways to decrease the error. In view of the fact that the true minima are unknown, classical or nonadaptive methods enlarge the discrete feasible sets in such a way that any element of the infinite-dimensional feasible set is approximated by elements from discrete feasible sets; see, e.g., [7]. In contrast, adaptive methods aim only at the approximation of solutions and enlarge the discrete feasible sets with the help of information extracted from data and previous approximate minima; see, e.g., [1, 2, 26]. In many examples, in particular in the presence of singularities, adaptive methods lead to a much more efficient use of the computational resources.

The well-known convergence proofs of the classical finite element methods do not apply to the adaptive framework. In the case of the infinite-dimensional quadratic minimizations associated with linear elliptic boundary value problems, there has been recent progress in the analysis of adaptive finite element methods. We mention the convergence results of Dörfler [9] and Morin, Nochetto, and Siebert [15, 16, 17] that are based upon a result which, under certain conditions, guarantees a strict error reduction in one adaptive iteration. Combining this strict error reduction result with a coarsening procedure, Binev, Dahmen, and DeVore [5] ensured that the finite ele-

ment solutions are near-best approximations, while Stevenson [23] established optimal convergence rates in terms of the number of the degrees of freedom (DOFs) without invoking coarsening.

The sole convergence of adaptive finite elements without coarsening has been established also for a nonquadratic but convex minimization by Veeser [25] and an "equality-constrained" quadratic minimization by Bänsch, Morin, and Nochetto [3]. Similarly to Dahlke, Hochmuth, and Urban [8] in the context of wavelets, the latter is based upon an adaptively approximated Uzawa iteration, and thus the iterates are not Galerkin approximations to the original problem.

This article concerns adaptive (Ritz–)Galerkin approximations with finite elements and their convergence for the following infinite-dimensional "inequality-constrained" quadratic minimization. Let $\Omega \subset \mathbb{R}^d$, $d = 2, 3$, be a polyhedral Lipschitz domain and $f \in L_2(\Omega)$ a load term. The lower obstacle is given by a finite sequence of pairs $\{(K_i, \psi_i)\}_{i=1}^n$ such that

- each $K_i \subset \Omega$ is a nondegenerate closed m-simplex, $m \in \{d-1, d\}$,
- their interiors (with respect to the induced topology) are pairwise disjoint,
- each ψ_i is an affine function over K_i satisfying $\psi_i \le 0$ on $\partial\Omega \cap K_i$.

Let u be the typically unknown minimizer of the "inhomogeneous Dirichlet energy"

$$I[v] := \int_\Omega \tfrac{1}{2}|\nabla v|^2 - fv \tag{1.1}$$

in the set

$$\mathcal{F} := \{v \in H_0^1(\Omega) \mid v \ge \psi_i \text{ on } K_i \text{ for } i = 1, \dots, n\}, \tag{1.2}$$

which is nonempty, convex, and closed thanks to the trace theorem. The minimizer u exists, is unique, and is characterized by the variational inequality

$$\forall\, v \in \mathcal{F} \quad \langle \nabla u, \nabla(v-u)\rangle \ge \langle f, v-u\rangle\,, \tag{1.3}$$

where $\langle\cdot,\cdot\rangle$ indicates the L_2-scalar product; see, e.g., [12, Chapter II, Theorem 2.1].

In order to approximate such minimum computionally, in section 2 we design an adaptive algorithm with continuous linear finite elements. The algorithm is based upon an iteration of the following main steps:

$$\text{minimize} \to \text{estimate} \to \text{select} \to \text{include}, \tag{1.4}$$

that is, determine the minimum u_k of I in the current finite element subset $\mathcal{F}_k$ of $\mathcal{F}$ and estimate its error to test if it already meets a prescribed tolerance; if not, select new basis functions that allow for the inclusion of new directions in the next discrete feasible set $\mathcal{F}_{k+1}$.

The steps "estimate" and "select" involve an a posteriori estimator $\mathcal{E}_k$ for the error in the energy minimum

$$I[u_k] - I[u] \ge 0. \tag{1.5}$$

This is a quantity that is, in terms of the approximate minimizer u_k and data, computable and splits into contributions associated with possibly new basis functions. Although some part of the estimator $\mathcal{E}_k$ is related to the heuristical one of Kornhuber [13], it is new and differs from those in [4, 11, 18, 19, 24] in various aspects, e.g., error notion, accumulation of indicators, and range of covered obstacles.

Its derivation in section 3 is based upon the quantity

$$\sup\{\langle -\mathcal{D}_k, \varphi\rangle \mid \varphi \in H^1_0(\Omega) \text{ such that } \|\nabla\varphi\| \le 1,\ u_k + \varphi \in \mathcal{F}\}, \tag{1.6}$$

where $\mathcal{D}_k \in H^{-1}(\Omega) := H^1_0(\Omega)^*$ denotes the derivative of I (or the residual) in the current approximate minimizer u_k,

$$\forall\, \varphi \in H^1_0(\Omega) \quad \langle \mathcal{D}_k, \varphi\rangle = \langle \nabla u_k, \nabla\varphi\rangle - \langle f, \varphi\rangle\,, \tag{1.7}$$

and $\langle\cdot,\cdot\rangle$ stands for the duality pairing of $H^{-1}(\Omega)$ and $H^1_0(\Omega)$ or the L_2-scalar product. Although (1.6) is used in finite-dimensional constrained optimization as criticality measure, it has not yet been used to derive a posteriori error estimators. Further important ingredients of the derivation are the concept of full contact introduced in [11], an adaptation of the projection operators on stars in [17], and the technique for lower bounds from [25].

In section 4 we prove that the sequence of approximate minima $\{u_k\}_k$ produced by the algorithm converges to the true minimum u in the following sense:

$$I[u_k] \to I[u] \qquad \text{and} \qquad u_k \to u \quad \text{in } H^1(\Omega). \tag{1.8}$$

The described algorithm has been implemented within the framework of the finite element toolbox ALBERTA [20, 21]. Our numerical results in section 5 corroborate and complement the theoretical results of sections 3 and 4. In particular, they illustrate properties of the a posteriori error estimator $\mathcal{E}_k$ and address the convergence speed in (1.8) with respect to the number of DOFs, a key ingredient for the overall complexity of the algorithm. In particular for a singular solution, the observed convergence rate is superior to nonadaptive refinement and coincides with the one of nonlinear or adaptive approximation where the exact solution u is supposed to be known, the obstacle is disregarded, and the (Besov) regularity of u essentially determines the convergence rate.

2. Adaptive minimization with linear finite elements. In this section we introduce the adaptive algorithm for the minimization of I in $\mathcal{F}$ with the help of linear finite elements. Notice that, since finite element functions are defined over meshes, the sequence of approximate minima $\{u_k\}_k$ has to be accompanied by a corresponding sequence of meshes $\{\mathcal{T}_k\}_k$. We start with the initialization of iteration (1.4), then present its single steps, and conclude with some elementary properties.

We denote by $L_2(\Omega)$ the set of measurable functions that are square integrable in Ω with respect to the d-dimensional Lebesgue measure $\mathcal{L}^d$, by $H^1_0(\Omega)$ the $L_2(\Omega)$-functions with first weak derivatives in $L_2(\Omega)$ and zero trace on $\partial\Omega$, and by $H^{-1}(\Omega)$ the dual space of $H^1_0(\Omega)$. For any subset $\omega \subset \Omega$ with nonempty interior, we denote the $L_2(\omega)$-norm by $\|\cdot\|_\omega$ and set $\|\cdot\| = \|\cdot\|_\Omega$.

2.1. Initialization. In order to start and execute iteration (1.4), three inputs are needed:

$$\mathsf{tol} \ge 0, \quad \theta \in (0,1), \quad \text{and } \mathcal{T}_0.$$

The first quantity tol is used as tolerance in the stopping test of step "estimate." If $\mathsf{tol} = 0$, then the algorithm stops only when the current approximate minimizer is the exact one.

The second quantity θ is a parameter in step "select" that affects the number of iterations and the way new DOFs are introduced, two ingredients for the complexity of

the algorithm. On one hand, the closer θ to 1, the lower the number of iterations (1.4). On the other hand, the closer θ to 0, the more selective new DOFs will be introduced. In all our numerical experiments in section 5, we have used the compromise $\theta = 0.3$. See also section 2.6 below for an interpretation of this parameter.

The last quantity $\mathcal{T}_0$ is the initial mesh, i.e., a decomposition of Ω into closed triangles (if $d = 2$) or closed tetrahedrons (if $d = 3$) such that

- $\overline{\Omega} = \cup_{T\in\mathcal{T}_0} T$ and
- the intersection $T_1 \cap T_2$ of each pair $T_1, T_2 \in \mathcal{T}_0$ is empty or a common m-subsimplex, $m = 0, \ldots, d$.

Moreover, we suppose that $\mathcal{T}_0$ is subordinated to $\{K_i\}_{i=1}^n$ in the following sense:

$$\text{each } K_i \text{ is a union of (sub)simplices from } \mathcal{T}_0. \tag{2.1}$$

The successive meshes, which are generated in step "include," inherit this property. This property is crucial to guarantee that the discrete feasible sets are nested and subsets of the nondiscrete one $\mathcal{F}$.

Denoting by $\sigma(T)$ the ratio of the minimum diameter of a ball containing T over the maximum diameter of a ball contained in T, the quantity

$$\sigma_0 := \max_{T\in\mathcal{T}_0} \sigma(T) \in [1, \infty) \tag{2.2}$$

is called the shape regularity of $\mathcal{T}_0$. It affects the decisions that are taken in steps "estimate" and "select." In particular, for a fixed tolerance tol, the stopping test may get less stringent if σ_0 gets bigger.

2.2. Minimize with respect to admissible finite element functions. Suppose that the mesh $\mathcal{T}_k$ has been constructed. In order to define the corresponding finite element minimizer u_k, let

$$V_k := \{v \in C(\overline{\Omega}) \mid \forall\, T \in \mathcal{T}_k \ v_{|T} \text{ is affine}\}$$

be the space of linear finite elements over $\mathcal{T}_k$ and define the discrete feasible set in step k as

$$\mathcal{F}_k := \big\{v \in V_k \mid v(z) = 0 \text{ for } z \in \mathcal{N}_k \cap \partial\Omega \text{ and } v(z) \geq \psi^*(z) \text{ for } z \in \mathcal{N}_k\big\}, \tag{2.3}$$

where $\mathcal{N}_k$ indicates the nodes (or vertices) of $\mathcal{T}_k$ and

$$\psi^*(x) := \max\big\{\psi_i(x) \mid i \in \{1, \ldots, n\} \text{ such that } K_i \ni x\big\}, \qquad x \in \overline{\Omega}, \tag{2.4}$$

with the convention $\max \emptyset = -\infty$. Like $\mathcal{F}$, the set $\mathcal{F}_k$ is closed, convex, and nonempty due to $\psi^* \leq 0$ on $\partial\Omega$. Consequently, I has an unique minimizer u_k in $\mathcal{F}_k$ that is characterized by the discrete variational inequality

$$\forall\, v \in \mathcal{F}_k \quad \langle \nabla u_k, \nabla(v - u_k)\rangle \geq \langle f, v - u_k\rangle\,. \tag{2.5}$$

The approximate minimizer u_k can be computed, e.g., by the SOR method with projection analyzed by Elliott [10] or by the multigrid method of Kornhuber [14]. These and other iterative solvers can be conveniently started with the finite element minimizer u_{k-1} of the previous step.

FIG. 1. *Example of a test function φ_S associated with an interior side S (left) and finite element star ω_z with skeleton γ_z (indicated by dashed lines) for $d = 2$ (right).*

2.3. Estimate error in minimum. In order to estimate the error (1.5), we will use hierarchical indicators related to the underlying operator and indicators related to the load term f. We shall omit the iteration counter k for these indicators and similar quantities that are parametrized by an index set depending on k.

We first introduce the hierarchical indicators. Let $\mathcal{S}_k$ denote the set of interior sides (edges or faces in two or three dimensions, respectively) of $\mathcal{T}_k$. With each such side $S \in \mathcal{S}_k$, we associate a test function $\varphi_S \notin V_k$ with the following properties:

- the support of φ_S is contained in $\omega_S := \{T \in \mathcal{T}_k \mid T \supset S\}$;
- φ_S is continuous and piecewise affine over a finer mesh in ω_S that may be generated in step "include" and contains a node x_S in the interior of S (which will be specified in step "include" more precisely);
- φ_S is positive, attains its maximum in x_S, and is normalized: $\|\nabla\varphi_S\| = 1$.

A construction of φ_S is given in the beginning of section 5; see Figure 1 (left) for an example in $d = 2$.

Given φ_S, we define the computable quantities

$$\rho_S := \langle -\mathcal{D}_k, \varphi_S \rangle \qquad \text{and} \qquad d_S := \frac{u_k(x_S) - \psi^*(x_S)}{\varphi_S(x_S)} \geq 0. \tag{2.6}$$

If $\rho_S > 0$, then φ_S is a descent direction, which points upwards, and thus any correction of u_k in the direction of φ_S is admissible. If $\rho_S < 0$, then $-\varphi_S$ is a downwards correcting descent direction. Hence a correction in this direction may be not admissible. The quantity d_S measures the maximal available space for an admissible correction in the direction of $-\varphi_S$. In other words,

$$u_k + \beta\varphi_S \in \mathcal{F} \qquad \Longleftrightarrow \qquad \beta \geq -d_S. \tag{2.7}$$

If we add the test function φ_S to V_k, the corresponding reduction of the approximate minimum value is at least

$$\xi_S := I[u_k] - I[u_k + \alpha_S\varphi_S] = \alpha_S\rho_S - \tfrac{1}{2}\alpha_S^2, \tag{2.8}$$

where α_S is the solution of a one-dimensional constrained quadratic minimization:

$$I[u_k + \alpha_S\varphi_S] = \min_{\beta \geq -d_S} I[u_k + \beta\varphi_S]. \tag{2.9}$$

The *unconstrained* minimization $\min_{\beta\in\mathbb{R}} I[u_k + \beta\varphi_S]$ has the solution $\beta = \rho_S$. Consequently, if $\rho_S \geq -d_S$, then $\alpha_S = \rho_S$ and $\xi_S = \frac{1}{2}\rho_S^2$; otherwise, there holds $\alpha_S = -d_S$ and $\xi_S = d_S|\rho_S| - \frac{1}{2}d_S^2 > \frac{1}{2}d_S|\rho_S|$; see also Figure 2. Note that in the first case ξ_S depends on $|\rho_S|$ in a quadratic manner, while in the second one essentially in a linear

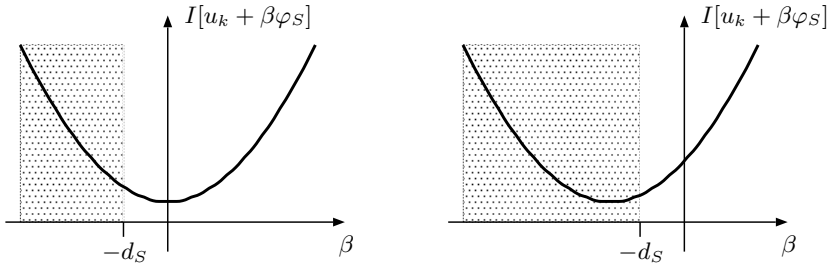

FIG. 2. *The two cases of "unconstrained" (left) and "constrained" (right) new direction.*

manner. The relationship between the reduction ξ_S and the pair (ρ_S, d_S) suggests distinguishing "unconstrained" and "constrained" sides:

$$S \in \mathcal{S}_k^2 \iff \rho_S \geq -d_S \qquad \text{and} \qquad S \in \mathcal{S}_k^1 \iff \rho_S < -d_S \tag{2.10a}$$

such that

$$\xi_S = \tfrac{1}{2}\rho_S^2, \quad S \in \mathcal{S}_k^2, \qquad \text{and} \qquad \xi_S > \tfrac{1}{2} d_S|\rho_S|, \quad S \in \mathcal{S}_k^1. \tag{2.10b}$$

In light of (2.10), we associate ρ_S^2 with an unconstrained side $S \in \mathcal{S}_k^2$ and $d_S|\rho_S|$ with a constrained one $S \in \mathcal{S}_k^1$.

Next, we introduce the notion of full contact and then the indicators related to the load term f. For each node $z \in \mathcal{N}_k$, let $\omega_z := \bigcup\{T \in \mathcal{T}_k \,:\, T \ni z\}$ be the star around z and let $\gamma_z = \bigcup\{S \in \mathcal{S}_k \,:\, S \ni z\}$ be the skeleton of the star ω_z; see Figure 1 (right). Moreover, denote by j_k the normal component of the jumps in ∇u_k across interior sides. More precisely, if $S \in \mathcal{S}_k$, $\omega_S = T^- \cup T^+$ with $T^-, T^+ \in \mathcal{T}_k$, and n is the normal of S pointing from T^- to T^+, then

$$j_{k|S} = \big(\nabla u_{k|T^+} - \nabla u_{k|T^-}\big) \cdot n.$$

The set of full contact nodes is defined as

$$\mathcal{N}_k^0 := \big\{z \in \mathcal{N}_k \mid u_k = \psi_* \text{ in } \omega_z \setminus \partial\omega_z,\ f \leq 0 \text{ in } \omega_z, \text{ and } j_k \leq 0 \text{ on } \gamma_z\big\}, \tag{2.11}$$

where

$$\psi_*(x) := \min\big\{\psi_i(x) \mid i \in \{1, \ldots, n\} \text{ such that } K_i \ni x\big\}, \qquad x \in \overline{\Omega}, \tag{2.12}$$

with the convention $\min \emptyset = +\infty$. Thus u_k is in full contact around a node if it is in contact and additional conditions hold; these additional conditions are necessary for $u_k = u$ around that node. The full contact nodes in turn determine the full contact elements $\mathcal{T}_k^0 := \{T \in \mathcal{T}_k \mid \mathcal{N}_k \cap T \subset \mathcal{N}_k^0\}$ and their complement

$$\mathcal{T}_k^+ := \mathcal{T}_k \setminus \mathcal{T}_k^0. \tag{2.13}$$

Only with "nonfull-contact" elements $T \in \mathcal{T}_k^+$ do we associate indicators $\int_T h_k^2 |f|^2$, where h_k denotes the piecewise constant function with

$$h_{k|T} = \mathcal{L}^d(T)^{1/d}, \qquad T \in \mathcal{T}_k.$$

We finally define the estimator as

$$\mathcal{E}_k := \left(\sum_{S \in \mathcal{S}_k^2} \rho_S^2 \right)^{1/2} + \sum_{S \in \mathcal{S}_k^1} d_S |\rho_S| + \left(\sum_{T \in \mathcal{T}_k^+} \int_T h_k^2 |f|^2 \right)^{1/2}, \tag{2.14}$$

and we stop the algorithm if there holds

$$\mathcal{E}_k \leq \mathsf{tol}. \tag{2.15}$$

The reliability, stability, and efficiency properties of this stopping test are investigated theoretically in sections 3.2 and 3.3, as well as practically in section 5.2 and also in section 5.3.

2.4. Select effective new descent directions. If the stopping test (2.15) is not satisfied, we have to enlarge the discrete feasible set. To this end, we select certain sides for which their corresponding test functions φ_S will be included in V_{k+1}. Denoting the hierarchical part of the estimator by

$$\eta_k := \left(\sum_{S \in \mathcal{S}_k^2} \rho_S^2 \right)^{1/2} + \sum_{S \in \mathcal{S}_k^1} d_S |\rho_S|, \tag{2.16}$$

we choose $\hat{\mathcal{S}}_k \subset \mathcal{S}_k$ such that

$$\left(\sum_{S \in \hat{\mathcal{S}}_k \cap \mathcal{S}_k^2} \rho_S^2 \right)^{1/2} + \sum_{S \in \hat{\mathcal{S}}_k \cap \mathcal{S}_k^1} d_S |\rho_S| \geq \theta \eta_k. \tag{2.17a}$$

Moreover, regarding the third term of the estimator $\mathcal{E}_k$, we define

$$\hat{\mathcal{T}}_k := \left\{ T \in \mathcal{T}_k^+ \mid \int_T h_k^2 |f|^2 \geq \frac{\eta_k^2}{N_k^+} \right\}, \tag{2.17b}$$

where $N_k^+ := \#\mathcal{T}_k^+$ denotes the number of nonfull-contact elements of $\mathcal{T}_k$. In section 4 we will prove that the properties of the estimator (2.14) in combination with the selection criterion (2.17) and the refinement rule (2.18) below imply convergence. Notice that, since $\theta < 1$ in (2.17a), the set $\hat{\mathcal{S}}_k$ of "marked" sides is typically a proper subset of $\mathcal{S}_k$ and not unique. In order to keep the dimension of the next finite element space V_{k+1} low, one should choose $\hat{\mathcal{S}}_k$ such that $\#\hat{\mathcal{S}}_k$ is as small as possible by collecting the biggest indicators. Following an idea of Dörfler [9], such a minimal choice can be approximated with an algorithm that is easy to implement within the data structures of adaptive meshes, has complexity $\#\mathcal{S}_k$, and thus avoids a sort of complexity $\#\mathcal{S}_k \ln \#\mathcal{S}_k$.

2.5. Include selected descent directions. We refine $\mathcal{T}_k$ into $\mathcal{T}_{k+1}$ by bisecting selected elements appropriately. More precisely, given the selected sides $\hat{\mathcal{S}}_k$ and the selected elements $\hat{\mathcal{T}}_k$ from the previous step, we apply the following refinement rule:

(2.18) if an element $T \in \mathcal{T}_k$ belongs to $\hat{\mathcal{T}}_k$ or one of its side to $\hat{\mathcal{S}}_k$, then create by bisection all its children of 2nd (if $d = 2$) or 5th (if $d = 3$) generation.

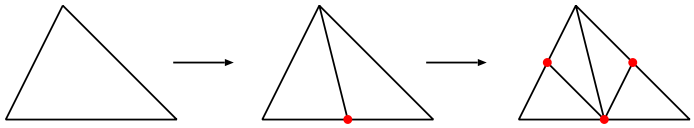

FIG. 3. *A triangle with its children of first and second generation using bisection.*

In order to ensure that the resulting triangulation is conforming, it may happen that additional elements have to be bisected. The required bisections (2.18) can be realized, e.g., with the help of the recursive bisection algorithms described in [21, section 1.1.1]. The refinement by bisection has the following properties:

$$\mathcal{T}_{k+1} \text{ is conforming and its shape regularity is bounded in terms of } \sigma_0, \tag{2.19a}$$

$$\forall\, T \in \mathcal{T}_k \quad h_{k+1|T} < h_{k|T} \implies h_{k+1|T} \le \tfrac{1}{2}\, h_{k|T}, \tag{2.19b}$$

$$V_k \subset V_{k+1}. \tag{2.19c}$$

In two dimensions, the refinement rule (2.18) ensures that for each selected edge $S \in \hat{\mathcal{S}}_k$ the midpoint x_S belongs to the nodes of $\mathcal{T}_{k+1}$; see Figure 3. Now consider a marked face $S \in \hat{\mathcal{S}}_k$ in three dimensions. The refinement rule (2.18) here guarantees that at least the edge which is created first inside this face is also bisected. This generates the vertex $x_S = \frac{1}{4}(a_0 + a_1) + \frac{1}{2}a_2$ as a node of $\mathcal{T}_{k+1}$, where a_0, a_1, a_2 is an appropriate enumeration of the vertices of that face. Hence in two and three dimensions, for each marked side, the associated test function φ_S is in the new finite element space:

$$\forall\, S \in \hat{\mathcal{S}}_k \quad \varphi_S \in V_{k+1}. \tag{2.20}$$

The refinement rule (2.18) enters the convergence proof through the properties (2.19) and (2.20).

Now a new mesh $\mathcal{T}_{k+1}$ has been constructed, and we can increment k and repeat the iteration starting with step "minimize."

2.6. A line search interpretation. We now interpret the described algorithm as a line search method. This interpretation also serves as a guideline for the convergence proof in the following sections.

The algorithm defines a finite or infinite sequence $\{u_k\}_k$ of approximate minimizers, accompanied in particular by sequences of triangulations $\{\mathcal{T}_k\}_k$, of finite element spaces $\{V_k\}_k$, and discrete feasible sets $\{\mathcal{F}_k\}_k$.

In view of (2.1), (2.19c), (2.3), and (2.4), there holds the identity

$$\mathcal{F}_k = \{v \in V_k \mid v = 0 \text{ on } \partial\Omega \text{ and } v \ge \psi_i \text{ on } K_i \text{ for } i = 1, \dots, n\},$$

which in turn yields that the discrete feasible sets are nested and the minimization in each iteration is an inner approximation of (or a conforming method for) the original minimization:

$$\mathcal{F}_k \subset \mathcal{F}_{k+1} \subset \mathcal{F}. \tag{2.21}$$

This implies

$$I[u_k] \ge I[u_{k+1}] \ge I[u]. \tag{2.22}$$

In descent methods, the convergence is usually ensured with the help of a suitable strengthening of the strict decrease $I[u_{k+1}] < I[u_k]$. Here such strict decrease typically holds (see Remark 4.1), but, although there holds $\mathcal{F}_{k+1} \neq \mathcal{F}_k$ whenever $\mathcal{E}_k > 0$, there may be exceptions: for example, if the obstacle is negative and the load term f is $L_2(\Omega)$-orthogonal to the new finite element space V_{k+1} and thus not visible in (2.5), then $I[u_{k+1}] = I[u_k]$; see also [15]. This may happen for any refinement rule that generates a fixed finite number of subelements. We therefore decided to deal with the presence of degenerate iterations with $I[u_{k+1}] = I[u_k]$.

The strengthening of $I[u_{k+1}] < I[u_k]$ in line search methods consists of conditions on the search direction (e.g., the angle condition) and the step length (e.g., Armijo–Goldstein–Wolfe conditions) which imply that the criticality measure for u_k is bounded in terms of the decrease $I[u_{k+1}] - I[u_k]$. Here the derivation of such a bound, as well as the determination of a computable search direction, is complicated by the fact that the derivative $\mathcal{D}_k$ is an infinite-dimensional object and by the presence of the aforementioned degenerate iterations.

In step "estimate," the hierarchical part η_k of the estimator investigates the restriction of $\mathcal{D}_k$ to the enlarged finite element space $\tilde{V}_k := V_k \cup \operatorname{span}\{\varphi_S \mid S \in \mathcal{S}_k\}$, while the nonhierarchical part in particular checks for components of f that are orthogonal to $\tilde{V}_k$; the latter happens only in the nonfull-contact region, which thus plays the role of an active or working set for the nonhierarchical part. The full estimator $\mathcal{E}_k$ bounds the noncomputable criticality measure (1.6); see Proposition 3.2 below.

Steps "select" and "refine" then essentially produce the next finite element space V_{k+1}. The construction is such that the following hold:

- The hierarchical part η_k of the estimator can be shown to be controlled by the energy decrease $I[u_{k+1}] - I[u_k]$; see step 2 in the proof of Theorem 4.1 below. To this end, condition (2.17a), which involves the input parameter θ, replaces the angle condition, with the difference that not $\mathcal{D}_k$ on $H^1_0(\Omega)$ but rather its restriction to $\tilde{V}_k \cap H^1_0(\Omega)$ is taken as a reference.
- The most promising directions of $\tilde{V}_k$ are contained in V_{k+1}.
- The active components of f that are orthogonal to $\tilde{V}_k$ will eventually be resolved.

The fact that u_{k+1} is then the (Ritz–)Galerkin approximation in $\mathcal{F}_{k+1}$ implies that the step length is optimal and the search direction is given by the restriction of $-\mathcal{D}_k$ to $V_{k+1} \cap H^1_0(\Omega)$ and the Lagrange multiplier associated with u_{k+1}. More precisely, the search direction is the Riesz representation of their sum in $V_{k+1} \cap H^1_0(\Omega)$ endowed with the $H^1_0(\Omega)$-scalar product $(v, w) \mapsto \langle \nabla v, \nabla w \rangle$. Furthermore, if the Lagrange multipliers of u_{k+1} and u_k are equal, the search direction corresponding to $u_{k+1} - u_k$ is conjugate with respect to the $H^1_0(\Omega)$-scalar product to all previous search directions.

Thus, iteration (1.4) may be seen as a line search method in which the search direction is adaptively determined with the help of an a posteriori error estimator and the step length is optimal.

3. A posteriori estimator for the error in the minimum. The purpose of this section is twofold: on one hand, we theoretically investigate reliability and efficiency of the stopping test (2.15); on the other hand, we prepare the convergence proof in section 4 by starting to establish the link between the criticality measure (1.6) and the decrease $I[u_k] - I[u_{k+1}]$.

Estimates with "$\preccurlyeq$" instead of "$\leq$" indicate a hidden constant, i.e., $a \preccurlyeq b \Leftrightarrow a \leq Cb$ with a constant $C > 0$, that, if not stated otherwise, depends only on the dimension d and the shape regularity σ_0 of $\mathcal{T}_0$ in (2.2).

3.1. Criticality measure and abstract error control. In the unconstrained minimization $\mathcal{F} = H_0^1(\Omega)$, the a posteriori error analysis is based upon the identities

$$I[u_k] - I[u] = \tfrac{1}{2}\|\nabla(u_k - u)\|^2 = \tfrac{1}{2}\|\mathcal{D}_k\|^2_{H^{-1}(\Omega)}, \tag{3.1}$$

where the dual norm of the residual (1.7),

$$\|\mathcal{D}_k\|_{H^{-1}(\Omega)} := \sup\{\langle \mathcal{D}_k, \varphi\rangle \mid \varphi \in H_0^1(\Omega) \text{ such that } \|\nabla\varphi\| \le 1\}, \tag{3.2}$$

depends only on the approximate minimizer u_k and the load f.

For $\mathcal{F}$ as in (1.2), however, already the first identity in (3.1) may not hold. More specifically, the quadratic nature of I readily leads to

$$I[u_k] - I[u] = \langle \mathcal{D}, u_k - u\rangle + \tfrac{1}{2}\|\nabla(u_k - u)\|^2, \tag{3.3}$$

where $\mathcal{D}$ denotes the derivative of I in the minimizer u. Therefore, (1.3) implies

$$\tfrac{1}{2}\|\nabla(u_k - u)\|^2 \le I[u_k] - I[u], \tag{3.4}$$

while an opposite inequality has to take into account the "linear" term $\langle \mathcal{D}, u_k - u\rangle$ when this term is strictly positive; see also the analog situation illustrated in Figure 2 (right).

In addition, a test function (or correction) φ in (3.2) may correspond to a function that is not admissible; i.e., $u_k + \varphi \in \mathcal{F}_k$ may not hold. We therefore consider

$$\rho_k(-\mathcal{D}_k) := \sup\{\langle -\mathcal{D}_k, \varphi\rangle \mid \varphi \in H_0^1(\Omega) \text{ such that } \|\nabla\varphi\| \le 1,\ u_k + \varphi \in \mathcal{F}\}. \tag{3.5}$$

Notice that ρ_k is a seminorm in $H^{-1}(\Omega)$ that is definite in the set of positive functionals:

- thanks to $u_k \in \mathcal{F}$, it is nonnegative, positively 1-homogeneous, and sublinear (and so convex) but not symmetric;
- if $u_k = \psi_i$ in K_i for some $i \in \{1, \dots, n\}$, there are negative functionals $F \neq 0$ with $\rho_k(F) = 0$;
- there holds

$$\rho_k(F) = 0 \implies \langle F, \varphi\rangle \le 0 \ \forall\ \varphi \in H_0^1(\Omega) \text{ with } \varphi \ge 0. \tag{3.6}$$

With the help of $\rho_k(-\mathcal{D}_k)$, the relationship (3.1) can be replaced as follows.

PROPOSITION 3.1 (abstract error control). *The error in the energy minimum is controlled by $\rho_k(-\mathcal{D}_k)$ from* (3.5)*. More precisely, there holds*

$$\tfrac{1}{2}\min\big\{\rho_k(-\mathcal{D}_k)^2, \rho_k(-\mathcal{D}_k)\big\} \le I[u_k] - I[u] \le \max\big\{\tfrac{1}{2}\rho_k(-\mathcal{D}_k)^2, \rho_k(-\mathcal{D}_k)\big\}.$$

Proof. 1. Similarly to (3.3), we obtain

$$I[u_k] - I[u_k + \alpha\varphi] = \alpha\langle -\mathcal{D}_k, \varphi\rangle - \frac{\alpha^2}{2}\|\nabla\varphi\|^2 \tag{3.7}$$

for $\varphi \in H_0^1(\Omega)$ and $\alpha \in \mathbb{R}$.

2. In order to prove the upper bound for $I[u_k] - I[u]$, we choose $\varphi = u - u_k$ and $\alpha = 1$ in (3.7) to obtain

$$I[u_k] - I[u] = \langle -\mathcal{D}_k, u - u_k\rangle - \frac{1}{2}\|\nabla(u - u_k)\|^2. \tag{3.8}$$

The estimation of $\langle -\mathcal{D}_k, u-u_k\rangle$ in terms of $\rho_k(-\mathcal{D}_k)$ from (3.5) suggests considering two cases.

Case 1: $u_k + \|\nabla(u-u_k)\|^{-1}(u-u_k) \in \mathcal{F}$. Then

$$\langle -\mathcal{D}_k, u-u_k\rangle - \frac{1}{2}\|\nabla(u-u_k)\|^2 \leq \rho_k(\mathcal{D}_k)\|\nabla(u-u_k)\| - \frac{1}{2}\|\nabla(u-u_k)\|^2 \leq \frac{1}{2}\rho_k(-\mathcal{D}_k)^2 \tag{3.9}$$

by using $ab \leq \frac{1}{2}a^2 + \frac{1}{2}b^2$.

Case 2: $u_k + \|\nabla(u-u_k)\|^{-1}(u-u_k) \notin \mathcal{F}$. Then, since $u, u_k \in \mathcal{F}$ implies $u_k + \alpha(u-u_k) \in \mathcal{F}$ for all $\alpha \in [0,1]$, we have $\|\nabla(u-u_k)\| < 1$. Consequently, the definition (3.5) of $\rho_k(-\mathcal{D}_k)$ directly gives

$$\langle -\mathcal{D}_k, u-u_k\rangle - \frac{1}{2}\|\nabla(u-u_k)\|^2 \leq \rho_k(\mathcal{D}_k). \tag{3.10}$$

Inserting the two cases (3.9) and (3.10) into the identity (3.8) then yields the claimed upper bound for $I[u_k] - I[u]$.

3. It remains to show the lower bound for $I[u_k] - I[u]$. To this end, choose $\varphi^* \in H_0^1(\Omega)$ such that

$$\rho_k(-\mathcal{D}_k) = \langle -\mathcal{D}_k, \varphi^*\rangle, \quad \|\nabla\varphi^*\| \leq 1, \quad \text{and} \quad u_k + \varphi^* \in \mathcal{F}.$$

Such φ^* can be constructed with the help of a maximizing sequence, weak compactness, and Mazur's lemma. We again consider two cases.

Case 1: $u_k + \rho_k(-\mathcal{D}_k)\varphi^* \in \mathcal{F}$. This, (3.7) with $\varphi = \varphi^*$, and $\alpha = \rho_k(-\mathcal{D}_k)$, as well as the properties of φ^*, imply

$$I[u_k] - I[u] \geq I[u_k] - I[u_k + \rho_k(-\mathcal{D}_k)\varphi^*] = \rho_k(-\mathcal{D}_k)^2 - \frac{\rho_k(-\mathcal{D}_k)^2}{2}\|\nabla\varphi^*\|^2 \geq \frac{1}{2}\rho_k(-\mathcal{D}_k)^2. \tag{3.11}$$

Case 2: $u_k + \rho_k(-\mathcal{D}_k)\varphi^* \notin \mathcal{F}$. Then, in view of $u_k + \varphi^*, u_k \in \mathcal{F}$, we derive $\rho_k(-\mathcal{D}_k) > 1$, and so

$$I[u_k] - I[u] \geq I[u_k] - I[u_k + \varphi^*] = \rho_k(-\mathcal{D}_k) - \frac{1}{2}\|\nabla\varphi^*\|^2 \geq \frac{1}{2}\rho_k(-\mathcal{D}_k) \tag{3.12}$$

by using also (3.7) with $\varphi = \varphi^*$, $\alpha = 1$, and the properties of φ^*.

Combining the inequalities (3.11) and (3.12) yields the claimed lower bound for $I[u_k] - I[u]$. ∎

Suppose for a moment that $I[v] = \frac{1}{2}|v|^2$, $v \in \mathbb{R}$, and that $u_k \in \mathbb{R}$ is *some* approximation of the exact minimum $u = 0$. In this case, straightforward calculations for different cases in the spirit of Figure 2 show that the bounds in the corresponding one-dimensional counterpart of Proposition 3.1 are sharp. Consequently, a proof of improved bounds has to rely on additional information about u_k. The following remark, which will be useful in section 5.4, is an example for such an improvement.

Remark 3.1 (more stringent error control). Suppose that $u_k = \psi_i$ on K_i for all $i = 1, \ldots, n$ and that $\rho_k(-\mathcal{D}_k) \leq 1$. After the computation of u_k, the first condition can be directly checked and the second one may be verified with the help of Proposition 3.2 below. The first condition implies that $u - u_k \geq 0$ in $\bigcup_{i=1}^n K_i$. Consequently, Case 1 in

the proof of the upper bound in Proposition 3.1 applies, and there holds $I[u_k]-I[u] \leq \frac{1}{2}\rho_h(-\mathcal{D}_k)^2$. The second condition excludes Case 2 of the proof of the lower bound since Case 2 entails $\rho_k(-\mathcal{D}_k) > 1$. Thus, there holds also $I[u_k] - I[u] \geq \frac{1}{2}\rho_h(-\mathcal{D}_k)^2$ by the corresponding Case 1. To summarize, under the aforementioned assumptions, we perfectly mimic (3.1) by

$$I[u_k] - I[u] = \tfrac{1}{2}\rho_k(-\mathcal{D}_k)^2. \tag{3.13}$$

3.2. On reliability. The goal of this section is to derive an upper bound of the error $I[u_k]-I[u]$ in the energy minimum in terms of the a posteriori estimator $\mathcal{E}_k$ from (2.14). To this end, in view of Proposition 3.1, we may estimate $\rho_k(-\mathcal{D}_k)$ by $\mathcal{E}_k$, that is, by "local" and, partially, "finite-dimensional" quantities, while the evaluation of $\rho_k(-\mathcal{D}_k)$ corresponds to an infinite-dimensional optimization that involves, in addition to the usual $H^1_0(\Omega)$-constraint, also one of pointwise nature.

A device for "localization" is the partition of unity

$$\sum_{z\in\mathcal{N}_k} \phi_z = 1 \qquad \text{in } \Omega, \tag{3.14}$$

where ϕ_z, $z \in \mathcal{N}_k$, are the hat functions defined by $\phi_z \in V_k$ and $\phi_z(y) = \delta_{yz}$ for all $y \in \mathcal{N}_k$. Notice that the support of ϕ_z is the star around $z \in \mathcal{N}_k$, i.e., $\operatorname{supp}\phi_z = \omega_z$.

Additionally, we need a projection operator Π which allows us, together with the fact that u_k is piecewise affine, to reduce the high flexibility of a generic test function in the definition of $\rho_k(-\mathcal{D}_k)$. The operator Π has to have local properties that are subordinated to the localization induced by the partition of unity (3.14). We define $\Pi : H^1_0(\Omega) \to \operatorname{span}\{\varphi_S \mid S \in \mathcal{S}_k\}$ by requiring, for all $\varphi \in H^1_0(\Omega)$,

$$\forall\, S \in \mathcal{S}_k \quad \int_S \varphi = \int_S \Pi\varphi. \tag{3.15}$$

The latter is, writing $\Pi\varphi = \sum_{S\in\mathcal{S}_k} \alpha_S(\varphi)\varphi_S$, equivalent to

$$\forall\, S \in \mathcal{S}_k \quad \alpha_S(\varphi) = \frac{\int_S \varphi}{\int_S \varphi_S}.$$

To state the local properties of Π, we introduce the following notion: given a side $S \in \mathcal{S}_k$, a function $\varphi \in H^1_0(\Omega)$ is *S-admissible* whenever

$$\forall\, i \in \{1,\dots,n\} \text{ with } S \subset K_i, \text{ there holds } \int_S (u_k + \varphi) \geq \int_S \psi_i. \tag{3.16}$$

Note that $u_k + \varphi \in \mathcal{F}$ implies that φ is S-admissible for all $S \in \mathcal{S}_k$.

LEMMA 3.1 (local properties of Π). *The coefficients α_S, $S \in \mathcal{S}_k$, of Π are stable and monotone on $H^1_0(\Omega)$. More precisely, for all $S \in \mathcal{S}_k$ there holds*

$$\begin{aligned} |\alpha_S(\varphi)| &\preccurlyeq \operatorname{diam}(\omega_S)^{-1}\|\varphi\|_{\omega_S} + \|\nabla\varphi\|_{\omega_S}, \\ \varphi \geq 0 \text{ on } S &\implies \alpha_S(\varphi) \geq 0, \\ \varphi \text{ is } S\text{-admissible} &\implies \alpha_S(\varphi) \succcurlyeq -d_S. \end{aligned}$$

Proof. 1. To show the first claim, we set $h_S := \operatorname{diam}(\omega_S)$ and observe that, thanks to (2.19a), the measures of elements and sides involved in the definition of φ_S are about h_S^d and h_S^{d-1}, respectively. The piecewise affine function φ_S attains

its maximum in x_S and equals 0 outside ω_S. The normalization $\|\nabla\varphi_S\|_{\omega_S} = 1$ now readily implies $h_S^{1-d/2} \preccurlyeq \varphi_S(x_S) \preccurlyeq h_S^{1-d/2}$. From this, one directly computes the lower bound

$$\int_S \varphi_S \succcurlyeq h_S^{d/2}. \tag{3.17}$$

Moreover, if $T \in \mathcal{T}_k$ with $T \supset S$, there holds the "scaled" trace theorem

$$\|\varphi\|_S \preccurlyeq h_S^{-1/2}\|\varphi\|_T + h_S^{1/2}\|\nabla\varphi\|_T. \tag{3.18}$$

The scaling of the norms can be determined by transforming to a reference element, applying there the corresponding trace inequality, and transforming back; see also [7, section 15]. Combining (3.18) with the Cauchy–Schwarz inequality on S yields

$$\int_S \varphi \le h_S^{(d-1)/2}\|\varphi\|_S \preccurlyeq h_S^{d/2}\big(h_S^{-1}\|\varphi\|_{\omega_S} + \|\nabla\varphi\|_{\omega_S}\big),$$

and therefore, in view of (3.17), the first claim is proven.

2. The second claim readily follows from (3.17) and the monotonicity of the integral $\int_S$.

3. It remains to prove the last claim. Suppose that φ is S-admissible. If there is no $i \in \{1,\dots,n\}$ with $K_i \supset S$, then $d_S = \infty$ and the claim is trivial. Otherwise, fix any $i \in \{1,\dots,n\}$ with $K_i \supset S$ and observe

$$\alpha_S(\varphi) \ge \frac{\int_S(\psi_i - u_k)}{\int_S \varphi_S} = -\frac{\int_S(u_k - \psi_i)}{\int_S \varphi_S}.$$

Thus, if we can show

$$\int_S (u_k - \psi_i) \preccurlyeq \big[u_k(x_S) - \psi_i(x_S)\big]\,\mathcal{H}^{d-1}(S), \tag{3.19}$$

then the third claim follows because of $\mathcal{H}^{d-1}(S) \le h_S^{d-1}$, $\varphi_S(x_S) \preccurlyeq h_S^{1-d/2}$, (3.17), and the definition (2.4) of ψ^*.

For $d = 2$, the node x_S is the midpoint of S, and thus (3.19) is a consequence of the midpoint rule since $u_k - \psi_i$ is affine on S. For $d = 3$, the verification of (3.19) is a bit more involved. Denoting by a_0, a_1, a_2 an appropriate enumeration of the vertices of S, we can write $x_S = \frac{1}{4}(a_0 + a_1) + \frac{1}{2}a_2$; see section 2.5. A calculation yields that x_S is the barycenter of S with respect to the measure induced by ϕ_{a_2}, i.e., $x_S = \int_S x\phi_{a_2}(x)dx$, where $\phi_{a_2} \in V_k$ is the hat function at node a_2. Consequently,

$$g \text{ affine } \implies \int_S g\phi_{a_2} = g(x_S)\int_S \phi_{a_2} = g(x_S)\frac{\mathcal{H}^{d-1}(S)}{d}.$$

We now observe $u_k - \psi_i \ge 0$ on S because of $u_k \in \mathcal{F}$, and so the equivalence of norms on the affine functions over a reference side yields

$$\int_S u_k - \psi_i \preccurlyeq \int_S [u_k - \psi_i]\phi_{a_2} = [u_k(x_S) - \psi_i(x_S)]\frac{\mathcal{H}^{d-1}(S)}{d},$$

which is (3.19). Thus, the proof of the last claim is also concluded. ∎

For given $\varphi \in H^1_0(\Omega)$ and $z \in \mathcal{N}_k$, we will apply the projection operator Π to the localized function $\varphi\,\phi_z$:

$$\Pi(\varphi\,\phi_z) = \sum_{S \in \mathcal{S}_z} \alpha_S(\varphi\,\phi_z)$$

with $\mathcal{S}_z := \{S \in \mathcal{S}_k \mid S \ni z\}$ being the set of interior sides in the star ω_z. The first claim of Lemma 3.1, combined with $\|\varphi_S\|_{\omega_S} \preccurlyeq \operatorname{diam}(\omega_S)$, ensures

$$\begin{aligned} \|\Pi(\varphi\,\phi_z)\|_{\omega_z} &\preccurlyeq \|\varphi\,\phi_z\|_{\omega_z} + \operatorname{diam}(\omega_z)\|\nabla(\varphi\,\phi_z)\|_{\omega_z} \\ &\preccurlyeq \|\varphi\|_{\omega_z} + \operatorname{diam}(\omega_z)\|\nabla\varphi\|_{\omega_z}. \end{aligned} \tag{3.20}$$

The last inequality follows from $\|\nabla(\varphi\,\phi_z)\|_{\omega_z} \preccurlyeq \operatorname{diam}(\omega_z)^{-1}\|\varphi\|_{\omega_z} + \|\nabla\varphi\|_{\omega_z}$ since $\phi_z \le 1$ and $|\nabla\phi_z| \preccurlyeq \operatorname{diam}(\omega_z)^{-1}$.

The first bound in Lemma 3.1 and also (3.20) involve not only an H^1-seminorm but also an L_2-norm. In order to estimate the latter ones by the previous ones locally, we shall invoke a suitable Poincaré inequality. It is based upon a cancellation on one of the (not necessarily interior) sides of $\mathcal{T}_k$ containing z. The set of all these sides is indicated with $\bar{\mathcal{S}}_z$. Notice that $\int_S \phi_z = \frac{1}{d}\,\mathcal{H}^{d-1}(S) > 0$ holds for all $S \in \bar{\mathcal{S}}_z$.

LEMMA 3.2 (Poincaré inequality). *Let ω_z be any star of $\mathcal{T}_k$ and $\varphi \in H^1(\omega_z)$. If $\int_S \varphi\phi_z = 0$ for some $S \in \bar{\mathcal{S}}_z$, then there holds*

$$\|\varphi\|_{\omega_z} \preccurlyeq \operatorname{diam}(\omega_z)\|\nabla\varphi\|_{\omega_z}.$$

Proof. Let $S \in \bar{\mathcal{S}}_z$ and suppose $\int_S \varphi\phi_z = 0$. Then we may write

$$\varphi = \varphi - \left[\int_S \phi_z\right]^{-1} \int_S \varphi\phi_z = (\varphi - c) - \left[\int_S \phi_z\right]^{-1} \int_S (\varphi - c)\phi_z,$$

where c is any real. We thus obtain

$$\begin{aligned} \|\varphi\|_{\omega_z} &\preccurlyeq \|\varphi - c\|_{\omega_z} + \frac{\mathcal{L}^d(\omega_z)^{1/2}}{\left[\int_S \phi_z\right]^{1/2}} \left(h_S^{-1/2}\|\varphi - c\|_{\omega_S} + h_S^{1/2}\|\nabla\varphi\|_{\omega_S}\right) \\ &\preccurlyeq \|\varphi - c\|_{\omega_z} + \operatorname{diam}(\omega_z)\|\nabla\varphi\|_{\omega_z} \end{aligned}$$

with the help of a "weighted" Cauchy–Schwarz inequality on S, $\phi_z \le 1$, the scaled trace theorem (3.18), $\mathcal{L}^d(\omega_z) \preccurlyeq \operatorname{diam}(\omega_z)^d$, $\int_S \phi_z \succcurlyeq h_S^{d-1}$, and $h_S \approx \operatorname{diam}(\omega_z)$. The variant [22, eq. (4.2)] of the Bramble–Hilbert lemma then finishes the proof. ∎

After these preparations we now turn to the upper bound for $\rho_h(-\mathcal{D}_k)$. We refer to a node $z \in \mathcal{N}_k \setminus \partial\Omega$ as a *proper contact node* if $u_k(z) = \psi^*(z)$ and (2.5) is "locally" strict in that $\langle \nabla u_k, \nabla\phi_z\rangle > \langle f, \phi_z\rangle$ holds. If in addition there is no side $S \in \mathcal{S}_z$ and no $i \in \{1, \dots, n\}$ such that $S \subset K_i$ and $u_k = \psi_i$ on S, we call z an *isolated* proper contact node and set

$$\mathcal{N}_k^{\perp} := \{z \in \mathcal{N}_k \setminus \partial\Omega \mid z \text{ is an isolated proper contact node}\}. \tag{3.21}$$

PROPOSITION 3.2 (upper bound for criticality measure). *We have*

$$\rho_k(-\mathcal{D}_k) \preccurlyeq \mathcal{E}_k,$$

where the hidden constant depends on d and σ_0 and, only if $\mathcal{N}_k^{\perp} \neq \emptyset$, in addition on f, $\{\psi_i\}_{i=1}^n$, and $\mathcal{T}_0$.

Proof. 1. Let $\varphi \in H^1_0(\Omega)$ such that $\|\nabla\varphi\| \le 1$ and $u_k + \varphi \in \mathcal{F}$. We have to show that $\langle -\mathcal{D}_k, \varphi\rangle \preccurlyeq \mathcal{E}_k$. To this end, we derive the representation formula

$$\begin{aligned}\langle -\mathcal{D}_k, \varphi\rangle &= \sum_{T\in\mathcal{T}_k} \int_T \big(f\varphi - \nabla u_k\cdot\nabla\varphi\big) = \sum_{S\in\mathcal{S}_k}\int_S j_k\varphi + \sum_{T\in\mathcal{T}_k}\int_T f\varphi \\ &= \sum_{z\in\mathcal{N}_k}\left(\int_{\gamma_z} j_k\varphi\phi_z + \int_{\omega_z} f\varphi\phi_z\right)\end{aligned} \tag{3.22}$$

with the help of elementwise integration by parts and the partition of unity (3.14). We set

$$\rho_z(\varphi) := \int_{\gamma_z} j_k\varphi\phi_z + \int_{\omega_z} f\varphi\phi_z, \qquad z\in\mathcal{N}_k, \tag{3.23}$$

and observe that the definition of u_k implies, for any interior node $z \in \mathcal{N}_k\cap\Omega$,

$$\rho_z(1) \le 0, \tag{3.24a}$$

$$u_k(z) > \psi^*(z) \implies \rho_z(1) = 0. \tag{3.24b}$$

In fact, (3.24a) follows by choosing $v = u_k + \phi_z$ in (2.5), while (3.24b) by choosing $v = u_k - \epsilon\phi_z$ with $\epsilon > 0$ sufficiently small. In what follows, we shall estimate the terms $\rho_z(\varphi)$, $z\in\mathcal{N}_k$, separately, depending on the node type.

2. We consider the full contact nodes (2.11). If $z\in\mathcal{N}_k^0$, then $\omega_z = \bigcup_{i\in I_z} K_i\cap\omega_z$ with $I_z := \{i\in\{1,\dots,n\} \mid K_i\cap\omega_z \ne \emptyset\}$; for otherwise there exists a $x\in\omega_z\setminus\partial\omega_z$ such that $\psi_*(x) = \infty$, which is in contradiction with $\psi_*(x) = u_k(x) < \infty$. In view of $u_k + \varphi \in \mathcal{F}$, we also have

$$\varphi \ge \psi_i - u_k \ge \psi_* - u_k = 0$$

on $K_i\cap\omega_z$ for any $i\in I_z$ and, thus, $\varphi\ge 0$ on the whole star ω_z. Consequently, the sign conditions on j_k and f in (2.11) yield

$$\rho_z(\varphi) = \int_{\gamma_z} j_k\varphi\phi_z + \int_{\omega_z} f\varphi\phi_z \le 0 \qquad \text{for any } z\in\mathcal{N}_k^0. \tag{3.25}$$

Because $\rho_z(\varphi)$ is nonpositive, these values do not contribute to the upper bound.

3. For the remaining nodes $z\in\mathcal{N}_k\setminus\mathcal{N}_k^0$, we first derive the following conditional auxiliary estimate for $\zeta\in H^1(\omega_z)$:

If $\zeta\phi_z$ is S-admissible $\forall\ S\in\mathcal{S}_z$, then $\rho_z(\zeta)$ is bounded by

$$\sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^1} d_S|\rho_S| + \left(\sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^2} |\rho_S|^2 + \|h_k f\|^2_{\omega_z}\right)^{1/2}\left(\frac{\|\zeta\|_{\omega_z}}{\operatorname{diam}(\omega_z)} + \|\nabla\zeta\|_{\omega_z}\right). \tag{3.26}$$

Exploiting (3.15) and the fact that j_k is constant on any side, we may write

$$\begin{aligned}\rho_z(\zeta) &= \int_{\gamma_z} j_k\zeta\phi_z + \int_{\omega_z} f\zeta\phi_z \\ &= \int_{\gamma_z} j_k\Pi(\zeta\phi_z) + \int_{\omega_z} f\Pi(\zeta\phi_z) + \int_{\omega_z} f\big[\zeta\phi_z - \Pi(\zeta\phi_z)\big]\end{aligned}$$

such that we obtain

$$\begin{aligned}\int_{\gamma_z} j_k\Pi(\zeta\phi_z) + \int_{\omega_z} f\Pi(\zeta\phi_z) &= \langle -\mathcal{D}_k, \Pi(\zeta\phi_z)\rangle = \sum_{S\in\mathcal{S}_z} \alpha_S(\zeta\phi_z)\rho_S \\ &= \sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^1} \big[-\alpha_S(\zeta\phi_z)\big]|\rho_S| + \sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^2} \alpha_S(\zeta\phi_z)\rho_S \\ &\preccurlyeq \sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^1} d_S|\rho_S| + \sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^2} |\rho_S|\big[\operatorname{diam}(\omega_S)^{-1}\|\zeta\|_{\omega_S} + \|\nabla\zeta\|_{\omega_S}\big]\end{aligned}$$

by Lemma 3.1 and $\|\nabla(\zeta\phi_z)\|_{\omega_S} \preccurlyeq \operatorname{diam}(\omega_S)^{-1}\|\zeta\|_{\omega_S} + \|\nabla\zeta\|_{\omega_S}$. In addition,

$$\int_{\omega_z} f\big[\zeta\phi_z - \Pi(\zeta\phi_z)\big] \preccurlyeq \|h_k f\|_{\omega_z}\big[\operatorname{diam}(\omega_z)^{-1}\|\zeta\|_{\omega_z} + \|\nabla\zeta\|_{\omega_z}\big]$$

by (3.20) and $h_k \succcurlyeq \operatorname{diam}(\omega_z)$ on ω_z. Summing up the two estimates gives the claimed bound (3.26) for $\rho_z(\zeta)$.

4. In order to apply (3.26) and then Lemma 3.2, it is convenient to write

$$\rho_z(\varphi) = \rho_z(\varphi^+) + \rho_z(\varphi^-), \tag{3.27}$$

where $\varphi^+ = \max\{\varphi, 0\}$ and $\varphi^- = \min\{\varphi, 0\}$ denote the positive and negative part of φ, respectively. Since φ^+ is the "unconstrained" part of the test function φ, the corresponding terms $\rho_z(\varphi^+)$ should be treated in a similar way as in an unconstrained problem. We first estimate these terms and then the ones associated with φ^-. Let $z \in \mathcal{N}_k \setminus \mathcal{N}_k^0$ be arbitrary. Then there exist a nonnegative real $c_z^+ \geq 0$ and a side $S_z \in \bar{\mathcal{S}}_z$ in ω_z such that

$$\int_{S_z} (\varphi^+ - c_z^+)\phi_z = 0. \tag{3.28}$$

In fact, if $z \in \partial\Omega$ is a boundary vertex, then take $c_z^+ = 0$ and a side in $\partial\omega_z \cap \partial\Omega$ for S_z; otherwise, choose

$$c_z^+ := \min\left\{ \left[\int_S \phi_z\right]^{-1} \int_S \varphi^+\phi_z \mid S \in \mathcal{S}_z \right\} \geq 0$$

together with the minimizing side S_z. By construction of c_z^+, the locally shifted test function $\zeta\phi_z$ with $\zeta = \varphi^+ - c_z^+$ is S-admissible for all $S \in \mathcal{S}_z$. Exploiting (3.24a), applying (3.26) and Lemma 3.2 with (3.28), we derive

$$\begin{aligned}\rho_z(\varphi^+) &= \rho_z(\varphi^+ - c_z^+) + c_z^+\rho_z(1) \leq \rho_z(\varphi^+ - c_z^+) \\ &\preccurlyeq \sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^1} d_S|\rho_S| + \left(\sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^2} |\rho_S|^2 + \|h_k f\|_{\omega_z}^2\right)^{1/2} \|\nabla\varphi^+\|_{\omega_z}.\end{aligned} \tag{3.29}$$

Notice that (3.28) and the sign $c_z^+\rho_z(1) \leq 0$ are crucial for deriving (3.29).

5. Next, we estimate those $\rho_z(\varphi^-)$, $z \in \mathcal{N}_k \setminus \mathcal{N}_k^0$, for which we can proceed similarly as for $\rho_z(\varphi^+)$. More precisely, we suppose that there exist a nonpositive real $c_z^- \leq 0$ and a side $S_z \in \bar{\mathcal{S}}_z$ in ω_z such that

$$\int_{S_z} (\varphi^- - c_z^-)\phi_z = 0 \quad \text{and} \quad c_z^-\,\rho_z(1) \leq 0. \tag{3.30}$$

Then (3.26) with $\zeta = \varphi^- - c_z^-$ and Lemma 3.2 yield

$$\rho_z(\varphi^-) = \rho_z(\varphi^- - c_z^-) + c_z^-\rho_z(1) \le \rho_z(\varphi^- - c_z^-) \tag{3.31}$$
$$\preccurlyeq \sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^1} d_S|\rho_S| + \left(\sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^2} |\rho_S|^2 + \|h_k f\|_{\omega_z}^2\right)^{1/2} \|\nabla\varphi^-\|_{\omega_z}.$$

Condition (3.30) is verified for boundary nodes with $c_z^- = 0$ and a boundary side S_z. For interior nodes z with $\rho_z(1) = 0$, we can choose, for instance,

$$c_z^- := \max\left\{\left[\int_S \phi_z\right]^{-1} \int_S \varphi^-\phi_z \mid S\in\mathcal{S}_z\right\} \le 0$$

and S_z as the maximizing side.

In view of (3.24), the remaining nodes are necessarily proper contact nodes. For contact nodes that are not isolated, there exist a side $S_z \in \mathcal{S}_z$ and some $i \in \{1,\dots,n\}$ such that

$$0 \ge \varphi^- \ge \psi_i - u_k = 0 \quad \text{on } S_z$$

and, thus, (3.30) holds with $c_z^- = 0$.

6. It remains to estimate $\rho_z(\varphi^-)$ for isolated proper contact nodes $z \in \mathcal{N}_k^\perp$. In order to compensate a missing cancellation as in (3.30), we observe that for isolated proper contact nodes there is some $i \in \{1,\dots,n\}$ and some side $S \in \mathcal{S}_z$ such that

$$u_k(z) = \psi_i(z) \quad \text{and} \quad u_k + \varphi^- \ge \psi_i \text{ on } S$$

because z is in contact. Hence, by a "discrete" Poincaré inequality and $h_S\,\mathcal{H}^{d-1}(S) \preccurlyeq \mathcal{L}^d(\omega_S)$,

$$\|\varphi^-\|_S \le \|\psi_i - u_k\|_S \preccurlyeq h_S\|\nabla_S(\psi_i - u_k)\|_S$$
$$\preccurlyeq \operatorname{diam}(\omega_S)^{1/2}\Big(\|\nabla u_k\|_{\omega_S} + \mathcal{L}^d(\omega_S)^{1/2}M\Big),$$

where ∇_S is the tangential gradient on S and $M := \max\{|\nabla\psi_i| \mid i = 1,\dots,n\}$. Therefore $c_z^- := \big[\int_S \phi_z\big]^{-1}\int_S \varphi^-\phi_z$ satisfies

$$\|c_z^-\|_{\omega_z} \le \frac{\mathcal{L}^d(\omega_z)^{1/2}}{\big[\int_S \phi_z\big]^{1/2}}\|\varphi^-\|_S \preccurlyeq \operatorname{diam}(\omega_z)\big[\|\nabla u_k\|_{\omega_z} + \mathcal{L}^d(\omega_z)^{1/2}M\big],$$

whence

$$\|\varphi^-\|_{\omega_z} \le \|\varphi^- - c_z^-\|_{\omega_z} + \|c_z^-\|_{\omega_z}$$
$$\preccurlyeq \operatorname{diam}(\omega_z)\big[\|\nabla\varphi^-\|_{\omega_z} + \|\nabla u_k\|_{\omega_z} + \mathcal{L}^d(\omega_z)^{1/2}M\big]$$

by using Lemma 3.2 for the first term. Combining this with (3.26) for $\zeta = \varphi^-$, we obtain

$$\rho_z(\varphi^-) \preccurlyeq \sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^1} d_S|\rho_S| + \left(\sum_{S\in\mathcal{S}_z\cap\mathcal{S}_k^2} |\rho_S|^2 + \|h_k f\|_{\omega_z}^2\right)^{1/2} \tag{3.32}$$
$$\times \big[\|\nabla\varphi^-\|_{\omega_z} + \|\nabla u_k\|_{\omega_z} + \mathcal{L}^d(\omega_z)^{1/2}M\big].$$

7. Using (3.23) and (3.27), we insert (3.25), (3.29), (3.31), and (3.32) into (3.22). Moreover, we note that each element (side) is contained at most in $d+1$ (d) stars and that $\|\nabla\varphi^+\|^2 + \|\nabla\varphi^-\|^2 = \|\nabla\varphi\|^2 \le 1$. Thus, we finally arrive at

$$\langle -\mathcal{D}_k, \varphi\rangle \preccurlyeq \left[\sum_{S\in\mathcal{S}_k^1} d_S|\rho_S| + \left(\sum_{S\in\mathcal{S}_k^2} |\rho_S|^2\right)^{1/2} + \left(\sum_{T\in\mathcal{T}_k^+}\int_T h_k^2|f|^2\right)^{1/2}\right] \times \left[1 + \|\nabla u_k\|_{\Omega_k^\perp} + \mathcal{L}^d(\Omega_k^\perp)^{1/2}M\right],$$

where $\Omega_k^\perp := \bigcup_{z\in\mathcal{N}_k^\perp}\omega_z$ denotes the union of all stars associated with isolated proper contact nodes. The stability of $\{u_k\}_k$, which is proved in the following lemma, then finishes the proof. ∎

LEMMA 3.3 (stability). *The approximate minimizers $\{u_k\}_k$ are stable: there is a constant C depending on f, $\{\psi_i\}_{i=1}^n$, and $\mathcal{T}_0$ such that, for any admissible k,*

$$\|\nabla u_k\| \le C. \tag{3.33}$$

Proof. Let ψ denote the Lagrange interpolation of $\max\{0,\psi^*\}$ onto the initial finite element space V_0. Then $\psi\in\mathcal{F}_k$ for any k, and so we can choose $v=\psi$ in (2.5) and obtain (3.33) by standard manipulations. ∎

The combination of Propositions 3.1 and 3.2 yields the main result of this section.

THEOREM 3.1 (upper bound). *The error estimator $\mathcal{E}_k$ in* (2.14) *bounds the error $I[u_k]-I[u]$ in the energy minimum from above. More precisely, there holds*

$$I[u_k] - I[u] \preccurlyeq \max\{\tfrac12\mathcal{E}_k^2, \mathcal{E}_k\}.$$

The hidden constant depends on d and the shape regularity σ_0 in (2.2) *and, only if the set of isolated proper contact nodes $\mathcal{N}_k^\perp$ defined in* (3.21) *is not empty, in addition on the initial mesh $\mathcal{T}_0$, the load term f, and the obstacle functions $\{\psi_i\}_{i=1}^n$.*

Remark 3.2 (isolated proper contact nodes). The existence of isolated, proper contact nodes can be easily verified a posteriori. They appear on relatively coarse meshes, e.g., if the obstacle is a pyramid. On finer meshes, they do not persist and get proper contact nodes that are not isolated. Thus, at least in this generic situation, the hidden constant in Theorem 3.1 asymptotically depends only on d and σ_0.

Remark 3.3 (localization and stability). In view of the definition (2.13) of $\mathcal{T}_k^+$, the evaluation of the nonhierarchical part

$$\left(\sum_{T\in\mathcal{T}_k^+}\int_T h_k^2|f|^2\right)^{1/2}$$

might appear unstable because small changes in u_k may produce big changes in $\mathcal{T}_k^+$. However, in light of the results of Brezzi and Caffarelli [6], this occurs only when $|f|$ is small in the corresponding regions.

3.3. On efficiency. In this section we theoretically investigate the sharpness of the upper bound in Theorem 3.1, which is related to the efficiency of the stopping test (2.15).

We first consider the hierarchical part (2.16) of the estimator $\mathcal{E}_k$. By construction, its indicators satisfy the following local lower bounds with respect to an error in a "local" energy minimum ξ_S given by (2.8); see (2.10b):

$$\xi_S = \tfrac12\rho_S^2, \quad S\in\mathcal{S}_k^2, \qquad \text{and} \qquad \xi_S > \tfrac12 d_S|\rho_S|, \quad S\in\mathcal{S}_k^1. \tag{3.34}$$

Their global counterparts follow with the help of the convexity of the Lagrangian associated with I.

THEOREM 3.2 (lower bounds for hierarchical part of estimator). *The two sums of the hierarchical estimator part η_k from* (2.16) *bound the error $I[u_k] - I[u]$ in the energy minimum from below:*

$$\max\left\{\sum_{S\in\mathcal{S}_k^2}\rho_S^2,\ \sum_{S\in\mathcal{S}_k^1} d_S\,|\rho_S|\right\} \le 2(d+1)\big(I[u_k]-I[u]\big).$$

Proof. 1. For notational convenience, denote by $\bar{\mathcal{S}}_k$ all sides of $\mathcal{T}_k$, including the boundary ones, and define φ_S, ω_S also for $S\in\bar{\mathcal{S}}_k\setminus\mathcal{S}_k$. Let

$$\varphi = \frac{1}{d+1}\sum_{S\in\bar{\mathcal{S}}_k}\beta_S\varphi_S \tag{3.35}$$

be a linear combination of the test functions involved in η_k and observe that, on each element $T\in\mathcal{T}_k$, $u_k+\varphi$ is a convex combination of certain $v_S := u_k+\beta_S\varphi_S$, $S\in\bar{\mathcal{S}}_k$:

$$(u_k+\varphi)_{|T} = \frac{1}{d+1}\sum_{S\in\bar{\mathcal{S}}_k,\,S\subset T} v_{S|T}. \tag{3.36}$$

Thus, the convexity of $\mathbb{R}^d\ni p\mapsto\frac12|p|^2$ implies

$$\begin{aligned} I[u_k+\varphi] &= \sum_{T\in\mathcal{T}_k}\int_T \tfrac12|\nabla(u_k+\varphi)|^2 - f(u_k+\varphi)\\ &\le \frac{1}{d+1}\sum_{T\in\mathcal{T}_k}\sum_{S\in\bar{\mathcal{S}}_k,\,S\subset T}\int_T \tfrac12|\nabla v_S|^2 - fv_S. \end{aligned}$$

Subtracting this from $I[u_k] = \frac{1}{d+1}\sum_{T\in\mathcal{T}_k}\sum_{S\in\bar{\mathcal{S}}_k,\,S\subset T}\int_T\big(\frac12|\nabla u_k|^2-fu_k\big)$ and reorganizing the sum leads to

$$\begin{aligned} &I[u_k]-I[u_k+\varphi]\\ &\quad\ge \frac{1}{d+1}\sum_{S\in\bar{\mathcal{S}}_k}\left[\int_{\omega_S}\big(\tfrac12|\nabla u_k|^2-fu_k\big)-\int_{\omega_S}\big(\tfrac12|\nabla v_S|^2-fv_S\big)\right]\\ &\quad\ge \frac{1}{d+1}\sum_{S\in\bar{\mathcal{S}}_k}\big(I[u_k]-I[u_k+\beta_S\varphi_S]\big). \end{aligned} \tag{3.37}$$

2. We first bound the sum associated with $\mathcal{S}_k^2$, and therefore we choose

$$\beta_S = \begin{cases}\alpha_S & \text{if } S\in\mathcal{S}_k^2,\\ 0 & \text{otherwise}\end{cases}\qquad \text{with } \alpha_S \text{ from (2.9)}$$

in (3.35). Since $\alpha_S\ge -d_S$, (2.7) implies $u_k+\alpha_S\varphi_S\in\mathcal{F}$ for all $S\in\mathcal{S}_k$. The convexity of $\mathcal{F}$ in combination with (3.36) then yields $u_k+\varphi\in\mathcal{F}$. For all interior sides $S\in\mathcal{S}_k$ the identity $I[u_k]-I[u_k+\alpha_S\varphi_S]=\xi_S=\frac12\rho_S^2$ holds by (2.8) and (3.34). With the help of (3.37), we thus obtain

$$I[u_k]-I[u]\ge I[u_k]-I[u_k+\varphi] = \frac{1}{d+1}\sum_{S\in\mathcal{S}_k^2}\xi_S = \frac{1}{2(d+1)}\sum_{S\in\mathcal{S}_k^2}\rho_S^2.$$

The sum over $\mathcal{S}_k^1$ is bounded analogously. ∎

We next discuss the efficiency of the estimator part related to the load f and then finish the section by confronting Theorems 3.1 and 3.2.

Remark 3.4 (lower bounds for nonhierarchical estimator part). Introducing φ_T, x_T, ρ_T, d_T, and ξ_T for elements $T \in \mathcal{T}_k^+$ in an analog manner as for sides, one can prove that, on unconstrained elements $T \in \mathcal{T}_k^2 := \{T \in \mathcal{T}_k^+ \mid \rho_T \geq -d_T\}$, there hold the local lower bounds

$$\int_T h_k^2 |f|^2 \preccurlyeq \xi_T + \int_T h_k^2 |f - \bar{f}_T|^2$$

with $\bar{f}_T := \mathcal{L}^d(T)^{-1} \int_T f$ in the oscillation term. This implies the global lower bound

$$\sum_{T \in \mathcal{T}_k^2} \int_T h_k^2 |f|^2 \preccurlyeq I[u_k] - I[u] + \sum_{T \in \mathcal{T}_k^2} \int_T h_k^2 |f - \bar{f}_T|^2;$$

that is, the nonhierarchical part of the estimator is sharp apart from a higher order term and the contribution associated with $\mathcal{T}_k^1 := \mathcal{T}_k^+ \setminus \mathcal{T}_k^2$. The latter is typically also of higher order because it is localized to a narrowing stripe around the exact free boundary. We omit the proof since this property is not used below.

As in the unconstrained problem, it is also possible to derive an upper bound that deals also with the load term in a hierarchical way apart from a higher oscillation part. Since the cost for computing such an estimator is higher (especially for $d = 3$), we used the estimator given in (2.14).

Remark 3.5 (gap between upper and lower bound). The powers appearing in Theorems 3.1 and 3.2 do not match, thus producing a gap between upper and lower bounds; e.g., the asymptotically relevant one corresponds to the second case in Proposition 3.1 and amounts to

$$I[u_k] - I[u] \preccurlyeq \mathcal{E}_k \preccurlyeq \big(I[u_k] - I[u]\big)^{1/2}$$

for $f = 0$ and $I[u_k] - I[u] \leq 1$. The reason for the gap is that, in Proposition 3.1, we distinguish an "unconstrained" and a "constrained" case in a global manner, while in Theorem 3.2, the cases are distinguished in a local manner, which may mismatch with the global choice. Notice, however, that our numerical experiments indicate a linear estimator-error relationship $\mathcal{E}_k \approx \big(I[u_k] - I[u]\big)^{1/2}$ as in the unconstrained problem; see, e.g., section 5.2.

4. Convergence of approximate minima. The goal of this section is to prove that the algorithm described in section 2 converges for $\mathsf{tol} = 0$. Since the algorithm depends on tol only through the stopping test (2.15), this implies in particular that, for any strictly positive tolerance $\mathsf{tol} > 0$, the algorithm finishes after a finite number of steps. Notice that the algorithm of section 2 does not ensure that the maximum meshsize $\max_\Omega h_k$ decreases to 0. In fact, this may not happen; see, e.g., section 5.1. Therefore, the convergence theory for nonadaptive finite elements does not apply.

THEOREM 4.1 (convergence). *Suppose that* $\mathsf{tol} = 0$ *and that the initial triangulation* $\mathcal{T}_0$ *is subordinated to the lower obstacle in the sense of* (2.1).

Then the algorithm of section 2 *converges in a finite number of steps or produces an infinite sequence of approximate minima* $\{u_k\}_{k \in \mathbb{N}}$ *such that*

$$I[u_k] \to I[u] \quad \textit{and} \quad u_k \to u \textit{ in } H^1(\Omega) \quad (k \to \infty).$$

Proof. 1. If the algorithm finishes after a finite number of steps, the upper bound in Theorem 3.1 guarantees that the last approximate minimizer coincides with the exact one.

Suppose that the algorithm never finishes. Then (2.22) ensures that

$$m := \lim_{k\to\infty} I[u_k]$$

exists, and we need to check that $m = I[u]$. In view of the characterization (1.3) of the exact minimizer and the property (3.6) of the seminorm ρ_k, we may do this by showing

$$\lim_{k\to\infty} \rho_k(-\mathcal{D}_k) = 0. \tag{4.1}$$

To this end, our starting point is the convergence of the energy reduction in one adaptive iteration,

$$\lim_{k\to\infty} \big(I[u_k] - I[u_{k+1}]\big) = 0, \tag{4.2}$$

which is an immediate consequence of the existence of $\lim_{k\to\infty} I[u_k]$.

2. As a first step towards (4.1), we show that the hierarchical part (2.16) of the estimator tends to 0, i.e., $\lim_{k\to\infty} \eta_k = 0$. The idea is, exploiting (2.20), to modify the proof of the lower bounds in Theorem 3.2. Let us choose

$$\beta_S = \begin{cases} \alpha_S & \text{if } S \in \hat{\mathcal{S}}_k \cap \mathcal{S}_k^2, \\ 0 & \text{otherwise} \end{cases} \qquad \text{with } \alpha_S \text{ from (2.9)}$$

in (3.35). Then (2.20) implies $\varphi_S \in V_{k+1}$ for all $S \in \hat{\mathcal{S}}_k$, and thus we conclude $u_k + \varphi \in \mathcal{F}_{k+1}$ with the same arguments used in the proof of Theorem 3.2. By (3.37) we then obtain

$$\sum_{S\in\hat{\mathcal{S}}_k\cap\mathcal{S}_k^2} \rho_S^2 \le 2(d+1)\big(I[u_k] - I[u_k+\varphi]\big) \le 2(d+1)\big(I[u_k] - I[u_{k+1}]\big).$$

Analogously we derive

$$\sum_{S\in\hat{\mathcal{S}}_k\cap\mathcal{S}_k^1} d_S|\rho_S| \le 2(d+1)\big(I[u_k] - I[u_{k+1}]\big).$$

Combining these two inequalities with the selection criterion (2.17a) for $\hat{\mathcal{S}}_k$, we obtain

$$\eta_k \le \frac{1}{\theta}\left[\left(\sum_{S\in\hat{\mathcal{S}}_k\cap\mathcal{S}_k^2} \rho_S^2\right)^{1/2} + \sum_{S\in\hat{\mathcal{S}}_k\cap\mathcal{S}_k^1} d_S|\rho_S|\right] \le g\big(I[u_k] - I[u_{k+1}]\big) \tag{4.3}$$

with $g(t) := 4\theta^{-1}(d+1)\max\{\sqrt{t}, t\}$ for all $t \ge 0$. Thanks to (4.2), we thus devise

$$\lim_{k\to\infty} \eta_k = 0. \tag{4.4}$$

3. Next, we verify the convergence of the nonhierarchical estimator part with the help of (2.17b) and (2.19b). We may write

$$\sum_{T\in\mathcal{T}_k^+} \int_T h_k^2|f|^2 = \int_\Omega h_k^2|f|^2\chi_k,$$

where $\chi_k(x) = 1$ if there is a $T \in \mathcal{T}_k^+$ with $T \ni x$ and $\chi_k(x) = 0$ otherwise. In view of Lebesgue's theorem about dominated convergence, it is sufficient to show that the integrand $h_k^2|f|^2\chi_k$ tends to 0 a.e. in Ω. Note that the set $\Gamma_\infty = \bigcup\{\partial T : T \in \mathcal{T}_k,\ k \in \mathbb{N}\}$ has Lebesgue measure 0 and that, for each $x \in \Omega \setminus \Gamma_\infty$, the sequence $\{h_k(x)\}_{k\in\mathbb{N}}$ is nonincreasing and nonnegative. Consequently, $h_\infty(x) := \lim_{k\to\infty} h_k(x)$ exists and is nonnegative for almost all $x \in \Omega$. Obviously, there holds

$$\lim_{k\to\infty} h_k^2|f|^2\chi_k = 0 \text{ a.e. in } \{h_\infty = 0\} \tag{4.5}$$

with $\{h_\infty = 0\} := \{x \in \Omega \mid h_\infty(x) = 0\}$. In view of (2.19b), the remaining set $\{h_\infty > 0\}$ is covered by the elements of $\mathcal{T}_* := \bigcup_{k\in\mathbb{N}} \bigcap_{\ell\geq k} \mathcal{T}_\ell$ that, after a certain step, will never be refined. Let $T \in \mathcal{T}_*$ be arbitrary and consider two cases.

Case 1: There exists $k \in \mathbb{N}$ such that $T \notin \mathcal{T}_\ell^+$ for all $\ell > k$. Then we readily obtain $\lim_{\ell\to\infty} h_\ell^2|f|^2\chi_\ell = 0$ a.e. in T from $\chi_\ell = 0$ on T for all $\ell > k$.

Case 2: For all $k \in \mathbb{N}$ exists $\ell > k$ with $T \in \mathcal{T}_\ell^+$. The fact that $T \in \mathcal{T}_*$ is not refined after a certain step implies the existence of a subsequence $\{\mathcal{T}_{k_\ell}\}_{\ell\in\mathbb{N}}$ of $\{\mathcal{T}_k\}_{k\in\mathbb{N}}$ such that $T \in \mathcal{T}_{k_\ell}^+ \setminus \hat{\mathcal{T}}_{k_\ell}$ for all $\ell \in \mathbb{N}$. The selection criterion (2.17b) then yields

$$\int_T h_\infty^2|f|^2 = \int_T h_{k_\ell}^2|f|^2 \leq \frac{\eta_{k_\ell}^2}{N_{k_\ell}^+} \leq \eta_{k_\ell}^2,$$

which in turn entails $f = 0$ a.e. in T thanks to (4.4) and $h_{\infty|T} > 0$. Consequently, we obtain $\lim_{k\to\infty} h_k^2|f|^2\chi_k = 0$ a.e. in T also in this case.

Combining the two cases, taking into account that $\mathcal{T}_*$ is separable, and invoking (4.5) yields

$$\lim_{k\to\infty} h_k^2|f|^2\chi_k = 0 \text{ a.e. in } \Omega.$$

Hence, the dominated convergence theorem implies

$$\lim_{k\to\infty} \left(\sum_{T\in\mathcal{T}_k^+} \int_T h_k^2|f|^2 \right)^{1/2} = 0. \tag{4.6}$$

4. Inserting (4.4) and (4.6) into (2.14) yields $\lim_{k\to\infty} \mathcal{E}_k = 0$. Thanks to Proposition 3.2 and Theorem 3.1, we thus obtain $\lim_{k\to\infty} \rho_k(-\mathcal{D}_k) = 0$ as well as

$$m = \lim_{k\to\infty} I[u_k] = I[u].$$

The convergence $u_k \to u$ in $H^1(\Omega)$ then follows from (3.4) and the well-known Poincaré inequality $\|u\| \leq C_\Omega \|\nabla u\|$. □

Remark 4.1 (strict decrease). The estimate (4.3) in step 2 shows that there holds $I[u_{k+1}] < I[u_k]$ whenever the hierarchical part η_k of the estimator is nonzero.

5. Numerical results. In this section we present a couple of examples implemented within the finite element toolbox ALBERTA of Schmidt and Siebert [20, 21]. The computation of the hierarchical estimator involves a global refinement of $\mathcal{T}_k$ that contains for all sides $S \in \mathcal{S}_k$ the corresponding nodes x_S. This globally refined mesh contains the mesh $\mathcal{T}_{k+1}$ of the next step but is in general larger, because not all elements in $\mathcal{T}_k$ are refined when creating $\mathcal{T}_{k+1}$. In order to obtain a cheap realization

of the global refinement of $\mathcal{T}_k$, we correspondingly refine all elements of $\mathcal{T}_k$ in a separate and virtual manner. More precisely, with the help of the rules for refinement by bisection, each element is virtually refined without using information on neighbors and without changing the data structures of the current mesh $\mathcal{T}_k$. The contributions of the hierarchical estimator are then computed on the virtual subelements. If an element is actually refined later on (e.g., when producing $\mathcal{T}_{k+1}$), it is refined in the same way it was virtually refined.

For the virtual refinement of a single element, we use refinement patterns for reference situations that ensure the additional nodes for all sides. In two dimensions, the situation is rather simple, and we need only the one refinement pattern depicted in Figure 3, which exactly corresponds to all children of the second generation. In three dimensions, the situation is more involved: There are elements of three different types where the element type is uniquely assigned by the refinement procedure; see [21, section 1.1.1]. The creation of all children of the fifth generation is sufficient to ensure interior nodes for all sides, but these nodes are already created with fewer bisections producing a certain mixture of children of the fourth and fifth generations. In order to minimize work in the computation of the estimator, we have stored for each element type a refinement pattern with the fewest number of children that guarantees the additional nodes for all faces. However, for the sake of simplicity of the refinement of $\mathcal{T}_k$ into $\mathcal{T}_{k+1}$, we create in (2.18) all children of fifth generation. Note that the test functions φ_S created by the virtual refinement can be written as linear combinations of few hat functions in V_{k+1}.

The estimator is implemented in the form $\mathcal{E}_k := \mathcal{E}_{k,1} + \mathcal{E}_{k,2} + \mathcal{E}_{k,3}$, where

$$\mathcal{E}_{k,1} := c_1 \sum_{S\in\mathcal{S}_k^1} d_S|\rho_S|, \quad \mathcal{E}_{k,2} := c_2 \left(\sum_{S\in\mathcal{S}_k^2} \rho_S^2 \right)^{1/2}, \quad \mathcal{E}_{k,3} := c_3 \left(\sum_{T\in\mathcal{T}_k^+} \int_T h_k^2 |f|^2 \right)^{1/2}$$

and the constants are chosen in all experiments as $c_1 = c_2 = 0.25$ and $c_3 = 0.5$.

5.1. Effect of localization for a Lipschitz obstacle. In order to illustrate the effect of the localization of the estimator $\mathcal{E}_k$ to nonfull-contact regions, we consider an example with Lipschitz obstacle as in [18, section 7.4] and [19, section 3.2]. On the diamond domain $\Omega := \{x = (x_1, x_2) \mid |x_1| + |x_2| < 1\}$, let

$$\psi(x) := \operatorname{dist}(x, \partial\Omega) - \tfrac{1}{2},$$

and $f(x) := -15$. The graph of ψ is a pyramid with a square base centered at the origin; see Figure 4 (left), where also the initial mesh is depicted. Hence, due to the relatively heavy load, the exact solution is in contact in the middle of the domain, then detaches, and finally increases towards the boundary; see Figure 4 (right) for the finite element minimizer u_5 of iteration $k = 5$. Figure 5 displays the meshes for iterations $k \in \{4, 5, 6\}$. Notice that they remain coarse in the contact region, even where the gradient of the finite element minimizers jumps. This saving of degrees of freedoms (DOFs), which is also helpful for solving (2.5) in less stable situations, is thanks to the localization of $\mathcal{E}_k$ to the nonfull-contact region.

5.2. Estimator effectivity for stable free boundaries in two and three dimensions. Next, in the situation of stable free boundaries, we examine the error-estimator relationship and the importance of $\mathcal{E}_{k,1}$—the estimator part that is built up with the "constrained" sides $\mathcal{S}_k^1$. On the domains $\Omega = (-1, 1)^d$ with $d \in \{2, 3\}$,

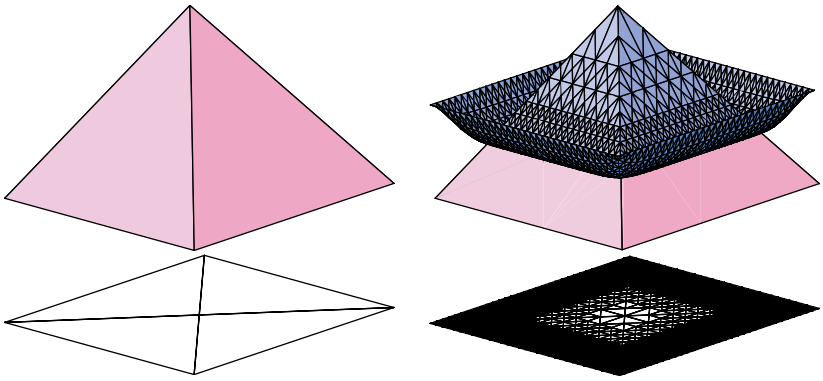

FIG. 4. *Lipschitz obstacle: graphs of the obstacle with initial mesh (left) and finite element minimizer u_5 with corresponding mesh $\mathcal{T}_5$ (right).*

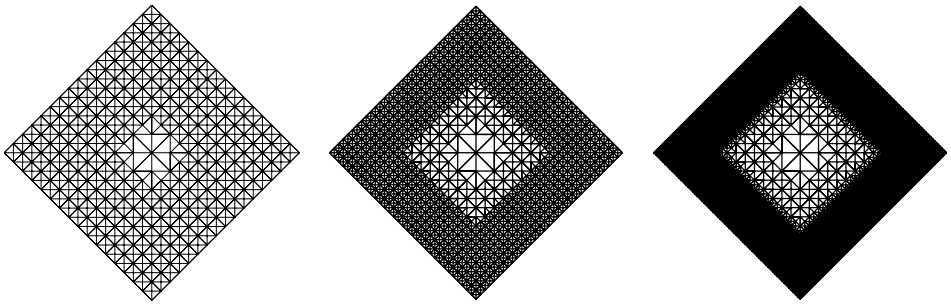

FIG. 5. *Lipschitz obstacle: meshes $\mathcal{T}_k$ for $k \in \{4,5,6\}$. The meshes remain coarse in the contact region thanks to the localization of $\mathcal{E}_k$ to the nonfull-contact region.*

consider a constant obstacle $\psi(x) := 0$, the continuous load

$$f(x) := \begin{cases} -4\left(2\,|x|^2 + d\,(|x|^2 - r^2)\right), & |x| > r, \\ -8\,r^2\left(1 - (|x|^2 - r^2)\right), & |x| \le r, \end{cases}$$

and the Dirichlet boundary values $g(x) := (|x|^2 - r^2)^2$ with $r = 0.7$. (We neglect the approximation of the boundary data that is not piecewise affine.) The exact minimizer to this problem is

$$u(x) = \left(\max\{|x|^2 - r^2, 0\}\right)^2;$$

see Figure 6 for a finite element minimizer in the case $d = 2$. Figure 7 depicts the estimator $\mathcal{E}_k$ from (2.14), the square root of the error $\left(I[u_k] - I[u]\right)^{1/2}$ in the energy minimum, and the energy norm error $\|\nabla(u_k - u)\|$ versus the number of DOFs in a log-log scale. We can see that, at least in these cases, the estimator $\mathcal{E}_k$ is equivalent with $\left(I[u_k] - I[u]\right)^{1/2}$ and $\|\nabla(u_k - u)\|$. Table 5.1 reveals that the constrained part $\mathcal{E}_{k,1}$ is clearly dominated by the unconstrained part $\mathcal{E}_{k,2}+\mathcal{E}_{k,3}$, thus providing a partial explanation for the aforementioned equivalence. These two observations are valid also for the experiments of the following sections, which cover unstable free boundaries. This indicates that, at least typically, the stopping test (2.15) is reliable and efficient

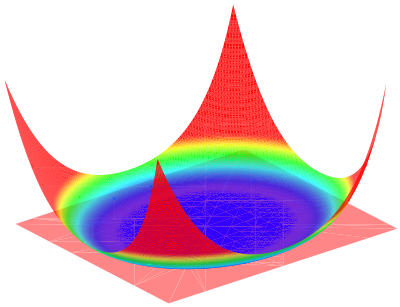

FIG. 6. *Stable free boundary: a finite element minimizer with obstacle for* $d = 2$.

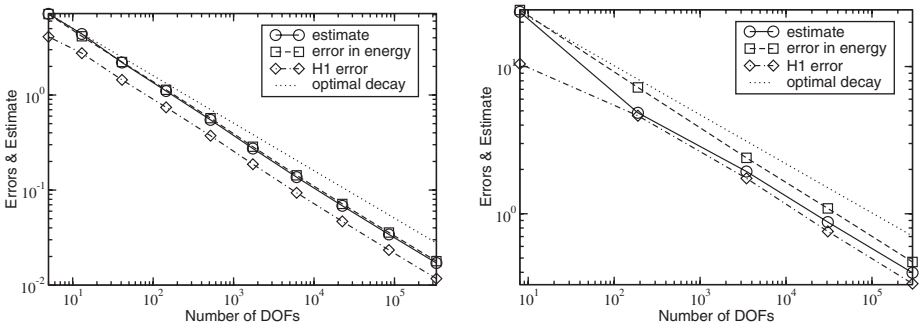

FIG. 7. *Stable free boundary: estimator, error in energy minimum, and energy norm error versus DOFs in log-log scale for* $d = 2$ *(left) and* $d = 3$ *(right). Estimator and errors are equivalent, and their asymptotic decays coincide with the best possible decay rate* $-1/2$ *and* $-1/3$ *for linear finite elements in two and three dimensions, respectively.*

TABLE 5.1

Stable free boundary: comparison of the estimator contributions for $d = 2$ *(left) and* $d = 3$ *(right). The constrained part* $\mathcal{E}_{k,1}$ *is clearly dominated by the unconstrained part* $\mathcal{E}_{k,2} + \mathcal{E}_{k,3}$.

in the usual linear sense; i.e., there holds $\mathcal{E}_k \approx \big(I[u_k] - I[u]\big)^{1/2} \approx \|\nabla(u_k - u)\|$; see also Remarks 3.1 and 3.5.

5.3. Insensitivity to ineffective data changes. The following examples serve to investigate the behavior of the adaptive algorithm with respect to changes in the data that are not reflected in the exact solution. Recall that the adaptive algorithm aims only at the approximation of the exact minimizer and therefore should be insensitive to such changes.

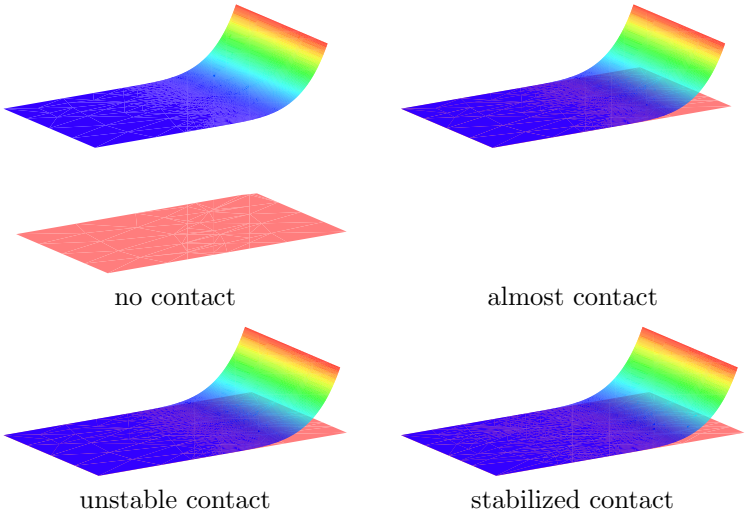

FIG. 8. *Ineffective data changes: comparison of finite element minimizers that approximate the same solution for different data ranging from "no contact" to "stabilized contact." There is no visual difference between the discrete minimizers.*

We consider four examples that all have the same exact solution,

$$u(x_1,x_2) := \begin{cases} \frac{1}{2}x_1^4 & \text{if } x_1 \geq 0, \\ 0 & \text{else} \end{cases} \qquad \text{for } (x_1,x_2) \in \Omega := (-1,1)^2,$$

but different obstacles and loads so that this solution is

- unconstrained,
- "almost in contact" with the obstacle,
- just and thus in a "unstable" manner in contact, and
- in "stabilized contact."

More precisely, let

$$\psi_1 \equiv -1, \quad \psi_2 \equiv -0.001, \quad \psi_3 \equiv \psi_4 \equiv 0$$

and

$$f_i(x_1,x_2) := \begin{cases} -6x_1^2 & \text{if } x_1 \geq 0, \\ 0 & \text{if } x_1 \leq 0 \text{ and } i \in \{1,2,3\}, \\ x_1 & \text{if } x_1 \leq 0 \text{ and } i = 4. \end{cases}$$

The initial mesh is the same for all four examples and not aligned with the one-dimensional structure of the exact solution. Figure 8 depicts for all four examples the finite element minimizers u_4 and Figure 9 the corresponding meshes $\mathcal{T}_4$, while Figure 10 shows the decays of estimator and errors versus number of DOFs in a log-log scale.

We notice that the finite element minimizers and their meshes do not depend, or only little, on the four different data regimes. The same holds true for the decays and, moreover, the single estimator contributions; see Table 5.2. This indicates that the estimator and adaptive algorithm depend essentially only on the approximated exact solution. In particular, it appears insensitive to contact set changes that are not reflected in the solution, even if they are discontinuous; see also Remark 3.3.

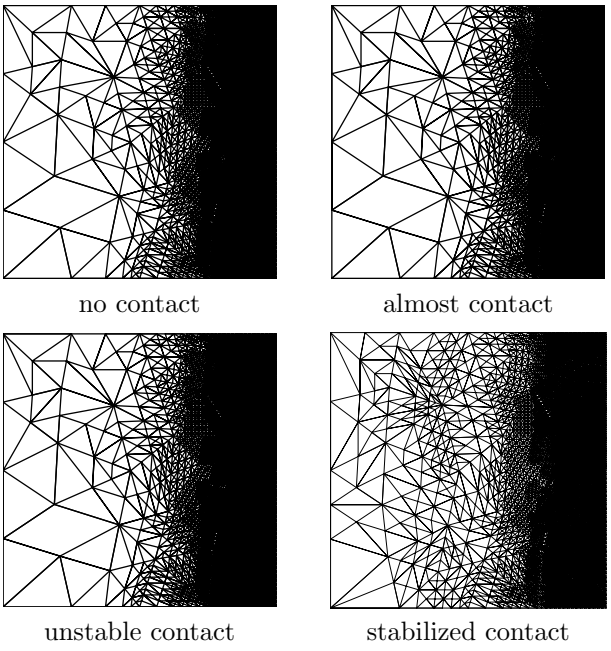

FIG. 9. *Ineffective data changes: comparison of the meshes $\mathcal{T}_4$. Only in the last case of stabilized contact is there a slight difference around the free boundary $x_1 = 0$.*

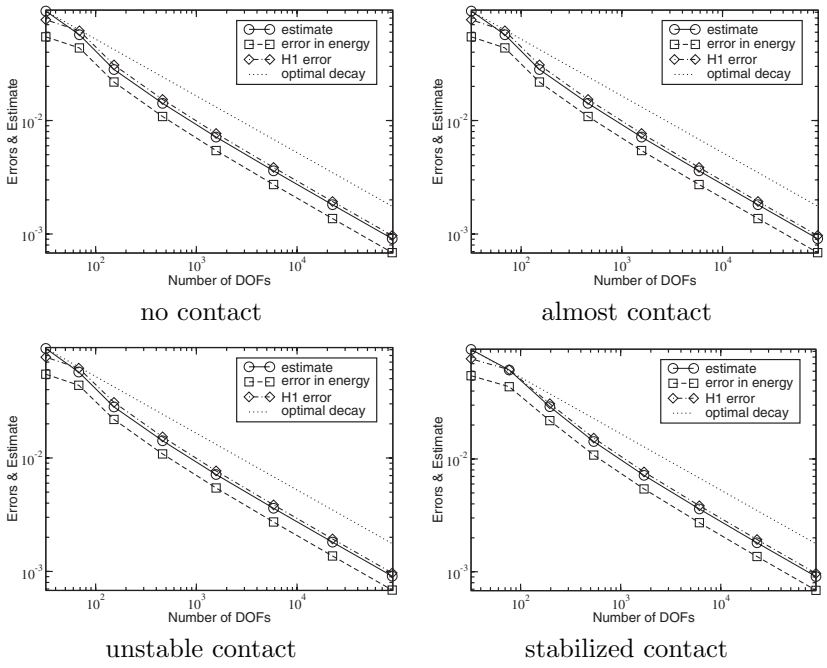

FIG. 10. *Ineffective data changes: comparison of convergence histories of estimator, error in energy minimum, and energy norm error versus number of DOFs in log-log scale. The histories are essentially independent of the varying data, and their asymptotic decays coincide with the best possible decay rate $-1/2$ for linear finite elements.*

TABLE 5.2

Ineffective data changes: comparison of estimator contributions from "no contact" (top) to "stabilized contact" (bottom). Single contributions are essentially independent of varying data.

5.4. Optimal convergence speed for a discontinuous and thin obstacle. The main features of our last example are the singularities of the exact solution that are induced by the discontinuous and thin nature of the obstacle. Figure 11 (left) depicts a finite element minimizer in $\Omega = (-1,1) \times (-\frac{1}{2},\frac{1}{2})$ and reveals also the obstacle that is made of two parts: a "triangle-shaped" one with constant level, and a "segment-shaped" one with increasing level; to be more precise,

$$K_1 := \text{conv hull}\{(0,0),\, (\tfrac{1}{2},0),\, (\tfrac{1}{2},\tfrac{1}{4})\}, \qquad \psi_1(x_1,x_2) = 1,$$
$$K_2 := \text{conv hull}\{(-1,\tfrac{1}{2}),\, (-\tfrac{1}{2},\tfrac{1}{4})\}, \qquad \psi_2(x_1,x_2) = 2 + 2x_1.$$

The load term f is set to 0. Obviously, the induced singularities are related to the ones of solutions to Poisson's equation on domains with reentrant corners or on the crack domain. The solution u is at most in $H^{3/2}(\Omega)$, and thus, for nonadaptive

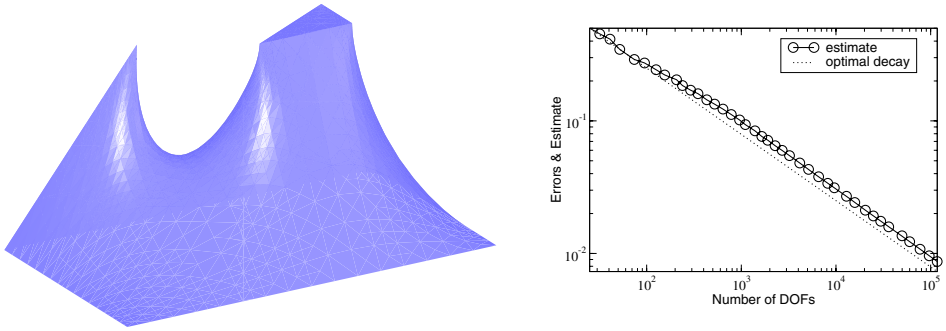

FIG. 11. *Discontinuous and thin obstacle: a finite element minimizer (left) and decay of estimator versus number of DOFs, together with maximum decay rate for nonlinear approximation with linear finite elements, in log-log scale (right).*

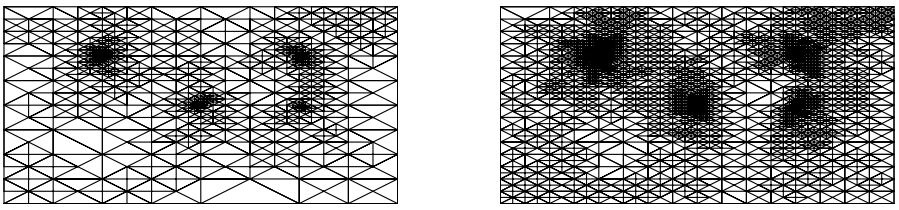

FIG. 12. *Discontinuous and thin obstacle: adaptive meshes $\mathcal{T}_k$ for iteration $k = 15$ (left) and $k = 22$ (right).*

uniform refinement, the decay rate of the energy norm error with respect to the number of DOFs is not better than $-1/4$, see, e.g., [7, Ch. 23]. However, the second derivatives of u are better than $L_1(\Omega)$, entailing that u in the energy norm error can be approximated on adaptive meshes with rate $-1/2$, which is the best decay rate that can be attained with linear finite elements for $d = 2$; see [5, Theorem 9.1 and Remark 9.2].

Figure 12 depicts two correspondingly adapted meshes, and Figure 11 (right) indicates the decay of the estimator $\mathcal{E}_k$ versus the number of DOFs in a log-log scale. The numerically observed decay rate of the estimator is $-1/2$. Notice that in the present case our theory ensures

$$\tfrac{1}{2}\|\nabla(u_k - u)\|^2 \leq I[u_k] - I[u] \approx \tfrac{1}{2}\mathcal{E}_k^2. \tag{5.1}$$

Indeed, the first inequality is just (3.4) and "$\approx$" holds because, on one hand, (3.13) applies, see Remark 3.1, while on the other hand, we need only estimate the term with the unconstrained sides $\mathcal{S}_k^2$ in Theorem 3.2 since the constrained sides $\mathcal{S}_k^1$ in Proposition 3.2 do not contribute. Consequently, (5.1) and the observation that the estimator decays with the best possible rate for the energy norm error mean that the estimator, the error in the energy minimum, and the energy norm error decay with the optimal rate.

Acknowledgment. We thank an anonymous referee for various comments that improved the presentation.

A VECTOR LABELING METHOD FOR SOLVING DISCRETE ZERO POINT AND COMPLEMENTARITY PROBLEMS*

GERARD VAN DER LAAN†, DOLF TALMAN‡, AND ZAIFU YANG§

Abstract. In this paper we establish the existence of a discrete zero point of a function from the n-dimensional integer lattice $\mathbb{Z}^n$ to the n-dimensional Euclidean space $\mathbb{R}^n$ under very general conditions with respect to the behavior of the function. The proof is constructive and uses a combinatorial argument based on a simplicial algorithm with vector labeling and lexicographic linear programming pivot steps. The algorithm provides an efficient method to find an exact solution. We also discuss how to adapt the algorithm for two related problems, namely, to find a discrete zero point of a function under a general antipodal condition and to find a solution to a discrete nonlinear complementarity problem. In both cases the modified algorithm provides a constructive existence proof, too. We further show that the algorithm for the discrete nonlinear complementarity problem generalizes the well-known Lemke's method to nonlinear environments. An economic application is also presented.

Key words. integer lattice, zero point, vector labeling rule, simplicial algorithm, discrete complementarity

1. Introduction.

We consider the problem of finding a point $x^* \in \mathbb{Z}^n$ such that

$$f(x^*) = 0^n,$$

where 0^n is the n-vector of zeroes, $\mathbb{Z}^n$ is the integer lattice of the n-dimensional Euclidean space $\mathbb{R}^n$, and f is a function from $\mathbb{Z}^n$ to $\mathbb{R}^n$. Such an integral point x^* is called a *discrete zero point* of f. Recently, the existence problem of an integral solution has been investigated in several papers. These papers were all inspired by the discrete fixed point statement given in Iimura [11]. In Iimura, Murota, and Tamura [12] and Danilov and Koshevoy [4], the existence theorems concern functions that exhibit the so-called *direction-preserving property* proposed by Iimura [11], which can be seen as the counterpart of the continuity property for functions defined on the Euclidean space $\mathbb{R}^n$. The existence results in Yang [37] and [38] hold for the class of so-called *locally gross direction-preserving* mappings, which is substantially more general and richer than the class of Iimura's direction-preserving mappings and which contains the results in [4] and [12] as special cases. Besides establishing these more general existence results, Yang also initiated in [37] the study of discrete nonlinear complementarity problems and provided several general theorems for the existence of solutions for this class of problems. All this literature, however, is not concerned with the problem of finding an integral solution. In fact, all these existence proofs are nonconstructive.

To provide constructive proofs based on a combinatorial argument, we apply the technique of the so-called simplicial algorithms originally designed to find approximate zero or fixed points of continuous functions or upper semicontinuous mappings. The first of such algorithms was developed by Scarf [28], and subsequent algorithms proposed by Eaves [5], Eaves and Saigal [6], Merrill [23], and van der Laan and Talman [17], among others, substantially improved Scarf's original algorithm in terms of efficiency and applicability. For comprehensive treatments on such algorithms we refer to Allgower and Georg [1], Todd [30], and Yang [36]. The $2n$-ray integer labeling algorithm in [18] and [26] has been modified by van der Laan, Talman, and Yang in [20] to find an integral zero point of a function satisfying the direction-preserving property and in [21] to find a solution of a discrete nonlinear complementarity problem.

The aim of this paper is to provide a combinatorial algorithm for finding an integral zero point of a function satisfying the more general simplicially local gross direction-preserving property. This algorithm is also a modification of the $2n$-ray simplicial algorithm introduced in [18] and [26]. However, in this case we cannot rely on integer labeling anymore; instead we have to apply the more subtle concept of vector labeling. The modified algorithm makes use of a triangulation of $\mathbb{R}^n$, being a family of integral simplices, constructed in such a way that the set of vertices of the simplices of the triangulation is equal to $\mathbb{Z}^n$ and the mesh size of each simplex in the triangulation is equal to 1 according to the maximum norm. Starting with some integral point in $\mathbb{Z}^n$, the algorithm leaves the starting point along one out of $2n$ directions and then generates a sequence of adjacent simplices of varying dimension by making lexicographic linear programming pivot steps in a system of linear equations. We show that under a mild convergence condition the algorithm ends in a finite number of steps with an exact integral zero point. It is worth mentioning that in the case of a continuous function on $\mathbb{R}^n$, algorithms for finding a zero (or fixed) point find only an approximate solution, whereas the current algorithm for the discrete case finds an exact solution.

We also discuss how to adapt the algorithm for two related problems, namely, to find a discrete zero point of a function under a general antipodal condition and to find a solution to a discrete nonlinear complementarity problem. In the first case the antipodal condition guarantees convergency; in the second case we also propose a convergence condition. We show that the modified algorithm for the discrete nonlinear complementarity problem generalizes the well-known Lemke's method. In particular, when the function $f(x)$ is affine, i.e., $f(x) = Mx + q$, where M is an $n \times n$ matrix and q is an integral n-vector, it is shown that the algorithm finds an integral solution provided that M is totally unimodular and copositive-plus, and the system of $Mx+q \geq 0^n$, $x \geq 0^n$, is feasible.

This paper is organized as follows. In section 2 we introduce the concepts of triangulation and simplicially local gross direction-preservingness and describe the algorithm. In section 3 we state a convergence condition guaranteeing the existence of an integral solution to the discrete zero point problem and provide a constructive proof. In section 4 we modify the algorithm for the case that the function satisfies a general antipodal condition. In section 5 we modify the algorithm for the discrete complementarity problem and show that this modified algorithm generalizes Lemke's method. An economic application is discussed in section 6.

2. A method for solving discrete nonlinear equations. For a given positive integer n, let N denote the set $\{1, 2, \ldots, n\}$. For $i \in N$, $e(i)$ denotes the ith unit vector of $\mathbb{R}^n$. Given a set $D \subset \mathbb{R}^n$, $\mathrm{Co}(D)$ and $\mathrm{Bd}(D)$ denote the convex hull of D and the relative boundary of D, respectively. For any x and y in $\mathbb{R}^n$, we say y is

lexicographically greater than x and denote it by $y \succeq x$, if the first nonzero component of $y - x$ is positive.

Two integral points x and y in $\mathbb{Z}^n$ are said to be *cell-connected* if $\max_{h \in N} |x_h - y_h| \leq 1$, i.e., their distance is less than or equal to 1 according to the maximum norm. In other words, two integral points x and y are cell-connected if and only if there exists $q \in \mathbb{Z}^n$ such that both x and y belong to the hypercube $[0,1]^n + \{q\}$.

For an integer t, $0 \leq t \leq n$, the t-dimensional convex hull of $t+1$ affinely independent points $x^1, \ldots, x^{t+1}$ in $\mathbb{R}^n$ is called a *t-simplex* or simply a *simplex* and will be denoted by $\langle x^1, \ldots, x^{t+1} \rangle$. The extreme points $x^1, \ldots, x^{t+1}$ of a t-simplex $\sigma = \langle x^1, \ldots, x^{t+1} \rangle$ are called the *vertices* of σ. The convex hull of any subset of $k+1$ vertices of a t-simplex σ, $0 \leq k \leq t$, is called a *face* or *k-face* of σ. A k-face of a t-simplex σ is called a *facet* of σ if $k = t-1$, i.e., if the number of vertices is just one less than the number of vertices of the simplex. A simplex is said to be *integral* if all of its vertices are integral vectors and are cell-connected. Any two vertices x and y of an integral simplex are said to be *simplicially connected*.

Given an m-dimensional convex set D, a collection $\mathcal{T}$ of m-dimensional simplices is a *triangulation* or *simplicial subdivision* of the set D if (i) D is the union of all simplices in $\mathcal{T}$, (ii) the intersection of any two simplices of $\mathcal{T}$ is either empty or a common face of both, and (iii) any neighborhood of any point in D meets only a finite number of simplices of $\mathcal{T}$. A facet of a simplex of $\mathcal{T}$ either lies on the boundary of D and is a facet of no other simplex of $\mathcal{T}$ or it is a facet of precisely one other simplex of $\mathcal{T}$. A triangulation is called *integral* if all its simplices are integral simplices. One of the most well-known integral triangulations of $\mathbb{R}^n$ is the K-triangulation owing to Freudenthal [8]. This triangulation is the collection of all integral simplices $\sigma(y, \pi)$ with vertices $y^1, \ldots, y^{n+1}$, where, for $y \in \mathbb{Z}^n$ and $\pi = (\pi(1), \ldots, \pi(n))$ a permutation of the elements $1, 2, \ldots, n$, the vertices are given by $y^1 = y$ and $y^{i+1} = y^i + e(\pi(i))$, $i = 1, \ldots, n$. Furthermore, a triangulation $\mathcal{T}$ is *symmetric* if $\sigma \in \mathcal{T}$ implies $-\sigma \in \mathcal{T}$. An example of symmetric integral triangulations of $\mathbb{R}^n$ is the K'-triangulation of Todd [31].

Now we introduce the class of simplicially local gross direction-preserving functions on $\mathbb{Z}^n$ on which the existence theorems of this paper are based. Locally gross direction-preservingness replaces the continuity condition for the existence of a zero point of a function defined on $\mathbb{R}^n$. Let $a \cdot b$ denote the inner product of two n-vectors a and b.

DEFINITION 2.1. (i) *A function $f : \mathbb{Z}^n \to \mathbb{R}^n$ is* locally gross direction-preserving *if, for any cell-connected points x and y in $\mathbb{Z}^n$,*

$$f(x) \cdot f(y) \geq 0.$$

(ii) *A function $f : \mathbb{Z}^n \to \mathbb{R}^n$ is* simplicially local gross direction-preserving *with respect to some given integral triangulation $\mathcal{T}$ of $\mathbb{R}^n$ if, for any vertices x and y of a simplex of $\mathcal{T}$,*

$$f(x) \cdot f(y) \geq 0.$$

The locally gross direction-preserving property was originally introduced in Yang [38] and prevents the function from changing too drastically in direction within one cell. The simplicially local gross direction-preserving condition is weaker and requires only that the function does not change too drastically in direction within any integral simplex of the given integral triangulation. Since any two vertices of a simplex of an integral triangulation are cell-connected, we have the property that every locally gross direction-preserving function is also simplicially local gross direction-preserving with respect to any integral triangulation.

To compute a discrete zero point of a simplicially local gross direction-preserving function, we adapt the $2n$-ray vector labeling algorithm of van der Laan and Talman [18] (see also Reiser [26] for integer labeling) to the current discrete setting. Let f be a simplicially local gross direction-preserving function with respect to some given integral triangulation $\mathcal{T}$ of $\mathbb{R}^n$. Let v be an arbitrarily chosen integral vector in $\mathbb{Z}^n$. The point v will be the starting point of the algorithm. For a nonzero sign vector $s \in \{-1, 0, +1\}^n$, the subset $A(s)$ of $\mathbb{R}^n$ is defined by

$$A(s) = \left\{ x \in \mathbb{R}^n \mid x = v + \sum_{h \in N} \alpha_h s_h e(h),\ \alpha_h \geq 0,\ h \in N \right\}.$$

Clearly, the set $A(s)$ is a t-dimensional subset of $\mathbb{R}^n$, where t is the number of nonzero components of the sign vector s, i.e., $t = |\{i \mid s_i \neq 0\}|$. Since $\mathcal{T}$ is an integral triangulation of $\mathbb{R}^n$, it triangulates every set $A(s)$ into t-dimensional integral simplices. For some s with t nonzero components, denote $\{h_1, \ldots, h_{n-t}\} = \{h \mid s_h = 0\}$, and let $\sigma = \langle x^1, \ldots, x^{t+1} \rangle$ be a t-simplex of the triangulation in $A(s)$. Following Todd [32], who improved the original system of equations used by van der Laan and Talman [18], we say that σ is *almost s-complete* if there is an $(n+2) \times (n+1)$ matrix W satisfying

$$\begin{bmatrix} 1 & \cdots & 1 & 0 & \cdots & 0 & 0 \\ f(x^1) & \cdots & f(x^{t+1}) & e(h_1) & \cdots & e(h_{n-t}) & -s \end{bmatrix} W = I \tag{2.1}$$

and having rows $w^1, \ldots, w^{n+2}$ such that $w^h \succeq 0^{n+1}$ for $1 \leq h \leq t+1$, $w^{n+2} \succeq w^i$ and $w^{n+2} \succeq -w^i$ for $t+1 < i \leq n+1$, and $w^{n+2} \succeq 0^{n+1}$. Here I denotes the identity matrix of rank $n+1$. If $w_1^{n+2} = 0$, then we say that the simplex σ is complete. Further, let τ be a facet of σ, and without loss of generality, index the vertices of σ such that $\tau = \langle x^1, \ldots, x^t \rangle$. We say that τ is *s-complete* if there is an $(n+1) \times (n+1)$ matrix W satisfying

$$\begin{bmatrix} 1 & \cdots & 1 & 0 & \cdots & 0 & 0 \\ f(x^1) & \cdots & f(x^t) & e(h_1) & \cdots & e(h_{n-t}) & -s \end{bmatrix} W = I \tag{2.2}$$

and having rows $w^1, \ldots, w^{n+1}$ such that $w^h \succeq 0^{n+1}$ for $1 \leq h \leq t$, $w^{n+1} \succeq w^i$ and $w^{n+1} \succeq -w^i$ for $t+1 \leq i \leq n$, and $w^{n+1} \succeq 0^{n+1}$. If $w_1^{n+1} = 0$, then we say that τ is complete.

The lemma below says that the zero-dimensional simplex $\langle v \rangle$ is an s^0-complete facet for a uniquely determined sign vector s^0. Let $\alpha = \max_h |f_h(v)|$. If $f_h(v) = -\alpha$ for some h, then we take $s_k^0 = -1$, where k is the smallest index h such that $f_h(v) = -\alpha$, and $s_j^0 = 0$ for $j \neq k$. If $f_h(v) > -\alpha$ for all h, then we take $s_k^0 = 1$, where k is the largest index h such that $f_h(v) = \alpha$, and $s_j^0 = 0$ for $j \neq k$. Let σ^0 be the unique one-dimensional simplex in $A(s^0)$ containing $\langle v \rangle$ as a facet. Clearly, s^0 contains only one nonzero element.

LEMMA 2.2. *The simplex $\langle v \rangle$ is an s^0-complete facet of σ^0. Moreover, s^0 is uniquely determined.*

Proof. Consider the system

$$\begin{bmatrix} 1 & 0 & \cdots & 0 & 0 & \cdots & 0 & 0 \\ f(v) & e(1) & \cdots & e(k-1) & e(k+1) & \cdots & e(n) & -s_k^0 e(k) \end{bmatrix} V = I.$$

Clearly, the first matrix on the left-hand side is regular, and therefore its inverse exists and equals the matrix V. The rows of V are given by

$$v^1 = (1, 0, \ldots, 0),$$

$$v^h = (-f_{h-1}(v), 0, \ldots, 0, 1, 0, \ldots, 0), \quad h = 2, \ldots, k \text{ if } k > 1,$$

with 1 being the hth component,

$$v^h = (-f_{h-1}(v), 0, \ldots, 0, 1, 0, \ldots, 0), \quad h = k+1, \ldots, n \text{ if } k < n,$$

with 1 being the $(h+1)$th component, and

$$v^{n+1} = (s_k^0 f_k(v), 0, \ldots, 0, -s_k^0, 0, \ldots, 0),$$

with $-s_k^0$ being the $(k+1)$th component. Clearly, v^1 is lexicographically positive. Moreover, v^{n+1} is lexicographically positive, because we have either $s_k^0 f_k(v) > 0$ or $s_k^0 f_k(v) = 0$ and $-s_k^0 > 0$. For $j = 2, \ldots, k$, we have $v^{n+1} \succeq v^j$, because $s_k^0 f_k(v) > 0$ and $s_k^0 f_k(v) > -f_{j-1}(v)$, and we also have $v^{n+1} \succeq -v^j$, because $s_k^0 f_k(v) > 0$ and $s_k^0 f_k(v) > f_{j-1}(v)$. For $j = k+1, \ldots, n$ and $s_k^0 = -1$, we have $v^{n+1} \succeq v^j$, because either $s_k^0 f_k(v) > 0$ and $s_k^0 f_k(v) > -f_j(v)$ or $s_k^0 f_k(v) = -f_j(v)$ and the $(j+1)$th component of v^j is 0, but the same component of v^{n+1} is 1; we also have $v^{n+1} \succeq -v^j$, because either $s_k^0 f_k(v) > 0$ and $s_k^0 f_k(v) > f_j(v)$ or $s_k^0 f_k(v) = f_j(v)$ and the $(j+1)$th component of v^j is 0, but the same component of v^{n+1} is 1. For $j = k+1, \ldots, n$ and $s_k^0 = 1$, we have $v^{n+1} \succeq v^j$, because $s_k^0 f_k(v) > 0$ and $s_k^0 f_k(v) > -f_j(v)$, and we also have $v^{n+1} \succeq -v^j$, because either $s_k^0 f_k(v) > 0$ and $s_k^0 f_k(v) > f_j(v)$ or $s_k^0 f_k(v) = f_j(v)$ and the $(j+1)$th component of $-v^j$ is -1, but the same component of v^{n+1} is 0. Hence, V satisfies all the requirements of the matrix W in system (2.2), and thus $\langle v \rangle$ is an s^0-complete facet of σ^0. Clearly, there is no other sign-vector s for which $\langle v \rangle$ is s-complete. □

We are now able to describe the algorithm for finding an integral solution to the system of equations $f(x) = 0^n$. When for some nonzero sign vector s a t-simplex $\sigma = \langle x^1, \ldots, x^{t+1} \rangle$ in $A(s)$ is almost s-complete, the system (2.1) has two "basic solutions." At each of these solutions exactly one row of the solution matrix W is binding. If $w_1^{n+2} = 0$, then σ is complete. If $w^h \succeq 0^{n+1}$ is binding for some h, $1 \le h \le t+1$, then the facet τ of σ opposite the vertex x^h is s-complete, and so τ is either (i) the zero-dimensional simplex $\langle v \rangle$ or (ii) a facet of precisely one other almost s-complete t-simplex σ' of the triangulation in $A(s)$ or (iii) τ lies on the boundary of $A(s)$ and is an almost s'-complete $(t-1)$-simplex in $A(s')$ for some unique nonzero sign vector s' with $t-1$ nonzero elements differing from s in only one element. If $w^{n+2} \succeq w^i$ ($w^{n+2} \succeq -w^i$) is binding for some $t+1 < i \le n+1$, σ is an s'-complete facet of precisely one almost s'-complete $(t+1)$-simplex in $A(s')$ for some nonzero sign vector s' differing from s in only the ith element, namely, $s'_i = +1$ (-1).

Since $\langle v \rangle$ is s^0-complete, σ^0 is an almost s^0-complete one-dimensional simplex in $A(s^0)$. Starting with σ^0, the $2n$-ray algorithm generates a sequence of adjacent almost s-complete simplices in $A(s)$ with s-complete common facets for varying sign vectors s. Moving from one s-complete facet to the next s'-complete facet corresponds to making a lexicographic linear programming pivot step from one of the two basic solutions of system (2.1) to the other. The algorithm stops as soon as it finds a complete simplex. We will show that in that case one of its vertices is a discrete zero point of the function f.

LEMMA 2.3. *Let f be simplicially local gross direction-preserving with respect to $\mathcal{T}$. Then any complete simplex contains a discrete zero point of the function f.*

Proof. Let $x^1, \ldots, x^{k+1}$ be the vertices of a complete simplex σ in $A(s)$, and let t be the number of nonzeros in s. Notice that $k = t-1$ or $k = t$ depending on whether σ is a t-simplex in $A(s)$ or a facet of a t-simplex in $A(s)$. From the system (2.1) or (2.2) it follows that there exists $\lambda_1 \geq 0, \ldots, \lambda_{k+1} \geq 0$ with sum equal to 1 such that $\sum_{j=1}^{k+1} \lambda_j f(x^j) = 0^n$. Let j^* be such that $\lambda_{j^*} > 0$. Then by premultiplying $f(x^{j^*})$ on both sides of $\sum_{j=1}^{k+1} \lambda_j f(x^j) = 0^n$, we obtain

$$\lambda_1 f(x^1) \cdot f(x^{j^*}) + \cdots + \lambda_{j^*} f(x^{j^*}) \cdot f(x^{j^*}) + \cdots + \lambda_{k+1} f(x^{k+1}) \cdot f(x^{j^*}) = 0.$$

Since f is simplicially local gross direction-preserving, it is easy to see that every term in the above expression is nonnegative. Therefore every term is equal to 0. In particular, $f(x^{j^*}) = 0^n$, and so x^{j^*} is a discrete zero point of the function f. ∎

Formally, the steps of the above algorithm are given below in detail.

1. Initial Step: Compute $f(v)$. If $f(v) = 0^n$, then the algorithm terminates with v as a solution. Otherwise $\langle v \rangle$ is an s^0-complete facet of a unique 1-simplex $\sigma^0 = \langle v, v^+ \rangle$ in $A(s^0)$. Let $s = s^0$, $t = |\{i \mid s_i \neq 0\}|$, and $\sigma = \sigma^0$. Go to main step 1 with the system (2.1) corresponding to σ^0.
2. Main Step 1: Perform a lexicographic linear programming (LLP) pivot step in the system (2.1) with the column $(1, f(v^+))$. If $w_1^{n+2} = 0$, the algorithm terminates with a complete simplex which yields a solution. Otherwise, in the case that $w^h \succeq 0^{n+1}$ is binding for some h, $1 \leq h \leq t+1$, then the facet τ of σ opposite the vertex x^h is s-complete, and go to main step 2. In the case that $w^{n+2} \succeq w^i$ ($w^{n+2} \succeq -w^i$) is binding for some $t+1 < i \leq n+1$, go to main step 3.
3. Main Step 2: If τ is a facet of precisely one other almost s-complete t-simplex σ' of the triangulation in $A(s)$, let v^+ be the vertex of σ' differing from those of τ, let $\sigma = \sigma'$, and go to main step 1. Otherwise, τ lies on the boundary of $A(s)$ and is an almost s'-complete $(t-1)$-simplex in $A(s')$ for some unique nonzero sign vector s' with $t-1$ nonzero elements differing from s in only one element. Let h be the unique element with $s_h \neq 0$ and $s'_h = 0$, $\sigma = \tau$ and $s = s'$, and go to main step 4.
4. Main Step 3: σ is an s'-complete facet of precisely one almost s'-complete $(t+1)$-simplex σ' in $A(s')$ for some nonzero sign vector s' differing from s in only the ith element, namely, $s'_i = +1$ (-1). Let v^+ be the vertex of σ' differing from those of σ, $s = s'$ and $\sigma = \sigma'$, and go to main step 1.
5. Main Step 4: Perform an LLP pivot step in the system (2.1) with the column $(0, e(h))$. If $w_1^{n+2} = 0$, the algorithm terminates with a complete simplex which yields a solution. Otherwise, in the case that $w^h \succeq 0^{n+1}$ is binding for some h, $1 \leq h \leq t+1$, then the facet τ of σ opposite the vertex x^h is s-complete, and go to main step 2. In the case that $w^{n+2} \succeq w^i$ ($w^{n+2} \succeq -w^i$) is binding for some $t+1 < i \leq n+1$, go to main step 3.

Because all steps are uniquely determined due to the lexicographically pivoting and the properties of a triangulation, the algorithm cannot visit any simplex more than once, and therefore either the algorithm terminates in a finite number of iterations with a complete simplex yielding a solution or the sequence of simplices generated by the algorithm goes to infinity. In the next section we present a convergence condition which prevents the latter case from happening and thus ensures the existence of a solution.

3. Convergence conditions. To present a convergence condition for the algorithm, for $x \in \mathbb{Z}^n$, let $N(x)$ denote the set of integer points being simplicially connected to x.

Assumption 3.1 (convergence condition). Given a function $f : \mathbb{Z}^n \to \mathbb{R}^n$, there exist vectors m, $M \in \mathbb{Z}^n$, with $m_h < M_h - 1$ for every $h \in N$, such that for every integral vector x on the boundary of the set $C^n = \{z \in \mathbb{R}^n \mid m \leq z \leq M\}$ the following conditions hold:

(i) If $x_i = m_i$, then $f_i(y) \geq 0$ for all $y \in N(x) \cap C^n$ satisfying $y_i = m_i$, or there exists $j \in N$ such that $f_j(y) < f_i(y)$ for all $y \in N(x) \cap C^n$ satisfying $y_i = m_i$.

(ii) If $x_i = M_i$, then $f_i(y) \leq 0$ for all $y \in N(x) \cap C^n$ satisfying $y_i = M_i$, or there exists $j \in N$ such that $f_j(y) > f_i(y)$ for all $y \in N(x) \cap C^n$ satisfying $y_i = M_i$.

The condition means that there exist lower and upper bounds such that, when x is an integral vector on the ith lower (upper) bound, then either $f_i(y)$ is nonnegative (nonpositive) for any integral vector y on the same lower (upper) bound being simplicially connected to x or, for some $j \neq i$, $f_i(y)$ is bigger (smaller) than $f_j(y)$ for any integral vector y on the same lower (upper) bound being simplicially connected to x. We show that under this condition any simplicially local gross direction-preserving function has a discrete zero point within the bounded set C^n induced by the lower and upper bounds. To do so, the starting point v of the $2n$-ray algorithm is taken to be an arbitrarily chosen integral vector in the interior of the set C^n. Then the constructive proof of Theorem 3.2 is based on the combinatorial argument that under the convergence condition the algorithm cannot cross the boundary of the set C^n, and therefore it must terminate in a finite number of steps with a simplex having one of its vertices as an integral solution to f. It is worth pointing out that while both the lower and upper bounds are part of the condition in the theorem, in our constructive proof we need only the starting point to lie between these bounds without need to know exactly what they are. Typically, in applications these bounds are naturally determined and indicate the domain of interest underlying the problem; see, for instance, the application in section 6.

THEOREM 3.2. *Let $f : \mathbb{Z}^n \to \mathbb{R}^n$ be a simplicially local gross direction-preserving function with respect to some integral triangulation $\mathcal{T}$. If f satisfies Assumption* 3.1*, then f has a discrete zero point.*

Proof. Take any integral vector in the interior of the set C^n as the starting point v of the algorithm. By definition of integral triangulation, $\mathcal{T}$ triangulates the set C^n and also the set $A(s) \cap C^n$ for any sign vector s into integral simplices.

For some nonzero sign vector s, let τ be an s-complete facet in $A(s)$ with vertices $x^1, \ldots, x^t$, where t is the number of nonzeros in s. We first show that τ is complete if it is on the boundary of C^n. From system (2.2) it follows that there exist $\lambda_1 \geq 0, \ldots, \lambda_t \geq 0$ with sum equal to 1, $\beta \geq 0$, and $-\beta \leq \mu_i \leq \beta$ for $s_i = 0$ such that $\bar{f}_i(z) = \beta$ if $s_i = 1$, $\bar{f}_i(z) = -\beta$ if $s_i = -1$, and $\bar{f}_i(z) = \mu_i$ if $s_i = 0$, where $z = \sum_{i=1}^t \lambda_i x^i$ and $\bar{f}(z) = \sum_{i=1}^t \lambda_i f(x^i)$; i.e., $\bar{f}$ is the piecewise linear extension of f with respect to $\mathcal{T}$. Since τ lies on the boundary of C^n, there exists an index h such that either $x_h^j = m_h$ for all j or $x_h^j = M_h$ for all j. In case $x_h^j = m_h$ for all j, we have $s_h = -1$ and therefore $\bar{f}_h(z) = -\beta$. Furthermore, by Assumption 3.1, we have (i) $f_h(x^j) \geq 0$ for all j or (ii) there exists k such that $f_k(x^j) < f_h(x^j)$ for all j. In case (ii) we obtain $\bar{f}_k(z) < \bar{f}_h(z)$. On the other hand, $\bar{f}_k(z) \geq -\beta = \bar{f}_h(z)$, yielding a contradiction; i.e., this case cannot occur. In case (i) we obtain $\bar{f}_h(z) \geq 0$. On the other hand $\bar{f}_h(z) = -\beta \leq 0$. Therefore $\bar{f}_h(z) = 0$ and also $\beta = 0$. Since $w_1^{n+1} = \beta$ we obtain that τ is complete. Similarly, we can show that the same results hold for the case of $x_h^j = M_h$ for all j.

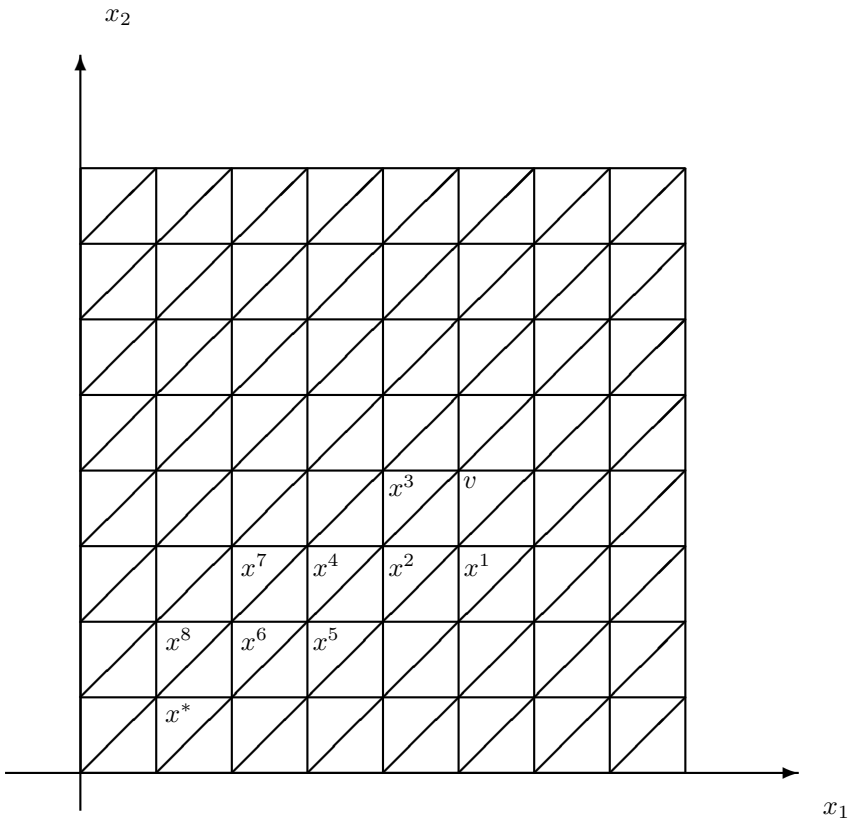

FIG. 1. *Illustration of the algorithm.*

Now, consider the algorithm as described at the end of the previous section. Due to the lexicographic pivoting rule, the algorithm will never visit any simplex more than once. So, because the number of simplices in C^n is finite, the algorithm finds in a finite number of steps a complete simplex. Since f is simplicially local gross direction-preserving, Lemma 2.3 guarantees that at least one of the vertices of this simplex is a discrete zero point of the function f. □

We conclude this section with an example to illustrate the conditions of the theorem and how the algorithm operates. Consider the function $f : \mathbb{Z}^2 \to \mathbb{R}^2$ defined by $f(x) = (2 - 2x_1, x_1 - x_2^2)$. This function is simplicially locally gross direction-preserving with respect to the K-triangulation described in the previous section. It is interesting to note that f is not locally gross direction-preserving since, e.g., for the cell-connected points $x = (1, 2)$ and $y = (2, 1)$, we have $f(x) = (0, -3)$ and $f(y) = (-2, 1)$ and so $f(x) \cdot f(y) = -3 < 0$. Further, the example satisfies Assumption 3.1 for any vector $m = (a, a)$ and $M = (b, b)$ with $a < 0$ and $b > 1$, implying that the convergence condition of Theorem 3.2 is satisfied. Hence, there exists a solution, and in fact $x^* = (1, 1)$ is a discrete zero point. Let the starting point v be $(5, 4)$. Then the sequence of points traced by the algorithm is shown in Figure 1 and given by $x^1 = (5, 3)$, $x^2 = (4, 3)$, $x^3 = (4, 4)$, $x^4 = (3, 3)$, $x^5 = (3, 2)$, $x^6 = (2, 2)$, $x^7 = (2, 3)$, and $x^8 = (1, 2)$ and leads to the solution $x^* = (1, 1)$ in 10 function evaluations. Observe that to apply the algorithm we do not need to fix the bounds a priori.

The following corollary strengthens a result of Yang [38] for locally gross direction-preserving functions and follows immediately from Theorem 3.2.

COROLLARY 3.3. *Let $f : \mathbb{Z}^n \to \mathbb{R}^n$ be a simplicially local gross direction-preserving function. Suppose that there exist vectors m, $M \in \mathbb{Z}^n$, with $m_h < M_h - 1$ for every $h \in N$, such that for every integral vector x on the boundary of the set $C^n = \{z \in \mathbb{R}^n \mid m \le z \le M\}$, $x_i = m_i$ implies $f_i(x) \ge 0$ and $x_i = M_i$ implies $f_i(x) \le 0$. Then f has a discrete zero point.*

Furthermore, we have the following discrete fixed point theorem.

COROLLARY 3.4. *Let $D^n = \{z \in \mathbb{Z}^n \mid m \le z \le M\}$, where m and M are vectors in $\mathbb{Z}^n$ with $m_h < M_h - 1$ for every $h \in N$. Assume that $f : D^n \to \mathrm{Co}(D^n)$ is a function such that $x - f(x)$ is a simplicially local gross direction-preserving function in x. Then f has a discrete fixed point.*

Proof. Define the function $g : D^n \to \mathbb{R}^n$ by $g(x) = x - f(x)$. Clearly, g satisfies the condition of Corollary 3.3. So there exists $x^* \in D^n$ such that $g(x^*) = 0$, i.e., $f(x^*) = x^*$. □

4. Convergency under an antipodal condition. In this section we modify the algorithm in section 2 to find a discrete zero point under a general antipodal condition to be stated next.

Assumption 4.1 (antipodal condition). Given a function $f : \mathbb{Z}^n \to \mathbb{R}^n$, there exists a vector $u \in \mathbb{Z}^n$ with $u_h \ge 1$ for all $h \in N$ such that $f(x) \cdot f(-y) \le 0$ for any cell-connected integral points x and y lying on a same proper face of the set $U^n = \{z \in \mathbb{R}^n \mid -u \le z \le u\}$.

This condition is very natural and might be viewed as a discrete analogue of a weak version of the Borsuk–Ulam antipodal condition for a continuous function saying that $f(x) \cdot f(-x) \le 0$ when x is on the boundary of U^n. It is known that under the latter condition a continuous function has a zero point; see for instance van der Laan [16] and Yang [36]. Todd and Wright [33] used a modification of the $2n$-ray algorithm to give a constructive proof of the Borsuk–Ulam theorem and Freund and Todd [9] used the modified algorithm to give a constructive proof for a combinatorial lemma of Tucker [34]. Yang [38] proposed the antipodal condition and showed that under the condition a locally gross direction-preserving function has a discrete zero point. The next theorem strengthens this result by allowing for simplicially local gross direction-preservingness on a symmetric triangulation in the interior of U^n.

THEOREM 4.2. *Let $f : \mathbb{Z}^n \to \mathbb{R}^n$ be a simplicially local gross direction-preserving function with respect to a symmetric integral triangulation $\mathcal{T}$ of $\mathbb{R}^n$, satisfying Assumption* 4.1 *and $f(x) \cdot f(y) \ge 0$ for any cell-connected integral points x and y lying on a same proper face of the set U^n. Then f has a discrete zero point.*

The next example illustrates the theorem. Let $f : \mathbb{Z}^2 \to \mathbb{R}^2$ be given by $f(x) = (x_1 - x_2 - 1,\ x_2 - 1)$. Then it is easy to see that f satisfies the antipodal property for $u_1 = u_2 = 4$. Further, it is easy to check that f is simplicially local gross direction-preserving with respect to the symmetric integral K'-triangulation of $\mathbb{R}^2$ (see section 2) on the interior of U^n and f is locally gross direction-preserving on the boundary of U^n, as required in the last condition of the theorem. So, f has a discrete zero point and in fact the point $(2, 1)$ is the unique discrete zero point. Observe that f is not locally gross direction-preserving in the interior of U^n and therefore the existence does not follow from the result of Yang [38]. For instance, for the cell-connected points $x = (2, 0)$ and $y = (1, 1)$, we have $f(x) \cdot f(y) = -1 < 0$.

Besides the relaxation to simplicially local gross direction-preserving, the main contribution of this section is that, in contrast to the nonconstructive proof in [38], below we give a constructive proof for the theorem. We now modify the $2n$-ray algorithm of section 2 to accomodate the antipodal condition. The modification is

based on a lemma on the extension V^n of the set U^n given by

$$V^n = \{x \in \mathbb{R}^n \mid -(u_i + 1) \le x_i \le u_i + 1 \ \ \forall i \in N\}.$$

Let the projection function $p : V^n \to U^n$ be defined by

$$p_h(x) = \max\{-u_h, \min\{u_h, x_h\}\} \ \ \forall h \in N.$$

Clearly, $p(x) = x$ if $x \in U^n$. Moreover, $p(x) \in U^n \cap \mathbb{Z}^n$ if $x \in V^n \cap \mathbb{Z}^n$. We now extend f to the function $g : V^n \cap \mathbb{Z}^n \to \mathbb{R}^n$ by setting $g(x) = f(x)$ for $x \in U^n$ and $g(x) = f(p(x)) - f(-p(x))$ for $x \in V^n \setminus U^n$. It follows straightforwardly that $g(x) = -g(-x)$ for any $x \in \mathbb{Z}^n \cap \mathrm{Bd}(V^n)$. We now have the following lemma.

LEMMA 4.3. *For $f : \mathbb{Z}^n \to \mathbb{R}^n$ as given in Theorem* 4.2*, the extension g of f to V^n is simplicially local gross direction-preserving on $\mathbb{Z}^n \cap V^n$ with respect to the given symmetric triangulation $\mathcal{T}$.*

Proof. Clearly, g is simplicially local gross direction-preserving on U^n. It remains to consider the following two cases.

First, let $x, y \in \mathbb{Z}^n$ be two vertices of a simplex of $\mathcal{T}$ on the boundary of V^n. Then $p(x)$ and $p(y)$ are two cell-connected points on a same proper face of U^n and thus satisfy $f(p(x)) \cdot f(p(y)) \ge 0$. The same holds for $-p(x)$ and $-p(y)$. Together with the antipodal Assumption 4.1 this yields

$$\begin{aligned} g(x) \cdot g(y) &= (f(p(x)) - f(-p(x))) \cdot (f(p(y)) - f(-p(y))) \\ &= f(p(x)) \cdot f(p(y)) - f(p(x)) \cdot f(-p(y)) - f(-p(x)) \cdot f(p(y)) \\ &\quad + f(-p(x)) \cdot f(-p(y)) \ge 0. \end{aligned}$$

Second, let $x, y \in \mathbb{Z}^n$ be two vertices of a simplex of $\mathcal{T}$ with x on the boundary of U^n and y on the boundary of V^n. Again x and $p(y)$ are two cell-connected points on a same proper face of U^n and thus $f(x) \cdot f(p(y)) \ge 0$. Together with the antipodal condition this again yields

$$\begin{aligned} g(x) \cdot g(y) &= f(x) \cdot (f(p(y)) - f(-p(y))) \\ &= f(x) \cdot f(p(y)) - f(x) \cdot f(-p(y)) \ge 0. \end{aligned}$$ □

Proof of Theorem 4.2. To prove the theorem, let the set V^n and the function g be defined as above. Take the origin 0^n of $\mathbb{R}^n$ as the starting point v of the algorithm as described in section 2. The underlying symmetric integral triangulation $\mathcal{T}$ for the function f subdivides each set $A(s)$ into t-simplices such that if σ is a simplex in $A(s)$, then $-\sigma$ is a simplex in $A(-s)$.

Starting with the origin, the algorithm generates a sequence of adjacent almost s-complete simplices with s-complete common facets in $A(s) \cap V^n$ for varying sign vectors s with the following modification. If in the main step 2 of the algorithm τ is an s-complete facet lying in $A(s)$ on the boundary of V^n, then the antipodal facet $-\tau$ is a $(-s)$-complete facet in $A(-s)$ on the boundary of V^n, since $g(x) = -g(-x)$ for any $x \in \mathbb{Z}^n \cap \mathrm{Bd}(V^n)$. The algorithm continues with main step 1 by letting $s = -s$, σ the unique almost $(-s)$-complete simplex in $A(-s) \cap V^n$ containing $-\tau$ as a facet and v^+ the vertex of σ opposite to facet $-\tau$. The algorithm therefore always stays in V^n and due to the lexicographic pivoting rule will never visit any simplex in V^n more than once. Since the number of simplices in V^n is finite, within a finite number of steps the algorithm terminates with a complete simplex σ^* in V^n. Since g is simplicially local gross direction-preserving, by the Lemmas 2.3 and 4.3 it follows that σ^* has a vertex z being a discrete zero point of g. It remains to prove that $p(z) \in U^n$ is a discrete

zero point of f. If z is not on the boundary of V^n, then $p(z) = z$ is an integral vector in U^n and $g(z) = f(z)$, and therefore z is a discrete zero point of f. Suppose z is on the boundary of V^n. Since $g(z) = 0^n$, this implies

$$\begin{aligned} 0 &= f(p(z)) \cdot g(z) = f(p(z)) \cdot (f(p(z)) - f(-p(z))) \\ &= f(p(z)) \cdot f(p(z)) - f(p(z)) \cdot f(-p(z)), \end{aligned}$$

and therefore

$$0 \leq f(p(z)) \cdot f(p(z)) = f(p(z)) \cdot f(-p(z)) \leq 0,$$

where the last inequality follows from the antipodal condition on f. Hence, $f(p(z)) \cdot f(p(z)) = 0$ and therefore $p(z)$ is a discrete zero point of f in U^n. □

5. A method for discrete complementarity problems. The complementarity problem is to find a point $x^* \in \mathbb{R}^n$ such that

$$x^* \geq 0^n, \quad f(x^*) \geq 0^n, \quad \text{and} \quad x^* \cdot f(x^*) = 0,$$

where f is a given function from $\mathbb{R}^n$ into itself. For an arbitrary function f, the problem is called the *nonlinear complementarity problem*. In case f is affine, i.e., $f(x) = Mx + q$ with M being an $n \times n$ matrix and q being an n-vector, the problem is called the *linear complementarity problem*, denoted by LCP(M, q). There is by now a voluminous literature on the complementarity problem; see Lemke [22], Cottle [2], Karamardian [13], Moré [24] and [25], Kojima [14], and van der Laan and Talman [19], among others. For comprehensive surveys on the subject, see, e.g., Kojima et al. [15], Cottle, Pang, and Stone [3], and Facchinei and Pang [7].

In the following we consider the problem that the solution of the complementarity problem is required to be integral or that the function f is defined only on the integer lattice $\mathbb{Z}^n$ of $\mathbb{R}^n$. In this case we call the problem the *discrete complementarity problem*, denoted by DCP(f). We first give sufficient conditions under which the general case DCP(f) has a solution, and we will give a constructive proof of this existence result by modifying the system of equations of the algorithm in section 2 to the current situation. Next we will show that when applied to the linear complementarity problem LCP(M, q), the algorithm reduces to the well-known Lemke's method [22] and finds an integral solution provided that M is totally unimodular and copositive-plus, and the system of $Mx + q \geq 0^n$, $x \geq 0^n$, is feasible.

In the following, for any $x, y \in \mathbb{R}^n$, let $I(x) = \{i \mid x_i > 0\}$, and let $I(x, y) = I(x) \cup I(y)$. We first modify the definition of simplicially local gross direction-preservingness for points on the boundary of the nonnegative orthant $\mathbb{R}^n_+$.

DEFINITION 5.1. *A function $f : \mathbb{Z}^n \to \mathbb{R}^n$ is* simplicially local gross direction-preserving *with respect to some given integral triangulation $\mathcal{T}$ of $\mathbb{R}^n$ if, for any two vertices x and y of a simplex of $\mathcal{T}$ in $\mathbb{R}^n_+$, it holds that*

$$f_i(x) f_i(y) \geq 0 \ \textit{whenever} \ x_i = y_i = 0 \ \textit{and} \ \sum_{h \in I(x,y)} f_h(x) f_h(y) \geq 0.$$

The next theorem establishes the existence of a solution to DCP(f) under a natural condition.

THEOREM 5.2. *Let $f : \mathbb{Z}^n \to \mathbb{R}^n$ be a simplicially local gross direction-preserving function on $\mathbb{Z}^n_+$. If there exists a vector $M \in \mathbb{Z}^n_{++}$ such that, for any $x \in \mathbb{Z}^n_+$ with $x \leq M$, $x_i = M_i$ implies $f_i(x) \geq 0$, then DCP(f) has a solution.*

We will provide a constructive proof by applying the algorithm in section 2 to the current situation. To do so, the origin 0^n is taken as the starting point v. Since 0^n lies on the boundary of $\mathbb{R}^n_+$, the sets $A(s)$ and s-completeness are defined only for nonnegative nonzero sign vectors s. Notice that $A(s) = \{x \in \mathbb{R}^n_+ \mid x_i = 0 \text{ whenever } s_i = 0\}$. Further, to apply the algorithm in this case, we have to adapt the concepts of an almost s-complete simplex and an s-complete facet. For some sign vector s with t positive components, denote $\{h_1, \ldots, h_{n-t}\} = \{h \mid s_h = 0\}$, and let $\sigma = \langle x^1, \ldots, x^{t+1}\rangle$ be a t-simplex of the triangulation in $A(s)$. Then σ is *almost s-complete* if there is an $(n+2) \times (n+1)$ matrix W being a solution to system

$$\begin{bmatrix} 1 & \cdots & 1 & 0 & \cdots & 0 & 0 \\ f(x^1) & \cdots & f(x^{t+1}) & -e(h_1) & \cdots & -e(h_{n-t}) & s \end{bmatrix} W = I \tag{5.1}$$

and having rows $w^1, \ldots, w^{n+2}$ such that $w^h \succeq 0^{n+1}$ for $1 \le h \le t+1$, $w^{n+2} \succeq -w^i$ for $t+1 < i \le n+1$, and $w^{n+2} \succeq 0^{n+1}$. If $w^{n+2}_1 = 0$, then we say that the simplex σ is complete. For τ a facet of σ, without loss of generality, letting $\tau = \langle x^1, \ldots, x^t\rangle$, τ is *s-complete* if there is an $(n+1) \times (n+1)$ matrix W being a solution to system

$$\begin{bmatrix} 1 & \cdots & 1 & 0 & \cdots & 0 & 0 \\ f(x^1) & \cdots & f(x^t) & -e(h_1) & \cdots & -e(h_{n-t}) & s \end{bmatrix} W = I \tag{5.2}$$

and having rows $w^1, \ldots, w^{n+1}$ such that $w^h \succeq 0^{n+1}$ for $1 \le h \le t$, $w^{n+1} \succeq -w^i$ for $t+1 \le i \le n$, $w^{n+1} \succeq 0^{n+1}$. If $w^{n+1}_1 = 0$, then we say that τ is complete.

With respect to the starting point 0^n, let $\alpha = \min_h f_h(0^n)$, and let s^0 be the sign vector with $s^0_k = 1$, where k is the smallest index h such that $f_h(0^n) = \alpha$, and $s^0_j = 0$ for $j \ne k$. To avoid triviality, we may assume that $f(0^n) \not\succeq 0^n$. Similarly as in section 2, it can be shown that the simplex $\langle 0^n\rangle$ is an s^0-complete facet of the unique one-dimensional simplex σ^0 in $A(s^0)$ having $\langle 0^n\rangle$ as one of its facets. Furthermore σ^0 is almost s^0-complete.

We now apply the algorithm as described in section 2. Starting with σ^0, by applying the steps as given in section 2 with the system (5.1) the algorithm generates a unique sequence of adjacent almost s-complete simplices in $A(s)$ with s-complete common facets for varying positive sign vectors s. The algorithm stops with a complete simplex in a finite number of steps under the assumption stated in the theorem. As shown below, a complete simplex gives a solution to the problem. Recall that $\bar{f}$ stands for the piecewise linear extension of the function f with respect to $\mathcal{T}$. Let $C^n = \{x \in \mathbb{R}^n \mid 0^n \le x \le M\}$.

LEMMA 5.3. *For some nonnegative sign vector s, let σ be a simplex in $A(s)$ with an s-complete facet τ on the upper boundary of C^n. Then τ is a complete simplex.*

Proof. From system (5.2) it follows that there exist $\lambda_1 \ge 0, \ldots, \lambda_t \ge 0$ with sum equal to 1, $\beta \ge 0$, and $\mu_i \ge -\beta$ for $s_i = 0$, such that $\bar{f}_i(z) = -\beta$ when $s_i = 1$ and $\bar{f}_i(z) = \mu_i$ when $s_i = 0$, where $z = \sum_{i=1}^t \lambda_i x^i$. Since τ lies on the upper boundary of C^n, there exists an index h such that $x^j_h = M_h$ for all j. But then we must have $s_h = 1$ and therefore $\bar{f}_h(z) = -\beta \le 0$. On the other hand, by assumption, we have $f_h(x^j) \ge 0$ for all j. Hence, we obtain $\bar{f}_h(z) \ge 0$. As a result, $\beta = 0$, which implies that τ is a complete simplex by definition. ∎

LEMMA 5.4. *For some nonnegative sign vector s, let σ be a complete simplex in $A(s)$. Then σ contains a solution to the nonlinear complementarity problem for $\bar{f}$.*

Proof. Let $x^1, \ldots, x^{k+1}$ be the vertices of the complete simplex σ in $A(s)$, and let t be the number of nonzeros in s. Note that $k = t-1$ or $k = t$ depending on whether

σ is a t-simplex in $A(s)$ or a facet of a t-simplex in $A(s)$. It follows from the system (5.1) or (5.2) that there exist $\lambda_1 \geq 0, \ldots, \lambda_{k+1} \geq 0$ with sum equal to 1 and $\mu_i \geq 0$ for $s_i = 0$ such that $\bar{f}_i(z) = 0$ if $s_i = 1$, and $\bar{f}_i(z) = \mu_i$ if $s_i = 0$, where $z = \sum_{i=1}^{k+1} \lambda_i x^i$. Since $z \in A(s)$, we also have $z_i = 0$ if $s_i = 0$ and $z_i \geq 0$ if $s_i = 1$. So, $\bar{f}_i(z) \geq 0$ if $z_i = 0$ and $\bar{f}_i(z) = 0$ if $z_i > 0$; i.e., z solves the nonlinear complementarity problem with respect to $\bar{f}$. □

The next lemma says that, for any complete simplex σ, at least one of its vertices is a solution to DCP(f).

LEMMA 5.5. *Let σ be a complete simplex of $\mathcal{T}$ in $A(s)$ for some sign vector s. Then σ contains a vertex being a solution to* DCP(f).

Proof. Because σ is a complete simplex in $A(s)$, as shown in Lemma 5.4, there is a point z in σ that is a solution to the nonlinear complementarity problem with respect to $\bar{f}$. Now let $\rho = \langle x^1, \ldots, x^k \rangle$ be the unique face of σ containing z in its relative interior. Namely, there exist unique positive numbers $\lambda_1, \ldots, \lambda_k$ summing up to 1 such that $z = \sum_{j=1}^{k} \lambda_j x^j$ and $\bar{f}(z) = \sum_{j=1}^{k} \lambda_j f(x^j)$. Take any j^* between 1 and k. Suppose first that $z_i = 0$ and $\bar{f}_i(z) > 0$ for some i. Clearly, $x_i^j = 0$ for all $j = 1, \ldots, k$. Since $\bar{f}_i(z) = \sum_{j=1}^{k} \lambda_j f_i(x^j)$ there exists h such that $f_i(x^h) > 0$. Since x^h and x^{j^*} are simplicially connected and $x_i^h = x_i^{j^*} = 0$, we have that $f_i(x^h) f_i(x^{j^*}) \geq 0$, and therefore $x_i^{j^*} = 0$ and $f_i(x^{j^*}) \geq 0$. Suppose next that $z_i = 0$ and $\bar{f}_i(z) = 0$ for some i. Again, $x_i^j = 0$ for all $j = 1, \ldots, k$. Since $\bar{f}_i(z) = \sum_{j=1}^{k} \lambda_j f_i(x^j)$ and $\bar{f}_i(z) = 0$, we obtain $\sum_{j=1}^{k} \lambda_j f_i(x^j) = 0$ and therefore $\sum_{j=1}^{k} \lambda_j f_i(x^j) f_i(x^{j^*}) = 0$. Since for all j it holds that x^j and x^{j^*} are simplicially connected and $x_i^j = x_i^{j^*} = 0$, we have $f_i(x^j) f_i(x^{j^*}) \geq 0$, and so each term in the summation must be zero. In particular, it holds that $\lambda_{j^*} f_i^2(x^{j^*}) = 0$. Since $\lambda_{j^*} > 0$, this implies $f_i(x^{j^*}) = 0$.

Thus far we have shown that whenever $z_i = 0$ both $f_i(x^{j^*}) \geq 0$ and $x_i^{j^*} = 0$ must hold. It remains to show that whenever $z_i > 0$ it holds that $f_i(x^{j^*}) = 0$ and hence that x^{j^*} is a solution to DCP(f). By construction, $\bar{f}_i(z) = \sum_{j=1}^{k} \lambda_j f_i(x^j) = 0$ whenever $z_i > 0$. Note that $I(x^j) \subseteq I(z)$ for any $j = 1, \ldots, k$. Therefore,

$$\sum_{h \in I(z)} \sum_{j=1}^{k} \lambda_j f_h(x^j) f_h(x^{j^*}) = 0$$

and so

$$\sum_{j=1}^{k} \left(\lambda_j \sum_{h \in I(z)} f_h(x^j) f_h(x^{j^*}) \right) = 0.$$

Since $I(z)$ contains the set $I(x^j, x^{j^*})$ and x^j and x^{j^*} are simplicially connected for all j, by hypothesis we have that each of the k terms between brackets is nonnegative and therefore must be zero. Hence,

$$\lambda_{j^*} \sum_{h \in I(z)} f_h^2(x^{j^*}) = 0.$$

Since $\lambda_{j^*} > 0$, we obtain $f_h(x^{j^*}) = 0$ for all $h \in I(z)$. Therefore $f_i(x^{j^*}) = 0$ if $z_i > 0$. □

Theorem 5.2 now follows from the lemmas stated above by a combinatorial argument.

Proof of Theorem 5.2. Due to the lexicographic pivoting rule, the algorithm will never visit any simplex more than once. Since the number of simplices in C^n is finite, the algorithm terminates in a finite number of steps with a complete simplex in $A(s)$. According to Lemma 5.5, the complete simplex gives a solution to DCP(f). □

In what follows, we turn our attention to the linear complementarity problem LCP(M, q). Recall that Lemke's method [22] introduces an artificial variable z_0 and operates by moving from one basic solution of the following system of linear equations to another:

$$\begin{aligned} Iz - Mx - z_0 e &= q, \\ x_j \geq 0,\ z_j \geq 0,\ z_0 \geq 0 &\text{ for } j = 1, 2, \ldots, n, \\ x_j z_j &= 0 \text{ for } j = 1, 2, \ldots, n, \end{aligned} \tag{5.3}$$

where e is the n-vector of all ones and I is the identity matrix of order n. The algorithm starts with a ray at $x = 0^n$ and terminates in a finite number of pivot steps when a solution is found or when another ray is encountered.

Lemke [22] shows that his method is guaranteed to find a solution of LCP(M, q) if M is copositive-plus and the system of $Mx + q \geq 0^n$ and $x \geq 0^n$ is feasible. Recall that a square matrix B is said to be *copositive* if $x \cdot Bx \geq 0$ for any $x \in \mathbb{R}^n_+$. Furthermore, B is said to be *copositive-plus* if B is copositive and in addition $x \geq 0^n$ and $x \cdot Bx = 0$ imply $(B + B^t)x = 0$, where B^t is the transpose of B. Of course, even if an LCP(M, q) has a solution, it may have no integral solution at all. To guarantee that an LCP(M, q) has an integral solution, we need to impose total unimodularity on the matrix M. Recall that a matrix B is said to be *totally unimodular* if the determinant of every subsquare matrix of B is -1, 0, or 1. Now we establish the following theorem on the existence of an integral solution to LCP(M, q).

THEOREM 5.6. *Suppose that M is totally unimodular, copositive-plus, that q is an integral vector, and that the system of $Mx + q \geq 0^n$ and $x \geq 0^n$ is feasible. Then the algorithm defined by system* (5.1) *reduces to Lemke's method and terminates at an integral solution in a finite number of steps.*

Proof. For the LCP(M, q), we first show that the algorithm defined by system (5.1) reduces to Lemke's method. We may assume that $q \not\geq 0^n$. In the initial step of Lemke's method the system defined by (5.3) at $x = 0^n$ is put in a tableau format, and a pivot step is made with the z_0 column on row k, where k is such that $q_k = \min\{q_h \mid h \in N\}$. This corresponds exactly to the initial step of the algorithm defined by system (5.1) at which 0^n is the starting point and the algorithm moves in the set $A(s^0)$, where $s^0 \in \mathbb{R}^n_+$ is the sign vector defined by $s^0_k = 1$ and $s^0_j = 0$ for $j \neq k$ with k being the smallest index h such that $q_h = \min q_j$. Here the choice of the smallest index is to avoid degeneracy.

In a general step, let $\sigma = \langle x^1, \ldots, x^{t+1} \rangle$ be an almost s-complete simplex in $A(s)$. Let $I^0(s) = \{h \mid s_h = 0\}$ and $I^+(s) = \{h \mid s_h = 1\}$. Now it follows from the system (5.1) that there exist $\lambda_h \geq 0$, $h = 1, \ldots, t+1$, $\mu_0 \geq 0$, and $\mu_0 \geq -\mu_h$ for every $h \in I^0(s)$ such that

$$\sum_j \lambda_j f(x^j) - \sum_{h \in I^0(s)} \mu_h e(h) + \mu_0 s = 0^n \tag{5.4}$$

and $\sum_j \lambda_j = 1$. Let $\beta_0 = \mu_0$ and $\beta_h = -\mu_h$. Let $x = \sum_j \lambda_j x^j$ for $h \in I^0(s)$. Since x is a convex combination of points $x^1, \ldots, x^{t+1}$ in $A(s)$, x also lies in $A(s)$. Further,

$f(x) = Mx + q = \sum_j \lambda_j (Mx^j + q) = \sum_j \lambda_j f(x^j)$. Thus equation (5.4) reduces to

$$Mx + q + \sum_{h \in I^0(s)} \beta_h e(h) + \beta_0 s = 0^n,$$

where $\beta_0 \geq 0$, $\beta_0 \geq \beta_h$ for every $h \in I^0(s)$, $x_h = 0$ for $s_h = 0$, and $x_h \geq 0$ for $s_h = 1$. We can rewrite the equation as follows:

$$-Mx + \sum_{h \in I^0(s)} (\beta_0 - \beta_h) e(h) - \beta_0 e = q,$$

Now let $z_h = \beta_0 - \beta_h$ for $h \in I^0(s)$, $z_h = 0$ for $h \in I^+(s)$, and $z_0 = \beta_0$. Then we have

$$\begin{aligned} Iz - Mx - z_0 e &= q, \\ z_0 \geq 0,\ z_h &\geq 0 \text{ for } h \in I^0(s), \\ z_h &= 0 \text{ for } h \in I^+(s), \\ x_h &= 0 \text{ for } h \in I^0(s), \\ x_h &\geq 0 \text{ for } h \in I^+(s). \end{aligned} \tag{5.5}$$

For this system we have $x_h z_h = 0$ for every $h = 1, \ldots, n$, and the algorithm finds a solution as soon as z_0 becomes zero. This shows that the system above coincides with the system (5.3). As a result, we have proved that the algorithm defined by system (5.1) indeed reduces to Lemke's method. It is worth pointing out that for the LCP(M, q), actually no triangulation is needed for the algorithm. In fact, for given sign vector s, all pivot steps of the $2n$-ray algorithm within the region $A(s)$ reduce to one pivot step in the Lemke algorithm because of the linearity of the function $f(x) = Mx + q$.

Concerning the second statement of the Theorem 5.6 (the termination of the algorithm), it follows from Lemke [22] that because M is copositive-plus and the system of $Mx + q \geq 0^n$ and $x \geq 0^n$ is feasible, the algorithm must end up with a solution x^* in a finite number of steps. More precisely, the algorithm stops with a solution $x^* \in A(s)$ for some sign vector $s \in \mathbb{R}^n_+$ corresponding to the $n \times n$ regular matrix $B = [(-M_h, h \in I^+(s)), (e(h), h \in I^0(s))]$, where M_h denotes the hth column of matrix M. Note that $x^* = B^{-1}q$. It remains to show that x^* is integral. Because M is totally unimodular, $[-M, I]$ is totally unimodular and so is B (see Schrijver [29]). Because B^{-1} exists and is also totally unimodular and q is integral, $x^* = B^{-1}q$ is integral. This shows that the algorithm indeed finds an integral solution of the LCP(M, q). □

Since a positive definite matrix M is copositive-plus and it holds that there exists $x \geq 0^n$ such that $Mx + q \geq 0^n$ (see Cottle, Pang, and Stone [3, p. 140, Lemma 3.1.3]), the next corollary follows immediately.

COROLLARY 5.7. *Suppose that M is totally unimodular, positive definite, and that q is an integral vector. Then the algorithm terminates at an integral solution in a finite number of steps.*

6. Applications. Discrete zero point (or fixed point) problems often occur in economics. For instance, in an exchange economy with n commodities, one of the most studied problems is the existence of a Walrasian equilibrium price system, in which a price vector $p \in \mathbb{R}^n_+$ solve the complementarity problem for the excess demand function z defined from the price space $\mathbb{R}^n_+$ into the commodity space $\mathbb{R}^n$, where $z_j(p)$ is the excess demand for commodity j at the (nonnegative) price system p, $j = 1, \ldots, n$. In

the literature the existence of an equilibrium price system $p^* \in \mathbb{R}^n_+$ has been studied extensively; nevertheless, in almost all real-life situations prices are in some monetary unit, implying that actually a price system belongs to $\mathbb{Z}^n_+$ for appropriately chosen units of the components of p. Hence, in fact an equilibrium price system should be a solution to the DCP(z).

In this section we apply Theorem 3.2 to the supermodular games; see for instance Fudenberg and Tirole [10]. A well-known example of such games is the Bertrand price competition model. Here we consider the Cournot oligopoly model with complementary commodities; see Vives [35]. There are n firms, each firm producing its own commodity. The goal of each firm is to choose an amount of product that maximizes its own profit given the production levels chosen by other firms. Let $q_i \geq 0$ denote the quantity of commodity i produced by firm i, and let $q_{-i} = (q_1, \ldots, q_{i-1}, q_{i+1}, \ldots, q_n)$ denote the vector of amounts of commodities produced by all firms but firm i. The price at which firm i can sell its product is decreasing in its own quantity q_i, and due to the complementarities, it is increasing in the quantities q_j, $j \neq i$. It is standard to assume that the price function of each firm $i = 1, \ldots, n$, is linear, i.e.,

$$P_i(q_i, q_{-i}) = a_i - b_i q_i + \sum_{j \neq i} d_{ij} q_j,$$

where all parameters a_i, b_i, and d_{ij} are positive. Each firm i has a linear cost function $C_i(q_i) = c_i q_i$ with $a_i > c_i > 0$. For quantities $(q_1, \ldots, q_n)$, the profit π_i of firm i is given by its quantity times price minus its cost of production, i.e.,

$$\pi_i(q_i, q_{-i}) = q_i P_i(q_i, q_{-i}) - c_i q_i.$$

A tuple $(q_1^*, q_2^*, \ldots, q_n^*) \in \mathbb{R}^n_+$ of nonnegative real numbers is a *Cournot–Nash equilibrium* if, for every firm i,

$$\pi_i(q_i^*, q_{-i}^*) \geq \pi_i(q_i, q_{-i}^*) \ \forall \ q_i \in \mathbb{R}_+.$$

It is well known that there exists a Cournot–Nash equilibrium if $2b_i > \sum_{j \neq i} \ d_{ij}$ for every firm $i = 1, \ldots, n$. However, in reality, it is often the case that the commodities are produced only in integer quantities. Here we will show that under the same condition a discrete Cournot–Nash equilibrium exists in this model. A tuple $(q_1^*, q_2^*, \ldots, q_n^*)$ of nonnegative integers is a *discrete Cournot–Nash equilibrium* if

$$\pi_i(q_i^*, q_{-i}^*) \geq \pi_i(q_i, q_{-i}^*) \ \forall \ q_i \in \mathbb{Z}_+, \ i = 1, \ldots, n.$$

That is, given the quantities chosen by other firms, each firm chooses an integer quantity that yields a profit which is at least as high as any other integer quantity could give.

For a real number x, the symbol $[x]$ denotes the greatest nearest integer to x. Given nonnegative integer quantities q_{-i} of all other firms, firm i maximizes its own profit $\pi_i(q_i, q_{-i})$ over all nonnegative integers q_i, and its optimal or reaction integer quantity is given by

$$r_i(q_{-i}) = \left[\frac{a_i - c_i}{2b_i} + \sum_{j \neq i} \frac{d_{ij}}{2b_i} q_j \right].$$

Observe that $r_i(q_{-i}) \geq 0$ for all $q \in \mathbb{Z}^n_+$, because $a_i > c_i > 0$. Define the function $f : \mathbb{Z}^n_+ \to \mathbb{Z}^n$ by

$$f_i(q_i, q_{-i}) = r_i(q_{-i}) - q_i, \quad i = 1, \ldots, n.$$

Clearly, a discrete zero point of f is a discrete Cournot–Nash equilibrium.

THEOREM 6.1. *Suppose that $2b_i > \sum_{j \neq i} d_{ij}$, $i = 1, \ldots, n$. Then there exists a discrete Cournot–Nash equilibrium in the above Cournot oligopoly competition model.*

Proof. We show that the function f satisfies the conditions of Corollary 3.3. First, we show that f satisfies the boundary condition. As a natural lower bound, take $m = 0^n$, and as an upper bound take, for all i, $M_i = M$, $i = 1, \ldots, n$, with $M > 1$ an integer satisfying $M > \max_i\{(a_i - c_i)/(2b_i - \sum_{j \neq i} d_{ij})\}$. Then for any i and any $q \in \mathbb{Z}^n_+$, $q_i = 0$ implies $f_i(q) = r_i(q_{-i}) \geq 0$. Further, $q_i = M$ and $q_j \leq M$ imply

$$\begin{aligned} f_i(q) &= \left[\frac{a_i - c_i}{2b_i} + \sum_{j \neq i} \frac{d_{ij}}{2b_i} q_j - q_i \right] \leq \left[\frac{a_i - c_i}{2b_i} + \sum_{j \neq i} \frac{d_{ij}}{2b_i} M - M \right] \\ &\leq \left[\frac{a_i - c_i - (2b_i - \sum_{j \neq i} d_{ij})M}{2b_i} \right] \leq 0, \end{aligned}$$

where the last inequality follows from the fact that $M > (a_i - c_i)/(2b_i - \sum_{j \neq i} d_{ij})$.

Second, we show that f is simplicially local gross direction-preserving with respect to the K-triangulation as described in section 2. Since the K-triangulation is given by integral simplices $\sigma(y, \pi)$ with vertices $y^1, \ldots, y^{n+1}$, with $y^1 = y$ and $y^{i+1} = y^i + e(\pi(i))$, $i = 1, \ldots, n$, for given $y \in \mathbb{Z}^n$ and $\pi = (\pi(1), \ldots, \pi(n))$ a permutation of the elements $1, 2, \ldots, n$, we have to check that $f(x) \cdot f(y) \geq 0$ for any pair $x \in \mathbb{Z}^n_+$ and $y = x + \sum_{h=1}^k e(\pi(h))$ for $k = 1, \ldots, n$ and any permutation π. Observe that for any such pair it holds that $y_i \in \{x_i, x_i + 1\}$ for all $i = 1, \ldots, n$. For some pair x, y and $i \in \{1, \ldots, n\}$, define $S_i(x, y) = \{j \neq i | y_j = x_j + 1\}$. Then $r_i(y) = [\frac{a_i - c_i}{2b_i} + \sum_{j \neq i} \frac{d_{ij}}{2b_i} y_j] = [\frac{a_i - c_i}{2b_i} + \sum_{j \neq i} \frac{d_{ij}}{2b_i} x_j + \sum_{j \in S_i(x,y)} \frac{d_{ij}}{2b_i}]$. Since $\sum_{j \neq i} \frac{d_{ij}}{2b_i} < 1$, it follows that $r_i(y) \in \{r_i(x), r_i(x) + 1\}$. Hence, since $y_i \in \{x_i, x_i + 1\}$, it follows that $f_i(y) \in \{f_i(x) - 1, f_i(x), f_i(x) + 1\}$. So, when $f_i(x) \geq 1$, then $f_i(y) \geq f_i(x) - 1 \geq 0$, and when $f_i(x) \leq -1$, then $f_i(y) \leq f_i(x) + 1 \leq 0$. So, $f_i(x) f_i(y) \geq 0$ for all i and thus $f(x) \cdot f(y) \geq 0$.

We have shown that f satisfies all the conditions of Corollary 3.3 and thus has a discrete zero point. As a result, there is a discrete Cournot–Nash equilibrium. ∎

It is worth mentioning that f may not be simplicially local gross direction-preserving with respect to other triangulations, as shown by the following example with $n = 2$. Let the parameters be given by $a_1 = 4$, $c_1 = 2.5$, $b_1 = 0.5$, $d_1 = d_{12} = 3/4$, $a_2 = 5$, $c_2 = 4$, $b_2 = 1/3$, and $d_2 = d_{21} = 1/12$. These parameters satisfy the stated condition for the model, and therefore there is a discrete Cournot–Nash equilibrium. In fact, the quantities $(3, 2)$ form the unique discrete Cournot–Nash equilibrium for this example. As shown above, the function f is simplicially local gross direction-preserving with respect to the K-triangulation. However, this function is not simplicially local gross direction-preserving with respect to the H-triangulation of Saigal [27]. For $\mathbb{R}^2$, this triangulation is given by the simplices $\langle y^1, y^2, y^3 \rangle$, with $y^1 \in \mathbb{Z}^2$, $y^2 = y^1 + p(\pi(1))$, $y^3 = y^2 + p(\pi(2))$, where $p(1) = (1, 0)$ and $p(2) = (-1, 1)$. Now take $\pi = (2, 1)$, $x = y^1 = (3, 1)$, and $y = y^2 = y^1 + p(2) = (2, 2)$. Since $f(x) = (-1, 1)$ and $f(y) = (1, 0)$, we have that $f(x) \cdot f(y) = -1 < 0$, and so the function is not

simplicially local direction-preserving with respect to the H-triangulation. Note that x and y do not belong to a same simplex of the K-triangulation.

CHARACTERIZATIONS OF LOCAL AND GLOBAL ERROR BOUNDS FOR CONVEX INEQUALITIES IN BANACH SPACES*

HUI HU†

Abstract. This paper studies local and global error bounds for a convex inequality defined by a proper convex function in a Banach space. The concept of weak basic constraint qualification (weak BCQ) is introduced to control the normal directions at a boundary point of the solution set. Local and global error bounds are characterized by a direction-length decomposition condition, which provides a way to independently verify the weak BCQ and the length control of the subdifferential. To further characterize global error bounds, the segment extension property is proposed and studied. It is shown that the verification of the direction-length condition for global error bounds can be sufficiently carried out on any subset having the segment extension property instead of the entire boundary. This leads to a simple formula for the smallest global error bound. In the Euclidean space, the verification of the condition and the computation of the smallest global error bound can be carried out on the set of extreme points.

Key words. local and global error bounds, weak basic constraint qualification, segment extension property, end set

1. Introduction.

Let X be a Banach space, let R be the set of real numbers, and let $f : X \to R \cup \{\infty\}$ be a proper convex function. For the convex inequality

$$f(x) \le 0, \tag{1.1}$$

let $S = \{x \in X : f(x) \le 0\}$ denote the solution set and $\mathrm{bd}(S)$ the boundary of S. Throughout this paper, it is assumed that S is closed and $\emptyset \ne S \ne X$. The study of a closed convex set defined by a non–lower-semicontinuous function arose from a broad class of outer approximation methods for convex optimization (see [3] and the references therein).

For any $P \subseteq X$ and $x \in X$, let $d_P(x) = \inf\{\|x - p\| : p \in P\}$ if $P \ne \emptyset$; otherwise, $d_P(x) = \infty$ by convention. Let $f_+(x) = \max\{f(x), 0\}$ and $R_+ = \{r \in R : r \ge 0\}$.

Let $x \in \mathrm{bd}(S)$. Inequality (1.1) is said to have a local error bound τ [8, 16, 19] at x if there exist $\tau, \delta \in (0, \infty)$ such that

$$d_S(z) \le \tau f_+(z) \quad \forall z \in B(x, \delta),$$

where $B(x, \delta)$ denotes the open ball centered at x with radius δ.

Inequality (1.1) is said to have a global error bound τ [12] if there exists $\tau \in (0, \infty)$ such that

$$d_S(z) \le \tau f_+(z) \quad \forall z \in X.$$

In recent years, local and global error bounds and their relations with other key concepts in optimization have been actively studied by many researchers (see, e.g., [7, 8, 9, 10, 12, 16, 19] and the references therein).

This paper studies local and global error bounds for a convex inequality defined by a single-valued proper convex function in a Banach space. In section 2, some useful results for dealing with discontinuity on $\mathrm{bd}(S)$ and nonclosed epigraphs are presented. In section 3, the concept of weak basic constraint qualification (weak BCQ) is introduced to control the normal directions at a boundary point of S without lower semicontinuity assumption on f. Local and global error bounds are characterized by a general direction-length decomposition condition, which provides a way to independently verify the direction control by the weak BCQ and the length control of the intersection of the normal cone and the end set of the subdifferential. This decomposition condition can reduce the verification difficulty. In addition, the length control provides a way to compute the error bounds. In section 4, the segment extension property is proposed and studied. It is shown that the verification of the direction-length condition for global error bounds can be sufficiently carried out on any subset having the segment extension property instead of the entire boundary. This leads to a simple formula for computing the smallest global error bound. In the Euclidean space, the verification of the condition and the computation of the smallest global error bound can be carried out on the set of extreme points.

The notation used in this paper is standard. For $P \subseteq X$, let $\overline{P}$, $\mathrm{conv}(P)$, $\mathrm{cone}(P)$, $\mathrm{int}(P)$ denote the closure, convex hull, convex cone, and interior of P. If P is convex, let $\mathrm{ext}(P)$ denote the set of extreme points of P, and P^∞ the recession cone of P.

For a convex set C in X and $x \in C$, let

$$N_C(x) = \{x^* \in X^* : \ \langle x^*, y - x\rangle \le 0 \ \ \forall y \in C\}$$

denote the normal cone of C at x, where X^* is the dual space of X and $\langle x^*, y - x\rangle$ denotes the value of linear functional x^* at $y - x$.

For $x \in \mathrm{bd}(S)$, let

$$T_S(x) = \overline{\cup_{t>0}\, t(S - x)}$$

denote the tangent cone of S at x.

Let $\mathrm{dom} f = \{x \in X : \ f(x) < \infty\}$ and $\mathrm{epi} f = \{(x, y) \in X \times R : \ f(x) \le y\}$. The subdifferential and singular subdifferential of f at $x \in \mathrm{dom} f$ are (cf. [5, 19])

$$\partial f(x) = \{x^* \in X^* : \ (x^*, -1) \in N_{\mathrm{epi} f}(x, f(x))\},$$

$$\partial^\infty f(x) = \{x^* \in X^* : (x^*, 0) \in N_{\mathrm{epi} f}(x, f(x))\}.$$

It is easy to verify that

$$\partial f(x) = \{x^* \in X^* : f(y) \ge f(x) + \langle x^*, y - x\rangle \ \forall y \in X\},$$

$$\partial^\infty f(x) = N_{\mathrm{dom} f}(x), \tag{1.2}$$

and if $\partial f(x) \ne \emptyset$, then

$$\partial f(x) = \partial f(x) + \lambda \partial^\infty f(x) \quad \forall \lambda \in [0, \infty). \tag{1.3}$$

Let $f'(x; h)$ denote the classical directional derivative of f at x in the direction h, i.e.,

$$f'(x; h) = \lim_{t \to 0^+} \frac{f(x + th) - f(x)}{t}.$$

For a nonempty interval $[\alpha,\beta]$ and a convex set C, if $C\neq\emptyset$, then $[\alpha,\beta]C=\{tc: t\in[\alpha,\beta],\ c\in C\}$; otherwise, $[\alpha,\beta]C=\{0\}$ by convention. It is easy to verify that $[0,1]C=\operatorname{conv}(\{0\}\cup C)$.

For a convex set C, the end set of C is defined as

$$E[C]=\{z\in\overline{[0,1]C}:\ tz\notin\overline{[0,1]C}\ \forall t>1\}.$$

Note that $0\notin E[C]$ and $E[C]\cap\operatorname{int}(C)=\emptyset$. The end set was first introduced in [19] and was further studied in [6]. A referee of the present paper pointed out that the definition of the end set is equivalent to the following.

LEMMA 1.1. *For a convex set C, let $\tilde{E}[C]=\{z\in\overline{C}:\ tz\notin\overline{C}$ for all $t>1\}$. Then $E[C]=\tilde{E}[C]$.*

Proof. First, we show that $E[C]\subseteq\tilde{E}[C]$. If $z\in E[C]$, then $z\in\overline{[0,1]C}$ and $tz\notin\overline{[0,1]C}$ for all $t>1$. In particular, $tz\notin\overline{C}$ for all $t>1$. It remains to show that $z\in\overline{C}$. There exist sequences $\tau_n\in[0,1]$ and $c_n\in C$ such that $\tau_nc_n\to z$. By passing to a subsequence if necessary, one may assume that $\tau_n\to\tau\in[0,1]$. By the convexity of $\overline{[0,1]C}$, $\tau_nc_n+(1-\tau_n)z\in\overline{[0,1]C}$. Thus, $\lim_{n\to\infty}\tau_nc_n+(1-\tau_n)z=(2-\tau)z\in\overline{[0,1]C}$. By the definition of $E[C]$, $2-\tau\leq1$. Therefore, one mast have $\tau=1$. Consequently, $z=(\lim_{n\to\infty}\frac{1}{\tau_n})(\lim_{n\to\infty}\tau_nc_n)=\lim_{n\to\infty}c_n\in\overline{C}$.

Next, we show that $\tilde{E}[C]\subseteq E[C]$. Let $z\in\tilde{E}[C]$. Since $z\in\overline{C}\subseteq\overline{[0,1]C}$, we only need to show that $tz\notin\overline{[0,1]C}$ for all $t>1$. Suppose, on the contrary, that there exists $t^*>1$ such that $t^*z\in\overline{[0,1]C}$. Then there exist sequences $\tau_n\in[0,1]$ and $c_n\in C$ satisfying $\tau_nc_n\to t^*z$. By passing to a subsequence if necessary, one may assume that $\tau_n\to\tau\in[0,1]$. By the convexity of $\overline{C}$, $\tau_nc_n+(1-\tau_n)z\in\overline{C}$. Thus, $\lim_{n\to\infty}\tau_nc_n+(1-\tau_n)z=t^*z+(1-\tau)z=(t^*+1-\tau)z\in\overline{C}$. But $t^*+1-\tau>1$, which is a contradiction to $tz\notin\overline{C}$ for all $t>1$. Therefore, $\tilde{E}[C]\subseteq E[C]$. ∎

2. Analysis without lower semicontinuity. Note that (1.1) is only defined by a proper convex function. Without a lower semicontinuity assumption, $\operatorname{epi}f$ is not necessarily closed; therefore, some standard results cannot be applied directly. Also, it is possible that $f(x)<0$ for some $x\in\operatorname{bd}(S)$. In this section, we present several useful results for dealing with such cases. First, we state some facts that are frequently used in the rest of this paper. Throughout this paper, f is a proper convex function on X.

FACT 2.1. *For each $h\in X$, the quotient $\frac{f(x+th)-f(x)}{t}$ is a nondecreasing function of $t>0$. Thus, $f'(x;h)$ exists ($+\infty$ and $-\infty$ being allowed as limits) and*

$$f'(x;h)=\inf\Big\{\frac{f(x+th)-f(x)}{t}:t>0\Big\}\leq f(x+h)-f(x).$$

FACT 2.2. (i) *$x^*\partial f(x)\Leftrightarrow\langle x^*,h\rangle\leq f'(x;h)$ for all $h\in X$.* (ii) *If f is continuous at $x\in\operatorname{dom}f$, then $f'(x;h)=\max\{\langle x^*,h\rangle:x^*\partial f(x)\}$ for all $h\in X$ (cf.* [18, Theorem 2.4.9]*).*

FACT 2.3. *If $x\in\operatorname{bd}(S)$, then $N_S(x)=N_{x+T_S(x)}(x)=N_{T_S(x)}(0)$.*

FACT 2.4. *If $x\in\operatorname{dom}f$ and $\partial f(x)\neq\emptyset$, then (see, e.g.,* [19, pp. 761–762]*) $\partial^\infty f(x)\subseteq\overline{[0,1]\partial f(x)}=[0,1]\partial f(x)+\partial^\infty f(x)$.*

Note that if $f(x)=0$, then $\partial f(x)\subseteq N_S(x)$ holds. When (1.1) is defined by a proper convex function f that is not continuous, it is possible that $f(x)<0$ for $x\in\operatorname{bd}(S)$. In such a case, $\partial f(x)\subseteq N_S(x)$ may fail to hold (see Example 3.1). The following two lemmas are useful in dealing with such discontinuity.

LEMMA 2.1. *If $x \in \mathrm{bd}(S)$ and $f(x) < 0$, then* (i) $\mathrm{dom} f \subseteq x + T_S(x)$, (ii) $f'(x;h) = \infty$ *for all* $h \notin T_S(x)$.

Proof. Given $y \notin x + T_S(x)$, let $h = y - x \notin T_S(x)$. By the definition of tangent cone, $x + th \notin S$ for all $t > 0$, which implies that $f(x + th) > 0$ for all $t > 0$. By Fact 2.1,

$$f(y) - f(x) \geq f'(x;h) = \lim_{t \to 0^+} \frac{f(x+th) - f(x)}{t} \geq \lim_{t \to 0^+} \frac{-f(x)}{t} = \infty.$$

Therefore, $y \notin \mathrm{dom} f$ and $f'(x;h) = \infty$. □

LEMMA 2.2. *If $x \in \mathrm{bd}(S)$ and $f(x) < 0$, then*

$$N_S(x) = \partial^\infty f(x) = \partial^\infty f_+(x) = \partial f_+(x).$$

Proof. By Lemma 2.1, $S \subseteq \mathrm{dom} f = \mathrm{dom} f_+ \subseteq x + T_S(x)$. Hence,

$$N_S(x) \supseteq N_{\mathrm{dom} f}(x) = N_{\mathrm{dom} f_+}(x) \supseteq N_{x + T_S(x)}(x).$$

It follows from (1.2) and Fact 2.3 that

$$N_S(x) = \partial^\infty f(x) = \partial^\infty f_+(x). \tag{2.1}$$

Since $f_+(x) = 0$ and $f_+(z) \geq 0$ for all $z \in X$, x minimizes f_+ and thus $0 \in \partial f_+(x)$. By (1.3), $\partial^\infty f_+(x) \subseteq \partial f_+(x) \subseteq N_S(x)$. It follows from (2.1) that $\partial^\infty f_+(x) = \partial f_+(x) = N_S(x)$. □

Without lower semicontinuity, the epigraph of f may not be closed, and some standard results for closed convex sets cannot be applied directly. Lemma 2.3 summarizes two results for dealing with epigraphs that are not closed.

LEMMA 2.3. *Let $f_1 = f$ and $f_2 = 0$.*

(i) $\overline{\mathrm{epi} f_1} \cap \mathrm{epi} f_2 = \overline{\mathrm{epi} f_1 \cap \mathrm{epi} f_2}$.

(ii) *If $\mathrm{dom} f_1 \cap \mathrm{dom} f_2 \neq \emptyset$, then* $\mathrm{cone}(\mathrm{dom} f_1 - \mathrm{dom} f_2) \times R = \mathrm{cone}(\mathrm{epi} f_1 - \mathrm{epi} f_2)$.

Proof. (i) Let $z = (y, r) \in \overline{\mathrm{epi} f_1} \cap \mathrm{epi} f_2 \subseteq X \times R_+$, where $y \in X$ and $r \in R_+$. Choose $z_n = (y_n, r_n) \in \mathrm{epi} f_1$ satisfying $y_n \to y$ and $r_n \to r$. Let $\tilde{z}_n = (y_n, \max\{r_n, 0\})$. We have $\tilde{z}_n \in \mathrm{epi} f_1 \cap \mathrm{epi} f_2$ and $\tilde{z}_n \to (y, r) \in \overline{\mathrm{epi} f_1 \cap \mathrm{epi} f_2}$. On the other hand, since $\mathrm{epi} f_2 = X \times R_+$ is closed, $\overline{\mathrm{epi} f_1 \cap \mathrm{epi} f_2} \subseteq \overline{\mathrm{epi} f_2} = \mathrm{epi} f_2$. Thus, $\overline{\mathrm{epi} f_1 \cap \mathrm{epi} f_2} \subseteq \overline{\mathrm{epi} f_1} \cap \mathrm{epi} f_2$.

(ii) Given $\lambda((x_1, r_1) - (x_2, r_2)) \in \mathrm{cone}(\mathrm{epi} f_1 - \mathrm{epi} f_2)$, where $\lambda \geq 0$, $f(x_1) \leq r_1$, and $f(x_2) \leq r_2$, one has

$$\lambda((x_1, r_1) - (x_2, r_2)) = (\lambda(x_1 - x_2), \lambda(r_1 - r_2)) \in \mathrm{cone}(\mathrm{dom} f_1 - \mathrm{dom} f_2) \times R.$$

On the other hand, for a given $(\lambda(x_1 - x_2), r) \in \mathrm{cone}(\mathrm{dom} f_1 - \mathrm{dom} f_2) \times R$, where $\lambda \geq 0$, $x_1 \in \mathrm{dom} f_1$, and $x_2 \in \mathrm{dom} f_2$, we consider two cases: $\lambda > 0$ and $\lambda = 0$. If $\lambda > 0$, then

$$\begin{aligned}
(\lambda(x_1 - x_2), r) &= (\lambda x_1, 2r) - (\lambda x_2, r) \\
&= \lambda\big[(x_1, 2r/\lambda) - (x_2, r/\lambda)\big] \\
&= \lambda\big[(x_1, 2r/\lambda + M) - (x_2, r/\lambda + M)\big] \\
&\in \mathrm{cone}(\mathrm{epi} f_1 - \mathrm{epi} f_2),
\end{aligned}$$

where M is sufficiently large such that $(x_1, 2r/\lambda + M) \in \mathrm{epi} f_1$ and $(x_2, r/\lambda + M) \in \mathrm{epi} f_2$. In the case of $\lambda = 0$, for $x \in \mathrm{dom} f_1 \cap \mathrm{dom} f_2$, we have $(0, r) = (x, 2r) - (x, r) =$

$(x, 2r+M)-(x, r+M) \in \text{cone}(\text{epi}f_1 - \text{epi}f_2)$, where M is sufficiently large such that $(x, 2r+M) \in \text{epi}f_1$ and $(x, r+M) \in \text{epi}f_2$. □

The following two lemmas are contained in Volle [15, p. 848]. They are needed for obtaining the subdifferential formula for $f_+ = \max\{f, 0\}$ in Lemma 2.6.

LEMMA 2.4 (see [15, p. 848]). *Let C_1 and C_2 be closed convex sets in X and $C_1 \cap C_2 \neq \emptyset$. If $\text{cone}(C_1 - C_2)$ is a closed subspace, then for all $x \in C_1 \cap C_2$, $N_{C_1 \cap C_2}(x) = N_{C_1}(x) + N_{C_2}(x)$.*

LEMMA 2.5 (see [15, p. 848]). *Let f_1 and f_2 be proper convex functions on X, $g = \max\{f_1, f_2\}$, and $a \in \text{dom}f_1 \cap \text{dom}f_2$. If $f_1(a) = f_2(a)$, $\partial g(a) \neq \emptyset$, and $N_{\text{epi}g}(a, g(a)) = N_{\text{epi}f_1}(a, f_1(a)) + N_{\text{epi}f_2}(a, f_2(a))$, then $\partial g(a) = \text{conv}(\partial f_1(a) \cup \partial f_2(a)) + N_{\text{dom}f_1}(a) + N_{\text{dom}f_2}(a)$.*

In the next lemma, we express $\partial f_+(x)$ in terms of $\partial f(x)$ and $\partial^\infty f(x)$ when $f(x) = 0$. Note that because f is not necessarily lower semicontinuous, $\text{epi}f$ may not be closed.

LEMMA 2.6. *If $f(x) = 0$, then $\partial f_+(x) = [0, 1]\partial f(x) + \partial^\infty f(x)$.*

Proof. Let $f_1 = f$, $f_2 = 0$, and $g(z) = \max\{f(z), 0\} = f_+(z)$. Then $\text{dom}f_2 = X$, $\text{cone}(\text{dom}f_1 - \text{dom}f_2) = X$, and $\text{epi}f_2 = X \times R_+$. It follows from Lemma 2.3(ii) that

$$\begin{aligned} X \times R &= \text{cone}(\text{dom}f_1 - \text{dom}f_2) \times R \\ &= \text{cone}(\text{epi}f_1 - \text{epi}f_2) \\ &\subseteq \text{cone}(\overline{\text{epi}f_1} - \text{epi}f_2) \\ &\subseteq X \times R. \end{aligned}$$

Therefore, $\text{cone}(\overline{\text{epi}f_1} - \text{epi}f_2) = X \times R$ is a closed subspace of $X \times R$. Because $f(x) = 0$, $(x, 0) \in \overline{\text{epi}f_1} \cap \text{epi}f_2$. From Lemma 2.4,

$$N_{\overline{\text{epi}f_1} \cap \text{epi}f_2}(x, 0) = N_{\overline{\text{epi}f_1}}(x, 0) + N_{\text{epi}f_2}(x, 0). \tag{2.2}$$

From Lemma 2.3(i), $\overline{\text{epi}f_1} \cap \text{epi}f_2 = \overline{\text{epi}f_1 \cap \text{epi}f_2}$. Because $(x, 0) \in \text{epi}f_1 \cap \text{epi}f_2$, we have

$$N_{\overline{\text{epi}f_1 \cap \text{epi}f_2}}(x, 0) = N_{\text{epi}f_1 \cap \text{epi}f_2}(x, 0) \quad \text{and} \quad N_{\overline{\text{epi}f_1}}(x, 0) = N_{\text{epi}f_1}(x, 0).$$

Consequently, (2.2) is reduced to

$$N_{\text{epi}f_1 \cap \text{epi}f_2}(x, 0) = N_{\text{epi}f_1}(x, 0) + N_{\text{epi}f_2}(x, 0). \tag{2.3}$$

Because $f_1(x) = f_2(x) = 0$, $0 \in \partial g(x) \neq \emptyset$, and (2.3) holds, from Lemma 2.5 one has that

$$\begin{aligned} \partial g(x) &= \text{conv}(\partial f_1(x) \cup \partial f_2(x)) + N_{\text{dom}f_1}(x) + N_{\text{dom}f_2}(x) \\ &= \text{conv}(\partial f_1(x) \cup \{0\}) + N_{\text{dom}f_1}(x) + N_X(x) \\ &= [0, 1]\partial f(x) + \partial^\infty f(x). \end{aligned}$$ □

3. Weak BCQ and direction-length characterization of error bounds. In this section, we characterize local and global error bounds in terms of normal cones, subdifferentials, and the end set of subdifferentials.

It is well known that for a continuous convex function f, (1.1) is said to satisfy the basic constraint qualification (BCQ) at $x \in bd(S)$ if $N_S(x) = [0, \infty)\partial f(x)$ (see, e.g., [5, 8, 9]). As defined in [19], (1.1) is said to satisfy the extended BCQ at $x \in bd(S)$ if $N_S(x) = [0, \infty)\partial f(x) + \partial^\infty f(x)$, and (1.1) is said to satisfy the strong BCQ at

$x \in \mathrm{bd}(S)$ if there exists $\tau \in (0,\infty)$ such that $N_S(x) \cap B^* \subseteq [0,\tau]\partial f(x) + \partial^\infty f(x)$, where B^* denotes the closed unit ball of X^*.

DEFINITION 3.1. *Inequality* (1.1) *is said to satisfy the weak BCQ at* $x \in S$ *if*

$$N_S(x) \subseteq [0,\infty)\partial f(x) + \partial^\infty f(x).$$

Note that the nontrivial case is when the point x is on the boundary. For any $x \in \mathrm{int}S$, $N_S(x) = \{0\}$ and the weak BCQ always holds. If $x \in \mathrm{bd}(S)$ and $f(x) = 0$, then $\partial f(x) \subseteq N_S(x)$. Under this condition, the weak BCQ is equivalent to the extended BCQ.

Example 3.1. Consider the following proper convex function on R^1:

$$f(x) = \begin{cases} -x - 1 & \text{if } |x| \le 1; \\ \infty & \text{otherwise.} \end{cases} \tag{3.1}$$

It is not difficult to verify that $S = [-1,1]$, $f(1) < 0$,

$$N_S(1) = \{x^* : x^*(y-1) \le 0 \ \forall y \in [-1,1]\} = [0,\infty) = \partial^\infty f(1),$$

$$\partial f(1) = \{x^* : -y - 1 \ge -2 + x^*(y-1) \ \forall y \in [-1,1]\} = [-1,\infty),$$

$$E[\partial f(1)] = \{-1\}, \quad \text{and} \quad d_{E[\partial f(1)]\cap N_S(1)}(0) = \infty.$$

In this case, the extended BCQ does not hold at $x = 1$. It is also interesting to observe that $\partial f(1) \not\subseteq N_S(1)$. However, we still have $N_S(1) \subset [0,\infty)\partial f(1) + \partial^\infty f(1)$ and $d_{E[\partial f(1)]\cap N_S(1)}(0) = \infty \ge 1/\tau$ for all $\tau > 0$. It is obvious (also confirmed by Theorem 3.1 and [1, 4, 16, 17, 18]) that $f(x) \le 0$ has a local error bound τ at $x = 1$ for any $\tau > 0$. This is a case not covered by [6, 19].

Example 3.1 illustrates that the weak BCQ is weaker than the extended BCQ. It requires only that all normal directions are controlled by the cone $[0,\infty)\partial f(x) + \partial^\infty f(x)$. We are going to use the weak BCQ plus the length control of $E[\partial f(x)] \cap N_S(x)$ to characterize local error bounds. The following fact is useful for computing $E[\partial f(x)] \cap N_S(x)$.

FACT 3.1. $E[\partial f(x)] \cap N_S(x) = \{x^* \in \overline{[0,1]\partial f(x)} \cap N_S(x) : \ tx^* \notin \overline{[0,1]\partial f(x)} \cap N_S(x)$ *for all* $t > 1\}$. *Indeed, if* $x^* \in E[\partial f(x)] \cap N_S(x)$, *then* $x^* \in \overline{[0,1]\partial f(x)} \cap N_S(x)$. *As* $x^* \in E[\partial f(x)]$, $tx^* \notin \overline{[0,1]\partial f(x)}$ *for all* $t > 1$, *which implies* $tx^* \notin [0,1]\partial f(x) \cap N_S(x)$ *for all* $t > 1$. *On the other hand, given* $x^* \in \overline{[0,1]\partial f(x)} \cap N_S(x)$ *and* $tx^* \notin \overline{[0,1]\partial f(x)} \cap N_S(x)$ *for all* $t > 1$, *since* $tx^* \in N_S(x)$, *one has* $tx^* \notin \overline{[0,1]\partial f(x)}$ *for all* $t > 1$. *Thus,* $x^* \in E[\partial f(x)] \cap N_S(x)$.

THEOREM 3.1. *Let* $a \in \mathrm{bd}(S)$ *and* $\tau \in (0,\infty)$. *Then* (1.1) *has a local error bound* τ *at* a *if and only if there exists* $r \in (0,\infty)$ *such that for all* $x \in B(a,r) \cap \mathrm{bd}(S)$, (A) *the weak BCQ holds at* x, *and* (B) $d_{E[\partial f(x)]\cap N_S(x)}(0) \ge \tau^{-1}$.

Proof. " $\Rightarrow$ " If (1.1) has a local error bound τ at a, there exists $r > 0$ such that $d_S(x) \le \tau f_+(x)$ for all $x \in B(a,r)$. For any $x \in B(a,r) \cap \mathrm{bd}(S)$, we discuss two cases: $f(x) = 0$ and $f(x) < 0$. In the first case of $f(x) = 0$, let $x^* \in \partial d_S(x)$. Because $d_S(\cdot)$ is

a continuous convex function, by Fact 2.2 and $x \in B(a,r)$, one has that for all $h \in X$,

$$\begin{aligned}\langle x^*, h\rangle &\le \sup\{\langle y^*, h\rangle : y^* \in \partial d_S(x)\}\\ &= \lim_{t\to 0^+} \frac{d_S(x+th) - d_S(x)}{t}\\ &\le \lim_{t\to 0^+} \frac{\tau f_+(x+th) - \tau f_+(x)}{t}\\ &= \tau f'_+(x;h).\end{aligned}$$

It follows from Fact 2.2 that $x^* \in \tau\partial f_+(x)$, and thus $\partial d_S(x) \subseteq \tau\partial f_+(x)$. By Lemma 2.6,

$$N_S(x) \cap B^* = \partial d_S(x) \subseteq \tau([0,1]\partial f(x) + \partial^\infty f(x)) = [0,\tau]\partial f(x) + \partial^\infty f(x), \tag{3.2}$$

which implies (A). Now we prove (B). Without loss of generality we may assume that $E[\partial f(x)] \cap N_S(x) \neq \emptyset$, i.e., $d_{E[\partial f(x)]\cap N_S(x)}(0) < \infty$. Given $x^* \in E[\partial f(x)] \cap N_S(x)$, by the definition of the end set, we have $x^* \neq 0$. By (3.2), there exist $\mu \in [0,\tau]$, $y^* \in \partial f(x)$, and $z^* \in \partial^\infty f(x)$ satisfying $\frac{x^*}{\|x^*\|} = \mu y^* + z^*$. If $\mu = 0$, then $x^* = \|x^*\|z^* \in \partial^\infty f(x)$. By Fact 2.4 and the fact that $\partial^\infty f(x)$ is a cone, $[0,\infty)x^* \subseteq \partial^\infty f(x) \subseteq \overline{[0,1]\partial f(x)}$, which contradicts $x^* \in E[\partial f(x)]$. Hence, $\mu > 0$ and

$$\frac{x^*}{\mu\|x^*\|} = y^* + \mu^{-1}z^* \in \partial f(x) + \mu^{-1}\partial^\infty f(x) = \partial f(x) \subseteq \overline{[0,1]\partial f(x)}.$$

Since $x^* \in E[\partial f(x)]$, by the definition of the end set, we must have $\frac{1}{\mu\|x^*\|} \le 1$, which implies that $\|x^*\| \ge \mu^{-1} \ge \tau^{-1}$. Therefore, $d_{E[\partial f(x)]\cap N_S(x)}(0) \ge \tau^{-1}$, which is (B).

In the second case of $f(x) < 0$, by Lemma 2.2, $N_S(x) = \partial^\infty f(x) \subseteq [0,\infty)\partial f(x) + \partial^\infty f(x)$, and thus (A) holds. We show that $d_{E[\partial f(x)]\cap N_S(x)}(0) = \infty$, i.e., $E[\partial f(x)] \cap N_S(x) = \emptyset$. Indeed, if $\partial f(x) = \emptyset$, then $E[\partial f(x)] = \emptyset$ and thus $E[\partial f(x)] \cap N_S(x) = \emptyset$. If $\partial f(x) \neq \emptyset$ and $f(x) < 0$, from Lemma 2.2 and Fact 2.4, $N_S(x) = \partial^\infty f(x) \subseteq \overline{[0,1]\partial f(x)}$, which implies $\overline{[0,1]\partial f(x)} \cap N_S(x) = N_S(x)$. By Fact 3.1, one has that $E[\partial f(x)] \cap N_S(x) = \{x^* \in N_S(x) : \ tx^* \notin N_S(x) \text{ for all } t > 1\} = \emptyset$, which implies $d_{E[\partial f(x)]\cap N_S(x)}(0) = \infty$.

" $\Leftarrow$ " We show that $d_S(x) \le \tau f_+(x)$ for all $x \in B(a, r/2)$. If $x \in S$ or $f_+(x) = \infty$, then $d_S(x) \le \tau f_+(x)$ holds. Now suppose that $x \notin S$ and $f_+(x) < \infty$. Given $x \in B(a,r/2)$, $d_S(x) \le \|x - a\| < r/2$. Choose $t \in (0,1)$ such that $d_S(x) < t(r/2)$. By [10, Lemma 1.1 and Proposition 1.3], for this t there exist $x_t \in \mathrm{bd}(S)$ and $x_t^* \in N_S(x_t) \cap B^* = \partial d_S(x_t)$ satisfying $t\|x - x_t\| \le \langle x_t^*, x - x_t\rangle$. Because $x_t^* \in \partial d_S(x_t)$ and $x_t \in \mathrm{bd}(S)$, one has

$$t\|x - x_t\| \le \langle x_t^*, x - x_t\rangle \le d_S(x) - d_S(x_t) = d_S(x) < t(r/2). \tag{3.3}$$

Hence, $\|x_t - a\| \le \|x_t - x\| + \|x - a\| < r/2 + r/2 = r$, and $x_t \in B(a,r) \cap \mathrm{bd}(S)$. We claim that

$$\partial d_S(x) \subseteq \tau\partial f_+(x) \quad \forall x \in B(a,r) \cap \mathrm{bd}(S). \tag{3.4}$$

Indeed, let $x \in B(a,r) \cap \mathrm{bd}(S)$ and $x^* \in \partial d_S(x) = N_S(x) \cap B^*$. Since $f_+(x) = 0$ and x minimizes f_+, $0 \in \tau\partial f_+(x)$. Thus we only need to show $x^* \in \tau\partial f_+(x)$ for $x^* \neq 0$. If $f(x) < 0$, by Lemma 2.2, $x^* \in N_S(x) = \partial f_+(x) = \tau\partial f_+(x)$. If $f(x) = 0$ and $\partial f(x) = \emptyset$, by (A) and Lemma 2.6, $x^* \in N_S(x) \subseteq \partial^\infty f(x) = [0,\tau]\partial f(x) + \partial^\infty f(x) =$

$\tau\partial f_+(x)$. If $f(x) = 0$ and $\partial f(x) \neq \emptyset$, by (A), there exist $\lambda \geq 0$, $u^* \in \partial f(x)$, and $v^* \in \partial^\infty f(x)$ satisfying $x^* = \lambda u^* + v^*$. If $\lambda = 0$, then by Lemma 2.6, $x^* = v^* \in \partial^\infty f(x) \subseteq [0,\tau]\partial f(x) + \partial^\infty f(x) = \tau\partial f_+(x)$. Otherwise,

$$\lambda^{-1}x^* = u^* + \lambda^{-1}v^* \in \partial f(x) + \lambda^{-1}\partial^\infty f(x) = \partial f(x) \subseteq \overline{[0,1]\partial f(x)}.$$

Let $M = \sup\{\alpha \geq 0 : \alpha x^* \in \overline{[0,1]\partial f(x)}\} \geq \lambda^{-1}$. If $M < \infty$, there exists an increasing sequence $\{t_n\}$ such that $\lim_{n\to\infty} t_n = M$, $t_n x^* \in \overline{[0,1]\partial f(x)}$, and $\lim_{n\to\infty} t_n x^* = Mx^* \in \overline{[0,1]\partial f(x)}$. By the definition of M, for all $t > 1$, $tMx^* \notin \overline{[0,1]\partial f(x)}$. Therefore, $Mx^* \in E[\partial f(x)]$. By (B),

$$M \geq \|Mx^*\| \geq d_{E[\partial f(x)]\cap N_S(x)}(0) \geq \frac{1}{\tau}.$$

Consequently, by Fact 2.4 and Lemma 2.6,

$$\begin{aligned} x^* = M^{-1}Mx^* &\in M^{-1}\overline{[0,1]\partial f(x)} \\ &= M^{-1}([0,1]\partial f(x) + \partial^\infty f(x)) \\ &\subseteq [0,\tau]\partial f(x) + \partial^\infty f(x) \\ &= \tau\partial f_+(x). \end{aligned}$$

If $M = \infty$, then by the convexity of $\overline{[0,1]\partial f(x)}$ and Fact 2.4,

$$[0,\infty)x^* \subseteq \overline{[0,1]\partial f(x)} = [0,1]\partial f(x) + \partial^\infty f(x).$$

By Lemma 2.6,

$$x^* = \tau\tau^{-1}x^* \in [0,\tau][0,\infty)x^* \subseteq [0,\tau]\partial f(x) + \partial^\infty f(x) = \tau\partial f_+(x).$$

Thus (3.4) is proved, and we have $x_t^* \in \partial d_S(x_t) \subseteq \tau\partial f_+(x_t)$. It follows from (3.3) and $x_t^* \in \tau\partial f_+(x_t)$ that

$$td_S(x) \leq t\|x - x_t\| \leq \langle x_t^*, x - x_t\rangle \leq \tau f_+(x) - \tau f_+(x_t) = \tau f_+(x). \tag{3.5}$$

Since (3.5) holds for all t sufficiently close to 1, one has $d_S(x) \leq \tau f_+(x)$. □

Remark 3.1. (i) For $x \in \mathrm{int}(S)$, $N_S(x) = \{0\}$ and $E[\partial f(x)] \cap N_S(x) = \emptyset$. Thus, (A), (B), and the strong BCQ hold. For $x \in \mathrm{bd}(S)$ and $f(x) < 0$, as indicated in the proof of Theorem 3.1, (A), (B), and the strong BCQ hold by Lemma 2.2. For $x \in \mathrm{bd}(S)$ and $f(x) = 0$, the strong BCQ (3.2) implies (A) and (B), and (A) and (B) imply (3.4), which is the strong BCQ. Therefore, the strong BCQ is pointwise equivalent to (A) and (B), and it characterizes local error bounds without the boundary restriction $\mathrm{bd}(S) \subseteq f^{-1}(0)$ and lower semicontinuity. This extends [6, Corollary 4.1] and [19, Theorem 2.2]. For a discontinuous function, the removal of the boundary restriction $\mathrm{bd}(S) \subseteq f^{-1}(0)$ is nontrivial.

(ii) When $x \in \mathrm{bd}(S)$ and $f(x) = 0$, the weak BCQ is equivalent to the extended BCQ and $E[\partial f(x)] \cap N_S(x) = E[\partial f(x)]$. Under this condition, (A) and (B) recover the decomposition of the strong BCQ in [6, Theorem 4.1].

(iii) When f is lower semicontinuous, the sufficient part of Theorem 3.1 can be derived from [19, Theorem 2.2], [6, Theorem 4.1], [13].

Theorem 3.1 explains that the nonexistence of a local error bound is possibly caused by either of the following: the cone $[0,\infty)\partial f(x) + \partial^\infty f(x)$ fails to represent all normal directions or the set $E[\partial f(x)] \cap N_S(x)$ is not separated from the origin. When

(A) and (B) hold uniformly on the entire boundary, we obtain a direction-length characterization for global error bounds.

THEOREM 3.2. *Let $\tau \in (0,\infty)$. Then $d_S(x) \le \tau f_+(x)$ for all $x \in X$ if and only if the weak BCQ and $d_{E[\partial f(x)]\cap N_S(x)}(0) \ge \tau^{-1}$ hold on* $\mathrm{bd}(S)$.

Proof. If $d_S(x) \le \tau f_+(x)$ for all $x \in X$, then (1.1) has a local error bound τ at every point of $\mathrm{bd}(S)$. By Theorem 3.1, the weak BCQ and $d_{E[\partial f(x)]\cap N_S(x)}(0) \ge \frac{1}{\tau}$ hold for all $x \in \mathrm{bd}(S)$. Conversely, for any $z \in X$, there exist $a \in \mathrm{bd}(S)$ and $r \in (0,\infty)$ such that $z \in B(a, \frac{r}{2})$. Since the weak BCQ and $d_{E[\partial f(x)]\cap N_S(x)}(0) \ge \frac{1}{\tau}$ hold for all $x \in B(a,r)\cap \mathrm{bd}(S)$, by the proof of Theorem 3.1, $d_S(x) \le \tau f_+(x)$ for all $x \in B(a, \frac{r}{2})$, and thus $d_S(z) \le \tau f_+(z)$. □

Note that the Slater condition implies the existence of a local error bound for any $x \in \mathrm{bd}(S)$ [13]. We have the following corollary.

COROLLARY 3.1. *If (1.1) satisfies the Slater condition, then for any $a \in \mathrm{bd}(S)$ there exist $r, \tau \in (0,\infty)$ such that for all $x \in B(a,r)\cap \mathrm{bd}(S)$,*

$$N_S(x) \subseteq [0,\infty)\partial f(x) + \partial^\infty f(x) \quad \textit{and} \quad d_{E[\partial f(x)]\cap N_S(x)}(0) \ge \tau^{-1}.$$

In the following examples, we use Theorems 3.1 and 3.2 to determine the existence or nonexistence of error bounds and to compute the smallest error bound if it exists.

Example 3.2. Let $\alpha > 1$, let x_i denote the ith component of $x \in R^n$, and let $g(x) = \frac{1}{\alpha}x_1$, $h(x) = \|x\| = (x_1^2 + \cdots + x_n^2)^{\frac{1}{2}}$, and $f(x) = g(x) + h(x)$. It is easy to verify that $S = \{0\}$ and $N_S(0) = R^n$. Since $ri(\mathrm{dom}(g)) \cap ri(\mathrm{dom}(h)) \ne \emptyset$, we have [14, Theorem 23.8]

$$\begin{aligned}\partial f(0) &= \partial g(0) + \partial h(0)\\ &= \{(\alpha^{-1}, 0, \ldots, 0)\} + \overline{B(0,1)}\\ &= \{x \in R^n : (x_1 - \alpha^{-1})^2 + x_2^2 + \cdots + x_n^2 \le 1\}.\end{aligned}$$

Thus, $E[\partial f(0)] = \{x \in R^n : (x_1 - \alpha^{-1})^2 + x_2^2 + \cdots + x_n^2 = 1\} = E[\partial f(0)] \cap N_S(0)$. In this case, the weak BCQ holds at 0 and $d_{E[\partial f(0)]\cap N_S(0)}(0) = 1 - \alpha^{-1}$. By Theorem 3.2 (or by [1, 4, 17, 18]), $\tau = \frac{\alpha}{\alpha - 1}$ is the smallest global error bound.

Example 3.3. Let $g(x) = x_1$, $h(x) = \|x\|$, and $f(x) = g(x) + h(x)$. One can verify that $S = \{(t, 0, \ldots, 0) \in R^n : t \le 0\}$, $N_S(0) = \{(x_1, x_2, \ldots, x_n) \in R^n : x_1 \ge 0\}$, and $\partial f(0) = \partial g(0) + \partial h(0) = \{x \in R^n : (x_1 - 1)^2 + x_2^2 + \cdots + x_n^2 \le 1\}$. In this case, $[0,\infty)\partial f(0) + \partial^\infty f(0)$ fails to represent all normal directions. In addition, $E[\partial f(0)] = \{x \ne 0 : (x_1 - 1)^2 + x_2^2 + \cdots + x_n^2 = 1\}$, and thus $d_{E[\partial f(0)]\cap N_S(0)}(0) = 0$. By Theorem 3.1, $f(x) \le 0$ does not have a local error bound at 0. Note that this example (for $n = 2$) was first used in [7] to illustrate the nonexistence of a global error bound. The nonexistence a local error bound at 0 can be derived from [2].

Example 3.4. Let $D = \{(x,y) : 0 < x \le 1, 0 \le y \le 1\} \cup \{(0,y) : 0 \le y \le \frac{1}{2}\}$, and define $f(x,y) = I_D(x,y) + x$, where $I_D(x,y)$ is the indicator function of D. Note that D is convex but not closed, and f is proper convex but not lower semicontinuous. It is not difficult to verify that

$$S = \{(x,y) : f(x,y) \le 0\} = \left\{(0,y) : 0 \le y \le \frac{1}{2}\right\},$$

$$N_S\left(0, \frac{1}{2}\right) = \{(x,y) : y \ge 0\},$$

$$\partial^\infty f\left(0,\frac{1}{2}\right) = N_{\mathrm{dom} f}\left(0,\frac{1}{2}\right) = N_D\left(0,\frac{1}{2}\right) = \{(x,0) : x \le 0\},$$

$$\partial f\left(0,\frac{1}{2}\right) = \partial I_D\left(0,\frac{1}{2}\right) + \{(1,0)\} = N_D\left(0,\frac{1}{2}\right) + \{(1,0)\} = \{(x,0) : x \le 1\}.$$

Hence, $[0,\infty)\partial f(0,\frac{1}{2}) + \partial^\infty f(0,\frac{1}{2}) = \{(x,0) : x \in R\}$, and the weak BCQ does not hold at $(0,\frac{1}{2})$. By Theorem 3.1, $f(x,y) \le 0$ does not have a local error bound at $(0,\frac{1}{2})$.

4. Segment extension property and global error bounds. In section 3 we have seen that (1.1) has a local error bound at a if (A) and (B) uniformly hold in a boundary neighborhood of a. When (A) and (B) uniformly hold in the entire boundary of S, we immediately obtain a characterization of global error bounds. In this section, we study global error bounds from a new aspect. We show that the verification of the direction-length decomposition can be sufficiently carried out on a small subset instead of the entire boundary. For this purpose, we introduce a useful new concept, the segment extension property.

DEFINITION 4.1. *Let $C \ne \emptyset$ be a convex set in X and $P \subseteq C$. Then P is said to have the segment extension property with respect to C (property SE) if for any $x \in C$ there exist $p \in P$ and $t > 1$ such that $p + t(x-p) \in C$.*

Note that the definition of property SE is equivalent to the following: For any $x \in C$, there exist $p \in P$, $c \in C$, and $\lambda \in (0,1)$ such that $x = (1-\lambda)p + \lambda c$.

Example 4.1. Given a convex set $C \ne \emptyset$, if there exists $P \subseteq C$ satisfying property R, i.e., $C = P + C^\infty$, then P has property SE. In particular, C has property SE with respect to itself. This was first introduced in [11, 20].

Example 4.2. If P has property SE with respect to C, then P contains all extreme points of C (if there are any). Indeed, if $e \in \mathrm{ext}(C)$ but $e \notin P$, then there exist $p \in P$ and $t > 1$ such that $x = p + t(e-p) \in C$. Hence, $e = (1-\frac{1}{t})p + \frac{1}{t}x$, which contradicts the definition of extreme point.

Example 4.3. If C is closed and $\emptyset \ne C \ne X$, then $\mathrm{bd}(C) \ne \emptyset$ has property SE.

In many cases a set having property SE could be much smaller than the entire boundary, as illustrated by the following examples.

Example 4.4. If C is a cone, then $P = \{0\}$ has property SE.

Example 4.5. Let $C = \{(x,y) : -\infty < x < \infty, -1 \le y \le 1\}$. Then $P = \{(0,1),(0,-1)\}$ has property SE.

Note that the convex set C in Example 4.5 has no extreme point. In general, let $L = C^\infty \cap (-C^\infty)$; then the set $P = \mathrm{ext}(C \cap L^\perp)$ has property SE, as proved in Lemma 4.1.

LEMMA 4.1. *Let $\emptyset \ne C \subset R^n$ be a closed convex set and $L = C^\infty \cap (-C^\infty)$. Then $\mathrm{ext}(C \cap L^\perp) \ne \emptyset$ has property SE. In particular, if $\mathrm{ext}(C) \ne \emptyset$, then $\mathrm{ext}(C)$ has property SE.*

Proof. First assume that C contains no lines. Then $L = \{0\}$, $L^\perp = R^n$, $C = C \cap L^\perp$, $\mathrm{ext}(C) \ne \emptyset$, and $C = \mathrm{conv}(\mathrm{ext}(C)) + C^\infty$ [14, pp. 166–167]. Given $x \in C$, there exist $e_i \in \mathrm{ext}(C)$ and $\lambda_i > 0$, $i = 1, \ldots, k$, $\sum_{i=1}^k \lambda_i = 1$, and $h \in C^\infty$ satisfying $x = \sum_{i=1}^k \lambda_i e_i + h$. If $k = 1$, then $e_1 + 2h = e_1 + 2(x - e_1) \in C$. If $k > 1$, let $\mu = \sum_{i=2}^k \lambda_i$ and $y = \sum_{i=2}^k \lambda_i e_i + h$. Then $\lambda_1 = 1 - \mu$, $\frac{1}{\mu} > 1$, $x = (1-\mu)e_1 + y$, and

$\mu e_1 + x - e_1 = y$. It follows that

$$e_1 + \frac{1}{\mu}(x - e_1) = \frac{1}{\mu}y = \sum_{i=2}^{k} \frac{\lambda_i}{\mu} e_i + \frac{1}{\mu}h \in C.$$

Therefore, $\text{ext}(C \cap L^{\perp}) = \text{ext}(C)$ has property SE.

In the case when C contains lines, the set $M = C \cap L^{\perp}$ contains no lines, $\text{ext}(M) \neq \emptyset$, and $C = M + L = \text{conv}(\text{ext}(M)) + M^{\infty} + L$ [14, p. 65]. The rest of the proof is similar to that of the first case and is omitted. □

In order to utilize property SE to reduce the verification of the weak BCQ and the length control of the subdifferential, we first study the relations between normal cones/subdifferentials at a point p and a point that can be extended from p.

LEMMA 4.2. *If C is a convex set in X, $a, b \in C$, $\lambda \in (0,1)$, and $x = (1-\lambda)a + \lambda b$, then $N_C(x) \subseteq N_C(a)$.*

Proof. Let $c = \lambda(b - a)$; then $x = a + c$ and $b = a + \frac{1}{\lambda}c$. For any $x^* \in N_C(x)$, $\langle x^*, a - x\rangle = \langle x^*, -c\rangle \leq 0$, which implies $\langle x^*, c\rangle \geq 0$. On the other hand, $\langle x^*, b - x\rangle = \langle x^*, (\frac{1}{\lambda} - 1)c\rangle \leq 0$, which implies $\langle x^*, c\rangle \leq 0$. Therefore, $\langle x^*, c\rangle = 0$. It follows that for all $u \in C$,

$$\langle x^*, u - a\rangle = \langle x^*, u - x + c\rangle = \langle x^*, u - x\rangle + \langle x^*, c\rangle = \langle x^*, u - x\rangle \leq 0.$$

Hence, $x^* \in N_C(a)$. □

LEMMA 4.3. *If $a, b \in S$, $\lambda \in (0,1)$, $x = (1-\lambda)a + \lambda b$, and $f(x) = f(a) = 0$, then $\partial f(x) = \partial f(a) \cap N_S(x)$.*

Proof. For any $x^* \in \partial f(x)$, $\langle x^*, u - x\rangle \leq f(u) - f(x)$ for all $u \in X$. By $f(x) = 0$ and Lemma 4.2, $\partial f(x) \subseteq N_S(x) \subseteq N_S(a)$, which implies $\langle x^*, x - a\rangle \leq 0$. Thus,

$$\langle x^*, u - a\rangle = \langle x^*, u - x\rangle + \langle x^*, x - a\rangle \leq \langle x^*, u - x\rangle \leq f(u) - f(x) = f(u) - f(a).$$

Therefore, $x^* \in \partial f(a)$ and thus $\partial f(x) \subseteq \partial f(a) \cap N_S(x)$. On the other hand, for $x^* \in \partial f(a) \cap N_S(x) \subseteq N_S(x)$, by the proof of Lemma 4.2, $\langle x^*, c\rangle = 0$, where $c = \lambda(b - a)$. Thus,

$$\begin{aligned} \langle x^*, u - x\rangle &= \langle x^*, u - x\rangle + \langle x^*, c\rangle \\ &= \langle x^*, u - x + c\rangle \\ &= \langle x^*, u - a\rangle \\ &\leq f(u) - f(a) \\ &= f(u) - f(x). \end{aligned}$$

Hence, $x^* \in \partial f(x)$ and $\partial f(a) \cap N_S(x) \subseteq \partial f(x)$. □

By using the above lemmas, we are ready to show that the weak BCQ and the length control of the subdifferential can be segment extended on S.

THEOREM 4.1. *Let $a, b \in S$, $\lambda \in (0,1)$, and $x = (1-\lambda)a + \lambda b$.*

(i) *If the weak BCQ holds at a, then it holds at x.*

(ii) *$E[\partial f(x)] \cap N_S(x) \subseteq E[\partial f(a)] \cap N_S(a)$, which implies that $d_{E[\partial f(x)] \cap N_S(x)}(0) \geq d_{E[\partial f(a)] \cap N_S(a)}(0)$.*

Proof. (i) If $x \notin \text{bd}(S)$, then $N_S(x) = \{0\} \subseteq [0,\infty)\partial f(x) + \partial^{\infty} f(x)$. If $x \in \text{bd}(S)$ and $f(x) < 0$, then by Lemma 2.2, $N_S(x) = \partial^{\infty} f(x) \subseteq [0,\infty)\partial f(x) + \partial^{\infty} f(x)$. If $x \in \text{bd}(S)$ and $f(x) = 0$, then by the convexity of f, we must have $f(a) = 0$. Since $\partial^{\infty} f(a)$ is a cone, by Lemma 2.6 we have

$$N_S(a) \subseteq [0,\infty)\partial f(a) + \partial^{\infty} f(a) = [0,\infty)([0,1]\partial f(a) + \partial^{\infty} f(a)) = [0,\infty)\partial f_+(a).$$

It follows that

$$\begin{aligned} N_S(x) &= N_S(a) \cap N_S(x) \quad \text{(by Lemma 4.2)} \\ &\subseteq [0,\infty)\partial f_+(a) \cap N_S(x) \\ &= [0,\infty)(\partial f_+(a) \cap N_S(x)) \\ &= [0,\infty)\partial f_+(x) \quad \text{(by Lemma 4.3)} \\ &= [0,\infty)\partial f(x) + \partial^\infty f(x) \quad \text{(by Lemma 2.6)}. \end{aligned}$$

It remains to prove (ii). Without loss of generality, we may assume that $\partial f(x) \neq \emptyset$. If $x \notin \mathrm{bd}(S)$, then $N_S(x) = \{0\}$. Because an end set cannot contain 0, $E[\partial f(x)] \cap N_S(x) = \emptyset$ and $d_{E[\partial f(x)]\cap N_S(x)}(0) = \infty$. If $x \in \mathrm{bd}(S)$ and $f(x) < 0$, then, as in the proof of Theorem 3.1, $E[\partial f(x)] \cap N_S(x) = \emptyset$ and $d_{E[\partial f(x)]\cap N_S(x)}(0) = \infty$. If $x \in \mathrm{bd}(S)$ and $f(x) = 0$, then by the convexity of f, we must have $f(a) = 0$. We claim that

$$E[\partial f(x)] \subseteq E[\partial f(a)]. \tag{4.1}$$

Indeed, since $f(x) = 0$ and $f(a) = 0$, by Fact 2.4 and Lemma 2.6, $\overline{[0,1]\partial f(x)} = \partial f_+(x)$ and $\overline{[0,1]\partial f(a)} = \partial f_+(a)$. For any $u^* \in E[\partial f(x)]$, $u^* \in \overline{[0,1]\partial f(x)} = \partial f_+(x)$ and $tu^* \notin \overline{[0,1]\partial f(x)} = \partial f_+(x)$ for all $t > 1$. By Lemma 4.3,

$$u^* \in \partial f_+(x) = \partial f_+(a) \cap N_S(x) \subseteq \partial f_+(a) = \overline{[0,1]\partial f(a)}$$

and

$$tu^* \notin \partial f_+(x) = \partial f_+(a) \cap N_S(x) \quad \forall t > 1.$$

Note that $tu^* \in N_S(x)$; we must have $tu^* \notin \partial f_+(a) = \overline{[0,1]\partial f(a)}$ for all $t > 1$. Consequently, $u^* \in E[\partial f(a)]$ by the definition of the end set, and (4.1) is proven. It follows from (4.1) and Lemma 4.2 that

$$E[\partial f(x)] \cap N_S(x) \subseteq E[\partial f(a)] \cap N_S(a),$$

which implies that

$$d_{E[\partial f(x)]\cap N_S(x)}(0) \geq d_{E[\partial f(a)]\cap N_S(a)}(0). \qquad \square$$

By Theorem 4.1 and the equivalent definition of a set with property SE, we immediately have the following theorem.

THEOREM 4.2. *Let $P \subseteq S$ have property SE with respect to S.*

(i) *The weak BCQ holds for all $x \in S$ if and only if it holds for all $x \in P$.*

(ii) *$d_{E[\partial f(x)]\cap N_S(x)}(0) \geq \frac{1}{\tau}$ holds for all $x \in S$ if and only if it holds for all $x \in P$.*

Combining Theorems 4.2 and 3.2, we immediately obtain a characterization of global error bounds on any set $P \subseteq \mathrm{bd}(S)$ having property SE with respect to S.

THEOREM 4.3. *Let $\tau \in (0, +\infty)$ and $P \subseteq \mathrm{bd}(S)$ have property SE with respect to S. Then $d_S(x) \leq \tau f_+(x)$ for all $x \in X$ if and only if the weak BCQ and $d_{E[\partial f(x)]\cap N_S(x)}(0) \geq \frac{1}{\tau}$ hold on P.*

Note that when $x \in \mathrm{bd}(S) \cap f^{-1}(0)$, $\partial f(x) \subseteq N_S(x)$. Therefore, $E[\partial f(x)] \subseteq N_S(x)$ and $d_{E[\partial f(x)]\cap N_S(x)}(0) = d_{E[\partial f(x)]}(0)$. When $x \in \mathrm{bd}(S)$ and $f(x) < 0$, $d_{E[\partial f(x)]\cap N_S(x)}(0) = \infty$. Therefore, we obtain the following formula for the smallest global error bound.

COROLLARY 4.1. *Let $P \subseteq \mathrm{bd}(S)$ have property SE and $\gamma = \inf\{d_{E[\partial f(x)]}(0) : x \in P \cap f^{-1}(0)\}$. If the weak BCQ holds on P and $\gamma \in (0, \infty)$, then $\tau = \frac{1}{\gamma}$ is the smallest*

global error bound. If the weak BCQ holds on P and $\gamma = \infty$, then every $\tau \in (0, \infty)$ is a global error bound.

Finally, for the important special case of $X = R^n$, by Lemma 4.1, we obtain a characterization of global error bounds by conditions on extreme points.

THEOREM 4.4. *Let $\tau \in (0, +\infty)$, $X = R^n$, $L = S^\infty \cap (-S^\infty)$, and $\gamma = \inf\{d_{E[\partial f(x)]}(0) : x \in \operatorname{ext}(S \cap L^\perp) \cap f^{-1}(0)\}$. Then $d_S(x) \le \tau f_+(x)$ for all $x \in X$ if and only if the weak BCQ and $d_{E[\partial f(x)] \cap N_S(x)}(0) \ge \frac{1}{\tau}$ hold on $\operatorname{ext}(S \cap L^\perp)$. If a global error bound exists and $\gamma \in (0, \infty)$, then $\tau = \frac{1}{\gamma}$ is the smallest global error bound.*

Acknowledgments. The author wishes to express her sincere appreciation to the referees and Prof. Jiri Outrata for their careful reading of this paper and valuable comments.

STABILITY AND SENSITIVITY OF OPTIMIZATION PROBLEMS WITH FIRST ORDER STOCHASTIC DOMINANCE CONSTRAINTS*

DARINKA DENTCHEVA†, RENÉ HENRION‡, AND ANDRZEJ RUSZCZYŃSKI§

Abstract. We analyze the stability and sensitivity of stochastic optimization problems with stochastic dominance constraints of first order. We consider general perturbations of the underlying probability measures in the space of regular measures equipped with a suitable discrepancy distance. We show that the graph of the feasible set mapping is closed under rather general assumptions. We obtain conditions for the continuity of the optimal value and upper-semicontinuity of the optimal solutions, as well as quantitative stability estimates of Lipschitz type. Furthermore, we analyze the sensitivity of the optimal value and obtain upper and lower bounds for the directional derivatives of the optimal value. The estimates are formulated in terms of the dual utility functions associated with the dominance constraints.

Key words. stochastic programming, stochastic ordering, semi-infinite optimization, chance constraints, Lipschitz stability, metric regularity, directional differentiability

1. Introduction.

The notion of stochastic ordering (or *stochastic dominance of first order*) was introduced in statistics in [14, 13] and further applied and developed in economics [17, 7, 6]. It is defined as follows. For a random variable X we consider its distribution function, $F(X;\eta) = P[X \le \eta]$, $\eta \in \mathbb{R}$. We say that a random variable X *dominates in the first order* a random variable Y if

$$F(X;\eta) \le F(Y;\eta) \quad \forall\, \eta \in \mathbb{R}. \tag{1.1}$$

We denote this relation $X \succeq_{(1)} Y$. For a modern perspective on stochastic orders, see [15, 25].

Let $g : \mathbb{R}^n \times \mathbb{R}^s \to \mathbb{R}$ be continuous with respect to both arguments, and let V be an s-dimensional random vector, defined on a certain probability space $(\Omega, \mathscr{F}, P)$. For every $z \in \mathbb{R}^n$

$$X_z(\omega) = g(z, V(\omega)), \quad \omega \in \Omega,$$

is a random variable. Given a benchmark random variable Y (defined on the same probability space), an optimization model with first order stochastic dominance constraint is formulated as follows:

$$\begin{aligned} &\min\ f(z) \\ &\text{s.t. } X_z \succeq_{(1)} Y, \\ &\quad z \in Z, \end{aligned} \tag{1.2}$$

where $f : \mathbb{R}^n \to \mathbb{R}$ and $Z \subset \mathbb{R}^n$. Using definition (1.1), we can express the dominance constraint as a continuum of probabilistic constraints:

$$P\big[g(z,V) \geq \eta\big] \geq P\big[Y \geq \eta\big], \quad \eta \in \mathbb{R}.$$

In [5] optimality conditions for a relaxation of problem (1.2) were investigated, in which the dominance constraint was enforced on an interval $[a,b]$ rather than on the entire real line:

$$\begin{aligned} &\min\ f(z) \\ &\text{s.t. } P\big[g(z,V) \geq \eta\big] \geq P\big[Y \geq \eta\big], \quad \eta \in [a,b], \\ &\quad z \in Z. \end{aligned} \tag{1.3}$$

The restriction of the range of η to a compact interval is motivated by the need to satisfy a constraint qualification condition for the problem (see Definition 2.4). Both probability functions in problem (1.3) converge to 0 when $\eta \to \infty$ and to 1 when $\eta \to \infty$, which precludes Robinson-type conditions on the whole real line.

From now on, we shall assume that f is continuous and Z is a nonempty closed convex set. Our objective is to investigate the stability and sensitivity of the optimal value, the feasible set, and solution set, respectively, of problem (1.3) when the random variables V and Y are subject to perturbations.

For the purpose of our analysis it is convenient to formulate the dominance constraint with the use of "$\geq$" inequalities, as in (1.3). When the distributions are continuous, this formulation is equivalent to the formulation used in [5].

Problems with stochastic dominance constraints are new optimization models involving risk aversion (see [3, 4, 5]). As problems with a continuum of constraints on probability, they pose specific analytical and computational challenges. The probabilistic nature of the problem prevents the direct application of the theory of semi-infinite optimization. On the other hand, the specific structure of dominance constraints is significantly different from the structure of finitely many probabilistic constraints. Our stability analysis follows similar patterns to those in [8, 22, 23], where the focus was on probabilistic constraints. However, a straightforward application of those results (a recent overview of which can be found in [21]) is not possible due to the specific structure of problem (1.3). First, in (1.3) we deal with two separate probability terms due to the consideration of a benchmark variable. Second, and more importantly, problem (1.3) has a continuum of constraints which requires a more sophisticated analysis than the case of a finite family of constraints.

In section 2, we establish the closedness of the feasible set mapping, and we obtain stability results for the optimal value, for the feasible set, and for the solution set. In section 3, we analyze the sensitivity of the optimal value function, and we obtain bounds for its directional derivatives.

2. Stability. It is obvious from the formulation of the dominance constraint that only the distribution laws of V and Y matter there. Therefore, we introduce the measures μ_0 on $\mathbb{R}^s$ and ν_0 on $\mathbb{R}$ induced by V and Y. For all Borel sets $A \subset \mathbb{R}^s$ and $B \subset \mathbb{R}$,

$$\begin{aligned} \mu_0(A) &= P[V \in A], \\ \nu_0(B) &= P[Y \in B]. \end{aligned}$$

We denote the set of probability measures on $\mathbb{R}^m$ by $\mathscr{P}(\mathbb{R}^m)$.

Furthermore, we introduce the multifunction $H : \mathbb{R}^n \times \mathbb{R} \rightrightarrows \mathbb{R}^s$ defined by

$$H(z,\eta) := \{v \in \mathbb{R}^s : g(z,v) \geq \eta\}.$$

We consider the following parametric optimization problem:

$$\begin{aligned} &\min\ f(z) \\ &\text{s.t. } \mu(H(z,\eta)) - \nu([\eta,\infty)) \geq 0 \quad \forall \eta \in [a,b], \\ &\quad z \in Z, \end{aligned} \tag{2.1}$$

with parameters $\mu \in \mathscr{P}(\mathbb{R}^s)$ and $\nu \in \mathscr{P}(\mathbb{R})$. The original problem (1.3) is obtained when $(\mu,\nu) = (\mu_0,\nu_0)$. Our aim is to study the stability of solutions and of the optimal value to (2.1) under small perturbations of the underlying distributions μ_0 and ν_0.

For this purpose we equip the space $\mathscr{P}(\mathbb{R})$ with the Kolmogorov distance function:

$$\alpha_1(\nu_1,\nu_2) = \sup_{\eta\in\mathbb{R}} \left|\nu_1([\eta,\infty)) - \nu_2([\eta,\infty))\right|.$$

To introduce a distance function on $\mathscr{P}(\mathbb{R}^s)$, which is appropriate for our problem, we define the family of sets:

$$\mathscr{B} := \{H(z,\eta) : z \in Z, \eta \in [a,b]\} \cup \{v + \mathbb{R}^s_- : v \in \mathbb{R}^s\}.$$

The distance function on $\mathscr{P}(\mathbb{R}^s)$ is defined as the discrepancy

$$\alpha_{\mathrm{B}}\,(\mu_1,\mu_2) := \sup_{B\in\mathrm{B}} \left|\mu_1(B) - \mu_2(B)\right|.$$

On the product space $\mathscr{P}(\mathbb{R}^s) \times \mathscr{P}(\mathbb{R})$ we introduce the natural distance:

$$\alpha((\mu_1,\nu_1),(\mu_2,\nu_2)) := \max\{\alpha_{\mathrm{B}}\,(\mu_1,\mu_2), \alpha_1(\nu_1,\nu_2)\}. \tag{2.2}$$

Note that α is a metric, because the measures are compared, in particular, on all the cells of form $z + \mathbb{R}^s_-$ and $(-\infty,\eta)$, respectively.

We consider the constraint set mapping $\Phi : \mathscr{P}(\mathbb{R}^s) \times \mathscr{P}(\mathbb{R}) \rightrightarrows \mathbb{R}^n$, which assigns to every parameter (μ,ν) the feasible set of problem (2.1), i.e.,

$$\Phi(\mu,\nu) := \big\{z \in Z : \mu(H(z,\eta)) - \nu([\eta,\infty)) \geq 0 \quad \forall \eta \in [a,b]\,\big\}.$$

Given any open subset $U \subseteq \mathbb{R}^n$, we define the U-localized optimal value function, $\varphi_U : \mathscr{P}(\mathbb{R}^s) \times \mathscr{P}(\mathbb{R}) \to \overline{\mathbb{R}}$, of problem (2.1) as follows:

$$\varphi_U(\mu,\nu) := \inf\big\{f(z) : z \in \Phi(\mu,\nu) \cap \operatorname{cl} U\big\}.$$

The U-localized solution set mapping $\Psi_U : \mathscr{P}(\mathbb{R}^s) \times \mathscr{P}(\mathbb{R}) \rightrightarrows \mathbb{R}^n$ of problem (2.1) is defined by

$$\Psi_U(\mu,\nu) := \big\{z \in \Phi(\mu,\nu) \cap \operatorname{cl} U : f(z) = \varphi_U(\mu,\nu)\big\}.$$

When $U = \mathbb{R}^n$ we simply write $\varphi(\mu,\nu)$ and $\Psi(\mu,\nu)$.

The reason to consider localized mappings is that we allow general perturbations of the probability distributions. Then, without additional compactness conditions, no reasonable constraint qualification formulated at the solution points of the original problem (1.3) could guarantee stability of the global solution set mapping $\Psi := \Psi_{\mathbb{R}^n}$.

We recall a general stability result from [10, Proposition 1 and Theorem 1] in a version adapted to our setting. In the theorem below, the symbol $\mathbb{B}(z,r)$ denotes the ball about z of radius r.

THEOREM 2.1. *Let the following assumptions be satisfied in* (2.1):

1. *The original solution set $\Psi(\mu_0,\nu_0)$ is nonempty and bounded.*
2. *The graph of the constraint set mapping Φ is closed.*
3. *At every solution $z^0 \in \Psi(\mu_0,\nu_0)$ of the original problem, there exist $\varepsilon > 0$ and $L > 0$ such that for all $(\mu,\nu) \in \mathbb{B}((\mu_0,\nu_0);\varepsilon)$ the constraint set mapping satisfies the following two Lipschitz-like estimates:*

$$d(z,\Phi(\mu_0,\nu_0)) \le L\alpha((\mu,\nu),(\mu_0,\nu_0)) \quad \forall z \in \Phi(\mu,\nu) \cap \mathbb{B}(z^0;\varepsilon), \tag{2.3}$$

$$d(z,\Phi(\mu,\nu)) \le L\alpha((\mu,\nu),(\mu_0,\nu_0)) \quad \forall z \in \Phi(\mu_0,\nu_0) \cap \mathbb{B}(z^0;\varepsilon). \tag{2.4}$$

4. *f is locally Lipschitz.*

Then, for any bounded and open set Q containing the original solution set, the following stability properties hold true:

- *$\exists \delta' > 0 :\ \Psi_Q(\mu,\nu) \neq \emptyset$ for all $(\mu,\nu) \in \mathbb{B}((\mu_0,\nu_0);\delta')$.*
- *Ψ_Q is upper semicontinuous at (μ_0,ν_0) in the sense of Berge; i.e., for all open $V \supseteq \Psi(\mu_0,\nu_0) = \Psi_Q(\mu_0,\nu_0)$ there exists some $\delta_V > 0$ such that*

$$\Psi_Q(\mu,\nu) \subseteq V \quad \forall (\mu,\nu) \in \mathbb{B}((\mu_0,\nu_0);\delta_V).$$

- *φ_Q is continuous at (μ_0,ν_0) and satisfies the following Lipschitz-like estimate for some constants $\delta^*, L^* > 0$:*

$$|\varphi_Q(\mu,\nu) - \varphi_Q(\mu_0,\nu_0)| \le L^*\alpha((\mu,\nu),(\mu_0,\nu_0)) \quad \forall (\mu,\nu) \in \mathbb{B}((\mu_0,\nu_0);\delta^*).$$

We note that the first two assertions of the theorem already follow from [19, Theorem 4.3]. In the following we want to provide verifiable conditions for the assumptions of Theorem 2.1. As far as assumption 1 is concerned, it is of a purely technical nature and may be difficult to verify in the general setting. If, however, the abstract part Z of the constraint set in (2.1) happens to be compact, as is the case in many applied problems, then, of course, the boundedness assumption 1 in Theorem 2.1 is trivially satisfied. In this situation, one can even drop the localizations φ_Q and Ψ_Q in the statement of Theorem 2.1 and formulate the corresponding conclusions for the global optimal value function φ and the global solution set mapping Ψ. Indeed, as one may choose Q in Theorem 2.1 by compactness of Z such that $Q \supseteq Z \supseteq \Psi(\mu_0,\nu_0)$, it follows that

$$\Psi_Q(\mu,\nu) = \Psi(\mu,\nu)\ (\subset Z \subset Q) \quad \text{and} \quad \varphi_Q(\mu,\nu) = \varphi(\mu,\nu) \quad \forall (\mu,\nu).$$

Passing to assumption 2 in Theorem 2.1, this is generally satisfied under the data assumptions made for problem (1.3). To show this, we first adapt a result of [22].

LEMMA 2.2. *Assume that a multifunction $S : \mathbb{R}^n \rightrightarrows \mathbb{R}^s$ has a closed graph. Let $\bar{x} \in \mathbb{R}^n$ be such that $S(\bar{x}) \neq \emptyset$. Then for every nonnegative regular measure μ on $\mathbb{R}^s$ and for every $\varepsilon > 0$ there exists $\delta > 0$ such that*

$$\mu\big(S(x)\big) \le \mu\big(S(\bar{x})\big) + \varepsilon, \ \textit{whenever } \|x - \bar{x}\| \le \delta. \tag{2.5}$$

Proof. By the closedness of the graph,

$$S(\bar{x}) = \bigcap_{\delta>0} \mathrm{cl}\Big(\bigcup_{\|x-\bar{x}\|\le\delta} S(x)\Big).$$

Therefore, for every regular measure μ,

$$\mu\big(S(\bar{x})\big) = \inf_{\delta>0} \mu\Big(\mathrm{cl}\Big(\bigcup_{\|x-\bar{x}\|\le\delta} S(x)\Big)\Big).$$

Consequently, for every $\varepsilon > 0$ there exists $\delta > 0$ such that

$$\mu\big(S(\bar{x})\big) + \varepsilon \ge \mu\Big(\mathrm{cl}\Big(\bigcup_{\|x-\bar{x}\|\le\delta} S(x)\Big)\Big).$$

This implies the result. □

THEOREM 2.3. *The graph of the feasible set mapping Φ is closed.*

Proof. Consider a sequence (μ^n, ν^n, z^n) of the elements of the graph, which is convergent to some $(\bar{\mu}, \bar{\nu}, \bar{z})$ in the space $\mathscr{P}(\mathbb{R}^s) \times \mathscr{P}(\mathbb{R}) \times \mathbb{R}^n$. Since $z^n \in \Phi(\mu^n, \nu^n)$, then $z^n \in Z$ and

$$\mu^n(H(z^n, \eta)) - \nu^n([\eta, \infty)) \ge 0 \quad \forall \eta \in [a, b]. \tag{2.6}$$

As Z is closed, $\bar{z} \in Z$. By the definition of $\alpha_1(\cdot,\cdot)$, it follows that

$$\nu^n([\eta, \infty)) \to \bar{\nu}([\eta, \infty)) \quad \forall\, \eta \in [a, b]. \tag{2.7}$$

Let us consider the first term in (2.6). For a fixed $\eta \in [a, b]$ we have the inequality

$$\begin{aligned} &\mu^n(H(z^n, \eta)) - \bar{\mu}(H(\bar{z}, \eta)) \\ &= \big[\mu^n(H(z^n, \eta)) - \bar{\mu}(H(z^n, \eta))\big] + \big[\bar{\mu}(H(z^n, \eta)) - \bar{\mu}(H(\bar{z}, \eta))\big] \\ &\le \alpha_{\mathrm{B}}\,(\mu^n, \bar{\mu}) + \big[\bar{\mu}(H(z^n, \eta)) - \bar{\mu}(H(\bar{z}, \eta))\big]. \end{aligned} \tag{2.8}$$

By assumption, $\alpha_{\mathrm{B}}\,(\mu^n, \bar{\mu}) \to 0$, and we can focus on the term in brackets. By the continuity of g, the multifunction $H(\cdot, \eta)$ has a closed graph. We now apply Lemma 2.2 to conclude that for every $\varepsilon > 0$ there exists $\delta > 0$ such that

$$\bar{\mu}\big(H(z, \eta)\big) \le \bar{\mu}\big(H(\bar{z}, \eta)\big) + \varepsilon, \text{ whenever } \|z - \bar{z}\| \le \delta.$$

For all sufficiently large n one has $\|z^n - \bar{z}\| \le \delta$ and therefore

$$\bar{\mu}\big(H(z^n, \eta)\big) \le \bar{\mu}\big(H(\bar{z}, \eta)\big) + \varepsilon.$$

Passing to the limit with $n \to \infty$ and noting that $\varepsilon > 0$ was arbitrary, we obtain

$$\limsup_{n\to\infty} \bar{\mu}\big(H(z^n, \eta)\big) \le \bar{\mu}\big(H(\bar{z}, \eta)\big). \tag{2.9}$$

Combining relations (2.8) and (2.9), we conclude that

$$\limsup_{n\to\infty} \mu^n(H(z^n, \eta)) \le \bar{\mu}(H(\bar{z}, \eta)).$$

Using this in (2.6), with a view to (2.7), we obtain

$$\begin{aligned} \bar{\mu}(H(\bar{z}, \eta)) - \bar{\nu}(\eta, \infty)) &\ge \limsup_{n\to\infty} \mu^n(H(z^n, \eta)) - \lim_{n\to\infty} \nu^n([\eta, \infty)) \\ &= \limsup_{n\to\infty} \big[\mu^n(H(z^n, \eta)) - \nu^n([\eta, \infty))\big] \ge 0. \end{aligned}$$

Since η was arbitrary, we obtain the relation

$$\bar{\mu}(H(\bar{z},\eta)) - \bar{\nu}(\eta,\infty)) \geq 0 \quad \forall\, \eta \in [a,b].$$

This amounts to $\bar{z} \in \Phi(\bar{\mu},\bar{\nu})$, as desired. □

Remark 1. Let us observe that we did not use the compactness of the set $[a,b]$ in the proof, and therefore Theorem 2.3 holds true for the dominance relation enforced on the whole real line.

The verification of assumption 3 in Theorem 2.1 is less direct and will be based on an appropriate constraint qualification for problem (2.1) at the original parameter (μ_0,ν_0). To formulate this constraint qualification, we assume the following differential uniform dominance condition introduced in [5].

DEFINITION 2.4. *Problem* (2.1) *for* $\mu = \mu_0$ *and* $\nu = \nu_0$ *satisfies the* differential uniform dominance condition *at the point* $z^0 \in Z$ *if*

(i) $\mu_0(H(z,\eta))$ *is continuous with respect to* η *in* $[a,b]$*, differentiable with respect to* z *in a neighborhood of* z^0 *for all* $\eta \in [a,b]$*, and its derivative is jointly continuous with respect to both arguments;*

(ii) $\nu_0([\cdot,\infty))$ *is continuous;*

(iii) *there exists* $z^1 \in Z$ *such that*

$$\min_{a\leq\eta\leq b} \Big\{\mu_0\big(H(z^0,\eta)\big) + \nabla_z\mu_0\big(H(z^0,\eta)\big)(z^1 - z^0) - \nu_0\big([\eta,\infty)\big)\Big\} > 0.$$

The differentiability assumptions on $\mu_0(H(\cdot,\eta))$ can be guaranteed by assuming continuous differentiability of the function g with respect to both arguments, the existence of the probability density of the random vector V, and by mild regularity conditions (see [9]). Then

$$\nabla_z\mu_0\big(H(z,\eta)\big) = \int_{\partial H(z,\eta)} \frac{\varphi(v)}{\|\nabla_v g(z,v)\|}\nabla_z g(z,v)\,\lambda(dv),$$

where $\partial H(z,\eta)$ is the surface of the set $H(z,\eta)$ and λ is the surface Lebesgue measure. The regularity conditions mentioned require that the gradient $\nabla_v g(z,v)$ be nonzero and that the integrand above be uniformly bounded (in a neighborhood of z) by an integrable function.

For example, if $g(z,V) = \langle z,V\rangle$ and V has a nondegenerate multivariate normal distribution $\mathcal{N}(\bar{v},\Sigma)$, then

$$\mu_0(H(z,\eta)) = 1 - \Phi\Big(\frac{\eta - \langle z,\bar{v}\rangle}{\sqrt{\langle z,\Sigma z\rangle}}\Big),$$

where $\Phi(\cdot)$ is the distribution function of the standard normal variable. In this case condition (i) of Definition 2.4 is satisfied at every $z \neq 0$.

The differential uniform dominance condition has substantial consequences. Let $\mathscr{C}$ be the Banach space of continuous functions on $[a,b]$. Consider the mapping $\Gamma : \mathbb{R}^n \to \mathscr{C}$ defined as

$$\Gamma(z)(\eta) = \mu_0(H(z,\eta)) - \nu_0([\eta,\infty)), \quad \eta \in [a,b],$$

where $\nu_0([\cdot,\infty)) \in \mathscr{C}$. Denote by K the nonnegative cone in $\mathscr{C}$.

LEMMA 2.5. *Assume that* $\mu_0(H(z,\eta))$ *is continuously differentiable with respect to* z *in a neighborhood of* $z^0 \in Z$ *and for all* $\eta \in [a,b]$*,* $\mu_0(H(z,\cdot))$ *is continuous in*

$[a,b]$, and $\Gamma(z^0) \in K$. The differential uniform dominance condition is satisfied at z^0 if and only if the multifunction

$$z \mapsto \begin{cases} \Gamma(z) - K & \text{if } z \in Z, \\ \emptyset & \text{otherwise} \end{cases} \tag{2.10}$$

is metrically regular at $(z^0, 0)$.

Proof. We observe that the differential uniform dominance condition is equivalent to Robinson's constraint qualification condition (see [18])

$$0 \in \operatorname{int}\Big\{\Gamma(z^0) + \nabla_z \Gamma(z^0)(Z - z^0) - K\Big\}. \tag{2.11}$$

Indeed, it is easy to see that the uniform dominance condition implies Robinson's condition. On the other hand, if Robinson's condition holds true, then there exists $\varepsilon > 0$ such that the function identically equal to ε is an element of the set on the right-hand side of (2.11). Then we can find z^1 such that

$$\Gamma(z^0)(\eta) + \big[\nabla_z \Gamma(z^0)(\eta)\big](z^1 - z^0) \geq \varepsilon \quad \forall\, \eta \in [a,b].$$

Consequently, the uniform dominance condition is satisfied. On the other hand, Robinson's constraint qualification at z^0 is equivalent to the metric regularity of (2.10) at $(z^0, 0)$ (see [2]). □

The next proposition shows that the verification of assumption 3 in Theorem 2.1 can be reduced to the differential uniform dominance condition.

PROPOSITION 2.6. *Let the differential uniform dominance condition be satisfied at some $z^0 \in \Phi(\mu_0, \nu_0)$. Then relations* (2.3) *and* (2.4) *of Theorem* 2.1 *hold true at z^0.*

Proof. We introduce the multifunction $M : \mathscr{C} \rightrightarrows \mathbb{R}^n$ as the following parameter dependent constraint set mapping:

$$M(w) := \big\{z \in Z : \mu_0(H(z,\eta)) - w(\eta) \geq 0 \ \forall\, \eta \in [a,b]\big\}.$$

(The relation between M and Φ is given by $\Phi(\mu_0, \nu) = M\big(\nu([\cdot, \infty))\big)$ for all continuous distributions $\nu \in \mathscr{P}(\mathbb{R})$.) Define $w_0(\cdot) = \nu_0([\cdot, \infty))$. By assumption, $w_0 \in \mathscr{C}$.

By Lemma 2.5, the differential uniform dominance condition is equivalent to metric regularity of (2.10) at $(z^0, 0)$, which, upon passing to the inverse multifunction, is equivalent to the pseudo-Lipschitz property of M at (w^0, z^0) (see, e.g., [12, Lemma 1.12] and [20, Theorem 9.43]). Accordingly, there exist $\tilde{\varepsilon} > 0$ and $\tilde{L} > 0$ such that

$$d(z, M(w_2)) \leq \tilde{L} d(w_1, w_2) \quad \forall z \in M(w_1) \cap \mathbb{B}(z^0; \tilde{\varepsilon}) \ \forall w_1, w_2 \in \mathbb{B}(w_0; \tilde{\varepsilon}), \tag{2.12}$$

where the last ball is taken in the metric of $\mathscr{C}$. First, we verify the following chain of inclusions for all $(\mu, \nu) \in \mathscr{P}(\mathbb{R}^s) \times \mathscr{P}(\mathbb{R})$:

$$M(w_0 + 2\alpha((\mu,\nu),(\mu_0,\nu_0)) \cdot \mathbb{1}) \subseteq \Phi(\mu,\nu) \subseteq M(w_0 - 2\alpha((\mu,\nu),(\mu_0,\nu_0)) \cdot \mathbb{1}), \tag{2.13}$$

where $\mathbb{1}$ is the function on $[a,b]$ taking the constant value 1. Note that M is applied to continuous functions as required. Now, if

$$z \in M(w_0 + 2\alpha_{\mathrm{B}}\,((\mu,\nu),(\mu_0,\nu_0)) \cdot \mathbb{1}),$$

then $z \in Z$ and, by definition of α,

$$\begin{aligned} 0 &\le \mu_0(H(z,\eta)) - (w_0(\eta) + 2\alpha((\mu,\nu),(\mu_0,\nu_0))) \\ &= \mu_0(H(z,\eta)) - \nu_0([\eta,\infty)) - 2\alpha((\mu,\nu),(\mu_0,\nu_0))) \\ &\le \mu(H(z,\eta)) - \nu([\eta,\infty)) \quad \forall \eta \in [a,b]\,. \end{aligned}$$

This establishes the first inclusion of (2.13), and the second one is completely analogous.

In order to check (2.3), let $(\mu,\nu) \in \mathbb{B}((\mu_0,\nu_0);\tilde{\varepsilon}/2)$ and $z \in \Phi(\mu,\nu) \cap \mathbb{B}(z^0;\tilde{\varepsilon}/2)$ be arbitrary. Define $w_1 \in \mathscr{C}$ by $w_1 := w_0 - 2\alpha((\mu,\nu),(\mu_0,\nu_0)) \cdot \mathbb{1}$. Then the second inclusion of (2.13) entails that $z \in M(w_1)$. Furthermore,

$$d(w_1,w_0) = 2\alpha((\mu,\nu),(\mu_0,\nu_0)) \le \tilde{\varepsilon}.$$

Consequently, we may apply (2.12) to w_1 and to $w_2 := w_0 \in \mathscr{C}$:

$$d(z,\Phi(\mu_0,\nu_0)) = d(z,M(w_0)) \le \tilde{L}d(w_1,w_0) = 2\tilde{L}\alpha((\mu,\nu),(\mu_0,\nu_0)).$$

Therefore, (2.3) holds true with $L := 2\tilde{L}$ and $\varepsilon := \tilde{\varepsilon}/2$. As for (2.4), take arbitrary $(\mu,\nu) \in \mathbb{B}((\mu_0,\nu_0);\tilde{\varepsilon}/2)$ and $z \in \Phi(\mu_0,\nu_0) \cap \mathbb{B}(z^0;\tilde{\varepsilon}/2)$. Define $w_2 \in \mathscr{C}$ by $w_2 := w_0 + 2\alpha((\mu,\nu),(\mu_0,\nu_0)) \cdot \mathbb{1}$. Then

$$d(w_2,w_0) = 2\alpha((\mu,\nu),(\mu_0,\nu_0)) \le \tilde{\varepsilon},$$

and we may apply (2.12) to $w_1 := w_0$ and to w_2. Further taking into account the first inclusion of (2.13), one arrives at

$$d(z,\Phi(\mu,\nu)) \le d(z,M(w_2) \le \tilde{L}d(w_0,w_2) = 2\tilde{L}\alpha((\mu,\nu),(\mu_0,\nu_0)),$$

which is (2.4) with the same values $L := 2\tilde{L}$ and $\varepsilon := \tilde{\varepsilon}/2$ as for (2.3). □

3. Sensitivity of the optimal value.

3.1. Optimality conditions. In order to analyze the sensitivity of the optimal value function, we need to briefly recall optimality conditions for problem (1.3). From now on we assume that f is continuously differentiable.

We define the set $\mathscr{U}([a,b])$ of functions $u(\cdot)$ satisfying the following conditions:

$$\begin{aligned} &u(\cdot) \text{ is nondecreasing and right continuous;} \\ &u(t) = 0 \;\forall\; t \le a; \\ &u(t) = u(b) \;\forall\, t \ge b. \end{aligned}$$

It is evident that $\mathscr{U}([a,b])$ is a convex cone. The slight difference from the definition of the set $\mathscr{U}$ introduced in [5] is due to the fact that we formulate the stochastic dominance constraint in (1.3) via the $\ge$ inequality.

We introduce the functional $L : \mathbb{R}^n \times \mathscr{U}([a,b]) \times \mathscr{P}(\mathbb{R}^s) \times \mathscr{P}(\mathbb{R}) \to \mathbb{R}$ associated with problem (1.3):

$$L(z,u;\mu,\nu) := f(z) - \int u(g(z,v))\,\mu(dv) + \int u(y)\,\nu(dy). \tag{3.1}$$

As shown in [5], the functional L plays a similar role to that of a Lagrangian of the problem.

THEOREM 3.1. *Assume that the differential uniform dominance condition is satisfied at a local minimum $\hat{z}$ of problem* (1.3). *Then there exists a function $\hat{u} \in \mathscr{U}([a,b])$ such that*

$$-\nabla_z L(\hat{z}, \hat{u}; \mu_0, \nu_0) \in N_Z(\hat{z}), \tag{3.2}$$

$$\int \hat{u}(g(\hat{z}, v))\, \mu_0(dv) = \int \hat{u}(y)\, \nu_0(dy). \tag{3.3}$$

The proof follows the same line of argument as the proof in [5] and is omitted here. It uses the correspondence between a nonnegative measure λ on $[a,b]$ and a function $u \in \mathscr{U}([a,b])$:

$$u(\eta) = \lambda([a,\eta]), \quad \eta \in [a,b]. \tag{3.4}$$

Remark 2. The set $\hat{U}(\hat{z})$ of functions in $\mathscr{U}([a,b])$ satisfying (3.2)–(3.3) for the local minimum $\hat{z}$ is convex, bounded, and weakly* closed in the following sense: if a sequence of functions $u^k \in \hat{U}(\hat{z})$ and $u \in \mathscr{U}([a,b])$ are such that

$$\lim_{k\to\infty} \int_a^b c(\eta)\, du^k(\eta) = \int_a^b c(\eta)\, du(\eta) \quad \forall\, c \in \mathscr{C},$$

then $u \in \hat{U}(\hat{z})$. This follows from [1, Theorem 3.6] and the application of (3.4).

If the function $g(\cdot,\cdot)$ is quasi-concave and μ has an r-concave probability density function, with $r \geq -1/s$, then the feasible set of problem (1.3) is convex (see [16]). Therefore we can formulate the following sufficient conditions of optimality, as in [5].

THEOREM 3.2. *Assume that a point $\hat{z}$ is feasible for problem* (1.3). *Suppose that there exists a function $\hat{u} \in \mathscr{U}([a,b])$ such that conditions* (3.2)–(3.3) *are satisfied. If the function f is convex, the function $g(\cdot,\cdot)$ is quasi-concave, and V has an r-concave probability density function, with $r \geq -1/s$, then $\hat{z}$ is an optimal solution of problem* (1.3).

Let us observe that under the assumptions of Theorem 3.2 the functional (3.1) is, in general, not a quasi-convex function of z.

3.2. Upper bound. Consider the measures

$$\mu_t = \mu_0 + t\gamma,$$
$$\nu_t = \nu_0 + t\sigma,$$

where γ and σ are regular signed measures on $\mathbb{R}^s$ and $\mathbb{R}$, respectively, and $t > 0$. We shall bound the optimal value $\varphi(\mu_t, \nu_t)$ of the perturbed problem

$$\begin{aligned} &\min\ f(z) \\ &\text{s.t. } \mu_t(H(z,\eta)) - \nu_t([\eta,\infty)) \geq 0 \quad \forall \eta \in [a,b], \\ &\qquad z \in Z. \end{aligned} \tag{3.5}$$

Our objective is to develop bounds for the limit of the quotients $\big[\varphi(\mu_t,\nu_t) - \varphi(\mu_0,\nu_0)\big]/t$, when $t \downarrow 0$.

THEOREM 3.3. *Let $\hat{Z}$ be the set of optimal solutions of problem* (1.3). *Assume the following conditions:*

(i) *The differential uniform dominance condition is satisfied at each point $\hat{z} \in \hat{Z}$.*

(ii) $\gamma(H(z,\eta))$ *is continuous with respect to both arguments at* $(\hat{z},\eta)$ *for all* $\eta \in [a,b]$*, is differentiable with respect to* z *in a neighborhood of each* $\hat{z} \in \hat{Z}$ *for every value of* $\eta \in [a,b]$*, and its derivative is jointly continuous with respect to both arguments.*

(iii) $\sigma([\eta,\infty))$ *is a continuous function of* η.

Then

$$\begin{aligned}\limsup_{t\downarrow 0} \frac{1}{t}[\varphi(\mu_t,\nu_t) - \varphi(\mu_0,\nu_0)] \\ \leq \inf_{\hat{z}\in\hat{Z}} \sup_{\hat{u}\in\hat{U}(\hat{z})} \Big\{ \int \hat{u}(g(\hat{z},v))\,\gamma(dv) + \int \hat{u}(y)\,\sigma(dy)\Big\},\end{aligned} \tag{3.6}$$

where $\hat{U}(\hat{z})$ *is the set of functions in* $\mathscr{U}([a,b])$ *satisfying* (3.2)–(3.3) *at the minimum* $\hat{z}$.

Proof. Our result is close in spirit to that of [1, Proposition 4.22], but we work with weaker assumptions by exploiting the structure of the problem.

Fix $\hat{z} \in \hat{Z}$. We shall construct feasible points of the perturbed problem of the form

$$\tilde{z}_t = \hat{z} + th + o(t). \tag{3.7}$$

Define the set

$$\mathscr{A} = \big\{\eta \in [a,b] : \mu_0(H(\hat{z},\eta)) = \nu_0([\eta,\infty))\big\},$$

and let $T_Z(\hat{z})$ denote the tangent cone to Z at $\hat{z}$.

We assume that the direction h in (3.7) is an element of the tangent cone $T_Z(\hat{z})$ and satisfies the infinite system of linear inequalities:

$$\langle \nabla_z \mu_0(H(\hat{z},\eta)), h\rangle + \gamma(H(\hat{z},\eta)) - \sigma([\eta,\infty)) \geq 0 \quad \forall\, \eta \in \mathscr{A}. \tag{3.8}$$

It follows from the uniform dominance condition that there exists $\varepsilon > 0$ such that

$$\langle \nabla_z \mu_0(H(\hat{z},\eta)), z^1 - \hat{z}\rangle > \varepsilon$$

for all $\eta \in \mathscr{A}$. Therefore inequalities (3.8) can be satisfied by choosing $h = \tau(z^1 - \hat{z})$ with a sufficiently large τ.

Let $z_t = \hat{z} + th$. The uniform dominance condition implies that

$$\begin{aligned}\mu_t(H(z_t,\eta)) &= \mu_0(H(z_t,\eta)) + t\gamma(H(z_t,\eta)) \\ &= \mu_0(H(\hat{z},\eta)) + t\langle \nabla_z \mu_0(H(\hat{z},\eta)), h\rangle + t\gamma(H(z_t,\eta)) + o(t,\eta),\end{aligned} \tag{3.9}$$

where $o(t,\eta)/t \to 0$ as $t \to 0$, uniformly over $\eta \in [a,b]$.

We shall estimate the term $\gamma(H(z_t,\eta))$ from below. Choose any $\hat{\eta} \in [a,b]$. By the continuity of $\gamma(H(z,\eta))$ around the point $(\hat{z},\hat{\eta})$, for every $\varepsilon > 0$ there exists $\delta(\varepsilon,\hat{\eta}) > 0$ such that

$$\gamma(H(z,\eta)) \geq \gamma(H(\hat{z},\hat{\eta})) - \varepsilon \tag{3.10}$$

for all (z,η) such that $\|z - \hat{z}\| \leq \delta(\varepsilon,\hat{\eta})$ and $|\eta - \hat{\eta}| \leq \delta(\varepsilon,\hat{\eta})$. For each ε the intervals $|\eta - \hat{\eta}| \leq \delta(\varepsilon,\hat{\eta})$, where $\hat{\eta}$ runs through $[a,b]$, cover $[a,b]$. Choosing a finite subcovering, we conclude that there exists $\delta(\varepsilon) > 0$ such that (3.10) holds true for all z satisfying $\|z - \hat{z}\| \leq \delta(\varepsilon)$ and for all $\eta \in [a,b]$.

Define $r(t) = \inf\{\varepsilon > 0 : \delta(\varepsilon) \geq t\|h\|\}$. Observe that $r(t) \to 0$ as $t \downarrow 0$. It follows from (3.10) that

$$\gamma(H(z_t, \eta)) \geq \gamma(H(\hat{z}, \eta)) - r(t).$$

Substituting this estimate into (3.9), we obtain

$$\mu_t(H(z_t, \eta)) \geq \mu_0(H(\hat{z}, \eta)) + t\langle \nabla_z \mu_0(H(\hat{z}, \eta)), h\rangle + t\gamma(H(\hat{z}, \eta)) + o(t, \eta) - tr(t).$$

Using condition (3.8) and the feasibility of $\hat{z}$, we conclude that

$$\begin{aligned} \mu_t(H(z_t, \eta)) - \nu_t([\eta, \infty)) &= \big[\mu_0(H(\hat{z}, \eta)) - \nu_0([\eta, \infty))\big] \\ &\quad + t\big[\langle \nabla_z \mu_0(H(\hat{z}, \eta)), h\rangle + \gamma(H(\hat{z}, \eta)) - \sigma([\eta, \infty))\big] \\ &\quad + o(t, \eta) - tr(t) \\ &\geq o(t, \eta) - tr(t) \quad \forall\, \eta \in [a, b]. \end{aligned} \tag{3.11}$$

Consequently, the point z_t may violate the constraints of the perturbed problem only by quantities which are infinitely smaller than t. Define the mapping $\Gamma : \mathbb{R}^n \times \mathbb{R} \to \mathscr{C}$ as follows:

$$\Gamma(z, t)(\eta) = \mu_t(H(z, \eta)) - \nu_t([\eta, \infty)), \quad \eta \in [a, b].$$

The system

$$\begin{aligned} \Gamma(z, t) &\in K, \\ z &\in Z, \end{aligned}$$

is stable about $(\hat{z}, 0)$ (see, e.g., [1, Theorem 2.87]). Therefore, for all sufficiently small $t > 0$, we can slightly modify z_t to get a point $\tilde{z}_t$ such that

$$\begin{aligned} \Gamma(\tilde{z}_t, t) &\in K, \\ \tilde{z}_t &\in Z, \\ \|\tilde{z}_t - z_t\| &\leq C\big[\operatorname{dist}(\Gamma(z_t, t), K) + \operatorname{dist}(z_t, Z)\big], \end{aligned}$$

where C is some constant. Using (3.11) and the fact that h is tangent to Z, we obtain that

$$\lim_{t \downarrow 0} \frac{1}{t}\big(\tilde{z}_t - \hat{z}\big) = h.$$

As $\tilde{z}_t$ is feasible,

$$\varphi(\mu_t, \nu_t) \leq f(\tilde{z}_t).$$

Subtracting $\varphi(\mu_0, \nu_0)$, dividing by t, and passing to the limit, we obtain

$$\limsup_{t \downarrow 0} \frac{1}{t}[\varphi(\mu_t, \nu_t) - \varphi(\mu_0, \nu_0)] \leq \limsup_{t \downarrow 0} \frac{1}{t}[f(\tilde{z}_t) - f(\hat{z})] = \langle \nabla f(\hat{z}), h\rangle. \tag{3.12}$$

It follows that the limit on the left-hand side of (3.12) is bounded from above by the optimal value of the problem

$$\begin{aligned} &\min\ \langle \nabla f(\hat{z}), h\rangle \\ &\text{s.t. } \langle \nabla_z \mu_0(H(\hat{z}, \eta)), h\rangle \geq -\gamma(H(\hat{z}, \eta)) + \sigma([\eta, \infty)) \quad \forall\, \eta \in \mathscr{A}, \\ &\quad h \in T_Z(\hat{z}). \end{aligned} \tag{3.13}$$

The optimal value of the linear-conic problem (3.13) is equal to the optimal value of the following dual problem (see, e.g., [1, Theorem 5.106]):

$$\begin{aligned} &\max_{\lambda} \int_a^b \big[-\gamma(H(\hat z,\eta)) + \sigma([\eta,\infty))\big]\,\lambda(d\eta) \\ &\text{s.t. } -\nabla f(\hat z) - \int_a^b \nabla_z \mu_0(H(\hat z,\eta))\,\lambda(d\eta) \in N_Z(\hat z), \\ &\quad \lambda \ge 0. \end{aligned} \tag{3.14}$$

Here λ is a regular measure on $\mathscr{A}$. Moreover, it is sufficient to consider atomic measures λ with at most $n+1$ atoms.

Extending λ to $[a,b]$, associating with it a function $u(\cdot)=\lambda([a,\cdot])$, and changing the order of integration, we obtain the identity

$$\begin{aligned} \int_a^b \gamma(H(\hat z,\eta))\,\lambda(d\eta) &= \int_a^b \int_{v\in H(\hat z,\eta)} \gamma(dv)\,\lambda(d\eta) = \int_a^b \int_{\{v:g(\hat z,v)\ge\eta\}} \gamma(dv)\,\lambda(d\eta) \\ &= \int\int_a^{g(\hat z,v)} \lambda(d\eta)\,\gamma(dv) = \int u(g(\hat z,v))\,\gamma(dv). \end{aligned} \tag{3.15}$$

In a similar way we transform other integrals in (3.14) to obtain the following form of the dual problem:

$$\begin{aligned} &\max_{u(\cdot)} -\int u(g(\hat z,v))\,\gamma(dv) + \int u(y)\,\sigma(dy) \\ &\text{s.t. } -\nabla f(\hat z) - \nabla_z \int u(g(\hat z,v))\,\mu_0(dv) \in N_Z(\hat z), \\ &\quad u(\cdot) \in \mathscr{U}([a,b]), \\ &\quad u(\cdot) \text{ satisfies (3.3)}. \end{aligned} \tag{3.16}$$

We observe that the feasible set of this problem is the set $\hat U$ given by (3.2)–(3.3). Now we continue the estimate (3.12) as follows:

$$\limsup_{t\downarrow 0} \frac{1}{t}[\varphi(\mu_t,\nu_t)-\varphi(\mu_0,\nu_0)] \le \sup_{\hat u\in\hat U(\hat z)} \Big\{ -\int \hat u(g(\hat z,v))\,\gamma(dv) + \int \hat u(y)\,\sigma(dy)\Big\}.$$

As $\hat z\in\hat Z$ was arbitrary, we conclude that

$$\limsup_{t\downarrow 0} \frac{1}{t}[\varphi(\mu_t,\nu_t)-\varphi(\mu_0,\nu_0)] \le \inf_{\hat z\in\hat Z} \sup_{\hat u\in\hat U(\hat z)} \Big\{ -\int \hat u(g(\hat z,v))\,\gamma(dv) + \int \hat u(y)\,\sigma(dy)\Big\},$$

which was what we set out to prove. □

As discussed in the proof, it is sufficient to consider the supremum over piecewise constant functions $\hat u\in\hat U$ having at most $n+1$ jumps.

COROLLARY 3.4. *Suppose that $\mu_1=\mu_0+\gamma$ is a nonnegative measure and let $\nu_1=\nu_0+\sigma$. Then*

$$\limsup_{t\downarrow 0} \frac{1}{t}[\varphi(\mu_t,\nu_t)-\varphi(\mu_0,\nu_0)] \le \inf_{\hat z\in\hat Z} \sup_{\hat u\in\hat U(\hat z)} \int \hat u(y)\,\nu_1(dy).$$

Proof. We can rewrite the estimate (3.6) as follows:

$$\limsup_{t\downarrow 0}\frac{1}{t}[\varphi(\mu_t,\nu_t)-\varphi(\mu_0,\nu_0)]\le \inf_{\hat z\in\hat Z}\sup_{\hat u\in\hat U(\hat z)}\Big\{\int \hat u(g(\hat z,v))\,\mu_0(dv) - \int \hat u(g(\hat z,v))\,\mu_1(dv)+\int \hat u(y)\,\nu_1(dy)-\int \hat u(y)\,\nu_0(dy)\Big\}.$$

As the function $\hat u(\cdot)$ is nonnegative, we can skip the second term on the right-hand side. Using the complementarity condition (3.3), we get the required inequality. ∎

3.3. Lower bound. Let us start from the following observation.

LEMMA 3.5. *Consider any measures $\mu\in\mathscr{P}(\mathbb{R}^s)$ and $\nu\in\mathscr{P}(\mathbb{R})$ and a point $z\in Z$ such that*

$$\mu(H(z,\eta))\ge\nu([\eta,\infty)),\quad \eta\in[a,b]. \tag{3.17}$$

Then for every $u\in\mathscr{U}([a,b])$ we have

$$\int u(g(z,v))\,\mu(dv)\ge\int u(y)\,\nu(dy).$$

Proof. For a function $u\in\mathscr{U}([a,b])$ we define a nonnegative measure λ on $[a,b]$ by the relation $u(\cdot)=\lambda([a,\cdot])$. Integrating the inequalities (3.17), changing the order of integration as in (3.15), we obtain the postulated inequality. ∎

Suppose that $u\in\mathscr{U}([a,b])$. Employing Lemma 3.5, we obtain

$$\varphi(\mu,\nu)\ge\inf_{z\in Z}\Big\{f(z)-\int u(g(z,v))\,\mu(dv)\Big\}+\int u(y)\,\nu(dy).$$

We get the general dual lower bound

$$\varphi(\mu,\nu)\ge\sup_{u\in\mathrm{U}([a,b])}\inf_{z\in Z}\Big\{f(z)-\int u(g(z,v))\,\mu(dv)+\int u(y)\,\nu(dy)\Big\}.$$

In order to obtain tighter bounds we consider the perturbations in directions

$$\mu_t=\mu_0+t\gamma,$$
$$\nu_t=\nu_0+t\sigma.$$

We shall develop lower bounds for the differential quotients $\big[\varphi(\mu_t,\nu_t)-\varphi(\mu_0,\nu_0)\big]/t$ when $t\downarrow 0$. Our result is similar to the standard approach employed in [1, Theorem 4.24]. However, it is unrealistic to assume that the Lagrangian is convex (even under the assumptions of Theorem 3.2), and that is why we need Lipschitz stability of optimal solutions.

THEOREM 3.6. *Assume that $\hat z$ is the unique optimal solution of problem* (1.3) *and that the differential uniform dominance condition is satisfied at $\hat z$. Furthermore, assume that the perturbed problems* (3.5) *have solutions z_t such that $\|z_t-\hat z\|\le Lt$ with some constant L. Let $\hat U$ be the set of functions $\hat u(\cdot)$ satisfying the optimality conditions* (3.2)–(3.3). *Then*

$$\liminf_{t\to 0}\frac{1}{t}\big[\varphi(\mu_t,\nu_t)-\varphi(\mu_0,\nu_0)\big] \ge\sup_{\hat u\in\hat U}\Big\{-\int\hat u\big(g(\hat z,v)\big)\,\gamma(dv)+\int\hat u(y)\,\sigma(dy)\Big\}. \tag{3.18}$$

Proof. Consider problem (2.1) and its Lagrangian

$$\Lambda(z,\lambda;\mu,\nu) = f(z) - \int_a^b \big[\mu(H(z,\eta)) - \nu([\eta,\infty))\big]\,\lambda(d\eta),$$

where λ is a nonnegative regular measure on $[a,b]$. Fix $\mu = \mu_0$ and $\nu = \nu_0$. As in [5], owing to the differential uniform dominance condition at $\hat{z}$, there exists a measure $\hat{\lambda} \geq 0$ such that

$$\langle \nabla_z \Lambda(\hat{z},\hat{\lambda};\mu_0,\nu_0), z - \hat{z}\rangle \geq 0 \quad \forall\, z \in Z$$

and

$$\int_a^b \big[\mu_0(H(\hat{z},\eta)) - \nu_0([\eta,\infty))\big]\,\hat{\lambda}(d\eta) = 0.$$

Using the nonnegativity of $\hat{\lambda}$ and the complementarity condition, we can write the chain of inequalities

$$\begin{aligned}
&\varphi(\mu_t,\nu_t) - \varphi(\mu_0,\nu_0) \geq f(z_t) - \int_a^b \big[\mu_t(H(z_t,\eta)) - \nu_t([\eta,\infty))\big]\,\hat{\lambda}(d\eta) - f(\hat{z})\\
&\geq f(z_t) - \int_a^b \big[\mu_t(H(z_t,\eta)) - \nu_t([\eta,\infty))\big]\,\hat{\lambda}(d\eta)\\
&\quad - f(\hat{z}) + \int_a^b \big[\mu_0(H(\hat{z},\eta)) - \nu_0([\eta,\infty))\big]\,\hat{\lambda}(d\eta)\\
&= \Lambda(z_t,\hat{\lambda};\mu_0,\nu_0) - \Lambda(\hat{z},\hat{\lambda};\mu_0,\nu_0) - t\int_a^b \big[\gamma(H(z_t,\eta)) - \sigma([\eta,\infty))\big]\,\hat{\lambda}(d\eta)\\
&= \langle \nabla_z \Lambda(\hat{z},\hat{\lambda};\mu_0,\nu_0), z_t - \hat{z}\rangle + o(z_t,\hat{z}) - t\int_a^b \big[\gamma(H(z_t,\eta)) - \sigma([\eta,\infty))\big]\,\hat{\lambda}(d\eta),
\end{aligned}$$

where $o(z_t,\hat{z})/\|z_t - \hat{z}\| \to 0$ as $t \to 0$. By the optimality condition and by the assumption that $\|z_t - \hat{z}\| \leq Lt$, we conclude that

$$\liminf_{t\to 0} \frac{1}{t}\big[\varphi(\mu_t,\nu_t) - \varphi(\mu_0,\nu_0)\big] \geq -\int_a^b \big[\gamma(H(\hat{z},\eta)) - \sigma([\eta,\infty))\big]\,\hat{\lambda}(d\eta). \tag{3.19}$$

Now we use the correspondence between a nonnegative measure $\hat{\lambda}$ on $[a,b]$ and a function $\hat{u} \in \mathscr{U}([a,b])$ defined as follows:

$$\hat{u}(\eta) = \hat{\lambda}([a,\eta]), \quad \eta \in [a,b].$$

Changing the order of integration, as in (3.15), we obtain

$$\int_a^b \gamma(H(\hat{z},\eta))\,\hat{\lambda}(d\eta) = \int \hat{u}(g(\hat{z},v))\,\gamma(dv),$$

$$\int_a^b \sigma([\eta,\infty))\,\hat{\lambda}(d\eta) = \int \hat{u}(y))\,\sigma(y).$$

Using the last two equations, we can rewrite (3.19) as follows:

$$\liminf_{t\to 0} \frac{1}{t}\big[\varphi(\mu_t,\nu_t) - \varphi(\mu_0,\nu_0)\big] \geq -\int \hat{u}(g(\hat{z},v))\,\gamma(dv) + \int \hat{u}(y))\,\sigma(y).$$

As $\hat{\lambda}$ was an arbitrary optimal multiplier, we can take the supremum of the right-hand side over $\hat{u} \in \hat{U}$ to obtain (3.18). □

We point out that the assumption of Lipschitz stability of optimal solutions, $\|z_t - \hat{z}\| \leq Lt$, has an implicit character. In general stability studies, its fulfillment involves appropriate second order sufficient optimality conditions. In our case, due to the nature of the probability distribution functions, such an analysis is very difficult.

Finally, we obtain the directional differentiability result.

COROLLARY 3.7. *Under the assumptions of Theorems* 3.3 *and* 3.6 *the optimal value function is directionally differentiable in the direction* (γ, σ) *with the derivative*

$$\varphi'((\mu_0, \nu_0); (\gamma, \sigma)) = \sup_{\hat{u} \in \hat{U}} \Big\{ -\int \hat{u}\big(g(\hat{z}, v)\big)\, \gamma(dv) + \int \hat{u}(y)\, \sigma(dy) \Big\}.$$

The assumptions simplify considerably if we allow perturbations of the benchmark distribution only.

Acknowledgment. The authors are very grateful to Diethard Klatte and Alexander Shapiro for their insightful remarks and suggestions.

EFFICIENT LINE SEARCH METHODS FOR CONVEX FUNCTIONS*

EDGAR DEN BOEF† AND DICK DEN HERTOG‡

Abstract. In this paper we propose two new line search methods for convex functions. These new methods exploit the convexity property of the function, contrary to existing methods. The first method is an improved version of the golden section method. For the second method it is proven that after two evaluations the objective gap is at least halved. The practical efficiency of the methods is shown by applying our methods to a real-life bus and buffer size optimization problem and to several classes of convex functions.

Key words. convex optimization, golden section, line search

AMS subject classifications. 65K05, 90C25, 90C56

DOI. 10.1137/04061115X

1. Introduction.

Line searching is an important step for many optimization methods. In practice both exact and approximate line search methods are used. Well-known line search methods are quadratic and cubic interpolation, the golden section method, and backtracking, often combined with clever stopping criteria. For a general overview on line searches we refer to the books by Gill, Murray, and Wright [11], Hiriart-Urruty and Lemarechal [13], and Bazaraa, Sherali, and Shetty [3]. Line search is also an important issue in interior point methods for both linear programming [19] and convex programming [5], [9]. For a good survey on line search techniques within trust-region methods, see Conn, Gould, and Toint [6]. Recent papers on line search techniques in general or on a specific optimization method, like [1], [2], [4], [7], [14], [15], [16], [17], [18], [20], and [21], show that developing and analyzing efficient line search techniques is still an important issue.

The aim in such line search methods is to find a good or a (near) optimal solution w.r.t. an objective or merit function, along a given direction using a minimal number of function evaluations. Especially in the case of black-box functions, where often time-consuming simulation runs, i.e., function evaluations, have to be done, it is desirable to perform as few function evaluations as possible.

Now suppose the (black-box) function is known to be convex (or concave). Note that in practice it happens often that this information is available. For an example see the in-home network problem in section 4. If the function is convex, it has exactly one optimum[1] on a closed domain. This fact is used by the above mentioned methods. However, convexity of a function gives more information. For example, if a function is convex, then using the performed function evaluations, an upper and lower bound can be constructed for the function values. This information can be used to obtain better information on the location of the optimum.

[1]In this paper we use the term "optimum" to refer to both the optimal value and the optimal solution; the exact meaning should be clear from the context.

In this paper we will show how this convexity information can be used. We will show that existing methods propose new candidates which may a priori be detected as not optimal or even as nonimproving (w.r.t. the current best point) by using the information of the previous iterations and the convexity property. This means that methods for convex problems that use line searches can be easily improved by adding this simple check for nonimprovement, thereby avoiding unnecessary evaluations.

We will also describe two new methods: the *improved golden section method* and the *triangle section method*. We will show that the improved golden section method is theoretically at least as good as the regular golden section method. For the triangle section method we will show that the objective gap or range of uncertainty, i.e., the difference between the current best known objective value and the lower bound for the optimal value, is at least halved after two function evaluations. It is significant that this result is related to the objective of the optimization, namely, the function values, in contrast to the convergence result of the golden section method, which is related to the function domain values. We also describe the application of our methods to a real-life bus and buffer size optimization problem and to several classes of convex functions. Note that in practice it is much better to have a guarantee for the reduction factor for the function value gap than for the domain gap. We compare the performance of our methods with the performance of the golden section method.

During the revision of this paper we discovered a recent paper written by Gúerin, Marcotte, and Savard [12], in which they describe a method to approximate a univariate convex function. Several elements in their analysis resemble our analysis, although they use derivative information. It is straightforward to extend all our methods for the case in which you also get derivative (or subdifferential) information. In fact then the improvement w.r.t. the golden section is even better. Note, however, that there are many cases in which you do not get derivative information; see, e.g., our practical example in section 4.

In section 2 we show how convexity of a function can be used to reduce the interval in which an optimal solution can be found. For a concave function similar methods can be used. We continue with deriving performance guarantees on the interval reduction in section 3. In section 4 we describe an application involving bus and buffer size optimization in which a nondifferentiable function with computationally expensive function evaluations has to be optimized. We describe experimental results for this application and for other classes of convex functions in section 5. Finally, in section 6 we give our conclusions.

2. Interval reduction using convexity. In this section we describe how to use the convexity of a function to obtain upper and lower bounds for the function values. We show how they can be used to reduce the interval in the function domain in which the minimum can be found, which is called the *interval of uncertainty*. For concave functions a similar method can be used.

Let $f(x)$ be a continuous, univariate, convex function on a closed domain D. Assume that for a given set of points $\mathcal{X} = \{x_1, \ldots, x_n\}$ in D the function values of f are known.

Figure 1(a) gives an example of a convex function f of which six function evaluations are known. As f is convex, $\alpha f(x_i) + (1-\alpha) f(x_j) \geq f(\alpha x_i + (1-\alpha) x_j)$ with $\alpha \in [0,1]$ for each $x_i, x_j \in \mathcal{X}$. Using this property we obtain the piecewise-linear upper bound f^{u} of f with $f^{\mathrm{u}}(x) \geq f(x)$ for all $x \in D$ and $f^{\mathrm{u}}(x) = f(x)$ if $x \in \mathcal{X}$; cf. Figure 1(b). Now we consider the line segments BC and DE and extend them until they intersect at point K, as shown in Figure 1(c). Then, the lines CK and

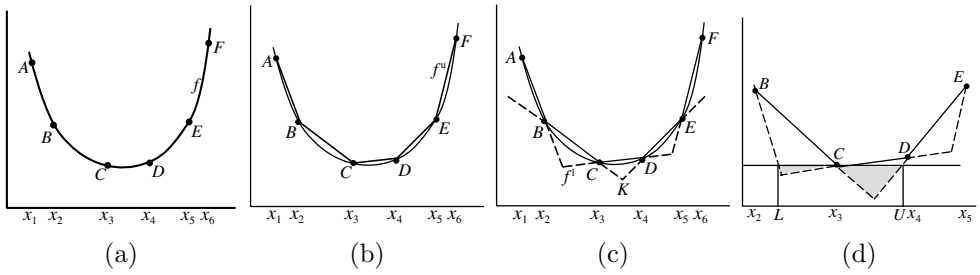

FIG. 1. (a) *Example of a convex function f with six function evaluations.* (b) *A piecewise-linear upper bound based on the convexity property.* (c) *A piecewise-linear lower bound based on the convexity property.* (d) *(Magnified in comparison with* (a)–(c)*.) The optimum lies somewhere in the gray areas, the areas of uncertainty. The interval of uncertainty based on the convexity property is given by $[L, U]$.*

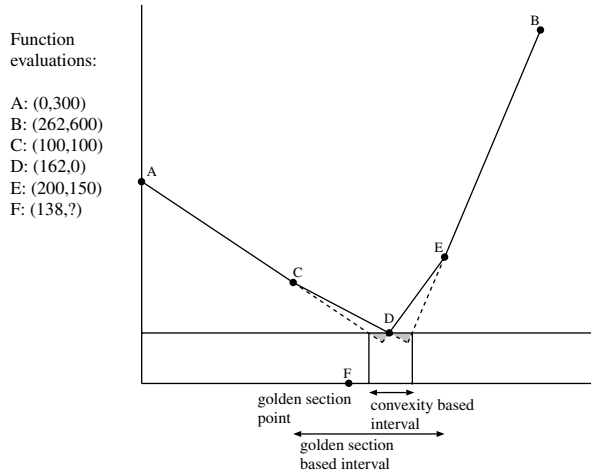

FIG. 2. *Example where the golden section method chooses a point outside the interval of uncertainty for function evaluation. Five function evaluations have already been made following the sequence $A, \ldots, E$. The sixth point for evaluation proposed by golden section is point F. However, the interval of uncertainty comprising the two small gray triangles is located to the right of F.*

KD give a lower bound for the function f between x_3 and x_4. This can be done for any four consecutive points, resulting in the lower bound f^{l} on f given in Figure 1(c) by the dashed line. Now let $x_k \in \mathcal{X}$ be a point with the lowest determined function evaluation, i.e., $f(x_k) \leq f(x)$ for all $x \in \mathcal{X}$. Then the minimum function value of f must lie between $f(x_k)$ and the minimum of $f^{\mathrm{l}}(x)$. The possible locations of the minimum are given in Figure 1(d) by the gray areas, the *areas of uncertainty*. The interval of uncertainty is $[L, U]$.

This shows how the interval of uncertainty can be decreased using the convexity property. The next step in finding the minimum of f is to choose a point for evaluation. Naturally, this should be a point in the interval of uncertainty. Taking one of the existing methods to choose a point, however, does not always give a point in the interval of uncertainty. Figures 2, 3, and 4 show three examples where the golden section method, unit search, and quadratic interpolation, respectively, would evaluate

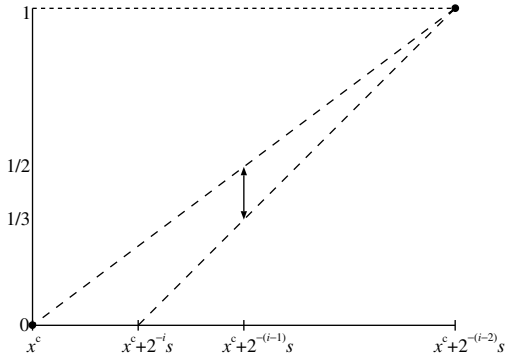

FIG. 3. *Example where unit search chooses a point outside the interval of uncertainty for function evaluation. The known function evaluations are* $f(x^c) = 0$ *and* $f(x^c + 2^{-(i-2)}s) = 1$. *Furthermore, we know* $f(x^c+2^{-(i-1)}s)$. *For the next iteration, unit search would evaluate* $x^c+2^{-i}s$. *However, if* $\frac{1}{3} \leq f(x^c + 2^{-(i-1)}s) \leq \frac{1}{2}$ *holds, then using convexity we know that* $f(x^c + 2^{-i}s) \geq 0$ *and therefore will not lead to a new minimum. Unit search can be improved by choosing each time the point in the middle of the interval of uncertainty based on convexity.*

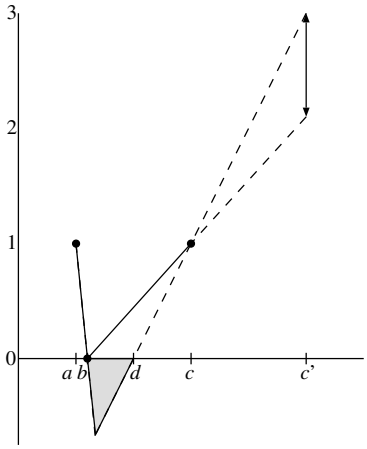

FIG. 4. *Example where quadratic interpolation chooses a point outside the interval of uncertainty for function evaluation. The points with known function evaluations are* $a = 0$, $b = \frac{1}{10}$, *and* $c = 1$, *with* $f(a) = f(c) = 1$ *and* $f(b) = 0$. *Furthermore, we know* $f(c')$. *Quadratic interpolation would take* $d = \frac{1}{2}$ *as the point for a new function evaluation. However, if* $2\frac{1}{9} \leq f(c') \leq 3$ *holds, then using convexity it is clear that* $f(d) \geq 0$ *and therefore will not lead to a new minimum.*

the function at a point that is outside the interval of uncertainty. In section 3 we discuss some strategies for choosing a new point. Finally, the interval of uncertainty may even be further decreased if, for an evaluated point, the gradient of the function is known. However, we leave this for future research.

3. Function evaluation strategies. In this section we discuss two strategies for choosing a new point that use the convexity property. In section 3.1 we show how to choose a new point for evaluation when the focus lies on the reduction of the interval of uncertainty. In section 3.2 we show how to choose a new point such that

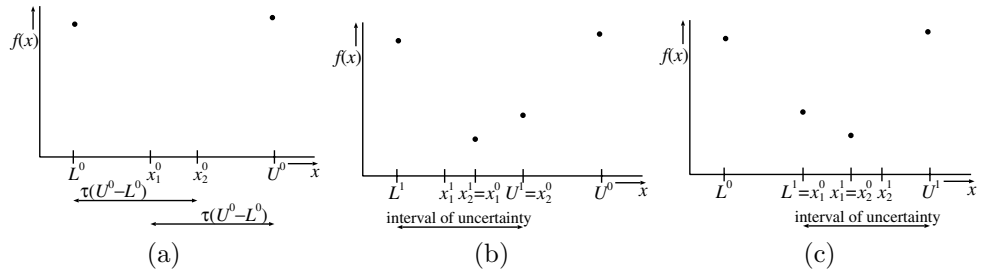

FIG. 5. *Starting the golden section method.* (a) *First two points,* x_1^0 *and* x_2^0*, are chosen in the interior of the starting interval of uncertainty,* $[L^0, U^0]$*. Next, the function is evaluated at these points, and depending on which one is lower, the interval of uncertainty is adjusted; see* (b) *and* (c).

the *range of uncertainty*, i.e., the interval consisting of all possible function values for the minimum, is at least halved for each two new function evaluations. Finally, in section 3.3 we shortly describe how known piecewise linearity of a function can be used to terminate the search procedure.

3.1. Function domain reduction. For the reduction of the interval of uncertainty in the function domain we have taken the golden section method and improved it with the reduction that follows from the convexity property, as described in the previous section. The golden section method chooses new points for function evaluation in such a way that the interval of uncertainty can be decreased by a constant factor $\tau = (\sqrt{5}-1)/2$ in each iteration. Figure 5 shows an example. Let $[L^0, U^0]$ be the initial interval of uncertainty. Then golden section method chooses the following two interior points x_1^0 and x_2^0 for evaluation: $x_1^0 = U^0 - \tau(U^0 - L^0)$ and $x_2^0 = L^0 + \tau(U^0 - L^0)$. Now, suppose x_1^0 has the lowest function evaluation. Then the new interval of uncertainty $[L^1, U^1]$ is equal to $[L^0, x_2^0]$. Furthermore, the new interior points to be evaluated are $x_1^1 = U^1 - \tau(U^1 - L^1)$ and $x_2^1 = L^1 + \tau(U^1 - L^1)$. However, as the interior points are chosen using the golden section factor τ, it follows that $x_2^1 = x_1^0$. Therefore, only x_1^1 has to be evaluated for the next step. Similarly, if x_2^0 has the lowest function evaluation, then $L^1 = x_1^0$ and $x_1^1 = x_2^0$.

The improved golden section method, shown in Algorithm 1, now works as follows. It starts in the same way as the regular golden section method. Let $[L, U]$ be the interval of uncertainty with two interior points x_1 and x_2 such that $x_2 - L = U - x_1 = \tau(U - L)$. We first consider the case in which the minimum function evaluation occurs at one of the interval boundaries, e.g., at L, so $f(L) = \min\{f(L), f(x_1), f(x_2), f(U)\}$. Then the new interval of uncertainty according to the golden section method is given by $[L, x_1]$. However, using the convexity property we can obtain a smaller interval of uncertainty $[L, U']$ with $U' \leq x_1$ for which two new interior points are selected. If $f(U) = \min\{f(L), f(x_1), f(x_2), f(U)\}$, then similarly a new interval $[L', U]$ can be obtained. Note that the minimum function evaluation can occur only at L or U if it has not occurred yet at an internal point of the interval of uncertainty. Furthermore, by evaluating the function f first at the boundaries L and U and then at the interior point closest to the boundary with the lowest function value, e.g., x_1 if $f(L) < f(U)$, the function does not need to be evaluated at the other interior point if the lowest function value is not improved by the new evaluation; see Figure 6 for an example and Algorithm 2 for a description of the algorithm loop during initialization.

Now we assume that x_1 has the lowest function value, i.e., $f(x_1) \leq f(x_2)$; if $f(x_2) < f(x_1)$ holds, then we can follow a strategy analogous to what we describe

Algorithm 1. The improved golden section method.

Input: Interval of uncertainty $[L, U]$, stop criterion ε,
Output: Interval of uncertainty $[L, U]$ with $U - L < \varepsilon$,
Parameter: Golden section $\tau = \frac{\sqrt{5}-1}{2}$.

Initialization:
Perform initialization loop of Algorithm 2 to obtain a new interval $[L, U]$ with interior point x;
Loop:
while $U - L > \varepsilon$ **do**
if $x = U - \tau(U - L)$ **then**
$x_1 := x$, $x_2 := L + \tau(U - L)$;
Determine $f(x_2)$;
else $(x = L + \tau(U - L))$
$x_1 := U - \tau(U - L)$, $x_2 := x$;
Determine $f(x_1)$;
endif
Determine new interval of uncertainty $[L', U']$ using convexity property;
Stretch $[L', U']$ to $[\tilde{L}, \tilde{U}]$ according to (1) and (2) to maintain golden section property;
Take as new interval of uncertainty $[L, U] := [\tilde{L}, \tilde{U}]$;
If $x_1 \in (L, U)$, then $x := x_1$, else if $x_2 \in (L, U)$, then $x := x_2$;
endwhile

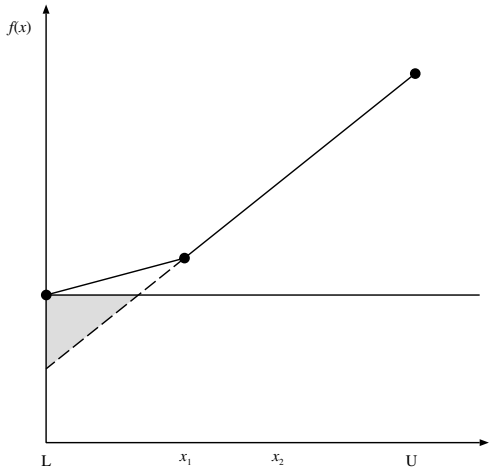

FIG. 6. *Initialization of improved golden section method where the minimum still lies at L after evaluation at x_1. As x_2 lies outside the new interval of uncertainty, it does not need to be evaluated anymore.*

here. The new interval of uncertainty using the golden section method is now given by $[L, x_2]$. Using the convexity property we can obtain a smaller interval of uncertainty $[L', U']$ for which $L' \geq L$ and $U' \leq x_2$ holds. For now we assume that x_1 is an interior point of $[L', U']$; the possibility that x_1 is not an interior point is handled later in this section.

Algorithm 2. Loop at initialization of the improved golden section method to obtain the lowest function evaluation at an interior point of the interval of uncertainty.

Input: Interval of uncertainty $[L, U]$, stop criterion ε,
Output: Interval of uncertainty $[L, U]$ with minimum at interior point x or $U - L < \varepsilon$,
Parameter: Golden section $\tau = \frac{\sqrt{5}-1}{2}$.

Initialization:
Determine $f(L)$ and $f(U)$;
Loop:
repeat
if $f(L) < f(U)$ **then**
$x := U - \tau(U - L)$;
else
$x := L + \tau(U - L)$;
Determine $f(x)$;
Determine new interval of uncertainty $[L, U]$ using convexity property;
until $U - L < \varepsilon$ or $f(x) \leq f(L)$ and $f(x) \leq f(U)$;

The golden section method would choose a new point $x_3 = x_2 - \tau(x_2 - L)$ so that $x_2 - x_3 = x_1 - L$. However, if we replace $[L, x_2]$ by $[L', U']$ and then choose $x_3 = U' - \tau(U' - L')$, $U' - x_3$ is generally not equal to $x_1 - L'$, meaning that the two interior points x_1 and x_3 do not satisfy the golden section property w.r.t. the interval of uncertainty $[L', U']$. Therefore, we will stretch the interval $[L', U']$ to a new interval $[\tilde{L}, \tilde{U}]$ such that the golden section property can be maintained for the new point to be evaluated. We distinguish four possibilities for this:

$$\begin{array}{ll} \text{(a)} & x_1 \leq U' - \tau(U' - L'), \\ \text{(b)} & U' - \tau(U' - L') < x_1 < \frac{1}{2}(U' + L'), \\ \text{(c)} & \frac{1}{2}(U' + L') \leq x_1 < L' + \tau(U' - L'), \\ \text{(d)} & x_1 \geq L' + \tau(U' - L'). \end{array} \tag{1}$$

Figure 7 shows an example of these four possibilities. The corresponding stretched intervals are the following:

$$\begin{array}{lll} \text{(a)} & \tilde{L} = U' - \frac{1}{\tau}(U' - x_1), & \tilde{U} = U', \\ \text{(b)} & \tilde{L} = L', & \tilde{U} = \frac{1}{1-\tau}(x_1 - \tau L'), \\ \text{(c)} & \tilde{L} = \frac{1}{1-\tau}(x_1 - \tau U'), & \tilde{U} = U', \\ \text{(d)} & \tilde{L} = L', & \tilde{U} = L' + \frac{1}{\tau}(x_1 - L'). \end{array} \tag{2}$$

The next lemma states that the obtained stretched interval is not larger than the interval of uncertainty obtained with the regular golden section method.

LEMMA 1. *The stretched interval, $[\tilde{L}, \tilde{U}]$, is not larger than the interval of uncertainty of the regular golden section method, $[L, x_2]$, i.e.,*

$$\tilde{U} - \tilde{L} \leq x_2 - L \, .$$

Proof. For (a),(c), and (d) we prove that $\tilde{U} - \tilde{L} \leq x_2 - L$ holds by showing that $\tilde{L} \geq L$ and $\tilde{U} \leq x_2$. For (b) it is possible that $\tilde{U} > x_2$. In the following derivations we use the fact that $\frac{1-\tau}{\tau} = \tau$.

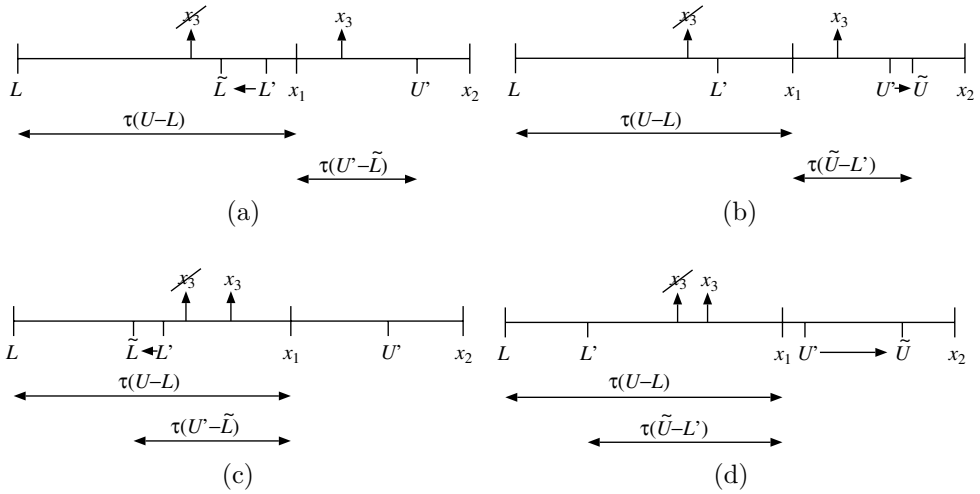

FIG. 7. *Stretching the interval of uncertainty obtained with the convexity property such that the golden section property is maintained for the new function evaluation. The four figures correspond to the four different possibilities.*

(a) As $\tilde{U} = U'$ it follows that $\tilde{U} \leq x_2$. For $\tilde{L}$ we can derive

$$\begin{aligned}
\tilde{L} &= U' - \frac{1}{\tau}(U' - x_1) \\
&= \left(1 - \frac{1}{\tau}\right) U' + \frac{1}{\tau}(L + \tau(x_2 - L)) \\
&= x_2 - \frac{1-\tau}{\tau}(U' - L) \\
&= x_2 - \tau(U' - L) \\
&\geq x_2 - \tau(x_2 - L) \\
&> x_2 - (x_2 - L) \\
&= L.
\end{aligned}$$

(b) From $x_1 \leq \frac{1}{2}(L' + U')$ it follows that $\frac{1}{2}(x_1 - L') \leq \frac{1}{2}(U' - x_1)$, and therefore $x_1 - L' \leq U' - x_1 \leq x_2 - x_1$. We can now make the following derivation:

$$\begin{aligned}
\tilde{U} - \tilde{L} &= \frac{x_1 - \tau L'}{1-\tau} - L' \\
&= \frac{x_1 - L'}{1-\tau} \\
&\leq \frac{x_2 - x_1}{1-\tau} \\
&= \frac{x_2 - (L + \tau(x_2 - L))}{1-\tau} \\
&= x_2 - L.
\end{aligned}$$

(c) As $\tilde{U} = U'$ it follows that $\tilde{U} \leq x_2$. For $\tilde{L}$ we can derive

$$\begin{aligned}\tilde{L} &= \frac{1}{1-\tau}(x_1 - \tau U') \\ &= \frac{1}{1-\tau}(L + \tau(x_2 - L)) - \frac{\tau}{1-\tau}U' \\ &= L + \frac{1}{\tau}(x_2 - U') \\ &\geq L.\end{aligned}$$

(d) As $\tilde{L} = L'$ it follows that $\tilde{L} \geq L$. For $\tilde{U}$ we can derive

$$\begin{aligned}\tilde{U} &= L' + \frac{1}{\tau}(x_1 - L') \\ &= \left(1 - \frac{1}{\tau}\right) L' + \frac{1}{\tau}(L + \tau(x_2 - L)) \\ &= x_2 - \left(\frac{1-\tau}{\tau}\right)(L' - L) \\ &= x_2 - \tau(L' - L) \\ &\leq x_2. \qquad \square\end{aligned}$$

This leads to the following strategy for choosing a new point for evaluation.

Improved golden section strategy, $f(x_1) \leq f(x_2)$. Determine the stretched interval $[\tilde{L}, \tilde{U}]$ as described above. Choose the new point x_3 for function evaluation as follows for the four previously distinguished possibilities:

(a) $x_1 \leq U' - \tau(U' - L')$, $\quad x_3 = \tilde{L} + \tau(\tilde{U} - \tilde{L}) = U' - \tau(U' - x_1)$.
(b) $U' - \tau(U' - L') < x_1 < \frac{1}{2}(L' + U')$, $\quad x_3 = \tilde{L} + \tau(\tilde{U} - \tilde{L}) = \frac{1}{\tau}x_1 - \tau L'$.
(c) $\frac{1}{2}(L' + U') \leq x_1 < L' + \tau(U' - L')$, $\quad x_3 = \tilde{U} - \tau(\tilde{U} - \tilde{L}) = \frac{1}{\tau}x_1 - \tau U'$.
(d) $x_1 \geq L' + \tau(U' - L')$, $\quad x_3 = \tilde{U} - \tau(\tilde{U} - \tilde{L}) = L' + \tau(x_1 - L')$.

In the following theorem we show that the improved golden section strategy performs at least as well as the regular golden section method, while ensuring that the new point chosen for function evaluation lies in the interval of uncertainty.

THEOREM 1. *Let $[L, U]$ be the interval of uncertainty, and let $x_1, x_2 \in [L, U]$ such that $U - x_1 = x_2 - L = \tau(U - L)$, i.e., x_1 and x_2 satisfy the golden section property. Without loss of generality (w.l.o.g.) assume that $f(x_1) \leq f(x_2)$. Then the following hold:*

(a) *The stretched interval of uncertainty $[\tilde{L}, \tilde{U}]$ obtained by the improved golden section method is at least a factor τ smaller than the starting interval of uncertainty $[L, U]$, i.e.,*

$$\tilde{U} - \tilde{L} \leq \tau(U - L)\ .$$

(b) *Let x_3 be the new point for function evaluation chosen according to the improved golden section strategy. Then, x_3 lies in the interval of uncertainty, i.e.,*

$$x_3 \in [L', U']\ .$$

Proof. (a) Using the golden section method, the interval of uncertainty $[L, U]$ with function evaluations at $x_1 = U - \tau(U - L)$ and $x_2 = L + \tau(U - L)$ reduces to

interval $[L, x_2]$ of size $\tau(U - L)$. The new point for function evaluation x_3 is then chosen such that the golden section property is maintained, i.e., $x_3 = x_2 - \tau(x_2 - L)$.

Using the improved golden section strategy, the new point for function evaluation is chosen to be either $x_3 = \tilde{U} - \tau(\tilde{U} - \tilde{L})$ or $x_3 = \tilde{L} + \tau(\tilde{U} - \tilde{L})$. Expressing the other internal point x_1 in $\tilde{L}$ and $\tilde{U}$ by rewriting the expressions for $\tilde{L}$ and $\tilde{U}$ given in (1) and (2) gives $x_1 = \tilde{L} + \tau(\tilde{U} - \tilde{L})$ for (c) and (d) and $x_1 = \tilde{U} - \tau(\tilde{U} - \tilde{L})$ for (a) and (b). So for the improved golden section strategy, the golden section property is maintained for the interval $[\tilde{L}, \tilde{U}]$. Lemma 1 states that $\tilde{U} - \tilde{L} \leq x_2 - L$ and thus $\tilde{U} - \tilde{L} \leq \tau(U - L)$. Therefore, the starting interval of uncertainty is reduced by at least a factor of τ. Furthermore, as the new interval of uncertainty has the golden section property, the same reduction factor is guaranteed for the following function evaluations.

(b) Now we show that $x_3 \in [L', U']$. For (a), $x_3 = U' - \tau(U' - x_1)$, so $x_3 < U'$ is obvious. Furthermore, using $\tau < 1$ and $x_1 > L'$ it follows that $x_3 > L'$. Likewise, for (d) $x_3 \in [L', U']$ holds. For (b) we can make the following derivations:

$$\begin{aligned} x_3 &= \frac{1}{\tau}x_1 - \tau L' \\ &\leq \frac{L' + U'}{2\tau} - \tau L' \\ &= \frac{U'}{\tau} - \frac{(U' - L')}{2\tau} - \tau U' + \tau(U' - L') \\ &= U' - \frac{1 - 2\tau^2}{2\tau}(U' - L') \\ &< U', \end{aligned}$$

$$\begin{aligned} x_3 &= \frac{1}{\tau}x_1 - \tau L' \\ &> \frac{1}{\tau}(U' - \tau(U' - L')) - \tau L' \\ &= \frac{1 - \tau}{\tau}U' + (1 - \tau)L' \\ &= \tau U' + (1 - \tau)L' \\ &> L'. \end{aligned}$$

In a symmetrical manner it can be shown for (c) that $x_3 \in [L', U']$. ∎

For completeness, we give the formula for the new point x_3 for evaluation in case $f(x_2) < f(x_1)$.

Improved golden section strategy, $f(x_2) < f(x_1)$. Determine the stretched interval $[\tilde{L}, \tilde{U}]$. Choose the new point x_3 for function evaluation as follows:

(a) $x_2 \geq L' + \tau(U' - L')$, $x_3 = L' + \tau(x_2 - L')$.
(b) $\frac{1}{2}(L' + U') \leq x_2 < L' + \tau(U' - L')$, $x_3 = \frac{1}{\tau}x_2 - \tau U'$.
(c) $U' - \tau(U' - L') < x_2 < \frac{1}{2}(L' + U')$, $x_3 = \frac{1}{\tau}x_2 - \tau L'$.
(d) $x_2 \leq U' - \tau(U' - L')$, $x_3 = U' - \tau(U' - x_2)$.

In a way analogous to the above, we can show that this reduces the interval of uncertainty by at least a factor of τ.

Finally, we consider the possibility in which $[L', U']$ does not have one of the previous interior points x_1, x_2 as an interior point. This can happen when $f(x_1) =$

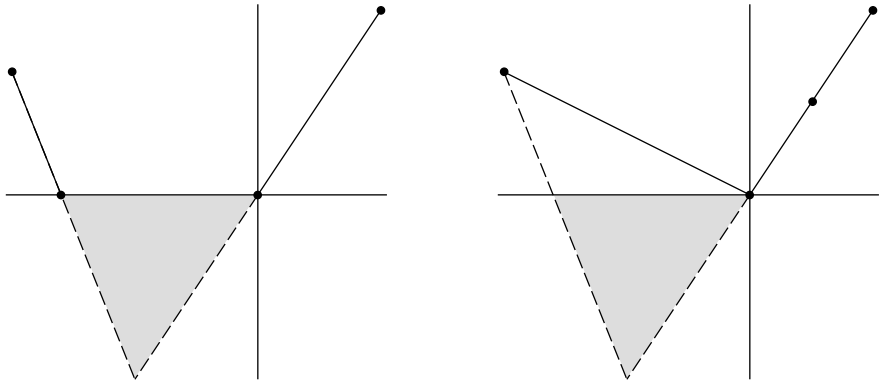

FIG. 8. *Two examples when the improved golden section method leads to an interval of uncertainty without an interior point. In* (a) *the two interior points of the previous interval of uncertainty both have the same function value. In* (b) *the lowest function evaluation lies on one line with two other function evaluations.*

$f(x_2)$ or when at least three consecutive points that have already been evaluated lie on one line (see Figure 8); in the latter case the function f is at least partially piecewise linear. Then the interval $[L', U']$ lies between x_1 and x_2, i.e., $[L', U'] \subseteq [x_1, x_2]$ with either $L' = x_1$ or $U' = x_2$ or both. Two new function evaluations are now required to decrease the interval further by at least a factor of τ. However, as $x_2 - x_1 = \tau^2(U - L)$, the previous function evaluation results in a reduction of τ^2. Therefore, the combined reduction of the previous function evaluation and the new function evaluation will also be at least τ^2, giving an average reduction of at least a factor of τ for each function evaluation.

We now choose one new point using the golden section property, i.e., either $x_3 = x_2 - \tau(x_2 - x_1)$ or $x_3 = x_1 + \tau(x_2 - x_1)$, which ensures that a reduction of at least τ can be guaranteed for the following function evaluations. The resulting function evaluation of x_3 is used to update the interval of uncertainty, and we choose another point according to the described improved golden section strategy.

Now we have shown how the convexity property can be used to choose new points for evaluation such that the interval of uncertainty is reduced by at least the same factor as for the golden section method. However, in practice the reduction will be larger as we show with empirical results in section 5. In this section we continue with a method that decreases the range of uncertainty by at least a factor of 1/2 after two new function evaluations.

3.2. Function range reduction. As is shown in Figure 1(d) the convexity property can be used to obtain upper and lower bounds for the function value of each point in the interval of uncertainty. As these upper and lower bounds tighten for each new function evaluation, they can be used for a strategy that guarantees a reduction of the range of uncertainty instead of the interval of uncertainty. Figure 9 depicts the area in which the optimum can be found, together with the points corresponding to the function evaluations and the interval of uncertainty.

Let M be the point with the lowest function evaluation so far, $f(M)$. Then $L' \leq M \leq U'$. Now we define Δf_1^k as the height of the triangle in the area of uncertainty between L' and M after k function evaluations, and we define Δf_2^k as the height of the triangle between M and U'. We can express Δf_1^k and Δf_2^k using known

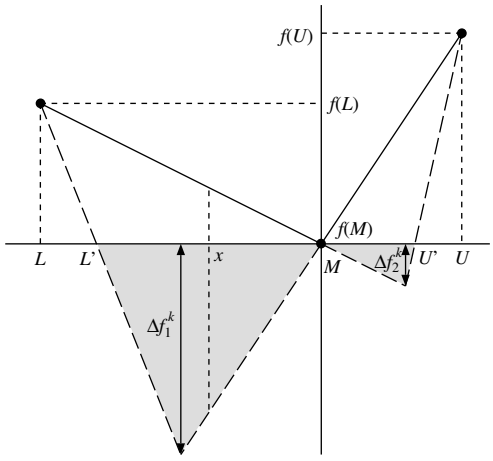

FIG. 9. *The areas of uncertainty. The three points with their function evaluations are given by L, M, and U. The interval of uncertainty in the function domain begins at L' and ends at U'. The height of the two areas after k function evaluations is given by Δf_1^k and Δf_2^k. The new point for function evaluation is x.*

function values and the interval of uncertainty, as derived in Appendix A, which gives the following formulas:

$$\Delta f_1^k = \frac{(M - L')(f(L) - f(M))(f(U) - f(M))}{(f(L) - f(M))(U - M) + (f(U) - f(M))(L' - L)}, \tag{3}$$

$$\Delta f_2^k = \frac{(U' - M)(f(L) - f(M))(f(U) - f(M))}{(f(L) - f(M))(U - U') + (f(U) - f(M))(M - L)}. \tag{4}$$

The range of uncertainty is now given by the maximum height of the area of uncertainty, i.e., $\max\{\Delta f_1^k, \Delta f_2^k\}$. The point x we choose for function evaluation now lies in the middle of the area with the largest height, i.e.,

$$x = \begin{cases} \frac{1}{2}(L' + M) & \text{if} \quad \Delta f_1^k \geq \Delta f_2^k, \\ \frac{1}{2}(M + U') & \text{if} \quad \Delta f_1^k < \Delta f_2^k. \end{cases} \tag{5}$$

We refer to the method that chooses a new point for function evaluation according to (5) as the *triangle section method*; see also Algorithm 3 for an overview of the method. A greedy strategy is to take the point where the lower bound is minimal. However, it can be easily shown that the performance bounds for this greedy strategy are worse than the performance bounds for the triangle section strategy which we give in this paper.

In the remainder of this section we normalize, w.l.o.g., the function values, the size of the interval of uncertainty, and the range of uncertainty in the following way:

$$M = 0, \qquad f(M) = 0, \qquad \Delta f_1^k = 1, \qquad L' = -1.$$

After substituting these values into the expression for Δf_1^k, it follows that $f(U) = \frac{f(L)U}{1+L+f(L)}$ if $1 + L + f(L) \neq 0$. The values of L, $f(L)$, U, and U' then determine the exact situation. For the ease of notation we make the following substitutions, as

Algorithm 3. The triangle section method.

Input: Interval of uncertainty $[L, U]$, stop criterion ε,
Output: Interval of uncertainty $[L, U]$ with size of range of uncertainty $\max\{\Delta f_1^k, \Delta f_2^k\} < \varepsilon$;

Initialization: Take $x = (U - L)/2$ and $k := 0$,
Loop:
repeat
$k := k + 1$;
Determine $f(x)$;
Determine new interval of uncertainty $[L', U']$ using convexity property;
Determine $\Delta f_1^k, \Delta f_2^k$;
Take as new interval of uncertainty $[L, U] := [L', U']$;
Determine new point x according to (5)
until $\max\{\Delta f_1^k, \Delta f_2^k\} < \varepsilon$

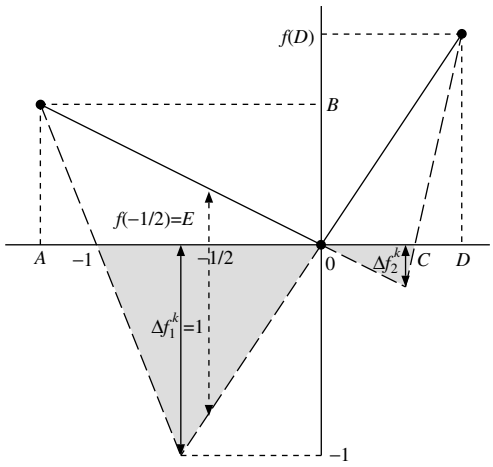

FIG. 10. *The areas of uncertainty with normalization of the function and interval values. The point* 0 *has the lowest function evaluation of* 0. *The size of the range of uncertainty is given by* Δf_1^k, *which is set to* 1. *The lower bound of the interval of uncertainty in the function domain is equal to* -1; *thus, the new point for function evaluation is* $-\frac{1}{2}$.

shown in Figure 10:

$$\begin{aligned} A &= L, \\ B &= f(L), \\ C &= U', \\ D &= U, \\ E &= f(x). \end{aligned}$$

Furthermore, w.l.o.g. we assume that $\Delta f_1^k \geq \Delta f_2^k$. The new point for evaluation then is $x = -\frac{1}{2}$.

For the values of A, B, C, D, and E we can derive the following properties:

(i) The lower corner of the left area should be to the left of M, i.e., $-D/f(D) \leq 0$. As $f(D) = f(U) = f(L)U/[1+L+f(L)] = BD/[1+A+B]$, if $1+A+B \neq 0$, we have $-[1+A+B]/B \leq 0$ and $D \neq 0$. Since $B = f(L) > 0$, it follows that $1 + A + B \geq 0$.

(ii) $L \leq L'$, i.e., $A \leq -1$ or $-1 - A \geq 0$ or $1 + A \leq 0$.

(iii) $U \geq U' \geq 0$, i.e., $D \geq C \geq 0$.

(iv) $\Delta f_2^k \leq \Delta f_1^k = 1$. Substitution of Δf_2^k gives $\Delta f_2^k = \frac{BCD}{(D-C)(1+A+B)-AD}$. So $BCD \leq (D - C)(1 + A + B) - AD$.

(v) Let $f^{\mathrm{u}}(x)$ denote the upper bound for point x, i.e., the line $(A, B) - (0, 0)$. Then $f(x) \leq f^{\mathrm{u}}(x)$ should hold, i.e., $E \leq -\frac{B}{2A}$ or $-2AE \leq B$.

(vi) Let $f^{\mathrm{l}}(x)$ denote the lower bound for point x, i.e., the line parts below the $y = 0$ line of the lines (A, B)–$(-1, 0)$ and $(0, 0)$–$(D, f(D))$. Then $f(x) \geq f^{\mathrm{l}}(x)$ should hold. The value of $f^{\mathrm{l}}(x)$ depends on whether the lowest corner of the left area lies to the left or to the right of x, i.e., $f^{\mathrm{l}}(x) = \max\{-\frac{B}{2(1+A+B)}, -\frac{B}{2(-1-A)}\}$. This gives $B \geq -2E(1 + A + B)$ and $B \geq -2E(-1 - A)$. Notice that this also holds if $1 + A + B = 0$ or $-1 - A = 0$.

We now show in Lemma 2 that in the special case the area of uncertainty consists of one triangle, i.e., $\Delta f_1^k = 0$ or $\Delta f_2^k = 0$; the triangle section method at least halves the range of uncertainty for a new function evaluation.

LEMMA 2. *Let a new function evaluation x_{k+1} be chosen according to* (5)*, and let either $\Delta f_1^k = 0$ or $\Delta f_2^k = 0$. Then the range of uncertainty decreases by at least a factor of $\frac{1}{2}$ after the function evaluation $f(x_{k+1})$ is known, i.e.,*

$$\max\{\Delta f_1^{k+1}, \Delta f_2^{k+1}\} \leq \frac{1}{2} \max\{\Delta f_1^k, \Delta f_2^k\} .$$

Proof. W.l.o.g. we assume that $\Delta f_2^k = 0$. We distinguish four possibilities for $f(x_{k+1})$; cf. Figure 11(a).

1. $f(x_{k+1}) = f^{\mathrm{u}}(x_{k+1})$; see Figure 11(b). Then the upper bound is equal to the lower bound for all points in $[L, U]$, and $M = 0$ is the optimum with function value $f(M) = 0$. Thus $\Delta f_1^{k+1} = 0$.
2. $f^{\mathrm{u}}(x_{k+1}) > f(x_{k+1}) \geq 0$; see Figure 11(c). If we write Δf_1^{k+1} as an expression of A, B, C, D, and E, we get

$$\Delta f_1^{k+1} = \frac{B(\frac{1}{2}B + AE)}{B(-\frac{1}{2} - A) + (B - E)(1 + A + B)}. \tag{6}$$

   Now we need to show that $\Delta f_1^{k+1} \leq \frac{1}{2}$ or $\frac{1}{2} - \Delta f_1^{k+1} \geq 0$. From properties (i), (ii), and (v) it follows that $B(-\frac{1}{2} - A) + (B - E)(1 + A + B) > 0$. So we need to show that $\frac{1}{2}B(-\frac{1}{2} - A) + \frac{1}{2}(B - E)(1 + A + B) - B(\frac{1}{2}B + AE) \geq 0$. Rewriting the left part of this inequality gives $\frac{1}{4}B + \frac{1}{2}E((-1 - A)(1 + B) - AB)$. Since $B, E, (-1 - A) \geq 0$ the inequality holds, and $\Delta f_1^{k+1} \leq \frac{1}{2}$.
3. $0 > f(x_{k+1}) > f^{\mathrm{l}}(x_{k+1})$; see Figure 11(d). Then both $\Delta f_1^{k+1} > 0$ and $\Delta f_2^{k+1} > 0$ will hold. If we write Δf_1^{k+1} as an expression of A, B, C, D, and E, we get

$$\Delta f_1^{k+1} = \frac{-E(\frac{1}{2}B + E(-1 - A))}{\frac{1}{2}B - E(-1 - A)}. \tag{7}$$

   Now we show that $\frac{1}{2} - \Delta f_1^{k+1} \geq 0$. As $B > 0$, $E < 0$, and $-1 - A > 0$, this can be done by showing that $\frac{1}{2}(\frac{1}{2}B - E(-1 - A)) - (-E(\frac{1}{2}B + E(-1 - A))) \geq 0$.

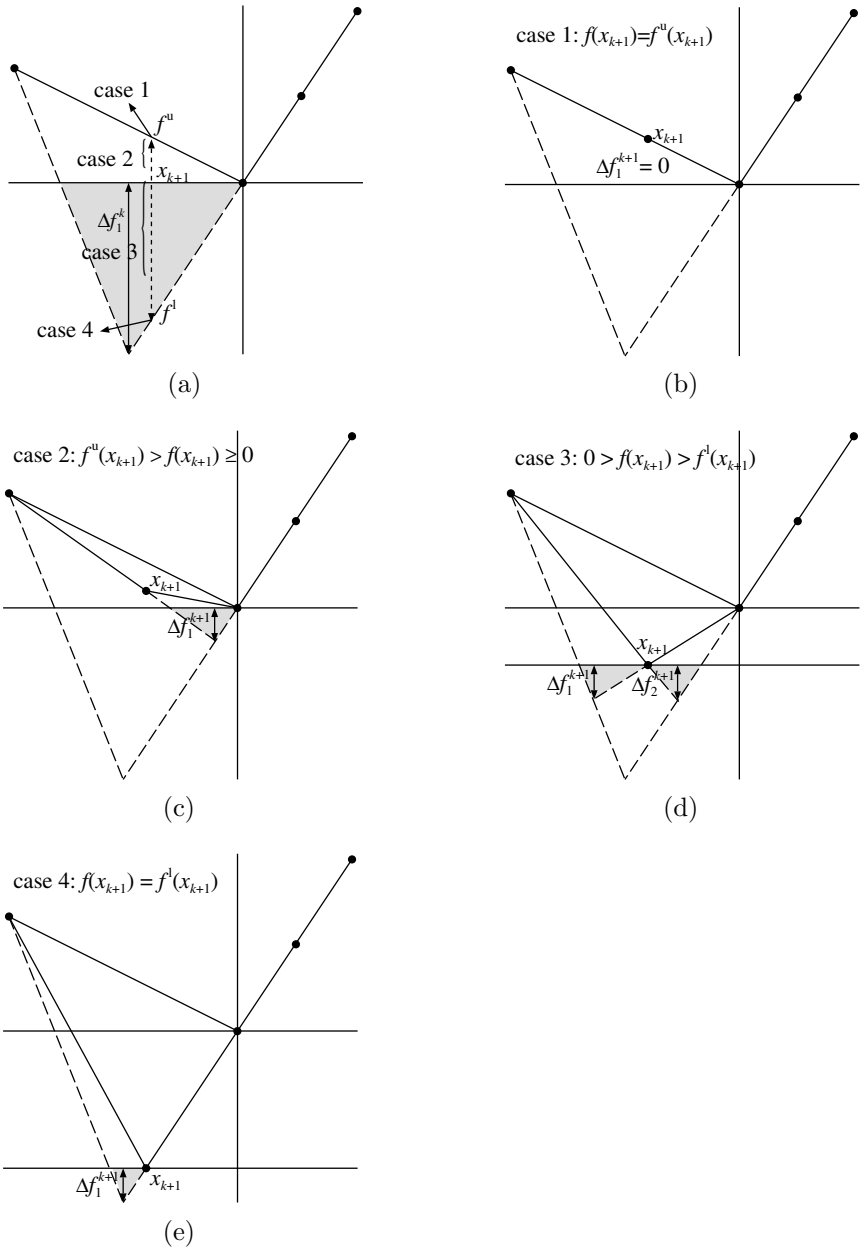

FIG. 11. *Decrease of range of uncertainty when* $\Delta f_2^k = 0$. (a) *Four possibilities are distinguished for the new function evaluation* $f(x_{k+1})$. (b) $f(x_{k+1}) = f^{\mathrm{u}}(x_{k+1})$. (c) $f^{\mathrm{u}}(x_{k+1}) > f(x_{k+1}) \geq 0$. (d) $0 > f(x_{k+1}) > f^{\mathrm{l}}(x_{k+1})$. (e) $f(x_{k+1}) = f^{\mathrm{l}}(x_{k+1})$.

Rewriting the left part of this inequality and using $B \geq -2E(1+A+B)$ from property (vi) gives $(-1-A)E^2 + \frac{1}{2}E(1+A+B) + \frac{1}{4}B \geq (-1-A)E^2 \geq 0$. If we write Δf_2^{k+1} as an expression of A, B, C, D, and E, we get

$$\Delta f_2^{k+1} = \frac{E(B-E)(1+A+B) + \frac{1}{2}B(B-E)}{(B-E)(1+A+B) + B(-\frac{1}{2}-A)}. \tag{8}$$

As $B > E$, $1+A+B > 0$, $B > 0$, and $-\frac{1}{2} - A > -1 - A \geq 0$, it suffices to show that $\frac{1}{2}((B-E)(1+A+B)+B(-\frac{1}{2}-A))-(E(B-E)(1+A+B)+\frac{1}{2}B(B-E)) \geq 0$. Rewriting the left part of this inequality and using $B \geq -2E(-1-A)$ from property (vi) gives $-\frac{1}{2}E(1+A)+\frac{1}{4}B-E(B-E)(1+A+B) \geq -\frac{1}{2}E(1+A)+\frac{1}{4}(-2E(-1-A))-E(B-E)(1+A+B) = -E(B-E)(1+A+B) \geq 0$.

4. $f(x_{k+1}) = f^{\mathrm{l}}(x_{k+1})$; see Figure 11(e). Then $\Delta f_2^{k+1} = 0$, and $\Delta f_1^{k+1} = \Delta f_1^k - (f(M) - f^{\mathrm{l}}(x^{k+1})) = \Delta f_1^k + f^{\mathrm{l}}(x_{k+1})$. So, for $\Delta f_1^{k+1} \leq \frac{1}{2}\Delta f_1^k = \frac{1}{2}$ we need to show that $-f^{\mathrm{l}}(x_{k+1}) - \frac{1}{2} \geq 0$. The lower bound is given by $f^{\mathrm{l}}(x_{k+1}) = \max\{-\frac{B}{2(1+A+B)}, -\frac{B}{2(-1-A)}\}$. If $f^{\mathrm{l}}(x_{k+1}) = -\frac{B}{2(1+A+B)}$ we have

$$\frac{B}{2(1+A+B)} - \frac{1}{2} = \frac{B-(1+A+B)}{2(1+A+B)} = \frac{-1-A}{2(1+A+B)} \geq 0.$$

If $f^{\mathrm{l}}(x_{k+1}) = -\frac{B}{2(-1-A)}$ we have

$$\frac{B}{2(-1-A)} - \frac{1}{2} = \frac{B-(-1-A)}{2(-1-A)} = \frac{1+A+B}{2(-1-A)} \geq 0. \qquad \square$$

We use Lemma 2 to show that the triangle section method at least halves the range of uncertainty after two new function evaluations.

THEOREM 2. *Let each new function evaluation x_{k+1} be chosen according to* (5). *Then the range of uncertainty is at least halved after two function evaluations, i.e., for all k,*

$$\max\{\Delta f_1^{k+2}, \Delta f_2^{k+2}\} \leq \frac{1}{2}\max\{\Delta f_1^k, \Delta f_2^k\}\,.$$

Proof. W.l.o.g. we assume that $\Delta f_1^k \geq \Delta f_2^k$. We distinguish three possibilities for the function value $f(x_{k+1})$.

1. $f(x_{k+1}) = f^{\mathrm{u}}(x_{k+1})$; see Figure 12(b). Then for all $y \in [L, M]$ we have $f^{\mathrm{u}}(y) = f^{\mathrm{l}}(y)$ and $\Delta f_1^{k+1} = 0$. Furthermore, $\Delta f_2^{k+1} = \Delta f_2^k$. Now it follows from Lemma 2 that $\max\{\Delta f_1^{k+2}, \Delta f_2^{k+2}\} \leq \frac{1}{2}\Delta f_2^{k+1} \leq \frac{1}{2}\max\{\Delta f_1^k, \Delta f_2^k\}$.
2. $0 \geq f(x_{k+1}) \geq f^{\mathrm{l}}(x_{k+1})$; see Figure 12(c). Then Δf_1^{k+1} and Δf_2^{k+1} are identical to those given in the proof of Lemma 2 for the corresponding value of $f(x_{k+1})$. It follows that $\max\{\Delta f_1^{k+1}, \Delta f_2^{k+1}\} \leq \frac{1}{2}\max\{\Delta f_1^k, \Delta f_2^k\}$ and thus $\max\{\Delta f_1^{k+2}, \Delta f_2^{k+2}\} \leq \frac{1}{2}\max\{\Delta f_1^k, \Delta f_2^k\}$.
3. $f^{\mathrm{u}}(x_{k+1}) > f(x_{k+1}) > 0$; see Figure 12(d). The expression for Δf_1^{k+1} is identical to the one given in the proof of Lemma 2, and it follows that $\Delta f_1^{k+1} \leq \frac{1}{2}\Delta f_1^k$. For Δf_2^{k+1} we distinguish two possibilities.
   - $\Delta f_2^{k+1} \leq \frac{1}{2}\Delta f_1^k$, as shown in Figure 12(d). Then $\max\{\Delta f_1^{k+1}, \Delta f_2^{k+1}\} \leq \frac{1}{2}\max\{\Delta f_1^k, \Delta f_2^k\}$ and thus $\max\{\Delta f_1^{k+2}, \Delta f_2^{k+2}\} \leq \frac{1}{2}\max\{\Delta f_1^k, \Delta f_2^k\}$.
   - $\Delta f_2^{k+1} > \frac{1}{2}\Delta f_1^k$, as shown in Figure 13(b). Then also $\Delta f_2^{k+1} > \Delta f_1^{k+1}$. A new point x_{k+2} is now chosen for function evaluation according to (5). For the function value $f(x_{k+2})$, we can also distinguish three possibilities.
     - $f(x_{k+2}) = f^{\mathrm{u}}(x_{k+2})$; see Figure 13(c). As $\Delta f_2^{k+1} > \Delta f_1^{k+1}$, it follows that $\Delta f_2^{k+2} = 0$. Thus,

$$\max\{\Delta f_1^{k+2}, \Delta f_2^{k+2}\} \leq \Delta f_1^{k+1} \leq \frac{1}{2}\max\{\Delta f_1^k, \Delta f_2^k\}.$$

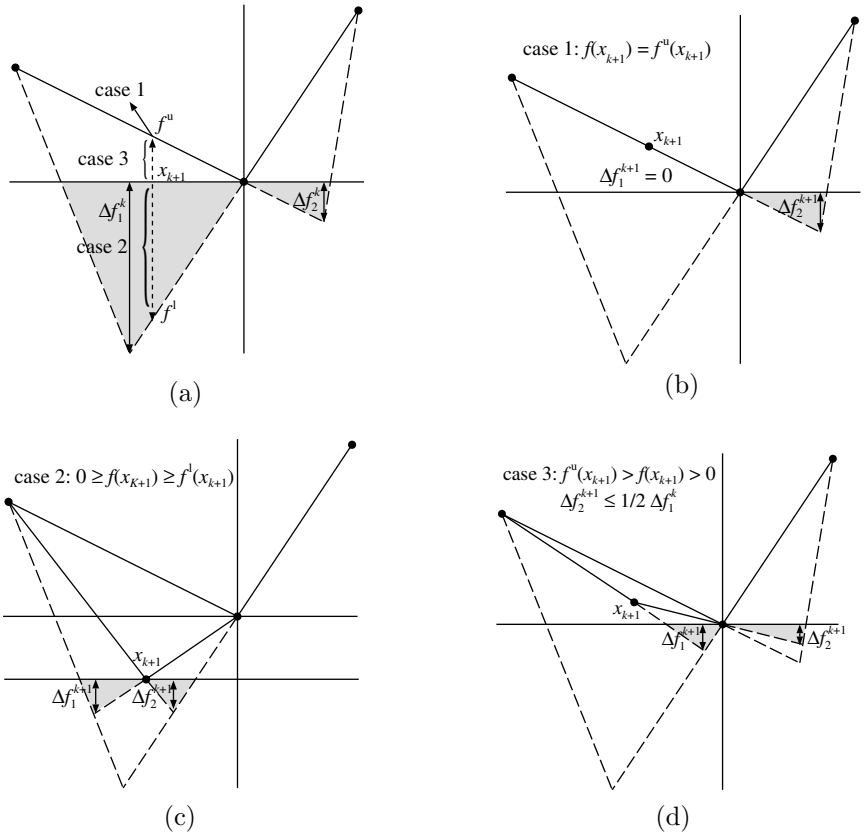

FIG. 12. *Decrease of range of uncertainty when* $\Delta f_1^k \geq \Delta f_2^k > 0$. (a) *Three possibilities are distinguished for the new function evaluation* $f(x_{k+1})$. (b) $f(x_{k+1}) = f^u(x_{k+1})$. (c) $0 \geq f(x_{k+1}) \geq f^l(x_{k+1})$. (d) $f^u(x_{k+1}) > f(x_{k+1}) > 0$.

– $0 \geq f(x_{k+2}) \geq f^l(x_{k+2})$; see Figure 13(d). Then,

$$\max\{\Delta f_1^{k+2}, \Delta f_2^{k+2}\} \leq \frac{1}{2}\Delta f_2^{k+1} \leq \frac{1}{2}\max\{\Delta f_1^k, \Delta f_2^k\}.$$

– $f^u(x_{k+2}) > f(x_{k+2}) > 0$; see Figure 13(e). As $\Delta f_2^{k+1} > \Delta f_1^{k+1}$, it follows that $\Delta f_2^{k+2} \leq \frac{1}{2}\Delta f_2^{k+1} \leq \frac{1}{2}\max\{\Delta f_1^k, \Delta f_2^k\}$. Furthermore, $\Delta f_1^{k+2} \leq \Delta f_1^{k+1} \leq \frac{1}{2}\max\{\Delta f_1^k, \Delta f_2^k\}$. □

COROLLARY 1. *Using the triangle section method, the decrease of the range of uncertainty is exponential in the number of function evaluations.*

Proof. Let the initial range of uncertainty be given by $\max\{\Delta f_1^0, \Delta f_2^0\}$, and let the range of uncertainty after k new function evaluations be given by $\max\{\Delta f_1^k, \Delta f_2^k\}$. Then $\max\{\Delta f_1^k, \Delta f_2^k\} \leq \frac{1}{2}\max\{\Delta f_1^{k-2}, \Delta f_2^{k-2}\} \leq \left(\frac{1}{2}\right)^{\lfloor \frac{k}{2} \rfloor}\max\{\Delta f_1^0, \Delta f_2^0\}$. □

So we have shown that the range of uncertainty is at least halved for each two new function evaluations. However, the average reduction of the range of uncertainty generally is considerably larger, which is backed up by the empirical results that we present in section 5.

3.3. Piecewise-linear functions. We now consider the case in which the function f is also known to be piecewise linear besides convex or concave. An example of such a function is given in section 4.

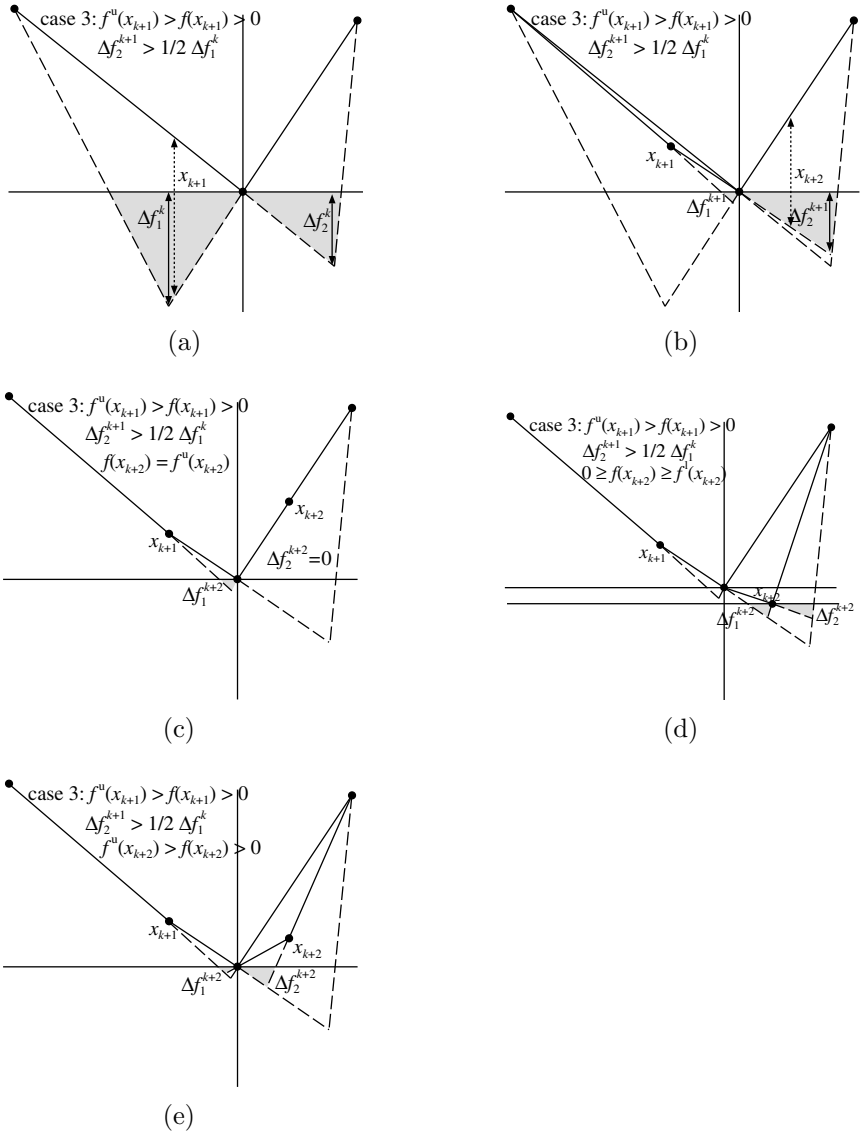

FIG. 13. *Decrease of range of uncertainty when* $\Delta f_1^k \geq \Delta f_2^k > 0$ *and* $\Delta f_2^{k+1} > \frac{1}{2}\Delta f_1^k$. (a) *Initial situation when determining the new function evaluation* $f(x_{k+1})$. (b) $f^u(x_{k+1}) > f(x_{k+1}) > 0$ *and* $\Delta f_2^{k+1} > \frac{1}{2}\Delta f_1^k$. (c) $f(x_{k+2}) = f^u(x_{k+2})$. (d) $0 \geq f(x_{k+2}) \geq f^l(x_{k+2})$. (e) $f^u(x_{k+2}) > f(x_{k+2}) > 0$.

The piecewise-linear property of f can be used as follows to terminate the improved golden section method or the triangle section method with the exact minimum. For a piecewise-linear function the slope of a line segment will be identified as soon as three function evaluations are made of points on the segment. Furthermore, the optimum lies at the intersection of two segments. When these two line segments have been identified, the exact minimum can be obtained by determining the intersection of the two line segments.

When dealing with piecewise-linear functions, we use this fact as follows. When a line segment containing the point with the lowest function evaluation so far has

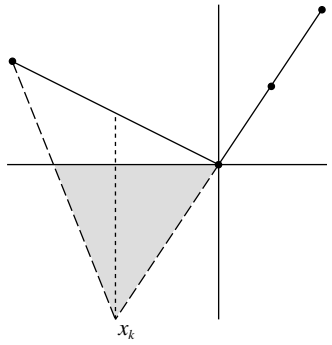

FIG. 14. *A line segment containing the point with the lowest function evaluation so far has been identified by three adjacent function evaluations. The next point x_k that is chosen for function evaluation is the point with the lowest lower bound value.*

been identified, then we evaluate the point x_k with the lowest lower bound value, i.e., $x_k = \arg\min f^{\mathrm{l}}(x)$; see Figure 14 for an example. For the improved golden section method this means that before each new function evaluation we check whether the point with the lowest function evaluation lies on one line segment with the two preceding or succeeding points. For the triangle section method, we check if either $\Delta f_1^k = 0$ or $\Delta f_2^k = 0$ holds. Note that $\Delta f_1^k = 0$ or $\Delta f_2^k = 0$ also holds when there are two points with the lowest function evaluation. If $f(x_k) = f^{\mathrm{l}}(x_k)$, then x_k is the point with the minimum function value, and we can stop. Otherwise, we continue with new function evaluations, also using the latest function evaluation $f(x_k)$.

4. Application to a practical problem: Bandwidth and buffer minimization. In previous sections we described how we can find the optimum for a concave or convex function of one variable with computationally expensive function evaluations. In this section we give a real-life example of such a function, stemming from resource management in an in-home network. For an elaborate description of the problem from which this example originates, we refer to Den Boef, Verhaegh, and Korst [8].

Consider a sender and a receiver of data and a network or data transportation device to which both the sender and receiver are connected. At the connections of the sender and the receiver to the network, buffers are placed. Time is discretized into time units t; for each time unit t, the amount of data supplied at the sender is given by $s(t)$, and the amount of data consumed at the receiver is given by $d(t)$. All data are supplied into the buffer at the sender and are consumed from the buffer at the receiver. Reservations of the buffers and the transportation device are based on the maximum usage during the time horizon. Costs of the buffers are given by c_{s} and c_{r} per unit buffer size, and cost of the transportation device is given by c_{b} per unit transportation capacity.

The problem is to determine reservations b of the transportation device, m_{s} and m_{r} of the buffers, and a feasible transmission schedule of the data given by $x(t)$ for each time unit t such that total costs are minimized. The transmission schedule has to be such that, whenever data is taken from a buffer, it also is available in the buffer (no buffer underflow) and such that, whenever data is put into a buffer, the buffer reservation is not exceeded. Also, the amount transmitted during a time unit may not exceed the transportation capacity reservation. This can be formulated as a linear

program as follows:

$$
\begin{array}{lll}
\text{minimize} & c_{\mathrm{b}}b + c_{\mathrm{s}}m_{\mathrm{s}} + c_{\mathrm{r}}m_{\mathrm{r}} & \\
\text{subject to} & x\,(t) \le b & \forall t, \\
& \sum_{k=1}^{t} s(k) - \sum_{k=1}^{t} x\,(k) \ge 0 & \forall t, \\
& \sum_{k=1}^{t} s(k) - \sum_{k=1}^{t-1} x\,(k) \le m_{\mathrm{s}} & \forall t, \\
& \sum_{k=1}^{t} x\,(k) - \sum_{k=1}^{t} d(k) \ge 0 & \forall t, \\
& \sum_{k=1}^{t} x\,(k) - \sum_{k=1}^{t-1} d(k) \le m_{\mathrm{r}} & \forall t.
\end{array} \tag{9}
$$

In this linear program (LP) all constraints must hold for every time unit t. A typical video stream has a time horizon that is split up into more than 100,000 time units. This leads to an LP that consists of more than $100,000$ variables and $500,000$ constraints, which requires a relatively long calculation time when standard LP-methods are used. However, we can obtain the solution in only a few seconds not by using LP but by using a line search method of this paper together with the following problem-specific method which has complexity $\mathcal{O}(|T|)$, where T denotes the set of time units.

Given a transportation capacity, we can minimize the total buffer costs by first minimizing the buffer with the highest cost coefficient and then minimizing the buffer with the lowest cost coefficient. Minimizing one buffer for a given bandwidth can be done in $\mathcal{O}(|T|)$ time using a specific algorithm [10]. So for a given value of b, optimal values of m_{s} and m_{r} can be determined quickly but without any information on the derivative. This leads to the following reformulation of the problem.

Let f be a function of transportation capacity b with function values that represent the minimum total costs. So, for input b, the function f determines optimal values of m_{s} and m_{r} given the cost coefficients c_{s} and c_{r} and then calculates the total costs $c_{\mathrm{b}}b + c_{\mathrm{s}}m_{\mathrm{s}} + c_{\mathrm{r}}m_{\mathrm{r}}$ which are returned as output. The problem now is to find the minimum of the function f. Since the original problem is an LP-problem with b appearing in the right-hand sides of the constraints, f is a continuous, piecewise-linear, convex function. So, the method described in this paper can be used to find an optimum. In section 5, we show some results of the improved golden section method and the triangle section method applied to this problem.

5. Numerical test results. In this section we present numerical test results for the improved golden section method and the triangle section method. These results are obtained by using these methods on the bandwidth-buffer application described in section 4 and on numerous mathematical functions, which can be divided into two types. Functions of type 1 are polynomial functions, given by $f(x) = a(x-b)^{2c}$, with $a = 0.5, 1, 1.5, \ldots, 9.5, 10$, $b = 1, 2, \ldots, 10$, and $c = 1, 2, \ldots, 5$. This gives a total of 1000 functions of type 1. Note that type 1 functions are symmetrical with a steep grade. A function f of type 2 is given by $f(x) = a\mathrm{e}^{b(x-c)} - dx$, with $a = 1, 2, \ldots, 10$, $b = 1, 2, \ldots, 5$, $c = -5, -4, \ldots, 5$, and $d = 0.01, 0.05, 0.25, 1.25, 6.25, 31.25, 156.25, 781.25, 3906.25$. This gives a total of 4950 functions of type 2. Note that type 2 functions are nonsymmetrical and have a steep grade on one side of the minimum and a weak grade on the other side of the minimum. For both functions of type 1 and functions of type 2 the objective was to find the minimum on the interval $[-10, 10]$. Finally, for the bandwidth-buffer application discussed in the previous section, we used 16 different video traces, each combined with a number of different cost coefficients c_{b}, c_{s}, and c_{r}, which resulted in 283 problem instances.

In Table 5.1 results are given for comparing the regular golden section, improved golden section, and triangle section methods using (a) the 1000 functions of type 1, (b) the 4950 functions of type 2, and (c) the 283 application instances. The results

TABLE 5.1

Results after 5–10 *function evaluations for the golden section method (gs), the improved golden section method (igs), and the triangle section method (ts).* (a), (b), *and* (c) *give the results for the functions of types* 1 *and* 2, *and for the bandwidth-buffer application, respectively. In each table, the leftmost column gives the number of function evaluations. The next three columns give for each method and number of function evaluations the average over all functions or bandwidth-buffer instances of the difference between the function value of the best found solution and the optimal function value. The three rightmost columns give for each method the average over all functions or bandwidth-buffer instances of the resulting interval of uncertainty after the given number of function evaluations. Finally, improved golden section and triangle section methods were stopped when for a function the range of uncertainty was less than* 0.01. *When this happened for a function, the last calculated result of the best found solution and the interval of uncertainty was also used as a result for the higher number of function evaluations in this table. For example, if the triangle section method was stopped after eight function evaluations with best found solution value* 2.5 *and interval of uncertainty size* 0.5, *then these values were also used for nine and ten function evaluations to compute the results in this table. This explains why, e.g., the average size of the interval of uncertainty for type* 1 *functions using the triangle section method is the largest, compared to regular and improved golden section methods, for ten function evaluations, while it is the smallest for fewer function evaluations.*

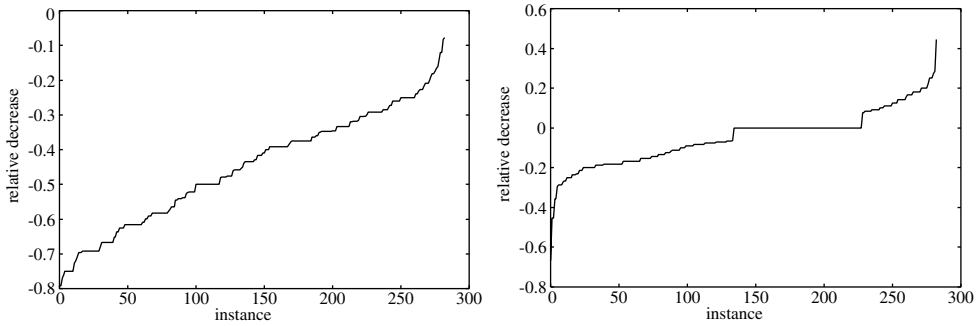
consist of the average difference between the best found solution and the optimal solution and the average size of the interval of uncertainty after a given number of function evaluations, with both averages over all functions or instances. These results show that for functions of type 1 and bandwidth-buffer instances, the triangle section method on average gets closest to the optimal function value. For functions of type 2, however, it is outperformed by the improved golden section method, possibly due to the largely asymmetrical shape of these functions. Regarding the interval of uncertainty, we notice that the improved golden section method improves upon the results of the regular golden section method especially for functions of type 2 and for the bandwidth-buffer instances. For functions of type 1, it also returns better results than the regular golden section method, but here the improvement is not so



(a) (b)

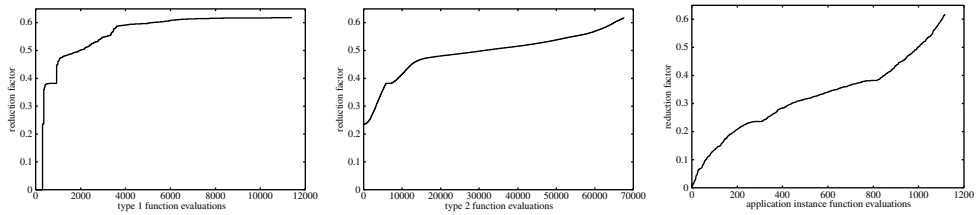
FIG. 15. *In these two graphs the number of function evaluations that two of the three methods require are compared.* (a) *compares the improved golden section method with the regular golden section method for the* 283 *bandwidth-buffer instances. Both methods were stopped when the interval of uncertainty was less than* 1. *The graph gives for all* 283 *instances the relative decrease in the number of function evaluations required by the improved golden section method compared to the regular golden section method, i.e., for each application instance* $(igs - gs)/gs$ *is given, where* igs *and* gs *denote the number of function evaluations required for the improved golden section and regular golden section methods, respectively. The instances are sorted on the horizontal axis in the order of nondecreasing relative decrease.* (b) *compares the triangle section method to the improved golden section method, both using the procedure that uses piecewise linearity to determine the exact optimum. The graph gives for all* 283 *instances the relative decrease in the number of function evaluations required by the triangle section method compared to the improved golden section method, i.e., for each bandwidth-buffer instance* $(ts - igs)/igs$ *is given, where* ts *and* igs *denote the number of function evaluations required for the triangle section and improved golden section methods, respectively.*

impressive. This can be explained by the relatively steep slopes of the functions of type 1 surrounding both sides of the optimum.

Figure 15(a) compares the improved golden section method with the regular golden section method using the bandwidth-buffer instances and as stopping criterion the size of interval of uncertainty being less than 1. It shows that the reduction in the number of function evaluations can be as high as 80%, and on average around 40%. Figure 15(b) compares the triangle section method with the improved golden section method using the application instances and the piecewise-linear property, thus obtaining the exact optimum. For about one-half of the instances the triangle section method requires fewer function evaluations than the improved golden section method. However, for about one-quarter of the instances it requires more function evaluations. Still, the average number of function evaluations is lower for the triangle section method than for the improved golden section method.

Figure 16 shows the reduction factors of the interval of uncertainty after a function evaluation, which were observed when applying the improved golden section method on all functions and instances. It shows that the reduction factor is often close to the golden section (≈ 0.618) for functions of type 1. However, for functions of type 2 and bandwidth-buffer instances, the reduction is much more significant, i.e., we get much smaller intervals of uncertainty.

Figure 17 shows again the reduction factors of the interval of uncertainty using the improved golden section method for functions of type 1, but now split into quadratic functions ($c = 1$) and functions of higher degree ($c \geq 2$). It shows that the reduction factors for quadratic functions are distributed evenly between 0.45 and 0.6 in contrast with the reduction factors for higher-degree functions, of which approximately 90%



(a) (b) (c)

FIG. 16. *These graphs show on the vertical axis the observed reduction factors of the interval of uncertainty after a function evaluation using the improved golden section method, where the function evaluations are sorted in the order of increasing reduction factor. Note that the number of performed function evaluations may vary for different functions and bandwidth-buffer instances. are close to 0.6. As the gradient of functions of higher degree at the evaluated points is larger than the gradient of quadratic functions, the lower bounds for the functions of higher degree have a steeper slope and thus lead to a smaller reduction of the interval of uncertainty.

Figure 18 shows the reduction factors of the range of uncertainty after a single function evaluation, which were observed when applying the triangle section method on all functions and instances. It shows that more than 90% of the recorded reduction factors are spread out over the interval $[0, 0.5]$, and only a small fraction of the recorded reduction factors are between 0.5 and 1. Figure 19 shows the reduction factors of the range of uncertainty after two consecutive function evaluations; cf. Theorem 2. It shows a similar distribution, with most of the observed reduction factors between 0 and 0.25 and only a small fraction between 0.25 and 0.5.

6. Conclusion. In this paper we have considered the line search problem for convex functions. We have shown how the convexity property can be used to obtain upper and lower bounds on the function using the performed function evaluations. For some well-known line search methods we have shown, using these upper and

lower bounds, that they may propose a candidate which is not optimal. We have presented two new line search methods which use the convexity property. The first method, the improved golden section method, uses the upper and lower bounds to improve upon the regular golden section method and always proposes a candidate which can be optimal. The second method, the triangle section method, focuses on minimizing the interval for possible objective values, the range of uncertainty, and we have shown that it at least halves the range of uncertainty after every two function evaluations.

Both methods were tested using a real-life example and two classes of convex functions. It was shown that the new methods give better approximations of the optimum than the regular golden section method after a fixed number of function evaluations. This also translated into a sometimes heavily reduced number of function evaluations that was required to obtain the optimum. A direct comparison of the new methods did not show a clear winner; depending on the instance either the improved golden section or the triangle section method gave the best results.

There are several possibilities for future research in line search methods for convex functions. The upper and lower bounds based on the convexity property can be used

to adapt other well-known line search methods. They can also be used to try to estimate the complete function as efficiently as possible instead of only the optimum. When information on the derivative in an evaluated point is known, it can be used to further improve the interval and range of uncertainty. This will also improve the performance of the methods presented in this paper. Finally, it would be interesting to see how the work presented in this paper extends to multivariate, convex functions.

Appendix A. Height of a triangle in the area of uncertainty. For the explanation of the triangle section method to obtain a guaranteed range reduction, the heights of the triangles in the area of uncertainty, Δf_1^k and Δf_2^k, need to be determined. The expressions of Δf_1^k and Δf_2^k in points L, M, and U with their function evaluations $f(L), f(M)$, and $f(U)$ and the interval of uncertainty $[L', U']$ can be obtained by determining the intersection of two appropriate lines and subtracting this from the smallest function evaluation so far. We first give a general expression of the intersection of two lines both determined by two points. Then we indicate for (3), (4), (6), (7), and (8) how they can be obtained.

Let $(a, f(a))$ and $(b, f(b))$ define a line l_1, and let $(c, f(c))$ and $(d, f(d))$ define a line l_2. So, $l_1(x)$ is given by

$$\frac{f(b) - f(a)}{b - a}x + \frac{f(a)b - f(b)a}{b - a},$$

and $l_2(x)$ is given by

$$\frac{f(d) - f(c)}{d - c}x + \frac{f(c)d - f(d)c}{d - c}.$$

Let line l_1 and line l_2 intersect at $(y, f(y))$. Then using the above line equations with $x = y$, we derive from $l_1(y) = l_2(y)$ that

$$y = \frac{\frac{f(c)d - f(d)c}{d - c} - \frac{f(a)b - f(b)a}{b - a}}{\frac{f(b) - f(a)}{b - a} - \frac{f(d) - f(c)}{d - c}}.$$

Simplifying the above equation gives

$$y = \frac{(f(c)d - f(d)c)(b - a) - (f(a)b - f(b)a)(d - c)}{(f(b) - f(a))(d - c) - (f(d) - f(c))(b - a)}.$$

Substituting the above equation for y into $l_1(y)$ or $l_2(y)$ gives for $f(y)$

$$f(y) = \frac{(f(c)d - f(d)c)(f(b) - f(a)) - (f(a)b - f(b)a)(f(d) - f(c))}{(f(b) - f(a))(d - c) - (f(d) - f(c))(b - a)}.$$

Equation (3):
$(a, f(a)) = (L, f(L))$, $(b, f(b)) = (L', f(M))$, $(c, f(c)) = (M, f(M))$, and $(d, f(d)) = (U, f(U))$.
$\Delta f_1^k = f(M) - f(y)$.

Equation (4):
$(a, f(a)) = (L, f(L))$, $(b, f(b)) = (M, f(M))$, $(c, f(c)) = (U', f(M))$, and $(d, f(d)) = (U, f(U))$.
$\Delta f_1^k = f(M) - f(y)$.

Equation (6):
$(a, f(a)) = (A, B)$, $(b, f(b)) = (-\frac{1}{2}, E)$, $(c, f(c)) = (0, 0)$, and $(d, f(d)) = (D, f(D))$.
$\Delta f_1^{k+1} = 0 - f(y)$.

Equation (7):
$(a, f(a)) = (A, B)$, $(b, f(b)) = (-1, 0)$, $(c, f(c)) = (-\frac{1}{2}, E)$, and $(d, f(d)) = (0, 0)$.
$\Delta f_1^{k+1} = E - f(y)$.

Equation (8):
$(a, f(a)) = (A, B)$, $(b, f(b)) = (-\frac{1}{2}, E)$, $(c, f(c)) = (0, 0)$, and $(d, f(d)) = (D, f(D))$.
$\Delta f_1^{k+1} = E - f(y)$.

NEW KORKIN–ZOLOTAREV INEQUALITIES*

R. A. PENDAVINGH† AND S. H. M. VAN ZWAM†

Abstract. Korkin and Zolotarev showed that if

$$\sum_i A_i \Big(x_i - \sum_{j>i} \alpha_{ij} x_j \Big)^2$$

is the Lagrange expansion of a Korkin–Zolotarev (KZ-) reduced positive definite quadratic form, then $A_{i+1} \geq \frac{3}{4} A_i$ and $A_{i+2} \geq \frac{2}{3} A_i$. They showed that the implied bound $A_5 \geq \frac{4}{9} A_1$ is not attained by any KZ-reduced form. We propose a method to optimize numerically over the set of Lagrange expansions of KZ-reduced quadratic forms using a semidefinite relaxation combined with a branch and bound process. We use a rounding technique to derive exact results from the numerical data. Applying these methods, we prove several new linear inequalities on the A_i of any KZ-reduced form, one of them being $A_{i+4} \geq (\frac{15}{32} - 2 \cdot 10^{-5}) A_i$. We also give a form with $A_5 = \frac{15}{32} A_1$. These new inequalities are then used to study the cone of outer coefficients of KZ-reduced forms, to find bounds on Hermite's constant, and to give better estimates on the quality of k-block KZ-reduced lattice bases.

Key words. lattice, quadratic form, semidefinite programming, Korkin–Zolotarev reduction, Hermite's constant, sphere packing

1. Preliminaries and overview.

The *Geometry of Numbers* is a field of mathematics initiated and named by Minkowski. The main objects studied are *lattices*, discrete subgroups of $\mathbb{R}^n$. Good introductions to the subject are the book by Cassels [2] and the excellent survey paper by Ryškov and Baranovskiĭ [13]. Typical problems are the search for a shortest vector within a given lattice and the search for a lattice with a dense *sphere packing*. Hermite's constant γ_n is a measure for the density of the densest lattice sphere packing in dimension n. This constant has been determined exactly for $n \leq 8$ and $n = 24$. Since Blichfeldt [1] determined γ_n for $n = 6, 7, 8$, no further low-dimensional cases have been computed. For example, the best known bounds for $n = 9$ are $512 \leq \gamma_9^9 < 913$, where the lower bound is the density of a specific lattice (see, for example, [4]), and the upper bound is the Cohn–Elkies bound [3].

Most of the early research in this subject was not in terms of lattices but in terms of quadratic forms. This approach proved very useful for our research, so in all but the last section we will talk exclusively about positive definite quadratic forms.

An n-ary positive definite quadratic form q can be written uniquely as

$$q(x_1, \ldots, x_n) = \sum_{i=1}^{n} A_i \Big(x_i - \sum_{j>i} \alpha_{ij} x_j \Big)^2. \tag{1.1}$$

This is the *Lagrange expansion* of q; the numbers A_i are the *outer coefficients* and

†Technische Universiteit Eindhoven, P.O. Box 513, 5600 MB Eindhoven, The Netherlands (rudi@win.tue.nl, svzwam@win.tue.nl).

the α_{ij} the *inner coefficients*. We write

$$q_k(x_k,\dots,x_n) := \sum_{i=k}^{n} A_i\Big(x_i - \sum_{j>i}\alpha_{ij}x_j\Big)^2. \tag{1.2}$$

A positive definite quadratic form q in n variables with Lagrange expansion (1.1) is *Korkin–Zolotarev (KZ-)*[1] *reduced* if

$$|\alpha_{ij}| \le \frac{1}{2} \text{ for all } i,j, \text{ and } \alpha_{i,i+1} \ge 0 \text{ for all } i; \tag{S}$$

and

$$A_k \le q_k(x) \text{ for all nonzero } x \in \mathbb{Z}^{n-k+1}, k = 1,\dots,n-1. \tag{M}$$

We say that two forms q, q' are *equivalent* if there is a unimodular matrix U, i.e., $U \in GL_n(\mathbb{Z})$, such that $q'(x) = q(Ux)$. It can be shown that any form is equivalent to a KZ-reduced form (see, for example, [13]).

Korkin and Zolotarev proved that the outer coefficients of a KZ-reduced form satisfy $A_2 \ge \frac{3}{4}A_1$ (the *first KZ-inequality*) and $A_3 \ge \frac{2}{3}A_1$ (the *second KZ-inequality*) [7]. If q is KZ-reduced, then so is the quadratic form q_k for $k \ge 1$, and hence the inequalities

$$A_{k+1} \ge \frac{3}{4}A_k \text{ and } A_{k+2} \ge \frac{2}{3}A_k,\ k = 1,2,\dots, \tag{1.3}$$

hold for the outer coefficients of any KZ-reduced form.

For each $n \in \mathbb{N}$, *Hermite's constant* is defined as

$$\gamma_n := \max\left\{ \frac{m(q)}{\det(q)^{\frac{1}{n}}} \mid q \text{ is an } n\text{-ary positive definite quadratic form}\right\}, \tag{1.4}$$

where $m(q) := \min\{q(x) \mid x \in \mathbb{Z}^n, x \ne 0\}$ is the *minimum* of the form q and $\det(q) := \det(Q)$, where Q is the symmetric matrix such that $q(x) = x^tQx$. Equivalent forms have the same minimum and the same determinant, so we may as well restrict the feasible set of (1.4) to KZ-reduced forms. Also, if $A_1,\dots,A_n$ are the outer coefficients of a form q, then $\det(q) = \prod_i A_i$, and if q is KZ-reduced, then $m(q) = f(1,0,\dots,0) = A_1$. Hence

$$\gamma_n^n = \max\left\{ \frac{A_1^n}{\prod_i A_i} \mid (A_1,\dots,A_n) = A(q) \text{ for some KZ-reduced form } q\right\}, \tag{1.5}$$

where $A(q) := (A_1,\dots,A_n)$ denotes the sequence of outer coefficients of the quadratic form q. Using (1.3), this implies the bound

$$\gamma_n^n \le \max\left\{ \frac{A_1^n}{\prod_{i=1}^n A_i} \mid A_{i+1} \ge \frac{3}{4}A_i, A_{i+2} \ge \frac{2}{3}A_i, A_1 = 1\right\}, \tag{1.6}$$

[1] In the literature one encounters several different ways of writing the names of Korkin and Zolotarev. We decided to follow some of the more recent publications (notably [5]) and have kept the original spelling in the references to facilitate the search for these papers.

which is tight for $n = 2, 3, 4$, as was shown in [6, 7]. In the right-hand side of (1.6) we have removed the scale invariance by requiring $A_1 = 1$. The right-hand side is equal to the inverse of

$$\min\left\{\prod_{i=1}^{n} A_i \mid A_{i+1} \geq \frac{3}{4}A_i, A_{i+2} \geq \frac{2}{3}A_i, A_1 = 1\right\}, \tag{1.7}$$

which is the minimum of a concave function on a polyhedron. It is a basic fact of convex optimization that this minimum is attained at one of the vertices. Enumerating all vertices now suffices to determine the bound.

The proof of the first KZ-inequality is elementary. The proof of the second KZ-inequality also uses elementary techniques but is already quite involved. To prove an upper bound on γ_5, Korkin and Zolotarev developed other techniques [8]: they characterized the local optima of the objective function of (1.4), which enabled them to enumerate all local optima for $n = 5$. This line of investigation has been continued and is still actively pursued [10].

In this paper, we return to the first approach and focus on the feasible set of (1.5). We develop a method to prove linear inequalities that hold for the outer coefficients of KZ-reduced forms. Our method is numerical and uses recently developed polynomial optimization techniques. We apply our method in particular to forms in five variables and obtain inequalities (Theorems 6.1 and 6.2) that imply, through (1.5), an upper bound on γ_n that is very close to the known value for $n = 5, 6, 7, 8$.

The structure of the paper is as follows. In the next section, we give preliminaries on KZ-reduced forms. In particular, we describe results of Novikova [11] that imply that the set of KZ-reduced forms can be defined by finitely many polynomial inequalities. Proving that a linear inequality on the outer coefficients holds for KZ-reduced forms thus amounts to minimizing the value of a polynomial under finitely many polynomial constraints.

Through recent developments in convex optimization it is possible to find lower bounds for such polynomial optimization problems using semidefinite optimization methods. We describe such a semidefinite relaxation in section 3.

We improve on the lower bound that results from simply computing the semidefinite relaxation by performing a *branch and bound* procedure, which is familiar from integer programming. By splitting the semialgebraic set over which we are optimizing we obtain a number of problems on smaller sets. The relaxation for each of these smaller problems is stronger than the original relaxation and will yield a higher lower bound. Then the smallest of these lower bounds is again a lower bound for the original problem. The branch and bound procedure is described in section 4.

Although we use a numerical method, our final results are exact in the sense that their validity does not depend on the accuracy with which the floating point computations were performed. Each of the many lower bounds we have computed is determined by a convex optimization problem which has a well-defined convex dual. By rounding each optimal dual solution to a nearby rational and feasible solution, an exact lower bound is obtained. Its validity can be verified independently, using only elementary rational arithmetic. The rounding method is described in section 5.

In section 6 we derive, using these tools, several new linear inequalities on the outer coefficients of KZ-reduced forms. We study the relation between these inequalities and the cone of outer coefficients of KZ-reduced forms. The most striking result is that only three of these new inequalities suffice to give very good bounds on Hermite's constant up to dimension 8.

Finally, in section 7 we show how our new inequalities on the outer coefficients lead to better quality estimates for the block KZ-reduction algorithm.

The implementation and verification of our numerical method is worked out in detail in [17].

2. A finite characterization of KZ-reduced forms. A positive definite quadratic form q of two or more variables is KZ-reduced if (**S**) holds, if q_2 is KZ-reduced, and if

$$A_1 \le q(x) \text{ for all nonzero } x \in \mathbb{Z}^n. \tag{2.1}$$

In [11], Novikova stated the following.

THEOREM 2.1. *For each $n \ge 2$, there is a finite set $X_n \subseteq \mathbb{Z}^n$ such that an n-ary form with Lagrange expansion* (1.1) *is KZ-reduced if and only if q_2 is KZ-reduced,* (**S**) *holds, and*

$$A_1 \le q(x) \text{ for all } x \in X_n. \tag{2.2}$$

The proof boils down to the fact that if q_2 is KZ-reduced, $q(0,1,0,\dots,0) \ge A_1$, and (**S**) holds, then $q(x) \ge A_1$ is implied for all but finitely many $x \in \mathbb{Z}^n$. This argument yields highly redundant sets X_n. But the theorem implies the existence of a unique irredundant set X_n, which we will denote by X_n^*. In [11], Novikova gives finite sets X_n for $n \le 8$ and claims irredundancy of these sets for $n \le 5$. It is unfortunate that the proofs were omitted from her paper, as it appears to be a significant challenge to determine these irredundant sets. We were only able to verify her claims for $n \le 4$. For $n \in \{5,6\}$ we find sufficient sets that are slightly larger, and for larger n the sets we compute are much smaller [16]. We have proven necessity for all vectors up to dimension 4 and all of Novikova's vectors in dimension 5.

It is easy to see that $X_n^* = \{x \in \mathbb{Z}^n \mid (x,0) \in X_{n+1}^*\}$ for any $n \ge 2$. Let $\bar{X} := \{(x,0) \mid x \in X\}$. One has

$$X_2^* = \left\{ \begin{bmatrix} 0 \\ 1 \end{bmatrix} \right\}, \tag{2.3}$$

$$X_3^* \setminus \bar{X}_2^* = \left\{ \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \right\}. \tag{2.4}$$

Moreover, $X_4^* \setminus \bar{X}_3^*$ is a set of 12 vectors, and according to Novikova $X_5^* \setminus \bar{X}_4^*$ is a set of 52 vectors [11].

Using Theorem 2.1 we find that in the definition of KZ-reducedness, the requirement (**M**) is equivalent to

$$A_k \le q_k(x) \text{ for all } x \in X_{n-k+1}^*, k = 1, \dots, n-1. \tag{**N**}$$

Thus $(A_1, \dots, A_n, \alpha_{12}, \dots, \alpha_{n-1,n})$ are the outer and inner coefficients of a KZ-reduced form if and only if they satisfy finitely many linear inequalities (**S**) and finitely many cubic inequalities (**N**). The number of inequalities of the second kind seems to grow much faster than that of the first kind as n increases.

It is possible to characterize the KZ-reduced forms using only linear and quadratic inequalities by using a different parametrization of the set of quadratic forms. Let Q

be a positive definite $n \times n$ matrix and let $q(x) := x^t Q x$. Then the Lagrange expansion (1.1) yields a decomposition

$$Q = \sum_{i=1}^{n} a_i^t a_i = C^t C, \tag{2.5}$$

where

$$a_i = \sqrt{A_i}(0, \ldots, 0, 1, -\alpha_{i,i+1}, \ldots, -\alpha_{in}) \tag{2.6}$$

is a row vector for $i = 1, \ldots, n$ and C is the matrix whose ith row is a_i.

Thus C is upper triangular, and $Q = C^t C$ is the Cholesky decomposition of Q.

Let $S^i := [0, \frac{1}{2}] \times [-\frac{1}{2}, \frac{1}{2}]^{n-i-1}$. Then

$$\left\{ \sqrt{A_i}(0, \ldots, 0, 1, -\alpha_{i,i+1}, \ldots, -\alpha_{in}) \mid A_i \geq 0, (\alpha_{i,i+1}, \ldots, \alpha_{in}) \in S^i \right\} \tag{2.7}$$

is a polyhedral cone, so there is a finite set of column vectors, which we call D_i, such that (2.7) equals

$$\{a \in \mathbb{R}^n \mid ad \geq 0 \text{ for all } d \in D_i\}. \tag{2.8}$$

For $x \in \mathbb{Z}^m$, $m \leq n$, we write $\widetilde{x} := (0, \ldots, 0, x_1, \ldots, x_m) \in \mathbb{Z}^n$. Now $q(x) = x^t Q x$ is KZ-reduced if and only if there are row vectors $a_i \in \mathbb{R}^n$ such that $Q = \sum_i a_i^t a_i$ and

(**S'**) $$a_k d \geq 0 \text{ for all } d \in D_k \text{ for } k = 1, \ldots, n;$$

and

(**N'**) $$\sum_{i=k}^{n} (a_i \widetilde{x})^2 \geq a_{kk}^2 \text{ for all } x \in X^*_{n-k+1}, k = 1, \ldots, n-1.$$

3. A semidefinite relaxation. The characterizations above describe the coefficient domain of KZ-reduced forms as a semialgebraic set. There is by now a standard machinery for constructing semidefinite relaxations for the problem of minimizing a polynomial over a semialgebraic set; see [9, 12]. We describe a semidefinite formulation that has the virtue of yielding a reasonable lower bound while using only a moderate number of variables and constraints.

THEOREM 3.1. *Let Q be an $n \times n$ positive definite matrix and let $q(x) = x^t Q x$. Then q is KZ-reduced if and only if there are $n \times n$ matrices $B^1, \ldots, B^n$ such that $Q = B^1 + \cdots + B^n$ and*

(**r**) $$B^k \text{ has rank 1 for } k = 1, \ldots, n;$$

(**p**) $$B^k \text{ is positive semidefinite for } k = 1, \ldots, n;$$

(**s**) $$d_1^t B^k d_2 \geq 0 \text{ for all } d_1, d_2 \in D_k, \text{ for } k = 1, \ldots, n; \text{ and}$$

(**n**) $$\sum_{i=k}^{n} \widetilde{x}^t B^i \widetilde{x} \geq B^k_{kk} \text{ for all } x \in X^*_{n-k+1}, \text{ for } k = 1, \ldots, n-1.$$

Proof. To see necessity, let q be KZ-reduced and let A_i, α_{ij} be its outer and inner coefficients. Put

$$a_i = \sqrt{A_i}(0, \ldots, 0, 1, -\alpha_{i,i+1}, \ldots, -\alpha_{in}). \tag{3.1}$$

Then $a_1, \dots, a_n \in \mathbb{R}^n$ are row vectors satisfying (**S'**) and (**N'**), and such that $Q = \sum_{i=1}^n a_i^t a_i$. Let

$$B^i = a_i^t a_i = A_i \begin{bmatrix} \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & 1 & -\alpha_{i,i+1} & \cdots & -\alpha_{in} \\ \mathbf{0} & -\alpha_{i,i+1} & \alpha_{i,i+1}\alpha_{i,i+1} & \cdots & \alpha_{i,i+1}\alpha_{in} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & -\alpha_{in} & \alpha_{in}\alpha_{i,i+1} & \cdots & \alpha_{in}\alpha_{in} \end{bmatrix}. \tag{3.2}$$

(Here the **0**'s are zero matrices and vectors of appropriate sizes.) Then $(B^1, \dots, B^n)$ satisfies (**r**), (**p**), (**s**), and (**n**).

For sufficiency, let $B^1, \dots, B^n$ be such that $Q = B^1 + \cdots + B^n$ and such that (**r**), (**p**), (**s**), and (**n**) hold. As B' has rank 1, we may write $B^i = a_i^t a_i$, where $a_{ii} \geq 0$. Then a_i satisfies (**N'**). To see that a_i satisfies (**S'**), let e_i be the ith unit vector in $\mathbb{R}^n$. Note that $e_i \in \operatorname{cone} D_i$ and that hence

$$e_i d^t \in \operatorname{cone}\{d_1 d_2^t \mid d_1, d_2 \in D_i\} \tag{3.3}$$

for any $d \in D_i$. From the fact that B^i satisfies (**s**) it follows that $(a_i^t a_i) \cdot D \geq 0$ for all $D \in \operatorname{cone}\{d_1 d_2^t \mid d_1, d_2 \in D_i\}$, and in particular that $(a_i e_i)(a_i d) \geq 0$ for all $d \in D_i$. Thus $a_i d \geq 0$ for all $d \in D_i$. □

So, for $(c_1, \dots, c_n) \in \mathbb{R}^n$, the minimum

$$\min\left\{ \sum_{i=1}^n c_i A_i \mid \sum_i A_i (x_i - \sum_{j>i} \alpha_{ij} x_j)^2 \text{ is KZ-reduced for some } \alpha_{ij}, A_n = 1 \right\} \tag{3.4}$$

equals

$$\min\left\{ \sum_k c_k B_{kk}^k \mid (B^1, \dots, B^n) \text{ satisfies } (\mathbf{r}), (\mathbf{p}), (\mathbf{s}), (\mathbf{n}), \text{ and } B_{nn}^n = 1 \right\}. \tag{3.5}$$

Here the extra condition at the end is added to remove scale invariance from the problem. Dropping the rank-1 constraint (**r**) yields a lower bound that is a semidefinite optimization problem:

$$z(c) := \min\left\{ \sum_{k=1}^n c_k B_{kk}^k \mid (B^1, \dots, B^n) \text{ satisfies } (\mathbf{p}), (\mathbf{s}), (\mathbf{n}), \text{ and } B_{nn}^n = 1 \right\}. \tag{3.6}$$

Note that it is possible to determine the value of (3.6) without knowing the Novikova sets X_i^* in advance, by using a cutting plane algorithm as follows. Replace in (3.6) the constraints (**n**) by the following for certain small sets X_i (for example, take $X_2 = X_2^*$ and the other X_i empty):

$$\sum_{i=k}^n \widetilde{x}^t B^i \widetilde{x} \geq B_{kk}^k \text{ for all } x \in X_{n-k+1}, \text{ for } k = 1, \dots, n-1. \tag{n'}$$

Repeatedly refine these constraints by solving the relaxation and finding, for some k, a nonzero vector $x \in \mathbb{Z}^{n-k+1}$ with $\sum_{i=k}^n \widetilde{x}^t B^i \widetilde{x} < B_{kk}^k$ for the optimal solution to the relaxation. Add this x to X^{n-k+1}. Eventually no such x will be found, and then the optimal solution to this relaxation will be equal to the optimal solution to (3.6).

One can use the techniques in the proof of Theorem 2.1 to bound the search space for these vectors.

A cutting plane algorithm may even be the only practical way to solve the relaxation for $n > 5$, since the cardinality of X_n^* seems to increase very rapidly with n. The following theorem, similar to Theorem 2.1, implies that such a cutting plane algorithm will finish.

THEOREM 3.2. *Let* $(B^1, \dots, B^n)$ *satisfy* (**p**), (**s**), *and suppose that*

$$\sum_{i=1}^{n} e_2^t B^i e_2 \geq B^1_{11}, \tag{3.7}$$

$$\sum_{i=k}^{n} \widetilde{x}^t B^i \widetilde{x} \geq B^k_{kk} \text{ for all nonzero } x \in \mathbb{Z}^{n-k+1}, k = 2, \dots, n-1. \tag{3.8}$$

Then there are only finitely many $x \in \mathbb{Z}^n \setminus \{0\}$ *such that* $\sum_{i=1}^n x^t B^i x < B^1_{11}$.

Compared to the method of Lasserre [9], in particular to a second-order moment relaxation of our polynomial optimization problem, our relaxation contains variables B^k_{ij} corresponding to products $a_{ki}a_{kj}$ but no variables corresponding to products $a_{ki}a_{lj}$ when $k \neq l$. Accordingly, we do not take products of linear inequalities $a_k d_1 \geq 0, a_l d_2 \geq 0$ into account.

4. Branch and bound. In this section we give an overview of the branching process. We refer to [17] for further details and a full implementation. In the definition of KZ-reducedness, the size-reduction requirement (**S**) asks that for $i = 1, \dots, n-1$ we have

$$(\alpha_{i,i+1}, \dots, \alpha_{in}) \in S^i := \left[0, \frac{1}{2}\right] \times \left[-\frac{1}{2}, \frac{1}{2}\right]^{n-i-1}. \tag{4.1}$$

There is nothing particular about the polyhedra S^i that makes the semidefinite relaxation (3.6) possible. Taking any set of polyhedra P^i instead of the S^i, a semidefinite lower bound $z(c, P^1, \dots, P^{n-1})$ analogous to (3.6) for

$$\min \Bigg\{ \sum c_i A_i \mid \sum_i A_i (x_i - \sum_{j>i} \alpha_{ij} x_j)^2 \text{ satisfies (**N**)}, \\ (\alpha_{i,i+1}, \dots, \alpha_{in}) \in P^i \text{ for } i = 1, \dots, n-1, \text{ and } A_n = 1 \Bigg\} \tag{4.2}$$

may be constructed. This new relaxation differs from (3.6) in the constraints (**s**). If the diameter of these polyhedra P^i is small, then the matrix B^i is close to a rank-1 matrix in the following sense. Suppose the width of P^i is small, i.e., for all j,

$$\max\{\alpha_{ij} \mid (\alpha_{i,i+1}, \dots, \alpha_{in}) \in P^i\} - \min\{\alpha_{ij} \mid (\alpha_{i,i+1}, \dots, \alpha_{in}) \in P^i\} < \varepsilon, \tag{4.3}$$

where we assume $\varepsilon < 1$ and $\max\{\alpha_{ij} \mid (\alpha_{i,i+1}, \dots, \alpha_{in}) \in P^i\} \leq 1/2$. Let $(B^1, \dots, B^n)$ be any feasible solution corresponding to $z(c, P^1, \dots, P^{n-1})$. Let $(\widetilde{B}^1, \dots, \widetilde{B}^n)$ be any feasible solution corresponding to $z(c, P^1, \dots, P^{n-1})$ such that $\widetilde{B}^i$ has rank 1. Then for all $j, k \in \{i, \dots, n\}$,

$$|B^i_{jk}/B^i_{ii} - \widetilde{B}^i_{jk}/\widetilde{B}^i_{ii}| \leq 2\varepsilon. \tag{4.4}$$

If we have a set of $(n-1)$-tuples of polyhedra $N = \{(P_s^1, \dots, P_s^{n-1}) \mid s = 1, \dots, t\}$ so that

$$S^1 \times \cdots \times S^{n-1} = \bigcup_{(P^1,\dots,P^{n-1})\in N} P^1 \times \cdots \times P^{n-1}, \tag{4.5}$$

then

$$\min\{z(c, P^1, \dots, P^{n-1}) \mid (P^1, \dots, P^{n-1}) \in N\} \tag{4.6}$$

is again a lower bound for (3.4). If we partition $S^1 \times \cdots \times S^{n-1}$ so that in each part the diameter of each of the P^i is small, then we would obtain a good lower bound. However, this would make the cardinality of N very large, even for moderately small ε. Therefore, we take an iterative approach. Initially we choose $N = \{(S^1, \dots, S^{n-1})\}$. Then we repeat the following. Suppose that the minimum of (4.6) is attained at $(P^1, \dots, P^{n-1}) \in N$. Then we choose an $i \in \{1, \dots, n-1\}$ and replace $(P^1, \dots, P^{n-1})$ in N by the two tuples

$$(P^1, \dots, P^{i-1}, Q, P^{i+1}, \dots, P^{n-1}) \text{ and } (P^1, \dots, P^{i-1}, Q', P^{i+1}, \dots, P^{n-1}), \tag{4.7}$$

where Q, Q' are polyhedra such that $P^i = Q \cup Q'$—so N retains property (4.5). This process of refining N continues until (4.6) is sufficiently close to the desired value or some other stopping criterion applies.

We choose i, Q, Q' with the aim of reducing the "distance" of an optimal solution to a rank-1 solution, as follows. If this optimal solution of the problem with optimum $z(c, P^1, \dots, P^{n-1})$ is $(B^1, \dots, B^n)$, then we take i, j so that

$$\sum_{k=i}^{n} \frac{1}{B_{ii}^i}(B_{ii}^i B_{jk}^i - B_{ij}^i B_{ik}^i) \tag{4.8}$$

is maximal. Then we put

$$\begin{aligned} Q &= \{(\alpha_{i,i+1}, \dots, \alpha_{in}) \in P^i \mid \alpha_{ij} \le \beta\}, \\ Q' &= \{(\alpha_{i,i+1}, \dots, \alpha_{in}) \in P^i \mid \alpha_{ij} \ge \beta\}, \end{aligned} \tag{4.9}$$

where β is (a rational number with modest denominator near) $-B_{ij}^i/B_{ii}^i$.

We have tried other methods for picking i, Q, Q', but this turned out to work best in practice, in the sense that the cardinality of N required to obtain a certain bound was the smallest we could attain. Only by constructing N by hand did we achieve a smaller set for one problem.

5. Rounding to obtain exact bounds. Every feasible solution y to the dual of (3.6) gives a lower bound on $z(c)$ and hence on the optimal solution to (3.4). A dual solution is feasible if and only if a number of matrices, say, $M_1(y), \dots, M_k(y)$, is positive semidefinite. In fact, in our computations we work only with solutions y that are *strictly* positive definite. This simplifies the verification of feasibility, but the crucial advantage is that it helps to counter the imprecision inherent in the computation with limited-precision floating point numbers.

In the dual of (3.6) such solutions can be obtained by replacing a dual constraint $M_i(y) \succeq 0$ with $M_i(y) \succeq \varepsilon I$, where I is an identity matrix of suitable dimension and ε is a small positive constant. Bringing this matrix to the other side, we get the perturbed constraint

$$M_i(y) - \varepsilon I \succeq 0, \tag{5.1}$$

which corresponds to a perturbation of the function that is being optimized in the primal problem. Again we refer the reader to [17] for further details.

A floating-point solution y to the perturbed problem can be approximated by a continued fraction expansion, a technique recently used in [15]. If this approximation $\widetilde{y}$ is sufficiently close to y, it might violate some of the perturbed dual constraints slightly, but it will be strictly feasible for the original problem. Positive definiteness can then be ascertained by evaluating $\sum_{i=1}^{k} \operatorname{rank}(M_i(\widetilde{y}))$ determinants.

Note that this approach can also be applied to find feasible solutions of the primal semidefinite problem but is quite useless when it comes to deriving an optimal solution of the original problem (3.4) or (4.2), that is, a solution that also satisfies the rank-1 constraints (**r**). This is of no concern when one is interested in lower bounds, but it is also interesting to find KZ-reduced forms that give a good upper bound. We do not have a very reliable automated method to obtain such forms—not even from the optimal solution of our branch and bound procedure, which is nonetheless close to rank 1 in the sense that (4.8) is small for all i, j.

6. New linear inequalities on the outer coefficients of KZ-reduced quadratic forms. We define

$$K_n := \operatorname{cone}\{A(q) \mid q \text{ is an } n\text{-ary KZ-reduced form}\}. \tag{6.1}$$

We have

$$K_n = \{x \in \mathbb{R}^n \mid (0, x) \in K_{n+1}\} \tag{6.2}$$

and

$$K_n = \{x \in \mathbb{R}^n \mid (x, y) \in K_{n+1} \text{ for some } y \in \mathbb{R}\}. \tag{6.3}$$

Table 6.1 gives several KZ-reduced forms, some of which come from [13], whereas others were found by manually rounding and tweaking primal solutions to (4.2) for suitably chosen c and polyhedra P^i. The format is as follows: the columns labeled "Outer" and "Inner" hold the vector and matrix

$$\begin{bmatrix} A_1 \\ \vdots \\ A_n \end{bmatrix}, \begin{bmatrix} 1 & -\alpha_{12} & \cdots & -\alpha_{1n} \\ 0 & 1 & \ddots & \vdots \\ \vdots & \ddots & \ddots & -\alpha_{n-1,n} \\ 0 & \cdots & 0 & 1 \end{bmatrix}, \tag{6.4}$$

respectively.

By the first KZ-inequality, K_2 is contained in

$$K_2' := \left\{ (A_1, A_2) \in \mathbb{R}_+^2 \mid \ A_2 \geq \frac{3}{4} A_1 \right\}. \tag{6.5}$$

It follows from Table 6.1 that K_2 contains

TABLE 6.1
Some KZ-reduced forms.

Name	Outer	Inner	Form
E1	$\begin{bmatrix}1\end{bmatrix}$	$\begin{bmatrix}1\end{bmatrix}$	$\begin{bmatrix}1\end{bmatrix}$
E2	$\begin{bmatrix}1\\3/4\end{bmatrix}$	$\begin{bmatrix}1&-1/2\\0&1\end{bmatrix}$	$\frac{1}{2}\begin{bmatrix}2&1\\1&2\end{bmatrix}$
E3a	$\begin{bmatrix}1\\3/4\\2/3\end{bmatrix}$	$\begin{bmatrix}1&-1/2&1/2\\0&1&-1/3\\0&0&1\end{bmatrix}$	$\frac{1}{2}\begin{bmatrix}2&-1&1\\-1&2&-1\\1&-1&2\end{bmatrix}$
E3b	$\begin{bmatrix}1\\8/9\\2/3\end{bmatrix}$	$\begin{bmatrix}1&-1/3&-1/3\\0&1&-1/2\\0&0&1\end{bmatrix}$	$\frac{1}{3}\begin{bmatrix}3&-1&-1\\-1&3&-1\\-1&-1&3\end{bmatrix}$
E4a	$\begin{bmatrix}1\\3/4\\2/3\\1/2\end{bmatrix}$	$\begin{bmatrix}1&-1/2&1/2&1/2\\0&1&-1/3&-1/3\\0&0&1&-1/2\\0&0&0&1\end{bmatrix}$	$\frac{1}{2}\begin{bmatrix}2&-1&1&1\\-1&2&-1&-1\\1&-1&2&0\\1&-1&0&2\end{bmatrix}$
E4b	$\begin{bmatrix}1\\8/9\\2/3\\5/8\end{bmatrix}$	$\begin{bmatrix}1&-1/3&-1/3&1/3\\0&1&-1/2&1/2\\0&0&1&-1/4\\0&0&0&1\end{bmatrix}$	$\frac{1}{6}\begin{bmatrix}6&-2&-2&2\\-2&6&-2&2\\-2&-2&6&-3\\2&2&-3&6\end{bmatrix}$
E4c	$\begin{bmatrix}1\\15/16\\45/64\\5/8\end{bmatrix}$	$\begin{bmatrix}1&-1/4&-1/4&-1/4\\0&1&-1/2&-1/2\\0&0&1&-1/3\\0&0&0&1\end{bmatrix}$	$\frac{1}{32}\begin{bmatrix}32&-8&-8&-8\\-8&32&-13&-13\\-8&-13&32&2\\-8&-13&2&32\end{bmatrix}$
E5a	$\begin{bmatrix}1\\3/4\\2/3\\1/2\\1/2\end{bmatrix}$	$\begin{bmatrix}1&-1/2&1/2&1/2&1/2\\0&1&-1/3&-1/3&-1/3\\0&0&1&-1/2&1/4\\0&0&0&1&-1/2\\0&0&0&0&1\end{bmatrix}$	$\frac{1}{2}\begin{bmatrix}2&-1&1&1&1\\-1&2&-1&-1&-1\\1&-1&2&0&1\\1&-1&0&2&0\\1&-1&1&0&2\end{bmatrix}$
E5b	$\begin{bmatrix}1\\8/9\\2/3\\5/8\\15/32\end{bmatrix}$	$\begin{bmatrix}1&-1/3&-1/3&-1/3&-1/3\\0&1&-1/2&7/16&-1/2\\0&0&1&-3/8&-1/4\\0&0&0&1&-1/2\\0&0&0&0&1\end{bmatrix}$	$\frac{1}{6}\begin{bmatrix}6&-2&-2&-2&-2\\-2&6&-2&3&-2\\-2&-2&6&-2&1\\-2&3&-2&6&-2\\-2&-2&1&-2&6\end{bmatrix}$
E5c	$\begin{bmatrix}1\\3/4\\2/3\\5/8\\15/32\end{bmatrix}$	$\begin{bmatrix}1&-1/2&1/2&-1/2&-1/2\\0&1&-1/3&1/3&1/3\\0&0&1&-1/4&-1/4\\0&0&0&1&-1/2\\0&0&0&0&1\end{bmatrix}$	$\frac{1}{16}\begin{bmatrix}16&-8&8&-8&-8\\-8&16&-8&8&8\\8&-8&16&-8&-8\\-8&8&-8&16&1\\-8&8&-8&1&16\end{bmatrix}$
E5d	$\begin{bmatrix}1\\3/4\\3/4\\9/16\\1/2\end{bmatrix}$	$\begin{bmatrix}1&-1/2&1/4&-1/4&1/2\\0&1&-1/2&-1/2&0\\0&0&1&-1/2&1/2\\0&0&0&1&-1/3\\0&0&0&0&1\end{bmatrix}$	$\frac{1}{4}\begin{bmatrix}4&-2&1&-1&2\\-2&4&-2&-1&-1\\2&-2&4&-1&2\\-1&-1&-1&4&-2\\2&-1&2&-2&4\end{bmatrix}$

$$K_2'' := \operatorname{cone}\left\{\begin{bmatrix}0\\1\end{bmatrix}, \begin{bmatrix}1\\3/4\end{bmatrix}\right\}. \tag{6.6}$$

Since $K_2' = K_2''$, we have equality throughout in $K_2' \supseteq K_2 \supseteq K_2''$.

Also, K_3 is contained in

$$K_3' := \left\{(A_1, A_2, A_3) \in \mathbb{R}^3_+ \mid A_2 \geq \frac{3}{4}A_1,\ A_3 \geq \frac{3}{4}A_2,\ A_3 \geq \frac{2}{3}A_1\right\} \tag{6.7}$$

by the first and second KZ-inequalities, and K_3 contains

$$K_3'' := \operatorname{cone}\left\{\begin{bmatrix}0\\0\\1\end{bmatrix}, \begin{bmatrix}0\\1\\3/4\end{bmatrix}, \begin{bmatrix}1\\3/4\\2/3\end{bmatrix}, \begin{bmatrix}1\\8/9\\2/3\end{bmatrix}\right\}. \tag{6.8}$$

Again we have equality throughout in $K_3' \supseteq K_3 \supseteq K_3''$, as $K_3' = K_3''$.

For $n = 4$ the classical KZ-inequalities no longer suffice to determine K_n. By the first and second KZ-inequalities, K_4 is contained in

$$\left\{(A_1, A_2, A_3, A_4) \in \mathbb{R}_+^4 \mid A_{i+1} \geq \frac{3}{4}A_i,\ A_{i+2} \geq \frac{2}{3}A_i\right\}. \tag{6.9}$$

But the extremal vector $(1, \frac{8}{9}, \frac{2}{3}, \frac{16}{27})$ of this cone cannot be realized as the sequence of outer coefficients of a KZ-reduced form.

THEOREM 6.1. *Let $A_1, \ldots, A_4$ be the outer coefficients of a KZ-reduced form in four variables. Then*

$$-25A_1 - 36A_2 + 48A_3 + 40A_4 \geq -7 \cdot 10^{-6} A_4. \tag{6.10}$$

This theorem was proven by the branch-and-bound and rounding processes described in the previous sections. The data required to verify this theorem can be found in [17].

Thus $K_4 \subseteq K_4'$, where

$$K_4' := \left\{(A_1, A_2, A_3, A_4) \in \mathbb{R}_+^4 \mid\ A_{i+1} \geq \frac{3}{4}A_i,\ A_{i+2} \geq \frac{2}{3}A_i,\ (6.10)\right\}. \tag{6.11}$$

We conjecture that in the above theorem we even have

$$-25A_1 - 36A_2 + 48A_3 + 40A_4 \geq 0. \tag{6.12}$$

By Table 6.1, K_4 contains the cone

$$K_4'' := \operatorname{cone}\left\{\begin{bmatrix}0\\0\\0\\1\end{bmatrix}, \begin{bmatrix}0\\0\\1\\3/4\end{bmatrix}, \begin{bmatrix}0\\1\\3/4\\2/3\end{bmatrix}, \begin{bmatrix}0\\1\\8/9\\2/3\end{bmatrix}, \begin{bmatrix}1\\3/4\\2/3\\1/2\end{bmatrix}, \begin{bmatrix}1\\8/9\\2/3\\5/8\end{bmatrix}, \begin{bmatrix}1\\15/16\\45/64\\5/8\end{bmatrix}\right\}, \tag{6.13}$$

and we have

$$K_4'' = \left\{(A_1, A_2, A_3, A_4) \in \mathbb{R}_+^4 \mid\ A_{i+1} \geq \frac{3}{4}A_i,\ A_{i+2} \geq \frac{2}{3}A_i,\ (6.12)\right\}. \tag{6.14}$$

Hence K_4 is nearly determined by $K_4'' \supseteq K_4 \supseteq K_4'$, and our conjecture would imply $K_4 = K_4''$.

In dimension 5, we prove the following linear bounds.

THEOREM 6.2. *Let $A_1, \ldots, A_5$ be the outer coefficients of a KZ-reduced form in five variables. Then*

$$-5A_1 + 2A_4 + 8A_5 \geq -3 \cdot 10^{-4} A_5 \tag{6.15}$$

and

$$-4A_1 - 3A_3 + 4A_4 + 8A_5 \geq -5 \cdot 10^{-5} A_5. \tag{6.16}$$

TABLE 6.2
Incidences between some inequalities and elements of K_5. The rightmost column gives the dimension of the face of K_5 defined by the inequality.

Inequality	"Tight" forms	Rank
$-3A_1 + 4A_2 \geq 0$	E1, E2, E3a, E3b	4
$-3A_2 + 4A_3 \geq 0$	E1, E2, E4a, E5b	4
$-3A_3 + 4A_4 \geq 0$	E1, E3a, E4b, E4c	4
$-3A_4 + 4A_5 \geq 0$	E2, E3b, E4a, E5b	4
$-2A_1 + 3A_3 \geq 0$	E1, E2, E5a, E5b	4
$-2A_2 + 3A_4 \geq 0$	E1, E4a, E4b, E5a	4
$-2A_3 + 3A_5 \geq 0$	E3a, E3b, E5b	≥ 3
$-25A_1 - 36A_2 + 48A_3 + 40A_4 \geq 0$	E1, E5a, E5b	≥ 3
$-25A_2 - 36A_3 + 48A_4 + 40A_5 \geq 0$	E4a, E4b, E4c	≥ 3
$-5A_1 + 2A_4 + 8A_5 \geq 0$	E5a, E5b, E5c	≥ 3
$-4A_1 - 3A_3 + 4A_4 + 8A_5 \geq 0$	E5a, E5d	≥ 2

Of course, we conjecture

$$-5A_1 + 2A_4 + 8A_5 \geq 0 \tag{6.17}$$

and

$$-4A_1 - 3A_3 + 4A_4 + 8A_5 \geq 0. \tag{6.18}$$

As before, these inequalities describe a superset K_5' of K_5, and the forms of Table 6.1 generate a subset K_5'' of K_5. But there is now a fundamental discrepancy between K_5' and K_5''. Table 6.2 lists the known and conjectured inequalities for K_5 and with each inequality gives the forms of Table 6.1 that satisfy these inequalities with equality. Experimentation suggests that both inclusions in $K_5'' \subseteq K_5 \subseteq K_5'$ are strict (even if we replace, in the definition of K_5', the inequalities proven in Theorem 6.2 by their conjectured counterparts).

As an example, the four forms E5a, E5b, E5c, and E5d satisfy the following inequality:

$$-8A_1 - 3A_3 + 4A_4 + 16A_5 \geq 0. \tag{6.19}$$

One could conjecture that this is a facet of K_5. This is false, however; it is violated by the KZ-reduced form

$$\begin{bmatrix} 134 & -54 & -40 & -54 & 54 \\ -54 & 134 & -40 & 67 & -67 \\ -40 & -40 & 134 & -40 & -27 \\ -54 & 67 & -40 & 134 & -67 \\ 54 & -67 & -27 & -67 & 134 \end{bmatrix}. \tag{6.20}$$

We could obtain several other extreme forms in five variables and more valid inequalities, but we never reached a close approximation of K_5. Therefore, we publish only the two inequalities that seemed most relevant to the applications here. We maintain a list of certified inequalities at our website,[2] where our software [17] can also be found.

TABLE 6.3

Relation between Hermite's constant and the approximation found. The first row gives the exact value of γ_n^n for $n \leq 8$, and the best known lower bound for $n = 9$. The second row gives the upper bound found using our approximation of K_n.

Dimension	1	2	3	4	5	6	7	8	9
(Lower bound on) γ_n^n	1	4/3	2	4	8	64/3	64	256	512
Upper bound	1	4/3	2	4	8.00005	21.3336	64.0012	256.008	1024.11

Even though we do not have a close approximation of K_5, we do have enough inequalities on the outer coefficients to bound Hermite's constant for $n \leq 8$ very well. Assuming the conjectured inequalities (6.12), (6.17), and (6.18), the upper bound on γ_n^n that would follow from the corresponding strengthening of (1.6) is exact for $n \leq 8$. Table 6.3 gives for $n = 1, \ldots, 8$ the known values of γ_n^n, and the upper bound on γ_n^n that follows from the proven inequalities (6.10), (6.15), and (6.16). In dimension 9 there is suddenly a huge gap between our upper bound and the best known lower bound. This gap is also larger than the gap obtained by the Cohn–Elkies bound. One or more new inequalities are needed to close this gap.

Blichfeldt observed in [1] that a tight upper bound on γ_n would follow for $n = 6, 7, 8$ from the two KZ-inequalities and "a certain inequality that we would reasonably expect to be true, namely, $A_{i+4} \geq \frac{1}{2}A_i$." But he immediately exhibits a set of forms showing that this inequality is false (the forms E5b and E5c of Table 6.1 are also counterexamples). Note that the inequalities we conjecture/approximate come near to this key inequality Blichfeldt suggests: (6.18) would imply that if $A_4 = \frac{3}{4}A_3$, then $A_5 \geq \frac{1}{2}A_1$, and (6.17) would imply that if $A_5 \leq (\frac{1}{2} - \epsilon)A_1$, then $A_4 \geq (\frac{1}{2} + 4\epsilon)A_1$.

7. The quality of block KZ-reduced lattice bases. If $L \subseteq \mathbb{R}^n$ is a full-dimensional lattice and $b_1, \ldots, b_n \in L$ are linearly independent vectors such that

$$L = \{x_1 b_1 + \cdots + x_n b_n \mid x_1, \ldots, x_n \in \mathbb{Z}\}, \tag{7.1}$$

then $b_1, \ldots, b_n$ is a *basis* of L. A basis of a lattice determines a positive definite quadratic form

$$q(x_1, \ldots, x_n) := \|x_1 b_1 + \cdots + x_n b_n\|^2. \tag{7.2}$$

A lattice basis $b_1, \ldots, b_n$ is said to be *KZ-reduced* if the associated form (7.2) is KZ-reduced.

Let $b_1^*, \ldots, b_n^*$ be the Gram–Schmidt orthogonalization of $b_1, \ldots, b_n$; that is, let $b_1^*, \ldots, b_n^*$ be pairwise orthogonal vectors so that

$$b_k = b_k^* - \sum_{i=1}^{k-1} \alpha_{ik} b_i^* \text{ for } k = 1, \ldots, n, \tag{7.3}$$

for some α_{ij}. Then these α_{ij} are exactly the inner coefficients of the associated form (7.2); and the outer coefficients of (7.2) satisfy

$$A_k = \|b_k^*\|^2. \tag{7.4}$$

So the classical KZ-inequalities and Theorems 6.1 and 6.2 can be read as inequalities relating the $\|b_i^*\|^2$ of a KZ-reduced lattice basis.

Block KZ-reduced lattice bases were introduced in [14] as a generalization of Lenstra–Lenstra–Lovasz (LLL-) reduced lattice bases. Such a basis gives a better estimate of the length of the shortest lattice vector and can still be computed in polynomial time when k is fixed. We say that a form

$$q(x_1,\dots,x_n)=\sum_{i=1}^{n} A_i\Big(x_i-\sum_{j>i}\alpha_{ij}x_j\Big)^2, \tag{7.5}$$

is *k-block KZ-reduced (k-BKZ-reduced)* if the derived forms

$$q_m^{m+k-1}(x_m,\dots,x_{m+k-1}):=\sum_{i=k}^{k+m-1} A_i\Big(x_i-\sum_{j=i+1}^{k+m-1}\alpha_{ij}x_j\Big)^2 \tag{7.6}$$

are KZ-reduced for $m=1,\dots,n-k+1$. Then a lattice basis is k-BKZ-reduced if the associated form is. In the remainder of this paper we will give some improved bounds on constants used in [14] for the analysis of the quality of k-BKZ-reduced lattice bases.

Let

$$\beta_{k,n}:=\max\frac{\|b_1^*\|^2}{\|b_n^*\|^2}, \tag{7.7}$$

where the maximum ranges over all k-BKZ-reduced lattice bases. Many of the useful properties of k-BKZ-reduced lattice bases are derived through upper bounds on $\beta_{k,n}$. As k increases toward n, $\beta_{k,n}$ is expected to decrease. Schnorr [14] defines $\alpha_k:=\beta_{k,k}$ and shows that

$$\beta_{k,1+m(k-1)}\le\alpha_k^m. \tag{7.8}$$

In terms of quadratic forms, one has

$$\beta_{k,n}=\max\left\{\frac{A_1}{A_n}\mid (A_1,\dots,A_n)=A(q),\ q \text{ a } k\text{-BKZ-reduced form}\right\} \tag{7.9}$$

and

$$\alpha_k=\max\left\{\frac{A_1}{A_k}\mid (A_1,\dots,A_k)=A(q),\ q \text{ a KZ-reduced form}\right\}. \tag{7.10}$$

It is immediate from the first KZ-inequality that $\alpha_2=\frac{4}{3}$ and from the second KZ-inequality that $\alpha_3=\frac{3}{2}$. A nonnegative combination of the inequalities (6.15) and $-\frac{3}{4}A_4+A_5\ge 0$ (the first KZ-inequality) is

$$-15A_1+32A_5\ge -9\cdot 10^{-4}A_5, \tag{7.11}$$

which implies

$$\alpha_5\le\frac{32}{15}+6\cdot 10^{-5}. \tag{7.12}$$

Since there exist KZ-reduced forms with $A_1/A_5=32/15$, we also have $\alpha_5\ge\frac{32}{15}$. For $k=4,5$, the bounds on $\beta_{k,n}$ that follow from (7.8) are only slightly weaker than those that follow directly from Theorems 6.1 and 6.2 by linear programming.

The limit

$$\widetilde{\beta}_k := \lim_{n\to\infty} \beta_{k,n}^{\frac{1}{n-1}} \tag{7.13}$$

also gives an indication of the relative effectiveness of k-BKZ-reduction. Observe that if an inequality $c_1 A_i + \cdots + c_k A_{i+k-1} \geq 0$ with $c_1 < 0$ holds for the outer coefficients of a KZ-reduced form in k variables, then $\widetilde{\beta}_k$ is bounded from above by the largest root of the polynomial $c_1 x^{k-1} + \cdots + c_k$. Thus the first KZ-inequality implies $\widetilde{\beta}_2 \leq 4/3 \approx 1.3333$, the second KZ-inequality implies $\widetilde{\beta}_3 \leq \sqrt{3/2} \approx 1.2247$, Theorem 6.1 implies $\widetilde{\beta}_4 \leq 1.2172$, and Theorem 6.2 (in particular (6.15)) implies $\widetilde{\beta}_5 \leq 1.2010$.

Acknowledgments. We thank Achill Schürmann and two anonymous referees for their comments, which improved the paper considerably.

CONVERGENCE OF THE GRADIENT SAMPLING ALGORITHM FOR NONSMOOTH NONCONVEX OPTIMIZATION*

KRZYSZTOF C. KIWIEL†

Abstract. We study the gradient sampling algorithm of Burke, Lewis, and Overton for minimizing a locally Lipschitz function f on $\mathbb{R}^n$ that is continuously differentiable on an open dense subset. We strengthen the existing convergence results for this algorithm and introduce a slightly revised version for which stronger results are established without requiring compactness of the level sets of f. In particular, we show that with probability 1 the revised algorithm either drives the f-values to $-\infty$, or each of its cluster points is Clarke stationary for f. We also consider a simplified variant in which the differentiability check is skipped and the user can control the number of f-evaluations per iteration.

1. Introduction.

In two recent papers [BLO02b, BLO05], Burke, Lewis, and Overton introduced and established convergence of the *gradient sampling* (GS) algorithm for minimizing a locally Lipschitz function $f : \mathbb{R}^n \to \mathbb{R}$ which is continuously differentiable on an open dense subset D of $\mathbb{R}^n$ and has bounded level sets.

At each iteration, the GS algorithm computes the gradient of f at the current iterate and at $m \geq n+1$ randomly generated nearby points. This bundle of gradients is used to find an approximate ϵ-steepest descent direction, where ϵ is the sampling radius, as the solution of a quadratic program. A standard Armijo line search along this direction produces a candidate for the next iterate, which is obtained by perturbing the candidate, if necessary, to stay in the set D where f is differentiable; the perturbation is random and small enough to maintain the Armijo sufficient descent property. The sampling radius ϵ may be fixed for all iterations or may be reduced dynamically. For ϵ fixed, the main convergence result of [BLO05, Theorem 3.4] established that, with probability 1, the GS algorithm generates a sequence with a cluster point that is ϵ-stationary for f (as defined in section 2). For ϵ reduced dynamically, the result of [BLO05, Theorem 3.8] established that if the GS algorithm converges to a point, this limit point is stationary for f with probability 1.

The GS algorithm is not only very interesting in theory (especially due to its ingenious use of gradients instead of subgradients [BLO02a]) but also widely applicable and robust in practice [BHLO06, BLO04, BLO05, Lew05].

This paper provides stronger convergence results for the GS algorithm. For ϵ fixed, we show that with probability 1 *every* cluster point of the GS algorithm is ϵ-stationary for f (see Theorem 3.6). For ϵ reduced dynamically, we show that with probability 1 every cluster point of a well-defined subsequence is stationary for f (see Theorem 3.4), without assuming that the whole sequence converges. In both cases, we show that suitable stopping criteria ensure with probability 1 that the algorithm

*Received by the editors September 6, 2005; accepted for publication (in revised form) October 20, 2006; published electronically May 7, 2007.

†Systems Research Institute, Polish Academy of Sciences, Newelska 6, 01–447 Warsaw, Poland (kiwiel@ibspan.waw.pl).

terminates with the required "optimality certificate" of [BLO05, p. 768]; this practical aspect was not analyzed in [BLO05, section 3].

We also introduce a slight revision of the GS algorithm, in which the perturbation of the Armijo candidate is controlled by the current step size (instead of ϵ as in the original method; see (2.6)). This tiny modification enables us to derive much stronger convergence results; in particular, we can dispense with the assumption of [BLO05] that f has compact level sets. For ϵ fixed, we show that with probability 1 either the algorithm drives the f-values to $-\infty$, or every cluster point of a well-defined subsequence of its iterates is ϵ-stationary for f (see Theorem 3.5). For ϵ reduced dynamically, we show that with probability 1 the algorithm either drives the f-values to $-\infty$, or *each* of its cluster points is stationary for f (see Theorem 3.3); in a sense, this is the best result one can hope for. If $\inf f > -\infty$, in both cases suitable stopping criteria ensure with probability 1 that the algorithm terminates with the required "optimality certificate."

Our further modifications of the GS algorithm are intended to improve its performance in practice. Since the GS algorithm employs search directions of unit 2-norm, the number of f-evaluations per Armijo's line search can grow to infinity as the algorithm converges. To mitigate this drawback, we consider using an "unscaled" search direction, i.e., the negative of the convex combination of the gradients in the bundle whose norm is minimized. (This direction was used in [BLO02b, section 3] for a different line search.) The third alternative is to scale the direction so that its length equals ϵ and the Armijo line search is made within the ball in which gradient sampling occurs.

Finally, we introduce a lower bound on step sizes tested by the Armijo search, accepting a null step size when this bound is reached. Here the idea is simple: when the search direction is good enough, a step size close to our lower bound should work, whereas if the search direction is poor, the Armijo search will produce a tiny step size anyway. In our limited Armijo line search (see Procedure 4.3), the number of f-evaluations can be controlled by the choice of an initial step size; in an extreme version, just one evaluation occurs. Further, for our limited line search there is no longer any need for keeping the iterates in the set D where f is differentiable. Skipping the differentiability check makes life easier for the user who provides gradient values and brings the simplified algorithm closer to the version implemented and tested in [BLO05, section 4].

Among other algorithms for minimizing locally Lipschitz functions, we should mention bundle methods (see the references in [BLO05, Kiw96]). Bundle methods require the computation of a single subgradient at each trial point in addition to the objective value. They generate search directions by solving quadratic programs based on accumulated subgradients and employ line searches which either produce descent or find a new subgradient that modifies the next search direction. At first sight, they have little in common with the GS algorithm, which does not accumulate gradients. We believe, however, that deeper understanding of their similarities and differences should lead to new variants. The first step in this direction is made here: the proof technique of section 3 is borrowed from [Kiw96, section 3], and the limited line search of section 4.3 is inspired by null steps of bundle methods. We defer consideration of gradient sampling in bundle methods, as well as numerical comparisons, to future work.

The paper is organized as follows. A slightly revised version of the GS algorithm is presented in section 2. A convergence analysis of the original and revised versions is given in section 3. Various modifications are discussed in section 4.

2. The GS algorithm. As in [BLO05], we assume that the objective function $f : \mathbb{R}^n \to \mathbb{R}$ is locally Lipschitz continuous and continuously differentiable on an open dense subset D of $\mathbb{R}^n$. The Clarke *subdifferential* [Cla83] of f at any point x is given by

$$\bar{\partial} f(x) = \mathrm{co}\big\{ \lim_j \nabla f(y^j) : y^j \to x, y^j \in D \big\},$$

where co denotes the convex hull, and the Clarke ϵ-*subdifferential* [Gol77] by

$$\bar{\partial}_\epsilon f(x) := \mathrm{co}\, \bar{\partial} f(B(x, \epsilon)), \tag{2.1}$$

where $B(x, \epsilon) := \{y : |y - x| \le \epsilon\}$ is the ball centered at x with radius $\epsilon \ge 0$ and $|\cdot|$ is the 2-norm. The Clarke ϵ-subdifferential $\bar{\partial}_\epsilon f(x)$ is approximated by the set of [BLO05]

$$G_\epsilon(x) := \mathrm{cl}\,\mathrm{co}\, \nabla f(B(x, \epsilon) \cap D), \tag{2.2}$$

since $G_\epsilon(x) \subset \bar{\partial}_\epsilon f(x)$, and $\bar{\partial}_{\epsilon_1} f(x) \subset G_{\epsilon_2}(x)$ for $0 \le \epsilon_1 < \epsilon_2$. We say that a point x is *stationary* for f if $0 \in \bar{\partial} f(x)$; x is called ϵ-*stationary* for f if $0 \in \bar{\partial}_\epsilon f(x)$.

We now state a slightly revised version of the GS algorithm [BLO05, section 2]. In particular, we do not require that the starting point $x^1 \in D$ is such that the level set $\{x : f(x) \le f(x^1)\}$ is compact. For a closed convex set G, $\mathrm{Proj}(0 \,|\, G)$ is its minimum-norm element.

Algorithm 2.1 (revised GS algorithm).

Step 0 (initialization). Select an initial point $x^1 \in D$, optimality tolerances $\nu_{\mathrm{opt}}, \epsilon_{\mathrm{opt}} \ge 0$, line search parameters β, γ in $(0, 1)$, reduction factors μ, θ in $(0, 1]$, a sampling radius $\epsilon_1 > 0$, a stationarity target $\nu_1 \ge 0$, and a sample size $m \ge n + 1$. Set $k := 1$.

Step 1 (approximate the Clarke ϵ-subdifferential by gradient sampling). Let $\{x^{ki}\}_{i=1}^m$ be sampled independently and uniformly from $B(x^k, \epsilon_k)$. If $\{x^{ki}\}_{i=1}^m \not\subset D$, then stop; otherwise, set

$$G_k := \mathrm{co}\big\{\nabla f(x^k), \nabla f(x^{k1}), \ldots, \nabla f(x^{km})\big\}. \tag{2.3}$$

Step 2 (direction finding). Set $g^k := \mathrm{Proj}(0 \,|\, G_k)$.

Step 3 (stopping criterion). If $|g^k| \le \nu_{\mathrm{opt}}$ and $\epsilon_k \le \epsilon_{\mathrm{opt}}$, terminate.

Step 4 (sampling radius update). If $|g^k| \le \nu_k$, set $\nu_{k+1} := \theta\nu_k$, $\epsilon_{k+1} := \mu\epsilon_k$, $t_k := 0$, and $x^{k+1} := x^k$ and go to Step 7. Otherwise, set $\nu_{k+1} := \nu_k$, $\epsilon_{k+1} := \epsilon_k$, and

$$d^k := -g^k/|g^k|. \tag{2.4}$$

Step 5 (line search). Set the step size

$$t_k := \max\big\{ t : f(x^k + td^k) < f(x^k) - \beta t|g^k|, t \in \{1, \gamma, \gamma^2, \ldots\} \big\}. \tag{2.5}$$

Step 6 (updating). If $x^k + t_k d^k \in D$, set $x^{k+1} := x^k + t_k d^k$. Otherwise, let x^{k+1} be any point in D satisfying

$$f(x^{k+1}) < f(x^k) - \beta t_k |g^k|, \tag{2.6a}$$

$$|x^k + t_k d^k - x^{k+1}| \le \min\{t_k, \epsilon_k\}. \tag{2.6b}$$

Step 7. Increase k by 1 and go to Step 1.

The algorithm keeps every iterate x^k in the set D. At Step 2, g^k is characterized by $g^k \in G_k$ and $\langle g, g^k\rangle \geq |g^k|^2$ for all $g \in G_k$; since $\nabla f(x^k) \in G_k$ by (2.3), (2.4) yields $\langle \nabla f(x^k), d^k\rangle \leq -|g^k|$. Hence the Armijo line search (2.5) is well defined, because there is $\bar{t} > 0$ such that $f(x^k + td^k) < f(x^k) - \beta t|g^k|$ for all $t \in (0, \bar{t})$.

The only significant difference between Algorithm 2.1 and the original GS algorithm [BLO05, section 2] lies in the slightly stronger requirement (2.6). Namely, if $x^k + t_k d^k \notin D$, x^{k+1} can be found as follows. For $i = 1, 2, \ldots$, sample x^{k+1} from a uniform distribution on $B(x^k + t_k d^k, \min\{t_k, \epsilon_k\}/i)$ until $x^{k+1} \in D$ and (2.6a) holds. By (2.5) and the continuity of f, this procedure terminates with probability 1. In contrast, the original GS algorithm requires finding $\hat{x}^k$ in $B(x^k, \epsilon_k)$ such that $\hat{x}^k + t_k d^k \in D$ and (2.6a) holds for $x^{k+1} := \hat{x}^k + t_k d^k$; to this end, one can sample $\hat{x}^k$ from a uniform distribution on $B(x^k, \epsilon_k/i)$ until these requirements are met. Further, if (2.6) holds, then $\hat{x}^k := x^{k+1} - t_k d^k$ satisfies the requirements of the original GS algorithm. This is the only reason for including ϵ_k in (2.6b). On the other hand, the presence of t_k in (2.6b) yields $|x^{k+1} - x^k| \leq 2t_k$ (using $|d^k| = 1$ by (2.4)) and hence the highly useful consequence of (2.6a)

$$f(x^{k+1}) \leq f(x^k) - \beta\tfrac{1}{2}|x^{k+1} - x^k||g^k|. \tag{2.7}$$

Note that this key inequality (2.7) holds also when $x^{k+1} := x^k + t_k d^k$ at Step 6 (thanks to (2.5)) or when $x^{k+1} := x^k$ at Step 4.

The stopping criterion of Step 3 delivers the "optimality certificate" of [BLO05, p. 768]: the final values of $|g^k|$ and ϵ_k provide an estimate of nearness to Clarke stationarity.

3. Convergence analysis. We start with two technical lemmas. The first lemma on approximate least-norm elements is a simplified version of [BLO05, Lemma 3.1].

LEMMA 3.1. *Let $\emptyset \neq C \subset \mathbb{R}^n$ be compact convex and $\beta \in (0,1)$. If $0 \notin C$, there exists $\delta > 0$ such that $u, v \in C$ and $|u| \leq \operatorname{dist}(0 \,|\, C) + \delta$ imply $\langle v, u\rangle > \beta|u|^2$.*

Proof. If the assertion were false, we could pick two sequences $\{u^i\}, \{v^i\} \subset C$ satisfying $|u^i| \leq \operatorname{dist}(0 \,|\, C) + 1/i$ and $\langle v^i, u^i\rangle \leq \beta|u^i|^2$. By compactness, we may assume $u^i \to \bar{u} \in C$, $v^i \to \bar{v} \in C$; thus $\langle \bar{v}, \bar{u}\rangle \leq \beta|\bar{u}|^2$. However, $\bar{u} = \operatorname{Proj}(0 \,|\, C) \neq 0$ satisfies $\langle v, \bar{u}\rangle \geq |\bar{u}|^2$ for all $v \in C$, a contradiction. ∎

The next lemma recalls from [BLO05, Lemma 3.2] basic properties of the set of points close to a given point $\bar{x}$ that can be used to provide a δ-approximation to the least-norm element of $G_\epsilon(\bar{x})$; its second part summarizes some useful ideas from the proof of [BLO05, Theorem 3.4]. For $\epsilon, \delta > 0$ and $\bar{x}, x \in \mathbb{R}^n$, using the measure of proximity to ϵ-stationarity

$$\rho_\epsilon(\bar{x}) := \operatorname{dist}(0 \,|\, G_\epsilon(\bar{x})), \tag{3.1}$$

let

$$D_\epsilon^m(x) := \prod_1^m (B(x, \epsilon) \cap D) \subset \prod_1^m \mathbb{R}^n \tag{3.2}$$

and

$$V_\epsilon(\bar{x}, x, \delta) := \big\{ (y^1, \ldots, y^m) \in D_\epsilon^m(x) : \operatorname{dist}(0 \,|\, \operatorname{co}\{\nabla f(y^i)\}_{i=1}^m) \leq \rho_\epsilon(\bar{x}) + \delta \big\}. \tag{3.3}$$

LEMMA 3.2. *Let $\epsilon > 0$ and $\bar{x} \in \mathbb{R}^n$.*

(i) *For any $\delta > 0$, there is $\tau > 0$ and a nonempty open set $\bar{V}$ satisfying $\bar{V} \subset V_\epsilon(\bar{x}, x, \delta)$ for all $x \in B(\bar{x}, \tau)$, and* $\operatorname{dist}(0 \,|\, \operatorname{co}\{\nabla f(y^i)\}_{i=1}^m) \le \rho_\epsilon(\bar{x}) + \delta$ *for all* $(y^1, \ldots, y^m) \in \bar{V}$.

(ii) *Assuming $0 \notin G_\epsilon(\bar{x})$, pick $\delta > 0$ as in Lemma* 3.1 *for $C := G_\epsilon(\bar{x})$, and then τ and $\bar{V}$ as in statement* (i). *Suppose at iteration k of Algorithm* 2.1, *Step* 5 *is reached with $x^k \in B(\bar{x}, \min\{\tau, \epsilon/3\})$, $\epsilon_k = \epsilon$, and $(x^{k1}, \ldots, x^{km}) \in \bar{V}$. Then $t_k \ge \min\{1, \gamma\epsilon/3\}$.*

(iii) *If $\underline{\lim}_k \max\{|x^k - \bar{x}|, |g^k|, \epsilon_k\} = 0$ with $g^k \in \bar{\partial}_{\epsilon_k} f(x^k)$ for all k, then $0 \in \bar{\partial} f(\bar{x})$.*

Proof. (i) Let $u \in \operatorname{co} \nabla f(B(\bar{x}, \epsilon) \cap D)$ be such that $|u| < \rho_\epsilon(\bar{x}) + \delta$. Then Carathéodory's theorem [Roc70] implies the existence of $(\bar{x}^1, \ldots, \bar{x}^m) \in D_\epsilon^m(\bar{x})$ and $\bar{\lambda} \in \mathbb{R}_+^m$ with $\sum_{i=1}^m \bar{\lambda}_i = 1$ such that $u = \sum_{i=1}^m \bar{\lambda}_i \nabla f(\bar{x}^i)$. Since f is continuously differentiable on the open set D, there is $\bar{\epsilon} \in (0, \epsilon)$ such that the set $\bar{V} := \prod_{i=1}^m \operatorname{int} B(\bar{x}^i, \bar{\epsilon})$ lies in $D_{\epsilon-\bar{\epsilon}}^m(\bar{x})$ and $|\sum_{i=1}^m \bar{\lambda}_i \nabla f(y^i)| < \rho_\epsilon(\bar{x}) + \delta$ for all $(y^1, \ldots, y^m) \in \bar{V}$. Hence for all $x \in B(\bar{x}, \tau)$ with $\tau := \bar{\epsilon}$, the fact that $B(\bar{x}, \epsilon - \bar{\epsilon}) \subset B(x, \epsilon)$ yields $\bar{V} \subset V_\epsilon(\bar{x}, x, \delta)$ by the definitions (3.2)–(3.3).

(ii) Let $\hat{G}_k := \operatorname{co}\{\nabla f(x^{ki})\}_{i=1}^m$. Since $(x^{k1}, \ldots, x^{km}) \in \bar{V} \subset V_\epsilon(\bar{x}, \bar{x}, \delta)$ in statement (i), we get $\operatorname{dist}(0 \,|\, \hat{G}_k) \le \rho_\epsilon(\bar{x}) + \delta$ and $\hat{G}_k \subset G_\epsilon(\bar{x})$ from (3.3), (3.2), and (2.2). We also have $\nabla f(x^k) \in G_\epsilon(\bar{x})$ from $x^k \in B(\bar{x}, \epsilon/3) \cap D$. Thus, by (2.3) and the construction of g^k at Step 2, $g^k \in G_\epsilon(\bar{x})$ and $|g^k| \le \rho_\epsilon(\bar{x}) + \delta$. Hence by (3.1) and the choice of δ in Lemma 3.1,

$$\langle v, g^k \rangle > \beta |g^k|^2 \quad \text{for all } v \in G_\epsilon(\bar{x}). \tag{3.4}$$

Suppose for contradiction that $t_k < \min\{1, \gamma\epsilon/3\}$. Then by construction (cf. (2.5))

$$-\beta\gamma^{-1} t_k |g^k| \le f(x^k + \gamma^{-1} t_k d^k) - f(x^k),$$

whereas Lebourg's mean value theorem (cf. [Cla83, Theorem 2.3.7]) yields the existence of $\tilde{x}^k \in [x^k + \gamma^{-1} t_k d^k, x^k]$ and $v^k \in \bar{\partial} f(\tilde{x}^k)$ such that

$$f(x^k + \gamma^{-1} t_k d^k) - f(x^k) = \gamma^{-1} t_k \langle v^k, d^k \rangle.$$

Hence using $d^k := -g^k/|g^k|$ gives $\langle v^k, g^k \rangle \le \beta |g^k|^2$, and so $v^k \notin G_\epsilon(\bar{x})$ by (3.4). But $\gamma^{-1} t_k |d^k| < \epsilon/3$ and $|x^k - \bar{x}| \le \epsilon/3$ imply $\tilde{x}^k \in B(\bar{x}, 2\epsilon/3)$ and thus $v^k \in G_\epsilon(\bar{x})$, a contradiction.

(iii) Note that $g^k \in \bar{\partial}_{\epsilon_k} f(x^k)$ at Step 2 by (2.1), whereas $\bar{\partial}_\cdot f(\cdot)$ is closed. ∎

As discussed in section 2, Algorithm 2.1 is a special case of the GS algorithm, which in turn corresponds to removing t_k in the right-hand side of (2.6b) and requiring that the level set $\{x : f(x) \le f(x^1)\}$ be bounded. Therefore, we give convergence results separately for Algorithm 2.1 and the original GS algorithm. We start with the case where ϵ_k and ν_k are allowed to decrease.

THEOREM 3.3. *Let $\{x^k\}$ be a sequence generated by Algorithm* 2.1 *with $\nu_1 > \nu_{\text{opt}} = \epsilon_{\text{opt}} = 0$ and $\mu, \theta < 1$. With probability* 1 *the algorithm does not stop, and either $f(x^k) \downarrow -\infty$, or $\nu_k \downarrow 0$, $\epsilon_k \downarrow 0$ and every cluster point of $\{x^k\}$ is stationary for f.*

Proof. (i) Since termination in Step 1 has zero probability, we may assume it does not occur. Similarly, if $f(x^k) \downarrow -\infty$, there is nothing to prove, and so assume $\inf_k f(x^k) > -\infty$. Then summing $\beta t_k |g^k| \le f(x^k) - f(x^{k+1})$ (cf. (2.6a)) and relation (2.7) gives

$$\sum_{k=1}^{\infty} t_k |g^k| < \infty, \tag{3.5}$$

$$\sum_{k=1}^{\infty} |x^{k+1} - x^k||g^k| < \infty. \tag{3.6}$$

(ii) Suppose there is k_1, $\bar\nu > 0$, and $\bar\epsilon > 0$ such that $\nu_k = \bar\nu$ and $\epsilon_k = \bar\epsilon$ for all $k \ge k_1$. Using $|g^k| \ge \bar\nu$ in (3.5)–(3.6) yields $t_k \to 0$, $\sum_k |x^{k+1} - x^k| < \infty$, and hence the existence of a point $\bar x$ such that $x^k \to \bar x$. Let $\epsilon := \bar\epsilon$. First, suppose $0 \notin G_\epsilon(\bar x)$. For δ, τ, and $\bar V$ chosen as in Lemma 3.2(ii), we can pick $k_2 \ge k_1$ such that $x^k \in B(\bar x, \min\{\tau, \epsilon/3\})$ and $t_k < \min\{1, \gamma\epsilon/3\}$ yield $(x^{k1}, \dots, x^{km}) \notin \bar V$ for all $k \ge k_2$. This event has probability 0, since for each $k \ge k_2$, $(x^{k1}, \dots, x^{km})$ is sampled independently and uniformly from $D_\epsilon^m(x^k)$, which contains the open set $\bar V \ne \emptyset$. Second, suppose $0 \in G_\epsilon(\bar x)$. For $\delta := \bar\nu/2$ and $\tau, \bar V$ chosen as in Lemma 3.2(i), we can pick $k_3 \ge k_1$ such that $x^k \in B(\bar x, \tau)$, $\bar\nu \le |g^k| \le \operatorname{dist}(0 \,|\, \operatorname{co}\{\nabla f(x^{ki})\}_{i=1}^m)$, and $\rho_\epsilon(\bar x) = 0$ imply $(x^{k1}, \dots, x^{km}) \notin \bar V$ for all $k \ge k_3$. This event has probability 0 as well.

(iii) Consider the event where $\nu_k \downarrow 0$, $\epsilon_k \downarrow 0$, and $\{x^k\}$ has a cluster point $\bar x$. If $x^k \to \bar x$, $0 \in \bar\partial f(\bar x)$ by Lemma 3.2(iii). If $x^k \not\to \bar x$, we claim that $\underline{\lim}_k \max\{|x^k - \bar x|, |g^k|\} = 0$. Otherwise, there exist $\bar\nu > 0$, $\bar k$, and an infinite set $K := \{k : k \ge \bar k, |x^k - \bar x| \le \bar\nu\}$ such that $|g^k| > \bar\nu$ for all $k \in K$, and so (3.6) gives $\sum_{k\in K} |x^{k+1} - x^k| < \infty$. Since $x^k \not\to \bar x$, there is $\epsilon > 0$ such that for each $k \in K$ with $|x^k - \bar x| \le \bar\nu/2$ there exists $k' > k$ satisfying $|x^{k'} - x^k| > \epsilon$ and $|x^i - \bar x| \le \bar\nu$ for all $k \le i < k'$. Therefore, by the triangle inequality, we have $\epsilon < |x^{k'} - x^k| \le \sum_{i=k}^{k'-1} |x^{i+1} - x^i|$ with the right-hand side being less than ϵ for large $k \in K$ from $\sum_{k\in K} |x^{k+1} - x^k| < \infty$, a contradiction. Therefore, $\underline{\lim}_k \max\{|x^k - \bar x|, |g^k|\} = 0$ yields $0 \in \bar\partial f(\bar x)$ by Lemma 3.2(iii). □

THEOREM 3.4. *Let $\{x^k\}$ be a sequence generated by the original GS algorithm with $\nu_1 > \nu_{\rm opt} = \epsilon_{\rm opt} = 0$ and $\mu, \theta < 1$. Suppose the level set $\{x : f(x) \le f(x^1)\}$ is bounded. Then with probability 1 the algorithm does not stop, $\nu_k \downarrow 0$, $\epsilon_k \downarrow 0$, there is a subsequence $K \subset \{1, 2, \dots\}$ such that $g^k \xrightarrow{K} 0$, and every cluster point of $\{x^k\}_{k\in K}$ is stationary for f.*

Proof. It suffices to reconsider part (ii) of the proof of Theorem 3.3 (since, for $\nu_k \downarrow 0$, we can take $K := \{k : \nu_{k+1} < \nu_k\}$).

Thus suppose there is k_1, $\bar\nu > 0$, and $\bar\epsilon > 0$ such that $\nu_k = \bar\nu$ and $\epsilon_k = \bar\epsilon$ for all $k \ge k_1$. Using $|g^k| \ge \bar\nu$ in (3.5) yields $t_k \to 0$. Since $\{f(x^k)\}$ is decreasing and the set $\{x : f(x) \le f(x^1)\}$ is compact, there are a set $J \subset \{1, 2, \dots\}$ and a point $\bar x$ such that $x^k \xrightarrow{J} \bar x$. Since $t_k \xrightarrow{J} 0$ as well, arguing as in part (ii) of the proof of Theorem 3.3 we deduce the existence of k_4 and an open set $\bar V \ne \emptyset$ such that $(x^{k1}, \dots, x^{km}) \notin \bar V \subset D_\epsilon^m(x^k)$ for all $k \ge k_4$, $k \in J$, and again conclude that this event has probability 0. □

Our convergence results for fixed sampling radius follow.

THEOREM 3.5. *Let $\{x^k\}$ be a sequence generated by Algorithm 2.1 with $\nu_1 = \nu_{\rm opt} = 0$, $\epsilon_1 = \epsilon_{\rm opt} = \epsilon > 0$, and $\mu = 1$. With probability 1 either the algorithm terminates at some iteration k with $0 \in G_\epsilon(x^k)$, or $f(x^k) \downarrow -\infty$, or there is a subsequence $K \subset \{1, 2, \dots\}$ such that $g^k \xrightarrow{K} 0$ and every cluster point $\bar x$ of $\{x^k\}_{k\in K}$ satisfies $0 \in \bar\partial_\epsilon f(\bar x)$.*

Proof. If the algorithm terminates at iteration k, then with probability 1 it does so at Step 3 with $0 = g^k \in G_\epsilon(x^k)$. Hence we may assume that no termination occurs and $\inf_k f(x^k) > -\infty$.

By the proof of Theorem 3.3, the event $\bar\nu := \inf_k |g^k| > 0$ has probability 0. In the remaining case of $\inf_k |g^k| = 0$, the conclusion follows from the closedness of $\bar\partial_\epsilon f(\cdot)$. □

THEOREM 3.6. *Let $\{x^k\}$ be a sequence generated by the original GS algorithm with $\nu_1 = \nu_{\text{opt}} = 0$, $\epsilon_1 = \epsilon_{\text{opt}} = \epsilon > 0$, and $\mu = 1$. Suppose the set $\{x : f(x) \le f(x^1)\}$ is bounded. With probability 1 either the algorithm terminates at some iteration k with $0 \in G_\epsilon(x^k)$, or $g^k \to 0$ and every cluster point $\bar{x}$ of $\{x^k\}$ satisfies $0 \in \bar{\partial}_\epsilon f(\bar{x})$.*

Proof. Arguing by contradiction, it suffices to consider the case where there are a set $J \subset \{1, 2, \dots\}$ and $\bar{\nu} > 0$ such that $\inf_{k \in J} |g^k| \ge \bar{\nu}$. Since $\{f(x^k)\}$ is decreasing and the set $\{x : f(x) \le f(x^1)\}$ is compact, we may assume with no loss of generality that there is a point $\bar{x}$ such that $x^k \xrightarrow{J} \bar{x}$. Since (3.5) gives $t_k \xrightarrow{J} 0$, arguing as in part (ii) of the proof of Theorem 3.3 we deduce the existence of k_5 and an open set $\bar{V} \ne \emptyset$ such that $(x^{k1}, \dots, x^{km}) \notin \bar{V} \subset D_\epsilon^m(x^k)$ for all $k \ge k_5$, $k \in J$. This event has probability 0, since for each k, $(x^{k1}, \dots, x^{km})$ is sampled independently and uniformly from $D_\epsilon^m(x^k)$. ∎

A few comments and comparisons with the results of [BLO05, section 3] are in order.

Remark 3.7.

(i) Since the framework of [BLO05, section 3] requires compactness of the level set $\{x : f(x) \le f(x^1)\}$, it has no results comparable to our Theorems 3.3 and 3.5.

(ii) Theorem 3.3 is essentially the best one can hope for. In particular, it implies that for positive optimality tolerances ν_{opt} and ϵ_{opt}, with probability 1 either $f(x^k) \downarrow -\infty$, or the algorithm terminates with the required "optimality certificate" of [BLO05, p. 768].

(iii) Theorem 3.3 is stronger than Theorem 3.4. Of course, Theorem 3.3 relies on our inclusion of t_k in the right-hand side of (2.6b), but this should be cheap in practice. With this fairly mild qualification, Theorem 3.3 gives a positive answer to the final open question of [BLO05, section 3] on whether all cluster points of the algorithm are stationary.

(iv) Theorem 3.4 subsumes [BLO05, Theorem 3.8], which assumes that $\{x^k\}$ converges.

(v) Theorem 3.6 subsumes [BLO05, Theorem 3.4], which asserts only the existence of a subsequence $K \subset \{1, 2, \dots\}$ such that $\rho_\epsilon(x^k) \xrightarrow{K} 0$ and every cluster point $\bar{x}$ of $\{x^k\}_{k \in K}$ satisfies $0 \in \bar{\partial}_\epsilon f(\bar{x})$, without showing that $\inf_k |g^k| = 0$. In contrast, Theorem 3.6 implies that for a positive optimality tolerance ν_{opt}, with probability 1 the algorithm terminates when the required "optimality certificate" is reached (similarly for Theorem 3.5 if $\inf f > -\infty$). A result similar to Theorem 3.6 is given in [BLO05, part 1 of Corollary 3.5] only for the case where the objective f is continuously differentiable everywhere. Finally, Theorem 3.6 disproves the conjecture raised in the open question number 2 at the end of [BLO05, section 3] that a counterexample with $\overline{\lim}_{k \in K} |g^k| > 0$ should exist.

4. Modifications. Although our revision of Step 6 yields stronger theoretical results, it makes no difference to its implementation in practice when, as explained in [BLO05, section 4], it is not possible or practical to check whether the iterates lie in the set D where f is differentiable. Further, the implementation of [BLO05, section 4] obtained best results for the Armijo parameter $\beta = 0$ (although $\beta > 0$ is required in theory). Thus there is still the need for further study of line searches. In this section we propose several themes, supported by theory, that might prove useful in improving the practical performance of the method.

4.1. Nonnormalized search directions. Since the GS algorithm employs search directions $d^k := -g^k/|g^k|$ of unit norm, the number of f-evaluations per

Armijo's line search (cf. (2.5)) can grow to infinity. This will happen in the generic case where $x^{k+1} = x^k + t_k d^k$ for almost all k and $t_k = |x^{k+1} - x^k| \to 0$ (e.g., $\{x^k\}$ converges). To mitigate this drawback, let us consider using $d^k := -g^k$ as in the steepest descent method with $d^k = -\nabla f(x^k)$ in the smooth case.

Formally, suppose relations (2.4)–(2.6) in Algorithm 2.1 are replaced by

$$d^k := -g^k, \tag{4.1}$$

$$t_k := \max\{\, t : f(x^k + td^k) < f(x^k) - \beta t|g^k|^2, t \in \{1, \gamma, \gamma^2, \dots\}\,\}, \tag{4.2}$$

$$f(x^{k+1}) < f(x^k) - \beta t_k |g^k|^2, \tag{4.3a}$$

$$|x^k + t_k d^k - x^{k+1}| \le \min\{t_k, \epsilon_k\}|d^k|. \tag{4.3b}$$

Then (2.7) still holds, since $|x^{k+1} - x^k| \le 2t_k|d^k| = 2t_k|g^k|$. Lemma 3.2(ii) is replaced by the following.

LEMMA 4.1. *Let $\epsilon > 0$ and $\bar{x} \in \mathbb{R}^n$. Assuming $0 \notin G_\epsilon(\bar{x})$, pick $\delta > 0$ as in Lemma 3.1 for $C := G_\epsilon(\bar{x})$, and then τ and $\bar{V}$ as in Lemma 3.2(i). Suppose $x^k \in B(\bar{x}, \min\{\tau, \epsilon/3\})$, $\epsilon_k = \epsilon$, and $(x^{k1}, \dots, x^{km}) \in \bar{V}$. Then $t_k \ge \min\{1, \gamma\epsilon/3\bar{\kappa}\}$, where $\bar{\kappa}$ is the Lipschitz constant of f on $B(\bar{x}, 2\epsilon)$.*

Proof. In the proof of Lemma 3.2(ii), assuming $t_k < \min\{1, \gamma\epsilon/3\bar{\kappa}\}$, use $d^k := -g^k$ to get $\langle v^k, g^k\rangle \le \beta|g^k|^2$ as before. Since $\gamma^{-1}t_k|d^k| < \epsilon/3$ yields $v^k \in G_\epsilon(\bar{x})$ as before, note that $|d^k| = |g^k| \le \bar{\kappa}$, since $|x^k - \bar{x}| \le \epsilon/3$ implies $g^k \in G_\epsilon(x^k) \subset G_{1.5\epsilon}(\bar{x})$ and hence $|g^k| \le \bar{\kappa}$. □

With the above replacements, the proofs of section 3 are modified in obvious ways. For instance, in the proof of Theorem 3.3, using (4.3a), we can replace (3.5) by

$$\sum_{k=1}^{\infty} t_k |g^k|^2 < \infty, \tag{4.4}$$

and in its part (ii) we can consider $t_k < \min\{1, \gamma\epsilon/3\bar{\kappa}\}$. In effect, Theorems 3.3–3.6 hold for this variant as well.

Although $d^k := -g^k$ may be better than $d^k := -g^k/|g^k|$ asymptotically, it can be worse initially when $|g^k|$ is still "large" (this, of course, depends on problem scaling). In general, we may wish to scale d^k so that the first trial point $x^k + d^k$ is at a "reasonable" distance from x^k; using the sampling radius ϵ_k as this distance gives the variant analyzed below.

4.2. Searching within the trust region. To restrict the Armijo line search to the sampled trust region $B(x^k, \epsilon_k)$, suppose relations (2.4)–(2.6) in Algorithm 2.1 are replaced by

$$d^k := -\epsilon_k g^k/|g^k|, \tag{4.5}$$

$$t_k := \max\{\, t : f(x^k + td^k) < f(x^k) - \beta t\epsilon_k|g^k|, t \in \{1, \gamma, \gamma^2, \dots\}\,\}, \tag{4.6}$$

$$f(x^{k+1}) < f(x^k) - \beta t_k \epsilon_k |g^k|, \tag{4.7a}$$

$$|x^k + t_k d^k - x^{k+1}| \le \min\{t_k, \epsilon_k\}|d^k|. \tag{4.7b}$$

Then (2.7) still holds, since $|x^{k+1} - x^k| \le 2t_k|d^k| = 2t_k\epsilon_k$. Lemma 3.2(ii) is replaced by the following.

LEMMA 4.2. *Let $\epsilon > 0$ and $\bar{x} \in \mathbb{R}^n$. Assuming $0 \notin G_\epsilon(\bar{x})$, pick $\delta > 0$ as in Lemma* 3.1 *for $C := G_\epsilon(\bar{x})$, and then τ and $\bar{V}$ as in Lemma* 3.2(i). *Suppose $x^k \in B(\bar{x}, \min\{\tau, \epsilon/3\})$, $\epsilon_k = \epsilon$, and $(x^{k1}, \dots, x^{km}) \in \bar{V}$. Then $t_k \geq \gamma/3$.*

Proof. In the proof of Lemma 3.2(ii), for $t_k < \gamma/3$, use $d^k := -\epsilon_k g^k/|g^k|$ to get $\langle v^k, g^k \rangle \leq \beta |g^k|^2$ as before, and then $v^k \in G_\epsilon(\bar{x})$ from $\gamma^{-1} t_k |d^k| < \epsilon/3$ with $|d^k| = \epsilon_k = \epsilon$. ∎

As in section 4.1, we deduce that Theorems 3.3–3.6 hold for this variant as well, since in the proof of Theorem 3.3, using (4.7a), we can replace (3.5) by

$$\sum_{k=1}^{\infty} t_k \epsilon_k |g^k| < \infty. \tag{4.8}$$

4.3. Limiting the line search. Note that relations (2.4)–(2.6), (4.1)–(4.3), and (4.5)–(4.7) have the form

$$d^k := -\alpha_k g^k \quad \text{with} \quad \alpha_k > 0, \tag{4.9}$$

$$t_k := \max\{\, t : f(x^k + t d^k) < f(x^k) - \beta t |d^k||g^k|, t \in \{1, \gamma, \gamma^2, \dots\}\,\}, \tag{4.10}$$

$$f(x^{k+1}) < f(x^k) - \beta t_k |d^k||g^k|, \tag{4.11a}$$

$$|x^k + t_k d^k - x^{k+1}| \leq \min\{t_k, \epsilon_k\} |d^k|, \tag{4.11b}$$

where $\alpha_k := 1/|g^k|$ in sections 2–3, $\alpha_k := 1$ in section 4.1, and $\alpha_k := \epsilon_k/|g^k|$ in section 4.2. The corresponding lower bounds on t_k produced by Lemmas 3.2(ii), 4.1, and 4.2 have the form $t_k \geq \min\{1, \gamma\epsilon/3|d^k|\}$. Procedure 4.3 tests only step sizes that satisfy this bound. It finds $t_k \geq \min\{1, \gamma\epsilon/3|d^k|\}$ when the search direction is good enough (see Lemma 4.4). Otherwise, a *null step* with $t_k := 0$ occurs; then Step 1 resamples (most of) the gradient bundle G_k, so that eventually the search direction is improved sufficiently (unless x^k is already stationary). It will be seen that this null step/resampling mechanism obviates the need for the iterates to be in the set D where f is differentiable.

PROCEDURE 4.3 (limited Armijo line search).

(i) Choose an initial step size $t \geq \min\{1, \gamma\epsilon_k/3|d^k|\}$.
(ii) If $f(x^k + t d^k) < f(x^k) - \beta t |d^k||g^k|$, return $t_k := t$.
(iii) If $t \leq \min\{1/\gamma, \epsilon_k/3|d^k|\}$, return $t_k := 0$.
(iv) Set $t := \gamma t$ and go to (ii).

LEMMA 4.4. *Let $\epsilon > 0$ and $\bar{x} \in \mathbb{R}^n$. Assuming $0 \notin G_\epsilon(\bar{x})$, pick $\delta > 0$ as in Lemma* 3.1 *for $C := G_\epsilon(\bar{x})$, and then τ and $\bar{V}$ as in Lemma* 3.2(i). *Suppose $x^k \in B(\bar{x}, \min\{\tau, \epsilon/3\})$, $\epsilon_k = \epsilon$, $(x^{k1}, \dots, x^{km}) \in \bar{V}$, and $d^k := -\alpha_k g^k$ with $\alpha_k > 0$. Then Procedure* 4.3 *finds a step size $t_k \geq \min\{1, \gamma\epsilon/3|d^k|\}$, and the conclusions of Lemmas* 3.2(ii), 4.1, *and* 4.2 *hold for $\alpha_k = 1/|g^k|$, 1, and $\epsilon_k/|g^k|$, respectively.*

Proof. As in the proof of Lemma 3.2(ii), using relation (3.4) and the form of $d^k := -\alpha_k g^k$, we obtain $\langle v, d^k \rangle < -\beta |d^k||g^k|$ for all $v \in G_\epsilon(\bar{x})$. Let $t \in (0, \epsilon/3|d^k|]$. By Lebourg's mean value theorem, $f(x^k + t d^k) - f(x^k) = t\langle v, d^k \rangle$ for some $v \in \bar{\partial} f(x)$ with $x \in [x^k + t d^k, x^k]$. Then $t|d^k| \leq \epsilon/3$ and $|x^k - \bar{x}| \leq \epsilon/3$ imply $x \in B(\bar{x}, 2\epsilon/3)$ and hence $v \in G_\epsilon(\bar{x})$. Therefore, $f(x^k + t d^k) < f(x^k) - \beta t |d^k||g^k|$ for all $t \in (0, \epsilon/3|d^k|]$, and the conclusion follows from the rules of Procedure 4.3. ∎

Remark 4.5.

(i) We conclude from Lemma 4.4 that Theorems 3.3–3.6 remain valid for step sizes t_k produced by Procedure 4.3 instead of the standard Armijo searches (2.5), (4.2), and (4.6). This follows easily from the proofs of section 3 and the remarks in sections 4.1–4.2.

(ii) The number of f-evaluations made by Procedure 4.3 can be controlled via the choice of the initial step size t at step (i). For instance, if $t := \min\{1, \epsilon_k/3|d^k|\}$, then only one evaluation occurs, and the procedure returns either $t_k := t$ or $t_k := 0$. If the initial step size t looks "too small," e.g., $f(x^k + td^k) < f(x^k) - 0.5t|d^k||g^k|$, we can try expansion by setting $t := t/\gamma$ until $f(x^k + td^k) \geq f(x^k) - \beta t|d^k||g^k|$, in which case $t_k := \gamma t$ is returned. Further, step (iii) of Procedure 4.3 can use a smaller threshold $0 < \underline{t} < \min\{1/\gamma, \epsilon_k/3|d^k|\}$, returning $t_k := 0$ if $t \leq \underline{t}$. Alternatively, the stopping criterion of step (iii) can be ignored until a given number of f-evaluations is reached. Such variations do not impair Lemma 4.4. Note that the theoretical guidelines above leave much freedom for implementations. For instance, choosing a smaller $\underline{t}$ involves the trade-off between the cost of additional f-evaluations during the line search versus the cost of evaluating m gradients at Step 1. On the other hand, using a positive $\underline{t}$ is essential in practice because otherwise an infinite loop might occur due to rounding errors.

(iii) Once Procedure 4.3 replaces the standard Armijo searches (2.5), (4.2), and (4.6), there is no longer any need for keeping x^k in D and including $\nabla f(x^k)$ in G_k at Step 1. This leads to the following simplified variant of Algorithm 2.1. At Step 0, select any $x^1 \in \mathbb{R}^n$. At Step 1, set $G_k := \mathrm{co}\{\nabla f(x^{ki})\}_{i=1}^m$. At Step 5, find t_k via Procedure 4.3. Finally, at Step 6, set $x^{k+1} := x^k + t_k d^k$. Then the requirements of (4.11) are met if $t_k > 0$, whereas the key inequality (2.7) always holds. In effect, Theorems 3.3–3.6 remain valid for this variant. Further, Theorems 3.3–3.6 still hold if the differentiability check of Step 1 is skipped, since $\{x^{ki}\}_{i=1}^m \subset D$ with probability 1. In other words, we may skip the differentiability check of Steps 1 and 6 as in the implementation of [BLO05, section 4], assuming that the user provides reasonable replacements for the gradient at points where it is not defined or that such points are not encountered. In this setting, we may also include $\nabla f(x^k)$ in G_k: although we can not show that the event $x^k \notin D$ has probability zero, it is unlikely to occur in practice.

Acknowledgments. I would like to thank the Associate Editor and the two anonymous referees for their help in improving the exposition of the main results of this paper.

CODERIVATIVE ANALYSIS OF QUASI-VARIATIONAL INEQUALITIES WITH APPLICATIONS TO STABILITY AND OPTIMIZATION*

BORIS S. MORDUKHOVICH† AND JIŘÍ V. OUTRATA‡

Abstract. We study equilibrium models governed by parameter-dependent quasi-variational inequalities important from the viewpoint of optimization/equilibrium theory as well as numerous applications. The main focus is on quasi-variational inequalities with parameters entering both single-valued and multivalued parts of the corresponding generalized equations in the sense of Robinson. The main tools of our variational analysis involve coderivatives of solution maps to quasi-variational inequalities, which allow us to obtain efficient conditions for robust Lipschitzian stability of quasi-variational inequalities and also to derive new necessary optimality conditions for mathematical programs with quasi-variational constraints. To conduct this analysis, we develop new results on coderivative calculus for structural settings involved in our models. The results obtained are illustrated by applications to some optimization and equilibrium models related to parameterized Nash games of two players and to oligopolistic market equilibria.

Key words. variational analysis, quasi-variational inequalities, equilibrium constraints, parametric optimization, Lipschitzian stability, generalized differentiation

1. Introduction.

This paper is devoted to the study of optimization and equilibrium problems involving the so-called parameterized *quasi-variational inequalities* (QVIs) of the following type: given a *parameter* $x \in \mathbb{R}^n$, find a *decision* vector $y \in \Gamma(x,y) \subset \mathbb{R}^m$ such that

$$\langle g(x,y), v-y\rangle \geq 0 \ \text{ for all } \ v \in \Gamma(x,y), \tag{1.1}$$

where $g\colon \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^m$ is a *single-valued* continuously differentiable vector function, while $\Gamma\colon \mathbb{R}^n \times \mathbb{R}^m \rightrightarrows \mathbb{R}^m$ is a *set-valued* mapping (multifunction) between the corresponding finite-dimensional spaces. We always assume in this paper that the mapping Γ is of *closed graph* and takes *convex values* $\Gamma(x,y)$.

QVIs were introduced by Bensoussan and Lions in a series of papers (see, e.g., [3]) in connection with *impulse optimal control* problems. They have been extensively studied in numerous publications, mainly from the viewpoints of existence of solutions and numerical methods; cf. [2, 5, 7, 10, 19, 29], among others. Besides the original motivation, models in the form of QVIs and their special subclass, *implicit complementarity problems*, were particularly used, e.g., in

- *continuum mechanics* (filtration through porous media [2], contact problems with compliant obstacles [33], contact problems with Coulomb friction [15, 4]);

- *economics* (noncooperative games [14, 11], oligopolistic markets [33], and network and traffic equilibria [7]); and
- *biology* (competition between different species or within a species [13]).

Much less attention has been paid to the study of *parameter-dependent* QVIs, especially those where *both* mappings g and Γ in (1.1) depend on parameters. The primary goal of this paper is to undertake such a study concentrating mainly on *sensitivity/stability* of solution maps to (1.1) defined by

$$S(x) := \big\{y \in \mathbb{R}^m \big| \ \langle g(x,y), v-y\rangle \geq 0 \ \text{ whenever } \ v \in \Gamma(x,y)\big\}, \quad x \in \mathbb{R}^n,$$

and *necessary optimality conditions* for local optimal solutions to mathematical programs with *equilibrium constraints* governed by QVIs of type (1.1).

Let us mention previous developments and results known in these directions for QVIs. The papers [18, 31] concern stability issues for QVIs and contain conditions ensuring the existence of a single-valued Lipschitzian localization of $S(\cdot)$ around a reference point. This localization is then described via generalized Jacobians [6] for Lipschitzian mappings. The same type of analysis can also be found in [4], where the authors consider a parameterized QVI describing a contact problem with Coulomb friction. QVIs typically have, however, rather complicated solution sets, and so the results of [4, 18, 31] can be applied only in problems of a special kind. A general study of sensitivity and optimality aspects for parameterized variational systems is given in [27], but the results obtained therein are not specified for QVIs and do not imply those derived in this paper. It is worth emphasizing that QVIs, even in rather simple settings, are significantly different from standard variational inequalities and complementarity problems, demanding therefore new devices and tools for their variational analysis. One of the most crucial characteristic features of QVIs is their *intrinsic nonsmoothness*, which unavoidably requires the usage of appropriate tools of generalized differentiation. In this paper we apply to the study of QVIs the generalized differential constructions and their calculus mainly developed by the first author (see, e.g., [22, 24, 26] and also [37] and the references therein). However, for our purposes we need new calculus results of generalized differentiation specified for applications to QVIs, which are developed in what follows.

Using the standard definition of the normal cone to convex sets, we can rewrite the QVI (1.1) in Robinson's form of the *generalized equation* (GE)

$$0 \in g(x,y) + N_{\Gamma(x,y)}(y), \quad y \in \Gamma(x,y), \tag{1.2}$$

where $N_{\Gamma(x,y)}(y)$ stands for the usual normal cone to the set $\Gamma(x,y)$ at y. Note that (1.2) is different from the conventional form of GEs introduced in [34] for the case of constant convex sets $\Gamma(x,y) \equiv \Gamma$ when (1.2) reduces to the classical variational inequality. The case of variable sets that is characteristic for QVIs (even with no dependence on parameters) happens to be significantly more involved.

The *solution map* $S(x)$ to the QVI (1.1) written in the GE form (1.2) is given by

$$S(x) = \big\{y \in \mathbb{R}^m \big| \ 0 \in g(x,y) + N_{\Gamma(x,y)}(y)\big\}. \tag{1.3}$$

One of the primary goals of local sensitivity analysis conducted in this paper is to find verifiable conditions ensuring *robust Lipschitzian stability* of the solution map (1.3) with respect to parameter perturbations. This can be done on the basic of the *coderivative criterion* for robust Lipschitzian behavior of multifunctions established in [22, 23] via the *coderivative* construction for set-valued mappings that reduces to the *adjoint* derivative operator in the smooth single-valued case.

In order to apply this criterion to QVIs, we need to derive efficient *upper estimates* of the coderivative for the solution map (1.3). This is one of the major technical achievements of the paper, obtained on the base of new rules of *coderivative calculus*. Furthermore, the established coderivative estimates are employed in the paper for deriving *new optimality conditions* for mathematical programs with *QVI constraints*. The results obtained are illustrated by applications to certain optimization and equilibrium models related to *parameterized Nash games* of two players and to *oligopolistic market equilibria*.

The *outline* of the paper is as follows. In section 2 we present and briefly discuss some basic definitions and preliminaries from *variational analysis* and *generalized differentiation* needed for formulating the main results. Section 3 is devoted to the study of *coderivatives* of the multivalued term in (1.2), which is done by deriving new coderivative *calculus rules* that take into account the specific *amenable* structure of the composition in (1.2). Observe that the obtained calculus rules involve new *calmness* assumptions on multifunctions, which are not conventional for subdifferential and coderivative calculus and are significantly weaker than those in known results. In section 4 we apply the new calculus rules to establish efficient *upper estimates* of the *coderivative* for the *solution map* (1.3) to the QVI (1.1) derived under appropriate calmness assumptions and *constraint qualifications*.

Section 5 is devoted to deriving verifiable conditions ensuring *robust Lipschitzian stability* of solutions maps to QVIs established on the base on the aforementioned coderivative criterion and calculus rules. We also present new *upper estimates* of the *exact Lipschitzian bound* for solution maps, which is certainly of interest for both qualitative and numerical analysis. The results obtained are illustrated by establishing Lipschitzian stability of the QVI corresponding to the parameterized *Nash games* studied in [14].

In the concluding section 6 we consider a class of *mathematical programs with QVI constraints*, which can be treated as a subclass of *mathematical programs with equilibrium constraints* (MPECs) intensively studied and used in modern optimization theory and its numerous applications; see, e.g., the books [10, 21, 27, 33] and the references therein. However, we are not familiar with any results that can be applied to optimization problems with equilibrium constraints governed by the QVIs (1.1) under consideration. The new *necessary optimality conditions* for such problems obtained in section 6 strongly employ the coderivative analysis developed in sections 3 and 4. The results obtained are illustrated by the applications to an MPEC with QVI constraints corresponding to the parameterized *Nash games* considered in section 5 and to an *oligopolistic market equilibrium model* in the vein of [11, 30].

Our *notation* is basically standard; see, e.g., [26, 37]. Recall that x^i stands for the ith component of a vector $x \in \mathbb{R}^n$ always considered as a vector-column, E is the unit matrix, $\mathbb{B}$ is the closed unit ball of the space in question, $\mathbb{N} := \{1, 2, \dots\}$, and $A^T (= A^*)$ signifies the transposition of (the adjoint operator to) the matrix A with the vector-row x^T corresponding to the vector-column $x \in \mathbb{R}^n$; thus $x^T y = \langle x, y \rangle$ connotes the inner product of the vectors x and y. Given a differentiable vector function $f\colon \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^l$ of two variables, say x and y, the symbol $\nabla_x f(x, y)$ stands for the partial Jacobian (or gradient in the scalar case of $l = 1$) with respect to x. In a special case of $x = y$, we use the notation $\nabla_1 f(y, y)$ to prevent confusion. Similarly, if $\varphi\colon \mathbb{R}^n \times \mathbb{R}^m \to \overline{\mathbb{R}} := (-\infty, \infty]$ is a nondifferentiable extended-real-valued function of x and y, then $\partial_x \varphi(x, y)$ signifies its partial subdifferential with respect to x. As usual, $\delta(x; \Omega) = \delta_\Omega(x)$ denotes the *indicator function* of the set Ω equal 0 for $x \in \Omega$

and ∞ for $x \notin \Omega$. The graph of a set-valued mapping $F\colon \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ is

$$\operatorname{gph} F := \big\{(x,y) \in \mathbb{R}^n \times \mathbb{R}^m \big|\ y \in F(x)\big\}.$$

2. Some concepts and tools of variational analysis. In this section we review certain preliminary material from *variational analysis* and *generalized differentiation* that is extensively used throughout the paper; see [22, 24, 26, 37] for more details and references. Given a set $\Omega \subset \mathbb{R}^n$ locally closed around $\bar{x} \in \Omega$, define the (basic, limiting) *normal cone* to Ω at $\bar{x}$ by

$$N_\Omega(\bar{x}) = N(\bar{x};\Omega) := \Big\{v \in \Omega \ \Big|\ \exists\, x_k \to \bar{x},\ \exists\, w_k \in \Pi_\Omega(x_k),\ \exists\, \alpha_k \ge 0 \ \text{ with } \ \alpha_k(x_k - w_k) \to v \ \text{ as } \ k \to \infty\Big\}, \tag{2.1}$$

where $\Pi_\Omega(x)$ stands for the *Euclidean projector* of x on Ω. There are several equivalent representations of the normal cone that can be found in the aforementioned references. For convex sets Ω, the normal cone (2.1) reduces to the normal cone of convex analysis, while it is generally *nonconvex* even for simple sets on the plane, e.g., for $\Omega = \operatorname{gph}|x|$ at $0 \in \mathbb{R}^2$. Moreover, the *convexification* (taking the closed convex hull) of N_Ω, which reduces to Clarke's normal cone [6], often gives the *whole space* (as for $\Omega = \operatorname{gph}|x|$) or at least a *linear subspace* of the maximal dimension. In particular, this always happens for the so-called *graphically Lipschitzian sets* around $\bar{x}$, i.e., those which are locally homeomorphic to the graph of a locally Lipschitzian vector function. The latter is automatically the case for graphs of *monotone operators* and *subdifferential mappings* generated by "nice" (e.g., convex, saddle, amenable, etc.) functions; see [26, 37] for precise results and discussions.

The normal cone (2.1) to graphical sets generates the following derivative-like construction for set-valued (and single-valued) mappings that plays the crucial role in the variational analysis for QVIs conducted in this paper. Given a set-valued mapping $F\colon \mathbb{R}^n \rightrightarrows \mathbb{R}^m$, we define its *coderivative* at $(\bar{x},\bar{y}) \in \operatorname{gph} F$ as a positive homogeneous multifunction $D^*F(\bar{x},\bar{y})\colon \mathbb{R}^m \rightrightarrows \mathbb{R}^n$ with the values

$$D^*F(\bar{x},\bar{y})(u) = \big\{v \in \mathbb{R}^n \big|\ (v,-u) \in N\big((\bar{x},\bar{y});\operatorname{gph} F\big)\big\}, \tag{2.2}$$

where $\bar{y} = f(\bar{x})$ is omitted if $F = f\colon \mathbb{R}^n \to \mathbb{R}^m$ is single-valued. If $f\colon \mathbb{R}^n \to \mathbb{R}^m$ is *smooth* (continuously differentiable) around $\bar{x}$, then

$$D^*f(\bar{x})(u) = \big\{\nabla f(\bar{x})^T u\big\} \ \text{ for all } \ u \in \mathbb{R}^m; \tag{2.3}$$

the latter holds when f is merely *strictly differentiable* at $\bar{x}$.

Given an extended-real-valued function $\varphi\colon \mathbb{R}^n \to \overline{\mathbb{R}}$ finite at $\bar{x}$ and lower semicontinuous around this point, define the (basic, limiting) *subdifferential* of φ at $\bar{x}$ by

$$\partial\varphi(\bar{x}) := \big\{v \in \mathbb{R}^n \big|\ (v,-1) \in N((\bar{x},\varphi(\bar{x}));\operatorname{epi}\varphi)\big\} \tag{2.4}$$

via the normal cone (2.1) to the epigraph

$$\operatorname{epi}\varphi := \big\{(x,\mu) \in \mathbb{R}^{n+1} \big|\ \mu \ge \varphi(x)\big\}.$$

There are well-known analytic representations of $\partial\varphi(\bar{x})$ via limits of Fréchet, proximal, viscosity subgradients, etc. Note the useful *scalarization formula*

$$D^*f(\bar{x})(u) = \partial\langle u, f\rangle(\bar{x}) \ \text{ whenever } \ u \in \mathbb{R}^m,$$

which relates the coderivative (2.2) of the mapping $f\colon \mathbb{R}^n \to \mathbb{R}^m$ locally Lipschitzian around $\bar{x}$ with the subdifferential (2.4) of its Lagrange scalarization

$$\langle u, f\rangle(x) := \langle u, f(x)\rangle, \quad u \in \mathbb{R}^m, \ \ x \in \mathbb{R}^n.$$

Observe also the subdifferential representation

$$N(\bar{x};\Omega) = \partial\delta(\bar{x};\Omega), \quad \bar{x} \in \Omega, \tag{2.5}$$

of the normal cone (2.1) via the subdifferential of the set indicator function.

In spite of (actually due to) the *nonconvexity* of our basic generalized differential constructions (2.1), (2.2), and (2.4), they possess *full calculus* (various rules for intersections of sets, compositions of mappings, mean and marginal values of functions, etc.), which happens to be significantly better than for their convex-valued counterparts. The fundamental fact behind this generalized differential calculus is the *extremal principle* of variational analysis that can be treated as a *variational* counterpart of the classical separation theorem in nonconvex settings and plays a crucial role in variational analysis in the absence (and also in the presence) of convexity; see [26, 27] for all the details.

As mentioned, one of the primary goals of the paper is to provide a local *sensitivity analysis* for solution maps to QVIs. In what follows, we focus our attention on *robust Lipschitzian stability* generated by the so-called Aubin's Lipschitz-like (or "pseudo-Lipschitzian" [1]) property, which happens to be the most natural extension of the classical local Lipschitz continuity to set-valued mappings; see [26, 37] for more discussions. Recall that $F\colon \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ has the (Aubin) *Lipschitz-like property* around $(\bar{x},\bar{y}) \in \operatorname{gph} F$ with modulus $\ell \geq 0$ if there are neighborhoods U of $\bar{x}$ and V of $\bar{y}$ such that

$$F(x) \cap V \subset F(u) + \ell\|x-u\|\mathbb{B} \ \text{ whenever } \ x,u \in U. \tag{2.6}$$

The infimum of all the moduli ℓ, for which (2.6) holds with some neighborhoods U and V, is called the *exact Lipschitzian bound* of F around $(\bar{x},\bar{y})$ and is denoted by $\operatorname{lip} F(\bar{x},\bar{y})$.

When $V = \mathbb{R}^m$ in (2.6), this property reduces to the (Hausdorff) *local Lipschitzian property* of F around the point of the *domain*

$$\bar{x} \in \operatorname{dom} F := \{x \in \mathbb{R}^n |\ F(x) \neq \emptyset\}$$

extending the classical local Lipschitzian behavior to the case of set-valued mappings. From this viewpoint, the main difference between Aubin's and Hausdorff's Lipschitzian properties is that the former is a localization of the latter around the point of the *graph* $(\bar{x},\bar{y}) \in \operatorname{gph} F$ versus that of merely the domain $\bar{x} \in \operatorname{dom} F$. The graph localization allows us to study efficiently Lipschitzian stability of *unbounded* multifunctions, which cannot be covered by the Hausdorff property. Furthermore, the Aubin property (2.6) of F around $(\bar{x},\bar{y})$ happens to be *equivalent* to the well-recognized *metric regularity* and *linear openness* properties of the inverse mapping F^{-1} around $(\bar{y},\bar{x})$; see [26, 37].

A great advantage of the coderivative (2.2) is the possibility to *fully characterize* in its terms the robust Lipschitzian (and metric regularity/linear openness) behavior of set-valued mappings that has been done in [22, 23]. The following *coderivative criterion* (or Mordukhovich criterion as in [37, Theorem 9.40]) holds true: a mapping

$F\colon \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ locally closed-graph around $(\bar{x},\bar{y})$ is *Lipschitz-like* around this point *if and only if*

$$D^*F(\bar{x},\bar{y})(0)=\{0\}. \tag{2.7}$$

Moreover, the *exact Lipschitzian bound* of F around $(\bar{x},\bar{y})$ is computed by

$$\operatorname{lip} F(\bar{x},\bar{y})=\|D^*F(\bar{x},\bar{y})\|=\sup\Big\{\|v\|\;\Big|\;v\in D^*F(\bar{x},\bar{y})(u),\ \|u\|\le 1\Big\} \tag{2.8}$$

via the *norm* of $D^*F(\bar{x},\bar{y})\colon \mathbb{R}^m \rightrightarrows \mathbb{R}^n$ as a positive homogeneous mapping.

In this paper we extensively use one more property of set-valued mappings, which is weaker than (2.6) and relates to linear rate/Lipschitzian behavior of F *at* the point in question. Following [37], we say that $F\colon \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ is *calm* at $(\bar{x},\bar{y})\in \operatorname{gph} F$ with modulus $\ell\ge 0$ if there are neighborhoods U of $\bar{x}$ and V of $\bar{y}$ such that

$$F(x)\cap V\subset F(\bar{x})+\ell\|x-\bar{x}\|\mathbb{B}\ \ \text{for all}\ \ x\in U. \tag{2.9}$$

If $V=\mathbb{R}^m$ in (2.9), then the calmness property defined in (2.9) reduces to Robinson's *upper Lipschitzian property* of F *at* $\bar{x}\in\operatorname{dom} F$; see [34].

The principal difference between properties (2.6) and (2.9) is that the former involves all *pairs* of independent domain vectors (x,u) around $\bar{x}$, while the latter *fixes* $u=\bar{x}$. By this, the calmness property *does not* get back the classical local Lipschitzian behavior for single-valued mappings; furthermore, it does not exclude that $F(x)\ne\emptyset$ for x near $\bar{x}$. On the other hand, the calmness/upper Lipschitzian property always holds [35] for *piecewise polyhedral* set-valued mappings, i.e., those whose graph can be represented as a union of finitely many convex polyhedral sets.

3. New rules of coderivative calculus. Throughout the paper, we assume that the set-valued mapping Γ generating the QVI in (1.1) admits the *representation*

$$\Gamma(x,y):=\{z\in\mathbb{R}^m|\ q(x,y,z)\in\Theta\}, \tag{3.1}$$

where $q\colon \mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^m\to\mathbb{R}^s$ is a vector function *twice continuously differentiable* around the points in question, and where Θ is a *closed convex* subset of $\mathbb{R}^s$. Additionally, q and Θ have to satisfy certain requirements ensuring that Γ in (3.1) is *convex-valued*, which is essential to ensure the *strong amenable* structure in the representation of $N_\Gamma(x,y)(z)$; see below. The convex-valuedness property of $\Gamma(x,y)$ holds, e.g., if Θ is a convex cone with vertex at 0 and if $q(x,y,\cdot)$ is Θ-*convex* (in the standard sense) for all $(x,y)\in\mathbb{R}^n\times\mathbb{R}^m$. Furthermore, we impose the basic *constraint qualification* (CQ) condition:

$$\left.\begin{aligned}(\nabla q(\bar{x},\bar{y},\bar{y}))^T u=0\\ u\in N_\Theta(q(\bar{x},\bar{y},\bar{y}))\end{aligned}\right\}\Longrightarrow u=0. \tag{3.2}$$

The main goal of this section is to study the *coderivative* (2.2) of the set-valued mapping $(x,y)\rightrightarrows N_{\Gamma(x,y)}(y)$ in the generalized equation form (1.2) of the QVI under consideration. As mentioned in section 1, the coderivative of this mapping plays a significant role in what follows. We intend to derive efficient *upper estimates* of this coderivative for Γ defined in (3.1), which provide new rules of coderivative calculus for set-valued mappings of a special structure that is characteristic for QVIs.

It follows from formula (2.5) and the structure of Γ in (3.1) that $N_{\Gamma(x,y)}$ admits the *composite subdifferential representation*

$$N_{\Gamma(x,y)}(z) = \partial_z \psi(x,y,z) \;\text{ with }\; \psi := \delta_\Theta \circ q.$$

Since the basic CQ (3.2) is persistent in a neighborhood, by the *robustness* (closed-graph) property of the normal cone (2.1), the composite function ψ is *strongly amenable* around $(\bar{x},\bar{y},\bar{y})$ in the sense of [37], and we have by [37, Theorem 10.49] that

$$N_{\Gamma(x,y)}(z) = (\nabla_z q(x,y,z))^T N_\Theta(q(x,y,z))$$

whenever (x,y,z) is sufficiently close to $(\bar{x},\bar{y},\bar{y})$. This means that, for the purpose of our local analysis, we can replace the GE (1.2) by

$$0 \in g(x,y) + (\nabla_3 q(x,y,y))^T N_\Theta(q(x,y,y)) \tag{3.3}$$

considered for all (x,y,z) around $(\bar{x},\bar{y},\bar{y})$, where $\nabla_3 q(x,y,y)$ signifies, according to our notation in section 1, the partial derivative of $q(x,y,z)$ with respect to z at (x,y,y).

In this section we focus our attention on deriving upper estimates for the coderivative of the multivalued term in (3.3) denoted by

$$Q(x,y) := (\nabla_3 q(x,y,y))^T N_\Theta(q(x,y,y)). \tag{3.4}$$

This set-valued mapping $Q\colon \mathbb{R}^n \times \mathbb{R}^m \rightrightarrows \mathbb{R}^m$ is *closed-graph* around $(\bar{x},\bar{y},\bar{y})$ due to the robustness of the normal cone and the continuity of q. To unburden the notation, put

$$r(x,y) := q(x,y,y) \;\text{ and }\; p(x,y) := \nabla_3 q(x,y,y). \tag{3.5}$$

We clearly have the representation

$$\nabla_y r(x,y) = \nabla_2 q(x,y,y) + \nabla_3 q(x,y,y).$$

The next theorem on *coderivative calculus* for multifunction of the special type (3.4) consists of two parts providing the corresponding *upper estimates* for the coderivative $D^*Q(\bar{x},\bar{y},\bar{v})$ of the set-valued term Q in (3.3) with some $\bar{v} \in Q(\bar{x},\bar{y})$. The first estimate valid under a *partial* modification of the basic *first-order* qualification condition (3.2) ends up with an expression containing the coderivative of the composition $N_\Theta \circ r$, while the second one elaborates the coderivative of the latter composition under an additional *calmness* assumption, which plays a role of some *second-order qualification condition*.

THEOREM 3.1 (coderivative calculus for special compositions). *Under the standing assumptions above, suppose that the basic CQ* (3.2) *is strengthened as*

$$\left.\begin{aligned}(p(\bar{x},\bar{y}))^T u = 0\\ u \in N_\Theta(r(\bar{x},\bar{y}))\end{aligned}\right\} \Longrightarrow u = 0, \tag{3.6}$$

and let $\bar{v} \in Q(\bar{x},\bar{y})$. *Then the following assertions hold:*

(i) *For all* $u \in \mathbb{R}^m$ *we have the coderivative upper estimate*

$$D^*Q(\bar{x},\bar{y},\bar{v})(u) \subset \bigcup_{\substack{d \in N_\Theta(r(\bar{x},\bar{y}))\\ (p(\bar{x},\bar{y}))^T d = \bar{v}}} \Big[(\nabla_{x,y}((p(\bar{x},\bar{y}))^T d))^T u + D^*(N_\Theta \circ r)(\bar{x},\bar{y},d)(p(\bar{x},\bar{y})u)\Big].$$

(ii) *Define the set-valued mapping* $M\colon R^s \times \mathbb{R}^s \rightrightarrows \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^s$ *by*

$$M(\vartheta) := \left\{(x,y,d) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^s \,\middle|\, \begin{bmatrix} r(x,y) \\ d \end{bmatrix} + \vartheta \in \operatorname{gph} N_\Theta \right\}, \tag{3.7}$$

and assume that it is calm at the points $(0,\bar{x},\bar{y},d)$ *satisfying*

$$d \in N_\Theta(r(\bar{x},\bar{y})) \;\text{ and }\; (p(\bar{x},\bar{y}))^T d = \bar{v}.$$

Then for all $u \in \mathbb{R}^m$ *we have the inclusion*

$$\begin{aligned} D^*Q(\bar{x},\bar{y},\bar{v})(u) \subset \bigcup_{\substack{d \in N_\Theta(r(\bar{x},\bar{y})) \\ (p(\bar{x},\bar{y}))^T d = \bar{v}}} & \Big[(\nabla_{x,y}((p(\bar{x},\bar{y}))^T d))^T u \\ & + (\nabla r(\bar{x},\bar{y}))^T D^* N_\Theta(r(\bar{x},\bar{y}),d)(p(\bar{x},\bar{y})u)\Big]. \end{aligned} \tag{3.8}$$

Proof. To justify assertion (i), we represent the multifunction Q under consideration (3.4) as the *composition*

$$Q(x,y) = (f \circ F)(x,y) \tag{3.9}$$

of the single-valued mapping $f\colon \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^s \to \mathbb{R}^m$ defined by

$$f(c,e,d) := (p(c,e))^T d$$

and the set-valued mapping $F\colon \mathbb{R}^n \times \mathbb{R}^m \rightrightarrows \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^s$ defined by

$$F(x,y) := \begin{bmatrix} x \\ y \\ N_\Theta(r(x,y)) \end{bmatrix}.$$

Observe that the mapping f in (3.9) is single-valued and *smooth* under the assumptions made, while F is always *set-valued*. The *coderivative chain rule* most appropriate in this setting is given in [24, Corollary 5.3]. To apply it, we denote

$$\begin{aligned} G(x,y,v) := F(x,y) \cap f^{-1}(v) = \Big\{(c,e,d) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^s \,\Big|\, & c = x,\ e = y, \\ & d \in N_\Theta(r(x,y)),\ (p(x,y))^T d = v\Big\} \end{aligned}$$

and show that this mapping is *uniformly bounded* around $(\bar{x},\bar{y},\bar{v})$ under the CQ (3.6). Arguing by contradiction, suppose that there are sequences

$$x_k \to \bar{x},\ y_k \to \bar{y},\ d_k \in N_\Theta(r(x_k,y_k)),\ v_k = (p(x_k,y_k))^T d_k, \;\text{ and }\; v_k \to \bar{v}$$

such that $\|d_k\| \ge k$ for all $k \in \mathbb{N}$. By passing to a subsequence if necessary, we find $d \in \mathbb{R}^s$ satisfying the relationships

$$\frac{d_k}{\|d_k\|} \to d \;\text{ as }\; k \to \infty \;\text{ with }\; \|d\| = 1.$$

By continuity of r and p in (3.5) and robustness of the normal cone $N_\Theta(\cdot)$, we get

$$d \in N_\Theta(r(\bar{x},\bar{y})) \;\text{ and }\; (p(\bar{x},\bar{y}))^T d = 0,$$

which contradicts (3.6). Hence, by the aforementioned coderivative chain rule from [24], we arrive at the inclusion

$$D^*Q(\bar{x},\bar{y},\bar{v})(u) \subset \bigcup_{\substack{d\in N_\Theta(r(\bar{x},\bar{y}))\\ (p(\bar{x},\bar{y}))^T d=\bar{v}}} D^*F(\bar{x},\bar{y},\bar{x},\bar{y},d)\circ D^*f(\bar{x},\bar{y},d)(u). \tag{3.10}$$

Furthermore, since p in (3.5) is smooth around $(\bar{x},\bar{y})$ due to the twice continuously differentiability of q, we get by (2.3) that

$$D^*f(\bar{x},\bar{y},d)(u)=\begin{bmatrix}(\nabla_{x,y}((p(\bar{x},\bar{y}))^Td))^T\\ p(\bar{x},\bar{y})\end{bmatrix}u.$$

To justify the coderivative upper estimate in (i), it remains to observe by the above relationships that for all $u=(x^*,y^*,d^*)$ one has the equality

$$D^*F(\bar{x},\bar{y},\bar{x},\bar{y},d)(u)=\begin{bmatrix}x^*\\ y^*\end{bmatrix}+D^*(N_\Theta\circ r)(\bar{x},\bar{y},d)(d^*)$$

due to the coderivative sum rule from [26, Theorem 1.62].

Next we show that the coderivative upper estimate in (i) implies the one in (ii) under the additional *calmness* assumption made in (ii). The difference between these two estimates is that instead of the coderivative $D^*(N_\Theta\circ r)$ of the composition $N_\Theta\circ r$ in (i) we obtain the estimate in (3.8) via the gradient of r and the coderivative of N_Θ *separately*, which is much more convenient for further applications. To proceed, consider the set-valued mapping $T:=N_\Theta\circ r$ and observe that

$$\operatorname{gph}T=\left\{(x,y,d)\in\mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^s\,\middle|\,\begin{bmatrix}r(x,y)\\ d\end{bmatrix}\in\operatorname{gph}N_\Theta\right\}.$$

Since $\operatorname{gph}T=M(0)$ for the mapping $M(\cdot)$ in (3.7), we apply [16, Theorem 4.1] under the aforementioned calmness assumption and get

$$N_{\operatorname{gph}T}(\bar{x},\bar{y},d)\subset\begin{bmatrix}(\nabla r(\bar{x},\bar{y}))^T & 0\\ 0 & E\end{bmatrix}N_{\operatorname{gph}N_\Theta}(r(\bar{x},\bar{y}),d),$$

which is equivalent to the inclusion

$$D^*(N_\Theta\circ r)(\bar{x},\bar{y},d)(d^*)\subset(\nabla r(\bar{x},\bar{y}))^TD^*N_\Theta(r(\bar{x},\bar{y}),d)(d^*),\quad d^*\in\mathbb{R}^s. \tag{3.11}$$

Substituting (3.11) into the one in (i), we arrive at the coderivative upper estimate (3.8) and complete the proof of the theorem. □

Observe that the expression $D^*N_\Theta=D^*\partial\delta_\Theta$ stands for the *second-order subdifferential* of the indicator function of Θ, according to the general definition of the second-order subdifferential for extended-real-valued functions φ as the coderivative of the first-order subdifferential of φ; see [24, 26, 28] for more details and second-order subdifferential calculus. Hence, the final upper estimate (3.8) of Theorem 3.1 contains *second-order information* on the data involved. Furthermore, the *calmness* assumption in Theorem 3.1(ii) automatically holds, by the *coderivative criterion* (2.7), under the *second-order CQ* condition imposed in the following corollary. Note that the second part of this corollary realizes another possibility to ensure the aforementioned calmness property: the *polyhedral structure* of the initial data of the QVI under consideration.

COROLLARY 3.2 (coderivative calculus under second-order CQ and polyhedrality assumptions). *In addition to first-order qualification condition* (3.6)*, suppose that either*

(a) *the second-order CQ*

$$D^*N_\Theta(r(\bar{x},\bar{y},d)(0)\cap \ker(\nabla r(\bar{x},\bar{y}))^T=\{0\} \tag{3.12}$$

is fulfilled for all $d\in N_\Theta(r(\bar{x},\bar{y}))$ *with* $(p(\bar{x},\bar{y}))^Td=\bar{v}$*; or*

(b) *the set* Θ *in* (3.1) *is polyhedral and the mapping* p *in* (3.5) *is affine.*

Then the coderivative upper estimate (3.8) *is satisfied.*

Proof. To justify (3.8) under the assumptions made, we need to check (by assertion (ii) of Theorem 3.1) that the fulfillment of either (a) or (b) in the corollary implies the calmness requirement of the theorem. As mentioned in section 2, the calmness property of a set-valued mapping at a reference point is automatic when the mapping is *Lipschitz-like* (2.6) around this point. The latter property is *characterized* via the coderivative criterion (2.7). Thus it is sufficient to compute the coderivative of the mapping $M(\cdot)$ given in (3.7). Mappings of this type have been done in [26, Theorem 4.31]. This gives us, by the specific structure of $M(\cdot)$ in (3.7), that the relationship (2.7) is *equivalent* to the second-order CQ (3.12). This justifies the coderivative upper estimate (3.8) in case (a).

To proceed in case (b), recall from section 2 that $M(\cdot)$ in (3.7) is also calm at $(0,\bar{x},\bar{y},d)$ if it is *upper Lipschitzian* at $\vartheta=0$. By [35, Proposition 3], this is always the case for *polyhedral* multifunctions. But the latter property is ensured, due to [35, Proposition 1], by the assumptions made in (b). This completes the proof of the corollary. □

Efficient applications of the coderivative estimate (3.8) largely depend on computing/estimating the second-order term D^*N_Θ. This has been done in various important settings in [9, 17, 20, 27, 28, 32, 38]; see also the references therein.

In numerous situations we have $\Theta=\mathbb{R}^s_-$, the nonpositive orthant of $\mathbb{R}^s$. This case corresponds to *complementarity conditions* and was first analyzed in [9]. To express the coderivative $D^*N_{\mathbb{R}^s_-}(c,d)$ at any point $(c,d)\in \operatorname{gph} N_{\mathbb{R}^s_-}$, consider the *index sets*:

$$\begin{aligned} L(c)&:=\{i\in\{1,\dots,s\}\mid c^i<0\},\\ I_+(d)&:=\{i\in\{1,\dots,s\}\mid d^i>0\},\\ I_0(c,d)&:=\{i\in\{1,\dots,s\}\mid c^i=0,\ d^i=0\}. \end{aligned}$$

Clearly, these sets form a partition of $\{1,\dots,s\}$. Then the *coderivative formula* for precisely computing $D^*N_{\mathbb{R}^s_-}(c,d)(u)$ whenever $u\in\mathbb{R}^s$ is

$$D^*N_{\mathbb{R}^s_-}(c,d)(u)=\left\{v\in\mathbb{R}^s\;\middle|\; v^i\begin{cases}=0 & \text{if}\quad i\in L(c),\text{ or }\ i\in I_0(c,d)\text{ and }u^i<0\\ \in\mathbb{R} & \text{if}\quad i\in I_+(d)\cup\ I_0(c,d)\text{ and }u^i=0\\ \in\mathbb{R}_+ & \text{if}\quad i\in I_0(c,d)\text{ and }\ u^i\ge 0\end{cases}\right\}.$$

Let us employ this formula in the following illustrative example, which is actually a part of some applied models considered below in this paper.

Example 3.3 (computing the coderivative of the normal cone mapping). Consider the mapping $Q(x,y)$ from (3.4) with $n=1,\ m=2,\ s=2,\ \Theta=\mathbb{R}^2_-$, and

$$q^1(x,y,z):=y^1+z^2-15-x,\quad q^2(x,y,z):=y^2+z^1-15-x.$$

Using our notation in (3.5), we have in this case

$$r(x,y)=\begin{bmatrix} y^1+y^2-15-x \\ y^2+y^1-15-x \end{bmatrix} \quad \text{and} \quad p(x,y)=\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

Pick the point $(\bar{x},\bar{y})=(0,9,6)$ and put $\bar{v}=(0,1)$. It is easy to see that $d=(1,0)^T$ is the only vector satisfying the equation $(p(\bar{x},\bar{y}))^T d=\bar{v}$. Clearly

$$r(\bar{x},\bar{y})=\begin{bmatrix} 0 \\ 0 \end{bmatrix} \quad \text{and thus} \quad (r(\bar{x},\bar{y}),d)\in \operatorname{gph} N_{\mathbb{R}^2_-}.$$

Furthermore, all the assumptions in case (b) of Corollary 3.2 are satisfied and we have

$$I_+(d)=\{1\}, \quad I_0(r(\bar{x},\bar{y}),d)=\{2\}$$

in the coderivative formula above. Taking into account that the first term on the right-hand side of (3.8) vanishes, we arrive at the coderivative upper estimate

$$D^*Q(\bar{x},\bar{y},\bar{v})(u)$$
$$\subset \left\{ \begin{bmatrix} -v^1-v^2 \\ v^1+v^2 \\ v^1+v^2 \end{bmatrix} \;\middle|\; v^1\in\mathbb{R},\ v^2 \begin{cases} =0 & \text{if} \quad u^1<0 \\ \in\mathbb{R} & \text{if} \quad u^1=0 \\ \in\mathbb{R}_+ & \text{if} \quad u^1>0 \end{cases} \right\} = \{(-a,a,a)\in\mathbb{R}^3 |\ a\in\mathbb{R}\}$$

whenever $u^2=0$. Otherwise $D^*Q(\bar{x},\bar{y},\bar{v})(u)=\emptyset$.

4. Coderivatives of solutions maps to QVIs. The main goal of this section is to derive upper estimates for the coderivative of the solution map (1.3) to the initial QVI (1.2) with $\Gamma(x,y)$ given in (3.1). The results obtained in what follows are largely based on the coderivative estimates for the multivalued term (3.4) of this QVI established in section 3 via coderivative calculus.

To begin, we consider the *parameter-dependent GE*

$$0\in g(x,y)+Q(x,y) \tag{4.1}$$

with both single-valued term $g\colon \mathbb{R}^n\times\mathbb{R}^m\to\mathbb{R}^m$ and set-valued term $Q\colon \mathbb{R}^n\times\mathbb{R}^m\rightrightarrows\mathbb{R}^m$ depending on the parameter $x\in\mathbb{R}^n$, where g is smooth as in section 1, while $Q\colon \mathbb{R}^n\times\mathbb{R}^m\rightrightarrows\mathbb{R}^m$ is an arbitrary set-valued mapping, which *may not* be in the special form (3.4). The following lemma provides a coderivative upper estimate for the solution map to the parameter-dependent GE (4.1) via the *adjoint Jacobian* of g and the *coderivative* of Q under the appropriate *calmness* assumption.

LEMMA 4.1 (coderivatives of solution maps to parameter-dependent GEs). *Let $(\bar{x},\bar{y})$ satisfy the GE (4.1), and let*

$$S(x):=\{y\in\mathbb{R}^m |\ 0\in g(x,y)+Q(x,y)\}$$

be the solution map to this GE. Assume that g is continuously differentiable around $(\bar{x},\bar{y})$, that Q is locally closed-graph around this point, and that the set-valued mapping $\Xi\colon \mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^m\rightrightarrows\mathbb{R}^n\times\mathbb{R}^m$ defined by

$$\Xi(\vartheta):=\left\{(x,y)\in\mathbb{R}^n\times\mathbb{R}^m \;\middle|\; \begin{bmatrix} x \\ y \\ -g(x,y) \end{bmatrix}+\vartheta\in\operatorname{gph} Q\right\} \tag{4.2}$$

is calm at $(0,\bar{x},\bar{y})$. *Then for all* $u\in\mathbb{R}^m$ *one has the estimate*

$$D^*S(\bar{x},\bar{y})(u)\subset\Bigg\{v\in\mathbb{R}^n\;\Big|\;\exists\, w\in\mathbb{R}^m \text{ with } \begin{bmatrix} v\\ -u\end{bmatrix}\in(\nabla g(\bar{x},\bar{y}))^Tw + D^*Q(\bar{x},\bar{y},-g(\bar{x},\bar{y}))(w)\Bigg\}. \tag{4.3}$$

Proof. Under the imposed calmness assumption, it holds by [16, Theorem 4.1] that

$$N_{\Xi(0)}(\bar{x},\bar{y})\subset\begin{bmatrix}E & 0 & -(\nabla_x g(\bar{x},\bar{y}))^T\\ 0 & E & -(\nabla_y g(\bar{x},\bar{y}))^T\end{bmatrix}\circ N_{\operatorname{gph}Q}(\bar{x},\bar{y},-g(\bar{x},\bar{y})).$$

Since $\operatorname{gph}S=\Xi(0)$ for the solution map to the GE (4.1), we arrive at the coderivative upper estimate (4.3). □

Remark 4.2 (more on coderivatives of solution maps to GEs). As above, we can present efficient conditions ensuring the fulfillment of the *calmness* requirement of Lemma 4.1. First it is automatic under the *polyhedrality* assumptions (in finite dimensions). Furthermore, the stronger *Lipschitz-like* property holds by the coderivative criterion (2.7) applied to the mapping Ξ in (4.2) in both finite and infinite dimensions, even for *nonsmooth* mappings g with replacing the adjoint Jacobian $\nabla g(\bar{x},\bar{y})^Tw$ by the coderivative $D^*g(\bar{x},\bar{y})(w)$ of g or its scalarization $\partial\langle w,g\rangle(\bar{x},\bar{y})$. In the framework of (4.2), the latter criterion amounts to saying (similarly to the *Fredholm alternative*) that the *adjoint GE*

$$0\in\nabla g(\bar{x},\bar{y})^Tw+D^*Q(\bar{x},\bar{y},-g(\bar{x},\bar{y}))(w)$$

has *only the trivial solution* $w=0$; see [26, Theorem 4.46]. Observe also that there are certain conditions given in [26, Theorem 4.44 and Corollary 4.45] ensuring the *equality* in (4.3). Unfortunately, the efficient realization of these conditions for *parameter-dependent* mappings $Q=Q(x,y)$ in (4.1) requires the *graph-convexity* of Q, which is not often the case for mappings (3.4) arising in QVIs. For *parameter-independent* $Q=Q(y)$ in (4.1), the equality in (4.3) is achieved under the *surjectivity* (full rank) requirement of the Jacobian matrix $\nabla g(\bar{x},\bar{y})$.

Now we proceed by studying the *solution map* (1.3) to the *QVI* (1.1) generated by the parameterized set Γ from (3.1). To simplify formulas of type (4.3) in what follows, we omit the text corresponding to "$\exists w\in\mathbb{R}^m$ with." By the same reason we introduce the *Lagrangian* mapping $\mathcal{L}\colon\mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^s\to\mathbb{R}^m$ defined by

$$\mathcal{L}(x,y,d):=g(x,y)+(p(x,y))^Td. \tag{4.4}$$

Therefore the adjoint Lagrangian partial derivative is represented as

$$(\nabla_{x,y}\mathcal{L}(x,y,d))^T=(\nabla g(x,y))^T+(\nabla_{x,y}((p(x,y))^Td))^T.$$

To formulate the main result of this section, define the mapping $\Lambda\colon\mathbb{R}^n\times\mathbb{R}^m\rightrightarrows\mathbb{R}^s$ by

$$\Lambda(x,y):=\{d\in\mathbb{R}^s|\;\mathcal{L}(x,y,d)=0\}. \tag{4.5}$$

THEOREM 4.3 (coderivative estimate for solution maps to QVIs). *Let* $S\colon\mathbb{R}^n\rightrightarrows\mathbb{R}^m$ *be the solution map* (1.3) *to the original QVI represented by* (3.3) *around the reference*

point $(\bar{x},\bar{y})\in\operatorname{gph}S$ *with the Lagrangian* $\mathcal{L}$ *defined in* (4.4). *Assume that the CQ* (3.6) *holds and that the multifunction* M *given by* (3.7) *is calm at all the points* $(0,\bar{x},\bar{y},d)$ *with* $d\in\Lambda(\bar{x},\bar{y})$. *We also suppose that the multifunction* $P\colon\mathbb{R}^m\times\mathbb{R}^s\times\mathbb{R}^s\rightrightarrows\mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^s$ *defined by*

$$P(z,\vartheta):=\Big\{(x,y,d)\in\mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^s\;\Big|\;\mathcal{L}(x,y,d)+z=0\Big\}\cap M(\vartheta)\tag{4.6}$$

is calm at the points $(0,0,\bar{x},\bar{y},d)$ *with* $d\in\Lambda(\bar{x},\bar{y})$. *Then for all* $u\in\mathbb{R}^m$ *we have*

$$\begin{aligned}D^*S(\bar{x},\bar{y})(u)\subset\bigcup_{d\in\Lambda(\bar{x},\bar{y})}\Big\{&(\nabla_x\mathcal{L}(\bar{x},\bar{y},d))^Tv+(\nabla_xr(\bar{x},\bar{y},d))^Tw\;\Big|\;0=u\\&+(\nabla_y\mathcal{L}(\bar{x},\bar{y},d))^Tv+(\nabla_yr(\bar{x},\bar{y},d))^Tw,\;\;w\in D^*N_\Theta(r(\bar{x},\bar{y}),d)(p(\bar{x},\bar{y})v)\Big\}.\end{aligned}\tag{4.7}$$

If, furthermore, the mappings $g(\cdot)$ *and* $r(\cdot)$ *are affine and the set* Θ *is polyhedral, then the above calmness requirements are automatic, and it suffices to assume only the CQ* (3.6).

Proof. First observe, similarly to the proof of Corollary 3.2 in case (b), that both calmness conditions imposed in the theorem are automatically fulfilled when the mappings g and r are affine and the set Θ is polyhedral. It remains to justify (4.7) under the calmness assumptions made.

We can easily see that inclusion (4.7) follows from assertion (ii) of Theorem 3.1 and Lemma 4.1 *provided that* the multifunction Ξ from (4.2) with Q given by (3.4) is *calm* at $(0,\bar{x},\bar{y})$. This can be ensured by requiring that the *expanded* multifunction $\overline{P}\colon\mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^m\rightrightarrows\mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^s$ defined by

$$\begin{aligned}\overline{P}(\vartheta_1,\vartheta_2,\vartheta_3):=\Big\{(x,y,d)\in\mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^s\;\Big|\;&-g(x,y)+\vartheta_3\\&=(p(x+\vartheta_1,y+\vartheta_2))^Td,\;\;d\in N_\Theta(r(x+\vartheta_1,y+\vartheta_2))\Big\}\end{aligned}$$

is calm at all the points $(0,0,0,\bar{x},\bar{y},d)$ with $d\in\Lambda(\bar{x},\bar{y})$. Indeed, in the case under consideration we have the representation

$$\begin{aligned}\Xi(\vartheta_1,\vartheta_2,\vartheta_3)=\Big\{(x,y)\in\mathbb{R}^n\times\mathbb{R}^m\;\Big|\;&\exists\,d\in N_\Theta(r(x+\vartheta_1,y+\vartheta_2))\\&\text{with}\;\;-g(x,y)+\vartheta_3=(p(x+\vartheta_1,y+\vartheta_2))^Td\Big\},\end{aligned}$$

which implies the relationship

$$\Xi(\vartheta_1,\vartheta_2,\vartheta_3)=\operatorname{proj}_{x,y}\overline{P}(\vartheta_1,\vartheta_2,\vartheta_3).$$

Invoking now the result of [17, Lemma 1], we conclude that the required calmness property of the mapping $\overline{P}$ is implied by the calmness of the (only *canonically perturbed*) mapping $\widehat{P}\colon R^m\times\mathbb{R}^s\times\mathbb{R}^s\rightrightarrows\mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^s$ defined by

$$\begin{aligned}&\widehat{P}(w_1,w_2,w_3)\\&\quad:=\left\{(x,y,d)\in\mathbb{R}^n\times\mathbb{R}^m\times\mathbb{R}^s\;\middle|\;\mathcal{L}(x,y,d)+w_1=0,\;\begin{bmatrix}r(x,y)+w_2\\d+w_3\end{bmatrix}\in\operatorname{gph}N_\Theta\right\}\end{aligned}$$

at the points $(0,0,0,\bar{x},\bar{y},d)$ with $d\in\Lambda(\bar{x},\bar{y})$. It remains to observe that

$$P(z,\vartheta)=\widehat{P}(w_1,w_2,w_3)$$

for $z = w_1$ and $\vartheta = (w_2, w_3)$, which completes the proof of the theorem. □

Similarly to the proof of Corollary 3.2 in case (a), we can get, on the basis of the coderivative criterion for the Lipschitz-like property (2.7), a *second-order* CQ ensuring the calmness property of the mapping P in (4.6). This will be done in the next section as a part of deriving a unified condition that implies both calmness properties assumed in Theorem 4.3 and simultaneously yields robust Lipschitzian stability of the solution map to the QVI under consideration.

It is clear that the above results can be used also in the case of

$$\Gamma(x) := \{y \in \mathbb{R}^m |\ q(x,y) \in \Theta\} \tag{4.8}$$

in (3.1) when (1.2) reduces to the parameter-dependent *variational inequality*

$$0 \in g(x,y) + N_{\Gamma(x)}(y), \quad y \in \Gamma(x),$$

which has been intensively investigated in many publications; see, e.g., [10] with the references therein and also [20] for the coderivative analysis of such variational inequalities and its application to parametric optimization. As a special case of such a variational inequality we can consider the *projection mapping* $\pi\colon \mathbb{R}^m \times \mathbb{R}^n \to \mathbb{R}^m$ defined by

$$\pi(z,x) := \mathrm{proj}_{\,\Gamma(x)}(z), \tag{4.9}$$

with $\Gamma(x)$ given in (4.8); see, e.g., [10, 20] for the importance of the projection mapping (4.9) and its coderivative in various applications. Observe that the projection mapping (4.9) happens to be *single-valued* due to the *convexity* of the sets $\Gamma(x)$. On the basis of Theorem 4.3 we now derive an upper estimate of the coderivative of π.

THEOREM 4.4 (coderivatives of projection mappings in variational inequalities). *Given $\bar{x} \in \mathrm{dom}\,\Gamma$ and $\bar{z} \in \mathbb{R}^m$, put $\bar{y} := \pi(\bar{z}, \bar{x})$ and impose the CQ*

$$\left.\begin{array}{c}(\nabla_y q(\bar{x},\bar{y}))^T u = 0\\ u \in N_\Theta(q(\bar{x},\bar{y}))\end{array}\right\} \Longrightarrow u = 0.$$

Define the mappings $r\colon \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^s$, $p\colon \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^{m+s}$, and $Q\colon \mathbb{R}^n \times \mathbb{R}^m \rightrightarrows \mathbb{R}^m$ by

$$r(x,y) := q(x,y), \quad p(x,y) := \nabla_y q(x,y), \quad Q(x,y) := (\nabla_y q(x,y))^T N_\Theta(q(x,y))$$

and assume that the multifunction $M(\vartheta)$ given by (3.7) via this mappings r is calm at every point $(\bar{x},\bar{y},d)$ with $d \in N_\Theta(r(\bar{x},\bar{y}))$ and $(p(\bar{x},\bar{y}))^T d = \bar{z} - \bar{y}$. Then for all $u \in \mathbb{R}^m$ we have the coderivative upper estimate

$$D^*\pi(\bar{z},\bar{x},\bar{y},)(u) \subset \bigcup_{\substack{d \in N_\Theta(q(\bar{x},\bar{y}))\\ (\nabla_y q(\bar{x},\bar{y}))^T d = \bar{z}-\bar{y}}} \left\{ (t,v) \in \mathbb{R}^m \times \mathbb{R}^n \;\middle|\; t = -w, \right.$$
$$\left. \begin{bmatrix} v \\ -u - w \end{bmatrix} \in D^*Q(\bar{x},\bar{y},\bar{z}-\bar{y})(w) \right\}, \tag{4.10}$$

where the coderivative D^*Q is in turn estimated by (3.8).

Proof. It is easy to observe from the construction of (4.9) and the normal cone definition in convex analysis that the projection relation $y = \pi(z, x)$ can be equivalently written as the *parameterized GE*

$$0 \in y - z + N_{\Gamma(x)}(y), \tag{4.11}$$

where besides x there is an additional parameter z. Thus we can apply the results of Lemma 4.1 and Theorem 4.3 to estimate the coderivative of the solution map to (4.11). To proceed, we need to check the two calmness requirements of Theorem 4.3 in the case of (4.11). Note that the presence of the additional parameter z has no influence on the first calmness requirement. The second one reduces for (4.11) to the calmness of the multifunction $P\colon \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m \rightrightarrows \mathbb{R}^m \times \mathbb{R}^n \times \mathbb{R}^m$ defined by

$$P(\vartheta) := \left\{ (z, x, y) \in \mathbb{R}^m \times \mathbb{R}^n \times \mathbb{R}^m \;\middle|\; \begin{bmatrix} x \\ y \\ z - y \end{bmatrix} + \vartheta \in \operatorname{gph} Q \right\} \tag{4.12}$$

at the point $(0, \bar{z}, \bar{x}, \bar{y})$. The latter holds, however, automatically due to the inclusion

$$D^*P(0, \bar{z}, \bar{x}, \bar{y})(0) \subset \left\{ v = (v_1, v_2, v_3) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m \;\middle|\; 0 = \begin{bmatrix} 0 & 0 & E \\ E & 0 & 0 \\ 0 & E & -E \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix}, \right.$$
$$\left. v \in N_{\operatorname{gph} Q}(\bar{x}, \bar{y}, \bar{z} - \bar{y}) \right\} = \{0\},$$

which ensures the Lipschitz-like property of the mapping (4.12) around $(0, \bar{z}, \bar{x}, \bar{y})$ by the coderivative criterion (2.7). The coderivative estimate (4.10) follows now from the modified inclusion (4.3) in the case of (4.11). □

5. Robust Lipschitzian stability of QVIs. By *robust Lipschitzian stability* of QVIs we understand in this paper the fulfillment of the Lipschitz-like property of the solution map (1.3) to the QVI (1.2) with the generating sets $\Gamma(x, y)$ given by (3.1) around the reference point $(\bar{x}, \bar{y})$. This type of Lipschitzian behavior has been well recognized as an appropriate stability property of local sensitivity analysis, which is *robust* (i.e., *preserved*) under small parameter perturbations. As mentioned in section 2, the Lipschitz-like property can be viewed as a graph localization of the classical *local Lipschitzian* behavior being closely related to the two other major *well-posedness* properties of nonlinear analysis known as *metric regularity* and *linear openness*; see [26, 37] for more details, discussions, and references.

To derive efficient conditions for robust Lipschitzian stability of the QVIs under consideration, we utilize in what follows the *coderivative criterion* (2.7) for the Lipschitz-like property combined with the constructive *coderivative estimate* for the solution map (1.3) established in the previous section on the base of new rules of coderivative calculus. Furthermore, the coderivative results developed above allow us to conduct not only qualitative but also *quantitative* analysis of robust Lipschitzian stability for QVIs by providing an estimate of the *exact Lipschitzian bound*. The second assertion of the following theorem contains efficient conditions, which simultaneously ensure the desired Lipschitzian stability and the calmness requirements needed for the validity of the crucial coderivative estimate established in Theorem 4.3.

THEOREM 5.1 (Lipschitzian stability of solution maps). *Let S be the solution map* (1.3) *to the QVI under consideration, with Γ given by* (3.1) *and with $(\bar{x}, \bar{y}) \in \operatorname{gph} S$. The following assertions hold:*

(i) *Suppose that all the assumptions of Theorem* 4.3 *are satisfied. Then the solution map S is Lipschitz-like around $(\bar{x},\bar{y})$ provided that*

$$\left.\begin{aligned} &0=(\nabla_y\mathcal{L}(\bar{x},\bar{y},d))^Tv+(\nabla_y r(\bar{x},\bar{y}))^Tw\\ &d\in\Lambda(\bar{x},\bar{y})\\ &w\in D^*N_\Theta(r(\bar{x},\bar{y}),d)(p(\bar{x},\bar{y})v)\end{aligned}\right\}\Longrightarrow(\nabla_x\mathcal{L}(\bar{x},\bar{y},d))^Tv+(\nabla_x r(\bar{x},\bar{y}))^Tw=0.$$

Furthermore, we have the upper estimate

$$\begin{aligned}\operatorname{lip}S(\bar{x},\bar{y})\le\sup\Big\{&\|(\nabla_x\mathcal{L}(\bar{x},\bar{y},d))^Tv+(\nabla_x r(\bar{x},\bar{y},d))^Tw\|\ \Big|\\ &d\in\Lambda(\bar{x},\bar{y}),\ \ 0\in u+(\nabla_y\mathcal{L}(\bar{x},\bar{y},d))^Tv+(\nabla_y r(\bar{x},\bar{y}))^Tw,\\ &w\in D^*N_\Theta(r(\bar{x},\bar{y}),d)(p(\bar{x},\bar{y})v),\ \ \|u\|\le1\Big\}\end{aligned}\tag{5.1}$$

for the exact Lipschitzian bound (2.8) *of the solution map in* (1.3), (3.1).

(ii) *Suppose that the CQ* (3.6) *is satisfied and that*

$$\left.\begin{aligned} &0=(\nabla_y\mathcal{L}(\bar{x},\bar{y},d))^Tv+(\nabla_y r(\bar{x},\bar{y}))^Tw\\ &d\in\Lambda(\bar{x},\bar{y})\\ &w\in D^*N_\Theta(r(\bar{x},\bar{y}),d)(p(\bar{x},\bar{y})v)\end{aligned}\right\}\Longrightarrow v=0,\ w=0.\tag{5.2}$$

Then the solution map S is Lipschitz-like around $(\bar{x},\bar{y})$ with the bound estimate (5.1).

Proof. To justify both statements in (i), recall that under the assumptions of Theorem 4.3 we have the coderivative estimate (4.7). Substituting the set on the right-hand side of (4.7) into the coderivative criterion (2.7) and the exact bound formula (2.8), we arrive at the sufficient condition for the Lipschitz-like property in (i) and the bound estimate (5.1).

To justify (ii), we first apply the coderivative criterion (2.7) to the mapping P in (4.6) and observe that the Lipschitz-like property of P around $(0,0,\bar{x},\bar{y},d), d\in\Lambda(\bar{x},\bar{y})$, and hence its calmness at this point required by Theorem 4.3, is ensured by the implication

$$\left.\begin{aligned} &0=(\nabla_{x,y}\mathcal{L}(\bar{x},\bar{y},d))^Tv+(\nabla r(\bar{x},\bar{y}))^Tw\\ &w\in D^*N_\Theta(r(\bar{x},\bar{y}),d)(p(\bar{x},\bar{y})v)\end{aligned}\right\}\Longrightarrow v=0,w=0.\tag{5.3}$$

This condition ensures simultaneously also the CQ (3.12) with $(p(\bar{x},\bar{y}))^Td=-g(\bar{x},\bar{y})$. It is now easy to conclude that implication (5.2) together with the CQ (3.6) imply the fulfillment of all requirements posed in assertion (i) of this theorem. Thus we arrive at both statements in (i) under (3.6) and (5.2) and complete the proof of the theorem. □

Let us illustrate the application of Theorem 5.1 to the study of robust Lipschitzian stability of the solution map to a QVI arising in *Nash equilibrium* modeling.

Example 5.2 (Lipschitzian stability in parameterized Nash games). Consider the parameter-dependent QVI of type (1.2) given as

$$0\in\begin{bmatrix}-34+2y^1+\frac{8}{3}y^2\\ -\frac{97}{4}+\frac{5}{4}y^1+2y^2\end{bmatrix}+N_{\Gamma(x,y)}(y),\quad x\in\mathbb{R},\ y=(y^1,y^2)\in\mathbb{R}^2,\tag{5.4}$$

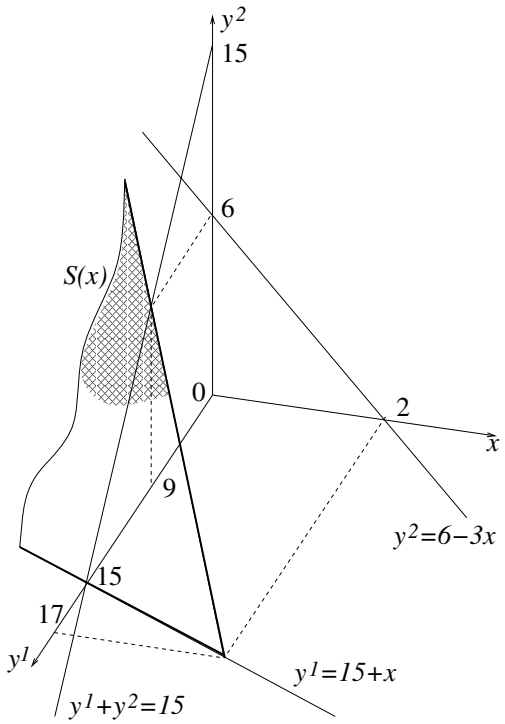

FIG. 1. *Local behavior of* $\operatorname{gph} S$ *around* $(0,9,6)$.

with $\Gamma(x,y)=\Gamma(x,y^1,y^2)$ defined by

$$\Gamma(x,y^1,y^2):=\big\{(z^1,z^2)\in\mathbb{R}^2\big|\ y^1+z^2-15-x\le 0,\ y^2+z^1-15-x\le 0\big\}.$$

This QVI is taken from [14] and corresponds to a *parameterized Nash game of two players* with the parameter-independent objectives

$$(y^1)^2-34y^1+\frac{8}{3}y^2,\quad \frac{5}{4}y^1-\frac{97}{4}y^2+(y^2)^2$$

subject to the parameter-dependent inequality constraint

$$y^1+y^2\le 15+x;$$

see [14] for more details and economic descriptions. Observe that the corresponding set-valued mapping $Q(x,y)$ from (3.4) is fully considered in Example 3.3 with constructively estimating its coderivative by Theorem 3.1.

Take the reference point $(\bar{x},\bar{y})=(0,9,6)$ (which is actually a local *optimal solution* to an MPEC involving the QVI constraint (5.4); see Example 6.3 for more details) and investigate the robust Lipschitzian stability of the solution map S to the QVI (5.4) around this point by employing the results of Theorem 5.1. S is depicted in Figure 1. We have $g(\bar{x},\bar{y})=\left[\begin{smallmatrix}0\\-1\end{smallmatrix}\right]$ for the single-valued term of (5.4), which is affine together with the function $q(x,y,z)$ describing the generating sets $\Gamma(x,y)$ in (5.4) via the polyhedral set $\Theta=\mathbb{R}^2{}_-$. By Theorem 5.1, the Lipschitz-like property of the solution map to (5.4) around the reference point $(\bar{x},\bar{y})$ is ensured by the implication

in assertion (i). It reduces to

$$\left.\begin{aligned} 0 &= 2v^1 + \tfrac{5}{4}v^2 + w \\ 0 &= \tfrac{8}{3}v^1 + 2v^2 + w \\ 0 &= v^2 \end{aligned}\right\} \Longrightarrow -w = 0,$$

which is trivially satisfied, and thus we have the desired stability.

Remark 5.3 (extensions and modifications of stability results for QVIs). Let us discuss some directions of possible extensions and modifications of the Lipschitzian stability results for QVIs obtained in this section.

(i) Based on the coderivative representations/estimates for solution maps to generalized equations of type (4.1) derived in [26, subsection 4.4.1], on the new results of this paper for coderivative estimates of the multivalued term in the QVI (1.2), and on the coderivative characterization (2.7) and (2.8) of the Lipschitz-like property, we can extend the Lipschitzian stability results obtained above to the case of *nonsmooth* mappings g in (1.2). Results in this direction involve the coderivative of g (or its subdifferential scalarization) replacing the adjoint Jacobian.

(ii) Another approach to robust Lipschitzian stability, generally *independent* of the one used above, can be developed in the framework of QVIs under consideration. This approach, which is the most efficient in the case of *canonical perturbations*, involves a preliminary *strong approximation* (in Robinson's sense [36]) of the single-valued term in the GE (1.2) and then employs the coderivative calculus for the multivalued term of (1.2) established in section 3. We refer the reader to [25] and [26, subsection 4.4.3] for more details in the case of GEs (4.1) and some of their specifications and emphasize that the efficient implementation of this approach (as well as the one developed in this paper) is based on the new coderivative calculus results for the multivalued term in (1.2) obtained in section 3.

(iii) The reader can observe that the *calmness* property of the corresponding mappings plays a significant role in the main results of the paper. The efficient realization of this property comes into play via either a kind of the *generalized Mangasarian–Fromovitz CQ* or via *polyhedrality*. They are indeed the two major cases of calmness; some other examples and related discussions can be found in [16, 17, 32]. It should be noted in this respect that the calmness property definitely requires further investigation, which should address first of all *calculus* issues for this property ensuring its preservation under various operations performed on set-valued mappings.

6. Optimality conditions for mathematical programs with QVI constraints. In this section we study a class of parametric optimization problems of the special type

$$\begin{cases} \text{minimize } \ \varphi(x,y) \\ \text{subject to} \\ 0 \in g(x,y) + N_{\Gamma(x,y)}(y), \quad (x,y) \in \Omega, \end{cases} \tag{6.1}$$

where $\varphi\colon \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ is an *objective/cost function*, and where $\Omega \subset \mathbb{R}^n \times \mathbb{R}^m$ is an nonempty, closed set imposing the so-called *geometric constraints* in (6.1). The moving set $\Gamma(x,y)$ under the normal cone operation in (6.1) is taken from (3.1). It generates the most crucial *QVI constraints* in (6.1), which incorporate the optimization problem (6.1) into a broad class of MPECs, whose importance has been well recognized in optimization theory and applications; see, e.g., the books [10, 21, 27, 33] with many references, examples, and discussions therein.

The underlying feature if the QVI constraints in (6.1) is that they are given in the form of *parametric GEs*

$$0 \in g(x,y) + Q(x,y) \;\text{ with }\; (x,y) \in \Omega, \tag{6.2}$$

where not only the single-valued term g but also the *set-valued term* Q *depend on the parameter* $x \in \mathbb{R}^n$. The latter class of MPECs has not attracted much attention in the literature; see [27] for quite recent results and commentaries. Furthermore, the results of [27, section 5.2] concerning necessary optimality conditions for MPECs governed by parameter-dependent generalized equations of type (6.2) cannot be directly applied to the QVI problem (6.1) without *new coderivative calculus rules* taking into account the specific nature of mappings $Q(x,y) = N_{\Gamma(x,y)}(y)$ under consideration, which are in fact the *main thrust* of this paper.

In what follows we pay the main attention to deriving *necessary optimality conditions* for local minimizers to problem (6.1), assuming, for brevity and simplicity, that the cost function φ is *continuously differentiable* around the reference point. There is plenty of room for extending the results obtained below to the case of nonsmooth cost functions φ (as well as nonsmooth mappings g in the QVI constraints of this problem); see Remark 6.2(iii) for more discussions.

In the following theorem we use the notation for the QVI data in the constraints of (6.1) introduced in sections 3 and 4.

THEOREM 6.1 (necessary conditions for optimal solutions to MPECs with QVI constraints). *Let* $(\bar{x},\bar{y})$ *be a local optimal solution to problem* (6.1). *Assume that the partial Jacobian matrix* $\nabla_3 g(\bar{x},\bar{y},\bar{y})$ *has the maximal/full row rank, and let* $\bar{d} \in \mathbb{R}^s$ *be the unique vector satisfying the equation*

$$\mathcal{L}(\bar{x},\bar{y},d) = 0, \tag{6.3}$$

with the Lagrangian $\mathcal{L}$ *defined in* (4.4). *Suppose further that the multifunction* M *from* (3.7) *is calm at* $(0,\bar{x},\bar{y},\bar{d})$ *and that the multifunction* $\widetilde{P}$ *defined by*

$$\widetilde{P}(z,\vartheta) := \Big\{(x,y,d) \in \Omega \times \mathbb{R}^s \;\Big|\; \mathcal{L}(x,y,d) + z = 0\Big\} \cap M(\vartheta)$$

is calm at $(0,0,\bar{x},\bar{y},\bar{d})$. *Then there exist multipliers* $v \in \mathbb{R}^m$ *and* $u \in \mathbb{R}^s$ *such that*

$$\begin{aligned} 0 &\in \nabla\varphi(\bar{x},\bar{y}) + (\nabla\mathcal{L}(\bar{x},\bar{y},\bar{d}))^T v + (\nabla r(\bar{x},\bar{y}))^T u + N_\Omega(\bar{x},\bar{y}),\\ 0 &\in -u + D^* N_\Theta(r(\bar{x},\bar{y}),\bar{d})(p(\bar{x},\bar{y})v). \end{aligned} \tag{6.4}$$

If, moreover, the mappings g, r *are affine and the sets* Θ, Ω *are polyhedral, then both calmness assumptions above hold automatically.*

Proof. Let Σ be the set of feasible solutions to (6.1) given by

$$\Sigma := \left\{(x,y) \in \Omega \;\middle|\; \begin{bmatrix} x\\ y\\ -g(x,y)\end{bmatrix} \in \operatorname{gph} Q\right\} \;\text{ with }\; Q(x,y) = N_{\Gamma(x,y)})(y). \tag{6.5}$$

We obviously have $\Sigma = \Omega \cap \Xi(0)$, where the mapping $\Xi(\vartheta)$ is defined by (4.2). Following the proof of Theorem 4.3 (based on Lemma 4.1 and Theorem 3.1) and employing [16, Theorem 4.1], which ensures the required calculus rules under the imposed *calmness* assumptions, we arrive at the normal cone upper estimate

$$\begin{aligned} N_\Sigma(\bar{x},\bar{y}) \subset \Big\{&(\nabla\mathcal{L}(\bar{x},\bar{y},\bar{d}))^T v + (\nabla r(\bar{x},\bar{y}))^T u \;\Big|\\ &u \in D^* N_\Theta(r(\bar{x},\bar{y}),\bar{d})(p(\bar{x},\bar{y})v)\Big\} + N_\Omega(\bar{x},\bar{y}). \end{aligned} \tag{6.6}$$

Observe that the MPEC (6.1) can be equivalently written as the optimization problem

$$\text{minimize } \varphi(x,y) \text{ subject to } (x,y)\in\Sigma, \tag{6.7}$$

with only the *geometric constraint* defined by (6.5). By [27, Proposition 5.1] one has the necessary optimality condition

$$0\in\nabla\varphi(\bar{x},\bar{y})+N_\Sigma(\bar{x},\bar{y}) \tag{6.8}$$

for the local solution $(\bar{x},\bar{y})$ to the latter (and the original) problem. Substituting (6.6) into (6.8), we arrive at (6.4). The fulfillment of the imposed calmness requirements under the linearity/polyhedrality assumptions in the last statement of the theorem is justified similarly to the proof of Corollary 3.2 in case (b). □

Remark 6.2 (discussions on optimality conditions for problems with QVI constraints). Let us discuss some specific features and possible extensions of the necessary conditions for MPECs with QVI constraints obtained in Theorem 6.1.

(i) By now it has been well recognized that the *calmness* assumptions play an important role as *CQs* for MPECs. Necessary conditions of type (6.4) with a calmness CQ were derived for the first time in [38] in the case of MPECs with variational inequality constraints. Observe that if Θ is a cone with vertex at the origin, the relation $d\in N_\Theta(r(x,y))$ can be replaced by $r(x,y)\in N_{\Theta^*}(d)$ via the *conjugate/dual* (or negative polar) cone Θ^* to Θ. This enables us to derive, following the approach in [32], the optimality conditions in the above theorem, which hold without the first calmness assumption in this case. We refer the reader to [27, subsection 5.2.3] for recent necessary optimality conditions in general MPECs with parameter-dependent constraints (6.2) under calmness CQs whose implementation in the case of QVI constraints requires the coderivative calculus rules developed in this paper.

(ii) The *full row rank* requirement imposed in Theorem 6.1 obviously ensures the fulfillment of the CQ (3.6) and the unique solvability of the Lagrangian equation (6.3) for $d\in\mathbb{R}^s$. If $\Gamma=\Gamma(x)$ and $\Theta=\mathbb{R}^s_-$, the latter reduces to the classical *strict Mangasarian–Fromovitz CQ*. In principal, we can proceed in the proof of Theorem 6.1 without the above full rank assumption for general set-valued mappings Q; see, e.g., [26, subsection 3.1.1] for computing/estimating the normal cone (2.1) to arbitrary closed sets of type (6.5). It happens, however, that the *upper estimate* (3.8) of the coderivative of Q arising in the QVI constraint of (6.1) may be *very poor* in the absence of the full rank condition. This phenomenon can be observed not only in the case of QVIs but also for standard variational inequalities with $\Gamma(x)$ given by (4.8) with $n=m=1$, $s=2$, $\Theta=\mathbb{R}^2_-$, and

$$q(x,y)=\begin{bmatrix} y-x\\ y+x-2\end{bmatrix}.$$

One can check that in this case the right-hand side of the coderivative estimate (3.8) for Q is *all* $\mathbb{R}$, although the required assumptions (except the full rank one) are satisfied; cf. [8].

(iii) Following the MPEC developments in [27, section 5.2] and having in hand the new calculus results obtained in this paper, we *do not have any difficulties* extending the necessary optimality conditions of Theorem 6.1 for QVI optimization problems of type (6.1) to the case of *nonsmooth cost functions* φ (as well as to the case of nonsmooth constraint functions g in (6.1); see the discussions in Remark 4.2 for the latter case). Indeed, the proof of Theorem 6.1 reduces the matter to deriving necessary

optimality conditions for the optimization problem (6.7) with merely *geometric constraints* of the *special type* handled by the calculus rules of this paper. Concerning the geometric constrained problem (6.7) per se, *two major types* of necessary optimality conditions are derived in [27] for this problem in general nonsmooth frameworks: the so-called *lower subdifferential* and *upper subdifferential* optimality conditions. These results allow us to replace (6.8) by its far-reaching extensions to nonsmooth cost functions, which are formulated via lower and upper subgradients of φ at the reference local minimizer; see [27, sections 5.1 and 5.2] for precise formulations and discussions. In this way we can readily extend Theorem 6.1 to nonsmooth problems with QVI constraints.

We conclude this paper by applications of Theorem 6.1 to two optimization models with parameter-dependent QVI constraints arising in practical situations. The first model concerns an MPEC with QVI constraints describing the *Nash game of two players* [14] considered in Example 5.2 from the viewpoint of robust Lipschitzian stability.

Example 6.3 (optimality conditions for MPEC with Nash equilibrium constraints). Consider the MPEC (6.1) with the cost function

$$\varphi(x,y) := x - 3y^1 - \frac{11}{3}y^2 + \frac{1}{2}(y^1-9)^2, \quad x \in \mathbb{R}, \;\; y=(y^1,y^2) \in \mathbb{R}^2,$$

the equilibrium constraint governed by the QVI (5.4) from Example 5.2, and the geometric constraint $(x,y) \in [-1,1] \times \mathbb{R}^2$. The *numerical approach* developed in [12] and the corresponding *SQP code* SNOPT allow us to compute the local optimal solution $(\bar{x},\bar{y}) = (0,9,6)$ to the MPEC under consideration. Since all the assumptions of Theorem 6.1 are clearly fulfilled, we can verify the application of the necessary optimality conditions (6.4) in this setting. We have

$$\mathcal{L}(x,y,d) = \begin{bmatrix} -34 + 2y^1 + \frac{8}{3}y^2 + d^2 \\ -\frac{97}{4} + \frac{5}{4}y^1 + 2y^2 + d^1 \end{bmatrix}, \quad \nabla_x \mathcal{L}(x,y,d) = \begin{bmatrix} 0 \\ 0 \end{bmatrix},$$

$$(\nabla_y \mathcal{L}(x,y,d))^T = \begin{bmatrix} 2 & \frac{5}{4} \\ \frac{8}{3} & 2 \end{bmatrix}, \quad (\nabla_x r(x,y))^T = [-1,-1], \quad (\nabla_y r(x,y))^T = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}.$$

Taking into account that $N_\Omega(\bar{x},\bar{y}) = \{0\}$ due to $\Omega = [-1,1] \times \mathbb{R}^2$ and the choice of $(\bar{x},\bar{y})$, we easily compute from the first inclusion in (6.4) that

$$v^1 = 1, \quad v^2 = 0, \quad u^1 + u^2 = 1.$$

The second line of (6.4) gives the relationships

$$0 \in -u^1 + D^* N_{\mathbb{R}_-}(0,1)v^2,$$
$$0 \in -u^2 + D^* N_{\mathbb{R}_-}(0,0)v^1,$$

and so we can put $u^1 = 1$ and $u^2 = 0$. Thus the reference point $(\bar{x},\bar{y})$ satisfies the necessary optimality conditions of Theorem 6.1.

The final example concerns an MPEC with QVI constraints related to *oligopolistic market equilibrium*; cf. [11, 30] for more detailed descriptions of this and related models.

Example 6.4 (optimization model for determining oligopolistic market equilibrium). Consider two firms sharing the same resource of input commodity (e.g., row

material) and an authority determining the amount of this commodity x available for the next time period. Let x_0 be a certain reasonable consumption of x, and let (y_0^1, y_0^2) be target productions of the firms announced in advance. The authority, playing the role of the *Leader*, may look for a reasonable trade-off between the *consumption excess* $\max\{0, x - x_0\}$ and the *production differences* $y^i - y_0^i,\ i = 1, 2$, where y^i is the actual production of the ith firm. The firms, being *Followers* in this game, behave *noncooperatively* and compute their productions y^1, y^2 by solving the QVI

$$0 = \begin{bmatrix} k_1 - (a - b(y^1 + y^2)) + y^1 b \\ k_2 - (a - b(y^1 + y^2)) + y^2 b \end{bmatrix} + N_{\Gamma(x,y)}(y), \tag{6.9}$$

where the positive numbers k_i specify the linear *production costs* of the firms, and where $a - b(y^1 + y^2)$ is the *inverse demand curve* that assigns to the quantity $y^1 + y^2$ available on the market the corresponding *price* at which consumers are willing to demand [30].

Let us specify the initial data of (6.9) by $k_1 = 24,\ k_2 = 28,\ a = 100,\ b = 1$, and

$$\Gamma(x, y) := \{(y^1, y^2) \in \mathbb{R}^2_+ \,|\, y^1 + y^2 \le 0.333x\},$$

and let the Leader's objective be given by

$$\varphi(x, y^1, y^2) := [\max\{0, x - x_0\}]^2 + \gamma[(y^1 - y_0^1)^2 + (y^2 - y_0^2)^2],$$

with $x_0 = 135,\ \gamma = 0.6,\ y_0^1 = 34$, and $y_0^2 = 16$.

Thus we arrive at the optimization problem of MPEC type (6.1) without any nonequilibrium (geometric) constraints. Using the *numerical approach* and *SQP code* mentioned in Example 6.3, compute the *optimal solution*

$$\bar{x} = 135.15, \quad \bar{y}^1 = 30.95, \quad \bar{y}^2 = 14.1$$

to the MPEC under consideration. Now applying Theorem 6.1, we have

$$r(x, y) = \begin{bmatrix} y^1 + y^2 - 0.333x \\ y^1 + y^2 - 0.333x \end{bmatrix}, \quad p(x, y) = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix},$$

$$\mathcal{L}(x, y, d) = \begin{bmatrix} -76 + 2y^1 + y^2 \\ -72 + y^1 + 2y^2 \end{bmatrix} + \begin{bmatrix} d^2 \\ d^1 \end{bmatrix},$$

and then compute $\bar{d} = (12.85,\ 0)$ from (6.3). All the assumptions of Theorem 6.1 are clearly satisfied, and we can check that both relationships in (6.4) are fulfilled with $v = (1.38,\ 0)$ and $u = (0.3,\ 0.6)$. Indeed, the first relationship in (6.4) reduced to the system of linear equations

$$\begin{aligned} 0.333(-u^1 - u^2) &= -2(x - x_0), \\ 2v^1 + v^2 + u^1 + u^2 &= -2\gamma(y^1 - y_0^1), \\ v^1 + 2v^2 + u^1 + u^2 &= -2\gamma(y^2 - y_0^2), \end{aligned} \tag{6.10}$$

while the second one gives

$$u^1 \in D^* N_{\mathbb{R}_-}(0, 12.86)(v^2), \quad u^2 \in D^* N_{\mathbb{R}_-}(0, 0)(v^1). \tag{6.11}$$

From the first relationship in (6.11) we immediately get that $v^2 = 0$ and u^1 is free. The multipliers v^1, u^1, u^2 can be computed from the linear system (6.10). Since they fulfill the second relationship in (6.11), the optimality conditions have been verified.

Similarly we can consider oligopolistic market models with more realistic production costs and inverse demand curves taken, e.g., from [30]. This, however, requires more work for computing and verifications.

ABSTRACT CONVEXITY AND AUGMENTED LAGRANGIANS*

REGINA SANDRA BURACHIK† AND ALEX RUBINOV‡

Abstract. The ultimate goal of this paper is to demonstrate that abstract convexity provides a natural language and a suitable framework for the examination of zero duality gap properties and exact multipliers of augmented Lagrangians. We study augmented Lagrangians in a very general setting and formulate the main definitions and facts describing the augmented Lagrangian theory in terms of abstract convexity tools. We illustrate our duality scheme with an application to stochastic semi-infinite optimization.

Key words. abstract convexity, nonconvex programming, Lagrange-type functions, augmented Lagrangians, exact penalty representation, stochastic semi-infinite programming

DOI. 10.1137/050647621

1. Introduction.

The classical augmented Lagrangian is defined by means of two addends; one of them is a classical Lagrangian, the other is a penalty term. Due to the term "augmented Lagrangian" the first addend is considered the main one and the second term is considered as something auxiliary. This is true from the numerical point of view. However, the penalty term is crucial for the examination of theoretical issues such as the existence of an exact penalty representation and/or the calmness of the perturbation function.

In [13, Chapter 11], an augmented Lagrangian with a convex augmenting term was introduced for the primal problem of minimizing an extended real-valued function, and, under mild assumptions, strong duality and exact penalty representation were established [13, Theorems 11.59 and 11.61].

Augmented Lagrangians with a nonconvex augmenting function have been intensively studied as well (see [9, 17, 8, 19, 6, 23, 24, 25] and the references therein). Some of these references (e.g., [9, 17, 6, 19]) use abstract convexity tools in their analysis.

Our aim is (i) to present a unified analysis for the examination of nonconvex augmented Lagrangians for a wider family of augmenting terms, and (ii) to express the main definitions and facts describing the augmented Lagrangian theory in terms of abstract convexity tools.

We extend to our general setting main theoretical facts such as the criterion for exact penalty representation based on local growth properties of the perturbation function (Theorem 6.2), the equivalence between calmness and existence of Lagrange multipliers (Corollary 4.1), and the connection between calmness and existence of exact penalty parameters (Proposition 5.3).

In order to deal with our more general augmenting terms, we translate these main theoretical facts into the language of abstract convexity. Our approach is inspired by the works [13, 17, 8, 23, 25, 10].

Recall that a function f is called *abstract convex* with respect to a set of *elementary functions* H if f is represented as the upper envelope of a subset of H. For example, if H is the set of all continuous affine functions, then a function is abstract convex if and only if this function is convex, proper, and lower semicontinuous. In order to apply abstract convexity to the problem at hand we need to define a convenient set H of elementary functions. Since we want to study augmented Lagrangians, we need to consider a set of elementary functions that explicitly depend on a parameter $r > 0$; this parameter is to be identified with a penalty parameter.

Our set of elementary functions is constructed by combining two families of functions. One of these families consists of the "linear" or "ordinary" augmenting terms, and the other provides the "penalty" terms. Our resulting augmenting term includes, as a particular case, the ones studied in [13, 17, 8, 23, 25].

First we prove, in Proposition 4.1, that our augmented Lagrangian scheme has no duality gap. Second, in Proposition 4.2, we establish existence of abstract subgradients of the perturbation function, assuming a local validity of the (abstract) subgradient inequality. Third, we extend the notion of calmness (see Definition 4.1) to our setting and prove in Corollary 4.1 that this new concept is equivalent to the existence of abstract subgradients of the perturbation function at 0. Fourth, we introduce a level boundedness assumption on the problem, which guarantees lower semicontinuity of the perturbation function. We apply these results to the constrained optimization problem and we prove that our concept of calmness implies the existence of an exact penalty parameter. Fifth, we express all previous results in terms of the Lagrangian scheme. More precisely, we prove in Theorem 6.1 the well-definedness of the central path associated with the problem, and we prove optimality of all primal weak accumulation points. The latter result is an extension of [8, Theorem 2.1] and [23, Theorem 3.1] to our general family of augmenting terms. In Theorem 6.2 we establish a criterion for exact penalty representation based on a local behavior of the perturbation function, extending to our setting [8, Theorem 3.1] and [23, Theorem 4.1].

The structure of the paper is as follows: Section 2 contains some preliminaries from abstract convexity and abstract Lagrangians. Generalized augmented Lagrangians are defined in section 3. Abstract subdifferential and approximate abstract subdifferentials of a lower semicontinuous function are discussed in section 4, where we prove zero duality gap and analyze existence of (abstract) subgradients of the perturbation function. Also in this section we establish equivalence between existence of Lagrange multipliers and calmness of the problem. In section 5 we prove that a level-bounded problem guarantees lower semicontinuity of the perturbation function. Also in this section we apply our results to a general constrained optimization problem. In section 6 our previous results (which are expressed in terms of abstract convexity tools) are applied to our augmented Lagrangian scheme. Finally, in section 7 we discuss the application of our duality scheme to a semi-infinite stochastic programming problem.

We use the following notation: $\mathbb{R} = (-\infty, +\infty)$ is the real line; $\bar{\mathbb{R}} = [-\infty, +\infty]$ is the extended real line; $\mathbb{R}_{+\infty} = \mathbb{R} \cup \{+\infty\}$.

Let $f : X \to \bar{\mathbb{R}}$, $g : X \to \bar{\mathbb{R}}$ be functions defined on a set X. Then the inequality $f \leq g$ means that $f(x) \leq g(x)$ for all $x \in X$.

2. Preliminaries.

2.1. Abstract convexity and generalized conjugation. All definitions and statements from this subsection can be found in [18, 21].

Let X be a set and let H be a set of functions $h : X \to \bar{\mathbb{R}}$. Let $f : X \to \bar{\mathbb{R}}$. The set $\operatorname{supp}(f, H) = \{h \in H \mid h \leq f\}$ is called the *support set* of f with respect to H.

The function $\mathrm{co}_H f : X \to \bar{\mathbb{R}}$ defined by $\mathrm{co}_H f(x) = \sup\{h(x) \mid h \in \mathrm{supp}\ (f, H)\}$ is called the H-convex hull of f. A function $f : X \to \bar{\mathbb{R}}$ is called abstract convex with respect to H (H-convex) at a point $x \in X$ if there exists a set $U \subseteq \mathrm{supp}\ (f, H)$ such that $f(x) = \sup\{h(x) \mid h \in U\}$. It is clear that f is H-convex at x if and only if $f(x) = \mathrm{co}_H f(x)$. If f is H-convex at each point $x \in X$, then f is called H-convex on X. Classical convexity is equivalent to abstract convexity with respect to the set A of continuous affine functions. More exactly, if X is a Banach space, then a lower semicontinuous function $f : X \to \mathbb{R}_{+\infty}$ is convex if and only if f is A-convex. Similarly we can define abstract concave with respect to H (H-concave) functions.

Let L be a set of functions defined on a set X. Functions $h_{l,\gamma}$ of the form $h_{l,\gamma}(x) = l(x) - \gamma,\ x \in X$, with $l \in L$ and $\gamma \in \mathbb{R}$ are called L-affine. Denote by H_L the set of all L-affine functions.

Let (X, L) be a pair of sets with a coupling function $\rho : X \times L :\to \mathbb{R}$. The function ρ allows us to consider X as a set of functions $x(\cdot)$ defined on L and L as a set of functions $l(\cdot)$ defined on X. Here

$$x(l) = \rho(x, l) \quad (l \in L), \qquad l(x) = \rho(x, l) \quad (x \in X).$$

Denote by F_X the union of the set of all functions $f : X \to \mathbb{R}_{+\infty}$ and the function $-\infty$, where $-\infty(x) = -\infty$ for all $x \in X$. Let $f \in F_X$. The function

$$f^\rho(l) = \sup_{x \in X}(\rho(x, l) - f(x)), \qquad l \in L,$$

is called the Fenchel–Moreau conjugate of f. This function is H_X-convex. It is easy to check that $f^\rho \in F_L$. The function

$$f^{\rho\rho}(x) = \sup_{l \in L}(\rho(x, l) - f^\rho(l))$$

is called the Fenchel–Moreau biconjugate to f. This function is H_L-convex.

The classical result of abstract convex analysis (the Fenchel–Moreau theorem) states that $f \in F_X$ is abstract convex with respect to H_L at a point x if and only if $f(x) = f^{\rho\rho}(x)$.

Let (X, L) be a pair of sets with a finite coupling function ρ. Let f be H_L convex and $x_0 \in \mathrm{dom}\, f := \{x \in X \mid f(x) < +\infty\}$. The set

$$\begin{aligned}\partial_\rho f(x_0) &= \{l \in L \mid f(x) \geq f(x_0) - l(x_0) + l(x), \quad x \in X\} \\ &= \{l \in L \mid f(x) \geq f(x_0) - \rho(x_0, l) + \rho(x, l), \quad x \in X\}\end{aligned}$$

is called the ρ-subdifferential of f at a point x_0. The ρ-subdifferential $\partial_\rho f(x_0)$ is nonempty if and only if $f(x_0) = \max\{h(x_0) \mid h \in \mathrm{supp}\ (f, H_L)\}$. Elements of $\partial_\rho f(x_0)$ are called ρ-subgradients (abstract subgradients) of f at x_0.

The *approximate* abstract subgradients are inspired by the concept of ε-subgradients introduced in [2]. Fix $\varepsilon \geq 0$. We say that $l \in \partial_{\rho,\varepsilon} f(x_0)$ whenever

$$f(x) \geq f(x_0) - \rho(x_0, l) + \rho(x, l) + \varepsilon \quad \text{for all} \quad x \in X.$$

2.2. Abstract Lagrangians. Definitions and results presented in this subsection are found in [21, 19] (see also the references therein). Let X, Z be reflexive Banach spaces. We consider the optimization problem

$$\text{(P)} \qquad \text{minimize} \ \ \varphi(x) \quad \text{subject to } x \text{ in } X,$$

where the function $\varphi : X \to \mathbb{R}_{+\infty}$ is an extended real-valued function. We will assume that the function φ is proper, that is, $\operatorname{dom}\varphi \neq \emptyset$.

A function $f : X \times Z \to \bar{\mathbb{R}}$ is called a *dualizing parameterization function* for φ if $f(x,0) = \varphi(x)$ for all $x \in X$. This parameterization induces the *perturbation function* given by

$$\beta(z) := \inf_{x\in X} f(x,z).$$

Our assumption on φ forces $\beta(0) < +\infty$.

We introduce duality for problem (P) in the following way. Let Ω be a set of parameters (or dual variables) and consider a coupling function $\rho : Z \times \Omega \to \mathbb{R}$. The *Lagrangian-type function* for problem (P) induced by this coupling function ρ is defined as

$$l(x,\omega) := \inf_{z\in Z}\{f(x,z) - \rho(z,\omega)\}. \tag{2.1}$$

Let $f_x(z) = f(x,z)$. We have

$$l(x,\omega) = -\sup_{z\in Z}\{\rho(z,\omega) - f_x(z)\} = -f_x^{\rho}(\omega).$$

The above expression establishes a relationship between the Lagrangian and the Fenchel–Moreau conjugate to f. This relationship is the key to using conjugations to study duality.

Associated with the Lagrangian function above, we define the *generalized dual function* $q : \Omega \to \bar{\mathbb{R}}$ in a canonical way:

$$q(\omega) := \inf_{x\in X} l(x,\omega) = \inf_{x\in X}(-f_x^{\rho}(\omega)). \tag{2.2}$$

With these definitions, the *generalized dual problem* becomes

$$\sup_{\omega\in\Omega} q(\omega).$$

Assume in what follows that the coupling function ρ verifies $\rho(0,\omega) = 0$ for all $\omega \in \Omega$. Then by (2.1) and (2.2) we get

$$\sup_{\omega} q(\omega) \leq \inf_{x} \varphi(x), \tag{2.3}$$

which is known as the *weak duality property*. When also the opposite inequality holds in (2.3), we say that the *zero duality gap property* holds for the Lagrangian l. The definitions give $\sup_\omega q(\omega) = \beta^{\rho\,\rho}(0)$, where $\beta^{\rho\,\rho}$ is the biconjugate to β with respect to ρ. Altogether, we can write the zero duality gap property as

$$\beta(0) = \beta^{\rho\,\rho}(0).$$

An element $\bar{\omega} \in \Omega$ is called an *exact Lagrange multiplier* if $\beta(0) = q(\bar{\omega}) = \max_{\omega\in\Omega} q(\omega)$. The following result is well known (see, e.g., [19, Theorem 5.2]).

PROPOSITION 2.1. *An element $\bar{\omega} \in \Omega$ is an exact Lagrange multiplier if and only if $\bar{\omega}$ is a ρ-subgradient of β at zero.*

3. Generalized augmented Lagrangians. An abstract Lagrangian is called augmented Lagrangian if $\Omega = Y \times \mathbb{R}_+$, where $Y = Z^*$ is a conjugate to Z space and for $\omega = (y, r) \in \Omega$ we have $\rho(z, (y, r)) = y(z) - r\sigma(z)$. Here σ is an *augmenting* function. It is assumed that σ enjoys some properties; in particular $\sigma(0) = 0$ and $\sigma(z) > 0$ for $z \neq 0$. From the numerical point of view the presence of the linear term $y(z)$, which can be considered as a coupling function generating the classical Lagrangian, is important. However, the role of this term is not essential in the examination of some important theoretical questions, such as the zero duality gap property or the existence of exact penalty parameters. We show that the key role in the study of these questions is played by the penalty term $r\sigma(z)$. In order to underline this key role, we consider a generalized augmented Lagrangian, which contains the augmented Lagrangian described above as a very special case. In order to introduce this generalized augmented Lagrangian we need a function $p : \mathbb{R}^2 \to \mathbb{R}$ which possesses the following properties:

(a) $p(0, 0) = 0$;

(b) there exists a strictly increasing function $\psi : \mathbb{R}_+ \to \mathbb{R}_+$ such that $\psi(0) = 0$ and for each $a \in \mathbb{R}$ and $b_1, b_2 \in \mathbb{R}$ with $b_1 \geq b_2$ it holds that

$$p(a, b_1) - p(a, b_2) \geq \psi(b_1 - b_2). \tag{3.1}$$

We will always assume that p verifies conditions (a) and (b).

The simplest example of a function p with such properties is $p(a, b) = a + b$. More generally, we can have $p(a, b) = g(a) + h(b)$ with $g(0) = h(0) = 0$ and h a strictly increasing function. We now give a less trivial example. Let $p(a, b) = g(a)h(b)$, where $g(a) \geq 1$ for all $a \in \mathbb{R}$, and let $h : \mathbb{R} \to \mathbb{R}$ be a differentiable function such that $h'(x) \geq \gamma > 0$ for all x and $h(0) = 0$. Let $b_1 > b_2$. Then

$$p(a, b_1) - p(a, b_2) = g(a)(h(b_1) - h(b_2)) \geq h(b_1) - h(b_2) \geq \gamma(b_1 - b_2),$$

so (3.1) holds with $\psi(b) = \gamma b$.

We need to have two sets U, Y and two families of real-valued functions indexed by these sets: $\{\sigma_u\}_{u \in U}$ and $\{\nu_y\}_{y \in Y}$. We assume that the family $\{\sigma_u\}_{u \in U}$ verifies the following properties:

(U_1) $\sigma_u : Z \to \mathbb{R}_{+\infty}$ are proper, weakly lower semicontinuous for all $u \in U$.

(U_2) $\sigma_u(0) = 0$ and $\sigma_u(z) > 0$ for all $z \neq 0$.

(U_3) For all $u \in U$ there exists $K_u > 0$ such that the level set $\{z \mid \sigma_u(z) \leq K_u\}$ is bounded.

(U_4) For each neighborhood $V \subset Z$ of 0 and for each $u \in U$ we have that

$$\inf_{z \notin V} \sigma_u(z) > 0.$$

Remark 3.1. The function $\mu_u = -\sigma_u$, where σ_u enjoys U_2, U_4 and is continuous, is usually called a peak at zero (see [19]). Penot [10] used the term *potential* for functions similar to σ. In [24], a function that verifies properties U_1, U_2, and U_4 is said to be a *valley at* 0 in X.

We assume that the family $\{\nu_y\}_{y \in Y}$ verifies

(Y_1) $\nu_y(0) = 0$ for all $y \in Y$;

(Y_2) $\nu_y : Z \to \mathbb{R}$ is weakly upper semicontinuous.

Remark 3.2. Each member of the family $\{\sigma_u\}_{u \in U}$ represents a "penalty" term in the augmented Lagrangian, while the family $\{\nu_y\}_{y \in Y}$ consists of the "linear" or "ordinary" augmenting terms.

We now introduce a set of dual variables Ω and a coupling function $\rho : Z \times \Omega \to \mathbb{R}$ which will allow us to combine the elements of both families by using the function p:

$$\Omega := \mathbb{R}_+ \times Y \times U; \tag{3.2}$$

$$\rho(z, \omega) = \rho(z, (r, y, u)) := p(\nu_y(z), -r\sigma_u(z)). \tag{3.3}$$

Example 3.1. Let $\|\cdot\|$ be a norm in the Banach space Z. Take $Y := Z^*$ and $U = (0, +\infty)$. Consider the families $\{\sigma_u\}_{u\in U}$ and $\{\nu_y\}_{y\in Y}$ defined as $\nu_y(z) := y(z)$ and $\sigma_u(z) = \|z\|^u$. It is clear from the definitions that these families verify conditions U_1–U_4. Assume now that $U = (0, 1)$ and consider the family $\{\sigma_u\}_{u\in U}$ given by $\sigma_u(z) = \|z\|^u$ for all z with $\|z\| \le 1$ and $\sigma_u(z) = 1$ otherwise. It has been proved in [24, Lemma 2.1] that the family $\{\sigma_u\}_{u\in U}$ verifies U_1–U_4.

Remark 3.3. Assume that U consists of one element u and call $\sigma_u =: \sigma$. Then Ω consists of vectors $\omega = (r, y)$ with $r \in \mathbb{R}_+$ and $y \in Y$. Let β be a function defined on Z. Then supp $(\beta, H_\Omega) \neq \emptyset$ means that there exists $c \in \mathbb{R}$ and $(r, y) \in \mathbb{R}_+ \times Y$ such that $\beta(z) \ge \nu_y(z) - r\sigma(z) - c$ for all $z \in Z$. This property is related to the concept of growth condition studied in [10]. In [25] this inequality is considered when it holds outside some neighborhood of zero, and it is also called a growth condition.

Remark 3.4. Let $p(a, b) = a + b$ and let $Y = Z^*$ be the dual of the Banach space Z. Assume that U consists of one element u and call $\sigma_u =: \sigma$. Then the augmented Lagrangian $l(x, \omega)$ with $\omega = (r, y)$ has the form

$$l(x, \omega) = \inf_{z\in Z}\{f(x, z) - y(z) + r\sigma(z)\},$$

so the Lagrangian obtained above reduces to the classical augmented Lagrangian defined by the augmenting function σ (see [13, Chapter 11]).

Remark 3.5. Assume that Y consists of one element y and $\nu_y = 0$. Then Ω consists of vectors $\omega = (r, u)$ with $r \in \mathbb{R}_+$ and $u \in U$. In such a case the so-obtained Lagrangian $l(x, \omega) = \inf_{z\in Z}\{f(x, z) + r\sigma_u(z)\}$ is interpreted as a generalized penalty function.

4. Abstract subdifferential and approximate subdifferentials. In this section we examine abstract subdifferential and approximate subdifferential of a lower semicontinuous function β with respect to a coupling function defined by (3.3). Let Ω be a set defined by (3.2). Recall that the set of Ω-affine functions H_Ω consists of functions h of the form $h(z) = \rho(z, (r, y, u)) - c = p(\nu_y(z), -r\sigma_u(z)) - c$, where $\omega = (r, y, u) \in \Omega$ and $c \in \mathbb{R}$.

We consider only functions β such that the support set supp $(\beta, H_\Omega) \neq \emptyset$. This means that there exist $\omega = (r, y, u) \in \Omega$ and $c \in \mathbb{R}$ such that $\beta(z) \ge p(\nu_y(z), -r\sigma_u(z)) - c$ for all $z \in Z$. By definition of β^ρ, the latter inequality holds if and only if $\omega = (r, y, u) \in \operatorname{dom}\beta^\rho$. So our basic assumption supp $(\beta, H_\Omega) \neq \emptyset$ is equivalent to $\operatorname{dom}\beta^\rho \neq \emptyset$.

THEOREM 4.1. *Let X, Z be reflexive Banach spaces. Take $\rho : Z \times \Omega \to \mathbb{R}$ as in* (3.3) *for families of functions verifying U_1–U_3 and Y_1–Y_2. Assume also that $p(\nu_y(\cdot), -r\sigma_u(\cdot))$ is upper semicontinuous for every $(r, y, u) \in \Omega$. Let $\beta : Z \to \mathbb{R}_{+\infty}$ be a lower semicontinuous function such that $\beta(0) < +\infty$ and* supp $(\beta, H_\Omega) \neq \emptyset$. *Then there exists $r_0 > 0$ and $(\bar u, \bar y) \in U \times Y$ such that for all $r > r_0$ the following hold:*

(i) *there exists $z_r \in Z$ such that $(r, \bar y, \bar u) \in \partial_\rho\beta(z_r)$;*

(ii) $(r, \bar y, \bar u) \in \partial_{\rho,\varepsilon_r}\beta(0)$,

where $\varepsilon_r := \beta(0) - \beta(z_r) + p(\nu_{\bar y}(z_r), -r\sigma_{\bar u}(z_r)) \geq 0$. *Furthermore,* $\lim_{r\to\infty} \varepsilon_r = 0$.

Proof. Since supp $(\beta, H_\Omega) \neq \emptyset$, there exist $\bar\omega := (r, \bar y, \bar u) \in \Omega$ and $\bar c \in \mathbb{R}$ such that

$$p(\nu_{\bar y}(z), -\bar r\sigma_{\bar u}(z)) - \bar c \leq \beta(z) \quad \text{for all} \quad z \in Z.$$

For any $r \geq 0$ call $m(r) := \inf_{z\in Z}\{\beta(z) - p(\nu_{\bar y}(z), -r\sigma_{\bar u}(z))\}$. The equalities $\nu_{\bar y}(0) = \sigma_{\bar u}(0) = 0$ and $p(0,0) = 0$ imply $m(r) \leq \beta(0)$. Fix $r > \bar r > 0$. Since p is increasing on the second argument and $\sigma_u \geq 0$ it follows that

$$\begin{aligned} -\infty < m(\bar r) &= \inf_{z\in Z}\{\beta(z) - p(\nu_{\bar y}(z), -\bar r\sigma_{\bar u}(z))\} \\ &\leq \inf_{z\in Z}\{\beta(z) - p(\nu_{\bar y}(z), -r\sigma_{\bar u}(z))\} = m(r) \leq \beta(0). \end{aligned}$$

Take a sequence $\{z_n\}$ such that $\lim_{n\to\infty} \beta(z_n) - p(\nu_{\bar y}(z_n), -r\sigma_{\bar u}(z_n)) = m(r)$. Call $\theta_n := \beta(z_n) - p(\nu_{\bar y}(z_n), -r\sigma_{\bar u}(z_n))$. There exists n_0 such that $\theta_n < \beta(0) + 1$ for all $n \geq n_0$. We can write for $n \geq n_0$

$$\begin{aligned} m(\bar r) &\leq \beta(z_n) - p(\nu_{\bar y}(z_n), -\bar r\sigma_{\bar u}(z_n)) \\ &= \beta(z_n) - p(\nu_{\bar y}(z_n), -r\sigma_{\bar u}(z_n)) + p(\nu_{\bar y}(z_n), -r\sigma_{\bar u}(z_n)) - p(\nu_{\bar y}(z_n), -\bar r\sigma_{\bar u}(z_n)) \\ &= \theta_n + (p(\nu_{\bar y}(z_n), -r\sigma_{\bar u}(z_n)) - p(\nu_{\bar y}(z_n), -\bar r\sigma_{\bar u}(z_n))). \end{aligned}$$

Let $d_1 = -\bar r\sigma_{\bar u}(z_n), d_2 = -r\sigma_{\bar u}(z_n)$. Then $d_1 \geq d_2$. Due to (3.1), we have

$$p(\nu_{\bar y}(z_n), d_1) - p(\nu_{\bar y}(z_n), d_2) \geq \psi(d_1 - d_2) = \psi((r - \overline{r})\sigma_{\bar u}(z_n)).$$

Hence for $n \geq n_0$ we can write

$$m(\overline{r}) \leq \theta_n - \psi((r - \overline{r})\sigma_{\bar u}(z_n)) \leq \beta(0) + 1 - \psi((r - \overline{r})\sigma_{\bar u}(z_n)).$$

Rearranging the above expression we get for $n \geq n_0$

$$\psi((r - \bar r)\sigma_{\bar u}(z_n)) \leq \beta(0) + 1 - m(\overline{r}),$$

so it holds that

$$\sigma_{\bar u}(z_n) \leq \frac{\psi^{-1}(\beta(0) + 1 - m(\bar r))}{r - \bar r}$$

for $n \geq n_0$. Let $K_{\bar u}$ be as in condition U_3. Take

$$r_0 := \bar r + \frac{\psi^{-1}(\beta(0) + 1 - m(\bar r))}{K_{\bar u}}.$$

Then for all $r > r_0$ and all $n \geq n_0$ we get $\sigma_{\bar u}(z_n) \leq K_{\bar u}$. By condition U_3, this implies that $\{z_n\}_{n\geq n_0}$ is bounded. Therefore there exists a subsequence $\{z_{n_j}\}$ of $\{z_n\}$ weakly converging to some z_r. By lower semicontinuity of all functions involved, we can write

$$\begin{aligned} \beta(z_r) - p(\nu_{\bar y}(z_r), -r\sigma_{\bar u}(z_r)) &\leq \liminf_j \beta(z_{n_j}) - p(\nu_{\bar y}(z_{n_j}), -r\sigma_{\bar u}(z_{n_j})) \\ &= \liminf_j \theta_{n_j} = m(r). \end{aligned}$$

By definition of $m(r)$, the above inequality implies that for all $r > r_0$ and for all z we have

$$\beta(z_r) - p(\nu_{\bar y}(z_r), -r\sigma_{\bar u}(z_r)) \leq \beta(z) - p(\nu_{\bar y}(z), -r\sigma_{\bar u}(z))$$

or, equivalently,

$$\beta(z) \geq \beta(z_r) + \rho(z,(r,\bar{y},\bar{u})) - \rho(z_r,(r,\bar{y},\bar{u})). \tag{4.1}$$

This means that $\bar{\omega} = (r,\bar{y},\bar{u}) \in \partial_\rho \beta(z_r)$. This completes the proof of (i).

Let us prove (ii). The fact that $\varepsilon_r \geq 0$ follows readily from (4.1) for $z = 0$. Since $\rho(0,\omega) = 0$, the inclusion in condition (ii) is equivalent to checking that

$$\beta(z) - \beta(0) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z)) + \varepsilon_r \geq 0 \quad \text{for all } \ z \in Z. \tag{4.2}$$

Indeed, since $\bar{\omega} \in \partial_\rho \beta(z_r)$ we have

$$\begin{aligned} 0 &\leq \beta(z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z)) - \beta(z_r) + p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) \\ &= \beta(z) - \beta(0) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z)) - \beta(z_r) + \beta(0) + p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) \\ &= \beta(z) - \beta(0) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z)) + \varepsilon_r, \end{aligned}$$

which establishes (4.2). For proving that $\lim_{r\to\infty} \varepsilon_r = 0$ we need to establish the following fact.

Fact 1. The function $r \mapsto z_r$ $(r > r_0)$ is bounded and converges weakly to 0 as $r \to +\infty$.

Indeed, assume Fact 1 is true. Without loss of generality we can assume that $r_0 \geq 1$. Since p is increasing on the second argument and $\nu_{\bar{y}}(0) = \sigma_{\bar{u}}(0) = 0$ it follows from (4.1) with $z = 0$ that

$$\begin{aligned} \beta(0) &\geq \limsup_{r\to+\infty}(\beta(z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r))) \\ &\geq \liminf_{r\to+\infty}(\beta(z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r))) \\ &\geq \liminf_{r\to+\infty} \beta(z_r) + \liminf_{r\to+\infty} -p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) \geq \beta(0), \end{aligned}$$

where we used the upper semicontinuity assumption on p and lower semicontinuity of β. Therefore $\beta(0) = \lim_{r\to+\infty}(\beta(z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r))$. Now the definition of ε_r shows that $\lim_{r\to\infty} \varepsilon_r = 0$. So let us prove Fact 1.

Proof of Fact 1. From the definition of $m(\overline{r})$ we can write for every $r > r_0$

$$\begin{aligned} m(\overline{r}) &\leq \beta(z_r) - p(\nu_{\bar{y}}(z_r), -\overline{r}\sigma_{\bar{u}}(z_r)) \\ &= \beta(z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) + p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) - p(\nu_{\bar{y}}(z_r), -\overline{r}\sigma_{\bar{u}}(z_r)). \end{aligned}$$

Since $r > \overline{r}$ it follows that

$$p(\nu_{\bar{y}}(z_r), -\overline{r}\sigma_{\bar{u}}(z_r)) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) \geq \psi((r-\overline{r})\sigma_{\bar{u}}(z_r)),$$

so

$$m(\overline{r}) \leq \beta(z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) - \psi((r-\overline{r})\sigma_{\bar{u}}(z_r)).$$

We also have

$$\beta(z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) = m(r) \leq \beta(0).$$

Therefore

$$\psi((r-\overline{r})\sigma_{\bar{u}}(z_r)) \leq \beta(z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) - m(\overline{r}) \leq \beta(0) - m(\overline{r}).$$

It follows from this inequality that

$$\sigma_{\bar{u}}(z_r) \le \frac{\psi^{-1}(\beta(0) - m(\overline{r}))}{r - \overline{r}}. \tag{4.3}$$

Using the definition of r_0 and the fact that $r > r_0$ we conclude that

$$\sigma_{\bar{u}}(z_r) \le K_{\bar{u}} \frac{\psi^{-1}(\beta(0) - m(\overline{r}))}{\psi^{-1}(\beta(0) + 1 - m(\overline{r}))} \le K_{\bar{u}}.$$

So the function $r \mapsto z_r$ $(r \ge r_0)$ is bounded. Now let $\overline{z}$ be a weak accumulation point of this function as $r \to +\infty$. Expression (4.3) yields

$$\begin{aligned} 0 \le \sigma_{\bar{u}}(\overline{z}) &\le \liminf_{r\to\infty} \sigma_{\bar{u}}(z_r) \\ &\le \liminf_{r\to\infty} \frac{\psi^{-1}(\beta(0) - m(\overline{r}))}{r - \overline{r}} = 0. \end{aligned}$$

Hence $\overline{z} = 0$. Since this is the unique possible accumulation point, the function converges weakly to 0 as $r \to +\infty$. The proof of (ii) is now complete. □

Now we use the previous result to prove that the function β is abstract convex with respect to H_Ω at zero. In other words, our duality scheme has zero duality gap.

PROPOSITION 4.1. *The equality*

$$\beta(0) = \beta^{\rho\,\rho}(0)$$

holds under the assumptions of Theorem 4.1.

Proof. Since $\rho(0, \omega) = 0$ for all $\omega \in \Omega$, it is enough to prove that $\beta(0) \le \beta^{\rho\,\rho}(0)$. With the notation of Theorem 4.1(i), there exists $r_0 > 0$ such that for all $r \ge r_0$ we have $(r, \bar{y}, \bar{u}) \in \partial_\rho \beta(z_r)$. It is easy to see from the definition of abstract subdifferential that this inclusion implies $\beta^\rho(r, \bar{y}, \bar{u}) = p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) - \beta(z_r)$. By Fact 1 in the proof of Theorem 4.1, $\{z_r\}$ weakly converges to zero as $r \to +\infty$. Hence,

$$\beta^{\rho\,\rho}(0) = \sup_{\omega\in\Omega} \rho(\omega, 0) - \beta^\rho(\omega) \ge -\beta^\rho(r, \bar{y}, \bar{u}) = -p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) + \beta(z_r).$$

Altogether we have

$$\beta^{\rho\,\rho}(0) \ge \liminf_{r\to\infty} \beta(z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) \ge \beta(0).$$

The proof is complete. □

The definition of abstract subdifferential shows that an abstract subgradient has a global nature in the sense that we need to check a certain inequality for all points $z \in Z$ in order to check that an element $\omega \in \Omega$ is a subgradient of a function β defined on Z at a point $z_0 \in Z$. It is interesting to establish conditions under which we can check the required inequality only in a certain neighborhood of a point z. The next statement shows that this local property is valid for the coupling function ρ defined by (3.3) for large enough r.

PROPOSITION 4.2. *Assume all hypotheses of Theorem* 4.1 *hold (in particular,* $\operatorname{dom}\beta^\rho \ne \emptyset$*). Take* $(r, \bar{y}, \bar{u}) \in \operatorname{dom}\beta^\rho$ *and assume that condition* U_4 *is satisfied by* $\sigma_{\overline{u}}$*. If there exists a neighborhood* V *of* 0 *and* $r' > 0$ *such that for all* $z \in V$ *it holds that*

$$\beta(z) \ge \beta(0) + p(\nu_{\bar{y}}(z), -r'\sigma_{\bar{u}}(z)), \tag{4.4}$$

then there exists $r^* \geq r'$ *such that* $(r, \bar{y}, \bar{u}) \in \partial_\rho \beta(0)$ *for all* $r > r^*$.

Proof. Take r_0 as in Theorem 4.1. By Theorem 4.1(ii) we have that $(r, \bar{y}, \bar{u}) \in \partial_{\rho,\varepsilon_r}\beta(0)$ for all $r > r_0$, with $\lim_{r\to\infty} \varepsilon_r = 0$. Fix $\varepsilon_0 > 0$. Since ε_r tends to 0, there exists $r_1 > r_0$ such that $\varepsilon_0 \geq \varepsilon_r$ for all $r > r_1$. By condition U_4, there exists $c(V, \bar{u}) > 0$ such that

$$c(V, \bar{u}) < \inf_{z \notin V} \sigma_{\bar{u}}(z).$$

Fix $r_2 > r_1$ and choose

$$r^* > \max\left\{r', \frac{\psi^{-1}(\varepsilon_0)}{c(V, \bar{u})} + r_2\right\}. \tag{4.5}$$

Since $r^* > r'$ we have by assumption (4.4) and condition (b) on p that the inequality

$$\beta(z) \geq \beta(0) + p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z))$$

holds for all $z \in V$ and all $r > r^*$. Assume now that $z \notin V$ and $r > r^*$. Because $r_2 > r_0$ we have that $(r_2, \bar{y}, \bar{u}) \in \partial_{\rho,\varepsilon_{r_2}}\beta(0)$. Hence

$$\begin{aligned}\beta(0) - \varepsilon_{r_2} &\leq \beta(z) - p(\nu_{\bar{y}}(z), -r_2\sigma_{\bar{u}}(z)) \\ &= \beta(z) - p(\nu_{\bar{y}}(z), -r^*\sigma_{\bar{u}}(z)) + p(\nu_{\bar{y}}(z), -r^*\sigma_{\bar{u}}(z)) - p(\nu_{\bar{y}}(z), -r_2\sigma_{\bar{u}}(z)).\end{aligned}$$

Since $r^* \geq r_2$, it follows that

$$p(\nu_{\bar{y}}(z), -r_2\sigma_{\bar{u}}(z)) - p(\nu_{\bar{y}}(z), -r^*\sigma_{\bar{u}}(z)) \geq \psi((r^* - r_2)\sigma_{\bar{u}}(z)),$$

so

$$\beta(0) - \varepsilon_{r_2} \leq \beta(z) - p(\nu_{\bar{y}}(z), -r^*\sigma_{\bar{u}}(z)) - \psi((r^* - r_2)\sigma_{\bar{u}}(z)).$$

Since $\sigma_{\bar{u}}(z) > c(V, \bar{u})$ and ψ is increasing we have

$$\beta(0) - \varepsilon_{r_2} \leq \beta(z) - p(\nu_{\bar{y}}(z), -r^*\sigma_{\bar{u}}(z)) - \psi((r^* - r_2)c(V, \bar{u})). \tag{4.6}$$

According to (4.5) we have $\varepsilon_0 < \psi((r^* - r_2)c(V, \bar{u}))$; therefore $-\psi((r^* - r_2)c(V, \bar{u})) \leq -\varepsilon_0 \leq -\varepsilon_{r_2}$, which combined with (4.6) gives

$$\beta(0) - \varepsilon_{r_2} \leq \beta(z) - p(\nu_{\bar{y}}(z), -r^*\sigma_{\bar{u}}(z)) - \varepsilon_{r_2}.$$

Hence we get

$$\beta(0) \leq \beta(z) - p(\nu_{\bar{y}}(z), -r^*\sigma_{\bar{u}}(z))$$

for all $z \notin V$. By condition (b) in the definition of p, the inequality holds for all $r > r^*$. The proof is complete. □

We quoted in Proposition 2.1 the equivalence between the existence of an exact penalty parameter and nonemptiness of the subgradient of the perturbation function β at zero. In the classical framework another equivalent property holds. This property is known as *calmness at zero* of the perturbation function. Under some constraint qualifications (see, e.g., [13, Proposition 8.32]), calmness at zero of β is equivalent to nonemptiness of the subdifferential of β at 0. In our context, we need to introduce a

concept of calmness which is related to the family $\{\sigma_u\}$. This concept reduces to the classical one when $\sigma_u = \|\cdot\|$ for all $u \in U$.

DEFINITION 4.1. *Fix $u \in U$ and let $h : Z \to \bar{\mathbb{R}}$. We say that h is* σ_u-calm at 0 *when*

$$\liminf_{z\to 0,\, z\neq 0} \frac{h(z) - h(0)}{\sigma_u(z)} > -\infty.$$

In order to establish the relation between calmness at zero and abstract subdifferentiability, we need to assume a growth condition on p. Our definition was inspired from [10, Definition 2.6].

DEFINITION 4.2. *Fix $u \in U$ and $y \in Y$. We say that p verifies a* growth condition with respect to the functions ν_y *and* σ_u *when there exists $r = r(y,u) > 0$ such that*

$$\text{(i)} \quad \liminf_{z\to 0,\, z\neq 0} \frac{p(\nu_y(z), -r\sigma_u(z))}{\sigma_u(z)} > -\infty.$$

We say that σ_u is a penalty function *for p and ν_y when*

$$\text{(ii)} \quad \limsup_{z\to 0,\, z\neq 0,\, r\to+\infty} \frac{p(\nu_y(z), -r\sigma_u(z))}{\sigma_u(z)} = -\infty.$$

Example 4.1. Let $p(a,b) = a + b$ and let the families $\{\nu_y\}_y$ and $\{\sigma_u\}_u$ be as in Example 3.1 with $U = (0,1]$. Then both (i) and (ii) of Definition 4.2 hold for every pair σ_u, ν_y.

The proposition below relates Definition 4.2 with nonemptiness of $\partial_\rho\beta(0)$.

PROPOSITION 4.3.

(a) *Assume $\partial_\rho\beta(0)$ is nonempty and take $(\bar r, \bar y, \bar u) \in \partial_\rho\beta(0)$. If p verifies a growth condition with respect to the functions $\nu_{\bar y}$ and $\sigma_{\bar u}$, then β is $\sigma_{\bar u}$-calm at 0.*

(b) *Assume all hypotheses of Theorem* 4.1 *hold, and fix $(\bar r, \bar y, \bar u) \in \operatorname{dom}\beta^\rho$. If β is $\sigma_{\bar u}$-calm at 0 and $\sigma_{\bar u}$ is a penalty function for p and $\nu_{\bar y}$, then the subdifferential $\partial_\rho\beta(0)$ is nonempty.*

Proof. (a) We have that $\partial_\rho\beta(0) \neq \emptyset$ and $(r, \overline{y}, \overline{u}) \in \partial_\rho\beta(0)$. Then $\beta(z) \geq \beta(0) + p(\nu_{\overline{y}}(z), -r\sigma_{\overline{u}}(z))$. This gives

$$\liminf_{z\to 0} \frac{\beta(z) - \beta(0)}{\sigma_{\bar u}(z)} \geq \liminf_{z\to 0} \frac{p(\nu_{\overline{y}}(z), -r\sigma_{\bar u}(z))}{\sigma_{\bar u}(z)} > -\infty,$$

which implies the $\sigma_{\bar u}$-calmness at 0.

(b) Assume now that there exists $\bar u \in U$ such that β is $\sigma_{\bar u}$-calm at 0. Hence there exists $L > 0$ and a neighborhood W of 0 such that for all $z \in W \setminus \{0\}$ we have

$$\frac{\beta(z) - \beta(0)}{\sigma_{\bar u}(z)} > -L.$$

On the other hand, by condition (ii) in Definition 4.2 we have that for the given $\bar u$ there exists $\bar y \in Y$ such that

$$\limsup_{z\to 0,\, z\neq 0,\, r\to+\infty} \frac{p(\nu_{\overline{y}}(z), -r\sigma_{\bar u}(z))}{\sigma_{\bar u}(z)} < -L.$$

In other words, there exists $r_0 > 0$ and a neighborhood W_0 of 0 such that for all $r > r_0$ and all $z \in W_0 \setminus \{0\}$ we have

$$\frac{p(\nu_{\overline{y}}(z), -r\sigma_{\bar u}(z))}{\sigma_{\bar u}(z)} < -L.$$

Altogether, for all $z \in W \cap W_0 \setminus \{0\}$ and all $r > r_0$ we can write

$$\beta(z) - \beta(0) > -L\sigma_{\bar{u}}(z) > p(\nu_{\overline{y}}(z), -r\sigma_{\bar{u}}(z)).$$

So inequality (4.4) holds for a neighborhood of 0. By Proposition 4.2 we conclude that the inequality holds globally, and hence $(r, \overline{y}, \overline{u}) \in \partial_\rho \beta(0)$ for all $r > r_0$. In particular, $\partial_\rho \beta(0) \neq \emptyset$. □

The result below combines both items of the last proposition.

COROLLARY 4.1. *Assume the hypotheses of Theorem* 4.1 *hold with* $(\bar{r}, \bar{y}, \bar{u}) \in \operatorname{dom} \beta^\rho$. *Suppose also that* p, $\nu_{\overline{y}}$, *and* $\sigma_{\overline{u}}$ *verify conditions* (i)–(ii) *of Definition* 4.2. *Then the subdifferential* $\partial_\rho \beta(0)$ *is nonempty if and only if* β *is* $\sigma_{\bar{u}}$*-calm at* 0.

5. Lower semicontinuity of abstract concave functions. Let H be a set of functions defined on a topological space Z and let $\beta : Z \to \mathbb{R}_{-\infty}$ be an H-concave function; that is, there is a set $U \subset H$ such that $\beta(z) = \inf_{h \in U} h(z)$. If H consists of continuous functions, then β is upper semicontinuous. On the other hand, a basic assumption in Theorem 4.1 is lower semicontinuity of β. Therefore, we are interested in assumptions which guarantee the latter property, assuming that H consists of lower semicontinuous functions.

Let $f : X \times Z \to \mathbb{R}_{+\infty}$ be a function and

$$\beta(z) = \inf_{x \in X} f(x, z). \tag{5.1}$$

We can consider β as an abstract concave function with respect to a set H of elementary functions which contains all functions $(f_x)_{x \in X}$, where $f_x(z) = f(x, z)$. We will apply Theorem 4.1 for the function β defined by (5.1). For this we need to describe functions f such that the function β is weakly lower semicontinuous. The following definition will be used.

DEFINITION 5.1. *A function* $f : X \times Z \to \bar{\mathbb{R}}$ *is said to be* weakly level-compact *if for every* $\overline{z} \in Z$ *there exists a weak neighborhood* $W \subset Z$ *of* $\overline{z}$ *such that, for every* $\alpha \in \mathbb{R}$, *the set*

$$\{x \in X \mid f(x, z) \leq \alpha\} \subset \bar{B} \text{ for all } z \in W,$$

where $\bar{B} \subset X$ *is weakly compact.*

Remark 5.1. If in Definition 5.1 we require $\bar{B}$ to be a bounded set, then we recover the definition of uniform level boundedness given in [13, Definition 1.16].

Remark 5.2. Since X is a reflexive Banach space, Alaoglu's theorem implies that a set is weakly compact if and only if it is bounded and weakly closed. Moreover, every bounded sequence has a weakly convergent subsequence.

PROPOSITION 5.1. *Let* $f : X \times Z \to \bar{\mathbb{R}}$ *be weakly lower semicontinuous and weakly level-compact. Then the function* β *defined by* (5.1) *is weakly lower semicontinuous.*

Proof. Assume that β is not weakly lower semicontinuous, which means that there exist a point $\overline{z}$, a net $\{z_i\}_{i \in I}$, and $\varepsilon > 0$ such that

(i) $\overline{z} = (w) - \lim_i z_i$;

(ii) $\liminf_i \beta(z_i) < \beta(\overline{z}) - \varepsilon$.

By Definition 5.1, there exists a weak neighborhood W of $\overline{z}$ such that the set

$$\{x \in X \,:\, f(x, z) \leq \beta(\overline{z}) - \varepsilon\} \subset B \text{ for all } z \in W,$$

where B is weakly compact. Item (i) means that there exists a terminal subset J of I ($J \subset I$ is *terminal* when there exists $i_0 \in I$ such that whenever $j \geq i_0$ we must have

$j \in J$) such that $z_j \in W$ for all $j \in J$. Using this fact in (ii) we get

$$\beta(\overline{z}) - \varepsilon > \sup_{I' \subset I,\, I' \text{ terminal}} \inf_{j \in I'} \beta(z_j) \geq \inf_{j \in J} \beta(z_j).$$

Now take $k_0 \in \mathbb{N}$ such that for all $k \geq k_0$ we have

$$\beta(\overline{z}) - \varepsilon - 1/k > \inf_{j \in J} \beta(z_j) = \inf_{j \in J} \inf_{x \in X} f(x, z_j).$$

For every fixed $k \geq k_0$, we can choose $x_k \in X$, $j_k \in J$ such that $f(x_k, z_{j_k}) < \beta(\overline{z}) - \varepsilon - 1/k$. Because B is weakly compact and the sequence $\{x_k\} \subset B$, there exists a subsequence $\{x_{k_l}\}_{l \in \mathbb{N}}$ weakly converging to some $\overline{x}$. Altogether, the subsequence $\{(x_{k_l}, z_{j_{k_l}})\}_l$ weakly converges to $(\overline{x}, \overline{z})$ and by weak lower semicontinuity of f we get

$$\beta(\overline{z}) \leq f(\overline{x}, \overline{z}) \leq \liminf_l f(x_{k_l}, z_{j_{k_l}}) \leq \liminf_l \beta(\overline{z}) - \varepsilon - 1/k_l = \beta(\overline{z}) - \varepsilon,$$

which is impossible. We conclude that β must be weakly lower semicontinuous. ∎

5.1. Application to constrained minimization and exact penalization. We propose now a duality scheme for a general constrained problem. Given X, Z reflexive Banach spaces, consider the constrained problem

$$\text{(P)} \quad \min_{x \in C} h(x), \tag{5.2}$$

where $C \subset X$ and $\varphi : X \to \mathbb{R}_{+\infty}$. Denote by δ_A the indicator function of the set A, i.e., $\delta_A(x) = 0$ if $x \in A$ and $\delta_A(x) = +\infty$ if $x \notin A$. Problem (5.2) can be reformulated as our original problem (P) with $\varphi(x) := h(x) + \delta_C(x)$. In order to define the perturbed problems, we consider a point to set mapping $D : Z \rightrightarrows X$ such that $D(0) = C$. This induces a duality parameterization $f(x, z) := h(x) + \delta_{D(z)}(x)$, so the perturbed problems become

$$(P_z) \qquad \min_{x \in X} f(x, z) = \min_{x \in D(z)} h(x).$$

Remark 5.3. Assume the original problem is a classical nonlinear programming problem with constraint set $C = \{x \in X \,:\, g_i(x) \leq 0,\, i = 1, \ldots, m\}$, where $g_i : X \to \mathbb{R}_{+\infty}$. We can define perturbed problems using the point-to-set mapping $D : \mathbb{R}^m \rightrightarrows X$ given by

$$D(v) := \{x \in X \,:\, g_i(x) \leq v_i,\, i = 1, \ldots, m\}.$$

This choice of D corresponds to the *canonical perturbations* given in [11, Example 1, eq. (2.8)] or [12, section 6].

We will make the following basic assumptions on problem (P) and its perturbations (P_z).

(H0) D is weakly outer semicontinuous (i.e., the graph of D is weakly closed).

(H1) $h : X \to \mathbb{R}_{+\infty}$ is weakly lower semicontinuous.

Remark 5.4. Note that the mapping D defined in Remark 5.3 verifies (H0) when the constraint functions g_i are weakly lower semicontinuous.

Our first step is to guarantee weak lower semicontinuity of β.

PROPOSITION 5.2. *Let* (H0)–(H1) *hold. Assume that h is coercive, i.e.,* $\lim_{\|x\| \to \infty} h(x) = +\infty$. *Consider* $f(x, z) := h(x) + \delta_{D(z)}(x)$. *Then* $\beta(z) := \inf_{x \in X} f(x, z)$ *is weakly lower semicontinuous.*

Proof. Our first step is to prove that f is weakly level-compact. Indeed, for every $\bar{z} \in Z$ and every $W \subset Z$ such that $\bar{z} \in W$ we can write

$$\begin{aligned} \cup_{z\in W} A_\alpha(z) &= \cup_{z\in W}\{x \in X \,:\, f(x,z) \le \alpha\} \\ &= \cup_{z\in W}\{x \in X \,:\, h(x) \le \alpha \text{ and } x \in D(z)\} \\ &\subset h^{-1}((-\infty,\alpha]). \end{aligned}$$

By (H1) and the coercivity assumption, the set $h^{-1}((-\infty,\alpha])$ is bounded and weakly closed, and therefore weakly compact. Hence, f is weakly level-compact. Let us prove now that f is weakly lower semicontinuous at every $(\overline{x},\overline{z}) \in X \times Z$. Let $\{(x_i,z_i)\}_{i\in I}$ be a net converging weakly to $(\overline{x},\overline{z})$. Denote by $J \subset_T I$ the fact that $J \subset I$ and J is terminal. We can write

$$\begin{aligned} \liminf_{i\in I} f(x_i,z_i) &= \sup_{J\subset_T I} \inf_{j\in J} f(x_j,z_j) \\ &= \sup_{J\subset_T I} \inf_{j\in J,\, x_j\in D(z_j)} h(x_j) \\ &\ge \sup_{J\subset_T I} \inf_{j\in J} h(x_j) \ge h(\bar{x}), \end{aligned}$$

where we used assumption (H1) in the last inequality. On the other hand, by (H0) we have that $\bar{x} \in D(\bar{z})$ and therefore $f(\bar{x},\bar{z}) = h(\bar{x})$. The latter fact and the above expression yield the weak lower semicontinuity of f. The conclusion of the proposition now follows from Proposition 5.1. ∎

The concept of calmness is related with exact penalization (see, e.g., [3, Proposition 6.4.3]). Indeed, we establish next a connection between σ_u-calmness and the existence of an exact penalty parameter. More precisely, we prove that under σ_u-calmness of the perturbation function, every solution of problem (5.2) is also a local solution of the penalized problem, as long as the penalty parameter r is large enough. In other words, σ_u is an exact penalty function for problem (5.2). We need extra assumptions on our Lagrangian function.

(H2) The function ψ in (3.1) verifies

$$\liminf_{t\to 0^+} \frac{\psi(t)}{t} \ge \delta > 0$$

for some $\delta > 0$.

(H3) The function ψ in (3.1) verifies

$$\liminf_{r\to+\infty} \psi(r) = +\infty.$$

Remark 5.5. For instance, $\psi(t) = t^\alpha$ with $0 < \alpha \le 1$ verifies (H2) and (H3). In particular, the choice $p(a,b) = a + b$ corresponds to $\psi(t) = t$ for every $t \ge 0$.

PROPOSITION 5.3. *Assume that* (H0)–(H2) *hold. Let* σ_u *satisfy* U_1–U_3 *and let* Y *be such that* $0 \in Y$ *and* $\nu_0(z) = 0$ *for every* $z \in Z$. *Suppose also that either of the following two assumptions holds:*

(i) ψ *in* (3.1) *verifies* (H3).

(ii) h *is continuous on every solution of problem* (5.2).

If β *is* σ_u*-calm at* 0, *then for every solution* x^* *of problem* (5.2), *there exists* $M > 0$ *such that* x^* *is a local (with respect to the strong topology in* X*) solution of*

$$\min_{x\in X} \tilde{l}(x,(M,u)), \tag{5.3}$$

where $\tilde{l}(x,(M,u)) := l(x,(M,0,u))$.

Proof. As in Proposition 5.2, we take $f(x,z) = h(x) + \delta_{D(z)}(x)$. Note that $\rho(z,(r,0,u)) = p(\nu_0(z), -r\sigma_u(z)) = p(0,-r\sigma_u(z))$, so the augmented Lagrangian corresponding to ρ in the element $(x,(r,0,u))$ has the form

$$\begin{aligned} l(x,(r,0,u)) &= \inf_{z\in Z}\{f(x,z) - \rho(z,(r,0,u))\} \\ &= h(x) + \inf_{z\in D^{-1}(x)}\left[-p(0,-r\sigma_u(z))\right]. \end{aligned} \tag{5.4}$$

Note that $0 \in D^{-1}(x^*)$ because $x^* \in C = D(0)$. Using this fact in the above expression for $x = x^*$ yields

$$l(x^*,(r,0,u)) \le h(x^*). \tag{5.5}$$

By (3.1) for $a = b_1 = 0$ and $b_2 = -r\sigma_u(z) \le 0$ we have that

$$-p(0,-r\sigma_u(z)) \ge \psi(r\sigma_u(z)) \ge 0. \tag{5.6}$$

Combining (5.6) with (5.4) we get

$$\begin{aligned} l(x,(r,0,u)) &= h(x) + \inf_{z\in D^{-1}(x)}\left[-p(0,-r\sigma_u(z))\right] \\ &\ge h(x) + \inf_{z\in D^{-1}(x)}\psi(r\sigma_u(z)) \ge h(x). \end{aligned} \tag{5.7}$$

From (5.7) and (5.5) we obtain $l(x^*,(r,0,u)) = h(x^*)$. Assume that the conclusion of the proposition is not true. This implies that for every $k \in \mathbb{N}$ there exists $x_k \in X$ such that $\|x^k - x^*\| < 1/k$ and

$$\tilde{l}(x_k,(k,u)) = h(x_k) + \inf_{z\in D^{-1}(x_k)}\left[-p(0,-k\sigma_u(z))\right] < \tilde{l}(x^*,(k,u)) = h(x^*). \tag{5.8}$$

Call $a_k := \inf_{z\in D^{-1}(x_k)}\left[-p(0,-k\sigma_u(z))\right]$. We claim that $a_k > 0$ for all k. Indeed, if there exists k_0 such that $a_{k_0} = 0$, then we can find a sequence $\{z_j\} \subset D^{-1}(x_{k_0})$ such that $\lim_{j\to\infty} -p(0,-k_0\sigma_u(z_j)) = 0$. But the latter can hold only when $\lim_{j\to\infty}\sigma_u(z_j) = 0$. Indeed, suppose that for some $b > 0$ there is a subsequence $\{z_{j_l}\}_l$ such that $\sigma_u(z_{j_l}) > b$ for all $l \in \mathbb{N}$. Using (5.6) and the fact that ψ is strictly increasing we get

$$0 = \lim_{l\to\infty} -p(0,-k_0\sigma_u(z_{j_l})) \ge \lim_{l\to\infty}\psi(k_0\sigma_u(z_{j_l})) \ge \psi(b) > 0,$$

where we also used $\psi(0) = 0$ in the last inequality. The above expression entails a contradiction, and hence we must have $\lim_{j\to\infty}\sigma_u(z_j) = 0$. Take j_0 large enough such that $\sigma_u(z_j) \le K_u$ for all $j \ge j_0$, where $K_u > 0$ is as in condition U_3. Then $\{z_j\}_{j\ge j_0}$ is bounded and hence it has a weak accumulation point $\tilde{z}$. By (H0) we have that $\tilde{z} \in D^{-1}(x_{k_0})$. Because σ_u is weakly lower semicontinuous we also have $\sigma_u(\tilde{z}) \le \lim_{j\to\infty}\sigma_u(z_j) = 0$ so $\tilde{z} = 0 \in D^{-1}(x_{k_0})$. This yields x_{k_0} feasible for the problem and hence $h(x_{k_0}) \ge h(x^*)$, a contradiction with (5.8) for $k = k_0$. This implies that our claim is true and $a_k > 0$ for every k. By (5.8) we have

$$0 < a_k < h(x^*) - h(x_k) = \beta(0) - h(x_k).$$

By definition of a_k this implies the existence of $z_k \in D^{-1}(x_k)$ with $-p(0,-k\sigma_u(z_k)) < \beta(0) - h(x_k)$. Using (5.6) we can write

$$0 \le \psi(k\sigma_u(z_k)) \le -p(0,-k\sigma_u(z_k)) < \beta(0) - h(x_k) = h(x^*) - h(x_k). \tag{5.9}$$

Note that h is weakly lower semicontinuous and $\{x_k\}$ is bounded (because it converges to x^*). Therefore, there exists $L > 0$ such that $h(x_k) \geq -L$ for every k. Using also (5.9) we get

$$\psi(k\sigma_u(z_k)) \leq \beta(0) + L.$$

If (i) holds, the above implies that $\lim_{k\to\infty} \sigma_u(z_k) = 0$. On the other hand, if (ii) holds, the rightmost expression in (5.9) must tend to zero, and because $\psi(0) = 0$ we must have $\lim_{k\to\infty} \sigma_u(z_k) = 0$. Therefore, either under (i) or (ii) we have $\lim_{k\to\infty} \sigma_u(z_k) = 0$. By an argument similar to the one used above (which uses condition U_3) we conclude again that $\{z_k\}$ converges weakly to 0. Because $z_k \in D^{-1}(x_k)$ we get $\beta(z_k) = \inf_{x\in D(z_k)} h(x) \leq h(x_k)$ and (5.9) yields

$$\frac{\beta(z_k) - \beta(0)}{\sigma_u(z_k)} \leq \frac{h(x_k) - h(x^*)}{\sigma_u(z_k)} \leq \frac{p(0, -k\sigma_u(z_k))}{\sigma_u(z_k)} \leq \frac{-\psi(k\sigma_u(z_k))}{\sigma_u(z_k)}.$$

Using the above expression and the σ_u-calmness of β at 0 we get

$$\begin{aligned} -\infty < \liminf_k \tfrac{\beta(z_k)-\beta(0)}{\sigma_u(z_k)} &\leq \liminf_k \tfrac{p(0,-k\sigma_u(z_k))}{\sigma_u(z_k)} \leq \liminf_k \tfrac{-\psi(k\sigma_u(z_k))}{\sigma_u(z_k)} \\ &= \liminf_k (-k)\tfrac{\psi(k\sigma_u(z_k))}{(k\sigma_u(z_k))} \leq \liminf_k (-k)\delta = -\infty, \end{aligned}$$

where we used (H2) in the last inequality. The above expression entails a contradiction, and hence x^* must be a local minimizer of problem (5.3). ∎

6. Application to Lagrangian scheme. In this section we apply the abstract convexity results in order to analyze the properties of our augmented Lagrangian scheme. We start by defining exact penalty representation.

DEFINITION 6.1. *We say that* $(\bar{u}, \bar{y}) \in U \times Y$ supports an exact penalty representation *for problem* (P) *if there exists* $\bar{r} > 0$ *such that, for all* $r \geq \bar{r}$, *the original problem* (P) *is equivalent to minimizing* $l(\cdot, (r, \bar{y}, \bar{u}))$ *in the sense that*

$$\begin{aligned} &\text{(a)} \quad \beta(0) = \inf_{x\in X} l(x, (r, \bar{y}, \bar{u})), \ \textit{and} \\ &\text{(b)} \quad \operatorname{argmin}_{x\in X} h(x) = \operatorname{argmin}_{x\in X} l(x, (r, \bar{y}, \bar{u})) \end{aligned} \tag{6.1}$$

for all $r \geq \bar{r}$. *In this situation, the value* $\bar{r}$ *is said to be an exact* penalty parameter.

Remark 6.1. In the particular case in which the Lagrangian is the generalized penalty function (see Remark 3.5), the value of $\bar{r}$ reduces to the classical exact penalty parameter.

The previous definitions readily give the following characterization of (6.1)(a).

LEMMA 6.1. *With the notation of Definition* 6.1, *the following statements are equivalent:*

(i) $(\bar{u}, \bar{y})$ *verifies* (6.1)(a) *for the threshold* $r' > 0$.

(ii) $(r, \bar{y}, \bar{u}) \in \partial_\rho \beta(0)$ *for all* $r \geq r'$.

Proof. Using the definition of Lagrangian and perturbation function we can rewrite (6.1)(a) as

$$\begin{aligned} \beta(0) &= \inf_{x\in X} \inf_{z\in Z} f(x,z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z)) \\ &= \inf_{z\in Z} \inf_{x\in X} f(x,z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z)) \\ &= \inf_{z\in Z} \beta(z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z)) \\ &\leq \beta(z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z)) \end{aligned}$$

for all $z \in Z$ and all $r \geq r'$. Since $\sigma_{\bar{u}}(0) = \nu_{\bar{y}}(0) = 0$ this yields $(r, \bar{y}, \bar{u}) \in \partial_\rho \beta(0)$ for all $r \geq r'$. □

Remark 6.2. Proposition 4.3(b) provides conditions under which $\sigma_{\bar{u}}$-calmness at 0 implies that $\partial_\rho \beta(0) \neq \emptyset$. Applying also Lemma 6.1, we conclude that $\sigma_{\bar{u}}$-calmness at 0 implies the existence of $\bar{y} \in Y$ and $r' > 0$ such that $(\bar{u}, \bar{y})$ verifies (6.1)(a) for the threshold $r' > 0$.

Remark 6.3. Under the assumptions of Proposition 5.1, problem (P) has solutions. Indeed, because $f : X \times Z \to \bar{\mathbb{R}}$ is weakly lower semicontinuous and weakly level-compact, φ must be weakly lower semicontinuous and level-bounded, which clearly yields the nonemptiness and boundedness of the solution set.

Combining (6.1) with the definition of l we see that the exact penalty representation is connected with the optimal value and solution set of the family of problems given by

$$P(r, y, u) \qquad \inf_{(x,z) \in X \times Z} \{f(x, z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z))\}. \tag{6.2}$$

Fix $(u, y) \in U \times Y$ and consider all values of $r > 0$. The set

$$\cup_{r>0} \{(x_r, z_r) \mid (x_r, z_r) \text{ solves } P(r, y, u)\}$$

is called an *optimal path* for problem (P). Let us define the *primal optimal path* as the set

$$\cup_{r>0} \{x_r \mid (x_r, z_r) \text{ solves } P(r, y, u)\}.$$

Our next step is to establish conditions under which every weak accumulation point of the primal optimal path is a solution of the original problem.

THEOREM 6.1. *Assume all hypotheses of Theorem* 4.1 *hold and consider in* (6.2) *a duality parameterization $f : X \times Z \to \bar{\mathbb{R}}$ which is weakly lower semicontinuous and weakly level-compact. Then the following hold:*

(1) *There exists $r_0 > 0$ such that (x_r, z_r) solves problem $P(r, \bar{y}, \bar{u})$ for all $r > r_0$. In other words, the optimal path*

$$Q_{r_0} := \cup_{r \geq r_0} \{(x_r, z_r) \mid (x_r, z_r) \text{ solves } P(r, \bar{y}, \bar{u})\}$$

is well defined.

(2) *The sequence $\{z_r\}$ converges weakly to* 0*, and every weak accumulation point of $\{x_r\}$ is a solution of problem* (P).

Proof. Let us prove (1). Our assumptions on f and Proposition 5.1 imply that β is weakly lower semicontinuous. By Theorem 4.1(i) we have that for some $r_0 > 0$ and for every $r > r_0$ there exists $z_r \in Z$ such that $(r, \bar{y}, \bar{u}) \in \partial_\rho \beta(z_r)$. This means that for all $r > r_0$ we can write

$$\beta(z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) \leq \beta(z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z))$$

for all $z \in Z$. The above inequality implies that $z_r \in \operatorname{argmin} \{\beta(z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z))\}$ for all $r > r_0$, and taking $z = 0$ we get $\beta(z_r) \leq \beta(0)$. Fix $r > r_0$. By definition of β we can find a sequence $\{x_k\}$ such that

$$f(x_k, z_r) < \beta(z_r) + \frac{1}{k} \leq \beta(0) + 1.$$

By Theorem 4.1, $\{z_r\}$ converges weakly to 0. By the weak-level-compactness assumption on f we know that there exists a weak neighborhood W of 0 such that for all $z \in W$ we have

$$\{x \in X \,:\, f(x,z) \le \beta(0)+1\} \subset \tilde{B},$$

where $\tilde{B}$ is weakly compact. Without restriction, we can assume that $z_r \in W$ for all $r > r_0$. Therefore, $\{x_k\} \subset \tilde{B}$, and hence it has a weak accumulation point, which we call x_r. By weak lower semicontinuity of f, we can write

$$f(x_r,z_r) \le \liminf_k f(x_k,z_r) \le \liminf_k \beta(z_r) + \frac{1}{k} = \beta(z_r).$$

Hence $f(x_r,z_r) = \beta(z_r)$. Altogether,

$$\begin{aligned} &\inf_{x,z}\{f(x,z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z))\} = \inf_z\{\beta(z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z))\} \\ &\quad = \beta(z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) = f(x_r,z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)), \end{aligned} \tag{6.3}$$

so (x_r, z_r) solves $P(r,\bar{y},\bar{u})$ for all $r > r_0$. This proves (1).

From (6.3) we have for every $x \in X$

$$f(x_r,z_r) - p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) \le f(x,0). \tag{6.4}$$

The upper semicontinuity of p and the fact that $\{z_r\}$ converges weakly to 0 allow us to write

$$0 \le \liminf_{r\to\infty} -p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)).$$

Therefore there exists $r_1 \ge r_0$ such that

$$p(\nu_{\bar{y}}(z_r), -r\sigma_{\bar{u}}(z_r)) \le 1$$

for all $r > r_1$. Now fix $x \in X$. Using (6.4) and the above inequality for $r > r_1$ we get

$$f(x_r,z_r) \le f(x,0) + 1.$$

Using again the weak-level-compactness assumption we conclude that $\{x_r\}_{r>r_1}$ has weak accumulation points. Let us prove now that every weak accumulation point of $\{x_r\}$ is a solution of problem (P). Take x^* a weak accumulation point of $\{x_r\}$ and $\{x_{r_j}\}$ a subnet weakly converging to x^*. By (6.4) and weak lower semicontinuity,

$$f(x^*,0) \le \liminf_j f(x_{r_j},z_{r_j}) - p(\nu_{\bar{y}}(z_{r_j}), -r\sigma_{\bar{u}}(z_{r_j})) \le f(x,0),$$

where we also used the fact that $\{z_r\}$ converges weakly to 0. Now taking $\inf_{x\in X}$ we conclude that $f(x^*,0) \le \beta(0)$, which implies that x^* solves (P). This establishes (2). □

Remark 6.4. Assume there exists $(\bar{u},\bar{y})$ supporting an exact penalty representation for problem (P) with threshold $r' > 0$. Then by Lemma 6.1 we will have $(r,\bar{y},\bar{u}) \in \partial_\rho\beta(0)$ for all $r \ge r'$. In this case inequality (4.4) holds for all $z \in Z$. An application of Proposition 4.2 allows us to obtain a converse of this fact, where it is enough to check (4.4) in some neighborhood of 0. The result below, which is a criterion for the existence of exact penalty representation, has been established in

[13, Theorem 11.61] for a convex augmenting term (i.e., where $\sigma_u = \sigma$ for all $u \in U$ and σ is proper, lower semicontinuous, and convex) in finite dimensions. Theorem 6.2 extends analogous results recently proved in [23, 25, 8].

THEOREM 6.2 (criterion for exact penalty representation). *Assume all hypotheses of Theorem* 4.1 *hold (in particular,* $\operatorname{dom}\beta^\rho \neq \emptyset$*). Let* $(r, \bar{y}, \bar{u}) \in \operatorname{dom}\beta^\rho$ *be such that the function* $\sigma_{\bar{u}}$ *verifies condition* U_4*. Then* $(\bar{u}, \bar{y})$ *supports an exact penalty representation for problem* (P) *if there exists* $r' > 0$ *and a neighborhood* $V \subset Z$ *of* 0 *such that for all* $z \in V$ *the following inequality holds:*

$$\beta(0) \leq \beta(z) - p(\nu_{\bar{y}}(z), -r'\sigma_{\bar{u}}(z)). \tag{6.5}$$

Proof. We are in conditions of Proposition 4.2, which, together with (6.5), yields the existence of an $r^* > r'$ such that $(r, \bar{y}, \bar{u}) \in \partial_\rho\beta(0)$ for all $r \geq r^*$. Using now Lemma 6.1 we conclude that (6.1)(a) holds, or, equivalently,

$$\beta(0) \leq \beta(z) - p(\nu_{\bar{y}}(z), -r^*\sigma_{\bar{u}}(z)) \quad \text{for all } z \in Z. \tag{6.6}$$

An important consequence of the above inequality and condition U_4 is that

$$\operatorname{argmin}_{z\in Z}\beta(z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z)) = \{0\} \tag{6.7}$$

for all $r > r^*$. Indeed, fix $z' \neq 0$. Take $r > r^*$ and choose W a neighborhood of 0 such that $z' \notin W$. Call $c(W) := \inf_{z\notin W} \sigma_{\bar{u}}(z)$. We know by U_4 that $c(W) > 0$. We can write

$$\begin{aligned}
\beta(z') - p(\nu_{\bar{y}}(z'), -r\sigma_{\bar{u}}(z')) &= \beta(z') - p(\nu_{\bar{y}}(z'), -r^*\sigma_{\bar{u}}(z')) \\
&\quad + p(\nu_{\bar{y}}(z'), -r^*\sigma_{\bar{u}}(z')) - p(\nu_{\bar{y}}(z'), -r\sigma_{\bar{u}}(z')) \\
&\geq \beta(0) + \psi((r - r^*)\sigma_{\bar{u}}(z')) \\
&\geq \beta(0) + \psi((r - r^*)\sigma_{\bar{u}}(z')) > \beta(0),
\end{aligned}$$

where we used (6.6) and assumption (b) on p. Now we proceed to establish (6.1)(b), i.e., that there exists $r_1 \geq r^*$ such that for all $r > r_1$ we have

$$\operatorname{argmin}_{x\in X}\varphi(x) = \operatorname{argmin}_{x\in X} l(x, (r, \bar{y}, \bar{u})). \tag{6.8}$$

Define the function $h(x, z) := f(x, z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z))$. It is directly checked from the definitions that

$$\begin{aligned}
&\text{(a)} \quad \operatorname{argmin}_{(x,z)\in X\times Z} h(x, z) = \{(x', z') \mid x' \in \operatorname{argmin}_{x\in X} h(x, z') \text{ and} \\
&\qquad\qquad z' \in \operatorname{argmin}_{z\in Z}\beta(z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z))\} \\
&\text{(b)} \qquad\qquad = \{(x', z') \mid x' \in \operatorname{argmin}_{x\in X} l(x, (r, \bar{y}, \bar{u})) \text{ and} \\
&\qquad\qquad z' \in \operatorname{argmin}_{z\in Z} h(x', z)\}.
\end{aligned} \tag{6.9}$$

Let us start the proof of (6.8) by taking $\bar{x} \in \operatorname{argmin}_{x\in X} l(x, (\bar{u}, \bar{y}, r))$. We claim that there exists $r_1 > r^*$ such that for all $r > r_1$ we have

$$\operatorname{argmin}_{z\in Z} h(\bar{x}, z) = \{0\}. \tag{6.10}$$

By the definition of Lagrangian, the definition of $\bar{x}$, and (6.6) we can write

$$\begin{aligned}
\inf_{z\in Z} h(\bar{x}, z) &= l(\bar{x}, (r, \bar{y}, \bar{u})) = \inf_{x\in X} l(x, (r, \bar{y}, \bar{u})) \\
&= \inf_{x\in X} \inf_{z\in Z} h(x, z) = \inf_{z\in Z} \inf_{x\in X} h(x, z) \\
&= \inf_{z\in Z} \beta(z) - p(\nu_{\bar{y}}(z), -r\sigma_{\bar{u}}(z)) = \beta(0).
\end{aligned} \tag{6.11}$$

Inequality (6.6) yields $\inf_{z\in Z} f(x,z) - p(\nu_{\bar y}(z), -r^*\sigma_{\bar u}(z)) \geq \inf_{z\in Z}\beta(z) - p(\nu_{\bar y}(z), -r^*\sigma_{\bar u}(z)) \geq \beta(0) > -\infty$. Thus the optimal value of $P(r^*, \bar y, \bar u)$ is greater than $-\infty$. Fix $r > r^*$. Using (6.11) and an argument similar to that in the proof of Theorem 4.1, we can find a sequence $\{z_n\} \subset Z$ such that $\lim_{n\to\infty}\beta(z_n) - p(\nu_{\bar y}(z_n), -r\sigma_{\bar u}(z_n)) = \beta(0)$ and

$$\sigma_{\bar u}(z_n) \leq \frac{\psi^{-1}(\beta(0) + 1 - m(r^*))}{r - r^*}$$

for all $n \geq n_0$. Take now $r_1 > r^* + \frac{\psi^{-1}(\beta(0)+1-m(r^*))}{K_{\bar u}}$, where $K_{\bar u}$ is as in U_3. This yields $\sigma_{\bar u}(z_n) \leq K_{\bar u}$, and hence by U_3 the sequence $\{z_n\} \subset Z$ is bounded. Take a weak accumulation point z_r along with a subsequence $\{z_{n_j}\} \subset \{z_n\}$ weakly converging to it. Then by lower semicontinuity of the functions and (6.11), we get

$$f(\bar x, z_r) - p(\nu_{\bar y}(z_r), -r\sigma_{\bar u}(z_r)) \leq \liminf_{j\to\infty} f(\bar x, z_{n_j}) - p(\nu_{\bar y}(z_{n_j}), -r\sigma_{\bar u}(z_{n_j})) = \beta(0).$$

By definition of β we always have $f(\bar x, z_r) \geq \beta(z_r)$. Combining the last two facts and (6.6) we get

$$\beta(0) \leq \beta(z_r) - p(\nu_{\bar y}(z_r), -r\sigma_{\bar u}(z_r)) \leq \beta(0),$$

so by (6.11) we must have $z_r \in \operatorname{argmin}_{z\in Z}\beta(z) - p(\nu_{\bar y}(z), -r\sigma_{\bar u}(z))$ for all $r > r_1$ and by (6.7) this means that $z_r = 0$. This establishes (6.10). As a consequence of (6.10), we have that the pair $(\bar x, 0) \in X \times Z$ verifies the conditions $\bar x \in \operatorname{argmin}_{x\in X} l(x, (r, \bar y, \bar u))$ and $0 \in \operatorname{argmin}_{z\in Z} h(\bar x, z)$. Now using (6.9)(b) we conclude that $(\bar x, 0) \in \operatorname{argmin}_{(x,z)\in X\times Z} h(x,z)$. Using the latter fact in (6.11) we obtain

$$\inf_{z\in Z} h(\bar x, z) = \inf_{x\in X}\inf_{z\in Z} h(x,z) = h(\bar x, 0) = f(\bar x, 0).$$

Hence, for all $x \in X$ we have that

$$\varphi(\bar x) = f(\bar x, 0) = h(\bar x, 0) \leq h(x,0) = f(x,0) = \varphi(x),$$

which yields $\bar x \in \operatorname{argmin}_{x\in X}\varphi(x)$.

Conversely, now take $\bar x \in \operatorname{argmin}_{x\in X}\varphi(x)$ and $r > r_1$. For all $x \in X$ we have that

$$h(\bar x, 0) = \varphi(\bar x) \leq \varphi(x) = f(x,0) = h(x,0),$$

so that $\bar x \in \inf_{x\in X} h(x,0)$. Since $r_1 > r^*$ we can use (6.7), and hence we have that $0 \in \operatorname{argmin}_{z\in Z}\beta(z) - p(\nu_{\bar y}(z), -r\sigma_{\bar u}(z))$, so the pair $(\bar x, 0)$ belongs to the set on the right-hand side of (6.9)(a). We then conclude again that $(\bar x, 0) \in \operatorname{argmin}_{(x,z)\in X\times Z} h(x,z)$. Use now (6.9)(b) to get $\bar x \in \operatorname{argmin}_{x\in X} l(x, (r, \bar y, \bar u))$, as we wanted.

Hence we conclude that $\operatorname{argmin}_{x\in X}\varphi(x) = \operatorname{argmin}_{x\in X} l(x, (r, \bar y, \bar u))$ for all $r > r_1$, where $r_1 > r^*$. □

7. Semi-infinite programming. Consider semi-infinite stochastic programming problems of the form

$$\text{minimize} \quad h(x) \quad \text{subject to} \quad g(x,\xi) \leq 0 \text{ a.e. } \xi \in \Xi, \tag{7.1}$$

where $h : \mathbb{R}^n \to \mathbb{R}_{+\infty}$ is a lower semicontinuous function, and Ξ is a set equipped with a σ-algebra $\mathcal{M}$ and a finite measure μ defined on $\mathcal{M}$. In the above formulation,

a feasible point x verifies the inequalities $g(x,\xi) \le 0$ a.e. $\xi \in \Xi$ if and only if there is a subset $A \in \mathcal{M}$ such that $\mu(A) = 0$ and the inequality $g(x,\xi) \le 0$ holds for every $\xi \in \Xi \setminus A$. This kind of formulation is relevant, for example, in stochastic programming (cf. [14, 15, 16]). Semi-infinite programming problems are studied in detail in [1, 7, 22, 20]. We assume that

(H4) h is coercive, i.e., $\lim_{\|x\|\to\infty} h(x) = +\infty$;

(G1) for every fixed $x \in \mathbb{R}^n$ the function $g(x,\cdot) : \Xi \to \mathbb{R}$ is measurable;

(G2) $g(\cdot,\xi) : \mathbb{R}^n \to \mathbb{R}$ is lower semicontinuous in $\mathbb{R}^n$.

Call $C := \{x \in \mathbb{R}^n \mid g(x,\xi) \le 0 \text{ a.e. } \xi \in \Xi\}$ the feasible set of problem (7.1). Denote by h^* the optimal value of problem (7.1). Let $X = \mathbb{R}^n$ and $Z = L_p$. Fix a function $\eta : L_p \to L_p$ such that

(A_0) the function $\eta(\cdot)(\xi) : L_p \to \mathbb{R}$ is weakly lower semicontinuous a.e. in Ξ and $\eta(0) = 0$.

Define the point-to-set mapping $D : L_p \rightrightarrows X$ as

$$D(z) := \{x \in \mathbb{R}^n \mid g(x,\xi) + \eta(z)(\xi) \le 0 \text{ a.e. } \xi \in \Xi\}. \tag{7.2}$$

Note that the assumption $\eta(0) = 0$ yields $D(0) = C$. We can formulate problem (7.1) in terms of a dualizing parameterization f which verifies the assumptions of Theorem 4.1. Indeed, let

$$\varphi(x) := h(x) + \delta_C(x) \quad \text{and} \quad f(x,z) := h(x) + \delta_{D(z)}(x).$$

Then it is direct to check that f is a dualizing parametrization for φ.

LEMMA 7.1. *If h is lower semicontinuous and assumptions* (H4), (G1), (G2), *and* (A_0) *hold, then f is weakly level-compact and weakly lower semicontinuous. Consequently, the perturbation function $\beta : L_p \to \mathbb{R} \cup \{-\infty\}$ is weakly lower semicontinuous.*

Proof. By Proposition 5.2 and (H4), it is enough to check assumptions (H0) and (H1). Condition (H1) is the lower semicontinuity of h. Condition (H0) follows from conditions (G2) and (A0). ∎

Remark 7.1. Let us note that the coercivity assumption (H4) and lower semicontinuity of h directly yield nonemptiness and boundedness of the solution set.

Let us now construct the Lagrangian scheme. Let Y and U be two sets and define $\Omega := \mathbb{R}_+ \times Y \times U$. We use $p(a,b) = a + b$ in (3.3) to get $\rho(z,(r,y,u)) = \nu_y(z) - r\sigma_u(z)$, where the families $\{\nu_y\}_{y\in Y}$ and $\{\sigma_u\}_{u\in U}$ are functions from Z to $\mathbb{R}$ verifying properties Y_1–Y_2 and U_1–U_4, respectively (for instance, as in Remark 3.4, we can take $Y = L_q(\Xi,\mathcal{M},\mu)$ with $1/p + 1/q = 1$ and $\nu_y(z) = \langle y, z\rangle$; and we recover a classical augmented Lagrangian). The definition of f yields

$$\beta(z) = \inf_{x\in X} f(x,z) = \inf_{x\in D(z)} h(x).$$

Recall that $x \in D(z)$ if and only if $z \in D^{-1}(x) := \{z' \mid x \in D(z')\}$. Then the augmented Lagrangian corresponding to ρ in a fixed element $(x,(r,y,u))$ has the form

$$\begin{aligned} l(x,(r,y,u)) &= \inf_{z\in Z}\{f(x,z) - \rho(z,\omega)\} = \inf_{z\in D^{-1}(x)} h(x) - \nu_y(z) + r\sigma_u(z) \\ &= h(x) + \inf_{z\in D^{-1}(x)}\{-\nu_y(z) + r\sigma_u(z)\}. \end{aligned} \tag{7.3}$$

From the expression for the Lagrangian we obtain the family of problems $P(r,y,u)$ given by

$$\min_{(x,z)\in\mathbb{R}^n\times L_p} f(x,z) - \nu_y(z) + r\sigma_u(z). \tag{7.4}$$

The optimal path associated with a fixed pair $(\overline{y}, \bar{u}) \in Y \times U$ is defined as the set

$$\cup_{r>0}\{(x_r, z_r) \mid (x_r, z_r) \text{ solves } P(r, \overline{y}, \bar{u})\}.$$

We state below conditions guaranteeing existence of the optimal path for r large enough.

THEOREM 7.1. *Under the assumptions of Lemma* 7.1 *and Theorem* 4.1 *we have that*

(a) *there exist* $r_0 > 0$ *and* $\bar{y} \in Y$ *such that* (x_r, z_r) *solves* $P(r, \overline{y}, \bar{u})$ *for all* $r > r_0$*;*
(b) *the sequence* $\{z_r\}$ *converges weakly to* 0*, and every accumulation point of* $\{x_r\}$ *is a solution of problem* (7.1).

Proof. Note that the assumptions of Theorem 6.1 hold, and the conclusions of the latter theorem are precisely conclusions (a) and (b). ∎

Next we apply Proposition 5.3 in order to prove that calmness of the perturbation function implies the existence of an exact penalty parameter.

PROPOSITION 7.1. *Consider the Lagrangian scheme defined in* (7.3)–(7.4). *Assume that* h *is lower semicontinuous and suppose also that* (H4), (G2), *and* (A_0) *hold. Let* σ_u *satisfy* U_1–U_3 *and let* Y *be such that* $0 \in Y$ *and* $\nu_0(z) = 0$ *for every* $z \in Z$. *If* β *is* σ_u*-calm at* 0*, then for every solution* x^* *of problem* (7.1)*, there exists* $M > 0$ *such that* x^* *is a local solution of*

$$\min_{x \in X} \tilde{l}(x, (M, u)),$$

where $\tilde{l}(x, (M, u)) := l(x, (M, 0, u))$.

Proof. By Proposition 5.3, it is enough to check that assumptions (H0)–(H3) hold for our Lagrangian scheme. Note first that our choice $p(a, b) = a + b$ entails $\psi(t) = t$ for all $t \geq 0$, yielding (H2)–(H3). As noted before, (H0) is a consequence of (G2) and (A_0). Finally, (H1) is our basic assumption of lower semicontinuity of h. ∎

The following result is a direct consequence of Theorem 6.2.

THEOREM 7.2. *Assume all hypotheses of Theorem* 4.1 *hold, where* $(\bar{r}, \overline{y}, \bar{u}) \in \operatorname{dom} \beta^\rho$. *Then* $(\bar{r}, \overline{y}, \bar{u})$ *supports an exact penalty representation for problem* (7.1) *if there exist* $r' > 0$ *and a neighborhood* V *of* 0 *in* L_p *such that for all* $z \in V$ *we have*

$$h^* \leq [\inf_{x \in D(z)} h(x)] - \nu_{\overline{y}}(z) + r' \sigma_{\overline{u}}(z).$$

Combining the above result with Example 4.1, we can characterize nonemptiness $\partial_\rho \beta(0)$. The proof of this result follows readily from Corollary 4.1 and the fact that p and the functions $\nu_{\overline{y}}$ and $\sigma_{\overline{u}}$ verify conditions (i) and (ii) of Definition 4.2.

COROLLARY 7.1. *Let the families of functions* $\{\nu_y, \sigma_u\}$ *be given as in Example* 4.1. *Assume all hypotheses of Theorem* 4.1 *hold, where* $(\bar{r}, \overline{y}, \bar{u}) \in \operatorname{dom} \beta^\rho$. *Then* $\partial_\rho \beta(0) \neq \emptyset$ *if and only if the perturbation function* β *is* $\sigma_{\overline{u}}$*-calm at* 0.

Remark 7.2. We apply the result above to the augmented Lagrangians constructed in [13, Chapter 11], where the family $\{\nu_y\}$ is the dual of Z (i.e., $\nu_y(z) = \langle y, z \rangle$ for all $z \in Z$) and the family $\{\sigma_u\}$ has a single element σ with $\sigma(0) = 0$. The function p is given by $p(a, b) = a + b$ so that the coupling function becomes $\rho(z, \omega) = \rho(z, (r, y)) = \langle y, z \rangle - r\sigma(z)$. We have that ν_y, p, and σ verify conditions (i) and (ii) of Definition 4.2 when $\limsup_{z \to 0, z \neq 0} \frac{\|z\|}{\sigma(z)} < +\infty$. When $\sigma(\cdot) := \|\cdot\|$ then the latter condition trivially holds.

An important particular case of problem (7.1) is the semi-infinite programming problem, stated as

$$\text{minimize} \quad h(x) \quad \text{subject to} \quad g(x, t) \leq 0,\ t \in T, \tag{7.5}$$

where $T \subset \mathbb{R}^p$ is a compact set, $h : \mathbb{R}^n \to \mathbb{R}_{+\infty}$ is lower semicontinuous, and $g(\cdot, t) : \mathbb{R}^n \to \mathbb{R}$, $g(x, \cdot) : \mathbb{R}^p \to \mathbb{R}$ are also lower semicontinuous for every $(x, t) \in \mathbb{R}^n \times \mathbb{R}^p$. A popular choice of penalty function for these problems is the standard L_∞-penalty function (see, e.g., [4, 5]), given by

$$\tilde{l}(x, r) := h(x) + r \max_{t \in T} |[g(x, t)]_+|,$$

where $[a]_+ = \max\{a, 0\}$ for every $a \in \mathbb{R}$. In the following example, we show that our setting includes this kind of penalty function as a particular case.

Example 7.1. Consider the semi-infinite programming problem (7.5) and take $Z := L_\infty(T)$ with the norm $\|z\|_\infty := \sup_{t \in T} |z(t)|$. Assume also that $g(x, \cdot) \in L_\infty(T)$ for every $x \in \mathbb{R}^n$ (in other words, $g(x, \cdot)$ is bounded above on the set T for every x). Let $\eta : L_\infty(T) \to L_\infty(T)$ be defined as $\eta(z) = z$. Our perturbed problems become

$$\text{minimize} \quad h(x) \quad \text{subject to} \quad g(x, t) + z(t) \leq 0,\ t \in T.$$

As in (7.2), consider the set

$$D(z) := \{x \in \mathbb{R}^n \ : \ g(x, t) + z(t) \leq 0,\ t \in T\}$$

and the duality parameterization $f(x, z) := h(x) + \delta_{D(z)}(x)$. If we take $\nu_y = 0$ for every $y \in Y$ and $\sigma_u = \|\cdot\|_\infty$ for every $u \in U$, then (7.3) gives

$$\tilde{l}(x, r) = h(x) + r \inf_{z \in D^{-1}(x)} \|z\|_\infty.$$

We claim that $\inf_{z \in D^{-1}(x)} \|z\|_\infty = \| [g(x, \cdot)]_+ \|_\infty$. Indeed, define $\bar{z}(t) := \min\{-g(x, t), 0\}$ for all $t \in T$. It can be checked that (i) $\bar{z} \in D^{-1}(x)$, (ii) $\|\bar{z}\|_\infty = \| [g(x, \cdot)]_+ \|_\infty$, and (iii) $\|z\|_\infty \geq \|\bar{z}\|_\infty$ for every $z \in D^{-1}(x)$. Items (i) and (ii) follow directly from the definitions, so let us prove (iii). Assume there exist $z \in D^{-1}(x)$ and $a \in \mathbb{R}$ with $\|z\|_\infty < a < \|\bar{z}\|_\infty = \| [g(x, \cdot)]_+ \|_\infty$. This implies that there exists $\bar{t} \in T$ such that

$$|z(t)| < a < [g(x, \bar{t})]_+ \tag{7.6}$$

for every $t \in T$. The above inequality can hold only if $g(x, \bar{t}) > 0$. Now using the fact that $z \in D^{-1}(x)$ we have that $z(\bar{t}) \leq -g(x, \bar{t}) < 0$. By (7.6) for $t = \bar{t}$ we get $-z(\bar{t}) = |z(\bar{t})| < a < [g(x, \bar{t})]_+ = g(x, \bar{t})$, which yields $z(\bar{t}) + g(x, \bar{t}) > 0$, a contradiction to the fact that $z \in D^{-1}(x)$. Hence the claim is true and the Lagrangian simplifies to

$$\tilde{l}(x, r) = h(x) + r \max_{t \in T} |[g(x, t)]_+|,$$

which is the classical L_∞-penalty function. We point out that a similar analysis to the one in Lemma 7.1 can be carried out in order to prove lower semicontinuity of the perturbation function, so that the subsequent theoretical results, such as well-definedness of the central path and the criterion for exact penalty representation, can also be established for this problem with this kind of augmenting term.

Acknowledgment. The authors are very grateful to the two referees for their helpful and valuable suggestions, which greatly improved earlier versions of the manuscript.

METRIC SUBREGULARITY AND CONSTRAINT QUALIFICATIONS FOR CONVEX GENERALIZED EQUATIONS IN BANACH SPACES*

XI YIN ZHENG† AND KUNG FU NG‡

Abstract. Several notions of constraint qualifications are generalized from the setting of convex inequality systems to that of convex generalized equations. This is done and investigated in terms of the coderivatives and the normal cones, and thereby we provide some characterizations for convex generalized equations to have the metric subregularity. As applications, we establish formulas of the modulus of calmness and provide several characterizations of the calmness. Extending the classical concept of extreme boundary, we introduce a notion of recession cores of closed convex sets. Using this concept, we establish global metric subregularity (i.e., error bound) results for generalized equations.

Key words. metric subregularity, calmness, constraint qualification, normal cone, coderivative, recession core, generalized extreme point

1. Introduction.

Let X and Y be Banach spaces and $F : X \to 2^Y$ a closed multifunction. Following Dontchev and Rockafellar [7], the multifunction F is said to be metrically subregular at a for $b \in F(a)$ if there exists $\tau \in [0, +\infty)$ such that

$$d(x, F^{-1}(b)) \le \tau d(b, F(x)) \quad \forall x \text{ close } to\ a. \tag{1.1}$$

The metric subregularity has already been studied by many authors under various names (cf. [2, 15, 21, 26, 32]).

Let A be a closed subset of X and b be a given point in Y. Consider the generalized equation with constraint

$$b \in F(x) \ \text{ subject to } x \in A, \tag{GEC}$$

which includes most of the systems in optimization. Let S denote the solution set of (GEC), that is, $S = \{x \in A : \ b \in F(x)\}$.

We say that (GEC) is metrically subregular at $a \in S$ if there exists $\tau \in (0, \infty)$ such that

$$d(x, S) \le \tau(d(b, F(x)) + d(x, A)) \quad \forall x \text{ close to } a. \tag{1.2}$$

When $F(x) = [f(x), +\infty)$, $b = 0$, and $A = X$, (GEC) reduces to the inequality system $f(x) \le 0$ and (1.2) means that this inequality has a local error bound at a.

Another special case is when $F(x) = [f(x), +\infty)$ and $b = \inf\{f(x) : x \in A\}$. In this case, (GEC) reduces to the following optimization problem:

$$\text{(OP)} \qquad \min f(x) \ \text{ subject to } x \in A$$

and (1.2) means that a is a weak sharp minimum of (OP). Error bounds and weak sharp minima have important applications in mathematical programming and have been extensively studied (cf. [3, 18, 19, 21, 34, 35]). In this paper, we mainly study the metric subregularity of (GEC) in the case when F and A are convex.

The notion of the basic constraint qualification (BCQ) of systems of continuous convex inequalities plays an important role in convex optimization and has been studied by many researchers (see, e.g., [11, 307–309 and 19, 20]). Dropping the continuity assumption and adopting the singular subdifferential, the authors [36] introduced and discussed the generalized BCQ and strong BCQ. Very recently, Hu [12] further studied the generalized BCQ and strong BCQ. In section 3, in terms of the coderivative, we extend the concept of the generalized BCQ and strong BCQ to cover the case of a generalized equation with constraint (GEC). Using the BCQ and strong BCQ, we provide several characterizations of the metric subregularity of (GEC).

A stronger condition is the metric regularity of a multifunction that has been well studied in variational analysis (see [13, 15, 22, 24, 30] and references therein). Explicitly, F is metrically regular at a for $b \in F(a)$ if there exists $\tau \in (0, +\infty)$ such that

$$d(x, F^{-1}(y)) \le \tau d(y, F(x)) \quad \forall (x, y) \text{ close } to\ (a, b). \tag{1.3}$$

It is well known (as the Robinson–Ursescu theorem) that (1.3) holds if F is a closed convex multifunction and $b \in \operatorname{int}(F(X))$. Under the assumption that both X and Y are finite dimensional, Mordukhovich [22] proved that F is metrically regular at a for $b \in F(a)$ if and only if $D^*F(a, b)^{-1}(0) = \{0\}$; moreover,

$$\inf\{\tau : \text{ (1.3) holds}\} = \|D^*F(a, b)^{-1}\|^+ = \limsup_{(x,y) \overset{\mathrm{Gr}(F)}{\longrightarrow} (a,b)} \|D^*F(x, y)^{-1}\|^+, \tag{1.4}$$

where $D^*F(a, b)$ is the coderivative of F at (a, b) and

$$\|D^*F(a, b)^{-1}\|^+ = \sup_{x^* \in B_{X^*}} \sup_{y^* \in D^*F(a,b)^{-1}(x^*)} \|y^*\|.$$

When X and Y are infinite dimensional, some sufficient and necessary conditions for the metric regularity were also established (see [17, 23], Mordukhovich's recent books [24, 25], and references therein). To the best of our knowledge, no one has considered duality formulas similar to (1.4) for the modulus of the metric subregularity. In section 3, we provide such formulas under the convexity assumption.

Similar to the relationship between Aubin's pseudo-Lipschitz property and the metric regularity, the calmness is related very closely to the metric subregularity. In section 4, as applications of results obtained in section 3, we consider the calmness of convex multifunctions. We establish formulas of the modulus of the calmness and present several characterizations of the calmness in terms of the normal cone and the coderivative. In this section, we also provide characterizations of the strong calmness. Reducing to special kinds of convex multifunctions such as that recently considered by Henrion and Jourani in [8], our approach sheds light on some existing results on

the calmness; in fact Corollary 4.2 provides a version that is sharper than the main result in [8].

The notion of the extreme point set of a convex set is very useful in convex analysis. In section 5, as an extension of an extreme point set, we introduce and discuss the notion of a recession core. In terms of recession cores, we study the global metric subregularity. In particular, we show that (GEC) is globally metrically subregular if and only if (GEC) has the τ-strong BCQ at each point of some recession core of the solution set S for some $\tau \in (0, +\infty)$. When the solution set S is a polyhedron, we obtain a sharp result that (GEC) is globally metrically subregular if and only if (GEC) has the BCQ at each point of some recession core of S. This implies in particular that if the graph of F is a polyhedron, then (GEC) is always globally metrically subregular; thus the classical Hoffman result on the error bound for linear inequality systems are extended and improved to cover some nonlinear inequality systems without the Slater condition.

2. Preliminaries. Throughout this paper, we assume that X and Y are Banach spaces. We denote by B_X and B_Y the closed unit balls of X and Y, respectively. For $a \in X$ and $\delta > 0$, let $B(a, \delta)$ denote the open ball with center a and radius δ.

For a closed convex subset A of X and $a \in A$, we use $T(A, a)$ to denote the tangent cone of A at a in Bouligand's sense. Thus $v \in T(A, a)$ if and only if there exist a sequence $\{a_n\}$ in A and a sequence $\{t_n\}$ of positive numbers convergent to 0 such that $\frac{a_n - a}{t_n}$ converges to v.

We denote by $N(A, a)$ the normal cone of A at a, that is,

$$N(A, a) := \{x^* \in X^* : \langle x^*, x - a\rangle \le 0 \ \ \forall x \in A\}.$$

Let $F : X \to 2^Y$ be a multifunction and denote by $\mathrm{Gr}(F)$ the graph of F, that is,

$$\mathrm{Gr}(F) := \{(x, y) \in X \times Y : \ y \in F(x)\}.$$

As usual, F is said to be closed (resp., convex) if $\mathrm{Gr}(F)$ is a closed (resp., convex) subset of $X \times Y$. It is known that F is convex if and only if

$$tF(x_1) + (1 - t)F(x_2) \subset F(tx_1 + (1 - t)x_2) \quad \forall x_1, x_2 \in X \text{ and } \forall t \in [0,\ 1].$$

For a closed convex multifunction F and $(x, y) \in \mathrm{Gr}(F)$, the tangent derivative $DF(x, y)$ of F at (x, y) is defined by

$$DF(x, y)(u) = \{v \in Y : \ (u, v) \in T(\mathrm{Gr}(F), (x, y))\} \quad \forall u \in X \tag{2.1}$$

(cf. [1]).

Let $D^*F(x, y)$ denote the coderivative of F at (x, y), which is defined by

$$D^*F(x, y)(y^*) := \{x^* \in X^* : \ (x^*, -y^*) \in N(\mathrm{Gr}(F), (x, y))\} \quad \forall y^* \in Y^* \tag{2.2}$$

(cf. [22, 26, 32]).

Let $G : X \to 2^Y$ be a sublinear multifunction (i.e., $\mathrm{Gr}(G)$ is a convex cone in $X \times Y$). As in Dontchev, Lewis, and Rockafellar [6], the outer norm and inner norm of G are, respectively, defined as

$$\|G\|^+ = \sup_{x \in B_X} \sup_{y \in Gx} \|y\| \quad \text{and} \quad \|G\|^- := \sup_{x \in B_X} \inf_{y \in Gx} \|y\|,$$

where the infimum and supremum over an empty set are understood as $+\infty$ and 0, respectively. For a convex cone C in X, let $\|G|_C\|^+$ and $\|G|_C\|^-$ be, respectively, defined by

$$\|G|_C\|^+ := \sup_{x\in B_X\cap C}\sup_{y\in Gx}\|y\| \quad\text{and}\quad \|G|_C\|^- := \sup_{x\in B_X\cap C}\inf_{y\in Gx}\|y\|. \tag{2.3}$$

We denote by $\mathrm{bd}(A)$ the topological boundary of a subset A of X. The following lemma is known (cf. [27, Proposition 1.3] or [28, Lemma 2.1]) and useful for us.

LEMMA 2.1. *Let X be a Banach space and A a closed convex nonempty subset of X. Then, for any $\beta \in (0,\ 1)$ and any $x \in X \setminus A$ there exist $z \in \mathrm{bd}(A)$ and $x^* \in N(A, z)$ with $\|x^*\| = 1$ such that*

$$\beta\|x - z\| < d(x, A) \ \text{ and } \ \beta\|x - z\| < \langle x^*, x - z\rangle.$$

3. BCQ, strong BCQ, and metric subregularity. Throughout this section, we assume that $F : X \to 2^Y$ is a closed convex multifunction, A is a closed convex subset of X, and b is a given point in Y. Recall that $S = \{x \in A :\ b \in F(x)\}$ is the solution set of the corresponding generalized equation with constraint (GEC).

Recently, in dealing with the inequality defined by a proper lower semicontinuous convex function, the authors [36] introduced and discussed the generalized BCQ and strong BCQ.

In terms of the coderivative replacing the subdifferential and the singular subdifferential, we can extend the concept of the generalized BCQ and strong BCQ to the case of a generalized equation with constraint (GEC). Explicitly, we say that (GEC) has the BCQ at $a \in S$ if

$$N(S, a) = D^*F(a, b)(Y^*) + N(A, a) \tag{3.1}$$

and (GEC) has the strong BCQ at $a \in S$ if there exists $\tau \in (0,\ +\infty)$ such that

$$N(S, a) \cap B_{X^*} \subset \tau(D^*F(a, b)(B_{Y^*}) + N(A, a)) \cap B_{X^*}. \tag{3.2}$$

The following theorem establishes the relationship between the metric subregularity and strong BCQ.

THEOREM 3.1. *Let $a \in S$. Then, the generalized equation (GEC) is metrically subregular at a if and only if there exist $\tau,\ \delta \in (0,\ +\infty)$ such that (GEC) has the strong BCQ at all points in $\mathrm{bd}(S) \cap B(a, \delta)$ with the same constant.*

Proof. Suppose that (GEC) is metrically subregular at a. Then there exist $\tau, \delta \in (0,\ +\infty)$ such that (1.2) holds. For any $(x, y) \in X \times Y$, let $\|(x, y)\|_\tau := \frac{\tau+1}{\tau}\|x\| + \|y\|$. Then $\|\cdot\|_\tau$ is a norm on $X \times Y$ inducing the product topology, and the unit ball of the dual space of $(X \times Y, \|\cdot\|_\tau)$ is $(\frac{\tau}{\tau+1}B_{X^*}) \times B_{Y^*}$. We claim that

$$d(x, S) \le \tau(d_{\|\cdot\|_\tau}((x, y), \mathrm{Gr}(F)) + \|y-b\| + d(x, A)) \quad \forall (x, y) \in B\left(a, \frac{\delta}{2}\right) \times Y, \tag{3.3}$$

where the distance $d_{\|\cdot\|_\tau}$ is with respect to the norm $\|\cdot\|_\tau$. Suppose to the contrary that (3.3) does not hold. Then there exists $(x_0, y_0) \in B(a, \frac{\delta}{2}) \times Y$ such that

$$d(x_0, S) > \tau[d_{\|\cdot\|_\tau}((x_0, y_0), \mathrm{Gr}(F)) + \|y_0 - b\| + d(x_0, A)].$$

It follows that there exists $u \in X$ such that

$$d(x_0, S) > \tau\left(\frac{\tau + 1}{\tau}\|u - x_0\| + d(y_0, Fu) + \|y_0 - b\| + d(x_0, A)\right),$$

and hence

$$d(x_0, S) > \|u - x_0\| + \tau(d(b, Fu) + d(u, A)).$$

Noting that

$$\|u - a\| \le \|u - x_0\| + \|x_0 - a\| < d(x_0, S) + \|x_0 - a\| \le 2\|x_0 - a\| < \delta,$$

it follows from (1.2) and the triangle inequality that

$$d(x_0, S) > \|u - x_0\| + d(u, S) \ge d(x_0, S),$$

which is a contradiction. Hence (3.3) holds.

We will establish the necessary part by showing that

$$N(S, z) \cap B_{X^*} \subset \tau(D^*F(z, b)(B_{Y^*}) + N(A, z) \cap B_{X^*}) \quad \forall z \in B\left(a, \frac{\delta}{2}\right) \cap S. \tag{3.4}$$

To do this, let $z \in S \cap B(a, \frac{\delta}{2})$ and $x^* \in N(S, z) \cap B_{X^*}$. Since A is convex, $N(S, z) \cap B_{X^*} = \partial d(\cdot, S)(z)$ (cf. [4, Theorem 1]). Thus,

$$\langle x^*, x - z\rangle \le d(x, S) - d(z, S) = d(x, S) \ \ \forall x \in X.$$

It follows from (3.3) that

$$\langle x^*, x - z\rangle \le \tau(d_{\|\cdot\|_\tau}((x, y), \mathrm{Gr}(F)) + \|y - b\| + d(x, A)) \quad \forall (x, y) \in B\left(z, \frac{\delta}{2} - \|z - a\|\right) \times Y.$$

Together with the convexity of F and A, this implies that $(\frac{x^*}{\tau}, 0) \in \partial\phi(z, b)$, where ϕ is the convex function defined by

$$\phi(x, y) := d_{\|\cdot\|_\tau}((x, y), \mathrm{Gr}(F)) + \|y - b\| + d(x, A) \quad \forall (x, y) \in X \times Y.$$

Noting that

$$\partial d_{\|\cdot\|_\tau}(\cdot, \mathrm{Gr}(F))(z, b) \subset N(\mathrm{Gr}(F), (z, b)),$$

it follows from [5, Proposition 2.3.2] that

$$\left(\frac{x^*}{\tau}, 0\right) \in N(\mathrm{Gr}(F), (z, b)) + \{0\} \times B_{Y^*} + (N(A, z) \cap B_{X^*}) \times \{0\}.$$

This implies that $x^* \in \tau(D^*F(z, b)(B_{Y^*}) + N(A, z) \cap B_{X^*})$, and hence that (3.4) holds, as is required to show.

Conversely, suppose that there exist $\tau', \delta' \in (0, +\infty)$ such that (GEC) has the strong BCQ at each point of $\mathrm{bd}(S) \cap B(a, \delta')$ with the constant τ'. Let $x \in B(a, \frac{\delta'}{2}) \setminus S$. Then, $d(x, S) \le \|x - a\| < \frac{\delta'}{2}$. Let $\beta \in (\frac{2d(x,S)}{\delta'}, 1)$. Then, by Lemma 2.1 there exists $u \in \mathrm{bd}(S)$ and $x^* \in N(S, u)$ with $\|x^*\| = 1$ such that $\beta\|x - u\| \le d(x, S)$ and

$$\beta\|x - u\| \le \langle x^*, x - u\rangle. \tag{3.5}$$

Thus, $\|x - u\| < \frac{\delta'}{2}$. Hence $\|u - a\| \le \|u - x\| + \|x - a\| < \delta'$, and so (GEC) has the strong BCQ at u with the constant τ. Therefore, there exists $y^* \in B_{Y^*}$,

$x_1^* \in D^*F(u,b)(y^*)$, and $x_2^* \in N(A,u) \cap B_{X^*} = \partial d(\cdot, A)(u)$ (by [4, Theorem 1]) such that $x^* = \tau'(x_1^* + x_2^*)$. By the convexity of F and A, one has

$$\langle x_1^*, x-u\rangle \le \langle y^*, y-b\rangle \quad \forall y \in F(x) \text{ and } \langle x_2^*, x-u\rangle \le d(x,A) - d(u,A) = d(x,A).$$

Hence,

$$\langle x^*, x-u\rangle \le \tau'(\langle y^*, y-b\rangle + d(x,A)) \le \tau'(\|y-b\| + d(x,A)) \quad \forall y \in F(x).$$

This and (3.5) imply that $\beta\|x-u\| \le \tau'(d(b,F(x)) + d(x,A))$. It follows from $u \in S$ that $\beta d(x,S) \le \tau'(d(b,F(x)) + d(x,A))$. Since β can be arbitrarily close to 1, $d(x,S) \le \tau'(d(b,F(x)) + d(x,A))$. This shows that (GEC) is metrically subregular at a. This completes the proof. □

Theorem 3.1 recaptures some earlier results dealing only with numerical valued functions. Let $f : X \to R \cup \{+\infty\}$ be a proper lower semicontinuous convex function. When $F(x) = [f(x), +\infty)$, $b = 0$, and $A = X$, then Theorem 3.1 is obtained in [36]. A slightly earlier result is due to Burke and Deng who showed in [3, Theorem 5.2] that if X is a Hilbert space, $F(x) = [f(x), +\infty)$, $b = \inf_{x\in X} f(x)$, and $A = X$, then (GEC) is metrically subregular at a if and only if there exists $\tau \in [0, +\infty)$ such that

$$N(S,x) \cap B_{X^*} \subset \tau \mathrm{cl}^*(\partial f(a)),$$

where cl^* denotes the weak* closure.

Remark 3.1. Let $\tau(F,a,b;A) := \inf\{\tau > 0 : \text{ (1.2) holds}\}$. For $u \in S$, let

$$\gamma(F,u,b;A) := \inf\{\tau > 0 : \text{ (GEC) has the strong BCQ at } u \text{ with the constant } \tau\}.$$

By the proof of Theorem 3.1, one can see that

$$\tau(F,a,b;A) = \limsup_{u \overset{\mathrm{bd}(S)}{\longrightarrow} a} \gamma(F,u,b;A) \ge \gamma(F,a,b;A). \tag{3.6}$$

In general, (GEC) is not necessarily metrically subregular at a if (GEC) has the strong BCQ only at a (see [36, Example 2]). But, when S is assumed to be "locally conical" at a, Theorem 3.1 and (3.6) can be sharpened. To do this, we need the following lemma.

LEMMA 3.1. *Let $s_1, s_2 \in S$ be such that $\langle u^*, s_1\rangle = \langle u^*, s_2\rangle$. Then,*

$$u^* \in D^*F(s_1,b)(B_{Y^*}) + N(A,s_1) \cap B_{X^*} \Leftrightarrow u^* \in D^*F(s_2,b)(B_{Y^*}) + N(A,s_2) \cap B_{X^*}.$$

Proof. Obviously we need only prove one direction of the implications, say " $\Rightarrow$." Let

$$\psi(x,y) := \|y-b\| + d(x,A) + \delta_{\mathrm{Gr}(F)}(x,y) \quad \forall (x,y) \in X \times Y,$$

where $\delta_{\mathrm{Gr}(F)}$ denotes the indicator function of $\mathrm{Gr}(F)$. It follows from [4, Theorem 1] and [5, Proposition 2.3.2] that

$$\partial\psi(s,b) = \{0\} \times B_{Y^*} + (N(A,s) \cap B_{X^*}) \times \{0\} + N(\mathrm{Gr}(F),(s,b)) \quad \forall s \in S. \tag{3.7}$$

Suppose that $u^* \in D^*F(s_1,b)(B_{Y^*}) + N(A,s_1) \cap B_{X^*}$. Then, by (3.7), one has $(u^*,0) \in \partial\psi(s_1,b)$. Hence,

$$\langle u^*, x-s_1\rangle \le \psi(x,y) - \psi(s_1,b) \quad \forall (x,y) \in X \times Y.$$

Since $\langle u^*, s_1\rangle = \langle u^*, s_2\rangle$ and $\psi(s_1, b) = \psi(s_2, b) = 0$,

$$\langle u^*, x - s_2\rangle \le \psi(x, y) - \psi(s_2, b) \quad \forall (x, y) \in X \times Y.$$

Therefore, $(u^*, 0) \in \partial\psi(s_2, b)$. It follows from (3.7) that $u^* \in D^*F(s_2, b)(B_{Y^*}) + N(A, s_2) \cap B_{X^*}$. This shows that the implication " $\Rightarrow$ " holds. Hence, the proof is completed. □

THEOREM 3.2. *Let $a \in S$. Suppose that there exist a cone C and a neighborhood V of a such that $S \cap V = (a + C) \cap V$. Then*

$$\tau(F, a, b; A) = \gamma(F, a, b; A).$$

Consequently, (GEC) is metrically subregular at a if and only if (GEC) has the strong BCQ at a.

Proof. In view of (3.6), we need only show that

$$\limsup_{u \overset{\mathrm{bd}(S)}{\longrightarrow} a} \gamma(F, u, b; A) \le \gamma(F, a, b; A). \tag{3.8}$$

Let $\delta > 0$ be such that $B(a, \delta) \subset V$. To prove (3.8), it suffices to show that for any $u \in S \cap B(a, \delta)$,

$$\gamma(F, u, b; A) \le \gamma(F, a, b; A). \tag{3.9}$$

We first show that

$$N(S, u) \subset N(S, a) \quad \forall u \in S \cap B(a, \delta). \tag{3.10}$$

To do this, let $u \in S \cap B(a, \delta)$ and $x^* \in N(S, u)$. Noting that V is a neighborhood of u, we have

$$N(S, u) = N(S \cap V, u) = N((a + C) \cap V, u) = N(a + C, u).$$

Choosing $c_u \in C$ such that $u = a + c_u$, it follows that

$$\langle x^*, a + c_u\rangle = \sup\{\langle x^*, a + c\rangle : \ c \in C\}.$$

Since C is a cone, it follows that $\langle x^*, c_u\rangle = 0$ and hence

$$\langle x^*, u\rangle = \langle x^*, a\rangle = \sup\{\langle x^*, a + c\rangle : \ c \in C\}. \tag{3.11}$$

This implies that $x^* \in N(a + C, a) = N(S, a)$. Therefore, (3.10) holds. Since (3.9) trivially holds if $\gamma(F, a, b; A) = +\infty$, we assume henceforth that $\gamma(F, a, b; A) < +\infty$. Let $r \in (\gamma(F, a, b; A), \ +\infty)$. Then,

$$N(S, a) \cap B_{X^*} \subset r(D^*F(a, b)(B_{Y^*}) + N(A, a) \cap B_{X^*}).$$

Let $u \in S \cap B(a, \delta)$ and $x^* \in N(S, u) \cap B_{X^*}$. By (3.10), one has

$$x^* \in r(D^*F(a, b)(B_{Y^*}) + N(A, a) \cap B_{X^*}).$$

It follows from (3.11) and Lemma 3.1 that $x^* \in r(D^*F(u, b)(B_{Y^*}) + N(A, u) \cap B_{X^*})$. Therefore,

$$N(S, u) \cap B_{X^*} \subset r(D^*F(u, b)(B_{Y^*}) + N(A, u) \cap B_{X^*}).$$

This implies that $\gamma(F,u,b;A)\le r$. Letting $r\to\gamma(F,a,b;A)$, one sees that (3.9) holds. Hence, the proof is completed. □

Remark 3.2. If the solution set S is a polyhedron, then for each $a\in S$ there exist a cone C and a neighborhood V of a such that $S\cap V=(a+C)\cap V$; in fact, in this case we can choose C to be the tangent cone of S at a.

THEOREM 3.3. *Let $a\in S$,*

$$\tau_1:=\inf\{\tau>0:\ d(x,a+T(S,a))\le\tau(d(b,F(x))+d(x,A))\ \ \forall x \text{ close to } a\},$$

and

$$\tau_2:=\inf\{\tau>0:\ d(h,T(S,a))\le\tau(d(0,DF(a,b)(h))+d(h,T(A,a)))\quad\forall h\in X\}.$$

Then

$$\tau_1=\tau_2=\gamma(F,a,b;A).$$

Moreover,

$$\tau_2<+\infty\Longrightarrow T(S,a)=T(A,a)\cap DF(a,b)^{-1}(0). \tag{3.12}$$

Consequently, (GEC) has the strong BCQ at a if and only if the sublinear generalized equation (with constraint)

$$0\in DF(a,b)(x)\ \text{ subject to } x\in T(A,a)$$

is metrically subregular at 0.

Proof. We first show that $\tau_1=\tau_2$. Let $h\in X$, $y\in DF(a,b)(h)$, $u\in T(A,a)$, and $\varepsilon>0$. Then, there exists $t>0$ small enough that

$$(h,y)\in\frac{\mathrm{Gr}(F)-(a,b)}{t}+\varepsilon B_X\times\varepsilon B_Y\ \text{ and }\ u\in\frac{A-a}{t}+\varepsilon B_X.$$

Therefore, there exists $z\in B_X$ such that

$$b+ty\in F(a+th+t\varepsilon z)+t\varepsilon B_Y\ \text{ and }\ a+tu\in A+t\varepsilon B_X.$$

This implies that

$$d(b,F(a+th+t\varepsilon z))\le t\|y\|+t\varepsilon\ \text{ and }\ d(a+th+t\varepsilon z,A)\le t\|h-u\|+2t\varepsilon.$$

Considering an arbitrary $\tau>\tau_1$ and noting that $t>0$ is small enough, it follows that

$$\begin{aligned}\tau t(\|y\|+\|h-u\|+3\varepsilon)&\ge d(a+th+t\varepsilon z,a+T(S,a))\\&\ge d(th,T(S,a))-t\varepsilon\\&=td(h,T(S,a))-t\varepsilon,\end{aligned}$$

where the last equality holds because $T(S,a)$ is a cone. Therefore,

$$d(h,T(S,a))\le\tau(d(0,DF(a,b)(h))+d(h,T(A,a)))+(3\tau+1)\varepsilon.$$

Letting $\varepsilon\to0$ and $\tau\to\tau_1$, one has

$$d(h,T(S,a))\le\tau_1(d(0,DF(a,b)(h))+d(h,T(A,a))).$$

Hence, $\tau_2 \le \tau_1$. Conversely, by the convexity of F, one has

$$\mathrm{Gr}(F) - (a,b) \subset T(\mathrm{Gr}(F),(a,b)) = \mathrm{Gr}(DF(a,b)).$$

Then, for any $x \in X$, $F(x) - b \subset DF(a,b)(x-a)$, and so

$$d(0, DF(a,b)(x-a)) \le d(b, F(x)).$$

On the other hand, the convexity of A implies that

$$d(x-a, T(A,a)) \le d(x-a, A-a) \le d(x,A).$$

Hence, for any $x \in X$,

$$d(x-a, T(S,a)) \le \tau_2(d(0, DF(a,b)(x-a)) + d(x-a, T(A,a))) \le \tau_2(d(b, F(x)) + d(x,A)).$$

Therefore $\tau_1 \le \tau_2$ and so $\tau_1 = \tau_2$ is shown. Next, we show that $\gamma(F,a,b;A) = \tau_2$. By the definition of τ_2, we have

$$d(x, T(S,a)) \le \tau_2(d(0, DF(a,b)(x)) + d(x, T(A,a))) \quad \forall x \in X.$$

In the case when $\tau_2 < +\infty$, this implies that $T(A,a) \cap DF(a,b)^{-1}(0) \subset T(S,a)$ and hence (3.12) is seen to hold, as the converse inclusion is easy to verify by the convexity of F and A. From (3.12) it is straightforward to verify that

$$\gamma(F,a,b;A) = \gamma(DF(a,b),0,0;T(A,a)) \text{ and } \tau_2 = \tau(DF(a,b),0,0;T(A,a)).$$

This and Theorem 3.2 imply that $\tau_2 = \gamma(F,a,b;A)$. In the case when $\tau_2 = +\infty$, suppose to the contrary that $\tau_2 \ne \gamma(F,a,b;A)$. Then, $\gamma(F,a,b;A) < +\infty$. Let $x \in X \setminus T(S,a)$ and $\beta \in (0,\ 1)$. By Lemma 2.1 there exist $u \in T(S,a)$ and $x^* \in N(T(S,a),u)$ such that

$$\|x^*\| = 1 \text{ and } \langle x^*, x-u\rangle \ge \beta\|x-u\|. \tag{3.13}$$

Noting that $N(T(S,a),u) \subset N(T(S,a),0)$ (because $T(S,a)$ is a closed convex cone), it follows that $x^* \in N(T(S,a),0) = N(S,a)$ and $\langle x^*, u\rangle = 0$. Take a fixed η in $(\gamma(F,a,b;A),\infty)$. Then there exist $y^* \in \eta B_{Y^*}$, $x_1^* \in D^*F(a,b)(y^*)$, and $x_2^* \in \eta N(A,a) \cap B_{X^*}$ such that $x^* = x_1^* + x_2^*$. Equipping the product space $X \times Y$ with norm $\|(x,y)\|_\eta = \frac{\eta}{1+\eta}\|x\| + \|y\|$ for all $(x,y) \in X \times Y$ and noting that the unit ball of the dual space of $(X \times Y, \|\cdot\|_\eta)$ is $(\frac{\eta+1}{\eta}B_{X^*}) \times B_{Y^*}$, it follows from (2.1) and the convexity of $DF(a,b)$ and A that

$$\begin{aligned}\frac{1}{\eta}(x_1^*, -y^*) &\in N(\mathrm{Gr}(F),(a,b)) \cap \left(\left(\frac{\eta+1}{\eta}B_{X^*}\right) \times B_{Y^*}\right)\\ &= N(\mathrm{Gr}(DF(a,b)),(0,0)) \cap \left(\left(\frac{\eta+1}{\eta}B_{X^*}\right) \times B_{Y^*}\right)\\ &= \partial d_{\|\cdot\|_\eta}(\cdot, \mathrm{Gr}(DF(a,b)))(0,0)\end{aligned}$$

and

$$\frac{1}{\eta}x_2^* \in N(A,a) \cap B_{X^*} = N(T(A,a),0) \cap B_{X^*} = \partial d(\cdot, T(A,a))(0).$$

Therefore,

$$\frac{1}{\eta}\langle x_1^*, x\rangle \le d_{\|\cdot\|_\eta}((x,0), \mathrm{Gr}(DF(a,b)) \le d(0, DF(a,b)(x))$$

and $\frac{1}{\eta}\langle x_2^*, x\rangle \le d(x, T(A,a))$. Noting that $\langle x^*, u\rangle = 0$, it follows from (3.13) that

$$\frac{\beta\|u-x\|}{\eta} \le d(0, DF(a,b)(x)) + d(x, T(A,a)).$$

Therefore, $\frac{\beta d(x,T(S,a))}{\eta} \le d(0, DF(a,b)(x)) + d(x, T(A,a))$. Letting $\beta \to 1$, one has

$$d(x, T(S,a)) \le \eta(d(0, DF(a,b)(x)) + d(x, T(A,a))).$$

This contradicts $\tau_2 = +\infty$. Hence, the proof is completed. □

Let $\phi : X \to R \cup \{+\infty\}$ be a proper lower semicontinuous convex function. Consider the special case when $A = X$ and $F(x) = [\phi(x), +\infty)$ for all $x \in X$. In this case, $N(A,x) = \{0\}$ for any $x \in A$. For $a \in \mathrm{dom}(\phi)$, let $\partial^\infty\phi(a)$ denote the singular subdifferential of ϕ at a, namely $\partial^\infty\phi(a) = D^*F(a, \phi(a))(0)$. It is easy to verify from the convexity of ϕ that $\mathrm{dom}(D^*F(a,\phi(a))) \subset R_+$. Thus, noting that

$$D^*F(a,\phi(a))(1) = \partial\phi(a) \text{ and } \partial\phi(a) = \partial\phi(a) + \partial^\infty\phi(a)$$

and adopting the convention that $R_+\partial\phi(a)$ and $[0,\ 1]\partial\phi(a)$ are $\{0\}$ if $\partial\phi(a) = \emptyset$, one has

$$\begin{aligned} D^*F(a,\phi(a))(R) &= D^*F(a,\phi(a))(0) \bigcup D^*F(a,\phi(a))(R_+ \setminus \{0\}) \\ &= D^*F(a,\phi(a))(0) \bigcup R_+ D^*F(a,\phi(a))(1) \\ &= \partial^\infty\phi(a) + R_+\partial\phi(a) \end{aligned}$$

and

$$D^*F(a,\phi(a))([-1,\ 1]) = \partial^\infty\phi(a) + [0,\ 1]\partial\phi(a).$$

Therefore, our definitions of the BCQ and strong BCQ for generalized equations are, respectively, natural generalizations of the BCQ and strong BCQ of a convex inequality system (cf. [18, 19, 20, 36]). Thus, Theorems 3.1 and 3.3 extend Theorems 2.2 and 2.3 in [36] from the setting of a convex inequality to that of a convex generalized equation with constraint.

Since the strong BCQ implies the BCQ, the following proposition shows that the converse also holds in some interesting cases.

PROPOSITION 3.4. *Let $a \in S$ and suppose that $N(S,a)$ is a polyhedron in a finite dimensional subspace of X^*. Then (GEC) has the BCQ at a if and only if it has the strong BCQ at a.*

Proof. We need only show the necessity part. Suppose that (GEC) has the BCQ at a. It suffices to show that there exists $\tau > 0$ such that

$$N(S,a) \cap B_{X^*} \subset \tau(D^*F(a,b)(B_{Y^*}) + N(A,a) \cap B_{X^*}). \tag{3.14}$$

Let E be a finite dimensional subspace of X^* such that $N(S,a) \subset E$. Let

$$L := N(S,a) \cap -N(S,a),$$

namely L is the largest subspace contained in $N(S,a)$. Take a subspace $L^\perp$ of E such that

$$L \cap L^\perp = \{0\} \text{ and } E = L + L^\perp. \tag{3.15}$$

Since $N(S,a)$ is a polyhedral cone in E, by [31, Theorem 19.1] there exists a polyhedron cone $C \subset L^\perp$ containing no lines such that

$$N(S,a) = C + L. \tag{3.16}$$

On the other hand, $\dim(E) < \infty$ and (3.15) imply that there exists $\delta \in (0, +\infty)$ such that $(C+L) \cap B_{X^*} \subset \delta(C \cap B_{X^*} + L \cap B_{X^*})$. It follows from (3.16) that

$$N(S,a) \cap B_{X^*} \subset \delta(C \cap B_{X^*} + L \cap B_{X^*}). \tag{3.17}$$

Since L is a finite dimensional space, there exist $l_1, \ldots, l_m \in L$ such that

$$B_{X*} \cap L \subset \text{co}(l_1, \ldots, l_m). \tag{3.18}$$

Take $c_1, \ldots, c_n \in C$ such that $C = R^+\text{co}(c_1, \ldots, c_n)$ and $0 \notin \text{co}(c_1, \ldots, c_n)$ (because C is a finite dimensional polyhedron cone containing no lines). Without loss of generality, we assume that $\text{co}(c_1, \ldots, c_n) \cap B_{X^*} = \emptyset$. We note that

$$C \cap B_{X*} \subset \text{co}(0, c_1, \ldots, c_n). \tag{3.19}$$

By (3.16) and the BCQ assumption, there exist

$$\{y_1^*, \ldots, y_n^*, \tilde{y}_1^*, \ldots, \tilde{y}_m^*\} \subset Y^* \text{ and } \{a_1^*, \ldots, a_n^*, \tilde{a}_1^*, \ldots, \tilde{a}_m^*\} \subset N(A,a)$$

such that

$$c_i \in D^*F(a,b)(y_i^*) + a_i^*,\ 1 \le i \le n \text{ and } l_j \in D^*F(a,b)(\tilde{y}_j^*) + \tilde{a}_j^*,\ 1 \le j \le m.$$

Let $\kappa := \max_{1 \le i \le n, 1 \le j \le m} \|y_i^*\| + \|a_i^*\| + \|\tilde{y}_j^*\| + \|\tilde{a}_j^*\|$. It follows from (3.18) and (3.19) that

$$C \cap B_{X^*} + L \cap B_{X^*} \subset \kappa(D^*F(a,b)(B_{Y^*}) + N(A,a) \cap B_{X^*}).$$

This and (3.17) imply that (3.14) holds with $\tau = \delta\kappa$. □

COROLLARY 3.5. *Let $f_1, \ldots, f_n : X \to R \cup \{+\infty\}$ be proper lower semicontinuous convex functions and consider generalized equation (GEC) with $A = X$, $Y = R^n$, $b = (b_1, \ldots, b_n) \in R^n$, and F being defined by*

$$F(x) = (f_1(x), \ldots, f_n(x)) + R_+^n \quad \forall x \in X.$$

Suppose that each f_i is differentiable at $a \in S$. Then, for the said generalized equation, the BCQ and strong BCQ are equivalent at a.

Proof. In view of Proposition 3.4, it suffices to show that

$$D^*F(a,b)(R^n) = R_+\text{co}\{f_i'(a) :\ i \in J(a)\}, \tag{3.20}$$

where $J(a) := \{1 \le i \le n :\ f_i(a) = b_i\}$. To do this, we first note that $\text{dom}(D^*F(a,b)) = R_+^n$ (because each convex function f_i is differentiable at a). Let $(r_1, \ldots, r_n) \in R_+^n \setminus \{0\}$ and $x^* \in D^*F(a,b)(r_1, \ldots, r_n)$. Then

$$\langle x^*, x\rangle - \sum_{i=1}^n r_i(f_i(x) + t_i) \le \langle x^*, a\rangle - \sum_{i=1}^n r_i b_i$$

for any $x \in X$ and $(t_1, \ldots, t_n) \in R^n_+$. Noting that $f_i(a) = b_i$ for any $i \in J(a)$, $f_i(a) < b_i$ for any $i \notin J(a)$, and $a \in \text{int}(\text{dom}(f_i))$ for $1 \le i \le n$, it follows that $r_i = 0$ for any $i \notin J(a)$ and

$$\langle x^*, x - a\rangle \le \sum_{i\in J(a)} r_i f(x) - \sum_{i\in J(a)} r_i f_i(a)$$

for all $x \in X$. This implies that $x^* = \sum_{i\in J(a)} r_i f_i'(a)$. Thus, $x^* \in R_+\text{co}\{f_i'(a) : i \in J(a)\}$. This shows that $D^*F(a,b)(R^n) \subset R_+\text{co}\{f_i'(a) : \ i \in J(a)\}$. Conversely, let $x^* \in R_+\text{co}\{f_i'(a) : \ i \in J(a)\}$. Then there exists $(c_1, \ldots, c_n) \in R^n_+$ with $c_i = 0$ for all $i \notin J(a)$ such that $x^* = \sum_{i=1}^n c_i f_i'(a)$. Noting that for each i,

$$\langle c_i f_i'(a), x - a\rangle \le c_i(f_i(x) + t_i - b_i) \quad \forall x \in X \text{ and } \forall t_i \ge 0,$$

it follows that $x^* \in D^*F(a,b)(c_1, \ldots, c_n)$. This shows that

$$R_+\text{co}\{f_i'(a) : \ i \in J(a)\} \subset D^*F(a,b)(R^n).$$

Hence, (3.20) holds. □

4. Calmness of convex multifunctions. Throughout this section, let $M : Y \to 2^X$ be a closed convex multifunction and A be a closed convex subset of X. Let $\bar{y} \in Y$ and $\bar{x} \in M(\bar{y}) \cap A$.

Recall (cf. [8, 9, 10] and [15]) that M is said to be calm at $(\bar{y}, \bar{x})$ if there exists a constant Ł > 0 such that

$$d(x, M(\bar{y})) \le L\|y - \bar{y}\| \quad \forall (y,x) \in \text{Gr}(M) \text{ close to } (\bar{y}, \bar{x}). \tag{4.1}$$

More generally, M is said to be calm at $(\bar{y}, \bar{x})$ over A if there exists a constant Ł > 0 such that

$$d(x, M(\bar{y}) \cap A) \le L(\|y - \bar{y}\| + d(x, A)) \quad \forall (y,x) \in \text{Gr}(M) \text{ close to } (\bar{y}, \bar{x}). \tag{4.2}$$

Let $\tilde{M} : Y \times X \to 2^X$ be defined by

$$\tilde{M}(y,z) = M(y) \cap (-z + A) \text{ for any } (y,z) \in Y \times X$$

and $Y \times X$ be equipped with the norm $\|(y,z)\| = \|y\| + \|z\|$ for any $(y,z) \in Y \times X$. Then, as observed by one of the referees, (4.2) holds if and only if

$$d(x, \tilde{M}(\bar{y}, 0)) \le L\|(y,z) - (\bar{y}, 0)\| \quad \forall (y,z;x) \in \text{Gr}(\tilde{M}) \text{ close to } (\bar{y}, 0; \bar{x}).$$

Hence, M is calm at $(\bar{y}, \bar{x})$ over A if and only if $\tilde{M}$ is calm at $(\bar{y}, 0; \bar{x})$. A more general intersection map has been studied by Klatte and Kummer [16].

Since $d(x, \emptyset) = +\infty$ and $d(x, M(\bar{y})) \le \|x - \bar{x}\|$, it is easy to verify that (4.2) holds if and only if

$$d(x, M(\bar{y}) \cap A) \le L(d(\bar{y}, M^{-1}(x)) + d(x, A)) \quad \forall x \text{ close to } \bar{x}. \tag{4.3}$$

Letting $b = \bar{y}$ and $F(x) = M^{-1}(x)$, it follows that (GEC) is metrically subregular at $\bar{x}$ if and only if M is calm at $(\bar{y}, \bar{x})$ over A. Thus, by Theorems 3.1 and 3.3, we have the following results.

THEOREM 4.1. *The following statements are equivalent.*

(i) *M is calm at $(\bar{y}, \bar{x})$ over A.*
(ii) *There exist $\tau, \delta \in (0, +\infty)$ such that for all $u \in B(\bar{x}, \delta) \cap \mathrm{bd}(M(\bar{y}) \cap A)$,*

$$N(M(\bar{y}) \cap A, u) \cap B_{X^*} \subset \tau(D^*M^{-1}(\bar{x}, \bar{y})(B_{Y^*}) + N(A, u) \cap B_{X^*}).$$

(iii) *There exists $\delta \in (0, +\infty)$ such that for all $u \in \mathrm{bd}(M(\bar{y}) \cap A)$ close to $\bar{x}$, the tangent derivative $DM(\bar{y}, u)$ is calm at $(0, 0)$ over $T(A, u)$ with the same constant.*

Using Theorem 4.1, we can establish some characterization of the strong calmness: M is called strongly calm at $(\bar{y}, \bar{x})$ over A if there exists $L \in [0, +\infty)$ such that

$$\|x - \bar{x}\| \le L(\|y - \bar{y}\| + d(x, A)) \quad \forall (y, x) \in \mathrm{Gr}(M) \text{ close to } (\bar{y}, \bar{x}). \tag{4.4}$$

When $A = X$, the strong calmness means the local upper Lipschitz property presented in [15, p. 6]. From the convexity of $M(\bar{y}) \cap A$, it is clear that M is strongly calm at $(\bar{y}, \bar{x})$ over A if and only if $M(\bar{y}) \cap A = \{\bar{x}\}$ and M is calm at $(\bar{y}, \bar{x})$ over A.

Corollary 4.2. *The following statements are equivalent.*
(i) *M is strongly calm at $(\bar{y}, \bar{x})$ over A.*
(ii) *There exists $L \in [0, +\infty)$ such that*

$$\|x - \bar{x}\| \le L(\|y - \bar{y}\| + d(x, A)) \quad \forall (y, x) \in \mathrm{Gr}(M).$$

(iii) *The tangent derivative $DM(\bar{y}, \bar{x})$ is strongly calm at $(0, 0)$ over $T(A, \bar{x})$.*
(iv) $0 \in \mathrm{int}(D^*M^{-1}(\bar{x}, \bar{y})(Y^*) + N(A, \bar{x}))$.
(v) *There exists $r > 0$ such that*

$$rB_{X^*} \subset D^*M^{-1}(\bar{x}, \bar{y})(B_{Y^*}) + N(A, \bar{x}) \cap B_{X^*}.$$

Proof. First, we show that (i)⇔(v). By the evident fact $N(\{\bar{x}\}, \bar{x}) = X^*$ and by Theorem 4.1, we need only show that (v)⇒$M(\bar{y}) \cap A = \{\bar{x}\}$. Take an arbitrary $x \in M(\bar{y}) \cap A$ and $x^* \in B_{X^*}$ such that $\|x - \bar{x}\| = \langle x^*, x - \bar{x}\rangle$. By (v), there exist $y^* \in B_{Y^*}$, $x_1^* \in D^*M^{-1}(\bar{x}, \bar{y})(y^*)$ and $x_2^* \in N(A, \bar{x}) \cap B_{X^*}$ such that $rx^* = x_1^* + x_2^*$. Hence,

$$r\|x - \bar{x}\| = \langle x_1^*, x - \bar{x}\rangle + \langle x_2^*, x - \bar{x}\rangle.$$

Noting that $\langle x_1^*, x - \bar{x}\rangle \le \langle y^*, \bar{y} - \bar{y}\rangle = 0$ and $\langle x_2^*, x - \bar{x}\rangle \le 0$, it follows that $r\|x - \bar{x}\| \le 0$ for any $x \in M(\bar{y}) \cap A$. This shows that $M(\bar{y}) \cap A = \{\bar{x}\}$.

Noting that $D^*M^{-1}(\bar{x}, \bar{y}) = D^*(DM(\bar{y}, \bar{x}))^{-1}(0, 0)$, (iii)⇔(v) is immediate from (i)⇔(v).

It is clear that (ii)⟹(i) and (v)⟹(iv).

Suppose that (i) holds. Then there exists $L \in [0, +\infty)$ such that (4.4) holds. Let (y, x) be an arbitrary element in $\mathrm{Gr}(M)$ and $t \in (0, 1)$ be small enough such that $(ty + (1 - t)\bar{y}, tx + (1 - t)\bar{x})$ close enough to $(\bar{y}, \bar{x})$. By (4.4) and the convexity of M, one has

$$\|tx + (1 - t)\bar{x} - \bar{x}\| \le L(\|ty + (1 - t)\bar{y} - \bar{y}\| + d(tx + (1 - t)\bar{x}, A)).$$

It follows from the convexity of A and $\bar{x} \in A$ that $\|x - \bar{x}\| \le L(\|y - \bar{y}\| + d(x, A))$. This shows that (i)⟹(ii).

It remains to show that (iv)⇒(v). Suppose that (iv) holds. Since $N(A, x)$ and $D^*M^{-1}(x, \bar{y})(Y^*)$ are cones,

$$X^* = D^*M^{-1}(\bar{x}, \bar{y})(Y^*) + N(A, \bar{x}) = \bigcup_{n=1}^{\infty} (D^*M^{-1}(\bar{x}, \bar{y})(nB_{Y^*}) + N(A, \bar{x}) \cap nB_{X^*}).$$

Noting that, by the Alaoglu theorem, each set $D^*M^{-1}(\bar{x},\bar{y})(nB_{Y^*})+N(A,\bar{x})\cap nB_{X^*}$ is weak* closed, it follows from the well known Baire category theorem and (iv) that

$$0\in \operatorname{int}(D^*M^{-1}(\bar{x},\bar{y})(B_{Y^*})+N(A,\bar{x})\cap B_{X^*}).$$

Hence there exists $r>0$ such that (v) holds. Hence, the proof is completed. □

Remark. In a recent paper [8], Henrion and Jourani considered the calmness of the convex multifunction M_0 of the following type:

$$M_0(y)=\{x\in C:\ f(x)\le y\}\quad \forall y\in R, \tag{4.5}$$

where C is a closed convex subset of X and $f: X\to R\cup\{+\infty\}$ is a proper lower semicontinuous convex function. In particular, as a main result, they established the following result.

THEOREM HJ (see [8, Theorem 3.3]). Let M_0 be defined by (4.5). Then M_0 is calm at $(0,\bar{x})\in \operatorname{Gr}(M_0)$ if one of the following conditions is satisfied:

(C1) $f(\bar{x})<0$,

(C2) $\operatorname{bd}\partial f(\bar{x})\cap \operatorname{bd}N(C,\bar{x})\ne \partial f(\bar{x})\cap N(C,\bar{x})$,

(C3) $\operatorname{bd}\partial f(\bar{x})\cap \operatorname{bd}N(C,\bar{x})=\emptyset$ and (CD*) (see [8] for the definition of condition (CD*)).

As observed by Henrion and Jourani [8], (C3)$\Longrightarrow$either (C2) or (C1) and

$$\text{(C2)}\Longrightarrow \operatorname{int}\partial f(\bar{x})\cap -N(C,\bar{x})\ne\emptyset \text{ or } \partial f(\bar{x})\cap -\operatorname{int}N(C,\bar{x})\ne\emptyset.$$

Considering that (C1)$\Longrightarrow$the calmness of M_0 at $(0,\bar{x})$ is an immediate consequence of the Robinson–Ursescu theorem (cf. [29, 33]), the main part of Theorem HJ can be rewritten as follows: M_0 is calm at $(0,\bar{x})\in \operatorname{Gr}(M_0)$ if

$$\operatorname{int}(\partial f(\bar{x}))\cap -N(C,\bar{x})\ne\emptyset \ \text{ or } \ \partial f(\bar{x})\cap -\operatorname{int}N(C,\bar{x})\ne\emptyset. \tag{4.6}$$

Let $A=C$, $Y=R$ and $M(y)=\{x\in X:\ f(x)\le y\}$ for all $y\in Y$. It is clear that M_0 is calm at $(0,\bar{x})$ if M is calm at $(0,\bar{x})$ over A. Since

$$\partial f(\bar{x})=D^*M^{-1}(\bar{x},f(\bar{x}))(1)\subset D^*M^{-1}(\bar{x},f(\bar{x}))(Y^*),$$

we see immediately that (iv) in Corollary 4.2 holds whenever (4.6) holds. On the other hand, below is a simple example for which Corollary 4.2 is applicable but Theorem HJ is not.

Let $X=R^2$, $C=R\times\{0\}$, $\bar{x}=(0,0)$, and $f(x_1,x_2)=|x_1|$ for all $(x_1,x_2)\in R^2$. Then (4.6) is not satisfied because

$$M_0(0)=\{\bar{x}\},\ \partial f(\bar{x})=[-1,\ 1]\times\{0\} \text{ and } N(C,\bar{x})=\{0\}\times R.$$

However, Corollary 4.2 is applicable because (iv) holds as $D^*M^{-1}(\bar{x},f(\bar{x}))(Y^*)=R\times\{0\}$ and so $D^*M^{-1}(\bar{x},f(\bar{x}))(Y^*)+N(C,\bar{x})=R^2$.

The calmness modulus of M at $(\bar{y},\bar{x})$ is denoted by $\eta(M;\bar{y},\bar{x})$ and is defined by

$$\eta(M;\bar{y},\bar{x}):=\inf\{L\in(0,\ +\infty):\ (4.1)\text{ holds}\}.$$

As applications of Theorems 3.1 and 3.2, we establish formulas representing $\eta(M;\bar{y},\bar{x})$.

THEOREM 4.3. $\eta(M;\bar{y},\bar{x})=\limsup_{u\overset{\operatorname{bd}(M(\bar{y}))}{\longrightarrow}\bar{x}}\|D^*M(\bar{y},u)|_{-N(M(\bar{y}),u)}\|^-$.

Proof. Let $F = M^{-1}$ and $A = X$. Since (4.2)$\Leftrightarrow$(4.3), $\eta(M; \bar{y}, \bar{x}) = \tau(F, \bar{x}, \bar{y}; A)$. By (3.6), it suffices to show that

$$\gamma(F, u, \bar{y}; A) = \|D^*M(\bar{y}, u)|_{-N(M(\bar{y}),u)}\|^- \quad \forall u \in F^{-1}(\bar{y}) = M(\bar{y}). \tag{4.7}$$

Let $u \in F^{-1}(\bar{y}) = M(\bar{y})$. By definitions, it is clear that

$$x^* \in D^*F(u, \bar{y})(y^*) \Longleftrightarrow -y^* \in D^*M(\bar{y}, u)(-x^*).$$

Let $\tau > \gamma(F, u, \bar{y}; A)$. Noting that $N(A, u) = N(X, u) = \{0\}$, one has

$$N(M(\bar{y}), u) \cap B_{X^*} \subset D^*F(u, \bar{y})(\tau B_{Y^*}).$$

Hence, for any $x^* \in N(M(\bar{y}), u) \cap B_{X^*}$ there exists $y^* \in B_{Y^*}$ such that $x^* \in D^*F(u, \bar{y})(\tau y^*)$, that is, $-\tau y^* \in D^*M(\bar{y}, u)(-x^*)$. It follows that

$$\|D^*M(\bar{y}, u)|_{-N(M(\bar{y}),u)}\|^- \le \tau.$$

Therefore, $\|D^*M(\bar{y}, u)|_{-N(M(\bar{y}),u)}\|^- \le \gamma(F, u, \bar{y}; A)$. To prove the converse inequality, let $\tau > \|D^*M(\bar{y}, u)|_{-N(M(\bar{y}),u)}\|^-$ and take $x^* \in N(F^{-1}(\bar{y}), u) = N(M(\bar{y}), u)$. Then, there exists $y^* \in D^*M(\bar{y}, u)(-x^*)$ such that $\|y^*\| < \tau$; this means $x^* \in D^*F(u, \bar{y})(\tau B_{Y^*})$. Hence, $N(F^{-1}(\bar{y}), u) \cap B_{X^*} \subset D^*F(u, \bar{y})(\tau B_{Y^*})$. It follows that $\gamma(F, u, \bar{y}; A) \le \tau$. Therefore, $\gamma(F, u, \bar{y}; A) \le \|D^*M(\bar{y}, u)|_{-N(M(\bar{y}),u)}\|^-$. This shows that (4.7) holds. □

Remark. In contrast to formula (1.4) of the modulus of the metric regularity, $\eta(M; \bar{y}, \bar{x})$ is not necessarily equivalent to $\|D^*M(\bar{y}, \bar{x})|_{-N(M(\bar{y}),\bar{x})}\|^-$ even when $Y = R^2$ and $X = R$ (cf. [36, p. 763, Example 2]). Nevertheless, the following theorem shows an interesting case for which the equality holds.

THEOREM 4.4. *Suppose that there exist a cone C and a neighborhood V of $\bar{x}$ such that $M(\bar{y}) \cap V = (\bar{x} + C) \cap V$. Then $\eta(M; \bar{y}, \bar{x}) = \|D^*M(\bar{y}, \bar{x})|_{-N(M(\bar{y}),\bar{x})}\|^-$.*

The proof of Theorem 4.4 is similar to that of Theorem 4.3 but using Theorem 3.2 in place of Theorem 3.1.

5. Recession core and global metric subregularity. Let K be a closed convex subset of X.

Recall that $e \in K$ is called an extreme point of K if $x_1 = x_2$ whenever $e = tx_1 + (1 - t)x_2$ with $x_1, x_2 \in K$ and $t \in (0,\ 1)$. We denote by $\mathrm{ext}(K)$ the set of all extreme points of K (usually $\mathrm{ext}(K)$ is called the extreme boundary of K).

Let K^∞ denote the recession cone of K, that is,

$$K^\infty := \{h \in X :\ K + th \subset K \quad \forall t \ge 0\}.$$

It is known that K^∞ is a closed convex cone, and

$$\begin{aligned} K^\infty &= \{h \in X :\ x + R_+h \subset K \text{ for some } x \in K\} \\ &= \{h \in X :\ \exists x_n \in K \text{ and } \exists t_n > 0 \text{ such that } t_n \to 0 \text{ and } t_n x_n \to h\}. \end{aligned}$$

Clearly, $K + K^\infty = K$. It is well known that if K is a closed convex subset of R^n containing no lines, then $K = \mathrm{co}(\mathrm{ext}(K)) + K^\infty$.

As a generalization of $\mathrm{co}(\mathrm{ext}(K))$, the authors [28] introduced the concept of recession property: a convex subset A of K is said to have the recession property if $K = A + K^\infty$.

Simplifying the recession property, we can now give a generalization of ext(K): a subset C of K is said to be a recession core of K if

$$K = \mathrm{co}(C) + K^\infty. \tag{5.1}$$

Thus, C is a recession core of K if and only if co(C) is a subset of K with recession property.

Let "$\leq_{K^\infty}$" denote the order induced by the cone K^∞, that is, $x_1 \leq_{K^\infty} x_2$ if and only if $x_2 - x_1 \in K^\infty$.

Let A be a subset of X. We say that $a \in A$ is a minimal element of A with respect to "$\leq_{K^\infty}$" if $a \leq_{K^\infty} x$ whenever $x \in A$ and $x \leq_{K^\infty} a$. We denote by $\mathrm{Min}(A, K^\infty)$ the set of all minimal elements of A.

Let

$$\mathrm{Lin}(K) := K^\infty \cap -K^\infty.$$

Then

$$\mathrm{Lin}(K) = \{h \in X : \ K + Rh \subset K\} = \{h \in X : \ x + Rh \subset K \text{ for some } x \in K\}.$$

Moreover, $K = K + \mathrm{Lin}(K)$ and $L \subset \mathrm{Lin}(K)$ whenever L is a subspace of X such that $K = K + L$. Therefore, K contains no lines if and only if $\mathrm{Lin}(K) = \{0\}$.

PROPOSITION 5.1. *Let X be a reflexive Banach space and K a closed convex nonempty subset of X. Suppose that there exists a closed convex bounded set Θ such that*

$$\mathrm{Lin}(K) \cap \Theta = \emptyset \ \text{ and } \ K^\infty = \mathrm{Lin}(K) + R_+\Theta. \tag{5.2}$$

Then

$$K = \mathrm{Min}(K, K^\infty) + K^\infty. \tag{5.3}$$

In particular, $\mathrm{Min}(K, K^\infty)$ *is a recession core of K.*

Proof. By the reflexivity of X, the bounded closed convex set Θ is weakly compact. Letting $K_0 := R_+\Theta$, it follows that K_0 is a closed convex pointed cone. Let x be an arbitrary point in K. We claim that $K \cap (x - K_0)$ is bounded. If this is not the case, then there exist a sequence $\{s_n\}$ in R_+ and a sequence $\{\theta_n\}$ in Θ such that $s_n \to \infty$ and $x - s_n\theta_n \in K$ for all n. Thus, for any $t > 0$,

$$x - t\theta_n = \left(1 - \frac{t}{s_n}\right) x + \frac{t}{s_n}(x - s_n\theta_n) \in K \quad \forall n \text{ large enough.}$$

By the weak compactness of Θ, without loss of generality we can assume that $\{\theta_n\}$ converges weakly to some $\theta \in \Theta$. Therefore, $x - t\theta \in K$ for any $t \geq 0$. This implies that $-\theta \in K^\infty$. On the other hand, by the second equality in (5.2), one has $\theta \in K^\infty$ and so $\theta \in \mathrm{Lin}(K)$. This contradicts the first equality in (5.2) and therefore $K \cap (x - K_0)$ must be bounded (and hence weakly compact). It follows from [14, Corollary 3.1.16]) that $\mathrm{Min}(K \cap (x - K_0), K_0) \neq \emptyset$. Take $x' \in \mathrm{Min}(K \cap (x - K_0), K_0)$. Then $x' \in \mathrm{Min}(K, K_0)$ and $x \in x' + K_0$. Hence $K \subset \mathrm{Min}(K, K_0) + K_0$. Now to show (5.3), it suffices to show that $\mathrm{Min}(K, K_0) \subset \mathrm{Min}(K, K^\infty)$. Let $z \in \mathrm{Min}(K, K_0)$ and $y \in K$ with $y \leq_{K^\infty} z$. Then $z - y \in K^\infty$. By the second equality of (5.2), there exists $e \in \mathrm{Lin}(K)$ such that $z - y - e \in K_0$, that is, $y + e \leq_{K_0} z$. Noting that $y + e \in K$,

one has that $y + e - z \in K_0$ and hence $y - z \in \mathrm{Lin}(K) + K_0 = K^\infty$. This shows that $z \in \mathrm{Min}(K, K^\infty)$. Hence, the proof is completed. □

In the case when X is finite dimensional, the assumption made in (5.2) automatically holds (by $K = \mathrm{Lin}(K) + C$ and Klee's Theorem (cf. [14]), where C is a closed convex pointed cone). The following example shows that the reflexivity of X cannot be removed in Proposition 5.1.

Example. Let $X = l^1$ and $K = \{x = (t_1, t_2, \cdots) \in l^1 : \ t_n \geq -n \text{ for all } n\}$. It is easy to verify that $\mathrm{Lin}(K) = \{0\}$ and $K^\infty = \{x = (t_1, t_2, \cdots) \in l^1 : \ t_n \geq 0 \text{ for all } n\}$. Let $\Theta := \{x = (t_1, t_2, \cdots) \in K^\infty : \ \sum_{n=1}^\infty t_n = 1\}$. Then, Θ is a bounded closed convex set, $\mathrm{Lin}(K) \cap \Theta = \emptyset$ and $K^\infty = R^+\Theta$. But $\mathrm{Min}(K, K^\infty) = \emptyset$, and hence $K \neq \mathrm{Min}(K, K^\infty) + K^\infty$. Indeed, let $x = (t_1, t_2, \cdots)$ be any point in K. Noting that $\sum_{n=1}^\infty |t_n| < \infty$, there exists a natural number n_0 such that $|t_n| < n_0$ for all $n \geq n_0$. Take $x_0 = (s_1, s_2, \cdots)$ to satisfy $s_n = t_n$ for any $n \neq n_0$ and $s_{n_0} = -n_0$. It is clear that $x_0 \in K \setminus \{x\}$ and $x - x_0 \in K^\infty$. It follows that $x \notin \mathrm{Min}(K, K^\infty)$. This shows that $\mathrm{Min}(K, K^\infty) = \emptyset$.

It is clear that K has no extreme points if K contains lines. This motivates us to introduce a new concept—what we shall refer to as "generalized extreme points." Let X be a Hilbert space. For a closed convex subset K of X, let

$$\mathrm{Lin}(K)^\perp := \{x \in X : \ \langle x, y\rangle = 0 \quad \forall y \in \mathrm{Lin}(K)\}.$$

We say that e is a generalized extreme point of K if $e \in K \cap \mathrm{Lin}(K)^\perp$ and

$$x_1, x_2 \in K \text{ and } e = \frac{x_1 + x_2}{2} \Longrightarrow x_1 - x_2 \in \mathrm{Lin}(K). \tag{5.4}$$

We denote by $\mathrm{ext}_E(K)$ the set of all generalized extreme points of K. Clearly, $\mathrm{ext}_E(K) = \mathrm{ext}(K)$ if K contains no lines (i.e., $\mathrm{Lin}(K) = \{0\}$). Moreover, one has that

$$\mathrm{ext}_E(K) \subset \mathrm{Min}(K, K^\infty). \tag{5.5}$$

To see this, let $e \in \mathrm{ext}_E(K)$ and $x \in K$ with $x \leq_{K^\infty} e$. Then $e - x \in K^\infty$ and hence $2e - x = e + (e - x) \in K$. Since $e = \frac{x + (2e - x)}{2}$, it follows that $2(e - x) \in \mathrm{Lin}(K)$, which means $x - e \in \mathrm{Lin}(K) \subset K^\infty$. Hence $e \leq_{K^\infty} x$. This shows that $e \in \mathrm{Min}(K, K^\infty)$. Thus (5.5) is true.

PROPOSITION 5.2. *Let X be a Hilbert space and K a closed convex subset of X. Then*

$$\mathrm{ext}_E(K) = \mathrm{ext}(K \cap \mathrm{Lin}(K)^\perp). \tag{5.6}$$

Proof. By definition it is clear that $\mathrm{ext}_E(K) \subset \mathrm{ext}(K \cap \mathrm{Lin}(K)^\perp)$. Conversely, let $e \in \mathrm{ext}(K \cap \mathrm{Lin}(K)^\perp)$ and $x_1, x_2 \in K$ satisfy $e = \frac{x_1 + x_2}{2}$. Noting that for each $x \in X$ there exists a unique pair $(u, v) \in \mathrm{Lin}(K) \times \mathrm{Lin}(K)^\perp$ such that $x = u + v$, take $(u_1, v_1), (u_2, v_2) \in \mathrm{Lin}(K) \times \mathrm{Lin}(K)^\perp$ such that $x_1 = u_1 + v_1$ and $x_2 = u_2 + v_2$. Then $e = \frac{u_1 + u_2}{2} + \frac{v_1 + v_2}{2}$. It follows from $e \in \mathrm{ext}(K \cap \mathrm{Lin}(K)^\perp)$ that $u_1 + u_2 = 0$ and $e = v_1 = v_2$. Thus, $x_1 - x_2 = u_1 - u_2 \in \mathrm{Lin}(K)$ and hence $e \in \mathrm{ext}_E(K)$. This shows that $\mathrm{ext}_E(K) \supset \mathrm{ext}(K \cap \mathrm{Lin}(K)^\perp)$ and (5.6) is proved. □

PROPOSITION 5.3. *Let K be a closed convex subset of a Hilbert space X and $\prod$ be the project operator to $\mathrm{Lin}(K)^\perp$. Suppose that C is a recession core of K. Then $\mathrm{ext}_E(K) \subset \prod(C)$.*

Proof. Let $e \in \text{ext}_E(K)$. Then, by (5.1) there exist $x_1, \ldots, x_n \in C$, $t_1, \ldots, t_n \in [0,\ 1]$ with $\sum_{i=1}^n t_i = 1$, and $h \in K^\infty$ such that $e = \sum_{i=1}^n t_i x_i + h$. Then,

$$e = \frac{\left(\sum_{i=1}^n t_i x_i + \frac{1}{2}h\right) + \left(\sum_{i=1}^n t_i x_i + \frac{3}{2}h\right)}{2}.$$

Thus, by (5.4), one has $h \in \text{Lin}(K)$. It follows from the linearity of $\prod$ that

$$e = \prod(e) = \prod\left(\sum_{i=1}^n t_i x_i + h\right) = \sum_{i=1}^n t_i \prod(x_i) \in \prod(C).$$

This shows that $\text{ext}_E(K) \subset \prod(C)$. □

The following proposition shows that $\text{ext}_E(K)$ is a recession core of K when X is finite dimensional.

PROPOSITION 5.4. *Let K be a closed convex nonempty subset of R^n. Then*

$$K = \text{co}(\text{ext}_E(K)) + K^\infty. \tag{5.7}$$

Proof. Let $h \in R^n$ be such that $x + Rh \subset K \cap \text{Lin}(K)^\perp$ for some $x \in R^n$. Then $h \in \text{Lin}(K)$, and hence $\langle x + th, h\rangle = 0$ for all $t \in R$. It follows that $h = 0$. Therefore $K \cap \text{Lin}(K)^\perp$ is a closed convex subset containing no lines. It follows from [31, Theorem 18.5] that

$$K \cap \text{Lin}(K)^\perp = \text{co}(\text{ext}(K \cap \text{Lin}(K)^\perp)) + (K \cap \text{Lin}(K)^\perp)^\infty.$$

This and Proposition 5.2 imply that $K \cap \text{Lin}(K)^\perp \subset \text{co}(\text{ext}_E(K)) + K^\infty$. Noting that $K^\infty + \text{Lin}(K) = K^\infty$, one then has

$$K \cap \text{Lin}(K)^\perp + \text{Lin}(K) \subset \text{co}(\text{ext}_E(K)) + K^\infty. \tag{5.8}$$

Let $x \in K$ and take $x_1 \in \text{Lin}(K)$ and $x_2 \in \text{Lin}(K)^\perp$ such that $x = x_1 + x_2$. Hence $x_2 \in x + \text{Lin}(K) \subset K$ and so $x_2 \in K \cap \text{Lin}(K)^\perp$. Therefore, $K \subset \text{Lin}(K) + K \cap \text{Lin}(K)^\perp$. It follows from (5.8) that

$$K \subset \text{co}(\text{ext}_E(K)) + K^\infty.$$

Thus (5.7) holds as the converse inclusion is obvious. □

Remark. Proposition 5.4 shows that $\text{ext}_E(K)$ is a recession core of K and has the minimality property "up to $\text{Lin}(K)$" in the sense as indicated in Proposition 5.3. In particular, if K contains no lines, then $\text{ext}_E(K) = \text{ext}(K)$ is the least recession core of K.

In terms of recession cores and the BCQs, we now study the global metric subregularity of generalized equation (GEC). Hoffman, in his pioneering work, proved that (GEC) has an error bound (or equivalently, is globally metrically subregular) if $A = X = R^n$ and $F(x) := Qx + R^n_+$ for all $x \in R^n$, where Q is an $m \times n$ matrix. The research on error bounds, especially for inequality systems, has attracted the interest of many researchers and there are a vast number of publications reporting progress in this area. For more details, see [18, 19, 21, 27, 28, 33, 34] and a special issue of Mathematical Programming (Vol. 88, No. 2, 2000). In what follows, we assume that X, Y are general Banach spaces (except when explicitly stated otherwise), F is a closed convex multifunction from X to Y, and A is a closed convex subset of X. In

the case when $A = X$, while the equivalence of (iv) with (v) in the following result is [28, Theorem 3.1], we can now sharpen the result by considering recession cores of S. In what follows, we assume that the solution set S is nonempty.

THEOREM 5.5. *Let C be a recession core of the solution set S of (GEC) and $\tau \in [0, +\infty)$. Then the following statements are equivalent.*

(i) *(GEC) has the strong BCQ at each $x \in C$ with the constant τ.*

(ii) *(GEC) has the strong BCQ at each $x \in S$ with the constant τ.*

(iii) *(GEC) is metrically subregular at each point in C with the constant τ.*

(iv) *(GEC) is metrically subregular at each point in S with the constant τ.*

(v) *(GEC) is globally metrically subregular with the constant τ.*

Proof. (i)⇒(ii) Let $x \in S$. Since C is a recession cone of S, there exist $x_1, \ldots, x_n \in C$, $t_1, \ldots, t_n \in [0, +\infty)$, and $e \in S^\infty$ such that

$$\sum_{i=1}^{n} t_i = 1 \text{ and } x = \sum_{i=1}^{n} t_i x_i + e. \tag{5.9}$$

Let $x^* \in N(S, x) \cap B_{X^*}$. Then $\langle x^*, \sum_{i=1}^n t_i x_i + e\rangle = \max\{\langle x^*, z\rangle : z \in S\}$. Noting that $\sum_{i=1}^n t_i x_i + R_+ e \subset S$, it follows that

$$\langle x^*, e\rangle = 0 \text{ and } \left\langle x^*, \sum_{i=1}^{n} t_i x_i \right\rangle = \max\{\langle x^*, z\rangle : z \in S\}.$$

This implies that for each integer $i \in [1, n]$,

$$\langle x^*, x\rangle = \langle x^*, x_i\rangle = \max\{\langle x^*, z\rangle : z \in S\},$$

and hence $x^* \in N(S, x_i) \cap B_{X^*}$. By (i), one has

$$x^* \in \tau(D^*F(x_i, b)(B_{Y^*}) + N(A, x_i) \cap B_{X^*}), i = 1, \ldots, n.$$

It follows from Lemma 3.1 that $x^* \in \tau(D^*F(x, b)(B_{Y^*}) + N(A, x) \cap B_{X^*})$. Therefore,

$$N(S, x) \cap B_{X^*} \subset \tau(D^*F(x, b)(B_{Y^*}) + N(A, x) \cap B_{X^*}).$$

This shows that (ii) holds. (ii)⇒(i), (iv)⇒(iii), and (v)⇒(iv) are trivial. (iii)⇒(i) and (ii)⇒(iv) are consequences of formula (3.6) in Remark 3.1. The proof of (iv)⇒(v) is similar to that of [28, Theorem 3.1]. Hence, the proof is completed. □

In the special case when $A = X$, $Y = R$, $F(x) = [f(x), +\infty)$ for all $x \in X$, and $b = \inf\{f(x) : x \in X\}$ with f being a proper lower semicontinuous convex function from X to $R \cup \{+\infty\}$, Burke and Deng [3, Theorem 2.3] proved that (GEC) is globally τ-metrically subregular if and only if

$$N(S, z) \cap B_{X^*} \subset \mathrm{cl}^*(\partial f(z)) \quad \forall z \in S.$$

Since $\mathrm{ext}_E(S)$ is a recession core of S if $X = R^n$, the following corollary is a consequence of Theorem 5.5.

COROLLARY 5.6. *Let $X = R^n$. Then (GEC) is globally metrically subregular if and only if there exists $\tau \in (0, +\infty)$ such that (GEC) has the strong BCQ at each generalized extreme point of S with the constant τ.*

Similar to the proof of the equivalent relation (i)⇔(ii) in Theorem 5.5, one can prove the following result.

PROPOSITION 5.7. *Let C be a recession core of S. Then (GEC) has the BCQ at each point in C if and only if (GEC) has the BCQ at each point in S.*

As in the finite dimensional case, let us say that a subset P of X is a polyhedron if there exist $x_n^*, \ldots, x_n^* \in X^*$ and $c_1, \ldots, c_n \in R$ such that

$$P = \{x \in X : \langle x_i^*, x\rangle \le c_i,\ i = 1, \ldots, n\}.$$

It is known that

$$N(P,x) = \left\{ \sum_{i \in I(x)} t_i x_i^* : t_i \ge 0,\ i \in I(x) \right\} \quad \forall x \in P, \tag{5.10}$$

where $I(x) := \{1 \le i \le n : \langle x_i^*, x\rangle = c_i\}$. We say that a multifunction $F : X \to 2^Y$ is polyhedral if its graph is a polyhedron in $X \times Y$. If F is polyhedral, it is easy to verify from (5.10) that

$$N(F^{-1}(b), x) = D^*F(x,b)(Y^*) \quad \forall x \in F^{-1}(b). \tag{5.11}$$

THEOREM 5.8. *Let C be a recession core of the solution set S of (GEC). Suppose that S is a polyhedron in X. Then (GEC) is globally metrically subregular if and only if (GEC) has the BCQ at each point in C.*

Proof. By Theorem 5.5, it suffices to prove the sufficiency. Suppose that (GEC) has the BCQ at each point in C. Then, (GEC) has the BCQ at each point of S (by Proposition 5.7). Since S is a polyhedron, there exist $x_n^*, \ldots, x_n^*$ and $c_1, \ldots, c_n \in R$ such that

$$S = \{x \in X : \langle x_i^*, x\rangle \le c_i,\ i = 1, \ldots, n\}.$$

Let $X_1 := \{x \in X : \langle x_i^*, x\rangle = 0,\ i = 1, \ldots, n\}$. Then X_1 is a closed subspace of X with finite codimension. Thus, there exists a finite dimensional subspace X_2 of X such that $X = X_1 + X_2$ and $X_1 \cap X_2 = \{0\}$. Let

$$P := \{z \in X_2 : \langle x_i^*, z\rangle \le c_i,\ i = 1, \ldots, n\}.$$

It is easy to verify that $S = P + X_1$ and P is a polyhedron containing no lines in X_2. By [31, Theorems 18.5 and 19.1], $P = \mathrm{co}(\mathrm{ext}(P)) + P^\infty$. Hence $S = \mathrm{co}(\mathrm{ext}(P)) + P^\infty + X_1$. Noting that $P^\infty + X_1 \subset (S)^\infty$, it follows that $\mathrm{ext}(P)$ is a recession core of S. Let $e \in \mathrm{ext}(P)$. Then, by (5.10), $N(S,e)$ is a polyhedron in a finite dimensional subspace of X^*. It follows from Proposition 3.4 that there exists $\tau_e \in (0, +\infty)$ such that (GEC) has the strong BCQ with the constant τ_e. Do this for each e in $\mathrm{ext}(P)$ and let $\tau := \max\{\tau_e : e \in \mathrm{ext}(P)\}$. Then $\tau < +\infty$ because $\mathrm{ext}(P)$ is a finite set (cf. [31, Theorem 19.1]). Hence, (GEC) has the strong BCQ at each point of $\mathrm{ext}(P)$ with the constant τ. Since $\mathrm{ext}(P)$ is a recession core of S, it follows from Theorem 5.5 that (GEC) is globally metrically subregular. Hence, the proof is completed. □

In view of the proof of Theorem 5.8, one sees that any polyhedron in a Banach space has a recession core consisting of finitely many elements.

Robinson [30] studied the continuity properties of polyhedral multifunctions. In particular, under the finite dimension assumption, he [30, Corollary] proved that if the graph of F is the union of finitely many polyhedra and $b \in F(X)$, then there exists $\varepsilon, \tau \in [0, +\infty)$ such that

$$d(x, F^{-1}(b)) \le \tau d(b, F(x)) \quad \forall x \in X \text{ with } d(b, F(x)) < \varepsilon.$$

This result can be regarded as a generalization of Hoffman's classical error bound theorem. In the setting of Theorem 5.8, F is not required to be polyhedral but merely the solution set S is required to be polyhedral. When F is a convex polyhedral multifunction and $A = X$, (5.11) implies that generalized equation (GEC) has the BCQ at each $x \in S = F^{-1}(b)$. Hence, in this case, Theorem 5.8 improves the above Robinson's result. But, in the nonconvex case, one cannot use Theorem 5.8 to deduce Robinson's result.

Let $\Gamma(X)$ denote the family of all functions f each of which satisfies the following property: There exist $x_i^* \in X^*$ and continuous convex functions $\phi_i : R \to R$ with $\inf_{t\in R} \phi_i(t) < 0$ $(1 \le i \le n\ )$ such that $f(x) = \max_{1\le i\le n} \phi_i(\langle x_i^*, x\rangle)$ for all $x \in X$. By taking ϕ_i to be affine or quadratic convex functions, we see that $\Gamma(X)$ properly contains the family of all piecewise affine convex functions on X and so the following corollary can be regarded as another generalization of Hoffman's error bound theorem.

COROLLARY 5.9. *Let X be finite dimensional, A be a polyhedron in X, $Y = R$, and $b = 0$. Suppose that there exists $f \in \Gamma(X)$ such that $F(x) = [f(x),\ +\infty)$ for all $x \in X$. Then (GEC) is globally metrically subregular.*

Proof. Let $x_i^* \in X^*$ and $\phi_i : R \to R$ be a continuous convex function with $\inf_{t\in R} \phi_i(t) < 0$ $(1 \le i \le n)$ such that $f(x) = \max_{1\le i\le n} \phi_i(\langle x_i^*, x\rangle)$ for all $x \in X$. Let $P_i = \{x \in X : \langle x_i^*, x\rangle \in \phi_i^{-1}(-\infty, 0]\}$. Since each $\phi_i^{-1}(-\infty, 0]$ is an interval in R, P_i is a polyhedron in X. Hence $S = \bigcap_{i=1}^n A \cap P_i$ is a polyhedron. Let $e \in \mathrm{ext}_E(S)$ and $I(e) := \{1 \le i \le n :\ \phi_i(\langle x_i^*, e\rangle) = f(e)\}$. Then

$$N(S, e) = N(A, e) + \sum_{i=1}^{n} N(P_i, e) = N(A, e) + \sum_{i\in I(e)} N(P_i, e). \tag{5.12}$$

Let $i \in I(e)$. Then, $\phi_i(\langle x_i, e\rangle) = f(e) = 0$ (because $\mathrm{ext}_E(S) \subset \mathrm{bd}(S)$). It follows from $\inf_{t\in R} \phi_i(t) < 0$ that $0 \notin \partial\phi_i(\langle x_i^*, e\rangle)$. By the definition of P_i, there exists $e_i^* \in X^*$ such that $R_+\partial\phi_i(\langle x_i^*, e\rangle)x_i^* \subset N(P_i, e) = R_+e_i^*$. Hence, $N(P_i, e) = R_+\partial\phi_i(\langle x_i^*, e\rangle)x_i^*$ when $x_i^* \ne 0$. Noting that $x_i^* = 0$ implies that $N(P_i, e) = N(X, e) = \{0\}$, it follows from (5.12) that

$$N(S, e) = N(A, e) + \sum_{i\in I(e)} R_+\partial\phi_i(\langle x_i^*, e\rangle)x_i^*. \tag{5.13}$$

On the other hand, by the definition of F, it is easy to verify that

$$D^*F(e, 0)(R) = D^*F(e, 0)(R_+) = R_+\mathrm{co}\left(\bigcup_{i\in I(e)} \partial\phi_i(\langle x_i^*, e\rangle)x_i^*\right).$$

Since $D^*F(e, 0)(R_+)$ is a convex cone, $D^*F(e, 0)(R) = \sum_{i\in I(e)} R_+\partial\phi_i(\langle x_i^*, e\rangle)x_i^*$. This and (5.13) implies that (GEC) has the BCQ at e. It follows from Proposition 5.4 and Theorem 5.8 that (GEC) is globally metrically subregular. The proof is completed. ∎

Let $X = R$ and $f(x) = \max\{(x - 1)^2 - 1,\ (x + 1)^2 - 1\}$ for all $x \in R$. Then $f \in \Gamma(R)$ is not a piecewise affine function and the inequality $f(x) \le 0$ does not satisfy the Slater condition. Examples of this kind provide some interesting cases covered by Corollary 5.9 but neither by Hoffman's error bound theorem nor by the Robinson–Ursescu theorem.

Remark. Let $M : Y \to 2^X$ be a closed convex multifunction and with $(\bar{y}, \bar{x}) \in \mathrm{Gr}(M)$. We say that M is globally calm at $\bar{y}$ over A if there exists $\tau \in (0, +\infty)$ such that

$$d(x, M(\bar{y}) \cap A) \le \tau(\|y - \bar{y}\| + d(x, A)) \quad \forall (x, y) \in \mathrm{Gr}(M).$$

Let C be a recession core of $M(\bar{y}) \cap A$. Theorem 5.5 implies that M is globally calm at $\bar{y}$ over A if and only if there exists $\tau \in (0, +\infty)$ such that

$$N(M(\bar{y}) \cap A, u) \cap B_{X^*} \subset \tau(D^*M^{-1}(u, \bar{y})(B_{Y^*}) + N(A, u) \cap B_{X^*}) \quad \forall u \in C.$$

In the case when $M(\bar{y}) \cap A$ is a polyhedron, Theorem 5.8 implies that M is globally calm at $\bar{y}$ over A if and only if

$$N(M(\bar{y}) \cap A, u) = D^*M^{-1}(u, \bar{y})(Y^*) + N(A, u) \quad \forall u \in C.$$

To end this paper, we provide a procedure to find the generalized extreme points of a polyhedron in a finite dimensional space. Let $a_1, \ldots, a_m \in R^n$, $c_1, \ldots, c_m \in R$, and let P denote the polyhedron determined by a_i and c_i $(i = 1, \ldots, m)$, that is,

$$P = \{x \in R^n : \langle a_i, x\rangle \le c_i,\ i = 1, \ldots, m\}.$$

For convenience, let $I := \{1, \ldots, m\}$ and $I(x) = \{i \in I : \langle a_i, x\rangle = c_i\}$ for $x \in P$. Let $\mathcal{M}(I)$ denote the family of all subsets D of I with the property that $\{a_i : i \in D\}$ is a maximal linearly independent subset of $\{a_i : i \in I\}$. Thus elements of $\mathcal{M}(I)$ can be obtained by the Gram–Schmidt process. For each $D \in \mathcal{M}(I)$, the linear equation system

$$\sum_{j \in D} \langle a_i, a_j\rangle t_j = c_i \quad \forall i \in D$$

has a unique solution which will be denoted by $(\bar{t}_j)_{j \in D}$; we shall also write e_D for $\sum_{j \in D} \bar{t}_j a_j$. Let

$$\mathcal{E}(I) = \{D \in \mathcal{M}(I) : \langle a_i, e_D\rangle \le c_i,\ i \in I \setminus D\}.$$

THEOREM 5.10. $\mathrm{ext}_E(P) = \{e_D : D \in \mathcal{E}(I)\}$.

Proof. Note that $\mathrm{Lin}(P) = \{x \in R^n : \langle a_i, x\rangle = 0,\ i \in I\}$. Hence,

$$\mathrm{Lin}(P)^\perp = \mathrm{span}\{a_i : i \in I\} = \mathrm{span}\{a_i : i \in D\} \quad \forall D \in \mathcal{M}(I), \tag{5.14}$$

where span$A$ denotes the linear hull of A. Let $e \in \mathrm{ext}_E(P)$ and pick a $D_0 \subset I(e)$ such that $\{a_i : i \in D_0\}$ is a maximal linearly independent subset of $\{a_i : i \in I(e)\}$. We claim that $D_0 \in \mathcal{M}(I)$. Indeed, if this is not the case, then $\mathrm{span}\{a_i : i \in I(e)\}$ is a proper subspace of $\mathrm{span}\{a_i : i \in I\}$. It follows from the first equality of (5.14) that there exists $h \in \mathrm{Lin}(P)^\perp \setminus \{0\}$ such that $\langle a_i, h\rangle = 0$ for all $i \in I(e)$. Since $\langle a_i, e\rangle < c_i$ for all $i \in I \setminus I(e)$, there exists $\varepsilon > 0$ small enough such that $e \pm \varepsilon h \in P$. Since $e = \frac{e+\varepsilon h+(e-\varepsilon h)}{2}$, it follows from (5.4) that $2\varepsilon h \in \mathrm{Lin}(P)$. This contradicts $h \in \mathrm{Lin}(P)^\perp \setminus \{0\}$. Hence $D_0 \in \mathcal{M}(I)$. Noting that $e \in \mathrm{Lin}(P)^\perp$ (by Proposition 5.2), it follows from (5.14) that there exists $(\bar{t}_j)_{j \in D_0} \in R^{|D_0|}$ such that $e = \sum_{j \in D_0} \bar{t}_j a_j$, where $|D_0|$ denotes the number of elements of D_0. It follows from $e \in P$ and $D_0 \subset I(e)$ that $D_0 \in \mathcal{E}(I)$ and $e = e_{D_0}$. Therefore, $\mathrm{ext}_E(P) \subset \{e_D : D \in \mathcal{E}(I)\}$. It remains to be seen whether $\{e_D : D \in \mathcal{E}(I)\} \subset \mathrm{ext}_E(P)$. To do this, let $D \in \mathcal{E}(I)$. Then

$e_D \in P \cap \mathrm{Lin}(P)^{\perp}$ (by (5.14) and the definition of e_D). Let $x_1, x_1 \in P$ satisfy $e_D = \frac{x_1+x_2}{2}$. It follows that $\langle a_i, x_1\rangle = \langle a_i, x_2\rangle = c_i$ for all $i \in D$ and so $\langle a_i, x_1 - x_2\rangle = 0$ for all $i \in D$. Since $\{a_i : i \in D\}$ is a maximal linearly independent subset of $\{a_i : i \in I\}$, $\langle a_i, x_1 - x_2\rangle = 0$ for all $i \in I$. Hence $x_1 - x_2 \in \mathrm{Lin}(P)$. This shows that $e_D \in \mathrm{ext}_E(P)$. Hence, the proof is completed. □

SOME GLOBAL UNIQUENESS AND SOLVABILITY RESULTS FOR LINEAR COMPLEMENTARITY PROBLEMS OVER SYMMETRIC CONES*

M. SEETHARAMA GOWDA† AND R. SZNAJDER‡

Abstract. This article deals with linear complementarity problems over symmetric cones. Our objective here is to characterize global uniqueness and solvability properties for linear transformations that leave the symmetric cone invariant. Specifically, we show that, for algebra automorphisms on the Lorentz space $\mathcal{L}^n$ and for quadratic representations on any Euclidean Jordan algebra, global uniqueness, global solvability, and the $\mathbf{R}_0$-properties are equivalent. We also show that for Lyapunov-like transformations, the global uniqueness property is equivalent to the transformation being positive stable and positive semidefinite.

Key words. Euclidean Jordan algebra, symmetric cone, algebra/cone automorphism, $\mathbf{R}_0$-property, **Q**-property, **GUS**-property

1. Introduction.

Given a finite dimensional real inner product space H, a closed convex set K in H, a continuous function $f : K \to H$, and a vector $q \in H$, the *variational inequality problem* $\mathrm{VI}(f, K, q)$ is to find an $x^* \in K$ such that

$$\langle f(x^*) + q, x - x^* \rangle \geq 0 \ \forall \ x \in K.$$

There is an extensive literature associated with this problem covering theory, applications, and computation of solutions; see, e.g., [7]. When K is a closed convex cone, this problem reduces to the cone complementarity problem $\mathrm{CP}(f, K, q)$, which further reduces to the linear complementarity problem $\mathrm{LCP}(f, K, q)$ when f is linear. In particular, when $H = R^n$ (with the usual inner product), $f\,(= M)$ is linear, and $K = R^n_+$, this reduces to the *standard linear complementarity problem* $\mathrm{LCP}(M, R^n_+, q)$ [3].

An unsolved problem in the variational inequality theory is the characterization of the global uniqueness property: Given H and K, find a necessary and sufficient condition on f so that for all $q \in H$, $\mathrm{VI}(f, K, q)$ has a unique solution. This is related to the question of global invertibility of the normal map $F(x) := f(\Pi_K(x)) + x - \Pi_K(x)$ on H; see [7]. When K is polyhedral and f is linear, there is a well-known result of Robinson [20] that describes the invertibility of this map in terms of the determinants of a certain collection of matrices. This result, when specialized to the standard linear complementarity problem, says that for a square real matrix M, the standard linear complementarity problem $\mathrm{LCP}(M, R^n_+, q)$ has a unique solution for all q if and only if M is a **P**-matrix (which means that all principal minors of M are positive). The result of Robinson motivated researchers to consider the (more general) question of

global invertibility of piecewise affine functions; see [24], [8] for necessary and sufficient conditions.

Moving away from the polyhedral settings (where the underlying cone is the nonnegative orthant in R^n) and inspired by the recent interest in conic programming, various researchers have started looking at cone linear complementarity problems, particularly on semidefinite and second-order cones, and more generally on symmetric cones. While symmetric cones are, in general, nonpolyhedral, they have a lot of structure. In spite of this, even in this special case (of a linear transformation on a symmetric cone) the global uniqueness problem remains unsolved. At present, various authors have studied this problem by restricting the symmetric cone and the linear transformation to specific classes. Here are some such results:

(1) Given a matrix $A \in R^{n\times n}$, consider the Lyapunov transformation L_A defined on the space $\mathcal{S}^n$ of all $n \times n$ real symmetric matrices by

$$L_A(X) := AX + XA^T.$$

Then it has been shown by Gowda and Song [10] that L_A has the global uniqueness property on the semidefinite cone $\mathcal{S}^n_+$ (i.e., for all $q \in \mathcal{S}^n$, LCP$(L_A, \mathcal{S}^n_+, q)$ has a unique solution) if and only if A is both positive stable (i.e., all of its eigenvalues have positive real parts) and positive semidefinite.

(2) Given a matrix $A \in R^{n\times n}$, define the multiplication transformation M_A defined on $\mathcal{S}^n$ by

$$M_A(X) := AXA^T.$$

Then it has been shown by Bhimasankaram et al. [2] and Gowda, Song, and Ravindran [11] that M_A has the global uniqueness property on the semidefinite cone if and only if $\pm A$ is positive definite.

(3) On the Lorentz space $\mathcal{L}^n$ (see section 2 for the definition), consider the quadratic representation P_a of an element $a \in \mathcal{L}^n$:

$$P_a(x) := 2a \circ (a \circ x) - a^2 \circ x.$$

In this setting, Malik and Mohan [17] have shown that P_a has the global uniqueness property on the Lorentz cone if and only if $\pm a$ is in the interior of that cone.

Another issue in the variational inequality/complementarity theory is the global solvability: Given H and K, find a necessary and sufficient condition on f so that VI(f, K, q) has a solution for all $q \in H$. We note that this remains unsolved even in the setting of the standard linear complementarity problem. So, as in the uniqueness issue, one has to work within a class of cones/transformations to get meaningful results. Our motivation for this part comes from the following:

(a) For a nonnegative matrix M, Murty [18] has shown that M has the global solvability property with respect to the nonnegative orthant R^n_+ (i.e., LCP(M, R^n_+, q) has a solution for all $q \in R^n$) if and only if the diagonal of M is positive.

(b) The Lyapunov transformation L_A (defined earlier) has the global solvability property with respect to $\mathcal{S}^n_+$ if and only if A is positive stable [10].

(c) For matrix $A \in R^{n\times n}$, consider the Stein transformation S_A defined on the space $\mathcal{S}^n$ by

$$S_A(X) := X - AXA^T.$$

Then S_A has the global solvability property on $\mathcal{S}^n_+$ if and only if A is Schur stable (that is, all eigenvalues of A lie in the open unit disk of the complex plane) [9].

(d) Given a real matrix A, consider the multiplication transformation M_A (defined earlier) on $\mathcal{S}^n$. In [21] [19], Sampangi Raman, has shown that when A is symmetric M_A has the global solvability property with respect to the semidefinite cone in $\mathcal{S}^n_+$ if and only if $\pm A$ is positive definite.

(e) In [17], Malik and Mohan have shown that P_a on $\mathcal{L}^n$ has the global solvability property with respect to the Lorentz cone if and only if $\pm a$ is in the interior of the Lorentz cone.

In keeping with the above global uniqueness/solvability issues, we consider linear complementarity problems over symmetric cones in Euclidean Jordan algebras. With the observation (elaborated in various sections of the paper) that all of the transformations considered in items (1)–(3) and (a)–(e) either leave the symmetric cone invariant or are related to one such, we characterize global uniqueness/solvability properties for algebra automorphisms, quadratic representations, and Lyapunov-like transformations.

Here is a brief description/outline of our paper. Let V be a Euclidean Jordan algebra V with the corresponding symmetric cone K. For a linear transformation $L : V \to V$ and a $q \in V$, we define the (cone) linear complementarity problem $\mathrm{LCP}(L, K, q)$ as the problem of finding $x \in V$ such that

$$x \in K,\ L(x) + q \in K, \quad \text{and} \quad \langle L(x) + q, x\rangle = 0.$$

Given L, we consider the following statements:

(α) For all $q \in V$, $\mathrm{LCP}(L, K, q)$ has a unique solution.

(β) For all $q \in V$, $\mathrm{LCP}(L, K, q)$ has a solution.

(γ) $\mathrm{LCP}(L, K, 0)$ has zero as the only solution.

• In section 4, we show that for algebra automorphisms on $\mathcal{L}^n$ (these are invertible linear transformations satisfying $L(x \circ y) = L(x) \circ L(y) \quad \forall\, x, y$) the above three properties are equivalent; this result may be regarded as an analog of item (2) above for algebra automorphisms on $\mathcal{L}^n$.

• In section 5, we show that the above three properties are equivalent for any quadratic representation (given by $P_a(x) = 2a \circ (a \circ x) - a^2 \circ x$) on any Euclidean Jordan algebra, thereby extending Malik–Mohan's result (items (3) and (e) above) to arbitrary Euclidean Jordan algebras.

• In section 6, we show that if L is Lyapunov-like, that is, if it satisfies the condition

$$x, y \in K, \text{ and } \langle x, y\rangle = 0 \Rightarrow \langle L(x), y\rangle = 0,$$

then the global uniqueness property (α) holds if and only if L is positive stable and positive semidefinite, thereby extending the result of item (1) above to general Euclidean Jordan algebras.

2. Preliminaries.

2.1. Euclidean Jordan algebras. In this paper we deal with Euclidean Jordan algebras. For the sake of completeness, we provide a short introduction (as in [22]); for full details, see [6].

A *Euclidean Jordan algebra* is a triple $(V, \circ, \langle\cdot,\cdot\rangle)$, where $(V, \langle\cdot,\cdot\rangle)$ is a finite dimensional inner product space over R and $(x, y) \mapsto x \circ y : V \times V \to V$ is a bilinear mapping satisfying the following conditions:

(i) $x \circ y = y \circ x$ for all $x, y \in V$;

(ii) $x \circ (x^2 \circ y) = x^2 \circ (x \circ y)$ for all $x, y \in V$, where $x^2 := x \circ x$; and

(iii) $\langle x \circ y, z\rangle = \langle y, x \circ z\rangle$ for all $x, y, z \in V$.

We also assume that there is an element $e \in V$ (called the *unit* element) such that $x \circ e = x$ for all $x \in V$.

In a Euclidean Jordan algebra V, the set of squares

$$K := \{x \circ x : x \in V\}$$

is a *symmetric cone* (see p. 46, Faraut and Korányi [6]). This means that K is a self-dual closed convex cone (i.e., $K = K^* := \{x \in V : \langle x, y\rangle \geq 0 \; \forall y \in K\}$) and for any two elements $x, y \in K^\circ (= \text{interior}(K))$, there exists an invertible linear transformation $\Gamma : V \to V$ such that $\Gamma(K) = K$ and $\Gamma(x) = y$. We use the notation

$$x \geq 0 \quad \text{and} \quad x > 0$$

when $x \in K$ and $x \in K^\circ$, respectively.

An element $c \in V$ is an *idempotent* if $c^2 = c$; it is a *primitive idempotent* if it is nonzero and cannot be written as a sum of two nonzero idempotents.

We say that a finite set $\{e_1, e_2, \ldots, e_m\}$ of idempotents in V is a *a complete system of orthogonal idempotents* if

$$e_i \circ e_j = 0 \text{ for } i \neq j, \text{ and } \sum_1^m e_i = e.$$

(Note that $\langle e_i, e_j\rangle = \langle e_i \circ e_j, e\rangle = 0$ whenever $i \neq j$.) Further, if each e_i is also primitive, we say that the system is a *Jordan frame*.

THEOREM 2.1 (the spectral decomposition theorem) (Thms. III.1.1 and III.1.2, Faraut and Korányi [6]). *Let V be a Euclidean Jordan algebra. Then there is a number r (called the rank of V) such that for every $x \in V$, there exists a Jordan frame $\{e_1, \ldots, e_r\}$ and real numbers $\lambda_1, \ldots, \lambda_r$, with*

$$x = \lambda_1 e_1 + \cdots + \lambda_r e_r. \tag{2.1}$$

Also, for each $x \in V$, there exists a unique set of distinct real numbers $\{\mu_1, \mu_2, \ldots, \mu_k\}$ and a unique complete system of orthogonal idempotents $\{f_1, f_2, \ldots, f_k\}$ such that

$$x = \mu_1 f_1 + \mu_2 f_2 + \cdots + \mu_k f_k.$$

For an x given by (2.1), the numbers $\lambda_1, \lambda_2, \ldots, \lambda_r$ are called the eigenvalues of x. We say that x is *invertible* if every λ_i is nonzero. Corresponding to (2.1), we define

$$\text{trace}(x) := \lambda_1 + \lambda_2 + \cdots + \lambda_r.$$

In addition, when $x \geq 0$ (or, equivalently, every λ_i is nonnegative), we define

$$\sqrt{x} := \sqrt{\lambda_1} e_1 + \cdots + \sqrt{\lambda_r} e_r.$$

In a Euclidean Jordan algebra V, for a given $x \in V$, we define the corresponding *Lyapunov transformation* $L_x : V \to V$ by

$$L_x(z) = x \circ z.$$

We say that elements x and y *operator commute* if $L_x L_y = L_y L_x$. It is known that x and y operator commute if and only if x and y have their spectral decompositions with respect to a common Jordan frame (Lem. X.2.2, Faraut and Korányi [6]).

Here are some standard examples.

Example 1. R^n is a Euclidean Jordan algebra with the inner product and the Jordan product defined, respectively, by

$$\langle x, y\rangle = \sum_{i=1}^{n} x_i y_i \quad \text{and} \quad x \circ y := (x_i y_i).$$

Here R^n_+ is the corresponding symmetric cone.

Example 2. $\mathcal{S}^n$, the set of all $n \times n$ real symmetric matrices, is a Euclidean Jordan algebra with the inner and Jordan products given by

$$\langle X, Y\rangle := \text{trace}(XY) \quad \text{and} \quad X \circ Y := \frac{1}{2}(XY + YX).$$

In this setting, the symmetric cone $\mathcal{S}^n_+$ is the set of all positive semidefinite matrices in $\mathcal{S}^n$. Also, X and Y operator commute if and only if $XY = YX$.

Example 3. Consider R^n $(n > 1)$ where any element x is written as

$$x = \begin{bmatrix} x_0 \\ \overline{x} \end{bmatrix},$$

with $x_0 \in R$ and $\overline{x} \in R^{n-1}$. The inner product in R^n is the usual inner product. The Jordan product $x \circ y$ in R^n is defined by

$$x \circ y = \begin{bmatrix} x_0 \\ \overline{x} \end{bmatrix} \circ \begin{bmatrix} y_0 \\ \overline{y} \end{bmatrix} := \begin{bmatrix} \langle x, y\rangle \\ x_0\overline{y} + y_0\overline{x} \end{bmatrix}.$$

We shall denote this Euclidean Jordan algebra $(R^n, \circ, \langle\cdot,\cdot\rangle)$ by $\mathcal{L}^n$. In this algebra, the cone of squares, denoted by $\mathcal{L}^n_+$, is called the *Lorentz cone* (or the second-order cone). It is given by

$$\mathcal{L}^n_+ = \{x : x_0 \geq ||\overline{x}||\},$$

in which case interior$(\mathcal{L}^n_+) = \{x : x_0 > ||\overline{x}||\}$.

We note the spectral decomposition of any x with $\overline{x} \neq 0$:

$$x = \lambda_1 e_1 + \lambda_2 e_2,$$

where

$$\lambda_1 := x_0 + ||\overline{x}||, \ \lambda_2 := x_0 - ||\overline{x}||,$$

and

$$e_1 := \frac{1}{2}\begin{bmatrix} 1 \\ \frac{\overline{x}}{||\overline{x}||} \end{bmatrix}, \quad e_2 := \frac{1}{2}\begin{bmatrix} 1 \\ -\frac{\overline{x}}{||\overline{x}||} \end{bmatrix}.$$

In $\mathcal{L}^n$, elements x and y operator commute if and only if either $\overline{x}$ is a multiple of $\overline{y}$ or $\overline{y}$ is a multiple of $\overline{x}$.

We recall the following from Gowda, Sznajder, and Tao [12] (with the notation $x \geq 0$ when $x \in K$).

PROPOSITION 2.2. *For x, $y \in V$, the following conditions are equivalent:*

1. *$x \geq 0$, $y \geq 0$, and $\langle x, y\rangle = 0$.*
2. *$x \geq 0$, $y \geq 0$, and $x \circ y = 0$.*

In each case, elements x and y operator commute.

The Peirce decomposition. Fix a Jordan frame $\{e_1, e_2, \ldots, e_r\}$ in a Euclidean Jordan algebra V. For $i, j \in \{1, 2, \ldots, r\}$, define the eigenspaces

$$V_{ii} := \{x \in V : x \circ e_i = x\} = R\, e_i,$$

and when $i \neq j$,

$$V_{ij} := \left\{x \in V : x \circ e_i = \frac{1}{2}x = x \circ e_j\right\}.$$

Then we have the following result.

THEOREM 2.3 (Thm. IV.2.1, Faraut and Korányi [6]). *The space V is the orthogonal direct sum of spaces V_{ij} $(i \leq j)$. Furthermore,*

$$\begin{aligned} &V_{ij} \circ V_{ij} \subset V_{ii} + V_{jj}, \\ &V_{ij} \circ V_{jk} \subset V_{ik} \text{ if } i \neq k, \\ &V_{ij} \circ V_{kl} = \{0\} \text{ if } \{i, j\} \cap \{k, l\} = \emptyset. \end{aligned}$$

Thus, given any Jordan frame $\{e_1, e_2, \ldots, e_r\}$, we have the *Peirce decomposition* of $x \in V$:

$$x = \sum_{i=1}^{r} x_{ii} + \sum_{i<j} x_{ij} = \sum_{i=1}^{r} x_i e_i + \sum_{i<j} x_{ij},$$

where $x_i \in R$ and $x_{ij} \in V_{ij}$.

A Euclidean Jordan algebra is said to be *simple* if it is not a direct sum of two Euclidean Jordan algebras. The classification theorem (Chap. V, Faraut and Korányi [6]) says that every simple Euclidean Jordan algebra is isomorphic to one of the following:

(1) the algebra $\mathcal{S}^n$ of $n \times n$ real symmetric matrices,
(2) the algebra $\mathcal{L}^n$,
(3) the algebra $\mathcal{H}_n$ of all $n \times n$ complex Hermitian matrices with a trace inner product and $X \circ Y = \frac{1}{2}(XY + YX)$,
(4) the algebra $\mathcal{Q}_n$ of all $n \times n$ quaternion Hermitian matrices with a (real) trace inner product and $X \circ Y = \frac{1}{2}(XY + YX)$, and
(5) the algebra $\mathcal{O}_3$ of all 3×3 octonion Hermitian matrices with a (real) trace inner product and $X \circ Y = \frac{1}{2}(XY + YX)$.

The following result characterizes all Euclidean Jordan algebras.

THEOREM 2.4 (Props. III.4.4 and III.4.5 and Thm. V.3.7, Faraut and Korányi [6]). *Any Euclidean Jordan algebra is, in a unique way, a direct sum of simple Euclidean Jordan algebras. Moreover, the symmetric cone in a given Euclidean Jordan algebra is, in a unique way, a direct sum of symmetric cones in the constituent simple Euclidean Jordan algebras.*

2.2. Complementarity concepts. Let V be a Euclidean Jordan algebra with the corresponding symmetric cone K. Recall that for a linear transformation $L : V \to V$ and $q \in V$, the *linear complementarity problem* $\mathrm{LCP}(L, K, q)$ is to find an $x \in V$ such that

$$x \in K,\ L(x) + q \in K, \quad \text{and} \quad \langle L(x) + q, x\rangle = 0.$$

As mentioned previously, this is a particular instance of a variational inequality problem. The standard linear complementarity problem (over the nonnegative orthant

in R^n), the semidefinite linear complementarity problem, and the Lorentz cone (also known as the second-order cone) linear complementarity problem are some of the special cases and have been well studied in the literature. Given L on V, we say that L has the

(i) positive definite property if $\langle L(x), x\rangle > 0$ for all $x \neq 0$;
(ii) **GUS** (globally uniquely solvable)-property if for all $q \in V$, LCP(L, K, q) has a unique solution;
(iii) **P**-property if

$$x \text{ and } L(x) \text{ operator commute and } x \circ L(x) \leq 0 \Rightarrow x = 0;$$

(iv) $\mathbf{R}_0$-property if zero is the only solution of LCP$(L, K, 0)$;
(v) **Q**-property if for all $q \in V$, LCP(L, K, q) has a solution;
(vi) **S**-property if there exists a $d > 0$ such that $L(d) > 0$.

Henceforth, we will use **P**, $\mathbf{R}_0$, **Q**, **S**, etc., to denote the set of maps L that satisfy the respective property.

The above properties have been well studied. In particular (see Thms. 17, 14, and 12, [12]), we always have the implications (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii) $\Rightarrow$ (iv). That (v) $\Rightarrow$ (vi) follows from perturbing a solution of LCP$(L, K, -e)$, where e is the unit element of V.

The following well-known result shows that under an additional assumption, (iv) $\Rightarrow$ (v).

THEOREM 2.5 (Karamardian [15]). *Suppose that $L : V \to V$ is a linear transformation such that for some $d > 0$, zero is the only solution of the problems* LCP$(L, K, 0)$ *and* LCP(L, K, d). *Then L has the* **Q***-property with respect to K.*

2.3. Automorphisms. Let V be a Euclidean Jordan algebra and K be the corresponding cone of squares. We consider the following sets of transformations:

- $Aut(V)$—set of all invertible linear transformations $L : V \to V$ such that

$$L(x \circ y) = L(x) \circ L(y) \ \forall x, y \in V,$$

- $Aut(K)$—set of all (invertible) linear transformations $L : V \to V$ such that $L(K) = K$,
- $\overline{Aut(K)}$—closure of $Aut(K)$ (with respect to the operator norm), and
- $\Pi(K)$—set of all linear transformations $L : V \to V$ such that $L(K) \subseteq K$.

We note that

$$Aut(V) \subseteq Aut(K) \subseteq \overline{Aut(K)} \subseteq \Pi(K).$$

Also, if V is simple or if the inner product in V is given by $\langle x, y\rangle = c \text{ trace}(x \circ y)$ (for some fixed c), then every L in $Aut(V)$ is orthogonal (that is, it preserves the inner product); see p. 57, [6].

3. Cone invariant transformations. Recall that $\Pi(K)$ is the set of all linear transformations on V that leave K invariant; for properties, see [1]. We begin by describing some complementarity properties of $\Pi(K)$ and $\overline{Aut(K)}$.

PROPOSITION 3.1. *For $L \in \Pi(K)$, the following are equivalent:*

(a) *L has the $\mathbf{R}_0$-property.*
(b) *For any primitive idempotent $u \in V$, $\langle L(u), u\rangle > 0$.*
(c) *L is strictly copositive on K; i.e., $\langle L(x), x\rangle > 0$ for all $0 \neq x \geq 0$.*

In particular, if L has the $\mathbf{R}_0$-property, then it has the **Q***-property.*

Proof. From $L \in \Pi(K)$, we see that L is copositive on K; that is, $\langle L(x), x\rangle \geq 0$ for all $x \geq 0$. Now assume (a). For any primitive idempotent u, we have $L(u) \in K$, and so $\langle L(u), u\rangle \geq 0$. If $\langle L(u), u\rangle = 0$, then u will be a nonzero solution of LCP$(L, K, 0)$ contradicting condition (a). Hence (b) holds. Now suppose (b) holds. We know that L is copositive on K. Suppose, if possible, $\langle L(x), x\rangle = 0$ for some nonzero $x \in K$. Let $x = \sum \lambda_i e_i$ be the spectral decomposition of x with some eigenvalue, say, $\lambda_k \neq 0$. As $\lambda_i \geq 0$ for all i, $\langle L(x), x\rangle = \sum_{i,j} \lambda_i \lambda_j \langle L(e_i), e_j\rangle \geq \lambda_k^2 \langle L(e_k), e_k\rangle > 0$ by condition (b). This is a contradiction. Hence (c) holds. Finally, the implication (c) $\Rightarrow$ (a) is obvious.

Now assume that (a) holds. Then L is strictly copositive on K, and so the problems LCP$(L, K, 0)$ and LCP(L, K, e) have zero as the only solution. By Karamardian's theorem, LCP(L, K, q) has a solution for all $q \in V$. Thus L has the **Q**-property. ∎

PROPOSITION 3.2. *If $L \in \overline{Aut(K)}$ is invertible, then $L \in Aut(K)$.*

Proof. Let $L_k \in Aut(K)$ such that $L_k \to L$ (with respect to the operator norm) on V with L invertible. From $L_k(K) \subseteq K$, we get $L(K) \subseteq K$. Also, $L_k^{-1} \to L^{-1}$. From $(L_k)^{-1}(K) \subseteq K$, we get $L^{-1}(K) \subseteq K$. Thus we have $L(K) = K$. ∎

PROPOSITION 3.3. $\overline{Aut(K)} \cap \mathbf{S} = Aut(K)$.

Proof. Recall that $L \in \mathbf{S}$ if there exists a $p > 0$ such that $L(p) > 0$. Then, clearly, $Aut(K)$ is contained in $\overline{Aut(K)} \cap \mathbf{S}$. Now suppose that $L \in \overline{Aut(K)} \cap \mathbf{S}$. Let $L = \lim L_k$, where $L_k \in Aut(K)$. As $L_k^T \in Aut(K)$ (See Prop. I.1.7, [6]) and $L^T = \lim L_k^T$, we have $L^T \in \overline{Aut(K)}$. We show that L^T is invertible (or, equivalently, L is invertible) and then conclude (thanks to the previous proposition) that $L \in Aut(K)$. Now to show that L^T is invertible, we show that for each $d > 0$ there is an $x \in K$ such that $L^T(x) = d$. This then shows that the range of L^T contains the open set K°, thus proving the invertibility of L^T. Now fix a $d > 0$. Since $L_k^T \in Aut(K)$ for each k, there exists a sequence $x_k \in K$ such that $L_k^T(x_k) = d$ for all k. Assume, if possible, that the sequence x_k is unbounded, say, $||x_k|| \to \infty$. As x_k is nonzero, we can let $\frac{x_k}{||x_k||} \to y \in K$ with $L^T(y) = 0$. Now because L has the **S**-property, there exists a $p > 0$ such that $L(p) > 0$. If u is a suitable multiple of p, then $u \geq 0$ and $v = L(u) - d \geq 0$. Then

$$0 \leq \langle y, v\rangle = \langle y, L(u) - d\rangle = \langle L^T(y), u\rangle - \langle y, d\rangle = -\langle y, d\rangle \leq 0.$$

Thus, $\langle y, d\rangle = 0$. Since $y \geq 0$ and $d > 0$, we must have $y = 0$, which is a contradiction. Hence the sequence x_k is bounded. Letting $x_k \to x \in K$, we have $L^T(x) = d$. ∎

COROLLARY 3.4.

$$\overline{Aut(K)} \cap \mathbf{R}_0 \subseteq \overline{Aut(K)} \cap \mathbf{Q} \subseteq \overline{Aut(K)} \cap \mathbf{S} = Aut(K).$$

Proof. The first inclusion comes from Proposition 3.1. The second inclusion follows from the fact that the **Q**-property implies the **S**-property; see section 2.2. The last equality comes from the previous proposition. ∎

This corollary shows that

$$Aut(K) \cap \mathbf{Q} = Aut(K) \cap \mathbf{R}_0 \Rightarrow \overline{Aut(K)} \cap \mathbf{Q} = \overline{Aut(K)} \cap \mathbf{R}_0.$$

This means that, to show the equivalence of $\mathbf{R}_0$- and **Q**-properties in $\overline{Aut(K)}$, it is enough to prove such an equivalence in $Aut(K)$.

Motivated by Murty's result—item (a) in the introduction—we may ask if $\mathbf{R}_0$- and **Q**-properties are equivalent when $L \in \Pi(K)$. While the resolution of this question is our ultimate goal (or a road map), for lack of results describing objects of $\Pi(K)$, in the next two sections we deal with a subset of $\Pi(K)$, namely, $\overline{Aut(K)}$. In particular, we deal with algebra automorphisms and quadratic representations.

4. Algebra automorphisms. Recall that L is an algebra automorphism on V if L is invertible and

$$L(x \circ y) = L(x) \circ L(y)$$

for all x and y. In this section, we describe complementarity properties of such transformations.

To motivate our results, we first consider some examples.

Example 4. Consider $V = R^n$ with the usual inner product and Jordan product (= componentwise product). In this setting, every algebra automorphism of V is given by a permutation matrix. Then Murty's result (see item (a) of the introduction) shows that such an automorphism has the $\mathbf{R}_0$-property if and only if the matrix is the identity matrix; thus **GUS**-, **Q**-, and $\mathbf{R}_0$-properties are equivalent for algebra automorphisms on R^n.

Example 5. Consider $V = \mathcal{S}^n$ with the trace inner product and the usual Jordan product. Then it is known (as a consequence of Schneider's result in [23]) that every algebra automorphism on $\mathcal{S}^n$ is given by

$$L(X) = UXU^T,$$

where U is a (real) orthogonal matrix. In this setting it is known ([2], [11]) that **GUS**-, **Q**-, and $\mathbf{R}_0$-properties are equivalent (to $\pm U$ being positive definite).

Example 6. Consider the Lorentz space $\mathcal{L}^n$. Since the underlying space is R^n, we think of a transformation L on $\mathcal{L}^n$ as given by a matrix

$$L = \begin{bmatrix} a & b^T \\ c & D \end{bmatrix},$$

where $a \in R$, $b, c \in R^{n-1}$, and $D \in R^{(n-1)\times(n-1)}$.

Now suppose that $L \in Aut(\mathcal{L}^n)$. Since L preserves the unit element in $\mathcal{L}^n$, we must have

$$\begin{bmatrix} a & b^T \\ c & D \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix},$$

proving $a = 1$ and $c = 0$. As $L \in Aut(\mathcal{L}^n) \subset Aut(\mathcal{L}^n_+)$, by a result of Loewy and Schneider [16], there exists a $\mu > 0$ such that

$$L^T J_n L = \mu\, J_n,$$

where $J_n = \mathrm{diag}(1, -1, -1, \ldots, -1)$. A direct calculation shows that $b = 0$, $\mu = 1$, and $D^T D = I$, and so

$$L = \begin{bmatrix} 1 & 0 \\ 0 & D \end{bmatrix}, \tag{4.1}$$

where D is an orthogonal matrix. (We note that $D = I$ and $D = -I$ are likely candidates.) In this section, we show that for such an automorphism, **GUS**-, **Q**-, and $\mathbf{R}_0$-properties are equivalent.

First we describe the real eigenvalues of an algebra automorphism and a necessary condition for the $\mathbf{R}_0$-property. In what follows, $\sigma(L)$ denotes the spectrum of a linear transformation L.

PROPOSITION 4.1. *Let V be a Euclidean Jordan algebra. If $L \in Aut(V)$, then*

$$\sigma(L) \cap R \subseteq \{-1, 1\}.$$

In particular, $\sigma(L) \cap R = \{1\}$ if and only if $-1 \notin \sigma(L)$.

Proof. As $L(x \circ y) = L(x) \circ L(y)$ for all $x, y \in V$, we have $L(e) = e$, where e is the unit element in V. Thus $1 \in \sigma(L) \cap R$. Now suppose that λ is a real eigenvalue of L (which is nonzero since L is invertible), so that for some nonzero $x \in V$, $L(x) = \lambda x$. It follows that $L(x^2) = \lambda^2 x^2$, and more generally, $L(x^k) = \lambda^k x^k$ for all natural numbers k. Since $x \neq 0 \Rightarrow x^k \neq 0$ (this can be seen by considering the spectral decomposition of x), λ^k is an eigenvalue of L for all k. As V is finite dimensional, $\sigma(L)$ is finite, and so two distinct powers of λ are equal; that is, $\lambda^m = 1$ for some natural number m. As λ is real, we must have $\lambda = \pm 1$. Thus we have $\sigma(L) \cap R \subseteq \{-1, 1\}$. The second statement in the proposition is obvious. □

Remark. The above proposition can also be seen as follows. Given any Euclidean Jordan algebra $(V, \langle \cdot, \cdot \rangle, \circ)$, it is well known that $[x, y] := \text{trace}(x \circ y)$ induces another inner product on V that is compatible with the Jordan product. With respect to this inner product, any algebra automorphism is an orthogonal (i.e., $L^T L = I$). Working with the complexifications of $(V, \langle \cdot, \cdot \rangle)$, $(V, [\cdot, \cdot])$, and L, we see that the spectrum of L (which is independent of the inner product on V) is contained in the unit circle. The above proposition follows immediately from this.

THEOREM 4.2. *Let V be a Euclidean Jordan algebra, $L \in Aut(V)$, and $L \in \mathbf{R}_0$. Then $-1 \notin \sigma(L)$.*

Proof. Suppose $-1 \in \sigma(L)$. Then there exists a vector $0 \neq x \in V$ such that $L(x) = -x$. By Theorem 2.1, there exist unique real numbers $\mu_1, \ldots, \mu_k$, all distinct, and a unique complete system of orthogonal idempotents $f_1, \ldots, f_k$ such that

$$x = \mu_1 f_1 + \cdots + \mu_k f_k.$$

Without loss of generality assume that $\mu_1 \neq 0$. Then

$$-(\mu_1 f_1 + \cdots + \mu_k f_k) = -x = L(x) = \mu_1 L(f_1) + \cdots + \mu_k L(f_k).$$

Because $L \in Aut(V)$, $\{L(f_1), \ldots, L(f_k)\}$ is also a complete system of orthogonal idempotents. Since $\mu_1 \neq -\mu_1$, by the uniqueness property, $-\mu_1 = \mu_i$ and $f_1 = L(f_i)$ for some $1 < i \leq k$. Then f_i is a solution of LCP$(L, K, 0)$, contradicting the $\mathbf{R}_0$-property of L. This completes the proof. □

COROLLARY 4.3. *Let $L \in Aut(V)$, $L \in \mathbf{R}_0$, and $L = L^T$. Then $L = I$.*

Proof. Since $L = L^T$, $\sigma(L) \subseteq R$. As $\{1\} \subseteq \sigma(L) \cap R \subseteq \{-1, 1\}$ and $-1 \notin \sigma(L)$, we have $\sigma(L) = \{1\}$. By the spectral theorem (for operators), $L = I$. □

The following examples show that the converse in the above theorem need not hold.

Example 7. Consider the Euclidean Jordan algebra R^3 with the usual inner product and the Jordan product. Define $L : R^3 \to R^3$ by the matrix

$$L = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}.$$

Certainly, $L \in Aut(R^3)$ and $\sigma(L) = \{1, e^{\frac{2\pi i}{3}}, e^{-\frac{2\pi i}{3}}\}$, so $\sigma(L) \cap R = \{1\}$. For $x = (1, 0, 0)^T$, $L(x) = (0, 0, 1)^T$ and $\langle L(x), x \rangle = 0$; thus, $L \notin \mathbf{R}_0$. Note that R^3 is not a simple Jordan algebra.

Example 8. On the simple algebra $\mathcal{S}^3$, let

$$U = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix},$$

and define the transformation L on $\mathcal{S}^3$ by $L(X) = UXU^T$. As U is orthogonal, a simple argument shows that $UX + XU = 0 \Rightarrow X = 0$. Hence -1 is not an eigenvalue of L. By Proposition 4.1, $\sigma(L) \cap R = \{1\}$. As $\pm U$ is not positive definite, a result of Bhimasankaram et al. [2] (see also [11]) shows that L cannot have the $\mathbf{R}_0$-property.

5. A characterization of the global uniqueness property of an algebra automorphism on $\mathcal{L}^n$. In this section, we establish the equivalence of the global uniqueness property and the $\mathbf{R}_0$-property for an automorphism on $\mathcal{L}^n$.

THEOREM 5.1. *For $L \in Aut(\mathcal{L}^n)$, the following are equivalent:*

(i) *L has the* **GUS***-property.*
(ii) *L has the* **P***-property.*
(iii) *L has the* $\mathbf{R}_0$*-property.*
(iv) *L has the* **Q***-property.*
(v) *$-1 \notin \sigma(L)$ (or, equivalently, $-1 \notin \sigma(D)$ with D given in* (4.1)).

Proof. The implications (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii) follow from Theorem 14 in [12] and the definitions. The implication (iii) $\Rightarrow$ (iv) follows from Proposition 3.1. We show that (iv) $\Rightarrow$ (v). Now write L as in (4.1). Suppose L has the **Q**-property and -1 is an eigenvalue of L (as well as that of D), so that for some nonzero $u \in R^{n-1}$

$$Du = -u.$$

Now let x be a solution of $\mathrm{LCP}(L, \mathcal{L}^n_+, q)$, where

$$q = \begin{bmatrix} 0 \\ u \end{bmatrix} \quad \text{and} \quad x = \begin{bmatrix} x_0 \\ \overline{x} \end{bmatrix}.$$

Then

$$x \in \mathcal{L}^n_+,\ L(x) + q \in \mathcal{L}^n_+,\ \text{and}\ \langle x, L(x) + q \rangle = 0,$$

and so

$$x_0 \geq ||\overline{x}||,\ x_0 \geq ||D\overline{x} + u||,\ \text{and}\ x_0^2 + \langle \overline{x}, D\overline{x} + u \rangle = 0.$$

Now, in view of the Cauchy–Schwarz inequality, we have

$$x_0^2 = \langle -\overline{x}, D\overline{x} + u \rangle \leq ||\overline{x}||\,||D\overline{x} + u|| \leq x_0^2.$$

As $q \notin \mathcal{L}^n_+$, x cannot be zero; hence x_0, $\overline{x}$, and $D\overline{x} + u$ are all nonzero. Consequently,

$$D\overline{x} + u = -\theta\overline{x},\ x_0 = ||\overline{x}||,\ \text{and}\ x_0 = ||D\overline{x} + u||$$

for some positive θ. From these, we get $\theta = 1$ and

$$D\overline{x} + u = -\overline{x}.$$

As D is orthogonal, $Du = -u \Rightarrow D^T u = -u$. Thus,

$$-\langle \overline{x}, u \rangle = \langle D\overline{x} + u, u \rangle = \langle D\overline{x}, u \rangle + ||u||^2 = \langle \overline{x}, D^T u \rangle + ||u||^2 = -\langle \overline{x}, u \rangle + ||u||^2.$$

This leads to $||u||^2 = 0$, which is a contradiction. Hence L satisfies (v).

Now for the last implication (v) $\Rightarrow$ (i).

First we show that (v) implies (ii). So assume (v).

Let x be a vector such that x and $L(x)$ operator commute, with $x \circ L(x) \leq 0$. For

$$x = \begin{bmatrix} x_0 \\ \bar{x} \end{bmatrix} \quad \text{and} \quad L(x) = \begin{bmatrix} x_0 \\ D\bar{x} \end{bmatrix}$$

we have

$$x \circ L(x) = \begin{bmatrix} x_0^2 + \langle D\bar{x}, \bar{x} \rangle \\ x_0 D\bar{x} + x_0 \bar{x} \end{bmatrix} \leq 0.$$

Case (i). $D\bar{x} = 0$ or, equivalently, $\bar{x} = 0$ (as D is nonsingular). Then $\begin{bmatrix} x_0^2 \\ 0 \end{bmatrix} \leq 0$, so $x = 0$.

Case (ii). $D\bar{x} \neq 0$. Hence, $\bar{x} \neq 0$ and, by the operator commutativity, $D\bar{x} = \mu\bar{x}$ for some μ. Since $\mu \in \sigma(L) \cap R = \{1\}$, $\mu = 1$; thus, $D\bar{x} = \bar{x}$. Consequently, $x_0^2 + ||\bar{x}||^2 \leq 0$, so $x = 0$.

Hence, L has the **P**-property.

Now to show (i). Take any $q \in \mathcal{L}^n$, and let x and u be two solutions of LCP$(L, \mathcal{L}^n_+, q)$ so that

$$x \geq 0, \quad y = L(x) + q \geq 0, \quad \text{and} \quad \langle x, y \rangle = 0$$

and

$$u \geq 0, \quad v = L(u) + q \geq 0, \quad \text{and} \quad \langle u, v \rangle = 0.$$

We know that x and y operator commute and u and v operator commute (see Proposition 2.2). If we can show that x and v operator commute and u and y operator commute then $x - u$ operator commutes with $y - v$. In this situation,

$$(x - u) \circ L(x - u) = (x - u) \circ (y - v) = -(x \circ v + u \circ y) \leq 0,$$

where the last inequality follows from the fact that if two vectors in K operator commute, then their Jordan product is also in K. At this stage, we can apply the **P**-property (item (ii)) and get $x = u$. Thus (i) is proved provided the following claim can be proved.

Claim. u and y, as well as x and v, operator commute. (Equivalently, $\overline{u}$ and $\overline{y}$ are proportional and $\overline{x}$ and $\overline{v}$ are proportional.) We now proceed to prove the claim. Let

$$x = \begin{bmatrix} x_0 \\ \bar{x} \end{bmatrix}, \; u = \begin{bmatrix} u_0 \\ \bar{u} \end{bmatrix}, \; L(x) + q = \begin{bmatrix} x_0 + q_0 \\ D\bar{x} + \bar{q} \end{bmatrix}, \text{ and } L(u) + q = \begin{bmatrix} u_0 + q_0 \\ D\bar{u} + \bar{q} \end{bmatrix}.$$

We have

$$x_0 \geq ||\bar{x}||, \; u_0 \geq ||\bar{u}||, \; x_0 + q_0 \geq ||D\bar{x} + \bar{q}||, \text{ and } u_0 + q_0 \geq ||D\bar{u} + \bar{q}||,$$

and, moreover,

$$x_0(x_0 + q_0) + \langle D\bar{x} + \bar{q}, \bar{x} \rangle = 0 = u_0(u_0 + q_0) + \langle D\bar{u} + \bar{q}, \bar{u} \rangle.$$

If both x and u are positive, then $L(x) + q = 0 = L(u) + q$ and, by invertibility of L, $x = u$. In this case, the claim is true (because x and y operator commute).

Suppose that (exactly) one of x or u is on the boundary of $\mathcal{L}^n_+$, say, $x > 0$ and $u \in \partial\mathcal{L}^n_+$. Then $x_0 > 0$ and $0 = y = L(x) + q$. If $v > 0$, then $u = 0$, in which case $q > 0$. But then

$$\begin{bmatrix} x_0 \\ D\bar{x} \end{bmatrix} = L(x) = -q < 0$$

implies that $x_0 < 0$, which is a contradiction.

On the other hand, if $v \in \partial\mathcal{L}^n_+$, then

$$u_0 + q_0 = ||D\bar{u} + \bar{q}|| = ||D(\bar{u} - \bar{x})|| = ||\bar{u} - \bar{x}|| \geq ||\bar{u}|| - ||\bar{x}||.$$

As $x_0 = -q_0$, we have $u_0 - x_0 \geq ||\bar{u}|| - ||\bar{x}||$. Thus, $u_0 - ||\bar{u}|| \geq x_0 - ||\bar{x}|| > 0$, so $u > 0$, contradicting our assumption that $u \in \partial\mathcal{L}^n_+$.

Hence we may assume that both x and u are on the boundary of $\mathcal{L}^n_+$. Similarly, by considering L^{-1}, we may assume that both y and v are on the boundary of $\mathcal{L}^n_+$. (Note that $L^{-1} \in Aut(\mathcal{L}^n)$, y, and v are solutions of $\mathrm{LCP}(L^{-1}, K, L^{-1}q)$.)

So at this stage, $x, u, y, v \in \partial\mathcal{L}^n_+$. Thus,

$$x_0 = ||\bar{x}||,\ x_0 + q_0 = ||D\bar{x} + \bar{q}||,\ u_0 = ||\bar{u}||, \quad \text{and} \quad u_0 + q_0 = ||D\bar{u} + \bar{q}||.$$

Case 1. $\bar{x} = 0$. Then $x = 0$ and $q_0 = ||\bar{q}||$.

Subcase 1.1. $\bar{u} = 0$. Then $u = 0$, so $x = u = 0$, and the claim holds.

Subcase 1.2. $\bar{u} \neq 0$. Since u and v operator commute,

$$\bar{v} = D\bar{u} + \bar{q} = \beta\bar{u} \quad \text{for some} \quad \beta \in R. \tag{5.1}$$

Also, $u_0 + q_0 = ||D\bar{u} + \bar{q}|| \leq ||\bar{u}|| + q_0 \leq u_0 + q_0$. The equality in the triangle inequality gives, along with $\bar{u} \neq 0$,

$$D\bar{u} = \theta\bar{q} \quad \text{for some} \quad \theta > 0. \tag{5.2}$$

Now, by (5.2),

$$v = L(u) + q = \begin{bmatrix} u_0 + q_0 \\ D\bar{u} + \bar{q} \end{bmatrix} = \begin{bmatrix} u_0 + ||q|| \\ \theta\bar{q} + \bar{q} \end{bmatrix}$$

and

$$y = L(x) + q = 0 + q = \begin{bmatrix} q_0 \\ \bar{q} \end{bmatrix}.$$

Combining (5.1) and (5.2), we get $\theta\bar{q} + \bar{q} = \beta\bar{u}$. Hence, $\bar{q} = \frac{1}{\theta+1}\beta\bar{u}$ $(\theta > 0)$, so $\bar{q}$ and $\bar{u}$ are proportional, and u and q operator commute. Thus, u and $y\,(= q)$ operator commute. Also, $x = 0$ and v operator commute. Therefore, in Case 1, the claim holds.

Case 2. $\bar{x} \neq 0$.

Subcase 2.1. $\bar{u} = 0$. This is analogous to Subcase 1.2.

Subcase 2.2. $\bar{u} \neq 0$. Now we have $x, u, y, v \in \partial\mathcal{L}^n_+$, and $\bar{x} \neq 0$, $\bar{u} \neq 0$. Again, the complementarity property, hence operator commutativity, gives

$$D\bar{x} + \bar{q} = \alpha\bar{x} \quad \text{and} \quad D\bar{u} + \bar{q} = \gamma\bar{u}$$

for some α, $\gamma \in R$. Also,

$$x_0 + q_0 = ||D\bar{x} + \bar{q}|| = |\alpha| \cdot ||\bar{x}|| \quad \text{and} \quad u_0 + q_0 = ||D\bar{u} + \bar{q}|| = |\gamma| \cdot ||\bar{u}||.$$

Since $y = L(x) + q = \begin{bmatrix} x_0 + q_0 \\ \alpha\bar{x} \end{bmatrix}$ and $0 = \langle x, y \rangle = x_0(x_0 + q_0) + \alpha||\bar{x}||^2$, we have $\alpha \leq 0$. Similarly, $\gamma \leq 0$. Since $x_0 + q_0 = |\alpha| \cdot ||\bar{x}||$ and $x \in \partial\mathcal{L}^n_+$, $q_0 = |\alpha| \cdot ||\bar{x}|| - x_0 = (|\alpha| - 1)||\bar{x}||$; likewise, $q_0 = (|\gamma| - 1)||\bar{u}||$. Also, $\bar{q} = \alpha\bar{x} - D\bar{x} = \gamma\bar{u} - D\bar{u}$. Then

$$D(\bar{x} - \bar{u}) = \alpha\bar{x} - \gamma\bar{u}.$$

Since D is orthogonal, $||\bar{x} - \bar{u}|| = ||\alpha\bar{x} - \gamma\bar{u}||$ and $q_0 = (|\alpha| - 1)||\bar{x}|| = (|\gamma| - 1)||\bar{u}||$, $\alpha, \gamma \leq 0$. Put $\lambda := -\alpha$ and $\mu := -\gamma$, so $\lambda, \mu \geq 0$,

$$D(\overline{x} - \overline{u}) = \mu\overline{u} - \lambda\overline{x}, \ ||\bar{x} - \bar{u}|| = ||\mu\bar{u} - \lambda\bar{x}||, \quad \text{and} \quad (\lambda - 1)||\bar{x}|| = (\mu - 1)||\bar{u}||.$$

If $\overline{x}$ and $\overline{u}$ are proportional, then so are $\overline{y}\,(= \alpha\overline{x})$ and $\overline{u}$, and $\overline{x}$ and $\overline{v}\,(= \gamma\overline{u})$. In this setting, the claim holds. Suppose $\overline{x}$ and $\overline{u}$ are not proportional. Then, as the signs of $\lambda - 1$ and $\mu - 1$ are the same, two-dimensional (Euclidean) geometric considerations show that the quadrilateral with vertices $\bar{x}$, $\lambda\bar{x}$, $\mu\bar{u}$, and $\bar{u}$ (which is part of a triangle) can be a parallelogram only when $\lambda = 1$ and $\mu = 1$ (see the appendix for an algebraic proof). In this situation,

$$D(\bar{x} - \bar{u}) = -(\bar{x} - \bar{u}),$$

violating the condition (v) that $-1 \notin \sigma(D)$. Thus we have the claim in Subcase 2.2. This shows that the claim is proved for Case 2. Hence (v) $\Rightarrow$ (i). □

Remark. One may wonder if the above result (Theorem 5.1) is true for algebra automorphisms on a direct sum of $\mathcal{L}^n$'s. To address this, let $V := \mathcal{L}^{n_1} \oplus \mathcal{L}^{n_2} \oplus \cdots \oplus \mathcal{L}^{n_k}$ and $L \in Aut(V)$. If L is "diagonal," that is, if $L = L_1 \oplus L_2 \oplus \cdots \oplus L_k$, where $L_i : \mathcal{L}^{n_i} \to \mathcal{L}^{n_i}$, then $L_i \in Aut(\mathcal{L}^{n_i})$ for all i. In this situation, Theorem 5.1 extends to L on V. On the other hand, if L is not "diagonal," Theorem 5.1 may not extend to L. This can be seen by modifying Example 7:

Put $V = \mathcal{L}^n \oplus \mathcal{L}^n \oplus \mathcal{L}^n$ and $L(x, y, z) = (y, z, x)$. It is easily seen that $L \in Aut(V)$ and $-1 \notin \sigma(L)$, yet $L \notin \mathbf{R}_0$ (because $(e, 0, 0)$ is a solution of LCP$(L, K, 0)$).

6. Quadratic representations. The algebra automorphisms of a Euclidean Jordan algebra, studied in the previous section, form an important subclass of $Aut(K)$. In this section, we consider another important subclass of $\overline{Aut(K)}$, namely, quadratic representations. Given any element a in the Euclidean Jordan algebra V, the quadratic representation of a is defined by

$$P_a(x) := 2a \circ (a \circ x) - a^2 \circ x.$$

It is known that P_a is a self-adjoint linear transformation on V and belongs to $Aut(K)$ when a is invertible. Our main result below establishes the equivalence of global uniqueness, global solvability, and the $\mathbf{R}_0$-properties for such transformations. Our motivation comes from the following.

Consider $V = \mathcal{S}^n$ and $K = \mathcal{S}^n_+$. Then a linear transformation L on V belongs to $Aut(\mathcal{S}^n_+)$ if and only if there exists an invertible matrix $A \in R^{n \times n}$ such that

$$L(X) = AXA^T \quad (X \in \mathcal{S}^n);$$

see [23]. For such transformations, it has been shown in [2] (see also [11]) that global uniqueness and $\mathbf{R}_0$-properties are equivalent and that these properties hold if and only if $\pm A$ is positive definite.

Now when $A \in \mathcal{S}^n$, the above transformation coincides with P_A given by:

$$P_A(X) = AXA.$$

In [21], Sampangi Raman considers P_A on $\mathcal{S}^n$ and shows that the global solvability and the $\mathbf{R}_0$-properties are equivalent and that these properties hold if and only if $\pm A$ is positive definite. Working on $\mathcal{L}^n$, Malik and Mohan [17] prove a similar result for quadratic representations on $\mathcal{L}^n$.

In our main result below, we extend these two results to arbitrary Euclidean Jordan algebras. We remark that the crucial idea of our analysis comes from [21].

We recall the following from [6] (see Props. II.3.1, II.3.2, and III.2.2).

PROPOSITION 6.1. *Let $a \in V$. Then the following statements hold:*

(i) *a is invertible if and only if P_a is invertible.*
(ii) *$P_{P_a(x)} = P_a P_x P_a$.*
(iii) *If a is invertible, then $P_a(K) = K$. Hence $P_a(K) \subseteq K$ for all $a \in V$.*
(iv) *If for some x, $P_a(x)$ is invertible, then a is invertible.*

The following lemmas are needed to prove our main theorem. These lemmas and their proofs are somewhat similar, except for technical details, to those in [21], [17].

LEMMA 6.2. *Let V be any Euclidean Jordan algebra. Let a be invertible in V with spectral decomposition given by*

$$a = a_1 e_1 + a_2 e_2 + \cdots + a_r e_r.$$

Define $|a| := |a_1|e_1 + |a_2|e_2 + \cdots + |a_r|e_r$ and $s = \varepsilon_1 e_1 + \varepsilon_2 e_2 + \cdots + \varepsilon_r e_r$, where $\varepsilon_i = sign\,(a_i)$. If P_a has the $\mathbf{Q}$-property, then so does P_s.

Proof. Let $b := \sqrt{|a|}$. Then $P_b(s) = a$ (by using the definition) and $P_a = P_b P_s P_b$ using item (ii) in the previous lemma. Assume that P_a has the $\mathbf{Q}$-property, and let $q \in V$. Let x be a solution of LCP(P_a, K, r), where $r = P_b(q)$. Then $x \geq 0$, $y := P_a(x) + r \geq 0$, and $\langle x, y\rangle = 0$. From $P_a = P_{P_b(s)} = P_b P_s P_b$, we have $P_b^{-1} y = P_s(P_b(x)) + q$. Using item (iii) in the above lemma and the self-adjointness of P_b, we have $u := P_b(x) \geq 0$, $v := P_b^{-1} y \geq 0$, and $\langle u, v\rangle = \langle P_b(x), P_b^{-1} y\rangle = \langle x, y\rangle = 0$. This means that LCP$(P_s, K, q)$ has a solution, proving the result. □

LEMMA 6.3. *Let $\{e_1, e_2, \ldots, e_r\}$ be a Jordan frame in V and $x = \sum_1^r x_i e_i + \sum_{i<j} x_{ij}$ be the Peirce decomposition of an element $x \in V$ with respect to this Jordan frame. Let*

$$s = e_1 + e_2 + \cdots + e_k - (e_{k+1} + \cdots + e_r)$$

for some k, with $1 \leq k < r$ and $0 \neq q_{k\,k+1} \in V_{k\,k+1}$. Then the following hold:

(a) *$P_s(x) = \sum_1^r x_i e_i + \sum_\beta x_{ij} - \sum_\alpha x_{ij}$, where $\alpha := \{(i,j) : 1 \leq i \leq k, k+1 \leq j \leq r\}$ and $\beta := \{(i,j) : 1 \leq i < j \leq r\} \setminus \alpha$.*
(b) *The $(k\,k+1)$-term in the Peirce decomposition of $x \circ P_s(x)$ is zero.*
(c) *The $(k\,k{+}1)$-term in the Peirce decomposition of $x \circ q_{k\,k+1}$ is $\frac{1}{2}(x_k + x_{k+1}) q_{k\,k+1}$.*
(d) *If $x \geq 0$, then $x_k e_k + x_{k+1} e_{k+1} + x_{k\,k+1} \geq 0$.*

Proof. Let $f = e_1 + e_2 + \cdots + e_k$ so that $s = 2f - e$, where e is the unit element in V. Then $P_s(x) = 2s \circ (s \circ x) - s^2 \circ x$. Since $s^2 = e$ and $s = 2f - e$, simplification leads to $P_s(x) = 8f \circ (f \circ x) - 8f \circ x + x$. Using the properties

$$e_l \circ e_i = \delta_{il} e_l \quad \text{and} \quad e_l \circ x_{ij} = \frac{1}{2} x_{ij} \text{ if } l \in \{i, j\}, \text{ or } 0 \text{ if } l \notin \{i, j\},$$

we get

$$\begin{aligned} f \circ x &= x_1 e_1 + \frac{1}{2}(x_{12} + x_{13} + \cdots + x_{1r}) \\ &+ x_2 e_2 + \frac{1}{2}(x_{12} + x_{23} + x_{24} + \cdots + x_{2r}) \\ &+ x_3 e_3 + \frac{1}{2}(x_{13} + x_{23} + x_{34} + \cdots + x_{3r}) \\ &+ \cdots + \\ &+ x_k e_k + \frac{1}{2}(x_{1k} + x_{2k} + \cdots + x_{k-1\,k} + x_{k\,k+1} \cdots + x_{kr}). \end{aligned}$$

We note that, in the above expression, the term x_{ij} for $1 \le i \le k$ and $k+1 \le j \le r$ appears only once and the term x_{ij} for $1 \le i < j \le k$ appears twice. Hence

$$f \circ x = \sum_1^k x_i e_i + \sum_{1 \le i < j \le k} x_{ij} + \frac{1}{2} \sum_{1 \le i \le k, k+1 \le j \le r} x_{ij}.$$

From this, we get $f \circ (f \circ x) = \sum_1^k x_i e_i + \sum_{1 \le i < j \le k} x_{ij} + \frac{1}{4} \sum_\alpha x_{ij}$. Using $P_s(x) = 8f \circ (f \circ x) - 8f \circ x + x$, a simple calculation leads to item (a).

We now prove item (b). Consider any element y with its Peirce decomposition:

$$y = \sum_1^r y_i e_i + \sum_{m<n} y_{mn}.$$

Then, in view of the properties of the spaces V_{ij}, the $(k\,k+1)$-term in the Peirce decomposition of $x \circ y$ is obtained by adding all terms of the form $x_{ij} \circ y_{mn}$ and $x_{mn} \circ y_{ij}$, where

$$k \in \{i, j\},\ k+1 \in \{m, n\}, \text{ and } |\{i, j\} \cap \{m, n\}| = 1.$$

This sum reduces to

$$\begin{aligned} &\sum_{1 \le i < k} x_{ik} \circ y_{i\,k+1} + \sum_{1 \le i < k} y_{ik} \circ x_{i\,k+1} \\ &+ x_{kk} \circ y_{k\,k+1} + y_{kk} \circ x_{k\,k+1} \\ &+ x_{k\,k+1} \circ y_{k+1\,k+1} + y_{k\,k+1} \circ x_{k+1\,k+1} \\ &+ \sum_{k+1 < i \le r} x_{ki} \circ y_{k+1\,i} + \sum_{k+1 < i \le r} y_{ki} \circ x_{k+1\,i}. \end{aligned}$$

Now, when $y = P_s(x)$, we have $y_{ij} = -x_{ij}$ for $(i, j) \in \alpha$ and $y_{ij} = x_{ij}$ for $(i, j) \notin \alpha$. Putting these in the above sum and simplifying, we get item (b).

Upon putting $y = q_{k\,k+1}$, we see that the $(k\,k+1)$-term in the Peirce decomposition of $x \circ y$ is

$$x_{kk} \circ q_{k\,k+1} + x_{k+1\,k+1} \circ q_{k\,k+1} = \frac{1}{2}(x_k + x_{k+1}) q_{k\,k+1},$$

which is item (c).

Now we prove item (d). Suppose $x \ge 0$. Let

$$V_{\{e_k, e_{k+1}\}} = \{x \in V : x \circ (e_k + e_{k+1}) = x\}.$$

It is known (see Prop. IV.1.1 in [6]) that this is a Euclidean Jordan algebra and its corresponding symmetric cone is given by (Thm. 3.1, [13])

$$V^+_{\{e_k,e_{k+1}\}} := \{x \in K : x \circ (e_k + e_{k+1}) = x\}.$$

Let y belong to this (sub)cone. Then its Peirce decomposition in V with respect to $\{e_1, e_2, \ldots, e_r\}$ is given by (see Lem. 20, [12])

$$y = y_k e_k + y_{k+1} e_{k+1} + y_{k\,k+1}.$$

Then, using the orthogonality properties of spaces V_{ij}, we have

$$0 \le \langle x, y\rangle = \langle x_k e_k + x_{k+1} e_{k+1} + x_{k\,k+1}, y\rangle.$$

As y is arbitrary, we see from the self-duality of $V^+_{\{e_k,e_{k+1}\}}$ that $x_k e_k + x_{k+1} e_{k+1} + x_{k\,k+1} \in V^+_{\{e_k,e_{k+1}\}}$ and, in particular, belongs to K. □

PROPOSITION 6.4. *Suppose V is simple. Let $\{e_1, e_2, \ldots, e_r\}$ be a Jordan frame in V. Let $s = e_1 + e_2 + \cdots + e_k - (e_{k+1} + \cdots + e_r)$ for some k, with $1 \le k < r$. Then P_s does not have the* **Q***-property.*

Proof. As V is simple, $V_{k\,k+1}$ is nontrivial (see Prop. IV.2.3, [6]). Let $0 \ne q_{k\,k+1} \in V_{k\,k+1}$. We claim that $\mathrm{LCP}(P_s, K, q_{k\,k+1})$ has no solution. If possible, let x be a solution of this problem. Then $x \ge 0$, $y := P_s(x) + q_{k\,k+1} \ge 0$, and $x \circ y = 0$. Applying the previous lemma to this setting, we get

$$0 = (x \circ y)_{k\,k+1} = (x \circ P_s(x))_{k\,k+1} + (x \circ q_{k\,k+1})_{k\,k+1} = \frac{1}{2}(x_k + x_{k+1}) q_{k\,k+1}.$$

As $q_{k\,k+1} \ne 0$, we must have $x_k + x_{k+1} = 0$. But $x \ge 0$ implies that $x_k e_k + x_{k+1} e_{k+1} + x_{k\,k+1} \ge 0$. So x_k and x_{k+1} are both nonnegative, and hence $x_k = x_{k+1} = 0$. By Prop. 3.2 in [13], $x_{k\,k+1} = 0$. Now $y \ge 0$ implies that $y_k e_k + y_{k+1} e_{k+1} + y_{k\,k+1} \ge 0$. From $y = P_s(x) + q_{k\,k+1}$ and the above lemma, we get $x_k e_k + x_{k+1} e_{k+1} - x_{k\,k+1} + q_{k\,k+1} \ge 0$. As $0 = x_k = x_{k+1}$ and $x_{k\,k+1} = 0$, we have (by Prop. 3.2 in [13]) $q_{k\,k+1} = 0$, which is a contradiction. Hence $\mathrm{LCP}(P_s, K, q_{k\,k+1})$ has no solution. □

THEOREM 6.5. *Let V be any Euclidean Jordan algebra and $a \in V$. Then the following are equivalent:*

(1) *P_a is positive definite on V.*
(2) *P_a has the* **GUS***-property.*
(3) *P_a has the* **P***-property.*
(4) *P_a has the* $\mathbf{R}_0$*-property.*
(5) *P_a has the* **Q***-property.*

If, in addition, V is simple, then the above conditions are further equivalent to

(6) *$\pm a \in K^\circ$.*

Proof. The implications (1) ⇒ (2) ⇒ (3) ⇒ (4) hold for any linear transformation on V; see [12]. Now suppose that (4) holds. Since $P_a(K) \subseteq K$, by Prop. 3.1, P_a has the **Q**-property. Hence (5) holds. Now suppose that (5) holds. If x is a solution of $\mathrm{LCP}(P_a, K, -e)$, then $P_a(x) - e \ge 0$, and hence $P_a(x) > 0$. By Item (iv) in Proposition 6.1, a is invertible. Let $a = a_1 e_1 + a_2 e_2 + \cdots + a_r e_r$ be the spectral decomposition of a. Note that each a_i is nonzero. By Lemma 6.2, P_s has the **Q**-property where $s = \varepsilon_1 e_1 + \varepsilon_2 e_2 + \cdots + \varepsilon_r e_r$, with $s_i = sign\,(a_i)$. First suppose that V is simple. Then by Proposition 6.4, $s_i = 1$ for all i or $s_i = -1$ for all i. This means that $\pm a \in K^\circ$. Since $P_a = P_{-a}$, we may assume that $a > 0$. Then $P_a = P_{P_{\sqrt{a}}e} = P_{\sqrt{a}} P_e P_{\sqrt{a}} = P^2_{\sqrt{a}}$,

and so P_a is positive semidefinite on V. As P_a is invertible and symmetric (recall that a is invertible), P_a must be positive definite on V. Thus in the case of simple V, conditions (1)–(6) are equivalent. When V is not simple, we show that (5) is equivalent to (1) by decomposing V as a product of simple Euclidean Jordan algebras (cf. Theorem 2.4). Write $V = V^{(1)} \times V^{(2)} \times \cdots \times V^{(m)}$, where each $V^{(k)}$ is simple. Let $a = (a^{(1)}, a^{(2)}, \ldots, a^{(m)})$ in this product. As $P_a = P_{a^{(1)}} \times P_{a^{(2)}} \times \cdots \times P_{a^{(m)}}$, we see that each $P_{a^{(k)}}$ has the **Q**-property in $V^{(k)}$. By what has been proved, $\pm a^{(k)} > 0$ in $V^{(k)}$ and $P_{a^{(k)}}$ is positive definite on $V^{(k)}$. It follows that P_a is positive definite on V. This completes the proof. □

7. Lyapunov-like transformations. A real square matrix A is said to be a **Z**-matrix if all its off-diagonal entries are nonpositive. If $A \in R^{n\times n}$, then this property is equivalent to

$$x, y \in R^n_+,\ \langle x, y\rangle = 0 \Rightarrow \langle Ax, y\rangle \leq 0.$$

This concept can be extended to symmetric cones: Following [14], we say a linear transformation $L : V \to V$ has the **Z**-property if

$$x, y \in K,\ \langle x, y\rangle = 0 \Rightarrow \langle L(x), y\rangle \leq 0.$$

It has been shown (see [25], [5]) that this property is equivalent to $e^{-tL} \in \Pi(K)$ for all $t \geq 0$.

The recent article [14] contains properties of such transformations; in particular, it is shown in that paper that L has the global solvability property (item (β) of the introduction) if and only if L is positive stable. Examples of **Z**-transformations include both Lyapunov and Stein transformations on $\mathcal{S}^n$. We now say that a linear transformation L on V is a *Lyapunov-like* transformation if both L and $-L$ have the **Z**-property; that is,

$$x, y \in K,\ \langle x, y\rangle = 0 \Rightarrow \langle L(x), y\rangle = 0.$$

Recently, Damm [4] has shown that for $\mathcal{S}^n$ and $\mathcal{H}^n$ (the space of all $n \times n$ Hermitian matrices over complex numbers) L has the above property if and only if it is a Lyapunov transformation (that is, it is of the form L_A for some square matrix A). While the form of a Lyapunov-like transformation on a general Euclidean Jordan algebra is not known, it can be easily shown [26] that, on $\mathcal{L}^n$, a matrix is Lyapunov-like if and only if it is of the form

$$\begin{bmatrix} a & b^T \\ b & D \end{bmatrix},$$

where $a \in R$, $D \in R^{(n-1)\times(n-1)}$, with $D + D^T = 2aI$. For any Euclidean Jordan algebra V and $a \in V$, the transformation L_a (called a Lyapunov transformation) defined by

$$L_a(x) = a \circ x$$

is also a Lyapunov-like transformation.

Extending the result in item (1) of the introduction, we present the following global uniqueness result.

THEOREM 7.1. *Let $L : V \to V$ be a Lyapunov-like transformation. Then L has the* **GUS***-property if and only if L is positive stable (that is, all its eigenvalues have positive real parts) and positive semidefinite.*

Proof. Suppose L has the **GUS**-property. Then it has the global solvability property and so by Thm. 7 in [14], L is positive stable. Also, by Thm. 4.1 in [27],

$$\langle L(c), c\rangle \geq 0$$

for any primitive idempotent c in V. Now for any $x \in V$, we have the spectral decomposition

$$x = \sum_1^r \lambda_i e_i,$$

where $\{e_1, e_2, \ldots, e_r\}$ is a Jordan frame. Since L is a Lyapunov-like transformation, we have $\langle L(e_i), e_j\rangle = 0$ for all $i \neq j$, and so

$$\langle L(x), x\rangle = \sum_{i,j} \lambda_i \lambda_j \langle L(e_i), e_j\rangle = \sum_i \lambda_i^2 \langle L(e_i), e_i\rangle \geq 0.$$

This proves that L is positive semidefinite.

Now assume that L is positive stable and positive semidefinite. Because of positive stability, for every q, LCP(L, K, q) has a solution; see Thms. 6 and 7 in [14]. We now prove uniqueness. Fix q, and suppose that x and u are two solutions of LCP(L, K, q) so that

$$x \geq 0,\ y := L(x) + q \geq 0,\ \text{and } \langle x, y\rangle = 0$$

and

$$u \geq 0,\ v := L(u) + q \geq 0,\ \text{and } \langle u, v\rangle = 0.$$

Now, as L is positive semidefinite, the solution set of LCP(L, K, q) is convex (Thm. 2.3.5, [7]). So for any $t \in [0, 1]$, $tx + (1-t)u$ is also a solution of LCP(L, K, q). Writing out the complementarity conditions, we see that

$$\langle x, v\rangle = 0 = \langle u, y\rangle.$$

We conclude (by Proposition 2.2) that x and u operator commute with both y and v, and $x \circ v = 0 = u \circ y$; hence $z := x - u$ operator commutes with $y - v = L(z)$, and $z \circ L(z) = 0$. In this situation, there exists a Jordan frame $\{e_1, e_2, \ldots, e_r\}$ and scalars μ_i such that

$$z = \mu_1 e_1 + \mu_2 e_2 + \cdots + \mu_l e_l \quad \text{and} \quad L(z) = \mu_{l+1} e_{l+1} + \mu_{l+2} e_{l+2} + \cdots + \mu_r e_r$$

for some l between 1 and r. We then have

$$L(z) = \mu_1 L(e_1) + \mu_2 L(e_2) + \cdots + \mu_l L(e_l) = \mu_{l+1} e_{l+1} + \mu_{l+2} e_{l+2} + \cdots + \mu_r e_r. \tag{7.1}$$

Now for any i between $l+1$ and r, and k between 1 and l, we have $\langle e_k, e_i\rangle = 0$ and $\langle L(e_k), e_i\rangle = 0$. From (7.1), we get

$$\mu_i ||e_i||^2 = 0.$$

This implies that $L(z) = 0$. Since L is positive stable, it is invertible, and so $z = 0$, thus proving the the uniqueness of solution for LCP(L, K, q). Hence L has the **GUS**-property. □

Concluding remarks. In this article, we have proved that global uniqueness, global solvability, and the $\mathbf{R}_0$-properties are equivalent for algebra automorphisms over $\mathcal{L}^n$ and for quadratic representations over any Euclidean Jordan algebra. We have given a characterization of the global uniqueness property for Lyapunov-like transformations. All of the transformations considered in this paper are related to symmetric-cone-invariant transformations. Motivated by our results, we pose the following problems:

(1) Do global uniqueness and $\mathbf{R}_0$-properties coincide for algebra automorphisms on general Euclidean Jordan algebras?
(2) Do global solvability (i.e., the $\mathbf{Q}$-property) and $\mathbf{R}_0$-properties coincide for a cone automorphism? For an element of $\Pi(K)$?

8. Appendix. Here we justify an assertion made in the proof of Theorem 5.1.

LEMMA 8.1. *Let $\bar{x}$ and $\bar{u}$ be two nonzero vectors in a real inner product space that are not proportional. Assume that, for some nonnegative scalars λ and μ,*

$$||\bar{x} - \bar{u}|| = ||\mu\bar{u} - \lambda\bar{x}|| \quad \text{and} \quad (\lambda - 1)||\bar{x}|| = (\mu - 1)||\bar{u}||.$$

Then $\lambda = \mu = 1$.

Proof. The second equality shows that $(\lambda - 1)(\mu - 1) \geq 0$. Assume now that $(\lambda - 1)(\mu - 1) > 0$.

Case 1. $\lambda > 1$ and $\mu > 1$. Expanding the first equality above, applying the Cauchy–Schwarz inequality, and using the second equality, we get

$$\begin{aligned} 0 &= (\mu^2 - 1)||\bar{u}||^2 + (\lambda^2 - 1)||\bar{x}||^2 + 2(\lambda\mu - 1)\langle -\bar{x}, \bar{u}\rangle \\ &\geq (\mu^2 - 1)||\bar{u}||^2 + (\lambda^2 - 1)||\bar{x}||^2 - 2(\lambda\mu - 1)||\bar{u}|| \cdot ||\bar{x}|| \\ &= (\mu^2 - 1)||\bar{u}||^2 + (\lambda^2 - 1)\frac{(\mu - 1)^2}{(\lambda - 1)^2}||\bar{u}||^2 - 2\frac{(\lambda\mu - 1)}{(\lambda - 1)}(\mu - 1)||\bar{u}||^2. \end{aligned} \tag{8.1}$$

Simplifying (8.1), we get

$$0 \geq (\mu^2 - 1)(\lambda - 1)^2 + (\lambda^2 - 1)(\mu - 1)^2 - 2(\lambda\mu - 1)(\mu - 1)(\lambda - 1) = 0.$$

Since $\lambda\mu > 1$, we have equality in the Cauchy–Schwarz inequality $\langle \bar{x}, \bar{u}\rangle \leq ||\bar{x}|| \cdot ||\bar{u}||$. This means that the vectors $\bar{x}$ and $\bar{u}$ are proportional, which is a contradiction.

Case 2. $0 \leq \lambda < 1$ and $0 \leq \mu < 1$.

We omit the proof as it is similar to Case 1.

Contradictions obtained in both cases imply that $\lambda = \mu = 1$. ∎

STOCHASTIC R_0 MATRIX LINEAR COMPLEMENTARITY PROBLEMS*

HAITAO FANG†, XIAOJUN CHEN‡, AND MASAO FUKUSHIMA§

Abstract. We consider the expected residual minimization formulation of the stochastic R_0 matrix linear complementarity problem. We show that the involved matrix being a stochastic R_0 matrix is a necessary and sufficient condition for the solution set of the expected residual minimization problem to be nonempty and bounded. Moreover, local and global error bounds are given for the stochastic R_0 matrix linear complementarity problem. A stochastic approximation method with acceleration by averaging is applied to solve the expected residual minimization problem. Numerical examples and applications of traffic equilibrium and system control are given.

Key words. stochastic linear complementarity problem, R_0 matrix, expected residual minimization

1. Introduction.

Let $(\Omega, \mathcal{F}, P)$ be a probability space, where Ω is a subset of $\mathbb{R}^m$, and $\mathcal{F}$ is a σ-algebra generated by $\{\Omega \cap U : U \text{ is an open set in } \mathbb{R}^m\}$. We consider the stochastic linear complementarity problem (SLCP):

$$x \geq 0,\ M(\omega)x + q(\omega) \geq 0,\quad x^T(M(\omega)x + q(\omega)) = 0,$$

where $M(\omega) \in \mathbb{R}^{n\times n}$ and $q(\omega) \in \mathbb{R}^n$ for $\omega \in \Omega$. We denote this problem by SLCP$(M(\omega), q(\omega))$ for short. Throughout this paper, we assume that $M(\omega)$ and $q(\omega)$ are measurable functions of ω with the following property:

$$E\{\|M(\omega)^T M(\omega)\|\} < \infty \quad \text{and} \quad E\{\|q(\omega)\|^2\} < \infty,$$

where E stands for the expectation. If Ω only contains a single realization, then the SLCP reduces to the standard LCP. For the standard LCP, much effort has been made in developing theoretical analysis for the existence of a solution, numerical methods for finding a solution, and applications in engineering and economics [5,7,9]. On the other hand, in many practical applications, some data in the LCP cannot be known with certainty. The SLCP is aimed at a practical treatment of the LCP under uncertainty. However, only a little attention has been paid to the SLCP in the literature.

In general, there is no x satisfying the SLCP$(M(\omega), q(\omega))$ for almost all $\omega \in \Omega$. A deterministic formulation for the SLCP provides a decision vector which is optimal

in a certain sense. Different deterministic formulations may yield different solutions that are optimal in different senses.

Gürkan, Özge, and Robinson [12] considered the sample-path approach for stochastic variational inequalities and provided convergence theory and applications for the approach. When applied to the SLCP$(M(\omega), q(\omega))$, the approach is the same as the *expected value* (EV) method, which uses the expected function of the random function $M(\omega)x + q(\omega)$ and solves the deterministic problem

$$x \geq 0, \quad E\{M(\omega)x + q(\omega)\} \geq 0,\ x^T E\{M(\omega)x + q(\omega)\} = 0.$$

Using a simulation-based algorithm in [12], we can find a solution of this problem.

Recently, Chen and Fukushima [3] proposed a new deterministic formulation called the *expected residual minimization* (ERM) method, which is to find a vector $x \in \mathbb{R}^n_+$ that minimizes the expected residual of the SLCP$(M(\omega), q(\omega))$, i.e.,

$$\min_{x \in \mathbb{R}^n_+} E\{\|\Phi(x, \omega)\|^2\}, \tag{1.1}$$

where $\Phi : \mathbb{R}^n \times \Omega \to \mathbb{R}^n$ is defined by

$$\Phi(x, \omega) = \begin{pmatrix} \phi([M(\omega)x]_1 + q_1(\omega), x_1) \\ \vdots \\ \phi([M(\omega)x]_n + q_n(\omega), x_n) \end{pmatrix},$$

and $[x]_i$ denotes the ith component of the vector x. Here $\phi : \mathbb{R}^2 \to \mathbb{R}$ is an NCP function which has the property

$$\phi(a, b) = 0 \iff a \geq 0,\ b \geq 0,\ ab = 0.$$

Various NCP functions have been studied for solving complementarity problems [7]. In this paper, we will concentrate on the "min" function

$$\phi(a, b) = \min(a, b).$$

Similar results can be obtained for other NCP functions, such as the Fischer–Burmeister (FB) function [10], which have the same growth behavior as the "min" function.

Let ERM$(M(\cdot), q(\cdot))$ denote problem (1.1) and define

$$G(x) = \int_\Omega \|\Phi(x, \omega)\|^2 dF(\omega), \tag{1.2}$$

where $F(\omega)$ is the distribution function of ω. Then ERM$(M(\cdot), q(\cdot))$ is rewritten as

$$\min\ G(x) \qquad \text{s.t.}\ \ x \geq 0. \tag{1.3}$$

Recall that an $n \times n$ matrix A is called an R_0 matrix if

$$x \geq 0,\ Ax \geq 0,\ x^T Ax = 0 \qquad \Longrightarrow \qquad x = 0.$$

It is known [5, Theorem 3.9.23] that the solution set of the standard LCP(A, b)

$$x \geq 0,\ Ax + b \geq 0,\ x^T(Ax + b) = 0$$

is bounded for every $b \in \mathbb{R}^n$, if and only if A is an R_0 matrix. In addition, when A is a P_0 matrix, the LCP(A, b) has a nonempty solution set if and only if A is an R_0 matrix [5, Theorem 3.9.22]. Example 1 in [3] shows that the solution set of LCP$(M(\bar{\omega}), q(\bar{\omega}))$ being nonempty and bounded for some $\bar{\omega} \in \Omega$ does not imply that the ERM$(M(\cdot), q(\cdot))$ has a solution. The following results on the existence of a solution of ERM$(M(\cdot), q(\cdot))$ are given in [3].

(i) If $M(\cdot)$ is continuous in ω and there is an $\bar{\omega} \in \Omega$ such that $M(\bar{\omega})$ is an R_0 matrix, then the solution set of ERM$(M(\cdot), q(\cdot))$ is nonempty and bounded.

(ii) When $M(\omega) \equiv M$, the solution set of ERM$(M(\cdot), q(\cdot))$ is nonempty and bounded for any $q(\cdot)$ if and only if M is an R_0 matrix.

In this paper, we substantially extend and refine the results established in [3]. In particular, we introduce the concept of a stochastic R_0 matrix and show that $M(\cdot)$ being a stochastic R_0 matrix is a necessary and sufficient condition for the solution set of ERM$(M(\cdot), q(\cdot))$ to be nonempty and bounded. Moreover, we will extend the local and global error bound results for the R_0 matrix LCP given by Mangasarian and Ren [16] to the stochastic R_0 matrix LCP in the ERM formulation.

Throughout the paper, the norm $\|\cdot\|$ denotes the Euclidean norm and $\mathbb{R}^n_+ = \{x \in \mathbb{R}^n : x \geq 0\}$. For a given vector $x \in \mathbb{R}^n$, we denote $I(x) = \{i : x_i = 0\}$ and $J(x) = \{i : x_i \neq 0\}$. For vectors $x, y \in \mathbb{R}^n$, $\min(x, y)$ denotes the vector with components $\min(x_i, y_i)$, $i = 1, \ldots, n$.

The remainder of the paper is organized as follows: In section 2, the definition and some properties of a stochastic R_0 matrix are given. In section 3, we show a necessary and sufficient condition for the existence of a minimizer of the ERM problem with an arbitrary $q(\cdot)$ is that $M(\cdot)$ is a stochastic R_0 matrix. In section 4, the differentiability of G is considered. Some optimality conditions and error bounds of the ERM problem are given in section 5. In section 6, we use a stochastic approximation method [2, 14] with acceleration by averaging [18] to solve the general ERM problem, and use a Newton-type method to solve the ERM problem with $M(\omega) \equiv M$. Furthermore, applications to traffic equilibrium and system control are provided. Preliminary numerical results show that the ERM formulation has various advantages.

2. Stochastic R_0 matrix. A stochastic R_0 matrix is formally defined as follows.

DEFINITION 2.1. *$M(\cdot)$ is called a stochastic R_0 matrix if*

$$x \geq 0,\ M(\omega)x \geq 0,\ x^T M(\omega)x = 0, \quad a.e. \implies x = 0.$$

If Ω only contains a single realization, then the definition of a stochastic R_0 matrix reduces to that of an R_0 matrix.

Let G be defined by (1.2). We call $x^* \in \mathbb{R}^n_+$ a *local solution* of the ERM$(M(\cdot),\ q(\cdot))$, if there is $\gamma > 0$ such that $G(x) \geq G(x^*)$ for all $x \in \mathbb{R}^n_+ \cap B(x^*, \gamma) := \{x : \|x - x^*\| \leq \gamma\}$, and call x^* a *global solution* of ERM$(M(\cdot),\ q(\cdot))$, if $G(x) \geq G(x^*)$ for all $x \in \mathbb{R}^n_+$.

THEOREM 2.2. *The following statements are equivalent.*

(i) *$M(\cdot)$ is a stochastic R_0 matrix.*

(ii) *For any $x \geq 0$ $(x \neq 0)$, at least one of the following two conditions is satisfied:*
   (a) *$P\{\omega : [M(\omega)x]_i \neq 0\ \} > 0$ for some $i \in J(x)$;*
   (b) *$P\{\omega : [M(\omega)x]_i < 0\} > 0$ for some $i \in I(x)$.*

(iii) *ERM$(M(\cdot), q(\cdot))$ with $q(\omega) \equiv 0$ has zero as its unique global solution.*

Proof. The proof is given in the order (i) $\Rightarrow$ (iii) $\Rightarrow$ (ii) $\Rightarrow$ (i).

(i) $\Rightarrow$ (iii): It is easy to see that zero is a global solution of ERM$(M(\cdot), q(\cdot))$ with $q(\omega) \equiv 0$, since $G(x) \geq 0$ for all $x \in \mathbb{R}^n_+$ and $G(0) = 0$. Now we show the uniqueness of

the solution. Let $\bar{x} \in \mathbb{R}^n_+$ be an arbitrary vector such that $G(\bar{x}) = 0$. By the definition of G, we have

$$\Phi(\bar{x}, \omega) = \min(M(\omega)\bar{x}, \bar{x}) = 0, \quad \text{a.e.},$$

which implies

$$\bar{x} \geq 0, \quad M(\omega)\bar{x} \geq 0, \quad \bar{x}^T M(\omega)\bar{x} = 0, \quad \text{a.e.}$$

By the definition of a stochastic R_0 matrix, we deduce $\bar{x} = 0$.

(iii) $\Rightarrow$ (ii): Suppose (ii) does not hold, that is, there exists a nonzero $x^0 \geq 0$ such that

$$P\{\omega : \ [M(\omega)x^0]_i = 0\} = 1 \text{ for all } i \in J(x^0),$$

$$P\{\omega : \ [M(\omega)x^0]_i \geq 0\} = 1 \text{ for all } i \in I(x^0).$$

Then it follows from $q(\omega) \equiv 0$ that $G(x^0) = 0$. Moreover, it is easy to see that for any $\lambda > 0$, λx^0 is a solution of ERM$(M(\cdot), 0)$, i.e., zero is not the unique solution of ERM$(M(\cdot), 0)$.

(ii) $\Rightarrow$ (i): Assume that there exists $x \neq 0$ such that $x \geq 0$, $M(\omega)x \geq 0$, and $x^T M(\omega)x = 0$, a.e. Then, since $x^T M(\omega)x = 0$, we have for almost all ω, $[M(\omega)x]_i = 0$ for all $i \in J(x)$ and $[M(\omega)x]_i \geq 0$ for all $i \in I(x)$. This contradicts (ii). ∎

For $\nu > 0$, let us denote $B_\Omega(\bar{\omega}, \nu) := \{\omega : \|\omega - \bar{\omega}\| < \nu\}$ and

$$\text{supp}\Omega := \left\{ \bar{\omega} \in \Omega : \ \int_{B_\Omega(\bar{\omega}, \nu) \cap \Omega} dF(\omega) > 0 \text{ for any } \nu > 0 \right\}.$$

Here suppΩ is called the support set of Ω. When Ω consists of countable discrete points, i.e., $\Omega = \{\omega_1, \ldots, \omega_i, \ldots\}$ and $P(\omega_i) = p_i > 0$ for all i, we have supp$\Omega = \Omega$. In the case that there is a density function ρ such that $dF(\omega) = \rho(\omega)d\omega$, we have supp$\Omega = \bar{S}$, where $\bar{S}$ is the closure of set $S = \{\omega \in \Omega : \ \rho(\omega) > 0\}$.

COROLLARY 2.3. *Suppose that $M(\omega)$ is a continuous function of ω. Then $M(\cdot)$ is a stochastic R_0 matrix if and only if for any $x \geq 0\,(x \neq 0)$, at least one of the following two conditions is satisfied:*

(a) *there exists $\bar{\omega} \in$ suppΩ such that $[M(\bar{\omega})x]_i \neq 0$ for some $i \in J(x)$;*

(b) *there exists $\bar{\omega} \in$ suppΩ such that $[M(\bar{\omega})x]_i < 0$ for some $i \in I(x)$.*

Proof. By the continuity of $M(\omega)$ and the definition of suppΩ, conditions (a) and (b) in this corollary imply (a) and (b) in Theorem 2.2 (ii), respectively. ∎

COROLLARY 2.4. *Suppose that $M(\omega)$ is a continuous function of ω and $M(\bar{\omega})$ is an R_0 matrix for some $\bar{\omega} \in$ suppΩ. Then $M(\cdot)$ is a stochastic R_0 matrix.*

The following example shows that the condition that $M(\cdot)$ is a stochastic R_0 matrix is weaker than the condition that $M(\omega)$ is continuous in ω and there is an $\bar{\omega} \in$ suppΩ such that $M(\bar{\omega})$ is an R_0 matrix.

Example 2.1. Let

$$M(\omega) = \begin{pmatrix} -2\omega & \omega - |\omega| & 0 \\ 0 & \omega + |\omega| & -2\omega \\ 0 & 0 & 0 \end{pmatrix},$$

where $\omega \in \Omega = [-0.5, 0.5]$ and ω is uniformly distributed on Ω. Clearly, for $\omega < 0$, $M(\omega) = \begin{pmatrix} -2\omega & 2\omega & 0 \\ 0 & 0 & -2\omega \\ 0 & 0 & 0 \end{pmatrix}$. Then $x = (1, 1, 0)^T$ satisfies $M(\omega)x = 0$. On the other hand,

for $\omega > 0$, $M(\omega) = \begin{pmatrix} -2\omega & 0 & 0 \\ 0 & 2\omega & -2\omega \\ 0 & 0 & 0 \end{pmatrix}$. Then $x = (0,1,1)^T$ satisfies $M(\omega)x = 0$. In this example, there is no $\omega \in \Omega$ such that $M(\omega)$ is an R_0 matrix. However, $M(\cdot)$ is a stochastic R_0 matrix as verified by Theorem 2.2 (ii). For any $x \geq 0$ with $x \neq 0$, if $x_1 \neq 0$, then for any $\omega > 0$, $[M(\omega)x]_1 = -2\omega x_1 < 0$. If $x_1 = 0$ but $x_2 \neq 0$, then for any $\omega < 0$, $[M(\omega)x]_1 = 2\omega x_2 < 0$. If only $x_3 \neq 0$, then for any $\omega > 0$, $[M(\omega)x]_2 = -2\omega x_3 < 0$.

The following proposition shows a relation between $M(\cdot)$ and $\bar{M} := E\{M(\omega)\}$.

PROPOSITION 2.5. *If $\bar{M}$ is an R_0 matrix, then $M(\cdot)$ is a stochastic R_0 matrix.*

Proof. If $M(\cdot)$ were not a stochastic R_0 matrix, then by Theorem 2.2 (ii), there exists $x \geq 0$ such that $x \neq 0$ and, for almost all ω, $[M(\omega)x]_i = 0$ for $i \in J(x)$ and $[M(\omega)x]_i \geq 0$ for $i \in I(x)$. Therefore, $[\bar{M}x]_i = 0$ for $i \in J(x)$ and $[\bar{M}x]_i \geq 0$ for $i \in I(x)$. This is impossible, since $\bar{M}$ is an R_0 matrix. ∎

This proposition implies that for any given $\tilde{M}$, if $\tilde{M}$ is an R_0 matrix, then $M(\cdot) = \tilde{M} + M_0(\cdot)$ with $E\{M_0(\omega)\} = 0$ is a stochastic R_0 matrix. The converse of this proposition is not true. The next proposition gives a way to construct a stochastic R_0 matrix $M(\cdot)$ from a given $\tilde{M}$ which is not necessarily an R_0 matrix. Let

$$\Xi(M) := \{x : x \geq 0, x \neq 0,\ [Mx]_i = 0, i \in J(x) \text{ and } [Mx]_i \geq 0, i \in I(x)\}. \tag{2.1}$$

Obviously, if $\Xi(\tilde{M}) = \emptyset$, then $\tilde{M}$ is an R_0 matrix, and hence, by Proposition 2.5, $M(\cdot) = \tilde{M} + M_0(\cdot)$ with $E\{M_0(\omega)\} = 0$ is a stochastic R_0 matrix.

PROPOSITION 2.6. *Let $\tilde{M}$ and $M_0(\cdot)$ be such that $\Xi(\tilde{M}) \neq \emptyset$ and $E\{M_0(\omega)\} = 0$. Suppose that for any $x \in \Xi(\tilde{M})$, at least one of the following two conditions is satisfied:*

(1) *For some $i \in J(x)$, $E\{([M_0(\omega)x]_i)^2\} > 0$;*

(2) *For some $i \in I(x)$, $P\{\omega : [M_0(\omega)x]_i < -b\} > 0$ for any $b > 0$.*

Then $M(\cdot) = \tilde{M} + M_0(\cdot)$ is a stochastic R_0 matrix.

Proof. For $x \in \Xi(\tilde{M})$, these two conditions imply that the conditions in Theorem 2.2 (ii) hold for $M(\cdot)$. For $x \notin \Xi(\tilde{M})$, the same conditions also hold trivially. So $M(\cdot)$ is a stochastic R_0 matrix. ∎

This proposition suggests a way to obtain a stochastic R_0 matrix $M(\cdot)$ from an arbitrary matrix $\tilde{M}$. Specifically, we can construct a simple stochastic matrix $M_0(\cdot)$ such that $\tilde{M} + M_0(\cdot)$ is a stochastic R_0 matrix, as illustrated in the following example.

Example 2.2. We consider the following matrix [3]:

$$\tilde{M} = \begin{pmatrix} 0 & 0 & 1 & -2 & -3 \\ 0 & 0 & 1 & -6 & -3 \\ -1 & -1 & 0 & 0 & 0 \\ 2 & 6 & 0 & 0 & 0 \\ 3 & 3 & 0 & 0 & 0 \end{pmatrix},$$

which arises from a linear programming problem in [13]. Clearly, $\tilde{M}$ is not an R_0 matrix, and $\Xi(\tilde{M}) = \{x : x = (0,0,\lambda,\alpha,\beta)^T, \lambda > 0, \alpha, \beta \geq 0, \lambda - 6\alpha - 3\beta \geq 0\}$. Let ω_0 be a random variable whose distribution is $\mathcal{N}(0,1)$. Let

$$M_0(\omega_0) = \begin{pmatrix} 0 & 0 & 0.5\omega_0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ -0.5\omega_0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

Then for any $b > 0$, $P\{\omega_0 : [M_0(\omega_0)x]_1 < -b\} > 0$ holds for any $x \in \Xi(\tilde{M})$. Hence, by Proposition 2.6, $\tilde{M} + M_0(\cdot)$ is a stochastic R_0 matrix.

The following proposition shows that the sum of a stochastic R_0 matrix $M(\cdot)$ and a matrix $M_1(\cdot)$ with $E\{M_1(\omega_1)\} = 0$ yields a stochastic R_0 matrix.

PROPOSITION 2.7. *Let $\omega = (\omega_0, \omega_1)$ and $\hat{M}(\omega) = M(\omega_0) + M_1(\omega_1)$, where $M(\cdot)$ is a stochastic R_0 matrix, $E\{M_1(\omega_1)\} = 0$, and $M(\omega_0)$ is independent of $M_1(\omega_1)$. Then $\hat{M}(\cdot)$ is a stochastic R_0 matrix.*

Proof. If $\tilde{M} := E\{M(\omega_0)\}$ is an R_0 matrix, then from $E\{M_1(\omega_1)\} = 0$ and Proposition 2.5, $M(\cdot)+M_1(\cdot)$ is a stochastic R_0 matrix. Otherwise, let $M_0(\omega_0) = M(\omega_0)-\tilde{M}$ and choose any $x \in \Xi(\tilde{M})$. Suppose that the first condition of Proposition 2.6 holds for $M_0(\omega_0)$. Since $M(\omega_0)$ is independent of $M_1(\omega_1)$, we have

$$E\{([(M_0(\omega_0) + M_1(\omega_1))x]_i)^2\} = E\{([M_0(\omega_0)x]_i)^2\} + E\{([M_1(\omega_1)x]_i)^2\} > 0$$

for some $i \in J(x)$. Now, suppose that the second condition of Proposition 2.6 holds for $M_0(\omega_0)$, i.e., $P\{\omega_0 : [M_0(\omega_0)x]_i < -b\} > 0$ for some $i \in I(x)$. Note that

$$\begin{aligned} &P\{\omega : [(M_0(\omega_0) + M_1(\omega_1))x]_i < -b\} \\ &\quad \geq P\{(\omega_0, \omega_1) : [M_0(\omega_0)x]_i < -b \text{ and } [M_1(\omega_1)x]_i \leq 0\} \\ &\quad = P\{\omega_0 : [M_0(\omega_0)x]_i < -b\} P\{\omega_1 : [M_1(\omega_1)x]_i \leq 0\}. \end{aligned}$$

Since $E\{[M_1(\omega_1)x]_i\} = 0$, we have $P\{\omega_1 : [M_1(\omega_1)x]_i \leq 0\} > 0$. Thus, we have

$$P\{\omega : [(M_0(\omega_0) + M_1(\omega_1))x]_i < -b\} > 0,$$

i.e., the second condition of Proposition 2.6 also holds for $M_0(\omega_0) + M_1(\omega_1)$. Since

$$\hat{M}(\omega) = M(\omega_0) + M_1(\omega_1) = \tilde{M} + M_0(\omega_0) + M_1(\omega_1),$$

Proposition 2.6 ensures that $\hat{M}(\cdot)$ is a stochastic R_0 matrix. ∎

3. Boundedness of solution set. In this section, the boundedness of the solution set of the ERM problem (1.3) is studied.

THEOREM 3.1. *Let $q(\cdot)$ be arbitrary. Then $G(x) \to \infty$ as $\|x\| \to \infty$ with $x \in \mathbb{R}^n_+$ if and only if $M(\cdot)$ is a stochastic R_0 matrix.*

Proof. First, we prove the "if" part. For simplicity, we denote $|x| = (|x_1|, \ldots, |x_n|)^T$ and $\text{sign}(x) = (\text{sign}(x_1), \ldots, \text{sign}\ (x_n))^T$ for a vector x, where

$$\text{sign}(x_i) = \begin{cases} 1, & x_i > 0, \\ 0, & x_i = 0, \\ -1, & x_i < 0. \end{cases}$$

Note that for any $a, b \in \mathbb{R}$, we have

$$\begin{aligned} 2\min(a, b) &= a + b - \text{sign}(a - b)(a - b) \\ &= (1 - \text{sign}(a - b))a + (1 + \text{sign}(a - b))b \end{aligned}$$

and

$$\begin{aligned} 4(\min(a, b))^2 &= a(1 - \text{sign}(a - b))^2 a + b(1 + \text{sign}(a - b))^2 b + 2b(1 - \text{sign}^2(a - b))a \\ &= 2a(1 - \text{sign}(a - b))a + 2b(1 + \text{sign}(a - b))b. \end{aligned}$$

For any $x \in \mathbb{R}^n$ and $\omega \in \Omega$, we define the diagonal matrix

$$D(x,\omega) = \mathrm{diag}(\mathrm{sign}(M(\omega)x + q(\omega) - x)).$$

Then we have

$$\|\Phi(x,\omega)\|^2 = \frac{1}{2}[(M(\omega)x + q(\omega))^T(I - D(x,\omega))(M(\omega)x + q(\omega)) + x^T(I + D(x,\omega))x]. \tag{3.1}$$

Consider an arbitrary $x \geq 0$ with $\|x\| = 1$. Suppose condition (a) in Theorem 2.2 (ii) holds. Choose $i \in J(x)$ such that $P\{\omega : [M(\omega)x]_i \neq 0\} > 0$. Then there exists a sufficiently large $K > 0$ such that $P\{\omega : [M(\omega)x]_i \neq 0,\ |q_i(\omega)| \leq K\} > 0$.

First, consider the case where $P\{\omega : [M(\omega)x]_i < x_i,\ |q_i(\omega)| \leq K\} > 0$. Let

$$\Omega_1 := \{\omega : [M(\omega)x]_i < (1-\delta)x_i,\ |q_i(\omega)| \leq K\},$$

where $\delta > 0$. Then we have $P\{\Omega_1\} > 0$ whenever δ is sufficiently small. Moreover, for any sufficiently large $\lambda > 0$, $\mathrm{sign}(\lambda[M(\omega)x]_i + q_i(\omega) - \lambda x_i) = -1$ for any $\omega \in \Omega_1$. Therefore, by (1.2) and (3.1), we have

$$G(\lambda x) \geq \int_{\Omega_1} (\lambda[M(\omega)x]_i + q_i(\omega))^2 dF(\omega) \to \infty \text{ as } \lambda \to \infty. \tag{3.2}$$

Next, consider the case where $P\{\omega : [M(\omega)x]_i > x_i, |q_i(\omega)| \leq K\} > 0$. Let

$$\Omega_2 := \{\omega : [M(\omega)x]_i > (1+\delta)x_i, |q_i(\omega)| \leq K\}.$$

Then we have $P(\Omega_2) > 0$ for a sufficiently small $\delta > 0$. Moreover, for any sufficiently large $\lambda > 0$, $\mathrm{sign}(\lambda[M(\omega)x]_i + q_i(\omega) - \lambda x_i) = 1$ for $\omega \in \Omega_2$. Hence we have

$$G(\lambda x) \geq \int_{\Omega_2} (\lambda x_i)^2 dF(\omega) \to \infty \text{ as } \lambda \to \infty. \tag{3.3}$$

Finally, consider the case where $P\{\omega : [M(\omega)x]_i = x_i, |q_i(\omega)| \leq K\} > 0$. Let

$$\Omega_3 := \{\omega : [M(\omega)x]_i = x_i, |q_i(\omega)| \leq K\}.$$

Then we have

$$G(\lambda x) \geq \int_{\Omega_3} \{(\lambda x_i + q_i(\omega))^2 1_{\{q_i(\omega)<0\}} + (\lambda x_i)^2 1_{\{q_i(\omega)\geq 0\}}\} dF(\omega) \to \infty \text{ as } \lambda \to \infty. \tag{3.4}$$

Combining (3.2)–(3.4), we see that $G(\lambda x) \to \infty$ as $\lambda \to \infty$.

Now, suppose condition (b) in Theorem 2.2 (ii) holds. Choose $i \in I(x)$ such that $P\{\omega : [M(\omega)x]_i < 0\} > 0$. Let

$$\Omega_4 := \{\omega :\ [M(\omega)x]_i < -\delta,\ |q_i(\omega)| < K\}.$$

Then we have $P\{\Omega_4\} > 0$ for any sufficiently small $\delta > 0$ and sufficiently large $K > 0$. Moreover, for any $\lambda > 0$ large enough, $\lambda[M(\omega)x]_i + q_i(\omega) < 0$ for $\omega \in \Omega_4$. Thus we have

$$(1 - \mathrm{sign}(\lambda[M(\omega)x]_i + q_i(\omega)))(\lambda[M(\omega)x]_i + q_i(\omega))^2 = 2(\lambda[M(\omega)x]_i + q_i(\omega))^2,$$

which yields

$$G(\lambda x) \geq \int_{\Omega_4} (\lambda[M(\omega)x]_i + q_i(\omega))^2 dF(\omega) \to \infty \text{ as } \lambda \to \infty.$$

Since x is an arbitrary nonzero vector such that $x \geq 0$, we deduce from the above arguments that $G(x) \to \infty$ as $\|x\| \to \infty$ with $x \geq 0$, provided the statement (ii) in Theorem 2.2 holds.

Let us turn to proving the "only if" part. Suppose that $M(\cdot)$ is not a stochastic R_0 matrix, i.e., there exists $x \geq 0$ with $x \neq 0$ such that $[M(\omega)x]_i = 0$ for all $i \in J(x)$ and $[M(\omega)x]_i \geq 0$ for all $i \in I(x)$, a.e. For any $\lambda > 0$, from (1.2) and (3.1), we have

$$G(\lambda x) = \frac{1}{2} \sum_{i=1}^{n} E\{(1 - \text{ sign}(\lambda[M(\omega)x]_i + q_i(\omega) - \lambda x_i))(\lambda[M(\omega)x]_i + q_i(\omega))^2$$

$$+ (1 + \text{sign}(\lambda[M(\omega)x]_i + q_i(\omega) - \lambda x_i))(\lambda x_i)^2\}. \tag{3.5}$$

The ith term of the right-hand side of (3.5) with $x_i \neq 0$ equals

$$E\{(1 - \text{sign}(q_i(\omega) - \lambda x_i))q_i(\omega)^2 + (1 + \text{sign}(q_i(\omega) - \lambda x_i))(\lambda x_i)^2\}$$

$$= 2E\{q_i(\omega)^2 1_{\{q_i(\omega\} \leq \lambda x_i\}} + (\lambda x_i)^2 1_{\{q_i(\omega) > \lambda x_i\}}\} \leq 2E\{q_i(\omega)^2\},$$

while the ith term of the right-hand side of (3.5) with $x_i = 0$ equals

$$E\{(1 - \text{sign}(\lambda[M(\omega)x]_i + q_i(\omega)))(\lambda[M(\omega)x]_i + q_i(\omega))^2\}$$

$$= 2E\{(\lambda[M(\omega)x]_i + q_i(\omega))^2 1_{\{\lambda[M(\omega)x]_i < -q_i(\omega)\}}\} \leq 2E\{q_i(\omega)^2\},$$

where the last inequality follows from $0 > \lambda[M(\omega)x]_i + q_i(\omega) \geq q_i(\omega)$, implying $(\lambda[M(\omega)x]_i + q_i(\omega))^2 \leq q_i(\omega)^2$. So, we obtain

$$G(\lambda x) \leq E\{\|q(\omega)\|^2\} \text{ for any } \lambda > 0.$$

Since $x \geq 0$ with $x \neq 0$, this particularly implies that G is bounded above on a nonnegative ray in $\mathbb{R}^n_+$. This completes the proof of the "only if" part. □

The solution set of ERM$(M(\cdot), q(\cdot))$ may be bounded even if $M(\cdot)$ is not a stochastic R_0 matrix. It depends on the distribution of $q(\omega)$, as shown in the following two propositions.

PROPOSITION 3.2. *If $M(\cdot)$ is not a stochastic R_0 matrix, $P\{\omega : q_i(\omega) > 0\} > 0$ for some $i \in J(x)$, and $P\{\omega : q_i(\omega) \geq 0\} = 1$ for all $i \in I(x)$, where $x \neq 0$ is any nonnegative vector at which the conditions* (a) *and* (b) *in Theorem* 2.2 (ii) *fail to hold, then the solution set of ERM$(M(\cdot), q(\cdot))$ is bounded.*

Proof. Note that

$$G(0) = E\{\|\Phi(0, \omega)\|^2\} = \sum_{i=1}^{n} E\{q_i(\omega)^2 1_{\{q_i(\omega) < 0\}}\}. \tag{3.6}$$

For any nonnegative vector $x \neq 0$ satisfying the conditions (a) and (b) in Theorem 2.2 (ii), the proof of Theorem 3.1 indicates that

$$G(\lambda x) \to \infty \text{ as } \lambda \to 0. \tag{3.7}$$

Let $x \neq 0$ be any nonnegative vector which does not satisfy the conditions (a) and (b) in Theorem 2.2 (ii), i.e., $[M(\omega)x]_i = 0$ for $i \in J(x)$, and $[M(\omega)x]_i \geq 0$ for $i \in I(x)$, a.e. Then by (3.1), we have

$$G(\lambda x) = \sum_{i\in J(x)} E\{[(1-\operatorname{sign}(q_i(\omega)-\lambda x_i))q_i(\omega)^2 + (1+\operatorname{sign}(q_i(\omega)-\lambda x_i))(\lambda x_i)^2]/2\}$$

$$= \sum_{i\in J(x)} \{E\{q_i(\omega)^2\} - E\{1_{\{q_i(\omega)-\lambda x_i>0\}}[q_i(\omega)^2 - (\lambda x_i)^2]\}\}, \tag{3.8}$$

where the first equality follows from the assumption that $P\{\omega : q_i(\omega) \geq 0\} = 1$ for $i \in I(x)$ and hence $[M(\omega)x]_i + q_i(\omega) \geq 0$, a.e., for $i \in I(x)$. Note that

$$0 \leq E\{1_{\{q_i(\omega)-\lambda x_i>0\}}[q_i(\omega)^2 - (\lambda x_i)^2]\} = E\{1_{\{q_i(\omega)>\lambda x_i\}}[q_i(\omega)^2 - (\lambda x_i)^2]\}$$

$$\leq E\{1_{\{q_i(\omega)>\lambda x_i\}} q_i(\omega)^2\} \to 0 \text{ as } \lambda \to \infty,$$

which together with (3.8) implies

$$\lim_{\lambda\to\infty} G(\lambda x) = \sum_{i\in J(x)} E\{q_i(\omega)^2\}. \tag{3.9}$$

On the other hand, for any nonzero $x \geq 0$, we have

$$\sum_{i=1}^{n} E\{q_i(\omega)^2 1_{\{q_i(\omega)<0\}}\} = \sum_{i\in J(x)} E\{q_i(\omega)^2 1_{\{q_i(\omega)<0\}}\} < \sum_{i\in J(x)} E\{q_i(\omega)^2\}, \tag{3.10}$$

where the equality follows from the assumption that $P\{\omega : q_i(\omega) \geq 0\} = 1$ for all $i \in I(x)$, and the strict inequality follows from the assumption that $P\{\omega : q_i(\omega) > 0\} > 0$ for some $i \in J(x)$. Combining (3.6), (3.9), and (3.10), we have

$$G(0) < \lim_{\lambda\to+\infty} G(\lambda x). \tag{3.11}$$

Let $\Lambda := \{x \in \mathbb{R}^n_+ : G(x) \leq G(0)\}$. From (3.7) and (3.11), we have $\sup_{x\in\Lambda} \|x\| < +\infty$. Since any solution belongs to Λ, this implies that the solution set is bounded. ∎

PROPOSITION 3.3. *If $M(\cdot)$ is not a stochastic R_0 matrix and, for any i, $P\{\omega : -b \leq q_i(\omega) < 0\} = 1$ for some $b > 0$ and $P\{\omega : q_i(\omega) \neq 0$ and $M(\omega)x^0]_i = 0\} = 0$, where $x^0 \neq 0$ is any nonnegative vector at which the conditions* (a) *and* (b) *in Theorem* 2.2 (ii) *fail to hold, then the solution set of ERM$(M(\cdot), q(\cdot))$ is empty or unbounded.*

Proof. Let $x^0 \neq 0$ be any nonnegative vector which does not satisfy the conditions (a) and (b) in Theorem 2.2 (ii). From (1.2) and (3.1), we have

$$G(\lambda x^0) = \sum_{i=1}^{n} E\{[(1-\operatorname{sign}(\lambda[M(\omega)x^0]_i + q_i(\omega) - \lambda x_i^0))(\lambda[M(\omega)x^0]_i + q_i(\omega))^2$$

$$+ (1+\operatorname{sign}(\lambda[M(\omega)x^0]_i + q_i(\omega) - \lambda x_i))(\lambda x_i^0)^2]/2\}. \tag{3.12}$$

For every $i \in J(x^0)$, we have $[M(\omega)x^0]_i = 0$ and $q_i(\omega) = 0$, a.e., and hence the ith term of the right-hand side of (3.12) is zero for any $\lambda > 0$. For every $i \in I(x^0)$, we have $[M(\omega)x^0]_i \geq 0$ and $q_i(\omega) < 0$, a.e., which implies

$$\begin{aligned} &E\{(1 - \operatorname{sign}(\lambda[M(\omega)x^0]_i + q_i(\omega)))(\lambda[M(\omega)x^0]_i + q_i(\omega))^2\} \\ &\quad = 2E\{(\lambda[M(\omega)x^0]_i + q_i(\omega))^2 1_{\{\lambda[M(\omega)x^0]_i < -q_i(\omega), [M(\omega)x^0]_i > 0\}}\} \\ &\quad\quad + 2E\{q_i^2(\omega) 1_{\{[M(\omega)x^0]_i = 0\}}\}. \end{aligned} \tag{3.13}$$

By assumption, the second term on the right-hand side of (3.13) is zero for any $\lambda > 0$, and

$$\begin{aligned} &E\{(\lambda[M(\omega)x^0]_i + q_i(\omega))^2 1_{\{\lambda[M(\omega)x^0]_i < -q_i(\omega), [M(\omega)x^0]_i > 0\}}\} \\ &\quad \leq b^2 P\{\omega : 0 < \lambda[M(\omega)x^0]_i < b\} \to 0 \text{ as } \lambda \to \infty. \end{aligned}$$

Therefore, we obtain

$$\lim_{\lambda \to +\infty} G(\lambda x^0) = 0,$$

but for any $x \in \mathbb{R}^n_+$, $G(x) \geq 0$. So for any $\gamma > 0$, the level set $\Lambda_\gamma := \{x : G(x) \leq \gamma\}$ is unbounded, which means the solution set is unbounded if it is not empty. □

From Theorem 3.1, we have the following necessary and sufficient condition for the solution set of ERM$(M(\cdot), q(\cdot))$ to be bounded for any $q(\cdot)$.

THEOREM 3.4. *The solution set of ERM$(M(\cdot), q(\cdot))$ is nonempty and bounded for any $q(\cdot)$ if and only if $M(\cdot)$ is a stochastic R_0 matrix.*

4. Differentiability of G. The objective function G of ERM$(M(\cdot), q(\cdot))$ is, in general, not convex. If G is differentiable at x, then $\min(\nabla G(x), x) = 0$ implies that x is a stationary point of ERM$(M(\cdot), q(\cdot))$. The differentiability of G is studied in [3] for the special case where $M(\omega) \equiv M$, $q(\omega) = \bar{q} + T\omega$ with $M \in \mathbb{R}^{n \times n}$, $\bar{q} \in \mathbb{R}^n$, $T \in \mathbb{R}^{n \times m}$ being constants and T having at least one nonzero element in each row.

In this section, we will give a condition for the function G to be differentiable under a general setting. The continuity of $M(\cdot)$ and $q(\cdot)$ is not assumed.

DEFINITION 4.1. *We say that the strict complementarity condition holds at x with probability one if*

$$P\{\omega : [M(\omega)x]_i + q_i(\omega) = x_i\} = 0, \quad i = 1, \ldots, n.$$

Obviously, this definition is a generalization of the strict complementarity condition for the LCP. The proof for the differentiability of G at x under the strict complementarity condition with probability one is not trivial.

For any fixed ω, if $[M(\omega)x]_i + q_i(\omega) - x_i \neq 0$ for all i, then $\|\Phi(x, \omega)\|^2$ is differentiable at x and

$$\nabla_x \|\Phi(x, \omega)\|^2 = M(\omega)^T (I - D(x, \omega))(M(\omega)x + q(\omega)) + (I + D(x, \omega))x.$$

To simplify the notation, we define

$$f(x, \omega) := M(\omega)^T (I - D(x, \omega))(M(\omega)x + q(\omega)) + (I + D(x, \omega))x. \tag{4.1}$$

THEOREM 4.2. *The function $g(x) := \int_\Omega f(x, \omega) dF(\omega)$ is continuous at x if the strict complementarity condition holds at x with probability one.*

Proof. We will show that $\|g(x+h)-g(x)\| \to 0$ as $h \to 0$. Since

$$\begin{aligned} f(x,\omega)-f(x+h,\omega) &= (M(\omega)^T(I-D(x,\omega))M(\omega)+I+D(x,\omega))h \\ &+ M(\omega)^T(D(x+h,\omega)-D(x,\omega))(M(\omega)(x+h)+q(\omega)) \\ &- (D(x+h,\omega)-D(x,\omega))(x+h), \end{aligned}$$

there exist some constants c_1, $c_2 > 0$ such that

$$\begin{aligned} \|g(x+h)-g(x)\| &= \left\| \int_\Omega [f(x+h,\omega)-f(x,\omega)]dF(\omega) \right\| \\ &\le c_1\|h\| + c_2 \int_\Omega \|D(x+h,\omega)-D(x,\omega)\|dF(\omega). \end{aligned}$$

Then we just need to show that

$$\int_\Omega \|D(x+h,\omega)-D(x,\omega)\|dF(\omega) \to 0 \ \text{ as } \ h \to 0.$$

Note that

$$\{\omega : \|D(x+h,\omega)-D(x,\omega)\| \neq 0\} \subset \cup_{i=1}^n \{A_i \cup B_i\},$$

where

$$A_i := \{\omega : [M(\omega)x]_i + q_i(\omega) - x_i \ge 0,\ [M(\omega)(x+h)]_i + q_i(\omega) - x_i - h_i \le 0\},$$

$$B_i := \{\omega : [M(\omega)x]_i + q_i(\omega) - x_i \le 0,\ [M(\omega)(x+h)]_i + q_i(\omega) - x_i - h_i \ge 0\}.$$

For any $\varepsilon > 0$, since the strict complementarity condition holds at x with probability one, there is a $\delta > 0$ such that

$$P\{\omega : |[M(\omega)x]_i + q_i(\omega) - x_i| < \delta\} < \varepsilon/2. \tag{4.2}$$

Let

$$C_i := \{\omega : [M(\omega)x]_i + q_i(\omega) - x_i \ge \delta,\ [M(\omega)(x+h)]_i + q_i(\omega) - x_i - h_i \le 0\}.$$

Then, we have

$$\begin{aligned} A_i &\subset C_i \cup \{\omega : |[M(\omega)x]_i + q_i(\omega) - x_i| < \delta\}, \\ C_i &\subset \{\omega : [M(\omega)h]_i - h_i \le -\delta\}. \end{aligned}$$

Applying a similar procedure to B_i, we have

$$P\{A_i \cup B_i\} \le P\{\omega : |[M(\omega)h]_i - h_i| \ge \delta\} + P\{\omega : |[M(\omega)x]_i + q_i(\omega) - x_i| < \delta\}.$$

By the Chebyshev inequality, there is an $h_0 > 0$ such that for any h with $\|h\| < h_0$,

$$P\{\omega : |[M(\omega)h]_i - h_i| \ge \delta\} < \varepsilon/2.$$

This together with (4.2) implies that g is continuous at x. ∎

THEOREM 4.3. *If the strict complementarity condition holds at any x in an open set $U \subset \mathbb{R}^n$ with probability one, then G is Fréchet differentiable at $x \in U$ and*

$$\nabla G(x) = \int_\Omega f(x,\omega)dF(\omega). \tag{4.3}$$

Proof. First, we will show that for almost all ω, $\mu\{x \in U : \ [M(\omega)x]_i + q_i(\omega) = x_i\} = 0$ for any i, where μ is Lebesgue measure. If it were not true, then for some i

$$P\{\omega : \mu\{x \in U : \ [M(\omega)x]_i + q_i(\omega) = x_i\} > 0\} > 0,$$

which implies

$$\int_\Omega \int_U 1_{\{[M(\omega)x]_i + q_i(\omega) = x_i\}} dx dF(\omega) > 0. \tag{4.4}$$

But from the assumption and the Fubini theorem [11], we obtain

$$\int_\Omega \int_U 1_{\{[M(\omega)x]_i + q_i(\omega) = x_i\}} dx dF(\omega) = \int_U \int_\Omega 1_{\{[M(\omega)x]_i + q_i(\omega) = x_i\}} dF(\omega) dx = 0.$$

This contradicts (4.4), and hence for almost all ω, $\mu\{x \in U : \ [M(\omega)x]_i + q_i(\omega) = x_i\} = 0$ for any i.

Note that, for any $\omega \in \Omega$, $\|\Phi(x,\omega)\|^2$ is locally Lipschitz and hence absolutely continuous with respect to x. For any (x,ω) such that $[M(\omega)x]_i + q_i(\omega) \neq x_i$, $\|\Phi(x,\omega)\|^2$ is differentiable with respect to x. Therefore, by the Fundamental Theorem of Calculus for Lebesgue Integrals [11], for any x we have

$$\|\Phi(x + h_i e_i, \omega)\|^2 - \|\Phi(x,\omega)\|^2 = \int_0^{h_i} [f(x + s e_i, \omega)]_i ds \tag{4.5}$$

for almost all ω, where $e_i = (0, \ldots, 0, \underset{i}{1}, 0, \ldots, 0)^T$. Thus

$$\begin{aligned} &G(x+h) - G(x) \\ &= \sum_{i=1}^n \int_\Omega \left(\left\| \Phi\left(x + \sum_{k=i}^n h_k e_k, \omega \right) \right\|^2 - \left\| \Phi\left(x + \sum_{k=i+1}^n h_k e_k, \omega \right) \right\|^2 \right) dF(\omega). \end{aligned} \tag{4.6}$$

By (4.5), (4.6), and the Fubini theorem, we deduce that

$$\int_\Omega \int_0^{h_i} [f(y + s e_i, \omega)]_i ds dF(\omega) = \int_0^{h_i} \int_\Omega [f(y + s e_i, \omega)]_i dF(\omega) ds$$

for any i and $y \in B(x, \|h\|) \subset U$, and hence

$$\begin{aligned} &G\,(x+h) - G(x) - h^T \int_\Omega f(x,\omega) dF(\omega) \\ &= \sum_{i=1}^n \int_0^{h_i} \int_\Omega \left[f\left(x + \sum_{k=i+1}^n h_k e_k + s e_i, \omega \right) \right]_i dF(\omega) ds - \sum_{i=1}^n \int_0^{h_i} \int_\Omega [f(x,\omega)]_i dF(\omega) ds \\ &= \sum_{i=1}^n \int_0^{h_i} \int_\Omega \left(\left[f\left(x + \sum_{k=i+1}^n h_k e_k + s e_i, \omega \right) \right]_i - [f(x,\omega)]_i \right) dF(\omega) ds \\ &= \sum_{i=1}^n \int_0^{h_i} \left(g_i\left(x + \sum_{k=i+1}^n h_k e_k + s e_i \right) - g_i(x) \right) ds, \end{aligned}$$

where g is defined in Theorem 4.2. From Theorem 4.2, for any $\varepsilon > 0$, there exists a sufficiently small $h_0 > 0$ such that for any h with $\|h\| < h_0$,

$$\left| G(x+h) - G(x) - h^T \int_\Omega f(x,\omega) dF(\omega) \right| < \varepsilon \|h\|,$$

which implies

$$\frac{|G(x+h) - G(x) - h^T \int_\Omega f(x,\omega) dF(\omega)|}{\|h\|} \to 0 \quad \text{as} \quad \|h\| \to 0.$$

Therefore, G is Fréchet differentiable at x and (4.3) holds. □

Remark. When $M(\omega) \equiv M$ and $q(\omega) = \bar{q} + T\omega$, if $[T\omega]_i$ has no mass at any point for each i, i.e., $P\{\omega : [T\omega]_i = a\} = 0$ for any $a \in \mathbb{R}$, then $P\{\omega : [M(\omega)x]_i + q_i(\omega) = x_i\} = 0$, $i = 1, \ldots, n$. Therefore, if T has at least one nonzero element in each row [3], then for all $x \in \mathbb{R}^n$, the strict complementarity condition holds with probability one and G is differentiable in $\mathbb{R}^n_+$. This indicates that the result shown in Theorem 4.3 contains the results established in [3].

Let $F_{q_i}(s)$ be the distribution function of $q_i(\omega)$, i.e., $F_{q_i}(s) = P\{\omega : q_i(\omega) \le s\}$. Suppose $M(\omega) \equiv M$. Then, we have

$$\begin{aligned} G(x) &= \int_{-\infty}^{+\infty} \sum_{i=1}^n (\min([Mx]_i + s, x_i))^2 dF_{q_i}(s) \\ &= \sum_{i=1}^n \int_{-\infty}^{[(I-M)x]_i} ([Mx]_i + s)^2 dF_{q_i}(s) + \sum_{i=1}^n x_i^2 (1 - F_{q_i}([(I-M)x]_i)). \end{aligned} \tag{4.7}$$

It is shown in [3] that for some special distribution functions, $G(x)$ can be computed without using discrete approximation. The following proposition shows that, under some conditions, we can also compute $\nabla G(x)$ without using discrete approximation.

PROPOSITION 4.4. *If $M(\omega) \equiv M$ and $F_{q_i}(s)$ is a continuous function for all i, then*

$$\nabla G(x) = 2M^T H(x)x + 2(I - H(x))x - 2M^T v(x), \tag{4.8}$$

where

$$H(x) := \operatorname{diag}(F_{q_1}([(I-M)x]_1), \ldots, F_{q_n}([(I-M)x]_n),$$

$$v(x) := \left(\int_{-\infty}^{[(I-M)x]_1} F_{q_1}(s) ds, \ldots, \int_{-\infty}^{[(I-M)x]_n} F_{q_n}(s) ds \right)^T.$$

Proof. If $M(\omega) \equiv M$ and $F_{q_i}(s)$ is continuous for all i, then $P\{\omega : q_i(\omega) = a\} = 0$ for any $a \in \mathbb{R}$, and hence $P\{\omega : [Mx]_i + q_i(\omega) = x_i\} = 0$ for each $x \in \mathbb{R}^n_+$. Then, by Theorem 4.3, $G(x)$ is differentiable at any $x \in \mathbb{R}^n_+$ and

$$\begin{aligned} \nabla G(x) &= \int_\Omega [M^T(I - D(x,\omega))(Mx + q(\omega)) + (I + D(x,\omega))x] dF(\omega) \\ &= M^T \left[\int_\Omega (I - D(x,\omega)) dF(\omega) Mx + \int_\Omega (I - D(x,\omega)) q(\omega) dF(\omega) \right] \\ &\quad + \left(\int_\Omega (I + D(x,\omega)) dF(\omega) \right) x \\ &= 2M^T H(x) Mx + 2M^T R(x) + 2(I - H(x))x, \end{aligned} \tag{4.9}$$

where

$$R(x) := \left(\int_{-\infty}^{[(I-M)x]_1} sdF_{q_1}(s), \ldots, \int_{-\infty}^{[(I-M)x]_n} sdF_{q_n}(s) \right)^T.$$

By integration by parts, we have

$$\int_{-\infty}^{[(I-M)x]_i} sdF_{q_i}(s) = [(I-M)x]_i F_{q_i}([(I-M)x]_i) - \int_{-\infty}^{[(I-M)x]_i} F_{q_i}(s)ds.$$

This implies that

$$R(x) = \left(\int_{-\infty}^{[(I-M)x]_1} sdF_{q_1}(s), \ldots, \int_{-\infty}^{[(I-M)x]_n} sdF_{q_n}(s) \right)^T = H(x)(I-M)x - v(x).$$

Combining this with (4.9), we have the desired formula (4.8). ∎

From (4.8), we see that the smoothness of $G(\cdot)$ depends on the smoothness of $F_{q_i}(\cdot)$, $i = 1, \ldots, n$. If for all i, $F_{q_i}(\cdot)$ is differentiable at $[(I-M)x]_i$ and $\rho_i(\cdot)$, the derivative of $F_{q_i}(\cdot)$ is continuous at $[(I-M)x]_i$, then the Hessian matrix of $G(x)$ can be written as

$$\begin{aligned} \nabla^2 G(x) &= 2M^T H(x)M + 2(M^T S(x) + S(x)M) - 2M^T S(x)M + 2(I - S(x) - H(x)) \\ &= 2M^T H(x)M + 2(I - H(x)) - 2(I-M)^T S(x)(I-M), \end{aligned} \tag{4.10}$$

where

$$S(x) := \operatorname{diag}(x_1\rho_1([(I-M)x]_1), \ldots, x_n\rho_n([(I-M)x]_n)).$$

5. Optimality conditions and error bounds. In numerical algorithms, residual functions play an important role in terminating iterations and verifying accuracy of a computed solution. The following theorem shows the basic properties of the residual function defined by

$$r(x) = \| \min(\nabla G(x), x)\|.$$

THEOREM 5.1. *Suppose that the strict complementarity condition holds at any x in an open set U with probability one. Then the following statements are true.*

(1) *If $\bar{x} \in U$ is a local solution of ERM$(M(\cdot), q(\cdot))$, then $r(\bar{x}) = 0$.*
(2) *If $G(\cdot)$ is twice continuously differentiable at $\bar{x} \in \mathbb{R}^n_+$, where $r(\bar{x}) = 0$ and the Hessian matrix $\nabla^2 G(\bar{x})$ is positive definite, then there are an open set $\bar{U} \subset U$ and a constant $\tau > 0$ such that $\bar{x}$ is a unique local solution of ERM$(M(\cdot), q(\cdot))$ in $\bar{U}$, and for all $x \in \bar{U}$*

$$\|x - \bar{x}\| \le \tau r(x). \tag{5.1}$$

Proof. From Theorem 4.3, we can write the first order optimality condition for the ERM problem (1.3) as $r(x) = 0$. Now we show (5.1). Since $G(\cdot)$ is twice continuously differentiable at $\bar{x}$ and $\nabla^2 G(\bar{x})$ is positive definite, there is an open set $\bar{U} \subset U$ such that $\nabla G(x)$ is a locally Lipschitz continuous and uniform P function in $\bar{U}$. Applying Proposition 6.3.1 in [7] to the nonsmooth equation $\min(x, \nabla G(x)) = 0$, we obtain (5.1). ∎

COROLLARY 5.2. *If $\Omega = \{\omega_1, \ldots, \omega_N\}$ and the strict complementarity condition holds at $x \in \mathbb{R}^n_+$ with probability one, then $r(x) = 0$ implies x is a local solution of ERM$(M(\cdot), q(\cdot))$.*

Proof. Since the strict complementarity condition holds at $x \in \mathbb{R}^n_+$ with probability one, by (3.1), for each i, $\|\Phi(x, \omega_i)\|^2$ is twice continuously differentiable and

$$\nabla^2 G(x) = \sum_{i=1}^{N} [M(\omega_i)^T (I - D(x, \omega_i)) M(\omega_i) + (I + D(x, \omega_i))].$$

Since the Hessian matrix $\nabla^2 G(x)$ is positive semidefinite, and $G(x)$ is a quadratic function in $B(x, \nu)$ for a sufficiently small $\nu > 0$, x is a local solution. □

Now we consider error bounds for the case where G is not necessarily differentiable. Let

$$s(x) = G(x) - \min_{x \in \mathbb{R}^n_+} G(x).$$

When $\Omega = \{\omega_1, \ldots, \omega_N\}$, we can write

$$G(x) = \sum_{j=1}^{N} \sum_{i=1}^{n} |\min([M(\omega_j)x + q(\omega_j)]_i, x_i)|^2 p(\omega_j),$$

where $p(\omega_j)$ is the probability of ω_j. Clearly, there exist finitely many convex polyhedra such that G is a convex quadratic function on each polyhedron, i.e., G is a piecewise convex quadratic function. By Theorem 2.5 in [15], we have the following local error bound result.

PROPOSITION 5.3. *If $\Omega = \{\omega_1, \ldots, \omega_N\}$, then there exist constants $\tau > 0$ and $\varepsilon > 0$ such that for any $x \in \mathbb{R}^n_+$ with $s(x) \le \varepsilon$*

$$\|x - x^*(x)\| \le \tau s(x)^{1/2},$$

where $x^*(x)$ is a global solution of ERM$(M(\cdot), q(\cdot))$ closest to x under the norm $\|\cdot\|$.

Let us denote $s_\gamma(x) = s(x)^\gamma$ for $\gamma > 0$. For a general continuous distribution of ω, G may not be a piecewise convex function. The following example shows that the function s_γ provides a local error bound for the ERM$(M(\cdot), q(\cdot))$ with various values of γ depending on the distribution of ω.

Example 5.1. Consider the SLCP$(M(\omega), q(\omega))$ with

$$M(\omega) \equiv \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & -1 \\ 1 & 0 & -1 \end{pmatrix}, \; q(\omega) = \begin{pmatrix} -1 \\ -1 \\ \omega \end{pmatrix},$$

where ω is a random variable with supp$\Omega \subset [-1, 0]$. It is easy to check that $M(\omega)$ is an R_0 matrix. For any ω, the solution set of LCP$(M(\omega), q(\omega))$ is $\{(x_1, 1 - x_1, 0)^T : x_1 \in [-\omega, 1]\} \cup \{(-\frac{1}{2}\omega + \frac{1}{2}, 0, \frac{1}{2}\omega + \frac{1}{2})^T\}$. Let $\rho(\omega)$ be the density function of ω. We consider the following two cases: $\rho(\omega) \equiv 1$ and $\rho(\omega) = 2(\omega + 1)$. Clearly, $x^* = (1, 0, 0)^T$ is the unique global solution of ERM$(M(\cdot), q(\cdot))$ and $r(x^*) = 0$ for these two cases. But for any $x = (x_1, 1 - x_1, 0)^T$ with $x_1 \in [0, 1]$, if $\rho(\omega) \equiv 1$, then $s(x) = (1 - x_1)^{3/2}/\sqrt{3}$, but if $\rho(\omega) = 2(\omega + 1)$, then $s(x) = (1 - x_1)^2/\sqrt{6}$. Noticing that $\|x - x^*\| = \sqrt{2}(1 - x_1)$, we have $\|x - x^*\| \le \tau s_\gamma(x)$, where γ depends on the distribution of ω. So the general

form of local error bound for ERM$(M(\cdot), q(\cdot))$ with continuous random variables is difficult to obtain unless the information on the distribution of ω is known.

THEOREM 5.4. *Let $M(\cdot)$ be a stochastic R_0 matrix. Then for any $\varepsilon > 0$, there exists $\tau > 0$ such that for each $x \in \mathbb{R}^n_+$ with $s(x) > \varepsilon$*

$$\|x - x^*(x)\| \le \tau s(x)^{1/2},$$

where $x^*(x)$ is a global solution of ERM$(M(\cdot), q(\cdot))$ closest to x under the norm $\|\cdot\|$.

Proof. If the assertion were not true, then for any positive integer k, there exists x^k with $s(x^k) > \varepsilon$ such that

$$\|x^k - x^*(x^k)\| > k s(x^k)^{1/2} > k\varepsilon^{1/2}.$$

Since $M(\cdot)$ is a stochastic R_0 matrix, by Theorem 3.4 the global solution set of ERM$(M(\cdot), q(\cdot))$ is nonempty and bounded. Therefore, $\|x^k\| \to \infty$ as $k \to \infty$ and

$$\frac{s(x^k)^{1/2}}{\|x^k\|} \le \frac{\|x^k - x^*(x^k)\|}{k\|x^k\|} \to 0 \text{ as } k \to \infty. \tag{5.2}$$

Let $\{x^{n_k}/\|x^{n_k}\|\}$ be a convergent subsequence of $\{x^k/\|x^k\|\}$. Note that

$$\begin{aligned}\lim_{k\to\infty} \frac{s(x^{n_k})^{1/2}}{\|x^{n_k}\|} &= \lim_{k\to\infty} \frac{(G(x^{n_k}) - \min_{x\in\mathbb{R}^n_+} G(x))^{1/2}}{\|x^{n_k}\|} = \lim_{k\to\infty} \frac{G(x^{n_k})^{1/2}}{\|x^{n_k}\|} \\ &= \lim_{k\to\infty} \left(\int_\Omega \sum_{i=1}^n \left| \min\left(\frac{[M(\omega)x^{n_k}]_i + q_i(\omega)}{\|x^{n_k}\|}, \frac{x_i^{n_k}}{\|x^{n_k}\|} \right) \right|^2 dF(\omega) \right)^{1/2}.\end{aligned}$$

Since for any x with $\|x\| = 1$,

$$\int_\Omega \sum_{i=1}^n |\min([M(\omega)x]_i + q_i(\omega), x_i)|^2 dF(\omega) \le \int_\Omega (\|M(\omega)\|^2 + \|q(\omega)\|^2) dF(\omega) + 1 < \infty,$$

by the dominated convergence theorem, we obtain

$$\lim_{k\to\infty} \frac{s(x^{n_k})^{1/2}}{\|x^{n_k}\|} = \left(\int_\Omega \sum_{i=1}^n |\min([M(\omega)\hat{x}]_i, \hat{x}_i)|^2 dF(\omega) \right)^{1/2} < \infty,$$

where $\hat{x}$ is an accumulation point of $\{x^{n_k}/\|x^{n_k}\|\}$. This, together with (5.2) and $s(x^{n_k})^{1/2}/\|x^{n_k}\| \ge 0$, yields

$$\int_\Omega \sum_{i=1}^n |\min([M(\omega)\hat{x}]_i, \hat{x}_i)|^2 dF(\omega) = 0,$$

which implies that $\hat{x}$ is a solution of the ERM$(M(\cdot), 0)$. Since $\|\hat{x}\| = 1$, this contradicts the assumption that $M(\cdot)$ is a stochastic R_0 matrix from Theorem 2.2 (iii). ∎

Remark. If Ω contains only one element ω and LCP$(M(\omega), q(\omega))$ has a solution, then error bounds in Theorems 5.1 and 5.4 reduce to the local and global error bounds for the R_0 matrix LCP given in [16]. Hence the two theorems are extensions of error bounds for the R_0 matrix LCP given in [16] to the stochastic R_0 matrix LCP in the ERM formulation.

6. Examples and numerical results. In this section, we report numerical results of four examples of the stochastic R_0 matrix LCP in the ERM formulation.

Let the measure of feasibility of $x \in \mathbb{R}^n_+$ with tolerance $\varepsilon \geq 0$ be defined by

$$rel_\varepsilon(x) = P\{\omega : [M(\omega)x]_i + q_i(\omega) \geq -\varepsilon,\ i = 1, \ldots, n\}. \tag{6.1}$$

This measure indicates how much we may expect that x satisfies the constraints $M(\omega)x + q(\omega) \geq 0$ (with some tolerance).

Example 6.1. We use $\tilde{M}$ and $M_0(\omega_0)$ given in Example 2.2, and

$$M_1(\omega') = \begin{pmatrix} 0 & 0 & 0 & -\omega_1 & 0 \\ 0 & 0 & 0 & 0 & -0.4 - 0.4\ln\omega_2 \\ 0 & 0 & 0 & 0 & 0 \\ \omega_1 & 0 & 0 & -2\sqrt{3}\omega_3 & -2\sqrt{3}\omega_3 \\ 0 & 0.4 + 0.4\ln\omega_2 & 0 & -3\omega_4 & 3\omega_4 \end{pmatrix},$$

where $\omega' = (\omega_1, \ldots, \omega_4)^T$ with the distributions of ω_1, ω_2, ω_3, ω_4 being $\mathcal{U}[-0.8, 0.8]$, $\mathcal{U}[0, 1]$, $\mathcal{N}(0, 1)$, and $\mathcal{N}(0, 1)$, respectively. Let $\omega = (\omega_0, \omega_1, \ldots, \omega_4)^T$ and $M(\omega) = \tilde{M} + M_0(\omega_0) + M_1(\omega')$. From Example 2.2, we know that $\tilde{M} + M_0(\omega_0)$ is a stochastic R_0 matrix. It is easy to verify that $E\{M_1(\omega')\} = 0$. Hence by Proposition 2.7, $M(\cdot)$ is a stochastic R_0 matrix.

We set $q(\omega) = \tilde{q} + q_0(\omega)$, where $\tilde{q}$ is a constant vector and $E\{q_0(\omega)\} = 0$. In this example, we choose

$$q_0(\omega) = (0.1\omega_0, 0.1\omega_0, 0, -2\sqrt{3}\omega_3, -3\omega_4)^T$$

with three different cases for $\tilde{q}$,

$$\tilde{q}^1 = (2, 3, 100, -180, -162)^T,\ \tilde{q}^2 = (-5, -5, 0, 10, 10)^T,\ \tilde{q}^3 = (-5, -5, -5, -5, -5)^T.$$

The deterministic LCP$(\tilde{M}, \tilde{q}^i)$, $i = 1, 2, 3$, have a unique solution $(36, 18, 0, 0.25, 0.5)^T$, multiple solutions $(0, 0, \lambda, 0, 0)^T$ with $\lambda \geq 5$, and no feasible solution, respectively.

For all $q_i(\omega)$, we can check that for any $x = (x_1, \ldots, x_5)^T \in \mathbb{R}^5_+$ with $x_i \neq 0, i = 1, 2$, the strict complementarity condition holds at x with probability one and so $\nabla G(x)$ exists at these points. Hence we can use a stochastic approximation algorithm [2, 14, 18] to find a minimizer of $G(x)$ in $\mathbb{R}^n_+$. The iterative formula is given by

$$x^{k+1} = \max(x^k - a_k f(x^k, \omega^k), 0), \tag{6.2}$$

where $f(x, \omega)$ is defined by (4.1), a_k is a stepsize satisfying $\sum_{k=1}^{\infty} a_k = \infty$ and $a_k \to 0$, and ω^k is the kth sample of ω. By the convergence theorems of stochastic approximation algorithms (see [2, Theorem 2.2.1] and [14, Theorem 5.2.1]), the generated sequence $\{x^k\}$ will converge to a connected set S such that every $\bar{x} \in S$ satisfies $\min(g(\bar{x}), \bar{x}) = 0$ with $g(x)$ defined in Theorem 4.2. If $\bar{x}_i \neq 0, i = 1, 2$, then by Theorem 4.3, $\nabla G(\bar{x}) = g(\bar{x})$. In this example, a_k is chosen as

$$a_k = \begin{cases} 0.003, & k \leq 10^4, \\ 0.0025, & 10^4 < k \leq 10^5, \\ 0.002, & 10^5 < k \leq 5 \times 10^5, \\ \frac{1}{k^{0.6}}, & 5 \times 10^5 < k \leq 2 \times 10^6. \end{cases}$$

When $k \geq 5 \times 10^5$, we use the averaging technique proposed by [18] to accelerate the convergence.

The stochastic approximation algorithm is a local optimization algorithm. To avoid being trapped in a local minimum, for each $\tilde{q}^i$, $i = 1, 2, 3$, we executed 36 times simulation from different initial points $x^0 = (10l, 10l', 0, 0, 0)^T$, $l, l' \in \{0, 1, \ldots, 5\}$. The step size a_k and initial points were chosen based on suggestions for stochastic approximation algorithms in [14].

For each $\tilde{q}^i$, the information on the last iterate x^{kmax}, where $kmax = 2 \times 10^6$, obtained by (6.2) is shown in Table 6.1. The columns labeled as "$G(x)$" and "$r(x)$" show the respective values obtained by the Monte Carlo method with 10^6 samples. The row labeled as "average" shows the average of the values obtained from 36 different initial points. The rows labeled as "min" and "max" indicate the interval of those values, which represents the variability of the values obtained from 36 different initial points.

Recall that the EV method solves the deterministic LCP$(\tilde{M}, \tilde{q})$. Let $\tilde{x}$ be a solution of LCP$(\tilde{M}, \tilde{q})$. For $\tilde{q}^2 = (-5, -5, 0, 10, 10)^T$, since there are multiple solutions $(0, 0, \lambda, 0, 0)^T$ with $\lambda \geq 5$, $G(x)$, and $r(x)$ are evaluated at $\tilde{x} = (0, 0, 5, 0, 0)^T$. There is no feasible solution of LCP$(\tilde{M}, \tilde{q})$ with $\tilde{q}^3 = (-5, -5, -5, -5, -5)^T$.

By using the Monte Carlo method with 10^6 samples, we evaluated the measure of feasibility rel_ε defined by (6.1) for the case of $\tilde{q}^1 = (2, 3, 100, -180, -162)^T$, at $\tilde{x} = (36, 18, 0, 0.25, 0.5)^T$ and at the last iterates obtained by the iterative formula (6.2) from 36 different initial points. The results are presented in Table 6.2. The row labeled as "ave.rel_ϵ" shows the average values of $rel_\varepsilon(x^{kmax})$ obtained at the 36 last iterates x^{kmax}. For each $\tilde{q}^i$ and initial points, the computational time for obtaining the values in Table 6.1 is about 185 seconds by MATLAB 7.0 with a computer with a Pentium 4 3.06 GHz CPU.

Example 6.2. In this example, we consider the case where $M(\omega) \equiv \tilde{M}$ is a P matrix and $q(\omega)$ has continuous distribution. In this case, the EV formulation LCP$(\tilde{M}, \tilde{q})$ has a unique solution $\tilde{x}$. The objective function G of the ERM formulation is twice continuously differentiable and the values of $G(x)$, $\nabla G(x)$, and $\nabla^2 G(x)$ can be computed by (4.7), (4.8), (4.10), respectively, without resorting to stochastic approximation.

Let $q(\omega) = \tilde{q} + q_0(\omega)$, where $\tilde{q} = E\{q(\omega)\}$, $q_0(\omega) = B\omega$, $\omega = (\omega_1, \omega_2, \omega_3)^T \in$

$\mathcal{N}(0, I)$, $B \in \mathbb{R}^{n\times 3}$ is 100% dense, and the elements of B are randomly generated with the uniform distribution $\mathcal{U}(0, 5)$. We use Example 4.4 of [4] to generate $\tilde{M}$ and $\tilde{q}$. First, we randomly generate 100% dense $A \in \mathbb{R}^{n\times n}$ and $\bar{q} \in \mathbb{R}^n$ whose elements are uniformly distributed in $(-5, 5)$. Then we use the QR decomposition of A to get an upper triangular matrix N, and obtain a triangular matrix $\tilde{M}$ by replacing the diagonal elements of N by their absolute values.

We first use Lemke's method [8] to find a solution $\tilde{x}$ of LCP$(\tilde{M}, \tilde{q})$, and then take $\tilde{x}$ as an initial point to find a local solution $\bar{x}$ of the ERM formulation by applying the semismooth Newton method [7] to the equation $\min(\nabla G(x), x) = 0$.

The numerical experiments were carried out for $n = 20$, 50, and 100. For each n, we generated 100 problems and solved them by the above-mentioned procedure. The figures presented in Table 6.3 are the average of the results obtained in this manner.

The measures rel_ε of feasibility at $\tilde{x}$ and $\bar{x}$ obtained by the EV method and the ERM method, respectively, are presented in Table 6.4.

Example 6.3. To illustrate the application of stochastic R_0 matrix linear complementarity problems, we use a simple transportation network shown in Figure 6.1, which is based on an example of the deterministic traffic equilibrium network model in [6].

In the network, two cities West and East are connected by two two-way roads and one one-way road. More specifically, the network consists of five links, L1, L2, L3, R1, R2, where L1, L2, L3 are directed from West to East, and R1 and R2 are the returns of L1 and L2, respectively. L1-R1 is a mountain road, and L2-R2 and L3 are seaside roads. We are interested in the traffic flow between the two cities. The Wardrop equilibrium principle states that each driver will choose the minimum cost route between the origin-destination pair, and through this process the routes that are used will have equal cost; routes with costs higher than the minimum will have no flow. In a deterministic model, the parameters in the demand and cost function are fixed, and the problem can be formulated as a (deterministic) LCP based on the

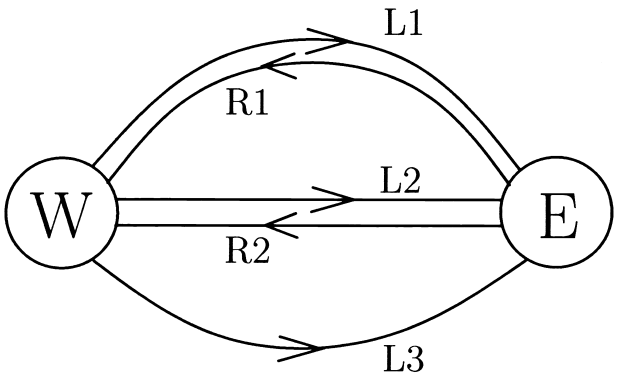

FIG. 6.1. *Road network.*

Wardrop equilibrium principle.

In practice, however, the traffic condition will be significantly affected by some uncertain factors such as weather. So we want to estimate the traffic flow and the travel time that are most likely to occur, before we know such uncertain factors.[1]

We suppose that there are three possible uncertain weather conditions; sunny, windy, and rainy. On a sunny day, the network is free from traffic congestion and the travel times of all roads are constant, which are given as $(c_1, c_2, c_3, c_4, c_5)^T = (1000, 950, 3000, 1000, 1300)^T$, where c_1, c_2, c_3, c_4, c_5 denote the travel times of roads L1, L2, L3, R1, R2, respectively. On a windy day, the seaside roads suffer from traffic jams due to congestion, and the travel times of the roads in the whole network are given by

$$\begin{pmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \\ c_5 \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 60 & 0 & 0 & 20 \\ 0 & 0 & 80 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 & 100 \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \\ v_5 \end{pmatrix} + \begin{pmatrix} 1000 \\ 950 \\ 3000 \\ 1000 \\ 1300 \end{pmatrix},$$

where v_1, v_2, v_3, v_4, v_5 denote the traffic volumes of roads L1, L2, L3, R1, R2, respectively. On the other hand, on a rainy day the mountain roads suffer from traffic jams, and the travel times of the roads in the whole network are given by

$$\begin{pmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \\ c_5 \end{pmatrix} = \begin{pmatrix} 40 & 0 & 0 & 20 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 8 & 0 & 0 & 80 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \\ v_5 \end{pmatrix} + \begin{pmatrix} 1000 \\ 950 \\ 3000 \\ 1000 \\ 1300 \end{pmatrix}.$$

Moreover, trip demands between the two cities are higher on a sunny day than on a windy or rainy day. Specifically, $(d_1, d_2)^T = (260, 170)^T$ on a sunny day and $(d_1, d_2)^T = (160, 70)^T$ on a windy or rainy day, where d_1 and d_2 are trip demands from West to East and from East to West, respectively.

It is convenient to represent the travel cost functions and trip demands in a unified

[1]It should be noted that we do not intend to construct a traffic equilibrium model in which the drivers choose their routes under uncertainty.

manner as follows:

$$c(v,\omega) = H(\omega)v + h,$$

where

$$c(v,\omega) = (c_1(v,\omega),\ldots,c_5(v,\omega))^T,$$

$$H(\omega) = \begin{pmatrix} 40\alpha(\omega) & 0 & 0 & 20\alpha(\omega) & 0 \\ 0 & 60\beta(\omega) & 0 & 0 & 20\beta(\omega) \\ 0 & 0 & 80\beta(\omega) & 0 & 0 \\ 8\alpha(\omega) & 0 & 0 & 80\alpha(\omega) & 0 \\ 0 & 4\beta(\omega) & 0 & 0 & 100\beta(\omega) \end{pmatrix},$$

$$\alpha(\omega) = \frac{1}{2}\omega(\omega-1), \quad \beta(\omega) = \omega(2-\omega), \quad h = (1000, 950, 3000, 1000, 1300)^T.$$

Here $\Omega = \{\omega^1, \omega^2, \omega^3\}$ with $\omega^1 = 0$, $\omega^2 = 1$, $\omega^3 = 2$ represents the set of uncertain events of the weather, {sunny, windy, rainy}, with probabilities $p_1 = \frac{1}{2}$, $p_2 = \frac{1}{4}$, $p_3 = \frac{1}{4}$, respectively. Also, the traffic flow $v = (v_1, v_2, v_3, v_4, v_5)^T$ should satisfy[2]

$$v \geq 0, \quad Bv \geq d(\omega),$$

where

$$B = \begin{pmatrix} 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 \end{pmatrix}, \quad d(\omega) = \begin{pmatrix} 260 - 100(\alpha(\omega) + \beta(\omega)) \\ 170 - 100(\alpha(\omega) + \beta(\omega)) \end{pmatrix}.$$

By Wardrop's principle, for each event $\omega \in \Omega$, the traffic equilibrium problem can be formulated as LCP$(M(\omega), q(\omega))$ with

$$M(\omega) = \begin{pmatrix} H(\omega) & -B^T \\ B & 0 \end{pmatrix}, \; q(\omega) = \begin{pmatrix} h \\ -d(\omega) \end{pmatrix}.$$

The solutions $x(\omega^i)$ of LCP$(M(\omega^i), q(\omega^i))$, $i = 1, 2, 3$ express the equilibrium traffic flow on each link as well as the minimum travel time between each origin-destination pair, on a sunny day, a windy day, and a rainy day, respectively. The average traffic flow is given by $(E\{x_1(\omega)\},\ldots,E\{x_5(\omega)\})$, and the average travel time on each direction is given by $(E\{x_6(\omega)\}, E\{x_7(\omega)\})$.

On the other hand, the average travel costs and demands are given by

$$E\{c(v,\omega)\} = \begin{pmatrix} 10 & 0 & 0 & 5 & 0 \\ 0 & 15 & 0 & 0 & 5 \\ 0 & 0 & 20 & 0 & 0 \\ 2 & 0 & 0 & 20 & 0 \\ 0 & 1 & 0 & 0 & 25 \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \\ v_5 \end{pmatrix} + \begin{pmatrix} 1000 \\ 950 \\ 3000 \\ 1000 \\ 1300 \end{pmatrix},$$

$$E\{d(\omega)\} = \begin{pmatrix} 210 \\ 120 \end{pmatrix},$$

[2]For the purpose of our presentation, we may replace the equality constraint $Bv = d(\omega)$ by the inequality constraint. In practice, this change will not affect the solution of the problem.

TABLE 6.5
Traffic flow and travel time for Example 6.3.

$x(\omega^3)$	(0, 160, 0, 3.75, 66.75, 950, 1300)
$E\{x(\omega)\}$	(39.8, 170.2, 0, 103.4, 16.6, 962.5, 1075)
$E\{\|\|x(\omega)-\tilde{x}\|\|\}$, $\|E\{x(\omega)\}-\tilde{x}\|\|$	2239.66, 2232.60
$E\{\|\|x(\omega)-\bar{x}\|\|\}$, $\|E\{x(\omega)\}-\bar{x}\|\|$	222.42, 127.16

which are exactly the same as those of the five-link example in [6].

Below we compare the estimates of the traffic flows and travel time obtained by the EV formulation and the ERM formulation.

The solution of the EV formulation, LCP$(E\{M(\omega)\}, E\{q(\omega)\})$, is denoted by $\tilde{x}$. The ERM formulation for this example is the problem of minimizing the function

$$G(x) = \sum_{i=1}^{3} p_i || \min(x, M(\omega^i)x + q)||^2.$$

We denote the solution by $\bar{x}$. In Table 6.5, we report numerical results.

It is observed from $\tilde{x}_3 = x(\omega^i) = 0, i = 1, 2, 3$ in Table 6.5 that the user-optimal load pattern estimated from the EV formulation has no flow on L3, which is the same as the user-optimal traffic pattern estimated from the LCPs for a sunny day, a windy day, and a rainy day, respectively. However, the estimated total travel time $\tilde{x}_6 + \tilde{x}_7 = 5190$ from the EV formulation is larger than the total travel time obtained from the LCP for any day. On the other hand, the user-optimal traffic pattern estimated from the ERM formulation has light flow on L3 and the total travel time $\bar{x}_6 + \bar{x}_7 = 1975$ is close to $x_6(\omega^i) + x_7(\omega^i), i = 1, 2, 3$.

The two formulations yield different estimates of the user-optimal traffic pattern and travel time, and both solutions, $\bar{x}$ and $\tilde{x}$, try to explain the phenomenon in the real world. The EV formulation uses the average of data to estimate the user-optimal traffic pattern. The ERM formulation uses the least square method to find a traffic pattern which has minimum total error to each user-optimal traffic pattern for each day. It is worth mentioning that, as far as this example is concerned, $\bar{x}$ may be considered closer to the realized traffic patterns than $\tilde{x}$ because $E\{\|x(\omega) - \tilde{x}\|\} > E\{\|x(\omega) - \bar{x}\|\}$ and $\|E\{x(\omega)\} - \tilde{x}\| > \|E\{x(\omega)\} - \bar{x}\|$.

Now, we use this example to show that the theoretical results given in this paper substantially extend the results in [3]. It is easy to verify that the matrix $E\{M(\omega)\}$ is an R_0 matrix. By Proposition 2.5, $M(\cdot)$ is a stochastic R_0 matrix. Hence by Theorem 3.1 the solution set of ERM$(M(\cdot), q(\cdot))$ is nonempty and bounded. However, for each ω^i, $M(\omega^i)$ is not an R_0 matrix. Hence the statement on the solution set cannot be obtained by using the results in [3].

Example 6.4. The last example is a simplified control problem: Let $\hat{\omega} \in \mathbb{R}^n$ be the system parameter. Based on prior experience, we assume that $\hat{\omega}$ is generated from $\mathcal{N}(a, B)$. At each time t, we have the following observer:

$$y_{t+1} = X_t\hat{\omega} + F_t v_t, \tag{6.3}$$

where $X_t \in \mathbb{R}^{m\times n}$ is a known input, $F_t \in \mathbb{R}^{m\times r}$ is a known matrix, and $v_t \in \mathbb{R}^r$ is an unknown noise which is independent identically and normally distributed with $E\{v_t\} = 0$, $E\{v_t v_t^T\} = I$.

Suppose $B \succ 0$ and $F_t F_t^T \succeq 0$. By the Kalman filter theory [1], we have the following recursive estimation for the parameter $\hat{\omega}$:

$$\begin{aligned} \omega_{t+1} &= \omega_t + K_{t+1}(y_{t+1} - X_t\omega_t), \\ K_{t+1} &= B_t X_t^T (X_t B_t X_t^T + F_t F_t^T)^+, \\ B_{t+1} &= B_t - B_t X_t^T K_{t+1}^T, \\ \omega_0 &= a, \ B_0 = B, \end{aligned} \tag{6.4}$$

where A^+ denotes the pseudoinverse of matrix A. Then the posterior distribution of $\hat{\omega}$ is given by $N(\omega_t, B_t)$. The control law u_t is obtained as a solution of the following convex quadratic program:

$$\begin{aligned} \min \ & c_t(\hat{\omega})^T u + \frac{1}{2} u^T Q_t(\hat{\omega}) u \\ \text{s.t.} \quad & A_t(\hat{\omega}) u \le b_t(\hat{\omega}) \\ & u \ge 0, \end{aligned} \tag{6.5}$$

where $Q_t(\hat{\omega})$, $A_t(\hat{\omega})$ are matrices and $c_t(\hat{\omega})$, $b_t(\hat{\omega})$ are vectors. The first order optimality condition of (6.5) is equivalent to the LCP$(M_t(\hat{\omega}), q_t(\hat{\omega}))$ with

$$M_t(\hat{\omega}) = \begin{pmatrix} Q_t(\hat{\omega}) & A_t(\hat{\omega})^T \\ -A_t(\hat{\omega}) & 0 \end{pmatrix}, \ q_t(\hat{\omega}) = \begin{pmatrix} c_t(\hat{\omega}) \\ b_t(\hat{\omega}) \end{pmatrix}.$$

In traditional adaptive control, we replace the unknown parameter $\hat{\omega}$ by its estimate ω_t in the quadratic program (6.5) to obtain an approximation $\check{u}_t$ of the control law u_t for each t, that is, $\check{u}_t$ is the vector whose elements are the first n components of the solution of the LCP$(M_t(\omega_t), q_t(\omega_t))$.

If ω_t is far away from the parameter $\hat{\omega}$, the error of $\check{u}_t$ is big and will cause trouble in some situations. Hence we take the variance of the estimate into account by using the solution $\bar{u}_t$ of the ERM formulation for SLCP$(M_t(\omega), q_t(\omega))$ with $\omega \sim \mathcal{N}(\omega_t, B_t)$. Here we report numerical results for a tracking problem with the ARX model $y_{t+1} = \hat{\omega}^{(1)} y_t + \hat{\omega}^{(2)} u_t + v_t$. The controller u_t would be designed so that y_{t+1} can track a given trajectory $\exp(0.5t)$. Let the performance function be $p(u_t, \omega) := (\omega^{(1)} y_t + \omega^{(2)} u_t - \exp(0.5t))^2$. Then, from

$$p(u_t, \omega) = (\omega^{(2)})^2 u_t^2 - 2(\exp(0.5t) - \omega^{(1)} y_t)\omega^{(2)} u_t + (\exp(0.5t) - \omega^{(1)} y_t)^2,$$

we have $c_t(\omega) = -2(\exp(0.5t) - \omega^{(1)} y_t)\omega^{(2)}$, $Q_t(\omega) = 2(\omega^{(2)})^2$. We set $X_t = (y_t, u_t)$ and choose $a = (0, 1)^T$, $B = \left(\begin{smallmatrix} 0.25 & 0 \\ 0 & 4 \end{smallmatrix}\right)$, $F_t = 1$, $A_t(\omega) \equiv 1$, $b_t(\omega) = 4 + 2(\omega^{(2)})^2$.

For $k \ge 1$, we generate a true parameter $\hat{\omega}^k$ from $\mathcal{N}(1, 1)$ and noise $\{v_t\}$ from $\mathcal{N}(0, 1)$. We solve the ERM formulation for SLCP$(M_t(\omega), q_t(\omega))$ with $\omega \sim \mathcal{N}(\omega_t, B_t)$ to obtain $\bar{u}_t^k$. We then set $X_t = (y_t^k, \bar{u}_t^k)$ and use (6.3) and (6.4) to obtain y_{t+1}^k, ω_{t+1}, and B_{t+1}. We also solve LCP$(M_t(\omega_t), q_t(\omega_t))$ and the EV formulation of SLCP$(M_t(\omega), q_t(\omega))$ with $\omega \sim \mathcal{N}(\omega_t, B_t)$ to get $\check{u}_t^k$ and $\tilde{u}_t^k$, respectively.

TABLE 6.6
Average performance for Example 6.4.

t	1	2	3	4	5
$\bar{\sigma}_t$	1.0103	1.9764	2.286	1.6755	1.8693
$\check{\sigma}_t$	1.7053	3.0257	2.3345	1.7385	1.8918
$\tilde{\sigma}_t$	1.2425	2.5505	2.3852	1.8015	2.0903

For the purpose of comparison, we define the average performance (for $k = 1, 2, \ldots, 100$) of these formulations by

$$\bar{\sigma}_t := \frac{1}{100}\sum_{k=1}^{100}(\bar{u}_t^k - u_t^*(\hat{\omega}^k))^2, \quad t = 1, 2, 3, 4, 5,$$

$$\check{\sigma}_t := \frac{1}{100}\sum_{k=1}^{100}(\check{u}_t^k - u_t^*(\hat{\omega}^k))^2, \quad t = 1, 2, 3, 4, 5,$$

$$\tilde{\sigma}_t := \frac{1}{100}\sum_{k=1}^{100}(\tilde{u}_t^k - u_t^*(\hat{\omega}^k))^2, \quad t = 1, 2, 3, 4, 5,$$

where $u_t^*(\hat{\omega}^k)$ is obtained by solving $\mathrm{LCP}(M_t(\hat{\omega}^k), q_t(\hat{\omega}^k))$ with true parameter $\hat{\omega}^k$.

From the results shown in Table 6.6, we find that the ERM formulation has better performance than $\mathrm{LCP}(M_t(\omega_t), q_t(\omega_t))$ and the EV formulation in the sense that $\bar{\sigma}_t < \check{\sigma}_t$ and $\bar{\sigma}_t < \tilde{\sigma}_t$ hold for all $t = 1, 2, 3, 4, 5$. This suggests that $\bar{u}_t^k$ is a better control law for $\hat{\omega}^k$ than $\tilde{u}_t^k$ and $\bar{u}_t^k$ in all cases.

7. Final remark. This paper proves that a necessary and sufficient condition for the $\mathrm{ERM}(M(\cdot), q(\cdot))$ having a nonempty and bounded solution set is that $M(\cdot)$ is a stochastic R_0 matrix. Proposition 2.5 shows that if the matrix $E\{M(\omega)\}$ is an R_0 matrix, then $M(\cdot)$ is a stochastic R_0 matrix. Moreover, Example 6.1 shows that there are many cases where $M(\cdot)$ is a stochastic R_0 matrix, but $E\{M(\omega)\}$ is not an R_0 matrix, and the EV formulation $\mathrm{LCP}(E\{M(\omega)\}, E\{q(\omega)\})$ either has no solution or has an unbounded solution set. Therefore, the condition for the $\mathrm{ERM}(M(\cdot), q(\cdot))$ having a nonempty and bounded solution set is weaker than the condition for the EV formulation having a nonempty and bounded solution set. Furthermore, when $\mathrm{ERM}(M(\cdot), q(\cdot))$ has a solution $\bar{x}$ and $\mathrm{LCP}(E\{M(\omega)\}, E\{q(\omega)\})$ has a solution $\tilde{x}$, the residuals always satisfy

$$G(\bar{x}) = E\{\|\min(M(\omega)\bar{x} + q(\omega), \bar{x})\|^2\} \le E\{\|\min(M(\omega)\tilde{x} + q(\omega), \tilde{x})\|^2\} = G(\tilde{x}).$$

Example 6.1 shows that $G(\bar{x})$ can be much smaller than $G(\tilde{x})$. Moreover, the values of rel_ε shown in Table 6.2 reveal that, for each tolerance level $\varepsilon \ge 0$, the number of ω^i at which $M(\omega^i)\bar{x} + q(\omega^i) < -\varepsilon$ holds is much less than the number of ω^i at which $M(\omega^i)\tilde{x} + q(\omega^i) < -\varepsilon$ holds. Example 6.2 shows that a local solution $\bar{x}$ of $\mathrm{ERM}(M(\cdot), q(\cdot))$ may conveniently be obtained from a solution $\tilde{x}$ of the EV formulation. Examples 6.3 and 6.4 show that the EV formulation and ERM formulation express different concerns in our real life. Solving the EV formulation is usually less expensive computationally than solving the ERM formulation. Nevertheless, since $\bar{x}$ is generally expected to have better reliability than $\tilde{x}$, we may recommend the ERM method to those decision makers who do not want to take the high risk of violating the conditions $M(\omega)x + q(\omega) \ge 0$.

Acknowledgments. We are very grateful to Professor Jong-Shi Pang and the referees of this paper for their helpful comments.

PEELING OFF A NONCONVEX COVER OF AN ACTUAL CONVEX PROBLEM: HIDDEN CONVEXITY*

Z. Y. WU†, D. LI‡, L. S. ZHANG§, AND X. M. YANG¶

Abstract. Convexity is, without a doubt, one of the most desirable features in optimization. Many optimization problems that are nonconvex in their original settings may become convex after performing certain equivalent transformations. This paper studies the conditions for such hidden convexity. More specifically, some transformation-independent sufficient conditions have been derived for identifying hidden convexity. The derived sufficient conditions are readily verifiable for quadratic optimization problems. The global minimizer of a hidden convex programming problem can be identified using a local search algorithm.

Key words. convexity, hidden convexity, hidden-convex function, hidden-convex programming problem, global optimization

1. Introduction.

We consider the following optimization problem:

$$(P) \qquad \begin{aligned} \min \ & g_0(x) \\ \text{s.t.} \ & g_k(x) \le b_k, k = 1, \ldots, m, \\ & x \in X, \end{aligned}$$

where $g_k : R^n \to R,\ k = 0, 1, \ldots, m,$ are second-order continuously differentiable functions and

$$X = \{x \in R^n \mid l_i \le x_i \le u_i,\ i = 1, \ldots, n\}. \tag{1.1}$$

Without loss of generality, we assume in this paper that $0 < l_i < u_i$ for all $i = 1, \ldots, n$.

When all of the functions g_k, $k = 0, 1, \ldots, m$, are convex, problem (P) is a convex programming problem that can be solved efficiently with many existing algorithms.

Convexity plays a central role in optimization theory. In addition to the many desirable properties that are enjoyed by convexity, convexity guarantees a local minimum to be a global solution at the same time. Observations and experiences of optimization, however, often reveal that convexity in many situations is a property that is associated with a given representation space. More specifically, an equivalent transformation may convert a nonconvex problem in its original setting to a convex problem in a transformed space. In this sense, convexity could be hidden, if the

representation space is "inappropriate." The purpose of this paper is to investigate the conditions for identifying such seemingly nonconvex problems that are actually hidden convex.

It is worth mentioning that convexity has been extended to various forms of generalized convexity in the literature [2], [3], [5], [10], [14], [15]. Examples of generalized convexities include pseudoconvexity and quasiconvexity. For many years, researchers have been exploring the situations in which the convexity condition can be relaxed to a certain degree, while, at the same time, some desirable properties that are similar to those enjoyed by convex functions are preserved.

Horst [8] discussed the concept of range and domain transformations that can convexify some nonconvex functions. Li et al. [12] derived specific sufficient conditions under which some nonconvex functions can be convexified by a domain transformation; especially, the relationship between monotonicity and domain transformation has been recently discussed in [11], [12], [16]. This paper considers specific sufficient conditions under which certain nonconvex functions can be convexified by using a range transformation or using both domain and range transformations. The results are then applied to the study of hidden-convex programming problems.

While the hidden convexity that can be identified by a domain transformation is confined to monotone functions [12], the hidden convexity that can be identified by a range transformation is limited to a subset of pseudoconvex functions. The most interesting finding of this paper is that a combined domain and range transformation is capable of identifying a general class of hidden-convex functions that goes beyond the class of second order differentiable quasiconvex functions. It is also worth pointing out that there is a significant difference between the methodologies involved in proving a hidden convexity only by a domain transformation [12] and those used in revealing a hidden convexity by a combined range and domain transformation. The identification of a general class of hidden-convex functions that is reported in this paper is accomplished by introducing a new concept of the constrained minimum eigenvalue of the Hessian of a transformed function, which requires a more complicated analysis than does the traditional approach of checking the minimum eigenvalue of the Hessian of a transformed function, as was used in [12] for a domain transformation.

This paper is organized as follows. In section 2, we derive some results on constrained minimum eigenvalues that are essential in later derivation for hidden convexity. Hidden convexity is introduced in section 3, and sufficient conditions are developed to recognize hidden-convex functions. The relationships among hidden convexity, pseudoconvexity, quasiconvexity, and monotonicity are discussed. Section 4 extends the earlier investigation to sufficient conditions for hidden-convex programming problems. The most promising results of this paper appear in section 5, in which implementable sufficient conditions are obtained for the identification of hidden-convex quadratic optimization problems. The paper finally concludes in section 6 with some discussion of future research topics.

2. Preliminaries.

2.1. Minimum eigenvalue and constrained minimum eigenvalue. Let $X \subset R^n$ be a compact set and S^n be the unit sphere in R^n, $\{d \in R^n \mid \|d\| = 1\}$. Let $A(x) = (a_{i,j}(x))_{n\times n}$ be a symmetric matrix defined on X with each $a_{i,j}(x)$ being assumed to be continuous and

$$b(x) = (b_1(x), \ldots, b_n(x))^T \tag{2.1}$$

be an n-dimensional vector function defined on X with each $b_i(x)$ being assumed to be continuous. We define the following for given matrix $A(x)$, vector $b(x)$, and a positive number q:

$$\lambda = \min_{x\in X, d\in S^n} d^T A(x) d, \tag{2.2}$$

$$\gamma = \min_{x\in X, d\in S^n, b^T(x)d=0} d^T A(x) d, \tag{2.3}$$

$$B_q(x) = qb(x)b^T(x) + A(x),$$

$$\mu_q = \min_{x\in X, d\in S^n} d^T B_q(x) d.$$

LEMMA 2.1. *For any $q > 0$,*

$$\lambda \le \mu_q \le \gamma$$

and

$$\lim_{q\to+\infty} \mu_q = \gamma.$$

Proof. The first part of the lemma is obvious. Therefore,

$$\limsup_{q\to+\infty} \mu_q \le \gamma. \tag{2.4}$$

For the second part of the lemma, we thus only need to prove that

$$\liminf_{q\to+\infty} \mu_q \ge \gamma. \tag{2.5}$$

Suppose that for any k, there exist $q_k > k$, $d_k \in S^n$, and $x_k \in X$, such that

$$d_k^T \Big(q_k b(x_k) b^T(x_k) + A(x_k) \Big) d_k \le \gamma - \alpha_0, \tag{2.6}$$

where α_0 is a positive number.

Because S^n and X are all compact sets, there must exist a subsequence $\{k_j\}$ of $\{k\}$, such that

$$\lim_{j\to\infty} d_{k_j} = d_0, \quad \lim_{j\to\infty} x_{k_j} = x_0,$$

where $d_0 \in S^n$ and $x_0 \in X$. We thus have the following from (2.6):

$$d_0^T A(x_0) d_0 + \limsup_{j\to\infty} q_{k_j} d_{k_j}^T b(x_{k_j}) b^T(x_{k_j}) d_{k_j} \le \gamma - \alpha_0. \tag{2.7}$$

Because $k_j \to \infty$ and $q_{k_j} > k_j$ for all j, we must have the following from (2.7):

$$(d_0^T b(x_0))^2 = 0.$$

Thus, (2.7) reduces to $d_0^T A(x_0) d_0 \le \gamma - \alpha_0$ which contradicts (2.3). Thus, (2.5) holds. Combining (2.5) with (2.4) yields $\lim_{q\to+\infty} \mu_q = \gamma$. ∎

We can conclude from Lemma 2.1 that $\gamma > 0$ if and only if there exists a positive number $q_0 > 0$ such that $\mu_q > 0$ when $q > q_0$.

COROLLARY 2.2. (1) *If $\gamma = \lambda$, then for any $q > 0$, $\mu_q = \lambda = \gamma$.*

(2) *If $\gamma > \lambda$, then for any $q > 0$, $\lambda < \mu_q \le \gamma$.*

Proof. (1). It is obvious from Lemma 2.1.

(2). From $\lambda = \min_{x\in X, d\in S^n} d^T A(x)d$, there exist $x_0 \in X$ and $d_0 \in S^n$ such that $\lambda = d_0^T A(x_0)d_0$. Next, we show that $(d_0^T b(x_0))^2 > 0$. If $(d_0^T b(x_0))^2 = 0$, then for any $q > 0$, we have $\mu_q \le q(d_0^T b(x_0))^2 + d_0^T A(x_0)d_0 = \lambda$. Thus, we have $\gamma = \lim_{q\to+\infty} \mu_q \le \lambda$. This contradicts $\gamma > \lambda$. Thus, we must have $(d_0^T b(x_0))^2 > 0$.

From $\mu_q = \min_{x\in X, d\in S^n} d^T \Big(A(x)+qb(x)b^T(x)\Big)d$, there exist $x_q \in X$ and $d_q \in S^n$, such that $\mu_q = q(d_q^T b(x_q))^2 + d_q^T A(x_q)d_q$. Obviously, we have

$$d_q^T A(x_q)d_q \ge d_0^T A(x_0)d_0.$$

If $d_q^T A(x_q)d_q = d_0^T A(x_0)d_0$, then, by the above proof, we have $(d_q^T b(x_q))^2 > 0$. Thus, $\mu_q > d_q^T A(x_q)d_q \ge \lambda$. If $d_q^T A(x_q)d_q > d_0^T A(x_0)d_0$, then we must have $\mu_q > \lambda$. In conclusion, if $\gamma > \lambda$, then for any $q > 0$, we have $\lambda < \mu_q \le \gamma$. ∎

2.2. Positiveness of constrained minimum eigenvalue. Compared to the minimum eigenvalue λ that is defined in (2.2), the exact value of the constrained minimum eigenvalue γ that is defined in (2.3) could be much more difficult to calculate. In certain cases, however, we only need to verify whether $\gamma > 0$ or not. Proposition 5 in [15] suggested a method to verify whether $\gamma > 0$ by working on an $(n+1)\times(n+1)$-bordered Hessian. In the following, we will give another method of verifying whether $\gamma > 0$ by checking whether an $(n-1)\times(n-1)$ matrix is positive definite or not.

We partition symmetric matrix A into the following form:

$$A(x) = \begin{pmatrix} A_1(x) & a(x) \\ a^T(x) & A_2(x) \end{pmatrix}_{n\times n},$$

where

$$A_1(x) = \begin{pmatrix} a_{1,1}(x) & \cdots & a_{1,n-1}(x) \\ \cdots & \cdots & \cdots \\ a_{n-1,1}(x) & \cdots & a_{n-1,n-1}(x) \end{pmatrix} = \Big(a_{i,j}(x)\Big)_{(n-1)\times(n-1)},$$
$$a(x) = \Big(a_{1,n}(x), \ldots, a_{n-1,n}(x)\Big)^T, \quad A_2(x) = \Big(a_{n,n}(x)\Big)_{1\times 1}.$$

For vector $b(x) = (b_1(x), \ldots, b_n(x))^T$ defined in (2.1), we assume that there exists an $i \in \{1, \ldots, n\}$, such that for any $x \in X$, $b_i(x) \ne 0$. Without loss of generality, we assume that $b_n(x) \ne 0$ for all $x \in X$. Let

$$c(x) = \left(\frac{b_1(x)}{b_n(x)}, \ldots, \frac{b_{n-1}(x)}{b_n(x)}\right)^T.$$

Define the following $(n-1)\times(n-1)$ matrix:

$$A_0(x) = A_1(x) - c(x)a^T(x) - a(x)c^T(x) + c(x)A_2(x)c^T(x).$$

THEOREM 2.3. *Assume that $a_{i,j}(x)$, $i, j = 1, \ldots, n$, and $b_i(x)$, $i = 1, \ldots, n$, are continuous on X, and $b_n(x) \ne 0$ for all $x \in X$. Then γ, as defined in* (2.3)*, is strictly positive if and only if $A_0(x)$ is positive definite for all $x \in X$.*

Proof. Because for any $x \in X,\ b_n(x) \neq 0$, we have

$$\begin{aligned}(d^T b(x))^2 = 0 &\Leftrightarrow \left(\sum_{i=1}^{n} b_i(x)d_i\right)^2 = 0\\ &\Leftrightarrow \sum_{i=1}^{n} b_i(x)d_i = 0\\ &\Leftrightarrow d_n = -\sum_{i=1}^{n-1}\frac{b_i(x)}{b_n(x)}d_i\\ &\Leftrightarrow d = \left(d_1, d_2, \ldots, d_{n-1}, -\sum_{i=1}^{n-1}\frac{b_i(x)}{b_n(x)}d_i\right)^T,\\ &= \left(d_1, \ldots, d_{n-1}, -\sum_{i=1}^{n-1} c_i(x)d_i\right)^T\\ &\qquad \text{for any } d_i \in R,\ i = 1, \ldots, n-1.\end{aligned}$$

Let $D_{n-1} = (d_1, \ldots, d_{n-1})^T$. Then, if d satisfies $(d^T b(x))^2 = 0$, then we have

$$d = \Big(D_{n-1}^T,\ -D_{n-1}^T c(x)\Big)^T \tag{2.8}$$

and

$$\begin{aligned}d^T A(x) d &= \Big(D_{n-1}^T,\ -D_{n-1}^T c(x)\Big)\begin{pmatrix} A_1(x) & a(x)\\ a^T(x) & A_2(x)\end{pmatrix}\begin{pmatrix} D_{n-1}\\ -c^T(x)D_{n-1}\end{pmatrix}\\ &= D_{n-1}^T\Big(A_1(x) - c(x)a^T(x) - a(x)c^T(x) + c(x)A_2(x)c^T(x)\Big)D_{n-1}\\ &= D_{n-1}^T A_0(x) D_{n-1}.\end{aligned}$$

From (2.8), we have $d \neq 0$ if and only if $D_{n-1} \neq 0$ and $d^T d = D_{n-1}^T\Big(I_{n-1} + c(x)c^T(x)\Big)D_{n-1}$. Thus, we have

$$\begin{aligned}\gamma &= \min_{x\in X, d\in S^n, b^T(x)d=0} d^T A(x) d\\ &= \min_{x\in X, D_{n-1}^T(c(x)c^T(x)+I_{n-1})D_{n-1}=1} D_{n-1}^T A_0(x) D_{n-1}.\end{aligned}$$

Because $c(x)c^T(x) + I_{n-1}$ is a positive definite matrix, there exists a symmetric nonsingular $(n-1)\times(n-1)$ matrix $E(x)$, such that

$$c(x)c^T(x) + I_{n-1} = E^T(x)E(x).$$

Let $\tilde{d}(x) = E(x)D_{n-1}$. Then,

$$D_{n-1}^T\Big(c(x)c^T(x) + I_{n-1}\Big)D_{n-1} = D_{n-1}^T E^T(x)E(x)D_{n-1} = \tilde{d}^T(x)\tilde{d}(x).$$

Thus, we have

$$\gamma = \min_{x\in X, \tilde{d}\in S^{n-1}} \tilde{d}^T (E^{-1}(x))^T A_0(x) E^{-1}(x)\tilde{d}.$$

Therefore, $\gamma > 0$ if and only if for any $x \in X$, $A_0(x)$ is positive definite. ∎

2.3. Linearly constrained minimum eigenvalue of a constant matrix. In this subsection, we further investigate the relationship between λ and γ, when A is a constant symmetric matrix and $b(x) = Ax + b$, $b \in R^n$. When A is a constant symmetric matrix, all of its eigenvalues can be readily obtained, for example, by using MATLAB programs. Let n eigenvalues of A be arranged as

$$\lambda_1 \le \lambda_2 \le \cdots \le \lambda_n.$$

Clearly, we have

$$\lambda = \min_{d \in S^n} d^T A d = \lambda_1.$$

There exists an orthogonal matrix Ω such that $\Omega^T = \Omega^{-1}$ and

$$\Omega^{-1} A \Omega = \Lambda = \operatorname{diag}(\lambda_1, \ldots, \lambda_n).$$

The orthogonal matrix Ω can be readily found by using, for example, the eigenvalue decomposition program in MATLAB. In general, we have

$$\gamma = \min_{(x,d) \in \Gamma} d^T A d \ge \lambda,$$

where $\Gamma = \{(x, d) \mid x \in X, d \in S^n, (Ax + b)^T d = 0\}$. If we let $d = \Omega \bar{d}$, then the expression of γ can be simplified to

$$\gamma = \min_{(x,\bar{d}) \in \bar{\Gamma}} \sum_{k=1}^{n} \lambda_k (\bar{d}_k)^2,$$

where $\bar{\Gamma} = \{(x, \bar{d}) \mid x \in X, \bar{d} \in S^n, (Ax + b)^T \Omega \bar{d} = 0\}$. If we further let $x = \Omega \widetilde{x}$, then the expression of γ can be further simplified to

$$\gamma = \min_{(\widetilde{x},\bar{d}) \in \widetilde{\Gamma}} \sum_{k=1}^{n} \lambda_k (\bar{d}_k)^2,$$

where $\widetilde{\Gamma} = \{(\widetilde{x}, \bar{d}) \mid \widetilde{x} \in \widetilde{X}, \bar{d} \in S^n, \sum_{i=1}^{n} (\lambda_i \widetilde{x}_i \bar{d}_i + \bar{b}_i \bar{d}_i) = 0\}$, $\widetilde{X} = \{\widetilde{x} \in R^n \mid L \le \Omega \widetilde{x} \le U\}$, $\bar{b} = \Omega^T b$, $L = (l_1, \ldots, l_n)^T$, and $U = (u_1, \ldots, u_n)^T$.

Let

$$O = \{i \mid \lambda_i = 0, i = 1, \ldots, n\}$$

and $\bar{O} = \{1, \ldots, n\} \setminus O$. Let $\varsigma_i = \frac{\bar{b}_i}{\lambda_i}$ if $i \in \bar{O}$ and $\varsigma_i = 0$ if $i \in O$. Let $\widetilde{x} = \bar{x}$ - ς, where $\varsigma = (\varsigma_1, \ldots, \varsigma_n)^T$. Finally, the expression of γ can be written in the following form:

$$\gamma = \min_{(\bar{x},\bar{d}) \in \hat{\Gamma}} \sum_{k=1}^{n} \lambda_k (\bar{d}_k)^2,$$

where $\hat{\Gamma} = \{(\bar{x}, \bar{d}) \mid \bar{x} \in \bar{X}, \bar{d} \in S^n, \sum_{i \in \bar{O}} \lambda_i \bar{x}_i \bar{d}_i + \sum_{i \in O} \bar{b}_i \bar{d}_i = 0\}$, $\bar{X} = \{\bar{x} \in R^n \mid L \le \Omega \bar{x} - \Omega \varsigma \le U\}$.

PROPOSITION 2.4. (i) *If* $\lambda_1 = \lambda_2$, *then* $\gamma = \lambda$;

(ii) *if* $0 = \lambda_1 < \lambda_2$, *then*

$$\gamma = \frac{(\bar{b}_1)^2}{(\bar{b}_1)^2 + (\lambda_2)^2 \beta_2} \lambda_2,$$

where $\beta_2 = \max_{x\in\bar{X}}(x_2)^2$*;*

(iii) *if* $\lambda_1 < \lambda_2$, $\lambda_1 \neq 0$, *and there exists a point* $\bar{x} \in \bar{X}$ *such that* $\bar{x}_1 = 0$, *then* $\gamma = \lambda$*;*

(iv) *if* $\lambda_1 < \lambda_2 = 0$ *and there does not exist any point* $\bar{x} \in \bar{X}$ *such that* $\bar{x}_1 = 0$, *then*

$$\gamma = \frac{(\bar{b}_2)^2}{(\bar{b}_2)^2 + (\lambda_1)^2\beta_1}\lambda_1,$$

where $\beta_1 = \max_{x\in\bar{X}}(x_1)^2$*; and*

(v) *if* $0 \neq \lambda_1 < \lambda_2 \neq 0$ *and there does not exist any point* $\bar{x} \in \bar{X}$ *such that* $\bar{x}_1 = 0$, *then*

$$\gamma = \lambda_1 + \frac{\lambda_2 - \lambda_1}{1 + (\frac{\lambda_2}{\lambda_1})^2\beta_{12}},$$

where $\beta_{12} = \max_{x\in\bar{X}}(\frac{x_2}{x_1})^2$.

Proof. (i) If $\lambda_1 = \lambda_2 = \lambda$, then, we have

$$\begin{aligned}\gamma &= \min_{\bar{x}\in\bar{X},\bar{d}\in S^n,\sum_{i\in\bar{O}}\lambda_i\bar{x}_i\bar{d}_i+\sum_{i\in O}\bar{b}_i\bar{d}_i=0}\sum_{k=1}^{n}\lambda_k(\bar{d}_k)^2\\ &= \min_{\bar{x}\in\bar{X},\sum_{i\in\bar{O}\cap\{1,2\}}\lambda_i\bar{x}_i\bar{d}_i+\sum_{i\in O\cap\{1,2\}}\bar{b}_i\bar{d}_i=0,\bar{d}_1^2+\bar{d}_2^2=1}\sum_{k=1}^{2}\lambda_k(\bar{d}_k)^2\\ &= \lambda.\end{aligned}$$

(ii) If $0 = \lambda_1 < \lambda_2$, then $1 \notin \bar{O}$ and $2 \notin O$. Thus,

$$\gamma = \min_{\bar{x}\in\bar{X},\sum_{i\in\bar{O}\cap\{2\}}\lambda_i\bar{x}_i\bar{d}_i+\sum_{i\in O\cap\{1\}}\bar{b}_i\bar{d}_i=0,\bar{d}_1^2+\bar{d}_2^2=1}\sum_{k=1}^{2}\lambda_k(\bar{d}_k)^2.$$

It is clear that if $\bar{b}_1 = 0$, then γ achieves its minimum of 0 by taking $\bar{d}_1 = 1$ and $\bar{d}_2 = 0$. Otherwise, if $\bar{b}_1 \neq 0$, then

$$\gamma = \min_{\bar{x}\in\bar{X},\bar{b}_1\bar{d}_1+\lambda_2\bar{x}_2\bar{d}_2=0,\bar{d}_1^2+\bar{d}_2^2=1}\lambda_2(\bar{d}_2)^2.$$

Because $\bar{b}_1\bar{d}_1 + \lambda_2\bar{x}_2\bar{d}_2 = 0$ and $\bar{d}_1^2 + \bar{d}_2^2 = 1$ imply $(\bar{d}_2)^2 = \frac{1}{1+(\frac{\lambda_2}{\bar{b}_1})^2(\bar{x}_2)^2}$, then we have that

$$\begin{aligned}\gamma &= \min_{\bar{x}\in\bar{X},\bar{b}_1\bar{d}_1+\lambda_2\bar{x}_2\bar{d}_2=0,\bar{d}_1^2+\bar{d}_2^2=1}\lambda_2(\bar{d}_2)^2\\ &= \min_{\bar{x}\in\bar{X}}\frac{\lambda_2}{1+(\frac{\lambda_2}{\bar{b}_1})^2(\bar{x}_2)^2}\\ &= \frac{\lambda_2}{1+(\frac{\lambda_2}{\bar{b}_1})^2\cdot\max_{\bar{x}\in\bar{X}}(\bar{x}_2)^2}\\ &= \frac{(\bar{b}_1)^2}{(\bar{b}_1)^2+(\lambda_2)^2\beta_2}\lambda_2.\end{aligned}$$

Thus, item (ii) of Proposition 2.4 is satisfied for both situations of $\bar{b}_1 = 0$ and $\bar{b}_1 \neq 0$.

(iii) If $\lambda_1 \neq 0$, then $1 \notin O$. Further, since there exists a point $\bar{x} \in \bar{X}$, such that $\bar{x}_1 = 0$, we have

$$\begin{aligned}\gamma &= \min_{\bar{x}\in\bar{X},\sum_{i\in\bar{O}\cap\{1,2\}}\lambda_i\bar{x}_i\bar{d}_i+\sum_{i\in O\cap\{2\}}\bar{b}_i\bar{d}_i=0,\bar{d}_1^2+\bar{d}_2^2=1}\sum_{k=1}^{2}\lambda_k(\bar{d}_k)^2\\ &\leq \min_{\bar{x}\in\{x|x\in\bar{X},\ x_1=0\},\sum_{i\in\bar{O}\cap\{2\}}\lambda_i\bar{x}_i\bar{d}_i+\sum_{i\in O\cap\{2\}}\bar{b}_i\bar{d}_i=0,\bar{d}_1^2+\bar{d}_2^2=1}\sum_{k=1}^{2}\lambda_k(\bar{d}_k)^2\\ &\leq \lambda_1(\text{where we take } \bar{d}_1 = 1, \bar{d}_2 = 0).\end{aligned}$$

Because $\gamma \geq \lambda_1$, we have $\gamma = \lambda_1 = \lambda$.

(iv) Because $\lambda_1 < \lambda_2 = 0$, then $1 \notin O$ and $2 \notin \bar{O}$. We have

$$\begin{aligned}\gamma &= \min_{\bar{x}\in\bar{X},\sum_{i\in\bar{O}\cap\{1\}}\lambda_i\bar{x}_i\bar{d}_i+\sum_{i\in O\cap\{2\}}\bar{b}_i\bar{d}_i=0,\bar{d}_1^2+\bar{d}_2^2=1}\sum_{k=1}^{2}\lambda_k(\bar{d}_k)^2\\ &= \min_{\bar{x}\in\bar{X},\lambda_1\bar{x}_1\bar{d}_1+\bar{b}_2\bar{d}_2=0,\bar{d}_1^2+\bar{d}_2^2=1}\lambda_1(\bar{d}_1)^2.\end{aligned}$$

If $\bar{b}_2 = 0$, then we must have $\bar{d}_1 = 0$ because $\lambda_1 < 0$, and there does not exist any $\bar{x} \in \bar{X}$, such that $\bar{x}_1 = 0$. Thus, $\gamma = 0$ when $\bar{b}_2 = 0$. Otherwise, when $\bar{b}_2 \neq 0$, $\lambda_1\bar{x}_1\bar{d}_1 + \bar{b}_2\bar{d}_2 = 0$ and $\bar{d}_1^2 + \bar{d}_2^2 = 1$ imply $(\bar{d}_1)^2 = \frac{1}{1+(\frac{\lambda_1}{b_2})^2\bar{x}_1^2}$. We then have

$$\begin{aligned}\gamma &= \min_{\bar{x}\in\bar{X},\lambda_1\bar{x}_1\bar{d}_1+\bar{b}_2\bar{d}_2=0,\bar{d}_1^2+\bar{d}_2^2=1}\lambda_1(\bar{d}_1)^2\\ &= \frac{\lambda_1}{1+(\frac{\lambda_1}{\bar{b}_2})^2\max\limits_{\bar{x}\in\bar{X}}(\bar{x}_1)^2}\\ &= \frac{(\bar{b}_2)^2}{(\bar{b}_2)^2+(\lambda_1)^2\beta_1}\lambda_1.\end{aligned}$$

Thus, item (iv) of Proposition 2.4 is satisfied for both situations of $\bar{b}_2 = 0$ and $\bar{b}_2 \neq 0$.

(v) Because both λ_1 and λ_2 are not equal to zero, neither 1 nor 2 belongs to O. Then,

$$\gamma = \min_{\bar{x}\in\bar{X},\lambda_1\bar{x}_1\bar{d}_1+\lambda_2\bar{x}_2\bar{d}_2=0,\bar{d}_1^2+\bar{d}_2^2=1}\sum_{k=1}^{2}\lambda_k(\bar{d}_k)^2.$$

Because for any $\bar{x} \in \bar{X}$, $\bar{x}_1 \neq 0$, then $\lambda_1\bar{x}_1\bar{d}_1 + \lambda_2\bar{x}_2\bar{d}_2 = 0$ and $\bar{d}_1^2 + \bar{d}_2^2 = 1$ imply that $(\bar{d}_2)^2 = \frac{1}{1+(\frac{\lambda_2}{\lambda_1})^2(\frac{\bar{x}_2}{\bar{x}_1})^2}$. Thus, we have

$$\begin{aligned}\gamma &= \min_{\bar{x}\in\bar{X},\lambda_1\bar{x}_1\bar{d}_1+\lambda_2\bar{x}_2\bar{d}_2=0,\bar{d}_1^2+\bar{d}_2^2=1}\sum_{k=1}^{2}\lambda_k(\bar{d}_k)^2\\ &= \min_{\bar{x}\in\bar{X}}\left[\left(1-\frac{1}{1+(\frac{\lambda_2}{\lambda_1})^2(\frac{\bar{x}_2}{\bar{x}_1})^2}\right)\lambda_1+\frac{1}{1+(\frac{\lambda_2}{\lambda_1})^2(\frac{\bar{x}_2}{\bar{x}_1})^2}\lambda_2\right]\\ &= \lambda_1+\frac{\lambda_2-\lambda_1}{1+(\frac{\lambda_2}{\lambda_1})^2\max_{\bar{x}\in\bar{X}}(\frac{\bar{x}_2}{\bar{x}_1})^2}\\ &= \lambda_1+\frac{\lambda_2-\lambda_1}{1+(\frac{\lambda_2}{\lambda_1})^2\beta_{12}}. \qquad \square\end{aligned}$$

Remark 2.1. (i) To judge whether there exists a point $\bar{x} \in \bar{X}$ such that $\bar{x}_1 = 0$, two linear programming problems can be constructed, $\{\max x_1 \mid x \in \bar{X}\}$ and $\{\min x_1 \mid x \in \bar{X}\}$. If $\max_{x\in\bar{X}} x_1 < 0$ or $\min_{x\in\bar{X}} x_1 > 0$, then there does not exist an $\bar{x} \in \bar{X}$, such that $\bar{x}_1 = 0$. Otherwise, there exists one.

(ii) For β_1 in (iv) and β_2 in (ii) of the above proposition, the convex maximization (or, equivalently, concave minimization) problem of $\{\max(x_i)^2 \mid x \in \bar{X}\}$, i = 1, 2, can be replaced by two linear programming problems, $\{\max x_i \mid x \in \bar{X}\}$ and $\{\min x_i \mid x \in \bar{X}\}$, because $\max_{x\in\bar{X}}(x_i)^2 = \max\{(\max_{x\in\bar{X}} x_i)^2, (\min_{x\in\bar{X}} x_i)^2\}$.

(iii) Consider β_{12} in (v) of the above proposition. Let $y_1 = \frac{1}{x_1}$ and $y_i = \frac{x_i}{x_1}$, $i = 2, \ldots, n$. If for every $\bar{x} \in \bar{X}$, $\bar{x}_1 > 0$, then problem $\{\max(\frac{x_2}{x_1})^2 \mid x \in \bar{X}\}$ is equivalent to $\{\max(y_2)^2 \mid y \in \bar{Y}_1\}$, where

$$\bar{Y}_1 = \{y \in R^n \mid y_1 L \le \Omega(1, y_2, \ldots, y_n)^T - \Omega\varsigma y_1 \le y_1 U\},$$

whereas convex maximization (or, equivalently, concave minimization) problem $\{\max(y_2)^2 \mid y \in \bar{Y}_1\}$ can be replaced by two linear programming problems, $\{\max y_2 \mid y \in \bar{Y}_1)$ and $(\min y_2 \mid y \in \bar{Y}_1\}$, because $\max_{y\in\bar{Y}_1}(y_2)^2 = \max\{\big(\max_{y\in\bar{Y}_1} y_2\big)^2, \big(\min_{y\in\bar{Y}_1} y_2\big)^2\}$. Similarly, if for every $\bar{x} \in \bar{X}$, $\bar{x}_1 < 0$, then $\max_{x\in\bar{X}}(\frac{x_2}{x_1})^2 = \max\{\big(\max_{y\in\bar{Y}_2} y_2\big)^2, \big(\min_{y\in\bar{Y}_2} y_2\big)^2\}$, where

$$\bar{Y}_2 = \{y \in R^n \mid y_1 L \ge \Omega(1, y_2, \ldots, y_n)^T - \Omega\varsigma y_1 \ge y_1 U\}.$$

Based on the above proposition, the computation of the linearly constrained minimum eigenvalue of a constant matrix can be carried out by the following algorithm.

Algorithm I (Calculation of γ).

Step 1. Calculate an orthogonal matrix Ω such that

$$\Omega^T A \Omega = \operatorname{diag}(\lambda_1, \ldots, \lambda_n),$$

where $\lambda_1, \ldots, \lambda_n$ are the eigenvalues of A satisfying $\lambda_1 \le \cdots \le \lambda_n$. Let $\bar{b} = (\bar{b}_1, \ldots, \bar{b}_n)^T := \Omega^T b$ and $\varsigma = (\varsigma_1, \ldots, \varsigma_n)^T$, where $\varsigma_i := \begin{cases} \frac{\bar{b}_i}{\lambda_i} & \text{if } \lambda_i \ne 0, \\ 0 & \text{if } \lambda_i = 0. \end{cases}$

Step 2. If $\lambda_1 = \lambda_2$, then $\gamma = \lambda_1$ and stop; otherwise go to Step 3.

Step 3. If $\lambda_1 = 0$, then solve the following linear programming problems:

$$(P_1) \qquad \begin{aligned} &\max x_2 \\ &L \le \Omega(x - \varsigma) \le U \end{aligned}$$

and

$$(P_2) \qquad \begin{aligned} &\min x_2 \\ &L \le \Omega(x - \varsigma) \le U. \end{aligned}$$

Let v_1 and v_2 be the optimal values of problems (P_1) and (P_2), respectively. Let $\beta_2 = \max\{v_1^2, v_2^2\}$. Then $\gamma = \frac{(\bar{b}_1)^2\lambda_2}{(\bar{b}_1)^2 + (\lambda_2)^2\beta_2}$ and stop. If $\lambda_1 \ne 0$, then go to Step 4.

Step 4. Solve the following linear programming problems:

$$(P_3) \qquad \begin{aligned} &\max x_1 \\ &L \le \Omega(x - \varsigma) \le U \end{aligned}$$

and

$$(P_4) \qquad \begin{aligned} &\min x_1 \\ &L \le \Omega(x-\varsigma) \le U. \end{aligned}$$

Let v_3 and v_4 be the optimal values of problems (P_3) and (P_4), respectively. If $v_3 \ge 0 \ge v_4$, then $\gamma = \lambda_1$ and stop; otherwise go to Step 5.

Step 5. If $\lambda_2 = 0$, let $\beta_1 = \max\{v_3^2, v_4^2\}$, then $\gamma = \frac{(\bar{b}_2)^2\lambda_1}{(\bar{b}_2)^2+(\lambda_1)^2\beta_1}$ and stop; otherwise go to Step 6.

Step 6. If $v_4 > 0$, then solve the following linear programming problems:

$$(P_5) \qquad \begin{aligned} &\max y_2 \\ &y_1 L \le \Omega(1-y_1\varsigma_1, y_2-y_1\varsigma_2, \ldots, y_n-y_1\varsigma_n)^T \le y_1 U \end{aligned}$$

and

$$(P_6) \qquad \begin{aligned} &\min y_2 \\ &y_1 L \le \Omega(1-y_1\varsigma_1, y_2-y_1\varsigma_2, \ldots, y_n-y_1\varsigma_n)^T \le y_1 U. \end{aligned}$$

Let v_5 and v_6 be the optimal values of problems (P_5) and (P_6), respectively. Let $\beta_3 = \max\{v_5^2, v_6^2\}$. Then, $\gamma = \lambda_1 + \frac{\lambda_2-\lambda_1}{1+\left(\frac{\lambda_2}{\lambda_1}\right)^2\beta_3}$ and stop; otherwise, solve the following linear programming problems:

$$(P_7) \qquad \begin{aligned} &\max y_2 \\ &y_1 L \ge \Omega(1-y_1\varsigma_1, y_2-y_1\varsigma_2, \ldots, y_n-y_1\varsigma_n)^T \ge y_1 U \end{aligned}$$

and

$$(P_8) \qquad \begin{aligned} &\min y_2 \\ &y_1 L \ge \Omega(1-y_1\varsigma_1, y_2-y_1\varsigma_2, \ldots, y_n-y_1\varsigma_n)^T \ge y_1 U. \end{aligned}$$

Let v_7 and v_8 be the optimal values of problems (P_7) and (P_8), respectively. Let $\beta_4 = \max\{v_7^2, v_8^2\}$. Then $\gamma = \lambda_1 + \frac{\lambda_2-\lambda_1}{1+\left(\frac{\lambda_2}{\lambda_1}\right)^2\beta_4}$ and stop.

3. Hidden-convex function.

DEFINITION 3.1 (see [11]). *A function $f : R^n \to R$ is strictly increasing (decreasing) on X with respect to x_i if*

$$f(x_1, \ldots, x_{i-1}, \tilde{x}_i, x_{i+1}, \ldots, x_n) < (>)\ f(x_1, \ldots, x_{i-1}, \bar{x}_i, x_{i+1}, \ldots, x_n)$$

for any $(x_1, \ldots, x_{i-1}, \tilde{x}_i, x_{i+1}, \ldots, x_n)^T$, $(x_1, \ldots, x_{i-1}, \bar{x}_i, x_{i+1}, \ldots, x_n)^T \in X$, and $\tilde{x}_i < (>)\ \bar{x}_i$.

DEFINITION 3.2. *A function f: $R^n \to R$ is said to be strictly monotone if for any $i = 1, \ldots, n$, f is either strictly increasing or strictly decreasing on X with respect to x_i.*

Let function h be a second order continuously differentiable function that is defined on the box X given in (1.1). Consider the following three transformations of function h:

$$\begin{aligned} \phi(y) &= h(t(y)), \\ \varphi(x) &= T(h(x)), \\ \psi(y) &= T(h(t(y))), \end{aligned} \tag{3.1}$$

where $T : R^1 \to R^1$ is a real function and $t : R^n \to R^n$ is a separable mapping, i.e., $t(y) = \Big(t_1(y_1), \ldots, t_n(y_n)\Big)^T$ for $y = (y_1, \ldots, y_n)^T$. We further assume that each t_i, $i = 1, \cdots, n$, is a strictly monotone mapping. It is clear that the domain of ϕ and ψ is

$$\begin{aligned} Y &= \{y \in R^n \mid y_i = t_i^{-1}(x_i), i = 1, \ldots, n,\ x \in X\} \\ &= \left\{ y \in R^n \;\middle|\; \begin{array}{ll} t_i^{-1}(l_i) \le y_i \le t_i^{-1}(u_i), & t_i(y_i) \text{ is strictly increasing,} \\ t_i^{-1}(u_i) \le y_i \le t_i^{-1}(l_i), & t_i(y_i) \text{ is strictly decreasing} \end{array} \right\}. \end{aligned}$$

Obviously, Y is also a box. For the purpose of convenience, let $\min_{x\in\emptyset} x = +\infty$ and $\max_{x\in\emptyset} x = -\infty$, where $x \in R$.

DEFINITION 3.3. *If there exists a separable strictly monotone mapping $x = t(y)$, such that $\phi(y) = h(t(y))$ is a (strictly) convex function on Y, then h is called a* d-hidden (strictly) convex function *on X.*

DEFINITION 3.4. *If there exists a strictly increasing and second order continuously differentiable function $T(\cdot) : h(X) \to R$ satisfying $T'(y) > 0$ for any $y \in h(X)$, such that $\varphi(x) = T(h(x))$ is a (strictly) convex function on X, then h is called an* r-hidden (strictly) convex function *on X.*

The r-hidden convex function is also called a G-convex function on X [4].

DEFINITION 3.5. *If there exist a strictly increasing and second order continuously differentiable function $T(\cdot)$ satisfying $T'(y) > 0$ for any $y \in h(X)$ and a separable strictly monotone mapping $x = t(y)$, such that the function $\psi(y) = T(h(t(y)))$ is (strictly) convex on Y, then h is called a* hidden (strictly) convex function *on X.*

Obviously, a convex function is also d-hidden convex, r-hidden convex, and hidden convex. From Definitions 3.3, 3.4, and 3.5, we know that if function h is d-hidden convex or r-hidden convex, then h is also hidden convex. From [1], we know that if function h is r-hidden convex, then h must be pseudoconvex. Because the hidden-convex function that is defined in Definition 3.5 confines its variable transformation to being separable, the hidden-convex function is thus a special case of the (t, T)-convex function that is defined in [8]. It is well known that any local minimizer of a pseudoconvex function on a convex set is also a global minimizer. In this paper, we will also show that any local minimizer of a hidden-convex function on a box set is also a global minimizer.

3.1. Necessary and sufficient conditions for r-hidden convex functions. Notice that

$$\begin{aligned} \frac{\partial\varphi(x)}{\partial x_i} &= T'(h(x))\frac{\partial h(x)}{\partial x_i},\ i = 1, \ldots, n, \\ \frac{\partial^2\varphi(x)}{\partial x_i^2} &= T'(h(x))\left[\frac{T''(h(x))}{T'(h(x))}\left(\frac{\partial h(x)}{\partial x_i}\right)^2 + \frac{\partial^2 h(x)}{\partial x_i^2}\right],\ i = 1, \ldots, n, \\ \frac{\partial^2\varphi(x)}{\partial x_i \partial x_j} &= T'(h(x))\left[\frac{T''(h(x))}{T'(h(x))}\frac{\partial h(x)}{\partial x_i}\frac{\partial h(x)}{\partial x_j} + \frac{\partial^2 h(x)}{\partial x_i \partial x_j}\right], \\ & \qquad i, j = 1, \ldots, n,\ i \ne j. \end{aligned}$$

Let $H(x)$ and $\bar{H}(x)$ be the Hessian of h and φ at x, respectively. Also let $a_h(x) = \nabla h(x) = \left(\frac{\partial h(x)}{\partial x_1}, \ldots, \frac{\partial h(x)}{\partial x_n}\right)^T$ be the gradient of $h(x)$ at x. Thus, we have

$$\bar{H}(x) = T'(h(x))\left[\frac{T''(h(x))}{T'(h(x))}a_h(x)a_h^T(x) + H(x)\right].$$

Let

$$\begin{aligned}\lambda^h &= \min_{x\in X, d\in S^n} d^T H(x) d,\\ \gamma^h &= \min_{x\in X, d\in S^n, a_h^T(x)d=0} d^T H(x) d,\\ B_q^h(x) &= q a_h(x) a_h^T(x) + H(x),\\ \mu_q^h &= \min_{x\in X, d\in S^n} d^T B_q^h(x) d.\end{aligned}$$

THEOREM 3.6. *Given a second order differentiable function h defined on the box set X, the following statements hold:*

(i) *h is an r-hidden strictly convex function if $\gamma^h > 0$ and*

(ii) *$\gamma^h \geq 0$ if h is an r-hidden convex function.*

Proof. (i) Clearly, h is an r-hidden strictly convex function if for any $x \in X$, $\bar{H}(x)$ is positive definite. Furthermore, because $T'(h(x)) > 0$ for any $x \in X$, $\bar{H}(x)$ is positive definite if and only if $\dfrac{T''(h(x))}{T'(h(x))} a_h(x) a_h^T(x) + H(x)$ is positive definite.

If we take $T(s) = \exp(qs)$ with $q > 0$, then T satisfies the following conditions:

$$T'(s) > 0, \ \frac{T''(s)}{T'(s)} = q \quad \forall s \in R.$$

Thus,

$$\frac{T''(h(x))}{T'(h(x))} a_h(x) a_h^T(x) + H(x) = q a_h(x) a_h^T(x) + H(x).$$

By Lemma 2.1, if $\gamma^h > 0$, then there exists a positive number $q > 0$, such that $\mu_q^h > 0$, i.e., $q a_h(x) a_h^T(x) + H(x)$ is positive definite on X. Thus, $\varphi(x)$ is strictly convex when $T(s)$ is selected as $\exp(qs)$ with a large enough q. This implies that h is an r-hidden strictly convex function on X.

(ii) If $h(x)$ is an r-hidden convex function, then there must exist a second order continuously differentiable function T, satisfying $T'(h(x)) > 0$ for any $x \in X$, such that $\dfrac{T''(h(x))}{T'(h(x))} a_h(x) a_h^T(x) + H(x)$ is a positive semidefinite matrix, i.e.,

$$\eta = \min_{x\in X, \ d\in S^n} d^T \left(\frac{T''(h(x))}{T'(h(x))} a_h(x) a_h^T(x) + H(x) \right) d \geq 0.$$

Because

$$\begin{aligned}\gamma^h &= \min_{x\in X, d\in S^n, d^T a_h(x)=0} d^T H(x) d\\ &= \min_{x\in X, d\in S^n, d^T a_h(x)=0} d^T \left(\frac{T''(h(x))}{T'(h(x))} a_h(x) a_h^T(x) + H(x) \right) d\\ &\geq \eta.\end{aligned}$$

Thus, we have that $\gamma^h \geq 0$. ∎

Theorem 3.6 gives a sufficient condition under which a function h can be converted into a strictly convex function only by a range transformation and a necessary condition under which a function h can be converted into a convex function only by

a range transformation. As is well known, these r-hidden convex functions must be pseudoconvex. Notice that a sufficient condition for pseudoconvexity of a second order differentiable function [5] is that for all $x \in X$, $\frac{1}{2}[\delta - h(x)]a_h(x)a_h^T(x) + H(x)$ is positive semidefinite for some $\delta > h(x)$.

In the following, we will give a condition under which a function can be converted into a convex function using both a range transformation and a domain transformation.

3.2. Sufficient conditions for hidden-convex functions. Let index set $NZ \subset \{1, \ldots, n\}$ be defined as

$$NZ = \left\{ i \in \{1, \ldots, n\} \mid \frac{\partial h(x)}{\partial x_i} \neq 0 \ \text{ for any } x \in X \right\}. \tag{3.2}$$

If $NZ \neq \emptyset$, then we assume, without loss of generality, that $NZ = \{l+1, \ldots, n\}$, where $l \in \{0, 1, \ldots, n-1\}$; otherwise, we can appropriately rearrange x_i, $i = 1, \ldots, n$. If $NZ = \emptyset$, then we let $l = n$. Note that l is the number of indices such that whenever $l > 0$ there exists an x, such that $\frac{\partial h(x)}{\partial x_i} = 0$ for $1 \leq i \leq l$.

For a given second order differentiable function h, let

$$H_k(x) = \begin{pmatrix} \dfrac{\partial^2 h(x)}{\partial x_1^2} & \cdots & \dfrac{\partial^2 h(x)}{\partial x_1 \partial x_k} \\ \vdots & \vdots & \vdots \\ \dfrac{\partial^2 h(x)}{\partial x_k \partial x_1} & \cdots & \dfrac{\partial^2 h(x)}{\partial x_k^2} \end{pmatrix}, \ k = 1, \ldots, n, \tag{3.3}$$

$$a_{h,k}(x) = \left(\frac{\partial h(x)}{\partial x_1}, \ldots, \frac{\partial h(x)}{\partial x_k} \right)^T, \ k = 1, \ldots, n, \tag{3.4}$$

$$\lambda_k^h = \min_{x \in X, d \in S^k} d^T (H_k(x)) d, \ k = 1, \ldots, n,$$

$$\gamma_k^h = \min_{x \in X, d \in S^k, a_{h,k}^T(x) d = 0} d^T (H_k(x)) d, \ k = 1, \ldots, n, \tag{3.5}$$

$$\Xi_k(x) = \left(\frac{\partial^2 h(x)}{\partial x_1 \partial x_k}, \ldots, \frac{\partial^2 h(x)}{\partial x_{k-1} \partial x_k} \right)^T, \ k = 2, \ldots, n,$$

$$C_{p,k}(x) = \operatorname{diag}\left(p_1 \frac{\partial h(x)}{\partial x_1}, \ldots, p_k \frac{\partial h(x)}{\partial x_k} \right), \ k = 1, \ldots, n, \tag{3.6}$$

$$\text{where } p_i \in R, \ i = 1, \ldots, k,$$

$$\nu_{k,p}^h = \min_{x \in X, d \in S^k, a_{h,k}^T(x) d = 0} d^T (H_k(x) + C_{p,k}(x)) d, \ k = 1, \ldots, n,$$

$$\nu_k^h = \sup_{p \in R^k} \nu_{k,p}^h.$$

If $l < n$, then let

$$\xi_k(x) = \left(\frac{\partial h(x)}{\partial x_1} / \frac{\partial h(x)}{\partial x_{k+1}}, \ldots, \frac{\partial h(x)}{\partial x_k} / \frac{\partial h(x)}{\partial x_{k+1}} \right)^T, \ k = l, \ldots, n-1.$$

Notice $H_n(x) = H(x)$, $a_{h,n}(x) = a_h(x)$, $\lambda_n^h = \lambda^h$, and $\gamma_n^h = \gamma^h$.

Furthermore, define the following set:

$$P_k = \{ p = (p_1, \ldots, p_k)^T \mid p \text{ is chosen such that } \nu_{k,p}^h > 0 \}, \ k = 1, \ldots, n.$$

For given $p_1, \ldots, p_n \in R$, let

$$t_{i,p_i}(y_i) = \begin{cases} y_i & p_i = 0, \\ -\dfrac{1}{p_i} \ln y_i & p_i \neq 0, \end{cases} \quad i = 1, \ldots, n,$$

$$Y_p = \{y \in R^n \mid (t_{1,p_1}(y_1), \ldots, t_{n,p_n}(y_n))^T \in X\},$$

$$Y_{i,p} = \{y_i \mid \exists y_j,\ j = 1, \ldots, i-1, i+1, \ldots, n \text{ such that } (y_1, \ldots, y_{i-1}, y_i, y_{i+1}, \ldots, y_n)^T \in Y_p\}.$$

Then, $t_{i,p_i}(y_i)$ is strictly monotone on $Y_{i,p}$ and satisfies

$$t'_{i,p_i}(y_i) \neq 0,$$
$$\frac{t''_{i,p_i}(y_i)}{\left[t'_{i,p_i}(y_i)\right]^2} = p_i \ \text{ for any } y_i \in Y_{i,p},\ i = 1, \ldots, n.$$

For given $q > 0$, let $T_q(s) = \exp(qs)$. Then $T_q(s)$ satisfies

$$T'_q(s) > 0,\ \frac{T''_q(s)}{T'_q(s)} = q \quad \forall s \in R.$$

Let $x = t_p(y) = (t_{1,p_1}(y_1), \ldots, t_{n,p_n}(y_n))^T$ and $\psi_{q,p}(y) = T_q(h(t_p(y)))$ for all $y \in Y_p$. Then, we have

$$\begin{aligned}
\frac{\partial \psi_{q,p}(y)}{\partial y_k} &= T'_q(h(x)) \frac{\partial h(x)}{\partial x_k} t'_{k,p_k}(y_k), \\
\frac{\partial^2 \psi_{q,p}(y)}{\partial y_k^2} &= T''_q(h(x)) \left[\frac{\partial h(x)}{\partial x_k} t'_{k,p_k}(y_k)\right]^2 + T'_q(h(x)) \frac{\partial^2 h(x)}{\partial x_k^2} [t'_{k,p_k}(y_k)]^2 \\
&\quad + T'_q(h(x)) \frac{\partial h(x)}{\partial x_k} t''_{k,p_k}(y_k) \\
&= T'_q(h(x)) [t'_{k,p_k}(y_k)]^2 \\
&\quad \times \left[\frac{T''_q(h(x))}{T'_q(h(x))} \left(\frac{\partial h(x)}{\partial x_k}\right)^2 + \frac{\partial^2 h(x)}{\partial x_k^2} + \frac{\partial h(x)}{\partial x_k} \frac{t''_{k,p_k}(y_k)}{[t'_{k,p_k}(y_k)]^2}\right] \\
&= T'_q(h(x)) [t'_{k,p_k}(y_k)]^2 \left[q\left(\frac{\partial h(x)}{\partial x_k}\right)^2 + \frac{\partial^2 h(x)}{\partial x_k^2} + p_k \frac{\partial h(x)}{\partial x_k}\right], \\
\frac{\partial^2 \psi_{q,p}(y)}{\partial y_k \partial y_j} &= T'_q(h(x)) t'_{k,p_k}(y_k) t'_{j,p_j}(y_j) \left[q \frac{\partial h(x)}{\partial x_k} \frac{\partial h(x)}{\partial x_j} + \frac{\partial^2 h(x)}{\partial x_k \partial x_j}\right], \\
&\qquad \text{for } k \neq j.
\end{aligned}$$

THEOREM 3.7. *Given a second order continuously differentiable function h, if $l \geq 1$ and $\nu_l^h > 0$, i.e., $P_l \neq \emptyset$, then h is a hidden strictly convex function.*

Proof. Let $\psi(y)$ in (3.1) be $\psi_{q,p}(y)$. Let $H_{q,p}(y)$ be Hessian of $\psi_{q,p}$ at y. Then, we have

$$H_{q,p}(y) = T'_q(h(x)) S(x) [q a_{h,n}(x) a_{h,n}^T(x) + H_n(x) + C_{p,n}(x)] S(x),$$

where

$$S(x) = \operatorname{diag}\Big(t'_{1,p_1}(y_1), t'_{2,p_2}(y_2), \ldots, t'_{n,p_n}(y_n)\Big),$$

and $H_n(x)$, $a_{h,n}(x)$ and $C_{p,n}(x)$ are defined in (3.3), (3.4), and (3.6), respectively.

Obviously, $H_{q,p}(y)$ is positive definite if and only if $qa_{h,n}(x)a_{h,n}^T(x) + H_n(x) + C_{p,n}(x)$ is positive definite. By Lemma 2.1, for a given vector $p \in R^n$, there exists a positive number q_0 such that $q_0 a_{h,n}(x)a_{h,n}^T(x) + H_n(x) + C_{p,n}(x)$ is positive definite if and only if $\nu_{n,p}^h > 0$. Note that

$$H_n(x) + C_{p,n}(x) = \begin{pmatrix} H_{n-1}(x) + C_{p,n-1}(x) & \Xi_n(x) \\ \Xi_n^T(x) & \dfrac{\partial^2 h(x)}{\partial x_n^2} + p_n \dfrac{\partial h(x)}{\partial x_n} \end{pmatrix}.$$

If $n \in NZ$, then, by Theorem 2.3, $\nu_{n,p}^h > 0$ if and only if $H_{n-1}(x) + C_{p,n-1}(x) - \Xi_n(x)\xi_{n-1}^T(x) - \xi_{n-1}(x)\Xi_n^T(x) + \left(\dfrac{\partial^2 h(x)}{\partial x_n^2} + p_n \dfrac{\partial h(x)}{\partial x_n}\right)\xi_{n-1}(x)\xi_{n-1}^T(x)$ is positive definite. Note that

$$\begin{aligned} &H_{n-1}(x) + C_{p,n-1}(x) - \Xi_n(x)\xi_{n-1}^T(x) - \xi_{n-1}(x)\Xi_n^T(x) \\ &+ \left(\frac{\partial^2 h(x)}{\partial x_n^2} + p_n \frac{\partial h(x)}{\partial x_n}\right)\xi_{n-1}(x)\xi_{n-1}^T(x) \\ &= H_{n-1}(x) + C_{p,n-1}(x) + (\xi_{n-1}(x) - \Xi_n(x))(\xi_{n-1}(x) - \Xi_n(x))^T \\ &- \Xi_n(x)\Xi_n^T(x) + \left(\frac{\partial^2 h(x)}{\partial x_n^2} + p_n \frac{\partial h(x)}{\partial x_n} - 1\right)\xi_{n-1}(x)\xi_{n-1}^T(x). \end{aligned}$$

For any $k \in NZ$, $\dfrac{\partial h(x)}{\partial x_k} \neq 0$ for any $x \in X$, i.e., $\left|\dfrac{\partial h(x)}{\partial x_k}\right| > 0$ for any $x \in X$. Let

$$\begin{aligned} m_k &= \min_{x \in X} \left|\frac{\partial h(x)}{\partial x_k}\right|, \\ \alpha_k &= \min_{x \in X} \frac{\partial^2 h(x)}{\partial x_k^2}, \\ q_k &= |p_k| m_k + \alpha_k - 1, \\ W_{k,p}(x) &= H_k(x) + C_{p,k}(x) + (\xi_k(x) - \Xi_{k+1}(x))(\xi_k(x) - \Xi_{k+1}(x))^T \\ &\quad -\Xi_{k+1}(x)\Xi_{k+1}^T(x). \end{aligned} \tag{3.7}$$

For any $k \in NZ$, let p_k satisfy

$$\operatorname{sign}(p_k) = \operatorname{sign}\left(\frac{\partial h(x)}{\partial x_k}\right), \tag{3.8}$$

where $\operatorname{sign}(t) = \begin{cases} 1 & t > 0, \\ 0 & t = 0, \\ -1 & t < 0. \end{cases}$

Then, for any $x \in X$, we have $\dfrac{\partial^2 h(x)}{\partial x_k^2} + p_k \dfrac{\partial h(x)}{\partial x_k} - 1 \geq q_k$.

If q_n and p_n are selected according to (3.7) and (3.8), respectively, then for any $x \in X$: if $W_{n-1,p}(x) + q_n \xi_{n-1}(x)\xi_{n-1}^T(x)$ is a positive definite matrix, then $W_{n-1,p}(x) + \left(\dfrac{\partial^2 h(x)}{\partial x_n^2} + p_n \dfrac{\partial h(x)}{\partial x_n} - 1\right)\xi_{n-1}(x)\xi_{n-1}^T(x)$ must be positive definite.

By Lemma 2.1, there exists a $q_n > 0$, such that for any $x \in X$, $W_{n-1,p}(x) + q_n \xi_{n-1}(x)\xi_{n-1}^T(x)$ is positive definite if and only if

$$\min_{x\in X, d\in S^{n-1}, d^T\xi_{n-1}(x)=0} d^T W_{n-1,p}(x) d > 0.$$

Note that

$$\begin{aligned}
&\min_{x\in X, d\in S^{n-1}, d^T\xi_{n-1}(x)=0} d^T W_{n-1,p}(x) d \\
&= \min_{x\in X, d\in S^{n-1}, d^T\xi_{n-1}(x)=0} \Big[d^T \Big(H_{n-1}(x) + C_{p,n-1}(x) \Big) d - d^T \Xi_n(x) \Xi_n^T(x) d \\
&\quad + d^T \Big((\xi_{n-1}(x) - \Xi_n(x))(\xi_{n-1}(x) - \Xi_n(x))^T \Big) d \Big] \\
&= \min_{x\in X, d\in S^{n-1}, d^T a_{h,n-1}(x)=0} d^T \Big(H_{n-1}(x) + C_{p,n-1}(x) \Big) d \\
&= \nu_{n-1,p}^h.
\end{aligned}$$

Thus, if $\nu_{n-1,p}^h > 0$, then there exists a $q_n^* > 0$, such that for any $x \in X$, $W_{n-1,p}(x) + q_n^* \xi_{n-1}(x)\xi_{n-1}^T(x)$ is positive definite. If we take p_n satisfying (3.8), and $|p_n|$ is large enough such that $q_n = |p_n| m_n + \alpha_n - 1 \geq q_n^*$, then for any $x \in X$, $W_{n-1,p}(x) + \left(\dfrac{\partial^2 h(x)}{\partial x_n^2} + p_n \dfrac{\partial h(x)}{\partial x_n} - 1 \right) \xi_{n-1}(x)\xi_{n-1}^T(x)$ is positive definite. Because for any $x \in X$, $W_{n-1,p}(x) + \left(\dfrac{\partial^2 h(x)}{\partial x_n^2} + p_n \dfrac{\partial h(x)}{\partial x_n} - 1 \right) \xi_{n-1}(x)\xi_{n-1}^T(x)$ is positive definite if and only if $\nu_{n,p}^h > 0$. Thus, we must have $\nu_n^h > 0$.

Similarly, we can prove that if $n-1 \in NZ$ and $\nu_{n-2}^h > 0$, then we can properly choose p_{n-1} such that $\nu_{n-1}^h > 0$. Repeating this process, we can prove for all $k = n-3$, $n-4, \ldots, l$, that if $\nu_k^h > 0$, then we can properly choose p_{k+1} such that $\nu_{k+1}^h > 0$.

From the above discussion, we know that if $l \geq 1$ and $\nu_l^h > 0$, i.e., $P_l \neq \emptyset$, then we can properly choose p_k, $k = l+1, \ldots, n$, such that $\nu_n^h > 0$. Note that $\nu_n^h > 0$ if and only if there exist a positive number $q_0 > 0$ and a vector $p \in R^n$, such that for any $x \in X$, $q_0 a_{h,n}(x) a_{h,n}^T(x) + H_n(x) + C_{p,n}(x)$ is positive definite. Thus, $H_{q_0,p}(y)$ is positive definite on Y_p which implies that $\psi_{q_0,p} = T_{q_0}(h(t_p(y)))$ is strictly convex on Y_p. Thus, if $l \geq 1$ and $\nu_l^h > 0$, i.e., $P_l \neq \emptyset$, then $h(x)$ must be a hidden strictly convex function on X. □

Based on Theorem 3.7, we have the following corollary.

COROLLARY 3.8. *If a second order continuously differentiable function h defined on X is either strictly increasing or strictly decreasing for all x_i, $i = 1, \ldots, n$, and satisfies for all $i = 1, \ldots, n$,*

$$\frac{\partial h(x)}{\partial x_i} \neq 0 \quad \forall x \in X, \tag{3.9}$$

i.e., $l = 0$, then h is hidden strictly convex.

Proof. If a second order continuously differentiable function h satisfies (3.9), i.e., $l = 0$, then we know from Theorem 3.7 that $h(x)$ is a hidden strictly convex function on X if $P_1 \neq \emptyset$. Because $1 \in NZ$, we can take p_1, satisfying $\operatorname{sign}(p_1) = \operatorname{sign}\left(\dfrac{\partial h(x)}{\partial x_1} \right)$ and $|p_1|$ large enough such that $\alpha_1 + |p_1| m_1 > 0$, resulting in $\nu_{1,p_1}^h > 0$. Thus, if $l = 0$,

then we can have $\nu_1^h > 0$, i.e., $P_1 \neq \emptyset$. Therefore, if $l = 0$, then h is hidden strictly convex. □

Corollary 3.8 reveals that if a second order continuously differentiable strictly monotone function does not have any of its partial derivatives equal to zero at any point on X, then the monotone function is hidden convex. Essentially, this result was proved earlier in [12], which found that such a monotone function is a d-hidden convex function on X.

Let the upper and lower bounds of $\dfrac{\partial h(x)}{\partial x_i}$, η_i and ζ_i, be defined as follows:

$$\eta_i \geq \max_{x \in X} \frac{\partial h(x)}{\partial x_i},$$
$$\zeta_i \leq \min_{x \in X} \frac{\partial h(x)}{\partial x_i}.$$

Recall l as defined in the beginning of subsection 3.2 and γ_l^h as defined in (3.5). Let

$$A_i = \{p_i \in R \mid \zeta_i \cdot p_i \cdot s(p_i) + \eta_i \cdot p_i \cdot s(-p_i) > -\gamma_l^h\}, \tag{3.10}$$
$$A = \{p = (p_1, \ldots, p_l)^T \mid p_i \in A_i,\ i = 1, \ldots, l\},$$

where

$$s(a) = \begin{cases} 1 & a \geq 0, \\ 0 & a < 0. \end{cases}$$

THEOREM 3.9. *Assume that h is second order continuously differentiable on X. If $A \neq \emptyset$, then h must be a hidden strictly convex function on X.*

Proof. For $d \in S^l$ and $x \in X$, we have

$$\begin{aligned}
\nu_{l,p}^h &= \min_{x \in X, d \in S^l, d^T a_{h,l}(x) = 0} d^T \Big(H_l(x) + C_{p,l}(x) \Big) d \\
&\geq \min_{x \in X, d \in S^l, d^T a_{h,l}(x) = 0} d^T H_l(x) d + \min_{x \in X, d \in S^l, d^T a_{h,l}(x) = 0} \sum_{i=1}^{l} p_i \frac{\partial h(x)}{\partial x_i} d_i^2 \\
&\geq \gamma_l^h + \min_{d \in S^l} \sum_{i=1}^{l} \Big(\zeta_i \cdot p_i \cdot s(p_i) + \eta_i \cdot p_i \cdot s(-p_i) \Big) d_i^2 \\
&\geq \gamma_l^h + \min_{1 \leq i \leq l} \Big(\zeta_i \cdot p_i \cdot s(p_i) + \eta_i \cdot p_i \cdot s(-p_i) \Big).
\end{aligned}$$

If $A \neq \emptyset$, i.e., there exists $(p_1, \ldots, p_l)^T \in R^l$, such that for any $i = 1, \ldots, l$, $\zeta_i \cdot p_i \cdot s(p_i) + \eta_i \cdot p_i \cdot s(-p_i) > -\gamma_l^h$, i.e., $\gamma_l^h + \min_{1 \leq i \leq l} (\zeta_i \cdot p_i \cdot s(p_i) + \eta_i \cdot p_i \cdot s(-p_i)) > 0$. Thus, there exists $(p_1, \ldots, p_l)^T \in R^l$, such that $\nu_{l,p}^h > 0$, which implies that h is a hidden strictly convex function based on Theorem 3.7. Thus, if $A \neq \emptyset$, then h must be a hidden strictly convex function. □

Remark 3.1. (i) Recall that a strictly positive γ^h gives an r-hidden strictly convex function. At the same time, if $\gamma^h > 0$, then any A_i is nonempty, as evidenced by $p_i = 0 \in A_i$, $i = 1, \ldots, n$. Thus, any function with $\gamma^h > 0$ is hidden strictly convex. (ii) Recall that a function is d-hidden strictly convex if $\{p_i \mid \zeta_i \cdot p_i \cdot s(p_i) + \eta_i \cdot p_i \cdot s(-p_i) > -\lambda_l^h\}$ is nonempty for all $i = 1, \ldots, n$ [12]. Because $\gamma_l^h \geq \lambda_l^h$, a nonempty $\{p_i \mid \zeta_i \cdot p_i \cdot s(p_i) + \eta_i \cdot p_i \cdot s(-p_i) > -\lambda_l^h\}$ is a subset of A_i. Thus, a function is hidden strictly convex if $\{p_i \mid \zeta_i \cdot p_i \cdot s(p_i) + \eta_i \cdot p_i \cdot s(-p_i) > -\lambda_l^h\}$ is nonempty for all $i = 1, \ldots, n$. In this regard, Theorem 3.9 includes r-hidden convex functions and d-hidden convex function as its special cases.

3.3. Relationship among hidden convexity, monotonicity, pseudoconvexity, and quasiconvexity. We have so far given some sufficient conditions to identify a hidden-convex function. Recall that all convex functions, r-hidden convex functions, d-hidden convex functions, and strictly monotone functions (with all partial derivatives being nonzero at all points in its domain) are hidden-convex functions, and any r-hidden convex function is a pseudoconvex function. We now explore the relationships among these different generalized convex functions.

We first introduce the following notations.

C: Family of second order continuously differentiable convex functions on X.

P: Family of second order continuously differentiable pseudoconvex functions on X.

Q: Family of second order continuously differentiable quasiconvex functions on X.

DH: Family of second order continuously differentiable d-hidden convex functions on X.

RH: Family of second order continuously differentiable r-hidden convex functions on X.

M: Family of second order continuously differentiable strictly monotone functions with all partial derivatives being nonzero at all points on X.

H: Family of second order continuously differentiable hidden-convex functions on X.

The following conclusions can now be obtained.

(1) $C \subset DH \subset H$;
(2) $C \subset RH \subset H$;
(3) $RH \subset P \subset Q$;
(4) $M \subset DH \subset H$;
(5) $M \cup RH$ is a strict subset of H; and
(6) $P \not\subseteq H,\ H \not\subseteq P$, and $H \not\subseteq Q$.

The first four inclusion relationships are apparent from our earlier discussion and from the literature. In the following, we will give some examples to show that $M \cup RH$ is a strict subset of H and that H has no inclusion relationship with either P or Q.

Example 3.1. Let $h(x) = x_1^3 - 4x_1^2 - x_1x_2 - \frac{1}{2}x_2^2 - x_1x_3 - \frac{1}{2}x_3^2 + 10x_3$ and $X = \{(x_1, x_2, x_3)^T \mid 1 \le x_1 \le 5,\ 1 \le x_i \le 2,\ i = 2, 3\}$. Obviously, we have

$$\frac{\partial h(x)}{\partial x_1} = 3x_1^2 - 8x_1 - x_2 - x_3, \quad \frac{\partial h(x)}{\partial x_2} = -x_1 - x_2,$$
$$\frac{\partial h(x)}{\partial x_3} = -x_1 - x_3 + 10.$$

It is easy to check that $NZ = \{2, 3\}$, where NZ is defined by (3.2). Because h is not monotone with respect to x_1, $h \notin M$. The Hessian of $h(x)$ is

$$H(x) = \begin{pmatrix} 6x_1 - 8 & -1 & -1 \\ -1 & -1 & 0 \\ -1 & 0 & -1 \end{pmatrix},$$

with eigenvalues

$$\lambda_1 = \frac{(6x_1 - 7) + \sqrt{(6x_1 - 7)^2 + 8}}{2} - 1,\ \lambda_2 = \frac{(6x_1 - 7) - \sqrt{(6x_1 - 7)^2 + 8}}{2} - 1$$
$$\lambda_3 = -1.$$

It is clear that $H(x)$ has two negative eigenvalues for any $x \in X$, which implies that h is not a pseudoconvex function, as the Hessian of any pseudoconvex function has at most one negative eigenvalue (see Corollary 3.18 in [1]). Thus, it is impossible for h to be an RH function, i.e., $h \notin RH$.

We can prove, however, that h is a hidden strictly convex function. In fact, because $NZ = \{2, 3\}$, $l = 1$, and $\gamma_l^h = \min_{x \in X, \frac{\partial h(x)}{\partial x_1} = 0}(6x_1 - 8) = \min_{x \in X} 2\Big(4 + \sqrt{16 + 3(x_2 + x_3)}\Big) - 8 = 2\sqrt{22} > 0$. Setting $p_1 = 0$ in (3.10) leads to $A_1 = A \neq \emptyset$. Thus, based on Theorem 3.9, h is a hidden strictly convex function on X, i.e., $h \in H$. The above example gives concrete evidence that $M \cup RH$ is a strict subset of H.

Example 3.2. Let $h(x) = \dfrac{x_2}{x_1}$ and $X = \{(x_1, x_2)^T \mid 1 \leq x_1 \leq 2, -1 \leq x_2 \leq 1\}$. Note that for any $\bar{x} \in X$, $\left(\dfrac{\partial h(\bar{x})}{\partial x}\right)^T (x - \bar{x}) = \left(-\dfrac{\bar{x}_2}{(\bar{x}_1)^2}, \dfrac{1}{\bar{x}_1}\right)(x_1 - \bar{x}_1, x_2 - \bar{x}_2)^T \geq 0$ implies $\dfrac{x_2}{x_1} \geq \dfrac{\bar{x}_2}{\bar{x}_1}$, i.e., $h(x) \geq h(\bar{x})$. Thus, based on the definition of pseudoconvexity given in section 3.1 of Chapter 9 of [10], $h(x)$ is a pseudoconvex function on X, i.e., $h(x) \in P$. Because

$$-1 \leq \frac{\partial h(x)}{\partial x_1} = -\frac{x_2}{x_1^2} \leq 1,$$
$$\frac{1}{2} \leq \frac{\partial h(x)}{\partial x_2} = \frac{1}{x_1} \leq 1,$$

the index set defined in (3.2) is $NZ = \{2\}$ and $h \notin M$. As the Hessian $H(x)$ of $h(x)$ is

$$H(x) = \begin{pmatrix} 2\dfrac{x_2}{x_1^3} & -\dfrac{1}{x_1^2} \\ -\dfrac{1}{x_1^2} & 0 \end{pmatrix},$$

h is nonconvex. Note that $l = 1$, $H_1(x) = \dfrac{2x_2}{x_1^3}$, $p_1 \in R$, $C_{p,1}(x) = -\dfrac{p_1 x_2}{x_1^2}$, $a_{h,1}(x) = -\dfrac{x_2}{x_1^2}$,

$$\gamma_1^h = \min_{x \in X, d \in S^1, d^T a_{h,1}(x) = 0} H_1(x) d^2 = 0,$$
$$\nu_1^h = \min_{x \in X, d \in S^1, d^T a_{h,1}(x) = 0} \Big(H_1(x) + C_{p,1}(x)\Big) d^2 = 0.$$

Thus, both P_1 in Theorem 3.7 and A_1 in Theorem 3.9 are empty sets. Neither Theorem 3.7 nor Theorem 3.9 can be used as a sufficient condition to show the hidden convexity of h.

Example 3.3. Let $h(x) = x_1^2 - 3x_1 - x_2^2 - x_3^2 + 5x_2 + x_3 - 3$ and $X = \{(x_1, x_2, x_3)^T \mid 1 \le x_i \le 2,\ i = 1, 2, 3\}$. Obviously, we have

$$\begin{aligned} -1 \le \frac{\partial h(x)}{\partial x_1} &= 2x_1 - 3 \le 1 \quad \text{for any } x \in X, \\ \frac{\partial h(x)}{\partial x_2} &= -2x_2 + 5 \ge 1 \quad \text{for any } x \in X, \\ \frac{\partial h(x)}{\partial x_3} &= -2x_3 + 1 \le -1 \quad \text{for any } x \in X. \end{aligned}$$

Thus, $h \notin M$. Because the Hessian of $h(x)$,

$$H(x) = \begin{pmatrix} 2 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & -2 \end{pmatrix}$$

has two negative eigenvalues, h is not a pseudoconvex function. Because $RH \subset P$, $h \notin RH$.

We can prove, however, that h is a hidden strictly convex function. In fact, because $NZ = \{2, 3\}$, $l = 1$ and $\gamma_l^h = \min_{x \in X, \frac{\partial h(x)}{\partial x_1} = 0} 2 = 2 > 0$. Setting $p_1 = 0$ in (3.10) leads to $A_1 = A \ne \emptyset$. Thus, based on Theorem 3.9, h is a hidden strictly convex function on X, i.e., $h \in H$.

Example 3.4. Let $h(x) = -x_1^2 - x_2^2$ and $X = \{(x_1, x_2)^T \mid 1 \le x_i \le 2,\ i = 1, 2\}$. Because the set $\{(x_1, x_2)^T \in X \mid h(x) \le -2\} = \{(x_1, x_2)^T \in X \mid x_1^2 + x_2^2 \ge 2\}$ is not convex, h is not a quasiconvex function on X. Clearly, h is a monotone function on X that satisfies (3.9). Thus, based on Corollary 3.8, h is a hidden-convex function. In summary, $h \in M \subset H$, but $h \notin Q$.

We note here that for quadratic functions, $RH = P$ (see [14]). Thus, for quadratic functions, we have $P \subseteq H$, and we can further conclude from Example 3.3 that P is a strict subset of H. The hidden convexity is a real expansion of pseudoconvexity for quadratic functions. In summary, we have the following relationships for quadratic functions:

$$C \subset RH = P \subset H,\ M \subset DH \subset H, \text{ and } M \cup P \text{ is a strict subset of } H.$$

The above inclusion relationship can be further extended as follows. Recall the definition of parameter l for the index set $NZ = \{l + 1, \ldots, n\}$ in (3.2). Let us introduce the following notations.

C_l: Family of second order continuously differentiable functions with $1 \le l < n$ that satisfy the following condition: For any fixed $(x_{l+1}, \ldots, x_n)$, h is strictly convex on X with respect to $(x_1, \ldots, x_l)$.

RH_l: Family of second order continuously differentiable functions with $1 \le l < n$ that satisfy the following condition: For any fixed $(x_{l+1}, \ldots, x_n)$, h is r-hidden convex on X with respect to $(x_1, \ldots, x_l)$.

P_l: Family of second order continuously differentiable functions with $1 \le l < n$ that satisfy the following condition: For any fixed $(x_{l+1}, \ldots, x_n)$, h is pseudoconvex on X with respect to $(x_1, \ldots, x_l)$.

The following proposition is obvious, and we thus omit its proof.

PROPOSITION 3.10.

1° $\cup_{l\in\{1,\ldots,n-1\}} C_l$ *is a strict subset of* H;
2° $\cup_{l\in\{1,\ldots,n-1\}} RH_l \subset H$; *and*
3° $\cup_{l\in\{1,\ldots,n-1\}} P_l \subset H$ *for quadratic functions.*

4. Hidden-convex programming problem. We consider the mathematical programming problem (P) in this section. The original problem can be converted into the following problem using the transformation in (3.1):

$$\begin{aligned}(E)\qquad &\min\ \psi_0(y) = T_0\left(g_0\left(t(y)\right)\right)\\ &\text{s.t. } \psi_k(y) = T_k\left(g_k\left(t(y)\right)\right) \le T_k(b_k),\ k = 1,\ldots,m,\\ &\qquad y \in Y,\end{aligned}$$

where $Y = \{y \in R^n \mid t(y) \in X\}$.

We have the following theorem for the equivalence between (P) and (E).

THEOREM 4.1. *If* $T_k : k = 0, 1, \ldots, m$, *are strictly increasing,* $t(y)$ *is a one-to-one mapping from* Y *to* X, *and both* t *and* t^{-1} *are continuous, then* y^* *is a global (local) minimizer of problem* (E) *if and only if* $x^* = t(y^*)$ *is a global (local) minimizer of problem* (P).

Proof. The proof can be found in Theorem 3.1 of [16]. □

DEFINITION 4.2. *If there exist strictly increasing functions* $T_0(\cdot)$, $T_1(\cdot)$, $\ldots$, $T_m(\cdot)$ *and domain transformation* $x = t(y)$ *satisfying the conditions in Theorem* 4.1 *such that the programming problem* (E) *is a (strictly) convex programming problem, then the original problem* (P) *is called a hidden (strictly) convex programming problem.*

COROLLARY 4.3. *If problem* (P) *is a hidden-convex programming problem, then any local minimizer of* (P) *must be a global minimizer.*

Proof. By Definition 4.2, we know that problem (E) is a convex programming problem if (P) is a hidden-convex programming problem. By Theorem 4.1, the local optimality of $\bar{x}$ of (P) implies the local optimality of $\bar{y} = t^{-1}(\bar{x})$ in (E). The convexity of (E) further indicates the global optimality of $\bar{y} = t^{-1}(\bar{x})$ in (E), which finally confirms the global optimality of $\bar{x}$ in (P), again by Theorem 4.1. □

Based on Corollary 4.3, if we identify problem (P) to be a hidden-convex programming problem, then we can obtain its global minimizer by solving the original problem (P) using local search methods. There is no need to actually implement a transformation.

In the following, we discuss the conditions for identifying hidden-convex programming problems.

Let η_i^k and ζ_i^k be the upper and lower bounds of $\dfrac{\partial g_k(x)}{\partial x_i}$ on X, respectively, $k = 0, 1, \ldots, m$, $i = 1, \ldots, n$, i.e.,

$$\eta_i^k \ge \max_{x\in X} \frac{\partial g_k(x)}{\partial x_i},$$
$$\zeta_i^k \le \min_{x\in X} \frac{\partial g_k(x)}{\partial x_i}.$$

Let $G_k(z)$ be the Hessian matrix of g_k at z, $k = 0, 1, \ldots, m$. Define

$$\begin{aligned} a_k(x) &= \Big(\frac{\partial g_k(x)}{\partial x_1}, \ldots, \frac{\partial g_k(x)}{\partial x_n}\Big)^T, \\ \lambda^{(k)} &= \min_{x \in X, d \in S^n} d^T G_k(x) d, \\ \gamma^{(k)} &= \min_{x \in X, d \in S^n, a_k^T(x) d = 0} d^T G_k(x) d. \end{aligned}$$

THEOREM 4.4. *Assume that in problem* (P)*, all* g_k*,* $k = 0, 1, \ldots, m$*, are second order continuously differentiable on* X*. For any* $k = 0, 1, \ldots, m,\ i = 1, \ldots, n$*, let*

$$\begin{aligned} A_k^i &= \{p_i \in R \mid \zeta_i^k \cdot p_i \cdot s(p_i) + \eta_i^k \cdot p_i \cdot s(-p_i) > -\gamma^{(k)}\}, \\ A^i &= \cap_{k=0}^m A_k^i, \\ A &= \{p = (p_1, \ldots, p_n)^T \mid p_i \in A^i,\ i = 1, \ldots, n\}. \end{aligned}$$

If $A \neq \emptyset$*, then the original problem* (P) *is a hidden strictly convex programming problem.*

Proof. The condition $A \neq \emptyset$ implies $A_k^i \neq \emptyset$ for any $i = 1, \ldots, n,\ k = 0, 1, \ldots, m$. Thus, for any $i = 1, \ldots, n,\ k = 0, 1, \ldots, m$, there exists a $p_i \in R$ such that $\zeta_i^k \cdot p_i \cdot s(p_i) + \eta_i^k \cdot p_i \cdot s(-p_i) > -\gamma^{(k)}$. If we take a $p = (p_1, \ldots, p_n)^T$ from A and perform the domain transformation $t_{i,p_i}(y_i) = \begin{cases} y_i & p_i = 0 \\ -\frac{1}{p_i} \ln y_i & p_i \neq 0 \end{cases}$ and the range transformations $T_{q,k}(s) = \exp(qs),\ k = 0, 1, \ldots, m,\ q > 0$, then $t_p(y)$ satisfies

$$\begin{aligned} & t'_{i,p_i}(y_i) \neq 0, \\ & \frac{t''_{i,p_i}(y_i)}{\Big[t'_{i,p_i}(y_i)\Big]^2} = p_i \ \text{ for any } y_i \in Y_{i,p},\ i = 1, \ldots, n, \end{aligned}$$

and $T_{q,k}(s),\ k = 0, 1, \ldots, m$, satisfy

$$T'_{q,k}(s) > 0,\ \frac{T''_{q,k}(s)}{T'_{q,k}(s)} = q \quad \forall s \in R.$$

From the proof of Theorem 3.7, we know that when q is large enough, the functions $T_{q,k}(g_k(t_p(y))),\ k = 0, 1, \ldots, m$, are all strictly convex functions on Y. Thus, problem (E) is a strictly convex programming problem on Y. Furthermore, the original problem (P) is a hidden strictly convex programming problem. ∎

Remark 4.1. Because for any $k = 0, 1, \ldots, m,\ \gamma^{(k)} \geq \lambda^{(k)}$, then for any $k = 0, 1, \ldots, m,\ i = 1, \ldots, n$, we have

$$\{p_i \in R \mid \zeta_i^k \cdot p_i \cdot s(p_i) + \eta_i^k \cdot p_i \cdot s(-p_i) > -\lambda^{(k)}\} \subseteq A_k^i.$$

Let

$$\begin{aligned} I_i &= \{k \mid \zeta_i^k > 0,\ k \in \{0, 1, \ldots, m\}\}, \\ J_i &= \{k \mid \eta_i^k < 0,\ k \in \{0, 1, \ldots, m\}\}, \\ \bar{I}_i &= \{0, 1, \ldots, m\} \setminus I_i, \\ \bar{J}_i &= \{0, 1, \ldots, m\} \setminus J_i. \end{aligned}$$

Without loss of generality, we assume that for any $k = 0, 1, \ldots, m,\ i = 1, \ldots, n$, $\zeta_i^k \neq 0$, and $\eta_i^k \neq 0$. Then, for any $i \in \{1, \ldots, n\}$, we have

$$A^i = \left\{ p_i \in R \,\middle|\, \max_{k \in I_i} \left\{ -\frac{\gamma^{(k)}}{\zeta_i^k} \right\} < p_i < \min_{k \in \bar{I}_i} \left\{ -\frac{\gamma^{(k)}}{\zeta_i^k} \right\} \text{ and } p_i \geq 0 \right\}$$
$$\cup \left\{ p_i \in R \,\middle|\, \max_{k \in \bar{J}_i} \left\{ -\frac{\gamma^{(k)}}{\eta_i^k} \right\} < p_i < \min_{k \in J_i} \left\{ -\frac{\gamma^{(k)}}{\eta_i^k} \right\} \text{ and } p_i < 0 \right\}.$$

From Theorem 4.4, we can obtain the following sufficient conditions for hidden-convex programming problems.

THEOREM 4.5. *Assume that for all $k = 0, 1, \ldots, m$, g_k are second order continuously differentiable on X. If for any $i = 1, \ldots, n$, one of the following conditions hold:*

$$\max \left\{ 0, \max_{k \in I_i} \left[-\frac{\gamma^{(k)}}{\zeta_i^k} \right] \right\} < \min_{k \in \bar{I}_i} \left\{ -\frac{\gamma^{(k)}}{\zeta_i^k} \right\} \tag{4.1}$$

$$\text{or} \quad \max_{k \in \bar{J}_i} \left\{ -\frac{\gamma^{(k)}}{\eta_i^k} \right\} < \min \left\{ 0, \min_{k \in J_i} \left[-\frac{\gamma^{(k)}}{\eta_i^k} \right] \right\}, \tag{4.2}$$

then the original problem (P) *is a hidden strictly convex programming problem.*

Proof. If for all $i = 1, \ldots, n$, either (4.1) or (4.2) holds, then for any $i = 1, \ldots, n$, $A^i \neq \emptyset$, which implies $A \neq \emptyset$. Thus, from Theorem 4.4, the original problem (P) is a hidden strictly convex programming problem. □

Because $\gamma^{(k)} \geq \lambda^{(k)}$ for $k = 0, 1, \ldots, m$, condition

$$\max \left\{ 0, \max_{k \in I_i} \left[-\frac{\lambda^{(k)}}{\zeta_i^k} \right] \right\} < \min_{k \in \bar{I}_i} \left\{ -\frac{\lambda^{(k)}}{\zeta_i^k} \right\}$$

leads to the satisfaction of (4.1) and

$$\max_{k \in \bar{J}_i} \left\{ -\frac{\lambda^{(k)}}{\eta_i^k} \right\} < \min \left\{ 0, \min_{k \in J_i} \left[-\frac{\lambda^{(k)}}{\eta_i^k} \right] \right\}$$

leads to the satisfaction of (4.2). Compared with Theorem 3.3 in [12], Theorem 4.5 includes d-hidden convexity as its special case.

Theorem 4.5 offers sufficient conditions to identify whether a programming problem is a hidden strictly convex programming problem or not. These conditions are transformation free, i.e., they can be determined only by the parameters that are derived from the original problem and are independent of the transformations T_i and t. We need to emphasize that, when using Theorem 4.5, the task to estimate the constrained minimum eigenvalue $\gamma^{(k)}$, in general, is very difficult. Without efficient numerical algorithms to determine $\gamma^{(k)}$ for general programming problems, the above results mainly serve as some promising theoretical findings at this stage. In the next section, however, we will show that for quadratic programming problems, the conditions for checking the hidden convexity are readily verifiable.

5. Hidden convex quadratic optimization problems. We consider the following general quadratic optimization problem:

$$(Q) \qquad \min\ g_0(x) = \frac{1}{2} x^T A^{(0)} x + [b^{(0)}]^T x + c^{(0)}$$
$$\text{s.t. } g_k(x) = \frac{1}{2} x^T A^{(k)} x + [b^{(k)}]^T x + c^{(k)} \leq 0,\ k = 1, \ldots, m,$$
$$x \in X = \{(x_1, \ldots, x_n) \mid l_i \leq x_i \leq u_i, i = 1, \ldots, n\},$$

where for $k = 0, 1, \ldots, m$, $A^{(k)} = \{a_{ij}^{(k)}\}_{n\times n}$ is an $n \times n$ symmetric constant matrix and $b^{(k)} = (b_1^{(k)}, \ldots, b_n^{(k)})^T$ is an n-dimensional constant vector. Obviously, matrix $A^{(k)}$ is the Hessian matrix of $g^{(k)}$ and

$$\frac{\partial g_k(x)}{\partial x} = A^{(k)}x + b^{(k)},\ k = 0, 1, \ldots, m.$$

Let $\lambda^{(k)}$ be the minimal eigenvalue of $A^{(k)}$ and $\gamma^{(k)}$ the constrained minimum eigenvalue of $A^{(k)}$, i.e.,

$$\gamma^{(k)} = \min_{x\in X, d\in S^n, (A^{(k)}x+b^{(k)})^T d=0} d^T A^{(k)} d.$$

The constrained minimum eigenvalue $\gamma^{(k)}$ for a constant matrix A can be easily obtained following the procedure suggested in subsection 2.3.

Let

$$\zeta_i^k = \min_{x\in X} \frac{\partial g_k(x)}{\partial x_i} = \min_{x\in X} \left[\sum_{j=1}^n a_{ij}^{(k)} x_j + b_i^{(k)}\right],$$
$$\eta_i^k = \max_{x\in X} \frac{\partial g_k(x)}{\partial x_i} = \max_{x\in X} \left[\sum_{j=1}^n a_{ij}^{(k)} x_j + b_i^{(k)}\right].$$

Note here that the minimum and maximum values of a linear function over a box, ζ_i^k and η_i^k, are easy to calculate.

Define

$$\begin{aligned}
I_i &= \{k \mid \zeta_i^k > 0,\ k = 0, 1, \ldots, m\},\\
\widetilde{I}_i &= \{k \mid \zeta_i^k < 0,\ k = 0, 1, \ldots, m\},\\
I_i^0 &= \{k \mid \zeta_i^k = 0,\ k = 0, 1, \ldots, m\},\\
J_i &= \{k \mid \eta_i^k < 0,\ k = 0, 1, \ldots, m\},\\
\widetilde{J}_i &= \{k \mid \eta_i^k > 0,\ k = 0, 1, \ldots, m\},\\
J_i^0 &= \{k \mid \eta_i^k = 0,\ k = 0, 1, \ldots, m\}.
\end{aligned}$$

From the results in the previous sections, the following lemma and theorem are obvious. We omit their proofs.

LEMMA 5.1. *If $\gamma^{(k)} \geq 0$ for all $k = 0, 1, \ldots, m$, then the quadratic optimization problem (Q) is hidden convex.*

THEOREM 5.2. *If, for any $i \in \{1, \ldots, n\}$, one of the following two conditions hold:*

$$\min_{k\in I_i^0} \gamma^{(k)} \geq 0 \quad \textit{and} \quad \max\left\{0, \max_{k\in I_i}\left[-\frac{\gamma^{(k)}}{\zeta_i^k}\right]\right\} \leq \min_{k\in \widetilde{I}_i}\left\{-\frac{\gamma^{(k)}}{\zeta_i^k}\right\},$$

or

$$\min_{k\in J_i^0} \gamma^{(k)} \geq 0 \quad \textit{and} \quad \max_{k\in \widetilde{J}_i}\left\{-\frac{\gamma^{(k)}}{\eta_i^k}\right\} \leq \min\left\{0, \min_{k\in J_i}\left[-\frac{\gamma^{(k)}}{\eta_i^k}\right]\right\},$$

then the quadratic optimization problem (Q) *is hidden convex.*

The following example illustrates how to check the hidden convexity of problem (Q) step by step.

Example 5.1.

$$\begin{aligned}
&\min g_0(x) = \frac{1}{2}x^T A^{(0)}x + [b^{(0)}]^T x,\\
&\text{s.t. } g_1(x) = \frac{1}{2}x^T A^{(1)}x + [b^{(1)}]^T x - 4200 \le 0,\\
&\qquad x \in X = \left\{ x \in R^3 \mid 4 \le x_1 \le \frac{9}{2},\ 1 \le x_2 \le 2,\ 1 \le x_3 \le 2 \right\},
\end{aligned}$$

where

$$A^{(0)} = \begin{pmatrix} -2 & 0 & 0 \\ 0 & \frac{7}{2} & -\frac{\sqrt{3}}{2} \\ 0 & -\frac{\sqrt{3}}{2} & \frac{5}{2} \end{pmatrix}, A^{(1)} = \begin{pmatrix} -2 & 0 & 0 \\ 0 & \frac{1}{4} & -\frac{3\sqrt{3}}{4} \\ 0 & -\frac{3\sqrt{3}}{4} & -\frac{5}{4} \end{pmatrix},$$

and

$$b^{(0)} = (0, -(4-\sqrt{3}), -(3-\sqrt{3}))^T, \quad b^{(1)} = (1009, -100, 20)^T.$$

Obviously, this problem is not convex.

By the eigenvalue decomposition software in MATLAB, we obtain

$$\Omega_0 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -0.5000 & -0.8660 \\ 0 & -0.8660 & 0.5000 \end{pmatrix},\ \Omega_1 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0.5000 & -0.8660 \\ 0 & 0.8660 & 0.5000 \end{pmatrix}$$

such that

$$\begin{aligned}
\Omega_0^{-1} A^{(0)} \Omega_0 &= \begin{pmatrix} -2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 4 \end{pmatrix}\\
\Omega_1^{-1} A^{(1)} \Omega_1 &= \begin{pmatrix} -2 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & 1 \end{pmatrix}.
\end{aligned}$$

Thus, the eigenvalues of $A^{(0)}$ are $\lambda^{(0)} = \lambda_1^{(0)} = -2$, $\lambda_2^{(0)} = 2$, $\lambda_3^{(0)} = 4$ and the eigenvalues of $A^{(1)}$ are $\lambda^{(1)} = \lambda_1^{(1)} = \lambda_2^{(1)} = -2$, $\lambda_3^{(1)} = 1$.

In the following, we use Theorem 5.2 to prove that the above example problem is hidden convex. First, we use Proposition 2.4 to obtain $\gamma^{(k)}$ for $k = 0, 1$, where

$$\gamma^{(k)} = \min_{x \in X, d \in S^3, [A^{(k)}x + b^{(k)}]^T d = 0} d^T A^{(k)} d.$$

It is clear from (i) of Proposition 2.4 that $\gamma^{(1)} = -2$. The calculation of $\gamma^{(0)}$

involves several steps:

$$\bar{b}^{(0)} = \Omega_0^T \begin{pmatrix} 0 \\ -(4-\sqrt{3}) \\ -(3-\sqrt{3}) \end{pmatrix} = \begin{pmatrix} 0 \\ -2.232 \\ 1.330 \end{pmatrix},$$

$$\varsigma = \left(\frac{\bar{b}_1^{(0)}}{\lambda_1^{(0)}}, \frac{\bar{b}_2^{(0)}}{\lambda_2^{(0)}}, \frac{\bar{b}_3^{(0)}}{\lambda_3^{(0)}} \right)^T = (0, -1.116, 0.3325)^T,$$

$$\bar{X}^{(0)} = \left\{ x \in R^3 \mid \begin{pmatrix} 4 \\ 1 \\ 1 \end{pmatrix} \leq \Omega_0 x - \Omega_0 \varsigma \leq \begin{pmatrix} \frac{9}{2} \\ 2 \\ 2 \end{pmatrix} \right\}.$$

Solving $\{\min x_1 \mid x \in \bar{X}^{(0)}\}$ yields $v(\min x_1 \mid x \in \bar{X}^{(0)}) = 4 > 0$. Thus, there does not exist any $\bar{x} \in \bar{X}^{(0)}$ such that $\bar{x}_1 = 0$. We further construct

$$\bar{Y}^{(0)} = \left\{ y \in R^3 \mid \begin{pmatrix} 4 \\ 1 \\ 1 \end{pmatrix} y_1 \leq \Omega_0 \begin{pmatrix} 1 \\ y_2 \\ y_3 \end{pmatrix} - \Omega_0 \varsigma y_1 \leq \begin{pmatrix} \frac{9}{2} \\ 2 \\ 2 \end{pmatrix} y_1 \right\}.$$

The value of $\max\{|v(\max y_2 \mid y \in \bar{Y}^{(0)})|^2, |v(\min y_2 \mid y \in \bar{Y}^{(0)})|^2\}$ yields $\beta_{12}^{(0)} = 0.9255$ in (v) of Proposition 2.4. From (v) of Proposition 2.4, we have

$$\gamma^{(0)} = \lambda_1^{(0)} + \frac{\lambda_2^{(0)} - \lambda_1^{(0)}}{1 + \beta_{12}^{(0)} \left(\frac{\lambda_2^{(0)}}{\lambda_1^{(0)}} \right)^2} = 0.0774.$$

It is not difficult to verify the following:

$$\zeta_1^0 = -9 \leq \frac{\partial g_0(x)}{\partial x_1} = -2x_1 \leq -8 = \eta_1^0,$$

$$\zeta_2^0 = -\frac{1}{2} \leq \frac{\partial g_0(x)}{\partial x_2} = \frac{7}{2}x_2 - \frac{\sqrt{3}}{2}x_3 - (4-\sqrt{3}) \leq 3 + \frac{\sqrt{3}}{2} = \eta_2^0,$$

$$\zeta_3^0 = -\frac{1}{2} \leq \frac{\partial g_0(x)}{\partial x_3} = \frac{5}{2}x_3 - \frac{\sqrt{3}}{2}x_2 - (3-\sqrt{3}) \leq 2 + \frac{\sqrt{3}}{2} = \eta_3^0,$$

$$\zeta_1^1 = 1000 \leq \frac{\partial g_1(x)}{\partial x_1} = -2x_1 + 1009 \leq 1001 = \eta_1^1,$$

$$\zeta_2^1 = -\frac{399 + 6\sqrt{3}}{4} \leq \frac{\partial g_1(x)}{\partial x_2} = \frac{1}{4}x_2 - \frac{3\sqrt{3}}{4}x_3 - 100 \leq -\frac{398 + 3\sqrt{3}}{4} = \eta_2^1,$$

$$\zeta_3^1 = \frac{35 - 3\sqrt{3}}{2} \leq \frac{\partial g_1(x)}{\partial x_3} = -\frac{5}{4}x_3 - \frac{3\sqrt{3}}{4}x_2 + 20 \leq \frac{75 - 3\sqrt{3}}{4} = \eta_3^1.$$

It is clear that both functions $g_0(x)$ and $g_1(x)$ are not convex, $g_1(x)$ is not pseudoconvex, and $g_0(x)$ is not monotone with respect to x_2 and x_3. Obviously, $I_1 = \{1\}$, $\widetilde{I}_1 = \{0\}$ and $J_2 = \{1\}$, $\widetilde{J}_2 = \{0\}$, $I_3 = \{1\}$, $\widetilde{I}_3 = \{0\}$. The conditions in Theorem 5.2 can be verified to satisfy for all $i = 1, 2, 3$.

When $i = 1$,

$$\begin{aligned}
&\max\left\{0, \max_{k\in I_1}\left[-\frac{\gamma^{(k)}}{\zeta_1^k}\right]\right\}\\
&= \max\left\{0, -\frac{\gamma^{(1)}}{\zeta_1^1}\right\} = \max\left\{0, -\frac{-2}{1000}\right\} = 0.0020\\
&< 0.0086 = -\frac{0.0774}{-9} = -\frac{\gamma_{(0)}}{\zeta_1^0}\\
&= \min_{k\in\tilde{I}_1}\left\{-\frac{\gamma^{(k)}}{\zeta_1^k}\right\}.
\end{aligned}$$

When $i = 2$,

$$\begin{aligned}
&\max_{k\in\tilde{J}_2}\left\{-\frac{\gamma_{(k)}}{\eta_2^k}\right\}\\
&= -\frac{\gamma^{(0)}}{\eta_2^0} = -\frac{0.0774}{3+\frac{\sqrt{3}}{2}} = -0.0200\\
&<= -0.0198 = -\frac{8}{398+3\sqrt{3}} = \min\left\{0, -\frac{-2}{-\frac{398+3\sqrt{3}}{4}}\right\} = \min\left\{0, -\frac{\gamma^{(1)}}{\eta_2^1}\right\}\\
&= \min\left\{0, \min_{k\in J_2}\left[-\frac{\gamma^{(k)}}{\eta_2^k}\right]\right\}.
\end{aligned}$$

When $i = 3$,

$$\begin{aligned}
&\max\left\{0, \max_{k\in I_3}\left[-\frac{\gamma^{(k)}}{\zeta_3^k}\right]\right\}\\
&= \max\left\{0, -\frac{\gamma^{(1)}}{\zeta_3^1}\right\} = \max\left\{0, -\frac{-2}{\frac{35-3\sqrt{3}}{2}}\right\} = 0.1342\\
&< 0.1548 = -\frac{0.0774}{-\frac{1}{2}} = -\frac{\gamma^{(0)}}{\zeta_3^0}\\
&= \min_{k\in\tilde{I}_3}\left\{-\frac{\gamma^{(k)}}{\zeta_3^k}\right\}.
\end{aligned}$$

We can thus conclude by Theorem 5.2 that Example 5.1 is hidden convex. The local minimizer of this problem, $x^* = (4.2760, 1.1421, 1.0000)^T$ with objective value $f^* = -19.5984$, which is obtained by the constrained nonlinear minimization function *fmincon* of the MATLAB optimization toolbox, must also be the global minimizer.

We present in the following an algorithm for checking the hidden convexity of problem (Q).

ALGORITHM II (Verification of the hidden convexity of problem (Q)).

Step 1. Calculate $\gamma^{(k)} = \min_{x\in X, d\in S^n, (A^{(k)}x+b^{(k)})^T d=0} d^T A^{(k)} d$, $k = 0, 1, \ldots, m$, by Algorithm I. Let $i = 1$.

Step 2. If $i > n$, then go to *Step* 5. Otherwise, for $k = 0, 1, \ldots, m$, calculate ζ_i^k and η_i^k. Let $\Gamma_i := \min_{k\in I_i^0} \gamma^{(k)}$ and $\Upsilon_i := \min_{k\in J_i^0} \gamma^{(k)}$ and go to *Step* 3.

Step 3. Let $\Lambda_i := \max\{0, \max_{k\in I_i}[-\frac{\gamma^{(k)}}{\zeta_i^k}]\}$, $\bar{\Lambda}_i := \min_{k\in\tilde{I}_i}\{-\frac{\gamma^{(k)}}{\zeta_i^k}\}$. If $\Gamma_i \geq 0$ and $\Lambda_i \leq \bar{\Lambda}_i$, then let $i := i + 1$ and go to *Step* 2. Otherwise, go to *Step* 4.

Step 4. Let $\Lambda_i := \max_{k\in\widetilde{J}_i}\{-\frac{\gamma_i^{(k)}}{\eta_i^k}\}$, $\bar{\Lambda}_i := \min\{0, \min_{k\in J_i}[-\frac{\gamma_i^{(k)}}{\eta_i^k}]\}$. If $\Upsilon_i \geq 0$ and $\Lambda_i \leq \bar{\Lambda}_i$, then let $i := i+1$ and go to *Step* 2. Otherwise, stop, and the hidden convexity of problem (Q) cannot be proved.

Step 5. Problem (Q) is hidden convex. Use an appropriate routine to find a local optimal solution of problem (Q), which is also a global optimal solution.

Remark 5.1. Using Algorithms I and II, we can verify whether problem (Q) is a hidden-convex programming problem by solving some linear programming problems. Note that the calculation of ζ_i^k and η_i^k can be simply carried out by determining whether x_j, $j = 1, \ldots, n$, takes its upper bound or its lower bound based on the positiveness or negativeness of the corresponding coefficient $a_{ij}^{(k)}$, $i = 1, \ldots, n$, $k = 0, \ldots, m$. The largest number of actual linear programming problems that we need to solve in Algorithms I and II is $4(m+1)$ and each linear programming problem involves n variables and $2n$ inequality constraints. The complexity analysis of linear programming has been well established and can be applied to estimate the worst-case complexity of the verification process for hidden convexity, given the size of the problem under investigation.

Algorithms I and II are coded in MATLAB 7.0 with the Windows XP operating system, and the Optimization Toolbox 3.0 is used in the coding. We demonstrate in the following how to use Algorithms I and II to check the hidden convexity for a 10-dimensional quadratic optimization problem.

Example 5.2.

$$\begin{aligned}
&\min g_0(x) = \frac{1}{2}x^T A^{(0)} x + [b^{(0)}]^T x\\
&\text{s.t. } g_1(x) = \frac{1}{2}x^T A^{(1)} x + [b^{(1)}]^T x - 1800 \leq 0,\\
&\qquad x \in X = \{x \in R^3 \mid 4 \leq x_1 \leq \frac{9}{2},\ 1 \leq x_i \leq 2,\ i = 2, \ldots, 10\},
\end{aligned}$$

where

$$A^{(0)} = \begin{pmatrix}
-2 & 0 & 0 & -\frac{1}{2} & 0 & 0 & 0 & 0 & 0 & -\frac{1}{2}\\
0 & \frac{7}{2} & -\frac{\sqrt{3}}{2} & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & -\frac{\sqrt{3}}{2} & \frac{5}{2} & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
-\frac{1}{2} & 0 & 0 & 2 & -\frac{1}{2} & 0 & 0 & 0 & 0 & 0\\

0 & 0 & 0 & 0 & 1 & -1 & 1 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 1 & -1 & 1 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 1 & -1 & 1 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & -1 & 1\\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & -1
\end{pmatrix},$$

and

$$b^{(0)} = (2, -(4-\sqrt{3}), -(3-\sqrt{3}), -1, -3, -3, -3, -3, -3, -1)^T,$$

$$b^{(1)} = (300, -50, 50, 50, 40, 60, 40, 50, 60, 50)^T.$$

Obviously, this problem is not convex. We first obtain $\gamma^{(0)} = 0.2328$ and $\gamma^{(1)} = -2.8659$ by using Algorithm I. Implementing Algorithm II, we find out that for all $i = 1, \ldots, 10$, $\Gamma_i = \Upsilon_i = \infty$, $[\Lambda_1, \ldots, \Lambda_{10}]^T = [0.0098, -0.0602, 0.0638, 0.0541, 0.0716, 0.0478, 0.0716, 0.0573, 0.0478, 0.0541]^T$ and $[\bar{\Lambda}_1, \ldots, \bar{\Lambda}_{10}]^T = [0.0259, -0.0564, 0.4657, 0.1035, 0.0776, 0.0776, 0.0776, 0.0776, 0.0776, 0.1035]^T$. Thus, we can conclude that Example 5.2 is hidden convex. The global minimizer of this problem is $x^* = (4.3827, 1.2917, 1.0000, 1.2577, 1.6279, 1.4911, 1.7009, 1.5632, 1.3535, 1.1918)^T$ with objective value $f^* = -34.2711$. The calculation is carried out on an Intel Pentium M with 1.60GHz and 512MB RAM and the total computational time is 2.053 seconds.

Remark 5.2. Let (Q_S) be a class of quadratic optimization problems with a single constraint ($m = 1$) and $X = R^n$. The solution properties of (Q_S) were discussed in [6] and [9] under an assumption that Slater's constraint qualification is satisfied. Appendix B of [6] pointed out that the strong duality holds for (Q_S) and its Lagrangian dual problem is a convex programming problem. Using the same notations as in (Q), [9] pointed out that $\bar{x}$ is a global minimizer of problem (Q_S) if and only if there exists a $\lambda \geq 0$ such that

$$A^{(0)} + \lambda A^{(1)} \succeq 0, b^{(0)} + \lambda b^{(1)} + (A^{(0)} + \lambda A^{(1)})\bar{x} = 0, \lambda g_1(\bar{x}) = 0.$$

Although many instances of (Q_S) are not hidden convex, a global minimizer of any problem (Q_S) that satisfies Slater's condition can always be characterized by a convex programming problem. A key point to be emphasized is that any nonconvex optimization problem with multiple minima cannot be hidden convex. Note that if, in (Q_S), X is bounded, as we are discussing in this paper, then the results that are derived in [6] and [9] will not hold true.

6. Conclusion. Transformation-independent sufficient conditions have been developed in this paper to peel off a nonconvex cover of certain actual convex programming problems. The reach of convex analysis can be thus extended to a class of hidden-convex functions. Most promisingly, some implementable checking procedures have been derived in this paper to identify hidden convex quadratic optimization problems.

One future research subject is to integrate the checking procedure for hidden convexity into a branch-and-bound framework to solve a class of global optimization problems. Let us consider the following simple example.

Example 6.1.

$$\begin{aligned} \text{(PE)} \qquad & \min g_0(x) = \frac{1}{2}x^2 + \frac{1}{2}x \\ & \text{s.t. } g_1(x) = -\frac{1}{2}x^2 - 2x - \frac{1}{2} \leq 0, \\ & x \in X = \{x \mid -1 \leq x \leq 1\}. \end{aligned}$$

It is easy to check for this problem that $\gamma^{(0)} = 1$, $\gamma^{(1)} = -1$, $\zeta^0 = \min_{x \in X}(x + \frac{1}{2}) = -\frac{1}{2}$, $\eta^0 = \max_{x \in X}(x + \frac{1}{2}) = \frac{3}{2}$, $\zeta^1 = \min_{x \in X}(-x - 2) = -3$, and $\eta^1 = \max_{x \in X}(-x - 2) = -1$. We further have $I = \emptyset$, $\tilde{I} = \{0, 1\}$, $J = \{1\}$, and $\tilde{J} = \{0\}$. Neither of the

two conditions in Theorem 5.2 is satisfied and we are not able to verify the hidden convexity of problem (PE).

We consider two subregions of X, $X_1 = \{x \mid -1 \le x \le 0\}$ and $X_2 = \{x \mid -\frac{1}{4} \le x \le 1\}$, such that $X = X_1 \cup X_2$. Consider two revised problems of (PE), (PE_1), and (PE_2), by replacing X with X_1 and X_2, respectively. For (PE_1), $\zeta^0 = -\frac{1}{2}$, $\eta^0 = \frac{1}{2}$, $\zeta^1 = -2$, $\eta^1 = -1$, $I = \emptyset$, $\tilde{I} = \{0, 1\}$, $J = \{1\}$, and $\tilde{J} = \{0\}$. For (PE_2), $\zeta^0 = \frac{1}{4}$, $\eta^0 = \frac{3}{2}$, $\zeta^1 = -3$, $\eta^1 = -\frac{7}{4}$, $I = \{0\}$, $\tilde{I} = \{1\}$, $J = \{1\}$, and $\tilde{J} = \{0\}$. For both problems (PE_1) and (PE_2), the second condition in Theorem 5.2 is satisfied and both problems (PE_1) and (PE_2) are thus hidden convex. Comparing the minimizer of problem (PE_1), $x_1^* = -0.2680$ with $g_0(x_1^*) = -0.0980$, and the minimizer of problem (PE_2), $x_2^* = -\frac{1}{4}$ with $g_0(x_2^*) = -0.0938$, we can conclude that $x_1^* = -0.2680$ is the global minimizer of problem (PE).

To extend the implementable computational procedure for checking hidden convexity in nonquadratic optimization situations, we will explore some possibilities in the near future for applying the results in the literature on eigenvalue bounds for interval matrices (see [7], [13]) to calculate a lower bound of the minimum eigenvalue or the constrained minimum eigenvalue for nonconstant matrices.

USING SAMPLING AND SIMPLEX DERIVATIVES IN PATTERN SEARCH METHODS*

A. L. CUSTÓDIO† AND L. N. VICENTE‡

Abstract. In this paper, we introduce ways of making a pattern search more efficient by reusing previous evaluations of the objective function, based on the computation of simplex derivatives (e.g., simplex gradients). At each iteration, one can attempt to compute an accurate simplex gradient by identifying a sampling set of previously evaluated points with good geometrical properties. This can be done using only past successful iterates or by considering all past function evaluations. The simplex gradient can then be used to reorder the evaluations of the objective function associated with the directions used in the poll step or to update the mesh size parameter according to a sufficient decrease criterion, neither of which requires new function evaluations. We present these procedures in detail and apply them to a set of problems from the CUTEr collection. Numerical results show that these procedures can enhance significantly the practical performance of pattern search methods.

Key words. derivative-free optimization, pattern search methods, simplex gradient, poll ordering, multivariate polynomial interpolation, poisedness

1. Introduction.

We are interested in this paper in designing efficient (derivative-free) pattern search methods for nonlinear optimization problems. We focus our attention on unconstrained optimization problems of the form $\min_{x\in\mathbb{R}^n} f(x)$.

The curve representing the objective function value as a function of the number of function evaluations frequently exhibits an L-shape for pattern search runs. This class of methods, perhaps because of their directional features, is relatively good at quickly decreasing the objective function from its initial value. However, they can be slow thereafter and especially towards stationarity, when the frequency of unsuccessful iterations tends to increase.

There has not been much effort in trying to develop efficient serial implementations of pattern search methods for the minimization of general functions. Some attention has been paid to parallelization (see Hough, Kolda, and Torczon [14]). In the context of generating set search methods, Frimannslund and Steihaug [12] rotated the generating sets based on curvature information extracted from function values. Other authors have considered particular instances where the problem structure can be exploited efficiently. Price and Toint [20] examined how to take advantage of partial separability. Alberto *et al.* [2] have shown ways of incorporating user-provided function evaluations. Abramson, Audet, and Dennis [1] looked at the case where some incomplete form of gradient information is available.

The goal of this paper is to develop strategies for improving the efficiency of the current pattern search iteration, based on function evaluations obtained at previous iterations. We make no use of or assumption about the structure of the objective function, so that one can apply the techniques here to any functions (in particular, those resulting from running black-box codes or performing physical experiments). More importantly, these strategies (i) require no extra function evaluation and (ii) do not interfere with existing requirements for global convergence.

The paper is organized as follows. Section 2 describes the pattern search framework over which we introduce the material of this paper. Section 3 summarizes geometrical features of sample sets (Λ–poisedness) and simplex derivatives, such as simplex gradients and simplex Hessians.

The key ideas of this paper are reported in section 4, where we show how to use sample sets of points previously evaluated in a pattern search to compute simplex derivatives. The sample sets can be built by storing points where the function has been evaluated or by storing only points which lead to a decrease. The main destination of this computation is the efficient ordering of the directions used for polling. In fact, a descent indicator direction (like a negative simplex gradient) can be used to order the polling directions according to a simple angle criterion.

In section 5 we describe one way of ensuring sample sets with adequate geometry at iterations succeeding unsuccessful ones. We study the pruning properties of negative simplex gradients in section 6. Other uses of simplex derivatives in a pattern search are suggested in section 7, namely, one way of updating the mesh size parameter according to a sufficient decrease condition.

These ideas were tested in a set of CUTEr [13] unconstrained problems, collected from papers on derivative-free optimization. The corresponding numerical results are reported in section 8 and show the effectiveness of using sampling-based simplex derivatives in pattern search. Section 9 states some concluding remarks and ideas for future work. The default norms used in this paper are Euclidean.

2. Pattern search. Pattern search methods are directional methods that make use of a finite number of directions with appropriate descent properties. In the unconstrained case, these directions must positively span $\mathbb{R}^n$. A positive spanning set is guaranteed to contain one positive basis, but it can contain more. A positive basis is a positive spanning set which has no proper subset positively spanning $\mathbb{R}^n$. Positive bases have between $n+1$ and $2n$ elements. Properties and examples of positive bases can be found in [2, 10, 17]. If the objective function possesses certain smoothness properties and the number of positive bases used remains finite, then the pattern search is known to exhibit global convergence to stationary points in the lim inf sense (see [3, 17]).

We present pattern search methods in the generalized format introduced by Audet and Dennis [3]. The positive spanning set used is represented by D and its cardinality by $|D|$. It is convenient to regard D as an $n \times |D|$ matrix whose columns are the elements of D. A positive basis in D is denoted by B and is also viewed as a matrix (an $n \times |B|$ column submatrix of D).

At each iteration k of a pattern search method, the next iterate x_{k+1} is selected among the points of a mesh M_k, defined as

$$M_k = \{x_k + \alpha_k D z : \ z \in \mathbb{Z}_+^{|D|}\},$$

where $\mathbb{Z}_+$ is the set of nonnegative integers. This mesh is centered at the current iterate x_k, and its fineness is defined by the mesh size (or step size) parameter $\alpha_k > 0$.

Each direction $d \in D$ must be of the form $d = G\bar{z},\ \bar{z} \in \mathbb{Z}^n$, where G is a nonsingular (generating) matrix. This property is crucial for global convergence, ensuring that the mesh has only a finite number of points in a compact set (provided that the mesh size parameter is also updated according to some rationality requirements, as we will point out later).

The process of finding a new iterate $x_{k+1} \in M_k$ can be described in two phases (the search step and the poll step). The search step is optional and unnecessary for the convergence properties of the method. It consists of evaluating the objective function at a finite number of points lying on the mesh M_k. The choice of points in M_k is totally flexible as long as its number remains finite. The points could be chosen according to specific application properties or following some heuristic algorithm. The search step is declared successful if a new mesh point x_{k+1} is found such that $f(x_{k+1}) < f(x_k)$.

The poll step is performed only if the search step has been unsuccessful. It consists of a local search around the current iterate, exploring the points in the mesh neighborhood defined by the parameter α_k and a positive basis $B_k \subset D$:

$$P_k \ = \ \{x_k + \alpha_k b : \ b \in B_k\} \ \subset \ M_k.$$

We call the points $x_k + \alpha_k b \in P_k$ the polling points and the vectors $b \in B_k$ the polling vectors or polling directions.

The purpose of the poll step is to ensure a decrease in the objective function for sufficiently small mesh sizes. Provided that the function retains some differentiability properties, one knows that the poll step must be eventually successful, unless the current iterate is a stationary point. In fact, given any vector w in $\mathbb{R}^n$, there exists at least one vector b in B_k such that $w^\top b \ > 0$ (see [10]). For instance, if the function f is continuously differentiable and one selects $w = -\nabla f(x_k)$, then one is guaranteed the existence of a descent direction in B_k.

The polling vectors (or points) are ordered according to some criterion in the poll step. The report [18] presents two distinct classes of pattern search algorithms, namely, the rank ordering and the positive bases pattern search methods. In the context of a rank ordering pattern search, it is suggested to order the simplex vertices but with the single purpose of identifying the vertices with the best and the worst objective function values in order to compute a crude estimate of the direction of steepest descent. The authors explicitly state in [18] that their intention was not reordering the remaining vertices. Most papers do not address the issue of poll ordering at all and, as a result, numerical testing is typically done using the ordering in which the vectors are originally stored. Another ordering we discuss later consists of bringing into the first column (in B_{k+1}) the polling vector b_k associated with the most recent successful polling iterate ($f(x_k + \alpha_k b_k) < f(x_k)$). This ordering procedure has been called *dynamic polling* (see Audet and Dennis [4]). Our presentation of a pattern search assumes that poll ordering is specified before polling starts.

If the poll step also fails to produce a point with a lower objective function value $f(x_k)$, then both the poll step and the iteration are declared unsuccessful. In this situation the mesh size parameter is decreased. On the other hand, the mesh size is held constant or increased if, in either the search or the poll step, a new iterate is found yielding an objective function decrease.

The class of pattern search methods used in this paper is described in Figure 2.1. Our description follows the one given in [3] for the generalized pattern search. We leave three procedures undetermined in the statement of the method: the search procedure in the search step, the order procedure that determines the order of the

Pattern Search Method

Initialization
Choose x_0 and $\alpha_0 > 0$. Choose a positive spanning set D. Select all constants needed for procedures `[search]`, `[order]`, and `[mesh]`. Set $k = 0$.

Search step
Call `[search]` to try to compute a point $x \in M_k$ with $f(x) < f(x_k)$ by evaluating the function only at a finite number of points in M_k. If such a point is found, then set $x_{k+1} = x$, declare the iteration as successful, and skip the poll step.

Poll step
Choose a positive basis $B_k \subset D$. Call `[order]` to order the polling set $P_k = \{x_k + \alpha_k b : b \in B_k\}$. Start evaluating f at the polling points following the order determined. If a polling point $x_k + \alpha_k b_k$ is found such that $f(x_k + \alpha_k b_k) < f(x_k)$, then stop polling, set $x_{k+1} = x_k + \alpha_k b_k$, and declare the iteration as successful. Otherwise declare the iteration as unsuccessful and set $x_{k+1} = x_k$.

Updating the mesh size parameter
Call `[mesh]` to compute α_{k+1}. Increment k by one and return to the search step.

FIG. 2.1. *Class of pattern search methods used in this paper.*

`procedure mesh`

The constant τ must satisfy $\tau \in \mathbb{Q}$ and $\tau > 1$ and should be initialized at iteration $k = 0$ together with $j_{max} \in \mathbb{Z}$, $j_{max} \geq 0$, and $j_{min} \in \mathbb{Z}$, $j_{min} \leq -1$.

If the iteration was successful, then maintain or expand the mesh by taking $\alpha_{k+1} = \tau^{j_k^+} \alpha_k$, with $j_k^+ \in \{0, 1, 2, \ldots, j_{max}\}$. Otherwise, contract the mesh by decreasing the mesh size parameter $\alpha_{k+1} = \tau^{j_k^-} \alpha_k$, with $j_k^- \in \{j_{min}, \ldots, -1\}$.

FIG. 2.2. *Updating the mesh size parameter (for rational lattice requirements).*

polling directions, and the mesh procedure that updates the mesh size parameter. These procedures are called within squared brackets for better visibility.

The search and order routines are not asked to meet any requirements for global convergence purposes (except for finiteness of the number of mesh points considered in search).

The mesh procedure, however, must update the mesh size parameter as described in Figure 2.2. The most common choice is to divide the parameter in half at unsuccessful iterations and to keep it or double it at successful ones. As noted by Hough, Kolda, and Torczon [14], increasing the mesh size parameter for all successful iterations can result in an excessive number of later contractions, each one requiring a complete polling, thus leading to an increase in the total number of function evaluations required. A possible strategy to avoid this behavior (fitting the procedure of Figure 2.2) has been suggested in [14] and consists of expanding the mesh only if two consecutive successful iterates have been computed using the same direction.

The global convergence analysis for this class of pattern search methods is divided into two parts. The first part establishes that a subsequence of mesh size parameters goes to zero. This result was first proved by Torczon in [21], and it is stated here as Theorem 2.1.

THEOREM 2.1. *Consider a sequence* $\{x_k\}$ *of pattern search iterates. If* $L(x_0) = \{x \in \mathbb{R}^n : f(x) \leq f(x_0)\}$ *is compact, then the sequence of the mesh size parameters satisfies* $\liminf_{k \to +\infty} \alpha_k = 0$.

The second part of the analysis requires some differentiability properties of the objective function and can be found, for instance, in [3, 17]. We formalize it here for unconstrained minimization.

THEOREM 2.2. *Consider a sequence* $\{x_k\}$ *of pattern search iterates. If* $L(x_0) = \{x \in \mathbb{R}^n : f(x) \leq f(x_0)\}$ *is compact, then there exists at least one convergent subsequence* $\{x_k\}_{k \in K}$ *(with limit point* x_**) of unsuccessful iterates for which the corresponding subsequence of the mesh size parameters* $\{\alpha_k\}_{k \in K}$ *converges to zero. If* f *is strictly differentiable near* x_**, then* $\nabla f(x_*) = 0$. *If* f *is continuously differentiable in an open set containing* $L(x_0)$*, then* $\liminf_{k \longrightarrow +\infty} \|\nabla f(x_k)\| = 0$.

Pattern search and direct search methods for unconstrained optimization are surveyed in the comprehensive paper of Kolda, Lewis, and Torczon [17].

3. Simplex derivatives. A simplex derivative of order one is known as a *simplex gradient*. Simplex gradients were used by Bortz and Kelley [5] in their implicit filtering method, which can be viewed as a line search method based on simplex gradients. Tseng [22] developed a class of simplex-based direct search methods imposing sufficient decrease conditions. He suggested the use of the norm of a simplex gradient in a stopping criterion for his class of methods. No numerical results were reported with this criterion, and no other use of the simplex gradient was suggested. In the context of the Nelder–Mead simplex-based direct search algorithm, Kelley [15] used the simplex gradient norm in a sufficient decrease-type condition to detect stagnation, and the simplex gradient signs to orient the simplex restarts.

Calculation of a simplex gradient first requires the selection of a set of sample points. The geometrical properties of the sample set determine the quality of the corresponding simplex gradient as an approximation to the exact gradient of the objective function. In this paper, we use (determined) simplex gradients as well as underdetermined and overdetermined (or regression) simplex gradients.

In the determined case, a simplex gradient is computed by first sampling the objective function at $n+1$ points. The convex hull of a set of $n+1$ affinely independent points $\{y^0, y^1, \ldots, y^n\}$ is called a simplex. The $n+1$ points are called the vertices of the simplex. Since the points are affinely independent, the matrix $S = [\, y^1 - y^0 \ \ldots \ y^n - y^0 \,]$ is nonsingular. Given a simplex of vertices $y^0, y^1, \ldots, y^n$, the simplex gradient at y^0 is defined as $\nabla_s f(y^0) = S^{-\top} \delta(f; S)$, with $\delta(f; S) = [\, f(y^1) - f(y^0), \ldots, f(y^n) - f(y^0) \,]^\top$.

The simplex gradient is intimately related to linear multivariate polynomial interpolation. In fact, it is easy to see that the linear model $m(y) = f(y^0) + \nabla_s f(y^0)^\top (y - y^0)$ centered at y^0 interpolates f at the points $y^1, \ldots, y^n$.

In practical instances, one might have $q+1 \neq n+1$ points from which to compute a simplex gradient. We say that a sample set is *poised* for a simplex gradient calculation if S is full rank, i.e., if $\operatorname{rank}(S) = \min\{n, q\}$. (The notions of poisedness and affine independence coincide for $q \leq n$, but affine independence is not defined when $q > n$.) Given the sample set $\{y^0, y^1, \ldots, y^q\}$, the simplex gradient $\nabla_s f(y^0)$ of f at y^0 can be defined as the "solution" g of the system

$$S^\top g \ = \ \delta(f; S),$$

where $S = [\, y^1 - y^0 \ \ldots \ y^q - y^0 \,]$ and $\delta(f; S) = [\, f(y^1) - f(y^0), \ldots, f(y^q) - f(y^0) \,]^\top$. This system is solved in the least-squares sense if $q > n$. A minimum norm solution is computed if $q < n$. This definition includes the determined case ($q = n$) as a particular case.

The formulas for the nondetermined simplex gradients can be expressed using the reduced singular value decomposition (SVD) of $S^\top$. However, to deal with the geometrical properties of the poised sample set and to better express the error bound for the corresponding gradient approximation, it is appropriate to take the reduced SVD of a scaled form of $S^\top$. For this purpose, let

$$\Delta \ = \ \max_{1 \leq i \leq q} \|y^i - y^0\|,$$

which is the radius of the smallest enclosing ball of $\{y^0, y^1, \ldots, y^q\}$ centered at y^0. Now we write the reduced SVD of the scaled matrix $S^\top/\Delta = U\Sigma V^\top$, which corresponds to a sample set in a ball of radius one centered around y^0. The underdetermined and overdetermined simplex gradients are both given by $\nabla_s f(y^0) = V\Sigma^{-1}U^\top \delta(f;S)/\Delta$.

The accuracy of simplex gradients is summarized in the following theorem. The proof of the determined case ($q = n$) is given, for instance, by Kelley [16]. The extension of the analysis to the nondetermined cases is developed by Conn, Scheinberg, and Vicente [6].

THEOREM 3.1. *Let $\{y^0, y^1, \ldots, y^q\}$ be a poised sample set for a simplex gradient calculation in $\mathbb{R}^n$. Consider the enclosing (closed) ball $\mathcal{B}(y^0;\Delta)$ of this sample set, centered at y^0, where $\Delta = \max_{1 \leq i \leq q} \|y^i - y^0\|$. Let $S = [\, y^1 - y^0 \ \ldots \ y^q - y^0 \,]$, and let $U\Sigma V^\top$ be the reduced SVD of $S^\top/\Delta$.*

Assume that ∇f is Lipschitz continuous in an open domain Ω containing $\mathcal{B}(y^0;\Delta)$ with constant $\gamma > 0$.

Then the error of the simplex gradient at y^0, as an approximation to $\nabla f(y^0)$, satisfies

$$\|\hat{V}^\top [\nabla f(y^0) - \nabla_s f(y^0)]\| \ \leq \ \left(q^{\frac{1}{2}} \frac{\gamma}{2} \|\Sigma^{-1}\| \right) \Delta,$$

where $\hat{V} = I$ if $q \geq n$ and $\hat{V} = V$ if $q < n$.

Notice that the error difference is projected over the null space of $S^\top/\Delta$. Unless we have enough points ($q + 1 \geq n + 1$), there is no guarantee of accuracy for the simplex gradient. Despite this observation, underdetermined simplex gradients contain relevant gradient information for q close to n and might be of some value in computations where the number of sample points is relatively low.

The quality of the error bound of Theorem 3.1 depends on the size of the constant $\sqrt{q}\gamma\|\Sigma^{-1}\|/2$, which multiplies Δ. This constant, in turn, depends essentially on an unknown Lipschitz constant γ and on $\|\Sigma^{-1}\|$, which is associated to the geometry of the sample set.

Conn, Scheinberg, and Vicente [7] introduced an algorithmic framework for building and maintaining sample sets with good geometry. They have suggested the notion of a Λ–poised sample set, where Λ is a positive constant. The notion of Λ–poisedness is closely related to Lagrange interpolation [7, 6]. If a sample set $\{y^0, y^1, \ldots, y^q\}$ is Λ–poised in the sense of [7, 6], then one can prove that $\|\Sigma^{-1}\|$ is bounded by a multiple of Λ. For the purpose of this paper, it is enough to consider $\|\Sigma^{-1}\|$ as a measure of the well-poisedness (quality of the geometry) of our sample sets. We therefore say that a poised sample set is Λ–*poised* if $\|\Sigma^{-1}\| \leq \Lambda$, for some positive constant Λ.

In a pattern search, we do not necessarily need an algorithm to build or maintain Λ–poised sets. Rather, we are given a sample set at each iteration, and our goal is just to identify a Λ–poised subset. The constant $\Lambda > 0$ is chosen at iteration $k = 0$.

The notion of the simplex gradient can be extended to higher order derivatives [6]. One can consider the computation of a simplex Hessian by extending the linear system $S^\top g = \delta(f;S)$ to the following system in the variables $g \in \mathbb{R}^n$ and $H \in \mathbb{R}^{n\times n}$, with $H = H^\top$:

$$(3.1)\quad (y^i - y^0)^\top g + \frac{1}{2}(y^i - y^0)^\top H(y^i - y^0) \;=\; f(y^i) - f(y^0), \quad i = 1,\ldots,p.$$

The number of points in the sample set $Y = \{y^0, y^1, \ldots, y^p\}$ must be equal to $p+1 = (n+1)(n+2)/2$ if one wants to compute a full symmetric simplex Hessian. Similarly to the linear case, the simplex gradient $g = \nabla_s f(y^0)$ and the simplex Hessian $H = \nabla_s^2 f(y^0)$, computed from system (3.1) with $p+1 = (n+1)(n+2)/2$ points, coincide with the coefficients of the quadratic multivariate polynomial interpolation model associated with Y. The notions of poisedness and Λ–poisedness and the derivation of the error bounds for simplex Hessians in determined and nondetermined cases are reported in [7, 6].

In our application to a pattern search we are interested in using sample sets with a relatively low number of points. One alternative is to consider fewer points than coefficients in the model and to compute solutions in the minimum norm sense. Another option is to choose to approximate only some portions of the simplex Hessian. For instance, if one is given $2n+1$ points one can compute the n components of a simplex gradient and an approximation to the n diagonal terms of a simplex Hessian. The system to be solved in this case is of the form

$$\begin{bmatrix} y^1 - y^0 & \cdots & y^{2n} - y^0 \\ (1/2)(y^1 - y^0).\hat{}2 & \cdots & (1/2)(y^{2n} - y^0).\hat{}2 \end{bmatrix}^\top \begin{bmatrix} g \\ \mathrm{diag}(H) \end{bmatrix} \;=\; \delta(f;S),$$

where $\delta(f;S) = [\, f(y^1) - f(y^0), \ldots, f(y^{2n}) - f(y^0)\,]^\top$ and the notation ".^2" stands for componentwise squaring. Once again, if the number of points is lower than $2n+1$ a minimum norm solution can be computed.

4. Ordering the polling in a pattern search. A pattern search method generates a number of function evaluations at each iteration. One can store some of these points and corresponding objective function values during the course of the iterations. Thus, at the beginning of each iteration, one can try to identify a subset of these points with desirable geometrical properties (Λ–poisedness in our context).

If successful in such an attempt, we compute some form of simplex derivatives, such as a simplex gradient. We can then compute, at no additional cost, a direction of potential descent or of potential steepest descent (a negative simplex gradient, for example). We call such a direction a *descent indicator*. There may be iterations (especially at the beginning) in which we fail to compute a descent indicator, but such failures cost no extra function evaluations either.

Our main goal is to use descent indicators based on simplex derivatives to order the poll vectors efficiently in the poll step. We can also explore the use of simplex derivatives in other components of a pattern search method such as the search step or the mesh size parameter update.

We adapt the description of a pattern search to follow the approach described above. The class of pattern search methods remains essentially the same and is spelled out in Figure 4.1. All modifications to the algorithm reported in Figure 2.1 are marked in italics in Figure 4.1 for better identification.

Pattern Search Method — Using Sampling and Simplex Derivatives

Initialization
Choose x_0 and $\alpha_0 > 0$. Choose a positive spanning set D. Select all constants needed for procedures `[search]`, `[order]`, and `[mesh]`. Set $k = 0$. *Set $X_0 = [x_0]$ to initialize the list of points maintained by* `[store]`. *Choose a maximum number p_{max} of points that can be stored. Choose also the minimum s_{min} and the maximum s_{max} number of points involved in any simplex derivatives calculation ($2 \leq s_{min} \leq s_{max}$). Choose $\Lambda > 0$ and $\sigma_{max} \geq 1$.*

Identifying a Λ–poised sample set and computing simplex derivatives
Skip this step if there are not enough points, i.e., if $|X_k| < s_{min}$. Set $\Delta_k = \sigma_k \alpha_{k-1} \max_{b \in B_{k-1}} \|b\|$, where $\sigma_k \in [1, \sigma_{max}]$. Try to identify a set of points Y_k in $X_k \cap \mathcal{B}(x_k; \Delta_k)$, with as many points as possible (up to s_{max}) and such that Y_k is Λ–poised and includes the current iterate x_k. If $|Y_k| \geq s_{min}$, compute some form of simplex derivatives based on Y_k (and from that compute a descent indicator d_k).

Search step
Call `[search]` to try to compute a point $x \in M_k$ with $f(x) < f(x_k)$ by evaluating the function only at a finite number of points in M_k *and calling* `[store]` *each time a point is evaluated.* If such a point is found, then set $x_{k+1} = x$, declare the iteration as successful, and skip the poll step.

Poll step
Choose a positive basis $B_k \subset D$. Call `[order]` to order the polling set $P_k = \{x_k + \alpha_k b : b \in B_k\}$. Start evaluating f at the polling points following the order determined *and calling* `[store]` *each time a point is evaluated.* If a polling point $x_k + \alpha_k b_k$ is found such that $f(x_k + \alpha_k b_k) < f(x_k)$, then stop polling, set $x_{k+1} = x_k + \alpha_k b_k$, and declare the iteration as successful. Otherwise declare the iteration as unsuccessful and set $x_{k+1} = x_k$.

Updating the mesh size parameter
Call `[mesh]` to compute α_{k+1}. Increment k by one and return to the *simplex derivatives* step.

FIG. 4.1. *The class of pattern search methods used in this paper, adapted now for identifying Λ–poised sample sets and computing simplex derivatives.*

The algorithm maintains a list X_k of evaluated points with maximum size p_{max}. Each time a new point is evaluated, the algorithm calls a new procedure store, which controls the adding (and deleting) of points to X_k.

A new step is included at the beginning of each iteration for computing simplex derivatives. In this step, the algorithm attempts first to extract from X_k a sample set Y_k with the appropriate size and desirable geometrical properties. The points in Y_k must be within a certain distance Δ_k to the current iterate:

$$\Delta_k \ = \ \sigma_k \, \alpha_{k-1} \max_{b \in B_{k-1}} \|b\|,$$

where $\sigma_k \in [1, \sigma_{max}]$, and $\sigma_{max} \geq 1$ is fixed a priori for all iterations. Note that Δ_k is chosen such that $\mathcal{B}(x_k; \Delta_k)$ contains all of the points in $P_{k-1} = \{x_{k-1} + \alpha_{k-1} b : b \in B_{k-1}\}$ when $k-1$ is an unsuccessful iteration. The dependence of Δ_k on α_{k-1} guarantees the asymptotic quality of the simplex derivatives computed at a subsequence of unsuccessful iterates (see Theorems 3.1 and 5.1).

```
procedure order
```
Compute $\cos(d_k, b)$ for all $b \in B_k$. Order the columns in B_k according to decreasing values of the corresponding cosines.

FIG. 4.2. *Ordering the polling vectors according to their angle distance to the descent indicator.*

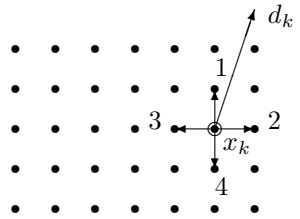

FIG. 4.3. *Ordering the polling vectors using a descent indicator. The positive basis considered is* $B_k = [\, I \; -I \,]$.

We consider two simple strategies for deciding whether or not to store a point, once the function has been evaluated there:

- `store-succ`: keeps only the successful iterates x_{k+1} (for which $f(x_{k+1}) < f(x_k)$);
- `store-all`: keeps every evaluated point.

In both cases, points are added sequentially to X_k at the top of the list. In store-succ, the points in the list X_k are ordered by increasing objective function values. When (and if) X_k has reached its predetermined size p_{max}, we must first remove a point before adding a new one. We assume that the points are removed from the end of the list. Note that both variants store successful iterates x_{k+1} (for which $f(x_{k+1}) < f(x_k)$). Clearly, the current iterate x_k is always in X_k, when store-succ is chosen. However, for store-all, x_k could be removed from the list if a number of consecutive unsuccessful iterates occur. We must therefore add a safeguard to prevent this from happening.

Having a descent indicator d_k at hand, we can order the polling vectors according to increasing magnitudes of the angles between d_k and the polling directions. So the first polling point to be evaluated is the one corresponding to the polling vector making the smallest angle with d_k. We describe this procedure order in Figure 4.2 and illustrate it in Figure 4.3.

The descent indicator could be a negative simplex gradient $d_k = -\nabla_s f(x_k)$, where $S_k = [\, y_k^1 - x_k \;\; \ldots \;\; y_k^{q_k} - x_k \,]$ is formed from the sample set $Y_k = \{y_k^0, y_k^1, \ldots, y_k^{q_k}\}$, with $q_k + 1 = |Y_k|$ and $y_k^0 = x_k$. We designate this approach by sgradient. Another possibility is to compute $d_k = -H_k^{-1} g_k$, where g_k is a simplex gradient and H_k approximates a simplex Hessian. In section 8, we test numerically the diagonal simplex Hessians described at the end of section 3. This approach is designated by shessian.

5. Geometry of the sample sets. If evaluated points are added to the list X_k according to the store-all criterion, it is possible to guarantee the quality of the sample sets Y_k used to compute the simplex derivatives after the occurrence of unsuccessful iterations.

Let us focus on the case where our goal is to compute simplex gradients. We define

$$s_{pb} \;=\; \min\{|B| : \; B \subset D, \; B \text{ positive basis}\}.$$

First we assume that $s_{min} \leq s_{pb}$, i.e., that simplex gradients can be computed from s_{pb} points of X_k with appropriate geometry. If iteration $k-1$ was unsuccessful, then at least $|B_{k-1}|$ points were added to X_{k-1} (the polling points $x_{k-1}+\alpha_{k-1}b$ for all $b \in B_{k-1}$). Such points are part of X_k as well as the current iterate $x_k = x_{k-1}$. It is shown in the next theorem that the sample set $Y_k = \{x_k\} \cup \{x_{k-1}+\alpha_{k-1}b : \ b \in B_{k-1}\} \subset X_k$ is poised for a simplex gradient calculation.

It is also shown that the sample set $Y_k \subset X_k$ formed by x_k and by only $|B_{k-1}|-1$ of the points $x_{k-1}+\alpha_{k-1}b$, $b \in B_{k-1}$, is also poised for a simplex gradient calculation. In this case, we set $s_{min} \leq s_{pb}-1$.

THEOREM 5.1. *Let $k-1$ be any unsuccessful iteration of the pattern search method of Figure* 4.1 *using the store-all strategy.*

- *Suppose $s_{min} \leq s_{pb}$. There exists a positive constant Λ_1 (independent of k) such that the sample set $Y_k \subset X_k$ formed by $x_k = x_{k-1}$ and the points $x_{k-1}+\alpha_{k-1}b$, $b \in B_{k-1}$, is Λ_1–poised for a (overdetermined) simplex gradient calculation.*
- *Suppose $s_{min} \leq s_{pb}-1$. There exists a positive constant Λ_2 (independent of k) such that the sample set $Y_k \subset X_k$ formed by $x_k = x_{k-1}$ and by only $|B_{k-1}|-1$ of the points $x_{k-1}+\alpha_{k-1}b$, $b \in B_{k-1}$, is Λ_2–poised for a (determined or overdetermined) simplex gradient calculation.*

Proof. To simplify the notation we write $B = B_{k-1}$. To prove the first statement, let $Y_k = \{y_k^0, y_k^1, \ldots, y_k^{q_k}\}$, with $q_k+1 = |Y_k| = |B|+1$ and $y_k^0 = x_k$. Then

$$S_k \ = \ [\, y_k^1 - x_k \ \ldots \ y_k^{q_k} - x_k \,] \ = \ [\, \alpha_{k-1}b_1 \ \ldots \ \alpha_{k-1}b_{|B|} \,] \ = \ \alpha_{k-1}B.$$

The matrix B has rank n since it linearly spans $\mathbb{R}^n$ by definition. Thus,

$$\frac{1}{\Delta_k}S_k \ = \ \frac{\alpha_{k-1}}{\sigma_k\,\alpha_{k-1}\max_{b\in B}\|b\|}B \ = \ \frac{1}{\sigma_k}\frac{1}{\max_{b\in B}\|b\|}B,$$

and the geometry constant associated with this sample set Y_k is given by

$$\frac{1}{\sigma_k}\|\Sigma^{-1}\| \qquad \text{with} \qquad \frac{1}{\max_{b\in B}\|b\|}B^\top \ = \ U\Sigma V^\top.$$

Since $\sigma_k \geq 1$, if we choose the poisedness constant such that

$$\Lambda_1 \ \geq \ \max\left\{\|\Sigma^{-1}\| : \ \begin{array}{l} \frac{1}{\max_{b\in B}\|b\|}B^\top \ = \ U\Sigma V^\top \\ \forall\, \text{positive bases } B \subset D \end{array}\right\},$$

then we are guaranteed to identify a Λ_1–poised sample set after any unsuccessful iteration.

In the second case, we have $q_k+1 = |Y_k| = |B|$ and

$$S_k \ = \ \alpha_{k-1}B_{|B|-1},$$

where $B_{|B|-1}$ is some column submatrix of B with $|B|-1$ columns. Since B is a positive spanning set, $B_{|B|-1}$ linearly spans $\mathbb{R}^n$ (see [10, Theorem 3.7]), and therefore it has rank n. The difference now is that we must consider all submatrices $B_{|B|-1}$ of B. Thus, if we choose the poisedness constant such that

$$\Lambda_2 \ \geq \ \max\left\{\|\Sigma^{-1}\| : \ \begin{array}{l} \frac{1}{\max_{b\in B}\|b\|}B_{|B|-1}^\top \ = \ U\Sigma V^\top \\ \forall\ B_{|B|-1} \subset B,\ \forall\, \text{positive bases } B \subset D \end{array}\right\},$$

we are guaranteed to identify a Λ_2–poised sample set after any unsuccessful iteration. ∎

We point out that a result of this type is not necessarily restricted to unsuccessful iterations. Other geometry scenarios can be explored at successful iterations.

6. Pruning the polling directions. Abramson, Audet, and Dennis [1] show that, for a special choice of the positive spanning set D, rough approximations to the gradient of the objective function can be used to reduce the polling step to a single function evaluation. The gradient approximations considered were ϵ–approximations to the large components of the gradient vector.

Let g be a nonzero vector in $\mathbb{R}^n$ and $\epsilon \geq 0$. Consider

$$J^\epsilon(g) \;=\; \{i \in \{1,\ldots,n\} : |g_i| + \epsilon \geq \|g\|_\infty\}\,,$$

and for every $i \in \{1,\ldots,n\}$ let

$$d^\epsilon(g)_i \;=\; \begin{cases} \operatorname{sign}(g_i) & \text{if } i \in J^\epsilon(g), \\ 0 & \text{otherwise.} \end{cases} \tag{6.1}$$

The vector g is said to be an ϵ–approximation to the large components of a nonzero vector $v \in \mathbb{R}^n$ if and only if $i \in J^\epsilon(g)$ whenever $|v_i| = \|v\|_\infty$ and $\operatorname{sign}(g_i) = \operatorname{sign}(v_i)$ for every $i \in J^\epsilon(g)$.

The question that arises now is whether a descent indicator d_k, and, in particular, a negative simplex gradient $-\nabla_s f(x_k)$, is an ϵ–approximation to the large components of $-\nabla f(x_k)$ for some $\epsilon > 0$. We show in the next theorem that the answer is affirmative, provided that the mesh size parameter α_k is sufficiently small, an issue we readdress at the end of this section.

We will use the notation previously introduced in this paper. We consider a sample set Y_k and the corresponding matrix S_k. The set Y_k is included in the ball $\mathcal{B}(x_k;\Delta_k)$ centered at x_k with radius $\Delta_k = \sigma_k\,\alpha_{k-1}\,\max_{b\in B_{k-1}}\|b\|$, where B_{k-1} is the positive basis used for polling at the previous iteration.

THEOREM 6.1. *Let Y_k be a Λ–poised sample set (for simplex gradients) computed at iteration k of a pattern search method, with $q_k + 1 \geq n + 1$ points.*

Assume that ∇f is Lipschitz continuous in an open domain Ω containing $\mathcal{B}(x_k;\Delta_k)$ with constant $\gamma > 0$.

Then, if

$$\alpha_k \;\leq\; \frac{\|\nabla f(x_k)\|_\infty}{\sqrt{q_k}\gamma\Lambda\sigma_{max}\max_{b\in B_{k-1}}\|b\|}, \tag{6.2}$$

the negative simplex gradient $-\nabla_s f(x_k)$ is an ϵ_k–approximation to the large components of $-\nabla f(x_k)$, where

$$\epsilon_k \;=\; \left(q_k^{\frac{1}{2}}\gamma\Lambda\sigma_{max}\max_{b\in B_{k-1}}\|b\|\right)\alpha_k.$$

Proof. For i in the index set

$$I_k \;=\; \{i \in \{1,\ldots,n\} :\; |\nabla f(x_k)_i| = \|\nabla f(x_k)\|_\infty\},$$

we get from Theorem 3.1 that

$$\begin{aligned} \|\nabla_s f(x_k)\|_\infty &\leq \|\nabla f(x_k) - \nabla_s f(x_k)\|_\infty + |\nabla f(x_k)_i| \\ &\leq 2\|\nabla f(x_k) - \nabla_s f(x_k)\| + |\nabla_s f(x_k)_i| \\ &\leq q_k^{\frac{1}{2}}\gamma\Lambda\Delta_k + |\nabla_s f(x_k)_i| \\ &\leq \epsilon_k + |\nabla_s f(x_k)_i|. \end{aligned}$$

From Theorem 3.1 we also know that

$$-\nabla_s f(x_k)_i \;=\; -\nabla f(x_k)_i + \xi_{k,i}, \quad \text{where} \quad |\xi_{k,i}| \le q_k^{\frac{1}{2}} \frac{\gamma}{2} \Lambda \Delta_k.$$

If $-\nabla f(x_k)_i$ and $\xi_{k,i}$ are equally signed, so are $-\nabla f(x_k)_i$ and $-\nabla_s f(x_k)_i$. Otherwise, they are equally signed if

$$|\xi_{k,i}| \;\le\; q_k^{\frac{1}{2}} \frac{\gamma}{2} \Lambda \Delta_k \;\le\; \frac{1}{2} \|\nabla f(x_k)\|_\infty \;=\; \frac{1}{2} |\nabla f(x_k)_i|.$$

The proof is concluded using the expression for Δ_k and the bound for α_k given in the statement of the theorem. □

Theorem 4 by Abramson, Audet, and Dennis [1] shows that an ϵ–approximation prunes the set of the polling directions to a singleton, when considering

$$D \;=\; \{-1, 0, 1\}^n$$

and the positive spanning set

$$D_k \;=\; \{d^\epsilon(g_k)\} \cup \mathbb{A}(-\nabla f(x_k)),$$

where g_k is an ϵ–approximation to $-\nabla f(x_k)$, $d^\epsilon(\cdot)$ is defined in (6.1), and

$$\mathbb{A}(-\nabla f(x_k)) \;=\; \{d \in D : -\nabla f(x_k)^\top d < 0\}$$

represents the set of the ascent directions in D. The pruning is to the singleton $\{d^\epsilon(g_k)\}$, meaning that $d^\epsilon(g_k)$ is the only vector d in D_k such that $-\nabla f(x_k)^\top d \ge 0$.

So, under the hypotheses of Theorem 6.1, it follows that the negative simplex gradient $-\nabla_s f(x_k)$ prunes the positive spanning set

$$D_k \;=\; \{d^{\epsilon_k}(-\nabla_s f(x_k))\} \cup \mathbb{A}(-\nabla f(x_k))$$

to a singleton, namely, $\{d^{\epsilon_k}(-\nabla_s f(x_k))\}$, where ϵ_k is given in Theorem 6.1.

Now we analyze in more detail the role of condition (6.2). There is no guarantee that this condition on α_k can be satisfied asymptotically. Condition (6.2) gives us only an indication of the pruning effect of the negative simplex gradient, and it is more likely to be satisfied at points where the gradient is relatively large. What is known is actually a condition that shows that α_k dominates $\|\nabla f(x_k)\|$ at unsuccessful iterations k:

$$\|\nabla f(x_k)\| \;\le\; \left(\gamma \kappa(B_k)^{-1} \max_{b \in B_k} \|b\|\right) \alpha_k,$$

where

$$\kappa(B_k) \;=\; \min_{d \in \mathbb{R}^n; d \neq 0} \max_{b \in B_k} \frac{d^\top b}{\|d\| \|b\|} \;>\; 0$$

is the cosine measure of the positive basis B_k (see [17, Theorem 3.3]). Since only a finite number of positive bases is used, $\kappa(B_k)^{-1}$ is uniformly bounded. So one can be assured that at unsuccessful iterations the norm of the gradient is bounded by a constant times α_k.

However, it has been observed in [11] that, for some problems, α_k goes to zero faster than $\|\nabla f(x_k)\|$. Our numerical experience with pattern search has also pointed us in this direction. It is more difficult, however, to sharply verify condition (6.2), since it depends on the Lipschitz constant of ∇f. A detailed numerical study of these asymptotic behaviors is beyond the scope of this paper.

procedure mesh-sd

The constants τ and ξ must satisfy $\tau \in \mathbb{Q}$, $\tau > 1$, and $\xi > 0$ and should be initialized at iteration $k = 0$ together with $j_{max} \in \mathbb{Z}$, $j_{max} \geq 0$, and $j_{min} \in \mathbb{Z}$, $j_{min} \leq -1$. The exponents satisfy $j_k^+ \in \{0, 1, 2, \ldots, j_{max}\}$ and $j_k^- \in \{j_{min}, \ldots, -1\}$.

If the iteration was successful, then compute

$$\rho_k \;=\; \frac{f(x_k) - f(x_{k+1})}{m_k(x_k) - m_k(x_{k+1})}.$$

If $\rho_k > \xi$, then $\alpha_{k+1} = \tau^{j_k^+} \alpha_k$,
If $\rho_k \leq \xi$, then $\alpha_{k+1} = \alpha_k$.

If the iteration was unsuccessful, then contract mesh by decreasing the mesh size parameter $\alpha_{k+1} = \tau^{j_k^-} \alpha_k$.

FIG. 7.1. *Updating the mesh size parameter (using a sufficient decrease but meeting rational lattice requirements).*

7. Other uses for simplex derivatives. Having computed before some form of simplex derivatives, one can use the available information for purposes other than ordering the polling vectors. In this section, we suggest two other uses for simplex derivatives in pattern search: the update of the mesh size parameter and the computation of a search step.

When a simplex gradient $\nabla_s f(x_k)$ is computed, a linear model $m_k(y) = f(x_k) + \nabla_s f(x_k)^\top (y - x_k)$ can be used to update the mesh size parameter α_k by imposing a sufficient decrease condition. In this case, we set

$$\rho_k \;=\; \frac{f(x_k) - f(x_{k+1})}{m_k(x_k) - m_k(x_{k+1})} \;=\; \frac{f(x_k) - f(x_{k+1})}{-\nabla_s f(x_k)^\top (x_{k+1} - x_k)}.$$

If x_{k+1} is computed in a successful poll step, then $x_{k+1} - x_k = \alpha_k b_k$ for some $b_k \in B_k$. In the quadratic case, the model is replaced by $m_k(y) = f(x_k) + g_k^\top (y - x_k) + (1/2)(y - x_k)^\top H_k (y - x_k)$. We call this procedure mesh-sd and describe it in Figure 7.1, where the sufficient decrease is applied only to successful iterations.

Since the expansion and contraction parameters are restricted to integer powers of τ and since the contraction rules match what was given in the mesh procedure of Figure 2.2, the modification introduced in mesh-sd has no influence on the global convergence properties of the underlying pattern search method.

There are many possibilities for a search step. One possibility is to first form a surrogate model $m_k(y)$ based on some form of simplex derivatives computed using the sample set Y_k and then to minimize this model in $\mathcal{B}(x_k; \Delta_k)$, after which we would project the minimizer onto the mesh M_k. We described above two examples of such a model $m_k(y)$, but many others could be considered. The use of surrogate models in the search step is the topic of separate research.

8. Implementation and numerical results. To serve as a baseline for numerical comparisons, we have implemented a basic pattern search algorithm of the form given in Figure 2.1. Specifically, no search step is used, the mesh size parameter is left unchanged at successful iterations, and points in the poll step are always evaluated in the same consecutive order as originally stored. We refer to this version of pattern search as basic.

TABLE 8.1

We have tested a number of pattern search methods of the form described in Figure 4.1. The strategies order (Figure 4.2) and mesh-sd (Figure 7.1) were run in four different modes according to the way of storing points (store-succ or store-all) and to the way of computing simplex derivatives and descent indicators (sgradient or shessian). Moreover, we implemented the strategy suggested in [14] and described in section 2 for updating the mesh size parameter (here named as mesh-HKT) and the dynamic polling strategy suggested in [4] for changing the order of the polling directions (see section 2). We tested a very crude search step based on taking a step along the descent indicator with a step size of the order of α_k (see [9] for the details).

The algorithms were coded in MATLAB and ran on 27 unconstrained problems belonging to the CUTEr collection [13], gathered mainly from papers on derivative-free optimization. The objective functions of these problems are twice continuously differentiable. Their dimensions are given in Table 8.1. The starting points used were those reported in CUTEr. Problems bdvalue, integreq, and broydn3d were posed as unconstrained optimization problems like originally in [19]. The stopping criterion consisted of the mesh size parameter becoming lower than 10^{-5} or a maximum number of 100000 iterations being reached.

The simplex derivatives were computed based on Λ-poised sets Y_k, where $\Lambda = 100$. The factor σ_k was chosen as 1 ($k-1$ unsuccessful), 2 ($k-1$ successful and $\alpha_k = \alpha_{k-1}$), and 4 ($k-1$ successful and $\alpha_k > \alpha_{k-1}$). The values for the parameters s_{min}, s_{max}, and p_{max} are given in Table 8.2. We started all runs with the mesh size parameter $\alpha_0 = 1$. In all versions, the contraction factor was set to $\tau^{j_k^-} = 0.5$, and the expansion

TABLE 8.2
Sizes of the list X_k and of the set Y_k.

	sgradient		shessian	
Size	store-succ	store-all	store-succ	store-all
p_{max}	$2(n+1)$	$4(n+1)$	$4(n+1)$	$8(n+1)$
s_{min}	$(n+1)/2$	$n+1$	n	$2n+1$
s_{max}	$n+1$	$n+1$	$2n+1$	$2n+1$

factor (when used) was set to $\tau^{j_k^+} = 2$. In the mesh-sd strategy of Figure 7.1, we set ξ equal to 0.75.

We draw conclusions based on two positive bases: $[\,I\ -I\,]$ and $[\,-e\ I\,]$. The maximal positive basis $[\,I\ -I\,]$ corresponds to a coordinate search, and it provided the best results for the basic version among a few positive bases stored in different orders (which included $[\,I\ -I\,]$, $[\,-I\ I\,]$, $[\,-e\ I\,]$, $[\,e\ -I\,]$, $[\,I\ -e\,]$, $[\,-I\ e\,]$, and a minimal basis with angles between vectors of uniform amplitude). The positive basis stored as $[\,-e\ I\,]$ was the minimal positive basis which behaved the best. In Table 8.1 we report the results obtained by the basic version for these two positive bases.

By combining all possibilities, we tested a total of 120 versions, 112 involving simplex derivatives. A summary of the complete numerical results is reported in [9].

8.1. Discussion based on complete results. First, we point out that 91% of the versions involving simplex derivatives lead to an average decrease in the number of function evaluations [9]. Moreover, 61 out of the 112 strategies tested provided a negative 75% percentile for the variation in the number of function evaluations. This means that for each of these 61 strategies, a reduction in the number of function evaluations was achieved for 75% of the problems tested.

The overall results [9] showed a superiority of sgradient over shessian, which is not surprising because the number of points required to identify Λ–poised sets in sgradient is lower than in shessian. Also, another reason for sgradient being possibly better than shessian is that, if the simplex gradient is sufficiently close to the true gradient, then directions making a small angle with the negative simplex gradient will be descent directions, while the same is not guaranteed when we use simplex Newton directions. Some shessian versions, however, have behaved relatively well [9].

For the positive basis $[\,I\ -I\,]$ there is a clear gain when using store-all compared to store-succ [9]. However, for the positive basis $[\,-e\ I\,]$, the advantage of store-all over store-succ is not as clear [9]. In general, the advantage of store-all may be explained by the frequent number of unsuccessful iterations that tend to occur in the last iterations of a pattern search run. The effect of the poll ordering is also more visible when using the positive basis $[\,I\ -I\,]$, due to the larger number of polling vectors.

Strategies mesh-sd and mesh-HKT made a clear positive impact when using the smaller positive basis $[\,-e\ I\,]$ (see [9]). This effect was lost in the larger positive basis $[\,I\ -I\,]$, where the order procedure seems to perform well on its own for this test set.

8.2. Discussion based on best results. We report in Table 8.3 a summary of the results for a number of versions based on $[\,I\ -I\,]$. Included in this restricted set of versions are the ones that lead to the best results among all of the 120 versions tested. (The results for the remaining versions are summarized in [9].)

An explanation about Table 8.3 is in order. For each strategy and for each problem, we calculated the percentage of iterations that used simplex descent indicators as well as the variation in the number of function evaluations required relatively to the basic version. These percentages were grouped by strategy, and their average values are

TABLE 8.3

Average percentage of iterations that used simplex descent indicators (second column), average variation of function evaluations by comparison to the basic version (third column), and cumulative percentages for the optimal gaps of the final iterates (fourth to sixth columns). Case sgradient and $D = [\, I \; -I \,]$.

Strategy	% poised	Number of evaluations	Optimal gap		
			10^{-7}	10^{-4}	10^{-1}
`basic`	—	—	33.33%	81.48%	92.59%
`mesh-HKT`	—	+4.02%	40.74%	81.48%	92.59%
`dynamic polling`	—	-10.99%	33.33%	81.48%	92.59%
`mesh-HKT,dynamic polling`	—	-15.17%	48.15%	81.48%	92.59%
`mesh-sd (store-succ)`	14.40%	-3.07%	33.33%	81.48%	92.59%
`mesh-sd (store-all)`	73.33%	+0.45%	33.33%	81.48%	92.59%
`order (store-all)`	27.26%	-51.16%	37.04%	85.19%	92.59%
`mesh-sd,order (store-all)`	28.56%	-51.47%	37.04%	85.19%	92.59%
`mesh-HKT,order (store-all)`	58.51%	-54.22%	51.85%	81.48%	88.89%

reported in the second and third columns of Table 8.3. The last three columns of the table represent the cumulative percentages for the optimal gaps of the final iterates.

The quality of the final objective function values obtained for the versions included in Table 8.3 is comparable to the basic version, as one see from the final cumulative optimal gaps reported.

It is clear that none of the strategies for updating the step size parameter (mesh-sd and mesh-HKT) made improvements on their one, the former being slightly better than the latter.

The best result without using simplex derivatives was obtained by combining dynamic polling and mesh-HKT (15% less function evaluations than the basic version).

Three versions that incorporated order reached a reduction of around 50% in the number of function evaluations. The order procedure in the store-all mode leads, on its own, to a 51% improvement, compared to 11% of dynamic polling.

The best version achieved a reduction of 54% in the number of evaluations by combining order and mesh-HKT in the store-all mode. In Table 8.4 we report the results obtained by this version as well as by the version that applies only the order procedure in the store-all mode.

8.3. Additional tests. We picked some of these problems and ran several versions for $n = 40$ and $n = 80$. Our conclusions remain essentially the same. The ratios of improvement in the number of function evaluations and the quality of the final iterates do not change significantly with the increase of the dimension of the problem but rather with the increase of the number of polling vectors in the positive spanning set or with the increase in its cosine measure (both of which happen, for instance, when going from $[\, -e \; I \,]$ to $[\, I \; -I \,]$).

We also tried to investigate how sensitive the different algorithmic versions are to the choice of the parameter ξ used in the mesh-sd strategy. We tried other values (for instance, 0.5 and 0.95), but the results did not improve.

We repeated these computational tests on a different set of test problems, consisting of seven randomly generated quadratic functions, each one of dimension 10. The quadratic functions were defined by $f(x) = x^\top Ax$, where $A = B^\top B$ and B is a matrix with random normal entries of mean 0 and standard deviation 1. We also randomly generated the starting point for the algorithm, using the same normal distribution. Once again, the conclusions for the different strategies remained essentially the same

(with improvement of the results for the minimal positive basis $[\, -e \; I \,]$). We used these examples to study the descent properties of the negative simplex gradient. In our experiments, the simplex gradient made an acute angle with the true gradient on average in 77% of the cases where it was computed. These occurrences tend to happen more towards the end of the runs when the mesh size parameter gets smaller.

8.4. Pruning. To better understand the theoretical results derived in section 6, we implemented a computational variant of the pruning strategy. We did not consider the generating set $D = \{-1, 0, 1\}^n$, as suggested by Abramson, Audet, and Dennis [1], nor did we verify condition (6.2) (or some approximated form of it by estimating the Lipschitz constant involved) before pruning the polling vectors. As a result, we are violating the conditions required for the analysis of the pruning strategy. We tested two different variants for pruning the positive bases $[\, I \; -I \,]$ and $[\, -e \; I \,]$: (i) pruning to a single direction, namely, the one that makes the angle of smallest amplitude with the descent indicator and (ii) pruning to all of the directions that make an acute angle with the descent indicator.

To reach a final iterate of quality nearly similar to the one obtained by the basic version, we had to use the positive basis $[\, I \; -I \,]$ and prune with more than one direction. In this case, pruning achieved an average reduction in the number of function evaluations of 10% and 42%, for the store-succ and store-all variants, respectively. Pruning tends to generate less polling points, which in turn decreases the chances of building well-poised sets.

More research is needed in order to evaluate the potential of the negative simplex gradient as an ϵ-approximation to the large components of the negative gradient vector and its use for pruning the polling directions. The use of the generating set $D = \{-1, 0, 1\}^n$ and the implementation of some form of the condition (6.2) might have a positive impact.

9. Concluding remarks and future work. We have proposed the use of simplex derivatives in pattern search methods in two ways: ordering the polling vectors and updating the mesh size parameter. For the calculation of the simplex derivatives, we considered sample sets constructed in two variants: storing only all recent successful iterates or storing all recent points where the objective function was evaluated. Finally, we studied two types of simplex derivatives: simplex gradients and diagonal simplex Hessians. It is important to remark that the incorporation of these strategies in a pattern search is done at no further expense in function evaluations.

The introduction of simplex derivatives in pattern search methods can lead to a significant reduction in the number of function evaluations for the same quality of the final iterates.

As a descent indicator, we recommend the use of the negative simplex gradient over the simplex Newton direction. In fact, most of the iterations of a pattern search run are performed for small values of the mesh size parameter. In such cases, the negative gradient is better than the Newton direction as an indicator for descent, and the same argument applies to their simplex counterparts.

For a coordinate search ($D = [\, I \; -I \,]$), ordering the polling directions according to a simplex descent indicator (negative simplex gradient) made a significant impact in the reduction of the number of function evaluations. For this type of positive basis, storing all recent points where the objective function was evaluated seems to be the best approach.

Our numerical findings showed that updating the mesh size parameter based on a sufficient decrease condition can be worthwhile applying when using minimal positive bases (such as $D = [\, -e \; I \,]$). In such cases, storing only all recent successful iterates may also be advantageous.

There are at least two natural generalizations of the ideas presented in this paper. One is to apply simplex derivative-based strategies to improve parallel versions of a pattern search. Another generalization consists of analyzing the properties of simplex gradients when direct search methods are applied to nonsmooth functions [8]. The use of simplex derivatives in the design of an efficient search step is also the subject of future research.

Acknowledgments. During the course of the revision of this paper, the first author visited the College of William & Mary. The authors are grateful to Robert Michael Lewis, Virginia Torczon, and Michael Trosset for many interesting and stimulating comments, which have contributed to improvements in the manuscript. We also thank the anonymous referees for their suggestions.

CLARKE SUBGRADIENTS OF STRATIFIABLE FUNCTIONS*

JÉRÔME BOLTE†, ARIS DANIILIDIS‡, ADRIAN LEWIS§, AND MASAHIRO SHIOTA¶

Abstract. We establish the following result: If the graph of a lower semicontinuous real-extended-valued function $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ admits a Whitney stratification (so in particular if f is a semialgebraic function), then the norm of the gradient of f at $x \in \operatorname{dom} f$ relative to the stratum containing x bounds from below all norms of Clarke subgradients of f at x. As a consequence, we obtain a Morse–Sard type of theorem as well as a nonsmooth extension of the Kurdyka–Łojasiewicz inequality for functions definable in an arbitrary o-minimal structure. It is worthwhile pointing out that, even in a smooth setting, this last result generalizes the one given in [K. Kurdyka, Ann. Inst. Fourier (Grenoble), 48 (1998), pp. 769–783] by removing the boundedness assumption on the domain of the function.

Key words. Clarke subgradient, Łojasiewicz inequality, critical point, nonsmooth analysis, Whitney stratification

1. Introduction.

Nonsmoothness in optimization seldom occurs in an arbitrary manner, but instead is often well-structured. Such structure can often be exploited in sensitivity analysis and algorithm convergence: Examples include "amenability," "subsmoothness," "prox-regularity" (see [32], for example), and more recently the idea of a "partly smooth" function, where a naturally arising manifold $\mathcal{M}$ contains the minimizer and the function is smooth along this manifold. We quote [24] for formal definitions, examples, and more details. In the past two decades, several researchers have tried to capture this intuitive idea in order to develop algorithms ensuring better convergence results: See, for instance, the pioneer work [23] and also [26], [9] for recent surveys.

In this work we shall be interested in a particular class of well-structured (nonsmooth) functions, namely, functions admitting a Whitney stratification (see section 2 for definitions). Since this class contains in particular the semialgebraic and the subanalytic functions (more generally, functions that are definable in some o-minimal structure over $\mathbb{R}$), the derived results can directly be applied in several concrete optimization problems involving such structures. Our central idea is to relate derivative ideas from two distinct mathematical sources: Variational analysis and differential ge-

ometry. Specifically, we derive a lower bound on the norms of Clarke subgradients at a given point in terms of the "Riemannian" gradient with respect to the stratum containing that point. This is a direct consequence of the "projection formula" given in Proposition 4 and has as corollaries a Morse–Sard type of theorem for Clarke critical points of lower semicontinuous Whitney stratifiable functions (Corollary 5(ii)) as well as a *global* nonsmooth version of the Kurdyka–Łojasiewicz inequality—which is hereby extended to unbounded domains; see Theorem 11—for lower semicontinuous definable functions (Theorem 14 and Corollary 15). Although these results seem natural, analogous ones fail for the (broader) convex-stable subdifferential (introduced and studied in [4]), unless f is assumed to be locally Lipschitz continuous; see Remark 8 and [3].

Theorems of the Morse–Sard type are central in many areas of analysis, typically describing the size of the set of ill-posed problem instances in a given class. Classical results deal with smooth functions [33], [22], but recent advances deal with a variety of nonsmooth settings [3], [13], [14], [15].

A further long-term motivation of this work is to understand the convergence of minimization algorithms. As one example, in order to treat nonconvex (and nonsmooth) minimization problems, the authors of [4] introduced an algorithm called the "gradient sampling algorithm." The idea behind this algorithm was to sample gradients of nearby points of the current iterate and to produce the next iterate by following the vector of minimum norm in the convex hull generated by the sampled negative gradients. In the case that the function is locally Lipschitz, the above method can be viewed as a kind of ε-Clarke subgradient algorithm for which both theoretical and numerical results are quite satisfactory; see [4]. The convergence of the whole sequence of iterates remains, however, an open question, and this is also the case for many classical subgradient methods for nonconvex minimization; see [19]. We hope that, just as in the smooth case, the nonsmooth Łojasiewicz inequality we develop (cf. (22) in section 4) may help in understanding the global convergence of subgradient methods.

As we outline above, we use a stratification approach to develop our results. Ioffe [14] has recently announced an extension of the work described here, leading to a remarkable and powerful Sard-type result for stratifiable multifunctions (see [15]).

2. Preliminaries. In this section we recall several definitions and results concerning nonsmooth analysis (subgradients, generalized critical points) and stratification theory. For nonsmooth analysis we refer to the comprehensive texts [5], [6], [28], [29], [32].

In what follows the vector space $\mathbb{R}^n$ is endowed with its canonical scalar product $\langle \cdot, \cdot \rangle$.

Nonsmooth analysis. Given an extended-real-valued function $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ we denote its domain by $\operatorname{dom} f := \{x \in \mathbb{R}^n : f(x) < +\infty\}$, its graph by

$$\operatorname{Graph} f := \{(x, f(x)) \in \mathbb{R}^n \times \mathbb{R} : x \in \operatorname{dom} f\},$$

and its epigraph by

$$\operatorname{epi} f := \{(x, \beta) \in \mathbb{R}^n \times \mathbb{R} : f(x) \leq \beta\}.$$

In this work we shall deal with *lower semicontinuous* functions, that is, functions for which $\operatorname{epi} f$ is a closed subset of $\mathbb{R}^n \times \mathbb{R}$. In this setting, we say that $x^* \in \mathbb{R}^n$ is a *Fréchet subgradient* of f at $x \in \operatorname{dom} f$ provided that

$$\liminf_{y \to x, y \neq x} \frac{f(y) - f(x) - \langle x^*, y - x \rangle}{\|y - x\|} \geq 0. \tag{1}$$

The set of all Fréchet subgradients of f at x is called the *Fréchet subdifferential* of f at x and is denoted by $\hat{\partial} f(x)$. If $x \notin \operatorname{dom} f$, then we set $\hat{\partial} f(x) = \emptyset$.

Let us give a geometrical interpretation of the above definition: It is well known that the gradient of a C^1 function $f : \mathbb{R}^n \to \mathbb{R}$ at $x \in \mathbb{R}^n$ can be defined geometrically as the vector $\nabla f(x) \in \mathbb{R}^n$ such that $(\nabla f(x), -1)$ is normal to the tangent space $\mathrm{T}_{(x,f(x))}\mathrm{Graph}\, f$ of (the C^1 manifold) $\mathrm{Graph}\, f$ at $(x, f(x))$, that is,

$$(\nabla f(x), -1) \perp \mathrm{T}_{(x,f(x))}\mathrm{Graph}\, f.$$

A similar interpretation can be stated for Fréchet subgradients. Let us first define the *(Fréchet) normal cone* of a subset C of $\mathbb{R}^n$ at $x \in C$ by

$$\hat{N}_C(x) = \left\{ v \in \mathbb{R}^n : \limsup_{\substack{y \to x \\ y \in C \setminus \{x\}}} \left\langle v, \frac{y - x}{||x - y||} \right\rangle \leq 0 \right\}. \tag{2}$$

Then it can be proved (see [32, Theorem 8.9], for example) that for a nonsmooth function f we have

$$x^* \in \hat{\partial} f(x) \quad \text{if and only if} \quad (x^*, -1) \in \hat{N}_{\mathrm{epi}\, f}(x, f(x)). \tag{3}$$

The Fréchet subdifferential extends the notion of a derivative in the sense that if f is differentiable at x, then $\hat{\partial} f(x) = \{\nabla f(x)\}$. However, it is not completely satisfactory in optimization, since $\hat{\partial} f(x)$ might be empty-valued at points of particular interest (think of the example of the function $f(x) = -||x||$, at $x = 0$). Moreover, the Fréchet subdifferential is not a closed mapping, so it is unstable computationally. For this reason we also consider (see [28], [32], for example):

(i) the *limiting* subdifferential $\partial f(x)$ of f at $x \in \operatorname{dom} f$:

$$x^* \in \partial f(x) \iff \exists (x_n, x_n^*) \subset \mathrm{Graph}\, \hat{\partial} f \ : \ \begin{cases} \lim_{n\to\infty} x_n = x, \\ \lim_{n\to\infty} f(x_n) = f(x), \\ \lim_{n\to\infty} x_n^* = x^*, \end{cases} \tag{4}$$

where $\mathrm{Graph}\, \hat{\partial} f := \{(u, u^*) : u^* \in \hat{\partial} f(u)\}$;

(ii) the *singular limiting* subdifferential $\partial^\infty f(x)$ of f at $x \in \operatorname{dom} f$:

$$y^* \in \partial^\infty f(x) \iff \exists (y_n, y_n^*) \subset \mathrm{Graph}\, \hat{\partial} f,\ \exists t_n \searrow 0^+ : \begin{cases} \lim_{n\to\infty} y_n = x, \\ \lim_{n\to\infty} f(y_n) = f(x), \\ \lim_{n\to\infty} t_n y_n^* = y^*. \end{cases} \tag{5}$$

When $x \notin \operatorname{dom} f$ we set $\partial f(x) = \partial^\infty f(x) = \emptyset$.

The *Clarke subdifferential* $\partial^\circ f(x)$ of f at $x \in \operatorname{dom} f$ is the central notion of this work. It can be defined in several (equivalent) ways; see [5]. The definition below (see [16, Proposition 3.3], [17, Proposition 3.4], or [30, Theorem 8.11]) is the most convenient for our purposes. (For any subset S of $\mathbb{R}^n$ we denote by $\overline{\mathrm{co}}\, S$ the closed convex hull of S.)

DEFINITION 1 (Clarke subdifferential). *The Clarke subdifferential* $\partial^\circ f(x)$ *of* f *at* x *is the set*

$$\partial^\circ f(x) = \begin{cases} \overline{\text{co}}\,\{\partial f(x) + \partial^\infty f(x)\} & \text{if } x \in \operatorname{dom} f, \\ \emptyset & \text{if } x \notin \operatorname{dom} f\,. \end{cases} \tag{6}$$

Remark 1. The construction (6) does not look very natural at first sight. However, it can be shown that an analogous to (3) formula holds also for the Clarke subdifferential, if $\hat{N}_{\operatorname{epi} f}(x, f(x))$ is replaced by the Clarke normal cone, which is the closed convex hull of the limiting normal cone. The latter cone comes naturally from the Fréchet normal cone by closing its graph; and see [32, pp. 305 and 336] for details.

From the above definitions it follows directly that for all $x \in \mathbb{R}^n$, one has

$$\hat{\partial} f(x) \subset \partial f(x) \subset \partial^\circ f(x). \tag{7}$$

The elements of the limiting (respectively, Clarke) subdifferential are called limiting (respectively, Clarke) subgradients.

The notion of a Clarke critical point (respectively, critical value, asymptotic critical value) is defined as follows.

DEFINITION 2 (Clarke critical point). *We say that* $x \in \mathbb{R}^n$ *is a* Clarke critical point *of the function* f *if*

$$\partial^\circ f(x) \ni 0.$$

DEFINITION 3 ((asymptotic) Clarke critical value). (i) *We say that* $\alpha \in \mathbb{R}$ *is a* Clarke critical value *of* f *if the level set* $f^{-1}(\{\alpha\})$ *contains a Clarke critical point.*

(ii) *We say that* $\lambda \in \mathbb{R} \cup \{\pm\infty\}$ *is an* asymptotic Clarke critical value *of* f*, if there exists a sequence* $(x_n, x_n^*)_{n\geq 1} \subset \operatorname{Graph} \partial^\circ f$ *such that*

$$\begin{cases} f(x_n) \to \lambda \\ (1 + ||x_n||)\,||x_n^*|| \to 0. \end{cases}$$

Let us make some observations concerning the above definitions.

Remark 2. (i) Both limiting and Clarke subgradients are generalizations of the usual gradient of smooth functions: Indeed, if f is C^1 around x (or more generally, strictly differentiable at x [32, Definition 9.17]), then we have

$$\partial^\circ f(x) = \partial f(x) = \{\nabla f(x)\}.$$

It should be noted that if f is only Fréchet differentiable at x, then $\partial^\circ f(x) \supset \partial f(x) \supset \{\nabla f(x)\}$, where the inclusions might be strict.

(ii) The singular limiting subdifferential should not be thought as a set of subgradients. Roughly speaking it is designed to detect "horizontal normals" to the epigraph of f. For instance, for the (nonsmooth) function $f(x) = x^{\frac{1}{3}}$ $(x \in \mathbb{R})$ we have $\partial^\infty f(0) = \mathbb{R}_+$. Note that, since the domain of the Fréchet subdifferential is dense in $\operatorname{dom} f$, we always have $\partial^\infty f(x) \ni 0$ for all $x \in \operatorname{dom} f$ (see also [32, Corollary 8.10]); therefore, this latter relation cannot be regarded as a meaningful definition of a critical point.

(iii) To illustrate the definition of the Clarke critical point (Definition 1), let us consider the example of the function $f : \mathbb{R} \to \mathbb{R}$ defined by

$$f(x) = \begin{cases} x & \text{if } x \leq 0, \\ -\sqrt{x} & \text{if } x > 0. \end{cases}$$

Then $\hat{\partial} f(0) = \emptyset$ and $\partial f(0) = \{1\}$. However, since $\partial^\infty f(0) = \mathbb{R}_-$, it follows from (6) that $\partial^\circ f(0) = (-\infty, 1]$, so $x = 0$ is a Clarke critical point.

(iv) It follows from Definition 3 that every Clarke critical value $\alpha \in \mathbb{R}$ is also an asymptotic Clarke critical value (indeed, given $x_0 \in f^{-1}(\{\alpha\})$ with $0 \in \partial^\circ f(x_0)$, it is sufficient to take $x_n := x_0$ and $x_n^* = 0$). Note that in the case that f has a bounded domain $\operatorname{dom} f$, Definition 3(ii) can be simplified in the following way: The value $\lambda \in \mathbb{R} \cup \{\pm\infty\}$ is asymptotically critical if and only if there exists a sequence $(x_n, x_n^*)_{n\geq 1} \subset \operatorname{Graph} \partial^\circ f$ such that $f(x_n) \to \lambda$ and $x_n^* \to 0$.

Stratification results. By the term *stratification* we mean a locally finite partition of a given set into differentiable manifolds, which, roughly speaking, fit together in a regular manner. Let us give a formal definition of a C^p stratification of a set. For general facts about stratifications we quote [27]; more specific results concerning tame geometry can be found in [34], [11], [18], [10], [21].

Let X be a nonempty subset of $\mathbb{R}^n$ and p a positive integer. A C^p *stratification* $\mathcal{X} = (X_i)_{i\in I}$ of X is a locally finite partition of X into C^p submanifolds X_i of $\mathbb{R}^n$ such that for each $i \neq j$

$$\overline{X_i} \cap X_j \neq \emptyset \implies X_j \subset \overline{X_i} \setminus X_i.$$

The submanifolds X_i are called *strata* of $\mathcal{X}$. Furthermore, given a finite collection $\{A_1, \ldots, A_q\}$ of subsets of X, a stratification $\mathcal{X} = (X_i)_{i\in I}$ is said to be *compatible with the collection* $\{A_1, \ldots, A_q\}$ if each A_i is a locally finite union of strata X_j.

In this work we shall use a special type of stratification (called a *Whitney stratification*) for which the strata are such that their tangent spaces also "fit regularly." To give a precise meaning to this statement, let us first define the *distance* (or *gap*) of two vector subspaces V and W of $\mathbb{R}^n$ by the following standard formula:

$$D(V, W) = \max \left\{ \sup_{v\in V,\, ||v||=1} d(v, W), \sup_{w\in W,\, ||w||=1} d(w, V) \right\}.$$

Note that

$$\sup_{v\in V,\, ||v||=1} d(v, W) = 0 \Longleftrightarrow V \subset W.$$

Further we say that a sequence $\{V_k\}_{k\in\mathbb{N}}$ of subspaces of $\mathbb{R}^n$ *converges* to the subspace V of $\mathbb{R}^n$ (in short, $V = \lim_{k\to+\infty} V_k$) provided

$$\lim_{k\to+\infty} D(V_k, V) = 0.$$

Notice that in this case the subspaces V_k will eventually have the same dimension (say, d); thus, the above convergence is essentially equivalent to the convergence in the Grassmannian manifold G_d^n.

A C^p stratification $\mathcal{X} = (X_i)_{i\in I}$ of X has the *Whitney-*(a) *property,* if for each $x \in \overline{X_i} \cap X_j$ (with $i \neq j$) and for each sequence $\{x_k\} \subset X_i$ we have

$$\left.\begin{array}{ll} & \lim_{k\to\infty} x_k = x \\ \text{and} & \\ & \lim_{k\to\infty} T_{x_k} X_i = \mathcal{T}, \end{array}\right\} \implies T_x X_j \subset \mathcal{T},$$

where $T_x X_j$ (respectively, $T_{x_k} X_i$) denotes the tangent space of the manifold X_j at x (respectively, of X_i at x_k). In what follows we shall use the term *Whitney stratification* to refer to a C^1 stratification with the Whitney-(a) property.

3. Projection formulas for subgradients. In this section we make precise the links between the Clarke subgradients of a lower semicontinuous function whose graph admits a Whitney stratification and the gradients of f (with respect to the strata). As a corollary we obtain a nonsmooth extension of the Morse–Sard theorem for such functions (see Corollary 5).

Let $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous function. We shall deal with *nonvertical* Whitney stratifications $\mathcal{S} = (S_i)_{i\in I}$ of the graph $\operatorname{Graph} f$ of f, that is, Whitney stratifications satisfying for all $i \in I$ and $u \in S_i$ the transversality condition

$$e_{n+1} \notin T_u S_i \qquad (\mathcal{H}),$$

where

$$e_{n+1} = (0, \dots, 0, 1) \in \mathbb{R}^{n+1}.$$

Remark 3. If f is locally Lipschitz continuous, then it is easy to check that any stratification of $\operatorname{Graph} f$ is nonvertical. This might also happen for other functions (think of the nonlocally Lipschitz function $f(x) = \sqrt{|x|}$: Every stratification of $\operatorname{Graph} f$ should contain the stratum $S_0 = \{(0,0)\}$). However, the example of the function $f(x) = x^{1/3}$ shows that this is not the case for any (continuous stratifiable) function f and any stratification of its graph (consider the trivial stratification consisting of the single stratum $S = \operatorname{Graph} f$ and take $u = (0,0)$).

Let us denote by $\Pi : \mathbb{R}^{n+1} \to \mathbb{R}^n$ the canonical projection on $\mathbb{R}^n$, that is,

$$\Pi(x_1, \dots, x_n, t) = (x_1, \dots, x_n).$$

For each $i \in I$ we set

$$X_i = \Pi(S_i) \qquad \text{and} \qquad f_i = f|_{X_i}. \tag{8}$$

Due to the assumption $(\mathcal{H})$ (nonverticality) one has that for all $i \in I$:

(i) X_i is a C^1 submanifold of $\mathbb{R}^n$, and

(ii) $f_i : X_i \to \mathbb{R}$ is a C^1 function.

If, in addition, the function f is continuous, then it can be easily seen that:

(iii) $\mathcal{X} = (X_i)_{i\in I}$ is a Whitney stratification of $\operatorname{dom} f = \Pi(\operatorname{Graph} f)$.

Notation. In what follows, for any $x \in \operatorname{dom} f$, we shall denote by X_x (respectively, S_x) the stratum of $\mathcal{X}$ (respectively, of $\mathcal{S}$) containing x (respectively, $(x, f(x))$). The manifolds X_i are here endowed with the metric induced by the canonical Euclidean scalar product of $\mathbb{R}^n$. Using the inherited Riemannian structure of each stratum X_i of $\mathcal{X}$ for any $x \in X_i$, we denote by $\nabla_R f(x)$ the gradient of f_i at x with respect to the stratum $X_i, \langle\cdot,\cdot\rangle$.

Proposition 4 (projection formula). *Let $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous function, and assume that* $\operatorname{Graph} f$ *admits a nonvertical Whitney stratification $\mathcal{S} = (S_i)_{i\in I}$. Then for all $x \in \operatorname{dom} f$ we have*

$$\operatorname{Proj}_{T_x X_x} \partial f(x) \subset \{\nabla_{\mathrm{R}} f(x)\}, \qquad \operatorname{Proj}_{T_x X_x} \partial^\infty f(x) = \{0\}, \tag{9}$$

and

$$\operatorname{Proj}_{T_x X_x} \partial^\circ f(x) \subset \{\nabla_{\mathrm{R}} f(x)\}, \tag{10}$$

where $\operatorname{Proj}_{\mathcal{V}} : \mathbb{R}^n \to \mathcal{V}$ *denotes the orthogonal projection on the vector subspace $\mathcal{V}$ of $\mathbb{R}^n$.*

Proof. We shall use the above notation (and in particular the notation of (8)).

Let us first describe the links between the Fréchet subdifferential $\hat{\partial} f(x)$ and the gradient of $f\,|_{X_x}$ at a point $x \in \operatorname{dom} f$. For any $v \in T_x X_x$ and any continuously differentiable curve $c : (-\varepsilon, \varepsilon) \to X_x$ $(\varepsilon > 0)$ with $c(0) = x$ and $\dot{c}(0) = v$, the function

$$f \circ c \,(:= f_i \circ c) \,: (-\varepsilon, \varepsilon) \to \mathbb{R}$$

is continuously differentiable. In view of [32, Theorem 10.6, p. 427], we have

$$\left\{ \langle x^*,\, v\rangle :\, x^* \in \hat{\partial} f(x) \right\} \,\subset\, \left\{ \frac{d}{dt}\, f(c(t))\,|_{t=0} \right\}.$$

Since $\frac{d}{dt} f(c(t))|_{t=0} = \langle \nabla_R f(x), v\rangle$ it follows that

$$\operatorname{Proj}_{T_x X_x} \hat{\partial} f(x) \,\subset\, \{\nabla_R f(x)\}. \tag{11}$$

In a second stage we prove successively that

$$\operatorname{Proj}_{T_x X_x} \partial f(x) \,\subset\, \{\nabla_R f(x)\} \quad \text{and} \quad \operatorname{Proj}_{T_x X_x} \partial^\infty f(x) \,\subset\, \{0\}. \tag{12}$$

To this end, take $p \in \partial f(x)$, and let $\{x_k\} \,\subset\, \operatorname{dom} \hat{\partial} f$, $x_k^* \in \hat{\partial} f(x_k)$ be such that $(x_k,\, f(x_k)) \to (x,\, f(x))$ and $x_k^* \to p$. Due to the local finiteness property of $\mathcal{S}$, we may suppose that the sequence $\{u_k := (x_k, f(x_k))\}$ lies entirely in some stratum S_i of dimension d.

If $S_i = S_x$, then by (11) we deduce that $\operatorname{Proj}_{T_x X_x}(x_k^*) = \nabla_R f(x_k)$; thus, using the continuity of the projection and the fact that $f\,|_{X_x}$ is C^1 (so $\nabla_R f(x_k) \to \nabla_R f(x)$), we obtain $\operatorname{Proj}_{T_x X_x}(p) = \nabla_R f(x)$.

If $S_i \neq S_x$, then from the convergence $(x_k,\, f(x_k)) \to (x,\, f(x))$ we deduce that $\overline{S_i} \cap S_x \neq \emptyset$ (thus $d = \dim S_i > \dim S_x$). Using the compactness of the Grassmannian manifold G_d^n, we may assume that the sequence $\{T_{u_k} S_i\}$ converges to some vector space $\mathcal{T}$ of dimension d. Then the Whitney-(a) property yields that $\mathcal{T} \supset T_{(x,f(x))} S_x$. Recalling (3), for each $k \geq 1$ we have that the vector $(x_k^*, -1)$ is Fréchet normal to the epigraph $\operatorname{epi} f$ of f at u_k; hence, it is also normal (in the classical sense) to the tangent space $T_{u_k} S_i$. By a standard continuity argument the vector

$$(p, -1) = \lim_{k \to \infty} (x_k^*, -1)$$

must be normal to $\mathcal{T}$ and a fortiori to $T_{(x,f(x))} S_x$. By projecting $(p, -1)$ orthogonally on $T_x X_x + \mathbb{R}\, e_{n+1} \supset T_{(x,f(x))} S_x$, we notice that $(\operatorname{Proj}_{T_x X_x}(p), -1)$ is still normal to $T_{(x,f(x))} S_x$. We conclude that

$$\operatorname{Proj}_{T_x X_x}(p) = \nabla_R f(x); \tag{13}$$

thus, the first part of (12) follows.

Let now any $q \in \partial^\infty f(x)$. By definition there exist $\{y_k\} \,\subset\, \operatorname{dom} \hat{\partial} f$, $y_k^* \in \hat{\partial} f(y_k)$, and a positive sequence $t_k \searrow 0^+$ such that $(y_k,\, f(y_k)) \to (y,\, f(y))$ and $t_k y_k^* \to q$. As above we may assume that the sequence $\{y_k\}$ belongs to some stratum S_i and that the tangent spaces $T_{u_k} S_i = T_{(x_k, f(x_k))} S_i$ converge to some $\mathcal{T}$. Since $t_k(y_k^*, -1)$ is normal to $T_{u_k} S_i$ we can similarly deduce that $(\operatorname{Proj}_{T_x X_x}(q),\, 0)$ is normal to $T_{(x,f(x))} S_x$. Since $\operatorname{Proj}_{\mathbb{R}^n \times \{0\}} T_{(x,f(x))} S_x = T_x X_x$ this implies that $\partial^\infty f(x) \subset (T_x X_x)^\perp$, and the second part of (12) is proved. It now follows from (12) and Remark 2(ii) that (9) holds.

In order to conclude let us recall (Definition 1) that $\partial^\circ f(x) = \overline{\text{co}}\,(\partial f(x)+\partial^\infty f(x))$. In view of (12) any element of co $(\partial f(x) + \partial^\infty f(x))$ admits $\nabla_R f(x)$ as a projection onto $T_x X_x$. By taking the closure of the previous set we obtain (10). □

Remark 4. The inclusion in (10) may be strict (think of the function $f(x) = -||x||^{1/2}$ at $x = 0$, where $\partial^\circ f(0) = \emptyset$). Of course, whenever $\partial^\circ f(x)$ is nonempty (for example, if f is locally Lipschitz), under the assumptions of Proposition 4 we have

$$\text{Proj}_{T_x X_x} \partial^\circ f(x) = \{\nabla_R f(x)\}.$$

COROLLARY 5. *Assume that f is lower semicontinuous and admits a nonvertical C^p-Whitney stratification. Then:*

(i) *for all $x \in \text{dom}\,\partial^\circ f$ we have*

$$||\nabla_{\text{R}} f(x)|| \;\le\; ||x^*|| \qquad \textit{for all } x^* \in \partial^\circ f(x). \tag{14}$$

(ii) (Morse–Sard theorem) *If $p \ge n$, then the set of Clarke critical values of f has Lebesgue measure zero.*

Proof. Assertion (i) is a direct consequence of (10) of Proposition 4. To prove (ii), set $C := [\partial^\circ f]^{-1}(\{0\}) = \{x \in \mathbb{R}^n : \partial^\circ f(x) \ni 0\}$. Since the set of strata is at most countable, the restrictions of f to each of those yield a countable family $\{f_n\}_{n\in\mathbb{N}}$ of C^p functions. In view of (14), we have that $C \subset \cup_{n\in\mathbb{N}}(\nabla f_n)^{-1}(0)$. The result follows by applying to each C^p-function f_n the classical Morse–Sard theorem [33]. □

As we see in the next section, several important classes of lower semicontinuous functions satisfy the assumptions (thus also the conclusions) of Proposition 4 and of Corollary 5.

4. Kurdyka–Łojasiewicz inequalities for o-minimal functions. Let us recall briefly a few definitions concerning o-minimal structures (see, for instance, Coste [7], van den Dries and Miller [11], Ta Lê Loi [35], and references therein).

DEFINITION 6 (o-minimal structure). *An o-minimal structure on $(\mathbb{R}, +, .)$ is a sequence of Boolean algebras $\mathcal{O}_n$ of "definable" subsets of $\mathbb{R}^n$ such that for each $n \in \mathbb{N}$:*

(i) if A belongs to $\mathcal{O}_n$, then $A \times \mathbb{R}$ and $\mathbb{R} \times A$ belong to $\mathcal{O}_{n+1}$;

(ii) if $\Pi : \mathbb{R}^{n+1} \to \mathbb{R}^n$ is the canonical projection onto $\mathbb{R}^n$, then for any A in $\mathcal{O}_{n+1}$ the set $\Pi(A)$ belongs to $\mathcal{O}_n$;

(iii) $\mathcal{O}_n$ contains the family of algebraic subsets of $\mathbb{R}^n$, that is, every set of the form

$$\{x \in \mathbb{R}^n : p(x) = 0\},$$

where $p : \mathbb{R}^n \to \mathbb{R}$ is a polynomial function;

(iv) the elements of $\mathcal{O}_1$ are exactly the finite unions of intervals and points.

DEFINITION 7 (definable function). *Given an o-minimal structure $\mathcal{O}$ (over $(\mathbb{R}, +, .)$), a function $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ is said to be* definable *in $\mathcal{O}$ if its graph belongs to $\mathcal{O}_{n+1}$.*

Remark 5 (examples). At first sight, o-minimal structures might appear artificial in optimization. The following fundamental properties (see [11] for the details) might convince the reader that this is not the case.

(i) (Tarski–Seidenberg) The collection of *semialgebraic sets* is an o-minimal structure. Recall that semialgebraic sets are Boolean combinations of sets of the form

$$\{x \in \mathbb{R}^n : p(x) = 0,\, q_1(x) < 0, \ldots,\, q_m(x) < 0\},$$

where p and q_i's are polynomial functions on $\mathbb{R}^n$.

(ii) (Gabrielov) There exists an o-minimal structure that contains the sets of the form

$$\{(x,t) \in [-1,1]^n \times \mathbb{R} : f(x) = t\},$$

where $f : \mathbb{R}^n \to \mathbb{R}$ is real analytic around $[-1,1]^n$.

(iii) (Wilkie) There exists an o-minimal structure that contains simultaneously the graph of the exponential function $\mathbb{R} \ni x \mapsto \exp x$ and all semialgebraic sets (respectively, all sets of the structure defined in (ii)).

We insist on the fact that these results are crucial foundation blocks on which o-minimal geometry rests.

Let us finally recall the following elementary but important result: The composition of mappings that are definable in some o-minimal structure remains in the same structure [11, section 2.1]. This is also true for the sum, the inf-convolution, and several other classical operations of analysis involving a finite number of definable objects. Another prominent fact about definable sets is that they admit, for each $k \geq 1$, a C^k–Whitney stratification with finitely many strata (see, for instance, [11, Result 4.8, p. 510]). This remarkable stability, combined with new techniques of finite-dimensional optimization, offers a large field of investigation. Several works have already been developed in this spirit; see, for instance, [1], [3], [12].

Given any o-minimal structure $\mathcal{O}$ and any lower semicontinuous definable function $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$, the assumptions of Proposition 4 are satisfied. More precisely, we have the following result.

LEMMA 8. *Let $\mathcal{O}$ be an o-minimal structure, $\mathcal{B} := \{B_1, \ldots, B_q\}$ be a collection of definable subsets of $\mathbb{R}^n$, and $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a definable lower semicontinuous function. Then for any $p \geq 1$, there exists a nonvertical definable C^p-Whitney stratification $\{S_1, \ldots, S_\ell\}$ of* Graph f *yielding (by projecting each stratum $S_i \subset \mathbb{R}^{n+1}$ onto $\mathbb{R}^n$) a C^p-Whitney stratification $\{X_1, \ldots, X_\ell\}$ of* dom f *compatible with $\mathcal{B}$.*

Proof. By transforming, using diffeomorphisms preserving verticality, $\mathbb{R}^n$ to $D := \{x \in \mathbb{R}^n : ||x|| < 1\}$ and $\mathbb{R}$ to $(-1,1)$, we may assume without loss of generality that f is defined in $D := \{x \in \mathbb{R}^n : ||x|| < 1\}$ with values in $(-1,1)$. Set $X =$ Graph f and $A_i = B_i \times (-1,1)$ for $i \in \{1, \ldots, q\}$, and let $\pi : X \to D$ denote the restriction to Graph f of the canonical projection of $D \times (-1,1)$ to D. The lemma follows from the canonical stratification of the mapping π according to [34, II.1.17]. ∎

COROLLARY 9 (Morse–Sard theorem for definable functions). *Let $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous definable function and $p \geq 1$. Then there exists a finite definable C^p-Whitney stratification $\mathcal{X} = (X_i)_{i \in I}$ of* dom f *such that for all $x \in$ dom f*

$$\text{Proj}_{T_x X_x} \partial^\circ f(x) \subset \{\nabla_{\mathrm{R}} f(x)\}. \tag{15}$$

As a consequence:

(i) *for all $x \in$ dom $\partial^\circ f$ and $x^* \in \partial^\circ f(x)$, we have $||\nabla_{\mathrm{R}} f(x)|| \leq ||x^*||$;*

(ii) *the set of Clarke critical values of f is finite;*

(iii) *the set of asymptotic Clarke critical values of f is finite.*

Proof. Assertion (i) is a direct consequence of (15). This projection formula follows directly by combining Lemma 8 with Proposition 4. To prove (iii), let f_i be the restriction of f to the stratum X_i. Then assertion (i), together with the fact that the number of strata is finite, implies that the set of the asymptotic Clarke critical values of f is the union (over the finite set I) of the asymptotic critical values of

each (definable C^1) function f_i. Thus the result follows from [8, Remarque 3.1.5]. Assertion (ii) follows directly from (iii) (cf. Remark 2(iii)). ∎

Remark 6. The fact that the set of the asymptotic critical values of a definable differentiable function f is finite has been established in [8, Théorème 3.1.4] (see also [20, Theorem 3.1] for the case that the domain of f is bounded). In [22, Proposition 2] a more general result (concerning functions taking values in $\mathbb{R}^k$) has been established in the semialgebraic case.

We shall now give another application of Proposition 4, namely, a nonsmooth version of the classical Kurdyka–Łojasiewicz inequality ([20, Theorem 1]). Before we proceed, we shall improve the latter in a way that allows us to deal directly with unbounded domains. To this end, we shall need the following proposition.

PROPOSITION 10 (uniform boundedness). *Let $I = [a, +\infty)$ for some $a \in \mathbb{R}$, and let $\mathcal{V}$ be a definable neighborhood of $\{0\} \times I$ in $\mathbb{R}_+ \times I$ and $\phi : \mathcal{V} \to \mathbb{R}_+$ a definable function, continuous throughout $\{0\} \times I$, satisfying $\phi(0, s) = 0$ for all $s \in I$. Then there exist $\varepsilon_0 > 0$ and continuous definable functions $\chi : I \to (0, \varepsilon_0)$ and $\psi : (0, \varepsilon_0) \to [0, +\infty)$ such that ψ is C^1 on $(0, \varepsilon_0)$, $\psi(0) = 0$, and*

$$\psi(t) \geq \phi(t, s) \quad \text{for all } s \in I, \qquad t \in (0, \chi(s)).$$

Proof. We can clearly assume that $a = 0$. Since $\mathcal{V}$ is a definable neighborhood of $\{0\} \times I$, we may assume there exists a continuous definable function $g : I \to (0, +\infty)$ such that $\{(t, s) \in \mathbb{R}_+ \times I : t \leq g(s)\} \subset \mathcal{V}$. Set

$$\delta(s) := \sup \left\{ \delta \in (0, g(s)) : \quad \phi(t, s) \leq \frac{1}{s+1} \quad \forall t \in [0, \delta) \right\}, \tag{16}$$

and note that $\delta(s)$, being definable, has a finite number of points of discontinuity. Since ϕ is continuous on $\{0\} \times I$ and $\phi(0, s) = 0$ for all $s \in I$, we infer that $\liminf_{s \to \bar{s}} \delta(s) > 0$ for all $\bar{s} \in I$. We deduce that there exists a continuous decreasing and definable function $\chi : I \to (0, +\infty)$ satisfying $\chi(s) \leq \delta(s)$ for all $s \in I$. Set $\varepsilon_0 = \sup \chi(I) = \chi(0) > 0$, and consider the definable function

$$\psi(t) = \max_{s \in [0, \chi^{-1}(t)]} \phi(t, s) \quad \text{for all } t \in [0, \varepsilon_0).$$

By the monotonicity lemma [7, Theorem 2.1] we conclude that ψ is C^1 on $(0, \beta)$ for some $\beta \leq \varepsilon_0$. Truncating χ if necessary (by defining $\tilde{\chi}(s) := \min\{\beta, \chi(s)\}$), we see that there is no loss of generality to assume $\beta = \varepsilon_0$. Note that $\psi(0) = 0$. Let us show that ψ is also continuous at $t = 0$. Let us assume, towards a contradiction, that there exists a sequence $t_n \searrow 0^+$ satisfying $\psi(t_n) > c > 0$. Then for every $n \in \mathbb{N}$ there exists $s_n \in [0, \chi^{-1}(t_n)]$ such that $\phi(t_n, s_n) > c > 0$. If $\{s_n\} \to +\infty$, then since $\delta(s_n) \geq \chi(s_n)$ we would deduce from (16) that $(s_n + 1)^{-1} \geq \phi(t_n, s_n) > c$, which is impossible for large values of n. Thus $\{s_n\}$ is bounded and has a convergent subsequence to some $s \in I$. Using the continuity of ϕ at $(0, s)$ and the fact that $\phi(0, s) = 0$, the contradiction follows. One can easily check that the definable functions ψ and χ satisfy the conclusion of the proposition. ∎

We now provide the following extension of the Kurdyka–Łojasiewicz inequality ([20, Theorem 1]) for unbounded sets in the smooth case.

THEOREM 11 (Kurdyka–Łojasiewicz inequality). *Let U be a nonempty definable submanifold of $\mathbb{R}^n$ (not necessarily bounded) and $f : U \to \mathbb{R}_+$ be a definable differentiable function. Then there exist a continuous definable function $\psi : [0, \varepsilon_0) \to \mathbb{R}_+$ satisfying $\psi(0) = 0$ and being C^1 on $(0, \varepsilon_0)$ and a continuous definable function $\chi : \mathbb{R}_+ \to (0, \varepsilon_0)$ such that*

$$||\nabla(\psi \circ f)(x)|| \geq 1 \quad \text{for all } 0 < f(x) \leq \chi(||x||). \tag{17}$$

Proof. With no loss of generality we can assume that f is not identically equal to 0 on U.

For each $(t, s) \in (0, +\infty) \times \mathbb{R}_+$ we set

$$F(t,s) := f^{-1}(t) \cap B(0,s) \subset U \qquad \text{and} \qquad m_f(t,s) = \inf\ \{||\nabla f(x)|| : x \in F(t,s)\}. \tag{18}$$

Note that $m_f(t, s) \equiv +\infty$ whenever $F(t, s)$ is empty. If $f^{-1}(0) = \emptyset$, then for every $s \geq 0$ there exists $\delta > 0$ such that for all $t \in (0, \delta)$ we have $F(t, s) = \emptyset$. Thus, the definable function

$$s \mapsto \delta(s) := \sup\{\delta > 0 : F(t,s) = \emptyset\ \ \forall t \in (0, \delta]\} < +\infty$$

is positive (cf. continuity of f), decreasing (since $F(t, s_1) \subset F(t, s_2)$ for $s_1 \leq s_2$), and continuous on $(\bar{s}, +\infty)$ for some $\bar{s} > 0$ (cf. monotonicity lemma [7, Theorem 2.1]). In this case (17) follows trivially by considering the continuous function

$$\chi(s) = \begin{cases} \delta(s)/2 & \text{if } s \geq \bar{s}, \\ \delta(\bar{s})/2 & \text{if } s \leq \bar{s}, \end{cases}$$

and any continuous definable function ψ.

Thus there is no loss of generality to assume that there exists $s_0 \geq 0$ and a decreasing continuous definable function $\rho : [s_0, +\infty) \to (0, +\infty)$ such that $F(t, s) \neq \emptyset$ for all $t \in [0, \rho(s)]$ and all $s \geq s_0$. It follows that for all $s \geq s_0$ and $t \in [0, \rho(s)]$ we have $m_f(t, s) \in \mathbb{R}_+$ and (since $\arg\min f = \{0\}$) $m_f(0, s) = 0$. Using an argument of Kurdyka ([20, Claim, p. 777]) we deduce that the function $t \mapsto m_f(t, s)$ is not identically 0 near the origin, and we set for all $s \geq s_0$

$$g(s) = \sup\ \{\, t_0 \in (0, \rho(s)) :\ m_f(t,s) > 0\ \forall t \in (0, t_0]\,\} \in (0, +\infty).$$

Then g is decreasing, positive, definable, and thus continuous on $[s_1, +\infty)$ for some $s_1 \geq s_0$. Set $D = \{(t, s) \in \mathbb{R}_+ \times [s_1, +\infty) : t \leq g(s)\}$, and consider the following definable point-to-set mapping $M : D \rightrightarrows U \subset \mathbb{R}^n$, with

$$M(t,s) := \{x \in F(t,s) : ||\nabla f(x)|| \leq\ 2\ m_f(t,s)\}.$$

Using the definable selection lemma (cf. [7, Theorem 3.1]), we obtain a definable mapping $\gamma : D \to \mathbb{R}^n$ such that $\gamma(t, s) \in M(t, s)$ for all $(t, s) \in D$. Note that for each s fixed, the function $(0, g(s)) \ni t \mapsto \gamma(t, s)$ is absolutely continuous and $\frac{\partial}{\partial t}\gamma_i(\cdot, s)$ changes sign only a finite number of times on D for all $i \in \{1, \ldots, n\}$. We set

$$\phi(t,s) = \int_0^t \max_{i \in \{1,\ldots,n\}} \left| \frac{\partial}{\partial t}\gamma_i(\tau, s) \right| \, d\tau$$

for all $(t, s) \in D$. Applying the monotonicity lemma we obtain the integrability of the function

$$\tau \mapsto \max_{i=1,\ldots,n} \left| \frac{\partial}{\partial t}\gamma_i(\tau, s) \right|.$$

Using routine arguments it is easily seen that ϕ is actually definable on D. Moreover, $\phi(t,s) > 0$ whenever $t > 0$ (else the curve $\gamma(\cdot, s)$ would be stationary, which is not possible since $f(\gamma(t,s)) = t$). Note also that $\phi(0,s) = 0$ and $\lim_{t \searrow 0^+} \phi(t,s) = 0$. Considering a stratification of ϕ we deduce that there exists $a \geq s_1$ and a definable neighborhood $\mathcal{V}$ of $\{0\} \times [a, +\infty)$ in D where ϕ is (jointly) continuous. Applying Proposition 10, we obtain $\varepsilon_0 > 0$, a continuous definable function $\chi : [a, +\infty) \to (0, \varepsilon_0)$, and a continuous definable function $\psi : [0, \varepsilon_0) \to \mathbb{R}$, with $\psi(0) = 0$, such that ψ is C^1 on $(0, \varepsilon_0)$ and $\psi(t) \geq \phi(t,s)$ for all $t \in [0, \chi(s)]$.

Fix $s \geq a$. Since $\psi(t) \geq \phi(t,s)$ for $t \in [0, \chi(s)]$ and $\psi(0) = \phi(0,s)$, it follows (see [2, Lemma 1(i)], for example) that for all $t > 0$ sufficiently small

$$\psi'(t) \geq \frac{\partial}{\partial t}\phi(t,s) > 0. \tag{19}$$

For each $s \in [a, +\infty)$ let us define $\varepsilon(s)$ to be the supremum of all $\varepsilon \in (0, \varepsilon_0)$ such that (19) holds true in the interval $(0, \varepsilon)$. It follows that $s \mapsto \varepsilon(s)$ is a positive definable function and is thus continuous on $[b, +\infty)$ for some $b \geq a$. Let us define

$$\tilde{\chi}(s) = \begin{cases} \min\{\chi(s), \varepsilon(s)\} & \text{if } s \geq b, \\ \min\{\chi(b), \varepsilon(b)\} & \text{if } s \in [0, b]. \end{cases}$$

We shall now show that (17) holds for $\tilde{\psi} = (\frac{1}{2\sqrt{n}})\psi$ and for $\tilde{\chi} : \mathbb{R}_+ \to (0, \varepsilon_0)$. Indeed, let $x \in U$ be such that $0 < f(x) \leq \tilde{\chi}(||x||)$ (hence $\nabla f(x) \neq 0$). Set $t = f(x)$ and $s = \max\{||x||, b\}$. Using the definition of γ we obtain

$$||\nabla(\psi \circ f)(x)|| = \psi'(t)||\nabla f(x)|| \geq \frac{1}{2}\psi'(t)||\nabla f(\gamma(t,s))||. \tag{20}$$

On the other hand, since $f(\gamma(t,s)) = t$, we have

$$\frac{d}{dt} f(\gamma(t,s)) = \left\langle \frac{\partial}{\partial t}\gamma(t,s), \nabla f(\gamma(t,s)) \right\rangle = 1$$

for all $(t,s) \in D$; hence

$$\sqrt{n} \max_{i=1,\ldots,n} \left| \frac{\partial}{\partial t}\gamma_i(\cdot, s) \right| \; ||\nabla f(\gamma(t,s))|| \geq \left\| \frac{\partial}{\partial t}\gamma(t,s) \right\| \; ||\nabla f(\gamma(t,s))|| \geq 1,$$

and thus

$$||\nabla f(\gamma(t,s))|| \geq \left[\sqrt{n} \max_{i=1,\ldots,n} \left| \frac{\partial}{\partial t}\gamma_i(\cdot, s) \right| \right]^{-1} = \left[\sqrt{n} \frac{\partial}{\partial t}\phi(t,s) \right]^{-1}. \tag{21}$$

Since $f(x) \leq \tilde{\chi}(||x||) \leq \varepsilon(s)$, by combining (19), (20), and (21) we finally obtain that

$$||\nabla(\psi \circ f)(x)|| \geq \frac{1}{2\sqrt{n}}\psi'(t) \left[\frac{\partial}{\partial t}\phi(t,s) \right]^{-1} \geq \frac{1}{2\sqrt{n}};$$

that is, (17) holds for $\tilde{\psi} = (\frac{1}{2\sqrt{n}})^{-1}\psi$. □

Remark 7. If in the statement of Theorem 11 the definable set U is not open, then ∇f is understood as the Riemannian gradient of f on U.

We easily obtain the following corollaries.

COROLLARY 12. *Let $f : U \to \mathbb{R}$ be a definable differentiable function, where U is a definable submanifold of $\mathbb{R}^n$ (not necessarily bounded). Then there exist a continuous definable function $\psi : [0, \varepsilon_0) \to \mathbb{R}_+$ which is C^1 on $(0, \varepsilon_0)$, with $\psi(0) = 0$, and a relatively open neighborhood V of $f^{-1}(0)$ in U such that*

$$||\nabla(\psi \circ |f|)(x)|| \geq 1$$

for all x in $V \setminus f^{-1}(0)$.

Proof. Let us first assume that f is nonnegative. The result holds trivially if $f^{-1}(0) = \emptyset$, so let us assume $f^{-1}(0) \neq \emptyset$. Take ψ and χ as in Theorem 11, and let $x \in f^{-1}(0)$. It suffices to show that the inequality holds on a ball around x. Take $r \in (0, \varepsilon_0)$ such that $\chi(||x||) > r$. Since χ and f are continuous, there exists $\delta > 0$ such that $y \in B(x, \delta) \cap U$ implies $\chi(||y||) > r > f(y)$. Applying Theorem 11, we conclude that for all $y \in B(x, \delta) \cap U$ inequality (17) holds. When f takes its values in $\mathbb{R}$ (not necessarily in $\mathbb{R}_+$), the conclusion follows easily by considering the submanifolds $\{x \in U : f(x) > 0\}$, $\{x \in U : f(x) < 0\}$ and by applying the monotonicity Lemma. ∎

COROLLARY 13. *Let $f : U \to \mathbb{R}$ be a definable differentiable function, where U is a definable submanifold of $\mathbb{R}^n$ (not necessarily bounded). Let us denote by $C_1, \ldots, C_m$ the connected components of $(\nabla f)^{-1}(\{0\})$ and by $c_1, \ldots, c_m$ the corresponding critical values. Then there exist a continuous definable function $\psi : [0, \varepsilon_0) \to \mathbb{R}_+$ which is C^1 on $(0, \varepsilon_0)$, with $\psi(0) = 0$, and relatively open neighborhoods V_i of C_i in U for each $i \in \{1, \ldots, m\}$ such that for all $x \in V_i \setminus C_i$ we have*

$$||\nabla[\psi \circ |f - c_i|](x)|| \geq 1.$$

Proof. Note that $(\nabla f)^{-1}(\{0\}) \subset \cup_{i=1}^m f^{-1}(c_i)$. For each $i \in \{1, \ldots, m\}$ we apply Corollary 12 to the function $f_i := f - c_i$ on U to obtain a relatively open neighborhood V_i of C_i and $\psi_i : [0, \varepsilon_i) \to \mathbb{R}_+$ such that for all $x \in V_i \setminus f^{-1}(c_i)$

$$||\nabla[\psi_i \circ |f - c_i|](x)|| \geq 1.$$

Set $\varepsilon_0 = \min\{\varepsilon_i : i \in \{1, \ldots, m\}\}$. Since ψ_i are definable functions, shrinking ε_0 if necessary, we may assume (cf. the monotonicity lemma) that $\psi'_{i_0}(t) \geq \psi'_i(t)$ for all $t \in (0, \varepsilon_0)$ and all $i \in \{1, \ldots, m\}$. The conclusion follows by setting $\psi := \psi_{i_0}$ on $[0, \varepsilon_0)$. ∎

We shall now use Corollary 9 to extend Theorem 11 to a nonsmooth setting.

THEOREM 14 (nonsmooth Kurdyka–Łojasiewicz inequality). *Let $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous definable function. There exist $\rho > 0$, a strictly increasing continuous definable function $\psi : [0, \rho) \to (0, +\infty)$ which is C^1 on $(0, \rho)$, with $\psi(0) = 0$, and a continuous definable function $\chi : \mathbb{R}_+ \to (0, \rho)$ such that*

$$||x^*|| \geq \frac{1}{\psi'(|f(x)|)}, \tag{22}$$

whenever $0 < |f(x)| \leq \chi(||x||)$ and $x^* \in \partial^\circ f(x)$.

Proof. Set $U_1 = \{x \in \operatorname{dom} f : f(x) > 0\}$ and $U_2 = \{x \in \operatorname{dom} f : f(x) < 0\}$, and let $X_1, \ldots, X_l$ be a finite definable stratification of $\operatorname{dom} f$ compatible with the (definable) sets U_1 and U_2 such that the definable sets $S_i = \{(x, f(x)) : x \in X_i\}$ are the strata of a nonvertical definable C^p-Whitney stratification of $\operatorname{Graph} f$ (cf. Lemma 8). For each $i \in \{1, \ldots, l\}$ such that $X_i \subset U_1$ we consider the positive

C^1 function $f_i := f|_{X_i}$ on the definable manifold X_i (thus for $x \in X_i$ we have $\nabla f_i(x) = \nabla_R f(x)$ and $f_i(x) = f(x)$), and we apply Theorem 11 to obtain $\varepsilon_i > 0$, a continuous definable function $\chi_i : \mathbb{R}_+ \to (0, \varepsilon_i)$, and a strictly increasing definable C^1-function $\psi_i : (0, \varepsilon_i) \to (0, +\infty)$ such that for all $x \in f^{-1}(0, \chi_i(||x||))$ we have $||\nabla_R f(x)|| \geq [\psi_i'(f(x))]^{-1}$. Similarly, for each $j \in \{1, \ldots, l\}$ such that $X_j \subset U_2$ we consider the positive C^1-function $f_j := -f|_{X_i}$ (note that for $x \in X_j$ we have $\nabla f_j(x) = -\nabla_R f(x)$ and $f_j(x) = -f(x)$) to obtain as before a definable function $\chi_j : \mathbb{R}_+ \to (0, \varepsilon_j)$ and a strictly increasing definable C^1-function $\psi_j : (0, \varepsilon_j) \to (0, +\infty)$ such that for all $x \in f^{-1}(0, \chi_i(||x||))$ we have $||\nabla_R f(x)|| \geq [\psi_j'(-f(x))]^{-1}$. Thus for all $i \in \{1, \ldots, l\}$ there exist a definable function $\chi_i : \mathbb{R}_+ \to (0, \varepsilon_i)$ and a strictly increasing definable C^1-function $\psi_i : (0, \varepsilon_i) \to \mathbb{R}$ such that

$$||\nabla_R f(x)|| \geq \frac{1}{\psi_i'(|f(x)|)} \qquad \text{for all } x \in f^{-1}(0, \chi_i(||x||)).$$

Set $\chi = \min \chi_i$, $\rho = \min \varepsilon_i$, and let $i_1, i_2 \in \{1, \ldots, l\}$. By the monotonicity theorem for definable functions of one variable (see [20, Lemma 2], for example), the definable function

$$(0, \rho) \ni r \quad \mapsto \quad 1/\psi_{i_1}'(r) - 1/\psi_{i_2}'(r)$$

has a constant sign in a neighborhood of 0. Repeating the argument for all couples i_1, i_2 and shrinking ρ if necessary, we obtain the existence of a strictly increasing, positive, definable function $\psi = \psi_{i_0}$ on $(0, \rho)$ of class C^1 that satisfies $1/\psi' \leq 1/\psi_i'$ on $(0, \rho)$ for all $i \in \{1, \ldots, l\}$. Evoking Corollary 9(i), we obtain

$$||x^*|| \geq ||\nabla_R f(x)|| \geq \frac{1}{\psi'(|f(x)|)},$$

whenever $x \in |f|^{-1}(0, \chi(||x||))$ and $x^* \in \partial^\circ f(x)$. Since ψ is definable and bounded from below, it can be extended continuously to $[0, \rho)$. By eventually adding a constant, we can also assume $\psi(0) = 0$. □

In a similar way to Corollary 13 we obtain the following result.

COROLLARY 15. *Let $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous definable function. Let us denote by $C_1, \ldots, C_m$ the connected components of $(\partial^\circ f)^{-1}(\{0\})$ and by $c_1, \ldots, c_m$ the corresponding critical values (cf. Corollary* 9(ii)*). Then there exist a continuous definable function $\psi : [0, \varepsilon_0) \to \mathbb{R}_+$ which is C^1 on $(0, \varepsilon_0)$, with $\psi(0) = 0$, and relatively open neighborhoods V_i of C_i in* dom f *for each $i \in \{1, \ldots, m\}$ such that for all $x \in V_i$ we have*

$$||x^*|| \geq \frac{1}{\psi'(|f(x) - c_i|)}, \tag{23}$$

whenever $0 < |f(x) - c_i| \leq \chi(||x||)$ and $x^* \in \partial^\circ f(x)$.

The assumption that the function f is definable is important for the validity of (22). It implies in particular that the connected components of the set of the Clarke critical points of f lie in the same level set of f (cf. Corollary 9(ii)). Let us present some examples of C^1-functions for which (22) is not true.

Example 1. (i) Consider the function $f : \mathbb{R} \to \mathbb{R}$, with

$$f(x) = \begin{cases} x^2 \sin \frac{1}{x} & \text{if } x \neq 0, \\ 0 & \text{if } x = 0. \end{cases}$$

Then the set $S = \{x \in \mathbb{R} : f'(x) = 0\}$ meets infinitely many level sets around 0. Consequently, (22) is not fulfilled since the critical value 0 is not isolated. Note also that f provides an example of a nondefinable function whose graph admits a Whitney stratification (in particular f satisfies the conclusion of Proposition 4).

(ii) A nontrivial example is proposed in [31, p. 14], where a C^∞ "Mexican-hat" function has been defined. An example of a similar nature has been given in [1] and will be described below: Let f be defined in polar coordinate on $\mathbb{R}^2$ by

$$f(r,\theta) = \begin{cases} \exp(-\frac{1}{1-r^2})\,[1 - \frac{4r^4}{4r^4+(1-r^2)^4}\,\sin(\theta - \frac{1}{1-r^2})] & \text{if } r \le 1, \\ \\ 0 & \text{if } r > 1. \end{cases}$$

The function f does not satisfy the Kurdyka–Łojasiewicz inequality for the critical value 0; i.e., one cannot find a strictly increasing C^1-function $\psi : (0,\rho) \to (0,+\infty)$, with $\rho > 0$, such that

$$||\nabla(\psi \circ f)(x)|| \ge 1$$

for small positive values of $f(x)$. To see this, let us notice that the proof of [20, Theorem 2] shows that for *any* C^1-function f (not necessarily definable) that satisfies the Kurdyka–Łojasiewicz inequality, the bounded trajectories of the gradient system

$$\dot{x}(t) + \nabla f(x(t)) = 0$$

have a bounded length. However, in the present example, taking as the initial condition $r_0 \in (0,1)$ and θ_0 such that $\theta_0(1-r_0)^2 = 1$, the gradient trajectory $\dot{x}(t) = -\nabla f(x(t))$ must comply with

$$\theta(t) = \frac{1}{1-r(t)^2},$$

where $r(t) \nearrow 1^-$ as $t \to +\infty$ (see [1] for details). The total length of the above curve is obviously infinite, which shows that the Kurdyka–Łojasiewicz inequality (for the critical value 0) does not hold.

Let us finally give an easy consequence of Theorem 14 for the case of subanalytic functions [25].

COROLLARY 16 (subgradient inequality). *Assume that $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ is a lower semicontinuous globally subanalytic function and $f(x_0) = 0$. There exist $\rho > 0$ and a continuous definable function $\chi : \mathbb{R}_+ \to (0,+\infty)$ such that*

$$|f(x)|^\theta \le \rho\,||x^*||,$$

whenever $0 < |f(x)| \le \chi(||x||)$ and $x^* \in \partial^\circ f(x)$.

Proof. In the case that f is globally subanalytic, one can apply [20, Theorem LI] to deduce that the continuous function ψ of Theorem 14 can be taken of the form $\psi(s) = s^{1-\theta}$, with $\theta \in (0,1)$. □

Remark 8. Corollary 9(ii) (and a fortiori Corollary 16) extends [3, Theorem 7] to the lower semicontinuous case. We also remark that the conclusions of Theorem 14 and of Corollary 16 remain valid for any notion of subdifferential that is included in the Clarke subdifferential and thus, in particular, in view of (7), for the Fréchet and the limiting subdifferential. However, let us point out that this is not the case

for broader notions of subdifferentials, as, for example, the *convex-stable* subdifferential introduced and studied in [4]. It is known that the convex-stable subdifferential coincides with the Clarke subdifferential whenever the function f is locally Lipschitz continuous, but it is strictly larger in general, creating more critical points. In particular, [3, section 4] constructs an example of a subanalytic continuous function on $\mathbb{R}^3$ that is strictly increasing in a segment lying in the set of its broadly critical points (that is, critical in the sense of the convex-stable subdifferential). Consequently, Theorem 14 and Corollary 16 do not hold for this subdifferential.

Acknowledgments. A part of this work has been done during a visit of the first author at the Autonomous University of Barcelona (July 2005) and at the University of Nagoya (June 2006). WEAK SHARP MINIMA FOR SEMI-INFINITE OPTIMIZATION PROBLEMS WITH APPLICATIONS*

XI YIN ZHENG† AND XIAO QI YANG‡

Abstract. We study local weak sharp minima and sharp minima for smooth semi-infinite optimization problems SIP. We provide several dual and primal characterizations for a point to be a sharp minimum or a weak sharp minimum of SIP. As applications, we present several sufficient and necessary conditions of calmness for infinitely many smooth inequalities. In particular, we improve some calmness results in [R. Henrion and J. Outrata, *Math. Program.*, 104 (2005), pp. 437–464].

Key words. semi-infinite optimization, sharp minima, weak sharp minima, subdifferential, normal cone

1. Introduction.

The notion of a sharp minimum, namely, a strong isolated minimum or a strong unique local minimum, of real-valued functions, introduced in [24], plays an important role in the convergence analysis of numerical algorithms in mathematical programming problems (see [4, 12, 22, 30]). As such, it has received extensive attention and investigation. As a generalization of sharp minima, weak sharp minima for real-valued functions were introduced and studied in [5]. Extensive study of weak sharp minima for real-valued convex functions has been done in the literature (cf. [2, 3, 28, 31, 33]). It has been found that the weak sharp minimum is closely related to the error bound in convex programming (cf. [32]), a notion that has received much attention and has produced a vast number of publications (see [16, 17, 23, 31, 32]).

The calmness is an important type of Lipschitz-like property for multifunctions, which play a key role in many issues of mathematical programming such as sensitivity analysis, error bounds, and optimality conditions. Thus, the study of the calmness has recently received increasing attention in the mathematical programming literature (see [8, 9, 10, 15]).

In this paper, we will study local weak sharp minima for the following semi-infinite optimization problem:

$$\text{(SIP)} \qquad \min f(x) \ \text{ subject to } \phi(x,y) \le 0 \text{ for all } y \in Y,$$

where $f : X \to R$ is a smooth function, X is an Euclidean space, Y is an infinite index set, and $\phi : X \times Y \to R$ is a function such that the function $x \mapsto \phi(x,y)$ is smooth for each index $y \in Y$. It is known that (SIP) has many important and interesting applications in engineering design, control of robots, mechanical stress of

materials, and social sciences; see the survey paper [11] and the books [6, 21, 25]. In the past three decades, (SIP) and its broad range of applications have been an active study area in mathematical programming (see [1, 7, 13, 14, 20, 27, 29] and references therein).

Let Z denote the set of all feasible points for (SIP); that is,

$$Z := \{x \in X : \ \phi(x, y) \leq 0 \text{ for all } y \in Y\}.$$

We say that $\bar{x} \in X$ is a local sharp minimum of (SIP) if $\bar{x} \in Z$ and there exist $\eta, \delta \in (0, \ +\infty)$ such that

$$\eta\|x - \bar{x}\| \leq f(x) - f(\bar{x}) + \sup_{y \in Y}[\phi(x, y)]_+ \ \text{ for all } x \in B(\bar{x}, \delta), \tag{1.1}$$

where $B(\bar{x}, \delta)$ denotes the open ball with center $\bar{x}$ and radius δ.

We say that $\bar{x}$ is a local weak sharp minimum of (SIP) if $\bar{x} \in Z$ and there exist $\eta, \delta \in (0, \ +\infty)$ such that

$$\eta d(x, L_f(\bar{x}) \cap Z) \leq f(x) - f(\bar{x}) + \sup_{y \in Y}[\phi(x, y)]_+ \ \text{ for all } x \in B(\bar{x}, \delta), \tag{1.2}$$

where $L_f(\bar{x}) := \{x \in X : \ f(x) = f(\bar{x})\}$ and $d(x, L_f(\bar{x}) \cap Z) := \inf\{\|x - u\| : \ u \in L_f(\bar{x}) \cap Z\}$.

Recall a known optimality condition of (SIP) (cf. [11, 13, 34]) that if $\bar{x}$ is a local minimum of (SIP) and a constraint qualification is satisfied at $\bar{x}$, then there exist $t_i \geq 0$ and $y_i \in I_0(\bar{x})$, $i = 1, \ldots, p$, such that

$$0 = f'(\bar{x}) + \sum_{i=1}^{p} t_i \phi'_x(\bar{x}, y_i), \tag{1.3}$$

where $I_0(\bar{x})$ denotes the index set of active inequality constraints at $\bar{x}$. Furthermore, under a convexity assumption, the optimality condition (1.3) also becomes sufficient.

When Y is a compact topological space and $\phi(x, y)$ and $\phi'_x(x, y)$ satisfy some continuity conditions, we will prove that $\bar{x}$ is a local weak sharp minimum of (SIP) if and only if there exist $\eta, \delta \in (0, \ +\infty)$ such that for all $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta)$

$$\tilde{N}(L_f(\bar{x}) \cap Z, u) \cap \eta B_{X^*} \subset f'(u) + [0, \ 1]\text{co}\{\phi'_x(u, y) : \ y \in I_0(\bar{x})\}, \tag{1.4}$$

where X^* denotes the dual space of X, B_{X^*} denotes the unit ball of X^*, and $\tilde{N}(A, u)$ is any one of the Fréchet, limiting, or Clarke normal cones of A at u; in particular, $\bar{x}$ is a local sharp minimum of (SIP) if and only if

$$0 \in \text{int}(f'(\bar{x}) + [0, \ 1]\text{co}\{\phi'_x(\bar{x}, y) : \ y \in I_0(\bar{x})\}). \tag{1.5}$$

It is interesting to compare (1.5) and (1.4) with (1.3). These are referred to as dual characterizations. We also obtain a set of primal ones for a local weak sharp minimum of (SIP). Moreover, we obtain mixed characterizations for a local (weak) sharp minimum.

Motivated by Henrion and Outrata [10], we consider the calmness of multifunctions defined by infinitely many smooth inequalities. As applications of several characterizations of weak sharp minima mentioned above, we provide several equivalent conditions for the calmness; in particular, we improve one of the main results in [10].

The outline of the paper is as follows. In section 2, some preliminaries on notions of variational analysis are given. In section 3, several characterizations for a local weak sharp minimum and a local sharp minimum of (SIP) are obtained. In section 4, some equivalent conditions for the calmness of the system of infinitely many smooth inequalities are provided.

2. Preliminaries. Let X be an Euclidean space and $\psi : X \to R \cup \{+\infty\}$ a proper lower semicontinuous function. For $x \in \mathrm{dom}(\psi) := \{x \in X : \ \phi(x) < +\infty\}$, let $\hat{\partial}\psi(x)$ denote the Fréchet subdifferential of ψ at x; that is,

$$\hat{\partial}\psi(x) := \left\{ x^* \in X^* : \ \liminf_{u \overset{\psi}{\to} x} \frac{\psi(u) - \psi(x) - \langle x^*, u - x\rangle}{\|u - x\|} \geq 0 \right\},$$

where $u \overset{\psi}{\to} x$ means $u \to x$ and $\psi(u) \to \psi(x)$. The limiting subdifferential of ψ at x is denoted by $\partial\psi(x)$ and is defined by

$$\partial\psi(x) := \limsup_{u \overset{\psi}{\to} x} \hat{\partial}\psi(u);$$

that is, $x^* \in \partial\psi(x)$ if and only if there exist sequences $x_k \overset{\psi}{\to} x$ and $x_k^* \to x^*$ with $x_k^* \in \hat{\partial}\psi(x_k)$.

The following proposition is well known (cf. [18, Theorem 2.33]) and is useful for us.

PROPOSITION 2.1. *Let $\psi_1, \psi_2 : X \to R \cup \{+\infty\}$ be proper lower semicontinuous functions and $x \in \mathrm{dom}(\psi_1) \cap \mathrm{dom}(\psi_2)$. Suppose that ψ_1 is locally Lipschitz at x. Then*

$$\partial(\psi_1 + \psi_2)(x) \subset \partial\psi_1(x) + \partial\psi_2(x).$$

For a closed subset A of X and $a \in A$, let $\hat{N}(A, a)$ and $N(A, a)$ denote the Fréchet normal cone and the limiting normal cone of A at a, respectively; that is,

$$\hat{N}(A, a) = \hat{\partial}\delta_A(a) \ \text{ and } \ N(A, a) = \partial\delta_A(a),$$

where δ_A denotes the indicator function of A. Thus, $x^* \in \hat{N}(A, a)$ if and only if $\limsup_{x \overset{A}{\to} a} \frac{\langle x^*, x-a\rangle}{\|x-a\|} \leq 0$, where $x \overset{A}{\to} a$ means $x \in A$ and $x \to a$, and $x^* \in N(A, a)$ if and only if there exist $x_k \overset{A}{\to} a$ and $x_k^* \to x^*$ such that $x_k^* \in \hat{N}(A, x_k)$ for all $k \in \mathbb{N}$, where $\mathbb{N}$ denotes the set of all natural numbers.

Let $T(A, a)$ denote the tangent cone of A at a; that is,

$$T(A, a) := \{h \in X : \ \exists t_k \to 0^+ \text{ and } h_k \to h \text{ such that } a + t_k h_k \in A \text{ for all } k \in \mathbb{N}\}.$$

It is known (cf. [26, Theorem 6.28]) that

$$\hat{N}(A, a) = \{x^* \in X^* : \ \langle x^*, h\rangle \leq 0 \text{ for all } h \in T(A, a)\}. \tag{2.1}$$

Let $T_c(A, a)$ denote the Clarke tangent cone; that is, $v \in T_c(A, a)$ if and only if, for each sequence $\{a_k\}$ in A converging to a and each sequence $\{t_k\}$ in $(0, \infty)$ decreasing to 0, there exists a sequence $\{v_k\}$ in X converging to v such that $a_k + t_k v_k \in A$ for all $k \in \mathbb{N}$. Let $N_c(A, a)$ denote the Clarke normal cone of A at a and be defined by

$$N_c(A, a) := \{x^* \in X^* : \ \langle x^*, v\rangle \leq 0 \quad \text{for all } v \in T_c(A, a)\}. \tag{2.2}$$

It is well known (cf. [26, Proposition 6.5] and [18, Theorem 3.57]) that

$$\hat{N}(A,a) \subset N(A,a) \subset N_c(A,a) \text{ and } N_c(A,a) = \overline{\text{co}}N(A,a). \tag{2.3}$$

Histories of the subdifferentials and the normal cones can be found in [18, 19, 26].

For any $x \in X$, let $P_A(x)$ denote the projection of x on A; that is,

$$P_A(x) := \{a \in A : \ \|x-a\| = d(x,A)\}.$$

We will need the following known result (cf. [26, Example 6.16]).

LEMMA 2.1. *Let A be a closed subset of X and $x \in X$. Then*

$$x - a \in \hat{N}(A,a) \text{ for any } a \in P_A(x). \tag{2.4}$$

3. Weak sharp minima for smooth semi-infinite optimization problems. Throughout the remainder of this paper, let X be an Euclidean space of dimension m and Y a compact topological space (e.g., a bounded closed subset of an Euclidean space). Let $f : X \to R$ and $\phi : X \times Y \to R$ be as in section 1. We always assume that the following properties hold:

(P1) The function $x \mapsto \phi(x,y)$ is smooth for each $y \in Y$, and the function $y \mapsto \phi(x,y)$ is continuous for each $x \in X$.

(P2) The functions $(x,y) \mapsto \phi(x,y)$ and $(x,y) \mapsto \phi'_x(x,y)$ are continuous on $X \times Y$, where $\phi'_x(x,y)$ denotes the derivative of the function $x \mapsto \phi(x,y)$.

In the literature on semi-infinite optimization, assumptions (P1) and (P2) have been extensively used.

Since Y is compact and (P1) holds, it is easy to verify that $\bar{x} \in Z$ is a local sharp minimum and a local weak sharp minimum of (SIP) if and only if there exist $\eta, \delta \in (0, \ +\infty)$ such that

$$\eta\|x-\bar{x}\| \le f(x) - f(\bar{x}) + \max_{y\in Y}[\phi(x,y)]_+ \text{ for all } x \in B(\bar{x},\delta) \tag{3.1}$$

and

$$\eta d(x, L_f(\bar{x}) \cap Z) \le f(x) - f(\bar{x}) + \max_{y\in Y}[\phi(x,y)]_+ \text{ for all } x \in B(\bar{x},\delta), \tag{3.2}$$

respectively.

It follows from (3.2) that every local weak sharp minimum of (SIP) is a local solution of (SIP). Clearly, $\bar{x}$ is a local sharp minimum of (SIP) if and only if $\bar{x}$ is a local weak sharp minimum of (SIP) and

$$L_f(\bar{x}) \cap Z \cap B(\bar{x},\delta) = \{\bar{x}\} \text{ for some } \delta > 0.$$

For convenience, let

$$\Phi(x) := \max\{\phi(x,y) : \ y \in Y\} \text{ and } I(x) := \{y \in Y : \ \phi(x,y) = \Phi(x)\}.$$

From (P1) and the compactness of Y, it is clear that $I(x) \neq \emptyset$ for all $x \in X$. For each $x \in Z$, let $I_0(x)$ denote the index set of active inequality constraints at x; that is,

$$I_0(x) := \{y \in Y : \ \phi(x,y) = 0\}.$$

We will provide characterizations for $\bar{x}$ to be a local weak sharp minimum or a local sharp minimum of (SIP). We need the following lemma.

LEMMA 3.1. *Let $\bar{x} \in X$ and $\varepsilon > 0$. Then there exists $\delta > 0$ such that for any $x \in B(\bar{x}, \delta)$ and $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta)$*

$$\langle f'(u), x - u\rangle \le f(x) - f(\bar{x}) + \varepsilon\|x - u\|$$

and

$$\langle \phi'_x(u, y), x - u\rangle \le \phi(x, y) + \varepsilon\|x - u\| \quad \textit{for all } y \in I_0(u).$$

Proof. Since $(x, y) \mapsto \phi'_x(x, y)$ is continuous, for any $y \in Y$ there exist open neighborhoods U_y and V_y of $\bar{x}$ and y, respectively, such that

$$\|\phi'_x(x_1, v_1) - \phi'_x(x_2, v_2)\| < \varepsilon \quad \text{for all } x_1, x_2 \in U_y \text{ and for all } v_1, v_2 \in V_y.$$

Since Y is compact, there exist $y_1, \ldots, y_k \in Y$ such that $Y = \bigcup_{i=1}^{k} V_{y_i}$. Let $U := \bigcap_{i=1}^{n} U_{y_i}$, and take $\delta > 0$ such that $B(\bar{x}, \delta) \subset U$. It is easy to verify that

$$\|\phi'_x(x_1, y) - \phi'_x(x_2, y)\| < \varepsilon \quad \text{for all } x_1, x_2 \in B(\bar{x}, \delta) \text{ and for all } y \in Y. \tag{3.3}$$

Since f is continuously differentiable, we assume without loss of generality that

$$\|f'(x_1) - f'(x_2)\| < \varepsilon \quad \text{for all } x_1, x_2 \in B(\bar{x}, \delta) \tag{3.4}$$

(considering smaller δ if necessary). Let $x \in B(\bar{x}, \delta)$, $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta)$, and $y \in I_0(u)$. By the mean value theorem, there exist $\theta_1, \theta_2 \in (u,\ x) := \{tu + (1 - t)x : 0 < t < 1\}$ such that

$$f(x) - f(\bar{x}) = f(x) - f(u) = \langle f'(\theta_1), x - u\rangle$$

and

$$\phi(x, y) = \phi(x, y) - \phi(u, y) = \langle \phi'_x(\theta_2, y), x - u\rangle.$$

It follows from (3.4) and (3.3) that

$$\begin{aligned}\langle f'(u), x - u\rangle &= \langle f'(u) - f'(\theta_1), x - u\rangle + \langle f'(\theta_1), x - u\rangle \\ &\le f(x) - f(\bar{x}) + \varepsilon\|x - u\|\end{aligned}$$

and

$$\langle \phi'_x(u, y), x - u\rangle \le \phi(x, y) + \varepsilon\|x - u\|.$$

The proof is completed. □

LEMMA 3.2. *Let $\bar{x} \in Z$ and $u \in L_f(\bar{x}) \cap Z$. Then*

$$\langle f'(u), h\rangle = 0 \ \text{ and } \ \langle \phi'_x(u, y), h\rangle \le 0, \quad \textit{for all } h \in T(L_f(\bar{x}) \cap Z, u) \textit{ and for all } y \in I_0(u).$$

Proof. Let $h \in T(L_f(\bar{x}) \cap Z, u)$ and $y \in I_0(u)$. Then there exist $t_k \to 0^+$ and $h_k \to h$ such that $u + t_k h_k \in L_f(\bar{x}) \cap Z$ for all $k \in \mathbb{N}$. Hence

$$f(u + t_k h_k) = f(u) = f(\bar{x}) \ \text{ and } \ \phi(u + t_k h_k, y) \le 0 \quad \text{for all } k \in \mathbb{N}.$$

Since f is continuously differentiable,

$$f(u + t_k h_k) - f(u) = \langle f'(u), t_k h_k\rangle + o(t_k).$$

It follows that $\langle f'(u), h_k\rangle + \frac{o(t_k)}{t_k} = 0$. This implies that $\langle f'(u), h\rangle = 0$. Let ε be an arbitrary positive number. Then Lemma 3.1 implies that

$$\langle \phi'(u,y), t_k h_k\rangle \le \phi(u + t_k h_k, y) + \varepsilon\|t_k h_k\| \le \varepsilon\|t_k h_k\|$$

for all k large enough, and so $\langle \phi'(u,y), h\rangle \le \varepsilon\|h\|$. Since ε is arbitrary, it follows that $\langle \phi'(u,y), h\rangle \le 0$. This completes the proof. □

In the next theorems we first provide some dual characterizations and then some primal characterizations for a feasible point of (SIP) to be a local weak sharp minimum. As usual, let co$A$ denote the convex hull of A. For convenience, we adopt the conventions that if $u \in L_f(\bar{x}) \cap Z$, with $I_0(u) = \emptyset$, then

$$[0,\ 1]\mathrm{co}\{\phi'_x(u,y):\ y \in I_0(u)\} := \{0\}$$

and

$$\max_{y\in I_0(u)} [\langle \phi'_x(u,y), h\rangle]_+ := 0 \ \text{ for all } h \in X.$$

THEOREM 3.1. *Let $\bar{x}$ be a feasible point of* (SIP) *(i.e., $\bar{x} \in Z$). Then the following statements are equivalent:*

(i) *$\bar{x}$ is a local weak sharp minimum of* (SIP).

(ii) *There exist $\eta, \delta \in (0,\ +\infty)$ such that*

$$\hat{N}(L_f(\bar{x}) \cap Z, u) \cap \eta B_{X^*} \subset f'(u) + [0,\ 1]\mathrm{co}\{\phi'_x(u,y):\ y \in I_0(u)\} \tag{3.5}$$

for all $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta)$.

(iii) *There exist $\eta, \delta \in (0,\ +\infty)$ such that*

$$N(L_f(\bar{x}) \cap Z, u) \cap \eta B_{X^*} \subset f'(u) + [0,\ 1]\mathrm{co}\{\phi'_x(u,y):\ y \in I_0(u)\} \tag{3.6}$$

for all $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta)$.

(iv) *There exist $\eta, \delta \in (0,\ +\infty)$ such that*

$$N_c(L_f(\bar{x}) \cap Z, u) \cap \eta B_{X^*} \subset f'(u) + [0,\ 1]\mathrm{co}\{\phi'_x(u,y):\ y \in I_0(u)\} \tag{3.7}$$

for all $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta)$.

Proof. (i)⇒(ii). Suppose that there exist $\eta, \delta \in (0,\ +\infty)$ such that (3.2) holds. Let $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \frac{\delta}{2})$ and $u^* \in \hat{N}(L_f(\bar{x}) \cap Z, u) \cap B_{X^*}$. Let $\varepsilon > 0$, and take $r \in (0,\ \frac{\delta}{2})$ such that

$$\langle u^*, v - u\rangle \le \varepsilon\|v - u\| \quad \text{for all } v \in L_f(\bar{x}) \cap Z \cap B(u, r).$$

Let $x \in B(u, \frac{r}{2}) \subset B(\bar{x}, \delta)$. Then there exists $v \in L_f(\bar{x}) \cap Z$ such that $\|x - v\| = d(x, L_f(\bar{x}) \cap Z)$. Hence,

$$\|v - u\| \le \|v - x\| + \|x - u\| \le 2\|x - u\| < r.$$

Therefore,

$$\begin{aligned}\langle u^*, x - u\rangle &= \langle u^*, x - v\rangle + \langle u^*, v - u\rangle \\ &\le \|x - v\| + \varepsilon\|v - u\| \\ &\le (1 + \varepsilon)\|x - v\| + \varepsilon\|x - u\| \\ &= (1 + \varepsilon)d(x, L_f(\bar{x}) \cap Z) + \varepsilon\|x - u\|.\end{aligned}$$

It follows from (3.2) and $B(u, \frac{r}{2}) \subset B(\bar{x}, \delta)$ that

$$\eta\langle u^*, x-u\rangle \le (1+\varepsilon)(f(x)-f(\bar{x})+[\Phi(x)]_+)+\eta\varepsilon\|x-u\| \quad \text{for all } x \in B\left(u, \frac{r}{2}\right).$$

Noting that $f(u) = f(\bar{x})$ and $[\Phi(u)]_+ = 0$, it follows that u is a local minimum of the function

$$x \mapsto -\eta\langle u^*, x-u\rangle + (1+\varepsilon)(f(x)-f(\bar{x})+[\Phi(x)]_+)+\eta\varepsilon\|x-u\|.$$

This and Proposition 2.1 imply that

$$\eta u^* \in (1+\varepsilon)(f'(u)+\partial[\Phi(\cdot)]_+(u))+\eta\varepsilon B_{X^*}.$$

Letting $\varepsilon \to 0$, one has

$$\eta u^* \in f'(u)+\partial[\Phi(\cdot)]_+(u) = f'(u)+\mathrm{co}(\{0\}\cup\partial\Phi(u)) = f'(u)+[0,\ 1]\partial\Phi(u).$$

Noting (by [26, Theorem 10.31]) that

$$\partial\Phi(u) = \begin{cases} \{0\} & I_0(u)=\emptyset, \\ \mathrm{co}\{\phi'_x(u,y):\ y\in I_0(u)\} & I_0(u)\neq\emptyset, \end{cases}$$

it follows that (3.5) holds.

(ii)⇒(iii). Suppose that there exist $\eta, \delta \in (0,\ +\infty)$ such that (3.5) holds for all $u \in L_f(\bar{x})\cap Z\cap B(\bar{x},\delta)$. Let $u \in L_f(\bar{x})\cap Z\cap B(\bar{x},\delta)$ and $u^* \in N(L_f(\bar{z})\cap Z, u)\cap\eta B_{X^*}$. Take a sequence $\{u_k\}$ in $L_f(\bar{x})\cap Z$ and a sequence $\{u_k^*\}$ in X^* such that $u_k \to u$, $u_k^* \to u^*$, and $u_k^* \in \hat{N}(L_f(\bar{x})\cap Z, u_k)$ for all $k \in \mathbb{N}$. Without loss of generality, we assume that $u_k \in B(\bar{x},\delta)$ and $u_k^* \in \eta B_{X^*}$ for each $k \in \mathbb{N}$. By (3.5), one has

$$u_k^* \in f'(u_k)+[0,\ 1]\mathrm{co}\{\phi'_x(u_k,y):\ y\in I_0(u_k)\} \quad \text{for all } k\in\mathbb{N}.$$

We divide into two cases: 1) $I_0(u_k)=\emptyset$ for infinitely many k and 2) $I_0(u_k)\neq\emptyset$ for infinitely many k.

Case 1. Without loss of generality we assume that $I_0(u_k)=\emptyset$ for all $k\in\mathbb{N}$ (passing to a subsequence if necessary). Thus, $u_k^* = f'(u_k)$ for all $k\in\mathbb{N}$. It follows that $u^* = f'(u)$. Hence (3.6) holds.

Case 2. We can assume that $I_0(u_k)\neq\emptyset$ for all $k\in\mathbb{N}$. Noting that X is of dimension m, it follows from the Caratheodory theorem (cf. [26, Theorem 2.29]) that there exist $t_{1k},\dots,t_{m+1k}\in[0,\ 1]$ and $y_{1k},\dots,y_{m+1k}\in I_0(u_k)$ such that

$$\sum_{i=1}^{m+1} t_{ik} \le 1 \ \text{ and } \ u_k^* = f'(u_k)+\sum_{i=1}^{m+1} t_{ik}\phi'_x(u_k,y_{ik}) \quad \text{for all } k\in\mathbb{N}.$$

Without loss of generality, we assume that

$$t_{ik}\to t_i \ \text{ and } \ y_{ik}\to y_i\in I_0(u) \ \text{ as } k\to\infty,\ i=1,\dots,m+1$$

(passing to subsequences if necessary). Thus,

$$\sum_{i=1}^{m+1} t_i \le 1 \quad \text{and} \quad u^* = f'(u)+\sum_{i=1}^{m+1} t_i\phi'_x(u,y_i).$$

This shows that (3.6) holds for all $u\in L_f(\bar{x})\cap Z\cap B(\bar{x},\delta)$.

(iii)⇒(iv). Suppose that there exist $\eta, \delta \in (0, +\infty)$ such that (3.6) holds for all $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta)$. It follows that

$$N(L_f(\bar{x})\cap Z, u) \subset R_+ f'(u)+R_+\mathrm{co}\{\phi'_x(u,y) :\ y \in I_0(u)\} \quad \text{for all } u \in L_f(\bar{x})\cap Z\cap B(\bar{x},\delta).$$

On the other hand, by (2.1) and Lemma 3.2 one has

$$R_+ f'(u) + R_+\mathrm{co}\{\phi'_x(u,y) :\ y \in I_0(u)\} \subset \hat{N}(L_f(\bar{x}) \cap Z, u) \quad \text{for all } u \in L_f(\bar{x}) \cap Z.$$

It follows that

$$\hat{N}(L_f(\bar{x}) \cap Z, u) = N(L_f(\bar{x}) \cap Z, u) \quad \text{for all } u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta).$$

By (2.1) and (2.3), one has

$$N(L_f(\bar{x}) \cap Z, u) = N_c(L_f(\bar{x}) \cap Z, u) \quad \text{for all } u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta).$$

Therefore, (iv) holds.

(iv)⇒(i). Suppose that there exist $\eta, \delta \in (0, +\infty)$ such that (3.7) holds for all $x \in L_f(\bar{x})\cap Z\cap B(\bar{x}, \delta)$. Let $x \in B(\bar{x}, \frac{\delta}{2}) \setminus L_f(\bar{x})\cap Z$, and take $u \in P_{L_f(\bar{x})\cap Z}(x)$. Then $u \in B(\bar{x}, \delta)$, and it follows from Lemma 2.1 and (2.3) that $\frac{x-u}{\|x-u\|} \in N_c(L_f(\bar{x}) \cap Z, u)$. We claim that $I_0(u) \neq \emptyset$. Suppose to the contrary that $I_0(u) = \emptyset$. Then, by the definition, $[0,\ 1]\mathrm{co}\{\phi'_x(u,y) :\ u \in I_0(u)\} = \{0\}$. This and (3.7) imply that the intersection $N_c(L_f(\bar{x}) \cap Z, u) \cap \eta B_{X^*}$ is the singleton $\{f'(u)\}$, contradicting the fact that it contains 0 and $\frac{\eta(x-u)}{\|x-u\|}$. Hence $I_0(u) \neq \emptyset$. By (3.7), there exist $t_1, \ldots, t_q \in [0, +\infty)$ and $y_1, \ldots, y_q \in I_0(u)$ such that

$$\sum_{i=1}^{q} t_i \leq 1 \ \text{ and } \ \frac{\eta(x-u)}{\|x-u\|} = f'(u) + \sum_{i=1}^{q} t_i \phi'_x(u, y_i).$$

Hence

$$\eta\|x-u\| = \langle f'(u), x-u\rangle + \sum_{i=1}^{q} t_i \langle \phi'_x(u,y_i), x-u\rangle.$$

Let $\varepsilon \in (0,\ \frac{\eta}{2})$. By Lemma 3.1, without loss of generality we assume that

$$\langle f'(u), x-u\rangle \leq f(x) - f(\bar{x}) + \varepsilon\|x-u\|$$

and

$$\langle \phi'_x(u,y), x-u\rangle \leq \phi(x,y) + \varepsilon\|x-u\| \quad \text{for all } y \in I_0(u)$$

(considering smaller δ if necessary). Therefore,

$$\begin{aligned}\eta\|x-u\| &\leq f(x) - f(\bar{x}) + \sum_{i=1}^{q} t_i \phi(x, y_i) + 2\varepsilon\|x-u\| \\ &\leq f(x) - f(\bar{x}) + \max_{y\in Y}[\phi(x,y)]_+ + 2\varepsilon\|x-u\|.\end{aligned}$$

It follows that

$$(\eta - 2\varepsilon)\|x-u\| \leq f(x) - f(\bar{x}) + \max_{y\in Y}[\phi(x,y)]_+;$$

that is,

$$(\eta - 2\varepsilon) d(x, L_f(\bar{x}) \cap Z) \leq f(x) - f(\bar{x}) + \max_{y\in Y}[\phi(x,y)]_+.$$

Since $f(x) = f(\bar{x})$ and $\max_{y\in Y}[\phi(x,y)]_+ = 0$ if $x \in L_f(\bar{x}) \cap Z$, the last inequality holds trivially if $x \in L_f(\bar{x}) \cap Z$. This shows that (i) holds. The proof is completed. □

Remark. In view of the proof of Theorem 3.1, one can see that the implication (i)⇒(ii) of Theorem 3.1 holds even when X is a Banach space of infinite dimension.

THEOREM 3.2. *Let $\bar{x} \in Z$. Then the following statements are equivalent:*

(i) *$\bar{x}$ is a local weak sharp minimum of* (SIP).

(ii) *There exist $\eta, \delta \in (0, +\infty)$ such that*

$$\eta d(h, T(L_f(\bar{x}) \cap Z, u)) \le \langle f'(u), h\rangle + \max_{y\in I_0(u)}[\langle \phi'_x(u,y), h\rangle]_+ \tag{3.8}$$

for all $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta)$ and $h \in X$.

(iii) *There exist $\eta, \delta \in (0, +\infty)$ such that*

$$\eta d(h, T_c(L_f(\bar{x}) \cap Z, u)) \le \langle f'(u), h\rangle + \max_{y\in I_0(u)}[\langle \phi'_x(u,y), h\rangle]_+ \tag{3.9}$$

for all $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta)$ and $h \in X$.

(iv) *There exist $\eta, \delta \in (0, +\infty)$ such that*

$$\eta\|x - u\| \le \langle f'(u), x - u\rangle + \max_{y\in I_0(u)}[\langle \phi'_x(u,y), x - u\rangle]_+ \tag{3.10}$$

for any $x \in B(\bar{x}, \delta)$ and $u \in P_{L_f(\bar{x})\cap Z}(x)$.

Proof. (i)⇒(iii). Suppose that (i) holds. Then by Theorem 3.1 there exist $\eta, \delta \in (0, +\infty)$ such that (3.7) holds for all $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta)$. Let $u \in L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta)$ and $h \in X$. By Lemma 3.2, (3.9) holds if $h \in T_c(L_f(\bar{x}) \cap Z, u)$. Now we assume that $h \notin T_c(L_f(\bar{x}) \cap Z, u)$. Take $h_0 \in P_{T_c(L_f(\bar{x})\cap Z,u)}(h)$. Then by Lemma 2.1 and (2.3) one has

$$h - h_0 \in N_c(T_c(L_f(\bar{x}) \cap Z, u), h_0).$$

Since $T_c(L_f(\bar{x}) \cap Z, u)$ is a convex cone,

$$\langle h - h_0, z - h_0\rangle \le 0 \quad \text{for all } z \in T_c(L_f(\bar{x}) \cap Z, u).$$

Hence

$$\langle h - h_0, h_0\rangle = 0 \ \text{ and } \ \langle h - h_0, z\rangle \le 0 \quad \text{for all } z \in T_c(L_f(\bar{x}) \cap Z, u).$$

This and (2.2) imply that $\frac{\eta(h-h_0)}{\|h-h_0\|} \in N_c(L_{f(\bar{x})} \cap Z, u)$. It follows from (3.7) that $I_0(u) \neq \emptyset$, and there exist $t_1, \ldots, t_q \in [0, +\infty)$ and $y_1, \ldots, y_q \in I_0(u)$ such that

$$\sum_{i=1}^{q} t_i \le 1 \ \text{ and } \ \frac{\eta(h - h_0)}{\|h - h_0\|} = f'(u) + \sum_{i=1}^{q} t_i \phi'_x(u, y_i).$$

Hence

$$\begin{aligned}
\eta d(h, T_c(L_f(\bar{x}) \cap Z, u)) &= \left\langle \frac{\eta(h - h_0)}{\|h - h_0\|}, h - h_0 \right\rangle \\
&= \left\langle \frac{\eta(h - h_0)}{\|h - h_0\|}, h \right\rangle \\
&= \langle f'(u), h\rangle + \sum_{i=1}^{q} t_i \langle \phi'_x(u, y_i), h\rangle \\
&\le \langle f'(u), h\rangle + \max_{y\in I_0(u)}[\langle \phi'_x(u,y), h\rangle]_+.
\end{aligned}$$

Therefore, (3.9) holds. This shows that (iii) holds.

Since $T_c(L_f(\bar{x})\cap Z,u)\subset T(L_f(\bar{x})\cap Z,u)$ for any $u\in L_f(\bar{x})\cap Z$,

$$d(h,T(L_f(\bar{x})\cap Z,u))\le d(h,T_c(L_f(\bar{x})\cap Z,u)) \quad \text{for all } h\in X \text{and for all } u\in L_f(\bar{x})\cap Z.$$

Hence (iii)⇒(ii) holds trivially.

Suppose that (ii) holds. Take $\eta,\delta\in(0,\ +\infty)$ such that (3.8) holds for all $u\in L_f(\bar{x})\cap Z\cap B(\bar{x},\delta)$ and $h\in X$. Let $x\in B(\bar{x},\frac{\delta}{2})\setminus L_f(\bar{x})\cap Z$, and take $u\in P_{L_f(\bar{x})\cap Z}(x)$. By Lemma 2.1, one has $\frac{x-u}{\|x-u\|}\in\hat{N}(L_f(\bar{x})\cap Z,u)$. Hence $\langle\frac{x-u}{\|x-u\|},z\rangle\le 0$ for any $z\in T(L_f(\bar{x})\cap Z,u)$. This implies that

$$\|x-u\|\le\left\langle\frac{x-u}{\|x-u\|},x-u-z\right\rangle\le\|x-u-z\| \quad \text{for all } z\in T(L_f(\bar{x})\cap Z,u).$$

Hence $\|x-u\|=d(x-u,T(L_f(\bar{x})\cap Z,u))$. Noting that $u\in B(\bar{x},\delta)$, it follows from (3.8) that (3.10) holds. This shows that the implication (ii)⇒(iv) holds.

Suppose that (iv) holds. Take $\eta,\delta\in(0,\ +\infty)$ such that (3.10) holds for any $x\in B(\bar{x},\delta)$ and $u\in P_{L_f(\bar{x})\cap Z}(x)$. Let $x\in B(\bar{x},\frac{\delta}{2})\setminus L_f(\bar{x})\cap Z$, and take $u\in P_{L_f(\bar{x})\cap Z}(x)$. Then $u\in B(\bar{x},\delta)$. Hence (3.10) holds for such x and u. Let $\varepsilon\in(0,\ \frac{\eta}{2})$. By Lemma 3.1, without loss of generality we assume that

$$\langle f'(u),x-u\rangle\le f(x)-f(\bar{x})+\varepsilon\|x-u\|$$

and

$$\langle\phi'_x(u,y),x-u\rangle\le\phi(x,y)+\varepsilon\|x-u\| \quad \text{for all } y\in I_0(u)$$

(taking smaller δ if necessary). Hence

$$[\langle\phi'_x(u,y),x-u\rangle]_+\le[\phi(x,y)]_+ +\varepsilon\|x-u\| \quad \text{for all } y\in I_0(u).$$

It follows from (3.10) that

$$\eta\|x-u\|\le f(x)-f(\bar{x})+\max_{y\in Y}[\phi(x,y)]_+ +2\varepsilon\|x-u\|.$$

Therefore,

$$(\eta-2\varepsilon)d(x,L_f(\bar{x})\cap Z)=(\eta-2\varepsilon)\|x-u\|\le f(x)-f(\bar{x})+\max_{y\in Y}[\phi(x,y)]_+.$$

This shows that (i) holds. The proof is completed. □

Now we provide a mixed characterization for $\bar{x}$ to be a weak sharp minimum of (SIP), which is inspired from [10, Theorem 4].

PROPOSITION 3.1. *Let $\bar{x}\in Z$. Then $\bar{x}$ is a local weak sharp minimum of* (SIP) *if and only if the following conditions are satisfied:*

(i) $T(L_f(\bar{x})\cap Z,\bar{x})=\{h\in X:\ \langle f'(\bar{x}),h\rangle+\max_{y\in I_0(\bar{x})}[\langle\phi'_x(\bar{x},y),h\rangle]_+\le 0\}$.

(ii) *There exist $\eta_0,\delta\in(0,\ +\infty)$ such that for any $u\in L_f(\bar{x})\cap Z\cap B(\bar{x},\delta)\setminus\{\bar{x}\}$*

$$\hat{N}(L_f(\bar{x})\cap Z,u)\cap\eta_0 B_{X^*}\subset f'(u)+[0,\ 1]\mathrm{co}\{\phi'_x(u,y):\ y\in I_0(u)\}.$$

Proof. By Lemma 3.2, one has

$$T(L_f(\bar{x})\cap Z,\bar{x})\subset\{h\in X:\ \langle f'(\bar{x}),h\rangle+\max_{y\in I_0(\bar{x})}[\langle\phi'_x(\bar{x},y),h\rangle]_+\le 0 \quad \text{for all } y\in I_0(\bar{x})\}.$$

It follows from (ii) of Theorem 3.2 and (ii) of Theorem 3.1 that the necessity part holds.

To prove the sufficiency part, suppose that (i) and (ii) hold. We claim that there exists $\eta_1 > 0$ such that

$$\eta_1\|h\| \le \langle f'(\bar{x}), h\rangle + \max_{y\in I_0(\bar{x})}[\langle \phi'_x(\bar{x}, y), h\rangle]_+ \quad \text{for all } h \in \hat{N}(L_f(\bar{x}) \cap Z, \bar{x}). \tag{3.11}$$

Suppose to the contrary that there exists a sequence $\{h_k\}$ in $\hat{N}(L_f(\bar{x}) \cap Z, \bar{x})$ such that

$$\|h_k\| = 1 \ \text{ and } \ \langle f'(\bar{x}), h_k\rangle + \max_{y\in I_0(\bar{x})}[\langle \phi'_x(\bar{x}, y), h_k\rangle]_+ < \frac{1}{k} \quad \text{for all } k \in \mathbb{N}.$$

Without loss of generality we assume that $h_k \to h_0$. Then

$$h_0 \in \hat{N}(L_f(\bar{x}) \cap Z, \bar{x}) \ \text{ and } \ \langle f'(\bar{x}), h_0\rangle + \max_{y\in I_0(\bar{x})}[\langle \phi'_x(\bar{x}, y), h_0\rangle]_+ \le 0.$$

It follows from (i) that $h_0 \in T(L_f(\bar{x}) \cap Z, \bar{x})$, contradicting $\|h_0\| = 1$ and (2.1). This shows that (3.11) holds. Let $x \in B(\bar{x}, \frac{\delta}{2}) \setminus L_f(\bar{x}) \cap Z$ and $u \in P_{L_f(\bar{x})\cap Z}(x)$. Then $u \in B(\bar{x}, \delta) \setminus \{x\}$ and $\frac{x-u}{\|x-u\|} \in \hat{N}(L_f(\bar{x}) \cap Z, u)$. In the case when $u = \bar{x}$, by (3.11) one has

$$\eta_1\|x - \bar{x}\| \le \langle f'(\bar{x}), x - \bar{x}\rangle + \max_{y\in I_0(\bar{x})}[\langle \phi'_x(\bar{x}, y), x - \bar{x}\rangle]_+. \tag{3.12}$$

In the case when $u \ne \bar{x}$, by (ii) there exist $t_i \in [0, +\infty)$ and $y_i \in I_0(u)$, $i = 1, \ldots, q$, such that

$$\sum_{i=1}^{q} t_i \le 1 \ \text{ and } \ \frac{\eta_0(x-u)}{\|x-u\|} = f'(u) + \sum_{i=1}^{q} t_i\phi'(u, y_i).$$

It follows that

$$\begin{aligned}\eta_0\|x-u\| &= \langle f'(u), x-u\rangle + \sum_{i=1}^{q} t_i\langle \phi'_x(u, y_i), x-u\rangle \\ &\le \langle f'(u), x-u\rangle + \max_{y\in I_0(u)}[\langle \phi'_x(u, y_i), x-u\rangle].\end{aligned}$$

This and (3.12) imply that (iv) of Theorem 3.2 holds with $\eta = \min\{\eta_0, \eta_1\}$. It follows from Theorem 3.2 that the sufficiency part holds. The proof is completed. □

Remark. Letting

$$\psi(x) := f(x) + \max_{y\in Y}[\phi(x, y)]_+ \ \text{ for all } x \in X,$$

it is clear that if $\bar{x}$ is a local weak sharp minimum of (SIP), then $\bar{x}$ is a local weak sharp minimum of ψ: There exist $\eta, \delta \in (0, +\infty)$ such that

$$\eta d(x, L_\psi(\bar{x})) \le \psi(x) - \psi(\bar{x}) \ \text{ for all } x \in B(\bar{x}, \delta).$$

The converse implication may not be true. Indeed, let $X = R$, $Y = \{y_0\}$, $f(x) = -x^2$, and $\phi(x, y_0) = x^2$ for all $x \in R$. Then $Z = \{0\}$, and $\bar{x} = 0$ is not a local weak sharp minimum of (SIP). But, noting that $\psi(x) = f(x) + \max_{y\in Y}[\phi(x, y)]_+ = 0$ for all $x \in X$, 0 is a weak sharp minimum of ψ.

When ψ is a convex function, in terms of the normal and tangent cones of the solution set as well as the subdifferential and the directional derivative of ψ, some characterizations for the weak sharp minimum of ψ have been established (cf. [2, 33]). To the best of our knowledge, in the nonconvex case no one considers corresponding characterizations.

Finally, we provide characterizations for $\bar{x} \in Z$ to be a local sharp minimum of (SIP).

THEOREM 3.3. *Let $\bar{x} \in Z$. Then the following statements are equivalent:*

(i) *$\bar{x}$ is a local sharp minimum of* (SIP).

(ii) *There exists $\eta > 0$ such that*

$$\eta B_{X^*} \subset f'(\bar{x}) + [0,\ 1]\mathrm{co}\{\phi'_x(\bar{x}, y) :\ y \in I_0(\bar{x})\}.$$

(iii) *There exists $\eta > 0$ such that*

$$\eta\|h\| \le \langle f'(\bar{x}), h\rangle + \max_{y\in I_0(\bar{x})}[\langle\phi'_x(\bar{x}, y), h\rangle]_+ \quad \textit{for all } h \in X.$$

(iv) $\{h \in X : \langle f'(\bar{x}), h\rangle + \max_{y\in I_0(\bar{x})}[\langle\phi'_x(\bar{x}, y), h\rangle]_+ \le 0\} = \{0\}$.

Proof. (i)⇒(ii) is immediate from Theorem 3.1 and $N(\{\bar{x}\}, \bar{x}) = X^*$. (ii)⇒(iii) and (iii)⇒(iv) are trivial.

It remains to prove (iv)⇒(i). Suppose that (iv) holds. Noting that $T(\{\bar{x}\}, \bar{x}) = \{0\}$, by Proposition 3.1 we need only show that $L_f(\bar{x}) \cap Z \cap B(\bar{x}, \delta) = \{\bar{x}\}$ for some $\delta > 0$. Suppose to the contrary that there exists a sequence $\{x_k\}$ in $L_f(\bar{x}) \cap Z \setminus \{\bar{x}\}$ such that $x_k \to \bar{x}$. Without loss of generality we assume that $\frac{x_k - \bar{x}}{\|x_k - \bar{x}\|} \to h$ (passing to a subsequence if necessary). Thus, $h \in T(L_f(\bar{x}) \cap Z, \bar{x})$. It follows from Lemma 3.2 that

$$\langle f'(\bar{x}), h\rangle + \max_{y\in I_0(\bar{x})}[\langle\phi'_x(\bar{x}, y), h\rangle]_+ \le 0,$$

contradicting (iv) and $\|h\| = 1$. The proof is completed. □

4. Calmness for infinitely many smooth inequalities. Recently Henrion and Outrata [10] studied the calmness of infinitely many smooth inequalities. Let $C(Y)$ denote the Banach space of all continuous functions on Y equipped with the maximum norm, and consider the multifunction $M : C(Y) \rightrightarrows X$ defined by

$$M(g) := \{x \in X :\ \phi(x, y) \le -g(y) \quad \text{for all } y \in Y\} \quad \text{for all } g \in C(Y), \tag{4.1}$$

where X, Y, and $\phi(x, y)$ are as in section 3. For $\bar{g} \in C(Y)$ and $\bar{x} \in M(\bar{g})$, recall that M is calm at $(\bar{g}, \bar{x})$ if there exist $L,\ \delta \in (0,\ +\infty)$ such that

$$d(x, M(\bar{g})) \le L\|g - \bar{g}\| \quad \text{for all } g \in B(\bar{g}, \delta) \text{ and for all } x \in B(\bar{x}, \delta) \cap M(g).$$

We say that M is strongly calm at $(\bar{g}, \bar{x})$ if there exist $L,\ \delta \in (0,\ +\infty)$ such that

$$\|x - \bar{x}\| \le L\|g - \bar{g}\| \quad \text{for all } g \in B(\bar{g}, \delta) \text{ and for all } x \in B(\bar{x}, \delta) \cap M(g).$$

It is clear that M is strongly calm at $(\bar{g}, \bar{x})$ if and only if M is calm at $(\bar{g}, \bar{x})$ and $M(\bar{g}) \cap B(\bar{x}, \delta) = \{\bar{x}\}$ for some $\delta > 0$. Let $\Lambda := \{g \in C(Y) :\ g(y) \le 0 \quad \text{for all } y \in Y\}$ and $\bar{x} \in M(0)$. It is known (cf. [10]) that M is calm at $(0, \bar{x})$ if and only if there exist $L,\ \delta \in (0,\ +\infty)$ such that

$$d(x, M(0)) \le Ld(\phi(x, \cdot), \Lambda) \quad \text{for all } x \in B(\bar{x}, \delta).$$

Noting that

$$M(0) = Z \text{ and } d(\phi(x,\cdot),\Lambda) = \max_{y\in Y}[\phi(x,y)]_+,$$

it follows that M is calm at $(0,\bar{x})$ if and only if there exist $\eta,\ \delta \in (0,\ +\infty)$ such that

$$\eta d(x,Z) \le \max_{y\in Y}[\phi(x,y)]_+ \quad \text{for all } x \in B(\bar{x},\delta). \tag{4.2}$$

Setting $f(x) = 0$ for all $x \in X$ in (SIP), one sees that (4.2) means that $\bar{x}$ is a local weak sharp minimum of (SIP). Thus, by Theorems 3.1 and 3.2 and Proposition 3.1 we have the following characterizations for M to be calm at $(0,\bar{x})$.

THEOREM 4.1. *Let M be as in* (4.1) *and $\bar{x} \in M(0)$. Then the following statements are equivalent:*

(i) *M is calm at $(0,\bar{x})$.*

(ii) *There exist $\tau,\delta \in (0,\ +\infty)$ such that*

$$\hat{N}(M(0),u)\cap B_{X^*} \subset [0,\ \tau]\mathrm{co}\{\phi'_x(u,y) :\ y \in I_0(u)\} \quad \text{for all } u \in M(0)\cap B(\bar{x},\delta).$$

(iii) *There exist $\tau,\delta \in (0,\ +\infty)$ such that*

$$N(M(0),u)\cap B_{X^*} \subset [0,\ \tau]\mathrm{co}\{\phi'_x(u,y) :\ y \in I_0(u)\} \quad \text{for all } u \in M(0)\cap B(\bar{x},\delta).$$

(iv) *There exist $\tau,\delta \in (0,\ +\infty)$ such that*

$$N_c(M(0),u)\cap B_{X^*} \subset [0,\ \tau]\mathrm{co}\{\phi'_x(u,y) :\ y \in I_0(u)\} \quad \text{for all } u \in M(0)\cap B(\bar{x},\delta).$$

(v) *There exist $\tau,\delta \in (0,\ +\infty)$ such that*

$$d(h,T(M(0),u)) \le \tau \max_{y\in I_0(u)}[\langle\phi'_x(u,y),h\rangle]_+$$

for all $u \in M(0)\cap B(\bar{x},\delta)$ and $h \in X$.

(vi) *There exist $\tau,\delta \in (0,\ +\infty)$ such that*

$$d(h,T_c(M(0),u)) \le \tau \max_{y\in I_0(u)}[\langle\phi'_x(u,y),h\rangle]_+$$

for all $u \in M(0)\cap B(\bar{x},\delta)$ and $h \in X$.

(vii) *There exist $\tau,\delta \in (0,\ +\infty)$ such that*

$$\|x-u\| \le \tau \max_{y\in I_0(u)}[\langle\phi'_x(u,y),x-u\rangle]_+$$

for any $x \in B(\bar{x},\delta)$ and $u \in P_{M(0)}(x)$.

(viii) *$T(M(0),\bar{x}) = \{h \in X :\ \langle\phi'_x(\bar{x},y),h\rangle \le 0 \quad \text{for all } y \in I_0(\bar{x})\}$, and there exist $\tau,\delta \in (0,\ +\infty)$ such that for any $u \in M(0)\cap B(\bar{x},\delta)\setminus\{\bar{x}\}$*

$$\hat{N}(M(0),u)\cap B_{X^*} \subset [0,\ \tau]\mathrm{co}\{\phi'_x(u,y) :\ y \in I_0(u)\}.$$

In the remainder of this section, we assume that Y is a compact subset of R^n. Following Henrion and Outrata [10], let

$$\mathcal{J} := \{S \in \mathcal{K}(Y) :\ \exists x_i \overset{\mathrm{bd}M(0)\setminus\{\bar{x}\}}{\longrightarrow} \bar{x} \text{ such that } d_H(S,I_0(x_i)) \to 0\},$$

where $\mathcal{K}(Y)$ denotes the family of all compact subsets of Y and d_H denotes the Hausdorff distance between compact sets.

COROLLARY 4.1. *Let M be as in* (4.1) *and $\bar{x} \in M(0)$. Suppose that the following conditions are satisfied:*

1. $T(M(0),\bar{x}) = \{h \in X :\ \langle \phi'_x(\bar{x},y), h\rangle \le 0 \quad \textit{for all } y \in I_0(\bar{x})\}$.
2. *There exists* $\rho > 0$ *such that*

$$d(0, \mathrm{co}\{\phi'_x(\bar{x},y) :\ y \in S)\}) > \rho \quad \textit{for all } S \in \mathcal{J}.$$

Then M *is calm at* $(0,\bar{x})$.

Proof. We claim that there exists $\delta > 0$ such that

$$d(0, \mathrm{co}\{\phi'_x(x,y) :\ y \in I_0(x)\}) > \rho \quad \text{for all } x \in \mathrm{bd}(M(0)) \cap B(\bar{x},\delta) \setminus \{\bar{x}\}. \tag{4.3}$$

If this is not the case, then there exists a sequence $\{x_i\}$ in $\mathrm{bd}(M(0)) \setminus \{\bar{x}\}$ such that

$$x_i \to \bar{x} \ \text{ and } \ d(0, \mathrm{co}\{\phi'_x(x_i,y) :\ y \in I_0(x_i)\}) \le \rho \quad \text{for all } i \in \mathbb{N}.$$

Noting that X is of dimension m, it follows from the Caratheodory theorem that for each $i \in \mathbb{N}$ there exist $t_{ji} \ge 0$ and $y_{ji} \in I_0(x_i)$, $j = 1,\dots,m+1$, such that

$$\sum_{j=1}^{m+1} t_{ji} = 1 \ \text{ and } \ \left\| \sum_{j=1}^{m+1} t_{ji}\phi'_x(x_i,y_{ji}) \right\| \le \rho.$$

By (P2) and the compactness of Y, without loss of generality we assume that

$$t_{ji} \to t_j \ge 0 \ \text{ and } \ y_{ji} \to y_j \in I_0(\bar{x}),\ j = 1,\dots,m+1.$$

Hence,

$$\sum_{j=1}^{m+1} t_j = 1 \ \text{ and } \ \left\| \sum_{j=1}^{m+1} t_j\phi'_x(\bar{x},y_j) \right\| \le \rho. \tag{4.4}$$

Since the space of compact subsets of X endowed with the Hausdorff distance is itself compact, without loss of generality we assume that there exists $S_0 \in \mathcal{J}$ such that $d_H(I_0(x_i), S_0) \to 0$. It is clear that $y_j \in S_0$, $j = 1,\dots,m+1$. This and (4.4) imply that $d(0, \mathrm{co}\{\phi'_x(\bar{x},y) :\ y \in S_0)\}) \le \rho$, contradicting condition 2. Hence there exists $\delta > 0$ such that (4.3) holds. Recalling (cf. [26, Definition 7.25 and Theorem 10.31]) that $\Phi(x) = \max_{y\in Y} \phi(x,y)$ is regular and $\partial\Phi(x) = \mathrm{co}\{\phi'(x,y) :\ y \in I(x)\}$, it follows from (4.3) and [26, Proposition 10.3] that

$$N(M(0),x) = R_+\mathrm{co}\{\phi'_x(x,y) :\ y \in I_0(x)\} \quad \text{for all } x \in \mathrm{bd}(M(0)) \cap B(\bar{x},\delta) \setminus \{\bar{x}\}.$$

Let $x \in \mathrm{bd}(M(0)) \cap B(\bar{x},\delta) \setminus \{\bar{x}\}$ and $x^* \in N(M(0),x) \cap B_{X^*}$. Then there exist $t \in [0,\ +\infty)$ and $u^* \in \mathrm{co}\{\phi'_x(x,y) :\ y \in I_0(x)\}$ such that $x^* = tu^*$. This and (4.3) imply that $t < \frac{1}{\rho}$. Hence,

$$N(M(0),x) \cap B_{X^*} \subset \left[0,\ \frac{1}{\rho}\right] \mathrm{co}\{\phi'_x(x,y) :\ y \in I_0(x)\}.$$

It is clear that

$$N(M(0),x) \cap B_{X^*} = \{0\} \subset \left[0,\ \frac{1}{\rho}\right] \mathrm{co}\{\phi'_x(\bar{x},y) :\ y \in I_0(x)\} \quad \text{for all } x \in \mathrm{int}(M(0)).$$

Hence, (viii) of Theorem 4.1 holds, and so M is calm at $(0,\bar{x})$. The proof is completed. □

Remark 4.1. Corollary 4.1 is a slight improvement of [10, Theorem 4], which, in addition to all assumptions on Corollary 4.1, requires that $(x,y) \mapsto \phi(x,y)$ is continuously differentiable and $(x,y) \mapsto \phi'(x,y)$ is locally Lipschitz. Noting that

$$\mathcal{J} = \{S \subset Y : \exists x_i \overset{\mathrm{bd}M(0)\setminus\{\bar{x}\}}{\longrightarrow} \bar{x} \text{ such that } I_0(x_i) = S \text{ for all } i \in \mathbb{N}\}$$

when Y is a finite set, Corollary 4.1 recaptures [10, Theorem 3].

The following example shows that implication (viii)⇒(i) of Theorem 4.1 properly improves [10, Theorems 4 and 3]. Let $X = R^2$, $Y = \{0,1\}$, $\phi((s,t),0) = 0$, and $\phi((s,t),1) = s - t$ for all $(s,t) \in R^2$. Then $M(0) = \{(s,t) \in R^2 : \ s \le t\}$ and $I_0(x) = Y$ for any $x \in \mathrm{bd}(M(0))$. Let $\bar{x} = (0,0)$. Then $\mathcal{J} = \{Y\}$. Noting that

$$\mathrm{co}\{\phi'((s,t),y) : \ y \in Y\} = \{(u,-u) : \ 0 \le u \le 1\} \quad \text{for all } (s,t) \in R^2,$$

it follows that $d(0, \mathrm{co}\{\phi'_x(\bar{x},y) : \ y \in S\}) = 0$ for all $S \in \mathcal{J}$. Thus, Corollary 4.1 and so [10, Theorems 4 and 3] are not applicable. On the other hand, noting that $\mathrm{bd}(M(0)) = \{(s,s) : \ s \in R\}$,

$$T(M(0),(s,s)) = M(0) \ \text{ and } \ N(M(0),(s,s)) = \{(t,-t) : \ t \ge 0\} \quad \text{for all } s \in R,$$

one can see that (viii) of Theorem 4.1 holds. Hence, applying implication (viii)⇒(i) of Theorem 4.1, one obtains that M is calm at $(0,\bar{x})$.

We conclude with characterizations for M to be strongly calm at $(0,\bar{x})$.

THEOREM 4.2. *Let M be as in* (4.1) *and $\bar{x} \in M(0)$. Then the following statements are equivalent:*

(i) *M is strongly calm at $(0,\bar{x})$.*

(ii) *There exists $\tau \in (0, +\infty)$ such that*

$$B_{X^*} \subset [0, \tau]\mathrm{co}\{\phi'_x(\bar{x},y) : \ y \in I_0(\bar{x})\}.$$

(iii) $X^* = R_+\mathrm{co}\{\phi'_x(\bar{x},y) : \ y \in I_0(\bar{x})\}$.

(iv) *There exists $\tau \in (0, +\infty)$ such that*

$$\|h\| \le \tau \max_{y \in I_0(\bar{x})} [\langle \phi'_x(\bar{x},y), h\rangle]_+ \quad \text{for all } h \in X.$$

(v) $\{h \in X : \ \langle \phi'_x(\bar{x},y), h\rangle \le 0 \quad \textit{for all } y \in I_0(\bar{x})\} = \{0\}$.

Proof. Noting that M is strongly calm at $(0,\bar{x})$ if and only if $\bar{x}$ is a local sharp minimum of (SIP) with $f \equiv 0$, (i)⇔(ii)⇔(iv)⇔(v) are immediate from Theorem 3.3. It is clear that (ii)⇒(iii)⇒(v) hold. The proof is completed. ∎

SECOND-ORDER NECESSARY CONDITIONS FOR NONLINEAR OPTIMIZATION PROBLEMS WITH ABSTRACT CONSTRAINTS: THE DEGENERATE CASE*

HELMUT GFRERER†

Abstract. In this paper we derive second-order necessary conditions for optimality for an optimization problem with abstract constraints in Banach spaces. Results for the nondegenerate case derived earlier [H. Gfrerer, *SIAM J. Control Optim.*, 45 (2006), pp. 972–997] are extended to the degenerate case. For the mathematical programming problem, where the constraints are given by equality and finitely many inequality constraints, our approach applies to the degenerate case, when the equality constraints are not regular; our results appear to be new even in this special case. Our second-order necessary conditions are contained in the gap between the standard necessary and sufficient conditions, where the only difference is the change from a nonstrict to a strict inequality. Our results are formulated in such a way to be applicable also to vector optimization problems.

Key words. second-order optimality conditions, abstract constraints, vector optimization

1. Introduction.

In this paper we study necessary second-order optimality conditions for minimization problems with abstract constraints of the form

$$g(x) \in K, \tag{1.1}$$

where the constraint mapping $g : X \to V$ carries a Banach space X into another Banach space V, and K is a closed convex subset of V.

The feasible sets of various optimization problems can be formulated in the form (1.1) in a natural way. For instance, the possibly infinite-dimensional mathematical programming problem with finitely many inequality constraints $g_i(x) \le 0$, $i = 1, \dots, m$, and an equality constraint $G(x) = 0$, where $G : X \to \hat{V}$ maps X into another Banach space $\hat{V}$, fits into the scheme with $V = \mathbb{R}^m \times \hat{V}$, $K = \mathbb{R}^m_- \times \{0\}$, and $g = (g_1, \dots, g_m, G)$. Other examples are provided by semi-infinite programming problems, semidefinite programming problems, and optimal control problems. We refer to the monograph [10] for a comprehensive overview.

When studying necessary optimality conditions at a point $\bar{x}$ satisfying (1.1), usually a condition on the constraints is needed, since otherwise the necessary conditions trivially hold and therefore their utility for describing optimality is very limited. One classical condition in this setting is Robinson's condition [30]:

$$0 \in \operatorname{int}\left(g(\bar{x}) + g'(\bar{x})X - K\right). \tag{1.2}$$

Note that in the case of the finite-dimensional mathematical programming problem, condition (1.2) reduces to the classical Mangasarian–Fromovitz constraint qualification. Under Robinson's condition, the structure of the set of tangent directions of the

†Institute of Computational Mathematics, Johannes Kepler University Linz, A-4040 Linz, Austria (gfrerer@numa.uni-linz.ac.at).

constraints is well established (see, e.g., [10]) and second-order conditions have been formulated by several authors; see [9], [14], [17], [23], [28], [29].

In a recent paper [15], we presented second-order necessary optimality conditions, which are shown to be the best possible in a certain sense, under the nondegeneracy assumption

$$\operatorname{int}(g'(\bar{x})X - K) \neq \emptyset. \tag{1.3}$$

This condition is clearly weaker than Robinson's condition (1.2). For instance, for the mathematical programming problem, condition (1.3) reduces to a condition on the equality constraint only, namely, the well-known Lyusternik condition $G'(\bar{x})X = \hat{V}$, which has been used by several authors (see, e.g., [7], [8], [27], [16]). However, it is well known that there exist second-order necessary conditions for the mathematical programming problem which do not require the Lyusternik condition $G'(\bar{x})X = \hat{V}$ to be satisfied. A generalization of the classical Lyusternik theorem for nonregular mappings $G'(\bar{x})$ was first derived and proved in [12]. Tret'yakov [33] and Avakov [4], [5] presented optimality conditions for this nonregular case. These results have been extended by several authors; see, e.g., [1], [2], [6], [11], [19], [25], [26].

In this paper we will derive second-order necessary optimality conditions in the degenerate case, i.e., condition (1.3) is dropped. The obtained results appear to be new even in the special case of the mathematical programming problem. Our approach is essentially based on the ideas presented in [15]. We will use both an observation made by Robinson [32]—that a certain multifunction built by the objective and the constraints obtains a singular behavior at a local minimizer—and an accurate characterization of metric regularity of this multifunction by means of a certain signed distance function.

With this approach, when dealing with general constraints of the form (1.1), it does not require great effort to consider also the case of general objective functions. Thus the problem we consider in this paper is given by

$$\text{L-minimize } f(x) \quad \text{subject to} \quad g(x) \in K, \tag{P}$$

where $f : X \to U$ is a mapping from the Banach space X to another Banach space U and where $L \subset U$ is a closed convex cone with nonempty interior, $\operatorname{int} L \neq \emptyset$. We define different kinds of local L-minimizers as follows.

Definition 1.1. *An element $\bar{x} \in X$ is called a* local weak minimizer *for* (P) *if $g(\bar{x}) \in K$ and if there exists a neighborhood N of $\bar{x}$ such that for each $x \in N$ with $g(x) \in K$, one has $f(x) - f(\bar{x}) \notin -\operatorname{int} L$. A local weak minimizer $\bar{x}$ is called a* strict local minimizer *for* (P) *if for each $x \in N \setminus \{\bar{x}\}$ with $g(x) \in K$, one has $f(x) - f(\bar{x}) \notin -L$. Finally, a weak local minimizer $\bar{x}$ is called an* essential local minimizer of second order *for problem* (P) *if there exists some real $\beta > 0$ such that*

$$\max\{d(f(x) - f(\bar{x}), -L), d(g(x), K)\} \geq \beta \|x - \bar{x}\|^2 \quad \forall x \in N. \tag{1.4}$$

Of course, each essential local minimizer of second order is also a strict local minimizer.

Note that (P) includes the very common problem of constrained scalar minimization, for which $U = \mathbb{R}$ and $L = \mathbb{R}_+$. Local weak minimizers for (P) then amount to usual local minimizers, and for essential local minimizers the so-called *quadratic growth condition* is satisfied:

$$f(x) - f(\bar{x}) \geq \beta \|x - \bar{x}\|^2 \quad \forall x \in N : \ g(x) \in K.$$

Another important particular case, for instance, is the Pareto maximization optimization problem with $U = \mathbb{R}^p$, $L = \mathbb{R}^p_-$.

For second-order optimality conditions for problem (P) in the multicriteria case we refer to [8], [13], [15], [20], [21], [22].

Given a feasible point $\bar{x} \in g^{-1}(K)$, fixed throughout this paper, we will now define a certain multifunction associated with (P) and $\bar{x}$. Let $h : X \to U \times V$ be defined by

$$h(x) := (f(x) - f(\bar{x}),\ g(x)), \qquad C := (-L) \times K, \qquad Y := U \times V. \tag{1.5}$$

Then the multifunction $\Gamma : X \rightrightarrows Y$, given by

$$\Gamma(x) := h(x) - C, \tag{1.6}$$

will form the basis of our investigations. Throughout this paper we will use the following smoothness assumption on h.

ASSUMPTION 1. *h is Fréchet differentiable at $\bar{x}$ and for some radius $\bar{r} > 0$ and some scalar $\eta \geq 0$ we have*

$$\|h(x_1) - h(x_2) - h'(\bar{x})(x_1 - x_2)\| \leq \eta \max\{\|x_1 - \bar{x}\|, \|x_2 - \bar{x}\|\}\|x_1 - x_2\|$$

for all $x_1, x_2 \in \bar{x} + \bar{r}\mathcal{B}_X$.

In what follows we will use the norm $\|(u, v)\| := \max\{\|u\|, \|v\|\}$ on the product space $Y = U \times V$.

Our notation is fairly standard. In a normed space Z, $\mathcal{B}_Z := \{z \in Z : \|z\| \leq 1\}$ denotes the closed unit ball and $\mathcal{S}_Z := \{z \in Z : \|z\| = 1\}$ denotes the unit sphere. The topological dual space is denoted by Z^*. $\langle z^*, z\rangle$ is the value $z^*(z)$ of the linear functional $z^* \in Z^*$ at $z \in Z$. For a set $D \subset Z$ we denote by $\sigma_D(\cdot)$ its support function, i.e., $\sigma_D(z^*) := \sup_{z\in D}\langle z^*, z\rangle$, and by $d(\cdot, D)$ the distance function, i.e., $d(z, D) = \inf_{y\in D} \|z - y\|$. For a convex set $D \subset Z$ we denote by $T_D(z)$ (respectively, $N_D(z)$) the common tangent cone (respectively, normal cone) of convex analysis at a point $z \in D$, i.e., we have $N_D(z) := \{z^* \in Z^* : \langle z^*, \zeta - z\rangle \leq 0 \text{ for all } \zeta \in D\}$ and

$$T_D(x) = \left\{ s : \liminf_{t\to 0_+} \frac{d(z + ts, D)}{t} = 0 \right\} = \left\{ s : \limsup_{t\to 0_+} \frac{d(z + ts, D)}{t} = 0 \right\}.$$

If W is another normed space, we denote by $L(Z, W)$ the space of all continuous linear operators from Z into W. If $A \in L(Z, W)$, then $A^* : W^* \to Z^*$ denotes the adjoint operator of A. Finally, we denote by $\mathbb{T}$ the set of all sequences $(t_n) \to 0_+$.

Fritz–John-type optimality conditions for problem (P) can be written in the form

$$f'(\bar{x})^*u^* + g'(\bar{x})^*v^* = 0, \quad 0 \neq (u^*, v^*) \in L^* \times N_K(g(\bar{x})) \subset U^* \times V^*, \tag{1.7}$$

where $L^* := \{u^* \in U^* : \langle u^*, u\rangle \geq 0 \text{ for all } u \in L\}$ is the dual cone of the cone L. Setting $y^* := (u^*, v^*)$ and using the notation of h and C, the condition (1.7) can also be written more shortly as

$$h'(\bar{x})^*y^* = 0, \quad y^* \in N_C(h(\bar{x})), \quad y^* \neq 0. \tag{1.8}$$

In what follows we will denote the set of multipliers y^* satisfying the Fritz–John conditions (1.8) by Λ_{FJ}. It should be noted that in general Λ_{FJ} may be empty. An additional condition has to be imposed to ensure the existence of a nontrivial multiplier y^* at a local weak minimizer for (P).

2. Preliminaries. In this section we will recapitulate partially the basic theory on second-order optimality conditions as presented in [15].

In a very general form, these conditions can be formulated by means of a function $\hat{d}_C(y, A, \kappa) : Y \times L(X, Y) \times \mathbb{R} \to \mathbb{R}$ given by

$$\hat{d}_C(y, A, \kappa) := \sup_{y^* \in \mathcal{S}_{Y^*}} \{\langle y^*, y\rangle - \sigma_C(y^*) - \kappa \|A^* y^*\|\}.$$

THEOREM 2.1 (see [15, Theorem 3.2]). *Suppose that Assumption* 1 *is satisfied at* $\bar{x}$. *If* $\bar{x}$ *is a local weak minimizer for* (P), *then*

$$\liminf_{\substack{x \to \bar{x} \\ \tau \to 0_+}} \frac{\hat{d}_C(h(x), h'(\bar{x}), \tau\|x - \bar{x}\|)}{\|x - \bar{x}\|^2} \geq 0. \tag{2.1}$$

Moreover, a feasible point $\bar{x}$ *is an essential local minimizer of second order for* (P) *if and only if*

$$\liminf_{\substack{x \to \bar{x} \\ \tau \to 0_+}} \frac{\hat{d}_C(h(x), h'(\bar{x}), \tau\|x - \bar{x}\|)}{\|x - \bar{x}\|^2} > 0. \tag{2.2}$$

The following theorem gives further details on the optimality conditions of Theorem 2.1 (see [15, Theorems 3.5, 3.6]).

THEOREM 2.2.

1. *Suppose that a feasible point* $\bar{x}$ *is not an essential local minimizer of second order for* (P). *Then there exists a twice continuously differentiable mapping* $\delta h := (\delta f, \delta g)$ *satisfying* $\delta h(\bar{x}) = 0$, $\delta h'(\bar{x}) = 0$, *and* $\delta h''(\bar{x}) = 0$, *such that* $\bar{x}$ *is not a local weak minimizer for* (P) *with* f *and* g *replaced by* $f + \delta f$ *and* $g + \delta g$, *respectively.*

2. *Assume that at a feasible point* $\bar{x}$ *condition* (2.1) *holds, and assume that*

$$\operatorname{int}(h'(\bar{x})X - C) \neq \emptyset. \tag{2.3}$$

Then there exists a mapping $\delta h = (\delta f, \delta g) : X \to Y$ *with* $\delta h(x) = \psi(\|x - \bar{x}\|)y$, *where* $y \in Y$ *and* $\psi : \mathbb{R}_+ \to \mathbb{R}_+$ *is a twice continuously differentiable function satisfying* $\psi(0) = \psi'(0) = \psi''(0) = 0$, *such that* $\bar{x}$ *is a strict local minimizer for* (P) *with* f *and* g *replaced by* $f + \delta f$ *and* $g + \delta g$, *respectively.*

Remark. It follows from the proof of [15, Theorem 3.6] that the assertion of the second part of Theorem 2.2 does not depend on the special form of h and C, respectively. Indeed, for any closed convex set $C \subset Y$ and any mapping $h : X \to Y$, differentiable at some point $\bar{x}$ satisfying $h(\bar{x}) \in C$ and conditions (2.1) and (2.3), there exist a neighborhood N of $\bar{x}$ and a mapping $\delta h(x) = \psi(\|x - \bar{x}\|)y$ of the same kind as in the second part of Theorem 2.2, such that $d\big((h + \delta h)(x), C\big) > 0$ for all $x \in N \setminus \{\bar{x}\}$.

DEFINITION 2.3. *We call* $\bar{x}$ nondegenerate *for the problem* (P) *if* $\operatorname{int}(h'(\bar{x})X - C) \neq \emptyset$. *Conversely, if* $\operatorname{int}(h'(\bar{x})X - C) = \emptyset$, *the element* $\bar{x}$ *is said to be* degenerate *for* (P).

The following theorem states some geometrical properties of the function $\hat{d}_C$: It can be treated as a signed distance function for certain sets.

THEOREM 2.4 (see [15, Proposition 2.6]). *For each* $A \in L(X, Y)$, *each* $y \in Y$, *and each* $\kappa \geq 0$ *let* $D_C(y, A, \kappa)$ *be given by* $D_C(y, A, \kappa) := y + \kappa A\mathcal{B}_X - C$. *Then one*

has

$$\hat{d}_C(y,A,\kappa)=\begin{cases} d(0,D_C(y,A,\kappa)) & \text{if } 0\notin \operatorname{cl} D_C(y,A,\kappa),\\ 0 & \text{if } 0\in \operatorname{bd} D_C(y,A,\kappa),\\ -\sup\{\rho\,:\,\rho\mathcal{B}_Y\subset D_C(y,A,\kappa)\} & \text{if } 0\in \operatorname{int} D_C(y,A,\kappa).\end{cases}$$

It follows easily from the definition that $\hat{d}_C(\cdot,A,\kappa)$ is Lipschitz continuous with constant 1. Moreover we have the following property.

LEMMA 2.5 (see [15, Lemma 2.8]). *Let $A\in L(X,Y)$, $y\in Y$, and $\kappa\geq 0$ be such that $\hat{d}_C(y,A,\kappa)<0$. Then*

$$d(0,A^{-1}(C-y))\leq \frac{\kappa}{d(y,C)-\hat{d}_C(y,A,\kappa)}d(y,C).$$

For the sake of completeness we mention some material from [15] also used in this paper. First, let us recall the notion of (local) metric regularity.

DEFINITION 2.6. *Let $\Psi: X\rightrightarrows Y$ be a set-valued map, $\bar{y}\in\Psi(\bar{x})$. The multifunction Ψ is called* metrically regular near $(\bar{x},\bar{y})$ *if there are neighborhoods $N_{\bar{x}}$, $N_{\bar{y}}$ of $\bar{x}$, $\bar{y}$, respectively, and some $k>0$ such that $d(x,\Psi^{-1}(y))\leq k\,d(y,\Psi(x))$ for each $(x,y)\in N_{\bar{x}}\times N_{\bar{y}}$.*

The following two theorems are the base for the necessary optimality conditions of Theorem 2.1 and are also of substantial significance for this paper.

THEOREM 2.7 (see [15, Proposition 2.4]). *Let (x_n) be a sequence converging to $\bar{x}$ such that for each n, Γ is metrically regular near $(x_n,0)$. Then $\bar{x}$ is not a local weak minimizer for* (P).

THEOREM 2.8 (see [15, Proposition 2.10]). *Let $\hat{x}\in X$ be given and suppose that there exist a continuous linear mapping $A\in L(X,Y)$, a vector $x^0\in X$, and scalars $R>0$, $\hat{\kappa}\geq 0$, and $\gamma>0$, such that the following conditions are satisfied:*

$$\|h(x')-h(x)-A(x'-x)\|\leq\gamma\|x'-x\|\ \forall x,x'\in\hat{x}+R\mathcal{B}_X, \tag{2.4}$$

$$h(\hat{x})+A(x^0-\hat{x})\in C,\ r:=\|x^0-\hat{x}\|<R/2, \tag{2.5}$$

$$2\gamma(\hat{\kappa}+3r)+\hat{d}_C(h(\hat{x}),A,\hat{\kappa})<0. \tag{2.6}$$

Then there exists some $\tilde{x}\in x^0+r\mathcal{B}_X$, such that $h(\tilde{x})\in C$ and Γ is metrically regular near $(\tilde{x},0)$. Moreover, $\hat{d}_C(h(\tilde{x}),A,\hat{\kappa}+\|\tilde{x}-\hat{x}\|)\leq\hat{d}_C(h(\tilde{x}),A,\hat{\kappa})+\gamma\|\tilde{x}-\hat{x}\|$.

3. A general necessary condition. The following theorem states an abstract necessary optimality condition for problem (P). In some sense it is contained in the gap between the necessary and sufficient optimality conditions of Theorem 2.1.

THEOREM 3.1. *Assume that Assumption* 1 *holds. Further assume that $\bar{x}$ is a local weak minimizer, but not an essential local minimizer of second order, and let $(z_n)\subset\mathcal{S}_X$, $(t_n)\in\mathbb{T}$, and $(\tau_n)\in\mathbb{T}$ be sequences such that*

$$\limsup_{n\to\infty} t_n^{-2}\hat{d}_C(h(\bar{x}+t_nz_n),h'(\bar{x}),\tau_nt_n)\leq 0. \tag{3.1}$$

Further assume that there is a sequence $(A_n)\subset L(X,Y)$ of continuous linear operators mapping X into Y such that, together with some positive scalars $\gamma',R'>0$ and a sequence $(\varphi_n')\in\mathbb{T}$, one has

$$\begin{aligned}&\|h(x')-h(x)-A_n(x'-x)\|\\ &\qquad\leq\big(\varphi_n't_n+\gamma'\max\{\|\bar{x}+t_nz_n-x'\|,\|\bar{x}+t_nz_n-x\|\}\big)\|x'-x\|\end{aligned} \tag{3.2}$$

for all $x', x \in \bar{x} + t_n(z_n + R'\mathcal{B}_X)$ *and for each* n. *Then for each* $T > 0$ *one has*

$$\liminf_{n\to\infty} t_n^{-2}\hat{d}_C(h(\bar{x}+t_nz_n), A_n, Tt_n) \geq 0. \tag{3.3}$$

Proof. By Theorem 2.4, for each n we can find some element $\delta z_n \in \mathcal{B}_X$ such that

$$\begin{aligned}\delta_n :&= t_n^{-2} d(h(\bar{x}+t_nz_n) + t_n\tau_n h'(\bar{x})\delta z_n, C)\\ &\leq t_n^{-2}\max\{\hat{d}_C(h(\bar{x}+t_nz_n), h'(\bar{x}), \tau_n t_n), 0\} + \frac{1}{n},\end{aligned}$$

and from (3.1) it follows that $\delta_n \to 0$. Let $z_n' := z_n + \tau_n\delta z_n$. Then $\|z_n'\| \leq 1+\tau_n$, and using Assumption 1 we obtain

$$\begin{aligned}\delta_n' &:= t_n^{-2} d(h(\bar{x}+t_nz_n'), C)\\ &\leq t_n^{-2}\big(d(h(\bar{x}+t_nz_n) + t_n\tau_n h'(\bar{x})\delta z_n, C)\\ &\qquad + \|h(\bar{x}+t_nz_n') - h(\bar{x}+t_nz_n) - t_n\tau_n h'(\bar{x})\delta z_n\|\big)\\ &\leq \delta_n + t_n^{-2}\eta\max\{\|t_nz_n'\|, \|t_nz_n\|\}\|t_n(z_n - z_n')\| \leq \delta_n + \eta(1+\tau_n)\tau_n,\end{aligned}$$

yielding $\delta_n' \to 0$. We will now prove by contraposition that (3.3) holds for arbitrarily fixed $T > 0$. Assume on the contrary that

$$\liminf_{n\to\infty} t_n^{-2}\hat{d}_C(h(\bar{x}+t_nz_n), A_n, Tt_n) \leq -2\epsilon < 0$$

for some $T > 0$. Using the Lipschitz continuity of $\hat{d}_C(\cdot, A_n, Tt_n)$, Theorem 2.4, and condition (3.2) we obtain

$$\begin{aligned}\hat{d}_C(h(\bar{x}+t_nz_n'), A_n, Tt_n) &\leq \hat{d}_C(h(\bar{x}+t_nz_n) + \tau_nt_nA_n\delta z_n, A_n, Tt_n)\\ &\qquad + \|h(\bar{x}+t_nz_n') - h(\bar{x}+t_nz_n) - \tau_nt_nA_n\delta z_n\|\\ &\leq \hat{d}_C(h(\bar{x}+t_nz_n), A_n, (T+\tau_n)t_n)\\ &\qquad + (\varphi_n't_n + \gamma'\tau_nt_n\|\delta z_n\|)\tau_nt_n\|\delta z_n\|\\ &= \hat{d}_C(h(\bar{x}+t_nz_n), A_n, (T+\tau_n)t_n) + o(t_n^2).\end{aligned}$$

Next define $T_n := T + \tau_n$ and $\mu_n := \max\{\tau_n, \varphi_n', \frac{T_n\delta_n'}{\epsilon}\}$ for each n. Since $\mu_n \to 0$, by passing to a subsequence if necessary, we may assume that

$$\begin{aligned}t_n^{-2}\hat{d}_C(h(\bar{x}+t_nz_n'), A_n, T_nt_n) &\leq -\epsilon,\\ (2+8\gamma')(\mu_nT_n + 3\mu_n^2) - \epsilon &< 0,\\ \tau_n + 3\mu_n &\leq R'\end{aligned}$$

for each n. Now let n be arbitrarily fixed. We will now show that the assumptions of Theorem 2.4 hold with data $\hat{x} = \bar{x} + t_nz_n'$, $A = A_n$, $R = 3\mu_nt_n$, $\hat{\kappa} = T_nt_n$, and $\gamma = (1+4\gamma')\mu_nt_n$. Since $\|t_n(z_n' - z_n)\| + R \leq t_n(\tau_n + 3\mu_n) \leq t_nR'$ it follows from (3.2) for all $x, x' \in \bar{x} + t_nz_n' + R\mathcal{B}_X \subset \bar{x} + t_n(z_n + R'\mathcal{B}_X)$ that

$$\begin{aligned}&\|h(x') - h(x) - A_n(x'-x)\|\\ &\qquad \leq (t_n\varphi_n' + \gamma'\max\{\|\bar{x}+t_nz_n - x'\|, \|\bar{x}+t_nz_n - x\|\})\|x - x'\|\\ &\qquad \leq (t_n\varphi_n' + \gamma'(R + t_n\|z_n - z_n'\|))\|x - x'\|\\ &\qquad \leq (\varphi_n' + \gamma'(3\mu_n + \tau_n))t_n\|x - x'\| \leq (1+4\gamma')\mu_nt_n\|x - x'\|,\end{aligned}$$

and hence (2.4) holds. Using Lemma 2.5 we have

$$d(0, A_n^{-1}(h(\bar{x}+t_nz_n')-C)) \le \frac{T_nt_nd(h(\bar{x}+t_nz_n'),C)}{d(h(\bar{x}+t_nz_n'),C)-\hat{d}_C(h(\bar{x}+t_nz_n'),A_n,T_nt_n)} \le \frac{T_nt_n\delta_n't_n^2}{\delta_n't_n^2+\epsilon{t_n}^2} < \frac{T_n\delta_n'}{\epsilon}t_n \le \mu_nt_n.$$

Thus there exists some x^0 such that

$$h(\bar{x}+t_nz_n')+A_n(x^0-(\bar{x}+t_nz_n')) \in C, \quad r := \|x^0-(\bar{x}+t_nz_n')\| \le \mu_nt_n = \frac{R}{3},$$

showing the validity of (2.5). Finally, we have

$$2\gamma(\hat{\kappa}+3r)+\hat{d}_C(h(\bar{x}+t_nz_n'),A_n,\hat{\kappa}) \le 2(1+4\gamma')\mu_nt_n(T_nt_n+3\mu_nt_n)-\epsilon t_n^2 = \big((2+8\gamma')(\mu_nT_n+3\mu_n^2)-\epsilon\big)t_n^2 < 0,$$

yielding (2.6). Thus we can apply Theorem 2.4 to establish the existence of some $\tilde{x}_n \in \bar{x}+t_nz_n'+3\mu_nt_n\mathcal{B}_X$ such that $h(\tilde{x}_n) \in C$ and the multifunction $h(\cdot)-C$ is metrically regular near $(\bar{x},0)$. This holds for each n, and since $\tilde{x}_n \to \bar{x}$ we conclude from Theorem 2.7 that $\bar{x}$ is not a local weak minimizer, a contradiction. □

It is easy to show that if h is continuously differentiable in a neighborhood of $\bar{x}$, then for a sequence $(A_n) \subset L(X,Y)$ of linear operators satisfying condition (3.2) one has $\|h'(\bar{x}+t_nz_n)-A_n\| \le \varphi_n't_n = o(t_n)$. The converse is also true if h is sufficiently smooth near $\bar{x}$.

LEMMA 3.2. *Suppose that h is continuously differentiable in some ball $\bar{x}+\rho\mathcal{B}_X$ around $\bar{x}$. Further suppose that either h is twice Fréchet differentiable at $\bar{x}$ or that $h'(\cdot)$ is Lipschitz continuous in $\bar{x}+\rho\mathcal{B}_X$. Then, for any sequences $(z_n) \subset \mathcal{S}_X$, $(t_n) \in \mathbb{T}$, and $(A_n) \subset L(X,Y)$ such that $\|h'(\bar{x}+t_nz_n)-A_n\| = o(t_n)$, there exist a sequence $(\varphi_n') \in \mathbb{T}$ and positive reals γ' and R' such that condition* (3.2) *holds for all n sufficiently large.*

Proof. Let $R' > 0$ be arbitrarily chosen and consider n chosen so large that $t_n(z_n+R'\mathcal{B}_X) \subset \rho\mathcal{B}_X$. Consider an arbitrary linear functional $y^* \in \mathcal{B}_{Y^*}$. For every pair $x, x' \in \bar{x}+t_n(z_n+R'\mathcal{B}_X)$, by the mean-value theorem, there exists some element ξ belonging to the line segment $[x,x']$ such that $\langle y^*, h(x')-h(x)\rangle = \langle y^*, h'(\xi)(x'-x)\rangle$ and

$$\langle y^*, h(x')-h(\bar{x})-A_n(x'-x)\rangle = \langle y^*, (h'(\xi)-A_n)(x'-x)\rangle \le \|y^*\|\|h'(\xi)-A_n\|\|x'-x\|$$

follows. Now, in order to prove the lemma it is sufficient to show the bound

$$\|h'(\xi)-A_n\| \le \varphi_n't_n+\gamma'\max\{\|\bar{x}+t_nz_n-x'\|, \|\bar{x}+t_nz_n-x\|\} \tag{3.4}$$

for some constant γ' and some sequence $(\varphi_n') \in \mathbb{T}$. When h is twice Fréchet differentiable at $\bar{x}$ we have

$$\|h'(\xi)-h'(\bar{x}+t_nz_n)\| \le \|h'(\xi)-(h'(\bar{x})+h''(\bar{x})(\xi-\bar{x}))\| + \|h''(\bar{x})(\xi-(\bar{x}+t_nz_n))\| + \|h'(\bar{x})+h''(\bar{x})t_nz_n-h'(\bar{x}+t_nz_n)\|.$$

Together with

$$\|h'(\xi)-A_n\| \le \|h'(\xi)-h'(\bar{x}+t_nz_n)\| + \|h'(\bar{x}+t_nz_n)-A_n\|$$

and $\|\bar{x}+t_nz_n-\xi\| \le \max\{\|\bar{x}+t_nz_n-x'\|, \|\bar{x}+t_nz_n-x\|\}$ condition (3.4) follows with $\varphi'_n := t_n^{-1}(2\sup\{\|h'(\bar{x})+h''(\bar{x})(\eta-\bar{x})-h'(\eta)\| : \eta \in \bar{x}+t_n(z_n+R'\mathcal{B}_X)\}+\|h'(\bar{x}+t_nz_n)-A_n\|) = o(1)$ and $\gamma' = \|h''(\bar{x})\|$. Similarly, when $h'(\cdot)$ is Lipschitz continuous in $\bar{x}+\rho\mathcal{B}_X$, condition (3.4) holds with $\varphi'_n := t_n^{-1}\|h'(\bar{x}+t_nz_n)-A_n\| = o(1)$ and with γ' being the Lipschitz constant of $h'(\cdot)$. Thus the lemma is proved. □

Note that a sequence $(A_n) \subset L(X,Y)$ satisfying (3.2) can also exist if h is not continuously differentiable. For instance, consider a twice continuously differentiable function $\Psi : \mathbb{R} \to \mathbb{R}$ with $\Psi(t) = o(t^2)$ for $t \to 0$, let $\tilde{y} \in Y$ be arbitrarily chosen, and set $h(x) := \Psi(\|x-\bar{x}\|)\tilde{y}$. Then it is easy to show that condition (3.2) holds with $A_n = 0$ for all n, but in general $h(\cdot)$ will be only continuously differentiable provided $\|\cdot-\bar{x}\|^2$ is.

In addition, this example together with the second part of Theorem 2.2 shows that the conclusion of Theorem 3.1 automatically holds at a point $\bar{x}$ which is nondegenerate for the problem (P) and where condition (2.1) is satisfied. On the other hand, when $\bar{x}$ is degenerate for the problem (P) (i.e., $\operatorname{int}(h'(\bar{x})X - C) = \emptyset$), then, as a consequence of Theorem 2.4, the necessary condition (2.1) is automatically satisfied regardless of whether the point $\bar{x}$ is a local weak minimizer for the problem (P) or not. However, as we will see, condition (3.3) of Theorem 3.1 may fail for nonoptimal points $\bar{x}$. We will present corresponding examples in sections 4 and 5.

Further note that sequences $(z_n), (t_n), (\tau_n)$ satisfying the assumption (3.1) exist if and only if condition (2.2) does not hold, or, equivalently, $\bar{x}$ is not an essential local minimizer of second order. Thus the necessary condition (3.3) reduces the gap between the necessary and sufficient conditions of Theorem 3.1 in the degenerate case.

4. Second-order necessary conditions for certain directions. We will now analyze Theorem 3.1 for the special case of convergent sequences $(z_n) \to z$, and we will rewrite condition (3.3) in terms of first- and second-order derivatives of h and first- and second-order approximation sets for the convex set C. Since we deal with rather general sets C, there is an inherent nonsmoothness when building second-order approximation sets. Hence it seems to be quite natural to assume a similar amount of smoothness on h only.

DEFINITION 4.1. *Let E, F be normed spaces and let an element $z \in E$ be given.*

1. *Let $k : E \to F$ be a mapping and let $\bar{e} \in E$ so that k is differentiable at $\bar{e}$. We define the following second-order one-sided directional derivative to k at $\bar{e}$ with respect to z as*

$$k''(\bar{e};z) := \left\{ f \in F \,:\, \exists (t_n) \in \mathbb{T} \text{ such that } f = \lim_{n\to\infty} \frac{k(\bar{e}+t_nz)-k(\bar{e})-t_nk'(\bar{e})z}{t_n^2/2} \right\}.$$

Further, for given $\vec{t} = (t_n) \in \mathbb{T}$ we write

$$k''_{\vec{t}}(\bar{e};z) := \lim_{n\to\infty} \frac{k(\bar{e}+t_nz)-k(\bar{e})-t_nk'(\bar{e})z}{t_n^2/2},$$

when the limit on the right-hand side exists.

2. *Let S be a subset of F, let $A \in L(E,F)$ be a continuous linear operator, and let $\bar{f} \in S$. Then for $z \in E$ the* second-order compound tangent set *to S at $(\bar{f}, z)$ (with respect to A) and a sequence $\vec{t} = (t_n) \in \mathbb{T}$ is the set*

$$S''_{A,\vec{t}}(\bar{f};z) := \left\{ w \in Y \,:\, \exists (z_n) \to z \;\; \text{such that} \;\; d\left(\bar{f}+t_nAz_n+\frac{t_n^2}{2}w, S\right) = o(t_n^2) \right\}.$$

We also define

$$S''_A(\bar f, z) := \bigcup_{\vec t\in\mathbb{T}} S''_{A,\vec t}(\bar f; z),$$

which corresponds to the second-order compound tangent set introduced in [28] and which played a crucial role in [15].

In order to have $C''_{h'(\bar x),\vec t}(h(\bar x); z) \neq \emptyset$ it must necessarily hold that

$$d(h(\bar x) + t_n h'(\bar x)z, C) = d(h(\bar x) + t_n h'(\bar x)z_n, C) + o(t_n) = O(t_n^2) + o(t_n) = o(t_n)$$

for some sequence $(z_n) \to z$, implying $h'(\bar x)z \in T_C(h(\bar x))$, i.e., z belongs to the so-called *critical cone* $\mathcal{C}(\bar x)$ defined by

$$\mathcal{C}(\bar x) := \{z \in X \,:\, h'(\bar x)z \in T_C(h(\bar x))\}.$$

LEMMA 4.2. *For any element $z \in \mathcal{C}(\bar x)$ and any sequence $\vec t = (t_n) \in \mathbb{T}$ with $C''_{h'(\bar x),\vec t}(h(\bar x); z) \neq \emptyset$, the inclusions*

$$\mathrm{cl}\,(C''_{h'(\bar x),\vec t}(h(\bar x); z) + T_C(h(\bar x)) + \mathrm{Im}\, h'(\bar x)) \subset C''_{h'(\bar x),\vec t}(h(\bar x); z) \subset \mathrm{cl}\,(T_C(h(\bar x)) + \mathrm{Im}\, h'(\bar x))$$

hold. Moreover, $C''_{h'(\bar x),\vec t}(h(\bar x); z)$ is a closed convex set.

Proof. The fact that $C''_{h'(\bar x),\vec t}(h(\bar x); z)$ is a closed convex set follows easily from the definition. To show the inclusions let $y \in C''_{h'(\bar x),\vec t}(h(\bar x); z)$ be arbitrarily fixed. By the definition we can find sequences $(z_n) \to z$ and $(y_n) \to y$ such that $h(\bar x) + t_n h'(\bar x)z_n + \frac{1}{2}t_n^2 y_n \in C$ for each n and $y_n \in 2t_n^{-2}(C - h(\bar x)) + h'(\bar x)(-t_n^{-1}z_n) \subset T_C(h(\bar x)) + \mathrm{Im}\, h'(\bar x)$ follows. Hence $y \in \mathrm{cl}\,(T_C(h(\bar x)) + \mathrm{Im}\, h'(\bar x))$. Now consider arbitrary elements $w \in T_C(h(\bar x))$ and $v = h'(\bar x)s \in \mathrm{Im}\, h'(\bar x)$. Then we can find a convergent sequence $(w_n) \to w$ such that $h(\bar x) + t_n w_n \in C$ for all n. For all n sufficiently large we have $t_n < 2$ and by using the convexity of C we conclude

$$\begin{aligned}\frac{t_n}{2}(h(\bar x) + t_n w_n) + \left(1 - \frac{t_n}{2}\right)\left(h(\bar x) + t_n h'(\bar x)z_n + \frac{1}{2}t_n^2 y_n\right)\\ = h(\bar x) + t_n h'(\bar x)\left(z_n - \frac{t_n}{2}(z_n + s)\right) + \frac{t_n^2}{2}(y_n + w_n + v) \in C.\end{aligned}$$

Since the sequence $(z_n - \frac{t_n}{2}(z_n + s))$ converges to z we obtain $y + w + v = \lim_n y_n + w_n + v \in C''_{h'(\bar x),\vec t}(h(\bar x); z)$, and since $C''_{h'(\bar x),\vec t}(h(\bar x); z)$ is closed, the proposed inclusion follows. □

LEMMA 4.3. *Suppose Assumption 1 is satisfied. Let $(z_n) \to z$ be a convergent sequence in X and let $\vec t = (t_n) \in \mathbb{T}$, such that $h''_{\vec t}(\bar x; z)$ exists. Then*

$$h''_{\vec t}(\bar x; z) = \lim_{n\to\infty} \frac{h(\bar x + t_n z_n) - h(\bar x) - t_n h'(\bar x)z_n}{t_n^2/2}$$

also holds. Moreover, there exists a sequence $\tau_n \to 0$ such that (3.1) holds if and only if $h''_{\vec t}(\bar x; z) \in C''_{h'(\bar x),\vec t}(h(\bar x); z)$.

Proof. Using Assumption 1, the first assertion follows immediately from the estimate

$$\|h(\bar x + t_n z_n) - h(\bar x + t_n z) - t_n h'(\bar x)(z_n - z)\| \le \eta t_n^2 \max\{\|z_n\|, \|z\|\}\|z_n - z\| = o(t_n^2).$$

Now assume $h''_{\bar t}(\bar x;z)\in C''_{h'(\bar x),\bar t}(h(\bar x);z)$. By the definition, there exists a sequence $(z'_n)\to z$ such that $d(h(\bar x)+t_nh'(\bar x)z'_n+(t_n^2/2)h''_{\bar t}(\bar x;z),C)=o(t_n^2)$. Hence,

$$\begin{aligned}&d(h(\bar x+t_nz_n)+t_nh'(\bar x)(z'_n-z_n),C)\\&\quad=d\left(h(\bar x)+t_nh'(\bar x)z_n+\frac{t_n^2}{2}h''_{\bar t}(\bar x;z)+t_nh'(\bar x)(z'_n-z_n),C\right)+o(t_n^2)=o(t_n^2)\end{aligned}$$

and (3.1) follows from Theorem 2.4 with $\tau_n=\|z'_n-z_n\|$. Now let $(\tau_n)\in\mathbb{T}$ be a sequence such that (3.1) holds. Then, as in the proof of Theorem 3.1, we can find some sequence $(z'_n)\to z$ with $z'_n=z_n+\tau_nt_n\delta z_n$, $\delta z_n\in\mathcal{B}_X$, such that

$$d(h(\bar x+t_nz'_n),C)=d\left(h(\bar x)+t_nh'(\bar x)z'_n+\frac{t_n^2}{2}h''_{\bar t}(\bar x;z),C\right)+o(t_n)^2=o(t_n^2),$$

showing $h''_{\bar t}(\bar x;z)\in C''_{h'(\bar x),\bar t}(h(\bar x);z)$. ∎

The second-order derivative $h''_{\bar t}(\bar x;z)$ is useful for building second-order approximations of h in the direction z. But we also need another type of second-order derivatives, namely, in the sense of first-order approximations of first derivatives. We know from the discussion following Theorem 3.1 that if h is sufficiently smooth near $\bar x$, then for given sequences $(z_n)\subset\mathcal{S}_X$ and $(t_n)\in\mathbb{T}$ a sequence of linear operators $(A_n)\subset L(X,Y)$ satisfies condition (3.2) if and only if $A_n=h'(\bar x+t_nz_n)+o(t_n)$ holds. We use condition (3.2) to define this other type of second-order derivative without assuming existence of $h'(\cdot)$ near $\bar x$.

LEMMA 4.4. *Let E,F be normed spaces, let $k:E\to F$ be a mapping, and let $\bar e\in E$ such that k is differentiable at $\bar e$. Further let an element $z\in E$ and a sequence $(t_n)\in\mathbb{T}$ be given. Then there exists at most one continuous linear operator $K\in L(E,F)$ such that, together with some positive scalars $\tilde\gamma$, $\tilde R$ and some sequence $(\tilde\varphi_n)\in\mathbb{T}$, one has*

$$\begin{aligned}&\|k(e')-k(e)-(k'(\bar e)+t_nK)(e'-e)\|\\&\qquad\le\big(\tilde\varphi_nt_n+\tilde\gamma\max\{\|\bar e+t_nz-e'\|,\|\bar e+t_nz-e\|\}\big)\|e'-e\|\end{aligned}\tag{4.1}$$

for all $e,e'\in\bar e+t_n(z+\tilde R\mathcal{B}_E)$ and all n.

Proof. We prove the lemma by contraposition. Assume that there exist two continuous linear operators $K_1\ne K_2$ satisfying (4.1) with parameters $\tilde\gamma_1,\tilde R_1,(\tilde\varphi_{1n})$ and $\tilde\gamma_2,\tilde R_2,(\tilde\varphi_{2n})$, respectively. Set $\tilde\gamma:=\max\{\tilde\gamma_1,\tilde\gamma_2\}$, $\tilde\varphi_n:=\max\{\tilde\varphi_{1n},\tilde\varphi_{2n}\}$ for all n, and $\tilde R=\min\{\tilde R_1,\tilde R_2\}$. By the triangle inequality we obtain

$$\begin{aligned}\|t_n(K_1-K_2)(e'-e)\|&\le\|k(e')-k(e)-(k'(\bar e)+t_nK_1)(e'-e)\|\\&\quad+\|k(e')-k(e)-(k'(\bar e)+t_nK_2)(e'-e)\|\\&\le2\big(\tilde\varphi_nt_n+\tilde\gamma\max\{\|\bar e+t_nz-e'\|,\|\bar e+t_nz-e\|\}\big)\|e'-e\|\end{aligned}$$

for all $e,e'\in\bar e+t_n(z+\tilde R\mathcal{B}_E)$ and all n. Let $d\in E$ denote a direction with $(K_1-K_2)d\ne0$ and $\|d\|\le R'$. Applying the above estimate successively with $e=\bar e+t_nz$, $e'=e+\frac{t_n}{n}d$ for each n we obtain

$$\left\|t_n(K_1-K_2)\frac{t_n}{n}d\right\|\le2\left(\tilde\varphi_nt_n+\tilde\gamma\left\|\frac{t_n}{n}d\right\|\right)\left\|\frac{t_n}{n}d\right\|=2\frac{t_n^2}{n}\left(\tilde\varphi_n+\frac{\tilde\gamma\|d\|}{n}\right)\|d\|.$$

Dividing by $\frac{t_n^2}{n}$ and passing to the limit yields $\|(K_1-K_2)d\|\le0$, a contradiction. ∎

DEFINITION 4.5. *Under the assumptions of Lemma* 4.4*, if the unique continuous linear operator* $K \in L(E,F)$ *satisfying condition* (4.1) *exists, we will denote it by* $(k')'_{\vec{t}}(\bar{e};z)$.

If k is differentiable near $\bar{e}$, then $\|k'(\bar{e}+t_nz)-(k'(\bar{e})+t_n(k')'_{\vec{t}}(\bar{e};z))\| = o(t_n)$ follows easily from condition (4.1). Thus, $(k')'_{\vec{t}}(\bar{e};z)$ is an element of the so-called *contingent derivative*, also called *graphical derivative* or *Bouligand derivative* (see, e.g., [24]), which in our case is given by

$$Ck'(\bar{e})z := \left\{ K \in L(E,F) \,:\, \exists (t_n) \in \mathbb{T}, z_n \to z \text{ with } \; K = \lim_{n\to\infty} \frac{k'(\bar{e}+t_nz_n)-k'(\bar{e})}{t_n} \right\}.$$

If $k'(\cdot)$ is Lipschitz continuous near $\bar{e}$, using arguments similar to those in Lemma 3.2 we can conclude that

$$\bigcup_{\vec{t}\in T} (k')'_{\vec{t}}(\bar{e};z) = Ck'(\bar{e})z,$$

and if k is twice Fréchet differentiable at $\bar{e}$, then $(k')'_{\vec{t}}(\bar{e};z) = k''(\bar{e})z$ for all $\vec{t} \in \mathbb{T}$ holds.

In general, when k is not twice differentiable at $\bar{e}$, we can have $(k')'_{\vec{t}}(\bar{e};z)z \neq k''_{\vec{t}}(\bar{e};z)$. However, $(k')'_{\vec{t}}(\bar{e};z)$ acts like a derivative for the mapping $\frac{1}{2}k''_{\vec{t}}(\bar{e};\cdot)$ at z for given $\vec{t}\in\mathbb{T}$. Indeed, from condition (4.1) the estimate

$$\left\| \frac{1}{2}k''_{\vec{t}}(\bar{e};s) - \frac{1}{2}k''_{\vec{t}}(\bar{e};z) - (k')'_{\vec{t}}(\bar{e};z)(s-z) \right\| \le \tilde{\gamma}\|s-z\|^2,$$

being valid for all $s \in z + \tilde{R}\mathcal{B}_X$ such that $k''_{\vec{t}}(\bar{e};s)$ exists, easily follows.

When $(h')'_{\vec{t}}(\bar{x};z)$ exists for some $z \in X$, $\vec{t}\in\mathbb{T}$, then it is easy to see that for any convergent sequence $(z_n) \to z$ condition (3.2) holds with $A_n = h'(\bar{x}) + t_n(h')'_{\vec{t}}(\bar{x};z)$, $\varphi'_n = \tilde{\varphi}_n + \tilde{\gamma}\|z_n - z\|$, $\gamma' = \tilde{\gamma}$, $R' = \tilde{R}/2$ for all n sufficiently large, such that $\|z_n - z\| \le \tilde{R}/2$.

We are now in a position to state the main result of this section. We state this result under the following technical assumption, which will be analyzed separately.

ASSUMPTION 2. *Each sequence* $(y^*_n) \subset \mathcal{S}_{Y^*}$ *with*

$$\lim_{n\to\infty} t_n^{-1}(\langle y^*_n, h(\bar{x})\rangle - \sigma_C(y^*_n)) = \lim_{n\to\infty} t_n^{-1}\|(h'(\bar{x}) + t_n(h')'_{\vec{t}}(\bar{x};z))^*y^*_n\| = 0 \tag{4.2}$$

has at least one weak- accumulation point which is not equal to* 0.

THEOREM 4.6. *Suppose that* $\bar{x}$ *is a local weak minimizer for problem* (P)*, that Assumption* 1 *holds, and that we are given an element* $z \in \mathcal{C}(\bar{x}) \cap \mathcal{S}_X$ *and a sequence* $(t_n) = \vec{t} \in \mathbb{T}$ *such that the second-order directional derivatives* $h''_{\vec{t}}(\bar{x};z)$ *and* $(h')'_{\vec{t}}(\bar{x};z)$ *exist, the inclusion* $h''_{\vec{t}}(\bar{x};z) \in C''_{h'(\bar{x}),\vec{t}}(h(\bar{x});z)$ *holds, and Assumption* 2 *is satisfied. Then there exist a multiplier* $\bar{y}^* \in \Lambda_{FJ}$ *and an element* $\bar{\mu}^* \in (\operatorname{Ker} h'(\bar{x}))^\perp$ *such that*

$$(h')'_{\vec{t}}(\bar{x};z)^*\bar{y}^* + \bar{\mu}^* = 0, \tag{4.3}$$

and for each pair (s,y) *with* $s \in \mathcal{C}(\bar{x})$ *and* $y \in C''_{h'(\bar{x}),\vec{t}}(h(\bar{x});s)$ *one has*

$$\langle \bar{\mu}^*, z-s\rangle + \frac{1}{2}\langle \bar{y}^*, h''_{\vec{t}}(\bar{x};z) - y\rangle \ge 0. \tag{4.4}$$

Proof. From the preceding discussion we know that the assumptions of Theorem 3.1 hold with $z_n := z$, $A_n := h'(\bar{x}) + t_n(h')'_{\bar{t}}(\bar{x}; z)$, and some sequence $(\tau_n) \in \mathbb{T}$ given by Lemma 4.3. Hence, applying Theorem 3.1 with $T = 1$ we have

$$\liminf_{n\to\infty} \sup_{y^*\in\mathcal{S}_{Y^*}} \left\{ \frac{\langle y^*, h(\bar{x}+t_nz)\rangle - \sigma_C(y^*)}{t_n^2} - \frac{1}{t_n}\|(h'(\bar{x}) + t_n(h')'_{\bar{t}}(\bar{x}; z))^* y^*\| \right\} \geq 0.$$

Now, for each n we can find some $y_n^* \in \mathcal{S}_{Y^*}$ approaching the supremum sufficiently accurate, such that

$$\liminf_{n\to\infty} \left\{ \frac{\langle y_n^*, h(\bar{x}+t_nz)\rangle - \sigma_C(y_n^*)}{t_n^2} - \frac{1}{t_n}\|(h'(\bar{x}) + t_n(h')'_{\bar{t}}(\bar{x}; z))^* y_n^*\| \right\} \geq 0.$$

Since $\limsup_{n\to\infty} t_n^{-2}\hat{d}_C(h(\bar{x}+t_nz), h'(\bar{x}), \tau_nt_n) \leq 0$ we also have

$$\begin{aligned}
0 &\geq \limsup_{n\to\infty} \sup_{y^*\in\mathcal{S}_{Y^*}} \left\{ \frac{\langle y^*, h(\bar{x}+t_nz)\rangle - \sigma_C(y^*)}{t_n^2} - \frac{\tau_n}{t_n}\|(h'(\bar{x})^* y^*\| \right\} \\
&= \limsup_{n\to\infty} \sup_{y^*\in\mathcal{S}_{Y^*}} \left\{ \frac{\langle y^*, h(\bar{x}+t_nz)\rangle - \sigma_C(y^*)}{t_n^2} - \frac{\tau_n}{t_n}\|h'(\bar{x})^* y^*\| + \tau_n\|(h')'_{\bar{t}}(\bar{x}; z)^* y^*\| \right\} \\
&\geq \limsup_{n\to\infty} \sup_{y^*\in\mathcal{S}_{Y^*}} \left\{ \frac{\langle y^*, h(\bar{x}+t_nz)\rangle - \sigma_C(y^*)}{t_n^2} - \frac{\tau_n}{t_n}\|(h'(\bar{x}) + t_n(h')'_{\bar{t}}(\bar{x}; z))^* y^*\| \right\}
\end{aligned}$$

and $\lim_{n\to\infty} t_n^{-1}\|(h'(\bar{x}) + t_n(h')'_{\bar{t}}(\bar{x}; z))^* y_n^*\| = 0$ follows. In particular we obtain

$$\mu_n^* := \frac{h'(\bar{x})^* y_n^*}{t_n} = O(1), \tag{4.5}$$

$$\lim_{n\to\infty} t_n^{-1}(h'(\bar{x}) + t_n(h')'_{\bar{t}}(\bar{x}; z))^* y_n^* = \lim_{n\to\infty} (h')'_{\bar{t}}(\bar{x}; z)^* y_n^* + \mu_n^* = 0, \tag{4.6}$$

$$\liminf_{n\to\infty} \frac{\langle y_n^*, h(\bar{x}+t_nz)\rangle - \sigma_C(y_n^*)}{t_n^2} \geq 0. \tag{4.7}$$

Because of (4.7) and the relation $h(\bar{x}+t_nz) = h(\bar{x}) + t_nh'(\bar{x})z + \frac{t_n^2}{2}h''_{\bar{t}}(\bar{x}; z) + o(t_n^2)$ we have

$$\liminf_{n\to\infty} \left\{ \frac{\langle y_n^*, h(\bar{x})\rangle - \sigma_C(y_n^*)}{t_n^2} + \frac{\langle y_n^*, h'(\bar{x})z\rangle}{t_n} + \frac{1}{2}\langle y_n^*, h''_{\bar{t}}(\bar{x}; z)\rangle \right\} \geq 0.$$

Together with $\langle y_n^*, h'(\bar{x})z\rangle = t_n\langle \mu_n^*, z\rangle = O(t_n)$ and $\langle y_n^*, h(\bar{x})\rangle - \sigma_C(y_n^*) \leq 0$ we obtain

$$\sigma_C(y_n^*) - \langle y_n^*, h(\bar{x})\rangle = O(t_n^2). \tag{4.8}$$

Together with (4.6) we may conclude from Assumption 2 that the sequence (y_n^*) has a nonzero accumulation point $\tilde{y}^*$. Then there exists some element $\tilde{y} \in Y$ with $\langle \tilde{y}^*, \tilde{y}\rangle = 1$, and we can choose a subsequence $(y_{k_n}^*)$ such that $\langle y_{k_n}^*, \tilde{y}\rangle \to 1$. $(y_{k_n}^*, \mu_{k_n}^*)$ is a bounded sequence in $Y^* \times X^* = (Y \times X)^*$ and by the Alaoglu–Bourbaki theorem at least one weak-$*$ accumulation point, say $(\bar{y}^*, \bar{\mu}^*)$, exists. Of course, $\bar{y}^*$ is also a weak-$*$ accumulation point of the sequence $(y_{k_n}^*)$. Hence $\langle \bar{y}^*, \tilde{y}\rangle = 1$, implying $\bar{y}^* \neq 0$. Note that $(\bar{y}^*, \bar{\mu}^*)$ is also a weak-$*$ accumulation point of the entire sequence (y_n^*, μ_n^*). Since $\mu_n^* \in \operatorname{Im} h'(\bar{x})^* \subset (\operatorname{Ker} h'(\bar{x}))^\perp$ and the annihilator $(\operatorname{Ker} h'(\bar{x}))^\perp$ is weakly-$*$ closed in X^*, we have $\bar{\mu}^* \in (\operatorname{Ker} h'(\bar{x}))^\perp$. Further, (4.3) follows easily from (4.6).

Now let us show $\bar{y}^* \in \Lambda_{FJ}$. Since $\sigma_C(\cdot) - \langle \cdot, h(\bar{x})\rangle$ is weakly-$*$ lower semicontinuous, we obtain $\sigma_C(\bar{y}^*) - \langle \bar{y}^*, h(\bar{x})\rangle \leq 0$ from condition (4.8). Because of $h(\bar{x}) \in C$

we also have $\sigma_C(\bar{y}^*) - \langle \bar{y}^*, h(\bar{x})\rangle \geq 0$, showing $\bar{y}^* \in N_C(h(\bar{x}))$. From condition (4.5) it follows that $h'(\bar{x})y_n^* \to 0$ and, consequently, $h'(\bar{x})^*\bar{y}^* = 0$. Hence $\bar{y}^* \in \Lambda_{FJ}$. It remains to show that (4.4) holds. Let the pair $(s, y) \in \mathcal{C}(\bar{x}) \times C''_{h'(\bar{x}),\vec{t}}(h(\bar{x}); s)$ be arbitrarily fixed. Then by the definitions of the support function σ_C and the set $C''_{h'(\bar{x}),\vec{t}}(h(\bar{x}); s)$ we have $\sigma_C(y_n^*) \geq \langle y_n^*, h(\bar{x}) + t_n h'(\bar{x})s_n + \frac{t_n^2}{2}y\rangle + o(t_n^2)$ for some sequence $(s_n) \to s$. Together with condition (4.7) and the second-order expansion for $h(\bar{x} + t_n z)$ it follows that

$$0 \leq \liminf_{n\to\infty} \frac{\langle y_n^*, h(\bar{x}) + t_n h'(\bar{x})z + \frac{t_n^2}{2}h''_{\vec{t}}(\bar{x}; z)\rangle - \langle y_n^*, h(\bar{x}) + t_n h'(\bar{x})s_n + \frac{t_n^2}{2}y\rangle}{t_n^2}$$

$$= \liminf_{n\to\infty} \left\{ \langle \mu_n^*, z - s_n\rangle + \frac{1}{2}\langle y_n^*, h''_{\vec{t}}(\bar{x}; z) - y\rangle \right\} \leq \langle \bar{\mu}^*, z - s\rangle + \frac{1}{2}\langle \bar{y}^*, h''_{\vec{t}}(\bar{x}; z) - y\rangle,$$

and this completes the proof. □

Of course, Assumption 2 holds when Y is finite-dimensional. But there are also other situations when this assumption holds.

DEFINITION 4.7. *Let E, F be Banach spaces, let $S \subset F$ be a closed convex subset of F, let $k : E \to F$ be a mapping, which is differentiable at $\bar{e} \in E$, with $k(\bar{e}) \in S$, and let the multifunction $\Psi : E \rightrightarrows F$ be given by $\Psi(e) := k(e) - S$. Then k is said to be 2-nondegenerate at the point $\bar{e}$ in the direction $z \in E$ with respect to the set C and the sequence $\vec{t} \in \mathbb{T}$ if the following conditions are satisfied:*

1. *$(k')'_{\vec{t}}(\bar{e}; z)$ exists.*
2. *The set $k(\bar{e}) + k'(\bar{e})E - S$ has nonempty relative interior.*
3. *The interior of the set $KE - (S - k(\bar{E})) \times \{0\}$ is nonempty in $Q \times F/Q$, where $Q := \operatorname{aff}(k(\bar{e}) + k'(\bar{e})E - S) \subset F$ is the affine hull of the set $k(\bar{e}) + k'(\bar{e})E - S$, the continuous linear operator $K : E \to Q \times F/Q$ is given by $Ks := (k'(\bar{e})s, \pi(k')'_{\vec{t}}(\bar{e}; z)s)$, and π denotes the quotient map from F onto the quotient space F/Q.*

In what follows let Q denote the affine hull of the set $h(\bar{x}) + h'(\bar{x})X - C$ and let π denote the quotient map from Y onto the quotient space Y/Q.

THEOREM 4.8. *Let the mapping h be 2-nondegenerate at $\bar{x}$ in the direction $z \in X$ with respect to C and the sequence $\vec{t} \in \mathbb{T}$. Then it is sufficient for Assumption 2 to hold that either the quotient space Y/Q or the subspace $\operatorname{Im} h'(\bar{x}) \cap \operatorname{aff}(C - h(\bar{x}))$ is finite-dimensional.*

Proof. Let $(y_n^*) \subset \mathcal{S}_{Y^*}$ be a sequence satisfying condition (4.2). In order to prove the theorem we have to show that at least one nonzero weak-$*$ accumulation point of the sequence (y_n^*) exists. Since Q is a closed subspace of the Banach space Y, the quotient space $P := Y/Q$ and hence also $Q \times P$ are Banach spaces. Let $H : X \to Q \times P$ be the continuous linear operator according to Definition 4.7, i.e., $Hs = (h'(\bar{x})s, \pi(h')'_{\vec{t}}(\bar{x}; z)s)$ for all s. Now choose $(q, p) \in Q \times P$, $x \in X$, and $\bar{q} \in \hat{C} := C - h(\bar{x}) \subset Q$ such that $(q, p) = Hx - (\bar{q}, 0) \in \operatorname{int}(HX - \hat{C} \times \{0\})$. Application of the generalized open mapping theorem (see [31, Theorem 1]) yields $(q, p) \in \operatorname{int}(H(x + \mathcal{B}_X) - \hat{C} \times \{0\})$ and it follows that

$$\rho\mathcal{B}_{Q\times P} \subset \operatorname{int}((\bar{q}, 0) + H\mathcal{B}_X - \hat{C} \times \{0\}) \tag{4.9}$$

for some $\rho > 0$. Using Theorem 2.4 we obtain that

$$\sup_{(q^*,p^*)\in\mathcal{S}_{(Q\times P)^*}} \left\{ \langle q^*, \bar{q}\rangle - \sigma_{\hat{C}}(q^*) - \|H^*(q^*, p^*)\| \right\} \leq -\rho$$

and therefore

$$\langle q^*, \bar{q}\rangle - \sigma_{\hat{C}}(q^*) - \|H^*(q^*,p^*)\| \le -\rho(\|q^*\| + \|p^*\|)\ \forall (q^*,p^*) \in Q^* \times P^*. \tag{4.10}$$

Now let the linear operators $A \in L(X,Q)$ and $B \in L(X,P)$ be given by $As = h'(\bar{x})s$ and $Bs = \pi(h')'_{\bar{t}}(\bar{x};z)s$, respectively. Further let $i_Q : Q \to Y$ denote the natural embedding from Q into Y. Consequently, $h'(\bar{x}) = i_Q \circ A$. For each n, let $q_n^* := i_Q^* y_n^* \in Q^*$ be the restriction of the linear functional y_n^* to Q. By the Hahn–Banach theorem we can extend the linear form $q_n^* \in Q^*$ to a linear functional $y_{Q,n}^*$ over Y such that $\|y_{Q,n}^*\| = \|q_n^*\|$. Setting $y_{P,n}^* := y_n^* - y_{Q,n}^*$ we have $i_Q^* y_{P,n}^* = i_Q^* y_n^* - i_Q^* y_{Q,n}^* = 0$, i.e., $y_{P,n}^*$ belongs to the annihilator $Q^\perp := \{y^* \in Y^* : \langle y^*, y\rangle = 0 \text{ for all } y \in Q\}$ of the subspace $Q \subset Y$. The mapping $\pi^* : P^* \to Y^*$ is isometric and allows us to identify the dual space $P^* = (Y/Q)^*$ with $Q^\perp$. For each n let $p_n^* \in P^*$ denote the linear functional uniquely given by the relation $\pi^* p_n^* = y_{P,n}^*$. Finally, let $\bar{y}_Q := i_Q \bar{q}$. Then we have

$$\langle y_n^*, \bar{y}_Q\rangle = \langle q_n^*, \bar{q}\rangle, \tag{4.11}$$

$$\sigma_{\hat{C}}(q_n^*) = \sigma_{i_Q(\hat{C})}(y_n^*) = \sigma_C(y_n^*) - \langle y_n^*, h(\bar{x})\rangle, \tag{4.12}$$

$$\begin{aligned}(h'(\bar{x})^* + t_n(h')'_{\bar{t}}(\bar{x};z))^* y_n^* &= A^* q_n^* + t_n B^* p_n^* + t_n(h')'_{\bar{t}}(\bar{x};z)^* y_{Q,n}^* \\ &= H^*(q_n^*, t_n p_n^*) + t_n(h')'_{\bar{t}}(\bar{x};z)^* y_{Q,n}^*,\end{aligned} \tag{4.13}$$

and (4.10) implies

$$\begin{aligned}&\langle y_n^*, \bar{y}_Q\rangle + \langle y_n^*, h(\bar{x})\rangle - \sigma_C(y_n^*) - \|(h'(\bar{x})^* + t_n(h')'_{\bar{t}}(\bar{x};z))^* y_n^*\| \\ &\qquad \le -\rho(\|q_n^*\| + t_n\|p_n^*\|) + t_n\|(h')'_{\bar{t}}(\bar{x};\bar{z})^* y_{Q,n}^*\|.\end{aligned} \tag{4.14}$$

Now let us assume that $\limsup_{n\to\infty} \|q_n^*\| > 0$. By passing to a subsequence if necessary we may also assume that $\liminf_{n\to\infty} \|q_n^*\| = \epsilon > 0$. The sequence (y_n^*) has at least one weak-$*$ accumulation point $\bar{y}^*$ by the Alaoglu–Bourbaki theorem. Since $t_n \to 0$ and the sequence (y_n^*) satisfies condition (4.2) we obtain from condition (4.14) that $\langle \bar{y}^*, \bar{y}_Q\rangle \le -\rho\epsilon < 0$. Hence, $\bar{y}^* \ne 0$ and the theorem is proved in the case $\limsup_{n\to\infty} \|q_n^*\| > 0$.

Now let us assume that $\limsup_{n\to\infty} \|q_n^*\| = 0$. If we denote by $\bar{p}^*$ an arbitrary weak-$*$ accumulation point of the sequence (p_n^*), then $\bar{y}^* := \pi^* \bar{p}^*$ is a weak-$*$ accumulation point both of the sequence $(y_{P,n}^*)$ and the sequence (y_n^*), the latter because of $\|y_{Q,n}^*\| = \|y_n^* - y_{P,n}^*\| \to 0$. Further, $\bar{y}^* \ne 0$ if and only if $\bar{p}^* \ne 0$. Since $\|y_{P,n}^*\| = \|p_n^*\| \to 1$, the assertion of the theorem now follows immediately in the case that P and hence also P^* are finite-dimensional spaces.

It remains to prove the theorem in the case in which the subspace $W := \operatorname{Im} h'(\bar{x}) \cap \operatorname{aff}(C - h(\bar{x}))$ is finite-dimensional. To do this we will first show the inclusion

$$\rho\mathcal{B}_{Q\times P} \subset (\bar{q},0) + \left(\frac{A}{t}, B\right)\mathcal{B}_X - \left(\hat{C} + \frac{\rho + \|A\|}{t}\mathcal{B}_W\right) \times \{0\}\ \forall t \in \left]0, \frac{\rho}{\|A\|}\right[. \tag{4.15}$$

Let the element $(q,p) \in \rho\mathcal{B}_{Q\times P}$ and the scalar $t \in]0,\ \|A\|^{-1}\rho[$ be arbitrarily fixed. We observe that condition (4.9) together with $\bar{q} \in \hat{C}$ implies $\gamma\rho\mathcal{B}_{Q\times P} \subset (\bar{q},0) + \gamma H\mathcal{B}_X - \hat{C} \times \{0\}$ for all $\gamma \in]0,1]$. Hence we can find some $x_1 \in \rho^{-1}\|(p,q)\|\mathcal{B}_X$ and some $c_1 \in \hat{C}$ such that $(q,p) = (\bar{q} + Ax_1 - c_1, Bx_1)$. We have $\|t(q - \bar{q} + c_1)\| = \|tAx_1\| \le t\|A\|\|x_1\| \le \|(q,p)\|$, and $\|(t(q-\bar{q}+c_1),p)\| = \max\{\|t(q-\bar{q}+c_1)\|, \|p\|\} \le \|(q,p)\| \le \rho$

follows. Consequently, we can find some $x_2 \in \rho^{-1}\|(p,q)\|\mathcal{B}_X$ and some $c_2 \in \hat{C}$ with $(t(q-\bar{q}+c_1),p) = (\bar{q}+Ax_2-c_2, Bx_2)$. Thus

$$(q,p) = \left(\bar{q} + \frac{\bar{q}-c_2}{t} + \frac{1}{t}Ax_2 - c_1, Bx_2\right)$$

and $\bar{q}-c_2 = A(tx_1-x_2) \in W$. Moreover, we have

$$\|\bar{q}-c_2\| \le t\|Ax_1\| + \|A\|\|x_2\| \le \|(p,q)\|\left(1+\frac{\|A\|}{\rho}\right) \le \rho + \|A\|.$$

Therefore, $(p,q) \in (\bar{q},0) - (\hat{C} + t^{-1}(\rho+\|A\|)\mathcal{B}_W) \times \{0\} + (t^{-1}A, B)\mathcal{B}_X$ and, since $(p,q) \in \rho\mathcal{B}_{Q\times P}$ has been chosen arbitrarily, the inclusion (4.15) follows. Now, by Theorem 2.4 we obtain

$$\sup_{(q^*,p^*)\in\mathcal{S}^*_{Q\times P}} \left\{\langle q^*,\bar{q}\rangle - \sigma_{\hat{C}}(q^*) - (\rho+\|A\|)\frac{\sigma_{\mathcal{B}_W}(q^*)}{t} - \left\|A^*\frac{q^*}{t} + B^*p^*\right\|\right\} \le -\rho.$$

Consequently, for all n sufficiently large such that $t_n\|A\| < \rho$ we have

$$\langle q_n^*,\bar{q}\rangle - \sigma_{\hat{C}}(q_n^*) - (\rho+\|A\|)\frac{\sigma_{\mathcal{B}_W}(q_n^*)}{t_n} - \left\|A^*\frac{q_n^*}{t_n} + B^*p_n^*\right\| \le -\rho(\|q_n^*\| + \|p_n\|^*).$$

Taking into account conditions (4.2), (4.11)–(4.13), and $\|q_n^*\| = \|y^*_{Q,n}\| \to 0$ we obtain

$$\lim_{n\to\infty}\langle q_n^*,\bar{q}\rangle = 0,\ \lim_{n\to\infty}\sigma_{\hat{C}}(q_n^*) = 0,\ \lim_{n\to\infty}\left\|A^*\frac{q_n^*}{t_n} + B^*p_n^*\right\| = 0.$$

Since we also have $\|p_n^*\| \to 1$,

$$\liminf_{n\to\infty}\frac{\sigma_{\mathcal{B}_W}(q_n^*)}{t_n} \ge \frac{\rho}{\rho+\|A\|}$$

follows. Now, if W is finite-dimensional, and extracting if necessary a subsequence, there exists some $\tilde{x} \in X$ such that $\bar{w} := A\tilde{x} \in \mathcal{B}_W$ satisfies

$$\langle q_n^*,\bar{w}\rangle/t_n \ge \frac{\rho}{2(\rho+\|A\|)} := \tilde{\rho} > 0$$

for all n. Let $\bar{p}$ denote an arbitrary weak-$*$ accumulation point of the sequence (p_n^*). Extracting if necessary a subsequence, we have

$$\begin{aligned}\langle \bar{p}^*, B\tilde{x}\rangle &= \lim_{n\to\infty}\langle p_n^*, B\tilde{x}\rangle = \lim_{n\to\infty}\langle B^*p_n^*,\tilde{x}\rangle = -\lim_{n\to\infty}\left\langle A^*\frac{q_n^*}{t_n},\tilde{x}\right\rangle \\ &= -\lim_{n\to\infty}\left\langle\frac{q_n^*}{t_n},\bar{w}\right\rangle \le -\tilde{\rho},\end{aligned}$$

and $\bar{p}^* \ne 0$ follows. Then $\bar{y}^* = \pi^*\bar{p}^*$ is a nonzero weak-$*$ accumulation point of the sequence (y_n^*), and this completes the proof. □

Let us discuss the assumptions of Theorem 4.8 in further detail. In our case, the set C has the form $(-L)\times K$ with $\operatorname{int} L \ne \emptyset$, and so the assumption that $h(\cdot)$ is 2-nondegenerate in direction z with respect to C and $\vec{t}$ can be reduced to an assumption on the constraints, namely, that $g(\cdot)$ is 2-nondegenerate in direction z with respect to

K and $\vec{t}$. To be a little bit more general, let us consider the case when the Banach space Y and the set C can be decomposed in the form $C = C_1 \times C_2 \subset Y_1 \times Y_2 = Y$ with $\operatorname{int} C_1 \neq \emptyset$. Similarly, we denote by h_1, h_2, respectively, $(h_1')'_{\vec{t}}(\bar{x}; z), (h_2')'_{\vec{t}}(\bar{x}; z)$, the components of h, respectively, $(h')'_{\vec{t}}(\bar{x}; z)$. Then there holds $Q = Y_1 \times Q_2$ with $Q_2 = \operatorname{aff}(h_2(\bar{x}) + h_2'(\bar{x})X - C_2)$, and it follows that $h(\cdot)$ is 2-nondegenerate in direction z and with respect to C and $\vec{t}$ if and only if $h_2(\cdot)$ is of such a kind with respect to C_2.

Finally let us mention that the remaining assumption of Theorem 4.8, i.e., that either the quotient space Y/Q or the space $\operatorname{Im} h'(\bar{x}) \cap \operatorname{aff}(C - h(\bar{x}))$ is finite-dimensional, is satisfied in a variety of cases, e.g., when X or Y is finite-dimensional, or in the case of the scalar mathematical programming problem. Further, we know a lot of special cases where this assumption can be replaced, but we do not want to go down to the last detail here.

Example 4.1. Consider the problem

$$\min_{x \in \mathbb{R}^2} f(x) := x_1 - x_2^2$$
$$\text{subject to } g(x) := \begin{pmatrix} x_1 - \frac{1}{4}x_2^2 \\ x_1 x_2 \\ x_1 + \frac{1}{2}x_2^2 + \psi(x_2) \end{pmatrix} \in K,$$

where $K := \{(v_1, v_2, v_1 + v_2) : v_1 \geq |v_2|^{\frac{3}{2}}\}$ and

$$\psi(\xi) := \begin{cases} \xi^2 \sin(\ln|\xi|), & \xi \neq 0, \\ 0, & \xi = 0. \end{cases}$$

Note that ψ is not twice differentiable at 0; however, Assumption 1 is fulfilled. We show now that $\bar{x} := (0, 0)$ is not a local minimizer of this problem.

Define the set $C := \{(c_0, c_1, c_2, c_3) \colon c_0 \leq 0, (c_1, c_2, c_3) \in K\}$ and the mapping $h := (f - f(\bar{x}), g)$ according to (1.5). The set Λ_{FJ} consists of all multipliers $y_0^*, y_1^*, y_2^*, y_3^*, y_4^*$, not all 0, such that

$$y_0^* + y_1^* + y_3^* = 0, \quad y_0^* \geq 0, \quad y_1^* + y_3^* \leq 0, \quad y_2^* + y_3^* = 0. \tag{4.16}$$

Now let $z := (0, 1)$. Then we have $h'(\bar{x})z = 0$, implying $z \in \mathcal{C}(\bar{x})$, and for any sequence $\vec{t} \in \mathbb{T}$ the set $C''_{h'(\bar{x}), \vec{t}}(h(\bar{x}); z)$ is formed by limits of sequences $(y_0^n, y_1^n, y_2^n, y_3^n)$ such that

$$t_n z_1^n + \frac{t_n^2}{2} y_0^n \leq 0,$$
$$t_n z_1^n + \frac{t_n^2}{2} y_1^n \geq \left| \frac{t_n^2}{2} y_2^n \right|^{\frac{3}{2}},$$
$$t_n z_1^n + \frac{t_n^2}{2} y_3^n = t_n z_1^n + \frac{t_n^2}{2}(y_1^n + y_2^n)$$

hold for some sequence $(z_1^n, z_2^n) \to z$. It follows that

$$C''_{h'(\bar{x}), \vec{t}}(h(\bar{x}); z) = \{(y_0, y_1, y_2, y_3) : y_0 \leq y_1,\ y_3 = y_1 + y_2\}.$$

Now for $\alpha \in [0, 2\pi]$ define the sequence $\vec{t}^{\,\alpha} \in \mathbb{T}$ by $t_n^\alpha := e^{-2n\pi + \alpha}$ for all n. Then some straightforward calculations give

$$h''_{\vec{t}^{\,\alpha}}(\bar{x}; z) = \begin{pmatrix} -2 \\ -\frac{1}{2} \\ 0 \\ 1 + 2\sin\alpha \end{pmatrix}, \quad (h')'_{\vec{t}^{\,\alpha}}(\bar{x}; z) = \begin{pmatrix} 0 & -2 \\ 0 & -\frac{1}{2} \\ 1 & 0 \\ 0 & 1 + 2\sin\alpha + \cos\alpha \end{pmatrix},$$

and by taking $\alpha = -\arcsin\frac{3}{4}$ we obtain $h''_{\vec{t}^\alpha}(\bar{x};z) \in C''_{h'(\bar{x}),\vec{t}^\alpha}(h(\bar{x});z)$. Since Y is finite-dimensional, Assumption 2 holds, and hence we can apply Theorem 4.6. Assuming $\bar{x}$ to be a locally optimal solution, there exist multipliers $y^* \in \Lambda_{FJ} \cap \mathcal{S}_{Y^*}$ and $\mu^* \in \operatorname{Ker}(h'(\bar{x}))^\perp = \{(\mu_1,0) : \mu_1 \in \mathbb{R}\}$ such that conditions (4.3) and (4.4) with $s = z$ and $y = 0$ are fulfilled:

$$(h')'_{\vec{t}^\alpha}(\bar{x};z)^* y^* + \mu^* = \begin{pmatrix} y_2^* + \mu_1 \\ -2y_0^* - \frac{1}{2}y_1^* + y_3^*(1 + 2\sin\alpha + \cos\alpha) \end{pmatrix} = 0,$$
$$0 + \frac{1}{2}\langle y^*, h''_{\vec{t}^\alpha}(\bar{x};z) - 0\rangle = \frac{1}{2}\Big(-2y_0^* - \frac{1}{2}y_1^* + (1+2\sin\alpha)y_3^*\Big) \geq 0.$$

However, these conditions, together with condition (4.16), are fulfilled only for $y_0^* = y_1^* = y_2^* = y_3^* = \mu_1^* = 0$, contradicting $y^* \in \mathcal{S}_{Y^*}$. Hence, $\bar{x}$ is not a local minimizer.

5. Second-order necessary conditions for the scalar mathematical programming problem. We consider here the results of the preceding section for the special case of the scalar mathematical programming problem

$$\text{(MP)} \qquad \begin{aligned} &\min f(x) \\ &\text{s.t.} \quad g_i(x) \leq 0,\ i = 1,\dots,m, \\ &\qquad G(x) = 0, \end{aligned}$$

where $f : X \to \mathbb{R}$, $g_i : X \to \mathbb{R}$ for $i = 1,\dots,m$, $G : X \to \hat{V}$, and X and $\hat{V}$ are Banach spaces. Then $Y = \mathbb{R} \times \mathbb{R}^m \times \hat{V}$ and for a given feasible point $\bar{x}$ the mapping h and the set C according to (1.5) are given by $h(x) = (f(x) - f(\bar{x}), g_1(x),\dots,g_m(x), G(x))$ and $C = R_- \times \mathbb{R}^m_- \times \{0\}$. We will assume throughout this section that Assumption 1 holds. The set of multipliers Λ_{FJ} satisfying the first-order conditions of Fritz–John type consists of all multipliers $(\alpha,\lambda,v^*) \in \mathbb{R} \times \mathbb{R}^m \times \hat{V}^*$, such that

$$\begin{aligned} \mathcal{L}'_x(\bar{x},\alpha,\lambda,v^*) &= 0, \\ \alpha &\geq 0, \\ \lambda_i \geq 0,\ \lambda_i g_i(\bar{x}) &= 0,\ i = 1,\dots,m, \\ (\alpha,\lambda,v^*) &\neq (0,0,0), \end{aligned}$$

where the generalized Lagrangian $\mathcal{L}$ is given in the usual way by $\mathcal{L}(x,\alpha,\lambda,v^*) := \alpha f(x) + \sum_{i=1}^m \lambda_i g_i(x) + \langle v^*, G(x)\rangle$ and $\mathcal{L}'_x$ is the partial derivative of the Lagrangian with respect to x. For partial second-order directional derivatives of the Lagrangian with respect to the first variable we use the following notation:

$$\mathcal{L}''_{x\vec{t}}(\bar{x},\alpha,\lambda,v^*;z) := \alpha f''_{\vec{t}}(\bar{x};z) + \sum_{i=1}^m \lambda_i g_i{}''_{\vec{t}}(\bar{x};z) + \langle v^*, G''_{\vec{t}}(\bar{x};z)\rangle,$$
$$(\mathcal{L}'_x)'_{\vec{t}}(\bar{x},\alpha,\lambda,v^*;z) := \alpha(f')'_{\vec{t}}(\bar{x};z) + \sum_{i=1}^m \lambda_i (g_i')'_{\vec{t}}(\bar{x};z) + (G')'_{\vec{t}}(\bar{x};z)^* v^*.$$

Note that the multipliers (α,λ,v^*) form a linear functional $y^* \in Y^*$, and we have $\mathcal{L}'_x(\bar{x},\alpha,\lambda,v^*) = h'(\bar{x})^* y^*$, $\mathcal{L}''_{x\vec{t}}(\bar{x},\alpha,\lambda,v^*;z) = h''_{\vec{t}}(\bar{x};z)$ and $(\mathcal{L}'_x)'_{\vec{t}}(\bar{x},\alpha,\lambda,v^*;z) = (h')'_{\vec{t}}(\bar{x};z)^* y^*$.

In the case of the mathematical programming problem the second-order compound tangent sets have the property that

$$0 \in C''_{h'(\bar{x}),\vec{t}}(h(\bar{x});s) \quad \forall s \in \mathcal{C}(\bar{x}), \vec{t} \in \mathbb{T}. \tag{5.1}$$

This follows easily from the definition and the observation that for arbitrary $s \in \mathcal{C}(\bar{x})$ and $\vec{t} \in \mathbb{T}$ we have $h(\bar{x}) + t_n s \in C$ for all n sufficiently large. Condition (5.1) together with Lemma 4.2 implies

$$C''_{h'(\bar{x}),\vec{t}}(h(\bar{x}); s) = \mathrm{cl}\left(T_C(h(\bar{x})) + \mathrm{Im}\, h'(\bar{x})\right).$$

Hence, $C''_{h'(\bar{x}),\vec{t}}(h(\bar{x}); s)$ does not depend on the choice of the direction $s \in \mathcal{C}(\bar{x})$ and the sequence $\vec{t} \in \mathbb{T}$. Moreover, $C''_{h'(\bar{x}),\vec{t}}(h(\bar{x}); s)$ is a cone and its polar cone can be written as

$$C''_{h'(\bar{x}),\vec{t}}(h(\bar{x}); s)^\circ = N_C(h(\bar{x})) \cap (\mathrm{Im}\, h'(\bar{x}))^\perp = \Lambda_{FJ} \cup \{0\}.$$

It follows that $y \in C''_{h'(\bar{x}),\vec{t}}(h(\bar{x}); s)$ holds if and only if one has $\langle y^*, y\rangle \le 0$ for each $y^* \in \Lambda_{FJ}$.

In a next step, for fixed $z \in \mathcal{C}(\bar{x}) \cap \mathcal{S}_X$ and $\vec{t} \in \mathbb{T}$ with $h''_{\vec{t}}(\bar{x}; z) \in C''_{h'(\bar{x}),\vec{t}}(h(\bar{x}); z)$ we will analyze the conclusions (4.3) and (4.4) of Theorem 4.6 under condition (5.1). Using condition (4.4) with $s = z$ and $y = 0$ yields, together with the above characterization for $h''_{\vec{t}}(\bar{x}; z) \in C''_{h'(\bar{x}),\vec{t}}(h(\bar{x}); z)$,

$$\langle \bar{y}^*, h''_{\vec{t}}(\bar{x}; z)\rangle = \max_{y^* \in \Lambda_{FJ}} \langle y^*, h''_{\vec{t}}(\bar{x}; z)\rangle = 0.$$

Since $h''_{\vec{t}}(\bar{x}; z) \in C''_{h'(\bar{x}),\vec{t}}(h(\bar{x}); z)$ implies $h''_{\vec{t}}(\bar{x}; z) \in C''_{h'(\bar{x}),\vec{t}}(h(\bar{x}); s)$ for all $s \in \mathcal{C}(\bar{x})$ we obtain $\langle \bar{\mu}^*, z - s\rangle \ge 0$ for all $s \in \mathcal{C}(\bar{x})$. Thus $\bar{\mu}^* \in N_{\mathcal{C}(\bar{x})}(z)$ or, equivalently, since $\mathcal{C}(\bar{x})$ is a cone, $\bar{\mu}^* \in \{\mu^* \in \mathcal{C}(\bar{x})^\circ \,:\, \langle \mu^*, z\rangle = 0\}$, where $\mathcal{C}(\bar{x})^\circ$ denotes the polar cone of the critical cone $\mathcal{C}(\bar{x})$. Now in the case of (MP) the critical cone is given by

$$\mathcal{C}(\bar{x}) = \left\{ z \in X \,:\, \begin{array}{c} \langle f'(\bar{x}), z\rangle \le 0, \\ \langle g'_i(\bar{x}), z\rangle \le 0 \quad \forall i \in \bar{I}, \\ G'(\bar{x})z = 0 \end{array} \right\},$$

where $\bar{I} := \{i \in \{1, \dots, m\} \,:\, g_i(x) = 0\}$ denotes the index set of active inequality constraints. If $\mathrm{Im}\, G'(\bar{x})$ is closed, then by the generalized Farkas lemma (see, e.g., [10, Proposition 2.201]) the polar cone $\mathcal{C}(\bar{x})^\circ$ is given by the formula

$$\mathcal{C}(\bar{x})^\circ = \left\{ \alpha f'(x) + \sum_{i \in \bar{I}} \lambda_i g'_i(x)^* + G'(\bar{x})^* v^* \,:\, \alpha \ge 0, \lambda_i \ge 0, i \in \bar{I}, v^* \in \hat{V}^* \right\}.$$

Hence, $\bar{\mu}^* \in \{\mu^* \in \mathcal{C}(\bar{x})^\circ \,:\, \langle \mu^*, z\rangle = 0\}$ has the following representation:

$$\bar{\mu}^* = \tilde{\alpha} f'(x) + \sum_{i=1}^m \tilde{\lambda}_i g'_i(x) + G'(\bar{x})^* \tilde{v}^*,$$

where $\tilde{\alpha} \ge 0$, $\tilde{\lambda}_i \ge 0$, $\tilde{\lambda}_i g_i(\bar{x}) = 0$, $i = 1, \dots, m$, and $\tilde{v}^* \in \hat{V}^*$ are such that $\tilde{\alpha}\langle g'_i(\bar{x}), z\rangle + \sum_{i=0}^m \tilde{\lambda}_i \langle g'_i(\bar{x}), z\rangle + \langle \tilde{v}^*, G'(\bar{x})z\rangle = 0$, or, equivalently, since $z \in \mathcal{C}(\bar{x})$,

$$\tilde{\alpha}\langle f'(\bar{x}), z\rangle = 0, \quad \tilde{\lambda}_i g_i(\bar{x}) = \tilde{\lambda}_i \langle g'_i(\bar{x}), z\rangle = 0,\ i = 1, \dots, m.$$

Next let us consider Assumption 2. It surely holds if the space $\hat{V}^*$ is finite-dimensional. In the case of infinite-dimensional $\hat{V}$ let us examine the assumptions of

Theorem 4.8. Note that $\operatorname{aff}(C - h(\bar{x})) = \mathbb{R} \times \mathbb{R}^m \times \{0\}$ is always finite-dimensional for the problem (MP). From the discussion at the end of the preceding section we know that to verify 2-nondegeneracy of $h(\cdot)$ with respect to C we only have to consider the equality constraints $G(x) = 0$. It is straightforward to see that the mapping $G(\cdot)$ is 2-nondegenerate in direction z with respect to $\{0\}$ and the sequence $\vec{t} \in \mathbb{T}$, provided that $(G')'_{\vec{t}}(\bar{x}; z)$ exists if and only if $\operatorname{Im} G'(\bar{x})$ is closed in $\hat{V}$ and the mapping $s \to (G'(\bar{x})s, \pi G''_{\vec{t}}(\bar{x}; z)s)$ carries X onto $\operatorname{Im} G'(\bar{x}) \times \hat{V}/\operatorname{Im} G'(\bar{x})$, where π here denotes the quotient mapping onto the quotient space $\hat{V}/\operatorname{Im} G'(\bar{x})$. For twice, respectively, three times continuously differentiable mappings G this condition already appears in a lot of papers on optimality conditions for problems with degenerate equality constraints; see [4], [5], [25]. Further, in a slightly different version it is also known as the property of 2-*regularity* of the mapping G (see [6], [33]). We refer also to [19], where the theory of 2-regularity was applied to once differentiable mappings having a locally Lipschitzian derivative.

We summarize these considerations in the following corollary.

COROLLARY 5.1. *Let $\bar{x}$ be a local minimizer for the mathematical programming problem* (MP) *and let Assumption* 1 *hold. Then for each element $z \in \mathcal{C}(\bar{x})$ and each sequence $\vec{t} \in \mathbb{T}$ such that the second-order directional derivatives $h''_{\vec{t}}(\bar{x}; z)$ and $(h')'_{\vec{t}}(\bar{x}; z)$ exist, such that*

$$\sup_{(\alpha,\lambda,\hat{v}^*) \in \Lambda_{FJ}} \mathcal{L}''_{x\vec{t}}(\bar{x}, \alpha, \lambda, v^*; z) \le 0, \tag{5.2}$$

and such that either $\dim \hat{V} < \infty$ or $G(\cdot)$ is 2-nondegenerate in direction z with respect to $\{0\}$ and $(\vec{t})$, there exist multipliers $(\alpha, \lambda, v^*) \in \Lambda_{FJ}$ and $(\tilde{\alpha}, \tilde{\lambda}, \tilde{v}^*) \in \mathbb{R}_+ \times \mathbb{R}^m_+ \times \hat{V}^*$ such that

$$\mathcal{L}''_{x\vec{t}}(\bar{x}, \alpha, \lambda, v^*; z) = 0, \tag{5.3}$$

$$(\mathcal{L}'_x)'_{\vec{t}}(\bar{x}, \alpha, \lambda, v^*; z) + \mathcal{L}'_x(\bar{x}, \tilde{\alpha}, \tilde{\lambda}, \tilde{v}^*) = 0, \tag{5.4}$$

$$\tilde{\lambda}_i g_i(\bar{x}) = \tilde{\lambda}_i \langle g'_i(\bar{x}), z \rangle = 0, \ i = 1, \dots, m, \tag{5.5}$$

$$\tilde{\alpha} \langle f'(\bar{x}), z \rangle = 0. \tag{5.6}$$

Let us compare Corollary 5.1 with the standard second-order conditions (see, e.g., [16]) for (MP). For the sake of simplicity let us assume that f, g_i, $i = 1, \dots, m$, and G are twice continuously differentiable at $\bar{x}$ and that the range $\operatorname{Im} G'(\bar{x})$ is closed. If $\Lambda_{FJ} \neq \emptyset$ and if there is some $\beta > 0$ such that

$$\max_{(\alpha,\lambda,v^*) \in \Lambda_{FJ} \cap \mathcal{S}_{Y^*}} \mathcal{L}''_x(\bar{x}, \alpha, \lambda, v^*)(z, z) \ge \beta$$

for all $z \in \mathcal{C}(\bar{x}) \cap S_X$, then $\bar{x}$ is a strict local minimizer, and in fact one can show [15] that this condition is also equivalent for $\bar{x}$ to be an essential local minimizer of second order. On the other hand, the standard second-order necessary conditions state that at a local minimizer $\bar{x}$ the set Λ_{FJ} is not empty, and for each $z \in \mathcal{C}(\bar{x})$ there is some multiplier $(\alpha, \lambda, v^*) \in \Lambda_{FJ} \cap \mathcal{S}_{Y^*}$ such that

$$\mathcal{L}''_x(\bar{x}, \alpha, \lambda, v^*)(z, z) \ge 0.$$

It is also well known that on one hand this necessary condition is equivalent to condition (2.1) for nondegenerate points $\bar{x}$, i.e., when $\operatorname{Im} G'(\bar{x}) = \hat{V}$, and on the other hand that it is always satisfied when $\bar{x}$ is degenerate, whether $\bar{x}$ is a local minimizer or not.

Now, for degenerate points $\bar{x}$ Corollary 5.1 states the additional necessary conditions (5.4)–(5.6) for exactly those directions $z \in \mathcal{C}(\bar{x}) \cap \mathcal{S}_X$, where the sufficient conditions fail to hold, and thus reduces the gap between the standard necessary and sufficient conditions for the mathematical programming problem (MP).

Now let us compare our work with Avakov's results [4], [5]: For the sake of simplicity we consider only the case when no inequality constraints are present, i.e., $m = 0$. Avakov shows, assuming that f is Fréchet differentiable at $\bar{x}$ and G is twice Fréchet differentiable at a local minimizer $\bar{x}$ and the range $\operatorname{Im} G'(\bar{x})$ is closed, the following "first-order" conditions hold: For each $z \in X$ such that $G'(\bar{x})z = 0$, $G''(\bar{x})(z,z) \in \operatorname{Im} G'(\bar{x})$, and the operator $\mathcal{G}(\bar{x};z) : X \to \operatorname{Im} G'(\bar{x}) \times \hat{V}/\operatorname{Im} G'(\bar{x})$ given by $\mathcal{G}(\bar{x},z)s \to (G'(\bar{x})s, \pi G''(\bar{x})(z,s))$ has closed range, there exist multipliers $(0,0) \neq (\alpha, v^*) \in \mathbb{R}_+ \times \operatorname{Ker} G'(\bar{x})^*$ and $\tilde{v}^* \in \hat{V}^*$ such that

$$\alpha f'(\bar{x}) + G'(\bar{x})^*\tilde{v}^* + G''(\bar{x})(z,\cdot)^*v^* = 0. \tag{5.7}$$

Now let us demonstrate how this result follows from our work in the case in which the equality constraints are degenerate, i.e., $\operatorname{Im} G'(\bar{x}) \neq \hat{V}$, under the assumption that f is strictly differentiable at $\bar{x}$. Let $z \in X$ be fixed, satisfying $G'(\bar{x})z = 0$, $G''(\bar{x})(z,z) \in \operatorname{Im} G'(\bar{x})$. We can assume $\langle f'(\bar{x}), z\rangle \leq 0$, since otherwise we can take the direction $-z$. When $\mathcal{G}(\bar{x};z)$ is not surjective but has closed range, (5.7) with $\alpha = 0$ follows from the existence of a nontrivial functional in $(\operatorname{Im} \mathcal{G}(\bar{x};z))^\perp$ by using standard arguments.

Now assume that $\mathcal{G}(\bar{x};z)$ is surjective, i.e., G is 2-nondegenerate in direction z. It follows that $\pi G''(\bar{x})(z,\cdot) \neq 0$ and hence $z \neq 0$; w.l.o.g. $\|z\| = 1$. Let $p^* \in X^*$ denote a continuous linear functional with $\langle p^*, z\rangle = 1$ and consider the problem

$$(\mathrm{MP}_{\mathrm{p}^*}) \quad \min_{x \in X} \varphi(x) := \langle p^*, x - \bar{x}\rangle (f(x) - f(\bar{x})) \quad \text{s.t.} \quad \langle -p^*, x - \bar{x}\rangle \leq 0,\ G(x) = 0.$$

Then $\bar{x}$ is also a local minimizer for this problem and one can show that Assumption 1 is satisfied and also the second-order directional derivatives exist for every direction and every sequence $\vec{t} \in T$. In particular, we have $\varphi'(\bar{x}) = 0$, $\varphi''_{\vec{t}}(\bar{x};z) = 2\langle f'(\bar{x}), z\rangle\langle p, z\rangle$, and $(\varphi')'_{\vec{t}}(\bar{x};z) = \langle p^*, z\rangle f'(\bar{x}) + \langle f'(\bar{x}), z\rangle p^*$. It follows immediately that z belongs to the critical cone of problem $(\mathrm{MP}_{\mathrm{p}^*})$.

Now let $(0,0,0) \neq (\alpha, \lambda, v^*) \in \mathbb{R}_+ \times \mathbb{R}_+ \times \hat{V}^*$ be an arbitrary multiplier satisfying the Fritz–John conditions for $(\mathrm{MP}_{\mathrm{p}^*})$. We have $-\lambda p^* + G'(\bar{x})^*v^* = 0$ and consequently $\lambda = \lambda\langle p^*, z\rangle = \langle v^*, G'(\bar{x})z\rangle = 0$ and $G'(\bar{x})^*v^* = 0$. Due to our assumption on z we have $G''(\bar{x})(z,z) = G'(\bar{x})w$ for some $w \in X$ and therefore

$$\alpha\varphi''_{\vec{t}}(\bar{x};z) + 0 + \langle v^*, G''(\bar{x})(z,z)\rangle = 2\alpha\langle f'(\bar{x}), z\rangle\langle p^*, z\rangle + \langle v^*, G'(\bar{x})w\rangle = 2\alpha\langle f'(\bar{x}), z\rangle \leq 0.$$

This shows that condition (5.2) is satisfied and application of Corollary 5.1 proves the existence of multipliers $(0,0,0) \neq (\alpha, 0, v^*) \in \mathbb{R}_+ \times \mathbb{R}_+ \times \operatorname{Ker} G'(\bar{x})^*$ and $(\tilde{\alpha}, \tilde{\lambda}, \tilde{v}^*) \in \mathbb{R}_+ \times \mathbb{R}_+ \times \hat{V}^*$ such that we have $-\tilde{\lambda} = \tilde{\lambda}\langle -p^*, z\rangle = 0$ by condition (5.5), $\alpha\langle f'(\bar{x}), z\rangle = 0$ by condition (5.3), and also

$$\alpha(\varphi')'_{\vec{t}}(\bar{x};z) + G''(\bar{x})(z,\cdot)^*v^* + G'(\bar{x})^*\tilde{v}^* = \alpha f'(\bar{x}) + G'(\bar{x})^*\tilde{v}^* + G''(\bar{x})(z,\cdot)^*v^* = 0$$

by condition (5.4). Hence, condition (5.7) holds.

Note that condition (5.7) is called a "first-order" condition, although it contains the second derivative $G''(\bar{x})$. Similarly, Avakov and others presented "second-order" conditions (see [4], [5], [18], [25]), where third derivatives of the mapping G are involved. Of course, our results cannot cover such "second-order" conditions. Indeed,

as pointed out by an anonymous referee, the assertion of Corollary 5.1 follows from [5, Theorem 2] under such stronger differentiability assumptions.

There are also other second-order conditions known from the literature; see, for instance, the monograph of Arutyunov [2] and the references therein.

Example 5.1. This is a very easy example which can be treated by the results of this paper but not by results in the literature. Consider the problem

$$\min_{(x_1,x_2,x_3)\in\mathbb{R}^3} -x_1^2 + x_3 \quad \text{s.t.} \quad x_1x_2 + |x_1|^{5/2} = 0, \quad x_3 = 0,$$

at $\bar{x} = (0,0,0)$. Then $\bar{x} = (0,0,0)$ is not a local minimum, and this follows also from Corollary 5.1 since the second-order conditions (5.3)–(5.6) are not satisfied for the direction $z = (-1,0,0)$. However, the necessary "first-order" conditions (5.7) hold and the "second-order" conditions from [4], [25], [26] do not apply since the constraints are not three times differentiable at $\bar{x}$. Also the necessary conditions of Arutyunov [1, Theorems 3.1 and 3.2] and Belash and Tret'yakov [6, Theorem 3] are either satisfied or cannot be used since $f'(\bar{x}) \neq 0$ and $G'(\bar{x}) \neq 0$. Finally, if we replace the equality constraint $x_3 = 0$ by the inequality constraint $x_3 \geq 0$, then again the origin $\bar{x} = (0,0,0)$ can be classified as nonoptimal by Corollary 5.1, but the necessary conditions [3] cannot be used.

Example 5.2. Now consider the problem

$$\min_{(x_1,x_2)\in\mathbb{R}^2} x_1 \quad \text{s.t.} \quad x_2 \leq 0,\ x_1x_2 = 0,$$

at $\bar{x} = (0,0)$. Again, $\bar{x}$ is not a local minimum, but the second-order conditions of Corollary 5.1 now hold. To verify these conditions we have to consider the directions $z = (-1,0)$ and $z = (0,-1)$, and in both cases the multipliers $(\alpha,\lambda,v^*) \in \Lambda_{FJ}$ satisfying the conditions (5.3)–(5.6) are given by $(0,0,1)$. Moreover, for any direction $z \in \mathcal{C}(\bar{x}) \cap \mathcal{S}_X$ we have $\mathcal{L}''_{xt}(\bar{x},\alpha,\lambda,v^*;z) \geq 0$ for multipliers of the form $(\alpha,\lambda,v^*) = (0,0,t)$, $t > 0$.

Now we show that in a situation as in Example 5.2, where the multipliers corresponding to Corollary 5.1 are contained in a pointed closed convex cone, the second-order necessary conditions of Corollary 5.1 are sharp. We state this result in terms of the general problem (P).

THEOREM 5.2. *Let the point $\bar{x}$ be feasible for problem* (P) *and suppose that Assumption* 1 *holds, that* $\dim Y < \infty$, *and that*

$$\lim_{t\to 0_+} d\left(\frac{h(\bar{x}+tz) - h(\bar{x}) - th'(\bar{x})z}{t^2/2}, h''(\bar{x};z)\right) = 0 \tag{5.8}$$

holds uniformly for all $z \in \mathcal{C}(\bar{x}) \cap \mathcal{B}_X$. Further suppose that there is a pointed closed convex cone $\bar{\Lambda} \subset \Lambda_{FJ} \cup \{0\}$ such that for every $z \in \mathcal{C}(\bar{x})$ and every $y \in h''(\bar{x};z)$ there is some $\bar{y}^* \in \bar{\Lambda} \cap \mathcal{S}_{Y^*}$ with $\langle \bar{y}^*, y\rangle \geq 0$. Then there exists a mapping $\delta h = (\delta f, \delta g)$ with $\delta h(x) = \psi(\|x - \bar{x}\|)y$, where $y \in Y$ and $\psi : \mathbb{R}_+ \to \mathbb{R}_+$ is a twice continuously differentiable function satisfying $\psi(0) = \psi'(0) = \psi''(0) = 0$, such that $\bar{x}$ is a strict local minimizer for (P) *with f and g replaced by $f + \delta f$ and $g + \delta g$, respectively.*

Proof. Let $S := \bar{\Lambda}^\circ$ denote the polar cone of the pointed convex closed cone $\bar{\Lambda}$. Since $\dim Y < \infty$, we have $\operatorname{int} S \neq \emptyset$. Further we have $\operatorname{cl}(h'(\bar{x})X + T_C(h(\bar{x}))) = \Lambda_{FJ}^\circ \subset S$. Let the subspace Q be given by $Q := \operatorname{aff}(h'(\bar{x})X - T_C(h(\bar{x})))$. If $\dim Q < \dim Y$, then we can find $p := \dim Y - \dim Q$ linearly independent elements $y_i \in S \setminus Q$, $i = 1,\dots,p$, forming a basis for some topological complement Q^c to Q, such that

$\operatorname{int}(h'(\bar{x})X - \bar{C}) \neq \emptyset$, where $\bar{C} := h(\bar{x}) + T_C(h(\bar{x})) + \hat{S}$ and the cone $\hat{S}$ is given by $\hat{S} := \{\sum_{i=1}^{p} \alpha_i y_i \,:\, \alpha_i \geq 0,\ i = 1, \dots, p\}$. Note that $\bar{C}$ is closed since $T_C(h(\bar{x})) \subset Q$ and $\hat{S} \subset Q^c$ are closed and $Y = Q \oplus Q^c$. On the other hand, if $\dim Q = \dim Y$, take $\bar{C} := h(\bar{x}) + T_C(h(\bar{x}) + \hat{S}$ with $\hat{S} = \{0\}$. In any case we have $\operatorname{int}(h'(\bar{x})X - \bar{C}) \neq \emptyset$ and $C \subset h(\bar{x}) + T_C(h(\bar{x})) \subset \bar{C} \subset h(\bar{x}) + S$. By taking into account the remark following Theorem 2.2 we see that in order to prove the theorem it is sufficient to show

$$\liminf_{\substack{x \to \bar{x} \\ \tau \to 0_+}} \frac{\hat{d}_{\bar{C}}(h(\bar{x}), h'(\bar{x}), \tau\|x - \bar{x}\|)}{\|x - \bar{x}\|^2} \geq 0.$$

Assume on the contrary that there are sequences $(z_n) \subset \mathcal{S}_X$, $\vec{t} = (t_n) \in \mathbb{T}$, and $(\tau_n) \in \mathbb{T}$, and a real $\beta > 0$ such that $t_n^{-2} \hat{d}_{\bar{C}}(h(\bar{x} + t_n z_n), h'(\bar{x}), \tau_n t_n) \leq -\beta$ for all n. Then by Theorem 2.4 we have $0 \in h(\bar{x} + t_n z_n) + \tau_n t_n h'(\bar{x})\mathcal{B}_X - \bar{C}$, and using Assumption 1 we see $t_n^{-1}(h(\bar{x} + t_n z_n) - h(\bar{x})) = h'(\bar{x})z_n + O(t_n) \in t_n^{-1}(\bar{C} - h(\bar{x})) = T_C(h(\bar{x})) + \hat{S}$. Since $\dim Y < \infty$, $h'(\bar{x})z_n \subset Y$ is a bounded sequence and $\operatorname{Im} h'(\bar{x})$ is closed, we have, by passing to a subsequence if necessary, $h'(\bar{x})z_n \to h'(\bar{x})\bar{z}$ for some $\bar{z} \in X$. Then $h'(\bar{x})\bar{z} \in T_C(h(\bar{x})) + \hat{S}$ and since $h'(\bar{x})\bar{z} \in Q$, $T_C(h(\bar{x}) \subset Q$, and $\hat{S} \cap Q = \{0\}$, $h'(\bar{x}) \in T_C(h(\bar{x}))$ follows, i.e., $\bar{z} \in \mathcal{C}(\bar{x})$. Further, since $\operatorname{Im} h'(\bar{x})$ is closed we can find another sequence, say (z_n'), such that $h'(\bar{x})z_n' = h'(\bar{x})\bar{z}$ and $\|z_n' - z_n\| \leq \gamma\|h'(\bar{x})\bar{z} - h'(\bar{x})z_n\|$ for some $\gamma > 0$. By taking $\tilde{z}_n := z_n'/\|z_n'\|$ we have found a sequence $(\tilde{z}_n) \subset \mathcal{C}(\bar{x}) \cap \mathcal{S}_X$ with $\tilde{z}_n - z_n \to 0$. By our assumptions, there exists a sequence (w_n) with $w_n \in h''(\bar{x}; \tilde{z}_n)$ such that $\|h(\bar{x} + t_n\tilde{z}_n) - (h(\bar{x}) + t_n h'(\bar{x})\tilde{z}_n + \frac{t_n^2}{2} w_n)\| = o(t_n^2)$ and, together with Assumption 1,

$$\left\| h(\bar{x} + t_n z_n) - \left(h(\bar{x}) + t_n h'(\bar{x}) z_n + \frac{t_n^2}{2} w_n \right) \right\| \leq \eta t_n^2 \|z_n - \tilde{z}_n\| + o(t_n^2) = o(t_n^2)$$

follows. Now, for each n let $y_n^* \in \bar{\Lambda} \cap \mathcal{S}_{Y^*}$ be chosen such that $\langle y_n^*, w_n \rangle \geq 0$. Since $y_n^* \in \Lambda_{FJ}$ we have $h'(\bar{x})^* y_n^* = 0$ and because of $h(\bar{x}) \in \bar{C}$ we obtain $\sigma_{\bar{C}}(y_n^*) \geq \langle y_n^*, h(\bar{x}) \rangle$. Hence we conclude that

$$\begin{aligned} t_n^{-2} \hat{d}_{\bar{C}}(h(\bar{x} + t_n z_n), h'(\bar{x}), \tau_n t_n) &\leq t_n^{-2}(\langle y_n^*, h(\bar{x} + t_n z_n) \rangle - \sigma_{\bar{C}}(y_n^*) - \tau_n t_n \|h'(\bar{x})^* y_n^*\|) \\ &\leq t_n^{-2} \langle y_n^*, h(\bar{x} + t_n z_n) - h(\bar{x}) \rangle \\ &= t_n^{-2} \langle y_n^*, h(\bar{x} + t_n z_n) - h(\bar{x}) - t_n h'(\bar{x}) z_n \rangle \\ &= \frac{1}{2} \langle y_n^*, w_n \rangle + o(1) \geq o(1), \end{aligned}$$

a contradiction. □

Note that, as a consequence of Assumption 1 and $\dim Y < \infty$, convergence in condition (5.8) is always uniform with respect to z in compact sets. Hence, besides the case when h is twice Fréchet differentiable at $\bar{x}$, condition (5.8) holds uniformly for all $z \in \mathcal{C}(\bar{x})$ when $\dim X < \infty$.

It is easy to see that the perturbation δh is Fréchet differentiable at $\bar{x}$ with $\delta h(\bar{x}) = 0$, $\delta h'(\bar{x}) = 0$ and that Assumption 1 is fulfilled with arbitrarily small η. Moreover, for any sequence $\vec{t} \in \mathbb{T}$ and any element $z \in X$ we have $h_{\vec{t}}''(\bar{x}; z) = 0$ and $(h')_{\vec{t}}'(\bar{x}; z) = 0$. Consequently, our assumptions are also fulfilled for the perturbed problem and all the quantities used in the optimality conditions do not change. Further note that δh is even twice continuously differentiable and $\delta h''(\bar{x}) = 0$, provided X is a Hilbert space.

In the case when f is scalar and K is a polyhedral cone, using the notion of 2-*normal mappings*, Arutyunov [1], [2] presented conditions which are sufficient for the

existence of a cone $\bar{\Lambda}$ satisfying the assumptions of Theorem 5.2. Further, Arutyunov showed 2-normal mappings to be generic under certain circumstances. However, note that the constraint mapping of Example 5.2 is not 2-normal.

Arutyunov [1, Theorem 4.3] stated also a result which is very similar to Theorem 5.2 and from which he concluded that the "gap" between his necessary and sufficient second-order conditions is as minimal as possible. Note that the second derivatives of Arutyunov's perturbations can be made only arbitrary small, but they do not vanish at the point $\bar{x}$ under consideration.

MAJORIZING FUNCTIONS AND CONVERGENCE OF THE GAUSS–NEWTON METHOD FOR CONVEX COMPOSITE OPTIMIZATION*

CHONG LI† AND K. F. NG‡

Abstract. We introduce a notion of quasi regularity for points with respect to the inclusion $F(x) \in C$, where F is a nonlinear Fréchet differentiable function from $\mathbb{R}^v$ to $\mathbb{R}^m$. When C is the set of minimum points of a convex real-valued function h on $\mathbb{R}^m$ and F' satisfies the L-average Lipschitz condition of Wang, we use the majorizing function technique to establish the semilocal linear/quadratic convergence of sequences generated by the Gauss–Newton method (with quasi-regular initial points) for the convex composite function $h \circ F$. Results are new even when the initial point is regular and F' is Lipschitz.

1. Introduction.

The convex composite optimization to be considered is as follows:

$$\min_{x \in \mathbb{R}^v} f(x) := h(F(x)), \tag{1.1}$$

where h is a real-valued convex function on $\mathbb{R}^m$ and F is a nonlinear Fréchet differentiable map from $\mathbb{R}^v$ to $\mathbb{R}^m$ (with norm $\|\cdot\|$). We assume throughout that h attains its minimum $h_{\min}$.

This problem has recently received a great deal of attention. As observed by Burke and Ferris in their seminal paper [4], a wide variety of its applications can be found throughout the mathematical programming literature, especially in convex inclusion, minimax problems, penalization methods, and goal programming (see also [2, 6, 7, 15, 22]). The study of (1.1) provides not only a unifying framework for the development and analysis of algorithms for solutions but also a convenient tool for the study of first- and second-order optimality conditions in constrained optimization [3, 5, 7, 22]. As in [4, 13], the study of (1.1) naturally relates to the convex inclusion problem

$$F(x) \in C, \tag{1.2}$$

where

$$C := \operatorname{argmin} h, \tag{1.3}$$

the set of all minimum points of h. Of course, it is meaningful to study (1.2) in its own right for a general closed convex set (cf. [14, 16]). In section 3, we introduce a new notion of quasi regularity for $x_0 \in \mathbb{R}^v$ with respect to the inclusion (1.2). This new notion covers the case of regularity studied by Burke and Ferris [4] as well as the case when $F'(x_0) - C$ is surjective, employed by Robinson [18]. More importantly, we introduce notions of the quasi-regular radius r_{x_0} and of the quasi-regular bound function β_{x_0} attached to each quasi-regular point x_0. For the general case this pair (r_{x_0}, β_{x_0}) together with a suitable Lipschitz-type assumption on F' enables us to address the issue of convergence of Gauss–Newton sequences provided by the following well-known algorithm (cf. [4, 10, 13, 31]).

ALGORITHM A (η, Δ, x_0). Let $\eta \in [1, +\infty)$, $\Delta \in (0, +\infty]$, and for each $x \in \mathbb{R}^v$ define $D_\Delta(x)$ by

$$D_\Delta(x) = \{d \in \mathbb{R}^v : \|d\| \le \Delta, h(F(x) + F'(x)d) \le h(F(x) + F'(x)d') \quad \forall d' \in \mathbb{R}^v \text{ with } \|d'\| \le \Delta\}. \tag{1.4}$$

Let $x_0 \in \mathbb{R}^v$ be given. For $k = 0, 1, \ldots$, having $x_0, x_1, \ldots, x_k$, determine x_{k+1} as follows.

If $0 \in D_\Delta(x_k)$, then stop; if $0 \notin D_\Delta(x_k)$, choose d_k such that $d_k \in D_\Delta(x_k)$ and

$$\|d_k\| \le \eta d(0, D_\Delta(x_k)), \tag{1.5}$$

and set $x_{k+1} = x_k + d_k$. Here $d(x, W)$ denotes the distance from x to W in the finite-dimensional Banach space containing W.

Note that $D_\Delta(x)$ is nonempty and is the solution set of the following convex optimization problem:

$$\min_{d \in \mathbb{R}^v, \|d\| \le \Delta} h(F(x) + F'(x)d), \tag{1.6}$$

which can be solved by standard methods such as the subgradient method, the cutting plane method, the bundle method, etc. (cf. [9]).

If the initial point x_0 is a quasi-regular point with (r_{x_0}, β_{x_0}) and if F' satisfies a Lipschitz-type condition (introduced by Wang [28]) with an absolutely continuous function L satisfying a suitable property in relation to (r_{x_0}, β_{x_0}), our main results presented in section 4 show that the Gauss–Newton sequence $\{x_n\}$ provided by Algorithm A (η, Δ, x_0) converges at a quadratic rate to some x^* with $F(x^*) \in C$ (in particular, x^* solves (1.1)). Even in the special case when x_0 is regular and F' is Lipschitz, the advantage of allowing β_{x_0} and L to be functions (rather than constants) provides results which are new even for the above special case. Examples are given in section 6 to show there are situations where our results are applicable but not the earlier results in the literature; in particular, Example 6.1 is a simple example to demonstrate a quasi-regular point which is not regular. We shall show that the Gauss–Newton sequence $\{x_n\}$ is "majorized" by the corresponding numerical sequence $\{t_n\}$ generated by the classical Newton method with initial point $t_0 = 0$ for a "majorizing" function of the following type (again introduced by Wang [28]):

$$\phi_\alpha(t) = \xi - t + \alpha \int_0^t L(u)(t - u)\, \mathrm{d}u \quad \text{for each } t \ge 0, \tag{1.7}$$

where ξ, α are positive constants and L is a positive-valued increasing (more precisely, nondecreasing) absolutely continuous function on $[0, +\infty)$. In the case when L is a

constant function, (1.7) reduces to

$$\phi_\alpha(t) = \xi - t + \frac{\alpha L}{2}t^2 \quad \text{for each } t \geq 0, \tag{1.8}$$

the majorizing function used by Kantorovich [11] and by Kantorovich and Akilov [12]. In the case when

$$L(u) = \frac{2\gamma}{(1-\gamma u)^3}, \tag{1.9}$$

expression (1.7) reduces to

$$\phi_\alpha(t) = \xi - t + \frac{\alpha\gamma t^2}{1-\gamma t}, \tag{1.10}$$

the majorizing function that Wang made use of in his work [28] on approximate zeros of Smale (cf. [26]). Motivated by this and as an application of our results in section 4, we provide a sufficient condition ensuring that a point $x_0 \in \mathbb{R}^v$ will be an "approximate solution" of (1.1) in the sense that the Gauss–Newton sequence $\{x_n\}$ generated by Algorithm A (η, Δ, x_0) converges to a solution of (1.1) and satisfies the condition

$$\|x_{n+1} - x_n\| \leq \left(\frac{1}{2}\right)^{2^{n-1}} \|x_n - x_{n-1}\| \quad \text{for each } n = 1, 2, \ldots \tag{1.11}$$

(the last condition was used by Smale [26] in his study of approximate zeros for Newton's method).

2. Preliminaries. Let $\mathbf{B}(x, r)$ stand for the open ball in $\mathbb{R}^v$ or $\mathbb{R}^m$ with center x and radius r, while the corresponding closed ball is denoted by $\overline{\mathbf{B}(x, r)}$. Let W be a closed convex subset of $\mathbb{R}^v$ or $\mathbb{R}^m$. The negative polar of W is denoted by $W^\ominus$ and defined by

$$W^\ominus = \{z : \langle z, w\rangle \leq 0 \text{ for each } w \in W\}.$$

Let L be a positive-valued increasing absolutely continuous function on $[0, +\infty)$, and let $\alpha > 0$. Let $r_\alpha > 0$ and $b_\alpha > 0$ such that

$$\alpha \int_0^{r_\alpha} L(u)\ \mathrm{d}u = 1 \quad \text{and} \quad b_\alpha = \alpha \int_0^{r_\alpha} L(u)u\ \mathrm{d}u \tag{2.1}$$

(thus $b_\alpha < r_\alpha$). Let $\xi \geq 0$, and define

$$\phi_\alpha(t) = \xi - t + \alpha \int_0^t L(u)(t-u)\ \mathrm{d}u \quad \text{for each } t \geq 0. \tag{2.2}$$

Thus

$$\phi'_\alpha(t) = -1 + \alpha \int_0^t L(u)\ \mathrm{d}u, \quad \phi''_\alpha(t) = \alpha L(t) \quad \text{for each } t \geq 0, \tag{2.3}$$

and $\phi'''_\alpha(t)$ exists almost everywhere thanks to the assumption that L is absolutely continuous. Let $t_{\alpha,n}$ denote the sequence generated by Newton's method for ϕ_α with initial point $t_{\alpha,0} = 0$:

$$t_{\alpha,n+1} = t_{\alpha,n} - \phi'_\alpha(t_{\alpha,n})^{-1}\phi_\alpha(t_{\alpha,n}) \quad \text{for each } n = 0, 1, \ldots . \tag{2.4}$$

In particular, by (2.2) and (2.3),

$$t_{\alpha,1} = \xi. \tag{2.5}$$

Below we list a series of useful lemmas for our purpose. They are either known or can be verified easily by elementary methods (such as by differential calculus). In particular, Lemma 2.3 and Lemma 2.1(i) are taken from [28], while Lemma 2.1(ii) and (iii) are well known. Here we shall give a proof of Lemma 2.4 as an illustration.

LEMMA 2.1. *Suppose that* $0 < \xi \le b_\alpha$. *Then* $b_\alpha < r_\alpha$ *and the following assertions hold:*

(i) ϕ_α *is strictly decreasing on* $[0, r_\alpha]$ *and strictly increasing on* $[r_\alpha, +\infty)$ *with*

$$\phi_\alpha(\xi) > 0, \quad \phi_\alpha(r_\alpha) = \xi - b_\alpha \le 0, \quad \phi_\alpha(+\infty) \ge \xi > 0. \tag{2.6}$$

Moreover, if $\xi < b_\alpha$, ϕ_α *has two zeros, denoted respectively by* r_α^* *and* r_α^{**}, *such that*

$$\xi < r_\alpha^* < \frac{r_\alpha}{b_\alpha}\xi < r_\alpha < r_\alpha^{**}, \tag{2.7}$$

and if $\xi = b_\alpha$, *then* ϕ_α *has a unique zero* r_α^* *in* $(\xi, +\infty)$ *(in fact,* $r_\alpha^* = r_\alpha$*).*

(ii) $\{t_{\alpha,n}\}$ *is strictly monotonically increasing and converges to* r_α^*.

(iii) *The convergence of* $\{t_{\alpha,n}\}$ *is of quadratic rate if* $\xi < b_\alpha$, *and linear if* $\xi = b_\alpha$.

LEMMA 2.2. *Let* r_α, b_α, *and* ϕ_α *be defined by* (2.1) *and* (2.2). *Let* $\alpha' > \alpha$ *with the corresponding* $\phi_{\alpha'}$. *Then the following assertions hold:*

(i) *The functions* $\alpha \mapsto r_\alpha$ *and* $\alpha \mapsto b_\alpha$ *are strictly decreasing on* $(0, +\infty)$.

(ii) $\phi_\alpha < \phi_{\alpha'}$ *on* $(0, +\infty)$.

(iii) *The function* $\alpha \mapsto r_\alpha^*$ *is strictly increasing on the interval* $I(\xi)$, *where* $I(\xi)$ *denotes the set of all* $\alpha > 0$ *such that* $\xi \le b_\alpha$.

LEMMA 2.3. *Let* $0 \le c < +\infty$. *Define*

$$\chi(t) = \frac{1}{t^2}\int_0^t L(c+u)(t-u)\ \mathrm{d}u \qquad \text{for each } 0 \le t < +\infty. \tag{2.8}$$

Then χ *is increasing on* $[0, +\infty)$.

LEMMA 2.4. *Define*

$$\omega_\alpha(t) = \phi'_\alpha(t)^{-1}\phi_\alpha(t), \qquad \text{for each } t \in [0, r_\alpha^*).$$

Suppose that $0 < \xi \le b_\alpha$. *Then* ω_α *is increasing on* $[0, r_\alpha^*)$.

Proof. Since

$$\omega'_\alpha(t) = \frac{\phi'_\alpha(t)^2 - \phi_\alpha(t)\phi''_\alpha(t)}{\phi'_\alpha(t)^2} \quad \text{for each } t \in [0, r_\alpha^*),$$

it suffices to show that

$$\zeta_\alpha(t) := \phi'_\alpha(t)^2 - \phi_\alpha(t)\phi''_\alpha(t) \ge 0 \quad \text{for each } t \in [0, r_\alpha^*).$$

Since $\zeta_\alpha(r_\alpha^*) = \phi'_\alpha(r_\alpha^*)^2 \ge 0$, it remains to show that ζ_α is decreasing on $[0, r_\alpha^*]$. To do this, note that by (2.3), ζ_α is absolutely continuous, and so the derivative of ζ_α exists almost everywhere on $[0, r_\alpha^*]$ with

$$\zeta'_\alpha(t) = \phi'_\alpha(t)\phi''_\alpha(t) - \phi_\alpha(t)\phi'''_\alpha(t) \le 0 \qquad \text{for a.e.} \quad t \in [0, r_\alpha^*),$$

because $\phi'_\alpha \le 0$ while $\phi_\alpha,\ \phi''_\alpha,\ \phi'''_\alpha \ge 0$ almost everywhere on $[0, r^*_\alpha)$. Therefore, ζ_α is decreasing on $[0, r^*_\alpha)$, and the proof is complete. ∎

The following conditions were introduced by Wang in [28] but using the terminologies of "the center Lipschitz condition with the L average" and "the center Lipschitz condition in the inscribed sphere with the L, average," respectively, for (a) and (b).

DEFINITION 2.5. *Let Y be a Banach space and let $x_0 \in \mathbb{R}^v$. Let G be a mapping from $\mathbb{R}^v$ to Y. Then G is said to satisfy*

(a) *the weak L-average Lipschitz condition on $\mathbf{B}(x_0, r)$ if*

$$\|G(x) - G(x_0)\| \le \int_0^{\|x-x_0\|} L(u)\,\mathrm{d}u \quad \text{for each } x \in \mathbf{B}(x_0, r); \tag{2.9}$$

(b) *the L-average Lipschitz condition on $\mathbf{B}(x_0, r)$ if*

$$\|G(x) - G(x')\| \le \int_{\|x'-x_0\|}^{\|x-x'\|+\|x'-x_0\|} L(u)\,\mathrm{d}u \quad \text{for all } x,\ x' \in \mathbf{B}(x_0, r) \tag{2.10}$$

$$\text{with } \|x - x'\| + \|x' - x_0\| \le r.$$

3. Regularities. Let C be a closed convex set in $\mathbb{R}^m$. Consider the inclusion

$$F(x) \in C. \tag{3.1}$$

Let $x \in \mathbb{R}^v$ and

$$\mathcal{D}(x) = \{d \in \mathbb{R}^v :\ F(x) + F'(x)d \in C\}. \tag{3.2}$$

Remark 3.1. In the case when C is the set of all minimum points of h and if there exists $d_0 \in \mathbb{R}^v$ with $\|d_0\| \le \Delta$ such that $d_0 \in \mathcal{D}(x)$, then $d_0 \in D_\Delta(x)$, and for each $d \in \mathbb{R}^v$ with $\|d\| \le \Delta$ one has

$$d \in D_\Delta(x) \Longleftrightarrow d \in \mathcal{D}(x) \Longleftrightarrow d \in D_\infty(x). \tag{3.3}$$

Remark 3.2. The set $\mathcal{D}(x)$ defined in (3.2) can be viewed as the solution set of the following "linearized" problem associated with (3.1):

$$(P_x): \qquad F(x) + F'(x)\,d \in C. \tag{3.4}$$

Thus $\beta(\|x - x_0\|)$ in (3.5) is an "error bound" in determining how far the origin is away from the solution set of (P_x).

DEFINITION 3.1. *A point $x_0 \in \mathbb{R}^v$ is called a quasi-regular point of the inclusion* (3.1) *if there exist $r \in (0, +\infty)$ and an increasing positive-valued function β on $[0, r)$ such that*

$$\mathcal{D}(x) \ne \emptyset \quad \text{and} \quad d(0, \mathcal{D}(x)) \le \beta(\|x - x_0\|)\, d(F(x), C) \quad \text{for all } x \in \mathrm{B}(x_0, r). \tag{3.5}$$

Let $\mathbf{r}_{x_0}$ denote the supremum of r such that (3.5) holds for some increasing positive-valued function β on $[0, r)$. Let $r \in [0, \mathbf{r}_{x_0}]$, and let $\mathcal{B}_r(x_0)$ denote the set of all increasing positive-valued functions β on $[0, r)$ such that (3.5) holds. Define

$$\beta_{x_0}(t) = \inf\{\beta(t) : \beta \in \mathcal{B}_{\mathbf{r}_{x_0}}(x_0)\} \quad \text{for each } t \in [0, \mathbf{r}_{x_0}). \tag{3.6}$$

Note that each $\beta \in \mathcal{B}_r(x_0)$ with $\lim_{t\to r^-} \beta(t) < +\infty$ can be extended to an element of $\mathcal{B}_{\mathbf{r}_{x_0}}(x_0)$. From this we can verify that

$$\beta_{x_0}(t) = \inf\{\beta(t) : \beta \in \mathcal{B}_r(x_0)\} \quad \text{for each } t \in [0, r). \tag{3.7}$$

We call $\mathbf{r}_{x_0}$ and β_{x_0} respectively the quasi-regular radius and the quasi-regular bound function of the quasi-regular point x_0.

DEFINITION 3.2. *A point $x_0 \in \mathbb{R}^v$ is a regular point of the inclusion* (3.1) *if*

$$\ker(F'(x_0)^T) \cap (C - F(x_0))^{\ominus} = \{0\}. \tag{3.8}$$

The notion of regularity relates to some other notions of regularity that can be found in the papers [1, 3, 20, 21, 25], which have played an important role in the study of nonsmooth optimizations. Some equivalent conditions on the regular points for (3.1) are given in [4]. In the following proposition the existence of constants r and β is due to Burke and Ferris [4], and the second assertion then follows from a remark after Definition 3.1.

PROPOSITION 3.3. *Let x_0 be a regular point of* (3.1). *Then there are constants $r > 0$ and $\beta > 0$ such that* (3.5) *holds for r and $\beta(\cdot) = \beta$; consequently, x_0 is a quasi-regular point with the quasi-regular radius $\mathbf{r}_{x_0} \geq r$ and the quasi-regular bound function $\beta_{x_0} \leq \beta$ on $[0, r]$.*

Another important link of the present study relates to Robinson's condition [18, 19] that the convex process $d \mapsto F'(x)d - C$ is onto $\mathbb{R}^m$. To see this, let us first recall the concept of convex process, which was introduced by Rockafeller [23, 24] for convexity problems (see also Robinson [19]).

DEFINITION 3.4. *A set-valued mapping $T : \mathbb{R}^v \to 2^{\mathbb{R}^m}$ is called a convex process from $\mathbb{R}^v$ to $\mathbb{R}^m$ if it satisfies*

(a) *$T(x + y) \supseteq Tx + Ty$ for all x, $y \in \mathbb{R}^v$;*

(b) *$T\lambda x = \lambda Tx$ for all $\lambda > 0$, $x \in \mathbb{R}^v$;*

(c) *$0 \in T0$.*

Thus $T : \mathbb{R}^v \to 2^{\mathbb{R}^m}$ is a convex process if and only if its graph $Gr(T)$ is a convex cone in $\mathbb{R}^v \times \mathbb{R}^m$. As usual, the domain, range, and inverse of a convex process T are respectively denoted by $\mathrm{D}(T)$, $\mathrm{R}(T)$, T^{-1}; i.e.,

$$\mathrm{D}(T) = \{x \in \mathbb{R}^v : Tx \neq \emptyset\},$$

$$\mathrm{R}(T) = \cup\{Tx : x \in \mathrm{D}(T)\},$$

$$T^{-1}y = \{x \in \mathbb{R}^v : y \in Tx\}.$$

Obviously T^{-1} is a convex process from $\mathbb{R}^m$ to $\mathbb{R}^v$. Furthermore, for a set A in an $\mathbb{R}^v$ or $\mathbb{R}^m$, it would be convenient to use the notation $\|A\|$ to denote its distance to the origin, that is,

$$\|A\| = \inf\{\|a\| : \ a \in A\}. \tag{3.9}$$

DEFINITION 3.5. *Suppose that T is a convex process. The norm of T is defined by*

$$\|T\| = \sup\{\|Tx\| : \ x \in \mathrm{D}(T), \ \ \|x\| \leq 1\}.$$

If $\|T\| < +\infty$, we say that the convex process T is normed.

For two convex processes T and S from $\mathbb{R}^v$ to $\mathbb{R}^m$, the addition and multiplication are defined respectively as follows:

$$(T+S)(x) = Tx + Sx \quad \text{for each } x \in \mathbb{R}^v,$$

$$(\lambda T)(x) = \lambda(Tx) \quad \text{for each } x \in \mathbb{R}^v \text{ and } \lambda \in \mathbb{R}.$$

Let C be a closed convex set in $\mathbb{R}^m$ and let $x \in \mathbb{R}^v$. We define T_x by

$$T_x d = F'(x)\, d - C \quad \text{for each } d \in \mathbb{R}^v. \tag{3.10}$$

Then its inverse is

$$T_x^{-1} y = \{d \in \mathbb{R}^v : \ F'(x)\, d \in y + C\} \quad \text{for each } y \in \mathbb{R}^m. \tag{3.11}$$

Note that T_x is a convex process in the case when C is a cone. Note also that $\mathrm{D}(T_x) = \mathbb{R}^v$ for each $x \in \mathbb{R}^v$ and $\mathrm{D}(T_{x_0}^{-1}) = \mathbb{R}^m$ if $x_0 \in \mathbb{R}^v$ is such that the following condition of Robinson is satisfied:

$$T_{x_0} \text{ carries } \mathbb{R}^v \text{ onto } \mathbb{R}^m. \tag{3.12}$$

Proposition 3.7 below shows that the condition of Robinson (3.12) implies that x_0 is a regular point of (3.1), and an estimate of the quasi-regular bound function is provided. For its proof we need the following lemma, which is known in [18].

LEMMA 3.6. *Let C be a closed convex cone in $\mathbb{R}^m$, and let $x_0 \in \mathbb{R}^v$ be such that the condition of Robinson* (3.12) *is satisfied. Then the following assertions hold:* (i) *$T_{x_0}^{-1}$ is normed.*

(ii) *If S is a linear transformation from $\mathbb{R}^v$ to $\mathbb{R}^m$ such that $\|T_{x_0}^{-1}\|\|S\| < 1$, then the convex process $\tilde{T}$ defined by*

$$\tilde{T} = T_{x_0} + S$$

carries $\mathbb{R}^v$ onto $\mathbb{R}^m$. Furthermore, $\tilde{T}^{-1}$ is normed and

$$\|\tilde{T}^{-1}\| \le \frac{\|T_{x_0}^{-1}\|}{1 - \|T_{x_0}^{-1}\|\|S\|}.$$

PROPOSITION 3.7. *Let $x_0 \in \mathbb{R}^v$, and let T_{x_0} be defined as in* (3.10). *Suppose that the condition of Robinson* (3.12) *is satisfied. Then the following assertions hold:*

(i) *x_0 is a regular point of* (3.1).

(ii) *Suppose further that C is a closed convex cone in $\mathbb{R}^m$ and that F' satisfies the weak L-average Lipschitz condition on $\mathbf{B}(x_0, r)$ for some $r > 0$. Let $\beta_0 = \|T_{x_0}^{-1}\|$ and let r_{β_0} be defined by*

$$\beta_0 \int_0^{r_{\beta_0}} L(u)\ \mathrm{d}u = 1 \tag{3.13}$$

(cf. (2.1)*). Then the quasi-regular radius $\mathbf{r}_{x_0}$ and the quasi-regular bound function β_{x_0} satisfy $\mathbf{r}_{x_0} \ge \min\{r, r_{\beta_0}\}$ and*

$$\beta_{x_0}(t) \le \frac{\beta_0}{1 - \beta_0 \int_0^t L(u)\ \mathrm{d}u} \quad \text{for each } t \text{ with } 0 \le t < \min\{r, r_{\beta_0}\}. \tag{3.14}$$

Proof. Suppose that the condition (3.12) is satisfied, and let y belong to the set of the intersection in (3.8). Then, in view of the definition of T_{x_0}, there exist $u \in \mathbb{R}^v$ and $c \in C$ such that $-y - F(x_0) = F'(x_0)u - c$. Hence, by (3.8),

$$\langle y, F'(x_0)u\rangle = \langle F'(x_0)^T y, u\rangle = 0 \quad \text{and} \quad \langle y, c - F(x_0)\rangle \le 0. \tag{3.15}$$

It follows that

$$\langle y, y\rangle = \langle y, c - F(x_0) - F'(x_0)u\rangle = \langle y, c - F(x_0)\rangle \le 0 \tag{3.16}$$

and hence $y = 0$. This shows that (3.8) holds, and so x_0 is a regular point of the inclusion (3.1).

Now let $r > 0$ and suppose that F' satisfies the weak L-average Lipschitz condition on $\mathbf{B}(x_0, r)$. Let $x \in \mathbb{R}^v$ such that $\|x - x_0\| < \min\{r, r_{\beta_0}\}$. Then

$$\|F'(x) - F'(x_0)\| \le \int_0^{\|x-x_0\|} L(u)\ \mathrm{d}u < \int_0^{r_{\beta_0}} L(u)\ \mathrm{d}u;$$

hence, by (3.13),

$$\|T_{x_0}^{-1}\|\|F'(x) - F'(x_0)\| < \|T_{x_0}^{-1}\| \int_0^{r_{\beta_0}} L(u)\ \mathrm{d}u = 1.$$

This with Lemma 3.6 implies that the convex process defined by

$$T_x d = F'(x)\, d - C = T_{x_0} d + [F'(x) - F'(x_0)]\, d \quad \text{for each } d \in \mathbb{R}^v$$

carries $\mathbb{R}^v$ onto $\mathbb{R}^m$ and

$$\|T_x^{-1}\| \le \frac{\|T_{x_0}^{-1}\|}{1 - \|T_{x_0}^{-1}\|\|F'(x) - F'(x_0)\|} \le \frac{\|T_{x_0}^{-1}\|}{1 - \|T_{x_0}^{-1}\| \int_0^{\|x-x_0\|} L(u)\ \mathrm{d}u}. \tag{3.17}$$

Since T_x is surjective, we have that $\mathcal{D}(x)$ is nonempty; in particular, for each $c \in C$,

$$T_x^{-1}(c - F(x)) \subseteq \mathcal{D}(x). \tag{3.18}$$

To see this, let $d \in T_x^{-1}(c - F(x))$. Then, by (3.11), one has that $F'(x)\, d \in c - F(x) + C \subseteq C - F(x)$, and so $F(x) + F'(x)\, d \in C$, that is, $d \in \mathcal{D}(x)$. Hence (3.18) is true. Consequently,

$$d(0, \mathcal{D}(x)) \le \|T_x^{-1}(c - F(x))\| \le \|T_x^{-1}\|\|c - F(x)\|.$$

Since this is valid for each $c \in C$, it is seen that

$$d(0, \mathcal{D}(x)) \le \|T_x^{-1}\| d(F(x), C).$$

Combining this with (3.17) and (3.6) gives the desired result (3.14), and the proof is complete. ∎

4. Convergence criterion. We assume throughout the remainder of this paper that C is the set of all minimum points of h. Let $x_0 \in \mathbb{R}^v$ be a quasi-regular point of the inclusion (3.1) with the quasi-regular radius $\mathbf{r}_{x_0}$ and the quasi-regular bound function β_{x_0}. Let $\eta \in [1, +\infty)$ and let

$$\xi := \eta \beta_{x_0}(0)\, d(F(x_0), C). \tag{4.1}$$

For all $\mathbf{r} \in (0, \mathbf{r}_{x_0}]$, we define

$$\alpha_0(\mathbf{r}) := \sup\left\{ \frac{\eta\beta_{x_0}(t)}{\eta\beta_{x_0}(t)\int_0^t L(u)\ \mathrm{d}u + 1} : \xi \le t < \mathbf{r} \right\}, \tag{4.2}$$

with the usual convention that $\sup\emptyset = -\infty$.

THEOREM 4.1. *Let $\eta \in [1,\infty)$ and $\Delta \in (0,\infty]$. Let $x_0 \in \mathbb{R}^v$ be a quasi-regular point of the inclusion* (3.1) *with the quasi-regular radius $\mathbf{r}_{x_0}$ and the quasi-regular bound function β_{x_0}. Let $\xi > 0$, $0 < \mathbf{r} \le \mathbf{r}_{x_0}$, and $\alpha_0(\mathbf{r})$ be as described above. Let $\alpha \ge \alpha_0(\mathbf{r})$ be a positive constant and let b_α, r_α be defined by* (2.1). *Let r_α^* denote the smaller zero of the function ϕ_α defined by* (2.2). *Suppose that F' satisfies the L-average Lipschitz condition on $\mathbf{B}(x_0, r_\alpha^*)$, and that*

$$\xi \le \min\{b_\alpha, \Delta\} \quad \textit{and} \quad r_\alpha^* \le \mathbf{r} \tag{4.3}$$

(for example, (4.3) *is satisfied if*

$$\xi \le \min\left\{ b_\alpha,\ \frac{b_\alpha}{r_\alpha}\mathbf{r},\ \Delta \right\} \tag{4.4}$$

holds). Let $\{x_n\}$ denote the sequence generated by Algorithm A (η, Δ, x_0). *Then, $\{x_n\}$ converges to some x^* such that $F(x^*) \in C$, and the following assertions hold for each $n = 1, 2, \ldots$:*

$$\|x_n - x_{n-1}\| \le t_{\alpha,n} - t_{\alpha,n-1}, \tag{4.5}$$

$$\|x_{n+1} - x_n\| \le (t_{\alpha,n+1} - t_{\alpha,n}) \left(\frac{\|x_n - x_{n-1}\|}{t_{\alpha,n} - t_{\alpha,n-1}} \right)^2, \tag{4.6}$$

$$F(x_n) + F'(x_n)(x_{n+1} - x_n) \in C, \tag{4.7}$$

and

$$\|x_{n-1} - x^*\| \le r_\alpha^* - t_{\alpha,n-1}. \tag{4.8}$$

Proof. By (2.7) and (4.4),

$$r_\alpha^* \le \frac{r_\alpha}{b_\alpha}\xi \le \mathbf{r}. \tag{4.9}$$

Hence (4.4)$\Longrightarrow$(4.3). Thus it suffices to prove the theorem for the case when (4.3) is assumed. By (4.3), (2.5), and Lemma 2.1, one has that, for each n,

$$\xi \le t_{\alpha,n} < r_\alpha^* \le \mathbf{r} \le \mathbf{r}_{x_0}. \tag{4.10}$$

By the quasi regularity assumption, it follows that

$$\mathcal{D}(x) \ne \emptyset \quad \text{and} \quad d(0, \mathcal{D}(x)) \le \beta_{x_0}(\|x - x_0\|)\, d(F(x), C) \quad \text{for each } x \in \mathbf{B}(x_0, \mathbf{r}). \tag{4.11}$$

Let $k \ge 1$. We use $\overline{1,k}$ to denote the set of all integers n satisfying $1 \le n \le k$. Below we will verify the following implication:

$$\begin{aligned} &\text{(4.5) holds for all } n \in \overline{1,k}, \text{ and (4.7) holds for } n = k-1 \\ &\qquad \Longrightarrow \text{(4.6) and (4.7) hold for } n = k. \end{aligned} \tag{4.12}$$

To do this, suppose that (4.5) holds for each $n \in \overline{1,k}$, and set

$$x_k^\tau = \tau x_k + (1-\tau)x_{k-1} \quad \text{for each } \tau \in [0,1]. \tag{4.13}$$

Note that

$$\|x_k - x_0\| \le \sum_{i=1}^{k} \|x_i - x_{i-1}\| \le \sum_{i=1}^{k} (t_{\alpha,i} - t_{\alpha,i-1}) = t_{\alpha,k} \tag{4.14}$$

and

$$\|x_{k-1} - x_0\| \le t_{\alpha,k-1} \le t_{\alpha,k}. \tag{4.15}$$

It follows from (4.13) and (4.10) that $x_k^\tau \in \mathbf{B}(x_0, r_\alpha^*) \subseteq \mathbf{B}(x_0, \mathbf{r})$ for each $\tau \in [0,1]$. Hence (4.11) holds for $x = x_k$, namely,

$$\mathcal{D}(x_k) \ne \emptyset \quad \text{and} \quad d(0, \mathcal{D}(x_k)) \le \beta_{x_0}(\|x_k - x_0\|)\, d(F(x_k), C). \tag{4.16}$$

We claim that

$$\eta d(0, \mathcal{D}(x_k)) \le (t_{\alpha,k+1} - t_{\alpha,k}) \left(\frac{\|x_k - x_{k-1}\|}{t_{\alpha,k} - t_{\alpha,k-1}} \right)^2 \le t_{\alpha,k+1} - t_{\alpha,k} \tag{4.17}$$

(the second inequality needs no proof by the assumption of (4.12)). To show the first inequality, using (4.7) for $n = k-1$ and the fact that F' satisfies an L-average Lipschitz condition on $\mathbf{B}(x_0, r_\alpha^*)$, together with the elementary identity

$$\int_0^1 \int_A^{A+\tau B} L(u)\ \mathrm{d}u\, \mathrm{d}\tau = \int_0^B L(A+u)\left(1 - \frac{u}{B}\right)\ \mathrm{d}u \quad \text{for all } A,\ B > 0, \tag{4.18}$$

we have by (4.16) that

$$\begin{aligned}
\eta d(0, \mathcal{D}(x_k)) &\le \eta \beta_{x_0}(\|x_k - x_0\|) d(F(x_k), C) \\
&\le \eta \beta_{x_0}(\|x_k - x_0\|) \|F(x_k) - F(x_{k-1}) - F'(x_{k-1})(x_k - x_{k-1})\| \\
&\le \eta \beta_{x_0}(\|x_k - x_0\|) \left\| \int_0^1 (F'(x_k^\tau) - F'(x_{k-1}))(x_k - x_{k-1})\ \mathrm{d}\tau \right\| \\
&\le \eta \beta_{x_0}(\|x_k - x_0\|) \int_0^1 \left(\int_{\|x_{k-1} - x_0\|}^{\tau\|x_k - x_{k-1}\| + \|x_{k-1} - x_0\|} L(u)\ \mathrm{d}u \right) \\
&\quad \times \|x_k - x_{k-1}\|\ \mathrm{d}\tau \\
&= \eta \beta_{x_0}(\|x_k - x_0\|) \\
&\quad \times \left(\int_0^{\|x_k - x_{k-1}\|} L(\|x_{k-1} - x_0\| + u)(\|x_k - x_{k-1}\| - u)\ \mathrm{d}u \right) \\
&\le \eta \beta_{x_0}(t_{\alpha,k}) \left(\int_0^{\|x_k - x_{k-1}\|} L(t_{\alpha,k-1} + u)(\|x_k - x_{k-1}\| - u)\ \mathrm{d}u \right),
\end{aligned}$$

where the last inequality is valid because L and β_{x_0} are increasing and thanks to (4.14) and (4.15). Since (4.5) holds for $n = k$, Lemma 2.3 implies that

$$\frac{\int_0^{\|x_k - x_{k-1}\|} L(t_{\alpha,k-1} + u)(\|x_k - x_{k-1}\| - u)\ \mathrm{d}u}{\|x_k - x_{k-1}\|^2}$$

$$\leq \frac{\int_0^{t_{\alpha,k} - t_{\alpha,k-1}} L(t_{\alpha,k-1} + u)(t_{\alpha,k} - t_{\alpha,k-1} - u)\ \mathrm{d}u}{(t_{\alpha,k} - t_{\alpha,k-1})^2},$$

and it follows from the earlier estimate that

$$\eta d(0, \mathcal{D}(x_k)) \leq \eta\beta_{x_0}(t_{\alpha,k})\left(\int_0^{t_{\alpha,k} - t_{\alpha,k-1}} L(t_{\alpha,k-1} + u)(t_{\alpha,k} - t_{\alpha,k-1} - u)\mathrm{d}u\right)$$

$$\times \left(\frac{\|x_k - x_{k-1}\|}{t_{\alpha,k} - t_{\alpha,k-1}}\right)^2. \tag{4.19}$$

Similarly by (2.2), (2.3), (2.4), and (4.18), we have

$$\begin{aligned}
\phi_\alpha(t_{\alpha,k}) &= \phi_\alpha(t_{\alpha,k}) - \phi_\alpha(t_{\alpha,k-1}) - \phi'_\alpha(t_{\alpha,k-1})(t_{\alpha,k} - t_{\alpha,k-1}) \\
&= \left(\int_0^1 [\phi'_\alpha(t_{\alpha,k-1} + \tau(t_{\alpha,k} - t_{\alpha,k-1})) - \phi'_\alpha(t_{\alpha,k-1})]\ \mathrm{d}\,\tau\right)(t_{\alpha,k} - t_{\alpha,k-1}) \\
&= \left(\alpha\int_0^1 \int_{t_{\alpha,k-1}}^{\tau(t_{\alpha,k} - t_{\alpha,k-1}) + t_{\alpha,k-1}} L(u)\ \mathrm{d}u\ \mathrm{d}\tau\right)(t_{\alpha,k} - t_{\alpha,k-1}) \\
&= \alpha\int_0^{t_{\alpha,k} - t_{\alpha,k-1}} L(t_{\alpha,k-1} + u)(t_{\alpha,k} - t_{\alpha,k-1} - u)\ \mathrm{d}u. \qquad (4.20)
\end{aligned}$$

On the other hand, by (4.10) and (4.2),

$$\frac{\eta\beta_{x_0}(t_{\alpha,k})}{\alpha_0(\mathbf{r})} \leq \left(1 - \alpha_0(\mathbf{r})\int_0^{t_{\alpha,k}} L(u)\,\mathrm{d}u\right)^{-1}.$$

Since $\alpha \geq \alpha_0(\mathbf{r})$ and by (2.3), it follows that

$$\frac{\eta\beta_{x_0}(t_{\alpha,k})}{\alpha} \leq \left(1 - \alpha\int_0^{t_{\alpha,k}} L(u)\ \mathrm{d}u\right)^{-1} = -(\phi'_\alpha(t_{\alpha,k}))^{-1}. \tag{4.21}$$

Combining (4.19)–(4.21) together with (2.4), the first inequality in (4.17) is seen to hold. Moreover, by Lemma 2.4 and (4.3), we have

$$t_{\alpha,k+1} - t_{\alpha,k} = -\phi'_\alpha(t_{\alpha,k})^{-1}\phi_\alpha(t_{\alpha,k}) \leq -\phi'_\alpha(t_{\alpha,0})^{-1}\phi_\alpha(t_{\alpha,0}) = \xi \leq \Delta,$$

so (4.17) implies that $d(0, \mathcal{D}(x_k)) \leq \Delta$. Hence there exists $d_0 \in \mathbb{R}^v$ with $\|d_0\| \leq \Delta$ such that $F(x_k) + F'(x_k)d_0 \in C$. Consequently, by Remark 3.1,

$$D_\Delta(x_k) = \{d \in \mathbb{R}^v : \|d\| \leq \Delta,\ F(x_k) + F'(x_k)d \in C\}$$

and

$$d(0, D_\Delta(x_k)) = d(0, \mathcal{D}(x_k)).$$

Since $d_k = x_{k+1} - x_k \in D_\Delta(x_k)$ by Algorithm A (η, Δ, x_0), it follows that (4.7) holds for $n = k$. Furthermore, one has that

$$\|x_{k+1} - x_k\| \le \eta d(0, D_\Delta(x_k)) = \eta d(0, \mathcal{D}(x_k)).$$

This with (4.17) yields that (4.6) holds for $n = k$, and hence implication (4.12) is proved.

Clearly, if (4.5) holds for each $n = 1, 2, \ldots$, then $\{x_n\}$ is a Cauchy sequence by the monotonicity of $\{t_n\}$ and hence converges to some x^*. Thus (4.8) is clear. Therefore, to prove the theorem, we need to prove only that (4.5), (4.6), and (4.7) hold for each $n = 1, 2, \ldots$. We will proceed by mathematical induction. First, by (4.1), (4.3), and (4.11), $\mathcal{D}(x_0) \ne \emptyset$ and

$$\eta d(0, \mathcal{D}(x_0)) \le \eta \beta_{x_0}(\|x_0 - x_0\|)\, d(F(x_0), C) = \eta \beta_{x_0}(0) d(F(x_0), C) = \xi \le \Delta.$$

Then using the same arguments just used above, we have that (4.7) holds for $n = 0$ and

$$\|x_1 - x_0\| = \|d_0\| \le \eta d(0, D_\Delta(x_0)) \le \eta \beta_{x_0}(0) d(F(x_0), C) = \xi = t_{\alpha,1} - t_{\alpha,0};$$

that is, (4.5) holds for $n = 1$. Thus, by (4.12), (4.6) and (4.7) hold for $n = 1$. Furthermore, assume that (4.5), (4.6), and (4.7) hold for all $1 \le n \le k$. Then

$$\|x_{k+1} - x_k\| \le (t_{\alpha,k+1} - t_{\alpha,k}) \left(\frac{\|x_k - x_{k-1}\|}{t_{\alpha,k} - t_{\alpha,k-1}} \right)^2 \le t_{\alpha,k+1} - t_{\alpha,k}.$$

This shows that (4.5) holds for $n = k + 1$, and hence (4.5) holds for all n with $1 \le n \le k+1$. Thus, (4.12) implies that (4.6) and (4.7) hold for $n = k+1$. Therefore, (4.5), (4.6), and (4.7) hold for each $n = 1, 2, \ldots$. The proof is complete. □

Remark 4.1. (a) In Theorem 4.1 if one assumes in addition that either (i) $\xi < b_\alpha$ or (ii) $\alpha > \alpha_0 := \alpha_0(\mathbf{r})$, then the convergence of the sequence $\{x_n\}$ is of quadratic rate. For the case of (i), this remark follows immediately from Lemma 2.1(iii) thanks to (4.5) and (4.8). If (ii) is assumed, then, by Lemma 2.2, $\xi \le b_\alpha < b_{\alpha_0}$ and $r^*_{\alpha_0} \le r^*_\alpha \le \mathbf{r}$. Hence (4.3) holds with α_0 in place of α. Since $\xi < b_{\alpha_0}$, we are now in the case (i) if α is replaced by α_0, and hence our remark here is established.

(b) Refinements for results presented in the remainder of this paper can also be established in a similar manner as in (a) above.

Remark 4.2. Suppose that there exists a pair $(\bar\alpha, \bar{\mathbf{r}})$ such that

$$\begin{cases} \bar\alpha = \alpha_0(\bar{\mathbf{r}}), \\ r^*_{\bar\alpha} = \bar{\mathbf{r}}. \end{cases} \tag{4.22}$$

Note that the function $\alpha \mapsto b_\alpha$ is decreasing by Lemma 2.2. Then, if (4.3) holds for some $(\alpha, \mathbf{r})$ with $\alpha \ge \bar\alpha$ and $r \ge \bar{\mathbf{r}}$, (4.3) does for $(\alpha, \mathbf{r}) = (\bar\alpha, \bar{\mathbf{r}})$ (and hence Theorem 4.1 is applicable).

Recall from Proposition 3.3 that the assumption for the existence of r, β in the following corollary is automatically satisfied when $x_0 \in \mathbb{R}^v$ is a regular point of the inclusion (3.1). This remark also applies to Theorems 5.1 and 5.6 and Corollary 5.2.

COROLLARY 4.2. *Let $x_0 \in \mathbb{R}^v$ be a regular point of the inclusion* (3.1) *with $r > 0$ and $\beta > 0$ such that*

$$\mathcal{D}(x) \ne \emptyset \quad \text{and} \quad d(0, \mathcal{D}(x)) \le \beta\, d(F(x), C) \quad \text{for all } x \in \mathrm{B}(x_0, r). \tag{4.23}$$

Let $\eta \in [1,\infty)$, $\Delta \in (0,\infty]$, $\xi = \eta\beta d(F(x_0), C)$,

$$\alpha = \frac{\eta\beta}{1+\eta\beta\int_0^{\xi} L(u)\mathrm{d}\,u}, \tag{4.24}$$

and let b_α, r_α be defined by (2.1). *Let r_α^* denote the smaller zero of the function ϕ_α defined by* (2.2). *Suppose that F' satisfies the L-average Lipschitz condition on $\mathbf{B}(x_0, r_\alpha^*)$ and that*

$$\xi \le \min\{b_\alpha, \Delta\} \quad \textit{and} \quad r_\alpha^* \le r \tag{4.25}$$

(for example, (4.25) *is satisfied if*

$$\xi \le \min\left\{b_\alpha,\ \frac{b_\alpha}{r_\alpha} r,\ \Delta\right\} \tag{4.26}$$

holds). Then the conclusions of Theorem 4.1 *hold.*

Proof. Note that $\xi < {r_\alpha}^* \le r$ by Lemma 2.1 and (4.25). By (3.6) and (3.7), it is clear that $\mathbf{r}_{x_0} \ge r$ and $\beta_{x_0}(\cdot) \le \beta$ on $[0, r)$. Let $\mathbf{r} := r$, and let $\alpha_0(\mathbf{r})$ be defined by (4.2) as in Theorem 4.1. Then, by (4.24), we have that

$$\alpha \ge \frac{\eta\beta_{x_0}(t)}{1+\eta\beta_{x_0}(t)\int_0^t L(u)\,\mathrm{d}u} \quad \text{for each } t \in [\xi, r).$$

Hence $\alpha \ge \alpha_0(\mathbf{r})$ by (4.2). Note that (4.26) (resp., (4.25)) is identical to (4.4) (resp., (4.3)); Theorem 4.1 is applicable, and the proof is complete. □

COROLLARY 4.3. *Let $\eta \in [1, +\infty)$, $\Delta \in (0, +\infty]$, and let C be a cone. Let $x_0 \in \mathbb{R}^v$ be such that T_{x_0} carries $\mathbb{R}^v$ onto $\mathbb{R}^m$. Let*

$$\xi = \eta\|T_{x_0}^{-1}\|\, d(F(x_0), C), \tag{4.27}$$

$$\alpha = \frac{\eta\|T_{x_0}^{-1}\|}{1+(\eta-1)\|T_{x_0}^{-1}\|\int_0^{\xi} L(u)\ \mathrm{d}u}, \tag{4.28}$$

and let b_α, r_α be defined by (2.1). *Let r_α^* denote the smaller zero of the function ϕ_α defined by* (2.2). *Suppose that F' satisfies the L-average Lipschitz condition on $\mathbf{B}(x_0, r_\alpha^*)$ and that*

$$\xi \le \min\{b_\alpha, \Delta\}. \tag{4.29}$$

Then the conclusions of Theorem 4.1 *hold.*

Proof. Let $\beta_0 = \|T_{x_0}^{-1}\|$, and let r_{β_0} be defined by (3.13). Then, by Proposition 3.7(ii), we know that x_0 is a quasi-regular point with the quasi-regular radius

$$\mathbf{r}_{x_0} \ge \min\{r_\alpha^*, r_{\beta_0}\} \tag{4.30}$$

and the quasi-regular bound function

$$\beta_{x_0}(t) \le \frac{\beta_0}{1-\beta_0\int_0^t L(u)\ \mathrm{d}u} \quad \text{for each } t \text{ with } 0 \le t < \min\{r_\alpha^*, r_{\beta_0}\}. \tag{4.31}$$

Let $\mathbf{r} := \min\{r^*_\alpha, r_{\beta_0}\}$, and let $\alpha_0(\mathbf{r})$ be defined by (4.2). We claim that

$$\alpha \geq \alpha_0(\mathbf{r}) \tag{4.32}$$

and

$$r_{\beta_0} \geq r^*_\alpha. \tag{4.33}$$

Granting this, the minimum on the right-hand side of (4.30) is simply r^*_α, and so $\mathbf{r} = r^*_\alpha \leq \mathbf{r}_{x_0}$. Moreover, we note that $\beta_{x_0}(0) \leq \beta_0$ by (4.31), and so the ξ defined by (4.1) is majorized by that defined by (4.27); thus (4.29) entails that (4.3) holds and Theorem 4.1 is applicable. Therefore we need only to prove our claim. Note by (4.31) that, for each $\xi \leq t < \min\{r^*_\alpha, r_{\beta_0}\} = \mathbf{r}$, we have

$$\eta \int_0^t L(u)\ \mathrm{d}u + \frac{1}{\beta_{x_0}(t)} \geq \frac{1}{\beta_0} + (\eta-1)\int_0^t L(u)\ \mathrm{d}u \geq \frac{1}{\beta_0} + (\eta-1)\int_0^\xi L(u)\ \mathrm{d}u; \tag{4.34}$$

that is,

$$\frac{\beta_{x_0}(t)}{1+\eta\beta_{x_0}(t)\int_0^t L(u)\mathrm{d}u} \leq \frac{\beta_0}{1+(\eta-1)\beta_0\int_0^t L(u)\mathrm{d}u}. \tag{4.35}$$

Thus (4.32) follows by definitions of $\alpha_0(\mathbf{r})$ and of α, respectively given by (4.2) and (4.28). To verify (4.33), consider the two cases (i) $\alpha \geq \beta_0$ and (ii) $\alpha < \beta_0$. In (i), since by Lemma 2.2, r_α is decreasing with respect to α, we have that $r^*_\alpha \leq r_\alpha \leq r_{\beta_0}$. In (ii), since r^*_α is increasing with respect to α by Lemma 2.2, we have that $r^*_\alpha \leq r^*_{\beta_0} \leq r_{\beta_0}$. Therefore, (4.33) holds in all cases, and the proof is complete. □

Remark 4.3. (a) If the strict inequalities in (4.25) (resp., (4.29)) of Corollary 4.2 (resp., Corollary 4.3) hold, then the starting point x_0 of the sequence $\{x_n\}$ can be replaced by a nearby point; that is, there exists a neighborhood $U(x_0)$ of x_0 such that the sequence $\{x_n\}$ generated by Algorithm A $(\eta, \Delta, \bar{x})$ with initial point $\bar{x}$ from $U(x_0)$ converges to some solution of the inclusion problem (3.1) at a quadratic rate.

(b) Refinements for results presented in the remainder of this paper can also be established in a similar manner as in (a) above.

5. Special cases and applications. This section is devoted to some applications. First we specialize results of the preceding section to two important cases of the function L: L =constant and $L = \frac{2\gamma}{(1-\gamma u)^3}$. Second, mimicking Smale's γ-theory about the approximation zeros for Newton's method in solving nonlinear equations, we do the same for the Gauss–Newton method in solving composite convex optimization.

5.1. Kantorovich type. Throughout this subsection, we assume that the function L is a constant function. Then, by (2.1) and (2.2), we have that, for all $\alpha > 0$,

$$r_\alpha = \frac{1}{\alpha L}, \quad b_\alpha = \frac{1}{2\alpha L} \tag{5.1}$$

and

$$\phi_\alpha(t) = \xi - t + \frac{\alpha L}{2}t^2.$$

Moreover, if $\xi \leq \frac{1}{2\alpha L}$, then the zeros of ϕ_α are given by

$$\left.\begin{matrix} r^*_\alpha \\ r^{**}_\alpha \end{matrix}\right\} = \frac{1 \mp \sqrt{1-2\alpha L\xi}}{\alpha L}. \tag{5.2}$$

It is also known (see, for example, [8, 17, 29]) that $\{t_{\alpha,n}\}$ has the closed form

$$t_{\alpha,n} = \frac{1 - q_\alpha^{2^n-1}}{1 - q_\alpha^{2^n}} r_\alpha^* \quad \text{for each } n = 0, 1, \ldots, \tag{5.3}$$

where

$$q_\alpha := \frac{r_\alpha^*}{r_\alpha^{**}} = \frac{1 - \sqrt{1 - 2\alpha L\xi}}{1 + \sqrt{1 - 2\alpha L\xi}}. \tag{5.4}$$

For the present case (L is a positive constant), a commonly used version of Lipschitz continuity on $\mathbf{B}(x_0, r)$ is of course the following: a function G is Lipschitz continuous with modulus L (Lipschitz constant) if

$$\|G(x_1) - G(x_2)\| \le L\|x_1 - x_2\| \quad \text{for all } x_1,\, x_2 \in \mathbf{B}(x_0, r).$$

Clearly, this is a stronger requirement than the corresponding ones given in Definition 2.5. Although the weaker requirement of Definition 2.5(b) is sufficient for results in this subsection, we prefer to use the Lipschitz continuity in this regard to be in line with the common practice.

THEOREM 5.1. *Let $x_0 \in \mathbb{R}^v$ be a regular point of the inclusion* (3.1) *with $r > 0$ and $\beta > 0$ such that* (4.23) *holds. Let $L \in (0, +\infty)$, $\eta \in [1, +\infty)$, $\Delta \in (0, +\infty]$, $\xi = \eta\beta d(F(x_0), C)$,*

$$R^* = \frac{1 + L\eta\beta\xi - \sqrt{1 - (L\eta\beta\xi)^2}}{L\eta\beta} \quad \textit{and} \quad Q = \frac{1 - \sqrt{1 - (L\eta\beta\xi)^2}}{L\eta\beta\xi}. \tag{5.5}$$

Assume that F' is Lipschitz continuous on $\mathbf{B}(x_0, R^*)$ with modulus L, and that

$$\xi \le \min\left\{\frac{1}{L\beta\eta},\ \Delta\right\} \quad \textit{and} \quad r \ge R^* \tag{5.6}$$

(for example, (5.6) *is satisfied if*

$$\xi \le \min\left\{\frac{1}{L\beta\eta},\ \frac{1}{2}r,\ \Delta\right\} \tag{5.7}$$

holds). Let $\{x_n\}$ denote the sequence generated by Algorithm A *(η, Δ, x_0). Then $\{x_n\}$ converges to some x^* with $F(x^*) \in C$ and*

$$\|x_n - x^*\| \le \frac{Q^{2^n-1}}{\sum_{i=0}^{2^n-1} Q^i} R^* \quad \textit{for each } n = 0, 1, \ldots. \tag{5.8}$$

Proof. Let α be given as in (4.24), namely, $\alpha = \frac{\eta\beta}{1+L\eta\beta\xi}$. Moreover, by (5.1)–(5.5), one has that

$$r_\alpha^* = R^*, \quad q_\alpha = Q, \quad r_\alpha = \frac{1 + L\eta\beta\xi}{L\eta\beta}, \quad b_\alpha = \frac{1 + L\eta\beta\xi}{2L\eta\beta} \tag{5.9}$$

and

$$t_{\alpha,n} = \frac{1 - Q^{2^n-1}}{1 - Q^{2^n}} R^*. \tag{5.10}$$

Hence condition (4.3) (resp., (4.4)) is equivalent to the three inequalities

$$\xi \le \frac{1+L\eta\beta\xi}{2L\eta\beta}, \quad \xi \le \Delta, \quad \text{and} \quad r^*_\alpha \le r \ \left(\text{resp., } \ \xi \le \frac{b_\alpha}{r_\alpha} r\right),$$

and is hence, by (5.9), also equivalent to condition (5.6) (resp., (5.7)). Thus we apply Corollary 4.2 to conclude that the sequence $\{x_n\}$ converges to some x^* with $F(x^*) \in C$ and, for each $n = 1, 2, \ldots,$

$$\|x_n - x^*\| \le r^*_\alpha - t_{\alpha,n}.$$

Noting, by (5.9) and (5.10), that

$$r^*_\alpha - t_{\alpha,n} = \left(1 - \frac{1-Q^{2^n-1}}{1-Q^{2^n}}\right) R^* = \frac{Q^{2^n-1}}{\sum_{i=0}^{2^n-1} Q^i} R^*,$$

it follows that (5.8) holds, and the proof is complete. □

The following corollary (which requires no proof by virtue of Theorem 5.1 and Remark 4.3(a)) is a slight extension of [13, Theorem 1] (which, in turn, extends a result of Burke and Ferris [4, Theorem 4.1]), and our conditions such as (5.11) are more direct than the corresponding ones in [13]. In fact, the conditions (a)–(c) of [13, Theorem 1] clearly imply the condition (5.11) below. Moreover, by (a) and (b) of [13, Theorem 1], $\bar\delta > 4\eta\bar\beta d(F(\bar x), C) = 4\bar\xi$. Since, for each $\xi \le \frac{1}{L\bar\beta\eta}$,

$$\frac{1+L\eta\bar\beta\bar\xi - \sqrt{1-(L\eta\bar\beta\bar\xi)^2}}{L\eta\bar\beta\bar\xi} \le 2,$$

one has that

$$\frac{1+L\eta\bar\beta\bar\xi - \sqrt{1-(L\eta\bar\beta\bar\xi)^2}}{L\eta\bar\beta} = \frac{1+L\eta\bar\beta\bar\xi - \sqrt{1-(L\eta\bar\beta\bar\xi)^2}}{L\eta\bar\beta\bar\xi}\bar\xi \le 2\bar\xi < \bar\delta.$$

Hence, $\bar r^* := \bar\delta$ satisfies the requirements of Corollary 5.2 below.

COROLLARY 5.2. *Let $\bar x \in \mathbb{R}^v$ be a regular point of the inclusion* (3.1) *with positive constants $\bar r$ and $\bar\beta$ satisfying* (4.23) *in place of r and β, respectively. Let $L \in (0, +\infty)$, $\eta \in [1, +\infty)$, $\Delta \in (0, +\infty]$, $\bar\xi = \eta\bar\beta d(F(\bar x), C)$, and let $\bar r^* > \frac{1+L\eta\bar\beta\bar\xi - \sqrt{1-(L\eta\bar\beta\bar\xi)^2}}{L\eta\bar\beta}$. Assume that F' is Lipschitz continuous on $\mathbf{B}(\bar x, \bar r^*)$ with modulus L, and that*

$$\bar\xi < \min\left\{\frac{1}{L\bar\beta\eta}, \ \frac{1}{2}\bar r, \ \Delta\right\}. \tag{5.11}$$

Then, there exists a neighborhood $U(\bar x)$ of $\bar x$ such that the sequence $\{x_n\}$ generated by Algorithm A *(η, Δ, x_0) with $x_0 \in U(\bar x)$ converges at a quadratic rate to some x^* with $F(x^*) \in C$, and the estimate* (5.8) *holds.*

THEOREM 5.3. *Let $\eta \in [1, +\infty)$, $\Delta \in (0, +\infty]$, and let C be a cone. Let $x_0 \in \mathbb{R}^v$ be such that T_{x_0} carries $\mathbb{R}^v$ onto $\mathbb{R}^m$. Let $L \in (0, +\infty)$ and $\xi = \eta\|T^{-1}_{x_0}\| d(F(x_0), C)$. Instead of* (5.5)*, we write*

$$R^* = \frac{1+(\eta-1)L\|T^{-1}_{x_0}\|\xi - \sqrt{1-2L\|T^{-1}_{x_0}\|\xi - (\eta^2-1)(L\|T^{-1}_{x_0}\|\xi)^2}}{L\|T^{-1}_{x_0}\|\eta} \tag{5.12}$$

and

$$Q = \frac{1 - L\|T_{x_0}^{-1}\|\xi - \sqrt{1 - 2L\|T_{x_0}^{-1}\|\xi - (\eta^2 - 1)(L\|T_{x_0}^{-1}\|\xi)^2}}{L\|T_{x_0}^{-1}\|\eta\xi}. \tag{5.13}$$

Suppose that F' is Lipschitz continuous on $\mathbf{B}(x_0, R^*)$ with modulus L, and that

$$\xi \le \min\left\{\frac{1}{L\|T_{x_0}^{-1}\|(\eta+1)}, \Delta\right\}. \tag{5.14}$$

Then, the same conclusions hold as in Theorem 5.1.

Proof. Let α be defined as in (4.28); that is, $\alpha = \frac{\eta\|T_{x_0}^{-1}\|}{1+(\eta-1)L\|T_{x_0}^{-1}\|\xi}$. Then, by (5.1), the following equivalences hold:

$$\xi \le b_\alpha \Longleftrightarrow 2L\xi\eta\|T_{x_0}^{-1}\| \le 1 + (\eta-1)L\|T_{x_0}^{-1}\|\xi \Longleftrightarrow \xi L\|T_{x_0}^{-1}\|(1+\eta) \le 1;$$

that is, (4.29) and (5.14) are equivalent. Moreover, it is easy to verify that R^* and Q defined in (5.12) and (5.13), respectively, are equal to r_α^* and q_α defined in (5.2) and (5.4). Therefore, one can complete the proof in the same way as for Theorem 5.1 but using Corollary 4.3 in place of Corollary 4.2. ∎

5.2. Smale's type. Let $\gamma > 0$. For the remainder of this section we assume that L is the function defined by

$$L(u) = \frac{2\gamma}{(1-\gamma u)^3} \quad \text{for each } u \text{ with } 0 \le u < \frac{1}{\gamma}. \tag{5.15}$$

Then, by (2.1), (2.2), and elementary calculation (cf. [28]), one has that for all $\alpha > 0$,

$$r_\alpha = \left(1 - \sqrt{\frac{\alpha}{1+\alpha}}\right)\frac{1}{\gamma}, \quad b_\alpha = \left(1 + 2\alpha - 2\sqrt{\alpha(1+\alpha)}\right)\frac{1}{\gamma} \tag{5.16}$$

and

$$\phi_\alpha(t) = \xi - t + \frac{\alpha\gamma t^2}{1-\gamma t} \quad \text{for each } t \text{ with } 0 \le t < \frac{1}{\gamma}. \tag{5.17}$$

Thus, from [28], we have the following lemma.

LEMMA 5.4. *Let $\alpha > 0$. Assume that $\xi \le b_\alpha$, namely,*

$$\gamma\xi \le 1 + 2\alpha - 2\sqrt{\alpha(1+\alpha)}. \tag{5.18}$$

Then the following assertions hold:

(i) *ϕ_α has two zeros given by*

$$\left.\begin{matrix} r_\alpha^* \\ r_\alpha^{**} \end{matrix}\right\} = \frac{1 + \gamma\xi \mp \sqrt{(1+\gamma\xi)^2 - 4(1+\alpha)\gamma\xi}}{2(1+\alpha)\gamma}.$$

(ii) *The sequence $\{t_{\alpha,n}\}$ generated by Newton's method for ϕ_α with initial point $t_{\alpha,0} = 0$ has the closed form*

$$t_{\alpha,n} = \frac{1 - q_\alpha^{2^n-1}}{1 - q_\alpha^{2^n-1}p_\alpha} r_\alpha^* \quad \textit{for each } n = 0, 1, \ldots, \tag{5.19}$$

where

$$q_\alpha := \frac{1-\gamma\xi-\sqrt{(1+\gamma\xi)^2-4(1+\alpha)\gamma\xi}}{1-\gamma\xi+\sqrt{(1+\gamma\xi)^2-4(1+\alpha)\gamma\xi}} \quad \textit{and} \tag{5.20}$$

$$p_\alpha := \frac{1+\gamma\xi-\sqrt{(1+\gamma\xi)^2-4(1+\alpha)\gamma\xi}}{1+\gamma\xi+\sqrt{(1+\gamma\xi)^2-4(1+\alpha)\gamma\xi}}.$$

(iii)

$$\frac{t_{\alpha,n+1}-t_{\alpha,n}}{t_{\alpha,n}-t_{\alpha,n-1}} = \frac{1-q_\alpha^{2^n}}{1-q_\alpha^{2^{n-1}}}\cdot\frac{1-q_\alpha^{2^{n-1}-1}p_\alpha}{1-q_\alpha^{2^{n+1}-1}p_\alpha}q_\alpha^{2^{n-1}} \le {q_\alpha}^{2^n-1}. \tag{5.21}$$

For the following lemma, we define, for $\xi > 0$,

$$I(\xi) = \{\alpha > 0 :\ \xi \le b_\alpha\} = \{\alpha > 0 :\ \gamma\xi \le 1 + 2\alpha - 2\sqrt{\alpha(1+\alpha)}\}. \tag{5.22}$$

Sometimes in order to emphasize the dependence, we write $q(\alpha,\xi)$ for q_α defined by (5.20).

LEMMA 5.5. *The following assertions hold:*

(i) *For each $\alpha > 0$, the function $q(\alpha,\cdot)$ is strictly increasing on $(0, b_\alpha]$.*

(ii) *For each $\xi > 0$, the function $q(\cdot,\xi)$ is strictly increasing on $I(\xi)$.*

Proof. We prove only the assertion (i), as (ii) can be proved similarly. Let $\alpha > 0$. Define

$$g_1(t) = (1+t)^2 - 4(1+\alpha)t \quad \text{for each } t$$

and

$$g_2(t) = 1 - t + \sqrt{g_1(t)} \quad \text{for each } t \in (0, 1+2\alpha-2\sqrt{\alpha(1+\alpha)}].$$

Then,

$$g_1'(t) = 2(1+t) - 4(1+\alpha) \quad \text{for each } t$$

and

$$g_2'(t) = -1 + \frac{g_1'(t)}{2\sqrt{g_1(t)}} = \frac{g_1'(t) - 2\sqrt{g_1(t)}}{2\sqrt{g_1(t)}} \quad \text{for each } t \in (0, 1+2\alpha-2\sqrt{\alpha(1+\alpha)}].$$

Define

$$g(t) = 1 - \frac{2\sqrt{g_1(t)}}{g_2(t)} \quad \text{for each } t \in (0, 1+2\alpha-2\sqrt{\alpha(1+\alpha)}].$$

Then, for each $t \in (0, 1+2\alpha-2\sqrt{\alpha(1+\alpha)}]$,

$$g'(t) = -\frac{g_1'(t)g_2(t) + 2g_1(t) - \sqrt{g_1(t)}g_1'(t)}{g_2^2(t)\sqrt{g_1(t)}} = -\frac{(1-t)g_1'(t) + 2g_1(t)}{g_2^2(t)\sqrt{g_1(t)}}.$$

Since (as can be verified easily)

$$(1-t)g_1'(t) + 2g_1(t) = -4\alpha(1+t) < 0,$$

it follows that $g' > 0$ on $(0, 1 + 2\alpha - 2\sqrt{\alpha(1+\alpha)}]$, and hence g is increasing on $(0, 1 + 2\alpha - 2\sqrt{\alpha(1+\alpha)}]$. Noting that

$$q(\alpha, \xi) = g(\gamma\xi) \quad \text{for each } \xi \in (0, b_\alpha],$$

the desired conclusion holds. The proof is complete. □

THEOREM 5.6. *Let $x_0 \in \mathbb{R}^v$ be a regular point of the inclusion (3.1) with $r > 0$ and $\beta > 0$ such that (4.23) holds. Let $\eta \in [1, +\infty)$, $\Delta \in (0, +\infty]$, $\xi = \eta\beta d(F(x_0), C)$, and $\alpha = \frac{\eta\beta(1-\gamma\xi)^2}{\eta\beta + (1-\eta\beta)(1-\gamma\xi)^2}$. Set*

$$r^*_\alpha = \frac{1 + \gamma\xi - \sqrt{(1+\gamma\xi)^2 - 4(1+\alpha)\gamma\xi}}{2(1+\alpha)\gamma} \quad \text{and} \tag{5.23}$$

$$q_\alpha = \frac{1 - \gamma\xi - \sqrt{(1+\gamma\xi)^2 - 4(1+\alpha)\gamma\xi}}{1 - \gamma\xi + \sqrt{(1+\gamma\xi)^2 - 4(1+\alpha)\gamma\xi}}.$$

Assume that F' satisfies the L-average Lipschitz condition on $\mathbf{B}(x_0, r^*_\alpha)$ and that

$$\xi \le \min\left\{ \frac{1 + 2\eta\beta - 2\sqrt{\eta\beta(1+\eta\beta)}}{\gamma},\ \frac{\left(1 + 2\eta\beta - 2\sqrt{\eta\beta(1+\eta\beta)}\right)(1+\eta\beta)}{1 + \eta\beta - \sqrt{\eta\beta(1+\eta\beta)}} r,\ \Delta \right\}. \tag{5.24}$$

Let $\{x_n\}$ denote the sequence generated by Algorithm A (η, Δ, x_0). *Then $\{x_n\}$ converges at a quadratic rate to some x^* with $F(x^*) \in C$, and the following assertions hold:*

$$\|x_n - x^*\| \le {q_\alpha}^{2^n - 1} r^*_\alpha \quad \text{for all } n = 0, 1, \ldots \tag{5.25}$$

and

$$\|x_{n+1} - x_n\| \le q_\alpha^{2^{n-1}} \|x_n - x_{n-1}\| \quad \text{for all } n = 1, 2, \ldots . \tag{5.26}$$

Proof. By (5.15), $\int_0^\xi L(u)\,\mathrm{d}u = (1-\gamma\xi)^{-2} - 1$; hence α given in the statement of the theorem is consistent with (4.24). Set $\alpha' = \eta\beta$. Then, by (5.16),

$$b_{\alpha'} = \frac{1}{\gamma}\left(1 + 2\eta\beta - 2\sqrt{\eta\beta(1+\eta\beta)}\right) \tag{5.27}$$

and

$$\frac{b_{\alpha'}}{r_{\alpha'}} = \frac{\left(1 + 2\eta\beta - 2\sqrt{\eta\beta(1+\eta\beta)}\right)(1+\eta\beta)}{1 + \eta\beta - \sqrt{\eta\beta(1+\eta\beta)}}.$$

Thus (5.24) reads

$$\xi \le \min\left\{ b_{\alpha'},\ \frac{b_{\alpha'}}{r_{\alpha'}} r,\ \Delta \right\}. \tag{5.28}$$

Since $\gamma\xi < 1$ by (5.24), it is clear from the definition of α that $\alpha < \alpha'$ if $\xi > 0$ and $\alpha = \alpha'$ if $\xi = 0$. Since the function $u \mapsto b_u$ strictly decreasing by Lemma 2.2, it follows that if $\xi > 0$,

$$b_{\alpha'} < b_\alpha. \tag{5.29}$$

We claim that

$$\xi < b_\alpha, \quad \xi \le \Delta, \quad \text{and} \quad r_\alpha^* < r. \tag{5.30}$$

In fact, this claim is trivially true if $\xi = 0$, and so we can assume that $\xi > 0$. Then the first two inequalities follow from (5.28) and (5.29), while the last inequality follows from the fact that $r_\alpha^* < r_{\alpha'}^* \le \frac{r_{\alpha'}}{b_{\alpha'}}\xi \le r$ thanks to (5.28), Lemma 2.1(i), and Lemma 2.2(iii). Therefore, (5.30) is true. Moreover, by (5.30) and (5.16), $\gamma\xi < 1 + 2\alpha - 2\sqrt{\alpha(1+\alpha)}$, the smaller root of the function $t :\to (1+t)^2 - 4(1+\alpha)t$. Therefore, $(1+\gamma\xi)^2 - 4(1+\alpha)\gamma\xi > 0$, and so $q_\alpha < 1$ by (5.23). Now, by Corollary 4.2, the sequence $\{x_n\}$ converges to some x^* with $F(x^*) \in C$, and the following estimates hold for each n:

$$\|x_n - x^*\| \le r_\alpha^* - t_{\alpha,n}, \tag{5.31}$$

$$\begin{aligned} \|x_{n+1} - x_n\| &\le (t_{\alpha,n+1} - t_{\alpha,n}) \left(\frac{\|x_n - x_{n-1}\|}{t_{\alpha,n} - t_{\alpha,n-1}}\right)^2 \\ &\le \left(\frac{t_{\alpha,n+1} - t_{\alpha,n}}{t_{\alpha,n} - t_{\alpha,n-1}}\right) \|x_n - x_{n-1}\|. \end{aligned} \tag{5.32}$$

Hence (5.25) and (5.26) are true because, by (5.19) and (5.21), one has

$$r_\alpha^* - t_{\alpha,n} = \frac{q_\alpha^{2^n-1}(1-p_\alpha)}{1 - q_\alpha^{2^n-1}p_\alpha} r_\alpha^* \le {q_\alpha}^{2^n-1} r_\alpha^* \tag{5.33}$$

and

$$\frac{t_{\alpha,n+1} - t_{\alpha,n}}{t_{\alpha,n} - t_{\alpha,n-1}} \le {q_\alpha}^{2^n-1}. \tag{5.34}$$

Thus the convergence of $\{x_n\}$ is quadratic, and the proof is complete. □

The following result can be proved similarly, but applying Corollary 4.3 in place of Corollary 4.2, and using $\alpha' := \eta\|T_{x_0}^{-1}\|$ (thus $b_{\alpha'} = \frac{1+2\eta\|T_{x_0}^{-1}\| - 2\sqrt{\eta\|T_{x_0}^{-1}\|(1+\eta\|T_{x_0}^{-1}\|)}}{\gamma}$).

THEOREM 5.7. *Let $\eta \in [1, +\infty)$, $\Delta \in (0, +\infty]$, and let C be a cone. Let $x_0 \in \mathbb{R}^v$ such that T_{x_0} carries $\mathbb{R}^v$ onto $\mathbb{R}^m$. Let $\xi = \eta\|T_{x_0}^{-1}\| d(F(x_0), C)$ and*

$$\alpha = \frac{\eta\|T_{x_0}^{-1}\|(1-\gamma\xi)^2}{(\eta-1)\|T_{x_0}^{-1}\| + (1 - (\eta-1)\|T_{x_0}^{-1}\|)(1-\gamma\xi)^2}.$$

Set, as in (5.23),

$$r_\alpha^* = \frac{1 + \gamma\xi - \sqrt{(1+\gamma\xi)^2 - 4(1+\alpha)\gamma\xi}}{2(1+\alpha)\gamma} \quad \textit{and} \tag{5.35}$$

$$q_\alpha = \frac{1 - \gamma\xi - \sqrt{(1+\gamma\xi)^2 - 4(1+\alpha)\gamma\xi}}{1 - \gamma\xi + \sqrt{(1+\gamma\xi)^2 - 4(1+\alpha)\gamma\xi}}.$$

Suppose that F' satisfies the L-average Lipschitz condition on $\mathbf{B}(x_0, r_\alpha^*)$ and that

$$\xi \le \min\left\{\frac{1 + 2\eta\|T_{x_0}^{-1}\| - 2\sqrt{\eta\|T_{x_0}^{-1}\|(1+\eta\|T_{x_0}^{-1}\|)}}{\gamma},\ \Delta\right\}. \tag{5.36}$$

Then the conclusions hold as in Theorem 5.6.

5.3. Extension of Smale's approximate zeros. The following notion of approximate zeros was introduced in [26] for Newton's method. Let f be an operator from a domain D in a Banach space X to another one Y. Recall that Newton's iteration for f is defined as follows:

$$x_{n+1} = x_n - f'(x_n)^{-1} f(x_n), \quad n = 0, 1, \dots . \tag{5.37}$$

The sequence $\{x_n\}$ is said to satisfy Smale's condition if

$$\|x_{n+1} - x_n\| \le \left(\frac{1}{2}\right)^{2^{n-1}} \|x_n - x_{n-1}\| \quad \text{for each } n = 1, 2, \dots . \tag{5.38}$$

Note that (5.38) implies that $\{x_n\}$ is a Cauchy sequence and hence converges (with limit denoted by x^*). By (5.37) it follows that x^* is a zero of f.

DEFINITION 5.8. *Suppose that $x_0 \in D$ is such that Newton iteration* (5.37) *is well defined for f and $\{x_n\}$ satisfies Smale's condition. Then x_0 is said to be an approximate zero of f.*

Note that if x_0 is an approximate zero of f, then Newton iteration (5.37) converges to a zero x^* of f. We now extend the notion of approximate zeros to the Gauss–Newton method for convex composite optimization problems.

DEFINITION 5.9. *Suppose that $x_0 \in D$ is such that the sequence $\{x_n\}$ generated by Algorithm* A (η, Δ, x_0) *converges to a limit x^* solving* (1.1) *and satisfies Smale's condition. Then x_0 is said to be an (η, Δ)-approximate solution of* (1.1).

Recall that L is defined by (5.15).

THEOREM 5.10. *Let $x_0 \in \mathbb{R}^v$ be a regular point of the inclusion* (3.1) *with $r > 0$ and $\beta > 0$ such that* (4.23) *holds. Let $\eta \in [1, +\infty)$, $\Delta \in (0, +\infty]$, $\xi = \eta\beta d(F(x_0), C)$, and*

$$\hat{R} = \left(1 - \sqrt{\frac{\eta\beta}{1+\eta\beta}}\right)\frac{1}{\gamma}.$$

Suppose that F' satisfies the L-average Lipschitz condition on $\mathbf{B}(x_0, \hat{R})$ and that

$$\xi \le \min\left\{\frac{4 + 9\eta\beta - 3\sqrt{\eta\beta(9\eta\beta+8)}}{4\gamma},\ \frac{\left(1 + 2\eta\beta - 2\sqrt{\eta\beta(1+\eta\beta)}\right)(1+\eta\beta)}{1 + \eta\beta - \sqrt{\eta\beta(1+\eta\beta)}} r,\ \Delta\right\}. \tag{5.39}$$

Then, x_0 is an (η, Δ)-approximate solution of (1.1).

Proof. Let α be defined as in Theorem 5.6, and set $\alpha' = \eta\beta$. Then, as in the proof of Theorem 5.6, we have $\alpha \le \alpha'$ and $r_{\alpha'} = \hat{R}$ by (5.16). By Lemma 2.2(iii) and (2.7), it follows that

$$r^*_\alpha \le r^*_{\alpha'} \le r_{\alpha'} = \hat{R}.$$

Thus, by the assumptions, F' satisfies the L-average Lipschitz condition on $\mathbf{B}(x_0, r^*_\alpha)$. On the other hand, noting that

$$\frac{4 + 9\eta\beta - 3\sqrt{\eta\beta(9\eta\beta+8)}}{4\gamma} < \frac{1 + 2\eta\beta - 2\sqrt{\eta\beta(1+\eta\beta)}}{\gamma}, \tag{5.40}$$

we see that (5.39) implies (5.24). Therefore, one can apply Theorem 5.6 to conclude that the sequence $\{x_n\}$ converges to a solution x^* of (1.1) and

$$\|x_{n+1} - x_n\| \le q_\alpha^{2^{n-1}} \|x_n - x_{n-1}\| \quad \text{for all } n = 1, 2, \dots . \tag{5.41}$$

It remains to show that $q_\alpha \le \frac{1}{2}$. To do this we need to emphasize the dependence on the parameters, and so we write $q(\alpha, \xi)$ for q_α defined by (5.20) as before. Note that, by (5.27) the right-hand-side member of the inequality (5.40) is simply $b_{\alpha'}$, while the left-hand-side member majorizes ξ by (5.39). It follows from the monotonicity of $q(\cdot, \cdot)$ established in Lemma 5.5 that

$$q(\alpha, \xi) \le q(\alpha', \xi) \le q\left(\alpha', \frac{4 + 9\eta\beta - 3\sqrt{\eta\beta(9\eta\beta + 8)}}{4\gamma}\right) = \frac{1}{2},$$

where the last equality can be verified elementarily. This completes the proof. ∎

Similar to the above proof, we can use Theorem 5.7 in place of Theorem 5.6 to verify the following result.

THEOREM 5.11. *Let $\eta \in [1, +\infty)$, $\Delta \in (0, +\infty]$, and let C be a cone. Let $x_0 \in \mathbb{R}^v$ such that T_{x_0} carries $\mathbb{R}^v$ onto $\mathbb{R}^m$. Let $\xi = \eta \|T_{x_0}^{-1}\| d(F(x_0), C)$ and*

$$\tilde{R} = \left(1 - \sqrt{\frac{\eta\|T_{x_0}^{-1}\|}{1 + \eta\|T_{x_0}^{-1}\|}}\right) \frac{1}{\gamma}.$$

Suppose that F' satisfies the L-average Lipschitz condition on $\mathbf{B}(x_0, \tilde{R})$ and that

$$\xi \le \min\left\{\frac{4 + 9\eta\|T_{x_0}^{-1}\| - 3\sqrt{\eta\|T_{x_0}^{-1}\|(9\eta\|T_{x_0}^{-1}\| + 8)}}{4\gamma},\ \Delta\right\}. \tag{5.42}$$

Then, x_0 is an (η, Δ)-approximate solution of (1.1).

6. Examples. Let us begin with a simple example demonstrating a quasi-regular point which is not a regular point.

Example 6.1. Consider the operator F from $\mathbb{R}^2$ to $\mathbb{R}^2$ defined by

$$F(x) = \begin{pmatrix} 1 - t_1 + t_2 + t_1^2 \\ 1 - t_1 + t_2 \end{pmatrix} \quad \text{for each } x = (t_1, t_2) \in \mathbb{R}^2,$$

where $\mathbb{R}^2$ is endowed with the l_1-norm. Let $x_0 = 0 \in \mathbb{R}^2$ and $C = \{0\} \subseteq \mathbb{R}^2$. Then

$$F'(x) = \begin{pmatrix} -1 + 2t_1 & 1 \\ -1 & 1 \end{pmatrix} \quad \text{for each } x = (t_1, t_2) \in \mathbb{R}^2;$$

in particular, $F(x_0) = (1, 1)$ and

$$F'(x_0) = \begin{pmatrix} -1 & 1 \\ -1 & 1 \end{pmatrix}.$$

Thus x_0 does not satisfy (3.12). Moreover,

$$\ker F'(x_0) \cap (C - F(x_0))^\ominus = \{(t, t) :\ t \ge 0\} \ne \{0\},$$

and hence x_0 is not a regular point of the inclusion (3.1). In view of the definition of $\mathcal{D}(x)$ in (3.2), we have that, for $x = (t_1, t_2) \in \mathbb{R}^2$,

$$\mathcal{D}(x) = \begin{cases} \{(-\frac{t_1}{2}, -1 + \frac{t_1}{2} - t_2)\}, & t_1 \neq 0, \\ \{(d_1, d_1 - 1 - t_2) : \ d_1 \in \mathbb{R}\}, & t_1 = 0 \end{cases}$$

(note that $F'(x)$ is of full rank if and only if $t_1 \neq 0$). Therefore,

$$d(0, \mathcal{D}(x)) \leq 1 + |t_1| + |t_2| = 1 + \|x\| \quad \text{for each } x = (t_1, t_2) \in \mathbb{R}^2$$

and

$$d(F(x), C) = |1 - t_1 + t_2 + t_1^2| + |1 - t_1 + t_2| \geq 1 - \|x\| \quad \text{for each } x = (t_1, t_2) \in \mathbf{B}(x_0, 1).$$

This implies that

$$d(0, \mathcal{D}(x)) \leq \beta(\|x - x_0\|) d(F(x), C) \quad \text{for each } x = (t_1, t_2) \in \mathbf{B}(x_0, 1),$$

where $\beta(t) = \frac{1+t}{1-t}$ for each $t \in [0, 1)$. Thus, x_0 is a quasi-regular point with quasi-regular radius $\mathbf{r}_{x_0} \geq 1$. In fact, $\mathbf{r}_{x_0} = 1$ because

$$\lim_{t_1 \to 0+} \frac{d(0, \mathcal{D}(x))}{d(F(x), C)} = \lim_{t_1 \to 0+} \frac{1}{t_1} = +\infty$$

as x goes to $(0, -1)$ on the radial $l : 1 - t_1 + t_2 = 0$, $t_1 \geq 0$.

Next we give a few examples to illustrate some situations where our results are applicable but not the earlier results in the literature. For the following examples, recall that C is defined by (1.3) and we take

$$\eta = 1 \quad \text{and} \quad \Delta = +\infty. \tag{6.1}$$

Regarding the convergence issue of Gauss–Newton methods, the advantage of considering Wang's L-average Lipschitz condition rather than the classical Lipschitz condition is shown in the following example, for which Theorem 5.7 is applicable but not Theorem 5.3.

Example 6.2. Let $m = n = 1$ and h be defined by

$$h(y) = \begin{cases} 0, & y \leq 0, \\ y, & y \geq 0. \end{cases}$$

Let τ be a constant satisfying

$$10\sqrt{2} - 14 < \tau < 3 - 2\sqrt{2}, \tag{6.2}$$

and define

$$F(x) = \begin{cases} \tau - x + \frac{x^2}{1-x}, & x \leq \frac{1}{2}, \\ \tau - \frac{1}{2} + 2x^2, & x \geq \frac{1}{2}. \end{cases} \tag{6.3}$$

Then $C = (-\infty, 0]$,

$$F'(x) = \begin{cases} -2 + \frac{1}{(1-x)^2}, & x \leq \frac{1}{2}, \\ 4x, & x \geq \frac{1}{2}, \end{cases}$$

and

$$F''(x) = \begin{cases} \frac{2}{(1-x)^3}, & x < \frac{1}{2}, \\ 4, & x > \frac{1}{2}. \end{cases} \tag{6.4}$$

Let $\gamma = 1$, and let L be defined as in (5.15), that is

$$L(u) = \frac{2}{(1-u)^3} \quad \text{for each } u \text{ with } 0 \le u < 1. \tag{6.5}$$

Then

$$L(u) < L(v) \quad \text{whenever } 0 \le u < v < 1. \tag{6.6}$$

It follows from (6.4) that

$$\sup\{F''(x) : x \in [-r, r] \setminus \{1/2\}\} = \begin{cases} 16, & r \ge \frac{1}{2}, \\ \frac{2}{(1-r)^3}, & 0 < r \le \frac{1}{2}, \end{cases} \tag{6.7}$$

and that

$$0 < F''(u) \le F''(|u|) \le L(|u|) \quad \text{whenever } 1/2 \ne u < 1. \tag{6.8}$$

Let $x_0 = 0$. Then, for all x, $x' \in \mathbf{B}(x_0, 1)$ with $|x'| + |x - x'| < 1$, it follows from (6.6) and (6.8) that

(6.9)

$$|F'(x) - F'(x')| = |x - x'| \int_0^1 F''(x' + t(x - x'))\mathrm{d}t \le |x - x'| \int_0^1 L(|x'| + t|x - x'|)\mathrm{d}t.$$

Thus F' satisfies the L-average Lipschitz condition on $\mathbf{B}(x_0, 1)$ with L defined by (6.5). Note that T_{x_0} carries $\mathbb{R}$ onto $\mathbb{R}$ and $\|T_{x_0}^{-1}\| = 1$ as $F'(x_0) = -1$. Let ξ be defined as in Theorems 5.3 and 5.7. Since $F(x_0) = \tau$ and by (6.2), we have

$$\xi = \|T_{x_0}^{-1}\| d(F(x_0), C) = \tau < 3 - 2\sqrt{2}. \tag{6.10}$$

Thus (5.36) is satisfied. Recalling the definitions of α and r_α^* in Theorem 5.7, we have that $\alpha = 1$ and

$$r_\alpha^* = \frac{1 + \xi - \sqrt{(1+\xi)^2 - 8\xi}}{4} \le \frac{1+\xi}{4} \le \frac{1 + 3 - 2\sqrt{2}}{4} < 1.$$

Therefore Theorem 5.7 is applicable with initial point x_0. We show next that Theorem 5.3 is not applicable here. In fact, by (6.7), one has that, for any $r > 0$, F' is also Lipschitz continuous on $\mathbf{B}(x_0, r)$ with the (least) Lipschitz constant L_r given by

$$L_r = \begin{cases} \frac{2}{(1-r)^3}, & r \le \frac{1}{2}, \\ 16, & r \ge \frac{1}{2}. \end{cases} \tag{6.11}$$

Suppose that there are ξ, L, and R^* satisfying the assumptions stated in Theorem 5.3. For simplicity of notation we write r for R^*. Then by the least property of L_r, (5.12), (5.14), and by a similar argument as for (6.10), we have

$$L \ge L_r, \tag{6.12}$$

$$r = \frac{1 - \sqrt{1 - 2L\xi}}{L}, \tag{6.13}$$

and

$$\tau = \xi \le \frac{1}{2L} \le \frac{1}{2L_r}. \tag{6.14}$$

Since $\tau > 10\sqrt{2} - 14 > \frac{1}{32}$, we have from (6.14) that $L_r < 16$, and it follows from (6.11) that $r < 1/2$ and hence $L_r = \frac{2}{(1-r)^3} \ge 2$. Consequently, by (6.12) and (6.13), we have

$$\tau = \xi = r - \frac{Lr^2}{2} \le r - \frac{L_r r^2}{2} \le r - r^2. \tag{6.15}$$

Combining this with (6.14) and (6.11), we have that

$$\tau \le \min\left\{\frac{(1-r)^3}{4}, r - r^2\right\}. \tag{6.16}$$

Note that the function $r \mapsto \frac{(1-r)^3}{4}$ is decreasing and $r \mapsto r - r^2$ increasing on $[0, \frac{1}{2}]$. Hence

$$\tau \le \min\left\{\frac{(1-r)^3}{4}, r - r^2\right\} = r_0 - r_0^2 = 10\sqrt{2} - 14, \tag{6.17}$$

where $r_0 = 3 - 2\sqrt{2}$ is the least positive root of equation $\frac{(1-r)^3}{4} = r - r^2$. However, (6.17) contradicts (6.2), and therefore Theorem 5.3 is not applicable to x_0.

Even when initial point x_0 is regular, the advantage to considering the quasi regularity bound functions rather than a constant β with the property stated in Proposition 3.3 is shown in the following example, for which Theorem 5.1 (and hence results in [4, 13]) are not applicable while Theorem 5.3 is applicable, which is based on the quasi-regular bound function β_{x_0} satisfying (3.14) rather than the quasi-regular bound constant β given by Proposition 3.3.

Example 6.3. Let $m = n = 1$ and h be defined by

$$h(y) = |y| \quad \text{for each } y \in \mathbb{R}.$$

Then $C = \{0\}$. Let $\frac{\sqrt{3}-1}{4} < \tau \le \frac{1}{4}$ and define

$$F(x) = \tau - x + x^2 \quad \text{for each } x \in \mathbb{R}.$$

Then

$$F'(x) = -1 + 2x \quad \text{for each } x \in \mathbb{R};$$

hence F' is Lipschitz continuous with the modular $L = 2$. Let $x_0 = 0$. It is clear that T_{x_0} carries $\mathbb{R}$ onto $\mathbb{R}$ and $\|T_{x_0}^{-1}\| = 1$ as $F'(x_0) = -1$. Since

$$\|T_{x_0}^{-1}\| d(F(x_0), C) = \tau \le \frac{1}{4}, \tag{6.18}$$

Theorem 5.3 is applicable with initial point $x_0 = 0$. Below we shall show that Theorem 5.1 is not applicable. Suppose, on the contrary, that there exist $r > 0$ and $\beta > 0$ satisfying the assumptions stated in Theorem 5.1 for x_0. Then

$$\mathcal{D}(x) \text{ is nonempty} \quad \text{and} \quad d(0, \mathcal{D}(x)) \le \beta d(F(x), C) \quad \text{for each } x \in \mathbf{B}(x_0, r), \tag{6.19}$$

$$r \geq \frac{1+2\beta\xi-\sqrt{1-(2\beta\xi)^2}}{2\beta}, \tag{6.20}$$

and

$$\beta\tau = \xi \leq \frac{1}{2\beta}. \tag{6.21}$$

By definition, it is easy to see that, for each $x \in \mathbb{R}$,

$$\mathcal{D}(x) = \begin{cases} \{-F'(x)^{-1}F(x)\}, & x \neq \frac{1}{2}, \\ \emptyset, & x = \frac{1}{2}, \end{cases} \tag{6.22}$$

and it follows from (6.19) that $r \leq \frac{1}{2}$ and, for each $x \in \mathbf{B}(x_0, r)$,

$$d(0, \mathcal{D}(x)) = |F'(x)^{-1}F(x)| = \frac{1}{1-2|x|}|F(x)| = \frac{1}{1-2|x|}d(F(x), C). \tag{6.23}$$

By (6.19) this implies that

$$\frac{1}{1-2|x|} \leq \beta \quad \text{for each } x \in \mathbf{B}(x_0, r). \tag{6.24}$$

Considering $x_0 = 0$, this implies $\frac{1}{1-2r} \leq \beta$; that is,

$$2\beta r \leq \beta - 1. \tag{6.25}$$

It follows from (6.20) that

$$1+2\beta\xi-\sqrt{1-(2\beta\xi)^2} \leq \beta - 1, \tag{6.26}$$

or equivalently,

$$((2\xi-1)^2+(2\xi)^2)\beta^2 + 4(2\xi-1)\beta + 3 \leq 0. \tag{6.27}$$

Hence

$$(4(2\xi-1))^2 - 4\cdot 3((2\xi-1)^2+(2\xi)^2) \geq 0, \tag{6.28}$$

which implies that $\xi \leq \frac{\sqrt{3}-1}{4}$. This contradicts the assumption that $\tau > \frac{\sqrt{3}-1}{4}$ because $\xi = \beta\tau \geq \tau$ by (6.21) and (6.24).

We remark that, on one hand, the results in section 5 cover (and improve) the cases considered by Burke and Ferris and by Robinson (the initial points are regular in [4, 18]), and, on the other hand, there are examples of quasi-regular but not regular points x_0 for which Theorem 4.1 is applicable.

Example 6.4. Let $m = n = 3$. To ease our computation, let $\mathbb{R}^3$ be endowed with the l_1-norm. Let h be defined by

$$h(x) = \chi(t_1) + \chi(t_2) + \left|t_3 - t_1 - t_2 - \frac{1}{8}\right| \quad \text{for each } x = (t_1, t_2, t_3) \in \mathbb{R}^3,$$

where $\chi(t)$ is a real-valued function on $\mathbb{R}$ defined by

$$\chi(t) = \begin{cases} -1-t, & t \leq -1, \\ 0, & -1 \leq t \leq 0, \\ t, & t \geq 0. \end{cases}$$

Define

$$A = \{(c_1, c_2, c_3) : \ c_3 = c_1 + c_2\}, \tag{6.29}$$

and let $F : \mathbb{R}^3 \mapsto \mathbb{R}^3$ be defined by

$$F(x) = \begin{pmatrix} \frac{1}{16} - t_1 + t_1^2 + t_2 + t_3 \\ \frac{1}{16} + t_1 - t_2 + t_2^2 + t_3 \\ t_1^2 + t_2^2 + 2t_3 \end{pmatrix} \quad \text{for each } x = (t_1, t_2, t_3) \in \mathbb{R}^3. \tag{6.30}$$

Then

$$C = \left\{(c_1, c_2, c_3) : \ c_1, c_2 \in [-1, 0], \, c_3 = c_1 + c_2 + \frac{1}{8}\right\}, \tag{6.31}$$

$$C - F(x) \text{ is contained in } A, \tag{6.32}$$

$$F'(x) = \begin{pmatrix} -1 + 2t_1 & 1 & 1 \\ 1 & -1 + 2t_2 & 1 \\ 2t_1 & 2t_2 & 2 \end{pmatrix} \quad \text{for each } x = (t_1, t_2, t_3) \in \mathbb{R}^3, \tag{6.33}$$

and hence

$$C - F(x) \text{ is contained in } A = \{F'(x)d : \ d \in \mathbb{R}^3\} \quad \text{for each } x \in \mathbb{R}^3. \tag{6.34}$$

In particular, for $x_0 = 0$, we have that

$$F'(x_0) = \begin{pmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 0 & 0 & 2 \end{pmatrix}, \tag{6.35}$$

and hence

$$\ker F'(x_0) = \{(t, t, 0) : \ t \in \mathbb{R}\}. \tag{6.36}$$

Since $F(x_0) = (\frac{1}{16}, \frac{1}{16}, 0)$, one has that

$$\ker F'(x_0) \cap (C - F(x_0))^{\ominus} = \{(t, t, 0) : \ t \geq 0\}; \tag{6.37}$$

hence x_0 is not a regular point of (3.1), and the condition of Robinson is not satisfied (see Proposition 3.7). Below we shall show that x_0 is a quasi-regular point with the quasi-regular radius $\mathbf{r}_{x_0}$ and the quasi-regular bound function β_{x_0} satisfying respectively

$$\mathbf{r}_{x_0} \geq \frac{3}{4} \quad \text{and} \quad \beta_{x_0}(t) \leq \frac{2}{3 - 4t} \quad \text{for each } t \in \left[0, \frac{3}{4}\right). \tag{6.38}$$

To do this, we note first that F' satisfies the L-average Lipschitz condition on $\mathbb{R}^3$ with $L = 2$,

$$\|F'(x) - F'(y)\| \leq 2\|x - y\| \quad \text{for each } x, \, y \in \mathbb{R}^3, \tag{6.39}$$

and the rank of $F'(x)$ is given by

$$\operatorname{rank} F'(x) = 2 \quad \text{for each } x \in \mathbb{R}^3. \tag{6.40}$$

Since

$$F'(x) = F'(x_0) + F'(x) - F'(x_0) \quad \text{and} \quad \|F'(x) - F'(x_0)\| \le 2\|x - x_0\|,$$

it follows from the perturbation property of matrixes (cf. [27, 30]) that

$$\|F'(x)^\dagger\| \le \frac{\|F'(x_0)^\dagger\|}{1 - 2\|x - x_0\|\|F'(x_0)^\dagger\|} \tag{6.41}$$

holds for each $x \in \mathbb{R}^3$ with $2\|x - x_0\|\|F'(x_0)^\dagger\| < 1$, where $A^\dagger$ denotes the Moore–Penrose generalized inverse of the matrix A (cf. [27, 30]). By (6.35), one has that

$$F'(x_0)^\dagger = \begin{pmatrix} -\frac{1}{4} & \frac{1}{4} & 0 \\ \frac{1}{4} & -\frac{1}{4} & 0 \\ \frac{1}{6} & \frac{1}{6} & \frac{1}{3} \end{pmatrix} \quad \text{and} \quad \|F'(x_0)^\dagger\| = \frac{2}{3}. \tag{6.42}$$

This together with (6.41) implies that

$$\|F'(x)^\dagger\| \le \frac{2}{3 - 4\|x - x_0\|} \quad \text{for each } x \in \mathbf{B}\left(x_0, \frac{3}{4}\right). \tag{6.43}$$

On the other hand, by (6.33) and (3.2), we have

$$\mathcal{D}(x) = F'(x)^\dagger(C - F(x)) \quad \text{for each } x \in \mathbb{R}^3 \tag{6.44}$$

and, consequently, for each $x \in \mathbf{B}(x_0, \frac{3}{4})$,

$$d(0, \mathcal{D}(x)) \le \|F'(x)^\dagger\| d(F(x), C) \le \frac{2}{3 - 4\|x - x_0\|} d(F(x), C). \tag{6.45}$$

This shows that x_0 is a quasi-regular point with the quasi-regular radius $\mathbf{r}_{x_0}$ and the quasi-regular bound function β_{x_0} satisfying (6.38). Let $\mathbf{r} = \frac{3}{4}$. Recalling (4.2) and (6.1), it follows from (6.38) that

$$\alpha_0(\mathbf{r}) \le \sup\left\{\frac{\beta(t)}{\beta(t)2t + 1} : \xi \le t < \mathbf{r}\right\} = \frac{2}{3}, \tag{6.46}$$

where $\beta(t) := \frac{2}{3-4t}$ for each $t \in [0, \frac{3}{4})$. Thus taking $\alpha = \frac{2}{3}$ in (2.1), we get that

$$r_\alpha = \frac{3}{4} \quad \text{and} \quad b_\alpha = \frac{3}{8}. \tag{6.47}$$

By (4.1) and (6.38),

$$\xi = \beta_{x_0}(0) d(F(x_0), C) \le \beta(0)\|F(x_0) - c_0\| = \frac{1}{6},$$

where $c_0 = (0, 0, \frac{1}{8})$. It follows that (4.4) is satisfied. Hence Theorem 4.1 is applicable with initial point x_0 even though it is not a regular point.

7. Conclusion. In connection with inclusion problem (1.2) and for a given point x_0 we introduce two new notions: (a) the L-average Lipschitz condition for F' and (b) quasi regularity (with the associate quasi-regular radius r_{x_0} and quasi-regular bound function β_{x_0}). The notion (a) extends the classical Lipschitz condition and Smale's condition, and notion (b) extends the regularity. When Robinson's condition (3.12) is satisfied, x_0 is shown to be a regular point, and the associate quasi-regular radius r_{x_0} as well as the associate quasi-regular bound function β_{x_0} are estimated if in addition F' satisfies (a) with suitable L. We provide sufficient conditions for convergence results with a quasi-regular initial point x_0 in the Gauss–Newton method for the convex composition optimization problem (1.1) with C given to be the set of all minimizers of a convex function h. These conditions are given in terms of r_{x_0}, β_{x_0}, and L in (a). Examples are given to show that the new concept and results are nontrivial extensions of the existing ones.

Acknowledgment. We thank the referees for suggestions which helped our presentation.
