THE SECQ, LINEAR REGULARITY, AND THE STRONG CHIP FOR AN INFINITE SYSTEM OF CLOSED CONVEX SETS IN NORMED LINEAR SPACES*

CHONG LI†, K. F. NG‡, AND T. K. PONG‡

Abstract. We consider a (finite or infinite) family of closed convex sets with nonempty intersection in a normed space. A property relating their epigraphs with their intersection's epigraph is studied, and its relations to other constraint qualifications (such as the linear regularity, the strong CHIP, and Jameson's (G)-property) are established. With suitable continuity assumption we show how this property can be ensured from the corresponding property of some of its finite subfamilies.

Key words. system of closed convex sets, interior-point condition, strong conical hull intersection property

1. Introduction.

In dealing with a lower semicontinuous extended real-valued function ϕ defined on a Banach space (or more generally, a normed linear space) X, it is not only natural but also useful to study its relation with the epigraph $\operatorname{epi}\phi := \{(x,r) \in X \times \mathbb{R} : \phi(x) \le r\}$, which is clearly a closed convex subset of the product $X \times \mathbb{R}$. Conversely, given a nonempty closed convex set C in X, let σ_C denote the support function of C, which is defined by

$$\sigma_C(x^*) = \sup\{\langle x^*, x\rangle : x \in C\}, \qquad x^* \in X^*,$$

where X^* denotes the dual space of X and $\langle x^*, x\rangle = x^*(x)$, the value of the functional x^* at x. Thus σ_C is a w^*-lower semicontinuous convex function and $\operatorname{epi}\sigma_C$ is a w^*-closed convex subset of $X^* \times \mathbb{R}$. In this paper, we shall apply this simple duality between C and $\operatorname{epi}\sigma_C$ to study several important aspects (including the regularity, the strong conical hull intersection property (CHIP), Jameson's property (G), and other constraint qualifications) for a *CCS*-system $\{C_i : i \in I\}$, by which we mean a family of closed convex sets in X with nonempty intersection $\cap_{i\in I} C_i$, where I is an index set.

For the case when I is finite, the concept of regularity and its quantitative versions were introduced in [4, 5, 6] by Bauschke, Borwein, and Li and were utilized to establish norm or linear convergence results. The concept of the strong CHIP was introduced by Deutsch, Li, and Ward in [12], and was utilized in [13], as well as in [9, 24, 25], to reformulate certain optimization problems with constraints. All the works cited above were in the Hilbert space or Euclidean space setting. The concept of property (G) was introduced by Jameson [17] for a pair of cones, and was utilized to give a duality

characterization of the linear regularity. In improving the partial results obtained by Lewis and Pang (see [23, 31]) and by Bauschke, Borwein, and Li [6], Jameson's result was extended by Ng and Yang [30] to the general case (without the additional assumption that each C_i is a cone), but still only for finite I. For the case when X is a Hilbert space, the same result was also independently obtained by Bakan, Deutsch, and Li in [3].

In this paper, we extend the above mentioned results to cover the case when I is infinite. From both theoretical and application points of view, the extension from the finite case to the infinite one is of importance. Regarding the strong CHIP, such an extension has already been done rather successfully with many interesting applications (see, for example, [27, 28]). Our investigation is made through the consideration of epigraphs, and in particular by virtue of that, of a new constraint qualification, defined below. Our works in this connection are inspired by the recent works of Jeyakumar and his collaborates (see [7, 18, 19, 20, 22], for example), who made use of epigraphs to provide sufficient conditions to ensure the strong CHIP (for a finite collection of closed convex sets), and study systems of convex inequalities. We say that a *CCS*-system $\{C_i : i \in I\}$ satisfies the SECQ (sum of epigraphs constraint qualification) if

$$\operatorname{epi} \sigma_{\cap_{i\in I} C_i} = \sum_{i\in I} \operatorname{epi} \sigma_{C_i}.$$

In section 4, we study the interrelationship between this property and other constraint qualifications, especially the linear regularity. Also, since this property is stronger than the strong CHIP (and the converse holds in some important cases; see Theorem 3.1), it is both natural and useful to inquire whether or not the sufficient conditions originally provided to ensure the strong CHIP can in fact ensure the SECQ. In this connection, let us recall the following results proved in [27] (see, in particular, Theorems 4.1 and 5.1 therein). For the remainder of this section, we assume that I is a compact metric space (needless to say, if I is finite, then it is compact under the discrete metric) and see the next section for definitions of the undefined terms.

THEOREM 1.1. *Consider the CCS-system $\{D, C_i : i \in I\}$. Suppose that*

(a) *D is of finite dimension;*

(b) *the set-valued map $i \mapsto (\operatorname{aff} D) \cap C_i$ is lower semicontinuous on I;*

(c) *there exist $x_0 \in D \cap (\cap_{i\in I} C_i)$ and $r > 0$ such that*

$$(\operatorname{aff} D) \cap B(x_0, r) \subseteq C_i \quad \text{for each } i \in I; \tag{1.1}$$

(d) *the pair $\{\operatorname{aff} D, C_i\}$ has the strong CHIP for each $i \in I$.*

Then $\{D, C_i : i \in I\}$ has the strong CHIP.

THEOREM 1.2. *Consider the CCS-system $\{D, C_i : i \in I\}$. Suppose that*

(a) *D is of finite dimension l;*

(b) *the set-valued map $i \mapsto (\operatorname{aff} D) \cap C_i$ is lower and upper semicontinuous on I;*

(c) *for any finite subset J of I with number of elements $|J| \leq l$, there exist $x_0 \in D$ and $r > 0$ such that*

$$(\operatorname{aff} D) \cap B(x_0, r) \subseteq C_i \quad \text{for each } i \in J;$$

(d) *for any finite subset J of I, the subsystem $\{D, C_j : j \in J\}$ has the strong CHIP.*

Then $\{D, C_i : i \in I\}$ *has the strong CHIP.*

In section 5, we present corresponding results for the SECQ, and as a consequence Theorems 1.1 and 1.2 are recaptured with some significant improvements. In our Corollary 5.5, condition (c) in Theorem 1.1 can be considerably weakened to require (1.1) to hold for each $i \in J$ with some finite subsets J of I and to allow r to depend on J. In our Corollary 5.6, we show that the words "and upper" in Theorem 1.2(b) can be dropped and that (d) can be weakened to require the strong CHIP to hold only for subsystems $\{D, C_j : j \in J\}$ with $|J| = l + 1$.

2. Notations and preliminary results. The notations used in the present paper are standard (cf. [8, 15]). In particular, we assume throughout the whole paper that X is a real normed linear space (we remark that some results in this section hold for general locally convex spaces). We use $\mathbf{B}(x, \epsilon)$ to denote the closed ball with center x and radius ϵ. For a set A in X (or in $\mathbb{R}^n$), the interior (resp., relative interior, closure, convex hull, convex cone hull, linear hull, affine hull, boundary) of A is denoted by $\operatorname{int} A$ (resp., $\operatorname{ri} A$, $\overline{A}$, $\operatorname{co} A$, $\operatorname{cone} A$, $\operatorname{span} A$, $\operatorname{aff} A$, $\operatorname{bd} A$), and the negative polar cone $A^{\ominus}$ is the set defined by

$$A^{\ominus} = \{x^* \in X^* \ : \ \langle x^*, z\rangle \le 0 \ \text{ for all } z \in A\},$$

which coincides with the polar A° of A when A is a cone. The normal cone of A at z_0 is denoted by $N_A(z_0)$ and defined by $N_A(z_0) = (A - z_0)^{\ominus}$. Let Z be a closed convex nonempty subset of X. The interior and the boundary of A relative to Z are, respectively, denoted by $\operatorname{rint}_Z A$ and $\operatorname{bd}_Z A$; they are defined to be, respectively, the interior and the boundary of the set $\operatorname{aff} Z \cap A$ in the metric space $\operatorname{aff} Z$. Thus, a point $z \in \operatorname{rint}_Z A$ if and only if there exists $\varepsilon > 0$ such that

$$z \in (\operatorname{aff} Z) \cap \mathbf{B}(z, \varepsilon) \subseteq A,$$

while $z \in \operatorname{bd}_Z A$ if and only if $z \in \operatorname{aff} Z$ and, for any $\varepsilon > 0$, $(\operatorname{aff} Z) \cap \mathbf{B}(z, \varepsilon)$ intersects A and its complement.

For a closed subset A of X, the indicator function δ_A and the support function σ_A of set A are, respectively, defined by

$$\delta_A(x) := \begin{cases} 0, & x \in A, \\ \infty, & \text{otherwise} \end{cases}$$

and

$$\sigma_A(x^*) := \sup_{x \in A} \langle x^*, x\rangle \quad \text{for each } x^* \in X^*.$$

Let f be a proper lower semicontinuous extended real-valued function on X. The domain of f is denoted by $\operatorname{dom} f := \{x \in X : f(x) < +\infty\}$. Then the subdifferential of f at $x \in \operatorname{dom} f$, denoted by $\partial f(x)$, is defined by

$$\partial f(x) := \{z^* \in X^* : \ f(x) + \langle z^*, y - x\rangle \le f(y) \quad \text{for all } y \in X\}.$$

Let f, g be proper functions, respectively, defined on X and X^*. Let f^*, g^* denote their conjugate functions, that is,

$$f^*(x^*) := \sup\{\langle x^*, x\rangle - f(x) : \ x \in X\} \quad \text{for each } x^* \in X^*,$$
$$g^*(x) := \sup\{\langle x^*, x\rangle - g(x^*) : \ x^* \in X^*\} \quad \text{for each } x \in X.$$

The epigraph of a function f on X is denoted by $\operatorname{epi} f$ and defined by

$$\operatorname{epi} f := \{(x,r) \in X \times \mathbb{R} :\ f(x) \le r\}.$$

Then, for proper lower semicontinuous extended real-valued convex functions f_1 and f_2 on X, we have

$$f_1 \le f_2 \Longleftrightarrow f_1^* \ge f_2^* \Longleftrightarrow \operatorname{epi} f_1^* \subseteq \operatorname{epi} f_2^*, \tag{2.1}$$

where the forward direction of the first arrow and the second equivalence are easy to verify, while the backward direction of the first arrow is standard (cf. [35, Theorem 2.3.3]).

For closed convex sets A, B, the following assertions are well known and easy to verify:

$$\sigma_A = \delta_A^*, \tag{2.2}$$

$$N_A(x) = \partial \delta_A(x) \quad \text{for each } x \in A, \tag{2.3}$$

$$\sigma_A(x^*) = \langle x^*, x\rangle \Leftrightarrow x^* \in N_A(x) \Longleftrightarrow (x^*,\, \langle x^*, x\rangle) \in \operatorname{epi} \sigma_A \quad \text{for each } x \in A, \tag{2.4}$$

and

$$\operatorname{epi} \sigma_A \subseteq \operatorname{epi} \sigma_B \quad \text{if } A \supseteq B.$$

Let $\{A_i :\ i \in J\}$ be a family of subsets of X containing the origin. The set $\sum_{i\in J} A_i$ is defined by

$$\sum_{i\in J} A_i = \begin{cases} \left\{\sum_{i\in J_0} a_i :\quad a_i \in A_i, \quad \emptyset \ne J_0 \subseteq J \text{ being finite}\right\} & \text{if } J \ne \emptyset, \\ \{0\} & \text{if } J = \emptyset. \end{cases}$$

Let I be an arbitrary index set. The following concept of the strong CHIP plays an important role in optimization theory (see [3, 6, 9, 10, 11, 33]) and is due to [12, 13] in the case when I is finite and to [26, 27] in the case when I is infinite.

DEFINITION 2.1. *Let $\{C_i :\ i \in I\}$ be a collection of convex subsets of X. The collection is said to have*

(a) *the strong CHIP at $x \in \cap_{i\in I} C_i$ if $N_{\cap_{i\in I} C_i}(x) = \sum_{i\in I} N_{C_i}(x)$, that is,*

$$\left(\bigcap_{i\in I} C_i - x\right)^{\ominus} = \sum_{i\in I} (C_i - x)^{\ominus};$$

(b) *the strong CHIP if it has the strong CHIP at each point of $\cap_{i\in I} C_i$;*

(c) *the SECQ if $\operatorname{epi} \sigma_{\cap_{i\in I} C_i} = \sum_{i\in I} \operatorname{epi} \sigma_{C_i}$.*

Note that $N_{\cap_{i\in I} C_i}(x) \supseteq \sum_{i\in I} N_{C_i}(x)$ holds automatically for $x \in \cap_{i\in I} C_i$. Hence $\{C_i :\ i \in I\}$ has the strong CHIP at x if and only if

$$N_{\cap_{i\in I} C_i}(x) \subseteq \sum_{i\in I} N_{C_i}(x).$$

To establish a similar property regarding the SECQ, we first need to extend [16, part X, Theorem 2.4.4] to the setting of normed linear spaces. We recall that for an arbitrary function f defined on X^*, we define $\overline{\operatorname{co}} f^{w^*}$ by (cf. [35, page 63])

$$\operatorname{epi}(\overline{\operatorname{co}} f^{w^*}) := \overline{\operatorname{co}(\operatorname{epi} f)}^{w^*}.$$

LEMMA 2.2. *Let $\{g_i : i \in I\}$ be a family of proper convex lower semicontinuous functions on X with $\sup_{i\in I} g_i(x_0) < +\infty$ for some $x_0 \in X$. Then for all $y^* \in X^*$, $(\sup_{i\in I} g_i)^*(y^*) = \overline{\mathrm{co}(\inf_{i\in I}(g_i^*))}^{w^*}(y^*)$.*

Proof. It is well known (and immediate from the definition of the conjugate) that for a family of proper convex lower semicontinuous functions $(f_i)_{i\in I}$ on X,

$$\left(\inf_{i\in I} f_i\right)^* = \sup_{i\in I} f_i^*. \tag{2.5}$$

Now, since g_i is proper convex lower semicontinuous for each $i \in I$, $g_i^{**} = g_i$ and g_i^* is proper (cf. [35, Theorem 2.3.3]). Applying (2.5) to g_i^* in place of f_i, we see that

$$\left(\inf_{i\in I} g_i^*\right)^* = \sup_{i\in I} g_i^{**} = \sup_{i\in I} g_i.$$

From this and the properness assumption on $\sup_{i\in I} g_i$, we obtain from [35, Theorem 2.3.4] that $(\inf_{i\in I} g_i^*)^{**} = \overline{\mathrm{co}(\inf_{i\in I} g_i^*)}^{w^*}$. The result follows. □

The following lemma was stated without proof in [21, page 902]. We give a proof here for the sake of completeness (note that the condition that "$\sup_{i\in I} g_i$ is proper" is needed).

LEMMA 2.3. *Let $\{g_i : i \in I\}$ be a system of proper convex lower semicontinuous functions on X with $\sup_{i\in I} g_i(x_0) < +\infty$ for some $x_0 \in X$. Then*

$$\mathrm{epi}\left(\sup_{i\in I} g_i\right)^* = \overline{\mathrm{co}\bigcup_{i\in I} \mathrm{epi}\, g_i^*}^{w^*}. \tag{2.6}$$

Proof. For the family $\{g_i^* : i \in I\}$ of proper convex lower semicontinuous functions on X we have $\cup_{i\in I} \mathrm{epi}\, g_i^* \subset \mathrm{epi}\,(\inf_{i\in I} g_i^*) \subset \overline{\mathrm{co}\cup_{i\in I} \mathrm{epi}\, g_i^*}^{w^*}$. This implies that $\overline{\mathrm{epi}\,(\inf_{i\in I} g_i^*)}^{w^*} = \overline{\mathrm{co}\cup_{i\in I} \mathrm{epi}\, g_i^*}^{w^*}$. The conclusion follows on invoking Lemma 2.2. □

PROPOSITION 2.4. *Let $\{C_i : i \in I\}$ be a collection of closed convex sets in X with $C := \cap_{i\in I} C_i \neq \emptyset$. Then*

$$\mathrm{epi}\,\sigma_C = \overline{\sum_{i\in I} \mathrm{epi}\,\sigma_{C_i}}^{w^*}.$$

Proof. Note that $\sup_{i\in I} \delta_{C_i} = \delta_C$ and that $\sigma_C = \delta_C^*$ by (2.2). It follows that $\mathrm{epi}\,\sigma_C = \mathrm{epi}(\sup_{i\in I} \delta_{C_i})^*$. Consequently, by (2.6) and (2.2), one has that

$$\mathrm{epi}\,\sigma_C = \overline{\mathrm{co}\bigcup_{i\in I} \mathrm{epi}\,\delta_{C_i}^*}^{w^*} = \overline{\mathrm{co}\bigcup_{i\in I} \mathrm{epi}\,\sigma_{C_i}}^{w^*} = \overline{\sum_{i\in I} \mathrm{epi}\,\sigma_{C_i}}^{w^*},$$

where the last equality holds because $\mathrm{epi}\,\sigma_{C_i}$ is clearly a cone for each $i \in I$. □

COROLLARY 2.5. *Let $\{C_i : i \in I\}$ be a collection of closed convex sets in X with $C := \bigcap_{i\in I} C_i \neq \emptyset$. Then the following equivalences are true:*

$$\begin{aligned} &\{C_i : i \in I\} \text{ satisfies the SECQ} \iff \textstyle\sum_{i\in I} \mathrm{epi}\,\sigma_{C_i} \text{ is } w^*\text{-closed} \\ &\iff \mathrm{epi}\,\sigma_C \subseteq \sum_{i\in I} \mathrm{epi}\,\sigma_{C_i}. \end{aligned} \tag{2.7}$$

The following simple proposition states that the SECQ is invariant under translation.

PROPOSITION 2.6. *Let $\{C_i : i \in I\}$ be a family of closed convex sets in X. Suppose that $C := \bigcap_{i\in I} C_i \neq \emptyset$. Then $\{C_i : i \in I\}$ satisfies the SECQ if and only if the system $\{C_i - x : i \in I\}$ does for each $x \in X$.*

Proof. Let $x \in X$. Note that

$$(y^*, \alpha) \in \operatorname{epi} \sigma_{C-x} \Longleftrightarrow (y^*, \alpha + \langle y^*, x\rangle) \in \operatorname{epi} \sigma_C$$

and

$$(y^*, \alpha) \in \sum_{i\in I} \operatorname{epi} \sigma_{C_i - x} \Longleftrightarrow (y^*, \alpha + \langle y^*, x\rangle) \in \sum_{i\in I} \operatorname{epi} \sigma_{C_i}.$$

Hence the conclusion follows from Corollary 2.5. □

We will need the following notion of semicontinuity of set-valued maps in sections 4 and 5. Readers may refer to standard texts such as [1, 32].

DEFINITION 2.7. *Let Q be a metric space. Let X be a normed linear space and let $t_0 \in Q$. A set-valued function $F : Q \to 2^Y \setminus \{\emptyset\}$ is said to be*

(i) *lower semicontinuous at t_0 if, for any $y_0 \in F(t_0)$ and any $\epsilon > 0$, there exists a neighborhood $U(t_0)$ of t_0 such that $\mathbf{B}(y_0, \epsilon) \cap F(t) \neq \emptyset$ for each $t \in U(t_0)$;*

(ii) *lower semicontinuous on Q if it is lower semicontinuous at each $t \in Q$.*

The following characterization regarding the lower semicontinuity is a reformulation of the equivalence of (i) and (ii) in [27, Proposition 3.1]. For a closed convex set S in a normed linear space X, let $d_S(\cdot)$ denote the distance function of S defined by $d_S(x) = \inf\{\|x - y\| : y \in S\}$ for each $x \in X$. Furthermore, let $\liminf_{t\to t_0} F(t)$ denote the lower limit of the set-valued function F at $t_0 \in Q$ which is defined by

$$\liminf_{t\to t_0} F(t) := \{z \in X : \exists\{z_t\}_{t\in Q} \text{ with } z_t \in F(t) \text{ such that } z_t \to z \text{ as } t \to t_0\}.$$

PROPOSITION 2.8. *Let Q be a metric space. Let $F : Q \to 2^X \setminus \{\emptyset\}$ be a set-valued function and let $t_0 \in Q$. Then the following statements are equivalent:*

(i) *F is lower semicontinuous at t_0.*

(ii) *For any $y_0 \in F(t_0)$, $\lim_{t\to t_0} d_{F(t)}(y_0) = 0$.*

(iii) *$F(t_0) \subseteq \liminf_{t\to t_0} F(t)$.*

We collect some properties of the lower limit of the set-valued function F at $t_0 \in Q$ in the following proposition. The first property is direct from the definition and the second property is a direct consequence of [32, Proposition 4.15].

PROPOSITION 2.9. *Let Q be a metric space and X a normed linear space. Let $F : Q \to 2^X \setminus \{\emptyset\}$ be a set-valued function such that $F(t)$ is convex for each $t \in Q$. Let $t_0 \in Q$. Then $\liminf_{t\to t_0} F(t)$ is convex.*

Moreover, if X is finite dimensional and B is a compact subset contained in $\operatorname{int}(\liminf_{t\to t_0} F(t))$ (e.g., F is lower semicontinuous and B is a compact set contained in $\operatorname{int}(F(t_0))$), then there exists a neighborhood $U(t_0)$ of t_0 such that $B \subseteq \operatorname{int} F(t)$ for each $t \in U(t_0)$.

3. The strong CHIP and the SECQ. Recall that I is an arbitrary index set and $\{C_i : i \in I\}$ is a collection of nonempty closed convex subsets of X. We denote $\bigcap_{i\in I} C_i$ by C and assume that $0 \in C$ throughout the whole paper. The following theorem describes a relationship between the strong CHIP and the SECQ for the system $\{C_i : i \in I\}$. Results in this section are folklore; we include their proofs here for the sake of completeness.

THEOREM 3.1. *If $\{C_i : i \in I\}$ satisfies the SECQ, then it has the strong CHIP; the converse conclusion holds if* $\operatorname{dom}\sigma_C \subseteq \operatorname{Im}\partial\,\delta_C$, *that is, if*

$$\operatorname{dom}\sigma_C \subseteq \bigcup_{x\in C} N_C(x). \tag{3.1}$$

Proof. Suppose that $\{C_i : i \in I\}$ satisfies the SECQ. Let $x \in C$ and $y^* \in N_C(x)$. Then $(y^*, \langle y^*, x\rangle) \in \operatorname{epi}\sigma_C$ by (2.4). Hence, if $\{C_i : i \in I\}$ satisfies the SECQ, one can apply (2.7) to express $(y^*, \langle y^*, x\rangle)$ as

$$(y^*, \langle y^*, x\rangle) = \sum_{j\in J}(y_j^*, u_j)$$

for some finite set $J \subseteq I$ and $(y_j^*, u_j) \in \operatorname{epi}\sigma_{C_j}(x)$ for each $j \in J$. Then $\langle y_j^*, x\rangle \le \sigma_{C_j}(y_j^*) \le u_j$ for all $j \in J$ and $\sum_{j\in J}\langle y_j^*, x\rangle = \sum_{j\in J} u_j$. It follows that $\langle y_j^*, x\rangle = u_j$ for each $j \in J$ and hence that $y_j^* \in N_{C_j}(x)$ by (2.4). Therefore $y^* \in \sum_{i\in I} N_{C_i}(x)$. Thus the strong CHIP for $\{C_i : i \in I\}$ is proved.

Conversely, assume that $\operatorname{dom}\sigma_C \subseteq \operatorname{Im}\partial\,\delta_C$ and that the strong CHIP for $\{C_i : i \in I\}$ is satisfied. We have to show that

$$\operatorname{epi}\sigma_C \subseteq \sum_{i\in I}\operatorname{epi}\sigma_{C_i}. \tag{3.2}$$

To do this, let $(y^*, \alpha) \in \operatorname{epi}\sigma_C$, that is, $\alpha \ge \sigma_C(y^*)$. Hence $y^* \in \operatorname{dom}\sigma_C$. Then, by the assumption and (2.4), there exists $x \in C$ such that $y^* \in N_C(x)$. By the strong CHIP assumption, it follows that there exist a finite index set $J \subseteq I$ and $y_j^* \in N_{C_j}(x)$ for each $j \in J$ such that

$$y^* = \sum_{j\in J} y_j^*. \tag{3.3}$$

Note that, for each $j \in J$, $\sigma_{C_j}(y_j^*) \le \langle y_j^*, x\rangle$ because $y_j^* \in N_{C_j}(x)$. Since $\alpha \ge \langle y^*, x\rangle = \sum_{j\in J}\langle y_j^*, x\rangle$, there exists a set $\{\alpha_j : j \in J\}$ of real numbers such that

$$\alpha = \sum_{j\in J}\alpha_j \quad\text{and}\quad \sigma_{C_j}(y_j^*) \le \langle y_j^*, x\rangle \le \alpha_j \quad \text{for each } j \in J.$$

This implies that $(y_j^*, \alpha_j) \in \operatorname{epi}\sigma_{C_j}$ for each j and $(y^*, \alpha) \in \sum_{i\in I}\operatorname{epi}\sigma_{C_i}$ thanks to (3.3). Hence (3.2) is proved. □

Given a closed convex set C and a finite dimensional linear subspace Y containing C, recall from [2, section 2.4] and [14] that $C \subseteq Y$ is said to be continuous if $y^* \mapsto \sup\{\langle y^*, y\rangle : y \in C\}$ is continuous on $Y^*\backslash\{0\}$. Here, the continuity at y_0^* with $\sup\{\langle y_0^*, y\rangle : y \in C\} = +\infty$ means that for each $\alpha \in \mathbb{R}$ there exists a neighborhood V_0 of y_0^* such that $\sup\{\langle v^*, y\rangle : y \in C\} > \alpha$ for all $v^* \in V_0$.

For convenience, we use $x^*|_Z$ to denote the restriction to Z of the functional $x^* \in X^*$, where Z is a linear subspace of X.

PROPOSITION 3.2. *Let C be a nonempty closed convex set in X. Then condition* (3.1) *holds in each of the following cases:*

(i) *There exists a weakly compact convex set D and a closed convex cone K such that $C = D + K$.*

(ii) $\dim C < \infty$, $\operatorname{Im}\partial\delta_C$ *is convex, and C is a continuous set as a subset of* $\operatorname{span} C$.

Proof. (i) Suppose that (i) holds and let $y^* \in \operatorname{dom}\sigma_C$. Then since K is a cone,

$$\sup_{d\in D}\langle y^*, d\rangle = \sup_{d\in D}\langle y^*, d\rangle + \sup_{k\in K}\langle y^*, k\rangle = \sup_{d\in D,\, k\in K}\langle y^*, d+k\rangle = \sigma_C(y^*) < +\infty. \tag{3.4}$$

Since D is weakly compact, there exists $\overline{x} \in D\ (\subseteq C)$ such that $\langle y^*, \overline{x}\rangle = \sup_{d\in D}\langle y^*, d\rangle$. Thus by (3.4), $\langle y^*, \overline{x}\rangle = \sigma_D(y^*) = \sigma_C(y^*)$. Hence $y^* \in N_C(\overline{x})$ and (3.1) is proved.

(ii) Suppose that (ii) holds. If C is bounded, then C is compact because $\operatorname{span} C$ is finite dimensional. Hence (3.1) in this case follows from part (i). If C is the whole space, then (3.1) holds trivially as $\operatorname{dom}\sigma_C = \operatorname{Im}\partial\,\delta_C = \{0\}$. Thus we may assume that C is a proper and unbounded subset of the finite dimensional space $Z := \operatorname{span} C$. Let $\hat{\delta}_C$ denote the indicator function of the set C as a set in the space Z, and let $\hat{\sigma}_C(c^*) := \sup\{\langle c^*, c\rangle : c \in C\}$ for each $c^* \in Z^*$; that is, $\hat{\delta}_C$ and $\hat{\sigma}_C$ are the indicator function and the support function of C as a subset of Z, respectively. It is easy to see from definitions that

$$\operatorname{dom}\sigma_C = \{y^* \in X^* : y^*|_Z \in \operatorname{dom}\hat{\sigma}_C\} \quad \text{and} \quad \operatorname{Im}\partial\delta_C = \{y^* \in X^* : y^*|_Z \in \operatorname{Im}\partial\,\hat{\delta}_C\}. \tag{3.5}$$

Now, by the assumption, it follows that $\operatorname{Im}\partial\,\hat{\delta}_C$ is convex in Z^*. We claim that

$$\operatorname{dom}\hat{\sigma}_C \subseteq \operatorname{Im}\partial\,\hat{\delta}_C. \tag{3.6}$$

Since C is proper, unbounded, and continuous as a subset of Z, we know from [2, Proposition 2.4.3] that

$$\operatorname{dom}\hat{\sigma}_C\backslash\{\mathbf{0}\} = \operatorname{int}(\operatorname{dom}\hat{\sigma}_C) \neq \emptyset. \tag{3.7}$$

On the other hand, since $\operatorname{Im}\partial\,\hat{\delta}_C$ is a convex set in the finite dimensional Banach space Z^*, one has (cf. [35, Proposition 1.2.1 and Corollary 1.3.4])

$$\operatorname{int}(\operatorname{Im}\partial\,\hat{\delta}_C) = \operatorname{int}(\overline{\operatorname{Im}\partial\,\hat{\delta}_C}). \tag{3.8}$$

Moreover, by [35, Theorem 3.1.2], one has $\operatorname{dom}\hat{\sigma}_C \subseteq \overline{\operatorname{Im}\partial\hat{\delta}_C}$. Consequently, by (3.6)–(3.8), we get that

$$\operatorname{dom}\hat{\sigma}_C\backslash\{\mathbf{0}\} = \operatorname{int}(\operatorname{dom}\hat{\sigma}_C) \subseteq \operatorname{int}(\overline{\operatorname{Im}\partial\,\hat{\delta}_C}) = \operatorname{int}(\operatorname{Im}\partial\,\hat{\delta}_C) \subseteq \operatorname{Im}\partial\,\hat{\delta}_C.$$

Therefore claim (3.6) stands because $0 \in \operatorname{Im}\partial\hat{\delta}_C$. Consequently, (3.1) follows from (3.5), (3.6), and the Hahn–Banach theorem. The proof is complete. □

Combining Theorem 3.1 and Proposition 3.2, we immediately have the following corollary.

COROLLARY 3.3. *Let $\{C_i : i \in I\}$ be a family of closed convex sets in X. Then the strong CHIP and the SECQ are equivalent for $\{C_i : i \in I\}$ in each of the following cases.*

(i) *There exists a weakly compact convex set D and a closed convex cone K such that $C = D + K$.*
(ii) $\dim C < \infty$, *$\operatorname{Im}\partial\delta_C$ is convex, and C is a continuous set as a subset of* $\operatorname{span} C$.

Remark 3.1. Part (i) was known in some special cases; see [7, Proposition 4.2] for the case when I is a two point set and $D = \{0\}$, and see [20] for the case when I is a finite set and $D = \{0\}$.

4. Linear regularity and the SECQ. Let I be an arbitrary index set and let $\{C_i : i \in I\}$ be a *CCS*-system with $0 \in C$, where $C = \bigcap_{i\in I} C_i$ as before. Throughout this section, we shall use $\mathbf{\Sigma}^*$ to denote the set $\mathbf{B}^* \times \mathbb{R}^+$, where $\mathbf{B}^*$ is the closed unit ball of X^*, while $\mathbb{R}^+$ consists of all nonnegative real numbers. This section is devoted to a study of the relationship between the linear regularity and the SECQ. We begin with the notion of the linear regularity for the system $\{C_i : i \in I\}$ and two simple lemmas (the first one is easy to verify). Recall that, for a closed convex set S in a normed linear space X, $d_S(\cdot)$ denotes the distance function of S.

DEFINITION 4.1. *The system $\{C_i : i \in I\}$ is said to be*

(i) *linearly regular if there exists a constant $\gamma > 0$ such that*

$$d_C(x) \le \gamma \sup_{i\in I} d_{C_i}(x) \quad \textit{for all } x \in X;$$

(ii) *boundedly linearly regular if, for each $r > 0$, there exists a constant $\gamma_r > 0$ such that*

$$d_C(x) \le \gamma_r \sup_{i\in I} d_{C_i}(x) \quad \textit{for all } x \in r\mathbf{B}.$$

LEMMA 4.2. *Let $\gamma > 0$. Then*

$$\overline{\operatorname{co} \cup_{i\in I}(\operatorname{epi} \sigma_{C_i} \cap \gamma\mathbf{\Sigma}^*)}^{w^*} + \{0\} \times \mathbb{R}^+ = \overline{\operatorname{co} \cup_{i\in I}(\operatorname{epi} \sigma_{C_i} \cap \gamma\mathbf{\Sigma}^*)}^{w^*}.$$

LEMMA 4.3. *Let $\gamma > 0$ and let $f_\gamma := \gamma d_S$. If $0 \in S$, then*

$$\operatorname{epi} f_\gamma^* = \operatorname{epi} \sigma_S \cap \left(\gamma\mathbf{B}^* \times \mathbb{R}^+\right). \tag{4.1}$$

Proof. By conjugation computation rules (cf. [35, Theorem 2.3.1(v) and Proposition 3.8.3(i)]), we have for any $x^* \in X^*$,

$$f_\gamma^*(x^*) = \gamma(\sigma_S + \delta_{\mathbf{B}^*})\left(\frac{x^*}{\gamma}\right) = \sigma_S(x^*) + \delta_{\gamma\mathbf{B}^*}(x^*).$$

Then (4.1) follows immediately. □

In the next two theorems, we shall use the graph $\operatorname{gph} f$ of a function f which is defined by

$$\operatorname{gph} f := \{(x, f(x)) \in X \times \mathbb{R} : \ x \in \operatorname{dom} f\}.$$

Clearly, $\operatorname{gph} f \subseteq \operatorname{epi} f$ for a function f on X.

THEOREM 4.4. *Let $\gamma > 0$. Then the following conditions are equivalent:*

(i) *For all $x \in X$, $d_C(x) \le \gamma \sup_{i\in I} d_{C_i}(x)$.*

(ii) $\operatorname{epi} \sigma_C \cap \mathbf{\Sigma}^* \subseteq \overline{\operatorname{co} \cup_{i\in I}(\operatorname{epi} \sigma_{C_i} \cap \gamma\mathbf{\Sigma}^*)}^{w^*}$.

(iii) $\operatorname{gph} \sigma_C \cap \mathbf{\Sigma}^* \subseteq \overline{\operatorname{co} \cup_{i\in I}(\operatorname{epi} \sigma_{C_i} \cap \gamma\mathbf{\Sigma}^*)}^{w^*}$.

Proof. By Lemmas 2.3 and 4.3, one has that

$$\operatorname{epi}\left(\sup_{i\in I} d_{C_i}\right)^* = \overline{\operatorname{co} \bigcup_{i\in I} \operatorname{epi} d_{C_i}^*}^{w^*} = \overline{\operatorname{co} \bigcup_{i\in I} (\operatorname{epi} \sigma_{C_i} \cap \mathbf{\Sigma}^*)}^{w^*}.$$

Noting that $\operatorname{epi} \sigma_S$ is a cone, we see that the equivalence of (i) and (ii) follows from (2.1) and Lemma 4.3.

By Lemma 4.2, (iii) implies that

$$\begin{aligned}\operatorname{epi}\sigma_C \cap \mathbf{\Sigma}^* &\subseteq \operatorname{gph}\sigma_C \cap \mathbf{\Sigma}^* + \{0\}\times\mathbb{R}^+\\ &\subseteq \overline{\operatorname{co}\cup_{i\in I}(\operatorname{epi}\sigma_{C_i}\cap\gamma\mathbf{\Sigma}^*)}^{w^*} + \{0\}\times\mathbb{R}^+\\ &= \overline{\operatorname{co}\cup_{i\in I}(\operatorname{epi}\sigma_{C_i}\cap\gamma\mathbf{\Sigma}^*)}^{w^*}.\end{aligned}$$

Therefore (iii)⇒(ii). Since (ii)⇒(iii) is obvious, the proof is complete. □

We give a simple application of our new characterization of the linear regularity in Theorem 4.4. The following theorem includes an important characterization of the linear regularity of finitely many closed convex sets in a Banach space, given in [30, Theorem 4.2].

THEOREM 4.5. *Let $\gamma > 0$ and suppose that X is a Banach space. Consider the following statements:*

(i) *For all $x \in X$, $d_C(x) \le \gamma \sup_{i\in I} d_{C_i}(x)$.*

(ii) *For all $x \in C$, $N_C(x)\cap\mathbf{B}^* \subseteq \overline{\operatorname{co}\cup_{i\in I}(N_{C_i}(x)\cap\gamma\mathbf{B}^*)}^{w^*}$.*

Then (ii) *implies* (i). *If we assume further that I is a compact metric space and $i \mapsto C_i$ is lower semicontinuous, then* (i) *and* (ii) *are equivalent. In particular, when I is finite,* (i), (ii), (ĩi), *and* (iii) *are equivalent, where* (ĩi) *and* (iii) *are defined in the following:*

(ĩi) *For all $x \in C$, $N_C(x)\cap\mathbf{B}^* \subseteq \operatorname{co}\cup_{i\in I}(N_{C_i}(x)\cap\gamma\mathbf{B}^*)$.*

(iii) *For all $x \in C$ and for all $x^* \in N_C(x)\cap\mathbf{B}^*$, there exist $x_i^* \in N_{C_i}(x)$, $i \in I$, such that $\sum_{i\in I}\|x_i^*\| \le \gamma$ and $x^* = \sum_{i\in I} x_i^*$.*

Remark 4.1. Let $\rho > 0$ and recall from [3, 30] that the collection $\{D_1,\dots,D_m\}$ in X is said to have property (G_ρ) if

$$\left(\sum_{i=1}^m D_i\right)\bigcap\mathbf{B} \subseteq \sum_{i=1}^m\left(D_i\bigcap\frac{1}{\rho}\mathbf{B}\right).$$

Clearly, when I is finite, there exists $\gamma > 0$ such that condition (iii) above holds if and only if the strong CHIP holds for all $x \in C$ and there exists $\rho > 0$ such that, for each $x \in C$, $\{N_{C_i}(x) : i \in I\}$ has the property (G_ρ) in X^*.

Proof. (ii)⇒(i). In view of Theorem 4.4, to establish (i), it is sufficient to show that

$$\operatorname{gph}\sigma_C \cap \mathbf{\Sigma}^* \subseteq \overline{\operatorname{co}\bigcup_{i\in I}(\operatorname{epi}\sigma_{C_i}\cap\gamma\mathbf{\Sigma}^*)}^{w^*}.$$

To do this, let $(y^*,\sigma_C(y^*)) \in \operatorname{gph}\sigma_C\cap\mathbf{\Sigma}^*$. We have to show that

$$(y^*,\sigma_C(y^*)) \in \overline{\operatorname{co}\bigcup_{i\in I}(\operatorname{epi}\sigma_{C_i}\cap\gamma\mathbf{\Sigma}^*)}^{w^*}. \tag{4.2}$$

Since the set on the right-hand side of (4.2) obviously contains the origin, we may suppose without loss of generality that $y^* \ne 0$.

Consider first the case when $y^* \in \operatorname{Im}\partial\,\delta_C$. Then $y^* \in N_C(x)\cap\mathbf{B}^*$ for some $x \in C$ by (2.3). Thus one can apply (ii) to find a net $\{\tilde{y}_V^*\}$ with w^*-limit y^* such that for each V, $\tilde{y}_V^*$ is representable as

$$\tilde{y}_V^* = \gamma\sum_{i\in J_V}\lambda_i y_i^*$$

for some finite index set $J_V \subseteq I$, $y_i^* \in N_{C_i}(x) \cap \mathbf{B}^*$, $i \in J_V$, and $\lambda_i \in [0,1]$ with $\sum_{i\in J_V} \lambda_i = 1$. Using (2.4) again, we obtain $(y_i^*, \langle y_i^*, x\rangle) \in \operatorname{epi} \sigma_{C_i}$ for each $i \in J_V$. In w^*-limits, it follows that

$$(y^*, \langle y^*, x\rangle) = \lim_V (\tilde{y}_V^*, \langle \tilde{y}_V^*, x\rangle) = \lim_V \gamma \sum_{i\in J_V} \lambda_i (y_i^*, \langle y_i^*, x\rangle);$$

hence,

$$(y^*, \langle y^*, x\rangle) \in \overline{\operatorname{co} \bigcup_{i\in I} (\operatorname{epi} \sigma_{C_i} \cap \gamma \mathbf{\Sigma}^*)}^{w^*} \tag{4.3}$$

and, in particular, (4.2) holds provided that $y^* \in \operatorname{Im} \partial\, \delta_C$ and $\|y^*\| \le 1$. For the general case (that is, we do not assume that $y^* \in \operatorname{Im} \partial\, \delta_C$), by [35, Theorem 3.1.4(ii)], there exists a sequence $(y_n, y_n^*) \in \operatorname{gph} \partial\, \delta_C$ such that y_n^* converges to y^* in norm and $\sigma_C(y_n^*)$ converges to $\sigma_C(y^*)$. Note that by (2.4), we have $(y_n^*, \langle y_n^*, y_n\rangle) \in \operatorname{gph} \sigma_C$. If $\|y_n^*\| \le 1$ for all but finitely many $n \in \mathbb{N}$, then one can apply (4.3) to $(y_n^*, \sigma_C(y_n^*))$ in place of $(y^*, \sigma_C(y^*))$ to conclude that

$$(y_n^*, \sigma_C(y_n^*)) \in \overline{\operatorname{co} \bigcup_{i\in I} (\operatorname{epi} \sigma_{C_i} \cap \gamma \mathbf{\Sigma}^*)}^{w^*}. \tag{4.4}$$

On the other hand, if it happens that $\|y_n^*\| > 1$ for infinitely many $n \in \mathbb{N}$, then we must have $\|y^*\| = 1$ and $\|y_n^*\| \to 1$ as $n \to \infty$. Since $\operatorname{Im} \partial\, \delta_C$ is a cone, we see that $\frac{y_n^*}{\|y_n^*\|} \in \operatorname{Im} \partial\, \delta_C$. Applying (4.3) to $(\frac{y_n^*}{\|y_n^*\|}, \sigma_C(\frac{y_n^*}{\|y_n^*\|}))$ in place of $(y^*, \sigma_C(y^*))$, we obtain

$$\left(\frac{y_n^*}{\|y_n^*\|}, \sigma_C\left(\frac{y_n^*}{\|y_n^*\|}\right)\right) \in \overline{\operatorname{co} \bigcup_{i\in I} (\operatorname{epi} \sigma_{C_i} \cap \gamma \mathbf{\Sigma}^*)}^{w^*}. \tag{4.5}$$

Taking limits in (4.4) and (4.5), we get (4.2), as required in both cases. This completes the proof of (ii)⇒(i).

For the converse implication, let us begin by noting that if (i) holds, then by the definition of subdifferential, we have

$$\partial\, d_C(x) \subseteq \gamma\, \partial \sup_{i\in I} d_{C_i}(x) \quad \text{for each } x \in C. \tag{4.6}$$

Now we suppose further that I is compact and that $i \mapsto C_i$ is lower semicontinuous. Then by [1, Corollary 1.4.17], $i \mapsto d_{C_i}(\cdot)$ is upper semicontinuous. Hence one can apply [35, Theorem 2.4.18] to get the inclusion $\partial \left(\sup_{i\in I} d_{C_i}\right)(x) \subseteq \overline{\operatorname{co} \cup_{i\in I} \partial\, d_{C_i}(x)}^{w^*}$, and it follows from (4.6) that $\partial\, d_C(x) \subseteq \gamma\, \overline{\operatorname{co} \cup_{i\in I} \partial\, d_{C_i}(x)}^{w^*}$; hence (ii) holds for all $x \in C$ thanks to the standard result that $\partial\, d_C(x) = N_C(x) \cap B^*$ and $\partial\, d_{C_i}(x) = N_{C_i}(x) \cap B^*$ (cf. [35, Proposition 3.8.3]).

Next, we consider the case when I is finite. We need only show that (ii)⇔($\tilde{\text{ii}}$) in this case. For any $x \in C$, we note that by the Banach–Alaoglu theorem, $N_{C_i}(x) \cap \mathbf{B}^*$ is w^*-compact for each $i \in I$; thus $\operatorname{co} \cup_{i\in I} (N_{C_i}(x) \cap \mathbf{B}^*)$ is w^*-closed as I is finite. Hence (ii) and ($\tilde{\text{ii}}$) are the same when I is finite.

Finally, we turn to prove that ($\tilde{\text{ii}}$)⇔(iii). The forward implication is obvious. For the converse implication, fix $x \in C$. Let $x^* \in N_C(x) \cap \mathbf{B}^*$; we wish to show that $x^* \in \operatorname{co} \cup_{i\in I} (N_{C_i}(x) \cap \gamma \mathbf{B}^*)$. By (iii), there exist $x_i^* \in N_{C_i}(x)$, $i \in I$, with

$\sum_{i\in I}\|x_i^*\| \le \gamma$ and $x^* = \sum_{i\in I} x_i^*$. If all the x_i^*'s are zero, then the inclusion holds trivially. Otherwise, set $\lambda := \sum_{i\in I}\|x_i^*\| > 0$. Then $\lambda \le \gamma$. Thus we see that

$$x^* = \lambda\left(\sum_{i\in I,\, x_i^*\neq 0}\frac{\|x_i^*\|}{\lambda}\frac{x_i^*}{\|x_i^*\|} + \left(1 - \sum_{i\in I,\, x_i^*\neq 0}\frac{\|x_i^*\|}{\lambda}\right)0\right) \in \operatorname{co}\bigcup_{i\in I}(N_{C_i}(x)\cap\gamma\mathbf{B}^*),$$

which completes the proof. □

THEOREM 4.6. *Suppose that*

$$\overline{\operatorname{co}\bigcup_{i\in I}(\operatorname{epi}\sigma_{C_i}\cap\mathbf{\Sigma}^*)}^{w^*} \subseteq \sum_{i\in I}\operatorname{epi}\sigma_{C_i}, \tag{4.7}$$

and that $\{C_i : i\in I\}$ is linearly regular. Then it satisfies the SECQ.

Proof. By the assumption, one can combine (4.7) with Theorem 4.4 to conclude that $\operatorname{epi}\sigma_C\cap\mathbf{\Sigma}^* \subseteq \sum_{i\in I}\operatorname{epi}\sigma_{C_i}$, and hence that $\operatorname{epi}\sigma_C \subseteq \sum_{i\in I}\operatorname{epi}\sigma_{C_i}$ for each $\operatorname{epi}\sigma_{C_i}$ is a cone. □

In the next theorem, we shall provide some sufficient conditions for (4.7). We first prove a simple lemma. We shall prove it in a bit more general context for later use. Recall that $\{C_i : i\in I\}$ is a *CCS*-system with $0\in C$.

LEMMA 4.7. *Let I be a metric space. Suppose that Z is a linear subspace of X and $i\mapsto Z\cap C_i$ is lower semicontinuous. Consider elements $i_0\in I$, $(x_0^*,\alpha_0)\in X^*\times\mathbb{R}$ and nets $\{i_k\}\subseteq I$, $\{(x_k^*,\alpha_k)\}\subseteq X^*\times\mathbb{R}$ with each $(x_k^*,\alpha_k)\in\operatorname{epi}\sigma_{C_{i_k}}$. Suppose further that $i_k\to i_0$, $\alpha_k\to\alpha_0$, and $x_k^*|_Z \to^{w^*} x_0^*|_Z$. If $\{x_k^*|_Z\}$ is bounded, then $(x_0^*,\alpha_0)\in\operatorname{epi}\sigma_{Z\cap C_{i_0}}$.*

Proof. Let $x\in Z\cap C_{i_0}$. We have to prove that $\langle x_0^*, x\rangle \le \alpha_0$. By the assumption, there exists a net $\{x_k\}\subseteq X$ with each $x_k\in Z\cap C_{i_k}$ such that $x_k\to x$. Since

$$\langle x_0^*, x\rangle = \langle x_0^* - x_k^*, x\rangle + \langle x_k^*, x - x_k\rangle + \langle x_k^*, x_k\rangle,$$

where on the right-hand side the first two terms converge to zero and the last term $\langle x_k^*, x_k\rangle \le \alpha_k$ for each k, it follows by passing to the limits that $\langle x_0^*, x\rangle \le \alpha_0$. □

THEOREM 4.8. *Let I be a compact metric space and $i\mapsto C_i$ be lower semicontinuous on I. Suppose that either I is finite or there exists an index $i_0\in I$ such that $\dim C_{i_0} < +\infty$. Then (4.7) holds. Consequently, if $\{C_i : i\in I\}$ is, in addition, linearly regular, then it satisfies the SECQ.*

Proof. We first assume that I is finite, say $I = \{1,2,\ldots,m\}$. Let $(\overline{x}^*,\overline{\alpha})\in \overline{\operatorname{co}\cup_{i=1}^m(\operatorname{epi}\sigma_{C_i}\cap\mathbf{\Sigma}^*)}^{w^*}$. Then there exists a net $\{(\overline{x}_k^*,\overline{\alpha}_k)\}$ in $\operatorname{co}\cup_{i=1}^m(\operatorname{epi}\sigma_{C_i}\cap\mathbf{\Sigma}^*)$ such that $(\overline{x}_k^*,\overline{\alpha}_k)$ w^*-converges to $(\overline{x}^*,\overline{\alpha})$. Without loss of generality, we assume that $0\le\overline{\alpha}_k\le\overline{\alpha}+1$ for all k. Each $(\overline{x}_k^*,\overline{\alpha}_k)$ can be expressed as a convex combination

$$(\overline{x}_k^*,\overline{\alpha}_k) = \sum_{i=1}^m \lambda_{k,i}(x_{k,i}^*,\alpha_{k,i}) \tag{4.8}$$

for some $(x_{k,i}^*,\alpha_{k,i})\in\operatorname{epi}\sigma_{C_i}\cap\Sigma^*$ and $\lambda_{k,i}\in[0,1]$ with $\sum_{i=1}^m\lambda_{k,i}=1$. Note that

$$\lambda_{k,i}(x_{k,i}^*,\alpha_{k,i})\in\operatorname{epi}\sigma_{C_i}\cap\mathbf{\Sigma}^* \quad\text{for each } k \text{ and } i. \tag{4.9}$$

By considering subnets if necessary and by the w^*-compactness of the closed unit ball in Banach dual space X^* (the Banach–Alaoglu theorem), we may assume without loss of generality that for each i, there exist $x_i^*\in\mathbf{B}^*$ and $\beta_i\in[0,\overline{\alpha}+1]$ such that

$$\lambda_{k,i}x_{k,i}^*\to x_i^*, \quad \lambda_{k,i}\alpha_{k,i}\to\beta_i \tag{4.10}$$

(note that $\lambda_{k,i}\alpha_{k,i} \le \overline{\alpha}+1$ for all k). By the w^*-closedness of the set $\operatorname{epi}\sigma_{C_i}$, we have from (4.10) and (4.9) that

$$(x_i^*, \beta_i) \in \operatorname{epi}\sigma_{C_i} \quad \text{for each } i. \tag{4.11}$$

Passing to the limits in (4.8), we arrive at

$$(\overline{x}^*, \overline{\alpha}) = \sum_{i=1}^{m}(x_i^*, \beta_i) \in \sum_{i=1}^{m}\operatorname{epi}\sigma_{C_i},$$

where the inclusion follows from (4.11).

Next we assume that there exists an index $i_0 \in I$ such that $\dim C_{i_0} < +\infty$. Let $Z_0 = \operatorname{span} C_{i_0}$ and let $(\overline{x}^*, \overline{\alpha}) \in \overline{\operatorname{co}\cup_{i\in I}(\operatorname{epi}\sigma_{C_i} \cap \mathbf{\Sigma}^*)}^{w^*}$. Then there exists a net $\{(\overline{x}_k^*, \overline{\alpha}_k)\}$ in $\operatorname{co}\cup_{i\in I}(\operatorname{epi}\sigma_{C_i} \cap \mathbf{\Sigma}^*)$ such that $(\overline{x}_k^*, \overline{\alpha}_k) \to^{w^*} (\overline{x}^*, \overline{\alpha})$. Since $Z_0 \times \mathbb{R}$ is of dimension $m+1$, one can apply the Carathéodory theorem to express each $(\overline{x}_k^*, \overline{\alpha}_k)$ as a convex combination of $m+2$ many elements of $\cup_{i\in I}(\operatorname{epi}\sigma_{C_i} \cap \mathbf{\Sigma}^*)$. Hence there exist indices $i_j^k \in I$, nonnegative scalars $\lambda_{k,j}$, and pairs

$$(x_{k,j}^*, \alpha_{k,j}) \in \operatorname{epi}\sigma_{C_{i_j^k}} \cap \mathbf{\Sigma}^* \quad \text{for each } 1 \le j \le m+2$$

with the properties $\sum_{j=1}^{m+2}\lambda_{k,j} = 1$ and

$$(\overline{x}_k^*|_{Z_0}, \overline{\alpha}_k) = \sum_{j=1}^{m+2}\lambda_{k,j}(x_{k,j}^*|_{Z_0}, \alpha_{k,j}). \tag{4.12}$$

Note that

$$\lambda_{k,j}(x_{k,j}^*, \alpha_{k,j}) \in \operatorname{epi}\sigma_{C_{i_j^k}} \cap \mathbf{\Sigma}^*. \tag{4.13}$$

Since $\{\overline{\alpha}_k\}$ is convergent, by passing to subnets if necessary, we may assume that $\overline{\alpha}+1 \ge \overline{\alpha}_k \ge 0$. Then we also have $\{\overline{\alpha}_k\}$ and $\{\lambda_{k,j}\alpha_{k,j}\}$ bounded for $1 \le j \le m+2$. Hence, considering subnets if necessary, we may assume that each of the nets $\{\lambda_{k,j}x_{k,j}^*\}$, $\{\overline{\alpha}_k\}$, $\{\lambda_{k,j}\alpha_{k,j}\}$ for $1 \le j \le m+2$ converges, say with limits,

$$x_{0,j}^*, \quad \overline{\alpha}, \quad \alpha_{0,j},$$

and we can assume further that i_j^k converges to some $i_j^0 \in I$ $(1 \le j \le m+2)$, thanks to the compactness assumption of I. Making use of (4.13) and thanks to the assumption that $i \mapsto C_i$ is lower semicontinuous, it follows from Lemma 4.7 (applied to X in place of Z) that

$$(x_{0,j}^*, \alpha_{0,j}) \in \operatorname{epi}\sigma_{C_{i_j^0}} \quad \text{for each } 1 \le j \le m+2.$$

Moreover, passing to the limits in (4.12), we have

$$(\overline{x}^*|_{Z_0}, \overline{\alpha}) = \sum_{j=1}^{m+2}(x_{0,j}^*|_{Z_0}, \alpha_{0,j}).$$

Noting the trivial relation that $\operatorname{epi}\sigma_{C_{i_0}}$ contains $Z_0^\perp \times \mathbb{R}^+$, where $Z_0^\perp := \{x^* \in X^* : x^*|_{Z_0} = 0\}$, it follows that

$$(\overline{x}^*, \overline{\alpha}) \in \sum_{j=1}^{m+2}(x_{0,j}^*, \alpha_{0,j}) + Z_0^\perp \times \mathbb{R}^+ \subseteq \sum_{i\in I}\operatorname{epi}\sigma_{C_i}.$$

This shows that (4.7) holds.

Finally, in addition we assume that $\{C_i : i \in I\}$ is linearly regular. Then it follows from Theorem 4.6 that this system satisfies the SECQ. □

We intend to relate bounded linear regularity with the strong CHIP. We first provide a sufficient condition for a system to be linearly regular. The result is known when the ambient space is a Hilbert space [4, Theorem 4.2.6, Corollary 4.4.4] or a Banach space [34, Corollary 5]. The corresponding theorems in those references are derived from a lemma whose proof is based on the open mapping theorem and thus does not work in general normed linear spaces. As some preparatory work, we first state the following lemma, which is a generalization of [7, Proposition 3.1(i)] to a normed linear space (or even locally convex space) setting. We shall omit its proof, as it is a direct application of [29, Remarque 10.2] (alternatively, the proof given for [7, Proposition 3.1(i)], which was based on a result in [34], can easily be adopted here).

LEMMA 4.9. *Let E, F be two closed convex sets in X with $E \cap \operatorname{int} F \neq \emptyset$. Then $\{E, F\}$ satisfies the SECQ.*

We now give a sufficient condition for a system to be linearly regular.

LEMMA 4.10. *Let E be a closed convex set in X containing the origin and let $r > 0$. Then*

$$d_{E\cap r\mathbf{B}}(x) \leq 4\max\{d_E(x), d_{r\mathbf{B}}(x)\} \quad \text{for each } x \in X. \tag{4.14}$$

Proof. We first show that

$$\operatorname{gph}\sigma_{E\cap r\mathbf{B}} \cap \mathbf{\Sigma}^* \subseteq \operatorname{co}\left((\operatorname{epi}\sigma_E \cap 4\mathbf{\Sigma}^*) \cup (\operatorname{epi}\sigma_{r\mathbf{B}} \cap 4\mathbf{\Sigma}^*)\right). \tag{4.15}$$

Take $(y^*, \sigma_{E\cap r\mathbf{B}}(y^*)) \in \operatorname{gph}\sigma_{E\cap r\mathbf{B}} \cap \mathbf{\Sigma}^*$. By Lemma 4.9, there exist $(y_1^*, \alpha_1) \in \operatorname{epi}\sigma_E$ and $(y_2^*, \alpha_2) \in \operatorname{epi}\sigma_{r\mathbf{B}}$ such that

$$(y^*, \sigma_{E\cap r\mathbf{B}}(y^*)) = (y_1^*, \alpha_1) + (y_2^*, \alpha_2).$$

This implies that

$$\sigma_{E\cap r\mathbf{B}}(y^*) = \alpha_1 + \alpha_2. \tag{4.16}$$

Since $0 \in E$, we have $0 \leq \sigma_E(y_1^*) \leq \alpha_1$ and hence $\alpha_2 \leq \sigma_{E\cap r\mathbf{B}}(y^*) \leq r$ thanks to (4.16). It follows that $r\|y_2^*\| = \sigma_{r\mathbf{B}}(y_2^*) \leq \alpha_2 \leq r$, and thus $\|y_1^*\| \leq \|y^*\| + \|y_2^*\| \leq 2$. Therefore,

$$(y^*, \sigma_{E\cap r\mathbf{B}}(y^*)) = \frac{1}{2}\left[(2y_1^*, 2\alpha_1) + (2y_2^*, 2\alpha_2)\right] \in \operatorname{co}((\operatorname{epi}\sigma_E \cap 4\mathbf{\Sigma}^*) \cup (\operatorname{epi}\sigma_{r\mathbf{B}} \cap 4\mathbf{\Sigma}^*))$$

and (4.15) is established. By the implication (iii)⇒(i) of Theorem 4.4 (with $\gamma = 4$), it follows that (4.14) holds. □

The following proposition on a relationship between bounded linear regularity and the linear regularity was shown in [4, Theorem 4.2.6(ii)] for the special case when X is a Hilbert space.

PROPOSITION 4.11. *Let $\{A_i : i \in I\}$ be a system of closed convex sets in X containing the origin, and suppose that $\{A_i : i \in I\}$ is boundedly linearly regular. Then for all $r > 0$, the system $\{r\mathbf{B}, A_i : i \in I\}$ is linearly regular.*

Proof. Write $A = \cap_{i\in I} A_i$ and let $r > 0$. By assumption, there exists $k_r > 0$ such that

$$d_A(x) \leq k_r \sup_{i\in I} d_{A_i}(x) \quad \text{for each } x \in r\mathbf{B}. \tag{4.17}$$

Let f be defined by $f(x) := k_r \sup_{i\in I} d_{A_i}(x) - d_A(x)$ for each $x \in X$. From (4.17), we see that $f(x) \geq 0$ for all $x \in r\mathbf{B}$, and the equality holds for all $x \in \bigcap_{i\in I} A_i \cap r\mathbf{B}$. Since f is clearly Lipschitz with modulus $k_r + 1$, it follows from [8, Proposition 2.4.3] that $f(x) + (k_r + 1)d_{r\mathbf{B}}(x) \geq 0$ for all $x \in X$. This implies

$$d_A(x) \leq (2k_r + 1) \max\left\{d_{r\mathbf{B}}(x), \sup_{i\in I} d_{A_i}(x)\right\} \quad \text{for each } x \in X.$$

It follows from Lemma 4.10 that

$$\begin{aligned} d_{A\cap r\mathbf{B}}(x) &\leq 4\max\{d_{r\mathbf{B}}(x), d_A(x)\} \\ &\leq 4(2k_r + 1) \max\left\{d_{r\mathbf{B}}(x), \sup_{i\in I} d_{A_i}(x)\right\} \quad \text{for each } x \in X. \end{aligned}$$

This completes the proof. □

For the following corollary, we need a lemma, which will also be used in the next section.

LEMMA 4.12. *Let $\{D, C_i : i \in I\}$ be a family of closed convex sets with nonempty intersection. Let A be a closed subset of X such that*

$$D \bigcap \left(\bigcap_{i\in I} C_i\right) \bigcap \operatorname{int} A \neq \emptyset. \tag{4.18}$$

If $\{D, C_i : i \in I\}$ has the strong CHIP, then so does $\{D \cap A, C_i : i \in I\}$. As a partial converse result, if $\{D \cap A, C_i : i \in I\}$ has the strong CHIP at some point $a \in D \cap (\cap_{i\in I} C_i) \cap \operatorname{int} A$, so does $\{D, C_i : i \in I\}$.

Proof. Set $E := D \cap (\cap_{i\in I} C_i)$. By hypothesis, $N_E(x) = N_D(x) + \sum_{i\in I} N_{C_i}(x)$ for each $x \in E$. Since $E \cap \operatorname{int} A \neq \emptyset$ and $D \cap \operatorname{int} A \neq \emptyset$,

$$\begin{aligned} N_{(A\cap D)\cap(\cap_{i\in I} C_i)}(x) = N_{A\cap E}(x) &= N_A(x) + N_E(x) = N_A(x) + N_D(x) + \sum_{i\in I} N_{C_i}(x) \\ &= N_{A\cap D}(x) + \sum_{i\in I} N_{C_i}(x) \qquad \text{for each } x \in A \cap E. \end{aligned}$$

This proves the first part. For the second part, observe that $N_A(a) = \{0\}$; hence $N_{A\cap D}(a) = N_D(a)$ and $N_{A\cap E}(a) = N_E(a)$. The conclusion is then immediate. □

COROLLARY 4.13. *Suppose that I is a compact metric space and the set-valued function $i \mapsto C_i$ is lower semicontinuous. Suppose that either I is finite or there exists an index $i_0 \in I$ such that $\dim C_{i_0} < +\infty$. If $\{C_i : i \in I\}$ is boundedly linearly regular, then it has the strong CHIP.*

Proof. Fix any $x \in \cap_{i\in I} C_i$. Let $r = \|x\| + 1$. Since $\{C_i : i \in I\}$ is boundedly linearly regular, we obtain from Proposition 4.11 that $\{r\mathbf{B}, C_i : i \in I\}$ is linearly regular. Taking an index $i_\infty \notin I$, set $I_\infty = I \cup \{i_\infty\}$ and $C_{i_\infty} = r\mathbf{B}$. Clearly the map $i \mapsto C_i$ is lower semicontinuous on I_∞. It now follows from the assumptions and Theorem 4.8 that $\{C_i : i \in I_\infty\}$ satisfies the SECQ and so does $\{r\mathbf{B}, C_i : i \in I\}$; thus $\{r\mathbf{B}, C_i : i \in I\}$ has the strong CHIP (thanks to Theorem 3.1). Then it follows from Lemma 4.12 (with $D = X$ and $A = r\mathbf{B}$) that $\{C_i : i \in I\}$ has the strong CHIP at x because $x \in \operatorname{int}(r\mathbf{B})$. The proof is complete. □

Corollary 4.13 and the implication (i)$\Longrightarrow$(ii) in Theorem 4.5 were established under the following conditions: (α) I is compact, and (β) the set-valued function

$i \mapsto C_i$ is lower semicontinuous. Below we give a simple example with several cases to illustrate that these conditions are needed.

Example 4.1. Let $X = \mathbb{R}^2$ and $J = \{\frac{1}{n} : n \in \mathbb{N}\}$. Define $C_j := \{x \in X : \|x\| \le j\}$ for each $j \in J$. Consider the system $\{X, C_i : i \in I\}$ with I defined in the following:

(a) $I = J$.

(b) $I = \{0\} \cup J$ and $C_0 := \{x \in X : \|x\| \le 1\}$.

(c) $I = \{0\} \cup J$ and $C_0 := \{0\}$.

Then, in each case, $C = \cap_{i\in I} C_i = \{0\}$. Moreover, for each $x \in X$, $d_{C_i}(x) = \max\{0, \|x\| - i\}$ for each $i \in J$, while $d_{C_0}(x) = \max\{0, \|x\| - 1\}$ in (b) and $d_{C_0}(x) = \|x\|$ in (c). It follows that

$$\sup_{i\in I} d_{C_i}(x) = \|x\| = d(x, 0) = d_{\bigcap_{i\in I} C_i}(x). \tag{4.19}$$

Thus the system $\{C_i : i \in I\}$ is linearly regular in each of (a), (b), and (c). Note also that (c) satisfies both (α) and (β) and hence that Theorem 4.5(ii) and the conclusion of Corollary 4.13 hold (and these can be verified directly too). For each of (a) and (b), we have $C = \{0\}$ and $N_{C_i}(0) = \{0\}$ for each $i \in I$, so $N_C(0) \cap \mathbf{B} = \mathbf{B}$ but $\operatorname{co} \cup_{i\in I}(N_{C_i}(0) \cap \mathbf{B}) = \{0\}$; thus the corresponding system does not have the strong CHIP (nor the SECQ, by Theorem 3.1), and Theorem 4.5(ii) does not hold. This failure of (a) and (b) is because each satisfies only one condition of (α), (β) (I is not compact in (a) and the set-valued function $i \mapsto C_i$ is not lower semicontinuous in (b)).

5. Interior-point conditions and the SECQ. Recall that I is an index-set and $C = \bigcap_{i\in I} C_i \subseteq X$. As in [27], the family $\{D, C_i : i \in I\}$ is called a closed convex set system with base-set D (*CCS*-system with base-set D) if D and all C_i's are closed convex subsets of X. Furthermore, throughout the remainder of this section, we always assume that I is a compact metric space and that $0 \in D \cap C$. Thus,

$$\sigma_D \text{ and } \sigma_{C_i} \text{ are nonnegative functions on } X^* \text{ for all } i \in I.$$

Let $|J|$ denote the cardinality of the set J.

DEFINITION 5.1. *Let $\{D, C_i : i \in I\}$ be a CCS-system with base-set D. Let m be a positive integer. Then the CCS-system $\{D, C_i : i \in I\}$ is said to satisfy*

(i) *the m-D-interior-point condition if, for any subset J of I with $|J| \le m$,*

$$D \bigcap \left(\bigcap_{i\in J} \operatorname{rint}_D C_i \right) \neq \emptyset;$$

(ii) *the m-interior-point condition if, for any subset J of I with $|J| \le m$,*

$$D \bigcap \left(\bigcap_{i\in J} \operatorname{int} C_i \right) \neq \emptyset.$$

Before proving our main theorems, we first give the following lemma. Recall that, for a linear subspace Z of X, $y^*|_Z \in Z^*$ is the restriction to Z of y^*.

LEMMA 5.2. *Let m be a positive integer and let $\{D, C_i : i \in I\}$ be a CCS-system with the base-set D. Let $Z := \operatorname{span} D$ and suppose that the following conditions are satisfied:*

(a) *D is finite dimensional.*

(b) *The set-valued mapping $i \mapsto Z \cap C_i$ is lower semicontinuous on I.*
(c) *The system $\{D, C_i : i \in I\}$ satisfies the m-D-interior-point condition.*
Let $(y^*, \alpha) \in X^* \times \mathbb{R}$ and let $\{(y_k^*, \alpha_k)\} \subseteq X^* \times \mathbb{R}$ be a sequence such that

$$(y_k^*|_Z, \alpha_k) \text{ converges to } (y^*|_Z, \alpha), \tag{5.1}$$

where each $(y_k^*|_Z, \alpha_k)$ can be expressed in the form

$$(y_k^*|_Z, \alpha_k) = (v_k^*|_Z, \beta_k) + \sum_{j=1}^{m} \left(x_{i_j^k}^*\Big|_Z, \alpha_{i_j^k} \right) \tag{5.2}$$

with

$$(v_k^*, \beta_k) \in \operatorname{epi} \sigma_D, \quad \left(x_{i_j^k}^*, \alpha_{i_j^k} \right) \in \operatorname{epi} \sigma_{C_{i_j^k}} \tag{5.3}$$

for some $i_1^k, \ldots, i_m^k \in I$. Then

$$(y^*, \alpha) \in \operatorname{epi} \sigma_D + \sum_{i \in I} \operatorname{epi} \sigma_{Z \cap C_i}. \tag{5.4}$$

Proof. Since I is compact, by considering subsequences if necessary we may assume that there exists $i_j \in I$ such that $i_j^k \to i_j$ for each $j = 1, \ldots, m$. By assumption (c), there exist $z \in D$ and $\delta' > 0$ such that

$$\mathbf{B}(z, \delta') \cap Z \subseteq C_{i_j} \cap Z \quad \text{for each } j = 1, 2, \ldots, m. \tag{5.5}$$

Set for convenience $B := \mathbf{B}(z, \delta) \cap Z$, where $\delta = \frac{\delta'}{2}$. Then B is compact, thanks to assumption (a). For each $j = 1, 2, \ldots, m$, we make use of assumption (b) and apply Proposition 2.9 at the point $t_0 := i_j$ of the lower semicontinuous function $i \mapsto C_i \cap Z$ to conclude from (5.5) that $B \subseteq C_{i_j^k} \cap Z$ for all large enough k. Do this for each $j = 1, 2, \ldots, m$ and take $k_0 \in \mathbb{N}$ large enough such that

$$B \subseteq C_{i_j^k} \cap Z \quad \text{for each } 1 \le j \le m \text{ and } k \ge k_0. \tag{5.6}$$

Note that, for each $1 \le j \le m$ and $k \in \mathbb{N}$,

$$\sigma_B \left(x_{i_j^k}^* \right) = \sup_{x \in B} \left\langle x_{i_j^k}^*, x \right\rangle = \sup_{x \in \delta \mathbf{B} \cap Z} \left\langle x_{i_j^k}^*, x \right\rangle + \left\langle x_{i_j^k}^*, z \right\rangle = \delta \left\| x_{i_j^k}^*\Big|_Z \right\| + \left\langle x_{i_j^k}^*, z \right\rangle.$$

It follows from (5.6) that

$$\alpha_{i_j^k} \ge \sigma_{C_{i_j^k}} \left(x_{i_j^k}^* \right) \ge \sigma_{C_{i_j^k} \cap Z} \left(x_{i_j^k}^* \right) \ge \sigma_B \left(x_{i_j^k}^* \right) = \delta \left\| x_{i_j^k}^*\Big|_Z \right\| + \left\langle x_{i_j^k}^*, z \right\rangle, \tag{5.7}$$

provided that $k \ge k_0$. Moreover, since $z \in D$ and $(v_k^*, \beta_k) \in \operatorname{epi} \sigma_D$, (5.2) establishes that

$$\alpha_k - \langle y_k^*, z \rangle = \beta_k - \langle v_k^*, z \rangle + \sum_{j=1}^{m} \left(\alpha_{i_j^k} - \left\langle x_{i_j^k}^*, z \right\rangle \right) \ge \sum_{j=1}^{m} \left(\alpha_{i_j^k} - \left\langle x_{i_j^k}^*, z \right\rangle \right). \tag{5.8}$$

Combining (5.7) and (5.8) yields that

$$\alpha_k - \langle y_k^*, z \rangle \ge \sum_{j=1}^{m} \left(\alpha_{i_j^k} - \left\langle x_{i_j^k}^*, z \right\rangle \right) \ge \sum_{j=1}^{m} \delta \left\| x_{i_j^k}^*\Big|_Z \right\|.$$

This implies that $\{x^*_{i^k_j}|_Z : k \in \mathbb{N}\}$ is bounded for each $1 \le j \le m$ thanks to (5.1). Consequently $\{v^*_k|_Z : k \in \mathbb{N}\}$ is bounded as, by (5.2), $(v^*_k|_Z)$ is the sum of $m+1$ bounded sequences. Since Z is finite dimensional (and by passing to subsequences if necessary) we may assume that for each $j = 1, 2, \ldots, m$, there exist $\tilde{x}^*_{i_j}$ and $\tilde{v}^* \in Z^*$ such that

$$x^*_{i^k_j}\Big|_Z \to \tilde{x}^*_{i_j} \text{ and } v^*_k|_Z \to \tilde{v}^* \text{ as } k \to \infty.$$

Now, observe from (5.1)–(5.3) that $\{\alpha_{i^k_j}\}$ and $\{\beta_k\}$ are bounded. Thus we may also assume that, for each j, $\alpha_{i^k_j} \to \hat{\alpha}_{i_j}$ for some $\hat{\alpha}_{i_j} \in \mathbb{R}$ and that $\beta_k \to \hat{\beta}$ for some $\hat{\beta} \in \mathbb{R}$. Then, by (5.1) and (5.2),

$$y^*|_Z = \tilde{v}^* + \sum_{j=1}^m \tilde{x}^*_{i_j} \quad \text{and} \quad \alpha = \hat{\beta} + \sum_{j=1}^m \hat{\alpha}_{i_j}. \tag{5.9}$$

Let $x^*_{i_j} \in X^*$ be an extension of $\tilde{x}^*_{i_j}$ to X and $v^* \in X^*$ be an extension of $\tilde{v}^*$ to X. It follows from Lemma 4.7 that $(x^*_{i_j}, \hat{\alpha}_{i_j}) \in \operatorname{epi} \sigma_{(C_{i_j} \cap Z)}$ and $(v^*, \hat{\beta}) \in \operatorname{epi} \sigma_D$. Write $\hat{y}^* = y^* - v^* - \sum_{j=1}^m x^*_{i_j}$. Then by (5.9), $\hat{y}^* \in Z^\perp$ and

$$(y^*, \alpha) = (\hat{y}^*, 0) + (v^*, \hat{\beta}) + \sum_{j=1}^m \left(x^*_{i_j}, \hat{\alpha}_{i_j}\right) \in Z^\perp \times \{0\} + \operatorname{epi} \sigma_D + \sum_{j=1}^m \operatorname{epi} \sigma_{C_{i_j} \cap Z}.$$

Thus, (5.4) holds, as $Z^\perp \times \{0\}$ is clearly contained in $\operatorname{epi} \sigma_D$. □

Remark 5.1. If, for (a) of Lemma 5.2, $\dim D \le m-1$, then the following implication is valid:

$$\text{(a)} \wedge \text{(b)} \wedge \text{(c)} \Rightarrow \{D, (\operatorname{span} D) \cap C_i : i \in I\} \text{ satisfies the SECQ.}$$

(This can be seen from (i) of Theorem 5.3 below, but with m replaced by $m-1$.)

THEOREM 5.3. *Let $m \in \mathbb{N}$ and let $\{D, C_i : i \in I\}$ be a CCS-system with the base-set D. We consider the following conditions:*

(a) *D is of finite dimension m.*
(b) *The set-valued mapping $i \mapsto (\operatorname{span} D) \cap C_i$ is lower semicontinuous on I.*
(c) *The system $\{D, C_i : i \in I\}$ satisfies the $(m+1)$-D-interior-point condition.*
(d) *For each $i \in I$, the pair $\{D, C_i\}$ has the property*

$$\operatorname{epi} \sigma_{(\operatorname{span} D) \cap C_i} \subseteq \operatorname{epi} \sigma_D + \operatorname{epi} \sigma_{C_i}$$

(e.g., $\{D, C_i\}$ satisfies the SECQ).
(c*) *The system $\{D, C_i : i \in I\}$ satisfies the m-D-interior-point condition.*
(d*) *For each finite subset J of I with $|J| = \min\{m+1, |I|\}$, the subsystem $\{D, C_j : j \in J\}$ satisfies the SECQ.*

Then the following assertions hold:

(i) *If* (a), (b), (c) *are satisfied, then $\{D, (\operatorname{span} D) \cap C_i : i \in I\}$ satisfies the SECQ.*
(ii) *If* (a), (b), (c), (d) *are satisfied, then $\{D, C_i : i \in I\}$ satisfies the SECQ.*
(iii) *If D is bounded and* (a), (b), (c*), (d*) *are satisfied, then $\{D, C_i : i \in I\}$ satisfies the SECQ.*

Proof. (i) Write $Z := \operatorname{span} D$ as before. For a subset H of $X^* \times \mathbb{R}$, we use $H|_Z \subseteq Z^* \times \mathbb{R}$ to denote the restriction to Z of H defined by

$$H|_Z = \{(x^*|_Z, \beta) : \ (x^*, \beta) \in H\}.$$

Let $(y^*, \alpha) \in \overline{\operatorname{epi}\sigma_D + \sum_{i\in I} \operatorname{epi}\sigma_{C_i}}^{w^*}$. Since Z is finite dimensional, there exists a sequence $\{(y_k^*, \alpha_k)\} \subseteq X^* \times \mathbb{R}$ with

$$(y_k^*, \alpha_k) \in \operatorname{epi}\sigma_D + \sum_{i\in I} \operatorname{epi}\sigma_{C_i} \quad \text{for each } k \in \mathbb{N} \tag{5.10}$$

such that $(y_k^*|_Z, \alpha_k)$ converges to $(y^*|_Z, \alpha)$. By (5.10) we express for each $k \in \mathbb{N}$,

$$(y_k^*, \alpha_k) = (v_k^*, \beta_k) + (u_k^*, \gamma_k), \tag{5.11}$$

where $(v_k^*, \beta_k) \in \operatorname{epi}\sigma_D$ and $(u_k^*, \gamma_k) \in \sum_{i\in I} \operatorname{epi}\sigma_{C_i}$. Since $(\sum_{i\in I} \operatorname{epi}\sigma_{C_i})|_Z$ is a convex cone in the $(m+1)$-dimensional space $Z^* \times \mathbb{R}$, it follows from [32, Theorem 3.15] that, for each k, there exist indices $\{i_1^k, \ldots, i_{m+1}^k\} \subseteq I$ and $\{(x_{i_1^k}^*, \alpha_{i_1^k}), \ldots, (x_{i_{m+1}^k}^*, \alpha_{i_{m+1}^k})\}$ with $(x_{i_j^k}^*, \alpha_{i_j^k}) \in \operatorname{epi}\sigma_{C_{i_j^k}}$ for each $1 \le j \le m+1$ such that

$$(u_k^*|_Z, \gamma_k) = \sum_{j=1}^{m+1} \left(x_{i_j^k}^*\Big|_Z, \alpha_{i_j^k} \right) \quad \text{for each } k \in \mathbb{N}. \tag{5.12}$$

Thus we have

$$(y_k^*|_Z, \alpha_k) = (v_k^*|_Z, \beta_k) + \sum_{j=1}^{m+1} \left(x_{i_j^k}^*\Big|_Z, \alpha_{i_j^k} \right) \quad \text{for each } k \in \mathbb{N}. \tag{5.13}$$

By Lemma 5.2 and thanks to assumptions (a), (b), (c),

$$(y^*, \alpha) \in \operatorname{epi}\sigma_D + \sum_{i\in I} \operatorname{epi}\sigma_{Z\cap C_i}.$$

We have just proved the inclusion

$$\overline{\operatorname{epi}\sigma_D + \sum_{i\in I} \operatorname{epi}\sigma_{C_i}}^{w^*} \subseteq \operatorname{epi}\sigma_D + \sum_{i\in I} \operatorname{epi}\sigma_{Z\cap C_i}. \tag{5.14}$$

Noting $D \cap (\cap_{i\in I}(Z \cap C_i)) = D \cap (\cap_{i\in I} C_i)$, it follows from Proposition 2.4 and (5.14) that

$$\operatorname{epi}\sigma_{D\cap(\cap_{i\in I}(Z\cap C_i))} = \overline{\operatorname{epi}\sigma_D + \sum_{i\in I} \operatorname{epi}\sigma_{C_i}}^{w^*} \subseteq \operatorname{epi}\sigma_D + \sum_{i\in I} \operatorname{epi}\sigma_{Z\cap C_i}. \tag{5.15}$$

Thus $\{D, (\operatorname{span} D) \cap C_i : \ i \in I\}$ satisfies the SECQ by Corollary 2.5. This proves assertion (i).

(ii) Now suppose in addition that (d) is also satisfied. Then (5.15) implies that

$$\operatorname{epi}\sigma_{D\cap\cap_{i\in I}C_i} \subseteq \operatorname{epi}\sigma_D + \sum_{i\in I}(\operatorname{epi}\sigma_D + \operatorname{epi}\sigma_{C_i}) \subseteq \operatorname{epi}\sigma_D + \sum_{i\in I} \operatorname{epi}\sigma_{C_i}.$$

By Corollary 2.5 again, this implies that $\{D, C_i : i \in I\}$ satisfies the SECQ; that is, (ii) holds.

(iii) Now suppose that (a), (b), (c*), (d*) are satisfied. Without loss of generality, we may assume that $|I| > m+1$ since, otherwise, the conclusion follows from assumption (d*). Consider (y^*, α), (y_k^*, α_k), (v_k^*, β_k), (u_k^*, γ_k) satisfying (5.10)–(5.13). Let $k \in \mathbb{N}$ and set $I^k = \{i_1^k, \ldots, i_{m+1}^k\}$. Then for any $z \in D \cap \cap_{j\in I^k} C_j$ $(\subseteq Z)$,

$$\alpha_k = \beta_k + \sum_{j\in I^k} \alpha_{i_j^k} \geq \sigma_D(v_k^*) + \sum_{j=1}^{m+1} \sigma_{C_j}\left(x_{i_j^k}^*\right) \geq \left\langle v_k^* + \sum_{j=1}^{m+1} x_{i_j^k}^*, z \right\rangle = \langle y_k^*, z\rangle,$$

thanks to (5.13). Since $D \cap (\bigcap_{j\in I^k} C_j)$ is compact, there exists $x^k \in D \cap (\bigcap_{j\in I^k} C_j)$ such that

$$\alpha_k \geq \langle y_k^*, x^k\rangle = \sigma_{D\cap(\bigcap_{j\in I^k} C_j)}(y_k^*), \tag{5.16}$$

i.e., $y_k^* \in N_{D\cap(\cap_{j\in I^k} C_j)}(x^k)$. It follows from assumption (d*) and Theorem 3.1 that $y_k^* \in N_D(x^k) + \sum_{j\in I^k} N_{C_j}(x^k)$. Applying [32, Theorem 3.15] to the m-dimensional linear subspace Z, $y_k^*|_Z$ can be expressed in the form

$$y_k^*|_Z = d_k^*|_Z + \sum_{j\in J^k} z_j^*|_Z \tag{5.17}$$

for some $d_k^* \in N_D(x^k)$ and $z_j^* \in N_{C_j}(x^k)$ $(j \in J^k)$, where J^k is a subset of I^k with m elements. Evaluating (5.17) at $x^k \in D \cap (\cap_{j\in I^k} C_j)$, and invoking (2.4) and (5.16), we have

$$\alpha_k \geq \langle y_k^*, x^k\rangle = \sigma_D(d_k^*) + \sum_{j\in J^k} \sigma_{C_j}(z_j^*). \tag{5.18}$$

Define

$$\mu_k = \alpha_k - \sum_{j\in J^k} \sigma_{C_j}(z_j^*).$$

Then $\mu_k \geq \sigma_D(d_k^*)$ by (5.18). Denoting $\sigma_{C_j}(z_j^*)$ by γ_j, this and (5.17) imply that

$$(y_k^*|_Z, \alpha_k) = (d_k^*|_Z, \mu_k) + \sum_{j\in J^k} (z_j^*|_Z, \gamma_j).$$

Note that $(d_k^*, \mu_k) \in \operatorname{epi}\sigma_D$ and $(z_j^*, \gamma_j) \in \operatorname{epi}\sigma_{C_j}$ for each $j \in J^k$. Since $|J^k| = m$ and thanks to assumptions (a), (b), and (c*), Lemma 5.2 asserts that

$$(y^*, \alpha) \in \operatorname{epi}\sigma_D + \sum_{i\in I} \operatorname{epi}\sigma_{(Z\cap C_i)}. \tag{5.19}$$

Let $i \in I$ and let J be any subset of I such that $i \in J$ and $|J| = m+1$. Then, by assumption (d*), one has that

$$\operatorname{epi}\sigma_{(Z\cap C_i)} \subseteq \operatorname{epi}\sigma_{(D\cap(\cap_{j\in J} C_j))} \subseteq \operatorname{epi}\sigma_D + \sum_{j\in J} \operatorname{epi}\sigma_{C_j}. \tag{5.20}$$

Therefore, by (5.19) and (5.20), $(y^*, \alpha) \in \operatorname{epi}\sigma_D + \sum_{i\in I}\operatorname{epi}\sigma_{C_i}$, and thus $\operatorname{epi}\sigma_D + \sum_{i\in I}\operatorname{epi}\sigma_{C_i}$ is weakly* closed in the case when assumptions (a), (b), (c*), and (d*) are satisfied. By Corollary 2.5, this implies that $\{D, C_i : i \in I\}$ satisfies the SECQ. The proof is complete. □

COROLLARY 5.4. *Let $m \in \mathbb{N}$ and let $\{D, C_i : i \in I\}$ be a CCS-system with the base-set D satisfying the following conditions:*

(a) *D is of finite dimension m.*
(b) *The set-valued mapping $i \mapsto (\operatorname{span} D) \cap C_i$ is lower semicontinuous on I.*
(c$^+$) *The system $\{D, C_i : i \in I\}$ satisfies the $(m+1)$-interior-point condition.*

Then $\{D, C_i : i \in I\}$ satisfies the SECQ.

Proof. By Lemma 4.9, (c$^+$) implies conditions (d) and (c) of Theorem 5.3. Thus, Theorem 5.3(ii) is applicable. □

The following corollary, which is a direct consequence of Theorem 5.3(i), is an improvement of Theorem 1.1.

COROLLARY 5.5. *Let $\{D, C_i : i \in I\}$ be a CCS-system with the base-set D. Let $m \in \mathbb{N}$ and let $x_0 \in D \cap C$. Suppose that the following conditions are satisfied:*

(a) *D is of finite dimension m.*
(b) *The set-valued mapping $i \mapsto (\operatorname{span} D) \cap C_i$ is lower semicontinuous on I.*
(c) *The system $\{D, C_i : i \in I\}$ satisfies the $(m+1)$-D-interior-point condition.*
(d̃) *For each $i \in I$, the pair $\{D, C_i\}$ has the property*

$$N_{(\operatorname{span} D)\cap C_i}(x_0) \subseteq N_D(x_0) + N_{C_i}(x_0).$$

Then the system $\{D, C_i : i \in I\}$ has the strong CHIP at x_0.

The following corollary is an important improvement of Theorem 1.2. Our main improvement lies in the fact that we need not require the upper semicontinuity of the set-valued map $i \mapsto (\operatorname{span} D) \cap C_i$ and that (d) can be weakened to require that only the subsystems $\{D, C_j : j \in J\}$ with $|J| = l + 1$ have the strong CHIP.

COROLLARY 5.6. *Let $m \in \mathbb{N}$ and let $\{D, C_i : i \in I\}$ be a CCS-system with the base-set D satisfying the following conditions:*

(a) *D is of finite dimension m.*
(b) *The set-valued mapping $i \mapsto (\operatorname{span} D) \cap C_i$ is lower semicontinuous on I.*
(c*) *The system $\{D, C_i : i \in I\}$ satisfies the m-D-interior-point condition.*
(d) *For each finite subset J of I with $|J| = \min\{m+1, |I|\}$, the subsystem $\{D, C_j : j \in J\}$ has the strong CHIP.*

Then the system $\{D, C_i : i \in I\}$ has the strong CHIP.

Proof. If $|I| < m + 1$, then $\min\{m + 1, |I|\} = |I|$, so the result is trivially true by (d). Thus we may assume that $|I| \geq m + 1$. Recall that $C = \cap_{i\in I} C_i$ and let $x \in D \cap C$. We have to show that the system has the strong CHIP at x. To this end, let $\tilde{D} = D \cap \mathbf{B}(x, r_x)$, where $r_x = \|x\| + 1$. Consider the system $\{\tilde{D}, C_i : i \in I\}$. We claim that the following conditions hold:

(ã) $\tilde{D}$ is of finite dimension and $\dim \tilde{D} = m$.
(b̃) The set-valued mapping $i \mapsto (\operatorname{span} \tilde{D}) \cap C_i$ is lower semicontinuous on I.
(c̃) The system $\{\tilde{D}, C_i : i \in I\}$ satisfies the m-$\tilde{D}$-interior-point condition.
(d̃) For each finite subset J of I with $|J| = m+1$, the subsystem $\{\tilde{D}, C_j : j \in J\}$ satisfies the SECQ.

In fact, by assumption (c*), for each finite subset J of I with $|J| = m$, there exist $\bar{x} \in D$ and $\delta > 0$ such that $\mathbf{B}(\bar{x}, \delta) \cap \operatorname{span} D \subseteq D \cap (\cap_{j\in J} C_j)$. Since $0 \in \operatorname{int} \mathbf{B}(x, r_x)$, there exists $\lambda \in (0, 1)$ such that $\lambda\mathbf{B}(\bar{x}, \delta) \subseteq \mathbf{B}(x, r_x)$. Consequently,

$$\lambda \mathbf{B}(\bar{x},\delta) \bigcap \operatorname{span} D \subseteq D \bigcap \mathbf{B}(x, r_x) \bigcap \left(\bigcap_{j\in J} C_j \right) \subseteq \tilde{D} \bigcap \left(\bigcap_{i\in J} C_i \right). \tag{5.21}$$

This implies that $\operatorname{int} \mathbf{B}(\bar{x},\delta) \cap \operatorname{ri} D \neq \emptyset$; hence

$$\operatorname{span} \tilde{D} = \operatorname{span} D. \tag{5.22}$$

Consequently, condition (c̃) holds by (5.21). Moreover, by (a), (b), and (5.22), it is seen that (ã) and (b̃) hold. As to condition (d̃), let J be any subset of I with $|J| = m + 1$. By (d) the subsystem $\{D, C_j : j \in J\}$ has the strong CHIP. Since $x \in \operatorname{int} \mathbf{B}(x, r_x) \cap (D \cap (\cap_{j\in J} C_j))$, and by applying Lemma 4.12 to the ball with center x, radius r_x, and J in place of A and I, it follows that $\{\tilde{D}, C_j : j \in J\}$ has the strong CHIP and consequently satisfies the SECQ, thanks to Corollary 3.2(i) because $\tilde{D} \cap (\cap_{j\in J} C_j)$ is compact. Thus (d̃) is established. Thus part (iii) of Theorem 5.3 is applicable for concluding that the system $\{\tilde{D}, C_i : i \in I\}$ satisfies the SECQ, which in turn implies that it has the strong CHIP at x. Consequently, the system has the strong CHIP at x by Lemma 4.12 applied to the ball with center x, radius r_x, and J in place of A and I. The proof is complete. □

Acknowledgments. The authors would like to express their sincere thanks to the two referees for many helpful comments and for shorter proofs of Theorem 4.6 and of other minor results.

ITERATIVE SOLUTION OF AUGMENTED SYSTEMS ARISING IN INTERIOR METHODS*

ANDERS FORSGREN†, PHILIP E. GILL‡, AND JOSHUA D. GRIFFIN§

Abstract. Iterative methods are proposed for certain augmented systems of linear equations that arise in interior methods for general nonlinear optimization. Interior methods define a sequence of *KKT equations* that represent the symmetrized (but indefinite) equations associated with Newton's method for a point satisfying the perturbed optimality conditions. These equations involve both the primal and dual variables and become increasingly ill-conditioned as the optimization proceeds. In this context, an iterative linear solver must not only handle the ill-conditioning but also detect the occurrence of KKT matrices with the wrong matrix inertia. A one-parameter family of equivalent linear equations is formulated that includes the KKT system as a special case. The discussion focuses on a particular system from this family, known as the "doubly augmented system," that is positive definite with respect to both the primal and dual variables. This property means that a standard preconditioned conjugate-gradient method involving both primal and dual variables will either terminate successfully or detect if the KKT matrix has the wrong inertia. Constraint preconditioning is a well-known technique for preconditioning the conjugate-gradient method on augmented systems. A family of constraint preconditioners is proposed that provably eliminates the inherent ill-conditioning in the augmented system. A considerable benefit of combining constraint preconditioning with the doubly augmented system is that the preconditioner need not be applied exactly. Two particular "active-set" constraint preconditioners are formulated that involve only a subset of the rows of the augmented system and thereby may be applied with considerably less work. Finally, some numerical experiments illustrate the numerical performance of the proposed preconditioners and highlight some theoretical properties of the preconditioned matrices.

1. Introduction.

This paper concerns the formulation and analysis of preconditioned iterative methods for the solution of augmented systems of the form

$$\begin{pmatrix} H & -A^T \\ A & G \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} b_1 \\ b_2 \end{pmatrix}, \tag{1.1}$$

with A an $m \times n$ matrix, H symmetric, and G symmetric positive semidefinite. These equations arise in a wide variety of scientific and engineering applications, where they are known by a number of different names, including "augmented systems," "saddle-point systems," "KKT systems," and "equilibrium systems." (The bibliography of the survey by Benzi, Golub, and Liesen [3] contains 513 related articles.) The main focus

of this paper will be on the solution of augmented systems arising in interior methods for general constrained optimization, in which case (1.1) is the system associated with Newton's method for finding values of the primal and dual variables that satisfy the perturbed KKT optimality conditions (see, e.g., Wright [49] and Forsgren, Gill, and Wright [15]). In this context H is the Hessian of the Lagrangian, A is the constraint Jacobian, and G is diagonal.

Many of the benefits associated with the methods discussed in this paper derive from formulating the interior method so that the diagonal G is *positive definite*. We begin by presenting results for G positive definite and consider the treatment of systems with positive semidefinite and singular G in section 5. Throughout, for the case where G is positive definite, we denote G by D and rewrite (1.1) as an equivalent *symmetric* system $Bx = b$, where

$$B = \begin{pmatrix} H & -A^T \\ -A & -D \end{pmatrix} \quad \text{and} \quad b = \begin{pmatrix} b_1 \\ -b_2 \end{pmatrix}, \tag{1.2}$$

with D positive definite and diagonal. We will refer to this symmetric system as the *KKT system*. (It is possible to symmetrize (1.1) in a number of different ways. The format (1.2) will simplify the linear algebra in later sections.) When D is nonsingular, it is well known that the augmented system is equivalent to the two smaller systems

$$(H + A^T D^{-1} A)x_1 = b_1 + A^T D^{-1} b_2 \quad \text{and} \quad x_2 = D^{-1}(b_2 - Ax_1), \tag{1.3}$$

where the system for x_1 is known as the *condensed system*. It is less well known that another equivalent system is the *doubly augmented system*

$$\begin{pmatrix} H + 2A^T D^{-1} A & A^T \\ A & D \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} b_1 + 2A^T D^{-1} b_2 \\ b_2 \end{pmatrix}, \tag{1.4}$$

which has been proposed for use with direct factorization methods by Forsgren and Gill [16]. In this paper we investigate the properties of preconditioned iterative methods applied to system (1.2) directly or to the equivalent systems (1.3) and (1.4).

If the underlying optimization problem is not convex, the matrix H may be indefinite. The KKT matrix B of (1.2) is said to have *correct inertia* if the matrix $H + A^T D^{-1} A$ is positive definite. This definition is based on the properties of the underlying optimization problem. Broadly speaking, the KKT system has correct inertia if the problem is locally convex (for further details see, e.g., Forsgren and Gill [16], Forsgren [18], and Griffin [32]). If the KKT matrix has correct inertia, then systems (1.2)–(1.4) have a common unique solution (see section 2).

1.1. Properties of the KKT system. The main issues associated with using iterative methods to solve KKT systems are (i) *termination control*, (ii) *inertia control*, and (iii) *inherent ill-conditioning*. The first of these issues is common to other applications where the linear system represents a linearization of some underlying nonlinear system of equations. Issues (ii) and (iii), however, are unique to optimization and will be the principal topics of this paper.

In the context of interior methods, the KKT system (1.2) is solved as part of a two-level iterative scheme. At the outer level, nonlinear equations that define the first-order optimality conditions are parameterized by a small positive quantity μ. The idea is that the solution of the parameterized equations should approach the solution of the optimization problem as $\mu \to 0$. At the inner level, equations (1.2) represent the symmetrized Newton equations associated with finding a zero of the

perturbed optimality conditions for a given value of μ. Although systems (1.2)–(1.4) have identical solutions, an iterative method will generally produce a different sequence of iterates in each case (see section 3 for a discussion of the equivalence of iterative solvers in this context). An iterative method applied to the augmented system (1.2) or the doubly augmented system (1.4) treats x_1 and x_2 as independent variables, which is appropriate in the optimization context because x_1 and x_2 are associated with independent quantities in the perturbed optimality conditions (i.e., the primal and dual variables). In contrast, an iterative solver for the condensed system (1.3) will generate approximations to x_1 only, with the variables x_2 being defined as $x_2 = D^{-1}(b_2 - Ax_1)$. This becomes an important issue when an *approximate* solution is obtained by *truncating* the iterations of the linear solver. During the early outer iterations, it is usually inefficient to solve the KKT system accurately, and it is better to accept an inexact solution that gives a residual norm that is less than some factor of the norm of the right-hand side (see, e.g., Dembo, Eisenstat, and Steihaug [7]). For the condensed system, the residual for the second block of equations will be zero regardless of the accuracy of x_1, which implies that termination must be based on the accuracy of x_1 alone. It is particularly important for the solver to place equal weight on x_1 and x_2 when system (1.2) is being solved in conjunction with a primal-dual trust-region method (see Gertz and Gill [20] and Griffin [32]). The conjugate-gradient version of this method exploits the property that the norms of the (x_1, x_2) iterates increase monotonically (see Steihaug [44]). This property does not hold for (x_1, x_2) iterates generated for the condensed system.

If the KKT matrix does not have the correct inertia, the solution of (1.2) is not useful, and the optimization continues with an alternative technique based on either implicitly or explicitly modifying the matrix H (see, e.g., Toint [45], Steihaug [44], Gould et al. [30], Hager [33], and Griffin [32]). It is therefore important that the iterative solver is able to detect if B does not have correct inertia.

As the perturbation parameter μ is reduced, the KKT systems become *increasingly ill-conditioned*. The precise form of this ill-conditioning depends on the formulation of the interior method, but a common feature is that some diagonal elements of D are big and some are small. (It is almost always possible to formulate an interior method that requires the solution of an *unsymmetric* system that does not exhibit inevitable ill-conditioning as $\mu \to 0$. This unsymmetric system could be solved using an unsymmetric solver such as GMRES or QMR. Unfortunately, this approach is unsuitable for general KKT systems because an unsymmetric solver is unable to determine if the KKT matrix has correct inertia.) In section 3 we consider a preconditioned conjugate-gradient (PCG) method that provably removes the inherent ill-conditioning. In particular, we define a one-parameter family of preconditioners related to the class of so-called *constraint preconditioners* proposed by Keller, Gould, and Wathen [34]. Several authors have used constraint preconditioners in conjunction with the conjugate-gradient method to solve the indefinite KKT system (1.2) with $b_2 = 0$ and $D = 0$ (see, e.g., Lukšan and Vlček [36], Gould, Hribar, and Nocedal [29], Perugia and Simoncini [40], and Bergamaschi, Gondzio, and Zilli [4]). Recently, Dollar [12] and Dollar et al. [11] have proposed constraint preconditioners for system (1.2) with no explicit inertial or diagonal condition on D, but a full row-rank requirement on A and the assumption that $b_2 = 0$.

Methods that require $b_2 = 0$ must perform an initial projection step that effectively shifts the right-hand side to zero. The constraint preconditioner then forces the x_1 iterates to lie in the null space of A. A disadvantage with this approach is that the

constraint preconditioner must be applied exactly if subsequent iterates are to lie in the null space. This limits the ability to perform approximate solves with the preconditioner, as is often required when the matrix A has a PDE-like structure that also must be handled using an iterative solver (see, e.g., Saad [41], Notay [37], Simoncini and Szyld [43], and Elman et al. [14]). In section 3 we consider preconditioners that do not require the assumption that $b_2 = 0$, and hence do not require an accurate solve with the preconditioner.

1.2. A PCG method for the KKT system. The goal of this paper is to formulate iterative methods that not only provide termination control and inertia control, but also eliminate the inevitable ill-conditioning associated with interior methods. All these features are present in an algorithm based on applying a PCG method to the doubly augmented system (1.4). This system is positive definite if the KKT matrix has correct inertia, and gives equal weight to x_1 and x_2 for early terminations. As preconditioner we use the constraint preconditioner

$$P = \begin{pmatrix} M + 2A^TD^{-1}A & A^T \\ A & D \end{pmatrix}, \tag{1.5}$$

where M is an approximation of H such that $M + A^TD^{-1}A$ is positive definite. The equations $Pv = r$ used to apply the preconditioner are solved by exploiting the equivalence of the systems

$$\begin{pmatrix} M + 2A^TD^{-1}A & A^T \\ A & D \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} r_1 \\ r_2 \end{pmatrix}, \tag{1.6a}$$

$$\begin{pmatrix} M & -A^T \\ -A & -D \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} r_1 - 2A^TD^{-1}r_2 \\ -r_2 \end{pmatrix}, \quad \text{and} \tag{1.6b}$$

$$(M + A^TD^{-1}A)v_1 = r_1 - A^TD^{-1}r_2, \;\; v_2 = D^{-1}(r_2 - Av_1) \tag{1.6c}$$

(see section 3). This allows us to compute the solution of (1.6a) by solving either (1.6b) or (1.6c). (The particular choice will depend on the relative efficiency of the methods available to solve the condensed and augmented systems.)

We emphasize that the doubly augmented systems are never formed or factored explicitly. The matrix associated with the doubly augmented equations (1.4) is used only as an operator to define products of the form $v = Bu$. As mentioned above, the equations (1.6a) that apply the preconditioner are solved using either (1.6b) or (1.6c). An important property of the method is that these equations also may be solved using an iterative method. (It is safe to use the augmented or condensed system for the preconditioner equations $Pv = r$ because the inertia of P is guaranteed by the choice of M (see section 3).)

In section 4 we formulate and analyze two variants of the preconditioner (1.5) that exploit the asymptotic behavior of the elements of D. The use of these so-called *active-set preconditioners* may require significantly less work when the underlying optimization problem has more constraints than variables. In section 5, we consider the case where G is positive semidefinite and singular. Finally, in section 6, we present some numerical examples illustrating the properties of the proposed preconditioners.

1.3. Notation and assumptions. Unless explicitly indicated otherwise, $\|\cdot\|$ denotes the vector two-norm or its subordinate matrix norm. The inertia of a real symmetric matrix A, denoted by $\mathrm{In}(A)$, is the integer triple (a_+, a_-, a_0) giving the number of positive, negative, and zero eigenvalues of A. The spectrum of a (possibly unsymmetric) matrix A is denoted by $\mathrm{eig}(A)$. As the analysis concerns matrices

with only real eigenvalues, $\mathrm{eig}(A)$ is regarded as an ordered set, with the least (i.e., "leftmost") eigenvalue, denoted by $\mathrm{eig}_{\min}(A)$, appearing first. The quantity $\sigma_k(A)$ denotes the kth largest singular value of A. Given a positive-definite A, the unique positive-definite X such that $X^2 = A$ is denoted by $A^{1/2}$. Given vectors x_1 and x_2, the column vector consisting of the elements of x_1 augmented by the elements of x_2 is denoted by (x_1, x_2).

When μ is a positive scalar such that $\mu \to 0$, the notation $p = O(\mu)$ means that there exists a constant K such that $|p| \leq K\mu$ for all μ sufficiently small. For a *positive* p, $p = \Omega(1/\mu)$ implies that there exists a constant K such that $1/p \leq K\mu$ for all μ sufficiently small. In particular, $p = O(1)$ means that $|p|$ is bounded, and, for a positive p, $p = \Omega(1)$ means that p is bounded away from zero. For a positive p, the notation $p = \Theta(1)$ is used for the case where both $p = O(1)$ and $p = \Omega(1)$, so that p remains bounded and is bounded away from zero as $\mu \to 0$.

As discussed in section 1.1, we are concerned with solving a sequence of systems of the form (1.2), where the matrices A, H, and D depend implicitly on μ. In particular, A and H are first and second derivatives evaluated at a point depending on μ, and D is an explicit function of μ. The notation defined above allows us to characterize the properties of H, A, and D in terms of their behavior as $\mu \to 0$. Throughout the analysis, it is assumed that the following properties hold:

- (A_1) $\|H\|$ and $\|A\|$ are both $O(1)$.
- (A_2) The row indices of A may be partitioned into disjoint subsets $\mathcal{S}$, $\mathcal{M}$, and $\mathcal{B}$ such that $d_{ii} = O(\mu)$ for $i \in \mathcal{S}$, $d_{ii} = \Theta(1)$ for $i \in \mathcal{M}$, and $d_{ii} = \Omega(1/\mu)$ for $i \in \mathcal{B}$.
- (A_3) If $A_{\mathcal{S}}$ is the matrix of rows of A with indices in $\mathcal{S}$ and $r = \mathrm{rank}(A_{\mathcal{S}})$, then r remains constant as $\mu \to 0$ and $\sigma_r(A_{\mathcal{S}}) = \Theta(1)$.

The second assumption reflects the fact that for μ sufficiently small, some diagonal elements of D are "small," some are "medium," and some are "big."

It is often the case in practice that the equations and variables corresponding to unit rows of A are eliminated directly from the KKT system. This elimination creates no additional nonzero elements and provides a smaller "partially condensed" system with an $\Omega(1/\mu)$ diagonal term added to H. It will be shown that preconditioners for both the full and partially condensed KKT systems depend on the eigenvalues of the same matrix (see Lemmas 3.4 and 3.5). It follows that our analysis also applies to preconditioners defined for the partially condensed system.

2. A parameterized system of linear equations. In this section, it is shown how the indefinite KKT system (1.2) may be embedded in a family of equivalent linear systems, parameterized by a scalar ν. This parameterization facilitates the simultaneous analysis of the three systems (1.2)–(1.4).

DEFINITION 2.1 (the parameterized system). *Let ν denote a scalar. Associated with the KKT equations $Bx = b$ of* (1.2)*, we define the parameterized equations $B(\nu)x = b(\nu)$, with*

$$B(\nu) = \begin{pmatrix} H + (1+\nu)A^T D^{-1} A & \nu A^T \\ \nu A & \nu D \end{pmatrix} \quad \text{and} \quad b(\nu) = \begin{pmatrix} b_1 + (1+\nu)A^T D^{-1} b_2 \\ \nu b_2 \end{pmatrix},$$

where H is symmetric and D is positive definite and diagonal.

The following proposition states the equivalence of the KKT system (1.2) and the parameterized system of Definition 2.1.

PROPOSITION 2.2 (equivalence of the parameterized systems). *Let ν denote a scalar parameter. If $\nu \neq 0$, then the system $Bx = b$ of* (1.2) *and the system $B(\nu)x =$*

$b(\nu)$ of Definition 2.1 *are equivalent, i.e.,* (1.2) *has a solution* (x_1, x_2) *if and only if* (x_1, x_2) *is a solution to* $B(\nu)x = b(\nu)$. *If* $\nu = 0$, *then* (1.2) *has a solution* (x_1, x_2) *if and only if* x_1 *is a solution of* $B(0)x = b(0)$ *and* $x_2 = D^{-1}(b_2 - Ax_1)$.

We are particularly interested in the parameterized system $B(\nu)x = b(\nu)$ for the values $\nu = -1$, $\nu = 0$, and $\nu = 1$. If $\nu = -1$, we obtain the symmetric KKT system (1.2). If $\nu = 0$, we obtain the condensed system

$$(H + A^T D^{-1} A)x_1 = b_1 + A^T D^{-1} b_2 \quad \text{with } x_2 \text{ arbitrary.} \tag{2.1}$$

In this case, x_2 does not appear in the augmented system and must be computed as $x_2 = D^{-1}(b_2 - Ax_1)$. Finally, if $\nu = 1$, we obtain the doubly augmented system

$$\begin{pmatrix} H + 2A^T D^{-1} A & A^T \\ A & D \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} b_1 + 2A^T D^{-1} b_2 \\ b_2 \end{pmatrix}. \tag{2.2}$$

The next result follows from Lemma A.1 of the appendix and gives the inertia of $B(\nu)$ as a function of ν.

PROPOSITION 2.3 (inertia of the parameterized system). *For the matrix* $B(\nu)$ *of Definition* 2.1*, it holds that*

(i) $\text{In}\big(B(\nu)\big) = \text{In}(H + A^T D^{-1} A) + (m, 0, 0)$ *if* $\nu > 0$;
(ii) $\text{In}\big(B(\nu)\big) = \text{In}(H + A^T D^{-1} A) + (0, m, 0)$ *if* $\nu < 0$; *and*
(iii) $\text{In}\big(B(\nu)\big) = \text{In}(H + A^T D^{-1} A) + (0, 0, m)$ *if* $\nu = 0$.

This proposition implies that the inertia of $B(\nu)$ may be determined from the inertia of $H + A^T D^{-1} A$ and the sign of ν. In particular, the result gives the inertia of the three alternate systems in the situation where the inertia of B is correct and the solver can be allowed to continue solving the system. If the inertia of B is correct, then (i) the doubly augmented system is positive definite; (ii) the KKT system has n positive eigenvalues and m negative eigenvalues; and (iii) the condensed system is positive definite (when regarded as a system involving only x_1).

Proposition 2.3 implies that it is not worth applying a conjugate-gradient method to the general indefinite KKT system (1.2) because this method is unable to estimate the *number* of negative eigenvalues of an indefinite matrix. In contrast, the conjugate-gradient method is appropriate for both the doubly augmented system and the condensed system because indefiniteness is immediately indicated by the occurrence of a negative value of $p_j^T C p_j$, where p_i is a conjugate direction and C is either the doubly augmented matrix or the matrix for the condensed system. In other words, the occurrence of a negative value of $p_j^T C p_j$ indicates that the inertia of the system is incorrect and the search for a solution of (1.2) should be abandoned.

3. Constraint preconditioning for the linear equations. The rate of convergence of the conjugate-gradient method may be accelerated by choosing an appropriate symmetric positive-definite preconditioner of the form $P = R^T R$, and applying the conjugate-gradient method to the preconditioned system $R^{-T} B R^{-1} R x = R^{-T} b$. As is well known, the computations may be arranged so that the preconditioner is applied by solving systems of the form $Pv = r$. It is the eigenvalues of the preconditioned matrix $R^{-T} B R^{-1}$ that determine the rate of convergence. As $\text{eig}(R^{-T} B R^{-1}) = \text{eig}(R^{-1} R^{-T} B R^{-1} R) = \text{eig}(P^{-1} B)$, the analysis may be written in terms of $P^{-1} B$ without regard to R. However, it must be emphasized that P must be symmetric positive definite for the standard PCG method to be well defined.

Several authors have suggested constraint preconditioners for (1.2) and (1.3), in which H is replaced by a "simpler" approximation matrix M such that $M + A^T D^{-1} A$ is

positive definite (see, e.g., Keller, Gould, and Wathen [34] and Bergamaschi, Gondzio, and Zilli [4]).

Under certain circumstances, the PCG method may be applied to all three systems and will give identical results in exact arithmetic.

PROPOSITION 3.1. *Assume that $H + A^TD^{-1}A$ is positive definite. Consider the PCG method applied to the KKT system* (1.2)*, the condensed system* (1.3)*, and the doubly augmented system* (1.4) *with preconditioners*

$$\text{(3.1)} \qquad \begin{pmatrix} M & -A^T \\ -A & -D \end{pmatrix}, \quad M + A^TD^{-1}A, \quad \textit{and} \quad \begin{pmatrix} M + 2A^TD^{-1}A & A^T \\ A & D \end{pmatrix},$$

respectively. If $b_2 = 0$, then the PCG method generates the same sequence of iterates for all three systems (where an x_2 iterate for the condensed system is defined as the product of $-D^{-1}A$ and the x_1 iterate).

The first preconditioner of (3.1) is not positive definite, which implies that it does not fit within the conventional PCG framework. However, Proposition 3.1 implies that the PCG method may be applied safely to the KKT system (1.2) in the special situation where $b_2 = 0$. The result is a *projected* PCG method that can be shown to be formally equivalent to the standard method applied to the condensed system; see, e.g., Lukšan and Vlček [36] and Gould, Hribar, and Nocedal [29].

The condition $b_2 = 0$ may be achieved by choosing a special initial point y. In particular, consider the point (y_1, y_2) such that $Ay_1 + Dy_2 = b_2$, and the appropriate preconditioner is used for each system. Let x denote the generic vector of unknowns (the dimension of x will depend on which of the three systems is to be solved). We may, for example, solve $Py = b$, where P is one of the three appropriate preconditioners, or we may set $y_1 = 0$, $y_2 = D^{-1}b_2$. Then use PCG with preconditioner P to solve

$$B\widehat{x} = b - By \quad \text{and set} \quad x = y + \widehat{x}.$$

In general, if $b_2 \neq 0$, it is not safe to apply the PCG method to the indefinite system (1.2). Moreover, the PCG method will usually generate different iterates for the condensed system (1.3) and the doubly augmented system (1.4).

Finally, we note that the condensed system (1.3) and doubly augmented system (1.4) may be viewed as being preconditioned versions of each other, as defined in the following result.

PROPOSITION 3.2. *Consider the PCG method applied to a generic symmetric system $Ax = b$ with symmetric positive-definite preconditioner P and initial iterate $x_0 = 0$. Let L be a nonsingular matrix with the same dimension as A. Then, if the PCG method is applied to $LAL^T\widehat{x} = Lb$ with preconditioner LPL^T and initial iterate $\widehat{x}_0 = 0$, the PCG iterates are related by the transformation $x = L^T\widehat{x}$.*

If we consider the decomposition

$$\begin{pmatrix} M + 2A^TD^{-1}A & A^T \\ A & D \end{pmatrix} = \begin{pmatrix} I & A^TD^{-1} \\ & I \end{pmatrix} \begin{pmatrix} M + A^TD^{-1}A & \\ & D \end{pmatrix} \begin{pmatrix} I & \\ D^{-1}A & I \end{pmatrix},$$

then Proposition 3.2 implies that the doubly augmented system may be viewed as a particular preconditioned version of the condensed system augmented by the diagonal D for the x_2 variables (or vice versa). This is a further illustration that the proposed approach gives equal weight to x_1 and x_2. We prefer to do the analysis in terms of the doubly augmented system because it provides the parameterization based on the scalar parameter ν.

3.1. Properties of the constraint preconditioners. We now embed the preconditioners of (3.1) within a family of preconditioners, parameterized by the scalar ν. This parameterization is analogous to the parameterization of the matrices of Proposition 2.2. The parameterization allows a unified analysis of the three preconditioners given in (3.1).

DEFINITION 3.3 (a parameterized preconditioner). *Associated with the matrix $B(\nu)$ of Definition* 2.1*, we define the preconditioner $P(\nu)$ as*

$$P(\nu) = \begin{pmatrix} M + (1+\nu)A^T D^{-1} A & \nu A^T \\ \nu A & \nu D \end{pmatrix},$$

where M is a symmetric approximation to H such that

(P_1) $\|M\| = O(1)$*;*

(P_2) $M + A^T D^{-1} A$ *is positive definite;*

(P_3) $\mathrm{eig}_{\min}(M + A^T D^{-1} A) = \Omega(1)$.

Given suitable A and D, a matrix M satisfying the conditions of Definition 3.3 may be found, for example, by using a suitable factorization when solving with $P(-1)$ (see Forsgren and Murray [17], Forsgren and Gill [16], and Forsgren [18]).

Proposition 2.3 gives $\mathrm{In}(P(\nu)) = \mathrm{In}(M + A^T D^{-1} A) + \mathrm{In}(\nu D)$. It follows that $P(\nu)$ is nonsingular for $\nu \neq 0$, positive definite for $\nu > 0$, and $\mathrm{In}(P(\nu)) = (n, m, 0)$ for $\nu < 0$. It is straightforward to show that for all nonzero ν, the eigenvalues of $P(\nu)^{-1} B(\nu)$ are real and independent of ν. The first lemma reveals the structure of $P(\nu)^{-1} B(\nu)$.

LEMMA 3.4 (structure of the parameterized preconditioner). *Let $B(\nu)$ and $P(\nu)$ be defined as in Definitions* 2.1 *and* 3.3*, respectively. Then, for $\nu \neq 0$, it holds that*

$$P(\nu)^{-1} B(\nu) = \begin{pmatrix} S & \\ T & I \end{pmatrix} = \begin{pmatrix} I & \\ -D^{-1}A & I \end{pmatrix} \begin{pmatrix} S & \\ & I \end{pmatrix} \begin{pmatrix} I & \\ D^{-1}A & I \end{pmatrix}, \tag{3.2}$$

where S and T are given by

$$S = (M + A^T D^{-1} A)^{-1} (H + A^T D^{-1} A), \tag{3.3a}$$

$$T = D^{-1} A (M + A^T D^{-1} A)^{-1} (M - H). \tag{3.3b}$$

In addition, the spectrum of $P(\nu)^{-1} B(\nu)$ is independent of ν and consists of m unit eigenvalues and the n eigenvalues of $(M + A^T D^{-1} A)^{-1} (H + A^T D^{-1} A)$.

Proof. The expressions for $P(\nu)^{-1} B(\nu)$ follow from the decomposition given in Lemma A.1 of the appendix. The similarity transform (3.2) implies that the spectrum of $P(\nu)^{-1} B(\nu)$ consists of the n eigenvalues of $(M + A^T D^{-1} A)^{-1} (H + A^T D^{-1} A)$ together with m unit eigenvalues. ∎

Next we relate the $O(\mu)$ diagonal elements in D to eigenvalues of size $1 + O(\mu^{1/2})$ in the $(1,1)$ block S of $P(\nu)^{-1} B(\nu)$ from (3.2).

LEMMA 3.5 (eigenvalues of the parameterized preconditioner). *Let M satisfy assumptions* (P_1)–(P_3) *of Definition* 3.3*. Let $A_{\mathcal{S}}$ denote the submatrix of rows of A associated with diagonal elements of D that are $O(\mu)$. Then the eigenvalues of*

$$(M + A^T D^{-1} A)^{-1} (H + A^T D^{-1} A)$$

are all $O(1)$ with at least $\mathrm{rank}(A_{\mathcal{S}})$ *being* $1 + O(\mu^{1/2})$.

Proof. First we show that $(M + A^T D^{-1} A)^{-1}$ has at least $\mathrm{rank}(A_{\mathcal{S}})$ eigenvalues that are $O(\mu)$. Let $m_1 = \mathrm{rank}(A_{\mathcal{S}})$. Without loss of generality it may be assumed that the rows of A are ordered so that the m_1 row indices in $\mathcal{S}$ corresponding to linearly

independent rows of $A_{\mathcal{S}}$ appear first. This implies that A and D may be partitioned as

$$A = \begin{pmatrix} A_1 \\ A_2 \end{pmatrix} \quad \text{and} \quad D = \begin{pmatrix} D_1 & \\ & D_2 \end{pmatrix},$$

where A_1 is $m_1 \times n$, and D_1 is $m_1 \times m_1$ with all eigenvalues $O(\mu)$. Then

$$A^T D^{-1} A = A_1^T D_1^{-1} A_1 + A_2^T D_2^{-1} A_2.$$

Consider the singular-value decomposition $A_1 = U \Sigma V^T$, where U and V are orthonormal matrices of dimension $m_1 \times m_1$ and $n \times m_1$, respectively, and Σ is an $m_1 \times m_1$ diagonal matrix. Let $v = Vp$, where p is an arbitrary m_1-vector of unit length. Then

$$v^T A_1^T D_1^{-1} A_1 v = p^T V^T A_1^T D_1^{-1} A_1 V p = p^T \Sigma U^T D_1^{-1} U \Sigma p \geq \sigma_{m_1}^2 \operatorname{eig}_{\min}(D_1^{-1}). \tag{3.4}$$

Assumption (A$_3$) implies that $\sigma_{m_1} = \Theta(1)$. In addition, all eigenvalues of D_1 are $O(\mu)$, and so (3.4) implies that $v^T A_1^T D_1^{-1} A_1 v = \Omega(1/\mu)$. It follows that

$$v^T (M + A^T D^{-1} A) v = v^T M v + v^T A_1^T D_1^{-1} A_1 v + v^T A_2^T D_2^{-1} A_2 v = \Omega(1/\mu), \tag{3.5}$$

since $v^T M v = O(1)$ and $v^T A_2^T D_2^{-1} A_2 v \geq 0$. As p is an arbitrary unit vector such that $v = Vp$, we conclude from (3.5) that there exists an m_1-dimensional subspace of vectors v such that $v^T (M + A^T D^{-1} A) v$ is $\Omega(1/\mu)$. The Courant–Fischer min-max theorem implies that $M + A^T D^{-1} A$ has at least m_1 eigenvalues that are $\Omega(1/\mu)$; see, e.g., [28, Theorem 8.1.2, p. 394]. It follows that there exists an $n \times m_1$ orthonormal matrix Y and $m_1 \times m_1$ diagonal Λ with $\operatorname{eig}_{\min}(\Lambda) = \Omega(1/\mu)$ such that $(M + A^T D^{-1} A) Y = Y \Lambda$. Since $M + A^T D^{-1} A$ is positive definite, it must hold that $(M + A^T D^{-1} A)^{-1} Y = Y \Lambda^{-1}$ and $(M + A^T D^{-1} A)^{-1/2} Y = Y \Lambda^{-1/2}$ with

$$\|(Y^T (M + A^T D^{-1} A)^{-1} Y)\| = O(\mu), \tag{3.6a}$$

$$\|(M + A^T D^{-1} A)^{-1/2} Y\| = O(\mu^{1/2}). \tag{3.6b}$$

Let $E = (M + A^T D^{-1} A)^{-1/2} (H - M) (M + A^T D^{-1} A)^{-1/2}$ and let Z be an $n \times (n - m_1)$ orthonormal matrix such that the columns of Z form a basis for the null space of Y^T. Then $Q = (Y \ Z)$ is orthonormal and E has the same eigenvalues as the matrix

$$Q^T E Q = \begin{pmatrix} Y^T E Y & Y^T E Z \\ Z^T E Y & Z^T E Z \end{pmatrix},$$

where

$$Y^T E Y = Y^T (M + A^T D^{-1} A)^{-1/2} (H - M) (M + A^T D^{-1} A)^{-1/2} Y, \tag{3.7a}$$

$$Y^T E Z = Y^T (M + A^T D^{-1} A)^{-1/2} (H - M) (M + A^T D^{-1} A)^{-1/2} Z, \tag{3.7b}$$

$$Z^T E Z = Z^T (M + A^T D^{-1} A)^{-1/2} (H - M) (M + A^T D^{-1} A)^{-1/2} Z. \tag{3.7c}$$

Then Definition 3.3 and the order estimates (3.6) imply that $\|Y^T E Y\| = O(\mu)$, $\|Z^T E Y\| = O(\mu^{1/2})$, and $\|Z^T E Z\| = O(1)$. Hence, since $\|Z^T E Y\| = O(\mu^{1/2})$, the eigenvalues of E differ by $O(\mu^{1/2})$ from the eigenvalues of $Y^T E Y$ together with the

eigenvalues of Z^TEZ. But, since $\|Y^TEY\| = O(\mu)$, we conclude that E has m_1 eigenvalues that are $O(\mu^{1/2})$. By similarity,

$$\operatorname{eig}\big((M + A^TD^{-1}A)^{-1}(H - M)\big) = \operatorname{eig}(E),$$

and it must hold that $(M + A^TD^{-1}A)^{-1}(H - M)$ has at least m_1 eigenvalues that are $O(\mu^{1/2})$. The required results now follow from the identity

$$(M + A^TD^{-1}A)^{-1}(H + A^TD^{-1}A) = I + (M + A^TD^{-1}A)^{-1}(H - M),$$

completing the proof. ∎

If $M - H$ is known to be a definite matrix, then the $O(\mu^{1/2})$ bound of Lemma 3.5 may be sharpened to be $O(\mu)$. In this case, the $O(\mu)$ curvature of the product $(M + A^TD^{-1}A)^{-1/2}(H-M)(M+A^TD^{-1}A)^{-1/2}$ over a $\operatorname{rank}(A_{\mathcal{S}})$-dimensional space implied by (3.7a) is sufficient to guarantee $\operatorname{rank}(A_{\mathcal{S}})$ eigenvalues $1 + O(\mu)$.

A combination of Lemmas 3.4 and 3.5 gives the following result on the eigenvalues of $P(\nu)^{-1}B(\nu)$.

THEOREM 3.6 (eigenvalues of the preconditioned matrix). *Let $\nu \neq 0$, and let $B(\nu)$ and $P(\nu)$ be defined as in Definitions* 2.1 *and* 3.3*, respectively. Let $A_{\mathcal{S}}$ denote the submatrix of rows of A associated with diagonal elements of D that are $O(\mu)$. The preconditioned matrix $P(\nu)^{-1}B(\nu)$ has the following properties*:

(a) *The spectrum of $P(\nu)^{-1}B(\nu)$ is independent of ν and consists of m unit eigenvalues and the n eigenvalues of $(M + A^TD^{-1}A)^{-1}(H + A^TD^{-1}A)$.*

(b) *Every eigenvalue of $P(\nu)^{-1}B(\nu)$ is of order $O(1)$. Moreover, $P(\nu)^{-1}B(\nu)$ has at least $m + \operatorname{rank}(A_{\mathcal{S}})$ eigenvalues $1 + O(\mu^{1/2})$, of which at least m are exactly one.*

This result implies that if $m_{\mathcal{S}}$ denotes the number of eigenvalues of D that are $O(\mu)$ and the corresponding $m_{\mathcal{S}} \times n$ submatrix $A_{\mathcal{S}}$ has full row rank, then the PCG method can be expected to give a solution that is $O(\mu^{1/2})$ accurate in at most $n - m_{\mathcal{S}}$ iterations.

4. Active-set preconditioning. An advantage of interior methods is that all inequality constraints are treated in the same way—i.e., the solution path does not depend on an explicit prediction of which constraints are active at the solution. However, this advantage also can be a weakness because all constraint gradients are included in the linear system, even those having little or no influence on the solution. For example, if an interior method is applied to a problem with 100 variables and 100,000 inequality constraints, then a KKT system with 100,100 rows and columns must be solved at each iteration. However, if only 50 (say) of the inequalities are active at the solution, an active-set method would need to solve a KKT system of order 150. In the context of an interior method, the partition of constraints into "active" and "inactive" is determined by the magnitude of the diagonals of D in the KKT system (1.2). Broadly speaking, the active set at the solution is estimated by the indices of the "small" diagonals, and the inactive set is estimated by the indices of the "big" diagonals.

In this section we formulate and analyze two *active-set* preconditioners based on discarding rows of A that correspond to the big diagonals of D. The preconditioners may be applied with a cost comparable to that of solving the KKT system in an active-set method. In addition, the preconditioners allow considerable flexibility in how the diagonals are partitioned into large and small elements—the partition affects

only the rate of convergence of the iterative solver, not the rate of convergence of the interior method. Similar preconditioners have been proposed by Gertz and Griffin [21] in the context of support vector machine classifiers for large data sets. Preconditioners for the solution of linear programs in standard form have been considered by Gill et al. [25] and Oliveira and Sorensen [38]. An active-set preconditioner for general nonlinear optimization has been proposed by Lukšan, Matonoha, and Vlček [35].

4.1. Two active-set preconditioners. Let $m_{\mathcal{S}}$, $m_{\mathcal{M}}$, and $m_{\mathcal{B}}$ denote the number of row indices in the sets $\mathcal{S}$, $\mathcal{M}$, and $\mathcal{B}$ of "small," "medium," and "big" elements of D (see section 1.3). These sets are disjoint, and together they contain all the row indices of A, so that $m_{\mathcal{S}} + m_{\mathcal{M}} + m_{\mathcal{B}} = m$. If strict complementarity holds for the underlying optimization problem, then $m_{\mathcal{M}}$ is zero for all μ sufficiently small (see, e.g., Forsgren, Gill, and Wright [15, p. 531]). The following analysis, does not assume strict complementarity and so $m_{\mathcal{M}}$ may be nonzero. However, it must be emphasized that in this situation, the assumption regarding the order of the small elements of D is a simplification of the real situation. Our assumption that $d_{ii} = O(\mu)$ for $i \in \mathcal{S}$ is sufficient to capture the behavior as μ converges to zero. For a detailed discussion regarding interior methods on degenerate problems, see, e.g., Wright and Orban [48].

In order to simplify the notation, the indices corresponding to the small and medium diagonals are combined into one set $\mathcal{C}$, i.e., $\mathcal{C} = \mathcal{S} \cup \mathcal{M}$. This set is the complement of $\mathcal{B}$, i.e., $\mathcal{C} \cap \mathcal{B} = \emptyset$ and $\mathcal{C} \cup \mathcal{B} = \{1, \ldots, m\}$. This simplification is possible because of our focus on preconditioners based on discarding information associated with the indices in $\mathcal{B}$. Given the partition induced by $\mathcal{B}$ and $\mathcal{C}$, the matrix $P(\nu)$ may be partitioned as

$$P(\nu) = \begin{pmatrix} M + (1+\nu)A^T D^{-1} A & \nu A_{\mathcal{C}}^T & \nu A_{\mathcal{B}}^T \\ \nu A_{\mathcal{C}} & \nu D_{\mathcal{C}} & \\ \nu A_{\mathcal{B}} & & \nu D_{\mathcal{B}} \end{pmatrix}. \tag{4.1}$$

By eliminating the $\nu D_{\mathcal{B}}$ block from $P(\nu)$, we may factor $P(\nu)$ as $P(\nu) = R_{\mathcal{P}} P_{\mathcal{P}}(\nu) R_{\mathcal{P}}^T$, with

$$R_{\mathcal{P}} = \begin{pmatrix} I & & A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} \\ & I & \\ & & I \end{pmatrix}, \tag{4.2a}$$

$$P_{\mathcal{P}}(\nu) = \begin{pmatrix} M + A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}} + (1+\nu) A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}} & \nu A_{\mathcal{C}}^T & \\ \nu A_{\mathcal{C}} & \nu D_{\mathcal{C}} & \\ & & \nu D_{\mathcal{B}} \end{pmatrix}. \tag{4.2b}$$

Here, the subscript "$\mathcal{P}$" identifies matrices that depend on the partition induced by $\mathcal{B}$ and $\mathcal{C}$ (note that $P(\nu)$ itself is independent of the partition).

The nontrivial step associated with applying the preconditioner in the factored form $P(\nu) = R_{\mathcal{P}} P_{\mathcal{P}}(\nu) R_{\mathcal{P}}^T$ requires a solve with the leading principal submatrix of (4.2b):

$$\begin{pmatrix} M + A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}} + (1+\nu) A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}} & \nu A_{\mathcal{C}}^T \\ \nu A_{\mathcal{C}} & \nu D_{\mathcal{C}} \end{pmatrix}. \tag{4.3}$$

This matrix, formed by eliminating the block $\nu D_{\mathcal{B}}$ from $P(\nu)$, has smaller dimension, $(n + m - m_{\mathcal{B}}) \times (n + m - m_{\mathcal{B}})$, compared to $(n + m) \times (n + m)$ for $P(\nu)$. Lukšan, Matonoha, and Vlček [35] propose an active-set preconditioner based on forming an

incomplete factorization of the $(1,1)$ block. This avoids unnecessary fill-in from the term $A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}$. We propose an alternative strategy based on the observation that since $\|D_{\mathcal{B}}^{-1}\| = O(\mu)$, then $\|A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}\| = O(\mu)$. In particular, the term $A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}$ may be omitted from the $(1,1)$ block of $P_{\mathcal{P}}(\nu)$ without significantly changing the preconditioner. This implies that (4.3) is replaced by $P_{\mathcal{C}}(\nu)$, where

$$P_{\mathcal{C}}(\nu) = \begin{pmatrix} M + (1+\nu) A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}} & \nu A_{\mathcal{C}}^T \\ \nu A_{\mathcal{C}} & \nu D_{\mathcal{C}} \end{pmatrix}. \tag{4.4}$$

The subscript "$\mathcal{C}$" indicates that $P_{\mathcal{C}}(\nu)$ depends only on the indices in $\mathcal{C}$. In active-set constraint preconditioning, $P_{\mathcal{C}}(\nu)$ plays the role of $P(\nu)$ in the analysis of the standard case in section 3.1. Analogous to the assumptions on M, A, and D in Definition 3.3, we require that

- (P'_1) $\|M\| = O(1)$;
- (P'_2) $M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}}$ is positive definite; and
- (P'_3) $\mathrm{eig}_{\min}(M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}}) = \Omega(1)$.

When $P_{\mathcal{C}}(\nu)$ replaces the leading principal submatrix in (4.2b) the product of the factors becomes

$$P_{\mathcal{P}}^1(\nu) = \begin{pmatrix} M + \nu A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}} + (1+\nu) A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}} & \nu A_{\mathcal{C}}^T & \nu A_{\mathcal{B}}^T \\ \nu A_{\mathcal{C}} & \nu D_{\mathcal{C}} & \\ \nu A_{\mathcal{B}} & & \nu D_{\mathcal{B}} \end{pmatrix}, \tag{4.5}$$

which alternatively may be viewed as the preconditioner obtained by subtracting the term $A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}$ from the $(1,1)$ block of $P(\nu)$.

The preconditioner (4.5) has the factorization $P_{\mathcal{P}}^1(\nu) = R_{\mathcal{P}} P_{\mathcal{P}}^2(\nu) R_{\mathcal{P}}^T$, where $R_{\mathcal{P}}$ is the upper-triangular matrix (4.2a) and $P_{\mathcal{P}}^2(\nu)$ is given by

$$P_{\mathcal{P}}^2(\nu) = \begin{pmatrix} M + (1+\nu) A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}} & \nu A_{\mathcal{C}}^T & \\ \nu A_{\mathcal{C}} & \nu D_{\mathcal{C}} & \\ & & \nu D_{\mathcal{B}} \end{pmatrix}. \tag{4.6}$$

The matrix $P_{\mathcal{P}}^2(\nu)$ is yet another active-set preconditioner, which may be derived differently by replacing the leading principal submatrix of $P_{\mathcal{P}}(\nu)$ by $P_{\mathcal{C}}(\nu)$ and replacing $R_{\mathcal{P}}$ by I. Observe that the replacement of $R_{\mathcal{P}}$ by I quantifies the difference between $P_{\mathcal{P}}^1(\nu)$ and $P_{\mathcal{P}}^2(\nu)$, and hence $P_{\mathcal{P}}^1(\nu)$ is always a "better" approximation to $P_{\mathcal{P}}(\nu)$ than $P_{\mathcal{P}}^2(\nu)$. However, regardless of the choice of preconditioner, the dominant cost is the solve with the matrix $P_{\mathcal{C}}(\nu)$ of (4.4). Note that $A_{\mathcal{B}}$ does not appear in $P_{\mathcal{P}}^2(\nu)$, which may make $P_{\mathcal{P}}^2(\nu)$ the more attractive preconditioner when it is expensive to form A, e.g., in PDE-constrained optimization [5].

It remains to establish the theoretical properties of the preconditioners $P_{\mathcal{P}}^1(\nu)$ and $P_{\mathcal{P}}^2(\nu)$. The next result shows that, asymptotically, the eigenvalues of $P(\nu)^{-1}B(\nu)$ and $P_{\mathcal{P}}^1(\nu)^{-1}B(\nu)$ are identical.

THEOREM 4.1 (properties of the preconditioner $P_{\mathcal{P}}^1(\nu)$). *Let $B(\nu)$ and $P_{\mathcal{P}}^1(\nu)$ be as defined in Definition* 2.1 *and* (4.5)*, respectively. In addition, assume that assumptions* (P'_1)–(P'_3) *hold. Then $P_{\mathcal{P}}^1(\nu)$ is positive definite for all $\nu > 0$. Moreover, the following properties hold for all $\nu \neq 0$:*

- (a) *The spectrum of $P_{\mathcal{P}}^1(\nu)^{-1}B(\nu)$ is independent of ν and consists of m unit eigenvalues and the n eigenvalues of $(M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{-1}(H + A^T D^{-1} A)$.*
- (b) *The matrix $P_{\mathcal{P}}^1(\nu)^{-1}B(\nu)$ has all eigenvalues of order $O(1)$ and at least $m + \mathrm{rank}(A_{\mathcal{S}})$ eigenvalues $1 + O(\mu^{1/2})$, of which at least m are exactly one.*

(c) *If $P(\nu)$ is the preconditioner of Definition* 3.3*, then* $\operatorname{eig}(P_{\mathcal{P}}^1(\nu)^{-1}B(\nu)) = \operatorname{eig}(P(\nu)^{-1}B(\nu)) + O(\mu)$.

Proof. Proposition 2.3 implies that the preconditioner $P_{\mathcal{P}}^1(\nu)$ is positive definite for all $\nu > 0$. For the remainder of the proof it will be assumed that ν is nonzero. It follows that $\operatorname{eig}(P_{\mathcal{P}}^1(\nu)^{-1}B(\nu)) = \operatorname{eig}(P_{\mathcal{P}}^2(\nu)^{-1}R_{\mathcal{P}}^{-1}B(\nu)R_{\mathcal{P}}^{-T})$, where

$$R_{\mathcal{P}}^{-1}B(\nu)R_{\mathcal{P}}^{-T} = \begin{pmatrix} H + A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}} + (1+\nu) A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}} & \nu A_{\mathcal{C}}^T & \\ \nu A_{\mathcal{C}} & \nu D_{\mathcal{C}} & \\ & & \nu D_{\mathcal{B}} \end{pmatrix}. \tag{4.7}$$

By successively replacing H by $H + A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}$, A by $A_{\mathcal{C}}$, and D by $D_{\mathcal{C}}$ in Lemma 3.4, a combination of (4.6) and (4.7) gives

$$P_{\mathcal{P}}^2(\nu)^{-1}R_{\mathcal{P}}^{-1}B(\nu)R_{\mathcal{P}}^{-T} = \begin{pmatrix} S_{\mathcal{C}} & & \\ T_{\mathcal{C}} & I & \\ & & I \end{pmatrix}, \tag{4.8}$$

where the matrices $S_{\mathcal{C}}$ and $T_{\mathcal{C}}$ are given by

$$S_{\mathcal{C}} = (M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{-1}(H + A^T D^{-1} A), \tag{4.9a}$$

$$T_{\mathcal{C}} = D_{\mathcal{C}}^{-1} A_{\mathcal{C}} (M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{-1}(M - H - A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}). \tag{4.9b}$$

The identity (4.8) implies that the spectrum of $P_{\mathcal{P}}^1(\nu)^{-1}B(\nu)$ consists of the eigenvalues of $S_{\mathcal{C}}$ and m unit eigenvalues, which proves part (a). Since $S_{\mathcal{C}}$ is independent of ν, the spectrum of $P_{\mathcal{P}}^1(\nu)^{-1}B(\nu)$ is also independent of ν. Lemma 3.5 implies that $S_{\mathcal{C}}$ has at least $\operatorname{rank}(A_{\mathcal{S}})$ eigenvalues that are $1 + O(\mu^{1/2})$, which establishes part (b).

To establish part (c), we need to estimate the difference between the eigenvalues of $S_{\mathcal{C}}$ and S, where S is given by (3.3a). This can be done using Lemma A.2 of the appendix. We may write

$$S_{\mathcal{C}} = I + (M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{-1}(H - M) + (M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{-1} A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}, \tag{4.10a}$$

$$S = I + (M + A^T D^{-1} A)^{-1}(H - M). \tag{4.10b}$$

By assumption, matrix $M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}}$ is positive definite with the smallest eigenvalue bounded away from zero, and $A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}$ is positive definite with $\|D_{\mathcal{B}}^{-1}\| = O(\mu)$. The identity (4.10a) implies that the matrix $(M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{1/2} S_{\mathcal{C}} (M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{-1/2}$ is symmetric and has the same eigenvalues as $S_{\mathcal{C}}$, and it follows from (4.10) that

$$\operatorname{eig}(S_{\mathcal{C}}) = 1 + \operatorname{eig}((M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{-1}(H - M)) + O(\mu), \tag{4.11a}$$

$$\operatorname{eig}(S) = 1 + \operatorname{eig}((M + A^T D^{-1} A)^{-1}(H - M)). \tag{4.11b}$$

If we define $M_1 = M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}}$, $M_2 = A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}$, and $M_3 = H - M$, then (4.11) gives $\operatorname{eig}(S_{\mathcal{C}}) = 1 + \operatorname{eig}(M_1^{-1} M_3) + O(\mu)$ and $\operatorname{eig}(S) = 1 + \operatorname{eig}((M_1 + M_2)^{-1} M_3)$. Lemma A.2 in conjunction with assumptions (P_1')–(P_3') gives the desired result. ∎

Next we establish that $P_{\mathcal{P}}^2(\nu)$ has the same asymptotic behavior as $P(\nu)$ and $P_{\mathcal{P}}^1(\nu)$. For $P_{\mathcal{P}}^2(\nu)$ it is assumed that $\nu > 0$, which ensures that the eigenvalues of $P_{\mathcal{P}}^2(\nu)^{-1}B(\nu)$ are real. The preconditioner $P_{\mathcal{P}}^2(\nu)$ is less expensive to apply than $P_{\mathcal{P}}^1(\nu)$, but the number of unit eigenvalues of the preconditioned matrix decreases from m to $m - \operatorname{rank}(A_{\mathcal{B}})$ because $A_{\mathcal{B}}$ does not appear in $P_{\mathcal{P}}^2(\nu)$. However, as the next theorem shows, for $\nu > 0$, $P_{\mathcal{P}}^2(\nu)$ behaves almost as well as $P_{\mathcal{P}}^1(\nu)$ in the sense that the eigenvalues of $P_{\mathcal{P}}^2(\nu)^{-1}B(\nu)$ differ from the eigenvalues of $P(\nu)^{-1}B(\nu)$ by $O(\mu^{1/2})$.

THEOREM 4.2 (properties of the preconditioner $P_{\mathcal{P}}^2(\nu)$). *Let $B(\nu)$ and $P_{\mathcal{P}}^2(\nu)$ be as defined in Definition* 2.1 *and* (4.6)*, respectively. In addition, assume that assumptions* (P_1')–(P_3') *hold. Then the following properties hold for all $\nu > 0$:*

(a) *$P_{\mathcal{P}}^2(\nu)$ is positive definite.*
(b) *The matrix $P_{\mathcal{P}}^2(\nu)^{-1}B(\nu)$ has all eigenvalues of order $O(1)$ and at least $m + \operatorname{rank}(A_{\mathcal{S}})$ eigenvalues $1 + O(\mu^{1/2})$, of which at least $m - \operatorname{rank}(A_{\mathcal{B}})$ are exactly one.*
(c) *If $P(\nu)$ is the preconditioner of Definition* 3.3*, then* $\operatorname{eig}(P_{\mathcal{P}}^2(\nu)^{-1}B(\nu)) = \operatorname{eig}(P(\nu)^{-1}B(\nu)) + O(\mu^{1/2})$.

Proof. The positive definiteness of $P_{\mathcal{P}}^2(\nu)$ for $\nu > 0$ follows from Proposition 2.3. For the remainder of the proof, assume that $\nu > 0$. Then, since $P_{\mathcal{P}}^2(\nu)$ is positive definite, the identity $\operatorname{eig}(P_{\mathcal{P}}^2(\nu)^{-1/2}B(\nu)P_{\mathcal{P}}^2(\nu)^{-1/2}) = \operatorname{eig}(P_{\mathcal{P}}^2(\nu)^{-1}B(\nu))$ ensures that $P_{\mathcal{P}}^2(\nu)^{-1}B(\nu)$ has real eigenvalues. Analogous to the proof of Theorem 4.1, by successively replacing the matrix H by $H + (1+\nu)A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}$, A by $A_{\mathcal{C}}$, and D by $D_{\mathcal{C}}$ in Lemma 3.4, and by using a combination of Proposition 2.3 and (4.6), we find that

$$P_{\mathcal{P}}^2(\nu)^{-1}B(\nu) = \begin{pmatrix} S_{\mathcal{C}} & & \\ T_{\mathcal{C}} & I & \\ & & I \end{pmatrix} + \begin{pmatrix} U & & X \\ V & & Y \\ W & & \end{pmatrix}, \tag{4.12}$$

where $S_{\mathcal{C}}$ and $T_{\mathcal{C}}$ are given by (4.9),

$$U = \nu(M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{-1} A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}, \tag{4.13a}$$

$$V = -\nu D_{\mathcal{C}}^{-1} A_{\mathcal{C}} (M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{-1} A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}}, \tag{4.13b}$$

$$W = D_{\mathcal{B}}^{-1} A_{\mathcal{B}}, \tag{4.13c}$$

$$X = \nu(M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{-1} A_{\mathcal{B}}^T, \tag{4.13d}$$

$$Y = -\nu D_{\mathcal{C}}^{-1} A_{\mathcal{C}} (M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}})^{-1} A_{\mathcal{B}}^T. \tag{4.13e}$$

It follows from (4.12) that $P_{\mathcal{P}}^2(\nu)^{-1}B(\nu)$ contains $m - m_{\mathcal{B}}$ columns from the identity matrix; hence it has at least $m - m_{\mathcal{B}}$ unit eigenvalues. The remaining eigenvalues are those of the matrix N given by

$$N = \begin{pmatrix} S_{\mathcal{C}} + U & X \\ W & I \end{pmatrix} = \begin{pmatrix} S_{\mathcal{C}} + \nu S_M^{-1} A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}} & \nu S_M^{-1} A_{\mathcal{B}}^T \\ D_{\mathcal{B}}^{-1} A_{\mathcal{B}} & I \end{pmatrix}, \tag{4.14}$$

with $S_M = M + A_{\mathcal{C}}^T D_{\mathcal{C}}^{-1} A_{\mathcal{C}}$. Observe that (4.14) implies that any nonzero vector x such that $A_{\mathcal{B}}^T x = 0$ induces an eigenvector corresponding to a unit eigenvalue of N. Hence, N has at least $m_{\mathcal{B}} - \operatorname{rank}(A_{\mathcal{B}})$ unit eigenvalues. Further, let $\widetilde{Q}$ be defined by

$$\widetilde{Q} = \begin{pmatrix} S_M^{1/2} & \\ & \nu^{1/2} D_{\mathcal{B}}^{1/2} \end{pmatrix}.$$

Then N and $\widetilde{Q}N\widetilde{Q}^{-1}$ have identical eigenvalues, and $\widetilde{Q}N\widetilde{Q}^{-1}$ is given by

$$\begin{aligned} \widetilde{Q}N\widetilde{Q}^{-1} &= \begin{pmatrix} S_M^{1/2} S_{\mathcal{C}} S_M^{-1/2} + \nu S_M^{-1/2} A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}} S_M^{-1/2} & \nu^{1/2} S_M^{-1/2} A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1/2} \\ \nu^{1/2} D_{\mathcal{B}}^{-1/2} A_{\mathcal{B}} S_M^{-1/2} & I \end{pmatrix} \\ &= \begin{pmatrix} S_M^{1/2} S_{\mathcal{C}} S_M^{-1/2} & \\ & I \end{pmatrix} + \begin{pmatrix} \nu S_M^{-1/2} A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}} S_M^{-1/2} & \nu^{1/2} S_M^{-1/2} A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1/2} \\ \nu^{1/2} D_{\mathcal{B}}^{-1/2} A_{\mathcal{B}} S_M^{-1/2} & \end{pmatrix}. \end{aligned}$$

Note that $S_M^{1/2} S_{\mathcal{C}} S_M^{-1/2}$ is symmetric, and hence $\widetilde{Q} N \widetilde{Q}^{-1}$ is symmetric. In addition, from our assumptions, it follows that $\|\nu^{1/2} S_M^{-1/2} A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1/2}\| = O(\mu^{1/2})$ and $\|\nu S_M^{-1/2} A_{\mathcal{B}}^T D_{\mathcal{B}}^{-1} A_{\mathcal{B}} S_M^{-1/2}\| = O(\mu)$. Hence, $\widetilde{Q} N \widetilde{Q}^{-1}$ has $m_{\mathcal{B}}$ eigenvalues that differ by $O(\mu^{1/2})$ from unity, and n eigenvalues that differ by $O(\mu^{1/2})$ from the eigenvalues of the matrix $S_M^{1/2} S_{\mathcal{C}} S_M^{-1/2}$. In addition, the eigenvalues of $S_M^{1/2} S_{\mathcal{C}} S_M^{-1/2}$ and $S_{\mathcal{C}}$ are identical. Consequently, it follows that the spectrum of $P_{\mathcal{P}}^2(\nu)^{-1} B(\nu)$ consists of $m - \operatorname{rank}(A_{\mathcal{B}})$ unit eigenvalues, $\operatorname{rank}(A_{\mathcal{B}})$ eigenvalues that are $1 + O(\mu^{1/2})$, and n eigenvalues that differ by $O(\mu^{1/2})$ from the eigenvalues of $S_{\mathcal{C}}$. Theorem 4.1 now shows that $\operatorname{eig}(P_{\mathcal{P}}^2(\nu)^{-1} B(\nu)) = \operatorname{eig}(P_{\mathcal{P}}^1(\nu)^{-1} B(\nu)) + O(\mu^{1/2})$, which gives the required result, since $O(\mu^{1/2})$ dominates $O(\mu)$. In particular, Theorem 4.1 implies that $P_{\mathcal{P}}^2(\nu)^{-1} B(\nu)$ has at least $m + \operatorname{rank}(A_{\mathcal{S}})$ eigenvalues that are $1 + O(\mu^{1/2})$. ∎

We conclude that it is possible to construct appropriate constraint preconditioners based on solving the smaller system (4.4). Moreover, the matrix $P_{\mathcal{C}}(\nu)$ of (4.4) has exactly the same structure as $P(\nu)$. The difference is that the number of rows and columns in the preconditioner has been reduced from $n + m$ to $n + m - m_{\mathcal{B}}$. Hence, all the previous analysis applies. For our example with 100 variables and 100,000 inequality constraints, a matrix of dimension 150 would need to be factored instead of a matrix of dimension 100,100.

As shown above, the partition of the row indices into $\mathcal{B}$ and its complement $\mathcal{C}$ provides active-set preconditioners $P_{\mathcal{P}}^1(\nu)$ and $P_{\mathcal{P}}^2(\nu)$ that are asymptotically equivalent to $P(\nu)$. If strict complementarity holds, then $m_{\mathcal{M}} = 0$ and the division into large and small elements is straightforward. If strict complementarity does not hold, then $m_{\mathcal{M}} > 0$ and we have chosen to append $\mathcal{M}$ to $\mathcal{S}$. Analogous preconditioners may be constructed by first identifying $\mathcal{S}$ and then forming the complementary set $\bar{\mathcal{S}}$, which is the set obtained by appending $\mathcal{M}$ to $\mathcal{B}$. The resulting KKT system analogous to (4.4) would have smaller dimension because $\mathcal{C}$ is replaced by $\mathcal{S}$. However, the resulting preconditioners would not be asymptotically equivalent in general. For $P_{\mathcal{P}}^1(\nu)$, the $1 + O(\mu^{1/2})$ cluster of eigenvalues would be the same as for $P(\nu)$, but the eigenvalues resulting from M would differ by an $O(1)$ term. The reason for this difference is that the norm of $D_{\bar{\mathcal{S}}}^{-1}$ would not be of order $O(\mu)$, but would include terms involving $m_{\mathcal{M}}$ eigenvalues of order one.

It should be emphasized that the choice of $\mathcal{C}$ and $\mathcal{B}$ affects only the efficiency of the active-set constraint preconditioners and not the definition of the linear equations that need to be solved. A poorly chosen partition may adversely affect the quality of the preconditioner, but not the solution of the linear equations. The partition analyzed here provides the largest $\mathcal{B}$ for which we can guarantee that the preconditioners $P_{\mathcal{P}}^1(\nu)$ and $P_{\mathcal{P}}^2(\nu)$ are asymptotically equivalent to $P(\nu)$ for $\nu > 0$. If elements are excluded from $\mathcal{B}$, then $P_{\mathcal{P}}^1(\nu)$ and $P_{\mathcal{P}}^2(\nu)$ become "better" approximations to $P(\nu)$, and the asymptotic performance is unchanged. However, this increases the dimension of the KKT system (4.4). As noted above, if $\mathcal{B}$ is chosen too large, in the sense that diagonal elements of D are included in $D_{\mathcal{B}}$ that are not $\Omega(1/\mu)$, then the quality of the active-set preconditioners can be expected to deteriorate. Hence, it is not essential that $\mathcal{B}$ is estimated correctly, but it is essential that $D_{\mathcal{B}}$ contains only large elements.

5. On semidefinite diagonal matrices. Up to this point we have assumed that the matrix D in the $(2,2)$ block of the KKT system is positive definite. In the general case, the last block of equations in the KKT system has the form

$$Ax_1 + Gx_2 = b_2, \tag{5.1}$$

where G is a diagonal matrix with positive and zero entries. If all the constraints of the optimization problem are nonlinear, it is always possible to formulate the interior method so that G is positive definite. For inequality constraints, standard formulations give positive elements in G that are of the order of the perturbation parameter μ (see, e.g., Vanderbei and Carpenter [46] and Forsgren and Gill [16]). Typically, zero elements of G are associated with linearized equality constraints, where the corresponding subset of equations (5.1) are the Newton equations for a zero of the constraint residual. An alternative to direct constraint linearization is to impose equality constraints approximately via a quadratic penalty function. It can be shown that this approach gives a positive element in G of the order of $\bar{\mu}$, where $\bar{\mu}$ is the inverse of the penalty parameter (see, e.g., Gould [31] and Forsgren and Gill [16]). The parameter $\bar{\mu}$ may be allowed to vary with μ, or may be fixed at some small value (see, e.g., Gill et al. [26] and Saunders and Tomlin [42]). Fixing $\bar{\mu}$ defines a *regularization* of the problem, which allows the formulation of methods that do not require an assumption on the rank of the equality constraint Jacobian. (For more details on the use of regularization in interior methods, see Gill et al. [24], Vanderbei and Shanno [47], and Altman and Gondzio [1].)

However, it may not always be beneficial to regularize *linear* constraints. Regularization in this context is less crucial because reliable techniques exist for discarding dependent equality constraints. Moreover, interior methods can be defined so that every iterate satisfies the linear equality constraints (see below). With an appropriate choice of constraints, this feature can be used to guarantee that the nonlinear functions and their derivatives are well defined at all points generated by the interior method.

In order to consider KKT systems with a semidefinite $(2,2)$ block, we assume that the variables and equations are preordered to give a system $Bx = b$ such that

$$\begin{pmatrix} H & -A^T & -F^T \\ -A & -D & \\ -F & & \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} b_1 \\ -b_2 \\ -b_3 \end{pmatrix}, \tag{5.2}$$

where D is positive definite. Note that we cannot compute the condensed or doubly augmented system for these equation because of the zero block. In this case, B has correct inertia if $N^T(H + A^T D^{-1} A)N$ is positive definite, where the columns of N form a basis for the null space of F (see Forsgren [18]).

The KKT system (5.2) may be solved using a projection technique similar to that described in section 3. First, an initial point y is found with first n components forming a vector y_1 such that $Fy_1 = b_3$. This vector may be computed in various ways—e.g., by computing an LU factorization of F^T (see, e.g., Gill, Murray, and Saunders [27]), or by solving a system for the preconditioning matrix associated with (5.2), where H is replaced by a suitable approximation M (see Gould, Hribar, and Nocedal [29]). Once y is known, the PCG method may be used to solve

$$\begin{pmatrix} H & -A^T & -F^T \\ -A & -D & \\ -F & & \end{pmatrix} \begin{pmatrix} \widehat{x}_1 \\ \widehat{x}_2 \\ \widehat{x}_3 \end{pmatrix} = \begin{pmatrix} \widehat{b}_1 \\ -\widehat{b}_2 \\ 0 \end{pmatrix}, \tag{5.3}$$

with $\widehat{b}_1 = b_1 - Hy_1 + A^T y_2 + F^T y_3$ and $\widehat{b}_2 = b_2 - Ay_1 - Dy_2$. The required solution is then $x = y + \widehat{x}$. Analogous to the situation when G is positive definite, we may

embed (5.3) into the parameterized system of linear equations

$$\begin{pmatrix} H+(1+\nu)A^TD^{-1}A & \nu A^T & -F^T \\ \nu A & \nu D & \\ -F & & \end{pmatrix} \begin{pmatrix} \widehat{x}_1 \\ \widehat{x}_2 \\ \widehat{x}_3 \end{pmatrix} = \begin{pmatrix} \widehat{b}_1+(1+\nu)A^TD^{-1}\widehat{b}_2 \\ \nu\widehat{b}_2 \\ 0 \end{pmatrix}, \tag{5.4}$$

with $\widehat{b}_1 = b_1 - Hy_1 + A^Ty_2 + F^Ty_3$ and $\widehat{b}_2 = b_2 - Ay_1 - Dy_2$. If the zero elements of G are associated with linear constraints, and the system (5.3) is solved exactly, it suffices to compute the special step y only once, when solving the first system. Then, provided that the constraint preconditioner is applied exactly at every PCG step, the right-hand side of (5.3) will remain zero for all subsequent iterations.

The linear equations (5.2), (5.3), and (5.4) do not require N. If the preconditioner cannot be applied exactly, then it is necessary to use an alternative method based on computing products of the form N^Tv and Nu. (Gill, Murray, and Saunders [27] describe how these products may be computed in a numerically stable way without needing to store N explicitly.) The requirement that $F\widehat{x}_1 = 0$ implies that $\widehat{x}_1$ can be written as $\widehat{x}_1 = N\hat{p}_1$. Substituting this expression in (5.3) gives the reduced KKT system

$$\begin{pmatrix} N^THN & -(AN)^T \\ -AN & -D \end{pmatrix} \begin{pmatrix} \hat{p}_1 \\ \hat{p}_2 \end{pmatrix} = \begin{pmatrix} N^T(b_1 - Hy_1 + A^Ty_2) \\ -b_2 + Ay_1 + Dy_2 \end{pmatrix}, \tag{5.5}$$

from which we can define $\widehat{x}_1 = N\hat{p}_1$ and $\widehat{x}_2 = \hat{p}_2$. This system has a nonsingular $(2,2)$ block and has correct inertia if (5.2) has correct inertia. Moreover, the iterates define exact projections regardless of the accuracy of the solves with the preconditioner. Hence, all the conditions needed for the application of the PCG method proposed in section 3 apply. The systems (5.3) and (5.5) are mathematically equivalent, which implies that we may apply the analysis of section 3 directly to both (5.3) and (5.4).

6. Some numerical examples. To illustrate the numerical performance of the proposed preconditioners, a PCG method was applied to a collection of illustrative large sparse KKT systems. The test matrices were generated from a number of realistic KKT systems arising in the context of primal-dual interior methods. We conclude with some randomly generated problems that illustrate some of the properties of the preconditioned matrices.

6.1. Examples from the COPS test set. First we describe some numerical results obtained on linear equations arising in a primal-dual interior method applied to optimization problems from the COPS 3.0 test collection [6, 9, 10] implemented in the AMPL modeling language [2, 19].

The equations are analogous to those generated by an interior-point method with barrier parameter μ. The data for the test matrices was generated using a primal-dual trust-region method (see, e.g., [16, 20, 32]) applied to eight problems, *Camshape*, *Channel*, *Gasoil*, *Marine*, *Methanol*, *Pinene*, *Polygon*, and *Tetra*, from the COPS 3.0 test collection [6, 8, 9, 10]. The interior-point method requires the solution of systems with a KKT matrix of the form

$$\begin{pmatrix} H & -J^T \\ -J & -\Gamma \end{pmatrix}, \tag{6.1}$$

where H is the $n \times n$ Hessian of the Lagrangian, J is the $m \times n$ Jacobian matrix of constraint gradients, and Γ is a positive-definite diagonal with some large and small

TABLE 6.1
Dimensions of the AMPL versions of the COPS problems.

Problem	n	m	$\|H - M\|$	$\sigma_k(J)$
Camshape	1200	3600	2.6e+0	1.3e-5
Channel	6398	6398	1.1e+2	4.1e-5
Gasoil	4001	4001	1.1e+1	0.0e+0
Marine	6415	6407	3.5e+1	0.0e+0
Methanol	4802	4802	3.1e+0	2.8e-3
Pinene	8000	8000	9.2e+3	6.8e-8
Polygon	398	20496	2.4e+2	0.0e+0
Tetra	1200	4254	2.7e+1	0.0e+0

elements. These systems have the same structure as the generic system (1.2). The dimensions of the eight problems are given in Table 6.1. The optimization problems in the COPS collection have a mixture of general nonlinear constraints and simple upper and lower bounds on the variables. The simple bounds lead to unit rows in J, and it is customary to define a smaller KKT system in which the unit rows and columns are eliminated. However, in the numerical experiments, the unit rows were included in order to more accurately illustrate the results of Theorems 3.6, 4.1, and 4.2. Hence the value of m also includes the bound constraints. The final column gives the kth largest singular value of J, where $k = \min\{m, n\}$.

For each of the eight featured COPS problems, matrices H, A, D and the right-hand side were generated from the matrices H, J, Γ and the right-hand side at a snapshot taken at iteration 30 of the interior method. For each problem snapshot, five systems of equations were generated by specifying five matrices D with entries parameterized by a scalar $\mu = 10^{-\ell}$ for $\ell = \{1, 2, 4, 6, 8\}$. For each value of μ, the matrices A and D were generated from J and Γ using the MATLAB code fragment

```
[D, ind] = sort(Gamma); % sort the diagonals of Gamma
A  = J(ind,:);          % reorder the rows of J
k  = min([m,n]);        %
if k < m, D(k+1:end) = max(D(k+1:end), 1/mu); end
D(1:k) = min(D(1:k),mu);
```

This choice of D implicitly defines a sequence of systems associated with a vertex solution of the underlying optimization problem for which strict complementarity holds. This was done deliberately to minimize the effect of the matrix M on the efficiency of the preconditioner (see the definition of $P(\nu)$ in (4.1)). Asymptotically, the matrix M defines the efficiency of the preconditioner within the null space of the matrix of active constraints (see, e.g., Dollar et al. [11]). In our analysis we have focused on the part of the preconditioner associated with the constraint part of the KKT system. The formulation and analysis of effective choices for M are beyond the scope of this paper. (For some possible approaches, see, e.g., [22, 23].) In the experiments reported here, M was a diagonal matrix with entries $M_{jj} = \max\left(|H_{jj}|, \delta\right)$, where $\delta = 10^{-1}$.

Figure 6.1 depicts the number of PCG iterations required to solve the resulting 8 sets of 5 systems of linear equations. The bar charts give the PCG iterations for the condensed system (top) and doubly augmented system (bottom). The MATLAB version of SYMMLQ [39] was used as the PCG solver. The symmetric indefinite solver MA27 was used to factor the constraint preconditioner (see Duff and Reid [13]). The

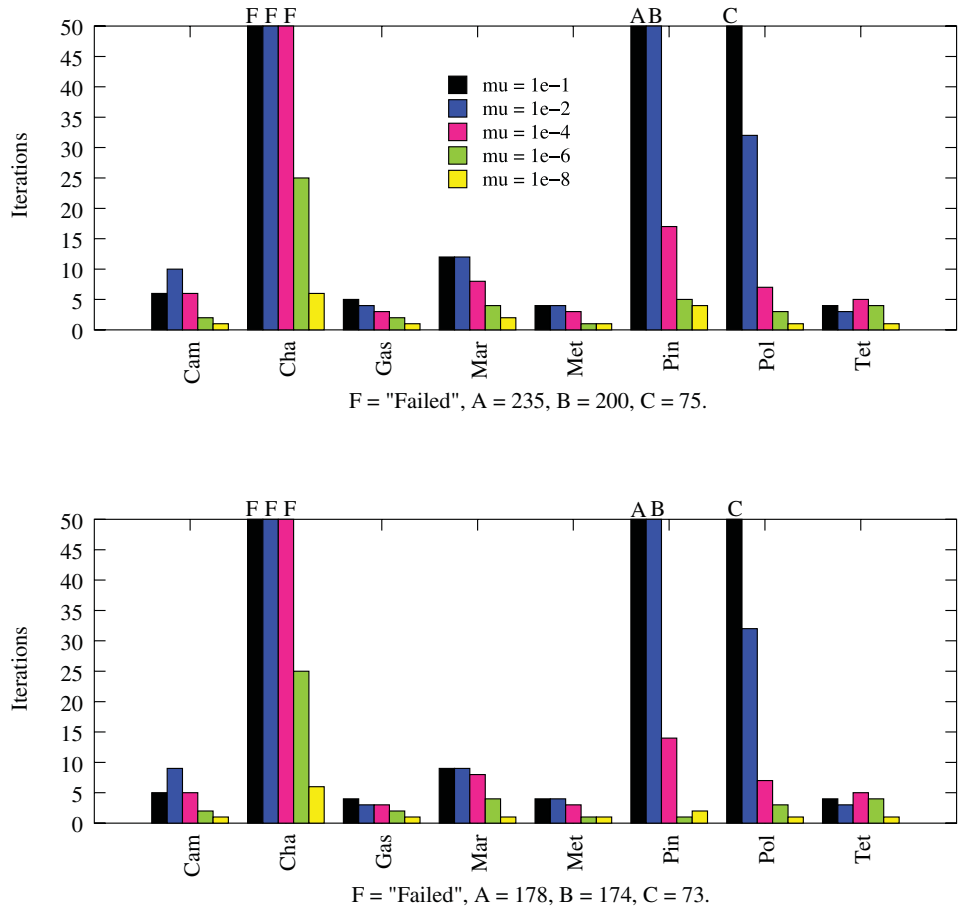

FIG. 6.1. *Results on the COPS problems. The graphs give the number of PCG iterations for* $P(0)$ *(above) and* $P(1)$ *(below). The vertical axis is limited to* 50 *iterations. The number of iterations needed for each off-scale case is given by the appropriate key code "A", "B", or "C".*

value of 10^{-6} was used for the SYMMLQ relative convergence tolerance. For problem *Channel*, with the three larger values of μ, PCG did not converge within the pre-assigned limit of 10^6 iterations (a more sophisticated choice of M is needed in this case). Note the similar number of PCG iterations needed to solve the condensed system and doubly augmented system.

Figure 6.2 gives the number of PCG iterations for the active-set preconditioners on the COPS problems *Camshape*, *Polygon*, and *Tetra*. These problems have significantly more constraints than variables and provide good examples on which to test the active-set preconditioners. In order to illustrate the behavior of the active-set preconditioner, we scale D so that exactly n elements are less than μ and the remaining elements are greater than $1/\mu$. We emphasize that the motivation for manipulating D in this way is to illustrate the effect of changing μ for fixed H and J.

```
mS = min([n,m,k]);
JS = J(1:mS,:);     JB = J(mS+1:end,:);
DS = D(1:mS);       DB = D(mS+1:end);
DS = spdiags(DS,0,mS,mS);
```

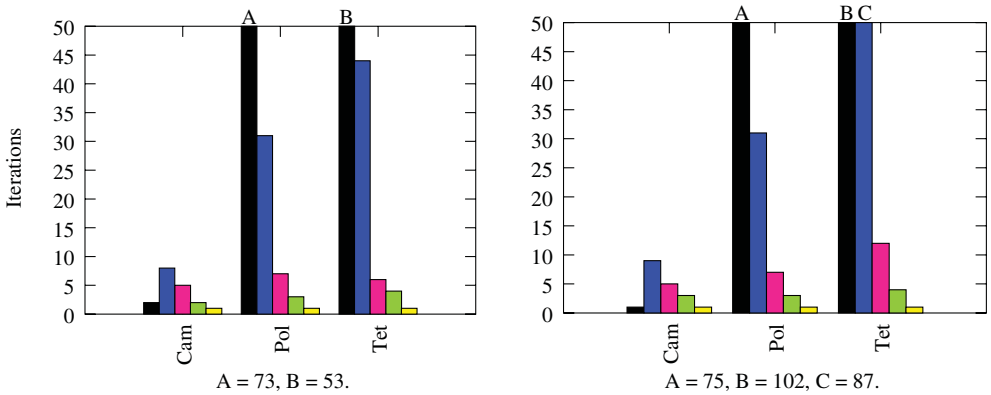

FIG. 6.2. *COPS problems: PCG iterations for $P^1_{\mathcal{P}}(1)$ (left) and $P^2_{\mathcal{P}}(1)$ (right). The vertical axis is limited to 50 iterations. The number of iterations needed for each off-scale case is given by the appropriate key code "A", "B", or "C".*

6.2. Results from randomly generated problems. Additional experiments were performed on randomly generated KKT systems. The purpose of these experiments was to illustrate the clustering of the eigenvalues of the preconditioned matrices associated with the doubly augmented system. The first set of experiments involved applying the preconditioners $P(1)$, $P^1_{\mathcal{P}}(1)$, and $P^2_{\mathcal{P}}(1)$ to randomly generated problems satisfying the assumptions of Theorems 4.1 and 4.2. Of particular interest is the "strict complementarity" assumption that every element of the diagonal D is either big or small. Given values $n = 400$, $m = 600$, and $\mu = 10^{-\ell}$ for $\ell = \{1, 2, 4, 6, 8\}$, matrices H, $A_{\mathcal{S}}$, $A_{\mathcal{B}}$, $D_{\mathcal{S}}$, and $D_{\mathcal{B}}$ were generated using the MATLAB code fragment

```
mS = 100; d  = 10^(-2);
H  = sprandsym(n,d);          JS = sprand(mS,n,d,0.1);  JB = sprand(m-mS,n,d);
DS = diag(mu*ones(mS,1));     DB = diag((1/mu)*ones(m-mS,1));
```

Table 6.2 gives details of the eigenvalues of the preconditioned matrices associated with each of the preconditioners $P(1)$, $P^1_{\mathcal{P}}(1)$, and $P^2_{\mathcal{P}}(1)$, where the diagonal preconditioner M was defined as in the COPS examples of the previous section. In all these runs, the resulting KKT matrix satisfies $\|H - M\| = 4.95$ and $\sigma_n(J_{\mathcal{S}}) = 10^{-1}$. These linear systems would be typical for a primal-dual method applied to an optimization problem with 100 active constraints at a point satisfying a strict complementarity assumption. Theorems 3.6 and 4.1 predict that for the preconditioners $P(1)$ and $P^1_{\mathcal{P}}(1)$, 700 $(= m + \text{rank}(A_{\mathcal{S}}))$ eigenvalues of the preconditioned matrix will cluster close to unity, with 600 of these eigenvalues exactly equal to one. Theorem 4.2 predicts that as μ is reduced, $P^2_{\mathcal{P}}(1)$ also will give 700 eigenvalues close to one, whereas 200 $(= m - n)$ eigenvalues will be exactly one.

The last four columns of Table 6.2 illustrate the degree of clustering of the eigenvalues of the preconditioned matrix. Clustering is measured by means of the function $l(\theta)$ defined as follows. Given a matrix C with real eigenvalues, the function

$$l(\theta) = \text{card}\{\lambda \in \text{eig}(C) : |\lambda - 1| \leq \theta\}$$

gives the number of eigenvalues of C within distance θ of unity. Table 6.2 gives the values of $l(\theta)$ for the three preconditioned matrices $C = P(1)^{-1}B(1)$, $P^1_{\mathcal{P}}(1)^{-1}B(1)$, and $P^2_{\mathcal{P}}(1)^{-1}B(1)$. In this strict-complementarity case, we expect that the proposed preconditioners would asymptotically give a cluster of 700 unit eigenvalues. Note that

	10^{-4}	200	215	563	653
	10^{-6}	215	563	653	675
	10^{-8}	544	653	675	675

for small values of μ, $P(1)$ and $P^1_{\mathcal{P}}(1)$ produce very similar numbers of eigenvalues close to unity. The preconditioner $P^2_{\mathcal{P}}(1)$ tends to give fewer accurate eigenvalues than $P(1)$ and $P^1_{\mathcal{P}}(1)$ for the larger values of μ, although the differences become less marked as μ is reduced.

Table 6.3 was generated with the same data used for Table 6.2, with the one exception that strict complementarity was assumed not to hold. As in Table 6.2, we simulate an optimization problem with 100 active constraints, but in this case we set $m_{\mathcal{S}} = 75$ and $m_{\mathcal{M}} = 25$. The corresponding diagonal elements of $D_{\mathcal{M}}$ were set at one.

In this non-strict-complementarity case, Theorems 3.6, 4.1, and 4.2 predict that the proposed preconditioners would asymptotically give a cluster of 675 ($= m + m_{\mathcal{S}}$) unit eigenvalues, which is reflected in the results. The performance of the preconditioners is very similar to that depicted in Table 6.2.

7. Summary and further research. A framework has been proposed for applying the PCG method to KKT systems of the form (1.1) that arise in interior methods for general nonconvex optimization. The proposed methods are based on applying the conjugate-gradient method to the doubly augmented system (1.4), which is positive definite if the underlying optimization problem satisfies the second-order sufficient conditions for optimality. An advantage of the doubly augmented system is that it is positive definite with respect to all of the variables.

We also have proposed a class of constraint preconditioners for the doubly augmented system. In particular, we have analyzed two ways of using an estimate of the active set to reduce the cost of applying the preconditioner when there are many inequality constraints. As the solution of the optimization problem is approached, these active-set preconditioners have theoretical performance comparable to constraint preconditioners that include all the constraints. An advantage of using preconditioning in conjunction with the doubly augmented system is that the linear equations used to apply the preconditioner need not be solved exactly. Future work will consider the analysis associated with these approximate preconditioners.

The focus of this paper has been on the formulation and analysis of *constraint* preconditioners. The next step is to consider "full" preconditioners based on estimating the matrix H in the $(1,1)$ block of the KKT equations. For example, a preconditioner may be defined using an incomplete inertia-controlling factorization of the KKT system (1.2). For more details on the inertia-controlling factorization for augmented systems in interior methods, see Forsgren and Gill [16] and Forsgren [18].

Appendix. Linear algebra. Here we review two results from linear algebra. The first gives the structure of the inverse of $B(\nu)$ and may be verified by direct multiplication.

LEMMA A.1. *Given a nonsingular symmetric matrix D, consider the matrix*

$$B(\nu) = \begin{pmatrix} H + (1+\nu)A^T D^{-1} A & \nu A^T \\ \nu A & \nu D \end{pmatrix},$$

where ν is a scalar. Then $B(\nu)$ may be factored in the form

$$B(\nu) = \begin{pmatrix} I & A^T D^{-1} \\ & I \end{pmatrix} \begin{pmatrix} H + A^T D^{-1} A & \\ & \nu D \end{pmatrix} \begin{pmatrix} I & \\ D^{-1} A & I \end{pmatrix}.$$

Moreover, if $H + A^T D^{-1} A$ is nonsingular and $\nu \neq 0$, then $B(\nu)$ is nonsingular, with inverse

$$\begin{aligned} B(\nu)^{-1} &= \begin{pmatrix} (H + A^T D^{-1} A)^{-1} & -(H + A^T D^{-1} A)^{-1} A^T D^{-1} \\ -D^{-1} A (H + A^T D^{-1} A)^{-1} & \frac{1}{\nu} D^{-1} + D^{-1} A (H + A^T D^{-1} A)^{-1} A^T D^{-1} \end{pmatrix} \\ &= \begin{pmatrix} I & \\ -D^{-1} A & I \end{pmatrix} \begin{pmatrix} (H + A^T D^{-1} A)^{-1} & \\ & \frac{1}{\nu} D^{-1} \end{pmatrix} \begin{pmatrix} I & -A^T D^{-1} \\ & I \end{pmatrix}. \end{aligned}$$

The second result provides bounds on the perturbation of the eigenvalues of $M_1^{-1} M_3$ when M_1 is perturbed by a positive-semidefinite matrix M_2.

LEMMA A.2. *Let M_1, M_2, and M_3 be $n \times n$ symmetric matrices with M_1 positive definite and M_2 positive semidefinite. Let $\{\lambda_i\}$ and $\{\widetilde{\lambda}_i\}$ denote the eigenvalues of $M_1^{-1}M_3$ and $(M_1+M_2)^{-1}M_3$, respectively. Assume that the $\{\lambda_i\}$ are ordered so that $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n$, with the same ordering for $\{\widetilde{\lambda}_i\}$. Then*

$$0 \leq \lambda_i - \widetilde{\lambda}_i \leq \|M_1^{-1/2}M_2M_1^{-1/2}\|\widetilde{\lambda}_i \quad \textit{for all } i \textit{ such that } \lambda_i \geq 0,$$
$$0 \leq \widetilde{\lambda}_i - \lambda_i \leq -\|M_1^{-1/2}M_2M_1^{-1/2}\|\widetilde{\lambda}_i \quad \textit{for all } i \textit{ such that } \lambda_i < 0.$$

Proof. Let M, $\widetilde{M}$, and $\widetilde{I}$ be defined such that

$$M = M_1^{-1/2}M_3M_1^{-1/2}, \quad \widetilde{I} = I + M_1^{-1/2}M_2M_1^{-1/2}, \quad \text{and} \quad \widetilde{M} = \widetilde{I}^{-1/2}M\widetilde{I}^{-1/2}.$$

Then M, $\widetilde{I}$, and $\widetilde{M}$ are symmetric with $\widetilde{I}$ positive definite. A similarity transformation gives $\operatorname{eig}(M_1^{-1}M_3) = \operatorname{eig}(M_1^{-1/2}M_3M_1^{-1/2}) = \operatorname{eig}(M)$, which means that M has eigenvalues λ_i, $i = 1:n$. Similarly, we have

$$\begin{aligned}(M_1+M_2)^{-1}M_3 &= M_1^{-1/2}(I + M_1^{-1/2}M_2M_1^{-1/2})^{-1}M_1^{-1/2}M_3 \\ &= M_1^{-1/2}\widetilde{I}^{-1}MM_1^{1/2}. \end{aligned} \tag{A.1}$$

Successive similarity transformations of (A.1) with $M_1^{1/2}$ and $\widetilde{I}^{1/2}$ give

$$\operatorname{eig}\big((M_1+M_2)^{-1}M_3\big) = \operatorname{eig}(\widetilde{I}^{-1}M) = \operatorname{eig}(\widetilde{I}^{-1/2}M\widetilde{I}^{-1/2}) = \operatorname{eig}(\widetilde{M}),$$

which means that $\widetilde{M}$ has eigenvalues $\widetilde{\lambda}_i$, $i = 1:n$.

Now we relate λ_i to $\widetilde{\lambda}_i$. First, consider the case $\lambda_i \geq 0$. Since λ_i is an eigenvalue of M and $\widetilde{\lambda}_i$ is an eigenvalue of $\widetilde{M}$, with $\widetilde{M} = \widetilde{I}^{-1/2}M\widetilde{I}^{-1/2}$, the Courant–Fischer min-max theorem gives

$$\frac{1}{\|\widetilde{I}^{-1}\|}\widetilde{\lambda}_i \leq \lambda_i \leq \|\widetilde{I}\|\widetilde{\lambda}_i; \tag{A.2}$$

see, e.g., Golub and Van Loan [28, pp. 403–404]. Since $\widetilde{I} = I + M_1^{-1/2}M_2M_1^{-1/2}$ with M_2 positive semidefinite, it follows that $\|\widetilde{I}^{-1}\| \leq 1$ and $\|\widetilde{I}\| \leq 1 + \|M_1^{-1/2}M_2M_1^{-1/2}\|$. Hence, (A.2) gives

$$\widetilde{\lambda}_i \leq \lambda_i \leq (1 + \|M_1^{-1/2}M_2M_1^{-1/2}\|)\widetilde{\lambda}_i,$$

which is equivalent to the desired result when $\lambda_i \geq 0$,

$$0 \leq \lambda_i - \widetilde{\lambda}_i \leq \|M_1^{-1/2}M_2M_1^{-1/2}\|\widetilde{\lambda}_i.$$

For the case $\lambda_i < 0$, we apply the analysis above to the matrices $-\widetilde{M}$ and $-M$. Then, since $-\lambda_i$ is a positive eigenvalue of $-M$ and $-\widetilde{\lambda}_i$ is an eigenvalue of $-\widetilde{M}$, we conclude that

$$0 \leq -\lambda_i + \widetilde{\lambda}_i \leq -\|M_1^{-1/2}M_2M_1^{-1/2}\|\widetilde{\lambda}_i,$$

as required. ∎

Acknowledgments. The authors would like to thank Michael Gertz for many stimulating discussions on the theoretical and practical aspects of interior methods. The authors are also grateful to the referees for many constructive comments that significantly improved the presentation.

DUALITY AND THE COMPUTATION OF APPROXIMATE INVARIANT DENSITIES FOR NONSINGULAR TRANSFORMATIONS*

CHRISTOPHER J. BOSE† AND RUA MURRAY‡

Abstract. We investigate a class of optimization problems which arise in the approximation of invariant densities for a nonsingular, measurable transformation T acting on a finite measure space. The problems under consideration have convex integral-type objectives and finite moment constraints and include, for example, the maximum entropy and quadratic programming approaches previously studied in the literature. This article is a natural sequel to those investigations and to the paper [C. Bose and R. Murray, *Discrete Contin. Dyn. Syst.*, 14 (2006), pp. 597–615], where a general class of convergent moment approximations were defined such that the limiting optimal solution is an invariant density for T. This article mainly concerns the solution of a single finite moment problem arising from this general approximation scheme. Both theoretical aspects and computational issues are treated. Although the problem fits easily into the standard theory of duality in convex optimization, its dynamical origins lead to technical obstructions in the derivation of optimality conditions. In particular, the dual functional for our problem is neither strictly convex nor coercive, relating in part to the fact that the moment generating functions for the approximation scheme need not be pseudo-Haar. The method of the paper circumvents these obstructions and yields an unexpected benefit: each finite moment approximation leads to rigorous bounds on the support of all invariant densities for T.

Key words. invariant measure, Frobenius–Perron operator, entropy-like objective, moment constraint, strong duality

1. Introduction.

Let $X = (X; \mathcal{B}, \mu)$ be a Borel measure space. When $T : X \to X$ is measurable and nonsingular with respect to μ, (T, X) is a dynamical system, and we are motivated by the question: *Can one find a T-invariant probability measure with a density function $f \in L^p(X; \mu)$ (usually $p = 1$)?* A measure ν is T-invariant, or an *invariant measure,* if $\nu = \nu \circ T^{-1}$. Invariant measures determine equilibrium statistics of the dynamical system (T, X) (via Birkhoff's ergodic theorem) and those with densities do so for a μ-nontrivial set of orbits. T-invariant measures with densities are *absolutely continuous invariant measures* (ACIMs). Usually, they cannot be found in closed form, and it is highly desirable to develop computational strategies for approximating them. In [5] we studied a class of convex optimization problems on classical Banach spaces whose solutions robustly approximate T-invariant densities: the solutions $\{f_n\}$ to appropriately chosen sequences of optimization problems (P_n) converge (in L^p) to a T-invariant density. In the current paper we investigate some of the technical issues that arise in solving such (P_n) as well as provide complete and explicit solutions for some special cases.

The optimization problems have the general form

$$(P_n) \qquad \begin{aligned} &\text{Minimize } \Phi(f) = \int_X \phi(f(x))\, d\mu(x) \\ &\text{subject to } f \in L^p(X;\mu) \text{ and } Mf = \mathbf{b} \in \mathbb{R}^{N+1} \end{aligned}$$

(hereafter we denote $L^p(X;\mu) = L^p$). The constraint $M : L^p \to \mathbb{R}^{N+1}$ is of moment type, i.e., is defined with respect to a given finite collection[1] $g_0, g_1, \dots g_N$ of *moment test functions* in $L^q(X)$ and

$$(Mf)_i = \int f\, g_i\, d\mu, \quad i = 0, 1, \dots N.$$

For each n, the vector $\mathbf{b}$ is fixed and q is the conjugate index: $\frac{1}{p} + \frac{1}{q} = 1$ (when $p = 1$, $q = \infty$). This setup generalizes a study of Ding [6].

Our aim is to develop numerical algorithms for invariant density approximations which work in practice: the methods must produce a convergent sequence of approximately invariant densities, and each iteration must involve the computation of a well-defined function, which can be performed on a computer. Our optimization based program requires the following:

1. a suitable choice of *generating functions* (in L^q) such that any limit as $n \to \infty$ of solutions to (P_n) is an invariant density of the dynamical system (T, X); the dynamics of T are thus "encoded into M";
2. a choice of Φ which ensures norm convergence of the solutions of (P_n) as $n \to \infty$;
3. any refinements needed to ensure that the solution of (P_n) can be reduced to the solution of a finite number of algebraic equations; and
4. application of the method to specific examples to produce a convergent sequence of *approximately invariant densities*.

All of these steps lead to nontrivial considerations. Most of 1 is addressed in [5], where we refer the interested reader. The main requirement is that the moment test functions are derived from a sequence whose span is weak*-dense in L^q; the necessary details are given in section 2. The requirements of 2 can be addressed with standard results from the literature [1, 3, 12, 11], and some details are collected in section 2. Several example formulations are also presented in section 2.

The main effort in this paper is directed toward 3: establishing conditions which allow the *primal* optimization problems (P_n) to be solved on a computer. Since each (P_n) is convex, it is natural to write down the Lagrangian and pass to a *dual* (or conjugate) optimization problem, obtaining a concave, finite-dimensional, and unconstrained problem (D_n). While (D_n) is derived easily using standard methods, for a large (and reasonable) choice of moment formulations of the invariant measure problem, the dual objective function is noncoercive.[2] This leads to difficulty in the derivation of necessary and sufficient optimality conditions, and possibly to failure of dual attainment (with consequent impediments in the practical solution of the optimization problems). We have identified two mechanisms leading to noncoercivity of (D_n): (i) the moment test functions defining the constraint operators M may not be *pseudo-Haar*[3] leading to unbounded contours (in fact hyperplanes) in the

[1] Note that N may not equal n in some applications.
[2] That is, it has unbounded (upper) level sets; see [2].
[3] That is, they may not be linearly independent μ-almost everywhere.

objective of (D_n); and (ii) regions of X which are *transient* under the dynamics of T can prevent the dual problem (D_n) from attaining its maximum at all. Our main result (Theorem 3.3) is a condition which ensures dual attainment, leading to necessary and sufficient optimality conditions for the solution (Theorem 3.7). In the remainder of section 3 we develop a *domain restriction* which guarantees that the conditions in the theorems are met. Despite the ad hoc appearance of the restriction, it is intimately connected with the dynamics of T, and its imposition does not alter the solution of the underlying invariant measure problem. Moreover, the restriction yields useful dynamical information (see Lemma 3.8 (2)) which is not normally revealed by other methods for invariant density approximation (for example, Ulam's method [15, 9, 7, 10, 5]).

In section 4 we present several examples, illustrating how noncoercivity of the dual problems arises and how it is dealt with. In particular, we show how to accomplish the domain restriction for an "Entropy method" with simple moment test functions.

2. Optimization formulation of the invariant measure problem. The T-invariance condition for densities can be encoded into a sequence of constraint operators M for problems (P_n), and the optimization of Φ provides a convenient method of selecting a convergent sequence of approximately invariant measures. We now give a brief discussion of the dynamical origins of (P_n); further detail and discussion about connections between this and other methods for invariant measure approximation may be found in [5].

2.1. Encoding dynamics as moment constraints. Let (T, X) be a dynamical system. A σ-finite Borel measure ν is *absolutely continuous* if it has the form $d\nu = f d\mu$ for some measurable function[4] f. We write $\nu \ll \mu$ for absolute continuity and $f = \frac{d\nu}{d\mu}$. We also assume that T is *nonsingular*: $\mu \circ T^{-1} \ll \mu$, from which one can quickly deduce that $\nu \circ T^{-1} \ll \mu$ whenever $\nu \ll \mu$. As noted above, it is particularly interesting to find absolutely continuous probability measures which are invariant under T. For such a ν, $f = \frac{d\nu}{d\mu}$ is called an *invariant density*.

Invariant densities can be investigated via a transfer operator on L^p (usually, $p = 1$). If $d\nu = f d\mu$ then $\nu \circ T^{-1} \ll \mu$ so there is a function $\hat{f}$ satisfying $d(\nu \circ T^{-1}) = \hat{f} d\mu$. Thus, T induces an action P on L^1 by $Pf \stackrel{\text{def}}{=} \hat{f} = \frac{d(\nu \circ T^{-1})}{d\mu}$. The operator P is linear and positive (in the sense that $f \geq 0$ implies $Pf \geq 0$) and preserves integrals. P is called the *Frobenius–Perron* operator associated to T. Invariant densities $0 \leq f \in L^1$ are fixed points of P. An alternative[5] characterization of P is

$$\int Pf\, h\, d\mu = \int f\, h \circ T\, d\mu \quad \text{for all } f \in L^1,\ h \in L^\infty, \tag{2.1}$$

from which

$$Pf = f \text{ if and only if } \int f\,(h \circ T - h)\, d\mu = 0 \text{ for all } h \in L^\infty. \tag{2.2}$$

In view of (2.2), it is natural to express the invariant density condition via a sequence of moment approximations. Suppose $\mathcal{H} = \{h_1, h_2, \ldots h_N\} \subseteq L^\infty$ is a finite collection

[4]Normally we require $f \geq 0$, although signed absolutely continuous measures also make sense in this context. The usual definition of absolute continuity is $\mu(B) = 0 \Rightarrow \nu(B) = 0$; the equivalence of the two is part of the Lebesgue–Radon–Nikodym theorem.

[5]If B is a measurable set, then $\int Pf\, \mathbf{1}_B\, d\mu = \nu(T^{-1}B) = \int f\, \mathbf{1}_B \circ T\, d\mu$. For any simple h, linearity of the integral gives $\int Pf\, h\, d\mu = \int f\, h \circ T\, d\mu$, and the general case follows since simple functions are dense in L^∞.

of functions. We say that f is *approximately invariant up to* $\mathcal{H}$ if

$$\int f(h_i \circ T - h_i)\, d\mu = 0, \quad i = 1, 2, \dots N. \tag{2.3}$$

Setting $g_i = h_i \circ T - h_i$ and[6] $g_0 = \mathbf{1}$, we define the set of approximately invariant functions to be the *feasible set* for (P_n):

$$\mathcal{F}_n = \left\{ f \in L^1 \;\middle|\; \int f\, g_0\, d\mu = 1, \int f\, g_i\, d\mu = 0,\ i = 1, 2, \dots N \right\} = \left\{ f \in L^1 \mid Mf = \mathbf{b} \right\},$$

where $M : L^1 \to \mathbb{R}^{N+1}$ is defined by $(Mf)_i = \int f\, g_i\, d\mu$ and $\mathbf{b} = (1, 0, \dots, 0)$. (P_n) will be called *feasible* if $\mathcal{F}_n \neq \emptyset$, and each $f \in \mathcal{F}_n$ is *feasible for* (P_n). We call the collection $\mathcal{G} = \{g_0, g_1, g_2, \dots g_N\}$ the set of *moment test functions* and $\mathcal{H}$ the set of *generating functions* for the approximation. Notice that we do not explicitly include the non-negativity constraint $f \geq 0$ in the definition of the feasible set; we prefer to impose this, when desired, using the objective function Φ. (In [5] we present the case of $\Phi(f) = \frac{1}{2}\|f\|_{L^2}^2$ where allowing f to assume negative values is convenient.) The function g_0 ensures that the approximate invariant densities are normalized.[7] Note that each (P_n) has its own N, feasible set, moment test functions, and generating functions. When there is any possibility of ambiguity, these will be denoted $N(n), \mathcal{F}_n, \mathcal{G}_n$, and $\mathcal{H}_n$ (respectively). The possibility that $N \neq n$ should be emphasized. For example, when the moment generating functions arise from n-steps in a process of binary partition of the underlaying space, $N(n) = 2^n$. (See section 2.3 for this and other examples.)

Finally, we make the standing assumption that $\mu(X) < \infty$. Then, in the definition of $\mathcal{F}_n$, the function space L^1 can be replaced by $L^p,\ 1 < p < \infty$. This is due to the fact that $L^p \subseteq L^1,\ 1 \leq p < \infty$, and $L^\infty \subseteq L^q,\ 1 \leq q \leq \infty$, so all the integrals in $\mathcal{F}_n$ remain well defined. This allows us to consider a range of objectives Φ (such as H, V, and V^+ defined below).

Convergence of approximately invariant densities. The application of the problems (P_n) relies on the constraints being such that $\mathcal{F}_\infty = \bigcap_{n \geq 1} \mathcal{F}_n$ consists precisely of T-invariant densities. This condition is certainly satisfied when there exists an L^p T-invariant density, $\mathcal{H}_\infty = \{h_i\}_{i=1}^\infty$ is a sequence whose span is weak*-dense in L^q, and $\mathcal{H}_n = \{h_1, \dots, h_n\}$. In this situation, the sets $\{\mathcal{F}_n\}$ are *nested* ($\mathcal{F}_n \subseteq \mathcal{F}_m$ whenever $n \geq m$), so

$$\mathcal{F}_\infty = \left\{ f \;\middle|\; \int f\, d\mu = 1, \int (Pf - f)\, h\, d\mu = 0 \text{ for all } h \in \operatorname{span}(\mathcal{H}_\infty) \right\},$$

guaranteeing the condition in (2.2). (See [13] for generalizations of the L^q weak*-density condition.) The nested condition on $\mathcal{F}_n$ and the density condition on $\{\mathcal{H}_n\}$ can be weakened,[8] allowing other reasonable choices of $\{\mathcal{H}_n\}$. The role of the objective functional Φ is to specify a selection of $f_n \in \mathcal{F}_n$ such that $\lim_{n\to\infty} f_n$ exists and is in $\mathcal{F}_\infty$.

2.2. Choice of convex functional. The objective functionals Φ are chosen for mathematical and practical convenience. Let $\mu(X) < \infty$ and $\phi : X \to \mathbb{R} \cup \{\infty\}$ be *proper* [11], lower semicontinuous, and strictly convex. Define

$$\Phi(f) = \int \phi(f(x))\, d\mu(x).$$

[6] $\mathbf{1}_B$ denotes the characteristic function of the measurable subset B and $\mathbf{1} = \mathbf{1}_X$.

[7] This constraint also eliminates the trivial solution $f = 0$ from (P_n).

[8] In [5, section 3] we establish a suitable convergence result under "lattice" and "weak eventual clustering" conditions.

(So ϕ is a normal convex integrand in the sense of Rockafellar [11].) We require Φ to be strictly convex and weakly lower semicontinuous and to have weakly compact lower level sets and the *Kadec* property [3]: if $\Phi(f_n) \to \Phi(f) < \infty$ and $f_n \to f$ weakly as $n \to \infty$, then $\|f - f_n\|_{L^p} \to 0$.

Remarks.

1. The function $\phi(f)$ need not be integrable for every $f \in L^p$; however, we assume $[\phi(f)]^-$ (its negative part) is integrable, and consequently $\Phi(f)$ is unambiguously an element of $(-\infty, \infty]$. For the examples below, this assumption holds.
2. Provided there is an invariant density f_* for T with $f_* \in L^p$, (P_n) will be feasible for every choice of generators $\mathcal{H}$.

Natural choices for Φ. In [5] we studied the following choices for $\phi : \mathbb{R} \to \mathbb{R}$:

$$\phi(t) = \eta(t) \stackrel{\text{def}}{=} \begin{cases} t \log t & \text{for } t > 0, \\ 0 & \text{if } t = 0, \\ +\infty & \text{if } t < 0, \end{cases}$$

after which we adopt the standard notation $\Phi = H$, the (negative) Boltzmann–Shannon entropy on L^1. Notice that $H(f) < \infty$ implies that $f \geq 0$ μ-almost everywhere. If

$$\phi(t) = v(t) \stackrel{\text{def}}{=} \frac{1}{2} t^2,$$

we optimize with respect to an "Energy" functional which we denote by $\Phi = V$, and when

$$\phi(t) = v_+(t) \stackrel{\text{def}}{=} \begin{cases} \frac{1}{2} t^2 & \text{if } t \geq 0, \\ +\infty & \text{if } t < 0, \end{cases}$$

we get a positively constrained Energy functional, denoted $\Phi = V_+$. Of course the appropriate Banach space domains for the energy functionals V and V_+ would be L^2. Properties of these and other "Entropy-like" functionals are investigated in many papers (for example, [3, 2, 12]).

2.3. Three example setups.

Partition generating functions with "Energy" objective. Let $\mathcal{P}$ be a partition of X into measurable subsets $\mathcal{P} = \{B_i\}_{i=1}^N$, and let $\mathcal{H} = \{\mathbf{1}_{B_i}\}_{i=1}^N$ be the set of generating functions (in a slight abuse of terminology, we call this a *partition basis*). The moment test functions are therefore

$$g_i = \mathbf{1}_{B_i} \circ T - \mathbf{1}_{B_i} = \mathbf{1}_{T^{-1}B_i} - \mathbf{1}_{B_i},$$

and the approximately invariant densities can be considered as "invariant up to the discretization imposed by $\mathcal{P}$." Let $\Phi(f) = \frac{1}{2}\|f\|_{L^2}^2$. This example is studied in detail in [5] and leads to a convergent invariant density approximation scheme under the assumption that T admits an invariant density in L^2. The main complication that arises with this method is that $\sum_{i=1}^N g_i = \sum_{i=1}^N (h_i \circ T - h_i) = \mathbf{1}_X \circ T - \mathbf{1}_X = 0$ since $\sum_{i=1}^N h_i = \sum_{i=1}^N \mathbf{1}_{B_i} = \mathbf{1}_{\cup B_i} = \mathbf{1}_X$. Consequently, the M^* (defined below) has nontrivial kernel, leading to noncoercivity of the dual problem (D_n) (see section 3.2). This is dealt with easily, both analytically (section 3.2) and numerically [5,

Remark 7.1]. From a computational viewpoint, the case of a binary partition of the space is natural. Then we would have $N(n) = 2^n$ in the dimension of the moment problem n-steps into the associated approximation scheme.

Partition generating functions with "Entropy" objective. Again one uses a partition basis $\mathcal{H} = \{\mathbf{1}_{B_1}, \mathbf{1}_{B_2}, \dots \mathbf{1}_{B_N}\}$, but now $\Phi(f) = H(f) = \int_X \eta(f)\, d\mu = \int_X f(x) \log f(x)\, d\mu(x)$. For many interesting densities f (for example, the invariant densities for the logistic family of maps on $[0,1]$), $H(f) < \infty$ while $V(f) = \infty$. So, one gains applicability with this choice of Φ, but at cost: the dual optimization problem is potentially less tractable. In fact, the dual problem can suffer from noncoercivity, wherein the optimizer occurs "at infinity." In section 3.4 we elaborate and resolve these difficulties by restricting the domain of integration in (P_n).

Polynomial basis functions with "Entropy" objective. Let $X = [0,1] \subseteq \mathbb{R}$, let μ be Lebesgue measure, and let $\mathcal{H}_n = \{x, x^2, \dots x^n\}$. Here, quite naturally, $N(n) = n$. In Ding [6] this generating set is used, along with the entropy objective H to derive approximately invariant densities under the following dynamical assumptions:

(D1) The moment test functions $g_i(x) = (Tx)^i - x^i$, $i = 1, 2 \dots n$, are linearly independent; and

(D2) T admits a unique invariant density f_*, and further, this density satisfies $f_* > 0$ and $H(f_*) < \infty$.

In [4] we show, using techniques derived later in this article, that Ding's method can be extended to dynamical systems satisfying only the following:

(D3) T admits an invariant density f_* with $H(f_*) < \infty$ such that T is not of finite order with respect to $f_*\, d\mu$. (That is, there is no $n > 0$ so that $T^n = \mathrm{id}$, $f_*\, d\mu$-almost everywhere).

3. Main results.

3.1. The dual problem (D_n). Since ϕ is a *normal convex integrand* in the sense of Rockafellar [11], we have a simple closed form for the dual functional, which we denote by Q,

$$(D_n) \qquad \begin{aligned} &\text{Maximize } Q(\lambda) = \langle \lambda, \mathbf{b} \rangle - \int \phi^*([M^*\lambda](x))\, d\mu(x) \\ &\text{subject to } \lambda \in \mathbb{R}^{N+1}, \end{aligned}$$

where $M^* : \mathbb{R}^{N+1} \to L^q$ is the adjoint map defined by

$$M^*\lambda = \sum_i \lambda_i g_i \in L^q, \tag{3.1}$$

and where ϕ^* denotes the classical Fenchel (convex) conjugate of ϕ. Finally, weak duality holds:

$$\text{for all } \lambda \in \mathbb{R}^{N+1}, \text{ for all } f \in L^p \text{ such that } Mf = \mathbf{b},\ Q(\lambda) \le \Phi(f). \tag{3.2}$$

We refer readers not familiar with this type of argument to [2, 12] and provide a short, self-contained derivation of these facts in the appendix. The function ϕ^* is automatically convex (a fact we will need below), and the main work is in identifying conditions which guarantee that (D_n) attains its maximum at a finite λ (*dual attainment*); this is accomplished by proving that Q is coercive. As often occurs, dual attainment leads to necessary and sufficient conditions for both the dual and primal problems (section 3.3).

3.2. Dual attainment. A critical issue for solution of (P_n) is whether or not the dual problem (D_n) attains its maximum value. We remark at the outset that for many of our examples, the functional Q fails to be coercive. The treatment we give is motivated by [2], although immediate application of the results of that paper is impeded by the fact that our (P_n) do not necessarily admit feasible solutions in the quasirelative interior of L^p (the interesting T-invariant measures may not be supported on all of X). The first problem that can occur is that the operator M^* can have nontrivial kernel; this problem was noted in the partition basis examples above and is elaborated further in section 4.1 below.

LEMMA 3.1. *Suppose that (P_n) is feasible and write*[9] $\mathbb{R}^{N+1} = \mathrm{Ker}(M^*) \oplus \mathrm{Range}(M)$, *the canonical orthogonal direct sum. Then the following hold:*

1. $\mathbf{b} = (1, 0, 0, \ldots, 0) \in \mathrm{Range}(M)$.
2. $Q(\cdot)$ *is upper semicontinuous and constant on hyperplanes parallel to the subspace* $\mathrm{Ker}(M^*)$.
3. *If* $\mathrm{Ker}(M^*) \neq \{0\}$, *then Q is not coercive; however, in any event*
$$\mathrm{Max}_{\lambda \in \mathbb{R}^{N+1}} Q(\lambda) = \mathrm{Max}_{\lambda \in \mathrm{Range}(M)} Q(\lambda).$$
Moreover, (D_n) will attain its maximal value if and only if $Q|_{\mathrm{Range}(M)}$ attains its (relative) maximal value.
4. *Write* $\mathrm{Range}(M) = span\{\mathbf{b}\} \oplus \hat{\Lambda}$. *If f is feasible for (P_n) and $\hat{\lambda} \in \hat{\Lambda}$, then*
$$\int M^* \hat{\lambda}\, f \, d\mu = \langle \hat{\lambda}, Mf \rangle = \langle \hat{\lambda}, \mathbf{b} \rangle = 0$$
(where $\langle \cdot, \cdot \rangle$ is the usual inner product on $\mathbb{R}^{N+1}$).
5. *If $\lambda = \lambda_0 + \alpha \mathbf{b} + \hat{\lambda}$, where $\lambda_0 \in \mathrm{Ker}(M^*)$ and $\hat{\lambda} \in \hat{\Lambda}$, then*
$$Q(\lambda) = \alpha - \int \phi^*(\alpha\, \mathbf{1} + M^* \hat{\lambda})\, d\mu.$$

Proof. 1. Since (P_n) is feasible, there is an $f \in L^p$ for which $Mf = \mathbf{b}$. Thus $\mathbf{b} \in \mathrm{Range}(M)$. Statements 2–3 follow immediately from 1 and the formula for Q in (D_n). Statements 4–5 are direct computations. □

Given this lemma, dual attainment will follow once we have established that the upper level sets of $Q|_{\mathrm{Range}(M)}$ are bounded. This is done by exploiting the superlinear growth of the term $\int \phi^*(M^*(\cdot))\, d\mu$ (restricted to the linear subspace $\mathrm{Range}(M)$) to produce a bound on the decay of $Q(\lambda)$ as $\lambda \to \infty$.

LEMMA 3.2. *With notation as in Lemma* 3.1, *and with $\|\cdot\|$ denoting the Euclidean norm in $\mathbb{R}^{N+1}$, assume also the following:*

1. $\phi^* \geq 0$ *and* $\phi^*|_{[0,\infty)}$ *is nondecreasing.*
2. *For every $\hat{\lambda} \in \hat{\Lambda}$ with $\hat{\lambda} \neq 0$ one has $[M^* \hat{\lambda}]^+ \neq 0$.*

Then there exist $\gamma_0, \delta_0 > 0$ such that if $\lambda = \lambda_0 + \alpha \mathbf{b} + \hat{\lambda}$ and $\alpha + \|\hat{\lambda}\|\, \gamma_0 \geq 0$, then
$$Q(\lambda) \leq \alpha - \delta_0\, \phi^*(\alpha + \|\hat{\lambda}\|\, \gamma_0).$$

Proof. First, note that $\int [M^*(\cdot)]^+\, d\mu$ is continuous on $\mathbb{R}^{N+1}$ and, by hypothesis 2, is positive for every nonzero $\hat{\lambda} \in \hat{\Lambda}$. Since the unit sphere in $\hat{\Lambda}$ is compact in $\mathbb{R}^{N+1}$, there is a $\gamma > 0$ such that
$$\|\hat{\lambda}\| = 1 \;\Rightarrow\; \int_X [M^* \hat{\lambda}]^+\, d\mu \geq \gamma.$$

[9] Here, $\mathrm{Ker}(M^*) = \{\lambda \in \mathbb{R}^{N+1} \mid M^* \lambda = 0 \ \mu\text{-almost everywhere}\}$.

Let $0 < \gamma_0 < \frac{\gamma}{\mu(X)}$ and put $A_\lambda = \{x : [M^*(\frac{\hat{\lambda}}{\|\hat{\lambda}\|})](x) > \gamma_0\}$. Then

$$\gamma \le \int_X \left[M^* \tfrac{\hat{\lambda}}{\|\hat{\lambda}\|}\right]^+ d\mu = \int_{A_\lambda} \left[M^* \tfrac{\hat{\lambda}}{\|\hat{\lambda}\|}\right]^+ d\mu + \int_{X-A_\lambda} \left[M^* \tfrac{\hat{\lambda}}{\|\hat{\lambda}\|}\right]^+ d\mu$$
$$\le \|M^*\| \, [\mu(A_\lambda)]^{1/p} + [\mu(X)] \, \gamma_0,$$

where $\|M^*\|$ denotes the operator norm of $M^* : \mathbb{R}^{N+1} \to L^q$. We therefore conclude that

$$\mu(A_\lambda) \ge \left(\frac{\gamma - \mu(X)\,\gamma_0}{\|M^*\|}\right)^p \quad \stackrel{\text{def}}{=} \quad \delta_0. \tag{3.3}$$

Next, restricted to A_λ, $M^*(\lambda) = \alpha\,\mathbf{1} + M^*(\hat{\lambda}) \ge \alpha + \|\hat{\lambda}\|\,\gamma_0 \ge 0$. Thus

$$\frac{1}{\mu(A_\lambda)} \int_{A_\lambda} M^*\lambda \, d\mu \ge \alpha + \|\hat{\lambda}\|\,\gamma_0. \tag{3.4}$$

Now, since ϕ^* is convex, we have by Jensen's inequality

$$\mu(A_\lambda)\,\phi^*\left(\frac{1}{\mu(A_\lambda)} \int_{A_\lambda} M^*\lambda \, d\mu\right) \le \int_{A_\lambda} \phi^*(M^*\lambda)\, d\mu.$$

Since ϕ^* is nondecreasing, (3.3) and (3.4) lower bound the left-hand side by

$$\delta_0\,\phi^*(\alpha + \|\hat{\lambda}\|\,\gamma_0),$$

and since $\phi^* \ge 0$ we can upper bound the right-hand side to obtain

$$\delta_0\,\phi^*(\alpha + \|\hat{\lambda}\|\,\gamma_0) \le \int_X \phi^*(M^*\lambda)\, d\mu.$$

The lemma now follows from Lemma 3.1 (5). ∎

THEOREM 3.3. *With notation as in Lemma* 3.1, *assume that*

1. $\phi^* \ge 0$ *and* $\phi^*|_{[0,\infty)}$ *is nondecreasing;*
2. $\lim_{s\to+\infty} \frac{\phi^*(s)}{s} = \infty$*; and*
3. *for every* $\hat{\lambda} \in \hat{\Lambda}$ *with* $\hat{\lambda} \ne 0$ *one has* $[M^*\hat{\lambda}]^+ \ne 0$.

Then

$$\lim_{\|\lambda\|\to\infty,\ \lambda\in\mathrm{Range}(M)} Q(\lambda) = -\infty,$$

and the dual optimization problem (D_n) *attains its supremum.*

Proof. It suffices to establish that for any sequence $\{\lambda_n\} \subset \mathrm{Range}(M)$ with $\|\lambda_n\| \to \infty$, $Q(\lambda_n)$ is unbounded below. First, note that $\lambda_n = \alpha_n\,\mathbf{b} + \hat{\lambda}_n$. If any subsequence $\{\lambda_{n_i}\}$ has $\alpha_{n_i} \to -\infty$, then $Q(\lambda_{n_i}) \le \alpha_{n_i} \to -\infty$ by Lemma 3.1 (5) (recall that $\phi^* \ge 0$). Thus, we need only consider sequences $\{\lambda_n\}$ for which $\{\alpha_n\}$ is bounded below. If $\{\alpha_n\}$ is also bounded above, then since $\|\lambda_n\| \to \infty$, we must have $\lim_{n\to\infty} \|\hat{\lambda}_n\| \to \infty$ so that $\alpha_n + \|\hat{\lambda}_n\|\,\gamma_0 \to \infty$. In particular, $\alpha_n + \|\hat{\lambda}_n\|\,\gamma_0 \ge 0$ for all large enough n, so by Lemma 3.2,

$$Q(\lambda_n) \le \alpha_n - \delta_0\,\phi^*(\alpha_n + \|\hat{\lambda}_n\|\,\gamma_0) \to -\infty$$

(since $\lim_{s\to\infty}\phi^*(s)=\infty$). The only other possibility is that $\{\alpha_n\}$ is unbounded above, in which case there is a subsequence $\{\lambda_{n_j}\}$ of $\{\lambda_n\}$ for which $\lim_{j\to\infty}\alpha_{n_j}=\infty$. Then, in view of hypothesis 2, there is an N such that

$$\alpha_{n_j}\geq 0 \quad\text{and}\quad \frac{\phi^*(\alpha_{n_j})}{\alpha_{n_j}}\geq\frac{2}{\delta_0} \quad\text{for } j\geq N.$$

Then use Lemma 3.2 to estimate

$$Q(\lambda_{n_j})\leq\alpha_{n_j}-\delta_0\,\phi_*(\alpha_{n_j})\leq-\alpha_{n_j}\to-\infty \quad\text{as}\quad j\to\infty. \qquad \square$$

Note. The limit in condition 2 could be replaced by a lim sup since ϕ^* is convex. Theorem 3.3 is analogous to [2, Theorem 4.8], but condition 3 is unnecessary there due to the assumption of a strictly positive feasible point for (P_n).

Example 3.4. Suppose $X=[0,1]$, μ is Lebesgue measure, and

$$T(x)=\begin{cases}2x & \text{if } 0\leq x<1/2,\\ 2(x-\frac{1}{2})+\frac{1}{2} & \text{if } \frac{1}{2}\leq x<\frac{3}{4},\\ 2(x-\frac{1}{2}) & \text{if } \frac{3}{4}\leq x\leq 1.\end{cases}$$

Then $f_*=2\mathbf{1}_{[\frac{1}{2},1]}$ is the unique invariant probability density for T. Let $\mathcal{P}=\{[0,\frac{1}{2}),[\frac{1}{2},1]\}$. The functions g_i are

$$g_0=\mathbf{1},\qquad g_1=-\mathbf{1}_{[\frac{1}{4},\frac{1}{2})},\qquad g_2=\mathbf{1}_{[\frac{1}{4},\frac{1}{2})},$$

so $\mathrm{Ker}(M^*)=\mathrm{span}\{(0,1,1)^T\}$, $\mathrm{Range}(M)=\mathrm{span}\{(1,0,0)^T,(0,1,-1)^T\}$, and $\hat{\Lambda}=\mathrm{span}\{(0,1,-1)^T\}$. But evidently, $M^*(0,1,-1)^T=-2\mathbf{1}_{[\frac{1}{4},\frac{1}{2})}\leq 0$, so that hypothesis 3 of Theorem 3.3 fails. In fact, using the entropy functional H as the objective, one easily computes the dual functional Q on the two-dimensional subspace $\mathrm{Range}(M)$ (where vectors take the form $(\alpha,\beta,-\beta)^T$) as

$$Q((\alpha,\beta,-\beta)^T)=\alpha-e^{(\alpha-1)}\left\{\frac{1}{4}e^{-2\beta}+\frac{3}{4}\right\}.$$

So Q is noncoercive, $\sup_{\mathrm{Range}(M)}Q=\log(4/3)$, but it is not reached at any point of $\mathrm{Range}(M)$, so dual attainment fails.

Example 3.5. We can immediately apply Theorem 3.3 to establish coercivity of Q for Ding's polynomial basis maximum entropy method [6]. The condition (D1) (above) implies that $\mathrm{Ker}(M^*)=\{0\}$, so the decomposition in Lemma 3.1 is $\mathbb{R}^{n+1}=\mathrm{Range}(M)$ and the set $\hat{\Lambda}=\{\lambda\in\mathbb{R}^{n+1}\mid\lambda_0=0\}=(\mathrm{span}\{\mathbf{b}\})^\perp$. Now suppose $\lambda\neq 0$ and $\lambda^T\mathbf{b}=0$ so that $M^*(\lambda)\neq 0$. If $[M^*\lambda]^+=0$ then $M^*\lambda=[M^*\lambda]^-$ (almost everywhere), so whenever $f>0$ is feasible for (P_n),

$$\langle\lambda,\mathbf{b}\rangle=\langle\lambda,Mf\rangle=\int M^*\lambda f\,d\mu<0.$$

Since (D2) guarantees the existence of a feasible, almost everywhere positive invariant density f_*, this calculation contradicts $\lambda^T\mathbf{b}=0$. We conclude that $[M^*\lambda]^+\neq 0$ and Theorem 3.3 yields dual attainment. Even without condition (D1), the restriction of (D_n) to $\mathrm{Range}(M)$ will yield dual attainment by the same argument.

3.3. Necessary and sufficient optimality conditions. Once dual attainment is established, the dual (D_n) and primal (P_n) problems are linked by a standard derivation of optimality conditions [2, 11]. We begin by quoting a calculus lemma.

LEMMA 3.6. *Assume $\mu(X) < \infty$ and that $\varphi : \mathbb{R} \to \mathbb{R}$ with $\varphi \in C^1$. Suppose $A : \mathbb{R}^{N+1} \to L^\infty(X)$ is linear and set, for every $\mathbf{z} \in \mathbb{R}^{N+1}$,*

$$q(\mathbf{z}) = \int_X \varphi((A\mathbf{z})(x))\, d\mu(x).$$

Then

1. *for every $\mathbf{z}_0 \in \mathbb{R}^{N+1}$, $\varphi'(A\mathbf{z}_0(\cdot)) \in L^1$;*
2. *for every $\mathbf{z}_0 \in \mathbb{R}^{N+1}$, $(\nabla_{\mathbf{z}} A)\mathbf{z}_0(\cdot) \in [L^\infty]^{N+1}$; and*
3. *q is Gateaux differentiable at every $\mathbf{z}_0 \in \mathbb{R}^{N+1}$ and in particular*

$$(\nabla_{\mathbf{z}} q(\mathbf{z}_0))_i = \int \varphi'(A\mathbf{z}_0(x)) Ae_i(x)\, d\mu(x) \in \mathbb{R}.$$

THEOREM 3.7 (necessary and sufficient optimality conditions). *Assume that the primal problem (P_n) is feasible and $\varphi = \phi^*$ is smooth and satisfies the hypothesis of Lemma 3.6. If $\lambda(n)$ yields a global maximum of Q in the dual formulation (D_n), then*

1. *$\lambda(n)$ satisfies*

$$\int [\phi^*]'([M^*\lambda(n)](x)) g_i(x)\, d\mu(x) = \mathbf{b}_i, \quad i = 0, 1, 2 \ldots n; \tag{3.5}$$

2. *$f_n = [\phi^*]'(M^*\lambda(n)) \in L^1$ is feasible for (P_n); and*
3. *$Q(\lambda(n)) = \int \phi(f_n(x))\, d\mu(x)$, and hence, from the weak duality condition (3.2), we conclude that f_n is a minimizer in the primal problem (P_n).*

In particular, (3.5) is also sufficient for an optimal value of λ in (D_n) and the function f_n defined in part 2 is optimal in the primal problem.

Proof. Using Lemma 3.6 we establish necessary conditions for $\lambda(n)$ to maximize Q:

$$0 = -\mathbf{b}_i + \int [\phi^*]'([M^*\lambda(n)](x)) g_i(x)\, d\mu(x), \qquad i = 0, 1, 2 \ldots N,$$

so f_n defined in part 2 satisfies $f_n \in L^1$ and the constraint $Mf_n = \mathbf{b}$. Now, since ϕ^* is convex, proper, and smooth, one easily derives from classical facts (see the appendix) that for all $s \in \mathbb{R}$

$$\phi^*(s) + \phi^{**}([\phi^*]'(s)) = s[\phi^*]'(s),$$

which, combined with $\phi^{**} = \phi$, yields

$$\phi([\phi^*]'(s)) + \phi^*(s) = s[\phi^*]'(s).$$

If we now substitute $s = [M^*\lambda(n)](x)$ and rearrange to obtain

$$\phi(f_n(x)) = [M^*\lambda(n)](x) f_n(x) - \phi^*([M^*\lambda(n)](x)),$$

we see that $\phi(f_n(\cdot))$ is an integrable function since both functions on the right are integrable. Conclude that f_n is feasible for (P_n). Finally, integrating this last expression over $x \in X$ yields

$$\Phi(f_n) = Q(\lambda(n)),$$

closing the duality gap and proving both that f_n is a minimizer of Φ in (P_n) and that $\lambda(n)$ is a maximizer of Q in (D_n) if and only if (3.5) holds. ∎

3.4. Domain restriction with a partition basis. In Example 3.4, the existence of a nonpositive, nonzero $M^*\lambda$ prevented Q from being coercive and destroyed any prospect of dual attainment. However, $\text{supp}(M^*\lambda)$ was contained in a part of X that was transient under the action of T. In general, if f is feasible[10] for (P_n) and $M^*\lambda \leq 0$, then $\text{supp}(M^*\lambda) \cap \text{supp}(f) = \emptyset$, so any noncoercivity of Q because of failure of condition 3 in Theorem 3.3 can be attributed to the behavior of M^* on an unimportant part of X. Motivated by this (and justified in Lemma 3.8 and section 4.2 below), we employ a (P_n)-specific *domain restriction*.

Consider the (sub)cone of $\mathbb{R}^{N+1}$ defined by $\mathcal{C} = \{\hat{\lambda} \in \hat{\Lambda} \mid M^*\hat{\lambda} \leq 0\}$ and set $X_0(n) = X \setminus \bigcup_{\hat{\lambda}\in\mathcal{C}}\{x \in X \mid [M^*\hat{\lambda}](x) < 0\}$.

LEMMA 3.8. *Let $\mathcal{P}$ be a finite measurable partition of X and let the constraints in (P_n) be with respect to the corresponding partition basis. Then the following hold:*

1. *$X_0(n)$ belongs to the σ-algebra generated by $\mathcal{P} \vee T^{-1}\mathcal{P}$ (and so is measurable).*
2. *Assume that ϕ satisfies the hypothesis of Theorem 3.3 and that $\Phi(f) < \infty \implies f \geq 0$ almost everywhere. Then $\Phi(f) < \infty$, and f feasible for (P_n) implies $\text{supp}(f) \subseteq X_0(n)$.*
3. *Under the same condition as in part 2, $X_0(n)$ is not a null-set of X and the value of the problem*

$$(P_n') \qquad \begin{aligned} &\textit{Minimize} \quad \Phi_0(f) = \int_{X_0(n)} \phi(f(x))\, d\mu(x) \\ &\textit{subject to} \quad f \in L^p(X_0(n)) \quad \textit{and} \quad Mf = \mathbf{b} \in \mathbb{R}^{N+1} \end{aligned}$$

is identical to the value of (P_n). Dual attainment holds in the case of the problem (P_n'),

$$Q_0(\lambda) \stackrel{def}{=} \text{Max}_{\lambda\in\mathbb{R}^{N+1}}\{\langle\lambda, \mathbf{b}\rangle - \textstyle\int_{X_0(n)} \phi^*(M^*(\lambda))\, d\mu\}.$$

Proof. 1. Observe that for each λ, $\{x | M^*\lambda(x) < 0\}$ is an element of the *finite* σ-algebra generated by $\mathcal{P} \vee T^{-1}\mathcal{P}$ (cf. Lemma 4.1 below). It follows that $X_0(n)$ is measurable, even though the union is over an uncountable parameter set. 2. When $\Phi(f) < \infty$ and f is feasible for (P_n), $\int M^*\hat{\lambda} f\, d\mu = 0$ for all $\hat{\lambda}$ by Lemma 3.1 (4). This implies that $\text{supp}(f) \subseteq X_0(n)$. 3. Since $f_0 \in L^p(X_0(n))$ is feasible for (P_n') if and only if $f_0\mathbf{1}_{X_0(n)} \in L^p(X)$ is feasible for (P_n), either both problems are infeasible, or there is a feasible $f \neq 0$. In this case, $\int_{X_0(n)} f\, d\mu = 1$, so $X_0(n) \neq \emptyset$. Furthermore, $\Phi_0(f) = \Phi(f)$ for all feasible f. Dual attainment holds since restricted to $X_0(n)$, hypothesis 3 of Theorem 3.3 holds. □

In effect, we have moved troublesome vectors λ where $M^*\lambda \leq 0$ into $\text{Ker}(M^*)$ over the restricted measure space $X_0(n)$. Of course, the domain for (P_n) is therefore changed, as is Φ, but our argument shows that the values of the two problems are identical, and the restricted problem has dual attainment.

Example 3.4 *revisited.* Recall that dual attainment failed due to the noncoercivity of Q. However, observe that if $0 \neq \hat{\lambda} \in \hat{\Lambda}$ and $M^*\hat{\lambda} \leq 0$, then we have $\text{supp}(M^*\hat{\lambda}) = [\frac{1}{4}, \frac{1}{2})$ (note that $M^*\hat{\lambda} \neq 0$ since $\hat{\lambda} \in \text{Range}(M) = (\text{Ker}(M^*))^\perp$). By Lemma 3.1 (4) $\int M^*\hat{\lambda} f\, d\mu = 0$ and $f \geq 0$ (provided f is feasible). Thus, $\text{supp}(f) \subseteq ([0,1] \setminus [1/4, 1/2))$, so we let $X_0 = ([0,1] \setminus [1/4, 1/2))$ and solve

$$\text{Minimize} \quad H_0(f) = \int_{X_0} \eta(f(x))\, d\mu(x) \quad \text{s.t.} \quad f \in L^1(X_0) \text{ and } Mf = \mathbf{b}.$$

[10] For example, any T-invariant density.

4. Applications. We now discuss some of the computational details when the method is applied to the specific case of a partition basis. For the rest of the paper, we assume for simplicity that $N(n) = n$ and let $\mathcal{P} = \{B_1, \ldots, B_n\}$ be the measurable partition defining the basis.

4.1. The "Energy" method with kernel. Recall that $\phi(t) = \frac{1}{2}t^2$. Then, since

$$Q(\lambda) = \langle \lambda, \mathbf{b} \rangle - \frac{1}{2} \int (M^*\lambda(x))^2 \, d\mu(x)$$

and the conjugate in the second term is weakly (in fact, norm) lower semicontinuous, Q is norm upper semicontinuous, so it attains its supremum over compact subsets. Let

$$\mathbb{R}^{n+1} = \mathbb{R}^{N+1} = \mathrm{Ker}(M^*) \oplus \mathrm{Range}(M),$$

the canonical decomposition relative to the operator M. This decomposition is nontrivial since $\sum_{i=1}^n g_i = \sum_{i=1}^n \mathbf{1}_{T^{-1}B_i} - \mathbf{1}_{B_i} = \mathbf{1} - \mathbf{1} = 0$, so $(0, 1, 1, \ldots 1)^T \in \mathrm{Ker}(M^*)$ (cf. Lemma 3.1.) Clearly, if Q restricted to the subspace $\mathrm{Range}(M)$ attains its (relative) maximum at λ^*, then Q will also be maximized at λ^*. To see why dual attainment holds in this case, note that

$$\begin{aligned} \mathrm{Max}_\lambda Q(\lambda) = \mathrm{Max}_{\lambda \in \mathrm{Range}(M)} Q(\lambda) &= \mathrm{Max}_{\lambda \in \mathrm{Range}(M)} \left\{ \langle \lambda, \mathbf{b} \rangle - \frac{1}{2} \textstyle\int (M^*\lambda)^2 \, d\mu(x) \right\} \\ &= \mathrm{Max}_{\lambda \in \mathrm{Range}(M)} \left\{ \langle \lambda, \mathbf{b} \rangle - \frac{1}{2} \langle \lambda, MM^*\lambda \rangle \right\}. \end{aligned}$$

The linear operator MM^* maps $\mathrm{Range}(M)$ into $\mathrm{Range}(M)$ and for $\lambda \neq 0$ in $\mathrm{Range}(M)$ we have $\langle \lambda, MM^*\lambda \rangle > 0$ so the operator $MM^*|_{\mathrm{Range}(M)}$ is positive definite. It follows that the restricted functional $Q|_{\mathrm{Range}(M)}$ is a negative definite quadratic form, is therefore coercive, and attains its maximum value.

There is no need to identify the restricted measure space $X_0(n)$ from this point of view, and applying Theorem 3.7 yields the necessary equation for the optimal value of $\lambda(n)$,

$$\sum_j [\lambda(n)]_j \textstyle\int g_i(x) \, g_j(x) \, d\mu(x) = b_i, \quad i = 0, 1, \ldots n, \tag{4.1}$$

and the formula for the optimal solution f_n,

$$f_n = M^*\lambda(n) = \sum_j [\lambda(n)]_j g_j. \tag{4.2}$$

Since $[\phi^*]'(s) = s$, the equation to be solved is linear and consistent in $n + 1$ variables:

$$A[\lambda(n)] = \mathbf{b},$$

where $A = \{a_{ij}\}$ is the $(n+1)\times(n+1)$ matrix of correlations: $a_{ij} = \int g_i(x) g_j(x) \, d\mu(x)$. Notice that $A = MM^*$ with $\mathrm{Ker}(A) = \mathrm{Ker}(MM^*) = \mathrm{Ker}(M^*)$, along which we know Q is constant, so *any* solution of (4.1) will lead to optimal values for both primal and dual (see also Theorem 3.7). In section 4.3 we present results of some numerical experiments concerning this problem with respect to the basis $\phi_i = \mathbf{1}_{B_i}$ generated by a partition.

Further details (including some issues about numerical implementation) are in [5].

4.2. The "Entropy" method and domain restriction. In the case of a partition basis, the X_0 of Lemma 3.8 may be needed to ensure dual attainment. We show below how to identify $X_0(n)$ by a finite computation. Once this is done, Theorem 3.7 can be invoked to derive the optimality equations in concrete form:

$$\int_{X_0(n)} \exp\{[M^*\lambda(n)](x) - 1\} g_i(x)\, d\mu(x) = \mathbf{b}_i, \quad i = 0, 1, \dots n, \tag{4.3}$$

from which the primal optimal points will be computed according to the formula in Theorem 3.7(2). That is, we recover the solution to (P_n) by solving (P_n') with $\lambda(n)$ satisfying (4.3). The solution to (P_n) is then $f_0(x) = \mathbf{1}_{X_0(n)} \exp\{[M^*\lambda(n)](x) - 1\}$.

Identification of restricted domain. We now let $\mathcal{P} = \{B_1, \dots, B_n\}$ be a fixed partition of X. Thus, $n = N$ is fixed, and we suppress, where possible, explicit notational dependence on n. For example, from now on we will write X_0 instead of $X_0(n)$. Recall the decomposition $\text{Range}(M) = \{\mathbf{b}\} \oplus \hat{\Lambda}$. Then $\mathcal{C} = \{\lambda \in \hat{\Lambda} | M^*\lambda \le 0\}$ and $X_0 = X \setminus \bigcup_{\lambda \in \mathcal{C}} \{x | M^*\lambda(x) < 0\}$.

LEMMA 4.1. *For each $i, j = 1, \dots, n$,*

$$M^*\lambda|_{B_i \cap T^{-1}B_j} = (\lambda_0 + \lambda_j - \lambda_i)\mathbf{1}_{B_i \cap T^{-1}B_j}.$$

Proof. Since both $\{B_k\}_{k=1}^n$ and $\{T^{-1}B_k\}_{k=1}^n$ are partitions of X, the lemma follows directly from the facts that $M^*\lambda = \sum_{k=0}^n \lambda_k g_k$ and $\mathbf{1}_{B_i \cap T^{-1}B_j} = \mathbf{1}_{B_i}\mathbf{1}_{T^{-1}B_j}$. ∎

LEMMA 4.2. *Let A be the $(n \times n)$ matrix with entries $A_{ij} = \mu(B_i \cap T^{-1}B_j)$, and let $\lambda \in \hat{\Lambda}$ be such that $M^*\lambda \le 0$. If $(A^{m_1})_{ij} > 0$ and $(A^{m_2})_{ji} > 0$ for some $m_1, m_2 > 0$, then $\lambda_i = \lambda_j$.*

Proof. Since $\lambda \in \hat{\Lambda}$, $\lambda_0 = 0$. Since each $A_{kl} \ge 0$, there is a sequence $\{i_k\}_{k=0}^{m_1+m_2}$ such that $i_0 = i = i_{m_1+m_2}$, $i_{m_1} = j$ and each $A_{i_l i_{l+1}} > 0$. Then, by Lemma 4.1,

$$(\lambda_{i_{l+1}} - \lambda_{i_l})\, A_{i_l i_{l+1}} = \int (\lambda_{i_{l+1}} - \lambda_{i_l}) \mathbf{1}_{B_{i_l} \cap T^{-1}B_{i_{l+1}}}\, d\mu = \int_{B_{i_l} \cap T^{-1}B_{i_{l+1}}} M^*\lambda\, d\mu \le 0.$$

Thus $\lambda_{i_0} \ge \lambda_{i_1} \ge \cdots \ge \lambda_{i_{m_1}} \ge \cdots \ge \lambda_{i_{m_1+m_2}} = \lambda_{i_0}$. In particular, $\lambda_i = \lambda_{i_0} = \lambda_{i_{m_1}} = \lambda_j$. ∎

PROPOSITION 4.3. *The following are equivalent:*

(i) *$A_{ij} > 0$ and $(A^m)_{ji} > 0$ for some $m > 0$;*

(ii) *$\mu(B_i \cap T^{-1}B_j) > 0$ and $B_i \cap T^{-1}B_j \subset X_0$ (mod μ).*

Proof. (i)⇒(ii) Suppose that $\mu(B_i \cap T^{-1}B_j) = A_{ij} > 0$, $(A^m)_{ji} > 0$, and let $\lambda \in \mathcal{C}$. Then, using Lemma 4.2 with $m_1 = 1$ and $m_2 = m$ gives $\lambda_i = \lambda_j$. By Lemma 4.1, $M^*\lambda(x) = \lambda_j - \lambda_i = 0$ when $x \in B_i \cap T^{-1}B_j$. This establishes that $B_i \cap T^{-1}B_j \subset X_0$.

(ii)⇒(i) We assume that $\mu(B_i \cap T^{-1}B_j) = A_{ij} > 0$ but that $(A^m)_{ji} = 0$ for all $m > 0$. We need to construct a $\hat{\lambda} \in \mathcal{C}$ such that $M^*\hat{\lambda}|_{B_i \cap T^{-1}B_j} < 0$, since this will show that $B_i \cap T^{-1}B_j$ is disjoint from X_0 μ-almost everywhere. Let $\mathcal{I} = \{j\} \cup \{k : (A^m)_{jk} > 0 \text{ for some } m > 0\}$ and define λ by putting $\lambda_l = -\mathbf{1}_{\mathcal{I}}(l)$ and $\lambda_0 = 0$. Observe that (a) $\lambda_i = 0$ and $\lambda_j = -1$; and (b) if $k \in \mathcal{I}$ and $A_{kl} > 0$ then $l \in \mathcal{I}$. Now, by Lemma 4.1, if $A_{kl} > 0$ then $M^*\lambda|_{B_k \cap T^{-1}B_l} = \lambda_l - \lambda_k$. By observation (a), $M^*\lambda|_{B_i \cap T^{-1}B_j} = -1$. We now check that $M^*\lambda \le 0$: by observation (b), if $\lambda_k = -1$ and $A_{kl} > 0$ then $\lambda_l = -1$ so $M^*\lambda|_{B_k \cap T^{-1}B_l} = 0$; on the other hand, if $\lambda_k = 0$ then $\lambda_l - \lambda_k \le 0$, so in any event $M^*\lambda \le 0$. Finally, decompose $\lambda = \hat{\lambda} + z$, where $\hat{\lambda} \in \hat{\Lambda}$ and $z \in \text{Ker}(M^*)$. Then $M^*\hat{\lambda} = M^*\lambda \le 0$ and $M^*\hat{\lambda}|_{B_i \cap T^{-1}B_j} < 0$. ∎

Proposition 4.3 suggests an elementary iterative procedure for identifying X_0 up to a set of measure 0:

1. Calculate the $n \times n$ matrix $A_{ij} = \mu(B_i \cap T^{-1}B_j)$.
2. For each $A_{ij} > 0$, determine $\mathcal{I}(j) = \{k | (A^m)_{jk} > 0 \text{ for some } m > 0\}$. If $i \in \mathcal{I}(j)$, then $B_i \cap T^{-1}B_j \subset X_0$, and set $\hat{A}_{ij} := A_{ij}$. Otherwise, set $\hat{A}_{ij} := 0$.

At the end of this procedure, set $\mathcal{I}_0 = \{(i,j) | \hat{A}_{ij} > 0\}$. Then take

$$X_0 = \cup_{(i,j)\in\mathcal{I}_0} B_i \cap T^{-1}B_j.$$

Remarks 4.4.

1. For reasonably regular maps T the matrix A is very sparse, with $O(n)$ nonzero entries which can be stored as a list of triples (i, j, A_{ij}). Consequently each set $\mathcal{I}(j)$ can be determined in $O(n)$ operations (mostly array look-ups); the identification of $\mathcal{I}_0$ via the above procedure thus requires at most $O(n^2)$ operations.
2. Proposition 4.3 essentially characterizes X_0 as elements of the partition $\mathcal{P} \vee T^{-1}\mathcal{P}$ which correspond to *strongly connected components* of a certain directed graph.[11] If A has $O(n)$ nonzero entries, all of these components (and the edges connecting them) can be found with $O(n)$ computational effort by Tarjan's algorithm [14]. See [8] for related work on the use of discrete models to obtain recurrent components and Lyapunov functions of dynamical systems.

The following corollary to Proposition 4.3 will be used below.

COROLLARY 4.5. *If* $(\hat{A}^m)_{ik} > 0$ *then there is an* $M > 0$ *such that* $(\hat{A}^M)_{ki} > 0$.

Proof. There are indices $i = i_0, i_1, \ldots, i_m = k$, and integers $M_1, \ldots, M_m$ such that $\hat{A}_{i_{l-1}i_l} > 0$ and $(\hat{A}^{M_l})_{i_l i_{l-1}} > 0$ for $l = 1, \ldots, m$. Then

$$(\hat{A}^{M_1+\cdots+M_m})_{ki} \geq (\hat{A}^{M_m})_{i_m i_{m-1}} \cdots (\hat{A}^{M_1})_{i_1 i_0} > 0. \qquad \square$$

Solution of the necessary conditions. Since the solution to (P_n) is obtained via (D_n), one needs to maximize

$$Q(\lambda) = \langle \lambda, \mathbf{b} \rangle - \int_{X_0} \exp\{M^*\lambda(x) - 1\}\, d\mu(x).$$

Using Lemma 4.1 and Proposition 4.3, we have

$$Q(\lambda) = \lambda_0 - \exp\{\lambda_0 - 1\} \sum_{(i,j)\in\mathcal{I}_0} \hat{A}_{ij} \exp\{\lambda_j - \lambda_i\},$$

so that (D_n) is solved by minimizing $G(\lambda) = \sum_{(i,j)\in\mathcal{I}_0} \hat{A}_{ij} \exp\{\lambda_j - \lambda_i\}$ and setting $\lambda_0 = 1 - \log(\sum_{(k,l)\in\mathcal{I}_0} \hat{A}_{kl} \exp\{\lambda_l - \lambda_k\})$. The optimal values of λ can then be used to recover the solution to (P_n) as in Theorem 3.7(2). The minimum of $G(\lambda)$ can be calculated using standard optimization algorithms, although we obtained rapid convergence with a fixed point method that we now describe.

The equations $\frac{\partial G}{\partial \lambda_i} = 0$ reduce to $\sum_l \hat{A}_{il} \exp\{\lambda_l - \lambda_i\} = \sum_k \hat{A}_{ki} \exp\{\lambda_i - \lambda_k\}$. Thus, for $i = 1, \ldots, n$,

$$(e^{-\lambda_i})^2 = \frac{\sum_{k\neq i} \hat{A}_{ki}\, e^{-\lambda_k}}{\sum_{l\neq i} \hat{A}_{il}\, e^{\lambda_l}},$$

[11] The vertices are the elements of $\mathcal{P}$ and the edge set corresponds to those ij with $A_{ij} > 0$.

which suggests an iterative scheme $(\lambda_i)^{(m+1)} = -\frac{1}{2}\log F_i(e^{-\lambda_1^{(m)}}, \ldots, e^{-\lambda_n^{(m)}})$ with the choice $F_i(x_1, \cdots, x_n) = \frac{\sum_{k\neq i}\hat{A}_{ki}\,x_k}{\sum_{l\neq i}\hat{A}_{il}\,\frac{1}{x_l}}$. In practice, it is more convenient to work directly with the values $x_i^{(m)} = e^{-(\lambda_i)^{(m)}}$, updating according to

$$x_i^{(m+1)} = \frac{\sqrt{F_i(\mathbf{x}^{(m)})}}{\sum_j \sqrt{F_j(\mathbf{x}^{(m)})}}.$$

We have no general proof for convergence of this iteration but note that it worked in all cases we tested, using $(x_i)^{(0)} = 1$.

Remarks 4.6.

1. The definition of F_i needs slight modification to allow for the possibilities that (i) $\sum_{l\neq i}\hat{A}_{il} = 0$ or (ii) $x_l = 0$. In the case of (i), Corollary 4.5 ensures that $\sum_{k\neq i}\hat{A}_{ki} = 0$, from which it follows that $G(\lambda)$ is independent of λ_i. In this case, set $F_i(\mathbf{x}) := 1$. In the case of (ii), an indeterminate expression is obtained only for those i with $\hat{A}_{il} > 0$, and continuity of F_i can then be ensured by putting $F_i(\mathbf{x}) = 0$.
2. The normalization of $\mathbf{x}^{(m+1)}$ ensures that the iteration scheme preserves the unit simplex in $(\mathbb{R}_+)^n$, without altering the value of $G(\lambda)$ (if $\mathbf{x} \mapsto c\,\mathbf{x}$, the effect on $x_i = e^{-\lambda_i}$ is $\lambda_i \mapsto \lambda_i - \log c$, and for any $\log c \in \mathbb{R}$, $G(\lambda) = G(\lambda - \log c)$).
3. The iteration is not a uniform contraction of the unit simplex since it preserves the boundary.

4.3. Numerical examples. We now apply the energy and entropy minimization approaches to approximate the invariant measures for several examples on the unit interval. μ in this case is Lebesgue measure.

Example 1. Let

$$T(x) = \begin{cases} 2\,x, & x \in [0, 1/2), \\ 2x - 1/2, & x \in [1/2, 3/4), \\ 2\,x - 1, & x \in [3/4, 1]. \end{cases}$$

The invariant measure for T has density $f_*(x) = 2\,\mathbf{1}_{[1/2,1]}$. For a sequence of values of n, approximations $f_n^{(V)}, f_n^{(H)}$ have been calculated which minimize $V(f) = \frac{1}{2}\int f^2\,d\mu$ and $H(f) = \int f\log f\,d\mu$, respectively. The approximation errors $\|f - f_n^{(V)}\|_{L^1}$ and $\|f - f_n^{(H)}\|_{L^1}$ are displayed in Table 1. The density approximations for $n = 729$ are displayed in the first row of Figure 1. Notice that $f_{729}^{(V)}$ has some negative values in $[0, 1/2)$; this is possible because our formulation of the optimization problem (with V) imposes no positivity condition although $[f_n]_- \to 0$ and $[f_n]_+ \to f$ (see [5, Remark 5.3(2)]). The spikes in $f_{729}^{(H)}$ occur at preimages of $\frac{1}{2}$ (a boundary point of $\mathrm{supp}(f_*)$) and disappear when $\frac{1}{2}$ is a boundary of a B_i.

Example 2. Let

$$T(x) = \begin{cases} 3\,x, & x \in [0, 1/4), \\ x + 1/2, & x \in [1/4, 1/2), \\ x - 1/2, & x \in [1/2, 3/4), \\ 3\,x - 2, & x \in [3/4, 1]. \end{cases}$$

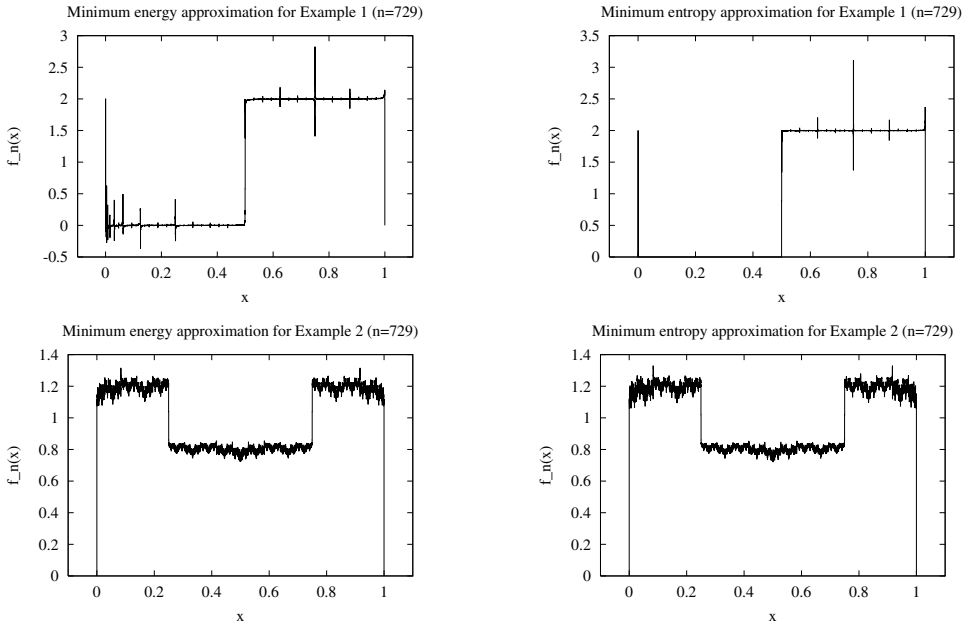

FIG. 1. *$n = 729$ density approximations for the maps in Examples 1 and 2 using Energy and Entropy minimization.*

The invariant measure for T has density $f_*(x) = 1.2\,\mathbf{1}_{[0,1/4)\cup(3/4,1]} + 0.8\mathbf{1}_{[1/4,3/4]}$. For a sequence of values of n, approximations $f_n^{(V)}, f_n^{(H)}$ have been calculated which minimize $V(f) = \frac{1}{2}\int f^2\,d\mu$ and $H(f) = \int f \log f\,d\mu$, respectively. The approximation errors $\|f - f_n^{(V)}\|_{L^1}$ and $\|f - f_n^{(H)}\|_{L^1}$ are displayed in Table 1. The density approximations for $n = 729$ are displayed in the second row of Figure 1.

Example 3. The tent map $T_r(x) = r(0.5 - |x - 0.5|)$ admits an invariant density f_r (of bounded variation) whenever $r \in (1, 2]$. Therefore, $H(f_r) < \infty$, and a sequence of f_n solving the finitely constrained optimization problems (P_n) will converge in L^1 to f_r as $n \to \infty$. In fact, if $r \in (2^{2^{-(k+1)}}, 2^{2^{-k}})$, then the density is supported on a union of 2^k intervals. In Figure 2, the $n = 729$ minimum entropy approximation is displayed for the tent map with $r = 1.3$. The displayed density is supported on $X_0(n)$, a union

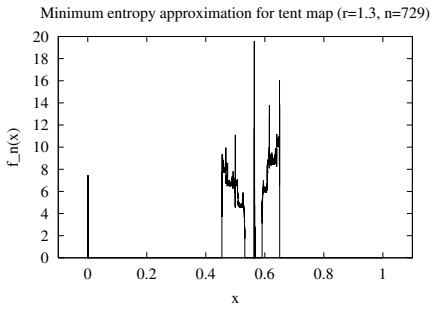

FIG. 2. *Entropy minimization with* $n = 729$ *for density approximation for the tent map (Example* 3*).*

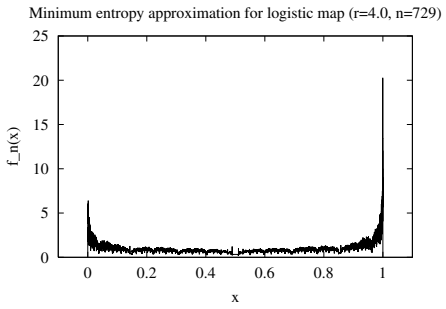

FIG. 3. *Entropy minimization with* $n = 729$ *for density approximation for the fully developed logistic map (Example* 4*).*

of several intervals, the larger two contain the support of the invariant density for T_r, and the remaining (small) intervals are clustered near the unstable fixed points for T_r at $x = 0, \frac{r}{1+r} \approx 0.565$. The correct density has no simple formula at this parameter value, so a direct calculation of the approximation error is not possible.

Example 4. The logistic map $T_r(x) = r\,x\,(1-x)$ admits an invariant density $f_*(x) = \frac{1}{\pi\sqrt{x\,(1-x)}}$ when $r = 4.0$. Then, $H(f_*) = 0.241564\cdots < \infty$, so the minimum entropy method will produce a sequence of density approximations f_n such that $\lim_{n\to\infty} \|f_n - f\|_{L^1} = 0$, even though neither T_r, nor any of its iterates, is expanding. The $n = 729$ minimum entropy approximation is displayed in Figure 3. (The error $\|f_n - f_*\|_{L^1} = 0.24683$.)

Appendix. Derivation of (D_n). The Lagrangian for (P_n) is

$$L(f,\lambda) = \Phi(f) - \langle \lambda, Mf - \mathbf{b}\rangle, \quad f \in L^p,\ \lambda \in \mathbb{R}^{N+1},$$

where $\langle\cdot,\cdot\rangle$ denotes the inner product in $\mathbb{R}^{N+1}$. Next, define

$$\begin{aligned} Q(\lambda) &= \inf_{f\in L^p} L(f,\lambda) \\ &= \langle \lambda, \mathbf{b}\rangle - \sup_{f\in L^p}\{\langle \lambda, Mf\rangle - \Phi(f)\} \\ &= \langle \lambda, \mathbf{b}\rangle - \Phi^*(M^*\lambda), \end{aligned}$$

where $\Phi^* : L^q \to \mathbb{R}$ denotes the Fenchel (convex) conjugate of Φ, that is,

$$\Phi^*(g) = \sup_{f \in L^p} \left\{ \int f(x)g(x)\, d\mu(x) - \Phi(f) \right\},$$

and the adjoint $M^* : \mathbb{R}^{N+1} \to L^q$ is calculated as

$$M^*\lambda = \sum_{k=0}^{n} \lambda_k g_k.$$

We note that Φ^* is easily seen to be both convex and weakly lower semicontinuous on L^q.

The functional Φ^* is the Banach space generalization of the classical convex conjugate ϕ^* for real functions $\phi : \mathbb{R} \to (-\infty, \infty]$. See Rockafellar [12] for definitions and elementary properties. When Φ is of integral type, there are some important connections between the two concepts.

For example, if $f \in L^p$ is such that $\phi(f(\cdot))$ is integrable, then for all $g \in L^q$, from Fenchel's inequality $\phi(t) + \phi^*(s) \geq ts$, after substituting $t = f(x)$ and $s = g(x)$ and integrating, one obtains $\int \phi^*(g(x))\, d\mu(x) \geq \int f(x)g(x)\, d\mu(x) - \int \phi(f(x))\, d\mu(x)$. It follows that $\int \phi^*(g(x))\, d\mu(x) \in (-\infty, \infty]$ unambiguously and $\int \phi^*(g(x))\, d\mu(x) \geq \Phi^*(g)$. These and many other properties of integral-type objectives are derived in Rockafellar [11]. We summarize the facts that we will use.

LEMMA A.1. *Let $\phi : \mathbb{R} \to (-\infty, \infty]$ be a convex, lower semicontinuous, and proper function.*

1. *Suppose that for every $f \in L^p$, $\Phi(f) = \int \phi(f(x))\, d\mu(x)$ is unambiguously an element of $(-\infty, \infty]$. Then for each $g \in L^q$, $\int \phi^*(g(x))\, d\mu(x)$ is unambiguously defined as an element of $(-\infty, \infty]$ and*

$$\Phi^*(g) = \int \phi^*(g(x))\, d\mu(x).$$

2. *If $\phi^*(g)$ is integrable for at least one $g \in L^q$ then the integral $\int \phi(f(x))\, d\mu(x)$ is well defined (possibly $= \infty$) for every $f \in L^p$. This will be the case, for example, if ϕ^* is proper and $\mu(X) < \infty$.*

Equipped with these tools, we can write down the dual optimization problem associated to (P_n) as

$$(D_n) \qquad \begin{aligned} &\text{Max} \quad Q(\lambda) = \langle \lambda, \mathbf{b} \rangle - \int_X \phi^*(M^*\lambda)(x)\, d\mu(x) \\ &\text{subject to} \quad \lambda \in \mathbb{R}^{N+1}, \end{aligned}$$

an unconstrained, finite-dimensional, and concave problem. It follows directly from the definitions of Q and L that

$$Q(\lambda) \leq \inf_{f \in L^p,\, Mf = \mathbf{b}} L(f, \lambda) \leq \Phi(f) \tag{A.1}$$

whenever f is feasible for (P_n) and $\lambda \in \mathbb{R}^{N+1}$. Hence, the (maximal) value of (D_n) is majorized by the (minimal) value of (P_n), the so-called principle of *weak duality*. Thus, solving the unconstrained dual problem (D_n) is equivalent to solving the primal (P_n) precisely when this "duality gap" can be closed. Theorem 3.7 describes one

situation which is tailored to our applications and where the duality gap can be closed.

Acknowledgments. Both authors would like to thank the Department of Mathematics and Statistics, University of Victoria, and the Department of Mathematics, University of Waikato, for hospitality during the period when this research was conducted.

SPECIAL ISSUE ON VARIATIONAL ANALYSIS AND OPTIMIZATION

This issue of *SIAM Journal on Optimization* was motivated by the September 2005 Workshop on Well-Posedness of Optimization Problems and Related Topics, held in Borovets, Bulgaria. This workshop was the tenth event of a series initiated in 1987 as a small meeting of Bulgarian and Italian mathematicians working on the subject. Since then, this series has gained a high international reputation, and its workshops are attractive scientific events where modern research of leading experts is presented and lively discussions stimulate and motivate young scientists. The workshops have substantially increased their scope by including stability, sensitivity, and well-posedness of problems in optimization, optimal control, and calculus of variations, variational principles, advances in stochastic optimization, vector optimization, set-valued analysis, and so on.

We view variational analysis as a large area of modern mathematics encompassing not only ideas of the classical calculus of variations and optimization but also to a large extent perturbations and approximations, set-valued analysis, generalized differential calculus, and generalized convexity. Interaction with other branches of mathematics and with engineering and economics brought interesting and unexpected applications of variational analysis and nonsmooth optimization. Recent developments in mathematical finance, actuarial mathematics, and statistics have been major driving forces for the theory and numerical methods of optimization.

This volume presents 23 papers authored or co-authored by the participants. The topics reflect the field's diversity and vitality. They highlight many interesting recent advances and indicate some problems that may become focus of future research.

Many people have made this collection possible. We would like to express our gratitude to all organizations who supported the Borovets workshop and to the local organizers who created the productive and supportive atmosphere of the meeting. We are grateful to the authors for their contributions and to the referees for their excellent and timely work. Finally, we offer our thanks to the SIAM Vice-President for Publications, Tim Kelley; to the Editor-in-Chief of *SIAM Journal on Optimization*, Nick Gould; and SIAM staffers Mitch Chernoff and Brian Fauth, who have encouraged us to prepare this special issue and have supported us in the process of editing it.

We hope that this collection of papers provides an interesting mathematical lecture and an inspiration for further research.

UNIQUENESS AND COMPARISON RESULTS FOR FUNCTIONALS DEPENDING ON ∇u AND ON u^*

A. CELLINA†

Abstract. We introduce a family of solutions to a variational problem and we prove uniqueness and comparison results.

Key words. strict convexity, comparison theorem, uniqueness

AMS subject classification. 49K20

DOI. 10.1137/060657455

1. Introduction.

We consider the problem of minimizing the functional

$$\mathcal{J}(u) = \int_\Omega [f(\nabla u(x)) + \alpha u(x)]\, dx, \tag{1}$$

where $\alpha \neq 0$ is a constant, on a suitable class of functions. We shall say that a function $w \in W^{1,1}(\Omega)$ is a *solution* if the functional attains its minimum among all the functions in $W^{1,1}(\Omega)$ that satisfy the same boundary conditions as w. Our purpose is to provide a comparison result and a result on uniqueness of solutions. A comparison result is a statement of the following kind: "For w and v solutions (satisfying different boundary conditions), $w \leq v$ on $\partial\Omega$ implies $w \leq v$ on Ω." A uniqueness result instead concerns solutions with the same boundary datum.

The assumptions we make on the convex function f are very general and apply to convex Lagrangeans that can be extended valued and not necessarily differentiable; moreover, f can be such that the domain of the subdifferential is strictly smaller than the domain of the function. Apart from this, our main point is that we do not assume that f is strictly convex: in this sense, this paper is a sequel to [1]. Notice, however, that the uniqueness result we present does not hold no matter what the boundary data are (a result of this kind would be rather unlikely, without any assumption of strict convexity), but holds only for a restricted class of boundary conditions.

The boundary conditions are those satisfied by a family of solutions that we are going to describe. We emphasize the fact that this family is explicit, i.e., that it can be computed directly from the Lagrangean f.

2. A family of solutions.

In what follows, f^* is the *polar* of f; for its main properties, we refer to [3] and [2].

THEOREM 1. *Let Ω be an open bounded set, regular enough so that the divergence theorem holds, and let $f : R^N \to R \cup \{+\infty\}$ be an extended valued, convex, lower semicontinuous function. For x_0 and θ in R^N and $c \in R$, consider the function*

$$\omega_\alpha(x) = \frac{N}{\alpha} f^* \left(\theta + \frac{x - x_0}{N} \alpha \right) + c.$$

†Dipartimento di Matematica e Applicazioni, Universitá degli Studi di Milano-Bicocca, Via R. Cozzi 53, 20125 Milano, Italy (arrigo.cellina@unimib.it).

If ω_α is defined on Ω and belongs to $W^{1,1}(\Omega)$, then it is the only minimum of the functional

$$\mathcal{J}(u) = \int_\Omega [f(\nabla u(x)) + \alpha u(x)]\, dx,$$

in the class of functions

$$\mathcal{S} = \left\{ u \in W^{1,1}(\Omega), u - \omega_\alpha \in W_0^{1,1}(\Omega) \right\}.$$

As an example, the polar to the convex function

$$f(\xi) = \begin{cases} \|\xi\| - \sqrt{\|\xi\|} & \text{if } \|\xi\| \geq \sqrt{1}, \\ 0 & \text{if } \|\xi\| \leq \sqrt{1} \end{cases}$$

is given by

$$f^*(p) = \begin{cases} \frac{3}{4(1-\|p\|)} & \text{if } \frac{1}{2} \leq \|p\| < 1, \\ \|p\| & \text{if } \|p\| \leq \frac{1}{2}. \end{cases}$$

For $N = 1$, $\alpha = 1$, $\Omega = (-1, 1)$, $\theta = 0$, $x_0 = 0$, the function

$$\omega(x) = f^*(x)$$

is defined on Ω but does not belong to $W^{1,1}(\Omega)$. However, one has the following result.

Remark 1. If, in addition, f has superlinear growth, then, for Ω bounded, for every x_0 and θ, the function $\omega_\alpha(x)$ is defined on $\overline{\Omega}$ and belongs to $W^{1,\infty}(\Omega)$.

Indeed, by the superlinear growth of f, we obtain that $f^*(p) < +\infty$ for every $p \in R^N$. In particular, for every θ and x_0 in R^N, the convex function $\omega_\alpha(x)$ is defined and Lipschitzian on $\overline{\Omega}$.

The proof of Theorem 1 is direct and does not depend on the validity of the Euler–Lagrange equation, since, to this author's knowledge, the validity of this equation, for the class of problems considered in this paper, is yet to be established. We shall need the following lemma.

LEMMA 1. *Let f be convex, let $\xi_1 \neq \xi_2$, and let p be in both $\partial f(\xi_1)$ and $\partial f(\xi_2)$. Then, f^* is not differentiable at p.*

Proof. Since $p \in \partial f(\xi_2)$, for $\lambda > 0$ we have

$$\frac{1}{\lambda}(f^*(p + \lambda(\xi_2 - \xi_1)) - f^*(p))$$

$$= \frac{1}{\lambda}\left(\sup_\xi \{\langle p + \lambda(\xi_2 - \xi_1), \xi\rangle - f(\xi)\} - (\langle p, \xi_2\rangle - f(\xi_2)) \right) \geq \langle (\xi_2 - \xi_1), \xi_2\rangle.$$

Analogously, since $p \in \partial f(\xi_1)$, we have

$$\frac{1}{\lambda}(f^*(p + \lambda(\xi_1 - \xi_2)) - f^*(p)) \geq \langle (\xi_1 - \xi_2), \xi_1\rangle$$

so that, if f^* is differentiable at p, we obtain

$$\langle (\xi_2 - \xi_1), \xi_1\rangle \geq \langle \nabla f^*(p), \xi_2 - \xi_1\rangle \geq \langle (\xi_2 - \xi_1), \xi_2\rangle,$$

i.e., $\|\xi_2 - \xi_1\|^2 \leq 0$. □

Proof of Theorem 1. Consider the case $\alpha > 0$; in this case, ω_α is a convex function (it would be concave for $\alpha < 0$).

(a) We shall prove that for every $u \in \mathcal{S}$, we have $\mathcal{J}(\omega_\alpha) \leq \mathcal{J}(u)$. By assumption, the effective domain of the convex function ω_α contains Ω; hence, ω_α is locally Lipschitzian, hence differentiable almost everywhere, on Ω. Let $x \in \Omega$ be such that $\nabla\omega_\alpha(x)$ exists, and set $p(x) = \theta + \frac{x-x_0}{N}\alpha$. Then $f^*(p)$ is differentiable in p at $p = p(x)$, with gradient $z = \nabla f^*(p) = \nabla f^*(p(x))$. Since $z \in \nabla f^*(p)$ implies $p \in \partial f(z)$, we obtain that

$$p(x) \in \partial f\left(\nabla f^*\left(p(x)\right)\right) = \partial f(z),$$

so that, for every $q \in R^N$,

$$f(q) - f(z) \geq \langle p(x), q - z\rangle .$$

We have that

$$\nabla\omega_\alpha(x) = \nabla f^*\left(\theta + \frac{x-x_0}{N}\alpha\right) = \nabla f^*(p(x)) = z.$$

Hence, in particular, for $u(x) \in \mathcal{S}$ and for almost every $x \in \Omega$, we obtain

$$f\left(\nabla u(x)\right) - f\left(\nabla\omega_\alpha(x)\right) \geq \langle p(x), \nabla u(x) - \nabla\omega_\alpha(x)\rangle , \tag{2}$$

so that

$$\int_\Omega \left[f\left(\nabla u(x)\right) - f\left(\nabla\omega_\alpha(x)\right)\right] dx \geq \int_\Omega \left\langle \theta + \frac{\alpha}{N}(x-x_0), \nabla u(x) - \nabla\omega_\alpha(x)\right\rangle dx.$$

We have that $u - \omega \in W_0^{1,1}(\Omega)$; recalling the divergence theorem, we obtain

$$\int_\Omega \langle \theta, \nabla u(x) - \nabla\omega_\alpha(x)\rangle \, dx = \int_\Omega \operatorname{div}((u(x) - \omega_\alpha(x))\theta)\, dx = 0$$

and

$$\begin{aligned}
&\int_\Omega \left\langle \frac{\alpha}{N}(x-x_0), \nabla u(x) - \nabla\omega_\alpha(x)\right\rangle dx \\
&= \int_\Omega \left[\operatorname{div}\left((u(x) - \omega_\alpha(x))\frac{\alpha}{N}(x-x_0)\right) - \frac{\alpha}{N}(u(x) - \omega_\alpha(x))\operatorname{div}(x-x_0)\right] dx \\
&= -\int_\Omega \alpha(u(x) - \omega_\alpha(x))\, dx,
\end{aligned}$$

so that

$$\int_\Omega \left[f\left(\nabla u(x)\right) - f\left(\nabla\omega_\alpha(x)\right)\right] dx \geq -\int_\Omega \alpha\left(u(x) - \omega_\alpha(x)\right) dx,$$

i.e.,

$$\int_\Omega \left[f\left(\nabla u(x)\right) + \alpha u(x)\right] dx \geq \int_\Omega \left[f\left(\nabla\omega_\alpha(x)\right) + \alpha\omega_\alpha(x)\right] dx.$$

Since u is arbitrary in $\mathcal{S}$, the above inequality shows that ω_α is a solution.

(b) Let w be another solution. Because it is a solution, we have

$$\int_\Omega \left([f(\nabla w(x)) - f(\nabla \omega_\alpha(x))] + \alpha[w(x) - \omega_\alpha(x)]\right) dx = 0. \tag{3}$$

Since

$$-\int_\Omega \langle p(x), \nabla w(x) - \nabla \omega_\alpha(x)\rangle \, dx = -\int_\Omega \left\langle \theta + \frac{x - x_0}{N}\alpha, \nabla w(x) - \nabla \omega_\alpha(x) \right\rangle dx$$

$$= \alpha \int_\Omega [w(x) - \omega_\alpha(x)] \, dx,$$

from (3) we obtain

$$\int_\Omega \left([f(\nabla w(x)) - f(\nabla \omega_\alpha(x))] - \langle p(x), \nabla w(x) - \nabla \omega_\alpha(x)\rangle\right) dx = 0.$$

From (2) applied to the solution w, we have that

$$[f(\nabla w(x)) - f(\nabla \omega_\alpha(x))] - \langle p(x), \nabla w(x) - \nabla \omega_\alpha(x)\rangle \geq 0,$$

so that, for a.e. $x \in \Omega$, we obtain

$$f(\nabla w(x)) - f(\nabla \omega_\alpha(x)) - \langle p(x), \nabla w(x) - \nabla \omega_\alpha(x)\rangle = 0.$$

Next, we claim that $p(x) \in \partial f(\nabla w(x))$ as well. In fact, for every ξ, from the above equality we obtain

$$f(\xi) - f(\nabla w(x)) = f(\xi) - [f(\nabla \omega_\alpha(x)) + \langle p(x), \nabla w(x) - \nabla \omega_\alpha(x)\rangle]$$

$$= f(\xi) - [f(\nabla \omega_\alpha(x)) + \langle p(x), \xi - \nabla \omega_\alpha(x)\rangle + \langle p(x), \nabla w(x) - \xi\rangle] \geq \langle p(x), \nabla w(x) - \xi\rangle$$

so that, by definition, $p(x) \in \partial f(\nabla w(x))$.

Apply Lemma 1. By assumption, we have that f^* is differentiable at $p = p(x)$; hence we infer that $\nabla w(x) = \nabla \omega_\alpha(x)$. The point x was arbitrary and the two functions satisfy the same boundary condition so that $w = \omega_\alpha$. □

The following is our comparison result; here, by saying that at $\partial\Omega$ we have $v \geq u$, we mean, as usual, that $(u - v)^+ \in W_0^{1,1}(\Omega)$.

Corollary 1 (comparison theorem). *Let w be a solution to the minimization of* (1) *in the class of those functions satisfying the same boundary conditions as w; assume that, on $\partial\Omega$, we have $w \leq \omega_\alpha$. Then, $w \leq \omega_\alpha$ a.e. in Ω.*

Proof. Set $\eta = (w - \omega_\alpha)^+$ so that $\eta \in W_0^{1,1}(\Omega)$. We have that $\tilde{\omega}_\alpha = \omega_\alpha + \eta$ is such that $\tilde{\omega}_\alpha - \omega_\alpha \in W_0^{1,1}(\Omega)$, while, defining $\tilde{w} = w - \eta$, we have that $\tilde{w}$ satisfies $\tilde{w} - w \in W_0^{1,1}(\Omega)$. Set $E^+ = \{x \in \Omega : \eta(x) > 0\}$: on E^+, $\nabla \tilde{\omega}_\alpha = \nabla w$ and $\tilde{\omega}_\alpha = w$, while $\nabla \tilde{w} = \nabla \omega_\alpha$ and $\tilde{w} = \omega_\alpha$.

Since ω_α is a solution on the set $\omega - \omega_\alpha \in W_0^{1,1}(\Omega)$, we have

$$0 \leq \int_\Omega [f(\nabla \tilde{\omega}_\alpha(x)) + \alpha \tilde{\omega}_\alpha(x)] \, dx - \int_\Omega [f(\nabla \omega_\alpha(x)) + \alpha \omega_\alpha(x)] \, dx$$

$$= \int_{E^+} [f(\nabla w(x)) + \alpha w(x)] \, dx - \int_{E^+} [f(\nabla \omega_\alpha(x)) + \alpha \omega_\alpha(x)] \, dx.$$

In the same way, since w is a solution on the set $v - w \in W_0^{1,1}(\Omega)$, we obtain

$$0 \leq \int_{E^+} [f(\nabla \omega_\alpha(x)) + \alpha \omega_\alpha(x)]\, dx - \int_{E^+} [f(\nabla w(x)) + \alpha w(x)]\, dx$$

so that

$$\int_{E^+} [f(\nabla \omega_\alpha(x)) + \alpha \omega_\alpha(x)]\, dx = \int_{E^+} [f(\nabla w(x)) + \alpha w(x)]\, dx$$
$$= \int_{E^+} [f(\nabla \tilde{\omega}_\alpha(x)) + \alpha \tilde{\omega}_\alpha(x)]\, dx$$

and $\tilde{\omega}_\alpha$ is a further solution to the minimization of (1) on $\{u : u - \omega_\alpha \in W_0^{1,1}(\Omega)\}$. This solution differs from ω_α when $m(E^+) > 0$, a contradiction to Theorem 1. Hence, $m(E^+) = 0$. □

3. The limit as $\alpha \to 0$. The functions ω_α are undefined for $\alpha = 0$. We are interested in the question of whether the functions ω_α converge to a limit as $\alpha \to 0$, and, if this is the case, of how this limit is related to the solutions of the minimum problem with $\alpha = 0$, i.e., of the problem

$$\text{minimize} \int_\Omega f(\nabla u(x))\, dx, \qquad u - u_0 \in W_0^{1,1}(\Omega). \tag{4}$$

In particular, write the arbitrary constant c as $c = -\frac{N}{\alpha} f^*(\theta) + \beta$ (β arbitrary) and consider the family of solutions to problem (1) given by

$$\omega_{(\alpha,\theta,\beta)}(x) = \frac{N}{\alpha} f^* \left(\theta + \frac{x - x_0}{N} \alpha \right) - \frac{N}{\alpha} f^*(\theta) + \beta.$$

A remarkable feature of this class of solutions to problem 1 is provided by the following result:

THEOREM 2. *Let f be an extended valued, convex, lower semicontinuous function with superlinear growth. Then*

(a) *when f^* is differentiable at θ, as α tends to 0, the function $\omega_{(\alpha,\theta,\beta)}$ converges to the affine map $\langle \nabla f^*(\theta), x - x_0 \rangle + \beta$, a solution to problem (4).*

(b) *in general, as α tends to 0^+, the function $\omega_{(\alpha,\theta,\beta)}$ converges to $h^+_{\theta,x_0,\beta}$, the solution to problem (4), presented in Theorem 1 of [1]; as α tends to 0^-, $\omega_{(\alpha,\theta,\beta)}$ converges to $h^-_{\theta,x_0,\beta}$.*

Proof.

(a) From the assumption of differentiability we have that

$$\lim_{\alpha \to 0} \frac{N}{\alpha} \left[f^* \left(\theta + \frac{x - x_0}{N} \alpha \right) - f^*(\theta) \right]$$
$$= \langle \nabla f^*(\theta), x - x_0 \rangle .$$

(b) By assumption, $\partial f^*(\theta)$ is nonempty, so by Theorem 23.4 of [3], we have

$$\lim_{\alpha \to 0^+} \frac{N}{\alpha} f^* \left(\theta + \frac{x - x_0}{N} \alpha \right) - \frac{N}{\alpha} f^*(\theta)) = \sup_{k \in \partial f^*(\theta)} \langle k, x - x_0 \rangle .$$

By Theorem 1 of [1], the map $\sup_{k\in\partial f^*(\theta)}\langle k, x-x_0\rangle$ is a solution to (4) and the claim follows. The proof is analogous for the second claim, taking into account that the function $\omega_{(\alpha,\theta,\beta)}$ becomes concave in this case. □

Example. Consider the problem

$$\text{minimize}\int_\Omega [G(u'(x))+\alpha u(x)]\,dx,$$

where $\alpha>0$ and G is

$$G(\xi)=\begin{cases}\sqrt{2}\|\xi\| & \text{if } \|\xi\|\le\sqrt{2},\\ 1+\frac{1}{2}\|\xi\|^2 & \text{if } \|\xi\|\ge\sqrt{2}.\end{cases} \tag{5}$$

We have

$$G^*(p)=\begin{cases}0 & \text{if } \|p\|\le\sqrt{2},\\ \frac{1}{2}\|p\|^2-1 & \text{if } \|p\|\ge\sqrt{2}.\end{cases}$$

In particular, for $\|\theta\|=\sqrt{2}$, so that $G^*(\theta)=0$, and $x_0=0$, we obtain

$$\omega_{(\alpha,\theta,0)}=\begin{cases}0 & \text{if } \|\theta+\frac{\alpha}{N}x\|\le\sqrt{2},\\ \frac{N}{\alpha}\left(\frac{1}{2}\|\theta+\frac{\alpha}{N}x\|^2-1\right) & \text{if } \|\theta+\frac{\alpha}{N}x\|\ge\sqrt{2}.\end{cases}$$

As $\alpha\downarrow 0$, the set of points $\{x:\|\theta+\frac{\alpha}{N}x\|\le\sqrt{2}\}$ grows to the half space $\{x:\langle x,\theta\rangle\le 2\}$, and $\omega_{(\alpha,\theta,0)}$ converges pointwise to

$$\begin{cases}0 & \text{if } \langle x,\theta\rangle\le 2,\\ \langle\theta,x\rangle & \text{if } \langle x,\theta\rangle\ge 2.\end{cases}$$

This last function is

$$\sup_{k\in\partial G^*(\theta)}\{\langle k,x\rangle\}=\left(I_{\partial G^*(\theta)}\right)^*(x),$$

a solution to (4).

METRIC REGULARITY IN CONVEX SEMI-INFINITE OPTIMIZATION UNDER CANONICAL PERTURBATIONS*

M. J. CÁNOVAS†, D. KLATTE‡, M. A. LÓPEZ§, AND J. PARRA†

Abstract. This paper is concerned with the Lipschitzian behavior of the optimal set of convex semi-infinite optimization problems under continuous perturbations of the right-hand side of the constraints and linear perturbations of the objective function. In this framework we provide a sufficient condition for the metric regularity of the inverse of the optimal set mapping. This condition consists of the Slater constraint qualification, together with a certain additional requirement in the Karush–Kuhn–Tucker conditions. For linear problems this sufficient condition turns out to be also necessary for the metric regularity, and it is equivalent to some well-known stability concepts.

Key words. metric regularity, optimal set, Lipschitz properties, semi-infinite programming, convex programming

1. Introduction.

We consider the canonically perturbed convex semi-infinite programming problem, in $\mathbb{R}^n$,

$$P(c,b): \quad \begin{array}{l} \text{Inf } f(x) + c'x \\ \text{s.t. } g_t(x) \le b_t, \ \ t \in T, \end{array} \tag{1}$$

where $x \in \mathbb{R}^n$ is the vector of decision variables, regarded as a column-vector, $c \in \mathbb{R}^n$, c' denotes the transpose of c, the index set T is a compact metric space, $f : \mathbb{R}^n \to \mathbb{R}$ and $g_t : \mathbb{R}^n \to \mathbb{R}$, $t \in T$, are given convex functions in such a way that $(t,x) \mapsto g_t(x)$ is continuous on $T \times \mathbb{R}^n$, and $b \in C(T,\mathbb{R})$, i.e., $T \ni t \mapsto b_t \in \mathbb{R}$ is continuous on T.

In this setting, the pair $(c,b) \in \mathbb{R}^n \times C(T,\mathbb{R})$ is regarded as the parameter to be perturbed. We denote by $\sigma(b)$ the constraint system associated with $P(c,b)$, i.e.,

$$\sigma(b) := \{ g_t(x) \le b_t, \ \ t \in T \}.$$

The parameter space $\mathbb{R}^n \times C(T,\mathbb{R})$ is endowed with the norm

$$\|(c,b)\| := \max \{ \|c\|, \|b\|_\infty \}, \tag{2}$$

where $\mathbb{R}^n$ is equipped with any given norm $\|\cdot\|$ and $\|b\|_\infty := \max_{t\in T} |b_t|$. The corresponding dual norm in $\mathbb{R}^n$ is given by $\|u\|_* := \max \{u'x \mid \|x\| \le 1\}$.

Associated with the parametric family of problems $P(c,b)$, we consider the set-valued mappings $\mathcal{G}:\mathbb{R}^n \rightrightarrows C(T,\mathbb{R})$ and $\mathcal{G}^*:\mathbb{R}^n \rightrightarrows \mathbb{R}^n \times C(T,\mathbb{R})$ given by

$$\mathcal{G}(x) := \{b \in C(T,\mathbb{R}) \mid g_t(x) \leq b_t \text{ for all } t \in T\},$$

$$\mathcal{G}^*(x) := \left\{(c,b) \in \mathbb{R}^n \times \mathcal{G}(x) \mid x \in \arg\min\left\{f(y) + c'y \mid y \in \mathcal{G}^{-1}(b)\right\}\right\}.$$

The corresponding inverse mappings will be denoted by $\mathcal{F}$ and $\mathcal{F}^*$, respectively. Observe that $\mathcal{F}(b)$ and $\mathcal{F}^*(c,b)$ are, respectively, the feasible set and the optimal set (set of optimal solutions) of $P(c,b)$, i.e.,

$$\mathcal{F}(b) := \{x \in \mathbb{R}^n \mid g_t(x) \leq b_t \text{ for all } t \in T\},$$

$$\mathcal{F}^*(c,b) := \arg\min\{f(x) + c'x \mid x \in \mathcal{F}(b)\}.$$

Finally, by Π_c and Π_s we denote the sets of parameters corresponding to consistent or solvable problems, respectively; i.e.,

$$\Pi_c := \{(c,b) \in \mathbb{R}^n \times C(T,\mathbb{R}) \mid \mathcal{F}(b) \neq \emptyset\}$$

and

$$\Pi_s := \{(c,b) \in \mathbb{R}^n \times C(T,\mathbb{R}) \mid \mathcal{F}^*(c,b) \neq \emptyset\}.$$

According to Corollary 8.3.3 and Theorem 8.7 in [24], if $\sigma(b)$ and $\sigma(b^1)$ are both consistent, $\mathcal{F}(b)$ and $\mathcal{F}(b^1)$ have the same recession cone.

This paper is concerned with the metric regularity of $\mathcal{G}^*$ at a given $\overline{x}$ for $(\overline{c},\overline{b}) \in \mathcal{G}^*(\overline{x})$, that is, with the existence of neighborhoods U of $\overline{x}$ and V of $(\overline{c},\overline{b})$ and a constant $\kappa \geq 0$ such that

$$d(x,\mathcal{F}^*(c,b)) \leq \kappa d((c,b),\mathcal{G}^*(x)) \text{ for all } x \in U \text{ and all } (c,b) \in V, \tag{3}$$

where, as usual, $d(x,\emptyset) = +\infty$. In section 3 we provide a sufficient condition, (10), for this property. Essentially, it is a Karush–Kuhn–Tucker (KKT) type condition with some additional requirements.

In the particular case of linear problems of the form

$$\begin{aligned} P(c,b): \quad & \operatorname{Inf} c'x \\ & \text{s.t. } a_t'x \geq b_t, \ \ t \in T, \end{aligned} \tag{4}$$

where $a \in C(T,\mathbb{R}^n)$ is a given function, this algebraic condition is given by (9), and it turns out to be equivalent to a condition introduced by Nürnberger [22, Condition (2) in Thm. 1.4], in relation to the stability of the strong uniqueness of minimizers (see also [11] and [13], dealing with linear optimization problems without continuity assumptions). Moreover in the linear setting, the referred condition is not only sufficient but also necessary for the metric regularity of $\mathcal{G}^*$ at $\overline{x}$ for $(\overline{c},\overline{b})$.

The metric regularity is a basic quantitative property of mappings in variational analysis which is widely used in both theoretical and computational studies. In order to illustrate how this concept works in our context, let $\overline{x}$ be an optimal solution of $P(\overline{c},\overline{b})$ and let (c_a,b_a) and x_a be close enough approximations to $(\overline{c},\overline{b})$ and $\overline{x}$, respectively. Then problem $P(c_a,b_a)$ has an optimal solution whose distance to x_a is bounded by κ times $d((c_a,b_a),\mathcal{G}^*(x_a))$. The latter distance is usually easy to compute

or estimate, while finding an exact solution of $P(c_a, b_a)$ might be considerably difficult. For instance, a possible choice of parameters which make x_a optimal is $c = \bar{c}$ and b such that x_a is feasible for $\sigma(b)$ and some suitably chosen constraints are active at x_a (according to the KKT condition). See section 3 for details. The metric regularity of a set-valued mapping turns out to be equivalent to the pseudo-Lipschitz property, also called the Aubin property, of the inverse mapping (see, for instance, [19], [25] and the references therein). Specifically, the Aubin property in our context reads as follows: There exist neighborhoods U of $\overline{x}$ and V of $\left(\bar{c}, \bar{b}\right)$ and a constant $\kappa \geq 0$ such that

$$d\left(x^2, \mathcal{F}^*\left(c^1, b^1\right)\right) \leq \kappa d\left(\left(c^1, b^1\right), \left(c^2, b^2\right)\right) \tag{5}$$

for all $\left(c^1, b^1\right), \left(c^2, b^2\right) \in V$ and all $x^2 \in U \cap \mathcal{F}^*\left(c^2, b^2\right)$. Other Lipschitz/regularity properties also can be traced back to [19], [25].

In our context of problems (1), the metric regularity of $\mathcal{G}^*$ (i.e., the pseudo-Lipschitz property of $\mathcal{F}^*$) at a point of its graph is equivalent to the *strong Lipschitz stability* of $\mathcal{F}^*$ (see Lemma 5), which reads as follows: There exist open neighborhoods U of $\overline{x}$ and V of $\left(\bar{c}, \bar{b}\right)$ and a constant $\kappa \geq 0$ such that $\mathcal{F}^*(c, b) \cap U$ is a singleton, $\{x(c, b)\}$, for all $(c, b) \in V$ and

$$\left\|x\left(c^1, b^1\right) - x\left(c^2, b^2\right)\right\| \leq \kappa \left\|\left(c^1, b^1\right) - \left(c^2, b^2\right)\right\| \text{ for all } \left(c^1, b^1\right), \left(c^2, b^2\right) \in V.$$

Note that because of the convexity of $\mathcal{F}^*(c, b)$, we already have $\mathcal{F}^*(c, b) = \{x(c, b)\}$ for all $(c, b) \in V$. In other words, the *strong Lipschitz stability* of $\mathcal{F}^*$ at $\left(\left(\bar{c}, \bar{b}\right), \overline{x}\right)$ is equivalent to the local single-valuedness and Lipschitz continuity of $\mathcal{F}^*$ near $\left(\left(\bar{c}, \bar{b}\right), \overline{x}\right)$ [17], [19], [26]. The fact that the pseudo-Lipschitz property of the global optimal solution set mapping $\mathcal{S}$ of a parametric optimization problem implies strong Lipschitz stability of $\mathcal{S}$ holds for a rather general class of optimization problems (see again Lemma 5). In the particular case of linear problems, we can add as a third equivalent property the *local single-valuedness and continuity* of $\mathcal{F}^*$ (a Kojima-type stability condition under specific perturbations [21], [26]).

Section 5.3 in [20] clarifies the relationship between the strong Lipschitz stability and the strong Kojima stability. Specifically, as a straightforward consequence of Corollary 5.5 there, one obtains the equivalence between these two properties when applied to finite linear optimization problems. In this way, Theorem 16 below, confined to the linear case, extends the fulfillment of these equivalences to the case of infinitely many constraints.

That paper [20] was concerned with the strong Lipschitz stability of the stationary solution map (in the KKT sense) in our context of problems (1), with T finite, where the functions included in the model are assumed to belong to the class $C^{1,1}$, and under the general assumption of the Mangasarian–Fromowitz constraint qualification (MFCQ). The more general case in which the functions f and g also depend on a parameter $\tau \in \mathcal{T} \subset \mathbb{R}^r$ is dealt with in [19, sect. 8]. Note that if the constraint functions g_t of the convex semi-infinite problem (1) are differentiable, then the (extended) MFCQ is nothing else but the Slater CQ (i.e., the existence of a strict solution of the associated constraint system). The fulfillment of both the Slater condition and the boundedness (and nonemptiness) of the set of optimal solutions yields high stability for optimization problems in different frameworks (see, for instance, [18, Thm. 1] and [5, Thm. 4.2] in relation to the Lipschitz continuity of the optimal value).

There are different contributions to the stability theory for the feasible and the optimal set mappings in linear semi-infinite optimization. The article [10] analyzed

the (Berge) lower semicontinuity of the feasible set mapping $\mathcal{F}$ in the more general context in which there is no continuity assumption and the parameters are $(a,b) \in (\mathbb{R}^n \times \mathbb{R})^T$, the latter being endowed with an appropriate extended distance. On the other hand, the lower and upper semicontinuity of $\mathcal{F}^*$ in the general context of parameters $(c,(a,b)) \in \mathbb{R}^n \times (\mathbb{R}^n \times \mathbb{R})^T$ were analyzed in [5] in the linear case, and in [8] in the convex case. More details about stability of linear semi-infinite problems and their constraint systems in this general context (no continuity assumption) are gathered in [9, Chapters 6 and 10]. The *continuous case*, in which T is a compact Hausdorff space, the functions a and b are continuous on T, and all the parameters may be (continuously) perturbed, was analyzed, e.g., in [3] and [7]. Note also that classical parametric optimization (see, e.g., [1], [2], [16]) applies to this and more general settings by writing the constraints as one aggregated inequality, like $\max_{t\in T}(g_t(x) - b_t) \leq 0$ in the case of (1). In the current context of continuous perturbations of only the right-hand side of the system, the metric regularity of the mapping $\mathcal{G}$, in the linear case, was approached in [4].

Next, we summarize the structure of the paper. Section 2 gathers some preliminaries about convex analysis and multifunctions. Moreover we include here some results about the stability of $\mathcal{F}$ and its relation with continuity properties of $\mathcal{F}^*$. Specifically, Lemma 3 shows the equivalence among some relevant stability criteria concerning the feasible set. Proposition 4 provides a sufficient condition for the lower semicontinuity of $\mathcal{F}^*$, which constitutes a key step in the analysis of the metric regularity of $\mathcal{G}^*$. In section 3 we introduce, after some motivation, condition (10). Some consequences of this condition are gathered in Proposition 9. Theorem 10 shows that condition (10) is sufficient for the metric regularity of $\mathcal{G}^*$ in the convex case. Section 4 deals with the linear case. Theorem 16 establishes the equivalence between the specification of (10) for the linear case and several well-known stability concepts concerning the optimal set, including the metric regularity of $\mathcal{G}^*$. Finally, section 5 shows at a glance the main results of the paper.

2. Preliminaries and first results. In this section we provide further notation and some preliminary results. Given $X \subset \mathbb{R}^k$, $k \in \mathbb{N}$, we denote by $conv\,(X)$ and $cone\,(X)$ the convex hull and the conical convex hull of X, respectively. We assume that $cone\,(X)$ always contains the zero vector of $\mathbb{R}^k$, 0_k. We shall also assume $conv\,(\emptyset) = \emptyset$ and $cone\,(\emptyset) := \{0_k\}$. If X is a closed convex set, $O^+(X)$ represents the recession cone of X.

If X is a subset of any topological space, $\mathrm{int}\,(X)$ and $\mathrm{cl}(X)$ will represent the interior and the closure of X, respectively. A typical element of $cone\,(\{x_i, i \in I\})$, where I is any index set, is represented as $\sum_{i\in I} \lambda_i x_i$, where $\lambda = (\lambda_i)_{i\in I}$ belongs to the cone $\mathbb{R}_+^{(I)}$ of all functions from I to $\mathbb{R}_+ := [0, +\infty[$ with finite support, i.e., taking positive values at only finitely many points of I. Generically, sequences will be indexed by $r \in \mathbb{N}$, and $\lim_r$ should be interpreted as $\lim_{r\to\infty}$.

Let $h : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a proper closed convex function. By $\partial h\,(x)$ we denote the *subdifferential* of h at x, and by $h0^+$ the *recession function* of h, i.e., the sublinear function whose epigraph is the recession cone of the epigraph of h.

Observe that our problem $P(c,b)$ is equivalent to the unconstrained problem

$$\operatorname*{Inf}_{x\in\mathbb{R}^n} \left\{h(x) := f(x) + c'x + \delta_{\mathcal{F}(b)}(x)\right\}, \tag{6}$$

where $\delta_{\mathcal{F}(b)}$ is the indicator function of $\mathcal{F}(b)$ (i.e., $\delta_{\mathcal{F}(b)}(x) = 0$ if $x \in \mathcal{F}(b)$, and $\delta_{\mathcal{F}(b)}(x) = +\infty$ if $x \notin \mathcal{F}(b)$). We shall use the recession function of h, which, thanks

to [24, Thm. 9.3], turns out to be

$$h0^+(y) = f0^+(y) + c'y + \delta_{\mathcal{F}(b)}0^+(y)$$
$$= f0^+(y) + c'y + \delta_{O^+(\mathcal{F}(b))}(y).$$

Associated with problem (1), for each $x \in \mathcal{F}(b)$ we consider

$$T_b(x) = \{t \in T \mid g_t(x) = b_t\} \quad \text{and} \quad A_b(x) = cone\left(\bigcup_{t\in T_b(x)} (-\partial g_t(x))\right).$$

Recall that $A_b(x) = \{0_n\}$ if $T_b(x) = \emptyset$. For our model (1), $\sigma(b)$ satisfies the *Slater condition* if $T_b(x^0)$ is empty for some $x^0 \in \mathcal{F}(b)$, in which case x^0 is referred to as a Slater point of $\sigma(b)$ (see [9, sect. 7.5]). Note that the continuity of $t \mapsto g_t\left(x^0\right)$ together with the compactness of T entails that x^0 is a Slater point of $\sigma(b)$ if and only if there exists some slack $\rho > 0$ such that $g_t\left(x^0\right) \leq b_t - \rho$ for all $t \in T$.

LEMMA 1. *Let $(c, b) \in \mathbb{R}^n \times C(T, \mathbb{R})$ and $x \in \mathbb{R}^n$. One has the following for the parametric problem* (1):

(i) *If $\sigma(b)$ satisfies the Slater condition, then $A_b(x)$ is closed* [9, Thm. 7.9].

(ii) *KKT conditions* (see [9, (7.9) and Thm. 7.8]): *If $x \in \mathcal{F}(b)$ and $(c + \partial f(x)) \cap A_b(x) \neq \emptyset$, then $x \in \mathcal{F}^*(c, b)$. The converse holds when $\sigma(b)$ satisfies the Slater condition.*

Next we recall some well-known continuity concepts for set-valued mappings. If $\mathcal{Y}$ and $\mathcal{Z}$ are two metric spaces and $\mathcal{H} : \mathcal{Y} \rightrightarrows \mathcal{Z}$ is a set-valued mapping, $\mathcal{H}$ is said to be *lower semicontinuous* (lsc, in brief), in the classical sense of Berge, at $y \in \mathcal{Y}$ if, for each open set $W \subset \mathcal{Z}$ such that $W \cap \mathcal{H}(y) \neq \emptyset$, there exists an open set $U \subset \mathcal{Y}$, containing y, such that $W \cap \mathcal{H}(y^1) \neq \emptyset$ for each $y^1 \in U$. The mapping $\mathcal{H}$ is *upper semicontinuous* (usc, for short), in the sense of Berge, at $y \in \mathcal{Y}$ if, for each open set $W \subset \mathcal{Z}$ such that $\mathcal{H}(y) \subset W$, there exists an open neighborhood of y in $\mathcal{Y}$, U, such that $\mathcal{H}(y^1) \subset W$ for every $y^1 \in U$. We say that $\mathcal{H}$ is *closed* at $y \in \mathcal{Y}$ if for all sequences $\{y^r\} \subset \mathcal{Y}$ and $\{z^r\} \subset \mathcal{Z}$ satisfying $\lim_{r\to\infty} y^r = y$, $\lim_{r\to\infty} z^r = z$, and $z^r \in \mathcal{H}(y^r)$, one has $z \in \mathcal{H}(y)$. Obviously, $\mathcal{H}$ is closed on $\mathcal{Y}$ (at every point $y \in \mathcal{Y}$) if the graph of $\mathcal{H}$, $gph(\mathcal{H}) := \{(y, z) \in \mathcal{Y} \times \mathcal{Z} : z \in \mathcal{H}(y)\}$, is closed (in the product topology). In what follows, $rge(\mathcal{H})$ will represent the image set of $\mathcal{H}$.

The following property of our optimal set mapping $\mathcal{F}^*$ is a straightforward consequence of [1, Thm. 4.3.3] and will be used later on.

LEMMA 2. *Let $(\bar{c}, \bar{b}) \in \mathbb{R}^n \times C(T, \mathbb{R})$. Assume that $\mathcal{F}$ is lsc at $\bar{b}$ and $\mathcal{F}^*(\bar{c}, \bar{b})$ is nonempty and bounded. Then $\mathcal{F}^*$ is usc at $(\bar{c}, \bar{b})$.*

Note that our mapping $\mathcal{F}$ is closed on $C(T, \mathbb{R})$ due to the continuity of each g_t. The lower semicontinuity of $\mathcal{F}$ turns out to be equivalent to other stability properties referred above (see [12] for a discussion about conditions (i)–(iii) in the following lemma).

LEMMA 3. (See [4, Thm. 2.1] for the linear case with equality/inequality constraints.) *Let $\bar{b} \in rge(\mathcal{G})$. The following statements are equivalent:*

(i) *$\sigma\left(\bar{b}\right)$ satisfies the Slater condition.*

(ii) *$\mathcal{F}$ is lsc at $\bar{b}$.*

(iii) $\bar{b} \in \text{int}(rge(\mathcal{G}))$.

(iv) *$\mathcal{G}$ is metrically regular at any $x \in \mathcal{F}\left(\bar{b}\right)$ for $\bar{b}$.*

(v)

$$0_n \notin conv\left(\bigcup_{t\in T_b(x)} \partial g_t(x)\right) \text{ for all } x \in \mathcal{F}\left(\overline{b}\right) \text{ such that } T_{\overline{b}}(x) \neq \emptyset. \tag{7}$$

Proof. (i)⇒(ii). Define the function $G : \mathbb{R}^n \times C(T,\mathbb{R}) \to \mathbb{R}$ by

$$G(x,b) := \max_{t\in T} (g_t(x) - b_t).$$

Hence $\mathcal{F}(b) = \{x \mid G(x,b) \leq 0\}$. By classical parametric optimization (cf., e.g., [2], [16]), G is continuous, since $(t,x,b) \mapsto g_t(x) - b_t$ is continuous and T is nonempty and compact. Obviously, for given b, $G(\cdot,b)$ is convex. Since for $x \in \mathcal{F}\left(\overline{b}\right)$ we have $G(x,\overline{b}) = 0$ if and only if $T_{\overline{b}}(x) \neq \emptyset$, statement (i) is equivalent to the existence of $\overline{x}$ such that $G(\overline{x},\overline{b}) < 0$. Now, Theorem 12 in [16] applies.

(ii)⇒(iii). It comes straightforwardly from the definitions, taking into account that (iii) may be interpreted as $\sigma\left(b^1\right)$ being consistent ($\mathcal{F}\left(b^1\right) \neq \emptyset$) for all b^1 in some neighborhood of $\overline{b}$.

(iii)⇒(i). It follows from the following fact: For $\varepsilon > 0$ small enough, $\mathcal{F}\left(b^\varepsilon\right) \neq \emptyset$, where $b^\varepsilon \in C\left(T,\mathbb{R}\right)$ is given by $b_t^\varepsilon := \overline{b}_t - \varepsilon$, $t \in T$. In this case, any feasible point of $\sigma\left(b^\varepsilon\right)$ is a Slater point of $\sigma\left(\overline{b}\right)$ with slack ε.

(iii)⇔(iv). This equivalence is established via the Robinson–Ursescu theorem (see, for instance, [6]) for mappings between Banach spaces having a closed convex graph. We have already mentioned that $gph(\mathcal{G})$ is closed, and it is also convex, due to the convexity of each g_t.

(i)⇔(v). With G as above, let $g(x) := G(x,\overline{b})$. Thus, (i) equivalently means that $g(\overline{x}) < 0$ is satisfied for some $\overline{x}$, which holds if and only if every point $x \in \mathcal{F}\left(\overline{b}\right)$ such that $T_{\overline{b}}(x) \neq \emptyset$ is not a minimum of g. By [15, Thm. VI.4.4.2], the latter is equivalent to the following fact: For every point $x \in \mathcal{F}\left(\overline{b}\right)$ such that $T_{\overline{b}}(x) \neq \emptyset$ we have

$$0_n \notin \partial g(x) = conv\left(\bigcup_{t\in T_b(x)} \partial g_t(x)\right),$$

and this is precisely (v). □

The following proposition accounts for some properties of $\mathcal{F}^*$ in relation to $\mathcal{F}$ (see also Lemma 2).

PROPOSITION 4. (i) *If* $(\overline{c},\overline{b}) \in \mathrm{int}(\Pi_s)$*, then* $\mathcal{F}^*(\overline{c},\overline{b})$ *is a nonempty bounded set.*

(ii) *Assume that* $(\overline{c},\overline{b}) \in \mathrm{int}(\Pi_c)$ *and that* $\mathcal{F}^*(\overline{c},\overline{b})$ *is a nonempty bounded set. Then* $(\overline{c},\overline{b}) \in \mathrm{int}(\Pi_s)$ *and* $\mathcal{F}^*(c,b)$ *is also a nonempty bounded set for* (c,b) *in a certain neighborhood of* $(\overline{c},\overline{b})$.

(iii) *If* $\mathcal{F}$ *is lsc at* $\overline{b}$*, then* $\mathcal{F}^*$ *is closed at* $\left(\overline{c},\overline{b}\right)$.

(iv) *If* $\mathcal{F}$ *is lsc at* $\overline{b}$ *and* $\mathcal{F}^*\left(\overline{c},\overline{b}\right)$ *is a singleton, then* $\mathcal{F}^*$ *is lsc at* $\left(\overline{c},\overline{b}\right)$.

Proof. (i) Let $(\overline{c},\overline{b}) \in \mathrm{int}(\Pi_s)$, and assume that $\mathcal{F}^*(\overline{c},\overline{b})$ is unbounded. Take $u \in O^+(\mathcal{F}^*(\overline{c},\overline{b}))$, $u'u = 1$, and consider the sequence in Π_c, $\left(\overline{c} - \frac{1}{r}u, \overline{b}\right)$, $r = 1,2,\ldots$, which obviously converges to $(\overline{c},\overline{b})$. Now, for $\lambda \geq 0$ and $\overline{x} \in \mathcal{F}^*(\overline{c},\overline{b}) \subset \mathcal{F}(\overline{b})$, and representing by v the optimal value of $P(\overline{c},\overline{b})$, we have

$$f(\overline{x} + \lambda u) + \left(\overline{c} - \frac{1}{r}u\right)'(\overline{x} + \lambda u) = v - \frac{1}{r}u'\overline{x} - \frac{\lambda}{r}.$$

By letting $\lambda \to +\infty$, it follows that the objective function of $P\left(\overline{c} - \frac{1}{r}u, \overline{b}\right)$ is unbounded from below, and this contradicts the assumption $(\overline{c}, \overline{b}) \in \operatorname{int}(\Pi_s)$.

(ii) Since $\mathcal{F}^*(\overline{c}, \overline{b})$ is nonempty and bounded, [15, Prop. IV.3.2.5] yields $\overline{h}0^+(y) > 0$ for all $y \neq 0_n$, where $\overline{h}$ is the function introduced in (6), associated to the nominal parameter $(\overline{c}, \overline{b})$. Since $\overline{h}0^+$ is lsc

$$\varepsilon := \min\{\overline{h}0^+(y) \mid \|y\|_* = 1\} > 0.$$

Consider any parameter (c, b) such that $\|c - \overline{c}\| < \varepsilon$ and that is close enough to $(\overline{c}, \overline{b})$ to be sure that $(c, b) \in \Pi_c$. If h is the associated function (see (6)) and $\|y\|_* = 1$, we can write

$$\begin{aligned} h0^+(y) &= f0^+(y) + c'y + \delta_{O^+(\mathcal{F}(b))}(y) \\ &= f0^+(y) + \overline{c}'y + \delta_{O^+(\mathcal{F}(\overline{b}))}(y) + (c - \overline{c})'y \\ &= \overline{h}0^+(y) + (c - \overline{c})'y \qquad (8) \\ &\geq \overline{h}0^+(y) - \|c - \overline{c}\| \\ &> \overline{h}0^+(y) - \varepsilon \geq 0. \end{aligned}$$

Since (8) entails $h0^+(y) > 0$ for all $y \neq 0_n$, [15, Prop. IV.3.2.5] implies that $\mathcal{F}^*(c, b)$ is a nonempty bounded set.

(iii) Since $\mathcal{F}$ is closed at $\overline{b}$, this is a classical result; see [16, Thm. 8].

(iv) Since $\mathcal{F}^*\left(\overline{c}, \overline{b}\right)$ is a singleton, it holds by definition that $\mathcal{F}^*$ is lsc at $\left(\overline{c}, \overline{b}\right)$ if $\mathcal{F}^*$ is both usc at $\left(\overline{c}, \overline{b}\right)$ and nonempty-valued near $\left(\overline{c}, \overline{b}\right)$. The first property follows from Lemma 2, the second one from Corollary 9.1 in [16]. ∎

Problem (1) fits into the more general class of parametric problems given by

$$\begin{aligned} \mathcal{P}(c, b): \quad & \operatorname{Inf} f(x) + c'x \\ & \text{s.t. } x \in \mathcal{M}(b), \end{aligned}$$

where f is any real-valued function defined on $\mathbb{R}^n$, $\mathcal{M}$ is any multifunction which maps a metric space $\mathcal{Y}$ to $\mathbb{R}^n$, and $(c, b) \in \mathbb{R}^n \times \mathcal{Y}$ varies in some neighborhood of $(\overline{c}, \overline{b}) \in \mathbb{R}^n \times \mathcal{Y}$. If we define

$$\mathcal{F}^*(c, b) := \arg\min\{f(x) + c'x \mid x \in \mathcal{M}(b)\},$$

we obtain the following result without any assumption about continuity.

LEMMA 5 (Corollary 4.7 in [19]). *Let $((\overline{c}, \overline{b}), \overline{x}) \in gph(\mathcal{F}^*)$. Then $\mathcal{F}^*$ is pseudo-Lipschitz at $((\overline{c}, \overline{b}), \overline{x})$ if and only if $\mathcal{F}^*$ is strongly Lipschitz stable at this point.*

Proof. To show the nontrivial direction, let $\mathcal{F}^*$ be pseudo-Lipschitz at $((\overline{c}, \overline{b}), \overline{x})$. Hence, by Corollary 4.7 in [19], $\mathcal{F}^*(c, b)$ is a singleton for (c, b) near $(\overline{c}, \overline{b})$. This implies strong Lipschitz stability at (and hence, by definition of that stability, *near*) $((\overline{c}, \overline{b}), \overline{x})$. ∎

3. A sufficient condition for the metric regularity of $\mathcal{G}^*$. This section provides a KKT-type condition which is sufficient for the metric regularity $\mathcal{G}^*$ at $\overline{x}$ for $\left(\overline{c}, \overline{b}\right) \in \mathcal{G}^*(\overline{x})$ in the context of convex problems (1). The relationship between this condition and the strong uniqueness of optimal solutions is explored, too. The specification of this KKT-type property for linear problems (4) turns out to be also

necessary for the metric regularity. The next example partially motivates this algebraic condition in the linear case.

Example 6. Consider the problem, in $\mathbb{R}^2$ (with the Euclidean norm),

$$P\left(\bar{c},\bar{b}\right) := \operatorname{Inf}\left\{x_1 \mid x_1 - x_2 \geq 0,\, x_1 + x_2 \geq 0,\, x_1 \geq 0\right\}.$$

Here $\bar{c} = (1,0)'$ and $\bar{b} = 0_3$.

One has $\mathcal{F}^*\left(\bar{c},\bar{b}\right) = \{0_2\}$. If we consider the perturbed problem $P\left(c^r,b^r\right)$, with $b^r := (0,0,1/r)'$ and $c^r = \left(1,-1/r^2\right)$, we have $\mathcal{F}^*\left(c^r,b^r\right) = \left\{\left(\frac{1}{r},\frac{1}{r}\right)\right\}$. So, by taking $x^r = \left(\frac{1}{r},0\right)'$, we obtain

$$d\left(x^r,\mathcal{F}^*\left(c^r,b^r\right)\right) = \frac{1}{r} \quad \text{and} \quad d\left(\left(c^r,b^r\right),\mathcal{G}^*\left(x^r\right)\right) \leq d\left(\left(c^r,b^r\right),\left(\bar{c},b^r\right)\right) = \frac{1}{r^2}.$$

Hence, $d\left(x^r,\mathcal{F}^*\left(c^r,b^r\right)\right) \geq r d\left(\left(c^r,b^r\right),\mathcal{G}^*\left(x^r\right)\right)$, $r = 1,2,\ldots$. Therefore, $\mathcal{G}^*$ is not metrically regular at 0_2 for $\left(\bar{c},\bar{b}\right)$.

The key fact in this example is that $\bar{c}$ belongs to the convex cone generated by *one* vector, associated with the active constraints in $\overline{x}$, in the *two*-dimensional Euclidean space. The following property, referred to as a given $\left(\overline{x},\left(\bar{c},\bar{b}\right)\right) \in gph(\mathcal{G}^*)$ in the linear case (4), avoids the previous situation (here $|D|$ denotes the cardinality of D):

$$\begin{array}{l} \sigma\left(\bar{b}\right) \text{ satisfies the Slater condition and there is no } D \subset T_{\bar{b}}\left(\overline{x}\right) \\ \text{with } |D| < n \text{ such that } \bar{c} \in cone\left(\{a_t,\ t \in D\}\right). \end{array} \tag{9}$$

The following natural extension of (9) for the convex problem (1) will play a crucial role in this section; in fact, it constitutes the announced sufficient condition for the metric regularity of $\mathcal{G}^*$ at $\left(\overline{x},\left(\bar{c},\bar{b}\right)\right)$:

$$\begin{array}{l} \sigma\left(\bar{b}\right) \text{ satisfies the Slater condition and there is no } D \subset T_{\bar{b}}\left(\overline{x}\right) \\ \text{with } |D| < n \text{ such that } \left(\bar{c} + \partial f(\overline{x})\right) \cap cone\left(\displaystyle\bigcup_{t\in D}\left(-\partial g_t\left(\overline{x}\right)\right)\right) \neq \emptyset. \end{array} \tag{10}$$

Remark 7. Observe that condition (9) does not imply the linear independence of $\{a_t,\ t \in T_{\bar{b}}(\overline{x})\}$. Consider the example resulting from replacing the third constraint in Example 6 with any of the other two (which would appear twice in the system).

Remark 8. In the case $n = 1$, condition (10) reads as follows: $\sigma\left(\bar{b}\right)$ satisfies the Slater condition and $0 \notin \bar{c} + \partial f(\overline{x})$ (which entails $T_{\bar{b}}\left(\overline{x}\right) \neq \emptyset$).

PROPOSITION 9. *Assume that* $\left(\overline{x},\left(\bar{c},\bar{b}\right)\right) \in gph(\mathcal{G}^*)$ *verifies* (10). *Then the following conditions hold:*

(i) *There exists a neighborhood* W *of* $\left(\overline{x},\left(\bar{c},\bar{b}\right)\right)$ *such that* (10) *is satisfied when* $\left(\overline{x},\left(\bar{c},\bar{b}\right)\right)$ *is replaced by any* $(x,(c,b)) \in W \cap gph(\mathcal{G}^*)$.

(ii) *There exist* $u \in \partial f(\overline{x})$ *as well as some* $u_{t_i} \in -\partial g_{t_i}\left(\overline{x}\right)$, $t_i \in T_{\bar{b}}\left(\overline{x}\right)$, *and some* $\lambda_i > 0$ *for* $i \in \{1,\ldots,n\}$, *such that* $\{u_{t_1},\ldots,u_{t_n}\}$ *is a basis of* $\mathbb{R}^n$ *and*

$$u + \bar{c} = \sum_{i=1}^{n} \lambda_i u_{t_i}.$$

(iii) $\mathcal{F}^*\left(\bar{c},\bar{b}\right) = \{\overline{x}\}$.

(iv) $\mathcal{F}^*$ *is lsc at* $\left(\bar{c},\bar{b}\right)$.

As a consequence of the previous statements, one has the following condition:

(v) *There exists a neighborhood V of $\left(\bar{c},\bar{b}\right)$ such that $\mathcal{F}^*$ is single-valued and continuous on V.*

Proof. (i) From the equivalence (i)⇔(iii) in Lemma 3, it is clear that $\sigma(b)$ fulfills the Slater condition for b close enough to $\bar{b}$. Now, reasoning by contradiction, assume that there exists $\{(x^r,(c^r,b^r))\}\subset gph(\mathcal{G}^*)$ converging to $\left(\overline{x},\left(\bar{c},\bar{b}\right)\right)$ as well as some subgradients $u^r\in\partial f(x^r)$, $u^r_{t^r_i}\in-\partial g_{t^r_i}(x^r)$, $t^r_i\in T_{b^r}(x^r)$, $\lambda^r_i\geq 0$, $i=1,\ldots,n-1$, $r=1,2,\ldots$, such that we can write

$$u^r+c^r=\sum_{i=1}^{n-1}\lambda^r_i u^r_{t^r_i}. \tag{11}$$

In this expression we have made use of the convexity of the involved subdifferential sets.

For each $i\in\{1,\ldots,n-1\}$ the sequence $\{t^r_i\}$ has a subsequence (still denoted by $\{t^r_i\}$, for simplicity) converging to certain $\bar{t}_i\in T_{\bar{b}}(\overline{x})$, since T is compact and $g_{\bar{t}_i}(\overline{x})-\bar{b}_{\bar{t}_i}=\lim_r\left(g_{t^r_i}(x^r)-b^r_{t^r_i}\right)=0$. Let us see that the sequence $\{\gamma_r\}_{r\in\mathbb{N}}$ given by $\gamma_r:=\sum_{i=1}^{n-1}\lambda^r_i$, $r=1,2,\ldots$, must be bounded. Otherwise, we may assume without loss of generality (considering suitable subsequences) that $\lim_{r\to\infty}\gamma_r=+\infty$ and the sequence $\left\{\frac{\lambda^r_i}{\gamma_r}\right\}_{r\in\mathbb{N}}$ converges to certain $\mu_i\geq 0$ for each $i\in\{1,\ldots,n-1\}$. So, dividing by γ_r in (11) and letting $r\to+\infty$ we have (considering again appropriate subsequences of $\left\{u^r_{t^r_i}\right\}_{r\in\mathbb{N}}$ for each i)

$$\begin{aligned} &0_n=\sum_{i=1}^{n-1}\mu_i u_{\bar{t}_i},\\ &\text{with }\sum_{i=1}^{n-1}\mu_i=1\ \text{ and }\ u_{\bar{t}_i}:=\lim_r u^r_{t^r_i}\in-\partial g_{\bar{t}_i}(\overline{x}),\quad i=1,\ldots,n-1, \end{aligned} \tag{12}$$

where we have applied [24, Thm. 24.5] to sequences $\left\{g_{t^r_i}\right\}_{r\in\mathbb{N}}$, $i=1,\ldots,n-1$, and $\{x^r\}_{r\in\mathbb{N}}$ (here the continuity of $t\mapsto g_t(x)$, for all $x\in\mathbb{R}^n$, is essential to allow the use of the referred theorem). In this way we attain a contradiction with (7) in Lemma 3.

Once we have established the boundedness of $\{\gamma_r\}_{r\in\mathbb{N}}$, we may assume without loss of generality that, for each $i\in\{1,\ldots,n-1\}$, the sequence $\{\lambda^r_i\}_{r\in\mathbb{N}}$ converges to certain $\beta_i\geq 0$, $\left\{u^r_{t^r_i}\right\}_{r\in\mathbb{N}}$ converges again to certain $u_{\bar{t}_i}\in-\partial g_{\bar{t}_i}(\overline{x})$, and $\{u^r\}_{r\in\mathbb{N}}$ converges to some $u\in\partial f(\overline{x})$ (appealing again to [24, Thm. 24.5]). Thus, letting $r\to\infty$ in (11) we obtain

$$u+\bar{c}=\sum_{i=1}^{n-1}\beta_i u_{\bar{t}_i},\ \text{with }\left\{\bar{t}_1,\ldots,\bar{t}_{n-1}\right\}\subset T_{\bar{b}}(\overline{x}),$$

contradicting (10).

(ii) It follows easily from the KKT conditions (see Lemma 1), property (10), and Carathéodory's theorem.

(iii) Let $u+\bar{c}$ be represented as in (ii). If there exists $y\in\mathcal{F}^*\left(\bar{c},\bar{b}\right)\setminus\{\overline{x}\}$, then we have, by using convexity of f and taking into account

$$0\geq g_{t_i}(y)-\bar{b}_{t_i}=g_{t_i}(y)-g_{t_i}(\overline{x})\geq-u'_{t_i}(y-\overline{x})$$

as well as $\lambda_i > 0$, $i = 1, 2, \ldots, n$,

$$0 = f(y) + \bar{c}'y - f(\overline{x}) - \bar{c}'\overline{x} \geq (u + \bar{c})'(y - \overline{x})$$

$$= \sum_{i=1}^{n} \lambda_i u'_{t_i}(y - \overline{x}) \geq 0.$$

Thus, we obtain $u'_{t_i}(y - \overline{x}) = 0$ for $i = 1, \ldots, n$, contradicting the fact that $\{u_{t_1,\ldots,}u_{t_n}\}$ is a basis of $\mathbb{R}^n$.

(iv) It is a straightforward consequence of (iii) above and Proposition 4(iv) (recall also that (i)⇔(ii) in Lemma 3).

(v) Take a neighborhood $U_0 \times V_0$ of $\left(\overline{x}, \left(\bar{c}, \bar{b}\right)\right)$ contained in certain W verifying (i). Due to (iv) we may consider a neighborhood of $\left(\bar{c}, \bar{b}\right)$, say $V \subset V_0$, such that $\mathcal{F}^*(c, b) \cap U_0 \neq \emptyset$ for all $(c, b) \in V$. Now, for each $(c, b) \in V$, there exists $x \in \mathcal{F}^*(c, b) \cap U_0$, and so $(x, (c, b)) \in W \cap gph(\mathcal{G}^*)$ and (i) together with (iii) entail $\mathcal{F}^*(c, b) = \{x\}$. Finally, the continuity of the single-valued mapping $\mathcal{F}^*|_V$ comes from (i) and (iv). □

Next we present a sufficient condition for metric regularity of $\mathcal{G}^*$. By Lemma 5, the latter is equivalent to the strong Lipschitz stability of $\mathcal{F}^*$.

THEOREM 10. *For the convex semi-infinite program* (1)*, let* $\left(\overline{x}, \left(\bar{c}, \bar{b}\right)\right) \in gph(\mathcal{G}^*)$. *If condition* (10) *holds, then* $\mathcal{G}^*$ *is metrically regular at* $\overline{x}$ *for* $\left(\bar{c}, \bar{b}\right)$.

Proof. Reasoning by contradiction, assume that (10) holds, but $\mathcal{G}^*$ is not metrically regular at $\overline{x}$ for $\left(\bar{c}, \bar{b}\right)$. According to the equivalence between metric regularity of a mapping and the Aubin property of its inverse (see (5)), there must exist a sequence $\{x^r\}_{r\in\mathbb{N}} \subset \mathbb{R}^n$ converging to $\overline{x}$ and two sequences of parameters $\{(c^r, b^r)\}_{r\in\mathbb{N}}$ and $\left\{\left(\bar{c}^r, \bar{b}^r\right)\right\}_{r\in\mathbb{N}}$, both converging to $\left(\bar{c}, \bar{b}\right)$, such that, for all $r \in \mathbb{N}$, $x^r \in \mathcal{F}^*(c^r, b^r)$ and

$$d\left(x^r, \mathcal{F}^*\left(\bar{c}^r, \bar{b}^r\right)\right) > r d\left((c^r, b^r), \left(\bar{c}^r, \bar{b}^r\right)\right). \tag{13}$$

Because of condition (v) in Proposition 9 we may assume without loss of generality that, for all r, $\mathcal{F}^*\left(\bar{c}^r, \bar{b}^r\right)$ is a singleton, say $\mathcal{F}^*\left(\bar{c}^r, \bar{b}^r\right) = \{\overline{x}^r\}$. The continuity of $\mathcal{F}^*$ at $\left(\bar{c}, \bar{b}\right)$ ensures that the sequence $\{\overline{x}^r\}$ converges to $\overline{x}$ (see again Proposition 9(v)). Moreover (13) ensures, for all r, $x^r \neq \overline{x}^r$ and

$$\frac{\sup_{t\in T}\left|b_t^r - \bar{b}_t^r\right|}{\|x^r - \overline{x}^r\|} < \frac{1}{r}. \tag{14}$$

According to conditions (i) and (ii) in Proposition 9 we can write, for r large enough,

$$u^r + c^r = \sum_{i=1}^{n} \lambda_i^r u_{t_i^r}^r \quad \text{and} \quad \overline{u}^r + \bar{c}^r = \sum_{i=1}^{n} \overline{\lambda}_i^r \overline{u}_{\overline{t}_i^r}^r \tag{15}$$

for certain subgradients $u^r \in \partial f(x^r)$, $\overline{u}^r \in \partial f(\overline{x}^r)$, $u_{t_i^r}^r \in -\partial g_{t_i^r}(x^r)$, $\overline{u}_{\overline{t}_i^r}^r \in -\partial g_{\overline{t}_i^r}(\overline{x}^r)$, associated with certain indices $t_i^r \in T_{b^r}(x^r)$ and $\overline{t}_i^r \in T_{\bar{b}^r}(\overline{x}^r)$, and certain positive scalars $\lambda_i^r, \overline{\lambda}_i^r$ for $i = 1, 2, \ldots, n$. Moreover, following the same argument as in the proof of Proposition 9(i), we may assume that for each $i = 1, \ldots, n$, the sequences $\left\{\lambda_i^r\right\}_{r\in\mathbb{N}}$ and $\left\{\overline{\lambda}_i^r\right\}_{r\in\mathbb{N}}$ converge to some λ_i and $\overline{\lambda}_i$, respectively. We may also assume that, for each i, the sequences $\left\{t_i^r\right\}_{r\in\mathbb{N}}$ and $\left\{\overline{t}_i^r\right\}_{r\in\mathbb{N}}$ involved in (15) converge to t_i and $\overline{t}_i$, respectively, both belonging to $T_{\bar{b}}(\overline{x})$, and that $\{u^r\}_{r\in\mathbb{N}}$, $\{\overline{u}^r\}_{r\in\mathbb{N}}$, $\left\{u_{t_i^r}^r\right\}_{r\in\mathbb{N}}$,

and $\left\{\overline{u}^r_{t^r_i}\right\}_{r\in\mathbb{N}}$ converge to certain u, $\overline{u}\in\partial f(\overline{x})$, $u_{t_i}\in-\partial g_{t_i}(\overline{x})$, and $\overline{u}_{\bar{t}_i}\in-\partial g_{\bar{t}_i}(\overline{x})$, respectively. Thus (15) leads us to

$$u+\overline{c}=\sum_{i=1}^{n}\lambda_i u_{t_i}\quad\text{ and }\quad\overline{u}+\overline{c}=\sum_{i=1}^{n}\overline{\lambda}_i\overline{u}_{\bar{t}_i}. \tag{16}$$

Moreover, condition (10) together with Carathéodory's theorem ensures all λ_i and $\overline{\lambda}_i$ are positive and that, at the same time, $\{u_{t_1},\ldots,u_{t_n}\}$ and $\left\{\overline{u}_{\bar{t}_1},\ldots,\overline{u}_{\bar{t}_n}\right\}$ are both bases of $\mathbb{R}^n$.

On the other hand, since, for each i and each r, we have $g_{t^r_i}(x^r)=b^r_{t^r_i}$, and $g_{t^r_i}(\overline{x}^r)\le\bar{b}^r_{t^r_i}$ (recall $t^r_i\in T_{b^r}(x^r)$ and $\overline{x}^r\in\mathcal{F}(\bar{b}^r)$), we can write

$$u'_{t^r_i}\frac{x^r-\overline{x}^r}{\|x^r-\overline{x}^r\|}=-u'_{t^r_i}\frac{\overline{x}^r-x^r}{\|x^r-\overline{x}^r\|}\le\frac{g_{t^r_i}(\overline{x}^r)-g_{t^r_i}(x^r)}{\|x^r-\overline{x}^r\|}\le\frac{\bar{b}^r_{t^r_i}-b^r_{t^r_i}}{\|x^r-\overline{x}^r\|}<\frac{1}{r}, \tag{17}$$

where the last inequality comes from (14). By considering again a suitable subsequence, it is clear that $\left\{\frac{x^r-\overline{x}^r}{\|x^r-\overline{x}^r\|}\right\}_{r\in\mathbb{N}}$ may be assumed to converge to some $z\in\mathbb{R}^n$ with $\|z\|=1$. Hence letting $r\to\infty$ in (17) we obtain $u'_{t_i}z\le0$ for all $i=1,\ldots,n$. Consequently, (16) ensures

$$(u+\overline{c})'z\le0. \tag{18}$$

A completely symmetric argument entails $\overline{u}'_{\bar{t}_i}z\ge0$ for $i=1,\ldots,n$, and, hence,

$$(\overline{u}+\overline{c})'z\ge0. \tag{19}$$

This yields $u'z\le\overline{u}'z$. To show that we have even equality, we note that by convexity of f,

$$f(x^r)\ge f(\overline{x}^r)+(\overline{u}^r)'(x^r-\overline{x}^r)\quad\text{ and }\quad f(\overline{x}^r)\ge f(x^r)+(u^r)'(\overline{x}^r-x^r).$$

This implies

$$(\overline{u}^r)'(x^r-\bar{x}^r)\le f(x^r)-f(\overline{x}^r)\le(u^r)'(x^r-\bar{x}^r).$$

Hence, dividing by $\|x^r-\bar{x}^r\|$ and taking the limit yields $\overline{u}'z\le u'z$, which establishes $\overline{u}'z=u'z$. Consequently, expressions (18) and (19) coincide, and then

$$(u+\overline{c})'z=(\overline{u}+\overline{c})'z=0.$$

Finally, appealing to the first equality of (16), and recalling that $u'_{t_i}z\le0$ and $\lambda_i>0$ for all i, we conclude $u'_{t_i}z=0$ for $i=1,\ldots,n$. This, recalling that $z\neq0_n$, represents a contradiction with the fact that $\{u_{t_1},\ldots,u_{t_n}\}$ is a basis of $\mathbb{R}^n$. This completes the proof. □

Remark 11. Condition (10) is not necessary for metric regularity of the mapping $\mathcal{G}^*$. Just consider the optimization problem, in $\mathbb{R}^2$,

$$\begin{aligned}P(c,b):\quad&\text{Inf } x_1^2+x_2+c_1x_1+c_2x_2\\&\text{s.t. } x_1\ge b_1,\ x_2\ge b_2.\end{aligned}$$

Note that, in a neighborhood of $\left(\bar{c},\bar{b}\right)=(0_2,0_2)$, $\mathcal{F}^*$ is the Lipschitz function given by $\mathcal{F}^*(c,b)=\{(\max\{-c_1/2,b_1\},b_2)\}$, and then $\mathcal{G}^*$ is metrically regular at $\bar{x}=0_2$ for $\left(\bar{c},\bar{b}\right)$. However, condition (10) fails.

Remark 12. In fact, condition (10) is in general rather strong for metric regularity: as we will see, it implies a first order growth condition on f at $\overline{x}$ with respect to $\sigma(\bar{b})$, namely, the strong uniqueness of $\overline{x}$ as a minimizer of $P\left(\bar{c},\bar{b}\right)$ (see (20)), and moreover at least n constraints have to be active at $\overline{x}$. It is well known for finite nonlinear optimization problems with twice differentiable data that already certain second order growth conditions—which also typically hold in the situation of less than n active constraints—are sufficient and necessary for metric regularity of $\mathcal{G}^*$; see, e.g., [19, Chap. 8] and [20]. Generalizing this to the nonlinear semi-infinite case remains an open problem. However, in the next section we will see that for linear semi-infinite programs, condition (10) is indeed needed for metric regularity of $\mathcal{G}^*$ at $\overline{x}$ for $(\bar{c},\bar{b})$.

The rest of this section is concerned with the relationship between condition (10) and the strong uniqueness of a minimizer in the context of convex optimization. For continuously differentiable data f and g_t and under the Slater condition, property (ii) of Proposition 9 (recall that it is a consequence of condition (10)) is known as a sufficient condition for $\overline{x}$ to be a (locally) strongly unique minimizer of $P(\bar{c},\bar{b})$; see Theorem 3.1.16 in [14]. In the linear case, condition (10) turns out to be equivalent even to persistence of strong unicity under small parameter changes (see section 4 for details). In the following paragraphs we show how condition (10) is still sufficient for the latter property but no longer necessary.

Here, we say that $x \in \mathcal{F}(b)$ is a *strongly unique minimizer* of $P(c,b)$ if there exists a positive scalar α such that

$$f(y) + c'y \geq f(x) + c'x + \alpha \|y - x\| \text{ for all } y \in \mathcal{F}(b). \tag{20}$$

Obviously, in that case $\mathcal{F}^*(c,b) = \{x\}$. (Note that the convexity assumptions allow us to formulate the previous definition in global terms, not only in a neighborhood of x.) The following lemma characterizes the strong uniqueness of optimal solutions in terms of perturbations of vector c (which generalizes the linear version given in [9, Thm. 10.5]).

LEMMA 13. *A point x is the* strongly unique optimal solution *of $P(c,b)$ if and only if there exists $\varepsilon > 0$ such that $\|\widetilde{c} - c\| < \varepsilon$ implies $x \in \mathcal{F}^*(\widetilde{c},b)$ (in fact, for possibly smaller ε, x is the strongly unique solution of $P(\widetilde{c},b)$).*

Proof. According to [23, Chap. 5, Lem. 3] and [24, Thm. 23.8], x is a strongly unique optimal solution of $P(c,b)$ or, equivalently, of the problem

$$\operatorname*{Inf}_{x\in\mathbb{R}^n} \left\{ f(x) + c'x + \delta_{\mathcal{F}(b)}(x) \right\},$$

if and only if

$$0_n \in \operatorname{int}\{c + \partial(f + \delta_{\mathcal{F}(b)})(x)\} = c + \operatorname{int}\{\partial(f + \delta_{\mathcal{F}(b)})(x)\}$$

holds. The latter is equivalent to

$$0_n \in \widetilde{c} + \partial(f + \delta_{\mathcal{F}(b)})(x) \text{ for } \widetilde{c} \text{ close enough to } c,$$

i.e., $x \in \mathcal{F}^*(\widetilde{c},b)$ for $\widetilde{c}$ close enough to c. To ensure the last assertion, just take $\widetilde{c}$ such that $0_n \in \widetilde{c} + \operatorname{int}\left\{\partial(f + \delta_{\mathcal{F}(b)})(x)\right\}$. □

PROPOSITION 14. *If condition* (10) *holds at $\left(\overline{x},\left(\bar{c},\bar{b}\right)\right) \in gph(\mathcal{G}^*)$, then $\overline{x}$ is the strongly unique optimal solution of $P\left(\bar{c},\bar{b}\right)$.*

Proof. From Proposition 9(ii) there exist $u \in \partial f(\overline{x})$ as well as some $u_{t_i} \in -\partial g_{t_i}(\overline{x})$, $t_i \in T_{\bar{b}}(\overline{x})$, and some $\lambda_i > 0$ for $i \in \{1,\ldots,n\}$, such that $\{u_{t_1},\ldots,u_{t_n}\}$ is

a basis of $\mathbb{R}^n$ and

$$u + \bar{c} = \sum_{i=1}^{n} \lambda_i u_{t_i}.$$

So, $u + \bar{c} \in \text{int}(cone\,(\{u_{t_1}, \ldots, u_{t_n}\}))$. Hence, if $\|\widetilde{c} - \bar{c}\|$ is small enough, then

$$u + \widetilde{c} \in cone\,(\{u_{t_1}, \ldots, u_{t_n}\}),$$

which entails $\overline{x} \in \mathcal{F}^*\left(\widetilde{c}, \overline{b}\right)$. Thus, applying the previous lemma, $\overline{x}$ is the strongly unique optimal solution of $P\left(\overline{c}, \overline{b}\right)$. □

Remark 15. Actually, under condition (10), we have that $\left(\overline{c}, \overline{b}\right) \in \text{int}(\{(c, b) : P(c, b) \text{ has a strongly unique optimal solution}\})$ as a consequence of Proposition 9(i) and (v) (the latter ensures that all problems in a certain neighborhood have optimal solutions and (i) entails that these solutions are strongly unique). However, the converse statement does not hold. Just consider the parametrized convex problem, in which condition (10) fails trivially ($|T| = 1$, while the problem is posed in $\mathbb{R}^2$):

$$P(c, b) := \text{Inf}\{c_1 x_1 + c_2 x_2 \mid |x_1| - x_2 \leq b\},$$

around $\left(\overline{c}, \overline{b}\right) = ((0, 1)', 0)$. In fact, one can easily check that

$$\mathcal{F}^*(c, b) = \{(0, -b)\} \text{ if } \|c - \overline{c}\| < \frac{1}{\sqrt{2}},$$

and, since $\mathcal{F}^*(c, b)$ does not depend on c, we immediately conclude that $(0, -b)$ is a strongly unique optimal solution of $P(c, b)$ when $\|c - \overline{c}\| < \frac{1}{\sqrt{2}}$. (We used the Euclidean norm.)

Finally, note that the metric regularity property is sufficient neither for condition (9) nor for strong uniqueness. Just consider the example of Remark 11 and note that $\overline{x}$ is not a locally strongly unique minimizer of $P(0_2, 0_2)$, considering the feasible ray $\{(t, 0) \mid t \geq 0\}$.

4. Characterization of the metric regularity of $\mathcal{G}^*$ for linear problems. The following theorem provides the announced characterizations of the metric regularity of $\mathcal{G}^*$ for linear semi-infinite problems (4). Note that condition (v) is nothing else but (9). Moreover, condition (vi) comes from adapting to our notation Nürnberger's condition introduced in [22]. Actually, [22, Thm. 1.4] provides the counterpart of the equivalence (vi)⇔(vii) in the context in which perturbations of the a_t's are also allowed. The equivalence also holds, requiring only the boundedness of the a_t's, without continuity assumptions in the model (see [13, Thm. 4.1]).

THEOREM 16. *For the linear semi-infinite program* (4)*, let* $\left(\overline{x}, \left(\overline{c}, \overline{b}\right)\right) \in gph(\mathcal{G}^*)$. *Then the following conditions are equivalent:*

(i) $\mathcal{G}^*$ *is metrically regular at* $\overline{x}$ *for* $\left(\overline{c}, \overline{b}\right)$.

(ii) $\mathcal{F}^*$ *is strongly Lipschitz stable at* $\left(\left(\overline{c}, \overline{b}\right), \overline{x}\right)$.

(iii) $\mathcal{F}^*$ *is locally single-valued and continuous in some neighborhood of* $(\overline{c}, \overline{b})$.

(iv) $\mathcal{F}^*$ *is single-valued in some neighborhood of* $\left(\overline{c}, \overline{b}\right)$.

(v) $\sigma\left(\overline{b}\right)$ *satisfies the Slater condition and there is no* $D \subset T_{\overline{b}}(\overline{x})$ *with* $|D| < n$ *such that* $\overline{c} \in cone\,(\{a_t,\ t \in D\})$.

(vi) $\sigma\left(\overline{b}\right)$ *satisfies the Slater condition and for each* $D \subset T_{\overline{b}}(\overline{x})$ *with* $|D| = n$ *such that* $\overline{c} \in cone\,(\{a_t,\ t \in D\})$*; we have that all the possible subsets with* n *elements of* $\{a_t,\ t \in D\} \cup \{\overline{c}\}$ *are linearly independent.*

(vii) $\left(\bar{c},\bar{b}\right) \in \operatorname{int}\left(\{(c,b) : \mathcal{F}^*(c,b) \text{ consists of a strongly unique minimizer}\}\right)$.

Proof. The equivalence (i)⇔(ii) is nothing else but Lemma 5.

(ii)⇒(iii)⇒(iv). They are obvious consequences of the respective definitions.

(iv)⇒(v). From (iv) we immediately conclude that $\left(\bar{c},\bar{b}\right) \in \operatorname{int}\left(rge(\mathcal{G}^*)\right)$, which obviously implies $\bar{b} \in \operatorname{int}\left(rge(\mathcal{G})\right)$ and, from Lemma 3, $\mathcal{G}$ is metrically regular at $\overline{x}$ for $\bar{b}$ and $\sigma\left(\bar{b}\right)$ satisfies the Slater condition. In fact, if $S\left(\bar{b}\right)$ denotes the set of Slater points of $\sigma\left(\bar{b}\right)$, then one has $S\left(\bar{b}\right) = \operatorname{int}\left(\mathcal{F}\left(\bar{b}\right)\right)$ [9, Ex. 6.1]. Take $\widehat{x} \in S\left(\bar{b}\right)$ and define, for each $r \in \mathbb{N}$,

$$x^r := \overline{x} + \frac{1}{r}\left(\widehat{x} - \overline{x}\right) \in \operatorname{int}\left(\mathcal{F}\left(\bar{b}\right)\right)$$

(by the accessibility lemma).

Suppose, reasoning by contradiction, that $\bar{c} = \sum_{i=1}^{k} \lambda_i a_{t_i}$, with $t_i \in T_{\bar{b}}(\overline{x})$ and $\lambda_i > 0$ for $i = 1,\ldots,k$ and $k < n$. Now choose $u \in \{a_{t_1},\ldots,a_{t_k}\}^{\perp}$ with $\|u\| = 1$, whose existence is guaranteed by $k < n$. Then, since $x^r \in \operatorname{int}\left(\mathcal{F}\left(\bar{b}\right)\right)$, there exists some scalar α_r such that $y^r := x^r + \alpha_r u \in \mathcal{F}\left(\bar{b}\right)$, and we shall take $\alpha_r \in \left]0, 1/r\right]$. Define, for each $r \in \mathbb{N}$,

$$b_t^r := (1 - \varphi_r(t)) \min\{a_t' x^r, a_t' y^r\} + \varphi_r(t)\,\bar{b}_t,$$

where $\varphi_r : T \to [0,1]$ is a continuous function verifying

$$\varphi_r(t) = 0 \ \text{ if } t \in \{t_1,\ldots,t_k\} \quad \text{and} \quad \varphi_r(t) = 1 \ \text{ if } a_t'\overline{x} - \bar{b}_t \geq \tfrac{1}{r}.$$

The existence of such a φ_r is guaranteed by Urysohn's lemma. If $\left\{t \in T \mid a_t'\overline{x} - \bar{b}_t \geq \frac{1}{r}\right\}$ is empty, we take $\varphi_r \equiv 0$. Observe that $x^r, y^r \in \mathcal{F}\left(\bar{b}\right)$ implies that $x^r, y^r \in \mathcal{F}\left(b^r\right)$ for all r. Moreover, from the choice of u, we have $\{t_1,\ldots,t_k\} \subset T_{b^r}(x^r) \cap T_{b^r}(y^r)$, and $\bar{c} = \sum_{i=1}^{k} \lambda_i a_{t_i}$ ensures $x^r, y^r \in \mathcal{F}^*\left(\bar{c}, b^r\right)$ for all r (see Lemma 1). Now, let us show that $\lim_{r\to\infty} b^r = \bar{b}$. In fact, in the nontrivial case $a_t'\overline{x} - \bar{b}_t < \frac{1}{r}$ (otherwise $b_t^r = \bar{b}_t$) we have

$$\begin{aligned}
\left|b_t^r - \bar{b}_t\right| &\leq (1 - \varphi(t))\left|\min\{a_t' x^r, a_t' y^r\} - \bar{b}_t\right| \\
&\leq \max\left\{\left|a_t' x^r - \bar{b}_t\right|, \left|a_t' y^r - \bar{b}_t\right|\right\} \\
&\leq \left|a_t' x^r - \bar{b}_t\right| + \left|a_t'\left(y^r - x^r\right)\right| \\
&\leq \left|a_t'\left(x^r - \overline{x}\right)\right| + \left(a_t'\overline{x} - \bar{b}_t\right) + \|a_t\|_* \frac{1}{r} \\
&\leq \frac{1}{r}\left(1 + (1 + \|\widehat{x} - \overline{x}\|) \max_{t\in T} \|a_t\|_*\right),
\end{aligned}$$

just recalling the definition of x^r. Hence

$$\left\|b^r - \bar{b}\right\|_\infty \leq \frac{1}{r}\left(1 + (1 + \|\widehat{x} - \overline{x}\|) \max_{t\in T} \|a_t\|_*\right).$$

In this way, we provided a sequence $\{b^r\}_{r\in\mathbb{N}}$ converging to $\bar{b}$ such that $\mathcal{F}^*\left(\bar{c}, b^r\right)$ is not a singleton, which contradicts (iv).

(v)⇒(i). This follows from Theorem 10.

(v)⇔(vi) comes from standard arguments of linear algebra. Once we have established the equivalence among all conditions (i) to (vi), note that (vi)⇒(vii) comes from [22, Thm. 1.4] by taking into account that perturbations (c, b) are a particular case of perturbations of all coefficients. Finally, (vii)⇒(iv) is trivial. □

Remark 17. Example 4.6 in [20] shows that in the convex case (even for finite programs) the metric regularity of $\mathcal{G}^*$ (or, equivalently, strong Lipschitz stability of $\mathcal{F}^*$) does not necessarily hold if $\mathcal{F}^*$ is Kojima-stable (locally single-valued and continuous). This is in contrast to the linear semi-infinite case treated in the foregoing theorem.

5. Concluding remarks. The following diagram summarizes the main results of the paper concerning the convex case (1). The question of whether or not the strong uniqueness of an optimal solution for (c, b) near $(\bar{c}, \bar{b})$ implies the metric regularity of $\mathcal{G}^*$ at $(\overline{x}, (\bar{c}, \bar{b}))$ remains an open problem. Observe that condition (10) strictly implies the others in the diagram. Nevertheless, it is the only one which can be checked from the nominal problem's data, without involving parameters in a neighborhood.

$$\left\{\begin{array}{c}\text{Condition (10)}\\ \text{at } (\overline{x}, (\bar{c}, \bar{b})) \in gph\mathcal{G}^*\end{array}\right\} \underset{\substack{\Rightarrow\\ \not\Leftarrow}}{\overset{\text{Rem. 15}}{\underset{\text{Rem. 15}}{}}} \left(\bar{c}, \bar{b}\right) \in \operatorname{int}\left\{(c,b): \begin{array}{c}P(c,b) \text{ has a}\\ \text{strongly unique}\\ \text{minimizer}\end{array}\right\}$$

$$\text{Thm. 10} \Downarrow \quad \not\Uparrow \text{ Rem. 11} \qquad\qquad \not\Uparrow \text{ Rem. 15}$$

$$\left\{\begin{array}{c}\mathcal{G}^*\text{is metrically regular}\}\\ \text{at } (\overline{x}, (\bar{c}, \bar{b})) \in gph\mathcal{G}^*\end{array}\right\} \underset{\text{Lemma 5}}{\Leftrightarrow} \left\{\begin{array}{c}\mathcal{F}^* \text{ is single-valued and Lipschitz}\\ \text{in a neighborhood of } (\overline{x}, (\bar{c}, \bar{b}))\\ \text{(strongly Lipschitz stable)}\end{array}\right\}$$

$$\text{obvious} \Downarrow \quad \not\Uparrow \text{ Rem. 17}$$

$$\left\{\begin{array}{c}\mathcal{F}^* \text{ is single-valued and continuous}\\ \text{in a neighborhood of } (\overline{x}, (\bar{c}, \bar{b}))\\ \text{(Kojima-type stability)}\end{array}\right\}$$

When confined to the linear case, Theorem 16 establishes the equivalence among all of the conditions above.

ON THE EXISTENCE OF SOLUTIONS TO DIFFERENTIAL INCLUSIONS WITH NONCONVEX RIGHT-HAND SIDES*

M. I. KRASTANOV†, N. K. RIBARSKA‡, AND TS. Y. TSACHEV§

Abstract. We study the existence of solutions of differential inclusions with upper semicontinuous right-hand sides. The investigation was prompted by the well-known Filippov examples. We define a new concept, "colliding on a set." In the case when the admissible velocities do not "collide" on the set of discontinuities of the right-hand side, we expect that at least one trajectory emanates from every point. If the velocities do "collide" on the set of discontinuities of the right-hand side, the existence of solutions is not guaranteed, as is seen from one of Filippov's examples. In this case we impose an additional condition in order to prove the existence of a solution starting at a point of the discontinuity set. For the right-hand sides under consideration, we assume the following: whenever the velocities "collide" on a set S there exist tangent velocities (belonging to the Clarke tangent cone to S) on a dense subset of S. Then we prove the existence of an ε-solution for every $\varepsilon > 0$. Under additional assumptions we can pass to the limit as $\varepsilon \to 0$ and obtain a solution of the considered differential inclusion.

Key words. differential inclusions with nonconvex right-hand sides, existence of solutions, colliding on a set

1. Introduction.

We study the existence of solutions of the differential inclusion

$$\dot{x} \in F(x), \quad x(0) = x_0, \tag{1.1}$$

with upper semicontinuous right-hand side F. Our attention is focused on the existence in the autonomous case alone, and we are not going to discuss questions like uniqueness of the solution, continuous dependence on the initial conditions, etc.

Filippov proved the existence of a solution of (1.1) for the case of upper semicontinuous right-hand side F with *convex* and compact values (cf., for example, [14], [15], [16]). Since then the convexity assumption on the right-hand side has been of universal use in the calculus of variations and optimal control when differential inclusions are involved. Filippov's convexifying approach, however, because of its generality, does not always provide the best result. A longstanding open problem is the existence of solutions of differential inclusions with upper semicontinuous right-hand sides with nonconvex values. As is seen from the well-known Filippov examples (cf., for example, [16]), such a solution does not always exist.

The question of whether solutions exist for continuous F without convex values was raised by Hermes in [18] and solved by Filippov in [15]. This was generalized to the case of lower semicontinuous right-hand sides, by Bressan [5] (cf. also [4], [6], [7]) by means of the selection approach, and by Lojasiewicz in [20] and [21] by means of

Filippov's method. Existence results unifying the continuous and the convex cases were obtained by Olech in [22] (cf. also [19]) and by Lojasiewicz in [21], who proved existence assuming lower semicontinuity on an open set and convexity plus upper semicontinuity on its complement.

Bressan, Cellina, and Colombo studied in [9] the existence of solutions to differential inclusions with upper semicontinuous cyclically monotone right-hand sides. Recall that a multifunction A: $R^n \to R^n$ is called cyclically monotone if for every cyclical sequence $x_0, x_1, \ldots, x_N = x_0$ (N-arbitrary) and every sequence $y_i \in A(x_i)$, $i = 1, \ldots, N$, we have $\sum_{i=1}^{N} \langle x_i - x_{i-1}, y_i \rangle \geq 0$, where as usual $\langle ., . \rangle$ denotes the inner product of R^n. These multifunctions are exactly the upper semicontinuous ones, the graph of which is contained in the subdifferential of a proper convex function (cf. [25]). The last result along these lines, known to the authors, was obtained in [3] by Bounkhel and Haddad. A direct corollary of their result is that (1.1) has a solution if the right-hand side is an upper semicontinuous map with compact values, the graph of which is contained in the graph of the proximal subdifferential of a uniformly regular lower semicontinuous function. Another result, obtained by Veliov in [26], already proved to be very useful in studying invariance, stability, and attainability properties of a given compact set with respect to a differential inclusion. It yields the existence of solutions of differential inclusions with right-hand sides of the form

$$F(x) = \left\{ \eta \in G(x) : \ D^- \psi(x; \eta) \leq \phi(x) \right\},$$

where G is an upper semicontinuous map with compact convex values, ψ is a locally Lipschitz function, ϕ is an upper semicontinuous real-valued function, and D^- denotes the lower Dini derivative. Another interesting result was presented by Cellina and Ornelas in [10].

As we already mentioned, Bressan in [5] and Lojasiewicz in [20] and [21] proved the existence of a solution with lower semicontinuous right-hand side F, possibly not convex valued. On the other hand, having an arbitrary upper semicontinuous multivalued mapping F, it is well known (cf. Fort [17]) that it is not lower semicontinuous on a first Baire category set. But a set of first Baire categories may have a very complicated structure. However, if a positive real ε is fixed, then the set where F is not ε-lower semicontinuous is contained in a closed set with empty interior. (It is said that F is ε-lower semicontinuous at the point $\hat{x}$ if there exists an open set U containing $\hat{x}$ and such that $F(\hat{x}) \subset F(x) + \varepsilon B$ for each $x \in U$.) This is one of the possible motivations to work with ε-approximations of F.

Another motivation is given by a general fact about upper semicontinuous multivalued mappings, namely, a selection theorem of Srivatsa. To formulate it, we need the following definition (cf. Ribarska [23]).

DEFINITION 1.1. *Let X be a topological space and let*

$$\mathcal{U} = \{U_\alpha : \ 1 \leq \alpha < \alpha_0\}$$

be a well-ordered family of its subsets. It is said that $\mathcal{U}$ is a relatively open partitioning of X iff

(i) *U_α is contained in $X \setminus \left(\bigcup_{\beta<\alpha} U_\beta \right)$ and it is relatively open in it for every α;*
(ii) *$X = \bigcup_{1 \leq \alpha < \alpha_0} U_\alpha$.*

Note that each element of a relatively open partitioning is an intersection of an open and a closed set. Particular cases of such partitionings appear in [8] (cf. also [13]) in a proof (much simpler than the original one) for the lower semicontinuous

case, and in [1] in the definition of the so-called *patchy vector field* which was used for constructing piecewise constant stabilizing feedback control.

Now we formulate the above-mentioned selection theorem (Srivatsa [24]).

THEOREM 1.2. *Let $F : X \Rightarrow Y$ be an upper semicontinuous multivalued mapping, where X is a metric space and Y is a convex subset of a normed linear space. Then F has a selector f which is of the first Baire class and which is a uniform limit of functions, each of them constant on the elements of some relatively open partitioning of X.*

The simple structure of the functions uniformly approximating the selector f prompts us to study the problem of the existence of ε-solutions of the original problem, i.e., we are looking for an absolutely continuous function $x : [0,T] \to R^n$ such that

$$\begin{cases} \dot{x}(t) \in F(x(t)) + \varepsilon \bar{B} \ \text{ a.e. on } [0,T], \\ x(0) = x_0. \end{cases}$$

But the simple Filippov examples show that finding an ε-solution is not a trivial task. Consider

$$F_1(x) = \begin{cases} 1 & \text{if } x < 0, \\ \{-1,1\} & \text{if } x = 0, \\ -1 & \text{if } x > 0 \end{cases} \quad \text{and} \quad F_2(x) = \begin{cases} -1 & \text{if } x < 0, \\ \{-1,1\} & \text{if } x = 0, \\ 1 & \text{if } x > 0. \end{cases}$$

The inclusion $\dot{x} \in F_1(x)$ does not have a solution when $x(0) = 0$. It does not even have an ε-solution for $\varepsilon \in (0,1)$ and $x(0) = 0$. The inclusion $\dot{x} \in F_2(x)$ has a solution for any x_0.

The geometric intuition suggests that the reason for the nonexistence of a solution in the first Filippov example is that the corresponding vector field "collides" on the set of discontinuity of the right-hand side. In the present paper we define rigorously the concept of "colliding on a set" (section 3). In the case when the admissible velocities do not "collide" on the set of discontinuity of the right-hand side, one can expect that at least one trajectory emanates from every point. If the velocities do "collide" on the set of discontinuity of the right-hand side, the existence of solutions is not guaranteed, as is seen from the first Filippov example. In this case one needs to impose an additional condition in order to prove the existence of a solution starting at a point of the discontinuity set. For the right-hand sides under consideration, we assume the following: whenever the velocities "collide" on a set S there exist tangent velocities (belonging to the Clarke tangent cone to S) on a dense subset of S. Then we prove the existence of an ε-solution of (1.1) for every $\varepsilon > 0$ (section 4). Under additional assumptions we can pass to the limit as $\varepsilon \to 0$ and obtain a solution of (1.1) (section 5).

2. Preliminaries and technical lemmas. For any sets $S_1, S_2 \subseteq R^n$ and $\eta \in R$, we set $S_1 + \eta S_2 := \{s_1 + \eta s_2 : s_1 \in S_1, s_2 \in S_2\}$. Also, $B_r(p) := \{x \in R^n : \|x - p\| < r\}$, $\bar{B}_r(p)$ is the closure of $B_r(p)$ for all $p \in R^n$, $B := B_1(0)$, and $\bar{B} := \bar{B}_1(0)$.

The principal nonsmooth objects used in this paper are the proximal subgradient and normal cone, and here we review these concepts; see [11] for a complete treatment. Let $S \subseteq R^n$ be closed and $s \in S$. A vector $\zeta \in R^n$ is called a *proximal normal* vector of S at s provided there exists $\sigma = \sigma(\zeta, s) > 0$ so that

$$\langle \zeta, s' - s \rangle \le \sigma ||s' - s||^2 \quad \text{for all } s' \in S. \tag{2.1}$$

The set of all proximal normals of S at s is denoted by $\hat{N}_S(s)$ and is a convex cone. One can show (cf. [11, p. 25]) that for each $\delta > 0$ and $s \in S$, $\zeta \in \hat{N}_S(s)$ iff there exists $\sigma = \sigma(\zeta, s) > 0$ so that

$$\langle \zeta, s' - s \rangle \leq \sigma ||s' - s||^2 \quad \text{for all } s' \in S \cap \delta \mathcal{B}_n(s). \tag{2.2}$$

By $N_S(x)$ we denote the set of all limiting normals to S at x, which is defined as follows:

$$N_S(x) := \left\{ \zeta : \zeta = \lim_{n\to\infty} \zeta_n,\ \zeta_n \in \hat{N}_S(x_n),\ x = \lim_{n\to\infty} x_n \right\}.$$

The Bouligand tangent cone $T_S(x)$ to S at the point x is defined in the following way:

$$T_S(x) := \left\{ v : v = \lim_{n\to\infty} \frac{x_n - x}{t_n},\ x_n \in S,\ x = \lim_{n\to\infty} x_n,\ \lim_{n\to\infty} t_n = 0,\ t_n > 0 \right\}.$$

At last, we say that v belongs to the Clarke tangent cone $\hat{T}_S(x)$ to S at x if for each sequence $\{x_n\}_{n=1}^{\infty}$ of points of S and for each sequence $\{t_n\}_{n=1}^{\infty}$ of positive numbers decreasing to zero there exists a sequence $\{v_n\}_{n=1}^{\infty}$ converging to v such that $x_n + t_n v_n \in S$ for all n.

Recall that the *distance function* $d_S(\cdot) : R^n \to R$ is given by $d_S(x) := \min\{\|x - s\| : s \in S\}$. Then $\zeta \in \hat{N}_S(s)$ iff there exists $\varepsilon > 0$ such that $d_S(s + t\zeta) = t\|\zeta\|$ for all $t \in (0, \varepsilon)$.

For the related functional concept, assume that $f : R^n \to (-\infty, \infty]$ is lower semicontinuous and let $x \in \text{domain}(f) := \{x' : f(x') < \infty\}$. Then $\xi \in R^n$ is called a *proximal subgradient* for f at x provided there exist $\sigma > 0$ and $\eta > 0$ so that

$$f(x') \geq f(x) + \langle \xi, x' - x \rangle - \sigma \|x' - x\|^2 \quad \text{for all } x' \in B_\eta(x). \tag{2.3}$$

The set of all proximal subgradients for f at x is denoted by $\partial^P f(x)$. This set could be empty at some points, even for C^1 functions (e.g., the proximal subgradient of $f(x) = -|x|^{3/2}$ at $x = 0$ is empty). Recall that the *epigraph* $\text{epi } f \subseteq R^{n+1}$ of $f : R^n \to [-\infty, +\infty]$ is the set $\{(x, r) : r \geq f(x)\}$, and is closed iff f is lower semicontinuous. Two fundamental facts are as follows:

$$\xi \in \partial^P f(x) \Longleftrightarrow (\xi, -1) \in \hat{N}_{\text{epi} f}(x, f(x)) \quad \text{for all } x \in \text{domain}(f),$$

$$\zeta \in \partial^P d_S(x) \Longleftrightarrow x + d_S(x)\zeta \in \text{proj}_S(x) \quad \text{for all } x \in R^n \setminus S, \tag{2.4}$$

where $\text{proj}_S(x) := \{s \in S : d_S(x) = \|x - s\|\}$ is called the set of all *projections* of x into S.

LEMMA 2.1. *Let $S = U \cap G$, where U is an open subset of R^n and G is a closed subset of R^n. Let $F : U \Rightarrow R^n$ be an upper semicontinuous map with convex and compact values. Moreover, let the set $F(U)$ be bounded. Then there exists an open subset V of U containing S such that $\text{proj}_G(x) \subset U$ for each point $x \in V$. If*

$$\min \{\langle x - z, v \rangle : z \in \text{proj}_G(x),\ v \in F(z)\} \leq 0 \tag{2.5}$$

for every $x \in V$, then the set S is weakly invariant with respect to F, i.e., for each point $x \in S$ there exist $t_x > 0$ and an absolutely continuous function $\varphi : [0, t_x] \to S$ such that $\dot{\varphi}(t) \in F(\varphi(t))$ for almost every $t \in [0, t_x]$.

Proof. Define the set V to be

$$V := \left\{x \in R^n : d_G(x) < d_{R^n \setminus U}(x)\right\}.$$

Clearly, V is an open subset of U containing S. If $x \in V$, then for every point $z \in \mathrm{proj}_G(x)$ we have

$$\|z - x\| = d_G(x) < d_{R^n \setminus U}(x),$$

i.e., $z \notin R^n \setminus U$. Thus $\mathrm{proj}_G(x) \subset U$.

According to (2.5), for each $x \in V$ there exist $z_x \in \mathrm{proj}_G(x)$ and $v_x \in F(z_x)$ such that $\langle x - z_x, v_x\rangle \le 0$. For every $x \in V$, take any of these v_x and define $\theta(x) := v_x$.

Let x be an arbitrary point of S. Take $t_x > 0$ in such a way that $x + t_x.cB \subset V$, where c is an upper bound of the set $\{\|y\| : y \in F(x),\, x \in U\}$. Let

$$\pi := \{t_0 = 0, t_1, \ldots, t_{n-1}, t_n = t_x\}$$

be a partition of the interval $[0, t_x]$ and let φ_π be the corresponding Euler arc, i.e.,

$$\varphi_\pi(t_0) := x,\ \varphi_\pi(t) := \varphi_\pi(t_{i-1}) + (t - t_{i-1})\,\theta\left(\varphi_\pi(t_{i-1})\right)$$

for $t_{i-1} \le t \le t_i$ and $i = 1, 2, \ldots, n$.

According to the choice of t_x, $\varphi_\pi(\cdot)$ is well defined on $[0, t_x]$ and is contained in V. We have for every $i = 1, 2, \ldots, n$ and for every $t \in (t_{i-1}, t_i]$

$$\begin{aligned} d_S^2\left(\varphi_\pi(t)\right) &\le \left\|\varphi_\pi(t) - z_{\varphi_\pi(t_{i-1})}\right\|^2 = \left\|\varphi_\pi(t_{i-1}) + (t - t_{i-1})\,\theta\left(\varphi_\pi(t_{i-1})\right) - z_{\varphi_\pi(t_{i-1})}\right\|^2 \\ &\le \left\|\varphi_\pi(t_{i-1}) - z_{\varphi_\pi(t_{i-1})}\right\|^2 + (t - t_{i-1})^2\,\left\|\theta\left(\varphi_\pi(t_{i-1})\right)\right\|^2 \\ &\quad + 2(t - t_{i-1})\left\langle \varphi_\pi(t_{i-1}) - z_{\varphi_\pi(t_{i-1})}, \theta\left(\varphi_\pi(t_{i-1})\right)\right\rangle \\ &\le d_S^2\left(\varphi_\pi(t_{i-1})\right) + (t - t_{i-1})^2\, c^2 \le d_S^2\left(\varphi_\pi(t_{i-1})\right) + (t_i - t_{i-1})^2\, c^2. \end{aligned}$$

Denote

$$\mu_\pi := \max_{1 \le i \le n} (t_i - t_{i-1}).$$

Then summing up the above inequalities for $i = 1, 2, \ldots, k$ and for $t \in (t_{k-1}, t_k)$, we obtain

$$d_S^2\left(\varphi_\pi(t)\right) \le d_S^2\left(\varphi_\pi(t_0)\right) + c^2 \sum_{i=1}^{k} (t_i - t_{i-1})^2 \tag{2.6}$$

$$\le d_S^2\left(\varphi_\pi(t_0)\right) + c^2 \mu_\pi \sum_{i=1}^{k} (t_i - t_{i-1}) \le d_S^2\left(\varphi_\pi(t_0)\right) + c^2 \mu_\pi t_x = c^2 \mu_\pi t_x.$$

Now let $\{\pi_j\}_{j=1}^{\infty}$ be a sequence of partitions such that $\mu_{\pi_j} \to 0$ as $j \to \infty$ and necessarily $n_j \to \infty$. Then the family $\left\{\varphi_{\pi_j}\right\}_{j=1}^{\infty}$ is equicontinuous and uniformly bounded. According to the Arzelà–Ascoli theorem, some subsequence of $\left\{\varphi_{\pi_j}\right\}_{j=1}^{\infty}$ converges uniformly to a continuous function $\varphi(\cdot)$ on $[0, t_x]$. The limiting function

inherits the Lipschitz constant c on $[0, t_x]$, and hence it is absolutely continuous. Passing to the limits in (2.6) with $\pi = \pi_j$ as $j \to \infty$, we obtain

$$d_S^2(\varphi(t)) \leq 0$$

for every $t \in [0, t_x]$, i.e., for $t \in [0, t_x]$

$$\varphi(t) \in S. \tag{2.7}$$

Define the multivalued map

$$F_S(x) := \overline{co} \bigcup_{y \in \mathrm{proj}_S(x)} F(y) \quad \text{for } x \in V.$$

Because of the upper semicontinuity and the boundedness of $F(\cdot)$, and of the compactness of the set $\mathrm{proj}_G(x)$ for every $x \in V$, $F_S(x)$ is a compact and convex set. Since the multivalued map $x \Rightarrow \mathrm{proj}_G(x)$ is upper semicontinuous, the map $x \Rightarrow F_S(x)$ is also upper semicontinuous. Moreover, by construction $\theta(\cdot)$ is a selection of $F_S(\cdot)$. By Corollary 1.12 on p. 186 in [11], $\varphi(\cdot)$ is a solution of

$$\begin{cases} \dot{x}(t) \in F_S(x(t)) \ \text{ a.e. on } [0, t_x], \\ x(0) = x. \end{cases}$$

Because $F_S(\cdot)$ and $F(\cdot)$ coincide on the set S, (2.7) implies that $\varphi(\cdot)$ is a solution of

$$\begin{cases} \dot{x}(t) \in F(x(t)) \ \text{ a.e. on } [0, t_x], \\ x(0) = x. \end{cases}$$

This completes the proof. □

Remark. If in the assumptions of Lemma 2.1 we replace (2.5) by

$$\min \{\langle \zeta, v \rangle : v \in F(z)\} \leq 0 \tag{2.8}$$

for each $z \in S$ with $\hat{N}_S(z) \neq \emptyset$ and for each $\zeta \in \hat{N}_S(z)$, the conclusion of Lemma 2.1 remains true, because (2.8) implies (2.5).

LEMMA 2.2. *Let $G : X \Rightarrow R^n$ be an upper semicontinuous uniformly bounded map defined on a complete metric space X and let $\varepsilon > 0$ be fixed. Then there exists an open and dense subset W of X such that for each $x_0 \in W$ there exists an open neighborhood V of x_0 with*

$$G(x_0) \subset G(x) + \varepsilon B \tag{2.9}$$

whenever $x \in V$.

Proof. Let $M > 0$ be such that $\|G(x)\| \leq M$ for each $x \in X$. Take $\{y_1, y_2, \ldots, y_k\} \subset R^n$ to be a finite $\varepsilon/2$-net for the closed ball $M\bar{B}$ centered at the origin with radius M. The upper semicontinuity implies that the sets

$$X_i = \left\{ x \in X : G(x) \bigcap \left(y_i + \frac{\varepsilon}{2} \bar{B} \right) \neq \emptyset \right\}, \ i = 1, 2, \ldots, k,$$

are closed. We set

$$W := \bigcap_{i=1}^{k} \left((X \setminus X_i) \bigcup \text{ int } X_i \right).$$

The set W is an open and dense subset of X. Take an arbitrary $x_0 \in W$ and denote

$$I(x_0) = \left\{ i : G(x_0) \bigcap \left(y_i + \frac{\varepsilon}{2} \bar{B} \right) \neq \emptyset \right\}.$$

Now, we set

$$V := \{ x \in W : I(x) = I(x_0) \}.$$

Clearly, V is an open subset of X and $x_0 \in V$. To validate the assertion of Lemma 2.2, take $x \in V$. Then verify

$$G(x_0) \subset \bigcup_{i \in I(x_0)} \left(y_i + \frac{\varepsilon}{2} \bar{B} \right) = \bigcup_{i \in I(x)} \left(y_i + \frac{\varepsilon}{2} \bar{B} \right) \subset \bigcup_{y \in G(x)} \left(y + \varepsilon \bar{B} \right) = G(x) + \varepsilon \bar{B}.$$

This completes the proof. □

LEMMA 2.3. *Let $S = U \bigcap K$, where U is an open subset of R^n and K is a closed subset of R^n. Let $c > 0$ and $\varepsilon > 0$ be fixed. Then there exists a relatively open and dense in S subset W of S such that for each $x_0 \in W$ there exists an open neighborhood V of x_0 with*

$$\hat{T}_S(x) \bigcap c \, \bar{B} \subset T_S(x_0) \bigcap c \, \bar{B} + \varepsilon B \tag{2.10}$$

for every point $x \in V$.

Proof. Let S be endowed with the inherited topology of R^n and let $G : S \Rightarrow R^n$ be defined as

$$G(x) := N_S(x) \bigcap c \, \bar{B}.$$

According to Proposition 6.6 on p. 202 in [25], G is upper semicontinuous and uniformly bounded. Applying Lemma 2.2, we get an open relatively dense in S set W such that for every point $x_0 \in W$ there exists a relatively open neighborhood V of x_0 with

$$N_S(x_0) \bigcap c \, \bar{B} \subset N_S(x) \bigcap c \, \bar{B} + \varepsilon B \tag{2.11}$$

whenever $x \in V$.

Assume that (2.10) does not hold. Then there exists $w \in \hat{T}_S(y) \bigcap c \, \bar{B}$ with $y \in V$ such that

$$w \notin T_S(x_0) \bigcap c \, \bar{B} + \varepsilon B.$$

According to Proposition 6.27 on p. 219 in [25], there exists $v \in N_S(x_0) \bigcap B$ satisfying

$$d_{T_S(x_0)}(w) = \langle v, w \rangle.$$

Because of (2.11),

$$cv \in N_S(x) \bigcap c \, \bar{B} + \varepsilon B,$$

i.e., $cv = v_1 + \varepsilon v_2$ with $v_1 \in N_S(x) \bigcap c \, \bar{B}$ and $v_2 \in B$. Hence,

$$\langle v, w \rangle = \left\langle \frac{v_1}{c}, w \right\rangle + \frac{\varepsilon}{c} \langle v_2, w \rangle \leq 0 + \varepsilon = \varepsilon,$$

i.e., $d_{T_S(x_0)}(w) \leq \varepsilon$, which is a contradiction. Thus (2.10) holds true. □

3. Colliding on a set. Let D be an intersection of an open and a closed subset of R^n, let $x_0 \in D$ and $T > 0$, and let $F : D \Rightarrow R^n$ be an upper semicontinuous mapping with nonempty compact values which are uniformly bounded.

DEFINITION 3.1. *Let us fix an arbitrary $\varepsilon > 0$. It is said that F does not ε-collide from D to the point $\hat{x}$ of D iff there exist a subset A of D and a multivalued map $G : A \Rightarrow R^n$ defined on it such that*

(i) *the set A is an intersection of an open and a closed set, and $\hat{x} \in A \cap \mathrm{cl}(\mathrm{int}\ A)$ (here* int *A denotes the interior of A relatively in D);*

(ii) *G is an upper semicontinuous convex valued map with $G(x) \subset F(x) + \varepsilon B$ for each $x \in A$;*

(iii) *for each point $x \in (\partial A) \cap A$ (here (∂A) denotes the boundary of A relatively in D) and for each $\zeta \in \hat{N}_A(x)$ there exists $v \in G(x)$ with*

$$\langle \zeta,\, v \rangle \,\leq\, 0. \tag{3.1}$$

Lemma 2.1 shows that the differential inclusion $\dot{x} \in F(x)$ with $x(0) = x_0$ has an ε-solution on a small time interval whenever $x_0 \in A$ and D is open in R^n (here A and D relate to $F(\cdot)$ as in Definition 3.1).

PROPOSITION 3.2. *The following assertions hold true:*

(a) *If F is ε-lower semicontinuous at $\hat{x} \in D$, then F does not ε-collide from D to the point $\hat{x}$. Therefore the subset of D consisting of all points to which F does not ε-collide contains a dense relatively open subset of D.*

(b) *If F is upper semicontinuous and convex valued on an open neighborhood V of $\hat{x} \in D$, then F does not ε-collide from D to $\hat{x}$.*

Proof. Part (b) is obvious, because we can set A to be $V \cap D$ and G to be F. For part (a), let V be an open (in D) neighborhood of $\hat{x}$ with $F(\hat{x}) \subset F(x) + \varepsilon B$ whenever $x \in V$. We set $A := V$ and $G(x) := \hat{y}$ for every $x \in A$, $\hat{y}$ being an arbitrarily fixed point of $F(\hat{x})$. The last statement in part (a) is an immediate corollary of Lemma 2.2 and the first statement. □

Another class of multivalued maps which do not ε-collide at any point consists of the monotone maps and some of their generalizations (cf. [12]).

DEFINITION 3.3. *The operator $T : X \Rightarrow X^*$ is called hypomonotone if for every $x_0 \in X$ there exist $\delta > 0$ and $\rho > 0$ such that for all $x_1,\ x_2 \in B_\delta(x_0)$ and for all $\xi_i \in T(x_i)$, $i = 1, 2$, we have*

$$\langle \xi_2 - \xi_1, x_2 - x_1 \rangle \geq -\rho \|x_1 - x_1\|^2.$$

PROPOSITION 3.4. *Let D be an open subset of R^n and let $F : D \Rightarrow R^n$ be an upper semicontinuous hypomonotone multivalued map with nonempty compact values. Then F does not ε-collide from D to any point $\hat{x}$ of D for every $\varepsilon > 0$.*

Proof. Let us fix $\hat{x} \in D$ and $\varepsilon > 0$. Denote $R := \max\{\|y\| :\ y \in F(\hat{x})\}$ and choose $\hat{y}$ in $F(\hat{x})$ with $\|\hat{y}\| = R$. The Euclidean norm in R^n being uniformly convex, we are able to find $r > 0$ and $\alpha > 0$ such that the slice

$$S = \left\{ y \in \bar{B}_{R+r}(\theta) :\ \langle y, \hat{y} \rangle \geq R^2 - \alpha \right\}$$

has diameter less than ε. Let $\tilde{S}$ be the smaller slice

$$\tilde{S} = \left\{ y \in \bar{B}_{R+r}(\theta) :\ \langle y, \hat{y} \rangle \geq R^2 - \frac{\alpha}{2} \right\}.$$

The positive numbers $\rho > 0$ and $\delta > 0$ come from the definition of hypomonotonicity of F at $\hat{x}$. Put

$$\beta = \min\left\{\frac{\delta}{2}, \frac{\alpha}{4\rho R^2}\right\} > 0.$$

Then the set $C = (F^{-1}(\tilde{S}) \cap \bar{B}_\beta(\hat{x})) + \left[0, \frac{\alpha}{2\rho R^2}\right]\hat{y}$ is closed in D because of the upper semicontinuity of F at $\hat{x}$. Here $F^{-1}(\tilde{S}) = \{x \in D : \ F(x) \cap \tilde{S} \neq \emptyset\}$. The set $U = B_\beta(\hat{x}) \cap \{x \in D : \ F(x) \subset B_{R+r}(\theta)\}$ is relatively open in D and contains $\hat{x}$. Now $A = C \cap U$ and $G(x) := S$ for each $x \in A$ satisfy the conditions in Definition 3.1. Indeed, let $z \in A$, that is, $z = x + t\hat{y}$ and $z \in U$ with $\|x - \hat{x}\| \leq \beta$ and $F(x) \cap \tilde{S} \neq \emptyset$. Let z^* be an arbitrary element of $F(z)$ and $y \in F(x) \cap \tilde{S}$. Then $\langle z^* - y, z - x\rangle \geq -\rho\|z - x\|^2$; therefore for each $t \in \left(0, \frac{\alpha}{2\rho R^2}\right]$

$$\begin{aligned}\langle z^*, \hat{y}\rangle &= \frac{1}{t}\langle z^*, z - x\rangle \geq \frac{1}{t}\langle y, z - x\rangle - \frac{\rho}{t}\|z - x\|^2 \\ &= \langle y, \hat{y}\rangle - \rho t\|\hat{y}\|^2 \geq R^2 - \frac{\alpha}{2} - \rho R^2 t \geq R^2 - \alpha.\end{aligned}$$

Thus $F(z) \subset S$ whenever $t > 0$. Otherwise $z \in F^{-1}(\tilde{S}) \subset F^{-1}(S)$. We see that in both cases (ii) is satisfied for every $z \in A$ because diam $(S) < \varepsilon$ and so $S \subset F(z) + \varepsilon B$.

The above reasoning (applied with $x := \hat{x}$ and $y := \hat{y}$) shows that if $z = \hat{x} + t\hat{y}$ with $t \in (0, \beta)$, then $\langle z^*, \hat{y}\rangle > R^2 - \frac{\alpha}{2}$ for each $z^* \in F(z)$, that is, $F(z) \subset$ int $\tilde{S}$, and by the upper semicontinuity of F we find a (relatively) open set V with $z \in V$ and $V \subset F^{-1}(\text{int } \tilde{S}) \cap B_\beta(\tilde{x}) \subset C$. So $\hat{x} \in A \cap$ cl(int A) and (i) is satisfied. Now let $x \in \partial A$ and $\xi \in \hat{N}_A(x)$. Then $x \in A$ implies that $x = \tilde{x} + \tilde{t}\hat{y}$ with $t \in \left[0, \frac{\alpha}{2\rho R^2}\right)$ and $\tilde{x} \in F^{-1}(\tilde{S}) \cap B_\beta(\hat{x})$ ($\tilde{t} \neq \frac{\alpha}{2\rho R^2}$ because $\beta \leq \frac{\alpha}{4\rho R^2}$). Hence again the points $z = x + t\hat{y}$ belong to A for all $t > 0$ sufficiently small. This yields

$$\langle \xi, z - x\rangle \leq \sigma\|z - x\|^2, \text{ i.e., } \langle \xi, \hat{y}\rangle \leq \sigma t\|\hat{y}\|^2$$

for every sufficiently small $t > 0$. Hence $\langle \xi, \hat{y}\rangle \leq 0$ and $\hat{y} \in S = G(x)$. This completes the proof of the proposition. □

In particular, since every monotone map is hypomonotone, monotone (and, of course, cyclically monotone) maps do not ε-collide. Also, the proximal subdifferentials of uniformly regular lower semicontinuous functions (see Definition 3.5 below) are hypomonotone too.

DEFINITION 3.5 (cf. [3]). *Let U be a nonempty open subset of R^n and let $f : U \to R^n$ be a lower semicontinuous function. We say that f is uniformly regular over U if there exists $\beta \geq 0$ such that for all $x \in U$ and for all $\xi \in \partial^P f(x)$ one has*

$$\langle \xi, x' - x\rangle \leq f(x') - f(x) + \beta\|x' - x\|^2 \quad \textit{for all } x' \in U.$$

To prove that $\partial^P f(x)$ is hypomonotone, take arbitrary $x_1, x_2 \in U$ and $\xi_i \in \partial^P f(x_i)$, $i = 1, 2$. Then summing the inequalities

$$f(x_2) - f(x_1) - \langle \xi_1, x_2 - x_1\rangle \geq -\beta\|x_2 - x_1\|^2,$$

$$f(x_1) - f(x_2) - \langle \xi_2, x_1 - x_2\rangle \geq -\beta\|x_2 - x_1\|^2,$$

we obtain

$$\langle \xi_2 - \xi_1, x_2 - x_1\rangle \geq -2\beta\|x_2 - x_1\|^2.$$

Example 1. Let C be the graph of a function $f : R \to R$ which is not absolutely continuous on any subinterval of R. Consider $F : R^2 \Rightarrow R^2$ defined by

$$F(x_1,x_2)=\begin{cases}\{(1,1)\} & \text{if } x_2 < f(x_1);\\ \text{co}\,\{(1,-1),(1,1),(1,-2)\} & \text{if } x_2 = f(x_1);\\ \{(1,-1)\} & \text{if } x_2 \in \left[f(x_1)+\dfrac{1}{4k}, f(x_1)+\dfrac{1}{4k-1}\right];\\ \{(1,-2)\} & \text{if } x_2 \in \left[f(x_1)+\dfrac{1}{4k+2}, f(x_1)+\dfrac{1}{4k+1}\right];\\ \{(1,-1),(1,-2)\} & \text{if } x_2 \in \left(f(x_1)+\dfrac{1}{4k+3}, f(x_1)+\dfrac{1}{4k+2}\right);\\ \{(1,-1),(1,-2)\} & \text{if } x_2 \in \left(f(x_1)+\dfrac{1}{4k+1}, f(x_1)+\dfrac{1}{4k}\right),\end{cases}$$

where k denotes a positive integer. Then F is lower semicontinuous on $R^2 \setminus C$ and upper semicontinuous and convex valued on C. As C is a closed set, the differential inclusion $\dot{x} \in F(x)$ has a solution according to Theorem 1 of [21]. It is easy to see that F does not satisfy Definition 3.1 for every point of C and each $\varepsilon \in (0, 1/2)$. Nevertheless, there exists an upper semicontinuous convex-valued map $G : R^2 \Rightarrow R^2$ (not contained in the ε-neighborhood of F) such that every solution of $\dot{x} \in G(x)$ is a solution of $\dot{x} \in F(x)$.

Example 2. Consider $F : R^3 \Rightarrow R^3$ defined by

$$F(x_1,x_2,x_3)=\begin{cases}\{(0,0,-1)\} & \text{if } x_3 > 0,\\ \{(0,0,1)\} & \text{if } x_3 < 0,\\ \{(0,0,\pm 1),(0,1,0)\} & \text{if } x_3 = 0 \text{ and } x_2 < 0,\\ \{(0,0,\pm 1),(0,-1,0)\} & \text{if } x_3 = 0 \text{ and } x_2 > 0,\\ \{(0,0,\pm 1),(0,\pm 1,0),(-1,0,0)\} & \text{if } x_3 = x_2 = 0 \text{ and } x_1 > 0,\\ \{(0,0,\pm 1),(0,\pm 1,0),(1,0,0)\} & \text{if } x_3 = x_2 = 0 \text{ and } x_1 < 0,\\ \{(0,0,\pm 1),(0,\pm 1,0),(\pm 1,0,0),(0,0,0)\} & \text{if } x_3 = x_2 = x_1 = 0.\end{cases}$$

This map F is upper semicontinuous, and it does not satisfy Definition 3.1 for any $\varepsilon \in (0,1)$ with $D = R^3$ and $\hat{x} \in D_1 := \{(x_1,x_2,x_3) : \ x_3 = 0\}$; $D = D_1$ and $\hat{x} \in D_2 := \{(x_1,x_2,x_3) : \ x_2 = x_3 = 0\}$; $D = D_2$ and $\hat{x} = (0,0,0)$.

Example 3. Consider $F : R^2 \Rightarrow R^2$ defined by

$$F(x_1,x_2)=\begin{cases}\{(0,-1)\} & \text{if } x_1 > 0 \text{ and } x_2 > 0,\\ \{(0,1)\} & \text{if } x_1 > 0 \text{ and } x_2 < 0,\\ \left\{-\dfrac{(x_1,x_2)}{\sqrt{x_1^2+x_2^2}}\right\} & \text{if } x_1 < 0,\\ \{(-1,0)\} & \text{if } x_1 > 0 \text{ and } x_2 = 0,\\ \{(y_1,y_2) : \ y_1^2+y_2^2 = 1\} & \text{if } x_1 = x_2 = 0.\end{cases}$$

This map F is upper semicontinuous and does not satisfy Definition 3.1 for any $\varepsilon \in (0,1)$ with $D = R^2$ and $\hat{x} \in D_1 := \{(x_1,x_2) : \ x_1 \geq 0, \ x_2 = 0\}$. On the other

hand, this map satisfies Definition 3.1 with the set D_1 and all of its points. Evidently, there is no trajectory of $\dot{x} \in F(x) + \varepsilon\bar{B}$, $x(0) = (0,0)$. The reason for this is the fact that the map $x \Rightarrow N_{D_1}(x) \cap c\bar{B}$ is not ε-lower semicontinuous at the point $(0,0)$.

These examples motivate the next two definitions.

DEFINITION 3.6. *Let C be a relatively closed (in D) subset of D. It is said that F ε-collides from D to C iff C is the closure (in D) of the complement in D of the set*

$$\{x \in D : F \text{ does not } \varepsilon\text{-collide from } D \text{ to } x\} \cap \left\{x \in D : N_D(x) \bigcap c\bar{B} \text{ is } \varepsilon\text{-lower semicontinuous at } x\right\},$$

where $c := \sup\{\|y\| : y \in F(x), x \in D\}$.

DEFINITION 3.7. *Let C be a relatively closed (in D) subset of D. It is said that F collides to the set C iff there exist $\varepsilon > 0$, a decreasing well-ordered family $\{D_\alpha\}_{1 \le \alpha < \alpha_0}$, and a family of upper semicontinuous multivalued maps $F_\alpha : D_\alpha \to R^n$ with nonempty compact values such that*

(i) *$D_1 = D$, $F_1 \equiv F$, $C = D_{\alpha_0}$;*
(ii) *D_α is a nonempty closed subset of $D_{\alpha-1}$ if α is not a limit ordinal and $D_\alpha = \bigcap_{\beta<\alpha} D_\beta$ if α is a limit ordinal;*
(iii) *$F_\alpha(x) \subseteq \left(T_{D_\alpha}(x) + \varepsilon\bar{B}\right) \bigcap F(x)$ for every $x \in D_\alpha \setminus D_{\alpha+1}$;*
(iv) *F_α ε-collides from D_α to $D_{\alpha+1}$.*

4. Basic assumption and existence of ε-solutions. The main idea of our approach is to assume that whenever the admissible velocities do "collide" on some set S, in order to have a solution of (1.1) which does not leave S, there exist tangent velocities to S. It is natural to assume that these velocities belong to the Bouligand tangent cone to S. The following example shows that this cone is too big for our purposes. The reason is that it lacks good continuity properties.

Example 4. We define the multivalued map $F : [0,1] \Rightarrow \{-1,1\}$ using a Cantor-like construction:

$$F(x) := \begin{cases} \{1\} & \text{if } x \in \left(\frac{1}{5}, \frac{2}{5}\right), \\ \{-1\} & \text{if } x \in \left(\frac{3}{5}, \frac{4}{5}\right), \\ \{1\} & \text{if } x \in \left(\frac{1}{5^2}, \frac{2}{5^2}\right) \cup \left(\frac{2}{5} + \frac{3}{5^2}, \frac{2}{5} + \frac{4}{5^2}\right) \cup \left(\frac{4}{5} + \frac{1}{5^2}, \frac{4}{5} + \frac{2}{5^2}\right), \\ \{-1\} & \text{if } x \in \left(\frac{3}{5^2}, \frac{4}{5^2}\right) \cup \left(\frac{2}{5} + \frac{1}{5^2}, \frac{2}{5} + \frac{2}{5^2}\right) \cup \left(\frac{4}{5} + \frac{3}{5^2}, \frac{4}{5} + \frac{4}{5^2}\right), \\ \ldots\ldots & \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \end{cases}$$

We define $F(x)$ to be $\{-1,1\}$ on the remaining Cantor set A. Clearly, A is the set of all points x at which F is not continuous. It is easy to check that F collides to A and $F(x) \bigcap T_A(x) \neq \emptyset$ for all $x \in A$. On the other hand, the differential inclusion $\dot{x} \in F(x)$ has no solution whenever the starting point belongs to a dense subset of A. Moreover, this differential inclusion has no ε-solution for each $\varepsilon \in (0,1)$ starting from the same points.

Let D be an intersection of an open and a closed subset of R^n, and let $F : D \Rightarrow R^n$ be an upper semicontinuous mapping with nonempty compact values which are uniformly bounded. Example 4 and Lemma 2.3 motivate the following assumption.

Basic assumption. For every $C \subseteq D$ such that F collides to C there exists a dense subset E of C such that

$$F(x) \bigcap \hat{T}_C(x) \neq \emptyset \quad \text{for all } x \in E.$$

It is straightforward to verify that Examples 1, 3, and 4 do not satisfy the basic assumption, and Example 2 satisfies it.

THEOREM 4.1. *Let D be an open subset of R^n and let $F : D \Rightarrow R^n$ be an upper semicontinuous mapping with nonempty compact values which are uniformly bounded. Moreover, let F satisfy the basic assumption. Then for each $\varepsilon > 0$, for each $T > 0$, and for each point x_0 of D there exists an absolutely continuous function $x : [0, T] \to R^n$ such that*

$$\begin{cases} \dot{x}(t) \in F(x(t)) + \varepsilon \overline{B} \quad \textit{a.e. on } [0, T], \\ x(0) = x_0. \end{cases}$$

Proof. We set $c := \sup\{\|y\| : \ y \in F(x), x \in D\}$ and $D_1 := D$. Let D_2 be the closed subset of D_1 to which F ε-collides from D_1. We set $W_1 := D_1 \setminus D_2$ and $F_1 \equiv F$. Then Proposition 3.2(a) implies that W_1 is a dense and relatively open (in D_1) subset of D_1.

According to the basic assumption, there exists a dense subset E_2 of D_2 such that

$$F(x) \bigcap \hat{T}_{D_2}(x) \neq \emptyset \quad \text{for all } x \in E_2. \tag{4.1}$$

We define $F_2 : D_2 \Rightarrow R^n$ as follows:

$$F_2(x) = \left\{ v \in R^n : \ x_n \to x, x_n \in E_2, \ v_n \to v, v_n \in F_1(x_n) \cap \hat{T}_{D_2}(x_n) \right\}.$$

It is straightforward to check that F_2 is an upper semicontinuous mapping with nonempty and compact values. Because of the upper semicontinuity of F, we have $F_2(x) \subseteq F(x)$ for each $x \in D_2$.

According to Lemma 2.3, there exists a relatively open and dense (in D_2) set $\tilde{W}_2$ such that for each point $\hat{x} \in \tilde{W}_2$ there exists an open neighborhood V of $\hat{x}$ with

$$\hat{T}_{D_2}(x) \bigcap c\,\bar{B} \subset T_{D_2}(\hat{x}) \bigcap c\,\bar{B} + \varepsilon \bar{B} \tag{4.2}$$

for every point $x \in V$. Let $v \in F_2(\hat{x})$ be arbitrary. Then there exist a sequence $\{x_n\}_{n=1}^{\infty}$ of points in E_2 converging to $\hat{x}$ and a sequence of velocities $v_n \to v$ with $v_n \in F_1(x_n) \bigcap \hat{T}_{D_2}(x_n)$. Then the upper semicontinuity of F_2 and (4.2) imply that

$$F_2(\hat{x}) \subseteq T_{D_2}(\hat{x}) \bigcap c\,\bar{B} + \varepsilon \bar{B}. \tag{4.3}$$

Let D_β and F_β be defined for each $\beta < \alpha$. If α is a limit ordinal, we put

$$D_\alpha = \bigcap_{\beta < \alpha} D_\beta, \ F_\alpha := F.$$

If α is not a limit ordinal, there exists $\beta = \alpha - 1 < \alpha$. Let D_α be the closed subset of $D_{\alpha-1}$ to which $F_{\alpha-1}$ ε-collides from $D_{\alpha-1}$.

We repeat the construction of F_2: According to the basic assumption, there exists a dense subset E_α of D_α such that

$$F(x) \bigcap \hat{T}_{D_\alpha}(x) \neq \emptyset \quad \text{for all } x \in E_\alpha. \tag{4.4}$$

We define $F_\alpha : D_\alpha \Rightarrow R^n$ as follows:

$$F_\alpha(x) = \left\{ v \in R^n : x_n \to x, x_n \in E_\alpha,\, v_n \to v, v_n \in F(x_n) \cap \hat{T}_{D_\alpha}(x_n) \right\}.$$

It is straightforward to check that F_α is an upper semicontinuous mapping with nonempty and compact values. Because of the upper semicontinuity of F, we have $F_\alpha(x) \subseteq F(x)$ for each $x \in D_\alpha$.

According to Lemma 2.3, there exists a relatively open and dense (in D_α) set $\tilde{W}_\alpha$ such that for each point $\hat{x} \in \tilde{W}_\alpha$ there exists an open neighborhood V of $\hat{x}$ with

$$\hat{T}_{D_\alpha}(x) \bigcap c\,\bar{B} \subset T_{D_\alpha}(\hat{x}) \bigcap c\,\bar{B} + \varepsilon \bar{B} \tag{4.5}$$

for every point $x \in V$. Let $v \in F_\alpha(\hat{x})$ be arbitrary. Then there exist a sequence $\{x_n\}_{n=1}^\infty$ of points in E_α converging to $\hat{x}$ and a sequence of velocities $v_n \to v$ with $v_n \in F(x_n) \bigcap \hat{T}_{D_\alpha}(x_n)$. Then the upper semicontinuity of F_α and (4.2) imply that

$$F_\alpha(\hat{x}) \subseteq T_{D_\alpha}(\hat{x}) \bigcap c\,\bar{B} + \varepsilon \bar{B}. \tag{4.6}$$

Thus we have constructed D_α and F_α. Let α_0 be the first ordinal number with $D_{\alpha_0} = \emptyset$.

Let x be an arbitrary point of D_1. We set

$$\alpha_x := \min \{\alpha : x \notin D_\alpha\}.$$

Let us assume that α_x is a limit ordinal, i.e., $\alpha_x = \sup\{\beta : \beta < \alpha_x\}$. The definition of α_x implies that for each $\beta < \alpha_x$ the point x belongs to D_β. Hence, $x \in \bigcap_{\beta<\alpha_x} D_\beta = D_{\alpha_x}$. The last inclusion contradicts the definition of α_x. So, α_x is not a limit ordinal. Then $x \in D_{\alpha_x - 1} \setminus D_{\alpha_x}$, and hence $F_{\alpha_x - 1}$ does not ε-collide to x from $D_{\alpha_x - 1}$. According to Definition 3.1, there exists a subset A of $D_{\alpha_x - 1}$ and a multivalued map $G : A \Rightarrow R^n$ such that

(i) the subset A is an intersection of an open and a closed set, and the point x belongs to $A \bigcap \mathrm{cl}\,(\mathrm{int}\, A)$;

(ii) G is an upper semicontinuous convex-valued map with $G(\hat{x}) \subset F_{\alpha_x - 1}(\hat{x}) + \varepsilon \bar{B}$ for each $\hat{x} \in A$;

(iii) for each point $\hat{x} \in \partial A \bigcap A$ and for each $\zeta \in \hat{N}_A(\hat{x})$ there exists $v \in G(\hat{x})$ with

$$\langle \zeta,\, v \rangle \leq 0. \tag{4.7}$$

Let $\hat{x}$ be an arbitrary point of A and let ζ be an arbitrary element of $\hat{N}_A(\hat{x})$. If $\hat{x}$ is in the interior of A relatively in $D_{\alpha_x - 1}$, then $\zeta \in \hat{N}_{D_{\alpha_x - 1}}(\hat{x})$. According to (4.6) and (ii),

$$G(\hat{x}) \subset F_{\alpha_x - 1}(\hat{x}) + \varepsilon \bar{B} \subset T_{D_{\alpha_x - 1}}(\hat{x}) \cap c\bar{B} + 2\varepsilon \bar{B},$$

and so there exists a vector $v \in T_{D_{\alpha_x - 1}}(\hat{x}) \cap (G(\hat{x}) + 2\varepsilon \bar{B})$. Hence, $\langle \zeta,\, v \rangle \leq 0$ holds true. If $\hat{x}$ is in the boundary of A relatively in $D_{\alpha_x - 1}$, then by (ii) and (iii) there exists $v \in G(\hat{x}) \subset F_{\alpha_x - 1}(\hat{x}) + \varepsilon \bar{B}$ satisfying (4.7). So, we can apply Lemma 2.1 to

the set A and the map $G + 2\varepsilon\bar{B}$. Thus we obtain the existence of $t_x > 0$ and of a trajectory $\varphi : [0, t_x) \to A$ which is a solution of

$$\begin{cases} \dot{x}(t) \in G(x(t)) + 2\varepsilon\bar{B} \subseteq F_{\alpha_x - 1}(x(t)) + 3\varepsilon\bar{B} \ \text{ a.e. on } [0, t_x], \\ x(0) = x. \end{cases}$$

In particular, there exist $t_{x_0} > 0$ and an absolutely continuous function $\varphi : [0, t_{x_0}) \to D_1$ which is well defined on $[0, t_x)$ and is a solution of the following differential inclusion:

$$\begin{cases} \dot{x}(t) \in F(x(t)) + 3\varepsilon\,\bar{B} \ \text{ a.e. on } [0, t_{x_0}), \\ x(0) = x_0. \end{cases}$$

Let $\hat{T}$ be the supremum of all $\bar{T} \geq 0$ for which the function φ has an absolutely continuous extension on the interval $[0, \bar{T})$ (which we denote again by φ) which is a solution of the above-written differential inclusion on the interval $[0, \bar{T})$. Clearly, $\hat{T} \geq t_{x_0} > 0$. Let us assume that $\hat{T} \leq T$. Then we have that

$$\begin{cases} \dot{\varphi}(t) \in F(\varphi(t)) + 3\varepsilon\,\bar{B} \ \text{ a.e. on } [0, \hat{T}), \\ \varphi(0) = x_0. \end{cases} \tag{4.8}$$

Then for each increasing sequence $\{t_n\}_{n=1}^{\infty} \to \hat{T}$ we have

$$\|\varphi(t_n) - \varphi(t_{n-1})\| \leq \int_{t_{n-1}}^{t_n} \|\dot{\varphi}(\tau)\|\, d\tau \leq c\,(t_n - t_{n-1}).$$

This means that the sequence $\{\varphi(t_n)\}_{n=1}^{\infty}$ is a Cauchy sequence. Hence, there exist $\varphi(\hat{T}) := \lim_{t \to \hat{T}} \varphi(t)$. But then we can find an absolutely continuous extension of the function φ which is a solution of (4.8) on the interval $\left[0, \hat{T} + t_{\varphi(\hat{T})}\right)$. This contradicts the definition of $\hat{T}$. Hence, $\hat{T} > T$ and this completes the proof. □

COROLLARY 4.2. *Let S be a closed set and let F be a uniformly bounded upper semicontinuous multivalued map with nonempty compact values which satisfies the basic assumption. If*

$$\max_{\xi \in \hat{N}_S(x)} \min_{v \in F(x)} \langle \xi, v \rangle \leq 0$$

for every $x \in S$, then (S, F_ε) is viable (weakly invariant) for each $\varepsilon > 0$, i.e., for each point $x_0 \in S$ there exists a solution $x(\cdot)$ of the differential inclusion $\dot{x} \in F_\varepsilon(x)$, $x(0) = x_0$, with $F_\varepsilon(x) = F(x) + \varepsilon\bar{B}$, defined on some interval $[0, t_{x_0})$, $t_{x_0} > 0$, such that $x(t) \in S$ for each $t \in [0, t_{x_0})$.

In contrast to the convex-valued case (cf., for example, [2] or [11]), the basic assumption is crucial for the validity of this corollary.

5. Existence of a solution. The question of when it is possible to pass to the limit as $\varepsilon \to 0$ and to obtain a real solution of (1.1) remains open. Assuming that F is an upper semicontinuous mapping satisfying the basic assumption, a relatively open partitioning $\mathcal{U}_\varepsilon$ is constructed in the proof of Theorem 4.1 for every $\varepsilon > 0$. Its elements are invariant with respect to the trajectories of the differential inclusion $\dot{x} \in F(x) + \varepsilon\bar{B}$.

The next theorem is inspired by Bressan's proof in the lower semicontinuous case. To prove it, we have additionally assumed that some refinements of the relatively open partitioning $\mathcal{U}_\varepsilon$ may be chosen finite and that their elements are invariant with respect to the trajectories of the differential inclusion $\dot{x} \in F(x) + \eta\bar{B}$ for each $0 < \eta < \varepsilon$.

THEOREM 5.1. *Let the set D be an intersection of an open and a closed subset of R^n and let $F : D \Rightarrow R^n$ be a uniformly bounded upper semicontinuous multivalued mapping with nonempty compact values. Let*

$$\mathcal{U}^k = \left\{U_\alpha^k : \ 1 \le \alpha < \alpha_0^k\right\}, \quad k = 1, 2, \dots,$$

be uniformly locally finite (i.e., every point of D has a neighborhood V which intersects at most finitely many members of $\mathcal{U}^k$ for each positive integer k) relatively open partitionings of D. Let $\mathcal{U}^{k+1}$ be a refinement of $\mathcal{U}^k$ for each k. Moreover, we assume that there exist multivalued mappings $F_k : D \Rightarrow R^n$ such that the restriction of F_k on an arbitrary element U of $\mathcal{U}^k$ is upper semicontinuous with nonempty convex compact values, the diameter of $F_k(U)$ is less than or equal to $\frac{1}{k}$, and $F_{k+1} \subset F_k$ and $F_k \subset F + \frac{1}{k}\bar{B}$ for each k. We also assume that for each point x_0 of D there exists $T > 0$ such that

(i) *for each positive integer k there exists an absolutely continuous function $x_k : [0, T] \to D$ such that*

$$\begin{cases} \dot{x}(t) \in F_k(x(t)) \ \ \textit{a.e. on } [0, T], \\ x(0) = x_0; \end{cases} \tag{5.1}$$

(ii) *for each positive integer k and m with $k \ge m$, and for each solution $x_k(\cdot)$ of (5.1), the function*

$$t \to \alpha(t), \ \textit{where } x_k(t) \in U_{\alpha(t)}^m,$$

is monotone increasing.

Then there exists an absolutely continuous function $x : [0, T] \to D$ such that

$$\begin{cases} \dot{x}(t) \in F(x(t)) \ \ \textit{a.e. on } [0, T], \\ x(0) = x_0. \end{cases}$$

Proof. Let us fix an arbitrary point $x_0 \in D$. Without loss of generality, we may think that $\{x_k(t) : \ t \in [0, T]\}$ is contained in the neighborhood V of x_0 that intersects at most finitely many members of $\mathcal{U}^k$ for every positive integer k. Let $\alpha_1^k < \alpha_2^k < \dots < \alpha_{s(k)}^k$ be such that $V \cap U_\alpha^k = \emptyset$ whenever $\alpha \ne \alpha_s^k$, $s = 1, \dots, s(k)$.

Let us fix for a moment the positive integer m and let k be an arbitrary integer with $k \ge m$. Then $\left\{x_k(t) : \ t \in [0, T]\right\} \subset \bigcup_{s=1}^{s(m)} U_{\alpha_s^m}^m$. We set

$$\Delta_s^{m,k} := \left\{t : \ x_k(t) \in U_{\alpha_s^m}^m\right\}, \quad s = 1, 2, \dots, s(m).$$

According to (ii), the sets $\Delta_s^{m,k}$, $s = 1, 2, \dots, s(m)$, are intervals such that $t_{s_1} < t_{s_2}$ for each point $t_{s_i} \in \Delta_{s_i}^{m,k}$, $i = 1, 2$, whenever $s_1 < s_2$. Of course, some of the sets $\Delta_s^{m,k}$ can be empty.

Without loss of generality (cf., for example, [21]) we may think that the sequence $\{x_k(\cdot)\}_{k=1}^\infty$ is uniformly convergent on the interval $[0, T]$ to an absolutely continuous function denoted by $x(\cdot)$.

Let us denote by $t_s^{m,k}$, $s = 1, 2, \ldots, s(m)$, the points of transition of the trajectory $x_k(\cdot)$ from the set $U^m_{\alpha^m_{s-1}}$ to the set $U^m_{\alpha^m_s}$. If the trajectory passes from $U^m_{\alpha^m_s}$ to $U^m_{\alpha^m_l}$ with $l \geq s+2$, then we set $t_s^{m,k} = t_{s+1}^{m,k} = \cdots = t_{l-1}^{m,k} = t_l^{m,k}$. Without loss of generality, we may think that each sequence $\left\{t_s^{m,k}\right\}_{k=1}^{\infty}$ is monotone and tends to the number t_s^m, $s = 1, 2, \ldots, s(m)$. The inequalities $t_s^{m,k} \leq t_{s+1}^{m,k}$ imply that $t_s^m \leq t_{s+1}^m$, $s = 1, 2, \ldots, s(m)$.

For almost all τ from $[0, T]$ (cf. Lemma 2 from [21]) the derivatives $\dot{x}(\tau)$ and $\dot{x}_k(\tau)$ exist and

$$\dot{x}(\tau) \in \ \overline{\text{co}}\ \{\dot{x}_k(\tau) : \ k \geq k_0\}$$

for any positive integer k_0.

If τ does not coincide with any of the points t_s^m, $s = 1, 2, \ldots, s(m)$, then $\tau \in (t_{s-1}^m, t_s^m)$ for some s, and so $x_k(\tau) \in U^m_{\alpha^m_{s-1}}$ for all sufficiently large k. If τ coincides with the point t_s^m for some s, then two cases are possible: the sequence $\left\{t_s^{m,k}\right\}_{k=1}^{\infty}$ is nonincreasing, and hence $x_k(\tau) \in U^m_{\alpha^m_s}$ for all sufficiently large k, or the sequence $\left\{t_s^{m,k}\right\}_{k=1}^{\infty}$ is increasing, and therefore $x_k(\tau) \in U^m_{\alpha^m_{s-1}}$ for all sufficiently large k.

In all cases $x_k(\tau)$, $k \geq k_0$, belong to one and the same element of the partitioning $\mathcal{U}^m$, say U, and thus

$$\dot{x}(\tau) \in \ \overline{\text{co}}\ \{\dot{x}_s(\tau) : \ s \geq k_0\} \subset \ \overline{\text{co}}\ \left(\bigcup_{s \geq k_0} F_s(x_s(\tau))\right) \subset \overline{\text{co}}\ \left(\bigcup_{s \geq k_0} F_m(x_s(\tau))\right)$$

$$\subset \ \overline{\text{co}}\ \left(F_m(x_k(\tau)) + \frac{1}{m}\bar{B}\right) = F_m(x_k(\tau)) + \frac{1}{m}\bar{B} \subset F(x_k(\tau)) + \frac{2}{m}\bar{B}$$

for all $k \geq \max(m, k_0)$. Now the upper semicontinuity of F and $x_k(\tau) \to x(\tau)$ imply

$$\dot{x}(\tau) \in \ F(x(\tau)) + \frac{2}{m}\bar{B}. \tag{5.2}$$

Since $\dot{x}(\tau)$ does not depend on m and F is compact valued, we obtain that

$$\dot{x}(\tau) \in \ F(x(\tau)).$$

This completes the proof. □

Remark 1. It is possible to consider the lower semicontinuous case as a corollary to this result. Indeed, let us consider the simplest case when D is a closed set. $G : D \to R^n$ is a uniformly bounded lower semicontinuous multivalued map with compact values such that $G(y) \subset T_D(y)$ for each $y \in D$. We set $x = (y, z)$, $F(x) := G(y) \times \{1\}$ and consider the differential inclusion $\dot{x} \in F(x)$. Starting from the relatively open partitioning constructed in the proof of Lemma 6.2 in [13, p. 67], one can refine it by dividing if necessary the elements of the partitioning by the finitely many hyperplanes $\{(y, z) : \ z = z_i\}$, where z_i is the sum of δ_i and the last coordinate of ω_i (these notations are from the proof of Lemma 6.2 in [13, p. 67]). Then the obtained partitioning can be ordered in such a way as to satisfy the assumptions of Theorem 5.1 with $F_k(x) = \left(f_k(y) + \frac{1}{2^{k-1}}\bar{B}\right) \times \{1\}$ (again f_k is from the above-mentioned proof). Note that in the proof of Theorem 5.1 the upper semicontinuity of F is used only to derive (5.2). In the lower semicontinuous case the limit trajectory $x(\cdot)$ cannot remain on the boundaries of the elements of the partitioning. Hence, for all τ except for finitely

many values, $x(\tau)$ belongs to the interior of the elements of the partitioning and we can pass to the limit as $k \to \infty$ without using the upper semicontinuity.

Remark 2. Theorem 5.1 can be applied to the differential inclusions with right-hand sides F_2 (cf. the end of the introduction), the multivalued mappings described in Example 2, Example 3 (if $(0,0)$ is added to $F(0,0)$), and Example 4 (if the origin is added to $F(x)$ for every $x \in A$). These multivalued mappings, clearly, are not lower semicontinuous everywhere. Moreover, the assumptions of Theorem 5.1 do not exclude the existence of periodic solutions (cf. the assumption (ii)). To show this, we consider the following example: We set $D = \bigcup_{i=1}^{4} D_i$, where

$$
\begin{aligned}
D_1 &= \{(x,y):\ x>0,\ y\geq 0,\ x+y<1\},\\
D_3 &= \{(x,y):\ x<0,\ y\leq 0,\ x+y>-1\},\\
D_2 &= \{(x,y):\ x\leq 0,\ y>0,\ y-x<1\},\\
D_4 &= \{(x,y):\ x\geq 0,\ y<0,\ y-x>-1\}.
\end{aligned}
$$

On the set D we consider the following differential inclusion:

$$
(\dot{x},\dot{y}) \in \begin{cases} \{(-x-y,x+y)\} & \text{for } (x,y) \in \text{ int } D_1 \cup \text{ int } D_3;\\ \{(x-y,x-y)\} & \text{for } (x,y) \in \text{ int } D_2 \cup \text{ int } D_4;\\ \{(-x-y,x+y),(x-y,x-y)\} & \text{for } (x,y) \in D \cap \{(x,y):\ xy=0\}. \end{cases}
$$

We denote the right-hand side of the considered differential inclusion by G. Clearly, G is a uniformly bounded compact-valued upper semicontinuous mapping. Let us fix an arbitrary point (x_0,y_0) from the set D. Then there exists a trajectory of the considered differential inclusion starting from (x_0,y_0) and defined on the interval $[0,+\infty)$. Moreover, this trajectory is a periodic function with respect to time with period 4.

To show how Theorem 5.1 can be applied in this case, we set $F(x,y,z) := G(x,y)\times\{1\}$ and consider the differential inclusion $(\dot{x},\dot{y},\dot{z}) \in F(x,y,z)$ on the set $\hat{D} = D\times[0,+\infty)$.

Let k be an arbitrary positive integer. We are going to define a relatively open partitioning $\mathcal{U}^k = \{U_s^k,\ s=0,1,2,\ldots\}$ of $\hat{D}$. Let us fix arbitrarily the positive integer k and the nonnegative integer s. Let us denote by m and r the quotient and the remainder of s over $8k$, respectively, i.e., $s = 8mk+r$, where $r \in \{0,1,\ldots,8k-1\}$. We set U_s^k to be the set

$$
\left\{(x,y)\in D_1:\ \frac{r}{k}\leq x+y<\frac{r+1}{k},\ m\leq z<m+\frac{y}{x+y}\right\}
$$

$$
\text{if } r=0,1,\ldots,k-1;
$$

$$
\left\{(x,y)\in D_2:\ \frac{r}{k}-1\leq y-x<\frac{r+1}{k}-1,\ m\leq z<m+\frac{x}{x-y}\right\}
$$

$$
\text{if } r=k,k+1,\ldots,2k-1;
$$

$$
\left\{(x,y)\in D_3:\ \frac{r}{k}-2\leq -x-y<\frac{r+1}{k}-2,\ m\leq z<m+\frac{y}{x+y}\right\}
$$

$$
\text{if } r=2k,2k+1,\ldots,3k-1;
$$

$$\left\{(x,y)\in D_4:\ \frac{r}{k}-3\le x-y<\frac{r+1}{k}-3,\ m\le z<m+\frac{x}{x-y}\right\}$$
$$\text{if } r=3k,3k+1,\dots,4k-1;$$

$$\left\{(x,y)\in D_1:\ \frac{r}{k}-4\le x+y<\frac{r+1}{k}-4,\ m+\frac{y}{x+y}\le z<m+1\right\}$$
$$\text{if } r=4k,4k+1,\dots,5k-1;$$

$$\left\{(x,y)\in D_2:\ \frac{r}{k}-5\le y-x<\frac{r+1}{k}-5,\ m+\frac{x}{x-y}\le z<m+1\right\}$$
$$\text{if } r=5k,5k+1,\dots,6k-1;$$

$$\left\{(x,y)\in D_3:\ \frac{r}{k}-6\le -x-y<\frac{r+1}{k}-6,\ m+\frac{y}{x+y}\le z<m+1\right\}$$
$$\text{if } r=6k,6k+1,\dots,7k-1;$$

$$\left\{(x,y)\in D_4:\ \frac{r}{k}-7\le x-y<\frac{r+1}{k}-7,\ m+\frac{x}{x-y}\le z<m+1\right\}$$
$$\text{if } r=7k,7k+1,\dots,8k-1.$$

On the set $\hat{D}$ we define F_k as follows:

$$F_k(x,y,z)=\begin{cases}\{(-x-y,x+y,1)\} & \text{for } (x,y)\in D_1\cup D_3;\\ \{(x-y,x-y,1)\} & \text{for } (x,y)\in D_2\cup D_4.\end{cases}$$

It could be directly checked that the diameter of $F_k(U_s^k)$ is less than or equal to $\frac{\sqrt{2}}{k}$, and $F_{k+1}=F_k$ and $F_k\subset F$ for each k and each s. One can directly verify that for each point x_0 of $\hat{D}$, for each $T>0$, and for each positive integer k there exists an absolutely continuous function $x_k:[0,T]\to\hat{D}$ such that

$$\left|\begin{array}{l}\dot{x}(t)\in F_k(x(t)) \ \text{ a.e. on } [0,T],\\ x(0)=x_0.\end{array}\right. \tag{5.3}$$

Moreover, for each positive integer k and m with $k\ge m$, and for each solution $x_k(\cdot)$ of (5.1), the function

$$t\to s(t),\ \text{where } x_k(t)\in U^m_{s(t)},$$

is monotone increasing. Hence, Theorem 5.1 can be applied.

VARIATIONAL ANALYSIS OF EVOLUTION INCLUSIONS*

BORIS MORDUKHOVICH†

Abstract. The paper is devoted to optimization problems of the Bolza and Mayer types for evolution systems governed by nonconvex Lipschitzian differential inclusions in Banach spaces under endpoint constraints described by finitely many equalities and inequalities with generally nonsmooth functions. We develop a variational analysis of such problems mainly based on their discrete approximations and the usage of advanced tools of generalized differentiation satisfying comprehensive calculus rules in the framework of Asplund (and hence any reflexive Banach) spaces. In this way we establish extended results on stability of discrete approximations (with the strong $W^{1,2}$-convergence of optimal solutions under consistent perturbations of endpoint constraints) and derive necessary optimality conditions for nonconvex discrete-time and continuous-time systems in the refined Euler–Lagrange and Weierstrass–Pontryagin forms accompanied by the appropriate transversality inclusions. In contrast to the case of geometric endpoint constraints in infinite dimensions, the necessary optimality conditions obtained in this paper do not impose any nonempty interiority/finite-codimension/normal compactness assumptions. The approach and results developed in the paper make a bridge between optimal control/dynamic optimization and constrained mathematical programming problems in infinite-dimensional spaces.

Key words. variational analysis, dynamic optimization and optimal control, evolution and differential inclusions, Banach and Asplund spaces, discrete/finite-difference approximations, nondifferentiable programming, generalized differentiation, necessary optimality conditions

1. Introduction.

This paper concerns the study of dynamic optimization problems governed by constrained evolution systems in infinite-dimensional spaces. We pay attention mainly to variational analysis of the following *generalized Bolza problem* (P) for differential inclusions in Banach spaces with endpoint constraints described by finitely many equalities and inequalities.

Let X be a Banach *state space* with the *initial state* $x_0 \in X$, and let $T := [a, b] \subset \mathbb{R}$ be a fixed *time interval*. Given a set-valued mapping $F\colon X \times T \rightrightarrows X$ and real-valued functions $\varphi_i\colon X \to \mathbb{R}$ as $i = 0, \ldots, m+r$ and $\vartheta\colon X \times X \times T \to \mathbb{R}$, consider the following problem:

$$\text{minimize} \quad J[x] := \varphi_0\big(x(b)\big) + \int_a^b \vartheta\big(x(t), \dot{x}(t), t\big)\, dt \tag{1.1}$$

subject to *dynamic constraints* governed by the evolution/differential inclusion

$$\dot{x}(t) \in F\big(x(t), t\big) \quad \text{a.e.} \quad t \in [a, b] \quad \text{with} \quad x(a) = x_0 \tag{1.2}$$

with *functional endpoint constraints* of the inequality and equality types given by

$$\varphi_i\big(x(b)\big) \le 0, \quad i = 1, \ldots, m, \tag{1.3}$$

†Department of Mathematics, Wayne State University, Detroit, MI 48202 (boris@math.wayne.edu).

$$\varphi_i\big(x(b)\big) = 0, \quad i = m+1, \ldots, m+r. \tag{1.4}$$

Note that $\dot{x}(t)$ stands in (1.1) for the time derivative of $x(t)$ and that "a.e." (almost everywhere) signifies as usual that the inclusion holds up to the Lebesgue measure zero on $\mathbb{R}$. The initial state x_0 and the time interval T are fixed in problem (P) for simplicity; the methods developed in this paper allow us to include $x(a)$ and $[a, b]$ in the optimization process and to derive necessary optimality conditions for these variable data.

Dynamic optimization problems for differential inclusions with the *finite-dimensional* state space $X = \mathbb{R}^n$ have been intensively studied over the years, especially during the last decade, mainly from the viewpoint of deriving necessary optimality conditions; see [3, 8, 12, 14, 17, 19] for various results, methods, and more references. Dynamic optimization problems governed by infinite-dimensional *evolution equations* have also been much investigated, motivated mainly by applications to optimal control of partial differential equations; see, e.g., the books [7, 10] and the references therein. To the best of our knowledge, deriving necessary optimality conditions in dynamic optimization problems for evolution systems governed by differential inclusions in *infinite-dimensional spaces* has not drawn attention in the literature till very recently.

In the book [14], the author developed the method of *discrete approximations* to study optimal control problems of minimizing the Bolza functional (1.1) over appropriate solutions to evolution systems governed by infinite-dimensional differential inclusions of type (1.2) with endpoint constrains given in the *geometric form*

$$x(b) \in \Omega \subset X \tag{1.5}$$

via closed subsets of Banach spaces satisfying certain requirements. The major assumption on Ω made in [14] is the so-called *sequential normal compactness* (SNC) property of Ω at the optimal endpoint $\bar{x}(b) \in \Omega$; see [13] for a comprehensive theory for this and related properties, which play a significant role in infinite-dimensional variational analysis and its applications. Loosely speaking, the SNC property means that Ω should be "sufficiently fat" around the reference point; e.g., it never holds for singletons unless X is finite-dimensional, where the SNC property is satisfied for every nonempty set. For *convex* sets in infinite-dimensional spaces, the SNC property automatically holds when $\operatorname{int}\Omega \neq \emptyset$. Furthermore, it happens to be closely related [14] to the so-called finite-codimension property of convex sets, which is known to be essential for the fulfillment of an appropriate counterpart of the Pontryagin maximum principle for infinite-dimensional systems of optimal control; see the books by Fattorini [7] and by Li and Yong [10] for the corresponding results, discussions, counterexamples, and more references.

In this paper we show that the dynamic optimization problem (P) formulated above, with the *functional* endpoint constraints (1.3) and (1.4) given by *finitely many* Lipschitz continuous functions on a broad class of Banach spaces (that particularly includes every reflexive space), admits necessary optimality conditions in the extended Euler–Lagrange form accompanied by the corresponding Weierstrass–Pontryagin/maximum and transversality relations with *no SNC* and similar assumptions imposed on the underlying endpoint constraint set. Moreover, the case of endpoint constraints (1.3) and (1.4) under consideration allows us to partly avoid some other rather restrictive assumptions (like "strong coderivative normality," which may not hold in infinite-dimensional spaces; see sections 6 and 7 for more details) imposed in [14] in the general case of geometric constraints (1.5). Our approach is based, in

addition to the results of [14], on certain delicate properties of appropriate *subdifferentials* of locally Lipschitzian functions on infinite-dimensional spaces, as well as on *dual/coderivative characterizations* of Lipschitzian and metric regularity properties of set-valued mappings.

The rest of the paper is organized as follows. In section 2 we formulate the standing assumptions on the initial data of (P), make more precise the solution concept for the evolution inclusion (1.1) and the types of local minimizers to (P) under consideration, and also discuss the relaxation procedure used for some results and proofs in the paper. Our main focus in this paper is on the so-called *intermediate local minimizers*, which occupy (strictly) an intermediate position between the classical weak and strong minima, being nevertheless closer to strong minimizers from the viewpoint of necessary optimality conditions for differential inclusions.

In section 3 we construct a sequence of the *well-posed discrete approximations* (P_N) to the original Bolza problem (P), which take into account specific features of the functional endpoint constraints (1.3) and (1.4) involving *consistent perturbations* of these constraints in the discrete approximation procedure. Then we present a major result on the *strong stability* of discrete approximations that justifies the $W^{1,2}$-norm convergence of optimal solutions for (P_N) to the fixed local minimizer for the original problem (P).

Section 4 contains an overview of the basic tools of *generalized differentiation* needed to perform the subsequent variational analysis of the discrete-time and continuous-time evolution systems under consideration in infinite-dimensional spaces. Most of the material in this section is taken from the author's book [13], where the reader can find more results and commentaries in this direction and related topics.

Section 5 is devoted to deriving necessary optimality conditions for the constrained *discrete-time* problems arising from the discrete approximation procedure whose well-posedness and stability are justified in section 3. These problems are reduced to (nondynamic) constrained problems of mathematical programming in infinite dimensions, which happen to be *intrinsically nonsmooth* and involve finitely many functional and geometric constraints generated by those in (1.2)–(1.4) via the discrete approximation procedure. Variational analysis of such problems requires applications of the full power of the generalized differential calculus in infinite-dimensional spaces developed in [13].

In section 6 we derive necessary optimality conditions of the extended *Euler–Lagrange* type for *relaxed* intermediate minimizers to the original Bolza problem (P) by passing to the limit from those obtained for discrete-time problems in section 5. It is worth emphasizing that the realization of the limiting procedure requires not only the strong convergence of optimal trajectories to discrete approximation problems established in section 3 but also justifying an appropriate convergence of *adjoint trajectories* in necessary optimality conditions for the sequence of discrete-time inclusions. The latter becomes passable due to specific properties of the basic generalized differential constructions reviewed in section 4, which include complete *dual characterizations* of Lipschitzian and metric regularity properties of set-valued mappings.

The concluding section 7 concerns necessary optimality conditions for arbitrary (*nonrelaxed*) intermediate minimizers to problem (P), considering for simplicity the Mayer form (P_M) with no integral term in (1.1), that are established in terms of the *extended Euler–Lagrange* inclusion accompanied by the *Weierstrass–Pontryagin/maximum* and transversality relations without imposing any SNC assumptions on the target/endpoint constraint set described by (1.3) and (1.4). The approach is

based on an additional approximation procedure that allows us to reduce (P_M) to an unconstrained (while nonsmooth and nonconvex) Bolza problem of the type treated in section 6, for which *any* intermediate local minimizer happens to be a relaxed one. The passage to the limit from the latter approximation is largely similar to that developed in section 6, not requiring, however, any relaxation requirement due to the usage of *Ekeland's variational principle*.

Our notation is basically standard; cf. [13, 14]. Unless otherwise stated, all the spaces considered are Banach with the norm $\|\cdot\|$ and the canonical dual pairing $\langle\cdot,\cdot\rangle$ between the space in question, say X, and its topological dual X^* whose weak* topology is denoted by w^*. We use the symbols $\mathbb{B}$ and $\mathbb{B}^*$ to signify the closed unit balls of the space under consideration and its dual, respectively. Given a set-valued mapping $F\colon X \rightrightarrows X^*$, its *sequential Painlevé–Kuratowski upper/outer limit* at $\bar{x}$ is defined by

$$\operatorname*{Lim\,sup}_{x\to\bar{x}} F(x) := \Big\{x^* \in X^* \;\Big|\; \exists \text{ sequences } x_k \to \bar{x},\ x_k^* \overset{w^*}{\to} x^* \text{ with } x_k^* \in F(x_k) \text{ as } k \in \mathbb{N} := \{1,2,\ldots\}\Big\}. \tag{1.6}$$

2. The generalized Bolza problem for evolution inclusions. For the sake of brevity and simplicity, we consider in this paper the Bolza problem (P) with *autonomous* (time-independent) data, i.e., when $\vartheta = \vartheta(x,v)$ in (1.1) and $F = F(x)$ in (1.2). The case of nonautonomous systems can be studied in a manner similar to that of [14, Chapter 6], which is devoted to problems with geometric constraints of type (1.5). Let us start with the precise definition of solutions (trajectories, arcs) to the differential inclusion (1.2) following the book by Deimling [6].

Definition 2.1 (solutions to differential inclusions in infinite-dimensional spaces). *By a* solution *to inclusion* (1.2) *we understand a mapping $x\colon T \to X$, which is Fréchet differentiable for a.e. $t \in T$ satisfying* (1.2) *and the* Newton–Leibniz formula

$$x(t) = x_0 + \int_a^t \dot{x}(s)\,ds \quad \textit{for all } \ t \in T,$$

where the integral in taken in the Bochner sense.

It is well known that for $X = \mathbb{R}^n$, $x(t)$ is a.e. differentiable on T and satisfies the Newton–Leibniz formula *if and only if* it is *absolutely continuous* on T in the standard sense. However, for infinite-dimensional spaces X even the Lipschitz continuity may not imply the a.e. differentiability. On the other hand, there is a *complete characterization* of Banach spaces X, where the absolute continuity of every $x\colon T \to X$ is *equivalent* to its a.e. differentiability and the fulfillment of the Newton–Leibniz formula: this is the class of spaces having the so-called *Radon–Nikodým property* (RNP), which is well investigated in the geometric theory of Banach spaces [4]. Observe, in particular, that every *reflexive* space enjoys the RNP.

Recall further that a Banach space X is *Asplund* if any of its separable subspaces has a separable dual. This is a major subclass of Banach spaces that particularly includes every space with a *Fréchet differentiable renorm* off the origin (i.e., every *reflexive* space), every space with a separable dual, etc.; see [4] for more details, characterizations, and references. There is a deep relationship between spaces having the RNP and Asplund spaces, which is used in what follows: *given a Banach space X, the dual space X^* has the RNP if and only if X is Asplund.*

It has been well recognized that differential inclusions (1.2), which are certainly interesting on their own, provide a useful generalization of *control systems* governed

by differential/evolution *equations* with control parameters:

$$\dot{x} = f(x,u), \quad u \in U, \tag{2.1}$$

where the control sets $U(\cdot)$ may also depend on time and *state* variables via $F(x,t) = f(x,U(x,t),t)$. In some cases, especially when the sets $F(\cdot)$ are convex, the differential inclusions (1.2) admit parametric representations of type (2.1), but in general they cannot be reduced to parametric control systems and should be studied for their own sake. Note also that the *ODE form* (2.1) in Banach spaces is strongly related to various control problems for evolution *partial differential equations* of parabolic and hyperbolic types, where solutions may be understood in some other appropriate senses; see, e.g., the books [7, 10, 14] for more discussions.

In what follows, we focus our attention on the study of *intermediate local minimizers* for problem (P) introduced by the author in [12]. Recall that a *feasible arc* to (P) is a solution to the differential inclusion (1.2), in the sense of Definition 2.1, for which $J[x] < \infty$ in (1.1) and the endpoint constraints (1.3) and (1.4) are satisfied.

DEFINITION 2.2 (intermediate local minimizers). *A feasible arc $\bar{x}(\cdot)$ is an* intermediate local minimizer *of rank $p \in [1,\infty)$ for (P) if there are numbers $\epsilon > 0$ and $\alpha \ge 0$ such that $J[\bar{x}] \le J[x]$ for any feasible arcs to (P) satisfying the relationships*

$$\|x(t) - \bar{x}(t)\| < \epsilon \ \text{ for all } \ t \in [a,b] \quad \text{and} \tag{2.2}$$

$$\alpha \int_a^b \|\dot{x}(t) - \dot{\bar{x}}(t)\|^p \, dt < \epsilon. \tag{2.3}$$

In fact, relationships (2.2) and (2.3) mean that we consider a neighborhood of $\bar{x}(\cdot)$ in the Sobolev space $W^{1,p}\big([a,b];X\big)$ with the norm

$$\|x(\cdot)\|_{W^{1,p}} := \max_{t\in[a,b]} \|x(t)\| + \Big(\int_a^b \|\dot{x}(t)\|^p \, dt \Big)^{1/p},$$

where the norm on the right-hand side is taken in the space X. If there is only the requirement (2.2) in Definition 2.2, i.e., $\alpha = 0$ in (2.3), then we get the classical *strong* local minimum corresponding to a neighborhood of $\bar{x}(\cdot)$ in the norm topology of $C\big([a,b];X\big)$. If instead of (2.3) one puts the more restrictive requirement

$$\|\dot{x}(t) - \dot{\bar{x}}(t)\| < \epsilon \ \text{ a.e. } \ t \in [a,b],$$

then we have the classical *weak* local minimum in the framework of Definition 2.2. Thus the introduced notion of intermediate local minimizers takes, for any $p \in [1,\infty)$, an *intermediate* position between the classical concepts of strong ($\alpha = 0$) and weak ($p = \infty$) local minima, being indeed different from both classical notions; see various examples in [20, 14]. Clearly all the necessary conditions for intermediate local minimizers automatically hold for strong (and hence for global) minimizers.

Considering the autonomous Bolza problem (P) in this paper, we impose the following *standing assumptions* on its initial data along a given intermediate local minimizer $\bar{x}(\cdot)$:

(H1) There are an open set $U \subset X$ and a number $\ell_F > 0$ such that $\bar{x}(t) \in U$ for all $t \in [a,b]$, and the sets $F(x)$ are nonempty and compact for all $x \in U$ and satisfy the inclusion

$$F(x) \subset F(u) + \ell_F \|x-u\| \mathbb{B} \ \text{ whenever } \ x,u \in U, \tag{2.4}$$

which implies the uniform boundedness of the sets $F(x)$ on U, i.e., the existence of some constant $\gamma > 0$ such that

$$F(x) \subset \gamma\mathbb{B} \quad \text{for all} \quad x \in U.$$

(H2) The integrand ϑ is Lipschitz continuous on $U \times (\gamma\mathbb{B})$.

(H3) The endpoint functions φ_i, $i = 0, \ldots, m+r$, are locally Lipschitzian around $\bar{x}(b)$ with the common Lipschitz constant $\ell > 0$.

Observe that (2.4) is equivalent to saying that the set-valued mapping F is *locally Lipschitzian* around $\bar{x}(\cdot)$ with respect to the classical Hausdorff metric on the space of nonempty and compact subsets of X.

In what follows, along with the original problem (P), we consider its "relaxed" counterpart significantly used in some results and proofs of the paper. Roughly speaking, the relaxed problem is obtained from (P) by a *convexification* procedure with respect to the *velocity* variable. It follows the route of Bogolyubov and Young in the classical calculus of variations and of Gamkrelidze and Warga in optimal control; see the book [14] and the references therein for more details and commentaries.

To construct an appropriate relaxation of the Bolza problem (P) under consideration, we first consider the extended-real-valued function

$$\vartheta_F(x, v) := \vartheta(x, v) + \delta\big(v; F(x)\big),$$

where $\delta(\cdot; \Omega)$ is the *indicator function* of the set Ω equal to 0 on Ω and to ∞ out of it. Denote by

$$\widehat{\vartheta}_F(x, v) := \big(\vartheta_F\big)_v^{**}(x, v), \quad (x, v) \in X \times X,$$

the *biconjugate/bipolar* function to $\vartheta_F(x, \cdot)$, i.e., the greatest proper, convex, and lower semicontinuous function with respect to v, which is majorized by ϑ_F. Then the *relaxed problem* (R) to (P), or the *relaxation* of (P), is defined as follows:

$$\text{minimize} \quad \widehat{J}[x] := \varphi_0\big(x(b)\big) + \int_a^b \widehat{\vartheta}_F\big(x(t), \dot{x}(t)\big)\, dt \tag{2.5}$$

over a.e. differentiable arcs $x\colon [a, b] \to X$ that are Bochner integrable on $[a, b]$ together with $\vartheta_F\big(x(t), \dot{x}(t)\big)$, satisfying the Newton–Leibniz formula and the endpoint constraints (1.3), (1.4).

Note that the feasibility requirement $\widehat{J}[x] < \infty$ in (2.5) is fulfilled only if $x(\cdot)$ is a solution (in the sense of Definition 2.1) to the *convexified differential inclusion*

$$\dot{x}(t) \in \operatorname{clco} F\big(x(t), \dot{x}(t)\big) \ \text{ a.e. } \ t \in [a, b] \ \text{ with } \ x(a) = x_0, \tag{2.6}$$

where "clco" stands for the convex closure of a set in X. Thus the relaxed problem (R) can be considered under explicit dynamic constraints given by the convexified differential inclusion (2.6). Any trajectory for (2.6) is called a *relaxed trajectory* for (1.2), in contrast to the *ordinary* (or *original*) trajectories for the latter inclusion.

Deep relationships exist between relaxed and ordinary trajectories for differential inclusions, which reflect the fundamental *hidden convexity* inherent in continuous-time (nonatomic measure) dynamic systems defined by differential and integral operators. In particular, *any relaxed trajectory* of (1.2) under assumption (H1) can be *uniformly approximated* (in the $C\big([a, b]; X\big)$-norm) by a sequence of ordinary trajectories; see,

e.g., [6, 18]. We need the following version [5] of this approximation/density property involving not only differential inclusions but also minimizing functionals.

LEMMA 2.3 (approximation property for the relaxed Bolza problem). *Let $x(\cdot)$ be a relaxed trajectory for the differential inclusion* (1.2) *with a separable state space X, where F and ϑ satisfy assumptions* (H1) *and* (H2)*, respectively. Then there is sequence of the ordinary trajectories $x_k(\cdot)$ for* (1.2) *such that $x_k(\cdot) \to x(\cdot)$ in $C\big([a,b];X\big)$ as $k \to \infty$ and*

$$\liminf_{k\to\infty} \int_a^b \vartheta\big(x_k(t),\dot{x}_k(t)\big)\,dt \le \int_a^b \widehat{\vartheta}_F\big(x(t),\dot{x}(t)\big)\,dt.$$

Note that Lemma 2.3 does *not* assert that the approximating trajectories $x_k(\cdot)$ satisfy the endpoint constraints (1.3) and (1.4). Indeed, there are examples showing that the latter may not be possible and, moreover, the property of *relaxation stability*

$$\inf(P) = \inf(R) \tag{2.7}$$

is violated; in (2.7) the infima of the cost functionals (1.1) and (2.5) are taken over all the feasible arcs in (P) and (R), respectively.

An obvious sufficient condition for the relaxation stability is the *convexity* of the sets $F(x,t)$ and of the integrand ϑ in v. However, the relaxation stability goes *far beyond* the standard convexity due to the *hidden convexity* property of continuous-time differential systems. In particular, Lemma 2.3 ensures the relaxation stability of nonconvex problems (P) with no constraints on the endpoint $x(b)$. There are various efficient conditions for the relaxation stability of nonconvex problems with endpoint and other constraints; see [14, subsection 6.1.2] with the commentaries therein for more details, discussions, and references.

A *local* version of the relaxation stability property (2.7) regarding intermediate minimizers for the Bolza problem (P) is postulated as follows.

DEFINITION 2.4 (relaxed intermediate local minimizers). *A feasible arc $\bar{x}(\cdot)$ to the Bolza problem (P) is a* relaxed intermediate local minimizer *of rank $p \in [1,\infty)$ for (P) if it is an intermediate local minimizer of this rank for the relaxed problem (R) providing the same value of the cost functionals: $J[\bar{x}] = \widehat{J}[\bar{x}]$.*

It is not hard to observe that, under the standing assumptions formulated above, the notions of intermediate local minima and relaxed intermediate local minima do not actually depend on rank p, i.e., they either hold or violate for all $p \in [1,\infty)$ simultaneously. In what follows we always take (unless otherwise stated in section 7) $p = 2$ and $\alpha = 1$ in (2.3) for simplicity.

The principal method of our study in this paper involves *discrete approximations* of the original Bolza problem (P) for constrained continuous-time evolution inclusions by a family of dynamic optimization problems of Bolza type governed by discrete-time inclusions with endpoint constraints. We show that this method generally leads to necessary optimality conditions for *relaxed* intermediate local minimizers of (P). Then an additional approximation procedure allows us to establish necessary optimality conditions for *arbitrary* (nonrelaxed) intermediate local minimizers by reducing them to problems which are *automatically* stable with respect to relaxation.

3. Stability of discrete approximations. In this section we present basic constructions of the method of discrete approximations in the theory of necessary optimality conditions for differential inclusions following the scheme of [12, 14] developed for the case of geometric constraints, with certain modifications required for the func-

tional endpoint constraints (1.3) and (1.4) under consideration in infinite-dimensional spaces.

Since we use discrete approximations mostly from a "theoretical" viewpoint (as a vehicle to derive necessary optimality conditions), in what follows we use just the simplest finite-difference replacement of the derivative by the *uniform Euler scheme*:

$$\dot{x}(t) \approx \frac{x(t+h)-x(t)}{h}, \quad h \to 0.$$

To formalize this process, we take any natural number $N \in \mathbb{N}$ and consider the *discrete mesh* on T defined by

$$T_N := \{a, a+h_N, \ldots, b-h_N, b\}, \quad h_N := (b-a)/N,$$

with the *stepsize of discretization* h_N and the *mesh points* $t_j := a + jh_N$ as $j = 0, \ldots, N$, where $t_0 = a$ and $t_N = b$. Then the differential inclusion (1.2) is replaced by a sequence of its *discrete approximations*

$$x_N(t_{j+1}) \in x_N(t_j) + h_N F\big(x_N(t_j)\big), \;\; j = 0, \ldots, N-1, \quad x(t_0) = x_0. \tag{3.1}$$

Given a discrete trajectory $x_N(t_j)$ satisfying (3.1), we consider its *piecewise linear extension* $x_N(t)$ to the continuous-time interval $T = [a, b]$, i.e., the *Euler broken lines*. We also define the *piecewise constant extension* to T of the corresponding *discrete velocity* by

$$v_N(t) := \frac{x_N(t_{j+1}) - x_N(t_j)}{h_N}, \quad t \in [t_j, t_{j+1}), \;\; j = 0, \ldots, N-1.$$

It follows from the very definition of the Bochner integral that

$$x_N(t) = x_0 + \int_a^t v_N(s)\, ds \;\; \text{for} \;\; t \in T.$$

The next result, which plays a significant role in the method of discrete approximations, establishes the *strong $W^{1,2}$-norm approximation* of *any* trajectory for the differential inclusion (1.2) by extended trajectories of the sequence of discrete inclusions (3.1) under the general assumptions made in (H1). Note that the norm convergence in $W^{1,2}\big([a, b]; X\big)$ implies the *uniform* convergence of the trajectories on $[a, b]$ and the *pointwise*, for a.e. $t \in [a, b]$, convergence of (some subsequence of) their *derivatives*. The latter is crucial for the purposes of this paper, especially in the case of *nonconvex-valued* differential inclusions. The proof of this result in given in [14, Theorem 6.4], which is an infinite-dimensional counterpart of the one in [12, Theorem 3.1].

LEMMA 3.1 (strong $W^{1,2}$-approximation by discrete trajectories). *Let $\bar{x}(\cdot)$ be an arbitrary solution to the differential inclusion* (1.2) *under the assumptions in* (H1)*, where X is a general Banach space. Then there is a sequence of solutions $\widehat{x}_N(t_j)$ to the discrete inclusions* (3.1) *such that their extensions $\widehat{x}_N(t)$, $a \le t \le b$, converge to $\bar{x}(t)$ strongly in the space $W^{1,2}\big([a, b]; X\big)$ as $N \to \infty$.*

Observe that the proof of the above result given in [12, 14] is *constructive* and provides efficient estimates of the convergence rate being of certain independent interest for numerical analysis.

Now fix an *intermediate local minimizer* $\bar{x}(\cdot)$ for the Bolza problem (P) and construct a sequence of discrete approximation problems (P_N), $N \in \mathbb{N}$, admitting

optimal solutions $\bar{x}_N(\cdot)$ whose extensions converge to $\bar{x}(\cdot)$ in the norm topology of $W^{1,2}\big([a,b];X\big)$ as $N\to\infty$.

To proceed, we take a sequence of the discrete trajectories $\widehat{x}_N(\cdot)$ approximating by Lemma 3.1 the given local minimizer $\bar{x}(\cdot)$ to (P) and denote

$$\eta_N := \max_{j\in\{1,\ldots,N\}} \|\widehat{x}_N(t_j)-\bar{x}(t_j)\| \to 0 \ \text{ as } \ N\to\infty. \tag{3.2}$$

In [14, subsection 6.1.1], the reader can find more information on computing and estimating η_N, which is not needed in what follows: it is sufficient to know that $\eta_N\to 0$ as $N\to\infty$.

Having $\epsilon>0$ from relations (2.2) and (2.3) for the intermediate minimizer $\bar{x}(\cdot)$ with $p=2$ and $\alpha=1$, we always suppose that

$$\bar{x}(t)+\epsilon/2\in U \ \text{ for all } \ t\in[a,b],$$

where U is a neighborhood of $\bar{x}(\cdot)$ from (H1). Let $\ell>0$ be the common Lipschitz constant of φ_i, $i=1,\ldots,m+r$, from (H3). Construct problems (P_N), $N\in\mathbb{N}$, as follows: minimize

$$\begin{aligned} J_N[x_N] := {}& \varphi_0\big(x_N(t_N)\big)+h_N\sum_{j=0}^{N-1}\vartheta\Big(x_N(t_j),\frac{x_N(t_{j+1})-x_N(t_j)}{h_N}\Big)\\ &+\sum_{j=0}^{N-1}\int_{t_j}^{t_{j+1}}\Big\|\frac{x_N(t_{j+1})-x_N(t_j)}{h_N}-\dot{\bar{x}}(t)\Big\|^2\,dt \end{aligned} \tag{3.3}$$

over discrete trajectories $x_N=x_N(\cdot)=\big(x_0,x_N(t_1),\ldots,x_N(t_N)\big)$ for the difference inclusions (3.1) subject to the constraints

$$\varphi_i\big(x_N(t_N)\big)\le\ell\eta_N \ \text{ for } \ i=1,\ldots,m, \tag{3.4}$$

$$-\ell\eta_N\le\varphi_i\big(x_N(t_N)\big)\le\ell\eta_N \ \text{ for } \ i=m+1,\ldots,m+r, \tag{3.5}$$

$$\|x_N(t_j)-\bar{x}(t_j)\|\le\frac{\epsilon}{2} \ \text{ for } \ j=1,\ldots,N, \quad \text{and} \tag{3.6}$$

$$\sum_{j=0}^{N-1}\int_{t_j}^{t_{j+1}}\Big\|\frac{x_N(t_{j+1})-x_N(t_j)}{h_N}-\dot{\bar{x}}(t)\Big\|^2\,dt\le\frac{\epsilon}{2}. \tag{3.7}$$

Considering in what follows (without further mentioning) the piecewise linear extension of $x_N(\cdot)$ to the whole interval $[a,b]$, we observe the relationships:

$$\begin{cases} x_N(t)=x_0+\displaystyle\int_a^t\dot{x}_N(s)\,ds \quad \text{for all } t\in[a,b] \quad \text{and}\\[2ex] \dot{x}_N(t)=\dot{x}_N(t_j)\in F\big(x_N(t_j)\big), \ \ t\in[t_j,t_{j+1}), \ \ j=0,\ldots,N-1. \end{cases} \tag{3.8}$$

In the next theorem, we establish that the given *relaxed* intermediate local minimizer $\bar{x}(\cdot)$ to (P) can be approximated by *optimal solutions* to (P_N) *strongly* in $W^{1,2}\big([a,b];X\big)$; the latter implies the a.e. *pointwise* convergence of the derivatives

significant for the main results of the paper. To justify such an approximation, we need to impose the *Asplund* structure on *both* the state space X and its dual X^*, which is particularly the case when X is *reflexive*. Note also there are *nonreflexive* (even separable) spaces for which both X and X^* are Asplund; see, e.g., [4].

THEOREM 3.2 (strong convergence of discrete optimal solutions). *Let $\bar{x}(\cdot)$ be a relaxed intermediate local minimizer for the Bolza problem (P) under the standing assumptions* (H1)–(H3) *in the Banach state space X, and let (P_N), $N \in \mathbb{N}$, be a sequence of discrete approximation problems built above. The following hold:*

(i) *Each (P_N) admits an optimal solution.*

(ii) *If in addition both X and X^* are Asplund, then any sequence $\{\bar{x}_N(\cdot)\}$ of optimal solutions to (P_N) converges to $\bar{x}(\cdot)$ strongly in $W^{1,2}\big([a,b];X\big)$.*

Proof. To justify assertion (i), we first observe that the set of *feasible* solutions to each problem (P_N) is *nonempty* for all $N \in \mathbb{N}$ sufficiently large. Indeed, pick the discrete trajectory $\widehat{x}_N(\cdot)$ approximating the given local minimizer $\bar{x}(\cdot)$ by Lemma 3.1 and show that it satisfies all the constraints (3.4)–(3.7) for large N. By assumption (H3) we have

$$\big|\varphi_i\big(\widehat{x}_N(t_N)\big) - \varphi_i\big(\bar{x}(b)\big)\big| \le \ell \,\|\widehat{x}(t_N) - \bar{x}(t_N)\| \le \ell\eta_N \;\text{ for all }\; i = 1,\dots,m+r$$

due to (3.2). This implies the fulfillment of the endpoint constraints (3.4) and (3.5) for $\widehat{x}_N(\cdot)$, since those in (1.3) and (1.4) hold for $\bar{x}(\cdot)$. The fulfillment of (3.6) for $\widehat{x}_N(\cdot)$ follows directly from the construction of $\eta_N \to 0$ in (3.2). Further, it is easy to check that

$$\sum_{j=0}^{N-1} \int_{t_j}^{t_{j+1}} \Big\| \frac{\widehat{x}_N(t_{j+1}) - \widehat{x}_N(t_j)}{h_N} - \dot{\bar{x}}(t) \Big\|^2 dt = \int_a^b \|\dot{\widehat{x}}_N(t) - \dot{\bar{x}}(t)\|^2 \, dt =: \alpha_N$$

for the piecewise linear extension of $\widehat{x}_N(\cdot)$ to $[a,b]$. By the $W^{1,2}$-approximation in Lemma 3.1 we have that $\alpha_N \to 0$ as $N \to \infty$, which justifies the fulfillment of (3.7) for large N. The *existence of optimal solutions* to (P_N) follows now from the classical Weierstrass theorem due to the compactness and continuity assumptions made in (H1)–(H3).

Let us now prove the convergence assertion (ii) under the additional assumptions on the state space. Check first the *value convergence*

$$J_N[\widehat{x}_N] \to J[\bar{x}] \quad \text{as} \quad N \to \infty \tag{3.9}$$

along a subsequence of $N \to \infty$. Considering the expression for $J_N[\widehat{x}_N]$ in (3.3) and using assumptions (H2) and (H3), we observe that (3.9) follows from

$$\begin{aligned} h_N \sum_{j=0}^{N-1} \vartheta\Big(\widehat{x}_N(t_j), \frac{\widehat{x}_N(t_{j+1}) - \widehat{x}_N(t_j)}{h_N}\Big) &= \sum_{j=0}^{N-1} \int_{t_j}^{t_{j+1}} \vartheta\big(\widehat{x}_N(t_j), \dot{\widehat{x}}_N(t)\big)\, dt \\ = \int_a^b \vartheta\big(\widehat{x}_N(t), \dot{\widehat{x}}_N(t)\big)\, dt + O(h_N) &\to \int_a^b \vartheta\big(\bar{x}(t), \dot{\bar{x}}(t)\big)\, dt \;\text{ as }\; N \to \infty, \end{aligned}$$

which hold by Lemma 3.1 ensuring the a.e. convergence $\dot{\widehat{x}}_N(t) \to \dot{\bar{x}}(t)$ along a subsequence and by the Lebesgue dominated convergence theorem valid for the Bochner integral.

None of the previous arguments used either the relaxation property of the intermediate minimizer or the Asplund property of X and X^*. Now we are going to

employ these properties to justify the relationship

$$\lim_{N\to\infty}\Big[\beta_N:=\int_a^b\|\dot{\bar{x}}_N(t)-\dot{\bar{x}}(t)\|^2\,dt\Big]=0 \tag{3.10}$$

for *every* sequence of optimal solutions $\bar{x}_N(\cdot)$ to (P_N).

Arguing by contradiction, pick a limiting point $\beta>0$ of $\{\beta_N\}$ in (3.10) and suppose for simplicity that $\beta_N\to\beta$ for all $N\to\infty$. To proceed, observe that both spaces X and X^* *enjoy the RNP*. Indeed, the one for X^* is equivalent to the Asplund property of X, while the Asplund property of X^* ensures the RNP for X due to the latter fact and that of $X\subset X^{**}$. Taking into account (H1) and (3.8), we apply to the sequence $\{\dot{\bar{x}}_N(\cdot)\}$ the Dunford theorem [4, Theorem IV.1] on the *weak compactness* in $L^1\big([a,b];X\big)$, which allows us to find a subsequence of $\{\dot{\bar{x}}_N(\cdot)\}$ and a mapping $v(\cdot)\in L^1\big([a,b];X\big)$ such that

$$\dot{\bar{x}}_N(\cdot)\to v(\cdot)\ \text{ weakly in }\ L^1\big([a,b];X\big)\ \text{ as }\ N\to\infty. \tag{3.11}$$

Using (3.8) and the compactness in $C\big([a,b];X\big)$ of solution sets for differential inclusions that holds under the assumptions made in (H1) (see, e.g., [18, Theorem 3.4.2]), we conclude that the sequence $\{\bar{x}_N(\cdot)\}$ contains a subsequence that converges to some $\widetilde{x}\in C\big([a,b];X\big)$ in the norm topology of the space $C\big([a,b];X\big)$. Passing to the limit in the first relationship of (3.8), while taking into account (3.11) and the weak continuity of the Bochner integral as an operator from $L^1\big([a,b];X\big)$ to X, we arrive at the representation

$$\widetilde{x}(t)=x_0+\int_a^t v(s)\,ds\ \text{ for all }\ t\in[a,b],$$

which implies that $v(t)=\dot{\widetilde{x}}(t)$ for a.e. $t\in[a,b]$.

Furthermore, the classical Mazur *weak closure* theorem ensures that $\widetilde{x}(\cdot)$ is a solution to the *convexified* differential inclusion (2.6). By the structure of problems (P_N) and by the construction of $\widetilde{x}(\cdot)$, it is not hard to conclude that $\widetilde{x}(\cdot)$ satisfies the endpoint constraints (1.3) and (1.4) and that it belongs to the prescribed ϵ-neighborhood of $\bar{x}(\cdot)$ in the norm topology of $W^{1,2}\big([a,b];X\big)$. By passing to the limit in the obvious inequality

$$J_N[\bar{x}_N]\le J_N[\widehat{x}_N]\ \text{ for all large }\ N\in\mathbb{N},$$

while taking into account (3.9) and the lower semicontinuity of the *convexified* integrand $\widehat{\vartheta}_F(x,\cdot)$ from (2.5) in the *weak* topology of $L^2\big([a,b];X\big)$, we get

$$\widehat{J}[\widetilde{x}]=\varphi_0\big(\widetilde{x}(b)\big)+\int_a^b\widehat{\vartheta}_F\big(\widetilde{x}(t),\dot{\widetilde{x}}(t)\big)\,dt+\beta\le J[\bar{x}].$$

Since $\beta>0$ and $J[\bar{x}]=\widehat{J}[\bar{x}]$, the latter gives $\widehat{J}[\widetilde{x}]<\widehat{J}[\bar{x}]$, which contradicts the choice of $\bar{x}(\cdot)$ as a relaxed intermediate local minimizer for (P). Thus (3.10) holds, and so $\bar{x}_N(\cdot)\to\bar{x}(\cdot)$ as $N\to\infty$ strongly in $W^{1,2}\big([a,b];X\big)$. This completes the proof of the theorem. □

The strong convergence result of Theorem 3.2 *makes a bridge* between the original continuous-time dynamic optimization problem (P) and its discrete-time counterparts (P_N), which allows us to derive necessary optimality conditions for (P) by passing to the limit from those for (P_N). The latter ones are *intrinsically nonsmooth* and require appropriate tools of generalized differentiation for their variational analysis.

4. Generalized differentiation. In this section, we define the main constructions of generalized differentiation used in what follows. Since the major framework in this paper is the class *Asplund spaces*, we present simplified definitions and some properties held in this setting. All the material reviewed and employed below is taken from the author's book [13], where the reader can find more details and references.

We start with generalized normals to closed sets $\Omega \subset X$. Given $\bar{x} \in \Omega$, the (basic, limiting) *normal cone* to Ω at $\bar{x}$ is defined by

$$N(\bar{x};\Omega) := \operatorname*{Lim\,sup}_{x\to\bar{x}} \widehat{N}(x;\Omega), \tag{4.1}$$

where "Lim sup" stands for the *sequential* upper/outer limit (1.6) of the *Fréchet normal cone* (or the *prenormal cone*) to Ω at $x \in \Omega$ given by

$$\widehat{N}(x;\Omega) := \left\{ x^* \in X^* \Big| \limsup_{u \overset{\Omega}{\to} x} \frac{\langle x^*, u-x\rangle}{\|u-x\|} \le 0 \right\}, \tag{4.2}$$

where $x \overset{\Omega}{\to} \bar{x}$ signifies that $x \to \bar{x}$ with $x \in \Omega$, and where $\widehat{N}(x;\Omega) := \emptyset$ for $x \notin \Omega$.

Given a set-valued mapping $F\colon X \rightrightarrows Y$ of closed graph

$$\operatorname{gph} F := \big\{(x,y) \in X \times Y \big| \; y \in F(x)\big\},$$

define its *normal coderivative* and *Fréchet coderivative* at $(\bar{x},\bar{y}) \in \operatorname{gph} F$ by, respectively,

$$D^*F(\bar{x},\bar{y})(y^*) := \big\{x^* \in X^* \big| \; (x^*,-y^*) \in N\big((\bar{x},\bar{y});\operatorname{gph} F\big)\big\}, \tag{4.3}$$

$$\widehat{D}^*F(\bar{x},\bar{y})(y^*) := \big\{x^* \in X^* \big| \; (x^*,-y^*) \in \widehat{N}\big((\bar{x},\bar{y});\operatorname{gph} F\big)\big\}. \tag{4.4}$$

If $F = f\colon X \to Y$ is *strictly differentiable* at $\bar{x}$ (in particular, if $f \in C^1$), then

$$D^*f(\bar{x})(y^*) = \widehat{D}^*f(\bar{x})(y^*) = \big\{\nabla f(\bar{x})^* y^*\big\}, \quad y^* \in Y^*,$$

i.e., both coderivatives (4.3) and (4.4) are positively homogeneous extensions of the classical *adjoint* derivative operator to nonsmooth and set-valued mappings.

Finally, consider a function $\varphi\colon X \to \mathbb{R}$ *locally Lipschitzian* around $\bar{x}$; in this paper we do not use more general functions. Then the (basic, limiting) *subdifferential* of φ at $\bar{x}$ is defined by

$$\partial\varphi(\bar{x}) := \operatorname*{Lim\,sup}_{x\to\bar{x}} \widehat{\partial}\varphi(x), \tag{4.5}$$

where the sequential outer limit (1.6) of the *Fréchet subdifferential* mapping $\widehat{\partial}\varphi(\cdot)$ is given by

$$\widehat{\partial}\varphi(x) := \left\{ x^* \in X^* \Big| \; \frac{\varphi(u)-\varphi(x)-\langle x^*, u-x\rangle}{\|u-x\|} \ge 0 \right\}. \tag{4.6}$$

We are not going to review in this section appropriate properties of the generalized differential constructions (4.1)–(4.6) used in sections 5–7; these properties will be invoked with the exact references to [13] in the corresponding places of the proofs in the subsequent sections. Just note here that our basic/limiting constructions (4.1),

(4.3), and (4.5) enjoy *full calculus* in the framework of Asplund spaces, while the Fréchet-like ones (4.2), (4.4), and (4.6) satisfy certain rules of "fuzzy calculus." Both of these calculi are employed in what follows. The reader can find some additional and related material in the books by Rockafellar and Wets [16], Smirnov [17], and Vinter [19] (concerning exact/full calculus in finite dimensions) and in the book by Borwein and Zhu [1] on fuzzy calculus in infinite dimensions; see also the references therein.

5. Optimality conditions for discrete inclusions. In this section we derive necessary optimality conditions for the sequence of discrete approximation problems (P_N) defined in (3.1) and (3.3)–(3.7). We present results only in the "fuzzy" form, which are more convenient for deriving necessary conditions for the original problem (P) by the limiting procedure in section 6. "Pointwise" necessary conditions for (P_N) and for related discrete-time problems (not used in this paper) can be found in [14, subsection 6.1.4].

Observe first that each discrete optimization problem (P_N) can be equivalently written in a special form of *constrained mathematical programming* problem in infinite-dimensional spaces:

$$\text{(5.1)}\qquad \begin{cases} \text{minimize } \ \psi_0(z) \ \text{ subject to} \\ \psi_j(z) \le 0, \quad j = 1, \dots, s, \\ f(z) = 0, \\ z \in \Theta_j \subset Z, \quad j = 1, \dots, l, \end{cases}$$

where ψ_j are real-valued functions on some Banach space Z, where $f\colon Z \to E$ is a mapping between Banach spaces, and where $\Theta_j \subset Z$. To see this, we let

$$z := (x_1, \dots, x_N, v_0, \dots, v_{N-1}) \in Z := X^{2N},$$
$$E := X^N, \ s := N + 2 + m + 2r, \ l := N - 1$$

and rewrite (P_N) as a mathematical programming problem (5.1) with the following data:

$$\text{(5.2)}\qquad \psi_0(z) := \varphi_0(x_N) + h_N \sum_{j=0}^{N-1} \vartheta(x_j, v_j) + \sum_{j=0}^{N-1} \int_{t_j}^{t_{j+1}} \|v_j - \dot{\bar{x}}(t)\|^2 \, dt,$$

$$\text{(5.3)}\qquad \psi_j(z) := \begin{cases} \|x_{j-1} - \bar{x}(t_{j-1})\| - \epsilon/2, \quad j = 1, \dots, N+1, \\ \displaystyle\sum_{i=0}^{N-1} \int_{t_i}^{t_{i+1}} \|v_i - \dot{\bar{x}}(t)\|^2 \, dt - \epsilon/2, \quad j = N+2, \\ \varphi_i(x_N) - \ell\eta_N, \quad j = N+2+i, \quad i = 1, \dots, m+r, \\ -\varphi_i(x_N) - \ell\eta_N, \quad j = N+2+m+r+i, \quad i = 1, \dots, r, \end{cases}$$

$$\text{(5.4)}\qquad \begin{cases} f(z) = \big(f_0(z), \dots, f_{N-1}(z)\big) \ \text{ with} \\ f_j(z) := x_{j+1} - x_j - h_N v_j, \quad j = 0, \dots, N-1, \end{cases}$$

$$\Theta_j := \Big\{ z \in X^{2N} \Big| \; v_j \in F(x_j) \Big\} \;\; \text{for} \;\; j = 0, \ldots, N-1 \tag{5.5}$$

in terms of the initial data of problem (P_N).

The next theorem establishes necessary optimality conditions for each problem (P_N) in the *approximate/fuzzy* form of refined *Euler–Lagrange* and *transversality inclusions* expressed in terms of Fréchet-like normals and subgradients. The proof is based on applying the corresponding *fuzzy calculus* rules and *neighborhood criteria* for *metric regularity and Lipschitzian behavior* of mappings from [13]. Note that fuzzy calculus rules provide representations of Fréchet subgradients and normals of sums and intersections at the reference points via those at points that are arbitrarily close to the reference ones. *Just for notational simplicity*, we suppose in the formulation and proof of the next theorem that these *arbitrarily close points reduce to the reference points in question*. This convention does not restrict the generality from the viewpoint of our main goal to derive necessary optimality conditions in the continuous-time problem (P). Indeed, the possible difference between the mentioned points obviously disappears in the limiting procedure.

THEOREM 5.1 (fuzzy Euler–Lagrange conditions for discrete approximations). *Let $\bar{x}_N(\cdot) = \{\bar{x}_N(t_j) | \; j = 0, \ldots, N\}$ be local optimal solutions to problems (P_N) as $N \to \infty$ under the assumptions* (H1)–(H3) *with the Asplund state space X. Consider the quantities*

$$\theta_{Nj} := 2 \int_{t_j}^{t_{j+1}} \Big\| \frac{\bar{x}_N(t_{j+1}) - \bar{x}_N(t_j)}{h_N} - \dot{\bar{x}}(t) \Big\| \, dt, \quad j = 0, \ldots, N-1. \tag{5.6}$$

Then there exists a sequence $\varepsilon_N \downarrow 0$ along some $N \to \infty$, and there are sequences of Lagrange multipliers λ_{iN}, $i = 0, \ldots, m+r$, and adjoint trajectories $p_N(\cdot) = \{p_N(t_j) \in X^* | \; j = 0, \ldots, N\}$ satisfying the following relationships:

- *the sign and nontriviality conditions*

$$\lambda_{iN} \ge 0 \;\; \textit{for all} \;\; i = 0, \ldots, m+r, \quad \sum_{i=0}^{m+r} \lambda_{iN} = 1; \tag{5.7}$$

- *the complementary slackness conditions*

$$\lambda_{iN} \Big[\varphi_i\big(\bar{x}_N(t_N)\big) - \ell\eta_N \Big] = 0 \;\; \textit{for} \;\; i = 1, \ldots, m; \tag{5.8}$$

- *the extended Euler–Lagrange inclusion in the approximate form*

$$\begin{aligned} \Big(\frac{p_N(t_{j+1}) - p_N(t_j)}{h_N}, p_N(t_{j+1}) - \lambda_{0N} \frac{\theta_{Nj}}{h_N} b^*_{N_j} \Big) &\in \lambda_{0N} \widehat{\partial} \vartheta \Big(\bar{x}_N(t_j), \frac{\bar{x}_N(t_{j+1}) - \bar{x}_N(t_j)}{h_N} \Big) \\ &+ \widehat{N} \Big(\Big(\bar{x}_N(t_j), \frac{\bar{x}_N(t_{j+1}) - \bar{x}_N(t_j)}{h_N} \Big); \operatorname{gph} F \Big) + \varepsilon \mathbb{B}^* \;\; \textit{with} \;\; b^*_{Nj} \in \mathbb{B}^*, \quad j = 0, \ldots, N-1; \end{aligned} \tag{5.9}$$

- *the approximate transversality inclusion*

$$\begin{aligned} -p_N(t_N) \in \sum_{i=0}^{m} \lambda_{iN} \widehat{\partial} \varphi_i\big(\bar{x}_N(t_N)\big) + \sum_{i=m+1}^{m+r} \lambda_{iN} \Big[\widehat{\partial} \varphi_i\big(\bar{x}_N(t_N)\big) \bigcup \widehat{\partial}\big(-\varphi_i\big)\big(\bar{x}_N(t_N)\big) \Big] \\ + \varepsilon \mathbb{B}^*. \end{aligned} \tag{5.10}$$

Proof. Consider problem (P_N) for any fixed $N \in N$ in the equivalent mathematical programming form (5.1) with the initial data (5.2)–(5.5). Denote

$$\bar{z} := \big(\bar{x}_N(t_1), \ldots, \bar{x}_N(t_N), \bar{v}_N(t_0), \ldots, \bar{v}_N(t_{N-1})\big)$$

and take N so large that the $W^{1,2}$-constraints (3.6) and (3.7) for $\bar{x}_N(\cdot)$ hold with the strict inequality, which is possible by Theorem 3.2. Thus the latter constraints can be simply *ignored* in what follows.

To prove the theorem, it is sufficient to examine the following two mutually exclusive cases, which completely cover the situation.

Case 1. Assume that the operator constraint mapping $f\colon X^{2N} \to X^N$ in (5.1) and (5.4) is *metrically regular* at $\bar{z}$ relative to the set $\Theta := \Theta_0 \cap \cdots \cap \Theta_{N-1}$ in (5.5) in the sense that there is a constant $\mu > 0$ and a neighborhood U of $\bar{z}$ satisfying the distance estimate

$$\operatorname{dist}(z; S) \le \mu \|f(z) - f(\bar{z})\| \ \text{ for all } \ z \in \Theta \cap U, \ \text{ where } \ S := \big\{z \in \Theta \big|\ f(z) = f(\bar{z})\big\}.$$

Then applying Ioffe's *exact penalization theorem* (see [14, Theorem 5.16]) and taking into account the specific structures of the inequality constraint functions ψ_j in (5.3) for $j = N + 2 + i$ as $i = 1, \ldots, m + r$, we conclude that $\bar{z}$ is a local optimal solution to the *unconstrained penalized problem*:

$$\begin{aligned} \text{minimize} \quad & \max\big\{\psi_0(z) - \psi_0(\bar{z}),\ \max_{i \in I(\bar{x}_N)} \varphi_i(x_N)\big\} \\ & + \ \mu\big(\|f(z)\| + \operatorname{dist}(z; \Theta)\big) \end{aligned} \tag{5.11}$$

for all $\mu > 0$ sufficiently large, where

$$I(\bar{x}_N) := \big\{i \in \{1, \ldots, m\}\big|\ \varphi_i(\bar{x}_N) = \ell\eta_N\big\}$$

$$\bigcup \big\{i \in \{m+1, \ldots, m+r\}\big|\ \text{either } \varphi_i(\bar{x}_N) = \ell\eta_N \text{ or } -\varphi_i(\bar{x}_N) = \ell\eta_N\big\}.$$

Applying the generalized Fermat rule [13, Proposition 1.114] to the local optimal solution $\bar{z}$ for (5.11), we arrive at the subdifferential inclusion

$$0 \in \widehat{\partial}\Big[\max\big\{\psi_0(\cdot) - \psi_0(\bar{z}),\ \max_{i \in I(\bar{x}_N)} \varphi_i(\cdot)\big\} + \mu\|f(\cdot)\| + \mu \operatorname{dist}(\cdot; \Theta)\Big](\bar{z}). \tag{5.12}$$

Fix any $\varepsilon > 0$ and apply the fuzzy sum rule for Fréchet subgradients from [13, Theorem 2.33(b)] to (5.12). This gives (remember out notational convention)

$$0 \in \widehat{\partial}\Big[\max\big\{\psi_0(\cdot) - \psi_0(\bar{z}),\ \max_{i \in I(\bar{x}_N)} \varphi_i(\cdot)\big\}\Big](\bar{z}) + \mu\,\widehat{\partial}\|f(\cdot)\|(\bar{z}) + \mu\,\widehat{\partial}\operatorname{dist}(\bar{z}; \Theta) + (\varepsilon/4)\mathbb{B}^*.$$

Computing now by [13, Proposition 1.85] the Fréchet subdifferential of the distance function $\operatorname{dist}(\bar{z}; \Theta)$ and using the simple chain rule for the composition $\|f(z)\| = (\phi \circ f)(z)$ with $\phi(y) := \|y\|$ and the smooth mapping f from (5.4), we get

$$0 \in \widehat{\partial}\Big[\max\big\{\psi_0(\cdot) - \psi_0(\bar{z}),\ \max_{i \in I(\bar{x}_N)} \varphi_i(\cdot)\big\}\Big](\bar{z}) + \sum_{j=0}^{N-1} \nabla f_j(\bar{z})^* e_j^* + \widehat{N}(\bar{z}; \Theta) + (\varepsilon/4)\mathbb{B}^*$$

for some $e_j^* \in X^*$ with, by the structure of f in (5.4),

$$\begin{aligned} \sum_{j=0}^{N-1} \nabla f_j(\bar{z})^* e_j^* = \big(& -e_0^*, e_0^* - e_1^*, \ldots, e_{N-2}^* \\ & - e_{N-1}^*, e_{N-1}^*, -h_N e_0^*, \ldots, -h_N e_{N-1}^*\big). \end{aligned} \tag{5.13}$$

To proceed further, we use the fuzzy intersection rule from [13, Lemma 3.1] ensuring that

$$\widehat{N}(\bar{z};\Theta)\subset\widehat{N}(\bar{z};\Theta_0)+\cdots+\widehat{N}(\bar{z};\Theta_{N-1})+(\varepsilon/4)\mathbb{B}^*$$

and also employ the fuzzy rule for Fréchet subgradients of the maximum function (cf. [13, Theorem 3.46] and its proof), giving, by the structure of the index set $I(\bar{x}_N)$, the inclusion

$$\begin{aligned}&\widehat{\partial}\Big[\max\big\{\psi_0(\cdot)-\psi_0(\bar{z}),\max_{i\in I(\bar{x}_N)}\varphi_i(\cdot)\big\}\Big](\bar{z})\\&\subset\sum_{i=0}^{m}\lambda_{iN}\widehat{\partial}\varphi_i(\bar{x}_N)+\sum_{i=m+1}^{m+r}\lambda_{iN}\Big[\widehat{\partial}\varphi_i(\bar{x}_N)\bigcup\widehat{\partial}(-\varphi_i)(\bar{x}_N)\Big]+(\varepsilon/4)\mathbb{B}^*,\end{aligned}$$

where the multipliers λ_{iN}, $i=0,\ldots,m+r$, satisfy the sign, nontriviality, and complementary slackness conditions in (5.7) and (5.8).

Applying the aforementioned fuzzy sum rule to the cost function (5.2) and taking into account the classical relationship

$$\partial\|\cdot\|^2(x)\subset 2\|x\|\mathbb{B}^*\ \text{ for any }\ x\in X,$$

as well as the subdifferentiation formula under the integral sign in (5.2) well known from convex analysis, we have the inclusion

$$\widehat{\partial}\psi_0(\bar{z})\subset\widehat{\partial}\varphi_0(\bar{x}_N)+h_N\sum_{j=0}^{N-1}\Big[\widehat{\partial}\vartheta\big(\bar{x}_j,\bar{v}_j\big)+\big(0,2\theta_{Nj}\mathbb{B}^*\big)\Big]+(\varepsilon/4)\mathbb{B}^*,$$

where θ_{Nj} are defined in (5.6). Finally, choose $p_N(t_0)\in X^*$ arbitrarily and let

$$p_N(t_j):=e^*_{j-1},\quad j=1,\ldots,N,$$

with e^*_j given in (5.13). Then taking into account the special separated structures of the sets Θ_j in (5.5), we arrive at the Euler–Lagrange and transversality inclusions (5.9) and (5.10) with $\varepsilon_N=\varepsilon$ by substituting the corresponding fuzzy relationships derived above into the generalized Fermat stationary condition (5.12). This completes the proof of the theorem in Case 1.

Case 2. It remains to consider the situation when the mapping f from (5.4) is *not metrically regular* at $\bar{z}$ relative to the set intersection $\Theta:=\Theta_0\cap\cdots\cap\Theta_{N-1}$. Let us show that this *never holds*, along some subsequences $\varepsilon_N\downarrow 0$ and $N\to\infty$, under the local Lipschitzian assumption imposed on F.

Indeed, in this case the *restriction* $f_\Theta\colon X^{2N}\to X^N$ of f to Θ defined by

$$f_\Theta(z):=\begin{cases}f(z) & \text{if }\ z\in\Theta,\\ \emptyset & \text{otherwise}\end{cases}$$

is obviously *not* metrically regular *around* $\bar{z}$ in the sense of [13, Definition 1.47]. Then the *characterization* of the latter property from [13, Theorem 4.5] allows us, for any fixed $\varepsilon>0$, to find $z\in\bar{z}+\varepsilon\mathbb{B}$ and $e^*=(e^*_0,\ldots,e^*_{N-1})\in(X^*)^N$ such that

$$\|e^*\|>1\ \text{ and }\ 0\in\widehat{D}^*f_\Theta(z)(e^*)$$

via the Fréchet coderivative (4.4) of f_Θ. Employing now the coderivative sum rule from [13, Theorem 1.62] and the fuzzy intersection rule from [13, Lemma 3.1], we get

$$0 \in \sum_{j=0}^{N-1} \nabla f_j(z)^* e_j^* + \sum_{j=0}^{N-1} \widehat{N}(z_j;\Theta_j) + \varepsilon\mathbb{B}^*$$

with some $z_j \in \Theta_j \cap (z+\varepsilon\mathbb{B})$. According to our notation agreement, we put $z_j = z = \bar{z}$ for simplicity. Thus there are $z_j^* \in \widehat{N}(\bar{z};\Theta_j)$ satisfying

$$-\sum_{j=0}^{N-1} z_j \in \sum_{j=0}^{N-1} \nabla f_j(\bar{z})^* e_j^* + \varepsilon\mathbb{B}^*. \tag{5.14}$$

Taking into account calculation (5.13) due to the form (5.4) of the mapping f and the specific structures of the sets Θ_j in (5.5), we find from (5.14) dual elements

$$(x_{ij}^*, v_{ij}^*) \in \widehat{N}\left(\Big(\bar{x}_N(t_j), \frac{\bar{x}_N(t_{j+1}) - \bar{x}_N(t_j)}{h_N}\Big); \operatorname{gph} F_j\right), \quad j = 0,\ldots,N-1,$$

satisfying the relationships

$$\begin{cases} -x_{jj}^* - e_{j-1}^* + e_j^* \in \varepsilon\mathbb{B}^*, \quad j = 0,\ldots,N-1, \\ -v_{jj}^* + h_N e_j^* \in \varepsilon\mathbb{B}^*, \quad j = 0,\ldots,N-1, \\ -e_{N-1}^* \in \varepsilon\mathbb{B}^*. \end{cases}$$

Define now the adjoint discrete trajectory $p_N(t_j)$, $j = 0,\ldots,N$, as in Case 1. Then the above relationships ensure that the pair $\big(\bar{x}_N(\cdot), p_N(\cdot)\big)$ satisfies the Euler–Lagrange inclusion (5.9) and the transversality inclusion (5.10) with

$$\lambda_{iN} = 0 \ \text{ for all } \ i = 0,\ldots,m+r$$

and the following nontriviality condition:

$$\|p_N(t_1)\| + \cdots + \|p_N(t_N)\| \ge 1 \ \text{ for all large } \ N \in \mathbb{N}. \tag{5.15}$$

Let us show that condition (5.15) *contradicts* (5.9) and (5.10) with $\lambda_{iN} = 0$ due the *locally Lipschitzian* property of F assumed in the theorem.

To proceed, we observe that the Euler–Lagrange inclusion (5.9) with $\lambda_{0N} = 0$ can be equivalently written as

$$\frac{p_N(t_{j+1}) - p_N(t_j)}{h_N} \in \widehat{D}^* F\Big(\bar{x}_N(t_j), \frac{\bar{x}_N(t_{j+1}) - \bar{x}_N(t_j)}{h_N}\Big)\big(-p_N(t_{j+1})\big) + \varepsilon\mathbb{B}^*, \quad j = 0,\ldots,N-1.$$

Then the local Lipschitzian property of F with modulus ℓ_F yields, by the *neighborhood coderivative characterization* of [13, Theorem 4.7], that

$$\|x_j^*\| \le \ell_F \|v_j^*\| \ \text{ whenever } \ x_j^* \in \widehat{D}^* F_j(x_j, v_j)(v_j^*)$$

and (x_j, v_j) near $\big(\bar{x}_N(t_j), [\bar{x}_N(t_{j+1}) - \bar{x}_N(t_j)]/h_N\big)$. Thus

$$\|p_N(t_{N-1})\| \le \|p_N(t_N)\|\big(1 + h_N \ell_F\big) + \varepsilon h_N$$

and then, as a discrete counterpart of the Gronwall lemma,

$$\|p_N(t_j)\| \le \exp\big(\ell_F(b-a)\big)\|p_N(t_N)\| + \varepsilon(b-a) \ \text{ for all } \ j=0,\dots,N. \tag{5.16}$$

Finally, take a sequence $\nu_k \downarrow 0$ as $k\to\infty$ and choose numbers N_k and ε_k such that

$$N_k := \big[1/\nu_k\big] \ \text{ and } \ \varepsilon_k \le \nu_k^2 \ \text{ as } \ k\in\mathbb{N},$$

where $[\cdot]$ stands for the greatest integer less than or equal to the given real number. By (5.16) and by the transversality condition (5.10) with $\lambda_{iN}=0$ along the chosen sequences of $\varepsilon_k=\varepsilon_{N_k}\downarrow 0$ and $N_k\to\infty$ as $k\to\infty$, we have the estimate

$$\sum_{j=1}^{N_k}\|p_{N_k}(t_j)\| \le \nu_k\exp\big(\ell_F(b-a)\big)+\nu_k(b-a)\downarrow 0 \ \text{ as } \ k\in\mathbb{N},$$

which contradicts (5.15) and completes the proof of the theorem. □

6. Extended Euler–Lagrange conditions for relaxed minimizers. In this section we derive necessary optimality conditions in the refined forms of the extended Euler–Lagrange and transversality inclusions for *relaxed* intermediate local minimizers of the original problem (P). The proof is based on the passing to the limit from the necessary optimality conditions for discrete approximation problems obtained in section 5 and on the usage of the *strong stability* of discrete approximations established in section 3. A crucial part of the proof involves the justification of an appropriate convergence of *adjoint arcs*; the latter becomes possible due to the *coderivative characterization* of Lipschitzian set-valued mappings taken from [13].

THEOREM 6.1 (extended Euler–Lagrange and transversality inclusions for relaxed intermediate minimizers). *Let $\bar{x}(\cdot)$ be a relaxed intermediate local minimizer for the Bolza problem (P) given in (1.1)–(1.4) under the standing assumptions of section 2, where the spaces X and X^* are Asplund. Then there are nontrivial Lagrange multipliers $0\ne(\lambda_0,\dots,\lambda_{m+r})\in\mathbb{R}^{m+r+1}$ and an absolutely continuous mapping $p\colon[a,b]\to X^*$ such that the following necessary conditions hold:*

- *the sign conditions*

$$\lambda_i\ge 0 \ \text{ for all } \ i=0,\dots,m+r; \tag{6.1}$$

- *the complementary slackness conditions*

$$\lambda_i\varphi_i\big(\bar{x}(b)\big)=0 \ \text{ for } \ i=1,\dots,m; \tag{6.2}$$

- *the extended Euler–Lagrange inclusion, for a.e., $t\in[a,b]$,*

$$\dot{p}(t)\in \operatorname{clco}\Big\{u\in X^*\Big|\ \big(u,p(t)\big)\in\lambda_0\partial\vartheta\big(\bar{x}(t),\dot{\bar{x}}(t)\big)+N\big((\bar{x}(t),\dot{\bar{x}}(t));\operatorname{gph}F\big)\Big\}; \tag{6.3}$$

- *and the transversality inclusion*

$$-p(b)\in\sum_{i=0}^{m}\lambda_i\partial\varphi_i\big(\bar{x}(b)\big)+\sum_{i=m+1}^{m+r}\lambda_i\Big[\partial\varphi_i\big(\bar{x}(b)\big)\bigcup\partial\big(-\varphi_i\big)\big(\bar{x}(b)\big)\Big]. \tag{6.4}$$

Proof. Given the intermediate local minimizer $\bar{x}(\cdot)$ to (P), employ Theorem 3.2, which ensures the strong $W^{1,2}$-approximation of $\bar{x}(\cdot)$ by a sequence of optimal solutions $\bar{x}_N(\cdot)$ to problems (P_N). Applying now the necessary optimality condition

of Theorem 5.1, we find sequence of multipliers λ_{iN}, $i=0,\ldots,m+r$, and adjoint trajectories $p_N(\cdot)$ satisfying conditions (5.7)–(5.10). Without loss of generality, we can and do suppose that

$$\lambda_{iN}\to\lambda_i \ \text{ as } \ N\to\infty \ \text{ for all } \ i=0,\ldots,m+r,$$

where the limiting multipliers λ_i, $i=0,\ldots,m+r$, are not zero simultaneously and satisfy the sign condition (6.1). Moreover, we get the complementarity slackness conditions (6.2) by passing to the limit in (5.8) with $\eta_N\to 0$ as $N\to\infty$.

Let us next justify the possibility of passing to the limit in the approximate Euler–Lagrange (5.9) and transversality (5.10) inclusions for the discrete-time problems (P_N). Having θ_{Nj} defined in (5.6), consider the corresponding sequence of functions $\theta_N\colon[a,b]\to\mathbb{R}$ given by

$$\theta_N(t):=\frac{\theta_{Nj}}{h_N}b^*_{Nj} \ \text{ for } \ t\in[t_j,t_{j+1}), \ \ j=0,\ldots,N-1.$$

It follows from the strong $W^{1,2}$-convergence of Theorem 3.2 that

$$\begin{aligned}\int_a^b\big\|\theta_N(t)\big\|\,dt \ &\le \sum_{j=0}^{N-1}\theta_{Nj}\le 2\sum_{j=0}^{N-1}\int_{t_j}^{t_{j+1}}\Big\|\frac{\bar x_N(t_{j+1})-\bar x_N(t_j)}{h_N}-\dot{\bar x}_N(t)\Big\|\,dt\\ &=2\int_a^b\|\dot{\bar x}_N(t)-\dot{\bar x}(t)\|\,dt\to 0,\end{aligned}$$

which allows us to suppose without loss of generality that

$$\dot{\bar x}_N(t)\to\dot{\bar x}(t) \ \text{ and } \ \theta_N(t)\to 0 \ \text{ a.e. } \ t\in[a,b] \ \text{ as } \ N\to\infty.$$

Furthermore, we derive from the approximate Euler–Lagrange condition (5.9) that there are

$$e^*_{Nj},\widetilde e^*_{Nj}\in\mathbb{B}^* \ \text{ and } \ (x^*_{Nj},v^*_{Nj})\in\widehat\partial\vartheta\Big(\bar x_N(t_j),\frac{\bar x_N(t_{j+1})-\bar x_N(t_j)}{h_N}\Big), \quad j=0,\ldots,N-1,$$

such that the discrete-time inclusions

$$\begin{aligned}&\Big(\frac{p_N(t_{j+1})-p_N(t_j)}{h_N}-\lambda_{0N}x^*_{Nj}\Big)+\varepsilon_N e^*_{N_j}\\ &\in\widehat D^*F\Big(\bar x_N(t_j),\frac{\bar x_N(t_{j+1})-\bar x_N(t_j)}{h_N}\Big)\Big(\lambda_N v^*_{Nj}+\lambda_{0N}\frac{\theta_{Nj}}{h_N}b^*_{Nj}-p_N(t_{j+1})+\varepsilon_N\widetilde e^*_{N_j}\Big)\end{aligned}$$

hold for all $j=0,\ldots,N-1$ and all $N\in\mathbb{N}$. Observe that, due to [13, Proposition 1.85], the sequences $\{(x^*_{Nj},v^*_{jN})\}$ are uniformly bounded for all $j=0,\ldots,N-1$ by the Lipschitz constant of ϑ. Since the mapping F is locally Lipschitzian with constant ℓ_F, we get by the coderivative condition for the Lipschitz continuity from [13, Theorem 1.43] that

$$\Big\|\frac{p_N(t_{j+1})-p_N(t_j)}{h_N}-\lambda_N x^*_{Nj}+\varepsilon_N e^*_{N_j}\Big\|\le\ell_F\Big\|\lambda_N v^*_{Nj}+\lambda_N\frac{\theta_{Nj}}{h_N}b^*_{Nj}-p_N(t_{j+1})+\varepsilon_N\widetilde e^*_{N_j}\Big\|$$

for $j=0,\ldots,N-1$. This allows us to conclude that the piecewise extensions $p_N(t)$, $a\le t\le b$, of the adjoint discrete arcs $p_N(\cdot)$ are uniformly bounded on $[a,b]$ with

$$\|\dot p_N(t)\|\le\alpha+\beta\|\theta_N(t)\| \ \text{ a.e. } \ t\in[a,b], \tag{6.5}$$

where the positive numbers α and β are independent of N. Using now the Dunford criterion for the weak compactness in $L^1\big([a,b];X^*\big)$ from [4, Theorem IV.1] (note that both X and X^* enjoy the RNP due to their assumed Asplund property) and arguing similarly to the proof of Theorem 3.2 above, we find an absolute continuous mapping $p\colon[a,b]\to X^*$ satisfying the Newton–Leibniz formula and such that $\dot p_N(\cdot)\to\dot p(\cdot)$ as $N\to\infty$ (with no loss of generality) in the weak topology of $L^1\big([a,b];X^*\big)$.

Next we conclude from the approximate transversality inclusion (5.10), the sign and nontriviality conditions in (5.7), and the local Lipschitz continuity of φ_i, $i=0,\dots,m+r$, with the common constant ℓ from (H3) that

$$\|p_N(b)\|\le\ell(m+2)+1\ \text{ for sufficiently large }\ N\in\mathbb{N}$$

due to the uniform boundedness of Fréchet subgradients of locally Lipschitzian functions by [13, Proposition 1.85]. Since X is Asplund, this implies the weak* sequential compactness of $\{p_N(b)\}$ in X^*. Thus, passing to the limit in (5.10) as $N\to\infty$ and using definition (4.5) of the basic subdifferential, we arrive at the transversality inclusion (6.4).

Considering now the approximate Euler–Lagrange inclusion (5.9), we equivalently rewrite it as

$$\begin{aligned}\dot p_N(t)\in\Big\{u\in X^*\ \Big|\ \big(u,p_N(t_{j+1})-\lambda_{0N}\theta_N(t)\big)\in\lambda_{0N}\widehat\partial\vartheta(\bar x_N(t_j),\dot{\bar x}_N(t))\\ +\ \widehat N\big((\bar x_N(t_j),\dot{\bar x}_N(t)\big);\operatorname{gph}F\big)+\varepsilon_N\mathbb{B}^*\Big\}\end{aligned}\tag{6.6}$$

for $t\in[t_j,t_{j+1})$ with $j=0,\dots,N-1$. Observe, by the weak continuity of the Bochner integral in the Newton–Leibniz formula and by $\dot p_N(\cdot)\to\dot p(\cdot)$ weakly in $L^1\big[a,b];X^*\big)$, that the values $p_N(t)$ converge to $p(t)$ weakly in X^*. Furthermore, the Mazur weak closure theorem ensures that some sequence of *convex combinations* of $\{\dot p_N(\cdot)\}$ converges to $\dot p(\cdot)$ strongly in $L^1\big([a,b];X^*\big)$ as $N\to\infty$, and hence its subsequence converges to $\dot p(t)$ *almost everywhere* on $[a,b]$. Passing finally to the limit in (6.6) and taking into account the established *pointwise* convergence together with (6.5), we arrive at the extended Euler–Lagrange inclusion (6.3) and complete the proof of the theorem. □

Note that the results obtained in Theorem 6.1 are different from those derived in [14, subsection 6.1.5] not only because of the *absence* of any SNC-like assumptions on the target/constraint set but also because here the "coderivative normality" property is *not* imposed on F, as is needed in [14] in similar settings. Observe also that the arguments developed above allow us to provide the correspondent improvements in the case of Lipschitzian endpoint constraints of the Euler–Lagrange-type necessary optimality conditions derived in [15] for evolution models governed by *semilinear inclusions*

$$\dot x(t)\in Ax(t)+F\big(x(t),t\big),\tag{6.7}$$

where A is an *unbounded* infinitesimal generator of a *compact* C_0*-semigroup* on X, and where continuous solutions to (6.7) are understood in the *mild* sense.

7. Euler–Lagrange and maximum conditions with no relaxation. The main objective of this section is to derive necessary optimality conditions for intermediate local minimizers $\bar x(\cdot)$ of evolution inclusions *without any relaxation*. We show that it can be done under certain more restrictive assumptions on the initial data in

comparison with those in Theorem 6.1. For simplicity, we consider here the *Mayer version* (P_M) of problem (P) with $\vartheta = 0$ in (1.1). In this case, the *Euler–Lagrange inclusion* (6.3) admits the *coderivative form*

$$\dot{p}(t) \in \operatorname{clco} D^*F\big(\bar{x}(t), \dot{\bar{x}}(t)\big)\big(-p(t)\big) \ \text{ a.e. } \ t \in [a,b], \tag{7.1}$$

which easily implies, due to the extremal property for coderivatives of convex-valued mappings given in [13, Theorem 1.34], the *Weierstrass–Pontryagin maximum condition*

$$\big\langle p(t), \dot{\bar{x}}(t)\big\rangle = \max_{v \in F(\bar{x}(t))} \big\langle p(t), v\big\rangle \ \text{ a.e. } \ t \in [a,b], \tag{7.2}$$

provided that the sets $F(x)$ are *convex* near $\bar{x}(t)$ for a.e. $t \in [a,b]$. Our goal is to justify the above Euler–Lagrange and Weierstrass–Pontryagin conditions, together with the other necessary optimality conditions of Theorem 6.1, for intermediate minimizers of the Mayer problem (P_M) subject to the Lipschitzian endpoint constraints (1.3) and (1.4), *without any convexity or relaxation* assumptions and with *no SNC-like* requirements imposed on the endpoint constraint set. To accomplish this goal, we employ a certain approximation technique involving *Ekeland's variational principle* combined with other advanced results of variational analysis and generalized differentiation, which allow us to reduce the constrained problem under consideration to an unconstrained (and thus *stable with respect to relaxation*) Bolza problem studied in section 6. However, this requires additional assumptions on the initial data of (P_M) imposed in what follows.

Recall that a set-valued mapping $F\colon X \rightrightarrows Y$ is *strongly coderivatively normal* at $(\bar{x}, \bar{y}) \in \operatorname{gph} F$ if its normal coderivative (4.3) admits the representation

$$\begin{aligned} D^*F(\bar{x},\bar{y})(y^*) = \Big\{ x^* \in X^* \Big| \ &\exists \text{ sequences } \ (x_k, y_k) \to (\bar{x}, \bar{y}),\ x_k^* \overset{w^*}{\to} x^*, \ \text{ and } \ y_k^* \to y^* \\ &\text{with } \ y_k \in F(x_k) \ \text{ and } \ x_k^* \in \widehat{D}^*F(x_k, y_k)(y_k^*) \ \text{ as } \ k \to \infty \Big\} \\ =: D_M^*F(\bar{x},\bar{y})(y^*), \end{aligned} \tag{7.3}$$

where $D_M^*F(\bar{x},\bar{y})$ is called the *mixed coderivative* of F at $(\bar{x},\bar{y})$. Observe that the only difference between the normal and mixed coderivatives of F at $(\bar{x},\bar{y})$ is that the *mixed* weak* convergence of $x_k^* \overset{w^*}{\to} x^*$ and the norm convergence of $y_k^* \to y^*$ is used for $D_M^*F(\bar{x},\bar{y})$ in (7.3), in contrast to the weak* convergence of *both* components $(x_k^*, y_k^*) \overset{w^*}{\to} (x^*, y^*)$ for $D^*F(\bar{x},\bar{y})$ in (4.3) via (4.1). Besides the obvious case of $\dim Y < \infty$, the strong coderivative normality holds in many important infinite-dimensional settings, and the property is preserved under various compositions; see [13, Proposition 4.9] describing major classes of mappings satisfying this property.

A mapping $F\colon X \rightrightarrows Y$ is called *sequentially normally compact* (SNC) at $(\bar{x},\bar{y}) \in \operatorname{gph} F$ if for any sequences $(x_k, y_k) \overset{\operatorname{gph} F}{\to} (\bar{x},\bar{y})$ and $(x_k^*, y^*) \in \widehat{N}\big((x_k, y_k); \operatorname{gph} F\big)$ one has

$$(x_k^*, y_k^*) \overset{w^*}{\to} 0 \Longrightarrow \|(x_k^*, y_k^*)\| \to 0 \ \text{ as } \ k \to \infty.$$

As was discussed in section 1, this property is a far-reaching extension of the "finite-codimension" and other related properties of sets and mappings. It always holds in finite dimensions, while in reflexive spaces it agrees with the "compactly epi-Lipschitzian" property by Borwein and Strójwas; see [13] for more details, discussions, and calculus.

Finally, recall that the given norm on a Banach space X is *Kadec* if the strong and weak convergences agree on the boundary of the unit sphere of X. It is well known that every reflexive space admits an equivalent Kadec norm.

THEOREM 7.1 (Euler–Lagrange and Weierstrass–Pontryagin conditions for intermediate local minimizers with no relaxation). *Let $\bar{x}(\cdot)$ be an intermediate local minimizer for the Mayer problem (P_M) in* (1.1)–(1.4) *under the standing hypotheses* (H1) *and* (H3) *on F and φ_i. Assume in addition that*

(a) *the state space X is separable and reflexive with the Kadec norm on it;*

(b) *the velocity mapping F is SNC at $\big(\bar{x}(t),\dot{\bar{x}}(t)\big)$ and strongly coderivatively normal with weakly closed graph around this point for a.e. $t\in[a,b]$.*

Then there are nontrivial Lagrange multipliers $0\neq(\lambda_0,\ldots,\lambda_{m+r})\in\mathbb{R}^{m+r+1}$ and an absolutely continuous mapping $p\colon[a,b]\to X^*$ satisfying the following relationships:

- *the sign and complementarity slackness conditions in* (6.1) *and* (6.2)*;*
- *the Euler–Lagrange inclusion* (7.1)*, where the closure operation is redundant;*
- *the Weierstrass–Pontryagin maximum condition* (7.2)*; and*
- *the transversality inclusion* (6.4)*.*

Proof. Denote

$$\varphi_0^+(x,\nu):=\max\big\{\varphi_0(x)-\nu,0\big\},\quad \varphi_i^+(x):=\max\big\{\varphi_i(x),0\big\},\ i=1,\ldots,m, \tag{7.4}$$

and, following the *method of metric approximations* [11], consider the parametric cost functional

$$\theta_\nu[x]:=\left[\big(\varphi_0^+\big)^2\big(x(b),\nu\big)+\sum_{i=1}^m\big(\varphi_i^+\big)^2\big(x(b)\big)+\sum_{i=m+1}^{m+r}\varphi_i^2\big(x(b)\big)\right]^{1/2},\quad \nu\in\mathbb{R}, \tag{7.5}$$

over trajectories for the evolution inclusion (1.1) with *no endpoint constraints*. Since $\bar{x}(\cdot)$ is an *intermediate local minimizer* for (P_M) and due to the constructions in (7.4) and (7.5), we have

$$\theta_\nu[x]>0\ \text{ for any }\ \nu<\bar{\nu}:=\varphi_0\big(\bar{x}(b)\big), \tag{7.6}$$

provided that $x(\cdot)$ is a trajectory for (1.2) belonging to the prescribed $W^{1,1}$-neighborhood of the given intermediate local minimizer and such that $x(t)\in U$ for all $t\in[a,b]$, where the open set $U\subset X$ is taken from the requirements in (H1) imposed on $\bar{x}(\cdot)$.

Form as in [2] the space $\mathcal{X}$ of all the trajectories $x(\cdot)$ for (1.2) satisfying *the only constraint* $x(t)\in\operatorname{cl}U$ as $t\in[a,b]$ with the metric

$$d[x,y]:=\int_a^b\|\dot{x}(t)-\dot{y}(t)\|\,dt.$$

We can easily check, based on Definition 2.1 of solutions to the original differential inclusion and on standard properties of the Bochner integral, that the metric space $\mathcal{X}$ is *complete* and that the function $\theta_\nu[\cdot]$ is (Lipschitz) continuous on $\mathcal{X}$ for any $\nu\in\mathbb{R}$. It follows from the above constructions that for every $\varepsilon>0$ there is $\nu_\varepsilon<\bar{\nu}$ such that $\nu_\varepsilon\to\bar{\nu}$ as $\varepsilon\downarrow0$ and

$$0\le\theta_\varepsilon[\bar{x}]<\varepsilon\le\inf_{x\in\mathcal{X}}\theta_\varepsilon[x]+\varepsilon\quad\text{with}\ \ \theta_\varepsilon:=\theta_{\nu_\varepsilon}.$$

Now applying the classical *Ekeland variational principle*, find an arc $x_\varepsilon(\cdot)\in\mathcal{X}$ satisfying

$$d[x_\varepsilon,\bar{x}]\le\sqrt{\varepsilon}\ \text{ and }\ \theta_\varepsilon[x]+\sqrt{\varepsilon}d[x,x_\varepsilon]\ge\theta_\varepsilon[x_\varepsilon]\ \text{ for all }\ x\in\mathcal{X}. \tag{7.7}$$

This distance estimate yields that $x_\varepsilon(t) \in U$ as $t \in [a,b]$ and that $x_\varepsilon(\cdot)$ belongs to the fixed $W^{1,1}$-neighborhood of the intermediate local minimizer $\bar{x}(\cdot)$ whenever $\varepsilon > 0$ is sufficiently small. Hence $\theta_\varepsilon[x_\varepsilon] > 0$ for such ε by (7.6).

Given positive numbers ε and $\eta > 0$, we form the Bolza functional

$$J_{\varepsilon,\eta}[x] := \theta_\varepsilon[x] + \sqrt{\varepsilon} d[x, x_\varepsilon] + \eta\sqrt{1+\ell_F^2} \int_a^b \operatorname{dist}\big((x(t), \dot{x}(t)); \operatorname{gph} F\big)\, dt$$

and show, following the proof of the claim in [14, Theorem 6.27], that there is a number $\eta \geq 1$ such that for every $\varepsilon \in (0, 1/\eta)$ the arc $x_\varepsilon(\cdot)$ built above is an *intermediate local minimizer* for this functional over all absolutely continuous mappings $x\colon [a,b] \to X$, *not necessarily trajectories* for (1.1), satisfying the constraints

$$x(a) = x_0 \;\text{ and }\; x(t) \in U \;\text{ for }\; t \in [a,b],$$

where the one $x(t) \in U$ can be *ignored* from the viewpoint of necessary optimality conditions, since the set U is open in X. Taking into account the structures of $\theta_\varepsilon[\cdot]$ and $d[\cdot,\cdot]$, we conclude that $x_\varepsilon(\cdot)$ is an intermediate minimizer for the following *unconstrained* Bolza problem with *Lipschitzian* data:

$$\text{minimize } \; \varphi_\varepsilon\big(x(b)\big) + \int_a^b \vartheta_\varepsilon\big(x(t), \dot{x}(t), t\big)\, dt \tag{7.8}$$

over absolutely continuous arcs $x\colon [a,b] \to X$ satisfying $x(a) = x_0$ and lying in a $W^{1,1}$-neighborhood of $\bar{x}(\cdot)$, where the functions $\varphi_\varepsilon\colon X \to \mathbb{R}$ and $\theta_\varepsilon\colon X \times X \times [a,b] \to \mathbb{R}$ are given by

$$\varphi_\varepsilon(x) := \left[(\varphi_0^+)^2(x, \nu_\varepsilon) + \sum_{i=1}^m \big(\varphi_i^+\big)^2(x) + \sum_{i=m+1}^{m+r} \varphi_i^2(x) \right]^{1/2}, \tag{7.9}$$

$$\vartheta_\varepsilon(x,v,t) := \eta\sqrt{1+\ell_F^2}\, \operatorname{dist}\big((x,v); \operatorname{gph} F\big) + \sqrt{\varepsilon}\|v - \dot{x}_\varepsilon(t)\|. \tag{7.10}$$

To apply the results of Theorem 6.1 to the case of problem (7.8), we first note that *every intermediate local minimizer* for the unconstrained problem (7.8) provides a *relaxed* intermediate local minimum for this problem. It follows from the *relaxation stability* of unconstrained Bolza problems with finite integrands, which is ensured by an appropriate infinite-dimensional extension of the classical Bogolyubov theorem valid under the assumptions made; see Lemma 2.3 above and its "intermediate" local counterpart given in [9, Theorem 4] whose proof holds in the infinite-dimensional setting under consideration. Furthermore, observe that although Theorem 6.1 is presented for autonomous problems, its results hold true with no change for the case of *summable* integrands as in (7.10); it can be justified similarly to the proof of [14, Theorem 6.22] given for problems with geometric endpoint constraints. Finally, it follows from the proof of Theorem 6.1 that the compactness of the velocity sets assumed in (H1) is, in fact, *not needed* for the unconstrained and $W^{1,1}$-bounded framework of the Bolza problem (7.8).

Applying the optimality conditions of Theorem 6.1 to problem (7.8) with the initial data (7.9) and (7.10), for all small $\varepsilon > 0$, we find an absolutely continuous adjoint arc $p_\varepsilon\colon [a,b] \to X^*$ satisfying

$$\dot{p}_\varepsilon(t) \in \operatorname{co}\Big\{ u \in X^* \;\Big|\; \big(u, p_\varepsilon(t)\big) \in \mu\, \partial \operatorname{dist}\big((x_\varepsilon(t), \dot{x}_\varepsilon(t)); \operatorname{gph} F\big) + \sqrt{\varepsilon}\big(0, \mathbb{B}^*\big) \Big\} \tag{7.11}$$

for a.e. $t\in[a,b]$ with $\mu:=\eta\sqrt{1+\ell_F^2}$ and

$$-p_\varepsilon(b)\in\partial\left[(\varphi_0^+)^2(\cdot,\nu_\varepsilon)+\sum_{i=1}^m\big(\varphi_i^+\big)^2(\cdot)+\sum_{i=m+1}^{m+r}\varphi_i^2(\cdot)\right]^{1/2}\big(x_\varepsilon(b)\big). \tag{7.12}$$

Note that the last term on the right-hand side of (7.11) appears due to applying the sum rule from [13, Theorem 2.33(c)] to the integrand (7.10) and using the well-known subdifferential formula for the norm function. The other difference between (7.10) and (6.3) is that (7.11) *does not contain the closure operation* as in (6.3). The norm-closure operation can be omitted in (7.11), since the basic subdifferential sets for Lipschitzian functions are weak compact in reflexive spaces (which are weakly compactly generated) by [13, Theorem 3.59(i)], and hence the right-hand side of (7.11) is closed in the norm topology of the dual space X^*.

To deal further with (7.11), fix $t\in[a,b]$ and consider the two possible cases for the location of $\big(x_\varepsilon(t),\dot x_\varepsilon(t)\big)$ relative to the graph of the velocity mapping $F(\cdot)$:

$$\text{(i) }\big(x_\varepsilon(t),\dot x_\varepsilon(t)\big)\in\operatorname{gph}F\quad\text{ and }\quad\text{(ii) }\big(x_\varepsilon(t),\dot x_\varepsilon(t)\big)\notin\operatorname{gph}F.$$

In case (i) we use [13, Theorem 1.97] on basic subgradients of the distance function at set points, which gives the *approximate adjoint inclusion*

$$\dot p_\varepsilon(t)\in\operatorname{co}\Big\{u\in X^*\Big|\ \big(u,p_\varepsilon(t)\big)\in N\big((x_\varepsilon(t),\dot x_\varepsilon(t));\operatorname{gph}F\big)+\sqrt{\varepsilon}\big(0,\mathbb{B}^*\big)\Big\}. \tag{7.13}$$

The out-of-set case (ii) is more involved and requires the *Kadec norm* structure of X together with the *weak closedness* assumption on the graph of F. Then we obtain, by [13, Theorem 1.105], the relationship

$$\partial\operatorname{dist}\big((x_\varepsilon(t),\dot x_\varepsilon(t));\operatorname{gph}F\big)\subset\bigcup_{(x,v)\in\Pi\left((x_\varepsilon(t),\dot x_\varepsilon(t));\,\operatorname{gph}F\right)}N\big((x,v);\operatorname{gph}F\big)$$

via the *projection operator* $\Pi(\cdot;\operatorname{gph}F)$ at the reference point. Taking into account the a.e. pointwise convergence $\big(x_\varepsilon(t),\dot x_\varepsilon(t)\big)\to\big(\bar x(t),\dot{\bar x}(t)\big)$ as $\varepsilon\downarrow0$ that follows from (7.7), we come up to a modified inclusion (7.13) with the replacement of $\big(x_\varepsilon(t),\dot x_\varepsilon(t)\big)$ by some sequence $(\widetilde x_\varepsilon,\widetilde v_\varepsilon)\overset{\operatorname{gph}F}{\to}\big(\bar x(t),\dot{\bar x}(t)\big)$ as $\varepsilon\downarrow0$, while we keep the form (7.13) for simplicity.

Consider next the transversality condition (7.12) with φ_i^+ defined in (7.4). Employing the sum and chain rules [13, subsection 3.2.1] for basic subgradients in (7.12) and taking into account relationships (7.5) and (7.6) with $\nu_\varepsilon\uparrow\bar\nu$ as $\varepsilon\downarrow0$, we have

$$-p_\varepsilon(b)\in\sum_{i=0}^m\lambda_{i\varepsilon}\partial\varphi_i\big(x_\varepsilon(b)\big)+\sum_{i=m+1}^{m+r}\lambda_{i\varepsilon}\Big[\partial\varphi_i\big(x_\varepsilon(b)\big)\bigcup\partial\big(-\varphi_i\big)\big(x_\varepsilon(b)\big)\Big], \tag{7.14}$$

where the multipliers $\lambda_{i\varepsilon}$ satisfy the conditions

$$\lambda_{i\varepsilon}\ge0\ \text{ for all }\ i=0,\dots,m+r,\quad\sum_{i=0}^{m+r}\lambda_{i\varepsilon}^2=1\ \text{ as }\ \varepsilon\downarrow0. \tag{7.15}$$

By (7.15), we suppose without loss of generality that $\lambda_{i\varepsilon}\to\lambda_i$ as $\varepsilon\downarrow0$ for $i=0,\dots,m+r$, where the limiting multipliers λ_i are not zero simultaneously and satisfy

the sign and complementary slackness conditions in (6.1) and (6.2). Furthermore, it follows from (7.14) and (7.15) that the family $\{p_\varepsilon(b)\}_{\varepsilon>0}$ is uniformly bounded in X^* for ε sufficiently small. Proceeding as in the proof of Theorem 6.1, we observe that the strong coderivative normality assumption on F allows us, by (7.13), to use the *mixed coderivative characterization* of the Lipschitz property of F from [13, Corollary 4.11] and thus to find an absolutely continuous arc $p\colon[a,b]\to X^*$ such that $\dot p_\varepsilon(\cdot)\to\dot p(\cdot)$ weakly in $L^1\big([a,b];X^*\big)$ and $p_\varepsilon(t)\to p(t)$ weakly in X^* as $\varepsilon\downarrow 0$ for each $t\in[a,b]$.

To complete the proof of the Euler–Lagrange and transversality inclusions of the theorem, we pass to the limit in (7.13) and (7.14) as $\varepsilon\downarrow 0$ by using the Mazur theorem on the strong convergence of convex combinations for $\{\dot p_\varepsilon(\cdot)\}$. To accomplish this limiting procedure and to arrive at the desired inclusions (7.1) and (6.4), we use the *closed-graph* property of the basic normal cone in (7.13) and the basic subdifferential in (7.14). This follows from [13, Theorem 3.60] due to the SNC assumption on F and the Lipschitz continuity of φ_i in the reflexive state space X. Observe that the closedness operation in (7.1) is redundant, similar to (7.13), due to the *uniform boundedness* of $\big\{\big(\dot p_\varepsilon(\cdot),p_\varepsilon(\cdot)\big)\big\}$ in $X^*\times X^*$ and the arguments above involving now [13, Theorem 3.59(ii)].

The given proof justifies the extended Euler–Lagrange and transversality conditions in the theorem for arbitrary intermediate local minimizers to problem (P_M) with *no relaxation*. In the general nonconvex setting the Euler–Lagrange inclusion (7.1) does not automatically imply the maximum condition (7.2). To establish the latter condition supplementing the other necessary conditions of the theorem, we follow the proof of [19, Theorem 7.4.1] given for a Mayer problem of type (P_M) involving nonconvex differential inclusions in finite-dimensional spaces; it holds with minor changes in infinite dimensions under the assumptions imposed. The proof of the latter theorem is based on reducing the constrained Mayer problem for nonconvex differential inclusions to an unconstrained Bolza (finite Lagrangian) problem, which in turn is reduced to a problem of optimal control with *smooth dynamics* and *nonsmooth endpoint constraints* first treated in [11] via the nonconvex normal cone (4.1) and the corresponding subdifferential (4.5) introduced therein to describe the appropriate transversality conditions in the maximum principle. □

TWO-STAGE STOCHASTIC PROGRAMS WITH MIXED PROBABILITIES*

PAUL BOSCH†, ALEJANDRO JOFRÉ‡, AND RÜDIGER SCHULTZ§

Abstract. We extend the traditional two-stage linear stochastic program by probabilistic constraints imposed in the second stage. This adds nonlinearity such that basic arguments for analyzing the structure of linear two-stage stochastic programs have to be rethought from the very beginning. We identify assumptions under which the problem is structurally sound and behaves stably under perturbations of probability measures.

Key words. stochastic programming, two-stage models, stability analysis

AMS subject classifications. 90C15, 90C30

DOI. 10.1137/050648754

1. Introduction.

Stochastic programming deals with the optimization of decision making under uncertainty over time. When building stochastic programming models, two main approaches consist in introducing future costs and in fixing certain reliability levels for constraints. For earlier reviews on the various aspects in stochastic programming we refer, for example, to [5], [17], [22], [23], and [24].

Traditional two-stage stochastic programming is concerned with problems that require a here-and-now decision on the basis of given probabilistic information on the random data without making further observations. The costs to be minimized consist of the direct costs of the first-stage decision as well as the costs generated by the need of taking a recourse (or second-stage) decision in response to the random environment. The stability behavior of stochastic programming models when changing the probability measure is studied in many papers. We refer to the qualitative studies (continuity properties of optimal values and optimal solutions) found in [1], [7], [12], and [23] and to work on quantitative stability (quantitative continuity of optimal values and optimal solutions) found in [6], [14], [19], [20], and [21]. The bibliographical notes in section 5 of [14] provide a detailed account of the developments in stability analysis of stochastic programs.

Motivated by the study of stochastic programming problems coming from planning and operational management in power generation companies, we introduce the following parametric family of mixed-probability stochastic programs:

$$P(\mu,\lambda) \qquad \min\left\{c^T x + \int_{\mathbb{R}^s} Q(z-Ax,\lambda)\,\mu(dz) \;:\; x\in C\right\}, \quad (\mu,\lambda)\in\Delta\times\Lambda,$$

where

$$Q(t,\lambda) \;:=\; \min\{q^T y \;:\; Wy=t,\, y\geq 0,\, \lambda(H_j(y))\geq p_j, j=1,\dots,d\}. \tag{1.1}$$

Here $H_j, j = 1, \dots, d$, are set-valued mappings from $\mathbb{R}^m$ to $\mathbb{R}^r$ with closed graph, and $p_j, j = 1, \dots, d$, are predesigned probability levels. If $\mathcal{P}(\mathbb{R}^s)$, $\mathcal{P}(\mathbb{R}^r)$ denote the sets of all Borel probability measures on $\mathbb{R}^s$ and $\mathbb{R}^r$, respectively, we assume that Δ, Λ are subsets of $\mathcal{P}(\mathbb{R}^s)$, $\mathcal{P}(\mathbb{R}^r)$. Moreover, C is a closed subset of $\mathbb{R}^{\bar{m}}$, and all remaining vectors and matrices have suitable dimensions.

In the case of planning and operational management in power generation companies, the first stage variable x in the model represents generation capacity investment decisions, such as changes (continuous) of maximum generation capacity for thermal plants. The variable z is a random demand and y is the second-stage operational variable representing the level of production of energy. The latter is also limited by emission rights for carbon dioxide that may concern single plants or consortia of plants. The level of permitted emission is considered random, since emission rights are traded at predesigned markets via auctions, for instance, whose outcomes are uncertain to market participants. This motivates the modeling of limitations on the operational variables resulting from emission rights by probabilistic rather than deterministic constraints.

As an illustrative example consider a power system consisting of plants $i = 1, \dots, I$ to be operated over a time horizon with subintervals $t = 1, \dots, T$. The (first-stage) variables x_i denote (continuous) capacity expansions for the individual plants. They must be within the bounds

$$0 \ \leq \ x_i \ \leq \ C_i, \qquad i = 1, \dots, I, \tag{1.2}$$

and they incur the costs

$$\sum_{i=1}^{I} c_i x_i. \tag{1.3}$$

The (second-stage) variable y_{it} denotes the power output of plant i at time t. Constraints concern the coverage of power demand over the whole planning horizon,

$$\sum_{i=1}^{I} y_{it} \ \geq \ z_t(\omega), \qquad t = 1, \dots, T, \tag{1.4}$$

and limitation of individual outputs by the base capacity b_i plus the capacity expansion x_i:

$$0 \ \leq \ y_{it} \ \leq \ b_i + x_i, \qquad i = 1, \dots, I, \ t = 1, \dots, T. \tag{1.5}$$

Production costs are assumed to be linear and sum up to

$$\sum_{t=1}^{T} \sum_{i=1}^{I} q_i y_{it}. \tag{1.6}$$

A generic formulation for the probabilistic limitations on the second-stage variables induced by emission rights reads as follows:

$$\lambda \left(\left\{ \bar{a}_j \ : \ \sum_{t \in \mathcal{T}_j} \sum_{i \in \mathcal{I}_j} \beta_i y_{it} \ \leq \ \bar{a}_j \right\} \right) \ \geq \ p_j, \qquad j = 1, \dots, d. \tag{1.7}$$

Here, $\mathcal{T}_j, \mathcal{I}_j$ are subsets of $\{1,\dots,T\}$ and $\{1,\dots,I\}$, respectively, to express limitations summed up over subhorizons and clusters of plants. The coefficients β_i denote emission intensities that may vary from plant to plant. The random levels of permitted emissions for the different subhorizons and clusters are the $\bar{a}_j = \bar{a}_j(\omega)$. Finally, p_j are the probability levels with which the limitations are to be met.

The model (1.2)–(1.7) illustrates in a simple example the relevance of the general model $P(\mu,\lambda)$. Further operational details of power planning such as ramp rates for power output in adjacent time intervals or fuel constraints can easily be added without leaving the frame of $P(\mu,\lambda)$. A next step is to go beyond $P(\mu,\lambda)$ by including unit commitment features and, thus, integer variables; see [16] for a first attempt in that direction, including numerical experiments.

In our example, the chance constraints (1.7) mathematically really matter for the second-stage optimization problem (1.1). Without them, the remaining second-stage problem, given by (1.4)–(1.6), is very simple. It is separable in t, and the individual subproblems are continuous knapsack problems that solve immediately.

Coming back to $P(\mu,\lambda)$ we see that this model extends the traditional two-stage linear stochastic program by introducing some probabilistic constraints $\lambda(H_j(y)) \geq p_j, j = 1,\dots,d$, in the second stage of the problem. These types of constraints add nonlinearities to the problem so that basic arguments to analyze the well-posedness of $P(\mu,\lambda)$ have to be rethought from the very beginning. The purpose of this paper is to identify assumptions under which $P(\mu,\lambda)$ is structurally well-behaved and stable under perturbations of (μ,λ).

Somewhat related two-stage stochastic programming formulations with probabilistic constraints are presented in Chapter 12.10 of [11]. In a first group of models, probabilistic constraints serve to replace the induced constraints by the requirement that the second-stage problem is solvable with a prescribed probability. Another group of two-stage models has probabilistic constraints in both stages. Neither model type had been studied any further at the time of the writing of [11], nor, to the best of our knowledge, were they further studied since then.

2. Basic well-posedness.

LEMMA 1. *For fixed $\lambda \in \Lambda$ and $t \in \mathbb{R}^s$ the constraint set in* (1.1) *is closed.*

Proof. Since the graphs of $H_j, j = 1,\dots,d$, are all closed we have

$$\limsup_{y_n \to y_o} H_j(y_n) \;\subseteq\; H_j(y_o), \quad j = 1,\dots,d,$$

where $\limsup_{y_n \to y_o} H_j(y_n)$ denotes the set of all points belonging to infinitely many of the sets $H_j(y_n)$. Hence, by the semicontinuity of the probability measure (see, for example, [4]) we have

$$\lambda(H_j(y_o)) \geq \lambda\left(\limsup_{y_n \to y_o} H_j(y_n)\right) \geq \limsup_{y_n \to y_o} \lambda(H_j(y_n)) \geq p_j$$

for all $j = 1,\dots,d$ and all sequences $y_n \to y_o$, which allows us to conclude the closedness of the constraint set (1.1). □

The major difficulty in understanding the structure of $P(\mu,\lambda)$ rests in a dilemma about the function Q. On the one hand, Q is the optimal-value function of a nonlinear program with parameters t and λ. Parametric optimization mainly provides local results about the structure of Q. Global results are very scarce and require specific assumptions that are often hard to verify. On the other hand, Q arises as an integrand in $P(\mu,\lambda)$. For studying properties of the related integral, global information about

Q is required. From this viewpoint, it is not surprising that most of the structural results about two-stage stochastic programs concern the purely linear and the linear mixed-integer cases, i.e., the widest problem classes where parametric optimization offers broader results about global stability.

To lay a foundation for the structural analysis of Q we formulate the following general assumptions:

(A1) For any $\lambda \in \Lambda$ there exist a nonempty set $\mathcal{R}_\lambda \subseteq \mathbb{R}^s$ and a Lebesgue null set $\mathcal{N}_\lambda \subseteq \mathbb{R}^s$ such that the function $Q(\cdot, \lambda)$ is real-valued and measurable on $\mathcal{R}_\lambda$ and continuous on $\mathcal{R}_\lambda \setminus \mathcal{N}_\lambda$.

(A2) It holds that

$$\bigcup_{\mu \in \Delta} \text{supp } \mu \ \subseteq \ \bigcap_{\lambda \in \Lambda} \bigcap_{x \in C} \{Ax + \mathcal{R}_\lambda\},$$

where supp μ denotes the smallest closed set in $\mathbb{R}^s$ with μ-measure 1.

(A3) There exists a real-valued, measurable function h on $\mathbb{R}^s$, which we call the bounding function, with the following properties:

1. (Q-majorization.) It holds that $|Q(t, \lambda)| \leq h(t)$ for all $t \in \mathcal{R}_\lambda$ and all $\lambda \in \Lambda$.
2. (Integrability.) It holds that $\int_{\mathbb{R}^s} h(z)\, \mu(dz) < +\infty$ for all $\mu \in \Delta$.
3. (Generalized subadditivity.) There exists a $\kappa > 0$ such that $h(t_1 + t_2) \leq \kappa(h(t_1) + h(t_2))$ for all $t_1, t_2 \in \mathbb{R}^s$.
4. (Local boundedness.) For each $t \in \mathbb{R}^s$ there exists an open neighborhood of t where h is bounded.

LEMMA 2. *Assume* (A1), (A2), *and* (A3). *Then*

$$G(x, \mu, \lambda) \ := \ \int_{\mathbb{R}^s} Q(z - Ax, \lambda)\, \mu(dz) \tag{2.1}$$

is real-valued for all $x \in C, \lambda \in \Lambda, \mu \in \Delta$.

Proof. Let $x \in C, \lambda \in \Lambda, \mu \in \Delta$ be fixed. By (A2) we have $z - Ax \in \mathcal{R}_\lambda$ for all $z \in$ supp μ. Together with (A1) this yields that $Q(\cdot - Ax, \lambda)$ is measurable on supp μ. By (A3.1) and (A3.3) it holds that

$$|Q(z - Ax, \lambda)| \ \leq \ h(z - Ax) \ \leq \ \kappa h(z) + \kappa h(-Ax)$$

for all $z \in$ supp μ. By (A3.2) the right-hand side above is μ-integrable, and the assertion follows. □

LEMMA 3. *Assume* (A1), (A3), *and*

(A2*) *there exists an open set* $C^* \supseteq C$ *such that* $\bigcup_{\mu \in \Delta} \text{supp } \mu \subseteq \bigcap_{\lambda \in \Lambda} \bigcap_{x \in C^*} \{Ax + \mathcal{R}_\lambda\}$.

Let $x \in C, \lambda \in \Lambda, \mu \in \Delta$ *such that* $\mu(Ax + \mathcal{N}_\lambda) = 0$. *Then* $G(\cdot, \mu, \lambda)$ *is continuous at* x.

Proof. Fix some (x, μ, λ) fulfilling the assumptions. Let $x_n \to x$ and assume without loss of generality that $x_n \in C^*$ for all n. (A2*) then implies $z - Ax_n \in \mathcal{R}_\lambda$ for all $z \in$ supp μ, and together with (A3.1)–(A3.3) it follows as in the proof of Lemma 2 that $G(x_n, \mu, \lambda) \in \mathbb{R}$ for all n. By (A1) and $\mu(Ax + \mathcal{N}_\lambda) = 0$ it follows that $Q(z - Ax_n, \lambda) \to Q(z - Ax, \lambda)$ for μ-almost all $z \in$ supp μ. By (A3.1) and (A3.3) it holds for all $z \in$ supp μ that

$$|Q(z - Ax_n, \lambda)| \ \leq \ h(z - Ax_n) \ \leq \ \kappa h(z) + \kappa h(-Ax_n),$$

yielding, together with (A3.2) and (A3.4), that there exists a uniform μ-integrable majorant for the functions $Q(\cdot - Ax_n)$. The assertion now follows from Lebesgue's theorem on dominated convergence. □

Remark 4. If μ is absolutely continuous with respect to the Lebesgue measure or, equivalently, has a density, then $\mu(Ax + \mathcal{N}_\lambda) = 0$ holds for all $x \in C$, since, by (A1), $Ax + \mathcal{N}_\lambda$ is a Lebesgue null set.

Remark 5. The essence of assumptions (A1)–(A3) is the following: Since $Q(\cdot, \lambda)$ is the optimal-value function of a minimization problem it well may attain the values $+\infty$ if the problem is infeasible and $-\infty$ if the problem is unbounded. Indeed, the following hold:

- (A1) makes sure that $Q(\cdot, \lambda)$ is finite on some set $\mathcal{R}_\lambda$.
- (A2) guarantees that the arguments $z - Ax$ are in $\mathcal{R}_\lambda$ for all relevant z and x. Otherwise, $Q(z - Ax, \lambda)$ would attain infinite values with positive probability, immediately preventing finiteness of the integral in (2.1).
- The continuity part of (A1) together with (A3) provides a framework for applying dominated convergence to show continuity of $G(\cdot, \mu, \lambda)$. Introducing the exceptional set $\mathcal{N}_\lambda$ in (A1) makes sense, since $Q(\cdot, \lambda)$ often lacks continuity on lower-dimensional subsets of its domain of finiteness. Furthermore, (A3) ensures an integrable upper-bound for the functions $|Q(\cdot - Ax, \lambda)|$ when x is varying in some neighborhood. Any other set of conditions ensuring this could be placed instead. Clearly, h reflects the global growth of $|Q(\cdot, \lambda)|$ whose quantitative analysis is acknowledged nontrivial for nonlinear problems.

Remark 6. Traditional two-stage linear stochastic programs form a class where verification of (A1)–(A3) is possible with low effort. There λ does not occur, and $Q(\cdot, \lambda)$ is given as

$$Q(t) := \min\{q^T y \,:\, Wy = t, y \geq 0\}.$$

With the assumptions of complete recourse ($W(\mathbb{R}^m_+) = \mathbb{R}^s$) and dual feasibility

$$\{u \in \mathbb{R}^s \,:\, W^T u \leq q\} \neq \emptyset$$

it holds that $Q(t) = \max_{k=1,\ldots,K} d_k^T t$, where d_k, $k = 1, \ldots, K$, are the vertices of $\{u \in \mathbb{R}^s \,:\, W^T u \leq q\}$. Then (A1) holds with $\mathcal{R}_\lambda = \mathcal{R} = \mathbb{R}^s, \mathcal{N}_\lambda = \mathcal{N} = \emptyset$, and (A2) becomes vacuous. The bounding function h in (A3) can be selected as $\kappa\|t\|$ with some positive constant κ. This reduces the integrability requirement to finiteness of the first moment of μ. For two-stage linear stochastic programs with integrality requirements in the second stage, similar results are valid, with the difference that the exceptional set $\mathcal{N}$ becomes effective, since continuity defects of Q may occur on lower-dimensional subsets [10].

The next proposition provides a sufficient condition for continuity of G jointly in the first two arguments. Convergence of the second argument is understood as weak convergence of probability measures on $\mathcal{P}(\mathbb{R}^s)$. We say that a sequence $\{\mu_n\}$ in $\mathcal{P}(\mathbb{R}^s)$ converges weakly to $\mu \in \mathcal{P}(\mathbb{R}^s)$, written $\mu_n \xrightarrow{w} \mu$, if for any bounded continuous function $g : \mathbb{R}^s \to \mathbb{R}$ it holds that

$$\int_{\mathbb{R}^s} g(z)\mu_n(dz) \to \int_{\mathbb{R}^s} g(z)\mu(dz) \quad \text{as} \quad n \to \infty.$$

A basic reference for weak convergence of probability measures is Billingsley's book [3].

PROPOSITION 7. *Assume* (A1), (A2*), (A3) *and that A has full row rank. Let $\rho > 1, \bar{h} > 0$ be constants and define*

$$\Delta_\rho \;:=\; \left\{\nu \in \Delta \;:\; \int_{\mathbb{R}^s} h(z)^\rho \,\nu(dz) \le \bar{h}\right\},$$

where h is the bounding function from (A3). *Let $x \in C, \lambda \in \Lambda, \mu \in \Delta_\rho$ such that $\mu(Ax + \mathcal{N}_\lambda) = 0$. Then $G(\cdot,\cdot,\lambda) : C^* \times \Delta_\rho \longrightarrow \mathbb{R}$ is continuous at (x,μ).*

Proof. Fix some (x,μ,λ) fulfilling the assumptions, and let $x_n \to x$, $\mu_n \xrightarrow{w} \mu$, $\mu_n \in \Delta_\rho$. Without loss of generality we assume that $x_n \in C^*$ for all n. Let $\mathcal{M} := \cup_{\nu\in\Delta_\rho} \operatorname{supp}\nu$ and define functions $h_n, h_o : \mathcal{M} \to \mathbb{R}$ by $h_n(z) := Q(z - Ax_n, \lambda)$ and $h_o(z) := Q(z - Ax, \lambda)$. Consider the set

$$E(x) \;:=\; \{z \in \mathcal{M} \;:\; \exists z_n \to z \text{ with } h_n(z_n) \not\to h_o(z)\}.$$

To see that $E(x) \subseteq Ax + \mathcal{N}_\lambda$ assume that $z \notin Ax + \mathcal{N}_\lambda$; hence $z - Ax \in \mathcal{R}_\lambda \setminus \mathcal{N}_\lambda$. By (A2*), there exists a neighborhood $N(x)$ of x such that $z - A\big(N(x)\big) \subseteq \mathcal{R}_\lambda$. Let $z_n \to z$ and rewrite $z_n - Ax_n = z - (Ax + z - z_n + Ax_n - Ax)$. Since A has full row rank, it holds that $Ax + z - z_n + Ax_n - Ax \in A\big(N(x)\big)$ for sufficiently large n. Therefore, $z_n - Ax_n \in \mathcal{R}_\lambda$ for sufficiently large n. Thus $h_n(z_n)$ is well-defined for these n. In view of (A1) we have $Q(z_n - Ax_n, \lambda) \to Q(z - Ax, \lambda)$; in other words, $h_n(z_n) \to h_o(z)$. Hence, $z \notin E(x)$.

By $\mu(Ax + \mathcal{N}_\lambda) = 0$ it follows that $\mu(E(x)) = 0$. Now Rubin's theorem on convergence of image measures (cf. [3]) yields

$$\mu_n \circ h_n^{-1} \xrightarrow{w} \mu \circ h_o^{-1}.$$

Next we establish the following uniform integrability

$$\lim_{a\to\infty} \sup_n \int_{|h_n(z)|\ge a} |h_n(z)|\,\mu_n(dz) \;=\; 0. \tag{2.2}$$

With $\rho > 1$ as in the assumptions we have

$$\begin{aligned}\int_{\mathcal{M}} |h_n(z)|^\rho \,\mu_n(dz) &\ge \int_{|h_n(z)|\ge a} |h_n(z)| \cdot |h_n(z)|^{\rho-1} \,\mu_n(dz)\\ &\ge a^{\rho-1} \cdot \int_{|h_n(z)|\ge a} |h_n(z)|\,\mu_n(dz).\end{aligned}$$

Therefore

$$\begin{aligned}\int_{|h_n(z)|\ge a} |h_n(z)|\,\mu_n(dz) &\le \Big(\frac{1}{a}\Big)^{\rho-1} \int_{\mathcal{M}} |h_n(z)|^\rho \,\mu_n(dz) \;=\; \Big(\frac{1}{a}\Big)^{\rho-1} \int_{\mathbb{R}^s} |h_n(z)|^\rho \,\mu_n(dz)\\ &\le \Big(\frac{1}{a}\Big)^{\rho-1} \int_{\mathbb{R}^s} \big(\kappa h(z) + \kappa h(-Ax_n)\big)^\rho \;\mu_n(dz)\\ &\le \Big(\frac{1}{a}\Big)^{\rho-1} \int_{\mathbb{R}^s} \big(\kappa h(z) + \kappa_o\big)^\rho \;\mu_n(dz),\end{aligned}$$

where we have used (A3.1) and (A3.3) in the second inequality, and where in the third inequality $\kappa_o > 0$ is a suitable constant selected according to (A3.4). The estimate continues as follows:

$$\begin{aligned}&\le \Big(\frac{1}{a}\Big)^{\rho-1} \Big((2\kappa_o)^\rho \;+\; (2\kappa)^\rho \int_{\mathbb{R}^s} h(z)^\rho \,\mu_n(dz)\Big)\\ &\le \Big(\frac{1}{a}\Big)^{\rho-1} \big((2\kappa_o)^\rho \;+\; (2\kappa)^\rho \bar{h}\big).\end{aligned}$$

This establishes the desired uniform integrability (2.2). The proof is completed by using (2.2) and Theorem 5.4 of [3]; see also the proof of Proposition 3.6 (ii) in [18]. □

3. The bounded convex case. The structural analysis of $P(\mu, \lambda)$ can be pushed ahead under suitable boundedness and convexity assumptions. We assume the following:

(A4) The set $Y_\lambda := \{y \in \mathbb{R}^m_+ \,:\, \lambda(H_j(y)) \geq p_j, j = 1, \ldots, d\}$ is convex for any $\lambda \in \Lambda$, and $Y := \cup_{\lambda\in\Lambda} Y_\lambda$ is bounded.

Sufficient conditions for the convexity in (A4) can be formulated for the case that the mappings H_j all have closed convex graphs—see (A.5) below, with the help of r-concave and logarithmic concave probability measures. The uniform distribution, the nondegenerate multivariate normal distribution, the multidimensional Dirichlet distribution, and the multivariate student and Pareto distributions all fit into this framework; for details consult [8] and [11].

LEMMA 8. *Under* (A4) *the following hold for any* $\lambda \in \Lambda$*:*

(i) $Q(t, \lambda) \in \mathbb{R}$*, whenever* $t \in W(Y_\lambda)$.

(ii) $Q(\cdot, \lambda)$ *is continuous on* $\operatorname{int} W(Y_\lambda)$.

(iii) *There exists a constant* $\bar\kappa > 0$*, uniformly for all* $\lambda \in \Lambda$*, such that* $|Q(t, \lambda)| \leq \bar\kappa$ *for all* $t \in W(Y_\lambda)$.

Proof. Assertions (i) and (iii) immediately follow from the compactness of each Y_λ, the boundedness of Y, and the continuity of $q^T y$. To confirm (ii), note that $Q(\cdot, \lambda)$ has to be convex as the value function of a convex program with parameters in the right-hand side. As a (real-valued) convex function (in finite dimension) $Q(\cdot, \lambda)$ is thus continuous on the open set $\operatorname{int} W(Y_\lambda)$. □

Remark 9. For fixed $\lambda \in \Lambda$ the above lemma immediately gives rise to specifications of Lemma 2, Lemma 3, and Proposition 7. Indeed, (A1) holds with $\mathcal{R}_\lambda = W(Y_\lambda)$ and $\mathcal{N}_\lambda \subseteq \partial W(Y_\lambda)$, where ∂ denotes the boundary. Since $W(Y_\lambda)$ is convex, its boundary has Lebesgue measure zero; see, e.g., [9]. Assumption (A3) can obviously be fulfilled with $h(t) \equiv \bar\kappa$.

We turn our attention to analyzing $P(\mu, \lambda)$ with both μ and λ variable. To this end we define the following distance (discrepancy) on Λ:

$$\alpha(\mu, \nu) \;:=\; \max_{j=1,\ldots,d} \sup\{|\mu(B) - \nu(B)| \,:\, B \in \mathcal{B}_j\},$$

where each $\mathcal{B}_j, j = 1, \ldots, d$, is a class of Borel sets of $\mathbb{R}^s$ such that $\{H_j(y) \,:\, y \in \mathbb{R}^m\} \subseteq \mathcal{B}_j$ and that α forms a metric. We fix a vector $\bar p$ of probability levels and introduce the notation

$$\begin{aligned}\Psi(t, \lambda) &:= \operatorname{argmin}\{q^T y \,:\, Wy = t,\, y \geq 0,\, \lambda(H_j(y)) \geq \bar p_j,\, j = 1, \ldots, d\},\\ C_p(t, \lambda) &:= \{y \in \mathbb{R}^m \,:\, Wy = t,\, y \geq 0,\, \lambda(H_j(y)) \geq p_j,\, j = 1, \ldots, d\}.\end{aligned}$$

Now the following holds.

LEMMA 10. *Assume* (A4)*, and fix some* $(t_o, \lambda_o) \in \mathbb{R}^s \times \Lambda$ *such that* $\Psi(t_o, \lambda_o) \neq \emptyset$*. For each* $y_o \in \Psi(t_o, \lambda_o)$ *let the function*

$$(\xi, t, p) \;\mapsto\; \inf\{\|\xi - y\| \,:\, y \in C_p(t, \lambda_o)\} \tag{3.1}$$

be Lipschitz continuous on some neighborhood of $(y_o, t_o, \bar p)$.

Then the multifunction Ψ *(acting from the metric space* $[(\mathbb{R}^s, \Lambda), (\|.\|, \alpha)]$ *into the subsets of* $\mathbb{R}^m$*) is upper semicontinuous at* (t_o, λ_o)*. Furthermore, there exist* $L > 0$

and $\delta > 0$ such that

$$\Psi(t,\lambda) \neq \emptyset \qquad \textit{and}$$
$$|Q(t,\lambda) - Q(t_o,\lambda_o)| \;\leq\; L \cdot (\|t - t_o\| + \alpha(\lambda,\lambda_o))$$

whenever $\|t - t_o\| + \alpha(\lambda,\lambda_o) < \delta$.

Proof. The proof employs Lemma A.2 from the appendix of [15]. It is sufficient to verify assumption (c) of that lemma. In our setting, this condition reads as follows: For each $y_o \in \Psi(t_o,\lambda_o)$ there exist a neighborhood $U = U(y_o)$ and positive reals δ_o and l such that the following hold for all $(t,\lambda) \in \mathbb{R}^s \times \Lambda$ with $\|t - t_o\| + \alpha(\lambda,\lambda_o) < \delta_o$:

$$y \in C_{\bar p}(t_o,\lambda_o) \cap U \quad \text{implies} \quad d(y, C_{\bar p}(t,\lambda)) \;\leq\; l \cdot (\|t - t_o\| + \alpha(\lambda,\lambda_o)) \tag{3.2}$$

and

$$y \in C_{\bar p}(t,\lambda) \cap U \quad \text{implies} \quad d(y, C_{\bar p}(t_o,\lambda_o)) \;\leq\; l \cdot (\|t - t_o\| + \alpha(\lambda,\lambda_o)). \tag{3.3}$$

Let $y_o \in \Psi(t_o,\lambda_o)$ be fixed. Assumption (3.1) is equivalent to the existence of neighborhoods U of y_o and V of $(t_o,\bar p)$ and of a constant $l > 0$ such that $d(y, C_p(t,\lambda_o))$ is finite and

$$d(y, C_{p^1}(t_1,\lambda_o)) \;\leq\; d(y, C_{p^2}(t_2,\lambda_o)) \;+\; l \cdot (\|t_1 - t_2\| + \|p^1 - p^2\|) \tag{3.4}$$

for all $y \in U$ and all $(t,p), (t_1,p^1), (t_2,p^2) \in V$.

Let $\delta_o > 0$ such that

$$\{(t,p) \;:\; \|t - t_o\| + \|p - \bar p\| \leq \delta_o\} \subseteq V$$

and let $\lambda \in \Lambda$ such that $\alpha(\lambda,\lambda_o) \leq \delta_o$. Then by definition of the distance α the following inclusions hold:

$$C_{\bar p + 1\alpha(\lambda,\lambda_o)}(t,\lambda_o) \;\subseteq\; C_{\bar p}(t,\lambda) \;\subseteq\; C_{\bar p - 1\alpha(\lambda,\lambda_o)}(t,\lambda_o). \tag{3.5}$$

(Here, 1 denotes the vector of all ones.) Let $y \in U$, and set in (3.4)

$$p^1 := \bar p + 1\alpha(\lambda,\lambda_o), \quad p^2 := \bar p, \quad t_1 := t, \quad \text{and} \quad t_2 := t_o.$$

Then (3.5) and (3.4) imply[1]

$$\begin{aligned} d(y, C_{\bar p}(t,\lambda)) &\leq d(y, C_{\bar p + 1\alpha(\lambda,\lambda_o)}(t,\lambda_o)) \\ &\leq d(y, C_{\bar p}(t_o,\lambda_o)) + l \cdot (\|t - t_o\| + \alpha(\lambda,\lambda_o)), \end{aligned}$$

yielding (3.2). Now set in (3.4)

$$p^1 := \bar p \;\;, \quad p^2 := \bar p - 1\alpha(\lambda,\lambda_o), \quad t_1 := t_o, \quad \text{and} \quad t_2 := t.$$

It follows that

$$d(y, C_{\bar p}(t_o,\lambda_o)) \;\leq\; d(y, C_{\bar p - 1\alpha(\lambda,\lambda_o)}(t,\lambda_o)) + l \cdot (\|t - t_o\| + \alpha(\lambda,\lambda_o)).$$

[1] To avoid further multiplicative constants we assume that the norm in $\|p^1 - p^2\|$ is $\|.\|_\infty$.

Together with (3.5) we obtain

$$d(y, C_{\bar{p}}(t_o, \lambda_o)) \;\leq\; d(y, C_{\bar{p}}(t, \lambda)) + l \cdot (\|t - t_o\| + \alpha(\lambda, \lambda_o)),$$

yielding (3.3) and completing the proof. □

Remark 11. The above result extends Theorem 3.2 in [15] to the present situation. As in [15] the result can be further extended to the nonconvex case, provided a suitable notion of local optimality (complete local minimizing set) is employed.

Remark 12. The essential assumption in Lemma 10 is (3.1). It can be equivalently restated as follows: The multifunction $(t, p) \mapsto C_p(t, \lambda_o)$ is pseudo-Lipschitzian in the sense of [13] at each $(y_o, t_o, \bar{p}) \in \Psi(t_o, \lambda_o) \times \{(t_o, \bar{p})\}$. Sufficient conditions for multifunctions to be pseudo-Lipschitzian have been derived in the literature. The following is a popular one, often called the Robinson–Ursescu theorem (here already adapted to our setting): Let Γ be a multifunction from $\mathbb{R}^s \times \mathbb{R}^d$ into $\mathbb{R}^m$ with closed convex graph. Then Γ is pseudo-Lipschitzian at each pair $(y_o, t_o, \bar{p}) \in \Gamma(t_o, \bar{p}) \times \mathbb{R}^{s+d}$ with $(t_o, \bar{p}) \in \operatorname{int}(\operatorname{dom}\Gamma)$, where $\operatorname{dom}\Gamma \;=\; \{(t, p) \in \mathbb{R}^{s+d} \,:\, \Gamma(t, p) \neq \emptyset\}$.

The above remark gives rise to the following assumption.

(A5) Each $H_j, j = 1, \ldots, d$, has a closed convex graph.

LEMMA 13. *Assume* (A4), (A5) *and let* $\lambda_o \in \Lambda$. *If* $t_o \in \operatorname{int} W(Y_{\lambda_o})$, *then*

$$(t_o, \bar{p}) \in \operatorname{int}(\operatorname{dom} C_{(\cdot)}(\cdot, \lambda_o)).$$

Proof. If $t_o \in \operatorname{int} W(Y_{\lambda_o})$, then there exists an open ball $B(t_o, r)$ such that $B(t_o, r) \subseteq \operatorname{int} W(Y_{\lambda_o})$. By continuity, the preimage under W of that ball is open, and the preimage is obviously contained in Y_{λ_o}. Let $y_s \in W^{-1}(\{t_o\})$. Then $y_s \in W^{-1}(B(t_o, r)) \subseteq \operatorname{int} Y_{\lambda_o}$. By convexity, this implies that $y_s > 0$ and $\lambda_o(H_j(y_s)) > \bar{p}_j$ for all j. Hence $(t_o, \bar{p}) \in \operatorname{int}(\operatorname{dom} C_{(\cdot)}(\cdot, \lambda_o))$. □

The combination of Lemmas 10 and 13 produces the following corollary.

COROLLARY 14. *Assume* (A4), (A5) *and let* $\lambda_o \in \Lambda$ *and* $t_o \in \operatorname{int} W(Y_{\lambda_o})$. *Then there exist* $L > 0$ *and* $\delta > 0$ *such that*

$$|Q(t, \lambda) - Q(t_o, \lambda_o)| \;\leq\; L \cdot (\|t - t_o\| + \alpha(\lambda, \lambda_o)) \quad \textit{whenever } \|t - t_o\| + \alpha(\lambda, \lambda_o) < \delta.$$

We are now in a position to formulate a sufficient condition for joint continuity of G. Assumption (A2*) adapts as follows to the setting of the present section:

(A2*) there exists an open set $C^* \supseteq C$ such that $\displaystyle\bigcup_{\mu \in \Delta} \operatorname{supp} \mu \subseteq \bigcap_{\lambda \in \Lambda} \bigcap_{x \in C^*} \{Ax + W(Y_\lambda)\}$.

PROPOSITION 15. *Assume* (A2*), (A4), (A5) *and let* A *have full row rank. Then* $G : C^* \times \Delta \times \Lambda \longrightarrow \mathbb{R}$ *is continuous at any triplet* $(x, \mu, \lambda) \in C \times \Delta \times \Lambda$ *fulfilling* $\mu\big(Ax + \partial W(Y_\lambda)\big) = 0$.

Proof. Let (x, μ, λ) be as in the assumption, $x_n \longrightarrow x$, $\mu_n \xrightarrow{w} \mu$, $\lambda_n \xrightarrow{\alpha} \lambda$, and assume without loss of generality that $x_n \in C^*$ for all n. In analogy to the proof of Proposition 7 let $\mathcal{M} := \cup_{\nu \in \Delta} \operatorname{supp} \nu$, define functions $h_n, h_o : \mathcal{M} \to \mathbb{R}$ by $h_n(z) := Q(z - Ax_n, \lambda_n)$ and $h_o(z) := Q(z - Ax, \lambda)$, and consider the set

$$E(x) \;:=\; \{z \in \mathcal{M} \,:\, \exists z_n \to z \text{ with } h_n(z_n) \not\to h_o(z)\}.$$

Adapting the corresponding argument from the proof of Proposition 7 and taking into account Corollary 14, we obtain that $E(x) \subseteq Ax + \partial W(Y_\lambda)$. The assumption

on (x, μ, λ) thus implies $\mu(E(x)) = 0$, and Rubin's theorem on weak convergence of image measures yields

$$\mu_n \circ h_n^{-1} \xrightarrow{w} \mu \circ h_o^{-1}. \tag{3.6}$$

With $\bar{\kappa}$ according to Lemma 8(iii) we consider the bounded continuous function

$$g(\tau) := \begin{cases} \bar{\kappa}, & \tau \geq \bar{\kappa}, \\ \tau, & -\bar{\kappa} \leq \tau \leq \bar{\kappa}, \\ -\bar{\kappa}, & \tau \leq -\bar{\kappa}. \end{cases}$$

By (3.6) it holds that

$$\int_{\mathbb{R}} g(\tau)\, \mu_n \circ h_n^{-1}(d\tau) \longrightarrow \int_{\mathbb{R}} g(\tau)\, \mu \circ h_o^{-1}(d\tau).$$

Changing variables yields

$$\int_{\mathcal{M}} h_n(z)\, \mu_n(dz) \longrightarrow \int_{\mathcal{M}} h_o(z)\, \mu(dz),$$

proving the assertion. □

Since $\partial W(Y_\lambda)$ always has Lebesgue measure zero, we obtain the following corollary; see also Remarks 4 and 9.

COROLLARY 16. *Assume* (A2*), (A4), (A5). *Let A have full row rank and let μ have a density. Then $G : C^* \times \Delta \times \Lambda \longrightarrow \mathbb{R}$ is continuous at any $(x, \mu, \lambda) \in C \times \{\mu\} \times \Lambda$.*

The joint continuity established in Proposition 15 and Corollary 16 paves the way for qualitative stability of $P(\mu, \lambda)$ under perturbations of (μ, λ). To illustrate this, we conclude the paper with a corresponding result based on Corollary 16. To this end, we write $P(\mu, \lambda)$ in a more compact form as

$$P(\mu, \lambda) \qquad \min\{c^T x + G(x, \mu, \lambda) \ : \ x \in C\}, \quad (\mu, \lambda) \in \Delta \times \Lambda.$$

Notice that in the setting of Corollary 16, $G(\cdot, \mu', \lambda')$ is convex for all $(\mu', \lambda') \in \Delta \times \Lambda$. We assume that, in addition, C is convex, and we introduce the following notation:

$$\begin{aligned} \phi(\mu, \lambda) &:= \inf\{c^T x + G(x, \mu, \lambda) \ : \ x \in C\}, \\ \psi(\mu, \lambda) &:= \{x \in C \ : \ c^T x + G(x, \mu, \lambda) = \phi(\mu, \lambda)\}. \end{aligned}$$

PROPOSITION 17. *Assume* (A2*), (A4), (A5). *Let A have full row rank, let $(\mu, \lambda) \in \Delta \times \Lambda$, and let μ have a density. Suppose further that $\psi(\mu, \lambda)$ is nonempty and bounded. Then it holds that*

(i) *the function $\phi : \Delta \times \Lambda \longrightarrow \mathbb{R}$ is continuous at (μ, λ);*

(ii) *the multifunction $\psi : \Delta \times \Lambda \longrightarrow 2^{\mathbb{R}^m}$ is upper semicontinuous at (μ, λ).*

With joint continuity of G in (x, μ, λ) established, the proof of the above proposition follows the lines of Berge's theory as, for instance, in the proof of Proposition 4.2.2 in [2].

FITZPATRICK FUNCTIONS AND CONTINUOUS LINEAR MONOTONE OPERATORS*

HEINZ H. BAUSCHKE†, JONATHAN M. BORWEIN‡, AND XIANFU WANG†

Abstract. The notion of a maximal monotone operator is crucial in optimization as it captures both the subdifferential operator of a convex, lower semicontinuous, and proper function and any (not necessarily symmetric) continuous linear positive operator. It was recently discovered that most fundamental results on maximal monotone operators allow simpler proofs utilizing Fitzpatrick functions. In this paper, we study Fitzpatrick functions of continuous linear monotone operators defined on a Hilbert space. A novel characterization of skew operators is presented. A result by Brézis and Haraux is reproved using the Fitzpatrick function. We investigate the Fitzpatrick function of the sum of two operators, and we show that a known upper bound is actually exact in finite-dimensional and more general settings. Cyclic monotonicity properties are also analyzed, and closed forms of the Fitzpatrick functions of all orders are provided for all rotators in the Euclidean plane.

Key words. cyclic monotonicity, Fitzpatrick family, Fitzpatrick function, linear operator, maximal monotone operator, Moore–Penrose inverse, paramonotone operator, rotator

1. Introduction.

Throughout this paper, we assume that

(1) X is a real Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and induced norm $\| \cdot \|$.

Recall that a set-valued operator $A\colon X \to 2^X$ is *monotone* if

$$\left.\begin{array}{l}(x,u) \in \operatorname{gra} A\\ (y,v) \in \operatorname{gra} A\end{array}\right\} \quad \Rightarrow \quad \langle x-y, u-v\rangle \geq 0, \tag{2}$$

where $\operatorname{gra} A = \big\{(x,u) \in X \times X \mid u \in Ax\big\}$ denotes the *graph* of A. The notion of a monotone operator is central to modern optimization and analysis [9, 10, 33, 34, 35, 36, 43]. Of particular importance are *maximal monotone operators*, i.e., monotone operators with graphs that cannot be enlarged without destroying monotonicity. Recently, several fundamental results on monotone operators have found—sometimes dramatically simpler—new proofs by utilizing *Fitzpatrick functions* [8, 9, 29, 39, 41, 42]. The Fitzpatrick function was first introduced by Fitzpatrick to study monotone operators via convex analysis [17]; see also [2, 6, 12, 13, 14, 15, 18, 24, 25, 31, 37, 38, 40]. The key classes of maximal monotone operators are subdifferential operators of proper, lower semicontinuous, and convex functions [32] and continuous, linear, and monotone operators. The former class is very well understood [36]; the latter class is the topic of this paper.

It is well known that continuous, linear, and monotone operators are automatically maximal monotone (see, e.g., [36, p. 30]); see also [1, 5, 7, 30, 36] for additional works on monotone-operator-theoretic properties of linear operators. Let $A\colon X \to X$ be continuous and linear. Linearity and (2) yield

$$A \text{ is monotone} \quad \Leftrightarrow \quad (\forall x \in X)\ \langle x, Ax\rangle \geq 0. \tag{3}$$

Thus monotonicity is determined solely by the behavior of the *symmetric part* of A. We now recall the relevant notions.

DEFINITION 1.1 (symmetric and skew part). *Let $A\colon X \to X$ be continuous and linear. Then $A_+ = \frac{1}{2}A + \frac{1}{2}A^*$ is the* symmetric part *of A, and $A_\circ = A - A_+ = \frac{1}{2}A - \frac{1}{2}A^*$ is the* skew part *of A.*

The next result is clear.

PROPOSITION 1.2. *Let $A\colon X \to X$ be continuous and linear. Then A is monotone if and only if A_+ is monotone.*

Let us define the Fitzpatrick function [17] for linear operators.

DEFINITION 1.3 (Fitzpatrick function). *Let $A\colon X \to X$ be continuous and linear. The* Fitzpatrick function *of A is*

$$F_A\colon X \times X \to \left]-\infty, +\infty\right]\colon (x,u) \mapsto \sup_{y\in X}\big(\langle x, Ay\rangle + \langle y, u\rangle - \langle y, Ay\rangle\big). \tag{4}$$

Before we survey some fundamental results concerning the Fitzpatrick function of a linear operator, we need to briefly explain our notation. We shall utilize throughout this paper notation and results that are standard in convex analysis and monotone operator theory. See [9, 33, 35, 36, 43] for comprehensive references. The *Fenchel conjugate* and *domain* of a function f is denoted by f^* and $\operatorname{dom} f$, respectively. The *ball* of radius ρ centered at x is denoted by $B(x;\rho)$. The *closure*, the *interior*, and the *indicator function* of a set $S \subseteq X$ are written as $\overline{S}$, $\operatorname{int} S$, and ι_S, respectively. For a continuous and linear operator $A\colon X \to X$, the *kernel* (also known as null space) of A is denoted by $\ker A$ and the *range* by $\operatorname{ran} A$. The identity operator is written as Id. If A is monotone and symmetric, it will occasionally be convenient to use the notation

$$(\forall x \in X)(\forall y \in X) \quad \langle x, y\rangle_A = \langle x, Ay\rangle \ \text{ and } \ \|x\|_A = \sqrt{\langle x, x\rangle_A} = \|\sqrt{A}x\|, \tag{5}$$

where $\sqrt{A}$ denotes the *square root* of A [23, section 9.4].

FACT 1.4 (see [17]). *Let $A\colon X \to X$ be continuous, linear, and monotone. Then*

(i) *F_A is convex, lower semicontinuous, and proper;*

(ii) *$F_A = \langle\cdot,\cdot\rangle$ on $\operatorname{gra} A$, and $F_A > \langle\cdot,\cdot\rangle$ outside $\operatorname{gra} A$;*

(iii) $\big(\forall (x,u) \in X \times X\big)\ F_A(x,u) \leq F_A^*(u,x) = \big(\iota_{\operatorname{gra} A} + \langle\cdot,\cdot\rangle\big)^{**}(x,u)$.

Fact 1.4(ii) motivates the following definition (see also [14]).

DEFINITION 1.5 (Fitzpatrick family). *Let $A\colon X \to X$ be continuous, linear, and monotone. The* Fitzpatrick family $\mathcal{F}_A$ *consists of all functions $F\colon X \times X \to \left]-\infty, +\infty\right]$ such that F is convex, lower semicontinuous, $F \geq \langle\cdot,\cdot\rangle$, and $F = \langle\cdot,\cdot\rangle$ on $\operatorname{gra} A$.*

FACT 1.6 (see [17]). *Let $A\colon X \to X$ be continuous, linear, and monotone. Then for every $(x,u) \in X \times X$,*

$$F_A(x,u) = \min_{F\in\mathcal{F}_A} F(x,u) \quad \text{and} \quad F_A^*(u,x) = \max_{F\in\mathcal{F}_A} F(x,u). \tag{6}$$

The plan for the remainder of the paper is as follows.

- In section 2, we describe completely the Fitzpatrick function and its conjugate (Theorem 2.3). Some examples and a new *characterization of skew operators* in terms of the Fitzpatrick family (Theorem 2.9) are provided.
- The *range* of a continuous, linear, and monotone operator is studied in section 3 and compared to the range of the adjoint. The closures of these two ranges coincide; however, the Volterra integral operator (Example 3.3) illustrates that the ranges themselves can differ.
- Section 4 deals with *rectangular*—also known as *property* $(*)$ *monotone*—operators, a class of operators introduced by Brézis and Haraux [11]. We state their main result and discuss some useful consequences. We also provide a characterization of rectangular operators in terms of their symmetric and skew parts (Corollary 4.10). This allows us to make a connection with *paramonotone operators* (Remark 4.11). A result by Brézis and Haraux is re-proved using the Fitzpatrick function (Theorem 4.12).
- We turn to the *Fitzpatrick function of the sum* in section 5. No general formula is known; in fact, Fitzpatrick posed this as an open problem (see [17, Problem 5.4]). We present a partial solution to his problem by showing that a known upper bound is actually exact in finite-dimensional spaces (Corollary 5.7) as well as in more general settings (Theorems 5.3 and 5.4 and Corollary 5.6).
- *Cyclic monotonicity* is a quantitative refinement of monotonicity that can be captured with higher-order Fitzpatrick functions. We begin in section 6 by reviewing known results about these functions. We then present a new closed form (Example 6.4), a novel recursion formula (Theorem 6.5), and a localization of the domain (Corollary 6.7).
- Finally, in section 7, we study cyclic monotonicity properties and higher-order Fitzpatrick functions of *rotators* in the Euclidean plane. Complete characterizations of n-cyclic monotonicity and explicit formulas for the Fitzpatrick functions are provided in all possible cases (Theorem 7.8). This considerably extends previously known results [2, section 4].

2. The Fitzpatrick function and skew operators. The Fitzpatrick function of a continuous linear operator will be formulated in terms of a quadratic function that we present next.

DEFINITION 2.1 (quadratic function). *Let $A\colon X \to X$ be continuous, linear, and symmetric. Then we set $q_A\colon X \to \mathbb{R}\colon x \mapsto \frac{1}{2}\langle x, Ax\rangle$.*

FACT 2.2. *Let $A\colon X \to X$ be continuous, linear, and symmetric. Then*

$$q_A \text{ is convex} \Leftrightarrow A \text{ is monotone.} \tag{7}$$

In this case, the following is true:

(i) $\nabla q_A = A$.
(ii) $q_A^* \circ A = q_A$.
(iii) $\operatorname{ran} A \subseteq \operatorname{dom} q_A^* \subseteq \overline{\operatorname{ran}}\, A$.
(iv) $q_A^* \geq 0$ *and* $(\forall u \in X)(\forall \rho \in \mathbb{R} \smallsetminus \{0\})\ q_A^*(\rho u) = \rho^2 q_A^*(u)$. *Consequently,* $\operatorname{dom} q_A^*$ *is a subspace.*
(v) *If* $\operatorname{ran} A$ *is closed, then* $q_A^* = \iota_{\operatorname{ran} A} + q_{A^\dagger}$, *where* $A^\dagger$ *is the* Moore–Penrose inverse [20] *of* A.
(vi) *If* A *is bijective, then* $q_A^* = q_{A^{-1}}$.

Proof. (See also [3, Proposition 12.3.6].) (i) and (ii) See [5, Theorem 3.6.(i)]. See also [30, Theorem 5.1] for a considerably more general version of (i). (iii) See [4, Fact

2.2(iii)]. (iv) The proof of item (iv) is elementary. (v) See [6, Proposition 3.7(iv)]. (vi) is clear from (v). ∎

THEOREM 2.3. *Let $A\colon X \to X$ be continuous, linear, and monotone. Then*

(i) $\big(\forall (x,u) \in X \times X\big)\quad F_A(x,u) = 2q^*_{A_+}\big(\frac{1}{2}u + \frac{1}{2}A^*x\big) = F_{A_+}(x, u - A_\circ x)$;

(ii) $\operatorname{ran} A_+ \subseteq (A^* \oplus \operatorname{Id})(\operatorname{dom} F_A) = \operatorname{dom} q^*_{A_+} \subseteq \overline{\operatorname{ran}}\, A_+$;

(iii) $\big(\forall (u,x) \in X \times X\big)\quad F_A^*(u,x) = \iota_{\operatorname{gra} A}(x,u) + \langle x, Ax\rangle$.

Proof. Fix $(x,u) \in X \times X$. (i) This follows from

$$\begin{aligned} F_A(x,u) &= \sup_{y\in X} \langle x, Ay\rangle + \langle y, u\rangle - \langle y, Ay\rangle = 2\sup_{y\in X}\langle y, \tfrac{1}{2}u + \tfrac{1}{2}A^*x\rangle - q_{A_+}(y) \\ &= 2q^*_{A_+}\big(\tfrac{1}{2}u + \tfrac{1}{2}A^*x\big) = 2q^*_{A_+}\big(\tfrac{1}{2}(u - A_\circ x) + \tfrac{1}{2}A_+x\big) = F_{A_+}(x, u - A_\circ x). \end{aligned} \tag{8}$$

(ii) The equality is a consequence of (i), and the inclusions are then clear from Fact 2.2(iii). (iii) This follows from Fact 1.4(iii) and the fact that the function $(u,x) \mapsto \iota_{\operatorname{gra} A}(x,u) + \langle x, u\rangle = \iota_{\operatorname{gra} A}(x,u) + \langle x, Ax\rangle$ is already convex, lower semicontinuous, and proper. ∎

The next two results play a role in the proof of Theorem 5.4 below.

Example 2.4. Let $A\colon X \to X$ be continuous, linear, monotone, and symmetric. Then

$$\big(\forall x \in X\big)\big(\forall y \in X\big)\quad F_A(x,Ay) = \tfrac{1}{4}\langle x+y, A(x+y)\rangle. \tag{9}$$

Proof. Take $x \in X$ and $y \in X$. Using Theorem 2.3(i) and Fact 2.2(ii), we obtain

$$F_A(x,Ay) = 2q^*_A\big(\tfrac{1}{2}Ay + \tfrac{1}{2}Ax\big) = 2q_A\big(\tfrac{1}{2}x + \tfrac{1}{2}y\big) = \tfrac{1}{4}\langle x+y, A(x+y)\rangle, \tag{10}$$

as required. ∎

Example 2.5 (closed range symmetric operator). Let $A\colon X \to X$ be continuous, linear, monotone, and symmetric such that $\operatorname{ran} A$ is closed. Then

$$\begin{aligned} \big(\forall (x,u) \in X \times X\big)\quad F_A(x,u) &= \iota_{\operatorname{ran} A}(u) + \tfrac{1}{4}\big(\langle x, Ax\rangle + 2\langle x, u\rangle + \langle A^\dagger u, u\rangle\big) \\ &= \iota_{\operatorname{ran} A}(u) + \tfrac{1}{4}\|x + A^\dagger u\|_A^2 \end{aligned} \tag{11}$$

and hence

$$\operatorname{dom} F_A = X \times \operatorname{ran} A. \tag{12}$$

Proof. Fix $(x,u) \in X \times X$. Using Theorem 2.3(i), Fact 2.2(v), and standard properties of the Moore–Penrose inverse [20], we deduce that

$$\begin{aligned} F_A(x,u) &= 2q^*_A\big(\tfrac{1}{2}u + \tfrac{1}{2}Ax\big) \\ &= 2\iota_{\operatorname{ran} A}\big(\tfrac{1}{2}u + \tfrac{1}{2}Ax\big) + 2q_{A^\dagger}\big(\tfrac{1}{2}u + \tfrac{1}{2}Ax\big) \\ &= \iota_{\operatorname{ran} A}(u) + \langle A^\dagger(\tfrac{1}{2}u + \tfrac{1}{2}Ax), \tfrac{1}{2}u + \tfrac{1}{2}Ax\rangle \\ &= \iota_{\operatorname{ran} A}(u) + \tfrac{1}{4}\big(\langle A^\dagger u, u\rangle + \langle A^\dagger u, Ax\rangle + \langle A^\dagger Ax, u\rangle + \langle A^\dagger Ax, Ax\rangle\big) \\ &= \iota_{\operatorname{ran} A}(u) + \tfrac{1}{4}\big(\langle A^\dagger u, u\rangle + \langle AA^\dagger u, x\rangle + \langle x, AA^\dagger u\rangle + \langle AA^\dagger Ax, x\rangle\big) \\ &= \iota_{\operatorname{ran} A}(u) + \tfrac{1}{4}\big(\langle x, Ax\rangle + 2\langle x, u\rangle + \langle A^\dagger u, u\rangle\big) \\ &= \iota_{\operatorname{ran} A}(u) + \tfrac{1}{4}\big(\langle x, Ax\rangle + \langle x, AA^\dagger u\rangle + \langle A^\dagger u, Ax\rangle + \langle A^\dagger u, AA^\dagger u\rangle\big) \\ &= \iota_{\operatorname{ran} A}(u) + \tfrac{1}{4}\langle x + A^\dagger u, A(x + A^\dagger u)\rangle \\ &= \iota_{\operatorname{ran} A}(u) + \tfrac{1}{4}\|x + A^\dagger u\|_A^2, \end{aligned} \tag{13}$$

as desired. ∎

Remark 2.6. Let A be as in Example 2.5. A referee pointed out that (12) can also be proved as follows: Take $(x,u)\in X\times X$. Utilizing Theorem 2.3(i) and Fact 2.2(iii), we have

$$(x,u)\in\operatorname{dom}F_A \;\Leftrightarrow\; \tfrac{1}{2}u+\tfrac{1}{2}Ax\in\operatorname{dom}q_A^*=\operatorname{ran}A \;\Leftrightarrow\; u\in\operatorname{ran}A. \tag{14}$$

Let us provide two further examples. The first one is related to [29, Example 1], while the second one generalizes [29, Example 3].

Example 2.7 (bijective symmetric operator). Let $A\colon X\to X$ be continuous, linear, monotone, symmetric, and bijective. Then

$$\begin{aligned}\big(\forall(x,u)\in X\times X\big)\quad F_A(x,u)&=\tfrac{1}{4}\big(\langle x,Ax\rangle+2\langle x,u\rangle+\langle A^{-1}u,u\rangle\big)\\&=\tfrac{1}{4}\|x+A^{-1}u\|_A^2.\end{aligned} \tag{15}$$

Proof. This is clear from Example 2.5. ∎

Example 2.8 (skew operator). Let $A\colon X\to X$ be continuous, linear, and skew. Then

$$\big(\forall(x,u)\in X\times X\big)\quad F_A(x,u)=F_A^*(u,x)=\iota_{\operatorname{gra}A}(x,u). \tag{16}$$

Proof. Since A is skew, $A^*=-A$, $A_+=0$ and thus $\operatorname{dom}q_{A_+}^*=\operatorname{ran}A_+=\{0\}$ is closed (Fact 2.2(iii)). Using Theorem 2.3(i), Fact 2.2(iv), and Theorem 2.3(iii), we obtain that

$$\begin{aligned}F_A(x,u)&=2q_{A_+}^*\big(\tfrac{1}{2}u+\tfrac{1}{2}A^*x\big)=2\iota_{\{0\}}\big(\tfrac{1}{2}u+\tfrac{1}{2}A^*x\big)\\&=2\iota_{\{0\}}\big(\tfrac{1}{2}u-\tfrac{1}{2}Ax\big)=\iota_{\{0\}}(u-Ax)=\iota_{\operatorname{gra}A}(x,u)\\&=\iota_{\operatorname{gra}A}(x,u)+\langle x,Ax\rangle=F_A^*(u,x),\end{aligned} \tag{17}$$

which completes the proof. ∎

We now present a new characterization of skew operators using the Fitzpatrick family.

THEOREM 2.9. *Let $A\colon X\to X$ be continuous, linear, and monotone. Then A is skew $\Leftrightarrow$ $\mathcal{F}_A$ is a singleton. In this case, $\mathcal{F}_A=\{\iota_{\operatorname{gra}A}\}$.*

Proof. Fix $(x,u)\in X\times X$.

"$\Leftarrow$": If $u-Ax\notin\operatorname{ran}A_+$, then $u-Ax\neq 0$. Now suppose that $u-Ax\neq 0$. Then $(x,u)\notin\operatorname{gra}A$ and hence $F_A^*(u,x)=+\infty$ by Theorem 2.3(iii). Fact 1.6 implies that $F_A(x,u)=+\infty$, i.e., $(x,u)\notin\operatorname{dom}F_A$. If $u+A^*x$ belonged to $\operatorname{ran}A_+$, then $q_{A_+}^*(u+A^*x)<+\infty$ (by Fact 2.2(iii)) and hence $(x,u)\in\operatorname{dom}F_A$ (by Theorem 2.3(i)), which is absurd. Thus $u+A^*x\notin\operatorname{ran}A_+$. Now $u+A^*x=u-Ax+2A_+x$, which implies $u-Ax\notin\operatorname{ran}A_+$. Altogether, we have verified the equivalence

$$\big(\forall(x,u)\in X\times X\big)\quad u-Ax\neq 0 \;\Leftrightarrow\; u-Ax\notin\operatorname{ran}A_+. \tag{18}$$

Since $(\forall u\in X\smallsetminus\{0\})\ u-A0=u\neq 0$, (18) yields $u=u-A0\notin\operatorname{ran}A_+$. Hence $\operatorname{ran}A_+=\{0\}$; equivalently, $A_+=0$ and therefore $A=A_\circ$.

"$\Rightarrow$": This follows from Example 2.8 and Fact 1.6. ∎

Remark 2.10. Loosely speaking, Theorem 2.9 states that a Fitzpatrick family with only one element corresponds to a "bad" (here, skew) monotone operator. The situation is similar for subdifferential operators: $\mathcal{F}_{\partial f}$ reduces to the singleton $\{f\oplus f^*\}$ when f is sublinear or an indicator function (see [12, 13] and also [2]).

3. Range. In this section, we compare the range of a continuous linear monotone operator to the range of its adjoint.

PROPOSITION 3.1. *Let $A: X \to X$ be continuous, linear, and monotone. Then* $\ker A = \ker A^*$ *and* $\overline{\operatorname{ran}}\, A = \overline{\operatorname{ran}}\, A^*$.

Proof. Take $x \in \ker A$ and $v \in \operatorname{ran} A$, say $v = Ay$. Then $(\forall \alpha \in \mathbb{R})\ 0 \leq \langle \alpha x + y, A(\alpha x + y)\rangle = \alpha\langle x, v\rangle + \langle y, Ay\rangle$. Hence $\langle x, v\rangle = 0$ and thus $\ker A \subset (\operatorname{ran} A)^\perp = \ker A^*$. Since A^* is also continuous, linear, and monotone, we obtain $\ker A^* \subset \ker A^{**} = \ker A$. Altogether, $\ker A = \ker A^*$ and therefore $\overline{\operatorname{ran}}\, A = \overline{\operatorname{ran}}\, A^*$. ∎

Remark 3.2.

(i) A referee pointed out that Proposition 3.1 also follows from [30, Corollary 3.5], which is more general.

(ii) Example 3.3 below illustrates that the closures in Proposition 3.1 are critical.

(iii) An operator $A: X \to X$ such that $\operatorname{ran} A = \operatorname{ran} A^*$ is called *range-symmetric* or *EP*; see [26, p. 408]. Proposition 3.1 implies that every continuous, linear, and monotone operator with closed range is range-symmetric. See [16, Theorem 2.3] for equivalent properties in the matrix case.

(iv) Every *normal matrix* A (i.e., $AA^* = A^*A$) is range-symmetric: indeed, we then have $\operatorname{ran} A = \operatorname{ran} AA^* = \operatorname{ran} A^*A = \operatorname{ran} A^*$ (the first and the last equalities follow, e.g., from [26, p. 212]).

(v) However, a range-symmetric monotone matrix need not be normal:

$$A = \begin{pmatrix} 2 & 1 \\ -1 & 1 \end{pmatrix} \tag{19}$$

is monotone, but $AA^* \neq A^*A$.

Example 3.3 (Volterra operator). Set $X = L_2[0,1]$. The *Volterra integration operator* [21, Problem 148] is defined by

$$V: X \to X: x \mapsto Vx, \quad \text{where} \quad Vx: [0,1] \to \mathbb{R}: t \mapsto \int_0^t x. \tag{20}$$

Fix $x \in X$. Then

$$(V^*x)(t) = \int_t^1 x \tag{21}$$

and $\ker V = \ker V^* = \{0\}$, so V and V^* have dense range. Set $e \equiv 1 \in X$. Now (20) and (21) imply $(V + V^*)x = \langle x, e\rangle e$ and thus $\langle x, (V + V^*)x\rangle = \langle x, e\rangle^2 \geq 0$. Hence

$$V \text{ is monotone and } V_+x = \tfrac{1}{2}\langle x, e\rangle e. \tag{22}$$

Moreover, $q_{V_+}(x) = \frac{1}{2}\langle x, V_+x\rangle = \frac{1}{4}\langle x, e\rangle^2$ and $\operatorname{ran} V_+ = \mathbb{R}e$ is closed. Now Fact 2.2(ii) and Theorem 2.3(i), (iii) result in

$$F_V: X \times X \to\ ]-\infty, +\infty] \tag{23}$$
$$(z, w) \mapsto \begin{cases} \frac{1}{2}\langle w + V^*z, e\rangle^2 & \text{if } w + V^*z = \langle w + V^*z, e\rangle e; \\ +\infty & \text{otherwise} \end{cases}$$

and

$$F_V^*: X \times X \to\ ]-\infty, +\infty] \tag{24}$$
$$(w, z) \mapsto \begin{cases} \frac{1}{2}\langle z, e\rangle^2 & \text{if } w = Vz; \\ +\infty & \text{otherwise.} \end{cases}$$

Next, assume that $Vx = V^*y$, i.e., $(\forall t \in [0,1])\ \int_0^t x = \int_t^1 y$. Evaluating this at $t = 0$ and $t = 1$, we learn that $\langle y, e\rangle = \langle x, e\rangle = 0$. We thus have verified the implication

$$\left.\begin{array}{c} x \in X \\ y \in X \\ Vx = V^*y \end{array}\right\} \quad \Rightarrow \quad \langle x, e\rangle = \langle y, e\rangle = 0 \tag{25}$$

and the inclusion

$$\operatorname{ran} V \cap \operatorname{ran} V^* \subseteq \big\{Vx \mid x \in \{e\}^\perp\big\}. \tag{26}$$

Conversely, if $x \in \{e\}^\perp$, then

$$(\forall t \in [0,1]) \quad (Vx)(t) = \langle x, e\rangle - \int_t^1 x = \big(V^*(-x)\big)(t) \tag{27}$$

and hence $Vx \in \operatorname{ran} V \cap \operatorname{ran} V^*$. Altogether,

$$\operatorname{ran} V \cap \operatorname{ran} V^* = \{Vx \colon x \in \{e\}^\perp\}. \tag{28}$$

Since $\langle e, e\rangle = 1 \neq 0$, the implication (25) shows that $Ve \notin \operatorname{ran} V^*$ and that $V^*e \notin \operatorname{ran} V$. Therefore,

$$\operatorname{ran} V \nsubseteq \operatorname{ran} V^* \ \text{ and } \ \operatorname{ran} V^* \nsubseteq \operatorname{ran} V. \tag{29}$$

4. Rectangular monotone operators. We now turn to a property related to the domain of the Fitzpatrick function.

DEFINITION 4.1 (rectangular). *Let $A \colon X \to X$ be continuous, linear, and monotone. Then A is* rectangular *if $X \times \operatorname{ran} A \subseteq \operatorname{dom} F_A$.*

Remark 4.2.

(i) The property referred to in Definition 4.1 was first introduced by Brézis and Haraux [11]. In the literature it is also known as *property (*)* and as *3*-monotone*. However, we follow here Simons' [39] more descriptive naming convention, which is based on his observation that—since $\operatorname{dom} F_A \subseteq \overline{\operatorname{dom}}\, A \times \overline{\operatorname{ran}}\, A = X \times \overline{\operatorname{ran}}\, A$ is always true—the operator A is rectangular if and only if $\overline{\operatorname{dom}}\, F_A$ is the "rectangle" $X \times \overline{\operatorname{ran}}\, A$.

(ii) In the context of general monotone operators, the subdifferential operator is known to be rectangular [11].

(iii) As a consequence of (ii), we note that every continuous, linear, monotone, and symmetric operator is rectangular (Fact 2.2(i)). This will be reproved in Corollary 4.9 below.

The importance of rectangularity stems from a powerful result due to Brézis and Haraux [11], which we state next in the present context of linear operators.

FACT 4.3 (Brézis–Haraux). *Let A and B be continuous, linear, and monotone operators from X to X, and suppose that A or B is rectangular. Then $\overline{\operatorname{ran}}\,(A+B) = \overline{\operatorname{ran} A + \operatorname{ran} B}$ and $\operatorname{int} \operatorname{ran}(A+B) = \operatorname{int}(\operatorname{ran} A + \operatorname{ran} B)$.*

Proof. See [11], and also [36, 39] for different proofs. ∎

It is worthwhile to list some of the most important consequences of Fact 4.3.

COROLLARY 4.4. *Let A and B be continuous, linear, and monotone operators from X to X. Suppose that A or B is rectangular, and that A or B is surjective. Then $A + B$ is surjective.*

Proof. Fact 4.3 yields $X = \operatorname{int} X = \operatorname{int}(\operatorname{ran} A + \operatorname{ran} B) = \operatorname{int} \operatorname{ran}(A+B)$. Therefore, $X = \operatorname{ran}(A+B)$ and $A+B$ is surjective. ∎

COROLLARY 4.5. *Let A and B be continuous, linear, and monotone operators from X to X such that A or B is rectangular. Then* $\ker(A+B) = \ker A \cap \ker B$.

Proof. Using Proposition 3.1 and Fact 4.3, we obtain

$$\begin{aligned}(\ker A \cap \ker B)^\perp &= \overline{(\ker A)^\perp + (\ker B)^\perp} = \overline{\operatorname{ran} A^* + \operatorname{ran} B^*} \\ &= \overline{\operatorname{ran} A + \operatorname{ran} B} = \overline{\operatorname{ran}}\,(A+B) \\ &= \big(\ker(A+B)\big)^\perp. \end{aligned} \tag{30}$$

The result follows by taking orthogonal complements. ∎

COROLLARY 4.6. *Let A and B be continuous, linear, and monotone operators from X to X. Suppose that A or B is rectangular, and that A or B is injective. Then $A+B$ is injective.*

COROLLARY 4.7. *Let A and B be continuous, linear, and monotone operators from X to X. Suppose that A or B is rectangular, and that A or B is bijective. Then $A+B$ is bijective.*

PROPOSITION 4.8. *Let $A\colon X \to X$ be continuous, linear, and monotone. Then the following are equivalent:*

(i) *A is rectangular.*
(ii) $\operatorname{ran} A + \operatorname{ran} A^* \subseteq \operatorname{dom} q^*_{A_+}$.
(iii) $\operatorname{ran} A_\circ \subseteq \operatorname{dom} q^*_{A_+}$.

Proof. (i)⇔(ii): This is a direct consequence of Theorem 2.3(i). (ii)⇒(iii): $\operatorname{ran} A_\circ = \operatorname{ran}(A - A^*) \subseteq \operatorname{ran} A - \operatorname{ran} A^* = \operatorname{ran} A + \operatorname{ran} A^* \subseteq \operatorname{dom} q^*_{A_+}$. (ii)⇐(iii): This follows from Fact 2.2(iii), (iv) and the fact that $A^* = A_+ - A_\circ$ yield $\operatorname{ran} A + \operatorname{ran} A^* = \operatorname{ran}(A_+ + A_\circ) + \operatorname{ran}(A_+ - A_\circ) \subseteq \operatorname{ran} A_+ + \operatorname{ran} A_\circ \subseteq \operatorname{dom} q^*_{A_+} + \operatorname{dom} q^*_{A_+} = \operatorname{dom} q^*_{A_+}$. ∎

COROLLARY 4.9. *Let $A\colon X \to X$ be continuous, linear, monotone, and symmetric. Then A is rectangular.*

Proof. Utilizing Fact 2.2(iii), we see that $\operatorname{ran} A + \operatorname{ran} A^* = \operatorname{ran} A_+ \subseteq \operatorname{dom} q^*_{A_+}$. The result follows from Proposition 4.8. ∎

COROLLARY 4.10. *Let $A\colon X \to X$ be continuous, linear, and monotone, and suppose that* $\operatorname{ran} A_+$ *is closed. Then A is rectangular if and only if* $\operatorname{ran} A_\circ \subseteq \operatorname{ran} A_+$.

Proof. Fact 2.2(iii) shows that $\operatorname{dom} q^*_{A_+} = \operatorname{ran} A_+$. Applying Proposition 4.8, we obtain the proof. ∎

Remark 4.11 (paramonotone operators). Let $X = \mathbb{R}^n$ and let $A \in \mathbb{R}^{n\times n}$ be monotone. By [22, Proposition 3.2.(ii)], A is *paramonotone* ⇔ $\ker A_+ \subseteq \ker A$. On the other hand, using Corollary 4.5 (applied to A_+ and $A_\circ$) and Corollary 4.10, we have the equivalences $\ker A_+ \subseteq \ker A \Leftrightarrow \ker A_+ \subseteq \ker A_+ \cap \ker A_\circ \Leftrightarrow \ker A_+ \subseteq \ker A_\circ$ ⇔ $\operatorname{ran} A_\circ \subseteq \operatorname{ran} A_+ \Leftrightarrow A$ is rectangular. Altogether,

A is paramonotone if and only if A is rectangular. (31)

See [22] for further information on paramonotone operators.

The next result can be deduced from [11, Proposition 2]. The proof provided here is somewhat simpler and based on the Fitzpatrick function, and the result is stated in a more applicable form.

THEOREM 4.12. *Let $A\colon X \to X$ be continuous, linear, and monotone. Then the following are equivalent:*

(i) *A is rectangular.*
(ii) *For some $\gamma > 0$, $\|\gamma A - \mathrm{Id}\| \leq 1$.*
(iii) *A^* is rectangular.*

Proof. The conditions all hold when $A = 0$, so assume that $A \neq 0$.

(i)⇒(ii): Consider the function

$$f\colon X \to \left]-\infty,+\infty\right]\colon x \mapsto F_A(x,0). \tag{32}$$

Then f is convex, lower semicontinuous, and proper by Fact 1.4(i), (ii). Since A is rectangular, $X \times \{0\} \subseteq X \times \operatorname{ran} A \subseteq \operatorname{dom} F_A$. Hence $\operatorname{dom} f = X$. It follows, e.g., from [43, Theorem 2.2.20] that there exist $\delta > 0$ and $\beta > 0$ such that $(\forall x \in B(0;\delta))$ $f(x) = F_A(x,0) = \sup_{y\in X}\langle x, Ay\rangle - \langle y, Ay\rangle \leq \beta$. Fix $x \in B(0;\delta)$ and $y \in X$. Then

$$(\forall \rho \in \mathbb{R}) \quad 0 \leq \beta + \langle \rho y, A(\rho y)\rangle - \langle x, A(\rho y)\rangle = \beta + \rho^2\langle y, Ay\rangle - \rho\langle x, Ay\rangle. \tag{33}$$

We claim that

$$(\forall x \in B(0;\delta))(\forall y \in X) \quad \langle x, Ay\rangle^2 \leq 4\beta\langle y, Ay\rangle. \tag{34}$$

If $\langle y, Ay\rangle = 0$, then (33) shows that $\langle x, Ay\rangle = 0$, and hence (34) holds. Now assume that $\langle y, Ay\rangle \neq 0$. In terms of ρ, the right side of (33) is a nonnegative quadratic function. Substituting the minimizer $\langle x, Ay\rangle/(2\langle y, Ay\rangle)$ of this quadratic function into (33) yields an inequality that is equivalent to (34). In turn, (34) leads to

$$(\forall y \in X) \quad \delta^2\|Ay\|^2 \leq 4\beta\langle y, Ay\rangle. \tag{35}$$

Set $\alpha = \delta^2/(4\beta)$. We deduce that $(\forall y \in X)$ $\langle y, \alpha Ay\rangle \geq \|\alpha Ay\|^2$, i.e., αA is firmly nonexpansive. This (see [19]) is equivalent to the nonexpansivity of $2\alpha A - \mathrm{Id}$, i.e., to $\|2\alpha A - \mathrm{Id}\| \leq 1$.

(ii)⇒(i): Set $\alpha = \gamma/2$. Fix x and y in X and take $z \in X$. Utilizing the equivalences αA is firmly nonexpansive $\Leftrightarrow \|2\alpha A - \mathrm{Id}\| \leq 1 \Leftrightarrow \|2\alpha A^* - \mathrm{Id}\| \leq 1 \Leftrightarrow \alpha A^*$ is firmly nonexpansive, we estimate

$$\begin{aligned}\langle x, Az\rangle + \langle z, Ay\rangle - \langle z, Az\rangle &= \big(\langle x, Az\rangle - \tfrac{1}{2}\langle z, Az\rangle\big) + \big(\langle A^*z, y\rangle - \tfrac{1}{2}\langle z, A^*z\rangle\big)\\ &\leq \big(\|x\|\,\|Az\| - \tfrac{1}{2}\alpha\|Az\|^2\big) + \big(\|A^*z\|\,\|y\| - \tfrac{1}{2}\alpha\|A^*z\|^2\big)\\ &\leq \tfrac{1}{2\alpha}\big(\|x\|^2 + \|y\|^2\big),\end{aligned} \tag{36}$$

where the last inequality was obtained by computing the maxima of the quadratic functions $\rho \mapsto \|x\|\rho - \frac{1}{2}\alpha\rho^2$ and $\rho \mapsto \|y\|\rho - \frac{1}{2}\alpha\rho^2$, respectively. It follows from (36) that

$$(\forall x \in X)(\forall y \in X) \quad F_A(x, Ay) \leq \tfrac{1}{\gamma}\big(\|x\|^2 + \|y\|^2\big), \tag{37}$$

hence $X \times \operatorname{ran} A \subset \operatorname{dom} F_A$.

(ii)⇔(iii): Apply the equivalence (i)⇔(ii) to A^*. □

COROLLARY 4.13. *The continuous, linear, monotone, and rectangular operators form a convex cone.*

Proof. It is clear that they form a cone. Suppose A and B are continuous, linear, monotone, and rectangular. Then there exist $\gamma_A > 0$ and $\gamma_B > 0$ such that $\|\gamma_A A - \mathrm{Id}\| \leq 1$ and $\|\gamma_B B - \mathrm{Id}\| \leq 1$. Set $\gamma = \frac{1}{2}\min\{\gamma_A, \gamma_B\}$ and estimate

$\|\gamma(A+B)-\mathrm{Id}\| \leq \frac{1}{2}\|2\gamma A-\mathrm{Id}\|+\frac{1}{2}\|2\gamma B-\mathrm{Id}\| \leq 1$. Hence $A+B$ is rectangular and the proof is complete. ∎

The next example was established by direct computation in [4]; however, Theorem 4.12 yields a very transparent and simple proof.

Example 4.14. Let $R\colon X^n \to X^n\colon (x_1,x_2,\ldots,x_n) \mapsto (x_n,x_1,\ldots,x_{n-1})$ be the *right-shift operator* on X^n. Then $\mathrm{Id}-R$ is rectangular.

Proof. Since $\|1\cdot(\mathrm{Id}-R)-\mathrm{Id}\| = \|-R\| = 1$, the result is a consequence of Theorem 4.12. ∎

We conclude this section by providing a novel nonsmooth proof of a result on the domain of the Fitzpatrick function of the subdifferential operator (see also [6, Theorem 2.6]).

THEOREM 4.15. *Let $f\colon X \to]-\infty,+\infty]$ be convex, lower semicontinuous, and proper. Then*

$$\operatorname{dom} f \times \operatorname{dom} f^* \subseteq \operatorname{dom} F_{\partial f} \subseteq \overline{\operatorname{dom}}\, f \times \overline{\operatorname{dom}}\, f^*. \tag{38}$$

Proof. The first inclusion is elementary (see also [6, Proposition 2.1]). Now take $(x,u) \in \operatorname{dom} F_{\partial f}$ and set $C = \overline{\operatorname{dom}}\, f$. Assume to the contrary that $x \notin C$; hence $f(x) = +\infty$ and $d_C(x) = \inf\|x-C\| > 0$. Fix $x_0 \in \operatorname{dom} f$ and define the family of nonconvex but lower semicontinuous functions

$$(\forall \rho > 0) \quad f_\rho\colon X \to]-\infty,+\infty]\colon y \mapsto \begin{cases} f(y) & \text{if } y \neq x;\\ f(x_0)+\rho & \text{if } y = x. \end{cases} \tag{39}$$

The *approximate mean value theorem* of Mordukhovich and Shao (see [27, Theorem 3.49] or [28, Theorem 8.2]), applied to f_ρ and the points x_0 and x, shows that for every $\rho > 0$, there exist $y_\rho \in [x_0,x[$ and a sequence $(y_{\rho,n},v_{\rho,n})_{n\in\mathbb{N}}$ in $\operatorname{gra}\partial f$ such that $y_{\rho,n} \to y_\rho$ and

$$\varliminf_{n\in\mathbb{N}} \Big\langle \frac{x-y_{\rho,n}}{\|x-y_{\rho,n}\|}, v_{\rho,n}\Big\rangle \geq \frac{f_\rho(x)-f_\rho(x_0)}{\|x-x_0\|} = \frac{\rho}{\|x-x_0\|}. \tag{40}$$

Therefore, there exists a sequence $((z_n,w_n))_{n\in\mathbb{N}}$ in $\operatorname{gra}\partial f$ such that

$$\Big\langle \frac{x-z_n}{\|x-z_n\|}, w_n\Big\rangle \to +\infty. \tag{41}$$

By definition of $F_{\partial f}$, the Cauchy–Schwarz inequality, and (41), we obtain

$$\begin{aligned} F_{\partial f}(x,u) &= \sup_{(y,v)\in\operatorname{gra}\partial f} \big(\langle x,v\rangle + \langle y,u\rangle - \langle y,v\rangle\big)\\ &= \sup_{(y,v)\in\operatorname{gra}\partial f} \big(\langle x-y,v\rangle + \langle y-x,u\rangle + \langle x,u\rangle\big)\\ &\geq \sup_{(y,v)\in\operatorname{gra}\partial f} \left(\|x-y\|\Big(\Big\langle \frac{x-y}{\|x-y\|}, v\Big\rangle - \|u\|\Big) + \langle x,u\rangle\right)\\ &\geq \varlimsup_{n\in\mathbb{N}} \left(\|x-z_n\|\Big(\Big\langle \frac{x-z_n}{\|x-z_n\|}, w_n\Big\rangle - \|u\|\Big) + \langle x,u\rangle\right)\\ &\geq \varlimsup_{n\in\mathbb{N}} \left(d_C(x)\Big(\Big\langle \frac{x-z_n}{\|x-z_n\|}, w_n\Big\rangle - \|u\|\Big) + \langle x,u\rangle\right)\\ &= +\infty. \end{aligned} \tag{42}$$

This contradicts the assumption that $F_{\partial f}(x,u) < +\infty$. Therefore, $x \in \overline{\operatorname{dom}}\, f$. An analogous argument (applied to f^*) implies that $u \in \overline{\operatorname{dom}}\, f^*$. ∎

5. The Fitzpatrick function of the sum. One of Fitzpatrick's open problems [17, Problem 5.4] is to find the Fitzpatrick function of the sum of two operators. This has proven to be a difficult problem. However, an upper bound is always readily available.

DEFINITION 5.1. *Let $A\colon X \to X$ and $B\colon X \to X$ be continuous, linear, and monotone operators, and set*

$$(\forall (x,u) \in X \times X) \quad \Phi_{\{A,B\}}(x,u) = \big(F_A(x,\cdot) \,\square\, F_B(x,\cdot)\big)(u) = \inf_{v+w=u} F_A(x,v) + F_B(x,w). \tag{43}$$

PROPOSITION 5.2 (upper bound). *Let $A\colon X \to X$ and $B\colon X \to X$ be continuous, linear, and monotone operators. Then $F_{A+B} \leq \Phi_{\{A,B\}}$.*

Proof. See [6, Proposition 4.2]. □

In [6, section 4] it is shown that in the context of subdifferential operators, this upper bound is sometimes—but not always—tight. In the remainder of this section we investigate the upper bound in the present context of continuous, linear, and monotone operators.

THEOREM 5.3. *Let $A\colon X \to X$ and $B\colon X \to X$ be continuous, linear, and monotone operators. Suppose that one of the following conditions is satisfied:*

(i) *A is skew, and B is skew.*

(ii) *A is symmetric, and B is skew.*

Then $F_{A+B} = \Phi_{\{A,B\}}$.

Proof. Fix $(x,u) \in X \times X$. (i) Repeated application of Example 2.8 yields

$$\begin{aligned} F_{A+B}(x,u) &= \iota_{\operatorname{gra}(A+B)}(x,u) \\ &= \inf_{v+w=u} \iota_{\{Ax\}}(v) + \iota_{\{Bx\}}(w) \\ &= \inf_{v+w=u} \iota_{\operatorname{gra} A}(x,v) + \iota_{\operatorname{gra} B}(x,w) \\ &= \inf_{v+w=u} F_A(x,v) + F_B(x,w) \\ &= \Phi_{\{A,B\}}(x,u). \end{aligned} \tag{44}$$

(ii) Theorem 2.3(i) and Example 2.8 result in

$$\begin{aligned} F_{A+B}(x,u) &= F_A(x, u - Bx) \\ &= \inf_{v \in Bx} F_A(x, u - v) \\ &= \inf_{v \in X} F_A(x, u - v) + \iota_{\operatorname{gra} B}(x,v) \\ &= \inf_{v \in X} F_A(x, u - v) + F_B(x,v) \\ &= \Phi_{\{A,B\}}(x,u). \end{aligned} \tag{45}$$

The proof is complete. □

The "purely symmetric" counterpart to Theorem 5.3 seems to require a closedness assumption. We are grateful to a referee for providing us with a simpler and more powerful proof.

THEOREM 5.4. *Let $A\colon X \to X$ and $B\colon X \to X$ be continuous, linear, monotone, and symmetric. Then $F_{A+B} = \Phi_{\{A,B\}}$ on $\operatorname{ran}(A+B)$. Consequently, if $\operatorname{ran}(A+B)$ is closed, then $F_{A+B} = \Phi_{\{A,B\}}$.*

Proof. Fix $x \in X$ and $y \in X$. Utilizing Example 2.4 thrice, we obtain

$$\begin{aligned}\Phi_{\{A,B\}}\big(x,(A+B)y\big) &\leq F_A(x,Ay)+F_B(x,By)\\ &= \tfrac{1}{4}\langle x+y, A(x+y)\rangle + \tfrac{1}{4}\langle x+y, B(x+y)\rangle\\ &= \tfrac{1}{4}\langle x+y,(A+B)(x+y)\rangle\\ &= F_{A+B}\big(x,(A+B)y\big).\end{aligned} \tag{46}$$

Thus

$$\Phi_{\{A,B\}} \leq F_{A+B} \text{ on } X\times \operatorname{ran}(A+B). \tag{47}$$

On the other hand, by Proposition 5.2, $F_{A+B} \leq \Phi_{\{A,B\}}$. Altogether, $F_{A+B} = \Phi_{\{A,B\}}$ on $X\times\operatorname{ran}(A+B)$. If $\operatorname{ran}(A+B)$ is closed, we deduce from (12) that $F_{A+B} = \Phi_{\{A,B\}}$ everywhere. ∎

Remark 5.5. We do not know whether or not the conclusion of Theorem 5.4 remains true when the assumption on the closedness of the range of the sum of the operators is omitted. Indeed, we do not know whether or not two continuous, linear, and monotone operators $A\colon X\to X$ and $B\colon X\to X$ exist for which $F_{A+B}\neq\Phi_{\{A,B\}}$.

COROLLARY 5.6. *Let $A\colon X\to X$ and $B\colon X\to X$ be continuous, linear, and monotone operators such that* $\operatorname{ran}(A_+ + B_+)$ *is closed. Then $F_{A+B} = \Phi_{\{A,B\}}$.*

Proof. Fix $(x,u)\in X\times X$. Using Theorems 5.3(ii), 5.4, 5.3(i), and 5.3(ii) again, we obtain

$$\begin{aligned}&F_{A+B}(x,u)\\ &= F_{A_+ + A_\circ + B_+ + B_\circ}(x,u) = F_{(A_+ + B_+)+(A_\circ+B_\circ)}(x,u)\\ &= \inf_{v+w=u} F_{A_+ + B_+}(x,v) + F_{A_\circ+B_\circ}(x,w)\\ &= \inf_{v+w=u}\Big(\inf_{v_1+v_2=v} F_{A_+}(x,v_1)+F_{B_+}(x,v_2) + \inf_{w_1+w_2=w} F_{A_\circ}(x,w_1)+F_{B_\circ}(x,w_2)\Big)\\ &= \inf_{v_1+v_2+w_1+w_2=u} F_{A_+}(x,v_1)+F_{A_\circ}(x,w_1)+F_{B_+}(x,v_2)+F_{B_\circ}(x,w_2)\\ &= \inf_{u_1+u_2=u}\Big(\inf_{v_1+w_1=u_1} F_{A_+}(x,v_1)+F_{A_\circ}(x,w_1) + \inf_{v_2+w=u_2} F_{B_+}(x,v_2)+F_{B_\circ}(x,w_2)\Big)\\ &= \inf_{u_1+u_2=u} F_A(x,u_1)+F_B(x,u_2)\\ &= \Phi_{\{A,B\}}(x,u),\end{aligned} \tag{48}$$

as required. ∎

COROLLARY 5.7. *Suppose that X is finite-dimensional, and let $A\colon X\to X$ and $B\colon X\to X$ be continuous, linear, and monotone operators. Then $F_{A+B} = \Phi_{\{A,B\}}$.*

6. Cyclic monotonicity. An interesting quantitative grading of monotonicity is the notion of cyclic monotonicity of order n. As demonstrated in [2], this property is captured with a Fitzpatrick function of the corresponding order. In this section, we study these notions for continuous linear operators. Let us start with the relevant definitions.

DEFINITION 6.1 (n-cyclic monotonicity). *Let $A\colon X\to X$ be continuous and linear. Then A is* n-cyclically monotone *if $n\in\{2,3,\dots\}$ and*

$$(\forall (x_1,\dots,x_n)\in X^n)\quad \left(\sum_{i=1}^{n-1}\langle x_{i+1}-x_i, Ax_i\rangle\right) + \langle x_1-x_n, Ax_n\rangle \leq 0. \tag{49}$$

The operator A is cyclically monotone *if A is n-cyclically monotone for every $n \in \{2,3,\dots\}$.*

Note that an operator is monotone if and only if it is 2-cyclically monotone.

DEFINITION 6.2 (Fitzpatrick function of order n). *Let $A\colon X \to X$. For every $n \in \{2,3,\dots\}$, the* Fitzpatrick function of A of order n *is*

(50)
$$F_{A,n}(x,u) = \sup_{(x_1,\dots,x_{n-1})\in X^{n-1}} \Big(\sum_{i=1}^{n-2}\langle x_{i+1}-x_i, Ax_i\rangle\Big) + \langle x - x_{n-1}, Ax_{n-1}\rangle + \langle x_1, u\rangle.$$

We set $F_{A,\infty} = \sup_{n\in\{2,3,\dots\}} F_{A,n}$.

Note that $F_{A,2} = F_A$. We refer the reader to [2], where it is shown that $F_{A,n}$ is well suited to study n-cyclic monotonicity of A. Most relevant for our current setting is the following result.

FACT 6.3 (see [2, Theorem 2.9]). *Let $A\colon X \to X$ be maximal monotone, and let $n \in \{2,3,\dots\}$. Then A is n-cyclically monotone* $\Leftrightarrow \operatorname{gra} A = \big\{(x,u) \in X\times X \mid F_{A,n}(x,u) = \langle x,u\rangle\big\}$.

Let us compute the Fitzpatrick functions of an arbitrary continuous, linear, symmetric, and positive definite operator. This result generalizes [2, Example 4.4].

Example 6.4. Let $A\colon X \to X$ be continuous, linear, symmetric, and positive definite, and let $n \in \{2,3,\dots\}$. Then

$$F_{A,n}\colon X\times X \to \mathbb{R}\colon (x,u) \mapsto \tfrac{n-1}{2n}\big(\|x\|_A^2 + \|u\|_{A^{-1}}^2\big) + \tfrac{1}{n}\langle x,u\rangle \tag{51}$$

and

$$F_{A,\infty} = \tfrac{1}{2}\|\cdot\|_A^2 \oplus \tfrac{1}{2}\|\cdot\|_{A^{-1}}^2. \tag{52}$$

Proof. By [2, Example 4.4], we have

$$F_{\mathrm{Id},n}\colon X\times X \to \mathbb{R}\colon (x,u) \mapsto \tfrac{n-1}{2n}\big(\|x\|^2 + \|u\|^2\big) + \tfrac{1}{n}\langle x,u\rangle \tag{53}$$

and

$$F_{\mathrm{Id},\infty} = \tfrac{1}{2}\|\cdot\|^2 \oplus \tfrac{1}{2}\|\cdot\|^2. \tag{54}$$

Fix $(x,u) \in X\times X$. By definition, $F_{A,n}(x,u)$ is equal to

$$\begin{aligned}&\sup_{(x_1,\dots,x_{n-1})\in X^{n-1}} \Big(\sum_{i=1}^{n-2}\langle x_{i+1}-x_i, Ax_i\rangle\Big) + \langle x - x_{n-1}, Ax_{n-1}\rangle + \langle x_1,u\rangle \\ &= \sup_{(x_1,\dots,x_{n-1})\in X^{n-1}} \Big(\sum_{i=1}^{n-2}\langle x_{i+1}-x_i, x_i\rangle_A\Big) + \langle x - x_{n-1}, x_{n-1}\rangle_A + \langle x_1, A^{-1}u\rangle_A.\end{aligned} \tag{55}$$

The result now follows by applying (53) and (54) to Id, viewed as an operator on $(X, \langle\cdot,\cdot\rangle_A)$. ∎

We now provide a simple, yet powerful, recursion formula.

THEOREM 6.5 (recursion). *Let $A\colon X \to X$ be monotone, and let $n \in \{2,3,\dots\}$. Then*

$$\big(\forall (x,u)\in X\times X\big)\quad F_{A,n+1}(x,u) = \sup_{y\in X}\big(F_{A,n}(y,u) + \langle x-y, Ay\rangle\big). \tag{56}$$

Proof. Fix $(x,u) \in X \times X$. Using the definition, we see that $F_{A,n+1}(x,u)$ is equal to

$$\begin{aligned}
&\sup_{(x_1,\ldots,x_n)\in X^n} \Big(\sum_{i=1}^{n-1} \langle x_{i+1}-x_i, Ax_i\rangle \Big) + \langle x-x_n, Ax_n\rangle + \langle x_1, u\rangle \\
&= \sup_{x_n\in X} \Bigg(\sup_{(x_1,\ldots,x_{n-1})\in X^{n-1}} \Big(\sum_{i=1}^{n-2} \langle x_{i+1}-x_i, Ax_i\rangle \Big) + \langle x_n - x_{n-1}, Ax_{n-1}\rangle + \langle x_1, u\rangle \Bigg) \\
&\qquad\qquad + \langle x-x_n, Ax_n\rangle \\
&= \sup_{x_n\in X} \Big(F_{A,n}(x_n,u) + \langle x-x_n, Ax_n\rangle \Big).
\end{aligned} \tag{57}$$

The proof is complete. ∎

This section is concluded with two results on the domain of the Fitzpatrick function of order n.

THEOREM 6.6. *Let $f\colon X \to \left]-\infty,+\infty\right]$ be convex, lower semicontinuous, and proper, and let $n \in \{2,3,\ldots\}$. Then*

$$\operatorname{dom} f \times \operatorname{dom} f^* \subseteq \operatorname{dom} F_{\partial f,n} \subseteq \operatorname{dom} F_{\partial f} \subseteq \overline{\operatorname{dom}}\, f \times \overline{\operatorname{dom}}\, f^*. \tag{58}$$

Proof. By [2, Theorem 3.5], we know that $F_{\partial f,n} \le f \oplus f^*$, which implies the first inequality of (58). The second inequality is clear since $(F_{\partial f,n})_{n\in\{2,3,\ldots\}}$ is an increasing sequence. The third inequality follows from Theorem 4.15. ∎

COROLLARY 6.7. *Let $A\colon X \to X$ be continuous, linear, monotone, and symmetric, and let $n \in \{2,3,\ldots\}$. Then*

$$X \times \operatorname{ran} A \subseteq \operatorname{dom} F_{A,n} \subseteq X \times \overline{\operatorname{ran}}\, A. \tag{59}$$

7. Rotators in the Euclidean plane. This section covers rotators in the Euclidean plane. We characterize their cyclic monotonicity properties, and we provide formulas for the Fitzpatrick function of any order.

From now on, $X = \mathbb{R}^2$ and

$$A_\theta = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}, \quad \text{where } \theta \in [0,\pi/2]. \tag{60}$$

The main result of this section will be stated at the end. For clarity of presentation, we break up the proof into several propositions. The first proposition characterizes n-cyclic monotonicity. See also Asplund's paper [1] for characterizations for general matrices.

PROPOSITION 7.1. *Let $n \in \{2,3,\ldots\}$. Then A_θ is n-cyclically monotone $\Leftrightarrow$ $\theta \in [0,\pi/n]$.*

Proof. If $n = 2$, then the symmetric part of A_θ is $\cos\theta\,\mathrm{Id}$ and the equivalence is clear. Thus, we assume that $n \in \{3,4,\ldots\}$. We shall characterize the n-cyclic monotonicity of A_θ in terms of the positive semidefiniteness of an associated Hermitian matrix. Take n points $x_1 = (\xi_1,\eta_1),\ldots,x_n = (\xi_n,\eta_n)$ in X, and set $x_{n+1} = x_1$. We must show that

$$0 \ge \sum_{i=1}^{n} \langle x_{i+1}-x_i, A_\theta x_i\rangle. \tag{61}$$

Let us identify $\mathbb{R}^2$ with $\mathbb{C}$ in the standard way: $x = (\xi, \eta)$ in $\mathbb{R}^2$ corresponds to $\xi + \mathrm{i}\eta$ in $\mathbb{C}$, where $\mathrm{i} = \sqrt{-1}$, and $\langle x, y\rangle = \mathrm{Re}(\overline{x}y)$ for x and y in $\mathbb{C}$. The operator A_θ corresponds to complex multiplication by

$$\omega = \exp(\mathrm{i}\theta). \tag{62}$$

Thus we aim to show that $0 \geq \mathrm{Re}\left(\sum_{i=1}^n (\overline{x_{i+1} - x_i})\omega x_i\right) = \sum_{i=1}^n \mathrm{Re}\left(\overline{(x_{i+1} - x_i)}\omega x_i\right)$, an inequality which we now reformulate in $\mathbb{C}^n$. Denote the $n \times n$-identity matrix by $\mathbf{I}$, and set

$$\mathbf{B} = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \vdots \\ \vdots & & \ddots & \ddots & \\ & & & & 0 \\ 0 & & & & 1 \\ 1 & 0 & \cdots & & 0 \end{pmatrix} \in \mathbb{C}^{n\times n} \quad \text{and} \quad \mathbf{R} = \omega\mathbf{I} \in \mathbb{C}^{n\times n}. \tag{63}$$

Identifying $\mathbf{x} \in \mathbb{C}^n$ with $(x_1, \ldots, x_n) \in X^n$, we note that (61) means $0 \geq \mathrm{Re}\left(\left((\mathbf{B} - \mathbf{I})\mathbf{x}\right)^*\mathbf{R}\mathbf{x}\right)$; equivalently, $0 \geq \mathbf{x}^*(\mathbf{B}^* - \mathbf{I})\mathbf{R}\mathbf{x} + \mathbf{x}^*\mathbf{R}^*(\mathbf{B} - \mathbf{I})\mathbf{x}$. Set

$$\begin{aligned} \mathbf{C}_n &= (\mathbf{I} - \mathbf{B}^*)\mathbf{R} + \mathbf{R}^*(\mathbf{I} - \mathbf{B}) \\ &= \begin{pmatrix} (\omega + \overline{\omega}) & -\overline{\omega} & 0 & \cdots & 0 & -\omega \\ -\omega & (\omega + \overline{\omega}) & \ddots & & & 0 \\ 0 & \ddots & \ddots & \ddots & & \vdots \\ \vdots & & & & & 0 \\ 0 & & & & (\omega + \overline{\omega}) & -\overline{\omega} \\ -\overline{\omega} & 0 & \cdots & 0 & -\omega & (\omega + \overline{\omega}) \end{pmatrix} \in \mathbb{C}^{n\times n}. \end{aligned} \tag{64}$$

Then

$$A_\theta \text{ is } n\text{-cyclically monotone} \Leftrightarrow \mathbf{C}_n \text{ is positive semidefinite on } \mathbb{C}^n. \tag{65}$$

Note that the matrix $\mathbf{C}_n$ is a circulant Toeplitz matrix; e.g., by [26, Exercise 5.8.12], the set of eigenvalues of $\mathbf{C}_n$ is

$$\Lambda_n = \left\{p(1), p(\zeta), \ldots, p(\zeta^{n-1})\right\}, \quad \text{where} \quad p\colon t \mapsto (\omega + \overline{\omega}) - \omega t - \overline{\omega}t^{n-1}, \tag{66}$$

and where ζ is an arbitrary nth root of unity. It will be convenient to work with

$$\zeta_n = \exp(-2\pi\mathrm{i}/n). \tag{67}$$

Then

$$\begin{aligned} \left(\forall k \in \{0, 1, \ldots, n-1\}\right) \quad p(\zeta_n^k) &= \omega + \overline{\omega} - \omega\zeta_n^k - \overline{\omega}(\zeta_n^k)^{n-1} \\ &= \omega + \overline{\omega} - \omega\zeta_n^k - \overline{\omega}(\zeta_n^{n-1})^k \\ &= \omega + \overline{\omega} - \omega\zeta_n^k - \overline{\omega}(\overline{\zeta_n})^k \\ &= \omega + \overline{\omega} - (\omega\zeta_n^k + \overline{\omega\zeta_n^k}) \\ &= 2\big(\cos(\theta) - \cos(2k\pi/n - \theta)\big). \end{aligned} \tag{68}$$

"$\Leftarrow$": Assume that $\theta \in [0, \pi/n]$. If $k \in \{1, 2, \ldots, n-1\}$, then $\theta \leq 2k\pi/n - \theta < 2\pi - \theta$ and (68) implies that $p(\zeta_n^k) \geq 0$. On the other hand, $p(1) = 0$. Altogether, every eigenvalue in Λ_n is nonnegative and the Hermitian matrix $\mathbf{C}_n$ is thus positive semidefinite. Therefore, by (65), A_θ is n-cyclically monotone.

"$\Rightarrow$": Assume that $\theta \in]\pi/(n+1), \pi/n]$. It suffices to show that A_θ is not $(n+1)$-cyclically monotone. Now (68) implies that $p(\zeta_{n+1}) = 2\big(\cos(\theta) - \cos(2\pi/(n+1) - \theta)\big) < 0$ since $0 < 2\pi/(n+1) - \theta < \theta$. In view of (66) and (65), we deduce that Λ_{n+1} contains a strictly negative eigenvalue, i.e., the matrix $\mathbf{C}_{n+1}$ is not positive semidefinite, and therefore A_θ is not $(n+1)$-cyclically monotone. ∎

Remark 7.2. The symmetric part of every continuous linear monotone operator is a subdifferential and hence cyclically monotone. Hence, higher-order n-cyclic monotonicity properties are not captured in the symmetric part. In other words, the analogue of Proposition 1.2 for n-cyclically monotone operators, where $n \in \{3, 4, \ldots\}$, is false: $A_{\pi/2}$ is not 3-cyclically monotone (by Proposition 7.1), yet its symmetric part $\big(A_{\pi/2}\big)_+ = 0$ is cyclically monotone.

PROPOSITION 7.3. *Let $n \in \{2, 3, \ldots\}$ and suppose that $\theta \in]\pi/(n+1), \pi/n]$. Then $F_{A_\theta, n+1} \equiv +\infty$.*

Proof. We shall utilize the following result on tridiagonal Toeplitz matrices; see [26, Example 7.2.5]:

> If $\alpha \in \mathbb{C} \smallsetminus \{0\}$, $\beta \in \mathbb{C}$, and $\gamma \in \mathbb{C} \smallsetminus \{0\}$, then the eigenvalues and the eigenvectors of the $n \times n$ matrix
>
> $$\begin{pmatrix} \beta & \alpha & 0 & \cdots & 0 \\ \gamma & \beta & \alpha & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & 0 \\ \vdots & \ddots & \gamma & \beta & \alpha \\ 0 & \cdots & 0 & \gamma & \beta \end{pmatrix} \tag{69}$$
>
> are given by
>
> $$\lambda_k = \beta + 2\alpha\rho\cos\big(k\pi/(n+1)\big) \text{ and } \mathbf{x}_k = \begin{pmatrix} \rho\sin\big(k\pi/(n+1)\big) \\ \rho^2\sin\big(2k\pi/(n+1)\big) \\ \rho^3\sin\big(3k\pi/(n+1)\big) \\ \vdots \\ \rho^n\sin\big(nk\pi/(n+1)\big) \end{pmatrix}, \tag{70}$$
>
> respectively, where
>
> $$k \in \{1, 2, \ldots, n\} \quad \text{and} \quad \rho = \sqrt{\gamma/\alpha}. \tag{71}$$

We identify $\mathbb{R}^2$ with $\mathbb{C}$ as in the proof of Proposition 7.1, where we set $\omega = \exp(\mathrm{i}\theta)$. By (50), for an arbitrary $(x, u) \in \mathbb{R}^2 \times \mathbb{R}^2$, we have

$$\begin{aligned} F_{A_\theta, n+1}(x, u) &= \sup_{a_1, \ldots, a_n} \Big(\sum_{i=1}^{n-1} \langle a_{i+1} - a_i, A_\theta a_i \rangle \Big) + \langle x - a_n, A_\theta a_n \rangle + \langle a_1 - x, u \rangle + \langle x, u \rangle \\ &= \sup_{a_1, \ldots, a_n} \operatorname{Re}\Big(\Big(\sum_{i=1}^{n-1} \overline{(a_{i+1} - a_i)}\omega a_i \Big) + \overline{(-a_n)}\omega a_n + \overline{x}\omega a_n + \overline{a_1}u \Big) \qquad (72) \\ &= \sup_{\mathbf{a} \in \mathbb{C}^n} \tfrac{1}{2}\big(\mathbf{a}^*\mathbf{H}\mathbf{a} + (\overline{x}\omega a_n + x\overline{\omega a_n}) + (\overline{a_1}u + a_1\overline{u})\big), \end{aligned}$$

where $\mathbf{a} = (a_1, \ldots, a_n)^T \in \mathbb{C}^n$ and

$$\mathbf{H} = \begin{pmatrix} -(\omega+\overline{\omega}) & \overline{\omega} & 0 & \cdots & 0 \\ \omega & -(\omega+\overline{\omega}) & \overline{\omega} & 0 & \vdots \\ 0 & \ddots & \ddots & \ddots & \\ \vdots & & \omega & -(\omega+\overline{\omega}) & \overline{\omega} \\ 0 & \cdots & 0 & \omega & -(\omega+\overline{\omega}) \end{pmatrix} \in \mathbb{C}^{n\times n}. \tag{73}$$

By (70), the n eigenvalues of the Hermitian matrix $\mathbf{H}$ are given by

$$\begin{aligned} \big(\forall k \in \{1,\ldots,n\}\big) \quad \lambda_k &= -(\omega+\overline{\omega}) + 2\,\overline{\omega}\sqrt{\omega/\overline{\omega}}\cos\big(k\pi/(n+1)\big) \\ &= 2\big(\cos\big(k\pi/(n+1)\big) - \cos(\theta)\big). \end{aligned} \tag{74}$$

Since $0 < \pi/(n+1) < \theta \leq \pi/2$, we deduce that

$$\lambda_1 = 2\big(\cos(\pi/(n+1)) - \cos(\theta)\big) > 0. \tag{75}$$

Furthermore, since $\mathbf{H}$ is Hermitian, it can be unitarily diagonalized. There exists a unitary matrix $\mathbf{U} \in \mathbb{C}^{n\times n}$ such that $\mathbf{U}^*\mathbf{H}\mathbf{U} = \mathbf{D}$ is a diagonal matrix, with eigenvalues $\lambda_1, \ldots, \lambda_n$ on its diagonal. On one hand, changing variables via $\mathbf{a} = \mathbf{U}\mathbf{y}$, where $\mathbf{y} = (y_1, \ldots, y_n)^T \in \mathbb{C}^n$, we have

$$\mathbf{a}^*\mathbf{H}\mathbf{a} = \lambda_1|y_1|^2 + \cdots + \lambda_n|y_n|^2. \tag{76}$$

Note that if $\mathbf{y} = \tau(1, 0, \ldots, 0)^T$, then $\mathbf{a}^*\mathbf{H}\mathbf{a} = \lambda_1\tau^2$ is a convex quadratic in τ. On the other hand,

$$(\overline{x}\omega a_n + x\overline{\omega a_n}) + (\overline{a_1}x^* + a_1\overline{x^*}) \tag{77}$$

is $\mathbb{R}$-linear in $\mathbf{a}$, in $\mathbf{y}$, and in τ. Altogether, the supremum in (72) is equal to $+\infty$. This completes the proof. □

PROPOSITION 7.4. *Let $n \in \{2, 3, \ldots\}$ and suppose that $\theta = \pi/n$. Then $F_{A_\theta,n} = \iota_{\operatorname{gra} A_\theta} + \langle\cdot,\cdot\rangle$.*

Proof. Fix $(x, u) \in X \times X$. If $u = A_\theta x$, then $F_{A_\theta,n}(x, u) = \langle x, u\rangle$ by Fact 6.3. Thus assume that $u \neq A_\theta x$. Arguing as in the proof of Proposition 7.3, we see that

$$F_{A_\theta,n}(x,u) = \sup_{\mathbf{a}\in\mathbb{C}^{n-1}} \tfrac{1}{2}\big(\mathbf{a}^*\mathbf{H}\mathbf{a} + (\overline{x}\omega a_{n-1} + x\overline{\omega a_{n-1}}) + (\overline{a_1}u + a_1\overline{u})\big), \tag{78}$$

where $\omega = \exp(\mathrm{i}\theta) = \exp(\pi\mathrm{i}/n)$, $\mathbf{a} = (a_1, \ldots, a_{n-1})^T \in \mathbb{C}^{n-1}$, and

$$\mathbf{H} = \begin{pmatrix} -(\omega+\overline{\omega}) & \overline{\omega} & 0 & \cdots & 0 \\ \omega & -(\omega+\overline{\omega}) & \overline{\omega} & 0 & \vdots \\ 0 & \ddots & \ddots & \ddots & \\ \vdots & & \omega & -(\omega+\overline{\omega}) & \overline{\omega} \\ 0 & \cdots & 0 & \omega & -(\omega+\overline{\omega}) \end{pmatrix} \in \mathbb{C}^{(n-1)\times(n-1)}, \tag{79}$$

and where the eigenvalues $\mu_1, \ldots, \mu_{n-1}$ are given by (this is the counterpart of (74))

$$\big(\forall k \in \{1,\ldots,n-1\}\big) \quad \mu_k = 2\big(\cos(k\pi/n) - \cos(\theta)\big) \leq 0. \tag{80}$$

Note that $\mu_1 = 0$ and that, by (70),

$$\mathbf{b} = \begin{pmatrix} b_1 \\ b_2 \\ \vdots \\ b_{n-1} \end{pmatrix} = \begin{pmatrix} \exp(\pi\mathrm{i}/n)\sin(\pi/n) \\ \exp(2\pi\mathrm{i}/n)\sin(2\pi/n) \\ \vdots \\ \exp((n-1)\pi\mathrm{i}/n)\sin((n-1)\pi/n) \end{pmatrix} \tag{81}$$

is a corresponding eigenvector. Then $\mathbf{H}\mathbf{b} = \mathbf{0} \in \mathbb{C}^{n-1}$. Using $z\mathbf{b}$, where $z \in \mathbb{C}$, rather than the general vector $\mathbf{a}$ in (78), we estimate

(82)

$$\begin{aligned} &F_{A_\theta,n}(x,u) \\ &\geq \sup_{z\in\mathbb{C}} \operatorname{Re}\left(\overline{x}\omega z b_{n-1} + \overline{zb_1}u\right) \\ &= \sup_{z\in\mathbb{C}} \operatorname{Re}\left(\overline{x}\exp(\pi\mathrm{i}/n) z \exp((n-1)\pi\mathrm{i}/n)\sin((n-1)\pi/n) + \overline{z}\exp(-\pi\mathrm{i}/n)\sin(\pi/n)u\right) \\ &= \sin(\pi/n)\sup_{z\in\mathbb{C}} \operatorname{Re}\left(\overline{z}(u\exp(-\pi\mathrm{i}/n) - x)\right). \end{aligned}$$

Because $u \neq A_\theta x$, i.e., $u \neq \exp(\pi\mathrm{i}/n)x$ viewed in $\mathbb{C}$, we see that $u\exp(-\pi\mathrm{i}/n) - x \neq 0$. Thus, the last supremum is equal to $+\infty$. ∎

The following example will be utilized in Proposition 7.6.

Example 7.5. Suppose that $\theta \in [0, \pi/2[$. Then

$$F_{A_\theta,2}\colon \mathbb{R}^2 \times \mathbb{R}^2 \to \mathbb{R}\colon (x,u) \mapsto \frac{1}{4\cos\theta}\|u + A_\theta^* x\|^2. \tag{83}$$

Proof. The symmetric part of A_θ is equal to $\cos(\theta)\,\mathrm{Id}$ and hence invertible. The result follows by combining Theorem 2.3(i) and Fact 2.2(vi). ∎

PROPOSITION 7.6. *Let $n \in \{2,3,\dots\}$ and suppose that $\theta \in]0, \pi/n[$. Then*

(84)

$$F_{A_\theta,n}\colon \mathbb{R}^2 \times \mathbb{R}^2 \to \mathbb{R}$$

$$(x,u) \mapsto \frac{\sin(n-1)\theta}{2\sin n\theta}\left(\|x\|^2 + \|u\|^2\right) + \frac{\sin\theta}{\sin n\theta}\langle x, A_\theta^{n-1}u\rangle \tag{85}$$

$$= \frac{\sin\theta}{2\sin n\theta}\left(\left(\frac{\sin(n-1)\theta}{\sin\theta} - 1\right)\left(\|x\|^2 + \|A_\theta^{n-1}u\|^2\right) + \|x + A_\theta^{n-1}u\|^2\right). \tag{86}$$

Proof. Observe that (86) is a direct consequence of (85). It suffices to verify (84)–(85), and we do this by induction on n. Fix $(x,u) \in \mathbb{R}^2 \times \mathbb{R}^2$. Consider the case when $n = 2$. Using Example 7.5 and the trigonometric identity $(\sin\theta)/(\sin 2\theta) = 1/(2\cos\theta)$, we obtain

$$F_{A_\theta,2}(x,u) = \frac{1}{4\cos\theta}\|u + A_\theta^* x\|^2 = \frac{\sin\theta}{2\sin 2\theta}\left(\|x\|^2 + \|u\|^2 + 2\langle u, A_\theta^* x\rangle\right), \tag{87}$$

which yields (85). We now assume that (85) holds for some $n \in \{2,3,\dots\}$, and we shall show that it also holds for $n+1$, provided that $\theta \in]0, \pi/(n+1)[$. Utilizing

Theorem 6.5 and trigonometric identities, we obtain

(88)
$$\begin{aligned}
&F_{A_\theta,n+1}(x,u)\\
&=\sup_{y\in X} F_{A_\theta,n}(y,u)+\langle x-y, A_\theta y\rangle\\
&=\sup_{y\in X} \frac{\sin(n-1)\theta}{2\sin n\theta}\big(\|y\|^2+\|u\|^2\big)+\frac{\sin\theta}{\sin n\theta}\langle y, A_\theta^{n-1}u\rangle+\langle A_\theta^* x, y\rangle-\langle y, A_\theta y\rangle\\
&=\sup_{y\in X} \Big(\frac{\sin(n-1)\theta}{2\sin n\theta}-\cos\theta\Big)\|y\|^2+\frac{\sin(n-1)\theta}{2\sin n\theta}\|u\|^2+\frac{\sin\theta}{\sin n\theta}\langle y, A_\theta^{n-1}u\rangle+\langle A_\theta^* x, y\rangle
\end{aligned}$$

(89)
$$=\sup_{y\in X} \frac{-\sin(n+1)\theta}{2\sin n\theta}\|y\|^2+\frac{\sin(n-1)\theta}{2\sin n\theta}\|u\|^2+\frac{\sin\theta}{\sin n\theta}\langle y, A_\theta^{n-1}u\rangle+\langle A_\theta^* x, y\rangle.$$

Since $\theta\in\left]0,\pi/(n+1)\right[$, the coefficient of $\|y\|^2$ is strictly negative, which shows that the quadratic function of y of which we take the supremum in (89) is strictly concave. Setting the derivative of this quadratic function equal to 0, we find that the unique maximizer in (89) is

$$\frac{\sin n\theta}{\sin(n+1)\theta}\Big(\frac{\sin\theta}{\sin n\theta}A_\theta^{n-1}u+A_\theta^* x\Big). \tag{90}$$

Combining this with (88) and (89), followed by simplification and utilization of trigonometric identities, we deduce that

$$F_{A_\theta,n+1}(x,u)=\frac{\sin n\theta}{2\sin(n+1)\theta}\big(\|x\|^2+\|u\|^2\big)+\frac{\sin\theta}{\sin(n+1)\theta}\langle x, A_\theta^n u\rangle, \tag{91}$$

and this completes the proof. □

Remark 7.7. Consider the setting of Proposition 7.6. Since $n\in\{2,3,\dots\}$ and since $\theta\in\left]0,\pi/n\right[$, we have $\theta\leq(n-1)\theta<\pi-\theta$ and thus $\sin(n-1)\theta\geq\sin\theta$. While it is clear from the definition that $F_{A_\theta,n}$ is convex (see (50)), we see this also directly from (86).

We have obtained complete knowledge of all Fitzpatrick functions. Let us summarize our findings.

THEOREM 7.8. *Let $\theta\in[0,\pi/2]$ and let A_θ be the rotator by θ in the Euclidean plane, i.e.,*

$$A_\theta=\begin{pmatrix}\cos\theta & -\sin\theta\\ \sin\theta & \cos\theta\end{pmatrix}. \tag{92}$$

(i) Case $\theta=0$. *Then $A_\theta=\mathrm{Id}=\nabla\frac{1}{2}\|\cdot\|^2$ is cyclically monotone, $F_{\mathrm{Id},\infty}=\frac{1}{2}\|\cdot\|^2\oplus\frac{1}{2}\|\cdot\|^2$, and*
(93)
$$\big(\forall n\in\{2,3,\dots\}\big)\quad F_{\mathrm{Id},n}\colon\mathbb{R}^2\times\mathbb{R}^2\to\mathbb{R}\colon(x,u)\mapsto\frac{n-1}{2n}\big(\|x\|^2+\|u\|^2\big)+\frac{1}{n}\langle x,u\rangle.$$

(ii) Case $\theta\in\left]0,\pi/2\right]$. *If $n\in\{2,3,\dots\}\cap[2,\pi/\theta[$, then A_θ is n-cyclically monotone and*
(94)
$$F_{A_\theta,n}\colon\mathbb{R}^2\times\mathbb{R}^2\to\mathbb{R}\colon(x,u)\mapsto\frac{\sin(n-1)\theta}{2\sin n\theta}\big(\|x\|^2+\|u\|^2\big)+\frac{\sin\theta}{\sin n\theta}\langle x, A_\theta^{n-1}u\rangle.$$

If π/θ is an integer, then A_θ is (π/θ)-cyclically monotone and

$$F_{A_\theta,\pi/\theta} = \iota_{\operatorname{gra} A_\theta} + \langle \cdot, \cdot \rangle. \tag{95}$$

If $n \in \{2, 3, \dots\} \cap]\pi/\theta, +\infty[$, then A_θ is not n-cyclically monotone and

$$F_{A_\theta,n} \equiv +\infty. \tag{96}$$

Proof. (i) This follows from Example 6.4 with $A = \mathrm{Id}$. (ii) is a direct consequence of Propositions 7.1, 7.3, 7.4, and 7.6. □

Remark 7.9. Theorem 7.8 greatly expands the knowledge about rotators and their Fitzpatrick functions. In previous work [2], only rotators by 0 or by π/n, where $n \in \{2, 3, \dots\}$, were considered. In that restricted setting, item (i) of Theorem 7.8 was known [2, Example 4.4]. It was also known that $A_{\pi/n}$ is n-cyclically monotone but not $(n+1)$-cyclically monotone [2, Example 4.6]. The formula (95) was known only for $\theta = \pi/2$ [2, Example 4.5], and formula (96) was known only for $n \in \{2, 3, 4\}$ [2, Remark 4.7].

Acknowledgment. The authors wish to thank Sedi Bartz, Simeon Reich, and two anonymous referees for their pertinent comments which led to considerable improvements over the original version of this manuscript.

DIRECTIONAL REGULARITY AND METRIC REGULARITY*

ARAM V. ARUTYUNOV†, EVGENIY R. AVAKOV‡, AND ALEXEY F. IZMAILOV§

Abstract. For general constraint systems in Banach spaces, we present the directional stability theorem based on the appropriate generalization of the directional regularity condition, suggested earlier in [A. V. Arutyunov and A. F. Izmailov, *Math. Oper. Res.*, 31 (2006), pp. 526–543]. This theorem contains Robinson's stability theorem but does not reduce to it. Furthermore, we develop the related concept of directional metric regularity which is stable subject to small Lipschitzian perturbations of the constraint mapping, and which is equivalent to directional regularity for sufficiently smooth mappings. Finally, we discuss some applications in sensitivity theory.

Key words. metric regularity, Robinson's constraint qualification, directional regularity, directional metric regularity, feasible arc, sensitivity

DOI. 10.1137/060651616

1. Introduction. Directional regularity. Let Σ be a topological space, X and Y be Banach spaces, and Q be a fixed closed set in Y. Consider a smooth mapping $F : \Sigma \times X \to Y$ (our smoothness hypotheses will be specified below), and set

$$D(\sigma) = \{x \in X \mid F(\sigma, x) \in Q\} \tag{1.1}$$

with $\sigma \in \Sigma$ playing the role of a parameter. For a given (base) parameter value $\sigma_0 \in \Sigma$, fix $x_0 \in D(\sigma_0)$. In this paper we are concerned with the following question: For which $(\sigma, x) \in \Sigma \times X$ close to (σ_0, x_0), and under which assumptions can $\operatorname{dist}(x, D(\sigma))$ be estimated from above via the "residual" of constraints in (1.1), that is, via $\operatorname{dist}(F(\sigma, x), Q)$? Here $\operatorname{dist}(z, S) = \inf_{s \in S} \|z - s\|$ stands for the distance from a point z to a set S.

The answer to this question is well known provided Q is convex and the so-called Robinson's constraint qualification (CQ) is satisfied at x_0 for the mapping $F(\sigma_0, \cdot)$, that is,

$$0 \in \operatorname{int}\left(F(\sigma_0, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0, x_0) - Q\right), \tag{1.2}$$

where $\operatorname{int} S$ is the interior of a set S, and $\operatorname{im}\Lambda$ is the range (image space) of a linear operator Λ. According to Robinson's stability theorem [21] (see also [3, Theorem 2.87]),

under these assumptions there exists a constant $c > 0$ such that the estimate

$$\operatorname{dist}(x, D(\sigma)) \le c \operatorname{dist}(F(\sigma, x), Q) \tag{1.3}$$

holds *for all* $(\sigma, x) \in \Sigma \times X$ close enough to (σ_0, x_0).

In its turn, estimate (1.3) serves as a motivation for the very important concept of metric regularity. Apparently, the term "metric regularity" appeared for the first time in [4], but the concept dates back to earlier works [14, 20, 10] (or even to classical works [15, 12]; see also [6, 5, 19]), and it finds multiple applications in modern variational analysis. Specifically, the mapping $F : X \to Y$ is said to be metrically regular at $x_0 \in F^{-1}(Q)$ with respect to Q if there exists a constant $c > 0$ such that the estimate

$$\operatorname{dist}(x, F^{-1}(Q + y)) \le c \operatorname{dist}(F(x) - y, Q) \tag{1.4}$$

holds for all $(x, y) \in X \times Y$ close enough to $(x_0, 0)$. Note that (1.4) is nothing else but the estimate (1.3) for $F(\sigma, x) = F(x) - \sigma$ and $\sigma = y$, i.e., for the special parametrization of the mapping F in question (the "right-hand side" perturbations). Thus, by Robinson's stability theorem, if Q is convex, then Robinson's CQ

$$0 \in \operatorname{int}(F(x_0) + \operatorname{im} F'(x_0) - Q)$$

implies metric regularity of F at x_0 with respect to Q. Moreover, as is well known (see, e.g., [3, Proposition 2.89]), under the appropriate smoothness hypothesis, the converse implication is true as well, and thus, metric regularity and Robinson's CQ are actually equivalent.

For more recent developments and extensions of the metric regularity theory, see, e.g., [17, 22, 13, 18, 16] and references therein.

In particular, if Robinson's CQ does not hold, one cannot expect a smooth mapping to be metrically regular. Accordingly, for a parametric mapping F, estimate (1.3) for all (σ, x) close enough to (σ_0, x_0) cannot be guaranteed if (1.2) does not hold. However, we demonstrate below that under the regularity condition weaker than (1.2), estimate (1.3) is still valid but possibly not *for all* (σ, x) in a neighborhood of (σ_0, x_0); the set of appropriate (σ, x) will be specified. To this end, we give the following definition.

DEFINITION 1.1. *The mapping* $F(\sigma_0, \cdot) : X \to Y$ *is* regular at $x_0 \in D(\sigma_0)$ in a direction $\bar{y} \in Y$ *if*

$$0 \in \operatorname{int}\left(F(\sigma_0, x_0) + \operatorname{im} \frac{\partial F}{\partial x}(\sigma_0, x_0) - \operatorname{cone}\{\bar{y}\} - Q\right), \tag{1.5}$$

where $\operatorname{cone} S$ *stands for the conic hull of a set* S.

Note that for $\bar{y} = 0$, condition (1.5) reduces to Robinson's CQ (1.2). Moreover, if the latter is satisfied, the directional regularity condition (1.5) holds in any direction $\bar{y} \in Y$, including $\bar{y} = 0$.

Condition (1.5) and the corresponding directional stability result were first suggested in [1] for the case of finite-dimensional Y. However, the estimate obtained in [1, Theorem 4.1] is somewhat weaker than (1.3). This is a consequence of the general framework adopted in [1]. Specifically, the authors first consider the case of equality constraints and direct set constraints with a closed convex set P and prove the directional stability theorem with the estimate to the solution set only from points in P. Then they reduce (1.1) to this setting. On the other hand, the proof of the

directional stability theorem in [1] is very concise and clear, and, in particular, it does not appeal to any set-valued analysis. At the same time, the assumption $\dim Y < \infty$ cannot be dropped in that proof (and hence, in all the results obtained in [1]) because the argument there employs (the completely finite-dimensional) Brouwer's fixed point theorem. (We note, however, that in [1, Theorem 4.1], X can actually be just a normed linear space, not necessarily complete.)

In section 2, we prove the directional stability theorem (Theorem 2.3) under the same set of assumptions as in [1], but with the resulting estimate of the "proper" form (1.3), and for a (possibly infinite-dimensional) Banach space Y. In particular, Theorem 2.3 contains Robinson's stability theorem but does not reduce to it, in general.

Furthermore, in section 3, for a nonparametric mapping, we develop the directional metric regularity concept suggested by Theorem 2.3. In Theorem 3.2 we demonstrate that this property is stable subject to small Lipschitzian perturbations of F. This result combined with Theorem 2.3 implies the equivalence of directional regularity and directional metric regularity for sufficiently smooth mappings.

Finally, in section 4, we demonstrate that Theorem 2.3 can be used in order to directly obtain various stability results widely used in sensitivity analysis [3]. Specifically, assuming that Σ is a normed linear space, we consider the case when for a given direction $d \in \Sigma$ it holds that

$$0 \in \operatorname{int}\left(F(\sigma_0,\, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) + \operatorname{cone}\left\{\frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d\right\} - Q\right). \tag{1.6}$$

Note that (1.6) is a particular case of (1.5) for $\bar{y} = -\frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d$. On the other hand, (1.5) can be interpreted as (1.6) with F replaced by $\widetilde{F}(\sigma,\, y,\, x) = F(\sigma,\, x) - y$, where $y \in Y$ is regarded as an additional parameter, and with $d = (0,\, \bar{y}) \in \Sigma \times Y$.

In the context of mathematical programming problems, (1.6) is known as Gollan's condition [11]. It was extended to the general case in [2] (see also [3, Theorem 4.9]). Moreover, in parametric optimization, *this* condition (which is a particular case of (1.5)) is commonly known as the directional regularity condition. Taking into account the relations between the two conditions discussed above, the authors prefer to use the same name for the property stated in Definition 1.1. Note, however, that unlike (1.6), (1.5) does not depend on a specific parametrization at all: it is entirely a property of the unperturbed constraints. This makes our directional regularity particularly useful for unification of some diverse developments, like those based on Robinson's CQ and on customary directional regularity (1.6).

2. Directional stability theorem. In what follows, we shall need some equivalent formulations of the directional regularity condition introduced in Definition 1.1.

PROPOSITION 2.1. *Let Q be closed and convex.*

Then condition (1.5) *is equivalent to each of the following three conditions:*

$$\operatorname{cone}\{\bar{y}\} \cap \operatorname{int}\left(F(\sigma_0,\, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - Q\right) \neq \emptyset, \tag{2.1}$$

$$\bar{y} \in \operatorname{int}\left(\operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - R_Q(F(\sigma_0,\, x_0))\right), \tag{2.2}$$

and

$$\operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - \operatorname{cone}\{\bar{y}\} - R_Q(F(\sigma_0,\, x_0)) = Y, \tag{2.3}$$

where $R_S(z) = \operatorname{cone}(S - z)$ *stands for the radial cone to a set* S *at a point* $z \in S$.

Note that condition (2.1) can be expressed in the following form: there exists $\theta \geq 0$ such that

$$\theta\bar{y} \in \operatorname{int}\left(F(\sigma_0,\, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - Q\right). \tag{2.4}$$

Proof. (1.5) $\Rightarrow$ (2.1). The proof of this implication is almost identical to that of the corresponding assertion in [3, Theorem 4.9] (see the argument showing that (4.12) implies (4.13)). Define the multifunction $\Psi : X \times \mathbf{R} \to 2^Y$:

$$\Psi(x,\, \theta) = \begin{cases} F(\sigma_0,\, x_0) + \frac{\partial F}{\partial x}(\sigma_0,\, x_0)x - \theta\bar{y} - Q & \text{if } \theta \geq 0, \\ \emptyset & \text{if } \theta = 0. \end{cases} \tag{2.5}$$

Evidently, Ψ is a closed convex multifunction (that is, $\operatorname{graph}\Psi$ is a closed convex set; see, e.g., [3, p. 55]), and

$$\Psi(X \times \mathbf{R}) = F(\sigma_0,\, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - \operatorname{cone}\{\bar{y}\} - Q,$$

and thus, (1.5) means that $0 \in \operatorname{int}\Psi(X \times \mathbf{R})$. Furthermore, $0 \in \Psi(0,\, 0)$, and hence, by the generalized open mapping theorem [3, Theorem 2.70] and by (2.5), $0 \in \operatorname{int}\Psi(X \times [0,\, 1])$. This means that there exists $\delta > 0$ such that

$$\begin{aligned} B_\delta(0) &\subset \Psi(X \times [0,\, 1]) \\ &= F(\sigma_0,\, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - \{\theta\bar{y} \mid \theta \in [0,\, 1]\} - Q, \end{aligned} \tag{2.6}$$

where $B_\delta(z)$ stands for the ball centered at z and of radius δ.

Fix $\tilde{\delta} > 0$ small enough so that $\tilde{\delta}\bar{y} \in B_\delta(0)$. Then inclusion (2.6) implies that there exists $\tilde{\theta} \in [0,\, 1]$ such that

$$\tilde{\delta}\bar{y} \in F(\sigma_0,\, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - \tilde{\theta}\bar{y} - Q,$$

and hence,

$$(\tilde{\delta} + \tilde{\theta})\bar{y} \in F(\sigma_0,\, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - Q.$$

The set in the right-hand side of the latter inclusion is convex and contains 0, and thus

$$\{(\tilde{\delta} + \tilde{\theta})\theta\bar{y} \mid \theta \in [0,\, 1]\} \subset F(\sigma_0,\, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - Q.$$

Then inclusion (2.6) implies that

$$\begin{aligned} B_\delta(0) &\subset F(\sigma_0,\, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - \bar{y} + \{\theta\bar{y} \mid \theta \in [0,\, 1]\} - Q \\ &\subset (1 + 1/(\tilde{\delta} + \tilde{\theta}))\left(F(\sigma_0,\, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - Q\right) - \bar{y}. \end{aligned}$$

It follows that

$$\begin{aligned} B_{\delta\theta}(\theta\bar{y}) &= \theta\bar{y} + B_{\delta\theta}(0) \\ &\subset F(\sigma_0,\, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0,\, x_0) - Q \end{aligned}$$

holds with $\theta = (1 + 1/(\tilde{\delta} + \tilde{\theta}))^{-1} > 0$, and (2.4) (and hence (2.1)) is thus proved.

(2.1) $\Rightarrow$ (2.2). Since $Q - F(\sigma_0, x_0) \subset R_Q(F(\sigma_0, x_0))$, condition (2.1) clearly implies that

$$\operatorname{int}\left(\operatorname{im}\frac{\partial F}{\partial x}(\sigma_0, x_0) - R_Q(F(\sigma_0, x_0))\right) \neq \emptyset.$$

Suppose that (2.2) does not hold. Then by the first separation theorem [3, Theorem 2.13], there exists $\mu \in Y^*$ such that

$$\langle \mu, \bar{y}\rangle \leq \langle \mu, \eta\rangle \quad \forall\, \eta \in \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0, x_0) - R_Q(F(\sigma_0, x_0)).$$

This evidently implies that

$$\langle \mu, \theta\bar{y}\rangle \leq 0 \leq \langle \mu, y\rangle \quad \forall\, \theta \geq 0,\ \forall\, y \in F(\sigma_0, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0, x_0) - Q,$$

where the inclusion $Q - F(\sigma_0, x_0) \subset R_Q(F(\sigma_0, x_0))$ was again taken into account. Hence, μ separates $\operatorname{cone}\{\bar{y}\}$ and $F(\sigma_0, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0, x_0) - Q$, and according to the first separation theorem [3, Theorem 2.13], this contradicts (2.1).

(2.2) $\Rightarrow$ (2.3). By (2.2), there exists $\delta > 0$ such that

$$\begin{aligned}\bar{y} + B_\delta(0) &= B_\delta(\bar{y})\\ &\subset \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0, x_0) - R_Q(F(\sigma_0, x_0)),\end{aligned}$$

and hence

$$\begin{aligned}B_\delta(0) &\subset \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0, x_0) - \bar{y} - R_Q(F(\sigma_0, x_0))\\ &\subset \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0, x_0) - \operatorname{cone}\{\bar{y}\} - R_Q(F(\sigma_0, x_0)).\end{aligned}$$

Thus,

$$0 \in \operatorname{int}\left(\operatorname{im}\frac{\partial F}{\partial x}(\sigma_0, x_0) - \operatorname{cone}\{\bar{y}\} - R_Q(F(\sigma_0, x_0))\right)$$

holds, which evidently implies (2.3).

(2.3) $\Rightarrow$ (1.5). The proof of this implication is almost identical to that of the corresponding assertion in [3, Proposition 2.95] (see the argument showing that (2.180) implies (2.178)). Define the multifunction $\Psi : X \times \mathbf{R} \times \mathbf{R} \to 2^Y$:

$$\Psi(x, \theta, \tau) = \begin{cases} \frac{\partial F}{\partial x}(\sigma_0, x_0)x - \theta\bar{y} - \tau(Q - F(\sigma_0, x_0)) & \text{if } \theta \geq 0,\ \tau \geq 0,\\ \emptyset & \text{otherwise.}\end{cases} \tag{2.7}$$

Evidently, Ψ is a closed convex multifunction, and

$$\Psi(X \times \mathbf{R} \times \mathbf{R}) = \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0, x_0) - \operatorname{cone}\{\bar{y}\} - R_Q(F(\sigma_0, x_0)),$$

and thus, (2.3) implies that $0 \in \operatorname{int}\Psi(X \times \mathbf{R} \times \mathbf{R})$. Furthermore, $0 \in \Psi(0, 0, 0)$, and hence, by the generalized open mapping theorem [3, Theorem 2.70] and by (2.7),

$$0 \in \operatorname{int}\Psi(X \times \mathbf{R}_+ \times [0, 1]). \tag{2.8}$$

On the other hand,

$$\begin{aligned}\Psi(X \times \mathbf{R}_+ \times [0,\,1]) &= \operatorname{im} \frac{\partial F}{\partial x}(\sigma_0,\,x_0) - \operatorname{cone}\{\bar y\} \\ &\quad -\{\tau(q - F(\sigma_0,\,x_0)) \mid \tau \in [0,\,1],\, q \in Q\} \\ &= F(\sigma_0,\,x_0) + \operatorname{im} \frac{\partial F}{\partial x}(\sigma_0,\,x_0) - \operatorname{cone}\{\bar y\} \\ &\quad -\{\tau q + (1-\tau)F(\sigma_0,\,x_0) \mid \tau \in [0,\,1],\, q \in Q\} \\ &\subset F(\sigma_0,\,x_0) + \operatorname{im} \frac{\partial F}{\partial x}(\sigma_0,\,x_0) - \operatorname{cone}\{\bar y\} - Q,\end{aligned}$$

where the convexity of Q was taken into account. It follows that (2.8) implies (1.5). □

We shall also need the following proposition.

PROPOSITION 2.2. *Let Q be convex, $y_0 \in Q$.*

Then for any $\bar y \in Y$ and any $\delta_1 > 0$, $\delta_2 > 0$ there exist $\varepsilon > 0$ and $\delta > 0$ such that

$$(Q - \operatorname{cone} B_\delta(\bar y)) \cap B_\varepsilon(y_0) \subset Q \cap B_{\delta_1}(y_0) - \operatorname{cone} B_{\delta_2}(\bar y). \tag{2.9}$$

Proof. First suppose that $\bar y \in T_Q(y_0)$, where $T_Q(y_0) = \operatorname{cl} R_Q(y_0)$ is the tangent cone to Q at y_0. We claim that in this case

$$y_0 \in \operatorname{int}(Q \cap B_{\delta_1}(y_0) - \operatorname{cone} B_{\delta_2}(\bar y)), \tag{2.10}$$

and hence, (2.9) evidently holds with an arbitrary $\delta > 0$ and a sufficiently small $\varepsilon > 0$.

Indeed, the interior of the set in the right-hand side of (2.10) is nonempty, and if (2.10) does not hold then by the first separation theorem [3, Theorem 2.13] there exists $\mu \in Y^*$ such that

$$\langle \mu,\, y\rangle \geq \langle \mu,\, y_0\rangle \quad \forall\, y \in Q \cap B_{\delta_1}(y_0) - \operatorname{cone} B_{\delta_2}(\bar y). \tag{2.11}$$

Then evidently

$$\langle \mu,\, \eta\rangle \geq 0 \quad \forall\, \eta \in T_Q(y_0). \tag{2.12}$$

On the other hand, for any $y \in B_{\delta_2}(0)$ such that $\langle \mu,\, y\rangle > 0$, from (2.11) we obtain

$$\begin{aligned}\langle \mu,\, y_0 - \bar y\rangle &> \langle \mu,\, y_0 - (\bar y + y)\rangle \\ &\geq \langle \mu,\, y_0\rangle,\end{aligned}$$

and thus $\langle \mu,\, \bar y\rangle < 0$ which contradicts (2.12) (recall that $\bar y \in T_Q(y_0)$).

Now let $\bar y \notin T_Q(y_0)$. Since $T_Q(y_0)$ is closed, by the second separation theorem [3, Theorem 2.14] we then obtain the existence of $\mu \in Y^*$ such that (2.12) holds and $\langle \mu,\, \bar y\rangle < 0$.

Consider arbitrary sequences $\{q^k\} \subset Q$, $\{\eta^k\} \subset Y$ and a sequence of real numbers $\{t_k\}$ such that $t_k \geq 0$ for all k and $\{q^k - t_k\eta^k\} \to y_0$. Hence

$$\langle \mu,\, q^k - y_0\rangle + t_k(-\langle \mu,\, \eta^k\rangle) = \langle \mu,\, q^k - t_k\eta^k - y_0\rangle \to 0.$$

Note that $q^k - y_0 \in R_Q(y_0) \subset T_Q(y_0)$, and (2.12) implies that the first term in the left-hand side is nonnegative for all k. Furthermore, inequality $\langle \mu,\, \bar y\rangle < 0$ implies that the second term in the left-hand side is nonnegative as well for all k large enough,

and hence, $t_k \to 0$. The latter implies that $\{q^k\} \to y_0$. Thus, $q^k - t_k\eta^k \in Q \cap B_{\delta_1}(y_0) - \operatorname{cone} B_{\delta_2}(\bar{y})$ for all k large enough. This proves the needed inclusion (2.9) with sufficiently small $\varepsilon > 0$ and $\delta > 0$. □

We are now ready to prove the main result of this section.

THEOREM 2.3. *Let Q be closed and convex, and let $x_0 \in D(\sigma_0)$. Let F be continuous at (σ_0, x_0) and Fréchet-differentiable with respect to x near (σ_0, x_0), and let its derivative with respect to x be continuous at (σ_0, x_0).*

If the mapping $F(\sigma_0, \cdot)$ is regular at x_0 in a direction $\bar{y} \in Y$, then there exist a neighborhood U of σ_0 and $\varepsilon > 0$, $\delta > 0$, and $c > 0$ such that the estimate (1.3) *holds for all $(\sigma, x) \in U \times B_\varepsilon(x_0)$ satisfying the inclusion*

$$F(\sigma, x) \in Q - \operatorname{cone} B_\delta(\bar{y}). \tag{2.13}$$

Proof. From the equivalent form (2.1) of the directional regularity condition it evidently follows that there exists $\bar{\eta} \in \operatorname{cone}\{\bar{y}\}$ such that

$$\bar{\eta} \in \operatorname{int}\left(F(\sigma_0, x_0) + \operatorname{im}\frac{\partial F}{\partial x}(\sigma_0, x_0) - Q\right). \tag{2.14}$$

Note that if $\bar{y} = 0$ then necessarily $\bar{\eta} = 0$.

Define the multifunction $\bar{\mathcal{F}} : X \to 2^Y$:

$$\bar{\mathcal{F}}(\xi) = F(\sigma_0, x_0) + \frac{\partial F}{\partial x}(\sigma_0, x_0)\xi - Q.$$

According to (2.14), there exists $\bar{\xi} \in X$ such that $\bar{\mathcal{F}}(\bar{\xi}) = \bar{\eta}$, and moreover, by the Robinson–Ursescu stability theorem [23, 20] (see also [3, Theorem 2.83]) it follows that the multifunction $\bar{\mathcal{F}}$ is metrically regular at $(\bar{\xi}, \bar{\eta})$.

Fix $\bar{\varepsilon} > 0$. For each mapping $G : X \to Y$, define the multifunction $\mathcal{F}_G : X \to 2^Y$,

$$\mathcal{F}_G(\xi) = F(\sigma_0, x_0) + G(\xi) - Q.$$

Note that $\mathcal{F}_{\frac{\partial F}{\partial x}(\sigma_0, x_0)} = \bar{\mathcal{F}}$, and hence, by [3, Theorem 2.84] it follows that there exist $\bar{l} > 0$, $\delta > 0$, and $\bar{c} > 0$ such that the estimate

$$\begin{aligned}\operatorname{dist}(\bar{\xi}, \mathcal{F}_G^{-1}(y)) \le \bar{c}\operatorname{dist}(G(\bar{\xi}) - y, Q - F(\sigma_0, x_0))\\ \forall\, y \in B_\delta\left(\bar{\eta} - \frac{\partial F}{\partial x}(\sigma_0, x_0)\bar{\xi} + G(\bar{\xi})\right)\end{aligned} \tag{2.15}$$

holds for each G such that the difference mapping $G(\cdot) - \frac{\partial F}{\partial x}(\sigma_0, x_0)$ is Lipschitz-continuous on $B_{\bar{\varepsilon}}(\bar{\xi})$ with modulus $l \in (0, \bar{l})$.

It can be easily seen that there exists $\tilde{\delta}_2 \in (0, \delta/4]$ possessing the following property: if $\eta \in \operatorname{cone} B_{\tilde{\delta}_2}(\bar{\eta}) \setminus \{0\}$ then $\|\|\bar{\eta}\|\eta/\|\eta\| - \bar{\eta}\| \le \delta/4$. Put

$$\gamma = \begin{cases} \|\bar{\eta}\| & \text{if } \bar{\eta} \ne 0, \\ \frac{\delta}{4} & \text{if } \bar{\eta} = 0. \end{cases} \tag{2.16}$$

Set $\delta_1 = \min\{\delta/16, \gamma/4\}$, $\delta_2 = \|\bar{y}\|\tilde{\delta}_2/\|\bar{\eta}\|$ if $\bar{\eta} \ne 0$ (so that $\operatorname{cone} B_{\delta_2}(\bar{y}) = \operatorname{cone} B_{\tilde{\delta}_2}(\bar{\eta})$; if $\bar{\eta} = 0$, $\delta_2 > 0$ can be taken arbitrarily). Fix $(\sigma, x) \in \Sigma \times X$ satisfying

$$F(\sigma, x) \in Q \cap B_{\delta_1}(F(\sigma_0, x_0)) - \operatorname{cone} B_{\delta_2}(\bar{y}) \tag{2.17}$$

and such that $F(\sigma, x) \notin Q$ (otherwise estimate (1.3) holds trivially). Then there exists $q = q(\sigma, x) \in Q \cap B_{\delta_1}(F(\sigma_0, x_0))$ such that

$$-(F(\sigma, x) - q) \in \operatorname{cone} B_{\tilde{\delta}_2}(\bar{\eta}),$$

and hence, according to (2.16) and to the choice of $\tilde{\delta}_2$, it holds that

$$\left\| \frac{\gamma}{\|F(\sigma, x) - q\|}(F(\sigma, x) - q) + \bar{\eta} \right\| \leq \frac{\delta}{4} \tag{2.18}$$

(note that $\|F(\sigma, x) - q\|$ cannot be equal to 0 since $F(\sigma, x) \notin Q$).

Set

$$t = t(\sigma, x, q) = \min\left\{ \frac{16 \operatorname{dist}(F(\sigma, x), Q)}{\delta}, \frac{\|F(\sigma, x) - q\|}{\gamma} \right\}. \tag{2.19}$$

Note that $t > 0$ but t tends to 0 as (σ, x) tends to (σ_0, x_0). Define the mapping $G : X \to Y$,

$$G(\xi) = G(\sigma, x; \xi) = \frac{1}{t}(F(\sigma, x + t\xi) - F(\sigma, x)), \tag{2.20}$$

and the difference mapping $\Phi : X \to Y$,

$$\begin{aligned} \Phi(\xi) &= \Phi(\sigma, x; \xi) \\ &= G(\xi) - \frac{\partial F}{\partial x}(\sigma_0, x_0)\xi \\ &= \frac{1}{t}\left(F(\sigma, x + t\xi) - F(\sigma, x) - \frac{\partial F}{\partial x}(\sigma_0, x_0)t\xi \right). \end{aligned} \tag{2.21}$$

By the mean value theorem we obtain that for (σ, x) close enough to (σ_0, x_0), and for each $\xi^1, \xi^2 \in X$,

$$\|\Phi(\xi^1) - \Phi(\xi^2)\| \leq \sup_{\theta \in [0, 1]} \left\| \frac{\partial F}{\partial x}(\sigma, x + t(\theta\xi^1 + (1 - \theta)\xi^2)) - \frac{\partial F}{\partial x}(\sigma_0, x_0) \right\| \|\xi^1 - \xi^2\|,$$

and hence, there exist a neighborhood U of σ_0 and $\varepsilon > 0$ such that Φ is Lipschitz-continuous on $B_{\bar{\varepsilon}}(\bar{\xi})$ with modulus $l \in (0, \bar{l})$ provided $(\sigma, x) \in U \times B_\varepsilon(x_0)$. Throughout the rest of the proof we suppose that the latter inclusion holds. Then by choosing another ("smaller") U and by reducing $\varepsilon > 0$ (if necessary), we obtain

$$\|\Phi(\bar{\xi})\| \leq \sup_{\theta \in [0, 1]} \left\| \frac{\partial F}{\partial x}(\sigma, x + t\theta\bar{\xi}) - \frac{\partial F}{\partial x}(\sigma_0, x_0) \right\| \|\bar{\xi}\| \leq \frac{\delta}{2}. \tag{2.22}$$

Set

$$\theta = \theta(\sigma, x, q) = \frac{2\|F(\sigma, x) - q\|}{\gamma}, \tag{2.23}$$

$$\tilde{y} = \tilde{y}(\sigma, x, q) = \theta F(\sigma_0, x_0) + (1 - \theta)q. \tag{2.24}$$

Note that, by the definition of δ_1, $\theta \in (0, 1]$ provided U and $\varepsilon > 0$ are chosen appropriately. Choose an element $p = p(\sigma, x) \in Q$ such that

$$\|F(\sigma, x) - p\| \leq 2 \operatorname{dist}(F(\sigma, x), Q), \tag{2.25}$$

and set

$$\tau = \tau(\sigma, x, q) = \frac{\gamma t}{\|F(\sigma, x) - q\|}, \tag{2.26}$$

$$y = y(\sigma, x, p, q) = -\frac{1}{t}(\tau(F(\sigma, x) - \tilde{y}) + (1 - \tau)(F(\sigma, x) - p)). \tag{2.27}$$

Note that $\tau \in (0, 1]$, and moreover, $\tau = 1$ provided

$$\|F(\sigma, x) - q\|/\gamma \le 16\,\mathrm{dist}(F(\sigma, x), Q)/\delta,$$

that is, when $t = \|F(\sigma, x) - q\|/\gamma$ (see (2.19)). Taking this into account, by (2.18), (2.19), (2.23)–(2.27), and the definition of δ_1, we derive that

$$\begin{aligned}
\|y - \bar{\eta}\| &= \left\| \frac{\tau}{t}(F(\sigma, x) - \tilde{y}) + \frac{1 - \tau}{t}(F(\sigma, x) - p) + \bar{\eta} \right\| \\
&\le \left\| \frac{\gamma}{\|F(\sigma, x) - q\|}(F(\sigma, x) - \tilde{y}) + \bar{\eta} \right\| + (1 - \tau)\frac{\|F(\sigma, x) - p\|}{t} \\
&\le \left\| \frac{\gamma}{\|F(\sigma, x) - q\|}(F(\sigma, x) - q) + \bar{\eta} \right\| \\
&\quad + \theta\frac{\gamma\|q - F(\sigma_0, x_0)\|}{\|F(\sigma, x) - q\|} + \frac{2\delta\,\mathrm{dist}(F(\sigma, x), Q)}{16\,\mathrm{dist}(F(\sigma, x), Q)} \\
&\le \frac{\delta}{4} + \frac{\delta}{8} + \frac{\delta}{8} \\
&= \frac{\delta}{2}.
\end{aligned}$$

Thus, by the second equality in (2.21), and by (2.22), it holds that

$$\begin{aligned}
\left\| y - \bar{\eta} + \frac{\partial F}{\partial x}(\sigma_0, x_0)\bar{\xi} - G(\bar{\xi}) \right\| &\le \|y - \bar{\eta}\| + \|\Phi(\bar{\xi})\| \\
&\le \frac{\delta}{2} + \frac{\delta}{2} \\
&\le \delta.
\end{aligned} \tag{2.28}$$

Hence, the estimate (2.15) must be valid for y defined in (2.27) and for G defined in (2.20) provided U and $\varepsilon > 0$ are chosen appropriately. This means that there exist $\xi = \xi(\sigma, x, p, q) \in X$ and $\eta = \eta(\sigma, x, p, q) \in Q$ such that

$$G(\xi) = y + \eta - F(\sigma_0, x_0) \tag{2.29}$$

and

$$\begin{aligned}
\|\xi\| &\le \|\bar{\xi}\| + \|\xi - \bar{\xi}\| \\
&\le \|\bar{\xi}\| + \bar{c}\,\mathrm{dist}(G(\bar{\xi}) - y, Q - F(\sigma_0, x_0)) \\
&\le \|\bar{\xi}\| + \bar{c}\|G(\bar{\xi}) - y\| \\
&\le \|\bar{\xi}\| + \bar{c}\left(\left\| \frac{\partial F}{\partial x}(\sigma_0, x_0)\bar{\xi} - \bar{\eta} \right\| + \delta \right),
\end{aligned} \tag{2.30}$$

where (2.28) and the inclusion $0 \in Q - F(\sigma_0, x_0)$ were taken into account. Note that the right-hand side of the last relation is a constant independent of σ, x, p, and q.

Employing (2.21), (2.24), (2.27), and (2.29), we have

$$\begin{aligned} F(\sigma, x + t\xi) &= t\Phi(\xi) + F(\sigma, x) + t\frac{\partial F}{\partial x}(\sigma_0, x_0)\xi \\ &= t\Phi(\xi) + t\frac{\partial F}{\partial x}(\sigma_0, x_0)\xi \\ &\quad + \tau(F(\sigma, x) - \tilde{y}) + \tau\tilde{y} + (1-\tau)(F(\sigma, x) - p) + (1-\tau)p \\ &= tG(\xi) - ty + \tau\tilde{y} + (1-\tau)p \\ &= t(\eta - F(\sigma_0, x_0)) + \tau\tilde{y} + (1-\tau)p \\ &= t\eta - tF(\sigma_0, x_0) + \tau\theta F(\sigma_0, x_0) + \tau(1-\theta)q + (1-\tau)p \\ &= t\eta + (\tau\theta - t)F(\sigma_0, x_0) + \tau(1-\theta)q + (1-\tau)p, \end{aligned}$$

where the right-hand side is a convex combination of η, $F(\sigma_0, x_0)$, p, and q provided U and $\varepsilon > 0$ are chosen appropriately. However, all the elements η, $F(\sigma_0, x_0)$, p, and q belong to the convex set Q. Hence,

$$F(\sigma, x + t\xi) \in Q,$$

and moreover, by (2.19) and (2.30),

$$t\|\xi\| \le c\,\mathrm{dist}(F(\sigma, x), Q),$$

where $c = 16(\|\bar{\xi}\| + \bar{c}(\|\frac{\partial F}{\partial x}(\sigma_0, x_0)\bar{\xi} - \bar{\eta}\| + \delta))/\delta$.

We thus proved that (1.3) holds for all $(\sigma, x) \in U \times B_\varepsilon(x_0)$ satisfying (2.17). In order to complete the proof it suffices to refer the reader to Proposition 2.2. □

3. Directional metric regularity. Let (X, ρ) be a complete metric space and Y be a normed linear space. As will be explained below, the following definition is motivated by Theorem 2.3.

DEFINITION 3.1. *The multifunction* $\Psi\colon X \to 2^Y$ *is* metrically regular at a point $(x_0, y_0) \in \mathrm{graph}\,\Psi$ in a direction $\bar{y} \in Y$, *at a rate* $c > 0$, *if there exist* $\varepsilon > 0$ *and* $\delta > 0$ *such that the estimate*

$$\mathrm{dist}(x, \Psi^{-1}(y)) \le c\,\mathrm{dist}(y, \Psi(x)) \tag{3.1}$$

holds for all $(x, y) \in B_\varepsilon(x_0) \times B_\varepsilon(y_0)$ *satisfying the inclusion*

$$y \in \Psi(x) + \mathrm{cone}\,B_\delta(\bar{y}). \tag{3.2}$$

Evidently, if $\bar{y} = 0$, then directional metric regularity turns into the usual metric regularity. Moreover, if the latter holds, directional metric regularity holds in any direction $\bar{y} \in Y$, including $\bar{y} = 0$. At the same time, directional metric regularity can hold when the usual metric regularity is violated; see Example 3.1 below.

Recall that the multifunction $\Psi : X \to 2^Y$ is said to be *lower* (or *inner*) *semicontinuous at a point* $(x_0, y_0) \in \mathrm{graph}\,\Psi$ if for any sequence $\{x^k\} \subset X$ convergent to x_0 there exists a sequence $\{y^k\} \subset Y$ convergent to y_0 such that $y^k \in \Psi(x^k)$ for all k (see, e.g., [16, Definition 1.63]).

The next theorem follows the pattern of [3, Theorem 2.84], [16, Theorem 4.25]; it says that the property of directional metric regularity of Ψ in a given direction $\bar{y}$ is

stable subject to small Lipschitzian single-valued perturbations of Ψ. For the usual notion of metric regularity, this property was studied, e.g., in [9, 7, 8]. Yet another reference to be mentioned in relation with this property is [6], where the importance of stability of regularity properties with respect to perturbations is already completely clear.

THEOREM 3.2. *Let $(x_0, y_0) \in \operatorname{graph}\Psi$. Assume that the multifunction Ψ is closed, lower semicontinuous at (x_0, y_0), and metrically regular at (x_0, y_0) in a direction $\bar{y} \in Y$, at a rate $c > 0$. Let $\varepsilon > 0$ and $\delta > 0$ be chosen according to Definition* 3.1*, and set*

$$\alpha = \begin{cases} \frac{\delta}{\|\bar{y}\|} & \text{if } \|\bar{y}\| \geq \delta, \\ +\infty & \text{if } \|\bar{y}\| < \delta, \end{cases} \qquad \beta(\alpha) = \begin{cases} \frac{2}{1+\alpha} & \text{if } \alpha < +\infty, \\ 0 & \text{if } \alpha = +\infty. \end{cases} \tag{3.3}$$

Then for any mapping $\Phi : X \to Y$ which is Lipschitz-continuous on $B_\varepsilon(x_0)$ with modulus $l > 0$ such that

$$c\,l < \min\{1,\, \alpha/5\}, \tag{3.4}$$

the multifunction $\Psi + \Phi$ is metrically regular at $(x_0, y_0 + \Phi(x_0))$ in the direction $\bar{y}$, at a rate $\tilde{c} = c(1 - c\,l)^{-1}(1 + \beta(\alpha))$.

In the case of usual metric regularity (i.e., when $\bar{y} = 0$), Theorem 3.2 directly reduces to [16, Theorem 4.25] but with an extraneous assumption of lower semicontinuity. It is possible that this assumption can actually be removed in Theorem 3.2, though the authors did not manage to avoid it.

Remark 3.1. As can be seen from the proof below, the assertion of Theorem 3.2 can be replaced by a somewhat stronger one: Under the assumptions of this theorem, for each $l > 0$ satisfying (3.4) there exist $\tilde{\varepsilon} > 0$ and $\tilde{\delta} > 0$ such that the estimate

$$\operatorname{dist}(x,\, (\Psi + \Phi)^{-1}(y)) \leq \tilde{c}\operatorname{dist}(y,\, \Psi(x) + \Phi(x)) \tag{3.5}$$

holds for any mapping $\Phi : X \to Y$ which is Lipschitz-continuous on $B_\varepsilon(x_0)$ with modulus l, and for all $(x, y) \in B_{\tilde{\varepsilon}}(x_0) \times B_{\tilde{\varepsilon}}(y_0 + \Phi(x_0))$ satisfying the inclusion

$$y \in \Psi(x) + \Phi(x) + \operatorname{cone} B_{\tilde{\delta}}(\bar{y}). \tag{3.6}$$

That is, $\tilde{\varepsilon}$ and $\tilde{\delta}$ do not depend on a specific Φ but only on ε, δ, c, $\|\bar{y}\|$, and l.

Proof. Let $\varepsilon > 0$ and $\delta > 0$ be chosen according to Definition 3.1. Fix arbitrary $\tilde{\varepsilon} \in (0,\, \varepsilon]$, $\tilde{\delta} \in (0,\, \delta)$, and $\hat{\varepsilon} > 0$ satisfying the following set of conditions:

$$\tilde{\varepsilon} + \frac{\gamma(\hat{\varepsilon})}{l}(1 - \gamma(\hat{\varepsilon}))^{-1}(1 + \beta(\alpha))(\tilde{\varepsilon} + l\tilde{\varepsilon} + \omega(\tilde{\varepsilon})) < \varepsilon, \tag{3.7}$$

$$\tilde{\varepsilon} + l\tilde{\varepsilon} + \left(\gamma(\hat{\varepsilon})(1 - \gamma(\hat{\varepsilon}))^{-1}(1 + \beta(\alpha)) + \frac{\beta(\alpha)}{2}\right)(\tilde{\varepsilon} + l\tilde{\varepsilon} + \omega(\tilde{\varepsilon})) < \varepsilon, \tag{3.8}$$

$$\gamma(\hat{\varepsilon}) < \min\left\{1,\, \frac{\alpha(\delta - \tilde{\delta})}{5\delta}\right\}, \tag{3.9}$$

where $\omega(\tilde{\varepsilon}) = \sup_{x \in B_{\tilde{\varepsilon}}(x_0)} \operatorname{dist}(y_0,\, \Psi(x))$, $\gamma(\hat{\varepsilon}) = c\,l(1 + \hat{\varepsilon})$ (note that $\omega(\tilde{\varepsilon}) \to 0$ as $\tilde{\varepsilon} \to 0$ because of the lower semicontinuity Ψ at (x_0, y_0), and recall (3.4)).

Let $(x, y) \in B_{\tilde{\varepsilon}}(x_0) \times B_{\tilde{\varepsilon}}(y_0 + \Phi(x_0))$ satisfying (3.6) be fixed. In order to prove estimate (3.5) it suffices to establish the existence of $\chi(x) \in (\Psi + \Phi)^{-1}(y)$ such that

$$\rho(x, \chi(x)) \le c(1 - c\,l)^{-1}(1 + \beta(\alpha))\,\mathrm{dist}(y, \Psi(x) + \Phi(x)). \tag{3.10}$$

The needed point $\chi(x)$ will be defined by means of the auxiliary iterative process. For that purpose set $t = t(x, y) = \mathrm{dist}(y, \Psi(x) + \Phi(x))$ and define the sequence $\{\tau_k\} \subset \mathbf{R}_+$ by setting

$$\tau_1 = \begin{cases} \frac{\delta - \tilde{\delta}}{(\|\bar{y}\| + \delta)\delta} t & \text{if } \|\bar{y}\| \ge \delta, \\ 0 & \text{if } \|\bar{y}\| < \delta, \end{cases} \qquad \tau_{k+1} = \frac{2}{5}\tau_k,\ k = 1, 2, \ldots .$$

According to (3.3),

$$\tau_1 \|\bar{y}\| \le \frac{\beta(\alpha)}{2} t. \tag{3.11}$$

Note that by the definition of $\omega(\tilde{\varepsilon})$

$$\begin{aligned} t &= \mathrm{dist}(y - \Phi(x_0) + \Phi(x_0) - \Phi(x), \Psi(x)) \\ &\le \|y - y_0 - \Phi(x_0)\| + \|\Phi(x) - \Phi(x_0)\| + \mathrm{dist}(y_0, \Psi(x)) \\ &\le \tilde{\varepsilon} + l\tilde{\varepsilon} + \omega(\tilde{\varepsilon}). \end{aligned} \tag{3.12}$$

We shall construct a sequence $\{x^k\} \subset X$ such that $x^1 = x$ and for all $k = 1, 2, \ldots$

$$y - \Phi(x^k) - \tau_k \bar{y} \in \Psi(x^{k+1}), \tag{3.13}$$

$$\rho(x^{k+2}, x^{k+1}) \le \gamma(\hat{\varepsilon})\rho(x^{k+1}, x^k) + \frac{\gamma(\hat{\varepsilon})}{l}(\tau_k - \tau_{k+1})\|\bar{y}\|, \tag{3.14}$$

$$\rho(x^{k+1}, x_0) \le \tilde{\varepsilon} + \frac{\gamma(\hat{\varepsilon})}{l}(1 - \gamma(\hat{\varepsilon}))^{-1}(1 + \beta(\alpha))(\tilde{\varepsilon} + l\tilde{\varepsilon} + \omega(\tilde{\varepsilon})), \tag{3.15}$$

and if $\|\bar{y}\| \ge \delta$ then

$$\|\Phi(x^{k+1}) - \Phi(x^k)\| \le \delta(\tau_k - \tau_{k+1}). \tag{3.16}$$

By (3.6) we obtain the existence of $\theta \ge 0$ and $\eta \in Y$ such that $\|\eta\| \le \tilde{\delta}$ and

$$y - \Phi(x^1) - \theta(\bar{y} + \eta) \in \Psi(x^1). \tag{3.17}$$

Note that if $\theta = 0$ then $x = x^1 \in (\Psi + \Phi)^{-1}(y)$, and we are done. Thus, let $\theta > 0$.

Set

$$y^1 = y - \Phi(x^1) - \tau_1\bar{y}, \quad \eta_0 = \theta(\bar{y} + \eta), \quad \eta^1 = \eta_0 - \tau_1\bar{y}.$$

By (3.8), (3.11), and (3.12) we then derive

$$\begin{aligned} \|y^1 - y_0\| &= \|y^1 + \Phi(x_0) - y_0 - \Phi(x_0)\| \\ &\le \|y - y_0 - \Phi(x_0)\| + \|\Phi(x_0) - \Phi(x^1)\| + \tau_1\|\bar{y}\| \\ &\le \tilde{\varepsilon} + l\tilde{\varepsilon} + \frac{\beta(\alpha)}{2}(\tilde{\varepsilon} + l\tilde{\varepsilon} + \omega(\tilde{\varepsilon})) \\ &< \varepsilon. \end{aligned} \tag{3.18}$$

Furthermore,

$$\begin{aligned}\|\eta_0\| &\le \theta(\|\bar{y}\| + \tilde{\delta}) \\ &< \theta(\|\bar{y}\| + \delta),\end{aligned}$$

and hence,

$$\begin{aligned}\theta &> \frac{\|\eta_0\|}{\|\bar{y}\| + \delta} \\ &\ge \frac{t}{\|\bar{y}\| + \delta} \\ &\ge \tau_1,\end{aligned} \tag{3.19}$$

where it was taken into account that, by (3.17), $y - \eta_0 \in \Psi(x^1) + \Phi(x^1)$, and hence, by the definition of t, it holds that $t \le \|\eta_0\|$. From (3.19) (including the intermediate inequalities) and the definition of τ_1 it follows that

$$\begin{aligned}\frac{\theta\|\eta\|}{\theta - \tau_1} &\le \frac{\theta\tilde{\delta}}{\theta - \frac{\delta - \tilde{\delta}}{(\|\bar{y}\| + \delta)\delta} t} \\ &\le \frac{\theta\tilde{\delta}}{\theta - \theta\frac{\delta - \tilde{\delta}}{\delta}} \\ &= \delta,\end{aligned}$$

and hence, by (3.17),

$$\begin{aligned}\eta^1 &= (\theta - \tau_1)\bar{y} + \theta\eta \\ &= (\theta - \tau_1)\left(\bar{y} + \frac{\theta\eta}{\theta - \tau_1}\right) \\ &\in \operatorname{cone} B_\delta(\bar{y}).\end{aligned} \tag{3.20}$$

Taking into account the equality $y^1 = y - \Phi(x^1) - \theta(\bar{y} + \eta) + \eta^1$, we conclude by (3.17) and (3.20) that

$$y^1 \in \Psi(x^1) + \operatorname{cone} B_\delta(\bar{y});$$

that is, (3.2) holds with (x, y) replaced by $(x^1, y^1) \in B_\varepsilon(x_0) \times B_\varepsilon(y_0)$ (see (3.18)). Thus, by metric regularity of Ψ at a point (x_0, y_0) in a direction $\bar{y}$, there exists $x^2 \in X$ such that

$$y - \Phi(x^1) - \tau_1\bar{y} \in \Psi(x^2), \tag{3.21}$$

$$\begin{aligned}\rho(x^2, x^1) &\le c(1 + \hat{\varepsilon}) \operatorname{dist}(y - \Phi(x^1) - \tau_1\bar{y}, \Psi(x^1)) \\ &\le c(1 + \hat{\varepsilon})(t + \tau_1\|\bar{y}\|) \\ &\le \frac{\gamma(\hat{\varepsilon})}{l}\left(1 + \frac{\beta(\alpha)}{2}\right) t,\end{aligned} \tag{3.22}$$

where the definition of t and (3.11) were taken into account. In particular, (3.13) holds for $k = 1$.

Employing (3.7), (3.12), and (3.22), we derive

$$\begin{aligned}\rho(x^2, x_0) &\le \rho(x^1, x_0) + \rho(x^2, x^1)\\ &\le \tilde{\varepsilon} + \frac{\gamma(\hat{\varepsilon})}{l}\left(1 + \frac{\beta(\alpha)}{2}\right) t\\ &\le \tilde{\varepsilon} + \frac{\gamma(\hat{\varepsilon})}{l}\left(1 + \frac{\beta(\alpha)}{2}\right)(\tilde{\varepsilon} + l\tilde{\varepsilon} + \omega(\tilde{\varepsilon}))\\ &< \varepsilon,\end{aligned} \tag{3.23}$$

and, in particular, (3.15) holds for $k = 1$.

Furthermore, if $\|\bar{y}\| \ge \delta$, then by (3.3), (3.9), (3.22), and (3.23), we derive

$$\begin{aligned}\|\Phi(x^2) - \Phi(x^1)\| &\le \gamma(\hat{\varepsilon})\left(1 + \frac{\beta(\alpha)}{2}\right) t\\ &< \frac{\alpha(\delta - \tilde{\delta})}{5\delta}\left(1 + \frac{1}{1+\alpha}\right) t\\ &= \frac{\alpha(\delta - \tilde{\delta})(2+\alpha)}{5(1+\alpha)\delta} t\\ &\le \frac{3\alpha(\delta - \tilde{\delta})}{5(1+\alpha)\delta} t\\ &= \delta(\tau_1 - \tau_2);\end{aligned} \tag{3.24}$$

that is, (3.16) holds for $k = 1$.

Set

$$q^2 = y - \Phi(x^1) - \tau_1 \bar{y},$$

$$y^2 = y - \Phi(x^2) - \tau_2 \bar{y}, \quad \eta^2 = (\tau_1 - \tau_2)\bar{y} + \Phi(x^1) - \Phi(x^2).$$

Note that $q^2 \in \Psi(x^2)$ by (3.21), and by (3.24) we conclude that $\eta^2 \in \operatorname{cone} B_\delta(\bar{y})$ ((3.24) holds only if $\|\bar{y}\| \ge \delta$, but otherwise, $\operatorname{cone} B_\delta(\bar{y}) = Y$).

By (3.8), (3.11), and (3.12), and by (3.15) (for $k = 1$), it follows that

$$\begin{aligned}\|y^2 - y_0\| &= \|y - y_0 - \Phi(x_0)\| + \|\Phi(x^2) - \Phi(x_0)\| + \tau_2\|\bar{y}\|\\ &\le \tilde{\varepsilon} + l\tilde{\varepsilon} + \gamma(\hat{\varepsilon})(1 - \gamma(\hat{\varepsilon}))^{-1}(1 + \beta(\alpha))(\tilde{\varepsilon} + l\tilde{\varepsilon} + \omega(\tilde{\varepsilon}))\\ &\quad + \frac{\beta(\alpha)}{2}(\tilde{\varepsilon} + l\tilde{\varepsilon} + \omega(\tilde{\varepsilon}))\\ &< \varepsilon.\end{aligned} \tag{3.25}$$

The inclusions $q^2 \in \Psi(x^2)$ and $\eta^2 \in \operatorname{cone} B_\delta(\bar{y})$ imply that

$$\begin{aligned}y^2 &= y - \Phi(x^1) - \tau_1\bar{y} + \Phi(x^1) + \tau_1\bar{y} - \Phi(x^2) - \tau_2\bar{y}\\ &= q^2 + \eta^2\\ &\in \Psi(x^2) + \operatorname{cone} B_\delta(\bar{y});\end{aligned}$$

that is, (3.2) holds with (x, y) replaced by $(x^2, y^2) \in B_\varepsilon(x_0) \times B_\varepsilon(y_0)$ (see (3.23), (3.25)). Thus, by metric regularity of Ψ at a point (x_0, y_0) in a direction $\bar{y}$, there exists $x^3 \in X$ such that

$$y - \Phi(x^2) - \tau_2\bar{y} \in \Psi(x^3), \tag{3.26}$$

$$
\begin{aligned}
\rho(x^3,\,x^2) &\le c(1+\hat\varepsilon)\,\mathrm{dist}(y-\Phi(x^2)-\tau_2\bar y,\,\Psi(x^2))\\
&\le c(1+\hat\varepsilon)\|y-\Phi(x^2)-\tau_2\bar y-q^2\|\\
&\le c(1+\hat\varepsilon)(\|\Phi(x^2)-\Phi(x^1)\|+(\tau_1-\tau_2)\|\bar y\|)\\
&\le \gamma(\hat\varepsilon)\rho(x^2,\,x^1)+\frac{\gamma(\hat\varepsilon)}{l}(\tau_1-\tau_2)\|\bar y\|,
\end{aligned}
\tag{3.27}
$$

where the definition of q^2 was taken into account. In particular, (3.13) holds for $k=2$, and (3.14) holds for $k=1$.

Employing (3.11), (3.22), and (3.27), we derive

$$
\begin{aligned}
\rho(x^3,\,x^1) &\le \rho(x^2,\,x^1)+\rho(x^3,\,x^2)\\
&\le (1+\gamma(\hat\varepsilon))\rho(x^2,\,x^1)+\frac{\gamma(\hat\varepsilon)}{l}(\tau_1-\tau_2)\|\bar y\|\\
&\le (1+\gamma(\hat\varepsilon))\left(\rho(x^2,\,x^1)+\frac{\gamma(\hat\varepsilon)}{l}\tau_1\|\bar y\|\right)\\
&\le \frac{\gamma(\hat\varepsilon)}{l}(1+\gamma(\hat\varepsilon))\left(\left(1+\frac{\beta(\alpha)}{2}\right)t+\tau_1\|\bar y\|\right)\\
&\le \frac{\gamma(\hat\varepsilon)}{l}(1+\gamma(\hat\varepsilon))(1+\beta(\alpha))t,
\end{aligned}
$$

and thus, by (3.7) and (3.12),

$$
\begin{aligned}
\rho(x^3,\,x_0) &\le \rho(x^1,\,x_0)+\rho(x^3,\,x^1)\\
&\le \tilde\varepsilon+\frac{\gamma(\hat\varepsilon)}{l}(1+\gamma(\hat\varepsilon))(1+\beta(\alpha))t\\
&\le \tilde\varepsilon+\frac{\gamma(\hat\varepsilon)}{l}(1-\gamma(\hat\varepsilon))^{-1}(1+\beta(\alpha))(\tilde\varepsilon+l\tilde\varepsilon+\omega(\tilde\varepsilon))\\
&< \varepsilon,
\end{aligned}
\tag{3.28}
$$

where the evident inequality $1+\gamma(\hat\varepsilon)<(1-\gamma(\hat\varepsilon))^{-1}$ was also employed. In particular, (3.15) holds for $k=2$.

Furthermore, if $\|\bar y\|\ge\delta$, then by (3.3), (3.9), (3.24), and (3.28), and by the intermediate inequalities in (3.27), we derive

$$
\begin{aligned}
\|\Phi(x^3)-\Phi(x^2)\| &\le l\rho(x^3,\,x^2)\\
&\le \gamma(\hat\varepsilon)(\|\Phi(x^2)-\Phi(x^1)\|+(\tau_2-\tau_1)\|\bar y\|)\\
&\le \gamma(\hat\varepsilon)(\delta+\|\bar y\|)(\tau_1-\tau_2)\\
&< \frac{\alpha}{5}(\delta+\|\bar y\|)\frac{5}{2}\left(1-\frac{2}{5}\right)\tau_2\\
&= \frac{\delta}{2\|\bar y\|}(\delta+\|\bar y\|)(\tau_2-\tau_3)\\
&\le \delta(\tau_2-\tau_3);
\end{aligned}
$$

that is, (3.16) holds for $k=2$.

Suppose now that for some $s\ge 3$ we have already constructed points $x^k\in X$, $k=1,\dots,s$, such that (3.13), (3.15), and (3.16), if $\|\bar y\|\ge\delta$, hold for each $k=1,\dots,s-1$, and (3.14) holds for each $k=1,\dots,s-2$. Set

$$
q^s=y-\Phi(x^{s-1})-\tau_{s-1}\bar y,
$$

$$y^s = y - \Phi(x^s) - \tau_s\bar{y}, \quad \eta^s = (\tau_{s-1} - \tau_s)\bar{y} + \Phi(x^{s-1}) - \Phi(x^s).$$

Note that $q^s \in \Phi(x^s)$ by (3.13) (with $k = s-1$), and by (3.16) (with $k = s-1$) we conclude that $\eta^s \in \operatorname{cone} B_\delta(\bar{y})$ ((3.16) holds only if $\|\bar{y}\| \geq \delta$, but otherwise, $\operatorname{cone} B_\delta(\bar{y}) = Y$).

By (3.8), (3.11), and (3.12), and by (3.15) (for $k = s-1$), it follows that

$$\begin{aligned}(3.29)\qquad \|y^s - y_0\| &= \|y - y_0 - \Phi(x_0)\| + \|\Phi(x^s) - \Phi(x_0)\| + \tau_s\|\bar{y}\| \\ &\leq \tilde{\varepsilon} + l\tilde{\varepsilon} + \gamma(\hat{\varepsilon})(1-\gamma(\hat{\varepsilon}))^{-1}(1+\beta(\alpha))(\tilde{\varepsilon} + l\tilde{\varepsilon} + \omega(\tilde{\varepsilon})) \\ &\quad + \frac{\beta(\alpha)}{2}(\tilde{\varepsilon} + l\tilde{\varepsilon} + \omega(\tilde{\varepsilon})) \\ &< \varepsilon.\end{aligned}$$

The inclusions $q^s \in \Phi(x^s)$ and $\eta^s \in \operatorname{cone} B_\delta(\bar{y})$ imply that

$$\begin{aligned} y^s &= y - \Phi(x^{s-1}) - \tau_{s-1}\bar{y} + \Phi(x^{s-1}) + \tau_{s-1}\bar{y} - \Phi(x^s) - \tau_s\bar{y} \\ &= q^s + \eta^s \\ &\in \Psi(x^s) + \operatorname{cone} B_\delta(\bar{y}); \end{aligned}$$

that is, (3.2) holds with (x, y) replaced by $(x^s, y^s) \in B_\varepsilon(x_0) \times B_\varepsilon(y_0)$ (see (3.8), (3.15), (3.29)). Thus, by metric regularity of Ψ at a point (x_0, y_0) in a direction $\bar{y}$, there exists $x^{s+1} \in X$ such that

$$y - \Phi(x^s) - \tau_s\bar{y} \in \Psi(x^{s+1}),$$

$$\begin{aligned}(3.30)\qquad \rho(x^{s+1}, x^s) &\leq c(1+\hat{\varepsilon})\operatorname{dist}(y - \Phi(x^s) - \tau_s\bar{y}, \Psi(x^s)) \\ &\leq c(1+\hat{\varepsilon})\|y - \Phi(x^s) - \tau_s\bar{y} - q^s\| \\ &\leq c(1+\hat{\varepsilon})(\|\Phi(x^s) - \Phi(x^{s-1})\| + (\tau_{s-1} - \tau_s)\|\bar{y}\|) \\ &\leq \gamma(\hat{\varepsilon})\rho(x^s, x^{s-1}) + \frac{\gamma(\hat{\varepsilon})}{l}(\tau_{s-1} - \tau_s)\|\bar{y}\|,\end{aligned}$$

where the definition of q^s was taken into account. In particular, (3.13) holds for $k = s$, and (3.14) holds for $k = s-1$.

Employing (3.14) we derive that for each $k = 1, \ldots, s-1$

$$\begin{aligned}\sum_{i=1}^{k}\rho(x^{i+2}, x^{i+1}) &\leq \sum_{i=1}^{k}\left(\gamma(\hat{\varepsilon})\rho(x^{i+1}, x^i) + \frac{\gamma(\hat{\varepsilon})}{l}(\tau_i - \tau_{i+1})\|\bar{y}\|\right) \\ &\leq \gamma(\hat{\varepsilon})\sum_{i=1}^{k}\rho(x^{i+1}, x^i) + \frac{\gamma(\hat{\varepsilon})}{l}\tau_1\|\bar{y}\|.\end{aligned}$$

It can be easily seen by induction that the latter property implies the estimate

$$(3.31)\qquad \sum_{k=1}^{s-1}\rho(x^{k+2}, x^{k+1}) \leq \gamma(\hat{\varepsilon})(1-\gamma(\hat{\varepsilon}))^{-1}(\rho(x^2, x^1) + l^{-1}\tau_1\|\bar{y}\|).$$

Hence, by (3.11), (3.22),

$$\begin{aligned}(3.32)\ \rho(x^{s+1}, x^1) &\leq \rho(x^2, x^1) + \sum_{i=1}^{s-1}\rho(x^{i+2}, x^{i+1}) \\ &\leq \left(1 + \gamma(\hat{\varepsilon})(1-\gamma(\hat{\varepsilon}))^{-1}\right)\rho(x^2, x^1) + \frac{\gamma(\hat{\varepsilon})}{l}(1-\gamma(\hat{\varepsilon}))^{-1}\tau_1\|\bar{y}\| \\ &\leq \frac{\gamma(\hat{\varepsilon})}{l}(1-\gamma(\hat{\varepsilon}))^{-1}(1+\beta(\alpha))t,\end{aligned}$$

and thus, by (3.7) and (3.12),

$$\begin{aligned}\rho(x^{s+1}, x_0) &\le \rho(x^1, x_0) + \rho(x^{s+1}, x^1)\\ &\le \tilde{\varepsilon} + \frac{\gamma(\hat{\varepsilon})}{l}(1-\gamma(\hat{\varepsilon}))^{-1}(1+\beta(\alpha))t\\ &\le \tilde{\varepsilon} + \frac{\gamma(\hat{\varepsilon})}{l}(1-\gamma(\hat{\varepsilon}))^{-1}(1+\beta(\alpha))(\tilde{\varepsilon} + l\tilde{\varepsilon} + \omega(\tilde{\varepsilon}))\\ &< \varepsilon.\end{aligned} \tag{3.33}$$

In particular, (3.15) holds for $k = s$.

Finally, if $\|\bar{y}\| \ge \delta$, then by (3.3), (3.9), (3.16) (with $k = s-1$), and (3.33), and by the intermediate inequalities in (3.30), we derive

$$\begin{aligned}\|\Phi(x^{s+1}) - \Phi(x^s)\| &\le l\rho(x^{s+1}, x^s)\\ &\le \gamma(\hat{\varepsilon})(\|\Phi(x^s) - \Phi(x^{s-1})\| + (\tau_{s-1} - \tau_s)\|\bar{y}\|)\\ &\le \gamma(\hat{\varepsilon})(\delta + \|\bar{y}\|)(\tau_{s-1} - \tau_s)\\ &< \frac{\alpha}{5}(\delta + \|\bar{y}\|)\frac{5}{2}\left(1 - \frac{2}{5}\right)\tau_s\\ &= \frac{\delta}{2\|\bar{y}\|}(\delta + \|\bar{y}\|)(\tau_s - \tau_{s+1})\\ &\le \delta(\tau_s - \tau_{s+1});\end{aligned}$$

that is, (3.16) holds for $k = s$.

The sequence $\{x^k\}$ with the needed properties is thus constructed. Moreover, as was shown above, (3.14) implies that (3.31) and (3.32) hold for each $s = 2, 3, \ldots$. Clearly, (3.31) implies that $\{x^k\}$ is a Cauchy sequence, and by completeness of the metric space (X, ρ), this sequence converges to some element $\chi(x) \in B_\varepsilon(x_0)$, where the last inclusion follows from (3.7) and (3.15). Since $\tau_k \to 0$ as $k \to \infty$, by passing to the limit in (3.13) we conclude that $\chi(x) \in (\Psi + \Phi)^{-1}(y)$, where closedness Ψ and continuity of Φ on $B_\varepsilon(x_0)$ were taken into account. Finally, since $\hat{\varepsilon} > 0$ can be taken arbitrarily small, (3.32) implies (3.10). □

The set $\operatorname{cone} B_\delta(\bar{y})$ in the right-hand side of (3.2) can be regarded as a *conic neighborhood* of $\bar{y}$. Note that α defined in (3.3) is invariant with respect to the choice of specific $\bar{y}$ and δ defining the same conic neighborhood, and it is natural to refer to this quantity as the *radius* of the conic neighborhood in question.

We now turn our attention to the multifunctions of the form $\Psi(x) = \Psi_F(x) = F(x) - Q$, where $F : X \to Y$ is a given mapping and $Q \subset Y$ is a given set. Note that if F is continuous at x_0 then this multifunction is automatically lower semicontinuous at (x_0, y_0) for any $y_0 \in \Psi(x_0)$. Being applied to such a multifunction, estimate (3.1) takes the form (1.4), while condition (3.2) takes the form

$$F(x) - y \in Q - \operatorname{cone} B_\delta(\bar{y}). \tag{3.34}$$

Definition 3.1 applied to $\Psi = \Psi_F$ and $y_0 = 0$ takes the following form.

DEFINITION 3.3. *The mapping $F : X \to Y$ is* metrically regular at $x_0 \in F^{-1}(Q)$ with respect to Q in a direction $\bar{y} \in Y$, *at a rate $c > 0$, if there exist $\varepsilon > 0$ and $\delta > 0$ such that the estimate* (1.4) *holds for all $(x, y) \in B_\varepsilon(x_0) \times B_\varepsilon(0)$ satisfying the inclusion* (3.34).

Throughout the rest of the paper let X and Y be Banach spaces. For a nonparametric mapping F, the directional regularity condition in a direction $\bar{y}$ takes the

form

$$0 \in \operatorname{int}(F(x_0) + \operatorname{im} F'(x_0) - \operatorname{cone}\{\bar{y}\} - Q), \tag{3.35}$$

and if Q is closed and convex then according to Theorem 2.3 (applied to $F(\sigma, x) = F(x) - \sigma$, $\sigma = y$), under the appropriate smoothness assumptions, the latter condition implies metric regularity in a direction $\bar{y}$. The converse implication can be derived from Theorem 3.2, which results in the following proposition.

PROPOSITION 3.4. *Let Q be closed and convex, and let $x_0 \in F^{-1}(Q)$. Let F be Fréchet-differentiable near x_0, and let its derivative be continuous at x_0.*

Then F is metrically regular at x_0 with respect to Q in a direction $\bar{y} \in Y$ if and only if it is regular at x_0 in this direction.

Proof. Let F be metrically regular at x_0 with respect to Q in a direction $\bar{y} \in Y$, at a rate $c > 0$. Define the mapping $\Phi : X \to Y$:

$$\Phi(x) = F(x_0) + F'(x_0)(x - x_0) - F(x).$$

Then $F + \Phi$ is a linearization of F at x_0. By the mean value theorem, for all x^1, $x^2 \in X$ close enough to x_0 we obtain

$$\begin{aligned}\|\Phi(x^1) - \Phi(x^2)\| &= \|F(x^1) - F(x^2) - F'(x_0)(x^1 - x^2)\| \\ &\le \sup_{\theta \in [0,\,1]} \|F'(\theta x^1 + (1-\theta)x^2) - F'(x_0)\| \|x^1 - x^2\|,\end{aligned}$$

and hence, Φ is Lipschitz-continuous near x_0 with modulus l, with $l > 0$ as small as needed. Applying Theorem 3.2 to $\Psi = \Psi_F$, we conclude that the linearized mapping $F + \Phi$ is metrically regular at x_0 with respect to Q in a direction $\bar{y} \in Y$, at some rate $\tilde{c} > 0$ (note that $\Psi_F + \Phi = \Psi_{F+\Phi}$). This means that there exist $\tilde{\varepsilon} > 0$ and $\tilde{\delta} > 0$ such that the estimate

$$\begin{aligned}\operatorname{dist}(x, x_0 + (F'(x_0))^{-1}(Q + y - F(x_0))) \le \tilde{c} \operatorname{dist}(&F(x_0) \\ &+ F'(x_0)(x - x_0) - y, Q)\end{aligned} \tag{3.36}$$

holds for $(x, y) \in B_{\tilde{\varepsilon}}(x_0) \times B_{\tilde{\varepsilon}}(0)$ satisfying the inclusion

$$F(x_0) + F'(x_0)(x - x_0) - y \in Q - \operatorname{cone} B_{\tilde{\delta}}(\bar{y}). \tag{3.37}$$

Take $x = x_0$, $y = -\theta\eta$, where $\eta \in B_{\tilde{\delta}}(\bar{y})$ and $\theta \ge 0$. Then (3.37) is evidently satisfied, and $y \in B_{\tilde{\varepsilon}}(0)$ for all $\theta > 0$ small enough (specifically, for all $\theta \in (0, \tilde{\varepsilon}/(\|\bar{y}\| + \tilde{\delta}))$). Hence, (3.36) holds for chosen x and y, which implies that for all $\eta \in B_{\tilde{\delta}}(\bar{y})$ and all $\theta > 0$ small enough

$$(F'(x_0))^{-1}(Q + \theta\eta - F(x_0)) \ne \emptyset,$$

and hence, there exist $\xi \in X$ and $q \in Q$ such that

$$F'(x_0)\xi = q + \theta\eta - F(x_0),$$

i.e.,

$$\theta\eta \in F(x_0) + \operatorname{im} F'(x_0) - Q.$$

It follows that

$$B_{\tilde{\delta}}(\bar{y}) \subset \operatorname{im} F'(x_0) - R_Q(F(x_0)).$$

It remains to employ Proposition 2.1 (see (2.2)). □

As mentioned above, directional metric regularity can hold when the usual metric regularity is violated. Moreover, let, e.g., $\operatorname{int} Q \neq \emptyset$ (which in particular covers the case of finitely many inequality constraints). It can be shown that in this case directional regularity condition (1.5), and hence, the directional metric regularity condition hold in any direction $\bar{y} \in -\operatorname{int} R_Q(F(\sigma_0, x_0)) \neq \emptyset$.

Example 3.1. Let $X = Y = \mathbf{R}^2$, $F(x) = (x_1, x_1^2 - x_2^2)$, $Q = \mathbf{R}^2_+$. Robinson's CQ does not hold at $x_0 = 0$, and hence, the mapping F is not metrically regular at x_0. Moreover, estimate (1.4) does not hold even on the subspaces $\{x_0\} \times Y$ and $X \times \{0\}$. Indeed, if, e.g., $y = (0, y_2)$ with $y_2 < 0$, it holds that $\operatorname{dist}(x_0, F^{-1}(Q-y)) = (-y_2)^{1/2}$, and the estimate (1.4) does not hold even for $x = x_0$. Moreover, if, e.g., $x = (0, x_2)$ with $x_2 \neq 0$, then $\operatorname{dist}(x, F^{-1}(Q)) = |x_2|/\sqrt{2}$, while $\operatorname{dist}(F(x), Q) = x_2^2$, and the estimate (1.4) does not hold even for $y = 0$.

At the same time, directional regularity condition (3.35) holds at x_0 in any direction $\bar{y} \in \mathbf{R}^2$ with $\bar{y}_2 < 0$, and hence, F is metrically regular at x_0 in each such direction.

To complete this section we note that Theorem 2.3 can actually be derived from a "uniform version" of Theorem 3.2, following the line of the argument in [3, pp. 63, 64], justifying Robinson's stability theorem.

4. Applications to sensitivity theory. Let Σ be a normed linear space. As an application of Theorem 2.3, we next show how it can be used in order to directly (that is, without employing any additional tools, with the only exception for the mean value theorem) obtain some principal lemmas playing the crucial role in sensitivity analysis under the more special directional regularity condition (1.6). We emphasize that both results presented below are known; the difference is only in the proofs. The first result is [3, Lemma 4.10].

LEMMA 4.1. *Let Q be closed and convex, and let $x_0 \in D(\sigma_0)$. Let F possess the Lipschitz-continuous derivative near (σ_0, x_0).*

If (1.6) *holds at x_0 with respect to a direction $d \in \Sigma$, then there exist $\bar{t} > 0$, $\varepsilon_1 > 0$, $\varepsilon_2 > 0$, and $a > 0$ possessing the following property: for any mappings $\rho(\cdot) : \mathbf{R}_+ \to \Sigma$ and $x(\cdot) : \mathbf{R}_+ \to X$ such that $\rho(t) = o(t)$ and the estimates*

$$\|x(t) - x_0\| \leq \varepsilon_1 t^{1/2} \tag{4.1}$$

and

$$\operatorname{dist}(F(\sigma_0 + td + \rho(t),\, x(t)),\, Q) \leq \varepsilon_2 t \tag{4.2}$$

hold for all $t \geq 0$ small enough, the estimate

(4.3)

$$\operatorname{dist}(x(t),\, D(\sigma_0 + td + \rho(t))) \leq a \left(1 + \frac{\|x(t) - x_0\|}{t}\right) \operatorname{dist}(F(\sigma_0 + td + \rho(t),\, x(t)),\, Q)$$

holds for all $t \in (0, \bar{t}]$.

Proof. As was already mentioned in section 1, (1.6) precisely coincides with (1.5) with $\bar{y} = -\frac{\partial F}{\partial \sigma}(\sigma_0, x_0)d$. For this $\bar{y}$, define $\varepsilon > 0$, $\delta > 0$, and $c > 0$ according to Theorem 2.3. Let $l > 0$ stand for the Lipschitz constant of F and $L > 0$ stand for the Lipschitz constant for the derivative of F on $B_\varepsilon(\sigma_0) \times B_\varepsilon(x_0)$ (ε can be reduced,

if necessary). For each $t > 0$ put $\sigma(t) = \sigma_0 + td + \rho(t)$. Set $\varepsilon_1 = (\delta/6L)^{1/2}$ and $\varepsilon_2 = \delta/12$, and choose $\bar{t} > 0$ such that for all $t \in (0, \bar{t}]$

$$\delta t^{1/2} \le \varepsilon, \quad \|td + \rho(t)\| \le \varepsilon, \tag{4.4}$$

$$L\left(\frac{\|td + \rho(t)\|^2}{t} + 2\varepsilon_1 \left\|d + \frac{\rho(t)}{t}\right\| t^{1/2}\right) \le \frac{\delta}{6}, \tag{4.5}$$

$$\left\|\frac{\partial F}{\partial \sigma}(\sigma_0, x_0)\right\| \frac{\|\rho(t)\|}{t} \le \frac{\delta}{6}. \tag{4.6}$$

For each $t > 0$ put

$$\tau(t) = \frac{12\,\mathrm{dist}(F(\sigma(t), x(t)), Q)}{\delta t}, \tag{4.7}$$

$$\tilde{x}(t) = \tau(t)x_0 + (1 - \tau(t))x(t), \tag{4.8}$$

$$\Phi_1(t) = F(\sigma(t), \tilde{x}(t)) - F(\sigma(t), x(t)) + \tau(t)\frac{\partial F}{\partial x}(\sigma_0, x_0)(x(t) - x_0), \tag{4.9}$$

$$\begin{aligned}\Phi_2(t) = F(\sigma(t), x(t)) - F(\sigma_0, x_0) - \frac{\partial F}{\partial \sigma}(\sigma_0, x_0)(td + \rho(t)) \\ - \frac{\partial F}{\partial x}(\sigma_0, x_0)(x(t) - x_0),\end{aligned} \tag{4.10}$$

choose an element $p(t) \in Q$ such that

$$\|F(\sigma(t), x(t)) - p(t)\| \le 2\,\mathrm{dist}(F(\sigma(t), x(t)), Q), \tag{4.11}$$

and set

$$q(t) = \tau(t)F(\sigma_0, x_0) + (1 - \tau(t))p(t). \tag{4.12}$$

Throughout the rest of the proof we assume that $F(\sigma(t), x(t)) \notin Q$ (otherwise estimate (4.3) holds trivially). Then according to (4.2), (4.7), and the definition of ε_2, it holds that

$$0 < \tau(t) = \frac{12\,\mathrm{dist}(F(\sigma(t), x(t)), Q)}{\delta t} \le \frac{12\varepsilon_2}{\delta} = 1.$$

In particular, by (4.12), $q(t) \in Q$. Furthermore, by (4.2), (4.4), and (4.8) it holds that $\sigma(t) \in B_\varepsilon(\sigma_0)$, $\tilde{x}(t) \in B_\varepsilon(x_0)$.

We next estimate $\|\Phi_1(t)\|$ and $\|\Phi_2(t)\|$ for $t \in (0, \bar{t}]$. By (4.1), (4.5), (4.8), (4.9),

the mean value theorem, and the definition of ε_1, we obtain

(4.13)
$$\begin{aligned}
\|\Phi_1(t)\| &= \Big\| F(\sigma(t),\, x(t) - \tau(t)(x(t) - x_0)) - F(\sigma(t),\, x(t)) \\
&\quad - \frac{\partial F}{\partial x}(\sigma_0,\, x_0)(-\tau(t)(x(t) - x_0)) \Big\| \\
&\le \sup_{\theta \in [0,\, 1]} \left\| \frac{\partial F}{\partial x}(\sigma(t),\, x(t) - \theta\tau(t)(x(t) - x_0)) - \frac{\partial F}{\partial x}(\sigma_0, x_0) \right\| \tau(t)\|x(t) - x_0\| \\
&\le L \left(\|td + \rho(t)\| + \sup_{\theta \in [0,\, 1]} \|x(t) - \theta\tau(t)(x(t) - x_0) - x_0\| \right) \tau(t)\|x(t) - x_0\| \\
&\le L \left(\|td + \rho(t)\| + \sup_{\theta \in [0,\, 1]} (1 - \theta\tau(t))\|x(t) - x_0\| \right) \tau(t)\|x(t) - x_0\| \\
&\le L \left(\left\| d + \frac{\rho(t)}{t} \right\| t + \|x(t) - x_0\| \right) \tau(t)\|x(t) - x_0\| \\
&\le L \left(\left\| d + \frac{\rho(t)}{t} \right\| t + \varepsilon_1 t^{1/2} \right) \varepsilon_1 \tau(t) t^{1/2} \\
&\le \left(L\varepsilon_1 \left\| d + \frac{\rho(t)}{t} \right\| t^{1/2} + L\varepsilon_1^2 \right) \tau(t) t \\
&\le \left(\frac{\delta}{6} + \frac{\delta}{6} \right) \tau(t) t \\
&= \frac{\delta}{3} \tau(t) t.
\end{aligned}$$

Similarly, by (4.1), (4.5), (4.10), the mean value theorem, and the definition of ε_1, we obtain

(4.14)
$$\begin{aligned}
\|\Phi_2(t)\| &\le \sup_{\theta \in [0,\, 1]} \|F'(\sigma_0 + \theta(td + \rho(t)),\, x_0 + \theta(x(t) - x_0)) \\
&\quad - F'(\sigma_0,\, x_0)\|(\|td + \rho(t)\| + \|x(t) - x_0\|) \\
&\le L \sup_{\theta \in [0,\, 1]} \theta(\|td + \rho(t)\| + \|x(t) - x_0\|)^2 \\
&\le L(\|td + \rho(t)\|^2 + 2\varepsilon_1 \|td + \rho(t)\| t^{1/2} + \varepsilon_1^2 t) \\
&= \left(L \left(\frac{\|td + \rho(t)\|^2}{t} + 2\varepsilon_1 \left\| d + \frac{\rho(t)}{t} \right\| t^{1/2} \right) + L\varepsilon_1^2 \right) t \\
&\le \left(\frac{\delta}{6} + \frac{\delta}{6} \right) t \\
&= \frac{\delta}{3} t.
\end{aligned}$$

We are now in a position to show that for $t \in (0,\, \bar{t}]$

$$F(\sigma(t),\, \tilde{x}(t)) - q(t) \in \operatorname{cone} B_\delta \left(\frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0) d \right). \tag{4.15}$$

(This will mean that (2.13) is satisfied with $\sigma = \sigma(t)$, $x = \tilde{x}(t)$, and $\bar{y} = -\frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d$.)

Indeed, put

$$y^1(t) = F(\sigma(t),\, x(t)) - p(t), \quad y^2(t) = \frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)\rho(t). \tag{4.16}$$

Then according to (4.12), (4.9), and (4.10) we have

$$\begin{aligned}
&F(\sigma(t),\, \tilde{x}(t))\\
&\qquad -q(t) = F(\sigma(t),\, \tilde{x}(t)) - F(\sigma(t),\, x(t)) + F(\sigma(t),\, x(t))\\
&\qquad\qquad + \tau(t)\frac{\partial F}{\partial x}(\sigma_0,\, x_0)(x(t) - x_0) - \tau(t)\frac{\partial F}{\partial x}(\sigma_0,\, x_0)(x(t) - x_0)\\
&\qquad\qquad - \tau(t)F(\sigma_0,\, x_0) - (1 - \tau(t))p(t)\\
&\qquad\qquad = \Phi_1(t) + F(\sigma(t),\, x(t)) - p(t)\\
&\qquad\qquad\quad - \tau(t)\left(\frac{\partial F}{\partial x}(\sigma_0,\, x_0)(x(t) - x_0) + F(\sigma_0,\, x_0) - p(t)\right)\\
&\qquad\qquad = \Phi_1(t) + y^1(t)\\
&\qquad\qquad\quad + \tau(t)\left(\Phi_2(t) - F(\sigma(t),\, x(t)) + t\frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d + y^2(t) + p(t)\right)\\
&\qquad\qquad = \tau(t)t\left(\frac{\Phi_1(t)}{\tau(t)t} + \frac{y^1(t)}{\tau(t)t} + \frac{\Phi_2(t)}{t} - \frac{y^1(t)}{t} + \frac{y^2(t)}{t} + \frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d\right)\\
&\qquad\qquad = \tau(t)t\left(\frac{\Phi_1(t)}{\tau(t)t} + (1 - \tau(t))\frac{y^1(t)}{\tau(t)t} + \frac{\Phi_2(t)}{t} + \frac{y^2(t)}{t} + \frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d\right),
\end{aligned}$$

and hence, by (4.6), (4.7), (4.11), (4.13), (4.14), and (4.16),

$$\left\|\frac{F(\sigma(t),\, \tilde{x}(t)) - q(t)}{\tau(t)t} - \frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d\right\| \le \frac{\delta}{3} + \frac{2\delta\,\mathrm{dist}(F(\sigma(t),\, x(t)),\, Q)}{12\,\mathrm{dist}(F(\sigma(t),\, x(t)))} + \frac{\delta}{3} + \frac{\delta}{6} = \delta,$$

which proves (4.15).

By the choice of $\varepsilon > 0$, $\delta > 0$, and $c > 0$, the estimate (1.3) holds with $\sigma = \sigma(t)$ and $x = \tilde{x}(t)$. Thus, taking into account (4.7), (4.8), we conclude that for all $t \in (0,\, \bar{t}]$

$$\begin{aligned}
\mathrm{dist}(x(t),\, D(\sigma(t))) &\le \|x(t) - \tilde{x}(t)\| + \mathrm{dist}(\tilde{x}(t),\, D(\sigma(t)))\\
&\le \|x(t) - \tilde{x}(t)\| + c\,\mathrm{dist}(F(\sigma(t),\, \tilde{x}(t)),\, Q)\\
&\le \|x(t) - \tilde{x}(t)\|\\
&\quad + c(\|F(\sigma(t),\, x(t)) - F(\sigma(t),\, \tilde{x}(t))\| + \mathrm{dist}(F(\sigma(t),\, x(t)),\, Q))\\
&\le \|x(t) - \tilde{x}(t)\| + c(l\|x(t) - \tilde{x}(t)\| + \mathrm{dist}(F(\sigma(t),\, x(t)),\, Q))\\
&\le (1 + c\,l)\|x(t) - x_0\|\tau(t) + c\,\mathrm{dist}(F(\sigma(t),\, x(t)))\\
&\le \left(c + \frac{12(1 + c\,l)}{\delta}\,\frac{\|x(t) - x_0\|}{t}\right)\mathrm{dist}(F(\sigma(t),\, x(t))).
\end{aligned}$$

This implies (4.3) with $a = \max\{c,\, 12(1 + c\,l)/\delta\}$. □

Note that the proof above actually specifies all the constants appearing in the assertion of Lemma 4.1.

The second result is [3, Lemma 4.109]. Our proof is an evident modification of the proof in [1, Lemma 6.2].

LEMMA 4.2. *Let Q be closed and convex, and let $x_0 \in D(\sigma_0)$. Let F be Fréchet-differentiable at $(\sigma_0,\, x_0)$ and Fréchet-differentiable with respect to x near $(\sigma_0,\, x_0)$, and let its derivative with respect to x be continuous at $(\sigma_0,\, x_0)$.*

If (1.6) *holds at* x_0 *with respect to a direction* $d \in \Sigma$*, then there exists* $a > 0$ *possessing the following property: for any mappings* $\rho(\cdot) : \mathbf{R}_+ \to \Sigma$ *and* $x(\cdot) : \mathbf{R}_+ \to X$ *such that* $\rho(t) = o(t)$*,* $x(t) \to x_0$ *as* $t \to 0$*, and the estimate*

$$\operatorname{dist}(F(\sigma_0 + td + \rho(t),\, x(t)),\, Q) = o(t) \tag{4.17}$$

holds for $t \geq 0$*, and for any* $\theta > 0$*, the estimate*

$$\operatorname{dist}(x(t),\, D(\sigma_0 + (1+\theta)td + \rho((1+\theta)t))) \leq a\theta t \tag{4.18}$$

holds for all $t > 0$ *small enough.*

Proof. By the same argument as in the proof of Lemma 4.1 we can choose $\varepsilon > 0$, $\delta > 0$, and $c > 0$ such that the estimate (1.3) holds for all $(\sigma,\, x) \in B_\varepsilon(\sigma_0) \times B_\varepsilon(\sigma_0)$ satisfying inclusion (2.13) with $\bar{y} = -\frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d$. For each $t > 0$ put $\sigma(t) = \sigma_0 + td + \rho(t)$.

For a fixed $\theta > 0$ and for $t \geq 0$ we have

$$F(\sigma((1+\theta)t),\, x(t)) = F(\sigma(t),\, x(t)) + \theta t \frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d + o(t). \tag{4.19}$$

Select $q(t) \in Q$ such that

$$\|F(\sigma(t),\, x(t)) - q(t)\| = \operatorname{dist}(F(\sigma(t),\, x(t)),\, Q) + o(t).$$

Then for $t > 0$ small enough $\sigma(t) \in B_\varepsilon(\sigma_0)$, $x(t) \in B_\varepsilon(x_0)$, and by (4.17) and (4.19) it holds that

$$\begin{aligned} F(\sigma((1+\theta)t),\, x(t)) - q(t) &= \theta t \frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d + o(t) \\ &\in \operatorname{cone} B_\delta\left(\frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d\right); \end{aligned} \tag{4.20}$$

i.e., inclusion (2.13) holds with $\sigma = \sigma((1+\theta)t)$, $x = x(t)$, and with $\bar{y} = -\frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d$. Hence by (1.3) and the equality in (4.20) we conclude that

$$\begin{aligned} \operatorname{dist}(x(t),\, D(\sigma((1+\theta)t))) &\leq c \operatorname{dist}(F(\sigma((1+\theta)t),\, x(t))Q) \\ &\leq c\|F(\sigma((1+\theta)t),\, x(t)) - q(t)\| \\ &= c\left\|\frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d\right\|\theta t + o(t), \end{aligned}$$

and the needed estimate (4.18) holds with any $a > c\|\frac{\partial F}{\partial \sigma}(\sigma_0,\, x_0)d\|$ for all $t > 0$ small enough. ∎

Acknowledgments. We would like to thank the anonymous referees for their helpful comments. Proposition 2.2 was entirely motivated by the referee's suggestion to try to remove an extra localization in condition (2.13) of Theorem 2.3 in the original version of the paper. The current version of Theorem 2.3 is of course equivalent to the original one, but its statement and the subsequent presentation became much more elegant. We are especially thankful to the referee for this.

BOUNDARY HALF-STRIPS AND THE STRONG CHIP*

EMIL ERNST† AND MICHEL THÉRA‡

Abstract. When the subdifferential sum rule formula holds for the indicator functions ι_C and ι_D of two closed convex sets C and D of a locally convex space X, the pair (C, D) is said to have the strong conical hull intersection property (the strong CHIP). The specification of a well-known theorem due to Moreau to the case of the support functionals σ_C and σ_D subsumes the fact that the pair (C, D) has the strong CHIP whenever the inf-convolution of σ_C and σ_D is exact. In this article we prove, in the setting of Euclidean spaces, that if the pair (C, D) has the strong CHIP while the boundary of C does not contain any half-strip, then the inf-convolution of σ_C and σ_D is exact. Moreover, when the boundary of a closed and convex set C does contain a half-strip, it is possible to find a closed and convex set D such that the pair (C, D) has the strong CHIP while the inf-convolution of σ_C and σ_D is not exact. The validity of the converse of Moreau's theorem in Euclidean spaces is thus associated with the absence of half-strips within the boundary of concerned convex sets.

Key words. strong conical hull intersection property, convex programming with convex inequalities, Euclidean space, exact infimal convolution, qualification conditions

1. Introduction.

This study concerns an application of a geometrical notion called the *strong conical hull intersection property* (strong CHIP) introduced by Deutsch, Li, and Swetits (see [6]). We say that the pair (C, D) of closed and convex subsets of some locally convex space X has the strong CHIP if the subdifferential of the sum and sum of the subdifferentials of their indicator functions coincide:

$$\partial(\iota_C + \iota_D) = \partial\iota_C + \partial\iota_D. \tag{1.1}$$

As customary, ι_A is the indicator function of a subset A of X and is defined by $\iota_A(x) = 0$ if $x \in A$, and $\iota_A(x) = +\infty$ otherwise. We also recall that the convex subdifferential is an operator from X into the topological dual $X^\star$ of X, which assigns to each extended-real-valued mapping Φ on X a set-valued operator between X and $X^\star$ defined by

$$\partial\Phi(x_0) = \{x^\star \in X^* : \langle x - x_0, x^\star\rangle + \Phi(x_0) \le \Phi(x) \quad \forall x \in X\},$$

where $\langle\cdot,\cdot\rangle : X \times X^\star \to R$ is the duality pairing between X and $X^\star$.

Recalling that the normal cone $N_C(x)$ at $x \in X$ to a closed convex set C of X is the set $\partial\iota_C(x)$, the strong CHIP for the pair (C, D) amounts to saying that

$$N_{C\cap D}(x) = N_C(x) + N_D(x) \quad \forall x \in C \cap D; \tag{1.2}$$

i.e., every normal direction to $C \cap D$ at some point x can be expressed as the sum of normal directions at x to C and D.

This property is important in convex optimization because when we consider the problem of minimizing a convex functional Φ on the intersection of two sets C and D which have the strong CHIP, the optimality condition for $\bar{x}$ to be a minimizer becomes

$$0 \in \partial\Phi(\bar{x}) + N_C(\bar{x}) + N_D(\bar{x}).$$

In the case of convex differentiable optimization, it becomes

$$-\nabla f(\bar{x}) \in N_C(\bar{x}) + N_D(\bar{x}).$$

Let us quote only the result proved when X is a Hilbert space by Deutsch (see [4]). It says that the strong CHIP is the weakest constraint qualification under which a minimizer $\bar{x}$ of a convex function $\Phi : C_1 \cap C_2 \to R$ can be characterized using the subdifferential of Φ at x and the normal cones of C_1 and C_2 at x.

The existence of conditions ensuring that a pair of closed and convex sets has the strong CHIP is based on a classical result by Moreau ([9, Remarque 10.2]); the result initially published in [8] makes use of another key concept of convex analysis, namely the notion of *infimal convolution* (inf-convolution). Recall that, if Φ and Ψ are extended-real-valued lower semicontinuous convex functions over X (this class of functions from now on is denoted by $\Gamma_0(X)$), the inf-convolution of Φ and Ψ is the extended real-valued function $\Phi\square\Psi$ defined by

$$\Phi\square\Psi(x) = \inf_{y\in X} \left(\Phi(x-y) + \Psi(y)\right). \tag{1.3}$$

The infimal convolution between Φ and Ψ is said to be *exact* if $\Phi\square\Psi \in \Gamma_0(X)$ and the infimum is achieved in (1.3) whenever $\Phi\square\Psi(x) < +\infty$.

Let us also recall that given a convex closed set A in X, we note $\sigma_A : X^\star \to R \cup \{+\infty\}$, the support function of A. It is defined by

$$\sigma_A(f) = \sup_{x\in A} \langle x, f\rangle .$$

Using this concept, Moreau's theorem states that the subdifferential sum formula (1.1) holds, provided that the inf-convolution of the support functionals of C and D is exact. Remark that an equivalent way of expressing the exactness of the inf-convolution of the support functionals σ_C and σ_D is to say that every linear functional $f \in X^\star$ which is bounded above on $C \cap D$ may be expressed as the sum of two linear functionals f_1 and f_2, bounded above on C and D, respectively, such that

$$\sup_{x\in C\cap D} \langle x, f\rangle = \sup_{x\in C} \langle x, f_1\rangle + \sup_{x\in D} \langle x, f_2\rangle .$$

Let us observe that relation (1.2), i.e., the strong CHIP, is equivalent to the following property: *Every linear functional $f \in X^\star$ which achieves its maximum on $C \cap D$ may be expressed as the sum of two linear functionals f_1 and f_2, achieving their maximum on C and D, respectively, such that*

$$\max_{x\in(C\cap D)} \langle x, f\rangle = \max_{x\in C} \langle x, f_1\rangle + \max_{x\in D} \langle x, f_2\rangle .$$

The importance of Moreau's theorem comes from the fact that several very general *qualification conditions* are known to ensure the exactness of the inf-convolution of support functionals (the reader is referred for further information to the excellent

articles of Zălinescu [13], Gowda and Teboulle [10], and, respectively, Simons [11], in which he/she may find a clear picture of the topic, as well as self-contained proofs for most of the concerned results).

Accordingly, the result proved by Moreau gives the possibility of systematically specifying every qualification condition as a criterion for the strong CHIP (see for instance [5, Proposition 2.3]).

Let us remark that the exactness of the inf-convolution of the support functionals is stronger than the simple strong CHIP. Indeed, Moreau's condition concerns all the continuous linear functionals bounded above on the intersection $C \cap D$, while the strong CHIP is formulated only in terms of those elements from $X^\star$ which achieve their maximum on $C \cap D$. The question is thus raised of the validity of the converse to this theorem.

The converse to Moreau's theorem obviously holds for sets C and D such that every linear and continuous map bounded above on any one of the sets $C \cap D$, C, or D necessarily achieve their maximums on this set. On this ground, a first partial converse of the Moreau result has recently been proved by Bauschke, Borwein, and Li for Hilbert spaces (see [1, Proposition 6.4]); the result was extended to the setting of Banach spaces by Burachik and Jeyakumar [3, Proposition 4.2]. Their result states that, if C and D is a pair of closed and convex *cones* with the strong CHIP, then the inf-convolution of their support functionals is always exact.

However, it is not necessary to impose to every linear and continuous map which is bounded above on any one of the sets $C \cap D$, C, or D, to achieve its maximum on this set, in order to ensure the validity of the converse to the above mentioned Moreau's theorem. It is the aim of this article to clearly define the best conditions under which the converse of Moreau's theorem holds. More precisely, we characterize all the closed and convex subsets C of an Euclidean space X such that the following converse of Moreau's theorem holds: If, for some closed and convex set D, the pair (C, D) has the strong CHIP, then the inf-convolution of σ_C and σ_D is exact.

Our main result states that the validity of the converse of Moreau's theorem is ensured if and only if the boundary of the closed and convex subset C of the Euclidean space X does not contain any half-strip (by *half-strip* we mean, as customary, the convex hull of two disjoint and parallel half-lines). Note that the class of closed and convex sets without boundary half-strips is rather large, as it contains—the list is not exhaustive—all the bounded sets, the strictly convex sets, or even the continuous sets in the sense of Gale and Klee—sets such that their support functional is continuous except at the origin (see [7]).

The outline of the paper is as follows. The case of closed and convex sets without boundary half-strips is considered in section 2. We prove (Theorem 2.3) that, if the pair (C, D) has the strong CHIP, and if the boundary of one of the sets, say C, does not contain any half-strip, then the inf-convolution of the support functions of C and D must be exact.

The last section is concerned with convex sets which do admit at least one boundary half-strip. If the boundary of a closed and convex set C contains some half-strip, then we give a construction of a closed and convex set D such that the pair (C, D) has the strong CHIP, while the inf-convolution of σ_C and σ_D fails to be exact.

2. Convex sets without boundary half-strips. Now let us first collect some conditions ensuring in every reflexive Banach space the validity of the converse of Moreau's theorem.

PROPOSITION 2.1. *Let C and D be a pair of closed and convex subsets of a reflexive Banach space X. If C and D have the strong CHIP, and at least one of the following conditions holds:*

(i) *$C \cap D$ is bounded;*

(ii) *$C \cap D$ is a flat;*

(iii) *$C \cap D$ is a half-line,*

then the inf-*convolution of the support functions of C and D is exact. In other words, the converse of Moreau's theorem is valid.*

Proof of Proposition 2.1. We need the following standard convex analysis result.

LEMMA 2.2. *Let C and D be two closed and convex subsets of a locally convex space X, and consider an element y of $X^\star$ expressed as the sum $y = y_1 + y_2$ of two normal vectors $y_1 \in N_C(x)$ and $y_2 \in N_D(x)$, for some $x \in C \cap D$. Then the* inf-*convolution of the support functionals is exact at y, that is,*

$$\sigma_C \square \sigma_D(y) = \sigma_C(y_1) + \sigma_D(y_2) = \langle x, y \rangle . \tag{2.1}$$

Proof of Lemma 2.2. As $y_1 \in \partial \iota_C(x)$ and $y_2 \in \partial \iota_D(x)$, relation $y = y_1 + y_2$ implies that $y \in \partial \iota_{C \cap D}(x)$. Thus

$$\sigma_C(y_1) = \langle x, y_1 \rangle , \ \sigma_2(y_2) = \langle x, y_2 \rangle , \ \sigma_{C \cap D}(y) = \langle x, y \rangle ,$$

and hence

$$\sigma_{C \cap D}(y) = \sigma_C(y_1) + \sigma_D(y_2). \tag{2.2}$$

Recall that $\sigma_{C \cap D} \leq \sigma_C \square \sigma_D$, which means that

$$\sigma_{C \cap D}(y) \leq \sigma_C \square \sigma_D(y). \tag{2.3}$$

Finally, use the definition of the inf-convolution and the fact that $y = y_1 + y_2$ to deduce that

$$\sigma_C \square \sigma_D(y) \leq \sigma_C(y_1) + \sigma_D(y_2). \tag{2.4}$$

Relation (2.1) follows from relations (2.2), (2.3), and (2.4). □

Let us now return to the proof of Proposition 2.1 and consider that case (i) holds; i.e., we suppose that the pair (C, D) has the strong CHIP and $C \cap D$ is bounded.

As, in addition, X is a reflexive Banach space, it is easy to see that, for every $y \in X^\star$, there is an $x \in C \cap D$ such that $y \in \partial \iota_{C \cap D}(x)$. The pair (C, D) has the strong CHIP, and thus $y = y_1 + y_2$, for some $y_1 \in \partial \iota_C(x)$ and $y_2 \in \partial \iota_D(x)$; we may therefore apply Lemma 2.2 and deduce that

$$\sigma_C \square \sigma_D(y) = \sigma_C(y_1) + \sigma_D(y_2) = \langle x, y \rangle . \tag{2.5}$$

On one hand, from relation (2.5) we observe that the $\Gamma_0(X^\star)$-functional $\sigma_C \square \sigma_D$ is real-valued on $X^\star$ and thus, as $X^\star$ is a reflexive Banach space, it follows that $\sigma_C \square \sigma_D$ is continuous. Taking into account that relation (2.5) implies, on the other hand, that the infimum is always attained in the expression of the inf-convolution, we conclude that the inf-convolution of the support functions σ_C and σ_D is exact.

Case (ii). Let L be the closed subspace of X parallel to the flat $C \cap D$ (that is, $C \cap D = x_0 + L$ for every $x_0 \in C \cap D$), and factorize X with respect to L.

The quotient space X/L, say $\hat{X}$, is again a reflexive Banach space. Since $x_0 + L \subset C$ for every $x_0 \in C$, and $x_0 + L \subset D$ for every $x_0 \in D$, it follows that $\hat{C}$ and $\hat{D}$, the

quotients of the sets C and D, are closed and convex subsets of $\hat{X}$; moreover, it is straightforward to prove that the pair $(\hat{C}, \hat{D})$ has the strong CHIP if and only if the same holds for the pair (C, D), and that the inf-convolution of the support functions of $\hat{C}$ and $\hat{D}$ is exact if and only if the inf-convolution of the support functions of C and D is exact.

But the intersection between $\hat{C}$ and $\hat{D}$ reduces to a singleton, and case (ii) is proved by applying the conclusion of case (i) to the pair $(\hat{C}, \hat{D})$.

Case (iii). Set $x_0 + R_+\overline{x}$ for the half-line $C \cap D$. Obviously, when $y \in X^\star$ and $\langle \overline{x}, y\rangle \leq 0$ we have $y \in \partial\iota_{C\cap D}(x_0)$. Use the fact that the pair (C, D) has the CHIP to deduce that $y = y_1 + y_2$ for some $y_1 \in \partial\iota_C(x_0)$ and $y_2 \in \partial\iota_D(x_0)$, together with Lemma 2.2, to infer that

$$\sigma_C \square \sigma_D(y) = \sigma_C(y_1) + \sigma_D(y_2) = \langle x_0, y\rangle \quad \forall y \in X^\star,\ \langle \overline{x}, y\rangle \leq 0. \tag{2.6}$$

In order to obtain a similar relation for the case $\langle \overline{x}, y\rangle > 0$, note that for every $z \in X^\star$ such that $\langle \overline{x}, z\rangle > 0$, it holds that $\sigma_C(z) = \sigma_D(z) = +\infty$. Moreover, the inequality $\langle \overline{x}, z + v\rangle > 0$ means that at least one of the inequalities $\langle \overline{x}, z\rangle > 0$ and $\langle \overline{x}, v\rangle > 0$ holds. Combining these two facts, we deduce that

$$\sigma_C(z) + \sigma_D(v) = +\infty \quad \forall z, v \in X^\star \text{ such that } \langle \overline{x}, z + v\rangle > 0,$$

which means that

$$\sigma_C \square \sigma_D(y) = +\infty \quad \forall y \in X^\star,\ \langle \overline{x}, y\rangle > 0. \tag{2.7}$$

Combining relations (2.6) and (2.7) yields

$$\sigma_C \square \sigma_D = \iota_{\{y \in X^\star :\, \langle \overline{x}, y\rangle \leq 0\}} + \langle x_0, \cdot\rangle\,,$$

which means that the inf-convolution of σ_C and σ_D is the sum between the indicator function of a half-space and a linear and continuous functional, and clearly belongs to $\Gamma_0(X^\star)$. Use once more relation (2.6) to see that the infimum in the expression of the inf-convolution is achieved, and conclude that the inf-convolution of σ_C and σ_D is exact. □

Apparently, Proposition 2.1 lists three completely disparate conditions, each one being sufficient in its own way for the validity of the converse of Moreau's theorem. The geometric notion of a *half-strip*, that is, a convex hull of two parallel and disjoint half-lines, allows us to spot a common property of cases (i), (ii), and (iii) in Proposition 2.1.

THEOREM 2.3. *Let C and D two closed and convex subsets of the Euclidean space X, and assume that the boundary of the set C does not contain any half-strip. If the pair (C, D) has the strong CHIP, then the* inf*-convolution of σ_C and σ_D is exact (in other words, the converse of Moreau's theorem holds).*

Proof of Theorem 2.3. When the intersection $C \cap D$ meets the interior of C, we specify the well-known Moreau–Rockafellar internal point condition (see [9, Chap. 6, section 6.8]) to prove that the inf-convolution of the support functionals is exact.

If $C \cap D$ is a part of the boundary of C, use—as the boundary of C does not contain any half-strip—the obvious fact that the only closed and convex subsets of an Euclidean space which do not contain any half-strip are the bounded sets, the half-lines, and the lines, and completely prove Theorem 2.3 by making use of Proposition 2.1. □

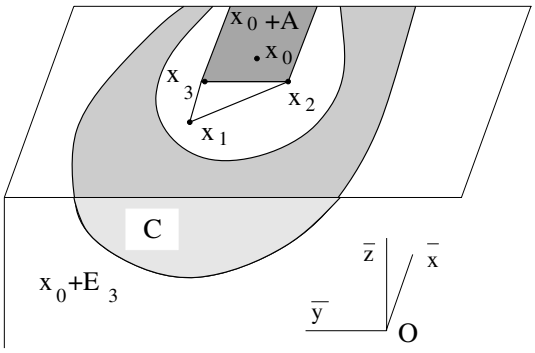

FIG. 3.1. *Closed and convex set with a boundary half-strip.*

3. Convex sets with boundary half-strips. The following result completes the analysis initiated in Theorem 2.3.

THEOREM 3.1. *Let C be a closed and convex subset of the Euclidean space X; assume moreover that the boundary of C contains at least one half-strip. Then there is a closed and convex set D such that the pair (C, D) has the CHIP while the* inf-*convolution between σ_C and σ_D is not exact.*

In other words, the existence of at least one boundary half-strip prevents the converse of Moreau's theorem from holding.

3.1. Construction and properties of the set D. Our strategy in this section is to construct the set D. The following easy result will be useful. It says that when X is Euclidean, every closed and convex set with a boundary half-strip may be contained within some half-space such that its boundary half-strip lies within the hyperplane which delimits this half-space.

PROPOSITION 3.2. *Let C be a closed and convex subset of an Euclidean space X such that its boundary contains a half-strip. Then, there is an orthonormal basis of X, $B = \{b_1, b_2, \ldots, b_n\}$, a positive parameter $a > 0$, and x_0, an element of X, such that*

$$x_0 + A \subset C \subset x_0 + E_3,$$

where A is the half-strip defined as

$$A = \{x \in X : 0 \leq x \cdot b_1,\ -2a \leq x \cdot b_2 \leq 2a,\ 0 = x \cdot b_i \quad \forall i \geq 3\},$$

and the half-space E_3 is given by the relation

$$E_3 = \{x \in X : \ x \cdot b_3 \leq 0\}.$$

Proof of Proposition 3.2. Let x_1, x_2, $\overline{x}$ in X be such that $\|\overline{x}\| = 1$ and the half-strip spanned by the half-lines $x_1 + R_+\overline{x}$ and $x_2 + R_+\overline{x}$ lies within the boundary of the set C. Assume (if necessary after changing x_1 into x_2) that $x_2 \cdot \overline{x} \geq x_1 \cdot \overline{x}$, and set $x_3 = x_1 + [(x_2 - x_1)\overline{x}]\overline{x}$.

Clearly, $x_3 \in x_1 + R_+\overline{x}$; as the half-lines $x_1 + R_+\overline{x}$ and $x_2 + R_+\overline{x}$ are disjoint, it follows that x_3 and x_2 cannot coincide. Set

$$a = \frac{\|x_3 - x_2\|}{4} \quad \text{and} \quad \overline{y} = \frac{x_3 - x_2}{4a} = \frac{x_3 - x_2}{\|x_3 - x_2\|}.$$

Note that

$$\overline{y}\cdot\overline{x}=\frac{1}{4a}(x_3\cdot\overline{x}-x_2\cdot\overline{x})=\frac{1}{4a}(x_1\cdot\overline{x}+(x_2-x_1)\overline{x}\,\overline{x}\cdot\overline{x}-x_2\cdot\overline{x})=0. \tag{3.1}$$

Finally, put

$$x_0=\frac{x_3+x_2}{2}+a\overline{x}=\frac{1}{2}(x_3+a\overline{x})+\frac{1}{2}(x_2+a\overline{x});$$

as $x_3+a\overline{x}\in x_1+R_+\overline{x}$ and $(x_2+a\overline{x})\in(x_2+R_+\overline{x})$, we deduce that x_0 belongs to the half-strip spanned by the half-lines $x_1+R_+\overline{x}$ and $x_2+R_+\overline{x}$, and thus belongs to the boundary of C.

Since x_0 is a boundary point of a closed and convex subset of an Euclidean space, it is well known that there is some linear mapping $\overline{z}\in X$, $\|\overline{z}\|=1$, which achieves its maximum on C at x_0,

$$\overline{z}\cdot x_0\geq\overline{z}\cdot x\qquad\forall x\in C. \tag{3.2}$$

Apply relation (3.2) for $x=x_0-a\overline{x}=\frac{x_3+x_2}{2}$ to deduce that $\overline{z}\cdot\overline{x}\geq 0$, and then for $x=x_0+a\overline{x}=\frac{1}{2}(x_3+2a\overline{x})+\frac{1}{2}(x_2+2a\overline{x})$ to obtain $\overline{z}\cdot\overline{x}\leq 0$ and therefore conclude that

$$\overline{z}\cdot\overline{x}=0. \tag{3.3}$$

Similarly, put $x_0-a\overline{x}-2a\overline{y}=x_2$ for x in relation (3.2), and using also relation (3.3), deduce that $\overline{z}\cdot\overline{y}\geq 0$. Finally, putting $x=x_0-a\overline{x}+2a\overline{y}=x_3$ in relation (3.2), and also taking into account relation (3.3), we infer $\overline{z}\cdot\overline{y}\leq 0$, that is,

$$\overline{z}\cdot\overline{y}=0. \tag{3.4}$$

Relations (3.1), (3.3), and (3.4) prove that it is possible to complete the set $\{\overline{x},\overline{y},\overline{z}\}$ depicted in Figure 3.1 up to $B=\{b_1,b_2,\ldots,b_n\}$, an orthonormal basis of X.

The proof of Proposition 3.2 will be completed if we remark that the set x_0+A is nothing but the half-strip spanned by the half-lines $(x_3+a\overline{x})+R_+\overline{x}$ and $(x_2+a\overline{x})+R_+\overline{x}$, and thus lies within the boundary of C, while relation (3.2) implies that C is a part of the half-space x_0+E_3. □

The basis B, the parameter a, and the element x_0 thus defined allow us to proceed to the construction of the set D. Let us first define the set F,

$$F=(P_1+S)\cap(P_2+T),$$

where $P_1\subset P_2$ are the sets bordered by two plane parabolae:

$$P_1=\left\{x\in X:\ x\cdot b_1\leq-\frac{a(x\cdot b_2)^2}{4},\ x\cdot b_i=0\quad\forall i\geq 3\right\},$$

$$P_2=\left\{x\in X:\ x\cdot b_1\leq-\frac{a(x\cdot b_2)^2}{8},\ x\cdot b_i=0\quad\forall i\geq 3\right\},$$

S is an orthogonal box in X:

$$S=\{x\in X:\ x\cdot b_1\leq 0,\ -1\leq ax\cdot b_2\leq 1,\ x\cdot b_3\leq 0\},$$

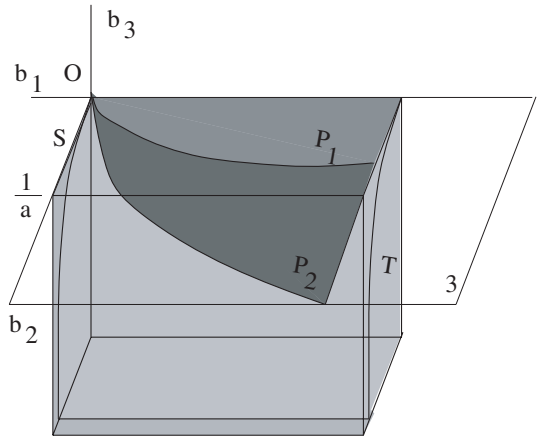

FIG. 3.2. *Sets needed in constructing the set D.*

T is a closed and convex subset of S:

$$T = \left\{ x \in X : \; x \cdot b_1 \le 0, \; -1 < ax \cdot b_2 < 1, \; x \cdot b_3 \le -\frac{a^2 (x \cdot b_2)^2}{1 - a^2 (x \cdot b_2)^2} \right\},$$

and, as customary, $Z^\star$ means the polar set of some subset Z of X,

$$Z^\star = \{ x \in X : \; x \cdot y \le 1 \quad \forall y \in Z \}.$$

Set now, as shown in Figure 3.2,

$$D = x_0 + F^\star = x_0 + ((P_1 + S) \cap (P_2 + T))^\star.$$

This definition grants to the set F (and thus D) several geometrical properties which are crucial for our purpose.

Let us first notice that F is contained in the half-space $E_1 = \{ x \in X : \; x \cdot b_1 \le 0 \}$; accordingly, the half-line $R_+ b_1$ lies within $F^\star$, and thus the half-line $x_0 + R_+ b_1$ is a part of both sets C and $D = x_0 + F^\star$. It follows that

$$\sigma_C(x) = \sigma_D(x) = +\infty \quad \forall x \in X \text{ such that } x \cdot b_1 > 0.$$

Let $x \in X$ be such that $x \cdot b_1 = 0$; if y is such that $y \cdot b_1 \ne 0$, then either $y \cdot b_1 > 0$ or $(x - y) \cdot b_1 > 0$, so

$$\sigma_C(y) + \sigma_D(x - y) = +\infty \quad \forall \, x \in X, \; x \cdot b_1 = 0, \; y \in X, \; y \cdot b_1 \ne 0; \tag{3.5}$$

hence for every element $x \in X$ such that $x \cdot b_1 = 0$ it results that

$$\sigma_C \square \sigma_D(x) = \inf_{y \in X, \; y \cdot b_1 = 0} \sigma_C(y) + \sigma_D(x - y). \tag{3.6}$$

The hyperplane $L_1 = \{ x \in X : \; x \cdot b_1 = 0 \}$ thus plays a very important role in computing the inf-convolution of the support functions σ_C and σ_D. The following lemma describes the intersection between the set F and L_1; for convenience, we state the result in terms of

$$\gamma_F(x) = \inf_{s > 0} \left\{ \frac{1}{s} : \; sx \in F \right\},$$

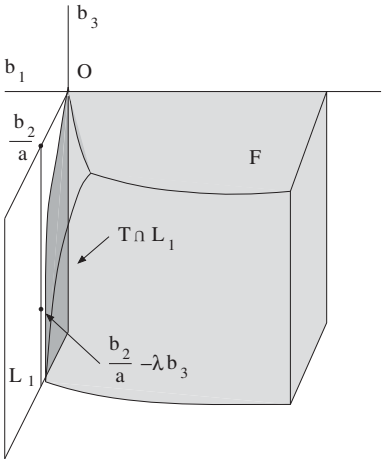

FIG. 3.3. *Intersection between F and L_1.*

the gauge function of the set F.

LEMMA 3.3. *The set F is a closed and convex subset of the Euclidean space X. Moreover, $F \cap L_1 = T \cap L_1$, and thus (see Figure* 3.3*)*

$$\gamma_F(x) \geq a|x \cdot b_2| \quad \forall x \in L_1, \tag{3.7}$$

$$\gamma_F(x) > 1 \quad \forall x \in L_1 \text{ such that } a|x \cdot b_2| = 1, \tag{3.8}$$

and

$$\lim_{\lambda \to +\infty} \gamma_F \left(\frac{b_2}{a} - \lambda b_3 \right) = 1. \tag{3.9}$$

Proof of Lemma 3.3. Recall that the sum $Z_1 + Z_2$ of two closed and convex subsets Z_1 and Z_2 of an Euclidean space is always convex. This sum is moreover closed, provided that Z_1 and $-Z_2$ do not contain two parallel half-lines (see [12, Corollary 9.1.2]). This is obviously the case for the pairs of closed and convex sets P_1 and S, as well as P_2 an T, and thus the sets $P_1 + S$ and $P_2 + T$ are closed and convex, and the same clearly holds also for the set F, which is their intersection.

It has already been noticed that all the sets P_1, P_2, S, and T lay within E_1; accordingly, the sum of two elements x_1 and x_2 from either P_1 and S, or P_2 and T, is contained within the delimiting hyperplane L_1 if and only if both elements x_1 and x_2 belong to L_1. In other words,

$$(P_1 + S) \cap L_1 = (P_1 \cap L_1) + (S \cap L_1),$$

$$(P_2 + T) \cap L_1 = (P_2 \cap L_1) + (T \cap L_1),$$

and note that $P_1 \cap L_1 = P_2 \cap L_1 = \{0\}$ to deduce that

$$\begin{aligned} F \cap L_1 &= ((P_1 + S) \cap L_1) \cap ((P_2 + T) \cap L_1) \\ &= (S \cap L_1) \cap (T \cap L_1) = (S \cap T) \cap L_1. \end{aligned}$$

Recall that $T \subset S$, and deduce that $F \cap L_1 = T \cap L_1$.

This relation may be used in order to compute the value of $\gamma_F(x)$ for elements $x \in L_1$, since it obviously holds that

$$\gamma_F(x) = \gamma_{F\cap L_1}(x) = \gamma_{T\cap L_1}(x) \quad \forall x \in L_1.$$

Use the fact that

$$T \cap L_1 \subset S \cap L_1 \subset M = \{x \in X : x \cdot b_1 = 0, -1 \le ax \cdot b_2 \le 1\}$$

to deduce that

$$\gamma_{T\cap L_1}(x) \ge \gamma_M(x) = a|x \cdot b_2| \quad \forall x \in L_1,$$

that is, relation (3.7).

In order to prove relation (3.8), note that, for every $x \in T \cap L_1$ we have $a|x\cdot b_2| < 1$. Accordingly, relation $a|x\cdot b_2| = 1$ implies that $x \notin T \cap L_1$. Let us now use [12, Corollary 9.7.1], which says that $T \cap L_1 = \{y : \ \gamma_{T\cap L_1}(y) \le 1\}$, and deduce that $\gamma_{T\cap L_1}(x) > 1$.

Finally, if $\lambda \ge 1$, standard computation shows

$$\frac{\sqrt{4\lambda^2+1}-1}{2\lambda}\left(\frac{b_2}{a} - \lambda b_3\right) \in T \cap L_1;$$

thus

$$\gamma_{T\cap L_1}\left(\frac{b_2}{a} - \lambda b_3\right) \le \frac{2\lambda}{\sqrt{4\lambda^2+1}-1}. \tag{3.10}$$

Use relation (3.8) for $x = \left(\frac{b_2}{a} - \lambda b_3\right)$ to see that

$$1 < \gamma_{T\cap L_1}\left(\frac{b_2}{a} - \lambda b_3\right); \tag{3.11}$$

relation (3.9) simply comes from relations (3.10) and (3.11). □

An important step in proving that the pair of closed and convex sets (C, D) has the strong CHIP is to determine their intersection $C \cap D$.

LEMMA 3.4. *It holds that*

$$C \cap D = x_0 + (F + Rb_3)^\star. \tag{3.12}$$

Proof of Lemma 3.4. Use the fact that $R_+(-b_3) \subset T \subset S$ to deduce that $R_+(-b_3) \subset F$, and thus that $F^\star \subset (-E_3)$. Accordingly, $D \subset x_0 + (-E_3)$, and as $C \subset x_0 + E_3$, we obtain that

$$C \cap D \subset (x_0 + E_3) \cap (x_0 + (-E_3)) = x_0 + L_3,$$

where by L_3 we mean

$$L_3 = \{x \in X : \ x \cdot b_3 = 0\}.$$

In other words,

$$x_0 \cdot b_3 = x \cdot b_3 \quad \forall x \in C \cap D. \tag{3.13}$$

Consequently,

$$C \cap D = C \cap (D \cap (x_0 + L_3)) = C \cap (x_0 + (F^\star \cap L_3)). \tag{3.14}$$

Recall (see [2, Chapter 4, section 1, Corollary of Proposition 3]) that, for every closed and convex sets A and B containing 0, it holds that $(A \cap B)^\star = \overline{\text{co}}(A^\star \cup B^\star)$, where $\overline{\text{co}}(A)$ denotes the closed convex hull of the set A.

Thus, by using the bipolar theorem (see [2, Chapter 4, section 1, Proposition 3]) applied to the set F, and the obvious fact that $L_3^\star = Rb_3$, we deduce that

$$(F^\star \cap L_3)^\star = \overline{\text{co}}(F^{\star\star} \cup L_3^\star) = \overline{\text{co}}(F \cup Rb_3). \tag{3.15}$$

It is well known that for every convex set A and flat W, $\overline{\text{co}}\,(A \cup W) = \overline{\text{co}}\,(A + W)$. Apply this relation to the convex set F and the one-dimensional flat Rb_3 to prove that $\overline{\text{co}}\,(F \cup Rb_3) = \overline{\text{co}}\,(F + Rb_3)$; by virtue of relation (3.15) it follows that

$$(F^\star \cap L_3)^\star = \overline{\text{co}}\,(F + Rb_3).$$

Accordingly, $F^\star \cap L_3 = (F^\star \cap L_3)^{\star\star} = (\overline{\text{co}}\,(F + Rb_3))^\star$; as the polar of any set coincides with the polar of its closure, we have

$$F^\star \cap L_3 = (F + Rb_3)^\star. \tag{3.16}$$

Let us prove that the set $(F + Rb_3)^\star$ lies within C. Indeed, after an easy computation it results that

$$\begin{aligned} \overline{(T + Rb_3)} &= S + Rb_3 \\ &= N = \{x \in X : \ x \cdot b_1 \le 0,\, -1 \le ax \cdot b_2 \le 1\}; \end{aligned} \tag{3.17}$$

thus $N \subset \overline{(F + Rb_3)}$, which means that $(F + Rb_3)^\star \subset N^\star$.

But as

$$N^\star = \{x \in X : \, 0 \le x \cdot b_1,\, -a \le x \cdot b_2 \le a,\, 0 = x \cdot b_i \quad \forall i \ge 3\},$$

we have (see Proposition 3.2) $N^\star \subset A$, and thus

$$x_0 + (F + Rb_3)^\star \subset (x_0 + N^\star) \subset (x_0 + A) \subset C. \tag{3.18}$$

Relation (3.12) follows now from relations (3.14), (3.16), and (3.18). □

It thus becomes necessary to determine the sum between the closed and convex set F and the line Rb_3.

LEMMA 3.5. *It holds that*

$$\{x \in (P_1 + S) : \, x \cdot b_1 < 0\} + Rb_3 \subset F + Rb_3 \subset (P_1 + S) + Rb_3; \tag{3.19}$$

accordingly,

$$C \cap D = x_0 + (P_1 + S + Rb_3)^\star. \tag{3.20}$$

Moreover, the gauge functions γ_F and $\gamma_{P_1+S+Rb_3}$ fulfill the following property: For every $x \in X$ such that $x \cdot b_1 < 0$, there is $\theta(x) \ge 0$ such that

$$\gamma_{P_1+S+Rb_3}(x) = \gamma_F\left(x - \theta(x) b_3\right). \tag{3.21}$$

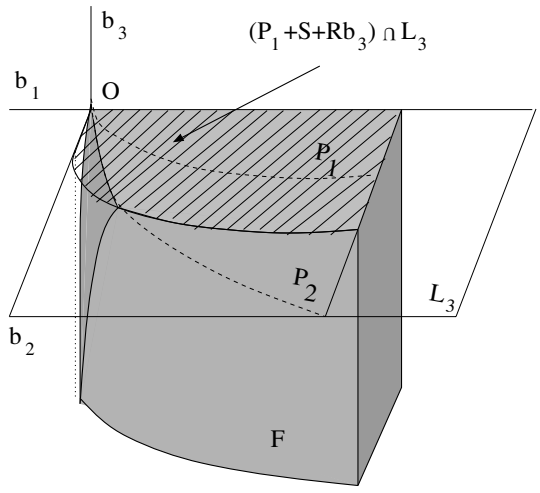

FIG. 3.4. *The sum between F and the line Rb_3.*

Proof of Lemma 3.5. On the basis of formula (3.17), we claim that $S + Rb_3$ is a closed and convex set. Moreover, there are no parallel half-lines within P_1 and $-(S + Rb_3)$, so, using again [12, Corollary 9.1.2], we deduce that the set $P_1 + S + Rb_3$ (see Figure 3.4) is closed and convex.

Let us prove the second inclusion in (3.19). As $F \subset (P_1 + S)$, it clearly follows that

$$F + Rb_3 \subset P_1 + S + Rb_3. \tag{3.22}$$

To establish the first inclusion in relation (3.19), we prove and use the fact that, for every $x \in P_1 + S$ such that $x \cdot b_1 < 0$, there is $\lambda(x) \geq 0$ such that $(x - \lambda(x)b_3) \in F$.

When $-1 < ax \cdot b_2 < 1$, it is easy to see that the value

$$\lambda(x) = x \cdot b_3 + \frac{a^2(x \cdot b_2)^2}{1 - a^2(x \cdot b_2)^2}$$

does the job. Indeed, the element $y = (x \cdot b_1)b_1$ lies within both P_1 and P_2, while

$$z = x - y - \lambda(x)b_3 = (x \cdot b_2)b_2 - \frac{a^2(x \cdot b_2)^2}{1 - a^2(x \cdot b_2)^2}b_3 + \sum_{i=4}^{n}(x \cdot b_i)b_i$$

is obviously contained in T, and thus in S. Accordingly,

$$x - \lambda(x)b_3 = y + (x - y - \lambda(x)b_3) \in (P_1 + S) \cap (P_2 + T) = F.$$

Let $x \in (P_1 + S)$ such that $x \cdot b_1 < 0$ and $a|x \cdot b_2| \geq 1$; to fix the ideas, admit that $ax \cdot b_2 \geq 1$. In order to define $\lambda(x)$ in this case, use the fact that x can be expressed as the sum $x = y + z$ of two elements y and z such that $y \in P_1$ and $z \in S$.

As $y \in P_1$, it follows that

$$y \cdot b_1 \leq -\frac{a(y \cdot b_2)^2}{4}; \tag{3.23}$$

since for every $z \in S$ it holds that $z \cdot b_1 \leq 0$, we deduce that thus $x \cdot b_1 \leq y \cdot b_1$. We may accordingly infer from relation (3.23) that

$$x \cdot b_1 \leq -\frac{a(y \cdot b_2)^2}{4}. \tag{3.24}$$

Use once more the fact that $z \in S$, to conclude that $-1 \leq az \cdot b_2 \leq 1$. Recall that $ax \cdot b_2 \geq 1$, and deduce that

$$(y \cdot b_2)^2 = (x \cdot b_2 - z \cdot b_2)^2 \geq \left(x \cdot b_2 - \frac{1}{a}\right)^2; \tag{3.25}$$

from relation (3.24) and (3.25) it follows that

$$x \cdot b_1 \leq -\frac{a\left(x \cdot b_2 - \frac{1}{a}\right)^2}{4}. \tag{3.26}$$

Combine the fact that $x \cdot b_1 \neq 0$ with relation (3.26) and deduce that

$$x \cdot b_1 < -\frac{a\left(x \cdot b_2 - \frac{1}{a}\right)^2}{8};$$

accordingly, for some parameter α such that $0 < a\alpha < 1$, we have

$$x \cdot b_1 < -\frac{a\left(x \cdot b_2 - \alpha\right)^2}{8}. \tag{3.27}$$

We can now define $\lambda(x)$ as

$$\lambda(x) = \frac{a^2\alpha^2}{1 - a^2\alpha^2}.$$

Inequality (3.27) proves that the element $(x - \alpha b_2 - \sum_{i=4}^{n}(x \cdot b_i)b_i)$ belongs to the set P_2; as obviously

$$\alpha b_2 - \frac{a^2\alpha^2}{1 - a^2\alpha^2}\, b_3 + \sum_{i=4}^{n}(x \cdot b_i)b_i \in T,$$

we deduce that

$$\begin{aligned} &x - \lambda(x)b_3 \\ &\quad = \left(x - \alpha b_2 - \sum_{i=4}^{n}(x \cdot b_i)b_i\right) + \left(\alpha b_2 - \frac{a^2\alpha^2}{1 - a^2\alpha^2}\, b_3 + \sum_{i=4}^{n}(x \cdot b_i)b_i\right) \\ &\quad \in P_2 + T. \end{aligned} \tag{3.28}$$

Remark that the case $ax \cdot b_2 \leq -1$ is similar to the case $ax \cdot b_2 \geq 1$. Indeed, when $ax \cdot b_2 \leq -1$, one has

$$(y \cdot b_2)^2 \geq \left(x \cdot b_2 + \frac{1}{a}\right)^2$$

instead of relation (3.25). The parameter α now lies between $-\frac{1}{a}$ and 0, and fulfills

$$x \cdot b_1 < -\frac{a\left(x \cdot b_2 + \alpha\right)^2}{8},$$

and not relation (3.26).

As in the case $ax \cdot b_2 \geq 1$, x is the sum of two elements: one in P_2, the other in T. However, when $ax \cdot b_2 \leq -1$, the element belonging to P_2 is $(x + \alpha b_2 - \sum_{i=4}^{n}(x \cdot b_i)b_i)$, and the one lying in T is $-\alpha b_2 - \frac{a^2\alpha^2}{1-a^2\alpha^2}\, b_3 + \sum_{i=4}^{n}(x \cdot b_i)b_i$.

Noticing that $S + R_+(-b_3) = S$, we have $(P_1 + S + R_+ b_3) = (P_1 + S)$. Thus, as $x \in P_1 + S$, we deduce that

$$x - \lambda b_3 \in P_1 + S \quad \forall \lambda \geq 0; \tag{3.29}$$

from (3.28) and (3.29) it follows that

$$(x - \lambda(x)b_3) \in (P_1 + S) \cap (P_2 + T) = F,$$

and therefore for every $x \in P_1 + S$ such that $x \cdot b_1 < 0$, there is $\lambda(x) \geq 0$ such that $x - \lambda(x)b_3 \in F$.

Use this observation to prove that

$$\{x \in P_1 + S : x \cdot b_1 < 0\} + Rb_3 \subset F + Rb_3,$$

which, together with relation (3.22), yields relation (3.19).

Relation (3.19) implies that the set $P_1 + S + Rb_3$ is the closure of the set $F + Rb_3$. Recalling that the polar of any set coincides with the polar of its closure, we deduce that

$$(F + Rb_3)^\star = (P_1 + S + Rb_3)^\star, \tag{3.30}$$

and relation (3.20) follows from formulas (3.12) and (3.30).

It remains to prove relation (3.21). To begin with, notice that from relation (3.19), it follows that $F \subset P_1 + S + Rb_3$, and thus

$$\gamma_{P_1+S+Rb_3} \leq \gamma_F. \tag{3.31}$$

Let us first prove that $\gamma_{P_1+S+Rb_3}(x)$ is real-valued for every $x \in X$ such that $x \cdot b_1 < 0$. In this respect, note that from relation (3.17) it results that $\{x \in X : x \cdot b_2 = x \cdot b_3 = 0\} \subset S + Rb_3$, and thus that

$$P_1 + \{x \in X : x \cdot b_1 = x \cdot b_2 = 0\} \subset (P_1 + S + Rb_3). \tag{3.32}$$

On the other hand, the set $P_1 + \{x \in X : x \cdot b_1 = x \cdot b_2 = 0\}$ contains all the elements $x \in X$ such that $x \cdot b_1 \leq -\frac{a(x \cdot b_2)^2}{4}$. As

$$\left(-\frac{4x \cdot b_1}{a(x \cdot b_2)^2}\, x\right) \cdot b_1 = -\frac{4(x \cdot b_1)^2}{a(x \cdot b_2)^2} = -\frac{a\left(\left(-\frac{4x \cdot b_1}{a(x \cdot b_2)^2}\, x\right) \cdot b_2\right)^2}{4},$$

this means that

$$-\frac{4x \cdot b_1}{a(x \cdot b_2)^2} x \in P_1 + \{x \in X : x \cdot b_1 = x \cdot b_2 = 0\}.$$

Combine the previous relation with formula (3.32) to deduce that

$$\gamma_{P_1+S+Rb_3}(x) \leq \frac{a(x \cdot b_2)^2}{|4x \cdot b_1|}.$$

Consequently, for every $x \in X$ such that $x \cdot b_1 < 0$ we have $\gamma_{P_1+S+Rb_3}(x) < +\infty$.

Let us first consider the case when $\gamma_{P_1+S+Rb_3}(x) = 0$, that is, when x belongs to a ray completely contained in $P_1 + S + Rb_3$. Taking into account the definitions of the sets P_1 and S, we have

$$[\gamma_{P_1+S+Rb_3}(x) = 0] \Leftrightarrow [x \cdot b_1 \leq 0 \text{ and } x \cdot b_2 = 0]\,;$$

similarly,

$$[\gamma_F(x) = 0] \Leftrightarrow [x \cdot b_1 \leq 0, x \cdot b_2 = 0 \text{ and } x \cdot b_3 \leq 0]\,.$$

In this case, $\theta(x) = \frac{x \cdot b_3 + |x \cdot b_3|}{2}$ obviously does the job.

Let us now turn to the case $\gamma_{P_1+S+Rb_3}(x) > 0$ and write that

$$\frac{x}{\gamma_{P_1+S+Rb_3}(x)} \in P_1 + S + Rb_3.$$

We deduce that there is a $\tilde{\lambda}(x) \in R$ such that

$$\frac{x}{\gamma_{P_1+S+Rb_3}(x)} - \tilde{\lambda}(x)b_3 \in P_1 + S.$$

Accordingly,

$$\left(\frac{x}{\gamma_{P_1+S+Rb_3}(x)} - \tilde{\lambda}(x)b_3\right) - \lambda\left(\frac{x}{\gamma_{P_1+S+Rb_3}(x)} - \tilde{\lambda}(x)b_3\right) b_3 \in F,$$

which means that

$$\gamma_F\left(x - \gamma_{P_1+S+Rb_3}(x)\left(\tilde{\lambda}(x) + \lambda\left(\frac{x}{\gamma_{P_1+S+Rb_3}(x)} - \tilde{\lambda}(x)b_3\right)\right) b_3\right) \leq \gamma_{P_1+S+Rb_3}(x). \tag{3.33}$$

Relations (3.31), (3.33) and the obvious fact that

$$\gamma_{P_1+S+Rb_3}(x) = \gamma_{P_1+S+Rb_3}(x + \nu b_3) \quad \forall \nu \in R$$

prove relation (3.21) with

$$\theta(x) = \gamma_{P_1+S+Rb_3}(x)\left(\tilde{\lambda}(x) + \lambda\left(\frac{x}{\gamma_{P_1+S+Rb_3}(x)} - \tilde{\lambda}(x)b_3\right)\right),$$

completing in this way the proof of Lemma 3.5. □

3.2. The main result. We claim that *the pair of closed and convex sets C and D has the strong CHIP.*

PROPOSITION 3.6. *The pair of closed and convex subsets C and D of the Euclidean space X has the strong CHIP.*

Proof of Proposition 3.6. Let $x_1 \in C \cap D$ and $y \in \partial\iota_{C\cap D}(x_1)$, $y \neq 0$. Our aim is to express y as the sum of two elements y_1 and y_2 from $\partial\iota_C(x_1)$ and $\partial\iota_D(x_1)$.

Let us first remark that, since $(x_0 + A) \subset C \subset (x_0 + E_3)$ (see Proposition 3.2), it follows that

$$R_+b_3 \subset \partial\iota_C(x) \tag{3.34}$$

for every $x \in x_0 + A$, in particular for every $x \in C \cap D$ (see Lemma 3.4 and relation (3.18)). Similarly, we deduce that

$$R_+(-b_3) \subset \partial\iota_D(x) \tag{3.35}$$

for every $x \in C \cap D$. The flat $\{x \in X :\ x \cdot b_i = 0\ \forall 1 \le i \le 3\}$ obviously lies within T, and thus in S and F. Thus D is contained within the flat $x_0 + \{x \in X :\ x \cdot b_i = 0\ \forall i \ge 4\}$, and we deduce that

$$\{x \in X :\ x \cdot b_1 = x \cdot b_2 = x \cdot b_3 = 0\} \subset \partial\iota_D(x) \quad \forall x \in D. \tag{3.36}$$

From relations (3.34), (3.35), and (3.36) it follows that

$$\{x \in X :\ x \cdot b_1 = x \cdot b_2 = 0\} \subset (\partial\iota_C(x) + \partial\iota_D(x)) \quad \forall x \in (C \cap D). \tag{3.37}$$

We address first the case when $y \cdot b_1 = 0$. A standard computation shows that

$$(P_1 + S + Rb_3)^\star \tag{3.38}$$

$$= \left\{ x \in X : x \cdot b_1 \ge \frac{(x \cdot b_2)^2}{a - |x \cdot b_2|}, -a < x \cdot b_2 < a,\ x \cdot b_i = 0 \quad \forall i \ge 3 \right\}.$$

From the previous relation it follows that the set $(P_1 + S + Rb_3)^\star$ is contained within the plane spanned by b_1 and b_2. For every $y \in X$ such that $y \cdot b_1 = 0$ it follows that

$$x \cdot y = (x \cdot b_2)(y \cdot b_2) \quad \forall x \in (P_1 + S + Rb_3)^\star. \tag{3.39}$$

The elements x_1 and x_0 are both in $C \cap D$; in view of relation (3.20) it appears that $(x_1 - x_0) \in (P_1 + S + Rb_3)^\star$.

From relation (3.38) it follows that $|(x_1 - x_0) \cdot b_2| < a$. Set

$$\alpha = \frac{a + |(x_1 - x_0) \cdot b_2|}{2},\ z_1 = \frac{\alpha^2}{a - \alpha} b_1 - \alpha b_2,\ z_2 = \frac{\alpha^2}{a - \alpha} b_1 + \alpha b_2;$$

thus $z_1, z_2 \in (P_1 + S + Rb_3)^\star$ and $z_1 \cdot b_2 < (x_1 - x_0) \cdot b_2 < z_2 \cdot b_2$.

Recall that, as $y \in \partial\iota_{C\cap D}(x_1)$, the linear functional $X \ni x \to (x \cdot y) \in R$ achieves its maximum on $C \cap D$ at x_1. Thus, on one hand,

$$(x_0 + z_1) \cdot y \le x_1 \cdot y,$$

that is, in view of relation (3.39),

$$(z_1 \cdot b_2)(y \cdot b_2) \le ((x_1 - x_0) \cdot b_2)\,(y \cdot b_2);$$

combine this relation with the fact that $z_1 \cdot b_2 < (x_1 - x_0) \cdot b_2$, and deduce that $y \cdot b_2 \ge 0$. On the other hand,

$$(x_0 + z_2) \cdot y \le x_1 \cdot y,$$

that is, once more by virtue of relation (3.39),

$$(z_2 \cdot b_2)(y \cdot b_2) \le ((x_1 - x_0) \cdot b_2)\,(y \cdot b_2);$$

in addition, as $(x_1 - x_0) \cdot b_2 < z_2 \cdot b_2$, we get $y \cdot b_2 \le 0$.

We may thus conclude that, when $y \cdot b_1 = 0$, it results that $y \cdot b_2 = 0$, and formula (3.37) proves that y is the sum of two elements from $\partial\iota_C(x_1)$ and $\partial\iota_D(x_1)$.

Consider now the case when $y \cdot b_1 \neq 0$, which, taking into account the fact that the half-line $(x_0 + R_+ b_1)$ is contained (as already remarked) within $C \cap D$, amounts to saying that $y \cdot b_1 < 0$.

It is well known (see [12, Theorem 14.5]) that for every closed and convex set Z containing 0, it holds $\sigma_Z = \gamma_{Z^\star}$. Use this relation for the set $(P_1 + S + Rb_3)^\star$ to obtain

$$\sigma_{(P_1+S+Rb_3)^\star} = \gamma_{P_1+S+Rb_3};$$

as (see 3.20) $(P_1 + S + Rb_3)^\star = (C \cap D) - x_0$, it follows that

$$\sigma_{(C\cap D)-x_0} = \gamma_{P_1+S+Rb_3}. \tag{3.40}$$

Similarly,

$$\sigma_{D-x_0} = \gamma_F. \tag{3.41}$$

From relations (3.21), (3.40), and (3.41) it follows that there is some $\theta(y) \geq 0$ such that

$$\sigma_{(C\cap D)-x_0}(y) = \sigma_{D-x_0}(y - \theta(y)b_3);$$

thus

$$\sigma_{C\cap D}(y) = \sigma_D(y - \theta(y)b_3) + \theta(y)x_0 \cdot b_3. \tag{3.42}$$

As $y \in \partial\iota_{C\cap D}(x_1)$, it results that $\sigma_{C\cap D}(y) = x_1 \cdot y$; use relation (3.42) to see that

$$\sigma_D(y - \theta(y)b_3) + \theta(y)x_0 \cdot b_3 = x_1 \cdot y. \tag{3.43}$$

Relation (3.13) reads $x_0 \cdot b_3 = x_1 \cdot b_3$. Equality (3.43) may thus be stated as

$$\sigma_D(y - \theta(y)b_3) + \theta(y)x_1 \cdot b_3 = x_1 \cdot y,$$

that is,

$$\sigma_D(y - \theta(y)b_3) = x_1 \cdot (y - \theta(y)b_3).$$

This means that $(y - \theta(y)b_3) \in \partial\iota_D(x_1)$.

Recall (see relation (3.34)) that $\lambda b_3 \in \partial\iota_C(x_1)$ for every $\lambda \geq 0$, and express y as $y = \theta(y)b_3 + (y - \theta(y)b_3)$, that is, the sum of an element from $\partial\iota_C(x_1)$ and the sum of another element from $\partial\iota_D(x_1)$. □

We finally claim that *the* inf-*convolution of the support functionals σ_C and σ_D is not exact at $\frac{b_2}{a}$*, a fact which completes the proof of Theorem 3.1.

PROPOSITION 3.7. *It holds that*

$$\sigma_C \square \sigma_D\left(\frac{b_2}{a}\right) = \frac{x_0 \cdot b_2}{a} + 1, \tag{3.44}$$

while

$$\sigma_C(y) + \sigma_D(z) > \frac{x_0 \cdot b_2}{a} + 1 \quad \forall y + z = \frac{b_2}{a}. \tag{3.45}$$

Proof of Proposition 3.7. Use the fact that (x_0+2ab_2) and (x_0-2ab_2) both belong to $x_0 + A$, and thus to C, to deduce that

$$\sigma_C(x) \geq \max\left((x_0 + 2ab_2) \cdot x, (x_0 - 2ab_2) \cdot x\right) = x_0 \cdot x + 2a|x \cdot b_2|. \tag{3.46}$$

From relation (3.7) it follows that

$$\gamma_F(x) \geq a|x \cdot b_2| \quad \forall x \in L_1.$$

Relation (3.41) reads $\sigma_{D-x_0} = \gamma_F$; hence, it results that

$$\sigma_D(x) = x_0 \cdot x + \gamma_F(x). \tag{3.47}$$

It follows that

$$\sigma_D(x) \geq x_0 \cdot x + a|x \cdot b_2| \quad \forall x \in L_1. \tag{3.48}$$

From relations (3.46) and (3.48) it results that

$$\begin{aligned} \sigma_C(x)+\sigma_D\left(\frac{b_2}{a} - x\right) & \\ \geq \; & x_0 \cdot x + 2a|x \cdot b_2| + x_0 \cdot \left(\frac{b_2}{a} - x\right) + a\left|\left(\frac{b_2}{a} - x\right) \cdot b_2\right| \\ \geq \; & \frac{x_0 \cdot b_2}{a} + 1 + a|x \cdot b_2| \quad \forall x \in X,\ x \cdot b_1 = 0. \end{aligned} \tag{3.49}$$

By taking into account relations (3.6) and (3.49) we prove that

$$\sigma_C \square \sigma_D\left(\frac{b_2}{a}\right) \geq \frac{x_0 \cdot b_2}{a} + 1. \tag{3.50}$$

As $x_0 \in C \subset (x_0 + E_3)$, it follows that

$$\sigma_C(\lambda b_3) = \lambda x_0 \cdot b_3 \quad \forall \lambda \geq 0.$$

Use relation (3.47) to deduce that

$$\begin{aligned} \sigma_C(\lambda b_3) + \sigma_D\left(\frac{b_2}{a} - \lambda b_3\right) & \\ = \lambda x_0 \cdot b_3 + \frac{x_0 \cdot b_2}{a} - \lambda x_0 \cdot b_3 + \gamma_F\left(\frac{b_2}{a} - \lambda b_3\right). & \end{aligned}$$

From the previous equality, together with relation (3.9), it yields that

$$\lim_{\lambda \to \infty}\left(\sigma_C(\lambda b_3) + \sigma_D\left(\frac{b_2}{a} - \lambda b_3\right)\right) = \frac{x_0 \cdot b_2}{a} + 1,$$

which, combined with inequality (3.50), proves relation (3.44).

Finally, let $x \in L_1$ be such that $x \cdot b_2 = 0$. Then (see relation (3.8))

$$\gamma_F\left(\frac{b_2}{a} - x\right) > 1,$$

and, as obviously $\sigma_C(x) \geq x_0 \cdot x$, it results that

$$\begin{aligned} \sigma_C(x) + \sigma_D\left(\frac{b_2}{a} - x\right) & \\ \geq x_0 \cdot x + \frac{x_0 \cdot b_2}{a} - x_0 \cdot x + \gamma_F\left(\frac{b_2}{a} - x\right) & \\ > \frac{x_0 \cdot b_2}{a} + 1 \quad \forall\, x \in X,\ x \cdot b_1 = x \cdot b_2 = 0. & \end{aligned} \tag{3.51}$$

Use relation (3.49) to deduce that, for every $x \in X$ such that $x \cdot b_1 = 0$ and $x \cdot b_2 \neq 0$, it holds that

$$\sigma_C(x) + \sigma_D\left(\frac{b_2}{a} - x\right) > \frac{x_0 \cdot b_2}{a} + 1. \tag{3.52}$$

Relation (3.45) follows from relations (3.5), (3.52), and (3.51). □

Acknowledgments. We would like to warmly thank the two anonymous referees. Their careful reading of the paper allowed us to correct a significant number of typos and errors and largely contributed to the final form of the article.

AMBIGUOUS RISK MEASURES AND OPTIMAL ROBUST PORTFOLIOS*

GIUSEPPE C. CALAFIORE†

Abstract. This paper deals with a problem of guaranteed (robust) financial decision-making under model uncertainty. An efficient method is proposed for determining optimal robust portfolios of risky financial instruments in the presence of ambiguity (uncertainty) on the probabilistic model of the returns. Specifically, it is assumed that a *nominal* discrete return distribution is given, while the *true* distribution is only known to lie within a distance d from the nominal one, where the distance is measured according to the Kullback–Leibler divergence. The goal in this setting is to compute portfolios that are worst-case optimal in the mean-risk sense, that is, to determine portfolios that minimize the maximum with respect to all the allowable distributions of a weighted risk-mean objective. The analysis in the paper considers both the standard variance measure of risk and the absolute deviation measure.

Key words. worst-case financial risk, portfolio selection, asset allocation, statistical ambiguity, robust optimization

1. Introduction.

A classical problem in computational finance is that of optimally selecting a portfolio of finitely many risky assets so as to maximize the expected return of the investment while keeping "risk" under control. In the mainstream approach, dating back to the seminal work of Markowitz [25], risk is measured according to the variance of the portfolio return, and the determination of an optimal portfolio amounts to the solution of a convex quadratic programming problem. Since the introduction of this basic mean-variance model for portfolio selection, however, many criticisms have been raised on its practical relevance, especially in regard to the sensitivity of the optimal portfolios with respect to the statistical errors in the parameters (the estimated expected returns and covariances of the assets), and possible remedies have been proposed. An in-depth overview of this literature is out of the scope of the present work, but the interested reader could find some useful pointers in [3, 6, 8, 26].

More recently, the issue of model uncertainty in portfolio optimization has been the subject of study from different groups of researchers; see, for instance, [13, 18, 24, 34, 37]. Many of these recent contributions propose ideas and computational tools derived from the robust convex optimization field [4, 14]. The general approach in this setting is to model the uncertain market parameters (expected returns and covariances) as deterministic unknown-but-bounded quantities, and then take a worst-case approach where an optimal portfolio is sought that minimizes the worst risk that the investor may face as the market parameters vary in any possible way inside their admissible domains. These deterministic models are practically and theoretically sound, since they either are naturally derived from confidence regions around the least-squares estimates of the market parameters (see [18]) or may reflect an analyst feeling

†Dipartimento di Automatica e Informatica, Politecnico di Torino, 10129 Torino, Italy (giuseppe.calafiore@polito.it).

of the reliability of the parameter estimates. In this latter case, the uncertainty model typically takes the form of elementwise bounds on some or all entries of the expected return vector and covariance matrix; see [13, 34]. Specifically, El Ghaoui, Oks, and Oustry in [13] consider the problem of computing and optimizing the worst-case value-at-risk of a portfolio, under bounded uncertainty on the mean and covariance matrix of the returns, and show how the computation can be efficiently performed by recasting the problem in the form of a semidefinite optimization program [33, 35]. Goldfarb and Iyengar in [18] develop a robust factor model for the returns, show how the uncertainty description can be naturally obtained from confidence regions of standard statistical estimation techniques, and pose the corresponding robust allocation problem in the form of a convex second order cone program (SOCP); see [23]. Tütüncü and Koenig in [34] propose the use of an interval uncertainty model for the return mean and covariance and solve the resulting worst-case Markowitz problem via an ad hoc saddle-point algorithm.

While the mentioned approaches are specific to portfolio selection problems, more general models dealing with uncertainty in the underlying probability measures have a long history and have been studied in different fields, such as economics, finance, and stochastic optimization; see, e.g., [7, 11, 12, 32, 36]. Uncertainty in the probabilistic model is usually referred to as *ambiguity* in the decision theory literature. The recent work from Erdoğan and Iyengar [15] discusses ambiguous chance-constrained problems and employs the Prohorov metric to describe the uncertainty "ball" of admissible distributions. As we shall see in section 2.1, in this paper we adopt a similar approach for describing the "ambiguity" set around a nominal distribution and employ the Kullback–Leibler divergence function as a distance measure among distributions. This distance measure has nice invariance and convexity properties, and the degree of ambiguity in this metric can be estimated from samples; see [20].

The main goal of this paper is to present an efficient computational framework for robust portfolio selection in the situation of asset returns described by an ambiguous discrete joint probability distribution. We consider two risk measures (see [2, 30]) given by composite objectives of the form $\rho(x,\pi) - \gamma\mu(x,\pi)$, where $\rho(x,\pi)$ is either the variance or the expected absolute deviation of the portfolio, $\mu(x,\pi)$ is the portfolio expected return, and γ is a nonnegative parameter. Here, x denotes the portfolio mix and π the discrete distribution of the returns (see section 2 for precise definitions and notation). The measure based on the expected absolute deviation is (for $\gamma \geq 2$) a *coherent* measure of risk in the sense of Artzner et al. [2]. The measure based on the variance is instead not coherent, since it violates a monotonicity condition; see [30]. However, the use of this latter measure is justified by both historical reasons and its wide popularity.

In the *nominal* case—i.e., when the probability distribution π is known and given—minimizing the above objectives is equivalent either to a standard Markowitz problem (in the case of the variance-based risk measure) or to the absolute deviation problem, discussed, for instance, in [21, 31]. It is well known that, in this latter case, the optimal portfolio can be found by solving a linear programming problem.

The key point in this paper is to consider the return distribution π to be imprecisely known. In particular, we assume that a nominal value η for the distribution is given, but that the actual π is only known to lie in a region at distance no larger than d from its nominal value, where d is a user-definable parameter that quantifies the (lack of) confidence in the nominal probability (the "index of ambiguity," in the terminology of [20]). To measure the distance among distributions, we use the stan-

dard metric given by the Kullback–Leibler divergence. In this setting, we define the worst-case risk of a portfolio x as the supremum of $\rho(x,\pi)-\gamma\mu(x,\pi)$ for π that ranges over its uncertainty set. An optimal worst-case portfolio is a composition vector x that minimizes this worst-case risk.

We detail in the paper two numerical schemes that permit us to efficiently evaluate and optimize the worst-case risk in both the variance and the absolute deviation cases. For the variance-based risk measure, the worst-case optimal portfolio can be determined using an interior-point barrier method, in conjunction with an analytic center cutting plane technique. The absolute deviation-based risk measure poses a slight additional complication, due to nonconcavity in π of this function. This issue is here resolved by adding a suitable line search to the algorithm.

The paper is organized as follows. Section 2 sets the stage by providing the basic definitions and introducing the distribution uncertainty model. Section 3 discusses a barrier method for computing the worst-case variance-based risk of a given portfolio, whereas section 4.1 describes the overall cutting plane algorithm for optimizing the worst-case risk over the portfolio composition. Section 5 extends the methodology to the absolute deviation-based risk measure. Some numerical examples are presented in section 6, and conclusions are finally drawn in section 7. To improve readability, some of the technical details have been relegated to appendices.

1.1. Notation. Whenever useful for notational compactness, we use MATLAB-like notation for operations on vectors. If x, y are two vectors of compatible dimensions, relational operators such as $>, \geq$, etc., are to be intended elementwise (e.g., $x > y$ means that all entries of vector $x - y$ are positive). Similarly, powers and operators $+, -, *, /$ work elementwise, and the same holds for standard functions. For example, $\log x/y$ denotes a vector whose ith entry is $\log x_i/y_i$.

2. Preliminaries. Consider a collection of assets or asset classes $a_1, \ldots, a_n$ and let

$$r \doteq \begin{bmatrix} r_1 & \cdots & r_n \end{bmatrix}^\top$$

be a random vector describing the returns of the considered assets over a fixed period of time. Let $r(1), \ldots, r(T)$ be T possible scenarios for the outcomes of the random return vector r, and let π_k be the probability associated to the scenario $r(k)$, with the obvious properties that

$$\pi_k \geq 0, \quad k = 1, \ldots, T,$$
$$\sum_{k=1}^{T} \pi_k = 1.$$

Defining the probability vector

$$\pi \doteq [\pi_1 \ \cdots \ \pi_T]^\top,$$

the two previous conditions are simply rewritten as $\pi \geq 0$, $\mathbf{1}^\top \pi = 1$, where $\mathbf{1}$ denotes a vector of ones of suitable dimensions. Now let

$$x \doteq \begin{bmatrix} x_1 & \cdots & x_n \end{bmatrix}^\top$$

be a vector such that x_i represents the fraction of an investor portfolio that is invested in asset a_i. We shall refer to x as the "portfolio composition," or "portfolio mix."

The portfolio composition can be subject to various kinds of constraints, which we assume to be representable by the condition

$$x \in \mathcal{X}, \quad \text{where } \mathcal{X} \text{ is a given polytope.}$$

For example, a typical form for the set $\mathcal{X}$ is

$$\mathcal{X} = \left\{ x : \sum_{i=1}^{n} x_i = 1,\ x_i \geq 0 \text{ for } i = 1, \ldots, n \right\}, \tag{2.1}$$

which reflects the standard situation where the investor cannot hold a negative amount of an asset (i.e., short-selling is not allowed). However, the results in this paper are not restricted to the specific admissible portfolios set in (2.1) and apply to the general polytopic case.

With the positions above, the investor's total return at the end of the investment period is represented by the random variable

$$w \doteq r^\top x, \tag{2.2}$$

whose expected value is

$$\mu(x, \pi) \doteq \mathrm{E}\left\{ r^\top x \right\} = \sum_{k=1}^{T} \pi_k r^\top(k) x = \left(\sum_{k=1}^{T} \pi_k r^\top(k) \right) x = \hat{r}^\top(\pi) x,$$

where $\hat{r}(\pi) \doteq \mathrm{E}\{r\} = \sum_{k=1}^{T} \pi_k r(k)$.

The portfolio risk is quantified as a measure of variability of w around its expectation. A classical measure of variability (see, e.g., [25]) is given by the *variance*

$$\rho_2(x, \pi) \doteq \mathrm{E}\left\{ \left(r^\top x - \mathrm{E}\left\{ r^\top x \right\} \right)^2 \right\} = x^\top \Sigma(\pi)\, x, \tag{2.3}$$

where

$$\Sigma(\pi) \doteq \mathrm{E}\left\{ (r - \hat{r}(\pi))(r - \hat{r}(\pi))^\top \right\} = \sum_{k=1}^{T} \pi_k (r(k) - \hat{r}(\pi))(r(k) - \hat{r}(\pi))^\top$$

is the covariance matrix of r. In this paper, we also consider an alternative measure of risk, which is based on the expected absolute deviation, and whose justification in the portfolio selection context is discussed, for instance, in [21, 31]:

$$\rho_1(x, \pi) \doteq \mathrm{E}\left\{ \left| r^\top x - \mathrm{E}\left\{ r^\top x \right\} \right| \right\} = \sum_{k=1}^{T} \pi_k |r^\top(k) x - \mu(x, \pi)|.$$

Following a mean-risk approach, we introduce an objective function which represents a tradeoff between risk (variance or expected absolute deviation) and expected return of the portfolio. Specifically, for given $\gamma \geq 0$, we define an objective based on the variance measure

$$\Upsilon_2(x, \pi) \doteq \rho_2(x, \pi) - \gamma \mu(x, \pi) \tag{2.4}$$

and one based on the absolute deviation measure

$$\Upsilon_1(x, \pi) \doteq \rho_1(x, \pi) - \gamma \mu(x, \pi). \tag{2.5}$$

Notice that if the probability distribution π is known and given, then minimizing $\Upsilon_2(x,\pi)$ over $x \in \mathcal{X}$ is a well-known Markowitz problem, whose solution can be obtained by solving numerically a convex quadratic programming problem. Minimizing $\Upsilon_1(x,\pi)$ in this same situation amounts instead to solving a linear programming problem; see, for instance, [21, 31].

The point of this paper is to propose computationally efficient schemes for determining optimal worst-case portfolios, when the probability distribution π is not precisely known. To this end, we introduce in the next section an uncertainty model for π and define the related robust risk functions.

2.1. Distribution ambiguity and robust measures of risk. Assume that a *nominal* return probability distribution η is given, for instance, as a result of estimation from samples. Then the Kullback–Leibler (KL) divergence (see [22]) represents a natural measure of the expected amount of information in a sample from the unknown distribution for discriminating against η [19], and it is a frequently used information-theoretic "distance" measure between probability distributions; see, e.g., [1, 10]. If π, η are two probability vectors in $\mathbb{R}^T$, with $\eta > 0$ describing the nominal probability, the KL distance between π and η is defined as

$$\mathrm{KL}(\pi,\eta) \doteq \sum_{k=1}^{T} \pi_k \log \frac{\pi_k}{\eta_k}.$$

We shall henceforth assume that the "true" probability π is only known to lie within KL distance $d \geq 0$ from η, i.e., $\pi \in \mathcal{K}(\eta,d)$, where

$$\mathcal{K}(\eta,d) \doteq \{\pi \in \Pi : \mathrm{KL}(\pi,\eta) \leq d\},$$

Π being the probability simplex $\Pi = \{\pi : \pi \geq 0,\ \mathbf{1}^\top \pi = 1\}$.

$\mathcal{K}(\eta,d)$ thus represents the *ambiguity set* for the return distribution, and $d \geq 0$ is the uncertainty level (radius of ambiguity). The risk functions (2.4), (2.5), with $\pi \in \mathcal{K}(\eta,d)$, are *ambiguous* risk functions. The nominal distribution η and the ambiguity level may either be assigned by expert advice or estimated from data; see, for instance, [20]. In what follows we shall not investigate further the issue of determination of η and d and shall assume that these quantities are given data.

Remark 1 (domain, range, and convexity of $\mathrm{KL}(\pi,\eta)$). Notice that, since $\pi_k \log \pi_k$ is a convex function over the domain $\pi_k \geq 0$,[1] then $\mathrm{KL}(\pi,\eta)$ is a convex function in π over Π, and hence the uncertainty set $\mathcal{K}(\eta,d)$ is convex.

The function $\mathrm{KL}(\pi,\eta)$, with $\pi \in \Pi$, takes values in the interval $[0,\ \log 1/\eta_{\min}]$, where $\eta_{\min} = \min_{k=1,\ldots,T} \eta_k$. The lower end of the interval is attained for $\pi = \eta$, whereas the higher end is attained for $\pi = e_i$, where i is the index of the smallest element in η, and e_i is the ith vector in the standard basis of $\mathbb{R}^T$.

Figure 2.1 gives a pictorial idea of the shape of the set $\mathcal{K}(\eta,d)$ in a three-dimensional example where η is assumed to be the uniform distribution.

We pursue a worst-case approach in dealing with ambiguity in the risk functions. Notice that it is known (see [30, Theorem 2]) that the risk functions (2.4), (2.5), for a fixed probability π, can be represented in dual form as the result of a maximization

$$\Upsilon(x,\pi) = \max_{\zeta \in A(\pi)} \left[\langle \zeta, r^\top x\rangle_\pi - \Upsilon^*(\zeta)\right],$$

[1] It is assumed by continuity that $0 \log 0 = 0$.

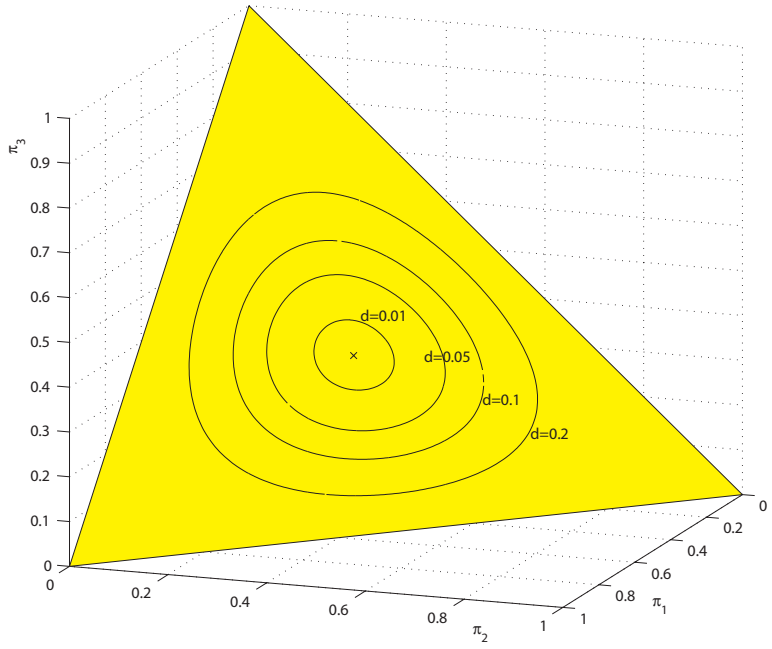

FIG. 2.1. *A visualization of the subsets $\mathcal{K}(\eta, d)$ of the probability simplex in a three-dimensional example with $\eta = [1/3\ 1/3\ 1/3]$ and $d = 0.01,\ 0.05,\ 0.1,\ 0.2$.*

where $A(\pi)$ is a closed convex set of measures, Υ^* is the conjugate of Υ, and $\langle \zeta, w \rangle_\pi = \sum_i \zeta_i w_i \pi_i$. In the the worst-case approach that we follow in this paper, the "robustness" of the nominal risk functions is improved by adding a second level of maximization over a set of admissible probabilities $\mathcal{K}$. That is, we shall consider robust risk functions of the form

$$\Upsilon_{\rm wc}(x) = \max_{\pi \in \mathcal{K}} \Upsilon(x, \pi) = \max_{\pi \in \mathcal{K}} \max_{\zeta \in A(\pi)} \left[\langle \zeta, r^\top x \rangle_\pi - \Upsilon^*(\zeta) \right].$$

Specifically, given the ambiguity model $\mathcal{K}(\eta, d)$ for the return distribution, we define the following worst-case (or robust) measures of risk for a portfolio with composition x:

$$\Upsilon_{\rm wc2}(x) \doteq \max_{\pi \in \mathcal{K}(\eta,d)} \rho_2(x, \pi) - \gamma \mu(x, \pi) \tag{2.6}$$

for the variance-based measure, and

$$\Upsilon_{\rm wc1}(x) \doteq \max_{\pi \in \mathcal{K}(\eta,d)} \rho_1(x, \pi) - \gamma \mu(x, \pi) \tag{2.7}$$

for the absolute deviation-based measure.

The distribution $\pi_{\rm wc}$ that attains the supremum in the above optimization problems is named the *worst-case distribution*, and the corresponding value function $\Upsilon_{\rm wc}(x)$ is the *worst-case risk* (to uncertainty level d) of the portfolio x. In the next section we provide an efficient numerical scheme for solving (2.6). We anticipate that the existence of a polynomial-time algorithm for computing the worst-case variance-based risk is due to the fact that we can construct a self-concordant barrier for the

convex domain $\mathcal{K}(\eta, d)$. Successively, in section 4, we develop a polynomial-time algorithm that permits us to further optimize $\Upsilon_{\text{wc2}}(x)$ with respect to x, and hence to find an optimal portfolio mix that minimizes the worst-case variance-based risk. In section 5, we describe a similar approach for dealing with the absolute deviation-based objective (2.7).

3. Computing the worst-case variance-based risk. Let the portfolio composition x be fixed, let $w(k) = r^\top(k)x$, $k = 1, \ldots, T$, and define

$$\mathbf{w} \doteq \left[\begin{array}{ccc} w(1) & \cdots & w(T) \end{array} \right]^\top.$$

Then from (2.2)–(2.3) we have

$$\rho_2(x, \pi) = \mathrm{E}\left\{(w - \mathrm{E}\{w\})^2\right\} = \mathrm{E}\left\{w^2\right\} - \mathrm{E}^2\{w\} = \pi^\top \mathbf{w}^2 - \pi^\top \Omega \pi,$$

where $\Omega \doteq \mathbf{w}\mathbf{w}^\top$. Since Ω is symmetric positive semidefinite, it follows that $\rho_2(x, \pi)$ is a concave function of the probability vector π. Therefore, the objective function (2.4),

$$\Upsilon_2(x, \pi) = \rho_2(x, \pi) - \gamma\mu(x, \pi) = -\pi^\top \Omega \pi - \pi^\top(\gamma \mathbf{w} - \mathbf{w}^2),$$

is also concave in π; hence problem (2.6) can be written in the equivalent form of a convex minimization problem as follows:

$$\Upsilon_{\text{wc2}} = -\min_{\pi} \pi^\top \Omega \pi + \pi^\top(\gamma \mathbf{w} - \mathbf{w}^2) \tag{3.1}$$

$$\text{subject to } \mathrm{KL}(\pi, \eta) \leq d, \tag{3.2}$$

$$\pi \geq 0, \tag{3.3}$$

$$\mathbf{1}^\top \pi = 1.$$

We next develop an interior-point barrier method for solving problem (3.1).

3.1. A logarithmic barrier method. For a fixed portfolio x, we solve problem (3.1) by solving a sequence of equality constrained problems of the form

$$\min_{\pi} \; f(\pi) \doteq t f_0(\pi) + \phi(\pi) \tag{3.4}$$

$$\text{subject to } \mathbf{1}^\top \pi = 1 \tag{3.5}$$

for increasing values of $t \geq 0$, where

$$f_0(\pi) \doteq \pi^\top \Omega \pi + \pi^\top(\gamma \mathbf{w} - \mathbf{w}^2)$$

is the objective function of (3.1),

$$b(\pi) \doteq \sum_{k=1}^{T} \pi_k \log \pi_k - \sum_{k=1}^{T} \pi_k \log \eta_k - d, \tag{3.6}$$

and

$$\phi(\pi) \doteq -\log\left(-b(\pi)\right) - \sum_{k=1}^{T} \log \pi_k \tag{3.7}$$

is a logarithmic barrier for the inequality constraints (3.2), (3.3). For fixed $t \geq 0$, we denote by $\pi^*(t)$ the corresponding optimal solution of (3.4). The *central path* is the curve $\pi^*(t)$ obtained varying t from 0 to ∞. A standard implementation of a barrier method is hence the following.

ALGORITHM 1 (barrier method [5]).
Given strictly feasible π, set $t = t(0) > 0$, $\varrho > 1$, tolerance $\epsilon > 0$.
repeat

1. Centering step:
   Compute $\pi^*(t)$ by solving (3.4) using the Newton method, starting at π.
2. Update: $\pi = \pi^*(t)$.
3. Stopping criterion: quit if $(T+1)/t < \epsilon$.
4. Increase t: $t = \varrho t$.

Notice that since $\eta > 0$, an initial feasible point for the algorithm is simply given by $\pi = \eta$. For this algorithm, $\pi^*(t)$ tends to the optimal solution of problem (3.1) as $t \to \infty$. The convergence properties of the method are analyzed in terms of the number of *outer iterations* (centering steps) needed to reach a solution with the desired accuracy ϵ and the number of *inner iterations* (i.e., the iterations required by the Newton method to compute each center, up to accuracy $\epsilon_{\rm nw}$). A standard result states that the number of outer iterations (centering steps) is given exactly by (see [5, section 11.3.3])

$$1 + \left\lceil \frac{\log(T+1)/(\epsilon t(0))}{\log \varrho} \right\rceil.$$

The analysis of complexity of each centering step relies on the property of *self-concordance* of the objective function in (3.4), which is discussed next.

3.2. Centering step and self-concordance. In their seminal work [28], Nesterov and Nemirovskii provided a key condition under which the complexity of the Newton method could be analyzed, that is, self-concordance of the objective function. We next show that the objective function in (3.4) is indeed self-concordant and provide a bound on the number of Newton steps required in each centering phase.

We start with some definitions. A function of a scalar variable $\psi(z) : \mathbb{R} \to \mathbb{R}$ is self-concordant if it is convex and

$$|\psi^{(3)}(z)| \leq k \psi^{(2)}(z)^{3/2}$$

for all z in the domain of ψ, where $\psi^{(2)}, \psi^{(3)}$ denote the second and the third derivatives of ψ, respectively, and k is a positive constant. A function $\psi(z)$ of vector variable $z \in \mathbb{R}^n$ is self-concordant if it is self-concordant along any line in its domain, i.e., if the function of scalar variable $\tilde{\psi}(\alpha) \doteq \psi(z + \alpha v)$ is a self-concordant function of $\alpha \in \mathbb{R}$ for all z in the domain of ψ and for all v.

The following proposition on the self-concordance of the barrier function (3.7) holds; see Appendix A for a proof.

PROPOSITION 3.1. *The function $\phi(\pi)$ in* (3.7) *is a self-concordant barrier for the domain*

$$\{(\pi, d) : \ \pi > 0, \varphi(\pi) < d\}.$$

Since the sum of self-concordant functions is self-concordant, and since convex quadratic functions are obviously self-concordant (they have zero third derivative; see also some standard rules of "self-concordant calculus" in [5]), we deduce from

Proposition 3.1 that the objective function in (3.4) is indeed self-concordant. It then follows that using an (equality-constrained) Newton method with backtracking line-search, each center can be computed up to accuracy ϵ_{nw} in at most (see, for instance, [5, section 11])

$$\frac{(T+1)(\varrho - 1 - \log \varrho)}{\ell} + \log_2 \log_2 \frac{1}{\epsilon_{\mathrm{nw}}}$$

Newton steps, where ℓ is a constant that depends on two technical parameters used in the line-search phase of the algorithm. We conclude this section by reporting explicitly the gradient and Hessian of the function $f(\pi)$ in (3.4). We have

$$\begin{aligned} \nabla f(\pi) &= t\nabla f_0(\pi) + \nabla \phi(\pi), \\ \nabla^2 f(\pi) &= t\nabla^2 f_0(\pi) + \nabla^2 \phi(\pi) \end{aligned}$$

with

$$\begin{aligned} \nabla f_0(\pi) &= 2\Omega\pi + (\gamma \mathbf{w} - \mathbf{w}^2), \\ \nabla \phi(\pi) &= \frac{1}{-b(\pi)} \nabla b(\pi) - \pi^{-1}; \quad \nabla b(\pi) = \mathbf{1} + \log \frac{\pi}{\eta} \end{aligned}$$

and

$$\begin{aligned} \nabla^2 f_0(\pi) &= 2\Omega, \\ \nabla^2 \phi(\pi) &= \frac{1}{-b(\pi)} \operatorname{diag}(\pi^{-1}) + \frac{1}{b^2(\pi)} \nabla b(\pi) \nabla^\top b(\pi) + \operatorname{diag}(\pi^{-2}). \end{aligned}$$

4. Minimizing the worst-case variance-based risk. In the previous section, we described a numerically efficient technique for computing the worst-case risk of a *given* portfolio mix x, i.e., for evaluating the function $\Upsilon_{\mathrm{wc2}}(x)$ in (2.6). We now elaborate on this technique and develop an efficient algorithm for determining a portfolio mix that minimizes the worst-case risk. That is, we now aim at solving the portfolio design problem

$$\min_{x \in \mathcal{X}} \ \Upsilon_{\mathrm{wc2}}(x). \tag{4.1}$$

We shall do so by employing an analytic center cutting plane technique, which is described in the next section. Notice preliminarily that function $\Upsilon_2(x, \pi)$ in (2.4),

$$\Upsilon_2(x, \pi) = x^T \Sigma(\pi) x - \gamma \hat{r}^\top(\pi) x,$$

is convex (and quadratic) in x for any given π, whence the function $\Upsilon_{\mathrm{wc2}}(x)$, which is defined as the pointwise maximum of $\Upsilon_2(x, \pi)$ over π, is also convex in x. At any given π, the gradient of $\Upsilon_2(x, \pi)$ with respect to x is

$$\nabla_x \Upsilon_2(x, \pi) = 2\Sigma(\pi) x - \gamma \hat{r}(\pi). \tag{4.2}$$

The gradient defines a supporting hyperplane for the epigraph of $\Upsilon_2(x, \pi)$, i.e.,

$$\Upsilon_2(z, \pi) \geq \Upsilon_2(x, \pi) + [\nabla_x \Upsilon_2(x, \pi)]^\top (z - x) \quad \forall z \in \mathcal{X}. \tag{4.3}$$

Now let x be a given point and let $\pi^*(x)$ be the probability vector that attains the optimal value in problem (2.6) (such an optimal argument is attained, since the feasible set is compact), so that

$$\Upsilon_{\mathrm{wc2}}(x) = \Upsilon_2(x, \pi^*(x)). \tag{4.4}$$

Evaluating (4.3) in $\pi = \pi^*(x)$, we get

$$\Upsilon_2(z, \pi^*(x)) \geq \Upsilon_2(x, \pi^*(x)) + [\nabla_x \Upsilon_2(x, \pi^*(x))]^\top (z - x) \quad \forall z \in \mathcal{X}.$$

Since $\Upsilon_{\rm wc2}(z) \geq \Upsilon_2(z, \pi^*(x))$, continuing the previous inequality on the left and using (4.4), we obtain

$$\Upsilon_{\rm wc2}(z) \geq \Upsilon_{\rm wc2}(x) + [\nabla_x \Upsilon_2(x, \pi^*(x))]^\top (z - x) \quad \forall z \in \mathcal{X}, \tag{4.5}$$

which means that $\nabla_x \Upsilon_2(x, \pi^*(x))$ is a subgradient of $\Upsilon_{\rm wc2}(x)$ at the point x. Notice that each time we solve problem (2.6)—or its equivalent formulation (3.1)—for a given x, we get both the value of $\Upsilon_{\rm wc2}(x)$ and the worst-case probability vector $\pi^*(x)$, and hence (evaluating (4.2) for $\pi = \pi^*(x)$) a subgradient of $\Upsilon_{\rm wc2}(x)$ at x.

4.1. An analytic center cutting plane algorithm for optimizing the portfolio mix. We now briefly describe an analytic center cutting plane (ACCP) method for solving problem (4.1). An overview of ACCP techniques for convex optimization can be found, for instance, in [29].

Let initially $\mathcal{P}_1 = \mathcal{X}$, and compute the analytic center $x^{(1)}$ of $\mathcal{P}_1$. The analytic center of a polytope can be efficiently computed by minimizing a logarithmic barrier via a Newton-type algorithm; see, for instance, [17]. Then solve problem (2.6) to get $\Upsilon_{\rm wc2}(x^{(1)})$, along with the worst-case probability $\pi^*(x^{(1)})$ and a subgradient

$$g_1 \doteq \nabla_x \Upsilon_2(x^{(1)}, \pi^*(x^{(1)}))$$

of $\Upsilon_{\rm wc2}(x)$ at $x = x^{(1)}$. Using inequality (4.5), notice next that for all points in the hyperplane

$$\{z : g_1^\top (z - x^{(1)}) > 0\}$$

we have that $\Upsilon_{\rm wc2}(z) > \Upsilon_{\rm wc2}(x^{(1)})$, hence all such points are worse than the current point $x^{(1)}$ in terms of the objective value that we are trying to minimize. Therefore, the optimal point should lie in the complementary hyperplane

$$\mathcal{H}_1 \doteq \{z : g_1^\top (z - x^{(1)}) \leq 0\}.$$

Hence, we update the current polytope by adding the constraint $\mathcal{H}_1$ to $\mathcal{P}_1$, i.e., we set

$$\mathcal{P}_2 = \mathcal{P}_1 \cap \mathcal{H}_1$$

and iterate the whole process (compute the analytic center $x^{(2)}$ of $\mathcal{P}_2$, etc.).

The convergence of this method relies on the fact that the polytopes $\mathcal{P}_k$ shrink at each iteration, thus eventually localizing the optimal solution x^*. The ACCP method converges to a solution in polynomial time. A precise assessment of the numerical complexity of the ACCP method and some of its variants has been discussed in several papers; see, for instance, [16, 17].

In a practical implementation of the method, we may terminate the iterations if either $\|x^{(k)} - x^{(k-1)}\|$ goes below a given threshold $\epsilon_{\rm ac}$ or the Chebyshev radius of $\mathcal{P}_k$ becomes sufficiently small.[2]

[2]The Chebyshev radius of a polytope is defined as the radius of the largest Euclidean hypersphere contained in the polytope. Computing the Chebyshev radius amounts to solving a linear programming problem; therefore checking the exit condition based on the Chebyshev radius requires some additional numerical effort.

A schematic implementation of an algorithm that permits us to solve (up to a numerical tolerance) the robust portfolio design problem is given next.

ALGORITHM 2 (ACCP).
Given the exit tolerance $\epsilon_{\text{ac}} > 0$, and the initial polytope $\mathcal{X}$, set $\mathcal{P} = \mathcal{X}$.
repeat

1. Centering step:
   Compute the analytic center x of $\mathcal{P}$.
2. Solve subproblem (2.6):
   Compute $\Upsilon_{\text{wc2}}(x)$, $\pi^*(x)$, and a subgradient g of Υ_{wc2} at x.
3. Stopping criterion:
   If Chebyshev-radius$(\mathcal{P}) < \epsilon_{\text{ac}}$, then quit.
4. Update the polytope:
   Set $\mathcal{P} = \mathcal{P} \cap \{z : g^\top (z - x) \leq 0\}$.

5. The worst-case absolute deviation-based risk. The robust design approach outlined in the previous section for the variance-based measure can be extended to the absolute deviation-based measure (2.7). In this section, we mainly discuss how to evaluate the worst-case absolute deviation risk of a given portfolio x,

$$\Upsilon_{\text{wc1}}(x) \doteq \max_{\pi \in \mathcal{K}(\eta,d)} \Upsilon_1(x,\pi), \tag{5.1}$$

and then hint at how to minimize $\Upsilon_{\text{wc1}}(x)$ over $x \in \mathcal{X}$ in section 5.1.1. This latter process is completely analogous to the one described for the variance-based risk function.

The main technical difference with respect to the case considered previously is that, contrary to the variance function $\rho_2(x,\pi)$, the absolute deviation function $\rho_1(x,\pi)$ is *not* concave in π; see, e.g., Figure 5.1, and Appendix B for a proof. Therefore, the inner problem (5.1) cannot be solved by directly using a logarithmic barrier method such as the one described in section 3.1. However, we show in the next section that (5.1) can still be solved efficiently to any given accuracy by using the barrier method in conjunction with a one-dimensional search.

5.1. Evaluating the worst-case absolute deviation risk. We assume the portfolio composition x to be fixed, and use the notation introduced in section 3. The absolute measure and objective function in (5.1) are then

$$\rho_1(\pi) \doteq \rho_1(x,\pi) = \sum_{k=1}^{T} \pi_k |w(k) - \mathbf{w}^\top \pi|, \tag{5.2}$$

$$\Upsilon_1(\pi) \doteq \Upsilon_1(x,\pi) = \sum_{k=1}^{T} \pi_k |w(k) - \mathbf{w}^\top \pi|, -\gamma \mathbf{w}^\top \pi. \tag{5.3}$$

As we mentioned before, the function $\rho_1(x,\pi)$, and hence $\Upsilon_1(x,\pi)$, is not concave (nor convex) over $\pi \in \Pi$. However, $\Upsilon_1(x,\pi)$ is concave (and actually linear) in π if we fix the value of the expected value: $\mathbf{w}^\top \pi \overset{!}{=} \mu$.

The solution idea is therefore the following one. First, determine the extreme feasible values for the portfolio mean return:

$$\mu_{\min} = \min_{\pi \in \mathcal{K}(\eta,d)} \mathbf{w}^\top \pi; \quad \mu_{\max} = \max_{\pi \in \mathcal{K}(\eta,d)} \mathbf{w}^\top \pi \tag{5.4}$$

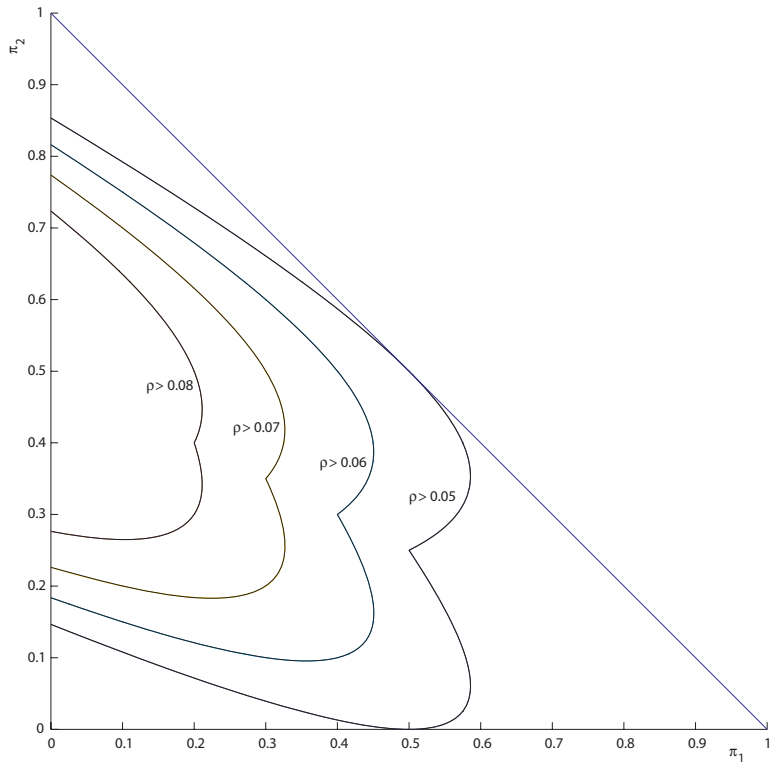

FIG. 5.1. *Projection of the superlevel sets of* (5.2) *on the* π_1, π_2 *plane in an example with* $T = 3$ *and* $\mathbf{w} = [0.1\ 0.2\ 0.3]^\top$.

(we show in Appendix C that these two values can be computed very quickly via a scalar bisection algorithm). Then, for $\mu \in [\mu_{\min},\ \mu_{\max}]$, define

$$\varphi(\mu) \doteq \max_{\pi \in \mathcal{K}(\eta,d)} \sum_{k=1}^{T} \pi_k |w(k) - \mu| - \gamma\mu \quad \text{subject to } \mathbf{w}^\top \pi = \mu. \tag{5.5}$$

Clearly, we have that

$$\Upsilon_{\mathrm{wc1}}(x) = \max_{\pi \in \mathcal{K}(\eta,d)} \Upsilon_1(x,\pi) = \max_{\mu \in [\mu_{\min},\ \mu_{\max}]} \varphi(\mu). \tag{5.6}$$

In practice, we divide the interval $[\mu_{\min},\ \mu_{\max}]$ into N grid points $\mu_1, \ldots, \mu_N$, where N is chosen in accordance to the desired solution accuracy. For $i = 1, \ldots, N$, computing $\varphi(\mu_i)$ is a convex optimization program that can be solved efficiently using, for instance, a barrier method such as the one described in section 3.1. An approximate solution to (5.1) is hence given by

$$\Upsilon_{\mathrm{wc1}}(x) \simeq \max_{i=1,\ldots,N} \varphi(\mu_i).$$

Notice that the main difficulty in (5.5) is due to the presence of the KL constraint. It is instructive to detail the solution of (5.5) in the particular situation when this

constraint is not present, since a closed-form solution is obtained in this case. The solution in (5.7) is computed basically at no cost, and it is optimal for problem (5.5) if the constraint $\mathrm{KL}(\pi, \eta) \le d$ happens to be inactive.

PROPOSITION 5.1. *Assume without loss of generality that the values* $w(1), \ldots, w(T)$ *are arranged in increasing order, and let* π *be such that*

$$\pi_1 = \frac{w(T) - \mu}{w(T) - w(1)}, \quad \pi_2 = 0, \ \ldots, \ \pi_{T-1} = 0, \quad \pi_T = \frac{\mu - w(1)}{w(T) - w(1)}. \tag{5.7}$$

If $\mathrm{KL}(\pi, \eta) \le d$, *then* π *is an optimal solution for problem* (5.5), *with corresponding optimal value function*

$$\varphi(\mu) = 2\frac{-\mu^2 + \mu(w(1) + w(T)) - w(1)w(T)}{w(T) - w(1)} - \gamma\mu. \tag{5.8}$$

A proof of this proposition is given in Appendix D.

5.1.1. Optimizing over the portfolio composition. The procedure described in the previous section can further be wrapped by a cutting plane scheme, similarly to the one described in section 4, in order to optimize $\Upsilon_{\mathrm{wc1}}(x)$ over the portfolio mix x.

Notice that the absolute deviation measure (2.5) is convex in x for any given π. A subgradient of $\Upsilon_1(x, \pi)$ at point x is given by

$$g_x(x, \pi) = \sum_{k=1}^{T} \pi_k (r(k) - \hat{r}(\pi)) s_k - \gamma \hat{r}(\pi),$$

where

$$s_k \doteq \begin{cases} 1 & \text{if } (r(k) - \hat{r})x \ge 0, \\ -1 & \text{otherwise.} \end{cases}$$

Now let $\pi^*(x)$ denote the probability of attaining the optimum in problem (5.6): following steps similar to (4.2)–(4.5) we have that $g_x(x, \pi^*(x))$ is a subgradient of $\Upsilon_{\mathrm{wc1}}(x)$ at x. This subgradient can be used in the cutting plane scheme of section 4.1, thus providing an overall polynomial-time method to solve the worst-case design problem $\min_{x \in \mathcal{X}} \Upsilon_{\mathrm{wc1}}(x)$.

6. Numerical examples. We considered a financial allocation problem over five asset classes, where each class is represented by a sector index. We used the following indices to represent the classes: (1) Russell 1000 Large Cap Growth Index (RKGR), (2) Russell 1000 Large Cap Value Index (RKVA), (3) Russell 2000 Small Cap Growth Index (R2KGR), (4) Russell 2000 Small Cap Value Index (R2KVA), (5) Merrill Lynch Intermediate Bond Index (MACTX), with historical data of daily logarithmic returns collected over the period from July 14, 2004 to December 30, 2005 ($T = 371$ scenarios). We assumed that the return on the next day after the observed period can take on any of the historical values, with equal probability. This amounts to choosing a uniform nominal distribution η on the scenarios, which also conforms to the approach undertaken in [21, 31].

Return-risk analysis. We first analyze a fixed portfolio x_{fix} which allocates 30% of the wealth in bonds, and the rest equally distributed among the remaining assets. The nominal expected return for this portfolio is $\mu(x_{\mathrm{fix}}, \eta) = 3.8782 \times 10^{-4}$, the nominal

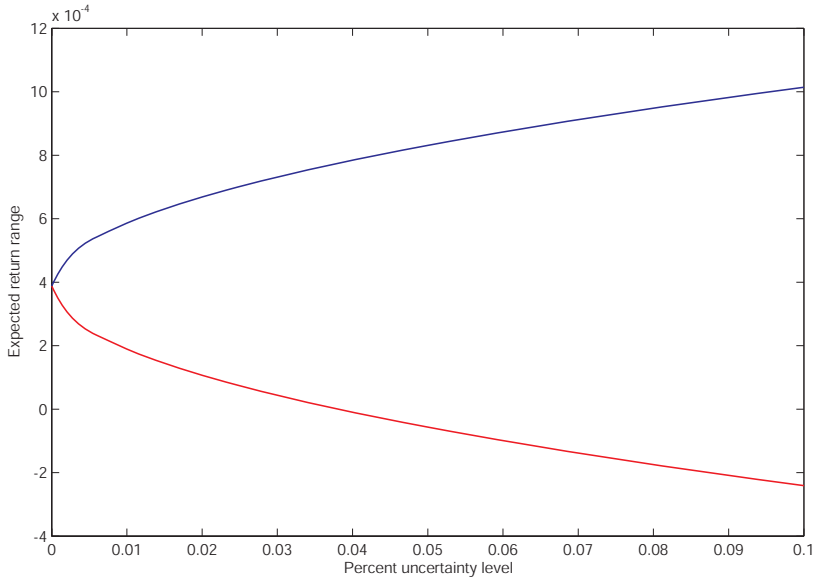

FIG. 6.1. *Upper and lower limits for the expected return of portfolio $x_{\rm fix}$ as a function of the percent uncertainty level (%u.l.).*

variance is $\rho_2(x_{\rm fix}, \eta) = 3.3307 \times 10^{-5}$, and the nominal absolute deviation risk is $\rho_1(x_{\rm fix}, \eta) = 0.0046$.

We can perform various worst-case analyses on this portfolio. First, we computed the range of variation of the expected return, using the technique discussed in Appendix C. The results are shown in Figure 6.1 (the uncertainty level in the plots is expressed in percent units of the maximum allowable value of d, i.e., $\%u.l. = 100\frac{d}{\log 1/\eta_{\min}}$).

Next, we evaluated the worst-case variance-based risk (2.6) of portfolio $x_{\rm fix}$, with $\gamma = 0.1$ and for increasing values of the percent uncertainty level; see Figure 6.2. An analogous plot, obtained from the absolute deviation-based risk measure (2.7) is instead shown in Figure 6.3. Notice from these plots that relatively low uncertainty levels may induce significant variations in the risk measure, with respect to the nominal (no uncertainty) situation.

Return-risk optimization. We next tested the ACCP algorithm described in section 4.1 for optimizing the worst-case variance-based risk. We computed worst-case optimal portfolios at different levels of uncertainty, which resulted in the plot shown in Figure 6.4. The composition of the worst-case optimal portfolios is shown in Figure 6.5.

Numerical performance. In the previous numerical tests, based on nonoptimized codes run under MATLAB 7.2 on an AMD Opteron 280 workstation, we experienced times of less than one minute to compute a worst-case optimal portfolio to an $\epsilon_{\rm ac} = 10^{-5}$ accuracy.

As a further example, we considered the 30 assets composing the Dow Jones Industrial Average Index (DJI) and collected $T = 138$ historical daily return scenarios from March 24, 2006 to October 9, 2006. We ran the variance-based ACCP algorithm on these data, setting $\gamma = 0.2$, $\%u.l. = 0.1$, and exit accuracy $\epsilon_{\rm ac} = 10^{-5}$. Algorithm 2 executed 82 iterations before returning the optimal portfolio. The total execution time was 23.9 seconds. Figure 6.6 shows the reduction in the Chebyshev radius of the

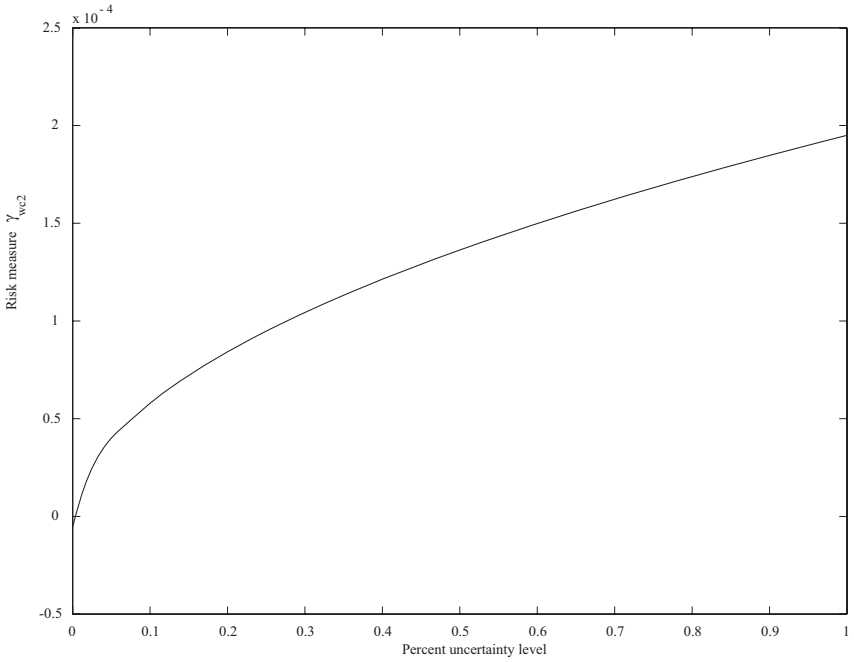

FIG. 6.2. *Worst-case variance-based risk measure of portfolio* x_{fix} *as a function of* %*u.l.*

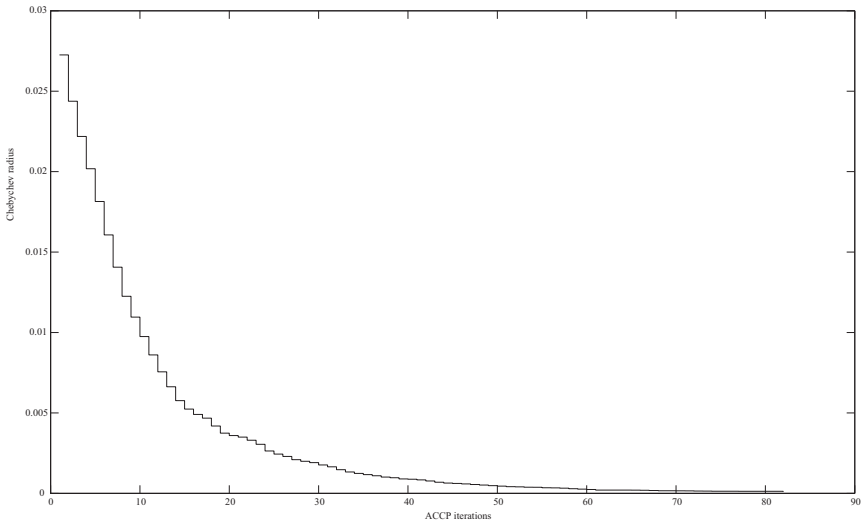

FIG. 6.6. *Chebyshev radius of the localization polytope versus iteration count for computing an optimal robust portfolio in the DJI example.*

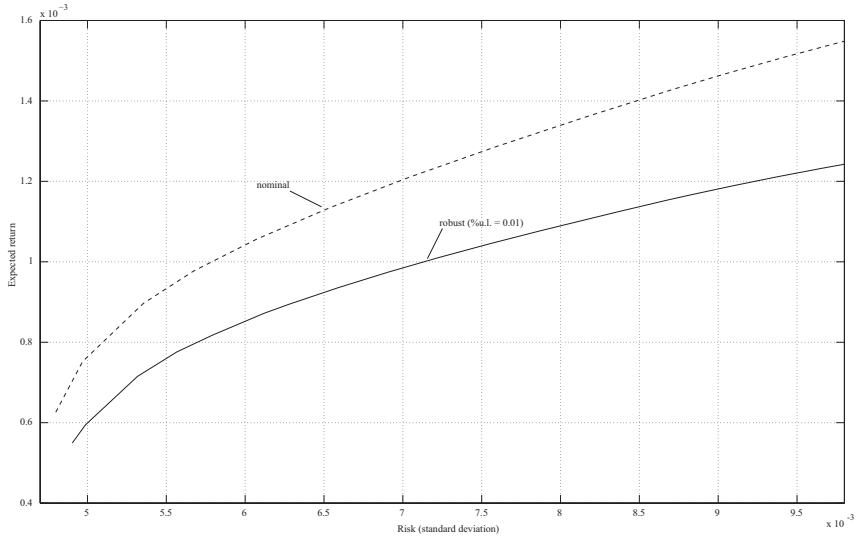

FIG. 6.7. *Nominal efficient frontier for DJI data (dashed), and robust version (solid) for ambiguity level* $\%u.l. = 0.01$.

localization polytope versus the iteration count.

Finally, Figure 6.7 shows a discrete approximation of a portion of the nominal and robust efficient frontiers for the DJI data. The frontiers have been computed at 20 discretized values of $\gamma \in [0.005, 0.3]$. The dashed curve plots the expected return and standard deviation of efficient portfolios under the nominal distribution η (uniform). The solid curve plots the expected return and standard deviation of efficient portfolios under the worst-case distributions (each value of γ results in a different worst-case distribution) for percent ambiguity level $\%u.l. = 0.01$. The worst-case curve was obtained in about 8.5 minutes.

7. Conclusions. Following the recent stream in the literature dealing with statistical model uncertainty (ambiguity) in asset allocation problems, this work explores the case where the ambiguity level in a discrete return distribution is measured according to the Kullback–Leibler divergence. A methodology is proposed for assessing and optimizing the worst-case risk of a portfolio under this type of uncertainty. Two standard risk measures (expected return composed with variance or absolute deviation) are examined, and polynomial-time algorithms are developed for solving efficiently the ensuing problems.

The proposed algorithms are based on interior-point barrier methods for convex optimization, in conjunction with a cutting plane technique. Although it is known in general that cutting plane methods have quite a high iterations-per-digit ratio, they do provide polynomial-time guaranteed convergence to the global optimum to any given practical accuracy. Moreover, in the specific application area discussed in this paper, they permit one to decouple a portfolio analysis phase (step 2 in Algorithm 2) from a mix optimization one (step 1). The numerical experiments show that worst-case optimal portfolios can be computed in reasonable time on a modern computer, and suggest that the proposed methods may be potentially useful in practice for controlling analytically the effects of model uncertainty on financial risk.

Appendix A. Proof of Proposition 3.1. Consider the function

$$\vartheta(\pi) = \sum_{k=1}^{T} \pi_k \log \pi_k - \sum_{k=1}^{T} \pi_k \log \eta_k,$$

which is convex and three times differentiable over the domain $\pi > 0$, and let $D^2\vartheta(\pi)[h,h]$, $D^3\vartheta(\pi)[h,h,h]$ denote, respectively, the second and third differentials of $\vartheta(\pi)$, taken at π along the direction $h \in \mathbb{R}^T$. That is,

$$D^2\vartheta(\pi)[h,h] = \frac{\mathrm{d}^2}{\mathrm{d}t^2}\vartheta(\pi+th)\bigg|_{t=0} = \sum_{k=1}^{T} \frac{h_k^2}{\pi_k},$$

$$D^3\vartheta(\pi)[h,h,h] = \frac{\mathrm{d}^3}{\mathrm{d}t^3}\vartheta(\pi+th)\bigg|_{t=0} = \sum_{k=1}^{T} \frac{-h_k^3}{\pi_k^2}.$$

We have that

$$\begin{aligned}
\left|D^3\vartheta(\pi)[h,h,h]\right| &\le \sum_{k=1}^{T} \frac{|h_k|^3}{\pi_k^2} = \sum_{k=1}^{T} \frac{h_k^2}{\pi_k} \cdot \frac{|h_k|}{\pi_k} \\
&\le \sqrt{\sum_{k=1}^{T} \left(\frac{h_k^2}{\pi_k}\right)^2} \cdot \sqrt{\sum_{k=1}^{T} \left(\frac{|h_k|}{\pi_k}\right)^2} \\
&\le \sum_{k=1}^{T} \frac{h_k^2}{\pi_k} \cdot \sqrt{\sum_{k=1}^{T} \left(\frac{|h_k|}{\pi_k}\right)^2} \\
&= D^2\vartheta(\pi)[h,h] \cdot \sqrt{\sum_{k=1}^{T} \frac{h_k^2}{\pi_k^2}},
\end{aligned}$$

where the first inequality in the chain is the triangle inequality, the second is Hölder's inequality, and the third follows from the inequality $\|x\|_2 \le \|x\|_1$ between the ℓ_2 and

ℓ_1 norms. Summarizing, the relation

$$\left|D^3\vartheta(\pi)[h,h,h]\right| \le D^2\vartheta(\pi)[h,h]\cdot\sqrt{\sum_{k=1}^{T}\frac{h_k^2}{\pi_k^2}}$$

holds for all $\pi > 0$ and $h \in \mathbb{R}^T$. We now apply a known result on logarithmic barriers: Due to the previous inequality, function $\vartheta(\pi)$ satisfies the hypotheses of Lemma 2 of [9], from which it follows that the function

$$-\log(d-\vartheta(\pi)) - \sum_{k=1}^{T}\log\pi_k$$

(which coincides with function $\phi(\pi)$ defined in (3.7)) is a self-concordant barrier for the domain $\{(\pi,d):\ \pi>0, \vartheta(\pi)<d\}$, thus concluding the proof. □

Appendix B. Nonconcavity of the absolute deviation function. Assume without loss of generality that the data $w(k)$ are arranged in increasing order. The function

$$\rho_1(\pi) = \sum_k \pi_k |w(k) - \mathbf{w}^\top\pi|$$

is not only nonconcave over the simplex, but it is nonconcave also on the restricted domains

$$R_i \doteq \{\pi\in\Pi : \mathbf{w}^\top\pi \in (w(i),\, w(i+1))\}.$$

For $\pi\in R_i$, we have that $w(k)-\mathbf{w}^\top\pi>0$ for $k\in K_+ \doteq \{i+1,\dots,T\}$ and $w(k)-\mathbf{w}^\top\pi<0$ for $k\in K_- \doteq \{1,\dots,i\}$. Hence, for $\pi\in R_i$, we may write

$$\begin{aligned}\rho_1(\pi) &= \sum_{k\in K_+}\pi_k(w(k)-\mathbf{w}^\top\pi) - \sum_{k\in K_-}\pi_k(w(k)-\mathbf{w}^\top\pi)\\ &= \sum_{k\in K_+}\pi_k w(k) - \sum_{k\in K_-}\pi_k w(k) - \mathbf{w}^\top\pi\left(\sum_{k\in K_+}\pi_k - \sum_{k\in K_-}\pi_k\right).\end{aligned}$$

From the latter expression, since $\sum_{k\in K_-}\pi_k = 1-\sum_{k\in K_+}\pi_k$ and $\sum_{k\in K_-}\pi_k w(k) = \mathbf{w}^\top\pi - \sum_{k\in K_+}\pi_k w(k)$, we further have

$$\rho_1(\pi) = 2\sum_{k\in K_+}\pi_k(w(k)-\mathbf{w}^\top\pi).$$

Now let $\pi^a,\pi^b\in R_i$ and consider

$$\begin{aligned}\rho_1\left(\frac{1}{2}(\pi^a+\pi^b)\right) &= 2\sum_{k\in K_+}\frac{\pi_k^a+\pi_k^b}{2}\left(w(k)-\mathbf{w}^\top\frac{\pi^a+\pi^b}{2}\right)\\ &= \frac{1}{2}\sum_{k\in K_+}\pi_k^a(w(k)-\mathbf{w}^\top\pi^a) + \frac{1}{2}\sum_{k\in K_+}\pi_k^b(w(k)-\mathbf{w}^\top\pi^b)\\ &\quad+\frac{1}{2}\sum_{k\in K_+}\pi_k^a(w(k)-\mathbf{w}^\top\pi^b) + \frac{1}{2}\sum_{k\in K_+}\pi_k^b(w(k)-\mathbf{w}^\top\pi^a)\end{aligned}$$

$$
\begin{aligned}
&= \frac{1}{2}\sum_{k\in K_+} \pi_k^a (w(k) - \mathbf{w}^\top \pi^a) + \frac{1}{2}\sum_{k\in K_+} \pi_k^b (w(k) - \mathbf{w}^\top \pi^b) \\
&+ \frac{1}{2}\sum_{k\in K_+} \pi_k^a (w(k) - \mathbf{w}^\top \pi^a) + \frac{1}{2}(\mathbf{w}^\top \pi^a - \mathbf{w}^\top \pi^b) \sum_{k\in K_+} \pi_k^a \\
&+ \frac{1}{2}\sum_{k\in K_+} \pi_k^b (w(k) - \mathbf{w}^\top \pi^b) - \frac{1}{2}(\mathbf{w}^\top \pi^a - \mathbf{w}^\top \pi^b) \sum_{k\in K_+} \pi_k^b \\
&= \frac{1}{2}\rho_1(\pi^a) + \frac{1}{2}\rho_1(\pi^b) + \frac{1}{2}(\mathbf{w}^\top \pi^a - \mathbf{w}^\top \pi^b) \sum_{k\in K_+} (\pi_k^a - \pi_k^b).
\end{aligned}
$$

The last term in the sum is sign-indefinite (in particular, it does not hold in general that $\mathbf{w}^\top \pi^a - \mathbf{w}^\top \pi^b > 0$ implies $\sum_{k\in K_+} \pi_k^a - \sum_{k\in K_+} \pi_k^b > 0$); hence ρ_1 is not concave over the domain R_i. To see this latter point, take, for instance, π^a all zero, except for $\pi_i^a = \pi_{i+1}^a = 1/2$, and π^b all zero, except for $\pi_{i-1}^b = 1/2 - \epsilon$, $\pi_{i+1}^b = 1/2 + \epsilon$, with

$$
\max\left(0,\, \epsilon_{\max} - \frac{1}{2}\frac{w(i+1) - w(i)}{w(i+1) - w(i-1)}\right) < \epsilon < \epsilon_{\max}; \quad \epsilon_{\max} \doteq \frac{1}{2}\frac{w(i) - w(i-1)}{w(i+1) - w(i-1)}.
$$

Then one can check by direct inspection that $\pi^a, \pi^b \in R_i$, $\mathbf{w}^\top \pi^a - \mathbf{w}^\top \pi^b > 0$, but $\sum_{k\in K_+} \pi_k^a - \sum_{k\in K_+} \pi_k^b < 0$.

Appendix C. Computing the range for the expected return. We discuss here an efficient technique for determining the extreme values (5.4) of the expected return of a given portfolio. Consider the problem

$$
\begin{aligned}
\mu_{\min} \doteq \min_{\pi} \quad & \mathbf{w}^\top \pi \\
\text{subject to } & \pi \in \mathcal{K}(\eta, d).
\end{aligned}
\tag{C.1}
$$

The Lagrangian for this problem is

$$
\mathcal{L}(\pi, \lambda_{(\pi)}, \lambda_{(\mathrm{kl})}, \nu_{(1)}) = \mathbf{w}^\top \pi - {\lambda_{(\pi)}}^\top \pi + \lambda_{(\mathrm{kl})}(\mathrm{KL}(\pi, \eta) - d) + \nu_{(1)}(\mathbf{1}^\top \pi - 1),
$$

where $\lambda_{(\pi)}, \lambda_{(\mathrm{kl})}, \nu_{(1)}$ are Lagrange multipliers (dual variables). We assume henceforth that $\lambda_{(\mathrm{kl})}$ is strictly positive.[3] The Lagrange dual function is

$$
\begin{aligned}
&g(\lambda_{(\pi)}, \lambda_{(\mathrm{kl})}, \nu_{(1)}) = \inf_{\pi} \mathcal{L}(\pi, \lambda_{(\pi)}, \lambda_{(\mathrm{kl})}, \nu_{(1)}) \\
&= -\lambda_{(\mathrm{kl})} d - \nu_{(1)} + \inf_{\pi} \left(\mathbf{q}^\top \pi + \lambda_{(\mathrm{kl})}\, \mathrm{KL}(\pi, \eta)\right),
\end{aligned}
$$

where

$$
\mathbf{q} \doteq \mathbf{w} - \lambda_{(\pi)} + \nu_{(1)}\mathbf{1}.
$$

Observe now that

$$
\nabla_\pi \left(\mathbf{q}^\top \pi + \lambda_{(\mathrm{kl})}\, \mathrm{KL}(\pi, \eta)\right) = \mathbf{q} + \lambda_{(\mathrm{kl})}(\mathbf{1} + \log \pi/\eta) = 0
$$

for

$$
\pi_k = \eta_k \mathrm{e}^{-\mathbf{q}_k/\lambda_{(\mathrm{kl})} - 1},
$$

[3] When the KL constraint is inactive at optimum, the optimal value of the dual variable $\lambda_{(\mathrm{kl})}$ is zero, due to the complementary slackness condition. However, in this case the solution to problem (C.1) is trivially given by $\min_k w(k)$.

which yields

$$\inf_{\pi}\left(\mathbf{q}^{\top}\pi+\lambda_{(\mathrm{kl})}\,\mathrm{KL}(\pi,\eta)\right)=-\lambda_{(\mathrm{kl})}\sum_{k}\eta_k\mathrm{e}^{-\mathbf{q}_k/\lambda_{(\mathrm{kl})}-1},$$

and hence the dual function

$$g(\lambda_{(\pi)},\lambda_{(\mathrm{kl})},\nu_{(1)})=-\lambda_{(\mathrm{kl})}d-\nu_{(1)}-\lambda_{(\mathrm{kl})}\sum_{k}\eta_k\mathrm{e}^{-\mathbf{q}_k/\lambda_{(\mathrm{kl})}-1}.$$

The dual to problem (C.1) is therefore

$$\begin{aligned}\mu_{\min}\doteq\ &\max -\lambda_{(\mathrm{kl})}d-\nu_{(1)}-\lambda_{(\mathrm{kl})}\sum_{k}\eta_k\mathrm{e}^{-\mathbf{q}_k/\lambda_{(\mathrm{kl})}-1}\\ \text{subject to }&\lambda_{(\mathrm{kl})}>0,\\ &\lambda_{(\pi)}\geq 0\end{aligned}$$

or, equivalently,

$$\begin{aligned}\mu_{\min}\doteq\ &-\min\ \lambda_{(\mathrm{kl})}d+\nu_{(1)}+\lambda_{(\mathrm{kl})}\sum_{k}\eta_k\mathrm{e}^{-\mathbf{q}_k/\lambda_{(\mathrm{kl})}-1}\\ \text{subject to }&\lambda_{(\mathrm{kl})}>0,\\ &\lambda_{(\pi)}\geq 0.\end{aligned}\tag{C.2}$$

Notice that, for fixed $\lambda_{(\mathrm{kl})},\lambda_{(\pi)}$, at the optimum the derivative of (C.2) with respect to $\nu_{(1)}$ must be zero, i.e.,

$$1+\lambda_{(\mathrm{kl})}\sum_{k}\eta_k\mathrm{e}^{-\mathbf{q}_k/\lambda_{(\mathrm{kl})}-1}\frac{-1}{\lambda_{(\mathrm{kl})}}\frac{\partial\mathbf{q}_k}{\partial\nu_{(1)}}=1-\sum_{k}\eta_k\mathrm{e}^{-\mathbf{q}_k/\lambda_{(\mathrm{kl})}-1}=0,$$

from which we obtain

$$\begin{gathered}\mathrm{e}^{-\nu_{(1)}/\lambda_{(\mathrm{kl})}}\sum_{k}\eta_k\mathrm{e}^{(\lambda_{(\pi),\mathrm{k}}-w(k))/\lambda_{(\mathrm{kl})}-1}=1\\ \Downarrow\\ \nu_{(1)}=\lambda_{(\mathrm{kl})}\left(\log\sum_{k}\eta_k\mathrm{e}^{(\lambda_{(\pi),\mathrm{k}}-w(k))/\lambda_{(\mathrm{kl})}}-1\right).\end{gathered}$$

Substituting this latter expression into (C.2), we write the dual in the following reduced form:

$$\begin{aligned}-\mu_{\min}\doteq&\min\lambda_{(\mathrm{kl})}d+\lambda_{(\mathrm{kl})}\log\sum_{k}\eta_k\mathrm{e}^{(\lambda_{(\pi),\mathrm{k}}-w(k))/\lambda_{(\mathrm{kl})}}\\ \text{subject to }&\lambda_{(\mathrm{kl})}>0,\\ &\lambda_{(\pi)}\geq 0.\end{aligned}$$

Observe further that, for any given $\lambda_{(\mathrm{kl})}>0$, the optimal choice for $\lambda_{(\pi)}$ is zero, which finally yields the dual in the form of a univariate convex problem:

$$\begin{aligned}-\mu_{\min}\doteq\min f_l(\lambda_{(\mathrm{kl})})\doteq&\lambda_{(\mathrm{kl})}d+\lambda_{(\mathrm{kl})}\log\sum_{k}\eta_k\mathrm{e}^{-\frac{w(k)}{\lambda_{(\mathrm{kl})}}}\\ \text{subject to }&\lambda_{(\mathrm{kl})}>0.\end{aligned}$$

An identical reasoning can be applied for computing the upper limit $\mu_{\max}$ of the mean range. In this case, we obtain

$$\mu_{\max} \doteq \min f_u(\lambda_{(\mathrm{kl})}) \doteq \lambda_{(\mathrm{kl})} d + \lambda_{(\mathrm{kl})} \log \sum_k \eta_k \mathrm{e}^{\frac{w(k)}{\lambda_{(\mathrm{kl})}}} \quad \text{subject to } \lambda_{(\mathrm{kl})} > 0. \tag{C.3}$$

Both problems can be readily solved via a bisection scheme (such as the one sketched in Algorithm 3 below), given the gradient of the objective function

$$g_l(\lambda) \doteq \frac{\partial f_l}{\partial \lambda} = \frac{1}{\lambda}\left(f_l(\lambda) + \frac{\sum_k w(k)\eta_k \mathrm{e}^{-w(k)/\lambda}}{\sum_k \eta_k \mathrm{e}^{-w(k)/\lambda}} \right)$$

for the lower mean limit, and

$$g_u(\lambda) \doteq \frac{\partial f_u}{\partial \lambda} = \frac{1}{\lambda}\left(f_u(\lambda) - \frac{\sum_k w(k)\eta_k \mathrm{e}^{-w(k)/\lambda}}{\sum_k \eta_k \mathrm{e}^{w(k)/\lambda}} \right)$$

for the upper limit.

ALGORITHM 3 (bisection).
Given initial $\lambda_l = 0$, $\lambda_r = 1$ and tolerance $\epsilon > 0$

1. while $g(\lambda_r) < 0$, let $\lambda_r = 2\lambda_r$, end while;
2. while $\lambda_r - \lambda_l > \epsilon$
   2.a let $\lambda = \frac{1}{2}(\lambda_r + \lambda_l)$
   2.b if $g(\lambda) > 0$, let $\lambda_r = \lambda$; else let $\lambda_l = \lambda$, end if
3. end while
4. return λ.

A perhaps interesting observation is that the function appearing in (C.3)

$$\lambda_{(\mathrm{kl})} \log \sum_k \eta_k \mathrm{e}^{\frac{w(k)}{\lambda_{(\mathrm{kl})}}}$$

tends to $\max_k w(k)$ as $\lambda_{(\mathrm{kl})} \to 0$. Indeed, for $\lambda_{(\mathrm{kl})} > 0$, this function is a "uniform smooth approximation" of the max function, using the terminology introduced in [27].

Appendix D. Proof of Proposition 5.1. Consider problem (5.5) *without* the KL constraint, and with the values $w(k)$ arranged in increasing order (see Figure D.1):

$$\varphi(\mu) \doteq \max_{\pi} \sum_{k=1}^{T} \pi_k |w(k) - \mu| \quad \text{subject to} \quad \begin{array}{r} \mathbf{w}^\top \pi = \mu, \\ \mathbf{1}^\top \pi = 1, \\ \pi \geq 0. \end{array} \tag{D.1}$$

It is immediate by inspection that (5.7) is a feasible solution for (D.1). We next show that this solution is actually optimal.

Let $d(k) \doteq |w(k) - \mu|$. The Lagrangian for problem (D.1) is

$$\mathcal{L}(\pi, \lambda, \nu) = -\sum_{k=1}^{T} \pi_k d(k) - \sum_{k=1}^{T} \lambda_k \pi_k + \nu_1 \left(\sum_{k=1}^{T} \pi_k w(k) - \mu \right) + \nu_2 \left(\sum_{k=1}^{T} \pi_k - 1 \right).$$

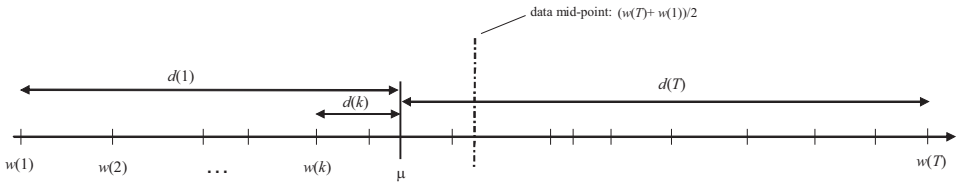

FIG. D.1. *Data arranged in increasing order. The $d(k)$ are the distances from the mean: $d(k) \doteq |w(k) - \mu|$.*

For a feasible π to be optimal, the Karush–Kuhn–Tucker (KKT) condition

$$\nabla_\pi \mathcal{L}(\pi, \lambda, \nu) = -\begin{bmatrix} d(1) \\ \vdots \\ d(T) \end{bmatrix} - \begin{bmatrix} \lambda_1 \\ \vdots \\ \lambda_T \end{bmatrix} + \nu_1 \begin{bmatrix} w(1) \\ \vdots \\ w(T) \end{bmatrix} + \nu_2 \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix} = 0 \tag{D.2}$$

must hold for some ν_1, ν_2 and $\lambda_k \geq 0$, along with the complementary slackness condition

$$\lambda_k \pi_k = 0, \quad k = 1, \ldots, T. \tag{D.3}$$

We now show that for the solution in (5.7) we can find ν_1, ν_2 and $\lambda_k \geq 0$ such that (D.2), (D.3) hold. From (D.2) we have

$$\lambda_k = \nu_1 w(k) + \nu_2 - d(k), \quad k = 1, \ldots, T. \tag{D.4}$$

Since $\pi_1 > 0, \pi_T > 0$, (D.3) implies $\lambda_1 = \lambda_T = 0$, and hence

$$\begin{aligned} \nu_1 w(1) + \nu_2 - d(1) &= 0, \\ \nu_1 w(T) + \nu_2 - d(T) &= 0, \end{aligned}$$

from which we obtain

$$\nu_1 = \frac{d(T) - d(1)}{w(T) - w(1)}, \quad \nu_2 = \frac{d(1)[w(T) - w(1)] - w(1)[d(T) - d(1)]}{w(T) - w(1)}. \tag{D.5}$$

Substituting into (D.4), for $k = 2, \ldots, T-1$, we get

$$\lambda_k = \frac{[d(T) - d(1)][w(k) - w(1)] + [w(T) - w(1)][d(1) - d(k)]}{w(T) - w(1)}. \tag{D.6}$$

We now verify that these λ_k are nonnegative. Define $K_- \doteq \{k : w(k) \leq \mu\}$ and $K_+ \doteq \{k : w(k) > \mu\}$. For $k \in K_-$ we have that (see Figure D.1)

$$w(k) - w(1) = d(1) - d(k); \quad w(T) - w(1) = d(1) + d(T),$$

which, once substituted in (D.6), give

$$\begin{aligned} \lambda_k &= \frac{[d(T) - d(1)][d(1) - d(k)] + [d(1) + d(T)][d(1) - d(k)]}{w(T) - w(1)} \\ &= \frac{2d(T)[d(1) - d(k)]}{w(T) - w(1)} \geq 0, \quad k \in K_-. \end{aligned}$$

Similarly, for $k \in K_+$ we have that

$$w(k) - w(1) = d(1) + d(k); \quad w(T) - w(1) = d(1) + d(T),$$

which, once substituted in (D.6), give

$$\begin{aligned}\lambda_k &= \frac{[d(T) - d(1)][d(1) + d(k)] + [d(1) + d(T)][d(1) - d(k)]}{w(T) - w(1)} \\ &= \frac{2d(1)[d(T) - d(k)]}{w(T) - w(1)} \geq 0, \quad k \in K_+.\end{aligned}$$

Overall, we have that the primal feasible solution (5.7), together with the dual feasible variables (D.5), (D.6), satisfies the KKT conditions (D.2), (D.3), and hence (5.7) is optimal for problem (D.1). If this solution satisfies the constraint $\mathrm{KL}(\pi, \eta) \leq d$, then clearly the solution is also optimal for the original problem (5.5).

Substituting (5.7) into the objective (D.1), we easily obtain the optimal value function in (5.8), which concludes the proof. □

Acknowledgments. I sincerely thank Fabrizio Dabbene, Constantino Lagoa, Arkadi Nemirovski, and Andrzej Ruszczyński for their useful discussions and correspondence. A special thanks goes to the Associate Editor and to the anonymous reviewers for their precious comments and suggestions.

ON THE REGULARIZATION OF SLIDING MODES*

LAURA LEVAGGI† AND SILVIA VILLA†

Abstract. Approximability of sliding motions for control systems governed by nonlinear finite-dimensional differential equations is considered. This regularity property is shown to be equivalent to Tikhonov well-posedness of a related minimization problem in the context of relaxed controls. This allows the derivation of a general approximability result, which in the autonomous case has an easy to verify geometrical formulation. In the second part of the paper, we consider nonapproximable sliding mode control systems. In the flavor of regularization of ill-posed problems, we propose a method of selection of well-behaved approximating trajectories converging to a prescribed ideal sliding.

Key words. sliding mode control, approximability, Tikhonov well-posedness, regularization

1. Introduction. Sliding mode control methods aim at fulfilling the control objective by constraining the system motion on a prescribed, suitably chosen manifold S (reference books on theory and applications are [12, 16]). In real-life applications, however, for various reasons the reaching of the ideal sliding (i.e., the evolution on S) is prevented. In fact, the required finite-time global attractivity of S forces the use of state-discontinuous feedback controllers. This is impossible in practice, both because nonidealities in the actuators such as small delays, hysteresis, and so on have to be taken into account and because discontinuity induces infinitely fast switching around the sliding surface (chattering), which is potentially damaging for mechanical components. Therefore the sliding condition can be only approximately satisfied, giving rise to the so-called real sliding motions. Hence, a key issue in sliding mode control theory is to establish conditions under which it is assured that real states enjoy the same dynamical properties of the ideal sliding. In the literature this topic goes under the broad definition of approximability [6, 7, 8, 9, 16, 17]. More precisely, a first result about the convergence of real sliding motions to the evolution obtained with the equivalent control method for affine control systems can be found in section 2.3 of [16]. A general mathematical formulation of approximability, requiring existence and uniqueness of the equivalent control, was then given in [8]. The authors consider nonlinear control systems, and approximability is proved for classes of systems satisfying particular structural properties. In [9] a new definition of approximability, called generalized approximability, is introduced: the new concept does not require the existence of the equivalent control. Criteria guaranteeing generalized approximability are obtained, extending results in [8]. Approximability and related regularity properties also have been investigated for second and higher order sliding modes in [6, 7]. A new and more appropriate definition of real states is then given in [17]: the class of approximating trajectories is enlarged to comprise both classical solutions

corresponding to continuous controls and evolutions generated by discontinuous feedback controls in the Filippov sense. The corresponding definition of approximability is therefore strengthened. Moreover, as a main result, it is shown that approximability is equivalent to Tikhonov well-posedness of a suitably defined minimization problem. New approximability criteria are then obtained as a consequence of known results characterizing well-posedness (for an introduction about this theory, see, e.g., [11]).

Nonapproximability is therefore a consequence of ill-posedness of a minimization problem on the set of trajectories of the control system. This in general means that there exist sequences of real sliding motions that either do not converge to a system motion or can approach different sliding trajectories. Is it then possible to use a regularization procedure to suitably choose approximating sequences and thus partially restore well-posedness? In this paper we are going to give a possible answer to this question. A classical regularization method is Tikhonov regularization, i.e., to consider approximate solutions of perturbed minimization problems obtained by adding a small uniformly convex term to the objective function (see Chapter I, section 7 of [11]). However, a straightforward application of this procedure is not possible in the setting of [17]. For example, it is not clear whether the set of trajectories $W(x_0)$, issued from an arbitrary point x_0, resulting from that choice of admissible controls is closed in the norm of uniform convergence. The key result needed to prove this property is contained in Theorem 2.1. There we show that, whenever the set of control values U is compact, $W(x_0)$ can be characterized as the solution set of a differential inclusion, which in turn coincides with the set of trajectories resulting from the application of relaxed controls (see Corollary 2.3). Even if the use of relaxed controls is a novelty in the context of sliding mode control theory, this result shows the existence of an underlying natural connection. In our paper we take advantage of this characterization in order to both show the compactness of $W(x_0)$ and prove in a more direct way the equivalence in [17] between approximability and well-posedness. The use of relaxed controls in fact avoids distinctions between Carathéodory and Filippov solutions, since these are now unified under a global framework. Moreover, by the compactness of $W(x_0)$, approximability is equivalent to the existence of a unique sliding motion. This, combined with the characterization of $W(x_0)$, allows us to obtain as a main result a complete geometrical characterization of approximability for regular autonomous sliding control systems. In these cases knowledge of both the velocity vector field and the tangent cone to the sliding surface is sufficient to establish whether approximability holds. Therefore, in contrast to previous results, a priori knowledge of the solutions is not required, and we obtain well-posedness without convexity assumptions. The compactness of $W(x_0)$ is furthermore exploited to devise a regularization strategy, allowing more flexibility in the design of the perturbations of the minimization problem. Theorem 4.1 gives a general, new regularization result, essentially different from Tikhonov's, inspired by variational convergences. The idea is to construct a sequence of perturbations of the given problem in such a way that the asymptotically minimizing sequences do converge to a well-defined sliding mode. A general method for choosing these regularizing functionals is also given when an equivalent control is known.

The paper is organized as follows: in section 2 we introduce the general setting of the problem with the standing regularity hypotheses. Next, we study the set of admissible trajectories $W(x_0)$, discussing in detail the choice of the class of admissible controls $\mathcal{U}$. We show in particular that, whenever U is compact and $\mathcal{U}$ is chosen as in [17], the set $W(x_0)$ coincides with the evolutions of the controlled system through the application of relaxed controls. This is contained in the main result of the sec-

tion, Theorem 2.1 along with Corollary 2.3. Section 3 is devoted to the relationship between approximability and well-posedness. The equivalence in our setting is proved in Theorem 3.1 using relaxed controls. Then, in Theorem 3.4, we give a geometrical characterization of approximability for regular autonomous systems, extending previous results. Finally, a class of control systems is presented for which approximability holds under general regularity assumptions. Section 4 is dedicated to the regularization of ill-posed sliding mode control systems. The classical nonapproximable model problem proposed by Izosimov is presented under a new perspective, showing in detail its main features. Then we give the main regularization result, Theorem 4.1, and discuss its applications.

2. The sliding mode control system. In this section we introduce the class of control systems and sliding manifolds we are going to consider, along with the family $\mathcal{U}$ of admissible controls of [17]. $\mathcal{U}$ contains both Carathéodory and state-discontinuous feedbacks, and the corresponding set $W(x_0)$ of admissible trajectories for an arbitrary starting point x_0 is made up of Carathéodory and Filippov solutions of closed loop equations. Real sliding motions are then defined as evolutions generated by admissible feedbacks, which fulfill only approximately the sliding constraint. Since in what follows we will be interested in examining their limit behavior, a better characterization of the sets $W(x_0)$ is very helpful. In Theorem 2.1 we show that

$$W(x_0) = \{x \in AC(0,T;\mathbb{R}^N) : \dot{x}(t) \in \operatorname{co} f(t,x(t),U), \text{ for a.e. } t,\ x(0) = x_0\}$$

for any x_0, whenever the set of control values U is compact. The differential inclusion in the above identity is related to relaxation techniques. In particular we can read this equality as a dynamic equivalence between the application (in the Filippov sense) of discontinuous feedbacks and relaxed controls.

Through the obtained characterization we are also able to directly prove the compactness of $W(x_0)$ in the supremum norm, under the regularity hypotheses of our setting. All subsequent results, not least the regularization of nonapproximable sliding mode control systems, will depend upon this key property.

2.1. General setting and regularity assumptions. We consider the following control system:

$$\begin{cases} \dot{x} = f(t,x,u), & x \in \mathbb{R}^N,\ u \in U,\ t \in [0,T], \\ x(0) = x_0 \end{cases} \tag{1}$$

with

$$f : [0,T] \times \mathbb{R}^N \times U \to \mathbb{R}^N$$

a Carathéodory function, $U \subset \mathbb{R}^M$ compact, and T fixed. Throughout the paper the following assumptions on f will be assumed to hold:

(F1) There exist $A, B \in L^1(0,T)$ such that

$$|f(t,x,u)| \le A(t)|x| + B(t), \qquad \text{for a.e. } t, \quad \forall x \in \mathbb{R}^N,\ \forall u \in U. \tag{2}$$

(F2) For any compact subset Z of $\mathbb{R}^N$ there exists $C \in L^1(0,T)$ such that

$$|f(t,x_1,u) - f(t,x_2,u)| \le C(t)|x_1 - x_2|, \quad \text{for a.e. } t \in [0,T], \quad \forall x_1, x_2 \in Z,\ \forall u \in U. \tag{3}$$

As for the sliding manifold, we suppose that, for any t, it is defined as the set of zeros of a continuous function

$$s : [0,T] \times \mathbb{R}^N \to \mathbb{R}^M;$$

i.e., $S(t) = \{x \in \mathbb{R}^N : s(t,x) = 0\}$.

2.2. The choice of admissible controls. In [17] the class $\mathcal{U}$ of admissible feedback control laws $u(t,x)$ is a subset of $L \otimes B$-measurable functions. Solutions of the resulting closed loop equation are intended in either the Carathéodory or Filippov sense, so that the set of trajectories of (1) corresponding to these admissible controls is

(4)
$$W(x_0) = \{x \in AC(0,T;\mathbb{R}^N) : \exists\, u \in \mathcal{U} \text{ s.t. } \dot{x} = f(t,x,u(t,x)) \text{ for a.e. } t,\ x(0) = x_0, \text{ or } \dot{x} \in F_u(t,x) \text{ for a.e. } t,\ x(0) = x_0\}.$$

Recall that for a feedback law $u(t,x)$ the Filippov multifunction is defined as

$$F_u(t,x) := \bigcap_{\varepsilon>0} \bigcap_{|N|=0} \overline{\text{co}}\, f(t, B(x,\epsilon) \setminus N, u(t, B(x,\epsilon) \setminus N)), \tag{5}$$

where $B(x,\epsilon)$ is the ball of center x and radius ϵ in $\mathbb{R}^N$ and $|N|$ is the Lebesgue measure of the set N. More precisely, in [17],

$$\mathcal{U} = \{u : [0,T]\times\mathbb{R}^N \to U,\ L\otimes B\text{-meas.},\ \|u(\cdot,x(\cdot))\|_\infty < \infty\ \forall x \in W(x_0),\ \forall x_0 \in \mathbb{R}^N\}.$$

If U is compact, the condition $\|u(\cdot,x(\cdot))\|_\infty < \infty$ is unnecessary, and it is possible to give a simpler characterization of $W(x_0)$.

THEOREM 2.1. *Let the hypotheses of the general setting be satisfied. Then*

$$W(x_0) = \{x \in AC(0,T;\mathbb{R}^N) : \dot{x}(t) \in \text{co}\, f(t,x(t),U),\ \textit{for a.e. } t,\ x(0) = x_0\}. \tag{6}$$

Proof. Let $z \in W(x_0)$. If z is a Carathéodory solution of (1), it trivially belongs to the right-hand side set of (6). It is also easy to see that for any admissible feedback u the Filippov multifunction F_u in (5) satisfies $F_u(t,x) \subseteq \overline{\text{co}}\, f(t,x,U)$ because of the continuity of f in the state variable. Since U is compact $\overline{\text{co}}\, f(t,x,U) = \text{co}\, f(t,x,U)$, therefore $W(x_0)$ is included in $\{x \in AC(0,T;\mathbb{R}^N) : \dot{x}(t) \in \text{co}\, f(t,x(t),U)$, for a.e. t, $x(0) = x_0\}$.

To prove that the converse is true, let $x : [0,T] \to \mathbb{R}^N$ be absolutely continuous and such that

$$\dot{x}(t) \in \text{co}\, f(t,x(t),U), \qquad \text{for a.e. } t \in [0,T], \quad x(0) = x_0.$$

Then, by Carathéodory's convexity theorem, we can write

$$\dot{x}(t) = \sum_{i=1}^{N+1} \tilde{\lambda}_i(t) f(t,x(t),\tilde{u}_i(t)), \qquad t \notin E,$$

for some E with $|E| = 0$ and $(\tilde{\lambda}(t),\tilde{u}(t)) \in [0,1]^{N+1} \times U^{N+1} =: X$. Let

$$\Gamma(t) = \begin{cases} \left\{(\lambda,u) \in X : \dot{x}(t) = \displaystyle\sum_{i=1}^{N+1} \lambda_i f(t,x(t),u_i)\right\}, & t \notin E, \\ \{(\lambda_0,u_0)\}, & t \in E, \end{cases}$$

with $(\lambda_0, u_0) \in [0,1] \times U$ arbitrarily fixed. Then obviously Γ has nonempty values. Moreover, by Corollary 1Q in [15] Γ is a closed-valued, measurable multifunction, since $\dot{x}$ is measurable, $\lambda \mapsto \sum_{i=1}^{N+1} \lambda_i f(t, x(t), u_i)$ is continuous, and f is Carathéodory. Therefore by Corollary 1C in [15] there exists a measurable selection $(\lambda(t), u(t)) \in \Gamma(t)$ for all t. Now we use the selected $u(t)$ in order to define a feedback control law $\hat{u}$ such that $x(\cdot)$ is a Filippov solution of the corresponding closed loop equation. The required feedback $\hat{u}$ has to be discontinuous at every point of the trajectory $x(t)$ and be such that in any neighborhood of $x(t)$ all values $u_1(t), \dots, u_{N+1}(t)$ are taken on. To this end we define the following partition of $[0,T] \times \mathbb{R}^N$:

$$\begin{aligned} A_1 &= \{(t,x) : x_1 < x_1(t), \dots, x_N < x_N(t)\}, \\ A_i &= \{(t,x) : x_k > x_k(t) \text{ for } k < i,\ x_r < x_r(t) \text{ for } r \geq i\}, \quad i = 2, \dots, N, \\ A_{N+1} &= \{(t,x) : x_1 > x_1(t), \dots, x_N > x_N(t)\}, \\ A_0 &= \complement \left(\bigcup_{i=1}^{N+1} A_i \right). \end{aligned}$$

Note that for arbitrary t, $\epsilon > 0$, $Z \subset \mathbb{R}^N$, with $|Z| = 0$, the set $B(x(t), \epsilon) \setminus Z$ has nonvoid intersection with every A_i, $i = 1, \dots, N+1$. Now, if $u_0(t) = u_0$, it is straightforward to see that the control law $\hat{u}$,

$$\hat{u}(t,x) = \sum_{i=0}^{N+1} u_i(t)\, \chi_{A_i}(t,x),$$

where χ_{A_i} is the characteristic function of the set A_i, has the required features. Thanks to the properties of the chosen partition, $x(\cdot)$ is a solution of the Filippov differential inclusion (see (5))

$$\dot{x}(t) \in F_{\hat{u}}(t, x(t)), \text{ for a.e. } t, \qquad x(0) = x_0.$$

It remains to prove that $\hat{u}$ is $L \otimes B$-measurable, i.e., that all the sets A_i, $i = 0, \dots, N+1$, are measurable. Since the functions $g_j(t,x) = x_j - x_j(t)$ for $j = 1, \dots, N$ are continuous, the sets $g_j^{-1}(0, +\infty)$ and $g_j^{-1}(-\infty, 0)$ are Borel sets for any j. Therefore the sets A_i are a finite intersection of Borel sets and hence measurable. ∎

The next lemma establishes the compactness of $W(x_0)$, which will be extensively used in what follows.

LEMMA 2.2. *Let $x_0 \in \mathbb{R}^N$ and z_n be any sequence in $W(x_0)$. Then z_n is equibounded and equicontinuous. Moreover, the set $W(x_0)$ is closed and thus compact as a subset of $C^0(0,T;\mathbb{R}^N)$ endowed with the norm of uniform convergence.*

Proof. The result depends upon the regularity properties of f and the compactness of U. Since f is Carathéodory, the set-valued map $F_1(t,x) = f(t,x,U)$ has compact values, is upper semicontinuous in x for a.e. t (see, e.g., Proposition 1.4.14 in [5]), and is measurable in t for any x. Thus $F(t,x) = \operatorname{co} F_1(t,x)$ enjoys the same properties, plus convexity of its values. Moreover, the Carathéodory convexity theorem and (2) yield

$$\begin{aligned} \|F(t,x)\| &= \sup \left\{ \left| \sum_{i=0}^{N} \alpha_i f(t,x,u_i) \right| : \alpha_i \in [0,1],\ \sum_{i=0}^{N} \alpha_1 = 1,\ u_i \in U \right\} \\ &\leq C(t)(1 + |x|) \end{aligned}$$

for some $C \in L^1(0,T)$. Therefore the hypotheses of Theorem 7.1 in [10] are satisfied, and the result follows. □

We have thus shown that if U is compact, the set in (4) is in fact the set of solutions of the differential inclusion $\dot{x}(t) \in \operatorname{co} f(t, x(t), U)$. It is a classical result (see, e.g., Theorem 13.4.1 in [13]) that the latter corresponds to the set of trajectories of (1) under the action of relaxed control laws [1, 2, 13]. These are measure-valued controls defined as functions $\mu(\cdot)$:

$$\mu : [0,T] \to \Sigma(U), \quad \mu \in L^\infty_w(0,T;\mathcal{M}(U)) = L^1(0,T;C(U))^*,$$

where $C(U)$ is the set of continuous functions on U, $\mathcal{M}(U) = C(U)^*$ is the space of Borel measures on U, and $\Sigma(U) = \{\mu \in \mathcal{M}(U) : \mu \geq 0,\ \mu(U) = 1\}$ is the set of Borel probability measures on U. Solutions of (1) under the application of a relaxed control law μ are absolutely continuous functions $x : [0,T] \to \mathbb{R}^N$ such that

$$x(t) = x_0 + \int_0^t \left(\int_U f(t, x(t), u)\, \mathrm{d}\mu_t \right) dt, \tag{7}$$

where μ_t denotes the measure $\mu(t) \in \Sigma(U)$. Therefore, we have the following corollary.

COROLLARY 2.3. *Let assumptions* (F1)–(F2) *on the function f be satisfied and U be compact. Call $R(x_0)$ the set of solutions of* (7) *as μ varies in the set of relaxed controls. Then*

$$\begin{aligned} W(x_0) &= \{x \in AC :\ \dot{x}(t) \in \operatorname{co} f(t, x(t), U),\ \textit{for a.e. } t,\ x(0) = x_0\} \\ &= R(x_0). \end{aligned} \tag{8}$$

This result gives us the possibility of taking advantage of the mathematical structure offered by relaxed controls while retaining $\mathcal{U}$ as the class of admissible controls, which is a more natural choice from a practical point of view.

3. Approximability and well-posedness. In this section we study the relationship between approximability of the sliding mode and Tikhonov well-posedness of a suitable minimization problem. After giving the definitions of sliding states and approximability for sliding motions, we introduce the concept of Tikhonov well-posedness. As in [17] we then prove that these regularity notions are equivalent. Moreover, we show that Tikhonov well-posedness (and thus approximability) has an easy characterization in our setting. Then we specialize our results in the autonomous case: for these systems, under some reasonable regularity assumptions, we are in fact able to give a purely geometric necessary and sufficient condition for approximability of the sliding mode control system. In the last part of the section we present a class of systems and surfaces for which sliding is well-posed and to which approximability criteria in [17] are not, in general, applicable.

3.1. Sliding modes approximability and Tikhonov well-posedness. Let us now consider the control system (1) in the general setting described in section 2.1. For any $x_0 \in \mathbb{R}^N$ such that $s(0, x_0) = 0$, we say that $y \in W(x_0)$ is a *sliding state* issued from x_0 if $s(t, y(t)) = 0$ for all $t \in [0,T]$. In the terminology of [3, 4, 5], y is a solution of the differential inclusion in (8), viable on the (time-varying) sliding manifold.

As in [17] we introduce the following *approximability property* for sliding modes:

(A) for any $x_0 \in S(0)$ there exists a unique sliding state y issued from x_0, and for any sequences $x_n \to x_0$, $y_n(\cdot) \in W(x_n)$ such that $\|s(\cdot, y_n(\cdot))\|_\infty \to 0$, one has $\|y_n - y\|_\infty \to 0$.

Property (A) is related to the Tikhonov well-posedness with value zero [11, Chap. 1] of the following optimization problem:

$$\min_{x\in W(x_0)} I(x), \qquad I(x)=\int_0^T |s(t,x(t))|\,dt,$$

where $|\cdot|$ is any norm in $\mathbb{R}^N$. In what follows we will refer to the above problem by writing $(W(x_0),I)$. The well-posedness requirement for $(W(x_0),I)$ consists in the following condition:

(TWP) there exists a unique minimizer $y\in W(x_0)$ for I, $I(y)=0$, and any minimizing sequence $z_n\in W(x_0)$ uniformly converges to y; i.e., $I(z_n)\to 0$ implies $\|z_n-y\|_\infty\to 0$.

Using Lemma 2.2 and the characterization (8) it is possible to prove the equivalence of properties (A) and (TWP) as in Theorem 3.1 in [17] under a unified framework, avoiding the distinction between different concepts of solution of (1).

THEOREM 3.1. *Let the hypotheses of the general setting be satisfied and x_0 be any vector such that $s(0,x_0)=0$. Then $(W(x_0),I)$ is Tikhonov well-posed with value zero for any such x_0 if and only if the approximability property* (A) *is fulfilled.*

Proof. Let x_0 be fixed; suppose that the problem $(W(x_0),I)$ satisfies property (TWP). Let x_n and y_n be as in condition (A). Then by Corollary 2.3 there exist relaxed controls μ^n such that

$$y_n(t)=x_n+\int_0^t\left(\int_U f(s,y_n(s),u)\,\mathrm{d}\mu_s^n\right)\mathrm{d}s.$$

Then calling z_n the solution of the integral equation

$$z_n(t)=x_0+\int_0^t\left(\int_U f(s,z_n(s),u)\,\mathrm{d}\mu_s^n\right)\mathrm{d}s,$$

using (3) and Lemma 2.2, and recalling that μ_s^n is a probability measure for any n and s, we obtain

$$\begin{aligned}|y_n(t)-z_n(t)| &\le |x_n-x_0|+\int_0^t \sup_{u\in U}|f(s,y_n(s),u)-f(s,z_n(s),u)|\,\mathrm{d}s\\ &\le |x_n-x_0|+\int_0^t C(s)|y_n(s)-z_n(s)|\,\mathrm{d}s,\end{aligned}$$

and by Gronwall's lemma $\|y_n-z_n\|_\infty\to 0$. Thus $\|s(\cdot,z_n)\|_\infty\to 0$, and a fortiori z_n is a minimizing sequence for $(W(x_0),I)$. Tikhonov well-posedness then implies the convergence of z_n, and thus of y_n, to the unique sliding state y as desired.

Suppose now that the approximability property (A) holds. To show the well-posedness of $(W(x_0),I)$, let z_n be a minimizing sequence. Then by Lemma 2.2 any of its subsequences admits a further subsequence which is uniformly convergent to some $z\in W(x_0)$. Also, since $s(\cdot,z_n(\cdot))\to 0$ in $L^1(0,T)$, eventually passing to a further subsequence (we do not relabel for simplicity), we have $s(t,z_n(t))\to 0$ a.e. on $[0,T]$. By continuity of s and uniform convergence,

$$s(t,z_n(t))\to 0, \quad s(t,z_n(t))\to s(t,z(t)) \quad \text{uniformly in } t.$$

Approximability then implies that z coincides with the unique sliding state y. Since this limit is independent of the chosen subsequence, we get the convergence of z_n to y as desired. □

Another consequence of Lemma 2.2 is the following characterization of Tikhonov well-posedness of $(W(x_0), I)$ and thus of the approximability of the associated sliding mode control system.

COROLLARY 3.2. *Property* (TWP) *is satisfied if and only if problem* $(W(x_0), I)$ *admits a unique minimizer* y *with* $I(y) = 0$.

We now show a geometric characterization of well-posedness in the above sense for a general class of sliding mode control systems. Before stating this result we recall the following lemma.

LEMMA 3.3 (Lemma 4 in [14]). *Let* $A \subset \mathbb{R}^N$ *be an open set, and let* G *and* H *be two set-valued maps from* A *to* $\mathbb{R}^N$. *Assume that* G *and* H *have nonempty convex closed values, that* G *is continuous, and that* H *is lower semicontinuous. If*

$$G(x) \cap H(x) \neq \varnothing \qquad \forall x \in A,$$

then there exists a continuous function $f : A \to \mathbb{R}^N$ *with*

$$f(x) \in G(x) \cap H(x) \qquad \forall x \in A.$$

Also, recall that for a subset S of $\mathbb{R}^N$ the *Bouligand tangent cone* $T_S(x)$ is defined as

$$T_S(x) = \left\{ v \in \mathbb{R}^N : \liminf_{h \to 0^+} \frac{d(x + hv, S)}{h} = 0 \right\}$$

and that S is *sleek* if the multivalued map $x \mapsto T_S(x)$ is lower semicontinuous (see, e.g., section 4.1.4 in [5] for the definition and properties of sleek subsets).

THEOREM 3.4. *Let us consider a general autonomous control system of the form*

$$\begin{cases} \dot{x} = f(x, u), \\ x(0) = x_0 \end{cases} \tag{9}$$

with f *satisfying conditions* (F1)–(F2) *and a time-independent sliding manifold* S *which is a sleek subset of* $\mathbb{R}^N$. *Then for any* $x_0 \in S$ *a sliding mode on* S *in* $W(x_0)$ *exists if and only if*

$$\operatorname{co} f(x, U) \cap T_S(x) \neq \varnothing \qquad \forall x \in S.$$

Moreover, let the above condition be satisfied; then the corresponding sliding motion is unique for any $x_0 \in S$ *if and only if*

$$\operatorname{co} f(x, U) \cap T_S(x) = \{\tau(x)\} \qquad \forall x \in S \tag{10}$$

with $\tau : S \to \mathbb{R}^N$ *such that any Cauchy problem associated with the differential equation* $\dot{x} = \tau(x)$ *admits a unique solution on* $[0, T]$.

Proof. By (6), the set of sliding modes of (9) on S will be given by solutions of $\dot{x}(t) \in F(x(t)) := \operatorname{co} f(x(t), U)$ such that $x(t) \in S$ for all t. Therefore by Lemma 1.1.4 in [3] any sliding mode $y(\cdot)$ must satisfy

$$\dot{y}(t) \in F(y(t)) \cap T_S(y(t)), \quad \text{for a.e. } t. \tag{11}$$

Also, by standard viability results (see, e.g., Proposition 4.2.1 and Theorem 4.2.1 in [4]) a sliding mode exists if and only if the intersection $F(x) \cap T_S(x)$ is nonvoid for any $x \in S$.

Moreover, if (10) is satisfied, from (11) the admissible sliding motions are the solutions of $\dot{x} = \tau(x)$. Thus uniqueness depends on the regularity of τ.

Suppose now that a sliding mode exists, but the intersection in (10) is not single-valued. By assumption (F2) we have Lipschitz continuity for F and thus continuity. Let $x_0 \in S$ and $y_0 \in F(x_0) \cap T_S(x_0)$; now define $H(x_0) = \{y_0\}$ and $H(x) = T_S(x)$ otherwise. Then H is lower semicontinuous, and by Lemma 3.3 there exists a continuous selection for the map $x \mapsto F(x) \cap H(x)$. Therefore for any $y_0 \in F(x_0) \cap T_S(x_0)$ we can construct a selection g of $F(\cdot) \cap T_S(\cdot)$ such that $g(x_0) = y_0$. By continuity, this shows that if the intersection between the velocity set $F(x)$ and the tangent cone $T_S(x)$ is not single-valued on S, different sliding modes exist in $W(x_0)$, since different selections can be constructed. □

As a consequence, by Theorem 3.1 and Corollary 3.2, we have the following corollary.

COROLLARY 3.5. *A sliding mode control problem with time-independent sleek sliding manifold for an autonomous nonlinear system is approximable for every $x_0 \in S$ if and only if condition* (10) *holds.*

Let us show a very simple and classical example.

Let $f(x,u) = Ax + Bu$ and $S = \{x \in \mathbb{R}^N : Cx = 0\}$ with A, B, and C matrices of the right dimensions. Then $T_S(x) = S$ for all $x \in S$, and condition (10) is satisfied if and only if the matrix CB is invertible. In this case there exists a uniquely defined equivalent control $u_{\mathrm{eq}}(x) = (CB)^{-1}CAx$ inducing sliding on S, $\tau(x) = [I - B(CB)^{-1}C]Ax$, and uniqueness of the sliding solution is obviously guaranteed. Note, however, that the existence and uniqueness of an equivalent control are not necessary for approximability, as we will show in the next section. Moreover, here, in contrast to results in [17], condition (10) depends just on the geometry of the control problem and is verifiable a priori, once the velocity field and the sliding manifold are known. Therefore the precise knowledge of the solution set $W(x_0)$ is not required, while in general the uniqueness of the sliding motion, needed, for example, in Corollary 4.1 of [17], has to be tested on the set of trajectories that can be issued from a point of the sliding manifold applying any feedback control and using the Filippov solution definition. This difference is the outcome of Theorem 2.1, which gives a characterization of $W(x_0)$ in terms of the solution set of a regular differential inclusion.

3.2. A class of well-posed sliding mode control systems. In this part of the paper we present a family of control systems satisfying the approximability property, in the spirit of Theorem 3.4 and Corollary 3.5. Also, we show that convexity of $f(x,U)$ is not required to belong to this class, in contrast to previous results, e.g., Corollary 4.1 in [17].

Let us consider the control system

$$\begin{cases} \dot{x}_1 = f_1(x), \\ \dot{x}_2 = f_2(x,u) \end{cases} \tag{12}$$

where $x = (x_1, x_2) \in \mathbb{R}^N$, $x_1 \in \mathbb{R}^{N-M}$, $x_2 \in \mathbb{R}^M$ with $M < N$, $u \in U \subset \mathbb{R}^M$, U compact, $f_1 : \mathbb{R}^N \to \mathbb{R}^{N-M}$, and $f_2 : \mathbb{R}^N \times U \to \mathbb{R}^M$. Then clearly

$$F(x) := \operatorname{co} f(x,U) = \{f_1(x)\} \times \operatorname{co} f_2(x,U)$$

for $f : \mathbb{R}^N \times U \to \mathbb{R}^N$, $f(x,u) = (f_1(x), f_2(x,u))$. Now letting $h : \mathbb{R}^{N-M} \to \mathbb{R}^M$ be a C^1 function, we define

$$s : \mathbb{R}^N \to \mathbb{R}^M, \qquad s(x) = x_2 - h(x_1) \tag{13}$$

and let the sliding surface S be the set $\{(x_1, x_2) \in \mathbb{R}^N : x_2 = h(x_1)\}$. Then we have $Js(x) = [-Jh(x_1), I_M]$, where we have used the symbol Jg for the Jacobian matrix of g and I_M is the identity matrix of dimension M. Then obviously Js is of maximal rank at any point and $T_S(x)$, the Bouligand tangent cone to S at x, coincides with the usual tangent space; i.e.,

$$T_S(x) = \{z \in \mathbb{R}^N : Js(x)z = 0\} = \ker Js(x) \quad \forall x \in S.$$

Therefore

$$\begin{aligned} F(x) \cap T_S(x) &= \{(f_1(x), v) : v \in \operatorname{co} f_2(x,U),\ Js(x)\,(f_1(x), v)^T = 0\} \\ &= \{(f_1(x), v) : v \in \operatorname{co} f_2(x,U),\ v - Jh(x_1)f_1(x) = 0\} \end{aligned}$$

for any $x = (x_1, x_2) \in S$, so that

$$F(x) \cap T_S(x) = \begin{cases} \varnothing & \text{if } Jh(x_1)f_1(x) \notin \operatorname{co} f_2(x,U), \\ \{(f_1(x), Jh(x_1)f_1(x))\} & \text{otherwise.} \end{cases}$$

Thus from Theorem 3.4 a sliding mode on S exists if and only if

$$Jh(x_1)f_1(x) \in \operatorname{co} f_2(x,U) \tag{14}$$

at any point $x = (x_1, h(x_1))$ with $x_1 \in \mathbb{R}^{N-M}$. Moreover, if this condition is satisfied, sliding modes for (12)–(13) are given by the solutions of

$$\begin{cases} \dot{x}_1 = f_1(x), & x_1(0) = \overline{x}_1, \\ \dot{x}_2 = Jh(x_1)f_1(x), & x_2(0) = h(\overline{x}_1) \end{cases}$$

or, equivalently, setting $g(x_1) = f_1(x_1, h(x_1))$,

$$\begin{cases} \dot{x}_1 = g(x_1), & x_1(0) = \overline{x}_1, \\ x_2(t) = h(x_1(t)). \end{cases}$$

Since h is C^1, if f_1 is Lipschitz continuous, the above differential equation admits a unique solution, and by Corollary 3.5, sliding mode control system (12)–(13) enjoys the approximability property (A).

In Corollary 4.1 in [17] it is proved that if $f(x,U)$ is convex and the sliding mode is unique, the approximability property is satisfied. We show here by an example that for the above class of systems convexity of the velocity field is not required.

Example 3.1. Let $N = 3$, $M = 2$, $x = (x_1, x_2, x_3)$, $u = (u_1, u_2)$ with $|u_i| \le 1$, $f_1 : \mathbb{R}^3 \to \mathbb{R}$, and

$$\begin{cases} \dot{x}_1 = f_1(x), \\ \dot{x}_2 = u_1, \\ \dot{x}_3 = u_1 u_2, \end{cases} \qquad f(x,u) = (f_1(x), u_1, u_1 u_2).$$

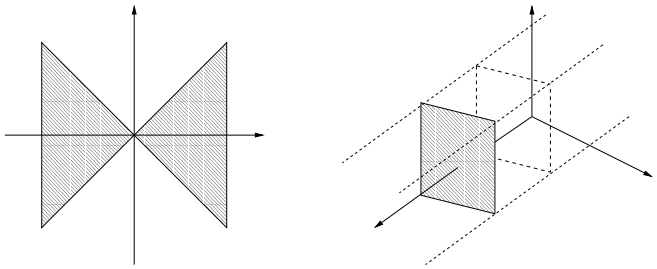

FIG. 1. *In* (A) *we depicted the set* $\{(u_1, u_1u_2) : |u_i| \le 1\}$*, while the set* $\operatorname{co} f(x, U)$ *for fixed* x *is shown in* (B)*. Note that this set always belongs to the intersection between the dashed parallelepiped and a plane orthogonal to the first axis, while for our choice of* S *the set* $T_S(x)$ *will always be a line passing through the origin.*

Then

$$f(x,U) = \left\{ f_1(x)\} \times \{(u_1, u_1u_2) : |u_i| \le 1\} = \{f_1(x)\} \times \bigcup_{|\alpha|\le 1} \{(t, \alpha t) : |t| \le 1 \right\}$$

(see Figure 1). Then $f(x,U)$ is not convex and $\operatorname{co} f(x,U) = \{f_1(x)\} \times [-1,1]^2$.

In this example we define $s : \mathbb{R}^3 \to \mathbb{R}^2$, $s(x) = (x_2, x_3) - h(x_1)$ with a regular $h : \mathbb{R} \to \mathbb{R}^2$ and $S = \{(x_1, h(x_1)) : x_1 \in \mathbb{R}\}$. Writing $h(x_1) = (h_1(x_1), h_2(x_1))$, we obtain $Jh(x_1) = (h_1'(x_1), h_2'(x_1))^T$. Letting $g_1(x_1) = f_1(x_1, h_1(x_1), h_2(x_1))$, the necessary and sufficient condition (14) for the existence of a sliding motion on S is $Jh(x_1)g_1(x_1) \in [-1,1]^2$, i.e.,

$$|h_i'(x_1)g_1(x_1)| \le 1, \qquad i = 1, 2.$$

For example, if $h_1 = h_2 = 0$, so that S is the first coordinate axis, the condition is satisfied, and the only admissible sliding motion on S is the solution of a Cauchy problem

$$\begin{cases} \dot{x}_1 = f_1(x_1, 0, 0), \\ x_1(0) = \overline{x}_1, \end{cases} \qquad x_2(t) = x_3(t) = 0.$$

Note that in this case, for any starting point on S, any choice of a control law $(0, u_2)$ with $|u_2| \le 1$ is able to maintain the motion on S; i.e., the equivalent is not uniquely defined.

4. Sliding modes, nonapproximability, and regularization. While in the first part of the paper we discussed well-posedness and found classes of sliding mode control systems satisfying the approximability property, here we focus our attention on systems which do not enjoy this property for a given surface S. In section 4.1 we discuss in detail an example, due to Izosimov[1] and studied in [16]. This system was considered by Utkin in order to show the existence of systems for which the sliding motion along the sliding manifold is not uniquely defined. It turns out in [16] that the motion on the manifold depends on the implemented sequence of real states and

[1]The same example has been dealt with in a different context in [6].

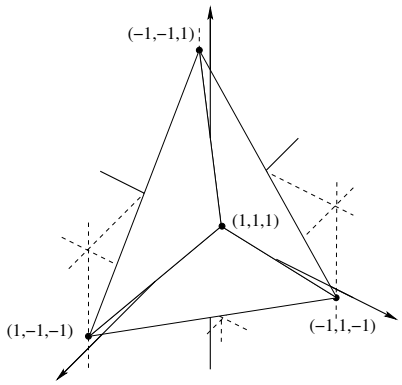

FIG. 2. $\operatorname{co} f(U)$.

that it is possible to find different ideal sliding motions passing to the limit. Here we study this example under different perspectives and we verify that in any case the system does not satisfy property (A).

A natural idea to find a regularization would be to find a sequence of manifolds S_n, converging to the starting one, for which the problem satisfies the approximability property. However, by Theorem 3.4 we show that in general this is not possible, and the aim of section 4.2 is to find an appropriate regularization of a sliding mode control system (1) which does not satisfy the approximability property. The main result is Theorem 4.1, which deals with the regularization of the integral functional corresponding to the system, as explained in section 3.1. Using this theorem, we are able to select special sequences of trajectories converging to an a priori chosen sliding state.

Finally, we make some remarks on the theorem and propose some possible applications.

4.1. A model example. We consider the following sliding mode control system (see [16], p. 35):

$$\begin{cases} \dot{x}_1 = u_1, \\ \dot{x}_2 = u_2, \\ \dot{x}_3 = u_1 u_2, \end{cases} \qquad s(t, x_1, x_2, x_3) = (x_1, x_2), \quad S = \{(0, 0, x_3) : x_3 \in \mathbb{R}\} \tag{15}$$

with $x = (x_1, x_2, x_3) \in \mathbb{R}^3$, $u = (u_1, u_2) \in U := [-1, 1]^2$, $t \in [0, 1]$, $f(t, x, u) = f(u) = (u_1, u_2, u_1 u_2)$, and initial point $x_0 \in S$.

The system defined by (15) fulfills the hypotheses stated in section 2.1. If we take relaxed controls as admissible controls, we have to consider all solutions of the differential inclusion $\dot{x}(t) \in \operatorname{co} f(U)$ and (see Figure 2)

$$\operatorname{co} f(U) = \operatorname{co}\{(1, 1, 1), (1, -1, -1), (-1, -1, 1), (-1, 1, -1)\}. \tag{16}$$

Note that in this example $\operatorname{co} f(U) = F_{\hat{u}}(x)$ for any $x \in S$ if the control $\hat{u}$ is given by

$$\hat{u}_1(t, x) = \operatorname{sign}(x_1), \qquad \hat{u}_2(t, x) = \operatorname{sign}(x_2)$$

and $F_{\hat{u}}(x)$ is the corresponding Filippov multifunction, as defined in (5). Consider now a sliding trajectory $x(t) = (0, 0, x_3(t))$. Then by Theorem 3.4, $x(\cdot)$ satisfies

$$\dot{x}(t) \in \operatorname{co} f(U) \cap T_S(x(t)), \quad \text{for a.e. } t,$$

where $T_S(x) = S$ in this case for every $x \in S$. We therefore get that the set of sliding states with initial point x_0 is

$$\{(0, 0, x_3(t)) \in AC(0, T; \mathbb{R}^3) : |\dot{x}_3(t)| \leq 1\}. \tag{17}$$

Therefore in this case the sliding trajectory is not unique, and consequently the system is not approximable. We remark that these sliding motions also were computed in [16], using a different argument.

If we take into account only Carathéodory solutions of system (15), the unique sliding state is the trajectory

$$x(t) = x_0$$

for every $t \in [0, 1]$, corresponding to the control $(u_1, u_2) = (0, 0)$.

Let us show, however, that this does not imply approximability. Choose for instance $x_0 = (0, 0, 0)$ and consider the sequence of controls

$$u_1^n(t) = \begin{cases} 1 & \text{if } t \in I_k^n, \\ -1 & \text{if } t \in D_k^n, \end{cases} \qquad u_2^n = u_1^n$$

and the corresponding trajectories solving system (15), starting from x_0,

$$x_1^n(t) = \begin{cases} t - \frac{2k}{2^n} & \text{if } t \in I_k^n, \\ -t + \frac{2k}{2^n} & \text{if } t \in D_k^n, \end{cases} \qquad x_2^n = x_1^n, \qquad x_3^n(t) = t,$$

where $I_k^n = [2k/2^n, (2k+1)/2^n]$ for $k \in \{0, \ldots, 2^{n-1}-1\}$ and $D_k^n = [(2k-1)/2^n, 2k/2^n]$ for $k \in \{1, \ldots, 2^{n-1}\}$. These trajectories are approaching the sliding manifold, because (x_1^n, x_2^n) is uniformly convergent to $(0, 0)$, but the whole sequence is convergent to $x(t) = (0, 0, t)$, which is not the unique Carathéodory sliding state. Thus the system does not satisfy property (A). Note that, in the same way, it is possible to construct sequences of Carathéodory real sliding states approaching any of the relaxed sliding solutions we found before.

The aim of the next section is to find a method to regularize such a system. One possibility would be to find a sequence of surfaces S_n such that

(S1) the sliding mode control defined by (15) with sliding manifold S_n satisfies property (A) for each n;

(S2) $S_n \to S$ in some sense;

(S3) S_n is of the "same kind" of S.

However, in this example, it is not possible. Consider condition (S3) and suppose we look for sliding manifolds S_n such that

$$S_n = \{x \in \mathbb{R} : s_n(x) = 0\}$$

with $s_n : \mathbb{R}^3 \to \mathbb{R}^2$ a C^2 function with Jacobian matrix $Js_n(x)$ of maximal rank at any point $x \in S_n$. With these assumptions, it follows that $T_{S_n}(x) = \{y \in \mathbb{R}^3 : Js_n(x)y = 0\}$. Regardless of the choice of S_n, the cone $T_{S_n}(x)$ is a line passing through the origin for every $x \in S_n$. Recall that here $\operatorname{co} f(U)$ does not depend on x and is the polyhedral set (16), containing the origin (see Figure 2). Thus $T_{S_n}(x) \cap \operatorname{co} f(U)$ is a segment of positive length. According to Theorem 3.4, every $x \in AC(0, T)$ solving

$$\begin{cases} \dot{x}(t) \in T_{S_n}(x(t)) \cap \operatorname{co} f(U) & \text{for a.e. } t, \\ x(0) \in S_n \end{cases}$$

is a trajectory sliding on S_n. Since the right-hand side admits more than one continuous selection, by Corollary 3.5, property (A) is not satisfied, regardless of the choice of S_n. Therefore requirements (S1) and (S3) are not compatible, no matter what convergence is chosen in (S2).

4.2. Regularization. As in the model problem, if a sliding mode exists, nonapproximability is the consequence of the lack of uniqueness of the sliding state (Corollary 3.2). Our aim here is to find a method to select sequences of real states converging to a prescribed sliding motion. Relying on the equivalence result in Theorem 3.1, what we need is to devise a way to appropriately select minimizing sequences of the ill-posed functional I,

$$I(x) = \int_0^T |s(t, x(t))|\, dt, \tag{18}$$

on the set $W(x_0)$. This can be done by using regularization processes such as Tikhonov's (see [11]). A sequence of functionals I_n is defined by adding a small uniformly convex term to I so that $(W(x_0), I_n)$ is well-posed for all n. Uniform convexity then assures that minimizing sequences for I can be generated through I_n and convergence to a fixed minimizer of I is guaranteed. In our setting, the compactness property of $W(x_0)$ allows us to weaken the required regularity of the perturbations and to obtain the following new regularization result.

THEOREM 4.1. *Assume that the set* $P := \operatorname{argmin}(W(x_0), I)$ *is nonempty and let* $J, J_n : W(x_0) \to \mathbb{R}$ *be lower semicontinuous functionals such that*

(i) J *has a unique minimizer* $\overline{y}$ *on the set* P*; i.e.,* $\operatorname{argmin}(P, J) = \{\overline{y}\}$ *and* $J(\overline{y}) = 0$*;*

(ii) $J(y) \le \liminf J_n(y_n)$ *for every* y *and any sequence* y_n *such that* $y_n \to y$ *uniformly;*

(iii) *there exists* $\overline{z} \in P$ *such that* $\limsup J_n(\overline{z}) = 0$.

Consider sequences $a_n > 0$, $\varepsilon_n \ge 0$ *such that* $a_n \to 0$, $\varepsilon_n \to 0$, *and* $(\varepsilon_n/a_n) \to 0$, *and define* $I_n = I + a_n J_n$. *Then for every sequence* $y_n \in W(x_0)$ *such that* $I_n(y_n) \le \varepsilon_n + \inf I_n$, *it follows that*

(a) y_n *is a minimizing sequence for* I*;*

(b) $y_n \to \overline{y}$.

Proof. For any $n \in \mathbb{N}$, let $y_n \in W(x_0)$ be such that $I_n(y_n) \le \epsilon_n + \inf I_n$. By the compactness property proved in Lemma 2.2, up to subsequences, y_n is convergent to a certain $y^* \in W(x_0)$.

From the definition it follows that

$$I(y_n) = I_n(y_n) - a_n J_n(y_n) \le \epsilon_n + \inf I_n - a_n J_n(y_n); \tag{19}$$

by assumption (ii), $\liminf J_n(y_n) \ge J(y^*)$ and it can be easily proved that $\inf I_n \to \inf I = 0$ (see Remark 4.1). Thus, passing to the upper limit in (19), we get

$$\limsup I(y_n) \le 0; \tag{20}$$

therefore y_n is minimizing for I. Moreover, since I is continuous, we obtain $I(y^*) = 0$, i.e., $y^* \in P$; therefore to show that $y^* = \overline{y}$, it is enough to prove that y^* is a minimizer of J on P. Since $I \ge 0$ and $a_n > 0$, from (19) we get

$$J_n(y_n) \le J_n(y_n) + \frac{I(y_n)}{a_n} \le \frac{\varepsilon_n}{a_n} + \frac{I_n(\overline{z})}{a_n} = \frac{\varepsilon_n}{a_n} + J_n(\overline{z}). \tag{21}$$

Thus, by assumptions (ii) and (iii), since $(\varepsilon_n/a_n) \to 0$, we have

$$0 \le J(y^*) \le \liminf J_n(y_n) \le \limsup J_n(y_n) \le 0. \tag{22}$$

Putting together (20) and (22), from assumption (i) it follows that $y^* = \overline{y}$. ∎

Remark 4.1. Assumptions (i), (ii), and (iii) imply variational convergence of the sequence J_n to J. Therefore from [11, Theorem 5, p. 122] it follows that $\lim_n \inf I_n = \inf I$.

Example 4.1. Consider the nonapproximable sliding mode control system defined in section 4.1 with $x_0 = (0, 0, 0)$. We show how to apply Theorem 4.1 in order to select suitable minimizing sequences converging to a fixed sliding motion.

Since by (17) we have $P = \{(0, 0, x_3(t)) : |\dot{x}_3(t)| \le 1,\ x_3(0) = 0\}$, a feasible choice for J is

$$J(y) = \int_0^1 |y_3(t)|\, dt.$$

This functional satisfies the hypotheses of Theorem 4.1; in fact it is lower semicontinuous on $W(x_0)$ with respect to the uniform convergence, since it is lower semicontinuous on the whole space $AC(0, T; \mathbb{R}^3)$ and it has the unique constant minimizer $x(t) = x_0$ on the set of sliding states P. Then we can either take $J_n = J$ for all n or define

$$J_n(y) = \int_0^1 g_n(y_3(t))\, dt \quad \text{with} \quad g_n(y_3) = \begin{cases} |y_3| & \text{if } |y_3| \le n, \\ 0 & \text{otherwise.} \end{cases}$$

In both cases, choosing $\overline{z} = x$, condition (iii) is satisfied. Note also that J is not uniformly convex, so that J is not an admissible perturbation of the Tikhonov type.

Supposing $J_n = J$, which kind of controls are then required in order to obtain convergent asymptotically minimizing trajectories? Suppose that u_n is an admissible control law such that the corresponding trajectory y_n satisfies $I_n(y_n) \le \varepsilon_n$. Since $\epsilon_n/a_n \to 0$, from (15), it follows that

$$\frac{u_1^n}{a_n} \to 0; \quad \frac{u_2^n}{a_n} \to 0; \quad u_1^n u_2^n \to 0 \text{ weakly in } L^2(0, T). \tag{23}$$

Therefore $\|u_2^n\| \le M a_n$ for some $M > 0$; i.e., $u_2^n \to 0$ in the L^2 norm. The same holds for u_1^n. This is therefore a necessary condition that "regularizing" controls must satisfy.

Conversely, let u_n fulfill condition (23) and let y_n be a corresponding solution of (15) with starting point "near" S. Then, by standard arguments we get that $y_n \to 0$ pointwise. By the compactness property proved in Lemma 2.2, we get that actually $y_n \to 0$ uniformly.

Consider an arbitrary sliding mode control system satisfying the hypotheses stated in section 2.1. It is always possible to select sequences of real states converging to a chosen sliding state $\overline{y}$ by choosing the distance functional, namely,

$$J(y) = J_n(y) = \int_0^T |y(t) - \overline{y}(t)|\, dt.$$

There is at least another possible choice when an equivalent control u_{eq} exists.

COROLLARY 4.2. *Let the hypotheses of the general setting of section* 2.1 *be satisfied. Suppose that there exists an equivalent control* $u_{\mathrm{eq}} \in \mathcal{U}$*, i.e., an admissible feedback satisfying*

$$\frac{\partial s}{\partial t} + J_x s(t,x) f(t,x,u_{\mathrm{eq}}(t,x)) = 0 \qquad \forall x \in S(t), \quad \text{for a.e. } t \in [0,T].$$

Suppose, moreover, that the corresponding sliding trajectory y_{eq} *is unique. Let*

$$J^{\mathrm{eq}}(y) = \int_0^T \left| y(t) - x_0 - \int_0^t f(s, y(s), u_{\mathrm{eq}}(s, y(s)))\, ds \right| dt.$$

Then the sequence $J_n = J^{\mathrm{eq}}$ *for any* n *fulfills the assumptions of Theorem* 4.1.

When J_n are integral functionals satisfying suitable hypotheses, it is possible, in some sense, to read Theorem 4.1 as a result in the direction outlined at the end of the previous section. In fact if $J_n(y) = \int_0^T g_n(t, y(t))\, dt$, then

$$I_n(y) = \int_0^T \left[|s(t, y(t))| + a_n g_n(t, y(t)) \right] dt.$$

If the integrand is positive, there exists $s_n : [0,T] \times \mathbb{R}^N \to \mathbb{R}^M$ such that $|s_n(t,y)| = |s(t,y)| + a_n g_n(t,y)$, and we can think of the sets of zeros of s_n as an approximating sequence for the sliding manifold. This is not in contrast with the outcomes of section 4.1. In fact, there we showed that the sliding mode control system is not approximable whenever the sliding manifold is a fixed regular surface, while here we see that this problem can be overcome by allowing time-dependent manifolds.

DISCRETE APPROXIMATIONS AND FIXED SET ITERATIONS IN BANACH SPACES*

TZANKO DONCHEV†, ELZA FARKHI‡, AND SIMEON REICH§

Abstract. We study autonomous differential inclusions with right-hand sides satisfying a one-sided Lipschitz (OSL) condition in Banach spaces with uniformly convex duals. We first show that the solution set is closed and obtain estimates for Euler-type discrete approximations. We then use these results to derive an analogue of the exponential formula for the reachable set, as well as results regarding the existence and approximation of a strongly invariant attractor in the case of a negative OSL constant. As a by-product, conditions for controllability of the reverse-time system are obtained.

Key words. Banach space, differential inclusion, duality mapping, Euler approximations, exponential formula, fixed set iterations, one-sided Lipschitz condition, upper hemicontinuous

1. Introduction and preliminaries.

We study the initial value problem

$$\dot{x}(t) \in F(x(t)),\ x(0) = x_0,\ t \in I, \tag{1.1}$$

in a Banach space E with a uniformly convex dual, where I is either the bounded interval $[0, T]$ or $[0, \infty)$. A solution is any absolutely continuous function $x(\cdot)$ satisfying (1.1) for a.a. t.

Here $F : E \rightrightarrows E$ is a multifunction with nonempty, convex and weakly compact values. We assume that $F(\cdot)$ is one-sided Lipschitz (OSL), possibly discontinuous, and, in the case of an infinite time interval, that the OSL constant is negative.

The OSL condition for multifunctions with values in $\mathbf{R}^n$ is studied in [7, 8, 9, 10, 17] and in infinite-dimensional spaces in [5, 6]. Under this condition, which is considerably weaker than the classical Lipschitz one, we establish in the present paper new results on the existence of solutions and stability of the solution set with respect to perturbations of the right-hand side and the initial conditions, as well as the strict contractivity of the reachable set mapping when the OSL constant is negative.

In the case of an infinite time domain, we obtain the existence of a strongly invariant attractor set which is the limit of Euler-type set iterations. These results extend those obtained in [9] for the finite-dimensional case. Our qualitative results are obtained using Euler-type discrete approximations of (1.1) defined in [11].

The method of discrete approximations is frequently used to obtain existence of solutions of differential equations and inclusions (see, e.g., [3, 4, 12, 16]) as well as

necessary optimality conditions [18]. We also mention [13], where discrete approximations of singularly perturbed systems are studied. Applications of infinite-dimensional differential equations and inclusions are presented in a number of papers and books; see, e.g., [15, 19]. In particular, suitable modifications of the partial differential inclusion described in [14, section I.7] and of the partial differential equation (4.1) in [19] can serve as examples of applications of our results.

We also remark in passing that descent methods for minimizing a (convex) function f,

$$x_{k+1} = x_k + h_k f_k,\ f_k \in F(x_k) = -\partial f(x_k),$$

where ∂f is the subdifferential of f, may be regarded as Euler-type discrete approximations of (1.1) . Under certain conditions on f, such iterations approach an invariant set for (1.1) containing the minimizers of f.

Our paper is organized as follows. In the next section a semidiscrete approximation of (1.1) is defined and error estimates for the solution and reachable sets, as well as the nonemptiness and closedness of the solution set of (1.1), are derived. In the third section these results are applied to obtain the main results of the paper on the Euler approximation of (1.1) for finite and infinite time intervals. In the last section we present conditions for controllability of the reverse-time system.

We now recall some definitions and notation and refer the reader to [3, 14, 15] for all concepts used in this paper, but not explicitly discussed here. Define the normalized duality mapping by $J(x) = \{l \in E^* : \langle l, x\rangle = |x|^2 = |l|^2\}$, $x \in E$. Since E^* is uniformly convex, $J(\cdot)$ is single-valued and uniformly continuous on bounded sets (see [3, 15]). For $M > 0$ we denote by $\omega(\delta, M) := \sup\{|J(x) - J(y)| :\ |x - y| \le \delta,\ |x| \le M,\ |y| \le M\}$ its modulus of continuity on the ball $\{x \in E : |x| \le M\}$.

The support function of the bounded set A is denoted by $\sigma(y, A) := \sup_{x\in A}\langle x, y\rangle$ and the Hausdorff distance between the (closed and bounded) sets A and C by $D_H(A, C) = \max\{ex(A, C), ex(C, A)\}$, where $ex(A, C) = \sup_{a\in A}\inf_{b\in C}|a - b|$. The multifunction $R(\cdot)$ is said to be upper hemicontinuous (UHC) when for every $l \in E^*$ the support function $\sigma(l, R(\cdot))$ is USC as a real-valued function. Also, $F(\cdot)$ is said to be lower semicontinuous (LSC) at y when for every $f \in F(y)$ and every $y_i \to y$ there exists $f_i \in F(y_i)$ with $f_i \to f$. The (multi)function $R : I \rightrightarrows E$ is said to be strongly measurable if for every bounded interval $[a, b]$ and every $\varepsilon > 0$, there exists a simple function $R_i(\cdot)$ such that $D_H(R_i(t), R(t)) < \varepsilon$ for a.a. $t \in [a, b]$. Equivalently, $R(\cdot)$ is strongly measurable if for every bounded interval $[a, b]$ and every $\varepsilon > 0$, there exists a compact I_ε with $\mathrm{meas}(I_\varepsilon) > b - a - \varepsilon$ such that $R(\cdot)$ is continuous on I_ε (with respect to the Hausdorff distance).

By $diam(C) = \sup\{|a - b| :\ a, b \in C\}$ we denote the diameter of the set C, $|C| = D_H(C, \{0\})$ is the "norm" of a bounded set, and by $\mathbb{B}$ we denote the open unit ball in E.

We let $\mathrm{Graph}_A F := \{(x, y) :\ x \in A,\ y \in F(x)\}$ be the graph of F on a set A.

DEFINITION 1.1. *The multifunction $F :\ E \rightrightarrows E$ is said to be OSL with a constant L (not necessarily positive) when*

$$\sigma(J(x - y), F(x)) - \sigma(J(x - y), F(y)) \le L|x - y|^2$$

for every $x, y \in E$.

In this paper we assume that $L < 0$ when $T = \infty$.

Given a partition $\Delta = \{0 = t_0 < t_1 < \cdots < t_n = T\}$, we set $h_\Delta = \max_{1\le i\le n}(t_i - t_{i-1})$ (when $T = \infty$ we assume that $n = \infty$ and replace max by sup). The semidiscrete

differential inclusion corresponding to (1.1) is

$$\dot{x}(t) \in F(x_i),\ x(0) = x_0,\ x_i = x(t_i),\ t \in [t_i, t_{i+1}],\ i = 0, 1, \ldots, n-1. \tag{1.2}$$

Let $A(t, x_0)$ be the reachable set of (1.1) at the time t. The reachable set of (1.2) at t_k will be denoted by $A^{\Delta}(k, x_0)$ or by $A^{\Delta}(k)$ when x_0 is fixed. We denote by R_2^{Δ} the solution set of (1.2) and by R_1 the solution set of (1.1).

In the next section we study the connections between the solution set of (1.1) and the solution set of (1.2) (the set of discrete trajectories of (1.1)).

We will use the following simple inequality:

$$\big||a|^2 - |b|^2\big| \le |a-b|\{|a| + |b|\}. \tag{1.3}$$

2. Approximation of the solution set. In this section we estimate the Hausdorff distance between the solution sets of (1.1) and (1.2) and their reachable sets. The more restrictive case of a compact-valued (and USC) F is studied in [4].

In particular, we present more general versions of some results of [6], when E is not a Hilbert but a Banach space with a uniformly convex dual. We also extend to infinite-dimensional spaces the main results of [9] and [10] .

We will make the following assumption.

A. *$F(\cdot)$ is bounded on bounded sets and UHC.*

LEMMA 2.1. *Let F be an OSL multifunction which satisfies assumption* A. *Then there exist constants M and N such that $|x(t)| \le M$ and $|F(x(t) + \mathbb{B})| \le N$ for a.e. $t \in I$ and every solution $x(\cdot)$ of*

$$\dot{x}(t) \in \overline{co}\ F(x(t) + \mathbb{B}) + \mathbb{B},\ x(0) \in x_0 + \mathbb{B}. \tag{2.1}$$

Proof. This result is proved when F is also compact-valued in [4]. The proof in our case is similar but is included here for the convenience of the reader. Let $R(x) := \overline{co}\ F(x + \mathbb{B}) + \mathbb{B}$. Note that $R(\cdot)$ is also OSL with constant L, and bounded on bounded sets. Indeed, $\sigma(l, F(x) + \mathbb{B}) = \sigma(l, F(x)) + \sigma(l, \mathbb{B})$ for every $l \in E^*$. Furthermore, for every $x, y \in E$ and every $\varepsilon > 0$, there exists $l_\varepsilon \in \mathbb{B}$ such that $\sigma(J(x-y), F(x+\mathbb{B})) \le \sigma(J(x-y), F(x+l_\varepsilon)) + \varepsilon$. Thus $\sigma(J(x-y), F(x+\mathbb{B})+\mathbb{B}) - \sigma(J(x-y), F(y+\mathbb{B})+\mathbb{B}) \le \sigma(J(x-y), F(x+l_\varepsilon)) + \varepsilon - \sigma(J(x-y), F(y+l_\varepsilon)) \le L|x-y|^2 + \varepsilon$. Hence the mapping $x \to \overline{co}\ F(x+\mathbb{B}) + \mathbb{B}$ is also OSL with constant L.

If $x(\cdot)$ is a solution of (2.1), then

$$\begin{aligned}
&\langle J(x(t)), \dot{x}(t) - 0\rangle \le \sigma(J(x(t)), R(x(t))) - \sigma(J(x(t)), R(0)) \\
&+\sigma(J(x(t)), R(0)) \le L|x(t)|^2 + |R(0)| \cdot |x(t)|,\ \text{i.e.,} \\
&\frac{d}{dt}|x(t)|^2 \le 2L|x(t)|^2 + 2|R(0)| \cdot |x(t)|.
\end{aligned}$$

Since $|x(\cdot)|$ is absolutely continuous, it is a.e. differentiable and, moreover, $\frac{d}{dt}|x(t)|^2 = 2|x(t)|\frac{d}{dt}|x(t)|$. Let $\mathcal{J} := \{t :\ |x(t)| = 0\}$. If $s \in \mathcal{J}$ is a point of density where $|x(\cdot)|$ is differentiable, then $\frac{d}{ds}|x(s)| = 0$. Thus $\frac{d}{dt}|x(t)| \le L|x(t)| + |R(0)|$ for a.a. $t \in I$. But $|R(0)| \le M'$. Hence there exists a number M such that $M \ge |x(t)|$ for all $t \in I$ and for all solutions $x(\cdot)$ of (2.1). Since R is bounded on bounded sets, we can also find $N \ge |R(M\mathbb{B})|$. □

It is easy to see that $|x(t)| \le e^{Lt}(|x_0| + \int_0^t e^{-Ls}|R(0)|ds)$. Suppose $L \ne 0$. Then $|x(t)| \le e^{Lt}|x_0| + \frac{e^{Lt}-1}{L}|R(0)|$. Hence, in case $L < 0$, the constants M and N do not depend on the time $t > 0$.

Once M is determined, we let $\omega_J(\delta) = \omega_J(\delta, M)$.

We will use the following properties of $\omega_J(\cdot)$:

(a) The modulus $\omega_J(\cdot)$ is increasing.

(b) If $K \geq 1$, then $\omega_J(K\delta) \leq K\omega_J(\delta)$.

Indeed, given $\varepsilon > 0$, let $|J(x) - J(y)| \geq \omega_J(K\delta) - \varepsilon$. Therefore,

$$\left|J\left(\frac{x}{K}\right) - J\left(\frac{y}{K}\right)\right| = \frac{1}{K}|J(x) - J(y)|.$$

However, one has $\left|J\left(\frac{x}{K}\right) - J\left(\frac{y}{K}\right)\right| \leq \omega_J\left(\delta, \frac{M}{K}\right) \leq \omega_J(\delta)$, i.e., $\omega_J(K\delta) - \varepsilon \leq K\omega_J(\delta)$. Since ε is arbitrary, the result follows.

From now on we assume that $F(\cdot)$ has convex values.

THEOREM 2.2. *If $F(\cdot)$ is OSL and satisfies assumption* A*, then R_1 is nonempty and closed, and there exists a constant $C = C(T)$ such that*

$$D_H(R_2^{\Delta}, R_1) \leq C\sqrt{h_\Delta + \omega_J(h_\Delta)}.$$

If $L < 0$, then $C(\infty) < \infty$.

Proof. Let $\dot{y}(t) \in F(y(t) + \varepsilon\mathbb{B})$, i.e., $\dot{y}(t) \in F(y(t) + h(t))$, where $|h(t)| \leq \varepsilon$, and let $\Delta = \{t_i\}_{i=1}^n$ be a partition of $[0, T]$. We look for a solution $x(\cdot)$ of the discrete inclusion which is close to $y(\cdot)$. Let $x(0) = x_0$. Assuming that $x(\cdot)$ is known on $[0, t_i]$, we find $x(\cdot)$ on $[t_i, t_{i+1}]$. Denote $x_i = x(t_i)$. The OSL condition implies that

$$\sigma(J(y(t) - x_i + h(t)), F(y(t) + h(t))) - \sigma(J(y(t) - x_i + h(t)), F(x_i)) \leq L|y(t) - x_i + h(t)|^2.$$

It is easy to see that $\sigma(J(y(t)-x_i+h(t)), F(x_i)) \leq N\omega_J(\varepsilon)+\sigma(J(y(t)-x_i), F(x_i))$ and that $\sigma(J(y(t) - x_i + h(t)), F(y(t) + h(t))) \geq \sigma(J(y(t) - x_i), F(y(t) + h(t))) - N\omega_J(\varepsilon)$.

Let $\tilde{z}(t) = y(t) - x_i$. Since the mapping $t \to \tilde{z}(t)$ is continuous, it follows that for every $\delta > 0$, there exists a strongly measurable selection $f_i(t) \in F(x_i)$ $(x_i = x(t_i))$ on the interval $[t_i, t_{i+1}]$ such that

$$\sigma(J(\tilde{z}(t)), F(x_i)) < \langle J(\tilde{z}(t)), f_i(t)\rangle + \delta.$$

There is even such a continuous selection because for every $\mu > 0$ the set-valued map $G_\mu(t) = \{\overline{y \in F(x_i) : \langle J(\tilde{z}(t)), y\rangle > \sigma(J(\tilde{z}(t)), F(x_i)) - \mu}\}$ is LSC with nonempty, convex, and weakly compact values.

Setting $x(t) = x_i + \int_{t_i}^t f_i(\tau)\, d\tau$ and $z(t) = y(t) - x(t)$, we obtain

$$\sigma(J(\tilde{z}(t)), F(y(t) + h(t))) - \sigma(J(\tilde{z}(t)), F(x_i)) \leq 2N\omega_J(\varepsilon) + L|\tilde{z}(t) + h(t)|^2$$

and

$$L|\tilde{z}(t) + h(t)|^2 \leq L|z(t)|^2 + |L|\left||\tilde{z} + h(t)|^2 - |z(t)|^2\right|.$$

From the triangle inequality and (1.3) it follows that

$$\begin{aligned}(2.2)\qquad &\sigma(J(\tilde{z}(t)), F(y(t) + h(t))) - \sigma(J(\tilde{z}(t)), F(x_i)) \\ &\leq 2N\omega_J(\varepsilon) + L|z(t)|^2 + |L||\tilde{z}(t) + h(t) - z(t)|\left(|\tilde{z}(t)| + |z(t)| + \varepsilon\right).\end{aligned}$$

Thus we have

$$\begin{aligned}&\langle J(z(t)), \dot{z}(t)\rangle \leq \langle J(\tilde{z}(t)), \dot{z}(t)\rangle + |J(z(t)) - J(\tilde{z}(t))||\dot{z}(t)| \\ &\leq \sigma(J(\tilde{z}(t)), F(y(t) + h(t))) - \sigma(J(\tilde{z}(t)), F(x_i)) + \delta + 2N\omega_J(|x(t) - x_i|).\end{aligned}$$

Since $\langle J(z(t)), \dot{z}(t)\rangle = \frac{1}{2}\frac{d}{dt}|y(t)-x(t)|^2$, taking into account (2.2) we derive

$$\frac{d}{dt}|y(t)-x(t)|^2 \le 2L|y(t)-x(t)|^2 + 4N^2\omega_J(h_\Delta) + 4N\omega_J(\varepsilon)$$
$$+2|L||x(t)-x_i+h(t)|(4M+\varepsilon) + 2\delta.$$

Hence $|y(t)-x(t)|^2 \le r(t)$, where $r(0)=0$ and

$$\dot{r}(t) = 2Lr(t) + 2|L|\,(\varepsilon + Nh_\Delta)\,(4M+\varepsilon) + 4N\omega_J(\varepsilon) + 4N^2\omega(h_\Delta) + 2\delta.$$

Let $S(T) := \max_{t\in[0,T]} e^{2Lt}\int_0^t e^{-2L\tau}d\tau$. Clearly, $S(\infty) < \infty$ for $L < 0$. Hence there exists a constant $C(T) = S(T)C_1(M,N)$ such that

$$|y(t)-x(t)| \le C(T)\sqrt{h_\Delta + \varepsilon + \omega_J(\varepsilon + h_\Delta) + 2\delta}. \tag{2.3}$$

Clearly, if $L < 0$, then $C(\infty) < \infty$.

Since $\delta, \varepsilon > 0$ are arbitrary, we get $ex(R_1, R_2^\Delta) \le C\sqrt{h_\Delta + \omega_J(h_\Delta)}$.

Now we are to prove that the solution set of (1.1) is nonempty and $C(I,E)$ closed, and that $ex(R_2^\Delta, R_1) \le C\sqrt{h_\Delta + \omega_J(h_\Delta)}$. To this end, we construct a Cauchy sequence of semidiscrete trajectories.

Let a partition $\Delta_1 = \{t_i\}_{i=1}^K$ with step h_1 be given, and let $\Delta_2 = \{\tau^j\}_{j=1}^P$ be a refinement of Δ_1 with step $h_2 \le \frac{h_1}{4}$, satisfying $\omega_J(h_2) \le \frac{\omega_J(h_1)}{4}$. Denote by $R_2^{\Delta_1}$ and $R_2^{\Delta_2}$ the solution set of (1.2) with respect to Δ_1 and Δ_2. For a given $x(\cdot) \in R_2^{\Delta_1}$, we define $y(\cdot) \in R_2^{\Delta_2}$ as follows.

Suppose $y(\cdot)$ is already defined on $[0,\tau^j]$. Let $[\tau^j, \tau^{j+1}] \subset [t_i, t_{i+1}]$. Put $y^j = y(\tau^j)$ and $x_i = x(t_i)$. For $t \in [\tau^j, \tau^{j+1}]$, we find a strongly measurable $f(t) \in F(y^j)$, where $y^j = y(\tau^j)$, such that

$$\langle J(x_i - y^j), \dot{x}(t) - f(t)\rangle \le L|x_i - y^j|^2.$$

Indeed, one can take $f(t) = l^j$, where $\langle J(x_i-y^j), l^j\rangle = \sigma(J(x_i-y^j), F(y^j))$. Define $y(t) = y^j + \int_{\tau^j}^t f(s)\,ds$. Similarly, we obtain

$$\langle J(x(t)-y(t)), \dot{x}(t)-\dot{y}(t)\rangle \le L|x(t)-y(t)|^2$$
$$+|J(x_i-y^j) - J(x(t)-y(t))||\dot{x}(t)-\dot{y}(t)| + |L|\left||x_i-y^j|^2 - |x(t)-y(t)|^2\right|.$$

Since $|F(x(t)+\mathbb{B})| \le N$ and $|x(t)| \le M$, we have

$$|(x_i-y^j) - (x(t)-y(t))| \le N(h_1+h_2); \quad |\dot{x}(t)-\dot{y}(t)| \le 2N.$$

Hence

$$\langle J(x(t)-y(t)), \dot{x}(t)-\dot{y}(t)\rangle \le L|x(t)-y(t)|^2 + 2N\omega_J(N(h_1+h_2)) + |L|4MN(h_1+h_2).$$

By property (b) of ω_J, $\omega_J(N(h_1+h_2)) \le N\omega_J(h_1+h_2)$. Denoting $r(t) = |x(t)-y(t)|^2$, one derives

$$\dot{r}(t) \le 2Lr(t) + 4N^2\omega_J(h_1+h_2) + 8MN|L|(h_1+h_2).$$

To complete the proof, one has to consider an appropriate sequence of partitions $\{\Delta_k\}_{k=1}^\infty$ with steps $h_{k+1} \le \frac{h_k}{4} \le \frac{h_1}{4^k}$, $\omega_J(h_{k+1}) \le \frac{\omega_J(h_k)}{4}$, and the corresponding

sequence of approximate solutions $\{x_k(\cdot)\}_{k=1}^{\infty}$ such that $|x_k(t) - x_{k+1}(t)|^2 = r_k(t)$. Here

$$\dot{r}_k(t) \le 2Lr_k(t) + 4N^2\omega_J\left(\frac{5h_k}{4}\right) + 10MN|L|h_k$$

and

$$r_k(t) \le \frac{Ce^{2Lt}t}{4^k}(h_1 + \omega_J(h_1)).$$

Hence $\sum_{k=1}^{\infty}\sqrt{r_k(t)}$ converges uniformly on $[0,T]$. Consequently, $\{x_k(\cdot)\}_{k=1}^{\infty}$ is a Cauchy sequence and there exists $x(t) = \lim_{k\to\infty} x_k(t)$. Since F is UHC, it is standard to show that $x(\cdot)$ is a solution of (1.1). The same method proves that the solution set is closed.

Let $s_n := \max_{t\in[0,T]}\sqrt{r_n(t)}$. Then

$$Ex(R_2^{\Delta}, R_1) \le \sum_{k+1}^{\infty} s_n \le C(T)\sqrt{h_{\Delta} + \omega_J(h_{\Delta})}.$$

Obviously, $C(\infty) < \infty$ when $L < 0$. □

The following corollary is a lemma of Filippov–Pliss type.

COROLLARY 2.3. *If $x(\cdot)$ is a solution of*

$$\dot{x}(t) \in F(x(t) + \varepsilon\mathbb{B}),\ x(0) = x_0,$$

then there exists a constant $C = C(T)$ such that $\operatorname{dist}(x(\cdot), R_1) \le C\sqrt{\varepsilon + \omega_J(\varepsilon)}$. *Furthermore, $C(\infty) < \infty$ when $L < 0$.*

Proof. Fix $h > 0$ and consider the uniform grid of I with length h. Replacing δ in (2.3) by 0, we see that there exists a constant C_1 such that $\operatorname{dist}(x(\cdot), R_2^{\Delta}) \le C_1\sqrt{h + \varepsilon + \omega_J(h+\varepsilon)}$. By Theorem 2.2, there exists a constant C_2 such that

$$D_H(R_2^{\Delta}, R_1) \le C_2\sqrt{h + \omega_J(h)}$$

for each $h > 0$. Since $\operatorname{dist}(x(\cdot), R_1) \le \operatorname{dist}(x(\cdot), R_2^{\Delta}) + D_H(R_2^{\Delta}, R_1)$, we can finish the proof by letting $h \to 0$. □

After some standard calculations one can also prove the following extension of Corollary 2.3.

If $x(\cdot)$ is a solution of

$$\dot{x}(t) \in \overline{co}\ F(x(t) + \varepsilon\mathbb{B}),\ x(0) = x_0,$$

then there exists a constant $C = C(T)$ such that $\operatorname{dist}(x(\cdot), R_1) \le C\sqrt{\varepsilon + \omega_J(\varepsilon)}$. Furthermore, $C(\infty) < \infty$ when $L < 0$.

COROLLARY 2.4. *Under the conditions of Theorem* 2.2, $D_H(A(T, x_0), A(T, y_0)) \le e^{LT}|x_0 - y_0|$.

The proof is standard (one can follow the proofs of the previous corollary and the second part of Theorem 2.2 (see, e.g., [7, 8])) and is therefore omitted.

If $F(\cdot)$ is compact-valued and USC, then the reachable set $A(t, x_0)$ is also compact for every $t > 0$. When F is only weakly compact-valued or UHC, it is not clear if $A(t, x_0)$ is always closed. Clearly, the solution set of (1.1) is $C([0,T], H)$ closed.

The following result may be viewed as a "robustness" property of the OSL property.

LEMMA 2.5. *Let $F, G_n : E \rightrightarrows E$ be bounded by N and suppose that for each $M > 0$,*

$$\lim_{n\to\infty} D_H(Graph_{M\mathbb{B}}\ F, Graph_{M\mathbb{B}}\ G_n) = 0.$$

If each G_n is OSL with constant L (not depending on n), then F is also OSL with the same constant L.

Proof. Given $\delta > 0$, let $D_H(\mathrm{Graph}_{M\mathbb{B}}\ F, \mathrm{Graph}_{M\mathbb{B}}\ G) < \delta$, and let G be OSL with a constant L. If $x, y \in M\mathbb{B}$, then there exist $l_x, l_y \in \delta\mathbb{B}$ such that $\sigma(J(x-y), F(x)) < \sigma(J(x-y), G(x+l_x)) + \delta$ and $\sigma(J(x-y), F(y)) > \sigma(J(x-y), G(y+l_y)) - \delta$. Consequently,

$$\begin{aligned}
&\sigma(J(x-y), F(x)) - \sigma(J(x-y), F(y)) \\
&\le \sigma(J(x-y), G(x+l_x)) - \sigma(J(x-y), G(y+l_y)) + 2\delta \\
&\quad \le \sigma(J(x+l_x-y-l_y), G(x+l_x)) - \sigma(J(x+l_x-y-l_y), G(y+l_y)) \\
&+ 2N\Big|J(x-y) - J(x+l_x-y-l_y)\Big| + 2\delta \\
&\le L|x+l_x-y-l_y|^2 + 4N\omega_J(\delta) + 2\delta \\
&\quad \le L|x-y|^2 + 4\delta|L|(2M+\delta) + 4N\omega_J(\delta) + 2\delta.
\end{aligned}$$

Since $\lim_{\delta\to 0}(4\delta|L|(M+\delta) + 4N\omega_J(\delta) + 2\delta) = 0$, one has $\sigma(J(x-y), F(x)) - \sigma(J(x-y), F(y)) \le L|x-y|^2$. ∎

Denote $h_i = t_i - t_{i-1}$. From Lemma 2.1 we know that there exist constants M and N (depending on L and T) such that $|x(t)| \le M$ and $|F(x(t)+\mathbb{B})| \le N$ for every solution $x(\cdot)$ of (1.1), when $F(x)$ is replaced by $F(x(t)+\mathbb{B})$. Thus for $h_\Delta N < 1$, every solution of (1.2) is a solution of $\dot{x}(t) \in F(t, x(t)+\mathbb{B})$.

To estimate the distance between the solution sets of (1.1) and (1.2), for a given partition Δ of $[0,T]$, we fix x_0 and set $d_k = D_H(A(t_k, x_0), A^\Delta(k))$.

COROLLARY 2.6. *Let $F(\cdot)$ be OSL, bounded on bounded sets, UHC, and convex weakly compact-valued. If $h_k \le \min\{1, \frac{1}{N}\}$, then there exists a constant C such that for every $1 \le k \le n$,*

$$d_{k+1}^2 \le e^{2Lh_k} d_k^2 + Ch_k(h_k + \omega_J(h_k)).$$

Proof. We will modify the proof of Lemma 3.13 in [9]. Let $x(\cdot)$ be a solution of (1.1) and let $\varepsilon > 0$ be given. We first find a solution $y(\cdot)$ of (1.2) such that $|x(t_k) - y(t_k)| < \mathrm{dist}(x(t_k), A^\Delta(k)) + \varepsilon$. Since $F(\cdot)$ is OSL and convex weakly compact-valued, there exists a strongly measurable selection $f(t) \in F(y(t_k))$ on $[t_k, t_{k+1}]$ such that

$$\langle J(x(t) - y(t_k)), \dot{x}(t) - f(t)\rangle \le L|x(t) - y(t_k)|^2.$$

For $t \in [t_k, t_{k+1}]$, define $y(t) = y(t_k) + \int_{t_k}^t f(\tau)\, d\tau$. We have

$$\begin{aligned}
&\langle J(x(t) - y(t)), \dot{x}(t) - \dot{y}(t)\rangle \le L|x(t) - y(t_k)|^2 \\
&+ |J(x(t) - y(t)) - J(x(t) - y(t_k))| \cdot |\dot{x}(t) - \dot{y}(t)| \\
&\le L|x(t) - y(t_k)|^2 + 2N\omega_J(N(t - t_k)).
\end{aligned}$$

Let $r(t) = x(t) - y(t)$. Then $\langle J(r(t)), \dot{r}(t)\rangle \le L|x(t) - y(t_k)|^2 + 2N^2\omega_J(t - t_k)$. Furthermore, by (1.3) and Lemma 2.1,

$$|x(t) - y(t_k)|^2 \le |x(t) - y(t)|^2 + 4MN(t - t_k).$$

Consequently, $\langle J(r(t)), \dot{r}(t)\rangle \le L|r(t)|^2 + 2N^2\omega_J(t - t_k) + 4MN|L|(t - t_k)$. Hence $\frac{d}{dt}|r(t)|^2 \le 2L|r(t)|^2 + C\left(\omega_J(t - t_k) + (t - t_k)\right)$. By standard calculations one can show that $|r(t_{k+1})|^2 \le e^{2Lh_k}|r(t_k)|^2 + O(h_k(h_k + \omega_J(h_k)))$. Therefore we derive

$$(\mathrm{dist}(x(t_{k+1}), A^\Delta(k+1)))^2 \le e^{2Lh_k}(\mathrm{dist}(x(t_k), A^\Delta(k)) + \varepsilon)^2 + O\left(h_k(h_k + \omega_J(h_k))\right).$$

Since $\varepsilon > 0$ is arbitrary, one may replace it by 0. The fact that for every solution $y(\cdot)$ of (1.2),

$$(\mathrm{dist}(y(t_{k+1}), A(t_{k+1})))^2 \le e^{2Lh_k}(\mathrm{dist}(y(t_k), A(t_k)))^2 + C(h_k(h_k + \omega_J(h_k)))$$

can be proved as in Theorem 2.2. Thus $d_{k+1}^2 \le e^{2Lh_k}d_k^2 + Ch_k(h_k + \omega_J(h_k))$. ∎

Using the discrete Gronwall inequality, we obtain another corollary.

COROLLARY 2.7. *Under the assumptions of the previous corollary, for a uniform partition of the interval* $[0, T]$ *with step* h *and* $T = nh$,

$$D_H(A(T, x_0), A^\Delta(n, y_0)) \le e^{LT}|y_0 - x_0| + C\sqrt{h + \omega_J(h)},$$

where C *does not depend on* T *if* $L < 0$.

3. The Euler method. We denote by $(I + hF)(X_0) = \bigcup_{x\in X_0}\{x + hF(x)\}$ an Euler step for the inclusion (1.1).

Higher powers of $I + hF$ are defined by

$$(I + hF)^{n+1}(X_0) = (I + hF)\left[\left(I + hF\right)^n(X_0)\right].$$

Consider the Euler discretization of (1.1) for a given partition Δ of $[0, T]$:

$$x(t) = x_i + (t - t_i)f_i, \tag{3.1}$$

where $f_i \in F(x_i),\ x_i = x(t_i),\ x(0) = x_0,\ t \in [t_i, t_{i+1}],\ i = 0, 1, \ldots$.

Denote the reachable set of (3.1) at time $t \in [0, T]$ by $Reach^\Delta(t, x_0)$ or by $Reach^\Delta(t)$ for short.

The following corollary extends the exponential formula of Wolenski [20] and its OSL extension in $\mathbb{R}^n$ [10] to the case of UHC differential inclusions in a Banach space.

COROLLARY 3.1 (exponential formula). *Under the conditions of Theorem* 2.2, *for every* $t \in [0, T]$ *we have*

$$A(T, x_0) = \lim_{n\to\infty}\left(I + \frac{T}{n}F\right)^n(x_0) := e^{TF}x_0.$$

Proof. For the uniform partition $t_i = \frac{iT}{n},\ i = 0, 1, \ldots, n-1$, with $h = \frac{T}{n}$, consider the Euler polygons (3.1).

Since $F(\cdot)$ is convex weakly compact-valued, the reachable set of (3.1) coincides at the points t_k with the reachable set of (1.2), i.e., $A^\Delta(t_k, x_0) = Reach^\Delta(t_k, x_0) = (I + hF)^k(x_0)$. It follows from Corollaries 2.6 and 2.7 that

$$D_H\left(A(T, x_0), \left(I + \frac{T}{n}F\right)^n(x_0)\right) \le C\sqrt{\frac{1}{n} + \omega\left(\frac{1}{n}\right)}.$$

The proof is therefore complete. ∎

Next we assume that $L < 0$ and study the asymptotic behavior of the reachable set when $T \to \infty$.

The following theorem extends Theorems 3.1 and 3.5 of [9].

THEOREM 3.2. *Suppose that $F(\cdot)$ satisfies all the assumptions of Theorem* 2.2 *with $L < 0$. Then there exists a closed and bounded set A^∞ such that $A^\infty = \lim_{t\to\infty} \overline{A(t, x_0)}$. Moreover,*

(i) *A^∞ is attracting the reachable sets; i.e., for bounded $B \neq A^\infty$, if $T > 0$, then $D_H(A(T, B), A^\infty) < D_H(B, A^\infty)$;*

(ii) *$\overline{A(T, A^\infty)} = A^\infty$ for every $T > 0$;*

(iii) *A^∞ does not depend on x_0;*

(iv) *A^∞ is a strongly invariant set for* (1.1)*; i.e., every solution $x(\cdot)$ of* (1.1) *with $x(0) \in A^\infty$ satisfies $x(t) \in A^\infty$ for every $t > 0$.*

Proof. We will follow the proofs of Theorems 3.1 and 3.5 of [9]. Let $0 < t < s$. Since for every bounded B, the sets $A(t, B)$ and $A(s, B)$ are bounded subsets of $M\mathbb{B}$, by Corollary 2.4, $D_H(A(t, B), A(s, B)) \le D_H(B, A((s - t), B))e^{L(s-t)} \le 2Me^{L(s-t)}$. Thus the net $\{A(t, B)\}_{t\ge 0}$ is a Cauchy net. Therefore, $\{\overline{A(t, B)}\}_{t\ge 0}$ is also a Cauchy net. Since the set of closed and bounded subsets of E equipped with the Hausdorff metric is a complete metric space, the limit A^∞ exists. By Corollary 2.4, this limit does not depend on the initial condition x_0 and satisfies (i) because $L < 0$. Moreover, for a given $T > 0$, the multivalued map $B \to \overline{A(T, B)}$ is a set-valued contraction. Hence there exists a unique nonempty closed set D_T with $\overline{A(T, D_T)} = D_T$. As in [9], it is easy to see that $D_T = A^\infty$. Hence $\overline{A(T, A^\infty)} = A^\infty$ for every $T \ge 0$. Thus A^∞ is a strongly invariant set. The rest of the proof is obvious. ∎

COROLLARY 3.3. *Under the conditions of Theorem* 3.2*, $A^\infty \subset B$ for every other strongly invariant set B of* (1.1)*.*

Proof. By (i) of Theorem 3.2, we see that $\lim_{t\to\infty} \overline{A(t, B)} = A^\infty \subset B$, because B is a strongly invariant set. ∎

We call A^∞ the *fixed set* (for (1.1)).

The next theorem shows that the fixed set may be approximated by the reachable set $Reach^\Delta(t, x_0)$ of (3.1) for special time step sequences and may be regarded as an infinite time exponential formula (cf. Corollary 3.15 of [9]) in the setting of Banach spaces.

THEOREM 3.4 (fixed set iterations). *Under the conditions of Theorem* 3.2*, there exists a partition Δ of $[0, \infty)$ such that the reachable set $Reach^\Delta(t, x_0)$ of* (3.1) *satisfies $\lim_{t\to\infty} D_H(Reach^\Delta(t, x_0), A^\infty) = 0$.*

Proof. By (ii) of Theorem 3.2, $A^\infty = \overline{A(t, A^\infty)}$. Furthermore, by Corollary 2.4 we know that

$$D_H(A(T, A_0), A(T, A^\infty)) \le e^{LT} D_H(A_0, A^\infty). \tag{3.2}$$

One may suppose that the constant $C(T)$ in Theorem 2.2 is increasing; i.e., $C(T) \le C(\infty)$.

We let $A_0 = \{x_0\}$, find $T > 0$ such that $e^{LT} < \frac{1}{4}$, and set $i := 0$. Now we proceed as follows.

Step A. Set $K_i = D_H(A_i, A^\infty)$. Hence $D_H(A^\infty, A(T, A_i)) < \frac{K_i}{4}$. Let h_i be so small that for $h_i := \frac{T}{k_i}$ one has $C(\infty)\sqrt{h_i + \omega_J(h_i)} < \frac{K_i}{4}$. Let Δ_i be the uniform partition of $[iT, (i + 1)T]$ corresponding to h_i. It follows from Corollary 3.1 that

$$D_H(A(T, A_i), Reach^{\Delta_i}(T, A_i)) \le C(\infty)\sqrt{h_i + \omega_J(h_i)} < \frac{K_i}{4}.$$

Let $A_{i+1} := Reach^{\Delta_i}(T, A_i)$. Consequently,

$$D_H(A_{i+1}, A^\infty) \le D_H(A_{i+1}, A(T, A_i)) + D_H(A(T, A_i), A^\infty) < 2\frac{K_i}{4} = \frac{K_i}{2}. \tag{3.3}$$

End of Step A.

Since the system is autonomous, one can start from A_1 and repeat Step A with A_0 replaced by A_1 and K_0 replaced by K_1 $\big($hence $K_1 < \frac{K_0}{4}\big)$. We find $h_1 < h_0$ and A_2 such that $D_H(A_2, A^\infty) < \frac{K_1}{2} < \frac{K_0}{4}$. Notice that A_2 is the reachable set of (3.1) for the time $2T$, where the partition Δ of the interval $[0, 2T]$ has step h_0 on $[0, T]$ and step h_1 on $[T, 2T]$.

Now we repeat Step A n times and derive a sequence $\{A_n\}_{n=1}^\infty$ where A_n is the reachable set of (3.1) for the time $nT := \sum_{i=0}^{n-1} T$ and $D_H(A_n, A^\infty) < \frac{K_0}{2^n}$. It is easy to see that $\lim_{n\to\infty} nT = \infty$ and $\lim_{n\to\infty} \overline{A_n} = A^\infty$, which yields the assertion of the theorem. □

Note that the choice of the time steps above depends on the modulus ω and therefore cannot be the same as in the corresponding result of [9].

4. Controllability of other-sided Lipschitz systems. We will call the multimap $F : E \rightrightarrows E$ other-sided (backward-sided) Lipschitz (BSL) when

$$\sigma(J(x-y), F(x)) - \sigma(J(x-y), F(y)) \ge L|x-y|^2 \text{ for all } x, y \in E.$$

It is easy to see that $F(\cdot)$ is BSL if and only if the mapping $-F(\cdot)$ is OSL.

Consider the differential inclusion

$$\dot{x}(t) \in F(x),\ x(0) = x_0 \in K. \tag{4.1}$$

If $F(\cdot)$ is BSL, it is not possible to prove either existence of solutions or qualitative properties. However, changing the time direction by setting $t = -s$, we obtain an OSL differential inclusion. Let $F(\cdot)$ be BSL with constant $L > 0$. In this case $-F(\cdot)$ is OSL with constant $-L$. Assume that $F(\cdot)$ has nonempty, convex, and weakly compact values and is bounded on bounded sets. By Theorem 3.2, there exists a backward fixed set $A^{-\infty} = \lim_{t\to-\infty} \overline{A(t, x_0)}$ such that

(i) $A^{-\infty}$ is a backward attractor of the reachable sets; that is, if $B \ne A^{-\infty}$ is bounded and $T < 0$, then $D_H(A(T, B), A^\infty) < D_H(B, A^\infty)$;

(ii) $\overline{A(T, A^{-\infty})} = A^{-\infty}$ for every $T < 0$;

(iii) $A^{-\infty}$ does not depend on x_0;

(iv) $A^{-\infty}$ is a strongly backward invariant set for (1.1); i.e., every solution $x(\cdot)$ of (1.1) with $x_0 \in A^{-\infty}$ satisfies $x(t) \in A^{-\infty}$ for every $t < 0$.

Note that the above assertions are those of Theorem 3.2 rewritten in the backward time direction. As a corollary we derive the following criterion for complete controllability.

THEOREM 4.1. *Let $F(\cdot)$ be UHC, with nonempty, convex, and weakly compact values, bounded on bounded sets, and BSL with positive constant L.*

(i) *If K is an open set such that $K \bigcap A^{-\infty} \ne \emptyset$, then for every $z \in E$, there exist $x_0 \in K$ and a finite time $T(z)$ such that z belongs to the reachable set of* (4.1) *at time $T(z)$; i.e.,* (4.1) *is completely quasi-controllable.*

(ii) *If K is an open set such that $K \bigcap A^{-\infty} = \emptyset$, then there exists $z \in E$ which cannot be reached in finite time from K; i.e.,* (4.1) *is not completely quasi-controllable.*

Finally, we present an example of a Hilbert space differential inclusion to which our results can be applied.

EXAMPLE 4.1. *Let $E = l^2$ be the Hilbert space of all square summable real sequences.*

Consider the following system:

$$
\begin{aligned}
&\dot{x}_0(t) \in -x_0(t) + [-1,1],\ x_0(0) = 0,\\
&\dot{x}_1(t) \in -x_1(t) - \frac{\sqrt[5]{x_1^3}}{\sqrt[3]{1}} + \frac{1}{2}[-|x_0(t)|, |x_0(t)|],\ x_1(0) = 0,\\
&\qquad \dots \qquad (4.2)\\
&\dot{x}_n(t) \in -x_n(t) - \frac{\sqrt[5]{x_n^3}}{\sqrt[3]{n}} + \frac{1}{2}[-|x_{n-1}(t)|, |x_{n-1}(t)|],\ x_n(0) = 0,\\
&\dots .
\end{aligned}
$$

It is not difficult to see that the right-hand side F of (4.2) *is OSL with a constant $L = -\frac{1}{2}$. We claim that F maps l^2 into l^2. If $\vec{x} \in l^2$, then obviously $-\vec{x} \in l^2$, too. Also, if $\vec{x} \in l^2$ with $\vec{x} = (x_0, x_1, \dots, x_n, \dots)$, then $\vec{y} = (0, |x_0|, |x_1|, \dots, |x_n|, \dots) \in l^2$. Thus we have only to check that if $\vec{x} = (x_0, x_1, \dots, x_n, \dots) \in l^2$, then $\sum_{n=0}^{\infty} \frac{\sqrt[5]{x_n^6}}{\sqrt[3]{n^2}}$ converges. But this is a trivial consequence of the Cauchy–Schwarz inequality ($\langle \vec{x}, \vec{y} \rangle \le |\vec{x}||\vec{y}|$) and the fact that the series $\sum_{n=1}^{\infty} \sqrt[5]{x_n^{12}}$ and $\sum_{n=1}^{\infty} \sqrt[3]{n^{-4}}$ converge.*

Note that in this example $F(\cdot)$ is continuous (not Lipschitz) with convex (strongly) compact values. The existence of solutions to the system (4.2) *is proved in* [4]. *This existence also follows from Theorem* 2.2.

Acknowledgments. All the authors thank the referees for many valuable comments and suggestions.

THE VECTOR-VALUED VARIATIONAL PRINCIPLE IN BANACH SPACES ORDERED BY CONES WITH NONEMPTY INTERIORS*

EWA M. BEDNARCZUK† AND MACIEJ J. PRZYBYŁA‡

Abstract. We prove sharpness of efficient solutions x_k to vector optimization problems resulting from Ekeland vector variational principles. We achieve this by sharpening some of the existing vector variational principles and showing that x_k remains efficient not only for perturbations in the direction k but also for other directions of perturbations.

Key words. vector-valued variational principle, Bishop–Phelps cone, sharp solutions

DOI. 10.1137/060658989

1. Introduction. In its classical formulation, the Ekeland variational principle [3] states that in a vicinity of an ε-solution to the minimization problem of a lower semicontinuous (*lsc*) bounded below real-valued function f defined on a complete metric space, one can always find a strict solution to a minimization problem with slightly perturbed function f. There exist many generalizations of this theorem, to metric spaces, e.g., [2, 8, 13], to locally convex topological spaces and to general topological spaces [4]. A parametrized version of Ekeland's variational principle was proved in [7].

In recent years variational principles for vector-valued functions taking values in partially ordered spaces have been studied by several authors [5, 6, 10, 11, 12, 16].

The following vector variational principle was proved in [5] and [16].

THEOREM 1.1 (see Theorem 8 in [5]). *Let X and Z be real Banach spaces and Z be partially ordered by a closed convex pointed cone $\mathcal{K}$. An element $+\infty \notin Z$ is such that $z \leq +\infty$ for all $z \in Z$. Let $f\colon X \to Z \cup \{+\infty\}$ be a quasi-lsc, bounded below proper function, $\bar{x} \in D(f)$, and let $k \in \mathcal{K} \setminus \{0\}$. If $f(X) \cap (f(\bar{x}) - \varepsilon k - \mathcal{K} \setminus \{0\}) = \emptyset$ for some $\varepsilon > 0$, then for every $\lambda > 0$ there exists x_k such that*

(i) $f(x_k) \leq f(\bar{x})$,
(ii) $\|\bar{x} - x_k\| \leq \lambda$,
(iii) $x_k \in E(f_{(x_k,k)})$, *where* $f_{(x_k,k)}(x) := f(x) + \frac{\varepsilon}{\lambda}\|x - x_k\|k$.

The following theorem [9, 10] relaxes the requirement for f to be bounded below, strengthens assertion (iii), and puts less stringent assumptions on X, Y, and $\mathcal{K}$.

THEOREM 1.2 (see Corollary 3.10.14 in [9]). *Let (X, d) be a complete metric space and Y be a separated locally convex space ordered by a closed cone $\mathcal{K}$. An element $+\infty \notin Y$ is such that $y \leq +\infty$ for all $y \in Y$. Let $f\colon X \to Y \cup \{+\infty\}$ be a proper function, $\bar{x} \in D(f)$, and let $k \in \mathcal{K} \setminus (-\mathcal{K})$. Suppose that for every $r \in \mathbb{R}$ the set $\{x \in X \mid f(x) \leq f(\bar{x}) + rk\}$ is closed. If $f(X) \cap (f(\bar{x}) - \varepsilon k - \mathcal{K} \setminus \{0\}) = \emptyset$ for some $\varepsilon > 0$, then for every $\lambda > 0$ there exists x_k such that*

(i) $f(x_k) + \lambda^{-1}\varepsilon d(x_k, \bar{x})k \leq f(\bar{x})$, $d(x_k, \bar{x}) \leq \lambda$,

(ii) *if* $f(x) + \lambda^{-1}\varepsilon d(x_k, x)k \leq f(x_k)$, *then* $x = x_k$.

In [6], Finet, Quarta, and Troestler introduced the notion of the order lower semicontinuity and deduced the vector-valued Ekeland variational principle for an order lower semicontinuous bounded below function f directly from the Deville–Godefroy–Zizler perturbed minimization principle (Corollary 31 of [6]). In [11] and [12], a relation between nuclearity of cones in product spaces and Ekeland's variational principle is considered.

Sharp efficiency can be viewed as one of the weakest types of proper efficiency and plays a crucial role in investigating stability to perturbed vector optimization problems (cf. [1]).

In the present paper we prove that x_k is a sharp efficient solution (in the sense of [1]) to function $f_{(x_k,k)}(x) = f(x) + \frac{\varepsilon}{\lambda}\|x - x_k\|$. Moreover, we introduce the new concept of ε-solutions to vector optimization problems with respect to Bishop–Phelps cones. By using this concept we derive another form of vector variational principle which gives an efficient solution x_0 to functions $f_{(x_0,k)}$ for all $k \in \operatorname{int} \mathcal{K}_\alpha$ with $\varphi(k) - \alpha\|k\|$ sufficiently large and we prove the sharpness of x_0.

The organization of the paper is as follows. In section 3 we introduce a new concept of ε-efficient solutions for f taking values in spaces ordered by Bishop–Phelps cones $\mathcal{K}_\alpha$. This concept strengthens some of the existing definitions of ε-efficiency and allows us to prove the vector-valued Ekeland variational principle for any $k \in \operatorname{int} \mathcal{K}_\alpha$ and to deduce the sharpness of solutions x_k. In section 4 we prove our main results, which are in Theorems 4.1 and 4.2.

2. Preliminaries. Let $X = (X, d)$ be a complete metric space. Let Z be a separated locally convex space ordered by the relation $\leq$ ($\geq$) induced by a closed cone $\mathcal{K}$ in the usual way; i.e., for any $z, y \in Z$ we put $z \leq y$ ($y \geq z$) iff $y - z \in \mathcal{K}$.

Let $\bar{Z} := Z \cup \{+\infty\}$, where $+\infty \notin Z$ is such that $z \leq +\infty$ for any $z \in Z$ and let f be a function from X to $\bar{Z}$. The domain $D(f)$ of f is defined as $D(f) := \{x \in X \mid f(x) \neq +\infty\}$ and f is called *proper* if $D(f) \neq \emptyset$. Consider the vector minimization problem

$$(P) \qquad \begin{array}{l} f(x) \to_{\mathcal{K}} \min \\ \text{subject to } x \in X. \end{array}$$

A point $\bar{x} \in X$ is an *efficient solution* to (P) if

$$(f(\bar{x}) - \mathcal{K}) \cap f(X) \subset f(\bar{x}) + \mathcal{K}.$$

We denote by $E(f)$ the set of all efficient solutions to (P).

A function $f\colon X \to \bar{Z}$ is quasi-*lsc* at $x_0 \in X$ [5], if for all $b \in Z$ such that $b \ngeq f(x_0)$ there exists a neighborhood U of x_0 in X such that $b \ngeq f(x)$ for all $x \in U$. f is quasi-*lsc* if f is quasi-*lsc* at each point of X. f is quasi-*lsc* iff for all $b \in Z$ the sets $\{x \in X \mid f(x) \leq b\}$ are closed in X.

A function $f\colon X \to \bar{Z}$ is *lsc* at $x_0 \in D(f)$ if for each neighborhood W of $f(x_0)$ there exists a neighborhood V of x_0 such that $f(V) \subset W + (\mathcal{K} \cup +\infty)$. If f is *lsc* at x_0, then f is quasi-*lsc* at x_0.

Definition 2.1 (see [16]). *For given* $\varepsilon > 0$ *and* $k \in \mathcal{K} \setminus \{0\}$, *a point* $\bar{x} \in D(f)$ *is* ε*-approximately efficient in the direction* k *if* $(f(\bar{x}) - \varepsilon k - \mathcal{K} \setminus \{0\}) \cap f(X) = \emptyset$.

The notion of ε-approximately efficient points is essential in proving Theorems 1.2 and 1.1 (see also [5, 9, 10, 16]).

Let Z^* be the dual space of all continuous linear functionals defined on Z and $\mathcal{K}^* := \{z^* \in Z^* \mid \forall\, z \in \mathcal{K}\ z^*(z) \geq 0\}$ the dual cone of $\mathcal{K}$. Since $\mathcal{K}$ is pointed, for any

$k \in \mathcal{K} \setminus \{0\}$, by the Hahn–Banach theorem there exists $k^* \in \mathcal{K}^*$ such that $k^*(k) = 1$. The functional k^* is order-preserving. Let us recall that a function $f\colon X \to Z$ is said to be *bounded below* if there exists $z \in Z$ such that $z \le f(x)$ for all $x \in X$. If f is bounded below, then $k^* \circ f$ is bounded below on X and $k^*(z) \le (k^* \circ f)(x)$ for all $x \in X$ and any $k^* \in \mathcal{K}^*$; on the other hand the function $k^* \circ f$ may not be *lsc*.

3. The variational principle for Bishop–Phelps cones. Let $0 < \alpha < 1$ be given. For an arbitrary $\varphi \in Z^*$, $\|\varphi\| = 1$ we define

$$\mathcal{K}_\alpha := \{z \in Z \mid \varphi(z) \ge \alpha\|z\|\}.$$

Let us notice that $\mathcal{K}_\alpha$ is a closed convex pointed cone with nonempty interior $\operatorname{int}\mathcal{K}_\alpha = \{z \in Z \mid \varphi(z) > \alpha\|z\|\}$ and a bounded base $\Theta = \{k \in \mathcal{K}_\alpha \mid \varphi(k) = 1\}$. The cone $\mathcal{K}_\alpha$ is called a Bishop–Phelps cone [14, 15].

In what follows we assume that Z is a real Banach space partially ordered by a cone $\mathcal{K}_\alpha$.

In what follows we use the functions $g\colon \bar{Z} \to \bar{\mathbb{R}} := \mathbb{R} \cup \{+\infty\}$ defined by

$$g(z) := \begin{cases} \varphi(z) - \alpha\|z\| & \text{for } z \in Z, \\ +\infty & \text{for } z = +\infty, \end{cases}$$

and the function $v\colon X \to \bar{\mathbb{R}}$ defined by $v := g \circ f$:

$$v(x) := \varphi(f(x)) - \alpha\|f(x)\|. \tag{3.1}$$

The function g is order-preserving since for any $z_1 \le z_2$ we have $g(z_1) \le g(z_2)$. In consequence, if f is bounded below on X, i.e., $z \le f(x)$ for any $x \in X$, the function v is also bounded below on X and $g(z) \le v(x)$ for all $x \in X$. The converse is not true.

Moreover,

$$S(v) := \operatorname{argmin}\{v(x) \ : \ x \in X\} \subset WE(f),$$

where $WE(f)$ denotes the set of all weakly efficient solutions to (P), i.e., $\bar{x} \in WE(f)$ if $(f(\bar{x}) - \operatorname{int}\mathcal{K}_\alpha) \cap f(X) = \emptyset$. To see this, take any $\bar{x} \notin WE(f)$. There exists $x \in X$ such that $f(\bar{x}) - f(x) \in \operatorname{int}\mathcal{K}_\alpha$ and, consequently,

$$\varphi(f(\bar{x})) - \alpha\|f(\bar{x})\| > \varphi(f(x)) - \alpha\|f(x)\|$$

which proves that $\bar{x} \notin S(v)$. Since g is not strongly increasing (i.e., $z_1 \ge z_2$ and $z_1 \ne z_2$ does not imply that $g(z_1) > g(z_2)$), we cannot prove that $S(v) \subset E(f)$.

We introduce the following notion of ε-approximate efficiency with respect to Bishop–Phelps cones.

Definition 3.1. *Let $\varepsilon > 0$ be given and $0 < \alpha < 1$. A point $\bar{x} \in X$ is an ε-efficient solution with respect to $\mathcal{K}_\alpha$ if*

$$v(\bar{x}) < \inf_{x \in X} v(x) + \varepsilon,$$

where the function v is defined by (3.1).

This means that $\bar{x}$ is an ε-solution of the scalar-valued function v.

The next lemma establishes the relationship between the ε-efficiency with respect to $\mathcal{K}_\alpha$ and the ε-approximate efficiency in the sense of Definition 2.1.

Lemma 3.2. *An ε-efficient solution $\bar{x} \in X$ with respect to $\mathcal{K}_\alpha$ is ε_0-approximately efficient in any direction $k \in \operatorname{int}\mathcal{K}_\alpha$ with $\varepsilon_0 \ge \varepsilon/g(k)$.*

Proof. Suppose on the contrary that $\bar{x} \in X$ is not ε_0-approximately efficient in the direction $k \in \operatorname{int} \mathcal{K}_\alpha$. Therefore, by the definition of the ε_0-approximate efficiency there exists $x \in X$ which satisfies

$$\varphi(f(\bar{x}) - (f(x) + \varepsilon_0 k)) \geq \alpha \|f(\bar{x}) - (f(x) + \varepsilon_0 k)\|.$$

Hence in view of the definition of v we obtain the inequality

$$v(\bar{x}) \geq v(x) + \varepsilon_0 g(k),$$

which contradicts the fact that $\bar{x}$ is a ε-efficient solution with respect to $\mathcal{K}_\alpha$. This completes the proof. □

Now we are ready to prove the following vector-valued Ekeland variational principle for a quasi-*lsc* function taking values in Banach spaces partially ordered by Bishop–Phelps cones.

THEOREM 3.3. *Let $f\colon X \to Z \cup \{+\infty\}$ be a quasi-lsc, bounded below function such that $D(f) \neq \emptyset$. Let $\varepsilon > 0$ be given and let $\bar{x} \in X$ be an ε-efficient solution with respect to $\mathcal{K}_\alpha$.*

Then for any $k \in \operatorname{int} \mathcal{K}_\alpha$ there exists $x_k \in X$ such that for any $l \geq k$ the following conditions hold:

(i) $f(x_k) \leq f(\bar{x})$,
(ii) $\|\bar{x} - x_k\| \leq 1/g(k)$,
(iii) *for any $x \in X$ the relation $f(x) + \varepsilon\|x - x_k\| l \leq f(x_k)$ implies $x = x_k$.*

Proof. Take any $k \in \operatorname{int} \mathcal{K}_\alpha$. Since $\bar{x}$ is an ε-efficient solution with respect to $\mathcal{K}_\alpha$, by Lemma 3.2 $\bar{x}$ is ε_0-approximately efficient in the direction k and $\varepsilon_0 = \varepsilon/g(k)$. By Theorem 1.2, taking $\lambda = 1/g(k)$, there exists $x_k \in X$ such that

(i) $f(x_k) \leq f(\bar{x})$,
(ii) $\|\bar{x} - x_k\| \leq 1/g(k)$,
(iii) for any $x \in X$ the relation $f(x) + \varepsilon\|x - x_k\| k \leq f(x_k)$ implies $x = x_k$.

Let $l \geq k$. Since $f(x) + \varepsilon\|x - x_k\| k \leq f(x) + \varepsilon\|x - x_k\| l$, then the relation $f(x) + \varepsilon\|x - x_k\| l \leq f(x_k)$ implies $x = x_k$. □

THEOREM 3.4. *Let X and Z be Banach spaces and let $f\colon X \to \bar{Z}$ be an lsc proper function. Let $\varepsilon > 0$ and $\lambda > 0$ be given and let $\bar{x} \in X$ be an ε-efficient solution with respect to $\mathcal{K}_\alpha$.*

There exists $x_0 \in D(f)$ such that for any $k \in \operatorname{int} \mathcal{K}_\alpha$ such that $g(k) \geq \frac{1}{\lambda}$ the following conditions hold:

(i) $v(x_0) + \frac{\varepsilon}{\lambda}\|\bar{x} - x_0\| \leq v(\bar{x})$,
(ii) $\|\bar{x} - x_0\| \leq \lambda$,
(iii) *for all $x \in X$ the relation $f(x) + \varepsilon\|x - x_0\| k \leq f(x_0)$ implies $x = x_0$.*

Proof. As v is a bounded below *lsc* function and $\bar{x}$ is an ε-solution to v, by the Ekeland variational principle there exists $x_0 \in D(f)$ such that $v(x_0) + \frac{\varepsilon}{\lambda}\|\bar{x} - x_0\| \leq v(\bar{x})$, $\|\bar{x} - x_0\| \leq \lambda$, and

$$\forall\ x \in X\ \ v(x) + \frac{\varepsilon}{\lambda}\|x - x_0\| \leq v(x_0) \ \ \Rightarrow \ \ x = x_0.$$

Take any $k \in \mathcal{K}_\alpha$ such that $g(k) \geq \frac{1}{\lambda}$. Since $g(z + \gamma k) \geq g(z) + \gamma g(k)$ for $z \in Z$ and $\gamma \in \mathbb{R}_+$,

$$\forall\ x \in X\ \ g(f(x) + \varepsilon\|x - x_0\| k) \leq g(f(x_0)) \ \ \Rightarrow \ \ x = x_0.$$

Since g is order-preserving, for any $x \in X$ the relation $f(x) + \varepsilon\|x, x_0\| k \leq f(x_0)$ implies $g(f(x) + \varepsilon\|x - x_0\| k) \leq g(f(x_0))$, which proves (iii). □

4. Sharp efficiency. In this section we assume that X and Z are normed spaces. In [1], Bednarczuk investigates the following notion of sharp efficiency: an $\bar{x} \in D(f)$ is a *sharp efficient solution of order* 1 to (P) if there exists a constant $\tau > 0$ such that

$$f(x) \notin f(\bar{x}) + \tau\|x - \bar{x}\|B_Z - \mathcal{K} \quad \text{for } x \in X,\ x \neq \bar{x},$$

where B_Z is open unit ball in Z. We denote the set of all sharp solutions of order 1 to (P) by $St^1(f)$. Let us note that if $\bar{x} \in St^1(f)$, then for all $x \in X$ $f(x) \leq f(\bar{x}) \Rightarrow x = \bar{x}$.

The following theorem sharpens the conclusion (iii) of Theorem 1.2 for cones with nonempty interiors.

THEOREM 4.1. *Let X and Z be normed spaces with Z ordered by a closed pointed cone $\mathcal{K}$, $\operatorname{int}\mathcal{K} \neq \emptyset$. Let $f\colon X \to \bar{Z}$ be a quasi-lsc proper function. Let $\varepsilon > 0$, $\lambda > 0$, and $k \in \operatorname{int}\mathcal{K}$. Let $\bar{x} \in D(f)$ be an ε-approximately efficient point in the direction $k \in \operatorname{int}\mathcal{K}$.*

There exists $x_k \in D(f)$ such that the following conditions hold:

(i) $f(x_k) \leq f(\bar{x})$,

(ii) $\|x_k - \bar{x}\| \leq \lambda$,

(iii) $x_k \in St^1(f_{(x_k,l)})$ *for any* $l \geq 2k$, *where* $f_{(x_k,l)}(x) := f(x) + \frac{\varepsilon}{\lambda}\|x - x_k\|l$.

Proof. By assumption, there exists $x_k \in X$ satisfying the conditions (i), (ii), and (iii) of Theorem 1.2. Since $k \in \operatorname{int}\mathcal{K}$, there exists a number $\tau > 0$ such that $2k - \frac{\lambda\tau}{\varepsilon}b \geq k$ for any $b \in B_Z$. Take any $l \geq 2k$, then $l - \frac{\lambda\tau}{\varepsilon}b \geq k$ for any $b \in B_Z$. By Theorem 1.2(iii),

$$f(x_k) - f(x) - \frac{\varepsilon}{\lambda}\|x - x_k\|\left(l - \frac{\lambda\tau}{\varepsilon}b\right) \notin \mathcal{K} \ \forall\ x \neq x_k.$$

Since the relation holds for any $b \in B_Z$ we have

$$f(x) + \frac{\varepsilon}{\lambda}\|x - x_k\|l \notin f(x_k) + \tau\|x - x_k\|B_Z - \mathcal{K} \ \forall\ x \neq x_k,$$

which proves that $x_k \in St^1(f_{(x_k,l)})$ with the constant τ. □

For $\mathcal{K} = \mathcal{K}_\alpha$ we get the estimation of the distance $\|x_k - \bar{x}\|$ in terms of $g(k)$ and the estimation of constant τ. This is the content of the next theorem.

THEOREM 4.2. *Let $f\colon X \to \bar{Z}$ be a quasi-lsc proper function. Let $\varepsilon > 0$ and let $\bar{x} \in D(f)$ be an ε-efficient solution with respect to $\mathcal{K}_\alpha$.*

For any $k \in \operatorname{int}\mathcal{K}_\alpha$ there exists $x_k \in X$ such that the following conditions are satisfied:

(i) $f(x_k) \leq f(\bar{x})$,

(ii) $\|\bar{x} - x_k\| \leq 1/g(k)$,

(iii) $x_k \in St^1(f_{(x_k,l)})$ *for any* $l \geq 2k$, *where* $f_{(x_k,l)}(x) := f(x) + \varepsilon\|x - x_k\|l$.

Proof. Take any $k \in \operatorname{int}\mathcal{K}$. Let $\tau > 0$ be such that $\tau \leq \varepsilon g(k)/(\|\varphi\| + \alpha)$. We will show that for any $b \in B_Z$ the inequality $2k - \frac{\tau}{\varepsilon}b \geq k$ holds. Indeed

$$\varphi\left(k - \frac{\tau}{\varepsilon}b\right) - \alpha\left\|k - \frac{\tau}{\varepsilon}b\right\| \geq g(k) - \frac{\tau}{\varepsilon}(\varphi(b) + \alpha\|b\|) \geq g(k) - \frac{\tau}{\varepsilon}(\|\varphi\| + \alpha) \geq 0,$$

hence $2k - \frac{\tau}{\varepsilon}b \geq k$ for all $b \in B_Z$. Take any $l \geq 2k$, then $l - \frac{\tau}{\varepsilon}b \geq k$ for any $b \in B_Z$. By Theorem 3.3 (iii), $f(x_k) - f(x) - \varepsilon\|x - x_k\|(l - \frac{\tau}{\varepsilon}b) \notin \mathcal{K}_\alpha$ for $x \neq x_k$. Since the relation holds for any $b \in B_Z$ we have

$$f(x) + \varepsilon\|x - x_k\|l \notin f(x_k) + \tau\|x - x_k\|B_Z - \mathcal{K}_\alpha \ \forall\ x \neq x_k,$$

which completes the proof. □

We close this section by showing two necessary conditions for sharp efficiency. In [6], Finet, Quarta, and Troestler give the following definition of strong efficient solutions.

DEFINITION 4.3 (see [6]). *An $\bar{x} \in E(f)$ is a strong efficient solution if for any $(x_n)_{n\geq 1} \subset D(f)$ such that $\|f(x_n) - f(\bar{x})\| \to 0$, the sequence $(x_n)_{n\geq 1}$ converges to $\bar{x}$.*

Let $\bar{x} \in E(f)$, $f(\bar{x}) = \eta$, $\epsilon \in \mathcal{K}_0 := \operatorname{int}\mathcal{K} \cup \{0\}$. Let $\pi : \mathcal{K}_0 \rightrightarrows \bar{Z}$ be a set-valued mapping defined as follows:

$$\pi(\epsilon) = f^{-1}(f(\bar{x}) + \epsilon - \mathcal{K}).$$

PROPOSITION 4.4. *Let X and Z be normed spaces and let Z be ordered by a closed cone $\mathcal{K}$, $\operatorname{int}\mathcal{K} \neq \emptyset$. Let $f\colon X \to \bar{Z}$ be a proper function. Let $f(\bar{x}) = \eta$ and $f^{-1}(\eta) = \{\bar{x}\}$. If $\bar{x} \in St^1(f)$, then π is upper Lipschitz at $\epsilon = 0$, i.e., there exist constants $L > 0$ and $t > 0$ such that*

$$f^{-1}(f(\bar{x}) + \epsilon - \mathcal{K}) \subset \bar{x} + L\|\epsilon\|B_X$$

for $\epsilon \in tB_Z \cap \mathcal{K}_0$.

Proof. Suppose that π is not upper Lipschitz at $\epsilon = 0$. For every $n \geq 1$ there exists $\epsilon_n \in \operatorname{int}\mathcal{K}$, $\epsilon_n \to 0$, such that

$$f(x_n) \in f(\bar{x}) + \epsilon_n - \mathcal{K}, \quad \|x_n - \bar{x}\| \geq n\|\epsilon_n\|.$$

Hence, $f(x_n) \in f(\bar{x}) + \frac{1}{n}\|x_n - \bar{x}\|B_Z - \mathcal{K}$ which proves that $\bar{x}$ is not sharp. □

THEOREM 4.5. *If $\bar{x} \in St^1(f)$, then $\bar{x}$ is strong in the sense of Definition 4.3.*

Proof. Let $\bar{x} \in St^1(f)$. Then $\|f(x) + k - f(\bar{x})\| \geq \tau\|x - \bar{x}\|$ for all $x \in D(f)$ and $k \in \mathcal{K}$. In particular $\|f(x) - f(\bar{x})\| \geq \tau\|x - \bar{x}\|$ for all $x \in D(f)$, which proves the assertion. □

In a straightforward way we get the following corollary.

COROLLARY 4.6. *Let X be a Banach space and let Z be a normed space ordered by a closed pointed cone $\mathcal{K}$, $\operatorname{int}\mathcal{K} \neq \emptyset$. Let $f\colon X \to \bar{Z}$ be a quasi-lsc proper function. Let $\varepsilon > 0$ and let $\bar{x} \in D(f)$ be an ε-efficient solution in the direction $k \in \mathcal{K}$.*

For any $k \in \operatorname{int}\mathcal{K}$ there exists $x_k \in X$ such that for any $l \geq 2k$ a point x_k is a strong efficient solution of $f_{(x_k,l)}(x) = f(x) + \frac{\varepsilon}{\lambda}\|x - x_k\|l$.

Proof. Take any $k \in \operatorname{int}\mathcal{K}$ and $l \geq 2k$. By Theorem 4.1 we obtain that $x_k \in St^1(f_{(x_k,l)})$ and therefore by Theorem 4.5 a solution x_k is strong in the sense of Definition 4.3 for any $l \geq 2k$. □

Acknowledgments. We are grateful to the anonymous referees for all the comments and remarks which helped us to improve the results of this paper.

DERIVING THE CONTINUITY OF MAXIMUM-ENTROPY BASIS FUNCTIONS VIA VARIATIONAL ANALYSIS*

N. SUKUMAR† AND R. J.-B. WETS‡

Abstract. In this paper, we prove the continuity of maximum-entropy basis functions using variational analysis techniques. The use of information-theoretic variational principles to derive basis functions is a recent development. In this setting, data approximation is viewed as an inductive inference problem, with the basis functions being synonymous with a discrete probability distribution, and the polynomial reproducing conditions acting as the linear constraints. For a set of distinct nodes $\{x^i\}_{i=1}^n$ in $\mathbb{R}^d$, the convex approximation of a function $u(x)$ is $u^h(x) = \sum_{i=1}^n p_i(x)u_i$, where $\{p_i\}_{i=1}^n$ are nonnegative basis functions, and $u^h(x)$ must reproduce affine functions $\sum_{i=1}^n p_i(x) = 1$, $\sum_{i=1}^n p_i(x)x^i = x$. Given these constraints, we compute $p_i(x)$ by minimizing the relative entropy functional (Kullback–Leibler distance), $D(p\|m) = \sum_{i=1}^n p_i(x)\ln\big(p_i(x)/m_i(x)\big)$, where $m_i(x)$ is a known prior weight function distribution. To prove the continuity of the basis functions, we appeal to the theory of epiconvergence.

1. Background and formulation.

Consider a set of distinct nodes in $\mathbb{R}^d$ that are located at x^i $(i = 1, 2, \ldots, n)$, with $D = \mathrm{con}(x^1, \ldots, x^n) \subset \mathbb{R}^d$ denoting the convex hull of the nodal set (Figure 1). For a real-valued function $u(x) : D \to \mathbb{R}$, the numerical approximation for $u(x)$ is written as

$$u^h(x) = \sum_{i=1}^{n} p_i(x)u_i, \tag{1}$$

where $p_i(x)$ is the basis function associated with node i, and u_i are coefficients. If $p_i(x)$ is a cardinal basis, $p_i(x^j) = \delta_{ij}$, then $u^h(x^i) = u(x^i) = u_i$.

In the univariate case, Lagrange and spline bases are well known, whereas for multivariate approximation, tensor-product splines, moving least squares (MLS) approximates [17], and radial basis functions [30] are popular. The need for scattered data approximation arises in many fields, for example, curve and surface fitting, computer graphics and geometric modeling, finite elements, and meshfree methods. Over the past decade, meshfree approximation schemes have been adopted in Rayleigh–Ritz (Galerkin) methods for the modeling and simulation of physical phenomena; see [4] for a review of meshfree methods and [28] for a review of meshfree basis functions. For second-order partial differential equations (PDEs), approximates that possess constant and linear precision are sufficient for convergence in a Galerkin method (cf., for

example, [25, Chapter 2]):

$$\forall x, \quad \sum_{i=1}^{n} p_i(x) = 1 \quad \text{and} \quad \sum_{i=1}^{n} p_i(x) x^i = x. \tag{2}$$

Furthermore, if the nonnegative restriction is imposed on the basis functions (convex combination), namely,

$$p_i(x) \geq 0 \quad \forall i,\, x, \tag{3}$$

then (1) is a convex approximation scheme [1] with many desirable properties: it satisfies the convex hull property, is not prone to the Runge phenomena, interior nodal basis functions $p_i(x)$ ($x^i \notin \operatorname{bdry} D$) vanish on $\operatorname{bdry} D$, which facilitates the imposition of linear Dirichlet boundary conditions in a Galerkin method, and, in addition, optimal conditioning can be established for nonnegative basis functions [8, 19].

In meshfree Galerkin methods, an approximation of the form in (1) is used, with MLS being the most common choice. A recent development in this direction has been the construction of maximum-entropy approximates [1, 26, 27]; continuity was obtained by Arroyo and Ortiz [1] for the case when the prior distributions are Gaussian. In this paper, we rely on *variational analysis* techniques, in particular on the theory of *epiconvergence*, to establish the continuity of maximum-entropy basis functions for *any* continuous prior distribution.

1.1. Minimum relative entropy principle. In information theory [7], the notion of entropy as a measure of uncertainty or incomplete knowledge was introduced by Shannon [22]. The Shannon entropy of a discrete probability distribution is

$$H(p) = \langle -\ln p \rangle = -\sum_{i=1}^{n} p_i \ln p_i, \tag{4}$$

where $\langle \cdot \rangle$ is the expectation operator, $p_i \equiv p(x^i)$ is the probability of the occurrence of the event x^i, $p \ln p \doteq 0$ if $p = 0$, and the above form of H satisfies the axiomatic requirements of an uncertainty measure; cf., for example, [14, Chapter 1].

Jaynes used the Shannon entropy measure to propose the principle of maximum entropy [11], in which it was shown that maximizing entropy provides the least-biased statistical inference when insufficient information is available. It was later recognized that for H to be invariant under invertible mappings of x, the general form of the entropy should be [12, 15, 23]

$$H(p,m) = -\int p(x)\ln\left(\frac{p(x)}{m(x)}\right)dx \quad \text{or} \quad H(p,m) = -\sum_{i=1}^{n} p_i \ln\left(\frac{p_i}{m_i}\right), \tag{5}$$

where m is a prior distribution that plays the role of a p-estimate. In the literature, the quantity $D(p\|m) = -H(p,m)$ is also referred to as the Kullback–Leibler distance (directed- or I-divergence) [16], and the variational principle is known as the principle of minimum relative entropy [23]. If a uniform prior, $m_i = 1/n$, is used in (5), then the Shannon entropy (modulo a constant) given in (4) is recovered. The nonnegativity of the relative entropy, $D(p\|m) \geq 0$, is readily derived from Jensen's inequality (cf., for example, [7, p. 25]).

Given a set of $\ell + 1$ linear constraints on an unknown probability distribution p and a prior m, which is an estimate for p, the minimum relative entropy principle is a rule for the most consistent (minimum-distance or -discrepancy from the prior m) assignment of the probabilities p_i [12]:

$$\min_{p\in\mathbb{R}^n_+}\left(D(p\|m) = \sum_{i=1}^{n} p_i \ln\left(\frac{p_i}{m_i}\right)\right) \quad \text{so that} \quad \sum_{i=1}^{n} p_i = 1, \tag{6a}$$

$$\sum_{i=1}^{n} p_i g_r(x^i) = \langle g_r(x)\rangle, \quad r = 1, 2, \ldots, \ell, \tag{6b}$$

where $g_r(x)$ and $\langle g_r(x)\rangle$ are known, and $\mathbb{R}^n_+$ is the nonnegative orthant.

The initial emphasis of the principle of maximum entropy was on equilibrium and nonequilibrium statistical mechanics [12], but it is equally applicable to any problem in inductive inference. The interested reader can refer to [13] and [24] for the Bayesian perspective on probability theory and rationale inference. The maximum entropy and minimum relative entropy principles have found applications in many areas of science and engineering—image reconstruction [10], natural language modeling [5], microstructure reconstruction [18], and nonparametric supervised learning [9] are a few examples.

Variational principles, which are used in finite element formulations, conjugate gradient methods, graphical models, dynamic programming, and statistical mechanics, also have strong roots in data approximation. For instance, kriging, thin-plate splines, B-splines, radial basis functions [30], MLS approximates [17], and Delaunay interpolates [20] are based on the extremum of a functional. In the same spirit, we now present the variational formulation to construct entropy approximates, and in so doing demonstrate its potential merits as a basis for the solution of PDEs.

1.2. Variational formulation for entropy approximates. To obtain the maximum-entropy principle, the Shannon entropy functional and a modified entropy functional were used in [26] and [1], respectively. In [27], as a unifying framework and generalization, the relative entropy functional with a prior was used—a uniform prior leads to Jaynes's maximum-entropy principle, and use of a Gaussian (radial basis function) prior, $m_i(x) = \exp(-\beta|x^i - x|^2)$, results in the entropy functional considered in [1]. The prior in the present context is a nodal weight function, and

the variational principle in effect provides a "correction" that minimally modifies the weight functions to form basis functions that also satisfy the linear constraints. Clearly, if $m_i(x)$ a priori satisfies all the constraints, then one obtains $p_i(x) = m_i(x)$ for all i. The flexibility of choosing different prior distributions (for example, radial basis functions, compactly supported weight functions used in MLS, etc.) within the minimum relative entropy formalism would lead to the construction of a wider class of convex approximation schemes. The parallels between the conditions on p_i in (2) and (3) and those on p_i in a maximum-entropy formulation are evident. Unlike univariate Bernstein basis functions (terms in the binomial expansion), where a probabilistic interpretation in relation to the binomial distribution [24, Chapter 5] is natural, here the connection is less transparent. Referring to the nodal sets shown in Figure 1, we note that the basis function value $p_i(x)$ is viewed as the "probability of influence of a node i at x." With a uniform prior, global basis functions are obtained, which do not lead to sparse system matrices in the numerical solution of PDEs. With a compactly supported prior, the basis functions $p_i(x)$ also inherit the support properties of the prior and hence are suitable in the Galerkin solution for PDEs. Entropic regularization with a prior is a novel approach to constructing convex approximation schemes with many desirable properties.

The variational formulation for entropy approximates is as follows: Find $x \mapsto p(x) : \mathbb{R}^d \to \mathbb{R}^n_+$ as the solution of the constrained convex optimization problem

$$\min_{p \in \mathbb{R}^n_+} f(x;p), \quad f(x;p) = \sum_{i=1}^{n} p_i(x) \ln\left(\frac{p_i(x)}{m_i(x)}\right), \tag{7a}$$

subject to the constraint set from (2) and (3):

$$\kappa(x) = \left\{ p \in \mathbb{R}^n_+ \,\middle|\, \sum_{i=1}^{n} p_i = 1, \sum_{i=1}^{n} p_i x^i = x \right\}, \tag{7b}$$

where $m_i(x)$ is a prior estimate, and the constraints form an underdetermined linear system. By introducing the Lagrange multipliers, one can write the solution of the variational problem as

$$p_i(x) = \frac{Z_i(x)}{Z(x)}, \quad Z_i(x) = m_i(x) \exp(-x^i \cdot \lambda),$$

where $\lambda \in \mathbb{R}^d$, and $Z(x) = \sum_j Z_j(x)$ is known as the partition function in statistical mechanics. The $p_i(x)$ in the preceding equation must satisfy the d linear constraints in (7b). This yields d nonlinear equations. On using shifted nodal coordinates $\tilde{x}^i = x^i - x$ and considering the dual formulation, we can write the solution for the Lagrange multipliers as (cf., for example, [21, Exercise 11.12] and [6, p. 222])

$$\lambda = \arg\min \ln Z(\lambda^t),$$

where Z is appropriately redefined. Convex optimization algorithms (gradient descent, Newton's method, etc.) are suitable for computing these basis functions. Numerical experimentation suggests that such basis functions may very well be continuous on D [1, 26], and this will be confirmed here by variational analysis techniques.

2. Continuity of the basis functions. One can always represent an optimization problem, involving constraints or not, as one of minimizing an extended real-valued function. In the case of a constrained-minimization problem, simply redefine the effective objective as taking on the value ∞ outside the feasible region, with the set determined by the constraints. In this framework, the canonical problem can be formulated as one of minimizing on all of $\mathbb{R}^n$ an extended real-valued function $f\colon \mathbb{R}^n \to \overline{\mathbb{R}}$. Approximation issues can consequently be studied in terms of the convergence of such functions. This has led to the notion of *epiconvergence* (cf. [2, 3] and [21, Chapter 7]; the latter will serve here as our basic reference). We provide a very brief survey and some relevant refinements of this theory.

Thus, at a conceptual level, it is convenient to think of optimization problems as elements of

$$\operatorname{fcns}(\mathbb{R}^n) = \{f\colon \mathbb{R}^n \to \overline{\mathbb{R}}\},$$

the set of extended real-valued functions that are defined on *all* of $\mathbb{R}^n$, even allowing for the possibility that they are nowhere finite valued; definitions, properties, limits, etc., usually do not refer specifically to the domain on which they are finite. The *effective domain* of f is $\operatorname{dom} f = \{x \in \mathbb{R}^n \mid f(x) < \infty\}$. The *epigraph* of a function f is the set of all points in $\mathbb{R}^{n+1}$ that lie on or above the graph of f, $\operatorname{epi} f = \{(x,\alpha) \in \mathbb{R}^{n+1} \mid \alpha \geq f(x)\}$. A function f is *lsc* (*lower semicontinuous*) if and only if its epigraph is closed as a subset of $\mathbb{R}^{n+1}$, i.e., $\operatorname{epi} f = \operatorname{cl}(\operatorname{epi} f)$ with cl denoting closure [21, Theorem 1.6]. The lsc-regularization of f is $\operatorname{cl} f$ defined by the identity $\operatorname{epi} \operatorname{cl} f = \operatorname{cl} \operatorname{epi} f$.

DEFINITION 2.1 (epiconvergence and tight epiconvergence). *Let* $\{f, f^\nu, \nu \in \mathbb{N}\}$ *be a collection of functions in* $\operatorname{fcns}(\mathbb{R}^n)$. *Then,* $f^\nu \xrightarrow{e} f$ *if and only if the following conditions are satisfied:*

(a) *For all* $x^\nu \to x$, $\operatorname{liminf}_\nu f^\nu(x^\nu) \geq f(x)$.

(b) *For all* x, $\exists\, x^\nu \to x$ *such that* $\operatorname{limsup}_\nu f^\nu(x^\nu) \leq f(x)$.

The sequence epiconverges tightly *to* f *if, in addition, for all* $\epsilon > 0$, *there exist a compact set* B_ϵ *and an index* ν_ϵ *such that*

$$\forall\, \nu \geq \nu_\epsilon : \quad \inf\nolimits_{B_\epsilon} f^\nu \leq \inf f^\nu + \epsilon.$$

Note that functions can be "epiclose" while "pointwise-far" (measured, for example, in term of the ℓ^∞-norm); e.g., consider the two step-functions $f(x) = 0$ if $x < 0$, $f(x) = 1$ when $x \geq 0$, and $g(x) = f(x - \epsilon)$ with $\epsilon > 0$ arbitrarily small.

The name "epiconvergence" is attached to this convergence notion because it coincides [21, Proposition 7.2] with the *set-convergence*, in the Painlevé–Kuratowski sense [21, section 4.B] of the epigraphs. It is known that (i) whenever C is a limit-set, it is *closed* [21, Proposition 4.4]; (ii) $C = \emptyset$ if and only if the sequence C^ν eventually "escapes" from any bounded set [21, Corollary 4.11]; and (iii) if the sequence $C^\nu \to C$ consists of convex sets, then also C is convex [21, Proposition 4.15]. This means that when $f^\nu \xrightarrow{e} f$, (i) f is lsc; (ii) $f \equiv \infty (\operatorname{dom} f = \emptyset)$ if and only if given any $\kappa > 0$, $f^\nu \geq \kappa$ for ν large enough; and (iii) the epilimit of convex functions is convex, if it exists.

THEOREM 2.2 (convergence of the minimizers and infimums). *Let* $f^\nu \xrightarrow{e} f$, *all in* $\operatorname{fcns}(\mathbb{R}^n)$, *with* $\inf f$ *finite. If* $f^\nu \xrightarrow{e} f$, $x^k \in \operatorname{argmin} f^{\nu_k}$ *for some subsequence* $\{\nu_k\}_{k\in\mathbb{N}}$ *and* $x^k \to \bar{x}$, *then* $\bar{x} \in \operatorname{argmin} f$ *and* $\min f^{\nu_k} \to \min f$.[1]

[1] One writes min when the infimum is actually attained.

If $\operatorname{argmin} f$ *is a singleton, then every convergent subsequence of minimizers converges to* $\operatorname{argmin} f$.

They epiconverge tightly if and only if $\inf f^\nu \to \inf f$.

Proof. The first two assertions follow from [21, Proposition 7.30, Theorem 7.33], and one can deduce the last one from [21, Theorem 7.31]. ∎

Let us conclude this review by a compilation of the facts that are going to be of immediate relevance to the problem at hand.

COROLLARY 2.3 (epiconvergence under strict convexity). *Suppose* $\{f^\nu : \mathbb{R}^n \to (-\infty, \infty]\}_{\nu\in\mathbb{N}}$ *is a collection of convex functions such that*

(a) *for all* ν, $\operatorname{dom} f^\nu \subset B$, *where* B *and each* $\operatorname{dom} f^\nu$ *are compact;*

(b) *the functions* f^ν *are finite valued, lsc, and strictly convex on* $\operatorname{dom} f^\nu$. *Then, for all* ν, $\emptyset \neq \operatorname{argmin} f^\nu$ *is a singleton.*

Moreover, if $f^\nu \xrightarrow{e} f$ *and* $\operatorname{argmin} f$ *is also a singleton, then* $\operatorname{argmin} f^\nu \to \operatorname{argmin} f$.

Proof. In view of (a) and (b), for each ν the minimization of f^ν is equivalent to minimizing a finite-valued, lsc, strictly convex function on a compact set, and such a problem always has a unique solution. Moreover, because for all ν, $\operatorname{dom} f^\nu$ is a (compact) subset of the compact set B, $f^\nu \xrightarrow{e} f$ implies that they epiconverge tightly. The convergence of $\operatorname{argmin} f^\nu \to \operatorname{argmin} f$ follows from combining the two last assertions of Theorem 2.2. ∎

Our task now is to show that the continuity of the basis functions can be derived as a consequence of this corollary. We begin with the strict convexity of the criterion function. The Kullback–Leibler criterion is a separable function, i.e.,

$$k(x;p) = \sum_{i=1}^{n} k_i(x;p_i), \quad \text{where } k_i(x;p_i) = p_i \ln(p_i/m_i(x)),$$

and its properties can be directly derived from those of the one-dimensional functions $k_i(x;\cdot) : \mathbb{R}_+ \to [0,\infty]$.

- When $m_i(x) > 0$, $k_i(x,\cdot)$ is finite valued, continuous, and strictly convex on $\mathbb{R}_+$; recall that $0\ln(0) = 0$. Indeed, the second derivative on $(0,\infty)$ is $1/p_i > 0$, which implies strict convexity [21, Theorem 2.13(c)]. The quantity $p_i \ln(p_i/m_i(x))$ is strictly increasing and converges to 0 as $p_i \searrow 0$, yielding both strict convexity and continuity on $\mathbb{R}_+$.
- When $m_i(x) = 0$, $k_i(x;p_i) = \infty$ unless $p_i = 0$ and then $k_i(x;0) = 0$.

It is conceivable, but certainly not reasonable, that the (continuous) weight functions $\{m_i : \mathbb{R}^n \to \mathbb{R}_+,\ i = 1,\dots,n\}$ have been chosen so that for some $x \in D$, $m_i(x) = 0$ for all $i = 1,\dots,n$. In such a situation, in the process of minimizing the Kullback–Leibler criterion, we would be led to choosing $p = 0$ and, of course, this would make it impossible to satisfy the constraint $\sum_{i=1}^n p_i = 1$; i.e., the problem, so formulated, would be infeasible! This brings us to the following assumption, in which we let

- $\text{s-supp}\, m_i = \{x \in \mathbb{R}^d \,|\, m_i(x) > 0\}$ denote the *strict support* of m_i, and
- $\operatorname{supp} m_i = \operatorname{cl}(\text{s-supp}\, m_i)$ the *support* of m_i.

ASSUMPTION 2.1 (well-posed assumption). *For each* $i = 1,\dots,n$, *the function* $m_i : \mathbb{R}^n \to \mathbb{R}_+$ *is continuous such that* $\text{s-supp}\, m_i$, *and consequently also* $\operatorname{supp} m_i$, *is nonempty.*[2] *Moreover, with* $I_{=0} = \{i \,|\, m_i(x) = 0\}$ *and* $I_{>0} = \{i \,|\, m_i(x) > 0\}$,

$$\forall\, x \in D: \quad x \in \operatorname{con}(x^i \,|\, i \in I_{>0}).$$

[2]Note that the continuity of m_i implies that $\text{s-supp}\, m_i$ is an open subset of $\mathbb{R}^d$, and thus so is $\bigcup_{i=1}^n \text{s-supp}\, m_i$.

This assumption requires that every $x \in D$ be obtained as a convex combination of some subcollection of the nodal locations x^i that are associated with weight functions m_i that have $m_i(x) > 0$. In particular, this implies that $\kappa(x)$ is never empty, or equivalently, that the constraints (7b) are certainly satisfied whenever $x \in D$.

PROPOSITION 2.4 (the Kullback–Leibler criterion). *Under the well-posed Assumption* 2.1*, for all $x \in D$, the Kullback–Leibler criterion $p \mapsto k(x;p) = \sum_{i=1}^n p_i \ln (p_i/m_i(x))$ is a strictly convex, lsc function on $\mathbb{R}^n_+$, taking into account the identity $0 \ln(0) = 0$.*

Proof. Convexity is well known; see [7, p. 30], [21, Exercise 3.51], for example. Again, with $I_{=0} = \{i \mid m_i(x) = 0\}$ and $I_{>0} = \{i \mid m_i(x) > 0\}$,

$$k(x;p) = \sum_{i \in I_{=0}} k_i(x;p_i) + \sum_{i \in I_{>0}} k_i(x;p_i),$$

$\operatorname{dom} k(x;\cdot) = \prod_{I_{=0}} \{0\} \times \prod_{I_{>0}} \mathbb{R}_+$, and $I_{>0}$ nonempty by Assumption 2.1. From our analysis of the functions $k_i(x;\cdot)$, it follows that $k(x;\cdot)$ is strictly convex, continuous on its effective domain $\operatorname{dom} k(x;\cdot)$. ∎

The tools are now at hand to derive our main result.

THEOREM 2.5 (continuity of the basis functions). *For $x \in D$, as in the formulation of maximum entropy* (7)*, let*

$$f(x;p)) = \begin{cases} \sum_{i=1}^n p_i \ln(p_i/m_i(x)) & \text{if } p \in \kappa(x), \\ \infty & \text{otherwise,} \end{cases}$$

where

$$\kappa(x) = \left\{ p \in \mathbb{R}^n_+ \,\middle|\, \sum_{i=1}^n p_i = 1, \sum_{i=1}^n p_i x^i = x \right\},$$

and where

$$p(x) = (p_1(x), \ldots, p_n(x)) = \operatorname{argmin} f(x;\cdot).$$

Under the well-posed Assumption 2.1*, when $x^\nu \to \bar{x}$ with $x^\nu \in D$, $\kappa(\bar{x})$ is nonempty and*

$$f(x^\nu;\cdot) \xrightarrow{e} f(\bar{x};\cdot) \quad \text{and} \quad p(x^\nu) \to p(\bar{x}).$$

In other words, the basis functions $p(\cdot)$ are continuous on D.

Proof. Since for all $x \in D$, $\kappa(x)$ is a compact, nonempty subset of the unit simplex $\Delta = \{p \in \mathbb{R}^n_+ \mid \sum_{i=1}^n p_i = 1\}$, it follows that for all $x \in D$, $\operatorname{dom} f(x;\cdot) \subset \Delta$ and, consequently, condition (a) of Corollary 2.3 is trivially satisfied. The rest of the proof is concerned with condition (b) and the epiconvergence of the sequence $f(x^\nu;\cdot)$ to $f(\bar{x};\cdot)$ when $x^\nu \to \bar{x}$.

The functions $f(x^\nu;\cdot)$ and $f(\bar{x};\cdot)$ can be written as $k(x^\nu;\cdot) + \iota_{\kappa(x^\nu)}$ and $k(\bar{x};\cdot) + \iota_{\kappa(\bar{x})}$, where $k(x;p)$ is the Kullback–Leibler criterion defined on $\mathbb{R}^n_+$ and ι_C is the indicator function of the set $C \subset \mathbb{R}^n$ with $\iota_C = 0$ on C; otherwise, $\iota_C = \infty$ on $\mathbb{R}^n \setminus C$.

The epiconvergence of $f(x^\nu;\cdot)$ to $f(\bar{x};\cdot)$ follows from [21, Theorem 7.46(b)], which asserts that the sum of two sequences of functions epiconverge to the sum of their limits if one sequence epiconvergences and the other converges continuously.

To obtain the epiconvergence of the indicator functions, or equivalently [21, Proposition 7.4(f)] the set convergence of the sets $\kappa(x^\nu) \to \kappa(\bar{x})$ with $\kappa(\bar{x}) \neq \emptyset$, we exploit the fact that these are polyhedral sets and that, on the bounded polyhedral set $D = \mathrm{con}(x^1, \ldots, x^n) \subset \mathbb{R}^d$, the mapping $x \mapsto \kappa(x)$ is Lipschitz continuous with respect to the Pompeiu–Hausdorff distance $d\!\!\!l_\infty$, i.e.,

$$\forall\, x, x' \in D\colon \quad d\!\!\!l_\infty(\kappa(x), \kappa(x')) \leq M|x - x'|$$

for some constant $M > 0$; here $|\cdot|$ denotes the Euclidean norm; cf. [29, Theorem 1]; see also [21, Example 9.35]. Of course, this means that κ is continuous on D and, in particular, for any $x^\nu \to \bar{x}$ in D, given any sequence $p^\nu \in \kappa(x^\nu) \to \bar{p}$, then $\bar{p} \in \kappa(\bar{x})$.

Thus, to assert continuous convergence of the functions $k(x^\nu;\cdot)$ to $k(\bar{x})$, one needs to show that $k(x^\nu;p^\nu) \to k(\bar{x};\bar{p})$ for such pairs (x^ν, p^ν). Let $I_{=0} = \{i \,|\, m_i(\bar{x}) = 0\}$ and $I_{>0} = \{i \,|\, m_i(\bar{x}) > 0\}$. By Assumption 2.1, $\kappa(\bar{x}) \bigcap (\bigcup_{I_{>0}} \text{s-supp}\, m_i) \neq \emptyset$. Furthermore, the open set $\bigcup_{I_{>0}} \text{s-supp}\, m_i$ not only includes $\bar{x}$ but also x^ν for all ν large enough. Thus, for all $i \in I_{>0}$, $p_i^\nu \ln(p_i^\nu)/m_i(x^\nu) \to \bar{p}_i \ln(\bar{p}_i)/m_i(\bar{x})$. When $i \in I_{=0}$, again for ν large enough, $p_i^\nu = 0 = \bar{p}_i$; otherwise the corresponding vectors p^ν and $\bar{p}$ would not belong to $\mathrm{dom}\, k(x^\nu;\cdot)$ or $\mathrm{dom}\, k(\bar{x};\cdot)$. Hence, $k(x^\nu;p^\nu) \to k(\bar{x};\bar{p})$. So, $f(x^\nu;\cdot) \to f(\bar{x},\cdot)$.

There only remains to observe that, for ν large enough, $\mathrm{argmin}\, f(x^\nu;\cdot)$ is unique, i.e., for $i \notin I_{>0}$, $p_i^\nu(x^\nu) = 0$, whereas for $i \in I_{>0}$, $p_i^\nu(x^\nu) = \mathrm{argmin}_{p_i \geq 0}\, p_i \ln(p_i/m_i(x^\nu))$; the strict convexity guarantees that argmin is a singleton. Since the same holds for $\bar{x}$, we are in the framework of Corollary 2.3, and thus $p(x^\nu) = \mathrm{argmin}\, f(x^\nu;\cdot) \to \mathrm{argmin}\, f(\bar{x};\cdot) = p(\bar{x})$. ∎

3. Numerical experiments. To illustrate Theorem 2.5, we present basis function plots to confirm the continuity of maximum-entropy basis functions. First, one-dimensional basis function plots are considered, and then two-dimensional basis function plots are presented.

To demonstrate a simple closed-form computation, consider one-dimensional approximation in $D = [0, 1]$ with three nodes located at $x_1 = 0$, $x_2 = 1/2$, and $x_3 = 1$. On using (7), the solution for $p_i(x)$ is obtained by solving a quadratic equation:

$$p_1(x) = \frac{1}{Z}, \quad p_2(x) = \frac{\eta}{Z}, \quad p_3(x) = \frac{\eta^2}{Z}, \quad \eta \equiv \eta(x) = \frac{2x - 1 + \sqrt{12x(1-x)+1}}{4(1-x)},$$

where $Z = 1 + \eta + \eta^2$. These basis functions are presented in Figure 2(a). For four equispaced nodes in $[0, 1]$, a cubic equation must be solved. In general, a numerical method is required to compute these basis functions; in our computations, we use a one-dimensional MATLAB implementation, whereas in two dimensions, a gradient descent algorithm [26, p. 2165] is adopted. Figure 2 depicts basis function plots on a uniform grid consisting of three nodes and five nodes (nodal locations are shown in Figure 1(a)). The plots are presented for a Gaussian prior distribution, $m_i(x) = \exp(-\beta(|x^i - x|^2)$, with varying β. The value $\beta = 0$ corresponds to a uniform prior, and for large β (theoretically when $\beta \to \infty$), the entropy basis functions tend to the finite element Delaunay interpolant [1]. From Figures 2(a) and 2(d), we observe that nodal interpolation is realized on the boundary but not at the interior nodes. However, as β is increased, the support of the basis functions shrinks and the basis functions become closer to being an interpolant at the interior nodes. For $\beta = 100$, the entropy basis functions are proximal to piecewise linear finite element basis functions (Figures 2(c) and 2(f)). The plots in Figure 2 evince the continuity of the basis functions, which provides numerical evidence in support of the theoretical proof in Theorem 2.5.

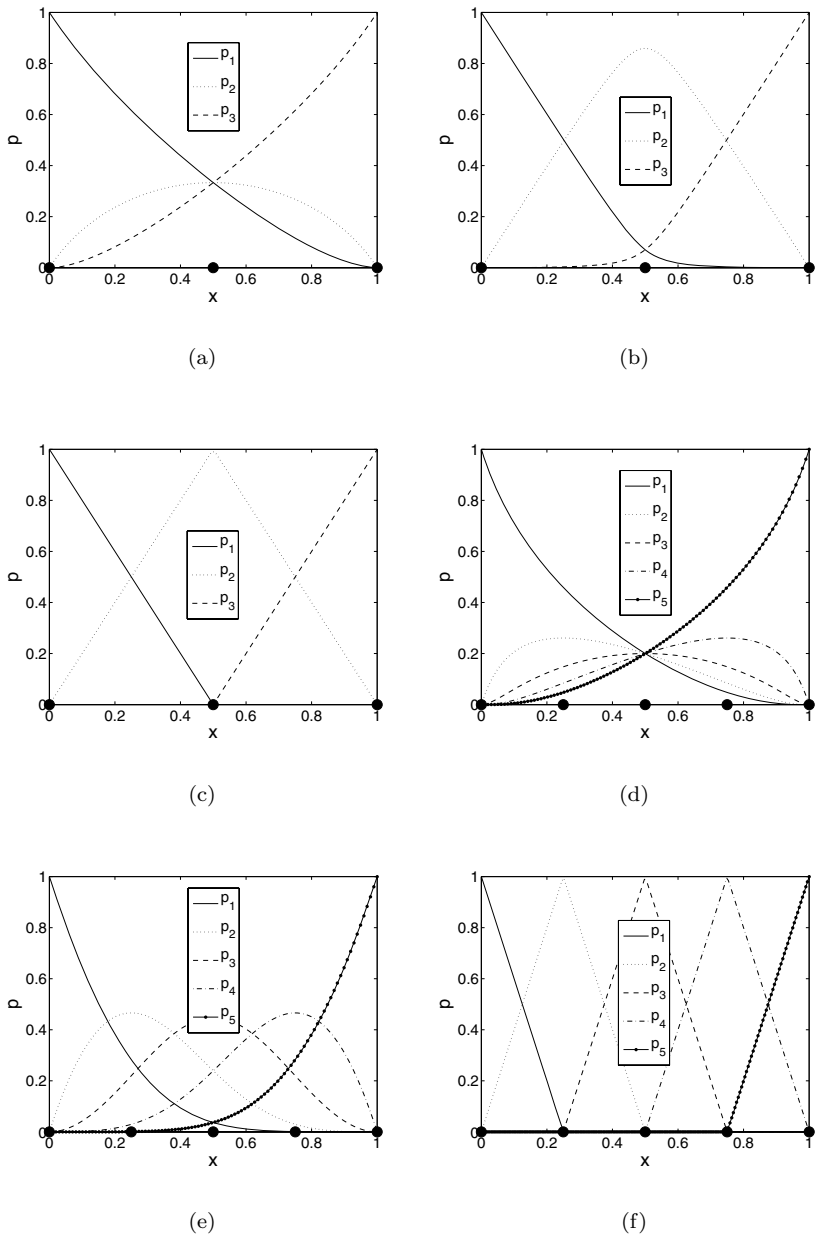

FIG. 2. *Entropy basis functions with a Gaussian prior.* (a)–(c) *show* $n = 3$ *and* $\beta = 0,\ 10,\ 100$*; and* (d)–(f) *show* $n = 5$ *and* $\beta = 0,\ 10,\ 100$. *The nodal locations along the* x*-axis are depicted by filled circles.*

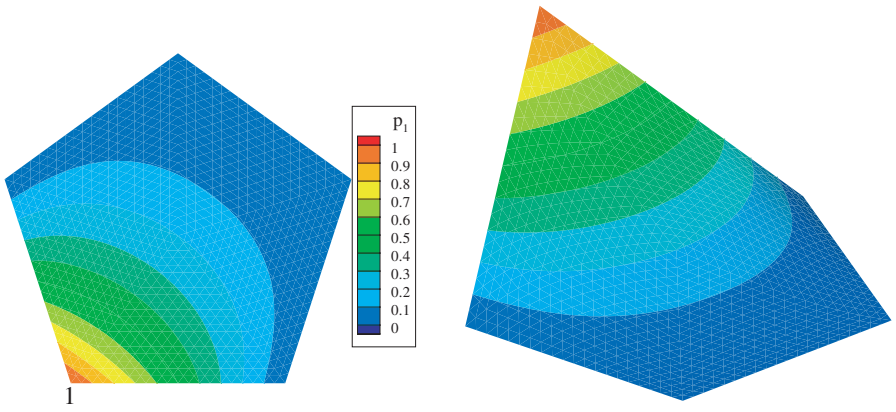
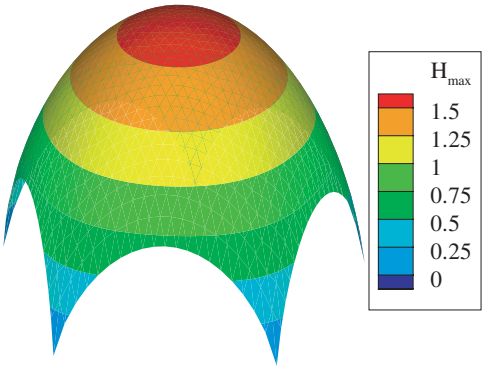
In Figure 3(a), a contour plot of $p_1(x)$ for node 1 in a regular pentagon (see Figure 1(b) for the nodal locations) is shown, whereas in Figure 3(b), the three-dimensional plot is illustrated. The variation of the maximum entropy within the pentagon is depicted in Figure 3(c), with the maximum value of $\ln 5$ being attained at the centroid of the pentagon. The basis function $p_1(x)$ satisfies the cardinal property,



(a) (b)



(c)

FIG. 3. *Entropy basis function* $p_1(x)$ *and variation of maximum entropy within a regular pentagon.* (a) *Contour plot;* (b) *three-dimensional plot; and* (c) H_{max}.

$p_i(x^j) = \delta_{ij}$, which is also met by all n nodal basis functions in a convex polygon [26]. Next, we consider the grid shown in Figure 1(d), where $D = [0,1]^2$. The basis functions for nodes 1 and 8 are plotted using a uniform prior, a Gaussian prior with $\beta = 20$, and a compactly supported C^2 quartic radial basis function as a prior. The quartic prior is given by $m_i(r) = 1 - 6r^2 + 8r^3 - 3r^4$ if $r = |x^i - x| \leq 1$, and zero otherwise. The contour plots are illustrated in Figure 4, and once again we observe that the basis functions are continuous in D. Furthermore, the interior basis functions (for example, $p_8(x)$) vanish on bdry D, which enables the direct imposition of Dirichlet boundary conditions in Galerkin methods [1]. The one- and two-dimensional basis function plots provide numerical proof in support of Theorem 2.5, thereby establishing the continuity of $p_i(x)$ for $x \in D$.

STABILITY ANALYSIS FOR NONLINEAR OPTIMAL CONTROL PROBLEMS SUBJECT TO STATE CONSTRAINTS*

K. MALANOWSKI†

Abstract. There is considered a family of nonlinear optimal control problems depending on a functional parameter. The problems are subject to state constraints. Conditions are derived under which the solutions and Lagrange multipliers are locally Lipschitz continuous functions of the parameter. Those conditions consist of constraint qualifications and weakened coercivity conditions.

Key words. optimal control, nonlinear ODEs, state constraints, parametric problems, second order sufficient conditions, Lipschitz stability of the solutions

1. Introduction.

In stability analysis for optimal control problems, conditions are investigated under which the solutions and Lagrange multipliers are locally Lipschitz continuous functions of the parameter. It is know that two types of assumptions are crucial in that analysis: constraint qualifications and a second order optimality condition (coercivity of the Hessian of Lagrangian). For control-constrained problems, a full characterization of stability properties was obtained in [4] (see also [9]) under the provision that the parameters are functions of time and the dependence of data on the parameter is strong. The situation was different for state-constrained problems. In papers [8, 3], devoted to stability analysis for that class of problems, a strong second order optimality condition (coercivity condition) was assumed, where the active state constraints were ignored. In the recent paper [11] of the author, an example was constructed in which the Lipschitz stability property was satisfied, but the strong second order condition of [8, 3] was violated. It shows that this condition is too strong. Note that, in the above mentioned example, the parameter is a function of time. In [11] a new second order condition was introduced, which was weakened by taking into account the strongly active state constraints, i.e., those active constraints for which the pointwise strict complementarity condition was satisfied with the margin $\alpha > 0$. It was shown in [11] and [12] that, under this weakened condition, the solutions and Lagrange multipliers for linear-quadratic optimal control problems remain stable under small perturbations. The crucial point in the proof of this result was the analysis of stability of the coercivity condition in a neighborhood of the reference point.

In the present paper, we still further weaken the second order condition used in [11] and we extend the stability results to nonlinear problems. Thus, our assumptions are essentially weaker than those in [8] and [3]. This weakening turns out to be crucial. As it will be shown in a forthcoming paper of the author, the new conditions are not only sufficient, but also necessary for Lipschitz stability and directional differentiability

of the solutions and Lagrange multipliers for a class of parametric optimal control problems, subject to the first order state constraints.

In the stability analysis for nonlinear optimal control problems, we follow [8] and [3] and use the implicit function theorem for strongly regular generalized equations [16, 2]. The crucial point in this approach is to show that the stationary points of the accessory problems are Lipschitz stable under sufficiently regular small perturbations. We use here the approach similar to that developed for linear-quadratic problems in [11].

The organization of this paper is the following. In section 2, some stability results for cone-constrained optimization problems are recalled. In section 3, the considered optimal control problem is formulated and the needed assumptions are introduced. Some basic results concerning state-constrained optimal control problems are presented. In particular, they include a coercivity condition, which is weakened by taking into account the strongly active state constraints. Following the idea developed in the paper [1], it is shown in the appendix that this coercivity condition constitutes a second order sufficient optimality condition. In section 4 the basic auxiliary lemmas and stability results are formulated. They are proved in section 5.

We use the following notations: Capital letters X, Y, V, etc., with superscripts denote Banach or Hilbert spaces. The norms are denoted by $\|\cdot\|$ with a subscript referring to the space. $\mathcal{B}_\rho^X(x_0) := \{x \in X \mid \|x - x_0\|_X < \rho\}$ is the open ball in X of radius ρ, centered at x_0. Asterisks denote dual spaces as well as adjoint operators. For $f : X \times Y \to Z$, $D_x f(x,y), D_y f(x,y), D^2_{x,y} f(x,y)$, etc., denote the Fréchet derivatives in the respective variables.

$\mathbb{R}^n$ is the n-dimensional Euclidean space, with the inner product denoted by $\langle x, y\rangle$ and the norm $|x| = \langle x, x\rangle^{\frac{1}{2}}$. Transposition is denoted by $*$.

$L^p(0,1;\mathbb{R}^n)$ is the Banach space of measurable functions $f : [0,1] \to \mathbb{R}^n$, supplied with the norm

$$\|f\|_p = \begin{cases} \left[\int_0^1 |f(t)|^p dt\right]^{1/p} & \text{for } p \in [1,\infty), \\ \operatorname{ess\,sup}_{t\in[0,1]} |f(t)| & \text{for } p = \infty. \end{cases}$$

$W^{1,p}(0,1;\mathbb{R}^n)$ denotes the Sobolev space of functions f absolutely continuous on $[0,1]$ with the norm

$$\|f\|_{1,p} = \begin{cases} [|f(0)|^p + \|\dot f\|_p^p]^{1/p} & \text{for } p \in [1,\infty), \\ \max\{|f(0)|, \|\dot f\|_\infty\} & \text{for } p = \infty. \end{cases}$$

We will need the subspace $W_0^{1,p}(0,1;\mathbb{R}^n) := \{f \in W^{1,p}(0,1;\mathbb{R}^n) \mid f(0) = 0\}$.

The inner product and the norm in $L^2(0,1;\mathbb{R}^n)$ are denoted by $(\cdot,\cdot)$ and $\|x\|_2 = (x,x)^{1/2}$, respectively. Similarly, for $W^{1,2}(0,1;\mathbb{R}^n)$ we denote $(\cdot,\cdot)_{1,2}$ and $\|x\|_{1,2} = (x,x)_{1,2}^{1/2}$. c, k, l, and ℓ are generic constants, not necessarily the same in different places.

2. Stability results for cone-constrained problems. In this section we recall some results for parametric cone-constrained optimization problems, which will be used in stability analysis for optimal control problems.

Let $H \subset Z, X$, and Y be Banach spaces of parameters, arguments, and constraints, respectively, where the inclusion $H \subset Z$ is dense and continuous. In the space Y there is given a closed convex cone $\mathcal{K}$, which induces a partial order in Y.

Further, $\mathcal{G}: X \times Z \to \mathbb{R}$ and $\phi: X \times Z \to Y$ are given functions. Consider the family of the following optimization problems depending on the parameter $h \in H$:

$$(\mathrm{P})_h \qquad \min_{\xi \in X} \mathcal{G}(\xi, h) \text{ subject to } \phi(\xi, h) \in \mathcal{K}.$$

Assume the following:

(B1) For each $h \in H$ the functions $\mathcal{G}(\cdot, h)$ and $\phi(\cdot, h)$ are Fréchet differentiable on X.

Let us introduce the following Lagrangian for $(\mathrm{P})_h$:

$$L: X \times \mathcal{K}^+ \times H \to \mathbb{R}, \quad L(\xi, \lambda; h) := \mathcal{G}(\xi, h) + (\lambda, \phi(\xi, h)), \tag{2.1}$$

where $\mathcal{K}^+ := \{\lambda \in Y^* \mid (\lambda, \xi) \le 0 \quad \text{for all } \xi \in \mathcal{K}\}$ is the cone polar to $\mathcal{K}$.

The first order optimality system for $(\mathrm{P})_h$ can be written in the form

$$\begin{aligned} &D_\xi L(\xi, \lambda; h) := D_\xi \mathcal{G}(\xi, h) + D_\xi \phi^*(\xi, h)\lambda = 0, \\ &\phi(\xi, h) \in N_{\mathcal{K}^+}(\lambda), \end{aligned} \tag{2.2}$$

where

$$N_{\mathcal{K}^+}(\lambda) = \left\{ y \in Y \;\middle|\; \begin{cases} (\mu - \lambda, y) \le 0 \quad \forall \mu \in \mathcal{K}^+ & \text{if } \lambda \in \mathcal{K}^+ \\ \emptyset & \text{if } \lambda \notin \mathcal{K}^+ \end{cases} \right\} \tag{2.3}$$

is the normal cone to $\mathcal{K}^+$. For the sake of simplicity, we denote

$$\begin{cases} \mathcal{F}: X \times Y^* \times H \to X^* \times Y, & \mathcal{T}: Y^* \to 2^{X^* \times Y}, \\ \mathcal{F}(\xi, \lambda, h) = \begin{bmatrix} D_\xi L(\xi, \lambda; h) \\ \phi(\xi, h) \end{bmatrix}, & \mathcal{T}(\lambda) = \begin{bmatrix} 0 \\ N_{\mathcal{K}^+} \end{bmatrix}. \end{cases} \tag{2.4}$$

Then (2.2) can be written in the form of the following inclusion (generalized equation):

$$\mathcal{F}(\xi, \lambda, h) \in \mathcal{T}(\lambda). \tag{2.5}$$

Let $\Xi \subset X$ and $\Lambda \subset Y^*$ be some closed and convex subsets. These subsets, endowed with the metric of X and Y^*, respectively, can be treated as complete nonlinear metric spaces (see Lemma 2.1 in [3]). In applications, Ξ and Λ are chosen as some sets of sufficiently regular functions. We will denote $\mathcal{B}_\tau^{\Xi \times \Lambda}(\cdot, \cdot) := (\Xi \times \Lambda) \cap \mathcal{B}_\tau^{X \times Y^*}(\cdot, \cdot)$.

In addition to (B1) we assume the following:

(B2) There exist closed convex sets $\Xi \subset X$ and $\Lambda \subset Y^*$ such that, for a fixed reference value $\widehat{h}$ of the parameter, there exists a pair $(\widehat{\xi}, \widehat{\lambda}) \in \Xi \times \Lambda$, which satisfies (2.2).

(B3) For any $h \in H$, $\mathcal{G}(\cdot, h)$ and $\phi(\cdot, h)$ are twice Fréchet differentiable on Ξ.

(B4) For any $\tau > 0$, there exists $k > 0$ such that

$$\begin{aligned} &\|\mathcal{F}(\xi, \lambda, h') - \mathcal{F}(\xi, \lambda, h'')\|_{X^* \times Y} \le k \|h' - h''\|_Z \\ &\qquad \forall\, (\xi, \lambda) \in \mathcal{B}_\tau^{\Xi \times \Lambda}(\widehat{\xi}, \widehat{\lambda}) \text{ and all } h', h'' \in H. \end{aligned} \tag{2.6}$$

Note that in (B4) both spaces Z and H are involved. We require that the estimate (2.6) hold for $h', h'' \in H$, whereas, on the right-hand side of this estimate, we have the norm of the space Z, which may be weaker than that of H.

Let us introduce the following *perturbed linearization* of (2.5):

$$\mathcal{F}(\widehat{\xi},\widehat{\lambda},\widehat{h})+D_\xi\mathcal{F}(\widehat{\xi},\widehat{\lambda},\widehat{h})(\eta-\widehat{\xi})+D_\lambda\mathcal{F}(\widehat{\xi},\widehat{\lambda},\widehat{h})(\kappa-\widehat{\lambda})-\delta\in\mathcal{T}(\kappa), \tag{2.7}$$

where $\delta:=(\delta_1,\delta_2)\in X^*\times Y$ is a perturbation. Note that, for $\delta=0$, $(\eta_0,\kappa_0)=(\widehat{\xi},\widehat{\lambda})$ is a solution of (2.7).

In view of (2.4), inclusion (2.7) can be interpreted as the optimality system for the following *accessory optimization problem*, depending on the perturbation δ:

$$(\mathrm{AP})_\delta \qquad \begin{array}{l}\min_{\eta\in X}\left\{\dfrac{1}{2}(\eta,D^2_{\xi\xi}L(\widehat{\xi},\widehat{\lambda};\widehat{h})\eta)-(\widehat{\delta}_1+\delta_1,\eta)\right\}\\ \text{subject to } D_\xi\phi(\widehat{\xi},\widehat{h})\eta-(\widehat{\delta}_2+\delta_2)\in\mathcal{K},\end{array}$$

where

$$\widehat{\delta}_1=D^2_{\xi\xi}L(\widehat{\xi},\widehat{\lambda};\widehat{h})\widehat{\xi}-D_\xi F(\widehat{\xi};\widehat{h}),\quad \widehat{\delta}_2=D_\xi\phi(\widehat{\xi},\widehat{h})\widehat{\xi}-\phi(\widehat{\xi};\widehat{h}). \tag{2.8}$$

Let us define the following function:

$$m(\xi,\lambda,h)=\mathcal{F}(\widehat{\xi},\widehat{\lambda},\widehat{h})+D_\xi\mathcal{F}(\widehat{\xi},\widehat{\lambda},\widehat{h})(\xi-\widehat{\xi})+D_\lambda\mathcal{F}(\widehat{\xi},\widehat{\lambda},\widehat{h})(\lambda-\widehat{\lambda})-\mathcal{F}(\xi,\lambda,h). \tag{2.9}$$

Our last assumptions are as follows:

(B5) There exist constants $\theta>0,\tau'>0,\pi'>0$, and $l>0$, as well as a subset $\Delta\subset X^*\times Y$ such that for each $\delta\in\mathcal{B}^\Delta_\theta(0):=\Delta\cap\mathcal{B}^{X^*\times Y}_\theta(0)$ there exists a unique stationary point $(\eta_\delta,\kappa_\delta)\in\mathcal{B}^{\Xi\times\Lambda}_{\tau'}(\widehat{\xi},\widehat{\lambda})$ of $(\mathrm{AP})_\delta$ and

$$\|\eta_{\delta'}-\eta_{\delta''}\|_X,\ \|\kappa_{\delta'}-\kappa_{\delta''}\|_{Y^*}\le l\|\delta'-\delta''\|_{X^*\times Y}\quad\forall\delta',\delta''\in\mathcal{B}^\Delta_\theta(0).$$

(B6) The inclusion $m(\xi,\lambda,h)\in\Delta$ is satisfied for all $(\xi,\lambda)\in\mathcal{B}^{\Xi\times\Lambda}_{\tau'}(\widehat{\xi},\widehat{\lambda})$ and all $h\in\mathcal{B}^H_{\pi'}(\widehat{h})$.

The following theorem will be the main tool in the stability analysis for nonlinear optimal control problems.

THEOREM 2.1. *Assume that* (B1)–(B6) *are satisfied. Then, there exist constants* $\pi>0$, $\tau>0$, *and* $\ell>0$ *such that for each* $h\in\mathcal{B}^H_\pi(\widehat{h})$ *there is a stationary point* (ξ_h,λ_h) *of* $(\mathrm{P})_h$, *unique in* $\mathcal{B}^{\Xi\times\Lambda}_\tau(\widehat{\xi},\widehat{\lambda})$, *and*

$$\|\xi_{h'}-\xi_{h''}\|_X,\ \|\lambda_{h'}-\lambda_{h''}\|_{Y^*}\le\ell\|h'-h''\|_H\quad\forall h',h''\in\mathcal{B}^H_\pi(\widehat{h}). \tag{2.10}$$

Remark 2.2. Theorem 2.1 is a slight modification of Robinson's implicit function theorem for strongly regular generalized equations (see Theorem 2.1 in [16]). The difference is that, in Theorem 2.1, there are considered subsets $\Delta\subset X^*\times Y$ and $\Xi\times\Lambda\subset X\times Y^*$ rather than the whole spaces. In applications to optimal control problems, this modification allows us to overcome the difficulty connected with the so-called *two-norm discrepancy* [13] by exploiting the regularity of the stationary points. The proofs of Theorem 2.1 are based on some modifications of the original Robinson's proof and they can be found in [7] (Theorem 2.2) and in [3] (Lemma 2.1).

3. Optimal control problem. In this section our model optimal control problem is formulated and basic assumptions are introduced. Let

$$\left\{\begin{array}{ll}H & =W^{2,\infty}(0,1;\mathbb{R}):=\{h\in L^\infty(0,1;\mathbb{R})\mid\ddot{h}\in L^\infty(0,1;\mathbb{R})\}\quad\text{and}\\ X^p & =W^{1,p}_0(0,1;\mathbb{R}^n)\times L^p(0,1;\mathbb{R}^m),\quad p\in[1,\infty],\end{array}\right. \tag{3.1}$$

be the spaces of parameters and arguments, respectively.

Consider the family of the following optimal control problems depending on $h \in H$:

$(\mathrm{O})_h$ Find $(x_h, u_h) \in X^2$ such that

$$F(x_h, u_h, h) = \min \left\{ F(x,u,h) := \int_0^1 \varphi(x(t), u(t), h(t))dt \right\} \tag{3.2}$$

subject to

$$\dot{x}(t) - f(x(t), u(t), h(t)) = 0 \quad \text{for almost all } t \in [0,1], \tag{3.3}$$

$$x(0) = 0, \tag{3.4}$$

$$\vartheta(x(t), h(t)) \le 0 \qquad \forall\, t \in [0,1], \tag{3.5}$$

where $\varphi:\ \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R} \to \mathbb{R},\ f:\ \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R} \to \mathbb{R}^n,\ \vartheta:\ \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$.

Remark 3.1. To minimize technicalities, we consider the simple homogeneous initial condition. However, the same approach can be applied to general two-point boundary value problems. Also vector-valued state constraints can be considered and additional control constraints can be included.

The following standing assumptions are assumed to be satisfied throughout the paper:

(I) There exist open sets $\mathcal{R}^n \subset \mathbb{R}^n$ and $\mathcal{R}^m \subset \mathbb{R}^m$ such that the functions $\varphi(\cdot,\cdot,\cdot)$, $D_x\varphi(\cdot,\cdot,\cdot)$, and $D_u\varphi(\cdot,\cdot,\cdot)$ as well as $f(\cdot,\cdot,\cdot)$, $D_x f(\cdot,\cdot,\cdot)$, and $D_u f(\cdot,\cdot,\cdot)$ are Fréchet differentiable in (x,u,h) on $\mathcal{R}^n \times \mathcal{R}^m \times \mathbb{R}$. The functions $\vartheta(\cdot,\cdot)$ and $D_x\vartheta(\cdot,\cdot)$ are twice Fréchet differentiable in (x,h) on $\mathcal{R}^n \times \mathbb{R}$.

(II) For a given reference value $\widehat{h} \in H$ of the parameter there exists a reference solution $(\widehat{x}, \widehat{u})$ of $(\mathrm{O})_{\widehat{h}}$, where $\widehat{u} \in C(0,1;\mathbb{R}^m)$ and $(\widehat{x}(t), \widehat{u}(t)) \in \mathcal{R}^n \times \mathcal{R}^m$ for all $t \in [0,1]$.

To simplify notation, the functions evaluated at the reference solution will be denoted by a hat, e.g., $\widehat{\varphi} := \varphi(\widehat{x}, \widehat{u}, \widehat{h})$, $\widehat{\vartheta} := \vartheta(\widehat{x}, \widehat{h})$. Let us define the spaces of multipliers

$$Y^p = L^p(0,1;\mathbb{R}^n) \times W^{1,p}(0,1;\mathbb{R}), \qquad p \in [1,\infty], \tag{3.6}$$

and introduce the Lagrangian and Hamiltonian for $(\mathrm{O})_h$:

$$\mathcal{L} : X^2 \times Y^2 \times H \to \mathbb{R}, \quad \mathcal{H} : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R} \times \mathbb{R} \to \mathbb{R},$$

$$\begin{cases} \mathcal{L}(x,u,p,\mu;h) = F(x,u,h) - (p, \dot{x} - f(x,u,h)) \\ \qquad +\mu(0)\vartheta(x(0),h(0)) + (\dot{\mu}, D_x\vartheta(x,h)f(x,u,h) + D_h\vartheta(x,h)\dot{h}), \end{cases} \tag{3.7}$$

$$\begin{cases} \mathcal{H}(x(t),u(t),p(t),\dot{\mu}(t);h(t),\dot{h}(t)) = \varphi(x(t),u(t)) + \langle p(t), f(x(t),u(t),h(t))\rangle \\ \qquad +\dot{\mu}(t)(D_x\vartheta(x(t),h(t))f(x(t),u(t),h(t)) + D_h\vartheta(x(t),h(t))\dot{h}(t)). \end{cases} \tag{3.8}$$

Remark 3.2. Lagrangian (3.7) is *normal*; i.e., the Lagrange multiplier corresponding to the functional $F(x,u,h)$ is different from zero. The Lagrangian is in the so-called *indirect* or Pontryagin form, with the absolute continuous adjoint variable (see section 5 in [6], as well as [5] and [14]). The state constraints are considered

in the space $W^{1,2}(0,1;\mathbb{R})$, where the general form of a linear functional is given by $\mu(0)y(0)+(\dot\mu,\dot y)$, with $\mu\in W^{1,2}(0,1;\mathbb{R})$. Hence, using the state equation, we get

$$\begin{aligned}&\mu(0)\vartheta(x(0),h(0))+\left(\dot\mu,\frac{d}{dt}\vartheta(x,h)\right)\\&\quad=\mu(0)\vartheta(x(0),h(0))+(\dot\mu,D_x\vartheta(x,h)f(x,u,h)+D_h\vartheta(x,h)\dot h).\end{aligned}$$

It turns out that, in stability analysis, the Lagrangian in indirect form is more convenient than that in direct form, thanks to the regularity of the Lagrange multiplier μ.

Denote by $K=\{d\in W^{1,2}(0,1;\mathbb{R})\mid d(t)\le 0\}$ the cone of nonpositive functions in $W^{1,2}(0,1;\mathbb{R})$. The cone polar to K is given (see, e.g., [15]) by

$$K^+=\left\{\mu\in W^{1,2}(0,1;\mathbb{R})\;\middle|\;\left\{\begin{array}{l}\mu(0)-\dot\mu(0+)\ge 0,\ \dot\mu(t)\ge 0\\ \text{and }\dot\mu(\cdot)\text{ is nonincreasing}\end{array}\right.\right\}. \tag{3.9}$$

Clearly, if $\mu\in W^{2,2}(0,1;\mathbb{R})$, the last condition in (3.9) reduces to $\ddot\mu^i(t)\le 0$ for almost all $t\in[0,1]$. By

$$\mathcal{N}_{K^+}(\mu):=\left\{\begin{array}{ll}\{y\in W^{1,2}(0,1;\mathbb{R})\mid (y,\nu-\mu)_{1.2}\le 0\ \forall\nu\in K^+\}&\text{if }\mu\in K^+,\\ \emptyset&\text{if }\mu\notin K^+,\end{array}\right. \tag{3.10}$$

we denote the normal cone to K^+ at μ.

The stationary conditions of Lagrangian (3.7) can be expressed by the following system:

$$\left\{\begin{array}{l}\dot p+D_x\mathcal{H}(x,u,p,\dot\mu;h,\dot h)\\ \quad=\dot p+D_xf^*(x,u,h)p+D_x\varphi(x,u,h)+(D_xf^*(x,u,h)D_x\vartheta^*(x,h)\\ \qquad+D^2_{xx}\vartheta(x,h)f(x,u,h)+D^2_{hx}\vartheta(x,h)\dot h)\dot\mu=0,\\ p(1)=0,\end{array}\right. \tag{3.11}$$

$$\left\{\begin{array}{l}D_u\mathcal{H}(x,u,p,\dot\mu;h,\dot h)\\ \quad=D_u\varphi(x,u,h)+D_uf^*(x,u,h)p+D_uf^*(x,u,h)D_x\vartheta^*(x,h)\dot\mu=0,\end{array}\right. \tag{3.12}$$

$$\vartheta(x,h)\in\mathcal{N}_{K^+}(\mu). \tag{3.13}$$

Note that condition (3.13) is equivalent to the standard Karush–Kuhn–Tucker sign and complementarity conditions for the inequality constraints. For the sake of simplicity, we will denote $\xi=(x,u)\in X^2$, $\lambda=(p,\mu)\in Y^2$.

The purpose of this paper is to study the local properties of the map $H\ni h\mapsto(\zeta_h,\lambda_h)\in X^2\times Y^2$. More precisely, we are looking for conditions under which there exist a constant $\pi>0$ and a subset $\mathcal{Z}\subset X^2\times Y^2$, containing the reference point $(\widehat\zeta,\widehat\lambda)$ such that for each $h\in\mathcal{B}^H_\pi(\widehat h)$ there exists a unique stationary point $(\zeta_h,\lambda_h)\in\mathcal{Z}$, which is a Lipschitz continuous function of h.

To cope with this problem, we will need several assumptions to be satisfied at the reference point. These assumptions consist of constraint qualifications and coercivity conditions. To formulate constraint qualifications, for a fixed $\alpha\ge 0$ we introduce the sets of α-active constraints:

$$M_\alpha=\{t\in[0,1]\mid\vartheta(\widehat x(t),\widehat h(t))\ge-\alpha\}. \tag{3.14}$$

Assume the following:

(H1) There exist $\alpha>0$ such that $0\notin M_\alpha$.

(H2) (*linear independence*). There exist $\alpha > 0$ and $\chi > 0$ such that

$$|D_u \widehat{f}^*(t) D_x \widehat{\vartheta}^*(t)| \geq \chi \quad \forall\, t \in M_\alpha.$$

Note that by (H2) the analysis is restricted to the so-called *first order state constraints* [6].

It will be more convenient to modify assumption (H2). To this end, for $\alpha \geq 0$ denote

$$T_\alpha(t) = \min\{\widehat{\vartheta}(t) + \alpha, 0\}. \tag{3.15}$$

It can be easily shown (see Lemma 2.1 in [9]) that (H2) is equivalent to the following condition:

(H2′) There exists $\alpha' > 0$ and $\chi' > 0$ such that

$$\left| \begin{array}{c} D_u \widehat{f}^*(t) D_x \widehat{\vartheta}^*(t) \\ T_{\alpha'}(t) \end{array} \right| \geq \chi' \quad \forall\, t \in [0,1].$$

Let us introduce the map

$$\mathcal{C}_\alpha :\ X^2 \times W^{1,2}(0,1;\mathbb{R}) \to L^2(0,1;\mathbb{R}^n) \times W^{1,2}(0,1;\mathbb{R}),$$

$$\mathcal{C}_\alpha \begin{bmatrix} y \\ v \\ \kappa \end{bmatrix} = \begin{bmatrix} \dot{y} - D_x \widehat{f} y - D_u \widehat{f} v \\ D_x \widehat{\vartheta} y + T_\alpha \kappa \end{bmatrix}. \tag{3.16}$$

By Lemma 4.1 and Theorem 4.3 in [10], we obtain the following.

LEMMA 3.3. *If assumptions* (H1) *and* (H2′) *are satisfied, then the map* $\mathcal{C}_{\alpha'}$ *is surjective.*

LEMMA 3.4. *If assumptions* (H1) *and* (H2′) *are satisfied, then there exists a unique Lagrange multiplier* $\widehat{\lambda} = (\widehat{p}, \widehat{\mu}) \in Y^2$ *such that the first order optimality conditions* (3.11)–(3.13) *hold at* $(\widehat{x}, \widehat{u}, \widehat{p}, \widehat{\mu})$.

In addition to the constraint qualifications, we will need some coercivity conditions. Assume the following:

(H3) (*Legendre–Clebsch condition*). There exists $\bar{\gamma} > 0$ such that

$$\langle v, D^2_{uu} \widehat{\mathcal{L}}\, v \rangle \geq \bar{\gamma} |v|^2 \qquad \forall\, v \in \mathbb{R}^m \text{ and all } t \in [0,1].$$

The following regularity result follows from Theorem 2.1 in [5] (see Proposition 6.6 in [8]).

LEMMA 3.5. *If assumptions* (H1)–(H3) *are satisfied, then* $\dot{\widehat{x}}, \widehat{u}, \dot{\widehat{p}}, \dot{\widehat{\mu}}$ *are Lipschitz continuous on* $[0,1]$*, with the Lipschitz modulus denoted by* $\widehat{\varsigma} > 0$.

In view of the uniqueness and regularity of $\widehat{\mu}$, we can introduce the following sets, depending on the parameter $\alpha > 0$:

$$N_\alpha = [0,1] \setminus \overline{\{t \in [0,1] \mid -\ddot{\widehat{\mu}}(t) \leq \alpha\}}, \quad \text{as well as } N_0 = \bigcup_{\alpha > 0} N_\alpha. \tag{3.17}$$

The sets N_α are open in $[0,1]$. Define the following subspace of X^2:

$$\mathcal{E}_\alpha = \left\{ (y,v) \in X^2 \;\middle|\; \left\{ \begin{array}{l} \dot{y}(t) - D_x \widehat{f}(t) y(t) - D_u \widehat{f}(t) v(t) = 0, \\ \langle D_x \widehat{\vartheta}(t), y(t) \rangle = 0 \ \forall\, t \in N_\alpha, \\ \langle D_x \widehat{\vartheta}(1), y(1) \rangle = 0 \ \text{ if } \dot{\widehat{\mu}}(1) > 0. \end{array} \right. \right\} \tag{3.18}$$

For the sake of simplicity we will denote $D^2\widehat{\mathcal{L}} := D^2_{(x,u)(x,u)}\mathcal{L}\,(\widehat{x},\widehat{u},\widehat{p},\widehat{\mu};\widehat{h})$.

Assume the following:

(H4) (*coercivity*). There exist constants $\alpha > 0$ and $\gamma > 0$ such that

$$\Big((y,v), D^2\widehat{\mathcal{L}}\,(y,v)\Big) \geq \gamma(\|y\|^2_{1,2} + \|v\|^2_2) \quad \forall\ (y,v) \in \mathcal{E}_\alpha. \tag{3.19}$$

Remark 3.6. The coercivity condition (H4) takes into account strongly active state constraints. It is weaker than the strong coercivity condition, where the active inequality constraints are ignored. The latter condition was used in stability analysis in [8] and in [3]. The application of the weaker condition (H4) is the main new contribution of this paper. It turns out that the weakening of the coercivity condition is crucial. Namely, as it will be shown in a forthcoming paper of the author, conditions of the form (H1)–(H4) are not only sufficient, but also necessary, for Lipschitz stability and directional differentiability of the solutions and Lagrange multipliers for a class of state-constrained optimal control problems. Thus, they constitute a characterization of these properties.

The following result is a slight modification of Theorem 4.1 in [1].

LEMMA 3.7. *Suppose that* (H1)–(H3), *as well as* (H4) *with* $\alpha = 0$, *hold. Then there exist* $\rho > 0$ *and* $c > 0$ *such that*

$$\begin{aligned} F(x,u,\widehat{h}) - F(\widehat{x},\widehat{u},\widehat{h}) \geq c(\|x-\widehat{x}\|^2_{1,2} + \|u-\widehat{u}\|^2_2), \\ \forall\ (x,u) \in \mathcal{B}^{X^\infty}_\rho(\widehat{x},\widehat{u}) \text{ feasible for } (\mathrm{O})_{\widehat{h}}. \end{aligned} \tag{3.20}$$

Thus $(\widehat{x},\widehat{u})$ *is a second order local minimizer of* $(\mathrm{O})_{\widehat{h}}$.

For the sake of completeness, the proof of Lemma 3.7 is given in Appendix A.

4. Stability analysis. In this section the abstract Theorem 2.1 will be applied to the optimal control problems $(\mathrm{O})_h$. To this end, we have to express $(\mathrm{O})_h$ in terms of the cone-constrained problem $(\mathrm{P})_h$. We set

$$\left\{\begin{array}{l} Z = W^{1,2}(0,1;\mathbb{R}), \quad H = W^{2,\infty}(0,1;\mathbb{R}), \quad X = X^2, \quad Y = Y^2, \\ (X^2)^* = L^2(0,1;\mathbb{R}^n) \times L^2(0,1;\mathbb{R}^m), \quad (Y^2)^* = Y^2, \\ \xi = (x,u), \quad \lambda = (p,\mu), \qquad \mathcal{K} = \{0\} \times K, \\ \\ \mathcal{G}(\xi,h) = F(x,u,h), \quad \phi(\xi,h) = \left[\begin{array}{c} \dot{x} - f(x,u,h) \\ \vartheta(x,h) \end{array}\right]. \end{array}\right. \tag{4.1}$$

It can be easily checked that by (I), condition (B1) is satisfied. In order to verify the remaining assumptions of Theorem 2.1, we have to introduce the sets Ξ and Λ needed in (B2)–(B6). We define

$$\Xi = \{(x,u) \in X \mid \|\ddot{x}\|_\infty,\ \|\dot{u}\|_\infty \leq \varsigma\}, \quad \Lambda = \{(p,\mu) \in Y^* \mid \|\ddot{p}\|_\infty,\ \|\ddot{\mu}\|_\infty \leq \varsigma\}, \tag{4.2}$$

where the constant $\varsigma > \widehat{\varsigma}$ will be given later.

It can be easily seen that the sets Ξ and Λ are convex and closed, and they can be treated as complete nonlinear metric spaces (see [3]). Thus in view of (II) and Lemma 3.5, condition (B2) is satisfied. Moreover, by (I), $\mathcal{G}(\cdot,h)$ and $\phi(\cdot,h)$ are twice Fréchet differentiable on Ξ, for any $h \in H$. So condition (B3) holds. Similarly, (B4) is satisfied.

To verify (B5), we have to construct the accessory problem $(\mathrm{AO})_\delta$ for $(\mathrm{O})_h$. To this end, we introduce perturbations

$$\left\{\begin{array}{l} \delta = (\delta_1,\delta_2,\delta_3,\delta_4) \in (X^2)^* \times Y^2, \qquad \text{where} \\ (\delta_1,\delta_2,\delta_3,\delta_4) \in L^2(0,1;\mathbb{R}^n) \times L^2(0,1;\mathbb{R}^m), \times L^2(0,1;\mathbb{R}^n) \times W^{1,2}(0,1;\mathbb{R}). \end{array}\right. \tag{4.3}$$

The accessory problem takes the form of the following linear-quadratic optimal control:

$$
\begin{aligned}
(\mathrm{AO})_\delta \qquad & \text{Find } \eta_\delta := (y_\delta, v_\delta) \in X^2 \text{ such that} \\
& J(y_\delta, v_\delta; \delta) = \min J(y, v; \delta) \quad \text{subject to} \\
& \dot{y}(t) - D_x \widehat{f}(t) y(t) - D_u \widehat{f}(t) v(t) - (\widehat{\delta}_3 + \delta_3(t)) = 0, \\
& D_x \widehat{\vartheta}(t) y(t) - (\widehat{\delta}_4(t) + \delta_4(t)) \le 0 \quad \forall\, t \in [0,1],
\end{aligned}
$$

where

$$
\begin{aligned}
& J(y, v; \delta) = \frac{1}{2}((y,v), D^2 \widehat{\mathcal{L}}\,(y,v)) - (\widehat{\delta}_1 + \delta_1, y) - (\widehat{\delta}_2 + \delta_2, v) \\
& \widehat{\delta}_1(t) = D^2_{xx} \widehat{\mathcal{H}}(t) \widehat{x}(t) + D^2_{xu} \widehat{\mathcal{H}}(t) \widehat{u}(t) - D_x \widehat{\varphi}(t), \\
& \widehat{\delta}_2(t) = D^2_{ux} \widehat{\mathcal{H}}(t) \widehat{x}(t) + D^2_{uu} \widehat{\mathcal{H}}(t) \widehat{u}(t) - D_u \widehat{\varphi}(t), \\
& \widehat{\delta}_3(t) = \widehat{f}(t) - D_x \widehat{f}(t) \widehat{x}(t) - D_u \widehat{f}(t) \widehat{u}(t), \\
& \widehat{\delta}_4(t) = D_x \widehat{\vartheta}(t) \widehat{x}(t) - \widehat{\vartheta}(t).
\end{aligned} \tag{4.4}
$$

Note that, in view of (I) and Lemma 3.5, there exists a constant $s > 0$ such that

$$
\|\dot{\widehat{\delta}}_1\|_\infty,\ \|\dot{\widehat{\delta}}_2\|_\infty,\ \|\dot{\widehat{\delta}}_3\|_\infty,\ \|\ddot{\widehat{\delta}}_4\|_\infty \le s. \tag{4.5}
$$

The set Δ needed in (B5)–(B6) is defined as

$$
\Delta = \{(\delta_1, \delta_2, \delta_3, \delta_4) \in X^* \times Y \mid \|\dot{\delta}_1\|_\infty, \|\dot{\delta}_2\|_\infty, \|\dot{\delta}_3\|_\infty, \|\ddot{\delta}_4\|_\infty \le s\}, \tag{4.6}
$$

where $s > 0$ is given in (4.5). To verify (B5), we have to show the existence, stability, and regularity of the stationary points of $(\mathrm{AO})_\delta$, for $\delta \in \Delta$.

To get the needed existence and stability results for $(\mathrm{AO})_\delta$, we will use two important lemmas. To formulate them, for any open set $D \subset [0,1]$, introduce the following superspace of the subspace $\mathcal{E}_\alpha$ defined in (3.18):

$$
\mathcal{E}_{\alpha,D} = \left\{ (y,v) \in X^2 \;\middle|\; \left\{ \begin{array}{l} \dot{y}(t) - D_x \widehat{f}(t) y(t) - D_u \widehat{f}(t) v(t) = 0, \\ \langle D_x \widehat{\vartheta}(t), y(t) \rangle = 0 \ \forall\, t \in N_\alpha \setminus D, \\ \langle D_x \widehat{\vartheta}(1), y(1) \rangle = 0 \ \text{ if } \dot{\widehat{\mu}}(1) > 0. \end{array} \right. \right\} \tag{4.7}
$$

Lemma 4.1. *Suppose that* (H1)–(H4) *hold. There exist constant* $\beta > 0$ *and* $\widetilde{\gamma} > 0$ *such that, if* $N_\alpha \cap D$ *does not contain any subinterval* (t', t'') *of the length larger than* β*, that is, if*

$$
|t'' - t'| \le \beta \quad \forall\, (t', t'') \in N_\alpha \cap D, \tag{4.8}
$$

then

$$
\Big((y,v), D^2 \widehat{\mathcal{L}}\,(y,v)\Big) \ge \widetilde{\gamma}(\|y\|^2_{1,2} + \|v\|^2_2) \quad \forall\, (y,v) \in \mathcal{E}_{\alpha,D}. \tag{4.9}
$$

The second lemma concerns a property of elements of $W^{1,2}_0(0,1;\mathbb{R})$, in a neighborhood of $\widehat{\mu}$. For an arbitrary $\nu \in W^{1,2}_0(0,1;\mathbb{R})$ denote

$$
D^\nu = \{t \in [0,1] |\ \dot{\nu}(\cdot) = \text{const a.e. in a neighborhood of } t\}. \tag{4.10}
$$

LEMMA 4.2. *Choose any $\eta > 0$ and let $\nu \in W_0^{1,2}(0,1;\mathbb{R})$ be such that*

$$\|\nu - \widehat{\mu}\|_{1,2} \leq \eta.$$

Let $(t', t'') \subset N_\alpha \cap D^\nu$ be any subinterval belonging to $N_\alpha \cap D^\nu$. Then

$$\text{meas}\,(t', t'') \leq \left(12\left(\frac{\eta}{\alpha}\right)^2\right)^{1/3}. \tag{4.11}$$

Using Lemmas 4.1 and 4.2, we get the following.

LEMMA 4.3. *If assumptions* (H1)–(H4) *are satisfied, then there exist constants $\theta > 0$, $\tau > 0$, and $r > 0$ such that, for each $\delta \in \mathcal{B}_\theta^{X^* \times Y}(0)$, there is a unique stationary point $(y_\delta, v_\delta, q_\delta, \nu_\delta) \in \mathcal{B}_\tau^{X^2 \times Y^2}(\widehat{\xi}, \widehat{\lambda})$ of* $(\text{AO})_\delta$, *and*

$$\begin{aligned} &\|y_\delta - \widehat{x}\|_{1,2}, \|v_\delta - \widehat{u}\|_2, \|q_\delta - \widehat{p}\|_{1,2}, \|\nu_\delta - \widehat{\mu}\|_{1,2} \leq r\|\delta\|_{X^* \times Y} \\ &\qquad \forall\ \delta \in \mathcal{B}_\theta^{X^* \times Y}(0). \end{aligned} \tag{4.12}$$

Moreover, there exists $\varsigma > \widehat{\varsigma}$ such that

$$\|\ddot{y}_\delta\|_\infty, \|\dot{v}_\delta\|_\infty, \|\ddot{q}_\delta\|_\infty, \|\ddot{\nu}_\delta\|_\infty \leq \varsigma \quad \forall\ \delta \in \mathcal{B}_\theta^\Delta(0). \tag{4.13}$$

In definition (4.2) of Ξ and Λ, we choose ς given in Lemma 4.3. Thus we get

$$(y_\delta, v_\delta) \in \Xi, \quad (q_\delta, v_\delta) \in \Lambda \quad \forall\ \delta \in \mathcal{B}_\theta^\Delta(0).$$

Using Lemma 4.3 together with Lemmas 4.1 and 4.2, we arrive at the following stability result for $(\text{AO})_\delta$.

PROPOSITION 4.4. *If assumptions* (H1)–(H4) *are satisfied, then there exist constants $\theta > 0$, $\tau > 0$, and $l > 0$ such that, for each $\delta \in \mathcal{B}_\theta^{X^* \times Y}(0)$, there is a unique stationary point $(y_\delta, v_\delta, q_\delta, \nu_\delta) \in \mathcal{B}_\tau^{\Xi \times \Lambda}(\widehat{\xi}, \widehat{\lambda})$ of* $(\text{AO})_\delta$, *and*

$$\begin{aligned} &\|y_{\delta'} - y_{\delta''}\|_{1,2}, \|v_{\delta'} - v_{\delta''}\|_2, \|q_{\delta'} - q_{\delta''}\|_{1,2}, \|\nu_{\delta'} - \nu_{\delta''}\|_{1,2} \\ &\qquad \leq l\|\delta' - \delta''\|_{X^* \times Y} \quad \forall\ \delta', \delta'' \in \mathcal{B}_\theta^\Delta(0). \end{aligned} \tag{4.14}$$

By Proposition 4.4, condition (B5) holds. To apply Theorem 2.1, we still have to verify (B6). The function m, given in (2.9), can be rewritten as follows:

$$\begin{aligned} m(\xi, \lambda, h) \ &= \int_0^1 \left[D_\xi \mathcal{F}(\widehat{\xi}, \widehat{\lambda}, \widehat{h}) - D_\xi \mathcal{F}(\xi_\beta, \lambda_\beta, \widehat{h})\right] d\beta\ (\xi - \widehat{\xi}) \\ &+ \int_0^1 \left[D_\lambda \mathcal{F}(\widehat{\xi}, \widehat{\lambda}, \widehat{h}) - D_\lambda \mathcal{F}(\xi_\beta, \lambda_\beta, \widehat{h})\right] d\beta\ (\lambda - \widehat{\lambda}) \\ &- \int_0^1 D_h \mathcal{F}(\xi, \lambda, h_\beta) d\beta\ (h - \widehat{h}), \end{aligned} \tag{4.15}$$

where $\mathcal{F}$ is as defined in (2.4), with $\mathcal{G}$ and ϕ as given in (4.1), whereas $\xi_\beta = (1-\beta)\widehat{\xi} + \beta\xi$, $\lambda_\beta = (1-\beta)\widehat{\lambda} + \beta\lambda$, $h_\beta = (1-\beta)\widehat{h} + \beta h$. By straightforward calculations, we get the following result, which shows that assumption (B6) holds.

LEMMA 4.5. *If assumptions* (H1)–(H4) *are satisfied, then there exist $\pi' > 0$ and $\tau > 0$ such that $m(\xi, \lambda, h)$ belongs to Δ, for any $(\xi, \lambda) \in \mathcal{B}_\tau^{\Xi \times \Lambda}(\widehat{\xi}, \widehat{\lambda})$ and any $h \in \mathcal{B}_{\pi'}^H(\widehat{h})$.*

Thus, all assumptions of Theorem 2.1 hold and, by that theorem, we obtain the following principal stability result of this paper.

THEOREM 4.6. *If assumptions* (H1)–(H4) *are satisfied, then there exist constants* $\pi > 0$, $\tau > 0$, *and* $\ell > 0$ *such that, for each* $h \in \mathcal{B}_\pi^H(\widehat{h})$, *there is a unique stationary point* $(\xi_h, \lambda_h) := (x_h, u_h, p_h, \mu_h) \in \mathcal{B}_\tau^{\Xi\times\Lambda}(\widehat{\xi}, \widehat{\lambda})$ *of* $(\mathrm{O})_h$ *and*

$$\begin{aligned} &\|x_{h'} - x_{h''}\|_{1,2}, \|u_{h'} - u_{h''}\|_2, \|p_{h'} - p_{h''}\|_{1,2}, \|\mu_{h'} - \mu_{h''}\|_{1,2} \le \ell\|h' - h''\|_Z \\ &\qquad \forall\ h', h'' \in \mathcal{B}_\pi^H(\widehat{h}). \end{aligned} \tag{4.16}$$

In view of the regularity (4.2) of (x_h, u_h, p_h, μ_h), the estimate (4.16) implies (see Lemma 3.1 in [3]) the following.

COROLLARY 4.7. *If the assumptions of Theorem* 4.6 *hold, then there exist* $\pi > 0$ *and* $\ell_\infty > 0$ *such that*

$$\begin{aligned} &\|x_{h'} - x_{h''}\|_{1,\infty}, \|u_{h'} - u_{h''}\|_\infty, \|p_{h'} - p_{h''}\|_{1,\infty}, \|\mu_{h'} - \mu_{h''}\|_{1,\infty} \le \ell_\infty\|h' - h''\|_Z^{2/3} \\ &\qquad \forall\ h', h'' \in \mathcal{B}_\pi^H(\widehat{h}). \end{aligned} \tag{4.17}$$

Using Theorem 4.6 and Lemma 3.7, we show that (x_h, u_h) in Theorem 4.6 is a solution of $(\mathrm{O})_h$. Thus we get the following.

COROLLARY 4.8. *If assumptions* (H1)–(H4) *are satisfied, then, for* $\pi > 0$ *sufficiently small, the stationary point* (ξ_h, λ_h) *in Theorem* 4.6 *corresponds to the solution and Lagrange multiplier of* $(\mathrm{O})_h$.

5. Proofs. In this section we present the proofs of the stability results formulated in section 4.

Proof of Lemma 4.1. Suppose that the assertion of the lemma is not true. Then, for each $\beta_i > 0$ and $\gamma_i > 0$ there exist an open set $D_i \subset [0, 1]$ and a pair $(y_i, v_i) \in \mathcal{E}_{\alpha,D_i}$, with $\|v_i\|_2 = 1$ such that

$$|t'' - t'| \le \beta_i \quad \forall\ (t', t'') \subset N_\alpha \cap D_i \tag{5.1}$$

and

$$\Big((y_i, v_i), D^2\widehat{\mathcal{L}}\,(y_i, v_i)\Big) < \gamma_i(\|y_i\|_{1,2}^2 + \|v_i\|_2^2). \tag{5.2}$$

Let us choose a sequence $\{(\beta_i, \gamma_i)\} \to (0, 0)$ and let $\{(y_i, v_i)\}$ be the corresponding sequence of normalized pairs $(y_i, v_i) \in \mathcal{E}_{\alpha,D_i}$ satisfying (5.1) and (5.2). From $\{(y_i, v_i)\}$, we can extract a weakly convergent subsequence, still denoted by $\{(y_i, v_i)\}$. Thus, there exists $(\widetilde{y}, \widetilde{v}) \in X^2$ such that

$$\begin{cases} v_i \rightharpoonup \widetilde{v} & \text{weakly in } L^2(0, 1; \mathbb{R}^m), \\ y_i \rightharpoonup \widetilde{y} & \text{weakly in } W^{1,2}(0, 1; \mathbb{R}^n), \text{ i.e., strongly in } C(0, 1; \mathbb{R}^n). \end{cases} \tag{5.3}$$

Since

$$\Big((y, v), D^2\widehat{\mathcal{L}}\,(y, v)\Big) = (y, D_{xx}^2\widehat{\mathcal{L}}\,y) + 2(y, D_{xu}^2\widehat{\mathcal{L}}\,v) + (v, D_{uu}^2\widehat{\mathcal{L}}\,v), \tag{5.4}$$

by (5.3), the first two components on the right-hand side of (5.4) are continuous in the weak topology of X^2, whereas by assumption (H3), the third component is

weakly lower semicontinuous in $L^2(0,1;\mathbb{R}^m)$. Hence $((y,v), D^2\widehat{\mathcal{L}}\,(y,v))$ is weakly lower semicontinuous in X^2. Thus, from (5.2) we obtain

$$\begin{aligned}\Big((\widetilde{y},\widetilde{v}), D^2\widehat{\mathcal{L}}\,(\widetilde{y},\widetilde{v})\Big) &\le \liminf \Big((y_i,v_i), D^2\widehat{\mathcal{L}}\,(y_i,v_i)\Big)\\ &\le \limsup \Big((y_i,v_i), D^2\widehat{\mathcal{L}}\,(y_i,v_i)\Big) \le 0.\end{aligned} \tag{5.5}$$

On the other hand, from (5.1) and (5.3) we get $(\widetilde{y},\widetilde{v}) \in \mathcal{E}_\alpha$. Hence, in view of (H3), we obtain from (5.5) that $0 = ((\widetilde{y},\widetilde{v}), D^2\widehat{\mathcal{L}}\,(\widetilde{y},\widetilde{v}))$, which by (H4) implies $(\widetilde{y},\widetilde{v}) = (0,0)$. Thus, by (5.3) and (5.4), we get from (5.5) that $0 = (\widetilde{v}, D^2_{uu}\widehat{\mathcal{L}}\widetilde{v}) = \lim(v_i, D^2_{uu}\widehat{\mathcal{L}}v_i)$. By coercivity of $D^2_{uu}\widehat{\mathcal{L}}$, that is equivalent to $0 = \|\widetilde{v}\|_2^2 = \lim\|v_i\|_2^2$, which, together with (5.3) implies that $v_i \to \widetilde{v}$ strongly in $L^2(0,1;\mathbb{R}^m)$. Since $\|v_i\|_2 = 1$, the strong convergence contradicts the fact that $\widetilde{v} = 0$ and completes the proof. □

Proof of Lemma 4.2. Using definitions (3.17) and (4.10), we obtain

$$\begin{aligned}\eta^2 &\ge \|\nu - \widehat{\mu}\|_{1,2}^2 \ge \int_{t'}^{t''} (\dot{\nu}(t) - \dot{\widehat{\mu}}(t))^2 dt \ge \min_{c\in\mathbb{R}} \int_{t'}^{t''} [c - \alpha\, t]^2 dt\\ &\ge \frac{1}{12}\alpha^2\ (\text{meas}\ ([t',t'']))^3,\end{aligned}$$

which implies (4.11). □

Proof of Lemma 4.3. Denote by $\mathcal{D}_\beta$ the family of all open subsets D of $(0,1)$ such that (4.8) holds. For a fixed $D \in \mathcal{D}_\beta$, we introduce the following modification of problem $(\text{AO})_\delta$:

$$\begin{aligned}(\text{AO})^D_\delta \qquad &\text{Find } \eta^D_\delta := (x^D_\delta, u^D_\delta) \in X^2 \text{ such that}\\ &J(x^D_\delta, u^D_\delta; \delta) = \min J(y,v;\delta) \quad \text{subject to}\\ &\dot{y}(t) - D_x\widehat{f}(t)y(t) - D_u\widehat{f}(t)v(t) - (\widehat{\delta}_3(t) + \delta_3(t)) = 0,\\ &D_x\widehat{\vartheta}(t)y(t) - (\widehat{\delta}_4(t) + \delta_4(t)) \begin{cases} = 0 & \text{for } t \in N_\alpha \setminus D,\\ \le 0 & \text{for } t \in [0,1] \setminus (N_\alpha \setminus D).\end{cases}\end{aligned}$$

Note that $(\text{AO})^D_\delta$ differs from $(\text{AO})_\delta$ only in the form of the inequality constraints. In view of Lemma 4.1, the quadratic term in the cost functional $J(y,v,;\delta)$ of $(\text{AO})^D_\delta$ satisfies the coercivity condition (4.9) on the linear hull of the feasible set. Stability of coercive linear-quadratic problems was studied in, among others, [3]. By Lemmas 3.8 and 3.10 in [3], the coercivity condition (4.9), together with the constraint qualifications (H1) and (H2), ensures that there exists $\rho > 0$ such that for each $\delta \in \mathcal{B}_\rho^{X^*\times Y}(0)$ there is a unique stationary point $(x^D_\delta, u^D_\delta, p^D_\delta, \mu^D_\delta)$ of $(\text{AO})^D_\delta$, where (x^D_δ, u^D_δ) is the solution. Moreover, there is a constant $r > 0$ such that

$$\begin{aligned}&\|x^D_{\delta'} - x^D_{\delta''}\|_{1,2}, \|u^D_{\delta'} - u^D_{\delta''}\|_2, \|p^D_{\delta'} - p^D_{\delta''}\|_{1,2}, \|\mu^D_{\delta'} - \mu^D_{\delta''}\|_{1,2} \le r\|\delta' - \delta''\|_{X^*\times Y}\\ &\qquad \forall\ \delta', \delta'' \in \mathcal{B}_\rho^{X^*\times Y}(0).\end{aligned} \tag{5.6}$$

Constants ρ and r depend on χ and $\widetilde{\gamma}$ in (H2) and (4.9), respectively; however, they can be chosen independently of $D \in \mathcal{D}_\beta$.

Note that $(\widehat{x}, \widehat{u}, \widehat{p}, \widehat{\mu})$ is a stationary point of $(\text{AO})^D_0$. So (5.6) implies, in particular,

$$\|\mu^D_\delta - \widehat{\mu}\|_{1,2} \le r\|\delta\|_{X^*\times Y}. \tag{5.7}$$

Set

$$\theta \in \left(0, \min\left\{\rho, \frac{\alpha}{4r}\sqrt{\frac{\beta^3}{6}}\right\}\right), \tag{5.8}$$

where $\beta > 0$ is given as in (4.8). Choose an arbitrary $\delta \in \mathcal{B}_\theta^{X^* \times Y}(0)$ and an arbitrary $D \in \mathcal{D}_\beta$. Denote

$$P_\delta^D := \{t \in [0,1] \mid \dot{\mu}_\delta^D(\cdot) = \text{const a.e. in a neighborhood of } t\}.$$

By Lemma 4.2 and (5.7)–(5.8), there exists $\beta' \in (0, \beta/2)$ such that

$$\text{meas } ([t', t''] \cap N_\alpha) \le \beta' < \beta/2 \quad \text{for any } [t', t''] \subset P_\delta^D. \tag{5.9}$$

Thus condition (4.8) is satisfied with a margin.

Let $\{\zeta_\delta^D := (x_\delta^D, u_\delta^D)\}$ be a sequence of solutions to $(\mathrm{AO})_\delta^D$ minimizing $J(x_\delta^D, u_\delta^D; \delta)$ with respect to $D \in \mathcal{D}_\beta$, i.e.,

$$\lim_D J(x_\delta^D, u_\delta^D; \delta) = \inf_{D \in \mathcal{D}_\beta} J(x_\delta^D, u_\delta^D; \delta) := \bar{J}_\delta. \tag{5.10}$$

It follows from (4.9) and (5.6) that $\bar{J}_\delta$ is finite and the set $\{(x_\delta^D, u_\delta^D) \in X^2 \mid D \in \mathcal{D}_\beta\}$ is weakly compact in X^2. Hence we can extract a weakly convergent subsequence, still denoted by $\{(x_\delta^D, u_\delta^D)\}$. Thus, there exists an element $\eta_\delta := (y_\delta, v_\delta) \in X^2$ such that

$$\begin{cases} u_\delta^D \rightharpoonup v_\delta & \text{weakly in } L^2(0,1;\mathbb{R}^m), \\ x_\delta^D \rightharpoonup y_\delta & \text{weakly in } W_0^{1,2}(0,1;\mathbb{R}^n), \text{ i.e., strongly in } C(0,1;\mathbb{R}^n). \end{cases} \tag{5.11}$$

Clearly, (y_δ, v_δ) satisfies the state equation. Moreover, in view of the strong convergence $x_\delta^D \to y_\delta$ in $C(0,1;\mathbb{R}^n)$, $D_x\widehat{\vartheta}(t)y_\delta(t) - (\widehat{\delta}_4(t) + \delta_4(t)) \le 0$ for all $t \in [0,1]$ and the set

$$D_\delta := \{t \in [0,1] \mid D_x\widehat{\vartheta}(t)y_\delta(t) - (\widehat{\delta}_4(t) + \delta_4(t)) < 0\} \tag{5.12}$$

satisfies condition (5.9). Hence (y_δ, v_δ) is feasible for $(\mathrm{AO})_\delta^{D_\delta}$ and $D_\delta \in \mathcal{D}_\beta$. We will show that (y_δ, v_δ) is the solution of $(\mathrm{AO})_\delta^{D_\delta}$. Indeed, taking $(x_\delta^D, v_\delta^D) \in \{(x_\delta^D, v_\delta^D)\}$, passing to the limit, and using (5.10) and (5.11), as well as (5.4) and (H3), we get

$$\begin{aligned} \bar{J}_\delta - J(y_\delta, v_\delta; \delta) &= \lim_D \left\{J(x_\delta^D, u_\delta^D; \delta) - J(y_\delta, v_\delta; \delta)\right\} \\ &= \lim_D \left\{ \frac{1}{2}((x_\delta^D, u_\delta^D), D^2\widehat{\mathcal{L}}\,(x_\delta^D, u_\delta^D)) - \frac{1}{2}((y_\delta, v_\delta), D^2\widehat{\mathcal{L}}\,(y_\delta, v_\delta)) \right. \\ &\qquad \left. - (\widehat{\delta}_1 + \delta_1, x_\delta^D - y_\delta) + (\widehat{\delta}_2 + \delta_2, u_\delta^D - v_\delta) \right\} \\ &= \lim_D \frac{1}{2}\left((u_\delta^D, D_{uu}^2\widehat{\mathcal{L}}\,u_\delta^D) - (v_\delta, D_{uu}^2\widehat{\mathcal{L}}\,v_\delta)\right) \\ &= \lim_D \frac{1}{2}\left((u_\delta^D - v_\delta), D_{uu}^2\widehat{\mathcal{L}}\,(u_\delta^D - v_\delta)\right) \ge 0. \end{aligned} \tag{5.13}$$

Since (y_δ, v_δ) is feasible for $(\mathrm{AO})_\delta^{D_\delta}$, (5.10) together with (5.13) implies

$$J(y_\delta, v_\delta; \delta) = \bar{J}_\delta, \tag{5.14}$$

which shows that (y_δ, v_δ) is the solution of $(\mathrm{AO})_\delta^{D_\delta}$.

Denote by $(q_\delta, \nu_\delta) \in Y^2$ the unique Lagrange multiplier of $(\mathrm{AO})_\delta^{D_\delta}$ associated with (y_δ, v_δ). We will show that $(y_\delta, v_\delta, q_\delta, \nu_\delta)$ is a stationary point of $(\mathrm{AO})_\delta$. The stationarity conditions for $(\mathrm{AO})_\delta^{D_\delta}$ take the form

$$
\left\{
\begin{array}{l}
\dot{q}_\delta(t) + D_x\widehat{f}^*(t)q_\delta(t) + D_xJ(y_\delta, v_\delta; \delta)(t) \\
\qquad +(D_x\widehat{f}^*(t)D_x\widehat{\vartheta}^*(t) + D_{xx}^2\widehat{\vartheta}(t)\widehat{f}(t) + D_{hx}^2\widehat{\vartheta}(t)\dot{\widehat{h}})\dot{\nu}_\delta(t) = 0, \\
q_\delta(1) = 0, \\
D_uJ(y_\delta, v_\delta; \delta)(t) + D_u\widehat{f}^*(t)q_\delta(t) + D_u\widehat{f}^*(t)D_x\widehat{\vartheta}^*(t)\dot{\nu}_\delta(t) = 0, \\
\nu_\delta(0)(D_x\widehat{\vartheta}(0)y_\delta(0) - (\widehat{\delta}_4(0) + \delta_4(0))) \\
\qquad + \displaystyle\int_0^1 \dot{\nu}_\delta(t)\frac{d}{dt}\left(D_x\widehat{\vartheta}(t)y_\delta(t) - (\widehat{\delta}_4(t) + \delta_4(t))\right)dt = 0,
\end{array}
\right. \tag{5.15}
$$

where $\nu_\delta \in K_{D_\delta}^+$, with

$$
K_{D_\delta}^+ = \left\{ \mu \in W^{1,2}(0,1;\mathbb{R}) \;\middle|\; \left\{
\begin{array}{l}
\mu(0) - \dot{\mu}(0) \geq 0,\ \dot{\mu}(\cdot) \text{ is nonincreasing on} \\
\quad \text{each subinterval of } [0,1] \setminus (N_\alpha \setminus D_\delta); \\
\text{if } 1 \notin \overline{N_\alpha \setminus D_\delta}, \text{ then there is a} \\
\quad \text{subinterval } (\tau, 1) \text{ such that } \dot{\mu}(t) \geq 0 \text{ for } t \in (\tau, 1).
\end{array}
\right. \right\} \tag{5.16}
$$

It follows from (5.15) that to prove that $(y_\delta, v_\delta, q_\delta, \nu_\delta)$ is a stationary point of $(\mathrm{AO})_\delta$, it is enough to show that $\nu_\delta \in K^+$, where K^+ is defined as in (3.9). Hence, we have to show that the sign and monotonicity conditions are satisfied by $\dot{\nu}_\delta(\cdot)$ on $(0,1)$. Choose any $\tau \in (0,1)$. In view of (5.9), there is a neighborhood $\mathcal{O}(\tau) \subset (0,1)$ of τ such that there exists $D(\tau) \in \mathcal{D}_\beta$ with the property that $D_\delta \cup \mathcal{O}(\tau) \subset D(\tau)$, where D_δ is defined as in (5.12). Consider problem $(\mathrm{AO})_\delta^{D(\tau)}$. It has a unique stationary point $(x_\delta^{D(\tau)}, u_\delta^{D(\tau)}, p_\delta^{D(\tau)}, \mu_\delta^{D(\tau)})$, where $(x_\delta^{D(\tau)}, u_\delta^{D(\tau)})$ is the solution. Note that (y_δ, v_δ) is feasible for $(\mathrm{AO})_\delta^{D(\tau)}$. Hence, by (5.14) it is the solution of that problem, i.e., $(x_\delta^{D(\tau)}, u_\delta^{D(\tau)}) = (y_\delta, v_\delta)$. Since, for a fixed $(x_\delta^{D(\tau)}, u_\delta^{D(\tau)})$, the element $(p_\delta^{D(\tau)}, \mu_\delta^{D(\tau)})$ satisfying (5.15) is unique, we find that $(q_\delta, \nu_\delta) = (p_\delta^{D(\tau)}, \mu_\delta^{D(\tau)})$ is the unique multiplier of $(\mathrm{AO})_\delta^{D(\tau)}$. In view of (5.16), it shows that $\dot{\nu}_\delta(\cdot)$ must be nonincreasing on $\mathcal{O}(\tau)$. Since $\tau \in (0,1)$ is arbitrary, $\dot{\nu}_\delta(\cdot)$ must be nonincreasing on $(0,1)$. Suppose now that $\dot{\nu}_\delta(t)$ is negative at some $t \in (0,1)$; then, by the monotonicity of $\dot{\nu}(\cdot)$, it must be negative on a subinterval $\mathcal{O}$ left of the final point 1, and we must have $\underline{D_x\widehat{\vartheta}(t)y_\delta(t) - (\widehat{\delta}_4(t) + \delta_4(t))} = 0$ on $\mathcal{O}$. There are two possible situations: either $1 \notin \overline{N_\alpha \setminus D_\delta}$ or $1 \in \overline{N_\alpha \setminus D_\delta}$. In the first case, (5.16) implies that there exists a subinterval $(\tau, 1)$ such that $\dot{\nu}_\delta(t) \geq 0$ for $t \in (\tau, 1)$. In the second case, by (5.9) there exists $\tau < 1$ such that $D(\tau) := (D_\delta \cup (\tau, 1)) \in \mathcal{D}_\beta$. Hence (y_δ, v_δ) is the solution of $(\mathrm{AO})_\delta^{D(\tau)}$, and by (5.16) we must have again $\dot{\nu}_\delta(t) \geq 0$ for $t \in [\tau, 1]$. This contradicts the assumption that $\dot{\nu}_\delta(t) < 0$ for some $t \in (0,1)$ and proves that $(y_\delta, v_\delta, q_\delta, \nu_\delta)$ is a stationary point of $(AO)_\delta$. Finally, since condition (4.9) is satisfied for $D = D_\delta$, Lemma 3.7 implies that (y_δ, v_δ) is a solution of $(\mathrm{AO})_\delta$.

Clearly, (5.6) implies (4.12). To show (4.13), note that it follows from (4.12) and (3.14) that, for $\theta > 0$ sufficiently small, we have $\{t \in [0,1] \mid \widehat{\vartheta}(t)y_\delta(t) - (\widehat{\delta}_4(t) + \delta_4(t)) = 0\} \subset M_\alpha$. Hence, using (H2) and (H3), as well as the regularity (4.6) of δ, we can repeat the proof of Proposition 6.6 in [8], and we arrive at (4.13). In view of Lemma 3.5, $\varsigma > \widehat{\varsigma}$. ∎

Proof of Proposition 4.4. Let $\delta \in \mathcal{B}^{\Delta}_{\theta}(0)$, where θ is given as in Lemma 4.3, and let $(y_\delta, v_\delta, q_\delta, \nu_\delta)$ be a corresponding stationary point of $(\mathrm{AO})_\delta$, satisfying (4.12). In view of (4.13), we have $\nu_\delta \in W^{2,2}_0(0,1;\mathbb{R})$. Hence, in a similar way as in (3.17) and (3.18), we can define

$$N^{\delta}_{\alpha/2} = [0,1] \setminus \overline{\{t \in [0,1] \mid -\ddot{\nu}_\delta \le \tfrac{\alpha}{2}\}},$$

$$\mathcal{E}^{\delta}_{\alpha/2} = \left\{ (y,v) \in X^2 \,\middle|\, \begin{cases} \dot{y}(t) - D_x\widehat{f}(t)y(t) - D_u\widehat{f}(t)v(t) = 0, \\ \langle D_x\widehat{\vartheta}(t), y(t)\rangle = 0 \ \forall t \in N^{\delta}_{\alpha/2}, \\ \langle D_x\widehat{\vartheta}(1), y(1)\rangle = 0 \ \text{ if } \dot{\widehat{\mu}}(1) > 0. \end{cases} \right\}$$

Using (5.7) and the same argument as in the proof of Lemma 4.2, we find that, for any subinterval $(t', t'') \subset N_\alpha \setminus N^{\delta}_{\alpha/2}$, the following estimate holds:

$$|t'' - t'| \le \left(12 \left(\frac{\|\nu_\delta - \widehat{\mu}\|_{1,2}}{\alpha/2} \right)^2 \right)^{1/3} \le \left(48 \left(\frac{r}{\alpha} \right)^2 \|\delta\|^2_{X^* \times Y} \right)^{1/3}.$$

If necessary, shrink $\theta > 0$, so that

$$\theta \le \left(\frac{1}{6} \right)^{1/2} \left(\frac{\beta}{4} \right)^{3/2} \frac{\alpha}{r},$$

where β is given in (4.8). Hence we get

$$|t'' - t'| \le \frac{\beta}{2} \quad \text{for any } (t', t'') \subset N_\alpha \setminus N^{\delta}_{\alpha/2} \text{ and any } \delta \in \mathcal{B}^{\Delta}_{\theta}(0).$$

Therefore, by Lemma 4.1 there exists a constant $\widetilde{\gamma} > 0$ such that

$$\begin{aligned} \Big((y,v), D^2\widehat{\mathcal{L}}\,(y,v) \Big) &\ge \widetilde{\gamma}(\|y\|^2_{1,2} + \|v\|^2_2) \\ &\forall\ (y,v) \in \mathcal{E}^{\delta}_{\alpha/2} \text{ and all } \delta \in \mathcal{B}^{\Delta}_{\theta}(0). \end{aligned} \tag{5.17}$$

Using (5.17) and repeating the argument of the proof of (4.12), but around δ rather than around 0, we find that there exists $\theta(\delta) > 0$, as well as $l > 0$ independent of δ, such that

$$\begin{aligned} &\|y_\phi - y_\delta\|_{1,2},\ \|v_\phi - v_\delta\|_2,\ \|q_\phi - q_\delta\|_{1,2},\ \|\nu_\phi - \nu_\delta\|_{1,2} \\ &\qquad \le l\ \|\phi - \delta\|_{X^* \times Y} \quad \forall\ \phi \in \mathcal{B}^{\Delta}_{\theta(\delta)}(\delta). \end{aligned} \tag{5.18}$$

Let us choose any $\delta', \delta'' \in \mathcal{B}^{\Delta}_{\theta}(0)$. For each $\delta_\sigma := (1-\sigma)\delta' + \sigma\delta''$, $\sigma \in [0,1]$, there exists $\theta(\delta_\sigma)$ such that (5.18) holds. The family $\{\mathcal{B}^{\Delta}_{\theta(\delta_\sigma)}(\delta_\sigma) \mid \sigma \in [0,1]\}$ constitutes a cover of the compact set $\{\delta_\sigma \in \Delta \mid \sigma \in [0,1]\}$. From this cover we can extract a finite cover $\{\mathcal{B}^{\Delta}_{\theta(\delta_{\sigma_i})}(\delta_{\sigma_i}) \mid \sigma = 1, \dots, q\}$, where $\delta_{\sigma_1} = \delta'$ and $\delta_{\sigma_q} = \delta''$. For any $1 \le j < q$, we can choose $\bar{\sigma}_j \in (\sigma_j, \sigma_{j+1})$ such that $\delta_{\bar{\sigma}_j} \in \mathcal{B}^{\Delta}_{\theta(\delta_{r_\sigma})}(\delta_{\sigma_j}) \cap \mathcal{B}^{\Delta}_{\theta(\delta_{\sigma_{j+1}})}(\delta_{\sigma_j+1})$. From (5.18), we get

$$\begin{aligned} &\|y_{\delta_{\bar{\sigma}_j}} - y_{\delta_{\sigma_j}}\|_{1,2},\ \|v_{\delta_{\bar{\sigma}_j}} - v_{\delta_{\sigma_j}}\|_2,\ \|q_{\delta_{\bar{\sigma}_j}} - q_{\delta_{\sigma_j}}\|_{1,2},\ \|\nu_{\delta_{\bar{\sigma}_j}} - \nu_{\delta_{\sigma_j}}\|_{1,2} \\ &\qquad \le l\ \|\delta_{\bar{\sigma}_j} - \delta_{\sigma_j}\|_{X^* \times Y} = (\bar{\sigma}_j - \sigma_j)\ l\ \|\delta'' - \delta'\|_{X^* \times Y}, \\ &\|y_{\delta_{\sigma_{j+1}}} - y_{\delta_{\bar{\sigma}_j}}\|_{1,2},\ \|v_{\delta_{\sigma_{j+1}}} - v_{\delta_{\bar{\sigma}_j}}\|_2,\ \|q_{\delta_{\sigma_{j+1}}} - q_{\delta_{\bar{\sigma}_j}}\|_{1,2},\ \|\nu_{\delta_{\sigma_{j+1}}} - \nu_{\delta_{\bar{\sigma}_j}}\|_{1,2} \\ &\qquad \le\ (\sigma_{j+1} - \bar{\sigma}_j)\ l\ \|\delta'' - \delta'\|_{X^* \times Y}. \end{aligned}$$

Thus

$$\begin{aligned}&\|y_{\delta_{\sigma_{j+1}}} - y_{\delta_{\sigma_j}}\|_{1,2},\ \|v_{\delta_{\sigma_{j+1}}} - v_{\delta_{\sigma_j}}\|_2,\ \|q_{\delta_{\sigma_{j+1}}} - q_{\delta_{\sigma_j}}\|_{1,2},\ \|\nu_{\delta_{\sigma_{j+1}}} - \mu_{\delta_{\sigma_j}}\|_{1,2}\\ &\qquad \le\ (\sigma_{j+1} - \sigma_j)\ l\ \|\delta'' - \delta'\|_{X^*\times Y}.\end{aligned}$$

Summing this inequality over $j = 1, \dots, q-1$, we arrive at (4.14). In particular, it implies that, for each $\delta \in \mathcal{B}^{\Delta}_{\theta}(0)$, the stationary point $(y_\delta, v_\delta, q_\delta, \nu_\delta)$ of $(\mathrm{AO})_\delta$ is unique in $\mathcal{B}^{X^2\times Y^2}_{\tau}(\widehat{x}, \widehat{u}, \widehat{p}, \widehat{\mu})$, where $\tau = l\,\theta$. □

Proof of Lemma 4.5. We have to show that each component $m_i(\xi, \lambda, h)$, $i = 1, \dots, 4$, of the vector function $m(\xi, \lambda, h)$ satisfies conditions (4.6). Let us confine ourselves to checking the needed properties of $m_4(\xi, \lambda, h)$. For the remaining components the estimates are similar. From (4.15) we get

$$m_4(\xi, \lambda, h) = \int_0^1 \Big[D_x\vartheta(\widehat{x}, \widehat{h}) - D_x\vartheta(x_\beta, \widehat{h})\Big]\, d\beta\ (x - \widehat{x}) - \int_0^1 D_h\vartheta(x, h_\beta) d\beta\ (h - \widehat{h}).$$

Hence we have

$$\begin{aligned}\frac{d^2}{dt^2} m_4(\xi, \lambda, h)(t) \quad &= \int_0^1 \frac{d^2}{dt^2}\Big[D_x\vartheta(\widehat{x}(t), \widehat{h}(t)) - D_x\vartheta(x_\beta(t), \widehat{h}(t))\Big]\, d\beta\ (x(t) - \widehat{x}(t))\\ &+2\int_0^1 \frac{d}{dt}\Big[D_x\vartheta(\widehat{x}(t), \widehat{h}(t)) - D_x\vartheta(x_\beta(t), \widehat{h}(t))\Big]\, d\beta\ (\dot{x}(t) - \dot{\widehat{x}}(t))\\ &+\int_0^1 \Big[D_x\vartheta(\widehat{x}(t), \widehat{h}(t)) - D_x\vartheta(x_\beta(t), \widehat{h}(t))\Big]\, d\beta\ (\ddot{x}(t) - \ddot{\widehat{x}}(t))\\ &-\int_0^1 \frac{d^2}{dt^2} D_h\vartheta(x(t), h_\beta(t)) d\beta\ (h(t) - \widehat{h}(t))\\ &-2\int_0^1 \frac{d}{dt} D_h\vartheta(x(t), h_\beta(t)) d\beta\ (\dot{h}(t) - \dot{\widehat{h}}(t))\\ &-\int_0^1 D_h\vartheta(x(t), h_\beta(t)) d\beta\ (\ddot{h}(t) - \ddot{\widehat{h}}(t)).\end{aligned} \tag{5.19}$$

It can be easily seen that, in view of (I), the first three components on the right-hand side of (5.19) tend to zero as $\|x - \widehat{x}\|_{1,2} \to 0$, provided that condition (4.2) is satisfied. Similarly, it follows from (3.1) and (4.2) that the remaining three terms tend to zero as $\|h - \widehat{h}\|_H \to 0$. Thus, choosing $\tau > 0$ and $\pi' > 0$ sufficiently small, we get $\|d^2/dt^2\ m_4(\xi, \lambda, h)\|_\infty \le s$. Using the same argument, we find that the remaining components of $m(\xi, \lambda, h)$ also satisfy the required regularity conditions. Hence $m(\xi, \lambda, h)$ belongs to Δ and condition (B6) is satisfied. □

Proof of Corollary 4.8. Let us set $\varpi = \min\{\pi, \frac{\alpha}{\ell}\sqrt{\frac{\beta^3}{12}}\}$. By Theorem 4.6, for any $h \in \mathcal{B}^H_\varpi(\widehat{h})$, there is a unique stationary point (x_h, u_h, p_h, μ_h), whereas by (4.16) and Lemma 4.2 the sets $D_h := \{t \in [0,1] \mid \vartheta(x_h(t), h(t)) < 0\}$ satisfy condition (4.8). Hence, by Lemma 4.1 we get

$$\begin{aligned}&\Big((z, w), D^2\widehat{\mathcal{L}}\,(z, w)\Big) \ge \widetilde{\gamma}(\|z\|^2_{1,2} + \|w\|^2_2)\\ &\qquad \forall\ (z, w) \in \mathcal{E}_{\alpha, D_h} \text{ and all } h \in \mathcal{B}^H_\varpi(\widehat{h}).\end{aligned} \tag{5.20}$$

Denote

$$D^2\mathcal{L}^h = D^2_{(x,u)(x,u)}\mathcal{L}(x_h,u_h,p_h,\mu_h;h),$$

$$\mathcal{E}^h_\alpha = \left\{ (y,v)\in X^2 \,\middle|\, \left\{ \begin{array}{l} \dot y(t) - D_x f(x_h,u_h,h)(t)y(t) - D_u f(x_h,u_h,h)(t)v(t) = 0,\\ \langle D_x\vartheta(x_h,h)(t), y(t)\rangle = 0 \ \forall t\in N_\alpha\setminus D_h,\\ \langle D_x\vartheta(x_h,h)(t), y(t)\rangle = 0 \text{ if } \dot\mu_\delta(1)>0, \end{array}\right.\right\}$$

$$\mathcal{C}^h_\alpha \left[\begin{array}{c} y\\ v\\ \kappa\end{array}\right] = \left[\begin{array}{c} \dot y - D_x f(x_h,u_h,h)y - D_u f(x_h,u_h,h)v\\ D_x\vartheta(x_h,h)\,y + T_\alpha\kappa\end{array}\right].$$

We are going to show that, for $\varpi>0$ sufficiently small

$$\big((y,v), D^2\mathcal{L}^h(y,v)\big) \ge \frac{1}{2}\widetilde\gamma(\|y\|^2_{1,2}+\|v\|^2_2) \quad \forall\ (y,v)\in\mathcal{E}^h_\alpha, \tag{5.21}$$

which, by Lemma 3.7 shows that (x_h,u_h) is a second order local minimizer of $(\mathrm{O})_h$. Thus, the corollary will be proved.

By Lemma 3.3 the map

$$\mathcal{C}_\alpha\mathcal{C}^*_\alpha:\ L^2(0,1;\mathbb{R}^n)\times W^{1,2}(0,1;\mathbb{R}) \to L^2(0,1;\mathbb{R}^n)\times W^{1,2}(0,1;\mathbb{R})$$

is invertible. For any $(y,v)\in X^2$ define the following new variable:

$$\left[\begin{array}{c} z\\ w\\ \kappa\end{array}\right] = \Big[\mathcal{C}^*_\alpha\,(\mathcal{C}_\alpha\mathcal{C}^*_\alpha)^{-1}\,\mathcal{C}^h_\alpha + \big(I - \mathcal{C}^*_\alpha(\mathcal{C}_\alpha\mathcal{C}^*_\alpha)^{-1}\mathcal{C}_\alpha\big)\Big]\left[\begin{array}{c} y\\ v\\ 0\end{array}\right].$$

We get

$$\mathcal{C}_\alpha\left[\begin{array}{c} z\\ w\\ \kappa\end{array}\right] = \mathcal{C}^h_\alpha\left[\begin{array}{c} y\\ v\\ 0\end{array}\right].$$

Since in view of (3.15), $T_\alpha(t)=0$ for $t\in M_\alpha$, then for $(y,v)\in\mathcal{E}^h_\alpha$ we get

$$\begin{aligned} &\dot z - D_x\widehat f\, z - D_u\widehat f\, w = \dot y - D_x f(x_h,u_h,h)y - D_u f(x_h,u_h,h)v = 0,\\ &D_x\widehat\vartheta(t)z(t) = D_x\vartheta(x_h(t),h(t))y(t) = 0 \quad \text{for } t\in N_\alpha\setminus D_h. \end{aligned}$$

Moreover, it follows from (4.17) that, if $\dot{\widehat\mu}(1)>0$, then there exists $\varpi>0$ such that $\mu_h(1)>0$ for all $h\in\mathcal{B}^H_\varpi(\widehat h)$. That implies $\langle\vartheta(x_h(1),h(1)),z(1)\rangle = 0$. Thus, $(z,w)\in\mathcal{E}_{\alpha,D_h}$, i.e., it satisfies (5.20). On the other hand

$$\left[\begin{array}{c} \Delta y\\ \Delta v\\ -\kappa\end{array}\right] := \left[\begin{array}{c} y\\ v\\ 0\end{array}\right] - \left[\begin{array}{c} z\\ w\\ \kappa\end{array}\right] = \mathcal{C}^*_\alpha\,(\mathcal{C}_\alpha\mathcal{C}^*_\alpha)^{-1}\,\big(\mathcal{C}_\alpha - \mathcal{C}^h_\alpha\big)\left[\begin{array}{c} y\\ v\\ 0\end{array}\right]. \tag{5.22}$$

Using Young's inequality, we get

$$\begin{aligned} \big((y,v), D^2\mathcal{L}^h\ (y,v)\big) &= \Big((y,v),(D^2\mathcal{L}^h - D^2\widehat{\mathcal{L}})\ (y,v)\Big)\\ &+ \Big((z,w), D^2\widehat{\mathcal{L}}\ (z,w)\Big) + 2\Big((z,w), D^2\widehat{\mathcal{L}}\ (\Delta y,\Delta v)\Big) + \Big((\Delta y,\Delta v), D^2\widehat{\mathcal{L}}\ (\Delta y,\Delta v)\Big)\\ &\ge \frac{3}{4}\Big((z,w), D^2\widehat{\mathcal{L}}\ (z,w)\Big) - \Big|\Big((y,v),(D^2\mathcal{L}^h - D^2\widehat{\mathcal{L}})\ (y,v)\Big)\Big|\\ &-3\Big|\Big((\Delta y,\Delta v), D^2\widehat{\mathcal{L}}\ (\Delta y,\Delta v)\Big)\Big|. \end{aligned}$$

By (4.17) and (5.22) we have

$$\left|\Big((y,v),(D^2\mathcal{L}^h - D^2\widehat{\mathcal{L}})\ (y,v)\Big)\right| \to 0 \quad \text{and} \quad \|(\Delta y, \Delta v)\|_{X^2} \to 0,$$

uniformly in h, as $h \to 0$. Hence, in view of (5.20), condition (5.21) is satisfied, provided that ϖ is sufficiently small. ∎

Appendix A. Proof of Lemma 3.7. In the indirect proof, we follow the proof of Theorem 4.1 in [1]. Suppose that (3.19) is satisfied for $\alpha = 0$, but (3.20) is violated. Then, there exists a sequence $\{(x_j, u_j)\}$ of feasible pairs $(x_j, u_j) \in X^\infty$ such that $(x_j, u_j) \to (\widehat{x}, \widehat{u})$ and

$$F(x_j, u_j, \widehat{h}) \le F(\widehat{x}, \widehat{u}, \widehat{h}) + o(\|(x_j - \widehat{x}, u_j - \widehat{u})\|^2_{X^2}). \tag{A.1}$$

Denote $\epsilon_j := \|u_j - \widehat{u}\|_2$ and set $v_j = \epsilon_j^{-1}(u_j - \widehat{u})$. Thus, $\|v_j\|_2 = 1$. Let z_j be the solution of the linearized equation

$$\dot{z}_j(t) - D_x\widehat{f}(t)z_j(t) - D_u\widehat{f}(t)v_j(t) = 0, \quad z_j(0) = 0. \tag{A.2}$$

By the well-known result for differential equations we have

$$\|(x_j - \widehat{x})\|_{1,2} = O(\epsilon_j) \quad \text{and} \quad \|(x_j - \widehat{x}) - \epsilon_j z_j\|_{1,2} = o(\|x_j - \widehat{x}\|_{1,2}) = o(\epsilon_j). \tag{A.3}$$

From (A.1) and (A.3) we obtain

$$(D_xF(\widehat{x}, \widehat{u}, \widehat{h}), z_j) + (D_uF(\widehat{x}, \widehat{u}, \widehat{h}), v_j) \le O(\|(x_j - \widehat{x}, u_j - \widehat{u})\|_{X^2}) = O(\epsilon_j). \tag{A.4}$$

Since $\|v_j\|_2 = 1$, we can extract from $\{v_j\}$ a weakly convergent subsequence, still denoted by $\{v_j\}$. So, there is a pair $(\bar{y}, \bar{v})$ such that

$$\begin{cases} v_j \rightharpoonup \bar{v} & \text{weakly in } L^2(0,1,\mathbb{R}^m), \\ z_j \rightharpoonup \bar{z} & \text{weakly in } W^{1,2}(0,1,\mathbb{R}^n), \text{ i.e., strongly in } C(0,1;\mathbb{R}^n), \end{cases} \tag{A.5}$$

where $(\bar{z}, \bar{v})$ is a solution of (A.2). Passing to the limit in (A.4), we find that

$$(D_xF(\widehat{x}, \widehat{u}, \widehat{h}), \bar{z}) + (D_uF(\widehat{x}, \widehat{u}, \widehat{h}), \bar{v}) \le 0.$$

Note that, by stationarity of the Lagrangian we have

$$(D_xF(\widehat{x}, \widehat{u}, \widehat{h}), \bar{z}) + (D_uF(\widehat{x}, \widehat{u}, \widehat{h}), \bar{v}) = -\left(\dot{\widehat{\mu}}, \frac{d}{dt}(D_x\widehat{\vartheta}\bar{z})\right) = -\dot{\widehat{\mu}}(1)D_x\widehat{\vartheta}(1)\bar{z}(1) + (\ddot{\widehat{\mu}}, D_x\widehat{\vartheta}\bar{z}).$$

Hence

$$-\dot{\widehat{\mu}}(1)D_x\widehat{\vartheta}(1)\bar{z}(1) + (\ddot{\widehat{\mu}}, D_x\widehat{\vartheta}\bar{z}) \le 0. \tag{A.6}$$

From the definition (3.14) we have $\vartheta(x_j(t)) - \vartheta(\widehat{x}(t)) \le 0$ for all $t \in M_0$. Hence, by (A.3) and (A.5) we get $D_x\widehat{\vartheta}(t)\bar{z}(t) \le 0$ for all $t \in M_0$. Similarly, if $\dot{\widehat{\mu}}(1) > 0$, then $\vartheta(x_j(1)) - \vartheta(\widehat{x}(1)) \le 0$, and hence $D_x\widehat{\vartheta}(1)\bar{z}(1) \le 0$. Thus, in view of (3.17) and (3.18), (A.6) implies

$$D_x\widehat{\vartheta}(t)\bar{z}(t) = 0 \ \text{ for } t \in N_0 \quad \text{and} \quad D_x\widehat{\vartheta}(1)\bar{z}(1) = 0 \ \text{ if } \ \dot{\widehat{\mu}}(1) > 0,$$

which together with (A.2) shows that $(\bar{z}, \bar{v}) \in \mathcal{E}_0$.

Since $\widehat{\mu} \in K^+$, it follows from (3.7) and (A.3) that

$$\begin{aligned} & F(x_j, u_j, \widehat{h}) - F(\widehat{x}, \widehat{u}, \widehat{h}) \geq \mathcal{L}(x_j, u_j, \widehat{p}, \widehat{\mu}) - \mathcal{L}(\widehat{x}, \widehat{u}, \widehat{p}, \widehat{\mu}) \\ & = \frac{1}{2}\left((x_j - \widehat{x}, u_j - \widehat{u}), D^2\widehat{\mathcal{L}}\,(x_j - \widehat{x}, u_j - \widehat{u})\right) + o(\|(x_j - \widehat{x}, u_j - \widehat{u})\|^2_{X^2}) \\ & = \frac{1}{2}\epsilon_j^2\left(((z_j, v_j), D^2\widehat{\mathcal{L}}\,(z_j, v_j)) + O(\epsilon_j)\right). \end{aligned} \tag{A.7}$$

Substituting (A.1) into (A.7) and passing to the limit, we get

$$\liminf_{j\to\infty}\left((z_j, v_j), D^2\widehat{\mathcal{L}}\,(z_j, v_j)\right) \leq \limsup_{j\to\infty}\left((z_j, v_j), D^2\widehat{\mathcal{L}}\,(z_j, v_j)\right) \leq 0.$$

Since, in view of (5.4) and (H3), $((z, v), D^2\widehat{\mathcal{L}}\,(z, v))$ is weakly lower semicontinuous in X^2, by (A.5) we get

$$0 \geq \liminf_{j\to\infty}\left((z_j, v_j), D^2\widehat{\mathcal{L}}\,(z_j, v_j)\right) \geq \left((\bar{z}, \bar{v}), D^2\widehat{\mathcal{L}}\,(\bar{z}, \bar{v})\right).$$

Since $(\bar{z}, \bar{v}) \in \mathcal{E}_0$, (3.19) implies that

$$(\bar{z}, \bar{v}) = (0, 0). \tag{A.8}$$

Thus

$$\lim_{j\to\infty}\left((z_j, v_j), D^2\widehat{\mathcal{L}}\,(z_j, v_j)\right) = 0 = \left((\bar{z}, \bar{v}), D^2\widehat{\mathcal{L}}\,(\bar{z}, \bar{v})\right).$$

In particular we get $\lim_{j\to\infty}(v_j, D^2_{uu}\widehat{\mathcal{L}}\ v_j) = (\bar{v}, D^2_{uu}\widehat{\mathcal{L}}\ \bar{v})$. By (H3) and (A.5), it implies that $v_j \to \bar{v}$ strongly in $L^2(0, 1; \mathbb{R}^m)$. Since $\|v_j\|_2 = 1$, we get $\|\bar{v}\|_2 = 1$, which contradicts (A.8) and completes the proof. ∎

ASPLUND DECOMPOSITION OF MONOTONE OPERATORS*

JONATHAN BORWEIN† AND HERRE WIERSMA‡

Abstract. We establish representations of a monotone mapping as the sum of a maximal subdifferential mapping and a "remainder" monotone mapping, where the remainder is "acyclic" in the sense that it contains no nontrivial subdifferential component. This is the nonlinear analogue of a skew linear operator. Examples of indecomposable and acyclic operators are given. In particular, we present an explicit nonlinear acyclic operator.

Key words. monotone operators, cyclic monotonicity, decompositions, convex subgradients, acyclic operators

AMS subject classifications. 47H04, 52A41

DOI. 10.1137/060658357

1. Introduction.

Let X be a Banach space and X^* its topological dual. We denote the closed unit ball in X by B_X or B. Recall that a *monotone operator* $T : X \rightrightarrows X^*$ is a mapping that satisfies

$$\langle x^* - y^*, x - y\rangle \geq 0$$

whenever $x^* \in T(x)$ and $y^* \in T(y)$.

The *domain* of T is $\operatorname{dom} T = \{x \in \mathbb{R}^n \mid T(x) \neq \emptyset\}$, and the *range* of T is $\operatorname{ran} T = \{x^* \in \mathbb{R}^n \mid x^* \in T(x) \text{ for some } x \in \operatorname{dom} T\}$. The *graph* of T is the set $\operatorname{gr} T := \{(x, x^*) \in \mathbb{R}^n \times \mathbb{R}^n \mid x^* \in T(x)\}$. Of particular interest are maximal monotone operators: T is said to be *maximal monotone* if $\operatorname{gr} T \subset \operatorname{gr} S$ with S monotone implies that $T = S$.

In general, T could be a multivalued mapping on an infinite-dimensional space; however, the phenomena we wish to discuss are poorly understood, even for single valued mappings in $\mathbb{R}^n$. We will restrict ourselves largely to this setting where T is single valued, and X and X^* both are $\mathbb{R}^n$; in the following, the notation $T : \operatorname{dom} T \subset X \to X^*$ (single arrow) always denotes a single valued operator. This is not an unreasonable restriction, since the results that hold in $\mathbb{R}^n$, such as continuity or differentiability theorems, usually have a reasonable extension at least to separable Asplund spaces [4]. Moreover, in $\mathbb{R}^n$, T is almost everywhere single valued on $\operatorname{int} \operatorname{dom} T$, from which most of our results naturally extend to the multivalued case. Further background and references may be found in [2, 3, 4, 5].

One important instance of a maximal monotone operator is the subdifferential of a convex function. Let f be a proper convex lower semicontinuous function on $\mathbb{R}^n$. Then the *subdifferential* $\partial f : \operatorname{dom} \partial f \subset \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is the monotone mapping

$$\partial f(x) = \{x^* \in \mathbb{R}^n \mid \langle x^*, y - x\rangle + f(x) \leq f(y) \text{ for all } y \in \mathbb{R}^n\}.$$

Subdifferential mappings enjoy a variety of nice properties: they are single valued on large sets and automatically maximal monotone [11, 4, 14] and seemingly belong to all classes of well-behaved maximal monotone operators in nonreflexive spaces (see [8, 9, 12, 13, 14]. Thus, it appears that if $T = \partial f + R$ possesses any pathology, it is contributed by R. For an arbitrary monotone mapping T, it is therefore appealing to consider decompositions of the form $T = \partial f + R$, where R is a "remainder" to be made as small as possible in some sense. This is an extension of the decomposition of a linear operator into its symmetric and skew parts: $L = (L + L^*)/2 + (L - L^*)/2$.

The "nicest" form for R to take is the zero mapping, in which case T is just a subdifferential map. Barring that, perhaps the next simplest form for R to take is a *skew* or *skew-like* mapping. We investigate in section 2 when such a decomposition is possible. Examples of operators for which this decomposition is not possible are given in section 3. Even if R does not take such a simple form, a modernized version of a 1970 result of Asplund (see [1, 4]) shows that we can find a decomposition with R "acyclic," as described in section 4. Little is known about the properties of such acyclic mappings, however. We give the first explicit example of a nonlinear acyclic operator $\widehat{S} : \mathbb{R}^2 \to \mathbb{R}^2$ in section 5. We further explore this mapping in section 6 and conclude with some open questions.

Since our central goal is to better understand acyclicity, little will be lost if the reader assumes throughout that every monotone operator is everywhere defined and single valued.

2. Skew decompositions. In this section we introduce various weakenings of the notion of a skew symmetric linear mapping and then link them to the properties of an associated function f_T due to Fitzpatrick as defined later in this paper. A mapping $SL : \operatorname{dom} SL \subset \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is said to be *skew-like* if $\langle x^*, x\rangle = 0$ for all $(x, x^*) \in \operatorname{gr} SL$, and $S : \operatorname{dom} S \subset \mathbb{R}^n \to \mathbb{R}^n$ is *skew* if it is linear and $\langle Sx, x\rangle = 0$ for all $x \in \operatorname{dom} S$. We allow that $\operatorname{dom} S \neq \mathbb{R}^n$; in this case we require that $S = \widehat{S}|_{\operatorname{dom} S}$ for some skew linear $\widehat{S} : \mathbb{R}^n \to \mathbb{R}^n$. Thus, skew mappings are ab initio restrictions of skew and linear mappings.

FACT 1. *Let* $0 \in \operatorname{int} \operatorname{dom} S$.

(1) *If* $S : \operatorname{dom} S \subset \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ *is monotone and skew-like, then it is skew linear on* $\operatorname{dom} S$.

(2) *If* $S : \operatorname{dom} S \subset \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ *is monotone, and* $-S$ *is monotone with* $0 \in S(0)$, *then* S *is skew linear on* $\operatorname{dom} S$.

Proof. (1) Using monotonicity and the fact that $\langle x, x^*\rangle = 0$ when $x^* \in S(x)$, we have $\langle x^*, y\rangle \leq -\langle y^*, x\rangle$ for all $(x, x^*), (y, y^*) \in \operatorname{gr} S$.

Choose $\varepsilon > 0$ so that $\varepsilon B \subset \operatorname{int} \operatorname{dom} S$, where B is the closed unit ball in $\mathbb{R}^n$. For $y, z \in \varepsilon B$ choose $y_1^* \in S(y)$, $y_2^* \in S(-y)$, and $z^* \in S(z)$. Then $\langle y_1^*, z\rangle \leq -\langle z^*, y\rangle$ and $\langle z^*, -y\rangle \leq -\langle y_2^*, z\rangle$, which combine to give

$$\langle y_1^* + y_2^*, z\rangle \leq 0 \qquad \text{for all } z \in \varepsilon B.$$

Hence $y_1^* = -y_2^*$ for all $y_1^* \in S(y)$ and $y_2^* \in S(-y)$, so $S(y)$ is singleton with $S(y) = -S(-y)$ whenever $y \in \varepsilon B$.

Let $(x, x^*) \in \operatorname{gr} S$, $y \in \varepsilon B$. Then

$$\langle x^*, y\rangle \leq -\langle S(y), x\rangle = \langle S(-y), x\rangle \leq -\langle x^*, -y\rangle = \langle x^*, y\rangle,$$

so $\langle x^*, y\rangle = -\langle S(y), x\rangle$. Suppose $(x_1, x_1^*), (x_2, x_2^*), (\alpha x_1 + \beta x_2, w^*) \in \operatorname{gr} S$. Then

$$\begin{aligned}\langle w^*, y\rangle &= -\langle S(y), \alpha x_1 + \beta x_2\rangle = -\alpha\langle S(y), x_1\rangle - \beta\langle S(y), x_2\rangle \\ &= \alpha\langle x_1^*, y\rangle + \beta\langle x_2^*, y\rangle = \langle \alpha x_1^* + \beta x_2^*, y\rangle\end{aligned}$$

for all $y \in \varepsilon B$, so that $w^* = \alpha x_1^* + \beta x_2^*$. Choosing $x_2 = x_1$ and $\alpha + \beta = 1$ shows that S is single valued on $\operatorname{dom} S$. That is, $S(\alpha x + \beta y) = \alpha S(x) + \beta S(y)$ whenever $x, y, \alpha x + \beta y \in \operatorname{dom} S$.

Since $\varepsilon B \subset \operatorname{dom} S$, it is clear that there is a unique skew linear extension $\widehat{S}$ of S to the whole space: $\widehat{S}(x) = (\|x\|/\varepsilon) S(\varepsilon x/\|x\|)$.

(2) If $x^* \in S(x)$, then

$$\langle x^*, x\rangle = \langle x^* - 0, x - 0\rangle = 0$$

since $0 \in S(0)$ and both S and $-S$ are monotone. So S is skew-like and monotone, and we can apply (1) to see that S is skew linear on $\operatorname{dom} S$. □

We will say that a monotone operator $T : \operatorname{dom} T \subset \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is *weakly decomposable* if it can be written as the sum of a (possibly zero) skew-like operator and the subgradient of a proper lower semicontinuous convex function: $T = S + \partial f$; and *decomposable* if the skew-like part is actually skew. If T is not decomposable, we say that it is *indecomposable*. For example, the addition of a skew mapping to the subgradient of any norm produces a multivalued decomposable maximal monotone mapping.

Note that a skew-like operator need not be monotone. Note also that if $T(x)$ is single valued and nonempty, so necessarily is $S(x)$ and $\partial f(x)$.

For the following, we use the notation $DT(x)$ for the Jacobian matrix of $T : \mathbb{R}^n \to \mathbb{R}^n$ at x, and we note that T is $\mathcal{C}^1$ (Fréchet or, equivalently in finite dimensions, Gâteaux) on an open set C if and only if the mapping $x \to DT(x)$ is continuous on C.

FACT 2. *Let $T : \operatorname{dom} T \subset \mathbb{R}^n \to \mathbb{R}^n$ be a continuously Fréchet differentiable maximal monotone mapping on an open domain. Then the decomposition $T = S + \nabla f$ into a skew component S and a subdifferential component $\partial f = \{\nabla f\}$ is unique when it exists.*

Proof. From now on we will identify $\{\nabla f\}$ and ∇f. Suppose $T = S + \nabla f = S_1 + \nabla g$. Then $S(x) - S_1(x) = \nabla g(x) - \nabla f(x)$. Differentiating gives

$$S - S_1 = \nabla^2(g - f)(x);$$

the left-hand side is a skew matrix, and the right-hand side is symmetric, so both must be zero matrices. □

A useful observation is the following.

FACT 3. *Let $T : \operatorname{dom} T \subset \mathbb{R}^n \to \mathbb{R}^n$ be continuously Fréchet differentiable on an open convex set $C \subset \operatorname{dom} T$ with $0 \in C$ and $T(0) = 0$. Then T is monotone (resp., skew) on C if and only if $DT(z)$ is positive semidefinite (resp., skew) throughout C.*

Proof. We prove only the skew case; the monotone case is similar. Let $DT(z)$ be skew for each z in the interior of C, and take $x, y \in C \subset \operatorname{dom} T$. The mean-value theorem then provides $z \in [x, y]$ with

$$\langle T(x) - T(y), x - y\rangle = \langle DT(z)(x - y), x - y\rangle = 0,$$

so T and $-T$ are monotones. Fact 1 shows that T is skew linear. On the other hand, suppose T is skew, with $x \in \operatorname{int} \operatorname{dom} T$. Fixing h, we see that

$$\langle th, DT(x + sh)\ th\rangle = \langle T(x + th) - T(x), th\rangle = 0$$

for some $0 < s < t$. Thus

$$\langle h, DT(x + sh)\ h\rangle = 0;$$

letting $t \to 0$ shows that $DT(x)$ is skew. ∎

Define *Fitzpatrick's last function* f_T relative to a point $a \in \operatorname{int}\operatorname{dom} T$ by

$$f_T(x; a) := \int_0^1 \langle T\big(a + t(x - a)\big), x - a\rangle\, dt.$$

(This construction was suggested to the authors by Simon Fitzpatrick just months before his death in 2004.) We use the notation $f_T(x) := f_T(x; 0)$, where $0 \in \operatorname{int}\operatorname{dom} T$.

We may use f_T to characterize both weak decomposability and decomposability. We start with a technical lemma.

LEMMA 1. *For any continuously Fréchet differentiable monotone operator* $T : \operatorname{dom} T \subset \mathbb{R}^n \to \mathbb{R}^n$ *with* $0 \in \operatorname{int}\operatorname{dom} T$*, it is always the case that* $S := T - \nabla f_T$ *is skew-like on* $\operatorname{int}\operatorname{dom} T$*.*

Proof. Fix $x, y \in \operatorname{int}\operatorname{dom} T$, and define

$$h(t) := \langle T(tx), ty\rangle.$$

We check that

$$\langle T(x), y\rangle = h(1) - h(0) = \int_0^1 t\,\langle DT(tx)x, y\rangle\, dt + \int_0^1 \langle T(tx), y\rangle\, dt \tag{2.1}$$

and

$$\langle \nabla f_T(x), y\rangle = \int_0^1 t\,\langle DT(tx)^T x, y\,\rangle\, dt + \int_0^1 \langle T(tx), y\rangle\, dt; \tag{2.2}$$

we can switch the order of integration and differentiation since $(x, t) \to \langle T(tx), x\rangle$ is continuous. Then $S := T - \nabla f_T$ is skew-like, since $\langle T(x), x\rangle = \langle \nabla f_T(x), x\rangle$. ∎

Throughout the rest of this section we assume $\operatorname{dom} T$ is open so as to avoid technical complications at boundary points.

THEOREM 2 (weak decomposability). *Suppose* T *is a continuously Fréchet differentiable maximal monotone operator* $T : \operatorname{dom} T \subset \mathbb{R}^n \to \mathbb{R}^n$ *for which* $0 \in \operatorname{int}\operatorname{dom} T = \operatorname{dom} T$*. Then the following are equivalent:*

(1) T *is weakly decomposable on* $\operatorname{dom} T$*,*

(2) f_T *is convex on* $\operatorname{dom} T$*.*

Proof. Letting $S := T - \nabla f_T$, Lemma 1 shows that S is skew-like. Hence if f_T is convex, T is weakly decomposable.

Conversely, suppose that $T = \nabla g + S$ with g convex and S skew-like. Then $f_{\nabla g} = f_T$ as is seen by writing $h(1) - h(0) = \int_0^1 h'(t)\, dt$ with $h := t \mapsto g(xt)$, which implies that $g - g(0) = f_T$ and we are done. ∎

THEOREM 3 (decomposability). *Suppose we have a continuously differentiable maximal monotone operator* $T : \operatorname{dom} T \subset \mathbb{R}^n \to \mathbb{R}^n$ *for which* $0 \in \operatorname{int}\operatorname{dom} T = \operatorname{dom} T$*. Then* T *is decomposable on* $\operatorname{dom} T$ *if and only if* $T - \nabla f_T$ *is skew on* $\operatorname{dom} T$*.*

Proof. Without loss of generality, we may assume $T(0) = 0$.

If $T - \nabla f_T$ is skew, then

$$\langle \nabla f_T(x) - \nabla f_T(y), x - y\rangle = \langle T(x) - T(y), x - y\rangle \geq 0,$$

so ∇f_T is monotone. By Theorem 12.17 in [12] f_T is convex, so T is decomposable. On the other hand, suppose $T = \nabla g + S$ for some convex g and skew S. Then

$$\begin{aligned} f_T(x) &= \int_0^1 \langle \nabla g(tx) + S(tx), x\rangle dt \\ &= \int_0^1 \langle \nabla g(tx), x\rangle dt = g(x) - g(0), \end{aligned}$$

so $T - \nabla f_T = T - \nabla g = S$ is skew. □

So far we have not explicitly established that (weakly) indecomposable monotone operators actually exist. We address this in the next section.

3. Indecomposable examples. The next example specifies an entire class of everywhere-defined indecomposable operators. We require the following lemma.

LEMMA 4. *Let $T : \mathbb{R}^n \to \mathbb{R}^n$ be $\mathcal{C}^1$ and monotone. If there exist $x, y \in \mathbb{R}^n$ and $1 \le i < j \le n$ such that $DT(x)_{ij} - DT(x)_{ji} \ne DT(y)_{ij} - DT(y)_{ji}$, then T is indecomposable on $\mathbb{R}^n$.*

Proof. Suppose that $T = \nabla f + S$ with f convex and S skew. Then the Hessian matrix $\nabla^2 f(z) = DT(z) - S$ is symmetric for each $z \in \mathbb{R}^n$. Setting $\Delta_{ij} = S_{ij} - S_{ji}$, we have

$$DT(x)_{ij} = DT(x)_{ji} + \Delta_{ij} \quad \text{and} \quad DT(y)_{ij} = DT(y)_{ji} + \Delta_{ij},$$

which implies $DT(x)_{ij} - DT(x)_{ji} = DT(y)_{ij} - DT(y)_{ji}$, a contradiction. □

PROPOSITION 5. *Let $g \ge 0$ be a nonconstant and continuous real function such that either $g(x) \ge 1 = g(0)$ or $g(x) \le 1 = g(0)$. Let*

$$G(x) := \int_0^x g \quad \text{and} \quad K(x) := \int_0^x \left\{ \frac{(1+g)}{2} \right\}^2.$$

Then

(1) *$T(x, y) := (K(x) - G(y), K(y) - G(x))$ is both continuously differentiable and maximal monotone $\mathbb{R}^2$;*
(2) *T is indecomposable on $\mathbb{R}^2$.*

Proof. To check that T is monotone, we check that the symmetric part of the Jacobian DT of T is positive semidefinite as required by Fact 3. First we compute

$$DT = \begin{pmatrix} \left(\frac{1+g(y)}{2}\right)^2 & -g(y) \\ -g(x) & \left(\frac{1+g(x)}{2}\right)^2 \end{pmatrix},$$

so

$$DT_{sym} = \frac{DT + DT^T}{2} = \begin{pmatrix} \left(\frac{1+g(x)}{2}\right)^2 & -\frac{g(x)+g(y)}{2} \\ -\frac{g(x)+g(y)}{2} & \left(\frac{1+g(y)}{2}\right)^2 \end{pmatrix}.$$

Since $\left(\frac{1+g(x)}{2}\right)^2 \ge 0$, we need only check that $\operatorname{Det} DT_{sym} \ge 0$:

$$\begin{aligned} 16 \operatorname{Det} DT_{sym} &= (1+g(x))^2 (1+g(y))^2 - 4\,(g(x)+g(y))^2 \\ &= (g(x)-1)(g(y)-1)\big((g(x)+1)(g(y)+1) + 2(g(x)+g(y))\big) \\ &\ge 0. \end{aligned}$$

The maximality of T is a consequence of Example 12.7 in [12]. Lemma 4 with $i = 1, j = 2$ shows that T is indecomposable, since g is nonconstant. □

Example 6. If $g := x^2+1$ and T is constructed as in Proposition 5, then $T(x,y) = (x+1/20\,x^5+1/3\,x^3-1/3\,y^3-y, y+1/20\,y^5+1/3\,y^3-1/3\,x^3-x)$ is indecomposable. We have

$$f_T(x,y) = \frac{1}{120}\,x^6 + \frac{1}{120}\,y^6 + \frac{1}{12}\,x^4 + \frac{1}{12}\,y^4 - \frac{1}{12}\,xy^3 - \frac{1}{12}\,yx^3 + \frac{1}{2}\,x^2 - xy + \frac{1}{2}\,y^2,$$

and the Hessian of f_T is

$$\nabla^2 f_T(x,y) = \begin{bmatrix} 1/4\,x^4 + x^2 - 1/2\,xy + 1 & -1/4\,x^2 - 1/4\,y^2 - 1 \\ -1/4\,x^2 - 1/4\,y^2 - 1 & 1/4\,y^4 + y^2 - 1/2\,xy + 1 \end{bmatrix};$$

since $\nabla^2 f_T(x,y)_{11} < 0$ for large y and small positive x, f_T is not convex.

By Theorem 2, T is also not weakly decomposable.

Example 7. Consider the mapping

$$T(x,y) := \left(\sinh(x) - \alpha\,y^2/2, \sinh(y) - \alpha\,x^2/2)\right).$$

Then

$$DT = \begin{pmatrix} \cosh(x) & -\alpha y \\ -\alpha x & \cosh(y) \end{pmatrix}$$

which is monotone if and only if

$$\alpha^2 \le \frac{\cosh(x)}{x}\,\frac{\cosh(y)}{y}$$

for all $x, y > 0$. The right-hand side is a separable convex function, and is minimized at $x = y = x_0 = \coth(x_0) = 1.199678\ldots$. So T is monotone if and only if $\alpha^2 \le \sinh^2(x_0) = 2.276717\ldots$.

As before, since the difference between the off-diagonal entries of DT is nonconstant, T is indecomposable by Lemma 4.

We may now turn to the more general notion of an acyclic decomposition.

4. Acyclic decompositions. In this section, we reconstruct a modern version of a decomposition result found in [1]. We first need to recall some additional monotonicity notions. A mapping $T : \operatorname{dom} T \subset \mathbb{R}^n \to \mathbb{R}^n$ is said to be *N-monotone* for $N \ge 2$ if for every $x_1, x_2, \ldots, x_N \in \operatorname{dom} T$ we have

$$\sum_{i=1}^{N} \langle T(x_i), x_i - x_{i-1}\rangle \ge 0, \tag{4.1}$$

where $x_0 := x_N$. Note that 2-monotonicity is just monotonicity. We write $S \le_N T$ to indicate that $T = S + R$ for some N-monotone R. In particular, this means that $\operatorname{dom} T \subset \operatorname{dom} S$.

By duplicating entries in (4.1), it is easy to see that an N-monotone mapping is also M-monotone for $M \le N$; in particular, an N-monotone mapping is monotone. Asplund [1] showed that these classes are distinct via the following example.

Example 8. For $N \ge 2$ define a 2×2 matrix T_N by

$$T_N = \begin{pmatrix} \cos(\pi/N) & -\sin(\pi/N) \\ \sin(\pi/N) & \cos(\pi/N) \end{pmatrix}.$$

Then $x \to T_N(x)$ is N-monotone, but not $(N+1)$-monotone. A more explicit proof to this surprisingly difficult proposition can be found in [2, 3].

An operator that is N-monotone for every $N \geq 2$ is called *cyclically monotone* or *ω_0-monotone*. It is easy to see that subdifferential mappings are cyclically monotone; in fact, a classical result by Rockafellar [10] shows that subdifferential mappings are the only cyclically monotone mappings.

THEOREM 9 (maximal cyclic monotonicity [4, 10]). *Suppose $C : \operatorname{dom} C \subset \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is cyclically monotone. Then C has a maximal cyclically monotone extension $\widehat{C}$ of the form $\widehat{C} = \partial f$ for some proper lower semicontinuous convex function f. Furthermore,* $\operatorname{ran} \widehat{C} \subset \overline{\operatorname{conv}} \operatorname{ran} C$.

The fact that $\widehat{C}$ preserves the range of C is implicit in the proof of Theorem 1 in [10], where the convex function f is of the form $f(x) = \sup\{\langle x_\alpha^*, x\rangle - r_\alpha \mid x_\alpha^* \in \operatorname{ran} C\}$. For clarity, we prove the following lemma.

LEMMA 10. *Let X be a Banach space and let $x_\alpha^* \in X^*$ for $\alpha \in A$ and with each r_α real. Let $f(x) = \sup\{\langle x_\alpha^*, x\rangle - r_\alpha \mid \alpha \in A\}$. Then* $\operatorname{ran} \partial f \subset \overline{\operatorname{conv}}^*\{x_\alpha^* \mid \alpha \in A\}$.

Proof. Consider the convex function g defined on X^* by

$$g(x^*) := \inf\left\{\sum \lambda_{\alpha_i} r_{\alpha_i} \colon \sum \lambda_{\alpha_i} x_{\alpha_i} = x^*, \sum \lambda_{\alpha_i} = 1, \lambda_{\alpha_i} > 0\right\},$$

as we range over all finite subsets of $\{(x_\alpha^*, r_\alpha) \mid \alpha \in A\}$. It is easy to check that $g^*|_X = f$, and $f^* = g^{**}$ viewed in $\sigma(X^*, X)$. Now when $x^* \in \partial f(x)$ we have $f(x) + f^*(x^*) = \langle x^*, x\rangle$. Since $x \in \operatorname{dom} f$, we see that $g^{**}(x^*)$ is finite and we are done since $\operatorname{dom} g^{**} \subset \overline{\operatorname{dom} g}^*$.

Alternative proof. If the conclusion fails we may find $x^* \in \partial f(x)$, $\varepsilon > 0$, and $h \in X$ such that

$$\langle x^*, h\rangle > \varepsilon + \sup_{\alpha \in A} \langle x_\alpha^*, h\rangle, \tag{4.2}$$

by the Hahn–Banach theorem. Thus, for each $\alpha \in A$ we have

$$\begin{aligned}\langle x^*, h\rangle &\geq \varepsilon + \langle x_\alpha^*, x\rangle = \varepsilon + (\langle x_\alpha^*, x+h\rangle - r_\alpha) - (\langle x_\alpha^*, x\rangle - r_\alpha)\\ &\geq \varepsilon + \langle x_\alpha^*, x+h\rangle - r_\alpha - f(x).\end{aligned}$$

Now $f(x)$ is finite and so supremizing over $\alpha \in A$ yields

$$\langle x^*, h\rangle \geq \varepsilon + f(x+h) - f(x),$$

in contradiction to $x^* \in \partial f(x)$. ∎

Another range-preserving extension theorem we shall require is the following central case of the Debrunner–Flor theorem.

THEOREM 11 (Debrunner–Flor extension [4, 6]). *Suppose $T : \operatorname{dom} T \subset \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is monotone with range in MB_{X^*} for some $M > 0$. Then T has a bounded monotone extension $\widehat{T}$ with* $\operatorname{dom} \widehat{T} = \mathbb{R}^n$ *and* $\operatorname{ran} \widehat{T} \subset \overline{\operatorname{conv}} \operatorname{ran} T$.

The proof of the decomposition below hinges on a kind of monotone convergence theorem. We require the following definition: a monotone operator T is *3^--monotone* if

$$\langle T(x), y\rangle \leq \langle T(x), x\rangle + \langle T(y), y\rangle$$

for all $x, y \in \operatorname{dom} T$. In particular, this holds if T is N-monotone for $N \geq 3$, and $0 \in T(0)$.

THEOREM 12 (monotone convergence [1, 4]). *Let N be one of $3^-, 3, 4, \dots,$ or ω_0. Consider an increasing net of monotone operators $T_\alpha : \operatorname{dom} T_\alpha \subset \mathbb{R}^n \to \mathbb{R}^n$ satisfying*

$$0 \leq_N T_\alpha \leq_N T_\beta \leq_2 T,$$

whenever $\alpha < \beta \in \mathcal{A}$, for some monotone $T : \operatorname{dom} T \subset \mathbb{R}^n \to \mathbb{R}^n$. Suppose that $T(0) = 0$, $T_\alpha(0) = 0$ for all α, and that $0 \in \operatorname{int} \operatorname{dom} T$. Then

(i) *there is an N-monotone operator $T_{\mathcal{A}}$ with*

$$T_\alpha \leq_N T_{\mathcal{A}} \leq_2 T$$

for all $\alpha \in \mathcal{A}$;

(ii) *if T is maximal monotone and $\operatorname{ran} T \subset MB$ for some $M > 0$, then one may assume $\operatorname{ran} T_{\mathcal{A}} \subset MB$.*

Proof. (i) Let $\alpha < \beta$. Since $T(0) = 0$ and $0 \leq_2 T_\alpha \leq_2 T_\beta \leq_2 T$, we have

$$0 \leq \langle x, T_\alpha(x)\rangle \leq \langle x, T_\beta(x)\rangle \leq \langle x, T(x)\rangle \tag{4.3}$$

for $x \in \operatorname{dom} T$. So $\lim_{\alpha\to\infty}\langle x, T_\alpha(x)\rangle$ exists.

Writing $T_{\beta\alpha} = T_\beta - T_\alpha$ and using $T_{\beta\alpha} \geq_{3^-} 0$, we get

$$\langle y, T_{\beta\alpha}(x)\rangle \leq \langle x, T_{\beta\alpha}(x)\rangle + \langle y, T_{\beta\alpha}(y)\rangle \tag{4.4}$$

for $x, y \in \operatorname{dom} T$. A monotone operator is locally bounded on the interior of its domain (see [4]) and $0 \in \operatorname{int} \operatorname{dom} T$, so there exist $\varepsilon > 0$ and $M > 0$ with $T(\varepsilon B) \subset MB$ and $\varepsilon B \subset \operatorname{dom} T$. Then

$$0 \leq \langle y, T_{\beta\alpha}(y)\rangle \leq \langle y, T(y)\rangle \leq \varepsilon M \tag{4.5}$$

when $\|y\| \leq \varepsilon$.

For $x \in \operatorname{dom} T$, we may choose $\gamma(x)$ so that

$$0 \leq \langle x, T_{\beta\alpha}(x)\rangle \leq \varepsilon^2 \tag{4.6}$$

whenever $\beta > \alpha > \gamma(x)$, since $\langle x, T_\alpha(x)\rangle$ is convergent.

Combining (4.4), (4.5), and (4.6) gives

$$\langle y, T_{\beta\alpha}(x)\rangle \leq \langle x, T_{\beta\alpha}(x)\rangle + \langle y, T_{\beta\alpha}(y)\rangle \leq (M + \varepsilon)\varepsilon$$

for all $\|y\| \leq \varepsilon$ and $\beta > \alpha > \gamma(x)$. This shows that

$$\langle y, T_{\beta\alpha}(x)\rangle \to 0$$

for all $y \in \mathbb{R}^n$, so $\big(T_\alpha(x)\big)_\alpha$ is Cauchy, and thus has a limit. Setting $T_{\mathcal{A}}(x)$ to this limit, it is clear from the definitions that $T_{\mathcal{A}}$ is N-monotone. It is straightforward to check $T_\alpha \leq_N T_{\mathcal{A}} \leq_2 T$.

(ii) The Debrunner–Flor result shows that $\operatorname{dom} T = \mathbb{R}^n$, since T is maximal. Fixing $x \in \mathbb{R}^n$, we know that

$$\begin{aligned}\langle T_\alpha(x), y\rangle &\leq \langle T_\alpha(x), x\rangle + \langle T_\alpha(y), y\rangle \\ &\leq \langle T(x), x\rangle + \langle T(y), y\rangle\end{aligned}$$

for all $y \in \operatorname{dom} T = \mathbb{R}^n$.

From $\|T(y)\| \le M$ we get

$$\|T_\alpha(x)\|\ \|y\| \le \langle T(x), x\rangle + M\|y\|$$

for all $y \in \mathbb{R}^n$. Letting $\|y\| \to \infty$ in this expression gives $\|T_\alpha(x)\| \le M$. □

The maximality condition in part (ii) of Theorem 12 cannot be removed for $N \neq \omega_0$. Indeed, for a fixed $N \ge 3$ and T_N as in Example 8, define maps T_α and T on the unit ball B by $T_\alpha(x) := T_N(x)$ for each α in some directed set $\mathcal{A}$ and $T(x) := \left(\frac{T_N + T_N^T}{2}\right)x = \cos(\pi/N)Ix$. Then $0 \le_N T_\alpha \le T_\beta \le T$ for $\alpha < \beta$, and $T_{\mathcal{A}} = T_\alpha$, but

$$\operatorname{ran} T_{\mathcal{A}} = T_{\mathcal{A}}(B) = B \nsubseteq \cos(\pi/N)B = \operatorname{ran} T.$$

Now we are ready to present an updated version of a decomposition result provided in [1]. In this case, the decomposition takes the form of a subdifferential component, as before, and an *acyclic* (termed *irreducible* in [1]) remainder A.

Given a set $C \subset \mathbb{R}^n$, a monotone operator $A : \mathbb{R}^n \to \mathbb{R}^n$ is said to be *acyclic* with respect to C if $A = \partial f + R$ with R monotone implies that ∂f is constant on C (i.e., f is affine on C). That is, $A|_C$ has no nontrivial subdifferential component. If no set C is given, then $C = \operatorname{dom} A$ is implied.

THEOREM 13 (Asplund decomposition [1, 4]). *Suppose we are given a (single-valued) maximal monotone operator* $T : \operatorname{dom} T \subset \mathbb{R}^n \to \mathbb{R}^n$ *with* $\operatorname{int}\operatorname{dom} T \neq \emptyset$.

(i) *T may be decomposed as*

$$T = \nabla f + A,$$

where f is lower semicontinuous and convex, while A is acyclic with respect to $\operatorname{dom} T$.

(ii) *If* $\operatorname{ran} T \subset MB$, *we may assume that f is M-Lipschitz.*

Proof. (i) First, shift the graph of T so that $0 \in \operatorname{int}\operatorname{dom} T$. Consider the set

$$\mathcal{C} := \{C \mid 0 \le_{\omega_0} C \le_2 T,\ C(0) = 0\},$$

ordered by the partial order $\le_{\omega_0}$. Every chain in $\mathcal{C}$ has an upper bound $T_{\mathcal{A}}$ by Theorem 12, and $\mathcal{C}$ is nonempty since it contains the zero mapping, so Zorn's lemma provides a $\le_{\omega_0}$-maximal $\widehat{C}$ in $\mathcal{C}$ with

$$0 \le_{\omega_0} \widehat{C} \le_2 T.$$

So $T = \widehat{C} + A$ for some monotone A. To show that A is acyclic, suppose $A = \partial g + M$. Then

$$T = (\widehat{C} + \partial g) + M,$$

so, by adding a constant to ∂g and subtracting it from M if necessary, we have $\partial g + \widehat{C} \in \mathcal{C}$. Since $\widehat{C}$ is $\le_{\omega_0}$-maximal, we have $\widehat{C} + \partial g \le_{\omega_0} \widehat{C}$, so $\operatorname{gr}(-\partial g|_{\operatorname{dom} T}) \subset \operatorname{gr}\partial h$ for some lower semicontinuous convex $h : \mathbb{R}^n \to \mathbb{R}$. Thus g is both convex and concave, hence affine, on $\operatorname{dom} T$, and A is therefore acyclic with respect to $\operatorname{dom} T$.

Now, $\widehat{C}$ is cyclically monotone, so Rockafellar's result shows that $\operatorname{gr}\widehat{C} \subset \operatorname{gr}\partial f$ for some proper convex lower semicontinuous f. This gives

$$\operatorname{gr} T = \operatorname{gr}(\widehat{C} + A) \subset \operatorname{gr}(\partial f + A),$$

but $\partial f + A$ is monotone, and T is maximal monotone, so $T = \partial f + A$, as required.

(ii) Part (ii) of Theorem 12 shows that one may assume that $\operatorname{ran} \widehat{C} \subset MB$, so $\operatorname{ran} \partial f \subset MB$ by Rockafellar's result. It is straightforward to show that this implies that f is M-Lipschitz. ∎

An immediate corollary of this decomposition is the following.

COROLLARY 14 (nonlinear acyclicity). *Under the hypotheses of Theorem* 13*, if* $T : \operatorname{dom} T \subset \mathbb{R}^n \to \mathbb{R}^n$ *is maximal monotone with bounded range, then the acyclic part of the Asplund decomposition of* T *is either nonlinear or zero. In other words,* A *is nonlinear unless* T *is cyclically monotone.*

Proof. Since T is maximal monotone with bounded range, $\operatorname{dom} T = \mathbb{R}^n$. The decomposition $T = \partial f + A$ shows that $\operatorname{dom} \partial f = \operatorname{dom} A = \mathbb{R}^n$, and we know that the range of ∂f is bounded as well. If A is nonzero and linear, then the range of A is unbounded, which is impossible. ∎

Corollary 14 immediately implies the existence of many nonlinear acyclic operators, but it does not exhibit any explicitly. We remedy this in the next and final section.

5. Explicit acyclic examples. Skew linear mappings are canonical examples of monotone mappings that are not subdifferential mappings. It is therefore reassuring to know that they are acyclic.

PROPOSITION 15. *Suppose that* $S : \mathbb{R}^n \to \mathbb{R}^n$ *is a continuous linear operator satisfying* $\langle S(x), x\rangle = 0$ *for all* $x \in \mathbb{R}^n$*. Then* S *is acyclic.*

Proof. Let $S = F + R$, where F is a subdifferential mapping and R is maximal monotone. Since S is single valued, F and R are single valued. In particular, $F = \nabla f$ for some convex differentiable f. Since R is monotone, we have

$$\begin{aligned} 0 &\le \langle R(x) - R(y), x - y\rangle = \langle S(x) - S(y), x - y\rangle - \langle F(x) - F(y), x - y\rangle \\ &= -\langle F(x) - F(y), x - y\rangle = \langle \nabla(-f)(x) - \nabla(-f)(y), x - y\rangle. \end{aligned}$$

This shows that $-f$ is convex, so f is convex and concave, hence linear on its domain. But $\operatorname{dom} f \supset \operatorname{dom} S = \mathbb{R}^n$, so $f \in \mathbb{R}^n$. So $F = \nabla f$ is constant. In fact, by subtracting from F and adding to R, we may assume that $F = 0$. ∎

We leave it to the reader to check that the sum of an acyclic operator and a skew linear operator is still acyclic. It is not clear that the sum of two acyclic operators must be acyclic. For continuous linear monotone operators, then, the usual decomposition into symmetric and skew parts is the same as the Asplund decomposition into subdifferential and acyclic parts.

We recall that Asplund was unable to find explicit examples of nonlinear acyclic mappings [1], and we have found this quite challenging as well. In particular, we wish to determine a useful characterization of acyclicity. We make some progress in this direction by providing an explicit and, to our mind, surprisingly simple example: we present a nonlinear acyclic monotone mapping $\widehat{S} : \mathbb{R}^2 \to \mathbb{R}^2$.

Precisely, $\widehat{S}$ is constructed by restricting the range of the skew mapping $S(x, y) = (-y, x)$ to the unit ball and taking a range-preserving maximal monotone extension of the restriction. This extension is unique, as we see from the following corollary of Proposition 14 from [4], work that originates in [7].

COROLLARY 16 (unique extension [4, 7]). *Suppose* $T : \mathbb{R}^n \to \mathbb{R}^n$ *is maximal monotone and suppose that* $\operatorname{ran} T \cap \operatorname{int} B \neq \emptyset$*. Then there is a unique maximal monotone mapping* $\widehat{T}$ *such that* $T(x) \cap B \subset \widehat{T}(x) \subset B$*. Furthermore,*

$$\widehat{T}(x) = \{x^* \in B \mid \langle x^* - y^*, x - y\rangle \ge 0 \text{ for all } y^* \in T(y) \cap \operatorname{int} B\}. \tag{5.1}$$

Note that $\widehat{T}$ is either a Lipschitz subgradient or it has a nonlinear acyclic part: the acyclic part is bounded so it cannot be nontrivially linear. Hence in the construction of Proposition 17 we know that $\widehat{S}$ has nonlinear acyclic part, which we shall eventually show in Proposition 20 to be $\widehat{S}$ itself.

PROPOSITION 17. *Define $S : \mathbb{R}^2 \to \mathbb{R}^2$ by $S(x, y) = (-y, x)$ for $x^2 + y^2 \leq 1$. Then the unique maximal monotone extension $\widehat{S}$ of S with range restricted to the unit disc is*

$$\widehat{S}(x) = \begin{cases} S(x), & \|x\| \leq 1, \\ \sqrt{1 - \frac{1}{\|x\|^2}}\,\frac{x}{\|x\|} + \frac{1}{\|x\|} S\left(\frac{x}{\|x\|}\right), & \|x\| > 1. \end{cases}$$

Proof. From Corollary 16, we know that $\widehat{S}$ exists and is uniquely defined. In the interior of the unit ball, (5.1) shows that $\widehat{S}(x) = S(x)$. Indeed, let $t > 0$ be so small that $z = x + ty \in B$ for all unit length y. Then

$$\langle S(x + ty) - \widehat{S}(x), y\rangle \geq 0$$

for all unit y. Letting $t \to 0$ shows that $\widehat{S}(x) = S(x)$. To determine $(u, v) = \widehat{S}(x)$ for $\|x\| \geq 1$, it suffices by rotational symmetry to consider points $x = (a, 0)$ with $a \geq 1$. Then monotonicity requires that

$$\langle \widehat{S}(x) - S(z), x - z\rangle \geq 0$$

for all $\|z\| \leq 1$. Let $z = \left(\frac{1}{a}, -\frac{\sqrt{a^2-1}}{a}\right)$ so that $\widehat{S}(z) = S(z) = \left(\frac{\sqrt{a^2-1}}{a}, \frac{1}{a}\right)$. Then

$$\left\langle (u, v) - \left(\frac{\sqrt{a^2 - 1}}{a}, \frac{1}{a}\right), (a, 0) - \left(\frac{1}{a}, -\frac{\sqrt{a^2 - 1}}{a}\right)\right\rangle \geq 0.$$

Expanding this gives

$$u\left(a - \frac{1}{a}\right) + \sqrt{1 - \frac{1}{a^2}}(v - a) \geq 0,$$

and noting that $u \leq \sqrt{1 - v^2}$ gives

$$\sqrt{1 - v^2}(a^2 - 1) + \sqrt{a^2 - 1}(v - a) \geq 0$$

which reduces to $(av - 1)^2 \leq 0$, that is, $v = 1/a$. Similarly, setting $z = (\frac{1}{a}, -\frac{\sqrt{a^2-1}}{a})$ also shows that $u = \sqrt{1 - 1/a^2}$.

So

$$\widehat{S}(x) = \widehat{S}(a, 0) = \left(\sqrt{1 - \frac{1}{a^2}}, \frac{1}{a}\right) = \sqrt{1 - \frac{1}{\|x\|^2}}\,\frac{x}{\|x\|} + \frac{1}{\|x\|} S\left(\frac{x}{\|x\|}\right).$$

The same result holds for general $\|x\| \geq 1$ by considering the coordinate system given by the orthogonal basis $\{x, S(x)\}$. ∎

Figure 1 shows the graph of the vector field $\widehat{S}$. Having computed $\widehat{S}$, we commence to show that it is acyclic, with the aid of two technical lemmas.

LEMMA 18. *$\widehat{S}(x + tS(x)) = S(x)$ for all $t \geq 0$ and all $\|x\| = 1$.*

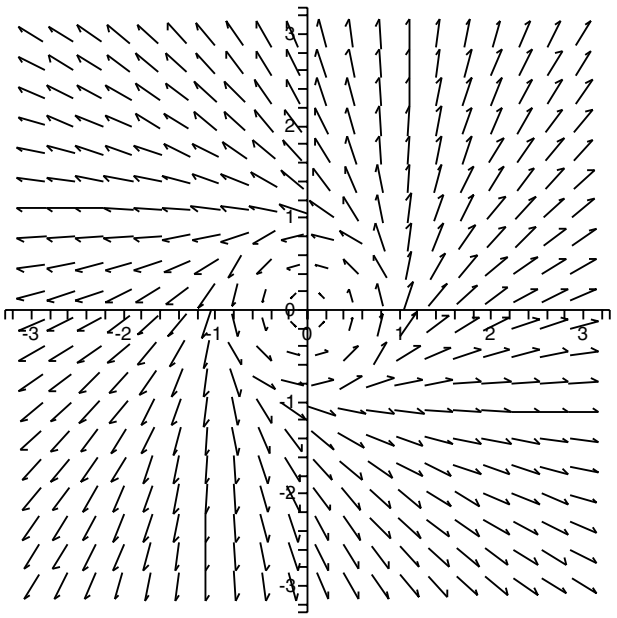

FIG. 1. *A field plot of* $\widehat{S}$.

Proof.

$$\begin{aligned}\widehat{S}(x+tS(x)) &= \sqrt{1-\frac{1}{1+t^2}}\,\frac{x+tS(x)}{\sqrt{1+t^2}} + \frac{1}{1+t^2}\,S(x+tS(x)) \\ &= \frac{t}{1+t^2}\,(x+tS(x)) + \frac{1}{1+t^2}\,(S(x)-tx) = S(x),\end{aligned}$$

since $S^2 = -I$. ∎

This construction does not extend immediately to all skew mappings, since it assumes that $S^2 = -I$, which can occur only in even dimensions.

FACT 4. *Skew orthogonal matrices exist only in even dimensions.*

Proof. $\operatorname{Det} S = \operatorname{Det}(S^\top) = \operatorname{Det}(-S) = (-1)^n \operatorname{Det} S$. ∎

However, such mappings do exist for each even-dimensional $\mathbb{R}^{2n}$, and these can be embedded in $\mathbb{R}^{2n+1}$ in an obvious way. Thus, our construction provides an acyclic nonlinear mapping for each $\mathbb{R}^n$, $n > 1$.

To show that $\widehat{S}$ is acyclic, we suppose that $\widehat{S} = F + R$, where $F = \partial f$ for some convex proper lower semicontinuous function f and R is maximal monotone, and we show that F is constant.

LEMMA 19. *Let* $\|x\| = 1$, $t \geq 0$, *and* $y(t) = x + tS(x)$. *Then* $\langle F(y(t)), S(x)\rangle = c(x)$ *for some constant* $c(x)$.

Proof. Suppose $t_1 \neq t_2$. Then $\widehat{S}(y(t_1)) = \widehat{S}(y(t_2)$, by Lemma 18, so

$$\begin{aligned}0 &\leq \langle R(y(t_1)) - R(y(t_2)),\, y(t_1) - y(t_2)\rangle \\ &= \langle \widehat{S}(y(t_1)) - \widehat{S}(y(t_2)),\, y(t_1) - y(t_2)\rangle - \langle F(y(t_1)) - F(y(t_2)),\, y(t_1) - y(t_2)\rangle \\ &= -\langle F(y(t_1)) - F(y(t_2)),\, y(t_1) - y(t_2)\rangle \leq 0,\end{aligned}$$

and so

$$\langle F(y(t_1)) - F(y(t_2)), x + t_1 S(x) - (x + t_2 S(x))\rangle = 0;$$

that is,

$$\langle F(y(t_1)), S(x)\rangle = \langle F(y(t_2)), S(x)\rangle$$

for any t_1, t_2. □

PROPOSITION 20. *The extension mapping $\widehat{S}$ given explicitly in Proposition* 17 *is nonlinear and acyclic with bounded range and full domain.*

Proof. First note that if $\widehat{S} = F + R$ with R monotone and $F = \partial f$, then both are single valued, so $F = \nabla f$. As in Proposition 15, we can assume that $f(x) = 0$ when $\|x\| \leq 1$.

Let $\|y\| > 1$. Then there are a unit vector x and a t such that $y = x + tS(x)$:

$$x = \widehat{x}(y) := \frac{y}{\|y\|^2} - \sqrt{\frac{1}{\|y\|^2} - \frac{1}{\|y\|^4}}\, S(y),$$

$$t = t(y) = \sqrt{\|y\|^2 - 1},$$

and we note that $y \to \widehat{x}(y)$ is continuous. We will determine $f(y)$ by integrating F along the ray $s \to x + sS(x)$. Using Lemma 19, we have

$$\begin{aligned}f(y) - f(x) &= \int_0^t \langle \nabla f(x + sS(x)), S(x)\rangle ds \\ &= \int_0^t c(x) ds = c(x)t.\end{aligned}$$

Since f is continuous and convex, c is continuous and positive, so $y \to c(\widehat{x}(y))$ is continuous and positive.

Plugging in $t(y)$ gives $f(y) = c(\widehat{x}(y))\sqrt{\|y\|^2 - 1}$ when $\|y\| > 1$ and $f = 0$ for $\|y\| \leq 1$. Suppose $c(y) > 0$ for some $\|y\| = 1$. Then for f to be convex on the segment $[y, 2y]$ we require that

$$(1 - \lambda) f(y) + \lambda f(2y) \geq f\big((1 + \lambda)y\big) \quad \text{for all } \lambda \in (0, 1).$$

This means that

$$0 + \lambda c\big(\widehat{x}(2y)\big)\sqrt{3} \geq c\big(\widehat{x}\big((1 + \lambda)y\big)\big)\sqrt{\lambda^2 + 2\lambda}$$

or

$$c\big(\widehat{x}(2y)\big)\sqrt{3} \geq c\big(\widehat{x}\big((1 + \lambda)y\big)\big)\sqrt{1 + \frac{2}{\lambda}}$$

for all $\lambda \in (0,1)$. Letting $\lambda \to 0$, we get $\widehat{x}\big((1+2\lambda)y\big) \to y$, so $c\big(\widehat{x}\big((1+\lambda)y\big)\big) \to c(y) > 0$. Since $\sqrt{1+2/\lambda} \to \infty$, the inequality does not hold for small λ unless $c(y) = 0$.

For f to be convex and everywhere defined, then, we require $c(y) = 0$ for all $\|y\| = 1$. That is, f is identically zero. ∎

It seems probable that the construction above applied to any nontrivial skew linear mapping always leads to an acyclic mapping—and that more ingenuity will allow some reader to prove this. We conclude the paper by exploring Fitzpatrick's last function for $\widehat{S}$ as above.

6. Computing $f_{\widehat{S}}$. We can also explicitly compute Fitzpatrick's last function $f_{\widehat{S}}$ as in the previous section. We have the following proposition.

PROPOSITION 21. *With $\widehat{S}$ as before, we have*

$$f_{\widehat{S}}(x) = \begin{cases} 0, & \|x\| \le 1, \\ \sqrt{\|x\|^2 - 1} + \arctan\left(\frac{1}{\sqrt{\|x\|^2-1}}\right) - \frac{\pi}{2}, & \|x\| > 1. \end{cases}$$

Proof. It is immediate from the definition that $f_{\widehat{S}}(x) = 0$ when $\|x\| \le 1$. For $\|x\| > 1$, we get

$$\begin{aligned} f_{\widehat{S}}(x) &= \int_0^1 \langle x, \widehat{S}(tx)\rangle dt \\ &= \int_0^{\frac{1}{\|x\|}} t\langle x, S(x)\rangle dt + \int_{\frac{1}{\|x\|}}^1 \sqrt{1 - \frac{1}{t^2\|x\|^2}}\,\frac{1}{\|x\|}\langle x, x\rangle dt + \int_{\frac{1}{\|x\|}}^1 \frac{1}{t\|x\|^2}\langle S(x), x\rangle dt \\ &= \int_{\frac{1}{\|x\|}}^1 \sqrt{1 - \frac{1}{t^2\|x\|^2}}\,\|x\| dt \\ &= \int_1^{\|x\|} \sqrt{1 - \frac{1}{s^2}}\, ds \\ &= \sqrt{\|x\|^2 - 1} + \arctan\left(\frac{1}{\sqrt{\|x\|^2 - 1}}\right) - \frac{\pi}{2}. \end{aligned}$$ ∎

Note that $f_{\widehat{S}}$ is convex, since it is a composition of the norm $x \to \|x\|$ with the increasing convex function $t \to \int_1^t \sqrt{1 - 1/s^2}\, ds$. So $\widehat{S}$ is weakly decomposable as $\widehat{S} = \nabla f_{\widehat{S}} + SL$ where SL is skew-like. To determine SL, we compute

$$\nabla f_{\widehat{S}}(x) = \begin{cases} 0, & \|x\| < 1, \\ \sqrt{1 - \frac{1}{\|x\|^2}}\,\frac{x}{\|x\|}, & \|x\| \ge 1. \end{cases}$$

So $\widehat{S}(x) = \nabla f_{\widehat{S}}(x) + h(\|x\|)S(x)$, where

$$h(t) = \begin{cases} 1, & t \le 1, \\ \frac{1}{t^2}, & t \ge 1. \end{cases}$$

So $\widehat{S}$ is not decomposable, but is weakly decomposable, since $SL = x \to h(\|x\|)S(x)$ is clearly skew-like. Note finally that SL is not monotone.

7. Conclusion. In this paper, we have provided some tools for the decomposition of monotone operators. This was originally motivated by observing that the classical counterexamples in monotone operator theory (see section 6 of [4]) are built from skew operators; in some sense, subgradients ("symmetric" operators) and acyclic mappings ("skew" operators) represent the extreme points of the space of monotone operators. The results we have given in this paper make this more concrete.

We remain convinced that a better understanding of acyclic operators will shed light on a number of open questions. For instance, if a Banach space has good differentiability properties, do all monotone operators defined on the space inherit these properties? Are such properties determined by the behavior of the acyclic part? In a more limited fashion it seems important to answer the following questions: (1) Is there an iterative construction to compute the acyclic part of a monotone operator in finite-dimensional space? (2) Is there an effective characterization of acyclicity that allows one to easily determine whether a given operator is acyclic? (3) When is the sum of acyclic mappings acyclic? (4) Can one exhibit an acyclic mapping whose domain is not the whole space?

Acknowledgments. We would like to thank Heinz Bauschke and the referees whose very careful reading greatly improved the paper's exposition.

STABILITY OF ε-APPROXIMATE SOLUTIONS TO CONVEX STOCHASTIC PROGRAMS*

W. RÖMISCH† AND R. J.-B. WETS‡

Abstract. An analysis of convex stochastic programs is provided when the underlying probability distribution is subjected to (small) perturbations. It is shown, in particular, that ε-approximate solution sets of convex stochastic programs behave Lipschitz continuously with respect to certain distances of probability distributions that are generated by the relevant integrands. It is shown that these results apply to linear two-stage stochastic programs with random recourse. We discuss the consequences on associating Fortet–Mourier metrics to two-stage models and on the asymptotic behavior of empirical estimates of such models, respectively.

Key words. stochastic programming, quantitative stability, approximate solutions, probability metrics, two-stage models, random recourse

1. Introduction.

Stochastic programming deals with models for optimization problems under (stochastic) uncertainty that require a decision on the basis of probabilistic information about random data. Typically, deterministic equivalents of such models are finite- or infinite-dimensional nonlinear programs depending on the properties of the distribution of the random components of the problems. Their solutions depend on the probability distribution of the random data via certain expectation functionals. Many deterministic equivalents of stochastic programming models take the form

$$\min\left\{\mathbb{E}^P f_0(x) := \int_{\Xi} f_0(\xi, x)\, P(d\xi) : x \in X\right\}, \tag{1.1}$$

where X is a closed convex subset of $\mathbb{R}^m$, Ξ is a closed subset of $\mathbb{R}^s$, P is a Borel probability measure on Ξ, and $\mathbb{E}^P$ denotes expectation with respect to P. The function f_0 from $\mathbb{R}^m \times \Xi$ to $\overline{\mathbb{R}} = [-\infty, \infty]$ is a *convex random lower semicontinuous (lsc) function*,[1] and, in particular, this means

- $(\xi, x) \mapsto f_0(\xi, x)$ is Borel measurable, and
- for all $\xi \in \Xi$, $f_0(\xi, \cdot)$ is lsc and convex.

It is part of the stochastic programming folklore, repeatedly observed in practice, that the solutions, or at least the approximating solutions, are quite robust with respect to reasonable perturbations of the probability distribution of the random components of the problem. In this paper, we substantiate this belief by focusing

[1] The concept of a random lsc function is due to Rockafellar [21], who introduced it in the context of the calculus of variations under the name of "normal integrand." Further properties of random lsc functions are set forth in [23, Chapter 14], [33].

our analysis on the approximating solutions for which we are able to derive Lipschitz continuity without even requiring fixed (deterministic) recourse.

In the following, we denote by $\mathcal{P}(\Xi)$ the set of all Borel probability measures on Ξ and by $v(P)$, $S(P)$, and $S_\varepsilon(P)$ ($\varepsilon \geq 0$) the infimum, the solution set, and the set of ε-approximate solutions to (1.1), i.e.,

$$\begin{aligned} v(P) &:= \inf \mathbb{E}^P f_0 := \inf \left\{ \mathbb{E}^P f_0(x) : x \in X \right\}, \\ S_\varepsilon(P) &:= \varepsilon\text{-argmin}\, \mathbb{E}^P f_0 := \left\{ x \in X \ : \mathbb{E}^P f_0(x) \leq v(P) + \varepsilon \right\}, \\ S(P) &:= \operatorname{argmin}\, \mathbb{E}^P f_0 := S_0(P). \end{aligned}$$

Since, in practice, the underlying probability distribution P is often not known precisely, the stability behavior of the stochastic program (1.1) when changing (perturbing, estimating, approximating) P is important. Here, stability refers to continuity properties of the optimal value function $v(.)$ and of the set-valued mapping $S_\varepsilon(.)$ at P, where both $v(.)$ and $S_\varepsilon(.)$ are regarded as mappings given on certain subsets of $\mathcal{P}(\Xi)$ equipped with some probability (semi)metric.

Early work on stability of stochastic programs is reported in [11, 19, 27] and later in [1]. Quantitative stability of two-stage models was studied, e.g., in [25, 26, 29, 18]. A recent survey of stability results in stochastic programming is given in [24]. Most of the recent contributions to (quantitative) stability use the general framework and the results of [3, 14] and [23, Chapter 7J], respectively.

In the present paper, we take up an issue brought to the fore in [38, section 4]. Since solutions derived, when actually solving (1.1), are usually ε-approximate solutions of an approximating problem where P has been replaced by an approximating measure Q, it is crucial to investigate the (quantitative) continuity properties of the (set-valued) mapping ε-argmin as a function of P, i.e., $P \mapsto S_\varepsilon(P)$, from $\mathcal{P}$ of probability measures to the space of closed convex subsets of $\mathbb{R}^m$.

Quantitative perturbation results for ε-approximate solutions in optimization are given in [4] and [23, Chapter 7J]. The corresponding estimates make use of the epi-distance between the objective functions of (1.1) and its perturbations. In our analysis, the corresponding subset $\mathcal{P}$ of probability measures is determined by satisfying certain moment conditions that are related to growth properties of the integrand f_0 with respect to ξ. The epi-distances of the objective functions can be bounded by some probability semimetric of the form

$$d_{\mathcal{F}}(P,Q) = \sup \left\{ \left| \int_\Xi f(\xi) P(d\xi) - \int_\Xi f(\xi) Q(d\xi) \right| \ : \ f \in \mathcal{F} \right\}, \tag{1.2}$$

where $\mathcal{F}$ is an appropriate class of measurable functions from Ξ to $\overline{\mathbb{R}}$ and P, Q are probability measures in $\mathcal{P}$. First, we show in section 2 that classes of the form $\mathcal{F}_\rho = \{f_0(\cdot, x) : x \in X \cap \rho\mathbb{B}\}$ for some $\rho > 0$ and $\mathbb{B}$ denoting the unit ball in $\mathbb{R}^m$ and the corresponding distance $d_{\mathcal{F}_\rho}$ are suitable to derive the desired stability results.

In section 3 we then provide characterizations of the function classes $\mathcal{F}_\rho$ for two-stage models with random recourse. Two-stage stochastic programs arise as deterministic equivalents of improperly posed random linear programs of the form

$$\min\{cx : x \in X, T(\xi)x = h(\xi)\},$$

where X is polyhedral and the (technology) matrix $T(\xi)$ and the vector $h(\xi)$ depend on a random vector ξ. Given a realization of ξ, a possible deviation $h(\xi) - T(\xi)x$

is compensated for by the additional cost $q(\xi)y(\xi)$, where $y = y(\xi)$ belongs to a polyhedral set Y and satisfies $W(\xi)y = h(\xi) - T(\xi)x$. Here, the cost coefficient $q(\xi)$ and the compensation or recourse matrix $W(\xi)$ (may) depend on the realization. The modeling idea consists in adding the expected compensation cost $\mathbb{E}[q(\xi)y(\xi)]$ to cx. By minimizing the objective function $cx + \mathbb{E}[q(\xi)y(\xi)]$ first with respect to $y(\xi)$, we arrive at the function

$$f_0(\xi, x) := cx + \inf\{q(\xi)y : y \in Y, W(\xi)y = h(\xi) - T(\xi)x\},$$

whose expectation has to be minimized with respect to $x \in X$. Since the decisions x and $y(\xi)$ are made before or after the realization of ξ, they are called first- and second-stage decisions, respectively.

While Lipschitz continuity properties of the integrands f_0 with respect to ξ are well understood for fixed recourse [36], much less is known for random recourse. In section 3 we deal with the following two cases: (i) full random recourse by imposing local Lipschitz continuity of the (second-stage) dual feasibility mapping and (ii) a specific lower diagonal randomness of the recourse matrix. The latter situation occurs, for example, in the following two important cases.

Let us first consider a dynamical decision process, as in a variety of applications, where the compensation idea is repeated l times after the realization of a new random vector ξ_j, $j = 1, \dots, l$. Then we have second-stage decisions $y_j = y_j(\xi_j)$ with corresponding cost $q_j(\xi_j)y_j$ which satisfy the constraints $y_j \in Y_j$ and $W_{jj}y_j = h_j(\xi_j) - W_{jj-1}(\xi_j)y_{j-1}$ for $j = 1, \dots, l$, where $l \in \mathbb{N}$, y_0 is the first-stage decision and $W_{jj-1}(\xi_j)$ are (random) technology matrices. This leads to the function

$$f_0(\xi, y_0) = cy_0 + \inf\left\{\sum_{j=1}^{l} q_j(\xi)y_j : W_{jj}y_j = h_j(\xi) - W_{jj-1}(\xi)y_{j-1}, y_j \in Y_j, j = 1, \dots, l\right\},$$

where $\xi = (\xi_1, \dots, \xi_l)$ and $q_j(\xi) := q_j(\xi_j)$, etc. The expectation of this function is to be minimized in multiperiod two-stage stochastic programming models. If we introduce the second-stage decision vector $y = (y_1, \dots, y_l)$, the corresponding recourse matrix $W(\xi)$ is a block lower triangular matrix containing W_{jj}, $j = 1, \dots, l$, in the main diagonal and $W_{jj-1}(\xi)$, $j = 1, \dots, l$, in the lower diagonal (see section 4). Hence, the recourse matrix $W(\xi)$ may be random even if the jth recourse matrix W_{jj} for the decision y_j is fixed, but (at least) one of the technology matrices $W_{jj-1}(\xi)$ is random.

Another interesting case appears, second, in risk averse two-stage stochastic programming models, if risk functionals (e.g., the conditional value-at-risk [22]) are incorporated into two-stage stochastic programs. The conditional or *average value-at-risk* (at level $\alpha \in (0, 1]$) may be defined by

$$\begin{aligned} AVaR_\alpha(z) &= \frac{1}{\alpha}\int_0^\alpha VaR_\gamma(z)d\gamma = \inf\left\{r + \frac{1}{\alpha}\mathbb{E}[\max\{0, -r - z\}] : r \in \mathbb{R}\right\} \\ &= \inf\left\{r_1 + \frac{1}{\alpha}\mathbb{E}[r_2^{(2)}] : r_1 \in \mathbb{R}, r_2 \in \mathbb{R}_+ \times \mathbb{R}_+, r_2^{(1)} - r_2^{(2)} = z + r_1\right\}, \end{aligned} \tag{1.3}$$

where z is a real random variable on some probability space. If the average value-at-risk replaces the expectation in a two-stage model with fixed recourse, the latter is of the form

$$\min\{cx + AVaR_\alpha(q(\xi)y) : x \in X, y \in Y, Wy = h(\xi) - T(\xi)x\}. \tag{1.4}$$

Using the two-stage representation (1.3) of $AVaR_\alpha$, the preceding optimization problem is equivalent to (1.1) with

$$f_0(\xi,(x,r_1)) := cx + r_1 + \inf\left\{ \frac{1}{\alpha} r_2^{(2)} : y \in Y, r_2 \geq 0, r_2^{(1)} - r_2^{(2)} = q(\xi)y + r_1, \right.$$
$$\left. Wy = h(\xi) - T(\xi)x \right\},$$

where (x, r_1) is the first-stage decision varying in $X \times \mathbb{R}$. When introducing the second-stage decision (y, r_2), the recourse cost $q_{\text{avar}}(\xi)$, recourse matrix $W_{\text{avar}}(\xi)$, and cone Y_{avar} take on the form

(1.5)
$$q_{\text{avar}}(\xi) = \begin{pmatrix} 0 \\ 0 \\ \alpha^{-1} \end{pmatrix}, \quad W_{\text{avar}}(\xi) = \begin{pmatrix} W & 0 & 0 \\ q(\xi)^\top & -1 & 1 \end{pmatrix}, \quad \text{and} \quad Y_{\text{avar}} = Y \times \mathbb{R}^2_+ .$$

Hence, the recourse matrix gets random if the recourse cost of the original model is random. The same lower diagonal randomness effect appears if general polyhedral convex risk measures are used instead of $AVaR$ (see [7, section 4.1.1]).

In sections 3 and 4 we characterize the local Lipschitz continuity behavior of the functions $\mathcal{F}_\rho$. We also show that the distances $d_{\mathcal{F}_\rho}$ are bounded by Fortet–Mourier (type) metrics and that the metric entropy of $\mathcal{F}_\rho$ in terms of bracketing numbers is reasonably "small." In this way, we obtain new results on stability (Corollaries 3.6 and 4.3 for the cases (i) and (ii), respectively) and on the asymptotic behavior of nonparametric statistical estimates (Theorem 5.2) of random recourse models.

2. Quantitative stability. Given the original probability measure P and a perturbation Q of P we will give quantitative estimates of the distance between $(v(Q), S_\varepsilon(Q))$ and $(v(P), S_\varepsilon(P))$ in terms of a probability metric of the type (1.2). Our analysis will be based on the general perturbation results for optimization models in [23, section 7J].

Let us now introduce functions, spaces, and probability measures that are useful for characterizing classes of probability distributions such that the stochastic program (1.1) is well defined and one can proceed with the perturbation analysis. We consider

$$\mathcal{F} = \{f_0(\cdot, x) \,:\, x \in X\},$$
$$\mathcal{P}_{\mathcal{F}} = \left\{ Q \in \mathcal{P}(\Xi) : \int_\Xi \inf_{x \in X \cap \rho\mathbb{B}} f_0(\xi, x) Q(d\xi) > -\infty \,, \right.$$
$$\left. \sup_{x \in X \cap \rho\mathbb{B}} \int_\Xi f_0(\xi, x) Q(d\xi) < \infty \quad \forall\, \rho > 0 \right\},$$

where $\mathbb{B}$ is the closed unit ball in $\mathbb{R}^m$. We note that the infimum function $\xi \mapsto \inf_{x \in X \cap \rho\mathbb{B}} f_0(\xi, x)$ is measurable for each $\rho > 0$ as f_0 is a random lsc function; cf. [23, Theorem 14.37].

For any $\rho > 0$ and probability measures P, $Q \in \mathcal{P}_{\mathcal{F}}$ we consider their $d_{\mathcal{F},\rho}$-distance defined by

$$d_{\mathcal{F},\rho}(P, Q) = \sup_{x \in X \cap \rho\mathbb{B}} \left| \mathbb{E}^P f_0(x) - \mathbb{E}^Q f_0(x) \right| .$$

Hence, $d_{\mathcal{F},\rho}$ is a distance of type (1.2), where the relevant class of functions is $\mathcal{F}_\rho = \{f_0(\cdot, x) : x \in X \cap \rho\mathbb{B}\}$. It is nonnegative, finite, and symmetric and satisfies the

triangle inequality; i.e., it is a semimetric on $\mathcal{P}_{\mathcal{F}}$. In general, however, the class $\mathcal{F}_\rho$ will not be rich enough to guarantee that $d_{\mathcal{F},\rho}(P,Q)=0$ implies $P=Q$. A valuable consequence of the definition of the class $\mathcal{P}_{\mathcal{F}}$ is that the function $x \mapsto \mathbb{E}^Q f_0(x) = \int_\Xi f_0(\xi,x)\,Q(d\xi)$ is lsc at any Q belonging to $\mathcal{P}_{\mathcal{F}}$ by appealing to Fatou's lemma. Moreover, it is convex on $\mathbb{R}^m$ and finite on X for any such Q.

Since our statements and proofs rely extensively on estimates for the epi-distance between (lsc) functions, we include a brief review of the relevant definitions and implications. Let $d_C(x)=d(x,C)$ denote the distance of a point to a nonempty closed set. The *ρ-distance* between two nonempty closed sets is by definition

$$\mathbb{d}_\rho(C,D) = \sup_{||x||\le\rho} |d_C(x) - d_D(x)|.$$

In fact, it is just a pseudodistance from which one can build a metric on the hyperspace of closed sets, for example, by setting $\mathbb{d}(C,D)=\int_0^\infty \mathbb{d}_\rho(C,D)e^{-\rho}\,d\rho$. Estimates for the ρ-distance can be obtained by relying on a "truncated" Pompeiu–Hausdorff-type distance:

$$\hat{\mathbb{d}}_\rho(C,D) = \inf\{\eta\ge 0:\ C\cap\rho\mathbb{B}\subset D+\eta\mathbb{B},\ \ D\cap\rho\mathbb{B}\subset C+\eta\mathbb{B}\}.$$

Indeed one always has [23, Proposition 4.37(a)]

$$\hat{\mathbb{d}}_\rho(C_1,C_2)\le \mathbb{d}_\rho(C_1,C_2)\le \hat{\mathbb{d}}_{\rho'}(C_1,C_2)$$

for $\rho'\ge 2\rho+\max\{d_{C_1}(0),d_{C_2}(0)\}$. Our main result is stated in terms of this latter distance notion. If we let $\rho\to\infty$, we end up with the Pompeiu–Hausdorff distance

$$\mathbb{d}_\infty(C,D)=\lim_{\rho\to\infty}\mathbb{d}_\rho(C,D)=\lim_{\rho\to\infty}\hat{\mathbb{d}}_\rho(C,D)$$

between the closed nonempty sets C and D; see [23, Corollary 4.38].

The distance between (lsc) functions is measured in terms of the distance between their epi-graphs, so for $\rho>0$,

$$\mathbb{d}_\rho(f,g)=\mathbb{d}_\rho(\operatorname{epi} f,\operatorname{epi} g),\qquad \hat{\mathbb{d}}_\rho(f,g)=\hat{\mathbb{d}}_\rho(\operatorname{epi} f,\operatorname{epi} g),$$

and $\mathbb{d}(f,g)=\mathbb{d}(\operatorname{epi} f,\operatorname{epi} g)$. However, since our sets are epi-graphs (in $\mathbb{R}^{m+1}$), it is convenient to rely on the "unit ball" to be $\mathbb{B}\times[-1,1]$; this brings us to an "auxiliary" distance $\hat{\mathbb{d}}^+_\rho(f_1,f_2)$ defined as the infimum of all $\eta\ge 0$ such that for all $x\in\rho\mathbb{B}$,

$$\min_{y\in\mathbb{B}(x,\eta)} f_2(y)\le\max\{f_1(x),-\rho\}+\eta,\qquad \min_{y\in\mathbb{B}(x,\eta)} f_1(y)\le\max\{f_2(x),-\rho\}+\eta.$$

For lsc $f_1,\ f_2:\mathbb{R}^n\to\mathbb{R}$, not identically ∞, one has [23, Theorem 7.61]

$$\hat{\mathbb{d}}^+_{\rho/\sqrt{2}}(f_1,f_2)\le\hat{\mathbb{d}}_\rho(f_1,f_2)\le\sqrt{2}\,\hat{\mathbb{d}}^+_\rho(f_1,f_2).$$

Our first stability result, already announced in [5], is concerned with the solution set $S(P)$, rather than $S_\varepsilon(P)$, which will be dealt with later.

THEOREM 2.1. *Let $P\in\mathcal{P}_{\mathcal{F}}$, and suppose $S(P)$ is nonempty and bounded. Then there exist constants $\rho>0$ and $\delta>0$ such that*

$$|v(P)-v(Q)|\le d_{\mathcal{F},\rho}(P,Q),$$
$$\emptyset\ne S(Q)\subset S(P)+\Psi_P(d_{\mathcal{F},\rho}(P,Q))\mathbb{B}$$

hold for all $Q \in \mathcal{P}_{\mathcal{F}}$ *with* $d_{\mathcal{F},\rho}(P,Q) < \delta$, *where* Ψ_P *is a* conditioning function *associated with our given problem* (1.1)*; more precisely,*

$$\Psi_P(\eta) := \eta + \psi_P^{-1}(2\eta), \quad \eta \geq 0,$$

with

$$\psi_P(\tau) := \min\left\{\mathbb{E}^P f_0(x) - v(P) : d(x, S(P)) \geq \tau, x \in X\right\}, \quad \tau \geq 0.$$

Proof. For any $Q \in \mathcal{P}_{\mathcal{F}}$, the function $\mathbb{E}^Q f_0$ is lsc, proper, and convex. Define

$$F_Q(x) := \begin{cases} \mathbb{E}^Q f_0(x), & x \in X, \\ +\infty & \text{else} \end{cases}$$

for each $Q \in \mathcal{P}_{\mathcal{F}}$ and rely on [23, Theorem 7.64] to derive the result. Let $\bar{\rho} > 0$ be chosen such that $S(P) \subset \bar{\rho}\mathbb{B}$ and $v(P) \geq -\bar{\rho}$. For $\rho > \bar{\rho}$ and δ such that $0 < \delta < \min\{\frac{1}{2}(\rho - \bar{\rho}), \frac{1}{2}\psi_P(\frac{1}{2}(\rho - \bar{\rho}))\}$, since F_Q and F_P are convex, Theorem 7.64 of [23] yields the estimates

$$\begin{aligned} |v(P) - v(Q)| &\leq \hat{\boldsymbol{d}}_\rho^+(\mathbb{E}^P f_0, \mathbb{E}^Q f_0), \\ \emptyset \neq S(Q) &\subseteq S(P) + \Psi_P(\hat{\boldsymbol{d}}_\rho^+(\mathbb{E}^P f_0, \mathbb{E}^Q f_0))\mathbb{B} \end{aligned}$$

for any $Q \in \mathcal{P}_{\mathcal{F}}$ with $\hat{\boldsymbol{d}}_\rho^+(\mathbb{E}^P f_0, \mathbb{E}^Q f_0) < \delta$.

Now, let η be chosen such that $\eta \geq \max_{x \in X \cap \rho\mathbb{B}} |\mathbb{E}^P f_0(x) - \mathbb{E}^Q f_0(x)|$. Clearly, the inequalities

$$\begin{aligned} \min_{y \in x + \eta\mathbb{B}} F_Q(y) &\leq \max\{F_P(x), -\rho\} + \eta, \\ \min_{y \in x + \eta\mathbb{B}} F_P(y) &\leq \max\{F_Q(x), -\rho\} + \eta \end{aligned}$$

are trivially satisfied when $x \notin X$. When $x \in X \cap \rho\mathbb{B}$, we have

$$\begin{aligned} \min_{y \in x + \eta\mathbb{B}} F_Q(y) \leq F_Q(x) \leq F_P(x) + \eta = \max\{F_P(x), -\rho\} + \eta, \\ \min_{y \in x + \eta\mathbb{B}} F_P(y) \leq F_P(x) \leq F_Q(x) + \eta \leq \max\{F_Q(x), -\rho\} + \eta, \end{aligned}$$

and, thus, $\hat{\boldsymbol{d}}_\rho^+(F_P, F_Q) \leq \eta$. Letting η pass to its lower limit leads to

$$\hat{\boldsymbol{d}}_\rho^+(F_P, F_Q) \leq \max_{x \in X \cap \rho\mathbb{B}} |\mathbb{E}^P f_0(x) - \mathbb{E}^Q f_0(x)| = d_{\mathcal{F},\rho}(P,Q). \tag{2.1}$$

Since the function Ψ_P is increasing, the proof is complete. □

Simple examples of two-stage stochastic programs show that, in general, the set-valued mapping $S(.)$ is not inner semicontinuous at P (cf. [24, Example 26]). Furthermore, explicit descriptions of conditioning functions ψ_P of stochastic programs (like linear or quadratic growth at solution sets) are known only in some specific cases—for example, for linear two-stage stochastic programs with finite discrete distribution or with strictly positive densities of random right-hand sides [28].

As we shall see, we are in much better shape when we consider the stability properties of the sets $S_\varepsilon(\cdot)$ of ε-approximate solutions. Indeed, $S_\varepsilon(\cdot)$ even satisfies a Lipschitz property under rather mild assumptions.

THEOREM 2.2. *Let $P, Q \in \mathcal{P}_{\mathcal{F}}$ and such that the corresponding solution sets $S(P)$ and $S(Q)$ are nonempty. Then there exist constants $\rho > 0$ and $\bar{\varepsilon} > 0$ such that*

$$\hat{\mathbb{d}}_{\rho}(S_{\varepsilon}(P), S_{\varepsilon}(Q)) \leq \frac{4\rho}{\varepsilon} d_{\mathcal{F},\rho+\varepsilon}(P, Q)$$

holds for any $\varepsilon \in (0, \bar{\varepsilon})$, where $d_{\mathcal{F},\rho+\varepsilon}(P, Q) < \varepsilon$.

Proof. The assumptions imply that both $\mathbb{E}^P f_0$ and $\mathbb{E}^Q f_0$ are proper, lsc, and convex on $\mathbb{R}^m$. Let ρ_0 be chosen such that both $S(P) \cap \rho_0 \mathbb{B}$ and $S(Q) \cap \rho_0 \mathbb{B}$ are nonempty and $\min\{v(P), v(Q)\} \geq -\rho_0$. For $\rho > \rho_0$ and $0 < \varepsilon < \bar{\varepsilon} = \rho - \rho_0$, one obtains, from the proof of [23, Theorem 7.69], the inclusion

$$S_{\varepsilon}(P) \cap \rho \mathbb{B} \subseteq S_{\varepsilon}(Q) + \frac{2\eta}{\varepsilon + 2\eta} 2\rho \mathbb{B} \subseteq S_{\varepsilon}(Q) + \frac{4\rho}{\varepsilon} \eta \mathbb{B}$$

for all $\eta > \hat{\mathbb{d}}^+_{\rho+\varepsilon}(\mathbb{E}^P f_0, \mathbb{E}^Q f_0)$. This implies

$$S_{\varepsilon}(P) \cap \rho \mathbb{B} \subseteq S_{\varepsilon}(Q) + \frac{4\rho}{\varepsilon} \hat{\mathbb{d}}^+_{\rho+\varepsilon}(\mathbb{E}^P f_0, \mathbb{E}^Q f_0) \mathbb{B}.$$

The same argument works with P and Q interchanged. Finally, we appeal to the estimate (2.1) to complete the proof. □

The above estimate for ε-approximate solution sets allows for the solution sets to be unbounded and, thus, extends [24, Theorem 13]. The result becomes somewhat more tangible if the original solution set $S(P)$ is assumed to be bounded.

COROLLARY 2.3. *Let $P \in \mathcal{P}_{\mathcal{F}}$ and $S(P)$ be nonempty and bounded. Then there exist constants $\hat{\rho} > 0$ and $\hat{\varepsilon} > 0$ such that*

$$\mathbb{d}_{\infty}(S_{\varepsilon}(P), S_{\varepsilon}(Q)) \leq \frac{4\hat{\rho}}{\varepsilon} d_{\mathcal{F},\hat{\rho}+\varepsilon}(P, Q)$$

holds for any $\varepsilon \in (0, \hat{\varepsilon})$ and $Q \in \mathcal{P}_{\mathcal{F}}$ such that $d_{\mathcal{F},\hat{\rho}+\varepsilon}(P, Q) < \varepsilon$.

Proof. Let δ and ρ be the constants from Theorem 2.1, and put $\hat{\varepsilon} = \delta$. Let $\varepsilon \in (0, \hat{\varepsilon})$ and $Q \in \mathcal{P}_{\mathcal{F}}$ such that $d_{\mathcal{F},\rho+\varepsilon}(P, Q) < \varepsilon$. Then $S(Q)$ is also nonempty and bounded. Since the functions $\mathbb{E}^P f_0$ and $\mathbb{E}^Q f_0$ are lsc and convex, the level sets $S_{\hat{\varepsilon}}(P)$ and $S_{\hat{\varepsilon}}(Q)$ are bounded since the sets $S_0(P)$ and $S_0(Q)$ are bounded (cf. [20, Corollary 8.7.1]). Next we choose ρ_0 as in Theorem 2.2 and $\hat{\rho}$ such that $\hat{\rho} > \max\{\rho, \rho_0 + \hat{\varepsilon}\}$ and both level sets $S_{\hat{\varepsilon}}(P)$ and $S_{\hat{\varepsilon}}(Q)$ are contained in $\hat{\rho}\mathbb{B}$. Then the result follows from Theorem 2.2 by taking into account that

$$\hat{\mathbb{d}}_{\hat{\rho}}(S_{\varepsilon}(P), S_{\varepsilon}(Q)) = \mathbb{d}_{\infty}(S_{\varepsilon}(P), S_{\varepsilon}(Q))$$

holds because of the choice of $\hat{\rho}$. □

The results illuminate the role of the probability distances $d_{\mathcal{F},\rho}$ given that the parameter $\rho > 0$ is properly chosen. These probability metrics process the minimal information about problem (1.1) and allow us to derive remarkable stability properties for the optimal values and (approximate) solutions. Clearly, the preceding stability results remain valid if the set $\mathcal{F}_{\rho}$ is enlarged to a set $\hat{\mathcal{F}}$ and the set $\mathcal{P}_{\mathcal{F}}$ is reduced to a subset on which the new distance $d_{\hat{\mathcal{F}}}$ is finite and well defined.

Hence, it is important to identify classes $\hat{\mathcal{F}}$ of functions that contain $\{f_0(\cdot, x) : x \in X \cap \rho\mathbb{B}\}$ for any $\rho > 0$. For many convex stochastic programming problems the functions $f_0(\cdot, x)$, $x \in X$, are locally Lipschitz continuous on Ξ with certain Lipschitz constants $L(r)$ on the sets $\{\xi \in \Xi : \|\xi - \xi_0\| \leq r\}$ for some $\xi_0 \in \Xi$ and any $r > 0$. In

many cases, the growth modulus $L(r)$ does not depend on x, particularly when x is varying only in a bounded subset of $\mathbb{R}^m$. Hence, function classes of the form

$$\mathcal{F}_H := \{f : \Xi \to \mathbb{R} : f(\xi) - f(\tilde{\xi}) \leq \max\{1, H(\|\xi - \xi_0\|), H(\|\tilde{\xi} - \xi_0\|)\}\|\xi - \tilde{\xi}\| \ \forall \xi, \tilde{\xi} \in \Xi\}$$

are of particular interest, where $H : \mathbb{R}_+ \to \mathbb{R}_+$ is nondecreasing, $H(0) = 0$, and $\xi_0 \in \Xi$. The distances introduced in (1.2), but with $\mathcal{F} = \mathcal{F}_H$, i.e.,

$$d_{\mathcal{F}_H}(P, Q) = \sup\left\{\left|\int_\Xi f(\xi)P(d\xi) - \int_\Xi f(\xi)Q(d\xi)\right| : f \in \mathcal{F}_H\right\},$$

are so-called *Fortet–Mourier metrics*, denoted by ζ_H and defined on

$$\mathcal{P}_H(\Xi) := \left\{Q \in \mathcal{P}(\Xi) : \int_\Xi \max\{1, H(\|\xi - \xi_0\|)\}\|\xi - \xi_0\|Q(d\xi) < \infty\right\} \tag{2.2}$$

(cf. [8, 17]). Important special cases come to light when the function H has the polynomial form $H(t) := t^{r-1}$ for $r \geq 1$. The corresponding function classes and distances are denoted by $\mathcal{F}_r$ and ζ_r, respectively. The distances ζ_r are well defined on the set

$$\mathcal{P}_r(\Xi) := \left\{Q \in \mathcal{P}(\Xi) : \int_\Xi \|\xi\|^r Q(d\xi) < \infty\right\} \tag{2.3}$$

of probability measures having finite rth order moments.

3. Stability of two-stage recourse models. We consider the linear two-stage stochastic program with recourse,

$$\min\left\{cx + \int_\Xi q(\xi)y(\xi)P(d\xi) : W(\xi)y(\xi) = h(\xi) - T(\xi)x,\ y(\xi) \in Y,\ x \in X\right\}, \tag{3.1}$$

where $c \in \mathbb{R}^m$, $X \subseteq \mathbb{R}^m$, and $\Xi \subseteq \mathbb{R}^s$ are polyhedral, $Y \subseteq \mathbb{R}^{\overline{m}}$ is a polyhedral cone, and $P \in \mathcal{P}(\Xi)$. We assume that $q(\xi) \in \mathbb{R}^{\overline{m}}$, $h(\xi) \in \mathbb{R}^d$, the recourse matrix $W(\xi) \in \mathbb{R}^{d \times \overline{m}}$, and the technology matrix $T(\xi) \in \mathbb{R}^{d \times n}$ may depend affinely on $\xi \in \Xi$.

Denoting by $\Phi(\xi, q(\xi), h(\xi) - T(\xi)x)$ the value of the optimal second-stage decision, problem (3.1) may be rewritten equivalently as a minimization problem with respect to the first stage decision x. We define the function $f_0 : \Xi \times \mathbb{R}^m \to \overline{\mathbb{R}}$ by

$$f_0(\xi, x) = \begin{cases} cx + \Phi(\xi, q(\xi), h(\xi) - T(\xi)x) & \text{if } h(\xi) - T(\xi)x \in W(\xi)Y,\ D(\xi) \neq \emptyset, \\ +\infty & \text{otherwise,} \end{cases}$$

where the optimal value function Φ and the dual feasible set $D(\xi)$ are given by

$$\Phi(\xi, u, t) := \inf\{uy : W(\xi)y = t, y \in Y\}, \qquad (\xi, u, t) \in \Xi \times \mathbb{R}^{\overline{m}} \times \mathbb{R}^d,$$
$$D(\xi) := \left\{z \in \mathbb{R}^d : W(\xi)^\top z - q(\xi) \in Y^*\right\}, \quad \xi \in \Xi,$$

with $W(\xi)^\top$ denoting the transpose of $W(\xi)$ and Y^* the polar cone of Y.

The (equivalent) minimization problem can thus be expressed as

$$\min\left\{\int_\Xi f_0(\xi, x)P(d\xi) : x \in X\right\}. \tag{3.2}$$

In order to utilize the general stability results of section 2, we first recall some well-known properties of the function Φ (cf. [34]).

LEMMA 3.1. *For any $\xi \in \Xi$, the function $\Phi(\xi, \cdot, \cdot)$ is finite and continuous on the polyhedral set $\mathcal{D}(\xi) \times W(\xi)Y$, where $\mathcal{D}(\xi) := \{u \in \mathbb{R}^{\overline{m}} : \{z \in \mathbb{R}^d : W(\xi)^\top z - u \in Y^*\} \neq \emptyset\}$. Furthermore, the function $\Phi(\xi, u, \cdot)$ is piecewise linear convex on the polyhedral set $W(\xi)Y$ for fixed $u \in \mathcal{D}(\xi)$, and $\Phi(\xi, \cdot, t)$ is piecewise linear concave on $\mathcal{D}(\xi)$ for fixed $t \in W(\xi)Y$.*

We impose the following conditions on problem (3.2).

(A1) *Relatively complete recourse*: For any $(\xi, x) \in \Xi \times X$, $h(\xi) - T(\xi)x \in W(\xi)Y$.

(A2) *Dual feasibility*: $D(\xi) \neq \emptyset$ holds for all $\xi \in \Xi$.

Conditions (A1) and (A2) are standard and render problem (3.2) well defined. Due to Lemma 3.1 they imply that f_0 is a convex random lsc function with $\Xi \times X \subseteq \operatorname{dom} f_0$. As earlier, with the notation

$$\mathcal{F}_\rho := \{f_0(\cdot, x) : x \in X \cap \rho\mathbb{B}\}, \tag{3.3}$$

we obtain our first stability result for model (3.1) as immediate consequences of Theorem 2.1 and Corollary 2.3.

THEOREM 3.2. *Suppose the stochastic program satisfies the relatively complete recourse* (A1) *and the dual feasibility* (A2) *conditions, $P \in \mathcal{P}_\mathcal{F}$, and $S(P)$ is nonempty and bounded. Then there exist constants $\rho > 0$ and $\hat{\varepsilon} > 0$ such that*

$$|v(P) - v(Q)| \leq d_{\mathcal{F},\rho}(P, Q),$$
$$\mathbb{d}_\infty(S_\varepsilon(P), S_\varepsilon(Q)) \leq \frac{4\rho}{\varepsilon} d_{\mathcal{F},\rho+\varepsilon}(P, Q)$$

hold for any $\varepsilon \in (0, \hat{\varepsilon})$ and each $Q \in \mathcal{P}_\mathcal{F}$ such that $d_{\mathcal{F},\rho+\varepsilon}(P, Q) < \varepsilon$.

The theorem establishes Lipschitz stability of $v(.)$ and S_ε in the two-stage case for fairly general situations. It extends the results in [24, section 3.1] to two-stage models with *random* recourse. However, the set of (perturbed) probability measures $\mathcal{P}_\mathcal{F}$ and, in particular, the metrics $d_{\mathcal{F},\rho}$ are rather sophisticated and could be difficult to use in applications.

To overcome this difficulty, we need to explore quantitative continuity properties of the integrand f_0. Such properties are well known in case of *fixed recourse*, i.e., in case $W(\xi) \equiv W$ [36], and have been used to analyze quantitative stability in [18]. Our first result for random recourse matrices follows the ideas in [37]. There, it is shown that (semi)continuity properties of parametric optimal value functions are consequences of the (semi)continuity of the primal and dual feasibility mapping with respect to the relevant parameters. Next, we verify that a local Lipschitz property of the dual feasible set-valued mapping $\xi \mapsto D(\xi)$ in addition to (A1) implies local Lipschitz continuity of $f_0(\cdot, x)$ with the modulus not depending on having x vary only in a bounded set.

PROPOSITION 3.3. *Suppose the stochastic program satisfies the relatively complete recourse* (A1) *and the dual feasibility* (A2) *conditions. Assume also that the mapping $\xi \mapsto D(\xi)$ is bounded-valued and locally Lipschitz continuous on Ξ with respect to the Pompeiu–Hausdorff distance (on the subsets of $\mathbb{R}^d$); i.e., there exists a constant $L > 0$, an element $\xi_0 \in \Xi$, and a nondecreasing function $h : \mathbb{R}_+ \to \mathbb{R}_+$ with $h(0) = 0$ such that*

$$\mathbb{d}_\infty(D(\xi), D(\tilde{\xi})) \leq L \max\{1, h(\|\xi - \xi_0\|), h(\|\tilde{\xi} - \xi_0\|)\}\|\xi - \tilde{\xi}\| \tag{3.4}$$

holds for all $\xi, \tilde{\xi} \in \Xi$.

Then, for any $\rho > 0$, there exist constants $\hat{L} > 0$ and $\hat{L}(\rho) > 0$ such that

$$f_0(\xi, x) - f_0(\tilde{\xi}, x) \le \hat{L}(\rho) \max\{1, H(\|\xi - \xi_0\|), H(\|\tilde{\xi} - \xi_0\|)\}\|\xi - \tilde{\xi}\|, \tag{3.5}$$

$$f_0(\xi, x) - f_0(\xi, \tilde{x}) \le \hat{L} \max\{1, H(\|\xi - \xi_0\|)\|\xi - \xi_0\|\}\|x - \tilde{x}\| \tag{3.6}$$

for all $\xi, \tilde{\xi} \in \Xi$, $x, \tilde{x} \in X \cap \rho\mathbb{B}$, where H is defined by

$$H(t) := h(t)t \quad \forall t \in \mathbb{R}_+. \tag{3.7}$$

Proof. Let $\rho > 0$. Due to (A1) and (A2), the function $f_0(\cdot, x)$ is real-valued for every $x \in X$. For any $x, \tilde{x} \in X \cap \rho\mathbb{B}$, and $\xi, \tilde{\xi} \in \Xi$, one has the estimate

$$f_0(\xi, x) - f_0(\tilde{\xi}, \tilde{x}) \le cx + (h(\xi) - T(\xi)x)z^*(\xi) - (h(\tilde{\xi}) - c\tilde{x} - T(\tilde{\xi})\tilde{x})z(\tilde{\xi}), \tag{3.8}$$

where $z^*(\xi) \in D(\xi)$ is a dual solution of the second-stage problem and $z(\tilde{\xi})$ is some element in $D(\tilde{\xi})$. We denote by $\bar{z}(\tilde{\xi}; \xi)$ the projection of $z^*(\xi)$ onto $D(\tilde{\xi})$, i.e.,

$$d(z^*(\xi), D(\tilde{\xi})) = \|z^*(\xi) - \bar{z}(\tilde{\xi}; \xi)\|,$$

yielding

$$\|z^*(\xi) - \bar{z}(\tilde{\xi}; \xi)\| \le \boldsymbol{d}_\infty(D(\xi), D(\tilde{\xi})) \le L \max\{1, h(\|\xi - \xi_0\|), h(\|\tilde{\xi} - \xi_0\|)\}\|\xi - \tilde{\xi}\|. \tag{3.9}$$

As $D(\xi_0)$ is bounded, there exists $r > 0$ such that $\|z\| \le r$ for each $z \in D(\xi_0)$. As the estimate

$$d(\bar{z}(\tilde{\xi}; \xi), D(\xi_0)) \le L \max\{1, h(\|\tilde{\xi} - \xi_0\|)\}\|\tilde{\xi} - \xi_0\|$$

holds for all $\xi, \tilde{\xi} \in \Xi$, according to (3.4), we have

$$\|\bar{z}(\tilde{\xi}; \xi)\| \le \max\{r, L\} \max\{1, h(\|\tilde{\xi} - \xi_0\|)\}\|\tilde{\xi} - \xi_0\|. \tag{3.10}$$

Now, we proceed with our estimate (3.8) when $x = \tilde{x}$, exploiting the affine linearity of $h(\cdot)$ and $T(\cdot)$, (3.9) and (3.10). Setting $z(\tilde{\xi}) := \bar{z}(\tilde{\xi}; \xi)$ we obtain

$$\begin{aligned}
f_0(\xi, x) - f_0(\tilde{\xi}, x) &\le (h(\xi) - T(\xi)x)(z^*(\xi) - \bar{z}(\tilde{\xi}; \xi)) \\
&\quad - ((h(\tilde{\xi}) - h(\xi)) - (T(\tilde{\xi}) - T(\xi))x)\bar{z}(\tilde{\xi}; \xi) \\
&\le \|h(\xi) - T(\xi)x\|\|z^*(\xi) - \bar{z}(\tilde{\xi}; \xi)\| \\
&\quad + (\|h(\tilde{\xi}) - h(\xi)\| + \|T(\tilde{\xi}) - T(\xi)\|\|x\|)\|\bar{z}(\tilde{\xi}; \xi)\| \\
&\le \Big(KL(1 + \rho) \max\{1, \|\xi - \xi_0\|\} \max\{1, h(\|\xi - \xi_0\|), h(\|\tilde{\xi} - \xi_0\|)\} \\
&\quad + \tilde{K} \max\{r, L\}(1 + \rho) \max\{1, h(\|\tilde{\xi} - \xi_0\|)\}\|\tilde{\xi} - \xi_0\|\Big)\|\xi - \tilde{\xi}\| \\
&\le \bar{L}(1 + \rho) \max\{1, H(\|\xi - \xi_0\|), H(\|\tilde{\xi} - \xi_0\|)\}\|\xi - \tilde{\xi}\|
\end{aligned}$$

for each $\xi, \tilde{\xi} \in \Xi$, and some positive constants K, $\tilde{K}$, and $\bar{L}$. Thus, (3.5) is proved with $\hat{L}(\rho) = \bar{L}(1 + \rho)$. Finally, we return to (3.8) in case $\xi = \tilde{\xi}$; choosing $\bar{z}(\xi) = z^*(\xi)$, we arrive at the estimate

$$\begin{aligned}
f_0(\xi, x) - f_0(\xi, \tilde{x}) &\le c(x - \tilde{x}) + T(\xi)(\tilde{x} - x)z^*(\xi) \le (\|c\| + \|T(\xi)\|\|z^*(\xi)\|)\|x - \tilde{x}\| \\
&\le \hat{L} \max\{1, H(\|\xi - \xi_0\|)\|\xi - \xi_0\|\}\|x - \tilde{x}\|
\end{aligned}$$

for some constant $\hat{L} > 0$ and all $\xi \in \Xi$, $x, \tilde{x} \in X \cap \rho\mathbb{B}$. Here, we used that $\|z^*(\xi)\|$ can be bounded in the same way as $\bar{z}(\tilde{\xi}; \xi)$ in (3.10). □

The next examples illustrate the local Lipschitz continuity property (3.4) of the dual feasibility mapping D.

Example 3.4. Let $\overline{m} = 4$, $d = 2$, $Y = \mathbb{R}^4_+$, and $\Xi = \mathbb{R}$, and consider the random recourse costs and matrix

$$W(\xi) = \begin{pmatrix} 1 & -1 & 0 & 0 \\ -\xi & 0 & 1 & -1 \end{pmatrix}, \qquad q(\xi) = \begin{pmatrix} 0 \\ 0 \\ \xi \\ -\xi \end{pmatrix}.$$

Then $W(\xi)Y = \mathbb{R}^2$ (complete recourse) and $D(\xi) = [0, \xi^2] \times \{\xi\}$. Hence, the conditions (A1) and (A2) and (3.4) are satisfied with $h(t) \equiv t$.

Example 3.5. We consider the second-stage program arising in the equivalent optimization problem to AVaR minimization (1.4) in section 1. Its dual feasible set is of the form

$$\begin{aligned} D_{\mathrm{avar}}(\xi) &= \{z = (z_1, z_2) \in \mathbb{R}^d \times \mathbb{R} : W_{\mathrm{avar}}(\xi)^\top z - q_{\mathrm{avar}}(\xi) \in Y^*_{\mathrm{avar}}\} \\ &= \{(z_1, z_2) \in \mathbb{R}^d \times [0, \alpha^{-1}] : W^\top z_1 + q(\xi) z_2 \in Y^*\} \\ &= \{(z_1, u) \in \mathbb{R}^d \times \mathbb{R}^{\overline{m}} : W^\top z_1 + u \in Y^*, u \in [0, \alpha^{-1}] q(\xi)\} \end{aligned}$$

due to (1.5), where $u \in [0, \alpha^{-1}]q(\xi)$ means that, for every $j = 1, \ldots, \overline{m}$, $0 \le u_j \le \alpha^{-1} q_j(\xi)$ holds if $q_j(\xi) \ge 0$ and $\alpha^{-1} q_j(\xi) \le u_j \le 0$ otherwise. Hence, if (A2) is satisfied, the set-valued mapping $\xi \to D_{\mathrm{avar}}(\xi)$ is Lipschitz continuous on Ξ with respect to the Pompeiu–Hausdorff distance $\boldsymbol{d}_\infty$ since its graph is convex polyhedral [35]. This means that Proposition 3.3 applies with $h(t) \equiv 1$.

We can reformulate the conclusions of the preceding proposition in terms of the Fortet–Mourier metrics defined on $\mathcal{P}_H(\Xi)$, the space (2.2) of probability measures.

COROLLARY 3.6. *Let the assumptions of Proposition* 3.3 *be satisfied,* $P \in \mathcal{P}_H(\Xi)$*, and* $S(P)$ *be nonempty and bounded. Then there exist constants* $\hat{L} > 0$*,* $\rho > 0$*, and* $\hat{\varepsilon} > 0$ *such that*

$$|v(P) - v(Q)| \le \hat{L} \zeta_H(P, Q),$$

$$\boldsymbol{d}_\infty(S_\varepsilon(P), S_\varepsilon(Q)) \le \frac{4\rho\hat{L}}{\varepsilon} \zeta_H(P, Q)$$

hold for any $\varepsilon \in (0, \hat{\varepsilon})$ *and each* $Q \in \mathcal{P}_H(\Xi)$ *such that* $\zeta_H(P, Q) < \varepsilon$*, where* H *is defined by* (3.7)*, and* $\zeta_H(P, Q)$ *is the Fortet–Mourier metric on* $\mathcal{P}_H(\Xi)$*.*

Proof. The estimate (3.5) implies $d_{\mathcal{F},\rho}(P, Q) \le \hat{L} \zeta_H(P, Q)$ with $\hat{L} = \hat{L}(\rho)$, and, hence, the result follows from Theorem 3.2. □

When $W(\xi) \equiv W$, the mapping $\xi \mapsto D(\xi)$ is even Lipschitz continuous with respect to the Pompeiu–Hausdorff distance $\boldsymbol{d}_\infty$ due to [35]. Hence, $H(t) \equiv t$ and $\mathcal{F}_H = \mathcal{F}_2$, and then the previous result boils down to [18, Proposition 3.2].

4. Two-stage multiperiod models. If the second stage of a stochastic program with recourse models a (stochastic) dynamical decision process (see section 1), our two-stage problem takes on the form

(4.1)

$$\min\left\{ cy_0 + \sum_{j=1}^{l} q_j(\xi) y_j : y_0 \in X, y_j \in Y_j, W_{jj} y_j = h_j(\xi) - W_{jj-1}(\xi) y_{j-1}, j = 1, \ldots, l \right\},$$

where for $j = 1, \dots, l$, $Y_j \in \mathbb{R}^{\overline{m}_j}$ are polyhedral sets for some finite l and first-stage decision $x := y_0$; the matrices $W_{j,j-1}(\xi)$ are (potentially) stochastic. Then the second-stage program has separable block structure; i.e., the recourse variable y has the form $y = (y_1, \dots, y_l)$, the polyhedral set Y is the Cartesian product of polyhedral sets $Y_j \in \mathbb{R}^{\overline{m}_j}$, $j = 1, \dots, l$, the element $T(\xi)x$ has the components $T_1(\xi)x := W_{10}(\xi)x$ and $T_j(\xi)x = 0$, $j = 2, \dots, l$, and the random recourse matrix $W(\xi)$ is of the form

$$W(\xi) = \begin{pmatrix} W_{11} & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\ W_{21}(\xi) & W_{22} & 0 & 0 & \cdots & 0 & 0 & 0 \\ 0 & W_{32}(\xi) & W_{33} & 0 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \\ 0 & 0 & 0 & 0 & \cdots & W_{l-1l-2}(\xi) & W_{l-1l-1} & 0 \\ 0 & 0 & 0 & 0 & \cdots & 0 & W_{ll-1}(\xi) & W_{ll} \end{pmatrix}, \tag{4.2}$$

i.e., all matrices W_{jj}, $j = 1, \dots, l$, in the diagonal of $W(\xi)$ are nonstochastic. Denoting by $q_j(\xi)$ and $h_j(\xi)$ the components of $q(\xi)$ and $h(\xi)$, respectively, the integrand f_0 is of the form

$$\begin{aligned} f_0(\xi, x) &= cx + \inf \left\{ \sum_{j=1}^{l} q_j(\xi) y_j : W_{jj} y_j = h_j(\xi) - W_{jj-1}(\xi) y_{j-1}, y_j \in Y_j, j = 1, \dots, l \right\} \\ &=: cx + \Psi_1(\xi, x), \end{aligned}$$

where the function Ψ_1 is given by the recursion

$$\Phi_j(\xi, u_{j-1}) := \inf \{ q_j(\xi) y_j + \Psi_{j+1}(\xi, y_j) : W_{jj} y_j = u_{j-1}, y_j \in Y_j \}, \tag{4.3}$$

$$\Psi_j(\xi, y_{j-1}) := \Phi_j(\xi, h_j(\xi) - W_{jj-1}(\xi) y_{j-1}) \tag{4.4}$$

for $j = l, \dots, 1$, where $y_0 = x$ and $\Psi_{l+1}(\xi, y_l) \equiv 0$.

While the continuity and growth properties of the function $f_0(\cdot, x)$ in case $l = 1$ may be derived from Lemma 3.1, we need an extended result for establishing Lipschitz continuity properties of the inf-projection Φ_j for $j = 1, \dots, l$. The results in [39] were developed precisely to deal with the present situation. To state the result, we denote by D^∞ the recession cone of a convex set $D \subseteq \mathbb{R}^m$. It consists of all elements $x_d \in \mathbb{R}^m$ such that $x + \lambda x_d \in D$ for all $x \in D$ and $\lambda \in \mathbb{R}_+$. Clearly, we have $D^\infty = \{0\}$ if D is bounded. Furthermore, D^∞ is polyhedral if D is polyhedral. Next we record [39, Proposition 4.4] and provide a self-contained proof for the convenience of the reader.

LEMMA 4.1. *Let $h \in \mathbb{R}^d$, $W \in \mathbb{R}^{d \times n}$, and $Y \subseteq \mathbb{R}^n$ be polyhedral. Let $u = (u_1, u_2) \in \mathbb{R}^n \times \mathbb{R}^d$ and*

$$\Phi(u) := \inf\{ f(u_1, y) : Wy = h - u_2, y \in Y \}.$$

Assume that $\ker(W) \cap Y^\infty = \{0\}$ *and that f is Lipschitz continuous on $\{(u_1, y) \in \mathbb{R}^n \times Y : \|u_1\| \le r, \|y\| \le r\}$ with constant $L(r)$ for every $r > 0$. Then, $\Phi(\cdot)$ is Lipschitz continuous on $\{(u_1, u_2) \in \operatorname{dom} \Phi : \|u_1\| \le r, \|u_2\| \le r\}$ with constant $L_M L(K_M \max\{1, r\})$ for every $r > 0$, where $L_M \ge 1$ and $K_M \ge 1$ are constants depending only on the set-valued mapping $M(u_2) := \{y \in Y : Wy = h - u_2\}$ from $\mathbb{R}^d$ to $\mathbb{R}^n$.*

Proof. The condition $\ker(W) \cap Y^\infty = \{0\}$ is equivalent to the local boundedness of the mapping M. M is Lipschitz continuous with respect to the Pompeiu–Hausdorff distance d_∞ (with constant $L_M \ge 1$) since its graph is polyhedral [23, Example

9.35]. Since the set $M(u_2)$ is compact, Φ is finite for all pairs (u_1, u_2) such that $u_2 \in \operatorname{dom} M$. Now, let $r > 0$ and $u = (u_1, u_2), \tilde{u} = (\tilde{u}_1, \tilde{u}_2) \in \operatorname{dom}\Phi \cap \{(u_1, u_2) \in \mathbb{R}^n \times \mathbb{R}^d : \|u_1\| \le r, \|u_2\| \le r\}$. Then there exist $y(u_2) \in M(u_2)$ and $y(\tilde{u}_2) \in M(\tilde{u}_2)$ such that $\Phi(u) = f(u_1, y(u_2))$ and $\|y(u_2) - y(\tilde{u}_2)\| \le L_M \|u_2 - \tilde{u}_2\|$. In particular, there exists a constant $K_M \ge 1$ such that

$$\max\{\|y(u_2)\|, \|y(\tilde{u}_2)\|\} \le K_M \max\{1, \|u_2\|, \|\tilde{u}_2\|\} \le K_M \max\{1, r\}.$$

We obtain

$$\begin{aligned}\Phi(\tilde{u}) - \Phi(u) &\le f(\tilde{u}_1, y(\tilde{u}_2)) - f(u_1, y(u_2)) \\ &\le L(K_M \max\{1, r\})(\|\tilde{u}_1 - u_1\| + \|y(\tilde{u}_2) - y(u_2)\|) \\ &\le L_M L(K_M \max\{1, r\})(\|\tilde{u}_1 - u_1\| + \|\tilde{u}_2 - u_2\|),\end{aligned}$$

and that completes the proof. □

PROPOSITION 4.2. *Let $W(\xi)$ be as described by* (4.2). *Assume the relatively complete recourse condition* (A1) *is satisfied and that* $\ker(W_{jj}) \cap Y_j^\infty = \{0\}$ *for* $j = 1, \dots, l-1$. *Then, there exist constants $L > 0$, $\hat{L} > 0$, and $K > 0$ such that the following holds for all $\xi, \tilde{\xi} \in \Xi$ and $x, \tilde{x} \in X \cap \rho\mathbb{B}$:*

$$\begin{aligned}|f_0(\xi, x) - f_0(\tilde{\xi}, x)| &\le L \max\{1, \rho, \|\xi\|^l, \|\tilde{\xi}\|^l\}\|\xi - \tilde{\xi}\|, \\ |f_0(\xi, x) - f_0(\xi, \tilde{x})| &\le \hat{L} \max\{1, \|\xi\|^{l+1}\}\|x - \tilde{x}\|, \\ |f_0(\xi, x)| &\le K \max\{1, \rho, \|\xi\|^{l+1}\}.\end{aligned}$$

Proof. Due to the assumptions, all sets of the form $M_j(v_j) := \{y_j \in Y_j : W_{jj} y_j = v_j\}$ are bounded polyhedra for all $v_j \in \mathbb{R}^{r_j}$ and $j = 1, \dots, l$. Furthermore, the set-valued mappings M_j from $\mathbb{R}^{r_j}$ to $\mathbb{R}^{\overline{m}_j}$ are Lipschitz continuous on $\operatorname{dom} M_j$ with constant L_j. Due to (A1), we have recursively $h_j(\xi) - W_{jj-1}(\xi) y_{j-1} \in \operatorname{dom} M_j$ for all $y_{j-1} \in Y_{j-1}$, $y_0 = x \in X$, $\xi \in \Xi$, and $j = 2, \dots, l$. Hence, if Lemma 4.1 is used recursively by setting $\Phi = \Phi_j$, $f_j(u_1, y_j) := q_j(\xi) y_j + \Psi_{j+1}(\xi, y_j)$ with $u_1 = \xi$ and $u_2 = u_{j-1}$, each subproblem (4.3) is solvable. First we consider the functions Φ_l and Ψ_l:

$$\begin{aligned}\Phi_l(\xi, u_{l-1}) &= \inf\{q_l(\xi) y_l : W_{ll} y_l = u_{l-1}, y_l \in Y_l\}, \\ \Psi_l(\xi, y_{l-1}) &= \Phi_l(\xi, h_l(\xi) - W_{ll-1}(\xi) y_{l-1}).\end{aligned}$$

Then the Lipschitz constant of f_j on $\{(\xi, y_l) \in \Xi \times Y_l : \|\xi\| \le r, \|y_l\| \le r\}$ has the form $L_l \max\{1, r\}$ and Lemma 4.1 implies that Φ_l has the Lipschitz constant $\hat{L}_l \max\{1, r\}$ on $\{(\xi, u_{l-1}) \in \Xi \times \operatorname{dom} M_l : \|\xi\| \le r, \|u_{l-1}\| \le r\}$. Due to the term $W_{ll-1}(\xi) y_{l-1}$ in the definition of Ψ_l, however, the function Ψ_l has the Lipschitz constant $\tilde{L}_l \max\{1, r^2\}$ on $\{(\xi, y_{l-1}) \in \Xi \times Y_{l-1} : \|\xi\| \le r, \|y_{l-1})\| \le r\}$. Since Ψ_l enters the definition of f_{l-1} and the infimum, Φ_{l-1} is Lipschitz continuous with constant $\hat{L}_{l-1} \max\{1, r^2\}$ on $\{(\xi, u_{l-2}) \in \Xi \times \operatorname{dom} M_{l-1} : \|\xi\| \le r, \|u_{l-2}\| \le r\}$ according to Lemma 4.1. Due to the term $W_{l-1l-2}(\xi) y_{l-2}$, the function Ψ_{l-1} is Lipschitz continuous with constant $\tilde{L}_{l-1} \max\{1, r^3\}$ on $\{(\xi, y_{l-2}) \in \Xi \times Y_{l-2} : \|\xi\| \le r, \|y_{l-2})\| \le r\}$, etc. This process may be continued until one concludes that Φ_1 is Lipschitz continuous with constant $\hat{L}_1 \max\{1, r^l\}$ on $\{(\xi, u_0) \in \Xi \times \operatorname{dom} M_1 : \|\xi\| \le r, \|u_0\| \le r\}$. Hence, the function Ψ_1 depending on (ξ, x) satisfies the Lipschitz continuity property

$$|\Psi_1(\xi, x) - \Psi_1(\tilde{\xi}, \tilde{x})| \le \tilde{L}_1 \max\{1, \rho, r^l\}(\max\{1, \rho\}\|\xi - \tilde{\xi}\| + \max\{1, r\}\|x - \tilde{x}\|)$$

on the set $\{(\xi, x) \in \Xi \times X : \|\xi\| \le r, \|x\| \le \rho\}$.

This yields the assertions about f_0 and completes the proof. □

Due to the previous result we obtain

$$\mathcal{P}_{\mathcal{F}} \supseteq \mathcal{P}_{l+1}(\Xi) = \{Q \in \mathcal{P}(\Xi) : \int_{\Xi} \|\xi\|^{l+1} Q(d\xi) < \infty\}$$
$$\text{and} \quad \frac{1}{L \max\{1, \rho\}} f_0(x, \cdot) \in \mathcal{F}_{l+1}(\Xi)$$

for each $x \in X \cap \rho\mathbb{B}$, and arrive, after specializing Theorem 3.2, at the following.

COROLLARY 4.3. *Let $W(\xi)$ be as described by* (4.2). *Assume the relatively complete recourse condition* (A1) *is satisfied and that* $\ker(W_{jj}) \cap Y_j^{\infty} = \{0\}$ *for* $j = 1, \dots, l-1$.

Then there exist constants $L > 0$ and $\hat{\varepsilon} > 0$ such that for any $\varepsilon \in (0, \hat{\varepsilon})$ the estimates

$$|v(P) - v(Q)| \le L\, \zeta_{l+1}(P, Q),$$
$$d_{\infty}(S_{\varepsilon}(P), S_{\varepsilon}(Q)) \le \frac{L}{\varepsilon} \zeta_{l+1}(P, Q)$$

hold whenever $Q \in \mathcal{P}_{l+1}(\Xi)$ and $\zeta_{l+1}(P, Q) < \varepsilon$.

The case $l = 1$ corresponds to the situation of two-stage models with fixed recourse, and that situation was already covered by [24, Theorem 24]. We note that the corollary remains valid for the slightly more general situation that $W_{jj-1}(\xi) y_{j-1}$ in (4.1) is replaced by $\sum_{i=1}^{j-1} W_{ji}(\xi) y_i$, and, hence, all lower diagonal blocks of $W(\xi)$ are random. We also note that the corollary applies to recourse matrices of the form (1.5) in risk averse two-stage models with polyhedral convex risk functionals.

If the recent stability result [10, Theorem 2.1] for linear multistage models is restricted to the two-stage model (4.1), it implies the existence of positive constants L and δ such that

$$|v(P) - v(Q)| \le L\, \ell_{l+1}(P, Q) \tag{4.5}$$

holds for every $Q \in \mathcal{P}_{l+1}(\Xi)$ with $\ell_{l+1}(P, Q) < \delta$; the distance ℓ_r denotes the L_r-*minimal* or Wasserstein metric

$$\ell_r(P, Q) := \left(\inf \left\{ \int_{\Xi \times \Xi} \|\xi - \tilde{\xi}\|^r \eta(d\xi, d\tilde{\xi}) : \eta \in \mathcal{P}(\Xi \times \Xi),\ \pi_1 \eta = P,\ \pi_2 \eta = Q \right\} \right)^{1/r} \tag{4.6}$$

on $\mathcal{P}_r(\Xi)$ for any $r \ge 1$, where π_1 and π_2 denote the projections onto the first and second components, respectively. It is known that sequences in $\mathcal{P}_r(\Xi)$ converge with respect to both metrics ζ_r and ℓ_r if they converge weakly and if their rth order absolute moments converge. To derive a quantitative estimate, let $\eta^* \in \mathcal{P}(\Xi \times \Xi)$ be a solution of the minimization problem on the right-hand side of (4.6). Such solutions exist according to [17, Theorem 8.1.1]. Then the duality theorem [17, Theorem 5.3.2]

for the Fortet–Mourier metric of order r implies, via Hölder's inequality, the estimate

$$\begin{aligned}\zeta_r(P,Q) &\le \int_{\Xi\times\Xi} \max\{1,\|\xi\|,\|\tilde{\xi}\|\}^{r-1}\|\xi-\tilde{\xi}\|\eta^*(d\xi,d\tilde{\xi})\\ &\le \Big(\int_{\Xi\times\Xi}\max\{1,\|\xi\|,\|\tilde{\xi}\|\}^r\eta^*(d\xi,d\tilde{\xi})\Big)^{\frac{r-1}{r}}\Big(\int_{\Xi\times\Xi}\|\xi-\tilde{\xi}\|^r\eta^*(d\xi,d\tilde{\xi})\Big)^{\frac{1}{r}}\\ &= \Big(\int_{\Xi\times\Xi}\max\{1,\|\xi\|,\|\tilde{\xi}\|\}^r\eta^*(d\xi,d\tilde{\xi})\Big)^{\frac{r-1}{r}}\ell_r(P,Q)\\ &\le \Big(1+\int_{\Xi}\|\xi\|^r(P+Q)(d\xi)\Big)^{\frac{r-1}{r}}\ell_r(P,Q).\end{aligned}$$

Since the convergence of probability measures with respect to ℓ_r and ζ_r implies the convergence of their rth order absolute moments, the stability result for optimal values obtained in Corollary 4.3 implies (4.5) (with some constant $L>0$). However, the convergence of $\zeta_r(P,P_n)$ to 0 may be faster than $\ell_r(P,P_n)$ for some sequence (P_n) of probability measures, as illustrated in [18, Example 3.4]. Hence, the stability result for optimal values in Corollary 4.3 strictly extends the estimate (4.5) for multiperiod two-stage stochastic programs.

5. Empirical approximations of two-stage models. Let $\xi_1,\xi_2,\dots,\xi_n,\dots$ be independent and identically distributed Ξ-valued random variables on some probability space $(\Omega,\mathcal{A},\mathbb{P})$ having the common distribution P, i.e., $P=\mathbb{P}\xi_1^{-1}$. We consider the empirical measures

$$P_n(\omega) := \frac{1}{n}\sum_{i=1}^n \delta_{\xi_i(\omega)} \qquad (\omega\in\Omega;\ n\in\mathbb{N})$$

and the *empirical approximation* of the stochastic program (1.1) with sample size n, i.e.,

$$\min\left\{\frac{1}{n}\sum_{i=1}^n f_0(\xi_i(\cdot),x) : x\in X\right\}. \tag{5.1}$$

Since the objective function of (5.1) is a random lsc function from $\mathbb{R}^m\times\Omega$ to $\overline{\mathbb{R}}$, the optimal value $v(P_n(\cdot))$ of (5.1) is measurable from Ω to $\overline{\mathbb{R}}$ and the ε-approximate solution set $S_\varepsilon(P_n(\cdot))$ is a closed-valued measurable set-valued mapping from Ω to $\mathbb{R}^m$ (see Chapter 14 and, in particular, Theorem 14.37 of [23]).

Qualitative and quantitative results on the asymptotic behavior of solutions to (5.1) are given, e.g., in [2, 6, 13] and [12, 15, 16, 18, 30], respectively.

Due to the results in the previous sections, the asymptotic behavior of $v(P_n(\cdot))$ and $S_\varepsilon(P_n(\cdot))$ is closely related to uniform convergence properties of the empirical process

$$\left\{\sqrt{n}(P_n(\cdot)-P)f = \frac{1}{\sqrt{n}}\sum_{i=1}^n (f(\xi_i(\cdot))-Pf)\right\}_{f\in\mathcal{F}}$$

indexed by the class $\mathcal{F}=\{f_0(x,\cdot):x\in X\}$. Here, we set $Qf:=\int_\Xi f(\xi)Q(d\xi)$ for any $Q\in\mathcal{P}(\Xi)$ and $f\in\mathcal{F}$. Uniform convergence properties refer to the convergence, or to the convergence rate, of

$$d_{\mathcal{F}}(P_n(\cdot),P) = \sup_{f\in\mathcal{F}}|P_n(\cdot)f-Pf| \tag{5.2}$$

to 0 in terms of some stochastic convergence. Since the supremum in (5.2) is nonmeasurable in general, the outer probability $\mathbb{P}^*$ (defined by $\mathbb{P}^*(B) = \inf\{\mathbb{P}(A) : B \subset A, A \in \mathcal{A}\}$ for any subset B of Ω) is used to describe convergence in probability and almost surely, respectively (cf. [32]).

The class $\mathcal{F}$ is called a *P–Glivenko–Cantelli class* if the sequence $(d_{\mathcal{F}}(P_n(\cdot), P))$ of random variables converges to 0 $\mathbb{P}^*$-almost surely or, equivalently, in outer probability. The empirical process is called *uniformly bounded in outer probability with tail $C_{\mathcal{F}}(\cdot)$* if the function $C_{\mathcal{F}}(\cdot)$ is defined on $(0, \infty)$ and decreasing to 0, and the estimate

$$\mathbb{P}^*(\{\omega : \sqrt{n}\, d_{\mathcal{F}}(P_n(\omega), P) \geq \varepsilon\}) \leq C_{\mathcal{F}}(\varepsilon) \tag{5.3}$$

holds for all $\varepsilon > 0$ and $n \in \mathbb{N}$.

Whether a given class $\mathcal{F}$ is a P–Glivenko–Cantelli class or the empirical process is uniformly bounded in outer probability depends on the size of the class $\mathcal{F}$ measured in terms of *bracketing numbers*, or of the corresponding *metric entropy numbers* defined as their logarithms (see [32]). To introduce this concept, let $\mathcal{F}$ be a subset of the normed linear space $L_p(\Xi, P)$ (for some $p \geq 1$) equipped with the usual norm $\|f\|_{P,\,p} = (P|f|^p)^{\frac{1}{p}}$. The bracketing number $N_{[\,]}(\varepsilon, \mathcal{F}, L_p(\Xi, P))$ is the minimal number of *brackets* $[l, u] = \{f \in L_p(\Xi, P) : l \leq f \leq u\}$ with $\|l - u\|_{P,\,p} < \varepsilon$ needed to cover $\mathcal{F}$. The following result provides criteria for the desired properties in terms of bracketing numbers. For its proof we refer to [32, Theorem 2.4.1] and [31, Theorem 1.3].

THEOREM 5.1. *Let $\mathcal{F}$ be a class of real-valued functions on Ξ. If*

$$N_{[\,]}(\varepsilon, \mathcal{F}, L_1(\Xi, P)) < \infty \tag{5.4}$$

holds for every $\varepsilon > 0$, then $\mathcal{F}$ is a P–Glivenko–Cantelli class.

If $\mathcal{F}$ is uniformly bounded and there exist constants $r \geq 1$ and $R \geq 1$ such that

$$N_{[\,]}(\varepsilon, \mathcal{F}, L_2(\Xi, P)) \leq \left(\frac{R}{\varepsilon}\right)^r \tag{5.5}$$

for every $\varepsilon > 0$, then the empirical process indexed by $\mathcal{F}$ is uniformly bounded in outer probability with exponential tail $C_{\mathcal{F}}(\varepsilon) = (K(R)\varepsilon r^{-\frac{1}{2}})^r \exp(-2\varepsilon^2)$ with some constant $K(R)$ depending only on R.

Next we consider the class $\mathcal{F} := \mathcal{F}_\rho$ of integrands defined by (3.3) in section 3 and derive conditions implying the assumptions of Theorem 5.1, particularly the assumptions (5.4) and (5.5) for the bracketing numbers $N_{[\,]}(\varepsilon, \mathcal{F}_\rho, L_p(\Xi, P))$ with $p \in \{1, 2\}$.

THEOREM 5.2. *Let the assumptions of Proposition 3.3 be satisfied and $H : \mathbb{R}_+ \to \mathbb{R}_+$ be defined by (3.7). If $P \in \mathcal{P}_H(\Xi)$, then $\mathcal{F}_\rho = \{f_0(\cdot, x) : x \in X \cap \rho\mathbb{B}\}$ is a P-Glivenko–Cantelli class for any $\rho > 0$, i.e.,*

$$\lim_{n\to\infty} \sup_{x \in X \cap \rho\mathbb{B}} \left| \int_\Xi f_0(\xi, x) P_n(\omega)(d\xi) - \int_\Xi f_0(\xi, x) P(d\xi) \right| = 0 \quad \mathbb{P}\text{- a.s.} \tag{5.6}$$

If, in addition, Ξ is bounded, then the empirical process indexed by $\mathcal{F}_\rho$ is uniformly bounded in probability with exponential tail; i.e.,

$$\mathbb{P}\left(\left\{\omega : \sqrt{n} \sup_{x \in X \cap \rho\mathbb{B}} \left| \int_\Xi f_0(\xi, x)(P_n(\omega) - P)(d\xi) \right| \geq \varepsilon \right\}\right) \leq (K(R)\varepsilon r^{-\frac{1}{2}})^r \exp(-2\varepsilon^2) \tag{5.7}$$

holds for some constant $K(R) > 0$, any $\varepsilon > 0$, and $n \in \mathbb{N}$.

Proof. According to (3.6) in Proposition 3.3, the functions $f_0(\xi, \cdot)$ satisfy the Lipschitz property

$$f_0(\xi, x) - f_0(\xi, \tilde{x}) \leq \hat{L} \max\{1, H(\|\xi - \xi_0\|)\|\xi - \xi_0\|\}\|x - \tilde{x}\|$$

for all $x, \tilde{x} \in X \cap \rho\mathbb{B}$, and $\xi \in \Xi$. Setting $F(\xi) := \hat{L} \max\{1, H(\|\xi - \xi_0\|)\|\xi - \xi_0\|\}$ for all $\xi \in \Xi$, we conclude from [32, Theorem 2.7.11] that

$$N_{[]}(2\varepsilon\|F\|_{P,1}, \mathcal{F}_\rho, L_1(\Xi, P)) \leq N(\varepsilon, X \cap \rho\mathbb{B}, \mathbb{R}^m) \leq K\varepsilon^{-m} \tag{5.8}$$

holds for some $K > 0$ and all $\varepsilon > 0$. Since $\|F\|_{P,1}$ is finite, we may replace ε by $\varepsilon/2\|F\|_{P,1}$ in (5.8) and obtain that $N_{[]}(\varepsilon, \mathcal{F}_\rho, L_1(\Xi, P))$ is finite for all $\varepsilon > 0$. Thus, condition (5.4) in Theorem 5.1 is satisfied.

If Ξ is bounded, the class $\mathcal{F}_\rho$ is uniformly bounded and condition (5.5) in Theorem 5.1 is also satisfied due to (5.8). It remains to note that the supremum $\sup_{x \in X \cap \rho\mathbb{B}}$ may be replaced by a supremum with respect to a countable dense subset of $X \cap \rho\mathbb{B}$. Hence, the suprema in (5.6) and (5.7) are measurable with respect to $\mathcal{A}$ and, thus, the outer probability $\mathbb{P}^*$ can be replaced by $\mathbb{P}$. □

When combining the previous result with Theorem 3.2, we arrive at conditions implying a Glivenko–Cantelli result and a large deviation result for the distances of empirical ε-approximate solution sets $S_\varepsilon(P_n(\cdot))$ to $S_\varepsilon(P)$ in the case of the two-stage model (3.2) with random recourse.

6. Conclusions. The quantitative stability results of section 3 extend earlier work for two-stage models with fixed recourse [18] and for multiperiod two-stage models [10]. Since Theorem 3.2 is stated in terms of the (uniform) semidistances $d_{\mathcal{F}_\rho}$, it allows two types of applications. First, it is possible to utilize metric entropy results and to quantify the asymptotic behavior of statistical approximations to two-stage stochastic programs with random recourse. Second, the analysis of continuity properties of the convex random lsc functions f_0 enables bounding semidistances by appropriate Fortet–Mourier metrics. Such metrics are easier to handle due to their relations to mass transportation problems and their dual representations, particularly for computational purposes (e.g., in scenario reduction algorithms developed in [5, 9]).

The general stability results for model (1.1) in section 2 provide continuity properties of infima and (approximate) solution sets relative to changes of the original probability distribution. They are simple consequences of general perturbation results for optimization problems. Presently, they are stated in terms of the uniform probability semidistance $d_{\mathcal{F}_\rho}$ on the space of probability measures, although the same results would be valid in terms of the corresponding epi-distances $\hat{d}_{\mathcal{I}_\rho}$ or $d_{\mathcal{I}_\rho}$, too. Such epi-distances would allow for richer spaces of probability measures $\mathcal{P}_\mathcal{F}$ and for extended real-valued objective functions $\mathbb{E}^P f_0(x)$ with different effective domains, respectively. But, since a theory for epi-counterparts of uniform distances of Fortet–Mourier type and of uniform large deviation results (see (5.3)) is not yet developed, the achieved generality would appear to be wasted. If, however, these gaps are filled in the future, the framework developed in section 2 forms the basis for extending the present results in sections 3, 4, and 5.

Acknowledgments. The authors wish to thank the guest editor Darinka Dentcheva and an anonymous referee for helpful comments.

ON A DISTRIBUTED CONTROL PROBLEM ARISING IN DYNAMIC OPTIMIZATION OF A FIXED-SIZE POPULATION*

GUSTAV FEICHTINGER† AND VLADIMIR M. VELIOV‡

Abstract. The practical motivation for this paper is provided by the recruitment problem faced by many organizations of fixed size: to keep the average age young (and thus keep innovation and productivity high) while at the same time keeping levels of recruitment high. A typical example is an academy of sciences. The problem is formalized by an infinite horizon optimal control model for a first order PDE with nonlocal dynamics (a McKendrick-type equation). Based on the nonstandard necessary optimality condition proved in the paper, the following results are established: (i) stationarity of the optimal recruitment density; (ii) strong ergodicity of the optimal solution; (iii) principle of "bipolar" recruitment in the case where the productivity of the organization is measured by the average age of the members. The analysis involves a new type of transversality condition for the costate system, the stability with respect to perturbations of the optimal solution of a noncoercive (bang-bang type) problem, boundedness, and stability of the solution of a specific Volterra integral equation of the second kind.

Key words. optimal control, distributed control, population dynamics, ergodicity, McKendrick equation, infinite horizon problems, stability analysis

1. Introduction.

The dynamics of populations of fixed size plays an important role in demography (e.g., migration to guarantee zero population growth for below-replacement fertility) and in manpower planning; see, e.g., [28, 16, 27, 5, 17, 29]. Optimal investment problems in a fixed-size firm with age-structured physical capital and fixed or variable scrapping age (in the framework of, e.g., [10]) lead to technical issues similar to the ones involved below.

The practical motivation for the fixed-size problem investigated in this paper is the following. It has been observed that in many organizations of fixed size, such as academies of sciences in many countries, the average age of the members has increased in past decades [24]. Therefore, the question of appropriate recruitment strategy arises, i.e., that of ensuring a reasonably low average age of the members of the organization while at the same time providing a reasonably high recruitment rate which is desirable for several reasons.[1] These two objectives turn out to be conflicting [24]. More generally, we consider the average productivity of the organization as one of the objectives to be maximized, the recruitment intensity being the second objective, where we assume that the productivity of the members of the organization

[1]For an academy of sciences, for example, a too-small number of elections would frustrate the scientists outside the academy and would decrease the stimulative role of the academy. Moreover, the new members bring new ideas, represent new areas, etc.

depends on the age. The following model for the dynamics of the age-structure of the organization involves a nonstandard version of the McKendrick equation [26, 33, 2]:

$$M_t(t,a) + M_a(t,a) = -\mu(t,a)M(t,a) + R(t)u(t,a), \tag{1.1}$$

$$R(t) = M(t,\omega) + \int_0^\omega \mu(t,a)M(t,a)\,\mathrm{d}a, \tag{1.2}$$

with the side conditions

$$M(0,a) = M_0(a), \quad M(t,0) = 0, \tag{1.3}$$

and the state constraint

$$M(t,a) \geq 0.$$

Here $M(t,\cdot)$ is the age-density of the members of the organization at time t; $\mu(t,a)$ is the mortality rate at time t and age a; $R(t)$ is the intensity of recruitment at time t; $u(t,\cdot)$ is the age-density[2] of recruitment at time t; $M_0(\cdot)$ is the initial age-density of members; ω is the (fixed) retirement age of members; and $M_t + M_a$ is the sum of the partial derivatives of M (strictly speaking, this is the derivative of M in the direction $(1,1)$ in the (t,a)-plane).

The dynamics is given by the classical McKendrick equation (1.1), while (1.2) means that the size of the organization is fixed and equals $\bar{M} = \int_0^\omega M_0(a)\,\mathrm{d}a$ (this can be easily seen by integrating (1.1) in a and utilizing the assumption for fixed size[3]).

The following constraints are posed for the recruitment density, $u(t,\cdot)$, which is considered further as a control variable:

$$0 \leq u(t,a) \leq \bar{u}(a), \quad \int_0^\omega u(t,a)\,\mathrm{d}a = 1. \tag{1.4}$$

The upper bound, $\bar{u}(a)$, for the control has a different meaning in different practical situations and is discussed in detail in [14] for the case of an academy of sciences. It will be proved in section 2 that the state constraint $M(t,a) \geq 0$ is automatically satisfied for any admissible control function u; therefore we do not refer to it further.

As mentioned above, we focus our analysis on two objectives that are to be maximized:

- the average productivity of the organization, $\int_0^\omega p(t,a)M(t,a)\,\mathrm{d}a$, and
- the recruitment intensity, $R(t)$.

Here $p(t,a)$ is the productivity of the members of age a. Productivity may have different meanings in different contexts, but for this paper it matters only that it depends on age. The average age of the members is a special case where $p(t,a) = -a/\bar{M}$ (taken with a minus sign since it is to be minimized).

A study of the above multiobjective and state-constrained problem in the spirit of the viability theory for age-structured systems [7] will be presented by the second author elsewhere.

[2]To avoid misunderstanding, we stress that $M(t,\cdot)$ need not be a probabilistic density, while $u(t,\cdot)$ is assumed to be a probabilistic density, in the sense given by the equality in (1.4) below.

[3]The extension for organizations with smoothly changing size is straightforward. The same applies to a time-dependent control constraint in (1.4) below (excepting the results in section 5).

In this paper we employ the Pareto optimization framework, considering the objective function

$$\max \int_0^\infty e^{-rt} \left[\alpha R(t) + \beta \int_0^\omega p(t,a) M(t,a)\, \mathrm{d}a \right] \mathrm{d}t, \tag{1.5}$$

where $r > 0$ is a time-preference rate, and $\alpha > 0$ and $\beta > 0$ are weights attributed to the two objectives.

Although the above problem is a rather specific one, it is of substantial interest and reflects the intensive policy-oriented discussions that have taken place in many academies of sciences during the past few years [24, 15]. What is more important for the present paper is that the problem provides a number of challenges: (i) it is nonlinear (although bilinear); (ii) the time horizon is infinite, which creates substantial difficulties in obtaining appropriate transversality conditions for the costate system which are strong enough to facilitate the stability analysis needed for the main results[4]; (iii) due to (1.2) the dynamics in (1.1) is nonlocal; and (iv) the optimal solution is of bang-bang type, which is known to create substantial difficulties in the stability analysis of the optimal control also for ODEs (cf., e.g., [23, 19]).

The main results are (i) time-invariance of the optimal recruitment distribution in the case of time-invariant data (section 5); (ii) strong ergodicity of the optimal solution (section 6); and (iii) characterization of the optimal control in a case of particular practical interest by the *principle of bipolar recruitment* (section 7).

All these results are based on the nonstandard optimality condition of Pontryagin type obtained in section 3, with a rather strong transversality condition, which is crucial for the main result (compare with the transversality conditions in the state-of-the-art paper [6]). The proof of the transversality condition is given in the appendix. Some basic properties of the problem under consideration are presented in section 2, and a basic auxiliary result is proved in section 4.

2. Basic properties. In this section we consider a somewhat more general objective function which arises in other models of organizations with fixed size:

$$\max \int_0^\infty e^{-rt} \left[\alpha R(t) + \beta \int_0^\omega A(t,a,M(t,a),R(t)u(t,a))\, \mathrm{d}a \right] \mathrm{d}t, \tag{2.1}$$

subject to (1.1)–(1.4) (the sign "∞" means everywhere "$+\infty$"). Assuming A is dependent on the size of the inflow $w = Ru$ is reasonable due to possible adjustment costs.

Denote for brevity $\Omega = [0,\omega]$, $D = [0,\infty) \times [0,\omega]$.

Standing assumptions. $\mu : D \mapsto [0,\bar{\mu}]$ is measurable; $\bar{u} : \Omega \mapsto [0,\bar{v}]$ is measurable, $\int_\Omega \bar{u}(a)\, \mathrm{d}a > 1$; $M_0 : \Omega \mapsto [0,\infty)$ is measurable and bounded; $A : D \times \mathbf{R} \times \mathbf{R}$ is bounded (locally in (M,w)), measurable in t,a, concave in (M,w), and differentiable in M and w; and the derivatives A_M and A_w are bounded and Lipschitz continuous in (M,w) uniformly in (t,a). Here $\bar{\mu} \geq 0$ and $\bar{v} > 0$ are constants.

By definition, $M \in L_\infty^{\mathrm{loc}}(D)$ is a solution of (1.1) (for given measurable functions R and u) if it can be represented by a function which is absolutely continuous on

[4] Out of many papers that consider optimal control of McKendrick equations, only [25] studies the asymptotic behavior of the adjoint variable for a special system (not including the problem considered here), but the transversality condition obtained there is based on an implicit assumption, the verification of which is, actually, the main trouble. Our approach is substantially different.

almost every (a.e.) characteristic line $t - a = \text{const}$ and satisfies (1.1) almost everywhere on a.e. characteristic line, where the symbol $M_t + M_a$ is interpreted as the directional derivative in direction $(1, 1)$. Notice that the trace of a solution, M, on every straight line which is transversal to the characteristic lines is well defined; in particular, $M(\cdot, \omega)$, $M(0, \cdot)$, $M(t, 0)$, etc. are well-defined elements of L_∞^{loc}. Consequently, the side conditions (1.3) are understood as equalities in L_∞^{loc} (more details are given in [18]; see also [33, 2]). Equation (1.2) has the meaning of an equality between L_∞-functions.

LEMMA 2.1. *For every measurable function u satisfying* (1.4)*, the system* (1.1)–(1.3) *has a unique solution in D; the solution is essentially bounded (uniformly in u) and satisfies $M(t, a) \geq 0$.*

Proof. For a given function $R \in L_\infty^{\mathrm{loc}}(0, \infty)$, the solution of (1.1), (1.3) has the following explicit representation, obtained by application of the Cauchy formula on the characteristic lines $t - a = \text{const}$:

$$M(t,a) = \psi(0,a,t)\chi_\Omega(a-t)M_0(a-t) + \int_0^t \psi(\tau,a,t)\chi_\Omega(a-t+\tau)R(\tau)u(\tau,a-t+\tau)\,\mathrm{d}\tau, \tag{2.2}$$

where χ_Ω is the characteristic function of the set Ω, and

$$\psi(\tau,a,t) = e^{-\int_\tau^t \mu(\theta,a-t+\theta)\,\mathrm{d}\theta}. \tag{2.3}$$

Plugging this into (1.2) and changing the order of integration we obtain the following equation for R:

$$R(t) = f(t) + \int_0^t K(t,\tau)R(\tau)\,\mathrm{d}\tau, \tag{2.4}$$

where

$$\begin{aligned} f(t) &= \psi(0,\omega,t)\chi_\Omega(\omega-t)M_0(\omega-t) + \int_\Omega \mu(t,a)\psi(0,a,t)\chi_\Omega(a-t)M_0(a-t)\,\mathrm{d}a, \\ K(t,\tau) &= \psi(\tau,\omega,t)\chi_\Omega(\omega-t+\tau)u(\tau,\omega-t+\tau) \\ &\quad + \int_\Omega \mu(t,a)\psi(\tau,a,t)\chi_\Omega(a-t+\tau)u(\tau,a-t+\tau)\,\mathrm{d}a. \end{aligned}$$

Since this is a Volterra integral equation of the second kind, it has a solution in $L_\infty^{\mathrm{loc}}(0, \infty)$ (see, e.g., [20, Theorem 4.2, Chapter 9]). It remains to prove that $R \in L_\infty(0, \infty)$, which is the main message of the lemma.

As already mentioned in the introduction, (1.2) is equivalent to

$$\int_0^\omega M(t,a)\,\mathrm{d}a = \bar{M}, \quad \text{where } \bar{M} = \int_0^\omega M_0(a)\,\mathrm{d}a.$$

Due to the conditions (1.4) for u, there exists $\theta > 0$ such that $\int_0^{\omega-\theta} u(t,s)\,\mathrm{d}s \geq 1/2$ for every t. Then, using (2.2), we have

$$\bar{M} \geq \int_0^\omega \int_0^t \psi(\tau,a,t)\chi_\Omega(a-t+\tau)R(\tau)u(\tau,a-t+\tau)\,\mathrm{d}\tau\,\mathrm{d}a.$$

If we extend R as $R(t) = 0$ for $t < 0$, we have

$$\bar{M} \geq \int_{t-\omega}^{t} \int_{t-\tau}^{\omega} \psi(\tau, a, t) R(\tau) u(\tau, a - t + \tau) \, \mathrm{d}a \, \mathrm{d}\tau \geq c \int_{t-\omega}^{t} \int_{0}^{\omega-t+\tau} R(\tau) u(\tau, s) \, \mathrm{d}s \, \mathrm{d}\tau,$$

where c is a lower bound for $\psi(\tau, a, t)$, which is positive since $t - \tau \leq \omega$. Hence,

$$\bar{M} \geq c \int_{t-\theta}^{t} \int_{0}^{\omega-t+\tau} R(\tau) u(\tau, s) \, \mathrm{d}s \, \mathrm{d}\tau \geq \frac{c}{2} \int_{t-\theta}^{t} R(\tau) \, \mathrm{d}\tau.$$

Since this inequality holds for every $t > 0$, we have

$$\int_{t-\omega}^{t} R(\tau) \, \mathrm{d}\tau \leq \int_{t-\theta}^{t} + \int_{t-2\theta}^{t-\theta} + \cdots + \int_{t-k\theta}^{t-(k-1)\theta} \leq \frac{2k}{c} \bar{M},$$

where k is the smallest natural number satisfying $k\theta \geq \omega$. Then formula (2.2), in which the integration is, in fact, carried out on the interval $[t - a, t] \subset [t - \omega, t]$ (due to the presence of the characteristic function of Ω), implies that

$$M(t, a) \leq \|M_0\|_{L_\infty(\Omega)} + \frac{2k\bar{u}}{c} \bar{M} \quad \text{almost everywhere.}$$

The essential boundedness of R follows from (1.2).

To prove that $M(t, a) \geq 0$ we note that $K(t, a) \geq 0$ and $f(t) \geq 0$; hence $R(t) \geq 0$ [20, Proposition 8.1, Chapter 9]. Then (2.2) implies $M(t, a) \geq 0$. □

PROPOSITION 2.1. *Problem* (1.1)–(1.4), (2.1) *has a solution. In particular, problem* (1.1)–(1.5) *has a solution.*

The proof is given in the appendix. Although the idea of the proof is applicable only to a rather restricted class of problems, it could be useful beyond the specific problem (1.1)–(1.4), (2.1).

Uniqueness of the optimal solution is proved under additional conditions in Theorem 5.1. In general, uniqueness is not granted, as Example 1 in section 5 shows. Here we mention only that the function "admissible control" $\longrightarrow$ "objective value" is not necessarily concave with respect to the control[5]; therefore, the uniqueness requires some additional assumptions such as the one formulated in section 5.

3. Optimality conditions. Problem (1.1)–(1.4), (2.1) is on the infinite horizon and involves the "advanced" term $M(t, \omega)$ in the right-hand side of the differential equation. For each of these two reasons the maximum principle obtained in [11, 18], and the other known optimality conditions for McKendrick-type control systems (see the references in [18] and footnote 4) are not applicable.

[5]The claim that the function "admissible control u" $\longrightarrow$ "objective value $J(u)$" is not concave is nonobvious. We have a (generic) counterexample with $\mu(a) = 0$, $A = -aM$, but the argument behind it is too long, and we skip it due to the page limitation. The main idea is first to consider the steady-state version of the problem, where (1.1)–(1.3) (with $M_t = 0$) are analytically solvable. This allows us to represent $J(u)$ in the form

$$J(u) = \frac{c + d\mu_2(u)}{\omega - \mu_1(u)}, \quad c, d > 0,$$

where $\mu_1(u)$ and $\mu_2(u)$ are the first and the second integral moments of u. It is easy to see that the above function is strictly convex on the segment between two controls u_1 and u_2 for which $\mu_1(u_1) = \mu_2(u_1)$ and $\mu_1(u_2) = \mu_2(u_2)$. After that we consider the intertemporal problem (1.1)–(1.4), (2.1) and argue that the nonconcavity is preserved there if the discount r is sufficiently small.

To obtain a necessary optimality condition we introduce the following *adjoint system* for given reference L_∞-functions M and u:

$$\xi_t(t,a)+\xi_a(t,a)=(r+\mu(t,a))\xi(t,a)-\mu(t,a)\eta(t) - \beta A_M(t,a,M(t,a),R(t)u(t,a)), \tag{3.1}$$

$$\eta(t)=\alpha+\int_0^\omega \xi(t,a)u(t,a)\,\mathrm{d}a+\int_0^\omega A_w(t,a,M(t,a),R(t)u(t,a))u(t,a)\,\mathrm{d}a, \tag{3.2}$$

with the boundary condition

$$\xi(t,\omega)=\eta(t). \tag{3.3}$$

The meaning of a solution is the same as for the primal system (1.1)–(1.3). However, the issue of existence and uniqueness here is much more complicated. Actually the above system has infinitely many solutions in $L_\infty^{\mathrm{loc}}(D)$, while it has exactly one solution belonging to $L_\infty(D)$. The proof of the next lemma is given in the appendix.

LEMMA 3.1. *Let u be a control function satisfying* (1.4). *Then system* (3.1)–(3.3) *has a unique solution (ξ,η) in the space $L_\infty(D)\times L_\infty(0,\infty)$.*

Remark 3.1. In general, certain transversality conditions are needed to ensure uniqueness of the solution of the adjoint system for infinite horizon optimal control problems. The usual form of the transversality condition for a discounted objective integrand (see [6]) adapted to our problem would be $\lim_{t\to\infty} e^{-rt}\|\xi(t,\cdot)\|_{L_\infty(\Omega)}=0$. Notice that the condition $\xi\in L_\infty(D)$ represents a stronger transversality condition which obviously implies the above one. This strong transversality condition plays a key role in the subsequent analysis.[6]

THEOREM 3.1. *Let (u,M,R) be an optimal solution, and let ξ be the unique solution of the adjoint system* (3.1)–(3.3) *in $L_\infty(D)$. Then for a.e. t the optimal control, $u(t,\cdot)$, maximizes the integral*

$$\int_0^\omega [\xi(t,a)R(t)v(a)+\beta A(t,a,M(t,a),R(t)v(a))]\,\mathrm{d}a$$

on the set of functions $v(\cdot)$ satisfying

$$0\le v(a)\le \bar u(a),\quad \int_0^\omega v(a)\,\mathrm{d}a=1. \tag{3.4}$$

The main difficulty is encapsulated in Lemma 3.1; therefore, below we only sketch the rest of the proof, which is a matter of technical manipulations with an appropriate needle variation.

Proof. Let us fix an arbitrary $s>0$ which is a Lebesgue point of the functions

$$t\longrightarrow\int_\Omega \xi(t,a)R(t)u(t,a)\,\mathrm{d}a \quad\text{and}\quad t\longrightarrow\int_\Omega A(t,a,M(t,a),u(t,a))\,\mathrm{d}a,$$

and also of every function of the form

$$t\longrightarrow\int_\Omega \xi(t,a)R(t)\tilde u(a)\,\mathrm{d}a \quad\text{and}\quad t\longrightarrow\int_\Omega A(t,a,M(t,a),\tilde u(a))\,\mathrm{d}a,$$

[6] One of the referees suggested that boundedness of the adjoint variable might be possible to prove also using the Lipschitz continuity of the value function of the problem and employing the Barron–Jensen [9, 8] approach for proving the maximum principle.

where $\tilde{u} \in L_\infty(\Omega)$ satisfies (3.4). Elementary measure-theoretic considerations, together with the separability of $L_1(\Omega)$ and the boundedness of R, M, and ξ, yield that a.e. s is a Lebesgue point of all these functions. The main point is to observe (we skip the easy proof of this) that if s is a Lebesgue point of the last two groups of functions for any $u = u_j$ belonging to a countable dense set in $L_1(\Omega)$, then it is a Lebesgue point for these functions for every $u \in L_1(\Omega)$ also.

Denote $T = s + \omega$. Let $h \in (0, s) \cap \Omega$ be a "small" parameter, and denote $S_h := [s - h, s + h] \times \Omega$. Let v be an arbitrary measurable function satisfying (3.4). Consider the variation

$$\Delta u(t,a) = \begin{cases} 0 & \text{for } (t,a) \notin S_h, \\ v(a) - u(t,a) & \text{for } (t,a) \in S_h. \end{cases}$$

Obviously $u+\Delta u$ satisfies (3.4) and therefore is an admissible control. For the solution $(M + \Delta M, R + \Delta R)$ of (1.1)–(1.3) corresponding to $u + \Delta u$ it holds that

$$\mathcal{D}\Delta M = -\mu\Delta M + \Delta R(t)(u+\Delta u) + R(t)\Delta u, \quad \Delta M(0,a) = 0, \quad \Delta M(t,0) = 0, \tag{3.5}$$

$$\Delta R(t) = \Delta M(t,\omega) + \int_0^\omega \mu(t,a)\Delta M(t,a)\,\mathrm{d}a, \tag{3.6}$$

where $\mathcal{D}$ is the derivative in the direction $(1,1)$, and we skip the arguments (t,a). Applying formula (2.2) to (3.5) and then substituting ΔM in (3.6) we obtain (as in the proof of Lemma 2.1) a Volterra equation of the second kind for ΔR:

$$\Delta R(t) = f(t) + \int_0^t K(t,\tau)\Delta R(\tau)\,\mathrm{d}\tau,$$

where $K(t,\tau) \le C(s)$ (here and below $C(s), C_1(s), \dots$ denote numbers that may depend on s but not on h) for $0 \le \tau \le t \le T$, and

$$\begin{aligned} f(t) = &\int_0^t \psi(\tau,\omega,t)\chi_\Omega(\omega - t + \tau)R(\tau)\Delta u(\tau,\omega - t + \tau)\,\mathrm{d}\tau \\ &+ \int_0^t \int_0^\omega \mu(t,a)\psi(\tau,a,t)\chi_\Omega(a - t + \tau)R(\tau)\Delta u(\tau,a - t + \tau)\,\mathrm{d}\tau\,\mathrm{d}a. \end{aligned}$$

From here one can estimate

$$|f(t)| \le C_1 h.$$

Since the above Volterra equation has a locally bounded resolvent kernel (see, e.g., [20, Corollary 4.3, Chapter 9]), $H(t,\tau)$, we may express

$$\Delta R(t) = f(t) + \int_0^t H(t,\tau)f(\tau)\,\mathrm{d}\tau.$$

Hence $|\Delta R(t)| \le C_2(s)h$. Then we have

$$\int_D |\Delta R(t)\Delta u(t,a)|\,\mathrm{d}(t,a) \le \int_{S_h} |\Delta R(t)\Delta u(t,a)|\,\mathrm{d}(t,a) = O_s(h^2),$$

where $O_s(h^2) \le C_3(s)h^2$.

We multiply (3.5) by $e^{-rt}\xi(t,a)$ and integrate on D:

$$\int_D e^{-rt}\xi(t,a)\mathcal{D}\Delta M(t,a)\,\mathrm{d}(t,a)$$
$$= \int_D e^{-rt}\xi(t,a)[-\mu(t,a)\Delta M(t,a) + \Delta R(t)u(t,a) + R(t)\Delta u(t,a)]\,\mathrm{d}(t,a) + O_s(h^2).$$

Due to the relations $\Delta M(t,0) = 0$, $\Delta M(0,a) = 0$, and $\xi \in L_\infty(D)$, simple calculations that we skip transform the left-hand side to

$$\int_0^\infty \xi(t,\omega)\Delta M(t,\omega)\,\mathrm{d}t - \int_D e^{-rt}\left[-r\xi(t,a) + \mathcal{D}\xi(t,a)\right]\Delta M(t,a)\,\mathrm{d}(t,a). \tag{3.7}$$

Due to (3.6), the right-hand side becomes

$$\int_D e^{-rt}\left[-\mu(t,a)\xi(t,a) + \mu(t,a)\int_\Omega \xi(t,b)u(t,b)\,\mathrm{d}b\right]\Delta M(t,a)\,\mathrm{d}(t,a) \tag{3.8}$$

$$+ \int_D e^{-rt}\xi(t,a)\Delta M(t,\omega)u(t,a)\,\mathrm{d}(t,a) + \int_D e^{-rt}\xi(t,a)R(t)\Delta u(t,a)\,\mathrm{d}(t,a) + O_s(h^2).$$

Since u is optimal, for the difference of the objective values, $J(u+\Delta u) - J(u) \le 0$, we have

$$0 \ge \int_0^\infty e^{-rt}\alpha\Delta M(t,\omega)\,\mathrm{d}t$$
$$+ \int_0^\infty e^{-rt}\int_0^\omega \left[\alpha\mu(t,a)\Delta M(t,a) + \beta A_M(t,a)\Delta M(t,a) + \beta A_w(t,a)\Delta R(t)u(t,a)\right.$$
$$\left. +\beta\left(A(t,a,M(t,a),R(t)(u(t,a)+\Delta u(t,a))) - A(t,a)\right)\right]\,\mathrm{d}a\,\mathrm{d}t + O_s(h^2),$$

where here and below the argument (t,a) of the functions A, A_w, and A_w is a substitution for $(t,a,M(t,a),R(t)u(t,a))$. We subtract from the right-hand side of the above inequality the expression in (3.7) and add the expression (3.8) which has the same value. Rearranging the terms and taking into account that ξ is the solution of the adjoint system (3.1)–(3.3), we obtain

$$O_s(h^2) \ge \int_D e^{-rt}[\xi(t,a)R(t)\Delta u(t,a)$$
$$+\beta\left(A(t,a,M(t,a),R(t)(u(t,a)+\Delta u(t,a))) - A(t,a)\right)]\,\mathrm{d}(t,a).$$

This is equivalent to

$$\frac{1}{2h}\int_{s-h}^{s+h} e^{-rt}\int_0^\omega \left[\xi(t,a)R(t)u(t,a) + \beta A(t,a,M(t,a),R(t)u(t,a))\right]\,\mathrm{d}a\,\mathrm{d}t$$
$$\ge \frac{1}{2h}\int_{s-h}^{s+h} e^{-rt}\int_0^\omega \left[\xi(t,a)R(t)v(a) + \beta A(t,a,M(t,a),R(t)v(a))\right]\,\mathrm{d}a\,\mathrm{d}t - O_s(h).$$

Then the claim of the theorem follows by taking the limit with $h \to 0$ and using the definition of a Lebesgue point. □

4. An auxiliary result. From now on we consider only the original problem (1.1)–(1.5).

Since for the objective (1.5) the function $A = p(t,a)M$ is independent of u, whenever $R(t) > 0$ we may equivalently rewrite the maximization condition in Theorem 3.1 as

$$\int_0^\omega \xi(t,a)u(t,a)\,\mathrm{d}a = \max_{v:(3.4)} \int_0^\omega \xi(t,a)v(a)\,\mathrm{d}a, \tag{4.1}$$

where (as indicated) the maximization is carried out on the set of functions $v \in L_\infty(\Omega)$ satisfying (3.4). If $R(t) = 0$ the value of u is of no meaning. For convenience we define in this case $u(t,\cdot)$ as an arbitrary maximizer in (4.1), so that with this convention (4.1) holds for every optimal control for a.e. t.[7]

Denote

$$\sigma(\lambda) = \max_v \int_0^\omega \lambda(a)v(a)\,\mathrm{d}a, \quad \lambda \in L_\infty(\Omega).$$

Then the adjoint system (3.1) can be rewritten in the following closed (feedback) form:

$$\xi_t + \xi_a = (r + \mu(t,a))\xi - \mu(t,a)(\alpha + \sigma(\xi(t,\cdot))) - \beta p(t,a), \tag{4.2}$$

$$\xi(t,\omega) = \alpha + \sigma(\xi(t,\cdot)). \tag{4.3}$$

The existence of a solution to (1.1)–(1.5) and the necessity of the maximum principle imply that the above functional-differential system has at least one solution in $L_\infty(D)$. It will be useful to study the stability of the solution with respect to perturbations in the right-hand side.

LEMMA 4.1. *Let $\xi \in L_\infty(D)$ be a solution of* (4.2), (4.3). *Let $\xi^\delta \in L_\infty(D)$ be a solution of* (4.2), (4.3) *(if such exists) with a perturbation $\delta \in L_\infty(D)$ added to the right-hand side of* (4.2). *Then for every $T > 0$*

$$\|\xi^\delta - \xi\|_{L_\infty([T,\infty)\times\Omega)} \le \frac{\|\delta\|_{L_\infty([T,\infty)\times\Omega)}}{1-q},$$

where $q \in (0,1)$ is a number depending only on ω, r, and μ.

Proof. First we shall prove that σ is Lipschitz continuous with a Lipschitz constant equal to one. Indeed, for λ_1, $\lambda_2 \in L_\infty(\Omega)$ we have (having in mind (3.4))

$$\sigma(\lambda_1) = \max_v \int_\Omega \lambda_1(a)v(a)\,\mathrm{d}a = \max_v \left[\int_\Omega \lambda_2(a)v(a)\,\mathrm{d}a + \int_\Omega (\lambda_1(a) - \lambda_2(a))v(a)\,\mathrm{d}a\right]$$
$$\le \max_v \int_\Omega \lambda_2(a)v(a)\,\mathrm{d}a + \max_v \int_\Omega |\lambda_1(a) - \lambda_2(a)|v(a)\,\mathrm{d}a = \sigma(\lambda_2) + \|\lambda_1 - \lambda_2\|_{L_\infty(\Omega)}.$$

If a solution ξ^δ exists, we consider $\xi^\delta(t,\omega)$ as known, and solve (4.2) along the characteristic lines, which gives for a.e. (t,a)

$$\xi^\delta(t,a) = \varphi(t,a,t+\omega-a)(\alpha + \sigma(\xi^\delta(t+\omega-a,\cdot)))$$

[7] This convention allows us to claim uniqueness of the optimal control later, without excluding the possibility that $R(t) = 0$ for some t. Without this convention the uniqueness of the optimal control proved later should be understood in the sense that for every optimal $u(t,a)$ the corresponding function $R(t)$ is the same, and the values $u(t,a)$ are also the same if $R(t)$ is strictly positive.

$$+\int_t^{t+\omega-a}\varphi(t,a,\tau)\big[\mu(\tau,a-t+\tau)(\alpha+\sigma(\xi^\delta(\tau,\cdot)))$$
$$+\beta p(\tau,a-t+\tau)-\delta(\tau,a-t+\tau)\big]\,\mathrm{d}\tau,$$

where φ is defined in (A.5) in the appendix.

Using the above formula also for $\delta=0$ and taking the difference, we obtain for a.e. $t\ge T$ and $a\in\Omega$ that

$$|\xi^\delta(t,a)-\xi(t,a)|\le\varphi(t,a,t+\omega-a)|\sigma(\xi^\delta(t+\omega-a,\cdot))-\sigma(\xi(t+\omega-a,\cdot))|$$
$$+\int_t^{t+\omega-a}\varphi(t,a,\tau)\left[\mu(\tau,a-t+\tau)|\sigma(\xi^\delta(\tau,\cdot))-\sigma(\xi^\delta(\tau,\cdot))|+|\delta(\tau,a-t+\tau)|\right]\,\mathrm{d}\tau$$
$$\le\left[\varphi(t,a,t+\omega-a)+\int_t^{t+\omega-a}\varphi(t,a,\tau)\mu(\tau,a-t+\tau)\,\mathrm{d}\tau\right]\|\xi^\delta-\xi\|_{L_\infty([t,t+\omega]\times\Omega)}$$
$$+\int_t^{t+\omega-a}|\delta(\tau,a-t+\tau)|\,\mathrm{d}\tau\le q\|\xi^\delta-\xi\|_{L_\infty([t,t+\omega]\times\Omega)}+\|\delta\|_{L_\infty([T,\infty)\times\Omega)},$$

where

$$q=\varphi(t,a,t+\omega-a)+\int_t^{t+\omega-a}\varphi(t,a,\tau)\mu(\tau,a-t+\tau)\,\mathrm{d}\tau.$$

Since from (A.5) we have

$$\varphi_\tau(t,a,\tau)=-\varphi(t,a,\tau)(r+\mu(\tau,a-t+\tau)),$$

it is an elementary exercise to prove that

$$q\le 1-\frac{r}{r+\bar\mu}\left(1-e^{-\omega(r+\bar\mu)}\right)<1.$$

Denote $\varepsilon=\|\delta\|_{L_\infty([T,\infty)\times\Omega)}$. Since the above (t,a) are arbitrary (with $t>T$), we estimate successively

$$|\xi^\delta(t,a)-\xi(t,a)|\le\varepsilon+q\|\xi^\delta-\xi\|_{L_\infty([t,t+\omega]\times\Omega)}\le\varepsilon+q(\varepsilon+q\|\xi^\delta-\xi\|_{L_\infty([t,t+2\omega]\times\Omega)})$$
$$\le\cdots\le\varepsilon+q(\varepsilon+q(\varepsilon+(\ldots)))\le\frac{\varepsilon}{1-q}.$$

Here we have used that $\xi^\delta-\xi\in L_\infty(D)$, so that $q^k\|\xi^\delta-\xi\|_{L_\infty([t,t+k\omega]\times\Omega)}\to 0$. The above estimation implies the lemma. □

COROLLARY 4.1. *Equations* (4.2), (4.3) *have a unique solution in* $L_\infty(D)$.

Proof. It is enough to apply the above lemma with $\delta=0$. □

5. Time-invariance and stability of the optimal control for stationary data. In this section we prove that in the case of stationary (independent of t) data μ and p, the optimal control of problem (1.1)–(1.5) is also stationary. (Of course, the recruitment intensity, $R(t)$, and the state density, $M(t,\cdot)$, are time-dependent in general.) This (at first glance) surprising property is a consequence of the linearity of the system with respect to the state, M, and of the stability with respect to perturbations of the closed-loop adjoint system (4.2), (4.3), established in Lemma 4.1. We also prove uniqueness of the optimal control and stability with respect to data perturbations, which plays a crucial role for the ergodicity theorem in the next section. Notice that the problem we consider has a bang-bang type solution; therefore,

the issue of stability of the optimal control is complicated (cf., e.g., the recent papers [19, 32]). Below we introduce an additional condition that implies the stability and, in fact, also implies sufficiency of the maximum principle, an issue which is still under investigation, also for bang-bang type ODEs (see, e.g., [31, 1, 23]).

Regularity assumption. For all real numbers $d > 0$ and e it holds that

$$\operatorname{meas}\{a \in \Omega : \ \mu(a) + dp(a) = e\} = 0.$$

Important cases where the regularity assumption is fulfilled are discussed in section 7.

THEOREM 5.1. *Let the regularity assumption hold. Let $\mu(t,a) = \mu(a)$ and $p(t,a) = p(a)$ be time-invariant. Then the optimal control for problem* (1.1)–(1.5) *is unique (see footnote* 7*) and time-invariant (that is, $u(t,a) = u(a)$) and satisfies the following two conditions:*

$$\text{(5.1)} \qquad \text{(i)} \qquad \int_\Omega \lambda(a)u(a)\,\mathrm{d}a = \max_v \int_\Omega \lambda(a)v(a)\,\mathrm{d}a,$$

subject to (3.4)*, and*

$$\text{(5.2)} \qquad \text{(ii)} \qquad \int_\Omega \lambda(a)u(a)\,\mathrm{d}a = -\alpha,$$

where λ is the solution of the equation

$$\text{(5.3)} \qquad \dot\lambda = (r + \mu(a))\lambda - \beta p(a) + \nu, \quad \lambda(\omega) = 0,$$

and ν is a "free" parameter.

In fact, the free parameter, ν, in the above formulation should be determined in such a way that the solution of (5.1), (3.4) for this value of ν also satisfies the equality (5.2) (with λ solving (5.3)). It is worth mentioning that the theorem implies that the optimal control is independent of the initial condition M_0. As a consequence of the linearity of (1.1), (1.2), where the optimal u is plugged, the discounted value function of the problem is linear. This fact does not seem to be obvious a priori.

Proof. For stationary data μ and p the adjoint system (4.2), (4.3) is also stationary. This alone does not imply that any solution is stationary, but below we prove first that a stationary solution $\xi(t,a) = \xi(a)$ exists.

Consider the equation

$$\text{(5.4)} \quad \xi_a(a) = (r + \mu(a))\xi(a) - \mu(a)(\alpha + \sigma(\xi(\cdot))) - \beta p(a), \quad \xi(\omega) = \alpha + \sigma(\xi(\cdot)).$$

Denote $\eta = \alpha + \sigma(\xi(\cdot))$. For a fixed (given) η the unique solution of the above equation can be explicitly written by the Cauchy formula. Replacing the expression for ξ in the implicit end-point condition $\xi(\omega) = \alpha + \sigma(\xi(\cdot))$, we obtain one linear equation for η: $b\eta = c$, where the coefficient b has the form

$$b = 1 - \int_\Omega \left[\varphi(a,a,\omega)u(a) - \int_a^\omega \varphi(a,a,\tau)\mu(\tau)u(\tau)\,\mathrm{d}\tau\right] \mathrm{d}a$$

(see (A.5) for the definition of φ). Using the specific form of φ and the inequality $r > 0$ one can easily prove that the above expression is strictly positive. This proves existence of a solution, ξ, of (5.4).

Obviously the extension of $\xi(a)$ on D as a time-invariant function, $\xi(t,a)=\xi(a)$, satisfies the adjoint system (4.2), (4.3), and according to Corollary 4.1, it is its unique solution. Then the maximum principle (Theorem 3.1) claims that for every optimal control and for a.e. fixed t, the function $u(a)=u(t,a)$ satisfies for a.e. t the conditions

$$\int_\Omega \xi(a)u(a)\,\mathrm{d}a = \max_{v:(3.4)} \int_\Omega \xi(a)v(a)\,\mathrm{d}a = \sigma(\xi). \tag{5.5}$$

For the time-invariance of $u(t,a)$ it remains to prove that (5.5) has a unique solution, $u(a)$ (that is, $u(t,a)$ must be the same for all t).

Introducing the function $\lambda(a)=\xi(a)-\eta$ (where $\eta=\alpha+\sigma(\xi(\cdot))$) we easily see that (5.3) (with $\nu=r\eta$) is satisfied, and equalities (5.2) and (5.1) follow from (5.5). Corollary 5.2 formulated below claims the uniqueness of the solution of (5.5) and completes the proof. □

COROLLARY 5.1. *Let the measurable and bounded functions λ and u on Ω satisfy conditions* (i) *and* (ii) *in Theorem* 5.1. *Then there is $l<0$ such that the optimal control $u(a)$ has the following structure:*

$$u(a)=0 \ \text{ for } \ a\in\Omega_-(l), \quad u(a)=\bar u(a) \ \text{ for } \ a\in\Omega_+(l), \tag{5.6}$$

where $\Omega_-(l)=\{a\in\Omega:\ \lambda(a)<l\}$, $\Omega_+(l)=\{a\in\Omega:\ \lambda(a)>l\}$.

Proof. We may apply the Kuhn–Tucker-type result in Theorem 4 [21, 22, Chapter 1] (in the space $L_1(\Omega)$). The inequality for $\bar u$ in the standing assumptions imply that the Lagrange multiplier to the objective function can be taken equal to one. Then the theorem claims that there exists $l\in\mathbf{R}$ (a Lagrange multiplier for the equality constraint in (3.4)) such that u solves the problem

$$\max_v \int_\Omega [\lambda(a)v(a)-lv(a)]\,\mathrm{d}a$$

subject to $0\le v(a)\le\bar u(a)$. Then (5.6) is obvious. Moreover, if $l>0$ then $u(a)$ may happen only if $\lambda(a)\ge 0$ and (5.2) cannot be fulfilled. □

Clearly, if λ is constant on some subset of Ω, then it may happen that $u(a)$ is not uniquely determined for such a and furthermore may have an arbitrary value in $[0,\bar u(a)]$. This will be the case in Example 1 given at the end of the section.

LEMMA 5.1. *Let the regularity assumption be fulfilled. Let λ be a solution of* (5.3) *(with some ν) and u be a solution of the problem* (5.1), (3.4). *Assume that* (5.2) *is fulfilled. Then for every $\varepsilon>0$ there exists $\delta>0$ such that for every $\tilde\lambda\in L_\infty(\Omega)$ for which $\|\tilde\lambda-\lambda\|_{L_\infty(\Omega)}<\delta$ and for every corresponding solution, $\tilde u$, of* (5.1), (3.4) *(with $\tilde\lambda$ substituted for λ) it holds that*

$$\mathrm{meas}\{a\in\Omega:\ \tilde u(a)\ne u(a)\}<\varepsilon.$$

Proof. Assume that the claim is false. Then there exist $\varepsilon>0$ and a sequence $\lambda_k\in L_\infty(\Omega)$ such that $\|\lambda_k-\lambda\|_{L_\infty(\Omega)}<1/k$, and there are corresponding solutions u_k of (5.1), (3.4) such that

$$\mathrm{meas}\{a\in\Omega:\ u_k(a)\ne u(a)\}\ge\varepsilon.$$

We apply Corollary 5.1 to u. The regularity assumption implies that the set $\Omega_0(l)=\Omega\setminus(\Omega_-(l)\cup\Omega_+(l))$ has measure zero. Indeed, in the opposite case there would exist a subset of $\Omega_0(l)$ on which $\lambda'(a)$ exists and equals zero. That is, $(r+\mu(a))l-\beta p(a)+\nu=0$

on a set of positive measure, which contradicts the regularity assumption since $l < 0$; hence $d = -\beta/l > 0$.

Applying Corollary 5.1 to u_k and λ_h, we define the sets $\Omega^k_-(l_k)$ and $\Omega^k_+(l_k)$ determining the structure of u_k. Then we have

$$\{a \in \Omega :\ u_k(a) \neq u(a)\} \subset \Omega_0(l) \cup (\Omega_-(l) \setminus \Omega^k_-(l_k)) \cup (\Omega_+(l) \setminus \Omega^k_+(l_k)). \tag{5.7}$$

If $\Omega_-(l) \setminus \Omega^k_-(l_k)$ has a positive measure, than on this set $l > \lambda(a) \geq \lambda_k(a) - 1/k \geq l_k - 1/k$. Similarly, if $\Omega_+(l) \setminus \Omega^k_+(l_k)$ is of positive measure, then $l < l_k + 1/k$.

Since the set in the right-hand side of (5.7) has a measure at least ε, and $\Omega_0(l)$ is of measure zero, at least one of the other two sets in (5.7) is of positive measure. However, since u and u_k satisfy the equality in (3.4), a standard measure-theoretic exercise shows that if one of the last two sets in (5.7) is of positive measure, then the other must also be of positive measure. Hence, from the paragraph after (5.7) we obtain that

$$|l_k - l| \leq \frac{1}{k}.$$

Due to Corollary 5.1 applied to u and u_k, we have that for a.e. a for which $u(a) \neq u_k(a)$ we have either

$$\left(\ \lambda(a) > l \ \text{ and } \ \lambda_k(a) \leq l_k \leq l + \frac{1}{k}\right) \ \text{ or } \ \left(\ \lambda(a) < l \ \text{ and } \ \lambda_k(a) \geq l_k \geq l - \frac{1}{k}\right).$$

Having in mind that $\|\lambda_k - \lambda\|_{L_\infty(\Omega)} < 1/k$, we obtain that for every k

$$|\lambda(a) - l| \leq \frac{2}{k}$$

on a set of measure ε. In a standard way this implies that $\Omega_0(l)$ is of positive measure, which is a contradiction. □

COROLLARY 5.2. *Let λ be as in Lemma* 5.1. *Then problem* (5.1) *subject to* (3.4) *has a unique solution.*

Proof. It is enough to apply the above lemma for $\tilde{\lambda} = \lambda$. □

Example 1. We shall define an example that will provide several counterfacts showing that the regularity assumption is essential. Let $\omega > 1$, $\bar{u}(a) = 1$, $\beta = 1$, and $\mu(a) = 0$. Let us fix $\kappa \in (0,1)$ and $\theta = \omega - 1 + \kappa$. Define $p(a) = 0$ for $a \in [\theta, \omega]$. The value of $p(a)$ for $a < \theta$ will be defined below. For a given $\nu > 0$ denote by $\lambda[\nu]$ the solution of (5.3) on $[\theta, \omega]$. Moreover, define

$$\alpha = -\kappa\lambda[1](\theta) - \int_\theta^\omega \lambda[1](a)\,\mathrm{d}a, \quad p(a) = p^0 := r\lambda[1](\theta) + 1 \ \text{ for } \ a \in [0, \theta).$$

This completes the definition of the problem. One can check directly that the solution $\lambda[1](a)$ of (5.3) with $\kappa = 1$ is constant and equals $\lambda[1](\theta)$ on $[0, \theta]$. Let $u^* : [0, \theta] \mapsto [0, 1]$ be any measurable function such that $\int u^*(a)\,\mathrm{d}a = \kappa$. Define

$$u(a) = \begin{cases} u^*(a) & \text{for } a \in [0, \theta), \\ 1 & \text{for } a \in [\theta, \omega]. \end{cases} \tag{5.8}$$

Since $\kappa + (\omega - \theta) = 1$, u is an admissible control. Moreover, due to the time-invariance of $\lambda[1]$ on $[0, \theta]$ and the inequality $\lambda[1](\theta) < \lambda[1](a)$ for $a > \theta$, u satisfies (5.1). Equality

(5.2) is also satisfied due to the choice of α. Thus u satisfies the necessary condition formulated in Theorem 5.1.

Now we shall perturb the function p on $[0,\theta]$ in the following way: for a "small" (in absolute value) real number δ, and for a given value of the parameter $\nu > 0$ we define

$$p[\nu,\delta](a) = \nu p^0 + (1 + r(\theta - a))\delta, \quad a \in [0,\theta].$$

If we solve (5.3) for any ν and the above $p[\nu,\delta]$ we obtain for the solution $\lambda[\nu,\delta]$

$$\lambda[\nu,\delta](a) = \nu\lambda[1](a), \ \ t \in [\theta,\omega], \qquad \lambda[\nu,\delta](a) = \nu\lambda[1](a) + (\theta - a)\delta, \ \ a \in [0,\theta).$$

Hence, there is a unique maximizer $u[\nu,\delta]$ in (5.1), and in the case of $\delta > 0$ its structure is

$$u[\nu,\delta](a) = \begin{cases} 1 & \text{if } a \in [0, x(\nu,\delta)] \cup [y(\nu,\delta),\omega], \\ 0 & \text{elsewhere,} \end{cases}$$

while in the case $\delta < 0$ (in which case $\lambda[\nu,\delta]$ is monotone increasing) it is

$$u[\nu,\delta](a) = \begin{cases} 1 & \text{if } a \in [\omega - 1,\omega], \\ 0 & \text{elsewhere.} \end{cases}$$

The values $x(\nu,\delta)$ and $y(\nu,\delta)$ can be specified as the solutions of the system of transcendent equations

$$\begin{aligned} &\lambda[\nu,\delta](x) = \lambda[\nu,\delta](y), \\ &x + (\omega - y) = 1. \end{aligned}$$

The last system is rather easy to investigate and one can prove that $x(\nu,\delta) = \kappa + O(|\delta| + |\nu - 1|)$, $y(\nu,\delta) = \theta + O(|\delta| + |\nu - 1|)$. Then we chose ν from (5.2). This has a unique solution $\nu(\delta)$, and $\nu(\delta) \longrightarrow 1$ as $\delta \longrightarrow 0$. We skip the obvious details of the above construction.

Denote $u_\delta = u[\nu(\delta),\delta]$, $\delta \neq 0$. The problem with $\delta \neq 0$ satisfies the regularity assumption, and u_δ is by its construction the only admissible control satisfying the maximum principle (4.1)–(4.3) for the function $p_\delta = p[\nu(\delta),\delta](a)$. Hence u_δ is optimal. We have that p_δ converges uniformly to p^0 and u_δ converges in measure (and even stronger) to either

$$u^+(a) = \begin{cases} 1 & \text{if } a \in [0,\kappa] \cup [\theta,\omega], \\ 0 & \text{elsewhere,} \end{cases} \qquad \text{or} \qquad u^-(a) = \begin{cases} 1 & \text{if } a \in [\omega - 1,\omega], \\ 0 & \text{elsewhere} \end{cases}$$

(depending on whether $\delta > 0$ or $\delta < 0$). Then a standard upper semicontinuity argument for the solution set implies that both u^+ and u^- are optimal controls for the problem with $p = p^0$. So if the regularity assumption is violated we obtain the following.

Counterfact 1. The uniqueness claim in Theorem 5.1 is false.

Since each of u^- and u^+ is optimal independently of the initial state, then

$$u(t,a) = \begin{cases} u^-(a) & \text{for } t \in [2k\omega, (2k+1)\omega), \\ u^+(a) & \text{for } t \in [(2k+1)\omega, (2k+2)\omega), \ \ k = 0,1,\ldots \end{cases}$$

is also optimal. We obtain the following.

Counterfact 2. The time-invariance claim in Theorem 5.1 is false.

Counterfact 3. There is an optimal control u such that neither $u(t,\cdot)$ nor the corresponding trajectory $(M(t,\cdot),R(t))$ converges with $t \longrightarrow \infty$.

The question remains whether a convex combination of u^- and u^+ is also a solution. The answer need not be positive because the objective value $J(u)$ need not be a concave functional of the control u (see footnote 5). We investigated this question numerically and found that $J(0.5(u^- + u^+)) << J(u^-) = J(u^+)$.

Numerical "counterfact" 4. If the regularity assumption is violated, then the maximum principle is not a sufficient condition.

6. Strong ergodicity of the optimal solution. It is accepted in the population dynamics (see, e.g., [13, 4]) that *weak ergodicity* means that two populations with different initial age-distributions and the same (time-dependent) data become asymptotically identical (although a limit may fail to exist). *Strong ergodicity* means that the age-density of the population tends to a steady-state, which is independent of the initial density, if the data of the problem are convergent at infinity. In this section we obtain a strong ergodicity result for the optimal control of problem (1.1)–(1.5). Having this result, the issue of the asymptotic convergence of the corresponding optimal trajectory becomes a classical one (cf. [12, 20]).[8] The issue of weak ergodicity of the optimal solution is more complicated, requires additional conditions, and will not be discussed in this paper.

THEOREM 6.1 (strong ergodicity of the optimal control). *Let* $(\tilde{M}_0,\tilde{\mu},\tilde{p})$ *and* (M_0,μ,p) *be two triples of data for which the standing assumptions are fulfilled. Let* (μ,p) *be time-invariant (i.e., independent of* t*) and satisfy the regularity assumption. Assume, moreover, that*

$$\lim_{T\to\infty} \|(\tilde{\mu},\tilde{p}) - (\mu,p)\|_{L_\infty([T,\infty)\times\Omega)} = 0. \tag{6.1}$$

Then for any optimal control, $\tilde{u}$*, corresponding to* $(\tilde{M}_0,\tilde{\mu},\tilde{p})$*, and for the unique control,* u*, corresponding to* (M_0,μ,p)*, it holds that*

$$\lim_{t\to\infty} \operatorname{meas}\{a:\ \tilde{u}(t,a) \neq u(a)\} = 0.$$

Proof. As shown in section 4, the standing assumptions imply that the closed adjoint system (4.2), (4.3) for the problem with "˜" has a solution $\tilde{\xi}$ in $L_\infty(D)$. This solution satisfies (4.2), (4.3) also for the data (μ,p), with an additional term

$$\delta(t,a) = (\tilde{\mu}-\mu)\tilde{\xi} - (\tilde{\mu}-\mu)(\alpha+\sigma(\tilde{\xi})) - \beta(\tilde{p}-p).$$

Since $\|\delta\|_{L_\infty([T,\infty)\times\Omega)} = 0$ due to $\tilde{\xi} \in L_\infty(D)$ and (6.1), we obtain from Lemma 4.1 that

$$\lim_{T\to\infty} \|\tilde{\xi} - \xi\|_{L_\infty([T,\infty)\times\Omega)} = 0.$$

We know from Theorem 5.1 that ξ is time-invariant. In the proof of this theorem we have seen that λ in the formulation of that theorem differs from ξ by a constant. The

[8] For example, in the stationary case, and with the optimal $u(a)$ plugged into (1.1), equation (2.4) for $R(t)$ is a convolution renewal equation and its solution is convergent with $t \longrightarrow \infty$ according to [20, Theorem 7.1, Chapter 15]. We note that the convergence of R may fail in a discrete-time model with a stationary mortality rate and a stationary recruitment rule. A trivial example is the one of recruitment only at age zero. In our considerations such behavior is prohibited by the constraint $u(t,a) \le \bar{u}(a)$.

maximum principle (Theorem 3.1) claims that for a.e. t the functions $\tilde{u}(t,\cdot)$ and $u(\cdot)$ maximize

$$\int_\Omega \tilde{\xi}(t,a)v(a)\,\mathrm{d}a \quad \text{and} \quad \int_\Omega \xi(a)v(a)\,\mathrm{d}a,$$

respectively, subject to (3.4). Moreover, for every $\delta > 0$ we have

$$\|\tilde{\xi}(t,\cdot) - \xi(\cdot)\|_{L_\infty(\Omega)} < \delta$$

for a.e. sufficiently large t. Then Lemma 5.1 implies the claim of the theorem. □

Remark 6.1. Counterfact 4 in Example 1, section 5, shows that the strong ergodicity does not hold unless an appropriate additional assumption, such as the regularity assumption, is posed.

7. The principle of bipolar recruitment. In the previous section we proved that under the regularity assumption the optimal solution with time-dependent data approaches (in the sense specified in Theorem 6.1) the solution for the limit (time-invariant) data if the data (μ, p) converge with time (in the sense of Theorem 6.1). On the other hand, in section 5 we proved that the optimal control (i.e., the recruitment density) for time-invariant data is time-invariant and (thanks to this) is characterized in terms of an ODE (see (5.3)). Therefore, in this section we study in more detail the structure of the optimal control for stationary data, focusing on the case $p(a) = -a$. In this case the meaning of the problem (1.1)–(1.5) is that two objectives are to be optimized in the Pareto sense: the number of recruitments are to be high, and the average age of the organization is to be low. As suggested in [24] these two objectives are contradictory, which makes the problem interesting. The reason for which we focus the analysis on the average age is that this specific problem is under intensive discussion in many European academies of sciences due to the considerable aging of their members [24, 14, 15]. The analysis for other reasonable productivity functions, $p(a)$, such as a concave first-increasing-then-decreasing-with-age productivity (which is reasonable, according to [30]) gives also interesting qualitative results under specific joint conditions for μ and p, which we do not present here.

PROPOSITION 7.1 (bipolar recruitment principle). *Consider problem* (1.1)–(1.5) *with* $p(t,a) = -a$. *Assume that* $\mu(t,a) = \mu(a)$ *is a time-invariant, continuously differentiable, and nondecreasing function which equals zero on some interval* $[0, a_0)$ *and is strongly convex on* $(a_0, \omega]$. *Then the optimal recruitment density,* u, *is unique, time-invariant, and independent of the initial density* M_0 *and has the following structure. There are numbers* $0 \le \theta < \tau < \omega$ *such that*

$$u(a) = \begin{cases} \bar{u}(a) & \text{for } a \in [0,\theta) \cup (\tau,\omega], \\ 0 & \text{for } a \in [\theta,\tau]. \end{cases} \tag{7.1}$$

Remark 7.1. The natural mortality rate in the ages above 30 satisfies the assumptions for μ. We stress also the remarkable fact that the second interval of recruitment is always nondegenerate: $\tau < \omega$.

Proof. We apply Theorem 5.1 and characterization (5.6) of the optimal control. The regularity assumption is apparently fulfilled, since the function $\mu(a) + dp(a) = e$ may have at most two zeros.

Since λ is twice continuously differentiable, all we have to prove is that λ has no local maxima in $(0, \omega)$.

Assume that $a \in (0, \omega)$ is a local maximizer of λ, and $\lambda(a) \geq 0$. Then

$$\lambda''(a) = \mu'(a)\lambda(a) + \beta > 0,$$

which is a contradiction. Now assume that $\lambda(a) < 0$. Since $\lambda(\omega) = 0$, there must be a local minimizer $b \in [a, \omega)$ with $\lambda(b) \leq \lambda(a)$. Then

$$0 \geq \lambda''(a) = \mu'(a)\lambda(a) + \beta \geq \mu'(b)\lambda(a) + \beta \geq \mu'(b)\lambda(b) + \beta = \lambda''(b) \geq 0.$$

Then all the inequalities must be equalities. Since $\lambda(a) < 0$, this implies $\mu'(a) = \mu'(b)$, which yields $a \in (0, a_0]$. Since μ is identically zero on $[0, a_0)$, we have $\lambda''(a) = \beta$, which is a contradiction. Thus the optimal $u(a)$ has the structure (7.1). It remains only to prove that $\tau < \omega$. If this is not the case, then $\lambda(a) \geq 0$ for all a, for which $u(a) > 0$. This contradicts (5.2). □

Now we give an intuitive argument showing that the additional assumptions in the above theorem are essential (although not necessary) for the obtained bipolar recruitment principle. If μ is a bounded approximation of the δ-function concentrated at $\omega/2$, then the age $\omega/2$ would appear as a premature retirement age, similarly to ω. Then by the same argument as in Proposition 7.1 $u(t, a)$ would be positive shortly before $\omega/2$. It would be positive also before ω (since μ is bounded). If ω is sufficiently large, then three disjoint intervals with $u(t, a) > 0$ would appear.

We stress that in practical applications the principle of bipolar recruitment should not be taken in an absolute sense, as far as usually many other criteria (different than the recruitment intensity and the average age of the members of the organization) are taken into account. The essence of the result is that if the last mentioned two criteria matter for the organization (which is, indeed, the case for many organizations such as academies of sciences or academies of awards), then they have a polarizing effect on the optimal recruitment policy: they shift the recruitment partly to younger and partly to older ages, decreasing in this way the middle-age recruitment. An interesting interpretation of this result is given by Warren Sanderson.[9] The essence is that an academy of awards should focus on awarding relatively young talents for recent outstanding achievements and, on the other hand, old persons for their life-long contributions. Detailed policy-oriented considerations and interpretations are given in the forthcoming paper [14].

Appendix. First we prove Proposition 2.1.

Proof. The proof uses the idea from [3]. This idea is substantially modified to fit to our problem; therefore, we present a detailed proof, as required by one of the referees.

As before we use the notation $D = [0, \infty) \times \Omega$ and also $D_T = [0, T] \times \Omega$. Consider a maximizing sequence $\{u_k\}$ of admissible controls such that

$$J(u_k) \geq J^* - \frac{1}{k}, \tag{A.1}$$

where $J(u_k)$ is the objective value for u_k, together with the corresponding solution (M_k, R_k) of (1.1)–(1.3), and J^* is the supremum of the objective function in the set of admissible controls. According to Lemma 2.1 the sequence $\{M_k\}$ is well defined in D, and the functions M_k are bounded uniformly in k. Then the sequence $e^{-rt}M_k \in L_1(D)$

[9] Warren Sanderson, Professor of Economics, SUNY-Stony Brook, Stony Brook, NY 11794-4384, USA. Personal communications with the authors.

is weakly relatively compact due to the Dunford–Pettis criterion.[10] Therefore, there exists a subsequence, denoted also by M_k, such that

$$e^{-rt}M_k \longrightarrow e^{-rt}M_0 \quad L_1(D)\text{-weakly.}$$

Clearly M_0 is bounded by the same constant as M_k. According to the Mazur theorem there exists a sequence

$$e^{-rt}\tilde{M}_k = \sum_{i=k}^{n_k} p_i^k e^{-rt}M_i, \quad p_i^k \geq 0, \quad \sum_{i=k}^{n_k} p_i^k = 1,$$

convergent to $e^{-rt}M_0$ in $L_1(D)$. Clearly $\tilde{M}_k$ are uniformly bounded, and $\tilde{M}_k \longrightarrow M_0$ in $L_1(D_T)$ for every $T > 0$. Define

$$\tilde{R}_k(t) = \sum_{i=k}^{n_k} p_i^k R_i(t) = \tilde{M}_k(t,\omega) + \int_\Omega \mu(t,a)\tilde{M}_k(t,a)\,\mathrm{d}a. \tag{A.2}$$

Let $\tilde{u}_0 : \Omega \mapsto \mathbf{R}$ be an arbitrary measurable function satisfying the control constraints (1.4). Let us define

$$\tilde{u}_k(t,a) = \begin{cases} \sum_{i=k}^{n_k} \frac{p_i^k R_i(t) u_i(t,a)}{\tilde{R}_k(t)} & \text{if } \tilde{R}_k(t) > 0, \\ \tilde{u}_0(a) & \text{elsewhere.} \end{cases}$$

Obviously $\tilde{u}_k$ satisfies (1.4); therefore, it is an admissible control. We have

$$\frac{\partial \tilde{M}_k}{\partial t} + \frac{\partial \tilde{M}_k}{\partial a} = \sum_{i=k}^{n_k} p_i^k(-\mu M_i + R_i u_i) = -\mu\tilde{M}_k + \sum_{i=k}^{n_k} p_i^k R_i u_i = -\mu\tilde{M}_k + \tilde{R}_k\tilde{u}_k.$$

Thus $(\tilde{u}_k, \tilde{M}_k, \tilde{R}_k)$ is an admissible control-trajectory triple, for which $\tilde{M}_k \longrightarrow M_0$ in $L_1(D_T)$ and $e^{-rt}\tilde{M}_k \longrightarrow e^{-rt}M_0$ in $L_1(D)$. Moreover, passing to a subsequence, we may assume that $\tilde{M}_k$ converges to M_0 almost everywhere and that $e^{-rt}\tilde{u}_k$ converges to some $e^{-rt}u_0$ weakly in $L_1(D)$. In the next paragraph we prove that u_0 is an admissible control.

For every measurable and bounded set $\Gamma \subset [0,\infty)$ we have that

$$\int_\Gamma \int_\Omega \tilde{u}_k(t,a)\,\mathrm{d}a\,\mathrm{d}t \longrightarrow \int_\Gamma \int_\Omega u_0(t,a)\,\mathrm{d}a\,\mathrm{d}t.$$

Since $\tilde{u}_k$ satisfies (1.4), the left-hand side equals $\mathrm{meas}(\Gamma)$; hence

$$\int_\Gamma \int_\Omega u_0(t,a)\,\mathrm{d}a\,\mathrm{d}t = \mathrm{meas}(\Gamma).$$

Since Γ is an arbitrary measurable and bounded set, this implies that u_0 satisfies the equality in (1.4) for a.e. t. The inequality in (1.4) is obviously also satisfied.

Next we prove that the sequence $\{e^{-rt}\tilde{R}_k\}$ is convergent in $L_1(0,\infty)$. According to the definition of a solution and Lemma 2.1 on a.e. characteristic line $\{(t-s,\omega-s)\}_{s\in[0,\min\{t,\omega\}]}$ the functions $\tilde{M}_k$ are Lipschitz continuous uniformly in k and t. On

[10] One can work in the space L_1 weighted by the factor e^{-rt}, but we prefer to keep this factor explicit.

the other hand, $\tilde{M}_k(t-\cdot,\omega-\cdot)$ converges pointwise to $M_0(t-\cdot,\omega-\cdot)$ for a.e. t. Then $\tilde{M}_k(t-\cdot,\omega-\cdot)$ converges to $M_0(t-\cdot,\omega-\cdot)$ uniformly; hence the latter function is Lipschitz with the same constant as $\tilde{M}_k(t-\cdot,\omega-\cdot)$. Then $M_0(t,\omega)$ is well defined in $L_\infty(0,\infty)$. Moreover, $\tilde{M}_k(\cdot,\omega)$ converges to $M_0(\cdot,\omega)$ almost everywhere; hence $e^{-rt}\tilde{M}_k(\cdot,\omega) \longrightarrow e^{-rt}M_0(\cdot,\omega)$ in $L_1(0,\infty)$. Due to (A.2), the sequence $\tilde{R}_k(t)$ converges almost everywhere to

$$R_0(t) = M_0(t,\omega) + \int_0^\omega \mu(t,a)M_0(t,a)\,\mathrm{d}a;$$

hence $e^{-rt}\tilde{R}_k$ converges to $e^{-rt}R_0$ in $L_1(0,\infty)$. To verify that (u_0, M_0, R_0) satisfies (1.1) we integrate in a the representation (2.2) for the solution triple $(\tilde{u}_k, \tilde{M}_k, \tilde{R}_k)$ on a measurable set $\Gamma \subset \Omega$. Due to the established properties of this sequence we may pass to the limit, (u_0, M_0, R_0). Since Γ is arbitrary, we obtain that (u_0, M_0, R_0) satisfies (2.2) for a.e. (t,a); hence it is a solution of (1.1).

From the convexity of A with respect to (M,w) we have

$$\begin{aligned}
J(\tilde{u}_k) &= \int_0^\infty e^{-rt}\left[\alpha\tilde{R}_k(t) + \beta\int_\Omega A(t,a,\tilde{M}_k(t,a),\tilde{R}_k(t)\tilde{u}_k(t,a))\,\mathrm{d}a\right]\mathrm{d}t\\
&= \int_0^\infty e^{-rt}\Bigg[\alpha\sum_{i=k}^{n_k} p_i^k R_i(t)\\
&\qquad + \beta\int_\Omega A\Bigg(t,a,\sum_{i=k}^{n_k} p_i^k M_i(t,a),\sum_{i=k}^{n_k} p_i^k R_i(t)u_i(t,a)\Bigg)\mathrm{d}a\Bigg]\mathrm{d}t\\
&\geq \sum_{i=k}^{n_k} p_i^k J(u_i) \geq \sum_{i=k}^{n_k} p_i^k\left(J^* - \frac{1}{i}\right) \geq J^* - \frac{1}{k}.
\end{aligned}$$

Finally, from the upper semicontinuity of the objective function with respect to u in the $L_1(T)$-weak topology (due to the concavity of A in w), the Lipschitz continuity of A in (M,w), the L_1-convergence of $\tilde{M}_k$ and $\tilde{R}_k$, and the boundedness of A in the domain of integration below, we obtain for every $T>0$

$$\begin{aligned}
J^* &\leq \limsup_k\left(J(\tilde{u}_k) + \frac{1}{k}\right) = \limsup_k J(\tilde{u}_k)\\
&= \limsup_k \int_0^\infty e^{-rt}\left[\alpha\tilde{R}_k(t) + \beta\int_\Omega A(t,a,\tilde{M}_k(t,a),\tilde{R}_k(t)\tilde{u}_k(t,a))\,\mathrm{d}a\right]\mathrm{d}t\\
&= \int_0^\infty e^{-rt}\alpha R_0(t) + \beta\limsup_k\int_0^\infty\int_\Omega e^{-rt}A(t,a,M_0(t,a),R_0(t)\tilde{u}_k(t,a))\,\mathrm{d}a\,\mathrm{d}t\\
&\leq \int_0^\infty e^{-rt}\alpha R_0(t) + \beta\limsup_k\int_0^T\int_\Omega e^{-rt}A(t,a,M_0(t,a),R_0(t)\tilde{u}_k(t,a))\,\mathrm{d}a\,\mathrm{d}t\\
&\qquad + \frac{\beta}{r}e^{-rT}C\\
&\leq \int_0^\infty e^{-rt}\alpha R_0(t) + \beta\int_0^T\int_\Omega e^{-rt}A(t,a,M_0(t,a),R_0(t)u_0(t,a))\,\mathrm{d}a\,\mathrm{d}t + \frac{\beta}{r}e^{-rT}C\\
&\leq J(u_0) + \frac{2\beta}{r}e^{-rT}C.
\end{aligned}$$

Since T is an arbitrary positive number, we obtain that $J^* \leq J(u_0)$; hence u_0 is an optimal control. □

Below we prove Lemma 3.1.

Proof. The proof is split into several steps.

Step 1. Let us fix a function $\eta \in L_\infty(0,\infty)$ and a positive number T and consider (3.1) in the domain $D_T = [0,T] \times \Omega$, with the side conditions (3.3) and

$$\xi(T,a) = 0, \quad a \in \Omega. \tag{A.3}$$

This equation is linear and can be solved along the characteristics, which results in the following explicit formula:

$$\begin{aligned}\xi(t,a) &= \varphi(t,a,t+\omega-a)\chi_{[0,T]}(t+\omega-a)\eta(t+\omega-a)\\ &\quad + \int_t^T \varphi(t,a,\tau)\chi_\Omega(a-t+\tau)[\mu(\tau,a-t+\tau)\eta(\tau) - \beta A_M(\tau,a-t+\tau)]\,\mathrm{d}\tau,\end{aligned} \tag{A.4}$$

where here and below the argument (t,a) of the function A_M is a substitution for $(t,a,M(t,a),u(t,a))$, χ_S is the indicator function of the set S, and

$$\varphi(t,a,\tau) = e^{-\int_t^\tau (r+\mu(\theta,a-t+\theta))\,\mathrm{d}\theta}. \tag{A.5}$$

We shall determine $\eta(t) = \eta_T(t)$ in such a way that (3.2) is also fulfilled. Due to formula (A.4) for ξ, (3.2) becomes

$$\begin{aligned}\eta(t) &= \alpha + \int_\Omega \varphi(t,a,t+\omega-a)\chi_{[0,T]}(t+\omega-a)\eta(t+\omega-a)u(t,a)\,\mathrm{d}a\\ &+ \int_\Omega\int_t^T \varphi(t,a,\tau)\chi_\Omega(a-t+\tau)[\mu(\tau,a-t+\tau)\eta(\tau) - \beta A_M(\tau,a-t+\tau)]u(t,a)\,\mathrm{d}\tau\,\mathrm{d}a\\ &+\beta\int_\Omega A_w(t,a)u(t,a)\,\mathrm{d}a.\end{aligned}$$

Changing the variable $t+\omega-a=\tau$ in the first integral and changing the order of integration in the second one, we obtain that η has to satisfy the integral equation

$$\eta(t) = f_T(t) + \int_t^T K(t,\tau)\eta(\tau)\,\mathrm{d}\tau, \tag{A.6}$$

where

$$\begin{aligned}f_T(t) &= \alpha - \beta\int_t^T\int_\Omega \varphi(t,a,\tau)\chi_\Omega(a-t+\tau)A_M(\tau,a-t+\tau)u(t,a)\,\mathrm{d}a\,\mathrm{d}\tau\\ &\quad +\beta\int_\Omega A_w(t,a)u(t,a)\,\mathrm{d}a,\\ K(t,\tau) &= \varphi(t,t+\omega-\tau,\tau)\chi_{[0,t+\omega]}(\tau)u(t,t+\omega-\tau)\\ &\quad + \int_\Omega \varphi(t,a,\tau)\chi_\Omega(a-t+\tau)\mu(\tau,a-t+\tau)u(t,a)\,\mathrm{d}a.\end{aligned}$$

Clearly, (A.6) is a Volterra equation of the second kind (inverse in time); therefore, it has a unique solution $\eta_T \in L_\infty(0,T)$.

Step 2. Next we shall prove uniform boundedness of $\eta_T(t)$ when $T \longrightarrow \infty$. First, since $\varphi(t,a,\tau) \le 1$ and u satisfies (1.4), we have

$$|f_T(t)| \le \alpha + \beta\bar{A}\int_t^{T(t)}\int_0^{t+\omega-\tau} u(t,a)\,\mathrm{d}a\,\mathrm{d}\tau + \beta\bar{A} \le \alpha + \beta\omega\bar{A} + \beta\bar{A} =: c_0, \tag{A.7}$$

where $T(t) = \min\{T, t+\omega\}$ and $\bar{A}$ is a bound for the derivatives A_M and A_w. Moreover, obviously

$$K(t,\tau) \le \bar{u} + \omega\bar{\mu} =: c_1. \tag{A.8}$$

Define the operator $\mathcal{F}_T : L_\infty(0,T) \mapsto L_\infty(0,T)$ by

$$\mathcal{F}_T(\eta)(t) = \int_t^T K(t,\tau)\eta(\tau)\,\mathrm{d}\tau.$$

Since K is nonnegative we have

$$\|\mathcal{F}_T(\eta)\|_\infty \le \operatorname*{ess\,sup}_{t\in[0,T]} \int_t^T K(t,\tau)\,\mathrm{d}\tau \|\eta\|_\infty. \tag{A.9}$$

For $t \le T-\omega$ we have

$$\begin{aligned}\int_t^T K(t,\tau)\,\mathrm{d}\tau = &\int_t^{t+\omega} \varphi(t,t+\omega-\tau,\tau)u(t,t+\omega-\tau)\,\mathrm{d}\tau \\ &+ \int_t^{t+\omega}\int_0^{t+\omega-\tau} \varphi(t,a,\tau)\mu(\tau,a-t+\tau)u(t,a)\,\mathrm{d}a\,\mathrm{d}\tau.\end{aligned}$$

Consider the expression

$$\begin{aligned}G(t) &= \int_t^{t+\omega} \frac{\partial}{\partial\tau}\int_0^{t+\omega-\tau} \varphi(t,a,\tau)u(t,a)\,\mathrm{d}a\,\mathrm{d}\tau \\ &= -\int_t^{t+\omega}\left[\varphi(t,t+\omega-\tau,\tau)u(t,t+\omega-\tau) - \int_0^{t+\omega-\tau}\frac{\partial\varphi}{\partial\tau}(t,a,\tau)u(t,a)\,\mathrm{d}a\right]\mathrm{d}\tau \\ &= -\int_t^{t+\omega}\Bigg[\varphi(t,t+\omega-\tau,\tau)u(t,t+\omega-\tau) \\ &\qquad + \int_0^{t+\omega-\tau}\varphi(t,a,\tau)(r+\mu(\tau,a-t+\tau))u(t,a)\,\mathrm{d}a\Bigg]\mathrm{d}\tau.\end{aligned}$$

Hence,

$$\int_t^T K(t,\tau)\,\mathrm{d}\tau = -G(t) - r\int_t^{t+\omega}\int_0^{t+\omega-\tau}\varphi(t,a,\tau)u(t,a)\,\mathrm{d}a\,\mathrm{d}\tau.$$

On the other hand, having in mind (1.4) and that $\varphi(t,a,t) = 1$ we obtain that

$$G(t) := \int_0^{t+\omega-\tau}\varphi(t,a,\tau)u(t,a)\,\mathrm{d}a\ \Big|_t^{t+\omega} = -1.$$

Thus

$$\int_t^T K(t,\tau)\,\mathrm{d}\tau \le 1 - r\int_t^{t+\omega}\int_0^{t+\omega-\tau}\varphi(t,a,\tau)u(t,a)\,\mathrm{d}a\,\mathrm{d}\tau.$$

We estimate

$$\begin{aligned}&r\int_t^{t+\omega}\int_0^{t+\omega-\tau}\varphi(t,a,\tau)u(t,a)\,\mathrm{d}a\,\mathrm{d}\tau \ge r\int_t^{t+\omega}\int_0^{t+\omega-\tau} e^{-(\tau-t)(r+\bar{\mu})}u(t,a)\,\mathrm{d}a\,\mathrm{d}\tau \\ &\ge re^{-\omega(r+\bar{\mu})}\int_0^\omega\int_t^{t+\omega-a}\mathrm{d}\tau u(t,a)\,\mathrm{d}a = re^{-\omega(r+\bar{\mu})}\int_0^\omega(\omega-a)u(t,a)\,\mathrm{d}a.\end{aligned}$$

The value of the last integral is at least

$$d := \int_{\omega-s}^{\omega} (\omega - a)\bar{u}(a)\,\mathrm{d}a > 0,$$

where s is determined from the equality

$$\int_{\omega-s}^{\omega} \bar{u}(a)\,\mathrm{d}a = 1.$$

Thus for $t \le T - \omega$

$$\int_t^T K(t,\tau)\,\mathrm{d}\tau \le 1 - \gamma, \tag{A.10}$$

where

$$0 < \gamma := re^{-\omega(r+\bar{\mu})}d.$$

Due to (A.7) and (A.8) it is standard to prove that the solution of the Volterra equation (A.6) is bounded on the interval $[T-\omega, T]$, uniformly in T, by a constant c_2. Combining this with (A.10) and using (A.9) we obtain

$$|\eta_T(t)| \le c_0 + \|\mathcal{F}_T(\eta)\| \le c_0 + \max\{(1-\gamma)\|\eta_T\|, c_1c_2\}.$$

Hence,

$$|\eta_T(t)| \le \max\left\{\frac{c_0}{\gamma}, c_0 + c_1c_2\right\}.$$

This proves the uniform boundedness of η_T in L_∞.

Step 3. Now we prove the following property: for every $\varepsilon > 0$ and $T > 0$ there exists $\bar{T} > T$ such that for every $T', T'' \ge \bar{T}$ it holds that

$$\|\eta_{T'} - \eta_{T''}\|_{L_\infty([0,T])} \le \varepsilon. \tag{A.11}$$

Let us take $T'' > T' \ge \bar{T}$, where $\bar{T}$ will be defined later, assuming now only that $\bar{T} \ge T + \omega$.

Denote $\Delta(t) = \eta_{T''}(t) - \eta_{T'}(t)$. For $t \le \bar{T} - \omega$ it holds that $f_{T'}(t) = f_{T''}(t)$ and for $\tau > t + \omega$ it holds that $K(t,\tau) = 0$. Therefore, for $t \le \bar{T} - \omega$ we have that

$$\begin{aligned}\Delta(t) &= f_{T''}(t) - f_{T'}(t) + \int_t^{T''} K(t,\tau)\eta_{T''}(\tau)\,\mathrm{d}\tau - \int_t^{T'} K(t,\tau)\eta_{T'}(\tau)\,\mathrm{d}\tau \\ &= \int_t^{t+\omega} K(t,\tau)\Delta(\tau)\,\mathrm{d}\tau.\end{aligned}$$

Denote $t_k = \bar{T} - k\omega$, $k = 0, \dots,$ and for the first $k = \bar{k}$ for which $t_k \le 0$ we redefine $t_{\bar{k}} = 0$. Then consider

$$\Delta_k = \operatorname{ess\,sup}\{\Delta(t) :\ t \in [t_{k+1}, t_k]\}, \quad k = 0, \dots, \bar{k}.$$

From Step 2 of the proof we know that $\Delta_0 \le c$, where c is independent of $T, \bar{T}, T', T''$. Moreover,

$$\begin{aligned}\Delta_k &= \operatorname*{ess\,sup}_{t\in[t_{k+1},t_k]} \Delta(t) \le \operatorname*{ess\,sup}_{t\in[t_{k+1},t_k]} \int_t^{t_k} K(t,\tau)\Delta(\tau)\,\mathrm{d}\tau + \int_{t_k}^{t+\omega} K(t,\tau)\Delta(\tau)\,\mathrm{d}\tau \\ &\le \max\{\Delta_k, \Delta_{k-1}\} \int_t^{t+\omega} K(t,\tau)\,\mathrm{d}\tau \le (1-\gamma)\max\{\Delta_k, \Delta_{k-1}\},\end{aligned}$$

which implies that

$$\Delta_k \le (1-\gamma)\Delta_{k-1} \le \cdots \le (1-\gamma)^k c.$$

Now, given $\varepsilon > 0$ and T, we choose $\bar{T}$ in such a way that for $k > (\bar{T} - T)/\omega$ it holds that $(1-\gamma)^k c < \varepsilon$. Then we have

$$|\Delta(t)| \le \varepsilon \quad \text{for} \quad t \le T.$$

Step 4. The uniform boundedness of η_T and (A.4) imply that the solution ξ_T of (3.1) on D_T with $\eta = \eta_T$ is also bounded uniformly in T.

Now we shall prove that ξ_T has the same property as that established in Step 5 for η_T: for every $\varepsilon > 0$ and $T > 0$ there exists $\bar{T} > T$ such that for every $T', T'' \ge \bar{T}$ it holds that

$$\|\xi_{T'} - \xi_{T''}\|_{L_\infty(D_T)} \le \varepsilon. \tag{A.12}$$

Let $\bar{T}$, T', and T'' be chosen as in Step 3, but for the numbers $T+\omega$ and $\varepsilon/(1+\omega\bar{\mu})$ (instead of T and ε). Then we have

$$|\Delta(t)| = |\eta_{T''}(t) - \eta_{T'}(t)| \le \frac{\varepsilon}{(1+\omega\bar{\mu})} \quad \text{for} \ \ t \le T+\omega.$$

Using (A.4) we obtain that for $t \le T$ and $a \in [0, \omega]$

$$|\xi_{T''}(t,a) - \xi_{T'}(t,a)| \le \left(1 + \int_t^{t+\omega} \bar{\mu}\, \mathrm{d}\tau\right) \|\Delta\|_{L_\infty(0,T+\omega)} \le \varepsilon.$$

Step 5. The properties of η_T and ξ_T proven in steps 3 and 4 imply that the sequence of restrictions $\{(\xi_{T_N}, \eta_{T_N})_{|[0,T]}\}_N$ (with $T_N \to +\infty$) is fundamental. From the completeness of L_∞ the limit exists, and letting $T \to \infty$, we extend it to $[0, \infty)$ (notice that the extension remains in L_∞ due to the uniform boundedness of ξ_{T_N} and η_{T_N}). For this limit function $(\xi, \eta) \in L_\infty$ it holds that for every $\varepsilon > 0$ and every $T > 0$ one can find $\bar{T} > T$ such that for every $\tilde{T} \ge \bar{T}$

$$\|\eta - \eta_{\tilde{T}}\|_{L_\infty([0,T])} + \|\xi - \xi_{\tilde{T}}\|_{L_\infty(D_T)} \le \varepsilon.$$

From here it easily follows that ξ is a solution of (3.1) in D, and η satisfies (3.2) almost everywhere in $[0, \infty)$.

Step 6. It remains to prove uniqueness of the solution. We skip this proof since it is identical to the proof of uniqueness for the closed adjoint system given in Corollary 4.1. ∎

STABILITY AND CONVERGENCE OF EULER'S METHOD FOR STATE-CONSTRAINED DIFFERENTIAL INCLUSIONS*

ROBERT BAIER†, ILYES AÏSSA CHAHMA‡, AND FRANK LEMPIO†

Abstract. A discrete stability theorem for set-valued Euler's method with state constraints is proved. This theorem is combined with known stability results for differential inclusions with so-called smooth state constraints. As a consequence, order of convergence equal to 1 is proved for set-valued Euler's method, applied to state-constrained differential inclusions.

Key words. Filippov theorem, set-valued Euler's method, differential inclusions with state constraints, stability and convergence of discrete approximations

DOI. 10.1137/060661867

1. Introduction and preliminaries.

Differential inclusions appear in various fields of applications, e.g., in the study of (deterministic) perturbations of differential equations, in dynamical systems with discontinuous system equations, optimal control problems, viability theory, and especially climate impact research; cf., e.g., [2, 3, 14, 10, 1, 6].

An important subclass consists of differential inclusions with additional monotonicity properties which, in general, guarantee uniqueness of the solution of the initial value problem (cf., e.g., [2, 3, 4, 5, 20, 21]). Differential inclusions with Lipschitz right-hand sides (with respect to Hausdorff distance) in the usual sense form another important subclass. This latter subclass is the principal focus of this paper, which deals with stability and convergence properties of set-valued Euler's method for differential inclusions with state constraints.

The main result of this paper is the proof of a discrete stability theorem for a difference inclusion with state constraints in section 3, which serves as a basis for the convergence analysis for set-valued Euler's method in section 4. Intrinsically, this result is a variant of the Gronwall–Filippov–Wazewski theorem and, in fact, an existence theorem as well. Whereas the proofs for explicit difference inclusions with appropriate Lipschitz properties offer no difficulties, additional state constraints cause essential problems.

Fortunately, remarkable stability results for state-constrained differential inclusions have become available in the literature; cf. [22, 15, 17, 18, 7, 8, 23]. But discrete analogues for the approximation of all feasible trajectories under comparably weak conditions are still missing. Therefore, we concentrate on the so-called smooth case, where the state constraint is described by a single scalar inequality, resp., by a smooth signed distance function. This case has already been treated in [6], but contrary to [6] we allow time-dependent state constraints and improve the final error estimate.

In section 3 we give a rather complete analysis of the discrete situation, which heavily relies on the proof strategy in [15, Theorem 4.1] for the continuous problem.

In some respects, the discrete analysis is rather technical, and some additional difficulties have to be overcome. In particular, a discrete solution might not hit exactly the boundary of the state constraints, neighboring continuous solutions of feasible discrete solutions could violate the state constraints outside the grid, and consequently additional error terms appear in Taylor expansions.

However, we want to urgently emphasize the fact that only both stability results, the continuous *and* the discrete one together, will give us convergence results for discrete approximations of state-constrained differential inclusions. This is the essential subject of section 4, where order of convergence $\mathcal{O}(h)$ with respect to the step-size h is proved for set-valued Euler's method in the presence of state constraints.

In section 5, the results are applied to a differential inclusion resulting from a state-constrained bilinear control problem, which originally served as an academic test example for unconstrained problems and was communicated to us by Petar Kenderov. The order of convergence of the reachable sets of Euler's difference inclusion with state constraints to the corresponding reachable sets of the differential inclusion is visualized by computer tests. For a more detailed discussion and applications to climate impact research, see [6].

Hence, the main objective of this paper is the discrete approximation of the *whole* solution set of state-constrained differential inclusions, especially the whole feasible set of state-constrained optimal control problems. But, in addition, the authors are convinced that this methodology, if combined with sufficient optimality conditions, could turn out to be another conceptual approach to order of convergence proofs for numerical methods for the direct computation of optimal solutions; cf., e.g., [13, 12].

Naturally, convergence of the whole set of discrete solutions to the solution set of the continuous differential inclusion implies the convergence of the corresponding reachable sets. Hence, at least for set-valued Euler's method, we need not distinguish between these two aspects, but in this connection see the papers [24, 25], which extend the results in [11] for set-valued Euler's method to Runge–Kutta methods of order at least equal to 2 for problems without state constraints.

We denote by $\mathrm{AC}(I)$ the set of all absolutely continuous functions $y : I \to \mathbb{R}^n$ and by $\Theta : I \rightrightarrows \mathbb{R}^n$ a set-valued map with nonempty subsets of $\mathbb{R}^n$ as images.

PROBLEM 1.1. *Given an interval $I = [t_0, T]$, a nonempty set $Y_0 \subset \mathbb{R}^n$, and set-valued maps $F : I \times \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ and $\Theta : I \rightrightarrows \mathbb{R}^n$ with nonempty images, find all absolutely continuous solutions $y(\cdot)$ of the state-constrained differential inclusion (DIC)*

$$y'(t) \in F(t, y(t)) \qquad (\text{a.e. } t \in I), \tag{1.1}$$

$$y(t) \in \Theta(t) \qquad (t \in I), \tag{1.2}$$

$$y(t_0) = y_0 \in Y_0. \tag{1.3}$$

Clearly, we must have $y_0 \in \Theta(t_0)$ as well.

The unconstrained problem (DI) is given by (1.1), (1.3). *The set of solutions of (DI) and (DIC) is denoted by $\mathcal{Y}[T, t_0, Y_0]$, resp., $\mathcal{Y}^{\Theta}[T, t_0, Y_0]$.*

ALGORITHM 1.2. *Euler's method for (DIC) in Problem* 1.1 *with number of subintervals $N \in \mathbb{N}$ and step-size $h = \frac{T-t_0}{N}$ is given by*

$$\mathcal{Y}_N^{\Theta}[t_0, t_0, Y_0] := Y_0 \cap \Theta(t_0), \tag{1.4}$$

$$\mathcal{Y}_N^{\Theta}[t_{j+1}, t_0, Y_0] := \bigcup_{\eta_j \in \mathcal{Y}_N^{\Theta}[t_j, t_0, Y_0]} \big(\eta_j + hF(t_j, \eta_j)\big) \cap \Theta(t_{j+1}) \tag{1.5}$$

for $j = 0, \dots, N-1$.

Problem (DDIC) describes the solution of (1.4)–(1.5)*; its set of solutions is denoted by* $\mathcal{Y}_N^\Theta[T, t_0, Y_0]$. *In the absence of state constraints, the problem is called (DDI) and* $\mathcal{Y}_N[T, t_0, Y_0]$ *denotes the corresponding set of solutions.*

To measure distances, we define for $\eta = (\eta_j)_{j=0,\dots,N} \in \mathcal{Y}_N^\Theta[T, t_0, Y_0]$,

$$\operatorname{dist}_\infty(y(\cdot), \mathcal{Y}_N^\Theta[T, t_0, Y_0]) := \inf\left\{ \sup_{j=0,\dots,N} \|y(t_j) - \eta_j\| \,:\, \eta \in \mathcal{Y}_N^\Theta[T, t_0, Y_0] \right\},$$

$$\operatorname{dist}_\infty(\eta, \mathcal{Y}^\Theta[T, t_0, Y_0]) := \inf\left\{ \sup_{j=0,\dots,N} \|\eta_j - y(t_j)\| \,:\, y(\cdot) \in \mathcal{Y}^\Theta[T, t_0, Y_0] \right\},$$

$$\begin{aligned} \mathrm{d}_{H,\infty}(\mathcal{Y}^\Theta[T, t_0, Y_0], \mathcal{Y}_N^\Theta[T, t_0, Y_0]) := \max\Bigg\{ & \sup_{y(\cdot)\in\mathcal{Y}^\Theta[T,t_0,Y_0]} \operatorname{dist}_\infty(y(\cdot), \mathcal{Y}_N^\Theta[T, t_0, Y_0]), \\ & \sup_{\eta\in\mathcal{Y}_N^\Theta[T,t_0,Y_0]} \operatorname{dist}_\infty(\eta, \mathcal{Y}^\Theta[T, t_0, Y_0]) \Bigg\}. \end{aligned}$$

Here, the Euclidean vector norm on $\mathbb{R}^n$ is denoted by $\|\cdot\|$. For a subset $U \subset \mathbb{R}^n$, we denote by $\operatorname{dist}(x, U)$ the infimum of all Euclidean distances of the point $x \in \mathbb{R}^n$ to the points in U. We denote by $\mathrm{d}(U, V) = \sup_{u\in U} \operatorname{dist}(u, V)$ the one-sided Hausdorff distance from a subset $U \subset \mathbb{R}^n$ to another subset $V \subset \mathbb{R}^n$, and $\mathrm{d_H}(U, V)$ is the Hausdorff-distance defined as

$$\mathrm{d_H}(U, V) = \max\{\mathrm{d}(U, V), \mathrm{d}(V, U)\}.$$

We pose some of the following basic assumptions on the right-hand side:

(H1) F satisfies a linear growth condition, i.e., there exists $C \geq 0$ with

$$\|F(t, x)\| := \sup_{y\in F(t,x)} \|y\| \leq C(\|x\| + 1) \quad (t \in I,\, x \in \mathbb{R}^n).$$

(H2) F has nonempty, compact, convex images in $\mathbb{R}^n$.

(H3) F is Lipschitz in (t, x) for all $t \in I$, $x \in \mathbb{R}^n$ with constant $L \geq 0$, i.e.,

$$\mathrm{d_H}(F(s, x), F(t, y)) \leq L \cdot (|s - t| + \|x - y\|) \quad (s, t \in I,\, x, y \in \mathbb{R}^n).$$

The linear growth condition (H1) gives locally a boundedness of the images $F(t, x)$. A sufficient condition for (H1) is (H3) together with one bounded set $F(\widehat{t}, \widehat{x})$ (or (H2)). Condition (H2) is needed, since we want to apply the results from [11] for the unconstrained case. For practical applications, the Lipschitz condition could be restricted onto a compact set in which all values of all trajectories remain.

The following assumptions are required for the state constraints:

(C1) $\Theta : I \rightrightarrows \mathbb{R}^n$ has nonempty images explicitly given as

$$\Theta(t) := \{x \in \mathbb{R}^n \,:\, g(t, x) \leq 0\}$$

by a single scalar function $g : I \times \mathbb{R}^n \to \mathbb{R}$ which fulfills $g(\cdot, \cdot) \in \mathcal{C}^{1,L}(I \times \mathbb{R}^n)$, i.e., the derivative $\nabla g(\cdot, \cdot)$ is Lipschitz on $I \times \mathbb{R}^n$.
Furthermore, points $x \in \partial\Theta(t)$ with $t \in I$ are characterized by $g(t, x) = 0$.

(C2) The boundary of $\Theta(\cdot)$ fulfills the "strict inwardness condition" (cf. [15, 17, 18, 7]), i.e., there exists $\alpha, \mu > 0$ such that for all $(t, x) \in B_\mu(\operatorname{graph} \partial\Theta(\cdot)) \cap (I \times \mathbb{R}^n)$ it follows that

$$\min_{v\in F(t,x)} \left\langle \nabla g(t, x), \binom{1}{v} \right\rangle \leq -\alpha,$$

where

$$B_\mu(\operatorname{graph}\partial\Theta(\cdot)) = \left\{ \binom{t}{x} \in \mathbb{R}^{1+n} \,:\, \operatorname{dist}\left(\binom{t}{x}, \operatorname{graph}\partial\Theta(\cdot)\right) \le \mu \right\}.$$

From (C1) it follows that the images of $\Theta(\cdot)$ are closed. Existence of viable solutions could be proved under weaker assumptions; in this respect, cf. [16]. But since we are interested mainly in stability results, which require stronger assumptions anyway and imply existence as well, we will not discuss weaker existence results for the continuous and discrete case in this paper.

For the discrete situation in section 2, it is sufficient to pose weaker assumptions on $F(\cdot,\cdot)$ as follows:

(H1′) F satisfies a linear growth condition in integrable form, i.e., there exists a nonnegative function $C(\cdot) \in \mathcal{L}_1(I,\mathbb{R})$ with

$$\|F(t,x)\| := \sup_{y\in F(t,x)} \|y\| \le C(t)\cdot(\|x\|+1) \quad (t\in I,\, x\in\mathbb{R}^n).$$

(H2′) F has nonempty, closed images in $\mathbb{R}^n$.

(H3′) F is $L(t)$-Lipschitz in x for all $t\in I$ with $L(\cdot)\in\mathcal{L}_1(I,\mathbb{R})$, i.e.,

$$\mathrm{d_H}(F(t,x),F(t,y)) \le L(t)\cdot\|x-y\| \quad (x,y\in\mathbb{R}^n).$$

Usually, uniform boundedness of $C(\cdot)$ is assumed in (H1′), i.e., (H1). The same remark applies to $L(\cdot)$ in (H3′).

2. Stability for the unconstrained case. The essential stability result for differential inclusions without state constraints is given by the following theorem (for a complete proof, cf. [9, Lemma 8.3]).

THEOREM 2.1 (Gronwall–Filippov–Wazewski theorem). *Let $F(\cdot,\cdot)$ have closed images in $\mathbb{R}^n$, and let $Y_0\subset\mathbb{R}^n$ be nonempty and closed. For a given $\eta(\cdot)\in\mathrm{AC}(I)$ with*

$$\begin{aligned} \operatorname{dist}(\eta(t_0),Y_0) &\le \delta_0,\\ \operatorname{dist}(\eta'(t),F(t,\eta(t))) &\le \delta(t) \quad (\textit{a.e. } t\in I), \end{aligned}$$

with $\delta_0\ge 0$ and nonnegative $\delta(\cdot)\in\mathcal{L}_1(I,\mathbb{R})$, assume that

$$S := \{(t,x)\in I\times\mathbb{R}^n \,:\, \|x-\eta(t)\|\le\gamma\} \subset \operatorname{dom}(F)$$

for some $\gamma>\delta_0$. Let $F(\cdot,x)$ be measurable in t for all $x\in S$ and fulfill (H3′) *on S.*

Let $z(\cdot)$ be the solution of

$$\begin{aligned} z'(t) &= L(t)z(t)+\delta(t) \quad (\textit{a.e. } t\in I),\\ z(t_0) &= \delta_0. \end{aligned}$$

Then for all $\widetilde{T}\in I$ with $z(\widetilde{T})\le\gamma$ there exists a solution $y(\cdot)$ on $[t_0,\widetilde{T}]\subset I$ with

$$\begin{aligned} y'(t) &\in F(t,y(t)) \qquad (\textit{a.e. } t\in[t_0,\widetilde{T}]),\\ y(t_0) &= y_0\in Y_0, \end{aligned}$$

fulfilling the estimates

$$\begin{aligned} \|y(t)-\eta(t)\| &\le z(t) \qquad (t\in[t_0,\widetilde{T}]),\\ \|y'(t)-\eta'(t)\| &\le L(t)z(t)+\delta(t) \quad (\textit{a.e. } t\in[t_0,\widetilde{T}]), \end{aligned}$$

where

$$z(t) = e^{\int_{t_0}^{t} L(\sigma)\,d\sigma} \cdot \delta_0 + \int_{t_0}^{t} e^{\int_{\tau}^{t} L(\sigma)\,d\sigma} \cdot \delta(\tau)\,d\tau.$$

It will turn out in section 3 that Theorem 2.1, together with the following discrete analogue, is essential for the proof of stability for state-constrained differential inclusions.

THEOREM 2.2 (discrete Gronwall–Filippov–Wazewski theorem). *Let* $F : [t_0, T] \times \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ *fulfill* (H2′) *and* (H3′).

Consider the discrete difference inclusion

$$\frac{y_{k+1} - y_k}{h} \in F(t_k, y_k) \qquad (k = 0, \dots, N-1), \tag{2.1}$$

$$y_0 \in Y_0 \tag{2.2}$$

for a given $N \in \mathbb{N}$, *the step-size* $h = \frac{T - t_0}{N}$, *and a closed, nonempty starting set* $Y_0 \subset \mathbb{R}^n$.

Let $(\eta_k)_{k=0,\dots,N}$ *be a grid function with values in* $\mathbb{R}^n$ *and*

$$\begin{aligned} \operatorname{dist}(\eta_0, Y_0) &\le \delta_0, \\ \operatorname{dist}\left(\frac{\eta_{k+1} - \eta_k}{h}, F(t_k, \eta_k)\right) &\le \delta_{k+1} \qquad (k = 0, \dots, N-1). \end{aligned}$$

Abbreviate $L_k = L(t_k)$, $k = 0, \dots, N$, *and let* $(z_k)_{k=0,\dots,N} \subset \mathbb{R}$ *be the solution of*

$$\begin{aligned} \frac{z_{k+1} - z_k}{h} &= L_k z_k + \delta_{k+1} \qquad (k = 0, \dots, N-1), \\ z_0 &= \delta_0. \end{aligned} \tag{2.3}$$

Then there exists a solution $(y_k)_{k=0,\dots,N}$ *of the discrete problem* (2.1)–(2.2) *with*

$$\begin{aligned} \|\eta_k - y_k\| &\le z_k \qquad (k = 0, \dots, N), \\ \left\| \frac{\eta_{k+1} - \eta_k}{h} - \frac{y_{k+1} - y_k}{h} \right\| &\le L_k z_k + \delta_{k+1} \qquad (k = 0, \dots, N-1). \end{aligned}$$

Proof. Since $Y_0 \subset \mathbb{R}^n$ is nonempty, there exists $y \in Y_0$ with $\operatorname{dist}(\eta_0, Y_0) \le \|\eta_0 - y\| =: r$. Hence, the best approximation y_0 of η_0 in Y_0 coincides with that in the compact set $Y_0 \cap B_r(\eta_0)$, i.e.,

$$\|\eta_0 - y_0\| = \operatorname{dist}(\eta_0, Y_0) \le \delta_0 = z_0.$$

Assume that the assertion is true for $j = 0, \dots, k$, $k \in \{0, \dots, N-1\}$. Arguing as in the case $k = 0$, there exists $\xi_k^y \in F(t_k, y_k)$ for $\xi_k^\eta = \frac{1}{h}(\eta_{k+1} - \eta_k)$ with

$$\begin{aligned} &\|\xi_k^\eta - \xi_k^y\| = \operatorname{dist}(\xi_k^\eta, F(t_k, y_k)), \\ &\|\xi_k^\eta - \xi_k^y\| \le \operatorname{dist}(\xi_k^\eta, F(t_k, \eta_k)) + \mathrm{d_H}(F(t_k, \eta_k), F(t_k, y_k)) \le L_k \|\eta_k - y_k\| + \delta_{k+1}. \end{aligned}$$

Setting $y_{k+1} := y_k + h\xi_k^y$ yields

$$\begin{aligned} \|\eta_{k+1} - y_{k+1}\| &= \|(\eta_k + h\xi_k^\eta) - (y_k + h\xi_k^y)\| \le \|\eta_k - y_k\| + h\|\xi_k^\eta - \xi_k^y\| \\ &\le (1 + hL_k)\|\eta_k - y_k\| + h\delta_{k+1} \le (1 + hL_k)z_k + h\delta_{k+1} = z_{k+1}. \end{aligned}$$

∎

The explicit solution formula for the linear difference equation (2.3) yields immediately the following more specific estimates of the growth of the error bounds z_k $(k = 0, \dots, N)$.

COROLLARY 2.3. *With the assumptions as in Theorem* 2.2 *and for a Riemann integrable* $L(\cdot)$ *in* (H3′), *we can estimate the error bounds* z_k *for* $k = 0, \dots, N$ *as*

$$z_k = \delta_0 \cdot \prod_{\mu=0}^{k-1}(1 + hL_\mu) + h\sum_{j=1}^{k}\delta_j \cdot \prod_{\mu=j}^{k-1}(1 + hL_\mu),$$

$$\prod_{\mu=j}^{k-1}(1 + hL_\mu) \le \prod_{\mu=j}^{k-1} e^{hL_\mu} = e^{h\sum_{\mu=j}^{k-1} L_\mu} \le e^{C_L} \quad (j = 0, \dots, k), \tag{2.4}$$

where C_L *is an upper bound for the Riemann sums of the integral* $\int_{t_0}^{T} L(t)\,dt$.

If, furthermore, $L_k = L$ *for* $k = 0, \dots, N$, *then* $(1 + hL)^k \le e^{Lkh}$ *and for* $L > 0$,

$$z_k \le e^{Lkh}\delta_0 + \begin{cases} \frac{1}{L}(e^{Lkh} - 1) \cdot \max\limits_{j=1,\dots,k} \delta_j, \\ e^{L(k-1)h} \cdot h \sum\limits_{j=1}^{k} \delta_j. \end{cases} \tag{2.5}$$

The following lemmas are simple consequences of the growth condition and are well known in the literature (cf., e.g., [11, 19, 6]). They exhibit interesting connections between the continuous situation and the discrete situation in the case when $N \to \infty$.

LEMMA 2.4. *Let* $F(\cdot,\cdot)$ *satisfy* (H1′). *Then all solutions* $y(\cdot)$ *of (DI) in Problem* 1.1 *with bounded starting set* $Y_0 \subset \mathbb{R}^n$ *are uniformly bounded by* $M := (\|Y_0\| + C_L) \cdot (1 + C_L e^{C_L})$ *with* $C_L := \|C(\cdot)\|_{\mathcal{L}_1(I)}$ *and stay in a compactum* $S \subset \mathbb{R}^n$.

LEMMA 2.5. *Let* $F(\cdot,\cdot)$ *satisfy* (H1). *Then all solutions* $y(\cdot)$ *of (DI) in Problem* 1.1 *with bounded starting set* $Y_0 \subset \mathbb{R}^n$ *have a uniform Lipschitz constant.*

LEMMA 2.6. *Let* $F(\cdot,\cdot)$ *satisfy* (H1′) *with Riemann integrable* $C(\cdot)$, *and let* C_R *denote an upper bound for the Riemann sums. Then all solutions* $(\eta_k)_{k=0,\dots,N}$ *of (DDI) in Euler's method, Algorithm* 1.2, *with bounded starting set* $Y_0 \subset \mathbb{R}^n$ *are bounded uniformly in* $N \in \mathbb{N}$ *by* $M := (\|Y_0\| + C_R) \cdot (1 + C_R e^{C_R})$ *and stay in a compactum* $S \subset \mathbb{R}^n$.

Choosing $C_R = \|C(\cdot)\|_{\mathcal{L}_1(I)} + \varepsilon$ for all $N \ge N_0(\varepsilon)$ emphasizes the similarity of Lemma 2.6 to Lemma 2.4.

LEMMA 2.7. *Let* $F(\cdot,\cdot)$ *satisfy* (H1). *Then all solutions* $(\eta_k)_{k=0,\dots,N}$ *of (DDI) in Euler's method, Algorithm* 1.2, *with bounded starting set* $Y_0 \subset \mathbb{R}^n$ *have a Lipschitz constant uniformly in* $N \in \mathbb{N}$.

Proof. Let M be the bound for all discrete solutions $(\eta_k)_{k=0,\dots,N}$ according to Lemma 2.6. Then it follows for $N \in \mathbb{N}$ and $j, k \in \{0, 1, \dots, N\}$ with $j \le k$ that

$$\begin{aligned}\|\eta_k - \eta_j\| &= \left\|\sum_{\mu=j}^{k-1}(\eta_{\mu+1} - \eta_\mu)\right\| \le h\sum_{\mu=j}^{k-1}\left\|\frac{1}{h}(\eta_{\mu+1} - \eta_\mu)\right\| \le h\sum_{\mu=j}^{k-1}\|F(t_\mu, \eta_\mu)\| \\ &\le h\sum_{\mu=j}^{k-1} C(\|\eta_\mu\| + 1) \le C(M+1)(k-j)h = C(M+1)(t_k - t_j). \qquad \square\end{aligned}$$

3. Stability analysis for the state-constrained case. There are several variants in the literature of the Gronwall–Filippov–Wazewski theorem for the continuous

state-constrained case (cf. [15, Theorems 4.1 and 4.2], [17, Lemmas 3.3 and 4.4], [18, Theorem 3.1], as well as [7, Lemma 3.9], [8], and [23, Lemma 2.2(b)], which are all based on Soner's work in [22]). These variants were also denoted as theorems on the "existence of feasible neighboring trajectories" or as "tracking lemmas." Exemplarily, we treat here the so-called "smooth" case, where the function $g(t,x)$ determines the state constraints $\Theta(t)$ and $g(\cdot,\cdot) \in \mathcal{C}^{1,L}(I \times \mathbb{R}^n)$.

A typical result for the continuous situation is given in the following.

THEOREM 3.1. *Consider Problem* 1.1 *with time-dependent state constraint* $\Theta(\cdot)$. *Assume conditions* (H2)–(H3) *on the right-hand side* $F(\cdot,\cdot)$ *and conditions* (C1)–(C2) *on the state constraints.*

Then for every $y_0 \in \Theta(t_0)$ *there exists a positive constant* C *such that for every* $\eta(\cdot) \in \mathcal{Y}[T,t_0,y_0]$ *there exists* $y(\cdot) \in \mathcal{Y}^{\Theta}[T,t_0,y_0]$ *with*

$$\sup_{t\in[t_0,T]} \|\eta(t) - y(t)\| \le C \sup_{t\in[t_0,T]} \operatorname{dist}(\eta(t),\Theta(t)).$$

We will omit the proof of this theorem, since it exploits a similar strategy as in [15, Theorem 4.1], using in addition a result from [6, Theorem 3.2.4].

The reader should be aware that under considerably weaker assumptions, e.g., when no convexity is needed, Lipschitz condition with respect to both variables can be weakened, and analogous results for the continuous situation hold. However, the proof of the discrete analogue presented here could be given only under stronger assumptions until now. Contrary to the assumptions (HC_1)–(HC_4) in [6], we allow time-dependent state constraints even in the discrete situation and simplify the conditions for the error estimate.

In any case, we want to emphasize the fact that *both* stability results for the continuous and discrete case are needed for convergence of discrete approximations of state-constrained differential inclusions described in section 4.

We now present a rather detailed analysis of the discrete analogue of Theorem 3.1, partly following [6], but admitting time-dependent state constraints. We want to stress that this discrete analysis is in some respects rather technical but nevertheless essential for the convergence analysis in section 4. It would be very desirable to have available the discrete analogues of all those refined results of [15, Theorem 4.2], [17, Lemma 3.3], [18, Theorem 3.1] (smooth case), resp., [15, Theorem 4.1], [17, Lemma 4.4] (nonsmooth case), for the continuous situation. See also [17] for a detailed discussion of the smooth and nonsmooth cases.

THEOREM 3.2. *Consider problem (DDIC) in* (1.4)–(1.5) *with time-dependent state constraint* $\Theta(\cdot)$. *Assume conditions* (H2)–(H3) *on the right-hand side* $F(\cdot,\cdot)$ *and conditions* (C1)–(C2) *on the state constraints.*

Then for every $y_0 \in \Theta(t_0)$ *there exist* $N_0 \in \mathbb{N}$ *and a positive constant* C *such that for all* $N \ge N_0$ *and for all discrete solutions* $(\eta_k)_{k=0,\dots,N} \in \mathcal{Y}_N[T,t_0,y_0]$ *there exists a discrete solution* $(y_k)_{k=0,\dots,N} \in \mathcal{Y}_N^{\Theta}[T,t_0,y_0]$ *with*

$$\max_{k=0,\dots,N} \|\eta_k - y_k\| \le C \left(h + \max_{k=0,\dots,N} \operatorname{dist}(\eta_k,\Theta(t_k)) \right).$$

Proof. Consider an arbitrary, in general nonfeasible, solution $(\eta_k)_{k=0,\dots,N}$ and set

$$\delta_N := \max_{k=0,\dots,N} \operatorname{dist}(\eta_k,\Theta(t_k)).$$

Case A. Solution η_k is feasible for $k \in \mathcal{I} = \{0,\dots,N\}$.

Clearly, $\delta_N = 0$ and the assertion is valid for $y_k := \eta_k$, $k \in \mathcal{I}$.

Case B. Solution η_k is not feasible for some $k \in \mathcal{I}$.

In this case, $\delta_N > 0$. On a small index set $\mathcal{I}_0 = \{0, \dots, k_1\}$ with k_1 independent from $(\eta_k)_{k\in\mathcal{I}}$ the result will be proved as a first step.

Denote by L_η the uniform Lipschitz constant for all discrete solutions according to Lemma 2.7; by L, resp., $L_{\nabla g}$, the Lipschitz constant of $F(\cdot,\cdot)$, resp., $\nabla g(\cdot,\cdot)$; and choose the constants μ and α as in (C2). Without loss of generality, $L > 0$. Let M_2 be the maximum of $\|\nabla g(t,x)\|$ for $(t,x) \in I \times S$, with S being the compactum according to Lemma 2.6.

Define

$$\tau_1 := \max\left\{ t \in [t_0, T] \,:\, t \le t_0 + \frac{\mu}{2(L_\eta + 1)}, \right. \tag{3.1}$$

$$L_{\nabla g}(t - t_0) \le \frac{M_2}{2(L_\eta + 1)}, \tag{3.2}$$

$$\left. \max\left\{ M_2(L_\eta + 1), (L_\eta + 1)^2 \cdot \frac{L_{\nabla g}}{L} \right\} \cdot (e^{L(t-t_0)} - 1) \le \frac{\alpha}{12} \right\}, \tag{3.3}$$

which is independent of all discrete solutions and all $N \in \mathbb{N}$.[1]

For the discrete case, additional assumptions on the step-size are necessary to construct a viable solution.

Choose $N_0 \in \mathbb{N}$ with

$$h_{N_0} = \frac{T - t_0}{N_0} \le \tau_1 - t_0, \tag{3.4}$$

$$h_{N_0} \le \frac{\mu}{2(L_\eta + 1)}, \tag{3.5}$$

$$h_{N_0} L_{\nabla g} \le \frac{\alpha}{2(L_\eta + 1)^2}, \tag{3.6}$$

$$h_{N_0} L_{\nabla g} \le \frac{M_2}{L_\eta + 1}, \tag{3.7}$$

determining the maximal allowed step-size h_{N_0}.[2]

Inequality (3.4) is needed to guarantee that at least one step of Euler's method can be performed to reach a time not exceeding τ_1. Inequality (3.5) follows from (3.1) and (3.4). It ensures that a discrete solution, before violating the state constraints at the next index, will be sufficiently near the boundary such that there exists a direction which steers the solution into the interior. Inequalities (3.6)–(3.7) are needed to show the viability of the solution in this phase and control the error of Taylor expansions.

From now on, let $N \ge N_0$, $h = \frac{T-t_0}{N}$, and define in view of (3.4),

$$k_1 := \left\lfloor \frac{\tau_1 - t_0}{h} \right\rfloor \ge 1, \tag{3.8}$$

$$\hat{k}_1 := \min\{k \in \mathcal{I} \,:\, \eta_{k+1} \notin \Theta(t_{k+1})\} < N,$$

where k_1 is the biggest natural number not exceeding $\frac{\tau_1 - t_0}{h}$.

It is clear that $t_{k_1} \le \tau_1$ also satisfies the requirements in (3.1)–(3.3).

[1] Inequalities (3.1)–(3.3) are used in (3.14), (3.27), resp., in (3.25), (3.26).

[2] Inequalities (3.4)–(3.7) are used in (3.8), (3.10), (3.16), resp., (3.24).

Case B(i). $k_1 \le \hat{k}_1$, i.e., the solution η_k is feasible for $k \in \widetilde{\mathcal{I}}_0 := \{0, \dots, \hat{k}_1\} \supset \mathcal{I}_0$. Define

$$y_k := \eta_k \quad (k \in \mathcal{I}_0),$$

which fulfills the assertion on $\mathcal{I}_0$.

Case B(ii). $k_1 > \hat{k}_1$, i.e., the solution η_k is feasible for $k \in \widetilde{\mathcal{I}}_0 \subsetneqq \mathcal{I}_0$.

In the first phase, set

$$y_k := \eta_k \quad (k \in \widetilde{\mathcal{I}}_0). \tag{3.9}$$

Since $\eta_{\hat{k}_1} \in \partial\Theta(t_{\hat{k}_1})$ cannot be guaranteed in the discrete case (only $\eta_{\hat{k}_1} \in \Theta(t_{\hat{k}_1})$), the distance to the boundary must be estimated and should not exceed $\frac{\mu}{2}$ to guarantee an inward steering direction. The function $\varphi(s) = g(t_{\hat{k}_1} + s,\ \eta_{\hat{k}_1} + s\frac{\eta_{\hat{k}_1+1} - \eta_{\hat{k}_1}}{h})$ is continuous on $[0, h]$ with

$$\varphi(0) = g(t_{\hat{k}_1}, \eta_{\hat{k}_1}) \le 0, \quad \varphi(h) = g(t_{\hat{k}_1+1}, \eta_{\hat{k}_1+1}) > 0.$$

Therefore, there exists a zero $\bar{s} \in [0, h]$ of the function $\varphi(\cdot)$. Now, use (3.5) and (C1) to show

$$\begin{aligned} &\operatorname{dist}\left(\begin{pmatrix} t_{\hat{k}_1} \\ \eta_{\hat{k}_1} \end{pmatrix}, \operatorname{graph} \partial\Theta(\cdot)\right) \le \left\| \begin{pmatrix} t_{\hat{k}_1} \\ \eta_{\hat{k}_1} \end{pmatrix} - \begin{pmatrix} t_{\hat{k}_1} + \bar{s} \\ \eta_{\hat{k}_1} + \bar{s}\frac{\eta_{\hat{k}_1+1} - \eta_{\hat{k}_1}}{h} \end{pmatrix} \right\| \\ &\le \bar{s}\left(1 + \frac{1}{h} \cdot \|\eta_{\hat{k}_1+1} - \eta_{\hat{k}_1}\|\right) \le (1 + L_\eta)h \le \frac{\mu}{2}. \end{aligned} \tag{3.10}$$

Define (without loss of generality, the Lipschitz constant L_g of $g(\cdot)$ is greater than 0)

$$\kappa_1 := \min\left\{ \frac{k_1 - \hat{k}_1}{1 + \frac{\delta_N}{h}}, \frac{3}{\alpha}(L_g + 3M_2(L_\eta + 1)) \right\}, \tag{3.11}$$

$$\begin{aligned} \bar{\delta}_1 &:= \left\lfloor \kappa_1 \left(1 + \frac{\delta_N}{h}\right) + 1 \right\rfloor \ge 1, \\ \bar{k}_1 &:= \hat{k}_1 + \bar{\delta}_1, \end{aligned} \tag{3.12}$$

which determines the length of the inward steering phase $\widehat{\mathcal{I}}_0 := \{\hat{k}_1, \hat{k}_1 + 1, \dots, \bar{k}_1\} \subset \mathcal{I}_0$.[3] The nonnegative number κ_1 controls whether the corresponding time interval reaches t_{k_1} or guarantees the feasibility on the second time interval; $\bar{\delta}_1$ is the number of steps in the second phase in Case B(ii.1), resp., B(ii.2) following. Notice that κ_1 and $\bar{k}_1$ depend on the individual solution.

Consider the solution $(\widehat{y}_k)_{k \in \widehat{\mathcal{I}}_0}$ of the discrete inclusion

$$\begin{aligned} \frac{1}{h}(x_{k+1} - x_k) &\in Y(t_k, x_k) \quad (k \in \widehat{\mathcal{I}}_0 \setminus \{\bar{k}_1\}), \\ x_{\hat{k}_1} &= y_{\hat{k}_1} \end{aligned}$$

[3]The first term in (3.11) is used in (3.19), the second one in (3.29), while (3.12) is used in (3.28) and (3.33).

on the second index set $\widehat{\mathcal{I}}_0$. Here, $Y(t,x)$ is defined as follows:

$$\varphi(t,x) = \min_{v\in F(t,x)} \left\langle \nabla g(t,x), \binom{1}{v} \right\rangle, \tag{3.13}$$
$$Y(t,x) = \left\{ v \in F(t,x) \,:\, \left\langle \nabla g(x), \binom{1}{v} \right\rangle = \varphi(t,x) \right\},$$

where $\varphi(\cdot,\cdot)$ is continuous on $\operatorname{graph}\Theta(\cdot)$ by [3, Theorem 1.4.16] and $Y(t,x)$ has compact, nonempty images and is upper semicontinuous by [2, section 1.2, Theorem 6].

We choose $\hat{k}_1$ so that inward steering is possible and show that this is the case for all $k \in \widehat{\mathcal{I}}_0$ as well. From the Lipschitz continuity of all discrete solutions by Lemma 2.7 and (3.10), we get for $k \in \widehat{\mathcal{I}}_0$ that

$$\begin{aligned} \|\widehat{y}_k - \widehat{y}_{\hat{k}_1}\| &\le L_\eta (k-\hat{k}_1)h, \\ \operatorname{dist}\left(\binom{t_k}{\widehat{y}_k}, \operatorname{graph}\partial\Theta(\cdot)\right) &\le \left\| \binom{t_k}{\widehat{y}_k} - \binom{t_{\hat{k}_1}}{\widehat{y}_{\hat{k}_1}} \right\| + \operatorname{dist}\left(\binom{t_{\hat{k}_1}}{\widehat{y}_{\hat{k}_1}}, \operatorname{graph}\partial\Theta(\cdot)\right) \\ &\le |t_k - t_{\hat{k}_1}| + \|\widehat{y}_k - \widehat{y}_{\hat{k}_1}\| + \frac{\mu}{2}. \end{aligned}$$

Estimate $(k-\hat{k}_1)h$ by $t_{k_1} - t_0$ and use (3.1) to show

$$\operatorname{dist}\left(\binom{t_k}{\widehat{y}_k}, \operatorname{graph}\partial\Theta(\cdot)\right) \le (L_\eta + 1)(k-\hat{k}_1)h + \frac{\mu}{2} \le \mu. \tag{3.14}$$

The proof of the feasibility of $(\widehat{y}_k)_{k\in\widehat{\mathcal{I}}_0}$ is not as simple as in the continuous case. Since $\widehat{y}_{\hat{k}_1} \in \Theta(t_{\hat{k}_1})$ per definition, we have $g(t_{\hat{k}_1}, \widehat{y}_{\hat{k}_1}) \le 0$ and

$$g(t_k, \widehat{y}_k) \le g(t_k, \widehat{y}_k) - g(t_{\hat{k}_1}, \widehat{y}_{\hat{k}_1}) = \sum_{j=\hat{k}_1}^{k-1} (g(t_{j+1}, \widehat{y}_{j+1}) - g(t_j, \widehat{y}_j)).$$

Set $\psi(s) = g(t_j + sh,\ \widehat{y}_j + s(\widehat{y}_{j+1} - \widehat{y}_j))$ for $s \in [0,1]$ and some $j \in \widehat{\mathcal{I}}_0$; then a Taylor expansion up to terms of order 1 yields, by the Lipschitz continuity of $\nabla g(\cdot,\cdot)$,

$$g(t_{j+1}, \widehat{y}_{j+1}) \le g(t_j, \widehat{y}_j) + \left\langle \nabla g(t_j, \widehat{y}_j), \binom{h}{\widehat{y}_{j+1} - \widehat{y}_j} \right\rangle + L_{\nabla g}(L_\eta + 1)^2 h^2. \tag{3.15}$$

Hence, due to (3.6) it follows that

$$\begin{aligned} g(t_k, \widehat{y}_k) &\le \sum_{j=\hat{k}_1}^{k-1} h \left\langle \nabla g(t_j, \widehat{y}_j), \binom{1}{\frac{\widehat{y}_{j+1} - \widehat{y}_j}{h}} \right\rangle + (L_{\nabla g}(L_\eta + 1)^2 h) \cdot (k - \hat{k}_1)h \\ &\le \sum_{j=\hat{k}_1}^{k-1} h \left\langle \nabla g(t_j, \widehat{y}_j), \binom{1}{\frac{\widehat{y}_{j+1} - \widehat{y}_j}{h}} \right\rangle + \frac{\alpha}{2} \cdot (k - \hat{k}_1)h. \end{aligned} \tag{3.16}$$

Using (C2) due to (3.14) and $\frac{\widehat{y}_{j+1} - \widehat{y}_j}{h} \in Y(t_j, \widehat{y}_j)$ together with (3.13), we progress to the inequalities

$$g(t_k, \widehat{y}_k) \le h \sum_{j=\hat{k}_1}^{k-1} \varphi(t_j, \widehat{y}_j) + \frac{\alpha}{2} \cdot (k - \hat{k}_1)h \le -\frac{\alpha}{2} \cdot (k - \hat{k}_1)h. \tag{3.17}$$

Therefore, we have finally proved that $\widehat{y}_k \in \Theta(t_k)$ and

$$\|\widehat{y}_k - \eta_k\| \le \|\widehat{y}_k - y_{\hat{k}_1}\| + \|\eta_{\hat{k}_1} - \eta_k\| \le 2L_\eta(k-\hat{k}_1)h \le 2L_\eta\bar{\delta}_1 h \quad (k \in \widehat{\mathcal{I}}_0). \tag{3.18}$$

Case B(ii.1). The inward steering phase reaches the end of index set $\mathcal{I}_0$.

If $\bar{k}_1 = \hat{k}_1 + \bar{\delta}_1 = k_1$, then the definition of the constructed solution is continued to $\widehat{\mathcal{I}}_0$ as

$$y_k := \widehat{y}_k \quad (k \in \widehat{\mathcal{I}}_0 \setminus \{\hat{k}_1\}),$$

so that the claim is verified on $\widehat{\mathcal{I}}_0$ and therefore also on $\mathcal{I}_0$.

Case B(ii.2). The Filippov solution follows the time-delayed solution for the rest of the indices in $\mathcal{I}_0 \setminus \widehat{\mathcal{I}}_0$.

Now $\bar{k}_1 = \hat{k}_1 + \bar{\delta}_1 < k_1$; set $\bar{\mathcal{I}}_0 := \{\bar{k}_1, \bar{k}_1 + 1, \dots, k_1\}$. From $\kappa_1(1 + \frac{\delta_N}{h}) < \bar{\delta}_1$ it follows that $\kappa_1 = \frac{3}{\alpha}(L_g + 3M_2(L_\eta + 1))$ since

$$\kappa_1 < \frac{k_1 - \hat{k}_1}{1 + \frac{\delta_N}{h}}. \tag{3.19}$$

Consider the Filippov solution $(\bar{y}_k)_{k\in\bar{\mathcal{I}}_0}$ of

$$\frac{1}{h}(x_{k+1} - x_k) \in F(t_k, x_k) \quad (k \in \bar{\mathcal{I}}_0 \setminus \{k_1\}),$$
$$x_{\bar{k}_1} = y_{\bar{k}_1}$$

following the solution $(\eta_{k-\bar{\delta}_1})_{k\in\bar{\mathcal{I}}_0}$. Since the discrete version of Filippov's theorem, Theorem 2.2, will be applied, we study the following error terms:

$$\begin{aligned} &\|\bar{y}_{\bar{k}_1} - \eta_{\bar{k}_1-\bar{\delta}_1}\| = \|y_{\bar{k}_1} - \eta_{\hat{k}_1}\| = \|y_{\bar{k}_1} - y_{\hat{k}_1}\| \le L_\eta\bar{\delta}_1 h, \\ &\operatorname{dist}\Bigg(\underbrace{\frac{1}{h}(\eta_{k+1-\bar{\delta}_1} - \eta_{k-\bar{\delta}_1})}_{\in F(t_{k-\bar{\delta}_1}, \eta_{k-\bar{\delta}_1})}, F(t_k, \eta_{k-\bar{\delta}_1})\Bigg) \le L\bar{\delta}_1 h. \end{aligned} \tag{3.20}$$

The time delay $\bar{\delta}_1$ not only helps in (3.20), since $\eta_{\bar{k}_1-\bar{\delta}_1}$ coincides with $y_{\hat{k}_1}$, but also allows us to reuse the estimates on the second index set $\widehat{\mathcal{I}}_0$ (namely (3.18)) for the starting values on the third index set. For the distance to the right-hand side of the difference inclusion, the Lipschitz continuity of $F(\cdot,\cdot)$ with respect to t was used. The discrete Filippov theorem, Theorem 2.2, together with Corollary 2.3, finally establishes the estimates

$$\begin{aligned} \|\bar{y}_k - \eta_{k-\bar{\delta}_1}\| &\le (1+hL)^{k-\bar{k}_1} L_\eta\bar{\delta}_1 h + ((1+hL)^{k-\bar{k}_1} - 1)\bar{\delta}_1 h \\ &= ((L_\eta + 1)(1+hL)^{k-\bar{k}_1} - 1)\bar{\delta}_1 h, \end{aligned} \tag{3.21}$$

$$\begin{aligned} &\left\|\frac{1}{h}(\eta_{k+1-\bar{\delta}_1} - \eta_{k-\bar{\delta}_1}) - \frac{1}{h}(\bar{y}_{k+1} - \bar{y}_k)\right\| \\ &\qquad \le L(L_\eta + 1)(1+hL)^{k-\bar{k}_1}\bar{\delta}_1 h \end{aligned} \tag{3.22}$$

on $\bar{I}_0$. They are used twice: first to estimate the deviation of the feasible solution to the given one in

$$\begin{aligned} \|\bar{y}_k - \eta_k\| &\le \|\bar{y}_k - \eta_{k-\bar{\delta}_1}\| + \|\eta_{k-\bar{\delta}_1} - \eta_k\| \\ &\le \Big((L_\eta + 1)e^{L(k-\bar{k}_1)h} + L_\eta - 1\Big)\bar{\delta}_1 h \end{aligned} \tag{3.23}$$

and second to show feasibility. To this purpose, the state constraint is split into four terms for each $k \in \bar{\mathcal{I}}_0$. Hereby, the Taylor expansion as in (3.15) will be used:

$$\begin{aligned}
g(t_k,\bar{y}_k) &= \underbrace{g(t_{\bar{k}_1},\bar{y}_{\bar{k}_1})}_{=T_A} + \underbrace{g(t_{k-\bar{\delta}_1},\eta_{k-\bar{\delta}_1}) - g(t_{\bar{k}_1-\bar{\delta}_1},\eta_{\bar{k}_1-\bar{\delta}_1})}_{=T_B} \\
&\quad + \sum_{j=\bar{k}_1}^{k-1} \big(g(t_{j+1},\bar{y}_{j+1}) - g(t_j,\bar{y}_j)\big) \\
&\quad - \sum_{j=\bar{k}_1}^{k-1} \big(g(t_{j+1-\bar{\delta}_1},\eta_{j+1-\bar{\delta}_1}) - g(t_{j-\bar{\delta}_1},\eta_{j-\bar{\delta}_1})\big) \\
&\le T_A + T_B + h \sum_{j=\bar{k}_1}^{k-1} \left\langle \nabla g(t_j,\bar{y}_j), \begin{pmatrix} 1 \\ \frac{\bar{y}_{j+1}-\bar{y}_j}{h} \end{pmatrix} \right\rangle + L_{\nabla g}(L_\eta+1)^2(k-\bar{k}_1)h^2 \\
&\quad - h \sum_{j=\bar{k}_1}^{k-1} \left\langle \nabla g(t_{j-\bar{\delta}_1},\eta_{j-\bar{\delta}_1}), \begin{pmatrix} 1 \\ \frac{\eta_{j+1-\bar{\delta}_1}-\eta_{j-\bar{\delta}_1}}{h} \end{pmatrix} \right\rangle + L_{\nabla g}(L_\eta+1)^2(k-\bar{k}_1)h^2 \\
&= T_A + T_B + \underbrace{h \sum_{j=\bar{k}_1}^{k-1} \left\langle \nabla g(t_j,\bar{y}_j), \begin{pmatrix} 1 \\ \frac{\bar{y}_{j+1}-\bar{y}_j}{h} \end{pmatrix} - \begin{pmatrix} 1 \\ \frac{\eta_{j+1-\bar{\delta}_1}-\eta_{j-\bar{\delta}_1}}{h} \end{pmatrix} \right\rangle}_{=T_C} \\
&\quad + \underbrace{h \sum_{j=\bar{k}_1}^{k-1} \left\langle \nabla g(t_j,\bar{y}_j) - \nabla g(t_{j-\bar{\delta}_1},\eta_{j-\bar{\delta}_1}), \begin{pmatrix} 1 \\ \frac{\eta_{j+1-\bar{\delta}_1}-\eta_{j-\bar{\delta}_1}}{h} \end{pmatrix} \right\rangle}_{=T_D} \\
&\quad + \underbrace{2L_{\nabla g}(L_\eta+1)^2(k-\bar{k}_1)h^2}_{=T_E} = T_A + T_B + T_C + T_D + T_E.
\end{aligned}$$

The next task will be to estimate each term separately. We estimate

$$T_A = g(t_{\bar{k}_1},\widehat{y}_{\bar{k}_1}) \le -\frac{\alpha}{2}\bar{\delta}_1 h$$

by (3.17), the corresponding inequality on the second index set.

The treatment of the second term is slightly more complicated, as in the continuous case, since we cannot assume that $g(t_{\hat{k}_1},\eta_{\hat{k}_1}) = 0$. Nevertheless, we know that at index $\hat{k}_1$ we are close to the boundary and at the next index $\hat{k}_1+1$ the iterate violates the state constraints so that

$$T_B = g(t_{k-\bar{\delta}_1},\eta_{k-\bar{\delta}_1}) - g(t_{\hat{k}_1},\eta_{\hat{k}_1}) < g(t_{k-\bar{\delta}_1},\eta_{k-\bar{\delta}_1}) + \underbrace{g(t_{\hat{k}_1+1},\eta_{\hat{k}_1+1})}_{>0} - g(t_{\hat{k}_1},\eta_{\hat{k}_1}).$$

The difference of the last two terms could be estimated as in (3.15):

$$\begin{aligned}
g(t_{\hat{k}_1+1},\eta_{\hat{k}_1+1}) - g(t_{\hat{k}_1},\eta_{\hat{k}_1}) &\le h\|\nabla g(t_{\hat{k}_1},\eta_{\hat{k}_1})\| \cdot \left(1 + \left\|\frac{\eta_{\hat{k}_1+1}-\eta_{\hat{k}_1}}{h}\right\|\right) \\
&\quad + L_{\nabla g}(L_\eta+1)^2h^2 \le \underbrace{\max_{(t,x)\in I\times S}\|\nabla g(t,x)\|}_{=M_2} \cdot (1+L_\eta)h + L_{\nabla g}(L_\eta+1)^2h^2,
\end{aligned}$$

where we used again the fact that all discrete solutions are contained within a compactum S by Lemma 2.6 and that all discrete solutions have a uniform Lipschitz constant L_η by Lemma 2.7. Mimicking the proof in the continuous case, we distinguish two cases to treat the first term in T_B.

If $\eta_{k-\bar\delta_1} \in \Theta(t_{k-\bar\delta_1})$, then $g(t_{k-\bar\delta_1}, \eta_{k-\bar\delta_1}) \le 0$ so that this first term has an advantageous sign. Otherwise, we introduce the projection $\eta^\pi_{k-\bar\delta_1} \in \partial\Theta(t_{k-\bar\delta_1})$ and estimate by using the definition of δ_N:

$$\begin{aligned}|g(t_{k-\bar\delta_1}, \eta_{k-\bar\delta_1}) - g(t_{k-\bar\delta_1}, \eta^\pi_{k-\bar\delta_1})| &\le L_g \|\eta_{k-\bar\delta_1} - \eta^\pi_{k-\bar\delta_1}\| \\ &= L_g \operatorname{dist}(\eta_{k-\bar\delta_1}, \Theta(t_{k-\bar\delta_1})) \le L_g\delta_N.\end{aligned}$$

In both cases, due to (3.7) we have

$$T_B \le L_g\delta_N + M_2 \cdot (1 + L_\eta)h + L_{\nabla g}(L_\eta + 1)^2h^2 \le L_g\delta_N + 2M_2 \cdot (1 + L_\eta)h. \tag{3.24}$$

In term T_C, the difference quotient of both solutions is compared, which was estimated in (3.22) by the discrete Filippov theorem. Moreover, the boundedness of the discrete solutions and the continuity of $\nabla g(\cdot,\cdot)$ are used, yielding

$$\begin{aligned}T_C &\le h \sum_{j=\bar k_1}^{k-1} \|\nabla g(t_j, \bar y_j)\| \cdot \left\| \frac{\bar y_{j+1} - \bar y_j}{h} - \frac{\eta_{j+1-\bar\delta_1} - \eta_{j-\bar\delta_1}}{h} \right\| \\ &\le M_2 h \sum_{j=\bar k_1}^{k-1} \left(L(L_\eta + 1)(1 + hL)^{j-\bar k_1}\bar\delta_1 h \right) = M_2(L_\eta + 1)((1 + hL)^{k-\bar k_1} - 1)\bar\delta_1 h.\end{aligned}$$

Since $(1 + hL)^{k-\bar k_1}$ can be estimated by Corollary 2.3 as $e^{L(k-\bar k_1)h} \le e^{Lk_1h} \le e^{L(\tau_1-t_0)}$, we can exploit that τ_1 was suitably chosen by (3.3), and we get

$$T_C \le \frac{\alpha}{12}\bar\delta_1 h. \tag{3.25}$$

The same estimate will be reached for the term T_D. The main keys are the Lipschitz continuity of $\nabla g(\cdot,\cdot)$, the uniform Lipschitz constant for all discrete solutions, and the estimates (3.21) from the discrete Filippov theorem, together with the estimate in (2.5):

$$\begin{aligned}T_D &\le h \sum_{j=\bar k_1}^{k-1} \|\nabla g(t_j, \bar y_j) - \nabla g(t_{j-\bar\delta_1}, \eta_{j-\bar\delta_1})\| \cdot \left(1 + \left\| \frac{\eta_{j+1-\bar\delta_1} - \eta_{j-\bar\delta_1}}{h} \right\| \right) \\ &\le h \sum_{j=\bar k_1}^{k-1} L_{\nabla g}(|t_j - t_{j-\bar\delta_1}| + \|\bar y_j - \eta_{j-\bar\delta_1}\|) \cdot (1 + L_\eta) \\ &\le (L_\eta + 1)L_{\nabla g} h \sum_{j=\bar k_1}^{k-1} (1 + (L_\eta + 1)(1 + hL)^{j-\bar k_1} - 1) \cdot \bar\delta_1 h \\ &\le (L_\eta + 1)L_{\nabla g} \frac{L_\eta + 1}{L} hL \sum_{j=\bar k_1}^{k-1} (1 + hL)^{j-\bar k_1} \cdot \bar\delta_1 h \\ &\le (L_\eta + 1)^2 \frac{L_{\nabla g}}{L}((1 + hL)^{k-\bar k_1} - 1) \cdot \bar\delta_1 h.\end{aligned}$$

Now, the reasoning is the same as for the term T_C, and hence

$$T_D \le \frac{\alpha}{12}\bar{\delta}_1 h. \tag{3.26}$$

For the estimation of T_E we need (3.2):

$$\begin{aligned} T_E &= 2L_{\nabla g}(L_\eta+1)^2(k-\hat{k}_1)h^2 \le 2L_{\nabla g}(L_\eta+1)^2(t_k - t_{\hat{k}_1})h \\ &\le 2L_{\nabla g}(L_\eta+1)^2(\tau_1 - t_0)h \le M_2(L_\eta+1)h. \end{aligned} \tag{3.27}$$

Now, we put all estimates together to show the feasibility. We have

$$\begin{aligned} g(t_k,\bar{y}_k) &\le T_A + T_C + T_D + T_B + T_E \le -\frac{\alpha}{2}\bar{\delta}_1 h + 2\cdot\frac{\alpha}{12}\bar{\delta}_1 h + T_B + T_E \\ &\le -\frac{\alpha}{3}\bar{\delta}_1 h + T_B + T_E. \end{aligned}$$

The definition (3.12) for $\bar{\delta}_1$ and $\kappa_1 = \frac{3}{\alpha}(L_g + 3M_2(L_\eta+1))$ yield

$$\frac{\alpha}{3}\bar{\delta}_1 h \ge \frac{\alpha}{3}\kappa_1\left(1+\frac{\delta_N}{h}\right)h \tag{3.28}$$

$$= (L_g + 3M_2(L_\eta+1))(h+\delta_N) \ge L_g\delta_N + 3M_2(L_\eta+1)h, \tag{3.29}$$

and hence the problematic term $L_g\delta_N$ could be eliminated by

$$\begin{aligned} g(t_k,\bar{y}_k) &\le -L_g\delta_N - 3M_2(L_\eta+1)h + L_g\delta_N + 2M_2(L_\eta+1)h \\ &\quad + M_2(L_\eta+1)h \le 0. \end{aligned} \tag{3.30}$$

Extend the feasible solution in the third phase to $\mathcal{I}_0$ by

$$y_k := \bar{y}_k \quad (k \in \bar{\mathcal{I}}_0 \setminus \{\bar{k}_1\}). \tag{3.31}$$

For all $k \in \mathcal{I}_0$, (3.9) and the estimates (3.18), (3.23) yield altogether

$$\|y_k - \eta_k\| \le \max\{2L_\eta, \underbrace{(L_\eta+1)e^{L(\tau_1-t_0)} + L_\eta - 1}_{=:M_3 \ge 2L_\eta}\}\cdot\bar{\delta}_1 h. \tag{3.32}$$

In the last inequality, $(k_1 - \bar{k}_1)h$ was estimated by $k_1 h \le \tau_1 - t_0$. Moreover,

$$\begin{aligned} \bar{\delta}_1 h &= \left\lfloor \kappa_1\left(1+\frac{\delta_N}{h}\right)+1\right\rfloor\cdot h \le \left(\kappa_1\left(1+\frac{\delta_N}{h}\right)+1\right)h \\ &\le \left(\frac{3}{\alpha}(L_g + 3M_2(L_\eta+1))\right)(h+\delta_N) + h = \mathcal{O}(h+\delta_N), \end{aligned} \tag{3.33}$$

$$\|y_k - \eta_k\| \le M_3\bar{\delta}_1 h \le \underbrace{M_3\left(1+\frac{3}{\alpha}(L_g+3M_2(L_\eta+1))\right)}_{=:\widetilde{M}}(h+\delta_N) = \mathcal{O}(h+\delta_N).$$

Extension to the whole index set $\mathcal{I}$. This process is well explained in the proof of [6, Theorem 3.2.6]: Divide the index set into J subsets with k_1 elements and set $\mathcal{I}_j := \{k_j, k_j+1, \dots, k_{j+1}\} \cap \{0,\dots,N\}$ with $k_j = jk_1$, $j = 0,\dots,J$.

(i) *First index set.* For $j=0$ the solution y_k is already constructed for $\mathcal{I}_0$. Set $\widetilde{C}_0 := 1 + \frac{\delta_N}{h}$ and $\Delta_0 = \lfloor \kappa_1\widetilde{C}_0 + 1\rfloor$.

(ii) *Recursive approach.* For $j > 0$ start the process by taking the end value of the feasible solution $y_{j\cdot k_1}$ on $\mathcal{I}_{j-1}$ as the starting value for the next iteration. Now, apply again the discrete Filippov theorem to construct the (in general, nonfeasible) solution $(z_k^{(j)})_{k\in\mathcal{I}_j}$ of

$$\frac{1}{h}(x_{k+1} - x_k) \in F(t_k, x_k) \quad (k \in \mathcal{I}_j),$$
$$x_{k_j} = y_{k_j}$$

that follows the nonfeasible solution $(\eta_k)_{k\in\mathcal{I}_j}$. The error term is governed by the difference of the starting values. Now, construct a feasible solution $(y_k)_{k\in\mathcal{I}_j}$ from $(z_k^{(j)})_{k\in\mathcal{I}_j}$. Then show that the deviation from $(y_k)_{k\in\mathcal{I}_j}$ to $(\eta_k)_{k\in\mathcal{I}_j}$ could be estimated by

$$\|y_k - \eta_k\| \le \widetilde{M} \sum_{\nu=0}^{j} e^{(j-\nu)Lk_1h} \Delta_\nu h \quad (k \in \mathcal{I}_j),$$

where for $j = 1, \dots, J$,

$$\widetilde{C}_j = \widetilde{C}_0 + \widetilde{M} \sum_{\nu=0}^{j-1} e^{(j-\nu)Lk_1h}, \quad \Delta_j = \lfloor \kappa_1 \widetilde{C}_j + 1 \rfloor.$$

Estimate J uniformly for all $N \in \mathbb{N}$ by $\lfloor \frac{T-t_0}{\tau_1 - h_{N_0}} + 1 \rfloor$ so that we finally prove the overall order $\mathcal{O}(h + \delta_N)$. ∎

Remark 3.3. Assume that $\Theta : I \Rightarrow \mathbb{R}^n$ with images in $\mathcal{C}(\mathbb{R}^n)$ has a $\mathcal{C}^{1,L}$-signed distance function

$$\widetilde{d}(t,x) := \begin{cases} \operatorname{dist}(x, \partial\Theta(t)) & \text{if } x \in \Theta(t), \\ -\operatorname{dist}(x, \partial\Theta(t)) = -\operatorname{dist}(x, \Theta(t)) & \text{if } x \in \mathbb{R}^n \setminus \Theta(t). \end{cases}$$

Then $\Theta(t) = \{x \in \mathbb{R}^n : -\widetilde{d}(t,x) \le 0\}$ fulfills the assumptions of Theorem 3.2.

4. Convergence analysis. Combining the stability results from section 3 for the continuous and discrete case, we are now in a position to prove order of convergence results for the discrete approximation of the set of all viable solutions of the differential inclusion by all viable discrete solutions.

An essential tool is the following result for differential inclusions without state constraints (cf. [11, section 1, Theorem]) which we formulate under stronger assumptions that will be needed later. The convexity is an important assumption for the convergence of Euler's method.

PROPOSITION 4.1. *Choose a compactum $S \subset \mathbb{R}^n$ containing all solutions of* (1.1), (1.3). *Let $F(\cdot,\cdot)$ fulfill* (H2)–(H3) *on S and let $Y_0 = \{y_0\}$.*

Then there exists a positive constant C such that for all $N \in \mathbb{N}$,

$$\mathrm{d}_{H,\infty}(\mathcal{Y}[T, t_0, y_0], \mathcal{Y}_N[T, t_0, y_0]) \le Ch.$$

The stability results from section 3 (Theorem 3.1 for the continuous case and Theorem 3.2 for the discrete case) are essential for the convergence proof of Euler's discretization of differential inclusions with state constraints.

THEOREM 4.2. *Assume hypotheses* (H2)–(H3) *together with* (C1)–(C2) *and let* $Y_0 = \{y_0\}$ *with* $y_0 \in \Theta(t_0)$.

Then there exist a positive constant C *and* $N_0 \in \mathbb{N}$ *such that for all* $N \geq N_0$,

$$\mathrm{d}_{H,\infty}(\mathcal{Y}^{\Theta}[T,t_0,y_0], \mathcal{Y}_N^{\Theta}[T,t_0,y_0]) \leq Ch.$$

Proof. This proof will use the notation of some constants from the proof of Theorem 3.2. Choose $N_0 \in \mathbb{N}$ from this theorem and $N \geq N_0$ so that additionally $h_{N_0} \leq \mu$ and $(C(M+1)+1)^2 L_{\nabla g} h_{N_0} \leq \frac{\alpha}{2}$, where M is the bound in Lemma 2.6 and α, μ are as in (C2).

Let us first construct a close discrete solution to a given $y(.) \in \mathcal{Y}^{\Theta}[T,t_0,y_0]$ to estimate the one-sided distance. According to Proposition 4.1, there exists $(\widetilde{\eta}_k)_{k=0,\dots,N} \in \mathcal{Y}_N[T,t_0,y_0]$ with

$$\max_{k=0,\dots,N} \|y(t_k) - \widetilde{\eta}_k\| \leq \widetilde{C}_1 h.$$

Since

$$\operatorname{dist}(\widetilde{\eta}_k, \Theta(t_k)) \leq \|\widetilde{\eta}_k - y(t_k)\| + \operatorname{dist}(y(t_k), \Theta(t_k)) \leq \widetilde{C}_1 h,$$

a solution $(\eta_k)_{k=0,\dots,N} \in \mathcal{Y}_N^{\Theta}[T,t_0,y_0]$ can be constructed by Theorem 3.2 with

$$\max_{k=0,\dots,N} \|\eta_k - \widetilde{\eta}_k\| \leq \widetilde{C}_2 h.$$

Hence, the grid function $y_N := (y(t_k))_{k=0,\dots,N}$ fulfills

$$\|\eta_k - y(t_k)\| \leq \|\eta_k - \widetilde{\eta}_k\| + \|\widetilde{\eta}_k - y(t_k)\| \leq (\widetilde{C}_1 + \widetilde{C}_2)h,$$
$$\operatorname{dist}_{\infty}(y_N, \mathcal{Y}_N^{\Theta}[T,t_0,y_0]) \leq (\widetilde{C}_1 + \widetilde{C}_2)h.$$

On the other hand, for a given discrete solution $\eta := (\eta_k)_{k=0,\dots,N} \in \mathcal{Y}_N^{\Theta}[T,t_0,y_0]$ one has to estimate the other one-sided distance. Proposition 4.1 shows the existence of $\widetilde{y}(\cdot) \in \mathcal{Y}[T,t_0,y_0]$ with

$$\max_{k=0,\dots,N} \|\eta_k - \widetilde{y}(t_k)\| \leq \widetilde{C}_1 h.$$

The reasoning is now more complicated since we need to estimate the following distance for all $t \in [t_k, t_{k+1}]$ and all $k \in \{0,\dots,N-1\}$:

$$\operatorname{dist}(\widetilde{y}(t), \Theta(t)) \leq \|\widetilde{y}(t) - \widetilde{y}(t_k)\| + \|\widetilde{y}(t_k) - \eta_k\| + \operatorname{dist}(\eta_k, \Theta(t)). \tag{4.1}$$

Since $\eta_k \in \Theta(t_k)$, the inequality $g(t_k, \eta_k) \leq 0$ holds.

(i) If $\binom{t_k}{\eta_k} \in B_\mu(\operatorname{graph} \partial\Theta(\cdot))$, then there exists $v_k \in F(t_k, \eta_k)$ by (C2) with

$$\left\langle \nabla g(t_k, \eta_k), \binom{1}{v_k} \right\rangle \leq -\alpha.$$

For $t \in [t_k, t_{k+1}]$, we set $\eta(t) := \eta_k + (t - t_k)v_k$ and consider

$$\begin{aligned} g(t,\eta(t)) &= g(t_k,\eta_k) + \int_{t_k}^{t} \frac{\mathrm{d}}{\mathrm{ds}} g(s,\eta(s))\, ds \leq \int_{t_k}^{t} \left\langle \nabla g(s,\eta(s)), \binom{1}{v_k} \right\rangle ds \\ &= \int_{t_k}^{t} \left\langle \nabla g(t_k,\eta_k), \binom{1}{v_k} \right\rangle ds + \int_{t_k}^{t} \left\langle \nabla g(s,\eta(s)) - \nabla g(t_k,\eta_k), \binom{1}{v_k} \right\rangle ds \\ &\leq -\alpha(t-t_k) + \int_{t_k}^{t} \|\nabla g(s,\eta(s)) - \nabla g(t_k,\eta_k)\| \cdot (1 + \|v_k\|)\, ds. \end{aligned}$$

Let us estimate both terms using (H1) and Lemma 2.6 by

$$\begin{aligned} 1 + \|v_k\| &\le 1 + \|F(t_k, \eta_k)\| \le 1 + C(\|\eta_k\| + 1) \le C(M+1) + 1, \\ \|\nabla g(s, \eta(s)) - \nabla g(t_k, \eta_k)\| &\le L_{\nabla g}(|s - t_k| + \|\eta(s) - \eta_k\|) \\ &\le L_{\nabla g}(1 + \|v_k\|)(s - t_k) \le (C(M+1)+1) L_{\nabla g} h \end{aligned}$$

and continue the inequality with

$$g(t, \eta(t)) \le -\alpha(t - t_k) + (C(M+1)+1)^2 L_{\nabla g} h (t - t_k) \le -\frac{\alpha}{2}(t - t_k) \le 0.$$

Therefore, $\eta(t) \in \Theta(t)$ is close to η_k with

$$\operatorname{dist}(\eta_k, \Theta(t)) \le \|\eta_k - \eta(t)\| = (t - t_k)\|v_k\| \le C(M+1)(t - t_k).$$

(ii) If $\binom{t_k}{\eta_k} \notin B_\mu(\operatorname{graph} \partial\Theta(\cdot))$, then $\binom{t_k}{\eta_k} \notin \operatorname{graph} \partial B_\mu(\Theta(\cdot))$ and $\operatorname{dist}(\eta_k, \partial\Theta(t_k))$ is greater than μ. Let us assume that $g(t, \eta_k) > 0$. With the continuous function $\varphi(s) := g(s, \eta_k)$ on $[t_k, t_{k+1}]$, we will soon arrive at a contradiction. Since the inequalities

$$\begin{aligned} \varphi(t_k) &= g(t_k, \eta_k) < 0, \\ \varphi(t) &= g(t, \eta_k) > 0 \end{aligned}$$

hold, there exists $\bar{t} \in (t_k, t) \subset (t_k, t_{k+1}]$ with $\varphi(\bar{t}) = 0$. Then $g(\bar{t}, \eta_k) = 0$ and $\eta_k \in \partial\Theta(\bar{t})$ such that $\binom{\bar{t}}{\eta_k} \in \operatorname{graph} \partial\Theta(\cdot)$. The following inequality shows the contradiction:

$$\operatorname{dist}\left(\binom{t_k}{\eta_k}, \operatorname{graph} \partial\Theta(\cdot)\right) \le \left\|\binom{t_k}{\eta_k} - \binom{\bar{t}}{\eta_k}\right\| = |\bar{t} - t_k| \le h \le \mu.$$

Hence, the assumption was wrong; consequently, it holds $g(t, \eta_k) \le 0$ so that $\eta_k \in \Theta(t)$.

In both cases (i) and (ii), $\operatorname{dist}(\eta_k, \Theta(t)) \le C(M+1)(t - t_k)$. Using (4.1), we get

$$\operatorname{dist}(\widetilde{y}(t), \Theta(t)) \le L_y |t - t_k| + \widetilde{C}_1 h + C(M+1)(t - t_k) \le (C(M+1) + \widetilde{C}_1 + L_y) h,$$

where L_y is the uniform Lipschitz constant from Lemma 2.5. Therefore, a solution $y(\cdot) \in \mathcal{Y}^\Theta[T, t_0, y_0]$ exists by Theorem 3.1 with

$$\sup_{t \in I} \|y(t) - \widetilde{y}(t)\| \le \widetilde{C}_3 h.$$

Hence,

$$\begin{aligned} \|\eta_k - y(t_k)\| &\le \|\eta_k - \widetilde{y}(t_k)\| + \|\widetilde{y}(t_k) - y(t_k)\| \le (\widetilde{C}_1 + \widetilde{C}_3) h, \\ \operatorname{dist}_\infty(\eta, \mathcal{Y}^\Theta[T, t_0, y_0]) &\le (\widetilde{C}_1 + \widetilde{C}_3) h. \qquad \square \end{aligned}$$

5. Example. The dynamical system, underlying the following two test examples, is due to Petar Kenderov. It serves as a model problem for the illustration of first order convergence. We restrict ourselves to the visualization of the convergence of reachable sets. The visualization of the convergence of the whole discrete solution sets would require much more space and the choice of more appropriate data structures.

Naturally, the realization of the set-valued Euler's method (1.4)–(1.5) on a computer amounts to an additional perturbation of the set-valued right-hand side of order 1 and an evaluation of the set union with a local error of order 2 (with respect to Hausdorff distance, uniformly in $t \in I$); for computational details, cf. [6].

Example 5.1. Consider the differential inclusion

$$
\begin{aligned}
&y'(t) \in F(t, y(t)) = \{Ay(t) + uBy(t) \in \mathbb{R}^2 \,:\, 0 \le u \le 1\} \quad \text{(a.e. } t \in [0, 8]),\\
&y(t) \in \Theta := \{y \in \mathbb{R}^2 \,:\, g(y) \le 0\},\\
&y(0) = y_0 = \tbinom{2}{2},
\end{aligned}
$$

where

$$
A = \begin{pmatrix} \sigma^2 - 1 & \sigma\sqrt{1-\sigma^2} \\ -\sigma\sqrt{1-\sigma^2} & \sigma^2 - 1 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & -2\sigma\sqrt{1-\sigma^2} \\ 2\sigma\sqrt{1-\sigma^2} & 0 \end{pmatrix},
$$

$$
g(y) := -\frac{1}{2}(y_1 - 2)^2 + 2 - y_2, \qquad y = \tbinom{y_1}{y_2},
$$

and $\sigma \in (0, 1)$ is a fixed parameter.

The reachable set for the unconstrained case can be expressed by representing its points with polar coordinates,

$$
\begin{aligned}
\mathcal{R}\Big(t, t_0, r_0 \tbinom{\cos(\phi_0)}{\sin(\phi_0)}\Big) = \Big\{ r(t) \tbinom{\cos(\phi(t))}{\sin(\phi(t))} \,:\, & r(t) = r_0 e^{(\sigma^2-1)t},\\
& \phi(t) = \phi_0 + \sigma\sqrt{1-\sigma^2}(2u-1)t, \quad 0 \le u \le 1 \Big\},
\end{aligned}
$$

where the initial point y_0 has polar coordinates $(r_0, \phi_0) = (2\sqrt{2}, \frac{\pi}{4})$. Further on, we fix $\sigma = \frac{9}{10}$.

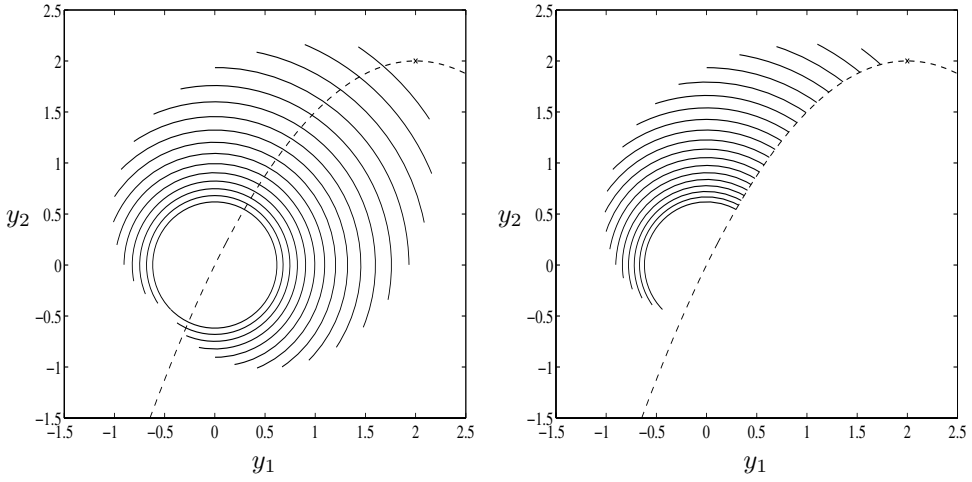

FIG. 5.1. *Reachable sets for different end times t (without, resp., with state constraints).*

In Figure 5.1 (left picture), the exact reachable sets for the unconstrained problem with varying end time $t_i = i \cdot \frac{1}{2}$, $i = 0, \ldots, 16$, and the boundary of the (quadratic) state constraint (dotted line), are illustrated. For $t = 0$, the starting set is just the upper right point in this figure (marked by the cross); for increasing time t the reachable set moves to the lower left of the figure and the two ends of the arcs approach each other. Approximately for $t \ge 8$, the two end points of the arc will overlap and the reachable sets form the boundary of a circle. In the right picture of Figure 5.1, the reachable sets for the state-constrained problem are visualized for the same times. In contrast to [6, Example 5.2.2] with a linear constraint, the reachable set cannot be gained by the intersection $\mathcal{R}(t, t_0, Y_0) \cap \Theta$, as the comparison of both pictures shows.

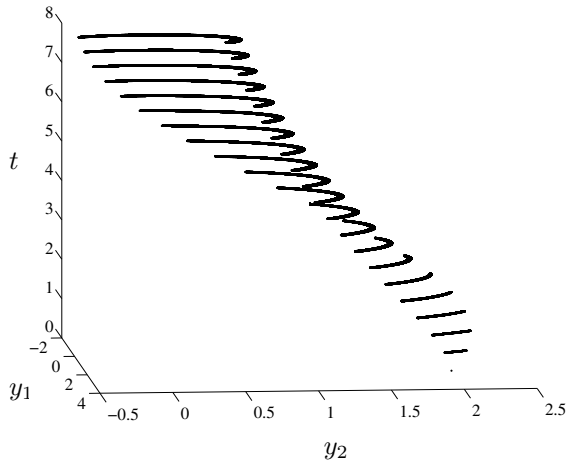

FIG. 5.2. *Integral funnel of Euler's method with* $N = 240$ *and state constraints.*

For $t \geq 7.2$, the small part of the circle that moves out of the interior of Θ (everything below the quadratic function) originates from points that were already cut off by the quadratic state constraint at an earlier time.

Figure 5.2 shows the integral funnel with state constraints. This figure was calculated with set-valued Euler's method for $N = 240$ on the interval $[0, 8]$ (cf. [6, Chapter 4] for details on the implementation of Euler's method for the approximation of nonlinear differential inclusions).

Let us check whether Theorem 4.2 for state-constrained Euler's method can be applied. Observe that $F(t, y) = \{f(t, y, u) : u \in [0, 1]\}$ with $f(t, y, u) = Ay + uBy$ is Lipschitz with respect to (t, y) and has nonempty, compact, convex images. Clearly, (H1) and (C1) are also fulfilled. Furthermore,

$$\langle \nabla g(y)^\top, v \rangle = -(\sigma^2 - 1) \cdot \frac{1}{2} y_1^2 + \sigma \sqrt{1 - \sigma^2} \cdot (1 - 2u) \cdot \frac{1}{2} y_1 \cdot (y_1^2 - 6y_1 + 10)$$

for all $y \in \partial\Theta$ and $v = f(t, y, u)$.

For $y_1 < 0$, the choice of $u = 0$ yields

$$\langle \nabla g(y)^\top, v \rangle = \frac{1}{2} y_1 \cdot \sigma \sqrt{1 - \sigma^2} \cdot \underbrace{\left(y_1^2 - \left(6 - \frac{1}{\sigma} \sqrt{1 - \sigma^2} \right) y_1 + 10 \right)}_{=: h(y_1)}.$$

A discussion of the function h shows $h(y_1) \geq (y_1 - 4)^2 - 6 \geq 10$ so that the scalar product is less than zero.

For $y_1 \in (0, \frac{5}{2}]$, $u = 1$ is chosen such that

$$\langle \nabla g(y)^\top, v \rangle = -\frac{1}{2} y_1 \cdot \sigma \sqrt{1 - \sigma^2} \cdot \left(y_1^2 - \left(6 + \frac{1}{\sigma} \sqrt{1 - \sigma^2} \right) y_1 + 10 \right).$$

The quadratic function in this term could be strictly estimated from below by the function $\widetilde{h}(y_1) = y_1^2 - \frac{13}{2} y_1 + 10$ which is strictly decreasing and is not less than $\widetilde{h}(\frac{5}{2}) = 0$. Hence, the scalar product is also negative.

Let us note that the final reachable set is a circle avoiding the origin; cf. Figure 5.1. Therefore, all discrete reachable sets for small step-sizes have a positive distance to

TABLE 5.1
Estimated order of convergence for $T = 0.5$ (state-constrained problem).

N	Estimated Hausdorff distance from the reference set	Difference to Ch^p
16	0.0897488	-1.1E-02
32	0.0280925	9.2E-03
64	0.0182812	-6.6E-04
128	0.0104471	-2.1E-03
256	0.0036226	3.2E-04
512	0.0018178	4.8E-05

TABLE 5.2
Estimated order of convergence for $T = 7.5$ (state-constrained problem).

N	Estimated Hausdorff distance from the reference set	Difference to Ch^p
16	0.3275207	1.1E-02
32	0.1842108	-7.3E-03
64	0.0923952	-1.2E-04
128	0.0483326	-2.0E-04
256	0.0250892	2.0E-05
512	0.0129622	1.4E-04

the origin so that on a compactum containing all Euler solutions and near to the boundary of Θ we have a positive distance to the origin. A compactness argument yields therefore the validity of (C2). Hence, order of convergence 1 with respect to the step-size h holds by Theorem 4.2.

For the state-constrained case, Tables 5.1 and 5.2 visualize the order of convergence for the approximation of the reachable set $\mathcal{R}(0.5, 0, \binom{2}{2})$, resp., $\mathcal{R}(7.5, 0, \binom{2}{2})$. The tables are calculated by using the theoretical reachable set as reference set. Based on these data, a least squares problem with the function $\log(Ch^p)$ with unknowns $C, p \geq 0$ yields the values $p = 1.0800$ and $C = 1.1812$, resp., $p = 0.9388$ and $C = 1.9156$. The estimated order of convergence for $T = 7.5$ is slightly worse than for $T = 0.5$ due to possible increasing rounding errors.

In Figure 5.3 the difference between the discrete reachable sets generated by Euler's method (gray shaded sets) and the theoretical one (arc with black solid line, almost included in the gray sets) is depicted. The pictures show the approximations of the reachable set with state constraints at time $t = 7.5$ for several numbers N of subintervals: $N = 16$ (upper left), 32 (upper right), 64 (lower left), and 128 (lower right).

Example 5.2. Consider the modified Example 5.1 in which the state constraint is now time-dependent, i.e.,

$$y(t) \in \Theta(t) := \{y \in \mathbb{R}^2 \,:\, g(t,y) \leq 0\},$$
$$g(t,y) := -\frac{1}{4} \cdot \left(2 - \frac{t^2}{64}\right) \cdot (y_1 - 2)^2 + \left(2 - \frac{t^2}{64}\right) - y_2, \quad y = \binom{y_1}{y_2}.$$

Observe that $g(0, y)$ equals the time-independent state constraint in Example 5.1. From Figure 5.4, it is clear that in the case of time-dependent constraints (right picture), the reachable sets are bigger than in the time-independent case (left picture). This figure shows the discrete reachable sets for the constrained problem at the times $t \in \{0, \frac{1}{2}, 1, \frac{3}{2}, 2, 3, 4, 6, 8\}$. For these times, the boundaries of the state constraints $g(t, \cdot) = 0$ are depicted in the right picture with dotted lines.

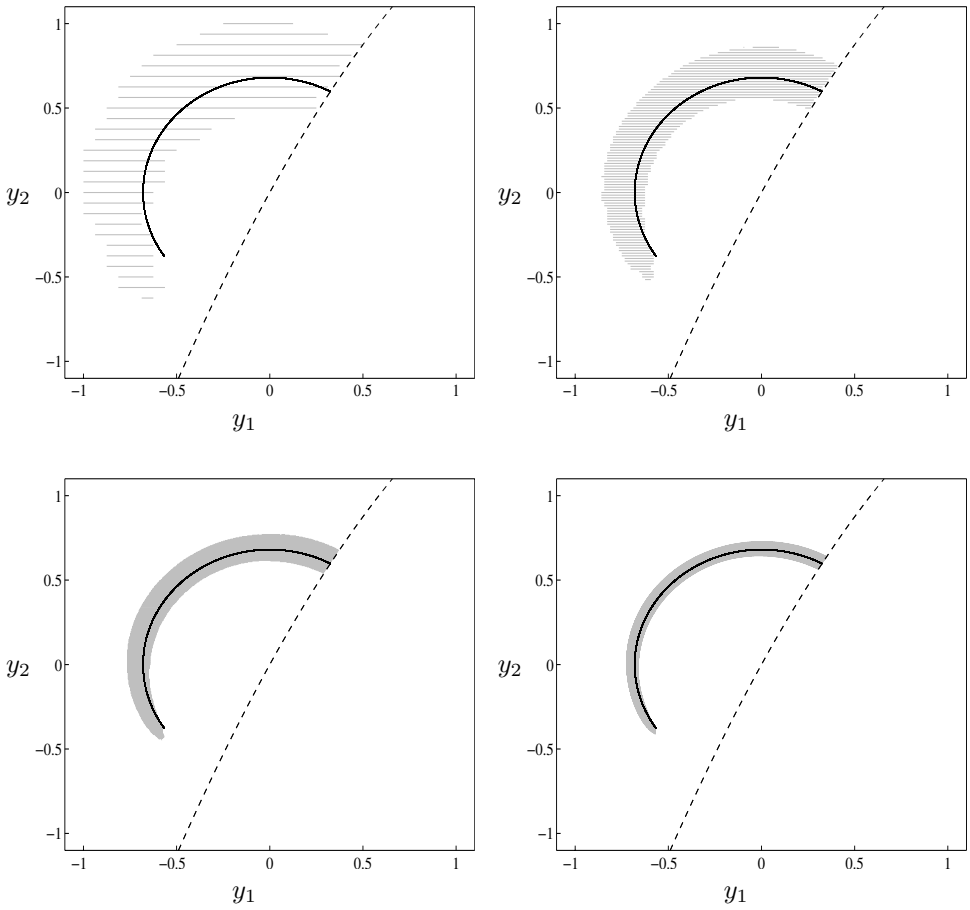

FIG. 5.3. *Discrete reachable sets for* $T = 7.5$ *and various step-sizes* $N = 16, 32, 64, 128$.

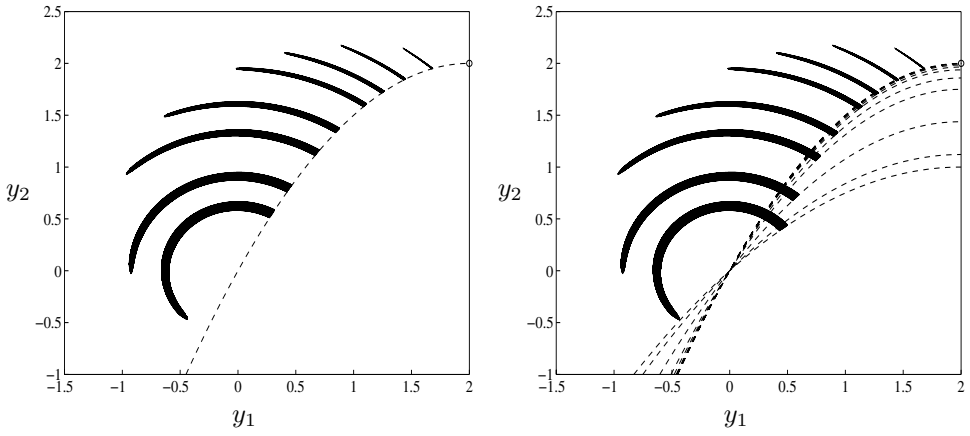

FIG. 5.4. *Discrete reachable sets from Euler's method with* $N = 128$ *for both examples.*

TABLE 5.3
Estimated order of convergence for $T = 7.5$ (time-dependent state-constrained problem).

N	Estimated Hausdorff distance from the reference set	Difference to Ch^p
16	0.3371631	7.2E-03
32	0.1842111	-5.1E-03
64	0.0931844	-4.1E-05
128	0.0483323	1.1E-04
256	0.0250866	1.1E-04
512	0.0130925	1.2E-05

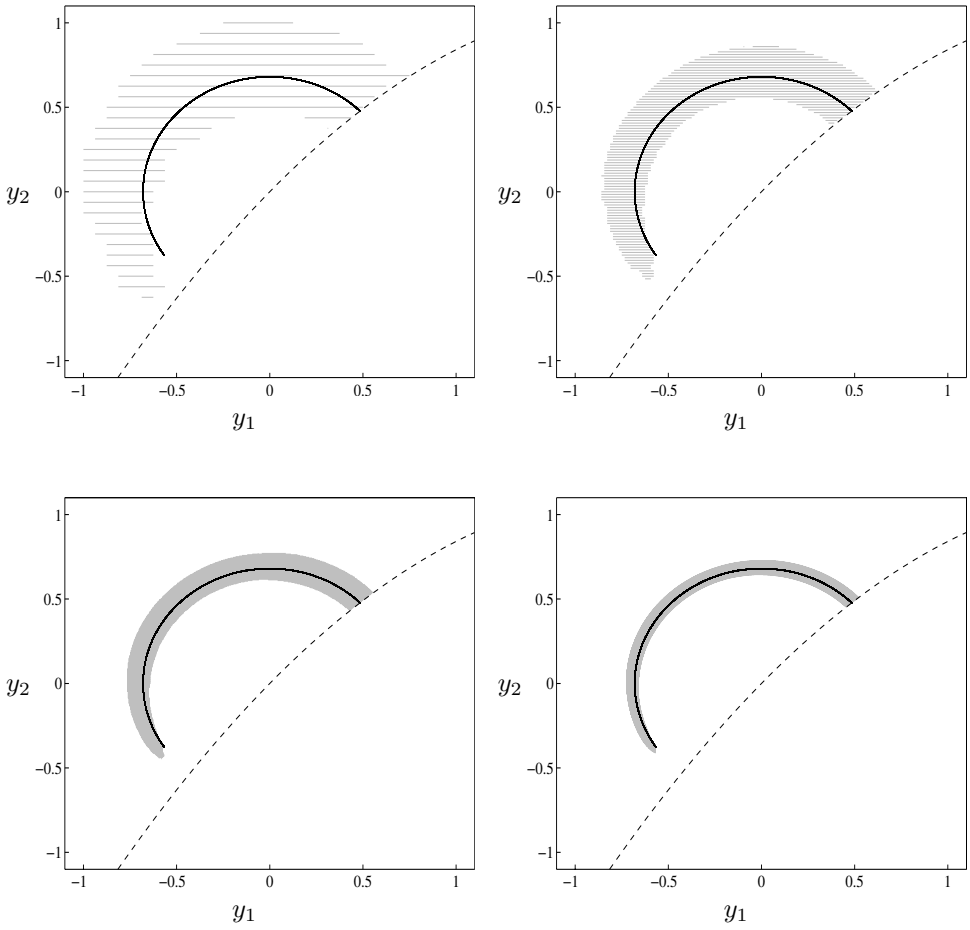

FIG. 5.5. *Discrete reachable sets for $T = 7.5$ and various step-sizes $N = 16, 32, 64, 128$.*

With considerably more effort, it is even possible to show the validity of (C2) by choosing the same values u depending on the sign of y_1 as in Example 5.1.

Table 5.3 is created for the time $T = 7.5$ similarly to the tables for the previous example, but includes the data for the time-dependent state constraint. A least squares approximation with $\log(Ch^p)$ yields the values $p = 0.9431$ and $C = 1.9387$.

Figure 5.5 visualizes how the discrete reachable sets (gray shaded) generated by Euler's method approximate the theoretical reachable set.

SOME NONLINEAR MAPS AND RENORMINGS OF BANACH SPACES*

S. LAJARA†, A. J. PALLARÉS‡, AND S. TROYANSKI‡

Abstract. We consider two classes of nonlinear maps between normed spaces which are relevant for the study of Banach spaces that admit equivalent locally uniformly rotund and midpoint locally uniformly rotund norms. It turns out to be a useful characterization of such maps in terms of optimization, topology, and probability. Using these characterizations we obtain some renorming results.

Key words. σ-midpoint continuous map, σ-slicely continuous map, midpoint locally uniformly rotund norm

DOI. 10.1137/060656280

1. Introduction.

Renorming a Banach space X consists in finding equivalent norms on X with good geometrical properties of convexity or differentiability, as close as possible to those of the euclidean norms in finite dimensional Banach spaces.

Among the notions related to the convexity we have that of a locally uniformly rotund norm, which plays an important role in the geometry of Banach spaces as well as in optimization theory (see, e.g., [4, 5, 17, 18]). A normed space X (or a norm $\|\cdot\|$ on X) is said to be *locally uniformly rotund* (LUR) if, for every $x \in X$ and every sequence $(x_n)_n \subset X$ such that $\lim_n \|x_n\| = \|x\|$ and $\lim_n \|x_n + x\| = 2\|x\|$, we have $\lim_n \|x_n - x\| = 0$.

The class of normed spaces that admit an equivalent LUR norm was characterized in [12] (see also [16]), involving the notion of ϵ-denting point. Recall that an element x of a set K in a normed space X is an *ϵ-denting point* of K if there exists an open half space $H \subset X$ (i.e., a set of the form $f^{-1}(a, \infty)$ with $f \in X^*$ and $a \in \mathbb{R}$) such that $x \in H$ and $\operatorname{diam}(H \cap K) < \epsilon$. The set $H \cap K$ is called a *slice* of K.

THEOREM 1 (see [12, Main Theorem]). *A normed space X admits an equivalent LUR norm if and only if for every $\epsilon > 0$ we can write*

$$X = \bigcup_{n \in \mathbb{N}} X_{n,\epsilon}$$

in such a way that every $x \in X_{n,\epsilon}$ is an ϵ-denting point of the set $X_{n,\epsilon}$.

It is rather difficult to apply directly the above theorem to get LUR norms in concrete normed spaces. In [14] a new class of maps was introduced and studied, the σ-slicely continuous maps. Using this class of maps, a transfer technique for

LUR renorming was established. It turns out that this class of maps admits characterizations in terms of optimization (subdifferentials), probability (expectations and distributions of random variables), and topology (σ-discrete families of sets).

As a variant of the LUR property we have the notion of MLUR norm. A normed space X (or a norm $\|\cdot\|$ on X) is said to be *midpoint locally uniformly rotund* (MLUR) if, for every $x \in X$ and every sequence $(x_n)_n \subset X$ such that $\|x_n + x\| \to \|x\|$ and $\|x_n - x\| \to \|x\|$, we have $\|x_n\| \to 0$.

It is well known that the MLUR property lies between local uniform rotundity and strict convexity. In the paper [7], devoted to the renorming of spaces of continuous functions on trees, Haydon provided the first example of MLUR space with no equivalent LUR renorming. On the other hand, the space ℓ_∞ (which admits an equivalent dual strictly convex norm being the dual of a separable space) does not have any equivalent MLUR renorming (see, e.g., [2] and [8], where it was shown that there is not any equivalent MLUR renorming on ℓ_∞ using a variant of the argument in [11] about the impossibility of LUR renormability of that space).

The class of MLUR renormable spaces was characterized in a linear topological way in [13], using the concept of ϵ-strongly extreme point, introduced in [9]. The following definition provides an equivalent formulation of this concept.

DEFINITION 2. *Let K be a subset of a normed space X, and let $\epsilon, \delta > 0$. An element $x \in K$ is said to be an (ϵ, δ)-strongly extreme point of K if*

$$\|u - x\| \le \epsilon \quad \text{and} \quad \|v - x\| \le \epsilon \quad \text{whenever} \quad u, v \in K \quad \text{and} \quad \left\| x - \frac{u+v}{2} \right\| < \delta.$$

The point x is called an ϵ-strongly extreme point *of K if there exists $\delta > 0$ such that x is an (ϵ, δ)-strongly extreme point of K.*

It is easy to see that every ϵ-denting point is a 2ϵ-strongly extreme point. It is also well known that a normed space is MLUR if and only if every element of its unit sphere is an ϵ-strongly extreme point of the unit ball for each $\epsilon > 0$. The aforementioned characterization of MLUR renormability is given by the following theorem.

THEOREM 3 (see [13, Theorem 1]). *A normed space X admits an equivalent MLUR norm if and only if for every $\epsilon > 0$ we can write*

$$X = \bigcup_{n=1}^{\infty} X_{n,\epsilon}$$

in such a way that each $x \in X_{n,\epsilon}$ is an ϵ-strongly extreme point of the set $\mathrm{co}(X_{n,\epsilon})$, *where* $\mathrm{co}(A)$ *denotes the convex hull of A.*

In this paper we provide some more characterizations of the σ-slicely continuous maps. Also, motivated by the notion of ϵ-strongly extreme point and the above characterization of MLUR renormability, we introduce and study a new class of nonlinear maps between normed spaces that we call σ-midpoint continuous maps. This class includes that of the σ-slicely continuous maps and is relevant for the study of normed spaces that admit equivalent MLUR norms. In terms of this new class we obtain some results which cover all the known cases of MLUR renorming.

2. σ-slicely continuous and σ-midpoint continuous maps. As we mentioned in the introduction, in the recent memoir [14], a nonlinear transfer technique for LUR renormability has been developed. The following notion, introduced there, plays the main role in this technique.

DEFINITION 4. *Let X and Y be normed spaces, and let A be a subset of X. A map $\Phi : A \longrightarrow Y$ is said to be σ-slicely continuous if, for every $\epsilon > 0$, we may write*

$$A = \bigcup_{n\in\mathbb{N}} A_{n,\epsilon}$$

in such a way that for every $x \in A_{n,\epsilon}$ *there exists an open half space* $H_x \subset X$ *such that* $x \in H_x$ *and* $\operatorname{diam}\Phi(A_{n,\epsilon} \cap H_x) < \epsilon$.

This concept can be regarded as the countable covering counterpart of the notion of slice continuity. Recall that if A is a subset of X, then a map $\Phi : A \longrightarrow Y$ is said to be *slicely continuous* at a point $x \in A$ if there exists an open half space $H_x \subset X$ containing x such that $\operatorname{diam}\Phi(A \cap H_x) < \epsilon$.

The characterization of LUR renormable spaces given in Theorem 1 shows that a normed space X is LUR renormable if and only if the identity operator $Id : X \longrightarrow X$ is σ-slicely continuous.

Let us note that if Y is a separable normed space, then every map $\Phi : X \longrightarrow Y$ is σ-slicely continuous. Indeed, for any $\epsilon > 0$ we can write $Y = \bigcup_{n\in\mathbb{N}} B_n$, where each B_n is a ball of diameter less than ϵ. The sequence $\{\Phi^{-1}(B_n)\}_n$ is then a countable covering of X that satisfies the required properties. Therefore, the natural framework for the study of the class of σ-slicely continuous maps is that of nonseparable spaces.

In [14], many examples of maps in this class are given. Let us mention that it includes, among others, bounded linear operators whose domain or range is an LUR renormable space and positive convex maps with values in an LUR lattice. Recall that a map Φ from a normed space X into a Banach lattice Y is said to be positive and convex if for every $x_1, x_2 \in X$ and $\lambda, \mu \geq 0$ such that $\lambda + \mu = 1$ we have

$$0 \leq \Phi(\lambda x_1 + \mu x_2) \leq \lambda\Phi x_1 + \mu\Phi x_2.$$

Also, in [14], the σ-slicely continuous maps are characterized using the notion of ϵ-subdifferential, used by Asplund and Rockafellar [3] in nonlinear analysis. Recall that if A is a subset of a linear topological space X and ϕ is a map from A into $\mathbb{R}$, the ϵ-subdifferential of ϕ at a point $x \in C \subseteq A$ is the set

$$\partial_\epsilon\phi(x|C) = \{f \in X^* : f(y) \geq \phi(x) + f(y - x) - \epsilon \quad \forall y \in C\}$$

and the subdifferential of ϕ at x is $\partial\phi(x|C) = \bigcap_{\epsilon>0} \partial_\epsilon\phi(x|C)$.

In the next theorem we complete the characterization of σ-slicely continuous maps in a probabilistic way. Before establishing that theorem, we make some comments about the notations and background from measure theory to be used in its statement and proof (as well as in other definitions and results in this work).

We shall consider a probability space (Ω, Σ, P), where Σ is a σ-algebra of subsets of Ω. A function $U : \Omega \longrightarrow X$ is said to be *simple* if there exist $x_1, \ldots, x_m \in X$ and $E_1, \ldots, E_m \in \Sigma$ such that $U = \sum_{k=1}^m x_k \mathbb{1}_{E_k}$, where $\mathbb{1}_{E_k}$ denotes the characteristic function of the set E_k. A function $U : \Omega \longrightarrow X$ is called *strongly measurable* if there exists a sequence of simple functions $U_n : \Omega \longrightarrow X$ such that $\lim_n \|U - U_n\| = 0$ almost everywhere. A strongly measurable function $U : \Omega \longrightarrow X$ is said to be *Bochner integrable* whenever there is a sequence of simple functions U_n such that $\lim_n \int \|U - U_n\| dP = 0$. In this case, the integral with respect to a set $E \in \Sigma$ is $\lim_n \int_E U_n dP$, where the integral for simple functions is defined in the usual way. The symbol $L^1(P, X)$ stands for the Banach space of all Bochner integrable random variables $U : \Omega \longrightarrow X$ endowed with the norm $\|\cdot\|_1$. We refer the reader to the survey [6] for a complete study of the Bochner integral.

We shall consider random variables $U : \Omega \longrightarrow X$, which we always assume to be Bochner integrable functions. We write $\mathbb{E}(U) = \int_\Omega U\, dP$ for the expectation of U

with respect to the probability P, and $\mathbb{E}_B V = (\int_B V dP)/P(B)$ for its conditional expectation with respect to a measurable set $B \subset \Omega$ such that $P(B) > 0$.

Since every Bochner integrable function $U : \Omega \longrightarrow X$ can be approximated in the $L^1(P, X)$-norm by a sequence of functions taking finitely many values in $\mathrm{co}(U(\Omega))$ (see, e.g., [6, Chapters II.2.8 and V.2.2]), for our purposes it is enough to consider random variables U which take finitely many values $\{u_i\}_{i\in I}$ with probabilities $\{p_i\}_{i\in I}$. In this case, clearly $\mathbb{E}(U) = \sum_{i\in I} p_i u_i$. However, in order to simplify our presentation we shall consider general Bochner integrable random variables.

In the definition of σ-slicely continuous map, it is not considered any additional property ensuring the strong measurability of the map $\Phi \circ U$ whenever U is a strongly measurable function. However, in most of the examples and applications, Φ is norm continuous, and when we are able to ensure that $\Phi \circ U$ is bounded, we also have that this function is Bochner integrable.

THEOREM 5. *Let X and Y be normed spaces, A be a subset of X, and Φ be a map from A into Y. The following conditions are equivalent:*

(a) *Φ is σ-slicely continuous;*
(b) *for every $\epsilon > 0$ we can write $A = \bigcup_{n\in\mathbb{N}} A_{n,\epsilon}$ in such a way that for every $x \in A_{n,\epsilon}$ and every 1-Lipschitzian function $g : \Phi(A_{n,\epsilon}) \longrightarrow \mathbb{R}$ we have $\partial_\epsilon g \circ \Phi(x|A_{n,\epsilon}) \neq \emptyset$;*
(c) *for every $\epsilon > 0$ and every $\xi > 0$, we can write $A = \bigcup_{n\in\mathbb{N}} A_{n,\epsilon,\xi}$ in such a way that for every $x \in A_{n,\epsilon,\xi}$ there exists a number $\delta > 0$ with the property that if $U : (\Omega, \Sigma, P) \to A_{n,\epsilon,\xi}$ is a random variable such that ΦU is also a random variable and $\|x - \mathbb{E}(U)\| < \delta$, then $P(\{\|\Phi x - \Phi U\| > \epsilon\}) < \xi$;*
(d) *for every $\epsilon > 0$ we can write $A = \bigcup_{n\in\mathbb{N}} A_{n,\epsilon}$ in such a way that for every $x \in A_{n,\epsilon}$ there exists a number $\delta > 0$ with the property that if $U : (\Omega, \Sigma, P) \to A_{n,\epsilon}$ is a random variable such that ΦU is also a random variable and $\|x - \mathbb{E}(U)\| < \delta$, then $\mathbb{E}(\|\Phi x - \Phi U\|) < \epsilon$.*

In order to complete the proof of this theorem we need the following lemma, which will be used in other results through this paper. In its proof, we take advantage of some technical ideas from [13, Proposition 1] and [14, Lemma 4.21]. Let us observe that if U is a random variable and $f \in X^*$, $f \circ U$ is a measurable function, and that if $H = f^{-1}(\alpha, \infty)$ is an open half space, then the set $\{U \in H\} = \{\omega \in \Omega : f(U\omega) > \alpha\}$ is measurable.

LEMMA 6. *Let A be a subset of a normed space X. Assume that for each $x \in A$ we have chosen an open half space $H_x \subset X$ such that $x \in H_x$. Then for each fixed $\xi > 0$ we can write $A = \bigcup_{n\in\mathbb{N}} A_n$ in such a way that for every $n \in \mathbb{N}$ and every $x \in A_n$ there exist an open half space H'_x, a number $\eta_x > 0$, and an element $w_x \in A$ with the following properties:*

(a) *$x \in H'_x \cap A_n \subset H_{w_x} \cap A$;*
(b) *if U is a random variable on a probability space (Ω, Σ, P) with values in A_n such that $\|x - \mathbb{E}(U)\| < \eta_x$, then $P(\{U \notin H'_x\}) < \xi$.*

Proof. We can assume without loss of generality that the set A is bounded. So,

$$\sup\{f(x) : x \in A,\ f \in X^*,\ \|f\| = 1\} < \infty. \tag{1}$$

Let us fix, for each $x \in X$, a norm-one functional $f_x \in X^*$ and rational numbers q_x and r_x (with $r_x > 0$) such that $\{z \in X : f_x(z) > q_x\} \subseteq H_x$ and

$$f_x(x) > q_x + r_x.$$

We make an initial decomposition of the set A by defining, for each $q \in \mathbb{Q}$,

$$A_q = \{x \in A : q_x = q\}.$$

Now for each pair $r, s \in \mathbb{Q}^+$ we write

$$A_{q,r,s} = \left\{ x \in A_q : s < \xi r_x/2,\ q + r < \sup_{w \in A_q} f_w(x) < q + r + s \right\}.$$

Thanks to (1) we have

$$A = \bigcup_{q \in \mathbb{Q},\, r,s \in \mathbb{Q}^+} A_{q,r,s}.$$

Let us fix $x \in A_{q,r,s}$, let us take an element $w_x \in A_q$ such that

$$f_{w_x}(x) > q + r,$$

and let

$$H'_x = \{z \in X : f_{w_x}(z) > f_{w_x}(x) - r\}.$$

If $z \in H'_x \cap A_{q,r,s}$, then $f_{w_x}(z) > q = q_{w_x} = q_x$ and

$$f_{w_x}(z) < q + r + s < f_{w_x}(x) + s.$$

The first inequality means that $H'_x \cap A_{q,r,s} \subseteq H_{w_x}$. From the second we deduce that

$$f_{w_x}(x - z) > -s. \tag{2}$$

On the other hand, for each $z \in A_{q,r,s} \setminus H'_x$ we have

$$f_{w_x}(x - z) \geq r. \tag{3}$$

Note also that because of the definition of the set $A_{q,r,s}$ we have

$$r + s > f_x(x) - q > r_x. \tag{4}$$

Now choose a number $0 < \eta_x < \min\{s, 1\}$, and let $U : (\Omega, \Sigma, P) \to A_{q,r,s}$ be a random variable such that $\|x - \mathbb{E}(U)\| < \eta_x$. Then, using inequalities (2), (3), and (4) we obtain

$$\begin{aligned}
\eta_x &> \|\mathbb{E}(x - U)\| \geq \mathbb{E}(f_{w_x}(x - U)) \\
&= P(\{U \notin H'_x\})\, \mathbb{E}_{\{U \notin H'_x\}}(f_{w_x}(x - U)) \\
&\quad + P(\{U \in H'_x\})\, \mathbb{E}_{\{U \in H'_x\}}(f_{w_x}(x - U)) \\
&\geq r P(\{U \notin H'_x\}) - s P(\{U \in H'_x\}) \\
&= (r + s) P(\{U \notin H'_x\}) - s \\
&> r_x P(\{U \notin H'_x\}) - s
\end{aligned}$$

and, consequently,

$$P(\{U \notin H'_x\}) < \frac{s + \eta_x}{r_x} < \frac{2s}{r_x} < \xi. \qquad \square$$

Proof of Theorem 5. We start by proving the implication (a) ⇒ (c). Let us fix $\epsilon, \xi > 0$. Since Φ is σ-slicely continuous we have a countable decomposition of A,

$$A = \bigcup_{n\in\mathbb{N}} A_n,$$

in such a way that for every $x \in A_n$ there is an open half space $H_x \subset X$ such that $x \in H_x$ and

$$\operatorname{diam} \Phi(A_n \cap H_x) < \frac{\epsilon}{2}. \tag{5}$$

By Lemma 6, for each $n \in \mathbb{N}$ we can write

$$A_n = \bigcup_{m\in\mathbb{N}} A_{n,m}$$

in such a way that for every $x \in A_{n,m}$ there exist a number $\eta_x > 0$, an open half space $H'_x \subset X$, and an element $w_x \in A_n$ such that $x \in H'_x \cap A_{n,m} \subseteq H_{w_x} \cap A_n$ and if $U : (\Omega, \Sigma, P) \to A_{n,m}$ is a random variable such that $\|x - \mathbb{E}(U)\| < \eta_x$, then $P(\{U \notin H'_x\}) < \xi$. By (5) it follows that $\{\|\Phi x - \Phi U\| > \epsilon\} \subset \{U \notin H'_x\}$. So (assuming that ΦU is also a random variable) we get $P(\|\Phi x - \Phi U\| > \epsilon) < \xi$, and assertion (c) is proved.

To show that (c) ⇒ (d) we assume that there exists $M > 0$ such that $\|\Phi y\| \le M$ for all $y \in A$. Let us fix $\epsilon > 0$. By hypothesis we can write

$$A = \bigcup_{n\in\mathbb{N}} A_n$$

in such a way that for every $x \in A_n$ there is a number $\delta_x > 0$ with the property that if $U : (\Omega, \Sigma, P) \to A_n$ is a random variable such that ΦU is also a random variable and $\|x - \mathbb{E}(U)\| < \delta_x$, then $P(C) < \frac{\epsilon}{4M}$, where $C = \{\|\Phi x - \Phi U\| > \frac{\epsilon}{2}\}$. Thus,

$$\begin{aligned}\mathbb{E}(\|\Phi x - \Phi U\|) &= P(C)\,\mathbb{E}_C(\|\Phi x - \Phi U\|) + P(\Omega \setminus C)\,\mathbb{E}_{\Omega\setminus C}(\|\Phi x - \Phi U\|)\\ &\le 2MP(C) + \frac{\epsilon}{2}P(\Omega \setminus C) < \epsilon,\end{aligned}$$

as we wanted to show.

Now we prove that (d) ⇒ (a). As before we fix $\epsilon > 0$. Let $\{A_{n,\epsilon}\}_n$ be a covering of A such that for every $x \in A_{n,\epsilon}$ there is a number $\delta_x > 0$ with the property that if $U : (\Omega, \Sigma, P) \to A_{n,\epsilon}$ is a random variable such that ΦU is also a random variable and $\|x - \mathbb{E}(U)\| < \delta_x$, then $\mathbb{E}(\|\Phi x - \Phi U\|) < \epsilon$. We are going to prove that this decomposition also satisfies condition (a).

Take $n \in \mathbb{N}$ and $x \in A_{n,\epsilon}$. Let

$$C = \overline{\operatorname{co}\left(\{z \in A_{n,\epsilon} : \|\Phi z - \Phi x\| \ge \epsilon\}\right)}^{\|\cdot\|}.$$

We claim that $\operatorname{dist}(x, C) \ge \frac{\delta_x}{2}$. Indeed, assuming the contrary, we can find positive numbers $p_1, \dots, p_r$ and vectors $u_1, \dots, u_r \in A_{n,\epsilon}$ such that $\sum_{i=1}^r p_i = 1$,

$$\left\| x - \sum_{i=1}^r p_i u_i \right\| < \delta_x, \tag{6}$$

and

$$\|\Phi x - \Phi u_i\| > \epsilon \quad \forall i = 1, \dots, r. \tag{7}$$

Let U be a random variable which takes the values u_i with probabilities p_i. Using (6) and the hypothesis we get $\mathbb{E}(\|\Phi x - \Phi U\|) = \sum_{i=1}^{r} p_i \|\Phi x - \Phi u_i\| < \epsilon$, which is a contradiction with (7).

So, $\operatorname{dist}(x, C) \geq \frac{\delta_x}{2}$. Since the set C is convex and closed, it follows by Hahn–Banach separation theorem the existence of an open half space $H_x \subset X$ such that $x \in H_x$ and $C \subset X \setminus H_x$. In particular, $\operatorname{diam} \Phi(A_{n,\epsilon} \cap H_x) < 2\epsilon$ and the map Φ is σ-slicely continuous.

The equivalence between (a) and (b) is proved in [13]. □

Let us mention that in [13] are given more characterizations of σ-slicely continuous maps in topological terms.

Now we consider a simple particular case of this class of maps that will be used for establishing one of the main renorming results in the next section.

Definition 7. *Let X be a normed space and Λ be a set. A map $\tau : X \longrightarrow \Lambda$ is said to be σ-slicely constant if we can write*

$$X = \bigcup_{n \in \mathbb{N}} X_n$$

in such a way that for every $x \in X_n$ there is an open half space $H_x \subset X$ such that $x \in H$ and $\tau(z) = \tau(x)$ for every $z \in X_n \cap H_x$.

The concept of a σ-slicely constant map has been introduced in [15]. There, it is proved that every σ-slicely continuous map between two normed spaces can be expressed as a norm pointwise limit of a sequence of σ-slicely constant maps.

The rigidity property of the space $c_0(\Gamma)$ provides examples of σ-slicely constant maps in those normed spaces X that admit a σ-slicely continuous map $\Phi : X \longrightarrow c_0(\Gamma)$.

Proposition 8. *Let A be a subset of a normed space X, let $\Phi : A \longrightarrow c_0(\Gamma)$ be a σ-slicely continuous map, and let $\epsilon > 0$. Then the set valued map $M_{\Phi,\epsilon} : A \longrightarrow 2^{\Gamma}$ defined by the formula*

$$M_{\Phi,\epsilon}(x) := \{\gamma \in \Gamma : |\Phi x(\gamma)| \geq \epsilon\}$$

is σ-slicely constant.

Proof. Set, for each $k \in \mathbb{N}$,

$$A_k = \left\{ x \in A : \sup\{|\Phi x(\gamma)| : \gamma \notin M_{\Phi,\epsilon}(x)\} < \epsilon - \frac{1}{k} \right\}.$$

By the σ-slicely continuity of Φ we can write

$$A_k = \bigcup_{n \in \mathbb{N}} A_{n,k}$$

in such a way that for every $x \in A_{n,k}$ there is an open half space $H_x \subset X$ such that $x \in H_x$ and

$$\operatorname{diam} \Phi\left(H_x \cap A_{n,k}\right) < \frac{1}{k}. \tag{8}$$

It is clear that

$$A = \bigcup_{k,n\in\mathbb{N}} A_{n,k}.$$

Now fix $k, n \in \mathbb{N}$, and let $z \in H_x \cap A_{n,k}$. We claim that $M_{\Phi,\epsilon}(z) \subseteq M_{\Phi,\epsilon}(x)$. Assuming the contrary we can find an element $\beta \in \Gamma$ such that $|\Phi z(\beta)| \geq \epsilon$ and $|\Phi x(\beta)| < \epsilon - \frac{1}{k}$. From these inequalities we get

$$|\Phi z(\beta) - \Phi x(\beta)| \geq |\Phi z(\beta)| - |\Phi x(\beta)| > \epsilon - \left(\epsilon - \frac{1}{k}\right) = \frac{1}{k},$$

which is a contradiction with (8). In a similar way we can deduce that $M_{\Phi,\epsilon}(x) \subseteq M_{\Phi,\epsilon}(z)$, and the proposition is proved. □

Now our aim is to introduce new classes of maps between normed spaces to be useful for the study of MLUR renormings. As may be expected, these classes will be inspired by the notion of strongly extreme point and the covering type characterization of MLUR renormability given by Theorem 3. Before formulating the corresponding concepts it is convenient to prove the following simple fact concerning strongly extreme points.

LEMMA 9. *Let K be a set of a normed space X, let $\epsilon, \delta > 0$, and let $x \in K$. Then the following conditions are equivalent:*

(a) *x is an (ϵ, δ)-strongly extreme point of the set $\mathrm{co}(K)$;*

(b) *if $U : (\Omega, \Sigma, P) \to K$ is a random variable such that $\|x - \mathbb{E}(U)\| < \delta$, then for any measurable subset $C \subset \Omega$ with $P(C) \geq \frac{1}{2}$ we have*

$$\|x - \mathbb{E}_C(U)\| \leq \epsilon.$$

Proof. Assume that x is an (ϵ, δ)-strongly extreme point of $\mathrm{co}(K)$. It is also an (ϵ, δ)-strongly extreme point of $\overline{\mathrm{co}(K)}$. Let $U : (\Omega, \Sigma, P) \to K$ be a random variable such that $\|x - \mathbb{E}(U)\| < \delta$, and let $C \in \Sigma$ with $1 > P(C) = \lambda \geq \frac{1}{2}$. Define $w_1 = \mathbb{E}_C(U)$ and $w_2 = \mathbb{E}_{\Omega\setminus C}(U)$. It is clear that $w_1, w_2 \in \overline{\mathrm{co}(K)}$ and that $\mathbb{E}(U) = \lambda w_1 + (1-\lambda)w_2$. The vector $w_3 = (2\lambda - 1)w_1 + (2 - 2\lambda)w_2$ belongs to the line segment joining w_1 and w_2, in particular $w_3 \in \overline{\mathrm{co}(K)}$. Moreover, $\frac{w_1+w_3}{2} = \mathbb{E}(U)$, and then $\left\|x - \frac{w_1+w_3}{2}\right\| < \delta$. Since x is an (ϵ, δ)-strongly extreme point of $\overline{\mathrm{co}(K)}$ we deduce that $\|w_1 - x\| \leq \epsilon$, and assertion (b) is proved.

For the implication (b) $\Rightarrow$ (a) just consider the midpoint of two vectors u, v in $\mathrm{co}(K)$ as the expectation of a random variable U that takes values in K in such a way that there is a set C with $P(C) = \frac{1}{2}$, $u = \mathbb{E}_C(U)$, and $v = \mathbb{E}_{\Omega\setminus C}(U)$. □

DEFINITION 10. *Let X and Y be normed spaces, and let A be a subset of X. A map $\Phi : A \longrightarrow Y$ is said to be midpoint continuous at a point $x \in A$ if, for every $\epsilon > 0$, there is a number $\delta > 0$ with the following property: if U is a simple random variable on the probability space (Ω, Σ, P) with values in A, and $\|x - \mathbb{E}(U)\| < \delta$, then for every measurable set $C \subseteq \Omega$ such that $P(C) \geq \frac{1}{2}$ we have $\|\Phi x - \mathbb{E}_C(\Phi U)\| \leq \epsilon$.*

Let us mention that the number $\frac{1}{2}$ in the above definition can be replaced with any positive constant less than $\frac{1}{2}$.

According to Lemma 9 it follows that the space X is MLUR if and only if the restriction of the identity operator on X to the unit ball is midpoint continuous on the unit sphere of X. If Φ is bounded and A is convex, we can consider arbitrary random variables in the above definition. This is due to the fact that if U is such a random variable, then U can be approximated pointwise and in the $L^1(P, X)$-norm by

a sequence of simple functions U_n with values in A, and ΦU by ΦU_n simultaneously, as a consequence of the dominated convergence theorem.

It is clear that every midpoint continuous map is continuous. The property of being midpoint continuous is, indeed, much stronger than the simple continuity. In fact, if I is an interval of $\mathbb{R}$ and $\Phi : I \longrightarrow \mathbb{R}$ is a midpoint continuous map, then for each $a, b \in I$ we have $\Phi((a+b)/2) = \Phi(a) = \Phi(b)$, and Φ is constant.

It is not difficult to check directly the midpoint continuity of the identity operator of some concrete spaces at some points. We will present a detailed discussion of this fact in the cases of Hilbert and $C(K)$ spaces, in order to make the reader familiar with the probabilistic techniques that we shall use in other results of this paper.

Let H be a Hilbert space. Fix $x \in H$ with $\|x\| = 1$ and $\epsilon > 0$. Let U be a random variable with values in the unit ball B_H such that $\|x - y\| < \delta$, where $0 < \delta < \min\{1, \epsilon^2/32\}$ and $y = \mathbb{E}(U)$. Bearing in mind that $\mathbb{E}(y - U) = 0$ we get

$$\mathbb{E}\left(\|x - y + U\|^2\right) = \mathbb{E}\left(\|x\|^2 + \|y - U\|^2\right).$$

Using this equality and the fact that P is a probability we have

$$\begin{aligned} &\left(\mathbb{E}(\|x - U\|)\right)^2 \leq \mathbb{E}\left((\|x - y\| + \|y - U\|)^2\right) \\ &\leq 2\,\mathbb{E}\left(\|x - y\|^2 + \|y - U\|^2\right) \leq 2\left(\delta^2 + \mathbb{E}(\|x - y + U\|^2) - \|x\|^2\right) \\ &\leq 2\left(\delta^2 + \mathbb{E}\left((\|x - y\| + \|U\|)^2\right) - 1\right) \leq \left(\delta^2 + (\delta + 1)^2 - 1\right) < 8\delta. \end{aligned} \tag{9}$$

So, if C is a measurable set with $P(C) \geq \frac{1}{2}$, then

$$\|x - \mathbb{E}_C(U)\| \leq \mathbb{E}_C\left(\|x - U\|\right) \leq \frac{1}{P(C)}\,\mathbb{E}\left(\|x - U\|\right) < 2\sqrt{8\delta} < \epsilon. \tag{10}$$

Thus, the restriction of the identity operator to the unit ball of H is midpoint continuous at every element of its unit sphere. Let us note that our argument shows that the identity operator on B_H is, actually, slicely continuous at each point of the unit sphere (see (d) $\Rightarrow$ (a) in Theorem 5).

Now let K be a compact set and x be an extreme point of the unit ball of the space $(C(K), \|\cdot\|_\infty)$. It is well known that $|x(t)| = 1$ for each $t \in K$. Fix $\epsilon > 0$, let U be a random variable with values in $B_{C(K)}$ such that $\|x - \mathbb{E}(U)\|_\infty < \delta$, where $0 < \delta < \min\{1, \epsilon^2/32\}$, and let C be a measurable set such that $P(C) \geq \frac{1}{2}$. For every fixed $t \in K$ we have $|x - \mathbb{E}(U(t))| < \delta$. So, applying (10) in the case where $H = \mathbb{R}$ we get $|x(t) - \mathbb{E}_C(U(t))| < \epsilon$, and taking the sumpremum over all $t \in K$ we obtain $\|x - \mathbb{E}_C(U)\|_\infty < \epsilon$. Therefore, the restriction of the identity operator on $C(K)$ to $B_{C(K)}$ is midpoint continuous at every extreme point of this set. Let us mention that if K is an infinite compact, the restriction of the identity operator on $C(K)$ to $B_{C(K)}$ is not slicely continuous at any element of the unit sphere of $C(K)$ (it is well known that every slice of $B_{C(K)}$ has diameter 2).

At this point, we state the counterpart of the above concept in terms of countable coverings. To avoid measurability problems, from now on we consider only simple random variables. Let us observe that if Φ is a map between the normed spaces X and Y and $U : \Omega \longrightarrow X$ is a simple random variable, then $\Phi \circ U$ is a simple random variable too.

DEFINITION 11. *Let X and Y be normed spaces, let $A \subseteq X$, and let $\epsilon > 0$. A map $\Phi : X \longrightarrow Y$ is said to be ϵ-σ-midpoint continuous on A if we can write*

$$A = \bigcup_{n \in \mathbb{N}} A_n$$

in such a way that for every $x \in A_n$ there is a number $\delta > 0$ such that if U is a simple random variable on the probability space (Ω, Σ, P) with values in A_n satisfying $\|x - \mathbb{E}(U)\| < \delta$, then for every measurable set $C \subset \Omega$ such that $P(C) \geq \frac{1}{2}$ we have $\|\Phi x - \mathbb{E}_C(\Phi U)\| \leq \epsilon$.

The map Φ is σ-midpoint continuous if it is ϵ-σ-midpoint continuous for each $\epsilon > 0$.

According to Theorem 3 and Lemma 9 it follows that if T is a bounded linear operator between two normed spaces X and Y, one of them being MLUR renormable, then T is σ-midpoint continuous on X. Also, from those results we have that the space X admits an equivalent MLUR norm if and only if the identity operator on X is σ-midpoint continuous.

As an example, we shall show the σ-midpoint continuity of the identity operator when X is a Hilbert space using probabilistic tools. Let $\epsilon > 0$, and define, for each positive rational number r, the set

$$X_r = \left(r + \frac{\epsilon^2}{1 + r^2} \right) B_X \setminus r B_X.$$

The sequence $\{X_r\}_{r \in \mathbb{Q}^+}$ is clearly a covering of $X \setminus \{0\}$. Let $x \in X \setminus \{0\}$, and choose $r \in \mathbb{Q}^+$ such that $x \in X_r$. Proceeding as in (9) we can deduce that if U is a (simple) random variable with values in X_r such that $\|x - \mathbb{E}(U)\| < \epsilon^2 \|x\|/(1 + r^2)$, then $(\mathbb{E}(\|x - U\|))^2 < 8\,\epsilon^2$. It follows that the identity operator on X is σ-midpoint continuous (the same argument shows that this operator is σ-slicely continuous). Let us mention that the construction of the above countable covering is based on the methods used in [12] and [13] to characterize the classes of normed spaces that admit an equivalent LUR or MLUR renorming.

The next result provides an example of σ-midpoint continuous map in the particular setting of spaces of bounded functions.

LEMMA 12. *Let V be a set, let $\epsilon > 0$, and let $V_1, \ldots, V_m$ be subsets of V. Assume that for each $r \in \{1, \ldots, m\}$ the identity map on $\ell_\infty(V_r)$ is ϵ-σ-midpoint continuous on some set $A_r \subseteq \ell_\infty(V_r)$. Then the map $\Phi : \ell_\infty(V) \to \ell_\infty(V)$ defined by the formula*

$$\Phi x = x \cdot \mathbb{1}_{\bigcup_{r=1}^m V_r}$$

is ϵ-σ-midpoint continuous on the set $\{x \in \ell_\infty(V) : x_{\restriction V_r} \in A_r \text{ for all } r = 1, \ldots, m\}$. (The symbol $x_{\restriction V_r}$ denotes the restriction of the function x to the set V_r.)

Proof. By hypothesis, for each $r = 1, \ldots, m$ we can write

$$A_r = \bigcup_{n \in \mathbb{N}} A_{r,n}$$

in such a way that every $z \in A_{r,n}$ is an (ϵ, δ)-strongly extreme point of $\mathrm{co}(A_{r,n})$, for some $\delta = \delta(r, n, z) > 0$.

For each $s = (s_1, \ldots, s_m) \in \mathbb{N}^m$ we define the set

$$A_s = \{x \in A : x_{\restriction V_r} \in A_{r,s_r} \quad \forall r = 1, \ldots, m\}.$$

It is clear that $A = \bigcup_{s \in \mathbb{N}^m} A_s$. Let us fix $s = (s_1, \ldots, s_m) \in \mathbb{N}$ and $x \in A_s$. Let $U : (\Omega, \Sigma, P) \to A_s$ be a simple random variable such that $\|x - \mathbb{E}(U)\|_\infty < \delta$, where $\delta = \min\{\delta(r, s_r, x) : r = 1, \ldots, m\}$. Let, for each $r = 1, \ldots, m$, U_r be the random variable defined by the formula $U_r(w) = U(w)_{\restriction V_r}$, $w \in \Omega$. Then U_r takes its values

in A_{r,s_r} and $\|x_{\restriction V_r} - \mathbb{E}(U_r)\|_\infty < \delta$. Since $x_{\restriction V_r}$ is an (ϵ,δ)-strongly extreme point of $\mathrm{co}(A_{r,s_r})$, from Lemma 9 it follows that if C is a measurable subset of Ω with $P(C) \geq \frac{1}{2}$, then $\|x_{\restriction V_r} - \mathbb{E}_C(U_r)\|_\infty \leq \epsilon$. As this inequality holds for each $r = 1, \ldots, m$ we get

$$\|\Phi x - \mathbb{E}_C(\Phi U)\|_\infty = \max_{r=1,\ldots,m} \|x_{\restriction V_r} - \mathbb{E}_C(U_r)\|_\infty \leq \epsilon,$$

as we wanted to show. □

Remark. In [7, Lemma 5.2] (see also [13, Lemma 3]) the author considered, for any set V and any $\epsilon > 0$, the set $E_\epsilon(V)$ made up of all the functions $x \in \ell_\infty(V)$ for which there exist $a, b \in \mathbb{R}$ and a binary partition $\{M, N\}$ of V such that $\|x - (a\mathbb{1}_M + b\mathbb{1}_N)\|_\infty < \epsilon$ and showed that the identity map of $\ell_\infty(V)$ is 15 ϵ-midpoint continuous on the set $E_\epsilon(V)$.

As may be conjectured, the class of σ-midpoint continuous maps includes that of the σ-slicely continuous maps.

PROPOSITION 13. *Let X and Y be normed spaces, let $A \subseteq X$, and let $\Phi : A \longrightarrow Y$ be a map. If Φ is σ-slicely continuous, then Φ is σ-midpoint continuous on A.*

Proof. Let us fix $\epsilon > 0$. According to Theorem 5 we can write

$$A = \bigcup_{n\in\mathbb{N}} A_n$$

in such a way that for every $x \in A_n$ there exists a number $\delta > 0$ with the property that $\mathbb{E}(\|\Phi x - \Phi U\|) < \epsilon$ whenever $U : (\Omega, \Sigma, P) \to A_n$ is a (simple) random variable such that $\|x - \mathbb{E}(U)\| < \delta$. So, for such a vector x, such a random variable U, and every measurable set $C \subset \Omega$ with $P(C) \geq \frac{1}{2}$ we have

$$\|\Phi x - \mathbb{E}_C(\Phi U)\| \leq \frac{1}{P(C)}\,\mathbb{E}(\|x - \Phi U\|) \leq 2\,\mathbb{E}(\|x - \Phi U\|) < 2\,\epsilon. \qquad \square$$

Note that the converse of this result does not hold in general. If X is MLUR renormable space with no equivalent LUR renorming, then the identity operator $Id : X \to X$ is σ-midpoint continuous but not σ-slicely continuous.

In [14], some stability properties for the class of σ-slicely continuous maps are established. There, it is shown that linear combinations, norm pointwise limits, and composition of σ-slicely continuous maps (as well as the composition of a continuous map $B : Y \longrightarrow Z$ with a σ-slicely continuous map $\Psi : X \longrightarrow Y$) are σ-slicely continuous too. The following results show that some of these properties are also shared by the class of σ-midpoint continuous maps.

PROPOSITION 14. *Let X and Y be normed spaces, let $\alpha, \beta \in \mathbb{R}$, and let Φ_1 and Φ_2 be two maps from X into Y, which are ϵ-σ-midpoint continuous on a set $A \subseteq X$. Then the map $\Phi = \alpha\Phi_1 + \beta\Phi_2$ is $(|\alpha| + |\beta|)\,\epsilon$-$\sigma$-midpoint continuous on A.*

In particular, linear combinations of σ-midpoint continuous maps are σ-midpoint continuous too.

Proof. It is straightforward to show that if $\{A_{1,n}\}_n$ and $\{A_{2,n}\}_n$ are coverings of A satisfying the conditions of Definition 11 for the maps Φ_1 and Φ_2, respectively, then the sequence of sets $\{A_{1,n} \cap A_{2,m} : n, m \in \mathbb{N}\}$ constitutes a covering of this type for the map Φ. □

PROPOSITION 15. *Let X and Y be normed spaces, let $\epsilon > 0$, and let Φ be a map from X into Y. Assume that there is a sequence $\{\Phi_n\}_n$ of maps from X into Y such that for all $x \in X$ there exists $m = m(x) \in \mathbb{N}$ satisfying*

$$\|\Phi x - \Phi_m x\| < \epsilon.$$

If for each $n \in \mathbb{N}$ the map Φ_n is ϵ-σ-midpoint continuous on X, then the map Φ is $3\,\epsilon$-σ-midpoint continuous on X.

In particular, the norm pointwise limit of a sequence of σ-midpoint continuous maps is also σ-midpoint continuous.

Proof. Let us define, for each $m \in \mathbb{N}$, the set

$$X_m = \{x \in X : \|\Phi x - \Phi_m x\| < \epsilon\}.$$

By the hypothesis we have $X = \bigcup_{m\in\mathbb{N}} X_m$.

Let $m \in \mathbb{N}$. Since the map Φ_m is ϵ-σ-midpoint continuous on X_m, we can write $X_m = \bigcup_{n\in\mathbb{N}} X_{m,n}$ in such a way that for every $x \in X_{m,n}$ there is a number $\delta = \delta_x > 0$ with the property that if $U : (\Omega, \Sigma, P) \to X_{m,n}$ is a simple random variable, and $\|x - \mathbb{E}(U)\| < \delta_x$, then for every measurable set $C \subseteq \Omega$ such that $P(C) \geq \frac{1}{2}$ we have $\|\Phi_m x - \mathbb{E}_C(\Phi_m U)\| \leq \epsilon$.

Hence, for such a point x, such a set C, and such a simple random variable U we have

$$\begin{aligned} \|\Phi x - \mathbb{E}_C(\Phi U)\| &\leq \|\Phi x - \Phi_m x\| + \|\Phi_m x - \mathbb{E}_C(\Phi_m U)\| \\ &\quad + \|\mathbb{E}_C(\Phi_m U - \Phi U)\| \\ &< \epsilon + \|\Phi x - \Phi_m x\| + \|\mathbb{E}_C(\Phi_m U - \Phi U)\|. \end{aligned} \tag{11}$$

On the other hand, by the definition of X_m we have $\|\Phi_m U(w) - \Phi U(w)\| < \epsilon$, for each $w \in \Omega$, and $\|\Phi x - \Phi_m x\| < \epsilon$. Combining these inequalities with (11) we obtain

$$\|\Phi x - \mathbb{E}_C(\Phi U)\| < 3\epsilon,$$

and the proposition is proved. □

Remark. A variant of the proof of Theorem 5 shows that if $\Phi : X \longrightarrow Y$ and $\Psi : Y \longrightarrow Z$ are, respectively, a σ-midpoint continuous map and a σ-slicely continuous map, then the map $\Xi = \Psi \circ \Phi$ is σ-midpoint continuous. It is also easy to show that the map Ξ is σ-midpoint continuous whenever Ψ is a bounded linear operator and Φ is σ-midpoint continuous, or whenever Φ and Ψ are bounded linear operators and one of them is σ-midpoint continuous. We do not know whether the composition of two σ-midpoint continuous maps is σ-midpoint continuous too. In the next section, we will see that the composition of a continuous and a σ-midpoint continuous map is not necessarily σ-midpoint continuous.

3. Renorming results. In this section we develop various techniques for constructing σ-midpoint continuous maps. As an application of these techniques, we obtain some results about MLUR renormings of Banach spaces.

In [10] it is shown that a normed space X is MLUR renormable whenever there exist a σ-slicely continuous map $\Psi : X \longrightarrow X$ and an MLUR renormable subspace $Y \subset X$ such that $x - \Psi x \in Y$ for all $x \in X$. The use of σ-midpoint continuous maps enables us to give the following improvement of that result.

THEOREM 16. *Let X and Y be normed spaces. Assume that there exist an MLUR renormable subspace $Y_1 \subset Y$, a bounded linear map $T : X \longrightarrow Y$, and a σ-midpoint continuous map $\Psi : X \longrightarrow Y$ such that the map $\Phi = T + \Psi$ takes its values in Y_1. Then the maps T and Φ are σ-midpoint continuous too.*

Proof. By Proposition 14 it is enough to show that T is σ-midpoint continuous. Let us fix $\epsilon > 0$. Since the space Y_1 is MLUR renormable we can write

$$Y_1 = \bigcup_{n,k\in\mathbb{N}} Y_{n,k}$$

in such a way that every $y \in Y_{n,k}$ is an $\left(\frac{\epsilon}{2}, \frac{1}{k}\right)$-strongly extreme point of $\mathrm{co}(Y_{n,k})$.

For each $n, k \in \mathbb{N}$ with $k > \frac{2}{\epsilon}$ we set $X_{n,k} = \Phi^{-1}(Y_{n,k})$.

As the map Ψ is σ-midpoint continuous on X there is a countable decomposition of $X_{n,k}$,

$$X_{n,k} = \bigcup_{p \in \mathbb{N}} X_{n,k,p},$$

in such a way that for each $x \in X_{n,k,p}$ there exists a number $0 < \delta_x < \frac{1}{2\|T\|k}$ with the property that if $U : (\Omega, \Sigma, P) \to X_{n,k,p}$ is a simple random variable and $\|x - \mathbb{E}(U)\| < \delta_x$, then for every measurable set $C \subset \Omega$ such that $P(C) \geq \frac{1}{2}$ we have

$$\|\Psi x - \mathbb{E}_C(\Psi U)\| \leq \frac{1}{2k}. \tag{12}$$

It is clear that the family of sets $\left\{X_{n,k,p} : n, k, p \in \mathbb{N},\ k > \frac{2}{\epsilon}\right\}$ is a countable covering of X.

Fix $n, k, p \in \mathbb{N}$ and $x \in X_{n,k,p}$, and let U be a simple random variable on the probability space (Ω, Σ, P) with values in $X_{n,k,p}$ such that $\|x - \mathbb{E}(U)\| < \delta_x$. Then

$$\begin{aligned}\|\Phi x - \mathbb{E}(\Phi U)\| &= \|\mathbb{E}(Tx - TU) + \Psi x - \mathbb{E}(\Psi U)\| \\ &\leq \|T\|\|x - \mathbb{E}(U)\| + \|\Psi x - \mathbb{E}(\Psi U)\| \\ &< \frac{1}{2k} + \|\Psi x - \mathbb{E}(\Psi U)\|.\end{aligned}$$

From this inequality and (12) (with $C = \Omega$) we get $\|\Phi x - \mathbb{E}(\Phi U)\| < \frac{1}{k}$. Since ΦU is a simple random variable with values in $Y_{n,k}$ and Φx is an $\left(\frac{\epsilon}{2}, \frac{1}{k}\right)$-strongly extreme point of $\mathrm{co}(Y_{n,k})$, from Lemma 9 it follows that if C is a measurable subset of Ω such that $P(C) \geq \frac{1}{2}$, then

$$\|\Phi x - \mathbb{E}_C(\Phi U)\| < \frac{\epsilon}{2}.$$

This inequality together with (12) implies that

$$\|Tx - \mathbb{E}_C(TU)\| \leq \|\Phi x - \mathbb{E}_C(\Phi U)\| + \|\Psi x - \mathbb{E}_C(\Psi U)\| < \frac{\epsilon}{2} + \frac{1}{2k} < \epsilon.$$

So, the map T is σ-midpoint continuous on X, as we wanted to show. □

As a consequence of this theorem we obtain the following result of G. Alexandrov concerning the three space problem for the MLUR property.

Corollary 17 (Alexandrov [1]). *Let X be a Banach space. Suppose that there is a closed MLUR renormable subspace $Y \subset X$ such that the quotient X/Y has an equivalent LUR norm. Then X admits an equivalent MLUR norm.*

Proof. Let Q denote the quotient map from X onto X/Y. According to the Bartle–Graves theorem (see, e.g., [5, Chapter VII.3]), there is a continuous map $B : X/Y \longrightarrow X$ such that $BQx \in Qx$ for all $x \in X$. If we define $\Phi = BQ$, then $x - \Phi x \in Y$ for every $x \in X$. Since the space X/Y is LUR renormable the maps Q and Φ are σ-slicely continuous. Therefore, Φ is σ-midpoint continuous. Applying Theorem 16 we deduce that the identity operator on X is σ-midpoint continuous. □

Let us mention that the property of having an equivalent MLUR norm is not a three space property. In [7] the existence of a Banach space X and a closed subspace

$Y \subset X$ is shown such that Y and X/Y both have an equivalent MLUR norm while X does not. This counterexample reveals that the composition of a continuous map and a σ-midpoint continuous map is not necessarily σ-midpoint continuous. Indeed, let Q be the quotient map from X onto X/Y and B be a Bartle–Graves continuous selector of Q^{-1}. Since Q is linear and bounded and the space X/Y is MLUR renormable it follows that Q is σ-midpoint continuous on X. Nevertheless, the map $\Phi = B \circ Q$ does not have this property (otherwise, the identity operator of X should be σ-midpoint continuous by Theorem 16).

The following theorem provides another approach for constructing σ-midpoint continuous maps.

THEOREM 18. *Let X and Y be normed spaces, let $\epsilon > 0$, and let Λ be a set. Let $\tau : X \longrightarrow \Lambda$ be a σ-slicely constant map, and let, for each $\alpha \in \Lambda$, $\psi_\alpha : X \longrightarrow Y$ be a map which is ϵ-σ-midpoint on some set $X_\alpha \subseteq X$. Then the map $\Psi : X \longrightarrow Y$ defined by the formula*

$$\Psi x = \psi_{\tau(x)}(x)$$

is $2\,\epsilon$-σ-midpoint continuous on the set $A = \{x \in X : x \in X_{\tau(x)}\}$.

Proof. For each $\alpha \in \Lambda$ we have a countable covering of X_α,

$$X_\alpha = \bigcup_{n \in \mathbb{N}} X_{\alpha,n},$$

in such a way that for every $x \in X_{\alpha,n}$ there is a number $0 < \delta_{\alpha,n,x} < \epsilon$ with the property that if $U : (\Omega, \Sigma, P) \to X_{\alpha,n}$ is a simple random variable such that $\|x - \mathbb{E}(U)\| < \delta_{\alpha,n,x}$, then for any measurable subset $C \subset \Omega$ with $P(C) \geq \frac{1}{2}$ we have

$$\|\psi_\alpha x - \mathbb{E}_C(\psi_\alpha U)\| < \epsilon. \tag{13}$$

Let $n, k \in \mathbb{N}$, and let $A_{n,k}$ denote the set made up of all the vectors $x \in X_{\tau(x),n,k}$ such that $\|x\| \leq k$, $\|\Psi x\| \leq k$, and $\delta_{\tau(x),n,x} > \frac{1}{k}$. It is clear that

$$A = \bigcup_{n,k \in \mathbb{N}} A_{n,k}.$$

Since the map τ is σ-slicely constant, for each $n, k \in \mathbb{N}$ we get another decomposition of $A_{n,k}$,

$$A_{n,k} = \bigcup_{m \in \mathbb{N}} A_{n,k,m},$$

with the property that for every $x \in A_{n,k,m}$ there is an open half space $H_x \subset X$ such that

$$\tau(u) = \tau(x) \quad \text{whenever} \quad u \in H_x \cap A_{n,k,m}. \tag{14}$$

Applying Lemma 6 to the set $A_{n,k,m}$, with $\xi = \frac{1}{4k^2}$, we can write

$$A_{n,k,m} = \bigcup_{p \in \mathbb{N}} A_{n,k,m,p}$$

in such a way that for every $x \in A_{n,k,m,p}$ there exist a number $\eta = \eta_x > 0$, an open half space $H'_x \subset X$, and an element $w_x \in A_{n,k,m}$ such that

$$x \in H'_x \cap A_{n,k,m,p} \subseteq H_{w_x} \cap A_{n,k,m} \tag{15}$$

and if $U : (\Omega, \Sigma, P) \to A_{n,k,m,p}$ is a random variable with $\|x - \mathbb{E}(U)\| < \eta_x$, and $N = \{w \in \Omega : U(w) \notin H'_x\}$, then

$$P(N) < \frac{1}{4k^2}. \tag{16}$$

Now let us fix natural numbers n, k, m, and p such that $A_{n,k,m,p} \neq \emptyset$. Take $x \in A_{n,k,m,p}$, and let $U : (\Omega, \Sigma, P) \to A_{n,k,m,p}$ be a simple random variable satisfying $\|x - \mathbb{E}(U)\| < \min\{\eta_x, \frac{1}{2k}\}$. Our goal is to show that if C is a measurable subset of Ω such that $P(C) \geq \frac{1}{2}$, then

$$\|\Psi x - \mathbb{E}_C(\Psi U)\| < 2\,\epsilon. \tag{17}$$

We will prove first that

$$\|x - \mathbb{E}(U)\| < \frac{1}{k} \quad \text{and} \quad U(w) \in H'_x \quad \forall w \in \Omega \Rightarrow \|\Psi x - \mathbb{E}_C(\Psi U)\| < \epsilon. \tag{18}$$

Thanks to (15) it follows that $U(w) \in A_{n,k,m} \cap H_{w_x}$ for all $w \in \Omega$. Using (14) we deduce that

$$\tau(U(w)) = \tau(x). \tag{19}$$

Hence, $U(w) \in X_{\tau(x),n,k}$. As $\delta_{\tau(x),n,x} > \frac{1}{k}$, thanks to (13) it follows that

$$\left\|\psi_{\tau(x)} x - \mathbb{E}_C(\psi_{\tau(x)} U)\right\| < \epsilon.$$

From (19) we also have $\psi_{\tau(x)} = \psi_{\tau(U(w))}$. Therefore,

$$\left\|\psi_{\tau(x)} x - \mathbb{E}_C(\psi_{\tau(U(w))} U(w))\right\| < \epsilon$$

and assertion (18) is proved.

To finish, suppose that not all the vectors $U(w)$ necessarily belong to the half space H'_x. Let $N = \{w \in \Omega : U(w) \notin H'_x\}$, and let U' be the simple random variable defined by the formula $U' = x\mathbb{1}_N + U\mathbb{1}_{\Omega\setminus N}$.

From inequality (16) and the fact $A_{n,k,m,p} \subseteq kB_X$ we get

$$\|x - \mathbb{E}(U')\| \leq \|\mathbb{E}(x - U)\| + P(N)\|\mathbb{E}_N(x - U)\| < \frac{1}{2k} + 2k\frac{1}{4k^2} = \frac{1}{k}.$$

Taking into account that U' takes its values in $A_{n,k,m,p} \cap H'_x$, from (18) it follows that $\|\Psi x - \mathbb{E}_C(\Psi U')\| < \epsilon$. Using again inequality (16) and the fact $\Psi(A_{n,k,m,p}) \subseteq kB_X$ we obtain

$$\begin{aligned}\|\Psi x - \mathbb{E}_C(\Psi U)\| &\leq \|\Psi x - \mathbb{E}_C(\Psi U')\| + \|\mathbb{E}_C(\Psi U - \Psi U')\| \\ &\leq \epsilon + P(N)\|\mathbb{E}_{C\cap N}(\Psi x - \Psi U)\| < 2\,\epsilon,\end{aligned}$$

as we wanted. □

Now we apply Theorem 18 and Proposition 8 to get some results about MLUR renormability in those Banach spaces X for which there exist a set Γ and a σ-slicely continuous map $\Phi : X \longrightarrow c_0(\Gamma)$.

COROLLARY 19. *Let X be a normed space, and let $\Phi : X \longrightarrow c_0(\Gamma)$ be a σ-slicely continuous map. Suppose that there exists a family $\{T_\gamma\}_{\gamma\in\Gamma}$ of bounded linear operators on X with the following properties:*

(1) *for each* $\gamma \in \Gamma$, $T_\gamma X$ *is an MLUR renormable subspace of* X*;*
(2) *for each* $x \in X$,

$$x \in \overline{\operatorname{span}\{T_\gamma x : \gamma \in \operatorname{supp}\Phi x\}}^{\|\cdot\|}.$$

Then X *admits an equivalent MLUR norm.*

Proof. Let us fix $\epsilon > 0$. We are going to demonstrate the existence of a sequence $\{\Psi_n\}_n$ of ϵ-σ-midpoint continuous maps on X such that

$$\lim_n \|x - \Psi_n x\| = 0$$

for all $x \in X$.

For technical reasons we introduce on Γ a well order $\prec$. Let Λ be the family of all finite sets $\{(\gamma_1, r_1), \dots, (\gamma_m, r_m)\} \in 2^{\Gamma\times\mathbb{Q}}$ such that $\gamma_i \neq \gamma_j$ whenever $i \neq j$, and let us define, for each $\alpha = \{(\gamma_1, r_1), \dots, (\gamma_m, r_m)\} \in \Lambda$, the map

$$\psi_\alpha = \sum_{i=1}^{m} r_i T_{\gamma_i}.$$

Since for each $i = 1, \dots, m$ the range of T_{γ_i} is an MLUR renormable space, it follows from Proposition 14 that the map ψ_α is ϵ-σ-midpoint continuous on X.

Let $n \in \mathbb{N}$. For each $x \in X$ we can choose a finite set

$$\Delta(x, n) = \{\gamma_1(x, n) \prec \cdots \prec \gamma_j(x, n)\} \subset \operatorname{supp}\Phi x$$

and a vector $(r_1(x, n), \dots, r_j(x, n)) \in \mathbb{Q}^j \setminus \{0\}$ such that

$$\left\| x - \sum_{i=1}^{j} r_i(x, n) T_{\gamma_i(x,n)} x \right\| < 1/n. \tag{20}$$

Now we define a map $\tau_n : X \longrightarrow \Lambda$ by setting, for each $x \in X$,

$$\tau_n(x) = \{(\gamma_i(x, n), r_i(x, n))\}_{i=1}^{j}.$$

This map is σ-slicely constant. Indeed, let $m \in \mathbb{N}$, $q \in \mathbb{Q}\cap(0, 1)$, and $r = (r_1, \dots, r_m) \in \mathbb{Q}^m$. Let $X_{m,q,r}$ denote the set made up of the vectors $x \in X$ such that $\Delta(x, n) \subseteq M_{\Phi,q}(x)$, $\#M_{\Phi,q}(x) = m$, and if $M_{\Phi,q}(x) = \{\gamma_1 \prec \cdots \prec \gamma_m\}$ and $\Delta(x, n) = \{\gamma_{t_1} \prec \cdots \prec \gamma_{t_j}\}$, then

$$r_i = 0 \quad \text{if and only if} \quad \gamma_i \notin \Delta(x, n) \tag{21}$$

and

$$r_i(x, n) = r_{t_i} \quad \text{for } i = 1, \dots, j. \tag{22}$$

It is clear that

$$X = \bigcup_{m\in\mathbb{N},\, q\in\mathbb{Q}\cap(0,1),\, r\in\mathbb{Q}^m} X_{m,p,r}.$$

Fix $m \in \mathbb{N}$, $q \in \mathbb{Q} \cap (0, 1)$, and $r \in \mathbb{Q}^m$. By Proposition 8 we can write

$$X_{m,q,r} = \bigcup_{p\in\mathbb{N}} X_{m,q,r,p}$$

in such a way that for every $p \in \mathbb{N}$ and every $x \in X_{m,q,r,p}$ there exists an open half space $H_x \subset X$ such that $x \in H_x$ and $M_{\Phi,q}(u) = M_{\Phi,q}(x)$ whenever $u \in H_x \cap X_{m,q,r,p}$. Combining this equality with conditions (21) and (22) we deduce that $\Delta(u,n) = \Delta(x,n)$ and that $r_i(u,n) = r_i(x,n)$ for each $i = 1,\dots,m$. In particular $\tau_n(u) = \tau_n(x)$, and the map τ_n is σ-slicely constant.

Now for each $x \in X$ we define

$$\Psi_n x = \psi_{\tau_n(x)} x = \sum_{i=1}^{j} r_i(x,n) T_{\gamma_i(x,n)} x.$$

According to Theorem 18 it follows that the map Ψ_n is ϵ-σ-midpoint continuous on X.

On the other hand, from (20) we get $\lim_n \|x - \lim_n \Psi_n x\| = 0$ for each $x \in X$. Applying Proposition 15 we deduce that the identity operator on X is $3\,\epsilon$-σ-midpoint continuous. As this assertion is true for every $\epsilon > 0$, the space X has an equivalent MLUR norm. □

As a consequence of this result, we obtain the following corollary, which is an MLUR version of the classical Zizler criterion in [19] about LUR renormability in Banach spaces with projectional resolutions of the identity.

COROLLARY 20. *Let X be a normed space, and let $\{T_\gamma\}_{\gamma\in\Gamma}$ be a family of bounded linear operators on X with the following properties:*

(1) *for every $\gamma \in \Gamma$, $T_\gamma X$ is an MLUR renormable subspace of X;*
(2) *for every $x \in X$, $\{\|T_\gamma x\|\}_{\gamma\in\Gamma} \in c_0(\Gamma)$, and*

$$x \in \overline{\operatorname{span}\{T_\gamma x : \gamma \in \Gamma\}}^{\|\cdot\|}.$$

Then X admits an equivalent MLUR norm.

Proof. It is enough to show that the map $\Phi : X \longrightarrow c_0(\Gamma)$ defined by the formula

$$\Phi x = \{\|T_\gamma x\|\}_{\gamma\in\Gamma}$$

is σ-slicely continuous. For all $x, y \in X$ and $\lambda, \mu \geq 0$ such that $\lambda + \mu = 1$ we have

$$0 \leq \Phi(\lambda x + \mu y) \leq \lambda \Phi x + \mu \Phi y,$$

and the result follows from the fact that every positive convex map with values in an LUR lattice is σ-slicely continuous. □

Our last application of Theorem 18 is the following corollary, which is a generalization of the main tool used by Haydon in [7] for the construction of MLUR norms in spaces of continuous functions on trees.

COROLLARY 21. *Let K be a locally compact space. Assume that there exist a σ-slicely continuous map $\Phi : C_0(K) \longrightarrow c_0(\Gamma)$ and a family $\{K_\gamma\}_{\gamma\in\Gamma}$ of closed and open subsets of K with the following properties:*

(1) *for each $\gamma \in \Gamma$ and each $\epsilon > 0$ there is a set $Y_{\gamma,\epsilon} \subseteq C(K_\gamma)$ such that the identity operator of $C_0(K_\gamma)$ is ϵ-σ-midpoint continuous on $Y_{\gamma,\epsilon}$;*
(2) *for each $\epsilon > 0$, each $x \in C_0(K)$, and $t \in K$ with $x(t) \neq 0$, there exists an element $\gamma \in \operatorname{supp} \Phi x$ such that $t \in K_\gamma$ and $x_{\restriction K_\gamma} \in Y_{\gamma,\epsilon}$.*

Then the space $C_0(K)$ is MLUR renormable.

Proof. Let $X = C_0(K)$. As in the proof of Corollary 19 we introduce a well order $\prec$ on the set Γ. Fix $\epsilon > 0$, and let Λ denote the set of all $\alpha \in 2^\Gamma$ such that $\#\alpha < \infty$.

Let $n \in \mathbb{N}$ such that $\epsilon > \frac{1}{n}$. Let us define, for each $\alpha \in \Lambda$,

$$\psi_\alpha x = x \cdot \mathbb{1}_{\bigcup_{\gamma\in\alpha} K_\gamma}.$$

It is clear that $\psi_\alpha x \in C_0(K)$ for all $x \in C_0(K)$, and from Lemma 12 it follows that the map ψ_α is ϵ-σ-midpoint continuous on the set

$$A_{\alpha,n} = \left\{ x \in C_0(K) : x_{\restriction K_\gamma} \in Y_{\gamma,\frac{1}{n}} \quad \forall \gamma \in \alpha \right\}.$$

On the other hand, because of the hypothesis, for each $x \in X$ we have

$$\{t \in K : |x(t)| \geq 1/n\} \subseteq \bigcup \left\{ K_\gamma : \gamma \in \operatorname{supp} \Phi x \text{ and } x_{\restriction K_\gamma} \in Y_{\gamma,\frac{1}{n}} \right\}.$$

By compactness we deduce the existence of a finite set $\Delta_n(x) \subseteq \operatorname{supp} \Phi x$ such that

$$\|x - x \cdot \mathbb{1}_{\bigcup_{\gamma \in \Delta_n(x)} K_\gamma}\|_\infty < 1/n \tag{23}$$

and

$$x_{\restriction K_\gamma} \in Y_{\gamma,1/n} \quad \forall \gamma \in \Delta_n(x). \tag{24}$$

Using the same argument as in Corollary 20 we get that the map $\tau_n : X \longrightarrow \Lambda$ defined by the formula

$$\tau_n(x) = \Delta_n(x), \quad x \in C_0(K),$$

is σ-slicely constant.

Now for each $x \in X$ we set

$$\Psi_n x = \psi_{\tau_n(x)} x = x \cdot \mathbb{1}_{\bigcup_{\gamma \in \Delta_n(x)} K_\gamma}.$$

According to Theorem 18 we deduce that Ψ_n is $2\,\epsilon$-σ-midpoint continuous on the set

$$A_n = \left\{ x \in C_0(K) : x \in X_{\tau(x)} \right\} = \left\{ x \in C_0(K) : x \in x_{\restriction K_\gamma} \in Y_{\gamma,\frac{1}{n}} \right\}.$$

By (24) we have $A_n = X$. Moreover, from (23) we get $\lim_n \|x - \Psi_n x\| = 0$ for each $x \in X$. Applying Proposition 15 we deduce that the identity operator on X is $6\,\epsilon$-σ-midpoint continuous. As this assertion holds for every $\epsilon > 0$, it follows that the space X is MLUR renormable. □

SOLUTION CONTINUITY IN MONOTONE AFFINE VARIATIONAL INEQUALITIES*

STEPHEN M. ROBINSON†

Abstract. In this paper we study the behavior of solutions of finite-dimensional monotone affine variational inequalities posed over graph-convex polyhedral multifunctions. We identify precisely the class of positive semidefinite linear transformations appearing in these variational inequalities for which the solution sets will be Lipschitzian in the argument of the underlying multifunction. This class is that of *cocoercive* linear transformations, which include, but are not limited to, those appearing in problems of linear or of convex quadratic programming.

Key words. multifunctions, affine variational inequalities, monotone operators, Lipschitz continuity, polyhedral multifunctions, cocoercivity, Dunn property, psd-plus

1. Introduction.

In this paper we study the behavior of solutions of monotone affine variational inequalities in $\mathbb{R}^n$ posed over graph-convex polyhedral multifunctions. The goal is to identify precisely the class of positive semidefinite linear transformations appearing in these variational inequalities for which the solution sets will be Lipschitzian in the argument of the underlying multifunction. For the simplest type of constraining multifunction, this simply means that we are varying the right-hand sides of the linear equations and inequalities defining the set, and we want to be sure that the set of solutions of the variational inequality is a Lipschitzian multifunction of those right-hand sides. Our main results are that if no restrictions are placed on the underlying set, then this Lipschitzian behavior occurs always when the linear transformation has a property that has been called *cocoercivity* in the literature and never otherwise. Thus, the cocoercive linear transformations are the largest class for which this stability property holds. Such results were previously known for linear and for convex quadratic programming problems, both of which belong to the cocoercive class but do not exhaust it.

This paper has five sections, of which this is the first. In the remainder of this section we fix notation and discuss some of the terminology used below. Section 2 develops various properties relating polyhedrality and the Lipschitz condition; these are the underlying tools that we will use in the remainder of this paper. Section 3 studies monotone affine variational inequalities, developing properties of their solution sets under assumptions starting with positive semidefiniteness and then defining and characterizing the cocoercivity property. That section also briefly reviews existing

literature on cocoercive linear transformations. Then, in section 4, we present the main results by first showing that cocoercivity plus a solvability condition suffices for Lipschitzian behavior, and then demonstrating that without cocoercivity one can define the underlying set in such a way that solutions of the problem fail even to be inner semicontinuous, much less Lipschitzian. Section 5 is an appendix containing the proof of one of the subsidiary results.

1.1. Notation and preliminaries. We give here some definitions required in the rest of the paper. These use extensively the relative topology induced on a subset X of $\mathbb{R}^n$ by the standard topology of $\mathbb{R}^n$. We will use the Euclidean norm throughout the paper.

The first definition defines a property originally called *upper Lipschitz continuity* [15, p. 208]. We have changed the term here to *outer Lipschitz continuity,* abbreviated OLC, in order to maintain some consistency with the terminology of [16]. The property is called *calmness* in that work [16, p. 399].

DEFINITION 1.1. *Let X be a subset of $\mathbb{R}^n$, x be a point of X, and $S : \mathbb{R}^n \to \mathbb{R}^m$ be a multifunction having closed values. S is* outer Lipschitz continuous at x relative to X with modulus λ *if there is some neighborhood V of x relative to X such that for each $x' \in V$ one has $S(x') \subset S(x) + \lambda\|x' - x\|B$, where B is the unit ball in $\mathbb{R}^m$.*

If F is OLC relative to X at a point $x \in X$, then it is also OLC relative to any subset of X that contains x. When X is not explicitly mentioned we take it to be the underlying space, in this case $\mathbb{R}^n$.

The second property of multifunctions that we require is inner semicontinuity. We will use the following definition rather than [16, Definition 5.4], but [16, Exercise 5.6] shows that the two are equivalent.

DEFINITION 1.2. *Let S be a multifunction from $\mathbb{R}^n$ to $\mathbb{R}^m$, X a subset of $\mathbb{R}^n$, and x a point of X. S is* inner semicontinuous at x relative to X *if for each open set Q that meets $S(x)$ there is a neighborhood V of x relative to X such that for each $x' \in V$, Q meets $S(x')$.*

For our purposes the most convenient measure of distance between sets will be the Pompeiu–Hausdorff distance. The following definition is compatible with [16, Example 4.13] if one adds the restriction that the sets U and V be nonempty and closed. We denote the closed ball of radius ρ about a point x of $\mathbb{R}^k$ by $B(x, \rho)$, and also use B to denote the unit ball $B(0, 1)$, the space involved being clear from the context.

DEFINITION 1.3. *The* Pompeiu–Hausdorff distance *between two subsets U and V of $\mathbb{R}^m$ is*

$$\rho[U, V] = \inf\{\eta \geq 0 \mid U \subset V + \eta B,\ V \subset U + \eta B\}.$$

Note that this distance may take the value $+\infty$.

The next definition applies the Pompeiu–Hausdorff distance to define Lipschitz continuity for multifunctions.

DEFINITION 1.4 (see [16, Def. 9.26]). *Let S be a multifunction from $\mathbb{R}^n$ to $\mathbb{R}^m$ having closed values on some subset X of $\mathbb{R}^n$, and let $\lambda \in \mathbb{R}_+$. S is* Lipschitz continuous *(equivalently,* Lipschitzian*) relative to X* with modulus λ *if for each x and x' in X, $\rho[S(x'), S(x)] \leq \lambda\|x' - x\|$.*

Note that to say S is Lipschitzian relative to X (or, as we often say below, on X) implies that a uniform modulus λ exists that works for each pair of points taken from X, even if that modulus is not explicitly mentioned. It is also often convenient

to speak of *local Lipschitz continuity* at a point $x \in X$, in which case the modulus need only exist for points in some neighborhood of x.

The following theorem is a slight sharpening of a result of Li [9, Theorem 2.1]. The sharpening consists of reducing the requirement of Hausdorff lower semicontinuity to inner semicontinuity. The proof, whose structure is similar to that of Li, is in section 5 (the appendix).

THEOREM 1.5. *Let S be a multifunction from $\mathbb{R}^n$ to $\mathbb{R}^m$ having closed values, let X be a convex subset of* $\operatorname{dom} S$*, and let λ be a nonnegative real number. The following are then equivalent:*

(a) *At each point of X, S is outer Lipschitz continuous relative to X with modulus λ and is inner semicontinuous relative to X.*

(b) *S is Lipschitz continuous relative to X with modulus λ.*

In the following sections we specialize the discussion first to polyhedral multifunctions and then to affine variational inequalities over polyhedral convex sets that need not be fixed, but may vary in a restricted way; specifically, they are sections of a graph-convex polyhedral multifunction.

2. Polyhedrality and the Lipschitz condition. In this section we demonstrate some applications of Theorem 1.5 to polyhedral multifunctions, which occur frequently in applications. A *polyhedral multifunction* is a multifunction whose graph is the union of a finite collection of convex polyhedral sets. If that collection consists of only a single set, then the multifunction is a *graph-convex polyhedral multifunction.* By [15, Proposition 1], if P is a polyhedral multifunction from $\mathbb{R}^n$ to $\mathbb{R}^m$, then there is some nonnegative number λ such that P is OLC with modulus λ at every point of $\mathbb{R}^n$. See also the result in [16, Example 9.57], which establishes, but does not state explicitly, the fact that a single modulus suffices, and which restricts the statement to $\operatorname{dom} P$.

The following corollaries combine Theorem 1.5 with the known OLC result for polyhedral multifunctions to derive results in forms convenient for application. We write $\operatorname{gph} F$ for the graph of a multifunction F.

COROLLARY 2.1. *Let F be a polyhedral multifunction from $\mathbb{R}^n$ to $\mathbb{R}^m$, let λ be its OLC modulus, and let C be a convex subset of* $\operatorname{dom} F$*. Then F is Lipschitzian with modulus λ on C if and only if it is inner semicontinuous relative to C at each point of C.*

Proof. As F is polyhedral, $\operatorname{gph} F$ is closed so F certainly has closed values, and we already know that F is everywhere OLC with modulus λ. Suppose first that F is inner semicontinuous relative to C at each point of C. By setting $X = C$ and applying Theorem 1.5, we conclude that F is Lipschitzian on C with modulus λ. On the other hand, if F is Lipschitzian on C with modulus λ, then Theorem 1.5 says that it must be inner semicontinuous relative to C at each point of C. ∎

The second corollary applies the first to a special case that is often easy to identify.

COROLLARY 2.2. *Let F be a polyhedral multifunction from $\mathbb{R}^n$ to $\mathbb{R}^m$, let λ be its OLC modulus, and let C be a convex subset of* $\operatorname{dom} F$ *on which F is single-valued. Then F is Lipschitzian on C with modulus λ.*

Proof. We need only show that F is inner semicontinuous relative to C at each point of C. Let x_0 be such a point, and let Q be any open set meeting $F(x_0)$. Because $F(x_0)$ is a singleton, we actually have $F(x_0) \in Q$, and because polyhedrality entails OLC there is a neighborhood V of x_0 such that if $x \in C \cap V$, then $F(x)$ is a singleton contained in Q. Therefore F is inner semicontinuous relative to C at x_0, and the claim then follows from Corollary 2.1. ∎

Our applications will involve variational inequalities posed over graph-convex polyhedral multifunctions. For a convex subset S of $\mathbb{R}^n$ and a point $x \in \mathbb{R}^n$, we use the symbol $N_S(x)$ to denote the *normal cone* of S at x, defined by

$$N_S(x) = \begin{cases} \{x^* \in \mathbb{R}^n \mid \text{for each } x' \in S,\ \langle x^*, x' - x\rangle \le 0\} & \text{if } x \in S, \\ \emptyset & \text{if } x \notin S. \end{cases}$$

The polyhedrality of the normal-cone operator N_S is well known (see, e.g., [7, p. 108], and the argument can be adapted with little difficulty to the case in which for a graph-convex polyhedral multifunction $S(u)$ we consider the multifunction sending (u, x) to $N_{S(u)}(x)$. This results in the following lemma.

LEMMA 2.3. *Let S be a graph-convex polyhedral multifunction from $\mathbb{R}^k$ to $\mathbb{R}^n$. Then the multifunction $G : \mathbb{R}^k \times \mathbb{R}^n \to \mathbb{R}^n$ defined by*

$$G(u, x) = N_{S(u)}(x) \tag{2.1}$$

is polyhedral.

The next proposition combines Lemma 2.3 with Corollaries 2.1 and 2.2 to produce a result about the Lipschitz continuity of solutions of an affine generalized equation posed over a polyhedral convex set, as functions of both the constant term in the generalized equation and the right-hand side of the constraints defining the polyhedral convex set.

PROPOSITION 2.4. *Let A be an $n \times n$ matrix and let S be a graph-convex polyhedral multifunction from $\mathbb{R}^k$ to $\mathbb{R}^n$. Define a multifunction $X : \operatorname{dom} S \times \mathbb{R}^n \to \mathbb{R}^n$ by*

$$X(u, v) = \{x \in \mathbb{R}^n \mid 0 \in Ax + v + N_{S(u)}(x)\}. \tag{2.2}$$

If C is a convex subset of $\operatorname{dom} X$, then X is Lipschitzian on C if and only if it is inner semicontinuous relative to C at each point of C. In particular, if X is single-valued on C, then it is necessarily Lipschitzian on C.

Proof. If we can establish that X is polyhedral, then the two claims will follow from Corollaries 2.1 and 2.2, respectively. Lemma 2.3 shows that the multifunction taking (u, x) to $N_{S(u)}(x)$ is polyhedral. As the sum of two polyhedral multifunctions is also polyhedral, the multifunction H taking (u, x) to $Ax + N_{S(u)}(x)$ is also polyhedral. However, a point (u, v, x) of $(\operatorname{dom} S) \times \mathbb{R}^n \times \mathbb{R}^n$ belongs to $\operatorname{gph} X$ if and only if $(u, x, -v) \in \operatorname{gph} H$. Therefore X is polyhedral. □

Special cases of Proposition 2.4 are well known, such as the Lipschitz continuity of the solution of a positive definite quadratic programming problem as a function of the vector in the quadratic objective function and the right-hand sides of the constraints defining the feasible set [18, Theorem 2.1], [3, Exercise 7.6.10].

3. Solutions of monotone affine variational inequalities. In 1975, Adler and Gale [1] gave an explicit representation of the set of solutions of a linear complementarity problem in $\mathbb{R}^n$ having a positive semidefinite matrix. Specifically, they exhibited a polyhedral convex set, depending only on the data of the complementarity problem, one of whose faces was the set of solutions of that problem. Similar representations appear in the work of Klatte and Thiere [8, p. 109] on convex quadratic programming and in the work of Luo and Tseng [12, Lemma 2] on affine variational inequalities with cocoercive operators. In section 3.1 we first extend the Adler–Gale results to the case of a monotone affine variational inequality posed over a polyhedral convex set. When that set is the nonnegative orthant, we recover the Adler–Gale

results. We then use an example in $\mathbb{R}^2$ to show that when we extend the situation to the more general case in which the set is a graph-convex polyhedral multifunction $S(u)$ depending on a parameter u, without further assumptions the solution set may behave very badly as u varies. If we want better behavior, we must impose stronger assumptions.

In section 3.2 we describe the well-known cocoercivity property of a monotone operator f; that is, the strong monotonicity of f^{-1}. As we are interested here in cases for which the monotone operator is affine, we discuss properties characterizing the class of matrices for which the cocoercivity property holds. These results come from the work of several investigators, and we briefly review the literature in this area. The class of cocoercive matrices includes, but is not limited to, all positive semidefinite symmetric matrices (thus all matrices arising in problems of linear, or of convex quadratic, programming).

We then point out that in the presence of the cocoercivity property two additional features appear, each of which will be important for our purposes. First, even for a nonlinear problem, the same normal vector appears in every solution of our problem. In our particular (polyhedral) application, we can show that this normal vector is Lipschitzian in the parameter u. Second, the solvability of the parametric variational inequality with polyhedral set $S(u)$ is independent of the value of u provided that it remains in $\operatorname{dom} S$. That is, if we write $X(u)$ for the multifunction expressing the dependence of the solution set on u, then $\operatorname{dom} X = \operatorname{dom} S$.

3.1. Positive semidefinite matrices. We will first extend the results of Adler and Gale [1] to the case of an affine variational inequality posed over a polyhedral convex set. Later we will want to make the set depend on a parameter, but the presence of the parameter is unnecessary here so we suppress it.

Let F and A be linear transformations from $\mathbb{R}^n$ to $\mathbb{R}^m$ and $\mathbb{R}^n$, respectively, with A positive semidefinite. Let $f \in \mathbb{R}^m$ and $a \in \mathbb{R}^n$, and define S to be the polyhedral convex subset of $\mathbb{R}^n$ defined by $S = \{x \mid Fx \leq f\}$. Define X to be the (possibly empty) subset of $\mathbb{R}^n$ consisting of all points x, called *solutions,* satisfying

$$0 \in Ax + a + N_S(x). \tag{3.1}$$

For each solution x there is a unique point $x^* \in N_S(x)$ with $Ax + a + x^* = 0$. Because of the structure of N_S, we can represent x^* (generally not uniquely) in the form $x^* = F^*y^*$ with $y^* \in \mathbb{R}^m_+$ and $\langle y^*, Fx - f\rangle = 0$. Such y^* we call *multipliers associated with* x. For a solution x we write the set of all such multipliers y^* as $Y^*(x)$.

Now define a polyhedral convex subset Q of $\mathbb{R}^{n+m}$ by

$$Q = \{(x, y) \mid Fx \leq f,\ y^* \geq 0,\ Ax + a + F^*y^* = 0\}; \tag{3.2}$$

thus the definition of Q includes all conditions imposed on solutions and multipliers except the complementarity condition $\langle y^*, Fx - f\rangle = 0$. Define two subsets I and J of $\{1, \ldots, m\}$ by

$$I = \{i \in \{1, \ldots, m\} \mid \text{for each solution } x,\ (f - Fx)_i = 0\} \tag{3.3}$$

and

$$J = \{j \in \{1, \ldots, m\} \mid \text{for each multiplier } y^*,\ (y^*)_j = 0\}. \tag{3.4}$$

Finally, define Q_{IJ} by

$$Q_{IJ} = \{(x, y^*) \in Q \mid (f - Fx)_i = 0\ (i \in I),\ (y^*)_j = 0\ (j \in J)\}. \tag{3.5}$$

This Q_{IJ} is evidently a face of Q. The next theorem says that it consists precisely of solutions and their associated multipliers.

THEOREM 3.1. *One has*

$$Q_{IJ} = \{(x, y^*) \mid x \in X,\ y^* \in Y^*(x)\}. \tag{3.6}$$

Further, if x_0 and x_1 are elements of X with associated normal vectors $x_i^* = -(Ax_i + a)$ for $i = 0, 1$, then

$$\langle x_0^* - x_1^*, x_0 - x_1 \rangle = 0. \tag{3.7}$$

Proof. The proof has three main parts. We first show that the positive semidefiniteness of A implies (3.7) as well as a certain exchangeability of solution-multiplier pairs. Next, we use that information to show that each index in $\{1, \ldots, m\}$ is in I or in J (or possibly both), which we then use to prove (3.6).

Suppose that x_0 and x_1 are solutions, and let $y_i^* \in Y^*(x_i)$ for $i = 0, 1$. Then $x_i^* = F^* y_i^*$, $i = 0, 1$. The monotonicity of N_S and the positive semidefiniteness of A imply

$$0 \le \langle x_0^* - x_1^*, x_0 - x_1 \rangle = \langle -(Ax_0 - Ax_1), x_0 - x_1 \rangle \le 0, \tag{3.8}$$

which implies (3.7). Rewriting (3.7) as

$$0 = -\langle x_0^*, x_1 - x_0 \rangle - \langle x_1^*, x_0 - x_1 \rangle$$

and noting that each inner product is nonpositive because $x_i^* \in N_S(x_i)$ for each i, we see that each term is zero. Using $x_i^* = F^* y_i^*$ for $i = 0, 1$, we conclude that

$$0 = \langle x_0^*, x_1 - x_0 \rangle = \langle F^* y_0^*, x_1 - x_0 \rangle = \langle y_0^*, (Fx_1 - f) - (Fx_0 - f) \rangle = \langle y_0^*, Fx_1 - f \rangle,$$

as $\langle y_0^*, Fx_0 - f \rangle$ is zero by choice of y_0^*. Exchanging the roles of x_0 and x_1 yields $\langle y_1^*, Fx_0 - f \rangle = 0$.

Now choose any index $k \in \{1, \ldots, m\}$. If $k \notin I$, then there is some solution x with $(f - Fx)_k > 0$. If y^* is any multiplier associated with some solution x', then by what we have just shown we have $\langle y^*, Fx - f \rangle = 0$. As $y^* \ge 0$ and $Fx - f \le 0$, this implies that $(y^*)_k = 0$, so $k \in J$. Hence $I \cup J = \{1, \ldots, m\}$.

To prove (3.6), first suppose that $x \in X$ and $y^* \in Y^*(x)$. The definitions of I and J show that for each $i \in I$, $(Fx - f)_i = 0$ and for each $j \in J$, $(y^*)_j = 0$, so $(x, y) \in Q_{IJ}$.

Now choose $(x, y^*) \in Q_{IJ}$. The definition of Q shows that $Fx \le f$, so $x \in S$; also $y^* \ge 0$, and if we define $x^* = F^* y^*$, then $Ax + a + x^* = 0$. For each $i \in I$ we have $(Fx - f)_i = 0$ and for each $j \in J$ we have $(y^*)_j = 0$. As we have shown that $I \cup J = \{1, \ldots, m\}$, the inner product $\langle y^*, Fx - f \rangle$ must be zero, so that $x^* \in N_S(x)$. Therefore $x \in X$ and $y^* \in Y^*(x)$, which completes the proof of (3.6). ∎

In the case of a linear complementarity problem we have $F = -I$ and $f = 0$. Then (3.2) shows that we always have $y^* = Ax + a$, so that we can remove y^* from the problem and thus recover the Adler–Gale results.

Theorem 3.1 shows that the solution set of any monotone affine variational inequality over a polyhedral convex set is itself a polyhedral convex set, because it is the projection of a face of Q. We might wonder whether the information in the theorem could somehow be used to determine how this polyhedral convex solution set behaves

when one makes small changes in certain data of (3.1). For that purpose we now replace the set S by a graph-convex polyhedral multifunction defined for $u \in \mathbb{R}^k$ by

$$S(u) = \{x \mid Fx + Gu \leq g\}, \tag{3.9}$$

where G is a fixed $m \times k$ matrix and g is a fixed element of $\mathbb{R}^m$, and we consider the problem of finding x such that

$$0 \in Ax + a + N_{S(u)}(x). \tag{3.10}$$

For $u \in \mathbb{R}^k$ let $X(a, u)$ be the set of solutions of (3.1). This defines a multifunction $X : \mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n$, whose values are solution sets of (3.10) for particular pairs (a, u).

From the form of (3.10) together with Lemma 2.3, we can see that X is a polyhedral multifunction, and hence by [15, Proposition 1] it is everywhere OLC with the same modulus. This guarantees stability with respect to expansion, as the set cannot expand at a rate faster than linear, but on the other hand there are no limits on its ability to contract. Indeed, one has only to think of a linear programming problem such as the trivial problem of maximizing ax for $x \in [0, 1] \subset \mathbb{R}$ with $a = 0$ initially, to see that the optimal set may contract disastrously for even slight changes in a. Luo and Tseng [10, Corollary 1] have shown how, by further restricting the class of matrices A, one may establish Lipschitz continuity with respect to a. However, in the rest of this paper we leave a fixed and write $X(u)$ for $X(a, u)$. This new X is then a multifunction taking values of u into solutions of (3.10), and we will seek conditions on the matrix A, beyond positive semidefiniteness, under which $X(\cdot)$ will actually be Lipschitzian (in the Pompeiu–Hausdorff metric) as opposed to outer Lipschitzian.

Klatte and Thiere [8, Theorem 4.2] have shown that the solution set of any convex quadratic programming problem is Lipschitzian as a function of the right-hand side vector of the constraints. They also refer to an earlier proof of that fact in [6]. Thus, the class of matrices A that we want to find must include those that are symmetric and positive semidefinite. We might hope that the class could include all positive semidefinite matrices, but to dismiss that possibility it is enough to consider the linear complementarity problem in $\mathbb{R}^2$ with constant vector zero and matrix

$$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}; \tag{3.11}$$

that is,

$$0 \in Ax + N_{\mathbb{R}^2_+}(x),$$

where $\mathbb{R}^2_+$ is the nonnegative orthant of $\mathbb{R}^2$. We now parametrize this problem by defining, for $u \in \mathbb{R}$,

$$S(u) = \left\{ x \in \mathbb{R}^2 \mid (-I)x + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u \leq \begin{bmatrix} 0 \\ 0 \end{bmatrix} \right\},$$

and consider the problem of solving $0 \in Ax + N_{S(u)}(x)$. If $u > 0$, then there is no solution, so $X(u) = \emptyset$; if $u = 0$, then $X(u) = \mathbb{R}_+ \times \{0\}$; if $u < 0$, then $X(u) = \{0\} \times [u, 0]$. Accordingly, for this problem $X(u)$ is not Lipschitzian in the Pompeiu–Hausdorff metric, nor even inner semicontinuous, although A is certainly positive semidefinite. Therefore, the class of matrices we seek must lie between the symmetric positive semidefinite matrices and the positive semidefinite matrices. We define this class in the next section and then develop some of its properties.

3.2. Cocoercivity. This section develops some properties of *cocoercive* operators that we need in the rest of this paper. We first define these operators, then give a theorem that characterizes cocoercivity for the specific class of operators that we use here.

DEFINITION 3.2. *Let T be a monotone operator from a Hilbert space H into H. We say that T is* cocoercive *if for some $\mu > 0$, T^{-1} is strongly monotone with modulus μ; that is, if for each (h,t) and (h',t') in the graph of T one has $\langle t'-t, h'-h\rangle \geq \mu\|t'-t\|^2$.*

Operators with strongly monotone inverses have received attention in the literature. In particular, Brézis and Haraux present a strong result about such operators that we use below [2, Observation (b), p. 175]. Also, it was observed in [14, Proposition 1] that even just strict monotonicity of T^{-1} implies a simple but useful fact, which we shall also use below. Suppose that M is another monotone operator from H into H, and consider the problem of finding solutions x of

$$0 \in T(x) + M(x). \tag{3.12}$$

If x_1 and x_2 are two such solutions, then there exist t_1 and t_2 such that for $i = 1, 2$ the pairs (x_i, t_i) and $(x_i, -t_i)$ belong to the graphs of T and M, respectively. Then

$$0 = \langle x_2 - x_1, t_2 - t_1\rangle + \langle x_2 - x_1, (-t_2) - (-t_1)\rangle.$$

Each inner product is nonnegative because T and M are monotone, so it follows that each is zero, and then the strict monotonicity of T^{-1} implies that $t_2 = t_1$. Accordingly, in this situation, if there are any solutions of (3.12) at all, then there is a *unique* t such that the solution set of (3.12) is $T^{-1}(t) \cap M^{-1}(-t)$. Luo and Tseng [12, Lemma 1] made a similar observation for affine functions on $\mathbb{R}^n$.

More recently, several authors have studied different aspects of such operators. Tseng [17] gave them the name *cocoercive,* which we use here. Other names include "strongly f-monotone" [13], "positive semidefinite plus" (or "psd-plus") for the case in which T is affine, referring to the property that $\langle x, Tx\rangle \geq 0$ implies $Tx = 0$, and the "Dunn property." Luo and Tseng [11] showed that a psd-plus linear operator $A : \mathbb{R}^n \to \mathbb{R}^n$ has a representation $A = E^T P E$, where P is a positive definite matrix of dimension r, where r is the rank of A. They also showed that for such an operator, if $A = C + K$ with C symmetric and K skew, then $\ker C \subset \ker K$. Interestingly, Iusem [5, Corollary 2] made a very similar observation for the quite different case of a symmetric copositive-plus matrix. Zhu and Marcotte [19, Proposition 2.5] showed that a linear operator A is psd-plus if and only if it is cocoercive. The book of Facchinei and Pang defines cocoercive operators [4, Volume 1, p. 79] and, in section 2.3 of Volume 1, discusses their properties including several mentioned above.

The following theorem records some useful facts about cocoercive linear operators on $\mathbb{R}^n$ in the form in which we need them in this paper. In it, we write $\ker A$ and $\operatorname{im} A$ for the kernel and image of a linear operator A, and we write A^{-1} for the inverse of A in the sense of multifunctions, not of linear algebra.

THEOREM 3.3. *Let A be a positive semidefinite linear operator from $\mathbb{R}^n$ to $\mathbb{R}^n$. Write $C = (A + A^*)/2$ and $K = (A - A^*)/2$ for the symmetric and skew parts of A, respectively. The following are equivalent:*

(a) *A is cocoercive with some positive modulus μ;*
(b) *A^{-1} is strictly monotone;*
(c) $\ker C \subset \ker K$.

If these equivalent properties hold, then one has $\ker A = \ker C = \ker A^*$ *and* $\operatorname{im} A = \operatorname{im} C = \operatorname{im} A^*$. *Finally,* A *is cocoercive if and only if* A^* *is cocoercive.*

Proof. (a) implies (b). This is obvious.

(b) implies (c). Suppose A^{-1} is strictly monotone. If $Cx = 0$, then as $\langle x, Kx\rangle = 0$ we have $0 = \langle x - 0, Ax - 0\rangle$. Strict monotonicity of A^{-1} applied to the pairs $(0, 0)$ and (Ax, x) yields $0 = Ax = Cx + Kx$, but as $Cx = 0$ we have $x \in \ker K$.

(c) implies (a). Suppose that $\ker C \subset \ker K$. We first observe that if $x \in \ker A$, then we have

$$0 = \langle x, Ax\rangle = \langle x, Cx\rangle + \langle x, Kx\rangle = \langle x, Cx\rangle,$$

and as C is positive semidefinite this implies $x \in \ker C$. Conversely, if $x \in \ker C$, then by hypothesis $x \in \ker K$ also, and then $x \in \ker A$. Thus if $\ker C \subset \ker K$, then we actually have $\ker A = \ker C$. But we can restate hypothesis (c) as $\ker C \subset \ker(-K)$, and then the argument that we just made shows that $\ker A^* = \ker C$. Therefore under this hypothesis we have $\ker A = \ker C = \ker A^*$, and by taking orthogonal complements we obtain also $\operatorname{im} A^* = \operatorname{im} C = \operatorname{im} A$.

If A is the zero operator, then it is cocoercive with any modulus, so assume $A \neq 0$; then the subspace $\operatorname{im} A^*$ has dimension at least 1. Define a function α from the nonempty compact set $W = \{x \in \operatorname{im} A^* \mid \|x\| = 1\}$ to $\mathbb{R}$ by $\alpha(x) = \langle x, Ax\rangle/\|Ax\|^2$. This α is well defined because $\operatorname{im} A^* = (\ker A)^\perp$, so that W contains no point with $Ax = 0$, and it is continuous on W; hence it takes a minimum there, say μ. If $\mu = 0$, then there is $x \in W$ with

$$0 = \langle x, Ax\rangle = \langle x, Cx\rangle + \langle x, Kx\rangle = \langle x, Cx\rangle,$$

so $x \in \ker C$. We have shown that then $x \in \ker A$ also, which contradicts the fact that $x \in (\operatorname{im} A^*)\backslash\{0\}$. Therefore $\mu > 0$.

Now choose any $x \in \mathbb{R}^n$. We can write x uniquely as $x = c + d$, with $c \in \ker A$ and $d \in \operatorname{im} A^*$. Then

$$\langle x, Ax\rangle = \langle c, Ac\rangle + \langle c, Ad\rangle + \langle d, Ac\rangle + \langle d, Ad\rangle = \langle d, Ad\rangle \geq \mu\|Ad\|^2 = \mu\|Ax\|^2,$$

where we used the fact that $\ker A = \ker A^*$. This proves the equivalence of (a), (b), and (c). We have already shown that (c) implies $\ker A = \ker C = \ker A^*$ and $\operatorname{im} A = \operatorname{im} C = \operatorname{im} A^*$. For the final assertion note that A is cocoercive if and only if $\ker C \subset \ker K$, which is the same as saying $\ker C \subset \ker(-K)$, which is equivalent to the cocoercivity of A^*. ∎

It follows from the last assertion of the theorem that when A is cocoercive one also has $\ker A = (\operatorname{im} A)^\perp$. Thus, the class of cocoercive linear operators shares some of the properties of the subclass consisting of symmetric positive semidefinite linear operators, though not all; the example

$$A = \begin{bmatrix} 1 & -1 \\ 1 & 2 \end{bmatrix} \tag{3.13}$$

shows that they need not be normal.

Such operators are also ubiquitous in applications, as they include, in particular, the linear transformations A appearing when (3.1) expresses a problem of linear programming (in which $A = 0$) or of convex quadratic programming (in which A is symmetric and positive semidefinite). However, (3.13) shows that these special cases do not exhaust the class.

Returning to the parametric problem (3.10), we assume that A is cocoercive with some modulus $\mu > 0$. Then the uniqueness result from [14, Proposition 1] mentioned previously tells us that there is a function $x^* : \operatorname{dom} S \to \mathbb{R}^n$ such that for each $u \in \operatorname{dom} S$,

$$X(u) = N_{S(u)}^{-1}[x^*(u)] \cap \{x \mid Ax + a + x^*(u) = 0\}. \tag{3.14}$$

The set $N_{S(u)}^{-1}[x^*(u)]$ is the maximal face F of $S(u)$ on which $x^*(u)$ is everywhere a normal vector. As $\{x \mid Ax + a + x^*(u) = 0\}$ is a face of itself, and as the faces of an intersection of two convex sets are the intersections of their faces, $X(u)$ is a face of the polyhedral convex set

$$P(u) = S(u) \cap \{x \mid Ax + a + x^*(u) = 0\}. \tag{3.15}$$

Luo and Tseng [12, Lemma 2] gave a similar facial characterization of the optimal set of a cocoercive affine variational inequality, but for the case of a fixed underlying set and with a different proof.

The sets $X(u)$ and $P(u)$ play roles similar to those of $Q(u)$ and $Q_{IJ}(u)$ defined by (3.2) and (3.5), respectively, but with S replaced by the $S(u)$ defined in (3.9). However, they are simpler than $Q(u)$ and $Q_{IJ}(u)$, because the availability of $x^*(u)$ has enabled us to decouple the solutions x from the multipliers y^*; indeed, no multipliers appear in (3.15). This is entirely due to the cocoercivity assumption, and it is the crucial step in the analysis because without making very restrictive assumptions on F (such as a linear independence condition), we cannot control the behavior of the multipliers.

However, in order to make this new formulation tractable we have to establish good behavior of $x^*(u)$. We do this in two steps: First we show that under cocoercivity and a solvability condition $\operatorname{dom} X = \operatorname{dom} S$, and then we show that $x^*(\cdot)$ is Lipschitzian on that set.

We first observe that for each $u \in \operatorname{dom} S$, $\operatorname{im} N_{S(u)} = F^*(\mathbb{R}^m_+)$. Indeed, the form of $S(u)$ shows that $\operatorname{im} N_{S(u)} \subset F^*(\mathbb{R}^m_+)$. On the other hand, for any $y^* \in \mathbb{R}^m_+$ the objective value in the linear programming problem

$$\sup\{\langle F^* y^*, x\rangle \mid x \in S(u)\}$$

is bounded above by $\langle y^*, g - Gu\rangle$, and therefore the problem actually has a solution x'. Then $F^* y^* \in N_{S(u)}(x')$, so $F^*(\mathbb{R}^m_+) \subset \operatorname{im} N_S(u)$.

PROPOSITION 3.4. *Let $T(u,x) = Ax + a + N_{S(u)}(x)$. If A is cocoercive, then for each $u \in \operatorname{dom} S$ one has*

$$\operatorname{im} T(u,\cdot) = \operatorname{im} A + a + F^*(\mathbb{R}^m_+). \tag{3.16}$$

Proof. The operator $T(u,\cdot)$ is the sum of the two maximal monotone operators $A(\cdot)+a$ and $N_{S(u)}$. As the relative interiors of the domains of these two operators meet, the sum is also maximal monotone. As shown in [2, Proposition 2], the first operator satisfies the key condition $(*)$ of that work because it is cocoercive. Moreover, its domain includes that of the second operator. By [2, Theorem 4], the image of $T(u,\cdot)$ is then "almost equal" to the sum of the images of the two constituent operators, in the sense that the closures and the interiors of these two sets are equal. The operators being polyhedral, their images are unions of finite collections of polyhedral convex sets; hence each is closed and so is their sum. Therefore (3.16) holds. □

The expression on the right in (3.16) is independent of u. Hence we have the following corollary.

COROLLARY 3.5. *If A is cocoercive and*

$$0 \in \operatorname{im} A + a + F^*(\mathbb{R}^m_+), \tag{3.17}$$

then $\operatorname{dom} X = \operatorname{dom} S$.

Proof. Evidently $\operatorname{dom} X \subset \operatorname{dom} S$. If $u \in \operatorname{dom} S$, then the hypotheses together with (3.16) show that $0 \in \operatorname{im} T(u, \cdot)$, so that $u \in \operatorname{dom} X$ and so $\operatorname{dom} S \subset \operatorname{dom} X$. ∎

If the condition in (3.17) does not hold, then (3.10) has no solution for any u, whereas if it holds, then (3.10) is solvable for every $u \in \operatorname{dom} S$. In what follows we refer to (3.17) as the solvability condition.

Finally, we show that the unique normal vector $x^*(u)$ defined by (3.14) is Lipschitzian in u.

PROPOSITION 3.6. *If A is cocoercive and $0 \in \operatorname{im} A + a + F^*(\mathbb{R}^m_+)$, then $x^*(\cdot)$ is Lipschitzian on* $\operatorname{dom} S$.

Proof. The graph of $x^*(\cdot)$ is

$$\begin{aligned}\operatorname{gph} x^*(\cdot) = \{(u, x^*) \in \mathbb{R}^k \times \mathbb{R}^n \mid &\text{for some } x \in \mathbb{R}^n,\\ &Ax + a + x^* = 0 \text{ and } (x, x^*) \in N_{S(u)}\}.\end{aligned}$$

This set is the projection into $\mathbb{R}^k \times \mathbb{R}^n$ of the set

$$\{(u, x, x^*) \in \mathbb{R}^k \times \mathbb{R}^n \times \mathbb{R}^n \mid Ax + a + x^* = 0,\ (x, x^*) \in N_{S(u)}\},$$

which is a union of polyhedral convex sets; hence so is the graph of $x^*(\cdot)$, which is therefore a polyhedral multifunction. The domain of $x^*(\cdot)$ is $\operatorname{dom} X$, which under our hypotheses is $\operatorname{dom} S$. But we showed just after (3.12) that for each u there could be no more than one x^*, and if $u \in \operatorname{dom} X$, then there must be at least one x^*. Therefore $x^*(\cdot)$ is single-valued on the convex set $\operatorname{dom} S$. By Corollary 2.2, it is then Lipschitzian on $\operatorname{dom} S$. ∎

4. Lipschitz continuity of solution sets. In this section we apply the work of the preceding sections to show that if the assumptions of cocoercivity and solvability hold, then the solution multifunction $X(\cdot)$ of the problem (3.10) is Lipschitzian on $\operatorname{dom} S$ in the Pompeiu–Hausdorff metric. We then show that for any positive semidefinite A that is not cocoercive, there exists a graph-convex polyhedral multifunction S such that the problem (3.10) with $a = 0$ is solvable, but has a solution set that not only fails to be Lipschitzian, but fails even to be inner semicontinuous. Therefore cocoercivity is the weakest assumption that we can impose on A to ensure Lipschitz continuity of $X(\cdot)$.

THEOREM 4.1. *If A is cocoercive and $0 \in \operatorname{im} A + a + F^*(\mathbb{R}^m_+)$, then X is Lipschitzian in the Pompeiu–Hausdorff metric on* $\operatorname{dom} S$.

Proof. As we observed just after (3.10), X is a polyhedral multifunction, and therefore there is some modulus λ such that X is everywhere OLC with modulus λ. We will show that under our hypotheses, X is inner semicontinuous relative to $\operatorname{dom} S$ at each $u_0 \in \operatorname{dom} S$, and Theorem 1.5 will then establish that it is Lipschitzian as claimed.

Choose some u_0 in $\operatorname{dom} S$, which by Corollary 3.5 is also $\operatorname{dom} X$. Let Q be an open set meeting $X(u_0)$, and choose some $x_0 \in Q \cap X(u_0)$. The technique of the proof is to construct a finite number of graph-convex polyhedral multifunctions such that for each u near u_0, one of these will yield a point in the set $X(u)$ that is close to x_0.

Let L be the set of indices i in $\{1,\dots,m\}$ for which the inequality $(Fx_0+Gu_0)_i \le g_i$ is satisfied as an equality. Write cL for the complement of L in $\{1,\dots,m\}$. We can find neighborhoods U_0 of u_0 and V_0 of x_0, with $V_0 \subset Q$, so that whenever $(u,x) \in U_0 \times V_0$ the inequality $(Fx+Gu)_i \le g_i$ is strict for each $i \in cL$. Find a positive ϵ so that the ball $x_0 + \epsilon B$ lies in V_0.

Now for $u \in \operatorname{dom} S$ denote by $X_L(u)$ the solution set of the reduced problem

$$0 \in Ax + a + N_{S_L(x)}, \tag{4.1}$$

where $S_L(u) = \{x \in \mathbb{R}^n \mid F_L x + G_L u \le g_L\}$, and where we write F_L for the submatrix of F whose rows belong to the index set L, and similarly for G_L and g_L. If $L = \emptyset$, then we take $S_L(u) = \mathbb{R}^n$. We know the problem in (4.1) is solvable for $u = u_0$, because x_0 solves it. Therefore this reduced problem satisfies the solvability condition, as well as the cocoercivity condition. Accordingly, Corollary 3.5 shows that $\operatorname{dom} X_L = \operatorname{dom} S_L \supset \operatorname{dom} S$, where the inclusion holds because the reduced problem has fewer constraints than did the original one. Also, Proposition 3.6 shows that the function $x_L^*(\cdot)$ appearing in the reduced problem is Lipschitzian with some modulus ξ_L.

Now for all possible partitions (I,J) of L, consider the graph-convex polyhedral multifunction

$$P_{I,J}(b,c,d) = \{x \in \mathbb{R}^n \mid F_I x = b,\ F_J x \le c,\ Ax = d\}, \tag{4.2}$$

where $(b,c,d) \in \mathbb{R}^{|I|} \times \mathbb{R}^{|J|} \times \mathbb{R}^n$. Each of these multifunctions is Lipschitzian on its domain, and there are finitely many of them; let λ be the maximum of their Lipschitz constants. Write $s_L(u)$ for $g_L - G_L u$, and find a neighborhood U_1 of u_0, contained in U_0, such that whenever $u \in U_1 \cap \operatorname{dom} S$ we have

$$\lambda \left\| \begin{bmatrix} s_L(u) \\ -x_L^*(u) \end{bmatrix} - \begin{bmatrix} s_L(u_0) \\ -x_L^*(u_0) \end{bmatrix} \right\| < \epsilon. \tag{4.3}$$

Now choose any $u \in U_1 \cap \operatorname{dom} S$. Applying the discussion at (3.15) to the reduced problem, we see that $X_L(u)$ is a face of $P_L(u)$. Accordingly, there will be some partition I, J of L for which

$$X_L(u) = P_{I,J}(s_I(u), s_J(u), -[x_L^*(u) + a]). \tag{4.4}$$

We also have

$$x_0 \in P_{I,J}(s_I(u_0), s_J(u_0), -[x_L^*(u_0) + a]). \tag{4.5}$$

If we write $M(u)$ for $P_{I,J}(s_I(u), s_J(u), -[x_L^*(u)+a])$, then the Lipschitz continuity of $P_{I,J}$ in the Pompeiu–Hausdorff metric yields

$$M(u_0) \subset M(u) + \lambda \left\| \begin{bmatrix} s_L(u) \\ -x_L^*(u) \end{bmatrix} - \begin{bmatrix} s_L(u_0) \\ -x_L^*(u_0) \end{bmatrix} \right\| B \subset M(u) + \epsilon B.$$

As $M(u) = X_L(u)$ and $M(u_0)$ contains x_0, this implies that there is a point $x \in X_L(u)$ such that $x \in x_0 + \epsilon B$. In particular, $x \in Q$. Also, the pair (u,x) belongs to $U_0 \times V_0$, so every constraint $F_i x + G_i u \le g_i$ with index $i \in cL$ is slack there. That means that not only is $x_L^*(u)$ in $N_{S_L(u)}(x)$, but it also belongs to $N_{S(u)}(x)$, and therefore $x \in X(u)$. Therefore $X(u)$ is inner semicontinuous at u_0 relative to $\operatorname{dom} S$, which completes the proof. □

Theorem 4.1 shows that if cocoercivity and the solvability condition hold, then the solution set of (3.10) is Lipschitzian on its domain. The last theorem will show that if A is positive semidefinite but not cocoercive, then one can find a graph-convex polyhedral multifunction S so that the problem (3.10) is solvable, but its solution multifunction X is not inner semicontinuous, hence *a fortiori* not Lipschitzian. In fact, $S(u)$ can be taken to be a translated halfline.

THEOREM 4.2. *Let A be a positive semidefinite linear transformation from $\mathbb{R}^n$ to $\mathbb{R}^n$ that is not cocoercive. Then there exists a graph-convex polyhedral multifunction $S : \mathbb{R} \to \mathbb{R}^n$ such that the problem of finding x such that $0 \in Ax + N_{S(u)}(x)$ is solvable for $u_0 = 0$, but there are points u arbitrarily close to u_0 such that $X(u) \neq \emptyset$ but the inclusion $X(u_0) \subset X(u) + \alpha B$ holds for no real number α.*

Proof. As A is not cocoercive, by Theorem 3.3 its inverse is not strictly monotone. Therefore there is some $x \in \mathbb{R}^n$ such that $\langle x, Ax\rangle = 0$ but $Ax \neq 0$. Write $A = C + K$ with C symmetric and K skew. As $\langle x, Ax\rangle = 0$ we have $\langle x, Cx\rangle = 0$ and therefore $Cx = 0$, which with $Ax \neq 0$ implies that $Kx \neq 0$. As $A^* = C - K$, it follows that the point $y = A^*x$ is not zero. For $u \in \mathbb{R}$ define

$$S(u) = uy + (\mathbb{R}_+)x.$$

The graph of S is

$$\{(u, uy + \xi x) \mid u \in \mathbb{R}, \xi \geq 0\} = \{u(1, y) + \xi(0, x) \mid u \in \mathbb{R}, \xi \geq 0\},$$

which is a polyhedral convex set. Now fix $u \in \mathbb{R}$ and $\xi \geq 0$, and let $x(u, \xi) = uy + \xi x$. Then we have

$$\langle x, -Ax(u, \xi)\rangle = -u\|y\|^2.$$

For $u < 0$ this quantity is positive, so $-Ax(u, \xi)$ is not in $N_{S(u)}(x(u, \xi))$ for any $\xi \geq 0$; thus $X(u) = \emptyset$. For $u = 0$, $-u\|y\|^2 = 0$, so $-Ax(u, \xi) \in N_{S(u)}(x(u, \xi))$ for each $\xi \geq 0$, and $X(u)$ is the entire halfline $S(u)$. For $u > 0$ we have $-u\|y\|^2 < 0$, so $-Ax(u, \xi) \in N_{S(u)}(x(u, \xi))$ for $\xi = 0$ but for no $\xi > 0$, so $X(u) = \{uy\}$. Therefore, for $u > 0$ the set $X(u)$ is a singleton, and therefore the halfline $X(0)$ contains points arbitrarily far away from $X(u)$. ∎

5. Appendix: Proof of Theorem 1.5. If X is empty there is nothing to prove, so we assume X to be nonempty.

(a) *implies* (b). Choose two points of X and call them x_0 and x_1. For each $t \in (0, 1)$ let $x_t = (1 - t)x_0 + tx_1$. The OLC hypothesis ensures that for each $t \in [0, 1]$ there is a ball $B(x_t, \rho_t)$ about x_t with positive radius ρ_t such that for each x' in $X \cap B(x_t, \rho_t)$, $S(x') \subset S(x_t) + \lambda\|x' - x_t\|B$. Define

$$\tau = \sup\{t \in [0, 1] \mid \text{for each } s \in [0, t],\ S(x_s) \subset S(x_0) + \lambda\|x_s - x_0\|B\}.$$

We have $\tau > 0$ because ρ_0 is positive. We show first that

$$S(x_\tau) \subset S(x_0) + \lambda\|x_\tau - x_0\|B. \tag{5.1}$$

By assumption the set $S(x_0)$ is closed, and therefore so is $S(x_0) + \lambda\|x_\tau - x_0\|B$; let Q be the complement of the latter set. If (5.1) were not true, then $S(x_\tau)$ would meet the open set Q, and the inner semicontinuity hypothesis would then imply the existence

of $\sigma \in [0, \tau)$ for which $S(x_\sigma)$ also met Q. This cannot be true, because all such σ satisfy

$$S(x_\sigma) \subset S(x_0) + \lambda \|x_\sigma - x_0\| B \subset S(x_0) + \lambda \|x_\tau - x_0\| B.$$

This establishes (5.1).

If τ were less than 1 there would be $\kappa \in (\tau, 1)$ with $\|x_\kappa - x_\tau\| < \rho_\tau$, such that

$$S(x_\kappa) \not\subset S(x_0) + \lambda \|x_\kappa - x_0\| B. \tag{5.2}$$

However, we would then have from (5.1) and the definition of ρ_τ

$$\begin{aligned} S(x_\kappa) &\subset S(x_\tau) + \lambda \|x_\kappa - x_\tau\| B \\ &\subset S(x_0) + \lambda (\|x_\kappa - x_\tau\| + \|x_\tau - x_0\|) B \\ &= S(x_0) + \lambda \|x_\kappa - x_0\|) B, \end{aligned}$$

where the equality in the last line holds because x_0, x_τ, and x_κ are collinear. This contradicts (5.2), so τ must be 1. Putting $\tau = 1$ in (5.1) shows that $S(x_1) \subset S(x_0) + \lambda \|x_1 - x_0\| B$, and reversing the roles of x_0 and x_1 completes the proof.

(b) *implies* (a). If (b) holds, then S is *a fortiori* OLC relative to X at each point $x \in X$ with modulus λ. For inner semicontinuity, let $x \in X$ and let Q be an open set meeting $S(x)$. Then there exist a point $y \in S(x) \cap Q$ and a ball $B(y, \eta)$ with $\eta > 0$ such that $B(y, \eta) \subset Q$. Let ν be a positive number with $\lambda \nu \leq \eta$, and take V to be $X \cap B(x, \nu)$. If $x' \in V$, then (b) yields

$$y \in S(x) \subset S(x') + \lambda \|x' - x\| B \subset S(x') + \eta B.$$

This means that there is some $y' \in S(x')$ with $\|y' - y\| \leq \eta$, so that $y' \in B(y, \eta)$, and hence $y' \in S(x') \cap Q$. Therefore $S(x')$ meets Q, so S is inner semicontinuous at x relative to X. □

A NEW CLASS OF ALTERNATING PROXIMAL MINIMIZATION ALGORITHMS WITH COSTS-TO-MOVE*

H. ATTOUCH†, P. REDONT†, AND A. SOUBEYRAN‡

Abstract. Given two objective functions $f : \mathcal{X} \mapsto \mathbb{R} \cup \{+\infty\}$ and $g : \mathcal{Y} \mapsto \mathbb{R} \cup \{+\infty\}$ on abstract spaces $\mathcal{X}$ and $\mathcal{Y}$, and a coupling function $c : \mathcal{X} \times \mathcal{Y} \mapsto \mathbb{R}^+$, we introduce and study alternative minimization algorithms of the following type: $(x_0, y_0) \in \mathcal{X} \times \mathcal{Y}$ given; $(x_n, y_n) \to (x_{n+1}, y_n) \to (x_{n+1}, y_{n+1})$ as follows:
$\begin{cases} x_{n+1} \in \operatorname{argmin}\{f(\xi) + \beta_n c(\xi, y_n) + \alpha_n h(x_n, \xi) : \ \xi \in \mathcal{X}\}, \\ y_{n+1} \in \operatorname{argmin}\{g(\eta) + \mu_n c(x_{n+1}, \eta) + \nu_n k(y_n, \eta) : \ \eta \in \mathcal{Y}\}. \end{cases}$
Their most original feature is the introduction of the terms $h : \mathcal{X} \times \mathcal{X} \mapsto \mathbb{R}^+$ and $k : \mathcal{Y} \times \mathcal{Y} \mapsto \mathbb{R}^+$ which are costs to change or to move (distance-like functions, relative entropies) accounting for various inertial, friction, or anchoring effects. These algorithms are studied in a general abstract framework. The introduction of the costs to change h and k leads to proximal minimizations with corresponding dissipative effects. As a result, the algorithms enjoy nice convergent properties. Coefficients α_n, β_n, μ_n, ν_n are nonnegative parameters. When taking $\alpha_n = \nu_n = 0$ and quadratic costs on a Hilbert space, one recovers the classical alternating minimization algorithm, which itself is a natural extension of the alternating projection algorithm of von Neumann. A number of new significant results hold in general metric spaces. We pay particular attention to the following cases: (1.) $(\mathcal{X}, d_{\mathcal{X}})$ and $(\mathcal{Y}, d_{\mathcal{Y}})$ are complete metric spaces and $h \geq d_{\mathcal{X}}$, $k \geq d_{\mathcal{Y}}$ ("high local costs to move"); the algorithms then provide sequences that converge to Nash equilibria. (2.) $\mathcal{X} = \mathcal{Y} = \mathcal{H}$ is a Hilbert space, the costs to change are quadratic ("low local costs to move") and the functions $f, g : \mathcal{H} \mapsto \mathbb{R} \cup \{+\infty\}$ are closed, convex, proper; then some of the classical convergence theorems for alternating convex minimization algorithms, including those of Acker and Prestel, are properly extended with original proofs.

Key words. alternating minimization, alternating projection, proximal algorithms, costs to change, inertia, anchoring effect, dynamical game theory, Nash equilibria, steepest descent, dissipative dynamical systems

1. Introduction and general presentation.

1.1. Some classical results about alternating minimization. Let us first recall some basic facts about alternating minimization and proximal algorithms that will be most useful to throw light on the original aspects of our approach.

(a) The starting fundamental result is due to von Neumann (1950) [33]. Let H be a Hilbert space and let C_1, C_2 be two closed affine subspaces of H with $C_1 \cap C_2 \neq \emptyset$. Let P_{C_1} and P_{C_2} denote the orthogonal projections on C_1 and C_2. Then, for any x_0 in H, the sequence $(x_n)_{n \in \mathbb{N}}$ obtained by alternatively projecting on C_1 and on C_2, namely

$$x_n = (P_{C_1} \circ P_{C_2})^n x_0,$$

strongly converges to the projection of x_0 onto $C_1 \cap C_2$. This result, and its extension by Halperin [24] to the case of cyclic projections onto a finite number of closed affine subspaces, provides a powerful tool for solving convex feasibility problems in Hilbert spaces. A rich literature has been devoted to this subject; see, for example, the extensive studies by Deutsch [23], Bauschke, Borwein, and Lewis [14], and Combettes [22].

(b) A next decisive step in the understanding of the convergence analysis of these algorithms in the general framework of convex optimization has been made by Acker and Prestel [1]. Let $f, g : H \mapsto \mathbb{R} \cup \{+\infty\}$ be two closed convex proper functions on the Hilbert space H. Fix $(x_0, y_0) \in H \times H$ and consider the sequence generated by the alternating minimization algorithm

$$\begin{cases} x_{n+1} = \operatorname{argmin}\{f(x) + \frac{1}{2} \parallel x - y_n \parallel^2 : x \in H\}, \\ y_{n+1} = \operatorname{argmin}\{g(y) + \frac{1}{2} \parallel x_{n+1} - y \parallel^2 : y \in H\}. \end{cases}$$

Then, the sequence $(x_n, y_n)_{n\in\mathbb{N}}$ weakly converges to a solution of the joint minimization problem on $H \times H$,

$$\min \left\{ f(x) + g(y) + \frac{1}{2} \parallel x - y \parallel^2 : (x, y) \in H \times H \right\},$$

if we assume that the minimum point set is nonempty. This result can be formulated in an equivalent form by using the proximal mappings introduced by Moreau [32] and Rockafellar [36]: Recall that, for a closed convex proper function $\varphi : H \mapsto \mathbb{R} \cup \{+\infty\}$, the proximal mapping $\operatorname{prox}_\varphi$ is defined by

$$\forall z \in H, \quad \operatorname{prox}_\varphi(z) = \operatorname{argmin}_\xi \left\{ \varphi(\xi) + \frac{1}{2} \parallel z - \xi \parallel^2 \right\}.$$

When $\varphi = \delta_C$ is the indicator function of a closed convex nonempty set C, one has $\operatorname{prox}_\varphi = P_C$, the classical projection, whence the terminology. Like projections, proximal mappings are nonexpansive (more precisely they are firmly nonexpansive). Acker and Prestel's algorithm may be reformulated as

$$\begin{cases} x_{n+1} = \operatorname{prox}_f y_n, \\ y_{n+1} = \operatorname{prox}_g x_{n+1}. \end{cases}$$

In particular, it provides a nice extension of von Neumann's theorem to two closed convex nonempty sets of the Hilbert space H (take $f = \delta_{C_1}$, $g = \delta_{C_2}$); namely the following.

1. If $C_1 \cap C_2 \neq \emptyset$, then the sequences x_n, y_n generated by the alternating projection algorithm weakly converge,

$$w - \lim x_n = w - \lim y_n = \overline{z},$$

to a point $\overline{z} \in C_1 \cap C_2$.

2. If $C_1 \cap C_2 = \emptyset$, then $w - \lim x_n = \overline{x}$ and $w - \lim y_n = \overline{y}$ exist where $\overline{x} \in C_1$ and $\overline{y} \in C_2$ are such that $\parallel \overline{x} - \overline{y} \parallel$ achieves the distance between sets C_1 and C_2,

$$\parallel \overline{x} - \overline{y} \parallel = \inf\{\parallel x - y \parallel : x \in C_1,\, y \in C_2\}.$$

This last result has proved to be of fundamental importance for applications, especially when solving inverse problems (possibly ill-posed) arising in various fields of engineering (mechanics, signal reconstruction, image processing, statistics, etc.). Indeed, in

the case of inconsistent constraints ($C_1 \cap C_2 = \emptyset$) due to inaccurate measurements, for example, the previous result guarantees the convergence of the algorithm to a relaxed solution $(\overline{x}, \overline{y})$ taking the inconsistent constraints into account in the best possible way; see [22, 14].

Note that, and this will be important for further developments, the preceding algorithm can be viewed as the alternating minimization of the bivariate function

$$L : (x, y) \in H \times H \mapsto L(x, y) = f(x) + g(y) + \frac{1}{2} \parallel x - y \parallel^2 \in \mathbb{R} \cup \{+\infty\}$$

and provides a minimizing sequence for L. A related approach has recently been developed by Bauschke, Combettes, and Noll [15] who consider the alternating minimization procedure in the case of the Euclidean space for the bivariate function

$$L(x, y) = f(x) + g(y) + D(x, y),$$

where $D(x, y)$ is a coupling function of Bregman type, namely

$$D(x, y) = \theta(x) - \theta(y) - \langle \nabla\theta(y), x - y \rangle,$$

with θ a convex function designed for the developments of interior point methods in convex programming (note that $D(x, y) = 1/2 \parallel x - y \parallel^2$ when $\theta(x) = 1/2 \parallel x \parallel^2$).

(c) To complete this general portrait of alternating proximal methods, let us mention the approach via the asymptotic analysis of the composition of resolvents of maximal monotone operators. This allows us to treat in a unified way the case of convex functions, min-max, and complementary problems. The corresponding generated semigroups of contractions and the Trotter–Kato–Lie formula make a natural link with dynamical systems [16, 35, 19, 30].

1.2. Description of the alternating algorithms. Due to the wide potential range of applications of these algorithms (from engineering to decision sciences) we adopt a quite general terminology (the corresponding terminology in game theory is described in section 1.4).

$\mathcal{X}$ and $\mathcal{Y}$ are abstract spaces.

f: $\mathcal{X} \mapsto \mathbb{R} \cup \{+\infty\}$ is the "first" criterion or objective function.

g: $\mathcal{Y} \mapsto \mathbb{R} \cup \{+\infty\}$ is the "second" criterion or objective function.

Nonnegative bivariate functions h, k, c account for the following effects:

h: $(x, \xi) \in \mathcal{X} \times \mathcal{X} \mapsto h(x, \xi) \in \mathbb{R}^+ \cup \{+\infty\}$ is the cost to change from $x \in \mathcal{X}$ to $\xi \in \mathcal{X}$, which is involved in the minimization procedure of f on $\mathcal{X}$. For example, $h(x, \xi) = d_{\mathcal{X}}(x, \xi)$ in the case of a metric space $(\mathcal{X}, d_{\mathcal{X}})$.

k: $(y, \eta) \in \mathcal{Y} \times \mathcal{Y} \mapsto k(y, \eta) \in \mathbb{R}^+ \cup \{+\infty\}$ similarly is the cost to change from $y \in \mathcal{Y}$ to $\eta \in \mathcal{Y}$, which is involved in the minimization procedure of g on $\mathcal{Y}$.

For example, functions h and k may account for physical costs in transportation processes.

The function $c : \mathcal{X} \times \mathcal{Y} \mapsto \mathbb{R}^+$ couples the two problems. For example, in dynamical games (see section 1.4) it may account for attracting or repulsive coupling effects between two players.

We can now describe the algorithm:

- $(x_0, y_0) \in \mathcal{X} \times \mathcal{Y}$ given is the initial state;
- $(x_n, y_n) \mapsto (x_{n+1}, y_n) \mapsto (x_{n+1}, y_{n+1})$ as follows:

$$(\mathrm{CA}^2) \begin{cases} x_{n+1} \in \operatorname{argmin}\{f(\xi) + \beta_n c(\xi, y_n) + \alpha_n h(x_n, \xi) : \ \xi \in \mathcal{X}\}, \\ y_{n+1} \in \operatorname{argmin}\{g(\eta) + \mu_n c(x_{n+1}, \eta) + \nu_n k(y_n, \eta) : \eta \in \mathcal{Y}\}, \end{cases}$$

where α_n, β_n, μ_n, ν_n are nonnegative parameters. We call (CA^2) the cognitive alternating algorithm for two criteria or two agents.

Indeed, for numerical purposes as well as for the realism of our model, it is convenient to introduce an approximate version of (CA^2):

$$(\mathrm{ACA}^2)\quad \begin{cases} x_{n+1} \in \varepsilon_n\text{-argmin}\{f(\xi) + \beta_n c(\xi, y_n) + \alpha_n h(x_n, \xi) :\ \xi \in \mathcal{X}\}, \\ y_{n+1} \in \varepsilon_n\text{-argmin}\{g(\eta) + \mu_n c(x_{n+1}, \eta) + \nu_n k(y_n, \eta) : \eta \in \mathcal{Y}\}. \end{cases}$$

In order to describe the asymptotic behavior of the sequences generated by this algorithm, let us define the following notion of equilibrium.

DEFINITION 1.1. *Given nonnnegative constants α, β, μ, ν, an inertial Nash equilibrium, in short INE(α,β,μ,ν), is defined as a couple $(\overline{x}, \overline{y}) \in \mathcal{X} \times \mathcal{Y}$ such that*

- $\overline{x} \in \arg\min\{f(\xi) + \beta c(\xi, \overline{y}) + \alpha h(\overline{x}, \xi) : \xi \in \mathcal{X}\}$,
- $\overline{y} \in \arg\min\{g(\eta) + \mu c(\overline{x}, \eta) + \nu k(\overline{y}, \eta) : \eta \in \mathcal{Y}\}$.

Remark 1. When $\alpha = \nu = 0$, one recovers the usual notion of Nash equilibrium:

- $\overline{x} \in \arg\min\{F(\xi, \overline{y}) : \xi \in \mathcal{X}\}$,
- $\overline{y} \in \arg\min\{G(\overline{x}, \eta) : \eta \in \mathcal{Y}\}$,

where $F(\xi, \eta) = f(\xi) + \beta c(\xi, \eta)$, $G(\xi, \eta) = g(\eta) + \mu c(\xi, \eta)$.

Remark 2. Suppose the sequences α_n, β_n, μ_n, ν_n converge and set $\alpha = \lim \alpha_n$, $\beta = \lim \beta_n$, $\mu = \lim \mu_n$, and $\nu = \lim \nu_n$. We shall prove in Proposition 2.2 that the limit $(\overline{x}, \overline{y})$ of any sequence (x_n, y_n) generated by algorithm (CA^2) is an inertial Nash equilibrium INE(α,β,μ,ν). The terminology Nash equilibrium will be justified in section 1.4.

Algorithm (CA^2) bears a straight relationship with two classical topics:

(i) proximal algorithms and dynamical systems in optimization,

(ii) best response dynamics in game theory.

Let us make some of these links precise; this will help us motivate and introduce some important aspects of this paper (interpretation of the equilibria, and convergence properties of the algorithm).

1.3. Links with proximal algorithms and dynamical optimization. Dynamical systems provide a rich and unifying approach to the analysis of a number of iterative proximal algorithms in optimization (e.g., [4, 5, 11, 3, 6, 20, 25]).

Let $\varphi : H \mapsto \mathbb{R} \cup \{+\infty\}$ be a closed convex proper function on the Hilbert space H. Classical proximal algorithms for convex optimization

$$x_{n+1} = \mathrm{prox}_{\varphi} x_n = (I + \partial\varphi)^{-1} x_n$$

bear a close relationship with the steepest descent dynamical system

$$\dot{x}(t) + \partial\varphi(x(t)) \ni 0.$$

Indeed, they can be viewed as implicit discretizations of this differential inclusion. In the same spirit, if we recall that alternating proximal minimization algorithms minimize (in the convex setting) the bivariate function

$$L(x, y) = f(x) + g(y) + \frac{1}{2} \parallel x - y \parallel^2,$$

then it is natural to associate the steepest descent continuous dynamical system to L in $H \times H$. We obtain the system of coupled differential inclusions

$$\begin{cases} \dot{x}(t) + \partial f(x(t)) + (x(t) - y(t)) \ni 0, \\ \dot{y}(t) + \partial g(y(t)) + (y(t) - x(t)) \ni 0. \end{cases}$$

Noticing that L is closed convex on $H \times H$ we know, by Bruck's theorem [19], that $(x(t), y(t))$ weakly converges to a minimum point $(\overline{x}, \overline{y})$ of L. Thus, one can expect similar results by discretizing this system in an alternating and implicit way. Following the chain computation $y_n \to x_{n+1} \to y_{n+1} \to x_{n+2}$, one obtains

$$\begin{cases} \frac{1}{\lambda_n}(x_{n+1} - x_n) + \partial f(x_{n+1}) + (x_{n+1} - y_n) \ni 0, \\ \frac{1}{\lambda_n}(y_{n+1} - y_n) + \partial g(y_{n+1}) + (y_{n+1} - x_{n+1}) \ni 0. \end{cases}$$

Equivalently, one gets the following (CA^2) algorithm:

$$\begin{cases} x_{n+1} \in \operatorname{argmin}\{f(\xi) + \frac{1}{2\lambda_n} \parallel \xi - x_n \parallel^2 + \frac{1}{2} \parallel \xi - y_n \parallel^2 :\ \xi \in H\}, \\ y_{n+1} \in \operatorname{argmin}\{g(\eta) + \frac{1}{2\lambda_n} \parallel \eta - y_n \parallel^2 + \frac{1}{2} \parallel \eta - x_{n+1} \parallel^2 :\ \eta \in H\}. \end{cases}$$

Note the novelty consisting in introducing the additional terms $\frac{1}{2\lambda_n} \parallel \xi - x_n \parallel^2$ and $\frac{1}{2\lambda_n} \parallel \eta - y_n \parallel^2$ in these variational formulations. Their contributions $\parallel x_{n+1} - x_n \parallel^2$ and $\parallel y_{n+1} - y_n \parallel^2$ will vanish asymptotically. But they are important for the analysis of these algorithms, because they make the tools of dissipative dynamical systems available. Indeed, they make the bifunction L a *strict* Lyapunov function (without these terms $L(x_n, y_n)$ is only nonincreasing); see section 2 for precise statements. Moreover, these dissipative properties allow us to introduce and study these algorithms in a general setting.

1.4. Links with decision sciences and game theory: Inertial Nash equilibration processes. We do not aim at modeling; we just want to stress some relationships of the algorithm (CA^2) with decision sciences and justify the introduction of costs to move. Let us examplify it in the context of noncooperative dynamical game theory with real world interacting players.

"Inertia free" alternating games. Consider two interrelated players 1 and 2 departing from strict individualism to take each other's decision into account via a coupling function. Their static payoffs are made of two components: an individual payoff coming from their own action (decision, strategy, performance, etc., can be used as well) and a common payoff coming from their joint actions. Let $\mathcal{X}$ and $\mathcal{Y}$ be the strategy sets of players 1 and 2, with $\xi \in \mathcal{X}$ and $\eta \in \mathcal{Y}$ their respective current actions. Their static loss functions are

$$\begin{aligned} F &: (\xi, \eta) \in \mathcal{X} \times \mathcal{Y} \mapsto F(\xi, \eta) = f(\xi) + \beta c(\xi, \eta), \\ G &: (\xi, \eta) \in \mathcal{X} \times \mathcal{Y} \mapsto G(\xi, \eta) = g(\eta) + \mu c(\xi, \eta). \end{aligned}$$

The coupling term defines the more or less conflictual characteristic of the game, i.e., the nature of the interdependence between players. Coefficients $\beta > 0$ and $\mu > 0$ represent how much each player benefits from the joint payoff.

Inertial nonautonomous Nash equilibration processes. (i) First consider inertia aspects. We add to this classical static normal form game some costs to move for each player. Player 1 must pay the cost $h(x, \xi)$ to move from action $x \in \mathcal{X}$ to a new action $\xi \in \mathcal{X}$ and player 2 must pay the cost $k(y, \eta)$ to move from action $y \in \mathcal{Y}$ to a new action $\eta \in \mathcal{Y}$.

The general idea is that, in real life, changing, improving the gain, and the quality of actions has a cost. "Costs to move" covers various physical, physiological, psychological, and cognitive aspects. They reflect the bounded rationality and behavioral features of decision processes in real life (see Kahneman [27], Camerer and Loewenstein [21]; Simon [37] for the concept of deliberation costs; Attouch and Soubeyran

[9, 10] for the precise concept of costs to change; and Attouch, Buttazzo, and Michaille [7, section 3.4.2] for a dynamical cognitive approach of Ekeland's variational principle due to Attouch and Soubeyran). Here, these costs mainly describe an anchoring effect. Agents have a (local) vision of their environment which depends on their current actions. Each action is anchored to the preceding one, which means that the perception the agents have of the quality of their subsequent actions depends on the current ones. In economics and management, one may think of actions as routines, ways of doing, while costs to change reflect the difficulty of quitting a routine or entering another one or reacting quickly (reactivity costs). In our situation, suppose that the current action of the two players is $(x, y) \in \mathcal{X} \times \mathcal{Y}$. Suppose also that only player 1 can choose a new action (i.e., player 1 chooses a new action ξ while player 2 "stays" at y); then the inertial payoff of player 1 is

$$F(\xi, y) + \alpha h(x, \xi) = f(\xi) + \beta c(\xi, y) + \alpha h(x, \xi).$$

The second member of this expression is the sum of three costs: a cost to be far from the objective (frustration), a cost to be far from (or close to) the action of the other agent (coupling), and a cost to be far from the preceding action (anchoring or inertial effect). The coefficient α before the cost $h(x, \xi)$ usually reflects some dynamical cognitive features of player 1 (speed, reactivity, learning ability, etc.).

Symmetrically, suppose now that only player 2 can choose a new action (i.e., player 2 chooses a new action η while player 1 "stays" at x); then the inertial payoff of player 2 is

$$G(x, \eta) + \nu k(y, \eta) = g(\eta) + \mu c(x, \eta) + \nu k(y, \eta)$$

with the ν coefficient reflecting some dynamical cognitive features of player 2. The timing of the game follows an asynchronous dynamic where players move in alternation.

(ii) Then consider nonautonomous aspects. Suppose that both the weights $\beta_n > 0$ and $\mu_n > 0$ attached to the joint payoff and the "anchoring" (also called "inertial") coefficients $\alpha_n > 0$ and $\nu_n > 0$ vary from period to period for each player. Suppose that the current action of the two players is $(x_n, y_n) \in \mathcal{X} \times \mathcal{Y}$. Suppose that only player 1 can choose a new action ξ; then the inertial payoff of player 1 is

$$F_n(\xi, y_n) + \alpha_n h(x_n, \xi) = f(\xi) + \beta_n c(\xi, y_n) + \alpha_n h(x_n, \xi).$$

Symmetrically, suppose now that only player 2 can choose a new action; then the inertial payoff of player 2 is

$$G_n(x_n, \eta) + \nu_n k(y_n, \eta) = g(\eta) + \mu_n c(x_n, \eta) + \nu_n k(y_n, \eta).$$

These expressions describe the nonautonomous inertial payoffs of the two agents. Note that they depend both on the current period (time dependence) and the current position of the agents. Taking account of the fact that agents optimize their payoffs, we obtain the description of the alternating dynamic as (CA^2).

1.5. Examples. Algorithm (CA^2) covers, but is more general than, former algorithms to be found in the literature.

Suppose that f and g are proper convex lower semicontinuous functions defined on a Hilbert space, that the costs to move h and k vanish, and that the coupling c is a quadratic dissimilarity cost, namely $c(x, y) = \frac{1}{2} \parallel x - y \parallel^2$.

Then writing out the optimality conditions for algorithm (CA^2) yields

$$\begin{cases} 0 \in \partial f(x_{n+1}) + \beta_n(x_{n+1} - y_n), \\ 0 \in \partial g(y_{n+1}) + \mu_n(y_{n+1} - x_{n+1}), \end{cases} \quad \text{equivalently} \quad \begin{cases} x_{n+1} = (I + \frac{1}{\beta_n}\partial f)^{-1} y_n, \\ y_{n+1} = (I + \frac{1}{\mu_n}\partial g)^{-1} x_{n+1}, \end{cases}$$

where ∂f and ∂g are the subgradient operators of f and g in the sense of convex analysis [32, 36, 12]. If β_n and μ_n have a common constant value β, then this is exactly Acker and Prestel's alternating process, which is introduced in [1] to minimize the function $f(x) + g(y) + \frac{\beta}{2} \parallel x - y \parallel^2$ and which possesses interesting convergence properties. If β_n and μ_n coincide, and if the sequence $(1/\beta_n)$ belongs to $l^2(\mathbb{N}) \setminus l^1(\mathbb{N})$ (which implies $\beta_n \to +\infty$), then this is Passty's scheme for minimizing $f + g$ which possesses interesting properties too; see [35].

It may be useful to illustrate the behavior of algorithm (CA^2) with an example providing a simple geometric interpretation.

Suppose $\mathcal{X}$ and $\mathcal{Y}$ coincide with the same Hilbert space $\mathcal{H}$ endowed with the norm $\parallel \ \parallel$, $\mathcal{X} = \mathcal{Y} = \mathcal{H}$. Let F be a nonvoid closed convex set of $\mathcal{H}$, and define $f(x) = \frac{1}{2}d^2(x, F)$, where $d(x, F)$ denotes the distance from x to F; likewise define $g(y) = \frac{1}{2}d^2(y, G)$, where G is another nonvoid closed convex set in $\mathcal{H}$. Starting from an initial state (x_0, y_0) in $\mathcal{H} \times \mathcal{H}$, the agents seek to improve their decisions x and y subject to quadratic costs (both coupling and inertial terms) and are supposed to implement algorithm (CA^2):

$$\begin{cases} x_{n+1} = \operatorname{argmin}\{ \frac{1}{2}d^2(\xi, F) + \frac{1}{2}\alpha \parallel \xi - x_n \parallel^2 + \frac{1}{2}\beta \parallel \xi - y_n \parallel^2 \colon \xi \in \mathcal{H} \}, \\ y_{n+1} = \operatorname{argmin}\{ \frac{1}{2}d^2(\eta, G) + \frac{1}{2}\mu \parallel \eta - x_{n+1} \parallel^2 + \frac{1}{2}\nu \parallel \eta - y_n \parallel^2 \colon \eta \in \mathcal{H} \}, \end{cases}$$

where α, β, μ, ν are nonnegative constants (owing to the strict convexity and the coerciveness of the functions to be minimized the sequence (x_n, y_n) is uniquely defined). Due to the simple form of the problem, x_{n+1} and y_{n+1} may be explicitly computed; just write the optimality conditions for x_{n+1} and y_{n+1},

$$\begin{cases} x_{n+1} - P_F x_{n+1} + \alpha(x_{n+1} - x_n) + \beta(x_{n+1} - y_n) = 0, \\ y_{n+1} - P_G y_{n+1} + \mu(y_{n+1} - x_{n+1}) + \nu(y_{n+1} - y_n) = 0. \end{cases}$$

Here, P_F and P_G are the projection operators onto the convex sets F and G; for $\partial(1/2)d^2(x, F) = x - P_F(x)$ in general Hilbert space, see [32, p. 286] or [18, p. 46, example 2.8.2]. Set $u_{n+1} = \frac{1}{\alpha+\beta}(\alpha x_n + \beta y_n)$ and $v_{n+1} = \frac{1}{\mu+\nu}(\mu x_{n+1} + \nu y_n)$. The system above reads

$$\begin{cases} x_{n+1} - P_F x_{n+1} + (\alpha + \beta)(x_{n+1} - u_{n+1}) = 0, \\ y_{n+1} - P_G y_{n+1} + (\mu + \nu)(y_{n+1} - v_{n+1}) = 0, \end{cases}$$

which shows that x_{n+1}, $P_F x_{n+1}$, and u_{n+1} are collinear. Hence $P_F x_{n+1} = P_F u_{n+1}$; likewise $P_F y_{n+1} = P_F v_{n+1}$. Finally, x_{n+1} and y_{n+1} are defined by

$$\begin{cases} x_{n+1} = \frac{1}{1+(\alpha+\beta)}(P_F u_{n+1} + (\alpha + \beta)u_{n+1}), \\ y_{n+1} = \frac{1}{1+(\mu+\nu)}(P_G v_{n+1} + (\mu + \nu)v_{n+1}). \end{cases}$$

Observe that x_{n+1}, y_{n+1} and u_{n+1}, v_{n+1} may be defined in quite simple geometric terms: u_{n+1} is the weighted mean of x_n and y_n with weights α and β, and x_{n+1} itself is the weighted mean of $P_F u_{n+1}$ and u_{n+1} with weights 1 and $\alpha + \beta$; likewise v_{n+1} is the weighted mean of x_{n+1} and y_n with weights μ and ν, and y_{n+1} itself is

the weighted mean of $P_G v_{n+1}$ and v_{n+1} with weights 1 and $\mu+\nu$. Figure 1.1, left, displays the first three steps of the algorithm applied to the example with $\mathcal{H}=\mathbb{R}^2$. Figure 1.1, right, displays the particular case where $\alpha=\nu=0$ and $\beta=\mu$; this is Acker and Prestel's alternating minimization process, and the sequences x_n and y_n are then known to converge to (x_∞, y_∞), a minimizer of $f(x)+g(y)+\frac{\beta}{2}\parallel x-y\parallel^2$.

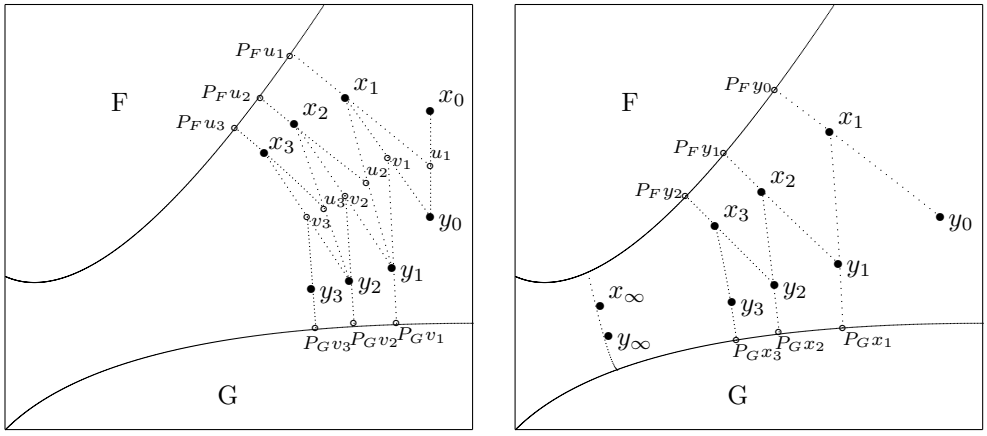

FIG. 1.1. *Illustration of algorithm (CA²) (left); Acker and Prestel's process (right).*

A limit case of the above example occurs when f and g are the respective indicator functions of the sets F and G (that is, $f(x)=0$ if $x\in F$ and $f(x)=+\infty$ if $x\notin F$, and g is similarly defined). The algorithm (CA²) then takes the form

$$\begin{cases} x_{n+1}\in \operatorname{argmin}\{\frac{1}{2}\alpha\parallel \xi-x_n\parallel^2+\frac{1}{2}\beta\parallel \xi-y_n\parallel^2 : \xi\in F\},\\ y_{n+1}\in \operatorname{argmin}\{\frac{1}{2}\mu\parallel \eta-x_{n+1}\parallel^2+\frac{1}{2}\nu\parallel \eta-y_n\parallel^2 : \eta\in G\}. \end{cases}$$

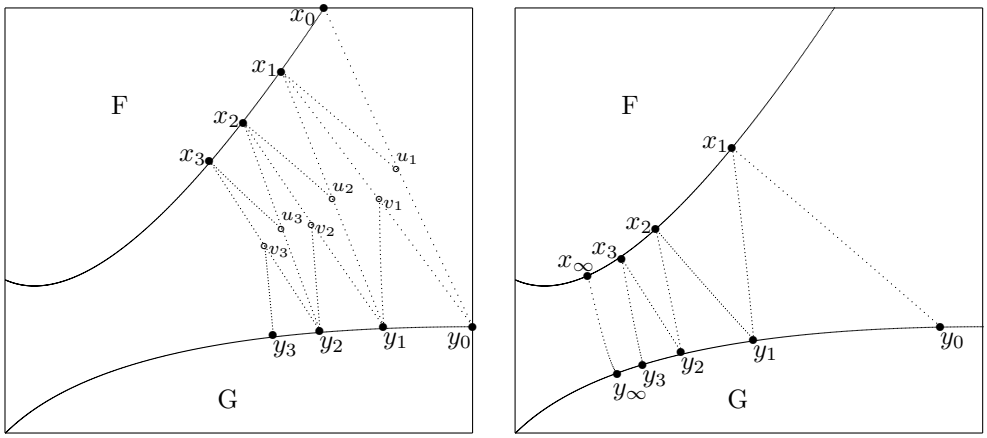

FIG. 1.2. *Illustration of algorithm (CA²) (left); alternating projections (right).*

Writing the optimality conditions for x_{n+1} and y_{n+1} yields

$$\begin{cases} 0\in N_F(x_{n+1})+\alpha(x_{n+1}-x_n)+\beta(x_{n+1}-y_n)=0,\\ 0\in N_G(y_{n+1})+\mu(y_{n+1}-x_{n+1})+\nu(y_{n+1}-y_n)=0, \end{cases}$$

where $N_F(x_{n+1})$ is the outward normal cone to F at point x_{n+1} and $N_G(y_{n+1})$ is the outward normal cone to G at point y_{n+1}. Let us retain the same notation as before for u_{n+1} and v_{n+1}; the above system reads

$$\begin{cases} 0 \in N_F(x_{n+1}) + (x_{n+1} - u_{n+1}), & \text{equivalently } x_{n+1} = P_F u_{n+1}, \\ 0 \in N_G(y_{n+1}) + (y_{n+1} - v_{n+1}), & \text{equivalently } y_{n+1} = P_G v_{n+1}. \end{cases}$$

If $\alpha = \nu = 0$, algorithm (CA^2) reduces to $x_{n+1} = P_F y_n$, $y_{n+1} = P_G x_{n+1}$. This is the celebrated alternating projection algorithm used to find a point in the intersection of the sets, or if the latter is void, to find a couple of points realizing the distance between the two sets; see von Neumann [33], Halperin [24], Bregman [17], and Bauschke, Borwein, and Lewis [14] for further references. Figure 1.2 illustrates this example with $\mathcal{H} = \mathbb{R}^2$.

2. General dissipative and convergence properties of the alternating algorithm (CA^2). Let us fix the general mathematical setting and properties of algorithm (CA^2). In the next two sections, we shall make these results more precise by specifying the type of inertial costs to move which is considered: high local costs to move (section 3) or low local costs to move (section 4). Let us recall that algorithm (CA^2), also called the inertial Nash equilibration process (see section 1.4), is defined by $(x_n, y_n) \to (x_{n+1}, y_n) \to (x_{n+1}, y_{n+1})$ as follows:

$$\begin{cases} x_{n+1} = \operatorname{argmin}\{f(\xi) + \beta_n c(\xi, y_n) + \alpha_n h(x_n, \xi) : \ \xi \in \mathcal{X}\}, \\ y_{n+1} = \operatorname{argmin}\{g(\eta) + \mu_n c(x_{n+1}, \eta) + \nu_n k(y_n, \eta) : \ \eta \in \mathcal{Y}\}. \end{cases}$$

2.1. Convergence to an inertial Nash equilibrium. First let us specify the general topological assumptions in this section.

$\mathcal{H}11$. $\mathcal{X}$ and $\mathcal{Y}$ are topological spaces;

$\mathcal{H}12$. $f : \mathcal{X} \mapsto \mathbb{R} \cup \{+\infty\}$ and $g : \mathcal{Y} \mapsto \mathbb{R} \cup \{+\infty\}$ are proper, bounded below, lower semicontinuous functions;

$\mathcal{H}13$. $h : \mathcal{X} \times \mathcal{X} \mapsto \mathbb{R}^+$, $k : \mathcal{Y} \times \mathcal{Y} \mapsto \mathbb{R}^+$, and $c : \mathcal{X} \times \mathcal{Y} \mapsto \mathbb{R}^+$ are lower semicontinuous and separately continuous;

$\mathcal{H}14$. α_n, β_n, μ_n, and ν_n are nonnegative sequences and $\beta_n \to \beta_\infty$, $\mu_n \to \mu_\infty$.

If algorithm (CA^2) generates a sequence (x_n, y_n) that furthermore converges, then, under some extra assumptions, we are going to prove that the limit is an inertial Nash equilibrium.

PROPOSITION 2.1. *In addition to $\mathcal{H}11$–$\mathcal{H}14$ suppose that $\alpha_n \to \alpha_\infty$ and $\nu_n \to \nu_\infty$. Then the limit $(\overline{x}, \overline{y})$ of any sequence (x_n, y_n) generated by algorithm (CA^2) is an inertial Nash equilibrium INE(α_∞, β_∞, μ_∞, ν_∞).*

Proof. Algorithm (CA^2) reads

$$\begin{aligned} (2.1) \qquad & f(x_{n+1}) + \alpha_n h(x_n, x_{n+1}) + \beta_n c(x_{n+1}, y_n) \\ & \qquad \le f(\xi) + \alpha_n h(x_n, \xi) + \beta_n c(\xi, y_n) \ \forall \xi \in \mathcal{X}, \\ (2.2) \qquad & g(y_{n+1}) + \mu_n c(x_{n+1}, y_{n+1}) + \nu_n k(y_n, y_{n+1}) \\ & \qquad \le g(\eta) + \mu_n c(x_{n+1}, \eta) + \nu_n k(y_n, \eta) \ \forall \eta \in \mathcal{Y}. \end{aligned}$$

The right-hand member of (2.1) converges to $f(\xi) + \alpha_\infty h(\overline{x}, \xi) + \beta_\infty c(\xi, \overline{y})$. Taking the lower limit of the left-hand member of (2.1) gives

$$\begin{aligned} (2.3) \qquad & \underline{\lim}\{f(x_{n+1}) + \alpha_n h(x_n, x_{n+1}) + \beta_n c(x_{n+1}, y_n)\} \\ & \qquad \ge \underline{\lim} f(x_{n+1}) + \underline{\lim} \alpha_n h(x_n, x_{n+1}) + \underline{\lim} \beta_n c(x_{n+1}, y_n) \\ & \qquad \ge f(\overline{x}) + \alpha_\infty h(\overline{x}, \overline{x}) + \beta_\infty c(\overline{x}, \overline{y}), \end{aligned}$$

which yields the first condition for $(\overline{x},\overline{y})$ to be an inertial Nash equilibrium. The second condition is proved likewise from (2.2). □

The proof of the following proposition runs along the same lines.

PROPOSITION 2.2. *In addition to* $\mathcal{H}11$–$\mathcal{H}14$, *suppose*

(i) $h(\xi,\xi)=0, \forall \xi \in \mathcal{X}$, $k(\eta,\eta)=0, \forall \eta \in \mathcal{Y}$;

(ii) $\overline{\alpha}=\overline{\lim}\alpha_n$ *and* $\overline{\nu}=\overline{\lim}\nu_n$ *are finite.*

Then the limit $(\overline{x},\overline{y})$ *of any sequence* (x_n,y_n) *generated by algorithm* (CA^2) *is an inertial Nash equilibrium INE*$(\alpha,\ \beta_\infty,\ \mu_\infty,\ \nu)$, *where* α *is any number greater than or equal to* $\overline{\alpha}$, *and* ν *is any number greater than or equal to* $\overline{\nu}$.

2.2. General dissipative properties of the alternating algorithm (CA^2). The assumptions in this section are

$\mathcal{H}21$. $\mathcal{X}$ and $\mathcal{Y}$ are abstract spaces;

$\mathcal{H}22$. $f:\mathcal{X}\mapsto\mathbb{R}\cup\{+\infty\}$ and $g:\mathcal{Y}\mapsto\mathbb{R}\cup\{+\infty\}$ are proper, bounded below;

$\mathcal{H}23$. $h:\mathcal{X}\times\mathcal{X}\mapsto\mathbb{R}^+$, $k:\mathcal{Y}\times\mathcal{Y}\mapsto\mathbb{R}^+$ and $c:\mathcal{X}\times\mathcal{Y}\mapsto\mathbb{R}^+$ are nonnegative functions satisfying $h(x,x)=k(y,y)=0\,\forall\, x\in\mathcal{X},\ y\in\mathcal{Y}$;

$\mathcal{H}24$. $\beta_n>0,\ \mu_n>0,\ \alpha_n\geq 0,\ \nu_n\geq 0$.

LEMMA 2.3. *Assume* $\mathcal{H}21$–$\mathcal{H}24$. *Then, for any sequence* (x_n,y_n) *generated by* (CA^2), *one has*

$$
\begin{aligned}
(2.4)\qquad &[\mu_n f(x_{n+1})+\beta_n g(y_{n+1})+\beta_n\mu_n c(x_{n+1},y_{n+1})]\\
&\qquad+[\mu_n\alpha_n h(x_n,x_{n+1})+\beta_n\nu_n k(y_n,y_{n+1})]\\
&\qquad\leq[\mu_n f(x_n)+\beta_n g(y_n)+\beta_n\mu_n c(x_n,y_n)].
\end{aligned}
$$

Proof. Set $\xi=x_n$ and $\eta=y_n$ in (2.1) and in (2.2); sequences x_n and y_n verify

$$
\begin{cases}
f(x_{n+1})+\alpha_n h(x_n,x_{n+1})+\beta_n c(x_{n+1},y_n)\leq f(x_n)+\beta_n c(x_n,y_n),\\
g(y_{n+1})+\mu_n c(x_{n+1},y_{n+1})+\nu_n k(y_n,y_{n+1})\leq g(y_n)+\mu_n c(x_{n+1},y_n).
\end{cases}
$$

Multiplying the first inequality by μ_n and the second one by β_n we obtain

$$
\begin{aligned}
&[\mu_n f(x_{n+1})]+[\mu_n\alpha_n h(x_n,x_{n+1})]+[\mu_n\beta_n c(x_{n+1},y_n)]\\
&\qquad\leq[\mu_n f(x_n)+\mu_n\beta_n c(x_n,y_n)]
\end{aligned}
$$

and

$$
\begin{aligned}
&[\beta_n g(y_{n+1})+\beta_n\mu_n c(x_{n+1},y_{n+1})]+[\beta_n\nu_n k(y_n,y_{n+1})]\\
&\qquad\leq[\beta_n g(y_n)]+[\beta_n\mu_n c(x_{n+1},y_n)].
\end{aligned}
$$

Add the two inequalities to get (2.4). □

Depending on various monotonicity assumptions on coefficients β_n and μ_n, inequality (2.4) gives prominence to quantities decreasing along the trajectories, and hence acting as Lyapunov functions. We first consider the particular case where $\beta_n\equiv\mu_n$ before the general case.

THEOREM 2.4. *In addition to assumption* $\mathcal{H}21$–$\mathcal{H}24$ *assume that* β_n *and* μ_n *coincide and that* $\beta_n\equiv\mu_n$ *is a nonincreasing sequence. Then, the following marginal analysis result holds: for any sequence* (x_n,y_n) *generated by* (CA^2), *one has*

(a) $f(x_n)+g(y_n)+\beta_n c(x_n,y_n)$ *is nonincreasing and has a limit as* $n\to\infty$;

(b) $\sum_{n=0}^{+\infty}[\alpha_n h(x_n,x_{n+1})+\nu_n k(y_n,y_{n+1})]<+\infty$.

Proof. Dividing inequality (2.4) by $\beta_n\equiv\mu_n$, we obtain

$$
\begin{aligned}
&[f(x_{n+1})+g(y_{n+1})+\beta_n c(x_{n+1},y_{n+1})]+[\alpha_n h(x_n,x_{n+1})+\nu_n k(y_n,y_{n+1})]\\
&\qquad\leq[f(x_n)+g(y_n)+\beta_n c(x_n,y_n)].
\end{aligned}
$$

Since β_n is nonincreasing, we may replace β_n with β_{n+1} in the left-hand member,

$$[f(x_{n+1}) + g(y_{n+1}) + \beta_{n+1}c(x_{n+1}, y_{n+1})] + [\alpha_n h(x_n, x_{n+1}) + \nu_n k(y_n, y_{n+1})] \\ \leq [f(x_n) + g(y_n) + \beta_n c(x_n, y_n)],$$

which shows that the quantity $f(x_n) + g(y_n) + \beta_n c(x_n, y_n)$ is nonincreasing; as it is nonnegative it is convergent, which proves point (a).

Summing the inequality above from $n = 0$ to N, we obtain

$$\sum_{n=0}^{N} [\alpha_n h(x_n, x_{n+1}) + \nu_n k(y_n, y_{n+1})] \\ \leq [f(x_0) + g(y_0) + \beta_0 c(x_0, y_0)] - [f(x_{N+1}) + g(y_{N+1}) + \beta_{N+1} c(x_{N+1}, y_{N+1})] \\ \leq [f(x_0) + g(y_0) + \beta_0 c(x_0, y_0)] - [\inf_{\mathcal{X}} f + \inf_{\mathcal{Y}} g],$$

which proves point (b). □

The preceding theorem can be extended to monotone (i.e., nonincreasing or nondecreasing) sequences β_n and μ_n. Define δ_n according to the following cases:

- if β_n and μ_n are nonincreasing sequences, then $\delta_n = 1$;
- if β_n and μ_n are nondecreasing sequences, then $\delta_n = \beta_n \mu_n$;
- if β_n is nonincreasing and μ_n is nondecreasing, then $\delta_n = \mu_n$;
- if β_n is nondecreasing and μ_n is nonincreasing, then $\delta_n = \beta_n$.

THEOREM 2.5. *Assume $\mathcal{H}21$–$\mathcal{H}24$ and let (x_n, y_n) be any sequence generated by (CA^2). If β_n and μ_n are monotone sequences, then*

(a) $\frac{\mu_n}{\delta_n}(f(x_n) - \inf_{\mathcal{X}} f) + \frac{\beta_n}{\delta_n}(g(y_n) - \inf_{\mathcal{Y}} g) + \frac{\beta_n \mu_n}{\delta_n} c(x_n, y_n)$ *is nonincreasing and has a limit as $n \to \infty$;*

(b) $\sum_{n=0}^{\infty} \left[\frac{\mu_n \alpha_n}{\delta_n} h(x_n, x_{n+1}) + \frac{\beta_n \nu_n}{\delta_n} k(y_n, y_{n+1})\right] < +\infty$.

Proof. Divide inequality (2.4) in Lemma 2.3 by δ_n, and display positive quantities like $f(x_n) - \inf_{\mathcal{X}} f$ and $g(y_n) - \inf_{\mathcal{Y}} g$. Then

$$\left[\frac{\mu_n}{\delta_n}\left(f(x_{n+1}) - \inf_{\mathcal{X}} f\right) + \frac{\beta_n}{\delta_n}\left(g(y_{n+1}) - \inf_{\mathcal{Y}} g\right) + \frac{\beta_n \mu_n}{\delta_n} c(x_{n+1}, y_{n+1})\right] \\ + \left[\frac{\mu_n \alpha_n}{\delta_n} h(x_n, x_{n+1}) + \frac{\beta_n \nu_n}{\delta_n} k(y_n, y_{n+1})\right] \\ \leq \left[\frac{\mu_n}{\delta_n}\left(f(x_n) - \inf_{\mathcal{X}} f\right) + \frac{\beta_n}{\delta_n}\left(g(y_n) - \inf_{\mathcal{Y}} g\right) + \frac{\beta_n \mu_n}{\delta_n} c(x_n, y_n)\right].$$

Each sequence $\frac{\mu_n}{\delta_n}$, $\frac{\beta_n}{\delta_n}$, and $\frac{\beta_n \mu_n}{\delta_n}$ is nonincreasing; so we have

$$\left[\frac{\mu_{n+1}}{\delta_{n+1}}\left(f(x_{n+1}) - \inf_{\mathcal{X}} f\right) + \frac{\beta_{n+1}}{\delta_{n+1}}\left(g(y_{n+1}) - \inf_{\mathcal{Y}} g\right) + \frac{\beta_{n+1} \mu_{n+1}}{\delta_{n+1}} c(x_{n+1}, y_{n+1})\right] \\ + \left[\frac{\mu_n \alpha_n}{\delta_n} h(x_n, x_{n+1}) + \frac{\beta_n \nu_n}{\delta_n} k(y_n, y_{n+1})\right] \\ \leq \left[\frac{\mu_n}{\delta_n}\left(f(x_n) - \inf_{\mathcal{X}} f\right) + \frac{\beta_n}{\delta_n}\left(g(y_n) - \inf_{\mathcal{Y}} g\right) + \frac{\beta_n \mu_n}{\delta_n} c(x_n, y_n)\right],$$

which completes the proof. □

3. High local costs to move. The following assumptions will be valid throughout this section:

- $\mathcal{H}31$. $\mathcal{X}$ and $\mathcal{Y}$ are complete metric spaces endowed with distances $d_{\mathcal{X}}$ and $d_{\mathcal{Y}}$;
- $\mathcal{H}32$. $f : \mathcal{X} \mapsto \mathbb{R} \cup \{+\infty\}$ and $g : \mathcal{Y} \mapsto \mathbb{R} \cup \{+\infty\}$ are proper, bounded below, lower semicontinuous functions;
- $\mathcal{H}33$. $c : \mathcal{X} \times \mathcal{Y} \mapsto \mathbb{R}^+ \cup \{+\infty\}$ is a proper, lower semicontinuous function;
- $\mathcal{H}34$. $h : \mathcal{X} \times \mathcal{X} \mapsto \mathbb{R}^+$ and $k : \mathcal{Y} \times \mathcal{Y} \mapsto \mathbb{R}^+$ are continuous functions satisfying $h(\xi,\xi) = k(\eta,\eta) = 0$ and $h(x,\xi) \geq d_{\mathcal{X}}(x,\xi)$, $k(y,\eta) \geq d_{\mathcal{Y}}(y,\eta)\, \forall\, (x,\xi,y,\eta)$ in $\mathcal{X}^2 \times \mathcal{Y}^2$;
- $\mathcal{H}35$. β_n and μ_n are monotone (i.e., nonincreasing or nondecreasing) converging sequences: $\beta_\infty = \lim_n \beta_n$, $\mu_\infty = \lim_n \mu_n$;
- $\mathcal{H}36$. α_n and ν_n are nonnegative sequences, bounded and bounded away from 0: $0 < \underline{\alpha} = \underline{\lim}\alpha_n \leq \overline{\alpha} = \overline{\lim}\alpha_n < +\infty$, $0 < \underline{\nu} = \underline{\lim}\nu_n \leq \overline{\nu} = \overline{\lim}\nu_n < +\infty$;
- $\mathcal{H}37$. ε_n is a positive sequence such that $\sum_{n=0}^{+\infty} \varepsilon_n < \infty$.

Of importance are the completeness of spaces $\mathcal{X}$ and $\mathcal{Y}$, the inequalities $h \geq d_{\mathcal{X}}$, and $k \geq d_{\mathcal{Y}}$ in $\mathcal{H}34$. We call this last condition *high local costs to move*, in contrast with a condition like $h = d_{\mathcal{X}}^2$, $k = d_{\mathcal{Y}}^2$ which expresses low local costs to move (see section 4).

3.1. Convergence of algorithm (ACA^2) to an inertial Nash equilibrium. Theorem 2.5 can very simply be used to demonstrate the convergence of the sequence (x_n, y_n) when the "local" costs to move are significant; in decision terms it means that the agents are reluctant to switch from their current state to another state because the cost to move is a deterrent even if the next state lies in a neighborhood of the current one. It may be guessed that the agents, in this evolution process, will stop somewhere in the end. The following theorem gives a precise mathematical meaning to this remark.

THEOREM 3.1. *In addition to hypotheses $\mathcal{H}31$–$\mathcal{H}37$ assume that c is separately continuous. Then any sequence generated by algorithm (ACA^2) converges to an inertial Nash equilibrium INE($\overline{\alpha}$,β_∞,μ_∞,$\overline{\nu}$), i.e.,*

$$\begin{cases} \overline{x} \in \mathit{argmin}\{f(\xi) + \overline{\alpha} h(\overline{x},\xi) + \beta_\infty c(\xi,\overline{y}) : \xi \in \mathcal{X}\}, \\ \overline{y} \in \mathit{argmin}\{g(\eta) + \mu_\infty c(\overline{x},\eta) + \overline{\nu} k(\overline{y},\eta) : \eta \in \mathcal{Y}\}. \end{cases}$$

In particular, INE($\overline{\alpha}$,β_∞,μ_∞,$\overline{\nu}$) is nonempty.

Proof. Let (x_n, y_n) be a sequence generated by algorithm (ACA^2). Using the same reasoning as in Theorem 2.5, and with the same definition for δ_n, we obtain

$$\begin{aligned} (3.1)\quad & \left[\frac{\mu_{n+1}}{\delta_{n+1}}\left(f(x_{n+1}) - \inf_{\mathcal{X}} f\right) + \frac{\beta_{n+1}}{\delta_{n+1}}\left(g(y_{n+1}) - \inf_{\mathcal{Y}} g\right) + \frac{\beta_{n+1}\mu_{n+1}}{\delta_{n+1}} c(x_{n+1}, y_{n+1})\right] \\ & + \left[\frac{\mu_n \alpha_n}{\delta_n} h(x_n, x_{n+1}) + \frac{\beta_n \nu_n}{\delta_n} k(y_n, y_{n+1})\right] \\ & \leq \left[\frac{\mu_n}{\delta_n}\left(f(x_n) - \inf_{\mathcal{X}} f\right) + \frac{\beta_n}{\delta_n}\left(g(y_n) - \inf_{\mathcal{Y}} g\right) + \frac{\beta_n \mu_n}{\delta_n} c(x_n, y_n)\right] + \left(\frac{\mu_n}{\delta_n} + \frac{\beta_n}{\delta_n}\right)\varepsilon_n. \end{aligned}$$

In view of the definition of δ_n, according to the behavior of β_n and μ_n, the sequences μ_n/δ_n and β_n/δ_n are nonincreasing; hence we have

$$\sum_{n=0}^{\infty}\left(\frac{\mu_n}{\delta_n} + \frac{\beta_n}{\delta_n}\right)\varepsilon_n \leq \left(\frac{\mu_0}{\delta_0} + \frac{\beta_0}{\delta_0}\right)\sum_{n=0}^{\infty} \varepsilon_n. < +\infty.$$

Adding the inequalities (3.1), as in the proof of Theorem 2.5, yields the convergence of the series

$$\sum_{n=0}^{\infty} \frac{\mu_n}{\delta_n}\alpha_n h(x_n, x_{n+1}) + \frac{\beta_n}{\delta_n}\nu_n k(y_n, y_{n+1}) < +\infty.$$

Let δ_∞ be the limit of sequence δ_n (it does converge). In view of $\mathcal{H}36$ there exists some $N \in \mathbb{N}$ such that

$$\frac{\mu_n}{\delta_n}\alpha_n > \frac{1}{2}\frac{\mu_\infty}{\delta_\infty}\underline{\alpha} > 0, \quad \frac{\beta_n}{\delta_n}\nu_n > \frac{1}{2}\frac{\beta_\infty}{\delta_\infty}\underline{\nu} > 0 \ \ \forall n \geq N.$$

Hence

$$\sum_{n=0}^{\infty} h(x_n, x_{n+1}) + k(y_n, y_{n+1}) < +\infty$$

and finally

$$\sum_{n=0}^{\infty} d_{\mathcal{X}}(x_n, x_{n+1}) + d_{\mathcal{Y}}(y_n, y_{n+1}) < +\infty.$$

The sequences (x_n) and (y_n) are thus Cauchy sequences in the complete metric spaces $\mathcal{X}$ and $\mathcal{Y}$. Let $\overline{x}$ and $\overline{y}$ be their limits.

Recall that, by the definition of x_{n+1}, we have, for every $\xi \in \mathcal{X}$,

$$f(x_{n+1}) + \alpha_n h(x_n, x_{n+1}) + \beta_n c(x_{n+1}, y_{n+1}) \leq f(\xi) + \alpha_n h(x_n, \xi) + \beta_n c(\xi, y_n).$$

Taking the lower limit of the left-hand side yields

$$\begin{aligned}\liminf\{f(x_{n+1}) + \alpha_n h(x_n, x_{n+1}) + \beta_n c(x_{n+1}, y_n)\} \\ \geq \liminf f(x_{n+1}) + \liminf \alpha_n h(x_n, x_{n+1}) + \liminf \beta_n c(x_{n+1}, y_n) \\ \geq f(\overline{x}) + \beta_\infty c(\overline{x}, \overline{y}).\end{aligned}$$

And taking the upper limit of the right-hand side yields

$$\limsup\{f(\xi) + \alpha_n h(x_n, \xi) + \beta_n c(\xi, y_n)\} \leq f(\xi) + \overline{\alpha} h(\overline{x}, \xi) + \beta_\infty c(\xi, \overline{y}).$$

Hence

$$f(\overline{x}) + \beta_\infty c(\overline{x}, \overline{y}) \leq f(\xi) + \overline{\alpha} h(\overline{x}, \xi) + \beta_\infty c(\xi, \overline{y}).$$

Likewise we can prove

$$g(\overline{y}) + \mu_\infty c(\overline{x}, \overline{y}) \leq g(\eta) + \overline{\nu} k(\overline{y}, \eta) + \mu_\infty c(\overline{x}, \eta) \ \forall \eta \in \mathcal{Y}.$$

And that shows that $(\overline{x}, \overline{y})$ is an inertial Nash equilibrium INE($\overline{\alpha}$, β_∞, μ_∞, $\overline{\nu}$). ∎

Let us come back to the decision theory point of view. If the costs to move h and k are locally low, then we can imagine that the agents are inclined to trying to improve his lot. The inequalities $h(x, \xi) \geq d^2_{\mathcal{X}}(x, \xi)$ and $k(y, \eta) \geq d^2_{\mathcal{Y}}(y, \eta)$ may account for low costs to move; they are locally (i.e., for small distances) less stringent than $h(x, \xi) \geq d_{\mathcal{X}}(x, \xi)$ and $k(y, \eta) \geq d_{\mathcal{Y}}(y, \eta)$. Then the convergence of the series $(h(x_n, x_{n+1}))$ and $(k(y_n, y_{n+1}))$ only yields $\Sigma_{n=0}^{+\infty} d^2_{\mathcal{X}}(x_n, x_{n+1}) < +\infty$ and $\Sigma_{n=0}^{+\infty} d^2_{\mathcal{Y}}(y_n, y_{n+1}) < +\infty$ which is not enough to guarantee the convergence of the sequence (x_n, y_n). A parallel may be drawn with the friction phenomenon in mechanics: dry friction, with a potential proportional to the modulus of the velocity, usually leads a system to rest within a finite time interval, while viscous friction, with a potential proportional to the square of the velocity modulus, usually leads to rest only asymptotically and may even fail to reach an equilibrium state (see [2, 8]).

3.2. Links with proximal algorithms. For (x_0, y_0) given in $\mathcal{X} \times \mathcal{Y}$, consider the following algorithm:

$$(3.2)\qquad (x_{n+1}, y_{n+1}) \in \operatorname{argmin}\{\ \mu_n f(\xi) + \beta_n g(\eta) + \mu_n\beta_n c(\xi,\eta) + \mu_n\alpha_n h(x_n,\xi) + \beta_n\nu_n k(y_n,\eta),\ (\xi,\eta) \in \mathcal{X}\times\mathcal{Y}\}.$$

It is not difficult to realize that its alternating version is exactly algorithm (CA^2):

- first fix $\eta = y_n$ and minimize with respect to ξ, which yields some x_{n+1} satisfying

$$x_{n+1} = \operatorname{argmin}\{f(\xi) + \alpha_n h(x_n,\xi) + \beta_n c(\xi, y_n),\ \xi \in \mathcal{X}\},$$

- then fix $\xi = x_{n+1}$ and minimize with respect to η, which yields some y_{n+1} satisfying

$$y_{n+1} = \operatorname{argmin}\{g(\eta) + \mu_n c(x_{n+1},\eta) + \nu_n k(y_n,\eta),\ \eta \in \mathcal{Y}\}.$$

Now algorithm (3.2) may be termed a proximal algorithm. Indeed, at each step the sum of the function $(\xi,\eta) \mapsto \mu_n f(\xi) + \beta_n g(\eta) + \mu_n\beta_n c(\xi,\eta)$ and of a perturbation term around (x_n, y_n), namely $\mu_n\alpha_n h(x_n,\xi) + \beta_n\nu_n k(y_n,\eta)$, is to be minimized. Besides, if $\beta_n \equiv \mu_n \equiv \beta$, and if $h = d_{\mathcal{X}}$ (or $d^2_{\mathcal{X}}$) and $k = d_{\mathcal{Y}}$ (or $d^2_{\mathcal{Y}}$), then algorithm (3.2) is exactly the classical proximal algorithm applied to the function $(x,y) \mapsto f(x) + g(y) + \beta c(x,y)$.

Thus algorithm (CA^2) appears as the alternating version of a proximal-like algorithm applied to $\mu_n f + \beta_n g + \beta_n\mu_n c$ with h and k acting as distances on $\mathcal{X}$ and $\mathcal{Y}$.

4. Low local costs to move: The convex case with quadratic costs. In this section we assume the following:

- $\mathcal{H}41$. $\mathcal{X}$ and $\mathcal{Y}$ coincide with the same Hilbert space $\mathcal{H} = \mathcal{X} = \mathcal{Y}$, endowed with the inner product $\langle x, y\rangle$ and the norm $\| x \| = \langle x, x\rangle^{\frac{1}{2}}$;
- $\mathcal{H}42$. functions $f, g : \mathcal{H} \mapsto \mathbb{R} \cup \{+\infty\}$ are convex, lower semicontinuous and proper, with $\inf_{\mathcal{H}} f > -\infty$, $\inf_{\mathcal{H}} g > -\infty$;
- $\mathcal{H}43$. costs to change and dissimilarity costs are quadratic: $h(\xi,\eta) = k(\xi,\eta) = c(\xi,\eta) = c(\xi,\eta) = \frac{1}{2} \| \xi - \eta \|^2\ \forall (\xi,\eta) \in \mathcal{H}^2$;
- $\mathcal{H}44$. $\alpha_n \geq 0$, $\nu_n \geq 0$;
- $\mathcal{H}45$. β_n and μ_n are constant and positive: $\beta_n \equiv \beta > 0$, $\mu_n \equiv \mu > 0$;
- $\mathcal{H}46$. the set of inertial Nash equilibria is nonvoid; namely there exists some $(x,y) \in \mathcal{H}^2$ that is an INE(0,β,μ,0), i.e.,

$$\begin{cases} x \in \operatorname{argmin}\{f(\xi) + \dfrac{\beta}{2} \| \xi - y \|^2 \colon \xi \in \mathcal{H}\}, \\ y \in \operatorname{argmin}\{g(\eta) + \dfrac{\mu}{2} \| \eta - x \|^2 \colon \eta \in \mathcal{H}\}; \end{cases}$$

- $\mathcal{H}47$. $\sum_{n=0}^{+\infty} (\alpha_{n+1} - \alpha_n)^+ < +\infty$, $\sum_{n=0}^{+\infty} (\nu_{n+1} - \nu_n)^+ < +\infty$, and consequently the sequences α_n, ν_n are convergent: $\alpha_n \to \alpha$, $\nu_n \to \nu$.

The quadratic cost hypothesis $\mathcal{H}43$ means that the sequence (x_n, y_n) is generated, and uniquely defined indeed, by the following algorithm:

$$(\mathrm{CA}^2)\quad \begin{cases} x_{n+1} = \operatorname{argmin}\{f(\xi) + \dfrac{\alpha_n}{2} \| \xi - x_n \|^2 + \dfrac{\beta}{2} \| \xi - y_n \|^2 \colon \xi \in \mathcal{H}\}, \\ y_{n+1} = \operatorname{argmin}\{g(\eta) + \dfrac{\mu}{2} \| \eta - x_{n+1} \|^2 + \dfrac{\nu_n}{2} \| \eta - y_n \|^2 \colon \eta \in \mathcal{H}\}. \end{cases}$$

Let us define the function $L_{\beta,\mu} : (\xi,\eta) \in \mathcal{H}^2 \mapsto L_{\beta,\mu}(\xi,\eta) = \mu f(\xi) + \beta g(\eta) + \frac{1}{2}\beta\mu \parallel \xi - \eta \parallel^2$. The purpose of this section is to prove the following theorem.

THEOREM 4.1. *Assume* $\mathcal{H}41$–$\mathcal{H}47$. *Then*

(a) *the sequence* (x_n, y_n) *generated by (CA*^{2}*) weakly converges to some* $(\overline{x},\overline{y})$, *which is an inertial Nash equilibrium INE(*0,β,μ,0*);*

(b) (x_n, y_n) *is a minimizing sequence for the function* $L_{\beta,\mu}$ *and* $(\overline{x},\overline{y})$ *is a minimum point of* $L_{\beta,\mu}$*;*

(c) $x_n - y_n \to \overline{x} - \overline{y}$ *relative to the norm topology in* $\mathcal{H}$, $f(x_n) \to f(\overline{x})$, $g(y_n) \to g(\overline{y})$.

Remark. The convergence asserted in point (a) may fail to be strong; see [26, 31].

The proof of the theorem requires some preparation.

In view of the convexity of f and g, the sequence (x_n, y_n) is characterized by

$$\begin{cases} 0 \in \partial f(x_{n+1}) + \alpha_n(x_{n+1} - x_n) + \beta(x_{n+1} - y_n), \\ 0 \in \partial g(y_{n+1}) + \mu(y_{n+1} - x_{n+1}) + \nu_n(y_{n+1} - y_n), \end{cases}$$

where ∂f and ∂g are the subdifferential operators of f and g in the sense of convex analysis. If we introduce the resolvent operators $T_f^n = (I + \frac{1}{\alpha_n+\beta}\partial f)^{-1}$ and $T_g^n = (I + \frac{1}{\mu+\nu_n}\partial g)^{-1}$ we have equivalently

$$\begin{cases} x_{n+1} = T_f^n\left(\dfrac{\alpha_n x_n + \beta y_n}{\alpha_n + \beta}\right), \\ y_{n+1} = T_g^n\left(\dfrac{\mu x_{n+1} + \nu_n y_n}{\mu + \nu_n}\right). \end{cases} \tag{4.1}$$

Recall that resolvent operators are firmly nonexpansive, i.e.,

$$\langle T_f^n x - T_f^n x', x - x'\rangle \geq \parallel T_f^n x - T_f^n x' \parallel^2 \quad \forall x, x' \in \mathcal{H} \tag{4.2}$$

and likewise for T_g^n; see, e.g., [36, Proposition 1(b)].

The inertial Nash equilibrium (x, y), the existence of which is asserted by assumption $\mathcal{H}46$, is also an inertial Nash equilibrium INE(α,β,μ,ν), where α and ν are arbitrary nonnegative numbers

$$\begin{cases} x \in \operatorname{argmin}\{f(\xi) + \frac{\alpha}{2} \parallel \xi - x \parallel^2 + \frac{\beta}{2} \parallel \xi - y \parallel^2 : \xi \in \mathcal{H}\}, \\ y \in \operatorname{argmin}\{g(\eta) + \frac{\mu}{2} \parallel \eta - x \parallel^2 + \frac{\nu}{2} \parallel \eta - y \parallel^2 : \eta \in \mathcal{H}\}. \end{cases}$$

Indeed, the functions $\xi \mapsto f(\xi) + \frac{\beta}{2} \parallel \xi - y \parallel^2$ and $\xi \mapsto \frac{\alpha}{2} \parallel \xi - x \parallel^2$ are minimum at the same point x. Likewise the functions $\eta \mapsto g(\eta) + \frac{\mu}{2} \parallel \eta - x \parallel^2$ and $\eta \mapsto \frac{\nu}{2} \parallel \eta - y \parallel^2$ are minimum at the same point y.

Conversely, if (x, y) is an inertial Nash equilibrium INE(α,β,μ,ν), then it verifies

$$\begin{cases} 0 \in \partial f(x) + \alpha(x - x) + \beta(x - y), \\ 0 \in \partial g(y) + \mu(y - x) + \nu(y - y), \end{cases} \tag{4.3}$$

and these inclusions are also the optimality conditions for (x, y) to be an inertial Nash equilibrium INE(0,β,μ,0). Now, with $\alpha = \alpha_n$ and $\nu = \nu_n$ in (4.3), we see that (x, y) verifies

$$\begin{cases} x = T_f^n\left(\dfrac{\alpha_n x + \beta y}{\alpha_n + \beta}\right), \\ y = T_g^n\left(\dfrac{\mu x + \nu_n y}{\mu + \nu_n}\right). \end{cases} \tag{4.4}$$

LEMMA 4.2. *Assume $\mathcal{H}41$–$\mathcal{H}45$. The set of inertial Nash equilibria INE($0,\beta,\mu,0$) is the set of minimizers of $L_{\beta,\mu}$.*

Proof. The function $L_{\beta,\mu}$ is proper, lower semicontinuous, and convex. Its subgradient set is easily seen to verify

$$\partial L_{\beta,\mu}(\xi,\eta) = \{\mu\partial f(\xi) + \beta\mu(\xi-\eta)\} \times \{\beta\partial g(\eta) + \beta\mu(\eta-\xi)\}. \tag{4.5}$$

And notice that the conditions (4.3) for (x,y) to be an inertial Nash equilibrium are equivalent to $\partial L_{\beta,\mu}(x,y) \ni 0$. □

LEMMA 4.3. *Assume $\mathcal{H}41$–$\mathcal{H}46$. The sequence (x_n,y_n) generated by (CA^2) verifies the following inequalities:*

$$\text{(a)}\quad \| x_{n+1}-x \|^2 \le \frac{1}{\alpha_n+\beta}\{\, \alpha_n \| x_n-x \|^2 + \beta \| y_n-y \|^2 - \alpha_n \| x_{n+1}-x_n \|^2 - \beta \| y_n - x_{n+1} - y + x \|^2 \,\}.$$

$$\begin{aligned}\text{(b)}\quad \| y_{n+1}-y \|^2 \le \frac{1}{(\mu+\nu_n)(\alpha_n+\beta)}\{\, & \mu\alpha_n \| x_n-x \|^2 \\ & + (\mu\beta + \nu_n(\alpha_n+\beta)) \| y_n-y \|^2 - \mu\alpha_n \| x_{n+1}-x_n \|^2 \\ & - \nu_n(\alpha_n+\beta) \| y_{n+1}-y_n \|^2 - \mu\beta \| y_n - x_{n+1} - y + x \|^2 \\ & - \mu(\alpha_n+\beta) \| y_{n+1} - x_{n+1} - y + x \|^2 \,\}.\end{aligned}$$

$$\begin{aligned}\text{(c)}\quad & \alpha_n\mu \| x_{n+1}-x \|^2 + \beta(\mu+\nu_n) \| y_{n+1}-y \|^2 \\ & \le \alpha_n\mu \| x_n-x \|^2 + \beta(\mu+\nu_n) \| y_n-y \|^2 \\ & \quad - \alpha_n\mu \| x_{n+1}-x_n \|^2 - \beta\nu_n \| y_{n+1}-y_n \|^2 \\ & \quad - \beta\mu \| y_n - x_{n+1} - y + x \|^2 - \beta\mu \| y_{n+1} - x_{n+1} - y + x \|^2.\end{aligned}$$

Proof. The first two inequalities entail the third one; it suffices to multiply the first by $\alpha_n\mu$, the second by $\beta(\mu+\nu_n)$, and to add.

The proof of the first two inequalities relies on the firm nonexpansiveness property of the resolvent operators T_f^n and T_g^n (recall (4.2)). From (4.1) and (4.4) we deduce that

$$\| x_{n+1}-x \|^2 \le \frac{1}{\alpha_n+\beta}\{\alpha_n\langle x_{n+1}-x, x_n-x\rangle + \beta\langle x_{n+1}-x, y_n-y\rangle\},$$
$$\| y_{n+1}-y \|^2 \le \frac{1}{\nu_n+\mu}\{\mu\langle y_{n+1}-y, x_{n+1}-x\rangle + \nu_n\langle y_{n+1}-y, y_n-y\rangle\}.$$

Write each inner product as $\langle u,v\rangle = \frac{1}{2}\{\| u \|^2 + \| v \|^2 - \| v-u \|^2\}$ in the inequalities above. We then obtain

$$\begin{aligned}\| x_{n+1}-x \|^2 \le \frac{1}{\alpha_n+\beta}\Big\{ & \frac{\alpha_n}{2} \| x_{n+1}-x \|^2 + \frac{\alpha_n}{2} \| x_n-x \|^2 - \frac{\alpha_n}{2} \| x_{n+1}-x_n \|^2 \\ & + \frac{\beta}{2} \| x_{n+1}-x \|^2 + \frac{\beta}{2} \| y_n-y \|^2 - \frac{\beta}{2} \| y_n - x_{n+1} - y + x \|^2 \Big\}\end{aligned}$$

and

$$\begin{aligned}\| y_{n+1}-y \|^2 \le \frac{1}{\nu_n+\mu}\Big\{ & \frac{\mu}{2} \| x_{n+1}-x \|^2 + \frac{\mu}{2} \| y_{n+1}-y \|^2 \\ & + \frac{\nu_n}{2} \| y_{n+1}-y \|^2 + \frac{\nu_n}{2} \| y_n-y \|^2 \\ & - \frac{\mu}{2} \| y_{n+1} - x_{n+1} - y + x \|^2 - \frac{\nu_n}{2} \| y_{n+1}-y_n \|^2 \Big\}.\end{aligned}$$

Rearranging the terms we obtain

$$\| x_{n+1} - x \|^2 \leq \frac{1}{\alpha_n + \beta} \{ \alpha_n \| x_n - x \|^2 + \beta \| y_n - y \|^2 - \alpha_n \| x_{n+1} - x_n \|^2 - \beta \| y_n - x_{n+1} - y + x \|^2 \}$$

and

$$\| y_{n+1} - y \|^2 \leq \frac{1}{\nu_n + \mu} \{ \mu \| x_{n+1} - x \|^2 + \nu_n \| y_n - y \|^2 - \mu \| y_{n+1} - x_{n+1} - y + x \|^2 - \nu_n \| y_{n+1} - y_n \|^2 \}.$$

Now, in the last inequality, replace $\| x_{n+1} - x \|^2$ by its upper bound given by the last one to achieve the first two inequalities asserted by the lemma. □

PROPOSITION 4.4. *Assume $\mathcal{H}41$–$\mathcal{H}46$. The sequence (x_n, y_n) generated by (CA^2) is bounded.*

Proof. As a straightforward consequence of Lemma 4.3 we have

$$\begin{aligned} \| x_{n+1} - x \|^2 &\leq \frac{1}{\alpha_n + \beta} \{ \alpha_n \| x_n - x \|^2 + \beta \| y_n - y \|^2 \} \\ &\leq \max \left(\| x_n - x \|^2, \| y_n - y \|^2 \right), \\ \| y_{n+1} - y \|^2 &\leq \frac{1}{(\mu + \nu_n)(\alpha_n + \beta)} \{ \mu\alpha_n \| x_n - x \|^2 + (\mu\beta + \nu_n(\alpha_n + \beta)) \| y_n - y \|^2 \} \\ &\leq \max \left(\| x_n - x \|^2, \| y_n - y \|^2 \right). \end{aligned}$$

Hence $\max \left(\| x_{n+1} - x \|^2, \| y_{n+1} - y \|^2 \right) \leq \max \left(\| x_n - x \|^2, \| y_n - y \|^2 \right)$. This shows that the sequence (x_n, y_n) is bounded. □

We cannot dispense with assumption $\mathcal{H}47$ now. Note that it is fulfilled if the sequences α_n and ν_n are nonnegative (i.e., $\mathcal{H}44$) and monotonically convergent.

PROPOSITION 4.5. *Assume $\mathcal{H}41$–$\mathcal{H}47$. Then, for any (x, y) inertial Nash equilibrium INE(0,β,μ,0), the sequence (x_n, y_n) generated by (CA^2) satisfies*

(i) $y_n - x_n \to y - x$, $x_{n+1} - x_n \to 0$, $y_{n+1} - y_n \to 0$ *relative to the norm topology in $\mathcal{H}$;*

(ii) $\| x_{n+1} - x \|$ *and* $\| y_{n+1} - y \|$ *have a limit as $n \to +\infty$.*

Proof. Let us adopt some notations:

$$\begin{aligned} A_n &= \alpha_n\mu \| x_n - x \|^2 + \beta(\mu + \nu_n) \| y_n - y \|^2, \\ B_n &= \alpha_n\mu \| x_{n+1} - x_n \|^2 + \beta\nu_n \| y_{n+1} - y_n \|^2 \\ &\quad + \beta\mu \| y_n - x_{n+1} - y + x \|^2 + \beta\mu \| y_{n+1} - x_{n+1} - y + x \|^2 . \end{aligned}$$

So, inequality (c) in Lemma 4.3 reads

$$B_n \leq A_n - \{\alpha_n\mu \| x_{n+1} - x \|^2 + \beta(\mu + \nu_n) \| y_{n+1} - y \|^2\}.$$

Whence we easily derive

$$\begin{aligned} B_n &\leq A_n - A_{n+1} + \mu(\alpha_{n+1} - \alpha_n) \| x_{n+1} - x \|^2 + \beta(\nu_{n+1} - \nu_n) \| y_{n+1} - y \|^2 \\ &\leq A_n - A_{n+1} + [\mu(\alpha_{n+1} - \alpha_n)^+ + \beta(\nu_{n+1} - \nu_n)^+]M, \end{aligned}$$

where M denotes an upper bound for $\| x_{n+1} - x \|^2$ and $\| y_{n+1} - y \|^2$; M is finite in view of proposition 4.4. Define $C_n = [\mu(\alpha_n - \alpha_{n-1})^+ + \beta(\nu_n - \nu_{n-1})^+]M$, and observe

that the series $\sum_{n=1}^{+\infty} C_n$ is convergent owing to assumption $\mathcal{H}47$. The last inequality may be written

$$0 \;\leq\; B_n \;\leq\; \left(A_n - \sum_{k=1}^{n} C_k\right) - \left(A_{n+1} - \sum_{k=1}^{n+1} C_k\right).$$

Hence the sequence $n \mapsto A_n - \sum_{k=1}^{n} C_k$ is decreasing; as it is bounded below by $-\sum_{n=0}^{+\infty} C_n$, it converges. As a consequence A_n converges, too.

Now the inequality above shows that the series $\sum_{k=0}^{+\infty} B_k$ converges, and hence B_n tends to zero as $n \to +\infty$.

Since B_n vanishes as $n \to +\infty$, in particular, $\| y_n - x_{n+1} - y + x \|$ and $\| y_{n+1} - x_{n+1} - y + x \|$ tend to zero. Hence $y_n - x_n - y + x \to 0$, $y_{n+1} - y_n = (y_{n+1} - x_{n+1}) - (y_n - x_{n+1}) \to 0$, $x_{n+1} - x_n = (y_n - x_n) - (y_n - x_{n+1}) \to 0$, which proves point (i).

Further, writing $x_n - x = (y_n - y) - (y_n - x_n - y + x)$ in the expression of A_n yields

$$\begin{aligned} A_n = (\alpha_n\mu + \beta(\mu + \nu_n)) \,\| y_n - y \|^2 \, &- 2\alpha_n\mu\langle y_n - y, y_n - x_n - y + x\rangle \\ &+ \alpha_n\mu \,\| y_n - x_n - y + x \|^2 . \end{aligned}$$

The last two terms vanish as $n \to +\infty$, while $(\alpha_n\mu + \beta(\mu + \nu_n))$ tends to a positive limit. Hence $\| y_n - y \|$ admits a limit as $n \to +\infty$. In view of $x_n - x = (y_n - y) - (y_n - x_n - y + x)$, $\| x_n - x \|$ admits a limit, too. □

Before proceeding to the proof of Theorem 4.1, let us recall a classical argument used to prove the weak convergence of a sequence in a Hilbert space.

LEMMA 4.6 (see Opial [34]). *Let z_n be a sequence in a Hilbert space $\mathcal{H}$ such that there exists a nonvoid set $S \subset \mathcal{H}$ which verifies the following:*

(i) *any weak limit point of z_n belongs to S;*

(ii) $\forall \zeta \in S$, $\lim_{n\to+\infty} \| z_n - \zeta \|$ *exists.*

Then, z_n weakly converges as $n \to +\infty$ to some element of S.

Proof of Theorem 4.1. Recall that the sequences (x_n) and (y_n) are characterized by

$$\begin{cases} 0 \in \partial f(x_{n+1}) + \alpha_n(x_{n+1} - x_n) + \beta(x_{n+1} - y_n), \\ 0 \in \partial g(y_{n+1}) + \mu(y_{n+1} - x_{n+1}) + \nu_n(y_{n+1} - y_n). \end{cases}$$

(a) Let $(\bar{x}, \bar{y})$ be a weak limit point of the bounded sequence (x_n, y_n) (recall Proposition 4.4).

To simplify the notation we suppose for a while that the whole sequence converges. On the one hand $y_n - x_n$ weakly converges to $\bar{y} - \bar{x}$; on the other hand $y_n - x_n$ strongly converges to $y - x$ for any (x, y) inertial Nash equilibrium (Proposition 4.5). Hence $y_n - x_n$ strongly converges to $\bar{y} - \bar{x}$ indeed. Now x_{n+1} satisfies

$$0 \in \partial f(x_{n+1}) + \beta(x_{n+1} - y_{n+1}) + \alpha_n(x_{n+1} - x_n) + \beta(y_{n+1} - y_n).$$

From Proposition 4.5 we know that $x_{n+1} - x_n$ and $y_{n+1} - y_n$ strongly converge to 0; hence $\beta(x_{n+1} - y_{n+1}) + \alpha_n(x_{n+1} - x_n) + \beta(y_{n+1} - y_n)$ strongly converges to $\beta(\bar{x} - \bar{y})$ (α_n is bounded). Owing to the weak-strong closedness of the subgradient operator (see [18]), we have

$$0 \in \partial f(\bar{x}) + \beta(\bar{x} - \bar{y}).$$

Likewise we can prove

$$0 \in \partial g(\bar{y}) + \mu(\bar{y} - \bar{x}).$$

So far we have proved only that any weak limit point $(\overline{x}, \overline{y})$ of the sequence (x_n, y_n) is an inertial Nash equilibrium. But from Proposition 4.5 we know that $\| x_n - x \|$ and $\| y_n - y \|$ have a limit for any (x, y) which is an inertial Nash equilibrium. Opial's lemma (with $\mathcal{H} = \mathcal{X} \times \mathcal{Y}$, $z_n = (x_n, y_n)$ and S denoting the set of inertial Nash equilibrium INE(0,β,μ,0)) then shows that the whole sequence (x_n, y_n) weakly converges to an inertial Nash equilibrium.

(b) The sequence (x_n, y_n) verifies

$$\begin{cases} 0 \in \partial(\mu f)(x_{n+1} + \mu\beta(x_{n+1} - y_{n+1}) + u_n, \\ 0 \in \partial(\beta g)(y_{n+1}) + \beta\mu(y_{n+1} - x_{n+1}) + v_n, \end{cases}$$

where we have put $u_n = \mu\alpha_n(x_{n+1} - x_n) + \mu\beta(y_{n+1} - y_n)$ and $v_n = \beta\nu_n(y_{n+1} - y_n)$. In view of (4.5) this means that $(-u_n, -v_n)$ is a subgradient of $L_{\beta,\mu}$ at point (x_{n+1}, y_{n+1}). Hence, for all $(\xi, \eta) \in \mathcal{H} \times \mathcal{H}$ we have

$$L_{\beta,\mu}(\xi, \eta) \geq L_{\beta,\mu}(x_{n+1}, y_{n+1}) - \langle u_n, \xi - x_{n+1} \rangle - \langle v_n, \eta - y_{n+1} \rangle,$$

but u_n and v_n vanish relative to the norm topology of $\mathcal{H}$ as $n \to +\infty$. Let $(\overline{x}, \overline{y})$ be the weak limit of (x_n, y_n); we then have

$$L_{\beta,\mu}(\xi, \eta) \geq \overline{\lim} L_{\beta,\mu}(x_n, y_n) \geq \underline{\lim} L_{\beta,\mu}(x_n, y_n) \geq L_{\beta,\mu}(\overline{x}, \overline{y}).$$

(c) The strong convergence $y_n - x_n \to \overline{y} - \overline{x}$ has been proved in Proposition 4.5. From point (b) just above we know that $L_{\beta,\mu}(x_n, y_n) = \mu f(x_n) + \beta g(y_n) + \frac{1}{2} \| x_n - y_n \|^2 \to L_{\beta,\mu}(\overline{x}, \overline{y})$. Hence we have

$$\mu f(x_n) + \beta g(y_n) \to \mu f(\overline{x}) + \beta g(\overline{y}),\ n \to +\infty. \tag{4.6}$$

Further,

$$\begin{aligned} \limsup \mu f(x_n) &\leq \overline{\lim}(\mu f(x_n) + \beta g(y_n)) + \overline{\lim}(-\beta g(y_n)) \\ &\leq \mu f(\overline{x}) + \beta g(\overline{y}) - \underline{\lim} \beta g(y_n) \\ &\leq \mu f(\overline{x}), \end{aligned}$$

where the last inequality results from the lower semicontinuity of g. Now the lower semicontinuity of f gives $\overline{\lim} f(x_n) \leq f(\overline{x}) \leq \underline{\lim} f(x_n)$. Finally, with (4.6) we have $g(y_n) \to g(\overline{y})$. □

Remark 1. Condition $\mathcal{H}47$ is but one of various assumptions leading to Theorem 4.1. Indeed, the crux of the matter is inequality (c) of Lemma 4.3.

Let (ρ_n) be a given positive sequence bounded away from zero. Divide each member of inequality (c) in Lemma 4.3 by ρ_n. Proceeding as in the proof of Proposition 4.5, and with the same notation, we can derive

$$\frac{A_{n+1}}{\rho_{n+1}} \leq \frac{A_n}{\rho_n} + \left[\mu \left(\frac{\alpha_{n+1}}{\rho_{n+1}} - \frac{\alpha_n}{\rho_n} \right)^+ + \beta \left(\frac{\mu + \nu_{n+1}}{\rho_{n+1}} - \frac{\mu + \nu_n}{\rho_n} \right)^+ \right] M - \frac{B_n}{\rho_n}.$$

Under the assumption that the series $\sum_{n=0}^{+\infty} \left(\frac{\alpha_{n+1}}{\rho_{n+1}} - \frac{\alpha_n}{\rho_n} \right)^+$ and $\sum_{n=0}^{+\infty} \left(\frac{\mu+\nu_{n+1}}{\rho_{n+1}} - \frac{\mu+\nu_n}{\rho_n} \right)^+$ converge (and also that (α_n) and (ν_n) are bounded), Proposition 4.5 and

Theorem 4.1 can be proved. Relevant choices for ρ_n may be $\rho_n = \alpha_n$, $\rho_n = \nu_n$, $\rho_n = \alpha_n\nu_n$, or $\rho_n = \mu\alpha_n + \beta(\mu + \nu_n)$.

Remark 2. Many interesting questions asking for further developments naturally arise from Theorem 4.1.

Along the same line as in [16], one could try to obtain, by a duality argument, a variational or geometrical characterization of the limits of the sequences generated by our algorithm.

By specializing one of the two functions f or g to be the indicator function of a convex set, one obtains alternating projection-proximal methods for convex programming and variational inequalities (see [38]).

Perspectives. We expect to exploit the simplicity and robustness of such alternating algorithms and apply them to various situations: decomposition and splitting methods in partial differential equations [28, 29], image processing [13, 39], statistics, on-line decision, and so on. Further extensions may concern partial coupling, more than two players, and nonconvex setting (in the line of [5]).

TREE APPROXIMATIONS OF DYNAMIC STOCHASTIC PROGRAMS*

RADOSLAVA MIRKOV† AND GEORG CH. PFLUG†

Abstract. We consider a tree-based discretization technique utilizing conditional transportation distance, which is well suited for the approximation of multistage stochastic programming problems, and investigate corresponding convergence properties. We explain the relation between the approximation quality of the probability model and the quality of the solution.

Key words. stochastic programming, multistage, tree approximation, transportation distance, quality of solution

1. Introduction.

Dynamic stochastic optimization models are an up-to-date tool of modern management sciences and can be applied to a wide range of problems, such as financial portfolio optimization, energy contracts, insurance policies, supply chains, etc. While one-period models look for optimal decision values (or decision vectors) based on all available information now, the multiperiod models consider planned future decisions as functions of the information that will be available later. Hence, the natural decision spaces for multiperiod dynamic stochastic models, except for the first stage decisions, are spaces of functions. Consequently, only in some exceptional cases may solutions be found by analytical methods, which include investigating the necessary optimality conditions and solving a variational problem; i.e., only some functional equations have explicit solutions in observed spaces of functions. In the vast majority of cases, it is impossible to find a solution in this way, and we reach out for a numerical solution. However, numerical calculation on digital computers may never represent the underlying infinite-dimensional function spaces. The way out of this dilemma is to approximate the original problem by a simpler, surrogate finite-dimensional problem, which enables the calculation of the numerical solution.

As the optimal decision at each stage is a function of the random components observed so far, the only way to reduce complexity is to reduce the range of the random components. If the random component of the decision model is discrete (i.e., takes a finite and in fact only a few number of values), the variational problem is reduced to a vector optimization problem, which may be solved by well-known vector optimization algorithms. The natural question that arises is how to reconstruct a solution of the basic problem out of the solution of the finite surrogate problem.

Since every finite-valued stochastic process $\tilde{\xi}_1, \ldots, \tilde{\xi}_T$ is representable as a tree, we deal with tree approximations of stochastic processes. There are two contradicting goals to be considered. For the sake of the quality of approximation, the tree should be large and bushy, while for the sake of computational solution effort, it should be small. Thus the choice of the tree size is obtained through a compromise. The basic question in reaching this compromise is the assessment of the quality of the

†Department of Statistics and Decision Support Systems, University of Vienna, Universitätsstraße 5/3, 1010 Vienna, Austria (radoslava.mirkov@univie.ac.at, georg.pflug@univie.ac.at).

approximation in terms of the tree size. It is the purpose of this paper to shed some light on the relation between the approximation quality of the probability model for the random components and the quality of the solution.

Well-known limiting results are available, which show that by increasing the size of the approximating tree, one eventually gets convergence of the optimal values and the optimizing functions. Results in this direction were proved in [13], [14], etc. Recently, in [9] a stability result has been shown, and an estimate of the approximation error in terms of some distance between the continuous and the discrete models has been given.

Our approach is quite different. We start from the description of the decision model in terms of the system's dynamics functions, the constraint sets, and the objective function. We formulate the whole problem in terms of distributions, as the results are independent from the choice of the probability space. Then we approximate these distributions in an appropriate setting by simpler, discrete distributions and compare the decision functions and the optimal values in both cases.

In our distributional setup, there is no predefined probability space, and therefore there is no room for introducing filtrations other than those which are generated by the random process itself. Thus, we make the following assumption, which is common in stochastic optimization.

Assumption 1. No information other than the values of the scenario process ξ_s, $s \leq t$, is available to the decision maker at time t for $t = 1, \ldots, T$. To put it differently, we assume that the decision x_t is measurable w.r.t. σ-algebra $\mathcal{F}_t$, which is the one generated by $(\xi_1, \ldots, \xi_t)$.

Adopting this approach, there is no need to consider a filtration distance as done in [9].

A further consequence of the in-distribution setting is that we describe the decisions as functions of the random observations and not as functions defined on some probability space. To be more precise, let $\xi^t = (\xi_1, \ldots, \xi_t)$, $t = 1, \ldots, T$, denote the history of the random observations available up to time t. Then the tth decision is a function $\xi^t \mapsto x_t(\xi^t)$ lying in some function space. Noticing that we want to approximate a continuous probability distribution by a discrete one, we note that this function space should respect weak convergence; i.e., if $\xi^{(n)} \to \xi$ weakly, then also $x(\xi^{(n)}) \to x(\xi)$ weakly. Thus we must consider spaces of continuous functions or some subspaces. In this paper, we work with the space of Lipschitz functions. The class of all Lipschitz functions on $\mathbb{R}^n$ determines the weak topology on all probabilities, which have the finite first moment. Moreover, the weakest topology making all integrals of Lipschitz functions continuous is generated by the well-known transportation distance, which is convenient since it can be calculated or at least bounded in many examples.

A result of practical relevance to the decision maker will be shown under some strong regularity assumptions: Suppose that the distance between the original probability model and the approximate one is smaller than ε and that a δ_0-solution of the approximate problem is found. Then one may construct out of it a δ-optimal solution of the original problem. The relation between δ_0, δ, and ε is explicit (see Proposition 4.4). We measure the distance between the original probability model and its discrete approximation by the *conditional transportation distance*, which is finer than the usual *unconditional transportation distance* and accommodates the dynamic character of the problem.

The paper is organized as follows. In section 2 we describe the distance concepts for probability measures and for constraint sets. Section 3 contains the model, and in

section 4 we state the approximation results. Two examples are treated in section 5. In the appendix we have collected some auxiliary results.

2. Preliminaries.

2.1. The probability model. Let $\xi = (\xi_1, \dots, \xi_T)$ be a stochastic process with values in $\Xi \subset \mathbb{R}^{nT}$, and $u = (u_1, \dots, u_T)$ its realization, with $u_t = (u_{t(1)}, \dots, u_{t(n)})$, for each t. Ξ is endowed with the metric

$$d(u_t, v_t) = \sum_{i=1}^{n} |\chi(u_{t(i)}) - \chi(v_{t(i)})|,$$

where χ is a strictly monotonic mapping $\mathbb{R}$ into $\mathbb{R}$. (Ξ, d) is a complete separable metric space such that $\Xi = \Xi_1 \times \cdots \times \Xi_T$, and $\Xi_t \subset \mathbb{R}^n$, for each t. All metrics in all metric spaces appearing in this paper will be denoted by the same symbol d, since there is no danger of confusion. u^t, $t = 1, \dots, T-1$, denotes the history up to time t, i.e., $u^t = (u_1, \dots, u_t)$. Obviously, u^t is an element of the metric space $\Xi^t = \Xi_1 \times \cdots \times \Xi_t \subset \mathbb{R}^{nt}$, which is endowed with the metric

$$d(u^t, v^t) = \sum_{s=1}^{t} d(u_s, v_s).$$

For two Borel measures P, $\tilde{P}$ on a metric space Ξ, we recall that the transportation (Wasserstein) distance d_W between P and $\tilde{P}$ is given by

$$d_W(P, \tilde{P}) = \sup_{f \in Lip_1} \left(\int f(u)\, dP(u) - \int f(u)\, d\tilde{P}(u) \right),$$

where $u \in \Xi$, and Lip_1 is the set of all 1-Lipschitz functions f, i.e.,

$$|f(u) - f(v)| \le d(u, v) \quad \text{for all} \quad u, v \in \Xi.$$

The Wasserstein distance is related to the Monge mass transportation problem (see [20, p. 89]) through the following facts.

- Theorem of Kantorovich and Rubinstein:

  $$\begin{aligned} d_W(P, \tilde{P}) \quad = \quad & \inf\{\mathbb{E}[|Y - \tilde{Y}|], \text{ where the joint distribution } (Y, \tilde{Y}) \\ & \text{is arbitrary, but the marginal distributions are fixed} \\ & \text{such that } Y \sim P;\ \tilde{Y} \sim \tilde{P}\}. \end{aligned}$$

  The infimum here is attained. The optimal joint distribution $(Y, \tilde{Y})$ describes how the mass P should be transported with minimal effort to yield the new mass $\tilde{P}$ (see [20, Theorems 5.3.2 and 6.1.1]).
- For one-dimensional distributions, i.e., distributions on the real line endowed with the Euclidean metric $d(u, v) = |u - v|$, having distribution functions G, resp., $\tilde{G}$, it holds that

  $$d_W(P, \tilde{P}) = \int_{\Omega} |G(u) - \tilde{G}(u)|\, du = \int_0^1 |G^{-1}(u) - \tilde{G}^{-1}(u)|\, du,$$

  where $G^{-1}(u) = \sup\{v : G(v) \le u\}$ (see [25]).

- If χ is a strictly monotonic function mapping $\mathbb{R}$ into $\mathbb{R}$, defining the distance $d(u,v) = |\chi(u) - \chi(v)|$, the pertaining transportation distance is

$$d_W(P, \tilde{P}) = d_W(G \circ \chi^{-1}, \tilde{G} \circ \chi^{-1}) = \int_0^1 |\chi(G^{-1}(u)) - \chi(\tilde{G}^{-1}(u))|\, du.$$

  By an appropriate choice of χ, the convergence of higher moments under d_W-convergence may be ensured (see [16]).

If random variables $Y, \tilde{Y}$ have fixed marginal distributions $P, \tilde{P}$, it makes sense to write

$$d_W(P, \tilde{P}) = d_W(Y, \tilde{Y}) = d_W(G, \tilde{G}), \tag{2.1}$$

as marginal distributions are on par with the specifying random variables, and their distribution functions $G, \tilde{G}$, if they exist (see [27]).

The process ξ generates a Borel probability measure P on Ξ. This measure is characterized by its chain of regular conditional distributions:

$$\begin{aligned} &P(A_1 \times \cdots \times A_T) \\ &= \int_{A_1} \cdots \int_{A_T} P_T(du_T|u^{T-1}) \cdots P_3(du_3|u^2) P_2(du_2|u_1) P_1(du_1) \\ &= \int_{A_1} \cdots \int_{A_T} P_T(du_T|(u_1, \ldots, u_{T-1})) \cdots P_3(du_3|(u_1, u_2)) P_2(du_2|u_1) P_1(du_1). \end{aligned}$$

Here $P_t(A_t|u^{t-1})$ is the conditional probability of $\xi_t \in A_t$ given the past $\xi^{t-1} = u^{t-1}$, $t = 2, \ldots, T$, and P_1 is the probability of $\xi_1 \in A_1$ (not conditional). Since we deal with complete separable metric spaces, the existence of regular conditional probabilities is ensured (see, e.g., [6, Chapter 4, Theorem 1.6]).

The following assumption is imposed on the measure P.

Assumption 2. The conditional probabilities satisfy the Lipschitz condition, i.e.,

$$d_W(P_t(\cdot|u), P_t(\cdot|v)) \le K_t\, d(u,v)$$

for all $u, v \in \Xi^{t-1}$, and some constants K_t, for $t = 2, \ldots, T$.

Remark. Assumption 2 is trivially satisfied if the process is independent. For Markov processes, the condition in Assumption 2 reduces to

$$d_W(P_t(\cdot|u_{t-1}), P_t(\cdot|v_{t-1})) \le K_t\, d(u_{t-1}, v_{t-1}).$$

The ratio

$$\sup_{u,v} \frac{d_W(P(\cdot|u), P(\cdot|v))}{d(u,v)}$$

is called the *ergodic coefficient* of the Markov transition P. If this coefficient is smaller than one, geometric ergodicity holds. Ergodic coefficients were introduced in [4] and extensively applied to stochastic programming problems (see [15]).

Example (Lipschitz condition for multivariate normal distribution). Assume that the process ξ follows the multivariate normal distribution on $\mathbb{R}^T$ equipped with the usual Euclidean metric with mean vector $\mu = \mu^T$ and nonsingular covariance matrix

$\Sigma = \Sigma^T$, where $\mu^t = (\mu_1, \dots, \mu_t)^\top$, and $\Sigma^t = (\sigma_{i,j})$, $i = 1, \dots, t$, $j = 1, \dots, t$, for $t = 1, \dots, T$, are the main submatrices. It holds that

$$\Sigma^t = \begin{bmatrix} \Sigma^{t-1} & \sigma^t \\ (\sigma^t)^\top & \sigma_{t,t} \end{bmatrix}_{t \times t}.$$

Here σ^t, resp., $(\sigma^t)^\top$, denote the tth column, resp., row vector, of the covariance matrix Σ^t of the length $t-1$. According to [11, Theorem 13.1], the conditional distribution of ξ^t given the past realization u^{t-1} is normal with mean $\mu^t + (\sigma^t)^\top (\Sigma^t)^{-1}(u^{t-1} - \mu^{t-1})$ and covariance $\sigma_{t,t} - (\sigma^t)^\top (\Sigma^{t-1})^{-1}\sigma^t$. The transportation distance satisfies

$$d_W(P_t(\cdot|u^{t-1}), P_t(\cdot|v^{t-1})) \le \|(\sigma^t)^\top (\Sigma^t)^{-1}\|_\infty \, d(u^{t-1}, v^{t-1})$$

for $t = 2, \dots, T$, and the constants K_t in Assumption 2 amount to $\|(\sigma^t)^\top (\Sigma^t)^{-1}\|_\infty$.

Let $\tilde{P}$ be some other probability measure that can also be dissected into the chain of conditional probabilities. We introduce the notation

$$\bar{d}_W(P, \tilde{P}) \le (\varepsilon_1, \dots, \varepsilon_T)$$

if

$$\begin{aligned} d_W(P_1, \tilde{P}_1) &\le \varepsilon_1, \\ \sup_{u_1} d_W(P_2(\cdot|u_1), \tilde{P}_2(\cdot|u_1)) &\le \varepsilon_2, \\ \sup_{u^2} d_W(P_3(\cdot|u^2), \tilde{P}_3(\cdot|u^2)) &\le \varepsilon_3, \\ &\vdots \\ \sup_{u^{T-1}} d_W(P_T(\cdot|u^{T-1}), \tilde{P}_T(\cdot|u^{T-1})) &\le \varepsilon_T. \end{aligned}$$

If $\tilde{P}$ is the distribution of a stochastic process $(\tilde{\xi}_1, \dots, \tilde{\xi}_T)$ with finite support, denote by $\tilde{\Xi}^t$ the support of $(\tilde{\xi}_1, \dots, \tilde{\xi}_t)$. The conditional probabilities $\tilde{P}_t(\cdot|u^{t-1})$ are only well defined if $u^{t-1} \in \tilde{\Xi}^{t-1}$. If $u^{t-1} \notin \tilde{\Xi}^{t-1}$, we set $d_W(P_t(\cdot|u^{t-1}), \tilde{P}_t(\cdot|u^{t-1})) = 0$, which is the same as saying that the conditional probabilities of $\tilde{P}$ are set equal to those of P, for those values, which will not be taken by $\tilde{P}$ with positive probability.

Example (convergence of tree processes). We consider the tree process as in [9] shown in Figure 2.1.

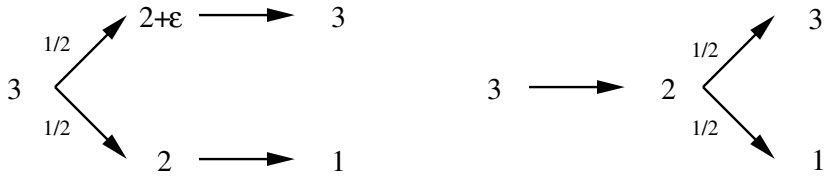

FIG. 2.1. *Tree processes and their conditional distributions.*

The processes describe the development of prices at time $t = 1, 2, 3$ used to determine an optimal purchase strategy over time under cost uncertainty by the means of multistage stochastic programming methods. The stochastic price processes as in Figure 2.1 (left) yield the probability distribution $P = (P_1, P_2, P_3)$ for $\varepsilon \in [0, 1)$, and

for $\varepsilon = 0$ we obtain the approximation $\tilde{P}$ of P (right). The filtrations of σ-fields generated by ξ and $\tilde{\xi}$ do not coincide.

Although the processes on the left obviously converge in distribution to the process on the right, as ε tends to zero, these processes are far apart in conditional transportation distance. First, the processes on the left do not satisfy the condition of Assumption 2 uniformly in ε, as

$$d_W(P_3(\cdot|(3,2)), P_3(\cdot|(3,2+\varepsilon))) = 2 = \frac{2}{\varepsilon} d(2, 2+\varepsilon).$$

Moreover, no convergence in the conditional transportation distance to the process on the right holds as ε tends to zero. A closer look at $d_W(P_t(\cdot|u^{t-1}), \tilde{P}_t(\cdot|u^{t-1}))$, $t = 1, 2, 3$, shows that

$$d_W(P_1, \tilde{P}_1) = 0,$$
$$d_W(P_2(\cdot|3), \tilde{P}_2(\cdot|3)) = \frac{\varepsilon}{2} \to 0,$$

but

$$d_W(P_3(\cdot|(3,2)), \tilde{P}_3(\cdot|(3,2))) = \frac{1}{2} d(3,1) = 1,$$
$$d_W(P_3(\cdot|(3,2+\varepsilon)), \tilde{P}_3(\cdot|(3,2+\varepsilon))) = 0,$$

and $\sup_{u^2} d_W(P_3(\cdot|u^2), \tilde{P}_3(\cdot|(u^2) = 1$; i.e., it does not tend to 0.

Associated with the process of observation ξ_t is the the process of decisions x_t, where x_t are continuous mappings from Ξ^t into $\mathbb{R}^{m_t}$. On $\mathbb{R}^m$, $m = \sum_{t=1}^T m_t$, we work with an appropriate distance d. We will assume that the optimal decisions are Lipschitz continuous. The next example shows why it is hopeless to get rid of assumptions on the smoothness of the solutions.

Example (mean absolute deviation regression). Let ξ_1 be a uniform $[0,1]$ variable and let ξ_2, conditional on ξ_1, have a normal distribution with mean $\xi_1/2$ and variance 1. Denote the distribution of (ξ_1, ξ_2) by P.

We want to solve

$$\min_{x(\xi_1)} \mathbb{E}_P(|x(\xi_1) - \xi_2|), \tag{2.2}$$

where $x(\xi_1)$ is a measurable function of ξ_1. Obviously, the solution is

$$x(u) = u/2 \tag{2.3}$$

since the normal distribution is symmetric around zero. However, consider a sequence of discrete measures $\tilde{P}^{(n)}$, converging weakly to P, and assume that these measures sit on $(\xi_{1,i}^{(n)}, \xi_{2,i}^{(n)})$ with equal probability $1/n$, such that all $\xi_{1,i}^{(n)}$ are distinct. Then the solutions of

$$\min_{x(\xi_1)} \frac{1}{n} \sum_{i=1}^n (|x(\xi_{1,i}^{(n)}) - \xi_{2,i}^{(n)}|) \tag{2.4}$$

would not converge to (2.3) in any sense.

Smoothing techniques (sieve techniques) are used in nonparametric regression for ensuring consistency. This technique would for fixed n search a solution $x(\cdot)$ in

a smooth function space and gradually but slowly increase the function space as n increases. The convergence rate depends on the degree of smoothness of the solution. To put this in terms of optimization, the approximate problem (2.4) is solved in nonparametric statistics under an additional constraint of smoothness, which is not present in the original problem (2.2). Sieve techniques were introduced by [2] and are standard in nonparametric curve estimation (see, for instance, [7]). Only in rare cases is the additional smoothness condition superfluous because of strong shape conditions [21], [3].

While in statistical applications one has to take the data as observed, one may choose the approximating model in stochastic optimization. In other words, and this is the approach we adopt here, one may choose the approximating model such that also the conditional probabilities of the approximations are close to the original ones. Let us see how this would solve the above nonparametric regression problem. Suppose we choose the points $i/(n+1)$, $i = 1, \dots, n$, each with probability $1/n$, as a good approximation of the uniform distribution in the first component. Then choose conditional on $\xi_1 = i/(n+1)$ a discrete distribution which would come close to the original normal distribution by a transportation distance not larger than ε. By doing so, also the median would not differ more than ε, and by a simple linear interpolation between the points sitting at $i/(n+1)$ and at $(i+1)/(n+1)$ we would have found the true regression line within a sup-norm distance of ε, too.

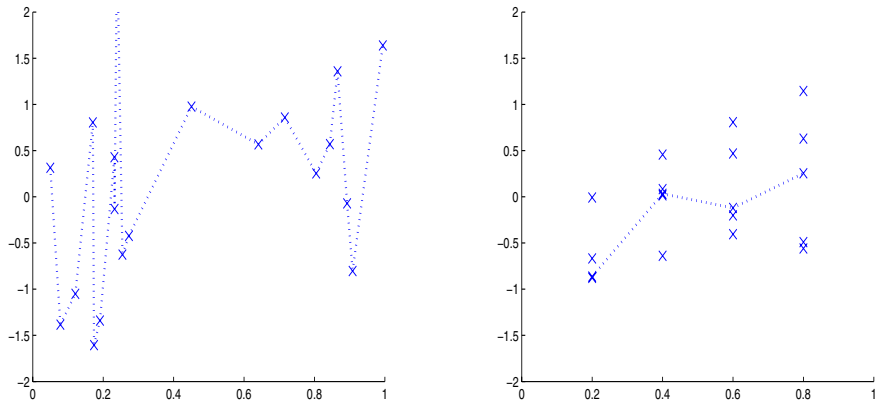

FIG. 2.2. *Discrete approximations of the distribution of* (ξ_1, ξ_2). *The distribution on the left is close in transportation distance, while the distribution on the right is in addition close in conditional transportation distance.*

For an illustration, see Figure 2.2. The left-hand side shows a sample of the two-dimensional distribution which approximates the uniform distribution on the square based on the transportation distance. On the right-hand side, we have chosen the x-coordinates as $i/5$, $i = 1, \dots, 4$, and sampled only the conditional distributions; i.e., we have a tree-structured distribution, which approximates in addition some conditional distributions. In both cases we have shown the (linearly interpolated) solution of problem (2.2) as a dotted line.

2.2. The projection distance. Let $\mathbb{B}(r) = \{x \in \mathbb{R}^m : d(0, x) \le r\}$ denote the ball with diameter $2r$ in $\mathbb{R}^m$. The projection distance $d_{P,r}$ between two closed, convex

sets $A, B \subseteq \mathbb{R}^m$ is defined as

$$d_{P,r}(A,B) = \sup_{x \in \mathbb{B}(r)} d(proj_A(x), proj_B(x)),$$

where $proj_A(x)$ denotes the convex projection of the point x onto A. We allow r to take the value ∞ and set

$$d_P(A,B) = d_{P,\infty}(A,B) = \sup_{x \in \mathbb{R}^m} d(proj_A(x), proj_B(x)).$$

The projection distance is larger than the usual Hausdorff distance, which is

$$d_H(A,B) = \max(\sup_{x \in A} d(x,B), \sup_{x \in B} d(x,A)),$$

since

$$d_H(A,B) = \sup_{x \in A \cup B} d(proj_A(x), proj_B(x)) \leq d_{P,\infty}(A,B).$$

Example (projection and Hausdorff distance). Let us show that there is no converse Lipschitz relation between d_H and $d_{P,\infty}$. Consider in $\mathbb{R}^2$ as set A the line segment connecting $[-1, \varepsilon]$ and $[1, -\varepsilon]$ and as B the line segment connecting $[-1, -\varepsilon]$ and $[1, \varepsilon]$. Here the Euclidean distance is used. A and B are closed convex sets with Hausdorff distance $d_H(A,B)$. However, choosing the point $x = (0, \varepsilon + 1/\varepsilon)$, one gets that the Hausdorff distance is smaller by an order than the projection distance, since $d_P(A,B)$ is the hypotenuse of a triangle whose one leg is $d_H(A,B)$. More precisely, $d_P(A,B) = 2$, and for $\varepsilon \in (0,1]$, $d_H(A,B) \leq 2\varepsilon$. In Figure 2.3 the corresponding distances for $\varepsilon = 1/2$ are represented by dotted lines.

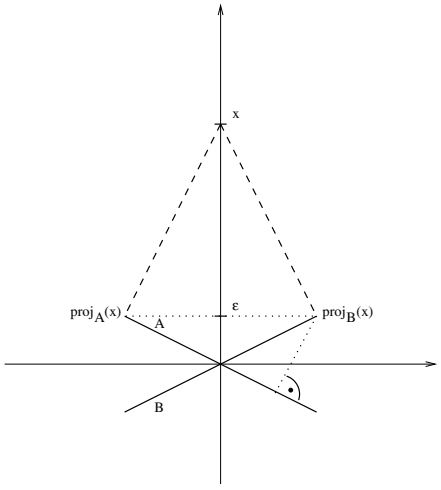

FIG. 2.3. *The Hausdorff and the projection distance.*

Example (Lipschitzian property of projection distance). Let A_1 and A_2 be the hyperplanes

$$A_i = \{x : s_i^\top x = w_i\} \subset \mathbb{R}^m, \qquad i = 1, 2.$$

Then

$$proj_{A_i}(x) = x + \frac{(w_i - s_i^\top x)s_i}{\|s_i\|^2}$$

and

$$\|proj_{A_1}(x) - proj_{A_2}(x)\|$$

$$\leq \left(|w_1| + \|s_1\|\|x\| + \frac{|w_2|}{\|s_2\|}(\|s_1\| + \|s_2\|)\right)\frac{\|s_1 - s_2\|}{\|s_1\|^2} + |w_1 - w_2|\frac{\|s_2\|}{\|s_1\|^2} + \|x\|\frac{\|s_1\| + \|s_2\|}{\|s_1\|}.$$

Suppose that s as well as w depend in a Lipschitz way on a parameter u. Then the set-valued mapping

$$u \mapsto \{x \in \mathbb{B}(r) : s(u)^\top x = w(u)\}$$

for $r < \infty$ is Lipschitz w.r.t. the projection distance $d_{P,r}$, if $\|s(u)\|$ and $|w(u)|$ are bounded, and $\|s(u)\|$ is bounded away from zero.

We utilize the projection distance in assumptions for the behavior of the constraint set.

Remark. Note that one could still use the weaker concept of the Hausdorff distance d_H, which would put the results in a more classical setting, and allow the use of already existing results (see, e.g., [23]). In that case there is no Lipschitz continuity, and at most (sub-)Hölder continuity can be obtained. If $\mathcal{X}(z)$ denotes the constraint set (for the definition of and assumptions about constraint sets see section 3), we say that d_r is sub-Hölder continuous with modulus α if, for each r, there exists a constant M_r such that

$$d_r(\mathcal{X}(z), \mathcal{X}(\bar{z})) \leq M_r[d(z, \bar{z})]^\alpha,$$

where d_r denotes the r-distance between closed, convex sets A and B, i.e.,

$$d_r(A, B) = \sup_{x \in \mathbb{B}(r)} |d(x, A) - d(x, B)|.$$

In our case we obtain sub-Hölder behavior of constraint sets with $\alpha = 1/2$ and $M_r = 2\sqrt{r}$ (see Lemma A.1). Still, Hölder property is weaker than Lipschitz and does not propagate well in multiperiod situations. For this reason we stick to the projection distance.

3. Dynamic decision models. We represent the multistage dynamic decision model as a state-space model. We assume that there is a state vector ζ_t, which describes the situation of the decision maker at time t immediately before he must make the decision x_t, for each $t = 1, \ldots, T$, and its realization is denoted by z_t. The initial state $\zeta_0 = z_0$, which precedes the deterministic decision at time 0, is known and is given by ξ_0. To assume the existence of such a state vector is no restriction at all, since we may always take the whole observed past and the decisions already made as the state:

$$\zeta_t = (x^{t-1}, \xi^t), \qquad t = 1, \ldots, T.$$

However, the vector of required necessary information for future decisions is often much shorter.

The state variable process $\zeta = (\zeta_1, \dots, \zeta_T)$, with realizations $z = (z_1, \dots, z_T)$, is a controlled stochastic process, which takes values in a metric state space $Z = Z_1 \times \cdots \times Z_T$. The control variables are the decisions x_t, $t = 1, \dots, T$. The state ζ_t at time t depends on the previous state ζ_{t-1}, the decision x_{t-1} following it, and the last observed scenario history ξ^t with realization u^t. A transition function g_t describes the state dynamics:

$$\zeta_t = g_t(\zeta_{t-1}, x_{t-1}, \xi^t), \qquad t = 1, \dots, T. \tag{3.1}$$

At the terminal stage T, no decisions are made; only the outcome $\zeta_T = z_T$ is observed.

Note that ζ_t, as a function of the random variable ξ^t, is a random variable with realization z_t, which is a function of u^t, the realization of ξ^t, for each $t = 1, \dots, T$.

The decision x of the multistage stochastic problem is a vector of continuous functions $x = (x_0, \dots, x_{T-1})$, where x_t, $t = 1, \dots, T-1$, maps Ξ^t to $\mathbb{R}^{m_t}$. We require that the feasible decision x_t at time t satisfies a constraint of the form

$$x_t \in \mathcal{X}_t(\zeta_t), \qquad t = 1, \dots, T,$$

where $\mathcal{X}_t$ are closed convex multifunctions with closed convex values. Let us now define a Ξ-feasible decision.

DEFINITION 3.1. *We say that x is a Ξ-feasible decision if the following are fulfilled:*

1. $x_0 \in \mathcal{X}_0(z_0)$;
2. $u \mapsto x_t(u)$ *is a continuous function* $\Xi^t \to \mathbb{R}^{m_t}$, $t = 1, \dots, T-1$;
3. *if, for* z_0 *given and* $(u_1, \dots, u_T) \in \Xi$, z_t *is recursively defined by*

$$z_t(u^t) = g_t(z_{t-1}(u^{t-1}), x_{t-1}(u^{t-1}), u^t), \qquad t = 1, \dots, T,$$

then

$$x_t(u^t) \in \mathcal{X}_t(z_t(u^t)), \qquad t = 1, \dots, T-1.$$

$\mathcal{X}$ denotes the set of all Ξ-feasible decisions $x = (x_0, x_1(\xi^1), \dots, x_{T-1}(\xi^{T-1}))$.

The objective to be minimized is

$$F(x, P) := \sum_{t=1}^{T} \mathbb{F}_t[\zeta_t], \tag{3.2}$$

where $\mathbb{F}_t$ are version-independent probability functionals, i.e., mappings from a space of random variables on Z_t to the real line, where the function values depend only on the distribution and not on the concrete version of the random variable. Examples for version-independent probability functionals are the expectation, the moments, the mean absolute deviation, and all typical risk functionals used in finance.

Finally, we obtain the multistage problem in the state-dynamics representation:

$$\begin{array}{ll} \text{minimize in } x & F(x, P) \\ \text{subject to} & x \in \mathcal{X}, \end{array} \tag{3.3}$$

i.e.,

$$\begin{array}{ll} \text{minimize in } x & \displaystyle\sum_{t=1}^{T} \mathbb{F}[\zeta_t] \\ \text{subject to} & x \in \mathcal{X}; \\ & \zeta_t \text{ is obtained through the recursion (3.1).} \end{array}$$

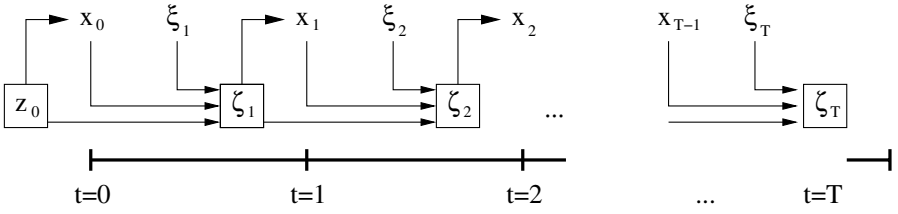

FIG. 3.1. *Multistage state-dynamics decision process.*

Its graphical representation is given in Figure 3.1.

Since the decisions x_t of the multistage problem are functions of the states ζ_t, the optimal set of decisions is expressed as a set of functions $x_t = x_t(\zeta_t)$. The problem (3.3) is a variational problem, and explicit solution methods for it exist only in exceptional cases.

Remark. The existence of continuous solutions (or better continuous selections from the arg min-sets) in our setting requires further consideration. We just mention here that such a type of result is contained in [22], where it is shown that under continuity and convexity assumptions, the existence of continuous measurable nonanticipative solutions is guaranteed if the probability measure is laminary. The property of laminarity is close to our Assumption 2 but is not implied by it. To be more precise, assume that $S_t(u^t)$ is the support of the conditional distribution of $(\xi_{t+1}, \dots, \xi_T)$ given $\xi^t = u^t$. It is not difficult to see that Assumption 2 implies that $u^t \mapsto S_t(u^t)$ is a closed-valued, lower semicontinuous multifunction. If $u^t \mapsto S_t(u^t)$ is, in addition, continuous (in the Painlevé–Kuratowski sense) for $t = 1, \dots, T$, then the distribution of ξ is laminary.

We now state a set of smoothness and dependence assumptions for the model.

Assumption 3. Let for each $t = 1, \dots, T$, and some real constants L_t, M_t, N_t, the following hold.

- The functions g_t satisfy

$$d\left(g_t(z,x,u), g_t(\bar{z},\bar{x},\bar{u})\right) \le L_t\left(d(z,\bar{z}) + d(x,\bar{x}) + d(u,\bar{u})\right)$$

  for $z, \bar{z}$ with values in Z_{t-1}, $x \in \mathcal{X}_{t-1}(z)$, $\bar{x} \in \mathcal{X}_{t-1}(\bar{z})$, $u, \bar{u} \in \Xi^t$.
- The constraints are described by closed convex sets $\mathcal{X}_t(z)$, which depend in a Lipschitz way on z, such that

$$d_{P,r}(\mathcal{X}_t(z), \mathcal{X}_t(\bar{z})) \le M_t d(z,\bar{z}),$$

  for $z, \bar{z}$ with values in Z_t, where $d_{P,r}$ denotes the projection distance between closed convex sets. Here r is finite if we know that the solutions lie in $\mathbb{B}(r)$; otherwise we set $r = \infty$.
- The version-independent probability functionals $\mathbb{F}_t$ satisfy

$$|\mathbb{F}_t(\zeta) - \mathbb{F}_t(\bar{\zeta})| \le N_t d_W(\zeta,\bar{\zeta}),$$

  where d_W is the Wasserstein distance, and $\zeta, \bar{\zeta}$ with distributions on Z_t.

In view of (2.1), we write $d_W(\zeta,\bar{\zeta})$ instead of $d_W(P,\bar{P})$ for some adequate probability measure $\bar{P}$.

Remark. The second Lipschitz condition of Assumption 3 assures that $\mathcal{X}_t(z)$ is a nonempty set, for all z with values in Z_t, for $t = 1, \dots, T$; i.e., no induced constraints are allowed.

Assumption 4. The components $\xi_t = (\xi_{t(1)}, \dots, \xi_{t(n)})$ of the random process ξ are conditionally independent given the past ξ^{t-1}.

This assumption is not as strong as it sounds. In the dynamics

$$\zeta_t = g_t(\zeta_{t-1}, x_{t-1}, \xi^{t-1}, \xi_{t(1)}, \dots, \xi_{t(n)}),$$

we may assume that the risk factors $(\xi_{t(1)}, \dots, \xi_{t(n)})$ are conditionally independent given the past ξ^{t-1}; otherwise we transform the originally dependent components into conditionally independent ones and reformulate the transition function g_t accordingly.

4. Approximations. Instead of the original problem (3.3) we consider a tree process $(\tilde{\xi}_1, \dots, \tilde{\xi}_T)$ with distribution $\tilde{P}$ and support $\tilde{\Xi}$. The decision based on the approximation is $\tilde{\Xi}$-feasible. We assume that $\tilde{\Xi} \subset \Xi$.

DEFINITION 4.1. *We say that x is a $\tilde{\Xi}$-feasible decision if the following are fulfilled:*

1. $x_0 \in \tilde{\mathcal{X}}_0(\tilde{z}_0)$;
2. $\tilde{u} \mapsto x_t(\tilde{u})$ *is a continuous function* $\tilde{\Xi}^t \to \mathbb{R}^{m_t}$, $t = 1, \dots, T-1$;
3. *if, for* $\tilde{z}_0$ *given and* $(\tilde{u}_1, \dots, \tilde{u}_T) \in \tilde{\Xi}$, $\tilde{z}_t$ *is recursively defined by*

$$\tilde{z}_t(\tilde{u}^t) = g_t(\tilde{z}_{t-1}(\tilde{u}^{t-1}), x_{t-1}(\tilde{u}^{t-1}), \tilde{u}^t), \qquad t = 1, \dots, T,$$

then

$$x_t(\tilde{u}^t) \in \tilde{\mathcal{X}}_t(\tilde{z}_t(\tilde{u}^t)), \qquad t = 1, \dots, T-1.$$

$\tilde{\mathcal{X}}$ *denotes the set of all* $\tilde{\Xi}$*-feasible decisions* $x = (x_0, x_1(\tilde{\xi}^1), \dots, x_{T-1}(\tilde{\xi}^{T-1}))$.

This yields the approximate problem

$$\begin{array}{ll} \text{minimize in } x & F(x, \tilde{P}) \\ \text{subject to} & x \in \tilde{\mathcal{X}}, \end{array} \tag{4.1}$$

i.e.,

$$\begin{array}{ll} \text{minimize in } x & \displaystyle\sum_{t=1}^{T} \mathbb{F}[\tilde{\zeta}_t] \\ \text{subject to} & x \in \tilde{\mathcal{X}}; \\ & \tilde{\zeta}_t \text{ is obtained through the recursion (3.1).} \end{array}$$

Remark. We do not propose the use of any random sampling technique to construct the tree but rather to control the transportation distance between the conditional distributions of the original problem and of the approximating tree. In particular, the first approximation is obtained by making $d_W(P_1, \tilde{P}_1)$ small. This amounts to finding a good solution of a facility location problem (see [10]). Suppose that n_1 points $u_{1(1)}, \dots, u_{1(n_1)}$ on the first stage have been selected. Then we choose the conditional probabilities $\tilde{P}(\cdot|u_{i(j)})$ such that they are close to $P(\cdot|u_{i(j)})$, $j = 1, \dots, n_1$, again in transportation distance. This procedure is then repeated through all stages.

The next two propositions tell us how to arrive from a solution of the original problem to a solution of the approximate problem, and vice versa. We assume that both problems have Lipschitz solutions. In section 5, we give examples, which show that the Lipschitz property of the solution is quite natural in problems from finance and supply chain management. In the inventory control problem the solution is Lipschitz continuous if the dependence between the under-/overshooting quantity and costs is linear, which is typically fulfilled.

PROPOSITION 4.2 (restriction). *Suppose that Assumption* 3 *holds, and*

$$\bar{d}_W(P, \tilde{P}) \le (\varepsilon_1, \dots, \varepsilon_T),$$

where P is supported by Ξ, and $\tilde{P}$ is supported by the finite set $\tilde{\Xi}$. Then every Ξ-feasible decision x, which is Q-Lipschitz, is also $\tilde{\Xi}$-feasible, and we have that

$$|F(x, P) - F(x, \tilde{P})| \le \delta_1, \tag{4.2}$$

with

$$\delta_1 = \sum_{s=1}^{T} \bar{\varepsilon}_s \sum_{t=s}^{T} N_t D_{t,s},$$

where

$$\bar{\varepsilon}_s = \sum_{i=1}^{s} \varepsilon_i \prod_{j=i+1}^{s} K_j, \tag{4.3}$$

and, for $Q = (Q_0, \dots, Q_{T-1})$, the constants $D_{s,t}$ fulfill the recursion

$$\begin{aligned} D_{t,t} &= L_t, \\ D_{t,s} &= L_t D_{t-1,s} + Q_{t-1}, \qquad s = 1, \dots, t-1. \end{aligned} \tag{4.4}$$

Proof. It is evident that every Ξ-feasible decision is automatically $\tilde{\Xi}$-feasible.

Under Assumption 2, one may construct for every t stochastic processes $\xi_t(u)$, $u \in \Xi^{t-1}$, and $\tilde{\xi}_t(u)$, $u \in \tilde{\Xi}^{t-1}$, sitting for every t on independent (product) probability spaces such that

(i) $\xi_t(u)$ has distribution $P_t(\cdot|u)$;

(ii) for all $u, v \in \Xi^{t-1}$,

$$\mathbb{E}[d(\xi_t(u), \xi_t(v))] = d_W(P_t(\cdot|u), P_t(\cdot|v)) \le K_t\, d(u, v);$$

(iii) if $u \in \tilde{\Xi}^{t-1}$, then

$$\mathbb{E}[d(\xi_t(u), \tilde{\xi}_t(u))] = d_W(P_t(\cdot|u), \tilde{P}_t(\cdot|u)) \le \varepsilon_t.$$

The construction of the processes is based on the following. Since the components $\xi_t = (\xi_{t,1}, \dots, \xi_{t,n})$ of the process ξ are conditionally independent (Assumption 4), their conditional distribution functions at $(y_1, \dots, y_n)$ given $u^{t-1} = u$ can be written as $G_{t,u,1}(y_1), \dots, G_{t,u,n}(y_n)$. Then $\xi_t(u)$ is defined as

$$\xi_t(u) = (G^{-1}_{t,u,1}(U_1), \dots, G^{-1}_{t,u,n}(U_n)),$$

where $U_1, \dots, U_n$ are independent and identically distributed Uniform$[0, 1]$. By this construction, (i) and (ii) are fulfilled. As to (iii), recall the theorem of Kantorovich and Rubinstein, and notice that the infimum is attained. This joint "minimal" distribution can be glued to the distribution $P_t(\cdot|u)$ to entail (iii) (see [26, Lemma 7.6]).

The processes ξ_t and $\tilde{\xi}_t$ then appear as compositions $\xi_t(\xi_{t-1}(\cdots(\xi_1)\cdots))$, resp., $\tilde{\xi}_t(\tilde{\xi}_{t-1}(\cdots(\tilde{\xi}_1)\cdots))$. We show that $\mathbb{E}[d(\xi_t, \tilde{\xi}_t)] \le \bar{\varepsilon}_t$. Obviously, $\mathbb{E}[d(\xi_1, \tilde{\xi}_1)] \le \varepsilon_1$. Suppose that it is already shown that $\mathbb{E}[d(\xi_{t-1}, \tilde{\xi}_{t-1})] \le \bar{\varepsilon}_{t-1}$. Then

$$\begin{aligned} \bar{\varepsilon}_t &= \mathbb{E}[d(\xi_t(\xi_{t-1}), \tilde{\xi}_t(\tilde{\xi}_{t-1}))] \\ &\le \mathbb{E}[d(\xi_t(\xi_{t-1}), \xi_t(\tilde{\xi}_{t-1}))] + \mathbb{E}[d(\xi_t(\tilde{\xi}_{t-1}), \tilde{\xi}_t(\tilde{\xi}_{t-1}))] \\ &\le K_t \bar{\varepsilon}_{t-1} + \varepsilon_t, \end{aligned}$$

leading to (4.3).

Now we argue pointwise for a specific ω in the standard probability space $[0,1]^{\mathbb{N}}$ with Lebesgue measure, which we have constructed. All of the following calculations are done for this specific ω. We use the fact that a pointwise argument implies a distributional result.

Setting $d(\xi_t, \tilde{\xi}_t) = d_t$ and $d(\xi^t, \tilde{\xi}^t) = d^t = \sum_{s=1}^t d_s$,

$$d(\zeta_1, \tilde{\zeta}_1) = d(g_1(z_0, x_0, \xi_1), g_1(z_0, x_0, \tilde{\xi}_1)) \le L_1 d^1$$

implies $D_{1,1} = L_1$. Suppose that

$$d(\zeta_{t-1}, \tilde{\zeta}_{t-1}) \le \sum_{s=1}^{t-1} D_{t-1,s} d_s.$$

Then

$$\begin{aligned} d(\zeta_t, \tilde{\zeta}_t) &= d(g_t(\zeta_{t-1}, x_{t-1}(\xi^{t-1}), \xi^t), g_t(\tilde{\zeta}_{t-1}, x_{t-1}(\tilde{\xi}^{t-1}), \tilde{\xi}^t)) \\ &\le L_t \left(\sum_{s=1}^{t-1} D_{t-1,s} d_s + Q_{t-1} \sum_{s=1}^{t-1} d_s + \sum_{s=1}^{t} d_s \right) \\ &= \sum_{s=1}^{t} D_{t,s} d_s, \end{aligned}$$

with

$$\begin{aligned} &D_{t,t} = L_t, \\ &D_{t,s} = L_t D_{t-1,s} + Q_{t-1}, \qquad s = 1, \dots, t-1. \end{aligned}$$

Therefore, taking the expectations,

$$\begin{aligned} \left| \sum_{t=1}^{T} (\mathbb{F}_t[\zeta_t] - \mathbb{F}[\tilde{\zeta}_t]) \right| &\le \sum_{t=1}^{T} N_t d_W(\zeta_t, \tilde{\zeta}_t) \\ &\le \sum_{t=1}^{T} N_t \mathbb{E}[d(\zeta_t, \tilde{\zeta}_t)] \\ &\le \sum_{t=1}^{T} N_t \sum_{s=1}^{t} \bar{\varepsilon}_s D_{t,s} \\ &= \sum_{s=1}^{T} \bar{\varepsilon}_s \sum_{t=1}^{T} N_t D_{t,s}, \end{aligned}$$

which yields (4.2). □

PROPOSITION 4.3 (extension). *Suppose that Assumption* 3 *holds, and*

$$\bar{d}_W(P, \tilde{P}) \le (\varepsilon_1, \dots, \varepsilon_T),$$

where P is supported by Ξ, and $\tilde{P}$ is supported by the finite set $\tilde{\Xi}$. Then for every $\tilde{\Xi}$-feasible decision $\tilde{x}$ of (3.3)*, which is Q-Lipschitz, there is a Ξ-feasible decision x, which is Q^e-Lipschitz, called the extension of $\tilde{x}$, such that*

$$|F(x, P) - F(\tilde{x}, \tilde{P})| \le \delta_2, \tag{4.5}$$

where

$$\delta_2 = \sum_{s=1}^{T} \bar{\varepsilon}_s \sum_{t=s}^{T} N_t D^e_{t,s}.$$

The $\bar{\varepsilon}$'s are given by (4.3) *and for $Q^e = (Q^e_0, \dots, Q^e_{T-1})$, the constants Q^e_t, and $D^e_{s,t}$ fulfill the recursions*

$$\begin{aligned} Q^e_t &= Q_t + M_t \sum_{s=1}^{t-1} D^e_{t-1,s}, \\ D^e_{t,t} &= L_t, \\ D^e_{t,s} &= L_t D^e_{t-1,s} + Q^e_{t-1}, \qquad s = 1, \dots, t-1. \end{aligned}$$

Proof. Again, we construct the processes ξ and $\tilde{\xi}$ on the standard probability space $[0,1]^{\mathbb{N}}$. As in Proposition 4.2, the argumentation is pointwise for a specific ω in this probability space.

Set $d(\xi_t, \tilde{\xi}_t) = d_t$, and $d(\xi^t, \tilde{\xi}^t) = d^t = \sum_{s=1}^{t} d_s$.

Let $\tilde{x}$ be a Q-Lipschitz, $\tilde{\Xi}$-feasible family of decisions. By the extension theorem (Theorem A.2), we may extend these functions to a family of functions x^e defined on the whole Ξ with the same Lipschitz constant.

It may happen that the x^e functions are not feasible. We have to make them feasible in a recursive way, starting with x^e_1, then x^e_2, and so on.

Let $\zeta_1(\xi_1) = g_1(\tilde{z}_0, \tilde{x}_0, \xi_1)$. Then

$$d(\zeta_1(\xi_1), \tilde{\zeta}_1(\tilde{\xi}_1)) \le L_1 d^1.$$

Now let

$$x_1(\xi_1) := proj_{\mathcal{X}(z_1)}(x^e_1(\xi_1)).$$

Since $\mathcal{X}(z_1(u))$ is $(M_1 L_1)$-Lipschitz and x^e_1 is Q_1-Lipschitz, we have by Lemma A.3 that x_1 is $(Q_1 + M_1 L_1)$-Lipschitz and that

$$d(\zeta_2, \tilde{\zeta}_2) \le L_2(L_1 d_1 + (Q_1 + M_1 L_1) d_1 + d_2).$$

This argument gets recursively iterated as in the proof of Proposition 4.2, leading to the indicated sequences of constants and finally to (4.5). □

Remark. There are various variants of Proposition 4.3, for instance, if norms are replaced by equivalent ones or if the process ξ is Markovian. For particular models, much finer and better estimates may be found.

Recall the notion of δ-optimal solutions. In the given setting, they belong to

$$\begin{aligned} \delta\text{-}\arg\min_x F(x,P) &= \{\bar{x} \in \mathcal{X} \mid F(\bar{x},P) \le \inf_x F(x,P) + \delta\}, \quad \text{resp.}, \\ \tilde{\delta}\text{-}\arg\min_x F(x,\tilde{P}) &= \{\bar{x} \in \mathcal{X} \mid F(\bar{x},\tilde{P}) \le \inf_x F(x,\tilde{P}) + \tilde{\delta}\}. \end{aligned}$$

The concept of approximately optimal solutions offers us more flexible framework, as the δ-$\arg\min$-mappings satisfy the Lipschitz continuity under some additional conditions; i.e., F has to be proper, lower semicontinuous, and convex (cf. [23, Chapter 7J]).

Based on the statements above, we have the following result.

PROPOSITION 4.4. *Suppose that Assumption* 3 *holds, and*

$$\bar{d}_W(P, \tilde{P}) \le (\varepsilon_1, \dots, \varepsilon_T),$$

where P is supported by Ξ, and $\tilde{P}$ is supported by the finite set $\tilde{\Xi}$, and the approximation has been chosen so that the values of $\delta_1 = \delta_1(\varepsilon)$ and $\delta_2 = \delta_2(\varepsilon)$ are given, for $\varepsilon = (\varepsilon_1, \dots, \varepsilon_T)$. If $\tilde{x}^*$ is a δ_0-optimal solution of the approximate problem (4.1)*, then its extension x^* is a $(\delta_0 + \delta_1 + \delta_2)$-optimal solution of the basic problem* (3.3).

Proof. Let y^* be a solution of the basic problem (3.3). Since $\tilde{x}^*$ is a δ_0-solution of the approximate problem (4.1),

$$F(\tilde{x}^*, \tilde{P}) - \delta_0 \le \inf_x F(x, \tilde{P}) \le F(y^*, \tilde{P}),$$

and by virtue of (4.2) and (4.5), we have

$$|F(y^*, P) - F(y^*, \tilde{P})| \le \delta_1,$$
$$|F(x^*, P) - F(\tilde{x}^*, \tilde{P})| \le \delta_2.$$

This implies

$$\begin{aligned} F(y^*, P) &\ge F(y^*, \tilde{P}) - \delta_1 \\ &\ge F(\tilde{x}^*, \tilde{P}) - \delta_0 - \delta_1 \\ &\ge F(x^*, P) - \delta_0 - \delta_1 - \delta_2. \end{aligned}$$ □

COROLLARY 4.5. *Suppose that Assumption* 3 *holds, and*

$$\bar{d}_W(P, \tilde{P}) \le (\varepsilon_1, \dots, \varepsilon_T),$$

where P is supported by Ξ, and $\tilde{P}$ is supported by the finite set $\tilde{\Xi}$, and the approximation has been chosen so that the values of $\delta_1 = \delta_1(\varepsilon)$ and $\delta_2 = \delta_2(\varepsilon)$ are given. If $\tilde{x}^*$ is the solution of the approximate problem (4.1)*, then its extension x^* is a $(\delta_1 + \delta_2)$-solution of the basic problem* (3.3).

Proof. Choosing $\delta_0 = 0$ and applying Proposition 4.4 we get the statement immediately. □

5. Examples.

5.1. Multistage portfolio optimization. Consider an investor, who has initial capital C and wants to invest in m different assets. The price of one unit of asset i at time t, $t = 1, \dots, T$, is the random quantity $\xi_{t,i}$. At starting time 0, the prices $\xi_{0,i}$ are deterministic.

Let $\xi_t = (\xi_{t,1}, \dots, \xi_{t,m})^\top$ be the vector price process. The optimization problem is to maximize the acceptability of the final wealth under the self-financing constraint, i.e.,

$$\begin{array}{lll} \text{maximize in } x & \mathcal{A}[x_{T-1}^\top \xi_T] & \\ \text{subject to} & x_0^\top \xi_0 = C, & \\ & x_{t-1}^\top \xi_t = x_t^\top \xi_t, & t = 1, \dots, T-1, \end{array} \tag{5.1}$$

where $\mathcal{A}$ denotes some acceptability functional (see [1], [18]). By introducing the wealth w_t at time t as

$$w_t = x_{t-1}^\top \xi_t,$$

and defining the state as

$$\zeta_t = \begin{pmatrix} w_t \\ \xi_t \end{pmatrix},$$

one gets the dynamics

$$\begin{pmatrix} w_t \\ \xi_t \end{pmatrix} = \begin{pmatrix} x_{t-1}^\top \xi_t \\ \xi_t \end{pmatrix}, \qquad t = 1, \dots, T.$$

The constraint sets are

$$\mathcal{X}_t(\zeta_t) = \{x_t \,:\, x_t^\top \xi_t = w_t\}, \qquad t = 1, \dots, T.$$

Under the realistic assumption that the returns are bounded from above and from below,

$$0 < a \le \xi_{t,i} \le b < \infty,$$

this dynamics is Lipschitz in the sense of Assumption 2, since x must be bounded due to the initial budget constraint. In addition, the constraint sets are Lipschitz; see the second example in section 2.2.

The tree approximation of (5.1) is given by

$$\begin{array}{ll} \text{maximize in } x & \mathcal{A}[x_{T-1}^\top \tilde{\xi}_T] \\ \text{subject to} & x_0^\top \tilde{\xi}_0 = C, \\ & x_{t-1}^\top \tilde{\xi}_t = x_t^\top \tilde{\xi}_t, \qquad t = 1, \dots, T-1. \end{array}$$

Probability functionals which are Lipschitz w.r.t. the transportation distance in $\mathbb{R}$ include the expectation, the mean absolute deviation, distortion functionals (and therefore the average value-at-risk as a special case), and linear combinations thereof [17].

As illustration, let us consider the average value-at-risk corrected expectation [24]

$$\mathcal{A}[z] := \mathbb{E}[z] - \beta \mathbb{A}V@R_\alpha(z), \qquad 0 \le \beta \le 1,$$

where $\mathbb{A}V@R_\alpha(z)$ is defined by (A.1).

By

$$\left| a - \frac{1}{\alpha}\mathbb{E}([z-a]^-) - a + \frac{1}{\alpha}\mathbb{E}[[\tilde{z}-a]^-] \right| \le \frac{1}{\alpha}\mathbb{E}[|z-\tilde{z}|]$$

one sees that $\mathbb{A}V@R_\alpha$ is Lipschitz w.r.t. the transportation metric. The Lipschitz constant of $\mathbb{E}[z] - \beta\,\mathbb{A}V@R_\alpha(z)$ is $1 + \beta/\alpha$.

5.2. Multistage inventory control problem. We consider a generalization of the well-known newsboy problem (see, e.g., [12]) to a multiperiod setting. The multiperiod inventory model allows for storing the unsold merchandise, while the newsboy keeps no unsold copies, as they are worthless the next day.

Suppose that the demand at times $t = 1, \dots, T$ is given by a random process $\xi_1, \dots, \xi_T$. The regular orders are to be placed one period ahead. The order cost per unit ordered is one. Let I_t be the inventory level right after all sales have been effectuated at time t. If a stock-out O_t occurs, i.e., if the demand exceeds the inventory

plus the arriving order, the demand is satisfied by a rapid order. The rapid order cost per unit ordered is $r_t > 1$. The unsold goods are stored, but a fraction $(1 - q_t)$ is a storage loss of the period t; i.e., the inventory volume at the beginning of the period $(t+1)$ is $q_t I_t$. The selling price at time t is $s_t > 1$. Notice that all prices may change from period to period. The decision x_t is the order size at time t, $t = 0, \ldots, T-1$.

A closer look at the inventory volume and shortage shows that $I_0 = O_0 = 0$, and for $t = 1, \ldots, T$,

$$I_t = \max(q_{t-1}I_{t-1} + x_{t-1} - \xi_t, 0) = [q_{t-1}I_{t-1} + x_{t-1} - \xi_t]^+$$

and

$$O_t = \max(-(q_{t-1}I_{t-1} + x_{t-1} - \xi_t), 0) = [q_{t-1}I_{t-1} + x_{t-1} - \xi_t]^-.$$

For $t = 1, \ldots, T$, these two equations can be merged into one:

$$q_{t-1}I_{t-1} + x_{t-1} - \xi_t = I_t - O_t, \qquad I_t \geq 0,\ O_t \geq 0. \tag{5.2}$$

The profit function is

$$F(x, P) = q_T I_T + \sum_{t=1}^{T} \left(s_t \xi_t - x_{t-1} - r_t O_t\right),$$

and the optimization problem is to maximize the expected profit, i.e.,

$$\begin{array}{ll} \text{maximize in } x & q_T I_T + \displaystyle\sum_{t=1}^{T} \mathbb{E}[s_t \xi_t - x_{t-1} - r_t O_t] \\ \text{subject to} & x_t \text{ is } \mathcal{F}_t\text{-measurable, and (5.2) holds for } t = 1, \ldots, T. \end{array}$$

Notice that $\sum_{t=1}^{T} s_t \xi_t$ does not depend on the decision x and can be removed from the optimization problem.

As usual, x^* is the optimal solution, and denote by $v(x^*)$ the optimal value of

$$\begin{array}{ll} \text{maximize in } x & q_T I_T + \displaystyle\sum_{t=1}^{T} \mathbb{E}[-x_{t-1} - r_t O_t] \\ \text{subject to} & x_t \text{ is } \mathcal{F}_t\text{-measurable, and (5.2) holds for } t = 1, \ldots, T. \end{array} \tag{5.3}$$

Since (5.3) is linear in the decision variables $x_0, x_1, \ldots, x_{T-1}$, it has a dual formulation. In order to obtain it, let us form the Lagrangian $L(x, I, O, \lambda)$, for some $\lambda = (\lambda_1, \ldots, \lambda_T) \in L_\infty$, and $I = (I_1, \ldots, I_T)$, $O = (O_1, \ldots, O_T)$:

$$\begin{aligned} & L(x, I, O, \lambda) \\ &= \mathbb{E}\left[q_t I_T + \sum_{t=1}^{T}(-x_{t-1} - r_t O_t)\right] - \mathbb{E}\left[\sum_{t=1}^{T} \lambda_t (I_t - O_t - q_{t-1}I_{t-1} - x_{t-1} + \xi_t)\right] \\ &= \sum_{t=1}^{T} \mathbb{E}[x_{t-1}(\lambda_t - 1)] + \sum_{t=1}^{T} \mathbb{E}[O_t(\lambda_t - r_t)] \\ &\quad + \mathbb{E}[I_T(q_T - \lambda_T)] + \sum_{t=1}^{T-1} \mathbb{E}[(I_t(q_t\lambda_{t+1} - \lambda_t)] - \sum_{t=1}^{T} \mathbb{E}[\xi_t \lambda_t] \end{aligned}$$

$$= \sum_{t=1}^{T} \mathbb{E}[x_{t-1}(\mathbb{E}[\lambda_t|\mathcal{F}_{t-1}] - 1)] + \sum_{t=1}^{T} \mathbb{E}[O_t(\lambda_t - r_t)]$$
$$+ \mathbb{E}[I_T(q_T - \lambda_T)] + \sum_{t=1}^{T-1} \mathbb{E}[I_t(q_t\mathbb{E}[\lambda_{t+1}|\mathcal{F}_t] - \lambda_t)] + \sum_{t=1}^{T} \mathbb{E}[(-\xi_t)\lambda_t].$$

Only if $\mathbb{E}[\lambda_t|\mathcal{F}_{t-1}] = 1$, and $q_t \le \lambda_t \le r_t$, a.s. for each $t = 1, \dots, T$, is the dual problem finite. Thus, the dual formulation of (5.3) reduces to the following:

$$\begin{array}{ll} \text{minimize in } \lambda & \displaystyle\sum_{t=1}^{T} \mathbb{E}[(-\xi_t)\lambda_t] \\ \text{subject to} & \lambda_t, I_T, O_t \text{ are } \mathcal{F}_t\text{-measurable,} \\ & q_t \le \lambda_t \le r_t, \;\; I_t \ge 0, \;\; O_t \ge 0, \;\; \text{and} \\ & \mathbb{E}[\lambda_t|\mathcal{F}_t] = 1, \;\; \text{for } t = 1, \dots, T, \;\; \text{a.s.} \end{array} \tag{5.4}$$

Now recall the dual representation of $\mathbb{A}V@R_\alpha(\xi)$ given by (A.2). Setting, for $t = 1, \dots, T$,

$$Y_t = \frac{\lambda_t - q_t}{1 - q_t}$$

yields

$$\mathbb{E}[Y_t|\mathcal{F}_t] = 1 \quad \text{and} \quad 0 \le Y_t \le \frac{r_t - q_t}{1 - q_t}.$$

So, for $\alpha_t = \frac{1-q_t}{r_t-q_t}$, according to (A.5), the objective to be minimized in (5.4) becomes

$$\sum_{i=1}^{T} \mathbb{E}\left[\mathbb{A}V@R_{\alpha_t}(\xi_t)\right] = \sum_{i=1}^{T} \Big(q_t\mathbb{E}[-\xi_t] + (1 - q_t)\mathbb{E}[\mathbb{A}V@R_{\alpha_t}(-\xi_t|\mathcal{F}_{t-1})] \Big).$$

Using the identity (A.3) with $\beta_t = 1 - \alpha_t = \frac{r_t-1}{r_t-q_t}$, we write the objective as

$$\sum_{i=1}^{T} \Big(r_t\mathbb{E}[-\xi_t] + (r_t - 1)\mathbb{E}[\mathbb{A}V@R_{\beta_t}(\xi_t|\mathcal{F}_t)] \Big). \tag{5.5}$$

The optimal solution of the given problem, for $\mathbb{V}@R_{\beta_{t+1}}(\xi_{t+1}|\mathcal{F}_t) = V_t$, is

$$x_t^* = \mathbb{V}@R_{\beta_{t+1}}(\xi_{t+1}|\mathcal{F}_t) - q_tI_t = V_t - q_tI_t, \qquad t = 0, \dots, T-1. \tag{5.6}$$

Indeed, if we insert (5.6) into (5.5), in view of (A.4) we get

$$v(x^*) = \sum_{i=1}^{T} \Big(r_t\mathbb{E}[-\xi_t] + (r_t - 1)\mathbb{E}[V_{t-1}] - (r_t - q_t)\mathbb{E}[[V_{t-1} - \xi_t]^+] \Big).$$

On the other hand, inserting the solutions (5.6) into the constraints of (5.3), we have that, for $t = 1, \dots, T$,

$$I_t = [V_{t-1} - \xi_t]^+,$$
$$O_t = [V_{t-1} - \xi_t]^-,$$

and (5.2) is

$$V_{t-1} - \xi_t = I_t - O_t, \qquad I_t \geq 0,\ O_t \geq 0.$$

The value of the objective in (5.3) for this choice of x becomes

$$\begin{aligned}
&q_T I_T + \sum_{t=1}^{T} \mathbb{E}[-x_{t-1} - r_t O_t] \\
&= \mathbb{E}\left[q_T I_t + \sum_{t=1}^{T} (-V_{t-1} - q_{t-1} I_{t-1} - r_t O_t) \right] \\
&= \mathbb{E}\left[\sum_{t=1}^{T} (q_t I_t - V_{t-1} - r_t (I_t - V_{t-1} + \xi_t)) \right] \\
&= \sum_{i=1}^{T} \Big(r_t \mathbb{E}[-\xi_t] + (r_t - 1)\mathbb{E}[V_{t-1}] - (r_t - q_t)\mathbb{E}[[V_{t-1} - \xi_t]^+] \Big) \\
&= v(x^*).
\end{aligned}$$

Thus, we have shown that (5.6) is really the solution of the given problem.

The state of the system at time $t = 1, \ldots, T$ is

$$\zeta_t = (\xi_1, \ldots, \xi_t, I_t, O_t, x_t).$$

The mapping

$$\begin{gathered}
\zeta_t \mapsto x_t^*, \ \text{i.e.,} \\
(\xi_1, \ldots, \xi_t, I_t) \mapsto \mathbb{V}@R_{\beta_t}(\xi_{t+1} | \mathcal{F}_t) - q_t I_t,
\end{gathered}$$

is Lipschitz if the mapping

$$(\xi_1, \ldots, \xi_t) \mapsto \mathbb{V}@R_{\beta_t}(\xi_{t+1} | \mathcal{F}_t) \tag{5.7}$$

is Lipschitz. This is true in many cases, e.g., for vector autoregressive processes.

Let $G(v|u_1, \ldots, u_{t-1})$ be the conditional distribution function of ξ_t given the past $\xi^{t-1} = u^{t-1}$. If

$$(u_1, \ldots, u_t) \mapsto G^{-1}(v|u_1, \ldots, u_t)$$

is Lipschitz for all v, then (5.7) is also Lipschitz.

In order to show how the Lipschitz constants in the inventory model behave, assume that the demand process $\xi = (\xi_1, \ldots, \xi_T)$ is normally distributed and follows an additive recursion. To this end, let

$$\xi_0 \sim \mathcal{N}(\mu_0, \sigma_0^2), \qquad \xi_t = b\xi_{t-1} + \epsilon_t \text{ with } \epsilon_t \sim \mathcal{N}(\mu, \sigma^2), \qquad t = 1, \ldots, T,$$

where $\mu = \mu_0(1 - b)$, $\sigma = \sigma_0(1 - b^2)$, and ξ_t and ϵ_t are independent. Under these assumptions, ξ is a stationary Gaussian Markov process.

The state of the system may be reduced to

$$\zeta_t = (\xi_t, I_t, O_t, x_t), \qquad t = 1, \ldots, T. \tag{5.8}$$

The conditional average value-at-risk is

$$\begin{aligned}\mathbb{A}V@R_\beta(\xi_t|\mathcal{F}_{t-1}) &= b\xi_{t-1} + \mathbb{A}V@R_\beta(\epsilon_t)\\ &= b\xi_{t-1} + \mu - \frac{1}{\beta\sqrt{2\pi}}\exp\left(\frac{1}{2}\Big(\Phi^{-1}(\min(\beta, 1-\beta))\Big)^2\right).\end{aligned}$$

The solution of (5.6) becomes

$$x_t^* = b\xi_{t-1} + \mu - \frac{1}{\beta_t\sqrt{2\pi}}\exp\left(\frac{1}{2}\Big(\Phi^{-1}(\min(\beta_t, 1-\beta_t))\Big)^2\right) - q_{t-1}I_{t-1}.$$

To calculate the constants K_t from Assumption 2, we need the conditional distribution of ξ_t given $\xi_{t-1} = u_{t-1}$. It holds that

$$(\xi_t|\mathcal{F}_{t-1}) = (\xi_t|\xi_{t-1} = u) \sim \mathcal{N}(\mu + bu, \sigma^2).$$

Thus,

$$d_W(P_t(\cdot|u), P_t(\cdot|v)) \le bd(u, v),$$

and $K_t = b$, for each $t = 1, \dots, T$.

For constants L_t, M_t, N_t from Assumption 3, observe the state ζ_t given by (5.8), and recall the transition function g_t defined by (3.1). Then

$$\begin{aligned}\zeta_{t+1} = (\xi_{t+1}, I_{t+1}, O_{t+1}, x_{t+1}) &= g_{t+1}((\zeta_t, I_t, O_t, x_t), x_t, \xi_{t+1})\\ &= g_{t+1}(g_t((\zeta_{t-1}, I_{t-1}, O_{t-1}, x_{t-1}), x_{t-1}, \xi_t), I_t, x_t, \xi_{t+1}),\end{aligned}$$

and so on. It follows that

$$\begin{aligned}&d(g_t(\zeta_{t-1}, x_{t-1}, \xi_t), g_t(\bar\zeta_{t-1}, \bar x_{t-1}, \bar\xi_t))\\ &= d\left([q_{t-1}I_{t-1} + x_{t-1} - \xi_t]^+ - [q_{t-1}\bar I_{t-1} + \bar x_{t-1} - \bar\xi_t]^+\right)\\ &\le \max(0, 1, 0, 0)\left(d(I_{t-1}, \bar I_{t-1}) + d(x_{t-1}, \bar x_{t-1}) + d(\xi_t, \bar\xi_t)\right),\end{aligned}$$

and $L_t = 1$. Since $\mathcal{X}_t(z) = \mathbb{R}^+$ for all z, we have that $d_{P,r}(\mathcal{X}_t(z), \mathcal{X}_t(\bar z)) = 0$, and trivially $M_t = 0$. For N_t, we see that

$$|\mathbb{F}_t(\zeta_t) - \mathbb{F}_t(\bar\zeta_t)| \le \max(1, 1, r_t)d_W(\zeta_t, \bar\zeta_t),$$

and so $N_t = r_t$.

The Lipschitz constant of the solution, as well as of the extension, is $Q_t = Q_t^e = 1$ for $t = 0, \dots, T-1$.

Eventually, we want to calculate constants δ_1, resp., δ_2, as obtained in Proposition 4.2, resp., Proposition 4.3. In this setting, we have that

$$\begin{aligned}\bar\varepsilon_s &= \sum_{i=1}^{s}\varepsilon_i b^{s-i}, \qquad s = 1, \dots, T,\\ D_{t,s} = D_{t,s}^e &= t - s + 1, \qquad s = 1, \dots, t-1,\end{aligned}$$

and

$$\delta_1 = \delta_2 = \sum_{s=1}^{T}\left(\sum_{i=1}^{s}\varepsilon_i b^{s-i}\sum_{t=s}^{T}(t-s+1)r_t\right).$$

Appendix. Auxiliary results. The following lemma is a generalization of [23, Chapter 7J, Exercise 7.67].

LEMMA A.1. *Let $\mathbb{B}(r)$ be as in section 2.2 and let $A, B \subseteq \mathbb{B}(r)$ be closed, convex sets for some $r > 0$. Let y be some point in $\mathbb{B}(r)$. Then*

$$\|proj_A(y) - proj_B(y)\| \leq 2\sqrt{r\, d_r(A,B)},$$

where

$$d_r(A,B) = \sup_{x \in \mathbb{B}(r)} |d(x,A) - d(x,B)|.$$

Proof. Define the half spaces

$$H_A = \{x : (x - proj_A(y))^\top (y - proj_A(y)) \leq 0\} \text{ and}$$
$$H_B = \{x : (x - proj_B(y))^\top (y - proj_B(y)) \leq 0\}.$$

Then $A \subseteq H_A$ and $B \subseteq H_B$. Assume without loss of generality that $\|y - proj_A(y)\| \leq \|y - proj_B(y)\|$.

Let $y' = proj_{H_B}(proj_A(y))$ and let y'' be the projection of y on the line connecting $proj_A(y)$ and $proj_B(y)$. Then, because $\|y - proj_A(y)\| \leq \|y - proj_B(y)\|$, one has that

$$\|y'' - proj_B(y)\| \geq \frac{1}{2}\|proj_A(y) - proj_B(y)\|.$$

Notice that

$$d_r(A,B) \geq d(proj_A(y), H_B) = \|proj_A(y) - y'\|,$$

since $proj_A(y) \in A$, and $B \subseteq H_B$. The five points $(y, proj_A(y), proj_B(y), y', y'')$ lie in one hyperplane. By geometrical consideration, using the similarity of triangles, one has

$$\frac{\|proj_A(y) - y'\|}{\|proj_A(y) - proj_B(y)\|} = \frac{\|y'' - proj_B(y)\|}{\|y - proj_B(y)\|} \geq \frac{\|proj_A(y) - proj_B(y)\|}{2\,\|y - proj_B(y)\|}.$$

Hence, using $\|y - proj_B(y)\| \leq 2r$, one gets

$$\|proj_A(y) - proj_B(y)\|^2 \leq 2\|y - proj_B(y)\|\,\|proj_A(y) - y'\| \leq 4r\, d_r(A,B). \qquad \square$$

For a real-valued Lipschitz function in finite-dimensional spaces, extension from an arbitrary subset is possible.

THEOREM A.2 (extension theorem). *Let $(\tilde{\Xi}, d)$ be any metric space, $\tilde{\Xi}$ any subset of Ξ, and x any $\mathbb{R}^m$-valued Lipschitz function on $\tilde{\Xi}$. Then x can be extended on Ξ without increasing the Lipschitz modulus.*

Proof. See [5, Theorem 6.1.1]. $\square$

In [8] one can read more about the extension of Lipschitz functions in the infinite-dimensional setting.

LEMMA A.3. *Let $x'(u)$ be a Q-Lipschitz function with values in $\mathbb{B}(r) \subseteq \mathbb{R}^m$ and let $\mathcal{X}(u)$ be a convex-valued multifunction which is M-Lipschitz w.r.t. the projection distance $d_{P,r}$. (The case $r = \infty$ is not excluded.) Then the convex projection $x(u) = proj_{\mathcal{X}(u)} x'(u)$ is $(Q + M)$-Lipschitz.*

Proof.

$$\begin{aligned} d(x(u),x(v)) &\le d(proj_{\mathcal{X}(u)}x'(u), proj_{\mathcal{X}(u)}x'(v)) + d(proj_{\mathcal{X}(u)}x'(v), proj_{\mathcal{X}(v)}x'(v)) \\ &\le d(x'(u),x'(v)) + d_{P,r}(\mathcal{X}(u),\mathcal{X}(v)) \\ &\le Qd(u,v) + Md(u,v) = (Q+M)d(u,v). \qquad \square \end{aligned}$$

LEMMA A.4. *The average value-at-risk is given by the following expressions:*

$$\begin{aligned} \mathbb{A}V@R_\alpha(\xi) &= \frac{1}{\alpha}\int_0^\alpha G^{-1}(u)\,du \\ &= \max_{a\in\mathbb{R}}\left(a - \frac{1}{\alpha}\mathbb{E}[[\xi-a]^-]\right) \qquad \text{(A.1)} \\ &= \min_Y\left\{\mathbb{E}[\xi Y] \,:\, 0\le Y\le\frac{1}{\alpha},\ \mathbb{E}[Y]=1\right\}, \qquad \text{(A.2)} \end{aligned}$$

where $G(u)=\mathbb{P}(\xi\le u)$. *If* $\mathbb{V}@R_\alpha(\xi)=G^{-1}(\alpha)$, *the following identities hold:*

$$\mathbb{A}V@R_\alpha(-Y) = \frac{1-\alpha}{\alpha}\mathbb{A}V@R_{1-\alpha}(Y) - \frac{1}{\alpha}\mathbb{E}[Y] \qquad \text{(A.3)}$$

and

$$\mathbb{A}V@R_\alpha(Y) = \mathbb{V}@R_\alpha(Y) - \frac{1}{\alpha}\mathbb{E}[[\mathbb{V}@R_\alpha(Y)-Y]^+]. \qquad \text{(A.4)}$$

The expected conditional average value-at-risk given the filtration $\mathcal{F}$ *is defined by*

$$\mathbb{E}[\mathbb{A}V@R_\alpha(\xi|\mathcal{F})] = \min_Y\left\{\mathbb{E}[\xi Y] \,:\, 0\le Y\le\frac{1}{\alpha},\ \mathbb{E}[Y|\mathcal{F}]=1\right\}. \qquad \text{(A.5)}$$

Proof. See [18] and [19]. $\square$

NONSMOOTH ANALYSIS OF LORENTZ INVARIANT FUNCTIONS*

HRISTO S. SENDOV†

Abstract. A real valued function $g(x,t)$ on $\mathbb{R}^n \times \mathbb{R}$ is called a *Lorentz invariant* if $g(x,t) = g(Ux,t)$ for all $n \times n$ orthogonal matrices U and all (x,t) in the domain of g. In other words, g is invariant under the linear orthogonal transformations preserving the *Lorentz cone*: $\{(x,t) \in \mathbb{R}^n \times \mathbb{R} \,|\, t \geq \|x\|\}$. It is easy to see that every Lorentz invariant function can be decomposed as $g = f \circ \beta$, where $f : \mathbb{R}^2 \to \mathbb{R}$ is a symmetric function and β is the root map of the *hyperbolic polynomial* $p(x,t) = t^2 - x_1^2 - \cdots - x_n^2$. We investigate a variety of important variational and nonsmooth properties of g and characterize them in terms of the symmetric function f.

Key words. nonsmooth analysis, convex analysis, hyperbolic polynomials, Lorentz cone, second-order cone, Clarke subdifferential, regular subdifferential, limiting subdifferential, proximal subdifferential, lower semicontinuous

1. Introduction and notation.

Denote the set of all orthogonal $n \times n$ matrices by $O(n)$. Let the function $g(x,t)$ be defined on an open subset of $\mathbb{R}^n \times \mathbb{R}$, taking values in $\mathbb{R}$. The inner product of two vectors, (x,t) and (y,r), in $\mathbb{R}^n \times \mathbb{R}$ is $\langle (x,t),(y,r),\rangle = x^T y + tr$. Throughout the entire paper we assume that

$$g(Ux,t) = g(x,t) \quad \text{for all } U \in O(n), \tag{1.1}$$

and all (x,t) in the domain of g. We call a function g with property (1.1) *Lorentz invariant* because it is invariant under the linear orthogonal transformations preserving the *Lorentz cone* $\{(x,t) \in \mathbb{R}^n \times \mathbb{R} \,|\, t \geq \|x\|\}$. A set $\Omega \subseteq \mathbb{R}^n \times \mathbb{R}$ is called *Lorentz invariant* if $(x,t) \in \Omega$ implies that $(Ux,t) \in \Omega$ for every $U \in O(n)$. Define the map

$$\beta(x,t) : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^2,$$
$$\beta(x,t) = \frac{1}{\sqrt{2}}(t + \|x\|, t - \|x\|).$$

The rationale behind the map β is the following. Consider the polynomial $p(x,t) : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$ defined by $p(x,t) = t^2 - x_1^2 - \cdots - x_n^2$ and let $d := (0,\ldots,0,\sqrt{2}) \in \mathbb{R}^n \times \mathbb{R}$. Then, the coordinates of $\beta(x,t)$ are the roots of the polynomial $\lambda \mapsto P((x,t) - \lambda d)$. In general, a homogeneous polynomial $p(x) : \mathbb{R}^n \to \mathbb{R}$ with degree of homogeneity m, for which there is a direction $d \in \mathbb{R}^n$, $p(d) \neq 0$, such that $\lambda \mapsto p(x - \lambda d)$ has m real roots for every $x \in \mathbb{R}^n$, is called *hyperbolic*. In 1997, Güler [6] pointed out the relevance of these polynomials for optimization. Further information and developments can be found in [2], [13], [12], [18].

Let the function $f(a,b)$ be defined on an open subset of $\mathbb{R}^2$ and assume that it is *symmetric*, that is, $f(a,b) = f(b,a)$ for all (a,b) in its domain. Necessarily, the

domain of f is a *symmetric subset* of $\mathbb{R}^2$, that is, $(a,b) \in A \Rightarrow (b,a) \in A$. The following easy lemma establishes the connection between g, β, and f.

LEMMA 1.1 (Lorentz invariant functions). *The following two properties of a function $g : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$ are equivalent:*

(i) *g is Lorentz invariant;*

(ii) *$g = f \circ \beta$ for some symmetric function $f : \mathbb{R}^2 \to \mathbb{R}$.*

If $g = f \circ \beta$, we say that f is the symmetric function corresponding to g. This correspondence is one-to-one, and given g the corresponding symmetric function is

$$f(a,b) = g\left(\frac{a-b}{\sqrt{2}}, 0, \ldots, 0, \frac{a+b}{\sqrt{2}}\right). \tag{1.2}$$

That (1.2) defines a symmetric function in (a,b) is guaranteed by (1.1).

The goal of this paper is to establish a variety of important variational and nonsmooth optimization properties of the function $g = f \circ \beta$ and how they arise from the corresponding properties of f. By deriving a wide range of nonsmooth formulae we hope this work will be a useful reference source. This work completes the similar investigations of spectral functions [8], [9], [11], [7] and singular value functions [10], [14], [15]. Optimization problems over the Lorentz cone, also known as the second-order cone, have a wide range of applications; see, for example, [16]. With the development of the nonsmooth Newton method and various smoothing techniques, the nonsmooth properties of functions associated with the Lorentz cone have been of interest lately. For example, the strong semismoothness of the projection onto the Lorentz cone was established in [23, Proposition 4.3]. A formula for the Bouligand subdifferential of the projection onto the Lorentz cone is derived in [24, Lemma 14]. Our paper is based on results that first appeared in the author's Ph.D. dissertation [21].

We conclude this section with an elementary fact.

LEMMA 1.2. *The composition $f \circ \beta$ is lower semicontinuous if and only if f is lower semicontinuous.*

Throughout the entire work, the functions g, β, and f will have the properties described in this section.

2. Fenchel conjugation. For a function $F : \mathbb{R}^n \to (-\infty, +\infty]$, the *Fenchel conjugate* $F^* : \mathbb{R}^n \to [-\infty, +\infty]$ is the function

$$F^*(y) = \sup_{x \in \mathbb{R}^n} \{x^T y - F(x)\}.$$

It is well known that F^* is lower semicontinuous and convex [19]. In this section we prove the following formula.

PROPOSITION 2.1. *We always have*

$$(f \circ \beta)^* = f^* \circ \beta. \tag{2.1}$$

Proof. Let $y \neq 0$. In the third equality below, we use the fact that f is symmetric to see that the given supremum is the same as the supremum over the set $\{(a,b) \in \mathbb{R}^2 \mid a - b \geq 0\}$. From the definition we have

$$\begin{aligned}
(f \circ \beta)^*(y,r) &= \sup_{(x,t) \in \mathbb{R}^{n+1}} \{\langle (y,r), (x,t) \rangle - (f \circ \beta)(x,t)\} \\
&= \sup_{(a,b) \in \mathbb{R}^2} \sup_{\substack{(x,\,t) \ \text{s.t.} \\ t + \|x\| = a\sqrt{2} \\ t - \|x\| = b\sqrt{2}}} \{\langle (y,r), (x,t) \rangle - f(a,b)\} \\
&= \sup_{(a,b) \in \mathbb{R}^2} \left\{ \left\langle (y,r), \left(\frac{y}{\|y\|} \frac{a-b}{\sqrt{2}}, \frac{a+b}{\sqrt{2}} \right) \right\rangle - f(a,b) \right\}
\end{aligned}$$

$$
\begin{aligned}
&= \sup_{(a,b)\in\mathbb{R}^2} \left\{ \|y\| \frac{a-b}{\sqrt{2}} + r\frac{a+b}{\sqrt{2}} - f(a,b) \right\} \\
&= \sup_{(a,b)\in\mathbb{R}^2} \left\{ \left\langle \left(\frac{r+\|y\|}{\sqrt{2}}, \frac{r-\|y\|}{\sqrt{2}} \right), (a,b) \right\rangle - f(a,b) \right\} \\
&= (f^* \circ \beta)(y,r).
\end{aligned}
$$

The case $y = 0$ is easy. □

An alternative proof of this result uses Theorem 5.5 and the example in section 7.5 in [2], where the proposition has been generalized to the subclass of so-called *isometric* hyperbolic polynomials. In [1, Theorem 6.1] the proposition has been shown to hold for symmetric functions composed with the eigenvalues of the elements of formally real Jordan algebras.

3. Convexity and convex subdifferentials.

3.1. Convexity.

THEOREM 3.1. *The composition $f \circ \beta$ is convex and lower semicontinuous if and only if f is convex and lower semicontinuous.*

Proof. Suppose f is convex and lower semicontinuous. If $f \equiv +\infty$, then $f \circ \beta \equiv +\infty$ and the theorem is clear. Suppose f assumes some finite values. Then using the convexity, one can show that $f > -\infty$, and by [19, Theorem 12.2] we have $f^{**} = f$. Since f^* is symmetric, we use (2.1) in $f \circ \beta = f^{**} \circ \beta = (f^* \circ \beta)^*$ to conclude that $f \circ \beta$ is convex and lower semicontinuous. The opposite direction follows from (1.2) and Lemma 1.2. □

The proof of the above theorem can be also deduced from Theorem 3.9 and the example in section 7.5 in [2]. Even though the proof of our Theorem 3.1 is quite elegant, a direct approach removes the condition that f be lower semicontinuous.

THEOREM 3.2. *The composition $f \circ \beta$ is convex if and only if f is convex.*

Proof. If $f \circ \beta$ is convex, then f is by (1.2). Suppose now that f is convex with domain C. The domain of $f \circ \beta$ is $\beta^{-1}(C)$. Let (x,t), $(y,r) \in \beta^{-1}(C)$, and $\alpha \in [0,1]$. Since $(t+\|x\|, t-\|x\|), (r+\|y\|, r-\|y\|) \in \sqrt{2}C$, and C is symmetric and convex, we find that the points

$$
\begin{aligned}
&(\alpha t + (1-\alpha)r + \alpha\|x\| + (1-\alpha)\|y\|, \alpha t + (1-\alpha)r - \alpha\|x\| - (1-\alpha)\|y\|), \\
&(\alpha t + (1-\alpha)r - \alpha\|x\| - (1-\alpha)\|y\|, \alpha t + (1-\alpha)r + \alpha\|x\| + (1-\alpha)\|y\|)
\end{aligned}
$$

are both in $\sqrt{2}C$. Denote the first displayed point by $a\sqrt{2}$ and the second by $b\sqrt{2}$. Since

$$
-\alpha\|x\| - (1-\alpha)\|y\| \le \|\alpha x + (1-\alpha)y\| \le \alpha\|x\| + (1-\alpha)\|y\|,
$$

there is a $\beta \in [0,1]$ such that for the point

$$
c\sqrt{2} := (\alpha t + (1-\alpha)r + \|\alpha x + (1-\alpha)y\|, \alpha t + (1-\alpha)r - \|\alpha x + (1-\alpha)y\|)
$$

we have $c = \beta a + (1-\beta)b \in C$. Thus,

$$
\begin{aligned}
f(c) &\le \beta f(a) + (1-\beta) f(b) = f(a) \\
&\le \alpha f((t+\|x\|, t-\|x\|)/\sqrt{2}) + (1-\alpha) f((r+\|y\|, r-\|y\|)/\sqrt{2}),
\end{aligned}
$$

where we used the facts that $f(a) = f(b)$ and that f is convex. □

The proof of Theorem 3.2 shows the following property.

LEMMA 3.3. *Let $C \subseteq \mathbb{R}^2$ be a convex and symmetric set. Then*

$$\beta^{-1}(C) := \{(x,t) \in \mathbb{R}^n \times \mathbb{R} \,|\, \beta(x,t) \in C\}$$

is convex and Lorentz invariant.

3.2. Convex subdifferentials. Let $f : \mathbb{R}^2 \to (-\infty, +\infty]$ be convex. For every point (a,b) such that $f(a,b) < +\infty$, we define the *subdifferential* of f at (a,b) to be the set

$$\partial f(a,b) = \{(a',b') | f(c,d) - f(a,b) \geq \langle (a',b'), (c,d) - (a,b) \rangle \text{ for all } (c,d)\}.$$

It is easy to see that $f(a,b) + f^*(a',b') = \langle (a,b), (a',b') \rangle$ if and only if $(a',b') \in \partial f(a,b)$. The set $\partial f(a,b)$ is a singleton $\{(a',b')\}$ if and only if f is differentiable at the point (a,b) with gradient $\nabla f(a,b) = (a',b')$; see [19, Theorem 25.1].

The following result gives a formula for the subgradient of the composition $f \circ \beta$.

THEOREM 3.4. *Suppose $f : \mathbb{R}^2 \to (-\infty, +\infty]$ is convex and lower semicontinuous. Then $(y,r) \in \partial(f \circ \beta)(x,t)$ if and only if $\beta(y,r) \in \partial f(\beta(x,t))$ and $x^T y = \|x\|\|y\|$.*

Proof. Suppose first that $(y,r) \in \partial(f \circ \beta)(x,t)$. Then using formula (2.1) we get

$$\begin{aligned}
\|x\|\|y\| + rt \;\geq x^T y + rt &= \langle (y,r), (x,t) \rangle \\
&= (f \circ \beta)(x,t) + (f \circ \beta)^*(y,r) \\
&= (f \circ \beta)(x,t) + (f^* \circ \beta)(y,r) \\
&= f\left(\frac{t + \|x\|}{\sqrt{2}}, \frac{t - \|x\|}{\sqrt{2}} \right) + f^*\left(\frac{r + \|y\|}{\sqrt{2}}, \frac{r - \|y\|}{\sqrt{2}} \right) \\
&\geq \big((t + \|x\|)(r + \|y\|) + (t - \|x\|)(r - \|y\|) \big)/2 \\
&= \|x\|\|y\| + rt.
\end{aligned}$$

Thus, we have equalities everywhere: $\beta(y,r) \in \partial f(\beta(x,t))$ and $x^T y = \|x\|\|y\|$. In the other direction the proof is clear by reversing the steps above. ∎

For a generalization of this proposition to formally real Jordan algebras see [1, Corollary 6.2].

4. Differentiability. The partial derivatives of the function f with respect to its first and second argument are denoted by f_1' and f_2', respectively.

THEOREM 4.1. *The composition $f \circ \beta$ is differentiable at the point (x,t) if and only if f is differentiable at $\beta(x,t)$. In that case we have the formulae*

$$\nabla_x (f \circ \beta)(x,t) = \begin{cases} \frac{f_1'(\beta(x,t)) - f_2'(\beta(x,t))}{\sqrt{2}\|x\|} x & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases}$$

and

$$\frac{d}{dt}(f \circ \beta)(x,t) = \frac{1}{\sqrt{2}}(f_1'(\beta(x,t)) + f_2'(\beta(x,t))).$$

Proof. Suppose first that f is differentiable at the point $\beta(x,t)$. If $x \neq 0$, the theorem and the formulae are trivial and follow from the chain rule. So let us assume now that $x = 0$. Let $h = (\bar{h}, h_{n+1}) \in \mathbb{R}^n \times \mathbb{R}$ and

$$d := \big(0, \ldots, 0, (f_1'(\beta(x,t)) + f_2'(\beta(x,t)))/\sqrt{2}\big) \in \mathbb{R}^n \times \mathbb{R}.$$

Then

$$\lim_{h\to 0}\frac{|(f\circ\beta)((0,t)+(\bar{h},h_{n+1}))-(f\circ\beta)((0,t))-d^Th|}{\|h\|}$$
$$=\lim_{h\to 0}\frac{|f(\beta(\bar{h},t+h_{n+1}))-f(\beta(0,t))-h_{n+1}(f_1'(\beta(0,t))+f_2'(\beta(0,t)))/\sqrt{2}|}{\|h\|}.$$

The fact that f is differentiable at $\beta(0,t)=(t/\sqrt{2},t/\sqrt{2})$ gives

$$f(\beta(\bar{h},t+h_{n+1}))\sim f(\beta(0,t))+f_1'(\beta(0,t))\frac{h_{n+1}+\|\bar{h}\|}{\sqrt{2}}+f_2'(\beta(0,t))\frac{h_{n+1}-\|\bar{h}\|}{\sqrt{2}},$$

where $\sim$ indicates that the difference of both sides is of order $o(\|h\|)$. Using the fact that, for a symmetric function f, $f_1'(\beta(0,t))=f_2'(\beta(0,t))$ and substituting above we see that the limit is zero, that is, $\nabla(f\circ\beta)(0,t)=d$.

The proof in the other direction is easy using formula (1.2). □

THEOREM 4.2. *Let f be symmetric and defined on an open symmetric subset of $\mathbb{R}^2$. Then $f\circ\beta$ is continuously differentiable at the point (x,t) if and only if f is continuously differentiable at $\beta(x,t)$.*

Proof. Suppose that f is continuously differentiable at $\beta(x,t)$. The theorem is clear if $x\neq 0$. So suppose $x=0$. Let $\{(x^k,t^k)\}$ be a sequence of points in $\mathbb{R}^n\times\mathbb{R}$ approaching $(0,t)$. We need only prove that $\nabla(f\circ\beta)(x^k,t^k)$ approaches $\nabla(f\circ\beta)(0,t)$. We consider two cases. The general case easily follows by combining them.

Case 1. If $x^k=0$ for all k, then using the formula in Theorem 4.1 we obtain

$$\lim_{k\to\infty}\nabla(f\circ\beta)(0,t^k)=\lim_{k\to\infty}\left(0,\dots,0,\frac{1}{\sqrt{2}}\big(f_1'(\beta(0,t^k))+f_2'(\beta(0,t^k))\big)\right)$$
$$=\nabla(f\circ\beta)(0,t)$$

by the continuity of ∇f at $\beta(0,t)$.

Case 2. If $x^k\neq 0$ for all k, then using again the formula in Theorem 4.1 for the derivative with respect to t we obtain

$$\lim_{k\to\infty}(f\circ\beta)_t'(x^k,t^k)=\lim_{k\to\infty}\frac{1}{\sqrt{2}}\big(f_1'(\beta(x^k,t^k))+f_2'(\beta(x^k,t^k))\big)=(f\circ\beta)_t'(0,t).$$

For the derivative with respect to x_i we get

$$\lim_{k\to\infty}(f\circ\beta)_{x_i}'(x^k,t^k)=\lim_{k\to\infty}\frac{x_i^k}{\sqrt{2}\|x^k\|}\big(f_1'(\beta(x^k,t^k))-f_2'(\beta(x^k,t^k))\big)=0$$

because $x_i^k/\|x^k\|$ is bounded and the continuity of ∇f at $\beta(0,t)$ gives us

$$\lim_{k\to\infty}(f_1'(\beta(x^k,t^k))-f_2'(\beta(x^k,t^k)))=f_1'(\beta(0,t))-f_2'(\beta(0,t))=0.$$

The last equality follows from the fact that f is symmetric.

The opposite direction of the theorem is easy to prove by using (1.2). □

5. The decomposition functions. In this section we define the functions d_z and d_z^* and summarize some of their properties which will be used frequently. We call them *decomposition* functions because they will be used to describe how the subgradients of $f\circ\beta$ are decomposed into subgradients of f.

DEFINITION 5.1. *For every nonzero vector z in $\mathbb{R}^n$, we define the map*

$$d_z : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^2,$$
$$d_z(y,t) = \frac{1}{\sqrt{2}}\left(t + \frac{z^T y}{\|z\|}, t - \frac{z^T y}{\|z\|}\right).$$

In cases when the direction (y,t) is fixed and clear from the context we simply write d_z instead of $d_z(y,t)$.

DEFINITION 5.2. *For every nonzero vector z in $\mathbb{R}^n$, we define the map*

$$d_z^* : \mathbb{R}^2 \to \mathbb{R}^n \times \mathbb{R},$$
$$d_z^*(a,b) = \left(\frac{z}{\|z\|}\frac{a-b}{\sqrt{2}}, \frac{a+b}{\sqrt{2}}\right).$$

The following lemma collects a few elementary properties of the maps d_z and d_z^*. The proof is omitted.

LEMMA 5.3. *Let z and w be nonzero vectors in $\mathbb{R}^n$.*

(i) *The maps $d_z(\cdot)$ and $d_z^*(\cdot)$ are linear and adjoint to each other.*

(ii) *For every point (γ_1, γ_2) in $\mathbb{R}^2$,*

$$d_w d_z^*(\gamma_1,\gamma_2) = \frac{1+\delta}{2}(\gamma_1,\gamma_2) + \frac{1-\delta}{2}(\gamma_2,\gamma_1),$$

where $\delta = \frac{w^T z}{\|w\|\|z\|} \in [-1,1]$. In particular, when $w = z$ we have

$$d_z d_z^*(\gamma_1,\gamma_2) = (\gamma_1,\gamma_2).$$

(iii) *For every point (y,r) in $\mathbb{R}^n \times \mathbb{R}$ such that $y = az$ for some $a \in \mathbb{R}$,*

$$d_z^* d_z(y,r) = (y,r).$$

LEMMA 5.4. *Let A and B be symmetric subsets of $\mathbb{R}^2$. The sets*

$$\mathcal{D}(A) = \{d_z^*(\gamma_1,\gamma_2) | (\gamma_1,\gamma_2) \in A,\ z \neq 0\},$$
$$\mathcal{C}(A) = \{(y,r) | d_z(y,r) \in A \text{ for all } z \neq 0\}$$

satisfy the following properties.

(i) *If A is convex, then*
  (a) *if (x,t) is in $\mathcal{D}(A)$, then $(\delta x, t)$ is in $\mathcal{D}(A)$ for every $\delta \in [-1,1]$.*
  (b) *$\mathcal{D}(A)$ is a convex set.*
  (c) *$\mathcal{D}(A) = \mathcal{C}(A)$.*
  (d) *If B is also convex, then $\operatorname{cl}(\mathcal{D}(A) + \mathcal{D}(B)) = \operatorname{cl}\mathcal{D}(A+B)$.*

(ii) *For any A we have*
  (a) $\operatorname{conv}\mathcal{D}(A) = \mathcal{D}(\operatorname{conv} A)$.
  (b) $\mathcal{D}(\operatorname{cl} A) = \operatorname{cl}\mathcal{D}(A)$.

Proof. Part (i)(a). Let $(x,t) = d_z^*(\gamma_1,\gamma_2)$ for some (γ_1,γ_2) in A and $z \neq 0$. Since the set A is symmetric and convex, (γ_2,γ_1) is in A, and for every $\alpha \in [0,1]$ the convex combination $(\alpha\gamma_1 + (1-\alpha)\gamma_2, \alpha\gamma_2 + (1-\alpha)\gamma_1)$ is in A. Thus,

$$d_z^*\big(\alpha\gamma_1 + (1-\alpha)\gamma_2, \alpha\gamma_2 + (1-\alpha)\gamma_1\big) = \left(\frac{z}{\|z\|}\frac{\gamma_1-\gamma_2}{\sqrt{2}}(2\alpha-1), \frac{\gamma_1+\gamma_2}{\sqrt{2}}\right)$$
$$= (x(2\alpha-1), t) \in \mathcal{D}$$

for all $\alpha \in [0,1]$. Now set $\delta := 2\alpha - 1$.

Part (i)(b). Since A is convex, for any two points (γ_1, γ_2) and (δ_1, δ_2) in A and $\mu \in [0,1]$, we have that $(\mu\gamma_1 + (1-\mu)\delta_1, \mu\gamma_2 + (1-\mu)\delta_2)$ is in A. Thus, for every $z \neq 0$,

$$\left(\frac{z}{\|z\|} \frac{\mu(\gamma_1 - \gamma_2) + (1-\mu)(\delta_1 - \delta_2)}{\sqrt{2}}, \frac{\mu(\gamma_1 + \gamma_2) + (1-\mu)(\delta_1 + \delta_2)}{\sqrt{2}} \right) \in \mathcal{D}. \tag{5.1}$$

Take two points (x^1, t^1) and (x^2, t^2) in $\mathcal{D}$ and a number $\mu \in (0,1)$. We want to show that $(\mu x^1 + (1-\mu)x^2, \mu t^1 + (1-\mu)t^2)$ is also in $\mathcal{D}$. Suppose

$$(x^1, t^1) = d^*_{z^1}(\gamma_1, \gamma_2), \qquad (x^2, t^2) = d^*_{z^2}(\delta_1, \delta_2)$$

for some (γ_1, γ_2) and (δ_1, δ_2) in A, $z^1 \neq 0$, and $z^2 \neq 0$. Set

$$z_\mu := \mu \frac{\gamma_1 - \gamma_2}{\sqrt{2}} \frac{z^1}{\|z^1\|} + (1-\mu) \frac{\delta_1 - \delta_2}{\sqrt{2}} \frac{z^2}{\|z^2\|}$$

and notice that

$$\|z_\mu\| \leq \mu \frac{|\gamma_1 - \gamma_2|}{\sqrt{2}} + (1-\mu) \frac{|\delta_1 - \delta_2|}{\sqrt{2}}.$$

Then

$$\mu(x^1, t^1) + (1-\mu)(x^2, t^2) = \left(z_\mu, \frac{\mu(\gamma_1 + \gamma_2) + (1-\mu)(\delta_1 + \delta_2)}{\sqrt{2}} \right). \tag{5.2}$$

If $z_\mu = 0$, then from (5.1) and part (i)(a) with $\delta = 0$ we see that

$$\mu(x^1, t^1) + (1-\mu)(x^2, t^2) \in \mathcal{D}.$$

Suppose now that $z_\mu \neq 0$. Choose one of the points (γ_1, γ_2), (γ_2, γ_1) in A and one of the points (δ_1, δ_2), (δ_2, δ_1) in A so that, using part (i)(a), inclusion (5.1) becomes

$$\left(\frac{z}{\|z\|} \frac{\mu|\gamma_1 - \gamma_2| + (1-\mu)|\delta_1 - \delta_2|}{\sqrt{2}} \delta, \frac{\mu(\gamma_1 + \gamma_2) + (1-\mu)(\delta_1 + \delta_2)}{\sqrt{2}} \right) \in \mathcal{D}$$

for all $z \neq 0$ and $\delta \in (0,1)$. Let δ be a number in $(0,1)$ such that

$$\frac{\mu|\gamma_1 - \gamma_2| + (1-\mu)|\delta_1 - \delta_2|}{\sqrt{2}} \delta = \|z_\mu\|.$$

Putting this all together we obtain that (5.2) is in $\mathcal{D}$, showing that $\mathcal{D}$ is a convex set.

Part (i)(c). Suppose $(y, r) \in \mathcal{C}$; then $d_z(y, r) \in A$ for all $z \neq 0$. Apply Lemma 5.3(iii) with $a = 0$ and any z if $y = 0$, or with $a = 1$ and $z = y$ if $y \neq 0$, to obtain

$$(y, r) = d^*_z d_z(y, r) = d^*_z(d_z(y, r)) \in \mathcal{D}.$$

This shows that $\mathcal{C} \subseteq \mathcal{D}$.

Suppose now that $(y, r) \in \mathcal{D}$. That is, $(y, r) = d^*_z(\gamma_1, \gamma_2)$ for some (γ_1, γ_2) in A and some $z \neq 0$. Let $\hat{z}$ be an arbitrary nonzero vector and set $\delta := \frac{z^T \hat{z}}{\|z\|\|\hat{z}\|} \in [-1, 1]$. Then by Lemma 5.3(ii) we have

$$d_{\hat{z}}(y, r) = d_{\hat{z}} d^*_z(\gamma_1, \gamma_2) = \frac{1+\delta}{2}(\gamma_1, \gamma_2) + \frac{1-\delta}{2}(\gamma_2, \gamma_1) \in A$$

because A is symmetric and convex. Thus, $\mathcal{D} \subseteq \mathcal{C}$.

Part (i)(d). By part (i)(b) we have that both $\mathcal{D}(A) + \mathcal{D}(B)$ and $\mathcal{D}(A + B)$ are convex sets. It is clear that the latter set is contained in the former:

$$\operatorname{cl}(\mathcal{D}(A) + \mathcal{D}(B)) \supseteq \operatorname{cl}\mathcal{D}(A + B).$$

In order to show that the sets are equal it suffices to show that their support functions are equal. Fix any $x \in \mathbb{R}^n$ and suppose first that $x \neq 0$. In the first and last equality below, we use the fact that A and B are symmetric sets:

$$\begin{aligned}
&\max\{\langle (x,t), (d^*_{z^1}(\gamma_1,\gamma_2) + d^*_{z^2}(\delta_1,\delta_2))\rangle | (\gamma_1,\gamma_2) \in A,\ (\delta_1,\delta_2) \in B,\ z^1 \neq 0,\ z^2 \neq 0\} \\
&\quad = \max\{\langle (x,t), (d^*_x(\gamma_1,\gamma_2) + d^*_x(\delta_1,\delta_2))\rangle | (\gamma_1,\gamma_2) \in A,\ (\delta_1,\delta_2) \in B\} \\
&\quad = \max\{\langle (x,t), d^*_x(\gamma_1+\delta_1, \gamma_2+\delta_2)\rangle | (\gamma_1,\gamma_2) \in A,\ (\delta_1,\delta_2) \in B\} \\
&\quad = \max\{\langle (x,t), d^*_x(\alpha_1,\alpha_2)\rangle | (\alpha_1,\alpha_2) \in A + B\} \\
&\quad = \max\{\langle (x,t), d^*_z(\gamma_1,\gamma_2)\rangle | (\gamma_1,\gamma_2) \in A + B,\ z \neq 0\}.
\end{aligned}$$

The case $x = 0$ is easy.

Part (ii)(a). The inclusion $A \subseteq \operatorname{conv} A$ implies $\mathcal{D}(A) \subseteq \mathcal{D}(\operatorname{conv} A)$. Since the set $\mathcal{D}(\operatorname{conv} A)$ is convex by part (i)(b), we obtain $\operatorname{conv}\mathcal{D}(A) \subseteq \mathcal{D}(\operatorname{conv} A)$. The opposite inclusion $\mathcal{D}(\operatorname{conv} A) \subseteq \operatorname{conv}\mathcal{D}(A)$ is easy.

Part (ii)(b). Let $\{d^*_{x^k}(\gamma_1^k, \gamma_2^k)\}$ be a sequence in $\mathcal{D}(A)$ approaching a vector (z, s). Since the unit sphere in $\mathbb{R}^n$ is compact, we can find a subsequence, denoted again by k, such that $x^k/\|x^k\|$ converges to a unit vector x. For this subsequence we have $|\gamma_1^k - \gamma_2^k| \to \sqrt{2}\|z\|$ and $\gamma_1^k + \gamma_2^k \to \sqrt{2}s$. Consequently, $\{(\gamma_1^k, \gamma_2^k)\}$ is bounded so there is a subsequence, denoted again by k, for which $(\gamma_1^k, \gamma_2^k) \to (\gamma_1, \gamma_2) \in \operatorname{cl} A$. So, the sequence $\{d^*_{x^k}(\gamma_1^k, \gamma_2^k)\}$ approaches $d^*_x(\gamma_1, \gamma_2)$ which is in $\mathcal{D}(\operatorname{cl} A)$. This shows that for an arbitrary set A we have the inclusion $\mathcal{D}(\operatorname{cl} A) \supseteq \operatorname{cl}\mathcal{D}(A)$. The opposite inclusion is easy. □

6. Clarke subdifferential: The Lipschitz case. Suppose that h is a real valued function defined on some subset of $\mathbb{R}^m$. We say that h is *locally Lipschitz* at x in $\mathbb{R}^m$ if there exists a scalar K such that

$$|h(x'') - h(x')| \leq K\|x'' - x'\| \quad \text{for all } x'', x' \text{ close to } x.$$

For locally Lipschitz functions, the *Clarke directional derivative* [4] at the point x in the direction v is defined as

$$h^\circ(x; v) = \limsup_{y \to x;\, \lambda \downarrow 0} \frac{h(y + \lambda v) - h(y)}{\lambda}.$$

For y close to x and λ close to 0, the difference quotient in the definition of $h^\circ(x; v)$ is bounded above by $K|v|$. Thus, $h^\circ(x; v)$ is well defined and finite. We need the following formula for the Clarke directional derivative, which can be found in [4, p. 64]:

$$h^\circ(x; v) = \limsup_{y \to x} \{\langle \nabla h(y), v\rangle \mid y \text{ is such that } \nabla h(y) \text{ exists}\}^1 \tag{6.1}$$

for every pair $(x; v)$. In other words, there exists a sequence $\{x^k\}$ in $\mathbb{R}^m$ approaching x such that f is differentiable at each x_n and

$$\langle \nabla h(x^k), v\rangle \to h^\circ(x; v). \tag{6.2}$$

[1] By Rademacher's theorem, locally Lipschitz functions are differentiable almost everywhere.

The *Clarke subdifferential* $\partial^c h(x)$ is defined as

$$\partial^c h(x) = \{\xi \,|\, \langle v, \xi\rangle \le h^\circ(x; v) \text{ for all } v\}.$$

In can be shown that the set $\partial^c h(x)$ is compact, nonempty, and convex. If h is convex and finite on a neighborhood of x, then $\partial^c h(x) = \partial h(x)$, and if h is continuously differentiable at x, then $\partial^c h(x) = \{\nabla h(x)\}$. In this sense the Clarke subdifferential generalizes both the convex subdifferential and the gradient of a C^1 function. Finally, Proposition 2.1.2 in [4] shows that the Clarke directional derivative is the *support function* of the Clarke subdifferential:

$$h^\circ(x; v) = \max\{\langle v, \xi\rangle \,|\, \xi \in \partial^c h(x)\}. \tag{6.3}$$

Now, we return to the symmetric, bivariate function f, which we now require to be locally Lipschitz. It is not difficult to see that f is locally Lipschitz if and only if $f \circ \beta$ is locally Lipschitz. We will present a formula expressing the Clarke subdifferential of $f \circ \beta$ in terms of the Clarke subdifferential of f.

The following elementary lemma shows that the Clarke directional derivative of $h \circ \beta$ is invariant under Lorentz orthogonal transformations of the argument and the direction.

LEMMA 6.1. *Let (x, t) be a point in the domain of $f \circ \beta$, let (y, r) be a direction, and let U be an orthogonal matrix. Then*

$$(f \circ \beta)^\circ((x, t); (y, r)) = (f \circ \beta)^\circ((Ux, t); (Uy, r)).$$

THEOREM 6.2 (Clarke directional derivative). *Let $(0, t)$ be a point in the domain of $f \circ \beta$ and let (y, r) be any direction. Then if $x = 0$,*

$$(f \circ \beta)^\circ((0, t); (y, r)) = \max\{f^\circ(\beta(0, t); d_z(y, r)) | z \in \mathbb{R}^n,\ z \ne 0\}. \tag{6.4}$$

Note 6.3. For the Clarke directional derivative at a point (x, t) with $x \ne 0$, see Corollary 6.6.

Proof. By (6.2), there is a sequence of points $\{(x^k, t^k)\}$ approaching $(0, t)$ such that

$$(f \circ \beta)^\circ((0, t); (y, r)) = \lim_{k\to\infty} \langle \nabla(f \circ \beta)(x^k, t^k), (y, r)\rangle.$$

In order to evaluate $\nabla(f \circ \beta)$ using Theorem 4.1 we need to consider two cases, depending on whether x^k is zero or not. The general situation follows from these two cases by considering subsequences.

Case 1.a. Suppose $x^k = 0$ for all k. Let $\beta^k := \beta(0, t^k)$ and note that $f_1'(\beta^k) = f_2'(\beta^k)$. Fix an arbitrary nonzero vector $z \in \mathbb{R}^n$. Then

$$\begin{aligned}
(f \circ \beta)^\circ((0, t); (y, r)) &= \lim_{k\to\infty} \langle \nabla(f \circ \beta)(0, t^k), (y, r)\rangle \\
&= \lim_{k\to\infty} \left\langle \left(0, \dots, 0, \frac{f_1'(\beta^k) + f_2'(\beta^k)}{\sqrt{2}}\right), (y, r) \right\rangle \\
&= \lim_{k\to\infty} \langle \nabla f(\beta^k), \beta(0, r)\rangle \\
&= \lim_{k\to\infty} \left\langle \nabla f(\beta^k), d_z(y, r)\right\rangle \\
&\le f^\circ(\beta(0, t); d_z(y, r)).
\end{aligned}$$

In the last inequality we used (6.1).

Case 1.b. Suppose $x^k \neq 0$ for all k, $\lim_{k\to\infty} \frac{x^k}{\|x^k\|} = \frac{z}{\|z\|}$, and let $\beta^k := \beta(x^k, t^k)$. Then we have

$$\begin{aligned}
(f\circ\beta)^\circ((0,t);(y,r)) &= \lim_{k\to\infty} \langle \nabla(f\circ\beta)(x^k,t^k),(y,r)\rangle \\
&= \lim_{k\to\infty} \left\langle \left(\frac{f_1'(\beta^k) - f_2'(\beta^k)}{\sqrt{2}\|x^k\|} x^k, \frac{f_1'(\beta^k)+f_2'(\beta^k)}{\sqrt{2}} \right), (y,r) \right\rangle \\
&= \lim_{k\to\infty} \frac{f_1'(\beta^k) - f_2'(\beta^k)}{\sqrt{2}\|x^k\|} (x^k)^T y + \frac{f_1'(\beta^k)+f_2'(\beta^k)}{\sqrt{2}} r \\
&= \lim_{k\to\infty} f_1'(\beta^k)\left(\frac{r}{\sqrt{2}} + \frac{(x^k)^T y}{\sqrt{2}\|x^k\|} \right) + f_2'(\beta^k)\left(\frac{r}{\sqrt{2}} - \frac{(x^k)^T y}{\sqrt{2}\|x^k\|} \right) \\
&= \lim_{k\to\infty} \left\langle \nabla f'(\beta^k), d_z(y,r) \right\rangle \\
&\leq f^\circ(\beta(0,t); d_z(y,r)),
\end{aligned}$$

where, in substituting $x^k/\|x^k\|$ by $z/\|z\|$ in the last equality, we used the fact that since f is locally Lipschitz the sequence $\{(f_1'(\beta^k), f_2'(\beta^k)\}$ is bounded. All this shows that if $x = 0$, then

$$(f\circ\beta)^\circ((0,t);(y,r)) \leq \sup\{f^\circ(\beta(0,t); d_z(y,r)) | z \in \mathbb{R}^n,\ z \neq 0\}.$$

To show the opposite inequality, fix a nonzero vector $z \in \mathbb{R}^n$. There is a sequence of points $\{(a_k, b_k)\}$ approaching $\beta(0,t)$ such that

$$f^\circ(\beta(0,t); d_z(y,r)) = \lim_{n\to\infty} \langle \nabla f(a_k,b_k), d_z(y,r)\rangle.$$

There is an infinite subsequence $\{(a_{k'}, b_{k'})\}$ of $\{(a_k,b_k)\}$ that satisfies one of the following three possibilities:

(i) $a_{k'} = b_{k'}$ for all k'.
(ii) $a_{k'} > b_{k'}$ for all k'.
(iii) $a_{k'} < b_{k'}$ for all k'.

For this subsequence we still have

$$f^\circ(\beta(0,t); d_z(y,r)) = \lim_{k'\to\infty} \langle \nabla f(a_{k'}, b_{k'}), d_z(y,r)\rangle.$$

Without loss of generality, we may assume that $\{(a_k,b_k)\}$ satisfies one of the three possibilities and we may consider them separately.

Case 2.a. Suppose $a_k = b_k$ for all k. Note that in this case we have $f_1'(a_k,a_k) = f_2'(a_k,a_k)$. Thus,

$$\begin{aligned}
f^\circ(\beta(0,t); d_z(y,r)) &= \lim_{k\to\infty} \langle \nabla f(a_k,a_k), d_z(y,r)\rangle \\
&= \lim_{k\to\infty} \frac{f_1'(a_k,a_k)+f_2'(a_k,a_k)}{\sqrt{2}} r \\
&= \lim_{k\to\infty} \langle \nabla(f\circ\beta)(0,a_k),(y,r)\rangle \\
&\leq (f\circ\beta)^\circ((0,t);(y,r)).
\end{aligned}$$

Case 2.b. Suppose $a_k > b_k$ for all k. Define the sequence of vectors

$$z^k := \left(\frac{a_k - b_k}{2}, 0, \ldots, 0 \right) \in \mathbb{R}^n$$

(notice that $\|z^k\| = (a_k - b_k)/2$) and let U be an orthogonal matrix such that

$$\lim_{k\to\infty} \frac{Uz^k}{\|z^k\|} = \frac{z}{\|z\|}. \tag{6.5}$$

In the third equality below, we use the fact that the Lipschitzness of f implies that the sequence $\{f_1'(a_k,b_k) - f_2'(a_k,b_k)\}$ is bounded, and thus in the limit we can replace $z/\|z\|$ by $Uz^k/\|z^k\|$. We calculate

$$\begin{aligned}
f^\circ(\beta(0,t); d_z(y,r)) &= \lim_{k\to\infty} \langle \nabla f(a_k,b_k), d_z(y,r)\rangle \\
&= \lim_{k\to\infty} \left\langle \frac{f_1'(a_k,b_k) - f_2'(a_k,b_k)}{\sqrt{2}\|z\|} z, y \right\rangle + \frac{f_1'(a_k,b_k) + f_2'(a_k,b_k)}{\sqrt{2}} r \\
&= \lim_{k\to\infty} \left\langle \frac{f_1'(a_k,b_k) - f_2'(a_k,b_k)}{\sqrt{2}\|z^k\|} z^k, U^T y \right\rangle + \frac{f_1'(a_k,b_k) + f_2'(a_k,b_k)}{\sqrt{2}} r \\
&= \lim_{k\to\infty} \left\langle \nabla(f\circ\beta)\left(\frac{a_k - b_k}{\sqrt{2}}, 0, \ldots, 0, \frac{a_k + b_k}{\sqrt{2}}\right), (U^T y, r) \right\rangle \\
&\le (f\circ\beta)^\circ((0,t); (U^T y, r)) \\
&= (f\circ\beta)^\circ((0,t); (y,r)).
\end{aligned}$$

In the last equality we used Lemma 6.1.

Case 2.c. Suppose $a_k < b_k$ for all k. Define the sequence of vectors

$$z^k := \left(\frac{b_k - a_k}{2}, 0, \ldots, 0\right) \in \mathbb{R}^n$$

(notice that $\|z^k\| = (b_k - a_k)/2$) and proceed analogously to the previous case. ∎

It is straightforward to check that for every $(y,r) \in \mathbb{R}^n \times \mathbb{R}$, and every nonzero $x \in \mathbb{R}^n$, we have

$$\lim_{(x',t')\to(x,t),\, \mu\downarrow 0} \frac{\beta((x',t') + \mu(y,r)) - \beta(x',t')}{\mu} = d_x(y,r).$$

Applying [3, Theorem 6.2.3] to the Lipschitz map $\beta(x,t)$, we obtain the following result.

LEMMA 6.4. *If $x \neq 0$, then $\beta(x,t)$ is strictly differentiable and its strict derivative is the linear map d_x. That is,*

$$\lim_{\substack{(x',t'),\,(x'',t'')\to(x,t)\\ (x',t')\neq(x'',t'')}} \frac{\beta(x',t') - \beta(x'',t'') - d_x(x'-x'', t'-t'')}{\|(x'-x'', t'-t'')\|} = 0.$$

We now turn our attention to the problem of characterizing the Clarke subdifferential $\partial^c(f\circ\beta)(x,t)$.

THEOREM 6.5. *The Clarke subgradient at (x,t) of a Lorentz invariant function $f\circ\beta$, locally Lipschitz at (x,t), is given by the following formulae:*

(i) *If $x \neq 0$, then*

$$\partial^c(f\circ\beta)(x,t) = \{d_x^*(\gamma_1,\gamma_2) \,|\, (\gamma_1,\gamma_2) \in \partial^c f(\beta(x,t))\};$$

(ii) *if $x = 0$, then*

$$\partial^c(f\circ\beta)(0,t) = \{d_z^*(\gamma_1,\gamma_2) \,|\, (\gamma_1,\gamma_2) \in \partial^c f(\beta(0,t)),\ z \neq 0\}.$$

Proof. Case (i). Suppose that $x \neq 0$. Then, by Lemma 6.4, β is strictly differentiable at (x,t) with strict derivative d_x. Moreover, d_x is a surjective linear map. So we can apply the chain rule for the Clarke subdifferential [4, Theorem 2.3.10], which in our situation holds with equality:

$$\partial^c(f \circ \beta)(x,t) = \partial^c f(\beta(x,t)) \circ d_x.$$

Now, if $(v,p) \in \partial^c(f \circ \beta)(x,t)$ and $(y,r) \in \mathbb{R}^n \times \mathbb{R}$, then there is a subgradient $(\gamma_1,\gamma_2) \in \partial^c f(\beta(x,t))$ such that

$$\langle (v,p),(y,r)\rangle = ((\gamma_1,\gamma_2) \circ d_x)(y,r) = \langle (\gamma_1,\gamma_2), d_x(y,r)\rangle = \langle d_x^*(\gamma_1,\gamma_2),(y,r)\rangle,$$

where the last equality follows by Lemma 5.3. So

$$\partial^c(f \circ \beta)(x,t) \subseteq \{d_x^*(\gamma_1,\gamma_2) | (\gamma_1,\gamma_2) \in \partial^c f(\beta(x,t))\};$$

the other inclusion is now clear.

Case (ii). Suppose that $x = 0$ and define

$$\mathcal{D} := \{d_z^*(\gamma_1,\gamma_2) | (\gamma_1,\gamma_2) \in \partial^c f(\beta(0,t)),\ z \neq 0\}.$$

Two closed, convex sets are equal whenever their support functions are the same. The support function for the set $\operatorname{conv}\mathcal{D}$, evaluated at (y,r), is

$$\begin{aligned}
&\max\{\langle (y,r),(z,s)\rangle \,|\, (z,s) \in \operatorname{conv}\mathcal{D}\} \\
&\quad = \max\{\langle (y,r),(z,s)\rangle \,|\, (z,s) \in \mathcal{D}\} \\
&\quad = \max\{\langle (y,r), d_z^*(\gamma_1,\gamma_2)\rangle \,|\, (\gamma_1,\gamma_2) \in \partial^c f(\beta(0,t)),\ z \neq 0\} \\
&\quad = \max\{\langle d_z(y,r),(\gamma_1,\gamma_2)\rangle \,|\, (\gamma_1,\gamma_2) \in \partial^c f(\beta(0,t)),\ z \neq 0\} \\
&\quad = \max\{\max\{\langle d_z(y,r),(\gamma_1,\gamma_2)\rangle \,|\, (\gamma_1,\gamma_2) \in \partial^c f(\beta(0,t))\} \,|\, z \neq 0\} \\
&\quad = \max\{f^\circ(\beta(0,t); d_z(y,r)) \,|\, z \neq 0\} \\
&\quad = (f \circ \beta)^\circ((0,t);(y,r)),
\end{aligned}$$

where, in the last two equalities, we used (6.3) and Theorem 6.2. By (6.3), again applied to the function $f \circ \beta$, we obtain

$$\operatorname{cl}\operatorname{conv}\mathcal{D} = \partial^c(f \circ \beta)(0,t)$$

because $\partial^c(f \circ \beta)(x,t)$ is a closed convex set [4, Proposition 2.1.2]. The fact that $\operatorname{conv}\mathcal{D} = \mathcal{D}$ follows from Lemma 5.4(i)(b) and the fact that $\mathcal{D}$ is closed follows by Lemma 5.4(ii)(b). □

COROLLARY 6.6 (Clarke directional derivative). *Let (x,t) be a point in the domain of $f \circ \beta$ and let (y,r) be a direction in $\mathbb{R}^n \times \mathbb{R}$. Then if $x \neq 0$,*

$$(f \circ \beta)^\circ((x,t);(y,r)) = f^\circ(\beta(x,t); d_x(y,r)).$$

Proof. Use again the fact that $(f \circ \beta)^\circ((x,t);(y,r))$ is the support function of $\partial^c(f \circ \beta)(x,t)$; see [4, Proposition 2.1.2]. □

7. Second-order properties. In this section, we let f be twice differentiable at the point (a,b). This means that f is differentiable in a neighborhood of this point, and the first derivative, ∇f, is differentiable again at (a,b). The question that we are going to answer now is whether $g := f \circ \beta$ is twice differentiable at any point (x,t) such that $\beta(x,t) = (a,b)$. Elementary calculus shows that, if $x \neq 0$, then g is twice differentiable. It turns out that this is always the case, as we prove in Theorem 7.1. A generalization of Theorems 7.1 and 7.2 to the setting of formally real Jordan algebras can be found in [25]. Our approach is direct and first appeared in [21].

7.1. Second-order differentiability.

THEOREM 7.1. *The function $g := f \circ \beta$ is twice differentiable at (x,t) if and only if f is twice differentiable at $\beta(x,t)$. In that case, we have the following:*

(i) *If $x \neq 0$, then*

$$\begin{aligned}
g''_{x_i x_j}(x,t) &= \frac{x_i x_j}{2\|x\|^2}(f''_{11} - f''_{12} - f''_{21} + f''_{22}) + \frac{\delta_{ij}\|x\|^2 - x_i x_j}{\sqrt{2}\|x\|^3}(f'_1 - f'_2),\\
g''_{tx_i}(x,t) &= \frac{x_i}{2\|x\|}(f''_{11} - f''_{12} + f''_{21} - f''_{22}),\\
g''_{x_i t}(x,t) &= \frac{x_i}{2\|x\|}(f''_{11} + f''_{12} - f''_{21} - f''_{22}),\\
g''_{tt}(x,t) &= \frac{1}{2}(f''_{11} + f''_{12} + f''_{21} + f''_{22}),
\end{aligned}$$

where δ_{ij} is 1 if $i = j$ and 0 otherwise;

(ii) *if $x = 0$, then*

$$\begin{aligned}
g''_{x_i x_j}(0,t) &= \begin{cases} \frac{1}{2}(f''_{11} - f''_{12} - f''_{21} + f''_{22}) & \text{if } i = j,\\ 0 & \text{otherwise,}\end{cases}\\
g''_{tx_i}(0,t) &= 0,\\
g''_{x_i t}(0,t) &= 0,\\
g''_{tt}(0,t) &= \frac{1}{2}(f''_{11} + f''_{12} + f''_{21} + f''_{22}).
\end{aligned}$$

All second-order derivatives of f, in both cases, are evaluated at $\beta(x,t)$.

Proof. The "only if" part follows easily from (1.2).

The verification of part (i) is straightforward. For part (ii) denote

$$\begin{aligned}
H_{ii} &:= \frac{1}{2}(f''_{11} - f''_{12} - f''_{21} + f''_{22}) \ \text{ for } i = 1,\dots,n,\\
H_{tt} &:= \frac{1}{2}(f''_{11} + f''_{12} + f''_{21} + f''_{22}),\\
H &:= \operatorname{Diag}(H_{11},\dots,H_{nn},H_{tt}),
\end{aligned}$$

where the second-order derivatives of f are evaluated at $\beta(0,t)$ and the operator Diag forms a diagonal matrix from its vector argument. Fix an arbitrary sequence $\{h^k\}$ in $\mathbb{R}^n \times \mathbb{R}$ converging to 0 and denote $\bar{h}^k := (h_1^k,\dots,h_n^k)^T$. Using Theorem 4.1 we show that the limit of the difference quotient

$$\lim_{k\to\infty} \frac{\|\nabla g(\bar{h}^k, t + h_{n+1}^k) - \nabla g(0,t) - Hh^k\|}{\|h^k\|}$$

is 0. We consider separately each coordinate in the difference quotient. Two cases are necessary: one for the coordinates from 1 to n and one for the $(n+1)$st coordinate. The sequence $\{h^k\}$ can be partitioned into two subsequences—one in which $\bar{h}^k = 0$ for all k and one in which $\bar{h}^k \neq 0$ for all k. We are done if we show that the limit of the difference quotient for each of the two subsequences is zero. That leads us to consider the following two subcases in each main case.

Subcase (a). Suppose $i \in \{1,\dots,n\}$. Then the difference quotient becomes

$$\lim_{k\to\infty} \frac{|g'_i(\bar{h}^k, t + h_{n+1}^k) - g'_i(0,t) - H_{ii}h_i^k|}{\|h^k\|}. \tag{7.1}$$

We use Theorem 4.1 to evaluate the derivatives g'_i. Notice that if $\bar{h}^k = 0$ for all k, then the limit is clearly 0. Thus, suppose $\bar{h}^k \neq 0$ for all k. Then (7.1) becomes

$$\lim_{k\to\infty} \frac{|\frac{\bar{h}^k}{\sqrt{2}\|\bar{h}^k\|}(f'_1(\beta(\bar{h}^k, t+h^k_{n+1})) - f'_2(\beta(\bar{h}^k, t+h^k_{n+1}))) - \frac{\bar{h}^k}{2}(f''_{11} - f''_{12} - f''_{21} + f''_{22})|}{\|h^k\|},$$

where the second derivatives of f are evaluated at $\beta(0,t)$. Because f'_1 and f'_2 exist in a neighborhood of $\beta(0,t)$ and are differentiable at $\beta(0,t)$, we have

$$f'_1(\beta(\bar{h}^k, t+h^k_{n+1})) \sim f'_1(\beta(0,t)) + f''_{11}(\beta(0,t))\frac{h^k_{n+1} + \|\bar{h}^k\|}{\sqrt{2}} + f''_{12}(\beta(0,t))\frac{h^k_{n+1} - \|\bar{h}^k\|}{\sqrt{2}},$$
$$f'_2(\beta(\bar{h}^k, t+h^k_{n+1})) \sim f'_2(\beta(0,t)) + f''_{21}(\beta(0,t))\frac{h^k_{n+1} + \|\bar{h}^k\|}{\sqrt{2}} + f''_{22}(\beta(0,t))\frac{h^k_{n+1} - \|\bar{h}^k\|}{\sqrt{2}},$$

where $\sim$ indicates that the difference of both sides is of order $o(\|h^k\|)$. Because f is symmetric, at the point $\beta(0,t)$ we have $f'_1 = f'_2$, $f''_{12} = f''_{21}$, and $f''_{11} = f''_{22}$. Substituting the two expansions into the limit shows that it is indeed 0.

Subcase (b). Suppose $i = n+1$. The arguments are analogous to the previous case. We use again Theorem 4.1 to evaluate the derivative g'_t and then substitute f'_1 and f'_2 with their first-order expansions. □

7.2. Continuity of the Hessian.

THEOREM 7.2. *The function $g := f \circ \beta$ is twice continuously differentiable at (x,t) if and only if f is at $\beta(x,t)$.*

Proof. The "only if" direction is also easy to obtain from (1.2). The "if" direction is clear in the case when $x \neq 0$. Thus, we suppose that f is twice continuously differentiable at $\beta(0,t)$ and we show that for any sequence of vectors $\{(x^k, t^k)\}$ in $\mathbb{R}^n \times \mathbb{R}$ approaching $(0,t)$, the Hessian $\nabla^2 g(x^k, t^k)$ is approaching $\nabla^2 g(0,t)$. Viewing, for a fixed basis, $\nabla^2 g(0,t)$ as a matrix, we prove the convergence for each entry. We again consider two cases, and the general situation follows easily from them. If $x^k = 0$ for all k, then the result follows directly from the continuity of $\nabla^2 f$ at the point $\beta(0,t)$; see Theorem 7.1. If $x^k \neq 0$ for all n, then from the continuity of $\nabla^2 f$ at the point $\beta(0,t)$ and the formulae given in Theorem 7.1, we have

$$\lim_{k\to\infty} g''_{x_i t}(x^k, t^k) = \lim_{k\to\infty} g''_{t x_i}(x^k, t^k) = 0,$$
$$\lim_{k\to\infty} g''_{tt}(x^k, t^k) = g''_{tt}(0,t),$$

where we also used the fact that since f is symmetric, $f''_{12} = f''_{21}$ and $f''_{11} = f''_{22}$ at the point $\beta(0,t)$. The interesting part is to show $\lim_{k\to\infty} g''_{x_i x_j}(x^k, t^k) = g''_{x_i x_j}(0,t)$. Denote

$$\beta^k_{+-} := \frac{1}{\sqrt{2}}(t^k + \|x^k\|, t^k - \|x^k\|),$$
$$\beta^k_{++} := \frac{1}{\sqrt{2}}(t^k + \|x^k\|, t^k + \|x^k\|),$$
$$\beta^k_{-+} := \frac{1}{\sqrt{2}}(t^k - \|x^k\|, t^k + \|x^k\|).$$

Because f is symmetric, $f_1'(\beta^k_{-+}) = f_2'(\beta^k_{+-})$. This allows us to evaluate the following limit using the mean value theorem:

$$\begin{aligned}\lim_{k\to\infty} \frac{1}{\sqrt{2}\|x^k\|}\big(f_1'(\beta(x^k,t^k)) - f_2'(\beta(x^k,t^k))\big)&\\ = \lim_{k\to\infty} \frac{1}{\sqrt{2}\|x^k\|}\big(f_1'(\beta^k_{+-}) - f_1'(\beta^k_{++}) + f_1'(\beta^k_{++}) - f_1'(\beta^k_{-+})\big)&\\ = \lim_{k\to\infty}\left(- f_{12}''\left(\frac{t^k+\|x^k\|}{\sqrt{2}},\nu^k\right) + f_{11}''\left(\mu^k,\frac{t^k+\|x^k\|}{\sqrt{2}}\right)\right)&\\ = \frac{1}{2}\big(f_{11}''(\beta(0,t)) - f_{12}''(\beta(0,t)) - f_{21}''(\beta(0,t)) + f_{22}''(\beta(0,t))\big).&\end{aligned}$$

Above, the numbers ν^k and μ^k are between $\frac{t^k-\|x^k\|}{\sqrt{2}}$ and $\frac{t^k+\|x^k\|}{\sqrt{2}}$, and the last equality uses the continuity of $\nabla^2 f$ and the fact that f is symmetric. Using the formula for $g''_{x_ix_j}$ given in Theorem 7.1, we can see that

$$\begin{aligned}\lim_{k\to\infty} g''_{x_ix_j}(x^k,t^k) &= \frac{\delta_{ij}}{2}\big(f_{11}''(\beta(0,t)) - f_{12}''(\beta(0,t)) - f_{21}''(\beta(0,t)) + f_{22}''(\beta(0,t))\big)\\ &= g''_{x_ix_j}(0,t).\end{aligned}$$

This concludes the proof. ∎

7.3. Positive definite Hessian. We begin with a simple lemma, and the main result of this subsection follows after it.

LEMMA 7.3. *Suppose that function f is continuously differentiable on an open convex subset of $\mathbb{R}^2$ and is strictly convex there. For any point (a,b) in its domain with $a > b$ we have $f_1'(a,b) > f_2'(a,b)$.*

THEOREM 7.4. *Suppose that f is twice continuously differentiable at $\beta(x,t)$. Then $\nabla^2(f\circ\beta)$ is positive definite at the point (x,t) if and only if $\nabla^2 f$ is positive definite at $\beta(x,t)$.*

Proof. Suppose that $\nabla^2 f(\beta(x,t))$ is positive definite. We use the formulae in Theorem 7.1 to give a matrix representation of the Hessian of $f\circ\beta$. Define the $(n+1)\times 2$ matrix:

$$X := \frac{1}{\sqrt{2}}\begin{pmatrix} \frac{x}{\|x\|} & -\frac{x}{\|x\|} \\ 1 & 1 \end{pmatrix}$$

and the $(n+1)\times(n+1)$ matrix:

$$M := \frac{1}{\sqrt{2}\|x\|}\begin{pmatrix} I_n - \frac{xx^T}{\|x\|^2} & 0 \\ 0 & 0 \end{pmatrix},$$

where I_n is the $n\times n$ identity matrix.

Case I. When $x \neq 0$, the Hessian of $f\circ\beta$ can be written as

$$\nabla^2(f\circ\beta)(x,t) = X\nabla^2 f(\beta(x,t))X^T + M\nabla f(\beta(x,t))\begin{pmatrix} 1 \\ -1 \end{pmatrix}.$$

For any nonzero vector (y,r), we have

$$\begin{aligned}(y,r)\big(\nabla^2(f\circ\beta)(x,t)\big)(y,r)^T &= \frac{1}{2}d_x(y,r)\nabla^2 f(\beta(x,t))d_x(y,r)^T\\ &\quad + \frac{1}{\sqrt{2}\|x\|^3}\big(\|y\|^2\|x\|^2 - (x^Ty)^2\big)\big(f_1'(\beta(x,t)) - f_2'(\beta(x,t))\big).\end{aligned}$$

Using Lemma 7.3 we see that the above expression is strictly positive.

Case II. In the case when $x = 0$, the Hessian of $f \circ \beta$ is a diagonal matrix, and the fact that it is positive definite can be easily seen.

In the other direction the result follows from (1.2). □

The proof of the next corollary is virtually the same as [22, Theorem 7.2], so we omit it.

COROLLARY 7.5. *Let C be a symmetric and convex subset of $\mathbb{R}^2$. Let $f : \mathbb{R}^2 \to \mathbb{R}$ be a twice continuously differentiable function defined on C. Then*

$$\min_{(a,b)\in C} \lambda_{\min}(\nabla^2 f(a,b)) = \min_{(x,t)\in\beta^{-1}(C)} \lambda_{\min}(\nabla^2(f\circ\beta)(x,t)). \tag{7.2}$$

Above, $\lambda_{\min}$ denotes the smallest eigenvalue of the matrix in its argument.

Multiplying both sides of (7.2) by -1, we obtain

$$\max_{(a,b)\in C} \lambda_{\max}(\nabla^2 f(a,b)) = \max_{(x,t)\in\beta^{-1}(C)} \lambda_{\max}(\nabla^2(f\circ\beta)(x,t)).$$

8. The regular and proximal subdifferentials. Given a function $h : \mathbb{R}^m \to [-\infty, +\infty]$ and a point x in $\mathbb{R}^m$ at which h is finite, we call a vector y of $\mathbb{R}^m$ a *regular subgradient* of h at x if

$$h(x+z) \geq h(x) + \langle y, z\rangle + o(\|z\|) \text{ as } z \to 0.$$

The set of regular subgradients is denoted $\hat{\partial}h(x)$ and is called the *regular subdifferential* of h at x. If h is infinite at x, then the set $\hat{\partial}h(x)$ is defined to be empty. It is not difficult to show that it is always a closed and convex set; see [20].

A vector y is called a *proximal subgradient* of the function h at x, a point where $h(x)$ is finite, if there exist $\rho > 0$ and $\delta > 0$ such that

$$h(x+z) \geq h(x) + \langle y, z\rangle - \frac{1}{2}\rho\|z\|^2 \quad \text{when } \|z\| \leq \delta.$$

The set of all proximal subgradients will be denoted $\partial_p h(x)$. If h is infinite at x, then the set $\partial_p h(x)$ is defined to be empty. It is not difficult to show that it is always a closed and convex set; see [5].

Now let f be the symmetric, bivariate function on $\mathbb{R}^2$ and $g := f \circ \beta$. We are going to derive a formula for $\hat{\partial}g(x,t)$ in terms of $\hat{\partial}f(\beta(x,t))$. The next lemma lists several properties of the map $\beta(x,t)$ that we need. By $\mathbb{R}^n_{\geq}$ we denote the cone of vectors x in $\mathbb{R}^n$ satisfying $x_1 \geq x_2 \geq \cdots \geq x_n$.

LEMMA 8.1.

(i) *For any vector w in $\mathbb{R}^2_{\geq}$, the function $w^T\beta$ is convex and any point (x,t) in $\mathbb{R}^n \times \mathbb{R}$ satisfies $d^*_x(w) \in \partial(w^T\beta)(x,t)$.*

(ii) *The directional derivative $\beta'((x,t);(y,r))$ is given by*

$$\beta'((x,t);(y,r)) = \begin{cases} d_x(y,r) & \text{if } x \neq 0, \\ \beta(y,r) & \text{if } x = 0. \end{cases}$$

(iii) *The map β is Lipschitz with global constant* 1.

(iv) *Given a point (x,t) in $\mathbb{R}^n \times \mathbb{R}$, all vectors (z,s) close to zero satisfy*

$$\beta((x,t)+(z,s)) = \beta(x,t) + \beta'((x,t);(z,s)) + O(\|(z,s)\|^2).$$

Proof. (i) The convexity is elementary. To check the second half we need to verify that

$$w^T\beta(y,r) - w^T\beta(x,t) \geq \langle d_x^*(w_1,w_2), (y-x, r-t)\rangle,$$

which expanded and simplified is equivalent to

$$\frac{w_1-w_2}{\sqrt{2}}(\|y\| - \|x\|) \geq \frac{x^T(y-x)}{\|x\|}\frac{w_1-w_2}{\sqrt{2}}.$$

After cancellation, the last inequality follows from the Cauchy–Schwarz inequality.

(ii) This part is a straightforward verification.

(iii) For any points (x,t) and (z,s) we have

$$\begin{aligned}
&\|\beta((x,t)+(z,s)) - \beta(x,t)\| \\
&\quad = \frac{1}{\sqrt{2}}\|(t+s+\|x+z\|, t+s-\|x+z\|) - (t+\|x\|, t-\|x\|)\| \\
&\quad = \frac{1}{\sqrt{2}}\|(s+\|x+z\|-\|x\|, s-(\|x+z\|-\|x\|))\| \\
&\quad = \sqrt{s^2+(\|x+z\|-\|x\|)^2} \\
&\quad \leq \sqrt{s^2+\|z\|^2} \\
&\quad = \|(z,s)\|.
\end{aligned}$$

(iv) Suppose first that $x \neq 0$. Then using part (ii) of this lemma and using the Cauchy–Schwarz inequality several times we get

$$\begin{aligned}
&\|\beta((x,t)+(z,s)) - \beta(x,t) - \beta'((x,t);(z,s))\|^2 \\
&\qquad = \frac{1}{2}\left\|\left(\|x+z\| - \|x\| - \frac{x^Tz}{\|x\|}, -\|x+z\| + \|x\| + \frac{x^Tz}{\|x\|}\right)\right\|^2 \\
&\qquad = \left(\|x+z\| - \|x\| - \frac{x^Tz}{\|x\|}\right)^2 \\
&\qquad = O(\|z\|^4) = O(\|(z,s)\|^4),
\end{aligned}$$

where the penultimate equality holds since $\nabla\|\cdot\|(x) = \frac{x}{\|x\|}$.

The case $x = 0$ is easy. ∎

Let L be a subset of $\mathbb{R}^m$ and fix a point x in $\mathbb{R}^m$. An element d belongs to the *contingent cone* to L at x, denoted $K(L|x)$, if either $d = 0$ or there is a sequence $\{x^k\}$ in L approaching x with $(x^k - x)/\|x^k - x\|$ approaching $d/\|d\|$. The *negative polar* of a subset H of $\mathbb{R}^m$ is the set

$$H^- = \{y \in \mathbb{R}^m | \langle x, y\rangle \leq 0 \text{ for all } x \in H\}.$$

We use the following lemmas from [11]; see Propositions 2.1 and 2.2 there.

LEMMA 8.2. *Given a function $f : \mathbb{R}^m \to [-\infty, +\infty]$ and a point x^0 in $\mathbb{R}^m$, any regular subgradient of f at x^0 is polar to the contingent cone of the level set $L = \{x \in E : f(x) \leq f(x^0)\}$ at x^0; that is,*

$$\hat{\partial} f(x^0) \subset (K(L|x^0))^-.$$

LEMMA 8.3. *If the function $f : \mathbb{R}^m \to [-\infty, +\infty]$ is invariant under a subgroup G of $O(m)$, then any point x in $\mathbb{R}^m$ and transformation g in G satisfy $\hat{\partial} f(gx) = g\hat{\partial} f(x)$. Corresponding results hold for the proximal, approximate horizon and Clarke subgradients (see the next sections).*

We define the action of the orthogonal group $O(n)$ on $\mathbb{R}^n \times \mathbb{R}$ by

$$U.(x,t) = (Ux,t) \text{ for every } U \in O(n).$$

For a fixed point (x,t) in $\mathbb{R}^n \times \mathbb{R}$ we define the orbit

$$O(n).(x,t) = \{(Ux,t) | U \in O(n)\}.$$

If $x \neq 0$, this orbit is just an $n-1$ dimensional sphere with radius $\|x\|$ at level t in $\mathbb{R}^n \times \mathbb{R}$. So it is an $n-1$ dimensional manifold, and one can easily calculate that its tangent and normal spaces at the point (x,t) are

$$\begin{aligned} T_{(x,t)}(O(n).(x,t)) &= \{(y,0) | y^T x = 0\}, \\ N_{(x,t)}(O(n).(x,t)) &= \{(ax,b) | (a,b) \in \mathbb{R}^2\}. \end{aligned}$$

If $x = 0$, then

$$\begin{aligned} T_{(0,t)}(O(n).(0,t)) &= \{0\}, \\ N_{(0,t)}(O(n).(0,t)) &= \mathbb{R}^{n+1}. \end{aligned}$$

Now, using these observations and Lemma 8.2 we can say more about $\hat{\partial}(f \circ \beta)(x,t)$ in the case when $x \neq 0$.

LEMMA 8.4. *If $x \neq 0$ and $(y,r) \in \hat{\partial}(f \circ \beta)(x,t)$, then $(y,r) = (ax,r)$ for some $a \in \mathbb{R}$.*

Proof. If $(y,r) \in \hat{\partial}(f \circ \beta)(x,t)$, then by Lemma 8.2 we have

$$\begin{aligned} (y,r) &\in (K(\{(z,s) | (f \circ \beta)(z,s) \leq (f \circ \beta)(x,t)\} | (x,t)))^- \\ &\subset (K(O(n).(x,t) | (x,t)))^- \\ &= N_{(x,t)}(O(n).(x,t)). \end{aligned}$$

The claim follows from the expression for the normal space above. □

The following is the main theorem of this section.

THEOREM 8.5. *The regular subdifferential of any Lorentz invariant function $f \circ \beta$ at the point (x,t) is given by the following formulae:*

(i) *If $x \neq 0$, then*

$$\hat{\partial}(f \circ \beta)(x,t) = \{d_x^*(\gamma_1, \gamma_2) | (\gamma_1, \gamma_2) \in \hat{\partial} f(\beta(x,t))\};$$

(ii) *if $x = 0$, then*

$$\hat{\partial}(f \circ \beta)(0,t) = \{d_z^*(\gamma_1, \gamma_2) | (\gamma_1, \gamma_2) \in \hat{\partial} f(\beta(0,t)),\ z \neq 0\}.$$

Similar formulae hold for the proximal subdifferential.

Proof. Case (i). This case follows immediately from the chain rule [20, Exercise 10.7].

Case (ii). Let $x = 0$. We show that

$$\hat{\partial}(f \circ \beta)(0,t) = \{(y,r) | d_z(y,r) \in \hat{\partial} f(\beta(0,t)) \text{ for all } z \neq 0\}.$$

The stated version follows from Lemma 5.4(i)(c).

Suppose $(y,r) \in \hat{\partial}(f\circ\beta)(0,t)$, let $z := (z_1,z_2) \in \mathbb{R}^2$ be small, and let w be an arbitrary nonzero vector in $\mathbb{R}^n$. Then

$$\begin{aligned} f(\beta(0,t)+(z_1,z_2)) &= (f\circ\beta)\left((0,t)+\left(\frac{w}{\|w\|}\frac{z_1-z_2}{\sqrt{2}},\frac{z_1+z_2}{\sqrt{2}}\right)\right)\\ &\geq (f\circ\beta)(0,t)+\frac{w^Ty}{\|w\|}\frac{z_1-z_2}{\sqrt{2}}+r\frac{z_1+z_2}{\sqrt{2}}+o(\|z\|)\\ &= f(\beta(0,t))+\langle d_w(y,r),(z_1,z_2)\rangle+o(\|z\|). \end{aligned}$$

Consequently $d_w(y,r) \in \hat{\partial}f(\beta(0,t))$ for all $w \neq 0$.

In the opposite direction suppose that $d_w(y,r) \in \hat{\partial}f(\beta(0,t))$ for all $w \neq 0$. If $y = 0$, then for any vector $(z,s) \in \mathbb{R}^n \times \mathbb{R}$ close to 0 we have

$$\begin{aligned} (f\circ\beta)((0,t)+(z,s)) &= f(\beta(0,t)+(\beta((0,t)+(z,s))-\beta(0,t)))\\ &\geq f(\beta(0,t))+\langle d_w(0,r),(\beta((0,t)+(z,s))-\beta(0,t))\rangle+o(\|(z,s)\|)\\ &= f(\beta(0,t))+rs+o(\|(z,s)\|)\\ &= (f\circ\beta)(0,t)+\langle(0,r),(z,s)\rangle+o(\|(z,s)\|). \end{aligned}$$

Thus, $(0,r) \in \hat{\partial}(f\circ\beta)(0,t)$.

If $y \neq 0$, then for $w = y$ we have $d_y(y,r) \in \hat{\partial}f(\beta(0,t))$. Let $(z,s) \in \mathbb{R}^n \times \mathbb{R}$ be a vector close to 0. Then

$$\begin{aligned} (f\circ\beta)((0,t)+(z,s)) &= f(\beta(0,t)+(\beta((0,t)+(z,s))-\beta(0,t)))\\ &\geq f(\beta(0,t))+\langle d_y(y,r),(\beta((0,t)+(z,s))-\beta(0,t))\rangle+o(\|(z,s)\|)\\ &= f(\beta(0,t))+\|y\|\|z\|+rs+o(\|(z,s)\|)\\ &\geq (f\circ\beta)(0,t)+\langle(y,r),(z,s)\rangle+o(\|(z,s)\|). \end{aligned}$$

Consequently $(y,r) \in \hat{\partial}(f\circ\beta)(0,t)$.

The proof for the proximal subdifferential is essentially identical. □

9. The approximate and horizon subdifferentials. Given a function $h : \mathbb{R}^m \to [-\infty,+\infty]$ and a point x in $\mathbb{R}^m$ at which h is finite, a vector y of $\mathbb{R}^m$ is called an *approximate subgradient* of h at x if there is a sequence of points $\{x^k\}$ in $\mathbb{R}^m$ approaching x with values $h(x^k)$ approaching $h(x)$ and a sequence of regular subgradients y^k in $\hat{\partial}h(x^k)$ approaching y. The set of all approximate subgradients is called the *approximate subdifferential* $\partial h(x)$. A vector y is called a *horizon subgradient* if either $y = 0$ or there is a sequence of points $\{xv\}$ in $\mathbb{R}^m$ approaching x with values $h(x^k)$ approaching $h(x)$, a sequence $\{t^k\}$ of reals decreasing to zero, and a sequence of regular subgradients y^k in $\hat{\partial}h(x^k)$ for which t^ky^k approaches y. The set of all horizon subgradients is denoted $\partial^\infty h(x)$. If h is infinite at x, then the set $\partial h(x)$ is defined to be empty and $\partial^\infty h(x)$ to be $\{0\}$.

Recall that we used the same notation, $\partial h(x)$, for the convex subgradient when h is a convex function. There is no danger of confusion because the subdifferentials coincide when h is a proper, convex function; see [20, Proposition 8.12].

THEOREM 9.1. *The approximate subdifferential of any Lorentz invariant function $f\circ\beta$ at the point (x,t) is given by the following formulae:*

(i) *If $x \neq 0$, then*

$$\partial(f\circ\beta)(x,t) = \{d_x^*(a,b) \mid (a,b) \in \partial f(\beta(x,t))\};$$

(ii) *if* $x = 0$, *then*

$$\partial(f \circ \beta)(0,t) = \{d_z^*(a,b) \,|\, (a,b) \in \partial f(\beta(0,t)),\ z \neq 0\}.$$

Similar formulae hold for the horizon subgradient.

Proof. Part (i) $x \neq 0$. This case follows immediately from the chain rule [20, Exercise 10.7].

Part (ii) $x = 0$. Suppose $(y,r) \in \partial(f \circ \beta)(0,t)$. By definition, there is a sequence of points $\{(x^k,t^k)\}$ approaching $(0,t)$ with $(f\circ\beta)(x^k,t^k)$ approaching $(f\circ\beta)(0,t)$ and a sequence of regular subgradients $(y^k,r^k) \in \hat\partial(f\circ\beta)(x^k,t^k)$ approaching (y,r).

Case 1.a. Suppose $x^k = 0$ for all k. Then Theorem 8.5 says that $(y^k,r^k) = d^*_{z^k}(a_k,a_k)$ such that $(a_k,a_k) \in \hat\partial f(\beta(0,t^k))$ for some $z^k \neq 0$. Since (y^k,r^k) approaches (y,r) we get that $y = 0$ and $a_k \to a := r/\sqrt{2}$. Thus, $(0,r) = (0,\sqrt{2}a) = d_z^*(a,a)$ for any $z \neq 0$ and $(a,a) \in \partial f(\beta(0,t))$.

Case 1.b. Suppose $x^k \neq 0$ for all k. Then Theorem 8.5 says that $(y^k,r^k) = d^*_{x_q}(a_k,b_k)$ such that $(a_k,b_k) \in \hat\partial f(\beta(x^k,t^k))$. Let us choose a subsequence k' for which $x^{k'}/\|x^{k'}\|$ converges to a unit vector z. Then we have that $|a_{k'} - b_{k'}|$ approaches $\sqrt{2}\|y\|$ and $a_{k'} + b_{k'}$ approaches $\sqrt{2}r$, that is, $(a_{k'},b_{k'})$ is a bounded sequence, so if necessary we may choose a convergent subsequence k''. Then $(a_{k''},b_{k''}) \to (a,b) \in \partial f(\beta(0,t))$ and $(y,r) = d_z^*(a,b)$.

Case 1.c. Suppose the sequence x^k has infinitely many elements that are equal to 0 and infinitely many elements that are not equal to 0. Let $\{x^k\} = \{x^{k'}\} \cup \{x^{k''}\}$, where $x^{k'} \neq 0$ and $x^{k''} = 0$. We now choose any of the subsequences k' or k'' and apply the corresponding subcase above.

To show the opposite inclusion, suppose that $(y,r) = d_z^*(a,b)$ for some $(a,b) \in \partial f(\beta(0,t))$ and some $z \neq 0$. By the definition of approximate subgradients there is a sequence (c_k,d_k) approaching $\beta(0,t)$, with $f(c_k,d_k)$ approaching $f(\beta(0,t))$, and a sequence of regular subgradients (a_k,b_k) approaching (a,b) such that $(a_k,b_k) \in \hat\partial f(c_k,d_k)$. We have three possible cases.

Case 2.a. Suppose first that there is an infinite subsequence k' such that $c_{k'} > d_{k'}$ for all k'. Then $d_z^*(c_{k'},d_{k'})$ approaches $d_z^*(\beta(0,t)) = (0,t)$ with $f(c_{k'},d_{k'}) = (f\circ\beta)(d_z^*(c_{k'},d_{k'}))$ approaching $f(\beta(0,t)) = (f\circ\beta)(0,t)$ and regular subgradients $(a_{k'},b_{k'}) \in \hat\partial f(\beta(d_z^*(c_{k'},d_{k'})))$. If we set $z^{k'} := \frac{z}{\|z\|}\frac{c_{k'}-d_{k'}}{\sqrt{2}}$, then Theorem 8.5 says that $d^*_{z^{k'}}(a_{k'},b_{k'}) \in \hat\partial(f\circ\beta)(d_z^*(c_{k'},d_{k'}))$. Notice that $z^{k'}/\|z^{k'}\|$ converges to $z/\|z\|$, so $d^*_{z^{k'}}(a_{k'},b_{k'})$ approaches $d_z^*(a,b) = (y,r)$, and thus (y,r) is in $\partial(f\circ\beta)(0,t)$.

Case 2.b. There is an infinite subsequence k' such that $c_{k'} < d_{k'}$ for all k'. We are going to revert to the previous case. We have that $(y,r) = d^*_{-z}(b,a)$, where $(b,a) \in \partial f(\beta(0,t))$ (see Lemma 8.3) and $z \neq 0$. We are given also that the sequence $(d_{k'},c_{k'})$ approaches $\beta(0,t)$, with $f(d_{k'},c_{k'})$ approaching $f(\beta(0,t))$, and the sequence of regular subgradients $(b_{k'},a_{k'})$ approaches (b,a) and is such that $(b_{k'},a_{k'}) \in \hat\partial f(d_{k'},c_{k'})$ (by Lemma 8.3 again). The rest is analogous to the previous case.

Case 2.c. Suppose finally that there is an infinite subsequence k' such that $c_{k'} = d_{k'}$ for all k'. Then $d_z^*(c_{k'},d_{k'})$ approaches $d_z^*(\beta(0,t)) = (0,t)$, with $f(c_{k'},d_{k'}) = (f\circ\beta)(d_z^*(c_{k'},d_{k'}))$ approaching $f(\beta(0,t)) = (f\circ\beta)(0,t)$ and regular subgradients $(a_{k'},b_{k'}) \in \hat\partial f(\beta(d_z^*(c_{k'},d_{k'})))$. But then by Theorem 8.5 we have that $d_z^*(a_{k'},b_{k'}) \in \hat\partial(f\circ\beta)(0,\sqrt{2}d_{q'})$. Since $d_z^*(a_{k'},b_{k'})$ approaches $d_z^*(a,b)$, we are done.

The proof of the formulae for the horizon subgradient is analogous. ∎

10. Clarke subgradients: The lower semicontinuous case. A function h is caller *lower semicontinuous* if its epigraph $\operatorname{epi} h = \{(x,\alpha) \in \mathbb{R}^n \times \mathbb{R} | h(x) \leq \alpha\}$ is a closed subset of $\mathbb{R}^n \times \mathbb{R}$. Let $C \subset \mathbb{R}^n$ and $\bar{x} \in C$. A vector $v \in \mathbb{R}^n$ is a *regular normal* to C at $\bar{x}$, written $v \in \hat{N}_C(\bar{x})$, if $\operatorname{limsup}_{x \to \bar{x}} \frac{\langle v, x-\bar{x}\rangle}{|x-\bar{x}|} \leq 0$. It is a *normal vector* to C at $\bar{x}$, written $v \in N_C(\bar{x})$, if there is a sequence of points x^k in C approaching $\bar{x}$ and a sequence of regular normals v^k in $\hat{N}_C(x^k)$ approaching v. The set of *Clarke subgradients* of a function h at $\bar{x}$, $\partial^c h(\bar{x})$, is defined by

$$\partial^c h(\bar{x}) = \{v | (v,-1) \in \operatorname{cl}\operatorname{conv} N_{\operatorname{epi} h}(\bar{x}, h(\bar{x}))\}.$$

It can be shown that if h is locally Lipschitz around $\bar{x}$, then this definition coincides with the definition given in section 6, so there is no danger of confusion; see [20, Theorems 9.13(b) and 8.49].

By [20, Theorem 8.9], if h is lower semicontinuous around $\bar{x}$, the following formula holds:

$$N_{\operatorname{epi} h}(\bar{x}, h(\bar{x})) = \{\lambda(v,-1) \,|\, v \in \partial h(\bar{x}),\ \lambda > 0\} \cup \{(v,0) \,|\, v \in \partial^\infty h(\bar{x})\}.$$

The following lemma can be found in [17, Proposition 2.6]. For an independent proof see [15, Lemma 4.1].

LEMMA 10.1. *If h is lower semicontinuous around $\bar{x}$, we have the representation*

$$\partial^c h(\bar{x}) = \operatorname{cl}(\operatorname{conv} \partial h(\bar{x}) + \operatorname{conv} \partial^\infty h(\bar{x})).$$

In particular, when the cone $\partial^\infty h(\bar{x})$ is pointed we have the simpler representation

$$\partial^c h(\bar{x}) = \operatorname{conv} \partial h(\bar{x}) + \operatorname{conv} \partial^\infty h(\bar{x}).$$

It is easy to see that f is lower semicontinuous if and only if $f \circ \beta$ is lower semicontinuous. Our final result is the following theorem.

THEOREM 10.2. *The Clarke subdifferential of any lower semicontinuous, Lorentz invariant function $f \circ \beta$ at the point (x,t) is given by the following formulae:*

(i) *If $x \neq 0$, then*

$$\partial^c(f \circ \beta)(x,t) = \{d_x^*(a,b) \,|\, (a,b) \in \partial^c f(\beta(x,t))\};$$

(ii) *if $x = 0$, then*

$$\partial^c(f \circ \beta)(0,t) = \{d_z^*(a,b) \,|\, (a,b) \in \partial^c f(\beta(0,t)),\ z \neq 0\}.$$

Proof. Suppose first that $x = 0$. Let $A := \partial f(\beta(x,t))$ and $B := \partial^\infty f(\beta(x,t))$. Using Lemmas 5.4 and 10.1 we get

$$\begin{aligned}
\partial^c(f \circ \beta)(x,t) &= \operatorname{cl}(\operatorname{conv} \partial(f \circ \beta)(x,t) + \operatorname{conv} \partial^\infty(f \circ \beta)(x,t)) \\
&= \operatorname{cl}(\operatorname{conv} \mathcal{D}(A) + \operatorname{conv} \mathcal{D}(B)) \\
&= \operatorname{cl}(\mathcal{D}(\operatorname{conv} A) + \mathcal{D}(\operatorname{conv} B)) \\
&= \operatorname{cl} \mathcal{D}(\operatorname{conv} A + \operatorname{conv} B) \\
&= \mathcal{D}(\operatorname{cl}(\operatorname{conv} A + \operatorname{conv} B)) \\
&= \mathcal{D}(\partial^c f(\beta(x,t))).
\end{aligned}$$

The case $x \neq 0$ is analogous. ∎

Acknowledgments. I am very grateful to an anonymous referee for very careful reading of the manuscript and generously providing many useful comments.

STRUCTURAL TOPOLOGY OPTIMIZATION WITH EIGENVALUES*

WOLFGANG ACHTZIGER† AND MICHAL KOČVARA‡

Abstract. The paper considers different problem formulations of topology optimization of discrete or discretized structures with eigenvalues as constraints or as objective functions. We study multiple-load case formulations of minimum volume or weight, minimum compliance problems, and the problem of maximizing the minimal eigenvalue of the structure, including the effect of nonstructural mass. The paper discusses interrelations of the problems and, in particular, shows how solutions of one problem can be derived from solutions of the others. Moreover, we present equivalent reformulations as semidefinite programming problems with the property that, for the minimum volume and minimum compliance problem, each local optimizer of these problems is also a global one. This allows for the calculation of guaranteed global optimizers of the original problems through the use of modern solution techniques of semidefinite programming. For the problem of maximization of the minimum eigenvalue we show how to verify the global optimality and present an algorithm for finding a tight approximation of a globally optimal solution. Numerical examples are provided for truss structures. Both academic and larger-size examples illustrate the theoretical results achieved and demonstrate the practical use of this approach. We conclude with an extension on multiple nonstructural mass conditions.

Key words. eigenvalue optimization, structural optimization, nonlinear semidefinite programming, vibration of structures

1. Introduction.

The subject of this paper is topology optimization of discrete and discretized structures with consideration of free vibrations of the optimal structure. Maximization of the fundamental eigenvalue of a structure is a classic problem in structural engineering. The (generalized) eigenvalue problem typically reads as

$$K(x)w = \lambda(M(x) + M_0)w,$$

where $K(x)$ and $M(x)$ are symmetric and positive semidefinite matrices that continuously (often linearly) depend on the parameter x. The problem has been extensively treated in the engineering literature since the late 1960s; see the papers [24, 21] and the overview [22] summarizing the early development. See also the recent book [26] for an up-to-date bibliography on this subject.

The key difficulty in optimization of structural eigenvalues is the nondifferentiability of the eigenvalues as functions of the design variable x. Many articles in the engineering literature dealing with highly interesting applications use efficient heuristic solution approaches (e.g., [23]). These heuristics are typically based on application-dependent update schemes of the iterates taking some "sensitivity information" into

account mimicking the first order derivative. There are a only few papers using non-heuristic, advanced calculus [25] or the machinery of nondifferentiable optimization [6, 19] to tackle the problems.

In topology optimization there is another serious difficulty coming into play: the fact that components of x can become zero. Notice that in this point topology optimization is different from classic shape optimization. In shape optimization, the design of a structure (a body) is typically described by a sort of parametrization of its boundary, and for each feasible parameter value the corresponding structure can be analyzed by the standard finite element discretization. In contrast to this, (discrete) topology optimization works with a finite element discretization of the whole design space, while the structure itself is given by a material distribution in this space. This means the shape of the structure, the smoothness of its boundary, the number of holes in the structure, the number of finite elements forming the structure, etc., are not predetermined by the user. This results in a set of feasible designs which is enormously rich; it does not require nor does it impose any preliminary knowledge on the resulting design and thus realizes a "free" optimal design process governed solely by the naturally given constraints and physical laws.

The main mathematical difficulty of (discrete) topology optimization is the correct treatment of finite elements which are "empty," i.e., represent holes in the structure. The corresponding matrices $K(x)$ and $M(x)$ then become singular. It seems that this difficulty has not been studied in full mathematical detail so far. The usual way to avoid this singularity is to add an additional constraint, $x \geq \varepsilon > 0$, solve the problem, and interpret the design variables on the lower bounds as zeros. We show in this article that the smallest eigenvalue may be non-Lipschitz and even discontinuous; in certain cases, this fact may cause serious troubles to the above technique.

The general problem of eigenvalue optimization belongs also to classic problems of linear algebra. When the matrix $M(x) + M_0$ is positive definite for all x, then one can resort to the theory developed for the standard eigenvalue problem; see [15] for an excellent overview. Not many papers studying the dependence of the eigenvalues on a parameter are available for the general case when $M(x) + M_0$ is only positive semidefinite; see, e.g., [4, 27, 29].

We present three different formulations of the structural design problem. In the first one we minimize the volume of the structure subject to equilibrium conditions and compliance constraints. Additionally, we require that the fundamental natural frequency of the optimal structure is bigger than or equal to a certain threshold value. The second formulation is analogous; we just switch the volume and the compliance. In the third formulation we maximize the fundamental frequency, i.e., the minimum eigenvalue of certain generalized eigenvalue problem, subject to equilibrium conditions and constraints on the volume and the compliance. Using the semidefinite programming (SDP) framework, we formulate all three problems in a unified way; while the first two problems lead to linear SDP formulations that were already studied earlier [20, 14], the third problem leads to an SDP with a bilinear matrix inequality (BMI) constraint. To our knowledge, the SDP formulation, however straightforward, has never been used for the numerical solution of the third problem. The reason for this was the lack of available SDP-BMI solvers. We solve the problem using the recently developed code PENBMI [10].

We further analyze the mutual relation of our three problems. We show that the problems are in a certain sense equivalent. More precisely, taking a certain specific solution from the solution set of one problem, we get a solution of another problem

with the same data. It is one of the goals of this paper to show that this equivalence does not hold for an arbitrary solution of the problem; this is also illustrated by several numerical examples. Note that there is a common belief that these problems are equivalent. We show that this is not completely true. The equivalence holds only for simplified problems, for instance, when neglecting one of the constraints and assuming that the design variables are strictly positive; see, e.g., [18, p. 212].

An important property of the SDP reformulations of the minimum volume and minimum compliance problem is that each local minimum of any of these problems is also a global minimum. This is not readily seen from the original problem formulations and brings important information to the designer. For the problem of maximization of the minimum eigenvalue we show how to verify the global optimality and present an algorithm for finding an ε-approximation of a globally optimal solution.

Numerical examples conclude the paper. They illustrate the various formulations and theorems developed in the paper and also demonstrate the solvability of the SDP formulations and thus their practical usefulness.

All formulations and theorems in the presentation are developed problems using the discrete structural models, the trusses. This is to keep the notation fixed and simple. The theory also applies to discretized structures, for instance, to the variable thickness sheet or the free material optimization problems [3].

We use standard notation; in particular the notation "$A \succeq 0$" means that the symmetric matrix A is positive semidefinite, and "$A \succ 0$" means that it is positive definite. For two symmetric matrices A, B the notation "$A \succeq B$" ("$A \succ B$") means that $A - B$ is positive semidefinite (positive definite). The $k \times k$ identity matrix is denoted by $I_{k\times k}$; $\ker(A)$ and $\operatorname{range}(A)$ denote the null space and the range space of a matrix A, respectively.

2. Problem definitions, relations.

2.1. Basic notation, generalized eigenvalues. We consider a general mechanical structure, discrete or discretized by the finite element method. The number of members or finite elements is denoted by m. The structure, yet to be optimized, is represented by the vector $x \in \mathbb{R}^m$, $x \geq 0$, of so-called design variables. The meaning of x_i differs from application to application. In truss topology optimization, x_i may represent the volume of a (potential) bar member or its cross-sectional area. In this situation, the m elements form a grid of so-called potential bars which in the classic literature is called a "ground structure" [7, 9]. In discretized problems of continuum topology optimization, x_i may represent the thickness of a sheet. Here the elements refer to a usual finite element discretization, and we must face the difficulty that some of the elements may have zero thickness. In problems of material optimization, x_i may represent a material parameter. Then $x_i = 0$ refers to an extreme material as, e.g., void. Examples of various applications of this modeling can be found in [3]. The total number of "free" degrees of freedom (i.e., not fixed by Dirichlet boundary conditions) is denoted by n. For a given set of n_ℓ (independent) load vectors

$$f_\ell \in \mathbb{R}^n, \quad f_\ell \neq 0, \qquad \ell = 1, \ldots, n_\ell, \tag{1}$$

the structure should satisfy linear equilibrium equations

$$K(x)u_\ell = f_\ell, \qquad \ell = 1, \ldots, n_\ell. \tag{2}$$

Here $K(x)$ is the stiffness matrix of the structure, depending on the design variable x. We will assume linear dependence of K on x,

$$K(x) = \sum_{i=1}^{m} x_i K_i, \tag{3}$$

with $x_i K_i$ being the element stiffness matrices. Note that the stiffness matrix of element (member) e_i is typically defined as

$$x_i K_i = x_i P_i \widehat{K}_i P_i^T, \tag{4}$$

where $P_i P_i^T$ is a projection from $\mathbb{R}^n$ to the space of element (member) degrees of freedom. In other words, $\widehat{K}_i$ is a matrix localized on the particular element, while K_i lives in the full space $\mathbb{R}^n$. Further,

$$x_i \widehat{K}_i = \int_{e_i} x_i B_i^T E_i B_i \, dV,$$

where the rectangular matrix B_i contains derivatives of shape functions of the respective degrees of freedom, and E_i is a symmetric matrix containing information about material properties. To exclude pathological situations, we assume that

$$f_\ell \in \operatorname{range}\left(\sum_{i=1}^{m} K_i\right) \qquad \forall \ell = 1, \dots, n_\ell, \tag{5}$$

which means that there exists a material distribution $x \geq 0$ that can carry all loads f_ℓ (i.e., there exist corresponding $u_1, \dots, u_\ell$ satisfying (2)).

Similarly to the definition of $K(x)$, the mass matrix $M(x)$ of the structure is assumed to be given as

$$M(x) = \sum_{i=1}^{m} x_i M_i, \quad M_i = P_i \widehat{M}_i P_i^T, \tag{6}$$

with element mass matrices

$$x_i \widehat{M}_i = \rho_i \int_{e_i} x_i N_i^T N_i \, dV\,; \tag{7}$$

here N_i contains the shape functions of the degrees of freedom associated with the ith element and ρ_i is the material density.

As already mentioned above, the design variables $x \in \mathbb{R}^m$ represent, for instance, the thickness, cross-sectional area, or material properties of the element. We will assume that

$$x_i \geq 0, \qquad i = 1, \dots, m\,.$$

Notice that the matrices $\widehat{K}_i$, $\widehat{M}_i$ have the properties $\widehat{K}_i \succeq 0$, $\widehat{M}_i \succ 0$, and thus $K(x) \succeq 0$, $M(x) \succeq 0$ for all $x \geq 0$. From a practical point of view, it is worth noticing that the element matrices K_i and M_i are very sparse with only nonzero elements corresponding to degrees of freedom of the ith element. That means, for each i, the matrices K_i and M_i have the same nonzero structure. The matrices $K(x)$, $M(x)$, however, may be dense, in general.

We assume that the discretized structure is connected and the boundary conditions are such that $K(e) \succ 0$ and $M(e) \succ 0$, where e is the vector of all ones. The latter condition simply excludes rigid body movement for any $x > 0$.

In what follows, we will sometimes collect the displacement vectors $u_1, \ldots, u_{n_\ell}$ for all the load cases in one vector,

$$u = (u_1^T, \ldots, u_{n_\ell}^T)^T \in \mathbb{R}^{n \cdot n_\ell},$$

for simplification of the notation.

In this paper we do not rely on any other properties of stiffness and mass matrices than those outlined above. Therefore, the problem formulations and the conclusions apply to a broad class of problems, e.g., to the variable thickness sheet problem or the free material optimization problem [3]. For the sake of transparency, however, we concentrate on a particular class of discrete structures, namely, trusses. A truss is an assemblage of pin-jointed uniform straight bars. The bars are subjected to only axial tension and compression when the truss is loaded at the joints. With a given load and a given set of joints at which the truss is fixed, the goal of the designer is to find a truss that is as light as possible and satisfies the equilibrium conditions. In the simplest, yet meaningful, approach, the number of the joints (nodes) and their position are kept fixed. The design variables are the bar volumes, and the only constraints are the equilibrium equation and an upper bound on the weighted sum of the displacements of loaded nodes, so-called *compliance*. Recently, this model (or its equivalent reformulations) has been extensively analyzed in the mathematical and engineering literature (see, e.g., [1, 3] and the references therein).

In this article, we will additionally consider free vibrations of the optimal structure. The free vibrations are the eigenvalues of the generalized eigenvalue problem

$$K(x)w = \lambda(M(x) + M_0)w\,. \tag{8}$$

The matrix $M_0 \in \mathbb{R}^{n \times n}$ is assumed to be symmetric and positive semidefinite. It denotes the mass matrix of a given nonstructural mass ("dead load"). For the sake of completeness, the choice $M_0 = 0$ is possible and will be treated in more detail below.

In what follows, we use the notation

$$X := \{x \in \mathbb{R}^m \mid x \geq 0,\ x \neq 0\}\,.$$

As a consequence of the construction of $K(x)$ and $M(x)$ we obtain our first result.

LEMMA 2.1. *For each $x \in X$ it holds that*

$$\ker(M(x) + M_0) \subseteqq \ker(K(x))\,.$$

Proof. Let $u \in \mathbb{R}^n$ be in $\ker(M(x) + M_0)$. Then $u^T(M(x) + M_0)u = 0$, that is (see (6)),

$$0 = u^T \left(\sum_{i=1}^m x_i P_i \widehat{M}_i P_i^T + M_0 \right) u = \sum_{i=1}^m x_i (P_i^T u)^T \widehat{M}_i (P_i^T u) + u^T M_0 u\,.$$

Because $\widehat{M}_i \succ 0$ for all i, and because $M_0 \succeq 0$, we conclude that

$$P_i^T u = 0 \qquad \forall i \text{ such that } x_i > 0.$$

Hence, by the definition of $K(x)$ and by (4),

$$K(x)u = \sum_{i=1}^{m} x_i K_i u = \sum_{i=1}^{m} x_i P_i \widehat{K}_i P_i^T u = \sum_{i:\, x_i \neq 0} x_i P_i \widehat{K}_i P_i^T u = 0,$$

and the proof is complete. □

We now want to define a function $\lambda_{\min}$ as the smallest eigenvalue λ of problem (8) for a given structure represented by $x \in X$. Before doing that, we mention the following dilemma in the generalized eigenvalue problem (8). If $x \in X$ is fixed and $(\lambda, w) \in \mathbb{R} \times \mathbb{R}^n$ is a solution of (8) with $w \neq 0$ but $w \in \ker(M(x) + M_0)$, then Lemma 2.1 shows that also $K(x)w = 0$. Hence (μ, w) is also a solution of (8) for arbitrary $\mu \in \mathbb{R}$. In this situation we say that this eigenvalue is *undefined*; otherwise it is *well defined*. Because undefined eigenvalues are meaningless from the engineering point of view, we want to exclude them from our considerations. This leads to the following definition.

DEFINITION 2.2. *For any $x \in X$, let $\lambda_{\min}(x)$ denote the smallest ined eigenvalue of* (8)*, i.e.,*

$$\lambda_{\min}(x) = \min\{\lambda \mid \exists w \in \mathbb{R}^n : \text{ (8) holds for } (\lambda, w) \text{ and } w \notin \ker(M(x) + M_0)\}.$$

This defines a function $\lambda_{\min} : X \longrightarrow \mathbb{R} \cup \{+\infty\}$.

The next proposition collects basic properties of $\lambda_{\min}(\cdot)$.

PROPOSITION 2.3.

(a) *$\lambda_{\min}(\cdot)$ is finite and nonnegative on X.*

(b) *For all $x \in X$,*

$$\lambda_{\min}(x) = \inf_{u:\,(M(x)+M_0)u \neq 0} \frac{u^T K(x) u}{u^T (M(x) + M_0) u}.$$

(c) *For all $x \in X$,*

$$\lambda_{\min}(x) = \sup\{\lambda \mid K(x) - \lambda(M(x) + M_0) \succeq 0\}.$$

(d) *$\lambda_{\min}(\cdot)$ is upper semicontinuous on X.*

(e) *Let $\varepsilon > 0$ be fixed. Then $\lambda_{\min}(\cdot)$ is continuous on $X_\varepsilon := \{x \in \mathbb{R}^m \mid x \geq \varepsilon > 0\}$.*

(f) *$-\lambda_{\min}(\cdot)$ is quasi-convex on X.*

A shorthand version of a proof of this proposition says that in Definition 2.2 we consider a naturally reduced eigenvalue problem which is defined on the space $\ker(A)^\perp$. One can then rely on classic theorems on generalized eigenvalue problems with positive definite matrices. A detailed proof of Proposition 2.3 can be found in Appendix A.1.

For a general $x \in X$ we cannot obtain more than upper semicontinuity of $\lambda_{\min}(\cdot)$ (see Proposition 2.3(d)). The following example shows that $\lambda_{\min}(\cdot)$ may be discontinuous at the boundary of X, when certain components of x are equal to zero.

Example 2.4. Consider the truss depicted in Figure 1. Let the truss be symmetric with respect to (w.r.t.) its horizontal axis, so consider only two design variables, x_1 and x_2. The corresponding stiffness and mass matrix have the following form (where rounded values are displayed for better illustration):

$$K(x) = \begin{pmatrix} x_1 \cdot 2 & 0 & 0 & 0 \\ 0 & x_1 \cdot 2 & 0 & 0 \\ 0 & 0 & x_2 \cdot 1.28 & 0 \\ 0 & 0 & 0 & x_2 \cdot 0.32 \end{pmatrix},$$

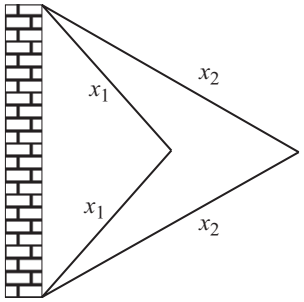

FIG. 1. *Example showing possible discontinuity of* $\lambda_{\min}$.

$$M(x) = \begin{pmatrix} x_1 \cdot 2.83 & 0 & 0 & 0 \\ 0 & x_1 \cdot 2.83 & 0 & 0 \\ 0 & 0 & x_2 \cdot 4.47 & 0 \\ 0 & 0 & 0 & x_2 \cdot 4.47 \end{pmatrix}.$$

The corresponding (unordered) eigenvalues are

$$(\lambda_1, \lambda_2, \lambda_3, \lambda_4) = \Big(\frac{2}{2.83}\frac{x_1}{x_1},\ \frac{2}{2.83}\frac{x_1}{x_1},\ \frac{1.28}{4.47}\frac{x_2}{x_2},\ \frac{0.32}{4.47}\frac{x_2}{x_2} \Big).$$

The function $\lambda_{\min}$ then has the following values:

$$\lambda_{\min}(x) = \frac{0.32}{4.47} \approx 0.07 \quad \text{for } x_2 > 0,$$
$$\lambda_{\min}(x) = \frac{2}{2.83} \approx 0.71 \quad \text{for } x_2 = 0$$

and is thus discontinuous at $x_2 = 0$. The reason for the discontinuity lies in the fact that when $x_2 = 0$ the eigenvalue $\frac{0.32}{4.47}\frac{x_2}{x_2}$ becomes undefined and $\lambda_{\min}$ "jumps" to what was before the second smallest eigenvalue.

Remark 2.5. Example 4.5 will indicate that $\lambda_{\min}(\cdot)$ may not even be Lipschitz continuous near the boundary of X.

2.2. The original formulations. We first give three formulations of the truss design problem that are well known in the engineering literature. These formulations are obtained by just "writing down" the primal requirements and natural constraints.

The minimum volume problem. In the traditional formulation of the truss topology problem, one minimizes the volume or weight of the truss subject to equilibrium conditions and constraints on the smallest eigenfrequency. As mentioned earlier, the meaning of x_i depends on the considered application. Throughout the paper the term $\sum x_i$ is referred to as the "volume" of the structure although its particular interpretation may be different. The term "volume" refers to the truss topology problem where x_i denotes the bar volume of the ith (potential) bar. If $\rho_i > 0$ denotes the density of the material used in this bar, then the substitutions $x_i' := \rho_i x_i$, $K_i' := \frac{1}{\rho_i} K_i$, $M_i' := \frac{1}{\rho_i} M_i$ for all i transform volume into weight. Hence, the following minimum volume problem (and, analogously, all other minimum volume problems in the paper) may be equivalently interpreted as a minimum weight problem, which is of paramount practical interest. In problems of material optimization, x_i may represent a material constant such as Young's modulus of the material in the ith element. In this case $\sum x_i$

represents a simple measure of the total stiffness of the structure. Depending on the precise mechanical meaning of the variables x_i, the matrices K_i and M_i eventually must be scaled by positive constants. Since this does not affect the mathematical properties of these matrices needed in this paper, these modifications are ignored in the following:

$$
\begin{aligned}
(\mathrm{P}_{\mathrm{vol}}) \qquad & \min_{x\in\mathbb{R}^m,\, u\in\mathbb{R}^{n\cdot n_\ell}} \sum_{i=1}^m x_i \\
& \text{subject to } \left(\sum_{i=1}^m x_i K_i\right) u_\ell = f_\ell, \quad \ell = 1,\dots,n_\ell, \\
& \qquad f_\ell^T u_\ell \le \overline{\gamma}, \quad \ell = 1,\dots,n_\ell, \\
& \qquad x_i \ge 0, \quad i = 1,\dots,m, \\
& \qquad \lambda_{\min}(x) \ge \overline{\lambda}\,.
\end{aligned}
$$

Here $\overline{\gamma}$ is a given upper bound on the compliance of the optimal structure and $\overline{\lambda} > 0$ is a given threshold eigenvalue. The simultaneous consideration of constraints on compliance and minimum eigenvalue is useful from a practical point of view. Suitable choices for $\overline{\gamma}$ and $\overline{\lambda}$ are often directly given by technical requirements on the considered application. If a compliance restriction shall not be considered, then $\overline{\gamma}$ formally may be chosen as a very big value. The objective function of this problem is the function $(x,u) \mapsto \sum x_i$. Notice that the eigenvalue constraint is discontinuous (see Example 2.4); this (and not only this) makes the problem rather difficult.

The minimum compliance problem. In this formulation one minimizes the worst-case compliance (maximizes the stiffness) of the truss subject to equilibrium conditions and constraints on the minimum eigenfrequency:

$$
\begin{aligned}
(\mathrm{P}_{\mathrm{compl}}) \qquad & \min_{x\in\mathbb{R}^m, u\in\mathbb{R}^{n\cdot n_\ell}} \max_{1\le\ell\le n_\ell} f_\ell^T u_\ell \\
& \text{subject to } \left(\sum_{i=1}^m x_i K_i\right) u_\ell = f_\ell, \quad \ell = 1,\dots,n_\ell, \\
& \qquad \sum_{i=1}^m x_i \le \overline{V}, \\
& \qquad x_i \ge 0, \quad i = 1,\dots,m, \\
& \qquad \lambda_{\min}(x) \ge \overline{\lambda}\,.
\end{aligned}
$$

Here $\overline{V} > 0$ is an upper bound on the volume of the optimal structure and, again, $\overline{\lambda} > 0$ is a given threshold eigenvalue. For this problem, the objective function is the nonsmooth function $(x,u) \mapsto \max_{1\le\ell\le n_\ell} f_\ell^T u_\ell$. Again, notice that the eigenvalue constraint is not continuous. Moreover, the volume restriction may be formally skipped by choosing $\overline{V}$ very large.

The problem of maximizing the minimal eigenvalue. Here we want to maximize the smallest eigenvalue of (8) subject to equilibrium conditions and constraints on the compliance and volume. Maximization of the smallest eigenfrequency

is of paramount importance in many industrial application, e.g., in civil engineering:

$$
\begin{aligned}
(\mathrm{P}_{\mathrm{eig}}) \qquad & \max_{x\in\mathbb{R}^m, u_\ell\in\mathbb{R}^n} \lambda_{\min}(x) \\
& \text{subject to } \left(\sum_{i=1}^m x_i K_i\right) u_\ell = f_\ell, \quad \ell = 1,\dots,n_\ell, \\
& \qquad f_\ell^T u_\ell \le \overline{\gamma}, \quad \ell = 1,\dots,n_\ell, \\
& \qquad \sum_{i=1}^m x_i \le \overline{V}, \\
& \qquad x_i \ge 0, \quad i = 1,\dots,m\,.
\end{aligned}
$$

Here the objective function is $(x,u) \mapsto \lambda_{\min}(x)$, which is a possibly discontinuous function. This discontinuity is the reason that a standard perturbation approach widely used by practitioners for the solution of $(\mathrm{P}_{\mathrm{eig}})$ may fail. If, with some small $\epsilon > 0$, the nonnegativity constraints are replaced by the constraints $x_i \ge \varepsilon$ for all i, and if x_ε^* denotes a solution of this perturbed problem (together with some u_ε^*), then x_ε^* may not converge to some solution x^* of the unperturbed problem (see Example 2.4 above).

We mention that each of the above three problems has already been considered in the literature with more or less small modifications, and that all problems find valuable interest in practical applications (see [22, 26, 15]). To the best of our knowledge, however, a rigorous treatment of these problems in the situation of positive semidefinite matrices K and M (i.e., permitting $x_i = 0$ for some i, as needed in topology optimization) has not been considered so far.

2.3. Interrelations of original formulations for $M_0 = 0$. In this section we study relations of the three problems $(\mathrm{P}_{\mathrm{vol}})$, $(\mathrm{P}_{\mathrm{compl}})$, and $(\mathrm{P}_{\mathrm{eig}})$ when $M_0 = 0$. These relations are directly given by rescaling arguments but will also appear as special cases of problems with arbitrary M_0 treated in the next section. Note that in the following theorems we do not discuss the *existence* of solutions. Instead, we discuss their interrelations when existence is guaranteed. We start with an auxiliary result.

LEMMA 2.6. *Let $(x,u) \in \mathbb{R}^m \times \mathbb{R}^{n\cdot n_\ell}$, $x \ge 0$, satisfy the equilibrium condition*

$$K(x)u_\ell = f_\ell \tag{9}$$

for some load vector f_ℓ. Then $f_\ell^T u_\ell > 0$ and $\sum_{i=1}^m x_i > 0$.

Proof. Because each of the matrices K_i is symmetric and positive semidefinite, it is clear that $f_\ell^T u_\ell = u_\ell^T K(x) u_\ell \ge 0$. Assume that $f_\ell^T u_\ell = 0$. Then $u_\ell^T K(x) u_\ell = 0$, and simple linear algebra shows that

$$K(x)u_\ell = 0_{\mathbb{R}^n}\,. \tag{10}$$

Equation (10), however, is a contradiction of the assumptions (9) and (1). If $\sum_{i=1}^m x_i = 0$, then $x = 0$, and the contradiction to (9) and (1) is obvious. ∎

Next we observe that the function $\lambda_{\min}(\,.\,)$ is independent of scaling of the structure, provided $M_0 = 0$. Recall that $\lambda_{\min}(x)$ is a well-defined nonnegative number for any $x \in X$ (see Proposition 2.3(a)).

LEMMA 2.7. *Let $M_0 = 0$ and $x \ge 0$ be any vector. Then*

$$\lambda_{\min}(\mu x) = \lambda_{\min}(x) \qquad \forall \mu > 0.$$

Proof. Because $K(\cdot)$ and $M(\cdot)$ are linear functions, the eigenvalue equation $K(\mu x)v = \lambda M(\mu x)v$ is equivalent to $K(x)v = \lambda M(x)v$ for all $\mu > 0$. ∎

We first show that each solution of $(\mathrm{P}_{\mathrm{vol}})$ immediately leads to a solution of $(\mathrm{P}_{\mathrm{compl}})$.

THEOREM 2.8. *Let $M_0 = 0$ and (x^*, u^*) be a solution of $(\mathrm{P}_{\mathrm{vol}})$.*

(a) *Then $\max_{1\le\ell\le n_\ell} f_\ell^T u_\ell^* = \overline{\gamma}$.*

(b) *Put $\overline{V} := \sum_{i=1}^m x_i^*$ in problem $(\mathrm{P}_{\mathrm{compl}})$ and copy the value of $\overline{\lambda}$ from problem $(\mathrm{P}_{\mathrm{vol}})$. Then (x^*, u^*) is optimal for $(\mathrm{P}_{\mathrm{compl}})$ with optimal objective function value $\overline{\gamma}$.*

Proof. For the proof of (a), denote

$$\gamma^* := \max_{1\le\ell\le n_\ell} f_\ell^T u_\ell^*.$$

We must show that $\gamma^* = \overline{\gamma}$. Due to Lemma 2.6 we have

$$\gamma^* > 0 \qquad \text{and} \qquad V^* := \sum x_i^* > 0.$$

Consider the couple

$$(\tilde{x}^*, \tilde{u}^*) := \Big(\frac{\gamma^*}{\overline{\gamma}}\, x^*,\ \frac{\overline{\gamma}}{\gamma^*}\, u^*\Big);$$

by the definition of γ^* we obtain

$$f_\ell^T \tilde{u}_\ell^* = \frac{\overline{\gamma}}{\gamma^*} f_\ell^T u_\ell^* \le \frac{\overline{\gamma}}{\gamma^*}\,\gamma^* = \overline{\gamma} \qquad \forall \ell = 1, \dots, n_\ell, \tag{11}$$

and, obviously,

$$\left(\sum_{i=1}^m \tilde{x}_i^* K_i\right) \tilde{u}_\ell^* = \frac{\gamma^*\overline{\gamma}}{\overline{\gamma}\gamma^*} \left(\sum_{i=1}^m x_i^* K_i\right) u_\ell^* = f_\ell \qquad \forall \ell = 1, \dots, n_\ell.$$

This, together with Lemma 2.7, shows that $(\tilde{x}^*, \tilde{u}^*)$ is feasible for $(\mathrm{P}_{\mathrm{vol}})$. Hence optimality of (x^*, u^*) in $(\mathrm{P}_{\mathrm{vol}})$ yields

$$V^* \le \sum_{i=1}^m \tilde{x}_i^* = \frac{\gamma^*}{\overline{\gamma}} \sum_{i=1}^m x_i^* = \frac{\gamma^*}{\overline{\gamma}} V^*.$$

Because $V^* > 0$, this means

$$\overline{\gamma} \le \gamma^*.$$

Equation (11), however, shows that $\gamma^* \le \overline{\gamma}$. All in all, we arrive at $\gamma^* = \overline{\gamma}$, as stated in (a).

Now we prove (b). Due to the choice of $\overline{V}$ it is clear that (x^*, u^*) is feasible for problem $(\mathrm{P}_{\mathrm{compl}})$. Moreover, (a) shows that the corresponding objective function value is $\overline{\gamma}$. Let (x, u) be an arbitrary feasible point of $(\mathrm{P}_{\mathrm{compl}})$. Lemma 2.6 shows that the value $\gamma := \max_{1\le\ell\le n_\ell} f_\ell^T u_\ell$ is positive, and hence the couple

$$(\tilde{x}, \tilde{u}) := \Big(\frac{\gamma}{\overline{\gamma}}\, x, \frac{\overline{\gamma}}{\gamma}\, u\Big)$$

is well defined. As in (a), we conclude that $(\tilde{x}, \tilde{u})$ is feasible for $(\mathrm{P}_{\mathrm{vol}})$. Optimality of (x^*, u^*) in $(\mathrm{P}_{\mathrm{vol}})$ gives

$$\sum_{i=1}^{m} x_i^* \le \sum_{i=1}^{m} \tilde{x}_i = \frac{\gamma}{\overline{\gamma}} \sum_{i=1}^{m} x_i. \tag{12}$$

Now, $\sum_{i=1}^m x_i^* = \overline{V}$ by the definition of $\overline{V}$, and we have $\sum_{i=1}^m x_i \le \overline{V}$ by the feasibility of (x, u) for $(\mathrm{P}_{\mathrm{compl}})$. Hence (12) becomes $\overline{V} \le \frac{\gamma}{\overline{\gamma}} \overline{V}$, which in turn means that $\overline{\gamma} \le \gamma$. Thus we have shown (use (a)) that

$$\max_{1 \le \ell \le n_\ell} f_\ell^T u_\ell^* \le \max_{1 \le \ell \le n_\ell} f_\ell^T u_\ell,$$

i.e., optimality of (x^*, u^*) for problem $(\mathrm{P}_{\mathrm{compl}})$. ∎

The first assertion of the theorem shows that, when $M_0 = 0$, the compliance constraint in $(\mathrm{P}_{\mathrm{vol}})$ is always active for at least one load case. Later we will demonstrate this theorem by means of a numerical example (see Example 4.1).

A completely analogous theorem to Theorem 2.8 can be stated when problems $(\mathrm{P}_{\mathrm{vol}})$ and $(\mathrm{P}_{\mathrm{compl}})$ are interchanged. The proof uses the same arguments and is thus omitted.

THEOREM 2.9. *Let $M_0 = 0$ and let (x^*, u^*) be a solution of $(\mathrm{P}_{\mathrm{compl}})$.*

(a) *Then $\sum_{i=1}^m x_i^* = \overline{V}$.*

(b) *Put $\overline{\gamma} := \max_{1 \le \ell \le n_\ell} f_\ell^T u_\ell^*$ in problem $(\mathrm{P}_{\mathrm{vol}})$ and copy $\overline{\lambda}$ from $(\mathrm{P}_{\mathrm{compl}})$. Then (x^*, u^*) is optimal for $(\mathrm{P}_{\mathrm{vol}})$ with optimal objective function value $\overline{V}$.*

The interrelations of $(\mathrm{P}_{\mathrm{vol}})$ (resp., of $(\mathrm{P}_{\mathrm{compl}})$) and $(\mathrm{P}_{\mathrm{eig}})$ are a bit more cumbersome because the objective function $(\mathrm{P}_{\mathrm{eig}})$ is invariant with respect to scaling, as shown in Lemma 2.7. As a first and simple result, we obtain the following proposition (where all sums run over $i = 1, \ldots, m$).

PROPOSITION 2.10. *Let $M_0 = 0$, and let (x^*, u^*) be a solution of problem $(\mathrm{P}_{\mathrm{eig}})$.*

(a) *Then for each*

$$\mu \in \left[\frac{\sum x_i^*}{\overline{V}}; \frac{\overline{\gamma}}{\max\limits_{1 \le \ell \le n_\ell} f_\ell^T u_\ell^*} \right] \tag{13}$$

the couple $(\frac{1}{\mu} x^*, \mu u^*)$ is also a solution of $(\mathrm{P}_{\mathrm{eig}})$.

(b) *In particular,*

$$\left(\frac{\overline{V}}{\sum x_i^*}\, x^*,\ \frac{\sum x_i^*}{\overline{V}}\, u^* \right)$$

is also a solution of $(\mathrm{P}_{\mathrm{eig}})$ where the volume constraint is attained as an equality.

(c) *Analogously to* (b),

$$\left(\frac{\max\limits_{1 \le \ell \le n_\ell} f_\ell^T u_\ell^*}{\overline{\gamma}}\, x^*,\ \frac{\overline{\gamma}}{\max\limits_{1 \le \ell \le n_\ell} f_\ell^T u_\ell^*}\, u^* \right)$$

is also a solution of $(\mathrm{P}_{\mathrm{eig}})$ where the compliance constraint is attained as an equality for at least one load case ℓ.

Proof. First, feasibility of (x^*, u^*) in $(\mathrm{P}_{\mathrm{eig}})$ and Lemma 2.6 yield

$$0 < \frac{\sum x_i^*}{\overline{V}} \le 1 \le \frac{\overline{\gamma}}{\max\limits_{1\le \ell \le n_\ell} f_\ell^T u_\ell^*},$$

and hence the interval in (13) is well defined and nonempty. Moreover, it is straightforward to see that

$$\sum \frac{1}{\mu} x_i^* \le \overline{V} \qquad \text{and} \qquad f_\ell^T u_\ell^* \le \overline{\gamma} \quad \forall \ell = 1, \dots, n_\ell$$

hold if and only if μ satisfies (13). Thus for each μ from (13), the point $(\frac{1}{\mu}x^*, \mu u^*)$ is feasible in problem $(\mathrm{P}_{\mathrm{eig}})$. Hence Lemma 2.7 shows that it is even an optimal solution. Assertions (b) and (c) are straightforward consequences of (a). ∎

This proposition relies on the fact that, for $M_0 = 0$, $\lambda_{\min}(\cdot)$ is invariant with respect to scaling of the structure. Hence, if either the volume constraint or the compliance constraints are inactive at the optimum, the optimal structure can be scaled without changing the value of the objective function $\lambda_{\min}(\cdot)$. This shows that (for $M_0 = 0$) problem $(\mathrm{P}_{\mathrm{eig}})$ rather looks for an optimal "shape" of the structure independently of the appropriate scaling. Later, in section 4, we will show a numerical example illustrating Proposition 2.10 (see Example 4.3).

2.4. Interrelations of original formulations for arbitrary M_0. In this section, we do not make any restrictions on M_0 apart from the general requirements already mentioned, i.e., that M_0 is symmetric and positive semidefinite. In the following, when relating two different optimization problems, the matrix M_0 is considered to be the same in both problems.

We start with a general result on the relation of optimization problems where the objective function of one problem acts as a constraint of the other one and vice versa. Through this result we will then be able to state all interrelationships of the formulations $(\mathrm{P}_{\mathrm{vol}})$, $(\mathrm{P}_{\mathrm{compl}})$, and $(\mathrm{P}_{\mathrm{eig}})$.

THEOREM 2.11. *Let $Y \subseteq \mathbb{R}^k$ be nonempty, and let the functions $f_1, f_2 : Y \longrightarrow \mathbb{R}$ be given. For $\overline{f}_1, \overline{f}_2 \in \mathbb{R}$ define the two optimization problems*

$$(\mathrm{P}_1[\overline{f}_2]) \qquad \min_{y\in Y}\{\, f_1(y) \mid f_2(y) \le \overline{f}_2 \,\}$$

and

$$(\mathrm{P}_2[\overline{f}_1]) \qquad \min_{y\in Y}\{\, f_2(y) \mid f_1(y) \le \overline{f}_1 \,\}.$$

Let $\overline{f}_2$ be fixed and the set Y_1^* of solutions to problem $(\mathrm{P}_1[\overline{f}_2])$ be nonempty. The optimal function value is denoted by

$$f_1^* := f_1(y^*) \qquad \forall y^* \in Y_1^*.$$

Put

$$f_2^* := \inf\{\, f_2(y^*) \mid y^* \in Y_1^* \,\}, \tag{14}$$

and let the infimum be attained at some $\hat{y}^* \in Y_1^*$. Consider problem $(\mathrm{P}_2[\overline{f}_1])$ with $\overline{f}_1 := f_1^*$.

Then $\hat{y}^*$ is optimal for problem $(\mathrm{P}_2[\overline{f}_1])$ with optimal objective function value f_2^*.

Proof. Optimality, and hence feasibility, of $\hat{y}^*$ for $(\mathrm{P}_1[\overline{f}_2])$ shows that this point is also feasible for $(\mathrm{P}_2[\overline{f}_1])$ due to the definition of $\overline{f}_1 := f_1^*$. By the choice of $\hat{y}^*$, the value of the objective function of $\hat{y}^*$ in $(\mathrm{P}_2[\overline{f}_1])$ is f_2^*. Now, let y be an arbitrary feasible point of $(\mathrm{P}_2[\overline{f}_1])$ with

$$f_2(y) \leq f_2^*. \tag{15}$$

We must prove that $f_2(y) \geq f_2^*$.

First, the choice of $\hat{y}^*$ shows that

$$f_2^* = f_2(\hat{y}^*) \leq \overline{f}_2.$$

Hence, using (15), we see that

$$f_2(y) \leq \overline{f}_2.$$

Thus, due to feasibility of y in $(\mathrm{P}_2[\overline{f}_1])$, it is clear that (x, u) is also feasible for $(\mathrm{P}_1[\overline{f}_2])$. The definition of $\overline{f}_1$ and the optimality of $\hat{y}^*$ for $(\mathrm{P}_1[\overline{f}_2])$ show that

$$\overline{f}_1 = f_1^* = f_1(\hat{y}^*) \leq f_1(y). \tag{16}$$

The feasibility of (x, u) for $(\mathrm{P}_2[\overline{f}_1])$, however, shows that

$$f_1(y) \leq \overline{f}_1,$$

which together with (16) and with the definition $\overline{f}_1 := f_1^*$ proves

$$f_1(y) = f_1^*.$$

We conclude that y is optimal for $(\mathrm{P}_1[\overline{f}_2])$, i.e., $y \in Y_1^*$. Hence, by the definition of f_2^*,

$$f_2(y) \geq f_2^*,$$

and the proof is complete. ∎

Now we collect certain tools which are needed to show that the infimum in (14) is attained in all situations. For this, we define the function

$$\begin{aligned} c: \ \{\, x \in \mathbb{R}^m \mid x \geq 0 \,\} &\longrightarrow \mathbb{R} \cup \{+\infty\}, \\ x &\mapsto \sup_{1 \leq \ell \leq n_\ell} \sup_{u_\ell \in \mathbb{R}^n} \left\{ 2 f_\ell^T u_\ell - u_\ell^T \left(\sum_{i=1}^m x_i K_i \right) u_\ell \right\}. \end{aligned}$$

Obviously, the function c denotes the maximum (over all load cases) of the negative minimum potential energies of the structure x.

PROPOSITION 2.12 (properties of the function c).

(a) *Let $x \geq 0$. Then $c(x) < +\infty$ if and only if there exist "displacement vectors" $u_1, \ldots, u_{n_\ell} \in \mathbb{R}^n$ such that*

$$K(x) u_\ell = f_\ell \qquad \forall \ell = 1, \ldots, n_\ell. \tag{17}$$

(b) *Let $x \geq 0$. If $c(x) < +\infty$, then*

$$c(x) = \max_{1 \leq \ell \leq n_\ell} f_\ell^T u_\ell$$

for all $u_1, \ldots, u_{n_\ell}$ which satisfy (17).

(c) *The function $c(\cdot)$ is finite and continuous on the set $\{x \in \mathbb{R}^m \mid x > 0\}$ and lower semicontinuous (l.s.c.) on $\{x \mid x \geq 0\}$, i.e.,*

$$\liminf_{\substack{x \to \bar{x} \\ x \geq 0}} c(x) \geq c(\bar{x}), \qquad \bar{x} \geq 0.$$

Proof. All assertions were proved in [2]. Assertions (a) and (b), however, are easily deduced from the necessary and sufficient conditions of the inner sup-problems over u_ℓ and from the fact that a convex quadratic function is unbounded if and only if it does not possess a stationary point. Concerning (c), we mention that the finiteness of c on $\{x \mid x > 0\}$ is based on assumption (5), and that c possesses much stronger continuity properties than just being l.s.c. on $\{x \mid x \geq 0\}$ (see [2]). ∎

For simplification of notation, we define

$$\mathrm{vol}(x) := \sum_{i=1}^{m} x_i$$

for $x \in \mathbb{R}^m$, $x \geq 0$. Moreover, we define

$$\mathcal{S}^*_{\mathrm{vol}}, \mathcal{S}^*_{\mathrm{compl}}, \mathcal{S}^*_{\mathrm{eig}} \subset \{x \in \mathbb{R}^m \mid x \geq 0\} \times \mathbb{R}^{n \cdot n_\ell}$$

as the solution sets of problems ($\mathrm{P_{vol}}$), ($\mathrm{P_{compl}}$), and ($\mathrm{P_{eig}}$), respectively. Notice that these sets may well be empty.

Our first result based on Theorem 2.11 relates problem ($\mathrm{P_{vol}}$) with problems ($\mathrm{P_{compl}}$) and ($\mathrm{P_{eig}}$), respectively.

THEOREM 2.13. *Let $\mathcal{S}^*_{\mathrm{vol}}$ be nonempty. Denote the optimal function value of problem ($\mathrm{P_{vol}}$) by V^*, i.e.,*

$$V^* := \sum_{i=1}^{m} x_i^* \qquad \forall (x^*, u^*) \in \mathcal{S}^*_{\mathrm{vol}}.$$

Put

$$\gamma^* := \inf \left\{ \max_{1 \leq \ell \leq n_\ell} f_\ell^T u_\ell^* \,\middle|\, (x^*, u^*) \in \mathcal{S}^*_{\mathrm{vol}} \right\} \tag{18}$$

and

$$\lambda^* := \sup \left\{ \lambda_{\min}(x^*) \,\middle|\, (x^*, u^*) \in \mathcal{S}^*_{\mathrm{vol}} \right\}. \tag{19}$$

Then the following assertions hold:

(a) *The infimum in (18) is attained at some $(\hat{x}^*, \hat{u}^*) \in \mathcal{S}^*_{\mathrm{vol}}$. Moreover, with $\overline{V} := V^*$, and with $\overline{\lambda}$ copied from problem ($\mathrm{P_{vol}}$), the point $(\hat{x}^*, \hat{u}^*)$ is optimal for problem ($\mathrm{P_{compl}}$) with optimal objective function value γ^*.*

(b) *The supremum in (19) is attained at some $(\tilde{x}^*, \tilde{u}^*) \in \mathcal{S}^*_{\mathrm{vol}}$. Moreover, with $\overline{V} := V^*$, and with $\overline{\gamma}$ copied from problem ($\mathrm{P_{vol}}$), the point $(\tilde{x}^*, \tilde{u}^*)$ is optimal for problem ($\mathrm{P_{eig}}$) with optimal objective function value λ^*.*

Proof. Consider the set

$$\mathcal{X}^*_{\mathrm{vol}} := \{\, x^* \mid (x^*, u^*) \in \mathcal{S}^*_{\mathrm{vol}} \}.$$

Using Proposition 2.12(a) and (b) it is easy to see that

$$\mathcal{X}^*_{\mathrm{vol}} = \left\{ x \geq 0 \,\middle|\, \mathrm{vol}(x) = V^*,\ c(x) \leq \overline{\gamma},\ \lambda_{\min}(x) \geq \overline{\lambda} \right\}. \tag{20}$$

Because $x \geq 0$ and $\mathrm{vol}(x) = V^*$ for all $x \in \mathcal{X}^*_{\mathrm{vol}}$, the set $\mathcal{X}^*_{\mathrm{vol}}$ is bounded. Moreover, because $\mathrm{vol}(\cdot)$ is continuous, $\lambda_{\min}(\cdot)$ is upper semicontinuous (u.s.c.) (see Proposition 2.3(d)) and $c(\cdot)$ is l.s.c. (see Proposition 2.12(c)), the set $\mathcal{X}^*_{\mathrm{vol}}$ is closed. All in all, $\mathcal{X}^*_{\mathrm{vol}}$ is a compact set.

We first prove (a). Proposition 2.12(a) and (b) show that

$$\gamma^* = \inf\{\, c(x) \mid x \in \mathcal{X}^*_{\mathrm{vol}} \,\} \tag{21}$$

and that the infimum in (18) is attained if and only if the infimum in (21) is attained. The latter, however, is straightforward because $c(\cdot)$ is an l.s.c. function, and $\mathcal{X}^*_{\mathrm{vol}}$ is a compact set (each l.s.c. function attains its infimum on a compact set; see, e.g., [17, Thm. 2.13.1]). The rest of the assertion follows directly from Theorem 2.11 with the settings

$$\begin{aligned} Y := \{\, (x,u) \in \mathbb{R}^m \times \mathbb{R}^{n\cdot n_\ell} \mid\ & K(x)u_\ell = f_\ell, && \ell = 1,\dots,n_\ell, \\ & x_i \geq 0, && i = 1,\dots,m, \\ & \lambda_{\min}(x) \geq \overline{\lambda}\}, \end{aligned}$$

$$f_1(x,u) := \mathrm{vol}(x), \qquad f_2(x,u) := c(x), \qquad \overline{f}_2 := \overline{\gamma}, \qquad \overline{f}_1 := V^*.$$

The proof of (b) is analogous. We have to show that the supremum

$$\lambda^* = \sup\{\, \lambda_{\min}(x) \mid x \in \mathcal{X}^*_{\mathrm{vol}} \,\}$$

is attained at some $\tilde{x}^*$. This is the case because $\lambda_{\min}(\cdot)$ is u.s.c. (see Proposition 2.3(d)) and $\mathcal{X}^*_{\mathrm{vol}}$ is compact (see above). Notice that $c(\tilde{x}^*) \leq \overline{\gamma} < +\infty$ (see (20)), and hence corresponding vectors $\tilde{u}^*_1, \dots, \tilde{u}^*_{e_\ell}$ exist by Proposition 2.12(a) and (b) such that $(\tilde{x}^*, \tilde{u}^*)$ is feasible (and optimal) for $(\mathrm{P}_{\mathrm{vol}})$. The rest of assertion (b) follows directly from Theorem 2.11 with the settings

$$\begin{aligned} Y := \{\, (x,u) \in \mathbb{R}^m \times \mathbb{R}^{n\cdot n_\ell} \mid\ & K(x)u_\ell = f_\ell, && \ell = 1,\dots,n_\ell, \\ & x_i \geq 0, && i = 1,\dots,m, \\ & f_\ell^T u_\ell \leq \overline{\gamma}, && \ell = 1,\dots,n_\ell\}, \end{aligned}$$

$$f_1(x,u) := \mathrm{vol}(x), \qquad f_2(x,u) := -\lambda_{\min}(x), \qquad \overline{f}_2 := -\overline{\lambda}, \qquad \overline{f}_1 := V^*. \qquad \square$$

Theorem 2.13(a) reflects the fact that at some solution (x^*, u^*) of $(\mathrm{P}_{\mathrm{vol}})$ none of the compliance constraints may be satisfied with equality, and hence "postoptimization" in (18) is needed to select a proper solution of $(\mathrm{P}_{\mathrm{vol}})$ to obtain a solution of $(\mathrm{P}_{\mathrm{compl}})$. Hence, in general, it is not true that every solution of $(\mathrm{P}_{\mathrm{vol}})$ is also a solution of $(\mathrm{P}_{\mathrm{compl}})$! The problems are thus not equivalent, as is commonly believed. Theorem 2.13(a) also shows that—with the appropriate settings of $\overline{V}$ and $\overline{\lambda}$—there is always a structure x^* which is optimal for *both* problems at the same time (provided there exists a solution at all).

Analogous comments, of course, can be made for Theorem 2.13(b) concerning solutions of $(\mathrm{P}_{\mathrm{eig}})$. A numerical example illustrating Theorem 2.13 is given in section 4 (Example 4.4).

Theorem 2.13 substantially simplifies in the following special situation.

COROLLARY 2.14. *Let the set* $\mathcal{X}^*_{\mathrm{vol}} = \{x^* \mid (x^*, u^*) \in \mathcal{S}^*_{\mathrm{vol}}\}$ *be a singleton. Then the following assertions hold:*

(a) *Put* $\overline{V} := \mathrm{vol}(x^*)$ *in problem* $(\mathrm{P}_{\mathrm{compl}})$ *and copy the value* $\overline{\lambda}$ *from problem* $(\mathrm{P}_{\mathrm{vol}})$. *Then* (x^*, u^*) *is optimal for problem* $(\mathrm{P}_{\mathrm{compl}})$ *with optimal objective function value* $\max_{1\le\ell\le n_\ell} f_\ell^T u_\ell^*$.

(b) *Put* $\overline{V} := \mathrm{vol}(x^*)$ *in problem* $(\mathrm{P}_{\mathrm{eig}})$ *and copy the value* $\overline{\gamma}$ *from problem* $(\mathrm{P}_{\mathrm{vol}})$. *Then* (x^*, u^*) *is optimal for problem* $(\mathrm{P}_{\mathrm{eig}})$ *with optimal objective function value* $\lambda_{\min}(x^*)$.

Proof. If $\mathcal{X}^*_{\mathrm{vol}} = \{x^*\}$, then the infimum in (18) is attained at any $(x^*, u^*) \in \mathcal{S}^*_{\mathrm{vol}}$ because for each $u^*, \tilde{u}^*$ with $K(x^*)u_\ell^* = K(x^*)\tilde{u}_\ell^* = f_\ell$ for all ℓ the compliance values

$$f_\ell^T u_\ell^* = \tilde{u}_\ell^{*T} K(x^*) u_\ell^* = \tilde{u}_\ell^{*T} f_\ell = f_\ell^T \tilde{u}_\ell^*, \qquad \ell = 1, \dots, n_\ell,$$

are constant. Because $\mathcal{X}^*_{\mathrm{vol}}$ is the singleton x^*, and because $\lambda_{\min}(\cdot)$ does not depend on u^*, it is trivial to see that the supremum in (19) is attained at each $(x^*, u^*) \in \mathcal{S}^*_{\mathrm{vol}}$. Now apply Theorem 2.13. ∎

Remark 2.15. Theorem 2.13(a) generalizes Theorem 2.8(b) of the previous chapter. If $M_0 = 0$ in Theorem 2.13(a), then Theorem 2.8(a) shows that

$$\max_{1\le\ell\le n_\ell} f_\ell^T u_\ell^* = \overline{\gamma} \qquad \forall (x^*, u^*) \in S^*_{\mathrm{vol}}.$$

Hence $\gamma^* = \overline{\gamma}$, and the infimum in (18) is attained at each solution $(x^*, u^*) \in \mathcal{S}^*_{\mathrm{vol}}$. A similar comment cannot be made for Theorem 2.13(b). The setting $M_0 = 0$ does not guarantee that for each solution (x^*, u^*) of $(\mathrm{P}_{\mathrm{vol}})$ the eigenvalue constraint is attained as an equality. This will also be demonstrated by Example 4.4 below. The background lies in the invariance of $\lambda_{\min}(\cdot)$ w.r.t. scaling of the structure; see Lemma 2.7.

Analogously to Theorem 2.13, we may derive solutions of problems $(\mathrm{P}_{\mathrm{vol}})$ and $(\mathrm{P}_{\mathrm{eig}})$, respectively, from solutions of problem $(\mathrm{P}_{\mathrm{compl}})$.

THEOREM 2.16. *Let* $\mathcal{S}^*_{\mathrm{compl}}$ *be nonempty. Denote the optimal function value of problem* $(\mathrm{P}_{\mathrm{compl}})$ *by* γ^*, *i.e.,*

$$\gamma^* := \max_{1\le\ell\le n_\ell} f_\ell^T u_\ell^* \qquad \forall (x^*, u^*) \in S^*_{\mathrm{compl}}.$$

Put

$$V^* := \inf \left\{ \sum_{i=1}^m x_i^* \,\middle|\, (x^*, u^*) \in \mathcal{S}^*_{\mathrm{compl}} \right\} \tag{22}$$

and

$$\lambda^* := \sup \left\{ \lambda_{\min}(x^*) \,\middle|\, (x^*, u^*) \in \mathcal{S}^*_{\mathrm{compl}} \right\}. \tag{23}$$

Then the following assertions hold:

(a) *The infimum in* (22) *is attained at some* $(\hat{x}^*, \hat{u}^*) \in \mathcal{S}^*_{\mathrm{compl}}$. *Moreover, with* $\overline{\gamma} := \gamma^*$, *and with* $\overline{\lambda}$ *copied from problem* $(\mathrm{P}_{\mathrm{compl}})$, *the point* $(\hat{x}^*, \hat{u}^*)$ *is optimal for problem* $(\mathrm{P}_{\mathrm{vol}})$ *with optimal objective function value* V^*.

(b) *The supremum in* (23) *is attained at some* $(\tilde{x}^*, \tilde{u}^*) \in \mathcal{S}^*_{\mathrm{compl}}$. *Moreover, with* $\overline{\gamma} := \gamma^*$, *and with* $\overline{V}$ *copied from problem* $(\mathrm{P}_{\mathrm{compl}})$, *the point* $(\tilde{x}^*, \tilde{u}^*)$ *is optimal for problem* $(\mathrm{P}_{\mathrm{eig}})$ *with optimal objective function value* λ^*.

Proof. We modify the proof of Theorem 2.13. Consider the set

$$\mathcal{X}^*_{\mathrm{compl}} := \{\, x^* \mid (x^*, u^*) \in \mathcal{S}^*_{\mathrm{compl}} \}.$$

In view of Proposition 2.12(a) and (b) it is easy to see that

$$\mathcal{X}^*_{\text{compl}} = \Big\{ x \geq 0 \;\Big|\; \text{vol}(x) \leq \overline{V},\ c(x) = \gamma^*,\ \lambda_{\min}(x) \geq \overline{\lambda} \Big\}. \tag{24}$$

Because γ^* is the optimal objective function value, there is no $x \geq 0$ such that $\text{vol}(x) \leq \overline{V}$, $c(x) < \gamma^*$, and $\lambda_{\min}(x) \geq \overline{\lambda}$. Hence the set $\mathcal{X}^*_{\text{compl}}$ remains unchanged if we change the equality sign in "$c(x) = \gamma^*$" to an inequality sign:

$$\mathcal{X}^*_{\text{compl}} = \Big\{ x \geq 0 \;\Big|\; \text{vol}(x) \leq \overline{V},\ c(x) \leq \gamma^*,\ \lambda_{\min}(x) \geq \overline{\lambda} \Big\}. \tag{25}$$

Because $x \geq 0$ and $\text{vol}(x) \leq \overline{V}$ for all $x \in \mathcal{X}^*_{\text{compl}}$, the set $\mathcal{X}^*_{\text{compl}}$ is bounded. Moreover, each of the functions $\text{vol}(\cdot)$, $-\lambda_{\min}(\cdot)$, and $c(\cdot)$ is l.s.c. (see Propositions 2.3(d) and 2.12(c)). Hence the description (25) shows that $\mathcal{X}^*_{\text{compl}}$ is a closed set, and thus $\mathcal{X}^*_{\text{compl}}$ is compact (notice that the *level line* of an l.s.c. function $f(\cdot)$ for some value α, i.e., the set $\{y \mid f(y) = \alpha\}$, need not be closed, but the *level set* $\{y \mid f(y) \leq \alpha\}$ is always closed).

First we prove (a). Obviously, the infimum in (22) is attained because $\mathcal{X}^*_{\text{compl}}$ is a compact set and $\text{vol}(\cdot)$ is continuous. Now apply Theorem 2.11 with the settings

$$\begin{aligned} Y := \{\, (x,u) \in \mathbb{R}^m \times \mathbb{R}^{n \cdot n_\ell} \mid\ & K(x)u_\ell = f_\ell, && \ell = 1, \ldots, n_\ell, \\ & x_i \geq 0, && i = 1, \ldots, m, \\ & \lambda_{\min}(x) \geq \overline{\lambda} \}, \end{aligned}$$

$$f_1(x,u) := \max_{1 \leq \ell \leq n_\ell} f_\ell^T u_\ell, \qquad f_2(x,u) := \text{vol}(x), \qquad \overline{f}_2 := \overline{V}, \qquad \overline{f}_1 := \gamma^*.$$

The proof of (b) is analogous to that of Theorem 2.13(b). □

The following corollary parallels Corollary 2.14. Its proof is even simpler because neither $\text{vol}(\cdot)$ nor $\lambda_{\min}(\cdot)$ in (22) and (23), respectively, depends on u^*.

COROLLARY 2.17. *Let the set* $\mathcal{X}^*_{\text{compl}} = \{x^* \mid (x^*, u^*) \in \mathcal{S}^*_{\text{compl}}\}$ *be a singleton. Then the following assertions hold:*

(a) *Put* $\overline{\gamma} := \max_{1 \leq \ell \leq n_\ell} f_\ell^T u_\ell^*$ *in problem* (P_{vol}) *and copy the value* $\overline{\lambda}$ *from problem* (P_{compl}). *Then* (x^*, u^*) *is optimal for problem* (P_{vol}) *with optimal objective function value* $\text{vol}(x^*)$.

(b) *Put* $\overline{\gamma} := \max_{1 \leq \ell \leq n_\ell} f_\ell^T u_\ell^*$ *in problem* (P_{eig}) *and copy the value* $\overline{V}$ *from problem* (P_{compl}). *Then* (x^*, u^*) *is optimal for problem* (P_{eig}) *with optimal objective function value* $\lambda_{\min}(x^*)$.

Remark 2.18. Similarly as in Remark 2.15, Theorem 2.16(a) generalizes Theorem 2.9(b). If $M_0 = 0$ in Theorem 2.16(a), then Theorem 2.9(a) shows that

$$\text{vol}(x^*) = \overline{V} \qquad \forall (x^*, u^*) \in S^*_{\text{compl}}.$$

Hence $V^* = \overline{V}$, and the infimum in (22) is attained at each solution $(x^*, u^*) \in \mathcal{S}^*_{\text{compl}}$.

Finally, we may derive solutions of problems (P_{vol}) and (P_{compl}) from solutions of (P_{eig}).

THEOREM 2.19. *Let* $\mathcal{S}^*_{\text{eig}}$ *be nonempty. Denote the optimal function value of problem* (P_{eig}) *by* λ^*, *i.e.,*

$$\lambda^* := \lambda_{\min}(x^*) \qquad \forall (x^*, u^*) \in S^*_{\text{eig}}.$$

Put

$$V^* := \inf \left\{ \sum_{i=1}^{m} x_i^* \,\middle|\, (x^*, u^*) \in \mathcal{S}_{\text{eig}}^* \right\} \tag{26}$$

and

$$\gamma^* := \inf \left\{ \max_{1 \le \ell \le n_\ell} f_\ell^T u_\ell^* \,\middle|\, (x^*, u^*) \in \mathcal{S}_{\text{eig}}^* \right\}. \tag{27}$$

Then the following assertions hold:

(a) *The infimum in* (26) *is attained at some* $(\hat{x}^*, \hat{u}^*) \in \mathcal{S}_{\text{eig}}^*$. *Moreover, with* $\overline{\lambda} := \lambda^*$, *and with* $\overline{\gamma}$ *copied from problem* (P_{eig}), *the point* $(\hat{x}^*, \hat{u}^*)$ *is optimal for problem* (P_{vol}) *with optimal objective function value* V^*.

(b) *The infimum in* (27) *is attained at some* $(\tilde{x}^*, \tilde{u}^*) \in \mathcal{S}_{\text{eig}}^*$. *Moreover, with* $\overline{\lambda} := \lambda^*$, *and with* $\overline{V}$ *copied from problem* (P_{eig}), *the point* $(\tilde{x}^*, \tilde{u}^*)$ *is optimal for problem* (P_{compl}) *with optimal objective function value* γ^*.

Proof. The proof of this theorem is analogous to that of Theorem 2.13 with the role of the functions $\text{vol}(\cdot)$ and $\lambda_{\min}(\cdot)$ interchanged. ∎

For an illustration of this theorem, we refer to Example 4.3. The proof of the following corollary is analogous to that of Corollary 2.14.

COROLLARY 2.20. *Let the set* $\mathcal{X}_{\text{eig}}^* = \{x^* \mid (x^*, u^*) \in \mathcal{S}_{\text{eig}}^*\}$ *be a singleton. Then the following assertions hold:*

(a) *Put* $\overline{\lambda} := \lambda_{\min}(x^*)$ *in problem* (P_{vol}) *and copy the value* $\overline{\gamma}$ *from problem* (P_{eig}). *Then* (x^*, u^*) *is optimal for problem* (P_{vol}) *with optimal objective function value* $\text{vol}(x^*)$.

(b) *Put* $\overline{\lambda} := \lambda_{\min}(x^*)$ *in problem* (P_{compl}) *and copy the value* $\overline{V}$ *from problem* (P_{eig}). *Then* (x^*, u^*) *is optimal for problem* (P_{compl}) *with optimal objective function value* $\max_{1 \le \ell \le n_\ell} f_\ell^T u_\ell^*$.

To conclude this theoretical study of relations of the three original problem formulations, we would like to give a few comments on their practical use. Obviously, a direct implementation of one of Theorems 2.13, 2.16, and 2.19 for numerical purposes is difficult because one would need to know the set of *all* solutions to one of the problems, or one should be able to solve the inf- or sup-problems on the optimal set. There are ways to do this, as have been recently shown in [11]. However, as we will see in section 3, there is no need to proceed from a solution of one (nonlinear!) problem to the solution of some other problem, because global solutions of some of the original problems can be calculated through equivalent (quasi-)convex problem formulations.

2.5. Brief discussion on the variation of M_0. In this section we want to briefly prove what is widely known among practitioners: what happens when the nonstructural mass is changed or even removed? For example, if volume minimization is considered, then a bigger nonstructural mass will generally increase the optimal volume. Similarly, if maximization of the minimal eigenvalue is considered, the removal of the nonstructural mass will generally lead to a smaller minimal eigenvalue. Hence, in this section, we briefly consider the variation of M_0 and use the extended notation (see Proposition 2.3(c))

$$\lambda_{\min}(x, M_0) := \sup\{\lambda \mid K(x) - \lambda(M(x) + M_0) \succeq 0\}. \tag{28}$$

LEMMA 2.21. *Let* $x \ge 0$, *and let* $\widetilde{M}_0, M_0 \in \mathbb{R}^{n \times n}$ *be symmetric with* $\widetilde{M}_0 \succeq M_0 \succeq 0$. *Then* $\lambda_{\min}(x, \widetilde{M}_0) \le \lambda_{\min}(x, M_0)$.

Proof. Put $\tilde{\lambda} := \lambda_{\min}(x, \widetilde{M}_0)$. Then

$$\begin{aligned} 0 \preceq K(x) - \tilde{\lambda}(M(x) + \widetilde{M}_0) &= K(x) - \tilde{\lambda}M(x) - \tilde{\lambda}\widetilde{M}_0 \\ \preceq K(x) - \tilde{\lambda}M(x) - \tilde{\lambda}M_0 &= K(x) - \tilde{\lambda}(M(x) + M_0). \end{aligned}$$

Hence,

$$\tilde{\lambda} \leq \sup\{\lambda \mid K(x) - \lambda(M(x) + M_0) \succeq 0\} = \lambda_{\min}(x, M_0). \qquad \square$$

As a simple conclusion concerning the optimal objective function values of our three problems we obtain the following.

PROPOSITION 2.22. *Consider two problems of type* ($\mathrm{P_{vol}}$) *(resp.,* ($\mathrm{P_{compl}}$) *or* ($\mathrm{P_{eig}}$)*), with the same constraint bounds* $\overline{\gamma}$ *and* $\overline{\lambda}$ *(resp.,* $\overline{V}$ *and* $\overline{\lambda}$*, or* $\overline{V}$ *and* $\overline{\gamma}$*) but with different nonstructural mass matrices* $M_0, \widetilde{M}_0$*, where* $\widetilde{M}_0 \succeq M_0$*. Let both problems possess a solution, and denote the optimal objective function values by* $V^*, \widetilde{V}^*$ *(resp.,* $\gamma^*, \widetilde{\gamma}^*$*, or* $\lambda^*, \widetilde{\lambda}^*$*). Then* $V^* \geq \widetilde{V}^*$ *(resp.,* $\gamma^* \geq \widetilde{\gamma}^*$*, or* $\lambda^* \leq \widetilde{\lambda}^*$*).*

Proof. Consider the pair of minimum volume problems. Notice that each feasible point (x, u) of problem ($\mathrm{P_{vol}}$) with nonstructural mass $\widetilde{M}_0$ is also feasible for the problem with nonstructural mass M_0 due to Lemma 2.21(a). Hence, $\tilde{V}^* \leq V^*$.

The proof for the pair of min-max compliance problems is analogous. For the pair of max-min eigenvalue problems it is even simpler, because the set of feasible points is the same for both problems, and Lemma 2.21(a) applies directly on the objective function values. (Notice that for this type of problem, we are *max*imizing, and thus we have "$\leq$" in the assertion.) $\square$

More detailed results than in the above proposition can hardly be obtained, apart from the effect of simple joint scalings of the bounds $\overline{V}, \overline{\gamma}, \overline{\lambda}$, and M_0. Because the total mass matrix in the problem is $(M(x)+M_0)$, a pure change of only M_0 always has nonlinear impact in the problem, and hence is difficult to describe. As a consequence, the optimal topology changes as well with a change of M_0. Such a numerical example is presented section 4 (see Example 4.6).

3. SDP reformulations. All the original formulations are nonconvex, some even discontinuous. Furthermore, all of them implicitly include the computation of the smallest eigenvalue of (8). Below we give reformulations of problems ($\mathrm{P_{vol}}$), ($\mathrm{P_{compl}}$), ($\mathrm{P_{eig}}$) to problems that are much easier to analyze and solve numerically. All these reformulations have been known. The third one, however, has never been used for the numerical treatment, to our knowledge. We will further use a unified approach to these reformulations that offers a clear look at their mutual relations.

We start with an auxiliary result.

PROPOSITION 3.1. *Let* $x \in \mathbb{R}^m$*,* $x \geq 0$*, and* $\gamma \in \mathbb{R}$ *be fixed, and fix an index* $\ell \in \{1, \ldots, n_\ell\}$*. Then there exists* $u_\ell \in \mathbb{R}^n$ *satisfying*

$$K(x)u_\ell = f_\ell \qquad \text{and} \qquad f_\ell^T u_\ell \leq \gamma$$

if and only if

$$\begin{pmatrix} \gamma & -f_\ell^T \\ -f_\ell & K(x) \end{pmatrix} \succeq 0\,.$$

Proof. Note that $K(x)$ may be singular in our case, so that we cannot directly use the Schur complement theorem. We first write the matrix inequality equivalently as

$$\alpha^2\gamma - 2\alpha f_\ell^T v + v^T K(x) v \geq 0 \quad \forall \alpha \in \mathbb{R},\ \forall v \in \mathbb{R}^n\,. \tag{29}$$

"⇒" As $K(x) \succeq 0$, we know that u_ℓ minimizes the quadratic functional $v \mapsto v^T K(x)v - 2f_\ell^T v$ with the minimal value $-f_\ell^T u_\ell$. Thus

$$v^T K(x)v - 2f_\ell^T v \geq -f_\ell^T u_\ell \geq -\gamma \quad \forall v \in \mathbb{R}^n\,.$$

Using the substitution $v = \sigma w$, $\sigma \in \mathbb{R}$, we can write this as

$$(\sigma w)^T K(x)(\sigma w) - 2f_\ell^T(\sigma w) \geq -\gamma \quad \forall \sigma \in \mathbb{R},\ \forall w \in \mathbb{R}^n;$$

hence

$$w^T K(x)w - \frac{1}{\sigma}2f_\ell^T w \geq -\frac{1}{\sigma^2}\gamma \quad \forall \sigma \in \mathbb{R}\setminus\{0\},\ \forall w \in \mathbb{R}^n,$$

which is just (29) with $\alpha = \frac{1}{\sigma}$.

"⇐" Put $\alpha = 1$; then we get from (29)

$$\gamma - 2f_\ell^T v + v^T K(x)v \geq 0 \quad \forall v \in \mathbb{R}^n,$$

meaning that the corresponding convex quadratic function in v is bounded from below. By this, standard linear algebra shows that this function possesses a global minimizer $u_\ell \in \mathbb{R}^n$, and the necessary optimality condition yields

$$K(x)u_\ell = f_\ell\,.$$

Inserting this into (29) with $\alpha = 1$, we have $\gamma - 2f_\ell^T u_\ell + u_\ell^T f_\ell \geq 0$, that is, $\gamma \geq f_\ell^T u_\ell$, and we are done. □

With this proposition, we immediately get the following reformulations of our three original problems.

The minimum volume problem. In this problem, $\overline{\gamma}$ and $\overline{\lambda}$ are given, and we minimize the upper bound V on the volume:

$$(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}}) \qquad \begin{aligned} \min_{x\in\mathbb{R}^m, V\in\mathbb{R}} \ & V \\ \text{subject to } & \begin{pmatrix} \overline{\gamma} & -f_\ell^T \\ -f_\ell & K(x) \end{pmatrix} \succeq 0, \quad \ell = 1,\dots,n_\ell, \\ & \sum_{i=1}^m x_i \leq V, \\ & x_i \geq 0, \quad i = 1,\dots,m, \\ & K(x) - \overline{\lambda}(M(x) + M_0) \succeq 0\,. \end{aligned}$$

A closely related version of this problem was first formulated and studied by Ohsaki et al. [20]. They considered the problem without the compliance constraint and with positive lower bounds on the design variables x_i. Using SDP duality, global optima of this problem can be easily characterized by necessary and sufficient optimality conditions [8]. Analogous statements can be made for problem $(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}})$ as well.

The minimum compliance problem. Here $\overline{V}$ and $\overline{\lambda}$ are given, and we minimize the upper bound γ on the compliance:

$$
\begin{aligned}
(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{compl}}) \qquad & \min_{x\in\mathbb{R}^m,\gamma\in\mathbb{R}} \gamma \\
& \text{subject to } \begin{pmatrix} \gamma & -f_\ell^T \\ -f_\ell & K(x) \end{pmatrix} \succeq 0, \quad \ell = 1,\dots,n_\ell, \\
& \sum_{i=1}^m x_i \le \overline{V}, \\
& x_i \ge 0, \quad i = 1,\dots,m, \\
& K(x) - \overline{\lambda}(M(x) + M_0) \succeq 0\,.
\end{aligned}
$$

The problem of maximizing the minimal eigenvalue. Now $\overline{\gamma}$ and $\overline{V}$ are given, and λ is the variable. For the sake of a common problem structure in all three formulations, we *minimize* and put a minus in front of the objective function:

$$
\begin{aligned}
(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}}) \qquad & \min_{x\in\mathbb{R}^m,\lambda\in\mathbb{R}} -\lambda \\
& \text{subject to } \begin{pmatrix} \overline{\gamma} & -f_\ell^T \\ -f_\ell & K(x) \end{pmatrix} \succeq 0, \quad \ell = 1,\dots,n_\ell, \\
& \sum_{i=1}^m x_i \le \overline{V}, \\
& x_i \ge 0, \quad i = 1,\dots,m, \\
& K(x) - \lambda(M(x) + M_0) \succeq 0\,.
\end{aligned}
$$

The proof of the following proposition is immediate, and thus is skipped.

PROPOSITION 3.2.

(a) *If* (x^*,u^*) *is a global minimizer of* $(\mathrm{P}_{\mathrm{vol}})$*, then* (x^*,V^*) *is a global minimizer of* $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{vol}})$*, where* $V^* := \sum x_i^*$*, and the optimal values of both problems coincide.*

(b) *If* (x^*,V^*) *is a global minimizer of* $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{vol}})$*, then there exists* u^* *such that* (x^*,u^*) *is a global minimizer of* $(\mathrm{P}_{\mathrm{vol}})$*, and the optimal values of both problems coincide.*

Analogous statements hold for the pairs of problems $(\mathrm{P}_{\mathrm{compl}})$*,* $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{compl}})$ *and* $(\mathrm{P}_{\mathrm{eig}})$*,* $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$*, respectively, where in the latter case the optimal function values coincide up to a sign.*

Note that problems $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{vol}})$ and $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{compl}})$ are linear SDPs, while $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$ is an SDP problem with a BMI constraint, i.e., it is generally nonconvex. We should emphasize that, due to the SDP reformulation, the originally discontinuous problems became continuous, a fact of big practical value.

THEOREM 3.3. *Each local minimizer of problem* $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{vol}})$ *is also a global minimizer. An analogous statement holds for problem* $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{compl}})$*.*

Proof. Problems $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{vol}})$ and $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{compl}})$ are linear SDPs, i.e., convex problems, and the assertions follow. ∎

Needless to say that this theorem is of paramount interest from the practical point of view.

Clearly, a statement similar to Theorem 3.3 does not hold for problem $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$; see Example 2.4, where the function $\lambda_{\min}(\cdot)$ is constant for $x_2 > 0$ and has thus infinitely many local minima which are, however, greater than the global minimum attained at $x_2 = 0$.

We remark, however, that problem $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ hides a *quasi*-convex structure. To see this, use Definition 2.2 to write problem $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ in the form

$$\min\{\, -\lambda_{\min}(x) \mid x \in \mathcal{F}\,\} \tag{30}$$

with the feasible set

$$\mathcal{F} := \left\{ x \in \mathbb{R}^m \,\middle|\, x \geq 0;\ \begin{pmatrix} \overline{\gamma} & -f_\ell^T \\ -f_\ell & K(x) \end{pmatrix} \succeq 0,\ \ell = 1, \ldots, n_\ell;\ \sum_{i=1}^m x_i \leq \overline{V} \right\}.$$

Then Proposition 2.3(f) and the fact that the cone of positive semidefinite matrices is convex show that we minimize here a quasi-convex function over a convex feasible set $\mathcal{F}$. This fact might be useful, e.g., for the application of cutting plane algorithms from global optimization. Unfortunately, the function $-\lambda_{\min}(\cdot)$ fails to be strictly quasi-convex, as already explained in Example 2.4.

Formulation (30) of problem $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ immediately clarifies the existence of solutions.

THEOREM 3.4. *Problem* $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ *(or, equivalently, problem* $(\mathrm{P}_{\mathrm{eig}})$*) possesses a solution if and only if it possesses feasible points.*

Proof. Consider problem $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ in the form (30). Since the cone of positive semidefinite matrices is closed, the set $\mathcal{F}$ is compact. Moreover, $0 \notin \mathcal{F}$ due to assumption (1), and hence $(-\lambda_{\min})$ is l.s.c. on $\mathcal{F}$ by Proposition 2.3(d). Each l.s.c. function attains its infimum on a nonempty compact set (see, e.g., [17, Thm. 2.13.1]). ∎

Instead of using methods of global optimization for the calculation of a global minimizer of problem $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$, we may use the quasi-convex formulation (30) and the close relation to the convex problem $(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}})$. In the following we define a bisection technique that is based on a general algorithm for problems with quasi-convex objective function and convex constraints; see, e.g., [5, sect. 4.2.5]. This technique of finding a global solution of $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ is based on the solutions of a sequence of problems which are of the type $(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}})$. Alternatively, a sequence of problems of the type $(\mathrm{P}_{\mathrm{compl}}^{\mathrm{SDP}})$ can be used (not described here).

The methodology works as follows. We may consider problem $(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}})$ as a kind of feasibility problem for $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ where $\lambda := \overline{\lambda}$ is fixed. More precisely, by solving the convex problem $(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}})$ we can see whether $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ possesses feasible points with objective function value $\lambda \geq \overline{\lambda}$ or not. Hence, we may state a simple bisection technique playing with the value of $\overline{\lambda}$. Since the volume constraint of $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ is not a constraint of $(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}})$, we slightly modify $(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}})$. For fixed $\lambda \geq 0$ and fixed $\delta \geq 0$ consider the following linear SDP:

$$(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}}(\lambda, \delta)) \qquad \min_{x \in \mathbb{R}^m, V \in \mathbb{R}} V$$

$$\text{subject to } \begin{pmatrix} \overline{\gamma} & -f_\ell^T \\ -f_\ell & K(x) \end{pmatrix} \succeq 0, \quad \ell = 1, \ldots, n_\ell,$$

$$\sum_{i=1}^m x_i \leq V,$$

$$V \leq \overline{V},$$

$$x_i \geq 0, \quad i = 1, \ldots, m,$$

$$K(x) - (\lambda + \delta)(M(x) + M_0) \succeq 0\,.$$

In the following, the feasible set of this problem is denoted by

$$\mathcal{F}(\lambda, \delta),$$

for simplicity. Since $(\mathrm{P}^{\mathrm{SDP}}_{\overline{\mathrm{vol}}}(\lambda, \delta))$ is a convex SDP, modern solution procedures are able to recognize whether $\mathcal{F}(\lambda, \delta) = \varnothing$, and we may calculate a feasible point or even a global minimizer if $\mathcal{F}(\lambda, \delta) \neq \varnothing$.

The following proposition gives a tool for the estimation of the (globally) optimal objective function value of problem $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$. Its proof is a simple exercise.

PROPOSITION 3.5. *Let $(\tilde{x}, \lambda)$ be feasible for $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$, and let $(-\lambda^{**})$ denote the (globally) optimal function value of problem $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$. Moreover, let $\delta > 0$ be arbitrary, and consider problem $(\mathrm{P}^{\mathrm{SDP}}_{\overline{\mathrm{vol}}}(\lambda, \delta))$ with the parameters $\overline{\gamma}$ and $\overline{V}$ copied from $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$. Then the following assertions hold:*

(a) *If $\mathcal{F}(\lambda, \delta) \neq \varnothing$, then for each $(x, V) \in \mathcal{F}(\lambda, \delta)$ the point $(x, \lambda + \delta)$ is feasible for $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$, i.e., $-\lambda^{**} \leq -(\lambda + \delta) < -\lambda$.*

(b) *If $\mathcal{F}(\lambda, \delta) = \varnothing$, then $-(\lambda + \delta) < -\lambda^{**} \leq -\lambda$.*

The practical value of this proposition lies in the possibility of improving upper and lower bounds for λ^{**} which can be numerically calculated through solutions (or only feasible points) of convex linear SDPs.

As a preprocessing step, we first calculate initial lower and upper bounds λ_0^L, λ_0^U on λ^{**}. For this, first calculate a feasible point (x, λ) of $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$ and choose arbitrary $\bar{\delta} > 0$. Then find the smallest $k \in \mathbb{N}$ such that $\mathcal{F}(\lambda, 2^k\bar{\delta}) = \varnothing$ by solving $(\mathrm{P}^{\mathrm{SDP}}_{\overline{\mathrm{vol}}}(\lambda, 2^k\bar{\delta}))$ repeatedly. Set $\lambda_0^L := \lambda + 2^{k-1}\bar{\delta}$ and $\lambda_0^U := \lambda + 2^k\bar{\delta}$. Then Proposition 3.5 shows that

$$0 \leq \lambda_0^L \leq \lambda^{**} < \lambda_0^U \ .$$

With these bounds it is easy to construct a bisection-type algorithm which in each step reduces the gap $(\lambda_k^U - \lambda_k^L)$ by a factor of (at least) $\frac{1}{2}$.

ALGORITHM 3.6. Choose an accuracy $\eta > 0$, a feasible point $(\hat{x}, \hat{\lambda})$ for $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$. Put $(x_0, \lambda_0) := (\hat{x}, \hat{\lambda})$, $\delta_0 := \frac{1}{2}(\lambda_0^U - \lambda_0^L)$, and $k := 0$. Go to step 2.

1. Calculate a feasible point [or even a local minimizer] (x_k, λ_k) of $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$ with the additional constraint "$\lambda \geq \lambda_k^L$".
2. If $\lambda_k > \lambda_k^L$, then update λ_k^L by $\lambda_k^L := \lambda_k$.
3. If $\lambda_k^U - \lambda_k^L \leq \eta$, then EXIT with the result $(x^*, \lambda^*) := (x_k, \lambda_k)$.
4. Put $\delta_k := \frac{1}{2}(\lambda_k^U - \lambda_k^L)$, and consider problem $(\mathrm{P}^{\mathrm{SDP}}_{\overline{\mathrm{vol}}}(\lambda_k, \delta_k))$.
   If $\mathcal{F}(\lambda_k, \delta_k) \neq \varnothing$, then:
   4A. Put $\lambda_{k+1}^L := \lambda_k^L + \delta_k$, $k := k + 1$, and go to step 1.
   Otherwise, if $\mathcal{F}(\lambda_k, 2^k\bar{\delta}) = \varnothing$, then:
   4B. Put $\lambda_{k+1}^U := \lambda_k^U - \delta_l$, $k := k + 1$, and go to step 1.

Let $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$ possess a solution (x^{**}, λ^{**}) (see Theorem 3.4). Then it is straightforward to show that Algorithm 3.6 is well defined, and that after each iteration the inequalities $\lambda_k^L \leq \lambda^{**} < \lambda_k^U$ and $\lambda_k^U - \lambda_k^L \leq 2^{-k}(\lambda_0^U - \lambda_0^L)$ hold. Consequently, Algorithm 3.6 terminates after at most $\lceil(\ln(\lambda_0^U - \lambda_0^L) - \ln(\eta))/(\ln(2))\rceil$ iterations. Moreover, at termination, the result (x^*, λ^*) is feasible for $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$ with $\lambda^{**} - \lambda^* \leq \eta$.

Notice that the additional constraint "$\lambda \geq \lambda_k^L$" in step 1 does not cause any trouble but guarantees that $(\lambda_k)_k$ is monotonically increasing. Moreover, the calculation of global minimizers (in step 4A), respectively, local minimizers (in step 1), instead of just feasible points should significantly speed up the algorithm. In this case the update of λ_k^U in step 4B, respectively, of λ_k^L in step 2, may lead to a much bigger

reduction of the gap $\lambda_k^U - \lambda_k^U$. Obviously, step 1 must be carried out in each iteration. Notice also that λ_k^L is increased in step 4A, while it remains untouched in step 4B. Denote by K the number of iterations in which step 4A has been performed. Moreover, if step 4A has been performed in iteration $k-1$, let (x_k, λ_k) in step 1 be a local optimizer. Then, consequently,

$$K \leq \left| \left\{ \lambda \,|\, (x, \lambda) \text{ is a local optimizer of } (\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}}) \right\} \right|,$$

i.e., K is limited by the number of levels of the objective function which are attained at a local optimizer. We believe that this cardinality is very small in applications. As an illustration consider Example 2.4 where $K = 2$.

For the numerical treatment of the SDP problems $(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}})$, $(\mathrm{P}_{\mathrm{compl}}^{\mathrm{SDP}})$, $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ one must resort to methods of semidefinite programming. Such methods, and corresponding codes, are nowadays available for linear SDPs. The limiting factor of these codes is, however, the problem size which, compared to general nonlinear programs, is restricted to problems of medium size. The problem $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ even requires a method which can deal with BMIs. We will use such a method to solve examples in the next section. It should be noted, however, that algorithms and codes for SDPs with BMIs are on the edge of current research and are not yet standard. Notice that the BMI constraint in any generalized eigenvalue problem (GEVP) has a very simple structure. As above, being quasi-convex, the problem can be solved by a bisection algorithm, i.e., by solving a sequence of linear SDP problems of the same size and structure (again, see [5, sect. 4.2.5]). However, the crucial factor, in our opinion, is the *size* of the problem. To solve one GEVP problem formulated as BMI (for instance, by the code PENBMI), one needs about the same CPU time as to solve one linear SDP problem in the bisection algorithm! Hence, when we want to apply the approach to large-scale problems with thousands of variables (in particular, to problems discretized by the finite element method), the BMI formulation will use only a fraction of CPU time when compared to the bisection approach.

4. Numerical examples. In this chapter we present numerical examples which, on the one hand, will illustrate some of the theoretical results above and, on the other hand, demonstrate the practical use of the SDP problem formulations.

Intentionally, we do not specify realistic physical properties, like material elastic modulus E or density ρ. In all examples, they are assumed to be equal to one. This can be done without any loss of generality or applicability due to the linear dependence of the volume, compliance, and stiffness and mass matrices on x, E, and ρ. In this case, switching from our default values to realistic physical values (say, $E = 2.1 \cdot 10^{11}$ Pa and $\rho = 7.8 \cdot 10^3$ kg/m^3) is a matter of a simple linear scaling of our results. Further, when we speak of an $i \times j$ truss, we have in mind a regular equidistant grid of $i \cdot j$ nodes, i in the horizontal direction and j in the vertical direction. Thus the dimensions of the nodal grid are $(i-1) \times (j-1)$.

The code we have used for the treatment of the SDP formulations is PENBMI, version 2.0 [13]. This code implements the generalized augmented Lagrangian method, as described in [12, 28]. In particular, PENBMI can treat BMIs, as is necessary for problem $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ [10].

The examples were solved on a Pentium III-M 1GHz PC running Windows 2000. All problems were formulated and solved in MATLAB using the YALMIP parser [16] to PENBMI.

Example 4.1. This example illustrates Theorems 2.8, 2.9, and 2.19 with $M_0 = 0$. Consider a 3×3 truss with all nodes connected by potential bars. The nodes on the

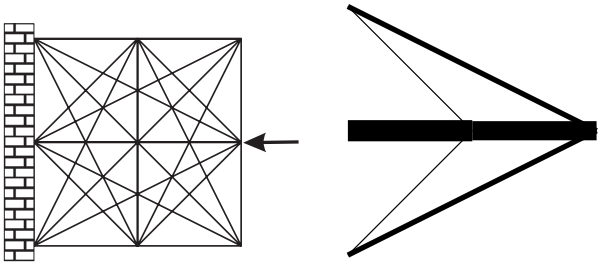

FIG. 2. *A* 3×3 *truss (Example* 4.1*): initial layout and optimal topology.*

left-hand side are fixed in both directions and a horizontal force $(-1, 0)$ is applied at the right-middle node; see Figure 2 (left). No nonstructural mass is considered, i.e., $M_0 = 0$. We consider the minimum volume problem $(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}})$ with $\overline{\gamma} = 1$ and $\overline{\lambda} = 5.0 \cdot 10^{-2}$. PENBMI calculated the (global) optimal solution (x^*, V^*) of this convex problem: the optimal design x^* is shown in Figure 2 (right), while $V^* = 1.20229$. Proposition 3.2(b) shows that there exists u^* such that (x^*, u^*) is optimal for problem $(\mathrm{P}_{\mathrm{vol}})$.

Now consider the minimum compliance problem $(\mathrm{P}_{\mathrm{compl}}^{\mathrm{SDP}})$ with $\overline{V} = 1.20229$ and $\overline{\lambda} = 5.0 \cdot 10^{-2}$. As expected by Proposition 3.2(b) and Theorem 2.9, we obtain the solution (x^*, γ^*) with the same structure x^* as before (Figure 2 (right)), and with $\gamma^* = 1$.

Finally, when solving the problem of maximizing the minimum eigenvalue $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ with $\overline{V} = 1.20229$ and $\overline{\gamma} = 1$, we again obtain x^* from before, and $\lambda^* = 5.0 \cdot 10^{-2}$. This shows that the value V^* in (26) and the value γ^* in (27) are attained for x^*, because otherwise this would yield a contradiction to Theorem 2.19. The authors believe that in this simple example the solution structure x^* is the unique solution, and thus Corollary 2.20 may be applied.

Example 4.2. In this example, as in Example 4.1 above, we again obtain the same optimal structure for all three problem formulations. Here, however, $M_0 \neq 0$, and thus these coincidences are somewhat unexpected.

We consider the same ground structure, boundary conditions, and external load as in the previous example. In addition, we assign a nonstructural mass of size 10 at the loaded node, i.e., $M_0 \neq 0$; see Figure 3 (left). Consider the minimum volume problem $(\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}})$ with $\overline{\gamma} = 1$ and $\overline{\lambda} = 5.0 \cdot 10^{-2}$. Figure 3 (right) shows the optimal design x^*. The corresponding optimal volume is $V^* = 7.10157$.

Now consider the minimum compliance problem $(\mathrm{P}_{\mathrm{compl}}^{\mathrm{SDP}})$ with $\overline{V} = 7.1015$ and $\overline{\lambda} = 5.0 \cdot 10^{-2}$. We obtain the solution (x^*, γ^*) with the same structure x^* as before (Figure 3 (right)), and with $\gamma^* = 1$.

Finally, when solving the problem of maximizing the minimum eigenvalue $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$ with $\overline{V} = 7.1015$ and $\overline{\gamma} = 1$, we again obtain x^* from above, and $\lambda^* = 5.0 \cdot 10^{-2}$. Again, we believe that the solution x^* is unique in each of the three problems. If this is the case, then the equivalence of the results holds by Corollaries 2.14, 2.17, and 2.20.

Example 4.3. This academic example illustrates the possible nonuniqueness of solutions to the problem $(\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}})$. Consider a 2×3 ground structure with boundary conditions and load as depicted in Figure 4 (left). Put $M_0 = 0$, $\overline{\gamma} = 10$, and $\overline{V} = 10$. The computed optimal structure x^* is presented in Figure 4 (right); the optimal

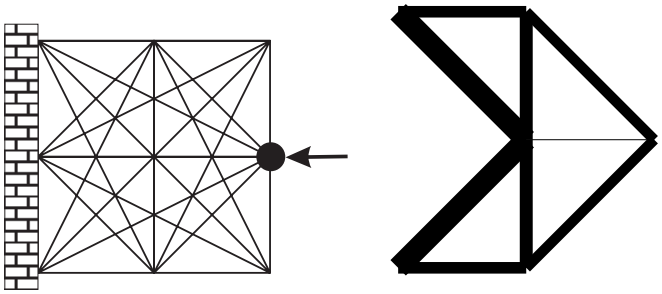

FIG. 3. *A* 3×3 *truss with nonstructural mass (Example* 4.2*): initial layout and optimal topology.*

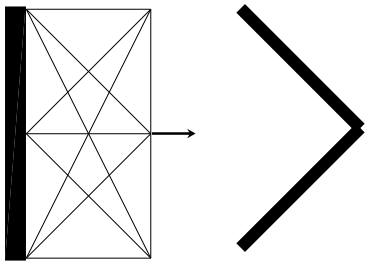

FIG. 4. *Example demonstrating possible nonuniqueness of solution of the* ($\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}}$) *problem.*

objective function value of ($\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}}$) is $-\lambda^* = -0.70711$, i.e., $\lambda_{\min}(x^*) = 0.70711$. While the volume constraint is active at x^*, the compliance constraint is inactive (more precisely, after calculating some u^* corresponding to x^*, we have $\gamma^* := f^T u^* = 0.1 < \overline{\gamma} = 10$). Proposition 2.10 suggests that if we scale the solution x^* by a certain factor μ, we will still get a solution to our problem. For instance, if we solve the same problem but with $\overline{V} = 1.0$, then we will obtain a solution with the same λ^* and with $\gamma^* = 1.0$, i.e., still within the $\overline{\gamma}$ limits. Table 1 summarizes these numbers. It also presents the results for the case when $M_0 = 10$ (and then Proposition 2.10 does not apply). In this case, the optimal solution is no longer scalable.

Example 4.4. Here we demonstrate the possible nonuniqueness of solutions to the minimum volume problem ($\mathrm{P}_{\mathrm{vol}}$) (or ($\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}}$)), and illustrate Theorem 2.13(b) in more detail. Consider the ground structure and boundary conditions as shown in Figure 5 (right). The load vector consists of a single vertical force $(0, 1)$ applied at the bottom-right node. Further, let $\overline{\gamma} := 0.5$, and consider the single-load min-volume problem without vibration constraint:

$$\begin{aligned} \min_{x \in \mathbb{R}^m,\, u \in \mathbb{R}^n} & \sum_{i=1}^{m} x_i \\ \text{subject to } & K(x)u = f, \\ & f^T u \le \overline{\gamma}, \\ & x_i \ge 0, \quad i = 1, \dots, m. \end{aligned} \tag{31}$$

This problem can be formulated as a linear program [1], and thus the set $\mathcal{X}^*_{(31)}$ of solution structures of (31) is given by the set of all convex combinations of the leftmost

TABLE 1
Results of Example 4.3 for different data.

M_0	$\overline{V}$	γ^*	λ^*
0	1	1	−0.70711
0	10	0.1	−0.70711
10	1	1	−0.08761
10	10	0.1	−0.41421

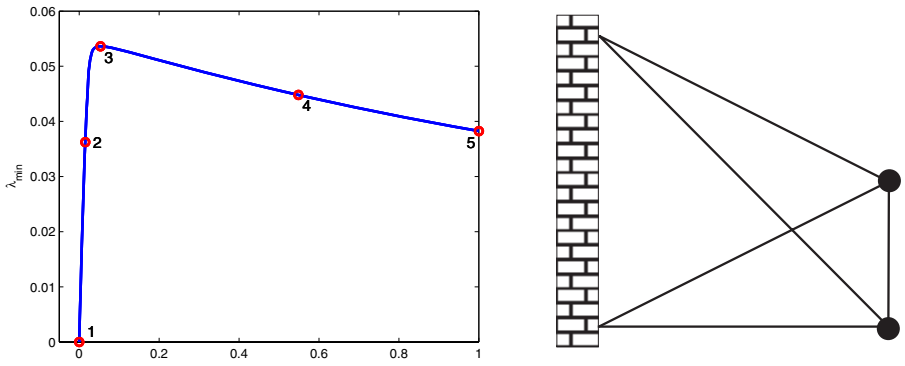

FIG. 5. *Example 4.4—graph of $\lambda_{\min}$ on interval between two structures of the same volume and compliance and ground structure (potential nodes and bars)*

and rightmost structures in Figure 6, i.e., by the set

$$\mathcal{X}^*_{(31)} = \{(1-\mu)x^{1*} + \mu x^{2*} \mid \mu \in [0,1]\},$$

where x^{1*} denotes the leftmost and x^{2*} the rightmost structures in Figure 6. We have $\mathrm{vol}(x^*) = 18$ and $c(x^*) = 1$ for all $x^* \in \mathcal{X}^*_{(31)}$. Figure 5 (left) shows the dependence of the minimum vibration eigenvalue on the parameter μ of this convex combination, i.e., a plot of the function

$$\mu \mapsto \lambda_{\min}((1-\mu)x^{1*} + \mu x^{2*})$$

over the interval $[0,1]$. The points 1–5 in the plot correspond to the structures in Figure 6, left to right. We observe that $\lambda_{\min}$ is maximized at $\mu \approx 0.0536$, i.e., at the third structure. Let us now add the vibration constraint to problem (31); thus we arrive at problem ($\mathrm{P}_{\mathrm{vol}}$). For example, put $\overline{\lambda} := 0.037$, which is the value of $\lambda_{\min}$ for the second structure in Figure 6. Then it is clear that any structure between the second and fifth trusses is a solution to problem ($\mathrm{P}_{\mathrm{vol}}$), and the vibration constraint will be inactive for the structures strictly in between. Moreover, the third truss is the structure $\hat{x}^*$ where the supremum in (19) in Theorem 2.13 is attained, i.e., the third truss is optimal for problem ($\mathrm{P}_{\mathrm{eig}}$) with the settings $\overline{V} := 18$ and $\overline{\gamma} := 1$ (according to Theorem 2.13(b)).

Example 4.5. This example shows that not only can the minimum eigenvalue function be discontinuous (see Example 2.4), but it may also behave in a non-Lipschitz way. This is slightly unexpected, given the well-known fact that the eigenvalues of the *standard* symmetric eigenvalue problem are Lipschitz.

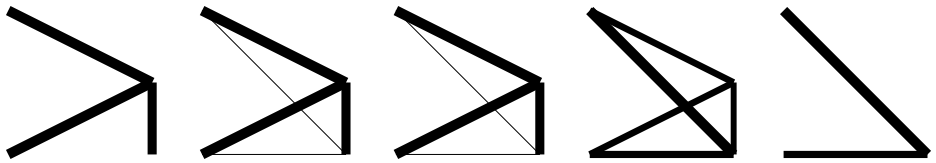

FIG. 6. *Example* 4.4—*structures corresponding to points* 1–5 *on the graph in Figure* 5.

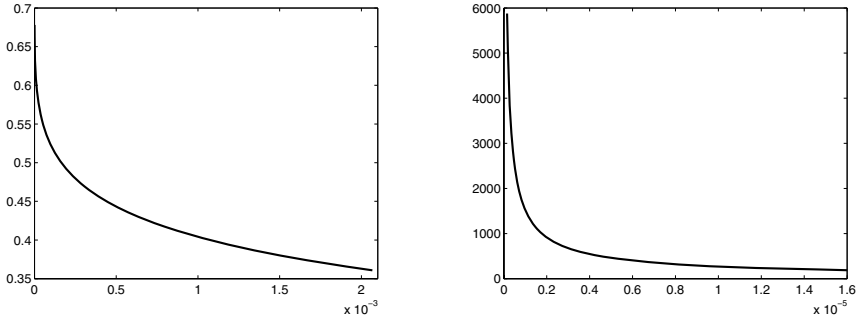

FIG. 7. *Example* 4.5 *demonstrating apparent non-Lipschitz behavior of the minimum eigenvalue function close to the boundary of the feasible region. The graph of the function (left) and its derivative (right) are shown.*

Consider again the 3×3 ground structure from Example 4.1 with all nodes connected. A horizontal force is applied at the central node. Figure 7 shows the behavior of the objective function $\lambda_{\min}(\cdot)$ of problem $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$ with $x \geq \varepsilon > 0$; denote the solution of this problem by x_ε. The left-hand figure shows the plot of the function $\lambda_{\min}(x_\varepsilon)$ for $1.5 \cdot 10^{-7} \leq \varepsilon \leq 2 \cdot 10^{-3}$; the function looks all but Lipschitz (for smaller values of ε we were unable to compute the function value due to round-off errors). To see its behavior more clearly, we plot in the right-hand figure the derivative (computed by finite differences) in the interval $[1.5 \cdot 10^{-7}, 1.6 \cdot 10^{-5}]$; this figure confirms the non-Lipschitz behavior. When we solve the minimum eigenvalue problem $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{eig}})$ with $x \geq 0$, we obtain the optimum value $\lambda^* = -0.7071068$. Obviously, the picture is not a proof of non-Lipschitz behavior, but it is very indicative of such. The optimal trusses for $\varepsilon = 2 \cdot 10^{-3}$ and for the problem with $x \geq 0$ are shown in Figure 8 (left and right, respectively). In the first case, only bars that are not equal to the lower bound are presented. In both cases, the compliance constraint was inactive.

Example 4.6. This example demonstrates that the change in M_0 may lead to a change in the topology of the optimal structure, as has been suggested in the discussion after Proposition 2.22. We take the same ground structure, boundary conditions, and loads as in Example 4.2. Consider the minimum volume problem $(\mathrm{P}^{\mathrm{SDP}}_{\mathrm{vol}})$ with three different values of M_0, namely, 0, 10, and 100. The bounds on compliance and minimum eigenvalue are $\overline{\gamma} = 20$ and $\overline{\lambda} = 1.0 \cdot 10^{-3}$. The optimal values of V^* are, respectively, 0.05012, 0.07284, and 0.63386. In the latter case ($M_0 = 100$), the compliance constraint was inactive. The respective optimal structures are presented in Figure 9.

Example 4.7. With practical applications in mind, we also present an example of larger ground structure with multiple loads. Consider a 7×3 nodal grid with the ground structure, boundary conditions, and loads as depicted in Figure 10 (top left).

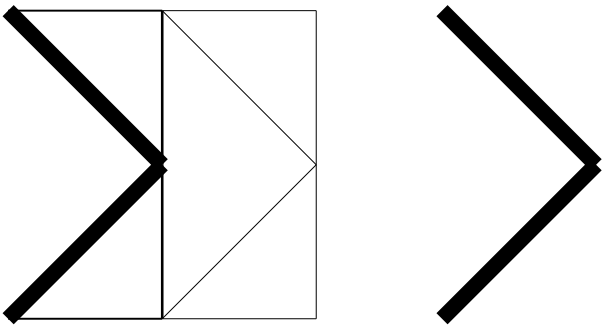

FIG. 8. *Example* 4.5—*optimal structures for* $x_i \geq 2 \cdot 10^{-3}$ *(left) and* $x_i \geq 0$ *(right).*

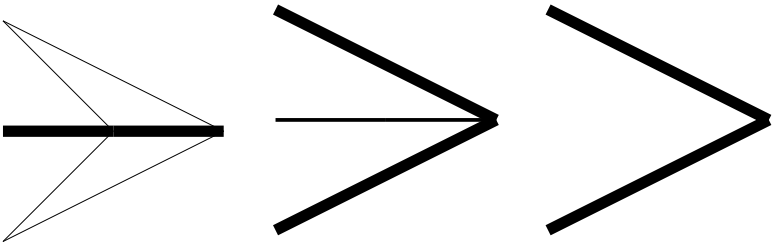

FIG. 9. *Example* 4.6 *demonstrating the dependence of the optimal structure on nonstructural mass changes; optimal results for* $M_0 = 0, 10, 100$ *are depicted left to right.*

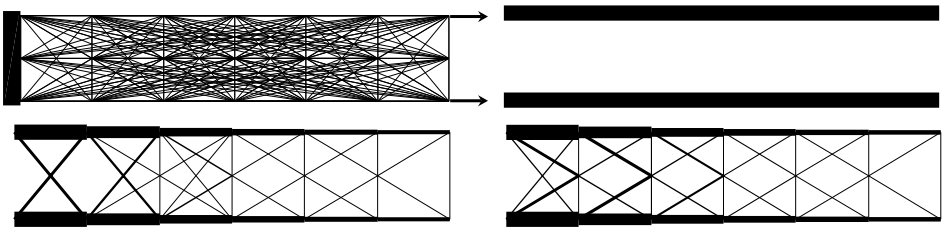

FIG. 10. *A medium-size multiple-load example (Example* 4.7*): initial layout (top left); optimal topology without (top right) and with (bottom left) vibration constraints; single-load optimal result with vibration constraints (bottom right).*

Each of the load arrows indicates an independent load case. The result of the standard minimum volume multiple-load problem (with no vibration constraints) with $\overline{\gamma} = 10$ is shown in Figure 10 (top right)—obviously resulting in two independent horizontal bars, one for each load. The volume of this structure is $V^* = 5.0$. Figure 10 (bottom left) shows the result for the multiple-load problem with a bound $\overline{\lambda} = 1.0 \cdot 10^{-3}$ on the minimum eigenvalue with the optimal volume $V^* = 7.8309$. For a comparison, we also show a result of the single-load problem (both forces considered as a single load) with $\overline{\gamma} = 20$ and $\overline{\lambda} = 1.0 \cdot 10^{-3}$; the optimal structure with $V^* = 7.6166$ is presented in Figure 10 (bottom right). All solutions were obtained by PENBMI in less than 10 seconds.

Example 4.8. We consider the same problem scenario as in Example 4.2 but with a 7×7 full ground structure with 1176 potential bars; see Figure 11 (left). Again

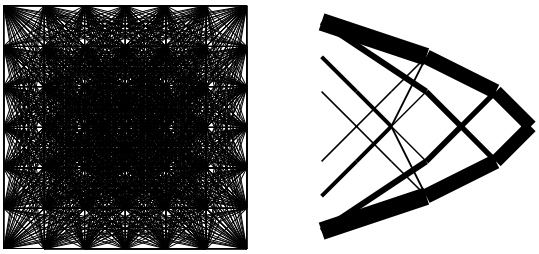

FIG. 11. *Example* 4.8—*a medium-size problem, initial layout and optimal topology.*

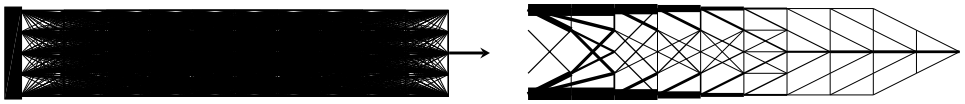

FIG. 12. *Example* 4.9—*a medium-size problem, initial layout and optimal topology.*

we solve the minimum volume problem ($\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}}$) with $\overline{\gamma} = 1$ and $\overline{\lambda} = 5.0 \cdot 10^{-2}$ (and a nonstructural mass of size 10 at the loaded node). Figure 11 (right) shows the calculated optimal design x^*. The optimal volume is $V^* = 3.59874$, i.e., just one-half of the optimal volume of the 3×3 ground structure from before in Example 4.2. To solve the minimum volume problem by PENBMI, we needed 5 min. 16 sec. To solve the other two formulations, ($\mathrm{P}_{\mathrm{compl}}^{\mathrm{SDP}}$) and ($\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}}$), the code needed 11 min. 41 sec. and 20 min. 15 sec., respectively. As expected, formulation ($\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}}$) is computationally the most demanding one due to the presence of BMIs.

Example 4.9. Here we consider a medium-size example with an 11×5 ground structure, having 100 degrees of freedom and 1485 potential bars. The bounds on compliance and on the eigenvalue were $\overline{\gamma} = 20$ and $\overline{\lambda} = 5.0 \cdot 10^{-4}$. A horizontal force $(-10, 0)$ is applied at the right-middle node; see Figure 12 (left). No nonstructural mass is considered. The minimum volume problem was solved by PENBNI in 33 min. 37 sec. and resulted in the optimal structure shown in Figure 12 (right) with $V^* = 1542.65$. According to Theorem 2.8 this structure is also optimal for the minimum compliance problem ($\mathrm{P}_{\mathrm{compl}}$) with $\overline{V} := 1542.65$ and $\overline{\lambda}$ as above.

5. An extension: The multiple-mass problem. Here we propose an extension to each of the three original problem formulations, which to the best of our knowledge has not been considered before. Assume that we have n_k matrices $M_0^{(k)}$, $k = 1, \ldots, n_k$, corresponding to n_k different nonstructural masses that can be applied independently. The corresponding eigenvalue constraint extending the constraint "$\lambda_{\min}(x) \geq \overline{\lambda}$" in problem ($\mathrm{P}_{\mathrm{vol}}$) or in problem ($\mathrm{P}_{\mathrm{compl}}$) would then be stated as

$$\lambda_{\min}(x, M_0^{(k)}) \geq \overline{\lambda} \qquad \forall k = 1, \ldots, n_k,$$

where we have used the notation (28) from section 2.5 for different nonstructural mass matrices. Similarly, the objective function $\lambda_{\min}(\cdot)$ in problem ($\mathrm{P}_{\mathrm{eig}}$) becomes

$$x \mapsto \min_{1 \leq k \leq n_k} \lambda_{\min}(x, M_0^{(k)})$$

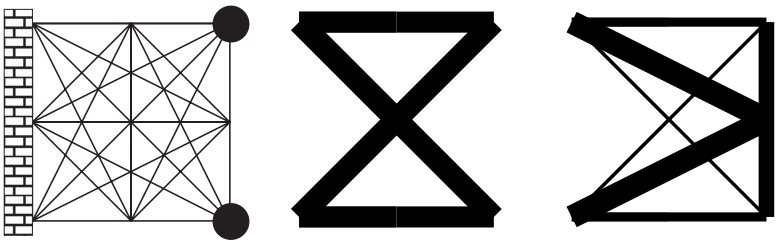

FIG. 13. *A multiple-mass problem (Example* 5.1*: initial layout (left), a "single-mass" result (middle), and a multiple-mass optimal structure (right).*

(which is to be maximized). Generalizing the SDP problem ($\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}}$), we arrive at the following formulation possessing the same problem structure:

$$
\begin{aligned}
(32)\qquad \min_{x\in\mathbb{R}^m,\lambda\in\mathbb{R}} \; & -\lambda \\
\text{subject to } & \begin{pmatrix} \gamma & f_\ell^T \\ f_\ell & K(x) \end{pmatrix} \succeq 0, \quad \ell = 1,\dots,n_\ell, \\
& \sum_{i=1}^{m} x_i \le V, \\
& x_i \ge 0, \quad i = 1,\dots,m, \\
& K(x) - \lambda(M(x) + M_0^{(k)}) \succeq 0, \quad k = 1,\dots,n_k\,.
\end{aligned}
$$

In an analogous way we may extend the SDP problems ($\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}}$) and ($\mathrm{P}_{\mathrm{compl}}^{\mathrm{SDP}}$) from section 3 to the case of multiple masses. Because the mathematical structure of these formulations is the same as that of problems ($\mathrm{P}_{\mathrm{vol}}^{\mathrm{SDP}}$), ($\mathrm{P}_{\mathrm{compl}}^{\mathrm{SDP}}$), and ($\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}}$), we may use again the code PENBMI to numerically solve these problems. We finish with a numerical example.

Example 5.1. Consider a 3×3 truss with all nodes connected by potential bars. The nodes on the left-hand side are fixed in both directions, and two balls (nonstructural masses) are placed in the corners on the right-hand side; see Figure 13 (left). Figure 13 (middle) shows the optimal design for formulation ($\mathrm{P}_{\mathrm{eig}}^{\mathrm{SDP}}$) when both masses are considered a "single" nonstructural mass. Figure 13 (right) presents the result of the multiple-mass formulation (32), where the two nonstructural masses are considered being independent from each other. The volume bound in both problems was $\overline{V} := 1$, and the resulting optimal eigenvalues were $\lambda^* = 4.758 \cdot 10^{-3}$ in the single-mass case and $\lambda^* = 7.365 \cdot 10^{-3}$ in the multiple-mass case.

Appendix.

A.1. Proof of Proposition 2.3. For the proof of (a) and (b) let $x \in X$ be fixed, and let $K := K(x)$ and $M := M(x) + M_0$, for simplicity. Because M is symmetric, there exists an orthonormal basis $\{v_1,\dots,v_r\} \subset \mathbb{R}^n$ of range(M) where $r = \mathrm{rank}(M)$. Consider the matrix $P := (v_1 \cdots v_r) \in \mathbb{R}^{n\times r}$ consisting columnwise of the vectors v_j. We state the generalized eigenvalue problem

$$
P^T K P z = \lambda P^T M P z, \tag{33}
$$

with $z \in \mathbb{R}^r$.

First we show that P^TMP is positive definite. To see this, let $z \neq 0$ be arbitrary, and assume that $z^TP^TMPz = 0$. Because M is positive semidefinite, this implies $Pz = 0$. But the columns of P are linearly independent, and hence we arrive at $z = 0$, a contradiction. This shows that all eigenvalues of (33) are well defined, and (as often seen) problem (33) can be equivalently written as an ordinary eigenvalue problem

$$\widetilde{K}z = \lambda z \tag{34}$$

with $\widetilde{K} := (P^TMP)^{-1/2}P^TKP(P^TMP)^{-1/2}$.

Next we prove that λ is a well-defined eigenvalue of problem (8) if and only if it is an eigenvalue of problem (33) (and thus also an eigenvalue of $\widetilde{K}$ in (34)). First, let (λ, w) be a solution of (8) with $w \notin \ker(M)$. The latter property shows that there exist $w_1 \in \ker(M)$ and $w_2 \in \operatorname{range}(M)$, $w_2 \neq 0$, such that $w = w_1 + w_2$. Inserting $w = w_1 + w_2$ into (8) gives $Kw_1 + Kw_2 = \lambda(Mw_1 + Mw_2)$, i.e.,

$$Kw_2 = \lambda Mw_2 \tag{35}$$

due to Lemma 2.1. Notice that $w_2 \neq 0$, and thus (λ, w_2) is also a solution of (8). Because $w_2 \in \operatorname{range}(M)$, there exists $z \in \mathbb{R}^r$ such that $w_2 = Pz$. Hence, (35) becomes

$$KPz = \lambda MPz,$$

and multiplication by P^T from the left shows that (λ, z) is a solution of (33).

Conversely, let (λ, z) be a solution of (33) with $z \neq 0$. Consider $w := Pz$. Because the columns of P form a basis of $\operatorname{range}(M)$, it is $w \neq 0$ and $w \in \operatorname{range}(M)$. Through the general identity $\operatorname{range}(M)^\perp = \ker(M^T) = \ker(M)$ we see that $w \notin \ker(M)$. Moreover, as z is a solution of (33), $P^TKw = \lambda P^TMw$, which we may multiply by P from the left to end up with

$$PP^TKw = \lambda PP^TMw. \tag{36}$$

Now, Lemma 2.1 shows that $\operatorname{range}(K) \subseteq \operatorname{range}(M)$, i.e., $Kw \in \operatorname{range}(M)$. By construction, PP^T is a projection matrix onto $\operatorname{range}(M)$, and thus (36) becomes $Kw = \lambda Mw$. (Alternatively, notice that $P^TP = I_{r\times r}$. Hence, for each $\tilde{w} = P\tilde{z} \in \operatorname{range}(M)$, $PP^T\tilde{w} = PP^TP\tilde{z} = P\tilde{z} = \tilde{w}$.) As $w \notin \ker(M)$ this proves that λ is a well-defined eigenvalue of problem (8). Because $\widetilde{K} \succeq 0$, each eigenvalue λ in (34) is nonnegative, and we are done with the proof of (a).

To finish the proof of (b), we use formulation (34) and the Rayleigh quotient to see that

$$\lambda_{\min}(x) = \inf_{z\neq 0} \frac{z^T\widetilde{K}z}{z^Tz}.$$

Inserting the definition of $\widetilde{K}$, and using the substitutions $\tilde{z} := (P^TMP)^{-1/2}z$ and $w := P\tilde{z}$, we conclude

$$\lambda_{\min}(x) = \inf_{z\neq 0} \frac{z^T(P^TMP)^{-1/2}P^TKP(P^TMP)^{-1/2}z}{z^Tz} \tag{37}$$

$$= \inf_{\tilde{z}\neq 0} \frac{\tilde{z}^TP^TKP\tilde{z}}{\tilde{z}^TP^TMP\tilde{z}}$$

$$= \inf_{w\in\operatorname{range}(M):\, w\neq 0} \frac{w^TKw}{w^TMw}. \tag{38}$$

Now, for each $\tilde{u}$ with $M\tilde{u} \neq 0$ there exist $\tilde{v} \in \ker(M)$ and $\tilde{w} \in \ker(M)^\perp = \mathrm{range}(M)$ such that $\tilde{u} = \tilde{v} + \tilde{w}$. Hence, by Lemma 2.1,

$$\frac{\tilde{u}^T K \tilde{u}}{\tilde{u}^T M \tilde{u}} = \frac{\tilde{w}^T K \tilde{w}}{\tilde{w}^T M \tilde{w}}.$$

Thus we can continue (37) to (38) with

$$\lambda_{\min}(x) = \inf_{w \in \mathrm{range}(M):\, w \neq 0} \frac{w^T K w}{w^T M w} = \inf_{u:\, Mu \neq 0} \frac{u^T K u}{u^T M u},$$

which proves (b).

(c) Let us first show the "$\geq$" part. For this, take arbitrary $\lambda \in \mathbb{R}$ satisfying $K(x) - \lambda(M(x) + M_0) \succeq 0$, i.e.,

$$v^T K(x) v - \lambda v^T (M(x) + M_0) v \geq 0 \quad \forall v \neq 0, \tag{39}$$

and consider arbitrary u with $(M(x) + M_0)u \neq 0$. Then $u \neq 0$, and (39) for $v := u$ shows that

$$\frac{u^T K(x) u}{u^T (M(x) + M_0) u} \geq \lambda\,.$$

Because λ and u were arbitrary, we can write "inf" in front of the fraction and "sup" in front of λ, and the inequality remains valid, i.e.,

$$\inf_{u:\, (M(x)+M_0)u \neq 0} \frac{u^T K(x) u}{u^T (M(x) + M_0) u} \geq \sup\{\, \lambda \mid K(x) - \lambda(M(x) + M_0) \succeq 0 \,\}\,.$$

By (b) the value on the left-hand side coincides with $\lambda_{\min}(x)$, and hence we have proved "$\geq$".

The proof of the "$\leq$" part is similar: Let

$$\tilde{\lambda} := \inf_{u:\, (M(x)+M_0)u \neq 0} \frac{u^T K(x) u}{u^T (M(x) + M_0) u}.$$

Then

$$\begin{aligned}
\tilde{\lambda} &\leq \frac{u^T K(x) u}{u^T (M(x) + M_0) u} && \forall u : (M(x) + M_0)u \neq 0 \\
&\iff u^T K u - \tilde{\lambda} u^T (M(x) + M_0) u \geq 0 && \forall u : (M(x) + M_0)u \neq 0 \\
&\iff u^T K u - \tilde{\lambda} u^T (M(x) + M_0) u \geq 0 && \forall u \in \mathbb{R}^n \quad \text{(see Lemma 2.1)} \\
&\iff K(x) - \tilde{\lambda}(M(x) + M_0) \succeq 0 \\
&\iff \tilde{\lambda} \leq \sup\{\lambda \mid K(x) - \lambda(M(x) + M_0) \succeq 0\}\,.
\end{aligned}$$

(d) Let $\bar{x} \in \mathbb{R}^m$, $\bar{x} \geq 0$, and let $\{x^k\}_k$ be an arbitrary sequence such that $x^k \to \bar{x}$. We want to show that $\limsup_{x \to \bar{x}} \lambda_{\min}(x) \leq \lambda_{\min}(\bar{x})$. Take a subsequence $\{x_j^k\}_j$ of $\{x^k\}_k$ such that

$$\lim_{j \to \infty} \lambda_{\min}(x_j^k) = \bar{\lambda} := \limsup_{x \to \bar{x}} \lambda_{\min}(x)\,.$$

By definition,

$$K(x_j^k) - \lambda_{\min}(x_j^k)(M(x_j^k) + M_0) \succeq 0 \quad \forall j$$

and, passing with j to the infinity, we get

$$K(\bar{x}) - \bar{\lambda}(M(\bar{x}) + M_0) \succeq 0\,,$$

using the continuous dependence of $K(x)$ and $M(x)$ on x and closedness of the cone of positive semidefinite matrices. Hence

$$\bar{\lambda} \leq \sup\{\lambda \mid K(\bar{x} - \lambda(M(\bar{x}) + M_0) \succeq 0\} = \lambda_{\min}(\bar{x})$$

and we are done.

(e) By construction, $M(x) \succ 0$ for $x \in X_\varepsilon$. Then the pencil $(K(x), M(x) + M_0)$ is definite and we can apply general theory, saying that the eigenvalues of (8) depend continuously on parameter x [4, 29].

(f) For each $u : (M(x) + M_0)u \neq 0$, the function $u \mapsto \frac{u^T K(x) u}{u^T (M(x)+M_0) u}$ is a linear-fractional function in $(K(x), (M(x) + M_0)$, hence a quasi-linear function in variables $(K(x), (M(x) + M_0))$ (see [5]) and thus in x. Using point (b), we conclude that $-\lambda_{\min}(x)$ is quasi-convex in x, because it is the supremum of a family of quasi-linear (and thus quasi-convex) functions (here we use the fact that $-\inf g(x) = \sup -g(x)$). ∎

Remark A.1. The projection PP^T defined in the above proof takes, in fact, a particularly simple structure. Assume that $x \in X$ is given and that $\ker(M(x)) \subset \ker(M_0)$. Denote by $\mathcal{B} \subseteqq \{1, \ldots, n\}$ the degrees of freedom associated only with elements j such that $x_j = 0$ and by $\mathcal{A}$ its complement. With $k := |\mathcal{A}|$ we assume without restriction that $\mathcal{A} = \{1, \ldots, k\}$, and $\mathcal{B} = \{k + 1, \ldots, n\}$. Then $K(x)$ and $M(x) + M_0$ can be partitioned as follows:

$$K(x) = \begin{pmatrix} K_{\mathcal{A}\mathcal{A}} & K_{\mathcal{A}\mathcal{B}} \\ K_{\mathcal{B}\mathcal{A}} & K_{\mathcal{B}\mathcal{B}} \end{pmatrix}, \quad M(x) + M_0 = \begin{pmatrix} M_{\mathcal{A}\mathcal{A}} & M_{\mathcal{A}\mathcal{B}} \\ M_{\mathcal{B}\mathcal{A}} & M_{\mathcal{B}\mathcal{B}} \end{pmatrix}.$$

Clearly, $K_{\mathcal{A}\mathcal{A}} \succeq 0$; further (see Appendix A.2) $M_{\mathcal{A}\mathcal{A}} \succ 0$, and, by Lemma 2.1, $K_{\mathcal{A}\mathcal{B}} = K_{\mathcal{B}\mathcal{A}}^T = M_{\mathcal{A}\mathcal{B}} = M_{\mathcal{B}\mathcal{A}}^T = 0$ and $K_{\mathcal{B}\mathcal{B}} = M_{\mathcal{B}\mathcal{B}} = 0$ (as, e.g., $K_{\mathcal{B}\mathcal{B}} = \sum_{i:x_i=0} x_i K_i$). By this, each eigenvalue $\lambda_{\mathcal{A}}$ of the problem

$$K_{\mathcal{A}\mathcal{A}} w = \lambda_{\mathcal{A}} M_{\mathcal{A}\mathcal{A}} w$$

is a well-defined eigenvalue of problem (8).

A.2. On the representation of the mass matrix. Let $x \in X$ be given and, for simplicity of notation, assume that $M_0 = 0$ (in general, we would assume that $\ker(M(x)) \subset \ker(M_0)$). We want to show that $M(x)$, after a suitable permutation, can be partitioned into the form

$$\begin{pmatrix} M_{\mathcal{A}\mathcal{A}} & 0 \\ 0 & 0 \end{pmatrix},$$

where $M_{\mathcal{A}\mathcal{A}} \succ 0$.

LEMMA A.2. *Let $Z_i \in \mathbb{R}^{n\times n}$, $Z_i \succ 0$, and $P_i \in \mathbb{R}^{k\times n}$, $k < n$, for $i = 1, \ldots, \mu$. Then, for any $z \neq 0$,*

$$\sum_{i=1}^{\mu} P_i Z_i P_i^T z = 0 \quad \Longrightarrow \quad \sum_{i=1}^{\mu} P_i P_i^T z = 0\,.$$

Proof. From the assumption we know that $\sum_{i=1}^{\mu} z^T P_i Z_i P_i^T z = 0$ and $z^T P_i Z_i P_i^T z \geq 0$ for each i (as $P_i Z_i P_i^T \succeq 0$). Thus $z^T P_i Z_i P_i^T z = 0$ for all i and therefore

$$\|Z^{1/2} P_i^T z\|_2^2 = 0.$$

As $Z^{1/2} \succ 0$, this immediately gives $P_i^T z = 0$ for all i, and the lemma follows. ∎

Now let $\mathcal{I}$ include the indices of all nonzero components x_i of x. Without loss of generality, let us assume that the nonzero components of x are equal to one, i.e., $x_i = 1$ for $i \in \mathcal{I}$. Hence $M = \sum_{i=1}^{m} x_i P_i \widehat{M}_i P_i^T = \sum_{i \in \mathcal{I}} P_i \widehat{M}_i P_i^T$. Define the projection

$$S = I_{n \times n} - \prod_{i \in \mathcal{I}} (I_{n \times n} - P_i P_i^T)\,;$$

clearly, S projects a vector $z \in \mathbb{R}^n$ to a subspace generated by Euclidean unit vectors associated with all degrees of freedom belonging to elements $i \in \mathcal{I}$, i.e., to the space span $\{P_i P_i^T e,\ i \in \mathcal{I}\}$, where $e \in \mathbb{R}^n$ is the vector of all ones. From this definition, and from the construction of M, we immediately have that $M = SMS$. Without loss of generality, assume that S is of the form

$$S = \begin{pmatrix} I_{k \times k} & 0 \\ 0 & 0 \end{pmatrix},$$

where k is the rank of S. Hence M also has the form

$$M = \begin{pmatrix} \widetilde{M} & 0 \\ 0 & 0 \end{pmatrix},$$

with $\widetilde{M} \in \mathbb{R}^{k \times k}$.

LEMMA A.3. *$\widetilde{M}$ is positive definite.*

Proof. Assume that $Mz = 0$ for some $z \neq 0$. We need to show that $\widetilde{M}\tilde{z} = 0$ only for $\tilde{z} = 0$, where $\tilde{z}$ includes the first k components of z. By definition,

$$Mz = \sum_{i \in \mathcal{I}} P_i \widehat{M}_i P_i^T z = 0\,.$$

From the above lemma, we have that

$$\sum_{i \in \mathcal{I}} P_i P_i^T z = 0\,.$$

Now, the matrix $\sum_{i \in \mathcal{I}} P_i P_i^T$ is of the same form as S and M, and its upper-left block consists of a (full) positive diagonal. Hence $\tilde{z} = 0$. ∎

Acknowledgment. The authors would like to thank two anonymous referees for their valuable comments improving the presentation.

SUCCESSIVE LINEAR APPROXIMATION SOLUTION OF INFINITE-HORIZON DYNAMIC STOCHASTIC PROGRAMS*

JOHN R. BIRGE† AND GONGYUN ZHAO‡

Abstract. Models for long-term planning often lead to infinite-horizon stochastic programs that offer significant challenges for computation. Finite-horizon approximations are often used in these cases, but they may also become computationally difficult. In this paper, we directly solve for value functions of infinite-horizon stochastic programs. We show that a successive linear approximation method converges to an optimal value function for the case with convex objective, linear dynamics, and feasible continuation.

Key words. stochastic programming, dynamic programming, infinite horizon, linear approximation, cutting planes

DOI. 10.1137/060665506

1. Introduction.

Many long-term planning problems can be expressed as infinite-horizon stochastic programs. The infinite horizon often arises because of uncertainty about any specific end point (e.g., the lifetime of an individual or organization). Solving such problems with multiple decision variables and random parameters presents obvious computational difficulties. A common technique is to use a finite-horizon approximation, but even these problems become quite difficult for a practical size.

The approach in this paper is to assume stationary data and to solve for the infinite-horizon value function directly. A motivating example is an infinite-horizon portfolio problem, which involves decisions on amounts to invest in different assets and amounts to consume over time. For simple cases, such as those by Samuelson [14] for discrete time and Merton [10] for continuous time, optimality conditions can be solved directly; however, if general transaction costs and constraints on consumption or investment are present, more complex versions of the infinite-horizon problem considered here are required.

The problems in this paper also relate to the dynamic programming literature (see, for example, Bertsekas [3]) and particularly to methods for solving partially observed Markov decision processes (see the survey by Lovejoy [8]). Our method is most similar to the piecewise linear construction by Smallwood and Sondik [15] for finite horizons and the bounding approximations used by Lovejoy [9] for both finite and infinite horizons. The main differences between our model and those in [9, 15] are that we do not assume a finite action space and do not use finite-horizon approximations. Our method also does not explicitly find a policy or approximate the state space with a discrete grid; instead, we use the convexity of the value function

and the contraction properties of the dynamic programming operator in the form of an approximate value iteration.

Our approach also is similar to the linear programming approach to approximate dynamic programming (LP-ADP; see, e.g., De Farias and Van Roy [4]), but that approach again focuses on discrete state and action spaces and uses a preselected set of linear basis functions to approximate the value function. Our method uses linear support functions as an outer linearization in contrast to inner linearization in the LP-ADP approach. Our support functions are also generated within the method and achieve arbitrary accuracy. To obtain this result, our method takes advantage of continuity and convexity properties and, on all iterations, maintains bounds not available in the LP-ADP framework.

In the next section, we describe the general problem setting. Section 3 describes the algorithm and its convergence properties. Section 4 discusses the construction of the value function domain as required for algorithm convergence. Section 5 describes two examples and implementation of the algorithm. Section 6 concludes with a discussion of further issues.

2. Problem setting. We seek to find the value function V^* of the infinite-horizon problem

$$
\begin{aligned}
(2.1)\quad V^*(x) = \quad & \min_{y_1,y_2,\ldots} \quad E_{\xi_0,\xi_1,\ldots} \sum_{t=0}^{\infty} \delta^t c_t(x_t, y_t) \\
& \text{subject to (s.t.)} \ x_{t+1} = A_t x_t + B_t y_t + b_t \qquad \text{for } t = 0, 1, 2, \ldots, \\
& \qquad\qquad\qquad\quad x_0 = x.
\end{aligned}
$$

In this problem, $\xi_t = (A_t, B_t, b_t)$ is random data for stage $t = 0, 1, 2, \ldots$, A_t, B_t are matrices, and b_t is a vector. A_t is a square matrix. The equation $x_{t+1} = A_t x_t + B_t y_t + b_t$ characterizes the transition of state from stage t to $t+1$, the dynamics of the problem. $y_1, y_2, \ldots$ are controls/decision variables. State x_t and control y_t are continuous variables in certain finite-dimensional Euclidean spaces X and Y, respectively. The cost function $c_t : X \times Y \to \Re \cup \{+\infty\}$ is a generalized function. The static constraints in each stage, e.g., $(x_t, y_t) \in G_t$ for some subset G_t of $X \times Y$, are not explicitly formulated. They are implicitly captured by the effective domain of c_t, say, $dom(c_t) = G_t$. The number $0 < \delta < 1$ is a discount factor.

The above problem can be represented as

$$
\begin{aligned}
& \min_{y_0} \{c_0(x_0, y_0) + \delta E_{\xi_0} \min_{y_1} \{c_1(x_1, y_1) + \delta E_{\xi_1} \min_{y_2} \{c_2(x_2, y_2) + \ldots\}\}\} \\
& \text{s.t. } x_{t+1} = A_t x_t + B_t y_t + b_t \qquad \text{for } t = 0, 1, 2, \ldots, \\
& \qquad x_0 = x.
\end{aligned}
$$

In this paper we consider a simple version of (2.1), namely, $c_t = c$ and $(A_t, B_t, b_t) = (A, B, b)$, for all $t = 0, 1, 2, \ldots$, are identically and independently distributed random variables. For the presentation below, we assume that $\xi = (A, B, b)$ is a discrete random vector with $p_i = \text{Prob}(\xi = (A_i, B_i, b_i))$, $i = 1, \ldots, L$. (The general algorithm does not require finite realizations, but practical implementations make this assumption necessary.) The equality constraints in (2.1) characterize the dynamics of the problem. The static constraints (e.g., $y_t \geq 0$) in each stage are implicitly captured by the effective domain of the generalized function c.

The value function V^* defined by (2.1) is a solution of $V = M(V)$, where the map M (often called the *dynamic programming operator*) is defined by

$$M(V)(x) = \min_y \{c(x,y) + \delta E_\xi V(Ax + By + b)\}$$

$$= \min_y \left\{ c(x,y) + \delta \sum_{i=1}^{L} p_i V(A_i x + B_i y + b_i) \right\}. \tag{2.2}$$

Note. The problem of finding a solution of $V = M(V)$ and the infinite-horizon problem (2.1) are different. The value function V^* defined by the infinite-horizon problem is a solution to $V = M(V)$; however, the equation $V = M(V)$ may have many solutions. We will discuss this later. For the time being, we need to know only that a solution of $V = M(V)$ is equal to V^* if the effective domain of the solution coincides with $dom(V^*)$.

More precisely, let $D^* = dom(V^*)$ be compact and convex. Let $\mathcal{B}(D^*)$ be the Banach space of all functions finite on D^* and equipped with the norm $\|f\|_{D^*} = \sup_{x \in D^*}\{|f(x)|\}$.

THEOREM 2.1. *M is a contraction on $\mathcal{B}(D^*)$.*

Proof. The proof can be found, e.g., in Theorem 3.8 of [7]. □

The above theorem ensures that the equation $V = M(V)$ has a unique solution on $\mathcal{B}(D^*)$. Since V^* solves $V = M(V)$ and $V^* \in \mathcal{B}(D^*)$, V^* is the unique solution of $V = M(V)$ on $\mathcal{B}(D^*)$.

An assumption throughout this paper is that the cost function c is convex. This assumption ensures the convexity of the value function as shown below and enables the use of a cutting plane method.

LEMMA 2.2. *$M(V)$ is convex if V is convex. Consequently, V^* is convex.*

Proof. See Lemma 3.10 and Corollary 3.11 in [7]. □

In the next section, we will propose a cutting plane method to construct a piecewise linear value function V^k which approximately solves the problem $V = M(V)$. The cut generated at iteration k is a supporting plane of $M(V^k)$ at a selected point x^k. The convexity of $M(V^k)$ shown by Lemma 2.2 guarantees the existence of such cuts.

For any functions f and $g : \Re^n \to \Re \cup \{+\infty\}$, we say $f \geq g$ if $f(z) \geq g(z)$ for all $z \in \Re^n$.

3. A cutting plane method. In this section, we assume that the domain $D^* = dom(V^*)$ is known and is a compact polyhedral set. All functions are regarded as elements in $\mathcal{B}(D^*)$; thus, we will define only values of functions on D^*.

3.1. An algorithm. Our cutting plane method is based on the following observations.

LEMMA 3.1. *For any $\tilde{V}, V \in \mathcal{B}(D^*)$, $\tilde{V} \leq V$ implies $M(\tilde{V}) \leq M(V)$.*

Proof. For any $x \in D^*$,

$$\begin{aligned} M(\tilde{V})(x) &= \min_y \{c(x,y) + \delta E\tilde{V}(Ax + By + b)\} \\ &\leq \min_y \{c(x,y) + \delta EV(Ax + By + b)\} \\ &= M(V)(x). \end{aligned}$$ □

THEOREM 3.2. *Let $V \in \mathcal{B}(D^*)$, with $V \leq V^*$. Then*

(i) *$M(V) \leq V^*$;*

(ii) *$V = V^*$ if $M(V) \leq V$.*

Proof. (i) By Lemma 3.1 and $V \le V^*$, we have

$$M(V) \le M(V^*) = V^*.$$

(ii) It follows from $M(V) \le V$ and Lemma 3.1 that

$$V \ge M(V) \ge M^2(V) \ge \cdots \ge M^k(V) \ge \cdots.$$

Since M is a contraction on $\mathcal{B}(D^*)$ by Theorem 2.1, $M^k(V) \to V^*$. This shows that $V \ge V^*$. Now we have $V^* \ge V \ge V^*$, which implies $V = V^*$. □

We will employ a cutting plane algorithm to construct piecewise linear functions V^k defined by a set of cuts $\{t \ge Q^i x + q^i : i = 1, \ldots, u_k\}$ in the form

$$V^k(x) = \max\{Q^i x + q^i : i = 1, \ldots, u_k\}$$

which approximate V^* from below. Theorem 3.2 suggests adding a cut to V^k, cutting off an area where $M(V^k)(x) > V^k(x)$ so that V^{k+1} can move up towards V^*. The algorithm stops when there is no $x \in D^*$ such that $M(V^k)(x) > V^k(x)$.

ALGORITHM 3.1.

1. *Initialization: Find a piecewise linear convex function $V^0 \in \mathcal{B}(D^*)$ satisfying $V^0 \le V^*$. Set $k \leftarrow 0$.*
2. *If $V^k \ge M(V^k)$, stop; V^k is the solution. Otherwise, find a point $x^k \in D^*$ with $V^k(x^k) < M(V^k)(x^k)$.*
3. *Find a supporting hyperplane of $M(V^k)$ at x^k, say, $t = Q^{k+1}x + q^{k+1}$. Define $V^{k+1}(x) = \max\{V^k(x), Q^{k+1}x + q^{k+1}\}$.*
   $k \leftarrow k + 1$. Go to Step 2.

3.2. Details of the algorithm.

Step 1. Usually, we can find V^0 easily. For instance, if $c(x, y) \ge c_0$ for all (x, y) in its domain, then we can choose $V^0(x) = c_0/(1 - \delta)$, a constant function on D^*. It is clear that

$$V^*(x) \ge \sum_{t=0}^{\infty} \delta^t c_0 = V^0(x) \quad \forall\, x \in D^*.$$

Step 2 consists of two parts. Part 1 is the valuation of $M(V^k)(x)$, and Part 2 describes how to find a point $x^k \in D^*$ with $V^k(x^k) < M(V^k)(x^k)$.

Part 1. Assume that V^k is defined by k linear cuts, i.e., for any $x \in D^*$,

$$\begin{aligned} V^k(x) &= \max\{Q^i x + q^i : i = 1, \ldots, k\} \\ &= \min\{\theta \mid \theta \ge Q^i x + q^i,\ i = 1, \ldots, k\}. \end{aligned}$$

Then

$$\begin{aligned} M(V^k)(x) &= \min_y \left\{ c(x, y) + \delta \sum_{j=1}^{L} p_j V^k(A_j x + B_j y + b_j) \right\} \\ &= \min_{y,\theta} \left\{ c(x, y) + \delta \sum_{j=1}^{L} p_j \theta^j \mid \theta^j \ge Q^i z^j + q^i \,\forall\, i = 1, \ldots, k; \right. \\ &\qquad \left. z^j = A_j x + B_j y + b_j \in D^*,\ j = 1, \ldots, L \right\}. \end{aligned} \tag{3.1}$$

Part 2. We seek to find x^k by approximately minimizing $V^k(x) - M(V^k)(x)$ on D^*. Notice that $V^k - M(V^k)$ is a d.c. function (difference of two convex functions) on D^*. There are rich results on solving d.c. programs, originated by Horst and Tuy [6]. In Appendix A, we describe a method based on [5]. This method can find an exact global minimizer; however, finding an exact global minimizer of this d.c. function is time-consuming and thus is not recommended in general. Fortunately, for Algorithm 3.1 to work, an approximate minimizer x^k suffices (see Theorem 3.4). Selecting a computationally low-cost method for finding a sufficiently good x^k is important for enhancing the efficiency of the algorithm. The method described in Appendix A certainly is not the only choice for finding x^k. In the second example of numerical experiments, we take a small sample of 5 points and choose the best point as x^k. This simple strategy works well for the example.

Step 3. Suppose that the polytope D^* is defined by a system of inequalities $\mathbf{F}x \le \mathbf{f}$ for some matrix $\mathbf{F}$ and vector $\mathbf{f}$, i.e., $D^* = \{x \mid \mathbf{F}x \le \mathbf{f}\}$. Let

$$V^k(x) = \begin{cases} \min\{\theta \mid \mathbf{Q}^k x + \mathbf{q}^k \le \theta e\} & \text{if } \mathbf{F}x \le \mathbf{f}, \\ +\infty & \text{otherwise,} \end{cases}$$

where $\mathbf{Q}^k$ is a matrix and $\mathbf{q}^k$ and $e = (1, \ldots, 1)^T$ are vectors. $\mathbf{Q}^k x + \mathbf{q}^k$ represents the set of cuts generated up to the kth iteration.

Let (y^k, θ^k) and $\{(\lambda_j^k, \mu_j^k) : j = 1, \ldots, L\}$ be an optimal solution and optimal multipliers, respectively, of the problem

$$\min_{y,\theta} \left\{ c(x^k, y) + \delta \sum_{j=1}^{L} p_j \theta^j \mid \mathbf{Q}z^j + \mathbf{q} \le \theta^j e, \right.$$
$$\left. \mathbf{F}z^j \le \mathbf{f},\ z^j = A_j x^k + B_j y + b_j, j = 1, \ldots, L \right\}.$$

Let $\zeta^k = (\zeta_x^k; \zeta_y^k)$ be a subgradient of c at (x^k, y^k). Then

$$\xi^k = \zeta_x^k + \sum_{j=1}^{L} ((\lambda_j^k)^T \mathbf{Q} A_j + (\mu_j^k)^T \mathbf{F} A_j)$$

is a subgradient of $M(V^k)$ at x^k. (See Appendix B for the proof.)

A supporting hyperplane of $M(V^k)$ at x^k is

$$t = M(V^k)(x^k) + \xi^k (x - x^k).$$

That is,

$$Q^{k+1} = \xi^k, \qquad q^{k+1} = M(V^k)(x^k) - \xi^k x^k.$$

3.3. A modification of the algorithm. Since a global search takes considerable computational effort, a more efficient algorithm should limit global searches. We can perform a number of local search iterations between two global searches. A simple modification of the algorithm follows.

Algorithm 3.2.

1. *Initialization: Find a piecewise linear convex function* $V^0 \in \mathcal{B}(D^*)$ *satisfying* $V^0 \le V^*$. *Set* $k \leftarrow 0$.

2. *If* $V^k \geq M(V^k)$*, stop;* V^k *is the solution. Otherwise, find a point* $\bar{x} \in D^*$ *with* $V^k(\bar{x}) < M(V^k)(\bar{x})$*. Let* $V \leftarrow V^k$*.*
3. *Find a supporting hyperplane of* $M(V)$ *at* $\bar{x}$*, say,* $t = Qx+q$*. Define* $V^+(x) = \max\{V(x), Qx + q\}$*.*
4. *If the improvement of* V^+ *over* V *is larger than a certain tolerance, then let* $V \leftarrow V^+$ *and repeat Step* 3*. Otherwise, let* $V^{k+1} \leftarrow V^+$*,* $k \leftarrow k + 1$*, and go to Step* 2*.*

The time required for Step 3 is negligible compared to Step 2. The implementation on the first example in the paper shows a reduction by 3/4 of the number of iterations (of Step 2); i.e., the modified algorithm requires only 1/4 of the original number of iterations. Furthermore, it obtains better approximate solutions.

3.4. Comparison with other methods. We make comparisons in two perspectives: in improvement and in representation of an approximate value function V^k.

We refer to our method as the *successive linear approximation method* (SLAM).

Comparison between SLAM and PIM. The policy iteration method (PIM) is widely used for solving Markovian decision problems; cf. [13]. Thus we shall make a comparison between our method SLAM and PIM.

At the kth iteration, for a given V^k, PIM finds $y^k : D^* \to Y$ (which is the policy in the notation of our problem setting) by solving

$$y^k(x) = \operatorname{argmin}_y\{c(x, y) + \delta EV^k(Ax + By + b)\} \qquad \forall\, x \in D^* \tag{3.2}$$

and then finds V^{k+1} by solving

$$V^{k+1}(x) = c(x, y^k(x)) + \delta EV^{k+1}(Ax + By^k(x) + b) \quad \forall\, x \in D^*. \tag{3.3}$$

SLAM performs the kth iteration as follows: Given V^k, find a point $\bar{x}^k \in D^*$ by approximately solving

$$\max_x MV^k(x) - V^k(x) \tag{3.4}$$

and then construct V^{k+1} by adding to V^k a cutting plane at $\bar{x}^k$.

Since

$$MV^k(x) = \min_y\{c(x, y) + \delta EV^k(Ax + By + b)\},$$

finding the action $y^k(x)$ at a point x takes the same computational effort as the valuation of MV^k at x; thus, the determination of y^k, i.e., the valuation of $y^k(x)$ at all $x \in D^*$, is more expensive than the determination of $\bar{x}^k$. The construction of V^{k+1} in PIM requires solving an infinite-dimensional equation, which is again more difficult than determining a cutting plane in SLAM. In return, one can expect that each iteration of PIM improves the value function V^k more than SLAM does.

Comparison of approximation methods for the continuous-state DP. All existing approximation methods for continuous-state DP can be roughly categorized into *discrete approximations (DAs)* and *parametric approximations (PAs)*; cf. [1]. The former approximate V on a grid of D^*, and the latter approximate V by a linear combination of a set of basis functions. Our method, the *cutting plane approximation (CPA)*, approximates V by the maximum function of a set of cutting planes.

The CPA method is similar to PA in the sense that both methods use a set of continuous functions to approximate V. The superiority of PA over DA is that, in many cases, one can obtain a good global approximation to V using a small number of basis functions, whereas in high-dimensional problems the DA approach requires a very large number of grid points to obtain a comparably accurate approximation; see [1]. CPA has the same advantages as PA over DA and, moreover, is more flexible than PA, because cuts are generated where they are most needed in CPA, whereas basis functions are preselected in PA. A disadvantage of the CPA method is, however, that cuts can be accumulated rapidly. A computational challenge is to find effective ways to delete unnecessary cuts.

3.5. Convergence. If Algorithm 3.1 stops at an iteration with $V^K \geq M(V^K)$, then we have $V^K = V^*$ by Theorem 3.2.

If the algorithm does not terminate in a finite number of iterations, then the convergence of V^k to V^* is not so obvious. We notice that each cut is related to a testing point $\bar{x}$. Such a process can lead to pointwise convergence but not necessarily uniform convergence. A danger is that the limit of a pointwise convergent sequence $\{V^k\}$ may not be V^*, because V^k may be updated only in some area of the domain but not over the full domain. Our convergence analysis shall answer the following two questions: Under what conditions can the sequence $\{V^k\}$ converge uniformly? If $\{V^k\}$ converges uniformly, is the limit function equal to V^*? Our main condition for uniform convergence is that D^* is a polytope. Indeed, if D^* is an arbitrary convex compact set, one can construct a monotone increasing sequence of convex functions $\{V^k\}$ which converges pointwise but not uniformly. The assumption that D^* is a polytope ensures the continuity of the limit function of $\{V^k\}$. Then, by Theorem 7.13 in [12], $\{V^k\}$ converges uniformly; see the details in the proof of Theorem 3.4. For the second question, we will give a positive answer. The result is presented in Theorem 3.4.

LEMMA 3.3. $V^k \leq V^{k+1} \leq V^*$.

Proof. From Step 2 of Algorithm 3.1, it is obvious that $V^k \leq V^{k+1}$.

The initial function $V^0 \leq V^*$. Suppose $V^k \leq V^*$; then, by Theorem 3.2 (i), $M(V^k) \leq V^*$; thus, for any $x \in D^*$,

$$V^{k+1}(x) \leq \max\{V^k(x),\, M(V^k)(x)\} \leq V^*(x). \qquad \square$$

THEOREM 3.4. *Suppose that D^* is a polytope and suppose that, at the kth iteration, a point $x^k \in D^*$ is selected such that*

$$M(V^k)(x^k) - V^k(x^k) \geq \alpha \max\{M(V^k)(x) - V^k(x) \mid x \in D^*\}$$

for some constant $\alpha > 0$; then, $V^k \to V^*$ uniformly.

Proof. First, suppose that Algorithm 3.1 stops at a finite iteration K with $V^K \geq M(V^K)$. By Lemma 3.3, $V^K \leq V^*$. Thus, by Theorem 3.2, $V^K = V^*$.

Now suppose that Algorithm 3.1 generates a sequence $\{V^k\}$ which converges to $\tilde{V}$ pointwise.

Because $V^k \leq V^{k+1} \to \tilde{V}$, $epi(\tilde{V}) = \cap_k epi(V^k)$, which is a closed set since every V^k is closed. Thus, $\tilde{V}$ is a closed convex function on D^*. By our assumption, D^* is a polytope; thus, by Theorem 10.2 in [11], $\tilde{V}$ is continuous on D^*. By Theorem 7.13 in [12], $V^k \to \tilde{V}$ uniformly on D^*.

Assume that there exists an $\hat{x} \in D^*$ such that

$$M(\tilde{V})(\hat{x}) - \tilde{V}(\hat{x}) = 2\sigma > 0.$$

By Theorem 2.1, $M(V^k) \to M(\tilde{V})$ uniformly on D^* since $V^k \to \tilde{V}$ uniformly; thus, there exists a $\hat{k}$ such that $M(V^k)(\hat{x}) \geq M(\tilde{V})(\hat{x}) - \sigma$ for all $k \geq \hat{k}$. This yields

$$M(V^k)(\hat{x}) - V^k(\hat{x}) \geq M(\tilde{V})(\hat{x}) - \sigma - \tilde{V}(\hat{x}) = \sigma.$$

Since the supporting hyperplane at iteration k satisfies $Q^{k+1}x^k + q^{k+1} = M(V^k)(x^k)$, we have

$$\begin{aligned} V^{k+1}(x^k) - V^k(x^k) &= M(V^k)(x^k) - V^k(x^k) \\ &\geq \alpha[M(V^k)(\hat{x}) - V^k(\hat{x})] \\ &\geq \alpha\sigma. \end{aligned}$$

Thus

$$\tilde{V}(x^k) - V^k(x^k) \geq \alpha\sigma \qquad \forall\, k \geq \hat{k}.$$

The above contradicts the uniform convergence of $V^k \to \tilde{V}$ on D^*.

The contradiction implies that

$$M(\tilde{V})(x) \leq \tilde{V}(x) \qquad \forall\, x \in D^*.$$

Then, by Theorem 3.2, $\tilde{V} = V^*$. This means that V^k converges to V^* uniformly on D^*. □

4. Construction of the domain D^*. Recall that $D^* = dom(V^*)$, where V^* is the value function defined by (2.1). This section discusses how to find D^*. We do not have a complete answer for this problem; nevertheless, the method proposed can find D^* in a finite number of iterations for many cases.

4.1. An algorithm. Although the domain of a solution of $V = M(V)$ does not necessarily coincide with D^*, it does provide useful information for finding D^*. We first represent the domain of $M(V)$.

From (2.2) one can see that $x \in dom(M(V))$ if and only if there exists a y such that $c(x, y) < +\infty$ and $A_i x + B_i y + b_i \in dom(V)$ for all $i = 1, \ldots, L$. Denote

$$\begin{aligned} D_c(x) &= \{y \mid c(x, y) < +\infty\}, \\ G(x, D) &= \{y \mid A_i x + B_i y + b_i \in D\, \forall i = 1, \ldots, L\}. \end{aligned}$$

Then $x \in dom(M(V))$ if and only if $D_c(x) \cap G(x, dom(V)) \neq \emptyset$.

Denote

$$\Gamma(D) = \{x \mid D_c(x) \cap G(x, D) \neq \emptyset\}.$$

Then

$$dom(M(V)) = \Gamma(dom(V)).$$

The following are some basic properties of the operator Γ.

LEMMA 4.1.

(i) *If $D_1 \subseteq D_2$ then $\Gamma(D_1) \subseteq \Gamma(D_2)$.*

(ii) $\Gamma(D^*) = D^*$.

(iii) *If $D^* \subseteq D$, then $D^* \subseteq \Gamma(D)$.*

Proof. (i) If $D_1 \subseteq D_2$, then, for any x, $G(x, D_1) \subseteq G(x, D_2)$. Now, for any $x \in \Gamma(D_1)$, $D_c(x) \cap G(x, D_1) \neq \emptyset$. This implies $D_c(x) \cap G(x, D_2) \neq \emptyset$. Therefore, $x \in \Gamma(D_2)$.

(ii) It follows from $M(V^*) = V^*$ that $dom(M(V^*)) = dom(V^*)$, which yields $\Gamma(D^*) = D^*$ by the definition.

(iii) If $D^* \subseteq D$, then, by (i), $\Gamma(D^*) \subseteq \Gamma(D)$; hence, by (ii), we have $D^* \subseteq \Gamma(D)$. □

The following lemma shows that, if $dom(V) \subseteq dom(M(V))$, then $dom(V) \subseteq dom(V^*)$.

LEMMA 4.2. *Suppose c is bounded on its domain. If $D \subseteq \Gamma(D)$, then $D \subseteq D^*$.*

Proof. For any $x_t \in D$, we have $x_t \in \Gamma(D)$; thus,

$$\exists y_t \in D_c(x_t) : A_i x_t + B_i y_t + b_i \in D \,\forall\, i = 1, \ldots, L. \tag{4.1}$$

For any $\bar{x} \in D$, let $x_0 = \bar{x}$. There exists y_0 satisfying (4.1). For each realization of $\xi = (A, B, b)$ (where the subscript is omitted for ease of exposition), let $x_1 = Ax_0 + By_0 + b$. By (4.1), $x_1 \in D$. Since $D \subseteq \Gamma(D)$, $x_1 \in \Gamma(D)$. Therefore, there exists y_1 satisfying (4.1), and so on; so, we obtain a sequence $\{(x_t, y_t) : t = 0, 1, \ldots\}$ (here (x_t, y_t) are random vectors) satisfying $(x_t, y_t) \in dom(c)$ because $y_t \in D_c(x_t)$. Since c is bounded on its domain, $E\sum_{t=0}^{\infty} \delta^t c(x_t, y_t) < \infty$; thus, $V^*(\bar{x})$, defined by (2.1), is finite, i.e., $\bar{x} \in D^*$. Therefore, $D \subseteq D^*$. □

Suppose we use a cutting plane method to construct D^* and start with a set $D \supseteq D^*$. The above lemma suggests that one should cut off a portion of $D \setminus \Gamma(D)$ if $D \not\subseteq \Gamma(D)$.

Because

$$D^* \subseteq D_{cx} := \{x \mid D_c(x) \neq \emptyset\} = \{x \mid \exists y \text{ such that } c(x, y) < +\infty\},$$

we start with D_{cx} to find D^*. A generic cutting plane method which constructs D^* with this idea is as follows.

ALGORITHM 4.1.

1. *Let $D^0 = D_{cx}$. $k = 0$.*
2. *If $D^k \subseteq \Gamma(D^k)$, stop. Otherwise, find a cut $F^{k+1}x \leq f^{k+1}$ which cuts off a portion of $D^k \setminus \Gamma(D^k)$.*
3. *Let $D^{k+1} = D^k \cap \{x \mid F^{k+1}x \leq f^{k+1}\}$. $k \leftarrow k + 1$. Repeat.*

The algorithm stops when D^k with $D^k \subseteq \Gamma(D^k)$ is found. Question: Is $D^k = D^*$?

THEOREM 4.3. *If the algorithm terminates at a finite iteration K, then $D^K = D^*$.*

Proof. The algorithm starts with D_{cx}, which contains D^*. By Lemma 4.1, $D^* \subseteq \Gamma(D^k)$ for $k = 0, 1, \ldots, K$; thus, no cut cuts off any point of D^*. This implies $D^K \supseteq D^*$. When the algorithm stops with $D^K \subseteq \Gamma(D^K)$, Lemma 4.2 yields $D^K \subseteq D^*$; thus, $D^K = D^*$. □

Unfortunately, if Algorithm 4.1 does not stop in a finite number of iterations, the sequence $\{D^k\}$ need not converge to D^* (see Remark (iii) after Example 1 below). How to modify the algorithm to guarantee convergence is still an open question.

4.2. Generating cuts. Now we discuss Step 2 of Algorithm 4.1 in detail. First, we propose a method which finds a point $\bar{x} \in D^k \setminus \Gamma(D^k)$ and generates a cut which cuts off a portion of $D^k \setminus \Gamma(D^k)$.

For simplicity we consider only the case that $dom(c)$ is a polyhedral set. More precisely, let $dom(c) = \{(x, y) : Tx + Wy \leq r\}$. Let $D^k = \{x : F^i x \leq f^i : i = 1, \ldots, k\}$.

$\bar{x} \notin \Gamma(D^k)$ if and only if

$$\begin{aligned} T\bar{x} + Wy &\le r, \\ F^i(A_j\bar{x} + B_j y + b_j) &\le f^i, \quad i = 1, \dots, k \quad j = 1, \dots, L, \end{aligned}$$

has no feasible solution; then, by Farkas' theorem, if and only if

$$\begin{aligned} \sum_{i=1}^{k}\sum_{j=1}^{L} \pi_{ij} F^i B_j + \lambda^T W &= 0, \\ \sum_{i=1}^{k}\sum_{j=1}^{L} \pi_{ij}[F^i(A_j\bar{x} + b_j) - f^i] + \lambda^T(T\bar{x} - r) &> 0, \\ \pi \ge 0, \lambda &\ge 0, \end{aligned} \tag{4.2}$$

it has a solution.

Thus, finding a point $\bar{x} \in D^k$ such that $\bar{x} \notin \Gamma(D^k)$ is equivalent to finding a triple $(\bar{x}, \lambda, \pi)$ satisfying $\bar{x} \in D^k$ and (4.2). (Note that finding a solution to (4.2) is equivalent to determining the sign of the supremum of an indefinite quadratic function subject to linear constraints, which would also require global optimization methods as in Horst, Pardalos, and Thoai [5].)

Once a solution $(\bar{x}, \lambda, \pi)$ is found, one can construct a feasibility cut:

$$\sum_{i=1}^{k}\sum_{j=1}^{L} \pi_{ij}[F^i(A_j x + b_j) - f^i] + \lambda^T(Tx - r) \le 0, \tag{4.3}$$

i.e.,

$$F^{k+1} = \sum_{i=1}^{k}\sum_{j=1}^{L} \pi_{ij} F^i A_j + \lambda^T T, \quad f^{k+1} = \sum_{i=1}^{k}\sum_{j=1}^{L} \pi_{ij}[f^i - F^i b_j] + \lambda^T r.$$

We can add an objective to find the "best" cut in the sense, e.g., that F^{k+1} is the normal direction of a facet of D^* or, perhaps more realistically, a facet of $\Gamma(D^k)$.

Let us look at a simple example to see how $\Gamma^k(D_{cx})$ approximates D^*.

Example 1. Suppose

$$\begin{aligned} dom(c) &= \{(x, y) : x \in [-1, 1]^2,\ y \in [-\beta, \beta]\}, \\ Ax + By + b &= \alpha x + e_1 y \quad \text{for } x \in \Re^2, y \in \Re^1 \qquad \text{(deterministic)}. \end{aligned}$$

Here $0 < \alpha \in \Re^1$ and $e_1 = (1, 0)^T$, meaning that $A = \alpha I \in \Re^{2\times 2}, B = e_1 \in \Re^{2\times 1}$, and $b = (0, 0)^T$. For this example, we have

$$\begin{aligned} D_c(x) = \{y : (x, y) \in dom(c)\} &= \begin{cases} [-\beta, \beta] & \text{if } x \in [-1, 1]^2, \\ \emptyset & \text{otherwise.} \end{cases} \\ D_{cx} = \{x : D_c(x) \ne \emptyset\} &= [-1, 1]^2, \\ G(x, D) = \{y : \alpha x + e_1 y \in D\} &\qquad \text{for } D \subset \Re^2. \end{aligned}$$

Thus,

$$\begin{aligned} D_c(x) \cap G(x, D) \ne \emptyset &\iff x \in [-1, 1]^2,\ [-\beta, \beta] \cap \{y : \alpha x + e_1 y \in D\} \ne \emptyset \\ &\iff x \in [-1, 1]^2,\ (\alpha x + e_1[-\beta, \beta]) \cap D \ne \emptyset, \end{aligned} \tag{4.4}$$

where

$$\begin{aligned}\alpha x + e_1[-\beta,\beta] &= \{\alpha x + y e_1 : y \in [-\beta,\beta]\} \\ &= \left\{\alpha \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + \begin{pmatrix} y \\ 0 \end{pmatrix} : y \in [-\beta,\beta]\right\}.\end{aligned}$$

For any $D = \{|x_1| \le p, |x_2| \le q\}$, with $p, q \ge 0$,

$$\begin{aligned}\Gamma(D) &= \{x \in [-1,1]^2 : (\alpha x + e_1[-\beta,\beta]) \cap D \ne \emptyset\} \\ &= \{x \in [-1,1]^2 : [\alpha x_1 - \beta, \alpha x_1 + \beta] \cap [-p,p] \ne \emptyset,\ |\alpha x_2| \le q\} \\ &= \{x \in [-1,1]^2 : |x_1| \le (p+\beta)/\alpha,\ |x_2| \le q/\alpha\} \\ &= \{|x_1| \le \min\{1,(p+\beta)/\alpha\},\ |x_2| \le \min\{1, q/\alpha\}\}.\end{aligned}$$

For $0 < \alpha \le 1$,

$$\Gamma(D_{cx}) = [-1,1]^2 = D_{cx}.$$

Thus, by Lemma 4.2, $D_{cx} \subseteq D^*$, but $D^* \subseteq D_{cx}$. Thus $D^* = D_{cx} = [-1,1]^2$.

Note. For the case $\alpha = 1$, any subset D of $[-1,1]^2$ of the form $\{|x_1| \le 1,\ |x_2| \le t\}$ for some $0 \le t \le 1$ satisfies $D = \Gamma(D)$. Thus, M is a contraction on the Banach space $\mathcal{B}(D)$, and $V = M(V)$ has a solution (fixed point) V_D in $\mathcal{B}(D)$. This shows that the equation $V = M(V)$ may have many solutions.

For $1 < \alpha \le 1 + \beta$,

$$\begin{aligned}\Gamma(D_{cx}) &= \{|x_1| \le 1,\ |x_2| \le 1/\alpha\}, \\ \Gamma^2(D_{cx}) &= \Gamma(\Gamma(D_{cx})) = \{|x_1| \le 1,\ |x_2| \le 1/\alpha^2\}, \\ &\vdots \\ \Gamma^k(D_{cx}) &= \{|x_1| \le 1,\ |x_2| \le 1/\alpha^k\};\end{aligned}$$

thus, $D^* = \lim_{k\to\infty} \Gamma^k(D_{cx}) = \{|x_1| \le 1,\ x_2 = 0\} \ne D_{cx}$.

For $\alpha > 1 + \beta$,

$$\begin{aligned}\Gamma(D_{cx}) &= \left\{|x_1| \le \frac{1+\beta}{\alpha},\ |x_2| \le 1/\alpha\right\}, \\ \Gamma^2(D_{cx}) &= \left\{|x_1| \le \frac{1+\beta+\alpha\beta}{\alpha^2},\ |x_2| \le 1/\alpha^2\right\}, \\ &\vdots \\ \Gamma^k(D_{cx}) &= \left\{|x_1| \le \frac{1+\beta+\alpha\beta+\ldots+\alpha^{k-1}\beta}{\alpha^k},\ |x_2| \le 1/\alpha^k\right\};\end{aligned}$$

thus, $D^* = \lim_{k\to\infty} \Gamma^k(D_{cx}) = \{|x_1| \le \frac{\beta}{\alpha-1},\ x_2 = 0\} \ne D_{cx}$. □

Remarks.

(i) In some case ($\alpha \le 1$), $D^* = D_{cx}$, which can be obtained directly.

(ii) In some case ($\alpha > 1$), infinitely many iterations are required to reach D^*.

(iii) Suppose the cutting plane algorithm generates only single-side cuts in the case of $\alpha > 1$, e.g., only the cuts $x_2 \ge -1/\alpha^k$; then $D^k \to \{|x_1| \le 1, 0 \le x_2 \le 1\} \ne D^*$.

(iv) If we can directly generate the cut $x_2 \ge 0$ instead of infinitely many cuts $\{x_2 \ge -1/\alpha^k : k = 1,2,\ldots\}$, then we can construct D^* in 2 iterations for the problem with $1 < \alpha \le 1 + \beta$ and 4 iterations for the problem with $\alpha > 1 + \beta$.

4.3. Generating the deepest cut. A cut generated by (4.3) cuts off only points in $D^k \setminus \Gamma(D^k)$; i.e., it does not cut off any point in $\Gamma(D^k)$. As shown in Example 1, the cutting plane method using such cuts may fail to approximate D^* even with infinitely many iterations. In order to fulfill the goal in Remark (iv), we must find a deeper cut (a smaller f^{k+1}), which cuts into $\Gamma(D^k)$, hopefully reaching the boundary of D^*.

Given a D, suppose that we have obtained a cut $d^T x \le t_0$ which cuts off a portion of $D \setminus \Gamma(D)$ (but does not cut into $\Gamma(D)$). Denote $D_t := D \cap \{d^T x \le t\}$. If the plane $d^T x = t_0$ has touched the boundary of $\Gamma(D)$, then no point of $D_{t_0} \setminus \Gamma(D)$ can be cut off by any cut of the form $d^T x \le t$ for arbitrary t. However, since $\Gamma(D_{t_0})$ is smaller than $\Gamma(D)$, a portion of $D_{t_0} \setminus \Gamma(D_{t_0})$ may be cut off by some cut $d^T x \le t$. We wish to find $\bar{t} < t_0$ such that no point of $D_{\bar{t}} \setminus \Gamma(D_{\bar{t}})$ can be cut off by any cut of the form $d^T x \le t$. In other words, the plane $d^T x = \bar{t}$ touches the boundary of $\Gamma(D_{\bar{t}})$ (a supporting plane of $\Gamma(D_{\bar{t}})$). Thus, for any $t > \bar{t}$, the plane $d^T x = t$ does not touch $\Gamma(D_t)$, and, for any $t \le \bar{t}$, the half-space $d^T x \le t$ intersects with $\Gamma(D_t)$. The latter means that there exists $x \in \Gamma(D_t)$ satisfying $d^T x \ge t$. The latter interpretation suggests determining $\bar{t}$ by the following linear program:

$$\bar{t} = \max \{t \mid d^T x \ge t,\ x \in \Gamma(D_t)\}. \tag{4.5}$$

Because $d^T x \le t_0$ does not cut into $\Gamma(D)$ (then does not cut into $\Gamma(D_t)$), there exists no x satisfying $d^T x \ge t$ and $x \in \Gamma(D_t)$ if $t > t_0$. This implies that $\bar{t} \le t_0$. Therefore, the cut $d^T x \le \bar{t}$ is deeper than the cut $d^T x \le t_0$.

On the other hand, the following lemma guarantees that the cut $d^T x \le \bar{t}$ will not cut off any point in D^*.

LEMMA 4.4. *Suppose that $D^* \subset D$. Let $\bar{t}$ be the optimal objective value of problem (4.5); then, $d^T x \le \bar{t}$ is satisfied by all $x \in D^*$.*

Proof. Let

$$x^* = \operatorname{argmax}\{d^T x \mid x \in D^*\}, \qquad t^* = d^T x^*.$$

Because $x^* \in D^*$, there exist $\{(x_t, y_t) : t = 0, 1, 2, \ldots\}$ such that

$$V^*(x^*) = E\left[\sum_{t=0}^{\infty} \delta^t c(x_t, y_t)\right] < \infty,$$
$$x_{t+1} = Ax_t + By_t + b, \qquad x_0 = x^*.$$

For any integer $K \ge 0$, let $\tilde{x}_l = x_{l+K}$ and $\tilde{y}_l = y_{l+K}$. Because $E[\sum_{t=K}^{\infty} \delta^{t-K} c(x_t, y_t)] < \infty$, we have

$$V^*(x_K) \le E\left[\sum_{l=0}^{\infty} \delta^l c(\tilde{x}_l, \tilde{y}_l)\right] < \infty.$$

Therefore, $x_K \in D^*$.

Now $y_0 \in D_c(x^*)$ follows from $c(x^*, y_0) < \infty$ and $y_0 \in G(x^*, D^*)$ follows from $x_1 = A_i x^* + B_i y_0 + b_i \in D^*$ for every $i = 1, \ldots, L$. Thus $x^* \in \Gamma(D^*)$. Because $D^* \subseteq D$ and $D^* \subseteq \{x : d^T x \le t^*\}$, we have $D^* \subseteq D_{t^*}$. Therefore, $x^* \in \Gamma(D_{t^*})$. This, together with $d^T x^* = t^*$, shows that (x^*, t^*) is a feasible point of (4.5); thus $t^* \le \bar{t}$, from which the claim of the lemma follows. ∎

The following example shows the effect of the deepest cut.

Example 1 (continued). Consider $\alpha > 1$. Consider the cut of the form $-x_2 \le t$ for some $t \in R$ to be determined. So, $d = (0, -1)^T$ in (4.5). Start with $D = D_{cx} = [-1, 1]^2$; then

$$D_t = \{x \in [-1, 1]^2 : -x_2 \le t\}.$$

Linear program (4.5) is

$$\begin{aligned} \bar{t} = \max\, & t \\ \text{s.t. } & -x_2 \ge t, \\ & -1 \le \alpha x_1 + y \le 1, \\ & -t \le \alpha x_2 \le 1, \\ & -\beta \le y \le \beta. \end{aligned}$$

A feasible solution must satisfy

$$-t/\alpha \le x_2 \le -t.$$

This can be satisfied only when $t \le 0$ since $\alpha > 1$. Thus, we have $\bar{t} = 0$. The cut $-x_2 \le 0$ reaches the bottom of D^*. With one more cut from above ($d = (0, 1)^T$), D^* will be completely determined for the case of $1 < \alpha \le 1 + \beta$.

For the case of $\alpha > 1 + \beta$, suppose we have $d = (1, 0)^T$. Then

$$D_t = \{x \in [-1, 1]^2 : x_1 \le t\}.$$

Linear program (4.5) is

$$\begin{aligned} \bar{t} = \max\, & t, \\ \text{s.t. } & x_1 \ge t, \\ & -1 \le \alpha x_1 + y \le t, \\ & -1 \le \alpha x_2 \le 1, \\ & -\beta \le y \le \beta. \end{aligned}$$

Feasible solutions must satisfy

$$t \le x_1 \le \frac{t + \beta}{\alpha}.$$

This implies

$$t \le \frac{\beta}{\alpha - 1}.$$

Thus $\bar{t} = \frac{\beta}{\alpha - 1}$; so we obtain a cut $x_1 \le \frac{\beta}{\alpha - 1}$ which cuts exactly to the boundary of D^* on the right. One more cut from the left ($d = (-1, 0)^T$) will completely determine D^*; hence, in total, we need only 4 cuts. □

5. Examples.

5.1. Infinite-horizon portfolio. As noted in the introduction, this work was motivated by solving infinite-horizon investment problems that face long-enduring institutions. We will demonstrate how the algorithm performs on a small example where an infinite-horizon optimum can be found analytically (as done, for example, in [14, 10]). The goal is to maximize the discounted expected utility of consumption over an infinite horizon. The decisions in each period are how much to consume and how much to invest in a risky asset (or in a variety of assets).

The state variable x in this case corresponds to wealth or the current market value of all assets. The control variable y has two components: y_1, which corresponds to consumption, and y_2, which corresponds to the amount invested in a risky asset with random return ξ. The assumption in this model is that any remaining funds, after consuming y_1 and investing y_2 in the risky asset, are invested in a risk-free asset (e.g., U.S. Treasury bills) with a known rate of return r. For this model, $c(x, y)$ is either ∞ if $x < 0$ or $-y_1^\gamma/\gamma$ for some nonzero parameter $\gamma < 1$, giving (the negative of) the common utility function with constant relative risk aversion (i.e., such that risk preferences do not depend on the level of wealth).

With these assumptions, $M(V)$ takes the following form (for $x \geq 0$):

$$M(V)(x) = \min_y \left\{ -y_1^\gamma/\gamma + \delta \sum_{i=1}^{L} p_i V((1+r)x - (1+r)y_1 + (\xi_i - r)y_2) \right\}, \tag{5.1}$$

where ξ_i is the ith realization of the random return with probability p_i. The solution V^* of $M(V) = V$ can be found analytically by observing that the optimal value function is proportional to x^γ (by, for example, considering the limiting case of a finite-horizon problem). We then have that

$$\begin{aligned}
&\sum_{i=1}^{L} p_i V((1+r)x - (1+r)y_1 + (\xi_i - r)y_2) \\
&= -K \sum_{i=1}^{L} p_i ((1+r)x - (1+r)y_1 + (\xi_i - r)y_2)^\gamma \\
&= -K(x - y_1)^\gamma \sum_{i=1}^{L} p_i ((1+r) + (\xi_i - r)[y_2/(x - y_1)])^\gamma \\
&= -K(x - y_1)^\gamma \sum_{i=1}^{L} p_i ((1+r) + (\xi_i - r)z)^\gamma,
\end{aligned}$$

where $z = \frac{y_2}{x - y_1}$ is the fractional risky investment after consuming y_1 and K is some positive constant. The optimal z^* then must solve

$$\sum_{i=1}^{L} p_i \gamma (\xi_i - r)((1+r) + (\xi_i - r)z)^{\gamma - 1} = 0, \tag{5.2}$$

which is independent of y_1. With $\bar{V}^* = -\sum_{i=1}^{L} p_i ((1+r) + (\xi_i - r)z^*)^\gamma$, optimal y_1^* now must solve

$$-y_1^{\gamma - 1} + \delta \gamma K \bar{V}^* (x - y_1)^{\gamma - 1} = 0 \tag{5.3}$$

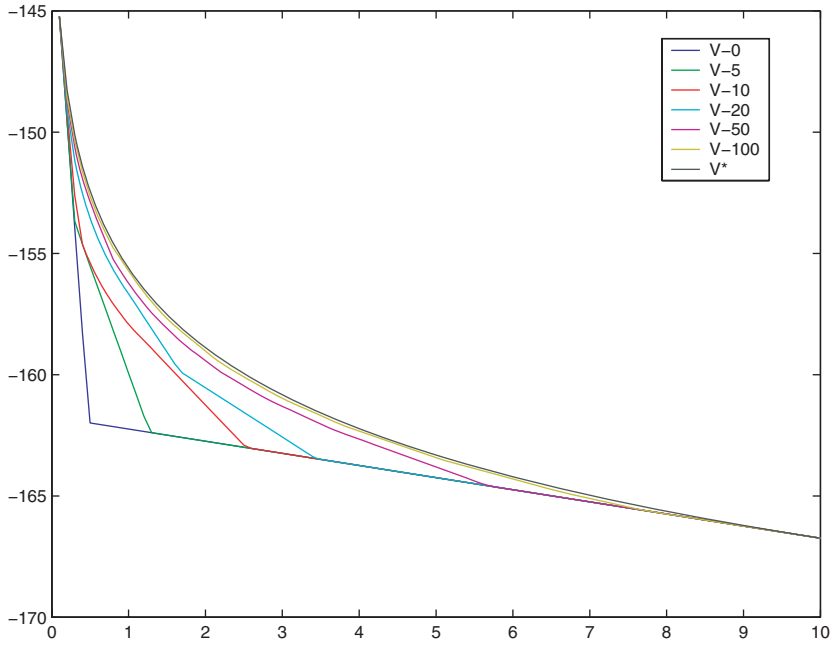

FIG. 1. *Value function approximations for portfolio example* $\delta = 1/1.25$. *The horizontal axis stands for the state variable* x *and the vertical axis for the value function* V.

or

$$y_1^* = x\frac{(\delta\gamma K\bar{V}^*)^{1/(\gamma-1)}}{1+(\delta\gamma K\bar{V}^*)^{1/(\gamma-1)}} = xw^* \tag{5.4}$$

for an optimal consumption fraction w^*. The last step is to find K from $M(V) = V$, using

$$-x^\gamma((w^*)^\gamma/\gamma + \delta K\bar{V}^*(1-w^*)^\gamma) = M(V(x)) = V(x) = -Kx^\gamma \tag{5.5}$$

to obtain $K = \frac{((\delta\bar{V}^*)^{1/(\gamma-1)}-1)^{\gamma-1}}{\delta\gamma\bar{V}^*}$.

While this function can be found explicitly (up to solving the nonlinear equation (5.2)), various other constraints on investment (such as transaction costs and limits on consumption changes from period to period) make analytical solutions impossible. We use the analytical solution here to observe Algorithm 3.1's performance and convergence behavior. We also use the analytical solution to derive initial upper bounding approximations. For our test, we use the linear supports of V^* at $x = 0.1$ and $x = 10$ as initial cuts and restrict our search in x to the interval $[0.1, 10]$, although the feasible region is unbounded.

For our test, we used $\gamma = 0.03$, $r = 0.05$, and ξ_i chosen as a discrete approximation of the lognormal return distribution with a mean return of 0.08 and a standard deviation of 0.4. Algorithm 3.1 was implemented in MATLAB using `fmincon` to solve the optimization subproblems and a linesearch to find x^k in Step 2. We tried different values for the discount factor δ. The results for $\delta = \frac{1}{1.25}$ appear in Figure 1, which includes V^0, V^5, V^{10}, V^{20}, V^{50}, V^{100}, and V^*. In this case, after 100 iterations, the approximation almost perfectly matches the true infinite-horizon value function.

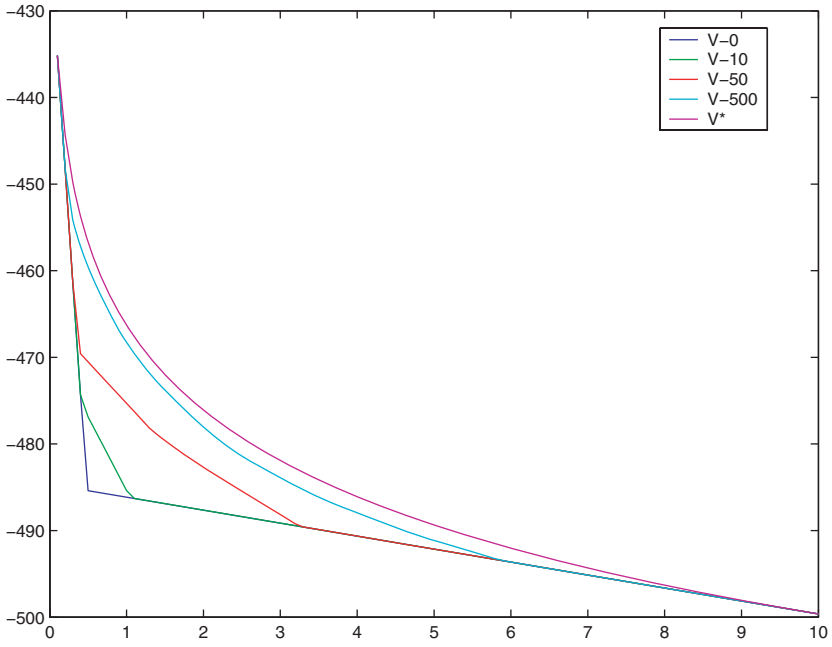

FIG. 2. *Value function approximations for portfolio example* $\delta = 1/1.07$. *The horizontal axis stands for the state variable* x *and the vertical axis for the value function* V.

With a larger δ, the value of K increases rapidly as $(\delta \bar{V}^*)^{1/(\gamma-1)}$ approaches one. For $\delta = \frac{1}{1.25}$, K is 155.6, while for $\delta = \frac{1}{1.07}$, K is 466.3. The result is that larger δ values (corresponding to lower discount rates) require additional iterations of Algorithm 3.1 to approach V^*. The results for the same data as in Figure 1 except with $\delta = \frac{1}{1.07}$ appear in Figure 2. After 500 iterations, the approximating V^{500} agrees relatively well with V^* as shown in the figure but has not converged to nearly the same accuracy as the approximations (with fewer iterations) in Figure 1.

For this example, Algorithm 3.2 gains a notable speedup. For the instance with $\delta = \frac{1}{1.25}$, it requires only 25 iterations to obtain the approximating V^{25} which is as good as V^{100} obtained by Algorithm 3.1. For the case of $\delta = \frac{1}{1.07}$, Algorithm 3.2 requires only about 1/4 of the iterations needed by Algorithm 3.1. Moreover, Algorithm 3.2 can generate more accurate approximating value functions.

Understanding the numerical behavior of Algorithm 3.1 and finding mechanisms to speed convergence should be topics for further investigation. Comparing V^k to V^* in the figures shows how the algorithm forces a closer approach in some areas of the curve over others. The behavior of the algorithm is generally to move along the curve V^k to create tighter cuts and then to repeat that process with less improvement on a new sequence of iterations. These observations suggest that procedures with multiple cut generation and tightening tolerances should be considered for accelerating convergence.

5.2. Quadratic-linear stochastic control problems. This example is intended to test the algorithm for high-dimensional problems. The quadratic-linear stochastic control problems are well known. We will use these examples following section 6.5 of [2]. The value function in a quadratic-linear stochastic control problem

is defined as follows:

$$V^*(x) = \min_{y_1,y_2,\ldots} E_{\xi_0,\xi_1,\ldots} \sum_{t=0}^{\infty} \delta^t [x_t^T Q x_t + y_t^T R y_t]$$
$$\text{s.t.} \quad x_{t+1} = Ax_t + By_t + b \qquad \text{for } t = 0, 1, 2, \ldots,$$
$$x_0 = x.$$

In the above expression, $x_t \in \Re^n$, $y_t \in \Re^m$, and the matrices A, B, Q, R are given and have appropriate dimensions. We assume that Q is a symmetric positive semidefinite matrix and that R is also symmetric and positive definite. The disturbances $\xi_t = b$ form independent random vectors with given probability distributions that do not depend on x_t, y_t. Furthermore, the vector b has zero mean and finite second moment. The controls y_t are unconstrained. The problem above represents a popular formulation of a regulation problem whereby we desire to keep the state of the system close to the origin. Such problems are common in the theory of automatic control of a motion or a process. For computational purposes, we assume $\xi = b$ is a discrete random vector with $p_i = \text{Prob}(\xi = b_i)$, $i = 1, \ldots, L$.

The value function V^* is the solution of $M(V) = V$, where the mapping M is determined by

$$M(V)(x) = \min_y \left\{ x^T Q x + y^T R y + \delta \sum_{i=1}^{L} p_i V(Ax + By + b_i) \right\}.$$

We choose the quadratic-linear stochastic control problem because its exact solution on $\Re^n$ can be computed. In the following, to be consistent with standard notation for these problems, we reuse the notation K and c as a matrix and a constant, respectively. To find the exact solution for V^*, we first compute a symmetric positive semidefinite matrix K by solving the algebraic matrix Riccati equation:

$$K = A^T[\delta K - \delta^2 K B(\delta B^T K B + R)^{-1} B^T K]A + Q.$$

Then the exact value function V^* is given by

$$V^*(x) = x^T K x + c,$$

where

$$c = \frac{\delta}{1-\delta} \sum_{i=1}^{L} p_i b_i^T K b_i.$$

The above formula determines the exact value function on $\Re^n$; however, a numerical method can determine only a value function on a bounded set. In this example, we will find the value function on the box $D^* = [-t, t]^n$. The solutions of $M(V) = V$ on $\mathcal{B}(\Re^n)$ and $\mathcal{B}([-t, t]^n)$ need not be the same; however, for reasonably large t, the two solutions should be close. Thus, we still use the exact value function on $\mathcal{B}(\Re^n)$ as the reference for numerically generated value functions.

Finding a point $\bar{x}$ which maximizes $M(V)(x) - V(x)$ is computationally very expensive. The method for minimizing a d.c. function described in Appendix A can be applied to finding $\bar{x}$; however, this is difficult to program and expensive in computation. Thus, we use the following approach. We randomly sample J points,

x^j, $j = 1, \ldots, J$ (e.g., $J = 5$). At each point x^j, we evaluate $M(V)(x^j)$ and compute the gradient of $M(V)$ (or a subgradient if $M(V)$ is not smooth) ξ^j, which generates at the point a supporting plane H^j of $M(V)$. Then we find a point $\bar{x}^j$ by maximizing $H^j(x) - V(x)$, which can be viewed as a local approximation of $M(V)(x) - V(x)$. Suppose that the current approximate value function

$$V(x) = \max\{Q^i x + q^i : i = 1, \ldots, p\}, \qquad x \in [-t, t]^n.$$

Using the supporting plane formula from section 3.2, we have

$$H^j(x) = M(V)(x^j) + \xi^j(x - x^j).$$

Thus, maximizing $H^j(x) - V(x)$ can be formulated as a linear program

$$\sigma^j = \max\{M(V)(x^j) + \xi^j(x - x^j) - \theta : x \in [-t, t]^n,\ Q^i x + q^i \le \theta,\ i = 1, \ldots, p\};$$

then $\bar{x}$ is chosen as the point among $\bar{x}^j$, $j = 1, \ldots, J$, with the largest σ^j.

We implemented SLAM for the quadratic-linear stochastic control problem with various dimensions and summarize the results in the tables below. The accuracy of an approximate solution to the exact solution is measured by the *relative error*,

$$\|V^* - V\|_{D^*} / \|V^*\|_{D^*}.$$

Although the exact value function $V^*(x) = x^T K x + c$ is known, computing the approximation error is still difficult due to the high dimension of $D^* = [-t, t]^n$. To estimate the error, we generate a sample of 5000 points plus points on the line of the eigenvector corresponding to the maximum eigenvalue of K and estimate $\|f\|_{D^*}$ by $\max\{|f(x)| : \text{for all sample points } x\}$. This sample size is generally small for high-dimensional problems, causing potential inaccuracy in the errors shown in the table. The result can, however, be understood as a tendency. For each dimension, we computed 3 instances. The errors shown in the table are the average of the 3 instances.

$(n, m) =$	Number of Iterations: 10	25	50	100	200
$(1, 1)$	0.3540	0.1238	0.0473	0.0125	0.0037
$(2, 2)$	0.1680	0.0750	0.0466	0.0191	0.0105
$(4, 2)$	0.1444	0.0649	0.0541	0.0309	0.0196
$(4, 4)$	0.1140	0.0512	0.0380	0.0190	0.0153
$(10, 5)$	0.1311	0.1255	0.0785	0.0499	0.0455
$(10, 10)$	0.1429	0.1403	0.0868	0.0751	0.0670

Relative Errors

The experiments show that fairly good solutions can be obtained for low-dimensional instances. For the high-dimensional cases, errors are rapidly reduced in the first several iterations but are not clearly reduced after the initial iterations through the 200th iteration. We display only the first iterations for the examples of dimensions $(n, m) = (20, 20)$ and $(50, 50)$.

# Iterations	1	2	3	4	6	8	200
(20,20)	1.0000	0.3935	0.3926	0.1383	0.1221	0.1159	0.1126
(50,50)	1.0000	0.7774	0.3442	0.1794	0.0939	0.0925	0.0925

Relative Errors

A positive aspect of these tests is that the method appears to work well for high-dimensional problems in the sense that it can find a relatively good solution in the first few iterations, with relative errors reduced to around 0.1. Considering that it is not possible for a direct state-discretization method to work for a 20-dimensional problem (since that requires q^{20} points if each dimension is discretized into q points), our method can be considered as a useful alternative for solving high-dimensional stochastic dynamic programs for which the curse of dimensionality is a major concern.

The negative result from this example is that, after a few iterations, the method converges very slowly, particularly for high-dimensional problems. This can be seen from the examples of dimensions $(n, m) = (20, 20)$ and $(50, 50)$. Useful cuts continue to be added in these examples, but, while reducing local errors about the iteration points, errors still remain unaffected in other portions of the domain.

6. Observations and future issues. We have described an algorithm for solving a general class of discrete-time convex infinite-horizon optimization problems and demonstrated the method on two simple examples. As the first example demonstrates, many iterations may be required to achieve accuracy for highly nonlinear value functions. The second example, however, demonstrates that approximate solutions converge very quickly at the beginning and can produce approximate solutions with a relative error of around 0.1, even for high-dimensional problems.

Since each iteration involves additional optimization steps, the selection of $\bar{x}$ (or potentially multiple points on each iteration) has a critical effect on performance. We mentioned the d.c. methods as one possibility for finding good points, but other methods that require fewer function evaluations may also be useful. In the second example, we select $\bar{x}$ from a small sample. The results from this example are encouraging. To see if this selection is effective in general, more numerical experiments are needed. The effect of different options also requires further study.

Our method relies on identification of the feasible domain D^*. In that case, we are left with the following questions:

(i) Under what condition is D^* a polytope?
(ii) Can Algorithm 4.1 terminate in a finite number of iterations if D^* is a polytope?
(iii) How can one modify the algorithm if D^* is not a polytope?

These questions and further implementation issues are additional subjects for future research.

Appendix A. This appendix describes a method for finding a minimizer to the problem

$$\min_{x \in D^*} V(x) - M(V)(x),$$

where both V and $M(V)$ are convex. This problem is equivalent to

$$\begin{aligned} &\min x_{n+1}, \\ x, x_{n+1} &: V(x) - M(V)(x) - x_{n+1} \le 0, \\ &x \in D^*, \end{aligned}$$

which is equivalent to

$$\begin{aligned} &\min x_{n+1}, \\ x, x_{n+1}, x_{n+2} &: V(x) - x_{n+1} - x_{n+2} \le 0, \\ &M(V)(x) - x_{n+2} \ge 0, \\ &x \in D^*. \end{aligned}$$

Suppose that

$$V(x) = \max\{Q^i x + q^i : i = 1, \ldots, k\} \qquad \forall\, x \in D^* \subset \Re^n;$$

then the above problem is equivalent to

$$\begin{aligned} &\min x_{n+1}, \\ x, x_{n+1}, x_{n+2} : &Q^i x + q^i - x_{n+1} - x_{n+2} \le 0, \qquad i = 1, \ldots, k, \\ &x \in D^*, \\ &M(V)(x) - x_{n+2} \ge 0. \end{aligned}$$

The first $k+1$ constraints define a polyhedral set, denoted by D. (In order to use the algorithm described in [5], D should be bounded. This can be done by adding appropriate lower and upper bounds on x_{n+1} and x_{n+2}, without changing the solution of the minimization problem.) The function in the $k+2$nd constraint is convex, denoted by g. Such a program can be solved by Algorithm 4.1 in [5]. Here we describe it briefly. The algorithm solves

$$\begin{aligned} &\min c^T x \\ &\text{s.t. } x \in D,\ g(x) \ge 0. \end{aligned} \tag{A.1}$$

Initialization: Solve $\min\{c^T x : x \in D\}$ to obtain $x^0 \in D$. Assume $g(x^0) < 0$ (otherwise, x^0 is an optimal solution to (A.1)). Construct a simple polytope S_0, e.g., a simplex, containing D, such that x^0 is a vertex of S_0; compute the vertex set $V(S_0)$ of S_0. $j \leftarrow 0$.

Iterations: Choose $z \in V(S_j)$ satisfying $g(z) = \max\{g(x) : x \in V(S_j)\}$.

If $g(z) = 0$ and $z \in D$, then stop; z is an optimal solution.

Otherwise, apply the simplex algorithm with starting vertex z to solve $\min\{c^T x : x \in S_j\}$ until an edge $[u, v]$ of S_j is found such that $g(u) \ge 0$ and $g(v) < 0$ and $c^T v < c^T u$; compute the intersection point s of $[u, v]$ with $\{x : g(x) = 0\}$.

If $s \in D$, then $S_{j+1} \leftarrow S_j \cap \{x : c^T x \le c^T s\}$.

If $s \notin D$, then $S_{j+1} \leftarrow S_j \cap \{x : l(x) \le 0\}$, where $l(x) \le 0$ is one of the linear constraints defining D satisfying $l(s) > 0$.

$j \leftarrow j + 1$; repeat.

Appendix B. Define the function $\rho = M(V)$ by

$$\rho(x) = \min_{y,\theta} \left\{ c(x, y) + \delta \sum_{j=1}^{L} p_j \theta^j \mid \mathbf{Q} z^j + \mathbf{q} \le \theta^j e,\ \mathbf{F} z^j \le \mathbf{f}, \right.$$
$$\left. z^j = A_j x + B_j y + b_j,\ j = 1, \ldots L \right\},$$

and let $(\bar{y}, \bar{\theta})$ and $(\bar{\lambda}, \bar{\mu})$ be an optimal solution and multiplier, respectively, of the above minimization problem. We will show that

$$\xi = \zeta_x + \sum_{j=1}^{L} (\bar{\lambda}_j^T \mathbf{Q} A_j + \bar{\mu}_j^T \mathbf{F} A_j)$$

is a subgradient of ρ at $\bar{x}$, where $\zeta = (\zeta_x, \zeta_y)$ is a subgradient of c at $(\bar{x}, \bar{y})$.

We can write

$$\begin{aligned}\rho(x) = \min\ & c(x,y) + \delta \sum_{j=1}^{L} p_j \theta^j, \\ & y, \theta : \mathbf{Q}(A_j x + B_j y + b_j) + \mathbf{q} \le \theta^j e, \\ & \qquad \mathbf{F}(A_j x + B_j y + b_j) \le \mathbf{f}, \qquad j = 1, \dots, L, \\ = \max\ & h(\lambda, \mu; x) \\ \text{s.t. } & \lambda_j^T e = \delta p_j, \qquad j = 1, \dots, L, \\ & \lambda \ge 0,\ \mu \ge 0, \end{aligned} \tag{B.1}$$

where $\lambda = (\lambda_1, \dots, \lambda_L)$, $\mu = (\mu_1, \dots, \mu_L)$, and

$$\begin{aligned} h(\lambda, \mu; x) = \min_y\ & c(x,y) + \sum_{j=1}^{L} [\lambda_j^T (\mathbf{Q}(A_j x + B_j y + b_j) + \mathbf{q}) \\ & + \mu_j^T (\mathbf{F}(A_j x + B_j y + b_j) - \mathbf{f})]. \end{aligned} \tag{B.2}$$

Let $(\bar\lambda, \bar\mu)$ be the optimal solution of the problem (B.1) with $x = \bar x$. Then $\rho(\bar x) = h(\bar\lambda, \bar\mu; \bar x)$.

The necessary and sufficient condition for $\bar y$ to be an optimal solution of the problem (B.2) (given $(\bar\lambda, \bar\mu; \bar x)$) is that there exists a subgradient $\zeta = (\zeta_x, \zeta_y)$ of c at $(\bar x, \bar y)$ such that

$$\zeta_y + \sum_{j=1}^{L} [\bar\lambda_j^T \mathbf{Q} B_j + \bar\mu_j^T \mathbf{F} B_j] = 0. \tag{B.3}$$

For fixed $(\lambda, \mu) = (\bar\lambda, \bar\mu)$ and for any x, denote by y_x an optimal solution of (B.2). Then

$$\begin{aligned} \rho(x) &= \max_{\lambda,\mu} \{h(\lambda, \mu; x) \mid \lambda_j^T e = \delta p_j,\ j = 1, \dots, L;\ \lambda \ge 0,\ \mu \ge 0\} \\ &\ge h(\bar\lambda, \bar\mu; x) \\ &= c(x, y_x) + \sum_{j=1}^{L} [\bar\lambda_j^T (\mathbf{Q}(A_j x + B_j y_x + b_j) + \mathbf{q}) + \bar\mu_j^T (\mathbf{F}(A_j x + B_j y_x + b_j) - \mathbf{f})]. \end{aligned}$$

Because c is convex,

$$c(x,y) \ge c(\bar x, \bar y) + \zeta_x (x - \bar x) + \zeta_y (y - \bar y).$$

Note that $y_{\bar x} = \bar y$ and

$$\begin{aligned} \rho(\bar x) &= h(\bar\lambda, \bar\mu; \bar x) \\ &= c(\bar x, \bar y) + \sum_{j=1}^{L} [\bar\lambda_j^T (\mathbf{Q}(A_j \bar x + B_j \bar y + b_j) + \mathbf{q}) + \bar\mu_j^T (\mathbf{F}(A_j \bar x + B_j \bar y + b_j) - \mathbf{f})]. \end{aligned}$$

Thus,

$$\begin{aligned}\rho(x) &\geq \rho(\bar{x}) + \zeta_x(x-\bar{x}) + \zeta_y(y_x - \bar{y}) \\ &\quad + \sum_{j=1}^{L}[\bar{\lambda}_j^T(\mathbf{Q}A_j(x-\bar{x}) + \mathbf{Q}B_j(y_x-\bar{y})) + \bar{\mu}_j^T(\mathbf{F}A_j(x-\bar{x}) + \mathbf{F}B_j(y_x-\bar{y}))] \\ &= \rho(\bar{x}) + \left\{\zeta_x + \sum_{j=1}^{L}(\bar{\lambda}_j^T\mathbf{Q}A_j + \bar{\mu}_j^T\mathbf{F}A_j)\right\}(x-\bar{x}),\end{aligned}$$

where the last equation uses (B.3). The above inequality shows that

$$\xi = \zeta_x + \sum_{j=1}^{L}(\bar{\lambda}_j^T\mathbf{Q}A_j + \bar{\mu}_j^T\mathbf{F}A_j)$$

is a subgradient of ρ at $\bar{x}$.

THE ADAPTIVE CONVEXIFICATION ALGORITHM: A FEASIBLE POINT METHOD FOR SEMI-INFINITE PROGRAMMING*

CHRISTODOULOS A. FLOUDAS† AND OLIVER STEIN‡

Abstract. We present a new numerical solution method for semi-infinite optimization problems. Its main idea is to adaptively construct convex relaxations of the lower level problem, replace the relaxed lower level problems equivalently by their Karush–Kuhn–Tucker conditions, and solve the resulting mathematical programs with complementarity constraints. This approximation produces *feasible iterates* for the original problem. The convex relaxations are constructed with ideas from the αBB method of global optimization. The necessary upper bounds for second derivatives of functions on box domains can be determined using the techniques of interval arithmetic, where our algorithm already works if only one such bound is available for the problem. We show convergence of stationary points of the approximating problems to a stationary point of the original semi-infinite problem within arbitrarily given tolerances. Numerical examples from Chebyshev approximation and design centering illustrate the performance of the method.

1. Introduction.

We consider the optimization problem

$$\text{SIP}: \qquad \min_{x\in X} f(x) \quad \text{subject to} \quad g(x,y) \le 0 \text{ for all } y \in Y,$$

with objective function $f \in C^2(\mathbb{R}^n, \mathbb{R})$, constraint functions $g \in C^2(\mathbb{R}^n \times \mathbb{R}^m, \mathbb{R}^p)$, a box constraint set $X = [x^\ell, x^u] \subset \mathbb{R}^n$, with $x^\ell < x^u \in \mathbb{R}^n$, and a box index set $Y = [y^\ell, y^u] \subset \mathbb{R}^m$, with $y^\ell < y^u \in \mathbb{R}^m$, where the vector inequalities are understood componentwise. Problems of this type, in which a finite-dimensional decision variable is subject to infinitely many inequality constraints, are called (standard) semi-infinite. In this article we will focus our attention on the simplest case $p = 1$ (one semi-infinite constraint) and $m = 1$; that is, without loss of generality we put $Y = [0, 1]$. More general problem formulations allow Y to be a nonempty compact subset of $\mathbb{R}^m$ or even to be nonfixed but x-dependent. In the latter case the problem is called generalized semi-infinite. Moreover, in applications additional inequality and equality constraints may be present. Whereas the techniques and results presented in this article may be used to tackle these more general problems (with more or less additional effort), for the sake of clarity we develop the main ideas only for SIP with $p = 1$ and $Y = [0, 1]$.

Standard semi-infinite problems have been studied systematically since the 1960s. Important early contributions regarding optimality conditions and duality theory for standard semi-infinite problems are given in [6, 15] for linear semi-infinite problems and in [20, 49] for nonlinear problems. For excellent reviews with hundreds of references on semi-infinite programming, we refer to [21, 36]. A standard reference for

linear semi-infinite problems is [16], and [23, 37, 38] overview the existing numerical methods. Generalized semi-infinite optimization is treated in detail in [45].

Until recently the numerical methods for SIP suffered from the major drawback that their approximations of the feasible set $X \cap M$, with

$$M \;=\; \{\, x \in \mathbb{R}^n |\; g(x,y) \le 0 \text{ for all } y \in Y \,\},$$

may contain infeasible points. In fact, discretization and exchange methods approximate M by finitely many inequalities corresponding to finitely many indices in Y, yielding an outer approximation of M, and reduction-based methods solve the Karush–Kuhn–Tucker system of SIP (cf. section 2.1) by a Newton-SQP approach. As a consequence, the iterates of these methods are not necessarily feasible for SIP, but only their limit might be. Even to ensure the latter, active index sets of the iterates have to be determined. As we will explain, this amounts to the solution of certain global optimization problems.

The recent articles [4, 5] present a branch-and-bound framework for the global solution of SIP which generates convergent sequences of lower and upper bounds for the globally optimal value. Whereas the lower bounds are obtained by usual discretization, the upper bounds are computed using inclusion bounds and interval arithmetic. Whereas [4, 5] focus on the global solution of SIP, they also present the first algorithm with feasible iterates for SIP, to our knowledge.

In fact, checking feasibility of a given point $\bar{x} \in \mathbb{R}^n$ is the crucial problem in semi-infinite optimization. Clearly we have $\bar{x} \in M$ if and only if $\varphi(\bar{x}) \le 0$ holds with the function

$$\varphi :\; \mathbb{R}^n \to \mathbb{R},\; x \mapsto \max_{y \in Y} g(x,y)\,.$$

The latter function is the optimal value function of the so-called lower level problem of SIP,

$$Q(x): \qquad \max_{y \in \mathbb{R}} g(x,y) \quad \text{subject to} \quad 0 \le y \le 1\,.$$

The difficulty lies in the fact that $\varphi(\bar{x})$ is the *globally* optimal value of $Q(\bar{x})$ which might be hard to determine numerically. In fact, standard NLP solvers can only be expected to produce a *local* maximizer y_{loc} of $Q(\bar{x})$ which is not necessarily a global maximizer y_{glob}. Even if $g(\bar{x}, y_{\text{loc}}) \le 0$ is satisfied, $\bar{x}$ might be infeasible since $g(\bar{x}, y_{\text{loc}}) \le 0 < \varphi(\bar{x}) = g(\bar{x}, y_{\text{glob}})$ may hold.

To avoid this effect one could simply assume that the lower level is a convex optimization problem, since then its local and global maximizers coincide. As the feasible set $Y = [0,1]$ of $Q(x)$ is convex, only concavity of g with respect to y for each $x \in X$ is needed to ensure lower level convexity.

The known numerical methods for standard semi-infinite optimization have not taken this approach since the concavity assumption on g fails in most applications. In generalized semi-infinite optimization, however, a number of real-life applications with convex lower level problems exist, so that this structure was exploited in [40, 45, 48]. We will recall the main ideas in section 2.2.

In this article we aim at constructing a sequence of convexifications of the lower level problem and using the techniques from [45, 48] to solve the auxiliary problems with convex lower levels. The convexifications will be produced using the ideas of the αBB method [1, 2, 12] which is explained in section 2.3. As αBB allows one to construct concave overestimators of g, all iterates of our method will be *feasible* for SIP.

Note that in this article we are mainly interested in the feasibility of the iterates, that is, in global solutions of the lower level problem, and *not* in a possibly global solution of SIP (the upper level problem). For this reason we neither make any global assumptions on the defining functions of the upper level such as linearity or convexity with respect to x, nor do we convexify the problem or branch-and-bound with respect to x. Consequently our solution concept will be that of local minimizers or stationary points. This is a main difference to the branch-and-bound approach presented in [4, 5]. While we cannot guarantee global solutions of SIP, our approach can easily be combined with other methods, should a special structure of SIP with respect to x be present. If no special structure is present, our method promises to compute local minimizers with less numerical effort than a method aiming at global minimizers. We point out that our procedure involves the solution of auxiliary optimization problems involving equality constraints, whereas the approach from [4, 5] generally leads to auxiliary problems with nonsmooth inequality constraints.

Section 3 develops our new solution method, Algorithm 3.4, and section 4 provides corresponding convergence results. Numerical examples illustrate the performance of the method in section 5. Finally, in section 6 we point out possible improvements and generalizations of our method as well as some open questions.

2. Background.

2.1. Stationarity conditions. First order necessary optimality conditions for SIP and a natural constraint qualification are well-known and briefly recalled in what follows. To keep the exposition concise, throughout this paper we assume that the box X is so large that the considered stationary points are contained in its interior. Since φ is continuous [9], M is a closed set, and a feasible point $\bar{x}$, with $\varphi(\bar{x}) < 0$, lies in the interior of M. A local minimizer $\bar{x}$ of SIP, with $\varphi(\bar{x}) < 0$, hence necessarily satisfies $\nabla f(\bar{x}) = 0$. Here and in the following, the column vector ∇F denotes the gradient of a C^1 function F and $\nabla_z F$ the gradient of F with respect to the vector z.

For $\bar{x} \in \partial M$, the topological boundary of M, we define the active index set

$$Y_0(\bar{x}) = \{y \in Y | g(\bar{x}, y) = 0\}.$$

Note that $Y_0(\bar{x})$ is nonempty and compact and that it coincides with the set of global maximizers of $Q(\bar{x})$. The following theorem is due to John. For our formulation we use the $(n+1)$-dimensional standard simplex

$$S^{n+1} = \left\{ s \in \mathbb{R}^{n+2} \middle| s \geq 0, \sum_{i=1}^{n+2} s_i = 1 \right\}.$$

THEOREM 2.1 (see [25]). *Let $\bar{x} \in \partial M$ be a local minimizer of* SIP. *Then there exist $y^k \in Y_0(\bar{x})$, $1 \leq k \leq n+1$, and $(\kappa, \lambda) \in \mathbb{R} \times \mathbb{R}^{n+1}$, with $(\kappa, \lambda) \in S^{n+1}$, and*

$$\kappa \nabla f(\bar{x}) + \sum_{k=1}^{n+1} \lambda_k \nabla_x g(\bar{x}, y^k) = 0, \tag{2.1}$$

$$\lambda_k \cdot g(\bar{x}, y^k) = 0, 1 \leq k \leq n+1. \tag{2.2}$$

A point $\bar{x} \in M$ is said to satisfy the *extended Mangasarian–Fromovitz constraint qualification (EMFCQ)* if

$$\nabla_x^\top g(\bar{x}, y) d < 0 \quad \text{for all} \quad y \in Y_0(\bar{x})$$

holds with some vector $d \in \mathbb{R}^n$. Under EMFCQ at $\bar{x}$, one can choose $\kappa = 1$ in (2.1) and thus obtain a *Karush–Kuhn–Tucker* condition [23]. Note that, in the case when strictly less than $n+1$ active indices are sufficient for stationarity, we can satisfy (2.1), (2.2) by artificially listing the same active index an appropriate number of times and setting the corresponding multipliers to zero.

2.2. Convex lower level problems. Assume for the moment that $Q(x)$ is actually a convex optimization problem for all $x \in X$; that is, $g(x, \cdot)$ is concave on $Y = [0, 1]$ for these x. The approach from [45, 48] then takes advantage of the fact that the solution set of a differentiable convex lower level problem satisfying a constraint qualification is characterized by its first order optimality condition. As a first step for this, observe that SIP and the Stackelberg game

$$\text{SG}: \quad \min_{x,y} f(x) \quad \text{subject to} \quad g(x, y) \leq 0, \text{ and } y \text{ solves } Q(x),$$

are equivalent problems (this can even be shown for generalized semi-infinite problems; cf. [47]). Next, the restriction "y solves $Q(x)$" in SG can be equivalently replaced by its Karush–Kuhn–Tucker condition. For this reformulation we use that the Lagrange function of $Q(x)$

$$\mathcal{L}(x, y, \gamma_\ell, \gamma_u) = g(x, y) + \gamma_\ell y + \gamma_u(1 - y)$$

satisfies

$$\nabla_y \mathcal{L}(x, y, \gamma_\ell, \gamma_u) = \nabla_y g(x, y) + \gamma_\ell - \gamma_u$$

and obtain that the Stackelberg game is equivalent to the following mathematical program with complementarity constraints:

$$\begin{aligned} \text{MPCC}: \quad \min_{x,y,\gamma_\ell,\gamma_u} f(x) \quad \text{subject to} \quad & g(x, y) \leq 0 \\ & \nabla_y g(x, y) + \gamma_\ell - \gamma_u = 0 \\ & \gamma_\ell y = 0 \\ & \gamma_u(1 - y) = 0 \\ & \gamma_\ell, \gamma_u \geq 0 \\ & y, 1 - y \geq 0. \end{aligned}$$

Unfortunately standard numerical software cannot be expected to solve this problem since due to the appearance of complementarity conditions the Mangasarian-Fromovitz constraint qualification (MFCQ) is violated at all points of the feasible set of MPCC [42]. In [27, 39] it is shown that MFCQ is a necessary condition for the stability of smooth nonlinear programs under data perturbations and thus for the stability of numerical methods in the presence of roundoff errors. Note that in [11] it is shown, however, that at least certain SQP methods will converge locally for MPCC. For overviews of MPCC solution methods we refer to [29, 30, 43].

One approach to solve MPCC is the reformulation of the complementarity constraints by a so-called NCP function, that is, a function $\phi : \mathbb{R}^2 \to \mathbb{R}$, with

$$\phi(a, b) = 0 \quad \text{if and only if} \quad a \geq 0, b \geq 0, ab = 0.$$

Examples are the natural residual or min-function

$$\phi^{NR}(a, b) = \frac{1}{2}\left(a + b - \sqrt{(a - b)^2}\right),$$

and the Fischer–Burmeister function [10]

$$\phi^{FB}(a,b) = a + b - \sqrt{a^2 + b^2}.$$

For numerical purposes one can regularize these nondifferentiable NCP functions. The so-called Chen–Harker–Kanzow–Smale function [7, 28, 44] is given by

$$\phi_\tau^{NR}(a,b) = \frac{1}{2}\left(a + b - \sqrt{(a-b)^2 + 4\tau^2}\right),$$

whereas the so-called smoothed Fischer–Burmeister function is

$$\phi_\tau^{FB}(a,b) = a + b - \sqrt{a^2 + b^2 + 2\tau^2}.$$

Obviously ϕ_τ^{NR} and ϕ_τ^{FB} are continuously differentiable for all $\tau \neq 0$, and for $\tau = 0$ they coincide with ϕ^{NR} and ϕ^{FB}, respectively.

With ϕ denoting one of the NCP functions ϕ^{NR} and ϕ^{FB}, MPCC can now be equivalently rewritten as the nonsmooth problem

$$\begin{aligned} P: \quad \min_{x,y,\gamma_\ell,\gamma_u} \ f(x) \quad \text{subject to} \quad & g(x,y) \le 0 \\ & \nabla_y g(x,y) + \gamma_\ell - \gamma_u = 0 \\ & \phi(\gamma_\ell, y) = 0 \\ & \phi(\gamma_u, 1-y) = 0, \end{aligned}$$

where, in particular, the inequality constraints on y, γ_ℓ, γ_u are now modeled by ϕ. Problem P is embedded into the parameterized family of optimization problems

$$\begin{aligned} P_\tau: \quad \min_{x,y,\gamma_\ell,\gamma_u} \ f(x) \quad \text{subject to} \quad & g(x,y) \le 0 \\ & \nabla_y g(x,y) + \gamma_\ell - \gamma_u = 0 \\ & \phi_\tau(\gamma_\ell, y) = 0 \\ & \phi_\tau(\gamma_u, 1-y) = 0, \end{aligned}$$

which are smooth for $\tau \neq 0$ and satisfy $P_0 = P$. Given a sequence of regularization parameters $\tau^\nu \searrow 0$, the problems P_{τ^ν} can be solved by standard software, and in [45, 48] it is shown that under weak assumptions each cluster point $x^\star$ of the solution components x^ν is a solution of SIP.

2.3. The αBB method. In αBB, a convex underestimator of a nonconvex function is constructed by decomposing it into a sum of nonconvex terms of special type (e.g., linear, bilinear, trilinear, fractional, fractional trilinear, convex, univariate concave) and nonconvex terms of arbitrary type. The first type is then replaced by its convex envelope or very tight convex underestimators which are already known. A complete list of the tight convex underestimators of the above special-type nonconvex terms is provided in [12]. Recent comprehensive reviews on the state of the art in global optimization can be found [13, 14].

To keep the exposition concise, in this article we will treat all terms as arbitrarily nonconvex. For these terms, αBB constructs convex underestimators by adding a quadratic relaxation function ψ. With the obvious modification we use this approach to construct a concave overestimator for a nonconcave function $g : [y^\ell, y^u] \to \mathbb{R}$ being C^2 on an open neighborhood of $[y^\ell, y^u]$. With

$$\psi(y; \alpha, y^\ell, y^u) = \tfrac{\alpha}{2}(y - y^\ell)(y^u - y), \tag{2.3}$$

we put

$$\tilde{g}(y;\alpha,y^\ell,y^u) = g(y) + \psi(y;\alpha,y^\ell,y^u).$$

In what follows we will suppress the dependence of $\tilde{g}$ on y^ℓ, y^u. For $\alpha \geq 0$ the function $\tilde{g}$ clearly is an overestimator of g on $[y^\ell, y^u]$, and it coincides with g at the end points y^ℓ, y^u of the domain. Moreover, $\tilde{g}$ is twice continuously differentiable with the second derivative

$$\nabla_y^2 \tilde{g}(y;\alpha) = \nabla^2 g(y) - \alpha$$

on $[y^\ell, y^u]$. Consequently $\tilde{g}$ is concave on $[y^\ell, y^u]$ for

$$\alpha \geq \max_{y\in[y^\ell,y^u]} \nabla^2 g(y) \tag{2.4}$$

(cf. also [1, 2]). The computation of α thus involves a global optimization problem itself. Note, however, that we may use *any* upper bound for the right-hand side in (2.4). Such upper bounds can be provided by interval methods (see, e.g., [12, 19, 33]). We will call α satisfying (2.4) a *convexification parameter*.

Combining these facts shows that for

$$\alpha \geq \max\left(0, \max_{y\in[y^\ell,y^u]} \nabla^2 g(y)\right) \tag{2.5}$$

the function $\tilde{g}(y;\alpha)$ is a concave overestimator of g on $[y^\ell, y^u]$. A representative measure of the quality of an overestimator is the separation distance between itself and the nonconcave function it overestimates. The smaller the separation distance, the tighter the overestimator is. The separation distance between $g(y)$ and $\tilde{g}(y;\alpha)$ is defined by the difference of these functions; that is,

$$d_{\alpha BB}(y;\alpha) = \tilde{g}(y;\alpha) - g(y) = \tfrac{\alpha}{2}(y - y^\ell)(y^u - y).$$

The separation distance is hence maximal at the midpoint of the interval $[y^\ell, y^u]$, and its value is

$$\max_{y\in[y^\ell,y^u]} d_{\alpha BB}(y;\alpha) = \tfrac{\alpha}{8}(y^u - y^\ell)^2 \tag{2.6}$$

(see also [32]). On the one hand, (2.6) quantifies the improvement of the maximal separation distance for better bounds α with (2.5) on a fixed set $[y^\ell, y^u]$; on the other hand, it shows that the maximal separation distance decreases quadratically for $|y^u - y^\ell| \to 0$, even if α is bounded below by some positive number.

Whereas the presented ideas are used in the αBB approach to global optimization in a branch-and-bound framework [12], here we will use them for adaptive convexifications of the lower level problem of SIP.

3. The numerical approach. For $N \in \mathbb{N}$ let $0 = \eta^0 < \eta^1 < \cdots < \eta^{N-1} < \eta^N = 1$ define a subdivision of $Y = [0,1]$; that is, with $K = \{1,\ldots,N\}$ and

$$Y^k = [\eta^{k-1}, \eta^k], \quad k \in K,$$

we have

$$Y = \bigcup_{k\in K} Y_k. \tag{3.1}$$

A trivial but very useful observation is that the single semi-infinite constraint

$$g(x,y) \le 0 \quad \text{for all } y \in Y$$

is equivalent to the finitely many semi-infinite constraints

$$g(x,y) \le 0 \quad \text{for all } y \in Y^k, k \in K.$$

Given a subdivision, we will construct concave overestimators for each of these finitely many semi-infinite constraints, solve the corresponding optimization problem, and adaptively refine the subdivision.

The following lemma formulates the obvious fact that replacing g by overestimators on each subdivision node Y^k results in an approximation of M by *feasible* points.

LEMMA 3.1. *For each $k \in K$ let $g^k : X \times Y^k \to \mathbb{R}$, and let $\bar{x} \in X$ be given such that for all $k \in K$ and all $y \in Y^k$ we have $g(\bar{x},y) \le g^k(\bar{x},y)$. Then the constraints*

$$g^k(\bar{x},y) \le 0 \quad \textit{for all } y \in Y^k, k \in K,$$

entail $\bar{x} \in M$.

Proof. The proof immediately follows from (3.1). ∎

3.1. αBB for the lower level. For the construction of these overestimators we use ideas of the αBB method. In fact, for each $k \in K$ we put

$$g^k : X \times Y^k \to \mathbb{R}, (x,y) \mapsto g(x,y) + \psi(y; \alpha_k, \eta^{k-1}, \eta^k) \tag{3.2}$$

with the quadratic relaxation function ψ from (2.3) and

$$\alpha_k > \max\left(0, \max_{(x,y) \in X \times Y^k} \nabla_y^2 g(x,y)\right). \tag{3.3}$$

Note that the latter condition on α_k is uniform in x. We emphasize that with the single bound

$$\bar{\alpha} > \max\left(0, \max_{(x,y) \in X \times Y} \nabla_y^2 g(x,y)\right) \tag{3.4}$$

the choices $\alpha_k := \bar{\alpha}$ satisfy (3.3) for all $k \in K$. Moreover, the α_k can always be chosen such that $\alpha_k \le \bar{\alpha}$, $k \in K$.

The following properties of g^k are easily verified.

LEMMA 3.2. *For each $k \in K$ let g^k be given by (3.2). Then the following holds:*

(i) *For all $(x,y) \in X \times Y^k$ we have $g(x,y) \le g^k(x,y)$.*
(ii) *For all $x \in X$, the function $g^k(x,\cdot)$ is concave on Y^k.*
(iii) *The maximal separation distance (compare (2.6)) between g^k and g on $X \times Y^k$ is $\frac{\alpha_k}{8}(\eta^k - \eta^{k-1})^2$.*

Now we consider the following approximation of the feasible set M, where $E = \{\eta^k | k \in K\}$ denotes the set of subdivision points and α the vector of convexification parameters:

$$M_{\alpha BB}(E,\alpha) = \{x \in \mathbb{R}^n | g^k(x,y) \le 0 \quad \text{for all } y \in Y^k, k \in K\}.$$

By Lemmas 3.1 and 3.2(i) we have $M_{\alpha BB}(E,\alpha) \subset M$. This means that any solution concept for

$$\mathrm{SIP}_{\alpha BB}(E,\alpha): \quad \min_{x \in X} f(x) \quad \text{subject to} \quad x \in M_{\alpha BB}(E,\alpha),$$

be it global solutions, local solutions or stationary points, will at least lead to feasible points of SIP (provided that $\mathrm{SIP}_{\alpha BB}(E,\alpha)$ is consistent, i.e., its feasible set is nonvoid).

The problem $\mathrm{SIP}_{\alpha BB}(E,\alpha)$ has finitely many lower level problems $Q^k(x)$, $k \in K$, with

$$Q^k(x): \qquad \max_{y\in\mathbb{R}} g^k(x,y) \quad \text{subject to} \quad \eta^{k-1} \le y \le \eta^k.$$

Since the inequality (3.3) is strict, the convex problem $Q^k(x)$ has a unique solution $y^k(x)$ for each $k \in K$ and $x \in X$. Note that the functions y^k, $k \in K$, are even Lipschitz continuous on X, since the strong second order sufficiency condition and the linear independence constraint qualification hold at $y^k(x)$ [39].

Recall that $y \in Y^k$ is called active for the constraint $\max_{y\in Y^k} g^k(x,y) \le 0$ at $\bar{x}$ if $g^k(\bar{x},y) = 0$ holds. By the uniqueness of the global solution of $Q^k(\bar{x})$ there exists *at most one* active index for each $k \in K$, namely, $y^k(\bar{x})$. Thus, we can consider the finite active index sets

$$\begin{aligned} K_0(\bar{x}) &= \{k \in K | g^k(\bar{x}, y^k(\bar{x})) = 0\},\\ Y_0^{\alpha BB}(\bar{x}) &= \{y^k(\bar{x}) | k \in K_0(\bar{x})\}. \end{aligned}$$

3.2. The MPCC reformulation. Following the ideas of section 2.2 we find that y^k solves $Q^k(x)$ if and only if $(x, y^k, \gamma_\ell^k, \gamma_u^k)$ solves the system

$$\begin{aligned} \nabla_y g^k(x,y) + \gamma_\ell - \gamma_u &= 0,\\ \phi(\gamma_\ell, y - \eta^{k-1}) &= 0,\\ \phi(\gamma_u, \eta^k - y) &= 0, \end{aligned}$$

with some γ_ℓ^k, γ_u^k, and ϕ denoting one of the NCP functions ϕ^{NR} and ϕ^{FB}. With

$$\begin{aligned} w &:= (x, y^k, \gamma_\ell^k, \gamma_u^k, k \in K),\\ F(w) &:= f(x),\\ G^k(w;E,\alpha) &:= g(x,y^k) + \tfrac{\alpha_k}{2}(y^k - \eta^{k-1})(\eta^k - y^k),\\ H^k(w;E,\alpha) &:= \begin{pmatrix} \nabla_y g(x,y^k) + \alpha_k\left(\frac{\eta^{k-1}+\eta^k}{2} - y^k\right) + \gamma_\ell^k - \gamma_u^k \\ \phi(\gamma_\ell^k, y^k - \eta^{k-1}) \\ \phi(\gamma_u^k, \eta^k - y^k) \end{pmatrix}, \end{aligned}$$

we can thus replace $\mathrm{SIP}_{\alpha BB}(E,\alpha)$ equivalently by the nonsmooth problem

$$P(E,\alpha): \qquad \min_w F(w) \qquad \text{subject to} \qquad \begin{aligned} &G^k(w;E,\alpha) \le 0,\\ &H^k(w;E,\alpha) = 0, k \in K. \end{aligned}$$

The latter problem can be solved numerically by regularization of the NCP functions; that is, H^k is replaced by

$$H^k(w;E,\alpha,\tau) = \begin{pmatrix} \nabla_y g(x,y^k) + \alpha_k\left(\frac{\eta^{k-1}+\eta^k}{2} - y^k\right) + \gamma_\ell^k - \gamma_u^k \\ \phi_\tau(\gamma_\ell^k, y^k - \eta^{k-1}) \\ \phi_\tau(\gamma_u^k, \eta^k - y^k) \end{pmatrix},$$

and for $\tau \neq 0$ we obtain the smooth problem

$$P(E,\alpha,\tau): \qquad \min_w F(w) \qquad \text{subject to} \qquad \begin{aligned} &G^k(w;E,\alpha) \le 0,\\ &H^k(w;E,\alpha,\tau) = 0, k \in K. \end{aligned}$$

It may be tackled by numerical standard software which we will consider to be a "black box." One possibility is to compute solutions of these problems for a user-defined sequence $\tau^\nu \searrow 0$, as suggested in [45, 48]. In view of the simple structure of the complementarity constraints, in the present setting one can also try to let the NLP solver itself drive τ from a positive initial value to zero while solving the problem

$$\tilde{P}(E,\alpha): \quad \min_{(w,\tau)} F(w) \quad \text{subject to} \quad \begin{aligned} &G^k(w;E,\alpha) \le 0,\\ &H^k(w;E,\alpha,\tau) = 0, k \in K,\\ &\tau = 0. \end{aligned}$$

For our numerical examples in section 5 this alternative works well. In any case we assume that the black box NLP solver generates a local minimizer $\bar{w}$ of $P(E,\alpha)$. The subvector $\bar{x}$ of $\bar{w}$ is then a local minimizer and, hence, a stationary point of $\mathrm{SIP}_{\alpha BB}(E,\alpha)$. Note that in the present article we do not discuss the effects of numerical inaccuracies in the solution of $P(E,\alpha)$ on the feasibility of iterates for SIP.

3.3. The adaptive convexification algorithm. The main idea of our numerical method is to compute a stationary point $\bar{x}$ of $\mathrm{SIP}_{\alpha BB}(E,\alpha)$ by the approach from section 3.2 and terminate if $\bar{x}$ is also stationary for SIP within given tolerances. If $\bar{x}$ is not stationary we refine the subdivision E in the spirit of exchange methods [21, 38] by adding the active indices $Y_0^{\alpha BB}(\bar{x})$ to E and construct a refined problem $\mathrm{SIP}_{\alpha BB}(E \cup Y_0^{\alpha BB}(\bar{x}), \tilde{\alpha})$ by the following procedure. Note that, in view of Carathéodory's theorem (compare also Theorem 2.1), the number of elements of $Y_0^{\alpha BB}(\bar{x})$ may be bounded by $n+1$.

Refinement step:

For any $\tilde{\eta} \in Y_0^{\alpha BB}(\bar{x})$, let $k \in K$ be the index with $\tilde{\eta} \in [\eta^{k-1}, \eta^k]$. Put $Y^{k,1} = [\eta^{k-1}, \tilde{\eta}]$, $Y^{k,2} = [\tilde{\eta}, \eta^k]$, let $\alpha_{k,1}$ and $\alpha_{k,2}$ be the corresponding convexification parameters, put

$$\begin{aligned} g^{k,1}(x,y) &= g(x,y) + \frac{\alpha_{k,1}}{2}(y-\eta^{k-1})(\tilde{\eta}-y),\\ g^{k,2}(x,y) &= g(x,y) + \frac{\alpha_{k,2}}{2}(y-\tilde{\eta})(\eta^k-y), \end{aligned}$$

and define $M_{\alpha BB}(E \cup \{\tilde{\eta}\}, \tilde{\alpha})$ by replacing the constraint

$$g^k(x,y) \le 0 \quad \text{for all } y \in Y^k$$

in $M_{\alpha BB}(E,\alpha)$ by the two new constraints

$$g^{k,i}(x,y) \le 0 \quad \text{for all } y \in Y^{k,i}, i = 1,2,$$

and by replacing the entry α_k of α by the two new entries $\alpha_{k,i}$, $i = 1,2$.

The point $\bar{x}$ is stationary for $\mathrm{SIP}_{\alpha BB}(E,\alpha)$ (in the sense of John; compare Theorem 2.1) if $\bar{x} \in M_{\alpha BB}(E,\alpha)$ and if there exist $y^k \in Y_0^{\alpha BB}(\bar{x})$, $1 \le k \le n+1$, and $(\kappa,\lambda) \in S^{n+1}$ with

$$\kappa \nabla f(\bar{x}) + \sum_{k=1}^{n+1} \lambda_k \nabla_x g(\bar{x}, y^k) = 0, \tag{3.5}$$

$$\lambda_k \cdot g^k(\bar{x}, y^k) = 0, 1 \le k \le n+1. \tag{3.6}$$

Note that in (3.5) we simplified

$$\nabla_x g^k(\bar{x}, y^k) = \nabla_x \left(g(x, y^k) + \psi(y^k; \alpha_k, \eta^{k-1}, \eta^k) \right) = \nabla_x g(x, y^k).$$

For the numerical algorithm it is crucial to relax the notions of *active index*, *stationarity*, and *set unification* by certain tolerances.

DEFINITION 3.3. *For $\varepsilon_{act}, \varepsilon_{stat}, \varepsilon_{\cup} > 0$ we say that*

(i) *y^k is ε_{act}-*active for g^k at $\bar{x}$ *if $g^k(\bar{x}, y^k) \in [-\varepsilon_{act}, 0]$,*

(ii) *$\bar{x}$ is ε_{stat}-*stationary for SIP with *ε_{act}-*active indices *if $\bar{x} \in M$ and if there exist $y^k \in Y$, $1 \le k \le n+1$, and $(\kappa, \lambda) \in S^{n+1}$ such that*

$$\left\| \kappa \nabla f(\bar{x}) + \sum_{k=1}^{n+1} \lambda_k \nabla_x g(\bar{x}, y^k) \right\| \le \varepsilon_{stat}, \tag{3.7}$$

$$\lambda_k \cdot g(\bar{x}, y^k) \in [-\lambda_k \cdot \varepsilon_{act}, 0],\ 1 \le k \le n+1, \tag{3.8}$$

hold, and

(iii) *the $\varepsilon_{\cup}$-*union of E and $\tilde{\eta}$ *is $E \cup \{\tilde{\eta}\}$ if*

$$\min\{\tilde{\eta} - \eta^{k-1}, \eta^k - \tilde{\eta}\} > \varepsilon_{\cup} \cdot (\eta^k - \eta^{k-1})$$

holds for the $k \in K$ with $\tilde{\eta} \in [\eta^{k-1}, \eta^k]$, and E otherwise (i.e., $\tilde{\eta}$ is not unified with E if its distance from E is too small).

ALGORITHM 3.4 (adaptive convexification algorithm).

Step 1: *Determine a uniform convexification parameter $\bar{\alpha}$ with* (3.4)*, choose $N \in \mathbb{N}$, $\eta^k \in Y$, and $\alpha_k \le \bar{\alpha}$, $k \in K = \{1, \dots, N\}$, such that* $\mathrm{SIP}_{\alpha BB}(E, \alpha)$ *is consistent, as well as tolerances $\varepsilon_{act}, \varepsilon_{stat}, \varepsilon_{\cup} > 0$, with $\varepsilon_{\cup} \le 2\varepsilon_{act}/\bar{\alpha}$.*

Step 2: *By solving $P(E, \alpha)$, compute a stationary point x of* $\mathrm{SIP}_{\alpha BB}(E, \alpha)$ *with ε_{act}-active indices y^k, $1 \le k \le n+1$, and multipliers (κ, λ).*

Step 3: *Terminate if x is ε_{stat}-stationary for* SIP *with $(2\varepsilon_{act})$-active indices y^k, $1 \le k \le n+1$, from Step 2 and multipliers (κ, λ) from Step 2.*
Otherwise construct a new set $\tilde{E}$ of subdivision points as the $\varepsilon_{\cup}$-union of E and $\{y^k | 1 \le k \le n+1\}$ and perform a refinement step for the elements in $\tilde{E} \setminus E$ to construct a new feasible set $M_{\alpha BB}(\tilde{E}, \tilde{\alpha})$.

Step 4: *Put $E = \tilde{E}$, $\alpha = \tilde{\alpha}$, and go to Step 2.*

In section 4 we will show that Algorithm 3.4 is well-defined, convergent, and finitely terminating. Note that after its termination we can exploit that the set $E \subset Y$ contains indices that should also yield a good *outer* approximation of M. The optimal value of the problem

$$P_{outer}: \qquad \min_{x \in X} f(x) \quad \text{subject to} \quad g(x, \eta) \le 0, \eta \in E,$$

yields a rigorous *lower* bound for the optimal value of SIP. If P_{outer} can actually be solved to global optimality (e.g., if a standard NLP solver is used, due to convexity with respect to x), then a comparison of this lower bound for the optimal value of SIP with the upper bound from Algorithm 3.4 can yield a certificate of global optimality for SIP (see also section 5).

3.4. A consistent initial approximation. Even if the feasible set M of SIP is consistent, there is of course no guarantee that its approximations $M_{\alpha BB}(E, \alpha)$ are also consistent. For Step 1 of Algorithm 3.4 we thus suggest the following phase I approach: Use Algorithm 3.4 to construct adaptive convexifications of

$$\mathrm{SIP}^{ph.I}: \qquad \min_{(x,z) \in X \times \mathbb{R}} z \quad \text{subject to} \quad g(x, y) \le z \text{ for all } y \in Y$$

until a feasible point $(\bar{x}, \bar{z})$, with $\bar{z} \le 0$, of $\mathrm{SIP}^{ph.I}_{\alpha BB}(E, \alpha)$ is found with some subdivision E and convexification parameters α. The point $\bar{x}$ is then obviously also feasible for $\mathrm{SIP}_{\alpha BB}(E, \alpha)$ and can be used as an initial point to solve the latter problem. Due to the possible nonconvexity of the upper level problem of SIP, this phase I approach is not necessarily successful, but in our numerical examples in section 5 it works well. If it does not work although SIP is consistent, one can try to initialize phase I with different starting values or use an exhaustive subdivision of the index set like in the subsequent Proposition 4.1.

To initialize Algorithm 3.4 for phase I, select some point $\bar{x}$ in the box X and put $E^1 = \{0, 1\}$, that is, $Y^1 = Y = [0, 1]$. Compute α_1 according to (3.3), and solve the convex optimization problem $Q^1(\bar{x})$ with standard software. With its optimal value $\bar{z}$, the point $(\bar{x}, \bar{z})$ is feasible for $\mathrm{SIP}^{ph.I}_{\alpha BB}(E^1, \alpha_1)$.

4. Convergence results. To obtain a first impression of the approximation properties of our approach, for the following result we temporarily assume that the subdivision of $Y = [0, 1]$ is not adaptive in each step, but equidistant, that is, $\eta^k = k/N$, $k \in K = \{0, \dots, N\}$, with some $N \in \mathbb{N}$. Owing to this exhaustion property, each interior point $\bar{x}$ of M with $\varphi(\bar{x}) < 0$ is feasible for $\mathrm{SIP}_{\alpha BB}(E, \alpha)$ for sufficiently large N (see also [5]). Moreover, boundary points of M are "approximated at a quadratic rate."

PROPOSITION 4.1. *Let $\eta^k = k/N$, and choose $\alpha_k \le \bar{\alpha}$ according to* (3.4)*, $k \in K$.*

(i) *For $\bar{x} \in M$, with $\varphi(\bar{x}) < 0$, let*

$$N \ge \frac{1}{2}\sqrt{\frac{\max_{k \in K} \alpha_k}{|\varphi(\bar{x})|}}. \tag{4.1}$$

Then $\bar{x}$ is feasible for $\mathrm{SIP}_{\alpha BB}(E, \alpha)$.

(ii) *For $\bar{x} \in M$, with $\varphi(\bar{x}) = 0$, the infeasibility measure*

$$\max(0, \max_{k \in K} \max_{y \in Y^k} g^k(\bar{x}, y))$$

of $\bar{x}$ with respect to $M_{\alpha BB}(E, \alpha)$ is of order $O(1/N^2)$.

Proof. For all $k \in K$ and all $y \in Y^k = [k-1, k]/N$, Lemma 3.2(iii) yields

$$\begin{aligned} g^k(\bar{x}, y) &= g(\bar{x}, y) + \frac{\alpha_k}{2}\left(y - \frac{k-1}{N}\right)\left(\frac{k}{N} - y\right) \\ &\le \varphi(\bar{x}) + \frac{\alpha_k}{8N^2} \le \varphi(\bar{x}) + \frac{\max_{k \in K} \alpha_k}{8N^2}. \end{aligned} \tag{4.2}$$

In the case $\varphi(\bar{x}) < 0$ the last term is nonpositive for N with (4.1), which shows the assertion of part (i).

To see part (ii) note that, for $\varphi(\bar{x}) = 0$, (4.2) implies

$$\max_{k \in K} \max_{y \in Y^k} g^k(\bar{x}, y) \le \frac{\bar{\alpha}}{8N^2}$$

and that of course we also have $0 \le \bar{\alpha}/(8N^2)$. ∎

However, in Algorithm 3.4 the subdivision of Y is *not* exhaustive, and we cannot expect the method to approximate the whole interior of M. In particular, the method might not find a global minimizer of SIP contained in a region of M which is not approximated by the method. Recall, on the other hand, that our algorithm is not designed to find global minimizers. Instead of exponential growth of the number of

subdivision points in the exhaustive case, in view of Carathéodory's theorem each of our refinement steps adds at most $n+1$ new points to the subdivision. That is, the growth in the number of new constraints and, thus, in the number of auxiliary variables and auxiliary constraints (cf. section 3.2) is *linear* in n.

Note that Proposition 4.1 will not be used in what follows, where we will focus on adaptive instead of exhaustive subdivisions for the index set. The next results show that even adaptive subdivisions entail at least certain monotonicity properties for the feasible sets and optimal values of the approximating problems.

LEMMA 4.2. *With given E and α, let $\bar{x} \in M_{\alpha BB}(E, \alpha)$. For any additional subdivision point $\tilde{\eta} \notin E$, let $M_{\alpha BB}(E \cup \{\tilde{\eta}\}, \tilde{\alpha})$ be constructed by the refinement step from section* 3.3. *Then we also have $\bar{x} \in M_{\alpha BB}(E \cup \{\tilde{\eta}\}, \tilde{\alpha})$.*

Proof. Let $\tilde{\eta} \in [\eta^{k-1}, \eta^k]$ for some $k \in K$. For $i \in \{1, 2\}$ simple monotonicity arguments show that all $y \in Y^{k,i}$ satisfy $g^{k,i}(\bar{x}, y) \leq g^k(\bar{x}, y) \leq 0$, where the second inequality is due to $Y^{k,i} \subset Y^k$. ∎

PROPOSITION 4.3. *Let $(E^\nu)_\nu$ be a sequence of subdivisions of $Y = [0, 1]$ such that for all $\nu \in \mathbb{N}$ we have $E^\nu \subset E^{\nu+1}$, let the sets $M^\nu := M_{\alpha BB}(E^\nu, \alpha^\nu)$ be constructed by the refinement steps from section* 3.3, *and let v^ν denote the optimal values of $\mathrm{SIP}_{\alpha BB}(E^\nu, \alpha^\nu)$, $\nu \in \mathbb{N}$ (with $v^\nu := +\infty$ for $X \cap M^\nu = \emptyset$). Then the following holds:*

(i) *The feasible sets M^ν satisfy*

$$M^1 \subset M^2 \subset \cdots \subset M^\nu \subset M^{\nu+1} \subset \cdots \subset M.$$

(ii) *If* SIP *is solvable, then the optimal values v^ν converge to an upper bound for the optimal value of* SIP.

(iii) *Each sequence $(x^\nu)_\nu$, with $x^\nu \in X \cap M^\nu$, $\nu \in \mathbb{N}$, has an accumulation point $x^\star$, and all such accumulation points are elements of $X \cap M$.*

Proof. Assertion (i) follows immediately from Lemmas 3.1 and 4.2.

Assertion (ii) is trivial if all sets $X \cap M^\nu$, $\nu \in \mathbb{N}$, are empty. Otherwise, for $X \cap M^{\nu_0} \neq \emptyset$ the sequence $(v^\nu)_{\nu \geq \nu_0}$ is real-valued, monotonically decreasing by part (i), and bounded below by the optimal value of SIP. This shows part (ii).

To see assertion (iii) recall that $X \cap M$ is compact. This implies the existence of an accumulation point $x^\star$. By part (i) we have $x^\nu \in X \cap M$ for all $\nu \in \mathbb{N}$, so that the closedness of $X \cap M$ yields the assertion. ∎

The following corollary is immediate.

COROLLARY 4.4. *Let $(x^\nu)_\nu$ be a sequence of points generated by Algorithm* 3.4. *Then all x^ν, $\nu \in \mathbb{N}$, are feasible for* SIP, *the sequence $(x^\nu)_\nu$ has an accumulation point, each such accumulation point $x^\star$ is feasible for* SIP, *and $f(x^\star)$ provides an upper bound for the optimal value of* SIP.

Next we make sure that Algorithm 3.4 is well defined. The following lemma shows that in Step 3 at least one subdivision point is added to E if the termination criterion is violated.

LEMMA 4.5. *Let Algorithm* 3.4 *be initialized by Step* 1, *and for given E and α in Step* 2 *let x be a stationary point of $\mathrm{SIP}_{\alpha BB}(E, \alpha)$ with ε_{act}-active indices y^k, $1 \leq k \leq n+1$, and multipliers (κ, λ). Then, if the termination criterion in Step* 3 *is violated, the set of new subdivision points $\tilde{E}$ in Step* 3 *is strictly larger than E.*

Proof. Assume $\tilde{E} = E$. By Proposition 4.3(i), x is feasible for SIP, and the stationarity condition (3.5) with certain multipliers implies (3.7) with the same multipliers for arbitrary $\varepsilon_{stat} > 0$.

Since the $y^k \in Y$ are ε_{act}-active, we have

$$g^k(x, y^k) = g(x, y^k) + \frac{\alpha_k}{2}(y^k - \eta^{k-1})(\eta^k - y^k) \in [-\varepsilon_{act}, 0]$$

and thus

$$0 \geq -\frac{\alpha_k}{2}(y^k - \eta^{k-1})(\eta^k - y^k) \geq g(x, y^k) \geq -\varepsilon_{act} - \frac{\alpha_k}{2}(y^k - \eta^{k-1})(\eta^k - y^k).$$

Because of $\tilde{E} = E$, for each k at least one of the terms $y^k - \eta^{k-1}$, $\eta^k - y^k$ is bounded above by $\varepsilon_\cup$, and the other one trivially by 1 (the length of Y). According to Step 1 of the algorithm we also have $\alpha_k \leq \bar{\alpha}$ and $\varepsilon_\cup \leq 2\varepsilon_{act}/\bar{\alpha}$. Combining these estimates yields $g(x, y^k) \in [-2\varepsilon_{act}, 0]$; that is, each y^k, $1 \leq k \leq n+1$, is a $(2\varepsilon_{act})$-active index for x in the original problem SIP.

We have thus shown that x is ε_{stat}-stationary for SIP with $(2\varepsilon_{act})$-active indices y^k, $1 \leq k \leq n+1$, from Step 2 and multipliers (κ, λ) from Step 2. This contradicts the assumption that the termination criterion in Step 3 is violated. ∎

THEOREM 4.6. *Algorithm* 3.4 *terminates after finitely many iterations.*

Proof. Assume that the algorithm does not terminate. Then there exist sequences $(E^\nu)_\nu$, $(\alpha^\nu)_\nu$, $(x^\nu)_\nu$, $(y^{k,\nu})_\nu$, $1 \leq k \leq n+1$, and $(\kappa^\nu, \lambda^\nu)_\nu$ such that for each $\nu \in \mathbb{N}$ the point x^ν is stationary for $\mathrm{SIP}_{\alpha BB}(E^\nu, \alpha^\nu)$ with ε_{act}-active indices $y^{k,\nu}$, $1 \leq k \leq n+1$, and multipliers $(\kappa^\nu, \lambda^\nu)$, but the termination criterion is not satisfied for any $\nu \in \mathbb{N}$.

As the sequence $(x^\nu, y^{1,\nu}, \ldots, y^{n+1,\nu}, \kappa^\nu, \lambda^\nu)_\nu$ is contained in the compact set $X \times Y^{n+1} \times S^{n+1}$, it possesses an accumulation point $(x^\star, y^{1,\star}, \ldots, y^{n+1,\star}, \kappa^\star, \lambda^\star)$ in the same set. By continuity (3.5) yields

$$\kappa^\star \nabla f(x^\star) + \sum_{k=1}^{n+1} \lambda_k^\star \nabla_x g(x^\star, y^{k,\star}) = 0,$$

so that for some $\nu_0 \in \mathbb{N}$ and infinitely many $\nu \geq \nu_0$ we have

$$\left|\left| \kappa^\nu \nabla f(x^\nu) + \sum_{k=1}^{n+1} \lambda_k^\nu \nabla_x g(x^\nu, y^{k,\nu}) \right|\right| < \varepsilon_{stat}.$$

In view of Proposition 4.3 each such point x^ν lies in M, and by the construction in Step 2 we have $g^k(x^\nu, y^{k,\nu}) \in [-\varepsilon_{act}, 0]$, which implies

$$\lambda_k^\nu \cdot g^k(x^\nu, y^{k,\nu}) \in [-\lambda_k^\nu \cdot \varepsilon_{act}, 0], 1 \leq k \leq n+1. \tag{4.3}$$

It remains to be shown that for some $\nu \in \mathbb{N}$ we can replace (4.3) by

$$\lambda_k^\nu \cdot g(x^\nu, y^{k,\nu}) \in [-2\lambda_k^\nu \cdot \varepsilon_{act}, 0], 1 \leq k \leq n+1. \tag{4.4}$$

Then x^ν is ε_{stat}-stationary for SIP with $(2\varepsilon_{act})$-active indices $y^{k,\nu}$ and multipliers $(\kappa^\nu, \lambda^\nu)$, in contradiction to the assumption that the termination criterion is not satisfied for any $\nu \in \mathbb{N}$.

By the definition and by the overestimation property of g^k, (4.3) implies (4.4) if for all $k \in \{1, \ldots, n+1\}$ we can show

$$\lim_{\nu \to \infty} \frac{\alpha_k^\nu}{2}(y^{k,\nu} - \eta^{k-1,\nu})(\eta^{k,\nu} - y^{k,\nu}) = 0. \tag{4.5}$$

Because of

$$0 \leq \frac{\alpha_k^\nu}{2}(y^{k,\nu} - \eta^{k-1,\nu})(\eta^{k,\nu} - y^{k,\nu}) \leq \frac{\bar{\alpha}}{8}(\eta^{k,\nu} - \eta^{k-1,\nu})^2$$

(compare (2.6)) it is sufficient to show that the lengths $(\eta^{k,\nu} - \eta^{k-1,\nu})$ of $Y^{k,\nu}$ tend to zero for each $k \in \{1, \dots, n+1\}$.

In fact, Lemma 4.5 guarantees that in each iteration of Algorithm 3.4 at least one of the existing subdivision nodes $Y^{\nu,k}$ is divided into two subintervals with lengths bounded above by $(1 - \varepsilon_\cup)(\eta^{k,\nu} - \eta^{k-1,\nu})$. So for each $p \in \mathbb{N}$ at least one node with length bounded by $(1 - \varepsilon_\cup)^p$ is generated. Moreover, no subdivision node can be visited twice by the algorithm, so that for each $k \in \{1, \dots, n+1\}$ all $Y^{\nu,k}$, $\nu \in \mathbb{N}$, are pairwise different. As for each $p \in \mathbb{N}$ only finitely many nodes of length greater than $(1 - \varepsilon_\cup)^p$ exist, the lengths of $Y^{\nu,k}$, $\nu \in \mathbb{N}$, must tend to zero. ∎

5. Numerical examples. For the numerical illustrations in this section we implemented Algorithm 3.4 in *Matlab* 6.5 and used the routine *fmincon* from its *Optimization Toolbox* 2.2 with default tolerances as the black box NLP solver in Step 2 of the algorithm. In particular, the tolerance for constraint violations was 10^{-6}. All examples were run on a 1.2 GHz Pentium III processor.

For the examples in this article the convexification parameters can be determined analytically. We emphasize that, for more general examples which go beyond the scope of this article, we obtained good results using the *Matlab* toolbox *Intlab* 5.3 [41].

5.1. Chebyshev approximation. As a first test example we consider Chebyshev approximation of the function $\sin(\pi y)$ by a quadratic function on the interval $Y = [0, 1]$; that is, we wish to solve

$$\text{CA}: \qquad \min_{x \in \mathbb{R}^3} \| \sin(\pi y) - (x_3 y^2 + x_2 y + x_1) \|_{\infty,[0,1]},$$

with

$$\| \sin(\pi y) - (x_3 y^2 + x_2 y + x_1) \|_{\infty,[0,1]} = \max_{y \in [0,1]} | \sin(\pi y) - (x_3 y^2 + x_2 y + x_1) |.$$

For a survey on semi-infinite treatment of Chebyshev approximation problems see [23]. The epigraph reformulation of CA yields the equivalent problem

$$\min_{x \in \mathbb{R}^4} x_4 \quad \text{subject to} \quad \max_{y \in [0,1]} | \sin(\pi y) - (x_3 y^2 + x_2 y + x_1) | \le x_4$$

and thus the semi-infinite problem

$$\text{SIP}_{CA}: \qquad \min_{x \in \mathbb{R}^4} x_4 \quad \text{subject to} \quad \pm \left(\sin(\pi y) - x_3 y^2 - x_2 y - x_1 \right) \le x_4 \quad \text{for all } y \in [0, 1].$$

We search for a solution in the box $X = [x^\ell, x^u]$, with $x^\ell = (-1, 3, -5, -1)^\top$ and $x^u = (1, 5, -3, 3)^\top$.

Convexification parameters for the two semi-infinite constraints are readily available. In fact, for

$$g_\pm(x, y) = \pm \left(\sin(\pi y) - x_3 y^2 - x_2 y - x_1 \right) - x_4$$

we obtain $\nabla_y^2 g_\pm(x, y) = \mp \left(\pi^2 \sin(\pi y) + 2x_3 \right)$, so that an upper bound on $X \times Y$ is $\alpha_+ = 10$ for $\nabla_y^2 g_+$ and $\alpha_- = \pi^2 - 6$ for $\nabla_y^2 g_-$. Moreover, upper bounds on subdomains $[\eta^\ell, \eta^u] \subset [0, 1]$ are given by

$$\alpha_+(\eta^\ell, \eta^u) = \max \left(0, -\pi^2 \min(\sin(\pi \eta^\ell), \sin(\pi \eta^u)) + 10 \right), \tag{5.1}$$

$$\alpha_-(\eta^\ell, \eta^u) = \max \left(0, \pi^2 \theta(\eta^\ell, \eta^u) - 6 \right), \tag{5.2}$$

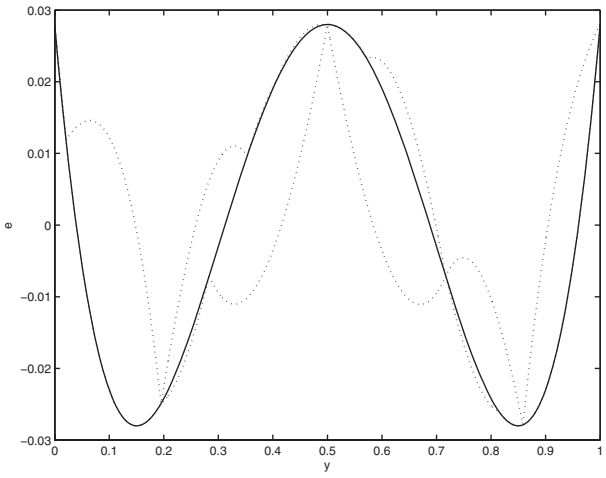

FIG. 1. *The optimal error function for SIP$_{CA}$ with convex relaxations.*

with

$$\theta(\eta^\ell, \eta^u) = \begin{cases} \sin(\pi\eta^u), & \eta^u \le 0.5, \\ 1, & \eta^\ell < 0.5 < \eta^u, \\ \sin(\pi\eta^\ell), & 0.5 \le \eta^\ell. \end{cases}$$

We initialize phase I with the (even infeasible) point $x^0 = (1, 1, 1, 1)^\top$ and use the tolerances $\varepsilon_{stat} = \varepsilon_{act} = 10^{-3}$ as well as $\varepsilon_\cup = 2\varepsilon_{act} \cdot \min(1, 1/\alpha_+, 1/\alpha_-)$.

In the following we compare the performance of Algorithm 3.4 for the two cases that either the uniform bounds $\alpha_\pm$ are used on all computed subdomains of Y or that $\alpha_\pm$ is adaptively improved on the subdomains according to (5.1), (5.2).

Case 1 (uniform convexification parameters). After one iteration (0.371 CPU seconds), phase I finds a feasible starting point $\bar{x}$ for SIP$_{CA}$ with the objective value $\bar{x}_4 = 1.54$. Note that, due to the *feasibility* of $\bar{x}$, this value is already a *valid upper bound* for the maximal error.

After nine more iterations (46.285 CPU seconds) the algorithm terminates with the point $x^\star = (-0.028, 4, -4, 0.028)^\top$ and objective value $x_4^\star = 0.028364$. The norm of the stationarity condition at $x^\star$ is less than 10^{-14}, and the solution of the problem P_{outer} with the obtained subdivision points E as discretization points yields the optimal value 0.028003. Since P_{outer} is a linear problem, this value is actually the *global* optimal value of P_{outer} and yields a valid *lower* bound for the optimal value of SIP$_{CA}$. As $x_4^\star = 0.028364$ is a valid *upper* bound for the latter optimal value, we have a certificate that we determined the globally optimal value of SIP$_{CA}$ within a tolerance of 10^{-3}.

Case 2 (adaptive convexification parameters). The performance of phase I is identical to Case 1, and after six more iterations (6.26 CPU seconds) the algorithm terminates with $x^\star = (-0.028, 4, -4, 0.028)^\top$ and objective value $x_4^\star = 0.028011$. Figure 1 illustrates the error function $e(x^\star, y) = \sin(\pi y) - (x_3^\star y^2 + x_2^\star y + x_1^\star)$ in the solution point, together with the convex relaxations upon termination. Note that the approximations of $e(x^\star, y)$ are depicted for both semi-infinite constraints, where in the figure one approximation appears as piecewise concave and the other as piecewise convex.

The norm of the stationarity condition at $x^\star$ is less than 10^{-9}, and the solution of the problem P_{outer} yields the optimal value 0.028004. We thus obtain a certificate that we determined the global optimal value of SIP_{CA} within a tolerance of 10^{-5}.

Comparison of the two cases shows that the use of adaptive convexification parameters can speed up the algorithm significantly, here almost by the factor 10 in CPU time. We emphasize, however, that in this example the formula for adaptive convexification parameters is explicitly available and easy to evaluate, whereas in other applications the additional computations by, for instance, interval methods can lead to a significant increase of CPU time.

5.2. Design centering. A design-centering problem considers a container set $C \subset \mathbb{R}^m$ and a parameterized body $B(x) \subset \mathbb{R}^m$, with parameter vector $x \in \mathbb{R}^n$. The task is to inscribe $B(x)$ into C such that some functional f (e.g., the volume of $B(x)$) is maximized:

$$\text{DC}: \quad \max_{x\in\mathbb{R}^n} f(x) \quad \text{subject to} \quad B(x) \subset C.$$

Design-centering problems with special sets $B(x)$ and C have been studied extensively; see, for instance, [18] for the complexity of inscribing a convex body into a convex container, [24] for maximization of a production yield under uncertain quality parameters, and [34, 50] for the problem of cutting a diamond with prescribed shape features and maximal volume from a raw diamond. Also cutting stock problems [8] and set containment problems [31] are examples of design centering. An implementable solution method is given in [35], and the so-called maneuverability problem of a robot from [17] is the first design-centering problem that was analyzed in its reformulation as a semi-infinite problem [22]. A structural analysis of the special semi-infinite problems arising as reformulated design-centering problems is given in [46].

Here we consider DC with a simply connected container set $C \subset \mathbb{R}^2$ and the parameterized body $B(x) = \{z \in \mathbb{R}^2 | \|z-(x_1, x_2)\|_2 \le x_3\}$, that is, a disk with variable midpoint (x_1, x_2) and radius x_3. We put $f(x) = x_3$, corresponding to maximization of the area of $B(x)$. Since C is simply connected, the constraint $B(x) \subset C$ is equivalent to $\partial B(x) \subset C$, where $\partial B(x) = \{z \in \mathbb{R}^2 | \|z - (x_1, x_2)\|_2 = x_3\}$ denotes the boundary of the disk. We can parameterize this set by $\partial B(x) = \{z(x, y) | y \in [0, 2\pi]\}$, with

$$z(x, y) = \left(\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + x_3 \begin{pmatrix} \cos(y) \\ \sin(y) \end{pmatrix} \right).$$

For the semi-infinite reformulation of DC we assume that the container set is described by finitely many smooth inequality constraints:

$$C = \{z \in \mathbb{R}^2 | c_i(z) \le 0, i \in I\}.$$

The constraint $B(x) \subset C$ is then equivalent to

$$c_i(z) \le 0 \quad \text{for all } z \in \partial B(x), i \in I,$$

and also to

$$g_i(x, y) := c_i(z(x, y)) \le 0 \quad \text{for all } y \in Y := [0, 2\pi], i \in I,$$

so that we arrive at the semi-infinite problem

$$\text{SIP}_{DC}: \qquad \max_{x\in\mathbb{R}^3} x_3 \quad \text{subject to} \quad g_i(x, y) \le 0 \quad \text{for all } y \in Y, i \in I.$$

If C is contained in the box X_C with side lengths ℓ_1, ℓ_2, then each feasible point x is necessarily contained in $X = X_C \times [0, \min(\ell_1, \ell_2)/2]$. For the computation of convexification parameters we calculate

$$\nabla_y^2 g_i(x,y) = x_3^2 \begin{pmatrix} -\sin(y) \\ \cos(y) \end{pmatrix}^\top \nabla^2 c_i(z(x,y)) \begin{pmatrix} -\sin(y) \\ \cos(y) \end{pmatrix} - x_3 \nabla^\top c_i(z(x,y)) \begin{pmatrix} \cos(y) \\ \sin(y) \end{pmatrix}$$

for each $i \in I$. The vectors with trigonometric entries have length one, so that we obtain coarse upper bounds for $\nabla_y^2 g_i$ as follows:

$$\begin{pmatrix} -\sin(y) \\ \cos(y) \end{pmatrix}^\top \nabla^2 c_i(z(x,y)) \begin{pmatrix} -\sin(y) \\ \cos(y) \end{pmatrix} \le \lambda_{max}\left(\nabla^2 c_i(z(x,y))\right),$$

with λ_{max} denoting the maximal eigenvalue of a symmetric matrix, and due to $x_3 \ge 0$

$$-x_3 \nabla^\top c_i(z(x,y)) \begin{pmatrix} \cos(y) \\ \sin(y) \end{pmatrix} \le x_3 \|\nabla c_i(z(x,y))\|_2.$$

A combination of these estimates yields for each $i \in I$

$$\begin{aligned} &\max_{(x,y)\in X\times Y} \nabla^2 g_i(x,y) \\ &\le \max_{(x,y)\in X\times Y} \left(x_3^2 \lambda_{max}\left(\nabla^2 c_i(z(x,y))\right) + x_3 \|\nabla c_i(z(x,y))\|_2\right). \end{aligned} \tag{5.3}$$

For our computational experiment we consider the functions

$$\begin{aligned} c_1(z) &= 0.3\sin(\pi z_1) - z_2, \\ c_2(z) &= z_1^2 + 0.3 z_2^2 - 1. \end{aligned}$$

The set C is then contained in $X_C = [-1.5, 1.5] \times [-1, 2]$, so that we can put $X = X_C \times [0, 1.5]$. With the aid of (5.3) we obtain uniform convexification parameters $\alpha_1 = 8.723$ and $\alpha_2 = 17.485$ for the constraints g_1 and g_2 , respectively. As the initial point x^0 we choose the midpoint of X, and we use the tolerances $\varepsilon_{stat} = \varepsilon_{act} = 10^{-3}$ as well as $\varepsilon_\cup = 2\varepsilon_{act} \cdot \min(1, 1/\alpha_1, 1/\alpha_2)$.

After 15 iterations (22.793 CPU seconds) phase I finds a feasible starting point for SIP_{DC}, and the corresponding approximating problem has the solution $\bar{x} = (-0.116, 1.026, 0.397)^\top$ with the objective value $\bar{x}_3 = 0.397$. Due to the *feasibility* of $\bar{x}$, the corresponding disk $B(\bar{x})$ is guaranteed to be contained in C. Figure 2 illustrates this fact.

After 57 more iterations (181.566 CPU seconds) the algorithm terminates with the point $x^\star = (0, 0.962, 0.776)^\top$ with objective value $x_3^\star = 0.77612$, illustrated in Figure 3.

The norm of the stationarity condition at $x^\star$ is less than 10^{-8}, and the solution of the problem P_{outer} yields the optimal value 0.77697. However, since P_{outer} is a nonconvex problem, this value is *not* necessarily an upper bound for the optimal value of SIP_{DC}. Thus, we do not obtain a certificate for global optimality in this example.

While Algorithm 3.4 can certainly be accelerated by exploiting special features of SIP_{DC} (see also section 6), for certain applications a user might have to terminate it prematurely due to time restrictions. It is worth pointing out that even then the last iterate is feasible; that is, at least *some* disk $B(\bar{x}) \subset C$ is generated.

6. Future challenges.

6.1. Improvements. In this article we presented the adaptive convexification algorithm in its simplest form. Although it can be improved in a number of ways, our aim was to explain its basic ideas and to show that these already result in a well-defined, convergent, and implementable method. Convergence proofs for the following possible improvements are subject of future research.

A major potential for acceleration of the algorithm certainly lies in the magnitude of the convexification parameters and in their adaptive refinement. Lemma 3.2(iii) and Proposition 4.1 quantify the obvious fact that tighter convex relaxations, that is, better bounds in (3.3), (3.4), can speed up the algorithm. Moreover, tighter relaxations also lead to a less restrictive bound on the tolerance $\varepsilon_\cup$ in Step 1 of Algorithm 3.4.

As mentioned in section 2.3, tighter relaxations are already available for a large number of specially structured functions [12]. Improvements of the αBB method itself like the generalized αBB method [3] also lead to significantly tighter convex relaxations, however, at higher computational cost. In special examples also modeling of the problem can influence the size of convexification parameters. In design centering they depend, for instance, on the scaling of the functions c_i, $i \in I$.

We emphasize that in (3.3) we only consider adaptation of the convexification parameters with respect to the index variable y while they are uniform in the decision variable $x \in X$. Additional adaptation with respect to x is possible by restricting the distance of a new iterate $x^{\nu+1}$ generated by Step 2 of Algorithm 3.4 to a ball $B^\nu \subset X$ around the current iterate x^ν. Tighter relaxations can then be computed using (3.3) with X replaced by B^ν. A main problem with this approach is that convexification parameters of previous steps may become invalid during the iteration, even if they correspond to inactive constraints. Hence, the relaxations on all subdomains have to be recomputed in each step, giving rise to a possibly high computational effort. To alleviate this difficulty, ideas from trust region methods might help.

As we pointed out, the number of new constraints in each step of Algorithm 3.4 is linear in n, as opposed to exponential growth for the exhaustive subdivision from Proposition 4.1. A possibility to further diminish the number of added constraints in each step, in the spirit of exchange methods, is to add only those active approximating constraints with the largest benefit for the activity of the original constraint; that is, $y \in Y_0^{\alpha BB}(\bar{x})$ only enters the $\varepsilon_\cup$-union with E if y minimizes $g(\bar{x}, y)$ over $Y_0^{\alpha BB}(\bar{x})$.

6.2. Generalizations. Algorithm 3.4 can be generalized straightforwardly to SIP with finitely many semi-infinite constraints (i.e., $p \geq 1$) and finitely many additional smooth equality and inequality constraints. Our implementation for the solution of the problems in section 5 actually handles this situation.

The generalization to higher dimensional box index sets Y (i.e., $m \geq 1$) is merely of technical nature. The two main new tasks are to manage the bookkeeping for the adaptive subdivisions of Y and to compute convexification parameters in higher dimensions. The latter problem can be solved with the techniques of αBB in higher dimensions [1, 2, 12]. There the main idea is to add a separable quadratic relaxation function to g in (3.2), with one parameter for each component of the vector y. Sufficiently large parameters then again lead to concavity, where, for instance, a Gerschgorin approach can guarantee the negative semi-definiteness of the interval Hessian matrix on a subdomain [1, 2, 12].

If the index set Y is not given in box form and cannot be simply transformed into a box, a possible approach is to approximate Y appropriately by boxes. Here again the trivial observation comes into play that a semi-infinite constraint can be equivalently replaced by finitely many semi-infinite constraints corresponding to a subdivision of the index set. A more efficient possibility might be to construct triangulations of Y, but then the αBB ideas also have to be transferred to triangular domains.

6.3. Open questions. In addition to outstanding convergence proofs for the above improvements and the implementation issues for higher dimensional index sets, our approach leads to a number of further open questions.

Regarding the stationarity concept, if the natural assumption EMFCQ [26] is satisfied everywhere in M, Algorithm 3.4 with the theoretical tolerances $\varepsilon_{stat} = \varepsilon_{act} = 0$ would of course generate a Karush–Kuhn–Tucker point of SIP. We conjecture that under EMFCQ this is also the case for sufficiently small tolerances $\varepsilon_{stat}, \varepsilon_{act} > 0$.

We focused our attention on the convergence of stationary points of approximating problems $\mathrm{SIP}_{\alpha BB}(E, \alpha)$ to a stationary point of SIP. Since we can actually expect the black box NLP solver to find local minimizers of $\mathrm{SIP}_{\alpha BB}(E, \alpha)$, one can try to prove convergence of such points to a local minimizer of SIP. At least in our numerical experiments we observed this convergence throughout.

The main purpose of Algorithm 3.4 is the generation of feasible iterates for SIP. Under weak assumptions these iterates should actually be *interior points* of the original feasible set M. We observed this in the numerical experiments, too.

Although our numerical results seem very promising, further work is needed on error estimates on the numerical solution of the auxiliary problem $P(E, \alpha)$. In fact, feasibility of the iterates may be jeopardized if feasibility and local optimality for $P(E, \alpha)$ are guaranteed only up to some tolerances. Handling this issue is beyond the scope of the present article, which is meant to give the basic ideas of adaptive convexification.

Regarding the performance of the algorithm, in sections 5.1 and 6.1 we have seen that adaptation of the convexification parameters as well as more sophisticated techniques for their computation can result in a significant acceleration of computing time. There is, however, an obvious tradeoff with the additional computational effort of these modifications. General statements about this tradeoff would be helpful for applications.

Acknowledgments. We thank the anonymous referees for their precise and substantial remarks which led to a significantly improved version of this article. The second author thanks the Department of Chemical Engineering at Princeton University for their hospitality during his visit, whereupon this work originated.

ON THE CONVERGENCE OF AUGMENTED LAGRANGIAN METHODS FOR CONSTRAINED GLOBAL OPTIMIZATION*

H. Z. LUO†, X. L. SUN‡, AND D. LI§

Abstract. In this paper, we present new convergence properties of the primal-dual method based on four types of augmented Lagrangian functions in the context of constrained *global* optimization. Convergence to a global optimal solution is first established for a basic primal-dual scheme under standard conditions. We then prove this convergence property for a modified augmented Lagrangian method using a safeguarding strategy without appealing to the boundedness assumption of the multiplier sequence. We further show that, under the same weaker conditions, the convergence to a global optimal solution can still be achieved by either modifying the multiplier updating rule or normalizing the multipliers in augmented Lagrangian methods.

Key words. nonconvex optimization, constrained global optimization, augmented Lagrangian functions, modified augmented Lagrangian methods, convergence to global solution

1. Introduction.

We consider in this paper the following inequality-constrained nonlinear optimization problem:

$$\begin{aligned}(P)\quad &\min\ f(x)\\ &\text{subject to (s.t.)}\ \ g_i(x)\le 0,\ i=1,\dots,m,\\ &\qquad x\in X,\end{aligned}$$

where f and all g_i, $i = 1, \ldots, m$, are continuously differentiable functions and X is a nonempty closed set in $\mathbb{R}^n$. Note that f and g_i, $i = 1, \ldots, m$, are not necessarily convex functions.

Lagrangian dual methods have been serving as a fundamental solution methodology in convex programming. It is well known, however, that classical Lagrangian dual methods may fail to identify the optimal solution of the nonconvex problem (P) due to the existence of a duality gap. Augmented Lagrangians have been proposed as a remedy to alleviate this situation. The first augmented Lagrangian method was independently proposed by Hestenes [13] and Powell [39] for equality-constrained problems by introducing a quadratic penalty term in the Lagrangian function. This method was extended by Rockafellar [40], [41] to deal with inequality constraints. Rockafellar's augmented Lagrangian function for (P) is continuously differentiable with respect to x but not twice differentiable even when f and all g_i are twice differentiable functions, thus preventing the use of Newton-type methods from solving the corresponding unconstrained Lagrangian relaxation problems. Mangasarian's augmented Lagrangian

[28], the exponential-type penalty function [6], [20], and the modified barrier function [35] are three important classes of twice differentiable augmented Lagrangian functions. Various augmented Lagrangians or nonlinear Lagrangians have also been proposed, and their duality and exact penalization properties have been studied (see, e.g., [16], [23], [24], [31], [32], [33], [44], [45], [52]).

Local convergence properties of augmented Lagrangian methods for nonconvex optimization have been studied by many researchers. Mangasarian [28] analyzed the local convergence of a class of augmented Lagrangians that include Rockafellar's augmented Lagrangian as a special case. Nguyen and Strodiot [30] proved the local convergence of the modified exponential Lagrangian method. The local convergence of the modified barrier Lagrangian method and log-sigmoid multiplier method for nonconvex problems was analyzed in [35] and [36], respectively. Contesse-Becker [**?**] proved the local convergence of Rockafellar's augmented Lagrangian method without the strict complementarity condition. Huang and Yang [17] showed that the first-order and second-order necessary optimality conditions of Rockafellar's augmented Lagrangian problems converge to those of the original problem. Polak and Tits [34], Hager [12], Bartholomew-Biggs [3], and Yamashita [53] investigated the global convergence of Rockafellar's augmented Lagrangian methods for nonconvex inequality-constrained problems. The convexification effect of adopting pth-power Lagrangian functions has been revealed for augmented Lagrangian functions in [25] and for the perturbation function in [23], [24]. The existence of a global saddle point of certain augmented or nonlinear Lagrangian functions has been investigated in [26], [27], [47].

Global convergence of the augmented Lagrangian method for nonconvex equality-constrained problems was analyzed in [6], [39]. An indispensable assumption in most existing global convergence analyses for augmented Lagrangian methods is that the multiplier sequence generated in the algorithms is bounded. This restrictive assumption confines applications of augmented Lagrangian methods in many situations. Conn et al. [8], Conn, Gould, and Toint [9], and Lewis and Torczon [22] presented modified augmented Lagrangian methods for nonconvex optimization with equality constraints and proved global convergence results without appealing to this assumption. Andreani et al. [1], [2] and Birgin, Castillo, and Martínez [7] investigated the augmented Lagrangian methods using safeguarding strategies for nonconvex constrained problems. Global convergence was established in [1], [2], [7] without requiring the boundedness condition of the multiplier sequence. Global convergence of augmented Lagrangian methods for convex programming has also been studied in [4], [6], [19], [21], [40], [42], [50]. To our knowledge, the convergence of augmented Lagrangian methods to a global solution of a constrained nonconvex global optimization problem has been investigated only in [41] for Rockafellar's augmented Lagrangian method and in [6] for the multiplier method of Hestenes and Powell for equality-constrained problems.

Constrained global optimization has been one of the challenging subjects in nonlinear optimization. On one hand, implementable methods for constrained global optimization have been developed only for some special problems such as concave minimization (see [5], [43]) and monotone optimization (see [48], [51]). On the other hand, various deterministic and stochastic methods have been proposed for unconstrained global optimization (see, e.g., [14], [15]). It is therefore desirable to reduce a constrained global optimization problem into a sequence of unconstrained global optimization problems so that the methods developed for unconstrained global optimization can be used. This solution scheme was adopted in constructing auxiliary functions for constrained global optimization (see [46], [49]).

The focus of this paper is on the convergence properties of augmented Lagrangian methods in the context of constrained global optimization. We will study four classes of prominent augmented Lagrangians in the literature: (i) Kort and Bertsekas's augmented Lagrangian, (ii) Mangasarian's augmented Lagrangian, (iii) the exponential-type augmented Lagrangian, and (iv) the modified barrier function. As we will see later in the paper, these four classes of augmented Lagrangians include many existing important augmented Lagrangian functions as their special cases. We first show that, under standard conditions, the basic primal-dual method employing these four classes of augmented Lagrangian functions converges to a global solution of (P) if the unconstrained relaxation problems is solved globally. Three modified augmented Lagrangian methods are then proposed that adopt a safeguarding strategy, modify multiplier updating criteria, and normalize the multiplier, respectively. Convergence results are proved for these modified augmented Lagrangian methods without appealing to the boundedness of the multiplier sequence. The convergence results obtained in this paper provide theoretical foundations for applying augmented Lagrangian methods in constrained global optimization.

The paper is organized as follows. In section 2, we describe four classes of augmented Lagrangian functions. We present the convergence results for the basic primal-dual method in section 3. The modified primal-dual scheme with safeguarding is investigated in section 4. In section 5, we establish the convergence results for the modified primal-dual scheme with conditional multiplier updating. The normalized multiplier method is discussed in section 6. Finally, some concluding remarks are given in section 7.

2. Four classes of augmented Lagrangian functions. In this section, we describe four classes of augmented Lagrangian functions. The augmented Lagrangian methods studied in this paper are based on these four classes of functions.

The following general class of augmented Lagrangians for (P) was introduced by Kort and Bertsekas [6], [21]:

$$L_1(x,\lambda,p) = f(x) + \frac{1}{p}\sum_{i=1}^{m} W(pg_i(x),\lambda_i), \tag{2.1}$$

where $p > 0$, $x \in X$, $\lambda = (\lambda_1,\dots,\lambda_m)^T \geq 0$, and the function $W : \mathbb{R}^2 \to \mathbb{R}$ satisfies the following conditions:

(A1) W is continuously differentiable on $\mathbb{R}\times(0,\infty)$ and possesses, for all $s \in \mathbb{R}$, the right derivative

$$\lim_{t\to 0^+} \frac{W(s,t) - W(s,0)}{t};$$

(A2) $W(s,\cdot)$ is concave on $\mathbb{R}_+$ for each fixed $s \in \mathbb{R}$, where $\mathbb{R}_+ = [0,\infty)$;

(A3) for each fixed $t \in \mathbb{R}_+$, $W(\cdot,t)$ is convex on $\mathbb{R}$ and satisfies the following strict convexity condition: If $s_0 > 0$ or $W'_s(s_0,t) > 0$, then $W(s,t) - W(s_0,t) > (s-s_0)W'_s(s_0,t)$ for $s \neq s_0$, where $W'_s(s,t)$ denotes the partial derivative of $W(s,t)$ with respect to s;

(A4) $W(0,t) = 0$, $W'_s(0,t) = t$ for all $t \in \mathbb{R}_+$;

(A5) $\lim_{s\to-\infty} W'_s(s,t) = 0$ for all $t \in \mathbb{R}_+$;

(A6) $\inf_{s\in\mathbb{R}} W(s,t) > -\infty$ for all $t \in \mathbb{R}_+$;

(A7) $\lim_{s\to\infty} \frac{W(s,t)}{s} = \infty$ for all $t \in \mathbb{R}_+$.

By the convexity of $W(\cdot,t)$, condition (A7) is equivalent to $\lim_{s\to\infty} W'_s(s,t)=\infty$ for all $t\in\mathbb{R}_+$. It then follows from (A3) and (A5) that

$$W'_s(s,t)\geq 0 \quad \forall (s,t)\in\mathbb{R}\times\mathbb{R}_+. \tag{2.2}$$

Special cases of L_1 include the augmented function in [21], the modified Courant-type augmented Lagrangian function [6], [39], the penalized exponential-type augmented Lagrangian [6], and the augmented Lagrangian functions in [18], [29], [40], [41]. For example, the augmented function introduced in [6], [21] is a special case of $L_1(x,\lambda,p)$ with $W(s,t)$ defined as

$$W(s,t)=\begin{cases} ts+\phi(s) & \text{if } t+\phi'(s)\geq 0,\\ \min_{\tau\in\mathbb{R}}[t\tau+\phi(\tau)] & \text{otherwise,}\end{cases} \tag{2.3}$$

where $\phi:\ \mathbb{R}\to\mathbb{R}$ satisfies the following conditions:

(E1) $\phi(\cdot)$ is a strictly convex function and continuous differentiable on $\mathbb{R}$;

(E2) $\phi(0)=0$, $\phi'(0)=0$, $\lim_{s\to-\infty}\phi'(s)=-\infty$;

(E3) $\frac{\phi(s)}{|s|}\to\infty$, $(|s|\to\infty)$.

It can be verified that $W(s,t)$ defined in (2.3) satisfies (A1)–(A7) and that Rockafellar's augmented Lagrangian function is a special case of L_1 with $\phi(s)=(1/2)s^2$ in $W(s,t)$ defined in (2.3).

Mangasarian [28] proposed another general class of augmented Lagrangians for (P). Let

$$L_2(x,\lambda,p)=f(x)+\frac{1}{p}\sum_{i=1}^{m}\left[\theta(pg_i(x)+\lambda_i)_+-\theta(\lambda_i)\right],\quad x\in X,\ \lambda\in\mathbb{R}^m, \tag{2.4}$$

where $p>0$, $\theta(s)_+=\begin{cases}\theta(s), & s\geq 0\\ 0, & s<0\end{cases}$, and the function $\theta:\ \mathbb{R}\to\mathbb{R}$ satisfies the following conditions:

(B1) θ is continuously differentiable and strictly convex on $\mathbb{R}$;

(B2) $\theta(0)=0$, θ' maps $\mathbb{R}$ onto $\mathbb{R}$ and $\theta'(0)=0$;

(B3) $\frac{\theta(s)}{|s|}\to\infty$, $(|s|\to\infty)$.

Let $W(s,t)=\theta(s+t)_+-\theta(t)$. It can be verified that $W(s,t)$ satisfies conditions (A1)–(A7) except (A2) (see Remark 2.13 in [28]). Note that L_2 also includes Rockafellar's augmented Lagrangian as a special case by setting $\theta(s)=\frac{1}{2}s^2$ (see [40], [41]). We also see that if θ is twice differentiable and $\theta''(0)=0$, then $L_2(x,\lambda,p)$ is twice differentiable with respect to x when f and all g_i are twice differentiable. Examples of θ that satisfy conditions (B1)–(B3) and $\theta''(0)=0$ include $\theta(s)=\frac{1}{\rho}|s|^\rho$, where $\rho>2$, $\theta(s)=\frac{1}{2}(e^s+e^{-s})-\frac{1}{2}s^2-1$, and $\theta(s)=\frac{1}{2}\left[(e^s+e^{-s})/2-1\right]^2$.

It is easy to see that conditions (B1)–(B2) imply that θ' is a strictly increasing function on $\mathbb{R}$ and $\theta(s)\geq 0$ for $s\in\mathbb{R}$. Furthermore, θ is strictly decreasing on $(-\infty,0]$ and strictly increasing on $[0,\infty)$. By the convexity of θ, condition (B3) is equivalent to $\theta'(s)\to\infty$ $(s\to\infty)$.

The exponential-type augmented Lagrangian functions can be derived by applying classical Lagrangian formulation to a reformulation of (P). Let $\psi:\ \mathbb{R}\to\mathbb{R}$ be a function satisfying the following conditions:

(C1) ψ is a continuously differentiable and strictly convex function on $\mathbb{R}$;

(C2) $\psi(0)=0$, $\psi'(0)=1$, $\lim_{t\to-\infty}\psi'(t)=0$;

(C3) $\lim_{t\to-\infty}\psi(t)>-\infty$, $\lim_{t\to\infty}\frac{\psi(t)}{t}=\infty$.

From condition (C1), ψ' is strictly increasing on $\mathbb{R}$, which together with (C2) implies that $\psi'(t) > 0$ for any t. Thus ψ is a strictly increasing function on $\mathbb{R}$. An obvious example of ψ that satisfies (C1)–(C3) is $\psi(t) = \mathrm{e}^t - 1$. Other interesting examples of ψ include the hyperbolic-exponential function, the hyperbolic-quadratic function, the exponential-quadratic function (see [7], [11], [38]), and the modified log-sigmoid function [37].

Now problem (P) can be rewritten in an equivalent form:

$$\begin{aligned} &\min\ f(x)\\ &\text{s.t.}\ \ (1/p)\psi(pg_i(x)) \le 0,\ i = 1, \dots, m,\\ &\qquad x \in X, \end{aligned} \tag{2.5}$$

where $p > 0$ is a parameter. Applying the classical Lagrangian formulation to (2.5) leads to the following exponential-type augmented Lagrangian:

$$L_3(x, \lambda, p) = f(x) + \frac{1}{p}\sum_{i=1}^{m} \lambda_i \psi(pg_i(x)), \qquad x \in X,\ \lambda \ge 0. \tag{2.6}$$

To avoid ill-conditional numerical behavior of the exponential-type augmented Lagrangian function, a modified barrier function was proposed by Polyak [35]. Good numerical behavior of the modified barrier functions was shown in several papers (see, e.g., [4], [11]). We now consider a general class of modified barrier functions. Let φ: $(-\infty, 1) \to \mathbb{R}$ satisfy the following conditions:

(D1) φ is a continuously differentiable and strictly convex function on $(-\infty, 1)$;

(D2) $\varphi(0) = 0$, $\varphi'(0) = 1$, $\lim_{s\to-\infty} \varphi'(s) = 0$;

(D3) $\lim_{s\to-\infty} \frac{\varphi(s)}{s} = 0$.

Note that conditions (D1) and (D2) imply that φ is a strictly increasing function on $(-\infty, 1)$. Let $\Omega_p = \{x \in X \mid pg_i(x) < 1,\ i = 1, \dots, m\}$. Define the modified barrier augmented Lagrangian as follows:

$$L_4(x, \lambda, p) = \begin{cases} f(x) + \frac{1}{p}\sum_{i=1}^{m} \lambda_i \varphi(pg_i(x)), & x \in \Omega_p,\\ \infty, & x \in X \setminus \Omega_p, \end{cases} \tag{2.7}$$

where $p > 0$ and $\lambda \ge 0$. Taking $\varphi(s) = -\ln(1 - s)$ or $\varphi(s) = 1/(1 - s) - 1$ in (2.7) gives rise to the modified Frish function or the modified Carroll function introduced in [35], respectively.

3. Basic augmented Lagrangian method. In this section, we discuss the basic primal-dual method using the above four classes of augmented Lagrangians L_j $(j = 1, 2, 3, 4)$.

Define $h(x, \lambda, p) = (h_1(x, \lambda, p), \dots, h_m(x, \lambda, p))^T$, with

$$h_i(x, \lambda, p) = \begin{cases} (1/p)\left[W_s'\left(pg_i(x), \lambda_i\right) - \lambda_i\right] & \text{for } L_1,\\ (1/p)\left[\theta'\left(pg_i(x) + \lambda_i\right)_+ - \theta'(\lambda_i)\right] & \text{for } L_2,\\ (\lambda_i/p)\left[\psi'\left(pg_i(x)\right) - 1\right] & \text{for } L_3,\\ (\lambda_i/p)\left[\varphi'\left(pg_i(x)\right) - 1\right] & \text{for } L_4. \end{cases} \tag{3.1}$$

Algorithm 1 (basic primal-dual method).

Step 0 *(initialization). Select two positive sequences* $\{p_k\}_{k=0}^{\infty}$ *and* $\{\epsilon_k\}_{k=0}^{\infty}$, *with* $\epsilon_k \to 0$ *as* $k \to \infty$. *Choose* $\lambda^0 > 0$. *Set* $k = 0$.

Step 1 *(relaxation problem). Compute an* $x^k \in X$ *such that*

$$L_j(x^k, \lambda^k, p_k) \le \min_{x \in X} L_j(x, \lambda^k, p_k) + \epsilon_k \quad (j = 1, 2, 3, 4). \tag{3.2}$$

Step 2 *(multiplier updating). The multiplier vector* λ^k *is updated by the following formulas* ($i = 1, \ldots, m$)*:*

$$\lambda_i^{k+1} = \lambda_i^k + p_k h_i(x^k, \lambda^k, p_k). \tag{3.3}$$

Step 3. *Set* $k = k + 1$*; go to Step* 1.

Remark 1. For L_j $(j = 1, 3, 4)$, the multiplier updating formulas (3.3) are derived by noticing the following fact:

$$\nabla_x L_j(x^k, \lambda^k, p_k) = 0 \Rightarrow \nabla_x L(x^k, \lambda^{k+1}) = 0,$$

where L is the classical Lagrangian function given by $L(x, \lambda) = f(x) + \sum_{i=1}^m \lambda_i g_i(x)$. Note that $\frac{\partial L_2(x,\lambda,p)}{\partial \lambda_i} = \frac{1}{p}[\theta'(pg_i(x) + \lambda_i)_+ - \theta'(\lambda_i)]$. The multiplier updating formula (3.3) for L_2 can be viewed as executing a steepest ascent step for maximizing the function $L_2(x^k, \cdot, p_k)$ with step size p_k.

To ensure Step 1 is well posed, we need the following assumptions.

Assumption 1. $\underline{f} = \inf_{x \in X} f(x) > -\infty$.

Assumption 2. $\underline{g} = \inf_{x \in X} \min_{1 \le i \le m} g_i(x) > -\infty$.

Obviously, a sufficient condition to ensure Assumptions 1 and 2 is that X is a compact set. It can be verified that, under Assumption 1, Step 1 is well defined for L_j $(j = 1, 2, 3)$ and that Step 1 is well defined for L_4 under Assumptions 1 and 2.

Throughout the paper, we assume that Assumption 1 is always satisfied for L_j $(j = 1, 2, 3)$ and Assumptions 1 and 2 are always satisfied for L_4.

The following theorem can be viewed as a generalization of Proposition 2.1 in [6] and can be proved by using arguments similar to [6].

THEOREM 1. *Assume that* (A1)–(A7) *for* W, (B1)–(B3) *for* θ, (C1)–(C3) *for* ψ, *and* (D1)–(D3) *for* φ *are satisfied. Suppose that* $\{\lambda^k\}$ *is bounded. If* $p_k \to \infty$ *as* $k \to \infty$ *then the following hold true.*

(i) *Each limit point of the sequence* $\{x^k\}$ *generated by Algorithm* 1 *associated with* L_j $(j = 1, 2, 4)$ *is a global optimal solution to* (P).

(ii) *If the sequence* $\{x_k\}$ *generated by Algorithm* 1 *associated with* L_3 *converges to* $\bar{x}$*, then* $\bar{x}$ *is a global optimal solution to* (P).

We point out that the multiplier updates in Step 2 of Algorithm 1 are not essential for the convergence analysis of Algorithm 1. In fact, no matter how λ^k is updated, Theorem 1 holds true as long as $\{\lambda^k\}$ is bounded. It turns out that this boundedness assumption for $\{\lambda^k\}$ is indispensable for the convergence of Algorithm 1 as shown by the counterexample in [41]. In the subsequent sections, we will discuss several approaches to modify the basic primal-dual scheme by using different strategies. The convergence results will be established for these modified augmented Lagrangian methods without assuming the boundedness of $\{\lambda^k\}$.

4. Modified augmented Lagrangian method using safeguarding. A natural way to relax the boundedness assumption of the Lagrangian multiplier in the basic augmented Lagrangian method is to adopt the safeguarding technique (see [1], [2], [7]) which projects the updated Lagrangian multipliers on suitable bounded intervals.

ALGORITHM 2 (modified primal-dual method using safeguarding).

Step 0 *(initialization). Choose a positive sequence* $\{\epsilon_k\}_{k=1}^{\infty}$ *satisfying* $\epsilon_k \to 0$ *as* $k \to \infty$. *Choose* $\gamma > 1$, $\tau \in (0,1)$, $p_1 > 0$, $\lambda^{\max}$, *and* $\bar{\lambda}^1 \in \mathbb{R}^m$ *such that* $0 < \bar{\lambda}_i^1 \leq \lambda_i^{\max}$ *for* $i = 1, \ldots, m$. *Let* $\sigma^0 = (\sigma_1^0, \ldots, \sigma_m^0)^T$, *with* $\sigma_i^0 = \max\{0, g_i(x^0)\}$, $i = 1, \ldots, m$. *Set* $k = 1$.

Step 1 *(relaxation problem). Compute an* $x^k \in X$ *such that*

$$L_j(x^k, \bar{\lambda}^k, p_k) \leq \min_{x \in X} L_j(x, \bar{\lambda}^k, p_k) + \epsilon_k \qquad (j = 1, 2, 3, 4). \tag{4.1}$$

Step 2 *(multiplier updating). Compute*

$$\lambda_i^{k+1} = \bar{\lambda}_i^k + p_k h_i(x^k, \bar{\lambda}^k, p_k), \qquad i = 1, \ldots, m, \tag{4.2}$$

where h_i *is defined in* (3.1).

Step 3 *(safeguarding projection). Compute*

$$\bar{\lambda}^{k+1} = \mathrm{Proj}_T(\lambda^{k+1}), \tag{4.3}$$

where $\mathrm{Proj}_T(\lambda^{k+1})$ *denotes the Euclidean projection of* λ^{k+1} *on* $T = \{\lambda \in \mathbb{R}^m \mid 0 \leq \lambda_i \leq \lambda_i^{\max},\ i = 1, \ldots, m\}$.

Step 4 *(parameter updating). Let* $\sigma^k = h(x^k, \bar{\lambda}^k, p_k)$. *If*

$$\|\sigma^k\| \leq \tau \|\sigma^{k-1}\|, \tag{4.4}$$

set $p_{k+1} = p_k$; *otherwise, set* $p_{k+1} = \gamma p_k$. *Set* $k := k + 1$, *and go to Step* 1.

Remark 2. The projection operation in (4.3) is a safeguarding strategy to ensure the boundedness of the multipliers used in (4.1). As will be shown later in this section, this safeguarding technique guarantees the convergence of the algorithm without appealing to the restrictive assumption that the multiplier sequence generated by the algorithm is bounded. In Step 4, the Euclidean norm of $h(x, \lambda, p)$ is used to measure the progress of feasibility/complementarity of the inequality constraints $g_i(x) \leq 0$, $i = 1, \ldots, m$.

We first discuss the convergence of Algorithm 2 using L_j $(j = 1, 2)$. We have the following result.

THEOREM 2. *Assume that* (A1)–(A7) *for* W *in* L_1 *and* (B1)–(B3) *for* θ *in* L_2 *are satisfied. Let* $\{x^k\}$ *be the sequence generated by Algorithm* 2 *when using* L_j $(j = 1, 2)$. *Then each limit point of* $\{x^k\}$ *is a global optimal solution to problem* (P).

In the following, we will prove only the theorem for the augmented Lagrangian L_1. The proof for L_2 can be constructed by using similar arguments and the properties (B1)–(B3).

We need the following proposition.

PROPOSITION 1 (Proposition 5.1, [6]). *Let* $s \in \mathbb{R}$ *and* $t \geq 0$. *Then*

(i) $W_t'(s,t) \geq s$;

(ii) $sW_s'(s,t) \geq W(s,t) \geq tW_t'(s,t) \geq st$;

(iii) $W_s'(s,t) = t \ \Rightarrow\ s \leq 0,\ st = 0$.

Proof of Theorem 2. Let $\bar{x}$ be a limit point of $\{x^k\}$, and let $\mathcal{K} \subset \{1, 2, \ldots\}$ be such that $\{x^k\} \to \bar{x}$, as $k \to \infty$ and $k \in \mathcal{K}$. By the closedness of X, $\bar{x} \in X$. We consider the following two cases.

Case (i): $p_k \to \infty$ as $k \to \infty$. By Step 3 of the algorithm, $0 \leq \bar{\lambda}^k \leq \lambda^{\max}$ for all k. Using condition (A6) and the fact that $\inf_{s \in \mathbb{R}} W(s,t) \leq 0$ for all $t \geq 0$, we have

$$0 \geq \inf_{s \in \mathbb{R}} W(s, \bar{\lambda}_i^k) > -\infty \ \text{ for all } k \text{ and } i, \tag{4.5}$$

which in turn implies

$$\lim_{k\to\infty} \frac{1}{p_k} \sum_{i=1}^{m} \inf_{s\in\mathbb{R}} W(s, \bar{\lambda}_i^k) = 0. \tag{4.6}$$

By (4.1), we have

$$L_1(x^k, \bar{\lambda}^k, p_k) \le L_1(x, \bar{\lambda}^k, p_k) + \epsilon_k \quad \forall x \in X.$$

Let x^* be a global solution to problem (P). Then

$$\begin{aligned} L_1(x^k, \bar{\lambda}^k, p_k) &\le L_1(x^*, \bar{\lambda}^k, p_k) + \epsilon_k \\ &= f(x^*) + \frac{1}{p_k} \sum_{i=1}^{m} W(p_k g_i(x^*), \bar{\lambda}_i^k) + \epsilon_k. \end{aligned} \tag{4.7}$$

Note from (2.2) that $W(s,t)$ is an increasing function of s on $\mathbb{R}$ for any fixed $t \ge 0$. Since $g_i(x^*) \le 0$ and $W(0,t) = 0$ for $t \ge 0$, we have

$$W(p_k g_i(x^*), \lambda_i^k) \le W(0, \bar{\lambda}_i^k) = 0$$

for all i and k. Therefore, from (4.7) and the definition of L_1, we have

$$f(x^k) + \frac{1}{p_k} \sum_{i=1}^{m} W(p_k g_i(x^k), \bar{\lambda}_i^k) \le f(x^*) + \epsilon_k. \tag{4.8}$$

Now we are going to show that $\bar{x}$ is feasible to problem (P), i.e., $g_i(\bar{x}) \le 0$, $i = 1, \ldots, m$. Suppose on the contrary that there exists some i_0 such that $g_{i_0}(\bar{x}) > 0$. Let $\epsilon = g_{i_0}(\bar{x})/2$. By the continuity of g_{i_0}, there exists $k_0 > 0$ such that $g_{i_0}(x^k) \ge \epsilon$ for all $k \ge k_0$, $k \in \mathcal{K}$. Since $W(\cdot, t)$ is increasing on $\mathbb{R}$ for any fixed $t \ge 0$ and $\bar{\lambda}^k \ge 0$ for all k, we get

$$W(p_k g_{i_0}(x^k), \bar{\lambda}_{i_0}^k) \ge W(p_k \epsilon, \bar{\lambda}_{i_0}^k) \ge W(p_k \epsilon, 0), \qquad k \ge k_0,\ k \in \mathcal{K}, \tag{4.9}$$

where the second inequality follows from the fact that $W(s, \cdot)$ is an increasing function of $t \ge 0$ for any fixed $s \ge 0$ (cf. Proposition 1(i)). Using (4.9), $\epsilon_k \to 0$, $p_k \to \infty$, and Assumption 1, we deduce from (4.8) that

$$\begin{aligned} f(x^*) + \epsilon_k &\ge f(x^k) + \frac{1}{p_k} \sum_{i=1}^{m} W(p_k g_i(x^k), \bar{\lambda}_i^k) \\ &= f(x^k) + \frac{1}{p_k} W(p_k g_{i_0}(x^k), \bar{\lambda}_{i_0}^k) + \frac{1}{p_k} \sum_{i \ne i_0} W(p_k g_i(x^k), \bar{\lambda}_i^k) \\ &\ge \underline{f} + \frac{1}{p_k} W(p_k \epsilon, 0) + \frac{1}{p_k} \sum_{i \ne i_0} \inf_{s\in\mathbb{R}} W(s, \bar{\lambda}_i^k) \\ &\to \infty \quad (k \to \infty,\ k \in \mathcal{K}), \end{aligned}$$

where the second term in the last inequality tends to ∞ due to the condition (A7), and by (4.6) the third term in the last inequality tends to 0. This contradiction implies that $g_i(\bar{x}) \le 0$ for $i = 1, \ldots, m$.

Next, we show that $\bar{x}$ is a global optimal solution to problem (P). Taking the limit superior in (4.8) and using $\epsilon_k \to 0$ give

$$f(\bar{x}) + \limsup_{k\to\infty, k\in\mathcal{K}} \frac{1}{p_k} \sum_{i=1}^{m} W(p_k g_i(x^k), \bar{\lambda}_i^k) \le f(x^*). \tag{4.10}$$

Since $\bar{x}$ is feasible, we have $f(x^*) \le f(\bar{x})$. Thus, we obtain from (4.10) that

$$\limsup_{k\to\infty, k\in\mathcal{K}} \frac{1}{p_k} \sum_{i=1}^{m} W(p_k g_i(x^k), \bar{\lambda}_i^k) \le 0. \tag{4.11}$$

On the other hand, we have

$$\frac{1}{p_k} \sum_{i=1}^{m} W(p_k g_i(x^k), \bar{\lambda}_i^k) \ge \frac{1}{p_k} \sum_{i=1}^{m} \inf_{s\in\mathbb{R}} W(s, \bar{\lambda}_i^k) \quad \forall k. \tag{4.12}$$

Taking the limit inferior in (4.12) and using (4.6) give rise to

$$\liminf_{k\to\infty, k\in\mathcal{K}} \frac{1}{p_k} \sum_{i=1}^{m} W(p_k g_i(x^k), \bar{\lambda}_i^k) \ge 0. \tag{4.13}$$

Combining (4.11) and (4.13) yields

$$\lim_{k\to\infty, k\in\mathcal{K}} \frac{1}{p_k} \sum_{i=1}^{m} W(p_k g_i(x^k), \bar{\lambda}_i^k) = 0.$$

Thus, we obtain from (4.10) that

$$f(\bar{x}) \le f(x^*).$$

Therefore, $f(\bar{x}) = f(x^*)$, and $\bar{x}$ is a global minimum of problem (P).

Case (ii): $\{p_k\}$ is bounded as $k \to \infty$. In this case, (4.4) in Step 4 is satisfied at each iteration for sufficiently large k. This, together with $\tau \in (0,1)$, implies that $\|\sigma_k\| \to 0$ $(k \to \infty)$ and that there exists $k_1 > 0$ such that $p_k = p_{k_1}$ for all $k \ge k_1$. Since $\sigma_k = h(x^k, \bar{\lambda}^k, p_k)$, it then follows from the definition of h (cf. (3.1)) that

$$\lim_{k\to\infty} \frac{1}{p_k} \left[W_s'\left(p_k g_i(x^k), \bar{\lambda}_i^k\right) - \bar{\lambda}_i^k \right] = 0, \ i = 1, \ldots, m. \tag{4.14}$$

Since $\{\bar{\lambda}^k\} \subset T$ is bounded, we can assume, without loss of generality, that $\bar{\lambda}^k \to \bar{\lambda} \ge 0$ $(k \to \infty, k \in \mathcal{K})$. From (4.14) and $p_k = p_{k_1}$ for all $k \ge k_1$, we obtain

$$W_s'\left(p_{k_1} g_i(\bar{x}), \bar{\lambda}_i\right) - \bar{\lambda}_i = 0, \ i = 1, \ldots, m, \tag{4.15}$$

which in turn implies by Proposition 1(iii) that

$$g_i(\bar{x}) \le 0, \ \bar{\lambda}_i g_i(\bar{x}) = 0, \ i = 1, \ldots, m. \tag{4.16}$$

On the other hand, by Proposition 1(ii), we get

$$st \le W(s,t) \le sW_s'(s,t) \quad \forall s \in \mathbb{R}, \ t \ge 0.$$

It then follows that, for k large enough,

$$\bar{\lambda}_i^k g_i(x^k) \le \frac{1}{p_k} W(p_k g_i(x^k), \bar{\lambda}_i^k) \le g_i(x^k) W_s'(p_k g_i(x^k), \bar{\lambda}_i^k)$$

for all i. Taking the limit in the above inequality and using (4.15) and (4.16), we obtain

$$\lim_{k\to\infty, k\in\mathcal{K}} \frac{1}{p_k} W(p_k g_i(x^k), \lambda_i^k) = \bar{\lambda}_i g_i(\bar{x}) = 0, \quad i = 1, \ldots, m. \tag{4.17}$$

Using (4.17) and the similar arguments as in Case (i), we can show that $\bar{x}$ is a global optimal solution to problem (P). □

Next, we give the convergence result for Algorithm 2 using augmented Lagrangians L_j $(j = 3, 4)$.

THEOREM 3. *Assume that* (C1)–(C3) *for* ψ *in* L_3 *and* (D1)–(D3) *for* φ *in* L_4 *are satisfied. Let* $\{x^k\}$ *be the sequence generated by Algorithm* 2 *using* L_j $(j = 3, 4)$*. If* $x^k \to \bar{x}$ $(k \to \infty)$*, then* $\bar{x}$ *is a global optimal solution to* (P)*.*

Proof. We prove only the theorem for the case of L_3. The case of L_4 can be proved similarly. Since $\bar{\lambda}^1 > 0$ and $\psi'(t) > 0$ for any t, by (4.2) and (4.3) of Algorithm 2, it holds that $\lambda^k > 0$ and $\bar{\lambda}^k > 0$ for all k. Let x^* be a global optimal solution to (P). From (4.1), we have

$$f(x^k) + \frac{1}{p_k} \sum_{i=1}^m \bar{\lambda}_i^k \psi\left(p_k g_i(x^k)\right) \le f(x^*) + \epsilon_k. \tag{4.18}$$

Suppose that $x^k \to \bar{x}$ $(k \to \infty)$. We consider two cases: (i) $p_k \to \infty$ as $k \to \infty$, and (ii) $\{p_k\}$ is bounded as $k \to \infty$. The proof of the theorem in case (i) is similar to that of Theorem 2. We now consider only case (ii). In this case, (4.4) in Step 4 is always satisfied at each iteration for sufficiently large k. This, together with $\tau \in (0, 1)$, implies that $\|\sigma_k\| = \|h(x^k, \bar{\lambda}^k, p_k)\| \to 0$ $(k \to \infty)$ and $p_k = p_{k_0}$ for all $k \ge k_0$ with some sufficiently large k_0. Hence, it follows from the definition of h (cf. (3.1)) that

$$\lim_{k\to\infty} \bar{\lambda}_i^k \left[\psi'(p_{k_0} g_i(x^k)) - 1\right] = 0, \ i = 1, \ldots, m. \tag{4.19}$$

We now show that $g_i(\bar{x}) \le 0$ for $i = 1, \ldots, m$. Suppose that there exists some i_0 such that $g_{i_0}(\bar{x}) > 0$. Then there exists an integer k_0 such that $g_{i_0}(x^k) > 0$ for all $k \ge k_0$. Since ψ' is a strictly increasing function and $\psi'(0) = 1$, we have $\psi'(p_k g_{i_0}(x^k)) > 1$ for all $k \ge k_0$, and hence by (4.2), we have $\lambda_{i_0}^{k+1} > \bar{\lambda}_{i_0}^k$ for all $k \ge k_0$. Also, from (4.3), it holds that $\bar{\lambda}_{i_0}^k \le \bar{\lambda}_{i_0}^{\max}$ for all k. Thus $\lambda_{i_0}^{\max} \ge \bar{\lambda}_{i_0}^{k+1} > \bar{\lambda}_{i_0}^k > 0$ for all $k \ge k_0$. Therefore, there exists $\bar{\lambda}_{i_0}^* > 0$ such that $\bar{\lambda}_{i_0}^k \to \bar{\lambda}_{i_0}^*$ as $k \to \infty$. It then follows from (4.19) that $\bar{\lambda}_{i_0}^* [\psi'(p_{k_0} g_{i_0}(\bar{x})) - 1] = 0$. Note that $\bar{\lambda}_{i_0}^* > 0$ and $\psi'(0) = 1$. Thus, $g_{i_0}(\bar{x}) = 0$. This gives a contradiction, and hence $g_i(\bar{x}) \le 0$ for $i = 1, \ldots, m$.

Since $\{\bar{\lambda}^k\}$ is bounded, we can suppose that $\bar{\lambda}^k \to \bar{\lambda} \ge 0$ as $k \to \infty$ and $k \in \mathcal{K} \subseteq \{1, 2, \ldots\}$. By (4.19), we have

$$\bar{\lambda}_i \psi'(p_{k_0} g_i(\bar{x})) = \bar{\lambda}_i, \quad i = 1, \ldots, m, \tag{4.20}$$

which in turn implies

$$\bar{\lambda}_i g_i(\bar{x}) = 0, \quad i = 1, \ldots, m. \tag{4.21}$$

Moreover, from the convexity of ψ and the condition $\psi(0) = 0$ and $\psi'(0) = 1$, we have

$$t \le \psi(t) \le \psi'(t) t \quad \forall t \in \mathbb{R}. \tag{4.22}$$

Therefore, we obtain

$$\bar{\lambda}_i^k g_i(x^k) \le \frac{1}{p_k}\bar{\lambda}_i^k \psi\left(p_k g_i(x^k)\right) \le g_i(x^k)\bar{\lambda}_i^k \psi'\left(p_k g_i(x^k)\right)$$

for all i and k. Taking the limit in the above inequality and using (4.20) and (4.21), we obtain

$$\lim_{k\to\infty, k\in\mathcal{K}} \frac{1}{p_k}\sum_{i=1}^m \bar{\lambda}_i^k \psi\left(p_k g_i(x^k)\right) = \sum_{i=1}^m \bar{\lambda}_i g_i(\bar{x}) = 0, \tag{4.23}$$

which, together with (4.18), implies $f(\bar{x}) \le f(x^*)$. Thus, $\bar{x}$ is a global optimal solution of (P). □

From the proof of Theorem 2, we see that the multiplier updates in Step 2 of Algorithm 2 are actually not essential for the convergence of Algorithm 2 when using L_j $(j = 1, 2)$. However, the proof of Theorem 3 does rely on the multiplier update in Step 2 when using L_j $(j = 3, 4)$.

5. Modified augmented Lagrangian method with conditional multiplier updating. In this section, we investigate an alternative strategy to modify the basic augmented Lagrangian algorithm for solving (P). The underlying idea is to modify Step 2 of Algorithm 1 for updating the multipliers: The Lagrangian multipliers are updated only when certain progress for the feasibility/complementarity is achieved.

The following modified augmented Lagrangian method for (P) using L_j $(j = 1, 3, 4)$ is an extension of the algorithm in [9] where the equality-constrained problem is considered.

ALGORITHM 3 (modified primal-dual method with conditional multiplier updating).

Step 0. *Choose positive constants*

$$\mu_0,\ \nu_0,\ \beta_\eta,\ \alpha_\epsilon,\ \beta_\epsilon,\ \tau > 1,\ \gamma_1 \in (0,1),\ \omega \ll 1,\ \alpha_\eta > 0.5.$$

Set the initial penalty parameter $p_0 > 1$, *and let*

$$\alpha_0 = \min\left(\frac{1}{p_0}, \gamma_1\right), \quad \epsilon_0 = \nu_0\left(\alpha_0\right)^{\alpha_\epsilon}, \text{ and } \eta_0 = \mu_0\left(\alpha_0\right)^{\alpha_\eta}.$$

Select an initial multiplier vector $\lambda^0 > 0$. *Set* $k = 0$.

Step 1. *Find an* x^k *satisfying*

$$L_j(x^k, \lambda^k, p_k) \le \min_{x\in X} L_j(x, \lambda^k, p_k) + \epsilon_k \qquad (j = 1, 3, 4). \tag{5.1}$$

If

$$\|h(x^k, \lambda^k, p_k)\| \le \eta_k, \tag{5.2}$$

go to Step 2, *where* h *is defined by* (3.1). *Otherwise, go to Step* 3.

Step 2. *If* $\|h(x^k, \lambda^k, p_k)\| \le \omega$, *stop. Otherwise, set*

$$\begin{cases} \lambda^{k+1} = \lambda^k + p_k h(x^k, \lambda^k, p_k), \\ p_{k+1} = p_k, \\ \alpha_{k+1} = \min(\frac{1}{p_{k+1}}, \gamma_1), \\ \epsilon_{k+1} = \epsilon_k(\alpha_{k+1})^{\beta_\epsilon}, \\ \eta_{k+1} = \eta_k\left(\alpha_{k+1}\right)^{\beta_\eta}. \end{cases} \tag{5.3}$$

Set $k := k + 1$, *and go to Step* 1.

Step 3. *Set*

$$\begin{cases} \lambda^{k+1} = \lambda^k, \\ p_{k+1} = \tau p_k, \\ \alpha_{k+1} = \min(\frac{1}{p_{k+1}}, \gamma_1), \\ \epsilon_{k+1} = \nu_0(\alpha_{k+1})^{\alpha_\epsilon}, \\ \eta_{k+1} = \mu_0\,(\alpha_{k+1})^{\alpha_\eta}. \end{cases} \tag{5.4}$$

Set $k := k + 1$, *and go to Step* 1.

Remark 3. In Step 3 of Algorithm 3, the multipliers are not updated when the progress of feasibility/complementarity of the inequality constraints is not satisfactory. It turns out that this scheme maintains the essential boundedness of the multipliers and thus guarantees the convergence of the algorithm when using L_j $(j = 1, 3, 4)$. Numerical comparison between the augmented Lagrangian methods using safeguarding and the above "updating only necessary" strategy can be found in [1], [7].

In the following convergence analysis for Algorithm 3, we set $\omega = 0$. We have the following lemmas regarding the boundedness of $\{\lambda^k\}$ generated by the above algorithm.

LEMMA 1. *If* $p_k \to \infty$ *when Algorithm* 3 *is executed, then* $\lim_{k\to\infty} \frac{\lambda^k}{\sqrt{p_k}} = 0$.

Proof. The proof is similar to that of Lemma 4.1 in [9], where equality constraints are considered. □

LEMMA 2. *If* $\{p_k\}$ *is bounded when Algorithm* 3 *is executed, then* $\{\lambda^k\}$ *is convergent.*

Proof. If $\{p_k\}$ is bounded, there exists $k_0 > 0$ such that Step 2 is executed at every iteration when $k \geq k_0$. Thus, (5.2) is satisfied when $k \geq k_0$. Moreover, from (5.3), we deduce that $p_k = p_{k_0}$ when $k \geq k_0$ and

$$\lambda_i^k = \lambda_i^{k_0} + p_{k_0} \sum_{l=0}^{k-1} h_i(x^{k_0+l}, \lambda^{k_0+l}, p_{k_0+l}), \quad k \geq k_0, \quad i = 1, \ldots, m. \tag{5.5}$$

From (5.3), we see that $\sum_{k=1}^{\infty} \eta_k$ is convergent. Hence, by (5.2), for each i, $\sum_{k=1}^{\infty} h_i(x^k, \lambda^k, p_k)$ is also convergent. It then follows from (5.5) that $\{\lambda^k\}$ is convergent. □

Based on the above lemmas, we are able to establish the convergence results of Algorithm 3 using L_j $(j = 1, 3, 4)$. We first discuss the Algorithm 3 using L_1. In addition to (A1)–(A7), let $W(s, t)$ in the definition of L_1 satisfy the following condition:

(A8) For any nonnegative sequences $\{t_k\} \subseteq \mathbb{R}$ and positive sequence $\{p_k\} \subseteq \mathbb{R}$, with $p_k \to \infty$ $(k \to \infty)$,

$$\lim_{k\to\infty} \frac{t_k}{\sqrt{p_k}} = 0 \Rightarrow \lim_{k\to\infty} \frac{1}{p_k} \inf_{s\in\mathbb{R}} W(s, t_k) = 0.$$

It can be verified that $W(s, t)$ in many augmented Lagrangian functions classified in the general class L_1 satisfies condition (A8). In particular, for $W(s, t)$ defined in (2.3), suppose that we replace condition (E3) by the following condition:

(E3′) There exists $\alpha > 0$ such that $\phi(s) \geq \alpha s^2/2$ for all $s \in \mathbb{R}$.

Then condition (A8) is satisfied. Clearly (E3′) holds if ϕ is strongly convex. We also note that condition (E3′) implies (E3).

THEOREM 4. *Assume that conditions* (A1)–(A8) *for* $W(s, t)$ *are satisfied. Let* $\{x^k\}$ *be the sequence generated by Algorithm* 3 *associated with* L_1. *Then each limit point of the sequence* $\{x^k\}$ *is a global optimal solution to problem* (P).

Proof. Let x^* be a global solution to problem (P). Similar to the proof of Theorem 2, we have

$$f(x^k) + \frac{1}{p_k}\sum_{i=1}^{m} W(p_k g_i(x^k), \lambda_i^k) \le f(x^*) + \epsilon_k. \tag{5.6}$$

Suppose that $x^k \to \bar{x} \in X$ as $k \to \infty$ and $k \in \mathcal{K} \subseteq \{1, 2, \ldots\}$. We consider the following two cases.

Case (i): $p_k \to \infty$ when the algorithm is executed. By Lemma 1, it holds that $\lim_{k\to\infty} \frac{\lambda^k}{\sqrt{p_k}} = 0$, which, by condition (A8), implies

$$\lim_{k\to\infty} \frac{1}{p_k}\sum_{i=1}^{m} \inf_{s\in\mathbb{R}} W(s, \lambda_i^k) = 0. \tag{5.7}$$

Using similar arguments as in the proof of Theorem 2, we can infer from (5.6) and (5.7) that $\bar{x}$ is a global optimal solution to (P).

Case (ii): $\{p_k\}$ is bounded when the algorithm is executed. In this case, there exists $k_0 \ge 0$ such that Step 2 is executed at each iteration when $k \ge k_0$. By the definition of h for L_1 and (5.3), we have

$$\lambda_i^{k+1} = W_s'(p_k g_i(x^k), \lambda_i^k), \quad k \ge k_0. \tag{5.8}$$

Thus, by (2.2) and $\lambda_i^0 > 0$, we infer that $\lambda^k \ge 0$ for all k, and hence by Lemma 2, $\lambda^k \to \bar{\lambda} \ge 0$. Taking the limit in (5.8), we get

$$W_s'\left(p_{k_0} g_i(\bar{x}), \bar{\lambda}_i\right) = \bar{\lambda}_i, \ i = 1, \ldots, m,$$

which, by Proposition 1(iii), implies

$$g_i(\bar{x}) \le 0, \qquad \bar{\lambda}_i g_i(\bar{x}) = 0, \quad i = 1, \ldots, m. \tag{5.9}$$

Using (5.9), we can show, using a proof similar to that of Theorem 2, that

$$\lim_{k\to\infty, k\in\mathcal{K}} \frac{1}{p_k} W(p_k g_i(x^k), \lambda_i^k) = \bar{\lambda}_i g_i(\bar{x}) = 0, \quad i = 1, \ldots, m. \tag{5.10}$$

Since $\epsilon_k \to 0$, we obtain from (5.6) and (5.10) that $f(\bar{x}) \le f(x^*)$. Thus, $\bar{x}$ is a global optimal solution to (P). □

Next, we discuss the convergence property of Algorithm 3 associated with L_3.

THEOREM 5. *Assume that conditions* (C1)–(C3) *for ψ are satisfied. Let $\{x^k\}$ be the sequence generated by Algorithm* 3 *associated with L_3. If $x^k \to \bar{x}$ $(k \to \infty)$, then $\bar{x}$ is a global optimal solution to problem (P).*

Proof. Let x^* be a global solution to problem (P). From (5.1) in Algorithm 3, we have

$$f(x^k) + \frac{1}{p_k}\sum_{i=1}^{m} \lambda_i^k \psi\left(p_k g_i(x^k)\right) \le f(x^*) + \epsilon_k. \tag{5.11}$$

Suppose that $x^k \to \bar{x} \in X$ $(k \to \infty)$. We consider the following two cases.

Case (i): $p_k \to \infty$ when the algorithm is executed. In this case, Step 3 of the algorithm must be executed for infinite times. Let $\mathcal{K} = \{k_0, k_1, k_2, \ldots\}$ be the set of the indices of the iterations in which Step 3 of the algorithm is executed. Then

$$\lambda^{k_j+1} = \lambda^{k_j} \quad \text{for all } j. \tag{5.12}$$

Let t be such that $k_j < k_j + l < k_{j+1}$ for $1 \le l \le t$. At iteration $k_j + l$, $1 \le l \le t$, Step 2 is executed, and hence, for all j and i,

$$\begin{cases} \lambda_i^{k_{j+1}} = \lambda_i^{k_j+t}\psi'(p_{k_j+t}g_i(x^{k_j+t})), \\ \lambda_i^{k_j+l+1} = \lambda_i^{k_j+l}\psi'(p_{k_j+l}g_i(x^{k_j+l})), \quad 1 \le l < t. \end{cases} \tag{5.13}$$

By Lemma 1, it holds that $\lim_{k\to\infty} \frac{\lambda^k}{\sqrt{p_k}} = 0$, which in turn implies

$$\lim_{k\to\infty} \frac{\lambda^k}{p_k} = 0. \tag{5.14}$$

We prove in the following that $g_i(\bar{x}) \le 0$ for $i = 1, \ldots, m$, which together with $\bar{x} \in X$ implies that $\bar{x}$ is a feasible solution to (P). Suppose, on the contrary, there exists some i_0 such that $g_{i_0}(\bar{x}) \ge \epsilon$ for some $\epsilon > 0$. Then there exists an integer $\bar{k}$ such that $g_{i_0}(x^k) \ge \epsilon/2$ for all $k \ge \bar{k}$. Since ψ is strictly increasing and $\psi(0) = 0$, we have

$$\psi(p_k g_{i_0}(x^k)) \ge \psi(p_k\epsilon/2) > 0, \qquad k \ge \bar{k}. \tag{5.15}$$

Since ψ' is a strictly increasing function and $\psi'(0) = 1$, we have

$$\psi'(p_k g_{i_0}(x^k)) > 1 \ \text{ for all } k \ge \bar{k}. \tag{5.16}$$

Note that $\lambda^k > 0$ for all k. Let j_0 be such that $k_{j_0} \ge \bar{k}$. It then follows from (5.12), (5.13), and (5.16) that $\lambda_{i_0}^{k_{j+1}} > \lambda_{i_0}^{k_j}$ for all $j \ge j_0$. Therefore, for all $j \ge j_0$, $\lambda_{i_0}^{k_j} > \lambda_{i_0}^{k_{j_0}} > 0$. Also, condition (C3) implies that $\underline{\psi} = \min_{t\in\mathbb{R}} \psi(t) > -\infty$. Moreover, by Assumption 1, $\underline{f} = \inf_{x\in X} f(x) > -\infty$. Therefore, for $j \ge j_0$, using (5.14) and (5.15), we obtain from (5.11) that

$$\begin{aligned} f(x^*) + \epsilon_{k_j} &\ge f(x^{k_j}) + (1/p_{k_j}) \sum_{i=1}^m \lambda_i^{k_j}\psi(p_{k_j}g_i(x^{k_j})) \\ &\ge \underline{f} + (1/p_{k_j})\lambda_{i_0}^{k_j}\psi(p_{k_j}\epsilon/2) + \frac{1}{p_{k_j}}\underline{\psi}\sum_{i\ne i_0}\lambda_i^{k_j} \\ &\ge \underline{f} + (1/p_{k_j})\lambda_{i_0}^{k_{j_0}}\psi(p_{k_j}\epsilon/2) + \frac{1}{p_{k_j}}\underline{\psi}\sum_{i\ne i_0}\lambda_i^{k_j} \\ &\to \infty \quad (j \to \infty), \end{aligned}$$

where the second term in the last inequality tends to ∞ since, by condition (C3) and $p_{k_j} \to \infty$, it holds that $\lambda_{i_0}^{k_{j_0}} > 0$ and $(1/p_{k_j})\psi(p_{k_j}\epsilon/2) \to \infty$ $(j \to \infty)$, and the third term in the last inequality tends to 0 due to (5.14). This contradiction indicates that $g_i(\bar{x}) \le 0$ for $i = 1, \ldots, m$.

On the other hand, from (5.11), we have

$$f(x^k) + \frac{1}{p_k}\sum_{i=1}^m \underline{\psi}\lambda_i^k \le f(x^*) + \epsilon_k \quad \forall k.$$

In view of (5.14) and $\epsilon_k \to 0$, taking a limit in the above inequality leads to $f(\bar{x}) \le f(x^*)$. Therefore, $\bar{x}$ is a global optimal solution of problem (P).

Case (ii): $\{p_k\}$ is bounded when the algorithm is executed. In this case, there exists $k_0 \geq 0$ such that Step 2 is executed at each iteration when $k \geq k_0$. This implies that $p_k = p_{k_0}$ and

$$\lambda_i^{k+1} = \lambda_i^k \psi'\left(p_k g_i(x^k)\right), \quad i = 1, \ldots, m, \tag{5.17}$$

when $k \geq k_0$. By Lemma 2, $\{\lambda^k\}$ converges to $\bar{\lambda} \geq 0$. Let $M = \{i \mid \bar{\lambda}_i = 0, i = 1, \ldots, m\}$. We claim that $g_i(\bar{x}) \leq 0$ for any $i \in M$. Suppose that there exists $i_0 \in M$ such that $g_{i_0}(\bar{x}) > 0$. Then there exists an integer $\bar{k}$ such that $g_{i_0}(x^k) > 0$ for all $k \geq \bar{k}$. Since ψ' is increasing and $\psi'(0) = 1$, we from (5.17) have that $\lambda_{i_0}^{k+1} \geq \lambda_{i_0}^k > 0$ for $k \geq \bar{k}$. Hence, $\bar{\lambda}_{i_0} > 0$, contradicting $i_0 \in M$. If $i \notin M$, i.e., $\bar{\lambda}_i > 0$, then we have from (5.17) and $\psi'(0) = 1$ that $g_i(\bar{x}) = 0$. Therefore,

$$g_i(\bar{x}) \leq 0, \ \bar{\lambda}_i g_i(\bar{x}) = 0, \quad i = 1, \ldots, m. \tag{5.18}$$

By the convexity of ψ and condition $\psi(0) = 0$ and $\psi'(0) = 1$, it holds that

$$t \leq \psi(t) \leq \psi'(t)t \quad \forall t \in \mathbb{R}. \tag{5.19}$$

Note also that $\lambda^k > 0$ and $p_k > 1$ for all k. Applying (5.17) and (5.19), we obtain

$$\lambda_i^k g_i(x^k) \leq \frac{1}{p_k}\lambda_i^k \psi\left(p_k g_i(x^k)\right) \leq \lambda_i^k \psi'\left(p_k g_i(x^k)\right) g_i(x^k) = \lambda_i^{k+1} g_i(x^k)$$

for all i and $k \geq k_0$. Taking the limit in the above inequality and using (5.18), we obtain

$$\lim_{k\to\infty} \frac{1}{p_k} \sum_{i=1}^m \lambda_i^k \psi\left(p_k g_i(x^k)\right) = \sum_{i=1}^m \bar{\lambda}_i g_i(\bar{x}) = 0. \tag{5.20}$$

Since $\epsilon_k \to 0$, it follows from (5.11) and (5.20) that $f(\bar{x}) \leq f(x^*)$. Thus, $\bar{x}$ is a global optimal solution to (P). □

Finally, we consider Algorithm 3 associated with L_4. Let condition (D3) for the function φ in (2.7) be replaced by the following condition:

(D3′) $\lim_{t\to\infty} \varphi(-t)/\sqrt{t} = 0$.

We observe that functions $\varphi(t) = -\ln(1-t)$ and $\varphi(t) = 1/(1-t) - 1$ satisfy (D3′). It is clear that condition (D3′) implies (D3).

THEOREM 6. *Assume that conditions* (D1)–(D2) *and* (D3′) *for* φ *are satisfied. Let* $\{x^k\}$ *be the sequence generated by Algorithm* 3 *associated with* L_4. *If* $\{x^k\}$ *converges to* $\bar{x}$, *then* $\bar{x}$ *is a global optimal solution to problem* (P).

Proof. Let x^* be a global optimal solution to (P). By (5.1), we have

$$f(x^k) + \frac{1}{p_k}\sum_{i=1}^m \lambda_i^k \varphi(p_k g_i(x^k)) \leq f(x^*) + \frac{1}{p_k}\sum_{i=1}^m \lambda_i^k \varphi(p_k g_i(x^*)) + \epsilon_k. \tag{5.21}$$

From Step 2 of Algorithm 3 and (3.1), we have

$$\lambda_i^{k+1} = \lambda_i^k \varphi'(p_k g_i(x^k)), \quad i = 1, \ldots, m. \tag{5.22}$$

It is clear that $x^k \in \Omega_{p_k}$ and hence $p_k g_i(x^k) < 1$. By (D1) and (D2), φ is a strictly increasing function on $(-\infty, 1)$. Thus, $\varphi'(p_k g_i(x^k)) > 0$ for any i and k. From Step 0 of Algorithm 3, $\lambda^0 > 0$. Hence, (5.22) implies $\lambda_i^k > 0$ for any i and k. Also, both

$\varphi(0) = 0$ and $g_i(x^*) \le 0$ imply $\varphi(p_k g_i(x^*)) \le 0$. Therefore, we obtain the following from (5.21):

$$f(x^k) + \frac{1}{p_k} \sum_{i=1}^{m} \lambda_i^k \varphi(p_k g_i(x^k)) \le f(x^*) + \epsilon_k. \tag{5.23}$$

Now suppose that $x^k \to \bar{x} \in X$ $(k \to \infty)$. Consider the following two cases.

Case (i): $p_k \to \infty$ when the algorithm is executed. Since $g_i(x^k) < 1/p_k$, we deduce that $\bar{x}$ is a feasible solution of (P). By Lemma 1, it holds that

$$\lim_{k\to\infty} \frac{\lambda^k}{\sqrt{p_k}} = 0. \tag{5.24}$$

Denote $I_1 = \{i \mid g_i(\bar{x}) = 0\}$ and $I_2 = \{i \mid g_i(\bar{x}) < 0\}$. Let $\epsilon > 0$ be a constant. For $i \in I_1$, there exists k_1 such that $g_i(x^k) \ge -\epsilon$ for $k \ge k_1$. Since φ is a strictly increasing function on $(-\infty, 1)$, we have

$$\frac{1}{\sqrt{p_k}} \varphi(p_k g_i(x^k)) \ge \frac{1}{\sqrt{p_k}} \varphi(-\epsilon p_k). \tag{5.25}$$

Taking the limit inferior in (5.25) and using condition (D3′) yield the following:

$$\liminf_{k\to\infty} \frac{1}{\sqrt{p_k}} \varphi(p_k g_i(x^k)) \ge 0. \tag{5.26}$$

For $i \in I_2$, there exists k_2 such that $(3/2)g(\bar{x}) \le g_i(x^k) \le (1/2)g(\bar{x}) < 0$ for $k \ge k_2$. Thus,

$$\frac{1}{\sqrt{p_k}} \varphi((3/2)g(\bar{x})p_k) \le \frac{1}{\sqrt{p_k}} \varphi(p_k g_i(x^k)) \le \frac{1}{\sqrt{p_k}} \varphi((1/2)g(\bar{x})p_k). \tag{5.27}$$

Again, taking the limit in (5.27) and using condition (D3′) yield

$$\lim_{k\to\infty} \frac{1}{\sqrt{p_k}} \varphi(p_k g_i(x^k)) = 0. \tag{5.28}$$

Note that $\lambda_i^k > 0$ for all k. Combining (5.24), (5.26), and (5.28) gives rise to the following:

$$\liminf_{k\to\infty} \frac{1}{p_k} \sum_{i=1}^{m} \lambda_i^k \varphi(p_k g_i(x^k) \ge 0.$$

Since $\epsilon_k \to 0$, the above inequality and (5.23) imply that $f(\bar{x}) \le f(x^*)$, that is, $\bar{x}$ is a global solution to (P).

Case (ii): $\{p_k\}$ is bounded when the algorithm is executed. The proof of the theorem in this case is similar to that of Theorem 5. □

6. Normalized multiplier method. In this section, we discuss another approach of achieving the convergence results of the augmented Lagrangian methods without appealing to the boundedness of the multipliers. The idea behind this modification is to normalize the multipliers in the augmented Lagrangian functions L_1, L_2, and L_4 such that the convergence to a global solution can be guaranteed without the boundedness assumption.

The modified augmented Lagrangian functions L_1, L_2, and L_4 are defined as follows:

$$\bar{L}_1(x,\lambda,p) = f(x) + \frac{1}{p}\sum_{i=1}^{m} W\left(pg_i(x), \frac{\lambda_i}{1+\|\lambda\|}\right), \tag{6.1}$$

$$\bar{L}_2(x,\lambda,p) = f(x) + \frac{1}{p}\sum_{i=1}^{m}\left[\theta\left(pg_i(x) + \frac{\lambda_i}{1+\|\lambda\|}\right)_+ - \theta\left(\frac{\lambda_i}{1+\|\lambda\|}\right)\right], \tag{6.2}$$

$$\bar{L}_4(x,\lambda,p) = \begin{cases} f(x) + \frac{1}{p}\sum_{i=1}^{m}\frac{\lambda_i}{1+\|\lambda\|}\varphi(pg_i(x)), & x \in \Omega_p, \\ \infty, & x \in X \setminus \Omega_p. \end{cases} \tag{6.3}$$

Note that the difference between the modified function $\bar{L}_j$ $(j = 1, 2, 4)$ and the original augmented Lagrangian function L_j $(j = 1, 2, 4)$ is the introduction of the factor $\frac{1}{1+\|\lambda\|}$, which can be viewed as a barrier factor to prevent λ from becoming too large. A similar idea was used in [33] for another type of augmented Lagrangian functions.

We describe now the primal-dual scheme using the modified augmented Lagrangians $\bar{L}_j$ $(j = 1, 2, 4)$.

ALGORITHM 4 (normalized multiplier method). *The algorithm is identical to Algorithm* 1 *except that* L_j $(j = 1, 2, 4)$ *in* (3.2) *of Step* 1 *are replaced by* $\bar{L}_j$ $(j = 1, 2, 4)$ *and Step* 2 *is replaced by the following step:*

Step 2. *The multiplier vector* λ^k *is updated by the following equations* $(i = 1, \ldots, m)$*:*

$$\lambda_i^{k+1} = \begin{cases} W'\left(p_k g_i(x^k), \frac{\lambda_i^k}{1+\|\lambda^k\|}\right) & (\text{for } \bar{L}_1), \\ \lambda_i^k + \left[\theta'\left(p_k g_i(x^k) + \frac{\lambda_i^k}{1+\|\lambda^k\|}\right)_+ - \theta'\left(\frac{\lambda_i^k}{1+\|\lambda^k\|}\right)\right] & (\text{for } \bar{L}_2), \\ \frac{\lambda_i^k}{1+\|\lambda^k\|}\varphi'(p_k g_i(x^k)) & (\text{for } \bar{L}_4). \end{cases} \tag{6.4}$$

The convergence of Algorithm 4 to a global solution of (P) is established in the following theorem.

THEOREM 7. *Assume that* (A1)–(A7) *for* W, (B1)–(B3) *for* θ, *and* (D1)–(D3) *for* φ *are satisfied. Suppose in Algorithm* 4 *that* $p_k \to \infty$ *as* $k \to \infty$. *Then each limit point of the sequence* $\{x^k\}$ *generated by Algorithm* 4 *associated with* $\bar{L}_j$ $(j = 1, 2, 4)$ *is a global optimal solution to* (P).

Proof. We prove only the theorem for $\bar{L}_1$. The cases for $\bar{L}_2$ and $\bar{L}_4$ can be proved similarly. From Step 2, we see that $\lambda^k \geq 0$ for all k. Let $\mu^k = (\mu_1^k, \ldots, \mu_m^k)^T$, with

$$\mu_i^k = \frac{\lambda_i^k}{1+\|\lambda^k\|}, \quad i = 1, \ldots, m.$$

Clearly, $\{\mu^k\}$ is bounded and $\mu^k \geq 0$ for all k. The function $\bar{L}_1$ defined in (6.1) can be rewritten as

$$\bar{L}_1(x,\mu,p) = f(x) + \frac{1}{p}\sum_{i=1}^{m} W\left(pg_i(x), \mu_i\right).$$

By Algorithm 4, we have

$$\bar{L}_1(x^k,\mu^k,p_k) \leq \min_{x\in X} \bar{L}_1(x,\mu^k,p_k) + \epsilon_k. \tag{6.5}$$

Also, since $\{\mu^k\}$ is bounded and $p_k \to \infty$, using property (A6), we have

$$\lim_{k\to\infty} \frac{1}{p_k} \sum_{i=1}^{m} \inf_{s\in\mathbb{R}} W(s, \mu_i^k) = 0. \tag{6.6}$$

Applying (6.5)–(6.6) and similar arguments as in the proof of Theorem 2, we can show that each limit point of the sequence $\{x^k\}$ is a global optimal solution to (P). □

Next, we describe a "local" version of Algorithm 4 in which an approximate stationary point of the augmented Lagrangian relaxation problem is computed at each iteration.

ALGORITHM 5.

Step 0. *Select two positive sequences* $\{p_k\}$ *and* $\{\epsilon_k\}$ *such that* $p_k \to \infty$ *and* $\epsilon_k \to 0$ *as* $k \to \infty$. *Select an initial* $\lambda^0 = (\lambda_1^0, \ldots, \lambda_m^0)^T \geq 0$. *Set* $k = 0$.

Step 1. *Compute an* $x^k \in X$ *such that*

$$\|\mathcal{P}[x^k - \nabla_x \bar{L}_j(x^k, \lambda^k, p_k)] - x^k\| \leq \epsilon_k, \quad j = 1, 2, 4, \tag{6.7}$$

where $\mathcal{P}$ *is the Euclidean projection operator onto* X.

Step 2. *Update the multiplier vector* λ_i^k $(i = 1, \ldots, m)$ *by the following formula:*

$$\lambda_i^{k+1} = \begin{cases} W_s'\left(p_k g_i(x^k), \frac{\lambda_i^k}{1+\|\lambda^k\|}\right) & (\text{for } \bar{L}_1), \\ \theta'\left(p_k g_i(x^k) + \frac{\lambda_i^k}{1+\|\lambda^k\|}\right)_+ & (\text{for } \bar{L}_2), \\ \frac{\lambda_i^k}{1+\|\lambda^k\|}\varphi'(p_k g_i(x^k)) & (\text{for } \bar{L}_4). \end{cases} \tag{6.8}$$

Step 3. *Set* $k := k + 1$, *and go to Step* 1.

Remark 4. Note that the multiplier updating formula in (6.8) for $\bar{L}_j$ $(j = 1, 2, 4)$ is motivated by recognizing the following fact:

$$\nabla_x \bar{L}_j(x^k, \lambda^k, p_k) = 0 \Rightarrow \nabla_x L(x^k, \lambda^{k+1}) = 0, \quad j = 1, 2, 4,$$

where $L(x, \lambda) = f(x) + \sum_{i=1}^m \lambda_i g_i(x)$.

DEFINITION 1 (see [7]). *A point* $x^* \in X$ *is said to be degenerate if there exists* $\lambda^* \in \mathbb{R}_+^m$ *such that*

$$\sum_{i\in I(x^*)} \lambda_i^* > 0, \quad \mathcal{P}\left[x^* - \sum_{i\in I(x^*)} \lambda_i^* \nabla g_i(x^*)\right] - x^* = 0,$$

where $I(x^*) = \{i : g_i(x^*) \geq 0,\ i = 1, \ldots, m\}$.

Similar to Theorem 2 in [7], we have the following global convergence results for Algorithm 5.

THEOREM 8. *Assume that condition* (A1)–(A7) *for* W, *conditions* (B1)–(B3) *for* θ, *and conditions* (D1)–(D3) *for* φ *are satisfied. Let* x^* *be a limit point of the sequence* $\{x^k\}$ *generated by the Algorithm* 5 *associated with* $\bar{L}_j$ $(j = 1, 2, 4)$. *Then either* x^* *is degenerate or* x^* *is a KKT point of* (P).

Proof. We prove only the theorem for the case of $\bar{L}_1$. The cases for $\bar{L}_2$ and $\bar{L}_4$ can proved using similar arguments. By (6.7) and (6.8), we have

$$\lim_{k\to\infty} \left\| \mathcal{P}\left[x^k - \nabla f(x^k) - \sum_{i=1}^{m} \lambda_i^{k+1} \nabla g_i(x^k)\right] - x^k \right\| = 0. \tag{6.9}$$

Let $\mathcal{K} \subseteq \{1, 2, \ldots\}$ be such that $\{x^k\}_{\mathcal{K}} \to x^* \in X$. We consider the following two cases.

Case (i): $\{\lambda^{k+1}\}_{\mathcal{K}}$ is unbounded. Then there exists an infinite subsequence $\mathcal{K}_1 \subseteq \mathcal{K}$ such that

$$\Lambda^k = \sum_{i=1}^m \lambda_i^{k+1} \to \infty, \quad k \to \infty,\ k \in \mathcal{K}_1.$$

Since $0 \le \frac{\lambda_i^{k+1}}{\Lambda^k} \le 1$, we may assume that

$$\frac{\lambda_i^{k+1}}{\Lambda^k} \to \lambda_i^*, \quad k \to \infty,\ k \in \mathcal{K}_1, \tag{6.10}$$

for $i = 1, \ldots, m$.

On the other hand, since $\Lambda^k \to \infty$, we have $0 < \frac{1}{\Lambda^k} < 1$ for sufficiently large $k \in \mathcal{K}_1$. By the property of Euclidean projection, we deduce from (6.9) that

$$\lim_{k\to\infty, k\in\mathcal{K}_1} \left\| \mathcal{P}\left[x^k - \frac{1}{\Lambda_k}\left(\nabla f(x^k) - \sum_{i=1}^m \lambda_i^{k+1} \nabla g_i(x^k)\right)\right] - x^k \right\| = 0. \tag{6.11}$$

Since $x^k \to x^*$ and $\Lambda^k \to \infty$ as $k \to \infty$, $k \in \mathcal{K}_1$, we obtain the following from (6.10) and (6.11):

$$\mathcal{P}\left[x^* - \sum_{i=1}^m \lambda_i^* \nabla g_i(x^*)\right] - x^* = 0. \tag{6.12}$$

For $i \notin I(x^*)$, $g_i(x^*) < 0$. Since $p_k \to \infty$, we have $p_k g_i(x^k) \to -\infty$ as $k \to \infty$, $k \in \mathcal{K}$. Note that $\{\frac{\lambda_i^k}{1+\|\lambda^k\|}\}$ is bounded. Using condition (A5) and (6.8), we obtain

$$\lim_{k\to\infty, k\in\mathcal{K}} \lambda_i^{k+1} = \lim_{k\to\infty, k\in\mathcal{K}} W'\left(p_k g_i(x^k), \frac{\lambda_i^k}{1+\|\lambda^k\|}\right) = 0.$$

Thus, by (6.10), $\lambda_i^* = 0$ for $i \notin I(x^*)$. Therefore, we obtain from (6.12) that

$$\mathcal{P}\left[x^* - \sum_{i\in I(x^*)} \lambda_i^* \nabla g_i(x^*)\right] - x^* = 0.$$

So, x^* is degenerate.

Case (ii): $\{\lambda^{k+1}\}_{\mathcal{K}}$ is bounded. In this case, there exists an infinite subsequence $\mathcal{K}_2 \subseteq \mathcal{K}$ such that $\lim_{k\to\infty, k\in\mathcal{K}_2} \lambda^{k+1} = \lambda^* \ge 0$. So, taking the limit in (6.9) gives rise to

$$\mathcal{P}\left[x^* - \nabla f(x^*) - \sum_{i=1}^m \lambda_i^* \nabla g_i(x^*)\right] - x^* = 0. \tag{6.13}$$

We claim that $g_i(x^*) \le 0$ for $i = 1, \ldots, m$. Otherwise, if $g_i(x^*) > 0$ for some i, then $p_k g_i(x^k) \to \infty$, $k \to \infty$, $k \in \mathcal{K}$. Since the convexity of $W(\cdot, t)$ and property (A7) imply that $\lim_{s\to\infty} W_s'(s, t) = \infty$ for any fixed $t \in [0, \infty)$, we have

$$\lambda_i^{k+1} = W_s'\left(p_k g_i(x^k), \frac{\lambda_i^k}{1+\|\lambda^k\|}\right) \to \infty, \quad k \to \infty,\ k \in \mathcal{K},$$

contradicting the boundedness of $\{\lambda_i^{k+1}\}$. Thus, x^* is a feasible solution to (P). If $g_i(x^*) < 0$ for some i, then, as in Case (i), we can show that $\lambda_i^* = 0$. Therefore, we have

$$g_i(x^*) \le 0,\ \lambda_i^* g_i(x^*) = 0, \quad i = 1, \ldots, m.$$

This together with (6.13) implies that x^* is a KKT point of (P) and λ^* is the corresponding optimal multiplier vector. □

7. Concluding remarks. Convergence analysis of the augmented Lagrangian methods has not been well established for constrained global optimization. We have advanced the state of the art of this subject by presenting in this paper new convergence results for the augmented Lagrangian methods in the context of constrained global optimization. The convergence to a global optimal solution has been established for the basic primal-dual scheme under standard conditions. One key assumption in the traditional convergence analysis is that the multiplier sequence generated by the algorithm is bounded. This assumption has been indispensable in the previous convergence analysis for many augmented Lagrangian methods. We have showed that this restrictive condition can be circumvented by using a safeguarding strategy. We have further proposed the modified primal-dual scheme using a conditional multiplier updating strategy and the normalized multiplier method which enable us to achieve the convergence results without the boundedness assumption for the multiplier sequence. Finally, we have established the convergence of the normalized multiplier method for a KKT point.

It turns out that there exist difficulties in the convergence analysis for Algorithm 3 under Mangasarian's augmented Lagrangian L_2 and for Algorithm 4 under the normalized exponential-type augmented Lagrangian L_3. It will be interesting to further investigate these problems in our future research. Another interesting research topic is to identify certain classes of nonconvex optimization problems whose augmented Lagrangian relaxation problems can be *globally* solved efficiently.

Acknowledgments. The authors are grateful to the two anonymous referees for their valuable comments and constructive suggestions for improving the paper. In particular, the investigation of the safeguarding strategy for the augmented Lagrangian methods was suggested by one of the anonymous referees.

MATHEMATICAL PROGRAMMING PROBLEMS GOVERNED BY NONLINEAR ELLIPTIC PDES*

M. D. VOISEI†

Abstract. The aim of this article is to find explicit necessary conditions for local optimal pairs of problems governed by divergence-type elliptic PDEs, in terms depending on the nonlinearities involved in the cost functional and state equation. Several examples of optimization problems governed by ODEs and PDEs are presented.

Key words. nonlinear programming, quasi-linear elliptic equations, generalized Jacobian, p-Laplacian, minimal surface equation

1. Introduction.

Our main purpose in this paper is to find the optimality conditions satisfied by local optimal pairs (x^*, u^*) of the problem

$$\begin{aligned} \text{(P)} \qquad & \text{Minimize } g(x) + h(u), \text{ on all } (x,u) \in H_0^1(\Omega) \times U, \text{ subject to} \\ \text{(NE)} \qquad & -\operatorname{div} a(\nabla x) + \beta(x) = Bu + f \qquad \text{in } \Omega, \\ & x = 0 \qquad \text{on } \partial\Omega. \end{aligned}$$

Here $\Omega \subset \mathbb{R}^N$ is a bounded C^2-domain, U is a Hilbert space or a reflexive Banach space with a separable dual, $g : L^2(\Omega) \to \mathbb{R}$ is Lipschitz continuous near x^*, $h : U \to \mathbb{R} \cup \{\infty\}$ is proper convex lower semicontinuous, $B \in L(U; L^2(\Omega))$, $f \in L^2(\Omega)$, $a : \mathbb{R}^N \to \mathbb{R}^N$ is strongly monotone and Lipschitz continuous, and $\beta : \mathbb{R} \to \mathbb{R}$ is Lipschitz continuous with a small Lipschitz constant or monotone.

There exists an extensive literature on optimality conditions associated to optimal pairs of optimization problems governed by elliptic PDEs. For state and boundary controlled problems in the semilinear elliptic case we mention [2, 4, 5, 8, 15], while the optimal control of differentiable quasi-linear elliptic PDEs has been studied in [6, 7, 11].

Until now, for quasi-linear elliptic PDEs of the form (NE) with Lipschitz continuous nonlinearities a and β, only selective cases of (P) have been studied; $\beta = 0$ or a linear (see, e.g., [3, 17, 18, 19]). The optimality conditions found in these special cases are not clearly expressed in terms of a and β. The nonlinear Lipschitzian a and β case has not been studied in the literature, and this is the goal of the present note. Moreover, the explicit form of our necessary optimality conditions broadens the area of applications to optimal control problems governed by nonlinear divergence-type elliptic PDEs (see section 3 below).

There is a significant difference between the linear and nonlinear "a" cases in problem (P). Recall that by the Helmholtz decomposition $a(\nabla x) = \nabla p + f_0$, where $x \in H_0^1(\Omega)$, $p \in L^2(\Omega)$, $\operatorname{div} f_0 = 0$ (see, e.g., [16, Lemma 2.5.1, p. 81]). For "a" linear we know that $f_0 = 0$ for every x. For a nonlinear a, the state equation (NE) provides information about p only indirectly.

There are several advances of this paper over previous results. On one hand, our necessary conditions are derived under less restricting hypotheses, they have an explicit form in terms of the generalized Jacobian of a and generalized gradient of β, and the controlling parameters have better regularity (see Theorem 2.1 below). On the other hand, all necessary conditions previously derived in these settings are particularizations of our conditions of optimality (see [3, 18, 19, 20]).

Our main approach to the maximum principle is based on a family of approximation problems governed by linear state equations. The approximative optimality conditions are found via the closed range theorem. Three primary difficulties must be overcome. First, the existence of approximative optimal solutions requires a special penalization of the cost functional. Second, the process of passing to limit demands a good regularity for a and the controlling parameters. Finally, generalized gradients of integral-type functionals need to be expressed in a clear form. All of these can be fulfilled under the present framework and set of assumptions.

For a general Banach space X we denote by $||\cdot||_X$ the norm in X, by $\langle\cdot,\cdot\rangle_{X\times X^*}$ the duality product between X and X^*, and by $(\cdot,\cdot)_X$ the inner product of X whenever X is a Hilbert space.

Recall that, for a linear operator $A : X \to Y$, $N(A) = \{x \in X;\ Ax = 0\}$ denotes the kernel or null space of A, $R(A) = \{y = Ax;\ x \in D(A)\}$ stands for the range of A, and the adjoint of A is the operator $A^* : Y^* \to X^*$ defined by $x^* = A^*y^*$ iff $\langle x, x^*\rangle_{X\times X^*} = \langle Ax, y^*\rangle_{Y\times Y^*}$ for every $x \in X$.

The indicator of a subset $M \subset X$ is given by $I_M(x) = 0$ for $x \in M$ and $I_M(x) = \infty$ otherwise.

The directional derivative of $f : X \to \mathbb{R}$ at $x \in X$ in the direction of $v \in X$ is given by

$$f^\circ(x; v) = \limsup_{\bar{x}\to x, t\downarrow 0} (1/t)(f(\bar{x} + tv) - f(\bar{x})). \tag{1}$$

Throughout this article "∂" will denote the Clarke generalized gradient or the convex subdifferential. We refer to Clarke [9] for the results about generalized gradients of locally Lipschitz functions and to Zălinescu [21] for the results of convex analysis used in this paper.

The plan of the paper is as follows. Section 2 deals with the abstract optimality conditions for optimal pairs of problem (P). In section 3 several examples of problems governed by ODEs and PDEs and diverse uses of the optimality conditions are presented.

2. A problem governed by a divergence-type elliptic PDE. In what follows we study the optimality conditions for local optimal pairs (x^*, u^*) of problem (P) under the assumptions that $N \geq 1$, Ω is a bounded C^2-domain in $\mathbb{R}^N$, U is a Hilbert space or a reflexive Banach space with a separable dual, $g : L^2(\Omega) \to \mathbb{R}$ is Lipschitz continuous near x^*, $h : U \to \mathbb{R}\cup\{\infty\}$ is proper convex lower semicontinuous, $B : U \to L^2(\Omega)$ is linear bounded, $f \in L^2(\Omega)$, $a : \mathbb{R}^N \to \mathbb{R}^N$ is strongly monotone and Lipschitz continuous; i.e., there exist $L \geq K > 0$ such that for every $r_1, r_2 \in \mathbb{R}^N$

$$(a(r_1) - a(r_2), r_1 - r_2)_{\mathbb{R}^N} \geq K\|r_1 - r_2\|^2_{\mathbb{R}^N}, \tag{2}$$

$$\|a(r_1) - a(r_2)\|_{\mathbb{R}^N} \leq L\|r_1 - r_2\|_{\mathbb{R}^N}, \tag{3}$$

and $\beta : \mathbb{R} \to \mathbb{R}$ is Lipschitz continuous; that is, for some $C_\beta > 0$,

$$|\beta(v_1) - \beta(v_2)| \leq C_\beta|v_1 - v_2|,\ v_1, v_2 \in \mathbb{R}. \tag{4}$$

In addition, we assume that one of the following hypotheses holds:

(H1) $K\lambda_1 > C_\beta$, where $\lambda_1 = \inf\{\frac{\int_\Omega \|\nabla x\|^2_{\mathbb{R}^N} d\omega}{\int_\Omega x^2 d\omega};\ x \in H^1_0(\Omega), x \neq 0\}$ is the first eigenvalue of $-\Delta$ in Ω, with zero Dirichlet boundary condition, or

(H2) β is monotone, i.e., $(\beta(v_1) - \beta(v_2))(v_1 - v_2) \geq 0$, for every $v_1, v_2 \in \mathbb{R}$.

We may assume, without loss of generality, that $\beta(0) = 0$ and $a(0) = 0$. Also, we implicitly understand that the set of admissible pairs is nonempty; i.e., at least (x^*, u^*) satisfies (NE) and $u^* \in \mathrm{dom}\,(h)$ (the domain of h).

As we will see in the subsequent Proposition 2.2, conditions (H1) or (H2) ensure the strong monotonicity of the operator $-\mathrm{div}\ a(\nabla\cdot) + \beta$. This allows us to consider problem (P) as a particular case of the general strongly monotone case studied in [19]. The main improvement provided by the present approach is that, for this specific problem, the optimality conditions can be precisely expressed in terms of the general Jacobian of a and the generalized gradient of β. Some reasons why the condition explicit form is important for applications are that numerical schemes can be built upon the optimality conditions and that the study of qualitative behavior of solutions for certain differential equations is enhanced (see section 3 below).

The analysis of the regularity for the solutions of (NE) as well as the structure of (NE) is needed for future purposes. It is easily seen that the operator $A = -\mathrm{div}\ a(\nabla\cdot) : H^1_0(\Omega) \to H^{-1}(\Omega)$, given by

$$\langle Ax, \varphi\rangle_{H^1_0(\Omega)\times H^{-1}(\Omega)} = \int_\Omega (a(\nabla x), \nabla\varphi)_{\mathbb{R}^N} d\omega,\ \varphi \in H^1_0(\Omega),\ x \in H^1_0(\Omega),$$

is maximal strongly monotone, Lipschitz continuous, invertible, with Lipschitz continuous inverse A^{-1}. The restriction of A to $L^2(\Omega)$

$$A_{L^2} : D(A_{L^2}) = \{x \in H^1_0(\Omega); Ax \in L^2(\Omega)\} \subset L^2(\Omega) \to L^2(\Omega)$$

given by $A_{L^2}x = Ax$, $x \in D(A_{L^2})$, is maximal strongly monotone. The realization $\beta : L^2(\Omega) \to L^2(\Omega)$ is C_β-Lipschitz continuous and monotone whenever β is monotone. Under these terms (NE) has the form

$$A_{L^2}\, x + \beta(x) = Bu + f \text{ in } L^2(\Omega). \tag{5}$$

LEMMA 2.1. *If $a : \mathbb{R}^N \to \mathbb{R}^N$ is strongly monotone and Lipschitz continuous, then*

(a) $D(A_{L^2}) = H^1_0(\Omega) \cap H^2(\Omega)$.

If, in addition, $\nabla^2 a = \left(\dfrac{\partial^2 a}{\partial r_i \partial r_j}\right)_{i,j=1}^N \in L^\infty(\mathbb{R}^N; \mathbb{R}^{N^3})$, *then*

(b) $A : H^1_0(\Omega) \cap H^2(\Omega) \to L^2(\Omega)$ *is locally Lipschitz continuous.*

Proof. (a) Since a is Lipschitz continuous, the superposition

$$a : \mathbb{H}^1(\Omega) := (H^1(\Omega))^N \to \mathbb{H}^1(\Omega),\ a(w) = a \circ w,\ w \in \mathbb{H}^1(\Omega),$$

is well-defined and continuous (see, e.g., [14, Theorem 1, p. 219]).

This makes $-\mathrm{div}\ a(\nabla\cdot) : H^1_0(\Omega) \cap H^2(\Omega) \to L^2(\Omega)$ well-defined; that is, $H^1_0(\Omega) \cap H^2(\Omega) \subset D(A_{L^2})$. For the converse inclusion consider the approximations

$$a_\epsilon(r) = \int_{\mathbb{R}^N} a(r - \epsilon s)J(s)ds = \int_{\mathbb{R}^N} a(s)J_\epsilon(r - s)ds,\ r \in \mathbb{R}^N, \tag{6}$$

where $J \in C_0^\infty(\mathbb{R}^N)$, $\int_{\mathbb{R}^N} J(s)ds = 1$, $J \geq 0$, $J(r) = 0$ for $\|r\|_{\mathbb{R}^N} \geq 1$, $J_\epsilon(r) = \epsilon^{-N} J(r/\epsilon)$, $r \in \mathbb{R}^N$. Recall that a_ϵ is C^1-smooth strongly monotone and Lipschitz continuous with

$$(a_\epsilon(r_1) - a_\epsilon(r_2), r_1 - r_2)_{\mathbb{R}^N} \geq K\|r_1 - r_2\|^2_{\mathbb{R}^N}, \tag{7}$$

$$\|a_\epsilon(r_1) - a_\epsilon(r_2)\|_{\mathbb{R}^N} \leq L\|r_1 - r_2\|_{\mathbb{R}^N}, \tag{8}$$

for every $r_1, r_2 \in \mathbb{R}^N$, and $\|a_\epsilon(r) - a(r)\|_{\mathbb{R}^N} \leq \epsilon L$, for every $r \in \mathbb{R}^N$, (see, e.g., [1, Lemma 2.18, p. 29]).

Whenever $b \in C^1(\mathbb{R}^N)$ the equation $-\text{div } b(\nabla x) = f$, with $f \in L^2(\Omega)$, has a unique solution $x \in H_0^1(\Omega) \cap H^2(\Omega)$ and

$$\|x\|_{H_0^1(\Omega)\cap H^2(\Omega)} \leq C(\|\nabla b\|_{L^\infty})(\|f\|_{L^2(\Omega)} + 1), \tag{9}$$

where $C = C(\|\nabla b\|_{L^\infty}) > 0$ depends proportionally on $\|\nabla b\|_{L^\infty}$ in the sense that the operator $||\nabla a||_{L^\infty} \to C$ is bounded (see, e.g., [12, Remark, p. 498]).

Consider $x \in D(A_{L^2})$. Let $x_\epsilon \in H_0^1(\Omega) \cap H^2(\Omega)$ be the unique solution of $-\text{div } a_\epsilon(\nabla x_\epsilon) = Ax$. We get the following uniform "a priori" estimate:

$$\|x_\epsilon\|_{H_0^1(\Omega)\cap H^2(\Omega)} \leq C(||Ax||_{L^2(\Omega)} + 1),$$

with $C < \infty$, because $\|\nabla a_\epsilon\|_{L^\infty} \leq \|\nabla a\|_{L^\infty} \leq L$ for every $\epsilon > 0$.

This shows that, eventually on a subnet, $x_\epsilon \to x_0$, weakly in $H_0^1(\Omega) \cap H^2(\Omega)$, strongly in $H_0^1(\Omega)$, $\nabla x_\epsilon \to \nabla x_0$, strongly in $L^2(\Omega)$, and $a_\epsilon(\nabla x_\epsilon) \to a(\nabla x_0)$, strongly in $L^2(\Omega)$, by the Lebesgue dominated convergence theorem.

We find that x_0 satisfies $-\text{div } a(\nabla x_0) = Ax$ in $H_0^1(\Omega)$; hence, $x = x_0 \in H_0^1(\Omega) \cap H^2(\Omega)$ and $\|x\|_{H_0^1(\Omega)\cap H^2(\Omega)} \leq C(||Ax||_{L^2(\Omega)}+1)$. Therefore $D(A_{L^2}) \subset H_0^1(\Omega)\cap H^2(\Omega)$.

(b) Condition $\nabla^2 a \in L^\infty(\mathbb{R}^N; \mathbb{R}^{N^3})$ is equivalent to

$$\|\nabla a(r_1) - \nabla a(r_2)\|_{\mathbb{R}^{N^2}} \leq M\|r_1 - r_2\|_{\mathbb{R}^N} \tag{10}$$

for every $r_1, r_2 \in \mathbb{R}^N$, where $M = \|\nabla^2 a\|_{L^\infty} < \infty$.

Since $a_\epsilon \in C^1(\mathbb{R}^N)$ for every $w \in \mathbb{H}^1(\Omega)$, the following chain rule holds:

$$\nabla(a_\epsilon(w)) = \nabla a_\epsilon(w) \cdot \nabla w, \text{ a.e. in } \Omega, \ \epsilon > 0. \tag{11}$$

Using the identity

$$\nabla(a_\epsilon(w_1)) - \nabla(a_\epsilon(w_2)) = [\nabla a_\epsilon(w_1) - \nabla a_\epsilon(w_2)] \cdot \nabla w_1 + \nabla a_\epsilon(w_2) \cdot [\nabla w_1 - \nabla w_2]$$

we find

$$\|\nabla(a_\epsilon(w_1)) - \nabla(a_\epsilon(w_2))\|_{\mathbb{L}^2} \leq \|\nabla^2 a_\epsilon\|_{L^\infty}\|w_1 - w_2\|_{\mathbb{L}^2}\|w_1\|_{\mathbb{H}^1} + L\|w_1 - w_2\|_{\mathbb{H}^1}$$

for every $w_1, w_2 \in \mathbb{R}^N$, where $\mathbb{L}^2(\Omega) := (L^2(\Omega))^N$.

Notice that $\nabla^2 a \in L^\infty(\mathbb{R}^N; \mathbb{R}^{N^3})$ implies $\nabla^2 a_\epsilon \in L^\infty(\mathbb{R}^N; \mathbb{R}^{N^3})$, with

$$\|\nabla^2 a_\epsilon\|_{L^\infty} \leq \|\nabla^2 a\|_{L^\infty} \text{ for every } \epsilon > 0.$$

From $\|\nabla(a(w_1)) - \nabla(a(w_2))\|_{\mathbb{L}^2} = \lim_{\epsilon\to 0} \|\nabla(a_\epsilon(w_1)) - \nabla(a_\epsilon(w_2))\|_{\mathbb{L}^2}$ we get

$$\|\nabla(a(w_1)) - \nabla(a(w_2))\|_{\mathbb{L}^2} \leq \|\nabla^2 a\|_{L^\infty}\|w_1 - w_2\|_{\mathbb{L}^2}\|w_1\|_{\mathbb{H}^1} + L\|w_1 - w_2\|_{\mathbb{H}^1} \tag{12}$$

for every $w_1, w_2 \in \mathbb{R}^N$; i.e., $a : \mathbb{H}^1(\Omega) \to \mathbb{H}^1(\Omega)$ is locally Lipschitz continuous. Taking into account that $-\mathrm{div} : \mathbb{H}^1(\Omega) \to L^2(\Omega)$ is bounded this yields that $A : H_0^1(\Omega) \cap H^2(\Omega) \to L^2(\Omega)$ is locally Lipschitz continuous. □

PROPOSITION 2.1. *Suppose that all of the above assumptions, including* (H1) *or* (H2)*, hold. Then, for every* $f \in L^2(\Omega)$*, the problem*

$$-\mathrm{div}\, a(\nabla x) + \beta(x) = f \text{ in } \Omega, \quad x = 0 \text{ on } \partial\Omega, \tag{13}$$

has a unique solution $x \in H_0^1(\Omega) \cap H^2(\Omega)$.

Proof. From Lemma 2.1 we know that $D(A_{L^2}) \subset H_0^1(\Omega) \cap H^2(\Omega)$. To conclude it is sufficient to prove that $A_{L^2} + \beta$ is surjective.

We claim that conditions (H1) or (H2) imply that $A_{L^2} + \beta$ is maximal strongly monotone and thus surjective. Clearly, this holds if (H2) is fulfilled. The strong monotonicity also assures the uniqueness of (NE) solutions.

Assume that (H1) holds. For every $\varphi_1, \varphi_2 \in D(A_{L^2})$, we have

$$\begin{aligned}((A_{L^2} + \beta)\varphi_1 - (A_{L^2} + \beta)\varphi_2, \varphi_1 - \varphi_2)_{L^2} &= \langle (A + \beta)\varphi_1 - (A + \beta)\varphi_2, \varphi_1 - \varphi_2 \rangle \\ &= \int_\Omega (a(\nabla\varphi_1) - a(\nabla\varphi_2), \nabla(\varphi_1 - \varphi_2))_{\mathbb{R}^N} d\omega + \int_\Omega (\beta(\varphi_1) - \beta(\varphi_2))(\varphi_1 - \varphi_2) d\omega \\ &\geq K\|\nabla(\varphi_1 - \varphi_2)\|_{\mathbb{L}^2}^2 - C_\beta\|\varphi_1 - \varphi_2\|_{L^2}^2 \geq (K\lambda_1 - C_\beta)\|\varphi_1 - \varphi_2\|_{L^2}^2,\end{aligned}$$

where $\langle \cdot, \cdot \rangle$ stands for the dual product in $H_0^1(\Omega) \times H^{-1}(\Omega)$, and we used the Poincaré inequality $\|\varphi\|_{H_0^1} = \|\nabla\varphi\|_{\mathbb{L}^2} \geq \lambda_1^{1/2}\|\varphi\|_{L^2}$, $\varphi \in H_0^1(\Omega)$.

Therefore $A_{L^2} + \beta$ is strongly monotone. It remains to show that $A_{L^2} + \beta$ is maximal monotone provided that $K\lambda_1 > C_\beta$.

Fix ν such that $C_\beta/\lambda_1 < \nu < K$. We write

$$(A_{L^2} + \beta)x = -\mathrm{div}(a - \nu)(\nabla x) + \nu(-\Delta x - (C_\beta/\nu)x) + (C_\beta x + \beta(x)),$$

$x \in D(A_{L^2})$. The operator $\mathbb{R}^N \ni y \longmapsto a(y) - \nu y$ is maximal strongly monotone, since it is continuous defined everywhere and $\nu < K$. This yields that $H_0^1(\Omega) \ni x \longmapsto -\mathrm{div}(a - \nu)(\nabla x) \in H^{-1}(\Omega)$ is maximal strongly monotone. Similarly $H_0^1(\Omega) \ni x \longmapsto -\Delta x - (C_\beta/\nu)x \in H^{-1}(\Omega)$ is maximal strongly monotone and defined everywhere because $C_\beta/\nu < \lambda_1$. Hence, the sum

$$H_0^1(\Omega) \ni x \longmapsto -\mathrm{div}(a - \nu)(\nabla x) + \nu(-\Delta x - (C_\beta/\nu)x) \in H^{-1}(\Omega)$$

is maximal strongly monotone, making its restriction to $L^2(\Omega)$ maximal monotone. Clearly, $L^2(\Omega) \ni x \longmapsto C_\beta x + \beta(x) \in L^2(\Omega)$ is maximal monotone continuous and defined everywhere. Using a perturbation theorem, we get that $A_{L^2} + \beta$ is maximal monotone in $L^2(\Omega)$. □

Remark 2.1. Without (H1), (H2) the state equation (NE) may not have solutions. Take $n = 1$, $a(r) = r$, $\beta(v) = -v$, $r, v \in \mathbb{R}$, $\Omega = (0, \pi)$, $B \equiv 0$, $f \in L^2(0, \pi)$. Then (NE) becomes

$$-x'' - x = f \text{ in } (0, \pi), \quad x(0) = x(\pi) = 0. \tag{14}$$

For this choice of a, β, and Ω we have $K = C_\beta = \lambda_1 = 1$, and (H1), (H2) fail. The general solution of the differential equation in (14) is

$$x(t) = C_1 \cos t + C_2 \sin t + \int_0^t \sin(t - s) f(s) ds, \ t \in (0, \pi), \tag{15}$$

with $C_{1,2}$ constants. The boundary condition reduces to

$$C_1 = 0,\ \int_0^\pi \sin(t)f(t)dt = 0.$$

Hence (14) has the solution $x(t) = C_2 \sin t + \int_0^t \sin(t-s)f(s)ds$ iff $\int_0^\pi \sin(t)f(t)dt = 0$.

The next proposition describes the generalized gradient of some special Lipschitz-type functionals together with some of its robustness properties and "a priori" estimates. The conclusions of this result form the main tool used in the derivation of optimality conditions via an approximation procedure.

PROPOSITION 2.2. *Let X be a Banach spaces, Y be a Hilbert space, and $f : X \to Y$ be a locally Lipschitz continuous function.*

Define $S : X \times Y \to \mathbb{R}$ by

$$S(x,y) = (1/2)||y - f(x)||_Y^2,\ x \in X,\ y \in Y. \tag{16}$$

For $\delta \in Y$, define $f_\delta : X \to \mathbb{R}$ by $f_\delta(x) = -(\delta, f(x))_Y,\ x \in X$, where $(\cdot,\cdot)_Y$ stands for the inner product of Y. Then

(a) *S is locally Lipschitz continuous in $X \times Y$, and f_δ is locally Lipschitz continuous in X for every $\delta \in Y$;*

(b) *$(\alpha, \delta) \in \partial S(x,y)$ iff $\delta = y - f(x)$ and $\alpha \in \partial f_\delta(x)$;*

(c) *$||\alpha||_{X^*} \le C||\delta||_Y$ for every $(\alpha,\delta) \in \partial S(x,y)$, where C is a Lipschitz constant of f near x;*

(d) *if $\alpha_\epsilon \in \partial f_{\delta_\epsilon}(x_\epsilon)$ for every $\epsilon > 0$, and for $\epsilon \downarrow 0$*

$$\begin{aligned} &(1/\epsilon)\alpha_\epsilon \to \alpha,\ \text{weakly in } X^*,\\ &(1/\epsilon)\delta_\epsilon \to \delta,\ \text{strongly in } Y,\\ &x_\epsilon \to x,\ \text{strongly in } X, \end{aligned}$$

then $\alpha \in \partial f_\delta(x)$;

(e) *if in addition $X = Y$ and f is strongly monotone, i.e., for some $K \ge 0$,*

$$(x_1 - x_2, f(x_1) - f(x_2))_Y \ge K||x_1 - x_2||_Y^2 \text{ for every } x_1, x_2 \in Y, \tag{17}$$

then every $\alpha \in \partial f_\delta(x)$ satisfies

$$(\alpha, -\delta)_Y \ge K||\delta||_Y^2 \text{ and } ||\alpha||_Y \ge K||\delta||_Y. \tag{18}$$

Remark 2.2. Note that if the Hilbert space Y is not identified with its dual Y^*, then we can restate (b) as

$$X^* \times Y^* \ni (\alpha,\delta) \in \partial S(x,y) \text{ iff } \delta = J_Y(y - f(x)),\ \alpha \in \partial f_\delta(x), \tag{19}$$

where $J_Y : Y \to Y^*$ is the dual mapping of Y and $f_\delta(x) = -\langle \delta, f(x)\rangle_{Y \times Y^*}$, $x \in X$.

Proof. The proof of (a) is plain. For every $x, v \in X$, $y, w \in Y$ we have

$$\begin{aligned} S^0(x,y;v,w) &= \limsup_{(\overline{x},\overline{y}) \to (x,y), t \downarrow 0} (1/2t)(||\overline{y} + tw - f(\overline{x} + tv)||_Y^2 - ||\overline{y} - f(\overline{x})||_Y^2)\\ &= \limsup_{\overline{x} \to x, t \downarrow 0} (y - f(x), w - (1/t)[f(\overline{x} + tv) - f(\overline{x})])_Y\\ &= (y - f(x), w)_Y + f^0_{(y-f(x))}(x; v). \end{aligned}$$

Therefore $S^0(x,y;v,w) = (y - f(x), w)_Y + f^0_{(y-f(x))}(x;v)$ for every $x, v \in X$, $y, w \in Y$, and (b) follows.

(c) If $X^* \times Y \ni (\alpha, \delta) \in \partial S(x,y)$, then, according to (b), $\delta = y - f(x)$ and $\alpha \in \partial f_\delta(x)$. From $\alpha \in \partial f_\delta(x)$ we find

$$\langle \alpha, v\rangle_{X\times X^*} \le \limsup_{\overline{x}\to x, t\downarrow 0} -(1/t)(\delta, f(\overline{x}+tv) - f(\overline{x}))_Y \le C||\delta||_Y||v||_X \quad \forall v \in X,$$

where C is a Lipschitz constant of f near x.

This final inequality provides us with $||\alpha||_{X^*} \le C||\delta||_Y$.

(d) Clearly $\alpha_\epsilon \in \partial f_{\delta_\epsilon}(x_\epsilon)$ means

$$\langle \alpha_\epsilon, v\rangle_{X\times X^*} \le \limsup_{\widetilde{x}\to x_\epsilon, t\downarrow 0} -(1/t)(\delta_\epsilon, f(\widetilde{x}+tv) - f(\widetilde{x}))_Y$$

for every fixed $v \in X$. Thus, there exist $t_\epsilon \in (0,\epsilon)$, $\widetilde{x}_\epsilon \in X$ such that $\|\widetilde{x}_\epsilon - x_\epsilon\|_X < \epsilon$ and $\langle \alpha_\epsilon, v\rangle_{X\times X^*} \le -(1/t_\epsilon)(\delta_\epsilon, f(\widetilde{x}_\epsilon + t_\epsilon v) - f(\widetilde{x}_\epsilon))_Y + \epsilon$ for every $\epsilon > 0$.

Hence

$$\begin{aligned}\langle (1/\epsilon)\alpha_\epsilon, v\rangle_{X\times X^*} \le{}& -(1/t_\epsilon)(\delta, f(\widetilde{x}_\epsilon + t_\epsilon v) - f(\widetilde{x}_\epsilon))_Y \\ & - (1/t_\epsilon)((1/\epsilon)\delta_\epsilon - \delta, f(\widetilde{x}_\epsilon + t_\epsilon v) - f(\widetilde{x}_\epsilon))_Y + \epsilon. \end{aligned} \tag{20}$$

Because $(1/\epsilon)\delta_\epsilon \to \delta$ strongly in Y and $((1/t_\epsilon)(f(\widetilde{x}_\epsilon + t_\epsilon v) - f(\widetilde{x}_\epsilon))_\epsilon$ is bounded in Y, we have $\lim_{\epsilon\downarrow 0}(1/t_\epsilon)((1/\epsilon)\delta_\epsilon - \delta, f(\widetilde{x}_\epsilon + t_\epsilon v) - f(\widetilde{x}_\epsilon))_Y = 0$.

Let $\epsilon \downarrow 0$ in (20). We get

$$\begin{aligned}\langle \alpha, v\rangle_{X\times X^*} &= \lim_{\epsilon\downarrow 0}\langle (1/\epsilon)\alpha_\epsilon, v\rangle_{X\times X^*} \le \limsup_{\epsilon\downarrow 0} -(1/t_\epsilon)(\delta, f(\widetilde{x}_\epsilon + t_\epsilon v) - f(\widetilde{x}_\epsilon))_Y \\ &\le \limsup_{\widetilde{x}\to x, t\downarrow 0} -(1/t)(\delta, f(\widetilde{x}+tv) - f(\widetilde{x}))_Y = f^0_\delta(x; v)\end{aligned}$$

for every $v \in X$, since $\widetilde{x}_\epsilon \to x$ strongly in X and $t_\epsilon \downarrow 0$ for $\epsilon \downarrow 0$. This shows that $\alpha \in \partial f_\delta(x)$.

(e) Notice that, by (17), for every $\bar{x} \in X$ we have

$$(1/t)\{f_\delta(\bar{x}+t\delta) - f_\delta(\bar{x})\} = -(1/t^2)(t\delta, f(\bar{x}+t\delta) - f(\bar{x}))_Y \le -K\,||\delta||^2_Y.$$

Hence $f^0_\delta(x;\delta) \le -K\,||\delta||^2_Y$. This is sufficient in order to conclude. □

It is known that $-\mathrm{div} : (L^2(\Omega))^N \to H^{-1}(\Omega)$ is linear bounded and $(-\mathrm{div})^* p = \nabla p = (\frac{\partial p}{\partial \omega_i})_{i=1}^N$, $p \in H^1_0(\Omega)$ (see, e.g., [16, p. 80]).

THEOREM 2.1. *Suppose that all the above assumptions, including* (H1) *or* (H2), *hold and* $\nabla^2 a \in L^\infty(\mathbb{R}^N; \mathbb{R}^{N^3})$. *If* $(x^*, u^*) \in H^1_0(\Omega) \times U$ *is a local solution of* (P), *then there exist* $p \in H^1_0(\Omega) \cap H^2(\Omega)$, $\gamma, l \in L^2(\Omega)$, $\eta \in \mathbb{L}^2(\Omega)$ *such that*

(i) $\partial g(x^*) + l + \gamma \ni 0$,
(ii) $B^* p \in \partial h(u^*)$,
(iii) $l = -\mathrm{div}\,\eta, \eta(\omega) \in \partial a(\nabla x^*(\omega))(\nabla p(\omega))$, *a.e.* ω *in* Ω,
(iv) $\gamma(\omega) \in p(\omega)\partial\beta(x^*(\omega))$, *a.e.* ω *in* Ω.

Here ∂a *stands for the generalized Jacobian of* a, *and* $\partial\beta$ *denotes the generalized gradient of* β.

Proof. Let $d = a - \nu i$, where $i(x) = x$, $x \in \mathbb{R}^N$, and $0 < \nu < K$. Notice that d is invertible, Lipschitz continuous with Lipschitz constant $L + \nu$, and maximal strongly monotone with constant $K - \nu > 0$. We denote by $D = -\mathrm{div}\; d(\nabla\cdot)$.

Consider the following approximations of (P):

$$(\mathrm{P}_\epsilon)\quad \begin{array}{l}\text{(locally) minimize } G(x,y,z)+H(u,v),\\ \text{on all } (x,y,z,u,v)\in H_0^1(\Omega)\times\mathbb{L}^2(\Omega)\times L^2(\Omega)\times U\times L^2(\Omega)=:\mathcal{X},\\ \text{subject to } (f,0)=\mathcal{A}(x,y,z,u,v),\end{array}$$

where $\epsilon>0$, $G: H_0^1(\Omega)\times\mathbb{L}^2(\Omega)\times L^2(\Omega)\to\mathbb{R}$ is defined by

$$G(x,y,z)=g(x)+(1/2\epsilon)\|y-d(\nabla x)\|_{\mathbb{L}^2}^2+(1/2\epsilon)\,\|z-\beta(x)\|_{L^2}^2\,, \tag{21}$$

$x\in H_0^1(\Omega)$, $y\in\mathbb{L}^2(\Omega)$, $z\in L^2(\Omega)$, $H: U\times L^2(\Omega)\to\mathbb{R}\cup\{\infty\}$ is given by

$$H(u,v)=h(u)+(1/2)\,\|u-u^*\|_U^2+(1/2)\|v-D(x^*)\|_{L^2}^2\,, \tag{22}$$

$u\in U$, $v\in L^2(\Omega)$, $\mathcal{A}: H_0^1(\Omega)\times\mathbb{L}^2(\Omega)\times L^2(\Omega)\times U\times L^2(\Omega)\to H^{-1}(\Omega)\times H^{-1}(\Omega)$,

$$\mathcal{A}(x,y,z,u,v)=(-\nu\Delta x+z+v-Bu,\ \operatorname{div} y+v),(x,y,z,u,v)\in\mathcal{X}.$$

Here $-\Delta: H_0^1(\Omega)\to H^{-1}(\Omega)$ is the Laplace operator with a zero Dirichlet boundary condition. Notice that the state equation of (P_ϵ) is exactly

$$-\nu\Delta x+z+v=Bu+f,\ v=-\operatorname{div} y. \tag{23}$$

In the statement of (P_ϵ), by local minimization we understand that $(x,u)\in\mathcal{N}$, where $\mathcal{N}$ is a convex closed and bounded neighborhood of (x^*,u^*) in $L^2(\Omega)\times U$ in which (x^*,u^*) is a solution of (P).

Let $(x_n,y_n,z_n,u_n,v_n)_n$ be a minimizing sequence of (P_ϵ); that is,

$$\inf(\mathrm{P}_\epsilon)\le G(x_n,y_n,z_n)+H(u_n,v_n)\le\inf(\mathrm{P}_\epsilon)+1/n, \tag{24}$$

and $(f,0)=\mathcal{A}(x_n,y_n,z_n,u_n,v_n)$ for every $n\ge1$.

From the local minimization sense in which our problem is understood, we know that $(u_n)_n$ is bounded in U and $(x_n)_n$, $(\beta(x_n))_n$ are bounded in $L^2(\Omega)$. Subsequently from (24) we find that $(z_n)_n$, $(v_n)_n$ are bounded in $L^2(\Omega)$. Using the state equation (23), we see that $(\Delta x_n)_n$ is bounded in $L^2(\Omega)$; that is, $(x_n)_n$ is bounded in $H_0^1(\Omega)\cap H^2(\Omega)$. Again from (24) we get the boundedness of $(y_n)_n$ in $\mathbb{L}^2(\Omega)$. Eventually, on a subnet, denoted for simplicity by the same index, we have

$$(x_n,y_n,z_n,u_n,v_n)_n\to(x,y,z,u,y)\text{ weakly in }\mathcal{H},$$

where $\mathcal{H}=H_0^1(\Omega)\cap H^2(\Omega)\times\mathbb{L}^2(\Omega)\times L^2(\Omega)\times U\times L^2(\Omega)$,

$$x_n\to x\text{ strongly in }H_0^1(\Omega);\ \text{that is, }\nabla x_n\to\nabla x\text{ strongly in }\mathbb{L}^2(\Omega).$$

If we let $n\to\infty$ in (24) then we get that $(x,y,z,u,v)=:(x_\epsilon,y_\epsilon,z_\epsilon,u_\epsilon,v_\epsilon)$ is a solution of (P_ϵ), because G is strongly×weakly×weakly lower semicontinuous in $H_0^1(\Omega)\times\mathbb{L}^2(\Omega)\times L^2(\Omega)$ and H is lower semicontinuous in $U\times L^2(\Omega)$.

Since $(x_\epsilon,y_\epsilon,z_\epsilon,u_\epsilon,v_\epsilon)$ is optimal for (P_ϵ) and $(x^*,d(\nabla x^*),\beta(x^*),u^*,D(x^*))$ satisfies its state equation, we have

$$\begin{aligned}G(x_\epsilon,y_\epsilon,z_\epsilon)+H(u_\epsilon,v_\epsilon)&\le G(x^*,d(\nabla x^*),\beta(x^*))+H(u^*,D(x^*))\\ &=g(x^*)+h(u^*)=\inf(\mathrm{P})<\infty\text{ for every }\epsilon>0.\end{aligned} \tag{25}$$

Similarly, inequality (25) and the state equation $-\nu\Delta x_\epsilon + z_\epsilon + v_\epsilon = Bu_\epsilon + f$ show that $(x_\epsilon, y_\epsilon, z_\epsilon, u_\epsilon, v_\epsilon)_\epsilon$ is bounded in $\mathcal{H}$ and for $\epsilon \downarrow 0$

$$\begin{aligned} y_\epsilon - d(\nabla x_\epsilon) &\to 0 \text{ strongly in } \mathbb{L}^2(\Omega), \\ z_\epsilon - \beta(x_\epsilon) &\to 0 \text{ strongly in } L^2(\Omega). \end{aligned}$$

Eventually on a subnet, we have

$$\begin{aligned} &(x_\epsilon, y_\epsilon, z_\epsilon, u_\epsilon, v_\epsilon) \to (x_0, y_0, z_0, u_0, v_0) \text{ weakly in } \mathcal{H}, \\ &x_\epsilon \to x_0 \text{ strongly in } H_0^1(\Omega), \\ &y_\epsilon \to d(\nabla x_0) = y_0 \text{ strongly in } \mathbb{L}^2(\Omega), \\ &z_\epsilon \to \beta(x_0) = z_0 \text{ strongly in } L^2(\Omega), \\ &v_0 = -\text{div } y_0 = D(x_0), \end{aligned}$$

and $-\text{div } a(\nabla x_0) + \beta(x_0) = Bu_0 + f$. Since (x^*, u^*) is optimal for (P), the last equality allows us to continue (25) by

$$G(x_\epsilon, y_\epsilon, z_\epsilon) + H(u_\epsilon, v_\epsilon) \le g(x^*) + h(u^*) \le g(x_0) + h(u_0) \ \forall \epsilon > 0. \tag{26}$$

By passing to lim sup in (26), we find

$$\limsup_{\epsilon \downarrow 0} (1/2)\{\|v_\epsilon - D(x^*)\|_{L^2}^2 + \|u_\epsilon - u^*\|_U^2\} = 0;$$

that is, $v_\epsilon \to D(x^*)$ strongly in $L^2(\Omega)$ and $u_\epsilon \to u^* = u_0$ strongly in U. But $v_\epsilon \to D(x_0)$ weakly in $L^2(\Omega)$, so $Dx_0 = Dx^*$ and $x_0 = x^*$ since D is invertible. From the state equation $-\nu\Delta x_\epsilon + z_\epsilon + v_\epsilon = Bu_\epsilon + f$, we actually get that $x_\epsilon \to x^*$ strongly in $H_0^1(\Omega) \cap H^2(\Omega)$.

We proved that, eventually on a subnet of $\epsilon \downarrow 0$,

$$(x_\epsilon, y_\epsilon, z_\epsilon, u_\epsilon, v_\epsilon) \to (x^*, d(\nabla x^*), \beta(x^*), u^*, D(x^*)) \text{ strongly in } \mathcal{H}.$$

Problem (P_ϵ) has the form

$$\text{(locally) minimize } \tilde{G}(x, y, z, u, v) + \tilde{H}(x, y, z, u, v) + I_M(x, y, z, u, v),$$

where

$$\tilde{G}(x, y, z, u, v) = G(x, y, z), \ \tilde{H}(x, y, z, u, v) = H(u, v), \ (x, y, z, u, v) \in \mathcal{X},$$

and

$$M = \{(x, y, z, u, v) \in \mathcal{X}; (f, 0) = \mathcal{A}(x, y, z, u, v)\}$$

is a closed affine subset of $\mathcal{X}$, since $\mathcal{A} : \mathcal{X} \to H^{-1}(\Omega) \times H^{-1}(\Omega)$ is linear continuous.

Because local minimum points are critical, $(x_\epsilon, y_\epsilon, z_\epsilon, u_\epsilon, v_\epsilon)$ is optimal for (P_ϵ), and $\tilde{G}$ is locally Lipschitz continuous, we find that

$$0 \in \partial\tilde{G}(x_\epsilon, y_\epsilon, z_\epsilon u_\epsilon, v_\epsilon) + \partial(\tilde{H} + I_M)(x_\epsilon, y_\epsilon, z_\epsilon, u_\epsilon, v_\epsilon) \tag{27}$$

The state equation is solvable for every $u \in U$; i.e., the domain of $\tilde{H}$ $\text{dom}\,(\tilde{H}) = H_0^1(\Omega) \times \mathbb{L}^2(\Omega) \times L^2(\Omega) \times \text{dom}\,(h) \times L^2(\Omega)$ satisfies

$$\text{dom}\,(\tilde{H}) - M = \mathcal{X}. \tag{28}$$

More precisely, for every $(x,y,z,u,v)\in\mathcal{X}$ we can write

$$(x,y,z,u,v)=(x,y,z+B(u^*-u)+f,u^*,v)-(0,0,B(u^*-u)+f,u^*-u,0),$$

with $(x,y,z+B(u^*-u)+f,u^*,v)\in\operatorname{dom}\tilde{H}$, $(0,0,B(u^*-u)+f,u^*-u,0)\in M$.

Condition (28) guarantees that $\partial(\tilde{H}+I_M)=\partial\tilde{H}+\partial I_M$, taking into account that $\tilde{H}$, I_M are convex proper lower semicontinuous (see, e.g., [21, Theorem 2.8.7 (vii), p. 126]).

Also, it is easily checked that $\partial I_M(x,y,z,u,v)=N(\mathcal{A})^{\perp}$, $(x,y,z,u,v)\in\mathcal{X}$.

Since $R(\mathcal{A})=H^{-1}(\Omega)\times H^{-1}(\Omega)$, the closed range theorem provides

$$N(\mathcal{A})^{\perp}=R(\mathcal{A}^*),$$

and the optimality condition (27) reduces to

$$0\in\partial\tilde{G}(x_\epsilon,y_\epsilon,z_\epsilon u_\epsilon,v_\epsilon)+\partial\tilde{H}(x_\epsilon,y_\epsilon,z_\epsilon,u_\epsilon,v_\epsilon)+\mathcal{A}^*(p_\epsilon,q_\epsilon) \tag{29}$$

for some $p_\epsilon,q_\epsilon\in H_0^1(\Omega)$.

We have

$$\begin{gathered}\partial\tilde{G}(x_\epsilon,y_\epsilon,z_\epsilon,u_\epsilon,v_\epsilon)=\partial G(x_\epsilon,y_\epsilon,z_\epsilon)\times\{0\}\times\{0\},\\ \partial\tilde{H}(x_\epsilon,y_\epsilon,z_\epsilon,u_\epsilon,v_\epsilon)=\{0\}\times\{0\}\times\{0\}\times\partial H(u_\epsilon,v_\epsilon),\\ \mathcal{A}^*(p_\epsilon,q_\epsilon)=(-\nu\Delta p_\epsilon,-\nabla q_\epsilon,p_\epsilon,-B^*p_\epsilon,p_\epsilon+q_\epsilon).\end{gathered}$$

Therefore (29) becomes

$$\partial G(x_\epsilon,y_\epsilon,z_\epsilon)+(-\nu\Delta p_\epsilon,-\nabla q_\epsilon,p_\epsilon)\ni 0, \tag{30}$$

$$\partial H(u_\epsilon,v_\epsilon)+(-B^*p_\epsilon,p_\epsilon+q_\epsilon)\ni 0. \tag{31}$$

Let $F(x,y)=(1/2)\left\|y-d(\nabla x)\right\|_{\mathbb{L}^2}^2$, $x\in H_0^1(\Omega)$, $y\in\mathbb{L}^2(\Omega)$.

According to Proposition 2.2(b) we have

$$H^{-1}(\Omega)\times\mathbb{L}^2(\Omega)\ni(\alpha,\delta)\in\partial F(x,y)\text{ iff }\delta=y-d(\nabla x),\ \alpha\in\partial d_\delta(x), \tag{32}$$

where $d_\delta(x)=-(\delta,d(\nabla x))_{\mathbb{L}^2}$, $x\in H_0^1(\Omega)$.

We have $d_\delta=f_\delta\circ\nabla$, where $f_\delta(v)=-(\delta,d(v))_{\mathbb{L}^2}$, $v\in\mathbb{L}^2(\Omega)$.

Since $-\operatorname{div}:\mathbb{L}^2(\Omega)\to H^{-1}(\Omega)$ is the adjoint of $\nabla:H_0^1(\Omega)\to\mathbb{L}^2(\Omega)$, by a well-known chain rule (see, e.g., [9, Theorem 2.3.10, p. 45]), we get

$$\partial d_\delta(x)=\{\alpha=-\operatorname{div}\zeta,\ \zeta\in\partial f_\delta(\nabla x)\},\ x\in H_0^1(\Omega).$$

Hence

$$(\alpha,\delta)\in\partial F(x,y)\text{ iff }\alpha=-\operatorname{div}\zeta,\ \delta=y-d(\nabla x),\ \zeta\in\partial f_\delta(\nabla x). \tag{33}$$

Similarly, for $K(x,z)=(1/2)\left\|z-\beta(x)\right\|_{L^2(\Omega)}^2$, $x,z\in L^2(\Omega)$, we find

$$\partial K(x,z)=\{(\gamma,\mu)\in L^2(\Omega)\times L^2(\Omega);\mu=z-\beta(x)),\gamma\in\partial k_\mu(x)\},$$

with $k_\mu(x)=-(\mu,\beta(x))_{L^2}$, $x,z\in L^2(\Omega)$.

Since $H_0^1(\Omega)$ is dense in $L^2(\Omega)$ we know that

$$\partial_{H_0^1}K(x,z)=\partial K(x,z),x\in H_0^1(\Omega),z\in L^2(\Omega)$$

where $\partial_{H_0^1} K$ is the generalized gradient of K seen as a locally Lipschitz function in $H_0^1(\Omega) \times L^2(\Omega)$ (see [9, Corollary, p. 47]).

From its definition we have

$$\begin{aligned} \partial G(x_\epsilon, y_\epsilon, z_\epsilon) = \partial_{H_0^1} g(x_\epsilon) \times \{0\} \times \{0\} + (1/\epsilon)\partial F(x_\epsilon, y_\epsilon) \times \{0\} \\ + (1/\epsilon)\partial_{H_0^1} K(x_\epsilon, z_\epsilon) \times \{0\}, \end{aligned} \tag{34}$$

where $\partial_{H_0^1} g$ is the generalized gradient of g in $H_0^1(\Omega)$.

Again, $\partial_{H_0^1} g(x_\epsilon) = \partial g(x_\epsilon)$ since $x_\epsilon \in H_0^1(\Omega)$, $H_0^1(\Omega)$ is dense in $L^2(\Omega)$, and g is Lipschitz near x^* in $L^2(\Omega)$.

Relation (30) becomes

$$\partial g(x_\epsilon) + (1/\epsilon)\alpha_\epsilon + (1/\epsilon)\gamma_\epsilon - \nu\Delta p_\epsilon \ni 0, \tag{35}$$

$$(1/\epsilon)\delta_\epsilon - \nabla q_\epsilon = 0, \tag{36}$$

$$(1/\epsilon)\mu_\epsilon + p_\epsilon = 0, \tag{37}$$

where $(\alpha_\epsilon, \delta_\epsilon) \in \partial F(x_\epsilon, y_\epsilon)$; that is, $\delta_\epsilon = y_\epsilon - d(\nabla x_\epsilon)$, $\alpha_\epsilon \in \partial d_{\delta_\epsilon}(x_\epsilon)$, or

$$\alpha_\epsilon = -\text{div } \zeta_\epsilon,\ \zeta_\epsilon \in \partial f_{\delta_\epsilon}(\nabla x_\epsilon),\ \delta_\epsilon = y_\epsilon - d(\nabla x_\epsilon), \tag{38}$$

and $(\gamma_\epsilon, \mu_\epsilon) \in \partial K(x_\epsilon, z_\epsilon)$; that is,

$$\gamma_\epsilon \in \partial k_{\mu_\epsilon}(x_\epsilon),\ \mu_\epsilon = z_\epsilon - \beta(x_\epsilon). \tag{39}$$

Relation (31) reduces to

$$B^* p_\epsilon \in \partial h(u_\epsilon) + u_\epsilon - u^*, \tag{40}$$

$$v_\epsilon - D(x^*) + p_\epsilon + q_\epsilon = 0, \tag{41}$$

where, for simplicity, U is considered to be a Hilbert space. If U is a Banach space with a separable dual, then it can be renormed such that its duality mapping is continuous (see, e.g., [10, p. 50]), and the argument below follows similarly.

Since g is Lipschitz near x^* in $L^2(\Omega)$ and $x_\epsilon \to x^*$ strongly in $L^2(\Omega)$ we know that $\cup_{\epsilon>0} \partial g(x_\epsilon)$ is bounded in $L^2(\Omega)$. Relation (35) yields that $((1/\epsilon)\alpha_\epsilon + (1/\epsilon)\gamma_\epsilon - \nu\Delta p_\epsilon)_\epsilon$ is bounded in $L^2(\Omega)$; i.e., for every $\epsilon > 0$

$$\|(1/\epsilon)\alpha_\epsilon + (1/\epsilon)\gamma_\epsilon - \nu\Delta p_\epsilon\|_{L^2} \le C_0 := \sup\left\{ \|w\|_{L^2};\ w \in \bigcup_{\epsilon>0} \partial g(x_\epsilon) \right\} < \infty. \tag{42}$$

Inequality (42) together with (36) and (41) imply

$$\begin{aligned} &\langle (1/\epsilon)\alpha_\epsilon + (1/\epsilon)\gamma_\epsilon - \nu\Delta p_\epsilon, p_\epsilon \rangle_{H_0^1 \times H^{-1}} = ((1/\epsilon)\alpha_\epsilon + (1/\epsilon)\gamma_\epsilon - \nu\Delta p_\epsilon, p_\epsilon)_{L^2} \\ &\quad \le C_0 \|p_\epsilon\|_{L^2} \le C_0 \|q_\epsilon\|_{L^2} + C_0 C_1 \le C_0 \lambda_1^{-1/2} \|q_\epsilon\|_{H_0^1} + C_0 C_1 \\ &\quad = C_0 \lambda_1^{-1/2} \|\nabla q_\epsilon\|_{\mathbb{L}^2} + C_0 C_1 = C_0 \lambda_1^{-1/2} \|(1/\epsilon)\delta_\epsilon\|_{\mathbb{L}^2} + C_0 C_1 \text{ for every } \epsilon > 0, \end{aligned} \tag{43}$$

where $\|v_\epsilon - D(x^*)\|_{L^2} \le C_1 < \infty$ for every $\epsilon > 0$.

From $\zeta_\epsilon \in \partial f_{\delta_\epsilon}(\nabla x_\epsilon)$, we get according to Proposition 2.2(c) and (e) that

$$\|\zeta_\epsilon\|_{\mathbb{L}^2} \le (L + \nu)\|\delta_\epsilon\|_{\mathbb{L}^2}, \tag{44}$$

$$(\zeta_\epsilon, -\delta_\epsilon)_{\mathbb{L}^2} \ge (K - \nu)\|\delta_\epsilon\|_{\mathbb{L}^2}^2. \tag{45}$$

Moreover, if we identify $H^{-1}(\Omega)$ with $H_0^1(\Omega)$, then we have

$$(-\Delta^{-1}\alpha_\epsilon, \delta_\epsilon) \in \partial F(x_\epsilon, y_\epsilon).$$

Since $x_\epsilon \in H_0^1(\Omega) \cap H^2(\Omega)$, F is Lipschitz continuous in $H_0^1(\Omega) \cap H^2(\Omega) \times \mathbb{L}^2(\Omega)$, and $H_0^1(\Omega) \cap H^2(\Omega)$ is dense in $H_0^1(\Omega)$, we know that

$$(-\Delta^{-1}\alpha_\epsilon, \delta_\epsilon) \in \partial F(x_\epsilon, y_\epsilon) \text{ in } H_0^1(\Omega) \cap H^2(\Omega) \times \mathbb{L}^2(\Omega). \tag{46}$$

Therefore, $(\alpha_\epsilon)_\epsilon \subset L^2(\Omega)$, and due to (35) $(p_\epsilon)_\epsilon \subset H_0^1(\Omega) \cap H^2(\Omega)$. Again, from Proposition 2.2(c) and the fact that $d \circ \nabla : H_0^1(\Omega) \cap H^2(\Omega) \to \mathbb{L}^2(\Omega)$ is Lipschitz continuous with Lipschitz constant $(L+\nu)\lambda_1^{-1/2}$, we obtain

$$\| - \Delta^{-1}\alpha_\epsilon\|_{H_0^1 \cap H^2} = \|\alpha_\epsilon\|_{L^2} \leq (L+\nu)\lambda_1^{-1/2}\|\delta_\epsilon\|_{\mathbb{L}^2}. \tag{47}$$

We get from (41), (38), (36), (45), and (47) that for every $\epsilon > 0$

$$\langle (1/\epsilon)\alpha_\epsilon, p_\epsilon\rangle_{H_0^1 \times H^{-1}} = \langle (1/\epsilon)\alpha_\epsilon, -q_\epsilon\rangle_{H_0^1 \times H^{-1}} + ((1/\epsilon)\alpha_\epsilon, D(x^*) - v_\epsilon)_{L^2}$$

$$\geq ((1/\epsilon)\zeta_\epsilon, -\nabla q_\epsilon)_{\mathbb{L}^2} - C_1\|(1/\epsilon)\alpha_\epsilon\|_{L^2} = (1/\epsilon)^2(\zeta_\epsilon, -\delta_\epsilon)_{\mathbb{L}^2} - C_1\|(1/\epsilon)\alpha_\epsilon\|_{L^2}$$

$$\geq (K-\nu)\|(1/\epsilon)\delta_\epsilon\|_{\mathbb{L}^2}^2 - C_1(L+\nu)\lambda_1^{-1/2}\|(1/\epsilon)\delta_\epsilon\|_{\mathbb{L}^2}. \tag{48}$$

Relation $\gamma_\epsilon \in \partial k_{\mu_\epsilon}(x_\epsilon)$ provides us with the estimate

$$\|\gamma_\epsilon\|_{L^2} \leq C_\beta\|\mu_\epsilon\|_{L^2}. \tag{49}$$

We obtain from (37), (49), (41), and (36) that

$$\langle (1/\epsilon)\gamma_\epsilon, p_\epsilon\rangle_{H_0^1 \times H^{-1}} = ((1/\epsilon)\gamma_\epsilon, p_\epsilon)_{L^2} \geq -C_\beta\|p_\epsilon\|_{L^2}^2$$

$$= -C_\beta\{\|q_\epsilon\|_{L^2}^2 + 2(q_\epsilon, v_\epsilon - D(x^*))_{L^2} + \|v_\epsilon - D(x^*)\|_{L^2}^2\}$$

$$\geq -C_\beta\|q_\epsilon\|_{L^2}^2 - 2C_\beta C_1\|q_\epsilon\|_{L^2} - C_\beta C_1^2$$

$$\geq -C_\beta\lambda_1^{-1}\|q_\epsilon\|_{H_0^1}^2 - 2C_\beta C_1\lambda_1^{-1/2}\|q_\epsilon\|_{H_0^1} - C_\beta C_1^2$$

$$= -C_\beta\lambda_1^{-1}\|(1/\epsilon)\delta_\epsilon\|_{\mathbb{L}^2}^2 - 2C_\beta C_1\lambda_1^{-1/2}\|(1/\epsilon)\delta_\epsilon\|_{\mathbb{L}^2} - C_\beta C_1^2. \tag{50}$$

Multiply $(1/\epsilon)\alpha_\epsilon + (1/\epsilon)\gamma_\epsilon - \nu\Delta p_\epsilon$ by p_ϵ in $L^2(\Omega)$ and take (43), (48), and (50) into account to find

$$(K - C_\beta/\lambda_1 - \nu)\|(1/\epsilon)\delta_\epsilon\|_{\mathbb{L}^2}^2 - C_2\lambda_1^{-1/2}\|(1/\epsilon)\delta_\epsilon\|_{\mathbb{L}^2} - C_3 \leq 0, \tag{51}$$

where $C_2 = C_1(L+\nu+2C_\beta) + C_0$, $C_3 = C_\beta C_1^2 + C_0C_1$.

Assume that (H1) is true. We can pick $\nu > 0$ sufficiently small such that $K - C_\beta/\lambda_1 - \nu > 0$. We infer, from (51), that $((1/\epsilon)\delta_\epsilon)_\epsilon$ is bounded in $\mathbb{L}^2(\Omega)$.

Assume that (H2) holds. According to Proposition 2.2(e), from $\gamma_\epsilon \in \partial k_{\mu_\epsilon}(x_\epsilon)$ we find $(\gamma_\epsilon, \mu_\epsilon)_{L^2} \leq 0$. From (37) we get $(\gamma_\epsilon, p_\epsilon)_{L^2} \geq 0$. Again, we multiply $(1/\epsilon)\alpha_\epsilon + (1/\epsilon)\gamma_\epsilon - \nu\Delta p_\epsilon$ by p_ϵ in $L^2(\Omega)$ and take (43) and (48) into account to obtain the boundedness of $((1/\epsilon)\delta_\epsilon)_\epsilon$ in $\mathbb{L}^2(\Omega)$.

Subsequently, we get that $((1/\epsilon)\alpha_\epsilon)_\epsilon$ is bounded in $L^2(\Omega)$ due to (47), $((1/\epsilon)\zeta_\epsilon)_\epsilon$ is bounded in $\mathbb{L}^2(\Omega)$ due to (44), $(q_\epsilon)_\epsilon$ is bounded in $H_0^1(\Omega)$ due to (36), $(p_\epsilon)_\epsilon$ is bounded in $L^2(\Omega)$ due to (41), $((1/\epsilon)\mu_\epsilon)_\epsilon$, $((1/\epsilon)\gamma_\epsilon)_\epsilon$ are bounded in $L^2(\Omega)$ (see (37) and (49)), and from (42) $(p_\epsilon)_\epsilon$ is bounded in $H_0^1(\Omega) \cap H^2(\Omega)$.

Eventually on a subnet, we may assume that

$$\begin{aligned}
&p_\epsilon \to p, \text{ strongly in } H_0^1(\Omega), \text{ weakly in } H_0^1(\Omega) \cap H^2(\Omega),\\
&q_\epsilon \to -p, \text{ strongly in } L^2(\Omega), \text{ weakly in } H_0^1(\Omega),\\
&(1/\epsilon)\delta_\epsilon \to -\nabla p, \text{ weakly in } \mathbb{L}^2(\Omega) \text{ (see (36))}.
\end{aligned}$$

Clearly

$$\begin{aligned}
&(1/\epsilon)\mu_\epsilon \to -p \text{ strongly in } L^2(\Omega) \text{ (see (37))},\\
&(1/\epsilon)\gamma_\epsilon \to \gamma \text{ weakly in } L^2(\Omega),\\
&(1/\epsilon)\zeta_\epsilon \to \zeta \text{ weakly in } \mathbb{L}^2(\Omega),\\
&(1/\epsilon)\alpha_\epsilon \to \alpha = -\text{div } \zeta \text{ weakly in } L^2(\Omega).
\end{aligned}$$

Let $\epsilon \downarrow 0$ in (35) and (40). We find, according to Proposition 2.2(d), that

$$\partial g(x^*) + \alpha + \gamma - \nu\Delta p \ni 0, \ B^*p \in \partial h(u^*) \tag{52}$$

where

$$\gamma \in \partial k_{(-p)}(x^*), \tag{53}$$

and

$$\zeta \in \partial f_{(-\nabla p)}(\nabla x^*), \ \alpha = -\text{div } \zeta \in \partial d_{(-\nabla p)}(x^*). \tag{54}$$

More precisely, we observe that we cannot apply Proposition 2.2(d) for $\zeta_\epsilon \in \partial f_{\delta_\epsilon}(\nabla x_\epsilon)$ to get (54) since $((1/\epsilon)\delta_\epsilon)_\epsilon$ is only weakly convergent in $\mathbb{L}^2(\Omega)$.

Instead, we use $\alpha_\epsilon \in \partial d_{\delta_\epsilon}(x_\epsilon)$ or $-\Delta^{-1}\alpha_\epsilon \in \partial d_{\delta_\epsilon}(x_\epsilon)$ in $H_0^1(\Omega)$. Again, $-\Delta^{-1}\alpha_\epsilon \in \partial d_{\delta_\epsilon}(x_\epsilon)$ in $H_0^1(\Omega) \cap H^2(\Omega)$ by density.

By Lemma 2.1 $D : H_0^1(\Omega) \cap H^2(\Omega) \to L^2(\Omega)$ is well-defined and locally Lipschitz continuous. This allows us to write, according to (36), that

$$\begin{aligned}
d_{\delta_\epsilon}(x) &= -(\delta_\epsilon, d(\nabla x))_{\mathbb{L}^2} = -\langle \epsilon q_\epsilon, D(x)\rangle_{H_0^1 \times H^{-1}}\\
&= -(\epsilon q_\epsilon, D(x))_{L^2} = g_{(\epsilon q_\epsilon)}(x), \ x \in H_0^1(\Omega) \cap H^2(\Omega),
\end{aligned}$$

where for $q \in L^2(\Omega)$, $g_q(x) = -(q, D(x))_{L^2}$, $x \in H_0^1(\Omega) \cap H^2(\Omega)$.

Now we can use Proposition 2.2(d) because $q_\epsilon \to -p$ strongly in $L^2(\Omega)$.

From

$$-\Delta^{-1}\alpha_\epsilon \in \partial d_{\delta_\epsilon}(x_\epsilon) = \partial g_{(\epsilon q_\epsilon)}(x_\epsilon) \text{ in } H_0^1(\Omega),$$

we find

$$-\Delta^{-1}\alpha \in \partial g_{(-p)}(x^*) = \partial d_{(-\nabla p)}(x^*) \text{ in } H_0^1(\Omega) \cap H^2(\Omega).$$

Equivalently, $-\Delta^{-1}\alpha \in \partial d_{(-\nabla p)}(x^*)$ in $H_0^1(\Omega)$, or

$$\alpha \in \partial d_{(-\nabla p)}(x^*) \text{ in } H_0^1(\Omega) \times H^{-1}(\Omega).$$

This final relation can be restated as $\alpha = -\text{div } \zeta$, with $\zeta \in \partial f_{(-\nabla p)}(\nabla x^*)$, and (54) is proved.

Clearly, $\gamma \in \partial k_{(-p)}(x^*)$ means $\gamma \in \partial \Gamma(x^*)$, where

$$\Gamma(x) = \int_\Omega p(\omega)\beta(x(\omega))d\omega,\ x \in L^2(\Omega),$$

and it can be described as $\gamma(\omega) \in p(\omega)\partial\beta(x^*(\omega))$, a.e. ω in Ω (see [9, Theorem 2.7.2, p. 76]).

The first part in (54) is equivalent to $\eta := \zeta + \nu\nabla p \in \partial\Psi_{(-\nabla p)}(\nabla x^*)$, where

$$\Psi_{(-\nabla p)}(v) = (\nabla p, a(v))_{\mathbb{L}^2} = \int_\Omega (a(v(\omega)), \nabla p(\omega))_{\mathbb{R}^N} d\omega,\ v \in \mathbb{L}^2(\Omega),$$

and it can be described as $\eta(\omega) \in \partial a(\nabla x^*(\omega))(\nabla p(\omega))$, a.e. ω in Ω (see [9, Theorem 2.6.6, p. 72, and Theorem 2.7.2, p. 76]). Take $l := \alpha - \nu\Delta p = -\text{div } \eta$. The proof is complete. □

Remark 2.3. Using a similar argument and slightly different computations one can show that Theorem 2.1 holds if instead of (H1) or (H2) we consider assumptions which ensure that $-\text{div } a(\nabla\cdot) + \beta : H_0^1(\Omega) \to H^{-1}(\Omega)$ is strongly monotone.

COROLLARY 2.1. *Assume that all of the assumptions of Theorem* 2.1 *hold, with the relaxed conditions: a is locally Lipschitz and $\nabla^2 a \in L^\infty_{loc}(\mathbb{R}^N; \mathbb{R}^{N^3})$. In addition, suppose that every solution $x \in H_0^1(\Omega) \cap H^2(\Omega)$ of* (NE) *satisfies the "a priori" estimate*

$$\|\nabla x\|_{L^\infty} \le \gamma = \gamma(\|u\|_U), \tag{55}$$

where $\gamma = \gamma(\|u\|_U)$ is a bounded function of $\|u\|_U$.

Then all of the conclusions of Theorem 2.1 *hold.*

Proof. Since a is locally Lipschitz and $\nabla^2 a \in L^\infty_{loc}(\mathbb{R}^N; \mathbb{R}^{N^3})$ we can modify a outside a bounded subset of $\mathbb{R}^N$ without locally changing the set of solutions of (NE) such that the new a is Lipschitz continuous with $\nabla^2 a \in L^\infty(\mathbb{R}^N; \mathbb{R}^{N^3})$, and we can apply Theorem 2.1 to get the conclusions. □

Remark 2.4. For $N = 1$ we have $\nabla x \in H^1(\Omega) \subset L^\infty(\Omega)$, and from the "a priori" estimate contained in the proof of Lemma 2.1(a) we know that $\|\nabla x\|_{H^1} \le C(\|Bu + f\|_{L^2} + 1)$, from which we find (55). More precisely,

$$\|\nabla x\|_{L^\infty} \le \frac{1}{(K\lambda_1 - C_\beta)\sqrt{6}}\|Bu + f\|_{L^2}.$$

Therefore, in the 1-dimensional case, the conclusions of Theorem 2.1 remain true with the relaxed conditions a locally Lipschitz continuous and $\nabla^2 a \in L^\infty_{loc}(\mathbb{R}^N; \mathbb{R}^{N^3})$.

3. Examples.

Example 3.1. Consider the optimization problem

$$\text{minimize } \frac{1}{2}\int_0^\pi |x(t)|^2 dt + \frac{1}{2}\int_0^\pi |u(t)|^2 dt \tag{56}$$

subject to

$$-x_{tt}(1 + e^{-x_t}) = u + f,\ \text{a.e. in } (0,\pi),\ x(0) = x(\pi) = 0, \tag{57}$$

where $u \in L^2(0,\pi)$.

This problem is of the form (P) with $g(x) = \frac{1}{2}\|x\|^2_{L^2}, h(u) = \frac{1}{2}\|u\|^2_{L^2}$, $x, u \in L^2(0,\pi)$, $a(r) = r - e^{-r}$, $r \in \mathbb{R}$, $\beta = 0$, $Bu = u$, $u \in L^2(0,\pi)$, $f \in L^2(0,\pi)$.

Notice that g, h, a, β, B, f satisfy the assumptions of Theorem 2.1 since a is locally Lipschitz continuous with $K = 1$, a'' is locally bounded (see Remark 2.4), and $C_\beta = 0$, $\lambda_1 = 1$.

Therefore, for every solution (x^*, u^*) there is a $p \in H^1_0(0,\pi) \cap H^2(0,\pi)$, $\gamma, l, \eta \in L^2(0,\pi)$ such that

$$x^* + l + \gamma = 0,\ p = u^*,\ l = -\eta_t,\ \eta = (1 + e^{-x^*_t})p_t,\ \gamma = 0; \tag{58}$$

that is,

$$x^* - ((1 + e^{-x^*_t})u^*_t)_t = 0 \text{ a.e. in } (0,\pi). \tag{59}$$

Combined with (57), relation (59) can answer several questions such as: Is it possible to bring the solutions x of (57) into the origin with minimal L^2-effort in u, or, in other words, is there an optimal pair of our problem of the form $(0, u^*)$? The answer is positive iff $f = 0$ since for $x^* = 0$ we get $u^*_{tt} = 0$ in $H^1_0(0,\pi) \cap H^2(0,\pi)$, i.e., $u^* = 0$, which contradicts (57) if $f \neq 0$.

Moreover, (57) and (59) together with the boundary conditions $x^*(0) = x^*(\pi) = u^*(0) = u^*(\pi) = 0$ can be used to determine (x^*, u^*) numerically.

Example 3.2. Consider the problem

$$\text{minimize } \ell^2 \int_0^T \cos^2\theta(t)dt + \frac{1}{2}\int_0^T |u(t)|^2 dt$$

subject to the pendulum problem

$$\theta_{tt} + \frac{g}{\ell}\sin\theta = u + f,\ \text{a.e. in } (0,T),\ \theta(0) = \theta(T) = 0. \tag{60}$$

Here g is the gravitational acceleration, ℓ is the length of the pendulum, $T > 0$ is fixed, and $f \in L^2(0,T)$.

The objective functional in this problem expresses the goal of maximizing the height of the pendulum $H = \ell - \ell\cos\theta$ with minimum L^2-effort in u, under the condition $\theta(0) = \theta(T) = 0$.

This problem is of type (P) with $g(\theta) = \ell^2 \int_0^T \cos^2\theta(t)dt$, $h(u) = \frac{1}{2}\|u\|^2_{L^2}$, $\theta, u \in L^2(0,T)$, $a(r) = r$, $\beta(r) = -\frac{g}{\ell}\sin r$, $r \in \mathbb{R}$, $Bu = -u$, $u \in L^2(0,T)$. We have $K = L = 1$, $C_\beta = \frac{g}{\ell}$, $\lambda_1 = \frac{\pi^2}{T^2}$. Therefore, for $\ell > \frac{gT^2}{\pi^2}$, we may apply Theorem 2.1 to get that for every optimal pair (θ^*, u^*) there exist $p \in H^1_0(0,T) \cap H^2(0,T)$, $\gamma, l, \eta \in L^2(0,T)$ such that

$$\partial g(\theta^*) + l + \gamma \ni 0,\ -p = u^*,\ l = -\eta_t,\ \eta = p_t,\ \gamma = -p\frac{g}{\ell}\cos\theta^*; \tag{61}$$

that is,

$$-\ell^2\sin(2\theta^*) + u^*_{tt} + \frac{g}{\ell}u^*\cos\theta^* = 0. \tag{62}$$

Various conclusions can be drawn from (60) and (62) including the possibility for numerical determination of optimal pairs. For example, if $(\theta^*(t) = \theta^*, u^*(t) = u(t))$ is a stationary optimal pair, then $\theta^* = \pm\pi/2$, $f(t) = -u^* \pm \frac{g}{\ell}$ or $\sin\theta^* = \frac{g}{2\ell^3}u^*$, $f(t) = (\frac{g^2}{2\ell^4} - 1)u^*$.

Example 3.3. Let $N \geq 1$, $C = (c_{ij})_{1 \leq i,j \leq N} \in \mathcal{M}_N(\mathbb{R})$ be a square positive definite matrix, i.e., $(Cr, r)_{\mathbb{R}^N} \geq c\|r\|^2_{\mathbb{R}^N}$, for every $r \in \mathbb{R}^N$, $c > k > 0$, and

$$a(r) = Cr + k(|r_1|, |r_2|, \dots, |r_N|)^T,\ r = (r_1, r_2, \dots, r_N)^T \in \mathbb{R}^N. \tag{63}$$

Here "^{T}" stands for the transpose of a matrix. Notice that a is Lipschitz continuous, strongly monotone with constant $c - k > 0$, nondifferentiable at 0, and $\nabla^2 a \in L^\infty(\mathbb{R}^N; \mathbb{R}^{N^3})$.

Problem (P) becomes in these settings

$$\begin{aligned} &\text{(P)} \quad \text{minimize } g(x) + h(u) \text{ on all } (x,u) \in H_0^1(\Omega) \times U, \text{ subject to} \\ &\text{(NE)} \quad -\sum_{i,j=1}^N c_{ij} \frac{\partial^2 x}{\partial \omega_i \partial \omega_j} - k \sum_{i=1}^N \operatorname{sign}\left(\frac{\partial x}{\partial \omega_i}\right) \frac{\partial^2 x}{\partial \omega_i^2} + \beta(x) = f \text{ in } \Omega, \\ &\quad x = 0 \text{ on } \partial\Omega. \end{aligned}$$

Whenever β satisfies (H1) or (H2), for every optimal pair (x^*, u^*) of (P) we have

$$\partial g(x^*) + l + \gamma \ni 0,\ B^* p \in \partial h(u^*),\ l = -\operatorname{div} \eta, \tag{64}$$

$$\eta \in \left(\sum_{j=1}^N c_{ij} \frac{\partial p}{\partial \omega_j} + k \operatorname{sign}\left(\frac{\partial x^*}{\partial \omega_i}\right) \frac{\partial p}{\partial \omega_i} \right)^T_{1 \leq i \leq N},\ \gamma \in p\partial\beta(x^*) \text{ a.e. in } \Omega, \tag{65}$$

for some $p \in H_0^1(\Omega) \cap H^2(\Omega)$, $\gamma, l, \eta \in \mathbb{L}^2(\Omega)$. Here $\operatorname{sign} \omega = \omega/|\omega|$, $\omega \neq 0$, $\operatorname{sign} 0 = [-1, 1]$.

Example 3.4. Let $N \geq 2$, $p \geq 3$, and $a(r) = r\|r\|^{p-2}$, $r \in \mathbb{R}^N$. In this case (P) has the form

$$\begin{aligned} &\text{(P)} \quad \text{minimize } g(x) + h(u) \text{ on all } (x,u) \in H_0^1(\Omega) \times U, \text{ subject to} \\ &\qquad \text{(NE)} \ -\ \Delta_p x + \beta(x) = Bu + f \ \text{ in } H_0^1(\Omega), \end{aligned}$$

where "Δ_p" denotes the p-Laplacian.

More precisely, $\Delta_p : W_0^{1,p}(\Omega) \to W^{-1,q}(\Omega)$, $-\Delta_p x = -\operatorname{div}(\nabla x \|\nabla x\|^{p-2}_{\mathbb{R}^N}) = g \in W^{-1,q}(\Omega)$ iff $x \in W_0^{1,p}(\Omega)$, and

$$\int_\Omega (\|\nabla x\|^{p-2}_{\mathbb{R}^N} \nabla x \cdot \nabla \varphi - g\varphi) d\omega = 0 \text{ for every } \varphi \in C_0^\infty(\Omega),$$

or, equivalently, x is a minimizer of the functional

$$E : W_0^{1,p}(\Omega) \to \mathbb{R},\ E(v) = \frac{1}{p} \int_\Omega \|\nabla v\|^p_{\mathbb{R}^N} d\omega - \int_\Omega gv\, d\omega,\ v \in W_0^{1,p}(\Omega).$$

The p-Laplacian operator arises in various physical contexts: nonlinear elasticity, reaction-diffusion problems, non-Newtonian fluid flow models, diffusive logistic equation, nonlinear elastic membranes, electrochemical machining, elastic-plastic torsional creep, the Monge mass transfer problem, etc.

We take $f \in L^\infty(\Omega)$ and $B \in L(U; L^\infty(\Omega))$.

A direct computation shows that, for $p \geq 3$, $\nabla^2 a \in L^\infty_{loc}(\mathbb{R}^N; \mathbb{R}^{N^3})$, and since a is locally Lipschitz continuous it is sufficient to show (55) in order to apply Corollary 2.1.

We take β with a sufficiently small Lipschitz constant or monotone, and after we multiply (NE) by x we find

$$\begin{aligned} -\Delta_p x(\omega)x(\omega) &\le -\beta(x(\omega))x(\omega) + |(Bu+f)(\omega)||x(\omega)| \\ &\le C^*_\beta |x(\omega)|^2 + ||Bu+f||_{L^\infty}|x(\omega)| \text{ a.e. } \omega \in \Omega, \end{aligned} \tag{66}$$

where $C^*_\beta = 0$ if β is monotone and $C^*_\beta = C_\beta$ if β is Lipschitz.

After integration over Ω we get

$$\|x\|^{p-1}_{W^{1,p}} \le \text{const}\|Bu+f\|_{L^2}. \tag{67}$$

According to [13, Theorem 1.5.5, p. 115] together with the Sobolev embedding $W^{1,p}_0(\Omega) \subset L^{p_0}(\Omega)$, where $p_0 = Np/(N-p)$ if $p < N$, $p_0 = 2p$ if $p \ge N$, relations (66), (67) imply $\|x\|_{L^\infty} \le \gamma(\|u\|_U)$, which, according to [13, Theorem 1.5.6, p. 116], provides us with $\|\nabla x\|_{L^\infty} \le \gamma(\|u\|_U)$; that is, (55) holds.

It must be noted that, in the case of the p-Laplacian, the strong ellipticity of a holds for $p \ge 2$ and has the form

$$(a(r_1) - a(r_2))(r_1 - r_2) \ge K||r_1 - r_2||^p_{\mathbb{R}^N},\ r_1, r_2 \in \mathbb{R}^N,\ K > 0.$$

This does not affect the computations in all of our previous results, since our state equation takes place in $L^\infty(\Omega)$; the only difference is that sometimes we replace the power 2 by p.

Therefore if (x^*u^*) is an optimal pair for our problem, then there exist $\pi \in H^1_0(\Omega) \cap H^2(\Omega)$, $\gamma, l, \eta \in \mathbb{L}^2(\Omega)$ such that

$$\partial g(x^*) + l + \gamma \ni 0,\ B^*\pi \in \partial h(u^*),\ l = -\text{div } \eta, \tag{68}$$

and a.e. ω in Ω

$$\gamma(\omega) \in \pi(\omega)\partial\beta(x^*(\omega))\ , \tag{69}$$

$$\eta \in \left((p-2)\|\nabla x^*\|^{p-4} \sum_{j=1}^N \frac{\partial x^*}{\partial \omega_i}\frac{\partial x^*}{\partial \omega_j}\frac{\partial \pi}{\partial \omega_j} + \|\nabla x^*\|^{p-2}\frac{\partial \pi}{\partial \omega_i} \right)^T_{1 \le i \le N}. \tag{70}$$

Example 3.5. Consider the following version of (P) where the state equation is a modified form of the minimal surface equation:

$$\text{(P)} \qquad \text{minimize } g(x) + h(u) \text{ on all } (x,u) \in H^1_0(\Omega) \times U, \text{ subject to}$$

$$\text{(NE)} \quad -\text{div}\left(\frac{\nabla x}{\sqrt{1 + \|\nabla x\|^2_{\mathbb{R}^N}}} + k\nabla x \right) + \beta(x) = Bu + f \text{ in } H^1_0(\Omega),$$

where $N \ge 1$, $k > 1$, and g, h, β, B satisfy the assumptions in Theorem 2.1.

The minimal surface equation $\text{div}\,(\frac{\nabla x}{\sqrt{1+\|\nabla x\|^2}}) = 0$ appears in the non-parametric plateau problem of finding a surface with a given boundary and least possible area. The variational interpretation of the modified minimal surface equation describes the solutions of (NE) as minimizers of the energy $E : H^1_0(\Omega) \to \mathbb{R}$ given by

$$\begin{aligned} E(x) = \int_\Omega \sqrt{1 + \|\nabla x\|^2_{\mathbb{R}^N}}\, d\omega + \frac{k}{2}\int_\Omega (1 + \|\nabla x\|^2_{\mathbb{R}^N})d\omega \\ + \int_\Omega j(x)d\omega - \int_\Omega (Bu+f)x\, d\omega, \end{aligned}$$

$x \in H_0^1(\Omega)$. Here $A(x) = \int_\Omega \sqrt{1 + \|\nabla x\|^2_{\mathbb{R}^N}} d\omega$ represents the area of the surface S: $x_{N+1} = x(\omega)$, $\omega \in \Omega$, $\int_\Omega 1 + \|\nabla x\|^2_{\mathbb{R}^N} d\omega = \int_S \|\overrightarrow{n}\|_{\mathbb{R}^{N+1}} dS$, where $\overrightarrow{n} = (\nabla x, -1)$ is the gradient vector field on S, and $\beta = \partial j$.

In this case $a(r) = \frac{r}{\sqrt{1+\|r\|^2_{\mathbb{R}^N}}} + kr$, $r \in \mathbb{R}^N$, and by a simple verification involving the inequality $(r_1, r_2)_{\mathbb{R}^N} \leq \frac{1}{2}(\|r_1\|^2_{\mathbb{R}^N} + \|r_2\|^2_{\mathbb{R}^N})$ one gets that a is strongly monotone with constant $K = k - 1 > 0$ and Lipschitz continuous with Lipschitz constant $L = k+1$. The last assumption $\nabla^2 a \in L^\infty(\mathbb{R}^N; \mathbb{R}^{N^3})$ is checked by direct computation. Hence, by Theorem 2.1, for $(x^* u^*)$ an optimal pair (P) there exist $p \in H_0^1(\Omega) \cap H^2(\Omega)$, $\gamma, l, \eta \in \mathbb{L}^2(\Omega)$ such that

$$\partial g(x^*) + l + \gamma \ni 0,\ B^* p \in \partial h(u^*),\ l = -\text{div } \eta, \tag{71}$$

and a.e. ω in Ω

$$\gamma(\omega) \in p(\omega) \partial \beta(x^*(\omega)), \tag{72}$$

$$\eta \in \left(\left(k + \frac{1}{\sqrt{1 + \|\nabla x^*\|^2_{\mathbb{R}^N}}} \right) \frac{\partial p}{\partial \omega_i} - \sum_{j=1}^N \frac{\partial x^*}{\partial \omega_i} \frac{\partial x^*}{\partial \omega_j} \frac{\partial p}{\partial \omega_j} \frac{1}{(1 + \|\nabla x^*\|^2_{\mathbb{R}^N})^{3/2}} \right)^T_{1 \leq i \leq N}. \tag{73}$$

PERTURBATION BOUNDS OF P-MATRIX LINEAR COMPLEMENTARITY PROBLEMS*

XIAOJUN CHEN† AND SHUHUANG XIANG‡

Abstract. We define a new fundamental constant associated with a P-matrix and show that this constant has various useful properties for the P-matrix linear complementarity problems (LCP). In particular, this constant is sharper than the Mathias–Pang constant in deriving perturbation bounds for the P-matrix LCP. Moreover, this new constant defines a measure of sensitivity of the solution of the P-matrix LCP. We examine how perturbations in the data affect the solution of the LCP and efficiency of Newton-type methods for solving the LCP.

Key words. perturbation bounds, sensitivity, linear complementarity problems

DOI. 10.1137/060653019

1. Introduction.

The linear complementarity problem (LCP) is to find a vector $x \in R^n$ such that

$$Mx + q \geq 0, \quad x \geq 0, \quad x^T(Mx + q) = 0,$$

or to show that no such vector exists, where $M \in R^{n\times n}$ and $q \in R^n$. We denote this problem by LCP(M, q). A matrix M is called a P-matrix if all of its principal minors are positive, which is equivalent to

$$\max_{1\leq i\leq n} x_i(Mx)_i > 0 \quad \text{for all} \quad x \neq 0.$$

It is well known that M is a P-matrix if and only if the LCP(M, q) has a unique solution for any $q \in R^n$ [3]. Moreover, if M is a P-matrix, then there is a neighborhood $\mathcal{M}$ of M, such that all matrices in $\mathcal{M}$ are P-matrices. Hence, we can define a solution function $x(A, b) : \mathcal{M} \times R^n \to R^n_+$, where $x(A, b)$ is the solution of LCP(A, b) and $R^n_+ = \{x \in R^n \mid x \geq 0\}$.

In [12], Mathias and Pang introduced the following fundamental quantity associated with a P-matrix:

$$c(M) = \min_{\|x\|_\infty=1} \max_{1\leq i\leq n} \{x_i(Mx)_i\}.$$

This constant has often been used in error analysis of the LCP [2, 3]. In particular, the following lemma has been widely applied in perturbation bounds.

LEMMA 1.1 (see [3]). *Let $M \in R^{n\times n}$ be a P-matrix. The following statements hold:*

(i) *For any two vectors q and p in R^n,*

$$\|x(M,q) - x(M,p)\|_\infty \le \frac{1}{c(M)}\|q-p\|_\infty.$$

(ii) *For each vector $q \in R^n$, there exist a neighborhood $\mathcal{U}$ of the pair (M,q) and a constant $c_0 > 0$ such that for any $(A,b),(B,p) \in \mathcal{U}$, A, B are P-matrices and*

$$\|x(A,b) - x(B,p)\|_\infty \le c_0(\|A-B\|_\infty + \|b-p\|_\infty).$$

Lemma 1.1 shows that when M is a P-matrix, for each q, $x(A,b)$ is a locally Lipschitzian function of (A,b) in a neighborhood of (M,q), and $x(M,b)$ is a globally Lipschitzian function of b. This property plays a very important role in the study of the LCP and mathematical programs with LCP constraints [11]. However, the constant $c(M)$ is difficult to compute, and c_0 is not specified. It is hard to use this lemma for verifying the accuracy of a computed solution of the LCP when the data (M,q) contain errors.

In this paper, we introduce a new constant for a P-matrix,

$$\beta_p(M) = \max_{d\in[0,1]^n} \|(I - D + DM)^{-1}D\|_p,$$

where $D = \operatorname{diag}(d)$ with $0 \le d_i \le 1$, $i = 1,2,\ldots,n$, and $\|\cdot\|_p$ is the matrix norm induced by the vector norm for $p \ge 1$.

Using the constant $\beta_p(M)$, we give perturbation bounds for M being a P-matrix as follows:

$$\|x(M,q) - x(M,p)\|_p \le \beta_p(M)\|q-p\|_p, \tag{1.1}$$

$$\|x(A,b) - x(B,p)\|_p \le \frac{\beta_p(M)^2}{(1-\eta)^2}\|(-p)_+\|_p\|A-B\|_p + \frac{\beta_p(M)}{1-\eta}\|b-p\|_p, \tag{1.2}$$

and

$$\frac{\|x(M,q) - x(A,b)\|_p}{\|x(M,q)\|_p} \le \frac{2\epsilon}{1-\eta}\beta_p(M)\|M\|_p, \tag{1.3}$$

where $\eta \in [0,1)$ and $\epsilon > 0$ can be chosen, $A, B \in \mathcal{M} := \{A \mid \beta_p(M)\|M - A\|_p \le \eta\}$, and $\|q-b\|_p \le \epsilon\|(-q)_+\|_p$.

The constant $\beta_p(M)$ has the following interesting properties.

- If M is a P-matrix, then for $\|\cdot\|_\infty$,

$$\beta_\infty(M) \le \frac{1}{c(M)}. \tag{1.4}$$

- If M is an H-matrix with positive diagonals, then for $\|\cdot\|_p$ with any $p \ge 1$,

$$\beta_p(M) \le \|\tilde{M}^{-1}\|_p, \tag{1.5}$$

where $\tilde{M}$ is the comparison matrix of M, that is,

$$\tilde{M}_{ii} = M_{ii}, \qquad \tilde{M}_{ij} = -|M_{ij}| \quad \text{for} \quad i \ne j.$$

- If M is an M-matrix, then for $\|\cdot\|_p$ with any $p \geq 1$,

$$\beta_p(M) = \|M^{-1}\|_p. \tag{1.6}$$

- If M is a symmetric positive definite matrix, then for $\|\cdot\|_2$,

$$\beta_2(M) = \|M^{-1}\|_2. \tag{1.7}$$

Inequalities (1.1) and (1.4) show that the constant $\beta(M)$ derives a new perturbation bound which is sharper than the bound in (i) of Lemma 1.1 in $\|\cdot\|_\infty$. Furthermore, Example 2.1 shows that $\beta(M)$ can be much smaller than $c(M)^{-1}$ in some cases. Inequality (1.3) indicates that the constant $\beta(M)\|M\|$ is a measure of sensitivity of the solution $x(M,q)$ of the LCP(M,q). Moreover, from (1.3), (1.6), and (1.7), it is interesting to see that the measure is expressed in the terms of the condition number of M, that is,

$$\kappa_p(M) := \|M^{-1}\|_p\|M\|_p = \beta_p(M)\|M\|_p$$

for M being an M-matrix with $p \geq 1$ and a symmetric positive definite matrix with $p = 2$. Hence, it makes a connection between perturbation bounds of the LCP and perturbation bounds of the systems of linear equations in the Newton-type methods for solving the LCP. Using this connection, we investigate the efficiency of Newton-type methods for solving the following two systems:

$$r(x) := \min(x, Mx + q) = 0 \tag{1.8}$$

and

$$F(x,y) := \begin{pmatrix} Mx + q - y \\ \min(x,y) \end{pmatrix} = 0. \tag{1.9}$$

It is known that for the P-matrix LCP, the system of linear equations in Newton-type methods for solving (1.8) or (1.9) is mathematically well defined; that is, the generalized Jacobian matrices are nonsingular [5]. However, the matrices can be computationally ill-conditioned. A matrix A is said to be an ill-conditioned (well-conditioned) matrix if $\kappa_p(A)$ is large (small) [8]. The condition number $\kappa_p(A)$ is a measure of sensitivity of the system of linear equations $Ax = b$ when A is nonsingular. Hence, a linear system is called ill-conditioned (well-conditioned) if $\kappa_p(A)$ is large (small) [4]. From (1.3), (1.6), and (1.7), we find that $\beta_p(M)\|M\|_p$ is a measure of sensitivity of the LCP(M,q) when M is a P-matrix, and $\beta_p(M)\|M\|_p = \kappa_p(M)$ when M is an M-matrix or a symmetric positive definite matrix. Moreover, we show that for the M-matrix LCP, the systems of linear equations in the Newton-type methods for solving (1.8) are well-conditioned if and only if the condition number $\kappa_p(M)$ is small. However, the system of linear equations in Newton-type methods for solving (1.9) can be ill-conditioned even when $\kappa_p(M)$ is small.

A word about our notation: For a vector $q \in R^n$, $q_+ = \max(0,q)$. Let $N = \{1,2,\ldots,n\}$. Let e be the vector whose elements are all 1. A matrix $A \in R^{n\times n}$ is called an M-matrix if $A^{-1} \geq 0$ and $A_{ij} \leq 0$ $(i \neq j)$ for $i,j \in N$; A is called an H-matrix if its comparison matrix is an M-matrix.

In the rest of this paper, we use $\beta(\cdot)$, $\|\cdot\|$, and $\kappa(\cdot)$ to represent $\beta_p(\cdot)$, $\|\cdot\|_p$, and $\kappa_p(\cdot)$ with any $p \geq 1$, respectively.

2. A new constant for the P-matrix LCP. In this section we introduce a new Lipschitz constant for the P-matrix LCP based on the observation that for any $x, x^*, y, y^* \in R^n$,

$$\min(x_i, y_i) - \min(x_i^*, y_i^*) = (1 - d_i)(x_i - x_i^*) + d_i(y_i - y_i^*), \qquad i \in N, \tag{2.1}$$

where

$$d_i = \begin{cases} 0 & \text{if } y_i \geq x_i,\ y_i^* \geq x_i^*, \\ 1 & \text{if } y_i \leq x_i,\ y_i^* \leq x_i^*, \\ \dfrac{\min(x_i, y_i) - \min(x_i^*, y_i^*) + x_i^* - x_i}{y_i - y_i^* + x_i^* - x_i} & \text{otherwise.} \end{cases}$$

It is easy to see that $d_i \in [0, 1]$. Set $x = x(A, q)$, $x^* = x(B, p)$, $y = Ax(A, q) + q$, and $y^* = Bx(B, p) + p$ in (2.1). We obtain

$$0 = (I - D)(x(A, q) - x(B, p)) + D(Ax(A, q) + q - Bx(B, p) - p),$$

which implies

$$(I - D + DA)(x(B, p) - x(A, q)) = D(A - B)x(B, p) + D(q - p). \tag{2.2}$$

Here D is a diagonal matrix whose diagonal elements are $d = (d_1, d_2, \ldots, d_n) \in [0, 1]^n$.

LEMMA 2.1 (Gabriel and Moré [7]). *A is a P-matrix if and only if $I - D + DA$ is nonsingular for any diagonal matrix $D = \operatorname{diag}(d)$ with $0 \leq d_i \leq 1$.*

For M being a P-matrix, we introduce the following constant:

$$\beta(M) = \max_{d \in [0,1]^n} \|(I - D + DM)^{-1} D\|.$$

From Lemma 2.1 and (2.2), we have

$$\|x(B, p) - x(A, q)\| \leq \beta(A)\|(A - B)x(B, p) + q - p\| \tag{2.3}$$

provided A is a P-matrix. In the following, we compare $\beta(M)$ with $c(M)^{-1}$ in $\|\cdot\|_\infty$ and give a simple version of $\beta(M)$ for M being an M-matrix, a symmetric positive definite matrix, and a positive definite matrix.

THEOREM 2.2. *Let M be a P-matrix. Then*

$$\beta_\infty(M) := \max_{d \in [0,1]^n} \|(I - D + DM)^{-1} D\|_\infty \leq \frac{1}{c(M)}.$$

Proof. We first prove that for any nonsingular diagonal matrix $D = \operatorname{diag}(d)$ with $d \in (0, 1]^n$,

$$\|(I - D + DM)^{-1} D\|_\infty \leq \frac{1}{c(M)}.$$

Let $x \in R^n$ with $\|x\|_\infty = 1$ such that $\|(I-D+DM)^{-1}D\|_\infty = \|(I-D+DM)^{-1}Dx\|_\infty$ and define $y = (I-D+DM)^{-1}Dx$. Then $Dx = (I-D+DM)y$, $My = x+y-D^{-1}y$. By the definition of $c(M)$, we have

$$0 < c(M)\|y\|_\infty^2 \leq \max_i y_i(My)_i = \max_i y_i \left(x_i + y_i - \frac{y_i}{d_i} \right).$$

Note that $f(t) = a(b + a - \frac{a}{t})$ is monotonically increasing for $t > 0$, where a, b are constants. Therefore, we deduce

$$y_i \left(x_i + y_i - \frac{y_i}{d_i} \right) \leq y_i x_i \leq \|y\|_\infty \|x\|_\infty = \|y\|_\infty,$$

which implies

$$0 < c(M)\|y\|_\infty^2 \leq \|y\|_\infty \quad \text{and} \quad \|(I - D + DM)^{-1} D\|_\infty = \|y\|_\infty \leq \frac{1}{c(M)}.$$

Now we consider $d \in [0,1]^n$. Let $d_\epsilon = \min(d + \epsilon e, e)$, where $\epsilon \in (0,1]$. Then, we have

$$\|(I - D + DM)^{-1} D\|_\infty = \lim_{\epsilon \downarrow 0} \|(I - D_\epsilon + D_\epsilon M)^{-1} D_\epsilon\|_\infty \leq \frac{1}{c(M)}. \qquad \square$$

It is known that an H-matrix with positive diagonals is a P-matrix, and a positive definite matrix is a P-matrix [3]. Now, we consider the two subclasses of P-matrix.

LEMMA 2.3 (see [3]). *If M is an M-matrix, then $I - D + DM$ is an M-matrix for $d \in [0,1]^n$.*

LEMMA 2.4. *Let A be an H-matrix with positive diagonals, and let $\tilde{A}$ be the comparison matrix of A. Then the following statements hold:*

(i) $|A^{-1}| \leq \tilde{A}^{-1}$.

(ii) *For $B \in R^{n \times n}$ with $\|B\|_\infty \|\tilde{A}^{-1}\|_\infty < 1$, $A + B$ is an H-matrix with positive diagonals.*

Proof. (i) See problem 31 in [10, page 131].

(ii) Let $x = \tilde{A}^{-1} e$. Since $\tilde{A}^{-1} \geq 0$, $x > 0$ and $\|x\|_\infty = \|\tilde{A}^{-1}\|_\infty$. Moreover, from $\tilde{A}x = e$, we have

$$a_{ii} x_i = 1 + \sum_{j \neq i} |a_{ij}| x_j \qquad \text{for } i \in N.$$

By $\|x\|_\infty \|B\|_\infty < 1$ and $\|B\|_\infty = \||B|e\|_\infty$, we get $\|x\|_\infty |B| e < e$. Hence for all $i \in N$,

$$a_{ii} x_i > \sum_{j=1}^{n} |b_{ij}| \|x\|_\infty + \sum_{j \neq i} |a_{ij}| x_j \geq \sum_{j \neq i} (|a_{ij}| + |b_{ij}|) x_j + |b_{ii}| x_i,$$

and

$$(a_{ii} + b_{ii}) x_i \geq (a_{ii} - |b_{ii}|) x_i > \sum_{j \neq i} (|a_{ij}| + |b_{ij}|) x_j.$$

By I_{27} of Theorem 2.3 in [1, Chap. 6], this implies that the comparison matrix of $A + B$ is an M-matrix. Hence $A + B$ is an H-matrix with positive diagonals. $\square$

THEOREM 2.5. *Let M be an H-matrix with positive diagonals. Then*

$$\beta(M) \leq \|\tilde{M}^{-1}\|,$$

where $\tilde{M}$ is the comparison matrix of M. In particular, if M is an M-matrix, then the equality holds with $M = \tilde{M}$.

Proof. First we will show that if M is an M-matrix, then

$$\beta(M) = \|M^{-1}\|.$$

Since for any $d \in (0,1]^n$, by Lemma 2.3,

$$(DM)^{-1} - (I - D + DM)^{-1} = (DM)^{-1}(I - D)(I - D + DM)^{-1} \geq 0,$$

we have

$$(DM)^{-1}D - (I - D + DM)^{-1}D = M^{-1} - (I - D + DM)^{-1}D \geq 0.$$

Note that for any matrices A and B, $|A| \leq B$ implies $\|A\| \leq \|B\|$. Hence the following inequalities hold:

$$M^{-1} \geq (I - D + DM)^{-1}D \geq 0, \qquad \|M^{-1}\| \geq \|(I - D + DM)^{-1}D\|.$$

Let $d_\epsilon = \min(d + \epsilon e, e)$, where $\epsilon \in (0,1]$. Then, we have

$$\beta(M) = \max_{d \in [0,1]^n} \lim_{\epsilon \downarrow 0} \|(I - D_\epsilon + D_\epsilon M)^{-1} D_\epsilon\| \leq \|M^{-1}\|.$$

It is obvious that $\beta(M) \geq \|M^{-1}\|$ as $e \in [0,1]^n$. Therefore, we obtain $\beta(M) = \|M^{-1}\|$.

For M being an H-matrix, $\tilde{M}$ is an M-matrix. From (i) of Lemma 2.4, we have

$$|(I - D + DM)^{-1}| \leq (I - D + D\tilde{M})^{-1}.$$

Hence, we obtain

$$\beta(M) = \max_{d \in [0,1]^n} \|(I - D + DM)^{-1}D\| \leq \max_{d \in [0,1]^n} \|(I - D + D\tilde{M})^{-1}D\| \leq \|\tilde{M}^{-1}\|. \qquad \square$$

LEMMA 2.6 (see [9]). *Let A and B be symmetric positive definite matrices.*

(i) *$B - A$ is positive semidefinite if and only if $A^{-1} - B^{-1}$ is positive semidefinite.*

(ii) *If $B - A$ is positive semidefinite, then $\lambda_i(B) \geq \lambda_i(A)$, where $\lambda_1(A) \geq \lambda_2(A) \geq \cdots \geq \lambda_n(A)$ and $\lambda_1(B) \geq \lambda_2(B) \geq \cdots \geq \lambda_n(B)$ are eigenvalues of A and B, respectively.*

THEOREM 2.7. *Let M be a symmetric positive definite matrix. Then*

$$\beta_2(M) := \max_{d \in [0,1]^n} \|(I - D + DM)^{-1}D\|_2 = \|M^{-1}\|_2.$$

Proof. It is obvious that $\beta_2(M) \geq \|M^{-1}\|_2$. Now we show $\beta_2(M) \leq \|M^{-1}\|_2$. For any nonsingular diagonal matrix $D = \operatorname{diag}(d)$ with $d \in (0,1]^n$, $M + D^{-1}(I - D)$ is positive definite. By (i) of Lemma 2.6, $M^{-1} - (M + D^{-1}(I - D))^{-1}$ is positive semidefinite. By (ii) of Lemma 2.6, we have

$$\|(M + D^{-1}(I - D))^{-1}\|_2 = \|(I - D + DM)^{-1}D\|_2 \leq \|M^{-1}\|_2.$$

Since the largest eigenvalue is a continuous function of elements of the matrix, we have

$$\beta_2(M) = \max_{d \in [0,1]^n} \lim_{\epsilon \downarrow 0} \|(I - D_\epsilon + D_\epsilon M)^{-1} D_\epsilon\|_2 \leq \|M^{-1}\|_2,$$

where $D_\epsilon = \operatorname{diag}(\min(d + \epsilon e, e))$. $\square$

In comparison to Lemma 1.1, the following theorem gives sharp perturbation error estimates for the P-matrix LCP.

THEOREM 2.8. *Let $M \in R^{n \times n}$ be a P-matrix. Then the following statements hold:*

(i) *For any two vectors q and p in R^n,*

$$\|x(M,q) - x(M,p)\| \le \beta(M)\|q-p\|.$$

(ii) *Every matrix $A \in \mathcal{M} := \{A \mid \beta(M)\|M-A\| \le \eta < 1\}$ is a P-matrix. Let*

$$\alpha(M) = \frac{1}{1-\eta}\beta(M).$$

Then for any $A, B \in \mathcal{M}$ and $q, p \in R^n$

$$\|x(A,q) - x(B,p)\| \le \alpha(M)^2\|(-p)_+\|\|A-B\| + \alpha(M)\|q-p\|.$$

Proof. (i) This part of the proof follows directly from (2.3) by setting $M = A = B$.
(ii) For every $A \in \mathcal{M}$, since $\|(I-D+DM)^{-1}D(A-M)\| \le \beta(M)\|M-A\| \le \eta < 1$,

$$(I - D + DA) = (I - D + DM)(I + (I - D + DM)^{-1}D(A - M))$$

is nonsingular for any diagonal matrix $D = \mathrm{diag}(d)$ with $0 \le d_i \le 1$. By Lemma 2.1, A is a P-matrix. Moreover, from

$$(I - D + DA)^{-1}D = (I + (I - D + DM)^{-1}D(A - M))^{-1}(I - D + DM)^{-1}D$$

and

$$\|(I + (I - D + DM)^{-1}D(A - M))^{-1}\| \le \frac{1}{1 - \beta(M)\|A - M\|} \le \frac{1}{1-\eta},$$

we find $\beta(A) \le \alpha(M)$.

Since matrices $A, B \in \mathcal{M}$ are P-matrices, using (2.3) yields

$$\|x(A,q) - x(B,p)\| \le \beta(A)\left(\|A-B\|\|x(B,p)\| + \|q-p\|\right). \tag{2.4}$$

Notice that 0 is the solution of LCP(B, p_+). Using (2.3) again, we get

$$\|x(B,p)\| \le \beta(B)\|(-p)_+\|. \tag{2.5}$$

Applying $\beta(A) \le \alpha(M)$ and $\beta(B) \le \alpha(M)$ to (2.4) and (2.5), respectively, we obtain the desired bounds in (ii). ∎

From Theorems 2.5 and 2.7, the Lipschitz constants $\beta(M)$ and $\alpha(M)$ can be estimated by matrix norms if M is an H-matrix with positive diagonals or a symmetric positive definite matrix. In particular, from Lemma 2.4, Theorem 2.5, and Theorem 2.7, we have the following two corollaries.

COROLLARY 2.9. *Let $M \in R^{n\times n}$ be an H-matrix with positive diagonals. Then the following statements hold:*
(i) *For any two vectors q and p in R^n,*

$$\|x(M,q) - x(M,p)\|_\infty \le \|\tilde{M}^{-1}\|_\infty\|q-p\|_\infty.$$

(ii) *Every matrix $A \in \mathcal{M}_\infty := \{A \mid \|\tilde{M}^{-1}\|_\infty\|M-A\|_\infty \le \eta < 1\}$ is an H-matrix with positive diagonals. Let*

$$\alpha_\infty(M) = \frac{1}{1-\eta}\|\tilde{M}^{-1}\|_\infty.$$

Then for any $A, B \in \mathcal{M}_\infty$ and $q, p \in R^n$

$$\|x(A,q) - x(B,p)\|_\infty \le \alpha_\infty(M)^2\|(-p)_+\|_\infty\|A-B\|_\infty + \alpha_\infty(M)\|q-p\|_\infty.$$

COROLLARY 2.10. *Let $M \in R^{n\times n}$ be a symmetric positive definite matrix. Then the following statements hold:*
(i) *For any two vectors q and p in R^n,*

$$\|x(M,q) - x(M,p)\|_2 \le \|M^{-1}\|_2 \|q-p\|_2.$$

(ii) *Every matrix $A \in \mathcal{M}_2 := \{A \mid \|M^{-1}\|_2\|M-A\|_2 \le \eta < 1\}$ is a P-matrix. Let*

$$\alpha_2(M) = \frac{1}{1-\eta}\|M^{-1}\|_2.$$

Then for any $A, B \in \mathcal{M}_2$ and $q, p \in R^n$

$$\|x(A,q) - x(B,p)\|_2 \le \alpha_2(M)^2\|(-p)_+\|_2\|A-B\|_2 + \alpha_2(M)\|q-p\|_2.$$

A matrix A is called positive definite if

$$x^T Ax > 0, \qquad 0 \ne x \in R^n.$$

Since $x^T Ax = x^T \frac{A+A^T}{2} x$, A is positive definite if and only if $\frac{A+A^T}{2}$ is symmetric positive definite. Note that a positive definite matrix is not necessarily symmetric. Such asymmetric matrices frequently appear in the context of the LCP.

Combining the ideas of Mathias and Pang [12] and Corollary 2.10, we present perturbation bounds for the positive definite matrix LCP.

THEOREM 2.11. *Let $M \in R^{n\times n}$ be a positive definite matrix. Then the following statements hold:*
(i) *For any two vectors q and p in R^n,*

$$\|x(M,q) - x(M,p)\|_2 \le \left\| \left(\frac{M+M^T}{2} \right)^{-1} \right\|_2 \|q-p\|_2.$$

(ii) *Every matrix $A \in \mathcal{M}_2 := \{A \mid \|(\frac{M+M^T}{2})^{-1}\|_2\|M-A\|_2 \le \eta < 1\}$ is positive definite. Let*

$$\alpha_2(M) = \frac{1}{1-\eta} \left\| \left(\frac{M+M^T}{2} \right)^{-1} \right\|_2.$$

Then for any $A, B \in \mathcal{M}_2$ and $q, p \in R^n$

$$\|x(A,q) - x(B,p)\|_2 \le \alpha_2(M)^2\|(-p)_+\|_2\|A-B\|_2 + \alpha_2(M)\|q-p\|_2.$$

Proof. We first show that

$$\|x(A,q) - x(B,p)\|_2 \le \left\| \left(\frac{A+A^T}{2} \right)^{-1} \right\|_2 (\|A-B\|_2\|x(B,p)\|_2 + \|p-q\|_2) \tag{2.6}$$

holds if A is a positive definite matrix and the LCP(B,p) has a solution $x(B,p)$.

Since $x(A,q)$ and $x(B,p)$ are solutions of LCP(A,q) and LCP(B,p), respectively, we have

$$\begin{aligned} 0 &\ge (x(A,q) - x(B,p))^T (Ax(A,q) + q - Bx(B,p) - p) \\ &= (x(A,q) - x(B,p))^T (A(x(A,q) - x(B,p)) + (A-B)x(B,p) + q - p), \end{aligned}$$

which implies

$$\begin{aligned}
&(x(A,q)-x(B,p))^T((B-A)x(B,p)+p-q)\\
&\geq (x(A,q)-x(B,p))^T A(x(A,q)-x(B,p))\\
&= (x(A,q)-x(B,p))^T \frac{A+A^T}{2}(x(A,q)-x(B,p))\\
&\geq \frac{1}{\|(\frac{A+A^T}{2})^{-1}\|_2}\|x(A,q)-x(B,p)\|_2^2.
\end{aligned}$$

Using the Cauchy–Schwarz inequality, we get (2.6).

(i) Set $A=B=M$ in (2.6); we get the desired bound.

(ii) Note that for any matrix C, $\|C\|_2=\|C^T\|_2$. For any $x\in R^n$ with $x\neq 0$, we have

$$\begin{aligned}
x^TAx &= x^T\frac{M+M^T}{2}x + x^T\left(\frac{A+A^T}{2}-\frac{M+M^T}{2}\right)x\\
&\geq x^T\frac{M+M^T}{2}x - \left(\left\|\frac{A-M}{2}\right\|_2+\left\|\frac{A^T-M^T}{2}\right\|_2\right)\|x\|_2^2\\
&\geq \left(\left\|\left(\frac{M+M^T}{2}\right)^{-1}\right\|_2\right)^{-1}\|x\|_2^2 - \|A-M\|_2\|x\|_2^2\\
&\geq \left(\left\|\left(\frac{M+M^T}{2}\right)^{-1}\right\|_2\right)^{-1}\left(1-\left\|\left(\frac{M+M^T}{2}\right)^{-1}\right\|_2\|M-A\|_2\right)\|x\|_2^2.
\end{aligned}$$

Hence for any $A\in\mathcal{M}_2$, $x^TAx>0$, and thus A is positive definite. Moreover, from

$$\left(\frac{A+A^T}{2}\right)^{-1}=\left(I+\left(\frac{M+M^T}{2}\right)^{-1}\left(\frac{A+A^T}{2}-\frac{M+M^T}{2}\right)\right)^{-1}\left(\frac{M+M^T}{2}\right)^{-1}$$

and

$$\left\|\frac{A+A^T}{2}-\frac{M+M^T}{2}\right\|_2\leq\frac{1}{2}(\|A-M\|_2+\|A^T-M^T\|_2)=\|M-A\|_2$$

we have

$$\begin{aligned}
\left\|\left(\frac{A+A^T}{2}\right)^{-1}\right\|_2 &\leq \frac{1}{1-\|(\frac{M+M^T}{2})^{-1}\|_2\|\frac{A+A^T}{2}-\frac{M+M^T}{2}\|_2}\left\|\left(\frac{M+M^T}{2}\right)^{-1}\right\|_2\\
&\leq \alpha_2(M).
\end{aligned}$$

Similarly, for $B\in\mathcal{M}_2$, $\|(\frac{B+B^T}{2})^{-1}\|_2\leq\alpha_2(M)$. Notice that 0 is the solution of LCP(B,p_+). Setting $A=B$ and $q=p_+$ in (2.6), we get

$$\|x(B,p)\|_2\leq\left\|\left(\frac{B+B^T}{2}\right)^{-1}\right\|_2\|(-p)_+\|_2.$$

Using these inequalities with (2.6), we obtain the perturbation bound in (ii). ∎

Example 2.1. Theorem 2.2 shows that for every P-matrix, $\beta_\infty(M) \le c(M)^{-1}$. Now we show that $\beta_\infty(M)$ can be much smaller than $c(M)^{-1}$ in some cases. Consider

$$M = \begin{pmatrix} 1 & -t \\ 0 & t \end{pmatrix}.$$

For $t \ge 1$, M is an M-matrix. By Theorem 2.5, $\beta_\infty(M) = \|M^{-1}\|_\infty = 2$. For $\bar{x} = (1, t^{-1})$, we have

$$c(M) \le \max_{i \in N} \bar{x}_i (M\bar{x})_i = \frac{1}{t}.$$

Hence, $c(M)^{-1} \ge t \to \infty$ as $t \to \infty$.

3. Relative perturbation bounds for the LCP. Using the results in the last section, we derive relative perturbation bounds expressed in the term of $\beta(M)\|M\|$.

THEOREM 3.1. *Suppose*

$$\begin{aligned} \min(x, Mx+q) &= 0, \qquad M \in R^{n\times n}, \ \ 0 \ne (-q)_+ \in R^n, \\ \min(y, (M+\triangle M)y + q + \triangle q) &= 0, \qquad \triangle M \in R^{n\times n}, \ \ \triangle q \in R^n, \end{aligned}$$

with

$$\|\triangle M\| \le \epsilon \|M\|, \qquad \|\triangle q\| \le \epsilon \|(-q)_+\|.$$

If M is a P-matrix and $\epsilon\beta(M)\|M\| = \eta < 1$, then $M + \triangle M$ is a P-matrix and

$$\frac{\|y - x\|}{\|x\|} \le \frac{2\epsilon}{1-\eta}\beta(M)\|M\|.$$

Proof. First we observe that x is a solution of LCP(M, q) and y is a solution of LCP$(M + \triangle M, q + \triangle q)$. Then following the proof of (ii) of Theorem 2.8, we obtain that $M + \triangle M$ is a P-matrix and

$$\beta(M + \triangle M) \le \frac{1}{1-\eta}\beta(M),$$

which, together with (2.3), gives

$$\|x - y\| \le \frac{1}{1-\eta}\beta(M)(\|\triangle M\|\|x\| + \|\triangle q\|). \tag{3.1}$$

From $Mx + q \ge 0$, we deduce $(-q)_+ \le (Mx)_+ \le |Mx|$. This implies $\|(-q)_+\| \le \|Mx\| \le \|M\|\|x\|$. Hence, we have

$$\|x\| \ge \frac{1}{\|M\|}\|(-q)_+\| > 0. \tag{3.2}$$

Combining (3.1) and (3.2), we obtain the desired bounds

$$\frac{\|y - x\|}{\|x\|} \le \frac{1}{1-\eta}\beta(M)\left(\|\triangle M\| + \frac{\|\triangle q\|}{\|x\|}\right) \le \frac{2\epsilon}{1-\eta}\beta(M)\|M\|. \qquad \blacksquare$$

Theorem 3.1 indicates that $\beta(M)\|M\|$ is a measure of sensitivity of the solution of the LCP(M,q) for M being a P-matrix. Moreover, Theorem 3.1 with Corollary 2.9, Corollary 2.10, and Theorem 2.11 gives $\beta(M)\|M\|$ in the term of condition number for the H-matrix LCP, symmetric positive definite LCP, and positive definite LCP.

COROLLARY 3.2. *Suppose*

$$\begin{aligned} \min(x, Mx+q) &= 0, \qquad M \in R^{n\times n}, \ \ 0 \neq (-q)_+ \in R^n, \\ \min(y, (M+\triangle M)y + q + \triangle q) &= 0, \qquad \triangle M \in R^{n\times n}, \ \ \triangle q \in R^n. \end{aligned}$$

(i) *If M is an H-matrix with positive diagonals, $\epsilon\kappa_\infty(\tilde{M}) = \eta < 1$, and*

$$\|\triangle M\|_\infty \leq \epsilon \|\tilde{M}\|_\infty, \qquad \|\triangle q\|_\infty \leq \epsilon \|(-q)_+\|_\infty,$$

then $M + \triangle M$ is an H-matrix with positive diagonals, and

$$\frac{\|y-x\|_\infty}{\|x\|_\infty} \leq \frac{2\epsilon}{1-\eta}\kappa_\infty(\tilde{M}).$$

(ii) *If M is a symmetric positive definite matrix, $\epsilon\kappa_2(M) = \eta < 1$, and*

$$\|\triangle M\|_2 \leq \epsilon \|M\|_2, \qquad \|\triangle q\|_2 \leq \epsilon \|(-q)_+\|_2,$$

then $M + \triangle M$ is a P-matrix, and

$$\frac{\|y-x\|_2}{\|x\|_2} \leq \frac{2\epsilon}{1-\eta}\kappa_2(M).$$

(iii) *If M is a positive definite matrix, $\epsilon\kappa_2(\frac{M+M^T}{2}) = \eta < 1$, and*

$$\|\triangle M\|_2 \leq \epsilon \left\| \frac{M+M^T}{2} \right\|_2, \qquad \|\triangle q\|_2 \leq \epsilon \|(-q)_+\|_2 \frac{\|M+M^T\|_2}{2\|M\|_2},$$

then $M + \triangle M$ is a positive definite matrix, and

$$\frac{\|x-y\|_2}{\|x\|_2} \leq \frac{2\epsilon}{1-\eta}\kappa_2\left(\frac{M+M^T}{2}\right).$$

Remark. Note that $\|(-q)_+\| \leq \|q\|$. If $Mx + q = 0$, then (i) of Corollary 3.2 for M being an M-matrix and (ii) of Corollary 3.2 reduce to the perturbation bounds for the system of linear equations [8].

For the H-matrix LCP, componentwise perturbation bounds based on the Skeel condition number $\||\tilde{M}^{-1}||\tilde{M}|\|_\infty$ can be represented as follows.

THEOREM 3.3. *Suppose*

$$\begin{aligned} \min(x, Mx+q) &= 0, \qquad M \in R^{n\times n}, \ \ 0 \neq (-q)_+ \in R^n, \\ \min(y, (M+\triangle M)y + q + \triangle q) &= 0, \qquad \triangle M \in R^{n\times n}, \ \ \triangle q \in R^n, \end{aligned}$$

with

$$|\triangle M| \leq \epsilon |M|, \qquad |\triangle q| \leq \epsilon (-q)_+. \tag{3.3}$$

If M is an H-matrix with positive diagonals and $\epsilon\kappa_\infty(\tilde{M}) = \eta < 1$, then $M + \triangle M$ is an H-matrix with positive diagonals, and

$$\frac{\|y - x\|_\infty}{\|x\|_\infty} \leq \frac{2\epsilon}{1-\eta}\|\tilde{M}^{-1}|\tilde{M}|\|_\infty. \tag{3.4}$$

Proof. From (3.3), we have

$$\|\triangle M\|_\infty \leq \epsilon\|\tilde{M}\|_\infty, \quad \text{and} \quad \|\triangle q\|_\infty \leq \epsilon\|(-q)_+\|_\infty \leq \epsilon\|M\|_\infty\|x\|_\infty,$$

where the last inequality uses $(-q)_+ \leq (Mx)_+ \leq |M|x$.

According to Corollary 3.2, $M + \triangle M$ is an H-matrix with positive diagonals. Moreover, the equality (2.2) gives

$$(I - D + DM)(y - x) = D\triangle My + D\triangle q \tag{3.5}$$

for some diagonal matrix $D = \mathrm{diag}(d)$ with $d \in [0,1]^n$.

Following the proof of Theorem 2.5, by Lemma 2.4, we get

$$\begin{aligned}
|y - x| &\leq |(I - D + DM)^{-1}D|(|\triangle M|y + |\triangle q|) \\
&\leq |(I - D + D\tilde{M})^{-1}D|(|\triangle M|y + |\triangle q|) \\
&\leq \tilde{M}^{-1}(|\triangle M|y + |\triangle q|) \\
&\leq \epsilon\tilde{M}^{-1}(|M|y + |M|x).
\end{aligned}$$

Therefore, we find

$$\|y - x\|_\infty \leq \epsilon\|\tilde{M}^{-1}|M|\|_\infty(\|y\|_\infty + \|x\|_\infty). \tag{3.6}$$

Furthermore, from (3.5), we obtain

$$y - ((I - D + DM)^{-1}D\triangle M)y = x + (I - D + DM)^{-1}D\triangle q.$$

Hence, it holds that

$$\begin{aligned}
(1 - \epsilon\|\tilde{M}^{-1}\|_\infty\|M\|_\infty)\|y\|_\infty &\leq (1 - \|(I - D + DM)^{-1}D\|_\infty\|\triangle M\|_\infty)\|y\|_\infty \\
&\leq \|y - (I - D + DM)^{-1}D\triangle My\|_\infty \\
&\leq \|x\|_\infty + \|(I - D + DM)^{-1}D\|_\infty\|\triangle q\|_\infty \\
&\leq (1 + \epsilon\|\tilde{M}^{-1}\|_\infty\|M\|_\infty)\|x\|_\infty.
\end{aligned}$$

This implies

$$\|y\|_\infty \leq \frac{1+\eta}{1-\eta}\|x\|_\infty. \tag{3.7}$$

Combining (3.6) and (3.7), we obtain the desired bounds (3.4). ∎

4. Newton-type methods. In the last two sections, we have given perturbation bounds for the LCP in the term of $\beta(M)$. In this section, we use the perturbation bounds to analyze the efficiency of Newton-type methods for solving the LCP based on the systems (1.8) and (1.9).

Many semismooth Newton methods, smoothing Newton methods, and path-following interior point methods [5] solve a system of linear equations in each iteration,

$$(I - D_k + D_k M)(x - x^k) = -r(x^k), \tag{4.1}$$

or

$$\begin{pmatrix} M & -I \\ I - D_k & D_k \end{pmatrix} \begin{pmatrix} x - x^k \\ y - y^k \end{pmatrix} = -F(x^k, y^k), \tag{4.2}$$

where D_k is a diagonal matrix whose diagonal elements are in $[0, 1]$.

Sensitivity of (4.1) and (4.2) will affect implementation of the methods and reliability of the computed solution. From the analysis of Dennis and Schnabel [4], if the condition number of the coefficient matrix of the linear equations is larger than $(macheps)^{-1/2}$, the numerical solution may not be trustworthy. Here *macheps* is computer precision. The linear systems (4.1) and (4.2) have the following relation regarding to the condition numbers.

PROPOSITION 4.1. *For any diagonal matrix* $D = \mathrm{diag}(d)$ *with* $0 \le d_i \le 1$, $i = 1, 2, \ldots, n$, *the following inequalities hold:*

$$\kappa_\infty \begin{pmatrix} M & -I \\ I - D & D \end{pmatrix} \ge \kappa_\infty (I - D + DM) \tag{4.3}$$

and

$$\kappa \begin{pmatrix} M & -I \\ I - D & D \end{pmatrix} \ge \frac{1}{2} \kappa (I - D + DM). \tag{4.4}$$

Proof. First, we observe

$$\left\| \begin{pmatrix} M & -I \\ I - D & D \end{pmatrix} \right\|_\infty \ge 1 + \|M\|_\infty \ge \max(1, \|M\|_\infty) \ge \|I - D + DM\|_\infty$$

and

$$\left\| \begin{pmatrix} M & -I \\ I - D & D \end{pmatrix} \right\| \ge \max(1, \|M\|) \ge \frac{\max(1, \|M\|)}{1 + \|M\|} \|I - D + DM\| \ge \frac{1}{2} \|I - D + DM\|.$$

Next, we consider the inverses. From

$$\begin{pmatrix} I & 0 \\ D & I \end{pmatrix} \begin{pmatrix} M & -I \\ I - D & D \end{pmatrix} = \begin{pmatrix} M & -I \\ I - D + DM & 0 \end{pmatrix}$$

and

$$\begin{pmatrix} M & -I \\ I - D + DM & 0 \end{pmatrix}^{-1} = \begin{pmatrix} 0 & (I - D + DM)^{-1} \\ -I & M(I - D + DM)^{-1} \end{pmatrix},$$

we find the inverse

$$\begin{aligned} \begin{pmatrix} M & -I \\ I - D & D \end{pmatrix}^{-1} &= \begin{pmatrix} 0 & (I - D + DM)^{-1} \\ -I & M(I - D + DM)^{-1} \end{pmatrix} \begin{pmatrix} I & 0 \\ D & I \end{pmatrix} \\ &= \begin{pmatrix} (I - D + DM)^{-1} D & (I - D + DM)^{-1} \\ M(I - D + DM)^{-1} D - I & M(I - D + DM)^{-1} \end{pmatrix}. \end{aligned}$$

Therefore, we have

$$\left\| \begin{pmatrix} M & -I \\ I-D & D \end{pmatrix}^{-1} \right\| \geq \|(I-D+DM)^{-1}\|.$$

By the definition of the condition number, (4.3) and (4.4) hold. □

Since D_k in the coefficient matrices of (4.1) and (4.2) changes at each step, we consider the worst case

$$K(M) := \max_{d\in[0,1]^n} \|(I-D+DM)^{-1}\|\|I-D+DM\|$$

and

$$\hat{K}(M) := \max_{d\in[0,1]^n} \left\| \begin{pmatrix} M & -I \\ D & I-D \end{pmatrix}^{-1} \right\| \left\| \begin{pmatrix} M & -I \\ D & I-D \end{pmatrix} \right\|.$$

From Proposition 4.1, we have

$$\hat{K}_\infty(M) \geq K_\infty(M),$$

which implies that if (4.2) is well-conditioned, then (4.1) is well-conditioned, and if (4.1) is ill-conditioned, then (4.2) is ill-conditioned. The following example shows that $\hat{K}_\infty(M)$ can be much larger than $K_\infty(M)$.

Example 4.1. Let $M = aI (a \geq 1)$. Straightforward calculation gives

$$\begin{aligned} \hat{K}_\infty(M) &\geq \left\| \begin{pmatrix} aI & -I \\ I & 0 \end{pmatrix} \right\|_\infty \left\| \begin{pmatrix} aI & -I \\ I & 0 \end{pmatrix}^{-1} \right\|_\infty \\ &= (1+a) \left\| \begin{pmatrix} 0 & I \\ -I & aI \end{pmatrix} \right\|_\infty = (1+a)^2 \end{aligned}$$

and

$$\begin{aligned} K_\infty(M) &= \max_{d\in[0,1]^n} \|(I-D+aD)^{-1}\|_\infty \|I-D+aD\|_\infty \\ &\leq \frac{\max_{0\leq\xi\leq 1} |(1+a\xi-\xi)|}{\min_{0\leq\xi\leq 1} |(1+a\xi-\xi)|} = a. \end{aligned}$$

For large a, $\hat{K}_\infty(M) - K_\infty(M)$ $(\geq a^2+a+1)$ is very large.

From Proposition 4.1 and Example 4.1, we may suggest that Newton-type methods for solving the nonlinear equations (1.8) have less perturbation error than Newton-type methods for (1.9). Now, we focus on Newton-type methods for (1.8). Obviously, it holds that

$$K(M) \geq \kappa(M)$$

as $e \in [0,1]^n$. For M being an H-matrix with positive diagonals, by Theorems 2.1 and 2.3 in [2], we have

$$K_\infty(M) \leq \max(1, \|M\|_\infty)\|\tilde{M}^{-1} \max(\Lambda, I)\|_\infty, \tag{4.5}$$

where Λ is the diagonal parts of M.

For M being an M-matrix with $\|M\|_\infty \geq 1$, we have

$$\kappa_\infty(M) \leq K_\infty(M) \leq \kappa_\infty(M)\|\max(\Lambda, I)\|_\infty. \tag{4.6}$$

Hence, the condition number $\kappa_\infty(M)$ is a measure of sensitivity of the solution of the system of linear equations for the worst case. Note that we have shown that $\kappa_\infty(M)$ is a measure of sensitivity of the solution of the LCP. Hence we may suggest that if Λ is not large, then the LCP is well-conditioned if and only if the system of linear equations (4.1) at each step of the Newton method is well-conditioned. Furthermore, for an M matrix, its diagonal elements are positive, and LCP$(\Lambda^{-1}M, \Lambda^{-1}q)$ and LCP(M, q) are equivalent. The inequalities in (4.6) yield $K_\infty(\Lambda^{-1}M) = \kappa_\infty(\Lambda^{-1}M)$.

5. Final remark. In [2], we provided the following error bound for the P-matrix LCP:

$$\|x - x(M, q)\| \leq \max_{d\in[0,1]^n} \|(I - D + DM)^{-1}\|\|r(x)\| \quad \text{for any } x \in R^n, \tag{5.1}$$

and we proved that (5.1) is sharper than the Mathias–Pang error bound [12]

$$\|x - x(M, q)\|_\infty \leq \frac{1 + \|M\|_\infty}{c(M)}\|r(x)\|_\infty \quad \text{for any } x \in R^n$$

in $\|\cdot\|_\infty$. Moreover, we showed that the error bound (5.1) can be computed easily for some special matrix LCP. For instance, if M is an H-matrix with positive diagonals, we have

$$\mu(M) := \max_{d\in[0,1]^n} \|(I - D + DM)^{-1}\| \leq \|\tilde{M}^{-1}\max(\Lambda, I)\|,$$

where Λ is the diagonal parts of M.

In this paper, we study the behavior of the solution $x(M, q)$ when there are some perturbations $\triangle M$ and $\triangle q$ in M and q. In particular, we show

$$\|x(M + \triangle M, q + \triangle q) - x(M, q)\| \leq \beta(M)\|\triangle M x(M + \triangle M, q + \triangle q) + \triangle q\|.$$

The constants $\mu(M)$ and $\beta(M)$ play different roles, where the former is for computation of error bounds and the latter is for sensitivity analysis.

Theorem 2.2 proves that $\beta(M)$ is smaller than the Mathias–Pang constant $1/c(M)$ for sensitivity and stability analysis [3]. Theorems 2.5 and 2.7 provide various interesting properties (1.5)–(1.7) of $\beta(M)$ when M is an H-matrix with positive diagonals, M-matrix, or symmetric positive definite matrix. These results show that the condition number $\kappa(M)$ is a measure of the sensitivity of the LCP(M, q). This means that if $\kappa(M)$ is small (large), then small changes in M or q result in small (large) changes in the solution $x(M, q)$ of the LCP(M, q).

When LCP(M, q) is used in the modeling of a practical application, the matrix M and vector q often contain errors due to inaccurate data, uncertain factors, etc. Hence, to make $x(M, q)$ useful and practical, it is very important to obtain some sensitivity information of the solution. This is one reason why sensitivity analysis of the LCP(M, q) has been studied so extensively [3]. On the web site http://www.st.hirosaki-u.ac.jp/∼chen/ExamplesLCP.pdf, we provide numerical examples including free boundary problems [14] and traffic equilibrium problems [3, 6] to illustrate the practical value of the new perturbation bounds (1.1)–(1.7).

STATISTICAL QUASI-NEWTON: A NEW LOOK AT LEAST CHANGE*

CHUANHAI LIU† AND SCOTT A. VANDER WIEL‡

Abstract. A new method for quasi-Newton minimization outperforms BFGS by combining least-change updates of the Hessian with step sizes estimated from a Wishart model of uncertainty. The Hessian update is in the Broyden family but uses a negative parameter, outside the convex range, that is usually regarded as the safe zone for Broyden updates. Although full Newton steps based on this update tend to be too long, excellent performance is obtained with shorter steps estimated from the Wishart model. In numerical comparisons to BFGS the new *statistical quasi-Newton (SQN)* algorithm typically converges with about 25% fewer iterations, functions, and gradient evaluations on the top 1/3 hardest unconstrained problems in the CUTE library. Typical improvement on the 1/3 easiest problems is about 5%. The framework used to derive SQN provides a simple way to understand differences among various Broyden updates such as BFGS and DFP and shows that these methods do not preserve accuracy of the Hessian, in a certain sense, while the new method does. In fact, BFGS, DFP, and all other updates with nonnegative Broyden parameters tend to inflate Hessian estimates, and this accounts for their observed propensity to correct eigenvalues that are too small more readily than eigenvalues that are too large. Numerical results on three new test functions validate these conclusions.

Key words. BFGS, DFP, negative Broyden family, Wishart model

1. Introduction.

Quasi-Newton methods for unconstrained optimization are important computational tools in many scientific fields and are a standard subject in textbooks on computation. The BFGS method, proposed individually in [6], [14], [20], and [30], is implemented in most optimization software and is widely recognized as efficient. Generalizations of BFGS are available for large problems with memory limitations, for problems with bound constraints, and for a parallel computing environment. In theoretical investigations BFGS is known as a special case of the Broyden class [5]. Some Broyden updates with negative Broyden parameters have been found to produce faster convergence than BFGS updates [31], [8] but, for various reasons, have not been widely adopted. Indeed, Byrd et. al. conclude that "practical algorithms that preserve the excellent properties of the BFGS method are difficult to design." Nocedal and Wright [29] state that "the BFGS formula... is presently considered to be the most effective of all quasi-Newton updating formulae." In our opinion, BFGS remains the most popular front-runner because of two important unanswered

questions: What is the "best" negative Broyden parameter? and What initial step sizes should be used with negative Broyden parameters? This paper answers these questions by solving a least-change problem to approximate Newton directions and by estimating step sizes through a statistical model of Hessian uncertainty. We call the new algorithm *statistical quasi-Newton* (SQN).

1.1. Quasi-Newton methods. Quasi-Newton methods solve the unconstrained optimization problem

$$\min_x f(x), \qquad x \in \mathcal{R}^n,$$

in which both the objective function $f(x)$ and its gradient $g(x) \equiv \nabla f(x)$ are easy to compute but Newton's method is not applicable because direct evaluation of the Hessian matrix $G(x) \equiv \nabla^2 f(x)$ is practically infeasible. Quasi-Newton methods build up an approximate Hessian matrix using successive gradient evaluations. The general method iterates between a minimization (M-) step consisting of a one-dimensional search for a good point along an approximate Newton direction and an estimation (E-) step consisting of an update to the Hessian estimate. A more specific definition follows.

Generic quasi-Newton algorithm. Select a starting point $x_0 \in \mathcal{R}^n$ and a symmetric positive definite estimate, B_0, of the Hessian matrix $G(x_0)$. Evaluate $g_0 = g(x_0)$ and iterate over $k = 0, 1, 2, \ldots$ the following two steps.

M-Step. Search in the direction $-B_k^{-1} g_k$ for a step size $s_k > 0$ to obtain a new evaluation point and gradient,

$$x_{k+1} = x_k - s_k B_k^{-1} g_k, \qquad g_{k+1} = g(x_{k+1}),$$

that satisfy *the Wolfe conditions* for sufficient decrease of the function and for curvature (see (2) and (3) below).

E-Step. Estimate the Hessian matrix at x_{k+1} using the quantities B_k, x_k, x_{k+1}, g_k, and g_{k+1}. The estimate, B_{k+1}, must be symmetric and positive definite and must satisfy the *quasi-Newton condition*

$$B_{k+1}\delta_k = \gamma_k, \tag{1}$$

where

$$\delta_k \equiv x_{k+1} - x_k \quad \text{and} \quad \gamma_k \equiv g_{k+1} - g_k.$$

Condition (1) requires the vector of estimated second derivatives in the current step direction, $B_{k+1}\delta_k/s_k$, to agree with the corresponding numerical second derivatives γ_k/s_k. Various principles have been used to derive Hessian update formulae, but the general goal has been to minimize the change from B_k to B_{k+1} in some sense. This paper derives an update that minimizes change in a canonical sense and provides a model-based estimate for the step size s_k.

The Wolfe conditions referenced in the M-step are two standard requirements to ensure that sufficient progress is made toward the optimum even when the line search is not required to find the exact minimum in the given search direction. The Wolfe *sufficient decrease condition*,

$$f(x_{k+1}) \le f(x_k) - \rho_1 s_k g_k' B_k^{-1} g_k \qquad (\rho_1 \in (0,1), \text{ say } \rho_1 = 10^{-4}), \tag{2}$$

requires a reduction in $f(x)$ that is at least a fraction ρ_1 of that predicted by the directional derivative $-g_k B_k^{-1} g_k$. The Wolfe *strong curvature condition*,

$$|g'_{k+1}(B_k^{-1}g_k)| \le \rho_2 g'_k(B_k^{-1}g_k) \qquad (\rho_2 \in (\rho_1, 1), \text{ say } \rho_2 = 0.9), \tag{3}$$

requires at least a proportional decrease in the magnitude of the derivative in the search direction. Some algorithms impose a weaker curvature condition in which the absolute value is removed from the left-hand side of (3). Nocedal and Wright [29] discuss the importance of the Wolfe conditions in ensuring that sufficient progress is made on each iteration.

The best-known class of Hessian estimates used in the E-step are the rank-two Broyden updates [5]:

$$B_{k+1} = B_k - \frac{B_k \delta_k \delta'_k B_k}{\delta'_k B_k \delta_k} + \frac{\gamma_k \gamma'_k}{\delta'_k \gamma_k} + c_k \omega_k \omega'_k, \tag{4}$$

where

$$\omega_k \equiv \frac{\gamma_k}{\delta'_k \gamma_k} - \frac{B_k \delta_k}{\delta'_k B_k \delta_k} \tag{5}$$

and c_k is a scalar parameter to be specified. The usual parameterization takes $c_k = \phi_k\,(\delta'_k B_k \delta_k)$, where ϕ_k is known as the *Broyden parameter*. However, our exposition is more natural with the parameterization

$$c_k = (\lambda_k - 1)\,(\delta'_k \gamma_k)\,, \tag{6}$$

where the parameter λ_k is shown in section 3 to regulate the inflation of B_{k+1} relative to B_k. BFGS is the Broyden update with $\lambda_k = 1$ (i.e., $\phi_k = c_k = 0$).

There is a critical value λ_k^c such that B_{k+1} is positive definite for any $\lambda_k > \lambda_k^c \equiv 1 - r_k^{-1}$, where

$$r_k \equiv \frac{\gamma'_k B_k^{-1} \gamma_k}{\gamma'_k \delta_k} - \frac{\delta'_k \gamma_k}{\delta'_k B_k \delta_k}. \tag{7}$$

It can be shown that $r_k \ge 0$ by making use of the curvature condition (3) and the Cauchy–Schwarz inequality. If $r_k = 0$, then λ_k^c is taken to be $-\infty$.

1.2. Preview of SQN. The SQN method is remarkably simple and effective. This section briefly defines SQN and demonstrates its superiority to BFGS. Derivations and additional experimental results are provided in the following sections.

SQN algorithm. Follow the generic quasi-Newton algorithm with the following additional specifications. Initialize $\hat{s}_0 = 1$.
M-Step. Begin the line search from an initial evaluation point $x_k - \hat{s}_k B_k^{-1} g_k$.
E-Step. Estimate the Hessian using a Broyden update (4)–(6) with parameter

$$\lambda_k = \max\{0, 1 - (1-\epsilon) r_k^{-1}\}, \tag{8}$$

where ϵ is a small positive constant (e.g., $\epsilon = 10^{-6}$) and if $r_k = 0$, the max is taken to be 0. Estimate the next step size as

$$\hat{s}_{k+1} = \frac{g'_{k+1} B_{k+1}^{-1} g_{k+1}}{g'_{k+1} B_{k+1}^{-1} g_{k+1} + (1-\lambda_k)(\delta'_k \gamma_k)(g'_{k+1} B_{k+1}^{-1} \omega_k)^2} \;<\; 1. \tag{9}$$

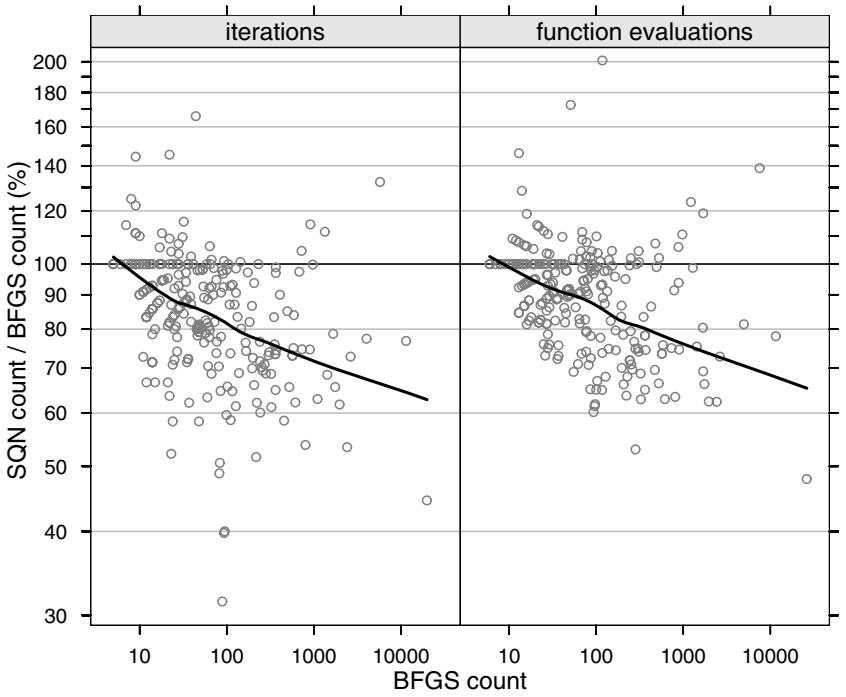

FIG. 1. *Improvement in SQN efficiency with problem difficulty for iterations, function evaluations, and gradient evaluations. Each point represents performance of SQN and BFGS on a given problem from the standard starting point.*

All the quantities needed to calculate $\hat{s}_{k+1}$ are readily available from the preceding M-step with no extra function or gradient evaluations required. Using $\epsilon > 0$ guarantees that B_{k+1} remains positive definite. The Broyden parameter corresponding to λ_k is $\phi_k = (\lambda_k - 1)\,(\delta_k'\gamma_k) \,/\, (\delta_k' B_k \delta_k)$, and this is negative because (3) implies $\delta_k'\gamma_k > 0$. Equation (9) is written in terms of the inverse Hessian estimate because Broyden updates are typically implemented on the inverse scale using the well-known dual form of (4). Similarly, $B_k\delta_k = -s_k g_k$ can be substituted into (7) for computational efficiency. See, for example, [29].

The shortened initial step size, $\hat{s}_k$, is crucial to improving the performance of Broyden updates with negative Broyden parameters. Zhang and Tewarson [31] use $\hat{s} = 1$ and comment that their negative Broyden algorithm improves iteration counts but that "less or no savings are achieved on the number of function evaluations" because initial steps are often too long to provide a sufficient decrease in the function value. SQN corrects this problem by effectively estimating the optimal step size for the given search direction.

Figure 1 shows that SQN typically converges with substantially fewer iterations and function evaluations than BFGS on 248 unconstrained optimization problems in the CUTE [3] suite. The left panel plots SQN iterations as a percent of BFGS iterations against BFGS iterations. The right panel shows the same information for function evaluations. SQN becomes more efficient relative to BFGS on the more difficult problems, as additional iterations offer additional opportunities for improvement. Performance on easy problems with few iterations is often dominated by the first iteration in which a poor choice of B_0 produces a poor search vector for any quasi-Newton

TABLE 1
Median percent improvement of SQN relative to BFGS by difficulty of problem.

	Easy	Medium	Hard
Iterations	8	14	26
Function evaluations	4	9	23

algorithm. In harder problems these start-up effects wash out so that the advantage of SQN over BFGS becomes more apparent. The trend curves in Figure 1 highlight this tendency. The smooth curves are robust local regressions [11] that follow the data without being unduly influenced by the low outlying points that would tend to make the trends even stronger.

Table 1 summarizes the improvement by splitting the test problems into three equal groups, *easy*, *medium*, and *hard*, according to the number of iterations for BFGS to converge. SQN's median improvement over BFGS is largest for the hardest 1/3 of the test problems, 25% in round numbers.

Our setup uses the line search [28] available from Argonne National Lab at ftp://info.mcs.anl.gov/pub/MINPACK-2/csrch in MINPACK-2. This line search evaluates the function value and gradient an equal number of times. The starting point x_0 is as given in the CUTE collection, and the initial Hessian estimate is $B_0 = c \cdot I_n$, where c is the geometric mean of the positive diagonal elements of the true Hessian at x_0. This is similar to the usual choice of $B_0 = I_n$, but scaling by c provides a more fair comparison because the true Hessian at x_0 tends to be much larger than I_n on the CUTE problems, and this gives an unfair advantage to BFGS, which has a bias toward inflating the Hessian estimate, as explained in section 3 below. For each test problem and starting point both SQN and BFGS are run until no valid step is found due to finite numerical precision. Then the best point x_* achieved by either algorithm is identified, and convergence is retrospectively declared at the first k for which

(10)
$$[f(x_k) - f(x_*)] + |(x_k - x_*)'g(x_*)| + |(x_k - x_*)'G(x_*)(x_k - x_*)| < 10^{-9}\,[1 + |f(x_*)|]\,.$$

This generalization of the assessment criterion [19] ensures that both the optima and the optimizers match.

The comparisons reported in Figure 1 and Table 1 are based on 248 problems in the CUTE collection. The test set consists of all unconstrained problems with maximum dimension of 500 that have continuous analytic second derivatives and compile with the default "large" version of the CUTE software. Of the 306 that fit these criteria, 15 appear to start at the optimum, 23 converge to a better local minimum with SQN than with BFGS, and 20 converge to a better minimum with BFGS. Removing these 58 cases leaves 248 test problems that support clean comparisons between SQN and BFGS.

We also conducted an initial study of the SQN algorithm, patterned after [31] using 20 of the test problems [27], each with 10 starting points. The results were similar: about 20% fewer iterations and gradient evaluations and about 10% fewer function evaluations compared to BFGS. This initial study used Fletcher's line search algorithm [15] with the tunable parameters set as suggested and utilizing his "sensible" choices for trial step lengths based on minimizing interpolating polynomials.

SQN compares favorably to other studies that have used negative Broyden parameters. Zhang and Tewarson [31] report 21% and 13% fewer iterations for their SDQN method relative to BFGS on problems of small and "increasing" dimension, respectively. However, their improvements were smaller using the EFE metric that

incorporates the number of function evaluations. Byrd, Liu, and Nocedal [8] report improvements of 18% on iterations and 12% on function evaluations for a smaller set of tests using their Method I, which is not practical as a quasi-Newton update because it requires evaluation of $G(x)$.

The remainder of the article is arranged as follows. Section 2 gives a select history of ideas in quasi-Newton development with emphasis on the least-change principle and argues for a particular scale-free matrix as the most appropriate measure of the change between consecutive Hessian estimates. Section 3 introduces a transformation into canonical coordinates, derives (4)–(8) as the new least-change update, and shows that it preserves Hessian accuracy from one iteration to the next in a certain sense. Section 4 introduces a Wishart model to describe Hessian uncertainty and derives (9) as an estimate of the optimal step size. Section 5 compares performance on three new test functions designed to verify our understanding of why SQN is better than other Broyden methods. Section 6 explores connections to other least-change derivations and mentions ideas for future research.

2. Least-change updates. Fletcher's overview [17] of methods for unconstrained optimization is an excellent introduction to the huge literature on quasi-Newton methods. This section briefly reviews the historical ideas that led to the least-change principle on which the most influential quasi-Newton methods are based. A line of reasoning is then given to suggest a certain relative-change matrix as being the most appropriate measure of change for the goal of approximating Newton search directions. This leads to the SQN update that was introduced in section 1.2. Although the SQN update happens to be in the Broyden class, it is derived in section 3 by minimizing change over *all possible* quasi-Newton updates.

2.1. Historical developments. Crockett and Chernoff [12] stated the idea of building up a Hessian estimate iteratively so as to approximate the Newton method:

> *..., it is possible to obtain, from the successive approximations, certain relevant information about terms of order higher than those actually computed, and to conveniently use this information to improve the rate of convergence.*

The basic idea of Broyden [4] as articulated in [7] was that the Hessian update *"should therefore require, if possible,...,* no change *to B_k in any direction orthogonal to δ_k."* Broyden was solving a system of differential equations, and his mathematical formulation [$B_{k+1}\delta_k = \gamma_k$ and $(B_{k+1} - B_k)q = 0 \;\; \forall q : q'\delta_k = 0$] produces an asymmetric update that is not appropriate for the problem $\min f(x)$.

Taking a more mathematical approach, Broyden [5] dropped the "orthogonality" part of his original intuition and sought instead a low-rank Hessian update. This led to the Broyden class (4) of symmetric rank-two updates. Subsequent researchers also focused on making small modifications to the Hessian without explicit concern for the space orthogonal to the search direction. Greenstadt [21], for example, wrote,

> *Let us ask for the "best" correction in some sense. There are many possible choices to make, but a good one is to ask for the* smallest *correction, in the sense of some norm. To a certain extent, this would tend to keep the elements of $[B_k^{-1}]$ from growing too large, which might cause an undesirable instability.*

The extensive review [25] emphasizes the importance of the *least-change principle* in deriving many of the most effective quasi-Newton methods.

The important special case of a Broyden update with $\lambda_k = 1$ is called BFGS after the four authors who individually published the update formula in 1970. Goldfarb [20]

worked with the scaled difference of inverse Hessian estimates

$$E_W^* \equiv W^{1/2}\left(B_{k+1}^{-1} - B_k^{-1}\right)W^{1/2}, \tag{11}$$

where the symmetric matrix W satisfies $W\delta_k = \gamma_k$. He derived the BFGS update by using the results in [21] to minimize the Frobenius norm $\|E_W^*\|_F \equiv [\mathrm{tr}\,(E_W^* E_W^*)]^{1/2}$ over the class of symmetric matrices B_{k+1} that satisfy the Newton condition (1). Thus, BFGS is a least-change update. But the metric of change is important. For example, using the same W but minimizing the Frobenius norm of

$$E_W \equiv W^{-1/2}\left(B_{k+1} - B_k\right)W^{-1/2} \tag{12}$$

produces the Broyden update with $\lambda_k = 1+\delta_k' B_k \delta_k/(\delta_k'\gamma_k)$. This is known as DFP [13], [18] and is generally regarded as inferior to BFGS.

Fletcher [14] advocated restricting attention to Broyden updates that are convex combinations of the BFGS and DFP updates because such updates satisfy a monotone eigenvalue property when used to minimize quadratic functions. Recently, however, various choices of negative Broyden parameters ($\phi_k < 0$ corresponding to $\lambda_k < 1$) have been studied. See, for example, [31], [8], [23], [17], and [26]. These authors report that negative Broyden parameters can reduce iteration counts, although in some cases this comes at the cost of increased numbers of function evaluations. The potential for improvement relative to BFGS seems to be best if the initial Hessian estimate is much too large. Robust improvement over BFGS has been elusive. Indeed, Zhang and Tewarson [31] concluded that such investigations have not shaken the position of BFGS as the most popular front-runner.

2.2. A new measure for least change. Minimizing the change from B_k to B_{k+1} is a generally accepted principle. There is no agreement, however, on how to measure that change. Zhao [32] derives 10 different optimal updates by considering five possible matrix norms applied to two different matrices that measure change. The function for measuring change is empirically important: BFGS outperforms DFP even though the two are least-change duals derived from E_W^* and E_W, respectively.

A sensible matrix measure of change that has received little attention in the literature is the difference $B_{k+1} - B_k$ scaled by the current estimate B_k, namely

$$E_B \equiv B_k^{-1/2}\left(B_{k+1} - B_k\right)B_k^{-1/2}. \tag{13}$$

Normalizing a difference is appropriate because, in every direction, E_B measures change of the Hessian estimate *relative to current nominal value*, and this produces a scale-free method. Greenstadt [22] states that such normalization "renders harmless the accidents of coordinate selection in a given problem." One possible danger in making E_B small is that B_{k+1} could become singular (or even indefinite if allowed), and this could produce unstable quasi-Newton search vectors, based on B_{k+1}^{-1}. However, applying no direct penalty to large differences on the inverse scale is more aggressive than BFGS, in the same spirit as employing negative values of the Broyden parameter. In fact, the next section will demonstrate that minimizing $\|E_B\|_F$ produces exactly a negative Broyden update.

Interestingly, minimizing E_B (with respect to commonly used scalar measures of matrices) is equivalent to minimizing

$$E_B^* \equiv B_{k+1}^{1/2}(B_k^{-1} - B_{k+1}^{-1})B_{k+1}^{1/2} \tag{14}$$

because E_B^* and E_B have the same eigenvalues, as shown in Appendix C. The matrix E_B^* scales the difference in inverse estimates by the still-to-be-determined update. Greenstadt [21] minimized a weighted change of the inverse estimates. In deriving BFGS, Goldfarb [20] writes, "If, instead, $[B_{k+1}]$ is substituted for [the weight matrix] in [Greenstadt's result], then [BFGS] is obtained." Although this sounds like minimizing E_B^*, Goldfarb in fact minimized E_W^* with a fixed weight matrix that satisfied the quasi-Newton condition required of B_{k+1}, namely $W\delta_k = \gamma_k$. SQN, on the other hand, can be viewed as directly using the unknown B_{k+1} as the weight matrix in Greenstadt's objective function.

3. SQN: Least relative change. The form of E_B in (13) as a measure of change motivates transforming the coordinates of x by $B_k^{1/2}$ so that the problem of updating the Hessian estimate takes a simple form. This section uses Broyden's original idea of making no change to the portion of B_k that is orthogonal to δ_k but applies the idea in a transformed coordinate system.

As the focus is on the kth step of the quasi-Newton algorithm, the notation is streamlined from this point forward by dropping subscripts k and replacing subscripts $k+1$ by "+."

3.1. Canonical coordinates. For conceptual convenience, at the kth iteration transform x in such a way that the line search is along the first component direction and the current Hessian estimate B transforms to the identity matrix. This is accomplished by the linear transformation

$$\tilde{x} = U'B^{1/2}x, \tag{15}$$

where U is an orthonormal rotation matrix with the first column equal to $B^{1/2}\delta(\delta'B\delta)^{-1/2}$. In the transformed space the current step is strictly along the first component direction:

$$\tilde{x}_+ - \tilde{x} = (\delta'B\delta)^{1/2}(1, 0, \ldots, 0)'.$$

The objective function and gradient become

$$\tilde{f}(\tilde{x}) \equiv f(x) \quad \text{and} \quad \tilde{g}(\tilde{x}) \equiv \nabla\tilde{f}(\tilde{x}) = U'B^{-1/2}g(x),$$

and the transformed Hessian is

$$\tilde{G}(\tilde{x}) \equiv \nabla^2\tilde{f}(\tilde{x}) = U'B^{-1/2}G(x)B^{-1/2}U. \tag{16}$$

Substituting the estimated Hessian B for $G(x)$ in (16) produces the transformed estimate $\tilde{B} = I_n$, the n-dimensional identity matrix.

3.2. Observed and missing information. Define second-order numerical derivatives of $\tilde{f}(\tilde{x})$ along the search direction as

$$\begin{bmatrix} a \\ b \end{bmatrix} \equiv \frac{\tilde{g}(\tilde{x}_+) - \tilde{g}(\tilde{x})}{(1, 0, \ldots, 0)(\tilde{x}_+ - \tilde{x})} = \frac{U'B^{-1/2}\gamma}{(\delta'B\delta)^{1/2}}, \tag{17}$$

where the first element a is a scalar and b is an $(n-1)$-dimensional vector. The curvature condition (3) implies that $a \geq (1-\rho_2)/s > 0$. The quasi-Newton condition (1) is equivalent to the intuitive idea that the numerical derivatives (17) form the first

column of the updated Hessian matrix. Since the Hessian is symmetric, the general form of update in transformed coordinates becomes

$$\tilde{B}_+ = \begin{bmatrix} a & b' \\ b & C \end{bmatrix}, \tag{18}$$

where symmetric C is to be determined subject only to the constraint $\tilde{B}_+ > 0$, which is equivalent to $C - a^{-1}bb' > 0$. (The notation $M > 0$ indicates that the matrix M is positive definite.) C represents curvature in the complimentary space, that is, the space canonically orthogonal to the current search direction.

Following Broyden's idea that no information is gained in directions orthogonal to δ suggests the updating scheme obtained by taking $C = I_{n-1}$ if doing so produces $\tilde{B}_+ > 0$, i.e., if $a > b'b$. But, what does one do if $a \leq b'b$? The question itself implies that certain information on C *is* provided by the observed data (a, b) along with the assumption that the Hessian matrix is positive definite. In general, C should be a function of a and b.

The following theorem provides the least-change update based on the Frobenius norm of E_B.

THEOREM 1 (SQN update). *The quasi-Newton update that minimizes* $\|E_B\|_F$ *(and hence also* $\|E_B^*\|_F$*) subject to* (1) *and* $B_+ \geq 0$ *has canonical form*

$$\tilde{B}_+ = \begin{bmatrix} a & b' \\ b & I_{n-1} + \lambda_{\text{SQN}}\, bb'/a \end{bmatrix}, \tag{19}$$

where, for $\tilde{r} \equiv b'b/a$,

$$\lambda_{\text{SQN}} = \begin{cases} 0 & \text{if } \tilde{r} \leq 1, \\ 1 - \tilde{r}^{-1} & \text{otherwise.} \end{cases} \tag{20}$$

$\tilde{B}_+$ *is singular for* $\tilde{r} \geq 1$.

Proof. Appendix C implies that $\|E_B\|_F = \|E_B^*\|_F$:

$$\begin{aligned} \|E_B\|_F^2 &= \left\| B^{-1/2}\left(B_+ - B\right)B^{-1/2} \right\|_F^2 = \left\| U'B^{-1/2}B_+B^{-1/2}U - I_n \right\|_F^2 = \left\| \tilde{B}_+ - I_n \right\|_F^2 \\ &= \operatorname{tr}\left(\left[\begin{pmatrix} a & b' \\ b & C \end{pmatrix} - I \right] \left[\begin{pmatrix} a & b' \\ b & C \end{pmatrix} - I \right] \right) \\ &= \operatorname{tr}\left(\Phi^2\right) - 2\operatorname{tr}\left(\Phi\right) + 2b'\Phi b/a + (a + \tilde{r})(a + \tilde{r} - 2) + n, \end{aligned}$$

where $\Phi \equiv C - bb'/a$ and we have used $\tilde{B}_+ = U'B^{-1/2}B_+B^{-1/2}U$ from (16). $B_+ \geq 0$ is equivalent to $\Phi \geq 0$ so that minimizing $\|E_B\|_F$ over $B_+ \geq 0$ is equivalent to minimizing the first three terms of the final expression over $\Phi \geq 0$.

Denote the eigenvalues of Φ by $0 \leq \eta_1 \leq \cdots \leq \eta_n$. Then

$$\operatorname{tr}\left(\Phi^2\right) - 2\operatorname{tr}\left(\Phi\right) + 2b'\Phi b/a \;\geq\; \sum_i \eta_i^2 - 2\sum_i \eta_i + 2\eta_1 b'b/a \tag{21}$$

with equality if and only if the first eigenvector of Φ is proportional to b. The right-hand side of (21) is minimized by $\eta_2 = \cdots = \eta_n = 1$ and

$$\eta_1 = \max\left\{0, 1 - \tilde{r}\right\}.$$

Thus, the left-hand side of (21) is minimized by a matrix with the specified eigenvalues and first eigenvector equal to $b/\sqrt{b'b}$. The required matrix is

$$\Phi = I + \left[\frac{\max\{0, 1-\tilde{r}\} - 1}{\tilde{r}}\right] \frac{bb'}{a},$$

and this corresponds to the optimal C given in the theorem. □

Theorem 1 demonstrates that making no change in the complementary space (i.e., $C = I_{n-1}$) does, in fact, produce a least-change update. The theorem also provides a larger estimate for C when needed to preserve nonnegative definiteness. Our implementation of SQN uses a safeguarded choice of λ_{SQN} to prevent the Hessian estimate from becoming singular. See (8).

Behind the intuition that one should make small alterations to the Hessian estimate in the complementary space lies a principle that accuracy obtained on previous iterations should be preserved as much as possible. The following proposition demonstrates that the SQN update achieves the goal of preserving Hessian accuracy in a certain sense.

PROPOSITION 1 (SQN accuracy preservation). *If the true Hessian in canonical coordinates is positive definite and given by*

$$\tilde{B}_+ = \begin{bmatrix} a & b' \\ b & C_{\text{TRUE}} \end{bmatrix}, \tag{22}$$

then $C_{\text{SQN}} \equiv I_{n-1} + \lambda_{\text{SQN}} bb'/a$ is at least as accurate as I_{n-1} for estimating C_{TRUE} in any direction either parallel to b or orthogonal to b. That is,

$$\left|u'\left(C_{\text{SQN}} - C_{\text{TRUE}}\right)u\right| \;\le\; \left|u'\left(I_{n-1} - C_{\text{TRUE}}\right)u\right| \tag{23}$$

for any u such that either $u'b = 0$ or $u \propto b$. Furthermore, this is not necessarily true for any larger estimate $\hat{C} = C_{\text{SQN}} + VV'$, where V is any nonzero matrix with $n-1$ rows.

See Appendix A for a proof.

The following proposition provides the canonical form for the well-known Broyden family and shows that SQN updates are particular members.

PROPOSITION 2 (canonical Broyden updates). *Under the canonical transform* (15) *the Broyden update* (4) *transforms to*

$$\tilde{B}_+ = \begin{bmatrix} a & b' \\ b & I_{n-1} + \lambda bb'/a \end{bmatrix}, \tag{24}$$

where $\lambda = 1 + c/(\delta'\gamma)$. In particular, the usual Broyden parameter is $\phi = (\lambda - 1)a$, and important special cases are given as follows:

Method	λ	ϕ
SQN	$\max\{0, 1-\tilde{r}^{-1}\}$	$\max\{-a, -a\tilde{r}^{-1}\}$,
BFGS	1	0
DFP	$1 + a^{-1}$	1

where if $\tilde{r} = 0$, the max *is taken to be the first argument.*

See Appendix B for a proof. The proof also provides formulae for a and b in terms of the usual quantities δ, γ, and B and shows that $\tilde{r} = r$, where $\tilde{r} = b'b/a$ is defined in Theorem 1 and r is given in (7).

Although BFGS minimizes several different measures of change [16], Proposition 2 indicates that BFGS *increases* the lower right block ($\lambda > 0$) over its previous value of I_{n-1}, whereas SQN leaves it unchanged if possible, or adds a fraction of the BFGS correction in order to preserve positive semidefiniteness. The conclusion of Proposition 1 is that neither BFGS nor DFP preserves accuracy of the previous Hessian estimate (in the canonical sense of (23)) over a large class of directions. It is interesting that DFP explodes as a becomes small.

4. Step size estimation. In trial experiments with the SQN update, we carried out the quasi-Newton M-step using a line search in which the initial step size was unity; that is, the line search used an initial evaluation point of $x - \hat{s}B^{-1}g$ with $\hat{s} = 1$, which is the Newton step under the assumption that B is the actual Hessian. The experiments demonstrated that the SQN update tended to reduce the number of iterations to convergence compared to BFGS but did not consistently reduce the number of function evaluations required. Further investigation showed the reason: unit steps are often too long when the SQN update is used. The steepest descent method (SDQN) [31] also uses negative Broyden parameters, and they state, "*SDQN tends to give steps longer than BFGS steps, and therefore is more likely to violate the [sufficient decrease] condition.*" When unit steps are used, fewer iterations seem to come with the price of more function evaluations per iteration. Some numerical results with unit step sizes on SQN and other Broyden updates are reported in section 5.

Why do negative Broyden parameters produce steps that are too long? A rough explanation is that a negative Broyden parameter produces a smaller Hessian estimate than BFGS. Compare $\lambda < 1$ in Proposition 2 with $\lambda = 1$. A smaller B implies a longer unit step $-B^{-1}g$. Therefore, if unit steps are suitable for BFGS, then unit steps may well be too long for use with negative Broyden parameters. This reasoning is admittedly rough; it does not account for differences in the step *direction* and does not provide guidance for selecting more appropriate step sizes. This section proposes a Wishart model to describe uncertainty of the unknown Hessian and then derives an estimate of the optimal step size as a function of the Broyden parameter used in updating the Hessian. The SQN initial step size (9) is a special case.

4.1. A Wishart model for the Hessian matrix. The unknown Hessian $\tilde{G}_+ = \tilde{G}(\tilde{x}_+)$ can be modeled as a random matrix whose probability distribution quantifies the plausibility of all possible canonical Hessians. It is reasonable to use a probability model for this purpose because the true Hessian varies unpredictably from one quasi-Newton iteration to the next and from one objective function to another. Therefore $\tilde{G}_+$ is never completely known. Furthermore, modeling $\tilde{G}_+$ as a random matrix provides a means of incorporating new curvature information obtained in a line search and appropriately updating the distribution of the unknown Hessian. The updated distribution is the key to determining what length of step should be taken in any given direction.

Several properties are desirable for the distribution of $\tilde{G}_+$. It should

(i) be centered at the previous estimate $\tilde{B} = I_n$,

(ii) have probabilities that taper off toward zero for matrices far from I_n, and

(iii) describe equal uncertainty in every direction because, although $\tilde{G}_+$ is likely less uncertain in the directions of recent steps, these directions are not available for use within the quasi-Newton framework.

The simplest statistical model for symmetric positive definite matrices that has the above properties is the Wishart distribution with expectation I_n:

$$\nu\tilde{G}_+ \sim \text{Wishart}_n\left(I_n, \nu\right), \tag{25}$$

where $\nu \geq n+1$ is the degrees of freedom parameter. The distribution of $\tilde{G}_+$ becomes more concentrated around I_n as ν increases. See, e.g., [2] for the definition and properties of the Wishart family. The probability density function of $\tilde{G}_+$ is proportional to

$$\left|\tilde{G}_+\right|^{(\nu-n-1)/2} \exp\left\{-\frac{\nu}{2}\text{tr}\left(\tilde{G}_+\right)\right\}. \tag{26}$$

Because (26) involves only $\tilde{G}_+$ through its determinant and trace, any orthogonal rotation, $R'\tilde{G}_+R$ where $R'R = I_n$, is distributed identically to $\tilde{G}_+$. This *directional symmetry* seems an appropriate requirement for modeling the Hessian in canonical coordinates.

In the quasi-Newton framework, the first row and column of $\tilde{G}_+$ are considered to be known from the numerical second derivatives (17). Therefore

$$\tilde{G}_+ = \begin{bmatrix} a & b' \\ b & C \end{bmatrix}, \tag{27}$$

where a and b are observed and C is not. Standard Wishart theory (see, e.g., [2]) provides the conditional distribution $[C|a,b]$ through

$$\nu\left[C - \frac{bb'}{a}\middle| a, b\right] \sim \text{Wishart}_{n-1}\left(I_{n-1}, \nu-1\right).$$

The conditional expectation and mode are

$$\text{E}(C|a,b) = \frac{\nu-1}{\nu} I_{n-1} + \frac{bb'}{a}, \tag{28}$$

$$\text{Mode}(C|a,b) = \frac{\nu}{\nu-n-1} I_{n-1} + \frac{bb'}{a}. \tag{29}$$

The two multipliers on I_{n-1} depend on the degrees of freedom, ν, and they differ because the Wishart model is skewed toward large positive definite matrices. But both coefficients approach unity as $\nu \to \infty$, the *large-sample* limit. Although ν could be estimated from a and b, using the large-sample limit is an attractive simplification that corresponds to modeling the current Hessian estimate as arbitrarily accurate *before* observing a and b.

Comparing (28) and (29) to (24) in Proposition 2 shows that the large-sample conditional expectation and mode under a Wishart model are exactly equal to the BFGS update. Specifically, let $B_+(\lambda)$ denote the Broyden update (4)–(6) with parameter λ and let $\tilde{B}_+(\lambda)$ denote the corresponding canonical form given by (24). Then

$$\begin{aligned} \lim_{\nu\to\infty} E\left(G_+|a,b\right) &= B^{1/2}U\left[\lim_{\nu\to\infty} E\left(\tilde{G}_+\middle| a,b\right)\right]U'B^{1/2} \\ &= B^{1/2}U\tilde{B}_+(1)U'B^{1/2} \\ &= B_+(1), \end{aligned} \tag{30}$$

which is the BFGS update.

Although (30) is the simplest statistical estimate of the Hessian, the SQN update is a better choice for *sequential* Hessian estimation because it preserves accuracy obtained in previous iterations (section 2.2 and Proposition 1). When estimating the optimal step size, however, accuracy preservation is not a concern—an appropriate step size in one iteration may or may not be appropriate in the next. Thus, while the SQN Hessian update is derived to preserve accuracy, the SQN step size, derived in the next section, uses conditional expectation to estimate the optimal step, given the most recent curvature information.

4.2. Optimal step size. An estimate of the optimal step size for any given Broyden update can be derived from the Wishart model. Let d_+ represent an arbitrary search direction to be taken in the M-step on iteration $k+1$. A second-order Taylor expansion of $f(\cdot)$ about the point x_+ gives the quadratic approximation

$$f(x_+ + sd_+) \approx f(x_+) + sd'_+g_+ + \frac{s^2}{2}d'_+G_+d_+ \tag{31}$$

with optimum step size

$$s^* = \frac{-d'_+g_+}{d'_+G_+d_+} \tag{32}$$

obtained by differentiating (31) with respect to s and setting the result to zero. The denominator of (32) involves the unknown Hessian, but an estimate of s^* can be obtained by replacing G_+ with its large-sample conditional expectation from (30):

$$\lim_{\nu\to\infty} E\left(G_+|a,b\right) = B_+(1) = B_+(\lambda) + (1-\lambda)(\delta'\gamma)\omega\omega', \tag{33}$$

where (4) has been used to express $B_+(1)$ in terms of a general Broyden update. The resulting optimum step size is obtained by plugging (33) into (32) and taking $d_+ = -B_+^{-1}(\lambda)g_+$, the next quasi-Newton step direction:

$$\hat{s}(\lambda) = \frac{g'_+B_+^{-1}(\lambda)g_+}{g'_+B_+^{-1}(\lambda)g_+ + (1-\lambda)(\delta'\gamma)(g'_+B_+^{-1}(\lambda)\omega)^2}. \tag{34}$$

This is the step size formula (9) of the SQN algorithm. For BFGS ($\lambda = 1$), the estimated optimum is $\hat{s}(1) = 1$, which suggests that unit steps may work better for BFGS than for any other Broyden update.

Results comparing BFGS to the SQN algorithm using (34) are shown in Figure 1 and demonstrate that SQN achieves consistent reduction in function evaluations, as well as iteration counts, compared to BFGS. Additional comparisons to SQN with unit initial steps for three new test functions are reported next.

5. Results on three new test functions. The CUTE test problems have become standard for comparing quasi-Newton algorithms, but they are not particularly useful for empirically validating our claim that BFGS tends to inflate B_k and that SQN is more neutral. This section uses three new test functions for that purpose.

It was found that BFGS is lopsided [8]: it can more readily increase Hessian estimates that are too small than shrink ones that are too large. This was surprising in light of the strong "self-correcting" property of the BFGS update that was established [10]: the relative error between the curvature predicted by B_k and the curvature observed in the current line search is transmitted exactly to the relative change of the

TABLE 2
Three test functions $f(x) = \sum_1^4 f_i(x_i)$ with simple Hessians.

	$f_i(x_i)$	$G_{ii}(x)$	Anticipated best λ_{NOM}
f^{dec} :	$\frac{1}{2}x_i^2 + \frac{1}{12}\eta_i^2 x_i^4$	$1 + (\eta_i x_i)^2$	negative
f^{inc} :	$\eta_i^{-2}\left[\eta_i x_i \arctan(\eta_i x_i) - \frac{1}{2}\ln(1+\eta_i^2 x_i^2)\right]$	$[1 + (\eta_i x_i)^2]^{-1}$	positive
f^{sin} :	$\frac{1}{2}x_i^2 + \eta_i^{-2}\left[\eta_i x_i - \sin(\eta_i x_i)\right]$	$1 + \sin(\eta_i x_i)$	near zero

determinant from $|B_k|$ to $|B_{k+1}|$. Proposition 2, on the other hand, shows that BFGS corrections actually inflate B_k in the space canonically orthogonal to the search direction, whereas SQN corrections leave that part of the Hessian unchanged (subject to positive definiteness) and therefore should cope equally well with estimates that need to shrink as with ones that need to grow. Furthermore, choosing λ_k to be less than 0 or greater than 1 should make these effects more pronounced.

To check this understanding, we employ three new test functions f^{dec}, f^{inc}, and f^{sin} with simple Hessians that respectively decrease, increase, and change sinusoidally as x_k moves in the direction of the optimum value. Each function has $n = 4$ dimensions and has the form $f(x) = \sum_1^4 f_i(x_i)$. The functions are defined in Table 2, where the values $(\eta_1, \eta_2, \eta_3, \eta_4) \equiv (1, 2, 4, 8)$ scale how quickly curvature changes in each coordinate direction. Each function is convex and has a diagonal Hessian with an ith diagonal element as listed in the table. In each case the minimizer is $x^* = (0, 0, 0, 0)$, $f(x^*) = 0$, and $G(x^*) = I_4$.

For these functions we implement a range of Broyden updates with

$$\lambda = \max\left\{\lambda_{\text{NOM}}, 1 - (1-\epsilon)r^{-1}\right\},$$

where λ_{NOM} is set between -2 and 3, $\epsilon = 10^{-6}$, and initial step sizes are given by (34). Special cases are $\lambda_{\text{NOM}} = 0$ and 1, which correspond to SQN and BFGS, respectively.

The rationale for testing with functions whose Hessians change monotonically (f^{dec}, f^{inc}) or unpredictably (f^{sin}) is to verify our claim that BFGS needlessly inflates the previous Hessian estimate whereas SQN treats it neutrally. With f^{inc}, for example, the most appropriate Hessian estimate in iteration $k+1$ will tend to be larger than in iteration k. BFGS could have an advantage over SQN because it tends to inflate the Hessian beyond its previous value in the complementary space. In this case, the best choice of λ_{NOM} should be larger than 0 and possibly even larger than 1, the BFGS value. For f^{dec}, on the other hand, SQN should have the advantage over BFGS and the optimal λ_{NOM} should be negative. For f^{sin}, there is no consistent pattern for the Hessian on one step compared to the previous step so that $\lambda_{\text{NOM}} = 0$ (i.e., SQN) should be nearly optimal. In each case, more extreme values of λ_{NOM} should produce more extreme effects.

5.1. Results for different λ_{NOM}. Figure 2 plots average counts to convergence as a function of λ_{NOM} with each panel representing one of the new test functions. Each plotted symbol represents an average count over 1000 random starting points. The vertical scales are set to support relative comparisons, the most obvious of which is that λ_{NOM} has the greatest effect for f^{dec} and the least for f^{sin}. Iterations, function evaluations, and gradient evaluations are shown using different plotting symbols. Fletcher's line search [15], as discussed in section 1.2, was used in this study. The true value is used for the starting Hessian estimate, $B_0 = G(x_0)$.

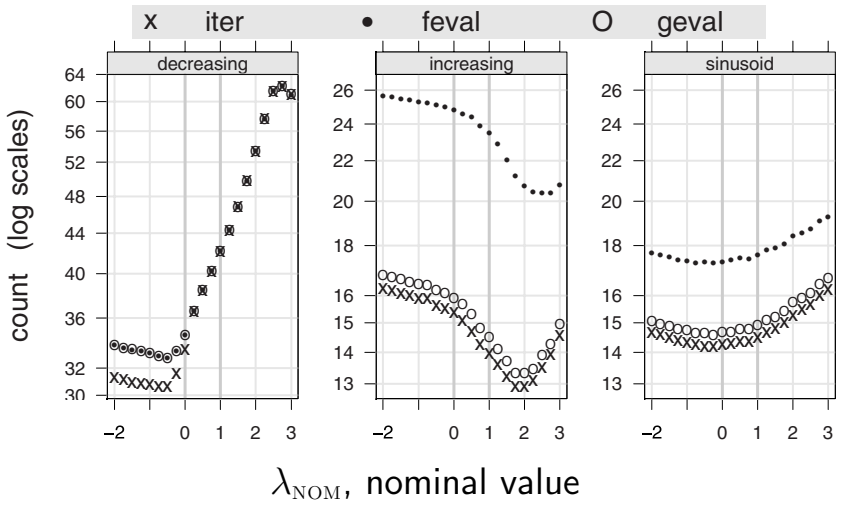

FIG. 2. *Performance counts versus* λ_{NOM} *on test functions with Hessians that are decreasing, increasing, and sinusoidal as* x_k *moves toward the minimum. Different symbols are used for iterations (*$\times$ *iter), function evaluations (*• *feval), and gradient evaluations (* O *geval). Initial steps are estimated using* (9). *The special value* $\lambda_{\text{NOM}} = 0$ *is SQN, and* $\lambda_{\text{NOM}} = 1$ *is BFGS.*

The starting points x_0 were chosen at random in such a way that they tend to be oriented in the direction of $(\eta_1, \eta_2, \eta_3, \eta_4)$. Specifically, the ith component of x_0 was drawn randomly as

$$x_{0,i} = K\eta_i(1 + z_i/3),$$

where the z_i are independent $\mathrm{N}(0,1)$ random variables and the scale was set as $K = 200$ for f^{dec}, $K = 50$ for f^{inc}, and $K = 1000\|\eta\|$ for f^{sin}. These choices reflect a little experimentation aimed at producing differences between BFGS and SQN that are large enough to be interesting without requiring unwieldy numbers of iterations. As far as we know, other choices produce similar results, though we have not studied this extensively. Convergence was declared when $f(x_k) < 10^{-10}$.

For f^{dec}, Figure 2 demonstrates that SQN is indeed better able to cope with a decreasing Hessian than BFGS, and further improvement is obtained by using slightly negative values of λ_{NOM}. The situation is reversed for f^{inc}. BFGS handles the increasing Hessian better than SQN, and further improvement is obtained by taking λ_{NOM} as large as 2. Finally, for f^{sin} the Hessian changes arbitrarily, and the SQN update ($\lambda_{\text{NOM}} = 0$) is nearly optimal.

Several additional comments on these results are worth noting. First, within each panel all three curves have nearly the same shape. But on f^{dec} function evaluations are always equal to gradient evaluations, whereas function evaluations are substantially higher on f^{inc} and f^{sin}. This indicates that the initial step size estimate is better for f^{dec} than for the other two functions because, with the Fletcher line search, if initial step sizes are too large to produce a sufficient decrease in the function value, then the function is reevaluated at additional trial steps with no gradient evaluations. Second, for any $\lambda_{\text{NOM}} < 1$ some values of λ_k will likely exceed λ_{NOM} because of the requirement that B_{k+1} remain positive definite. This produces an asymmetry in the results so that the performance differences between $\lambda_{\text{NOM}} = -1$ and 0 are not as great as the differences between 0 and 1. In fact, our selection of starting points that

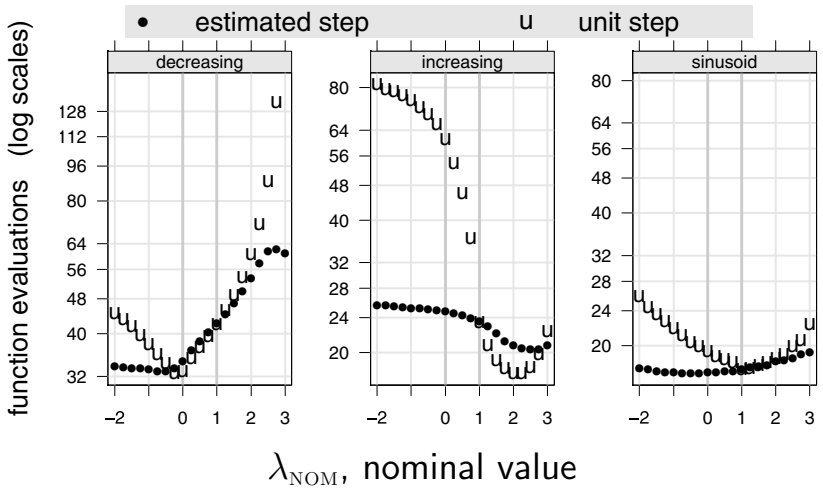

FIG. 3. *Function evaluation counts versus* λ_{NOM} *for three test functions. The plots compare performance with unit initial steps* (u) *against estimated initial steps* (•) *using* (9). *The dots in this figure are the same as in Figure* 2.

are biased in the direction of η was made to enhance the effect of λ_{NOM} below 1 on $f^{\mathrm{inc}}$and f^{sin}. The patterns in Figure 2 are smooth because they average across 1000 starting points. If counts from a single starting point were plotted, the patterns for f^{inc} and f^{sin} would be virtually impossible to discern because of noise in the data. Thus, it would be meaningless to compare different choices of λ_{NOM} based on only a few test cases.

5.2. Results for different step sizes. Figure 3 demonstrates the importance of using estimated step sizes, especially with $\lambda_{\mathrm{NOM}} < 1$. The experiment is the same as in Figure 2, except that the algorithm was also run with unit initial step sizes. The plots compare average function evaluation counts for unit initial steps against those for estimated steps. In each panel, as λ_{NOM} decreases from 1 (BFGS), the unit initial step results eventually become much worse than the results with estimated steps. The same appears to be true as λ_{NOM} becomes positive and large. The curves intersect at $\lambda_{\mathrm{NOM}} = 1$ because the estimated step size is 1.

At $\lambda_{\mathrm{NOM}} = 0$ (SQN) the results of Figure 3 are most revealing on f^{inc}. In this case the SQN Hessian estimate tends to be too small so that unit step sizes are too large. Estimated step sizes are smaller and perform much better, although they may still be too large, as indicated in Figure 2, by the gap between the number of function and gradient evaluations. The only case where unit steps perform substantially better than estimated ones is on f^{inc} with $1 < \lambda_{\mathrm{NOM}} < 3$. These values of λ_{NOM} inflate the Hessian estimates more than BFGS. We suspect that the inflated Hessians are producing estimated steps that are too short. Significantly, estimated steps are *uniformly better* than unit steps on f^{sin}, for which Hessian changes are fairly unpredictable.

6. Discussion. This paper has investigated two estimation problems that arise in the design of quasi-Newton algorithms: (1) estimation of Newton directions by way of sequential updates to a Hessian estimate; and (2) estimation of the optimum along a given search direction. SQN solves the two problems rather differently, using a least-change principle for the Hessian update and a statistical model for the step size. This raises the question of why the statistical model is not also used for the Hessian update.

Straightforward application of the Wishart model leads, in fact, to the BFGS update as is seen in (30). Another derivation of BFGS is obtained by taking the negative logarithm of the Wishart density (26), dividing by $\nu/2$, and taking $\nu \to \infty$. The result is the following function:

$$\psi(\tilde{B}_+) \equiv \operatorname{tr}\left(\tilde{B}_+\right) - \ln|\tilde{B}_+|.$$

Fletcher [16] demonstrated that BFGS minimizes $\psi(\tilde{B}_+) = \psi(E_B + I) = \psi(E_B^* + I)$, where E_B and E_B^* are defined in (13) and (14), respectively. Similarly DFP minimizes $\psi(\tilde{B}_+^{-1}) = \psi((E_B + I)^{-1}) = \psi((E_B^* + I)^{-1})$. Once again, the measure of change is influential.

We argue, however, that accuracy preservation (as measured by E_B^* and E_B) is more important than achieving the best one-step statistical estimate for the problem of *sequentially* estimating the Hessian matrix; this leads to the least-change formulation of Theorem 1. But the SQN update can also be derived from a statistical approach. We first obtained it by combining the Wishart model (25) with a prior distribution that strongly forced C toward the identity matrix. The prior was the statistical embodiment of the least-change principle. Details of this derivation are omitted to save space.

There is a fascinating historical connection that ties the relative change matrices E_B in (13) and E_B^* in (14) to BFGS, DFP, and the E_I method [21] from which Goldfarb [20] derived BFGS. E_W^* and E_W in (11) and (12) are well-known duals that measure change on the inverse and nominal scales and lead to the BFGS and DFP updates, respectively. In the same sense, the dual of E_B is

$$E_I \equiv B_k^{1/2}\left(B_{k+1}^{-1} - B_k^{-1}\right)B_k^{1/2},$$

which is the matrix that Greenstadt minimized. Therefore the SQN update derived from E_B and E_B^* is the dual of the E_I update in the same sense that BFGS is the dual of the older DFP method. Although Greenstadt did not constrain B_{k+1} to be positive definite, minimizing $\|E_I\|_F$ over positive semidefinite updates results in truncating Greenstadt's solution at the critical value of the Broyden parameter. E_B^* was used in [1] to derive an optimally scaled BFGS update. Lukšan [24] generalized the technique to the Broyden family. Specializing Lukšan's result to the case of no scaling produces $\lambda = 0$ for $r < 1$.

Use of a statistical framework to design a quasi-Newton method motivates several interesting topics. The numerical results on three new test functions suggest that information on the bias of previous Hessian estimates could be captured and used to obtain a better update that uses either varying values of λ_{NOM} within the Broyden family or a self-scaling update outside of the Broyden family. Use of the Wishart model to estimate the optimal step size also suggests a more general class of quasi-Newton methods obtained by searching not in the estimated Newton direction $-B^{-1}g$ but rather in an alternate direction determined from the conditional distribution $[-G(x)^{-1}g|a, b]$. We have obtained promising results in some limited tests of these ideas.

Appendix A. Proof of Proposition 1.

Proof. If $r \leq 1$, then $C_{\mathrm{SQN}} = I_{n-1}$ and (23) holds as an equality for *all* u. Suppose $r > 1$ so that $C_{\mathrm{SQN}} = I_{n-1} + (1 - r^{-1})a^{-1}bb'$. Then for any $u : u'b = 0$,

$$u'C_{\mathrm{SQN}}u = u'I_{n-1}u,$$

and thus (23) holds as an equality. Suppose $u = \rho b$ for some $\rho \neq 0$. Positive definiteness of the true Hessian implies $(C_{\mathrm{TRUE}} - a^{-1}bb') > 0$, and thus

$$\begin{aligned} u'C_{\mathrm{TRUE}}u \;>\; a^{-1}u'bb'u &= \rho^2(b'b)r \\ &= u'C_{\mathrm{SQN}}u > \rho^2(b'b) \;=\; u'I_{n-1}u \;>\; 0. \end{aligned}$$

That is, in the direction of u, C_{SQN} is closer to C_{TRUE} than I_{n-1} is, and this implies that (23) holds as a strict inequality.

To prove the final statement, suppose that $C_{\mathrm{TRUE}} = I_{n-1}$ so that the right-hand side of (23) equals zero and consider two cases as follows. First, suppose that $\|V'b\| > 0$ and take $u = \rho b$ with $\rho \neq 0$. Then

$$u'(\hat{C} - C_{\mathrm{TRUE}})u = \rho^2 b' \left(\lambda a^{-1}bb' + VV'\right) b \;> 0,$$

and (23) is violated. On the other hand, if $\|V'b\| = 0$, then assume, without loss of generality, that V has full column rank and take $u = V(V'V)^{-1}y$ for some vector $y \neq 0$. Then $u'b = y'(V'V)^{-1}V'b = 0$ but

$$u'(\hat{C} - C_{\mathrm{TRUE}})u = y'(V'V)^{-1}V'(VV')V(V'V)^{-1}y = y'y \;>\; 0,$$

which violates (23). □

Appendix B. Proof of Proposition 2.

Proof. Using (16), the relation between B_+ and $\tilde{B}_+$ is given by $B_+ = B^{1/2}U\,\tilde{B}_+U'B^{1/2}$. This can be expressed as follows:

$$\begin{aligned} B_+ &= B^{1/2}U \begin{bmatrix} a & b' \\ b & I_{n-1} + \lambda bb'/a \end{bmatrix} U'B^{1/2} \\ &= B + B^{1/2}U \begin{bmatrix} a-1 & b' \\ b & \lambda bb'/a \end{bmatrix} U'B^{1/2} \\ &= B + B^{1/2}U(D_1 + D_2 + D_3)U'B^{1/2}, \end{aligned} \tag{35}$$

where

$$D_1 = \begin{bmatrix} -1 & 0 \\ 0 & 0 \end{bmatrix}, \quad D_2 = \begin{bmatrix} a^2/a & b' \\ b & bb'/a \end{bmatrix}, \quad \text{and} \quad D_3 = \begin{bmatrix} 0 & 0 \\ 0 & a(\lambda-1)bb'/a^2 \end{bmatrix}.$$

Denote by $U[,1]$ the first column of U. Then

$$U[,1] = \frac{B^{1/2}\delta}{(\delta'B\delta)^{1/2}}, \quad \begin{bmatrix} a \\ b \end{bmatrix} = \frac{U'B^{-1/2}\gamma}{(\delta'B\delta)^{1/2}},$$

$$a = \frac{\delta'\gamma}{\delta'B\delta}, \quad \text{and} \quad r \equiv \frac{b'b}{a} = \frac{\gamma'B^{-1}\gamma}{\delta'\gamma} - \frac{\delta'\gamma}{\delta'B\delta}.$$

Simple algebraic operations lead to the following equalities:

$$B^{1/2}UD_1U'B^{1/2} = -B^{1/2}U[,1](U[,1])'B^{1/2} = -\frac{B\delta\delta'B}{\delta'B\delta},$$

$$B^{1/2}UD_2U'B^{1/2} = \frac{1}{a}B^{1/2}U \begin{bmatrix} a \\ b \end{bmatrix} [a, b']U'B^{1/2} = \frac{\gamma\gamma'}{\delta'\gamma},$$

and

$$B^{1/2}UD_3U'B^{1/2} = \frac{a(\lambda-1)}{a^2}B^{1/2}U\left(\begin{bmatrix}a\\b\end{bmatrix}-\begin{bmatrix}a\\0\end{bmatrix}\right)\left(\begin{bmatrix}a\\b\end{bmatrix}-\begin{bmatrix}a\\0\end{bmatrix}\right)'U'B^{1/2}$$
$$= (\lambda-1)(\delta'\gamma)\left(\frac{\gamma}{\delta'\gamma}-\frac{B\delta}{\delta'B\delta}\right)\left(\frac{\gamma}{\delta'\gamma}-\frac{B\delta}{\delta'B\delta}\right)'.$$

From these equalities and (35), we see that the expression for B_+ is identical to (4) with $c = (\lambda-1)(\delta'\gamma)$. ∎

Appendix C. Equivalence of change matrices E_B and E_B^*. A scalar measure is required to define the "size" of the matrix E_B defined in (13). Many of the most common scalar measures depend only on eigenvalues—for example, trace, determinant, spectral norm, Frobenius norm, and the ψ-function [9], $\psi(E_B+I) = \operatorname{tr}(E_B+I) - \ln|E_B+I|$.

LEMMA 1. *The eigenvalues of E_B in* (13) *are identical to those of E_B^* in* (14). *Also, the eigenvalues of E_B+I are identical to those of E_B^*+I.*

Proof. Let $\simeq$ denote equality of eigenvalues and note that $PQ \simeq QP$ for square P and Q. Thus,

$$E_B^* \simeq B_{k+1}\left(B_k^{-1}-B_{k+1}^{-1}\right) = \left(B_{k+1}-B_k\right)B_k^{-1} \simeq E_B$$

and

$$E_B^*+I = B_{k+1}^{1/2}B_k^{-1}B_{k+1}^{1/2} \simeq B_k^{-1/2}B_{k+1}B_k^{-1/2} = E_B+I. \quad ∎$$

ON AUGMENTED LAGRANGIAN METHODS WITH GENERAL LOWER-LEVEL CONSTRAINTS*

R. ANDREANI†, E. G. BIRGIN‡, J. M. MARTÍNEZ†, AND M. L. SCHUVERDT†

Abstract. Augmented Lagrangian methods with general lower-level constraints are considered in the present research. These methods are useful when efficient algorithms exist for solving subproblems in which the constraints are only of the lower-level type. Inexact resolution of the lower-level constrained subproblems is considered. Global convergence is proved using the constant positive linear dependence constraint qualification. Conditions for boundedness of the penalty parameters are discussed. The resolution of location problems in which many constraints of the lower-level set are nonlinear is addressed, employing the spectral projected gradient method for solving the subproblems. Problems of this type with more than 3×10^6 variables and 14×10^6 constraints are solved in this way, using moderate computer time. All the codes are available at http://www.ime.usp.br/~egbirgin/tango/.

Key words. nonlinear programming, augmented Lagrangian methods, global convergence, constraint qualifications, numerical experiments

1. Introduction.

Many practical optimization problems have the form

$$\text{Minimize } f(x) \text{ subject to } x \in \Omega_1 \cap \Omega_2, \tag{1.1}$$

where the constraint set Ω_2 is such that subproblems of type

$$\text{Minimize } F(x) \text{ subject to } x \in \Omega_2 \tag{1.2}$$

are much easier than problems of type (1.1). By this we mean that there exist efficient algorithms for solving (1.2) that cannot be applied to (1.1). In these cases it is natural to address the resolution of (1.1) by means of procedures that allow one to take advantage of methods that solve (1.2). Several examples of this situation may be found in the expanded report [3].

These problems motivated us to revisit augmented Lagrangian methods with arbitrary lower-level constraints. Penalty and augmented Lagrangian algorithms can take advantage of the existence of efficient procedures for solving partially constrained subproblems in a natural way. For this reason, many practitioners in Chemistry, Physics, Economics, and Engineering rely on empirical penalty approaches when they incorporate additional constraints to models that were satisfactorily solved by pre-existing algorithms.

The general structure of augmented Lagrangian methods is well known [7, 22, 39]. An outer iteration consists of two main steps: (a) Minimize the augmented

Lagrangian on the appropriate "simple" set (Ω_2 in our case); (b) update multipliers and penalty parameters. However, several decisions need to be made in order to define a practical algorithm. In this paper we use the Powell–Hestenes–Rockafellar (PHR) augmented Lagrangian function [33, 40, 42] (see [8] for a comparison with other augmented Lagrangian functions), and we keep inequality constraints as they are, instead of replacing them by equality constraints plus bounds. So, we pay the price of having discontinuous second derivatives in the objective function of the subproblems when Ω_1 involves inequalities.

A good criterion is needed for deciding that a suitable approximate subproblem minimizer has been found at step (a). In particular, one must decide whether subproblem minimizers must be feasible with respect to Ω_2 and which is the admissible level of infeasibility and lack of complementarity at these solutions. (Bertsekas [6] analyzed an augmented Lagrangian method for solving (1.1) in the case in which the subproblems are solved exactly.) Moreover, simple and efficient rules for updating multipliers and penalty parameters must be given.

Algorithmic decisions are taken looking at theoretical convergence properties and practical performance. Only experience tells one which theoretical results have practical importance and which do not. Although we recognize that this point is controversial, we would like to make explicit here our own criteria:

1. External penalty methods have the property that, when one finds the *global* minimizers of the subproblems, every limit point is a global minimizer of the original problem [24]. We think that this property must be preserved by the augmented Lagrangian counterparts. This is the main reason why, in our algorithm, we will force boundedness of the Lagrange multipliers estimates.
2. We aim for feasibility of the limit points, but, since this may be impossible (even an empty feasible region is not excluded), a "feasibility result" must say that limit points are stationary points for some infeasibility measure. Some methods require that a constraint qualification hold at all the (feasible or infeasible) iterates. In [15, 47] it was shown that, in such cases, convergence to infeasible points that are not stationary for infeasibility may occur.
3. Feasible limit points that satisfy a constraint qualification must be KKT. The constraint qualification must be as *weak* as possible. Therefore, under the assumption that all the *feasible* points satisfy the constraint qualification, all the feasible limit points should be KKT.
4. Theoretically, it is impossible to prove that the whole sequence generated by a general augmented Lagrangian method converges, because multiple solutions of the subproblems may exist and solutions of the subproblems may oscillate. However, since one uses the solution of one subproblem as the initial point for solving the following one, the convergence of the whole sequence generally occurs. In this case, under suitable local conditions, we must be able to prove that the penalty parameters remain bounded.

In other words, the method must have all the good global convergence properties of an external penalty method. In addition, when everything "goes well," it must be free of the asymptotic instability caused by large penalty parameters. Since we deal with nonconvex problems, the possibility of obtaining full global convergence properties based on proximal-point arguments is out of the question.

The algorithm presented in this paper satisfies those theoretical requirements. In particular, we will show that, if a feasible limit point satisfies the constant positive linear dependence (CPLD) condition, then it is a KKT point. A feasible point x

of a nonlinear programming problem is said to satisfy CPLD if the existence of a nontrivial null linear combination of gradients of active constraints with nonnegative coefficients corresponding to the inequalities implies that the gradients involved in that combination are linearly dependent for all z in a neighborhood of x. The CPLD condition was introduced by Qi and Wei [41]. In [4] it was proved that CPLD is a constraint qualification, being strictly weaker than the linear independence constraint qualification (LICQ) and than the Mangasarian–Fromovitz constraint qualification (MFCQ) [36, 43]. Since CPLD is weaker than (say) LICQ, theoretical results saying that *if a limit point satisfies CPLD then it satisfies KKT* are stronger than theoretical results saying that *if a limit point satisfies LICQ then it satisfies KKT*.

Most practical nonlinear programming methods published after 2001 rely on (a combination of) sequential quadratic programming (SQP), Newton-like, or barrier approaches [1, 5, 14, 16, 18, 19, 26, 27, 28, 29, 35, 38, 44, 45, 46, 48, 49, 50]. None of these methods can be easily adapted to the situation described by (1.1)–(1.2).

In the numerical experiments we will show that, in some very large scale location problems, using a specific algorithm for convex-constrained programming [11, 12, 13, 23] for solving the subproblems in the augmented Lagrangian context is much more efficient than using a general purpose method. We will also show that Algencan (the particular implementation of the algorithm introduced in this paper for the case in which the lower-level set is a box [9]) seems to converge to global minimizers more often than Ipopt [47, 48].

This paper is organized as follows. A high-level description of the main algorithm is given in section 2. The rigorous definition of the method is in section 3. Section 4 is devoted to global convergence results. In section 5 we prove boundedness of the penalty parameters. In section 6 we show the numerical experiments. Conclusions are given in section 7.

Notation. We denote $\mathbb{R}_+ = \{t \in \mathbb{R} \mid t \geq 0\}$, $\mathbb{N} = \{0, 1, 2, \ldots\}$, $\|\cdot\|$ as an arbitrary vector norm, and $[v]_i$ as the ith component of the vector v. If there is no possibility of confusion we may also use the notation v_i. For all $y \in \mathbb{R}^n$, $y_+ = (\max\{0, y_1\}, \ldots, \max\{0, y_n\})^T$. If $F : \mathbb{R}^n \to \mathbb{R}^m$, $F = (f_1, \ldots, f_m)^T$, we denote $\nabla F(x) = (\nabla f_1(x), \ldots, \nabla f_m(x)) \in \mathbb{R}^{n \times m}$. If $K = \{k_0, k_1, k_2, \ldots\} \subset \mathbb{N}$ ($k_{j+1} > k_j$ for all j), we denote $\lim_{k \in K} x_k = \lim_{j \to \infty} x_{k_j}$.

2. Overview of the method. We will consider the following nonlinear programming problem:

$$\text{Minimize } f(x) \text{ subject to } h_1(x) = 0,\ g_1(x) \leq 0,\ h_2(x) = 0,\ g_2(x) \leq 0, \tag{2.1}$$

where $f : \mathbb{R}^n \to \mathbb{R}, h_1 : \mathbb{R}^n \to \mathbb{R}^{m_1}, h_2 : \mathbb{R}^n \to \mathbb{R}^{m_2}, g_1 : \mathbb{R}^n \to \mathbb{R}^{p_1}, g_2 : \mathbb{R}^n \to \mathbb{R}^{p_2}$. We assume that all these functions admit continuous first derivatives on a sufficiently large and open domain. We define $\Omega_1 = \{x \in \mathbb{R}^n \mid h_1(x) = 0, g_1(x) \leq 0\}$ and $\Omega_2 = \{x \in \mathbb{R}^n \mid h_2(x) = 0, g_2(x) \leq 0\}$.

For all $x \in \mathbb{R}^n, \rho > 0, \lambda \in \mathbb{R}^{m_1}, \mu \in \mathbb{R}^{p_1}_+$, we define the augmented Lagrangian with respect to Ω_1 [33, 40, 42] as

$$L(x, \lambda, \mu, \rho) = f(x) + \frac{\rho}{2} \sum_{i=1}^{m_1} \left([h_1(x)]_i + \frac{\lambda_i}{\rho} \right)^2 + \frac{\rho}{2} \sum_{i=1}^{p_1} \left([g_1(x)]_i + \frac{\mu_i}{\rho} \right)_+^2. \tag{2.2}$$

The main algorithm defined in this paper will consist of a sequence of (approximate) minimizations of $L(x, \lambda, \mu, \rho)$ subject to $x \in \Omega_2$, followed by the updating of λ, μ, and ρ. A version of the algorithm with several penalty parameters may be found in [3]. Each approximate minimization of L will be called an *outer iteration*.

After each outer iteration one wishes for some progress in terms of *feasibility* and *complementarity*. The *infeasibility* of x with respect to the equality constraint $[h_1(x)]_i = 0$ is naturally represented by $|[h_1(x)]_i|$. The case of inequality constraints is more complicated because, besides feasibility, one expects to have a null multiplier estimate if $g_i(x) < 0$. A suitable combined measure of infeasibility and non-complementarity with respect to the constraint $[g_1(x)]_i \leq 0$ comes from defining $[\sigma(x, \mu, \rho)]_i = \max\{[g_1(x)]_i, -\mu_i/\rho\}$. Since μ_i/ρ is always nonnegative, it turns out that $[\sigma(x, \mu, \rho)]_i$ vanishes in two situations: (a) when $[g_1(x)]_i = 0$; and (b) when $[g_1(x)]_i < 0$ and $\mu_i = 0$. So, roughly speaking, $|[\sigma(x, \mu, \rho)]_i|$ measures infeasibility and complementarity with respect to the inequality constraint $[g_1(x)]_i \leq 0$. If, between two consecutive outer iterations, enough progress is observed in terms of (at least one of) feasibility and complementarity, the penalty parameter will not be updated. Otherwise, the penalty parameter is increased by a fixed factor.

The rules for updating the multipliers need some discussion. In principle, we adopt the classical first-order correction rule [33, 40, 43], but, in addition, we impose that the multiplier estimates must be bounded. So, we will explicitly project the estimates on a compact box after each update. The reason for this decision was already given in the introduction: we want to preserve the property of external penalty methods that global minimizers of the original problem are obtained if each outer iteration computes a global minimizer of the subproblem. This property is maintained if the quotient of *the square* of each multiplier estimate over the penalty parameter tends to zero when the penalty parameter tends to infinity. We were not able to prove that this condition holds automatically for usual estimates and, in fact, we conjecture that it does not. Therefore, we decided to force the boundedness condition. The price paid for this decision seems to be moderate: in the proof of the boundedness of penalty parameters we will need to assume that the true Lagrange multipliers are within the bounds imposed by the algorithm. Since "large Lagrange multipliers" are a symptom of "near-nonfulfillment" of the MFCQ, this assumption seems to be compatible with the remaining ones that are necessary to prove penalty boundedness.

3. Description of the augmented Lagrangian algorithm. In this section we provide a detailed description of the main algorithm. Approximate solutions of the subproblems are defined as points that satisfy the conditions (3.1)–(3.4) below. These formulae are relaxed KKT conditions of the problem of minimizing L subject to $x \in \Omega_2$. The first-order approximations of the multipliers are computed at Step 3. Lagrange multipliers estimates are denoted λ_k and μ_k, whereas their safeguarded counterparts are $\bar{\lambda}_k$ and $\bar{\mu}_k$. At Step 4 we update the penalty parameters according to the progress in terms of feasibility and complementarity.

Algorithm 3.1. Let $x_0 \in \mathbb{R}^n$ be an arbitrary initial point. The given parameters for the execution of the algorithm are $\tau \in [0, 1), \gamma > 1, \rho_1 > 0$, $-\infty < [\bar{\lambda}_{\min}]_i \leq [\bar{\lambda}_{\max}]_i < \infty$ for all $i = 1, \ldots, m_1$, $0 \leq [\bar{\mu}_{\max}]_i < \infty$ for all $i = 1, \ldots, p_1$, $[\bar{\lambda}_1]_i \in [[\bar{\lambda}_{\min}]_i, [\bar{\lambda}_{\max}]_i]$ for all $i = 1, \ldots, m_1$, $[\bar{\mu}_1]_i \in [0, [\bar{\mu}_{\max}]_i]$ for all $i = 1, \ldots, p_1$. Finally, $\{\varepsilon_k\} \subset \mathbb{R}_+$ is a sequence of tolerance parameters such that $\lim_{k\to\infty} \varepsilon_k = 0$.

Step 1. *Initialization.* Set $k \leftarrow 1$. For $i = 1, \ldots, p_1$, compute $[\sigma_0]_i = \max\{0, [g_1(x_0)]_i\}$.

Step 2. *Solving the subproblem.* Compute (if possible) $x_k \in \mathbb{R}^n$ such that there exist $v_k \in \mathbb{R}^{m_2}, u_k \in \mathbb{R}^{p_2}$ satisfying

$$\left\| \nabla L(x_k, \bar{\lambda}_k, \bar{\mu}_k, \rho_k) + \sum_{i=1}^{m_2} [v_k]_i \nabla [h_2(x_k)]_i + \sum_{i=1}^{p_2} [u_k]_i \nabla [g_2(x_k)]_i \right\| \leq \varepsilon_{k,1}, \tag{3.1}$$

$$[u_k]_i \geq 0 \text{ and } [g_2(x_k)]_i \leq \varepsilon_{k,2} \ \forall \ i = 1, \ldots, p_2, \tag{3.2}$$

$$[g_2(x_k)]_i < -\varepsilon_{k,2} \Rightarrow [u_k]_i = 0 \ \forall \ i = 1, \ldots, p_2, \tag{3.3}$$

$$\|h_2(x_k)\| \leq \varepsilon_{k,3}, \tag{3.4}$$

where $\varepsilon_{k,1}, \varepsilon_{k,2}, \varepsilon_{k,3} \geq 0$ are such that $\max\{\varepsilon_{k,1}, \varepsilon_{k,2}, \varepsilon_{k,3}\} \leq \varepsilon_k$. If it is not possible to find x_k satisfying (3.1)–(3.4), stop the execution of the algorithm.

Step 3. *Estimate multipliers.* For all $i = 1, \ldots, m_1$, compute

$$[\lambda_{k+1}]_i = [\bar{\lambda}_k]_i + \rho_k [h_1(x_k)]_i, \tag{3.5}$$

$$[\bar{\lambda}_{k+1}]_i \in [[\bar{\lambda}_{\min}]_i, [\bar{\lambda}_{\max}]_i]. \tag{3.6}$$

(Usually, $[\bar{\lambda}_{k+1}]_i$ will be the projection of $[\lambda_{k+1}]_i$ on the interval $[[\bar{\lambda}_{\min}]_i, [\bar{\lambda}_{\max}]_i]$.) For all $i = 1, \ldots, p_1$, compute

$$[\mu_{k+1}]_i = \max\{0, [\bar{\mu}_k]_i + \rho_k [g_1(x_k)]_i\}, \quad [\sigma_k]_i = \max\left\{[g_1(x_k)]_i, -\frac{[\bar{\mu}_k]_i}{\rho_k}\right\}, \tag{3.7}$$

$$[\bar{\mu}_{k+1}]_i \in [0, [\bar{\mu}_{\max}]_i].$$

(Usually, $[\bar{\mu}_{k+1}]_i = \min\{[\mu_{k+1}]_i, [\bar{\mu}_{\max}]_i\}$.)

Step 4. *Update the penalty parameter.* If

$$\max\{\|h_1(x_k)\|_\infty, \|\sigma_k\|_\infty\} \leq \tau \max\{\|h_1(x_{k-1})\|_\infty, \|\sigma_{k-1}\|_\infty\},$$

then define $\rho_{k+1} = \rho_k$. Else, define $\rho_{k+1} = \gamma \rho_k$.

Step 5. *Begin a new outer iteration.* Set $k \leftarrow k + 1$. Go to Step 2.

4. Global convergence. In this section we assume that the algorithm does not stop at Step 2. In other words, it is always possible to find x_k satisfying (3.1)–(3.4). Problem-dependent sufficient conditions for this assumption can be given in many cases.

We will also assume that at least a limit point of the sequence generated by Algorithm 3.1 exists. A sufficient condition for this is the existence of $\varepsilon > 0$ such that the set $\{x \in \mathbb{R}^n \mid g_2(x) \leq \varepsilon, \|h_2(x)\| \leq \varepsilon\}$ is bounded. This condition may be enforced, adding artificial simple constraints to the set Ω_2.

Global convergence results that use the CPLD constraint qualification are stronger than previous results for more specific problems: In particular, Conn, Gould, and Toint [21] and Conn et al. [20] proved global convergence of augmented Lagrangian methods for equality constraints and linear constraints, assuming linear independence of all the gradients of active constraints at the limit points. Their assumption is much stronger than our CPLD assumptions. On one hand, the CPLD assumption is weaker than LICQ (for example, CPLD always holds when the constraints are linear). On the other hand, our CPLD assumption involves only feasible points instead of all possible limit points of the algorithm.

Convergence proofs for augmented Lagrangian methods with equalities and box constraints using CPLD were given in [2].

We are going to investigate the status of the limit points of sequences generated by Algorithm 3.1. First, we will prove a result on the feasibility properties of a

limit point. Theorem 4.1 shows that either a limit point is feasible or, if the CPLD constraint qualification with respect to Ω_2 holds, it is a KKT point of the sum of squares of upper-level infeasibilities.

THEOREM 4.1. *Let $\{x_k\}$ be a sequence generated by Algorithm* 3.1. *Let x_* be a limit point of $\{x_k\}$. Then, if the sequence of penalty parameters $\{\rho_k\}$ is bounded, the limit point x_* is feasible. Otherwise, at least one of the following possibilities holds:*

(i) *x_* is a KKT point of the problem*

$$\text{(4.1)}\quad \textit{Minimize } \frac{1}{2}\left[\sum_{i=1}^{m_1}[h_1(x)]_i^2+\sum_{i=1}^{p_1}\max\{0,[g_1(x)]_i\}^2\right] \textit{ subject to } x\in\Omega_2.$$

(ii) *x_* does not satisfy the CPLD constraint qualification associated with Ω_2.*

Proof. Let K be an infinite subsequence in $\mathbb{N}$ such that $\lim_{k\in K} x_k = x_*$. Since $\varepsilon_k \to 0$, by (3.2) and (3.4), we have that $g_2(x_*)\le 0$ and $h_2(x_*)=0$. So, $x_*\in\Omega_2$.

Now, we consider two possibilities: (a) the sequence $\{\rho_k\}$ is bounded; and (b) the sequence $\{\rho_k\}$ is unbounded. Let us analyze first case (a). In this case, from some iteration on, the penalty parameters are not updated. Therefore, $\lim_{k\to\infty}\|h_1(x_k)\| = \lim_{k\to\infty}\|\sigma_k\| = 0$. Thus, $h_1(x_*)=0$. Now, if $[g_1(x_*)]_j > 0$ then $[g_1(x_k)]_j > c > 0$ for $k\in K$ large enough. This would contradict the fact that $[\sigma_k]_j\to 0$. Therefore, $[g_1(x_*)]_i\le 0$ for all $i=1,\dots,p_1$.

Since $x_*\in\Omega_2$, $h_1(x_*)=0$, and $g_1(x_*)\le 0$, x_* is feasible. Therefore, we proved the desired result in the case that $\{\rho_k\}$ is bounded.

Consider now case (b). So, $\{\rho_k\}_{k\in K}$ is not bounded. By (2.2) and (3.1), we have

$$\begin{aligned}\nabla f(x_k)+\sum_{i=1}^{m_1}([\bar\lambda_k]_i+\rho_k[h_1(x_k)]_i)\nabla[h_1(x_k)]_i+\sum_{i=1}^{p_1}\max\{0,[\bar\mu_k]_i\\ +\rho_k[g_1(x_k)]_i\}\nabla[g_1(x_k)]_i+\sum_{i=1}^{m_2}[v_k]_i\nabla[h_2(x_k)]_i+\sum_{j=1}^{p_2}[u_k]_j\nabla[g_2(x_k)]_j=\delta_k,\end{aligned}\tag{4.2}$$

where, since $\varepsilon_k\to 0$, $\lim_{k\in K}\|\delta_k\|=0$.

If $[g_2(x_*)]_i<0$, there exists $k_1\in\mathbb{N}$ such that $[g_2(x_k)]_i<-\varepsilon_k$ for all $k\ge k_1, k\in K$. Therefore, by (3.3), $[u_k]_i=0$ for all $k\in K, k\ge k_1$. Thus, by $x_*\in\Omega_2$ and (4.2), for all $k\in K, k\ge k_1$ we have that

$$\begin{aligned}\nabla f(x_k)+\sum_{i=1}^{m_1}([\bar\lambda_k]_i+\rho_k[h_1(x_k)]_i)\nabla[h_1(x_k)]_i+\sum_{i=1}^{p_1}\max\{0,[\bar\mu_k]_i\\ +\rho_k[g_1(x_k)]_i\}\nabla[g_1(x_k)]_i+\sum_{i=1}^{m_2}[v_k]_i\nabla[h_2(x_k)]_i+\sum_{[g_2(x_*)]_j=0}[u_k]_j\nabla[g_2(x_k)]_j=\delta_k.\end{aligned}$$

Dividing by ρ_k we get

$$\begin{aligned}\frac{\nabla f(x_k)}{\rho_k} &+ \sum_{i=1}^{m_1}\left(\frac{[\bar{\lambda}_k]_i}{\rho_k} + [h_1(x_k)]_i\right)\nabla[h_1(x_k)]_i \\ &+ \sum_{i=1}^{p_1}\max\left\{0, \frac{[\bar{\mu}_k]_i}{\rho_k} + [g_1(x_k)]_i\right\}\nabla[g_1(x_k)]_i \\ &+ \sum_{i=1}^{m_2}\frac{[v_k]_i}{\rho_k}\nabla[h_2(x_k)]_i \\ &+ \sum_{[g_2(x_*)]_j=0}\frac{[u_k]_j}{\rho_k}\nabla[g_2(x_k)]_j = \frac{\delta_k}{\rho_k}.\end{aligned}$$

By Caratheodory's theorem of cones (see [7, page 689]) there exist $\widehat{I}_k \subset \{1,\ldots,m_2\}$, $\widehat{J}_k \subset \{j \mid [g_2(x_*)]_j = 0\}$, $[\widehat{v}_k]_i$, $i \in \widehat{I}_k$, and $[\widehat{u}_k]_j \geq 0$, $j \in \widehat{J}_k$, such that the vectors $\{\nabla[h_2(x_k)]_i\}_{i\in\widehat{I}_k} \cup \{\nabla[g_2(x_k)]_j\}_{j\in\widehat{J}_k}$ are linearly independent and

$$\begin{aligned}\frac{\nabla f(x_k)}{\rho_k} &+ \sum_{i=1}^{m_1}\left(\frac{[\bar{\lambda}_k]_i}{\rho_k} + [h_1(x_k)]_i\right)\nabla[h_1(x_k)]_i \\ &+ \sum_{i=1}^{p_1}\max\left\{0, \frac{[\bar{\mu}_k]_i}{\rho_k} + [g_1(x_k)]_i\right\}\nabla[g_1(x_k)]_i \\ &+ \sum_{i\in\widehat{I}_k}[\widehat{v}_k]_i\nabla[h_2(x_k)]_i \\ &+ \sum_{j\in\widehat{J}_k}[\widehat{u}_k]_j\nabla[g_2(x_k)]_j = \frac{\delta_k}{\rho_k}.\end{aligned} \tag{4.3}$$

Since there exists a finite number of possible sets $\widehat{I}_k, \widehat{J}_k$, there exists an infinite set of indices K_1 such that $K_1 \subset \{k \in K \mid k \geq k_1\}$, $\widehat{I}_k = \widehat{I}$, and

$$\widehat{J} = \widehat{J}_k \subset \{j \mid [g_2(x_*)]_j = 0\} \tag{4.4}$$

for all $k \in K_1$. Then, by (4.3), for all $k \in K_1$ we have

$$\begin{aligned}\frac{\nabla f(x_k)}{\rho_k} &+ \sum_{i=1}^{m_1}\left(\frac{[\bar{\lambda}_k]_i}{\rho_k} + [h_1(x_k)]_i\right)\nabla[h_1(x_k)]_i \\ &+ \sum_{i=1}^{p_1}\max\left\{0, \frac{[\bar{\mu}_k]_i}{\rho_k} + [g_1(x_k)]_i\right\}\nabla[g_1(x_k)]_i \\ &+ \sum_{i\in\widehat{I}}[\widehat{v}_k]_i\nabla[h_2(x_k)]_i \\ &+ \sum_{j\in\widehat{J}}[\widehat{u}_k]_j\nabla[g_2(x_k)]_j = \frac{\delta_k}{\rho_k},\end{aligned} \tag{4.5}$$

and the gradients

$$\{\nabla[h_2(x_k)]_i\}_{i\in\widehat{I}} \cup \{\nabla[g_2(x_k)]_j\}_{j\in\widehat{J}} \tag{4.6}$$

are linearly independent.

We consider again two cases: (1) the sequence $\{\|(\widehat{v}_k, \widehat{u}_k)\|, k \in K_1\}$ is bounded; and (2) the sequence $\{\|(\widehat{v}_k, \widehat{u}_k)\|, k \in K_1\}$ is unbounded. If the sequence $\{\|(\widehat{v}_k, \widehat{u}_k)\|\}_{k\in K_1}$ is bounded, and $\widehat{I} \cup \widehat{J} \neq \emptyset$, there exist $(\widehat{v}, \widehat{u}), \widehat{u} \geq 0$, and an infinite set of indices $K_2 \subset K_1$ such that $\lim_{k\in K_2}(\widehat{v}_k, \widehat{u}_k) = (\widehat{v}, \widehat{u})$. Since $\{\rho_k\}$ is unbounded, by the boundedness of $\bar{\lambda}_k$ and $\bar{\mu}_k$, $\lim[\bar{\lambda}_k]_i/\rho_k = 0 = \lim[\bar{\mu}_k]_j/\rho_k$ for all i, j. Therefore, by $\delta_k \to 0$, taking limits for $k \in K_2$ in (4.5), we obtain

$$\begin{aligned}\sum_{i=1}^{m_1}[h_1(x_*)]_i\nabla[h_1(x_*)]_i + \sum_{i=1}^{p_1}\max\{0, [g_1(x_*)]_i\}\nabla[g_1(x_*)]_i \\ + \sum_{i\in\widehat{I}}\widehat{v}_i\nabla[h_2(x_*)]_i + \sum_{j\in\widehat{J}}\widehat{u}_j\nabla[g_2(x_*)]_j = 0.\end{aligned} \tag{4.7}$$

If $\widehat{I} \cup \widehat{J} = \emptyset$ we obtain $\sum_{i=1}^{m_1}[h_1(x_*)]_i\nabla[h_1(x_*)]_i + \sum_{i=1}^{p_1}\max\{0, [g_1(x_*)]_i\}\nabla[g_1(x_*)]_i = 0$.

Therefore, by $x_* \in \Omega_2$ and (4.4), x_* is a KKT point of (4.1).

Finally, assume that $\{\|(\widehat{v}_k, \widehat{u}_k)\|\}_{k\in K_1}$ is unbounded. Let $K_3 \subset K_1$ be such that $\lim_{k\in K_3}\|(\widehat{v}_k, \widehat{u}_k)\| = \infty$ and $(\widehat{v}, \widehat{u}) \neq 0, \widehat{u} \geq 0$, such that $\lim_{k\in K_3}\frac{(\widehat{v}_k, \widehat{u}_k)}{\|(\widehat{v}_k, \widehat{u}_k)\|} = (\widehat{v}, \widehat{u})$. Dividing both sides of (4.5) by $\|(\widehat{v}_k, \widehat{u}_k)\|$ and taking limits for $k \in K_3$, we deduce that $\sum_{i\in\widehat{I}}\widehat{v}_i\nabla[h_2(x_*)]_i + \sum_{j\in\widehat{J}}\widehat{u}_j\nabla[g_2(x_*)]_j = 0$. But $[g_2(x_*)]_j = 0$ for all $j \in \widehat{J}$. Then, by (4.6), x_* does not satisfy the CPLD constraint qualification associated with the set Ω_2. This completes the proof. ∎

Roughly speaking, Theorem 4.1 says that, if x_* is not feasible, then (very likely) it is a local minimizer of the upper-level infeasibility, subject to lower-level feasibility. From the point of view of optimality, we are interested in the status of feasible limit points. In Theorem 4.2 we will prove that, under the CPLD constraint qualification, feasible limit points are stationary (KKT) points of the original problem. Since CPLD is strictly weaker than the MFCQ, it turns out that the following theorem is stronger than results where KKT conditions are proved under MFCQ or regularity assumptions.

THEOREM 4.2. *Let $\{x_k\}_{k\in\mathbb{N}}$ be a sequence generated by Algorithm* 3.1. *Assume that $x_* \in \Omega_1 \cap \Omega_2$ is a limit point that satisfies the CPLD constraint qualification related to $\Omega_1 \cap \Omega_2$. Then, x_* is a KKT point of the original problem* (2.1). *Moreover, if x_* satisfies the MFCQ and $\{x_k\}_{k\in K}$ is a subsequence that converges to x_*, the set*

$$\{\|\lambda_{k+1}\|, \|\mu_{k+1}\|, \|v_k\|, \|u_k\|\}_{k\in K} \text{ is bounded.} \tag{4.8}$$

Proof. For all $k \in \mathbb{N}$, by (3.1), (3.3), (3.5), and (3.7), there exist $u_k \in \mathbb{R}^{p_2}_+$, $\delta_k \in \mathbb{R}^n$ such that $\|\delta_k\| \leq \varepsilon_k$ and

$$\begin{aligned}\nabla f(x_k) + \sum_{i=1}^{m_1}[\lambda_{k+1}]_i\nabla[h_1(x_k)]_i + \sum_{i=1}^{p_1}[\mu_{k+1}]_i\nabla[g_1(x_k)]_i \\ + \sum_{i=1}^{m_2}[v_k]_i\nabla[h_2(x_k)]_i + \sum_{j=1}^{p_2}[u_k]_j\nabla[g_2(x_k)]_j = \delta_k.\end{aligned} \tag{4.9}$$

By (3.7), $\mu_{k+1} \in \mathbb{R}^{p_1}_+$ for all $k \in \mathbb{N}$. Let $K \subset \mathbb{N}$ be such that $\lim_{k\in K} x_k = x_*$. Suppose that $[g_2(x_*)]_i < 0$. Then, there exists $k_1 \in \mathbb{N}$ such that for all $k \in K, k \geq k_1, [g_2(x_k)]_i < -\varepsilon_k$. Then, by (3.3), $[u_k]_i = 0$ for all $k \in K, k \geq k_1$.

Let us prove now that a similar property takes place when $[g_1(x_*)]_i < 0$. In this case, there exists $k_2 \geq k_1$ such that $[g_1(x_k)]_i < c < 0$ for all $k \in K, k \geq k_2$.

We consider two cases: (1) $\{\rho_k\}$ is unbounded; and (2) $\{\rho_k\}$ is bounded. In the first case we have that $\lim_{k\in K} \rho_k = \infty$. Since $\{[\bar{\mu}_k]_i\}$ is bounded, there exists $k_3 \geq k_2$ such that, for all $k \in K, k \geq k_3$, $[\bar{\mu}_k]_i + \rho_k[g_1(x_k)]_i < 0$. By the definition of μ_{k+1} this implies that $[\mu_{k+1}]_i = 0$ for all $k \in K, k \geq k_3$.

Consider now the case in which $\{\rho_k\}$ is bounded. In this case, $\lim_{k\to\infty}[\sigma_k]_i = 0$. Therefore, since $[g_1(x_k)]_i < c < 0$ for $k \in K$ large enough, $\lim_{k\in K}[\bar{\mu}_k]_i = 0$. So, for $k \in K$ large enough, $[\bar{\mu}_k]_i + \rho_k[g_1(x_k)]_i < 0$. By the definition of μ_{k+1}, there exists $k_4 \geq k_2$ such that $[\mu_{k+1}]_i = 0$ for $k \in K, k \geq k_4$.

Therefore, there exists $k_5 \geq \max\{k_1, k_3, k_4\}$ such that for all $k \in K$, $k \geq k_5$,

$$[[g_1(x_*)]_i < 0 \Rightarrow [\mu_{k+1}]_i = 0] \text{ and } [[g_2(x_*)]_i < 0 \Rightarrow [u_k]_i = 0]. \tag{4.10}$$

(Observe that, up to now, we did not use the CPLD condition.) By (4.9) and (4.10), for all $k \in K, k \geq k_5$, we have

$$\begin{aligned} \nabla f(x_k) + \sum_{i=1}^{m_1} [\lambda_{k+1}]_i \nabla [h_1(x_k)]_i + \sum_{[g_1(x_*)]_i=0} [\mu_{k+1}]_i \nabla [g_1(x_k)]_i \\ + \sum_{i=1}^{m_2} [v_k]_i \nabla [h_2(x_k)]_i + \sum_{[g_2(x_*)]_j=0} [u_k]_j \nabla [g_2(x_k)]_j = \delta_k, \end{aligned} \tag{4.11}$$

with $\mu_{k+1} \in \mathbb{R}^{p_1}_+, u_k \in \mathbb{R}^{p_2}_+$.

By Caratheodory's theorem of cones, for all $k \in K, k \geq k_5$, there exist

$$\widehat{I}_k \subset \{1, \ldots, m_1\}, \widehat{J}_k \subset \{j \mid [g_1(x_*)]_j = 0\}, \hat{I}_k \subset \{1, \ldots, m_2\}, \hat{J}_k \subset \{j \mid [g_2(x_*)]_j = 0\},$$

$$[\widehat{\lambda}_k]_i \in \mathbb{R}\ \forall i \in \widehat{I}_k, [\widehat{\mu}_k]_j \geq 0\ \forall j \in \widehat{J}_k, [\widehat{v}_k]_i \in \mathbb{R}\ \forall i \in \hat{I}_k, [\widehat{u}_k]_j \geq 0\ \forall j \in \hat{J}_k$$

such that the vectors

$$\{\nabla [h_1(x_k)]_i\}_{i\in\widehat{I}_k} \cup \{\nabla [g_1(x_k)]_i\}_{i\in\widehat{J}_k} \cup \{\nabla [h_2(x_k)]_i\}_{i\in\hat{I}_k} \cup \{\nabla [g_2(x_k)]_i\}_{i\in\hat{J}_k}$$

are linearly independent and

$$\begin{aligned} \nabla f(x_k) + \sum_{i\in\widehat{I}_k} [\widehat{\lambda}_k]_i \nabla [h_1(x_k)]_i + \sum_{i\in\widehat{J}_k} [\widehat{\mu}_k]_i \nabla [g_1(x_k)]_i \\ + \sum_{i\in\hat{I}_k} [\widehat{v}_k]_i \nabla [h_2(x_k)]_i + \sum_{j\in\hat{J}_k} [\widehat{u}_k]_j \nabla [g_2(x_k)]_j = \delta_k. \end{aligned} \tag{4.12}$$

Since the number of possible sets of indices $\widehat{I}_k, \widehat{J}_k, \hat{I}_k, \hat{J}_k$ is finite, there exists an infinite set $K_1 \subset \{k \in K \mid k \geq k_5\}$ such that $\widehat{I}_k = \widehat{I}, \widehat{J}_k = \widehat{J}, \hat{I}_k = \hat{I}, \hat{J}_k = \hat{J}$ for all $k \in K_1$.

Then, by (4.12),

$$\begin{aligned} \nabla f(x_k) + \sum_{i\in\widehat{I}} [\widehat{\lambda}_k]_i \nabla [h_1(x_k)]_i + \sum_{i\in\widehat{J}} [\widehat{\mu}_k]_i \nabla [g_1(x_k)]_i \\ + \sum_{i\in\hat{I}} [\widehat{v}_k]_i \nabla [h_2(x_k)]_i + \sum_{j\in\hat{J}} [\widehat{u}_k]_j \nabla [g_2(x_k)]_j = \delta_k \end{aligned} \tag{4.13}$$

and the vectors

$$\{\nabla[h_1(x_k)]_i\}_{i\in\widehat{I}} \cup \{\nabla[g_1(x_k)]_i\}_{i\in\widehat{J}} \cup \{\nabla[h_2(x_k)]_i\}_{i\in\hat{I}} \cup \{\nabla[g_2(x_k)]_i\}_{i\in\hat{J}} \tag{4.14}$$

are linearly independent for all $k \in K_1$.

If $\widehat{I} \cup \widehat{J} \cup \hat{I} \cup \hat{J} = \emptyset$, by (4.13) and $\delta_k \to 0$ we obtain $\nabla f(x_*) = 0$. Otherwise, let us define

$$S_k = \max\{\max\{|[\widehat{\lambda}_k]_i|, i \in \widehat{I}\}, \max\{[\widehat{\mu}_k]_i, i \in \widehat{J}\}, \max\{|[\widehat{v}_k]_i|, i \in \hat{I}\}, \max\{[\widehat{u}_k]_i, i \in \hat{J}\}\}.$$

We consider two possibilities: (a) $\{S_k\}_{k\in K_1}$ has a bounded subsequence; and (b) $\lim_{k\in K_1} S_k = \infty$. If $\{S_k\}_{k\in K_1}$ has a bounded subsequence, there exists $K_2 \subset K_1$ such that $\lim_{k\in K_2}[\widehat{\lambda}_k]_i = \widehat{\lambda}_i$, $\lim_{k\in K_2}[\widehat{\mu}_k]_i = \widehat{\mu}_i \geq 0$, $\lim_{k\in K_2}[\widehat{v}_k]_i = \widehat{v}_i$, and $\lim_{k\in K_2}[\widehat{u}_k]_i = \widehat{u}_i \geq 0$. By $\varepsilon_k \to 0$ and $\|\delta_k\| \leq \varepsilon_k$, taking limits in (4.13) for $k \in K_2$, we obtain

$$\nabla f(x_*) + \sum_{i\in\widehat{I}} \widehat{\lambda}_i \nabla[h_1(x_*)]_i + \sum_{i\in\widehat{J}} \widehat{\mu}_i \nabla[g_1(x_*)]_i + \sum_{i\in\hat{I}} \widehat{v}_i \nabla[h_2(x_*)]_i + \sum_{j\in\hat{J}} \widehat{u}_j \nabla[g_2(x_*)]_j = 0,$$

with $\widehat{\mu}_i \geq 0, \widehat{u}_i \geq 0$. Since $x_* \in \Omega_1 \cap \Omega_2$, we have that x_* is a KKT point of (2.1).

Suppose now that $\lim_{k\in K_2} S_k = \infty$. Dividing both sides of (4.13) by S_k we obtain

$$\begin{aligned} &\frac{\nabla f(x_k)}{S_k} + \sum_{i\in\widehat{I}} \frac{[\widehat{\lambda}_k]_i}{S_k} \nabla[h_1(x_k)]_i + \sum_{i\in\widehat{J}} \frac{[\widehat{\mu}_k]_i}{S_k} \nabla[g_1(x_k)]_i \\ &+ \sum_{i\in\hat{I}} \frac{[\widehat{v}_k]_i}{S_k} \nabla[h_2(x_k)]_i + \sum_{j\in\hat{J}} \frac{[\widehat{u}_k]_j}{S_k} \nabla[g_2(x_k)]_j = \frac{\delta_k}{S_k}, \end{aligned} \tag{4.15}$$

where $|\frac{[\widehat{\lambda}_k]_i}{S_k}| \leq 1, |\frac{[\widehat{\mu}_k]_i}{S_k}| \leq 1, |\frac{[\widehat{v}_k]_i}{S_k}| \leq 1, |\frac{[\widehat{u}_k]_j}{S_k}| \leq 1$. Therefore, there exists $K_3 \subset K_1$ such that $\lim_{k\in K_3} \frac{[\widehat{\lambda}_k]_i}{S_k} = \widehat{\lambda}_i, \lim_{k\in K_3} \frac{[\widehat{\mu}_k]_i}{S_k} = \widehat{\mu}_i \geq 0, \lim_{k\in K_3} \frac{[\widehat{v}_k]_i}{S_k} = \widehat{v}_i, \lim_{k\in K_3} \frac{[\widehat{u}_k]_j}{S_k} = \widehat{u}_j \geq 0$. Taking limits on both sides of (4.15) for $k \in K_3$, we obtain

$$\sum_{i\in\widehat{I}} \widehat{\lambda}_i \nabla[h_1(x_*)]_i + \sum_{i\in\widehat{J}} \widehat{\mu}_i \nabla[g_1(x_*)]_i + \sum_{i\in\hat{I}} \widehat{v}_i \nabla[h_2(x_*)]_i + \sum_{j\in\hat{J}} \widehat{u}_j \nabla[g_2(x_*)]_j = 0.$$

But the modulus of at least one of the coefficients $\widehat{\lambda}_i, \widehat{\mu}_i, \widehat{v}_i, \widehat{u}_i$ is equal to 1. Then, by the CPLD condition, the gradients

$$\{\nabla[h_1(x)]_i\}_{i\in\widehat{I}} \cup \{\nabla[g_1(x)]_i\}_{i\in\widehat{J}} \cup \{\nabla[h_2(x)]_i\}_{i\in\hat{I}} \cup \{\nabla[g_2(x)]_i\}_{i\in\hat{J}}$$

must be linearly dependent in a neighborhood of x_*. This contradicts (4.14). Therefore, the main part of the theorem is proved.

Finally, let us prove that the property (4.8) holds if x_* satisfies the MFCQ. Let us define

$$B_k = \max\{\|\lambda_{k+1}\|_\infty, \|\mu_{k+1}\|_\infty, \|v_k\|_\infty, \|u_k\|_\infty\}_{k\in K}.$$

If (4.8) is not true, we have that $\lim_{k\in K} B_k = \infty$. In this case, dividing both sides of (4.11) by B_k and taking limits for an appropriate subsequence, we obtain that x_* does not satisfy the MFCQ. ∎

5. Boundedness of the penalty parameters. When the penalty parameters associated with penalty or augmented Lagrangian methods are too large, the subproblems tend to be ill-conditioned and their resolution becomes harder. One of the main motivations for the development of the basic augmented Lagrangian algorithm is the necessity of overcoming this difficulty. Therefore, the study of conditions under which penalty parameters are bounded plays an important role in augmented Lagrangian approaches.

5.1. Equality constraints. We will consider first the case $p_1 = p_2 = 0$.

Let $f : \mathbb{R}^n \to \mathbb{R}, h_1 : \mathbb{R}^n \to \mathbb{R}^{m_1}, h_2 : \mathbb{R}^n \to \mathbb{R}^{m_2}$. We address the problem

$$\text{Minimize } f(x) \text{ subject to } h_1(x) = 0,\ h_2(x) = 0. \tag{5.1}$$

The Lagrangian function associated with problem (5.1) is given by $L_0(x, \lambda, v) = f(x) + \langle h_1(x), \lambda\rangle + \langle h_2(x), v\rangle$ for all $x \in \mathbb{R}^n$, $\lambda \in \mathbb{R}^{m_1}$, $v \in \mathbb{R}^{m_2}$.

Algorithm 3.1 will be considered with the following standard definition for the safeguarded Lagrange multipliers.

DEFINITION. *For all $k \in \mathbb{N}$, $i = 1, \ldots, m_1$, $[\bar\lambda_{k+1}]_i$ will be the projection of $[\lambda_{k+1}]_i$ on the interval $[[\bar\lambda_{\min}]_i, [\bar\lambda_{\max}]_i]$.*

We will use the following assumptions.

Assumption 1. The sequence $\{x_k\}$ is generated by the application of Algorithm 3.1 to problem (5.1) and $\lim_{k\to\infty} x_k = x_*$.

Assumption 2. The point x_* is feasible ($h_1(x_*) = 0$ and $h_2(x_*) = 0$).

Assumption 3. The gradients $\nabla[h_1(x_*)]_1, \ldots, \nabla[h_1(x_*)]_{m_1}, \nabla[h_2(x_*)]_1, \ldots,$ and $\nabla[h_2(x_*)]_{m_2}$ are linearly independent.

Assumption 4. The functions f, h_1, and h_2 admit continuous second derivatives in a neighborhood of x_*.

Assumption 5. The second-order sufficient condition for local minimizers [25, page 211], holds with Lagrange multipliers $\lambda_* \in \mathbb{R}^{m_1}$ and $v_* \in \mathbb{R}^{m_2}$.

Assumption 6. For all $i = 1, \ldots, m_1$, $[\lambda_*]_i \in ([\bar\lambda_{\min}]_i, [\bar\lambda_{\max}]_i)$.

PROPOSITION 5.1. *Suppose that Assumptions* 1, 2, 3, *and* 6 *hold. Then,* $\lim_{k\to\infty} \lambda_k = \lambda_*$, $\lim_{k\to\infty} v_k = v_*$, *and $\bar\lambda_k = \lambda_k$ for k large enough.*

Proof. The proof of the first part follows from the definition of λ_{k+1}, the stopping criterion of the subproblems, and the linear independence of the gradients of the constraints at x_*. The second part of the thesis is a consequence of $\lambda_k \to \lambda_*$, using Assumption 6 and the definition of $\bar\lambda_{k+1}$. ∎

LEMMA 5.2. *Suppose that Assumptions* 3 *and* 5 *hold. Then, there exists $\bar\rho > 0$ such that, for all $\pi \in [0, 1/\bar\rho]$, the matrix*

$$\begin{pmatrix} \nabla^2_{xx} L_0(x_*, \lambda_*, v_*) & \nabla h_1(x_*) & \nabla h_2(x_*) \\ \nabla h_1(x_*)^T & -\pi I & 0 \\ \nabla h_2(x_*)^T & 0 & 0 \end{pmatrix}$$

is nonsingular.

Proof. The matrix is trivially nonsingular for $\pi = 0$. So, the thesis follows by the continuity of the matricial inverse. ∎

LEMMA 5.3. *Suppose that Assumptions* 1–5 *hold. Let $\bar\rho$ be as in Lemma* 5.2. *Suppose that there exists $k_0 \in \mathbb{N}$ such that $\rho_k \geq \bar\rho$ for all $k \geq k_0$. Define*

$$\alpha_k = \nabla L(x_k, \bar\lambda_k, \rho_k) + \nabla h_2(x_k) v_k, \tag{5.2}$$

$$\beta_k = h_2(x_k). \tag{5.3}$$

Then, there exists $M > 0$ such that, for all $k \in \mathbb{N}$,

$$\|x_k - x_*\| \le M \max\left\{\frac{\|\bar\lambda_k - \lambda_*\|_\infty}{\rho_k}, \|\alpha_k\|, \|\beta_k\|\right\}, \tag{5.4}$$

$$\|\lambda_{k+1} - \lambda_*\| \le M \max\left\{\frac{\|\bar\lambda_k - \lambda_*\|_\infty}{\rho_k}, \|\alpha_k\|, \|\beta_k\|\right\}. \tag{5.5}$$

Proof. Define, for all $k \in \mathbb{N}$,

$$t_k = (\bar\lambda_k - \lambda_*)/\rho_k, \tag{5.6}$$

$$\pi_k = 1/\rho_k. \tag{5.7}$$

By (3.5), (5.2), and (5.3), $\nabla L(x_k, \bar\lambda_k, \rho_k) + \nabla h_2(x_k)v_k - \alpha_k = 0$, $\lambda_{k+1} = \bar\lambda_k + \rho_k h_1(x_k)$, and $h_2(x_k) - \beta_k = 0$ for all $k \in \mathbb{N}$.

Therefore, by (5.6) and (5.7), we have that $\nabla f(x_k) + \nabla h_1(x_k)\lambda_{k+1} + \nabla h_2(x_k)v_k - \alpha_k = 0$, $h_1(x_k) - \pi_k\lambda_{k+1} + t_k + \pi_k\lambda_* = 0$, and $h_2(x_k) - \beta_k = 0$ for all $k \in \mathbb{N}$. Define, for all $\pi \in [0, 1/\bar\rho]$, $F_\pi : \mathbb{R}^n \times \mathbb{R}^{m_1} \times \mathbb{R}^{m_2} \times \mathbb{R}^{m_1} \times \mathbb{R}^n \times \mathbb{R}^{m_2} \to \mathbb{R}^n \times \mathbb{R}^{m_1} \times \mathbb{R}^{m_2}$ by

$$F_\pi(x, \lambda, v, t, \alpha, \beta) = \begin{pmatrix} \nabla f(x) + \nabla h_1(x)\lambda + \nabla h_2(x)v - \alpha \\ [h_1(x)]_1 - \pi[\lambda]_1 + [t]_1 + \pi[\lambda_*]_1 \\ \cdot \\ \cdot \\ \cdot \\ [h_1(x)]_{m_1} - \pi[\lambda]_{m_1} + [t]_{m_1} + \pi[\lambda_*]_{m_1} \\ h_2(x) - \beta \end{pmatrix}.$$

Clearly,

$$F_{\pi_k}(x_k, \lambda_{k+1}, v_k, t_k, \alpha_k, \beta_k) = 0 \tag{5.8}$$

and, by Assumptions 1 and 2,

$$F_\pi(x_*, \lambda_*, v_*, 0, 0, 0) = 0 \ \ \forall \pi \in [0, 1/\bar\rho]. \tag{5.9}$$

Moreover, the Jacobian matrix of F_π with respect to (x, λ, v) computed at $(x_*, \lambda_*, v_*, 0, 0, 0)$ is

$$\begin{pmatrix} \nabla^2_{xx} L_0(x_*, \lambda_*, v_*) & \nabla h_1(x_*) & \nabla h_2(x_*) \\ \nabla h_1(x_*)^T & -\pi I & 0 \\ \nabla h_2(x_*)^T & 0 & 0 \end{pmatrix}.$$

By Lemma 5.2, this matrix is nonsingular for all $\pi \in [0, 1/\bar\rho]$. By continuity, the norm of its inverse is bounded in a neighborhood of $(x_*, \lambda_*, v_*, 0, 0, 0)$ uniformly with respect to $\pi \in [0, 1/\bar\rho]$. Moreover, the first and second derivatives of F_π are also bounded in a neighborhood of $(x_*, \lambda_*, v_*, 0, 0, 0)$ uniformly with respect to $\pi \in [0, 1/\bar\rho]$. Therefore, the bounds (5.4) and (5.5) follow from (5.8) and (5.9) by the implicit function theorem and the mean value theorem of integral calculus. ∎

THEOREM 5.4. *Suppose that Assumptions* 1–6 *are satisfied by the sequence generated by Algorithm* 3.1 *applied to the problem* (5.1). *In addition, assume that there*

exists a sequence $\eta_k \to 0$ *such that* $\varepsilon_k \leq \eta_k \|h_1(x_k)\|_\infty$ *for all* $k \in \mathbb{N}$. *Then, the sequence of penalty parameters* $\{\rho_k\}$ *is bounded.*

Proof. Assume, by contradiction, that $\lim_{k\to\infty} \rho_k = \infty$. Since $h_1(x_*) = 0$, by the continuity of the first derivatives of h_1 there exists $L > 0$ such that, for all $k \in \mathbb{N}$, $\|h_1(x_k)\|_\infty \leq L\|x_k - x_*\|$. Therefore, by the hypothesis, (5.4), and Proposition 5.1, we have that $\|h_1(x_k)\|_\infty \leq LM \max\{\frac{\|\lambda_k - \lambda_*\|_\infty}{\rho_k}, \eta_k \|h_1(x_k)\|_\infty\}$ for k large enough. Since η_k tends to zero, this implies that

$$\|h_1(x_k)\|_\infty \leq LM \frac{\|\lambda_k - \lambda_*\|_\infty}{\rho_k} \tag{5.10}$$

for k large enough.

By (3.6) and Proposition 5.1, we have that $\lambda_k = \lambda_{k-1} + \rho_{k-1} h_1(x_{k-1})$ for k large enough. Therefore,

$$\|h_1(x_{k-1})\|_\infty = \frac{\|\lambda_k - \lambda_{k-1}\|_\infty}{\rho_{k-1}} \geq \frac{\|\lambda_{k-1} - \lambda_*\|_\infty}{\rho_{k-1}} - \frac{\|\lambda_k - \lambda_*\|_\infty}{\rho_{k-1}}. \tag{5.11}$$

Now, by (5.5), the hypothesis of this theorem, and Proposition 5.1, for k large enough we have $\|\lambda_k - \lambda_*\|_\infty \leq M(\frac{\|\lambda_{k-1} - \lambda_*\|_\infty}{\rho_{k-1}} + \eta_{k-1}\|h_1(x_{k-1})\|_\infty)$. This implies that $\frac{\|\lambda_{k-1} - \lambda_*\|_\infty}{\rho_{k-1}} \geq \frac{\|\lambda_k - \lambda_*\|_\infty}{M} - \eta_{k-1}\|h_1(x_{k-1})\|_\infty$. Therefore, by (5.11), $(1 + \eta_{k-1})$ $\|h_1(x_{k-1})\|_\infty \geq \|\lambda_k - \lambda_*\|_\infty(\frac{1}{M} - \frac{1}{\rho_{k-1}}) \geq \frac{1}{2M}\|\lambda_k - \lambda_*\|_\infty$. Thus, $\|\lambda_k - \lambda_*\|_\infty \leq 3M\|h_1(x_{k-1})\|_\infty$ for k large enough. By (5.10), we have that $\|h_1(x_k)\|_\infty \leq \frac{3LM^2}{\rho_k}\|h_1(x_{k-1})\|_\infty$. Therefore, since $\rho_k \to \infty$, there exists $k_1 \in \mathbb{N}$ such that $\|h_1(x_k)\|_\infty \leq \tau\|h_1(x_{k-1})\|_\infty$ for all $k \geq k_1$. So, $\rho_{k+1} = \rho_k$ for all $k \geq k_1$. Thus, $\{\rho_k\}$ is bounded. ∎

5.2. General constraints. In this subsection we address the general problem (2.1). As in the case of equality constraints, we adopt the following definition for the safeguarded Lagrange multipliers in Algorithm 3.1.

DEFINITION. *For all* $k \in \mathbb{N}$, $i = 1, \ldots, m_1$, $j = 1, \ldots, p_1$, $[\bar{\lambda}_{k+1}]_i$ *will be the projection of* $[\lambda_{k+1}]_i$ *on the interval* $[[\bar{\lambda}_{\min}]_i, [\bar{\lambda}_{\max}]_i]$, *and* $[\bar{\mu}_{k+1}]_j$ *will be the projection of* $[\mu_{k+1}]_j$ *on* $[0, [\bar{\mu}_{\max}]_j]$.

The technique for proving boundedness of the penalty parameter consists of reducing (2.1) to a problem with (only) equality constraints. The equality constraints of the new problem will be the active constraints at the limit point x_*. After this reduction, the boundedness result is deduced from Theorem 5.4. The sufficient conditions are listed below.

Assumption 7. The sequence $\{x_k\}$ is generated by the application of Algorithm 3.1 to problem (2.1) and $\lim_{k\to\infty} x_k = x_*$.

Assumption 8. The point x_* is feasible ($h_1(x_*) = 0$, $h_2(x_*) = 0$, $g_1(x_*) \leq 0$, and $g_2(x_*) \leq 0$.)

Assumption 9. The gradients $\{\nabla[h_1(x_*)]_i\}_{i=1}^{m_1}$, $\{\nabla[g_1(x_*)]_i\}_{[g_1(x_*)]_i=0}$, $\{\nabla[h_2(x_*)]_i\}_{i=1}^{m_2}$, $\{\nabla[g_2(x_*)]_i\}_{[g_2(x_*)]_i=0}$ are linearly independent. (LICQ holds at x_*.)

Assumption 10. The functions f, h_1, g_1, h_2, and g_2 admit continuous second derivatives in a neighborhood of x_*.

Assumption 11. Define the tangent subspace T as the set of all $z \in \mathbb{R}^n$ such that $\nabla h_1(x_*)^T z = \nabla h_2(x_*)^T z = 0$, $\langle \nabla[g_1(x_*)]_i, z\rangle = 0$ for all i such that $[g_1(x_*)]_i = 0$ and

$\langle \nabla [g_2(x_*)]_i, z\rangle = 0$ for all i such that $[g_2(x_*)]_i = 0$. Then, for all $z \in T, z \neq 0$,

$$\left\langle z, \left[\nabla^2 f(x_*) + \sum_{i=1}^{m_1} [\lambda_*]_i \nabla^2 [h_1(x_*)]_i + \sum_{i=1}^{p_1} [\mu_*]_i \nabla^2 [g_1(x_*)]_i \right.\right.$$
$$\left.\left. + \sum_{i=1}^{m_2} [v_*]_i \nabla^2 [h_2(x_*)]_i + \sum_{i=1}^{p_2} [u_*]_i \nabla^2 [g_2(x_*)]_i \right] z \right\rangle > 0.$$

Assumption 12. For all $i = 1, \dots, m_1, j = 1, \dots, p_1$, $[\lambda_*]_i \in ([\bar{\lambda}_{\min}]_i, [\bar{\lambda}_{\max}]_i)$, $[\mu_*]_j \in [0, [\bar{\mu}_{\max}]_j)$.

Assumption 13. For all i such that $[g_1(x_*)]_i = 0$, we have $[\mu_*]_i > 0$.

Observe that Assumption 13 imposes strict complementarity related only to the constraints in the upper-level set. In the lower-level set it is admissible that $[g_2(x_*)]_i = [u_*]_i = 0$. Observe, too, that Assumption 11 is weaker than the usual second-order sufficiency assumption, since the subspace T is orthogonal to the gradients of *all* active constraints, and no exception is made with respect to active constraints with null multiplier $[u_*]_i$. In fact, Assumption 11 is not a second-order sufficiency assumption for local minimizers. It holds for the problem of minimizing $x_1 x_2$ subject to $x_2 - x_1 \leq 0$ at $(0,0)$, although $(0,0)$ is not a local minimizer of this problem.

THEOREM 5.5. *Suppose that Assumptions* 7–13 *are satisfied. In addition, assume that there exists a sequence* $\eta_k \to 0$ *such that* $\varepsilon_k \leq \eta_k \max\{\|h_1(x_k)\|_\infty, \|\sigma_k\|_\infty\}$ *for all* $k \in \mathbb{N}$. *Then, the sequence of penalty parameters* $\{\rho_k\}$ *is bounded.*

Proof. Without loss of generality, assume that $[g_1(x_*)]_i = 0$ if $i \leq q_1$, $[g_1(x_*)]_i < 0$ if $i > q_1$, $[g_2(x_*)]_i = 0$ if $i \leq q_2$, and $[g_2(x_*)]_i < 0$ if $i > q_2$. Consider the auxiliary problem:

$$\text{Minimize } f(x) \text{ subject to } H_1(x) = 0, H_2(x) = 0, \tag{5.12}$$

where

$$H_1(x) = \begin{pmatrix} h_1(x) \\ [g_1(x)]_1 \\ \vdots \\ [g_1(x)]_{q_1} \end{pmatrix}, \quad H_2(x) = \begin{pmatrix} h_2(x) \\ [g_2(x)]_1 \\ \vdots \\ [g_2(x)]_{q_2} \end{pmatrix}.$$

By Assumptions 7–11, x_* satisfies the Assumptions 2–5 (with H_1, H_2 replacing h_1, h_2). Moreover, by Assumption 8, the multipliers associated to (2.1) are the Lagrange multipliers associated to (5.12).

As in the proof of (4.10) (the first part of the proof of Theorem 4.2), we have that, for k large enough, $[[g_1(x_*)]_i < 0 \Rightarrow [\mu_{k+1}]_i = 0]$ and $[[g_2(x_*)]_i < 0 \Rightarrow [u_k]_i = 0]$.

Then, by (3.1), (3.5), and (3.7),

$$\left\| \nabla f(x_k) + \sum_{i=1}^{m_1} [\lambda_{k+1}]_i \nabla [h_1(x_k)]_i + \sum_{i=1}^{q_1} [\mu_{k+1}]_i \nabla [g_1(x_k)]_i \right.$$
$$\left. + \sum_{i=1}^{m_2} [v_k]_i \nabla [h_2(x_k)]_i + \sum_{i=1}^{q_2} [u_k]_i \nabla [g_2(x_k)]_i \right\| \leq \varepsilon_k$$

for k large enough.

By Assumption 9, taking appropriate limits in the inequality above, we obtain that $\lim_{k\to\infty} \lambda_k = \lambda_*$ and $\lim_{k\to\infty} \mu_k = \mu_*$.

In particular, since $[\mu_*]_i > 0$ for all $i \leq q_1$,

$$[\mu_k]_i > 0 \tag{5.13}$$

for k large enough.

Since $\lambda_* \in (\bar{\lambda}_{\min}, \bar{\lambda}_{\max})^{m_1}$ and $[\mu_*]_i < [\bar{\mu}_{\max}]_i$, we have that $[\bar{\mu}_k]_i = [\mu_k]_i$, $i = 1, \ldots, q_1$, and $[\bar{\lambda}_k]_i = [\lambda_k]_i$, $i = 1, \ldots, m_1$, for k large enough.

Let us show now that the updating formula (3.7) for $[\mu_{k+1}]_i$, provided by Algorithm 3.1, coincides with the updating formula (3.5) for the corresponding multiplier in the application of the algorithm to the auxiliary problem (5.12).

In fact, by (3.7) and $[\bar{\mu}_k]_i = [\mu_k]_i$, we have that, for k large enough, $[\mu_{k+1}]_i = \max\{0, [\mu_k]_i + \rho_k [g_1(x_k)]_i\}$. But, by (5.13), $[\mu_{k+1}]_i = [\mu_k]_i + \rho_k [g_1(x_k)]_i, i = 1, \ldots, q_1$, for k large enough.

In terms of the auxiliary problem (5.12) this means that $[\mu_{k+1}]_i = [\mu_k]_i + \rho_k [H_1(x_k)]_i, i = 1, \ldots, q_1$, as we wanted to prove.

Now, let us analyze the meaning of $[\sigma_k]_i$. By (3.7), we have $[\sigma_k]_i = \max\{[g_1(x_k)]_i, -[\bar{\mu}_k]_i/\rho_k\}$ for all $i = 1, \ldots, p_1$. If $i > q_1$, since $[g_1(x_*)]_i < 0$, $[g_1]_i$ is continuous, and $[\bar{\mu}_k]_i = 0$, we have that $[\sigma_k]_i = 0$ for k large enough. Now, suppose that $i \leq q_1$. If $[g_1(x_k)]_i < -\frac{[\bar{\mu}_k]_i}{\rho_k}$, then, by (3.7), we would have $[\mu_{k+1}]_i = 0$. This would contradict (5.13). Therefore, $[g_1(x_k)]_i \geq -\frac{[\bar{\mu}_k]_i}{\rho_k}$ for k large enough, and we have that $[\sigma_k]_i = [g_1(x_k)]_i$. Thus, for k large enough,

$$H_1(x_k) = \begin{pmatrix} h_1(x_k) \\ \sigma_k \end{pmatrix}. \tag{5.14}$$

Therefore, the test for updating the penalty parameter in the application of Algorithm 3.1 to (5.12) coincides with the updating test in the application of the algorithm to (2.1). Moreover, formula (5.14) also implies that the condition $\varepsilon_k \leq \eta_k \max\{\|\sigma_k\|_\infty, \|h_1(x_k)\|_\infty\}$ is equivalent to the hypothesis $\varepsilon_k \leq \eta_k \|H_1(x_k)\|_\infty$ assumed in Theorem 5.4.

This completes the proof that the sequence $\{x_k\}$ may be thought of as being generated by the application of Algorithm 3.1 to (5.12). We proved that the associated approximate multipliers and the penalty parameters updating rule also coincide. Therefore, by Theorem 5.4, the sequence of penalty parameters is bounded, as we wanted to prove. □

Remark. The results of this section provide a theoretical answer to the following practical question: What happens if the box chosen for the safeguarded multiplier estimates is too small? The answer is that the box should be large enough to contain the "true" Lagrange multipliers. If it is not, the global convergence properties remain, but, very likely, the sequence of penalty parameters will be unbounded, leading to hard subproblems and possible numerical instability. In other words, if the box is excessively small, the algorithm tends to behave as an external penalty method. This is exactly what is observed in practice.

6. Numerical experiments. For solving unconstrained and bound-constrained subproblems we use GENCAN [9] with second derivatives and a CG-preconditioner [10]. Algorithm 3.1 with GENCAN will be called ALGENCAN. For solving the convex-constrained subproblems that appear in the large location problems, we use the spectral projected gradient method (SPG) [11, 12, 13]. The resulting augmented Lagrangian algorithm is called ALSPG. In general, it would be interesting to apply ALSPG to any problem such that the selected lower-level constraints define a convex

set for which it is easy (cheap) to compute the projection of an arbitrary point. The codes are free for download at http://www.ime.usp.br/~egbirgin/tango/. They are written in FORTRAN 77 (double precision). Interfaces of ALGENCAN with AMPL, CUTEr, C/C++, MATLAB, Octave, Python, and R (language and environment for statistical computing) are available.

For the practical implementation of Algorithm 3.1, we set $\tau = 0.5$, $\gamma = 10$, $\bar{\lambda}_{\min} = -10^{20}$, $\bar{\mu}_{\max} = \bar{\lambda}_{\max} = 10^{20}$, $\varepsilon_k = 10^{-4}$ for all k, $\bar{\lambda}_1 = 0, \bar{\mu}_1 = 0$, and $\rho_1 = \max\{10^{-6}, \min\{10, \frac{2|f(x_0)|}{\|h_1(x_0)\|^2 + \|g_1(x_0)_+\|^2}\}\}$. As stopping criterion we used $\max(\|h_1(x_k)\|_\infty, \|\sigma_k\|_\infty) \leq 10^{-4}$. The condition $\|\sigma_k\|_\infty \leq 10^{-4}$ guarantees that, for all $i = 1, \ldots, p_1$, $g_i(x_k) \leq 10^{-4}$ and that $[\mu_{k+1}]_i = 0$ whenever $g_i(x_k) < -10^{-4}$. This means that, approximately, feasibility and complementarity hold at the final point. Dual feasibility with tolerance 10^{-4} is guaranteed by (3.1) and the choice of ε_k. All the experiments were run on a 3.2 GHz Intel(R) Pentium(R) with four processors, 1Gb of RAM, and Linux Operating System. Compiler option "-O" was adopted.

6.1. Testing the theory. In Discrete Mathematics, experiments should reproduce exactly what theory predicts. In the continuous world, however, the situation changes because the mathematical model that we use for proving theorems is not exactly isomorphic to the one where computations take place. Therefore, it is always interesting to interpret, in finite precision calculations, the continuous theoretical results and to verify to what extent they are fulfilled.

Some practical results presented below may be explained in terms of a simple theoretical result that was tangentially mentioned in the introduction: If, at Step 2 of Algorithm 3.1, one computes a global minimizer of the subproblem and the problem (2.1) is feasible, then every limit point is a global minimizer of (2.1). This property may be easily proved using boundedness of the safeguarded Lagrange multipliers by means of external penalty arguments. Now, algorithms designed to solve reasonably simple subproblems usually include practical procedures that actively seek function decrease, beyond the necessity of finding stationary points. For example, efficient line-search procedures in unconstrained minimization and box-constrained minimization usually employ aggressive extrapolation steps [9], although simple backtracking is enough to prove convergence to stationary points. In other words, from good subproblem solvers one expects much more than convergence to stationary points. For this reason, we conjecture that augmented Lagrangian algorithms like ALGENCAN tend to converge to global minimizers more often than SQP-like methods. In any case, these arguments support the necessity of developing global-oriented subproblem solvers.

Experiments in this subsection were made using the AMPL interfaces of ALGENCAN (considering all the constraints as upper-level constraints) and IPOPT. Presolve AMPL option was disabled to solve the problems exactly as they are. The ALGENCAN parameters and stopping criteria were the ones stated at the beginning of this section. For IPOPT we used all its default parameters (including the ones related to stopping criteria). The random generation of initial points was made using the function `Uniform01()` provided by AMPL. When generating several random initial points, the seed used to generate the ith random initial point was set to i.

Example 1. Convergence to KKT points that do not satisfy MFCQ.

$$\begin{aligned} \text{Minimize} \quad & x_1 \\ \text{subject to} \quad & x_1^2 + x_2^2 \leq 1, \\ & x_1^2 + x_2^2 \geq 1. \end{aligned}$$

The global solution is $(-1, 0)$ and no feasible point satisfies the MFCQ, although all feasible points satisfy CPLD. Starting with 100 random points in $[-10, 10]^2$, ALGENCAN converged to the global solution in all the cases. Starting from $(5, 5)$ convergence occurred using 14 outer iterations. The final penalty parameter was 4.1649E-01 (the initial one was 4.1649E-03), and the final multipliers were 4.9998E-01 and 0.0000E+00. IPOPT also found the global solution in all the cases and used 25 iterations when starting from $(5, 5)$.

Example 2. Convergence to a non-KKT point.

$$\begin{aligned} \text{Minimize} \quad & x \\ \text{subject to} \quad & x^2 = 0, \\ & x^3 = 0, \\ & x^4 = 0. \end{aligned}$$

Here the gradients of the constraints are linearly dependent for all $x \in \mathbb{R}$. In spite of this, the only point that satisfies Theorem 4.1 is $x = 0$. Starting with 100 random points in $[-10, 10]$, ALGENCAN converged to the global solution in all the cases. Starting with $x = 5$ convergence occurred using 20 outer iterations. The final penalty parameter was 2.4578E+05 (the initial one was 2.4578E-05), and the final multipliers were 5.2855E+01, -2.0317E+00, and 4.6041E-01. IPOPT was not able to solve the problem in its original formulation because the "Number of degrees of freedom is NIND $= -2$." We modified the problem in the following way:

$$\begin{aligned} \text{Minimize} \quad & x_1 + x_2 + x_3 \\ \text{subject to} \quad & x_1^2 = 0, \\ & x_1^3 = 0, \\ & x_1^4 = 0, \\ & x_i \geq 0, \quad i = 1, 2, 3, \end{aligned}$$

and, after 16 iterations, IPOPT stopped near $x = (0, +\infty, +\infty)$ saying the "Iterates become very large (diverging?)."

Example 3. Infeasible stationary points [18, 34].

$$\begin{aligned} \text{Minimize} \quad & 100(x_2 - x_1^2)^2 + (x_1 - 1)^2 \\ \text{subject to} \quad & x_1 - x_2^2 \leq 0, \\ & x_2 - x_1^2 \leq 0, \\ & -0.5 \leq x_1 \leq 0.5, \\ & x_2 \leq 1. \end{aligned}$$

This problem has a global KKT solution at $x = (0, 0)$ and a stationary infeasible point at $x = (0.5, \sqrt{0.5})$. Starting with 100 random points in $[-10, 10]^2$, ALGENCAN converged to the global solution in all the cases. Starting with $x = (5, 5)$ convergence occurred using 6 outer iterations. The final penalty parameter was 1.0000E+01 (the initial one was 1.0000E+00), and the final multipliers were 1.9998E+00 and 3.3390E-03. IPOPT found the global solution starting from 84 out of the 100 random initial points. In the other 16 cases IPOPT stopped at $x = (0.5, \sqrt{0.5})$ saying "Convergence

to stationary point for infeasibility" (this was also the case when starting from $x = (5, 5)$).

Example 4. Difficult-for-barrier [15, 18, 47].

$$\begin{aligned} \text{Minimize} \quad & x_1 \\ \text{subject to} \quad & x_1^2 - x_2 + a = 0, \\ & x_1 - x_3 - b = 0, \\ & x_2 \geq 0,\ x_3 \geq 0. \end{aligned}$$

In [18] we read "This test example is from [47] and [15]. Although it is well-posed, many barrier-SQP methods ('Type-I Algorithms' in [47]) fail to obtain feasibility for a range of infeasible starting points."

We ran two instances of this problem, varying the values of parameters a and b and the initial point x_0 as suggested in [18]. When $(a, b) = (1, 1)$ and $x_0 = (-3, 1, 1)$ ALGENCAN converged to the solution $\bar{x} = (1, 2, 0)$ using 2 outer iterations. The final penalty parameter was 5.6604E-01 (the initial one also was 5.6604E-01), and the final multipliers were 6.6523E-10 and -1.0000E+00. IPOPT also found the same solution using 20 iterations. When $(a, b) = (-1, 0.5)$ and $x_0 = (-2, 1, 1)$ ALGENCAN converged to the solution $\tilde{x} = (1, 0, 0.5)$ using 5 outer iterations. The final penalty parameter was 2.4615E+00 (the initial one also was 2.4615E+00), and the final multipliers were -5.0001E-01 and -1.3664E-16. On the other hand, IPOPT stopped declaring convergence to a stationary point for the infeasibility.

Example 5. Preference for global minimizers.

$$\begin{aligned} \text{Minimize} \quad & \sum_{i=1}^{n} x_i \\ \text{subject to} \quad & x_i^2 = 1, \quad i = 1, \ldots, n. \end{aligned}$$

Solution: $x_* = (-1, \ldots, -1)$, $f(x_*) = -n$. We set $n = 100$ and ran ALGENCAN and IPOPT starting from 100 random initial points in $[-100, 100]^n$. ALGENCAN converged to the global solution in all the cases while IPOPT never found the global solution. When starting from the first random point, ALGENCAN converged using 4 outer iterations. The final penalty parameter was 5.0882E+00 (the initial one was 5.0882E-01), and the final multipliers were all equal to 4.9999E-01.

6.2. Location problems. Here we will consider a variant of the family of *location* problems introduced in [12]. In the original problem, given a set of n_p disjoint polygons $P_1, P_2, \ldots, P_{n_p}$ in $\mathbb{R}^2$ one wishes to find the point $z^1 \in P_1$ that minimizes the sum of the distances to the other polygons. Therefore, the original problem formulation is

$$\min_{z^i,\, i=1,\ldots,n_p} \quad \frac{1}{n_p - 1} \sum_{i=2}^{n_p} \|z^i - z^1\|_2 \quad \text{subject to} \quad z^i \in P_i,\ i = 1, \ldots, n_p.$$

In the variant considered in the present work, we have, in addition to the n_p polygons, n_c circles. Moreover, there is an ellipse which has a nonempty intersection with P_1 and such that z_1 must be inside the ellipse and $z_i, i = 2, \ldots, n_p + n_c$, must be outside. Therefore, the problem considered in this work is

$$\min_{z^i,\, i=1,\ldots,n_p+n_c} \quad \frac{1}{n_c + n_p - 1} \left[\sum_{i=2}^{n_p} \|z^i - z^1\|_2 + \sum_{i=1}^{n_c} \|z^{n_p+i} - z^1\|_2 \right]$$

TABLE 1

Location problems and their main features. The problem generation is based on a grid. The number of city-circles (n_c) and city-polygons (n_p) depend on the number of points in the grid, the probability of having a city in a grid point (procit), and the probability of a city to be a polygon (propol) or a circle ($1 - propol$). The number of vertices of a city-polygon is a random number and the total number of vertices of all the city-polygons together is totnvs. Finally, the number of variables of the problem is $n = 2(n_c + n_p)$, the number of upper-level inequality constraints is $p_1 = n_c + n_p$, and the number of lower-level inequality constraints is $p_2 = n_c + totnvs$. The total number of constraints is $p_1 + p_2$. The central rectangle is considered here a "special" city-polygon. The lower-level constraints correspond to the fact that each point must be inside a city and the upper-level constraints come from the fact that the central point must be inside the ellipse and all the others must be outside.

Problem	n_c	n_p	$totnvs$	n	p_1	p_2

$$\begin{aligned} \text{subject to} \quad & g(z^1) \leq 0, \\ & g(z^i) \geq 0, \quad i = 2, \ldots, n_p + n_c, \\ & z^i \in P_i, \quad i = 1, \ldots, n_p, \\ & z^{n_p+i} \in C_i, \quad i = 1, \ldots, n_c, \end{aligned}$$

where $g(x) = (x_1/a)^2 + (x_2/b)^2 - c$, and $a, b, c \in \mathbb{R}$ are positive constants. Observe that the objective function is differentiable in a large open neighborhood of the feasible region. To solve this family of problems, we will consider $g(z^1) \leq 0$ and $g(z^i) \geq$

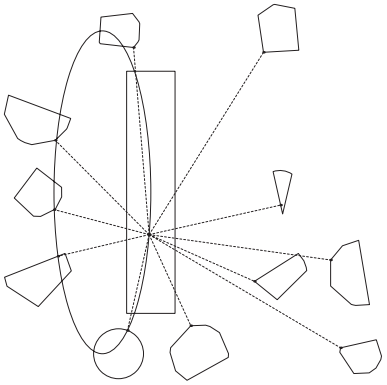

FIG. 1. *Twelve-sets very small location problem.*

$0, i = 2, \ldots, n_p + n_c$, as upper-level constraints, and $z^i \in P_i, i = 1, \ldots, n_p$, and $z^{n_p+i} \in C_i, i = 1, \ldots, n_c$, as lower-level constraints. In this way the subproblems can be efficiently solved by the SPG [11, 12] as suggested by the experiments in [12].

We generated 36 problems of this class, varying n_c and n_p and choosing randomly the location of the circles and polygons and the number of vertices of each polygon. Details of the generation, including the way in which we guarantee empty intersections (in order to have differentiability everywhere), may be found in [12] and its related code (also available at http://www.ime.usp.br/~egbirgin/tango/), where the original problem was introduced. Moreover, details of the present variant of the problem can be found within its fully commented FORTRAN 77 code (also available at http://www.ime.usp.br/~egbirgin/tango/). In Table 1 we display the main characteristics of each problem (number of circles, number of polygons, total number of vertices of the polygons, dimension of the problem, and number of lower-level and upper-level constraints). Figure 1 shows the solution of a very small twelve-sets problem that has 24 variables, 81 lower-level constraints, and 12 upper-level constraints.

The 36 problems are divided into two sets of 18 problems: small and large problems. We first solved the small problems with ALGENCAN (considering all the constraints as upper-level constraints) and ALSPG. Both methods use the FORTRAN 77 formulation of the problem (ALSPG needs an additional subroutine to compute the projection of an arbitrary point onto the convex set given by the lower-level constraints). In Table 2 we compare the performance of both methods for solving this problem. Both methods obtain feasible points and arrive at the same solutions. Due to the performance of ALSPG, we also used it to solve the set of large problems. Table 3 shows its performance. A comparison against IPOPT was made, and, while IPOPT was able to find equivalent solutions for the smaller problems, it was unable to handle the larger problems due to memory requirements.

7. Final remarks. In the last few years many sophisticated algorithms for nonlinear programming have been published. They usually involve combinations of interior-point techniques, SQP, trust regions, restoration, nonmonotone strategies, and advanced sparse linear algebra procedures. See, for example, [17, 28, 30, 31, 32, 37] and the extensive reference lists of these papers. Moreover, methods for solving efficiently specific problems or for dealing with special constraints are often introduced. Many times, a particular algorithm is extremely efficient for dealing with problems of a given type but fails (or cannot be applied) when constraints of a different class are

incorporated. This situation is quite common in engineering applications. In the augmented Lagrangian framework additional constraints are naturally incorporated into the objective function of the subproblems, which therefore preserve their constraint structure. For this reason, we conjecture that the augmented Lagrangian approach (with general lower-level constraints) will continue to be used for many years.

This fact motivated us to improve and analyze augmented Lagrangian methods with arbitrary lower-level constraints. From the theoretical point of view our goal was to eliminate, as much as possible, restrictive constraint qualifications. With this in mind, we used, both in the feasibility proof and in the optimality proof, the CPLD condition. This condition [41] has been proved to be a constraint qualification in [4], where its relations with other constraint qualifications have been given.

We provided a family of examples (location problems) where the potential of the arbitrary lower-level approach is clearly evidenced. This example represents a typical situation in applications. A specific algorithm (SPG) is known to be very efficient for a class of problems but turns out to be impossible to apply when additional constraints are incorporated. However, the augmented Lagrangian approach is able to deal with the additional constraints, taking advantage of the efficiency of SPG for solving the subproblems. In this way, we were able to solve nonlinear programming problems with more than 3,000,000 variables and 14,000,000 constraints in less than five minutes of CPU time.

Open problems related to theory and implementation of practical augmented Lagrangian methods may be found in the expanded report [3].

Acknowledgments. We are indebted to Prof. A. R. Conn, whose comments on a first version of this paper guided a deep revision, and to an anonymous referee for many constructive remarks.

ON HANDLING FREE VARIABLES IN INTERIOR-POINT METHODS FOR CONIC LINEAR OPTIMIZATION*

MIGUEL F. ANJOS† AND SAMUEL BURER‡

Abstract. We revisit a regularization technique of Mészáros for handling free variables within interior-point methods for conic linear optimization. We propose a simple computational strategy, supported by a global convergence analysis, for handling the regularization. Using test problems from benchmark suites and recent applications, we demonstrate that the modern code SDPT3 modified to incorporate the proposed regularization is able to achieve the same or significantly better accuracy over standard options of splitting variables, using a quadratic cone, and solving indefinite systems.

Key words. infeasible primal-dual path-following algorithm, semidefinite programming, equality constraints, free variables, regularization

1. Introduction.

Conic linear optimization, and in particular semidefinite optimization, has arisen since the early 1990s as an increasingly powerful and useful technique for tackling a variety of problems arising from both applications and theory. We refer the reader to the SDP webpage of Helmberg [8] as well as the books of de Klerk [5] and Wolkowicz, Saigal, and Vandenberghe [30] for thorough coverage of the theory and algorithms in this area, as well as of several application areas where researchers in conic linear optimization have made significant contributions.

Conic linear optimization refers to the class of optimization problems where a linear function of a variable x is optimized subject to linear constraints on the elements of x and the additional constraint that x lie in a symmetric self-dual cone. This includes linear programming (LP) problems as a special case, namely, when the cone is the nonnegative orthant. Since all of these cones can be described as a conic section of the cone of positive semidefinite matrices (in a polynomially bounded dimension, see [6]), attention has focused particularly on the development of algorithms for solving semidefinite linear optimization, commonly referred to as semidefinite programming (SDP). Beyond LP and SDP, a third specific cone that is useful in applications is the second-order (or Lorentz) cone, which gives rise to second-order cone programming (SOCP).

As a result, a variety of algorithms for solving LP, SOCP, and SDP problems, including polynomial-time infeasible path-following interior-point methods (IPMs), have been implemented and benchmarked (see, e.g., [18]), and several excellent solvers are available. Two of these solvers handle LP, SOCP, and SDP in a unified way, namely, SeDuMi [25] and SDPT3 [26].

Notwithstanding the substantial progress made in recent years, work continues on methods and software for conic linear optimization. One outstanding issue is that of handling free variables.

Handling free variables in conic linear optimization is an important modeling and algorithmic issue for IPMs. The issue arises from the fact that nearly all theories and algorithms for IPMs are based on the following standard-form primal and dual problems:

$$\min\left\{c^T x : Ax = b,\ x \in K\right\} \qquad \text{and} \qquad \max\left\{b^T y : A^T y + s = c,\ s \in K\right\},$$

where K is the symmetric self-dual cone (specifically, a direct product of linear, semidefinite, and second-order cones). However, in many applications, free variables naturally appear in the primal. Examples of such applications occur in quantum chemistry [36], polynomial optimization problems [21, 12], and combinatorial optimization problems [13, 2], among others.

Allowing free variables, the (nonstandard) primal problem is

$$\min\left\{c^T x + g^T z : Ax + Ez = b,\ x \in K\right\} \tag{1}$$

with the corresponding dual problem

$$\max\left\{b^T y : A^T y + s = c,\ E^T y = g,\ s \in K\right\}. \tag{2}$$

We denote by (n, p, m, n) the dimensions of the vectors (x, z, y, s), respectively, which determines the sizes of the data (A, b, c, E, g).

Theoretically, it is not so difficult to extend standard-form IPMs to handle (1)–(2). However, computation is not so easy. Each iteration of IPMs for the standard-form problem is based on solving a positive definite linear system, and accordingly most codes use high-quality, fast, sparsity-preserving implementations of the Cholesky factorization. When free variables are present, the corresponding system is still invertible but becomes indefinite, which makes it more difficult to solve in a quick, stable fashion. We emphasize that free variables are a computational issue and not a theoretical one.

Researchers have attempted various alternative ways to handle free variables computationally. Each method can be viewed as an attempt to enable the use of the Cholesky factorization.

Probably the simplest and most often suggested method is to split the variable z into a difference $z^+ - z^-$ of nonnegative vectors $z^+ \geq 0$ and $z^- \geq 0$ which transforms (1)–(2) into standard form. The effect in the dual is that the equality $E^T y = g$ is split into $E^T y \geq g$ and $E^T y \leq g$. In part because of its simplicity, this approach is often implemented as the default behavior for interior-point methods (e.g., in the LP code LIPSOL [34] that is the basis of Matlab's large-scale LP solver). For interior-point methods, this splitting of variables can be problematic because the primal optimal solution set becomes unbounded and the dual feasible set has no interior. Empirically, a typical behavior is that z^+ and z^- individually become unbounded, while their difference z stays bounded. For LP, Wright [31] asserts that, for methods which achieve superlinear convergence, the tendency of z^+ and z^- to grow large is mitigated in a satisfactory manner. Also, an alternative way to handle the splitting of variables in LP that leads to the solution of a symmetric quasi-definite system [27] is outlined in [28]. However, the recent results in [29, 9] suggest that the degeneracy caused by splitting free variables in SDP problems makes it difficult to solve the resulting SDPs stably and/or highly accurately.

A quick overview of other alternative methods for handling free variables is as follows:

- One can convert to standard form by eliminating z in the equations $Ax+Ez = b$. However, structural properties of (A, E) such as sparsity tend to be destroyed by such an approach. In the context of SDP, Kobayashi, Nakata, and Kojima [9] consider this approach and in particular make efforts to manage the loss of sparsity by eliminating z via different bases.
- One can convert to standard form by adding an auxiliary scalar variable z_0 and requiring that (z_0, z) be in a second-order cone. To the best of our knowledge, this was first suggested by Andersen [1], who reports good results and improved accuracy when solving SOCPs. This approach is also available as an option in the most recent release of SeDuMi, version 1.1 (see [23]).
- One can handle the free variables directly and regularize the indefinite system faced at each iteration, i.e., make the system symmetric quasi-definite by perturbing it in a controlled way. This approach was suggested by Mészáros [17] in the context of LP. Beyond permitting the use of the Cholesky factorization, another advantage of regularization is that the structure of (A, E) is not destroyed. On the other hand, the downside of this approach is that the solution of the system is also perturbed, and care must be taken to ensure that the global convergence of the method is not negatively affected.

Finally, we reiterate that one certainly still has the option to handle the free variables directly and solve the indefinite systems ((7) below). In fact, this is the default option of SDPT3 version 3.02, ostensibly because the authors of the software found this approach better than, say, splitting variables.

It seems safe to say that no consensus has been reached on how to handle free variables in all cases. Indeed, it is our opinion (and that of Kobayashi, Nakata, and Kojima [9]) that solving general conic linear optimization problems with free variables in a reliably stable and accurate manner remains a relevant research topic.

In this paper, we revisit the regularization method of Mészáros [17] and formalize a strategy for handling and updating the regularization so that global convergence is not affected. In contrast to the strategy suggested by Mészáros, which is based on iterative refinement and is somewhat ad hoc, our strategy is supported by a global convergence result. Using the code SDPT3, we illustrate the effectiveness of our regularization strategy on a diverse collection of problems. Our approach achieves the same or significantly better accuracy over the approaches of splitting variables, using a quadratic cone, and solving indefinite systems.

1.1. Some remarks. A few remarks are in order. First, our intention in this paper is not to claim that regularization is the best in all situations. Indeed, this is most likely *not* the case. Instead, we simply hope to establish that regularization, properly handled, is a viable alternative to other methods for handling free variables. (One consequence is that we have chosen not to compare with the method of eliminating z as in [9] in part because careful comparisons are given in [9] and because we prefer to maintain the structure of (A, E).)

Second, there are several different publicly available codes for LP, SOCP, and/or SDP on which we could test the regularization. Ultimately, we have chosen to test SDPT3 for several reasons: We wished to test both SOCP and SDP, which SDPT3 can handle; SDPT3's algorithm matches the algorithmic framework of our analysis very closely; and SDPT3's code is easily accessible, customizable, and verifiable in Matlab.

Finally, significant variation between different codes makes it unclear whether regularization would have the same effect within all codes as it does with SDPT3.

For example, tests that we have performed indicate that split variables perform quite well within SeDuMi. This is to be expected because, by design, the homogeneous self-dual embedding model used by SeDuMi has a bounded optimal solution set, and thus the iterates cannot diverge to infinity. Hence, SeDuMi will not suffer additional numerical instabilities from the splitting; in fact, split variables perform so well in SeDuMi that there does not appear to be much room for improvement in SeDuMi using regularization. In our opinion, these code-by-code differences make the discussion of free variables richer.

1.2. Structure of this paper. This paper is structured as follows. In section 2, we recall the basic framework of infeasible primal-dual path-following algorithms. In section 3, we summarize the key ideas behind a global convergence result of Kojima, Megiddo, and Mizuno [10], and in section 4, we recall the regularization approach originally proposed by Mészáros [17]. In section 5, we propose a specific methodology to update the regularization at each iteration and extend the analysis of Kojima, Megiddo, and Mizuno [10] to show that the resulting infeasible primal-dual path-following method is globally convergent. In section 6, we report computational results which show that the proposed regularization leads to an overall improvement in the performance of SDPT3 for instances with free variables. Finally, section 7 summarizes our findings and mentions some possible directions for future research.

2. The basic infeasible primal-dual path-following framework. In this section, we recall the basic framework of infeasible primal-dual path-following algorithms, which is implemented in nearly all interior-point codes for conic linear optimization. Even though standard texts treat the standard-form problem, we state the framework with respect to the problems (1)–(2). To recover the standard-form framework, one can simply take $p = 0$.

For simplicity, the framework (and indeed all of the results in the paper) are stated with K expressed as a linear cone; i.e., the SOCP and SDP cases are not explicitly handled. By now, it is well known that all standard convergence results for LP can be extended to SOCP and SDP. With this in mind and in hopes of keeping this paper as clean and accessible as possible, we choose to state everything in terms of LP.

Without loss of generality, we make the standard assumptions that A has full-row rank and E has full-column rank. We also assume that both (1)–(2) are interior feasible so that strong duality holds. Strong duality occurs when both primal and dual attain their optimal values with no gap; i.e., there exists a primal-dual feasible point (x, z, y, s) such that $\mu(x, s) = 0$, where $\mu(x, s) := x^T s/n$ is the (scaled) duality gap.

A consequence of these assumptions is that, for all $\nu > 0$, the system

$$Ax + Ez = b, \tag{3a}$$

$$A^T y + s = c, \tag{3b}$$

$$E^T y = g, \tag{3c}$$

$$XS\,e = \nu\,e, \tag{3d}$$

$$(X, S) \in K^0 \times K^0 \tag{3e}$$

has a unique solution, which we write as $(x_\nu, z_\nu, y_\nu, s_\nu)$. (We adopt common notation in the field of IPMs, so that $X := \mathrm{Diag}(x)$, $S := \mathrm{Diag}(s)$, $K^0 := \mathrm{int}(K)$, and e denotes the vector of all ones.) The set $\mathcal{C} := \{(x_\nu, z_\nu, y_\nu, s_\nu) : \nu > 0\}$ is called the *central path* and is a smooth trajectory that converges to the primal-dual optimal solution set as $\nu \to 0$ (note, for example, that $\mu(x_\nu, s_\nu) = \nu$).

Given an initial point (x^1, z^1, y^1, s^1)—which is not necessarily primal-dual feasible but does satisfy $(x^1, s^1) \in K^0 \times K^0$—the kth iteration of the path-following framework attempts to solve (3) for some $\nu_k \in (0, \mu(x^k, s^k))$ by taking a step via Newton's method. More specifically, the system

$$A\Delta x^k + E\Delta z^k = r_p^k, \tag{4a}$$

$$A^T\Delta y^k + \Delta s^k = r_{d_1}^k, \tag{4b}$$

$$E^T\Delta y^k = r_{d_2}^k, \tag{4c}$$

$$S^k\Delta x^k + X^k\Delta s^k = r_c^k, \tag{4d}$$

where

$$r_p^k := b - Ax^k - Ez^k, \tag{5a}$$

$$r_{d_1}^k := c - A^T y^k - s^k, \tag{5b}$$

$$r_{d_2}^k := g - E^T y^k, \tag{5c}$$

$$r_c^k := \nu_k\, e - X^k S^k e, \tag{5d}$$

is solved for $(\Delta x^k, \Delta z^k, \Delta y^k, \Delta s^k)$, and a step size $\alpha_k \in (0, 1]$ is selected such that

$$(x^{k+1}, z^{k+1}, y^{k+1}, s^{k+1}) := (x^k, z^k, y^k, s^k) + \alpha_k(\Delta x^k, \Delta z^k, \Delta y^k, \Delta s^k)$$

satisfies $\mu(x^{k+1}, s^{k+1}) < \mu(x^k, s^k)$ and $(x^{k+1}, s^{k+1}) \in K^0 \times K^0$. By construction,

$$(r_p^{k+1}, r_{d_1}^{k+1}, r_{d_2}^{k+1}) = (1 - \alpha_k)(r_p^k, r_{d_1}^k, r_{d_2}^k). \tag{6}$$

In other words, one can interpret a single iteration as decreasing the duality gap and decreasing infeasibility, while staying inside the cone. (An important technical issue is whether (4) is uniquely solvable. This is guaranteed by $(x^k, s^k) \in K^0 \times K^0$; see also below.)

Various implementations of the above basic framework are possible. For example, many implementations do not monitor the decrease of μ since, in practice, a decrease is typically observed all the way to the boundary of $K^0 \times K^0$. Most implementations also take different step sizes in the primal and dual spaces. Another popular variant is the predictor-corrector strategy of Mehrotra [16], which provides a highly effective scheme for choosing ν_k and for altering $(\Delta x^k, \Delta z^k, \Delta y^k, \Delta s^k)$ so that the central path is followed more closely.

The Newton system can be reduced to the following smaller system (where the superscript k is understood):

$$\begin{pmatrix} AXS^{-1}A^T & E \\ E^T & 0 \end{pmatrix} \begin{pmatrix} \Delta y \\ \Delta z \end{pmatrix} = \begin{pmatrix} AXS^{-1}r_{d_1} - AS^{-1}r_c + r_p \\ r_{d_2} \end{pmatrix}. \tag{7}$$

If $p > 0$ (i.e., if there are free variables), then this system is indefinite. On the other hand, if $p = 0$, then the system is positive definite and can be solved with the Cholesky factorization.

3. A basic global convergence analysis. As discussed in section 2, the infeasible primal-dual path-following framework reduces both the gap and the infeasibility in each iteration. Global convergence is achieved if the gap and infeasibility converge to zero. In this section, we recapitulate the first global convergence result, which

was given by Kojima, Megiddo, and Mizuno [10] (for the case of LP with no free variables). This will serve as the basis of the results in section 5. (Some comments on why we have chosen to present the approach of Kojima, Megiddo, and Mizuno are given below in section 3.2.)

We caution the reader that we do not present Kojima, Megiddo, and Mizuno's method verbatim, but instead we make some simplifying assumptions. The simplifications are for the sake of brevity; all of the fundamental content is retained. For example, Kojima, Megiddo, and Mizuno analyze the use of different primal and dual step sizes, whereas we analyze a common step size. Another simplification is the following assumption: The initial point (x^1, z^1, y^1, s^1) satisfies $(r_p^1, r_{d_1}^1) = (0, 0)$ so that $(r_p^k, r_{d_1}^k) = (0, 0)$ for all k. Our reasons for this assumption are as follows: The essentials of the global convergence result are clear with only one infeasible equation, and the assumption $r_{d_2}^k \neq 0$ is sufficient to develop the techniques of section 5. In accordance with this assumption, we will write $r^k := r_{d_2}^k$ to streamline notation. Also to make notation easier, we let $\mu_k := \mu(x^k, s^k)$.

Within the framework of section 2, convergence results typically require some restrictions on the iterates. Kojima, Megiddo, and Mizuno require that the iterates remain in a neighborhood of the central path having the following form, which is dependent on constants $\gamma \in (0, 1)$ and $\beta > 0$:

(8)
$$\mathcal{N}(\gamma, \beta) := \{(x, z, y, s) \in K^0 \times \Re^p \times \Re^m \times K^0 \ : \ XSe \geq \gamma\, \mu(x, s)\, e,\ \|r(y)\| \leq \beta\, \mu(x, s)\},$$

where $r(y) := g - E^T y$. In particular, γ and β should be chosen so that $(x^1, z^1, y^1, s^1) \in \mathcal{N}(\gamma, \beta)$. At times we will write $\mathcal{N} := \mathcal{N}(\gamma, \beta)$ for convenience. The neighborhood aids the convergence analysis by guaranteeing that the iterates do not get too close to the cone boundary and that infeasibility decreases at the same rate as the duality gap.

The precise algorithm is stated as Algorithm 1. Note that the algorithm depends on user-defined tolerances $\varepsilon > 0$ and $\omega > 0$ as well as a duality gap "dampening" factor $\sigma \in (0, 0.99)$. In addition, the algorithm also utilizes the following definitions for $\alpha \in [0, 1]$:

$$\begin{aligned}(x_\alpha, z_\alpha, y_\alpha, s_\alpha) &:= (x^k, z^k, y^k, s^k) + \alpha(\Delta x^k, \Delta z^k, \Delta y^k, \Delta s^k),\\ \mu_\alpha &:= \mu(x_\alpha, s_\alpha).\end{aligned}$$

The convergence result is stated next.

Algorithm 1. Infeasible Path-Following Algorithm.

Let $\varepsilon > 0$, $\omega > 0$, $\sigma \in (0, 0.99)$, and $(x^1, z^1, y^1, s^1) \in \mathcal{N}$ be given.

for $k = 1, 2, 3, \ldots$ **do**

If $\mu_k \leq \varepsilon$ or $\|(x^k, s^k)\|_1 \geq \omega$, then stop.

Set $\nu_k := \sigma\mu_k$ and solve (4) for $(\Delta x^k, \Delta z^k, \Delta y^k, \Delta s^k)$.

Set $(x^{k+1}, z^{k+1}, y^{k+1}, s^{k+1}) = (x_{\alpha_k}, z_{\alpha_k}, y_{\alpha_k}, s_{\alpha_k})$, where $\alpha_k \in (0, 1]$ is the largest step size such that the relations

$$(x_\alpha, z_\alpha, y_\alpha, s_\alpha) \in \mathcal{N}, \tag{9}$$

$$\mu_\alpha \leq (1 - 0.01\alpha)\mu_k \tag{10}$$

hold for every $\alpha \in [0, \alpha_k]$.

end for

THEOREM 3.1 (see [10]). *Let $\gamma \in (0,1)$, $\beta > 0$, and an initial point $(x^1, z^1, y^1, s^1) \in \mathcal{N}(\gamma, \beta)$ be given. Suppose, moreover, that positive tolerances ε and ω and a dampening factor $\sigma \in (0, 0.99)$ are specified. Then Algorithm 1 eventually generates an iterate $(x^k, z^k, y^k, s^k) \in \mathcal{N}(\gamma, \beta)$ such that $\mu_k \leq \varepsilon$ or $\|(x^k, s^k)\|_1 \geq \omega$. If the first case occurs, then $\|r^k\| \leq \beta\,\varepsilon$ as well.*

If the second case occurs, then Kojima, Megiddo, and Mizuno show that the infeasibility of (1)–(2) is implied over a wide region of the primal-dual ground space $K \times \Re^p \times \Re^m \times K$. Although this information is not a full infeasibility certificate, the intuition is that this is a strong indication of infeasibility, especially when ω is large.

The key to establishing Theorem 3.1 is to prove the existence of a positive constant α_* such that $\alpha_k \geq \alpha_*$ for all k generated by the algorithm. We state this lemma and prove the theorem; portions of the proof of the lemma, which are relevant to section 5, are given below in section 3.1.

LEMMA 3.2 (see [10]). *Suppose that there exists some constant $\eta > 0$ such that, for all k generated by the algorithm,*

$$|\,\Delta x_i^k \Delta s_i^k - \gamma\,(\Delta x^k)^T \Delta s^k/n\,| \leq \eta \quad \forall\ i = 1, \ldots, n, \tag{11a}$$

$$|\,(\Delta x^k)^T \Delta s^k/n\,| \leq \eta. \tag{11b}$$

Then $\alpha_k \geq \alpha_* > 0$, where

$$\alpha_* := \min\left\{1, \frac{(1-\gamma)\sigma\varepsilon}{\eta}, \frac{\sigma\varepsilon}{\eta}, \frac{(0.99-\sigma)\varepsilon}{\eta}\right\}. \tag{12}$$

Proof of Theorem 3.1. The proof is by contradiction. Assume that Algorithm 1 does not terminate. Then the entire infinite sequence $\{(x^k, z^k, y^k, s^k)\}$ lies in the compact set

$$\mathcal{N}^* := \{\ (x,z,y,s) \in \mathcal{N}\ :\ \mu(x,s) \geq \varepsilon,\ \|(x,s)\|_1 \leq \omega\ \}.$$

Combining this with the fact that the Newton direction is a continuous function of the iterates (since (4) is nonsingular for each k), any continuous function of the direction is uniformly bounded over all k. So the hypothesis of Lemma 3.2 holds, implying that $\alpha_k \geq \alpha_*$ for all k. Thus, by Algorithm 1, the duality gap is decreased by at least a multiplicative factor of $1 - 0.01\alpha_* < 1$ in each iteration, and so $\mu_k \to 0$, which contradicts the assumption that Algorithm 1 does not terminate. ∎

3.1. Proof of Lemma 3.2. Assume that (11) holds for all k generated by the algorithm, and note also that

$$\mu_k \geq \varepsilon \tag{13}$$

for the same k. We define $r_\alpha := g - E^T y_\alpha$ and recall that $r_\alpha = (1-\alpha)\,r$ by (6).

Using the definitions of $\mathcal{N}$ and Algorithm 1 together with the following three propositions, the proof of Lemma 3.2 is straightforward. We give only the proof of Proposition 3.4 because of its relevance for the results in section 5. The super- and subscripts k are dropped since the arguments below are irrespective of k.

PROPOSITION 3.3 (see [10]). *$X_\alpha S_\alpha\, e \geq \gamma\,\mu_\alpha\, e$ for all $\alpha \leq (1-\gamma)\,\sigma\,\varepsilon/\eta$.*

PROPOSITION 3.4 (see [10]). *$\|r_\alpha\| \leq \beta\mu_\alpha$ for all $\alpha \leq \sigma\varepsilon/\eta$.*

Proof. Recall the standard relation

$$\mu_\alpha = (1 - (1-\sigma)\alpha)\mu + \alpha^2 \Delta x^T \Delta s/n. \tag{14}$$

Thus, we have

$$\begin{aligned}\beta\mu_\alpha - \|r_\alpha\| &= \beta\left[(1-(1-\sigma)\alpha)\mu + \alpha^2\Delta x^T\Delta s/n\right] - (1-\alpha)\|r\| \\ &= (1-\alpha)(\beta\mu - \|r\|) + \beta\alpha\sigma\mu + \beta\alpha^2\Delta x^T\Delta s/n \\ &\geq \beta\alpha\sigma\mu - \beta\alpha^2\eta \geq \alpha\beta\left[\sigma\varepsilon - \alpha\eta\right],\end{aligned}$$

where the first equality follows from (14), the first inequality follows from $(x, z, y, s) \in \mathcal{N}$ and (11b), and the second inequality follows from (13). This proves the result. ∎

PROPOSITION 3.5 (see [10]). *$\mu_\alpha \leq (1 - 0.01\alpha)\mu$ for all $\alpha \leq (0.99 - \sigma)\varepsilon/\eta$.*

3.2. Other convergence results. Before proceeding, we discuss other known convergence results for the infeasible framework of section 2 and explain why we have chosen to analyze the result of Kojima, Megiddo, and Mizuno [10].

Following the above global convergence result of Kojima, Megiddo, and Mizuno and Zhang [32] strengthened the result by proving that an ε-approximate optimal solution is delivered within $O(n^2)$ iterations (if an optimal solution exists). In particular, Zhang resolved the ambiguity surrounding Kojima, Megiddo, and Mizuno's infeasibility "certificate" $\|(x, s)\|_1 > \omega$. For example, under the assumption of primal-dual interior feasibility, all iterates stay bounded. Later, Zhang [33] extended these ideas to the case of SDP.

Other implementations of the framework have also been analyzed. In particular, a few authors have studied variations of the original predictor-corrector strategy of Mehrotra [16]. First, Mehrotra himself suggests a proof of global convergence for his method by appealing to certain "fall back" search directions, which are different from his own predictor-corrector direction. Then Zhang and Zhang [35] prove polynomial convergence of a variation of Mehrotra's original method, which they suggest, but to our knowledge the Zhang–Zhang variant has not actually been implemented in practice. Finally, a third variant, which is used in most modern interior-point codes, is analyzed by Salahi, Peng, and Terlaky [24]. They make the simplifying assumption that all iterates are feasible and show by example that this variant can converge quite slowly on certain problems. By studying a suitable modification, they prove polynomial convergence. To our knowledge, no one has proved global or polynomial convergence of the infeasible version of this third variant (i.e., the one implemented in most codes).

A different line of research has analyzed the convergence of the framework when using inexact Newton directions, which are directions that satisfy (4) only approximately. Inexact directions arise, for example, when iterative methods are used to solve the system (7) to moderate accuracy. Depending on their precise form, inexact directions can lead to infeasible iterates, even if the algorithm is supplied with an initial feasible iterate. This is because the key relation (6) does not hold from iteration to iteration. Nevertheless, global and polynomial convergence results can be proved under suitable conditions on the degree of the inexactness of the direction (see [19, 11, 7] for LP and, more recently, [37] for SDP).

In section 5, we propose Algorithm 2, a variant of Algorithm 1 that is based on an inexact Newton direction arising from regularization. We also extend the analysis in this section to prove a global convergence result for Algorithm 2. Although we were unable to prove a polynomial convergence result for Algorithm 2, and although the aforementioned work on inexact Newton directions can be applied to obtain a provably polynomially convergent method with regularization, we deliberately choose to advocate Algorithm 2 for the following reasons:

- Our extension of the original result of Kojima, Megiddo, and Mizuno has the advantages that: (i) it allows for infeasible iterates and a straightforward analysis of our particular inexact direction; and (ii) the resulting regularization strategy is quite simple to implement and has an intuitive appeal.
- Our experiments in the direction of following the insights provided by the above research on inexact methods led us to the following conclusions: (i) the resulting regularization strategies are significantly more difficult to implement; and (ii) we implemented the approach of [7] and found by experimentation that it did not work as well as our proposed approach.

It should also be noted that we chose *not* to analyze a predictor-corrector variant because the theoretical basis for implemented predictor-corrector strategies is less well understood, especially with regards to infeasible and inexact aspects. Nonetheless, we did test our method successfully within such a strategy (more details are given in section 6).

Ultimately, we believe that our analysis allows us to identify the essence of a good regularization strategy. It should (i) be convergent, (ii) be easy to implement, and (iii) work well in practice.

4. The regularization approach of Mészáros. Mészáros [17] proposes to replace (4c) of the Newton system (4) with the following equation for a specified $\delta_k > 0$:

$$E^T \Delta y^k - \delta_k \, \Delta z^k = r_{d_2}^k. \tag{15}$$

Just as (4) can be reduced to (7), the regularized system of Mészáros can be reduced to

$$\begin{pmatrix} AXS^{-1}A^T & E \\ E^T & -\delta\, I \end{pmatrix} \begin{pmatrix} \Delta y \\ \Delta z \end{pmatrix} = \begin{pmatrix} AXS^{-1}r_{d_1} - AS^{-1}r_c + r_p \\ r_{d_2} \end{pmatrix}, \tag{16}$$

where the k subscript is understood. In contrast to (7), however, (16) can further be reduced to the positive definite system

$$\left(AXS^{-1}A^T + \delta^{-1}EE^T\right) \Delta y = AXS^{-1}r_{d_1} - AS^{-1}r_c + r_p + \delta^{-1}Er_{d_2}. \tag{17}$$

Hence, the Cholesky factorization can be employed to calculate the direction. The obvious downside is that the resulting direction is not the true Newton direction. It is shown in [17] that the difference between these two directions is $O(\delta)$.

Yet, a more important question in practice is the choice of δ_k throughout the course of the algorithm, since poor choices can certainly have a negative impact on convergence. Under restrictive assumptions, an adaptive heuristic for updating δ_k is proposed in [17], and iterative refinement is also suggested for improving the quality of the search direction at each iteration. Furthermore, Maros and Mészáros [15] investigate the choice of a constant δ_k throughout the algorithm. From our perspective, these suggestions are somewhat ad hoc and do not consider the effect of the regularization on the global convergence of the algorithm. We feel that the question of how to select a global strategy for updating δ_k was left open by Mészáros.

5. Global convergence with regularization. In contrast to Mészáros, we take the perspective that the regularization of the Newton system leads to an inexact interior-point method. In this section, we propose a specific methodology to update δ_k at each iteration and show that the resulting interior-point method is globally convergent.

Recall that the direction determined by the regularization differs from the true Newton direction in that (15) replaces (4c). Expressed differently, we allow the Newton direction to satisfy

$$E^T \Delta y^k = r_{d_2}^k + \delta_k \Delta z^k,$$

even though we hope that $E^T \Delta y^k$ could equal $r_{d_2}^k$. So the direction given by the regularization is an inexact direction. But what effect does the inexact direction have on convergence? If one tries to extend the convergence proof of Kojima, Megiddo, and Mizuno, all concepts and proofs extend easily except that we no longer have r_α equal to $(1-\alpha)r$, which in turn causes a direct extension of Proposition 3.4 to fail (see section 3.1).

However, it is not so difficult to repair the proof of Proposition 3.4. The key insight is that the degree of inexactness of the direction needs to be controlled in a certain manner. Specifically, if we have

$$\delta_k \|\Delta z^k\| \le \beta\sigma\mu_k/2 \tag{18}$$

for all k, then global convergence is established by Theorem 5.1 below.

Our method for enforcing (18) is essentially to decrease δ_k if (18) does not hold. The resulting algorithm is stated as Algorithm 2. Algorithm 2 incorporates all of the features of Algorithm 1, while adding steps to handle δ_k that are fairly straightforward. It is worth mentioning three items:

- In the `while` loop, each time δ_k is updated, it is decreased by a factor of at least 2. As a result, the `while` loop will terminate after a finite (usually quite small) number of loops.

Algorithm 2. Infeasible Path-Following Algorithm (with Regularization).

Let $\varepsilon > 0$, $\omega > 0$, $\sigma \in (0, 0.99)$, $\delta_1 > 0$, and $(x^1, z^1, y^1, s^1) \in \mathcal{N}$ be given.

for $k = 1, 2, 3, \ldots$ **do**
  If $\mu_k \le \varepsilon$ or $\|(x^k, s^k)\|_1 \ge \omega$, then stop.
  Set ACCEPT $= 0$.
  while ACCEPT $= 0$ **do**
    Set $\nu_k = \sigma\mu_k$ and solve (4) with (4c) replaced by (15) for $(\Delta x^k, \Delta z^k, \Delta y^k, \Delta s^k)$.
    if $\delta_k \|\Delta z^k\| \le \beta\sigma\mu_k/2$ **then**
      ACCEPT $= 1$
    else
      $\delta_k \leftarrow \frac{1}{2} \cdot \beta\sigma\mu_k/(2\|\Delta z^k\|)$
    end if
  end while
  Set $(x^{k+1}, z^{k+1}, y^{k+1}, s^{k+1}) = (x_{\alpha_k}, z_{\alpha_k}, y_{\alpha_k}, s_{\alpha_k})$, where $\alpha_k \in (0, 1]$ is the largest step size such that the relations

$$(x_\alpha, z_\alpha, y_\alpha, s_\alpha) \in \mathcal{N}, \tag{19}$$

$$\mu_\alpha \le (1 - 0.01\alpha)\mu_k \tag{20}$$

  hold for every $\alpha \in [0, \alpha_k]$.
  Set $\delta_{k+1} \leftarrow \beta\sigma\mu_{k+1}/(2\|\Delta z^k\|)$.
end for

- In each loop of the `while` loop, the direction must be recalculated. This necessitates reforming and refactoring the matrix $AXS^{-1}A^T + \delta_k^{-1}EE^T$ of (17) because of the dependence on δ_k. This is a potential downside of Algorithm 2. However, the computational results of section 6 (particularly Table 5) show that, overall, this extra work does not constitute a disadvantage, most likely because the `while` loop is repeated only a small number of times.
- The purpose of the `while` loop is to drive δ_k lower and lower until (18) holds. Based on the (ultimately flawed) idea that δ_k should never increase during the course of the algorithm, our initial implementation of Algorithm 2 maintained a nonincreasing sequence $\{\delta_k\}$. We found by experimentation, however, that sometimes δ_k would go to 0 too quickly, causing numerical difficulties. By this we mean, for example, that one iteration would require $\delta_k \leq 10^{-4}$ to enforce (18), while a later iteration would require only $\delta_k \leq 10^{-2}$. For numerical stability, it makes sense to take δ_k as large as possible, which was not allowed by our initial implementation. Hence, our final implementation (i.e., Algorithm 2) allows δ_k to increase via the last line of the `for` loop, which sets δ_{k+1} to our best guess given current information.

Regarding convergence, the following result holds for this algorithm.

THEOREM 5.1. *Let $\gamma \in (0,1)$, $\beta > 0$, and an initial point $(x^1, z^1, y^1, s^1) \in \mathcal{N}(\gamma, \beta)$ be given. Suppose, moreover, that positive tolerances ε and ω, a dampening factor $\sigma \in (0, 0.99)$, and an initial regularization parameter $\delta_1 > 0$ are specified. Then Algorithm 2 eventually generates an iterate $(x^k, z^k, y^k, s^k) \in \mathcal{N}(\gamma, \beta)$ such that $\mu_k \leq \varepsilon$ or $\|(x^k, s^k)\|_1 \geq \omega$. If the first case occurs, then $\|r^k\| \leq \beta\,\varepsilon$ as well.*

The proof of Theorem 5.1 follows the same steps as that of Theorem 3.1 with two changes: r_α and α_* are now given by

$$r_\alpha = (1-\alpha)r - \alpha\delta\Delta z \tag{21}$$

and

$$\alpha_* := \min\left\{1, \frac{(1-\gamma)\sigma\varepsilon}{\eta}, \frac{\sigma\varepsilon}{2\eta}, \frac{(0.99-\sigma)\varepsilon}{\eta}\right\},$$

respectively, and Proposition 3.4 is replaced by the following proposition.

PROPOSITION 5.2. *If $\delta_k\|\Delta z^k\| \leq \beta\sigma\mu_k/2$, then $\|r_\alpha\| \leq \beta\mu_\alpha$ for all $\alpha \leq \sigma\varepsilon/2\eta$.*

Proof. We have

$$\begin{aligned}
&\beta\mu_\alpha - \|r_\alpha\| \\
&\quad = \beta\left[(1-(1-\sigma)\alpha)\mu + \alpha^2\Delta x^T\Delta s/n\right] - \|(1-\alpha)r - \alpha\delta\Delta z\| \\
&\quad \geq \beta\left[(1-(1-\sigma)\alpha)\mu + \alpha^2\Delta x^T\Delta s/n\right] - (1-\alpha)\|r\| - \alpha\delta\|\Delta z\| \\
&\quad \geq \beta\left[(1-(1-\sigma)\alpha)\mu + \alpha^2\Delta x^T\Delta s/n\right] - (1-\alpha)\|r\| - \beta\alpha\sigma\mu/2 \\
&\quad = (1-\alpha)(\beta\mu - \|r\|) + \beta\alpha\sigma\mu/2 + \beta\alpha^2\Delta x^T\Delta s/n \\
&\quad \geq \beta\alpha\sigma\mu/2 - \beta\alpha^2\eta \geq \alpha\beta\left[\sigma\varepsilon/2 - \alpha\eta\right],
\end{aligned}$$

where the first equality follows from (14) and (21), the first inequality follows from $(x,z,y,s) \in \mathcal{N}$ and (11b), and the second inequality follows from the assumption $(x,z,y,s) \in \mathcal{N}^*$. This proves the result. ∎

6. Implementation and computational results. We compare our proposed regularization (hereafter denoted REGULARIZE) with

- explicitly solving the indefinite system (7) (EXPLICIT),
- splitting the free variables into the difference of two nonnegative variables (SPLIT), and
- putting the free variables into a second-order cone (QCONE).

The comparisons are carried out using SDPT3 (version 3.02), which supports EXPLICIT by default and supports SPLIT and QCONE via modified data input. Moreover, SDPT3 requires only simple code modifications to implement REGULARIZE. All tests are run on a dual Opteron 2.8 GHz, using the HKM direction and the predictor-corrector option.

We point out that, since our implementation is based on SDPT3, REGULARIZE differs from Algorithm 2 in the same ways that typical implementations of interior-point methods differ from theory. For example, the iterates are not explicitly forced to stay in a neighborhood, and Mehrotra's predictor-corrector method is used. The lack of explicit neighborhood does have an impact on how we enforce condition (18). In each iteration, (18) is enforced with the definition $\beta := \mu/\|r\|$. This can be interpreted as assigning to β the smallest value such that the current iterate is actually a member of $\mathcal{N}$ (if membership in $\mathcal{N}$ were maintained). In this sense, the choice of β is also conservative in that it results in the strictest realization of (18). One additional implementation detail: The parameter δ_k is initialized to $\delta_0 = \mu_0$.

As mentioned previously, SDPT3 has been chosen for several reasons, including the fact that its fundamental algorithm closely matches the algorithmic framework of our analysis. As a consequence, we caution that the conclusions supported by our computational results do not necessarily say anything about the effect of regularization within other codes (although we are optimistic that the regularization can have benefits elsewhere; see section 7).

We also note that SDPT3 offers the option of handling dense columns of (A, E) in such a way that computational effort is minimized. We have tested our regularization with this option enabled (which is the default) or disabled, and the method works just as well in both cases.

There do not appear to be many existing test instances of linear conic optimization problems with free variables. For example, the commonly used DIMACS set of benchmark problems [22] contains only 9 instances with free variables, while SDPLIB [3] contains none. We include the 9 DIMACS test problems in our experiments. Kobayashi, Nakata, and Kojima [9] generated modified problems having free variables from SDPLIB to test their approach; starting with the same SDPLIB problems, we generated our own sparse versions of these problems having free variables via a random matrix $E \in \Re^{m\times p}$, where $p := m/2$. In fact, we generated two sets of modified SDPLIB problems: one set with $\text{rank}(E) = p$ and a second set with $\text{rank}(E) = p/2$. In contrast to the theoretical assumption in section 2 that E has full-column rank, we test instances with E having small-column rank because in practice E may have (nearly) dependent columns.

On the other hand, problems with free variables have become very relevant due to recent applications of SDP to certain classes of problems. In particular, we report test results on two additional sets of problems: one from quantum chemistry and another obtained by generating moment relaxations of combinatorial optimization problems [13] using YALMIP [14]. The set of moment relaxations consists of (small) randomly generated maximum-cut, quadratic-knapsack, and stable-set instances. Half of the underlying instances have 15 variables; the other half have 17. The moment

Quantum chemistry	-5.1	-2.1	-1.8	-2.0
Moment relaxations	-6.0	-2.0	-2.5	-3.4

relaxations are of order 2. For the maximum-cut and stable-set instances, we wrote our own simple random generation procedure, whereas the quadratic-knapsack problems were generated as in the study by Caprara, Pisinger, and Toth [4]. The stable-set formulation is due to Motzkin and Straus [20]. The large number of free variables in these instances arises from the number of equality constraints in the original problems. Characteristics of the test problems that we use are summarized in Tables 1 and 2.

The main criterion for comparing the various methods is the resulting accuracy; i.e., we wish to determine which approach yields the most accurate solutions. Specifically, we report accuracies as $\log_{10}$ of the maximum of the standard DIMACS accuracy errors [18]. Roughly speaking, an accuracy of $-k$ in our results corresponds to k digits of accuracy in the reported optimal value.

It is important to point out that SDPT3 tries to the improve the accuracy of the solution from iteration to iteration, until the accuracy deteriorates for a few iterations, at which point SDPT3 stops. For all of the approaches, we let SDPT3 run until this happens and report the best accuracy obtained overall.

The results of our computational experiments are summarized in Tables 3, 4, and 5. Table 3 shows that, for the test sets *DIMACS challenge* and *modified SDPLIB*, the proposed regularization approach basically matches the best accuracy among the other three approaches. More interestingly, the accuracy obtained for the three other test sets is significantly higher. The results for the moment relaxations are particularly interesting because these instances contain the largest proportions of free variables.

TABLE 5
Average CPU time per iteration (as a percentage of REGULARIZE *time).*

Class	Reg	Exp	Split	qCone
(all)	100%	138%	107%	114%

Looking at the results for the set of problems with E having linearly dependent columns, we note that EXPLICIT achieves very poor accuracy for these problems due to numerical difficulties. The other three approaches, including REGULARIZE, seem unaffected by the dependencies in E.

Table 4 shows that the higher accuracy obtained by REGULARIZE typically requires a higher number of iterations (the other methods stop when accuracy deteriorates). Nonetheless, with respect to CPU time, Table 5 shows that REGULARIZE requires, on average, the same or less computational effort per iteration as that required by the other approaches. In summary, the proposed regularization seems to lead to an overall improvement in the performance of SDPT3 for instances with free variables.

7. Conclusion and future research. We have considered the regularization approach for handling free variables within interior-point methods for conic linear optimization. Using a global convergence analysis, we derive a simple computational strategy for handling and updating the regularization. Straightforward modifications to the modern code SDPT3 allow the regularization to be incorporated within an inexact infeasible primal-dual path-following interior-point framework. Computational results with SDPT3 on a variety of test problems suggest that the regularization is able to achieve the same or significantly better numerical accuracy than other strategies for handling free variables, while requiring less CPU time per iteration on average.

It remains to be studied what impact regularization can have within other SDP codes, including the well-known homogeneous self-dual embedding algorithm implemented in SeDuMi, a package known to yield excellent accuracy in its computations. As indicated in the introduction, our experience with SeDuMi confirms SeDuMi's reputation; SeDuMi achieves 10 to 11 digits of accuracy on the test problems of this paper. It would be interesting to investigate how regularization can be applied to SeDuMi and if it can improve SeDuMi further. Another intriguing possibility is the study of an easily implementable update strategy for the regularization that would permit a proof of polynomial-time convergence.

Finally, we hope that this paper will stimulate further research on techniques to handle conic linear optimization problems with a significant proportion of free variables, as such problems have become relevant in the context of recent applications of SDP to several challenging problems.

Acknowledgment. The authors are in debt to two anonymous referees for numerous insightful comments and suggestions, which have greatly improved the paper.

EXACT REGULARIZATION OF CONVEX PROGRAMS*

MICHAEL P. FRIEDLANDER† AND PAUL TSENG‡

Abstract. The regularization of a convex program is *exact* if all solutions of the regularized problem are also solutions of the original problem for all values of the regularization parameter below some positive threshold. For a general convex program, we show that the regularization is exact if and only if a certain selection problem has a Lagrange multiplier. Moreover, the regularization parameter threshold is inversely related to the Lagrange multiplier. We use this result to generalize an exact regularization result of Ferris and Mangasarian [*Appl. Math. Optim.*, 23 (1991), pp. 266–273] involving a linearized selection problem. We also use it to derive necessary and sufficient conditions for exact penalization, similar to those obtained by Bertsekas [*Math. Programming*, 9 (1975), pp. 87–99] and by Bertsekas, Nedić, and Ozdaglar [*Convex Analysis and Optimization*, Athena Scientific, Belmont, MA, 2003]. When the regularization is not exact, we derive error bounds on the distance from the regularized solution to the original solution set. We also show that existence of a "weak sharp minimum" is in some sense close to being necessary for exact regularization. We illustrate the main result with numerical experiments on the ℓ_1 regularization of benchmark (degenerate) linear programs and semidefinite/second-order cone programs. The experiments demonstrate the usefulness of ℓ_1 regularization in finding sparse solutions.

1. Introduction.

A common approach to solving an ill-posed problem—one whose solution is not unique or is acutely sensitive to data perturbations—is to construct a related problem whose solution is well behaved and deviates only slightly from a solution of the original problem. This is known as regularization, and deviations from solutions of the original problem are generally accepted as a trade-off for obtaining solutions with other desirable properties. However, it would be more desirable if solutions of the regularized problem were also solutions of the original problem. Here we present necessary and sufficient conditions for this to hold and study their implications for general convex programs.

Consider the general convex program

$$\text{(P)} \qquad \begin{array}{ll} \underset{x}{\text{minimize}} & f(x) \\ \text{subject to} & x \in \mathcal{C}, \end{array}$$

where $f : \mathbb{R}^n \to \mathbb{R}$ is a convex function, and $\mathcal{C} \subseteq \mathbb{R}^n$ is a nonempty closed convex set. In cases where (P) is ill-posed or lacks a smooth dual, a popular technique is to regularize the problem by adding a convex function to the objective. This yields the

regularized problem

$$(\mathrm{P}_\delta) \qquad \begin{array}{ll} \underset{x}{\text{minimize}} & f(x) + \delta\phi(x) \\ \text{subject to} & x \in \mathcal{C}, \end{array}$$

where $\phi : \mathbb{R}^n \to \mathbb{R}$ is a convex function, and δ is a nonnegative regularization parameter. The regularization function ϕ may be nonlinear and/or nondifferentiable.

In general, solutions of the regularized problem (P_δ) need not be solutions of (P). (Here and throughout, "solution" is used in lieu of "optimal solution.") We say that the regularization is *exact* if the solutions of (P_δ) are also solutions of (P) for all values of δ below some positive threshold value $\bar{\delta}$. We choose the term *exact* to draw an analogy with exact penalization that is commonly used for solving constrained nonlinear programs. An exact penalty formulation of a problem can recover a solution of the original problem for all values of the penalty parameter beyond a threshold value. See, for example, [4, 5, 9, 21, 24, 31] and, for more recent discussions, [7, 15].

Exact regularization can be useful for various reasons. If a convex program does not have a unique solution, exact regularization may be used to select solutions with desirable properties. In particular, Tikhonov regularization [45], which corresponds to $\phi(x) = \|x\|_2^2$, can be used to select a least two-norm solution. Specialized algorithms for computing least two-norm solutions of linear programs (LPs) have been proposed by [25, 26, 27, 30, 33, 48], among others. Saunders [42] and Altman and Gondzio [1] use Tikhonov regularization as a tool for influencing the conditioning of the underlying linear systems that arise in the implementation of large-scale interior-point algorithms for LPs. Bertsekas [4, Proposition 4] and Mangasarian [30] use Tikhonov regularization to form a smooth convex approximation of the dual LP.

More recently, there has been much interest in ℓ_1 regularization, which corresponds to $\phi(x) = \|x|_1$. Recent work related to signal processing has focused on using LPs to obtain sparse solutions (i.e., solutions with few nonzero components) of underdetermined systems of linear equations $Ax = b$ (with the possible additional condition $x \geq 0$); for examples, see [13, 12, 14, 18]. In machine learning and statistics, ℓ_1 regularization of linear least-squares problems (sometimes called lasso regression) plays a prominent role as an alternative to Tikhonov regularization; for examples, see [19, 44]. Further extensions to regression and maximum likelihood estimation are studied in [2, 41], among others.

There have been some studies of exact regularization for the case of differentiable ϕ, mainly for LP [4, 30, 34], but to our knowledge there has been only one study, by Ferris and Mangasarian [20], for the case of nondifferentiable ϕ. However, their analysis is mainly for the case of strongly convex ϕ, and thus is not applicable to regularization functions such as the one-norm. In this paper, we study exact regularization of the convex program (P) by (P_δ) for a general convex ϕ.

Central to our analysis is a related convex program that selects solutions of (P) of least ϕ-value:

$$(\mathrm{P}^\phi) \qquad \begin{array}{lll} \underset{x}{\text{minimize}} & \phi(x) & \\ \text{subject to} & x \in \mathcal{C}, & f(x) \leq p^*, \end{array}$$

where p^* denotes the optimal value of (P). We assume a nonempty solution set of (P), which we denote by $\mathcal{S}$, so that p^* is finite and (P^ϕ) is feasible. Clearly, any solution of (P^ϕ) is also a solution of (P). The converse, however, does not generally hold.

In section 2 we prove our main result: the regularization (P_δ) is exact if and only if the selection problem (P^ϕ) has a Lagrange multiplier μ^*. Moreover, the solution set of (P_δ) coincides with the solution set of (P^ϕ) for all $\delta < 1/\mu^*$; see Theorem 2.1 and Corollary 2.2.

A particular case of special interest is conic programs, which correspond to

$$f(x) = c^T x \qquad \text{and} \qquad \mathcal{C} = \{x \in \mathcal{K} \mid Ax = b\}, \tag{1.1}$$

where $A \in \mathbb{R}^{m\times n}$, $b \in \mathbb{R}^m$, $c \in \mathbb{R}^n$, and $\mathcal{K} \subseteq \mathbb{R}^n$ is a nonempty closed convex cone. In the further case where $\mathcal{K}$ is polyhedral, (P^ϕ) always has a Lagrange multiplier. Thus we extend a result obtained by Mangasarian and Meyer for LPs [34, Theorem 1]; their (weaker) result additionally assumes differentiability (but not convexity) of ϕ on $\mathcal{S}$, and proves that existence of a Lagrange multiplier for (P^ϕ) implies existence of a common solution x^* of (P) and (P_δ) for all positive δ below some threshold. In general, however, (P^ϕ) need not have a Lagrange multiplier even if $\mathcal{C}$ has a nonempty interior. This is because the additional constraint $f(x) = c^T x \le p^*$ may exclude points in the interior of $\mathcal{C}$. We discuss this further in section 2.

1.1. Applications. We present four applications of our main result. The first three show how to extend existing results in convex optimization. The fourth shows how exact regularization can be used in practice.

Linearized selection (section 3). In the case where f is differentiable, $\mathcal{C}$ is polyhedral, and ϕ is strongly convex, Ferris and Mangasarian [20, Theorem 9] show that the regularization (P_δ) is exact if and only if the solution of (P^ϕ) is unchanged when f is replaced by its linearization at any $\bar{x} \in \mathcal{S}$. We generalize this result by relaxing the strong convexity assumption on ϕ; see Theorem 3.2.

Exact penalization (section 4). We show a close connection between exact regularization and exact penalization by applying our main results to obtain necessary and sufficient conditions for exact penalization of convex programs. The resulting conditions are similar to those obtained by Bertsekas [4, Proposition 1], Mangasarian [31, Theorem 2.1], and Bertsekas, Nedić, and Ozdaglar [7, section 7.3]; see Theorem 4.2.

Error bounds (section 5). We show that in the case where f is continuously differentiable, $\mathcal{C}$ is polyhedral, and $\mathcal{S}$ is bounded, a necessary condition for exact regularization with any ϕ is that f has a "weak sharp minimum" [10, 11] over $\mathcal{C}$. In the case where the regularization is not exact, we derive error bounds on the distance from each solution of the regularized problem (P_δ) to $\mathcal{S}$ in terms of δ and the growth rate of f on $\mathcal{C}$ away from $\mathcal{S}$.

Sparse solutions (section 6). As an illustration of our main result, we apply exact ℓ_1 regularization to select sparse solutions of conic programs. In section 6.1 we report numerical results on a set of benchmark LPs from the NETLIB [36] test set and on a set of randomly generated LPs with prescribed dual degeneracy (i.e., nonunique primal solutions). Analogous results are reported in section 6.2 for a set of benchmark semidefinite programs (SDPs) and second-order cone programs (SOCPs) from the DIMACS test set [37]. The numerical results highlight the effectiveness of this approach for inducing sparsity in the solutions obtained via an interior-point algorithm.

1.2. Assumptions. The following assumptions hold implicitly throughout.

Assumption 1.1 (feasibility and finiteness). The feasible set $\mathcal{C}$ is nonempty and the solution set $\mathcal{S}$ of (P) is nonempty.

Assumption 1.2 (bounded level sets). The level set $\{x \in \mathcal{S} \mid \phi(x) \le \beta\}$ is bounded for each $\beta \in \mathbb{R}$, and $\inf_{x\in\mathcal{C}} \phi(x) > -\infty$. (For example, this assumption holds when ϕ is coercive.)

Assumption 1.1 implies that the optimal value p^* of (P) is finite. Assumptions 1.1 and 1.2 together ensure that the solution set of (P^ϕ), denoted by $\mathcal{S}^\phi$, is nonempty and compact, and that the solution set of (P_δ), denoted by $\mathcal{S}_\delta$, is nonempty and compact for all $\delta > 0$. The latter is true because, for any $\delta > 0$ and $\beta \in \mathbb{R}$, any point x in the level set $\{x \in \mathcal{C} \mid f(x) + \delta\phi(x) \leq \beta\}$ satisfies $f(x) \geq p^*$ and $\phi(x) \geq \inf_{x' \in \mathcal{C}} \phi(x')$, so that $\phi(x) \leq (\beta - p^*)/\delta$ and $f(x) \leq \beta - \delta \inf_{x' \in \mathcal{C}} \phi(x')$. Assumptions 1.1 and 1.2 then imply that ϕ, f, and $\mathcal{C}$ have no nonzero recession direction in common, so the above level set must be bounded [40, Theorem 8.7].

Our results can be extended accordingly if the above assumptions are relaxed to the assumption that $\mathcal{S}^\phi \neq \emptyset$ and $\mathcal{S}_\delta \neq \emptyset$ for all $\delta > 0$ below some positive threshold.

2. Main results. Ferris and Mangasarian [20, Theorem 7] prove that if the objective function f is linear, then

$$\bigcap_{0<\delta<\bar{\delta}} \mathcal{S}_\delta \subseteq \mathcal{S}^\phi \tag{2.1}$$

for any $\bar{\delta} > 0$. However, an additional constraint qualification on $\mathcal{C}$ is needed to ensure that the set on the left-hand side of (2.1) is nonempty (see [20, Theorem 8]). The following example shows that the set can be empty:

$$\underset{x}{\text{minimize}} \quad x_3 \quad \text{subject to} \quad x \in \mathcal{K}, \tag{2.2}$$

where $\mathcal{K} = \{(x_1, x_2, x_3) \mid x_1^2 \leq x_2 x_3,\ x_2 \geq 0,\ x_3 \geq 0\}$, i.e., $\mathcal{K}$ defines the cone of 2×2 symmetric positive semidefinite matrices. Clearly $\mathcal{K}$ has a nonempty interior, and the solutions have the form $x_1^* = x_3^* = 0$, $x_2^* \geq 0$, with $p^* = 0$. Suppose that the convex regularization function ϕ is

$$\phi(x) = |x_1 - 1| + |x_2 - 1| + |x_3|. \tag{2.3}$$

(Note that ϕ is coercive, but not strictly convex.) Then (P^ϕ) has the singleton solution set $\mathcal{S}^\phi = \{(0, 1, 0)\}$. However, for any $\delta > 0$, (P_δ) has the unique solution

$$x_1 = \frac{1}{2(1 + \delta^{-1})}, \quad x_2 = 1, \quad x_3 = \frac{1}{4(1 + \delta^{-1})^2},$$

which converges to the solution of (P^ϕ) as $\delta \to 0$, but is never equal to it. Therefore $\mathcal{S}_\delta$ differs from $\mathcal{S}^\phi$ for all $\delta > 0$ sufficiently small.

Note that the left-hand side of (2.1) can be empty even when ϕ is strongly convex and infinitely differentiable. As an example, consider the strongly convex quadratic regularization function

$$\phi(x) = |x_1 - 1|^2 + |x_2 - 1|^2 + |x_3|^2.$$

As with (2.3), it can be shown in this case that $\mathcal{S}_\delta$ differs from $\mathcal{S}^\phi = \{(0, 1, 0)\}$ for all $\delta > 0$ sufficiently small. In particular, $(\delta/2, 1, \delta^2/4)$ is feasible for (P_δ), and its objective function value is strictly less than that of $(0, 1, 0)$. Thus the latter cannot be a solution of (P_δ) for any $\delta > 0$.

In general, one can show that as $\delta \to 0$, each cluster point of solutions of (P_δ) belongs to $\mathcal{S}^\phi$. Moreover, there is no duality gap between (P^ϕ) and its dual because $\mathcal{S}^\phi$ is compact (see [40, Theorem 30.4(i)]). However, the supremum in the dual problem

might not be attained, in which case there would be no Lagrange multiplier for (P^ϕ)—and hence no exact regularization property. Thus, additional constraint qualifications are needed when f is not affine or $\mathcal{C}$ is not polyhedral.

The following theorem and corollary are our main results. They show that the regularization (P_δ) is exact if and only if the selection problem (P^ϕ) has a Lagrange multiplier μ^*. Moreover, $\mathcal{S}_\delta = \mathcal{S}^\phi$ for all $\delta < 1/\mu^*$. Parts of our proof bear similarity to the arguments used by Mangasarian and Meyer [34, Theorem 1], who consider the two cases $\mu^* = 0$ and $\mu^* > 0$ separately in proving the "if" direction. However, instead of working with the KKT conditions for (P) and (P_δ), we work with saddle-point conditions.

THEOREM 2.1.
(a) *For any $\delta > 0$, $\mathcal{S} \cap \mathcal{S}_\delta \subseteq \mathcal{S}^\phi$.*
(b) *If there exists a Lagrange multiplier μ^* for (P^ϕ), then $\mathcal{S} \cap \mathcal{S}_\delta = \mathcal{S}^\phi$ for all $\delta \in (0, 1/\mu^*]$.*
(c) *If there exists $\bar{\delta} > 0$ such that $\mathcal{S} \cap \mathcal{S}_{\bar{\delta}} \neq \emptyset$, then $1/\bar{\delta}$ is a Lagrange multiplier for (P^ϕ), and $\mathcal{S} \cap \mathcal{S}_\delta = \mathcal{S}^\phi$ for all $\delta \in (0, \bar{\delta}]$.*
(d) *If there exists $\bar{\delta} > 0$ such that $\mathcal{S} \cap \mathcal{S}_{\bar{\delta}} \neq \emptyset$, then $\mathcal{S}_\delta \subseteq \mathcal{S}$ for all $\delta \in (0, \bar{\delta})$.*

Proof. Part (a). Consider any $x^* \in \mathcal{S} \cap \mathcal{S}_\delta$. Then, because $x^* \in \mathcal{S}_\delta$,

$$f(x^*) + \delta\phi(x^*) \leq f(x) + \delta\phi(x) \quad \text{for all} \quad x \in \mathcal{C}.$$

Also, $x^* \in \mathcal{S}$, so $f(x) = f(x^*) = p^*$ for all $x \in \mathcal{S}$. This implies that

$$\phi(x^*) \leq \phi(x) \quad \text{for all} \quad x \in \mathcal{S}.$$

Thus $x^* \in \mathcal{S}^\phi$, and it follows that $\mathcal{S} \cap \mathcal{S}_\delta \subseteq \mathcal{S}^\phi$.

Part (b). Assume that there exists a Lagrange multiplier μ^* for (P^ϕ). We consider the two cases $\mu^* = 0$ and $\mu^* > 0$ in turn.

First, suppose that $\mu^* = 0$. Then, for any solution x^* of (P^ϕ),

$$x^* \in \arg\min_{x \in \mathcal{C}} \ \phi(x),$$

or, equivalently,

$$\phi(x^*) \leq \phi(x) \quad \text{for all} \quad x \in \mathcal{C}. \tag{2.4}$$

Also, x^* is feasible for (P^ϕ), so $x^* \in \mathcal{S}$. Thus

$$f(x^*) \leq f(x) \quad \text{for all} \quad x \in \mathcal{C}.$$

Multiplying the inequality in (2.4) by $\delta \geq 0$ and adding it to the above inequality yields

$$f(x^*) + \delta\phi(x^*) \leq f(x) + \delta\phi(x) \quad \text{for all} \quad x \in \mathcal{C}.$$

Thus $x^* \in \mathcal{S}_\delta$ for all $\delta \in [0, \infty)$.

Second, suppose that $\mu^* > 0$. Then, for any solution x^* of (P^ϕ),

$$x^* \in \arg\min_{x \in \mathcal{C}} \ \phi(x) + \mu^*(f(x) - p^*),$$

or, equivalently,

$$x^* \in \arg\min_{x\in\mathcal{C}} \; f(x) + \frac{1}{\mu^*}\phi(x).$$

Thus

$$f(x^*) + \frac{1}{\mu^*}\phi(x^*) \le f(x) + \frac{1}{\mu^*}\phi(x) \quad \text{for all} \quad x \in \mathcal{C}.$$

Also, x^* is feasible for (P^ϕ), so that $x^* \in \mathcal{S}$. Therefore

$$f(x^*) \le f(x) \quad \text{for all} \quad x \in \mathcal{C}.$$

Then, for any $\lambda \in [0,1]$, multiplying the above two inequalities by λ and $1-\lambda$, respectively, and summing them yields

$$f(x^*) + \frac{\lambda}{\mu^*}\phi(x^*) \le f(x) + \frac{\lambda}{\mu^*}\phi(x) \quad \text{for all} \quad x \in \mathcal{C}.$$

Thus $x^* \in \mathcal{S}_\delta$ for all $\delta \in [0, 1/\mu^*]$.

The above arguments show that $\mathcal{S}^\phi \subseteq \mathcal{S}_\delta$ for all $\delta \in [0, 1/\mu^*]$, and therefore $\mathcal{S}^\phi \subseteq \mathcal{S}\cap\mathcal{S}_\delta$ for all $\delta \in (0, 1/\mu^*]$. By Part (a) of the theorem, we must have $\mathcal{S}^\phi = \mathcal{S}\cap\mathcal{S}_\delta$ as desired.

Part (c). Assume that there exists $\bar\delta > 0$ such that $\mathcal{S} \cap \mathcal{S}_{\bar\delta} \neq \emptyset$. Then, for any $x^* \in \mathcal{S} \cap \mathcal{S}_{\bar\delta}$, we have $x^* \in \mathcal{S}_{\bar\delta}$, and thus

$$x^* \in \arg\min_{x\in\mathcal{C}} \; f(x) + \bar\delta\phi(x),$$

or, equivalently,

$$x^* \in \arg\min_{x\in\mathcal{C}} \; \phi(x) + \frac{1}{\bar\delta}(f(x) - p^*).$$

By Part (a), $x^* \in \mathcal{S}^\phi$. This implies that any $x \in \mathcal{S}^\phi$ attains the minimum because $\phi(x) = \phi(x^*)$ and $f(x) = p^*$. Therefore $1/\bar\delta$ is a Lagrange multiplier for (P^ϕ). By Part (b), $\mathcal{S} \cap \mathcal{S}_\delta = \mathcal{S}^\phi$ for all $\delta \in (0, \bar\delta]$.

Part (d). To simplify notation, define $f_\delta(x) = f(x) + \delta\phi(x)$. Assume that there exists a $\bar\delta > 0$ such that $\mathcal{S} \cap \mathcal{S}_{\bar\delta} \neq \emptyset$. Fix any $x^* \in \mathcal{S} \cap \mathcal{S}_{\bar\delta}$. For any $\delta \in (0, \bar\delta)$ and any $x \in \mathcal{C} \setminus \mathcal{S}$, we have

$$f_{\bar\delta}(x^*) \le f_{\bar\delta}(x) \quad \text{and} \quad f(x^*) < f(x).$$

Because $0 < \delta/\bar\delta < 1$, this implies that

$$f_\delta(x^*) = \frac{\delta}{\bar\delta} f_{\bar\delta}(x^*) + \left(1 - \frac{\delta}{\bar\delta}\right) f(x^*) < \frac{\delta}{\bar\delta} f_{\bar\delta}(x) + \left(1 - \frac{\delta}{\bar\delta}\right) f(x) = f_\delta(x).$$

Because $x^* \in \mathcal{C}$, this shows that $x \in \mathcal{C}\setminus\mathcal{S}$ cannot be a solution of (P_δ), and so $\mathcal{S}_\delta \subseteq \mathcal{S}$, as desired. □

Theorem 2.1 shows that existence of a Lagrange multiplier μ^* for (P^ϕ) is necessary and sufficient for exact regularization of (P) by (P_δ) for all $0 < \delta < 1/\mu^*$. Coerciveness

of ϕ on $\mathcal{S}$ is needed only to ensure that $\mathcal{S}^\phi$ is nonempty. If $\delta = 1/\mu^*$, then $\mathcal{S}_\delta$ need not be a subset of $\mathcal{S}$. For example, suppose that

$$n = 1, \quad \mathcal{C} = [0, \infty), \quad f(x) = x, \quad \text{and} \quad \phi(x) = |x - 1|.$$

Then $\mu^* = 1$ is the only Lagrange multiplier for (P^ϕ), but $\mathcal{S}_1 = [0, 1] \not\subseteq \mathcal{S} = \{0\}$. If $\mathcal{S}_\delta$ is a singleton for $\delta \in (0, 1/\mu^*]$, such as when ϕ is strictly convex, then Theorem 2.1(b) and $\mathcal{S}^\phi \neq \emptyset$ imply that $\mathcal{S}_\delta \subseteq \mathcal{S}$.

The following corollary readily follows from Theorem 2.1(b)–(d) and $\mathcal{S}^\phi \neq \emptyset$.

COROLLARY 2.2.
(a) *If there exists a Lagrange multiplier μ^* for (P^ϕ), then $\mathcal{S}_\delta = \mathcal{S}^\phi$ for all $\delta \in (0, 1/\mu^*)$.*
(b) *If there exists $\bar{\delta} > 0$ such that $\mathcal{S}_{\bar{\delta}} = \mathcal{S}^\phi$, then $1/\bar{\delta}$ is a Lagrange multiplier for (P^ϕ), and $\mathcal{S}_\delta = \mathcal{S}^\phi$ for all $\delta \in (0, \bar{\delta}]$.*

2.1. Conic programs. Conic programs (CPs) correspond to (P) with f and $\mathcal{C}$ given by (1.1). They include several important problem classes. LPs correspond to $\mathcal{K} = \mathbb{R}^n_+$ (the nonnegative orthant); SOCPs correspond to

$$\mathcal{K} = \mathcal{K}^{\text{soc}}_{n_1} \times \cdots \times \mathcal{K}^{\text{soc}}_{n_K} \qquad \text{with} \qquad \mathcal{K}^{\text{soc}}_n := \left\{ x \in \mathbb{R}^n \;\middle|\; \sum_{i=1}^{n-1} x_i^2 \le x_n^2, \; x_n \ge 0 \right\}$$

(a product of second-order cones); SDPs correspond to $\mathcal{K} = \mathbb{S}^n_+$ (the cone of symmetric positive semidefinite $n \times n$ real matrices). CPs are discussed in detail in [3, 8, 35, 38], among others.

It is well known that when $\mathcal{K}$ is polyhedral, the selection problem (P^ϕ), with f and $\mathcal{C}$ given by (1.1), must have a Lagrange multiplier [40, Theorem 28.2]. In this important case, Corollary 2.2 immediately yields the following exact-regularization result for polyhedral CPs.

COROLLARY 2.3. *Suppose that f and $\mathcal{C}$ have the form given by (1.1) and that $\mathcal{K}$ is polyhedral. Then there exists a positive $\bar{\delta}$ such that $\mathcal{S}_\delta = \mathcal{S}^\phi$ for all $\delta \in (0, \bar{\delta})$.*

Corollary 2.3 extends [34, Theorem 1], which additionally assumes differentiability (though not convexity) of ϕ on $\mathcal{S}$ and proves a weaker result that there exists a common solution $x^* \in \mathcal{S} \cap \mathcal{S}_\delta$ for all positive δ below some threshold. If $\mathcal{S}$ is furthermore bounded, then an "excision lemma" of Robinson [39, Lemma 3.5] can be applied to show that $\mathcal{S}_\delta \subseteq \mathcal{S}$ for all positive δ below some threshold. This result is still weaker than Corollary 2.3, however.

2.2. Relaxing the assumptions on the regularization function. The assumption that ϕ is coercive on $\mathcal{S}$ and is bounded from below on $\mathcal{C}$ (Assumption 1.2) ensures that the selection problem (P^ϕ) and the regularized problem (P_δ) have solutions. This assumption is preserved under the introduction of slack variables for linear inequality constraints. For example, if $\mathcal{C} = \{x \in \mathcal{K} \mid Ax \le b\}$ for some closed convex set $\mathcal{K}$, $A \in \mathbb{R}^{m \times n}$, and $b \in \mathbb{R}^m$, then

$$\tilde{\phi}(x, s) = \phi(x) \quad \text{with} \quad \tilde{\mathcal{C}} = \{(x, s) \in \mathcal{K} \times [0, \infty)^m \mid Ax + s = b\}$$

also satisfies Assumption 1.2. Here $\tilde{\phi}(x,s)$ depends only on x. Can Assumption 1.2 be relaxed?

Suppose that $\phi(x)$ depends only on a subset of coordinates x_J and is coercive with respect to x_J, where $x_J = (x_j)_{j\in J}$ and $J \subseteq \{1,\dots,n\}$. Using the assumption that (P) has a feasible point x^*, it is readily seen that (P_δ) has a solution with respect to x_J for each $\delta > 0$, i.e., the minimization in (P_δ) is attained at some x_J. For an LP (f linear and $\mathcal{C}$ polyhedral) it can be shown that (P_δ) has a solution with respect to all coordinates of x. However, in general this need not be true, even for an SOCP. An example is

$$n = 3, \quad f(x) = -x_2 + x_3, \quad \mathcal{C} = \left\{ x \mid \sqrt{x_1^2 + x_2^2} \le x_3 \right\}, \quad \text{and} \quad \phi(x) = |x_1 - 1|.$$

Here, $p^* = 0$ (since $\sqrt{x_1^2 + x_2^2} - x_2 \ge 0$ always) and solutions are of the form $(0,\xi,\xi)$ for all $\xi \ge 0$. For any $\delta > 0$, (P_δ) has optimal value of zero (achieved by setting $x_1 = 1$, $x_3 = \sqrt{1 + x_2^2}$, and taking $x_2 \to \infty$) but has no solution. In general, if we define

$$\widehat{f}(x_J) := \min_{(x_j)_{j\notin J} \mid x\in\mathcal{C}} f(x),$$

then it can be shown, using convex analysis results [40], that $\widehat{f}$ is convex and lower semicontinuous—i.e., the epigraph of $\widehat{f}$ is convex and closed. Then (P_δ) is equivalent to

$$\underset{x_J}{\text{minimize}} \ \widehat{f}(x_J) + \delta\phi(x_J),$$

with ϕ viewed as a function of x_J. Thus, we can in some sense reduce this case to the one we currently consider. Note that $\widehat{f}$ may not be real-valued, but this does not pose a problem with the proof of Theorem 2.1.

3. Linearized selection. Ferris and Mangasarian [20] develop a related exact-regularization result for the special case where f is differentiable, $\mathcal{C}$ is polyhedral, and ϕ is strongly convex. They show that (P_δ) is an exact regularization if the solution set of the selection problem (P^ϕ) is unchanged when f is replaced by its linearization at any $\bar{x} \in \mathcal{S}$. In this section we show how Theorem 2.1 and Corollary 2.2 can be applied to generalize this result. We begin with a technical lemma, closely related to some results given by Mangasarian [32].

LEMMA 3.1. *Suppose that f is differentiable on $\mathbb{R}^n$ and constant on the line segment joining two points x^* and $\bar{x}$ in $\mathbb{R}^n$. Then*

$$\nabla f(x^*)^T(x - x^*) = \nabla f(\bar{x})^T(x - \bar{x}) \quad \textit{for all} \quad x \in \mathbb{R}^n. \tag{3.1}$$

Moreover, ∇f is constant on the line segment.

Proof. Because f is convex differentiable and is constant on the line segment joining x^* and $\bar{x}$, $\nabla f(x^*)^T(\bar{x} - x^*) = 0$. Because f is convex,

$$f(y) - f(\bar{x}) = f(y) - f(x^*) \ge \nabla f(x^*)^T(y - x^*) \quad \text{for all} \quad y \in \mathbb{R}^n.$$

Fix any $x \in \mathbb{R}^n$. Taking $y = \bar{x} + \alpha(x - \bar{x})$ with $\alpha > 0$ yields

$$f(\bar{x} + \alpha(x - \bar{x})) - f(\bar{x}) \ge \nabla f(x^*)^T(\bar{x} + \alpha(x - \bar{x}) - x^*) = \alpha\nabla f(x^*)^T(x - \bar{x}).$$

Dividing both sides by α and then taking $\alpha \to 0$ yields in the limit

$$\nabla f(\bar{x})^T(x - \bar{x}) \geq \nabla f(x^*)^T(x - \bar{x}) = \nabla f(x^*)^T(x - x^*). \tag{3.2}$$

Switching $\bar{x}$ and x^* in the above argument yields an inequality in the opposite direction. Thus (3.1) holds, as desired.

By taking $x = \alpha(\nabla f(x^*) - \nabla f(\bar{x}))$ in (3.1) and letting $\alpha \to \infty$, we obtain that $\|\nabla f(x^*) - \nabla f(\bar{x})\|_2^2 = 0$ and hence $\nabla f(x^*) = \nabla f(\bar{x})$. This shows that ∇f is constant on the line segment. □

Suppose that f is differentiable at every $\bar{x} \in \mathcal{S}$, and consider a variant of the selection problem (P^ϕ) in which the constraint is linearized about $\bar{x}$:

$$(\mathrm{P}^{\phi,\bar{x}}) \qquad \begin{array}{ll} \underset{x}{\text{minimize}} & \phi(x) \\ \text{subject to} & x \in \mathcal{C}, \quad \nabla f(\bar{x})^T(x - \bar{x}) \leq 0. \end{array}$$

Lemma 3.1 shows that the feasible set of $(\mathrm{P}^{\phi,\bar{x}})$ is the same for all $\bar{x} \in \mathcal{S}$. Since f is convex, the feasible set of $(\mathrm{P}^{\phi,\bar{x}})$ contains $\mathcal{S}$, which is the feasible set of (P^ϕ). Let $\mathcal{S}^{\phi,\bar{x}}$ denote the solution set of $(\mathrm{P}^{\phi,\bar{x}})$. In general $\mathcal{S}^\phi \neq \mathcal{S}^{\phi,\bar{x}}$. In the case where ϕ is strongly convex and $\mathcal{C}$ is polyhedral, Ferris and Mangasarian [20, Theorem 9] show that exact regularization (i.e., $\mathcal{S}^\phi = \mathcal{S}_\delta$ for all $\delta > 0$ sufficiently small) holds if and only if $\mathcal{S}^\phi = \mathcal{S}^{\phi,\bar{x}}$. By using Theorem 2.1, Corollary 2.2, and Lemma 3.1, we can generalize this result by relaxing the assumption that ϕ is strongly convex.

THEOREM 3.2. *Suppose that f is differentiable on $\mathcal{C}$.*
(a) *If there exists a $\bar{\delta} > 0$ such that $\mathcal{S}_{\bar{\delta}} = \mathcal{S}^\phi$, then*

$$\mathcal{S}^\phi \subseteq \mathcal{S}^{\phi,\bar{x}} \quad \text{for all} \quad \bar{x} \in \mathcal{S}. \tag{3.3}$$

(b) *If $\mathcal{C}$ is polyhedral and (3.3) holds, then there exists a $\bar{\delta} > 0$ such that $\mathcal{S}_\delta = \mathcal{S}^\phi$ for all $\delta \in (0, \bar{\delta})$.*

Proof. Part (a). Suppose that there exists a $\bar{\delta} > 0$ such that $\mathcal{S}_{\bar{\delta}} = \mathcal{S}^\phi$. Then by Corollary 2.2, $\mu^* := 1/\bar{\delta}$ is a Lagrange multiplier for (P^ϕ), and for any $x^* \in \mathcal{S}^\phi$,

$$x^* \in \arg\min_{x \in \mathcal{C}} \ \phi(x) + \mu^* f(x). \tag{3.4}$$

Because ϕ and f are real-valued and convex, x^* and μ^* satisfy the optimality condition

$$0 \in \partial\phi(x^*) + \mu^* \nabla f(x^*) + N_{\mathcal{C}}(x^*).$$

Then x^* satisfies the KKT condition for the linearized selection problem

$$\underset{x \in \mathcal{C}}{\text{minimize}} \quad \phi(x) \quad \text{subject to} \quad \nabla f(x^*)^T(x - x^*) \leq 0, \tag{3.5}$$

and is therefore a solution of this problem. By Lemma 3.1, the feasible set of this problem remains unchanged if we replace $\nabla f(x^*)^T(x - x^*) \leq 0$ with $\nabla f(\bar{x})^T(x - \bar{x}) \leq 0$ for any $\bar{x} \in \mathcal{S}$. Thus $x^* \in \mathcal{S}^{\phi,\bar{x}}$. The choice of x^* was arbitrary, and so $\mathcal{S}^\phi \subseteq \mathcal{S}^{\phi,\bar{x}}$.

Part (b). Suppose that $\mathcal{C}$ is polyhedral and (3.3) holds. By Lemma 3.1, the solution set of $(\mathrm{P}^{\phi,\bar{x}})$ remains unchanged if we replace $\nabla f(\bar{x})^T(x - \bar{x}) \leq 0$ by $\nabla f(x^*)^T(x - x^*) \leq 0$ for any $x^* \in \mathcal{S}^\phi$. The resulting problem (3.5) is linearly constrained

and therefore has a Lagrange multiplier $\bar{\mu} \in \mathbb{R}$. Moreover, $\bar{\mu}$ is independent of x^*. By Corollary 2.2(a), the problem

$$\underset{x \in \mathcal{C}}{\text{minimize}} \ \phi(x) + \mu^* \nabla f(x^*)^T x$$

has the same solution set as (3.5) for all $\mu^* > \bar{\mu}$. The necessary and sufficient optimality condition for this convex program is

$$0 \in \partial\phi(x) + \mu^* \nabla f(x^*) + N_{\mathcal{C}}(x).$$

Because (3.3) holds, x^* satisfies this optimality condition. Thus (3.4) holds for all $\mu^* > \bar{\mu}$ or, equivalently, $x^* \in \mathcal{S}_\delta$ for all $\delta \in (0, 1/\bar{\mu})$. Because $\bar{\mu}$ is independent of x^*, this shows that $\mathcal{S}^\phi \subseteq \mathcal{S}_\delta$ for all $\delta \in (0, 1/\bar{\mu})$. And because $\emptyset \neq \mathcal{S}^\phi \subseteq \mathcal{S}$, it follows that $\mathcal{S} \cap \mathcal{S}_\delta \neq \emptyset$ for all $\delta \in (0, 1/\bar{\mu})$. By Theorem 2.1(a) and (d), $\mathcal{S}_\delta \subseteq \mathcal{S}^\phi$ for all $\delta \in (0, 1/\bar{\mu})$. Therefore $\mathcal{S}_\delta = \mathcal{S}^\phi$ for all $\delta \in (0, 1/\bar{\mu})$. □

In the case where ϕ is strongly convex, $\mathcal{S}^\phi$ and $\mathcal{S}^{\phi,\bar{x}}$ are both singletons, so (3.3) is equivalent to $\mathcal{S}^\phi = \mathcal{S}^{\phi,\bar{x}}$ for all $\bar{x} \in \mathcal{S}$. Thus, when $\mathcal{C}$ is also polyhedral, Theorem 3.2 reduces to [20, Theorem 9]. Note that in Theorem 3.2(b) the polyhedrality of $\mathcal{C}$ is needed only to ensure the existence of a Lagrange multiplier for (3.5) and can be relaxed by assuming an appropriate constraint qualification. In particular, if $\mathcal{C}$ is given by inequality constraints, then it suffices that ($\mathrm{P}^{\phi,\bar{x}}$) has a feasible point that strictly satisfies all nonlinear constraints [40, Theorem 28.2].

Naturally, (3.3) holds if f is linear. Thus Theorem 3.2(b) is false if we drop the polyhedrality assumption on $\mathcal{C}$, as we can find examples of convex coercive ϕ, linear f, and closed convex (but not polyhedral) $\mathcal{C}$ for which exact regularization fails; see example (2.2).

4. Exact penalization. In this section we show a close connection between exact regularization and exact penalization by applying Corollary 2.2 to obtain necessary and sufficient conditions for exact penalization of convex programs. Consider the convex program

$$\underset{x}{\text{minimize}} \quad \phi(x) \quad \text{subject to} \quad x \in \mathcal{C}, \quad g(x) := \big(g_i(x)\big)_{i=1}^m \leq 0, \tag{4.1}$$

where $\phi, g_1, \ldots, g_m$ are real-valued convex functions defined on $\mathbb{R}^n$, and $\mathcal{C} \subseteq \mathbb{R}^n$ is a nonempty closed convex set. The penalized form of (4.1) is

$$\underset{x}{\text{minimize}} \quad \phi(x) + \sigma P(g(x)) \quad \text{subject to} \quad x \in \mathcal{C}, \tag{4.2}$$

where σ is a positive penalty parameter and $P : \mathbb{R}^m \to [0, \infty)$ is a convex function having the property that $P(u) = 0$ if and only if $u \leq 0$; see [7, section 7.3]. A well-known example of such a penalty function is

$$P(u) = \|\max\{0, u\}\|_p, \tag{4.3}$$

where $\|\cdot\|_p$ is the p-norm ($1 \leq p \leq \infty$) [22, section 14.3].

The conjugate and polar functions of P [40, subsections 12, 15] are defined, respectively, by

$$P^*(w) := \sup_u \ w^T u - P(u) \qquad \text{and} \qquad P^\circ(w) := \sup_{u \not\leq 0} \ \frac{w^T u}{P(u)}.$$

Note that $P^\circ(\alpha w) = \alpha P^\circ(w)$ for all $\alpha \geq 0$. For P given by (4.3), $P^\circ(w)$ equals the q-norm of w whenever $w \geq 0$, where $1/p + 1/q = 1$. The following lemma gives key properties of these functions that are implicit in the analysis of [7, section 7.3].

LEMMA 4.1. *Suppose that $P : \mathbb{R}^m \to [0, \infty)$ is a convex function and $P(u) = 0$ if and only if $u \leq 0$. Then*

(a) *$P(u) \leq P(v)$ whenever $u \leq v$; and*

(b) $$P^*(w) \begin{cases} = \infty & \text{if } w \not\geq 0; \\ > 0 & \text{if } w \geq 0 \text{ and } P^\circ(w) > 1; \\ = 0 & \text{if } w \geq 0 \text{ and } P^\circ(w) \leq 1. \end{cases}$$

Proof. Part (a). Fix any $u, v \in \mathbb{R}^m$ with $u < v$, and define

$$\pi(\alpha) := P(u + \alpha(v - u)) \quad \text{for all} \quad \alpha \in \mathbb{R}.$$

We have $u + \alpha(v - u) < 0$ for all $\alpha < 0$ sufficiently negative, in which case $\pi(\alpha) = 0$. Because π is convex, this implies that π is nondecreasing and hence $\pi(0) \leq \pi(1)$—i.e., $P(u) \leq P(v)$. Thus $P(u) \leq P(v)$ whenever $u < v$. Because P is continuous on $\mathbb{R}^m$ [40, Theorem 10.1], this yields $P(u) \leq P(v)$ whenever $u \leq v$.

Part (b). Fix any $w \in \mathbb{R}^m$. If $w_i < 0$ for some $i \in \{1, \ldots, m\}$, then by letting $u_i \to -\infty$ and setting all other components of u to zero, we obtain $w^T u - P(u) = w_i u_i \to \infty$ and thus $P^*(w) = \infty$. If $w \geq 0$ and $P^\circ(w) > 1$, then $w^T u > P(u)$ for some $u \not\leq 0$ and thus $P^*(w) \geq w^T u - P(u) > 0$. If $w \geq 0$ and $P^\circ(w) \leq 1$, then $w^T u \leq 0 = P(u)$ for all $u \leq 0$, and $w^T u \leq P(u)$ for all $u \not\leq 0$, so that $w^T u \leq P(u)$ for all $u \in \mathbb{R}^m$ (with equality holding when $u = 0$). Therefore $P^*(w) = 0$. ∎

THEOREM 4.2. *Suppose that* (4.1) *has a nonempty compact solution set. If there exist Lagrange multipliers y^* for* (4.1)*, then the penalized problem* (4.2) *has the same solution set as* (4.1) *for all $\sigma > P^\circ(y^*)$. Conversely, if* (4.1) *and* (4.2) *have the same solution set for some $\sigma = \mu^* > 0$, then* (4.1) *and* (4.2) *have the same solution set for all $\sigma \geq \mu^*$, and there exists a Lagrange multiplier vector y^* for* (4.1) *with $\mu^* \geq P^\circ(y^*)$.*

Proof. Set $f(x) = P\big(g(x)\big)$ for all $x \in \mathbb{R}^n$. By the convexity of $g_1, \ldots, g_m$, P, and Lemma 4.1(a), f is a convex function and thus (4.2) is a convex program. Moreover, any feasible point x^* of (4.1) is a solution of (P) with optimal value $p^* = 0$. Accordingly, we identify (4.2) with (P_δ) (where ϕ is the regularization function and $\delta = 1/\sigma$ is the regularization parameter), and we identify the problem

$$\underset{x}{\text{minimize}} \quad \phi(x) \quad \text{subject to} \quad x \in \mathcal{C}, \quad P\big(g(x)\big) \leq 0 \tag{4.4}$$

with (P^ϕ). Assumptions 1.1 and 1.2 are satisfied because (4.1) has a nonempty compact solution set.

A primal-dual solution pair (x^*, y^*) of (4.1) satisfies the KKT conditions

$$0 \in \partial\phi(x) + \sum_{i=1}^m y_i \partial g_i(x) + N_{\mathcal{C}}(x), \quad y \geq 0, \quad g(x) \leq 0, \quad y^T g(x) = 0. \tag{4.5}$$

By [40, Theorem 23.5], the subdifferential of P at u has the expression $\partial P(u) = \{w \mid w^T u = P(u) + P^*(w)\}$. If $u \leq 0$, then $P(u) = 0$ and, by Lemma 4.1(b), $w^T u = P^*(w)$

only if $w \geq 0$ and $P^\circ(w) \leq 1$. This implies that

$$\partial P(u) = \{w \mid w \geq 0,\ P^\circ(w) \leq 1,\ w^T u = 0\} \quad \text{for all} \quad u \leq 0.$$

We can then express the KKT conditions for (4.4) as

(4.6)
$$0 \in \partial\phi(x) + \mu \sum_{i=1}^{m} w_i \partial g_i(x) + N_{\mathcal{C}}(x), \quad \left\{ \begin{array}{r} w \geq 0 \\ P^\circ(w) \leq 1 \\ \mu \geq 0 \end{array} \right\}, \quad g(x) \leq 0, \quad w^T g(x) = 0.$$

By scaling μ and w by $P^\circ(w)$ and $1/P^\circ(w)$, respectively, and using the positive homogeneous property of P°, we can without loss of generality assume that $P^\circ(w) = 1$ in (4.6). Then, upon comparing (4.5) and (4.6), we see that they are equivalent in the sense that (x^*, y^*) satisfies (4.5) if and only if (x^*, μ^*) satisfies (4.6), where

$$\mu^* w^* = y^* \quad \text{and} \quad \mu^* = P^\circ(y^*),$$

for some $w^* \geq 0$ with $P^\circ(w^*) = 1$. Note that μ^* is a Lagrange multiplier for (4.4). Therefore, by Corollary 2.2(a), (4.2) and (4.4) have the same solution set for all $\sigma > \mu^* = P^\circ(y^*)$.

Conversely, suppose that (4.2) and (4.4) have the same solution set for $\sigma = \mu^* > 0$. Then (P_δ) and (P^ϕ) have the same solution set for $\delta = 1/\mu^*$. By Corollary 2.2(b), μ^* is a Lagrange multiplier for (P^ϕ), and (P_δ) and (P^ϕ) have the same solution set for all $\delta \in (0, 1/\mu^*]$. Therefore, (4.1) and (4.2) have the same solution set for all $\sigma \geq \mu^*$. Moreover, for any $x^* \in \mathcal{S}^\phi$ there exists a vector w^* such that (x^*, μ^*, w^*) satisfies (4.6), and so $y^* := \mu^* w^*$ is a Lagrange multiplier vector for (4.1) that satisfies $P^\circ(y^*) = \mu^* P^\circ(w^*) \leq \mu^*$. □

We can consider a minimum P°-value Lagrange multiplier vector y^* and, similarly, a minimum exact penalty parameter σ. Theorem 4.2 asserts that these two quantities are equal—that is,

$$\left\{ \begin{array}{ll} \inf & P^\circ(y^*) \\ \text{such that} & y^* \in \mathbb{R}^m \text{ is a Lagrange multiplier for (4.1)} \end{array} \right\} = \left\{ \begin{array}{ll} \inf & \sigma \\ \text{such that} & \text{(4.2) has the same solution set as (4.1)} \end{array} \right\}.$$

Theorem 4.2 shows that the existence of Lagrange multipliers y^* with $P^\circ(y^*) < \infty$ is necessary and sufficient for exact penalization. There has been much study of sufficient conditions for exact penalization; see, e.g., [4], [5, Proposition 4.1], and [9]. The results in [4, Propositions 1 and 2] assume the existence of Lagrange multipliers y^* and, for the case of separable P (i.e., $P(u) = \sum_i P_i(u_i)$), prove necessary and sufficient conditions on P and y^* for exact penalization. For separable P, the condition $P^\circ(y^*) \leq \sigma$ reduces to

$$y_i^* \leq \sigma \lim_{u_i \downarrow 0} \frac{P_i(u_i)}{u_i}, \quad i = 1, \ldots, m, \tag{4.7}$$

as derived in [4, Proposition 1]. A similar result was obtained in [31, Theorem 2.1] for the further special case of $P_i(u_i) = \max\{0, u_i\}$. Thus Theorem 4.2 may be viewed as a generalization of these results. (For the standard quadratic penalty $P_i(u_i) = \max\{0, u_i\}^2$, the right-hand side of (4.7) is zero, so (4.7) holds only if $y_i^* = 0$, i.e., the constraint $g_i(x) \leq 0$ is redundant.)

The results in [9, Corollary 2.5.1 and Theorem 5.3] assume either the linear-independence or Slater constraint qualifications in order to ensure existence of Lagrange multipliers. Theorem 4.2 is partly motivated by and very similar to the necessary and sufficient conditions obtained in [7, Proposition 7.3.1]. The connection with exact regularization, however, appears to be new.

Although our results for exact regularization can be used to deduce results for exact penalization, the reverse direction does not appear possible. In particular, applying exact penalization to the selection problem (P^{ϕ}) yields a penalized problem very different from (P_{δ}).

5. Error bounds and weak sharp minimum. Even when exact regularization cannot be achieved, we can still estimate the distance from $\mathcal{S}_{\delta}$ to $\mathcal{S}$ in terms of δ and the growth rate of f away from $\mathcal{S}$. We study this type of error bound in this section.

THEOREM 5.1.
(a) *For any* $\bar{\delta} > 0$, $\cup_{0<\delta\leq\bar{\delta}}\mathcal{S}_{\delta}$ *is bounded.*
(b) *Suppose that there exist* $\tau > 0, \gamma \geq 1$ *such that*

$$f(x) - p^* \geq \tau \operatorname{dist}(x, \mathcal{S})^{\gamma} \quad \textit{for all} \quad x \in \mathcal{C}, \tag{5.1}$$

where $\operatorname{dist}(x, \mathcal{S}) = \min_{x^* \in \mathcal{S}} \|x - x^*\|_2$. *Then, for any* $\bar{\delta} > 0$ *there exists* $\tau' > 0$ *such that*

$$\operatorname{dist}(x_{\delta}, \mathcal{S})^{\gamma-1} \leq \tau'\delta \quad \textit{for all} \quad x_{\delta} \in \mathcal{S}_{\delta},\ \delta \in (0, \bar{\delta}].$$

Proof. Part (a). Fix any $x^* \in \mathcal{S}$ and any $\bar{\delta} > 0$. For any $\delta \in (0, \bar{\delta}]$ and $x_{\delta} \in \mathcal{S}_{\delta}$,

$$f(x^*) + \delta\phi(x^*) \geq f(x_{\delta}) + \delta\phi(x_{\delta}) \geq f(x^*) + \delta\phi(x_{\delta}),$$

and thus $\phi(x^*) \geq \phi(x_{\delta})$. Using $\phi(x_{\delta}) \geq \inf_{x\in\mathcal{C}} \phi(x)$, we have, similarly, that

$$f(x_{\delta}) \leq f(x^*) + \delta\Big(\phi(x^*) - \inf_{x\in\mathcal{C}} \phi(x)\Big) \leq f(x^*) + \bar{\delta}\Big(\phi(x^*) - \inf_{x\in\mathcal{C}} \phi(x)\Big).$$

This shows that $\cup_{0<\delta\leq\bar{\delta}}\mathcal{S}_{\delta} \subseteq \{x \in \mathcal{C} \mid \phi(x) \leq \beta,\ f(x) \leq \beta\}$ for some $\beta \in \mathbb{R}$. Since ϕ, f, and $\mathcal{C}$ have no nonzero recession direction in common (see Assumptions 1.1 and 1.2), the second set is bounded and therefore so is the first set.

Part (b). For any $\delta > 0$ and $x_{\delta} \in \mathcal{S}_{\delta}$, let $x^*_{\delta} \in \mathcal{S}$ satisfy $\|x_{\delta} - x^*_{\delta}\|_2 = \operatorname{dist}(x_{\delta}, \mathcal{S})$. Then

$$\begin{aligned} f(x^*_{\delta}) + \delta\phi(x^*_{\delta}) &\geq f(x_{\delta}) + \delta\phi(x_{\delta}) \\ &\geq f(x^*_{\delta}) + \tau\|x_{\delta} - x^*_{\delta}\|_2^{\gamma} + \delta\phi(x_{\delta}), \end{aligned}$$

which implies that

$$\tau\|x_{\delta} - x^*_{\delta}\|_2^{\gamma} \leq \delta\big(\phi(x^*_{\delta}) - \phi(x_{\delta})\big).$$

Because ϕ is convex and real-valued,

$$\phi(x_{\delta}) \geq \phi(x^*_{\delta}) + \eta_{\delta}^T(x_{\delta} - x^*_{\delta}) \geq \phi(x^*_{\delta}) - \|\eta_{\delta}\|_2\|x_{\delta} - x^*_{\delta}\|_2,$$

for some $\eta_{\delta} \in \partial\phi(x^*_{\delta})$. Combining the above two inequalities yields

$$\tau\|x_{\delta} - x^*_{\delta}\|_2^{\gamma-1} \leq \delta\|\eta_{\delta}\|_2.$$

By Part (a), x_δ lies in a bounded set for all $\delta > 0$, so x_δ^* lies in a bounded subset of $\mathcal{S}$ for all $\delta > 0$. Then η_δ lies in a bounded set [40, Theorem 24.7], so that $\|\eta_\delta\|_2$ is uniformly bounded. This proves the desired bound. □

Error bounds of the form (5.1) have been much studied, especially in the cases of linear growth ($\gamma = 1$) and quadratic growth ($\gamma = 2$); see [6, 10, 11, 28, 29, 46] and references therein. In general, it is known that (5.1) holds for some $\tau > 0$ and $\gamma \geq 1$ whenever f is analytic and $\mathcal{C}$ is bounded [28, Theorem 2.1].

Theorem 5.1 does not make much use of the convexity of f and ϕ, and it readily extends to nonconvex f and ϕ. In the case of $\gamma = 1$ in (5.1) (i.e., f has a "weak sharp minimum" over $\mathcal{C}$), Theorem 5.1(b) implies that $\operatorname{dist}(x_\delta, \mathcal{S}) = 0$ for all $x_\delta \in \mathcal{S}_\delta$—i.e., $\mathcal{S}_\delta \subseteq \mathcal{S}$, whenever $\delta < 1/\tau'$. In this case, then, $\mathcal{S}_\delta = \mathcal{S}^\phi$ whenever $\delta < 1/\tau'$ and $\mathcal{S}_\delta \neq \emptyset$. This gives another exact-regularization result.

The following result shows that it is nearly necessary for f to have a weak sharp minimum over $\mathcal{C}$ in order for there to be exact regularization by any strongly convex quadratic regularization function.

THEOREM 5.2. *Suppose that f is continuously differentiable on $\mathbb{R}^n$ and $\mathcal{S}$ is bounded. If there does not exist $\tau > 0$ such that* (5.1) *holds with $\gamma = 1$, then either*

(i) *there exists a strongly convex quadratic function of the form $\phi(x) = \|x - \widehat{x}\|_2^2$ ($\widehat{x} \in \mathbb{R}^n$) and a scalar $\bar{\delta} > 0$ for which $\mathcal{S}_\delta \neq \mathcal{S}^\phi$ for all $\delta \in (0, \bar{\delta}]$;*

or

(ii) *for every sequence $x^k \in \mathcal{C} \setminus \mathcal{S}$, $k = 1, 2, \ldots$, satisfying*

$$\frac{f(x^k) - p^*}{\operatorname{dist}(x^k, \mathcal{S})} \to 0, \tag{5.2}$$

and every cluster point (x^*, v^*) of $\{(s^k, \frac{x^k - s^k}{\|x^k - s^k\|_2})\}$, we have $x^* + \alpha v^* \notin \mathcal{C}$ for all $\alpha > 0$, where $s^k \in \mathcal{S}$ satisfies $\|x^k - s^k\|_2 = \operatorname{dist}(x^k, \mathcal{S})$.

If case (ii) *occurs, then $\mathcal{C}$ is not polyhedral, and for any $\bar{x} \in \mathcal{S}$,*

$$\mathcal{S} = \operatorname*{arg\,min}_{x \in \mathcal{C}} \ \nabla f(\bar{x})^T x. \tag{5.3}$$

Proof. Suppose that there does not exist $\tau > 0$ such that (5.1) holds with $\gamma = 1$. Then there exists a sequence $x^k \in \mathcal{C} \setminus \mathcal{S}$, $k = 1, 2, \ldots$, that satisfies (5.2). Let $s^k \in \mathcal{S}$ satisfy $\|x^k - s^k\|_2 = \operatorname{dist}(x^k, \mathcal{S})$. Let $v^k = (x^k - s^k)/\|x^k - s^k\|_2$, so that $\|v^k\|_2 = 1$. Because $\mathcal{S}$ is bounded, $\{s^k\}$ is bounded. By passing to a subsequence if necessary, we can assume that (s^k, v^k) converges to some (x^*, v^*). Because s^k is the nearest point projection of x^k onto $\mathcal{S}$, we have $v^k \in N_{\mathcal{S}}(s^k)$, i.e., $(x - s^k)^T v^k \leq 0$ for all $x \in \mathcal{S}$. Taking the limit yields $v^* \in N_{\mathcal{S}}(x^*)$, i.e., $(x - x^*)^T v^* \leq 0$ for all $x \in \mathcal{S}$.

Note that $\{x^k\}$ need not converge to x^* or even be bounded. Now, consider the auxiliary sequence

$$y^k = s^k + \epsilon^k (x^k - s^k) \quad \text{with} \quad \epsilon^k = \frac{1}{\max\{k, \|x^k - s^k\|_2\}},$$

$k = 1, 2, \ldots$. Then $\epsilon^k \in (0, 1]$, $y^k \in \mathcal{C} \setminus \mathcal{S}$, $(y^k - s^k)/\|y^k - s^k\|_2 = v^k$ for all k, and $y^k - s^k \to 0$ (so $y^k \to x^*$). Also, the convexity of f implies $f(y^k) \leq (1 - \epsilon^k) f(s^k) +$

$\epsilon^k f(x^k)$ which, together with $\|y^k - s^k\|_2 = \epsilon^k \|x^k - s^k\|_2$ and $f(s^k) = p^*$, implies

$$0 \le \frac{f(y^k) - f(s^k)}{\|y^k - s^k\|_2} \le \frac{\epsilon^k f(x^k) - \epsilon^k f(s^k)}{\|y^k - s^k\|_2} = \frac{f(x^k) - p^*}{\operatorname{dist}(x^k, \mathcal{S})} \to 0. \tag{5.4}$$

Because $f(y^k) - f(s^k) = \nabla f(s^k)^T (y^k - s^k) + o(\|y^k - s^k\|_2)$ and f is continuously differentiable, (5.4) and $y^k - x^k \to 0$ yield, in the limit,

$$\nabla f(x^*)^T v^* = 0. \tag{5.5}$$

Let $f_\delta(x) = f(x) + \delta\phi(x)$, with

$$\phi(x) = \|x - (x^* + v^*)\|_2^2.$$

Because $v^* \in N_{\mathcal{S}}(x^*)$, we have $\mathcal{S}^\phi = \{x^*\}$.

Suppose that there exists $\alpha > 0$ such that $x^* + \alpha v^* \in \mathcal{C}$. Then, for any $\beta \in (0, \alpha]$,

$$\begin{aligned} f_\delta(x^* + \beta v^*) &= f(x^* + \beta v^*) + \delta\|\beta v^* - v^*\|_2^2 \\ &= f(x^*) + \beta \nabla f(x^*)^T v^* + o(\beta) + \delta(\beta - 1)^2 \|v^*\|_2^2 \\ &= f(x^*) + o(\beta) + \delta(1 - 2\beta + \beta^2) \\ &= f_\delta(x^*) + o(\beta) - \delta\beta(2 - \beta), \end{aligned}$$

where the third equality uses (5.5) and $\|v^*\|_2 = 1$. Thus $x^* + \beta v^* \in \mathcal{C}$ and $f_\delta(x^* + \beta v^*) < f_\delta(x^*)$ for all $\beta > 0$ sufficiently small, implying $\mathcal{S}_\delta \ne \mathcal{S}^\phi$. Therefore, if case (ii) does not occur, then case (i) must occur.

Suppose that case (ii) occurs. First, we claim that, for any $\bar{x} \in \mathcal{S}$,

$$\nabla f(\bar{x})^T (x - \bar{x}) > 0 \quad \text{for all} \quad x \in \mathcal{C} \setminus \mathcal{S}.^1$$

Fix any $\bar{x} \in \mathcal{S}$. Because $\nabla f(\bar{x})^T (x - \bar{x}) = 0$ for all $x \in \mathcal{S}$, this yields (5.3). Next, we claim that $\mathcal{C}$ cannot be polyhedral. If $\mathcal{C}$ were polyhedral, then the minimization in (5.3) would be an LP, for which weak sharp minimum holds. Then there would exist $\tau > 0$ such that

$$\nabla f(\bar{x})^T (x - \bar{x}) \ge \tau \operatorname{dist}(x, \mathcal{S}) \quad \text{for all} \quad x \in \mathcal{C}.$$

Because f is convex and thus $f(x) - p^* = f(x) - f(\bar{x}) \ge \nabla f(\bar{x})^T (x - \bar{x})$ for all $x \in \mathcal{C}$, this would imply that (5.1) holds with $\gamma = 1$, contradicting our assumption. ∎

An example of case (ii) occurring in Theorem 5.2 is

$$n = 2, \quad f(x) = x_2, \quad \text{and} \quad \mathcal{C} = \{x \in \mathbb{R}^2 \mid x_1^2 \le x_2\}.$$

Here $\mathcal{S} = \{(0, 0)\}$, $p^* = 0$, and

$$\frac{f(x) - p^*}{\operatorname{dist}(x, \mathcal{S})} = \frac{x_2}{\|x\|_2} = \frac{1}{\sqrt{(x_1/x_2)^2 + 1}} \quad \text{for all} \quad x \in \mathcal{C} \setminus \mathcal{S}.$$

[1] If this were false, then there would exist $\bar{x} \in \mathcal{S}$ and $x \in \mathcal{C} \setminus \mathcal{S}$ such that $\nabla f(\bar{x})^T (x - \bar{x}) = 0$. (Note that $\nabla f(\bar{x})^T (x - \bar{x}) < 0$ cannot occur because $\bar{x} \in \mathcal{S}$.) Let $s \in \mathcal{S}$ satisfy $\|x - s\|_2 = \operatorname{dist}(x, \mathcal{S})$. By Lemma 3.1, $\nabla f(s)^T (x - s) = 0$. Then for $x^k = s + (x - s)/k$, we would have $x^k \in \mathcal{C} \setminus \mathcal{S}$, $f(x^k) - f(s) = o(1/k)$, and $\operatorname{dist}(x^k, \mathcal{S}) = \|x - s\|_2/k$, so x^k satisfies (5.2) and $s^k = s$ for $k = 1, 2, \ldots$. Because $(s^k, \frac{x^k - s^k}{\|x^k - s^k\|_2}) \to (s, \frac{x - s}{\|x - s\|_2})$ and $s + \alpha \frac{x - s}{\|x - s\|_2} \in \mathcal{C}$ for all $\alpha \in (0, \|x - s\|_2]$, this would contradict case (ii) occurring.

The right-hand side goes to 0 if and only if $x_1/x_2 \to \infty$, in which case $x/\|x\|_2 \to (\pm 1, 0)$, and $\alpha(\pm 1, 0) \notin \mathcal{C}$ for all $\alpha > 0$. Interestingly, we can still find $\phi(x) = \|x - \widehat{x}\|_2^2$ for which $\mathcal{S}_\delta \neq \mathcal{S}^\phi$ for all $\delta > 0$ sufficiently small. For example, take $\phi(x) = (x_1 - 1)^2 + (x_2 - 1)^2$. Then (P_δ) becomes

$$\underset{x}{\text{minimize}} \quad x_2 + \delta(x_1 - 1)^2 + \delta(x_2 - 1)^2 \quad \text{subject to} \quad x_1^2 \leq x_2.$$

It is straightforward to check that $(0, 0)$ does not satisfy the necessary optimality conditions for (P_δ) for all $\delta > 0$. This raises the question of whether case (ii) is subsumed by case (i) when $\mathcal{C}$ is not polyhedral. In section 8, we give an example showing that the answer is "no."

6. Sparse solutions. In this section we illustrate a practical application of Corollary 2.2. Our aim is to find sparse solutions of LPs and CPs that may not have unique solutions. To this end, we let $\phi(x) = \|x\|_1$, which clearly satisfies the required Assumption 1.2. (In general, however, some components of x may be more significant or be at different scales, in which case we may not wish to regularize all components or regularize them equally.)

Regularization based on the one-norm has been used in many applications, with the goal of obtaining sparse or even *sparsest* solutions of underdetermined systems of linear equations and least-squares problems. Some recent examples include [14, 16, 17, 18].

The AMPL model and data files and the MATLAB scripts used to generate all of the numerical results presented in the following subsections can be obtained at http://www.cs.ubc.ca/∼mpf/exactreg/.

6.1. Sparse solutions of linear programs. For underdetermined systems of linear equations $Ax = b$ that arise in fields such as signal processing, the studies in [13, 14, 18] advocate solving

$$\underset{x}{\text{minimize}} \quad \|x\|_1 \quad \text{subject to} \quad Ax = b \quad (\text{and possibly } x \geq 0), \tag{6.1}$$

in order to obtain a sparse solution. This problem can be recast as an LP and be solved efficiently. The sparsest solution is given by minimizing the so-called zero-norm, $\|x\|_0$, which counts the number of nonzero components in x. However, the combinatorial nature of this minimization makes it computationally intractable for all but the simplest instances. Interestingly, there exist reasonable conditions under which a solution of (6.1) is a sparsest solution; see [13, 18].

Following this approach, we use Corollary 2.2 as a guide for obtaining least one-norm solutions of a generic LP,

$$\underset{x}{\text{minimize}} \quad c^T x \quad \text{subject to} \quad Ax = b, \quad l \leq x \leq u, \tag{6.2}$$

by solving its regularized version,

$$\underset{x}{\text{minimize}} \quad c^T x + \delta\|x\|_1 \quad \text{subject to} \quad Ax = b, \quad l \leq x \leq u. \tag{6.3}$$

The vectors l and u are lower and upper bounds on x. In many of the numerical tests given below, the exact ℓ_1 regularized solution of (6.2) (given by (6.3) for small-enough values of δ) is considerably sparser than the solution obtained by solving (6.2) directly. In each instance, we solve the regularized and unregularized problems with

the same interior-point solver. We emphasize that, with an appropriate choice of the regularization parameter δ, the solution of the regularized LP is *also* a solution of the original LP.

We use two sets of test instances in our numerical experiments. The instances of the first set are randomly generated using a degenerate LP generator described in [23]. Those of the second set are derived from the infeasible LPs in the NETLIB collection (http://www.netlib.org/lp/infeas/). Both sets of test instances are further described in subsections 6.1.1–6.1.2.

We follow the same procedure for each test instance. First, we solve the LP (6.2) to obtain an unregularized solution x^* and the optimal value $p^* := c^T x^*$. Next, we solve (P^ϕ), reformulated as an LP, to obtain a Lagrange multiplier μ^* and the threshold value $\bar{\delta} = 1/\mu^*$. Finally, we solve (6.3) with $\delta := \bar{\delta}/2$, reformulated as an LP, to obtain a regularized solution x^*_δ.

We use the log-barrier interior-point algorithm implemented in CPLEX 9.1 to solve each LP. The default CPLEX options are used, except for `crossover = 0` and `comptol = 1e-10`. Setting `crossover = 0` forces CPLEX to use the interior-point algorithm only and to not "cross over" to find a vertex solution. In general, we expect the interior-point algorithm to find the analytic center of the solution set (see [47, Theorems 2.16 and 2.17]), which tends to be less sparse than vertex solutions. The `comptol` option tightens CPLEX's convergence tolerance from its default of `1e-8` to its smallest allowable setting. We do not advocate such a tight tolerance in practice, but the higher accuracy aids in computing the sparsity of a computed solution, which we determine as

$$\|x\|_0 = \mathrm{card}\{x_i \mid |x_i| > \epsilon\}, \tag{6.4}$$

where $\epsilon = 10^{-8}$ is larger than the specified convergence tolerance.

6.1.1. Randomly generated LPs. Six dual-degenerate LPs were constructed using Gonzaga's MATLAB generator [23]. This MATLAB program accepts as inputs the problem size and the dimensions of the optimal primal and dual faces, D_p and D_d, respectively. Gonzaga shows that these quantities must satisfy

$$0 \le D_p \le n - m - 1 \qquad \text{and} \qquad 0 \le D_d \le m - 1. \tag{6.5}$$

The six LPs are constructed with parameters $n = 1000$, $m = 100$, $D_d = 0$, and various levels of D_p set as 0%, 20%, 40%, 60%, 80%, and 100% of the maximum of 899 (given by (6.5)). The instances are, respectively, labeled `random-0`, `random-20`, `random-40`, and so on.

Table 6.1 summarizes the results. We confirm that in each instance the optimal values of the unregularized and regularized problems are nearly identical (at least to within the specified tolerance), so each regularized solution is exact. Except for the "control" instance `random-0`, the regularized solution x^*_δ has a strictly lower one-norm and is considerably sparser than the unregularized solution x^*.

6.1.2. Infeasible LPs. The second set of test instances is derived from a subset of the infeasible NETLIB LPs. For each infeasible LP, we discard the original objective and instead form the problem

$$(\mathrm{P}^{\mathrm{inf}}) \qquad \underset{x}{\text{minimize}} \quad \|Ax - b\|_1 \quad \text{subject to} \quad l \le x \le u,$$

and its regularized counterpart

$$(\mathrm{P}^{\mathrm{inf}}_\delta) \qquad \underset{x}{\text{minimize}} \quad \|Ax - b\|_1 + \delta\|x\|_1 \quad \text{subject to} \quad l \le x \le u.$$

TABLE 6.1

The unregularized problem (P^{inf}) models the plausible situation where we wish to fit a set of infeasible equations in the least one-norm sense. But because the one-norm is not strictly convex or the equations are underdetermined, a solution of (P^{inf}) may not be unique, and the regularized problem (P^{inf}_δ) is used to further select a sparse solution.

The following infeasible NETLIB LPs were omitted because CPLEX returned an error message during the solution of (P^{inf}) or (P^{inf}_δ): `lpi-bgindy`, `lpi-cplex2`, `lpi-gran`, `lpi-klein1`, `lpi-klein2`, `lpi-klein3`, `lpi-qual`, `lpi-refinery`, and `lpi-vol1`.

Table 6.2 summarizes the results. We can see that the regularized solution x^*_δ is exact (i.e., $c^T x^*_\delta = c^T x^*$) and has a one-norm lower than or equal to that of the unregularized solution x^* in all instances. In twelve of the twenty instances, x^*_δ is sparser than x^*. In five of the instances, they have the same sparsity. In three of the instances (`lpi-galenet`, `lpi-itest6`, and `lpi-woodinfe`), x^*_δ is actually less sparse, even though its one-norm is lower.

6.2. Sparse solutions of semidefinite/second-order cone programs. In section 6.1 we used Corollary 2.2 to find sparse solutions of LPs. In this section, we report our numerical experience in finding sparse solutions of SDPs and SOCPs that may not have unique solutions. These are conic programs (P) with f and $\mathcal{C}$ given by (1.1), and $\mathcal{K}$ being the Cartesian product of real space, orthant, second-order cones, and semidefinite cones.

The regularized problem (P_δ) can be put in the conic form

$$\begin{array}{ll} \underset{x,u,v}{\text{minimize}} & c^T x + \delta e^T (u+v) \\ \text{subject to} & Ax = b, \quad x - u + v = 0, \\ & (x,u,v) \in \mathcal{K} \times [0,\infty)^{2n}, \end{array} \tag{6.6}$$

where e is the vector of ones. The selection problem (P^ϕ) can also be put in conic form:

$$\begin{array}{ll} \underset{x,u,v,s}{\text{minimize}} & e^T (u+v) \\ \text{subject to} & Ax = b, \quad x - u + v = 0, \quad c^T x + s = p^*, \\ & (x,u,v,s) \in \mathcal{K} \times [0,\infty)^{2n+1}. \end{array} \tag{6.7}$$

As in section 6.1, we first solve (P) to obtain x^* and the optimal value $p^* := c^T x^*$. Then (6.7) is solved to obtain Lagrange multiplier μ^* and the corresponding threshold value $\bar{\delta} := 1/\mu^*$. Finally, we solve (6.6) with $\delta = \bar{\delta}/2$ to obtain x^*_δ. All three

problems—(P), (6.6), and (6.7)—are solved using the MATLAB toolbox SeDuMi (version 1.05) [43], which is a C implementation of a log-barrier primal-dual interior-point algorithm for solving SDP/SOCP. The test instances are drawn from the DIMACS Implementation Challenge library [37], a collection of nontrivial medium-to-large SDP/SOCP arising from applications. We omit those instances for which either (P) is infeasible (e.g., `filtinf1`) or if one of (P), (6.6), or (6.7) cannot be solved because of insufficient memory (e.g., `torusg3-8`). All runs were performed on a PowerPC G5 with 2GB of memory running MATLAB 7.3b.

Table 6.3 summarizes the results. For most of the instances, SeDuMi finds only an inaccurate solution (`info.numerr=1`) for at least one of (P), (6.6), or (6.7). For most instances, however, SeDuMi also finds a value of μ^* that seems reasonable. In some instances (`nb_L2_bessel`, `nql30`, `nql80`, `qssp30`, `qssp60`, `qssp180`, `sch_100_100_scal`, `sch_200_100_scal`, `truss8`), the computed multiplier μ^* is quite large relative to the solution accuracy, and yet $c^T x_\delta^*$ matches $c^T x^*$ in the first three significant digits; this suggests that the regularization is effectively exact. For `nb_L2`, `sch_100_50_scal`, and `sch_100_100_orig`, the discrepancies between $c^T x_\delta^*$ and $c^T x^*$ may be attributed to a SeDuMi numerical failure or primal infeasibility in solving either (P) or (6.7) (thus yielding inaccurate μ^*) or (6.6). For `hinf12`, SeDuMi solved all three problems accurately, and μ^* looks reasonable, whereas for `hinf13`, SeDuMi solved all three problems inaccurately, but μ^* still looks reasonable. Yet $c^T x_\delta^*$ is lower than $c^T x^*$ in both instances. We do not yet have an explanation for this.

The regularized solution x_δ^* has a one-norm lower than or equal to that of the unregularized solution x^* in all instances except `hinf12`, where $\|x_\delta^*\|_1$ is 1% higher (this small difference does not appear in Table 6.3). Solution sparsity is measured by

TABLE 6.3

the zero-norm defined in (6.4), where ϵ is based on the relative optimality gap

$$\epsilon = \frac{c^Tx^*_\delta - b^Ty^*_\delta}{1 + \|b\|\|y^*_\delta\| + \|c\|\|x^*_\delta\|}$$

of the computed solution of (6.6). For 52% of the instances, the regularized solution is sparser than the unregularized solution. For 28% of the instances, the solutions have the same sparsity. For the remaining six instances, the regularized solution is actually less sparse, even though its one-norm is lower (`nb_L2_bessel`, `sch_100_50_s`, `sch_100_100_o`) or the same (`hinf12`, `sch_50_50_o`, `sch_50_50_s`). SeDuMi implements an interior-point algorithm, so it is likely to find the analytic center of the solution set of (P).

The selection problem (6.7) is generally much harder to solve than (P) or (6.6). For example, on `nb_L2_bessel`, SeDuMi took 18, 99, and 16 iterations to solve (P), (6.7), and (6.6), respectively, and on `truss8` SeDuMi took, respectively, 24, 117, and 35 iterations. This seems to indicate that regularization is more efficient than solving the selection problem as a method for finding sparse solutions.

7. Discussion. We see from the numerical results in section 6 that regularization can provide an effective way of selecting a solution with desirable properties, such as

sparsity. However, finding the threshold value $\bar{\delta}$ for exact regularization entails first solving (P) to obtain p^*, and then solving (P^ϕ) to obtain μ^* and setting $\bar{\delta} = 1/\mu^*$; see Corollary 2.2. Can we find a $\delta < \bar{\delta}$ from (P) without also solving (P^ϕ)?

Consider the case of a CP, in which f and $\mathcal{C}$ have the form (1.1). Suppose that a value of $\delta < \bar{\delta}$ has been guessed (with $\bar{\delta}$ unknown), and a solution x^* of the regularized problem (P_δ) is obtained. By Corollary 2.2, x^* is also a solution of (P^ϕ). Suppose also that there exist Lagrange multipliers $y^* \in \mathbb{R}^m$ and $z^* \in \mathcal{K}^*$ for (P), where $\mathcal{K}^*$ is the dual cone of $\mathcal{K}$ given by

$$\mathcal{K}^* := \{y \in \mathbb{R}^n \mid y^T x \geq 0 \text{ for all } x \in \mathcal{K}\}.$$

Then (y^*, z^*) satisfy, among other conditions,

$$A^T y^* + z^* = c \qquad \text{and} \qquad b^T y^* = p^*.$$

Suppose, furthermore, that there exist Lagrange multipliers $y_\phi^* \in \mathbb{R}^m$, $z_\phi^* \in \mathcal{K}^*$, and $\mu^* \geq 0$ for (P^ϕ) that satisfy, among other conditions,

$$0 \in \partial\phi(x^*) - (A^T y_\phi^* + z_\phi^* - \mu^* c).$$

Then, analogous to the proof of Theorem 2.1, we can construct Lagrange multipliers for (P_δ) as follows:

Case 1. $\mu_\phi^* = 0$. The Lagrange multipliers for (P_δ) are given by

$$y_\delta^* := y^* + \delta y_\phi^* \quad \text{and} \quad z_\delta^* := z^* + \delta z_\phi^*.$$

Case 2. $\mu_\phi^* > 0$. The Lagrange multipliers for (P_δ) are given by

$$y_\delta^* := (1-\lambda) y^* + \frac{\lambda}{\mu_\phi^*} y_\phi^* \quad \text{and} \quad z_\delta^* := (1-\lambda) z^* + \frac{\lambda}{\mu_\phi^*} z_\phi^*,$$

for any $\lambda \in [0,1]$. The Lagrange multipliers (y_δ^*, z_δ^*) obtained for the regularized problem are therefore necessarily perturbed. Therefore, it is not possible to test the computed triple $(x^*, y_\delta^*, z_\delta^*)$ against the optimality conditions for the original CP in order to verify that x^* is indeed an exact solution.

In practice, if it were prohibitively expensive to solve (P) and (P^ϕ), we might adopt an approach suggested by Lucidi [27] and Mangasarian [33] for Tikhonov regularization. They suggest solving the regularized problem successively with decreasing values $\delta_1 > \delta_2 > \cdots$. If successive regularized solutions do not change for δ ranging over different orders of magnitude, then it is likely that a correct regularization parameter has been obtained. We note that in many instances, the threshold values $\bar{\delta}$ shown in Tables 6.1 and 6.2 are comfortably large, and a value such as $\delta = 10^{-4}$ would cover 85% of the these cases.

8. Appendix. In this appendix, we give an example of f and $\mathcal{C}$ that satisfy the assumptions of Theorem 5.2 and for which weak sharp minimum fails to hold and yet exact regularization holds for $\phi(x) = \|x - \widehat{x}\|_2^2$ and any $\widehat{x} \in \Re^n$.

Consider the example

$$n = 3, \quad f(x) = x_3, \quad \text{and} \quad \mathcal{C} = [0,1]^3 \cap \left(\cap_{k=2}^{\infty} \mathcal{C}^k\right),$$

where $\mathcal{C}^k = \{x \in \mathbb{R}^3 \mid x_1 - (k-1)x_2 - k^2 x_3 \leq 1/k\}$. Each $\mathcal{C}^k$ is a half-space in $\mathbb{R}^3$, so $\mathcal{C}$ is a closed convex set. Moreover, $\mathcal{C}$ is bounded and nonempty (since $0 \in \mathcal{C}$); see Figure 8.1(a). Clearly

$$p^* = 0 \quad \text{and} \quad \mathcal{S} = \{x \in \mathcal{C} \mid x_3 = 0\}. \tag{8.1}$$

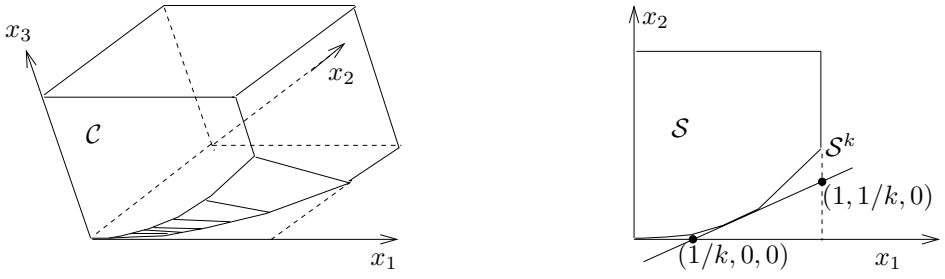

FIG. 8.1. (a) *The feasible set* $\mathcal{C}$. (b) *The solution set* $\mathcal{S}$ *and* $\mathcal{S}^k$.

First, we show that weak sharp minimum fails to hold, i.e., there does not exist $\tau > 0$ such that (5.1) holds with $\gamma = 1$. Let H^k be the hyperplane forming the boundary set of $\mathcal{C}^k$, i.e., $H^k = \{x \in \mathbb{R}^3 \mid x_1 - (k-1)x_2 - k^2 x_3 = 1/k\}$. Let x^k be the intersection point of H^k, H^{k+1} and the x_1x_3-plane. Direct calculation yields

$$x_1^k = \frac{1 - (1+1/k)^{-3}}{k(1-(1+1/k)^{-2})}, \quad x_2^k = 0, \quad x_3^k = \frac{x_1^k - 1/k}{k^2}, \tag{8.2}$$

for $k = 2, 3, \dots$. Since $\mathcal{C} \subset \mathcal{C}^k$, we have from (8.1) that $\mathcal{S} \subset \mathcal{S}^k$, where we let $\mathcal{S}^k = \{x \in \mathcal{C}^k \mid x_3 = 0\}$; see Figure 8.1(b). Thus

$$\operatorname{dist}(x^k, \mathcal{S}) \geq \operatorname{dist}(x^k, \mathcal{S}^k) \geq \operatorname{dist}((x_1^k, 0, 0), \mathcal{S}^k). \tag{8.3}$$

Since $\lim_{\alpha \to 1} \frac{1-\alpha^3}{1-\alpha^2} = \frac{3}{2}$, (8.2) implies that $kx_1^k \to 3/2$, i.e., $x_1^k = 1.5/k + o(1/k)$. The point in $\mathcal{S}^k$ nearest to $(x_1^k, 0, 0)$ lies on the line through $(1/k, 0, 0)$ and $(1, 1/k, 0)$ (with slope $1/(k-1)$ in the x_1x_2-plane), from which it follows that $\operatorname{dist}((x_1^k, 0, 0), \mathcal{S}^k) = 0.5/k^2 + o(1/k^2)$. Since $x_3^k = 1.5/k^3 + o(1/k^3)$ by (8.2), this together with (8.3) implies

$$\frac{x_3^k}{\operatorname{dist}(x^k, \mathcal{S})} \leq \frac{x_3^k}{\operatorname{dist}((x_1^k, 0, 0), \mathcal{S}^k)} = O(1/k) \to 0.$$

Moreover, for any $\ell \in \{2, 3, \dots\}$, we have from (8.2) and letting $\alpha = \ell/k$ that

$$\begin{aligned}
x_1^k - (\ell-1)x_2^k - \ell^2 x_3^k - \frac{1}{\ell} &= \left(1-\alpha^2\right) x_1^k - \frac{1}{\ell}\left(1-\alpha^3\right) \\
&= (1-\alpha)\left((1+\alpha)x_1^k - \frac{1}{\ell}\left(1+\alpha+\alpha^2\right)\right) \\
&= \frac{(1-\alpha)}{k}\left((1+\alpha)\frac{1-(1+1/k)^{-3}}{1-(1+1/k)^{-2}} - \frac{1}{\alpha}\left(1+\alpha+\alpha^2\right)\right) \\
&= \frac{(1-\alpha)}{k}(1+\alpha)\left(\frac{(1+1/k)^{-2}}{1+(1+1/k)^{-1}} - \frac{1}{\alpha(1+\alpha)}\right) \\
&= \frac{(1-\alpha^2)}{k}\left(\frac{k^2}{(2k+1)(k+1)} - \frac{k^2}{\ell(k+\ell)}\right) \\
&= \frac{(1-\alpha^2)}{k}\frac{(2k+\ell+1)(\ell-k-1)}{(2k+1)(k+1)\ell(k+\ell)},
\end{aligned}$$

where the second equality uses $1-\alpha^2 = (1-\alpha)(1+\alpha)$, $1-\alpha^3 = (1-\alpha)(1+\alpha+\alpha^2)$; the fourth equality uses the same identities but with $(1+1/k)^{-1}$ in place of α. By

considering the two cases $\ell \leq k$ and $\ell \geq k+1$, it is readily seen that the right-hand side of the previous equation is nonpositive. This in turn shows that $x^k \in \mathcal{C}^\ell$ for $\ell = 2, 3, \ldots$, and hence $x^k \in \mathcal{C}$.

Second, fix any $\widehat{x} \in \mathbb{R}^3$ and let $\phi(x) = \|x - \widehat{x}\|_2^2$. Let $x^* = \arg\min_{x \in \mathcal{S}} \phi(x)$ and $f_\delta(x) = f(x) + \delta\phi(x)$. Suppose $x^* \neq 0$. Then $\mathcal{C}$ is polyhedral in a neighborhood $\mathcal{N}$ of x^*. Since $x_\delta = \arg\min_{x \in \mathcal{C}} f_\delta(x)$ converges to x^* as $\delta \to 0$, we have that $x_\delta \in \mathcal{C} \cap \mathcal{N}$ for all $\delta > 0$ below some positive threshold, in which case exact regularization holds (see Corollary 2.3). Suppose $x^* = 0$. Then

$$\widehat{x} = -\nabla\phi(x^*) \in N_{\mathcal{S}}(x^*) = (-\infty, 0]^2 \times \mathbb{R},$$

where the second equality follows from $[0, \infty)^2 \times \{0\}$ being the tangent cone of $\mathcal{S}$ at 0. Thus $\widehat{x}_2 \leq 0, \widehat{x}_3 \leq 0$ and we see from

$$\nabla f_\delta(x^*) = (0, 0, 1)^T - \delta\widehat{x}$$

that $\nabla f_\delta(x^*) \geq 0$ for all $\delta \in [0, \bar{\delta}]$, where $\bar{\delta} = \infty$ if $\widehat{x}_3 \leq 0$ and $\bar{\delta} = 1/\widehat{x}_3$ if $\widehat{x}_3 > 0$. Because $\mathcal{C} \subset [0, \infty)^3$, it is implied that, for $\delta \in [0, \bar{\delta}]$,

$$\nabla f_\delta(x^*)^T(x - x^*) = \nabla f_\delta(x^*)^T x \geq 0 \quad \text{for all} \quad x \in \mathcal{C}.$$

Because $x^* \in \mathcal{C}$ and f_δ is strictly convex for $\delta \in (0, \bar{\delta}]$, it is implied that $x^* = \arg\min_{x \in \mathcal{C}} f_\delta(x)$ for all $\delta \in (0, \bar{\delta}]$. Hence exact regularization holds.

Acknowledgments. Sincere thanks to Dimitri Bertsekas for suggesting Lemma 4.1(a) and bringing to our attention the paper [4]. We also thank Kevin Leyton-Brown for generously giving us access to his CPLEX installation for the numerical experiments presented in section 6.

PROXIMAL THRESHOLDING ALGORITHM FOR MINIMIZATION OVER ORTHONORMAL BASES*

PATRICK L. COMBETTES† AND JEAN-CHRISTOPHE PESQUET‡

Abstract. The notion of soft thresholding plays a central role in problems from various areas of applied mathematics, in which the ideal solution is known to possess a sparse decomposition in some orthonormal basis. Using convex-analytical tools, we extend this notion to that of proximal thresholding and investigate its properties, providing, in particular, several characterizations of such thresholders. We then propose a versatile convex variational formulation for optimization over orthonormal bases that covers a wide range of problems, and we establish the strong convergence of a proximal thresholding algorithm to solve it. Numerical applications to signal recovery are demonstrated.

Key words. convex programming, deconvolution, denoising, forward-backward splitting algorithm, Hilbert space, orthonormal basis, proximal algorithm, proximal thresholding, proximity operator, signal recovery, soft thresholding, strong convergence

1. Problem formulation.

Throughout this paper, $\mathcal{H}$ is a separable infinite-dimensional real Hilbert space with scalar product $\langle \cdot \mid \cdot \rangle$, norm $\| \cdot \|$, and distance d. Moreover, $\Gamma_0(\mathcal{H})$ denotes the class of proper lower semicontinuous convex functions from $\mathcal{H}$ to $]-\infty,+\infty]$, and $(e_k)_{k\in\mathbb{N}}$ is an orthonormal basis of $\mathcal{H}$.

The standard denoising problem in signal theory consists of recovering the original form of a signal $\overline{x} \in \mathcal{H}$ from an observation $z = \overline{x} + v$, where $v \in \mathcal{H}$ is the realization of a noise process. In many instances, $\overline{x}$ is known to admit a sparse representation with respect to $(e_k)_{k\in\mathbb{N}}$, and an estimate x of $\overline{x}$ can be constructed by removing the coefficients of small magnitude in the representation $(\langle z \mid e_k \rangle)_{k\in\mathbb{N}}$ of z with respect to $(e_k)_{k\in\mathbb{N}}$. A popular method consists of performing a so-called soft thresholding of each coefficient $\langle z \mid e_k \rangle$ at some predetermined level $\omega_k \in]0,+\infty[$, namely

$$x = \sum_{k\in\mathbb{N}} \mathrm{soft}_{[-\omega_k,\omega_k]}\left(\langle z \mid e_k \rangle\right) e_k, \tag{1.1}$$

where (see Figure 2.1)

$$\mathrm{soft}_{[-\omega_k,\omega_k]} : \xi \mapsto \mathrm{sign}(\xi)\max\{|\xi| - \omega_k, 0\}. \tag{1.2}$$

This approach has received considerable attention in various areas of applied mathematics ranging from nonlinear approximation theory to statistics, and from harmonic analysis to image processing; see, for instance, [2, 7, 9, 21, 23, 29, 33] and the references therein. From an optimization point of view (see Remark 2.8), the vector x

exhibited in (1.1) is the solution to the variational problem

$$\underset{x\in\mathcal{H}}{\text{minimize}}\ \ \frac{1}{2}\|x-z\|^2+\sum_{k\in\mathbb{N}}\omega_k\,|\langle x\mid e_k\rangle|\,. \tag{1.3}$$

Attempts have been made to extend this formulation to the more general inverse problems in which the observation assumes the form $z=T\overline{x}+v$, where T is a nonzero bounded linear operator from $\mathcal{H}$ to some real Hilbert space $\mathcal{G}$, and where $v\in\mathcal{G}$ is the realization of a noise process. Thus, the variational problem

$$\underset{x\in\mathcal{H}}{\text{minimize}}\ \ \frac{1}{2}\|Tx-z\|^2+\sum_{k\in\mathbb{N}}\omega_k\,|\langle x\mid e_k\rangle| \tag{1.4}$$

has been considered and, since it admits no closed-form solution, the soft thresholding algorithm

$$x_0\in\mathcal{H}\quad\text{and}\quad(\forall n\in\mathbb{N})\ \ x_{n+1}=\sum_{k\in\mathbb{N}}\operatorname{soft}_{[-\omega_k,\omega_k]}\big(\langle x_n+T^*(z-Tx_n)\mid e_k\rangle\big)e_k \tag{1.5}$$

has been proposed to solve it [5, 19, 20, 24] (see also [36] and the references therein for related work). The strong convergence of this algorithm was formally established in [18].

PROPOSITION 1.1 (see [18, Theorem 3.1]). *Suppose that* $\inf_{k\in\mathbb{N}}\omega_k>0$ *and* $\|T\|<1$. *Then the sequence* $(x_n)_{n\in\mathbb{N}}$ *generated by* (1.5) *converges strongly to a solution to* (1.4).

In [16], (1.4) was analyzed in a broader framework, and the following extension of Proposition 1.1 was obtained by bringing into play tools from convex analysis and recent results from constructive fixed point theory (Proposition 1.2 reduces to Proposition 1.1 when $\|T\|<1$, $\gamma_n\equiv 1$, and $\lambda_n\equiv 1$).

PROPOSITION 1.2 (see [16, Corollary 5.19]). *Let* $(\gamma_n)_{n\in\mathbb{N}}$ *be a sequence in* $]0,+\infty[$, *and let* $(\lambda_n)_{n\in\mathbb{N}}$ *be a sequence in* $]0,1]$. *Suppose that the following hold:* $\inf_{k\in\mathbb{N}}\omega_k>0$, $\inf_{n\in\mathbb{N}}\gamma_n>0$, $\sup_{n\in\mathbb{N}}\gamma_n<2/\|T\|^2$, *and* $\inf_{n\in\mathbb{N}}\lambda_n>0$. *Then the sequence* $(x_n)_{n\in\mathbb{N}}$ *generated by the algorithm*

$$\begin{aligned}x_0\in\mathcal{H}\quad\text{and}\quad(\forall n\in\mathbb{N})\quad x_{n+1}&=x_n\\&+\lambda_n\Bigg(\sum_{k\in\mathbb{N}}\operatorname{soft}_{[-\gamma_n\omega_k,\gamma_n\omega_k]}\big(\langle x_n+\gamma_nT^*(z-Tx_n)\mid e_k\rangle\big)e_k-x_n\Bigg)\end{aligned} \tag{1.6}$$

converges strongly to a solution to (1.4).

In denoising and approximation problems, various theoretical, physical, and heuristic considerations have led researchers to consider alternative thresholding strategies in (1.1); see, e.g., [1, 33, 34, 35, 39]. However, the questions of whether alternative thresholding rules can be used in algorithms akin to (1.6) and of identifying the underlying variational problems remain open. These questions are significant because the current theory of iterative thresholding, as described by Proposition 1.2, can tackle only variational problems of the form (1.4), which offers limited flexibility in the penalization of the coefficients $(\langle x\mid e_k\rangle)_{k\in\mathbb{N}}$ and which is furthermore restricted to standard linear inverse problems. The aim of the present paper is to bring out general answers to these questions. Our analysis will revolve around the following variational formulation, where σ_Ω denotes the support function of a set Ω (see (2.2)).

PROBLEM 1.3. Let $\Phi \in \Gamma_0(\mathcal{H})$, let $\mathbb{K} \subset \mathbb{N}$, let $\mathbb{L} = \mathbb{N} \smallsetminus \mathbb{K}$, let $(\Omega_k)_{k\in\mathbb{K}}$ be a sequence of closed intervals in $\mathbb{R}$, and let $(\psi_k)_{k\in\mathbb{N}}$ be a sequence in $\Gamma_0(\mathbb{R})$. The objective is to

$$\underset{x\in\mathcal{H}}{\text{minimize}} \;\; \Phi(x) + \sum_{k\in\mathbb{N}} \psi_k(\langle x \mid e_k\rangle) + \sum_{k\in\mathbb{K}} \sigma_{\Omega_k}(\langle x \mid e_k\rangle), \tag{1.7}$$

under the following standing assumptions:

(i) the function Φ is differentiable on $\mathcal{H}$, $\inf \Phi(\mathcal{H}) > -\infty$, and $\nabla\Phi$ is $1/\beta$-Lipschitz continuous for some $\beta \in \left]0, +\infty\right[$;
(ii) for every $k \in \mathbb{N}$, $\psi_k \geq \psi_k(0) = 0$;
(iii) the functions $(\psi_k)_{k\in\mathbb{N}}$ are differentiable at 0;
(iv) if $\mathbb{L} \neq \varnothing$, then the functions $(\psi_k)_{k\in\mathbb{L}}$ are finite and twice differentiable on $\mathbb{R} \smallsetminus \{0\}$, and

$$(\forall \rho \in \left]0, +\infty\right[)(\exists\, \theta \in \left]0, +\infty\right[) \quad \inf_{k\in\mathbb{L}} \inf_{0<|\xi|\leq\rho} \psi_k''(\xi) \geq \theta; \tag{1.8}$$

(v) if $\mathbb{L} \neq \varnothing$, then the function $\Upsilon_{\mathbb{L}} \colon \ell^2(\mathbb{L}) \to \left]-\infty, +\infty\right] \colon (\xi_k)_{k\in\mathbb{L}} \mapsto \sum_{k\in\mathbb{L}} \psi_k(\xi_k)$ is coercive;
(vi) $(\exists\, \omega \in \left]0, +\infty\right[)\ [-\omega, \omega] \subset \bigcap_{k\in\mathbb{K}} \Omega_k$.

Let us note that Problem 1.3 reduces to (1.4) when $\Phi \colon x \mapsto \|Tx - z\|^2/2$, $\mathbb{K} = \mathbb{N}$, and, for every $k \in \mathbb{N}$, $\Omega_k = [-\omega_k, \omega_k]$, and $\psi_k = 0$. It will be shown (Proposition 4.1) that Problem 1.3 admits at least one solution. While assumption (i) on Φ may seem offhand to be rather restrictive, it will be seen in section 5.1 to cover important scenarios. In addition, it makes it possible to employ a forward-backward splitting strategy to solve (1.7), which consists essentially of alternating a forward (explicit) gradient step on Φ with a backward (implicit) proximal step on

$$\Psi \colon \mathcal{H} \to \left]-\infty, +\infty\right] \colon x \mapsto \sum_{k\in\mathbb{N}} \psi_k(\langle x \mid e_k\rangle) + \sum_{k\in\mathbb{K}} \sigma_{\Omega_k}(\langle x \mid e_k\rangle). \tag{1.9}$$

Our main convergence result (Theorem 4.5) will establish the *strong* convergence of an inexact forward-backward splitting algorithm (Algorithm 4.3) for solving Problem 1.3. Another contribution of this paper will be to show (Remark 3.4) that, under our standing assumptions, the function displayed in (1.9) is quite general in the sense that the operators on $\mathcal{H}$ that perform nonexpansive (as required by our convergence analysis) and increasing (as imposed by practical considerations) thresholdings on the closed intervals $(\Omega_k)_{k\in\mathbb{K}}$ of the coefficients $(\langle x \mid e_k\rangle)_{k\in\mathbb{K}}$ of a point $x \in \mathcal{H}$ are precisely those of the form prox_Ψ, i.e., the proximity operator of Ψ. Furthermore, we show (Proposition 3.6 and Lemma 2.3) that such an operator, which provides the proximal step of our algorithm, can be conveniently decomposed as

$$\operatorname{prox}_\Psi \colon \mathcal{H} \to \mathcal{H} \colon x \mapsto \sum_{k\in\mathbb{K}} \operatorname{prox}_{\psi_k}\big(\operatorname{soft}_{\Omega_k}\langle x \mid e_k\rangle\big) e_k + \sum_{k\in\mathbb{L}} \operatorname{prox}_{\psi_k}\langle x \mid e_k\rangle\, e_k, \tag{1.10}$$

where we define the soft thresholder relative to a nonempty closed interval $\Omega \subset \mathbb{R}$ as

$$\operatorname{soft}_\Omega : \mathbb{R} \to \mathbb{R} \colon \xi \mapsto \begin{cases} \xi - \underline{\omega} & \text{if } \xi < \underline{\omega}, \\ 0 & \text{if } \xi \in \Omega, \\ \xi - \overline{\omega} & \text{if } \xi > \overline{\omega}, \end{cases} \qquad \text{with} \quad \begin{cases} \underline{\omega} = \inf \Omega, \\ \overline{\omega} = \sup \Omega. \end{cases} \tag{1.11}$$

The remainder of the paper is organized as follows. In section 2, we provide a brief account of the theory of proximity operators, which play a central role in our analysis. In section 3, we introduce and study the notion of a proximal thresholder. Our algorithm is presented in section 4 and its strong convergence to a solution to Problem 1.3 is demonstrated. Signal recovery applications are discussed in section 5, where numerical results are presented.

2. Proximity operators. Let us first introduce some basic notation (for a detailed account of convex analysis, see [41]). Let C be a subset of $\mathcal{H}$. The indicator function of C is

$$\iota_C\colon \mathcal{H} \to \{0,+\infty\}\colon x \mapsto \begin{cases} 0 & \text{if } x \in C,\\ +\infty & \text{if } x \notin C, \end{cases} \tag{2.1}$$

its support function is

$$\sigma_C\colon \mathcal{H} \to [-\infty,+\infty] : u \mapsto \sup_{x\in C} \langle x \mid u\rangle, \tag{2.2}$$

and its distance function is $d_C\colon \mathcal{H} \to [0,+\infty] : x \mapsto \inf \|C - x\|$. If C is nonempty, closed, and convex, then, for every $x \in \mathcal{H}$, there exists a unique point $P_C x \in C$, called the projection of x onto C, such that $\|x - P_C x\| = d_C(x)$. A function $f\colon \mathcal{H} \to [-\infty,+\infty]$ is proper if $-\infty \notin f(\mathcal{H}) \neq \{+\infty\}$, and coercive if $\lim_{\|x\|\to+\infty} f(x) = +\infty$. The domain of $f\colon \mathcal{H} \to [-\infty,+\infty]$ is $\operatorname{dom} f = \big\{x \in \mathcal{H} \;\big|\; f(x) < +\infty\big\}$, its set of global minimizers is denoted by $\operatorname{Argmin} f$, and its conjugate is the function $f^*\colon \mathcal{H} \to [-\infty,+\infty] : u \mapsto \sup_{x\in\mathcal{H}} \langle x \mid u\rangle - f(x)$; if f is proper, its subdifferential is the set-valued operator

$$\partial f\colon \mathcal{H} \to 2^{\mathcal{H}}\colon x \mapsto \big\{u \in \mathcal{H} \;\big|\; (\forall y \in \operatorname{dom} f)\ \langle y - x \mid u\rangle + f(x) \leq f(y)\big\}. \tag{2.3}$$

If $f\colon \mathcal{H} \to \left]-\infty,+\infty\right]$ is convex and Gâteaux differentiable at $x \in \operatorname{dom} f$ with gradient $\nabla f(x)$, then $\partial f(x) = \{\nabla f(x)\}$.

Example 2.1. Let $\Omega \subset \mathbb{R}$ be a nonempty closed interval, let $\underline{\omega} = \inf \Omega$, let $\overline{\omega} = \sup \Omega$, and let $\xi \in \mathbb{R}$. Then the following hold:

(i) $$\sigma_\Omega(\xi) = \begin{cases} \underline{\omega}\xi & \text{if } \xi < 0,\\ 0 & \text{if } \xi = 0,\\ \overline{\omega}\xi & \text{if } \xi > 0. \end{cases}$$

(ii) $$\partial\sigma_\Omega(\xi) = \begin{cases} \{\underline{\omega}\} \cap \mathbb{R} & \text{if } \xi < 0,\\ \Omega & \text{if } \xi = 0,\\ \{\overline{\omega}\} \cap \mathbb{R} & \text{if } \xi > 0. \end{cases}$$

The infimal convolution of two functions $f, g\colon \mathcal{H} \to \left]-\infty,+\infty\right]$ is denoted by $f \,\square\, g$. Finally, an operator $R\colon \mathcal{H} \to \mathcal{H}$ is nonexpansive if $(\forall (x,y) \in \mathcal{H}^2)\ \|Rx - Ry\| \leq \|x - y\|$ and firmly nonexpansive if $(\forall (x,y) \in \mathcal{H}^2)\ \|Rx - Ry\|^2 \leq \langle x - y \mid Rx - Ry\rangle$.

Proximity operators (sometimes called "proximal mappings") were introduced by Moreau [30] and their use in signal theory goes back to [11] (see also [8, 16] for recent developments). We briefly recall some essential facts below and refer the reader to [16] and [31] for more details. Let $f \in \Gamma_0(\mathcal{H})$. The proximity operator of f is the operator $\operatorname{prox}_f\colon \mathcal{H} \to \mathcal{H}$ which maps every $x \in \mathcal{H}$ to the unique minimizer of the function $y \mapsto f(y) + \|x - y\|^2/2$. It is characterized by

$$(\forall x \in \mathcal{H})(\forall p \in \mathcal{H}) \quad p = \operatorname{prox}_f x \quad \Leftrightarrow \quad x - p \in \partial f(p). \tag{2.4}$$

LEMMA 2.2. *Let $f \in \Gamma_0(\mathcal{H})$. Then the following hold:*
(i) $(\forall x \in \mathcal{H})\ \big[\, x \in \operatorname{Argmin} f \Leftrightarrow 0 \in \partial f(x) \Leftrightarrow \operatorname{prox}_f x = x \,\big]$.
(ii) $\operatorname{prox}_{f^*} = \operatorname{Id} - \operatorname{prox}_f$.
(iii) prox_f *is firmly nonexpansive.*
(iv) *If f is even, then* prox_f *is odd.*

The next result provides a key decomposition property with respect to the orthonormal basis $(e_k)_{k\in\mathbb{N}}$.

LEMMA 2.3 (see [16, Example 2.19]). *Set*

$$f\colon \mathcal{H} \to \left]-\infty,+\infty\right] : x \mapsto \sum_{k\in\mathbb{N}} \phi_k(\langle x \mid e_k\rangle), \tag{2.5}$$

where $(\phi_k)_{k\in\mathbb{N}}$ are functions in $\Gamma_0(\mathbb{R})$ that satisfy $(\forall k \in \mathbb{N})\ \phi_k \geq \phi_k(0) = 0$. Then $f \in \Gamma_0(\mathcal{H})$ and $(\forall x \in \mathcal{H})\ \operatorname{prox}_f x = \sum_{k\in\mathbb{N}} \operatorname{prox}_{\phi_k}\langle x \mid e_k\rangle\, e_k$.

The remainder of this section is dedicated to proximity operators on the real line, the importance of which is underscored by Lemma 2.3.

PROPOSITION 2.4. *Let ϱ be a function defined from $\mathbb{R}$ to $\mathbb{R}$. Then ϱ is the proximity operator of a function in $\Gamma_0(\mathbb{R})$ if and only if it is nonexpansive and increasing.*

Proof. Let ξ and η be real numbers. First, suppose that $\varrho = \operatorname{prox}_\phi$, where $\phi \in \Gamma_0(\mathbb{R})$. Then it follows from Lemma 2.2(iii) that ϱ is nonexpansive and that $0 \leq |\varrho(\xi) - \varrho(\eta)|^2 \leq (\xi-\eta)(\varrho(\xi)-\varrho(\eta))$, which shows that ϱ is increasing since $\xi-\eta$ and $\varrho(\xi)-\varrho(\eta)$ have the same sign. Conversely, suppose that ϱ is nonexpansive and increasing and, without loss of generality, that $\xi \leq \eta$. Then, $0 \leq \varrho(\xi)-\varrho(\eta) \leq \xi-\eta$ and therefore $|\varrho(\xi)-\varrho(\eta)|^2 \leq (\xi-\eta)(\varrho(\xi)-\varrho(\eta))$. Thus, ϱ is firmly nonexpansive. However, every firmly nonexpansive operator $R\colon \mathcal{H} \to \mathcal{H}$ is of the form $R = (\operatorname{Id} + A)^{-1}$, where $A\colon \mathcal{H} \to 2^{\mathcal{H}}$ is a maximal monotone operator [6]. Since the only maximal monotone operators in $\mathbb{R}$ are subdifferentials of functions in $\Gamma_0(\mathbb{R})$ [32, section 24], we must have $\varrho = (\operatorname{Id} + \partial\phi)^{-1} = \operatorname{prox}_\phi$ for some $\phi \in \Gamma_0(\mathbb{R})$. ∎

COROLLARY 2.5. *Suppose that 0 is a minimizer of $\phi \in \Gamma_0(\mathbb{R})$. Then*

$$(\forall \xi \in \mathbb{R}) \quad \begin{cases} 0 \leq \operatorname{prox}_\phi \xi \leq \xi & \text{if } \xi > 0, \\ \operatorname{prox}_\phi \xi = 0 & \text{if } \xi = 0, \\ \xi \leq \operatorname{prox}_\phi \xi \leq 0 & \text{if } \xi < 0. \end{cases} \tag{2.6}$$

This is true, in particular, when ϕ is even, in which case prox_ϕ *is an odd operator.*

Proof. Since $0 \in \operatorname{Argmin}\phi$, Lemma 2.2(i) yields $\operatorname{prox}_\phi 0 = 0$. In turn, since prox_ϕ is nonexpansive by Lemma 2.2(iii), we have $(\forall \xi \in \mathbb{R})\ |\operatorname{prox}_\phi \xi| = |\operatorname{prox}_\phi \xi - \operatorname{prox}_\phi 0| \leq |\xi - 0| = |\xi|$. Altogether, since Proposition 2.4 asserts that prox_ϕ is increasing, we obtain (2.6). Finally, if ϕ is even, its convexity yields $(\forall \xi \in \operatorname{dom}\phi)$ $\phi(0) = \phi\big((\xi-\xi)/2\big) \leq \big(\phi(\xi)+\phi(-\xi)\big)/2 = \phi(\xi)$. Therefore $0 \in \operatorname{Argmin}\phi$, while the oddness of prox_ϕ follows from Lemma 2.2(iv). ∎

Let us now provide some elementary examples (Example 2.6 is illustrated in Figure 2.1 in the case when $\Omega = [-1,1]$).

Example 2.6. Let $\Omega \subset \mathbb{R}$ be a nonempty closed interval, let $\underline{\omega} = \inf\Omega$, let $\overline{\omega} = \sup\Omega$, and let $\xi \in \mathbb{R}$. Then the following hold:

(i) $\operatorname{prox}_{\iota_\Omega} \xi = P_\Omega \xi = \begin{cases} \underline{\omega} & \text{if } \xi < \underline{\omega}, \\ \xi & \text{if } \xi \in \Omega, \\ \overline{\omega} & \text{if } \xi > \overline{\omega}. \end{cases}$

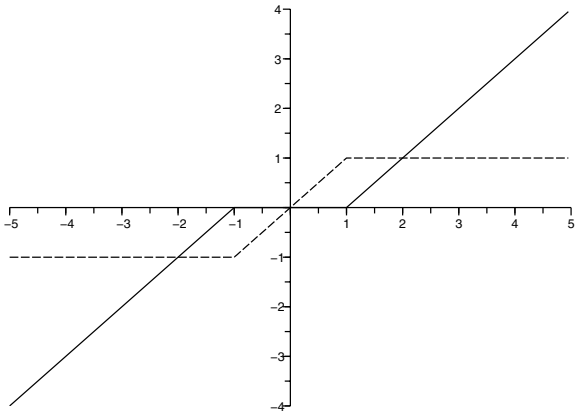

FIG. 2.1. *Graphs of* $\operatorname{prox}_{\phi} = \operatorname{soft}_{[-1,1]}$ *(solid line) and* $\operatorname{prox}_{\phi^*} = P_{[-1,1]}$ *(dashed line), where* $\phi = |\cdot|$ *and* $\phi^* = \iota_{[-1,1]}$ *(see Example* 2.6*).*

(ii) $\operatorname{prox}_{\sigma_\Omega}\xi = \operatorname{soft}_\Omega \xi$, where $\operatorname{soft}_\Omega$ is the soft thresholder defined in (1.11).

Proof. (i) is clear and, since $\sigma_\Omega^* = \iota_\Omega$, (ii) follows from (i) and Lemma 2.2(ii). □

Example 2.7 (see [8, Examples 4.2 and 4.4]). Let $p \in [1,+\infty[$, let $\omega \in]0,+\infty[$, let $\phi\colon \mathbb{R} \to \mathbb{R}\colon \eta \mapsto \omega|\eta|^p$, let $\xi \in \mathbb{R}$, and set $\pi = \operatorname{prox}_\phi \xi$. Then the following hold:

(i) $\pi = \operatorname{soft}_{[-\omega,\omega]}(\xi) = \operatorname{sign}(\xi)\max\{|\xi| - \omega, 0\}$ if $p = 1$;

(ii) $\pi = \xi + \dfrac{4\omega}{3\cdot 2^{1/3}}((\rho-\xi)^{1/3} - (\rho+\xi)^{1/3})$, where $\rho = \sqrt{\xi^2 + 256\omega^3/729}$ if $p = 4/3$;

(iii) $\pi = \xi + 9\omega^2 \operatorname{sign}(\xi)\big(1 - \sqrt{1 + 16|\xi|/(9\omega^2)}\,\big)/8$ if $p = 3/2$;

(iv) $\pi = \xi/(1+2\omega)$ if $p = 2$;

(v) $\pi = \operatorname{sign}(\xi)\big(\sqrt{1+12\omega|\xi|} - 1\big)/(6\omega)$ if $p = 3$;

(vi) $\pi = \big(\frac{\rho+\xi}{8\omega}\big)^{1/3} - \big(\frac{\rho-\xi}{8\omega}\big)^{1/3}$, where $\rho = \sqrt{\xi^2 + 1/(27\omega)}$ if $p = 4$.

Remark 2.8. The variational problem described in (1.3) is equivalent to minimizing over $\mathcal{H}$ the function $x \mapsto f(x) + \|z - x\|^2/2$, where $f\colon \mathcal{H} \to]-\infty,+\infty] : x \mapsto \sum_{k\in\mathbb{N}} \omega_k |\langle x \mid e_k\rangle|$. In view of Lemma 2.3 and Example 2.7(i), its solution is $\operatorname{prox}_f z = \sum_{k\in\mathbb{N}} \operatorname{soft}_{[-\omega_k,\omega_k]}(\langle z \mid e_k\rangle)e_k$, as displayed in (1.1).

PROPOSITION 2.9. *Let* ψ *be a function in* $\Gamma_0(\mathbb{R})$*, and let* ρ *and* θ *be real numbers in* $]0,+\infty[$ *such that*

(i) $\psi \geq \psi(0) = 0$,

(ii) ψ *is differentiable at* 0,

(iii) ψ *is twice differentiable on* $[-\rho,\rho] \smallsetminus \{0\}$ *and* $\inf_{0<|\xi|\leq\rho} \psi''(\xi) \geq \theta$.

Then $(\forall \xi \in [-\rho,\rho])(\forall \eta \in [-\rho,\rho])\ |\operatorname{prox}_\psi \xi - \operatorname{prox}_\psi \eta| \leq |\xi - \eta|/(1+\theta)$.

Proof. Set $R = [-\rho,\rho] \smallsetminus \{0\}$ and $\varphi\colon R \to \mathbb{R}\colon \zeta \mapsto \zeta + \psi'(\zeta)$. We first infer from (iii) that

$$(\forall \zeta \in R) \quad \varphi'(\zeta) = 1 + \psi''(\zeta) \geq 1 + \theta. \tag{2.7}$$

Moreover, (2.4) yields $(\forall \zeta \in R)\ \operatorname{prox}_\psi \zeta = \varphi^{-1}(\zeta)$. Note also that, in light of (2.4), (ii), and (i), we have $(\forall \zeta \in \mathbb{R})\ \operatorname{prox}_\psi \zeta = 0 \Leftrightarrow \zeta \in \partial\psi(0) = \{\psi'(0)\} = \{0\}$. Hence,

prox_ψ vanishes only at 0 and we derive from Lemma 2.2(iii) that

$$(\forall \zeta \in R) \quad 0 < |\varphi^{-1}(\zeta)| = |\operatorname{prox}_\psi \zeta - \operatorname{prox}_\psi 0| \leq |\zeta - 0| \leq \rho. \tag{2.8}$$

In turn, we deduce from (2.7) that

$$\sup_{\zeta \in R} \operatorname{prox}'_\psi \zeta = \frac{1}{\inf_{\zeta \in R} \varphi'\big(\varphi^{-1}(\zeta)\big)} \leq \frac{1}{\inf_{\zeta \in R} \varphi'(\zeta)} \leq \frac{1}{1+\theta}. \tag{2.9}$$

Now fix ξ and η in R. First, let us assume that either $\xi < \eta < 0$ or $0 < \xi < \eta$. Then, since prox_ψ is increasing by Proposition 2.4, it follows from the mean value theorem and (2.9) that there exists $\mu \in]\xi, \eta[$ such that

$$0 \leq \operatorname{prox}_\psi \eta - \operatorname{prox}_\psi \xi = (\eta - \xi) \operatorname{prox}'_\psi \mu \leq (\eta - \xi) \sup_{\zeta \in R} \operatorname{prox}'_\psi \zeta \leq \frac{\eta - \xi}{1+\theta}. \tag{2.10}$$

Next, let us assume that $\xi < 0 < \eta$. Then the mean value theorem asserts that there exist $\mu \in]\xi, 0[$ and $\nu \in]0, \eta[$ such that

$$\operatorname{prox}_\psi 0 - \operatorname{prox}_\psi \xi = -\xi \operatorname{prox}'_\psi \mu \quad \text{and} \quad \operatorname{prox}_\psi \eta - \operatorname{prox}_\psi 0 = \eta \operatorname{prox}'_\psi \nu. \tag{2.11}$$

Since prox_ψ is increasing and $\operatorname{prox}_\psi 0 = 0$, we obtain

$$0 \leq \operatorname{prox}_\psi \eta - \operatorname{prox}_\psi \xi = \eta \operatorname{prox}'_\psi \nu - \xi \operatorname{prox}'_\psi \mu \leq (\eta - \xi) \sup_{\zeta \in R} \operatorname{prox}'_\psi \zeta \leq \frac{\eta - \xi}{1+\theta}. \tag{2.12}$$

Altogether, we have shown that, for every ξ and η in R, $|\operatorname{prox}_\psi \xi - \operatorname{prox}_\psi \eta| \leq |\xi - \eta|/(1+\theta)$. We conclude by observing that, due to the continuity of prox_ψ (Lemma 2.2(iii)), this inequality holds for every ξ and η in $[-\rho, \rho]$. □

3. Proximal thresholding. The standard soft thresholder of (1.2), which was extended to closed intervals in (1.11), was seen in Example 2.6(ii) to be a proximity operator. As such, it possesses attractive properties (see Lemma 2.2(i) and (iii)) that prove extremely useful in the convergence analysis of iterative methods [13]. This remark motivates the following definition.

DEFINITION 3.1. *Let $R\colon \mathcal{H} \to \mathcal{H}$, and let Ω be a nonempty closed convex subset of $\mathcal{H}$. Then R is a* proximal thresholder *on Ω if there exists a function $f \in \Gamma_0(\mathcal{H})$ such that*

$$R = \operatorname{prox}_f \quad \textit{and} \quad (\forall x \in \mathcal{H}) \;\; Rx = 0 \;\Leftrightarrow\; x \in \Omega. \tag{3.1}$$

The next proposition provides characterizations of proximal thresholders.

PROPOSITION 3.2. *Let $f \in \Gamma_0(\mathcal{H})$, and let Ω be a nonempty closed convex subset of $\mathcal{H}$. Then the following are equivalent:*

(i) prox_f *is a proximal thresholder on Ω.*
(ii) $\partial f(0) = \Omega$.
(iii) $(\forall x \in \mathcal{H}) \; \big[\operatorname{prox}_{f^*} x = x \Leftrightarrow x \in \Omega \big]$.
(iv) $\operatorname{Argmin} f^* = \Omega$.

In particular, (i)–(iv) *hold when*

(v) $f = g + \sigma_\Omega$, *where $g \in \Gamma_0(\mathcal{H})$ is Gâteaux differentiable at 0 and $\nabla g(0) = 0$.*

Proof. (i)⇔(ii): Fix $x \in \mathcal{H}$. Then it follows from (2.4) that $\big[\operatorname{prox}_f x = 0 \Leftrightarrow x \in \Omega\big] \Leftrightarrow \big[x \in \partial f(0) \Leftrightarrow x \in \Omega\big] \Leftrightarrow \partial f(0) = \Omega$. (i)⇔(iii): Fix $x \in \mathcal{H}$. Then it follows from Lemma 2.2(ii) that $\big[\operatorname{prox}_f x = 0 \Leftrightarrow x \in \Omega\big] \Leftrightarrow \big[x - \operatorname{prox}_{f^*} x = 0 \Leftrightarrow x \in \Omega\big]$. (iii)⇔(iv): Since $f \in \Gamma_0(\mathcal{H})$, $f^* \in \Gamma_0(\mathcal{H})$, and we can apply Lemma 2.2(i) to f^*. (v)⇒(ii): Since (v) implies that $0 \in \operatorname{core} \operatorname{dom} g$, we have $0 \in (\operatorname{core} \operatorname{dom} g) \cap \operatorname{dom} \sigma_\Omega$, and it follows from [41, Theorem 2.8.3] that

$$\partial f(0) = \partial(g + \sigma_\Omega)(0) = \partial g(0) + \partial \sigma_\Omega(0) = \partial g(0) + \Omega, \tag{3.2}$$

where the last equality results from the observation that, for every $u \in \mathcal{H}$, Fenchel's identity yields $u \in \partial\sigma_\Omega(0) \Leftrightarrow 0 = \langle 0 \mid u\rangle = \sigma_\Omega(0) + \sigma_\Omega^*(u) \Leftrightarrow 0 = \sigma_\Omega^*(u) = \iota_\Omega(u) \Leftrightarrow u \in \Omega$. However, since $\partial g(0) = \{\nabla g(0)\} = \{0\}$, we obtain $\partial f(0) = \Omega$, and (ii) is therefore satisfied. □

The following theorem is a significant refinement of a result of Proposition 3.2 in the case when $\mathcal{H} = \mathbb{R}$ that characterizes all the functions $\phi \in \Gamma_0(\mathbb{R})$ for which prox_ϕ is a proximal thresholder.

THEOREM 3.3. *Let $\phi \in \Gamma_0(\mathbb{R})$ and let $\Omega \subset \mathbb{R}$ be a nonempty closed interval. Then the following are equivalent:*

(i) prox_ϕ *is a proximal thresholder on* Ω.

(ii) $\phi = \psi + \sigma_\Omega$, *where* $\psi \in \Gamma_0(\mathbb{R})$ *is differentiable at* 0 *and* $\psi'(0) = 0$.

Proof. In view of Proposition 3.2, it is enough to show that $\partial\phi(0) = \Omega \Rightarrow$ (ii). So let us assume that $\partial\phi(0) = \Omega$, and set $\underline{\omega} = \inf \Omega$ and $\overline{\omega} = \sup \Omega$. Since $\partial\phi(0) \neq \varnothing$, we deduce from (2.3) that $0 \in \operatorname{dom}\phi$ and that

$$(\forall \xi \in \mathbb{R}) \quad \sigma_\Omega(\xi) = \sup_{\nu \in \Omega} (\xi - 0)\nu \leq \phi(\xi) - \phi(0). \tag{3.3}$$

Consequently,

$$\operatorname{dom}\phi \subset \operatorname{dom}\sigma_\Omega. \tag{3.4}$$

Thus, in the case when $\Omega = \mathbb{R}$, Example 2.1(i) yields $\operatorname{dom}\phi = \operatorname{dom}\sigma_\Omega = \{0\}$ and we obtain $\phi = \phi(0) + \iota_{\{0\}} = \phi(0) + \sigma_\Omega$, hence (ii) with $\psi \equiv \phi(0)$. We henceforth assume that $\Omega \neq \mathbb{R}$ and set

$$(\forall \xi \in \mathbb{R}) \quad \varphi(\xi) = \begin{cases} \phi(\xi) - \phi(0) - \overline{\omega}\,\xi & \text{if } \xi > 0 \text{ and } \overline{\omega} < +\infty, \\ \phi(\xi) - \phi(0) - \underline{\omega}\,\xi & \text{if } \xi < 0 \text{ and } \underline{\omega} > -\infty, \\ 0 & \text{otherwise.} \end{cases} \tag{3.5}$$

Then Example 2.1(i) and (3.3) yield

$$\varphi \geq 0 = \varphi(0), \tag{3.6}$$

which also shows that φ is proper. In addition, we derive from Example 2.1(i) and (3.5) the following three possible expressions for φ:

(a) If $\underline{\omega} > -\infty$ and $\overline{\omega} < +\infty$, then σ_Ω is a finite continuous function and

$$(\forall \xi \in \mathbb{R}) \quad \varphi(\xi) = \phi(\xi) - \phi(0) - \sigma_\Omega(\xi). \tag{3.7}$$

(b) If $\underline{\omega} = -\infty$ and $\overline{\omega} < +\infty$, then

$$(\forall \xi \in \mathbb{R}) \quad \varphi(\xi) = \begin{cases} \phi(\xi) - \phi(0) - \overline{\omega}\,\xi & \text{if } \xi > 0, \\ 0 & \text{otherwise.} \end{cases} \tag{3.8}$$

(c) If $\underline{\omega} > -\infty$ and $\overline{\omega} = +\infty$, then

$$(\forall \xi \in \mathbb{R}) \quad \varphi(\xi) = \begin{cases} \phi(\xi) - \phi(0) - \underline{\omega}\,\xi & \text{if } \xi < 0 \\ 0 & \text{otherwise.} \end{cases} \tag{3.9}$$

Let us show that φ is lower semicontinuous. In case (a), this follows at once from the lower semicontinuity of ϕ and the continuity of σ_Ω. In cases (b) and (c), φ is clearly lower semicontinuous at every point $\xi \neq 0$ and, by (3.6), at 0 as well. Next, let us establish the convexity of φ. To this end, we set

$$(\forall \xi \in \mathbb{R}) \quad \overline{\varphi}(\xi) = \begin{cases} \phi(\xi) - \phi(0) - \overline{\omega}\,\xi & \text{if } \xi > 0 \text{ and } \overline{\omega} < +\infty, \\ 0 & \text{otherwise,} \end{cases} \tag{3.10}$$

and

$$(\forall \xi \in \mathbb{R}) \quad \underline{\varphi}(\xi) = \begin{cases} \phi(\xi) - \phi(0) - \underline{\omega}\,\xi & \text{if } \xi < 0 \text{ and } \underline{\omega} > -\infty, \\ 0 & \text{otherwise.} \end{cases} \tag{3.11}$$

By inspecting (3.5), (3.10), and (3.11) we learn that φ coincides with $\overline{\varphi}$ on $[0, +\infty[$ and with $\underline{\varphi}$ on $]-\infty, 0]$. Hence, (3.6) yields

$$\overline{\varphi} \geq 0 \quad \text{and} \quad \underline{\varphi} \geq 0, \tag{3.12}$$

and

$$\varphi = \max\{\underline{\varphi}, \overline{\varphi}\}. \tag{3.13}$$

Furthermore, since ϕ is convex, so are the functions $\xi \mapsto \phi(\xi) - \phi(0) - \overline{\omega}\,\xi$ and $\xi \mapsto \phi(\xi) - \phi(0) - \underline{\omega}\,\xi$, when $\overline{\omega} < +\infty$ and $\underline{\omega} > -\infty$, respectively. Therefore, it follows from (3.10), (3.11), and (3.12) that $\overline{\varphi}$ and $\underline{\varphi}$ are convex, and hence from (3.13) that φ is convex. We have thus shown that $\varphi \in \Gamma_0(\mathbb{R})$. We now claim that, for every $\xi \in \mathbb{R}$,

$$\phi(\xi) = \varphi(\xi) + \phi(0) + \sigma_\Omega(\xi). \tag{3.14}$$

We can establish this identity with the help of Example 2.1(i). In case (a), (3.14) follows at once from (3.7) since σ_Ω is finite. In case (b), (3.14) follows from (3.8) when $\xi \geq 0$, and from (3.3) when $\xi < 0$ since, in this case, $\sigma_\Omega(\xi) = +\infty$. Likewise, in case (c), (3.14) follows from (3.9) when $\xi \leq 0$, and from (3.3) when $\xi > 0$ since, in this case, $\sigma_\Omega(\xi) = +\infty$. Next, let us show that

$$0 \in \operatorname{int}(\operatorname{dom}\phi - \operatorname{dom}\sigma_\Omega). \tag{3.15}$$

In case (a), we have $\Omega = [\underline{\omega}, \overline{\omega}]$. Therefore, $\operatorname{dom}\sigma_\Omega = \mathbb{R}$ and (3.15) trivially holds. In case (b), we have $\Omega =]-\infty, \overline{\omega}]$ and, therefore, $\operatorname{dom}\sigma_\Omega = [0, +\infty[$. This implies, via (3.4), that $\operatorname{dom}\phi \subset [0, +\infty[$. Therefore, there exists $\nu \in \operatorname{dom}\phi \cap]0, +\infty[$ since otherwise we would have $\operatorname{dom}\phi = \{0\}$, which, in view of (2.3), would contradict the current working assumption that $\partial\phi(0) = \Omega \neq \mathbb{R}$. By convexity of ϕ, it follows that $[0, \nu] \subset \operatorname{dom}\phi$ and, therefore, that $]-\infty, \nu] \subset \operatorname{dom}\phi - \operatorname{dom}\sigma_\Omega$. We thus obtain (3.15) in case (b); case (c) can be handled analogously. We can now appeal to [32, Theorem 23.8] to derive from (3.14), (3.15), and Example 2.1(ii) that

$$\Omega = \partial\phi(0) = \partial\varphi(0) + \partial\sigma_\Omega(0) = \partial\varphi(0) + \Omega. \tag{3.16}$$

Now fix $\nu \in \partial\varphi(0)$. Then (3.16) yields $\nu + \Omega \subset \Omega$. There are three possible cases to study.

- In case (a), $\nu+\Omega\subset\Omega\Leftrightarrow[\nu+\underline{\omega},\nu+\overline{\omega}]\subset[\underline{\omega},\overline{\omega}]\Rightarrow\nu=0$.
- In case (b), $\nu+\Omega\subset\Omega\Leftrightarrow\,]-\infty,\nu+\overline{\omega}]\subset\,]-\infty,\overline{\omega}]\Rightarrow\nu\leq 0$. On the other hand, it follows from (2.3) and (3.8) that $(\forall\xi\in\,]-\infty,0[)\ \xi\nu\leq\varphi(\xi)=0$, hence $\nu\geq 0$. Altogether, $\nu=0$.
- In case (c), $\nu+\Omega\subset\Omega\Leftrightarrow[\nu+\underline{\omega},+\infty[\,\subset[\underline{\omega},+\infty[\,\Rightarrow\nu\geq 0$. Since (2.3) and (3.9) imply that $(\forall\xi\in\,]0,+\infty[)\ \xi\nu\leq\varphi(\xi)=0$, we obtain $\nu\leq 0$ and conclude that $\nu=0$.

We have thus shown in all cases that $\nu=0$ and, therefore, that $\partial\varphi(0)=\{0\}$. In turn, upon invoking [32, Theorem 25.1], we conclude that φ is differentiable at 0 and that $\varphi'(0)=0$. Altogether, we obtain (ii) by setting $\psi=\varphi+\phi(0)$. □

Remark 3.4. A standard requirement for thresholders on $\mathbb{R}$ is that they be increasing functions [1, 33, 34, 39]. On the other hand, nonexpansivity is a key property to establish the convergence of iterative methods [13] and, in particular, in Proposition 1.1 [18] and Proposition 1.2 [16]. As seen in Proposition 2.4 and Definition 3.1, the increasing and nonexpansive functions $\varrho\colon\mathbb{R}\to\mathbb{R}$ that vanish only on a closed interval $\Omega\subset\mathbb{R}$ coincide with the proximal thresholders on Ω. Hence, appealing to Theorem 3.3 and Lemma 2.3, we conclude that the operators that perform a componentwise increasing and nonexpansive thresholding on $(\Omega_k)_{k\in\mathbb{K}}$ of those coefficients of the decomposition in $(e_k)_{k\in\mathbb{N}}$ indexed by $\mathbb{K}$ are precisely the operators of the form prox_Ψ, where Ψ is as in (1.9).

Example 3.5. Let $\omega\in\,]0,+\infty[$ and set

$$\phi\colon\mathbb{R}\to\,]-\infty,+\infty]:\xi\mapsto\begin{cases}\ln(\omega)-\ln(\omega-|\xi|) & \text{if } |\xi|<\omega,\\ +\infty & \text{otherwise.}\end{cases}\tag{3.17}$$

The proximity operator associated with this function arises in certain Bayesian formulations involving the triangular probability density function with support $[-\omega,\omega]$ [8]. Let us set

$$\psi\colon\mathbb{R}\to\,]-\infty,+\infty]:\xi\mapsto\begin{cases}\ln(\omega)-\ln(\omega-|\xi|)-|\xi|/\omega & \text{if } |\xi|<\omega,\\ +\infty & \text{otherwise}\end{cases}\tag{3.18}$$

and $\Omega=[-1/\omega,1/\omega]$. Then $\psi\in\Gamma_0(\mathbb{R})$ is differentiable at 0, $\psi'(0)=0$, and $\phi=\psi+\sigma_\Omega$. Therefore, Theorem 3.3 asserts that prox_ϕ is a proximal thresholder on $[-1/\omega,1/\omega]$. Actually (see Figure 3.1), for every $\xi\in\mathbb{R}$, we have [8, Example 4.12]

$$\operatorname{prox}_\phi\xi=\begin{cases}\operatorname{sign}(\xi)\,\dfrac{|\xi|+\omega-\sqrt{\big||\xi|-\omega\big|^2+4}}{2} & \text{if } |\xi|>1/\omega,\\ 0 & \text{otherwise.}\end{cases}\tag{3.19}$$

Next, we provide a convenient decomposition rule for implementing proximal thresholders.

PROPOSITION 3.6. *Let $\phi=\psi+\sigma_\Omega$, where $\psi\in\Gamma_0(\mathbb{R})$ and $\Omega\subset\mathbb{R}$ is a nonempty closed interval. Suppose that ψ is differentiable at 0 with $\psi'(0)=0$. Then* $\operatorname{prox}_\phi=\operatorname{prox}_\psi\circ\operatorname{soft}_\Omega$.

Proof. Fix ξ and π in $\mathbb{R}$. We have $0\in\operatorname{dom}\sigma_\Omega$ and, since ψ is differentiable at 0, $0\in\operatorname{int}\operatorname{dom}\psi$. It therefore follows from (2.4) and [32, Theorem 23.8] that

$$\begin{aligned}\pi=\operatorname{prox}_\phi\xi&\Leftrightarrow\xi-\pi\in\partial\phi(\pi)=\partial\psi(\pi)+\partial\sigma_\Omega(\pi)\\ &\Leftrightarrow(\exists\,\nu\in\partial\psi(\pi))\quad\xi-(\pi+\nu)\in\partial\sigma_\Omega(\pi).\end{aligned}\tag{3.20}$$

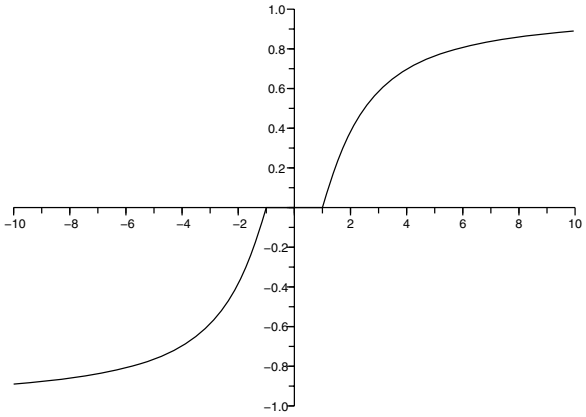

FIG. 3.1. *Graph of* prox_{ϕ}*, where* ϕ *is as in* (3.17) *with* $\omega = 1$.

Let us observe that, if $\nu \in \partial\psi(\pi)$, then, since $0 \in \operatorname{Argmin}\psi$, (2.3) implies that $(0-\pi)\nu + \psi(\pi) \leq \psi(0) \leq \psi(\pi) < +\infty$ and, in turn, that $\pi\nu \geq 0$. This shows that, if $\nu \in \partial\psi(\pi)$ and $\pi \neq 0$, then either $\pi > 0$ and $\nu \geq 0$, or $\pi < 0$ and $\nu \leq 0$; in turn, Lemma 2.1(ii) yields $\partial\sigma_{\Omega}(\pi) = \partial\sigma_{\Omega}(\pi+\nu)$. Consequently, if $\pi \neq 0$, we derive from (3.20) and Example 2.6(ii) that

$$\begin{aligned}
\pi = \mathrm{prox}_{\phi}\,\xi \Rightarrow (\exists\,\nu \in \partial\psi(\pi)) \quad & \xi - (\pi+\nu) \in \partial\sigma_{\Omega}(\pi+\nu) \\
\Leftrightarrow (\exists\,\nu \in \partial\psi(\pi)) \quad & \pi + \nu = \mathrm{prox}_{\sigma_{\Omega}}\,\xi = \mathrm{soft}_{\Omega}\,\xi \\
\Leftrightarrow\ & \mathrm{soft}_{\Omega}\,\xi - \pi \in \partial\psi(\pi) \\
\Leftrightarrow\ & \pi = \mathrm{prox}_{\psi}\big(\mathrm{soft}_{\Omega}\,\xi\big).
\end{aligned} \tag{3.21}$$

On the other hand, if $\pi = 0$, since $\partial\psi(0) = \{\psi'(0)\} = \{0\}$, then we derive from (3.20), Example 2.1(ii), (1.11), and Lemma 2.2(i) that

$$\pi = \mathrm{prox}_{\phi}\,\xi \Rightarrow \xi \in \partial\sigma_{\Omega}(0) = \Omega \Rightarrow \mathrm{soft}_{\Omega}\,\xi = 0 \Rightarrow \mathrm{prox}_{\psi}\big(\mathrm{soft}_{\Omega}\,\xi\big) = 0 = \pi. \tag{3.22}$$

The proof is now complete. □

In view of Proposition 3.6 and (1.11), the computation of the proximal thresholder $\mathrm{prox}_{\psi+\sigma_{\Omega}}$ reduces to that of prox_{ψ}. By duality, we obtain a decomposition formula for those proximal operators that coincide with the identity on a closed interval Ω.

PROPOSITION 3.7. *Let* $\phi = \psi \,\square\, \iota_{\Omega}$*, where* $\psi \in \Gamma_0(\mathbb{R})$ *and* $\Omega \subset \mathbb{R}$ *is a nonempty closed interval. Suppose that* ψ^* *is differentiable at* 0 *with* $\psi^{*\prime}(0) = 0$*. Then the following hold.*

(i) $\mathrm{prox}_{\phi} = P_{\Omega} + \mathrm{prox}_{\psi} \circ \mathrm{soft}_{\Omega}$.
(ii) $(\forall \xi \in \mathbb{R})\ \mathrm{prox}_{\phi}\,\xi = \xi \Leftrightarrow \xi \in \Omega$.

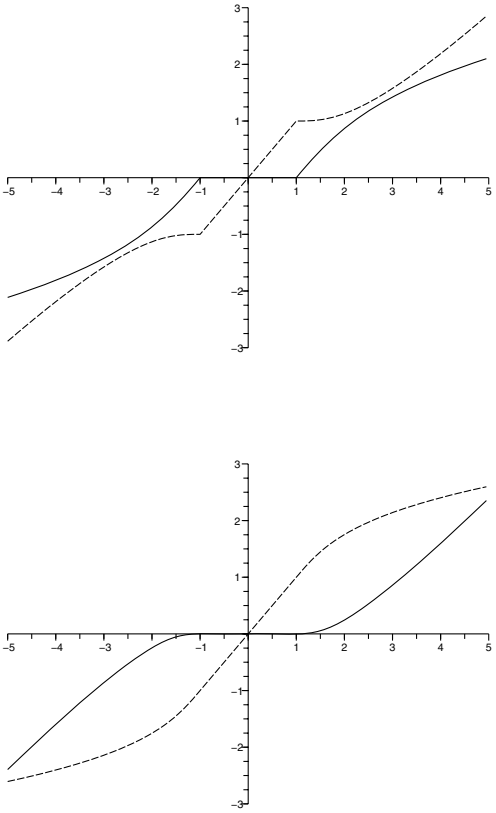

FIG. 3.2. *Graphs of the proximal thresholder* prox_ϕ *(solid line) and its dual* $\operatorname{prox}_{\phi^*}$ *(dashed line), where* $\phi = \tau|\cdot|^p + |\cdot|$. *Top:* $\tau = 0.05$ *and* $p = 4$. *Bottom:* $\tau = 0.9$ *and* $p = 4/3$. *Explicit expressions for these thresholders are provided by Example* 2.7(ii) *and* (vi), *Proposition* 3.6, *and Lemma* 2.2(ii).

Proof. It follows from [32, Theorem 16.4] that

$$\phi^* = \psi^* + \iota_\Omega^* = \psi^* + \sigma_\Omega. \tag{3.23}$$

Note also that, since $\psi \in \Gamma_0(\mathbb{R})$, we have $\psi^* \in \Gamma_0(\mathbb{R})$ [32, Theorem 12.2]. (i) Fix $\xi \in \mathbb{R}$. Then, by Lemma 2.2(ii), (3.23), Proposition 3.6, and Example 2.6,

$$\begin{aligned}
\operatorname{prox}_\phi \xi &= \xi - \operatorname{prox}_{\phi^*} \xi \\
&= \xi - \operatorname{prox}_{\psi^*+\sigma_\Omega} \xi \\
&= \xi - \operatorname{prox}_{\psi^*} \big(\operatorname{prox}_{\sigma_\Omega} \xi\big) \\
&= \xi - \operatorname{prox}_{\sigma_\Omega} \xi + \operatorname{prox}_{\psi} \big(\operatorname{prox}_{\sigma_\Omega} \xi\big) \\
&= \operatorname{prox}_{\sigma_\Omega^*} \xi + \operatorname{prox}_{\psi} \big(\operatorname{prox}_{\sigma_\Omega} \xi\big) \\
&= \operatorname{prox}_{\iota_\Omega} \xi + \operatorname{prox}_{\psi} \big(\operatorname{prox}_{\sigma_\Omega} \xi\big) \qquad (3.24) \\
&= P_\Omega \xi + \operatorname{prox}_{\psi} \big(\operatorname{soft}_\Omega \xi\big). \qquad (3.25)
\end{aligned}$$

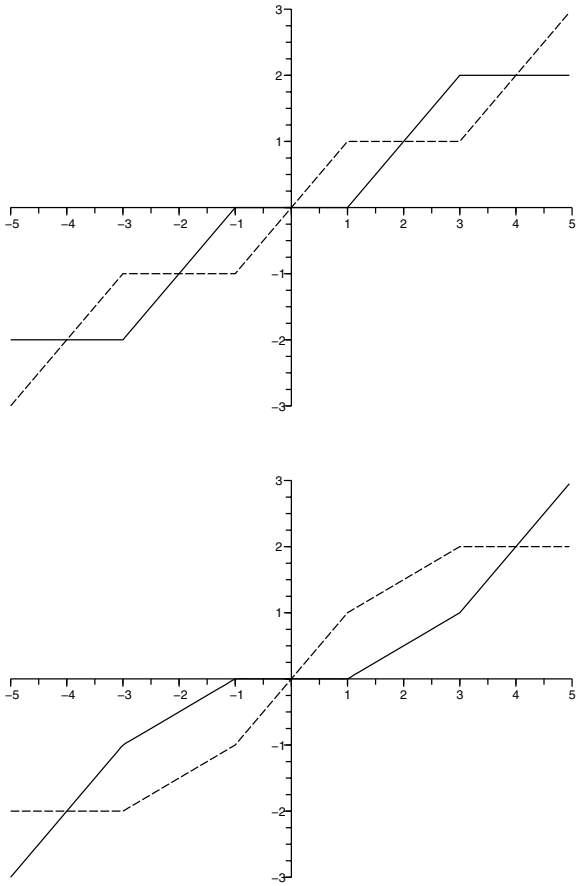

FIG. 3.3. *Graphs of the proximal thresholder* prox_ϕ *(solid line) and its dual* $\operatorname{prox}_{\phi^*}$ *(dashed line), where* $\phi = \psi + |\cdot|$. *Top:* $\psi = \iota_{[-2,2]}$. *Bottom:* $\psi\colon \xi \mapsto \xi^2/2$, *if* $|\xi| \leq 1; |\xi| - 1/2$, *if* $|\xi| > 1$ *is the Huber function* [27]. *The closed-form expressions of these thresholders are obtained via* [8, Example 4.5], *Proposition* 3.6, *and Lemma* 2.2(ii).

(ii): It follows from (3.23) and Theorem 3.3 that $\operatorname{prox}_{\phi^*}$ is a proximal thresholder on Ω. Hence, we derive from (3.24) and (3.1) that $(\forall \xi \in \mathbb{R})\ \operatorname{prox}_\phi \xi = \xi \Leftrightarrow \operatorname{prox}_{\phi^*} \xi = 0 \Leftrightarrow \xi \in \Omega$. □

Examples of proximal thresholders (see Proposition 3.6) and their duals (see Proposition 3.7) are provided in Figures 3.2 and 3.3 (see also Figure 2.1) in the case when $\Omega = [-1, 1]$.

4. Iterative proximal thresholding. Let us start with some basic properties of Problem 1.3.

PROPOSITION 4.1. *Problem* 1.3 *possesses at least one solution.*

Proof. Let Ψ be as in (1.9). We infer from the assumptions of Problem 1.3 and Lemma 2.3 that $\Psi \in \Gamma_0(\mathcal{H})$ and, in turn, that $\Phi + \Psi \in \Gamma_0(\mathcal{H})$. Hence, it suffices to show that $\Phi + \Psi$ is coercive [41, Theorem 2.5.1(ii)], i.e., since $\inf \Phi(\mathcal{H}) > -\infty$ by

assumption (i) in Problem 1.3, that Ψ is coercive. For this purpose, let $\mathsf{x} = (\xi_k)_{k\in\mathbb{N}}$ denote a generic element in $\ell^2(\mathbb{N})$, and let

$$\Upsilon\colon \ell^2(\mathbb{N}) \to \left]-\infty,+\infty\right] : \mathsf{x} \mapsto \sum_{k\in\mathbb{N}} \psi_k(\xi_k) + \sum_{k\in\mathbb{K}} \sigma_{\Omega_k}(\xi_k). \tag{4.1}$$

Then, by Parseval's identity, it is enough to show that Υ is coercive. To this end, set $\mathsf{x}_{\mathbb{K}} = (\xi_k)_{k\in\mathbb{K}}$ and $\mathsf{x}_{\mathbb{L}} = (\xi_k)_{k\in\mathbb{L}}$, and denote by $\|\cdot\|_{\mathbb{K}}$ and $\|\cdot\|_{\mathbb{L}}$ the standard norms on $\ell^2(\mathbb{K})$ and $\ell^2(\mathbb{L})$, respectively. Using (4.1), assumptions (ii) and (vi) in Problem 1.3, and Example 2.1(i), we obtain

$$\begin{aligned}(\forall\, \mathsf{x} \in \ell^2(\mathbb{N}))\quad \Upsilon(\mathsf{x}) &\geq \sum_{k\in\mathbb{K}} \sigma_{\Omega_k}(\xi_k) + \sum_{k\in\mathbb{L}} \psi_k(\xi_k)\\ &\geq \omega \sum_{k\in\mathbb{K}} |\xi_k| + \Upsilon_{\mathbb{L}}(\mathsf{x}_{\mathbb{L}})\\ &\geq \omega\|\mathsf{x}_{\mathbb{K}}\|_{\mathbb{K}} + \Upsilon_{\mathbb{L}}(\mathsf{x}_{\mathbb{L}}),\end{aligned} \tag{4.2}$$

where $\Upsilon_{\mathbb{L}}$ is defined in Problem 1.3(v). Now suppose that $\|\mathsf{x}\| = \sqrt{\|\mathsf{x}_{\mathbb{K}}\|_{\mathbb{K}}^2 + \|\mathsf{x}_{\mathbb{L}}\|_{\mathbb{L}}^2} \to +\infty$. Then (4.2) and assumption (v) in Problem 1.3 yield $\Upsilon(\mathsf{x}) \to +\infty$, as desired. ∎

PROPOSITION 4.2. *Let Ψ be as in (1.9), let $x \in \mathcal{H}$, and let $\gamma \in \left]0,+\infty\right[$. Then x is a solution to Problem 1.3 if and only if $x = \operatorname{prox}_{\gamma\Psi}(x - \gamma\nabla\Phi(x))$.*

Proof. Since Problem 1.3 is equivalent to minimizing $\Phi + \Psi$, this identity is a standard characterization; see, for instance, [16, Proposition 3.1(iii)]. ∎

Our algorithm for solving Problem 1.3 will be the following.

ALGORITHM 4.3. *Fix $x_0 \in \mathcal{H}$ and set, for every $n \in \mathbb{N}$,*

$$\begin{aligned}x_{n+1} = x_n + \lambda_n \Bigg(&\sum_{k\in\mathbb{K}} \Big(\alpha_{n,k} + \operatorname{prox}_{\gamma_n\psi_k}\big(\operatorname{soft}_{\gamma_n\Omega_k}\langle x_n - \gamma_n(\nabla\Phi(x_n) + b_n) \mid e_k\rangle\big)\Big)e_k\\ &+ \sum_{k\in\mathbb{L}} \Big(\alpha_{n,k} + \operatorname{prox}_{\gamma_n\psi_k}\langle x_n - \gamma_n(\nabla\Phi(x_n) + b_n) \mid e_k\rangle\Big)e_k - x_n\Bigg),\end{aligned} \tag{4.3}$$

where

(i) *$(\gamma_n)_{n\in\mathbb{N}}$ is a sequence in $\left]0,+\infty\right[$ such that $\inf_{n\in\mathbb{N}}\gamma_n > 0$ and $\sup_{n\in\mathbb{N}}\gamma_n < 2\beta$,*

(ii) *$(\lambda_n)_{n\in\mathbb{N}}$ is a sequence in $\left]0,1\right]$ such that $\inf_{n\in\mathbb{N}}\lambda_n > 0$,*

(iii) *for every $n \in \mathbb{N}$, $(\alpha_{n,k})_{k\in\mathbb{N}}$ is a sequence in $\ell^2(\mathbb{N})$ such that*

$$\sum_{n\in\mathbb{N}} \sqrt{\sum_{k\in\mathbb{N}} |\alpha_{n,k}|^2} < +\infty,$$

(iv) *$(b_n)_{n\in\mathbb{N}}$ is a sequence in $\mathcal{H}$ such that $\sum_{n\in\mathbb{N}}\|b_n\| < +\infty$.*

Remark 4.4. Let us highlight some features of Algorithm 4.3.

- The set $\mathbb{K}$ contains the indices of those coefficients of the decomposition in $(e_k)_{k\in\mathbb{N}}$ that are thresholded.
- The terms $\alpha_{n,k}$ and b_n stand for some numerical tolerance in the implementation of $\operatorname{prox}_{\gamma_n\psi_k}$ and the computation of $\nabla\Phi(x_n)$, respectively.
- The parameters λ_n and γ_n provide added flexibility to the algorithm and can be used to improve its convergence profile.

- The operator $\mathrm{soft}_{\gamma_n \Omega_k}$ is given explicitly in (1.11).

Our main convergence result can now be stated.

THEOREM 4.5. *Every sequence generated by Algorithm* 4.3 *converges strongly to a solution to Problem* 1.3.

Proof. Hereafter, $(x_n)_{n\in\mathbb{N}}$ is a sequence generated by Algorithm 4.3, and we define

$$(\forall k \in \mathbb{N}) \quad \phi_k = \begin{cases} \psi_k + \sigma_{\Omega_k} & \text{if } k \in \mathbb{K}, \\ \psi_k & \text{if } k \in \mathbb{L}. \end{cases} \tag{4.4}$$

It follows from the assumptions on $(\psi_k)_{k\in\mathbb{N}}$ in Problem 1.3 that $(\forall k \in \mathbb{N})\ \psi_k'(0) = 0$. Therefore, for every n in $\mathbb{N}$, Theorem 3.3 implies that

$$\text{for every } k \text{ in } \mathbb{K},\ \mathrm{prox}_{\gamma_n \phi_k} \text{ is a proximal thresholder on } \gamma_n \Omega_k, \tag{4.5}$$

while Proposition 3.6 supplies

$$(\forall k \in \mathbb{K}) \quad \mathrm{prox}_{\gamma_n \phi_k} = \mathrm{prox}_{\gamma_n \psi_k + \gamma_n \sigma_{\Omega_k}} = \mathrm{prox}_{\gamma_n \psi_k + \sigma_{(\gamma_n \Omega_k)}} = \mathrm{prox}_{\gamma_n \psi_k} \circ \mathrm{soft}_{\gamma_n \Omega_k}\,. \tag{4.6}$$

Thus, (4.3) can be rewritten as

$$x_{n+1} = x_n + \lambda_n \Bigg(\sum_{k\in\mathbb{N}} \big(\alpha_{n,k} + \mathrm{prox}_{\gamma_n \phi_k} \langle x_n - \gamma_n (\nabla \Phi(x_n) + b_n) \mid e_k \rangle\big) e_k - x_n \Bigg). \tag{4.7}$$

Now let Ψ be as in (1.9), i.e., $\Psi = \sum_{k\in\mathbb{N}} \phi_k(\langle \cdot \mid e_k \rangle)$, and set $(\forall n \in \mathbb{N})\ a_n = \sum_{k\in\mathbb{N}} \alpha_{n,k} e_k$. Then it follows from (4.4) and Lemma 2.3 that $\Psi \in \Gamma_0(\mathcal{H})$ and that (4.7) can be rewritten as

$$x_{n+1} = x_n + \lambda_n \Big(\mathrm{prox}_{\gamma_n \Psi} \big(x_n - \gamma_n (\nabla \Phi(x_n) + b_n)\big) + a_n - x_n \Big). \tag{4.8}$$

Consequently, since Proposition 4.1 asserts that $\Phi + \Psi$ possesses a minimizer, we derive from assumptions (i)–(iv) in Algorithm 4.3 and [16, Theorem 3.4] that

$$(x_n)_{n\in\mathbb{N}} \text{ converges weakly to a solution } x \text{ to Problem 1.3} \tag{4.9}$$

and that

$$\sum_{n\in\mathbb{N}} \|x_n - \mathrm{prox}_{\gamma_n \Psi} \big(x_n - \gamma_n \nabla \Phi(x_n)\big)\|^2 < +\infty \quad \text{and} \quad \sum_{n\in\mathbb{N}} \|\nabla \Phi(x_n) - \nabla \Phi(x)\|^2 < +\infty. \tag{4.10}$$

Hence, it follows from Lemma 2.2(iii) and assumption (i) in Algorithm 4.3 that

$$\begin{aligned}
(4.11)\quad & \frac{1}{2}\sum_{n\in\mathbb{N}} \|x_n - \operatorname{prox}_{\gamma_n\Psi}\big(x_n - \gamma_n\nabla\Phi(x)\big)\|^2 \\
&\leq \sum_{n\in\mathbb{N}} \|x_n - \operatorname{prox}_{\gamma_n\Psi}\big(x_n - \gamma_n\nabla\Phi(x_n)\big)\|^2 \\
&\quad + \sum_{n\in\mathbb{N}} \|\operatorname{prox}_{\gamma_n\Psi}\big(x_n - \gamma_n\nabla\Phi(x_n)\big) - \operatorname{prox}_{\gamma_n\Psi}\big(x_n - \gamma_n\nabla\Phi(x)\big)\|^2 \\
&\leq \sum_{n\in\mathbb{N}} \|x_n - \operatorname{prox}_{\gamma_n\Psi}\big(x_n - \gamma_n\nabla\Phi(x_n)\big)\|^2 + \sum_{n\in\mathbb{N}} \gamma_n^2\|\nabla\Phi(x_n) - \nabla\Phi(x)\|^2 \\
&\leq \sum_{n\in\mathbb{N}} \|x_n - \operatorname{prox}_{\gamma_n\Psi}\big(x_n - \gamma_n\nabla\Phi(x_n)\big)\|^2 + 4\beta^2\sum_{n\in\mathbb{N}} \|\nabla\Phi(x_n) - \nabla\Phi(x)\|^2 \\
&< +\infty.
\end{aligned}$$

Now define

$$(4.12)\qquad (\forall n\in\mathbb{N})\quad v_n = x_n - x \quad\text{and}\quad h_n = x - \gamma_n\nabla\Phi(x).$$

On the one hand, we derive from (4.9) that

$$(4.13)\qquad (v_n)_{n\in\mathbb{N}} \text{ converges weakly to } 0$$

and, on the other hand, we derive from (4.11) and Proposition 4.2 that

$$\begin{aligned}
\sum_{n\in\mathbb{N}} \|v_n - \operatorname{prox}_{\gamma_n\Psi}(v_n + h_n) + \operatorname{prox}_{\gamma_n\Psi} h_n\|^2 &= \sum_{n\in\mathbb{N}} \|x_n - \operatorname{prox}_{\gamma_n\Psi}\big(x_n - \gamma_n\nabla\Phi(x)\big)\|^2 \\
&< +\infty. \qquad (4.14)
\end{aligned}$$

By Parseval's identity, to establish that $\|v_n\| = \|x_n - x\| \to 0$, we must show that

$$(4.15)\qquad \sum_{k\in\mathbb{K}} |\nu_{n,k}|^2 \to 0 \quad\text{and}\quad \sum_{k\in\mathbb{L}} |\nu_{n,k}|^2 \to 0,$$

where $(\forall n\in\mathbb{N})(\forall k\in\mathbb{N})\ \nu_{n,k} = \langle v_n \mid e_k\rangle$. To this end, let us set, for every $n\in\mathbb{N}$ and $k\in\mathbb{N}$, $\eta_{n,k} = \langle h_n \mid e_k\rangle$ and observe that (4.14), Parseval's identity, and Lemma 2.3 imply that

$$(4.16)\qquad \sum_{k\in\mathbb{N}} |\nu_{n,k} - \operatorname{prox}_{\gamma_n\phi_k}(\nu_{n,k} + \eta_{n,k}) + \operatorname{prox}_{\gamma_n\phi_k}\eta_{n,k}|^2 \to 0.$$

In addition, let us set $r = 2\beta\nabla\Phi(x)$ and, for every $k\in\mathbb{N}$, $\xi_k = \langle x \mid e_k\rangle$ and $\rho_k = \langle r \mid e_k\rangle$. Then we derive from (4.12) and assumption (i) in Algorithm 4.3 that

$$(4.17)\qquad (\forall n\in\mathbb{N})(\forall k\in\mathbb{N})\quad |\eta_{n,k}|^2/2 \leq |\xi_k|^2 + \gamma_n^2\,|\langle\nabla\Phi(x) \mid e_k\rangle|^2 \leq |\xi_k|^2 + |\rho_k|^2.$$

To establish (4.15), let us first show that $\sum_{k\in\mathbb{K}} |\nu_{n,k}|^2 \to 0$. For this purpose, set $\delta = \gamma\omega$, where $\gamma = \inf_{n\in\mathbb{N}}\gamma_n$ and where ω is supplied by assumption (vi) in

Problem 1.3. Then it follows from assumption (i) in Algorithm 4.3 that $\delta > 0$ and that

$$[-\delta, \delta] \subset \bigcap_{n\in\mathbb{N}} \bigcap_{k\in\mathbb{K}} \gamma_n \Omega_k. \tag{4.18}$$

On the other hand, (4.17) yields

$$\sum_{k\in\mathbb{K}} \sup_{n\in\mathbb{N}} |\eta_{n,k}|^2/2 \leq \sum_{k\in\mathbb{N}} \big(|\xi_k|^2 + |\rho_k|^2\big) = \|x\|^2 + \|r\|^2 < +\infty. \tag{4.19}$$

Hence, there exists a finite set $\mathbb{K}_1 \subset \mathbb{K}$ such that

$$(\forall n \in \mathbb{N}) \quad \sum_{k\in\mathbb{K}_2} |\eta_{n,k}|^2 \leq \delta^2/4, \quad \text{where} \quad \mathbb{K}_2 = \mathbb{K} \smallsetminus \mathbb{K}_1. \tag{4.20}$$

In view of (4.13), we have $\sum_{k\in\mathbb{K}_1} |\nu_{n,k}|^2 \to 0$. Let us now show that $\sum_{k\in\mathbb{K}_2} |\nu_{n,k}|^2 \to 0$. Note that (4.18) and (4.20) yield

$$(\forall n \in \mathbb{N})(\forall k \in \mathbb{K}_2) \quad \eta_{n,k} \in [-\delta/2, \delta/2] \subset \gamma_n \Omega_k. \tag{4.21}$$

Therefore, (4.5) implies that

$$(\forall n \in \mathbb{N})(\forall k \in \mathbb{K}_2) \quad \operatorname{prox}_{\gamma_n \phi_k} \eta_{n,k} = 0. \tag{4.22}$$

Let us define

$$(\forall n \in \mathbb{N}) \quad \mathbb{K}_{21,n} = \big\{k \in \mathbb{K}_2 \;\big|\; \nu_{n,k} + \eta_{n,k} \in \gamma_n \Omega_k\big\}. \tag{4.23}$$

Then, invoking (4.5) once again, we obtain

$$(\forall n \in \mathbb{N})(\forall k \in \mathbb{K}_{21,n}) \quad \operatorname{prox}_{\gamma_n \phi_k}(\nu_{n,k} + \eta_{n,k}) = 0 \tag{4.24}$$

which, combined with (4.22), yields

$$\begin{aligned}(\forall n \in \mathbb{N}) \quad \sum_{k\in\mathbb{K}_{21,n}} |\nu_{n,k}|^2 &= \sum_{k\in\mathbb{K}_{21,n}} |\nu_{n,k} - \operatorname{prox}_{\gamma_n \phi_k}(\nu_{n,k} + \eta_{n,k}) + \operatorname{prox}_{\gamma_n \phi_k} \eta_{n,k}|^2 \\ &\leq \sum_{k\in\mathbb{N}} |\nu_{n,k} - \operatorname{prox}_{\gamma_n \phi_k}(\nu_{n,k} + \eta_{n,k}) + \operatorname{prox}_{\gamma_n \phi_k} \eta_{n,k}|^2. \end{aligned} \tag{4.25}$$

Consequently, it results from (4.16) that $\sum_{k\in\mathbb{K}_{21,n}} |\nu_{n,k}|^2 \to 0$. Next, let us set

$$(\forall n \in \mathbb{N}) \quad \mathbb{K}_{22,n} = \mathbb{K}_2 \smallsetminus \mathbb{K}_{21,n} \tag{4.26}$$

and show that $\sum_{k\in\mathbb{K}_{22,n}} |\nu_{n,k}|^2 \to 0$. It follows from (4.26), (4.23), and (4.18) that

$$(\forall n \in \mathbb{N})(\forall k \in \mathbb{K}_{22,n}) \quad \nu_{n,k} + \eta_{n,k} \notin \gamma_n \Omega_k \supset [-\delta, \delta]. \tag{4.27}$$

Hence, appealing to (4.21), we obtain

$$(\forall n \in \mathbb{N})(\forall k \in \mathbb{K}_{22,n}) \quad |\nu_{n,k} + \eta_{n,k}| \geq \delta \geq |\eta_{n,k}| + \delta/2. \tag{4.28}$$

Now take $n \in \mathbb{N}$ and $k \in \mathbb{K}_{22,n}$. We derive from (4.22) and Lemma 2.2(ii) that

$$\begin{aligned}(4.29)\quad &|\nu_{n,k} - \operatorname{prox}_{\gamma_n\phi_k}(\nu_{n,k}+\eta_{n,k}) + \operatorname{prox}_{\gamma_n\phi_k}\eta_{n,k}| \\ &\qquad = |(\nu_{n,k}+\eta_{n,k}) - \operatorname{prox}_{\gamma_n\phi_k}(\nu_{n,k}+\eta_{n,k}) - \eta_{n,k}| \\ &\qquad = |\operatorname{prox}_{(\gamma_n\phi_k)^*}(\nu_{n,k}+\eta_{n,k}) - \eta_{n,k}|.\end{aligned}$$

However, it results from (4.18), (4.5), and Proposition 3.2 that $\operatorname{prox}_{(\gamma_n\phi_k)^*}(\pm\delta) = \pm\delta$. We consider two cases. First, if $\nu_{n,k}+\eta_{n,k} \geq 0$, then, since $\operatorname{prox}_{(\gamma_n\phi_k)^*}$ is increasing by Proposition 2.4, (4.28) yields $\nu_{n,k}+\eta_{n,k} \geq \delta$ and

$$(4.30)\qquad \operatorname{prox}_{(\gamma_n\phi_k)^*}(\nu_{n,k}+\eta_{n,k}) \geq \operatorname{prox}_{(\gamma_n\phi_k)^*}\delta = \delta \geq \eta_{n,k} + \delta/2.$$

Likewise, if $\nu_{n,k}+\eta_{n,k} \leq 0$, then (4.28) yields $\nu_{n,k}+\eta_{n,k} \leq -\delta$ and

$$(4.31)\qquad \operatorname{prox}_{(\gamma_n\phi_k)^*}(\nu_{n,k}+\eta_{n,k}) \leq \operatorname{prox}_{(\gamma_n\phi_k)^*}(-\delta) = -\delta \leq \eta_{n,k} - \delta/2.$$

Altogether, we derive from (4.30) and (4.31) that

$$(4.32)\qquad (\forall n \in \mathbb{N})(\forall k \in \mathbb{K}_{22,n}) \quad |\operatorname{prox}_{(\gamma_n\phi_k)^*}(\nu_{n,k}+\eta_{n,k}) - \eta_{n,k}| \geq \delta/2.$$

In turn, (4.29) yields

$$(4.33)\qquad (\forall n \in \mathbb{N}) \quad \sum_{k\in\mathbb{K}_{22,n}} |\nu_{n,k} - \operatorname{prox}_{\gamma_n\phi_k}(\nu_{n,k}+\eta_{n,k}) + \operatorname{prox}_{\gamma_n\phi_k}\eta_{n,k}|^2 \geq \operatorname{card}(\mathbb{K}_{22,n})\delta^2/4.$$

However, it follows from (4.16) that, for n sufficiently large,

$$(4.34)\qquad \sum_{k\in\mathbb{N}} |\nu_{n,k} - \operatorname{prox}_{\gamma_n\phi_k}(\nu_{n,k}+\eta_{n,k}) + \operatorname{prox}_{\gamma_n\phi_k}\eta_{n,k}|^2 \leq \delta^2/5.$$

Thus, for n sufficiently large, $\mathbb{K}_{22,n} = \varnothing$. We conclude from this first part of the proof that $\sum_{k\in\mathbb{K}} |\nu_{n,k}|^2 \to 0$.

In order to obtain (4.15), we must now show that $\sum_{k\in\mathbb{L}} |\nu_{n,k}|^2 \to 0$. We infer from (4.13) that $(v_n)_{n\in\mathbb{N}}$ is bounded; hence

$$(4.35)\qquad \sup_{n\in\mathbb{N}} \sum_{k\in\mathbb{L}} |\nu_{n,k}|^2 \leq \sup_{n\in\mathbb{N}} \|v_n\|^2 \leq \rho^2/4$$

for some $\rho \in \left]0, +\infty\right[$. Now define

$$(4.36)\qquad \mathbb{L}_1 = \big\{k \in \mathbb{L} \;\big|\; (\exists\, n \in \mathbb{N}) \;\; |\eta_{n,k}| \geq \rho/2\big\}.$$

Then we derive from (4.17) that

$$(4.37)\qquad (\forall k \in \mathbb{L}_1)(\exists\, n \in \mathbb{N}) \quad |\xi_k|^2 + |\rho_k|^2 \geq |\eta_{n,k}|^2/2 \geq \rho^2/8.$$

Consequently, we have

$$(4.38)\qquad +\infty > \|x\|^2 + \|r\|^2 \geq \sum_{k\in\mathbb{L}_1} \big(|\xi_k|^2 + |\rho_k|^2\big) \geq (\operatorname{card}\mathbb{L}_1)\rho^2/8$$

and therefore $\operatorname{card}(\mathbb{L}_1) < +\infty$. In turn, it results from (4.13) that $\sum_{k\in\mathbb{L}_1} |\nu_{n,k}|^2 \to 0$. Hence, to obtain $\sum_{k\in\mathbb{L}} |\nu_{n,k}|^2 \to 0$, it remains to show that $\sum_{k\in\mathbb{L}_2} |\nu_{n,k}|^2 \to 0$, where $\mathbb{L}_2 = \mathbb{L} \smallsetminus \mathbb{L}_1$. In view of (4.36) and (4.35), we have

$$(\forall n \in \mathbb{N})(\forall k \in \mathbb{L}_2) \quad |\eta_{n,k}| < \rho/2 \quad \text{and} \quad |\nu_{n,k} + \eta_{n,k}| \leq |\nu_{n,k}| + |\eta_{n,k}| < \rho. \tag{4.39}$$

On the other hand, assumption (iv) in Problem 1.3 asserts that there exists $\theta \in]0, +\infty[$ such that

$$\inf_{n\in\mathbb{N}} \inf_{k\in\mathbb{L}_2} \inf_{0<|\xi|\leq\rho} (\gamma_n\psi_k)''(\xi) \geq \gamma \inf_{k\in\mathbb{L}_2} \inf_{0<|\xi|\leq\rho} \psi_k''(\xi) \geq \gamma\theta. \tag{4.40}$$

It therefore follows from assumptions (ii) and (iii) in Problem 1.3, Proposition 2.9, and (4.4) that

$$\begin{aligned}
(\forall n \in \mathbb{N})(\forall k \in \mathbb{L}_2) \quad |\nu_{n,k}| &\leq |\nu_{n,k} - \operatorname{prox}_{\gamma_n\psi_k}(\nu_{n,k} + \eta_{n,k}) + \operatorname{prox}_{\gamma_n\psi_k} \eta_{n,k}| \\
&\quad + |\operatorname{prox}_{\gamma_n\psi_k}(\nu_{n,k} + \eta_{n,k}) - \operatorname{prox}_{\gamma_n\psi_k} \eta_{n,k}| \\
&\leq |\nu_{n,k} - \operatorname{prox}_{\gamma_n\psi_k}(\nu_{n,k} + \eta_{n,k}) + \operatorname{prox}_{\gamma_n\psi_k} \eta_{n,k}| \\
&\quad + |\nu_{n,k}|/(1 + \gamma\theta) \\
&= |\nu_{n,k} - \operatorname{prox}_{\gamma_n\phi_k}(\nu_{n,k} + \eta_{n,k}) + \operatorname{prox}_{\gamma_n\phi_k} \eta_{n,k}| \\
&\quad + |\nu_{n,k}|/(1 + \gamma\theta).
\end{aligned} \tag{4.41}$$

Consequently, upon setting $\mu = 1 + 1/(\gamma\theta)$, we obtain

$$(\forall n \in \mathbb{N})(\forall k \in \mathbb{L}_2) \quad |\nu_{n,k}| \leq \mu|\nu_{n,k} - \operatorname{prox}_{\gamma_n\phi_k}(\nu_{n,k} + \eta_{n,k}) + \operatorname{prox}_{\gamma_n\phi_k} \eta_{n,k}|. \tag{4.42}$$

In turn,

$$(\forall n \in \mathbb{N}) \quad \sum_{k\in\mathbb{L}_2} |\nu_{n,k}|^2 \leq \mu^2 \sum_{k\in\mathbb{L}_2} |\nu_{n,k} - \operatorname{prox}_{\gamma_n\phi_k}(\nu_{n,k} + \eta_{n,k}) + \operatorname{prox}_{\gamma_n\phi_k} \eta_{n,k}|^2. \tag{4.43}$$

Hence, (4.16) forces $\sum_{k\in\mathbb{L}_2} |\nu_{n,k}|^2 \to 0$, as desired. □

Remark 4.6. An important aspect of Theorem 4.5 is that it provides a *strong* convergence result. Indeed, in general, only weak convergence can be claimed for forward-backward methods [16, 38] (see [3], [4], [16, Remark 5.12], and [25] for explicit constructions in which strong convergence fails). In addition, the standard sufficient conditions for strong convergence in this type of algorithm (see [13, Remark 6.6] and [16, Theorem 3.4(iv)]) are not satisfied in Problem 1.3. Further aspects of the relevance of strong convergence in proximal methods are discussed in [25, 26].

Remark 4.7. Let T be a nonzero bounded linear operator from $\mathcal{H}$ to a real Hilbert space $\mathcal{G}$, let $z \in \mathcal{G}$, and let τ and ω be in $]0, +\infty[$. Specializing Theorem 4.5 to the case when $\Phi\colon x \mapsto \|Tx - z\|^2/2$ and either

$$\mathbb{K} = \varnothing \quad \text{and} \quad (\forall k \in \mathbb{L}) \quad \psi_k = \tau_k|\cdot|^p, \quad \text{where} \quad p \in]1, 2] \ \text{ and } \ \tau_k \in [\tau, +\infty[\,, \tag{4.44}$$

or

$$\mathbb{L} = \varnothing \quad \text{and} \quad (\forall k \in \mathbb{K}) \quad \psi_k = 0 \quad \text{and} \quad \Omega_k = [-\omega_k, \omega_k], \quad \text{where} \quad \omega_k \in [\omega, +\infty[\,, \tag{4.45}$$

yields [16, Corollary 5.19]. If we further impose $\lambda_n \equiv 1$, $\|T\| < 1$, $\gamma_n \equiv 1$, $\alpha_{n,k} \equiv 0$, and $b_n \equiv 0$, we obtain [18, Theorem 3.1].

5. Applications to sparse signal recovery.

5.1. A special case of Problem 1.3. In (1.4), a single observation z of the original signal $\overline{x}$ is available. In certain problems, q such noisy linear observations are available, say $z_i = T_i\overline{x} + v_i$ $(1 \leq i \leq q)$, which leads to the weighted least-squares data fidelity term $x \mapsto \sum_{i=1}^{q} \mu_i \|T_i x - z_i\|^2$; see [12] and the references therein. Furthermore, signal recovery problems are typically accompanied with convex constraints that confine $\overline{x}$ to some closed convex subsets $(S_i)_{1\leq i\leq m}$ of $\mathcal{H}$. The violation of these constraints can be penalized via the cost function $x \mapsto \sum_{i=1}^{m} \vartheta_i d_{S_i}^2(x)$; see [10, 28] and the references therein. On the other hand, power functions are frequently used as cost functions in variational models for determining the coefficients of orthonormal basis decompositions, e.g., [1, 7, 8, 18]. Moreover, we aim at promoting sparsity of a solution $x \in \mathcal{H}$ with respect to $(e_k)_{k\in\mathbb{N}}$ in the sense that, for every k in $\mathbb{K}$, we wish to set to 0 the coefficient $\langle x \mid e_k\rangle$ if it lies in the interval Ω_k. The following formulation is consistent with these considerations.

PROBLEM 5.1. For every $i \in \{1,\ldots,q\}$, let $\mu_i \in]0,+\infty[$, let T_i be a nonzero bounded linear operator from $\mathcal{H}$ to a real Hilbert space $\mathcal{G}_i$, and let $z_i \in \mathcal{G}_i$. For every $i \in \{1,\ldots,m\}$, let $\vartheta_i \in]0,+\infty[$, and let S_i be a nonempty closed and convex subset of $\mathcal{H}$. Furthermore, let $(p_{k,l})_{0\leq l\leq L_k}$ be distinct real numbers in $]1,+\infty[$, let $(\tau_{k,l})_{0\leq l\leq L_k}$ be real numbers in $[0,+\infty[$, and let $l_k \in \{0,\ldots,L_k\}$ satisfy $p_{k,l_k} = \min_{0\leq l\leq L_k} p_{k,l}$, where $(L_k)_{k\in\mathbb{N}}$ is a sequence in $\mathbb{N}$. Finally, let $\mathbb{K} \subset \mathbb{N}$, let $\mathbb{L} = \mathbb{N} \smallsetminus \mathbb{K}$, and let $(\Omega_k)_{k\in\mathbb{K}}$ be a sequence of closed intervals in $\mathbb{R}$. The objective is to

$$\underset{x\in\mathcal{H}}{\text{minimize}} \ \frac{1}{2}\sum_{i=1}^{q} \mu_i \|T_i x - z_i\|^2 + \frac{1}{2}\sum_{i=1}^{m} \vartheta_i d_{S_i}^2(x) + \sum_{k\in\mathbb{N}} \sum_{l=0}^{L_k} \tau_{k,l} |\langle x \mid e_k\rangle|^{p_{k,l}} + \sum_{k\in\mathbb{K}} \sigma_{\Omega_k}(\langle x \mid e_k\rangle), \tag{5.1}$$

under the following assumptions:

(i) $\inf_{k\in\mathbb{L}} \tau_{k,l_k} > 0$,
(ii) $\inf_{k\in\mathbb{L}} p_{k,l_k} > 1$,
(iii) $\sup_{k\in\mathbb{L}} p_{k,l_k} \leq 2$,
(iv) $0 \in \operatorname{int} \bigcap_{k\in\mathbb{K}} \Omega_k$.

PROPOSITION 5.2. *Problem* 5.1 *is a special case of Problem* 1.3.

Proof. First, we observe that (5.1) corresponds to (1.7) where

$$\Phi\colon x \mapsto \frac{1}{2}\sum_{i=1}^{q} \mu_i \|T_i x - z_i\|^2 + \frac{1}{2}\sum_{i=1}^{m} \vartheta_i d_{S_i}^2(x) \quad \text{and} \quad (\forall k \in \mathbb{N}) \quad \psi_k\colon \xi \mapsto \sum_{l=0}^{L_k} \tau_{k,l} |\xi|^{p_{k,l}}. \tag{5.2}$$

Hence, Φ is a finite positive continuous convex function with Fréchet gradient

$$\nabla\Phi\colon x \mapsto \sum_{i=1}^{q} \mu_i T_i^*(T_i x - z_i) + \sum_{i=1}^{m} \vartheta_i (x - P_i x), \tag{5.3}$$

where P_i is the projection operator onto S_i. Therefore, since the operators $(\mathrm{Id} - P_i)_{1\leq i\leq m}$ are nonexpansive, it follows that assumption (i) in Problem 1.3 is satisfied with $1/\beta = \sum_{i=1}^{q} \mu_i \|T_i\|^2 + \sum_{i=1}^{m} \vartheta_i$. Moreover, the functions $(\psi_k)_{k\in\mathbb{N}}$ are in $\Gamma_0(\mathbb{R})$ and satisfy assumptions (ii) and (iii) in Problem 1.3.

Let us now turn to assumption (iv) in Problem 1.3. Fix $\rho \in]0,+\infty[$ and set $\tau = \inf_{k\in\mathbb{L}} \tau_{k,l_k}$, $p = \inf_{k\in\mathbb{L}} p_{k,l_k}$, and $\theta = \tau p(p-1)\min\{1, 1/\rho\}$. Then it follows from (i), (ii), and (iii) that $\theta > 0$ and that

$$
\begin{aligned}
\inf_{k\in\mathbb{L}} \inf_{0<|\xi|\le\rho} \psi_k''(\xi) &= \inf_{k\in\mathbb{L}} \inf_{0<|\xi|\le\rho} \sum_{l=0}^{L_k} \tau_{k,l} p_{k,l}(p_{k,l}-1)|\xi|^{p_{k,l}-2} \\
&\ge \inf_{k\in\mathbb{L}} \tau_{k,l_k} p_{k,l_k}(p_{k,l_k}-1) \inf_{0<\xi\le\rho} \xi^{p_{k,l_k}-2} \\
&\ge \tau p(p-1) \inf_{k\in\mathbb{L}} \inf_{0<\xi\le\rho} \xi^{p_{k,l_k}-2} \\
&\ge \tau p(p-1) \inf_{k\in\mathbb{L}} (1/\rho)^{2-p_{k,l_k}} \\
&\ge \theta,
\end{aligned} \tag{5.4}
$$

which shows that (1.8) is satisfied.

It remains to check assumption (v) in Problem 1.3. To this end, let $\|\cdot\|_{\mathbb{L}}$ denote the standard norm on $\ell^2(\mathbb{L})$, take $\mathsf{x} = (\xi_k)_{k\in\mathbb{L}} \in \ell^2(\mathbb{L})$ such that $\|\mathsf{x}\|_{\mathbb{L}} \ge 1$, and set $(\eta_k)_{k\in\mathbb{L}} = \mathsf{x}/\|\mathsf{x}\|_{\mathbb{L}}$. Then, for every $k \in \mathbb{L}$, $|\eta_k| \le 1$ and, since $p_{k,l_k} \in]1,2]$, we have $|\eta_k|^{p_{k,l_k}} \ge |\eta_k|^2$. Consequently,

$$
\begin{aligned}
\Upsilon_{\mathbb{L}}(\mathsf{x}) &= \sum_{k\in\mathbb{L}} \sum_{l=0}^{L_k} \tau_{k,l}|\xi_k|^{p_{k,l}} \ge \sum_{k\in\mathbb{L}} \tau_{k,l_k}|\xi_k|^{p_{k,l_k}} \\
&\ge \tau \sum_{k\in\mathbb{L}} |\xi_k|^{p_{k,l_k}} = \tau \sum_{k\in\mathbb{L}} \|\mathsf{x}\|_{\mathbb{L}}^{p_{k,l_k}} |\eta_k|^{p_{k,l_k}} \\
&\ge \tau \sum_{k\in\mathbb{L}} \|\mathsf{x}\|_{\mathbb{L}}^{p_{k,l_k}} |\eta_k|^2 = \tau \sum_{k\in\mathbb{L}} \|\mathsf{x}\|_{\mathbb{L}}^{p_{k,l_k}-2} |\xi_k|^2 \\
&\ge \tau \|\mathsf{x}\|_{\mathbb{L}}^{-1} \sum_{k\in\mathbb{L}} |\xi_k|^2 = \tau\|\mathsf{x}\|_{\mathbb{L}}.
\end{aligned} \tag{5.5}
$$

We conclude that $\Upsilon_{\mathbb{L}}(\mathsf{x}) \to +\infty$ as $\|\mathsf{x}\|_{\mathbb{L}} \to +\infty$. □

5.2. First example. Our first example concerns the simulated X-ray fluorescence spectrum $\overline{x}$ displayed in Figure 5.1, which is often used to test restoration methods, e.g., [14, 37]. The measured signal z shown in Figure 5.2 has undergone blurring by the limited resolution of the spectrometer and further corruption by addition of noise. In the underlying Hilbert space $\mathcal{H} = \ell^2(\mathbb{N})$, this process is modeled by $z = T\overline{x} + v$, where $T\colon \mathcal{H} \to \mathcal{H}$ is the operator of convolution with a truncated Gaussian kernel. The noise samples are uncorrelated and drawn from a Gaussian population with mean zero and standard deviation 0.15. The original signal $\overline{x}$ has support $\{0, \dots, N-1\}$ ($N = 1024$), takes on positive values, and possesses a sparse structure. These features can be promoted in Problem 5.1 by letting $(e_k)_{k\in\mathbb{N}}$ be the canonical orthonormal basis of $\mathcal{H}$ and setting $\mathbb{K} = \mathbb{N}$, $\tau_{k,l} \equiv 0$ and

$$
(\forall k \in \mathbb{N}) \quad \Omega_k = \begin{cases}]-\infty, \omega] & \text{if } 0 \le k \le N-1, \\ \mathbb{R} & \text{otherwise,} \end{cases} \tag{5.6}
$$

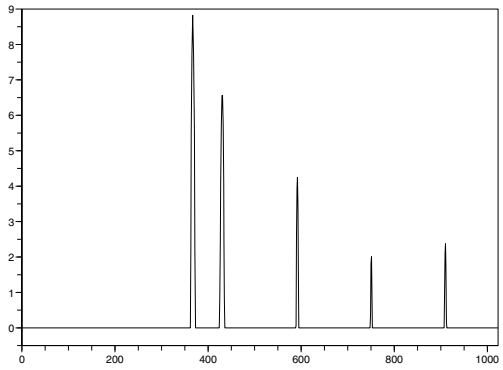

FIG. 5.1. *Original signal—first example.*

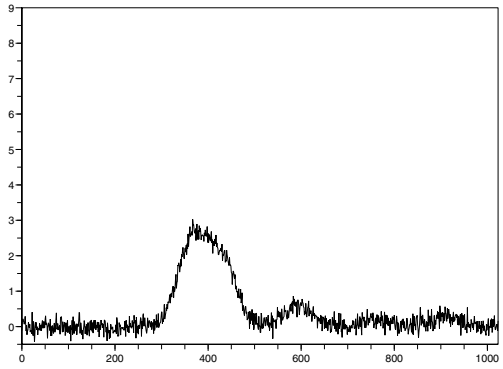

FIG. 5.2. *Degraded signal—first example.*

where the one-sided thresholding level is set to $\omega = 0.01$. On the other hand, using the methodology described in [37], the above information about the noise can be used to construct the constraint sets $S_1 = \big\{x \in \mathcal{H} \;\big|\; \|Tx - z\| \leq \delta_1\big\}$ and $S_2 = \bigcap_{l=1}^{N-1} \big\{x \in \mathcal{H} \;\big|\; |\widehat{Tx}(l/N) - \widehat{z}(l/N)| \leq \delta_2\big\}$, where $\widehat{a}\colon \nu \mapsto \sum_{k=0}^{+\infty} \langle a \mid e_k\rangle \exp(-\imath 2\pi k\nu)$ designates the Fourier transform of $a \in \mathcal{H}$. The bounds δ_1 and δ_2 have been determined so as to guarantee that $\overline{x}$ lies in S_1 and in S_2 with a 99 percent confidence level (see [15] for details). Finally, we set $q = 0$, $m = 2$, and $\vartheta_1 = \vartheta_2 = 1$ in (5.1) (the computation of the projectors P_1 and P_2 required in (5.3) is detailed in [37]). The solution produced by Algorithm 4.3 is shown in Figure 5.3. It is of much better quality than the restorations obtained in [14] and [37] via alternative methods.

5.3. Second example. We provide a wavelet deconvolution example in $\mathcal{H} = \mathbb{L}^2(\mathbb{R})$. The original signal $\overline{x}$ is the classical "bumps" signal [40] displayed in Figure 5.4. The degraded version shown in Figure 5.5 is $z_1 = T_1\overline{x} + v_1$, where T_1 models convolution with a uniform kernel and v_1 is a realization of a zero-mean white Gaussian noise.

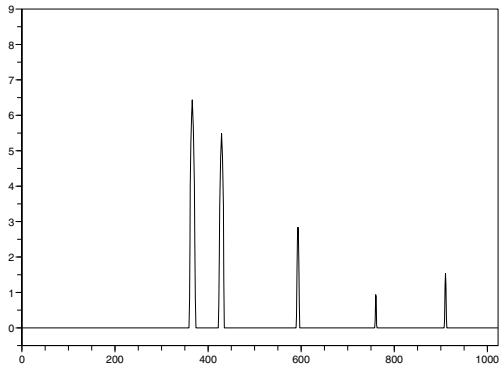

FIG. 5.3. *Signal restored by Algorithm* 4.3*—first example.*

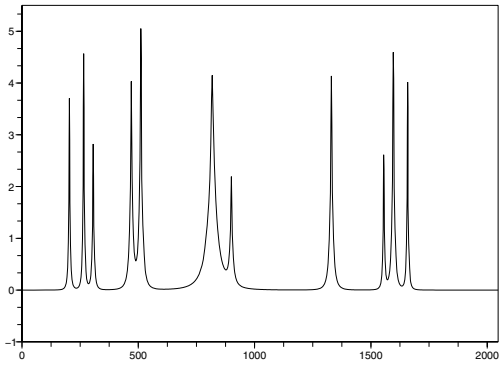

FIG. 5.4. *Original signal—second example.*

The basis $(e_k)_{k\in\mathbb{N}}$ is an orthonormal wavelet symlet basis with eight vanishing moments [17]. Such wavelet bases are known to provide sparse representations for a wide class of signals [22] such as this standard test signal. Note that there exists a strong connection between Problem 5.1 and maximum a posteriori techniques for estimating $\overline{x}$ in the presence of white Gaussian noise. In particular, setting $q = 1$, $m = 0$, $\mathbb{K} = \varnothing$ and $L_k \equiv 0$, and using suitably subband-adapted values of $p_{k,0}$ and $\tau_{k,0}$ amounts to fitting an appropriate generalized Gaussian prior distribution to the wavelet coefficients in each subband [1]. Such a statistical modeling is commonly used in wavelet-based estimation, where values of $p_{k,0}$ close to 2 may provide a good model at coarse resolution levels, whereas values close to 1 should preferably be used at finer resolutions.

The setting of the more general model we adopt here is the following: in Problem 5.1, $\mathbb{K}$ and $\mathbb{L}$ are the index sets of the detail and approximation coefficients [29],

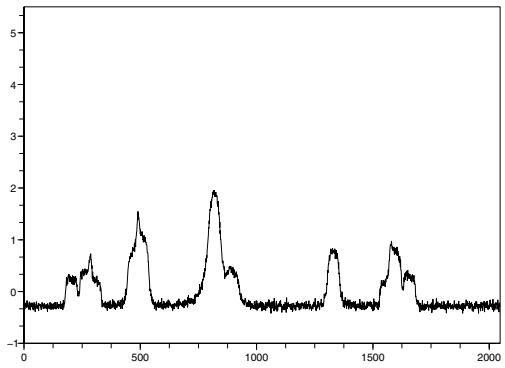

FIG. 5.5. *Degraded signal—second example.*

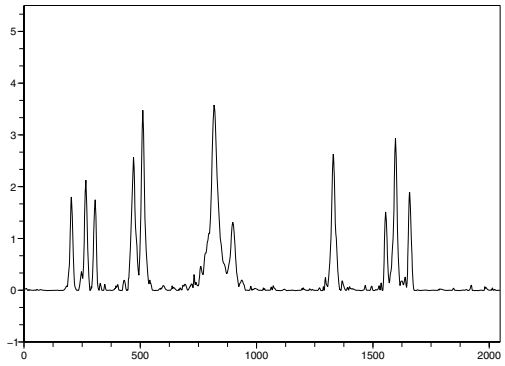

FIG. 5.6. *Signal restored by Algorithm* 4.3*—second example.*

respectively, and

- $(\forall k \in \mathbb{K})$ $\Omega_k = [-0.0023, 0.0023]$, $L_k = 1$, $(p_{k,0}, p_{k,1}) = (2, 4)$, $(\tau_{k,0}, \tau_{k,1}) = (0.0052, 0.0001)$,
- $(\forall k \in \mathbb{L})$ $L_k = 0$, $p_{k,0} = 2$, $\tau_{k,0} = 0.00083$.

For each k, the integer L_k and the exponents $(p_{k,l})_{0 \leq l \leq L_k}$ are imposed, while the set Ω_k and the coefficients $(\tau_{k,l})_{0 \leq l \leq L_k}$ are chosen empirically. In addition, we set $q = 1$, $\mu_1 = 1$, $m = 1$, $\vartheta_1 = 1$, and $S_1 = \big\{x \in \mathcal{H} \;\big|\; x \geq 0\big\}$ (pointwise positivity constraint). The solution x produced by Algorithm 4.3 is shown in Figure 5.6. The estimation error is $\|x - \overline{x}\| = 8.33$. For comparison, the signal $\widetilde{x}$ restored via (1.4) with Algorithm (1.5) is displayed in Figure 5.7. In Problem 5.1, this corresponds to $q = 1$, $m = 0$, $\mathbb{K} = \mathbb{N}$, $\tau_{k,l} \equiv 0$, $\Omega_k \equiv [-2.9, 2.9]$ for the detail coefficients, and $\Omega_k \equiv [-0.0062, 0.0062]$ for the approximation coefficients. This setup yields a worse error of $\|\widetilde{x} - \overline{x}\| = 14.14$ (the sets $(\Omega_k)_{k \in \mathbb{N}}$ have been adjusted so as to mininize this error). The above results have been obtained with a discrete implementation of the wavelet decomposition over four resolution levels using 2048 signal samples [29].

ON MEHROTRA-TYPE PREDICTOR-CORRECTOR ALGORITHMS*

M. SALAHI†, J. PENG‡, AND T. TERLAKY§

Abstract. In this paper we discuss the polynomiality of a feasible version of Mehrotra's predictor-corrector algorithm whose variants have been widely used in several interior point method (IPM)-based optimization packages. A numerical example is given that shows that the adaptive choice of centering parameter and correction terms in this algorithm may lead to small steps being taken in order to keep the iterates in a large neighborhood of the central path, which is important for proving polynomial complexity properties of this method. Motivated by this example, we introduce a safeguard in Mehrotra's algorithm that keeps the iterates in the prescribed neighborhood and allows us to obtain a positive lower bound on the step size. This safeguard strategy is also used when the affine scaling direction performs poorly. We prove that the safeguarded algorithm will terminate after at most $\mathcal{O}(n^2\log(x^0)^T s^0/\epsilon)$ iterations. By modestly modifying the corrector direction, we reduce the iteration complexity to $\mathcal{O}(n\log(x^0)^T s^0/\epsilon)$. To ensure fast asymptotic convergence of the algorithm, we changed Mehrotra's updating scheme of the centering parameter slightly while keeping the safeguard. The new algorithms have the same order of iteration complexity as the safeguarded algorithms but enjoy superlinear convergence as well. Numerical results using the McIPM and LIPSOL software packages are reported.

Key words. linear optimization, predictor-corrector method, interior point methods, Mehrotra-type algorithm, polynomial complexity, superlinear convergence

1. Introduction.

Since Karmarkar's landmark paper [11], the study on interior point methods (IPMs) has become one of the most active research areas in the field of optimization. Many IPMs have been proposed and analyzed [22, 26, 27], and several powerful IPM-based software packages have been developed and successfully applied to numerous applications [1, 5, 29, 30]. Among various variants of IPMs, the so-called predictor-corrector methods have attracted much attention in the IPM community due to its high efficiency and have become the backbones of several optimization packages. It should be mentioned that most implementations of predictor-corrector IPMs adopted a heuristics proposed first by Mehrotra in his remarkable paper [6, 13]. The practical importance of Mehrotra's algorithm motivated us to investigate its theoretical properties. Before going into the details of the algorithm, we briefly review the basics and unique results of IPMs and predictor-corrector IPMs.

We consider primal-dual IPMs for solving the following *linear optimization* (LO) problem

$$\text{(P)} \qquad \min \{c^T x : Ax = b,\ x \geq 0\},$$

where $A \in R^{m\times n}$ satisfies $\text{rank}(A) = m$, $b \in R^m$, $c \in R^n$, and its dual problem

$$\text{(D)} \qquad \max \{b^T y : A^T y + s = c,\ s \geq 0\}.$$

It is common in IPMs theory to assume that both (P) and (D) satisfy the interior point condition (IPC) [22]; i.e., there exists an (x^0, y^0, s^0) such that

$$Ax^0 = b\ x^0 > 0, \quad A^T y^0 + s^0 = c,\ s^0 > 0.$$

Finding optimal solutions of (P) and (D) is equivalent to solving the following system:

$$\begin{aligned} Ax &= b, \quad x \geq 0, \\ A^T y + s &= c, \quad s \geq 0, \\ Xs &= 0, \end{aligned} \tag{1}$$

where $X = \text{diag}\,(x)$. The basic idea of primal-dual IPMs is to replace the third equation in (1) by the parameterized equation $Xs = \mu e$, where e is the all one vector. This leads to the following system:

$$\begin{aligned} Ax &= b, \quad x \geq 0, \\ A^T y + s &= c, \quad s \geq 0, \\ Xs &= \mu e. \end{aligned} \tag{2}$$

If the IPC holds, then for each $\mu > 0$, system (2) has a unique solution. This solution, denoted by $(x(\mu), y(\mu), s(\mu))$, is called the μ-center of the primal-dual pair (P) and (D). The set of μ-centers with all $\mu > 0$ gives *the central path* of (P) and (D) [12, 24]. It has been shown that the limit of the central path (as μ goes to zero) exists and is an optimal solution of (P) and (D) [22].

Applying Newton's method to (2) for a given feasible point (x, y, s) gives the following linear system of equations:

$$\begin{aligned} A\Delta x &= 0, \\ A^T \Delta y + \Delta s &= 0, \\ x\Delta s + s\Delta x &= \mu e - xs, \end{aligned} \tag{3}$$

where $(\Delta x,\ \Delta y,\ \Delta s)$ give the Newton step.

Predictor-corrector algorithms use (3) with different values of μ in the predictor and corrector steps. The predictor-corrector algorithm with best iteration complexity is the Mizuno–Todd–Ye (MTY) algorithm for LO, which operates in two small neighborhoods of the central path [16]. In the predictor step the MTY algorithm uses the so-called primal-dual affine scaling step with $\mu = 0$ in (3) and moves to a slightly larger neighborhood. Then, in the corrector step, it uses $\mu = \mu_g = \frac{x^T s}{n}$, proportional to the duality gap, to bring the iterate towards the central path, back to the smaller neighborhood. In spite of its strong theoretical results for LO and conic linear optimization problems, the algorithm has not been used in developing IPM-based software packages. Several variants of MTY-type predictor-corrector algorithms operating in both small and large neighborhoods have been proposed in the past decade [2, 7, 8, 18, 10, 19, 20, 21, 23], and most of them follow a similar theoretical framework as in [16].

In what follows we describe in detail a feasible[1] version of Mehrotra's original predictor-corrector algorithm that has been widely used in implementations [1, 13, 30]. In the predictor step Mehrotra's algorithm computes the affine scaling search direction, i.e.,

$$\begin{aligned} A\Delta^{\mathrm{a}}x &= 0, \\ A^T\Delta^{\mathrm{a}}y + \Delta^{\mathrm{a}}s &= 0, \\ s\Delta^{\mathrm{a}}x + x\Delta^{\mathrm{a}}x &= -xs; \end{aligned} \tag{4}$$

then it computes the maximum feasible step size that ensures

$$(x + \alpha_{\mathrm{a}}\Delta^{\mathrm{a}}x, s + \alpha_{\mathrm{a}}\Delta^{\mathrm{a}}s) \geq 0.$$

However, the algorithm does not take such a step right away. It is worth mentioning that Mehrotra's original algorithm allows different step sizes in both primal and dual spaces, while here for simplicity of the analysis we consider only the case when they are equal. Mehrotra's algorithm then uses the information from the predictor step to compute the corrector direction that is defined as follows:

$$\begin{aligned} A\Delta x &= 0, \\ A^T\Delta y + \Delta s &= 0, \\ s\Delta x + x\Delta s &= \mu e - xs - \Delta^{\mathrm{a}}x\Delta^{\mathrm{a}}s, \end{aligned} \tag{5}$$

where μ is defined adaptively by

$$\mu = \left(\frac{g_{\mathrm{a}}}{g}\right)^2 \frac{g_{\mathrm{a}}}{n},$$

where $g_{\mathrm{a}} = (x + \alpha_{\mathrm{a}}\Delta^{\mathrm{a}}x)^T(s + \alpha_{\mathrm{a}}\Delta^{\mathrm{a}}s)$ and $g = x^Ts$. Since $(\Delta^{\mathrm{a}}x)^T\Delta^{\mathrm{a}}s = 0$, the previous relation implies

$$\mu = (1 - \alpha_{\mathrm{a}})^3\mu_g. \tag{6}$$

From (6) it is obvious that if only a small step in the affine scaling direction can be made, then we improve only the centrality of the iterate.

Finally, Mehrotra's algorithm makes a step in the $(\Delta x, \Delta y, \Delta s)$ direction by an appropriate step size, and let us denote the new iterate by

$$x(\alpha) := x + \alpha\Delta x, \quad y(\alpha) := y + \alpha\Delta y, \quad s(\alpha) := s + \alpha\Delta s.$$

We note that several variants of the previous algorithm have been well studied in the literature. For example, Mehrotra proposed an infeasible second order predictor-corrector IPM [14] based on a similar power series extension of Monteiro, Adler, and Resende [17]. In his infeasible variant, Mehrotra combined the adaptive scheme with a safeguard technique to stabilize the convergence of the algorithm. Zhang and Zhang [28] have analyzed this second order algorithm without using the adaptive update of the centrality parameter. Jarre and Wechs [9] have suggested generating several corrector directions first and then using the generated directions to construct a new

[1] The original Mehrotra algorithm is an infeasible algorithm. However, the self-dual embedding model [22] can be used to construct a slightly bigger LO problem that has an obvious starting point on the central path.

search direction along which a step can be taken. Gondzio [6] proposed using multiple centrality steps to bring the iterates back to the vicinity of the central path. Significant improvements have been reported for solving several challenge NETLIB test problems and problems arising from real applications. In a recent work [4], Gondzio further combined the idea of multiple centering with a symmetric neighborhood to avoid potential ill behaviors of Mehrotra's predictor-corrector algorithm. More recently, Mehrotra and Li [15] considered a Krylov subspace-based predictor-corrector method and established its global convergence. Promising numerical results are reported as well.

Different from the above-mentioned results, in this paper we first explore the potential flaws in the feasible version of Mehrotra's original algorithm. By a numerical example we show that Mehrotra's algorithm may result in very small steps in order to keep the iterate in a certain neighborhood of the central path, which is essential to prove the polynomiality of the algorithm. To avoid such a trap, we propose incorporating a safeguard in the algorithm so that we can guarantee a positive lower bound for the step size and subsequently the polynomial complexity. Further, to ensure the superlinear convergence of the algorithm we changed the updating scheme of the centering parameter so that the new scheme preserves the same iteration complexity with stronger asymptotic convergence results. It is worthwhile mentioning that our simple safeguard strategy is different from the most recent results by Colombo and Gondzio [4] and Mehrotra and Li [15], where they employ multiple centering with symmetric neighborhood and Krylov subspace-based corrections, respectively. Most recently, in [3] the author also provided another example that shows that the second order variant of Mehrotra's predictor-corrector algorithms may fail to converge to an optimal solution. However, there have not been any numerical experiments.

The rest of the paper is organized as follows. First, in section 2, we present a numerical example that motivates the introduction of a safeguard in Mehrotra's algorithm. Then, in section 3, we present the safeguard-based algorithm and establish its worst case iteration complexity. For readability of the paper we moved some technical lemmas that are used in section 3 to the appendix. In section 4, we further modify the algorithm of section 3 and discuss its iteration complexity. In section 5, Mehrotra's updating scheme of the centering parameter is slightly modified to ensure the superlinear convergence of both algorithms in sections 3 and 4. Some illustrative numerical results using the NETLIB and Kennington test problems are reported in section 6, and finally we conclude the paper by few remarks in section 7.

Conventions. Throughout the paper $\|\cdot\|$ denotes the 2-norm of vectors. We denote by $\mathcal{I}$ the index set $\{1, 2, \ldots, n\}$. For any two vectors x and s, xs denotes the componentwise product of the two vectors, and e denotes the vector with all components equal to one. For simplicity of notation we remove the iteration index in the coming sections. We also use the notation

$$\mathcal{I}_+ = \{i \in \mathcal{I} \mid \Delta x_i^a \Delta s_i^a > 0\}, \quad \mathcal{I}_- = \{i \in \mathcal{I} \mid \Delta x_i^a \Delta s_i^a < 0\},$$

$$\mathcal{F} = \{(x, y, s) \in R^n \times R^m \times R^n \mid (x, s) \geq 0,\ Ax = b,\ A^T y + s = c\},$$

and

$$\mathcal{F}^0 = \{(x, y, s) \in R^n \times R^m \times R^n \mid (x, s) > 0,\ Ax = b,\ A^T y + s = c\}.$$

2. Motivation. In this section first we introduce the neighborhood of the central path in which the algorithms operate. Then we give a numerical example showing that using the strategy described in the introduction might force the algorithm to make very small steps to keep the iterate in a certain neighborhood of the central path, which further implies the algorithm needs to take many iterations to convergence. The example indicates that Mehrotra's adaptive updating scheme of the centering parameter has to be combined with certain safeguards to get a warranted step size at each iteration.

Most efficient IPM solvers work in the negative infinity norm neighborhood defined by

$$\mathcal{N}_\infty^-(\gamma) := \{(x,y,s) \in \mathcal{F}^0 : \ x_i s_i \geq \gamma \mu_g \ \forall i = 1,\dots,n\}, \tag{7}$$

where $\gamma \in (0,1)$ is a constant independent of n and $\mu_g = \frac{x^T s}{n}$. In this paper, we consider algorithms that are working in $\mathcal{N}_\infty^-(\gamma)$ (called the large neighborhood).

Let us consider the following simple LO:

$$\begin{aligned} \min \quad & -x_2 \\ \text{s.t. } & 0 \leq x_1 \leq 1, \\ & 0 \leq x_2 \leq 1 + \delta x_1, \end{aligned} \tag{8}$$

where $\delta = 0.1$. Let the algorithm start with the following feasible points in the neighborhood $\mathcal{N}_\infty^-(0.1)$:

$$x^0 = (0.03; 0.9), \quad s^0 = (6.8; 1; 7; 2), \quad y^0 = (-7, -2).$$

For the given starting point, if we use identical step sizes for both primal and dual problems, in the third iteration the maximum step size in the predictor step will be $\alpha_{\mathrm{a}} = 0.96$, while the maximum step size in the corrector step is $\mathcal{O}(10^{-4})$, and this value is getting worse for later iterations. To explain what we observed, let us examine the constraints

$$x_i(\alpha) s_i(\alpha) \geq \gamma \mu_g(\alpha) \quad \forall i \in \mathcal{I} \tag{9}$$

for $\gamma = 0.1$ that keeps the next iterate in the $\mathcal{N}_\infty^-(0.1)$ neighborhood, where

$$\mu_g(\alpha) = \frac{x(\alpha)^T s(\alpha)}{n} = \left(1 - \alpha + \alpha \frac{\mu}{\mu_g}\right) \mu_g. \tag{10}$$

By expanding inequality (9) and reordering one has

$$(1-\alpha) x_i s_i + \alpha(1-0.1)\mu - \alpha \Delta x_i^{\mathrm{a}} \Delta s_i^{\mathrm{a}} + \alpha^2 \Delta x_i \Delta s_i \geq \gamma(1-\alpha)\mu_g \quad \forall i \in \mathcal{I}.$$

Note that for the given staring point, $x_1 s_1 - 0.1\mu_g$ is a very small nonnegative number, while $\Delta x_1^{\mathrm{a}} \Delta s_1^{\mathrm{a}}$ and $\Delta x_1 \Delta s_1$ are both negative numbers whose absolute values are dominated by $x_1 s_1$, and finally $\mu = \mathcal{O}(10^{-5})$ due to a big affine scaling step size. Incorporating all these information into (9) implies that the algorithm requires a very small step to satisfy (9). This phenomenon might be the result of the following:

- There is an aggressive update of centering parameter μ using (6).
- There is usage of the correction terms in the corrector system of equations.

To resolve these difficulties, we propose the following remedies:

- Use a fixed fraction of μ_g, for example, $\mu = \frac{\mu_g}{10}$, rather than an adaptive update.
- Cut the maximum step size in the predictor step if it is above a certain threshold. This might prevent the algorithm from having an aggressive update.
- Modify the correction terms in the corrector system of equations.

For this specific example, these ideas help us to solve the difficulty that might arise. However, in general modifying the second order correction terms may not be as effective as using a simple large update of the centering parameter.

These observations motivate us to introduce a safeguard strategy that will help us to have control on the minimal warranted step size from the theoretical and practical points of view. In our safeguard we simply use a fixed fraction of μ_g as the μ value. It is worthwhile mentioning that when the affine scaling step size is very small, for example, when $\alpha_{\rm a} < 0.1$, which implies marginal reduction of the complementarity gap, we also employ the same large update safeguard.

3. A safeguard-based algorithm. In this section we first discuss the step size estimation of the algorithm and then outline the safeguard-based algorithm. Finally, we establish its worst case iteration complexity.

The following technical lemma will be used in the next theorem, which estimates the maximum step size in the corrector step.

LEMMA 3.1. *Suppose the current iterate is* $(x, y, s) \in \mathcal{N}_\infty^-(\gamma)$*, and let* $(\Delta x, \Delta y, \Delta s)$ *be the solution of* (5)*, where* $\mu \geq 0$*. Then we have*

$$||\Delta x \Delta s|| \leq 2^{\frac{-3}{2}} \left(\frac{1}{\gamma} \left(\frac{\mu}{\mu_g} \right)^2 - \left(2 - \frac{1}{2\gamma} \right) \frac{\mu}{\mu_g} + \frac{17\gamma + n}{16\gamma} \right) n\mu_g.$$

Proof. If we multiply the third equation of (5) by $(XS)^{-\frac{1}{2}}$, then by Lemma 5.3 of [26] we have

$$\begin{aligned} ||\Delta x \Delta s|| &\leq 2^{\frac{-3}{2}} ||\mu (XSe)^{-\frac{1}{2}} - (XSe)^{\frac{1}{2}} - (XS)^{-\frac{1}{2}} \Delta x^{\rm a} \Delta s^{\rm a}||^2 \\ &= 2^{\frac{-3}{2}} \left(\mu^2 \sum_{i \in \mathcal{I}} \frac{1}{x_i s_i} + \sum_{i \in \mathcal{I}} x_i s_i + \sum_{i \in \mathcal{I}} \frac{(\Delta x_i^{\rm a} \Delta s_i^{\rm a})^2}{x_i s_i} - 2n\mu - 2\mu \sum_{i \in \mathcal{I}} \frac{\Delta x_i^{\rm a} \Delta s_i^{\rm a}}{x_i s_i} \right) \\ &\leq 2^{\frac{-3}{2}} \left(\frac{n\mu^2}{\gamma \mu_g} + n\mu_g + \frac{n\mu_g}{16} + \frac{n^2 \mu_g}{16\gamma} - 2n\mu + \frac{n\mu}{2\gamma} \right), \end{aligned}$$

where the last inequality follows from Lemma A.2 and the assumption that the previous iterate is in $\mathcal{N}_\infty^-(\gamma)$. By reordering and factorizing we get the statement of the lemma. ∎

Motivated from the computational practice, we use $\mu = \frac{\beta}{1-\beta}\mu_g$ as the value of safeguard, where $\gamma \leq \beta < \frac{1}{3}$. This is due to the fact that using $\mu = \frac{\gamma}{1-\gamma}\mu_g$ for small values of γ might imply an aggressive update of the barrier parameter. The following corollary, which follows from Lemma 3.1, gives an explicit upper bound for this specific value of μ.

COROLLARY 3.2. *If* $\mu = \frac{\beta}{1-\beta}\mu_g$*, where* $\gamma \leq \beta < \frac{1}{3}$ *and* $\gamma \in (0, \frac{1}{3})$*, then*

$$||\Delta x \Delta s|| \leq \frac{1}{2\gamma} n^2 \mu_g.$$

THEOREM 3.3. *Suppose the current iterate is* $(x, y, s) \in \mathcal{N}_\infty^-(\gamma)$*, where* $\gamma \in (0, \frac{1}{3})$*,*

and let $(\Delta x, \Delta y, \Delta s)$ *be the solution of* (5) *with*

$$\mu = \frac{\beta}{1-\beta}\mu_g,$$

where $\gamma \le \beta < \frac{1}{3}$. *Then the maximum step size* α_c, *which keeps* $(x(\alpha_c), y(\alpha_c), s(\alpha_c))$ *in* $\mathcal{N}_\infty^-(\gamma)$, *satisfies*

$$\alpha_c \ge \frac{3\gamma^2}{2n^2}.$$

Proof. The goal is to find the maximum nonnegative α for which the relation (9) holds. To do so, first let use define

$$t = \max_{i \in \mathcal{I}_+} \left\{ \frac{\Delta x_i^a \Delta s_i^a}{x_i s_i} \right\}. \tag{11}$$

Since $(\Delta x^a)^T \Delta s^a = 0$, then $\mathcal{I}_+ \neq \emptyset$. Now it is sufficient to prove (9) for $\Delta x_i^a \Delta s_i^a > 0$. To do so, we have

$$\begin{aligned} x_i(\alpha)s_i(\alpha) &= x_i s_i + \alpha(\mu - x_i s_i - \Delta x^a{}_i \Delta s^a{}_i) + \alpha^2 \Delta x_i \Delta s_i \\ &\ge (1-\alpha)x_i s_i + \alpha\mu - \alpha t x_i s_i - \frac{\alpha^2 n^2 \mu_g}{2\gamma} \\ &= (1-(1+t)\alpha)x_i s_i + \alpha\mu - \frac{\alpha^2 n^2 \mu_g}{2\gamma}, \end{aligned}$$

where the first inequality follows from $\alpha \ge 0$, (11), and Corollary 3.2. Moreover, from Lemma A.1 we have that $t \le \frac{1}{4}$, which implies $\frac{1}{1+t} \ge \frac{4}{5}$. Thus we further deduce that for $\alpha \in [0, \frac{4}{5}]$, we have

$$x_i(\alpha)s_i(\alpha) \ge (1-(1+t)\alpha)\gamma\mu_g + \alpha\mu - \frac{\alpha^2 n^2 \mu_g}{2\gamma}.$$

Now using (10), the next iterate belongs to $\mathcal{N}_\infty^-(\gamma)$, provided

$$(1-(1+t)\alpha)\gamma\mu_g + \alpha\mu - \frac{\alpha^2 n^2 \mu_g}{2\gamma} \ge \gamma\left(1 - \alpha + \alpha\frac{\mu}{\mu_g}\right)\mu_g,$$

which is equivalent to

$$(1-\gamma)\mu - \gamma t \mu_g \ge \frac{\alpha n^2 \mu_g}{2\gamma}. \tag{12}$$

Using Lemma A.1 and the definition of μ one has

$$(1-\gamma)\mu - \gamma t\mu_g \ge \frac{(1-\gamma)\beta}{(1-\beta)}\mu_g - \frac{\gamma\mu_g}{4} \ge \frac{3\gamma\mu_g}{4}.$$

Therefore, inequality (12) holds if

$$\frac{3\gamma\mu_g}{4} \ge \frac{\alpha n^2 \mu_g}{2\gamma}.$$

This inequality definitely holds for $\alpha = \frac{3\gamma^2}{2n^2}$. Now we can conclude that

$$\alpha_c \geq \min\left(\frac{4}{5}, \frac{3\gamma^2}{2n^2}\right) = \frac{3\gamma^2}{2n^2}. \qquad \square$$

We remind the readers that we use this safeguard when the affine scaling performs poorly, for example, when $\alpha_{\rm a} < 0.1$.

Now after all the previous discussions we may outline our new safeguard-based algorithm as follows.

ALGORITHM 1

Input:
A proximity parameters $\gamma \in (0, \frac{1}{3})$;
a safeguard parameter $\beta \in [\gamma, \frac{1}{3})$;
an accuracy parameter $\epsilon > 0$;
$(x^0, y^0, s^0) \in \mathcal{N}_\infty^-(\gamma)$.

begin
while $x^T s \geq \epsilon$ **do**
begin
Predictor Step Solve (4) and compute the maximum step size $\alpha_{\rm a}$ such that $(x(\alpha_{\rm a}), y(\alpha_{\rm a}), s(\alpha_{\rm a})) \in \mathcal{F}$;
end

begin
Corrector step
If $\alpha_{\rm a} \geq 0.1$, **then** solve (5) with $\mu = (1 - \alpha_{\rm a})^3 \mu_g$ and compute the maximum step size $\alpha_{\rm c}$ such that $(x(\alpha_{\rm c}), y(\alpha_{\rm c}), s(\alpha_{\rm c})) \in \mathcal{N}_\infty^-(\gamma)$;
If $\alpha_{\rm c} < \frac{3\gamma^2}{2n^2}$, **then** solve (5) with $\mu = \frac{\beta}{1-\beta}\mu_g$ and compute the maximum step size $\alpha_{\rm c}$ such that $(x(\alpha_{\rm c}), y(\alpha_{\rm c}), s(\alpha_{\rm c})) \in \mathcal{N}_\infty^-(\gamma)$;
end
else
Solve (5) with $\mu = \frac{\beta}{1-\beta}\mu_g$ and compute the maximum step size $\alpha_{\rm c}$ such that $(x(\alpha_{\rm c}), y(\alpha_{\rm c}), s(\alpha_{\rm c})) \in \mathcal{N}_\infty^-(\gamma)$;
end Set $(x(\alpha_{\rm c}), y(\alpha_{\rm c}), s(\alpha_{\rm c})) = (x + \alpha_{\rm c}\Delta x, y + \alpha_{\rm c}\Delta y, s + \alpha_{\rm c}\Delta s)$.
end
end

Remark 3.4. By using an identical step size for both the primal and the dual problems, comparing with the Mehrotra's algorithm, our new algorithm requires at most an extra backsolve to make a better step.

The following theorem gives an upper bound for the maximum number of iterations in which Algorithm 1 stops with an ϵ-approximate solution.

THEOREM 3.5. *Algorithm* 1 *stops after at most*

$$O\left(n^2 \log \frac{(x^0)^T s^0}{\epsilon}\right)$$

iterations with a solution for which $x^T s \leq \epsilon$.

Proof. If $\alpha_a < 0.1$ or $\alpha_c < \frac{3\gamma^2}{2n^2}$, then the algorithm uses the safeguard strategy. It follows from Theorem 3.3 and (10) that

$$\mu_g(\alpha) \leq \left(1 - \frac{3\gamma^2(1-2\beta)}{2(1-\beta)n^2}\right)\mu_g.$$

If $\alpha_a \geq 0.1$ and $\alpha_c \geq \frac{3\gamma^2}{2n^2}$, then the algorithm uses Mehrotra's updating strategy, which further implies that

$$\mu_g(\alpha) \leq \left(1 - \frac{2\gamma^2}{5n^2}\right)\mu_g,$$

which completes the proof conforming to [26, Theorem 3.2]. ∎

4. A modified version of Algorithm 1. In this section we propose a slightly modified version of Algorithm 1 (Algorithm 2) that enjoys much better iteration complexity than Algorithm 1 and also is computationally more appealing. The improvement in the iteration complexity is the result of the following proposition and modified corrector step that allow us to strengthen the bound in Lemma 3.1.

PROPOSITION 4.1. *For all $i \in \mathcal{I}_-$ one has*

$$-\Delta x_i^a \Delta s_i^a \leq \frac{1}{\alpha_a}\left(\frac{1}{\alpha_a} - 1\right) x_i s_i. \tag{13}$$

Proof. For the maximum step size in the predictor step, α_a, one has $x_i(\alpha_a)s_i(\alpha_a) \geq 0,\ i = 1, \ldots, n$. This is equivalent to $(1-\alpha_a)x_i s_i + \alpha_a^2 \Delta x_i^a \Delta s_i^a \geq 0,\ i = 1, \ldots, n$, which the statement of the proposition follows. ∎

The motivation for modifying the Newton system in the corrector step is the following observation. If the maximal feasible step size for the affine scaling direction is reasonably large, then the classical corrector direction should also be a good choice. However, if the maximal feasible step size for the affine scaling search direction is very small, then we should possibly try to bring the iterate back to the vicinity of the central path. In such a case, the second order correction terms in system (5) might not be a good choice since they might lead to a search direction moving towards the boundary of the feasible region. Therefore, we propose changing the second order correction terms in the corrector step proportional to the affine scaling step size when it does not perform good, for example, when $\alpha_a < 0.1$.

The new corrector system of equations when $\alpha_a < 0.1$, which by using Proposition 4.1 enables us to improve on the iteration complexity of Algorithm 1, is

$$\begin{aligned} A\Delta x &= 0, \\ A^T\Delta y + \Delta s &= 0, \\ s\Delta x + x\Delta s &= \mu e - xs - \alpha_a \Delta x^a \Delta s^a, \end{aligned} \tag{14}$$

where the centering parameter μ is defined as in the previous section. Changing the corrector system of equation to (14) when $\alpha_a < 0.1$ helps us avoid the potential ill behaviors of Mehrotra's original algorithm without sacrificing its practical efficiency (see section 6). Thus, in what follows we consider this variant for further analysis.

Analogous to Lemma 3.1 we have the following bound for $\|\Delta x \Delta s\|$ when $\alpha_a \in (0, 0.1)$.

LEMMA 4.2. *Suppose the current iterate is $(x, y, s) \in \mathcal{N}_\infty^-(\gamma)$, where $\alpha_a \in (0, 0.1)$, and let $(\Delta x, \Delta y, \Delta s)$ be the solution of* (14). *Then we have*

$$||\Delta x \Delta s|| \leq 2^{\frac{-3}{2}}\left(\frac{1}{\gamma}\left(\frac{\mu}{\mu_g}\right)^2 - \left(2 - \frac{\alpha_a}{2\gamma}\right)\frac{\mu}{\mu_g} + \frac{20 - 4\alpha_a + \alpha_a^2}{16}\right) n\mu_g.$$

Proof. Since $(\Delta x^a)^T \Delta s^a = 0$, both $\mathcal{I}_+$ and $\mathcal{I}_-$ are nonempty. If we multiply the third equation of (14) by $(XS)^{-\frac{1}{2}}$, then by Lemma 5.3 of [26] we have

$$\begin{aligned}
\|\Delta x \Delta s\| &\leq 2^{\frac{-3}{2}} ||\mu(XSe)^{-\frac{1}{2}} - (XSe)^{\frac{1}{2}} - \alpha_{\rm a}(XS)^{-\frac{1}{2}} \Delta x^a \Delta s^a||^2 \\
&= 2^{\frac{-3}{2}} \left(\mu^2 \sum_{i\in\mathcal{I}} \frac{1}{x_i s_i} + x^T s + \alpha_{\rm a}^2 \sum_{i\in\mathcal{I}} \frac{(\Delta x_i^{\rm a} \Delta s_i^{\rm a})^2}{x_i s_i} - 2n\mu - 2\alpha_{\rm a}\mu \sum_{i\in\mathcal{I}} \frac{\Delta x_i^{\rm a} \Delta s_i^{\rm a}}{x_i s_i} \right) \\
&\leq 2^{\frac{-3}{2}} \left(\frac{n\mu^2}{\gamma\mu_g} + n\mu_g + \frac{\alpha_{\rm a}^2 n\mu_g}{16} - (1-\alpha_{\rm a}) \sum_{i\in\mathcal{I}_-} \Delta x_i^{\rm a} \Delta s_i^{\rm a} - 2n\mu + \frac{\alpha_{\rm a} n\mu}{2\gamma} \right) \\
&\leq 2^{\frac{-3}{2}} \left(\frac{1}{\gamma} \left(\frac{\mu}{\mu_g} \right)^2 + 1 + \frac{\alpha_{\rm a}^2}{16} + \frac{(1-\alpha_{\rm a})}{4} - 2\frac{\mu}{\mu_g} + \frac{\alpha_{\rm a}}{2\gamma} \frac{\mu}{\mu_g} \right) n\mu_g \\
&= 2^{\frac{-3}{2}} \left(\frac{1}{\gamma} \left(\frac{\mu}{\mu_g} \right)^2 - \left(2 - \frac{\alpha_{\rm a}}{2\gamma} \right) \frac{\mu}{\mu_g} + \frac{20 - 4\alpha_{\rm a} + \alpha_{\rm a}^2}{16} \right) n\mu_g,
\end{aligned}$$

where the second inequality follows from (13), Lemmas A.1 and A.2, and the assumption that the previous iterate is in $\mathcal{N}_\infty^-(\gamma)$. The third inequality also follows from Lemma A.2. ∎

The following corollary gives an explicit upper bound for a specific μ.

COROLLARY 4.3. *Let* $\mu = \frac{\beta}{1-\beta}\mu_g$, *where* $\beta \in [\gamma, \frac{1}{3})$, $\gamma \in (0, \frac{1}{3})$, *and* $\alpha_{\rm a} \in (0, 0.1)$; *then*

$$||\Delta x \Delta s|| \leq \frac{\beta}{\sqrt{2}\gamma(1-\beta)} n\mu_g.$$

In the following theorem we estimate the maximum step size in the corrector step of the modified algorithm defined by (14) for $\alpha_{\rm a} \in (0, .01)$.

THEOREM 4.4. *Suppose the current iterate is* $(x, y, s) \in \mathcal{N}_\infty^-(\gamma)$, *where* $\gamma \in (0, \frac{1}{3})$, $\beta \in [\gamma, \frac{1}{3})$, *and* $\alpha_{\rm a} \in (0, 0.1)$, *and* $(\Delta x, \Delta y, \Delta s)$ *is the solution of* (14) *with* $\mu = \frac{\beta}{1-\beta}\mu_g$. *Then the maximum step size* $\alpha_{\rm c}$, *such that* $(x(\alpha_{\rm c}), y(\alpha_{\rm c}), s(\alpha_{\rm c})) \in \mathcal{N}_\infty^-(\gamma)$, *satisfies*

$$\alpha_{\rm c} \geq \frac{39\sqrt{2}\gamma(1-\gamma)}{40n}.$$

Proof. We need to estimate the maximum nonnegative α for which (9) holds. We know that $(\Delta x^{\rm a})^T \Delta s^{\rm a} = 0$; then $\mathcal{I}_+ \neq \emptyset$. It suffices to consider only the case when $\Delta x_i^{\rm a} \Delta s_i^{\rm a} > 0$. Therefore, we have

$$\begin{aligned}
x_i(\alpha) s_i(\alpha) &= x_i s_i + \alpha(\mu - x_i s_i - \alpha_{\rm a} \Delta x^{\rm a}{}_i \Delta s^{\rm a}{}_i) + \alpha^2 \Delta x_i \Delta s_i \\
&\geq (1-\alpha) x_i s_i + \alpha\mu - \alpha\alpha_{\rm a} t x_i s_i - \frac{\beta}{\sqrt{2}\gamma(1-\beta)} \alpha^2 n\mu_g \\
&= (1 - \alpha(1+\alpha_{\rm a} t))\, x_i s_i + \alpha\mu - \frac{\beta}{\sqrt{2}\gamma(1-\beta)} \alpha^2 n\mu_g,
\end{aligned}$$

where the first inequality follows from α being nonnegative, (11), and Corollary 4.3. Moreover, from Lemma A.1 we have that $t \leq \frac{1}{4}$, which implies $\frac{1}{1+\alpha_{\rm a} t} \geq \frac{4}{5}$. Thus we further deduce that for $\alpha \in [0, \frac{4}{5}]$, we have

$$x_i(\alpha) s_i(\alpha) \geq (1 - (1+\alpha_{\rm a} t)\alpha)\gamma\mu_g + \alpha\mu - \frac{\beta}{\sqrt{2}\gamma(1-\beta)} \alpha^2 n\mu_g.$$

By using (10), the new iterate is in $\mathcal{N}_\infty^-(\gamma)$ whenever

$$\gamma\left(1-\alpha(1+\alpha_{\mathrm{a}}t)\right)+\frac{\mu}{\mu_g}\alpha-\frac{\beta}{\sqrt{2}\gamma(1-\beta)}\alpha^2 n\geq\gamma\left(1-\alpha+\frac{\mu}{\mu_g}\alpha\right).$$

Analogous to Theorem 3.3, one can easily verify that this inequality holds for

$$\alpha=\frac{39\sqrt{2}\gamma(1-\gamma)}{40n}.$$

Therefore, we have

$$\alpha_c\geq\min\left(\frac{4}{5},\frac{39\sqrt{2}\gamma(1-\gamma)}{40n}\right)=\frac{39\sqrt{2}\gamma(1-\gamma)}{40n}:=\hat{\alpha}_c. \qquad \square$$

Now we can outline Algorithm 2 as follows.

ALGORITHM 2

Input:
A proximity parameters $\gamma\in(0,\frac{1}{3})$;
a safeguard parameter $\beta\in[\gamma,\frac{1}{3})$;
an accuracy parameter $\epsilon>0$;
$(x^0,y^0,s^0)\in\mathcal{N}_\infty^-(\gamma)$.

begin
while $x^Ts\geq\epsilon$ **do**
begin
Predictor Step
Solve (4) and compute the maximum step size α_{a} such that $(x(\alpha_{\mathrm{a}}),y(\alpha_{\mathrm{a}}),s(\alpha_{\mathrm{a}}))\in\mathcal{F}$;
end

begin
Corrector step
If $\alpha_{\mathrm{a}}\geq 0.1$, **then** solve (5) with $\mu=(1-\alpha_{\mathrm{a}})^3\mu_g$ and compute the maximum step size α_{c} such that $(x(\alpha_{\mathrm{c}}),y(\alpha_{\mathrm{c}}),s(\alpha_{\mathrm{c}}))\in\mathcal{N}_\infty^-(\gamma)$;
If $\alpha_{\mathrm{c}}<\hat{\alpha}_c$, **then** solve (5) with $\mu=\frac{\beta}{1-\beta}\mu_g$ and compute the maximum step size α_{c} such that $(x(\alpha_{\mathrm{c}}),y(\alpha_{\mathrm{c}}),s(\alpha_{\mathrm{c}}))\in\mathcal{N}_\infty^-(\gamma)$;
end
else
Solve (14) with $\mu=\frac{\beta}{1-\beta}\mu_g$ and compute the maximum step size α_{c} such that $(x(\alpha_{\mathrm{c}}),y(\alpha_{\mathrm{c}}),s(\alpha_{\mathrm{c}}))\in\mathcal{N}_\infty^-(\gamma)$;
end
Set $(x(\alpha_{\mathrm{c}}),y(\alpha_{\mathrm{c}}),s(\alpha_{\mathrm{c}}))=(x+\alpha_{\mathrm{c}}\Delta x,y+\alpha_{\mathrm{c}}\Delta y,s+\alpha_{\mathrm{c}}\Delta s)$.
end
end

The following theorem gives an upper bound for the number of iterations in which Algorithm 2 stops with an ϵ-approximate solution.

THEOREM 4.5. *Algorithm* 2*, the modified version of Algorithm* 1*, stops after at most*

$$\mathcal{O}\left(n \log \frac{(x^0)^T s^0}{\epsilon}\right)$$

iterations with a solution for which $x^T s \leq \epsilon$.

Proof. If $\alpha_{\rm a} < 0.1$ or $\alpha_{\rm c} < \hat{\alpha}_c$, then the algorithm uses the safeguard strategy. Then by (10) and Theorem 4.4 one has

$$\mu_g(\alpha) \leq \left(1 - \frac{39\sqrt{2}\gamma(1-\gamma)(1-2\beta)}{40(1-\beta)n}\right)\mu_g.$$

If $\alpha_{\rm a} \geq 0.1$ and $\alpha_{\rm c} \geq \hat{\alpha}_c$, then the algorithm uses Mehrotra's updating strategy, which further implies that

$$\mu_g(\alpha) \leq \left(1 - \frac{37\gamma(1-\gamma)}{100n}\right)\mu_g,$$

which completes the proof conforming to Theorem 3.2 of [26]. ∎

5. Superlinear convergence. In this section we analyze the asymptotic behavior of the previous algorithms using a modification of the centering parameter μ rather than using (6) due to the following observations.

We note that by Theorem 7.4 of [26] for $(x, s) \in \mathcal{N}_\infty^-(\gamma)$ the relations

$$|\Delta x_i^{\rm a} \Delta s_i^{\rm a}| \leq \mathcal{O}(\mu_g^2), \quad i = 1, \ldots, n, \tag{15}$$

hold. This further implies that $\alpha_{\rm a} \geq 1 - \mathcal{O}(\mu_g)$. Now, for the asymptotic case, one has to estimate α that satisfies the following inequalities for each $i \in \mathcal{I}$:

$$(1-\alpha)x_i^k s_i^k + (1-\gamma)\alpha\mu - \alpha\Delta x_i^{\rm a}\Delta s_i^{\rm a} + \alpha^2 \Delta x_i \Delta s_i \geq \gamma(1-\alpha)\mu_g^k.$$

By using (6) one also has $\mu \leq \mathcal{O}\left((\mu_g^k)^4\right)$. The worst asymptotic value for α might be the result of the case when $x_i s_i = \gamma\mu_g$ and $\Delta x_i^{\rm a}\Delta s_i^{\rm a} > 0$. Assuming this, it is not clear whether $\Delta x_i \Delta s_i$ is nonnegative or negative. In case of nonnegativity, the previous inequality holds for a positive value of α. However, if $\Delta x_i \Delta s_i < 0$, it might not hold due to the very small μ value which is the result of sufficiently small μ_g. Therefore, modifying Mehrotra's heuristic might be cast as a way of achieving the superlinear convergence. The new adaptive updating strategy is defined by

$$\mu = \frac{\gamma t + \gamma \min(\mu_g^{\frac{1}{2}}, 1)}{1-\gamma}\mu_g, \tag{16}$$

where t is given by (11) and $0 < \gamma < \frac{1}{3}$. The "γt" term in this definition guarantees the existence of a positive step size following the proof of Theorems 3.3 and 4.4. However, the second term enables us to prove the superlinear convergence as it will be proven in what follows, since for small μ_g it is not as aggressive as (6). The "$1-\gamma$" term in the denominator of (16) is used for simplicity of the theoretical analysis which follows. Following the analysis of sections 3 and 4, changing Mehrotra's updating scheme to this updating strategy in Algorithms 1 and 2, while preserving the large update safeguard, does not change the order of the iteration complexity. Since the

large update safeguard gives us a positive lower bound for the maximum step size in the corrector step, for simplicity those complexity proofs are omitted here.

THEOREM 5.1. *Let the iterate (x^k, y^k, s^k) be generated by Algorithm* 1 *or* 2*, where μ is given by* (16)*. When μ_g is sufficiently small, Algorithms* 1 *and* 2 *are superlinearly convergent in the sense that $\mu_g^{k+1} = \mathcal{O}\left((\mu_g^k)^{1+r}\right)$ for some $r \in (0,1)$.*

Proof. Since $\left|(\Delta x^{\mathrm{a}})_i^k (\Delta s^{\mathrm{a}})_i^k\right| \leq \mathcal{O}((\mu_g^k)^2)$ for all $i \in \mathcal{I}$, then similar to the proof of Theorem 7.4 of [26] one can show that

$$|(\Delta x)_i^k (\Delta s)_i^k| \leq \mathcal{O}\left((\mu_g^k)^2\right).$$

By the new definition of μ, the next iterate is in the neighborhood $\mathcal{N}_\infty^-(\gamma)$ if for each $i \in \mathcal{I}$

$$(1-\alpha)x_i^k s_i^k + \alpha(1-\gamma)\mu^k - \alpha\Delta x_i^{\mathrm{a}}\Delta s_i^{\mathrm{a}} + \alpha^2\Delta x_i\Delta s_i \geq \gamma(1-\alpha)\mu_g^k. \tag{17}$$

Our goal is to find $\alpha \in (0,1]$ for which (17) holds. For this, it is sufficient to prove (17) for the case where $(\Delta x^{\mathrm{a}})_i^k (\Delta s^{\mathrm{a}})_i^k > 0$ and $(\Delta x)_i^k (\Delta s)_i^k < 0$. Using the definition of t, for a positive component of $\Delta x^a \Delta s^a$ one also has $\Delta x_i^{\mathrm{a}}\Delta s_i^{\mathrm{a}} \leq t x_i s_i$. Therefore, it suffices to find $\alpha \in (0,1]$ for which the following inequality holds:

$$(1-\alpha(1+t))x_i^k s_i^k + \alpha(1-\gamma)\mu^k - \alpha^2\mathcal{O}((\mu_g^k)^2) \geq \gamma(1-\alpha)\mu_g^k. \tag{18}$$

If (18) holds for $\alpha \geq \frac{1}{1+t}$, then $\alpha \geq 1-\mathcal{O}(\mu_g^k)$, since $\frac{1}{1+t} = \frac{1}{1+\mathcal{O}(\mu_g^k)} \geq 1-\mathcal{O}(\mu_g^k)$. Now let us assume that $\alpha < \frac{1}{1+t}$. In order to have (18), using the fact that $x_i^k s_i^k \geq \gamma\mu_g^k$, it suffices to have

$$\begin{aligned}(1-\alpha(1+t))\gamma\mu_g^k \;+\; \alpha\gamma t\mu_g^k + \alpha\gamma\min\left(\mu_g^{\frac{1}{2}}, 1\right)\mu_g - \alpha^2\mathcal{O}((\mu_g^k)^2) \\ \geq \gamma(1-\alpha)\mu_g^k\end{aligned}$$

for some $\alpha \in (0,1]$, which is equivalent to

$$\gamma\mu_g^{\frac{3}{2}} - \alpha\mathcal{O}((\mu_g^k)^2) \geq 0. \tag{19}$$

Inequality (19) definitely holds for $\alpha \geq 1-\mathcal{O}\left((\mu_g^k)^r\right)$, where $r \in (0,1)$.

Now, by using (10), one further has

$$\mu_g^k(\alpha_{\mathrm{c}}^k) = \left(1-\alpha_c^k(1-\mathcal{O}(\mu_g^k))\right)\mu_g^k \leq \left(1-(1-\mathcal{O}((\mu_g^k)^r))(1-\mathcal{O}(\mu_g^k))\right)\mu_g^k \leq \mathcal{O}\left((\mu_g^k)^{1+r}\right).$$

This gives the superlinear convergence of Algorithm 1 with the new choice of the parameter μ. The superlinear convergence of Algorithm 2 also can be proved analogously. ∎

6. Numerical results. In this section we report some illustrative numerical results for different variants of Algorithm 2 due to its better computational performance than Algorithm 1 for few problems. The results are obtained by modifying some of the subroutines of the McIPM (a self-dual embedding model-based implementation) and the LIPSOL (an infeasible IPM implementation for LO problems), two software packages based in MATLAB [29, 30]. Our computational experiments are done on a Pentium 4 machine with 2.53 GHZ and 512 MB ram. Numerical results are reported for all feasible NETLIB and Kennington test problems. For each problem we report the number of iterations, the time it takes to load the problem and solve it, and the number of exact digits, respectively.

For the McIPM package we use the following abbreviations for the different implementations of Mehrotra's algorithm:

- **PMMcIPM:** Mehrotra's original algorithm presented in section 1.
- **HMcIPM:** Mehrotra's original algorithm presented in section 1 combined with heuristics in the definition of the centering parameter. The interested reader can consult the McIPM package for heuristics that are used there [30].
- **NMcIPMI:** Algorithm 2.
- **NMcIPMII:** Algorithm 2 with the new definition of the centering parameter (16) instead of using (6).

For all the above-mentioned variants we set $\gamma = 10^{-4}$ and $\mu = \frac{\mu_g}{10}$ as the safeguard. In the implementation of our new definition of μ given by (16), we use $\mu = \frac{1}{5}(t + \min(\mu^1/2_g, 1))\mu_g$ rather than using (16), which is introduced for theoretical easiness.

Tables 1 to 3 show that for 36 problems (total number of problems is 112), the number of iterations for PMcIPM is higher than NMcIPMI, for 63 problems is higher than NMcIPMII, and for 65 problems is higher than HMcIPM implementations. As one can notice from Tables 1 to 3, for some problems PMcIPM is doing better than the other implementations, and for the rest they all perform equally. Significant difference in time occurs when the number of iterations is significantly different; for example, see "dfl001" and "degen3" in Table 1 and "osa-60" and "pds-20" in Table 3. The comparison between our two new algorithms (NMcIPMI and NMcIPMII) shows that NMcIPMII is better than NMcIPMI for 56 problems, while NMcIPMI is doing better only for 22 problems, and they perform equally on the rest of the problems. Therefore, overall NMcIPMII performs better than NMcIPMI. Finally, the comparison between NMcIPMII and HMcIPM shows that HMcIPM is doing better for 26 problems, while HMcIPM is better for 27 problems, and they perform equally on the rest of the problems. This comparison also shows that our simple safeguard-based algorithm is at least as effective as the heuristics used in the package and sometimes overperforms HMcIPM on difficult problems as given in Table 3.

The following abbreviations are also used for different implementations of Mehrotra's algorithm in LIPSOL:

- **PLIPSOL:** Infeasible variant of Mehrotra's algorithm presented in section 1.
- **HLIPSOL:** Infeasible variant of Mehrotra's original algorithm presented in section 1 with heuristics that are used in the definition of the centering parameter by LIPOSL. One should consult the LIPSOL package for the details of the heuristics [29].
- **SLIPSOL:** Infeasible variant of Algorithm 2.

For all the above-mentioned versions of LIPSOL we use $\gamma = 10^{-4}$ and $\frac{\beta}{1-\beta} = 10^{-1}$.

It is worthwhile mentioning that we do not have the second modification of the LIPSOL, namely the new definition of the centering parameter, because it requires a detailed analysis of the infeasible Mehrotra algorithm that is left for future research.

In Tables 4 to 6 we report the numerical results using the above-mentioned variants of LIPSOL. The comparison of iterations numbers show that for 66 problems SLIPSOL and HLIPSOL are doing better than PLIPSOL, while PLIPSOL is better only for a few problems. The comparison between SLIPSOL and HLIPSOL shows that overall they perform equally. Finally, a significant difference in time occurs when the number of iterations dramatically differ; for example, see "dfl001" in Table 4 and "cre-d," "osa-14," "pds-10," and "pds-20" in Table 6.

7. Final remarks. In this paper we have discussed the polynomiality of Mehrotra's original predictor-corrector algorithm. By a numerical example we have shown that Mehrotra's algorithm might lead to an inefficient algorithm while keeping the it-

erate in the $\mathcal{N}_\infty^-(\gamma)$ neighborhood, which is essential to prove the polynomial iteration complexity. This motivated us to combine his idea with a safeguard strategy that allows us to get a positive lower bound for the step size in the corrector step. Further, by slightly changing the Newton system, the iteration complexity of the algorithm is significantly reduced. This also led us to superior computational performance of the algorithm. To ensure the superlinear convergence of the algorithm we changed Mehrotra's updating scheme of the centering parameter so that the new algorithms preserve the iteration complexity and exhibit stronger asymptotic convergence properties. Our illustrative numerical results show that our new safeguard-based algorithms are competitive with two state of the art software packages that are using heuristics to stabilize the convergence of the implemented algorithms.

There are several interesting questions regarding the proposed safeguard strategy. For example, one can analyze the infeasible variant of this prototype. It is also possible to extend this approach to other classes of optimization problems such as SDO, SOCO, and convex nonlinear optimization.

Appendix. In this section we prove two technical lemmas that have been used frequently during the analysis.

LEMMA A.1. *Let* $(\Delta x^a, \Delta y^a, \Delta s^a)$ *be the solution of* (4). *Then*

$$\Delta x_i^a \Delta s_i^a \leq \frac{x_i s_i}{4} \quad \forall i \in \mathcal{I}_+.$$

Proof. By (4) for $i \in \mathcal{I}_+$ we have

$$s_i \Delta x_i^a + x_i \Delta s_i^a = -x_i s_i.$$

If we divide this equation by $x_i s_i$ we get

$$\frac{\Delta x_i^a}{x_i} + \frac{\Delta s_i^a}{s_i} = -1.$$

Since $\Delta x_i^a \Delta s_i^a > 0$, this equality implies that both $\Delta x_i^a < 0$ and $\Delta s_i^a < 0$. Then from

$$0 \le \left(\frac{\Delta x_i^a}{x_i} - \frac{\Delta s_i^a}{s_i}\right)^2 = \left(\frac{\Delta x_i^a}{x_i}\right)^2 + \left(\frac{\Delta s_i^a}{s_i}\right)^2 - 2\frac{\Delta x_i^a \Delta s_i^a}{x_i s_i} = 1 - 4\frac{\Delta x_i^a \Delta s_i^a}{x_i s_i}$$

we get

$$\Delta x_i^a \Delta s_i^a \le \frac{x_i s_i}{4}. \qquad \square$$

LEMMA A.2. *Let* $(\Delta x^a, \Delta y^a, \Delta s^a)$ *be the solution of* (4)*; then we have*

$$\sum_{i \in \mathcal{I}_+} \Delta x_i^a \Delta s_i^a = \sum_{i \in \mathcal{I}_-} |\Delta x_i^a \Delta s_i^a| \le \frac{1}{4} \sum_{i \in \mathcal{I}_+} x_i s_i \le \frac{x^T s}{4}.$$

EFFICIENT REDUCTION OF POLYNOMIAL ZERO-ONE OPTIMIZATION TO THE QUADRATIC CASE*

CHRISTOPH BUCHHEIM† AND GIOVANNI RINALDI‡

Abstract. We address the problem of optimizing a polynomial with real coefficients over binary variables. We show that a complete polyhedral description of the linearization of such a problem can be derived in a simple way from the polyhedral description of the linearization of some quadratic optimization problem. The number of variables in the latter linearization is only slightly larger than in the former. If polynomial constraints are present in the original problem, then their linearized counterparts carry over to the linearized quadratic problem unchanged. If the original problem formulation does not contain any constraints, we obtain a reduction to unconstrained quadratic zero-one optimization, which is equivalent to the well-studied max-cut problem. The separation problem for general unconstrained polynomial zero-one optimization thus reduces to the separation problem for the cut polytope. This allows us to transfer the entire knowledge gained for the latter polytope by intensive research and, in particular, the sophisticated separation techniques that have been developed. We report preliminary experimental results obtained with a straightforward implementation of this approach.

Key words. polynomial zero-one optimization, integer nonlinear programming, pseudo-boolean functions, max-cut problem, multilinear function optimization

AMS subject classifications. 90C57, 65K05

DOI. 10.1137/050646500

1. Introduction.

We consider the problem of maximizing (or minimizing) a polynomial objective function over binary variables under arbitrary polynomial constraints, i.e., over all binary vectors belonging to a given semialgebraic set. We call it *polynomial zero-one optimization*.

Many different names and interpretations of this problem are circulating. For instance, if a set A is used to index the (original) variables, then one might think of the variables as modeling some subset of A. The possible monomials are then in one-to-one correspondence with the subsets of A, as we may assume that every variable appears with exponent at most one in every monomial. Consequently, maximizing a polynomial over these variables means searching for a subset S of A such that the sum of all coefficients of monomials that correspond to subsets of S is maximized. In other words, for every subset of A, one can arbitrarily reward or punish the fact that all elements of this set are chosen by S.

Still in the unconstrained case, assume that the objective function is multilinear. Then the constraints $x \in \{0,1\}^A$ can be replaced by $x \in [0,1]^A$, as an optimal solution is always attained at a vertex of the unit hypercube [25]. Moreover, as multilinear functions are closed under affine variable transformations, the unit hypercube can be replaced by an arbitrary box. Therefore, this case is equivalent to the problem of *maximizing a multilinear function over a box*.

A standard method to address such a problem is linearization: every nonlinear term in the problem formulation is replaced by a newly introduced binary variable. In other words, the new variables correspond to all monomials appearing in the objective function or in one of the constraints of the original problem. Over this new set of variables, the problem thus translates to an integer linear program, which can hopefully be solved by polyhedral methods.

However, additional constraints are now needed to link the newly introduced variables to the original ones. More precisely, the value of a variable representing a monomial $x_{i_1}x_{i_2}\dots x_{i_r}$ must equal the product of the values of $x_{i_1}, x_{i_2}, \dots, x_{i_r}$. The purpose of this paper is to show that, after adding a small number of new variables, this task can be reduced to the quadratic case in an efficient (and easily implementable) way. Using elementary polyhedral results, we show that the separation problem for the linearized original problem can be reduced to the separation problem for a linearized quadratic problem that is only slightly larger. The construction of the latter is "orthogonal" to the given polynomial constraints in the sense that their linearized counterparts carry over to the quadratic problem unchanged. By the equivalence of unconstrained quadratic zero-one optimization and max-cut, we can thus reduce the original problem to a max-cut problem with additional linear constraints.

The most promising application for this reduction method arises in the unconstrained case, which we examine in more detail in this paper, also experimentally. In this case, the separation problem reduces to the separation problem for the cut polytope, without further constraints. The cut polytope is one of the most important and best-studied objects in polyhedral combinatorics: many classes of cutting planes as well as sophisticated separation techniques are at hand for addressing the corresponding separation problem (see, e.g., [19] or [21]). Our approach aims at exploiting this knowledge for optimizing polynomials of arbitrary degree.

The polynomial zero-one optimization problem, with different types of constraints, has been studied extensively in the literature, often under the name of *pseudo-boolean optimization*. The reader is referred to a comprehensive survey by Boros and Hammer [5] that contains not only pointers to numerous applications but also approaches for solving this problem. In particular, two different approaches are mentioned: a reduction to the quadratic case due to Rosenberg [26] and the so-called *basic algorithm* by Hammer, Rosenberg, and Rudeanu [16]. The former approach can be combined with any max-cut algorithm and is briefly discussed in section 3.5. For the latter approach, to the best of our knowledge, an experimental evaluation exists only for a special case where it runs in linear time [7]. The ongoing interest in pseudo-boolean optimization is underlined by a recent special issue of the journal *Discrete Applied Mathematics* [14]. We would also like to point to the numerous theoretical results that have been obtained for pseudo-boolean functions, e.g., concerning persistency [15], and to interesting special cases such as hyperbolic pseudo-boolean functions or products of linear functions; see again [5].

This paper is organized as follows. In section 2, we define the general problem addressed and recall the standard linearization method. In section 3, we present the reduction method for polynomial zero-one programming to the quadratic case. The unconstrained case is considered in section 4; in particular, preliminary experimental results are reported. Some conclusions are drawn in section 5.

2. The standard linearization. Let A be any finite set of n elements, and consider the set of binary variables $\{x_a \mid a \in A\}$. Let $g_0, \dots, g_r$ be polynomials over

these variables. We consider the following polynomial zero-one optimization problem:

$$\begin{array}{rrcll} \max & g_0(x) & & & \\ \text{s.t.} & g_i(x) & \geq & 0 & \text{for all } i = 1, \dots, r, \\ & x & \in & \{0,1\}^A \, . & \end{array} \tag{2.1}$$

The standard way of linearizing the problem (2.1) is to consider the set $\mathcal{I}$ of all nonconstant monomials appearing in at least one of the g_i's and to use a binary variable z_I for every $I \in \mathcal{I}$, yielding the equivalent formulation

$$\begin{array}{rrcll} \max & h_0(z) & & & \\ \text{s.t.} & h_i(z) & \geq & 0 & \text{for all } i = 1, \dots, r, \\ & z_I & = & \prod_{a \in I} z_{\{a\}} & \text{for all } I \in \mathcal{I}, \\ & z & \in & \{0,1\}^{\mathcal{I}} \, . & \end{array} \tag{2.2}$$

Here we use h_i to denote the polynomial g_i considered as a linear function in the new set of variables z_I. As all variables in (2.1) are binary, we may assume that each g_i is multilinear. In particular, we can identify monomials with the corresponding subsets of A and thus consider $\mathcal{I}$ as a subset of $2^A \setminus \{\emptyset\}$; therefore, we will use expressions such as "union of monomials" in the following. Moreover, for the ease of exposition, we assume that $\{a\} \in \mathcal{I}$ for all $a \in A$. We denote the cardinality of $\mathcal{I}$ by m.

Throughout this paper, let F denote the set of feasible solutions of (2.2), and let P denote the convex hull of F, which is a polytope in $\mathbb{R}^{\mathcal{I}}$. Problem (2.2) is still a polynomial optimization problem, but the nonlinearity is restricted to the product formulae. The remaining problem is to model these constraints by linear inequalities. The easiest way to do this is the following: for every $I \in \mathcal{I}$ with $|I| \geq 2$, use the $|I|+1$ linear inequalities

$$z_I \leq z_{\{a\}} \quad \text{for all } a \in I \, , \tag{2.3}$$

$$z_I \geq \sum_{a \in I} z_{\{a\}} - |I| + 1 \, . \tag{2.4}$$

This standard linearization approach has been widely discussed in the literature; for early examples, see [10, 11, 12, 16, 28]. However, the relaxation of P given by the constraints (2.3) and (2.4) is rather weak when the integrality constraints are dropped. The aim of this paper is to present a general method for deriving much tighter relaxations of P.

A different approach to problem (2.1) is to replace each polynomial function g_i by a collection of linear functions in the same set of variables. This approach has been studied by Granot and Hammer [13] and later improved by Balas and Mazzola [2]. Unfortunately, the resulting LP has exponential size, and the corresponding relaxation is rather weak in general. On the other hand, our aim is to keep the construction as small as possible, at the same time allowing a tight polyhedral description.

Still another approach to solving problem (2.1) is to apply lift-and-project methods; for this topic, see the comparative survey by Laurent [20]. Here new polynomial constraints are created by multiplication of given ones. In the LP-based approaches, the resulting constraints are then linearized. According to the number of constraints multiplied, one obtains hierarchies of LP relaxations that coincide with the polytope P

at level n. Similar ideas have been used to develop cutting plane algorithms, e.g., by Balas et al., who proposed strengthening the standard linearization by applying the lifting to single fractional variables and computing most violated facets of the corresponding relaxations, always projecting them back to the original variable space in order to avoid exponential numbers of variables [1, 3].

Related methods based on semidefinite programming (SDP) have been introduced by Lasserre [18] and Parillo [24]. These are based on deep results from real algebraic geometry on representations of nonnegative polynomial as sums of squares. As shown in [20], the hierarchy of relaxations constructed by Lasserre is stronger than earlier hierarchies of LP-based relaxations [1, 22, 27]. However, in all these approaches the number of variables already becomes large in the first levels of the hierarchy.

3. The general reduction method. In the following, we present a general method of reducing polynomial zero-one optimization to the quadratic case via the separation problem. We first prove elementary polyhedral results that provide the theoretical background for the reduction (section 3.1). Then we give an algorithmic description of the reduction procedure (section 3.2). Special aspects of this method are discussed in sections 3.3 and 3.4. Finally, we compare this approach to the direct reduction method (section 3.5).

3.1. Basic results. Starting from the polytope P corresponding to (2.2), we first construct a new polytope P^* as follows: define the following subset of $2^{\mathcal{I}}$ whose elements are all sets of two (not necessarily distinct) monomials whose union is a monomial of $\mathcal{I}$:

$$\mathcal{I}^* = \left\{ \{I, J\} \mid I, J \in \mathcal{I} \text{ and } I \cup J \in \mathcal{I} \right\}.$$

As in the definition of $\mathcal{I}^*$ the sets I and J may coincide, we have $\{I\} \in \mathcal{I}^*$ for each $I \in \mathcal{I}$. If we associate a variable $y_{\{I,J\}}$ with every element $\{I, J\}$ of $\mathcal{I}^*$, every h_i gives rise to a linear function h_i^* over the new variables $\{y_S \mid S \in \mathcal{I}^*\}$ by replacing each variable z_I with the corresponding variable $y_{\{I\}}$. Now consider

$$\begin{array}{lrcll} \max & h_0^*(y) & & & \\ \text{s.t.} & h_i^*(y) & \geq & 0 & \text{for all } i = 1, \ldots, r, \\ & y_{\{I,J\}} & = & y_{\{I\}} y_{\{J\}} & \text{for all } \{I, J\} \in \mathcal{I}^*, \\ & y & \in & \{0,1\}^{\mathcal{I}^*}, & \end{array} \tag{3.1}$$

and let F^* be the set of feasible solutions of (3.1). Moreover, let P^* be the polytope in $\mathbb{R}^{\mathcal{I}^*}$ defined as the convex hull of F^*.

We do not aim to solve this optimization problem but rather are interested only in the separation problem for P^*. Note that the variables that appear in the objective function and in the r linear constraints are only those indexed by a single monomial. The variables indexed by sets of two monomials appear only in the product constraints. Thus problem (3.1) can be thought of as the linearization of a quadratic zero-one optimization problem. Our aim is to exploit this in the following. To do so, we define an injective linear map $\psi: \mathbb{R}^{\mathcal{I}} \to \mathbb{R}^{\mathcal{I}^*}$ componentwise by $(\psi(z))_{\{I,J\}} = z_{I \cup J}$, and we set

$$Y = \left\{ y \in \mathbb{R}^{\mathcal{I}^*} \mid y_{\{I \cup J\}} = y_{\{I,J\}} \text{ for all } I, J \in \mathcal{I} \text{ with } I \cup J \in \mathcal{I} \right\}.$$

From these definitions, it is readily checked that $Y = \psi(\mathbb{R}^{\mathcal{I}})$. The preimage z under ψ of a vector y in Y is determined by $z_I = y_{\{I\}}$.

LEMMA 3.1. *$\psi(F) \subseteq F^* \cap Y$.*

Proof. Let $z \in F$, and set $y = \psi(z)$. By definition, we have $h_i^*(y) = h_i(z)$, so that all inequalities in (3.1) are satisfied by y. It remains to show $y_{\{I,J\}} = y_{\{I\}} y_{\{J\}}$ for all $I, J \in \mathcal{I}$. Indeed, as z belongs to F, we have

$$y_{\{I,J\}} = z_{I \cup J} = \prod_{a \in I \cup J} z_{\{a\}} = \prod_{a \in I} z_{\{a\}} \prod_{a \in J} z_{\{a\}} = z_I z_J = y_{\{I\}} y_{\{J\}} \,. \qquad \square$$

Lemma 3.1 shows that every LP relaxation of P^* gives rise to an LP relaxation of P. The following results concern the quality of this relaxation. For this, call the set $\mathcal{I}$ *reducible* if every set in $\mathcal{I}$ containing more than one element is a union of two other sets in $\mathcal{I}$. Then we have the following.

THEOREM 3.2. *If $\mathcal{I}$ is reducible, then $\psi(F) = F^* \cap Y$.*

Proof. By Lemma 3.1, it remains to show that every $y \in F^* \cap Y$ belongs to $\psi(F)$. As mentioned above, the vector z defined by $z_I = y_{\{I\}}$ satisfies $\psi(z) = y$, and so we have to show that z belongs to F. As $h_i(z) = h_i^*(y)$, all inequalities in (2.2) are satisfied by z. As z is integer, it remains to show that

$$z_I = \prod_{a \in I} z_{\{a\}}$$

holds for all $I \in \mathcal{I}$. By definition of z, we thus have to prove

$$y_{\{I\}} = \prod_{a \in I} y_{\{\{a\}\}}$$

for all $I \in \mathcal{I}$. This is done by induction over the cardinality of I. If $|I| = 1$, the claim is trivial. Otherwise, as $\mathcal{I}$ is reducible, there exist two sets $I_1, I_2 \in \mathcal{I}$ that are smaller than I such that $I = I_1 \cup I_2$. For any $y \in F^*$, we have $y_{\{I_1,I_2\}} = y_{\{I_1\}} y_{\{I_2\}}$ by definition. By induction,

$$y_{\{I_1\}} = \prod_{a \in I_1} y_{\{\{a\}\}} \quad \text{and} \quad y_{\{I_2\}} = \prod_{a \in I_2} y_{\{\{a\}\}} \,.$$

Finally, the equations in Y enforce $y_{\{I_1,I_2\}} = y_{\{I_1 \cup I_2\}}$. Connecting all this, we derive

$$y_{\{I\}} = y_{\{I_1 \cup I_2\}} = y_{\{I_1,I_2\}} = y_{\{I_1\}} y_{\{I_2\}} = \prod_{a \in I_1} y_{\{\{a\}\}} \prod_{a \in I_2} y_{\{\{a\}\}} = \prod_{a \in I} y_{\{\{a\}\}} \,. \qquad \square$$

If $\mathcal{I}$ is not reducible, then Theorem 3.2 does not hold in general. To see this, consider the unconstrained case, and assume that there is an element $I \in \mathcal{I}$ with $|I| \geq 2$ such that $I \neq I_1 \cup I_2$ for all $I_1, I_2 \in \mathcal{I} \setminus \{I\}$. In other words, $I_1 \cup I_2 = I$ implies $I_1 = I$ or $I_2 = I$. Define $y \in \mathbb{R}^{\mathcal{I}^*}$ by

$$y_{\{I_1,I_2\}} = \begin{cases} 1 & \text{if } I_1 \cup I_2 \subseteq I \text{ but } I_1 \cup I_2 \neq I, \\ 0 & \text{otherwise.} \end{cases}$$

Then $y \in F^* \cap Y$, but the unique preimage $\psi^{-1}(y)$ of y in $\mathbb{R}^{\mathcal{I}}$ is not contained in F, as $\psi^{-1}(y)_I = y_{\{I\}} = 0$, while

$$\prod_{a \in I} \psi^{-1}(y)_{\{a\}} = \prod_{a \in I} y_{\{\{a\}\}} = 1 \,.$$

The latter is true because $|I| \geq 2$ implies that each $\{a\}$ is a proper subset of I.

THEOREM 3.3. *The polytope $P^* \cap Y$ is a face of P^* and thus integer.*

Proof. Consider the linear subspace of $\mathbb{R}^{\mathcal{I}^*}$ given as

$$Y' = \left\{ y \in \mathbb{R}^{\mathcal{I}^*} \mid y_{\{I \cup J\}} = y_{\{I, I \cup J\}} \text{ for all } I, J \in \mathcal{I} \text{ with } I \cup J \in \mathcal{I} \right\}.$$

As the equations defining Y' form a subset of those defining Y, we have $Y \subseteq Y'$. In particular, we have $P^* \cap Y = P^* \cap Y' \cap Y$. We will first intersect P^* with Y' and then with Y and show that in both steps the added equations are induced by valid inequalities for the corresponding polytope, so that we cut out a face in each step.

For the first step, notice that the inequality $y_{\{I \cup J\}} \geq y_{\{I, I \cup J\}}$ is valid for P^* for all $I, J \in \mathcal{I}$ with $I \cup J \in \mathcal{I}$. Hence $P^* \cap Y'$ is a face of P^* and thus integer. Now we claim that for $P^* \cap Y'$ the inequality $y_{\{I \cup J\}} \leq y_{\{I,J\}}$ is valid. As $P^* \cap Y'$ is integer, we have to show this only for integer vectors in this polytope. For these, we have $y_{\{I \cup J\}} = y_{\{I, I \cup J\}} = y_{\{I\}} y_{\{I \cup J\}}$ by definition, so that either $y_{\{I \cup J\}} = 0$ or $y_{\{I\}} = 1$. The same argument for J instead of I yields $y_{\{I \cup J\}} = 0$ or $y_{\{J\}} = 1$. Thus, if $y_{\{I \cup J\}} = 1$, we have $y_{\{I\}} = y_{\{J\}} = 1$, and hence $y_{\{I,J\}} = y_{\{I\}} y_{\{J\}} = 1$. We derive $y_{\{I \cup J\}} \leq y_{\{I,J\}}$. ∎

COROLLARY 3.4. *If $\mathcal{I}$ is reducible, then P is isomorphic to a face of P^* via ψ.*

To conclude this section, we consider the basic SDP relaxation of the quadratic problem (3.1). For any set B, define $\mathcal{P}_k(B) = \{B' \subseteq B \mid |B'| \leq k\}$. For $\mathcal{B} \subseteq 2^B$, let $M_{\mathcal{B}}(y)$ denote the restriction of the moment matrix of y over B to rows and columns indexed over $\mathcal{B}$, and let $*$ denote the shift operator [18, 20]. With these definitions, we have $\mathcal{I}^* \subseteq \mathcal{P}_2(\mathcal{I})$, and the basic SDP relaxation of P^* is

$$\left\{ y \in \mathbb{R}^{\mathcal{P}_2(\mathcal{I})} \mid M_{\mathcal{P}_1(\mathcal{I})}(y) \succeq 0,\ M_{\mathcal{P}_1(\mathcal{I})}(h_i^* * y) \succeq 0 \text{ for } i = 1, \ldots, r,\ y_\emptyset = 1 \right\}. \tag{3.2}$$

Note that $M_{\mathcal{P}_1(\mathcal{I})}(y)_{\{I\},\{J\}} = y_{\{I,J\}}$. Under the linear map ψ, the variable $y_{\{I,J\}}$ corresponds to $z_{I \cup J}$ in (2.2), so that (3.2) is equivalent to

$$\left\{ z \in \mathbb{R}^{\mathcal{I}_2 \cup \{\emptyset\}} \mid M_{\mathcal{I} \cup \{\emptyset\}}(z) \succeq 0,\ M_{\mathcal{I} \cup \{\emptyset\}}(h_i * z) \succeq 0 \text{ for } i = 1, \ldots, r,\ z_\emptyset = 1 \right\}, \tag{3.3}$$

where $\mathcal{I}_2 = \{I \cup J \mid I, J \in \mathcal{I}\}$. Projecting (3.3) to $\mathbb{R}^{\mathcal{I}}$ yields an SDP relaxation of P. Moreover, it is easy to see that the results of this section remain valid if we remove each element $\{I\}$ from $\mathcal{I}^*$ for which I is maximal in $\mathcal{I}$. Then instead of (3.3) we get

$$\left\{ z \in \mathbb{R}^{\mathcal{I}'_2 \cup \{\emptyset\}} \mid M_{\mathcal{I}' \cup \{\emptyset\}}(z) \succeq 0,\ M_{\mathcal{I}' \cup \{\emptyset\}}(h_i * z) \succeq 0 \text{ for } i = 1, \ldots, r,\ z_\emptyset = 1 \right\}, \tag{3.4}$$

where $\mathcal{I}'$ is the set of nonmaximal elements of $\mathcal{I}$ and $\mathcal{I}'_2 = \{I \cup J \mid I, J \in \mathcal{I}'\}$. Now reducibility of $\mathcal{I}$ implies $\mathcal{I} \subseteq \mathcal{I}'_2$, so that (3.4) in this case still induces a relaxation of P, defined by an even smaller number of variables. If the original problem (2.1) is already quadratic, then (3.4) is just the standard SDP relaxation of (2.1).

If $\mathcal{I}$ is reducible, then by Theorem 3.2 the integer points in (3.4) correspond bijectively to the solutions of (2.2). On the other hand, if $\mathcal{I}$ is not reducible, then the example given above shows that in general we can have $M_{\mathcal{I} \cup \{\emptyset\}}(z) \succeq 0$ even if z is integer and is infeasible for (2.2).

Using the framework of Laurent [20], the relaxation (3.4) can be compared to the ones presented by Sherali and Adams [27] and Lasserre [18]: in all three cases, the semidefiniteness of the (full) moment matrices is relaxed by requiring this property only for certain submatrices. In particular, one finds that (3.4) contains the tth Lasserre iterate if all monomials in $\mathcal{I}$ have degree at most $t + 2$ but not earlier in

general. On the other hand, our relaxation is not usually contained in any Lasserre iterate, as we restrict ourselves to very few rows and columns of the moment matrices, corresponding to our aim to keep the number of variables as small as possible.

3.2. The reduction procedure. We showed that the polytope P is isomorphic to a face of a polytope P^* corresponding to a quadratic instance if $\mathcal{I}$ is reducible. In particular, in this case, the separation problem for P reduces to the separation problem for P^*; i.e., the general separation problem reduces to the one for the quadratic case. More precisely, assume that a separation algorithm $\mathcal{A}$ is given for P^*; then we obtain the following induced separation algorithm for P.

Separation of a vector $\overline{z} \in \mathbb{R}^{\mathcal{I}}$ from P.
Compute the vector $\overline{y}^* = \psi(\overline{z}) \in \mathbb{R}^{\mathcal{I}^*}$
Apply the separation algorithm $\mathcal{A}$ to $\overline{y}^*$
if a violated constraint Γ is found
then
  Replace every variable $y_{\{I,J\}}$ in Γ by $z_{I \cup J}$
  Return the resulting constraint
else output "no cutting plane found"

By Lemma 3.1, any constraint returned by this algorithm is valid for P but violated by $\overline{z}$. In particular, the algorithm is correct whenever the answer is positive, i.e., whenever a cutting plane is found. On the other hand, its effectiveness, i.e., the probability of finding a violated cutting plane if one exists, obviously depends on the effectiveness of the underlying separation algorithm $\mathcal{A}$. According to Corollary 3.4, the former algorithm is an exact separation algorithm for P if the same is true for $\mathcal{A}$ and $\mathcal{I}$ is reducible. The reducibility of $\mathcal{I}$ can be obtained artificially by adding new zero-weight sets to $\mathcal{I}$ in a preprocessing step (see section 3.3).

The general idea supporting our approach is thus to solve all LP relaxations in the original variable space (including variables needed for making $\mathcal{I}$ reducible) and to move to the higher dimension of P^* only during separation. The advantage of dealing with P^* instead of P in the separation phase is that the former belongs to the smaller class of polytopes corresponding to quadratic problems, so that there is more hope in finding a good polyhedral description of P^*. For instance, in the unconstrained case, P^* is isomorphic to a cut polytope, while in the general case, the polytope P^* corresponds to a max-cut problem with additional constraints. For cut polytopes, several classes of cutting planes and sophisticated separation techniques are known, while nothing similar is at hand for the more general polytope P, even in the unconstrained case. The practical benefit of this approach is underlined by the results of a first experimental evaluation, presented in section 4.3.

3.3. How to make the instance reducible. As pointed out, our separation approach can be expected to have a good performance only if the given set $\mathcal{I}$ is reducible, even if the validity of the induced inequalities does not require reducibility of $\mathcal{I}$. Obviously, every set $\mathcal{I}$ can be made reducible by adding new elements, e.g., by adding all subsets of elements in $\mathcal{I}$. Unfortunately, the added elements have to be represented by additional variables, so that the problem size increases. This gives rise to the question of how many elements we have to add to $\mathcal{I}$ and how we can find a possibly small set of new elements algorithmically.

One can show that determining a smallest set of additional variables sufficient to make $\mathcal{I}$ reducible is an NP-hard problem, which remains true even for degree $d = 3$. This follows from the NP-hardness of finding an optimal replacement strategy

in the direct reduction approach [5] (see section 3.5). Hence we have to resort to heuristic methods. In our implementation, we use the following straightforward greedy approach: first, add all singletons $\{a\}$ to $\mathcal{I}$ if necessary. Then, as long as $\mathcal{I}$ is not reducible, determine two distinct variables $a_1, a_2 \in A$ such that the cardinality of

$$\mathcal{P}(a_1, a_2) = \Big\{ I \in \mathcal{I} \mid a_1, a_2 \in I \text{ and } I \neq I_1 \cup I_2 \text{ for all } I_1, I_2 \in \mathcal{I} \setminus \{I\} \Big\}$$

is maximal. Now add the sets $\{a_1, a_2\}$ and $I \setminus \{a_1, a_2\}$ to $\mathcal{I}$ for all $I \in \mathcal{P}(a_1, a_2)$. In the worst case, i.e., if all $I \in \mathcal{I}$ are pairwise disjoint and no singletons exist in $\mathcal{I}$, the number of new terms produced by this algorithm is $n + \sum_{I \in \mathcal{I}} (|I| - 2)$ and thus bounded by $n + (d-2)m$. For hard instances, however, the sets $I \in \mathcal{I}$ typically overlap to a significant extent; thus in practice the average number of new variables can be expected to be much smaller than $n + (d-2)m$.

3.4. How to define the separation instance. The set $\mathcal{I}^*$ as defined in section 3.1 has, in general, quadratic size in m. However, assuming that $\mathcal{I}$ is reducible, it is readily checked that all results of section 3.1 remain true if $\mathcal{I}^*$ is constructed in a sparser way as follows: for every $I \in \mathcal{I}$, choose two smaller elements $I_1, I_2 \in \mathcal{I}$ with $I = I_1 \cup I_2$ and add $\{I_1, I_2\}$, $\{I_1, I\}$, and $\{I_2, I\}$ to $\mathcal{I}^*$. In other words, we have to model only a single representation of I as a union of smaller elements in $\mathcal{I}$. Using this construction, the size of $\mathcal{I}^*$ is at most four times the size of $\mathcal{I}$. A further improvement is obtained by omitting any singleton $\{I\}$ for which I is maximal in $\mathcal{I}$.

In summary, these modifications yield a smaller instance $\mathcal{I}^*$ than the one proposed in section 3.1. For example, if the original instance $\mathcal{I}$ was already a quadratic instance, we now have $\mathcal{I} = \mathcal{I}^*$. So it might seem more appealing to use this *sparse* definition of $\mathcal{I}^*$. However, as for the quadratic case, a perfect separation algorithm is not available; this is not always preferable from a computational point of view, because the original *dense* definition leads to tighter LP relaxations in general.

Experimentally, we found that using the dense definition often leads to better results. This, however, might depend on the separation algorithm used for the underlying quadratic problem. It should be worthwhile to search for criteria that allow us to decide whether or not a given pair of monomials should be added to $\mathcal{I}^*$, i.e., whether it is likely that the resulting improvement of the relaxation justifies the new variable. One could even take this decision dynamically, at the beginning of each separation step, based on the current fractional solution $\overline{z}$ to be separated. We have not included this in our implementation yet but plan to examine such strategies in future work.

3.5. Connection to the direct reduction approach. The direct reduction approach, proposed by Rosenberg [26] for the unconstrained case, can be easily extended to arbitrary polynomial zero-one optimization problems as in (2.1). It proceeds as follows: choose two variables x_a and x_b and replace their product $x_a x_b$ by a new variable x_c wherever it appears in a monomial of any of the polynomials g_i, $i = 0, \ldots, r$. Add the quadratic term $-M(x_a x_b - 2x_a x_c - 2x_b x_c + 3x_c)$ with $M \gg 0$ to the objective function in order to enforce $x_c = x_a x_b$ for every optimal solution. Iterate this replacement until all monomials have been reduced to products of at most two variables. In this way, one obtains a quadratic problem instance; denote the corresponding monomial set by $\mathcal{I}'$. In the unconstrained case, the problem is now equivalent to the max-cut problem on some graph G'.

The size of $\mathcal{I}'$ strongly depends on the strategy of choosing the next pair of variables to replace. The connection to our approach is that, whatever strategy is

chosen, there is a corresponding strategy for making $\mathcal{I}$ reducible, such that the graph for which we have to separate from the cut polytope is just G'—if we use the sparse definition of $\mathcal{I}^*$. The opposite is also true: every strategy for making $\mathcal{I}$ reducible induces a replacement strategy such that the resulting graphs agree. Thus solving $\mathcal{I}'$ is equivalent to solving the max-cut problem on exactly the same graph that in our algorithm is used for separation. The main advantage of our approach is that all other parts of the algorithm are carried out on the instance arising from making $\mathcal{I}$ reducible, which is much smaller than $\mathcal{I}^*$. Experimental evidence of this claim is provided in section 4.3. Furthermore, we can also choose the dense definition of $\mathcal{I}^*$, which yields better results in most cases (see section 3.4). Another advantage of our approach is that there is no need for "big M" techniques to reduce the problem, which typically introduces numerical difficulties in the resulting problem.

4. The unconstrained case. In the remainder of this paper, we restrict ourselves to the unconstrained case; i.e., we consider the problem

$$\max\left\{g_0(x) \mid x \in \{0,1\}^A\right\} \tag{4.1}$$

and its standard linearization

$$\begin{array}{lrcl} \max & h_0(z) & & \\ \text{s.t.} & z_I & = & \prod_{a\in I} z_{\{a\}} \quad \text{for all } I \in \mathcal{I}, \\ & z & \in & \{0,1\}^{\mathcal{I}} \end{array} \tag{4.2}$$

with the corresponding polytope P and set of nonconstant monomials $\mathcal{I}$. Observe that P depends only on $\mathcal{I}$ now and that the feasible solutions correspond to all subsets $S \subseteq A$. From now on, the characteristic vector for S in P is denoted by $\overline{\chi}^S$; i.e., we define $\overline{\chi}^S \in \mathbb{R}^{\mathcal{I}}$ by

$$\overline{\chi}^S_I = \begin{cases} 1 & \text{if } I \subseteq S, \\ 0 & \text{otherwise.} \end{cases}$$

Problem (3.1) in section 3.1 now becomes (the linearization of) an unconstrained quadratic zero-one optimization problem. This implies that the corresponding polytope P^* is a *boolean quadric polytope*. These polytopes have been studied extensively by Padberg [23]. Later it was shown by De Simone that every boolean quadric polytope is in fact isomorphic to a cut polytope [8]. In our case, the graph corresponding to this cut polytope is just $(\mathcal{I}, \mathcal{I}^* \setminus \mathcal{I})$ extended by a root node r, i.e., a new node adjacent to all other nodes in $\mathcal{I}$. The transformation of variables between the two formulations yielding the isomorphism is

$$z_J \mapsto \begin{cases} x_{(r,I)} & \text{if } J = \{I\}, \\ \frac{1}{2}\left(x_{(r,I_1)} + x_{(r,I_2)} - x_{(I_1,I_2)}\right) & \text{if } J = \{I_1, I_2\}, \end{cases}$$

$$x_{(I_1,I_2)} \mapsto \begin{cases} z_{\{I_2\}} & \text{if } I_1 = r, \\ z_{\{I_1\}} & \text{if } I_2 = r, \\ z_{\{I_1\}} + z_{\{I_2\}} - 2z_{\{I_1,I_2\}} & \text{otherwise.} \end{cases}$$

Here $x_{(I_1,I_2)}$ denotes the variable in the maximum cut formulation corresponding to an edge (I_1, I_2) in the graph $(\mathcal{I}, \mathcal{I}^* \setminus \mathcal{I})$. From this, we derive the following.

COROLLARY 4.1. *The polytope P is isomorphic to a face of a cut polytope.*

This is a direct consequence of Corollary 3.4. In particular, the separation problem for our original polytope P reduces to a separation problem for a cut polytope in the way explained in section 3.2. As the cut polytope is one of the best-studied objects in polyhedral combinatorics, we can fall back upon a large number of known classes of cutting planes and, in particular, sophisticated separation techniques for the cut polytope in order to solve the unconstrained polynomial problem (4.1) (see, e.g., [21]).

Before reporting results of a straightforward implementation of this approach, we examine P in two special cases with respect to the monomial set $\mathcal{I}$, in which P has some useful properties: the case that $\mathcal{I}$ is closed under taking supersets, and the opposite case that $\mathcal{I}$ is closed under taking subsets.

4.1. Upward completeness. Throughout this section, we assume that $\mathcal{I}$ is closed under taking supersets, i.e., that

$$I \in \mathcal{I},\ J \in 2^A,\ I \subseteq J \quad \Longrightarrow \quad J \in \mathcal{I}\ .$$

In other words, the product of every monomial $I \in \mathcal{I}$ with every variable x_a, $a \in A$, is again a monomial in $\mathcal{I}$. In this case, we have the following.

THEOREM 4.2. *The polytope P is isomorphic to the simplex of dimension m.*

Proof. We first claim that P is given by the linear inequalities

$$(-1)^{|I|} \sum_{J \supseteq I} (-1)^{|J|} z_J \geq 0 \tag{4.3}$$

for every $I \in \mathcal{I}$ and

$$\sum_{I \in \mathcal{I}} (-1)^{|I|} \sum_{J \supseteq I} (-1)^{|J|} z_J \leq 1\ . \tag{4.4}$$

These constraints are valid, as for integer vectors in P we have

$$(-1)^{|I|} \sum_{J \supseteq I} (-1)^{|J|} z_J = \prod_{a \in I} x_a \prod_{a \in A \setminus I} (1 - x_a)\ .$$

Now an isomorphism between the simplex of dimension m and the polytope P' given by (4.3) and (4.4) is induced by the variable transformations

$$z_I \mapsto \sum_{J \supseteq I} z'_J \quad \text{and} \quad z'_I \mapsto (-1)^{|I|} \sum_{J \supseteq I} (-1)^{|J|} z_J \quad \text{for all } I \in \mathcal{I}\ .$$

These transformations are well defined because $\mathcal{I}$ is closed under taking supersets. Moreover, they are inverse to each other, as one can check with some patience.

Under the given transformation, the inequality (4.3) becomes $z'_I \geq 0$, while (4.4) is transformed into $\sum_{I \in \mathcal{I}} z'_I \leq 1$. Hence P' is isomorphic to the simplex of dimension m. Furthermore, it is readily checked that under this transformation all vertices of the simplex correspond to characteristic vectors $\overline{\chi}^S$ for suitable $S \subseteq A$. In particular, we derive $P' \subseteq P$. The validity of (4.3) and (4.4) implies $P = P'$. □

Note that the transformation used in the proof of Theorem 4.2 is a multiplication with the so-called *zeta matrix*; see, e.g., section 3.1 in [20]. The constraints (4.3) and (4.4) are sometimes called *bound-factor product constraints*.

The condition that $\mathcal{I}$ be closed under taking supersets is of purely theoretical interest, as usually it will not hold for practical instances. Moreover, the number

of elements that would have to be added to $\mathcal{I}$ in order to achieve this property is exponential in general. However, the complete variable set $2^A \setminus \{\emptyset\}$ meets this condition, and it is easy to see that every polytope P is a projection of the polytope $\overline{P}$ corresponding to $2^A \setminus \{\emptyset\}$, which is nothing but the n-th Sherali-Adams iterate [27] of the cube $[0,1]^A$. Theorem 4.2 states that $\overline{P}$ is a simplex of dimension $2^n - 1$, implying that P is full-dimensional for every $\mathcal{I}$. However, in general, more interesting properties of $\overline{P}$ do not carry over via this projection.

4.2. Downward completeness. In the previous section, we examined the special case where $\mathcal{I}$ is closed under taking supersets. In this case, the polytope P turned out to have a very simple structure. In this section, we assume, on the contrary, that $\mathcal{I}$ is closed under taking nonempty subsets; i.e., we suppose

$$I \in \mathcal{I},\ J \in 2^A \setminus \{\emptyset\},\ I \supseteq J \quad \Longrightarrow \quad J \in \mathcal{I}.$$

This case is practically much more relevant than the one considered previously. For instance, it contains all quadratic instances and hence the max-cut problem as a special case. However, in this case the polytope P shares some interesting properties with the cut polytope of which it can consequently be considered as the natural generalization.

A well-known property of the cut polytopes is their symmetry: for each two vertices, there is an automorphism of the polytope, called *switching*, that maps the first vertex to the second (see, e.g., [9]). We claim that this is true in general if $\mathcal{I}$ is closed under taking nonempty subsets. Moreover, switching has a most natural interpretation: switching with respect to $S \subseteq A$ amounts to switching the value of each variable x_a with $a \in S$.

THEOREM 4.3. *Let P be the convex hull of feasible solutions of* (4.2)*, and let $\{a\} \in \mathcal{I}$ for all $a \in A$. Then for each $S \subseteq A$, a switching π_S of the vertices of P is given by $\pi_S(\overline{\chi}^T) = \overline{\chi}^{T \triangle S}$. Furthermore, the following statements are equivalent:*

(a) *The set $\mathcal{I}$ is closed under taking nonempty subsets.*

(b) *Each switching π_S corresponds to an automorphism of P.*

Proof. Since $\{a\} \in \mathcal{I}$ for all $a \in A$, the characteristic vectors $\overline{\chi}^T$ for $T \subseteq A$ are pairwise distinct, so that the permutation π_S is well defined. To show that (a) implies (b), consider the affine map $\overline{\pi}_S \colon \mathbb{R}^{\mathcal{I}} \to \mathbb{R}^{\mathcal{I}}$, defined componentwise by

$$\overline{\pi}_S(z)_I = (-1)^{|I \setminus S|} \sum_{I \setminus S \subseteq J \subseteq I} (-1)^{|J|} z_J$$

for $z \in \mathbb{R}^{\mathcal{I}}$ and $I \in \mathcal{I}$. Here we set $z_\emptyset = 1$ for all $z \in \mathbb{R}^{\mathcal{I}}$. This map is well defined, as $\mathcal{I}$ is closed under taking subsets. Moreover, as observed in section 4.1, it brings $0-1$ points to $0-1$ points; thus it is an automorphism of P. It remains to show that $\overline{\pi}_S(\overline{\chi}^T) = \overline{\chi}^{T \triangle S}$ for all $T \subseteq A$, since this implies that $\overline{\pi}_S$ induces a switching of the vertices of P and hence an automorphism π_S of P. Indeed, arguing componentwise, we have

$$\begin{aligned}
\overline{\chi}_I^{T \triangle S} &= \prod_{a \in I} \overline{\chi}^{\{a\}} \cdot \overline{\chi}^{T \triangle S} = \prod_{a \in I \setminus S} \overline{\chi}^{\{a\}} \cdot \overline{\chi}^T \prod_{a \in I \cap S} \left(1 - \overline{\chi}^{\{a\}} \cdot \overline{\chi}^T\right) \\
&= (-1)^{|I \setminus S|} \sum_{I \setminus S \subseteq J \subseteq I} (-1)^{|J|} \prod_{a \in J} \overline{\chi}^{\{a\}} \cdot \overline{\chi}^T = (-1)^{|I \setminus S|} \sum_{I \setminus S \subseteq J \subseteq I} (-1)^{|J|} \overline{\chi}_J^T \\
&= \overline{\pi}_S(\overline{\chi}^T)_I
\end{aligned}$$

for all $I \in \mathcal{I}$. This completes the first part of the proof.

Now let (a) be violated. Then there are sets $S \subset T \subseteq A$ with $T \in \mathcal{I}$ but $T \setminus S \notin \mathcal{I}$. One may assume that S is maximal, so that all nonempty proper subsets of $T \setminus S$ belong to $\mathcal{I}$. We claim that the $2^{|T \setminus S|}$ vectors $\{\overline{\chi}^R \mid R \subseteq T \setminus S\}$ are affinely dependent in $\mathbb{R}^{\mathcal{I}}$, while their images under π_S are not. This implies that π_S is not induced by any automorphism of P.

Indeed, these vectors are 0 in all dimensions I with $I \not\subseteq T \setminus S$. As $\emptyset$ and $T \setminus S$ do not belong to $\mathcal{I}$, the corresponding dimensions do not exist in $\mathbb{R}^{\mathcal{I}}$. Therefore, the $2^{|T \setminus S|}$ vectors can differ only in the remaining $2^{|T \setminus S|} - 2$ dimensions and are thus affinely dependent. On the other hand, their images $\{\overline{\chi}^{R \cup S} \mid R \subseteq T \setminus S\}$ under π_S are affinely independent, as can be checked easily by inspecting the dimensions I with $\emptyset \neq I \subset T \setminus S$ and $I = T$, which by construction all exist in $\mathbb{R}^{\mathcal{I}}$. □

COROLLARY 4.4. *Any vertex of the polytope P can be mapped to any other vertex by a single automorphism π_S. In particular, all affine cones pointed at the vertices of P are isomorphic.*

COROLLARY 4.5. *Let $a \in \mathbb{R}^{\mathcal{I}}$ and $\alpha \in \mathbb{R}$. Then the inequality $a \cdot y \leq \alpha$ is valid for P if and only if the inequality $a \cdot \pi_S(y) \leq \alpha$ is valid for P. The former is facet-inducing for P if and only if the latter is.*

4.3. Experimental evaluation. In this section, we report preliminary experimental results obtained with a straightforward implementation of the ideas presented in section 3, applied to the unconstrained case. They are meant only to give a first indication of the practical performance and usability to be expected from the presented approach. Note that the entire implementation is a simple task if a separation procedure for the cut polytope is ready to hand; one has to only code the trivial transformations explained in section 3.2 and embed everything into a branch-and-cut framework. For this, we used ABACUS [17] in combination with CPLEX [6]. For the max-cut separation, we used only *cycle inequalities* here, with the well-known exact separation algorithm [4]. We did not apply any tailing off strategy; for enumeration we used the depth first approach.

We experimented with randomly generated instances of a given degree and density. In the following, we focus on instances with a small degree. For given degree d, number of variables n, and number of monomials m, the instances were obtained by randomly choosing m subsets of $\{1, \ldots, n\}$ with d elements each. Objective function coefficients were chosen randomly from the reals in the interval $[-1, 1]$.

For each selected set of parameters d, n, m, we solved 10 random instances on a Pentium 4 processor with 2.8 GHz and 1 GB of main memory. The results are displayed in Table 4.1. We report average figures for the total runtime in cpu-seconds needed to solve the instance to optimality (Time) and for the number of nodes in the enumeration tree (Subs). For comparison, we state these data for the CPLEX MIP-solver [6] applied to the basic relaxation given by (2.3) and (2.4), for the direct reduction approach discussed in section 3.5, and for the algorithm presented in this paper. In some cases, CPLEX MIP or direct reduction could not solve all instances within 24 cpu-hours. For these cases, we state lower bounds on both the runtime and the number of subproblems.

In order to obtain comparable figures, we used the same implementation framework for both the direct reduction and our algorithm; i.e., after reducing the objective function we applied our own implementation to the resulting quadratic instance. In Table 4.2, we show the average node degree of the corresponding separation graphs and the quality of the upper bound at the root node.

As we used only cycle inequalities for separation, the given bounds at the root node correspond to the relaxation of P induced by the cycle relaxation of P^*. The results in Table 4.1 show that these bounds are rather tight for the examined instances: few LPs and subproblems have to be solved in general. On the other hand, a single separation phase takes a lot of time—for some instances, separation consumed more than 50 % of the total runtime. To a certain extent, this is due to the nature of our approach, as the separation instance is considerably larger than the LPs to be solved. Nevertheless, there is a lot of room for improvement at this point, e.g., by using faster separation algorithms such as the spanning-tree heuristic for separation of cycle inequalities; see, for example, the recent survey [21].

For increasing degree d, the relaxation for P induced by the cycle relaxation of P^* will become weaker in general. Furthermore, the number of additional variables for making $\mathcal{I}$ reducible will increase. We thus expect runtimes to increase with d. On the other hand, higher degrees mean a stronger interrelation between different monomials, making branching more efficient in general, as setting a monomial to 0 or 1 has a greater effect in this case. Similar reasoning applies to the density m/n: for sparse instances, the LP bounds are much better than for dense ones, while branching has a greater effect for the latter instances. Therefore, our approach outperforms CPLEX MIP much more clearly for instances of small degree and density in general.

All instances considered so far have a small degree. To examine the effect of higher-degree monomials, we created another test set containing higher-degree instances; to keep density low at the same time, we used an exponential distribution for this. More precisely, each of the m monomials was chosen as follows: first, its degree $d \in \{2, \dots, n\}$ was determined randomly, where the probability of choosing degree $d < n$ was 2^{1-d}. Then the monomial was picked randomly from the set of all possible monomials of the chosen degree. Again, we created 10 instances for each combination of m and n. This generation method yields instances of high degree but

with many lower-degree monomials, which is a situation likely to arise in practical applications. Note that the expected degree of a monomial in these instances is almost three. Nevertheless, results were much better than for instances with all monomials of degree three (see Tables 4.3 and 4.4).

As pointed out, the results of Tables 4.1 and 4.3 were obtained by a vanilla implementation. Runtimes should decrease considerably by using faster separation routines, further classes of cutting planes, an adequate branching strategy, and so on. Implementing separation routines designed for denser graphs should improve runtimes considerably. As obvious from Tables 4.1 and 4.3, denser separation graphs are caused

by larger ratios m/n and by higher degrees d.

5. Conclusion. We presented a new approach for reducing polynomial zero-one optimization problems to the quadratic case. Unlike other approaches, we do not produce an equivalent quadratic instance directly but use a reduction of the general separation problem to the one for quadratic instances and thus to the separation problem for the cut polytope with additional linear constraints. All other components of a branch-and-cut algorithm such as the solution of the LP relaxations, primal heuristics, or branching can be performed on a much smaller instance that arises from making the original instance reducible.

Experimental results show that our reduction method is a promising approach for solving large unconstrained polynomial optimization problems. Here we make use of the fact that the separation problem for the quadratic case is well studied. Unfortunately, the situation is less comfortable in the presence of constraints. Certain constrained quadratic problems, such as the quadratic assignment problem or the quadratic knapsack problem, have been investigated from a polyhedral point of view; the corresponding separation algorithms can be applied in our approach in order to address the corresponding polynomial problems. However, general constrained polynomial problems are reduced to general constrained quadratic problems, which themselves are hard enough to solve. Our aim was to show that moving from quadratic to polynomial functions does not add much to the hardness of the problem.

Acknowledgment. We would like to thank the two anonymous referees for their helpful comments and suggestions that improved this paper significantly.

A HIGH-ORDER PATH-FOLLOWING METHOD FOR LOCATING THE LEAST 2-NORM SOLUTION OF MONOTONE LCPs*

ANHUA LIN†

Abstract. A high-order path-following method is proposed for finding the least 2-norm solution of a monotone LCP. This method follows the regularized central paths introduced in [Y. B. Zhao and D. Li, *SIAM J. Control Optim.*, 40 (2001), pp. 898–924]. By using the analyticity of these paths, we showed the global convergence under the assumption that the LCP has at least one solution and the superlinear rate of local convergence under the assumption that the least 2-norm solution is maximally complementary.

Key words. least 2-norm, monotone LCP, high-order method

AMS subject classifications. 90C33, 90C51, 49M29

DOI. 10.1137/060659752

1. Introduction.

In this paper we are concerned with finding the least 2-norm solution of the following monotone LCP:

$$0 \le x \perp Mx + q \ge 0, \tag{1}$$

where $q \in R^n$ and $M \in R^{n\times n}$ is positive semidefinite. A monotone LCP may have many solutions, but the least 2-norm solution is unique.

The problem of finding the least 2-norm solution to some optimization and complementarity problems has been extensively studied. See [23, 5, 9] for some recent results on linear programs and [18, 7, 21, 22, 24] on complementarity problems. Also, it is well known that the Tikhonov regularization trajectory of a monotone complementarity problem converges to the least 2-norm solution [1].

On the other hand, there is a vast literature on finding a general solution of LCPs. In particular, the local convergence analysis of interior-point-like methods for monotone LCPs has been studied, to name a few, by Wright and Zhang [19], Ye and Anstreicher [20], McShane [10], and Huang, Qi, and Sun [4], under the assumption that there exists a strictly complementary solution, and by Mizuno [11], Potra and Sheng [12], Sturm [17], Stoer, Wechs, and Mizuno [16], Stoer [14], and Zhao and Sun [25] without such an assumption. The results in the last few papers, namely, the second-order predictor-corrector method based on strictly feasible central paths proposed in [17] and the local analysis of high-order methods based on infeasible central paths presented in [16, 14, 25], are the direct motivation for this paper.

In [21, 22] Zhao and Li introduced a class of new paths for general complementarity problems. This class of paths has many nice properties. For example, it needs weaker conditions to be existent and bounded than the normal central path does. For monotone problems, these paths always converge to the least 2-norm solution as long as the problem has at least one solution. However, along with the good properties come some difficulties for algorithm design. The study of this class of paths

†Department of Mathematical Sciences, Middle Tennessee State University, Murfreesboro, TN 37132 (alin@mtsu.edu).

is still far less mature than that for the usual central path. In [23] a path-following method based on this class of paths was proposed to find the least 2-norm solution of a linear program. But no local convergence analysis was provided for that method. More recently, Zhao and Li proposed a globally and locally superlinearly convergent method based on these paths for P_0 LCP [24]. However, the superlinear convergence was proved under a rather strong assumption that the solution to the LCP is not only unique but also strictly complementary.

The goal of this paper is to use some variant of this class of paths to design a high-order path-following method to locate the least 2-norm solution of a monotone LCP. We will study the analytical property of these paths and use the result to obtain a much better local convergence under a weaker condition than [24].

The paper is organized as follows. In section 2 we introduce the paths that will be used. Then the algorithm will be presented in section 3. Sections 4 and 5 will be devoted to global and local convergence analysis, respectively. Then in section 6 we summarize and point out some future research directions.

We mention the following notation:

(i) For any matrix A, we use $A \succeq 0$ or $0 \preceq A$ to denote that A is square positive semidefinite, and $A \succ 0$ or $0 \prec A$ to denote that A is square positive definite. But A needs not to be symmetric.

(ii) For any vector x, we use $\|x\|$ and $\|x\|_\infty$ to denote the 2-norm and ∞-norm of x, respectively.

(iii) Given a vector x or vector function $f(s)$, we use the corresponding uppercase symbol X or $F(s)$ to denote the natural diagonal matrix generated by x or $f(s)$.

(iv) We use e to denote the all-1 vector with appropriate dimension.

(v) We use R^n_+ (respectively, R^n_{++}) to denote the nonnegative (respectively, positive) orthant in R^n.

2. A class of regularized central paths. In this paper, we consider the following system:

$$\begin{cases} Xy = t^2 w, \\ y = Mx + tx + q, \\ x, y \in R^n_{++}, \end{cases} \tag{2}$$

where $0 < t \in R$ and $0 < w \in R^n$ are parameters. For each fixed $w > 0$, the solutions form a path as t varies in R_{++}.

This class of paths is actually a subclass of the regularized central path proposed in [21] with different parametrization (which is very important for our purpose).

The following theorem about the basic properties of this class of paths can be easily obtained by following the proof of Theorem 2.1 in [23].

THEOREM 2.1.

(i) *For each $(t, w) > 0$, system (2) has a unique solution $(x(t, w), y(t, w)) > 0$.*

(ii) *For any fixed $w > 0$ and any finite number $0 < t_0 < \infty$, the set $\{x(t, w) | 0 < t \le t_0\}$ is bounded if and only if the monotone LCP (1) has at least one solution.*

(iii) *LCP (1) has at least one solution if and only if for any fixed $w > 0$, $x(t, w)$ converges as $t \longrightarrow 0+$; when this is the case, the limit is the unique least 2-norm solution, denoted by x^*.*

Proof. Let $a = w$, $b = 0$, $\theta = \frac{t^2}{1+t^2} \in (0, 1)$, $\phi(\theta) = \sqrt{\frac{\theta}{1-\theta}}$, and $f(x) = Mx + q$.

Then according to Theorem 4.2(a) of [21], system

$$\begin{cases} Xv = \theta a, \\ v = (1-\theta)(Mx + q + \phi(\theta)x), \\ x, v \in R^n_{++} \end{cases} \tag{3}$$

has a unique solution. While by letting $y = \frac{v}{1-\theta}$, it is easy to see that system (3) is equivalent to system (2). So (i) is proved.

For (ii), if $x(t,w)$ is bounded on $0 < t \le t_0$, then any limit point of $x(t,w)$ as $t \longrightarrow 0+$ solves the LCP (1). Conversely, if the LCP (1) has at least one solution, then noticing

$$0 < t \le t_0 \Longleftrightarrow 0 < \theta \le \frac{t_0^2}{1+t_0^2},$$

we have the boundedness of $x(\theta, w)$ and $x(t,w)$ by Theorem 5.1(b) of [21].

Result (iii) is an immediate consequence of Theorem 5.2 of [21]. □

It is easy to show that $(x(t,w), y(t,w))$ is an analytic vector function for $(t,w) > 0$. First we use the fact that for any $(x,y) > 0$ and a P_0 matrix P, $\left[\begin{smallmatrix} Y & X \\ P & -I \end{smallmatrix}\right]$ is nonsingular [6], and noticing that any monotone matrix is a P_0 matrix, we have the following lemma.

LEMMA 2.2. *For positive diagonal matrices $X, Y \in R^{n\times n}$ and any $t \ge 0$, the matrix*

$$J = \begin{bmatrix} Y & X \\ -(M+tI) & I \end{bmatrix}$$

is nonsingular.

THEOREM 2.3. *$(x(t,w), y(t,w))$ is an analytic vector function for $(t,w) > 0$.*

Proof. Let $(\bar{t}, \bar{w})$ be any vector in R^{n+1}_{++}, $(\bar{x}, \bar{y}) = (x(\bar{t}, \bar{w}), y(\bar{t}, \bar{w})) > 0$.

Let $\Phi(x,y,t,w) = \left(\begin{smallmatrix} Xy - t^2 w \\ y - (M+tI)x - q \end{smallmatrix}\right)$. Then $(\bar{x}, \bar{y}, \bar{t}, \bar{w})$ is a solution of $\Phi(x,y,t,w) = 0$.

The Jacobian of $\Phi(x,y,t,w)$ with respect to (x,y) at $(\bar{x}, \bar{y}, \bar{t}, \bar{w})$ is

$$\begin{bmatrix} \bar{Y} & \bar{X} \\ -(M+\bar{t}I) & I \end{bmatrix},$$

which is nonsingular according to Lemma 2.2.

Then from the implicit function theorem and the uniqueness of $(x(t,w), y(t,w))$ for any fixed $(t,w) > 0$, and noticing that $\Phi(x,y,t,w)$ is an analytic vector function of (x,y,t,w), we know that $(x(t,w), y(t,w))$ is an analytic vector function in a neighborhood of $(\bar{t}, \bar{w})$.

Because this is true for all $(\bar{t}, \bar{w}) > 0$, the theorem is then proved. □

Let

$$u(\gamma, t, w) = w + \frac{(\gamma - t)}{1+t}(w - e) = \frac{1+\gamma}{1+t}w + \frac{t-\gamma}{1+t}e. \tag{4}$$

LEMMA 2.4. *If $w > 0$, $t > -1$, and $-1 < \gamma < t + \frac{(1+t)\min\{w_i\}}{1+\min\{w_i\}}$, then $u(\gamma, t, w) > 0$.*

Proof. We consider two cases:

(i) $w_i \geq 1$:

$$\begin{aligned}(1+\gamma)w_i + (t-\gamma) &= w_i + t + \gamma(w_i - 1)\\ &\geq w_i + t - (w_i - 1)\\ &= t + 1\\ &> 0;\end{aligned}$$

(ii) $w_i < 1$:

$$\begin{aligned}(1+\gamma)w_i + (t-\gamma) &= w_i + t + \gamma(w_i - 1)\\ &\geq w_i + t + \left(t + \frac{(1+t)\min\{w_j\}}{1+\min\{w_j\}}\right)(w_i - 1)\\ &= w_i + t + tw_i - t + \frac{(1+t)\min\{w_j\}}{1+\min\{w_j\}}(w_i - 1)\\ &= (1+t)w_i + (1+t)\frac{(w_i - 1)\min\{w_j\}}{1+\min\{w_j\}}\\ &= (1+t)\frac{2w_i\min\{w_j\} + w_i - \min\{w_j\}}{1+\min\{w_j\}}\\ &\geq (1+t)\frac{2w_i\min\{w_j\}}{1+\min\{w_j\}}\\ &> 0.\end{aligned}$$

Therefore $u_i(\gamma,t,w) = \frac{(1+\gamma)w_i+(t-\gamma)}{1+t} > 0$ for all i, and hence $u(\gamma,t,w) > 0$. □

Consider the vector function

$$(\hat{x}(\gamma,t,w), \hat{y}(\gamma,t,w)) = (x(\gamma,u(\gamma,t,w)), y(\gamma,u(\gamma,t,w)))\,.$$

From Theorem 2.3, the definition of $u(\gamma,t,w)$ (4), and Lemma 2.4, it is clear that $(\hat{x}(\gamma,t,w), \hat{y}(\gamma,t,w))$ is a well-defined analytic vector function on the open set

$$\left\{(\gamma,t,w)\,\middle|\, w > 0, t > 0, 0 < \gamma < t + \frac{(1+t)\min\{w_i\}}{1+\min\{w_i\}}\right\}.$$

We will use the partial derivatives $\frac{\partial^l(\hat{x},\hat{y})}{\partial\gamma^l}(t,t,w)$ extensively in our algorithm. Fortunately, they can be easily calculated.

First we introduce the following notation:

(i) $\hat{x}^{(l)}(\gamma,t,w) := \frac{\partial^l\hat{x}}{\partial\gamma^l}(\gamma,t,w),\ \hat{y}^{(l)}(\gamma,t,w) := \frac{\partial^l\hat{y}}{\partial\gamma^l}(\gamma,t,w),\ l = 1,2,\ldots.$

(ii) $\hat{x}^{(0)}(\gamma,t,w) := \hat{x}(\gamma,t,w),\ \hat{y}^{(0)}(\gamma,t,w) := \hat{y}(\gamma,t,w).$

(iii) $(\hat{x}+\hat{y})^{(l)}(\gamma,t,w) := \sum_{i=0}^{l}\binom{l}{i}\hat{X}^{(i)}(\gamma,t,w)\hat{y}^{(l-i)}(\gamma,t,w),\ l = 1,2,\ldots.$

(iv) $(\hat{x}+\hat{y})^{(0)}(\gamma,t,w) := \hat{X}(\gamma,t,w)\hat{y}(\gamma,t,w).$

Since $(\hat{x}(\gamma,t,w), \hat{y}(\gamma,t,w))$ satisfies

$$\hat{X}(\gamma,t,w)\hat{y}(\gamma,t,w) = \gamma^2 u(\gamma,t,w), \tag{5}$$

$$\hat{y}(\gamma,t,w) = M\hat{x}(\gamma,t,w) + \gamma\hat{x}(\gamma,t,w) + q, \tag{6}$$

the next lemma can be easily proved by differentiating (5) and (6) l times with respect to γ and using the fact $u(t,t,w)=w$.

LEMMA 2.5.

$$(\hat{x}+\hat{y})^{(l)}(t,t,w)=\begin{cases} t^2w, & l=0,\\ 2tw+\dfrac{t^2}{1+t}(w-e), & l=1,\\ 2w+\dfrac{4t}{1+t}(w-e), & l=2,\\ \dfrac{6}{1+t}(w-e), & l=3,\\ 0, & l\geq 4, \end{cases}$$

and

$$\hat{y}^{(l)}(t,t,w)=(M+tI)\hat{x}^{(l)}(t,t,w)+l\hat{x}^{(l-1)}(t,t,w),\quad l\geq 1.$$

The following lemma shows how to find $\hat{x}^{(l)}(t,t,w)$ and $\hat{y}^{(l)}(t,t,w)$ assuming we have $(x(t,w),y(t,w),t,w)>0$.

LEMMA 2.6. *$(\hat{x}^{(l)}(t,t,w),\hat{y}^{(l)}(t,t,w))$ is the unique solution to the linear system for $l\geq 1$:*

$$\begin{bmatrix} Y(t,w) & X(t,w)\\ -(M+tI) & I \end{bmatrix}\begin{bmatrix} \hat{x}^{(l)}(t,t,w)\\ \hat{y}^{(l)}(t,t,w)\end{bmatrix}$$

$$=\begin{bmatrix} (\hat{x}+\hat{y})^{(l)}(t,t,w)-\sum_{i=1}^{l-1}\begin{pmatrix} l\\ i\end{pmatrix}\hat{X}^{(i)}(t,t,w)\hat{y}^{(l-i)}(t,t,w)\\ l\hat{x}^{(l-1)}(t,t,w)\end{bmatrix}.$$

Proof. This result simply follows from Lemmas 2.2 and 2.5 and the fact that $(\hat{x}(t,t,w),\hat{y}(t,t,w))=(x(t,w),y(t,w))$. ∎

Therefore each $(\hat{x}^{(l)}(t,t,w),\hat{y}^{(l)}(t,t,w))$ uniquely solves a linear system. And all these linear systems share the same coefficient matrix. Furthermore, the right-hand side of the linear system for solving $(\hat{x}^{(l)}(t,t,w),\hat{y}^{(l)}(t,t,w))$ depends only on $(\hat{x}^{(i)}(t,t,w),\hat{y}^{(i)}(t,t,w))$ for $0\leq i\leq l-1$.

Thus given $(x(t,w),y(t,w),t,w)$, we can sequentially solve L linear systems to find $(\hat{x}^{(1)}(t,t,w),\hat{y}^{(1)}(t,t,w))$, $(\hat{x}^{(2)}(t,t,w),\hat{y}^{(2)}(t,t,w))$, $\ldots$, $(\hat{x}^{(L)}(t,t,w),\hat{y}^{(L)}(t,w))$. Since all these linear systems share the same coefficient matrix, the computational cost is much less than solving L independent linear systems.

3. Algorithm. Let $N(\beta)$ be a neighborhood of the regularized central path $(x(t,e),y(t,e))$ defined as

$$N(\beta):=\{(x,y,t)|x\in R^n_{++},y\in R^n_{++},t\in R_{++},$$
$$\|Xy-t^2e\|_\infty\leq\beta t^2,y=Mx+tx+q\},$$

where $\beta>0$.

ALGORITHM 1.

1. *Select an integer* $L \geq 3$ *and three real numbers* $\alpha \in (0,1)$, $\beta \in (0,1)$, *and* $\theta \in (1, \frac{L}{2})$. *Then find* $(x^0, y^0, t_0) \in N(\beta)$. *Set iteration index* $k = 0$.

2. *At the* k*th iteration, we have* $(x^k, y^k, t_k) \in N(\beta)$. *Let* $w^k = X^k y^k / t_k^2$. *Clearly* $(x^k, y^k) = (x(t_k, w^k), y(t_k, w^k))$.

Then using Lemmas 2.5 *and* 2.6 *we solve* L *linear systems*

$$\begin{bmatrix} Y^k & X^k \\ -(M + t_k I) & I \end{bmatrix} \begin{bmatrix} \hat{x}^{(l)}(t_k, t_k, w^k) \\ \hat{y}^{(l)}(t_k, t_k, w^k) \end{bmatrix}$$

$$= \begin{bmatrix} (\hat{x} + \hat{y})^{(l)}(t_k, t_k, w^k) - \sum_{i=1}^{l-1} \begin{pmatrix} l \\ i \end{pmatrix} \hat{X}^{(i)}(t_k, t_k, w^k) \hat{y}^{(l-i)}(t_k, t_k, w^k) \\ l\hat{x}^{(l-1)}(t_k, t_k, w^k) \end{bmatrix}$$

to find $\left(\hat{x}^{(l)}(t_k, t_k, w^k), \hat{y}^{(l)}(t_k, t_k, w^k)\right)$ *for* $l = 1, 2, \ldots, L$.

Define

$$f^k(s) := \sum_{i=0}^{L} \frac{(s - t_k)^i}{i!} \hat{x}^{(i)}(t_k, t_k, w^k),$$

$$g^k(s) := \sum_{i=0}^{L} \frac{(s - t_k)^i}{i!} \hat{y}^{(i)}(t_k, t_k, w^k) + \frac{(s - t_k)^{L+1}}{L!} \hat{x}^{(L)}(t_k, t_k, w^k).$$

Let $\delta_k = t_k - \min\{(t_k)^\theta, \frac{t_k}{2}\}$. *We pick* t_{k+1} *as the first of* $\{t_k - \alpha^i \delta_k | i = 0, 1, \ldots\}$ *satisfying* $f^k(t_{k+1}) > 0$ *and* $\|F^k(t_{k+1}) g^k(t_{k+1}) - t_{k+1}^2 e\|_\infty \leq \beta {t_{k+1}}^2$.

Then we set $\left(x^{k+1}, y^{k+1}\right) = \left(f^k(t_{k+1}), g^k(t_{k+1})\right)$ *and show that* $\left(x^{k+1}, y^{k+1}, t_{k+1}\right) \in N(\beta)$.

Set $k = k + 1$. *Continue step* 2.

Before we study the convergence properties of this algorithm in next two sections, we first show its feasibility.

3.1. Step 1. There are many ways to find the starting point (x^0, y^0, t_0). For example, we can first find $t_0 > 0$ satisfying

$$\|t_0 Me + \sqrt{t_0} q\|_\infty \leq \beta t_0^2.$$

Then let $x^0 = \sqrt{t_0} e > 0$ and $y^0 = Mx^0 + t_0 x^0 + q$. We have

$$\|X^0 y^0 - t_0^2 e\|_\infty = \|t_0 Me + \sqrt{t_0} q\|_\infty \leq \beta t_0^2.$$

Since $x^0 > 0$ and $\beta \in (0,1)$, we must have $y^0 > 0$. Therefore $(x^0, y^0, t_0) \in N(\beta)$.

3.2. Step 2 . To simplify notation, we omit the super-/subscript k in this subsection; i.e., we use $(x, y, t, w, f, g, \delta)$ to denote $(x^k, y^k, t_k, w^k, f^k, g^k, \delta_k)$. Furthermore, we denote $\left(\hat{x}^{(l)}(t, t, w), \hat{y}^{(l)}(t, t, w), (\hat{x} + \hat{y})^{(l)}(t, t, w)\right)$ by $\left(\hat{x}^{(l)}, \hat{y}^{(l)}, (\hat{x} + \hat{y})^{(l)}\right)$, since (t, w) is fixed in this subsection. We have the following lemmas.

LEMMA 3.1.

$$g(s) = Mf(s) + sf(s) + q.$$

Proof. We have

$$\begin{aligned}
Mf(s)+sf(s)+q &= \sum_{i=0}^{L}\frac{(s-t)^i}{i!}M\hat{x}^{(i)}+\sum_{i=0}^{L}\frac{s(s-t)^i}{i!}\hat{x}^{(i)}+q\\
&= \sum_{i=0}^{L}\frac{(s-t)^i}{i!}M\hat{x}^{(i)}+\sum_{i=0}^{L}\frac{(s-t+t)(s-t)^i}{i!}\hat{x}^{(i)}+q\\
&= \sum_{i=0}^{L}\frac{(s-t)^i}{i!}(M+tI)\hat{x}^{(i)}+\sum_{i=0}^{L}\frac{(s-t)^{i+1}}{i!}\hat{x}^{(i)}+q\\
&= \sum_{i=0}^{L}\frac{(s-t)^i}{i!}(M+tI)\hat{x}^{(i)}+\sum_{i=1}^{L+1}\frac{i(s-t)^i}{i!}\hat{x}^{(i-1)}+q\\
&= (M+tI)\hat{x}^{(0)}+q+\sum_{i=1}^{L}\frac{(s-t)^i}{i!}\left((M+tI)\hat{x}^{(i)}+i\hat{x}^{(i-1)}\right)\\
&\quad+\frac{(s-t)^{L+1}}{L!}\hat{x}^{(L)}\\
&= \hat{y}^{(0)}+\sum_{i=1}^{L}\frac{(s-t)^i}{i!}\hat{y}^{(i)}+\frac{(s-t)^{L+1}}{L!}\hat{x}^{(L)}\\
&= g(s),
\end{aligned}$$

where we use Lemma 2.5. □

LEMMA 3.2.

$$F(s)g(s)=s^2u(s,t,w)+(s-t)^{L+1}R(s,t,w),$$

where

$$\begin{aligned}
R(s,t,w) &= \sum_{l=1}^{L}\sum_{i=0}^{l-1}\frac{(s-t)^i}{l!(i+L-l+1)!}\hat{X}^{(l)}\hat{y}^{(i+L-l+1)}\\
&\quad+\frac{1}{L!}\left(X^{(L)}\sum_{i=0}^{L}\frac{(s-t)^i}{i!}\hat{x}^{(i)}\right).
\end{aligned}\tag{7}$$

Proof. Since

$$\begin{aligned}
&\left(\sum_{i=0}^{L}\frac{(s-t)^i}{i!}\hat{X}^{(i)}\right)\left(\sum_{i=0}^{L}\frac{(s-t)^i}{i!}\hat{y}^{(i)}\right)\\
&\quad=\sum_{l=0}^{L}\sum_{i=0}^{l}\frac{(s-t)^i}{i!}\frac{(s-t)^{l-i}}{(l-i)!}\hat{X}^{(i)}\hat{y}^{(l-i)}+\sum_{l=1}^{L}\sum_{i=L-l+1}^{L}\frac{(s-t)^l}{l!}\frac{(s-t)^i}{i!}\hat{X}^{(l)}\hat{y}^{(i)}\\
&\quad=\sum_{l=0}^{L}\frac{(s-t)^l}{l!}\sum_{i=0}^{l}\begin{pmatrix} l\\ i\end{pmatrix}\hat{X}^{(i)}\hat{y}^{(l-i)}\\
&\qquad+(s-t)^{L+1}\sum_{l=1}^{L}\sum_{i=0}^{l-1}\frac{(s-t)^i}{l!(i+L-l+1)!}\hat{X}^{(l)}\hat{y}^{(i+L-l+1)}\\
&\quad=\sum_{l=0}^{L}\frac{(s-t)^l}{l!}(\hat{x}+\hat{y})^{(l)}+(s-t)^{L+1}\sum_{l=1}^{L}\sum_{i=0}^{l-1}\frac{(s-t)^i}{l!(i+L-l+1)!}\hat{X}^{(l)}\hat{y}^{(i+L-l+1)}\\
&\quad=\sum_{l=0}^{3}\frac{(s-t)^l}{l!}(\hat{x}+\hat{y})^{(l)}+(s-t)^{L+1}\sum_{l=1}^{L}\sum_{i=0}^{l-1}\frac{(s-t)^i}{l!(i+L-l+1)!}\hat{X}^{(l)}\hat{y}^{(i+L-l+1)}\\
&\quad=t^2w+(s-t)\left(2tw+\frac{t^2}{1+t}(w-e)\right)+\frac{(s-t)^2}{2}\left(2w+\frac{4t}{1+t}(w-e)\right)\\
&\qquad+\frac{(s-t)^3}{6}\frac{6}{1+t}(w-e)\\
&\qquad+(s-t)^{L+1}\sum_{l=1}^{L}\sum_{i=0}^{l-1}\frac{(s-t)^i}{l!(i+L-l+1)!}\hat{X}^{(l)}\hat{y}^{(i+L-l+1)}\\
&\quad=s^2u(s,t,w)+(s-t)^{L+1}\sum_{l=1}^{L}\sum_{i=0}^{l-1}\frac{(s-t)^i}{l!(i+L-l+1)!}\hat{X}^{(l)}\hat{y}^{(i+L-l+1)},
\end{aligned}$$

then

$$\begin{aligned}
F(s)g(s)&=\left(\sum_{i=0}^{L}\frac{(s-t)^i}{i!}\hat{X}^{(i)}\right)\left(\sum_{i=0}^{L}\frac{(s-t)^i}{i!}\hat{y}^{(i)}+\frac{(s-t)^{L+1}}{L!}\hat{x}^{(L)}\right)\\
&=\left(\sum_{i=0}^{L}\frac{(s-t)^i}{i!}\hat{X}^{(i)}\right)\left(\sum_{i=0}^{L}\frac{(s-t)^i}{i!}\hat{y}^{(i)}\right)\\
&\qquad+\frac{(s-t)^{L+1}}{L!}\left(X^{(L)}\sum_{i=0}^{L}\frac{(s-t)^i}{i!}\hat{x}^{(i)}\right)\\
&=s^2u(s,t,w)+(s-t)^{L+1}R(s,t,w).\qquad\square
\end{aligned}$$

LEMMA 3.3. *For $0 < s \le t$, we have*

$$\|F(s)g(s) - s^2 e\|_\infty - \beta s^2 \le -(t-s)\left(\frac{\beta s^2}{1+t} - (t-s)^L \|R(s,t,w)\|_\infty\right).$$

Proof. Since $(x, y, t) \in N(\beta)$, then $\|w - e\|_\infty \le \beta$. We have

$$\begin{aligned}
&\|F(s)g(s) - s^2 e\|_\infty - \beta s^2 \\
&\le \|F(s)g(s) - s^2 u(s,t,w)\|_\infty + s^2 \|u(s,t,w) - e\|_\infty - \beta s^2 \\
&= (t-s)^{L+1} \|R(s,t,w)\|_\infty + s^2 \left(1 + \frac{s-t}{1+t}\right) \|w - e\|_\infty - \beta s^2 \\
&\le (t-s)^{L+1} \|R(s,t,w)\|_\infty + s^2 \left(1 + \frac{s-t}{1+t}\right) \beta - \beta s^2 \\
&= -(t-s)\left(\frac{\beta s^2}{1+t} - (t-s)^L \|R(s,t,w)\|_\infty\right). \qquad \square
\end{aligned}$$

Since

$$\lim_{i \longrightarrow \infty} f(t - \alpha^i \delta) = f(t) = \hat{x}^{(0)}(t,t,w) = x > 0,$$

and from Lemma 3.3

$$\limsup_{i \longrightarrow \infty} \frac{\|F(t-\alpha^i\delta)g(t-\alpha^i\delta) - (t-\alpha^i\delta)^2 e\|_\infty - \beta(t-\xi^i\delta)^2}{t - (t - \xi^i \delta)} \le -\frac{\beta t^2}{1+t} < 0,$$

t_{k+1} can be found after a finite number of trials. In addition, we have $x^{k+1} > 0$ and $\|X^{k+1} y^{k+1} - t_{k+1}^2 e\|_\infty \le \beta t_{k+1}^2$. Because $\beta \in (0,1)$, so $y^{k+1} > 0$. Moreover, Lemma 3.1 gives $y^{k+1} = M x^{k+1} + t_{k+1} x^{k+1} + q$. Therefore $(x^{k+1}, y^{k+1}, t_{k+1}) \in N(\beta)$.

4. Global convergence analysis. We need the following assumption for the global and local convergence analysis.

Assumption 1. The LCP (1) has at least one solution.

In this section we show that $\{x^k\}$ converges to the unique least 2-norm solution x^*. First we need to show that t_k decreases to 0.

THEOREM 4.1. *Under Assumption* 1 *we have*

$$\lim_{k \longrightarrow \infty} t_k = 0.$$

Proof. Since $0 < t_{k+1} < t_k$, then $t_k \longrightarrow t_* \ge 0$. Now we prove $t_* = 0$ by contradiction.

Assume $t_* > 0$. Since $(\hat{x}(\gamma,t,w), \hat{y}(\gamma,t,w))$ is an analytic vector function on

$$\left\{(\gamma,t,w) \,\middle|\, w \in R^n_{++}, t \in R_{++}, 0 < \gamma < t + \frac{(1+t)\min\{w_i\}}{1 + \min\{w_i\}}\right\},$$

by the definition of $R(s,t,w)$ we know that $R(s,t,w)$ is bounded on the compact set

$$\left\{(s,t,w) \,\middle|\, \|w - e\|_\infty \le \beta, t_* \le t \le t_0, t - \min\left\{t^\theta, \frac{t}{2}\right\} \le s \le t\right\}.$$

In other words, there exists $C > 0$ such that $\|R(s,t,w)\|_\infty \le C$ when (s,t,w) lies in the above set.

Let k be sufficiently large such that t_k satisfies

$$0 < \epsilon := \left(\frac{\min\{t_*^\theta, \frac{t_*}{2}\}^2\beta}{2C(1+t_*)}\right)^{\frac{1}{L}} < \left(\frac{\min\{t_k^\theta, \frac{t_k}{2}\}^2\beta}{C(1+t_k)}\right)^{\frac{1}{L}}$$

and

$$\min\left\{t_k^\theta, \frac{t_k}{2}\right\} < t_* < t_k < t_* + \frac{\alpha}{2}\epsilon.$$

Using Lemma 3.3, for all $s \in [\min\{t_k^\theta, \frac{t_k}{2}\}, t_k] \cap [t_k - \epsilon, t_k]$ we have

$$\begin{aligned}\|F^k(s)g^k(s) - s^2 e\|_\infty &\le \beta s^2 - (t_k - s)\left(\frac{\beta s^2}{1+t_k} - C(t_k - s)^L\right)\\ &\le \beta s^2 - (t_k - s)\left(\frac{\beta \min\{t_k^\theta, \frac{t_k}{2}\}^2}{1+t_k} - C\epsilon^L\right)\\ &\le \beta s^2.\end{aligned}$$

Then from the continuity of $(f^k(s), g^k(s))$ and the fact that $(f^k(t_k), g^k(t_k)) = (x^k, y^k) > 0$, we know that $(f^k(s), g^k(s)) > 0$ for all $s \in [\min\{t_k^\theta, \frac{t_k}{2}\}, t_k] \cap [t_k - \epsilon, t_k]$.

If $\epsilon > \delta_k = t_k - \min\{t_k^\theta, \frac{t_k}{2}\}$, then $t_{k+1} = \min\{t_k^\theta, \frac{t_k}{2}\} < t_*$, which is a contradiction. So $\epsilon \le \delta_k$.

Let i be the integer such that $t_{k+1} = t_k - \alpha^i\delta_k$. Since $t_k - \alpha^0\delta_k = \min\{{t_k}^\theta, \frac{t_k}{2}\} < t_* < t_{k+1}$, then $i \ge 1$. By the definition of t_{k+1}, we must have $t_k - \alpha^{i-1}\delta_k < t_k - \epsilon$, and hence $\epsilon < \alpha^{i-1}\delta_k$.

Therefore we have

$$\begin{aligned}t_{k+1} = t_k - \alpha^i\delta^k > t_* &\Longrightarrow \frac{\alpha}{2}\epsilon > t_k - t_* > \alpha^i\delta^k > \alpha\epsilon\\ &\Longrightarrow \frac{1}{2} > 1\\ &\Longrightarrow \text{contradiction.}\end{aligned}$$

So $t_* = 0$. ∎

Now we can show the global convergence of $\{x^k\}$.

THEOREM 4.2. *Under Assumption* 1 *we have*

$$\lim_{k\longrightarrow\infty} x^k = x^*,$$

where x^* is the unique least 2*-norm solution of the monotone LCP* (1).

Proof. Since $(x^k, y^k, t_k) \in N(\beta)$, then $(1-\beta){t_k}^2 e \le X^k y^k \le (1+\beta){t_k}^2 e$, and hence ${x^k}^T y^k \le (1+\beta)n{t_k}^2$.

Using the facts that $0 \leq x^* \perp y^* := Mx^* + q \geq 0$, $x^k > 0$, and $y^k = Mx^k + t_k x^k + q > 0$, we have

$$\begin{aligned}(1+\beta)nt_k{}^2 &\geq x^{k^T} y^k - x^{k^T} y^* - x^{*^T} y^k + x^{*^T} y^* \\ &= (x^k - x^*)^T (y^k - y^*) \\ &= (x^k - x^*)^T \left(M(x^k - x^*) + t_k x^k\right) \\ &\geq t_k (x^k - x^*)^T x^k.\end{aligned}$$

Hence

$$(1+\beta)nt_k \geq \|x^k\|^2 - \|x^*\|\|x^k\|. \tag{8}$$

Since $0 < t_k < t_0$, then $\{x^k\}$ is bounded. Let $\bar{x}$ be any limit point of $\{x^k\}$. Because $t_k \longrightarrow 0$, it is easy to see that $\bar{x}$ is a solution to the LCP. Hence $\|\bar{x}\| \geq \|x^*\|$. From (8) we can get

$$0 \geq \|\bar{x}\|^2 - \|x^*\|\|\bar{x}\| = \|\bar{x}\|(\|\bar{x}\| - \|x^*\|).$$

So $\|\bar{x}\| = \|x^*\|$. By the uniqueness of the least 2-norm solution, we must have $\bar{x} = x^*$. Since $\bar{x}$ is any limit point of $\{x^k\}$, we then have

$$\lim_{k \longrightarrow \infty} x^k = x^*. \qquad \square$$

5. Local convergence analysis. First we introduce the following notation for this section:

(i) $S :=$ the solution set of the LCP (1).
(ii) $S_y := \{y \in R^n | y = Mx + q$ for some $x \in \mathcal{S}\}$.
(iii) $B := \{i | x_i > 0$ for some $x \in S\}$.
(iv) $N := \{i | y_i > 0$ for some $y \in S_y\}$.
(v) $J := \{i | x_i = y_i = 0 \ \forall x \in S, \forall y \in S_y\}$.

It is well known that the sets B, N, J form a partition of the index set $\{1, 2, \ldots, n\}$; i.e., they are pairwise disjoint and $B \cup N \cup J = \{1, 2, \ldots, n\}$. Therefore a solution x is called a maximally complementary solution if

$$x_B > 0 \quad \text{and} \quad (Mx + q)_N > 0.$$

If $J = \emptyset$, then a maximally complementary solution is called a strictly complementary solution. Note that if $J \neq \emptyset$, then LCP (1) has no strictly complementary solution.

In [24], a superlinearly convergent algorithm based on the same class of paths was proposed under the assumption that x^* is the only solution of the LCP and is strictly complementary. The assumption needed for our local analysis is weaker.

Assumption 2. x^* is maximally complementary.

Our analysis relies on the boundedness of $\{(\hat{x}^{(l)}, \hat{y}^{(l)})(t, t, w) | l = 1, 2, \ldots, L\}$ on the noncompact set $\{(t, w) | 0 < t \leq t_0, \|w - e\|_\infty \leq \beta\}$. But we will show a stronger result that $(\hat{x}(\gamma, t, w), \hat{y}(\gamma, t, w))$, an analytic vector function on

$$\left\{ (\gamma, t, w) \,\middle|\, w > 0, t > 0, 0 < \gamma < t + \frac{(1+t)\min\{w_i\}}{1 + \min\{w_i\}} \right\},$$

can be analytically extended to the set

$$\left\{(\gamma,t,w)\,\middle|\,w>0,t\geq 0,0\leq\gamma<t+\frac{(1+t)\min\{w_i\}}{1+\min\{w_i\}}\right\}.$$

From Theorem 2.1, for any fixed $w>0$ we have

$$\lim_{t\longrightarrow 0+}(x(t,w),y(t,w))=(x^*,y^*).$$

Now we first show that $(x(t,w),y(t,w))$ can be analytically extended to $\{(t,w)|t\geq 0,w>0\}$. The following two technical lemmas will be needed.

LEMMA 5.1. *For any fixed $w>0$, we have $x_j(t,w)=\Theta(t)$ and $y_j(t,w)=\Theta(t)$ for all $j\in J$ as $t\longrightarrow 0+$. Here we use the standard big-O notation: Given functions $f_1(t)$ and $f_2(t)$, we say $f_1(t)=O(t)$ and $f_2(t)=\Theta(t)$ as $t\longrightarrow 0+$ if and only if there exist positive constants C_1, C_2, and C_3 such that when t is sufficiently small we have $|f_1(t)|\leq C_1t$, and $C_2t\leq|f_2(t)|\leq C_3t$.*

Proof. For any $x,y\in R^n$, let $d(x,S)$ and $d(y,S_y)$ denote the distance between x and S and the distance between y and S_y, respectively.

Corollary 2.2 of [8] states that $r(x)+s(x)$ is a global error bound for a monotone LCP, where $r(x)=\|x-(x-Mx-q)_+\|$ and $s(x)=\|(-Mx-q,-x,X(Mx+q))_+\|$. So there exists $\tau>0$ such that for any $x\in R^n$, $d(x,S)\leq\tau(r(x)+s(x))$.

For fixed $w>0$, we consider $(x(t,w),y(t,w))>0$, the solution of

$$\begin{cases}X(t,w)y(t,w)=t^2w,\\ y(t,w)=Mx(t,w)+tx(t,w)+q,\end{cases}$$

where $0<t\leq 1$.

Since $(x(t,w),y(t,w))\longrightarrow(x^*,y^*)$ as $t\longrightarrow 0+$, and $(x(t,w),y(t,w))$ is an analytic vector function on $t>0$, then $\{(x(t,w),y(t,w))|0<t\leq 1\}$ is bounded.

Now we show that $s(x(t,w))=O(t)$ and $r(x(t,w))=O(t)$.

For $s(x(t,w))$ we have

$$\begin{aligned}(X(t,w)(Mx(t,w)+q))_+&=(X(t,w)(y(t,w)-tx(t,w)))_+\\&=(t^2w-tX(t,w)^2e)_+\leq t^2w=O(t^2),\\(-x(t,w))_+&=0,\\(-Mx(t,w)-q)_+&=(tx(t,w)-y(t,w))_+\leq tx(t,w)=O(t),\end{aligned}$$

and so $s(x(t,w))=O(t)$.

For $r(x(t,w))$ we have $r(x(t,w))=\|x(t,w)-((1+t)x(t,w)-y(t,w))_+\|$.

(i) If i is an index such that $(1+t)x_i(t,w)-y_i(t,w)>0$, then $0<y_i(t,w)<(1+t)x_i(t,w)\leq 2x_i(t,w)$, and so $y_i(t,w)^2<2x_i(t,w)y_i(t,w)=2w_it^2$, and hence $y_i(t,w)\leq\sqrt{2w_i}t$; then

$$\begin{aligned}|x_i(t,w)-((1+t)x_i(t,w)-y_i(t,w))_+|&=|y_i(t,w)-tx_i(t,w)|\\&\leq y_i(t,w)+tx_i(t,w)\\&\leq(\sqrt{2w_i}+\|x(t,w)\|)t.\end{aligned}$$

(ii) If i is an index such that $(1+t)x_i(t,w)-y_i(t,w) \le 0$, then $x_i(t,w) \le y_i(t,w)$, $x_i(t,w)^2 \le x_i(t,w)y_i(t,w) = w_i t^2$, and so $x_i(t,w) \le \sqrt{w_i}t$, and hence

$$|x_i(t,w) - ((1+t)x_i(t,w) - y_i(t,w))_+| = x_i(t,w) \le \sqrt{w_i}t.$$

Combining the above inequalities we have $r(x(t,w)) = O(t)$. Therefore $d(x(t,w), S) = O(t)$.

On the other hand, we also have

$$\begin{aligned} d(y(t,w), S_y) &= \min\{\|Mx(t,w) + tx(t,w) + q - (Mx+q)\| \,|x \in S\} \\ &= \min\{\|M(x(t,w)-x) + tx(t,w)\| | x \in S\} \\ &\le \min\{\|M\|\|x(t,w)-x\| + t\|x(t,w)\| | x \in S\} \\ &\le \|M\| d(x(t,w), S) + t\|x(t,w)\| \\ &= O(t). \end{aligned}$$

For all $j \in J$, since $x_j = y_j = 0$ for all $x \in S$ and $y \in S_y$, we have

$$0 < x_j(t,w) \le d(x(t,w), S) = O(t),$$

$$0 < y_j(t,w) \le d(y(t,w), S_y) = O(t).$$

Notice that $x_j(t,w)y_j(t,w) = t^2 w_j$ for all $t > 0$, we must have $x_j(t,w) = \Theta(t)$, and $y_j(t,w) = \Theta(t)$. □

LEMMA 5.2. *If $0 \preceq M \in R^{n\times n}$, then $\mathcal{N}(M) \cap \mathcal{R}(M) = \{0\}$, where $\mathcal{N}(M)$ and $\mathcal{R}(M)$ represent the null space and range space of M, respectively.*

Proof. Since $\mathcal{N}(M) \subseteq \mathcal{N}(M^2)$, $\dim(\mathcal{N}(M)) = n - \operatorname{rank}(M)$, and $\dim(\mathcal{N}(M^2)) = n - \operatorname{rank}(M^2)$, we have

$$\mathcal{N}(M) \cap \mathcal{R}(M) = \{0\} \Longleftrightarrow \mathcal{N}(M) = \mathcal{N}(M^2) \Longleftrightarrow \operatorname{rank}(M) = \operatorname{rank}(M^2).$$

Let $A = \frac{M+M^T}{2}$, $B = \frac{M-M^T}{2}$. Then A is symmetric positive semidefinite, while B is skew-symmetric. If A is nonsingular, then so is M. Hence $\mathcal{N}(M) = \mathcal{N}(M^2) = \{0\}$. So we need only to consider the case when A is singular.

If A is of the form $\left[\begin{smallmatrix} D & 0 \\ 0 & 0 \end{smallmatrix}\right]$, where D is symmetric positive definite, then we can partition B likewise: $B = \left[\begin{smallmatrix} C & F \\ -F^T & G \end{smallmatrix}\right]$, where both C and G are skew-symmetric.

Letting $z = \left[\begin{smallmatrix} u \\ v \end{smallmatrix}\right] \in \mathcal{N}(M)$, we have

$$Mz = \begin{bmatrix} D+C & F \\ -F^T & G \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} (D+C)u + Fv \\ -F^T u + Gv \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

So $u^T((D+C)u + Fv) + v^T(-F^T u + Gv) = u^T D u = 0$, and hence we get $u = 0$, $Fv = 0$, and $Gv = 0$.

Therefore

$$\mathcal{N}(M) = \left\{ \begin{bmatrix} 0 \\ v \end{bmatrix} \middle| \, v \in \mathcal{N}(F) \cap N(G) \right\}.$$

Now if $z = \left[\begin{smallmatrix} u \\ v \end{smallmatrix}\right] \in \mathcal{N}(M^2)$, then $Mz = \left[\begin{smallmatrix} (D+C)u + Fv \\ -F^T u + Gv \end{smallmatrix}\right] \in \mathcal{N}(M)$.

So $(D+C)u+Fv=0$, $F(-F^Tu+Gv)=0$, and $G(-F^Tu+Gv)=0$. Then we have

$$\begin{aligned}\|-F^Tu+Gv\|^2 &= (-u^TF+v^TG^T)(-F^Tu+Gv)\\ &= -u^TF(-F^Tu+Gv)+v^TG^T(-F^Tu+Gv)\\ &= -u^TF(-F^Tu+Gv)-v^TG(-F^Tu+Gv)\\ &= 0.\end{aligned}$$

Thus $-F^Tu+Gv=0$, and so $Mz=0$, $z\in\mathcal{N}(M)$. Therefore $\mathcal{N}(M)=\mathcal{N}(M^2)$, which is equivalent to $\operatorname{rank}(M)=\operatorname{rank}(M^2)$ when the symmetric part of M has this special form.

For general symmetric positive semidefinite matrix A, there exists an orthogonal matrix O such that $O^TAO=\left[\begin{smallmatrix} D & 0\\ 0 & 0\end{smallmatrix}\right]$, where D is symmetric positive definite. So $\operatorname{rank}(O^TMO)=\operatorname{rank}((O^TMO)^2)$.

Thus $\operatorname{rank}(M)=\operatorname{rank}(O^TMO)=\operatorname{rank}((O^TMO)^2)=\operatorname{rank}(O^TM^2O)=\operatorname{rank}(M^2)$, and hence $\mathcal{N}(M)=\mathcal{N}(M^2)$ and $\mathcal{N}(M)\cap\mathcal{R}(M)=\{0\}$. □

Now we can prove the main theorem.

THEOREM 5.3. *If x^* is maximally complementary, i.e., $(x_B^*,y_N^*)>0$, then $(x(t,w),y(t,w))$ can be analytically extended to an open set $\mathcal{P}$ containing $\{t\ge 0,w>0\}$. In other words, there exist analytic vector functions $f(t,w)$ and $g(t,w)$ on $\mathcal{P}$ such that $f(t,w)=x(t,w)$ and $g(t,w)=y(t,w)$ for all $(t,w)>0$.*

Proof. Without loss of generality, we assume $B=\{1,2,\dots,|B|\}$, $J=\{|B|+1,\dots,|B|+|J|\}$, and $N=\{|B|+|J|+1,\dots,n\}$. Then $x_B^*>0$, $y_B^*=0$, $x_N^*=0$, $y_N^*>0$, and $x_J^*=y_J^*=0$.

We consider only $t\le 1$.

Define the following vector functions for $t>0,w>0$:

$$\begin{aligned}\tilde{x}_B(t,w) &:= x_B(t,w),\\ \tilde{x}_N(t,w) &:= W_N y_N(t,w)^{-1}=t^{-2}x_N(t,w),\\ \tilde{x}_J(t,w) &:= t^{-1}x_J(t,w),\\ \tilde{y}_B(t,w) &:= W_B x_B(t,w)^{-1}=t^{-2}y_B(t,w),\\ \tilde{y}_J(t,w) &:= t^{-1}y_J(t,w),\\ \tilde{y}_N(t,w) &:= y_N(t,w),\\ \tilde{x}(t,w) &:= (\tilde{x}_B(t,w),\tilde{x}_J(t,w),\tilde{x}_N(t,w)),\\ \tilde{y}(t,w) &:= (\tilde{y}_B(t,w),\tilde{y}_J(t,w),\tilde{y}_N(t,w)).\end{aligned}$$

These are all positive analytic vector functions on $(t>0,w>0)$.

For fixed w, since $(x_B(t,w),y_N(t,w))\longrightarrow(x_B^*,y_N^*)>0$, and$(x_J(t,w),y_J(t,w))=\Theta(t)$, then $(\tilde{x}(t,w),\tilde{y}(t,w))$ is bounded when $0<t\le 1$. Let $\{t_k(w)\}$ be a positive sequence decreasing to 0 such that $(\tilde{x}(t_k(w),w),\tilde{y}(t_k(w),w))$ is convergent, and define $(\tilde{x}(0,w),\tilde{y}(0,w))$ to be the limit. Since $\tilde{X}(t,w)\tilde{y}(t,w)=w$ and $(\tilde{x}(t,w),\tilde{y}(t,w))>0$ for $t>0$, we must have $(\tilde{x}(0,w),\tilde{y}(0,w))>0$.

Therefore $(\tilde{x}(t,w),\tilde{y}(t,w))$ is the unique positive solution of the following system for any fixed $(t,w)>0$:

$$\begin{cases} \begin{bmatrix} M_{BB} & M_{BJ} & M_{BN} \\ M_{JB} & M_{JJ} & M_{JN} \\ M_{NB} & M_{NJ} & M_{NN} \end{bmatrix} \begin{bmatrix} \tilde{x}_B \\ t\tilde{x}_J \\ t^2\tilde{x}_N \end{bmatrix} + \begin{bmatrix} t\tilde{x}_B \\ t^2\tilde{x}_J \\ t^3\tilde{x}_N \end{bmatrix} - \begin{bmatrix} t^2\tilde{y}_B \\ t\tilde{y}_J \\ \tilde{y}_N \end{bmatrix} + \begin{bmatrix} q_B \\ q_J \\ q_N \end{bmatrix} = 0, \\ \tilde{X}\tilde{y} - w = 0, \end{cases}$$

while $(\tilde{x}(0,w),\tilde{y}(0,w))$ is a solution of this system for fixed $(t=0,w>0)$.

The Jacobian of this system with respect to $(\tilde{x}_B,\tilde{x}_J,\tilde{x}_N,\tilde{y}_B,\tilde{y}_J,\tilde{y}_N)$ is

$$\begin{bmatrix} M_{BB}+tI_B & tM_{BJ} & t^2M_{BN} & -t^2I_B & 0 & 0 \\ M_{JB} & tM_{JJ}+t^2I_J & t^2M_{JN} & 0 & -tI_J & 0 \\ M_{NB} & tM_{NJ} & t^2M_{NN}+t^3I_N & 0 & 0 & -I_N \\ \tilde{Y}_B(t,w) & 0 & 0 & \tilde{X}_B(t,w) & 0 & 0 \\ 0 & \tilde{Y}_J(t,w) & 0 & 0 & \tilde{X}_J(t,w) & 0 \\ 0 & 0 & \tilde{Y}_N(t,w) & 0 & 0 & \tilde{X}_N(t,w) \end{bmatrix}.$$

This matrix may become singular when $t=0$, which prevents us from using the implicit function theorem as in Theorem 2.3. In order to fix this problem, we use the technique of "adding redundant equations" which was used in [3, 2, 15, 13] to study the analyticity of the central path of LP, SDP, LCP, and SDLCP.

Let $r=\operatorname{rank}(\left[\begin{smallmatrix} M_{BB} \\ M_{JB} \end{smallmatrix}\right])$. Then there exists $P\in R^{(|B|+|J|-r)\times(|B|+|J|)}$ such that $P\left[\begin{smallmatrix} M_{BB} \\ M_{JB} \end{smallmatrix}\right]=0$, and $\mathcal{N}(P)=\mathcal{R}\big(\left[\begin{smallmatrix} M_{BB} \\ M_{JB} \end{smallmatrix}\right]\big)$.

Multiplying the first two equations by P from the left, we get

$$P\begin{bmatrix} M_{BB} & M_{BJ} & M_{BN} \\ M_{JB} & M_{JJ} & M_{JN} \end{bmatrix}\begin{bmatrix} \tilde{x}_B \\ t\tilde{x}_J \\ t^2\tilde{x}_N \end{bmatrix} + P\begin{bmatrix} t\tilde{x}_B \\ t^2\tilde{x}_J \end{bmatrix}$$

$$-P\begin{bmatrix} t^2\tilde{y}_B \\ t\tilde{y}_J \end{bmatrix} + P\begin{bmatrix} q_B \\ q_J \end{bmatrix} = 0$$

$\Longrightarrow$

$$P\begin{bmatrix} M_{BJ} & M_{BN} \\ M_{JJ} & M_{JN} \end{bmatrix}\begin{bmatrix} t\tilde{x}_J \\ t^2\tilde{x}_N \end{bmatrix} + P\begin{bmatrix} t\tilde{x}_B \\ t^2\tilde{x}_J \end{bmatrix} - P\begin{bmatrix} t^2\tilde{y}_B \\ t\tilde{y}_J \end{bmatrix} + P\begin{bmatrix} q_B \\ q_J \end{bmatrix} = 0.$$

Letting $t\longrightarrow 0$, we get $P\left[\begin{smallmatrix} q_B \\ q_J \end{smallmatrix}\right]=0$. Hence the above system is equivalent to

$$P\begin{bmatrix} M_{BJ} & M_{BN} \\ M_{JJ} & M_{JN} \end{bmatrix}\begin{bmatrix} t\tilde{x}_J \\ t^2\tilde{x}_N \end{bmatrix} + P\begin{bmatrix} t\tilde{x}_B \\ t^2\tilde{x}_J \end{bmatrix} - P\begin{bmatrix} t^2\tilde{y}_B \\ t\tilde{y}_J \end{bmatrix} = 0.$$

Factoring out t, we get

$$P\begin{bmatrix} M_{BJ} & M_{BN} \\ M_{JJ} & M_{JN} \end{bmatrix}\begin{bmatrix} \tilde{x}_J \\ t\tilde{x}_N \end{bmatrix} + P\begin{bmatrix} \tilde{x}_B \\ t\tilde{x}_J \end{bmatrix} - P\begin{bmatrix} t\tilde{y}_B \\ \tilde{y}_J \end{bmatrix} = 0.$$

Therefore $(\tilde{x}(t,w), \tilde{y}(t,w), t, w)$ solves the enlarged system for $t \geq 0$, $w > 0$:

$$\Phi(\tilde{x}, \tilde{y}, t, w) := \begin{pmatrix} P\begin{bmatrix} M_{BJ} & M_{BN} \\ M_{JJ} & M_{JN} \end{bmatrix}\begin{bmatrix} \tilde{x}_J \\ t\tilde{x}_N \end{bmatrix} + P\begin{bmatrix} \tilde{x}_B \\ t\tilde{x}_J \end{bmatrix} - P\begin{bmatrix} t\tilde{y}_B \\ \tilde{y}_J \end{bmatrix} \\ \begin{bmatrix} M_{BB} & M_{BJ} & M_{BN} \\ M_{JB} & M_{JJ} & M_{JN} \\ M_{NB} & M_{NJ} & M_{NN} \end{bmatrix}\begin{bmatrix} \tilde{x}_B \\ t\tilde{x}_J \\ t^2\tilde{x}_N \end{bmatrix} + \begin{bmatrix} t\tilde{x}_B \\ t^2\tilde{x}_J \\ t^3\tilde{x}_N \end{bmatrix} - \begin{bmatrix} t^2\tilde{y}_B \\ t\tilde{y}_J \\ \tilde{y}_N \end{bmatrix} + \begin{bmatrix} q_B \\ q_J \\ q_N \end{bmatrix} \\ \tilde{X}\tilde{y} - w \end{pmatrix} = 0.$$

We partition P as $P = [P_B, P_J]$; then the Jacobian of $\Phi(\tilde{x}, \tilde{y}, t, w)$ with respect to $(\tilde{x}_B, \tilde{x}_J, \tilde{x}_N, \tilde{y}_B, \tilde{y}_J, \tilde{y}_N)$ is

$$\Phi'(\tilde{x}_B, \tilde{x}_J, \tilde{x}_N, \tilde{y}_B, \tilde{y}_J, \tilde{y}_N, t, w)$$

$$= \begin{bmatrix} P_B & P\begin{bmatrix} M_{BJ} \\ M_{JJ} \end{bmatrix} + tP_J & tP\begin{bmatrix} M_{BN} \\ M_{JN} \end{bmatrix} & -tP_B & -P_J & 0 \\ M_{BB} + tI_B & tM_{BJ} & t^2M_{BN} & -t^2I_B & 0 & 0 \\ M_{JB} & tM_{JJ} + t^2I_J & t^2M_{JN} & 0 & -tI_J & 0 \\ M_{NB} & tM_{NJ} & t^2M_{NN} + t^3I_N & 0 & 0 & -I_N \\ \tilde{Y}_B(t,w) & 0 & 0 & \tilde{X}_B(t,w) & 0 & 0 \\ 0 & \tilde{Y}_J(t,w) & 0 & 0 & \tilde{X}_J(t,w) & 0 \\ 0 & 0 & \tilde{Y}_N(t,w) & 0 & 0 & \tilde{X}_N(t,w) \end{bmatrix},$$

which is simplified to

$$J = \begin{bmatrix} P_B & P\begin{bmatrix} M_{BJ} \\ M_{JJ} \end{bmatrix} & 0 & 0 & -P_J & 0 \\ M_{BB} & 0 & 0 & 0 & 0 & 0 \\ M_{JB} & 0 & 0 & 0 & 0 & 0 \\ M_{NB} & 0 & 0 & 0 & 0 & -I_N \\ \tilde{Y}_B(0,w) & 0 & 0 & \tilde{X}_B(0,w) & 0 & 0 \\ 0 & \tilde{Y}_J(0,w) & 0 & 0 & \tilde{X}_J(0,w) & 0 \\ 0 & 0 & \tilde{Y}_N(0,w) & 0 & 0 & \tilde{X}_N(0,w) \end{bmatrix}$$

at $(\tilde{x}(0,w), \tilde{y}(0,w), 0, w)$.

Considering the rank of J (after some simple row/column operations), we have

$$\operatorname{rank}(J) = \operatorname{rank}\left(\begin{bmatrix} P_B & P\begin{bmatrix} M_{BJ} \\ M_{JJ} \end{bmatrix} & 0 & 0 & -P_J & 0 \\ M_{BB} & 0 & 0 & 0 & 0 & 0 \\ M_{JB} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -I_N \\ 0 & 0 & 0 & \tilde{X}_B(0,w) & 0 & 0 \\ 0 & \tilde{Y}_J(0,w) & 0 & 0 & \tilde{X}_J(0,w) & 0 \\ 0 & 0 & \tilde{Y}_N(0,w) & 0 & 0 & 0 \end{bmatrix}\right)$$

$$= 2|N| + |B| + \operatorname{rank}\left(\begin{bmatrix} P_B & P\begin{bmatrix} M_{BJ} \\ M_{JJ} \end{bmatrix} & -P_J \\ M_{BB} & 0 & 0 \\ M_{JB} & 0 & 0 \\ 0 & \tilde{Y}_J(0,w) & \tilde{X}_J(0,w) \end{bmatrix}\right)$$

$$= 2|N| + |B| + \operatorname{rank}\left(\begin{bmatrix} P_B & P\begin{bmatrix} M_{BJ} \\ M_{JJ} \end{bmatrix} + P_J\tilde{X}_J(0,w)^{-1}\tilde{Y}_J(0,w) & 0 \\ M_{BB} & 0 & 0 \\ M_{JB} & 0 & 0 \\ 0 & \tilde{Y}_J(0,w) & \tilde{X}_J(0,w) \end{bmatrix}\right)$$

$$= |N| + n + \operatorname{rank}\left(\begin{bmatrix} P_B & P\begin{bmatrix} M_{BJ} \\ M_{JJ} \end{bmatrix} + P_J\tilde{X}_J(0,w)^{-1}\tilde{Y}_J(0,w) \\ M_{BB} & 0 \\ M_{JB} & 0 \end{bmatrix}\right).$$

Let $Z = \tilde{X}_J(0,w)^{-1}\tilde{Y}_J(0,w)$ and

$$A = \begin{bmatrix} P_B & P\begin{bmatrix} M_{BJ} \\ M_{JJ} \end{bmatrix} + P_JZ \\ M_{BB} & 0 \\ M_{JB} & 0 \end{bmatrix} \in R^{(2|B|+|J|)\times(|B|+|J|)}.$$

Now we show that A has full column rank. For all $\begin{bmatrix} u \\ v \end{bmatrix} \in \mathcal{N}(A)$, we have

$$P_Bu + P\begin{bmatrix} M_{BJ} \\ M_{JJ} \end{bmatrix} v + P_JZv = 0,$$

$$M_{BB}u = 0,$$

$$M_{JB}u = 0.$$

The first equation leads to

$$P\begin{bmatrix} u+M_{BJ}v \\ (M_{JJ}+Z)v \end{bmatrix} = 0 \Longrightarrow \begin{bmatrix} u+M_{BJ}v \\ (M_{JJ}+Z)v \end{bmatrix} \in \mathcal{R}\left(\begin{bmatrix} M_{BB} \\ M_{JB} \end{bmatrix}\right).$$

So there exists $a \in R^{|B|}$ such that $u + M_{BJ}v = M_{BB}a$ and $(M_{JJ} + Z)v = M_{JB}a$.

Since $M \succeq 0$ and $Z \succ 0$, then $M_{JJ} + Z \succ 0$ and $\left[\begin{smallmatrix} M_{BB} & M_{BJ} \\ M_{JB} & M_{JJ}+Z \end{smallmatrix}\right] \succeq 0$. So we have $v = (M_{JJ} + Z)^{-1}M_{JB}a$ and $u = (M_{BB} - M_{BJ}(M_{JJ} + Z)^{-1}M_{JB})a$.

Since

$$\begin{bmatrix} M_{BB} - M_{BJ}(M_{JJ}+Z)^{-1}M_{JB} & M_{BJ} - M_{JB}^T(M_{JJ}+Z)^{-T}(M_{JJ}+Z) \\ 0 & M_{JJ}+Z \end{bmatrix}$$

$$= \begin{bmatrix} I_B & -M_{JB}^T(M_{JJ}+Z)^{-T} \\ 0 & I_J \end{bmatrix} \begin{bmatrix} M_{BB} & M_{BJ} \\ M_{JB} & M_{JJ}+Z \end{bmatrix}$$

$$\times \begin{bmatrix} I_B & 0 \\ -(M_{JJ}+Z)^{-1}M_{JB} & I_J \end{bmatrix}$$

$$\succeq 0,$$

then $M_1 := M_{BB} - M_{BJ}(M_{JJ}+Z)^{-1}M_{JB} \succeq 0$. Now because $u \in \mathcal{N}(M_{BB}) \cap \mathcal{N}(M_{JB})$ and $u \in \mathcal{R}(M_1)$, we have $u \in \mathcal{N}(M_1) \cap \mathcal{R}(M_1)$, and hence by Lemma 5.2, $u = 0$.

So $(M_{BB} - M_{BJ}(M_{JJ} + Z)^{-1}M_{JB})a = 0$, and hence

$$0 = \begin{bmatrix} a^T & 0 \end{bmatrix}$$

$$\times \begin{bmatrix} M_{BB} - M_{BJ}(M_{JJ}+Z)^{-1}M_{JB} & M_{BJ} - M_{JB}^T(M_{JJ}+Z)^{-T}(M_{JJ}+Z) \\ 0 & M_{JJ}+Z \end{bmatrix}$$

$$\times \begin{bmatrix} a \\ 0 \end{bmatrix}$$

$$= \begin{bmatrix} a^T & 0 \end{bmatrix} \begin{bmatrix} I_B & -M_{JB}^T(M_{JJ}+Z)^{-T} \\ 0 & I_J \end{bmatrix} \begin{bmatrix} M_{BB} & M_{BJ} \\ M_{JB} & M_{JJ}+Z \end{bmatrix}$$

$$\times \begin{bmatrix} I_B & 0 \\ -(M_{JJ}+Z)^{-1}M_{JB} & I_J \end{bmatrix} \begin{bmatrix} a \\ 0 \end{bmatrix}$$

$$= \begin{bmatrix} a^T & -a^T M_{JB}^T(M_{JJ}+Z)^{-T} \end{bmatrix} \begin{bmatrix} M_{BB} & M_{BJ} \\ M_{JB} & M_{JJ}+Z \end{bmatrix}$$

$$\times \begin{bmatrix} a \\ -(M_{JJ}+Z)^{-1}M_{JB}a \end{bmatrix}$$

$$= \begin{bmatrix} a^T & -v^T \end{bmatrix} \left(\begin{bmatrix} M_{BB} & M_{BJ} \\ M_{JB} & M_{JJ} \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & Z \end{bmatrix} \right) \begin{bmatrix} a \\ -v \end{bmatrix}$$

$$\geq v^T Z v$$

$$\geq 0.$$

Because $Z \succ 0$, we must have $v = 0$.

Therefore $\mathcal{N}(A) = \{0\}$, and so $\operatorname{rank}(A) = |B| + |J|$, and hence $\operatorname{rank}(J) = 2n$.

Thus the system of $2n+|B|+|J|-r$ equations $\Phi(\tilde{x}, \tilde{y}, t, w) = 0$ contains a subsystem $\Phi_{\mathcal{L}}(\tilde{x}, \tilde{y}, t, w) = 0$ of $|\mathcal{L}| = 2n$ equations such that the Jacobian of the subsystem $\Phi_{\mathcal{L}}(\tilde{x}, \tilde{y}, t, w)$ with respect to $(\tilde{x}, \tilde{y})$ is nonsingular at the solution $(\tilde{x}(0, w), \tilde{y}(0, w), 0, w)$ for any $w > 0$. So by the implicit function theorem, for any fixed $\bar{w} > 0$, the subsystem $\Phi_{\mathcal{L}}(\tilde{x}, \tilde{y}, t, w)$ (depending analytically on every variable) has a locally unique analytic solution $(x_{\bar{w}}(t, w), y_{\bar{w}}(t, w))$. More specifically, there exist open balls $B_{xy}(\bar{w}) \subset R^{2n}$ and $B_{tw}(\bar{w}) \subset R^{n+1}$, centering at $(\tilde{x}(0, \bar{w}), \tilde{y}(0, \bar{w}))$ and $(t = 0, \bar{w})$, respectively, satisfying the following:

(i) For each $(t, w) \in B_{tw}(\bar{w})$, there is a unique solution $(x_{\bar{w}}(t, w), y_{\bar{w}}(t, w)) \in B_{xy}(\bar{w})$ of the system $\Phi_{\mathcal{L}}(\tilde{x}, \tilde{y}, t, w) = 0$.

(ii) $(x_{\bar{w}}(t, w), y_{\bar{w}}(t, w))$ is an analytic vector function for $(t, w) \in B_{tw}(\bar{w})$.

(iii) $(x_{\bar{w}}(0, \bar{w}), y_{\bar{w}}(0, \bar{w})) = (\tilde{x}(0, \bar{w}), \tilde{y}(0, \bar{w}))$.

Since $t_k(\bar{w}) \longrightarrow 0$ and $(\tilde{x}(t_k(\bar{w}), \bar{w}), \tilde{y}(t_k(\bar{w}), \bar{w})) \longrightarrow (\tilde{x}(0, \bar{w}), \tilde{y}(0, \bar{w}))$, there exists k such that $(t_k(\bar{w}), \bar{w}) \in B_{tw}(\bar{w})$ and $(\tilde{x}(t_k(\bar{w}), \bar{w}), \tilde{y}(t_k(\bar{w}), \bar{w})) \in B_{xy}(\bar{w})$. Then by the continuity of $(\tilde{x}(t, w), \tilde{y}(t, w))$, there exists a small open neighborhood $\mathcal{U}$ such that $(t_k(\bar{w}), \bar{w}) \in \mathcal{U} \subset B_{tw}(\bar{w})$ and $(\tilde{x}, \tilde{y})(\mathcal{U}) \subset B_{xy}(\bar{w})$. Since $(\tilde{x}(t, w), \tilde{y}(t, w), t, w)$ is also a solution of the system $\Phi_{\mathcal{L}}(\tilde{x}, \tilde{y}, t, w) = 0$, then by the uniqueness of $(x_{\bar{w}}(t, w), y_{\bar{w}}(t, w))$, we have $(x_{\bar{w}}(t, w), y_{\bar{w}}(t, w)) = (\tilde{x}(t, w), \tilde{y}(t, w))$ for $(t, w) \in \mathcal{U}$. Moreover, by the analyticity of $(x_{\bar{w}}(t, w), y_{\bar{w}}(t, w))$ and $(\tilde{x}(t, w), \tilde{y}(t, w))$, this equality extends to $B_{tw}(\bar{w}) \cap \{(t > 0, w > 0)\}$.

For any two different $w_1 > 0$ and $w_2 > 0$, if $B_{tw}(w_1) \cap B_{tw}(w_2) \neq \emptyset$, then $B_{tw}(w_1) \cap B_{tw}(w_2) \cap \{t > 0, w > 0\} \neq \emptyset$. Since $(x_{w_1}(t, w), y_{w_1}(t, w)) = (\tilde{x}(t, w), \tilde{y}(t, w)) = (x_{w_2}(t, w), y_{w_2}(t, w))$ on the open set $B_{tw}(w_1) \cap B_{tw}(w_2) \cap \{t > 0, w > 0\}$, by their analyticity, we must have $(x_{w_1}(t, w), y_{w_1}(t, w)) = (x_{w_2}(t, w), y_{w_2}(t, w))$ on $B_{tw}(w_1) \cap B_{tw}(w_2)$.

Therefore we are able to analytically extend $(\tilde{x}(t, w), \tilde{y}(t, w))$ to the open set $\mathcal{P} = \{t > 0, w > 0\} \bigcup (\cup_{w>0} B_{tw}(w))$, which obviously contains $\{t \geq 0, w > 0\}$.

Since $(x(t, w), y(t, w)) = (\tilde{x}_B(t, w),\ t\tilde{x}_J(t, w),\ t^2\tilde{x}_N(t, w),\ t^2\tilde{y}_B(t, w),\ t\tilde{y}_J(t, w), \tilde{y}_N(t, w))$, we can do the same thing to $(x(t, w), y(t, w))$. ∎

As an immediate consequence of Theorem 5.3, we know that $\frac{\partial x}{\partial t}(t, w)$ is bounded on the compact set $\{0 \leq t \leq t_0, \|w - e\|_\infty \leq \beta\}$. Since $x^k = x(t_k, w^k)$, $x(0, w^k) = x^*$, and $\|w^k - e\|_\infty \leq \beta$, by the mean value theorem we have $\|x^k - x^*\| = O(t_k)$.

Finally we are ready to prove the fast local convergence of Algorithm 1 in terms of t_k.

THEOREM 5.4. *Under Assumption* 2, *when* k *is sufficiently large, we have* $t_{k+1} = t_k^\theta$.

Proof. Recall that in step 1 Algorithm 1, we pick an integer $L \geq 3$ and a real number $\theta \in (1, \frac{L}{2})$.

From Theorem 5.3 and the definitions of $u(\gamma,t,w)$ and $(\hat{x}(\gamma,t,w),\hat{y}(\gamma,t,w))$, it is clear that we can analytically extend $(\hat{x}(\gamma,t,w),\hat{y}(\gamma,t,w))$ to the open set

$$\mathcal{O}=\{(\gamma,t,w)\,|(\gamma,u(\gamma,t,w))\in\mathcal{P},t>-1\},$$

which contains

$$\left\{(\gamma,t,w)\,\middle|\,w>0,t\geq 0,0\leq\gamma<t+\frac{(1+t)\min\{w_i\}}{1+\min\{w_i\}}\right\}.$$

Therefore $R(s,t,w)$ is an analytic vector function on $\{(s,t,w)|s\in R,t\geq 0,w>0\}$ and thus bounded on the compact set $\{0\leq s\leq t,0\leq t\leq t_0,\|w-e\|_\infty\leq\beta\}$. In other words, there exists a constant $\chi>0$ such that $\|R(s,t,w)\|_\infty\leq\chi$ when (s,t,w) lies in this compact set.

Since $1<\theta<\frac{L}{2}$, we have

$$t_k\leq\min\left\{2^{\frac{1}{1-\theta}},\left(\frac{\beta}{2\chi}\right)^{\frac{1}{L-2\theta}},1\right\}\Longrightarrow\sqrt{\frac{2\chi {t_k}^L}{\beta}}\leq {t_k}^\theta\leq\frac{t_k}{2}.$$

Therefore when t_k satisfies the above inequality, for all $s\in[t_k^\theta,t_k]$, by Lemma 3.3 we have

$$\begin{aligned}\|F^k(s)g^k(s)-s^2e\|_\infty-\beta s^2&\leq-(t_k-s)\left(\frac{\beta s^2}{1+t_k}-(t_k-s)^L\|R(s,t_k,w_k)\|_\infty\right)\\&\leq-(t_k-s)\left(\frac{\beta t_k^{2\theta}}{2}-\chi t_k^L\right)\\&=-\frac{\beta(t_k-s)}{2}\left(t_k^{2\theta}-\frac{2\chi t_k^L}{\beta}\right)\\&\leq 0.\end{aligned}$$

Then using the continuity of $(f^k(s),g^k(s))$ and the fact that $(f^k(t_k),g^k(t_k))=(x^k,y^k)>0$ we can show that $(f^k(s),g^k(s))>0$ for all $s\in[t_k^\theta,t_k]$.

So $t_{k+1}=t_k^\theta$. □

Remark. L denotes the number of linear systems (with the same coefficient matrix) we would like to solve in each predictor step. The bigger L is, the bigger γ can be chosen and the faster the local convergence will be. For example, when $L=3$, we can choose $\gamma=1.4$; while when $L=5$, we can choose $\gamma=2.4$.

6. Concluding remarks. In this paper we present a high-order path following method for locating the least 2-norm solution of monotone LCPs. The algorithm was partly motivated by the method proposed in [23] on finding the least 2-norm solution of linear programs. We proved the global convergence of our algorithm under the assumption that the LCP has at least one solution. We then showed the superlinear rate of convergence under the further assumption that the least 2-norm solution is maximally complementary.

Two directions are worthy of future research. The strength of this algorithm is on its superior local rate of convergence. But the high-order approximation is essentially a local technique. When the current estimate is far from the least 2-norm solution, it is usually better not to spend too much effort trying to approximate the path very

well. In order to make an efficient general algorithm, some fast globally convergent techniques have to be combined with the high-order idea.

On the other hand, the local convergence analysis itself also needs further improvement. Under the maximal complementarity assumption, we showed that $x(t,w)$ is an analytic function on $\{(t,w)|t \geq 0, w > 0\}$, and thus $\|x^k - x^*\| = \|x(t_k, w^k) - x(0, w^k)\| = O(t)$. Therefore when t_k is sufficiently small, it is generally safe to say that x^k is close to x^*. However, if the assumption does not hold, then we do not know whether $x(t,w)$ can still be analytically extended to $t = 0$. Hence it could happen that even though t is very small, x^k is still a little far from x^*. Thus it is natural and important to consider the possibility of removing the maximal complementarity assumption. Define $O_B := \{i \in B | x_i^* = 0\}$ and $O_N := \{i \in N | y_i^* = 0\}$. Then x^* satisfying the maximal complementarity condition is equivalent to $O_B = O_N = \emptyset$. Now assume $O_B \neq \emptyset$ and/or $O_N \neq \emptyset$. Based on our analysis, it is important to find an accurate bound for $x_i(t,w)$ for $i \in O_B, O_N$ as $t \longrightarrow 0+$. Some numerical examples seem to suggest that $x_i(t,w) = \Theta(t^{\frac{1}{2}})$ for $i \in O_B$, while $x_i(t,w) = \Theta(t^{\frac{3}{2}})$ for $i \in O_N$. If such bounds can be found, then we may be able to carry out the local analysis without assuming x^* to be maximally complementary, probably with a different parametrization.

Acknowledgment. The author thanks two anonymous referees for their helpful comments and suggestions.

EXPLICIT REFORMULATIONS FOR ROBUST OPTIMIZATION PROBLEMS WITH GENERAL UNCERTAINTY SETS*

IGOR AVERBAKH† AND YUN-BIN ZHAO‡

Abstract. We consider a rather general class of mathematical programming problems with data uncertainty, where the uncertainty set is represented by a system of convex inequalities. We prove that the robust counterparts of this class of problems can be reformulated equivalently as finite and explicit optimization problems. Moreover, we develop simplified reformulations for problems with uncertainty sets defined by convex homogeneous functions. Our results provide a unified treatment of many situations that have been investigated in the literature and are applicable to a wider range of problems and more complicated uncertainty sets than those considered before. The analysis in this paper makes it possible to use existing continuous optimization algorithms to solve more complicated robust optimization problems. The analysis also shows how the structure of the resulting reformulation of the robust counterpart depends both on the structure of the original nominal optimization problem and on the structure of the uncertainty set.

Key words. robust optimization, data uncertainty, mathematical programming, homogeneous functions, convex analysis

1. Introduction.

In classical optimization models, the data are usually assumed to be known precisely. However, there are numerous situations where the data are inexact/uncertain. In many applications, the optimal solution of the nominal optimization problem may not be useful because it may be highly sensitive to small changes of the parameters of the problem.

Sensitivity analysis and stochastic programming are two traditional methods to deal with uncertain optimization problems. The former offers only local information near the nominal values of the data, while the latter requires one to make assumptions about the probability distribution of the uncertain data which may not be appropriate. Moreover, the stochastic programming approach often leads to very large optimization problems and cannot guarantee satisfaction of certain hard constraints, which is required in some practical settings.

An increasingly popular approach to optimization problems with data uncertainty is *robust optimization*, where it is assumed that possible values of data belong to some well-defined *uncertainty set*. In robust optimization, the goal is to find a solution that satisfies all constraints for any possible scenario from the uncertainty set and optimizes the worst-case (guaranteed) value of the objective function. See, e.g., [5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 21, 22, 23, 24, 25, 26, 29, 35, 39, 40]. The solutions of robust optimization models are "uniformly good" for realizations of data from the

uncertainty set. Early work in this direction was done by Soyster [39, 40] and Falk [22] under the name of "inexact linear programming." The robust optimization approach has been applied to various problems in operations management, financial planning, and engineering design (see, e.g., [29, 26, 10, 6, 31, 35]).

A formulation of a robust model as a mathematical programming problem is called a *robust counterpart*. Since in the robust approach the constraints must be satisfied for all possible realizations of data from the uncertainty set, the robust counterpart is typically a complicated semi-infinite optimization problem. A fundamental question in robust optimization is whether the robust counterpart can be represented as a single finite and explicit optimization problem, so that existing optimization methods can be used to solve it. Such an analysis also helps to understand computational complexity of robust optimization problems.

So far, to obtain sufficiently simple robust counterparts, the uncertainty set was normally assumed to have a fairly simple structure, for example, a Cartesian product of intervals, an ellipsoid, an intersection of ellipsoids, or a set defined by certain norms (see, e.g., [2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 23, 24, 25, 26, 29]). Of course, the simpler the uncertainty set is, the easier it is to solve the robust optimization problem, and in some situations simplifying assumptions about uncertainty sets is natural when modelling a practical problem. However, more complicated uncertainty sets may be encountered in both theoretical study and in applications (see Remark 3.1 for details). Therefore, it is important to understand possibilities of the robust approach dealing with problems involving complicated or general uncertainty sets. Study of robust optimization problems with general uncertainty sets may provide additional tools for modelling intricate real-life situations and a unified treatment of specialized cases. Moreover, such a study can provide additional insights and results and even improve known results for some specialized cases when general results are reduced to such specialized cases (see section 6 for details).

In this paper, we consider robust optimization problems with uncertainty sets defined by a system of convex inequalities. The optimization problems we consider may be nonconvex and are wide enough to include linear programming, linear complementarity problems, quadratic programming, second order cone programming, and general polynomial programming problems. We prove that the robust counterparts of the considered problems with uncertainty are finite optimization problems which can be formulated by using the nominal data of the underlying optimization problem and the conjugates of the functions defining the uncertainty set. Compared with the original optimization problem, a major extra difficulty of the robust counterpart comes from the conjugates of the functions that define the uncertainty set. The conjugates of these functions usually are not given explicitly and may be difficult to compute. To identify explicit and simplified formulations of robust counterparts, we focus on a class of convex functions whose conjugates can be expressed explicitly. Our strongest results and simplest reformulations of robust counterparts correspond to the case where the uncertainty sets are defined by convex homogeneous functions. This class of uncertainty sets is broad enough to include most uncertainty models that have been investigated in the literature, as well as many other important cases, for example, where deviations of data from nominal values may be asymmetric and not even defined by norms.

We note that instead of optimizing the worst-case value of the objective function, another possibility is to optimize the worst-case regret, which is the worst-case deviation of the objective function value from the optimal value under the realized scenario,

or, in other words, to minimize the worst-case loss in the objective function value that may occur because the decision is made before the realized scenario is known. This criterion leads to minmax regret optimization models [29, 2, 1, 3, 4]. Minmax regret problems are typically computationally hard [29, 4], although there are exceptions (see, e.g., [2, 1, 3]). Minmax regret problems also fit the general paradigm of robust optimization, but we do not consider them in this paper. We also note that there are other concepts of robustness in the literature under the name of "model uncertainty" or "ambiguity." See, e.g., [42, 28, 17, 33, 18, 38, 27, 37, 16, 19, 20, 21, 31, 41].

This paper is organized as follows. In section 2, we describe the class of optimization problems that we consider. In section 3, we define the uncertainty set of data and provide an equivalent, deterministic representation of the robust optimization problems via Fenchel's conjugate functions. In section 4, we give an explicit representation for the robust counterpart when the uncertainty set is defined by (nonhomogeneous) convex functions that fall in the linear space generated by homogeneous functions of arbitrary degrees. The case of uncertainty sets defined by homogeneous functions is studied in section 5. Specializing the general results of sections 3, 4, and 5 to robust problems where the nominal problem is a linear programming problem and/or the uncertainty set is of a special type commonly used in the literature is discussed in section 6, and concluding remarks are provided in section 7.

2. A class of optimization problems with data uncertainty. We consider the following optimization problem:

$$\min\{c^T x : \ f_i(x) \le b_i, \ i = 1, \dots, m, \ F(x) \le 0\}, \tag{1}$$

where $c = (c_1, \dots, c_n)^T$ and $b = (b_1, \dots, b_m)^T$ are fixed vectors, and f_i's are functions of the form

$$f_i(x) = \left(W^{(i)}(x)\right)^T M^{(i)} V^{(i)}(x), \quad i = 1, \dots, m, \tag{2}$$

where $W^{(i)}(x)$ and $V^{(i)}(x)$ are two mappings from R^n to R^{N_i}, $M^{(i)}$ is an $N_i \times N_i$ real matrix, and N_i's are positive integers. We write $W^{(i)}(x)$ and $V^{(i)}(x)$ as $W^{(i)}(x) = (W_1^{(i)}(x), \dots, W_{N_i}^{(i)}(x))^T$ and $V^{(i)}(x) = (V_1^{(i)}(x), \dots, V_{N_i}^{(i)}(x))^T$, where each $W_j^{(i)}$ $(j = 1, \dots, N_i)$ is a function from R^n to R.

We assume that only the data $M^{(i)}$, $i = 1, \dots, m$, are subject to uncertainty. In (1), $F(x) \le 0$ denotes constraints without uncertainty, e.g., the simple constraints $x \ge 0$. We assume that c and b are certain without loss of generality, because a problem with uncertain c and b can be easily transformed into a problem with certain coefficients of the objective function and right-hand sides of the constraints. Also, if the objective function is not linear, it can be made linear by introducing an additional variable and a new constraint. We note that functions f_i are linear in the uncertain data $M^{(i)}$ (but can be nonlinear in the decision variables x).

The above optimization model is very general. For example, it includes the following important special cases.

Linear programming (LP). Let $A \in R^{m \times n}$ (i.e., an $m \times n$ matrix) and $b = (b_1, \dots, b_m)^T$. Without loss of generality, we assume $m \le n$. Consider functions $f_i(x)$ of the form (2), where

$$W^{(i)}(x) = e_i \in R^n, \quad V^{(i)}(x) = x \in R^n, \quad M^{(i)} = \begin{bmatrix} A \\ 0 \end{bmatrix}_{n \times n},$$

where e_i, throughout this paper, denotes the ith column of an $n \times n$ identity matrix, and 0 in $M^{(i)}$ denotes an $(n-m) \times n$ zero matrix. It is evident that the inequalities $f_i = (W^{(i)})^T M^{(i)} V^{(i)} \leq b_i,\ i = 1, \ldots, m$, are equivalent to $Ax \leq b$. Therefore, problem (1) with $F(x) = -x \leq 0$ reduces to the following LP problem:

$$\min\{c^T x : \ Ax \leq b,\ x \geq 0\}. \tag{3}$$

This implies that the LP problem (3) with uncertain coefficient matrix A is a special case of the optimization problem (1) with uncertain data $M^{(i)}$. There is also another way to write an LP problem in the form (1)–(2); see (38) and (39) in section 6.2 for details.

Linear complementarity problem (LCP). Given a matrix $M \in R^{n \times n}$ and a vector $q \in R^n$, the LCP is defined as

$$Mx + q \geq 0, \quad x \geq 0, \quad x^T(Mx + q) = 0.$$

Solutions to the LCP are very sensitive to changes in data because of the equation $x^T(Mx + q) = 0$. When the matrix M is uncertain, it is hard to find a solution that satisfies the above system and is "immune" to changes of M. Thus, it is reasonable to consider the optimization form of the LCP, i.e.,

$$\min\{x^T(Mx + q) : \ Mx + q \geq 0,\ x \geq 0\},$$

or equivalently

$$\min\{t : \ x^T(Mx + q) - t \leq 0,\ Mx + q \geq 0,\ x \geq 0\},$$

which is less sensitive in the sense that it is equivalent to the LCP if the LCP has a solution and can still have a solution even when the LCP has no solution. The above optimization problem can be reformulated as (2) by letting

$$W^{(1)}(x) = \begin{pmatrix} x \\ 1 \\ e_1 \end{pmatrix} \in R^{2n+1}, \quad W^{(i)} = \begin{pmatrix} 0^{(n+1)} \\ e_{i-1} \end{pmatrix} \in R^{2n+1} \quad \text{for } i = 2, \ldots, n+1,$$

$$M^{(i)} = \begin{bmatrix} M & q & 0 & \overbrace{0 \ \ldots 0}^{n-1} \\ 0 & 0 & -1 & 0 \ \ldots 0 \\ -M & -q & 0 & 0 \ \ldots 0 \end{bmatrix},$$

$$V^{(i)}(x) = \begin{pmatrix} x \\ 1 \\ t \\ 0^{(n-1)} \end{pmatrix} \in R^{2n+1}, \quad i = 1, \ldots, n+1,$$

where $t \in R$, and $0^{(n+1)}$ and $0^{(n-1)}$ denote $(n+1)$- and $(n-1)$-dimensional zero vectors, respectively. It is easy to verify that problem (1) with $F(x) = -x \leq 0$ and $f_i = (W^{(i)})^T M^{(i)} V^{(i)} \leq 0$ $(i = 1, \ldots, n+1)$ is the same as the optimization form of the LCP. It is worth mentioning that Zhang [43] considered equality constrained robust optimization, and his approach may be also used to deal with LCPs with uncertain data.

(Nonconvex) quadratic programming (QP). Consider functions $f_i(x)$ of the form (2), where

$$W^{(i)}(x) = \begin{pmatrix} x \\ 1 \end{pmatrix} \in R^{n+1} \quad \text{for } i = 0, \ldots, m,$$

$$V^{(0)}(x) = \begin{pmatrix} x \\ t \end{pmatrix} \in R^{n+1}, \; V^{(i)}(x) = \begin{pmatrix} x \\ 0 \end{pmatrix} \in R^{n+1} \quad \text{for } i = 1, \ldots, m$$

and

$$M^{(i)} = \begin{bmatrix} Q_i & 0 \\ q_i^T & -1 \end{bmatrix}_{(n+1)\times(n+1)} \qquad \text{for } i = 0, \ldots, m, \tag{4}$$

where each Q_i is an $n \times n$ symmetric matrix and each q_i is a vector in R^n. Then the optimization problem (1) with the objective t and constraints $f_i = (W^{(i)})^T M^{(i)} V^{(i)} \leq -c_i (i = 0, \ldots, m)$ is reduced to the following QP problem:

$$\begin{aligned} \min \quad & x^T Q_0 x + q_0^T x + c_0 \\ \text{s.t.} \quad & x^T Q_i x + q_i^T x + c_i \leq 0 \quad \text{for } i = 1, \ldots, m. \end{aligned}$$

Thus, a QP problem with uncertain coefficients $(Q_i, q_i)(i = 0, \ldots, m)$ can be represented as an optimization problem (1) with uncertain data $M^{(i)}$ given as (4).

Second order cone programming (SOCP). Let $A \in R^{m\times n}, b \in R^m, c \in R^n$, and β be a scalar. Let

$$W^{(1)}(x) = V^{(1)}(x) = \begin{pmatrix} x \\ 1 \end{pmatrix} \in R^{n+1}$$

and

$$M^{(1)} = \begin{bmatrix} A^T A - cc^T & 0 \\ 2b^T A - 2\beta c^T & b^T b - \beta^2 \end{bmatrix}, \tag{5}$$

and $W^{(2)}(x) = e \in R^n$ (the vector with all components equal to 1), $V^{(2)}(x) = x \in R^n$, and

$$M^{(2)} = \begin{bmatrix} -c^T \\ 0 \end{bmatrix}_{n\times n}.$$

Then the constraint $f_1 = (W^{(1)})^T M^{(1)} V^{(1)} \leq 0$, together with $f_2 = (W^{(2)})^T M^{(2)} V^{(2)} \leq \beta$, is equivalent to the second order cone constraint: $\|Ax + b\| \leq c^T x + \beta$. In fact, $f_1 \leq 0$ can be written as

$$(Ax + b)^T (Ax + b) \leq (c^T x + \beta)^2,$$

and $f_2 \leq \beta$ can be written as $c^T x + \beta \geq 0$. Combination of these two inequalities leads to a second order cone constraint. Thus, uncertainty of the data (A, B, c, β) leads to uncertainty of the matrices $M^{(1)}$ and $M^{(2)}$.

Polynomial programming. We recall that a monomial in $x_1, \ldots, x_n$ is a product of the form $x_1^{\alpha_1} \cdot x_2^{\alpha_2} \cdots x_n^{\alpha_n}$, where $\alpha_1, \ldots, \alpha_n$ are nonnegative integers. It is evident

that if the components of $W(x)$ and $V(x)$ are monomials, then for any given matrix M, a function of the form (2) is a polynomial. Conversely, any real polynomial is a linear combination of some monomials, i.e.,

$$P(x_1, x_2, \ldots, x_n) = \sum_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} C^{(\alpha_1,\alpha_2,\ldots,\alpha_n)} x_1^{\alpha_1} x_2^{\alpha_2} \ldots x_n^{\alpha^n},$$

where $C^{(\alpha_1,\ldots,\alpha_n)}$ are real coefficients. Then the simplest way to write it in the form (2) is to set $W(x) = e$, set $V(x)$ to be the vector of all monomials $x_1^{\alpha_1} x_2^{\alpha_2} \ldots x_n^{\alpha^n}$ appearing in $P(x)$, and set M to be the diagonal matrix with diagonal entries $C^{(\alpha_1,\alpha_2,\ldots,\alpha_n)}$. Thus polynomial optimization with uncertain coefficients is a special case of (1) with uncertain data $M^{(i)}$.

3. Robust counterparts as finite deterministic optimization problems. We start with a description of the uncertainty set. *Let K_i, $i = 1, \ldots, m$, be a bounded subset of $R^{N_i^2}$ that contains the origin.* Suppose that the uncertain data $M^{(i)}$ $(i = 1, \ldots, m)$ of the ith constraint of (1) are allowed to vary in such a way that the deviations from their fixed nominal values $\overline{M}^{(i)}$ fall in K_i. That is, the uncertainty set of the data $M^{(i)}$ is defined as

$$\mathcal{U}_i = \left\{ \widetilde{M}^{(i)} \,\middle|\, vec(\widetilde{M}^{(i)}) - vec(\overline{M}^{(i)}) \in K_i \right\}, \quad i = 1, \ldots, m, \tag{6}$$

where for a given matrix M, $vec(M)$ denotes the vector obtained by stacking the transposed rows of M on top of one another. Then the robust counterpart of the optimization problem (1) with uncertainty sets $\mathcal{U}_i$ is defined as follows:

$$\min c^T x$$

$$\text{s.t. } f_i = \left(W^{(i)}(x)\right)^T \widetilde{M}^{(i)} V^{(i)}(x) \le b_i \quad \forall \widetilde{M}^{(i)} \in \mathcal{U}_i, i = 1, \ldots, m, F(x) \le 0, \tag{7}$$

which is a semi-infinite optimization problem. The optimal solution to this problem is feasible for all realizations of the data $\widetilde{M}^{(i)}$.

We denote by $\delta(u|K)$ the indicator function of a set K (see [36]), and the conjugate function of $\delta(u|K)$ is denoted by $\delta^*(u|K)$, which is equal to the support function $\psi_K(u) = \max\{u^T v : v \in K\}$. First we state the following general result, which shows that the robust counterpart (7) can be written equivalently as a finite deterministic optimization problem, regardless of the type of uncertainty sets.

THEOREM 3.1. *The robust optimization problem* (7) *is equivalent to the following finite and deterministic optimization problem:*

$$\begin{aligned} &\min c^T x \\ &s.t. \left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \delta^*(\chi_i | \mathrm{cl}(\mathrm{co} K_i)) \le b_i, \quad i = 1, \ldots, m, \\ &\quad F(x) \le 0, \end{aligned}$$

where $\mathrm{cl}(\mathrm{co}K_i)$ *denotes the closure of the convex hull of set* K_i, *and* $\chi_i = W^{(i)}(x) \otimes V^{(i)}(x) \in R^{N_i^2}$, *i.e., is the Kronecker product of the vectors* $W^{(i)}(x)$ *and* $V^{(i)}(x)$.

Proof. In fact, the constraint $f_i = (W^{(i)}(x))^T \widetilde{M}^{(i)} V^{(i)}(x) \le b_i$ for all $vec(\widetilde{M}^{(i)}) - vec(\overline{M}^{(i)}) \in K_i$ is equivalent to

$$\sup \left\{ W^{(i)}(x)^T \widetilde{M}^{(i)} V^{(i)}(x) : vec(\widetilde{M}^{(i)}) - vec(\overline{M}^{(i)}) \in K_i \right\} \le b_i. \tag{8}$$

Notice that for any square matrices B, C, we have $\mathrm{tr}(BC) = (vec(B))^T vec(C^T)$. Thus, we have

$$\begin{aligned}\left(W^{(i)}(x)\right)^T \widetilde{M}^{(i)} V^{(i)}(x) &= \mathrm{tr}\left(\widetilde{M}^{(i)} V^{(i)}(x) \left(W^{(i)}(x)\right)^T\right) \\ &= \left(vec(\widetilde{M}^{(i)})\right)^T vec\left(W^{(i)}(x)\left(V^{(i)}(x)\right)^T\right) \\ &= \left(vec(\widetilde{M}^{(i)})\right)^T \left(W^{(i)}(x) \otimes V^{(i)}(x)\right).\end{aligned}$$

Denoting $\chi_i = W^{(i)}(x) \otimes V^{(i)}(x)$, the constraint (8) can be written as

$$\begin{aligned} b_i &\geq \sup\left\{\left(vec(\widetilde{M}^{(i)})\right)^T \chi_i : vec(\widetilde{M}^{(i)}) - vec(\overline{M}^{(i)}) \in K_i\right\} \\ &= \left(vec(\overline{M}^{(i)})\right)^T \chi_i + \sup_{u \in K_i} u^T \chi_i = \left(vec(\overline{M}^{(i)})\right)^T \chi_i + \sup_{u \in \mathrm{cl}(\mathrm{co}K_i)} u^T \chi_i \\ &= \left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \delta^*(\chi_i | \mathrm{cl}(\mathrm{co}K_i)).\end{aligned}$$

The original semi-infinite constraints become finite and deterministic constraints. □

For robust optimization, when the uncertainty set is not convex, the robust counterpart remains unchanged if we replace the uncertainty set by its closed convex hull. This observation was first mentioned in [7] and can be seen clearly from the above result. Because of this fact, we may assume without loss of generality that each K_i is a closed convex set. In applications, the convex set K_i is usually determined by a system of convex inequalities. So, *throughout the rest of the paper, we assume that K_i is a closed, bounded convex set containing the origin and it can be represented as*

$$K_i = \left\{u \;\middle|\; g_j^{(i)}(u) \leq \Delta_j^{(i)},\ j = 1, \ldots, \ell^{(i)}\right\}, \quad i = 1, \ldots, m, \tag{9}$$

where $\ell^{(i)}$'s are given integers, $\Delta_j^{(i)}$'s are constants, and $g_j^{(i)}$'s are proper closed convex functions from $R^{N_i^2}$ to $\overline{R}$. Here $\overline{R} = R \cup \{+\infty\}$ and "proper" means that the function is finite somewhere (throughout the paper, we use the terminology from [36]). Since $0 \in K_i$, we have $g_j^{(i)}(0) \leq \Delta_j^{(i)}$ for all $j = 1, \ldots, \ell^{(i)}$.

Remark 3.1. In this remark, we give additional motivation for considering the general uncertainty set (9) as opposed to special uncertainty sets studied in the literature. We note that the importance of studying robust problems with complicated uncertainty sets was emphasized, for example, in [15].

(i) Consider the following uncertainty set:

$$\mathcal{U} = \left\{D \;\middle|\; \exists z \in R^{|N|} : D = D_0 + \psi(z) = D_0 + \sum_{j \in N} \Delta D_j z_j,\ \|z\| \leq \Omega\right\}, \tag{10}$$

where Ω is a given number, D_0 is a given vector (nominal values of the uncertain data), and ΔD_j's are directions of data perturbation. This uncertainty set has been widely used in the literature (see, e.g., [5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 23, 24, 25, 26].

It is the image of a ball (defined by some norm) under linear transformation; i.e., the function $\psi(z)$ here is a linear function in z. This widely used uncertainty set can be written in the form (9) with only one convex inequality $g(u) \leq \Omega$, where function $g(u)$ is also homogeneous of 1-degree, and $g(u)$ is not a norm, in general, unless $|N|$ is equal to the number of data and the data perturbation directions ΔD^j's are linearly independent (see section 6.1 for details). This typical example shows that it is necessary to study the case when the functions $g_j^{(i)}(u)$ in (9) are convex and homogeneous (but not necessarily norms). Section 5 of this paper is devoted to this important case.

For the uncertainty set $\mathcal{U}$ defined by (10), the function $\psi(z)$ is linear in z. In some applications, however, such a model is insufficient for description of more complicated uncertainty sets. The next two examples show that in some situations the function $\psi(z)$ may be nonlinear, and hence the uncertainty set may be much more complicated.

(ii) Consider SOCP. It is often assumed that the data (A, b, c) are subject to an ellipsoidal uncertainty set which is the case of (10) where the norm is the 2-norm. When we reformulate SOCP into the form of (1), the data $M^{(1)}$ is determined by the matrix (5). It is easy to see the data $M^{(1)}$ belongs to the following uncertainty set:

$$\mathcal{U} = \left\{ D \,\middle|\, \exists z \in R^{|N|} : D = D^0 + \psi(z), \quad \|z\| \leq \Omega \right\}, \tag{11}$$

where $\psi(z)$ is a quadratic function in z. Thus, this example shows that a more complicated uncertainty set than (10) might appear when we make a reformulation of the problem. Such reformulations are often made when a problem is studied from different perspectives.

(iii) This example, taken from [23], shows that a nonlinear function $\psi(z)$ arises in (11) when robust interpolation problems are considered. Let $n \geq 1$ and k be given integers. We want to find a polynomial of degree $n-1$, $p(t) = x_1 + \cdots + x_n t^{n-1}$ that interpolates given points (a_i, b_i), i.e., $p(a_i) = b_i, i = 1, \ldots, k$. If interpolation points (a_i, b_i) are known precisely, we obtain the following linear equation:

$$\begin{bmatrix} 1 & a_1 & \cdots & a_1^{n-1} \\ \vdots & \vdots & & \vdots \\ 1 & a_k & \cdots & a_k^{n-1} \end{bmatrix} \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} = \begin{bmatrix} b_1 \\ \vdots \\ b_n \end{bmatrix}.$$

Now assume that a_i's are not known precisely, i.e., $a_i(\delta) = a_i + \delta_i, i = 1, \ldots, k$, where the $\delta = (\delta_1, \ldots, \delta_k)$ is unknown but bounded, i.e., $\|\delta\|_\infty \leq \rho$, where $\rho \geq 0$ is given. A robust interpolant is a solution x that minimizes $\|A(\delta)x - b\|$ over the region $\|\delta\|_\infty \leq \rho$, where

$$A(\delta) = \begin{bmatrix} 1 & a_1(\delta) & \cdots & a_1(\delta)^{n-1} \\ \vdots & \vdots & & \vdots \\ 1 & a_k(\delta) & \cdots & a_k(\delta)^{n-1} \end{bmatrix}$$

is an uncertain Vandermonde matrix. Such a matrix can be written in the form (11) with nonlinear function $\psi(z)$. In fact, we have (see [23] for details)

$$A(\delta) = A(0) + L\Delta(I - D\Delta)^{-1} R_A,$$

where L, D, and R_A are constant matrices determined by a_i's, and $\Delta = \oplus_{i=1}^k \delta_i I_{n-1}$.

(iv) Our model provides a unified treatment of many uncertainty sets in the literature. Note that (11) can be written in the form (9) by letting $g(D) = \inf\{\|z\| : D = \psi(z)\}$. Then $\mathcal{U} - \{D_0\} = \{D : \ g(D) \leq \Omega\}$. This can be proved by the same argument as Lemma 6.1.

(v) Studying problems with general uncertainty sets may in fact lead to new or stronger results for important special cases, as we demonstrate in section 6.

Since robust optimization problems, in general, are semi-infinite optimization problems which are hard to solve, the fundamental question is whether a robust optimization problem can be explicitly represented as an equivalent finite optimization problem, so that the existing optimization methods can be applied. We are addressing this question in this paper. It should be mentioned that, generally, two research directions are possible: (1) developing computationally tractable approximate (relaxed) formulations; (2) developing exact formulations which, naturally, will be computationally difficult for sufficiently complicated nominal problems and/or uncertainty sets. Our paper focuses on the second direction; the first direction was investigated, for instance, in Bertsimas and Sim [14]. We believe that both directions are important for theoretical and practical progress in robust optimization; we comment on this in more detail in section 6.

Let us mention some auxiliary results and definitions. Given a function f we denote its domain by $\mathrm{dom}(f)$ and denote its Fenchel's conjugate function by f^*, i.e.,

$$f^*(w) = \sup_{x \in \mathrm{dom}(f)} \left(w^T x - f(x)\right).$$

We recall that the infimal convolution function of $g_j (j = 1, \ldots, \ell)$, denoted by $g_1 \diamond g_2 \diamond \cdots \diamond g_\ell$, is defined as

$$(g_1 \diamond g_2 \diamond \cdots \diamond g_\ell)(u) = \inf \left\{ \sum_{j=1}^{\ell} g_j(u_j) : \sum_{j=1}^{\ell} u_j = u \right\}.$$

The following result will be used in our later analysis.

LEMMA 3.1 (see [36, Theorem 16.4]). *Let $f_1, \ldots, f_\ell : R^n \to \overline{R}$ be proper convex functions. Then $(\mathrm{cl}(f_1) + \cdots + \mathrm{cl}(f_\ell))^* = \mathrm{cl}(f_1^* \diamond \cdots \diamond f_\ell^*)$, where $\mathrm{cl}(f)$ denotes the closure of the convex function f. If the relative interiors of the domains of these functions, i.e., $ri(\mathrm{dom}(f_i)), i = 1, \ldots, \ell$, have a point in common, then*

$$\left(\sum_{i=1}^{\ell} f_i\right)^* (x) = (f_1^* \diamond \cdots \diamond f_\ell^*)(x) = \inf \left\{ \sum_{i=1}^{\ell} f_i^*(x_i) : \sum_{i=1}^{\ell} x_i = x \right\},$$

where for each $x \in R^n$ the infimum is attained.

Now we consider the robust programming problem (7) where the uncertainty set is determined by (6) and (9). We have the following general result.

THEOREM 3.2. *Let K_i $(i = 1, \ldots, m)$ be given by (9), where each $g_j^{(i)} (j = 1 \ldots, \ell^{(i)})$ is a closed proper convex function. Suppose that Slater's condition holds for each i; i.e., for each i, there exists a point $u_0^{(i)}$ such that $g_j^{(i)}(u_0^{(i)}) < \Delta_j^{(i)}$ for all $j = 1, \ldots, \ell^{(i)}$. Then the robust counterpart (7) is equivalent to*

$$\min c^T x$$

$$s.t.\ \left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \Delta_j^{(i)} + \left(\sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} g_j^{(i)}\right)^* (\chi_i) \le b_i,$$

$$i = 1, \ldots, m, \quad \lambda_j^{(i)} \ge 0, \quad j = 1, \ldots, \ell^{(i)}, \quad i = 1, \ldots, m,$$

$$F(x) \le 0,$$

where $\chi_i = W^{(i)}(x) \otimes V^{(i)}(x)$. *This problem can be further written as*

$$\min c^T x$$

$$s.t.\ \left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \Delta_j^{(i)} + \Upsilon^{(i)}(\lambda^{(i)}, u^{(i)}) \le b_i, \quad i = 1, \ldots, m,$$

$$\chi_i = \begin{cases} \sum_{j \in J_i} u_j^{(i)} & \text{if } J_i \neq \emptyset, \\ 0 & \text{otherwise,} \end{cases} \quad i = 1, \ldots, m, \tag{12}$$

$$\lambda_j^{(i)} \ge 0, \quad j = 1, \ldots, \ell^{(i)}, \quad i = 1, \ldots, m,$$

$$F(x) \le 0,$$

where $J_i = \{j : \lambda_j^{(i)} > 0, j = 1, \ldots, \ell^{(i)}\}$, $\lambda^{(i)}$ *denotes the vector whose components are* $\lambda_j^{(i)}$, $j = 1, \ldots, \ell^{(i)}$, $u^{(i)}$ *denotes the vector whose components are* $u_j^{(i)}, j \in J_i$, *and*

$$\Upsilon^{(i)}(\lambda^{(i)}, u^{(i)}) = \begin{cases} \sum_{j \in J_i} \lambda_j^{(i)} \left(g_j^{(i)}\right)^* \left(u_j^{(i)} / \lambda_j^{(i)}\right) & \text{if } J_i \neq \emptyset, \\ 0 & \text{otherwise.} \end{cases}$$

Proof. We see from the proof of Theorem 3.1 that x is feasible to the robust problem (7) if and only if $F(x) \le 0$ and for each i we have

$$\left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \max_{u \in K_i} u^T \chi_i \le b_i. \tag{13}$$

Let $Z(\chi_i) = \max\{u^T \chi_i : u \in K_i\}$, where K_i is given by (9), which by our assumption is a bounded, closed convex set. Thus the maximum value of the convex optimization problem $\max\{u^T \chi_i : u \in K_i\}$ is finite and attainable. Denote the Lagrangian multiplier vector for this problem by $\lambda^{(i)} = (\lambda_1^{(i)}, \lambda_2^{(i)}, \ldots, \lambda_{\ell^{(i)}}^{(i)}) \in R_+^{\ell^{(i)}}$. Since Slater's condition holds for the problem $\max\{u^T \chi_i : u \in K_i\}$, by Lagrangian saddle-point theorem (see, e.g., Theorem 28.3, Corollary 28.3.1, and Theorem 28.4 in [36]), we have

$$\begin{aligned} Z(\chi_i) &= -\min\{-u^T \chi_i : \ g_j^{(i)}(u) \le \Delta_j^{(i)}, j = 1, \ldots, \ell^{(i)}\} \\ &= -\sup_{\lambda^{(i)} \in R_+^{\ell^{(i)}}} \inf_{u \in R^{N_i^2}} \left(-u^T \chi_i + \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \left(g_j^{(i)}(u) - \Delta_j^{(i)}\right)\right) \\ &= -\sup_{\lambda^{(i)} \in R_+^{\ell^{(i)}}} \left[-\sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \Delta_j^{(i)} + \inf_{u \in R^{N_i^2}} \left(-u^T \chi_i + \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} g_j^{(i)}(u)\right)\right] \end{aligned} \tag{14}$$

$$= - \sup_{\lambda^{(i)} \in R_+^{\ell^{(i)}}} \left[- \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \Delta_j^{(i)} - \sup_{u \in R^{N_i^2}} \left(u^T \chi_i - \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} g_j^{(i)}(u) \right) \right]$$

$$= - \sup_{\lambda^{(i)} \in R_+^{\ell^{(i)}}} \left(- \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \Delta_j^{(i)} - \left(\sum_{i=1}^{\ell^{(i)}} \lambda_j^{(i)} g_j^{(i)} \right)^* (\chi_i) \right)$$

$$= \inf_{\lambda^{(i)} \in R_+^{\ell^{(i)}}} \left(\sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \Delta_j^{(i)} + \left(\sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} g_j^{(i)} \right)^* (\chi_i) \right).$$

Under our assumptions, the above infimum is attainable (by the existence of a saddle point of the Lagrangian function [36]). Substituting (14) into (13), we see that x satisfies (13) if and only if it satisfies the following inequalities for some $\lambda^{(i)}$:

$$\left(W^{(i)}(x) \right)^T \overline{M}^{(i)} V^{(i)}(x) + \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \Delta_j^{(i)} + \left(\sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} g_j^{(i)} \right)^* (\chi_i) \le b_i, \tag{15}$$

$$\lambda^{(i)} = (\lambda_1^{(i)}, \lambda_2^{(i)}, \ldots, \lambda_{\ell^{(i)}}^{(i)}) \in R_+^{\ell^{(i)}}. \tag{16}$$

Indeed, if x is feasible to (13), since the infimum in (14) is attainable, there exists some $\lambda^{(i)} \in R_+^{\ell^{(i)}}$ such that $(x, \lambda^{(i)})$ is feasible to the system (15)–(16). Conversely, if $(x, \lambda^{(i)})$ is feasible to (15) and (16), then by (14), we see that (15) implies (13). Replacing (13) by (15) together with (16), the first part of the desired result follows from Theorem 3.1.

We now derive the optimization problem (12). Suppose that $(x, \lambda^{(i)})$ satisfies (15) and (16). We have two cases.

Case 1. $J_i = \{j : \lambda_j^{(i)} > 0, j = 1, \ldots, \ell^{(i)}\} \neq \emptyset$. Denote by $u^{(i)}$ the vector whose components are $u_j^{(i)}, j \in J_i$. Notice that for any constant $\alpha > 0$, the conjugate $(\alpha f)^*(x) = \alpha f^*(x/\alpha)$. For given $\lambda^{(i)} \in R_+^{\ell^{(i)}}$, by Lemma 3.1, we have

$$\left(\sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} g_j^{(i)} \right)^* (\chi_i) = \inf_{u^{(i)}} \left\{ \sum_{j \in J_i} \lambda_j^{(i)} \left(g_j^{(i)} \right)^* (u_j^{(i)} / \lambda_j^{(i)}) : \chi_i = \sum_{j \in J_i} u_j^{(i)} \right\}.$$

Again, by Lemma 3.1, the infimum above is attainable, and hence there are $u_j^{(i)}$, $j \in J_i$, such that

$$\left(\sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} g_j^{(i)} \right)^* (\chi_i) = \sum_{j \in J_i} \lambda_j^{(i)} \left(g_j^{(i)} \right)^* (u_j^{(i)} / \lambda_j^{(i)}),$$

$$\chi_i = \sum_{j \in J_i} u_j^{(i)}.$$

Case 2. $J_i = \emptyset$. Notice that

$$\left(\sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} g_j^{(i)} \right)^* (w) = \sup_{u \in R^n} (w^T u - 0) = \begin{cases} \infty & \text{if } w \neq 0, \\ 0 & \text{if } w = 0. \end{cases}$$

Since $(x, \lambda^{(i)})$ is feasible to (15) and (16), we conclude that for this case

$$\chi_i = 0, \quad \left(\sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} g_j^{(i)}\right)^* (\chi_i) = 0.$$

Combining the above two cases leads to the optimization problem (12). □

We see from Theorem 3.2 that the level of complexity of the robust counterpart, compared with the nominal optimization problem, is determined mainly by the conjugate functions $(g_j^{(i)})^*$ $(j = 1, \ldots, \ell^{(i)}, i = 1, \ldots, m)$ and functions χ_i $(i = 1, \ldots, m)$. The more complicated the conjugate functions are, the more difficult the robust counterpart is. Notice that the constraint $\sum_{j \in J_i} u_j^{(i)} = \chi_i$ is an explicit expression, and in some cases, e.g., LP, χ_i is linear in x and thus does not add difficulty. We also note that when $\ell^{(i)} = 1$, i.e., when K_i is defined by only one constraint, then $u_j^{(i)} = \chi_i$, in which case the formula $\sum_{j \in J_i} u_j^{(i)} = \chi_i$ will not appear in (12). For an arbitrary function, however, its conjugate function is not given explicitly, and hence (12) is not an explicit optimization problem. As a result, to obtain an explicit formulation of the robust counterpart, one has to compute the conjugate functions of the constraint functions $g_j^{(i)}$, which except for very simple cases is not easy. This motivates us to investigate in the remainder of the paper under what conditions the robust counterpart in Theorem 3.2 can be further simplified, avoiding the computation of conjugate functions.

4. Explicit reformulation for robust counterparts. For any function f, let

$$\Re\mathcal{D}(f) = \bigcup_{x \in \mathrm{dom}(f)} \partial f(x);$$

that is, $\Re\mathcal{D}(f)$ is the range of the subdifferential mapping $\partial f(\cdot)$. If f is differentiable, $\Re\mathcal{D}(f)$ reduces to the range of its gradient mapping, i.e., $\Re\mathcal{D}(f) = \{\nabla f(x) : x \in \mathrm{dom}\ (f)\}$. In this section we make the following assumption.

Assumption 4.1. The functions $g_j^{(i)}(j = 1, \ldots, \ell^{(i)}, i = 1, \ldots, m)$ in (9) belong to the set of convex functions f that satisfy the condition

$$\mathrm{dom}(f^*) = \Re\mathcal{D}(f). \tag{17}$$

In fact, by the definition of subdifferential, the following relation always holds for any proper convex function: $\mathrm{dom}(f^*) \supseteq \Re\mathcal{D}(f)$. Condition (17) requires the converse also to be true. Indeed, condition (17) holds for many functions. It is evident that all convex functions defined on a subset of R^n with $\Re\mathcal{D}(f) = R^n$ satisfy condition (17). For example, when the function f is differentiable and strongly convex on R^n, the gradient $\nabla f(x)$ is a strongly monotone function from R^n to R^n. This implies that $\nabla f(x)$ is a bijective mapping [34, Theorem 6.4.4], and hence we have $\Re\mathcal{D}(f) = R^n$. A simple example is the quadratic function $f = \frac{1}{2}x^T Q x + bx + c$, where Q is a positive definite matrix; then $\Re\mathcal{D}(f) = \{Qx + b : x \in R^n\} = R^n$. When $\Re\mathcal{D}(f) \neq R^n$, (17) can still be satisfied in many cases. Later, we will show that all convex homogeneous of 1-degree functions satisfy (17) trivially, and $\Re\mathcal{D}(f)$ of any function of this class is a closed bounded region including the origin. Notice that for any (u, x) such that $u \in \partial f(x)$, we have $f^*(u) = u^T x - f(x)$. The importance of condition (17) is that under (17), for any $u \in \mathrm{dom}(f^*)$ there is $x \in \mathrm{dom}(f)$ such that $u \in \partial f(x)$ and therefore $f^*(u) = u^T x - f(x)$. Therefore, under Assumption 4.1, the robust counterpart

(12) can be represented explicitly. However, we omit the statement of this general result. We are now interested in functions that have more properties leading to further simplification of the robust counterpart.

We recall that a function $h : R^n \to \overline{R}$ is said to be positively homogeneous if there exists a constant $p > 0$ such that $h(\lambda x) = \lambda^p h(x)$ for all $\lambda \geq 0$ and $x \in \mathrm{dom}(h)$. If such a p exists, we simply say that the function h is homogeneous of p-degree. Notice that the definition implies $0 \in \mathrm{dom}(h)$ and $h(0) = 0$. We consider the linear space $\mathcal{L}_H$ generated by homogeneous functions; i.e., $\mathcal{L}_H$ is the collection of all functions that are finite linear combinations of homogeneous functions. Notice that for any real number α, $(\alpha h)(x)$ is also a homogeneous function if h is homogeneous. Therefore, $\mathcal{L}_H$ is the set of all finite sums of homogeneous functions. Clearly, a function f which is the sum of several homogeneous functions f_i is not necessarily homogeneous, unless all f_i have the same homogeneous degree. Linear space $\mathcal{L}_H$ includes many important classes of functions. Needless to say, all homogeneous functions (in particular, all norms $\|\cdot\|$) are in $\mathcal{L}_H$ and all polynomial functions are in $\mathcal{L}_H$.

The classical Euler homogeneous function theorem claims that if f is continuously differentiable and homogeneous of p-degree, then $pf(x) = x^T \nabla f(x)$, where $\nabla f(x)$ is the gradient of f. Below we establish a somewhat different version of the Euler homogeneous function theorem. This version allows the function to be nondifferentiable and nonhomogeneous but to belong to $\mathcal{L}_H$ and be convex.

LEMMA 4.1. *Let $f : R^n \to \overline{R}$ be a convex function in $\mathcal{L}_H$. Thus, f can be represented as $f(x) = f_1(x) + \cdots + f_N(x)$ for some N, where each f_i is homogeneous of p_i-degree, respectively.*

(i) *For any $x \in dom\ (f)$, we have*

$$\sum_{i=1}^{N} p_i f_i(x) = \inf_{y \in \partial f(x)} y^T x = \sup_{y \in \partial f(x)} y^T x;$$

i.e., for any $y \in \partial f(x)$, we have $\sum_{i=1}^{N} p_i f_i(x) = y^T x$.

(ii) *Suppose that $f : R^n \to \overline{R}$ is a convex function and is homogeneous of p-degree. Then for any $x \in \mathrm{dom}(f)$ and for any $y \in \partial f(x)$, we have $pf(x) = y^T x$.*

Proof. For any given $x \in \mathrm{dom}(f)$ and $y \in \partial f(x)$, by definition of subdifferential we have $f(u) \geq f(x) + y^T(u - x)$ for all $u \in \mathrm{dom}(f)$. Notice that $x \in \mathrm{dom}(f)$ if and only if $x \in \mathrm{dom}(f_i)$ for all $i = 1, \ldots, N$. Since all f_i's are homogeneous, for any $t > 0$, we have $u = tx \in \mathrm{dom}(f_i)$ for all $i = 1, \ldots, N$. This in turn implies that $u = tx \in \mathrm{dom}\ (f)$ for any $t > 0$. Setting $u = tx$ in the above inequality and by using homogeneity, we have

$$f(tx) = \sum_{i=1}^{N} f_i(tx) = \sum_{i=1}^{N} t^{p_i} f_i(x) \geq f(x) + y^T(tx - x)\ \forall\ t > 0,$$

i.e.,

$$\sum_{i=1}^{N} (t^{p_i} - 1) f_i(x) \geq (t - 1) y^T x\ \forall\ t > 0. \tag{18}$$

For $t > 1$, dividing both sides by $t-1$ and noting that y is any given element in $\partial f(x)$, we see from the above inequality that

$$\lim_{t \to 1_+} \sum_{i=1}^{N} \frac{t^{p_i} - 1}{t - 1} f_i(x) \geq \sup_{y \in \partial f(x)} y^T x.$$

Thus, we have $\sum_{i=1}^{N} p_i f_i(x) \geq \sup_{y \in \partial f(x)} y^T x$. Similarly, when $t < 1$, dividing both sides of (18) by $t-1$, we can prove that

$$\sum_{i=1}^{N} p_i f_i(x) = \lim_{t \to 1-} \sum_{i=1}^{N} \frac{t^{p_i} - 1}{t-1} f_i(x) \leq \inf_{y \in \partial f(x)} y^T x.$$

Combining the last two inequalities yields the desired result (i). Setting $N = 1$, we obtain the result (ii) from (i). ∎

Notice that when $N > 1$, Lemma 4.1 requires convexity of f but does not require convexity of individual functions f_i, which can be nonconvex. The next theorem is the main result of this section, which states that the robust counterpart can be represented explicitly by using only the nominal data and the constraint functions g_i together with their subdifferentials.

THEOREM 4.1. *Let K_i $(i = 1, \ldots, m)$ be given by (9), where each $g_j^{(i)} (j = 1, \ldots, \ell^{(i)}, i = 1, \ldots, m)$ is a closed proper convex function and belongs to the linear space $\mathcal{L}_H$, and is represented as*

$$g_j^{(i)}(x) = \sum_{k=1}^{m^{(ij)}} h_k^{(ij)}(x), \tag{19}$$

where each $h_k^{(ij)}(x)$ is homogeneous of $p_k^{(ij)}$-degree, and each $m^{(ij)} \geq 1$ is a given integer number. Let $g_j^{(i)}$ satisfy Assumption 4.1 and Slater's condition for each i. Then the robust programming problem (7) is equivalent to

$$\begin{aligned}
&\min c^T x \\
&s.t. \left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \Delta_j^{(i)} + \Upsilon^{(i)} \leq b_i, \quad i = 1, \ldots, m, \\
&\chi_i = \begin{cases} \sum_{j \in J_i} u_j^{(i)} & \text{if } J_i \neq \emptyset, \\ 0 & \text{otherwise}, \end{cases} \quad i = 1, \ldots, m, \qquad (20) \\
&\lambda_j^{(i)} \geq 0, \quad j = 1, \ldots, \ell^{(i)}, \quad i = 1, \ldots, m, \\
&F(x) \leq 0,
\end{aligned}$$

where $\chi_i = W^{(i)}(x) \otimes V^{(i)}(x)$ and $J_i = \{j : \lambda_j^{(i)} > 0, j = 1, \ldots, \ell^{(i)}\}$, and

$$\Upsilon^{(i)} = \begin{cases} \sum_{j \in J_i} \lambda_j^{(i)} \left(\sum_{k=1}^{m^{(ij)}} (p_k^{(ij)} - 1) h_k^{(ij)}(w_j^{(i)}) \right) & \text{if } J_i \neq \emptyset, \\ 0 & \text{otherwise}, \end{cases}$$

where $w_j^{(i)}$ satisfies that $u_j^{(i)} / \lambda_j^{(i)} \in \partial g_j^{(i)}(w_j^{(i)})$ for $j \in J_i \neq \emptyset$.

Proof. Let $f \in \mathcal{L}_H$ be any convex function such that $f(x) = f_1(x) + \cdots + f_N(x)$, where f_i is homogeneous of p_i-degree, and let f satisfy condition (17). Let y^* be any element in $\mathrm{dom}(f^*) = \Re\mathcal{D}(f)$. This implies that there exists some point $x^* \in \mathrm{dom}\ (f)$ such that $y^* \in \partial f(x^*)$. Then, for any $x \in \mathrm{dom}(f)$, we have $f(x) \geq f(x^*) + (y^*)^T$

$(x-x^*)$, which can be written as $(y^*)^T x - f(x) \le (y^*)^T x^* - f(x^*)$ for all $x \in \mathrm{dom}(f)$. This, together with Lemma 4.1, implies that

$$f^*(y^*) = (y^*)^T x^* - f(x^*) = \sum_{i=1}^{N} p_i f_i(x^*) - f(x^*) = \sum_{i=1}^{N} (p_i - 1) f_i(x^*). \tag{21}$$

Setting $f = g_j^{(i)}$ and $y^* = u_j^{(i)}/\lambda_j^{(i)}$, where $g_j^{(i)}$ is given by (19), it follows from (21) that

$$\left(g_j^{(i)}\right)^* (u_j^{(i)}/\lambda_j^{(i)}) = \sum_{k=1}^{m^{(ij)}} (p_k^{(ij)} - 1) h_k^{(ij)}(w_j^{(i)}),$$

where $w_j^{(i)}$ can be any point such that $u_j^{(i)}/\lambda_j^{(i)} \in \partial g_j^{(i)}(w_j^{(i)})$. Substituting the above into Theorem 3.2, we have the desired result. □

We now consider the case in which all the functions $g_j^{(i)} (j = 1, \ldots, \ell^{(i)})$ are homogeneous. This is a special case of (19) with $m^{(ij)} = 1$ (for all $j = 1, \ldots, \ell^{(i)}, i = 1, \ldots, m$). We have the following result.

COROLLARY 4.1. *Let K_i be given by* (9)*, where each $g_j^{(i)} (j = 1, \ldots, \ell^{(i)})$ is convex and homogeneous of $p_j^{(i)}$-degree, and $g_j^{(i)}$ satisfy Assumption* 4.1*. Then the robust programming problem* (7) *is equivalent to* (20)*, but $\Upsilon^{(i)}$ is given as follows:*

$$\Upsilon^{(i)} = \begin{cases} \sum_{j \in J_i} (p_j^{(i)} - 1) \lambda_j^{(i)} g_j^{(i)}(w_j^{(i)}) & \text{if } J_i \neq \emptyset, \\ 0 & \text{otherwise,} \end{cases}$$

where $w_j^{(i)}$ satisfies that $u_j^{(i)}/\lambda_j^{(i)} \in \partial g_j^{(i)}(w_j^{(i)})$ for $j \in J_i \neq \emptyset$.

It is worth mentioning that $\Upsilon^{(i)}$ can be written as

$$\Upsilon^{(i)} = \begin{cases} \sum_{j \in J_i} \left(1 - 1/p_j^{(i)}\right) (u_j^{(i)})^T w_j^{(i)} & \text{if } J_i \neq \emptyset, \\ 0 & \text{otherwise.} \end{cases}$$

This follows from (ii) of Lemma 4.1. Actually, for any function f satisfying Assumption 4.1, (21) can also be written as $f^*(y^*) = (y^*)^T x^* - f(x^*) = (1 - 1/p)(y^*)^T x^*$. Therefore,

$$\left(g_j^{(i)}\right)^* (u_j^{(i)}/\lambda_j^{(i)}) = (1 - 1/p_j^{(i)})(u_j^{(i)})^T w_j^{(i)}/\lambda_j^{(i)}$$

for some $w_j^{(i)}$ such that $u_j^{(i)}/\lambda_j^{(i)} \in \partial g_j^{(i)}(w_j^{(i)})$.

Remark 4.1. (i) Notice that in Corollary 4.1 we do not require Slater's condition, since it was shown in [32] that for homogeneous convex optimization, Lagrangian duality results hold without Slater's condition.

(ii) It should be mentioned that Slater's condition in Theorem 4.1 is not essential, and can be removed in many situations, or enforced by slightly changing the constants $\Delta_j^{(i)}$ in (9). Any function g in the linear space $\mathcal{L}_H$ is the sum of some homogeneous functions whose value is zero at the origin. Thus $0 \in K_i$ implies that $0 = g_j^{(i)}(0) \le \Delta_j^{(i)}$ for $j = 1, \ldots, \ell^{(i)}$; i.e., all constants $\Delta_j^{(i)}$ must be nonnegative in (9) when $g_j^{(i)} \in \mathcal{L}_H$. If all $\Delta_j^{(i)}$ are positive, Slater's condition holds trivially (this is the situation in most

practical applications; for example, when $g_j^{(i)}$ is a norm, $\Delta_j^{(i)}$ is positive since otherwise the uncertainty set contains at most one point). If not all $\Delta_j^{(i)}$ are positive, replacing $\Delta_j^{(i)}$ in (9) by $\widehat{\Delta}_j^{(i)}$, where $\widehat{\Delta}_j^{(i)} = \Delta_j^{(i)}$ if $\Delta_j^{(i)} > 0$, and $\widehat{\Delta}_j^{(i)} = \varepsilon$ otherwise, for some small $\varepsilon > 0$, allows us to satisfy Slater's condition.

In the next section, we show that in homogeneous cases the above results can be further improved without making Assumption 4.1.

5. Homogeneous cases. We now show that for homogeneous of 1-degree functions, Assumption 4.1 holds trivially, and for a degree $p \neq 1$, a simple transformation will make the resulting functions satisfy Assumption 4.1. We also further simplify the reformulation. We first prove some basic properties of homogeneous functions. Part (i) of the following lemma in fact follows from [30], but for completeness we provide a simple proof. It appears that the result of part (ii) of the following lemma should be valid for nondifferentiable functions as well, but for simplicity of the proof we state it for twice differentiable functions.

LEMMA 5.1. *Let $f : \mathrm{dom}(f) \subseteq R^n \to R$ be convex and homogeneous of p-degree.*

(i) *If the degree $p > 1$, then $f(x) \geq 0$ over its domain, and if $p < 1$, then $f(x) \leq 0$ over its domain.*

(ii) *Let f be twice differentiable over its domain. Then for $p > 1$, the function $(f(x))^{1/p}$ is convex and homogeneous of 1-degree; for $p < 1$, the function $-(-f(x))^{1/p}$ is convex and homogeneous of 1-degree.*

Proof. Let x be any point in dom (f). By homogeneity and convexity of f, we have

$$(1/2)^p f(x) = f(x/2) \leq f(x)/2 + f(0)/2 = f(x)/2.$$

Thus, $[(1/2)^p - 1/2]\, f(x) \leq 0$, and hence the result (i) follows.

We now prove the result of part (ii). Consider the case of $p > 1$. By (i), $p > 1$ implies that $f(x) \geq 0$ over its domain. Let $\varepsilon > 0$ be any given positive number. Denote $g_\varepsilon(x) := (f(x) + \varepsilon)^{1/p}$. Notice that $\mathrm{dom}(g_\varepsilon) = \mathrm{dom}\ (f)$, and g_ϵ is twice differentiable. We prove first that g_ε is a convex function for any given $\varepsilon > 0$. It suffices to show that $\nabla^2 g_\varepsilon(x) \succeq 0$ (positive semidefinite). Since

$$\nabla^2 g_\varepsilon(x) = \frac{1}{p}(f(x) + \varepsilon)^{\frac{1}{p}-2} \left[\left(\frac{1}{p} - 1 \right) \nabla f(x) \nabla f(x)^T + (f(x) + \varepsilon) \nabla^2 f(x) \right],$$

it is sufficient to prove that

$$\left(\frac{1}{p} - 1 \right) \nabla f(x) \nabla f(x)^T + (f(x) + \varepsilon) \nabla^2 f(x) \succeq 0.$$

By Schur complementarity property, this is equivalent to showing that

$$\begin{bmatrix} \frac{p}{p-1}(f(x) + \varepsilon) & \nabla f(x)^T \\ \nabla f(x) & \nabla^2 f(x) \end{bmatrix} \succeq 0.$$

Thus, we need to show for all $(t, u) \in R^{n+1}$ that

$$\begin{aligned} \varphi(t,u) &= (t, u^T) \begin{bmatrix} \frac{p}{p-1}(f(x) + \varepsilon) & \nabla f(x)^T \\ \nabla f(x) & \nabla^2 f(x) \end{bmatrix} \begin{pmatrix} t \\ u \end{pmatrix} \\ &= \frac{p}{p-1} t^2 (f(x) + \varepsilon) + 2t \nabla f(x)^T u + u^T \nabla^2 f(x) u \geq 0. \end{aligned}$$

Case 1. $t = 0$. By convexity of f, $u^T \nabla^2 f(x) u \geq 0$ for any $u \in R^n$; thus we have $\varphi(t, u) \geq 0$.

Case 2. $t \neq 0$. In this case, it suffices to show that for any $u \in R^n$

$$\varphi(1, u) = \frac{p}{p-1}(f(x) + \varepsilon) + 2\nabla f(x)^T u + u^T \nabla^2 f(x) u \geq 0.$$

Since $\nabla^2 f(x) \succeq 0$, the function $\varphi(1, u)$ is convex with respect to u, and its minimum is attained if there exists some u^* such that

$$\nabla f(x) = -\nabla^2 f(x) u^*, \tag{22}$$

and the minimum value is

$$\varphi(1, u^*) = \frac{p}{p-1}(f(x) + \varepsilon) + \nabla f(x)^T u^*.$$

By Euler's formula, we have $x^T \nabla f(x) = p f(x)$. Differentiating both sides of this equation, we have $(p-1)\nabla f(x) = \nabla^2 f(x) x$, which shows that the vector $u^* = -\frac{1}{p-1} x$ satisfies (22); thus the minimum value is

$$\varphi(1, u^*) = \frac{p}{p-1}(f(x) + \varepsilon) - \frac{1}{p-1}\nabla f(x)^T x = \frac{p}{p-1}\varepsilon > 0.$$

The last equation follows from Euler's formula again. Therefore $\varphi(t, u) \geq 0$ for any $(t, u) \in R^{n+1}$. Convexity of $g_\varepsilon(x)$ follows. Since $\varepsilon > 0$ is arbitrary and $(f(x))^{1/p} = \lim_{\epsilon \to 0} g_\varepsilon(x)$, we conclude that $(f(x))^{1/p}$ is convex.

The case of $p < 1$ is considered analogously. □

According to our definition of a homogeneous function, its domain includes the origin. The next lemma shows that Assumption 4.1 is satisfied for any homogeneous of 1-degree convex function, and its subdifferential at the origin defines the domain of the conjugate function.

LEMMA 5.2. *Let $h : \mathrm{dom}(h) \subseteq R^N \to \overline{R}$ be a closed proper convex function and be homogeneous of* 1*-degree. Then*

$$\Re\mathcal{D}(h) = \bigcup_{x \in \mathrm{dom}(h)} \partial h(x) = \partial h(0).$$

Moreover, $\mathrm{dom}(h^*) = \Re\mathcal{D}(h) = \partial h(0)$.

Proof. Let z be any subgradient of h at x; then for any given y and any positive number λ we have $h(\lambda y) \geq h(x) + z^T(\lambda y - x)$. Since λ is positive, dividing both sides of the inequality by λ and using homogeneity of h, we have

$$h(y) \geq \frac{h(x) - z^T x}{\lambda} + z^T y.$$

Let $\lambda \to \infty$. We have $h(y) \geq z^T y$, which holds for any y. Consider the set

$$S := \{z : \ z^T y \leq h(y) \text{ for any } \ y \in \mathrm{dom}(h)\}.$$

From the above proof, we have seen that $\partial h(x) \subseteq S$ for any x, i.e., $\Re\mathcal{D}(h) \subseteq S$. In particular, we have $\partial h(0) \subseteq S$. Conversely, since $h(0) = 0$, we see that any $z \in S$ is a subgradient of h at $x = 0$. Thus, we have $S \subseteq \partial h(0)$. We conclude that $\Re\mathcal{D}(h) = S = \partial h(0)$. The first part of the lemma has been proved.

We now prove the second part of the lemma. For any $y^* \in \Re\mathcal{D}(h)$, there exists an x^* such that $y^* \in \partial f(x^*)$, and by definition of subgradient, we have that $(y^*)^T x - h(x) \leq (y^*)^T x^* - h(x^*)$ for any $x \in \mathrm{dom}(h)$, which implies that $h^*(y^*) < \infty$, i.e., $y^* \in \mathrm{dom}(h^*)$. Thus, the inclusion $\Re\mathcal{D}(h) \subseteq \mathrm{dom}(h^*)$ holds trivially (we mentioned this observation at the beginning of section 4).

Now we show that converse inclusion is also valid. Suppose that $y^* \in \mathrm{dom}(h^*)$. We show that $y^* \in S$. Notice that for homogeneous of 1-degree function h, $\mathrm{dom}(h)$ is a cone. Thus, for any given positive number λ, we have

$$\lambda h^*(y^*) = \sup_{x \in \mathrm{dom}(h)} (y^*)^T(\lambda x) - \lambda h(x) = \sup_{x \in \mathrm{dom}(h)} (y^*)^T(\lambda x) - h(\lambda x) = h^*(y^*).$$

Since $\lambda > 0$ can be any positive number, we have $h^*(y^*) = 0$, which in turn implies that $(y^*)^T x - h(x) \leq h^*(y^*) = 0$ for any $x \in \mathrm{dom}(h)$, and therefore $y^* \in S$. The desired result follows. ∎

We can now simplify the robust counterpart for the homogeneous 1-degree case.

THEOREM 5.1. *Let K_i be defined by* (9), *where all the functions $g_j^{(i)}$, $i = 1, \ldots, \ell^{(i)}$, are closed proper convex functions and are homogeneous of* 1*-degree. Then the robust counterpart* (7) *is equivalent to*

$$\begin{aligned}
&\min c^T x \\
&s.t.\ \left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \Delta_j^{(i)} \leq b_i, \quad i = 1, \ldots, m, \\
&\chi_i = \begin{cases} \sum_{j \in J_i} u_j^{(i)} & \text{if } J_i \neq \emptyset, \\ 0 & \text{otherwise,} \end{cases} \quad i = 1, \ldots, m, \qquad (23) \\
&\lambda_j^{(i)} \geq 0, \quad j = 1, \ldots, \ell^{(i)}, \quad i = 1, \ldots, m, \\
&F(x) \leq 0,
\end{aligned}$$

where χ_i and J_i are the same as in Theorem 4.1, *and $u_j^{(i)}/\lambda_j^{(i)} \in \partial g_j^{(i)}(0)$ for $j \in J_i \neq \emptyset$, $i = 1, \ldots, m$.*

Proof. Under the conditions of the theorem, Lemma 5.2 claims that Assumption 4.1 holds, and, moreover, $\Re\mathcal{D}(g_j^{(i)}) = \partial g_j^{(i)}(0)$ for all $i = 1, \ldots, \ell^{(i)}$. From the proof of Theorem 4.1, when $J_i \neq \emptyset$, we can set $w_j^{(i)} = 0$, and hence $\Upsilon^{(i)} = (g_j^{(i)})^*(u_j^{(i)}/\lambda_j^{(i)}) = 0$. Thus, in this case, $\Upsilon^{(i)} \equiv 0$ no matter what J_i is. Therefore, the robust counterpart (7) eventually reduces to (23). As mentioned in Remark 4.1, we do not need Slater's condition for homogeneous cases. ∎

When $g_j^{(i)}$ is homogeneous of $p_j^{(i)}$-degree, where $p_j^{(i)} \neq 1$ and is twice differentiable, by (ii) of Lemma 5.1, we may transform it into a homogeneous of 1-degree function. Then we can use Theorem 5.1. When $p_j^{(i)} < 1$, by Lemma 5.1, the value of $g_j^{(i)}$ is nonpositive; thus the constraint $g_j^{(i)} \leq \Delta_j^{(i)}$ becomes redundant (since $\Delta_j^{(i)} \geq 0$) and thus can be removed from the list of constraints defining K_i. Therefore, without loss of generality, we assume that all $p_j^{(i)} \geq 1$. We now have the following result.

THEOREM 5.2. *Let K_i be defined by* (9), *where the functions $g_j^{(i)}$, $j = 1, \ldots, \ell^{(i)}$, are twice differentiable, convex, and homogeneous of $p_j^{(i)}$-degree ($p_j^{(i)} \geq 1$), respectively.*

Then the robust programming problem (7) *is equivalent to*

$$\min c^T x$$

$$s.t.\ \left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \widetilde{\Delta_j^{(i)}} \le b_i, \quad i = 1, \ldots, m,$$

$$\chi_i = \begin{cases} \sum_{j \in J_i} u_j^{(i)} & \text{if } J_i \neq \emptyset, \\ 0 & \text{otherwise}, \end{cases} \quad i = 1, \ldots, m,$$

$$\lambda_j^{(i)} \ge 0, \quad j = 1, \ldots, \ell^{(i)}, \quad i = 1, \ldots, m,$$

$$F(x) \le 0,$$

where χ_i *and* J_i *are the same as in Theorem* 4.1, $u_j^{(i)} \in \lambda_j^{(i)} \partial \mathcal{G}_j^{(i)}(0)$ *for* $j \in J_i \neq \emptyset$, $i = 1, \ldots, m$, *and*

$$\mathcal{G}_j^{(i)} = \begin{cases} (g_j^{(i)})^{1/p_j^{(i)}}, & p_j^{(i)} > 1, \\ g_j^{(i)}, & p_j^{(i)} = 1, \end{cases} \quad \widetilde{\Delta_j^{(i)}} = \begin{cases} (\Delta_j^{(i)})^{1/p_j^{(i)}}, & p_j^{(i)} > 1, \\ \Delta_j^{(i)}, & p_j^{(i)} = 1. \end{cases} \tag{24}$$

Proof. We note that for $p_j^{(i)} > 1$, since $g_j^{(i)}$ and $\Delta_j^{(i)}$ are nonnegative by Lemma 5.1, the constraint $g_j^{(i)} \le \Delta_j^{(i)}$ in (9) is equivalent to $(g_j^{(i)})^{1/p_j^{(i)}} \le (\Delta_j^{(i)})^{1/p_j^{(i)}}$. Define $\mathcal{G}_j^{(i)}$ and $\widetilde{\Delta_j^{(i)}}$ as in (24). Then this result is an immediate consequence of Theorem 5.1 and Lemma 5.1. □

From Theorems 5.1 and 5.2, the structure of robust counterparts of uncertain optimization problems mainly depends on the subdifferentials of $g_j^{(i)}$ or $\mathcal{G}_j^{(i)}$ at the origin when functions $g_j^{(i)}$ are homogeneous.

Notice that any norm is convex and homogeneous of 1-degree and can be defined on the whole space. (But the converse is not true; for example, consider $f(t) : R \to R$ given by $f(t) = t$ if $t \ge 0$ and $f(t) = 2|t|$ if $t < 0$. Clearly, f is convex and homogeneous of 1-degree, but it is not a norm, because $f(-1) \neq f(1)$.) Theorem 5.1 can be immediately applied to the case of an uncertainty set defined by a finite system of norm inequalities. For this case, however, in addition to the above formulation of the robust counterpart via subgradients at the origin, we can further simplify it using dual norms and eliminating all variables $\lambda_j^{(i)}$. For any norm $\|\cdot\|$, we denote its dual norm by $\|\cdot\|_*$, i.e., $\|u\|_* = \sup_{\|x\| \le 1} u^T x$. When $g_j^{(i)}$ is a norm, we denote it by $\|\cdot\|^{(ij)}$ and its dual norm by $\|\cdot\|_*^{(ij)}$.

COROLLARY 5.1. *Let* K_i *be defined by* (9), *where all* $g_j^{(i)} (j = 1, \ldots, \ell^{(i)}, i = 1, \ldots, m)$ *are norms, denoted, respectively, by* $\|\cdot\|^{(ij)} (j = 1, \ldots, \ell^{(i)}, i = 1, \ldots, m)$;

then the robust counterpart (7) *is equivalent to*

$$\min c^T x$$

$$s.t.\ \left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \sum_{j=1}^{\ell^{(i)}} \Delta_j^{(i)} \left\| u_j^{(i)} \right\|_*^{(ij)} \le b_i, \quad i = 1, \ldots, m,$$

$$\chi_i = \sum_{j=1}^{\ell^{(i)}} u_j^{(i)}, \quad i = 1, \ldots, m,$$

$$F(x) \le 0,$$

where $\chi_i = W^{(i)}(x) \otimes V^{(i)}(x)$.

Proof. Notice that $u \in \partial\|0\|$ if and only if $u^T x \le \|x\|$ for any x which can be written as $u^T(x/\|x\|) \le 1$, i.e., $\|u\|_* \le 1$. Therefore, for $j \in J_i \ne \emptyset$, $u_j^{(i)}/\lambda_j^{(i)} \in \partial g_j^{(i)}(0)$ is equivalent to $\|\frac{u_j^{(i)}}{\lambda_j^{(i)}}\|_*^{(ij)} \le 1$, or just $\|u_j^{(i)}\|_*^{(ij)} \le \lambda_j^{(i)}$. Therefore, the constraints of (23) can be further written as

$$\left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \Delta_j^{(i)} \le b_i, \quad i = 1, \ldots, m,$$

$$\chi_i = \begin{cases} \sum_{j \in J_i} u_j^{(i)} & \text{if } J_i \ne \emptyset, \\ 0 & \text{otherwise} \end{cases}, \quad i = 1, \ldots, m,$$

$$\lambda_j^{(i)} \ge 0, \quad j = 1, \ldots, \ell^{(i)}, \quad i = 1, \ldots, m,$$

$$\|u_j^{(i)}\|_*^{(ij)} \le \lambda_j^{(i)} \quad \forall j \in J_i \ne \emptyset, \quad i = 1, \ldots, m,$$

$$F(x) \le 0.$$

It is evident that the above system is equivalent to

$$\left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \sum_{j=1}^{\ell^{(i)}} \lambda_j^{(i)} \Delta_j^{(i)} \le b_i, \quad i = 1, \ldots, m,$$

$$\|u_j^{(i)}\|_*^{(ij)} \le \lambda_j^{(i)}, \quad j = 1, \ldots, \ell^{(i)}, \quad i = 1, \ldots, m,$$

$$\chi_i = \sum_{j=1}^{\ell^{(i)}} u_j^{(i)}, \quad i = 1, \ldots, m,$$

$$\lambda_j^{(i)} \ge 0, \quad j = 1, \ldots, \ell^{(i)}, \quad i = 1, \ldots, m,$$

$$F(x) \le 0.$$

Eliminating the variables $\lambda_j^{(i)}$, the above system becomes

$$\left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \sum_{j=1}^{\ell^{(i)}} \Delta_j^{(i)} \left\| u_j^{(i)} \right\|_*^{(ij)} \le b_i, \quad i = 1, \ldots, m,$$

$$\chi_i = \sum_{j=1}^{\ell^{(i)}} u_j^{(i)}, \quad i = 1, \ldots, m,$$

$$F(x) \le 0.$$

The desired result is obtained. □

6. Special cases. Complexity of robust counterparts depends both on the structure of the original optimization problems and on the structure of the uncertainty set. The harder the original optimization problem is and/or the more complex the uncertainty set is, the more difficult the robust counterpart is. In this section, we demonstrate how the general results developed above can be simplified by considering special optimization problems and/or special uncertainty sets. We take the LP problem as an example of a special optimization problem and take the widely used uncertainty set (10) as an example of a special uncertainty set. Thus we obtain new results for problem (1) with uncertainty set defined by (10) and for robust LP with general uncertainty sets. For this simplest of the considered cases (robust LP with uncertainty set (10)), we show that our results contain a number of related results in the literature, but they are under less restrictive assumptions, thus generalizing and strengthening these results.

6.1. Problem (1) with uncertainty set $\mathcal{U}$ defined by (10). Now we consider the uncertainty set (10), i.e.,

$$\mathcal{U} =: \left\{ D \;\middle|\; \exists z \in R^{|N|} : D = D_0 + \sum_{j \in N} \Delta D_j z_j, \quad \|z\| \le \Omega \right\}.$$

Since this model has been widely used in the literature (see, e.g., [5, 6, 7, 8, 9, 10, 11, 12, 13, 14]), it is interesting to see how our general results can be simplified when reduced to the above uncertainty set. Let H denote the matrix whose columns are $\Delta D_j, j = 1, \ldots, |N|$, i.e.,

$$H = [\Delta D_1, \ldots, \Delta D_{|N|}].$$

Define the function

$$g(u) = \inf\{\|z\| : Hz = u\}. \tag{25}$$

Then $g(u)$ is convex and homogeneous of 1-degree (convexity is proven in [36], and homogeneity can be checked directly). Now we show that the uncertainty set (10) can be represented equivalently in the form (9).

LEMMA 6.1. *Consider the uncertainty set $\mathcal{U}$ given by* (10). *Let $K = \{u|\ g(u) \le \Omega\}$, where g is given by* (25). *Then we have $K = \mathcal{U} - \{D_0\}$.*

Proof. Let u be any point in K. By the definition of $g(u)$, there exists a point z^* such that $g(u) = \|z^*\|$ and $Hz^* = u$. Since $u \in K$ implies $g(u) \le \Omega$, we have $\|z^*\| \le \Omega$. By the definition of $\mathcal{U}$, we see that $u \in \mathcal{U} - \{D_0\}$.

Conversely, suppose that $u \in \mathcal{U} - \{D_0\}$. Then there exists a point $D \in \mathcal{U}$ such that $u = D - D_0$. By the definition of $\mathcal{U}$, there exists a point z such that $u = Hz$ and $\|z\| \leq \Omega$. By the definition of g, this implies $g(u) \leq \Omega$, and hence $u \in K$. □

If the vectors $\{\Delta D_j : j = 1, \ldots, N\}$ are linearly independent, from $Hz = u$ we have $z = (H^T H)^{-1} H^T u$. Thus, we have

$$\mathcal{U} - \{D_0\} = K = \left\{ u \,\middle|\, g(u) = \|(H^T H)^{-1} H^T u\| \leq \Omega \right\}.$$

Since in general $|N|$ is less than the number of data of the problem, the term $H^T u$ can be zero even when $u \neq 0$. Thus, $g(u)$ is not a norm in this case, unless $\{\Delta D_j : j = 1, \ldots, N\}$ are linearly independent and $|N|$ equals the number of data of the problem, in which case H is an $|N| \times |N|$ invertible matrix.

Notice that K here has only one constraint which corresponds to the case $\ell^{(i)} = 1$ for all $i = 1, \ldots, m$, and by Theorem 16.3 in [36] the conjugate function of $g(u)$ is given by

$$g^*(w) = \begin{cases} 0 & \|H^T w\|_* \leq 1, \\ \infty & \text{otherwise}, \end{cases} \tag{26}$$

where $\|\cdot\|_*$ denotes the dual norm of $\|\cdot\|$.

We now consider our problem (1), where data $M^{(i)}$'s are subject to uncertainty of the type (10); i.e., for each i, the data $M^{(i)}$ belong to the set

$$\left\{ M^{(i)} \,\middle|\, \exists z \in R^{|N^{(i)}|} : M^{(i)} = \overline{M}_0^{(i)} + \sum_{j \in N^{(i)}} \Delta M_j^{(i)} z_j, \quad \|z\|^{(i)} \leq \Omega^{(i)} \right\}. \tag{27}$$

This can be written equivalently as

$$\mathcal{U}_i = \left\{ vec(M^{(i)}) \,\middle|\, \exists z \in R^{|N^{(i)}|} : vec(M^{(i)}) = vec(\overline{M}_0^{(i)}) + \sum_{j \in N^{(i)}} vec\left(\Delta M_j^{(i)}\right) z_j, \|z\|^{(i)} \leq \Omega^{(i)} \right\}, \tag{28}$$

$i = 1, \ldots, m$, where $N^{(i)}$ is the corresponding index set (not to be confused with N_i—the dimension of matrix $M^{(i)}$), and $\Omega^{(i)}$ is a given number. Note that we add the index (i) to the norm (i.e., $\|\cdot\|^{(i)}$), which allows us to use different norms for different constraints. Accordingly, we have the function

$$g^{(i)}(u) = \inf\{\|z\|^{(i)} : H^{(i)} z = u\},$$

where $H^{(i)} = [vec(\Delta M_1^{(i)}), vec(\Delta M_2^{(i)}), \ldots, vec(\Delta M_{|N^{(i)}|}^{(i)})]$, and thus by Lemma 6.1 we have

$$\mathcal{U}_i - \{vec(\overline{M}^{(i)})\} = K_i = \{u | g^{(i)}(u) \leq \Omega^{(i)}\}.$$

Using (26), we have

$$(g^{(i)})^*(w) = \begin{cases} 0, & \|(H^{(i)})^T w\|_*^{(i)} \leq 1, \\ \infty & \text{otherwise}. \end{cases} \tag{29}$$

Now we have all the necessary ingredients to develop our result. We first note that in this case, $\ell^{(i)} = 1$ for all $i = 1, \ldots, m$ since the uncertainty set $\mathcal{U}_i$ has only one

constraint $g^{(i)}(u) \le \Omega^{(i)}$. So, $\lambda^{(i)}$ is reduced to a scalar. Therefore, the constraints of the robust counterpart (12) that correspond to index i reduce to

$$\left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \lambda^{(i)}\Omega^{(i)} + \Upsilon^{(i)} \le b_i, \tag{30}$$

$$\chi_i = \begin{cases} u^{(i)}, & \lambda^{(i)} > 0, \\ 0, & \lambda^{(i)} = 0, \end{cases} \tag{31}$$

where

$$\Upsilon^{(i)} = \begin{cases} \lambda^{(i)}(g^{(i)})^*(u^{(i)}/\lambda^{(i)}), & \lambda^{(i)} > 0, \\ 0, & \lambda^{(i)} = 0. \end{cases} \tag{32}$$

When $\lambda^{(i)} > 0$, the system (30)–(32) becomes

$$\left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \lambda^{(i)}\Omega^{(i)} + \lambda^{(i)}(g^{(i)})^*(u^{(i)}/\lambda^{(i)}) \le b_i,$$

$$\chi_i = u^{(i)}.$$

Eliminating $u^{(i)}$ and using (29), the above system is equivalent to

$$\left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \lambda^{(i)}\Omega^{(i)} \le b_i,$$

$$\|(H^{(i)})^T(\chi_i)\|_*^{(i)} \le \lambda^{(i)}.$$

This can be written as

$$\left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \Omega^{(i)}\|(H^{(i)})^T\chi_i\|_*^{(i)} \le b_i. \tag{33}$$

When $\lambda^{(i)} = 0$, the system (30)–(32) is written as

$$\left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) \le b_i,$$

$$\chi_i = 0.$$

Clearly, this system can be written as (33), too. Hence, by Theorem 3.2, we have the following result.

THEOREM 6.1. *Under the uncertainty set* (27) *(or equally,* (28)*), the robust counterpart* (7) *is equivalent to*

$$\begin{aligned} &\min c^T x \\ &s.t.\ \left(W^{(i)}(x)\right)^T \overline{M}^{(i)} V^{(i)}(x) + \Omega^{(i)} \left\|(H^{(i)})^T\chi_i\right\|_*^{(i)} \le b_i, \quad i = 1, \ldots, m, \\ &\quad F(x) \le 0, \end{aligned}$$

where $\chi_i = W^{(i)}(x) \otimes V^{(i)}(x)$ *and* $H^{(i)} = [vec(\Delta M_1^{(i)}), vec(\Delta M_2^{(i)}), \ldots, \Delta vec(M_{N^{(i)}}^{(i)})]$.

6.2. LP with general uncertainty sets. Consider the LP problem discussed in section 2: $\min\{c^T x : \ Ax \le b, \ x \ge 0\}$, where $A \in R^{m\times n}, b \in R^m$, and $c \in R^n$. As discussed in section 2, without loss of generality, we assume that only the coefficients of A are subject to uncertainty.

There are two widely used ways to characterize the uncertain data of LP problems. One is the "row-wise" uncertainty model (a separate uncertainty set is specified for each row of A), and the other is what we may call the "global" uncertainty model (one uncertainty set for the whole matrix A is specified). We first consider the situation of "global" uncertainty.

Suppose that A is allowed to vary in such a way that its deviations from a given nominal $\overline{A}$ fall in a bounded convex set K of R^{mn} that contains the origin (zero). That is, the uncertainty set is defined as

$$\mathcal{U} = \{\widetilde{A} | vec(\widetilde{A}) - vec(\overline{A}) \in K\}, \tag{34}$$

where K is defined by convex inequalities:

$$K = \{u| \ g_j(u) \le \Delta_j, \ j = 1, \ldots, \ell\}. \tag{35}$$

Here Δ_j's are constants, and all g_j are closed proper convex functions. Then the robust counterpart of the LP problem with uncertainty set $\mathcal{U}$ is

$$\min\{c^T x : \widetilde{A}x \le b, \ x \ge 0 \ \forall \widetilde{A} \in \mathcal{U}\}. \tag{36}$$

First, from section 2 we know that for LP we can drop indexes i for $g_j^{(i)}$ and $\Delta_j^{(i)}$ in the previous discussion, since in the reformulation of LP as a special case of (1) and (2), the data matrix for each constraint (2) is the same; i.e., $M^{(i)} = \left[\begin{smallmatrix} A \\ 0 \end{smallmatrix}\right]_{n\times n}$ for all i (see section 2). Second, we note that for LP, the vector $\chi_i = W^{(i)} \otimes V^{(i)} = e_i \otimes x$ is linear in x. Therefore, the results in previous sections can be further simplified for LP. For example, Theorems 3.1, 3.2, and 5.2 and Corollary 5.1 can be stated as follows (Theorems 6.2 through 6.4 and Corollary 6.1, respectively).

THEOREM 6.2. *The robust LP problem* (36) *is equivalent to the convex programming problem*

$$\begin{aligned} &\min c^T x \\ &s.t. \ \bar{a}_i^T x + \delta^*(\chi_i | \mathrm{cl}(\mathrm{co}(K))) \le b_i, \quad i = 1, \ldots, m, \\ &\qquad x \ge 0, \end{aligned}$$

where $\mathrm{cl}(\mathrm{co}(K))$ *is the closed convex hull of the set* K, *and* $\chi_i = e_i \otimes x$.

Since $\delta^*(\cdot|\mathrm{cl}(\mathrm{co}K))$ is a closed convex function, the robust counterpart of any LP problem with the uncertainty set denoted by (34) and (35) is a convex programming problem.

THEOREM 6.3. *Let* K *be given by* (35), *where* $g_j (j = 1 \ldots, \ell)$, *are arbitrary closed proper convex functions. Suppose that Slater's condition holds; i.e., there exists a point* u_0 *such that* $g_j(u_0) < \Delta_j$ *for all* $j = 1, \ldots, \ell$. *Then the robust LP problem* (36)

is equivalent to

$$\min c^T x$$

$$s.t.\ \bar{a}_i^T x + \sum_{j=1}^{\ell} \lambda_j^{(i)} \Delta_j + \left(\sum_{j=1}^{\ell} \lambda_j^{(i)} g_j \right)^* (\chi_i) \le b_i, \quad i = 1, \ldots, m,$$

$$\lambda_j^{(i)} \ge 0, \quad j = 1, \ldots, \ell, \quad i = 1, \ldots, m,$$

$$x \ge 0,$$

or equivalently,

$$\min c^T x$$

$$s.t.\ \bar{a}_i^T x + \sum_{j=1}^{\ell} \lambda_j^{(i)} \Delta_j + \Upsilon^{(i)} \le b_i, \quad i = 1, \ldots, m,$$

$$\chi_i = \begin{cases} \sum_{j \in J_i} u_j^{(i)} & \text{if } J_i \ne \emptyset, \\ 0 & \text{otherwise,} \end{cases} \quad i = 1, \ldots, m, \tag{37}$$

$$\lambda_j^{(i)} \ge 0, \quad j = 1, \ldots, \ell, \quad i = 1, \ldots, m,$$

$$x \ge 0,$$

where $\chi_i = e_i \otimes x$, $J_i = \{j : \lambda_j^{(i)} > 0, j = 1, \ldots, \ell\}$, *and*

$$\Upsilon^{(i)} = \begin{cases} \sum_{j \in J_i} \lambda_j^{(i)} g_j^*(u_j^{(i)}/\lambda_j^{(i)}) & \text{if } J_i \ne \emptyset, \\ 0 & \text{otherwise.} \end{cases}$$

Remark 6.1. (i) For LP, the constraint "$\chi_i = \sum_{j \in J_i} u_j^{(i)}$" is a linear constraint.

(ii) It is well known that for any convex function f, the function $\hat{f}(x,t) = tf(x/t)$, where $t > 0$, is also convex in (x,t), and is positive homogeneous of 1-degree, that is, $\hat{f}(\alpha x, \alpha t) = \alpha \hat{f}(x,t)$, for any $\alpha > 0$. Problem (37) shows that all functions involved are homogeneous of 1-degree with respect to the variables $(x, \lambda^{(i)}, u^{(i)})$. Thus, the robust LP problem (36) is not only a convex programming problem but also a homogeneous programming problem, i.e., an optimization problem where all functions involved are homogeneous.

THEOREM 6.4. *Let K be defined by* (35), *where the functions $g_j, j = 1, \ldots, \ell$, are twice differentiable, convex, and homogeneous of p_j-degree ($p_j \ge 1$), respectively.*

Then the robust LP problem (36) *is equivalent to*

$$\begin{aligned}
&\min c^T x\\
&s.t.\ \bar{a}_i^T x + \sum_{j=1}^{\ell} \lambda_j^{(i)} \widetilde{\Delta_j} \le b_i, \quad i = 1, \dots, m,\\
&\chi_i = \begin{cases} \sum_{j \in J_i} u_j^{(i)} & \text{if } J_i \neq \emptyset, \\ 0 & \text{otherwise,} \end{cases} \qquad i = 1, \dots, m,\\
&\lambda_j^{(i)} \ge 0, \quad j = 1, \dots, \ell, \quad i = 1, \dots, m,\\
&x \ge 0,
\end{aligned}$$

where χ_i *and* J_i *are the same as in Theorem* 6.3, $u_j^{(i)} \in \lambda_j^{(i)} \partial \mathcal{G}_j(0)$ *for* $j \in J_i \neq \emptyset, i = 1, \dots, m$, *and*

$$\mathcal{G}_j = \begin{cases} (g_j)^{1/p_j}, & p_j > 1, \\ g_j, & p_j = 1, \end{cases} \qquad \widetilde{\Delta_j} = \begin{cases} (\Delta_j)^{1/p_j}, & p_j > 1, \\ \Delta_j, & p_j = 1. \end{cases}$$

COROLLARY 6.1. *Let* K *be defined by* (35), *where all* g_j $(j = 1, \dots, \ell)$ *are norms, denoted, respectively, by* $\|\cdot\|^{(j)}, j = 1, \dots, \ell$; *then the robust counterpart* (36) *is equivalent to*

$$\begin{aligned}
&\min c^T x\\
&s.t.\ \bar{a}_i^T x + \sum_{j=1}^{\ell} \Delta_j \|u_j^{(i)}\|_*^{(j)} \le b_i, \quad i = 1, \dots, m,\\
&e_i \otimes x = \sum_{j=1}^{\ell} u_j^{(i)}, \quad i = 1, \dots, m,\\
&x \ge 0.
\end{aligned}$$

Now we briefly discuss the situation of "row-wise" uncertainty sets. In this case, in order to apply our general results, we reformulate LP in the form (1) in a different way than in section 2. Consider functions $f_i(x)$ of the form (2), where $W^{(i)}(x) = e_i \in R^n$, $V^{(i)}(x) = x \in R^n$ (same as in section 2). Throughout the rest of the paper, we denote by $A_i (i = 1, \dots, m)$ the ith row of A. Thus, A_i is an n-dimensional row vector. The $n \times n$ matrix $M^{(i)}$ is the matrix having A_i as its ith row and 0 elsewhere, i.e.,

$$M^{(i)} = \begin{bmatrix} 0 \\ A_i \\ 0 \end{bmatrix}_{n \times n}, \quad i = 1, \dots, m. \tag{38}$$

Then the ith constraint of $Ax \le b$ can be written as

$$f_i = (W^{(i)})^T M^{(i)} V^{(i)} \le b_i \tag{39}$$

for $i = 1, \dots, m$. Then applying the results of sections 3, 4, and 5 to the optimization problem (1) with the above inequality constraints and $F(x) = -x \le 0$, we can obtain a formulation for robust LP with "row-wise" uncertainty sets. We omit these results.

The formulation for other special cases such as the LCP and QP can be derived similarly; we leave these derivations to interested readers.

6.3. LP with uncertainty set of type (10). In this section, we consider the LP problem $\min\{c^T x : Ax \le b, x \ge 0\}$ under uncertainty of type (10). We will show that our results in this section include a number of recent results on robust LP in the literature as special cases. From Theorems 6.1 and 6.3, we have the following result.

THEOREM 6.5. (i) *Under the "row-wise" uncertainty set*

$$\mathcal{U}_i = \left\{ A_i \,\middle|\, \exists u \in R^{N^{(i)}} : A_i = \overline{A}_i + \sum_{j \in N^{(i)}} \Delta A_j^{(i)} u_j,\ \|u\|^{(i)} \le \Omega^{(i)} \right\}, \tag{40}$$

the robust counterpart of LP is equivalent to

$$\begin{aligned} &\min c^T x \\ &s.t.\ \bar{a}_i^T x + \Omega^{(i)} \left\| \left(H^{(i)}\right)^T x \right\|_*^{(i)} \le b_i, \quad i = 1, \ldots, m, \\ &\quad x \ge 0, \end{aligned} \tag{41}$$

where the matrix $H^{(i)} = [(\Delta A_1^{(i)})^T, (\Delta A_2^{(i)})^T, \ldots, (\Delta A_{|N^{(i)}|}^{(i)})^T]$.

(ii) *Under the "global" uncertainty set*

$$\mathcal{U} = \left\{ A \,\middle|\, \exists u \in R^{|N|} : A = \overline{A} + \sum_{j \in N} \Delta A_j u_j,\ \|u\| \le \Omega \right\}, \tag{42}$$

where A is an $m \times n$ matrix, the robust counterpart of LP is equivalent to

$$\begin{aligned} &\min c^T x \\ &s.t.\ \bar{a}_i^T x + \Omega \left\| \widetilde{H}^T \widetilde{\chi}_i \right\|_* \le b_i, \quad i = 1, \ldots, m, \\ &\quad x \ge 0, \end{aligned} \tag{43}$$

where the matrix $\widetilde{H} = [vec(\Delta A_1), vec(\Delta A_2), \ldots, vec(\Delta A_{|N|})]$ *and* $\widetilde{\chi}_i = e_i^{(m)} \otimes x$, *where* $e_i^{(m)}$ *denotes the ith column of the $m \times m$ identity matrix. Equivalently, the inequality* (43) *can be written as*

$$\bar{a}_i^T x + \Omega \left\| \left(\widetilde{H}^{(i)}\right)^T x \right\|_* \le b_i, \quad i = 1, \ldots, m,$$

where the matrix $\widetilde{H}^{(i)} = [(\Delta A_1)^T e_i^{(m)}, (\Delta A_2)^T e_i^{(m)}, \ldots, (\Delta A_{|N|})^T e_i^{(m)}]$.

Proof. To prove the result (i), we show that it is an immediate corollary of Theorem 6.1. To apply Theorem 6.1, we first reformulate the LP problem in the form (1) as we did at the end of section 6.2. The ith constraint of $Ax \le b$, i.e., $A_i x \le b_i$, can be written as (39), where $M^{(i)}$ is given by (38). Clearly, we have

$$vec(M^{(i)}) = e_i \otimes A_i^T, \quad vec(\overline{M}^{(i)}) = e_i \otimes \overline{A}_i^T.$$

Notice that when A_i belongs to the uncertainty set (40), then the $vec(M^{(i)})$ belongs to the following uncertainty set:

$$\left\{ vec(M^{(i)}) \,\middle|\, \exists u \in R^{|N^{(i)}|} : vec(M^{(i)}) = e_i \otimes \overline{A}_i^T + \sum_{j \in N^{(i)}} \left(e_i \otimes (\Delta A_j^{(i)})^T\right) u_j,\ \|u\|^{(i)} \le \Omega^{(i)} \right\}.$$

By Theorem 6.1, robust LP is equivalent to

$$\begin{aligned} &\min c^T x \\ &\text{s.t. } \bar{a}_i^T x + \Omega^{(i)} \left\| \left(P^{(i)}\right)^T \chi_i \right\|_*^{(i)} \le b_i, \quad i = 1, \ldots, m, \\ &\qquad x \ge 0, \end{aligned}$$

where $\chi_i = e_i \otimes x$ and the matrix

$$P^{(i)} = \left[e_i \otimes (\Delta A_1^{(i)})^T,\ e_i \otimes (\Delta A_2^{(i)})^T, \ldots,\ e_i \otimes (\Delta A_{|N^{(i)}|}^{(i)})^T \right].$$

Notice that

$$\left(P^{(i)}\right)^T \chi_i = \left[(\Delta A_1^{(i)})^T, (\Delta A_2^{(i)})^T, \ldots, (\Delta A_{|N^{(i)}|}^{(i)})^T \right]^T x.$$

Therefore, the result (i) holds.

Using the uncertainty set (42), item (ii) can also be proved by applying Theorem 6.1. In fact, we can reformulate the LP problem in the form of (1) as in section 2, where all the data matrix $M^{(i)}$ are equal to $\left[\begin{smallmatrix} A \\ 0 \end{smallmatrix}\right]_{n \times n}$. Notice that the uncertainty set (42) can be written as

$$\left\{ vec\left(\left[\begin{smallmatrix} A \\ 0 \end{smallmatrix}\right]\right) \middle| \exists u \in R^{|N|} : vec\left(\left[\begin{smallmatrix} A \\ 0 \end{smallmatrix}\right]\right) = vec\left(\left[\begin{smallmatrix} \overline{A} \\ 0 \end{smallmatrix}\right]\right) + \sum_{j \in N} vec\left(\left[\begin{smallmatrix} \Delta A_j \\ 0 \end{smallmatrix}\right]\right) u_j,\ \|u\| \le \Omega \right\}.$$

This is the uncertainty set of the form (28). Thus, by Theorem 6.1, robust LP is equivalent to

$$\begin{aligned} &\min c^T x \\ &\text{s.t. } \bar{a}_i^T x + \Omega \|H^T \chi_i\|_* \le b_i, \quad i = 1, \ldots, m, \\ &\qquad x \ge 0, \end{aligned}$$

where $\chi_i = e_i \otimes x$ and the matrix

$$H = \left[vec\left(\left[\begin{smallmatrix} \Delta A_1 \\ 0 \end{smallmatrix}\right]\right), vec\left(\left[\begin{smallmatrix} \Delta A_2 \\ 0 \end{smallmatrix}\right]\right), \ldots, vec\left(\left[\begin{smallmatrix} \Delta A_{|N|} \\ 0 \end{smallmatrix}\right]\right) \right].$$

Denote by $\widetilde{\chi}_i = e_i^{(m)} \otimes x$, where $e_i^{(m)}$ denotes the ith column of the $m \times m$ identity matrix. It is easy to check that

$$H^T \chi_i = \widetilde{H}^T \widetilde{\chi}_i = \left(\widetilde{H}^{(i)}\right)^T x,$$

where the matrices

$$\widetilde{H} = \left[vec(\Delta A_1),\ vec(\Delta A_2),\ \ldots,\ vec(\Delta A_{|N|}) \right],$$

$$H^{(i)} = \left[(\Delta A_1)^T e_i^{(m)}, (\Delta A_2)^T e_i^{(m)}, \ldots, (\Delta A_{|N|})^T e_i^{(m)} \right].$$

Thus, the desired result (ii) follows. □

Notice that dual norms appear in (41) and (43). If the norms used are some special norms such as $\ell_1, \ell_2, \ell_\infty, \ell_1 \cap \ell_\infty, \ell_2 \cap \ell_\infty$, then their dual norms $\|\cdot\|_*$ are explicitly known (see, e.g., [14]).

In [12], Bertsimas, Pachamanova, and Sim studied the case of robust LP with uncertainty sets defined by general norms. Their result provides a unified treatment of the approaches in [23, 24, 6, 7, 11]. However, their result is a special case of Theorem 6.5. Their uncertainty set is defined by the inequality

$$\|M(vec(A) - vec(\overline{A}))\| \leq \Delta,$$

where M is an invertible matrix and Δ is a given constant. Clearly, this inequality can be written as

$$vec(A) = vec(\overline{A}) + M^{-1}u, \|u\| \leq \Delta.$$

This is a special case of the uncertainty model (42), corresponding to the case when $|N|$ is equal to the number of data and the perturbation directions ΔA_j's are linearly independent (here ΔA_j's are the column vectors of M^{-1}). So, when we apply Theorem 6.5(ii) to such a special uncertainty set, we obtain the same result as "Theorem 2" in [12]. But our result in Theorem 6.5(ii) is more general than the result in [12] because our result can even deal with the cases when the perturbation direction matrix H is singular and even not a square matrix.

It should be mentioned that "Theorem 2" in [12] can also be obtained from our Corollary 6.1. Since M is invertible, we can define the function $g(D) = \|MD\|$, which is a norm. The uncertainty set is defined by only one norm inequality, i.e., $g(D) \leq \Delta$. So, setting $\ell = 1$ in Corollary 6.1, we obtain "Theorem 2" in [12] again.

Now we compare Theorem 6.5 with the corresponding results for robust LP in Bertsimas and Sim [14]. For LP, Theorem 6.5(i) strengthens (generalizes) the corresponding result in [14] in the sense that we do not impose extra conditions on the norms, but in [14] a similar result is obtained under the additional assumption that the norms are absolute norms. Below we elaborate on this in more detail.

As we pointed out in section 2, without loss of generality, it is sufficient to consider the case when only A is subject to uncertainty. For LP, only "row-wise" uncertainty is considered in [14]; for the ith linear inequality $A_i x \leq b_i$, A_i belongs to the uncertainty set (40). Bertsimas and Sim [14] defined $f(x, A_i) = -(A_i x - b_i)$, and

$$s_j = g(x, \Delta A_j^{(i)}) =: \max\{-(\Delta A_j^{(i)})x, (\Delta A_j^{(i)})x\} = \left|(\Delta A_j^{(i)})x\right|, \quad j = 1, \ldots, N^{(i)}.$$

Bertsimas and Sim [14] proved that for LP, when the norm $\|\cdot\|^{(i)}$ used in (40) is an absolute norm, the robust LP constraint is equivalent to

$$f(x, \overline{A}_i) \geq \Omega^{(i)} \|s\|_*^{(i)} \quad \text{(or equally, } f(x, \overline{A}_i) \geq \Omega^{(i)} y,\ \|s\|_*^{(i)} \leq y).$$

That is,

$$-\overline{A}_i x - b_i \geq \Omega^{(i)} \left\| \left[(\Delta A_1^{(i)})^T, (\Delta A_2^{(i)})^T, \ldots, (\Delta A_{|N^{(i)}|}^{(i)})^T \right]^T x \right\|_*^{(i)},$$

which is

$$\overline{A}_i x + \Omega^{(i)} \left\| \left[(\Delta A_1^{(i)})^T, (\Delta A_2^{(i)})^T, \ldots, (\Delta A_{|N^{(i)}|}^{(i)})^T \right]^T x \right\|_*^{(i)} \leq b_i.$$

This is the same result as Theorem 6.5(i). So, Bertsimas and Sim [14] proved the result of Theorem 6.5(i) under the assumption that the norms used are absolute norms. We obtain this result without additional assumptions on the norms.

We can also apply our general results to nonlinear problems such as SOCP and QP. Let us comment on the differences of our approach from the approach of Bertsimas and Sim [14]. Applying our general results to robust QP would lead to *exact* formulations which, in general, would be computationally difficult. Bertsimas and Sim [14] aim at obtaining computationally tractable *approximate* formulations. These are two different ways of approaching nonlinear robust optimization problems. Computationally tractable approximate formulations are important for practical solution of large-scale problems: approximate solution is the price one has to pay for computational tractability. Exact formulations are also important. First, from a theoretical viewpoint, they allow us to gain more insight and to study the structure of the problems. Second, they can be used in practice to obtain exact solutions to small-scale problems. Third, they can provide new or strengthened results for important special cases when restricted to such cases, as demonstrated in this section.

7. Conclusion. One of our main goals was to show how the classic convex analysis tools can be used to study robust optimization. We showed that some rather general classes of robust optimization problems can be represented as explicit mathematical programming problems. We demonstrated how explicit reformulations of the robust counterpart of an uncertain optimization problem can be obtained if the uncertainty set is defined by convex functions that fall in the space $\mathcal{L}_H$ and satisfy the condition (17). Our strongest results correspond to the case where the functions defining the uncertainty set are homogeneous, because in this case the condition (17) holds trivially, and the robust counterpart can be further simplified. Our results provide a unified treatment of many situations that have been investigated in the literature. The analysis of this paper is applicable to much wider situations and more complicated uncertainty sets than those considered before; for example, it is applicable to cases where fluctuations of data may be asymmetric and not defined by norms.

A METHOD OF CENTERS WITH APPROXIMATE SUBGRADIENT LINEARIZATIONS FOR NONSMOOTH CONVEX OPTIMIZATION*

KRZYSZTOF C. KIWIEL†

Abstract. We give a proximal bundle method for constrained convex optimization. It requires only evaluating the problem functions and their subgradients with an unknown accuracy ϵ. Employing a combination of the classic method of centers' improvement function with an exact penalty function, it does not need a feasible starting point. It asymptotically finds points with at least ϵ-optimal objective values that are ϵ-feasible. When applied to the solution of linear programming problems via column generation, it allows for ϵ-accurate solutions of column generation subproblems.

Key words. nondifferentiable optimization, convex programming, proximal bundle methods, approximate subgradients, column generation

1. Introduction.

We are concerned with the solution of the following convex programming problem:

$$f_* := \inf\{\, f(u) : h(u) \le 0,\ u \in C \,\}, \tag{1.1}$$

where C is a "simple" closed convex set (typically a polyhedron) in the Euclidean space $\mathbb{R}^m$ with inner product $\langle\cdot,\cdot\rangle$ and norm $|\cdot|$, f and h are convex real-valued functions, and there exists a *Slater point*

$$\mathring{u} \in C \quad \text{such that} \quad h(\mathring{u}) < 0. \tag{1.2}$$

Further, we assume that for fixed (and possibly unknown) *accuracy tolerances* $\epsilon_f, \epsilon_h \ge 0$, for each $u \in C$ we can find *approximate values* f_u, h_u and *approximate subgradients* g_f^u, g_h^u that produce the *approximate linearizations* of f and h:

$$\bar{f}_u(\cdot) := f_u + \langle g_f^u, \cdot - u\rangle \le f(\cdot) \quad \text{with} \quad \bar{f}_u(u) = f_u \ge f(u) - \epsilon_f, \tag{1.3a}$$

$$\bar{h}_u(\cdot) := h_u + \langle g_h^u, \cdot - u\rangle \le h(\cdot) \quad \text{with} \quad \bar{h}_u(u) = h_u \ge h(u) - \epsilon_h. \tag{1.3b}$$

Thus $f_u \in [f(u) - \epsilon_f, f(u)]$ estimates $f(u)$, and $g_f^u \in \partial_{\epsilon_f} f(u)$; i.e., g_f^u is a member of

$$\partial_{\epsilon_f} f(u) := \{g : f(\cdot) \ge f(u) - \epsilon_f + \langle g, \cdot - u\rangle\},$$

the ϵ_f-subdifferential of f at u. Similar relations hold for f replaced by h.

This paper modifies the phase 1-phase 2 method of centers of [Kiw85, section 5.7] and extends it to approximate linearizations. We first discuss the *exact* case of $\epsilon_f = \epsilon_h = 0$. For an infeasible starting point, in phase 1 this method reduces the constraint violation while keeping the objective increase as small as possible; this is reasonable especially if the starting point is close to a solution. Once a feasible point is found, in phase 2 the method reduces the objective while maintaining feasibility. Both phases employ the same improvement function, and each iterate solves

a subproblem with f and h approximated via accumulated linearizations, stabilized by a quadratic term centered at the best point found so far. For phase 1, the analysis of [Kiw85, section 5.7] established optimality of all cluster points of the iterates without discussing their existence. A nontrivial sufficient condition for their existence was recently given in [SaS05, Prop. 4.3(ii)] for a modified variant. We show that this condition may be expected to hold only if problem (1.1) has a Lagrange multiplier $\bar{\mu} \leq 1$ (cf. Remark 3.13(ii)). We extend this condition to $\bar{\mu} > 1$ by replacing the current objective value in the improvement function with the value of an exact penalty function for penalty parameters $\hat{c} \geq \bar{\mu} - 1$. In effect, our results (cf. Theorems 3.8, 3.9, and 3.12) extend the main convergence results of [Kiw85, Thm. 5.7.4] and [SaS05, Thms. 4.4–4.5]. It is crucial for large-scale implementations that our results hold for various aggregation schemes that control the size of each quadratic programming (QP) subproblem, including the schemes of [Kiw85, section 5.7] and [SaS05] (see Remark 4.1).

Our combination of improvement and penalty functions with suitable penalty parameter updates seems to be necessary for our extension to inexact evaluations (otherwise, the method could jam at phase 1 when the standard improvement function cannot be reduced by more than $\max\{\epsilon_f, \epsilon_h\}$ for the tolerances ϵ_f, ϵ_h of (1.3); see Remark 3.5). Our method generates iterates in the set C, having f-values of at most $f_* + \epsilon_f$ and h-values of at most ϵ_h asymptotically (cf. Theorems 3.8–3.10), without *any* additional boundedness assumptions (such as boundedness of the feasible set, or the sufficient conditions discussed above). In a sense, this is the strongest convergence result one could hope for. Our algorithmic constructions and analysis combine the inexact linearization framework of [Kiw06a] (in a simplified version that highlights its crucial ingredients; cf. [Kiw06b]) with fairly intricate properties of improvement and penalty functions which have not been used so far in bundle methods.

As for other bundle methods, we note that the exact penalty function methods of [Kiw87, Kiw91] require additionally that the set C be bounded and may converge slowly when their penalty parameter estimates are too high. The level methods of [LNN95] (also see [Kiw95, Fáb00, BTN05]) need boundedness of the set C as well. Similar boundedness assumptions are employed in the filter methods of [FlL99, KRSS07]. Except for [Fáb00], all these methods work with exact linearizations. The conic bundle variant of [KiL07] employs inexact linearizations and does not need artificial merit functions, but it requires the knowledge of a Slater point and f being "simple" (e.g., linear or quadratic). We show elsewhere how to handle inexact linearizations in an exact penalty method [Kiw07b] and a filter method [Kiw07a], the latter being based on the present paper.

Our work was partly motivated by possible applications in column generation approaches to integer programming problems [LüD05], which lead to linear programming (LP) problems with huge numbers of columns. When the dual LP problems can be formulated as (1.1) (cf. [BLM$^+$07, LüD05, Sav97]), our approach allows for ϵ_h-accurate solutions of column generation subproblems as well as for recovering approximate solutions to the primal problems. (See [Kiw05, KiL07] for related developments and numerical results.)

The paper is organized as follows. In section 2, after reviewing basic properties of penalty and improvement functions, we present our bundle method. Its convergence is analyzed in section 3. Several modifications are given in section 4. Applications to column generation for LP problems are studied in section 5.

2. The proximal bundle method of centers.

2.1. Lagrange multipliers and exact penalties. We first recall some basic duality results for problem (1.1) (cf. [Ber99, sections 5.1 and 5.3]).

Consider the *Lagrangian* $L(\cdot;\mu) := f(\cdot) + \mu h(\cdot)$ with $\mu \in \mathbb{R}$, the *dual function* $q(\mu) := \inf_C L(\cdot;\mu)$, and the *dual problem* $q_* := \sup_{\mathbb{R}_+} q$ of (1.1). Under our assumptions, $f_* = q_*$. If $f_* > -\infty$, the *dual optimal set* $M := \operatorname{Arg\,max}_{\mathbb{R}_+} q$ is nonempty and compact and consists of *Lagrange multipliers* $\mu \geq 0$ such that $q(\mu) = f_*$; if $f_* = -\infty$, $M := \emptyset$. Thus, the quantity $\bar{\mu} := \inf_{\mu \in M} \mu$ is the *minimal* Lagrange multiplier if $f_* > -\infty$, $\bar{\mu} = \infty$ otherwise.

For a *penalty parameter* $c \geq 0$, the *exact penalty function*

$$\pi(\cdot;c) := f(\cdot) + ch(\cdot)_+ \quad \text{with} \quad h(\cdot)_+ := \max\{h(\cdot), 0\} \tag{2.1}$$

satisfies $\inf_C \pi(\cdot;c) = f_* > -\infty$ iff $c \geq \bar{\mu}$ (cf. [Ber99, section 5.4.5]).

2.2. Improvement functions. We associate with problem (1.1) the *improvement functions* defined for $\tau \in \mathbb{R}$ by

$$e(\cdot;\tau) := \max\{f(\cdot) - \tau, h(\cdot)\}, \quad e_C(\cdot;\tau) := e(\cdot;\tau) + i_C(\cdot), \quad E(\tau) := \inf e_C(\cdot;\tau), \tag{2.2}$$

where i_C is the *indicator* function of C ($i_C(u) = 0$ if $u \in C$, ∞ if $u \notin C$). In our context, τ will be an asymptotic estimate of f_* generated by our method, and to prove that $\tau \leq f_*$, we shall need the main property of the function E given in part (vi) of the lemma below.

LEMMA 2.1. (i) *The function E defined by* (2.2) *is nonincreasing and convex.*

(ii) *If E is improper, then $E(\cdot) = f_* = -\infty$ for f_* given by* (1.1).

(iii) *If E is proper, then E is Lipschitzian with modulus* 1.

(iv) *If E is proper and $f_* = -\infty$, then $E(\cdot) = \inf_C h \in (-\infty, 0)$.*

(v) *If $f_* > -\infty$, then $E(\tau) > 0$ for $\tau < f_*$, $E(f_*) = 0$, and $E(\tau) < 0$ for $f_* < \tau$.*

(vi) *If $E(\tau) \geq 0$ for some $\tau \in \mathbb{R}$, then $\tau \leq f_*$.*

Proof. (i) Monotonicity is obvious, and convexity follows from [Roc70, Thm. 5.7].

(ii) Since $\operatorname{dom} E = \mathbb{R}$, we have $E(\cdot) = -\infty$ by [Roc70, Thm. 7.2], and then $f_* = -\infty$ by (1.1).

(iii) E is finite on $\operatorname{dom} E = \mathbb{R}$, and $e(\cdot;\tau') \leq e(\cdot;\tau) + |\tau - \tau'|$ for any τ and τ'.

(iv) Since $f_* = -\infty$ implies $E(\cdot) \leq 0$, $E(\cdot)$ is constant and finite by [Roc70, Cor. 8.6.2], i.e., $E(\cdot) = \alpha \in \mathbb{R}$. Then, on the one hand, $\alpha \geq \inf_C h$ by (2.2). On the other hand, for $u \in C$ and $\tau \geq f(u) - h(u)$, the fact that $e(u;\tau) \leq h(u)$ yields $\alpha \leq \inf_C h < 0$ by (1.2).

(v) We have $E(f_*) \leq 0$ by (1.1), and $E(f_*) \geq 0$ (otherwise $f(u) < f_*$ and $h(u) < 0$ for some $u \in C$ would contradict (1.1)); thus $E(f_*) = 0$. By (1.2), for $\mathring{\tau} := f(\mathring{u}) - h(\mathring{u}) > f(\mathring{u}) \geq f_*$, $e(\mathring{u};\mathring{\tau}) = h(\mathring{u}) < 0$ implies $E(\mathring{\tau}) < 0$; so by convexity (consider the secant line $\bar{E}(\tau) := E(\mathring{\tau})(\tau - f_*)/(\mathring{\tau} - f_*)$), we have $E(\tau) > 0$ for $\tau < f_*$, $E(\tau) < 0$ for $\tau \in (f_*, \mathring{\tau}]$, and $E(\tau) < 0$ for $\tau > \mathring{\tau}$ by monotonicity.

(vi) E is proper by (ii), $f_* > -\infty$ by (iv), and (v) yields the conclusion. ∎

Let $U := \{u \in C : h(u) \leq 0\}$ and $U_* := \operatorname{Arg\,min}_U f$ denote the *feasible* and *optimal* sets of problem (1.1). We shall need the following extension of [Kiw85, Lem. 1.2.16].

LEMMA 2.2. *Let $\bar{u} \in C$, $\bar{c} \geq 0$, $\bar{\tau} := \pi(\bar{u};\bar{c})$ (cf.* (2.1)). *Then the following are equivalent*:

(a) $\bar{u} \in U_*$ (*i.e., $\bar{u}$ solves problem* (1.1));

(b) $E(\bar\tau) = e_C(\bar u;\bar\tau)$ (*i.e., $\bar u$ minimizes $e(\cdot;\bar\tau)$ over C*);
(c) $0 \in \partial e_C(\bar u;\bar\tau)$ (*i.e., $0 \in \partial\psi(\bar u)$, where $\psi(\cdot) := e_C(\cdot;\bar\tau)$*).

Proof. First, (a) implies $\bar\tau = f(\bar u) = f_*$, $e(\bar u;\bar\tau) = 0$, $E(\bar\tau) = 0$ by Lemma 2.1(v), and hence (b). Since (b) means $\bar u \in \operatorname{Arg\,min} e_C(\cdot;\bar\tau)$, (b) and (c) are equivalent. Next, note that

$$\partial e_C(\bar u;\bar\tau) = \partial i_C(\bar u) + \begin{cases} \partial f(\bar u) & \text{if} \quad f(\bar u) - \bar\tau > h(\bar u), \\ \operatorname{co}\{\partial f(\bar u) \cup \partial h(\bar u)\} & \text{if} \quad f(\bar u) - \bar\tau = h(\bar u), \\ \partial h(\bar u) & \text{if} \quad f(\bar u) - \bar\tau < h(\bar u). \end{cases} \tag{2.3}$$

Finally, (c) implies $h(\bar u) \le 0$ (otherwise $h(\bar u) > 0 \ge f(\bar u) - \bar\tau$ and $0 \in \partial e_C(\bar u;\bar\tau) = \partial h(\bar u) + \partial i_C(\bar u)$ would give $\min_C h = h(\bar u) > 0$, contradicting (1.2)); so the facts that $\bar\tau = f(\bar u)$ and $E(\bar\tau) = e(\bar u;\bar\tau) = 0$ yield $\bar\tau = f_*$ by Lemma 2.1(v), and hence (a). ∎

Lemma 2.2 suggests the following algorithmic scheme: Given the current iterate $\hat u \in C$ and the target $\hat\tau := \pi(\hat u;\hat c)$ for a penalty parameter $\hat c \ge 0$, find an approximate minimizer u of $e_C(\cdot;\hat\tau)$, replace $\hat u$ by u, and repeat. Note that if $e_C(u;\hat\tau) < e_C(\hat u;\hat\tau)$, then u is better than $\hat u$: either $f(u) < f(\hat u)$ and $u \in U$ if $\hat u \in U$, or $h(u) < h(\hat u)$ if $\hat u \notin U$. To progress towards the optimal set U_*, it helps if $e_C(\bar u;\hat\tau) \le e_C(\hat u;\hat\tau)$ for any optimal $\bar u \in U_*$; the sufficient condition given below employs the minimal multiplier $\bar\mu$ of section 2.1.

LEMMA 2.3. *Let $\bar u \in U_*$, $\hat u \in C$, $\hat c \ge 0$, $\hat\tau := \pi(\hat u;\hat c)$. Then $e(\hat u;\hat\tau) = h(\hat u)_+$, and $e(\bar u;\hat\tau) \le e(\hat u;\hat\tau)$ iff $f(\bar u) \le \pi(\hat u;\hat c+1)$. In particular, $f(\bar u) \le \pi(\hat u;\hat c+1)$ if $\hat c \ge \bar\mu - 1$.*

Proof. First, $\hat\tau = f(\hat u)$ and $e(\hat u;\hat\tau) = 0$ if $h(\hat u) \le 0$, $e(\hat u;\hat\tau) = h(\hat u)$ if $h(\hat u) > 0$. Next,

$$e(\bar u;\hat\tau) - e(\hat u;\hat\tau) = \max\{f(\bar u) - \pi(\hat u;\hat c+1), h(\bar u) - h(\hat u)_+\}$$

is nonpositive iff $f_* = f(\bar u) \le \pi(\hat u;\hat c+1)$; the latter holds if $\hat c + 1 \ge \bar\mu$ (see section 2.1). ∎

2.3. An overview of the method. Our method generates a sequence of *trial points* $\{u^k\}_{k=1}^\infty \subset C$ for evaluating the approximate values $f_u^k := f_{u^k}$, $h_u^k := h_{u^k}$, subgradients $g_f^k := g_f^{u^k}$, $g_h^k := g_h^{u^k}$, and linearizations $f_k := \bar f_{u^k}$, $h_k := \bar h_{u^k}$ of f and h at u^k, respectively, such that

$$f_k(\cdot) = f_u^k + \langle g_f^k, \cdot - u^k\rangle \le f(\cdot) \quad \text{with} \quad f_k(u^k) = f_u^k \ge f(u^k) - \epsilon_f, \tag{2.4a}$$

$$h_k(\cdot) = h_u^k + \langle g_h^k, \cdot - u^k\rangle \le h(\cdot) \quad \text{with} \quad h_k(u^k) = h_u^k \ge h(u^k) - \epsilon_h, \tag{2.4b}$$

as stipulated in (1.3). At iteration k, the polyhedral *cutting-plane models* of f and h

$$\check f_k(\cdot) := \max_{j\in J_f^k} f_j(\cdot) \le f(\cdot) \quad \text{with} \quad k \in J_f^k \subset \{1,\dots,k\}, \tag{2.5a}$$

$$\check h_k(\cdot) := \max_{j\in J_h^k} h_j(\cdot) \le h(\cdot) \quad \text{with} \quad k \in J_h^k \subset \{1,\dots,k\}, \tag{2.5b}$$

which stem from the accumulated linearizations, yield the relaxed version of problem (1.1)

$$\check f_*^k := \inf\big\{\check f_k(u) : u \in \check H_k \cap C\big\} \quad \text{with} \quad \check H_k := \big\{u : \check h_k(u) \le 0\big\}, \tag{2.6}$$

in which $\check{H}_k$ is an outer approximation of $H := \{u : h(u) \le 0\}$. The current *prox* (or *stability*) *center* $\hat{u}^k := u^{k(l)} \in C$ for some $k(l) \le k$ has the values $f^k_{\hat{u}} = f^{k(l)}_u$ and $h^k_{\hat{u}} = h^{k(l)}_u$:

$$f^k_{\hat{u}} \in [f(\hat{u}^k) - \epsilon_f, f(\hat{u}^k)] \quad \text{and} \quad h^k_{\hat{u}} \in [h(\hat{u}^k) - \epsilon_h, h(\hat{u}^k)]. \tag{2.7}$$

As in (2.2) and Lemma 2.2, our improvement function for subproblem (2.6) is given by

$$\check{e}_k(\cdot) := \max\{\check{f}_k(\cdot) - \tau_k, \check{h}_k(\cdot)\} \quad \text{with} \quad \tau_k := f^k_{\hat{u}} + c_k[h^k_{\hat{u}}]_+ \tag{2.8}$$

for some penalty coefficient $c_k \ge 0$ and $[\cdot]_+ := \max\{\cdot, 0\}$. We solve a proximal version of the relaxed improvement problem $\check{E}_k := \inf \check{e}^k_C$ with $\check{e}^k_C := \check{e}_k + i_C$ by finding the trial point

$$u^{k+1} := \arg\min \left\{ \phi_k(\cdot) := \check{e}_k(\cdot) + i_C(\cdot) + \tfrac{1}{2t_k}|\cdot - \hat{u}^k|^2 \right\}, \tag{2.9}$$

where $t_k > 0$ is a *stepsize* that controls the size of $|u^{k+1} - \hat{u}^k|$. For deciding whether u^{k+1} is better than $\hat{u}^k$, we use approximate values of the improvement function $e(\cdot; \tau_k)$. Thus, $e(\hat{u}^k; \tau_k)$ is approximated by $[h^k_{\hat{u}}]_+$, and $e(\hat{u}^k; \tau_k) - \check{e}_k(u^{k+1})$ by the *predicted decrease*

$$v_k := [h^k_{\hat{u}}]_+ - \check{e}_k(u^{k+1}). \tag{2.10}$$

When $f^k_{\hat{u}} < \check{f}_k(\hat{u}^k)$ or $h^k_{\hat{u}} < \check{h}_k(\hat{u}^k)$ due to inexact evaluations, v_k may be nonpositive; if necessary, we increase t_k, as well as c_k in (2.8) if $h^k_{\hat{u}} > 0$, and recompute u^{k+1} to decrease $\check{e}_k(u^{k+1})$ until $v_k \ge |u^{k+1} - \hat{u}^k|^2/2t_k$ (as motivated below). Of course, $e(u^{k+1}; \tau_k)$ is approximated by $\max\{f^{k+1}_u - \tau_k, h^{k+1}_u\}$. A *descent* step to $\hat{u}^{k+1} := u^{k+1}$ occurs if $\max\{f^{k+1}_u - \tau_k, h^{k+1}_u\} \le [h^k_{\hat{u}}]_+ - \kappa v_k$ for a fixed $\kappa \in (0, 1)$. Otherwise, a *null* step $\hat{u}^{k+1} := \hat{u}^k$ improves the next models $\check{f}_{k+1}$, $\check{h}_{k+1}$ with the new linearizations f_{k+1} and h_{k+1} (cf. (2.5)).

2.4. Aggregate linearizations and an optimality estimate. Extending the approach of [Kiw06a], we now use optimality conditions for subproblem (2.9) to derive aggregate linearizations (i.e., affine minorants) of the problem functions at u^{k+1} as well as an optimality estimate (see (2.22) below) related to Lemma 2.1(vi).

LEMMA 2.4. (i) *There exist subgradients* p^k_f, p^k_h, p^k_C *and a multiplier* ν_k *such that*

$$p^k_f \in \partial \check{f}_k(u^{k+1}),\ p^k_h \in \partial \check{h}_k(u^{k+1}),\ p^k_C \in \partial i_C(u^{k+1}), \tag{2.11}$$

$$\nu_k p^k_f + (1 - \nu_k)p^k_h + p^k_C = -\big(u^{k+1} - \hat{u}^k\big)/t_k, \tag{2.12}$$

$$\nu_k \in [0, 1],\ \nu_k[\check{e}_k(u^{k+1}) - \check{f}_k(u^{k+1}) + \tau_k] = 0,\ (1 - \nu_k)[\check{e}_k(u^{k+1}) - \check{h}_k(u^{k+1})] = 0. \tag{2.13}$$

(ii) *These subgradients determine the following* aggregate linearizations*:*

$$\bar{f}_k(\cdot) := \check{f}_k(u^{k+1}) + \langle p^k_f, \cdot - u^{k+1}\rangle \le \check{f}_k(\cdot) \le f(\cdot), \tag{2.14}$$

$$\bar{h}_k(\cdot) := \check{h}_k(u^{k+1}) + \langle p^k_h, \cdot - u^{k+1}\rangle \le \check{h}_k(\cdot) \le h(\cdot), \tag{2.15}$$

$$\bar{i}^k_C(\cdot) := i_C(u^{k+1}) + \langle p^k_C, \cdot - u^{k+1}\rangle \le i_C(\cdot), \tag{2.16}$$

$$\bar{e}^k_C(\cdot) := \nu_k[\bar{f}_k(\cdot) - \tau_k] + (1 - \nu_k)\bar{h}_k(\cdot) + \bar{i}^k_C(\cdot) \le \check{e}^k_C(\cdot) \le e_C(\cdot; \tau_k). \tag{2.17}$$

(iii) *For the* aggregate subgradient *and the* aggregate linearization error *given by*

$$p^k := \nu_k p_f^k + (1-\nu_k)p_h^k + p_C^k = \big(\hat{u}^k - u^{k+1}\big)/t_k \quad \textit{and} \quad \epsilon_k := [h_{\hat{u}}^k]_+ - \bar{e}_C^k(\hat{u}^k) \tag{2.18}$$

and the optimality measure

$$V_k := \max\big\{|p^k|, \epsilon_k + \langle p^k, \hat{u}^k\rangle\big\}, \tag{2.19}$$

we have

$$\bar{e}_C^k(\cdot) = \check{e}_k(u^{k+1}) + \langle p^k, \cdot - u^{k+1}\rangle, \tag{2.20}$$

$$[h_{\hat{u}}^k]_+ - \epsilon_k + \langle p^k, \cdot - \hat{u}^k\rangle = \bar{e}_C^k(\cdot) \le \check{e}_C^k(\cdot) \le e_C(\cdot;\tau_k), \tag{2.21}$$

$$e_C(u;\tau_k) \ge \check{e}_C^k(u) \ge \big[h_{\hat{u}}^k\big]_+ - V_k\big(1+|u|\big) \quad \textit{for all } u. \tag{2.22}$$

Proof. (i) Use the optimality condition $0 \in \partial\phi_k(u^{k+1})$ for (2.9) and the form (2.8) of $\check{e}_k$.

(ii) The first inequalities in (2.14)–(2.15) stem from (2.11) and the final ones from (2.5). Similarly, (2.11) gives (2.16) with $i_C(u^{k+1}) = 0$. Then (2.17) follows from the facts that $\nu \in [0,1]$ (cf. (2.13)) yields $\nu_k(\bar{f}_k - \tau_k) + (1-\nu_k)\bar{h}_k \le \check{e}_k$ by using $\bar{f}_k \le \check{f}_k$ and $\bar{h}_k \le \check{h}_k$ in (2.8) and that $\check{e}_C^k := \check{e}_k + i_C \le e_C(\cdot;\tau_k)$ by using $\check{f}_k \le f$ and $\check{h}_k \le h$ in (2.2).

(iii) For (2.20), use (2.12)–(2.13) and the definitions in (2.14)–(2.18); since $\bar{e}_C^k$ is affine, its expression in (2.21) follows from (2.18). Finally, since by the Cauchy–Schwarz inequality,

$$-\langle p^k, u\rangle + \epsilon_k + \langle p^k, \hat{u}^k\rangle \le |p^k||u| + \epsilon_k + \langle p^k, \hat{u}^k\rangle \le \max\{|p^k|, \epsilon_k + \langle p^k, \hat{u}^k\rangle\}(1+|u|)$$

in (2.21), we obtain (2.22) from the definition of V_k in (2.19). ∎

Observe that V_k is an optimality measure at phase 2: if $V_k = 0$ in (2.22), then $E(\tau_k) \ge 0$ gives $f_{\hat{u}}^k \le \tau_k \le f_*$ by Lemma 2.1(vi); similar relations hold asymptotically.

2.5. Ensuring sufficient predicted decrease. In view of the optimality estimate (2.22), we would like V_k to vanish asymptotically. Hence it is crucial to bound V_k via the predicted decrease v_k, since normally bundling and descent steps drive v_k to 0. The necessary bounds are given below.

LEMMA 2.5. (i) *In the notation of* (2.18)*, the predicted decrease* v_k *of* (2.10) *satisfies*

$$v_k = t_k|p^k|^2 + \epsilon_k. \tag{2.23}$$

(ii) *We have* $v_k \ge -\epsilon_k \Leftrightarrow t_k|p^k|^2/2 \ge -\epsilon_k \Leftrightarrow v_k \ge t_k|p^k|^2/2 = |u^{k+1} - \hat{u}^k|/2t_k$.

(iii) *For the* maximal evaluation error $\epsilon_{\max} := \max\{\epsilon_f, \epsilon_h\}$*, we have*

$$-\epsilon_k \le \epsilon_{\max}. \tag{2.24}$$

(iv) *The optimality measure of* (2.19) *satisfies* $V_k \le \max\{|p^k|, \epsilon_k\}(1+|\hat{u}^k|)$*. Moreover,*

$$v_k \ge \max\big\{t_k|p^k|^2/2, |\epsilon_k|\big\} \qquad \textit{if} \quad v_k \ge -\epsilon_k, \tag{2.25}$$

$$V_k \le \max\big\{(2v_k/t_k)^{1/2}, v_k\big\}\big(1+|\hat{u}^k|\big) \quad \textit{if} \quad v_k \ge -\epsilon_k, \tag{2.26}$$

$$V_k < (2\epsilon_{\max}/t_k)^{1/2}\big(1+|\hat{u}^k|\big) \qquad \textit{if} \quad v_k < -\epsilon_k. \tag{2.27}$$

Proof. (i) We have $\langle p^k, u^{k+1} - \hat{u}^k \rangle = -t_k |p^k|^2$ by (2.18), whereas by (2.20),

$$\check{e}_k(u^{k+1}) = \bar{e}_C^k(u^{k+1}) = \bar{e}_C^k(\hat{u}^k) + \langle p^k, u^{k+1} - \hat{u}^k \rangle;$$

so $v_k := [h_{\hat{u}}^k]_+ - \check{e}_k(u^{k+1}) = \epsilon_k + t_k |p^k|^2$ by (2.18). Note that $v_k \geq \epsilon_k$.

(ii) This follows from (2.23) and the first part of (2.18).

(iii) By the definitions of $\bar{e}_C^k$ and ϵ_k in (2.17)–(2.18), we may express $-\epsilon_k$ as follows:

$$-\epsilon_k = \nu_k [\bar{f}_k(\hat{u}^k) - \tau_k] + (1 - \nu_k) \bar{h}_k(\hat{u}^k) + \bar{\imath}_C^k(\hat{u}^k) - [h_{\hat{u}}^k]_+,$$

where $\nu_k \in [0,1]$ by (2.13), $\bar{f}_k(\hat{u}^k) \leq f(\hat{u}^k) \leq f_{\hat{u}}^k + \epsilon_f$, $\bar{h}_k(\hat{u}^k) \leq h(\hat{u}^k) \leq h_{\hat{u}}^k + \epsilon_h$, and $\bar{\imath}_C^k(\hat{u}^k) \leq i_C(\hat{u}^k) = 0$ by (2.14)–(2.16) and (2.7), and $\tau_k \geq f_{\hat{u}}^k$ by (2.8). Therefore, we have

$$-\epsilon_k \leq \nu_k \epsilon_f + (1 - \nu_k) h(\hat{u}^k) - (1 - \nu_k) \big[h_{\hat{u}}^k\big]_+ \leq \nu_k \epsilon_f + (1 - \nu_k) \epsilon_h \leq \epsilon_{\max}.$$

(iv) Since $V_k \leq \max\{|p^k|, \epsilon_k\}(1 + |\hat{u}^k|)$ by (2.19) and the Cauchy–Schwarz inequality, the bounds follow from the equivalences in statement (ii), using $v_k \geq \epsilon_k$ and (2.24). ∎

The bound (2.27) will imply that if $\tau_k > f_*$ (so that $E(\tau_k) < 0$ by Lemma 2.1(vi), and hence V_k cannot vanish in (2.22) as t_k increases), then both $v_k \geq -\epsilon_k$ and the bound (2.26) must hold for t_k large enough.

2.6. Linearization selection. For choosing the sets J_f^{k+1} and J_h^{k+1}, note that (2.4)–(2.5) and (2.11) yield the existence of multipliers α_j^k for the pieces f_j, $j \in J_f^k$, and β_j^k for the pieces h_j, $j \in J_h^k$, such that

$$(2.28a) \qquad (p_f^k, 1) = \sum_{j \in J_f^k} \alpha_j^k (\nabla f_j, 1)\ \alpha_j^k \geq 0,\ \alpha_j^k \big[\check{f}_k(u^{k+1}) - f_j(u^{k+1})\big] = 0,\ j \in J_f^k,$$

$$(2.28b) \qquad (p_h^k, 1) = \sum_{j \in J_h^k} \beta_j^k (\nabla h_j, 1)\ \beta_j^k \geq 0,\ \beta_j^k \big[\check{h}_k(u^{k+1}) - h_j(u^{k+1})\big] = 0,\ j \in J_h^k.$$

Denote the indices of linearizations f_j and h_j that are "strongly" active at u^{k+1} by

$$(2.29) \qquad \hat{J}_f^k := \big\{j \in J_f^k : \alpha_j^k \neq 0\big\} \quad \text{and} \quad \hat{J}_h^k := \big\{j \in J_h^k : \beta_j^k \neq 0\big\}.$$

These linearizations embody all the information contained in the aggregates $\bar{f}_k$ and $\bar{h}_k$ (which are actually their convex combinations; cf. (2.14)–(2.15) and (2.28)). To save storage and work per iteration, we may drop the remaining linearizations. (Alternative strategies based on aggregation instead of selection are discussed in section 4.2.)

2.7. The method. We now have the necessary ingredients to state our method in detail.

ALGORITHM 2.6.

Step 0 (initialization). Select $u^1 \in C$, a *descent parameter* $\kappa \in (0,1)$, an *infeasibility contraction bound* $\kappa_h \in (0,1]$, a *stepsize bound* $t_{\min} > 0$, a stepsize $t_1 \geq t_{\min}$, and a penalty coefficient $c_1 \geq 0$. Set $\hat{u}^1 := u^1$, $f_{\hat{u}}^1 := f_u^1 := f_{u^1}$, $g_f^1 := g_f^{u^1}$, $h_{\hat{u}}^1 := h_u^1 := h_{u^1}$, $g_h^1 := g_h^{u^1}$ (cf. (2.4)), $J_f^1 := J_h^1 := \{1\}$, $i_t^1 := 0$, $k := k(0) := 1$, and $l := 0$ ($k(l) - 1$ will denote the iteration of the lth descent step).

Step 1 (trial point finding). For $\check{e}_k$ given by (2.8), find u^{k+1} (cf. (2.9)) and multipliers α_j^k, β_j^k such that (2.28) holds. Set v_k by (2.10), $p^k := (\hat{u}^k - u^{k+1})/t_k$, and $\epsilon_k := v_k - t_k|p^k|^2$.

Step 2 (stopping criterion). If $V_k = 0$ (cf. (2.19)) and $h_{\hat{u}}^k \le 0$, stop ($f_{\hat{u}}^k \le f_*$).

Step 3 (phase 1 stepsize correction). If $h_{\hat{u}}^k \le 0$ or $\epsilon_{\max} = 0$ or $v_k \ge \kappa_h h_{\hat{u}}^k$, go to Step 4. Set $t_k := 10t_k$, $i_t^k := k$. If $c_k > 0$, set $c_k := 2c_k$; otherwise, pick $c_k > 0$. Go back to Step 1.

Step 4 (stepsize correction). If $v_k \ge -\epsilon_k$, go to Step 5. Set $t_k := 10t_k$, $i_t^k := k$. If $h_{\hat{u}}^k > 0$, set $c_k := 2c_k$ if $c_k > 0$; otherwise, pick $c_k > 0$. Go back to Step 1.

Step 5 (descent test). Evaluate f_{k+1} and h_{k+1} (cf. (2.4)). If the *descent test* holds,

$$\max\{f_u^{k+1} - \tau_k, h_u^{k+1}\} \le [h_{\hat{u}}^k]_+ - \kappa v_k, \tag{2.30}$$

set $\hat{u}^{k+1} := u^{k+1}$, $f_{\hat{u}}^{k+1} := f_u^{k+1}$, $h_{\hat{u}}^{k+1} := h_u^{k+1}$, $i_t^{k+1} := 0$, and $k(l+1) := k+1$ and increase l by 1 (*descent step*); else set $\hat{u}^{k+1} := \hat{u}^k$, $f_{\hat{u}}^{k+1} := f_{\hat{u}}^k$, $h_{\hat{u}}^{k+1} := h_{\hat{u}}^k$, and $i_t^{k+1} := i_t^k$ (*null step*).

Step 6 (bundle selection). For the active sets $\hat{J}_f^k$ and $\hat{J}_h^k$ given by (2.29), choose

$$J_f^{k+1} \supset \hat{J}_f^k \cup \{k+1\} \quad \text{and} \quad J_h^{k+1} \supset \hat{J}_h^k \cup \{k+1\}. \tag{2.31}$$

Step 7 (stepsize updating). If $k(l) = k+1$ (i.e., after a descent step), select $t_{k+1} \ge t_k$ and $c_{k+1} \ge 0$; otherwise, set $c_{k+1} := c_k$ and either set $t_{k+1} := t_k$, or choose $t_{k+1} \in [t_{\min}, t_k]$ if $i_t^{k+1} = 0$.

Step 8 (loop). Increase k by 1 and go to Step 1.

Several comments on the method are in order.

Remark 2.7. (i) When the set C is polyhedral, Step 1 may use the QP method of [Kiw94], which can efficiently solve sequences of related subproblems (2.9).

(ii) Step 2 may also use the test $\inf \check{e}_C^k \ge 0$ and $h_{\hat{u}}^k \le 0$ (see Lemma 3.1(i) below).

(iii) Step 3 is needed in phase 1 (for $h_{\hat{u}}^k > 0$) when inaccuracies occur ($\epsilon_{\max} > 0$); it increases t_k and τ_k (via c_k) to obtain $v_k \ge \kappa_h h_{\hat{u}}^k$, so that eventually a descent step (cf. (2.30)) will reduce the constraint violation significantly: $h_{\hat{u}}^{k+1} \le (1 - \kappa\kappa_h) h_{\hat{u}}^k$.

(iv) In the case of exact evaluations ($\epsilon_{\max} = 0$), Step 4 is redundant, since $v_k \ge \epsilon_k \ge 0$ (cf. (2.23)–(2.24)). When inexactness is discovered via $v_k < -\epsilon_k$, t_k is increased to produce descent or confirm that $\hat{u}^k$ is almost optimal. Namely, when $\hat{u}^k$ is bounded in (2.27), increasing t_k drives V_k to 0, so that $f_{\hat{u}}^k \le \tau_k \le f_*$ asymptotically. Whenever t_k is increased at Steps 3 or 4, the *stepsize indicator* $i_t^k \ne 0$ prevents Step 7 from decreasing t_k after null steps until the next descent step occurs (cf. Step 5). Otherwise, decreasing t_k at Step 7 aims at collecting more local information about f and h at null steps.

(v) When $\epsilon_{\max} := \max\{\epsilon_f, \epsilon_h\} = 0$, our method employs the exact function values

$$f_{\hat{u}}^k = f(\hat{u}^k), \quad h_{\hat{u}}^k = h(\hat{u}^k), \quad \tau_k = \pi(\hat{u}^k; c_k) \ge f(\hat{u}^k), \quad \text{and} \quad [h_{\hat{u}}^k]_+ = e(\hat{u}^k; \tau_k) \tag{2.32}$$

(cf. (2.7), (2.1), (2.8), and Lemma 2.3), and the aggregate inequality (2.21) means that

$$p^k \in \partial_{\epsilon_k} e_C(\hat{u}^k; \tau_k) \quad \text{with} \quad \epsilon_k \ge 0. \tag{2.33}$$

Thus, if $V_k = 0$ in (2.19), then $|p^k| = \epsilon_k = 0$ implies that $0 \in \partial e_C(\hat{u}^k; \tau_k)$ and hence that $\hat{u}^k \in U_*$ by Lemma 2.2; in particular, in this case we have $h_{\hat{u}}^k = h(\hat{u}^k) \le 0$.

(vi) At Step 5, we have $v_k > 0$ (using (2.26) and $V_k > 0$ at Step 2 if $h^k_{\hat{u}} \le 0$; otherwise $v_k \ge \kappa_h h^k_{\hat{u}} > 0$ by Step 3 if $\epsilon_{\max} > 0$, $V_k > 0$ by item (v) if $\epsilon_{\max} = 0$). When a descent step occurs, the descent test (2.30) with the target τ_k given by (2.8) implies that

$$h^{k+1}_{\hat{u}} \le h^k_{\hat{u}} - \kappa v_k \qquad \text{if } h^k_{\hat{u}} > 0, \tag{2.34a}$$

$$f^{k+1}_{\hat{u}} \le f^k_{\hat{u}} - \kappa v_k \quad \text{and} \quad h^{k+1}_{\hat{u}} \le 0 \quad \text{if } h^k_{\hat{u}} \le 0. \tag{2.34b}$$

Thus at phase 1 (i.e., when $h^k_{\hat{u}} > 0$), we have reduction in the constraint violation, whereas at phase 2 the objective value is decreased while preserving (approximate) feasibility. In the exact case (cf. (2.32)), the descent test (2.30) becomes

$$\max\left\{f(u^{k+1}) - f(\hat{u}^k) - c_k h(\hat{u}^k)_+, h(u^{k+1})\right\} \le h(\hat{u}^k)_+ - \kappa v_k,$$

coinciding with the tests used in [Kiw85, section 5.7] and [KRSS07, SaS05] with $c_k \equiv 0$.

(vii) An active-set method for solving (2.9) (cf. [Kiw94]) will produce $|\hat{J}^k_f| + |\hat{J}^k_h| \le m + 1$ (cf. (2.29)). Hence Step 6 can keep $|J^{k+1}_f| + |J^{k+1}_h| \le \bar{m}$ for any given bound $\bar{m} \ge m + 3$.

(viii) Step 7 may use the techniques of [Kiw90, LeS97] for updating t_k (or the proximity weight $1/t_k$) with obvious modifications. For updates of c_k, see section 4.4.

3. Convergence. Our analysis splits into several cases.

3.1. The case of an infinite cycle due to oracle errors. We first show that, in phase 2, the loop between Steps 1 and 4 is infinite iff $0 \le \inf \check{e}^k_C < \check{e}_k(\hat{u}^k)$, in which case $\hat{u}^k$ is *approximately optimal*: $f(\hat{u}^k) \le f_* + \epsilon_f$ and $h(\hat{u}^k) \le \epsilon_h$.

LEMMA 3.1. *Assuming that $h^k_{\hat{u}} \le 0$, recall that $\check{E}_k := \inf \check{e}^k_C$ with $\check{e}^k_C := \check{e}_k + i_C$. Then we have the following statements*:

(i) *If $\check{E}_k \ge 0$, then $f(\hat{u}^k) - \epsilon_f \le f^k_{\hat{u}} \le f_*$ and $h(\hat{u}^k) \le \epsilon_h$.*

(ii) *Step 2 terminates, i.e., $V_k := \max\{|p^k|, \epsilon_k + \langle p^k, \hat{u}^k\rangle\} = 0$, iff $0 \le \check{E}_k = \check{e}_k(\hat{u}^k)$.*

(iii) *If the loop between Steps 1 and 4 is infinite, then $\check{E}_k \ge 0$ and $V_k \to 0$.*

(iv) *If $\check{E}_k \ge 0$ at Step 1 and Step 2 does not terminate (i.e., $\check{E}_k < \check{e}_k(\hat{u}^k)$; cf. (ii)), then an infinite loop between Steps 4 and 1 occurs.*

Proof. (i) We have $E(\tau_k) \ge \check{E}_k$ and $\tau_k = f^k_{\hat{u}}$ (cf. (2.2), (2.8), (2.14)–(2.15)); so $f^k_{\hat{u}} \le f_*$ by Lemma 2.1(vi), whereas $f(\hat{u}^k) \le f^k_{\hat{u}} + \epsilon_f$ and $h(\hat{u}^k) \le h^k_{\hat{u}} + \epsilon_h$ by (2.7).

(ii) "⇒": Since $|p^k| = 0 \ge \epsilon_k$, (2.18) and (2.21) yield $u^{k+1} = \hat{u}^k$, $\bar{e}^k_C(\hat{u}^k) \le \check{e}^k_C(\cdot)$ and $0 \le \bar{e}^k_C(\hat{u}^k)$, whereas by (2.20), $\bar{e}^k_C(\hat{u}^k) = \check{e}_k(u^{k+1}) = \check{e}_k(\hat{u}^k)$. "⇐": Since $\check{e}^k_C(\hat{u}^k) = \min \check{e}^k_C$, using $\phi_k(\hat{u}^k) = \min \check{e}^k_C \le \phi_k(u^{k+1}) \le \phi_k(\hat{u}^k)$ in (2.9) gives $u^{k+1} = \hat{u}^k$; thus $\bar{e}^k_C(\hat{u}^k) = \check{e}^k_C(\hat{u}^k)$ by (2.20), and (2.18) yields $p^k = 0$ and $\epsilon_k = -\check{e}^k_C(\hat{u}^k) \le 0$.

(iii) At Step 4 during the loop the facts that $V_k < (2\epsilon_{\max}/t_k)^{1/2}(1 + |\hat{u}^k|)$ (cf. (2.27)) and $t_k \uparrow \infty$ as the loop continues give $V_k \to 0$; so $\check{e}^k_C(\cdot) \ge 0$ by (2.22).

(iv) We have $\check{e}_k(u^{k+1}) \ge \inf \check{e}^k_C \ge 0$. Thus $v_k = -\check{e}_k(u^{k+1}) \le 0$ (cf. (2.10)) and $v_k = t_k|p^k|^2 + \epsilon_k$ (cf. (2.23)) yield $\epsilon_k \le -t_k|p^k|^2$ at Step 4 with $p^k \ne 0$ (since $\max\{|p^k|, \epsilon_k + \langle p^k, \hat{u}^k\rangle\} =: V_k > 0$ at Step 2). Hence $\epsilon_k < -\frac{t_k}{2}|p^k|^2$; so $v_k < -\epsilon_k$ and Step 4 loops back to Step 1, after which Step 2 cannot terminate due to (ii). ∎

In view of Lemma 3.1, from now on we assume (unless stated otherwise) that the algorithm neither terminates nor cycles infinitely between Steps 1 and 4 at phase 2 (otherwise $\hat{u}^k$ is approximately optimal). For phase 1, our analysis will imply that any loop between Steps 1 and 3 or 4 is finite. We shall show that the algorithm generates points that are approximately optimal asymptotically by establishing upper bounds on the values $f^k_{\hat{u}}$ and $h^k_{\hat{u}}$.

3.2. Bounding the objective values. We first bound $f_{\hat{u}}^k$ via V_k.

LEMMA 3.2. *Let $K \subset \mathbb{N}$ satisfy $V_k \xrightarrow{K} 0$. Then $\overline{\lim}_{k\in K} f_{\hat{u}}^k \le \overline{\lim}_{k\in K} \tau_k \le f_*$.*

Proof. Pick $K' \subset K$ such that $\tau_k \xrightarrow{K'} \bar{\tau} := \overline{\lim}_{k\in K} \tau_k$. Since $f_{\hat{u}}^k \le \tau_k$ by (2.8), we need only show that $\bar{\tau} \le f_*$ when $\bar{\tau} > -\infty$. Note that $\bar{\tau} < \infty$, since otherwise for $\tau_k \ge f(\mathring{u}) - h(\mathring{u})$, the fact that $e(\mathring{u};\tau_k) = h(\mathring{u}) < 0$ (cf. (2.2), (1.2)) and the bound (2.22) would yield the following contradiction:

$$0 > h(\mathring{u}) = e_C(\mathring{u};\tau_k) \ge -V_k(1+|\mathring{u}|) \xrightarrow{K'} 0.$$

Thus $\bar{\tau}$ is finite. Since $e_C(u;\cdot)$ is continuous, letting $k \xrightarrow{K'} \infty$ in (2.22) gives $e_C(\cdot;\bar{\tau}) \ge 0$. Therefore, we have $E(\bar{\tau}) \ge 0$, and hence $\bar{\tau} \le f_*$ by Lemma 2.1(vi). ∎

The upper bound of Lemma 3.2 is complemented below with a lower bound (which is highly useful for the "dual" applications in sections 4.3 and 5).

LEMMA 3.3. *If $\overline{\lim}_k h_{\hat{u}}^k \le 0$, then for the minimal multiplier $\bar{\mu} := \inf_{\mu\in M} \mu$ of problem (1.1) (cf. section 2.1), we have*

$$\underline{\lim}_k f_{\hat{u}}^k + \epsilon_f \ge \underline{\lim}_k f(\hat{u}^k) \ge f_* - \bar{\mu}\epsilon_h \quad \text{and} \quad \overline{\lim}_k h(\hat{u}^k) \le \epsilon_h. \tag{3.1}$$

Proof. For all k, $\hat{u}^k \in C$ and (cf. section 2.1) $L(\hat{u}^k;\bar{\mu}) := f(\hat{u}^k) + \bar{\mu}h(\hat{u}^k) \ge f_*$, with $0 \le \bar{\mu} < \infty$ if $f_* > -\infty$, $\bar{\mu} = \infty$ otherwise. Moreover, $f(\hat{u}^k) \le f_{\hat{u}}^k + \epsilon_f$, and $h(\hat{u}^k) \le h_{\hat{u}}^k + \epsilon_h$ by (2.7). The conclusion follows. ∎

3.3. The case of finitely many descent steps. We now consider the case where only finitely many descent steps occur. After the last descent step, only null steps occur and $\{t_k\}$ becomes eventually monotone, since once Steps 3 or 4 increase t_k, Step 7 cannot decrease t_k; thus the limit $t_\infty := \lim_k t_k$ exists. After showing that $t_\infty = \infty$ may occur only at phase 2 in Lemma 3.4, we deal with the cases of $t_\infty = \infty$ in Lemma 3.6 and $t_\infty < \infty$ in Lemma 3.7.

LEMMA 3.4. *Suppose there exists $\bar{k}$ such that $h_{\hat{u}}^{\bar{k}} > 0$ and only null steps occur for all $k \ge \bar{k}$. Then Steps 3 and 4 can increase t_k only a finite number of times.*

Proof. For contradiction, suppose that $t_k \to \infty$. Since $\tau_k \to \infty$ (because $c_k \to \infty$; cf. Steps 3 and 4 and (2.8)), we may assume that $\tau_k \ge \mathring{\tau} := f(\mathring{u}) - h(\mathring{u})$ for the Slater point $\mathring{u}$ of (1.2) and for all $k \ge \bar{k}$; then, using the minorants $\check{f}_k \le f$ and $\check{h}_k \le h$ (cf. (2.4)) in the definitions (2.8) and (2.2) yields

$$\check{e}_k(\mathring{u}) \le \max\{\check{f}_k(\mathring{u}) - \mathring{\tau}, \check{h}_k(\mathring{u})\} \le e(\mathring{u};\mathring{\tau}) = h(\mathring{u}) < 0 \quad \text{with} \quad \mathring{u} \in C. \tag{3.2}$$

At Step 1, (2.9) gives the proximal projection property for the level set of $\check{e}_C^k := \check{e}_k + i_C$:

$$u^{k+1} = \arg\min\{\tfrac{1}{2}|u - \hat{u}^k|^2 : \check{e}_C^k(u) \le \check{e}_C^k(u^{k+1})\}, \tag{3.3}$$

whereas before Step 3 increases t_k, $v_k < \kappa_h h_{\hat{u}}^k$ yields $\check{e}_k(u^{k+1}) > (1-\kappa_h)h_{\hat{u}}^k \ge 0$ by (2.10); so for $k \ge \bar{k}$, (3.2) and (3.3) with $\hat{u}^k = \hat{u}^{\bar{k}}$ give $|u^{k+1} - \hat{u}^k| \le r := |\mathring{u} - \hat{u}^{\bar{k}}|$, and hence $|p^k| \le r/t_k$ by (2.18). Therefore, if Step 3 increases t_k at infinitely many iterations, indexed by K, say, then $t_k \to \infty$ yields $p^k \xrightarrow{K} 0$; thus, from (2.21), (2.20), the fact that $|u^{k+1} - \hat{u}^{\bar{k}}| \le r$, and the Cauchy–Schwarz inequality, we get

$$0 > h(\mathring{u}) \ge \check{e}_C^k(\mathring{u}) \ge \bar{e}_C^k(\mathring{u}) = \check{e}_k(u^{k+1}) + \langle p^k, \mathring{u} - u^{k+1}\rangle \ge \langle p^k, \mathring{u} - u^{k+1}\rangle \xrightarrow{K} 0,$$

a contradiction. Similarly, if Step 4 is entered with $v_k < -\epsilon_k$ for infinitely many iterations indexed by K, say, then $t_k \to \infty$ and (2.27) give $V_k \xrightarrow{K} 0$, and we obtain

$$0 > h(\mathring{u}) \ge \check{e}_C^k(\mathring{u}) \ge -V_k(1+|\mathring{u}|) \xrightarrow{K} 0$$

from (3.2) and (2.22), another contradiction. The conclusion follows. ∎

Remark 3.5. To illustrate the need for increasing c_k at Steps 3 and 4, suppose momentarily that $c_k \equiv 0$ for all k. Consider the following example. Let $m = 1$, $f(u) := u$, $h(u) := 1 - u$, $C := R$. Suppose that $u^1 := 0$, $f_1 := f$, $h_1 := h - 0.5$; so that $h^1_{\hat{u}} = 0.5$ for $\epsilon_h = 0.5$. For $k = 1$, $v_k \le 1/4$; so if $\kappa_h \in (1/2, 1)$, then a loop between Steps 3 and 1 occurs. Next, for $\kappa_h \in (0, 1/2]$, suppose $f_{k+1} = f$ and $h_{k+1} = h$ at Step 5; then a null step occurs, and at Step 1 for $k = 2$, $\check{e}_k = \max\{f, h\}$ is exact, $\min \check{e}_k = 1/2 = h^k_{\hat{u}}$, and $v_k \le 0$, so that a loop between Steps 3 and 1 occurs. Even if Step 3 were omitted, a loop between Steps 4 and 1 would occur.

The case where the stepsize t_k keeps growing at a fixed prox center is quite simple.

LEMMA 3.6. *Suppose there exists $\bar{k}$ such that only null steps occur for all $k \ge \bar{k}$, and $t_\infty := \lim_k t_k = \infty$. Let $K := \{k \ge \bar{k} : t_{k+1} > t_k\}$. Then $V_k \xrightarrow{K} 0$, and $h^{\bar{k}}_{\hat{u}} \le 0$.*

Proof. We have $h^{\bar{k}}_{\hat{u}} \le 0$ (otherwise Lemma 3.4 would imply $t_\infty < \infty$, a contradiction). For $k \in K$, before t_k is increased at Step 4 on the last loop to Step 1, we have $V_k < (2\epsilon_{\max}/t_k)^{1/2}(1 + |\hat{u}^{\bar{k}}|)$ by (2.27); so $t_k \to \infty$ gives $V_k \xrightarrow{K} 0$. ∎

The case where the stepsize t_k does not grow at a fixed prox center is analyzed as in [Kiw06a]. After showing that the optimal value $\phi_k(u^{k+1})$ of subproblem (2.9) is nondecreasing and bounded above, u^{k+1} is bounded, and $u^{k+2} - u^{k+1} \to 0$, we invoke the descent test (2.30) to get $v_k \to 0$; the rest follows from the bounds (2.25)–(2.26).

LEMMA 3.7. *Suppose that there exists $\bar{k}$ such that for all $k \ge \bar{k}$, only null steps occur, and Steps 3 and 4 do not increase t_k. Then $V_k \to 0$, and $h^{\bar{k}}_{\hat{u}} \le 0$.*

Proof. Fix $k \ge \bar{k}$. We show that the aggregate $\bar{e}^k_C$ minorizes the next model $\check{e}^{k+1}_C$:

$$\bar{e}^k_C(\cdot) \le \check{e}^{k+1}_C(\cdot) := \check{e}_{k+1}(\cdot) + i_C(\cdot). \tag{3.4}$$

Consider the selected model $\hat{f}_k := \max_{j \in \hat{J}^k_f} f_j$ of $\check{f}_k := \max_{j \in J^k_f} f_j$; then $\hat{f}_k \le \check{f}_k$. Using (2.29) in the expression (2.28a) of p^k_f gives $\hat{f}_k(u^{k+1}) = \check{f}_k(u^{k+1})$ and $p^k_f \in \partial \hat{f}_k(u^{k+1})$ (cf. [HUL93, Ex. VI.3.4]). Thus $\bar{f}_k \le \hat{f}_k$ by (2.14); so the choice of $\hat{J}^k_f \subset J^{k+1}_f$ implies that $\bar{f}_k \le \hat{f}_k \le \check{f}_{k+1}$. Similarly, for $\hat{h}_k := \max_{j \in \hat{J}^k_h} h_j$, (2.28b) yields $\bar{h}_k \le \hat{h}_k \le \check{h}_{k+1}$. Then using the definition (2.17) of $\bar{e}^k_C$ with $\nu_k \in [0, 1]$ (cf. (2.13)), the minorization $i^k_C \le i_C$ of (2.16), and the fact that $\tau_{k+1} = \tau_k$ (by (2.8) and Steps 3 and 4) gives the required bound

$$\bar{e}^k_C \le \nu_k[\check{f}_{k+1} - \tau_k] + (1 - \nu_k)\check{h}_{k+1} + i_C \le \max\{\check{f}_{k+1} - \tau_{k+1}, \check{h}_{k+1}\} + i_C = \check{e}^{k+1}_C.$$

(Note that this bound needs only the minorizations $\bar{f}_k \le \check{f}_{k+1} + i_C$ and $\bar{h}_k \le \check{h}_{k+1} + i_C$; this will be important when selection is replaced by aggregation in section 4.2.)

Next, consider the following partial linearization of the objective ϕ_k of (2.9):

$$\bar{\phi}_k(\cdot) := \bar{e}^k_C(\cdot) + \tfrac{1}{2t_k}|\cdot - \hat{u}^k|^2. \tag{3.5}$$

We have $\bar{e}^k_C(u^{k+1}) = \check{e}_k(u^{k+1})$ by (2.20) and $\nabla \bar{\phi}_k(u^{k+1}) = 0$ from $\nabla \bar{e}^k_C = p^k = (\hat{u}^k - u^{k+1})/t_k$ (cf. (2.20), (2.18)); hence $\bar{\phi}_k(u^{k+1}) = \phi_k(u^{k+1})$ by (2.9), and by Taylor's expansion

$$\bar{\phi}_k(\cdot) = \phi_k(u^{k+1}) + \tfrac{1}{2t_k}|\cdot - u^{k+1}|^2. \tag{3.6}$$

To bound $\bar{\phi}_k(\hat{u}^k)$ from above, notice that (3.5), (2.18), and (2.24) imply that

$$\bar{\phi}_k(\hat{u}^k) = \bar{e}^k_C(\hat{u}^k) = [h^k_{\hat{u}}]_+ - \epsilon_k \le [h^k_{\hat{u}}]_+ + \epsilon_{\max}.$$

Then by (3.6),

$$\phi_k(u^{k+1}) + \tfrac{1}{2t_k}|u^{k+1} - \hat{u}^k|^2 = \bar{\phi}_k(\hat{u}^k) \le \big[h^{\bar{k}}_{\hat{u}}\big]_+ + \epsilon_{\max}. \tag{3.7}$$

Now using the facts that $\hat{u}^{k+1} = \hat{u}^k$ and $t_{k+1} \le t_k$ and the model minorization property (3.4) in the definitions (3.5) of $\bar{\phi}_k$ and (2.9) of ϕ_{k+1} gives $\bar{\phi}_k \le \phi_{k+1}$. Hence by (3.6),

$$\phi_k(u^{k+1}) + \tfrac{1}{2t_k}|u^{k+2} - u^{k+1}|^2 = \bar{\phi}_k(u^{k+2}) \le \phi_{k+1}(u^{k+2}). \tag{3.8}$$

Thus the nondecreasing sequence $\{\phi_k(u^{k+1})\}_{k\ge\bar{k}}$, being bounded above by (3.7) with $\hat{u}^k = \hat{u}^{\bar{k}}$ for $k \ge \bar{k}$, must have a limit, say $\phi_\infty \le [h^{\bar{k}}_{\hat{u}}]_+ + \epsilon_{\max}$. Moreover, since the stepsizes satisfy $t_k \le t_{\bar{k}}$ for $k \ge \bar{k}$, we deduce from the bounds (3.7)–(3.8) that

$$\phi_k(u^{k+1}) \uparrow \phi_\infty, \quad u^{k+2} - u^{k+1} \to 0, \tag{3.9}$$

and the sequence $\{u^{k+1}\}$ is bounded. Then the sequence $\{g_f^{k+1}\}$ is bounded as well, since $g_f^k \in \partial_{\epsilon_f} f(u^k)$ by (2.4), whereas the mapping $\partial_{\epsilon_f} f$ is locally bounded [HUL93, section XI.4.1]; similarly, the sequence $\{g_h^{k+1}\}$ is bounded, since $g_h^k \in \partial_{\epsilon_h} h(u^k)$ by (2.4).

For $v_k := [h^k_{\hat{u}}]_+ - \check{e}_k(u^{k+1})$ and the following linearization of $e(\cdot;\tau_k)$ at u^{k+1},

$$e_{k+1}(\cdot) := \begin{cases} f_{k+1}(\cdot) - \tau_k & \text{if } f_u^{k+1} - \tau_k \ge h_u^{k+1}, \\ h_{k+1}(\cdot) & \text{otherwise,} \end{cases} \tag{3.10}$$

the descent test (2.30) reads $e_{k+1}(u^{k+1}) \le [h^k_{\hat{u}}]_+ - \kappa v_k$ or equivalently

$$\tilde{\epsilon}_k := e_{k+1}(u^{k+1}) - \check{e}_k(u^{k+1}) \le (1-\kappa)v_k. \tag{3.11}$$

We now show that this approximation error $\tilde{\epsilon}_k \to 0$. First, note that the linearization gradients $g_e^{k+1} := \nabla e_{k+1}$ are bounded, since $|g_e^{k+1}| \le \max\{|g_f^{k+1}|, |g_h^{k+1}|\}$ by (2.4). Further, the minorizations $f_{k+1} \le \check{f}_{k+1}$ and $h_{k+1} \le \check{h}_{k+1}$ due to $k+1 \in J_f^{k+1} \cap J_h^{k+1}$ (cf. (2.5)) yield $e_{k+1} \le \check{e}_{k+1}$ by (2.8), since $\tau_{k+1} = \tau_k$. Using the linearity of e_{k+1}, the bound $e_{k+1} \le \check{e}_{k+1}$, the Cauchy–Schwarz inequality, and (2.9) with $\hat{u}^k = \hat{u}^{\bar{k}}$ for $k \ge \bar{k}$, we estimate

$$\begin{aligned} \tilde{\epsilon}_k &:= e_{k+1}(u^{k+1}) - \check{e}_k(u^{k+1}) \\ &= e_{k+1}(u^{k+2}) - \check{e}_k(u^{k+1}) + \langle g_e^{k+1}, u^{k+1} - u^{k+2}\rangle \\ &\le \check{e}_{k+1}(u^{k+2}) - \check{e}_k(u^{k+1}) + |g_e^{k+1}||u^{k+1} - u^{k+2}| \\ &= \phi_{k+1}(u^{k+2}) - \phi_k(u^{k+1}) + \Delta_k + |g_e^{k+1}||u^{k+1} - u^{k+2}|, \end{aligned} \tag{3.12}$$

where $\Delta_k := |u^{k+1} - \hat{u}^{\bar{k}}|^2/2t_k - |u^{k+2} - \hat{u}^{\bar{k}}|^2/2t_{k+1}$. We have $\Delta_k \to 0$, since $t_{\min} \le t_{k+1} \le t_k$ (cf. Step 7), $|u^{k+1} - \hat{u}^{\bar{k}}|^2$ is bounded, $u^{k+2} - u^{k+1} \to 0$ by (3.9), and

$$|u^{k+2} - \hat{u}^{\bar{k}}|^2 = |u^{k+1} - \hat{u}^{\bar{k}}|^2 + 2\langle u^{k+2} - u^{k+1}, u^{k+1} - \hat{u}^{\bar{k}}\rangle + |u^{k+2} - u^{k+1}|^2.$$

Hence, using (3.9) and the boundedness of $\{g_e^{k+1}\}$ in (3.12) yields $\overline{\lim}_k \tilde{\epsilon}_k \le 0$. On the other hand, for $k \ge \bar{k}$, the descent test written as (3.11) fails: $(1-\kappa)v_k < \tilde{\epsilon}_k$, where $\kappa < 1$ and $v_k > 0$; it follows that $\tilde{\epsilon}_k \to 0$ and $v_k \to 0$.

Since $v_k \to 0$, $t_k \geq t_{\min}$, and $\hat{u}^k = \hat{u}^{\bar{k}}$ for $k \geq \bar{k}$, we have $V_k \to 0$ by (2.26), $\epsilon_k \to 0$, and $|p^k| \to 0$ by (2.25). It remains to prove that $h_{\hat{u}}^{\bar{k}} \leq 0$. If $\epsilon_{\max} > 0$, but $h_{\hat{u}}^{\bar{k}} > 0$, then the facts that $v_k \to 0$ with $v_k \geq \kappa_h h_{\hat{u}}^k$ (cf. Step 3), $\kappa_h > 0$, and $h_{\hat{u}}^k = h_{\hat{u}}^{\bar{k}}$ for $k \geq \bar{k}$ give in the limit $h_{\hat{u}}^{\bar{k}} \leq 0$, a contradiction. Finally, for $\epsilon_{\max} = 0$, recalling Remark 2.7(v) and using $\epsilon_k, |p^k| \to 0$ in (2.21) yields $e_C(\hat{u}^{\bar{k}}; \tau_{\bar{k}}) \leq e_C(\cdot; \tau_{\bar{k}})$. In other words, we have $0 \in \partial e_C(\hat{u}^{\bar{k}}; \tau_{\bar{k}})$; so $\hat{u}^{\bar{k}} \in U_*$ by Lemma 2.2, and thus $h_{\hat{u}}^{\bar{k}} = h(\hat{u}^{\bar{k}}) \leq 0$. ∎

We may now finish the case of infinitely many consecutive null steps.

THEOREM 3.8. *Suppose there exists $\bar{k}$ such that only null steps occur for all $k \geq \bar{k}$. Let $K := \{k \geq \bar{k} : t_{k+1} > t_k\}$ if $t_k \to \infty$, $K := \{k : k \geq \bar{k}\}$ otherwise. Then $V_k \xrightarrow{K} 0$, $f_{\hat{u}}^{\bar{k}} \leq f_*$ and $h_{\hat{u}}^{\bar{k}} \leq 0$. Moreover, the bounds of* (3.1) *hold.*

Proof. Steps 3, 4, 5, and 7 ensure that $\{t_k\}$ is monotone for large k (see above Lemma 3.4). We have $V_k \xrightarrow{K} 0$ and $h_{\hat{u}}^{\bar{k}} \leq 0$ from either Lemma 3.6 if $t_\infty = \infty$ or Lemma 3.7 if $t_\infty < \infty$. Then $f_{\hat{u}}^{\bar{k}} \leq f_*$ by Lemma 3.2 (since $\tau_k = f_{\hat{u}}^k = f_{\hat{u}}^{\bar{k}}$ for $k \geq \bar{k}$). The final assertion stems from Lemma 3.3. ∎

It may be interesting to observe that $u^k \to \hat{u}^{\bar{k}}$ if $t_\infty < \infty$ (since $|u^{k+1} - \hat{u}^k| = t_k|p^k|$ by (2.18), and $p^k \to 0$ in the proof of Lemma 3.7). In contrast, we may have $t_\infty = \infty$ and $|u^k| \to \infty$ (consider $m = 1$, $f(u) := e^u$, $h(u) \equiv -1$, $C := \mathbb{R}$, $u^1 := 0$, $f_u^1 := -1$, $g_f^1 = 1$, and exact evaluations for $k \geq 2$).

3.4. The case of infinitely many descent steps. We first analyze the case of infinitely many descent steps in phase 2.

THEOREM 3.9. *Suppose infinitely many descent steps occur, and $h_{\hat{u}}^{\bar{k}} \leq 0$ for some $\bar{k}$. Let $f_{\hat{u}}^\infty := \lim_k f_{\hat{u}}^k$ and $K := \{k \geq \bar{k} : f_{\hat{u}}^{k+1} < f_{\hat{u}}^k\}$. Then either $f_{\hat{u}}^\infty = f_* = -\infty$, or $-\infty < f_{\hat{u}}^\infty \leq f_*$ and $\underline{\lim}_{k \in K} V_k = 0$. Moreover, the bounds of* (3.1) *hold. In particular, if $\{\hat{u}^k\}$ is bounded, then $f_{\hat{u}}^\infty > -\infty$ and $V_k \xrightarrow{K} 0$.*

Proof. For $k \geq \bar{k}$, we have $h_{\hat{u}}^k \leq 0$, $\tau_k = f_{\hat{u}}^k$ (cf. (2.8)), and $f_{\hat{u}}^{k+1} \leq f_{\hat{u}}^k$, since by (2.34b), a descent step yields $h_{\hat{u}}^{k+1} \leq 0$ and $f_{\hat{u}}^{k+1} - f_{\hat{u}}^k \leq -\kappa v_k < 0$, so that $|K| = \infty$. First, suppose that $f_{\hat{u}}^\infty > -\infty$.

We have $0 < \kappa v_k \leq f_{\hat{u}}^k - f_{\hat{u}}^{k+1}$ if $k \in K$, $f_{\hat{u}}^{k+1} = f_{\hat{u}}^k$ otherwise; so $\sum_{k \in K} \kappa v_k \leq f_{\hat{u}}^{\bar{k}} - f_{\hat{u}}^\infty < \infty$ gives $v_k \xrightarrow{K} 0$ and hence $\epsilon_k, t_k|p^k|^2 \xrightarrow{K} 0$ by (2.25), as well as $|p^k| \xrightarrow{K} 0$, using $t_k \geq t_{\min}$. Now, for the descent iterations $k \in K$, we have $\hat{u}^{k+1} - \hat{u}^k = -t_k p^k$ by (2.18) and therefore

$$|\hat{u}^{k+1}|^2 - |\hat{u}^k|^2 = t_k\big\{t_k|p^k|^2 - 2\langle p^k, \hat{u}^k\rangle\big\}.$$

Sum up and use the facts that $\hat{u}^{k+1} = \hat{u}^k$ if $k \notin K$ and $\sum_{k \in K} t_k \geq \sum_{k \in K} t_{\min} = \infty$ to get

$$\overline{\lim_{k \in K}}\big\{t_k|p^k|^2 - 2\langle p^k, \hat{u}^k\rangle\big\} \geq 0$$

(since otherwise $|\hat{u}^k|^2 \to -\infty$, which is impossible). Combining this with $t_k|p^k|^2 \xrightarrow{K} 0$ gives $\underline{\lim}_{k \in K}\langle p^k, \hat{u}^k\rangle \leq 0$. Since also $\epsilon_k, |p^k| \xrightarrow{K} 0$, we have $\underline{\lim}_{k \in K} V_k = 0$ by (2.19).

Then using $\underline{\lim}_{k \in K} V_k = 0$ and $\tau_k \to f_{\hat{u}}^\infty$ in Lemma 3.2 shows that $f_{\hat{u}}^\infty \leq f_*$.

For the case of $f_{\hat{u}}^\infty = -\infty$ and the assertion on (3.1), invoke Lemma 3.3.

For the final assertion, if $\{\hat{u}^k\} \subset C$ is bounded, then $\inf_k f(\hat{u}^k) > -\infty$ (f is closed on C) implies that $f_{\hat{u}}^\infty > -\infty$ by (3.1); so we have $\epsilon_k, |p^k| \xrightarrow{K} 0$ as above. Hence the fact that $V_k \leq \max\{|p^k|, \epsilon_k\}(1 + |\hat{u}^k|)$ by Lemma 2.5(iv) gives $V_k \xrightarrow{K} 0$. ∎

We now deal with the case of infinitely many descent steps at phase 1 for $\epsilon_{\max} > 0$.

THEOREM 3.10. *Suppose infinitely many descent steps occur, $h^k_{\hat{u}} > 0$ for all k, and $\epsilon_{\max} > 0$. Let $K := \{k : h^{k+1}_{\hat{u}} < h^k_{\hat{u}}\}$. Then we have the following statements*:

(i) $h^k_{\hat{u}} \downarrow 0$ (*this relies upon the property that $v_k \geq \kappa_h h^k_{\hat{u}}$ at Step* 5).

(ii) $\underline{\lim}_{k\in K} V_k = 0$; *also* $\sum_{k\in K} v_k < \infty$, *and* $\lim_{k\in K} \max\{\epsilon_k, |p^k|\} = 0$.

(iii) *Let $K' \subset \mathbb{N}$ be such that $V_k \xrightarrow{K'} 0$. Then $\overline{\lim}_{k\in K'} f^k_{\hat{u}} \leq \overline{\lim}_{k\in K'} \tau_k \leq f_*$.*

(iv) *If $\{\hat{u}^k\}$ is bounded, then $\lim_{k\in K} V_k = 0$, and we may take $K' = K$ in* (iii).

(v) *The bounds of* (3.1) *hold, and $\underline{\lim}_k \tau_k \geq f_* - \epsilon_f - \bar{\mu}\epsilon_h$.*

(vi) *Assertions* (ii)–(iv) *above hold also if $\epsilon_{\max} = 0$.*

Proof. We have $h^{k+1}_{\hat{u}} - h^k_{\hat{u}} \leq -\kappa v_k < 0$ at descent steps by (2.34a); thus $|K| = \infty$.

(i) We have $0 < \kappa v_k \leq h^k_{\hat{u}} - h^{k+1}_{\hat{u}}$ if $k \in K$, $h^{k+1}_{\hat{u}} = h^k_{\hat{u}}$ otherwise; so $\sum_{k\in K} \kappa v_k \leq h^1_{\hat{u}}$ gives $\lim_{k\in K} v_k = 0$. Hence the fact that $v_k \geq \kappa_h h^k_{\hat{u}}$ (cf. Step 3) yields $h^k_{\hat{u}} \downarrow 0$.

(ii) Use $\sum_{k\in K} v_k < \infty$, and then $v_k \xrightarrow{K} 0$ (from the proof of (i)) as in the proof of Theorem 3.9 to get $\underline{\lim}_{k\in K} V_k = 0$, $\lim_{k\in K} \epsilon_k = 0$, and $\lim_{k\in K} |p^k| = 0$.

(iii) This follows from Lemma 3.2.

(iv) Invoke Lemma 2.5(iv) and the fact that $\lim_{k\in K} \max\{\epsilon_k, |p^k|\} = 0$ by (ii).

(v) This follows from (i), Lemma 3.3, and the fact that $\tau_k \geq f^k_{\hat{u}}$ for all k.

(vi) This statement is immediate from the preceding arguments and the rules of Step 3. ∎

It is instructive to examine the assumptions of the preceding results.

Remark 3.11. (i) Inspection of the preceding proofs reveals that Theorems 3.8–3.10 require only convexity and finiteness of f and h on C and *local boundedness* of the approximate subgradient mappings g^u_f of f and g^u_h of h on C. In particular, it suffices to assume that f and h are finite convex on a neighborhood of C.

(ii) Using the *evaluation errors* $\epsilon^k_f := f(u^k) - f^k_u$ and $\epsilon^k_h := h(u^k) - h^k_u$, our results are sharpened as follows; cf. [Kiw06b, section 4.2]. In general, $f(\hat{u}^k) = f^k_{\hat{u}} + \epsilon^{k(l)}_f$ and $h(\hat{u}^k) = h^k_{\hat{u}} + \epsilon^{k(l)}_h$, where $k(l) - 1$ denotes the iteration number of the lth descent step. Hence ϵ_f and ϵ_h in the bounds of (3.1) for Theorems 3.8–3.10 may be replaced by the *asymptotic errors* ϵ^∞_f and ϵ^∞_h, where ϵ^∞_f equals the final $\epsilon^{k(l)}_f$ if only finitely many descent steps occur, $\overline{\lim}_l \epsilon^{k(l)}_f$ otherwise, and ϵ^∞_h is defined analogously.

(iii) Concerning Theorem 3.10(iv), note that the sequence $\{\hat{u}^k\}$ is bounded if the feasible set U is bounded. Indeed, $h(\hat{u}^k) \leq h^k_{\hat{u}} + \epsilon_h$ (cf. (2.7)) with $h^k_{\hat{u}} \leq h^1_{\hat{u}}$ implies that $\{\hat{u}^k\}$ lies in the set $\{u \in C : h(u) \leq h^1_{\hat{u}} + \epsilon_h\}$, which is bounded, since such is U.

Finally, we analyze infinitely many descent steps in the exact case of $\epsilon_{\max} = 0$.

THEOREM 3.12. *Suppose that infinitely many descent steps occur and $\epsilon_{\max} = 0$. Let $K := \{k(l) - 1\}_{l=1}^\infty$ index the descent iterations* (*cf. Step* 5), *and let $\bar{k} := \inf\{k : h(\hat{u}^k) \leq 0\}$* (*so that phase* 2 *starts at iteration $k = \bar{k}$ iff $\bar{k} < \infty$*). *Then we have the following statements*:

(i) *If $\bar{k} < \infty$, then $f(\hat{u}^k) \to f_*$, $\tau_k \to f_*$, $h(\hat{u}^k)_+ \to 0$, and each cluster point of $\{\hat{u}^k\}$* (*if any*) *lies in the optimal set U_*; moreover, $\underline{\lim}_{k\in K} V_k = 0$ if $f_* > -\infty$.*

(ii) *If $\inf_k f(\hat{u}^k) > -\infty$ or $\bar{k} = \infty$, then $\sum_{k\in K} v_k < \infty$, $\epsilon_k \xrightarrow{K} 0$, and $p^k \xrightarrow{K} 0$.*

(iii) *If the sequence $\{\hat{u}^k\}$ is bounded, then all its cluster points lie in the optimal set U_*, and we have $f(\hat{u}^k) \to f_* > -\infty$, $\tau_k \to f_*$, $h(\hat{u}^k)_+ \to 0$, and $V_k \xrightarrow{K} 0$.*

(iv) *If $\{\hat{u}^k\}$ has a cluster point $\bar{u}$, then $\bar{u} \in U_*$, $h(\hat{u}^k)_+ \to 0$, and $\underline{\lim}_k \tau_k \geq \underline{\lim}_k f(\hat{u}^k) \geq f_* > -\infty$; moreover, if $K' \subset K$ is such that $\hat{u}^k \xrightarrow{K'} \bar{u}$, then $V_k \xrightarrow{K'} 0$.*

(v) *The sequence $\{\hat{u}^k\}$ has a cluster point if the set U_* is nonempty and bounded.*

(vi) *The sequence $\{\hat{u}^k\}$ is bounded if such is the set $U := \{u \in C : h(u) \leq 0\}$.*

(vii) *Suppose that $\bar{u} \in U_*$ and there exists an iteration index k' such that*

$$f(\bar{u}) \le \pi(\hat{u}^k; c_k + 1) \quad \text{for all } k \ge k', k \in K. \tag{3.13}$$

In particular, (3.13) *holds if $\hat{u}^{k'} \in U$ for some k', or $c_k \ge \bar{\mu} - 1$ for all $k \ge k', k \in K$. Further, suppose $\overline{\lim}_{k\in K} t_k < \infty$. Then the sequence $\{\hat{u}^k\}$ converges to a point in U_*.*

(viii) *Suppose that $\{\hat{u}^k\}$ is bounded, but we have only $\sum_{k\in K} t_k = \infty$ instead of $\inf_{k\in K} t_k \ge t_{\min}$. Then $\{\hat{u}^k\}$ has a cluster point in U_*. Moreover, assertion* (vii) *still holds.*

Proof. First, recalling the "exact" relations (2.32)–(2.33), note that $\epsilon_k \ge 0$ and

$$e_C(\cdot; \tau_k) \ge e_C(\hat{u}^k; \tau_k) + \langle p^k, \cdot - \hat{u}^k \rangle - \epsilon_k \quad \text{with} \quad e_C(\hat{u}^k; \tau_k) = h(\hat{u}^k)_+. \tag{3.14}$$

By Remark 2.7(vi), the descent test (2.30) ensures that $0 < h(\hat{u}^{k+1}) \le h(\hat{u}^k)$ for all k if $\bar{k} = \infty$, $f_* \le f(\hat{u}^{k+1}) \le f(\hat{u}^k)$, and $h(\hat{u}^k) \le 0$ for all $k \ge \bar{k}$ otherwise.

(i) Use $f_{\hat{u}}^{\infty} = \lim_k f(\hat{u}^k) = \lim_k \tau_k$ in Theorem 3.9 and the closedness of C, f, h.

(ii) Use the proof of Theorem 3.9 if $\bar{k} < \infty$ or Theorem 3.10(vi) otherwise.

(iii) First, suppose that $\bar{k} = \infty$; i.e., consider phase 1 with $h(\hat{u}^k) > 0$ for all k.

Let $\bar{u}$ be a cluster point of $\{\hat{u}^k\}$. Then $\bar{u} \in C$, since $\{\hat{u}^k\} \subset C$ and C is closed. Pick $K' \subset K$ such that $\hat{u}^k \xrightarrow{K'} \bar{u}$. Then $f(\hat{u}^k) \xrightarrow{K'} f(\bar{u})$, $h(\hat{u}^k) \xrightarrow{K'} h(\bar{u}) \ge 0$ (f, h are continuous on C). Since $\epsilon_k, |p^k| \xrightarrow{K} 0$ by (ii), Lemma 2.5(iv) yields $V_k \xrightarrow{K'} 0$. Let $\bar{\tau}$ be any cluster point of $\{\tau_k\}_{k\in K'}$. Pick $K'' \subset K'$ such that $\tau_k \xrightarrow{K''} \bar{\tau}$. We have $\bar{\tau} \ge f(\bar{u})$ ($\tau_k \ge f(\hat{u}^k)$) and $\bar{\tau} < \infty$; otherwise for large $k \in K''$, $\tau_k \ge f(\mathring{u}) - h(\mathring{u})$ would give $e(\mathring{u}; \tau_k) = h(\mathring{u}) < 0$ by (2.2) and (1.2), and by (3.14) with $\epsilon_k, |p^k| \xrightarrow{K} 0$,

$$0 > h(\mathring{u}) = e_C(\mathring{u}; \tau_k) \ge h(\hat{u}^k)_+ + \langle p^k, \mathring{u} - \hat{u}^k \rangle - \epsilon_k \xrightarrow{K''} h(\bar{u})_+ \ge 0,$$

a contradiction. Since e_C is continuous on $C \times \mathbb{R}$, letting $k \xrightarrow{K''} \infty$ in (3.14) gives $e_C(\cdot; \bar{\tau}) \ge e_C(\bar{u}; \bar{\tau})$, i.e., $0 \in \partial e_C(\bar{u}; \bar{\tau})$. Since $h(\bar{u}) \ge 0$ and $\bar{\tau} \ge f(\bar{u})$, $0 \in \partial e_C(\bar{u}; \bar{\tau})$ in (2.3) implies $\bar{\tau} = f(\bar{u})$ and $h(\bar{u}) = 0$ (otherwise for $h_C := h + i_C$, $0 \in \partial h_C(\bar{u})$ would give $\min_C h \ge 0$, contradicting (1.2)). Hence, $\bar{u} \in U_*$ by Lemma 2.2 (using $\bar{\tau} = \pi(\bar{u}; \bar{c})$ for any $\bar{c} \ge 0$) and $f(\bar{u}) = f_*$. Since $h(\bar{u}) = 0$ and $\{h(\hat{u}^k)\}$ is nonincreasing, we obtain that $h(\hat{u}^k) \to 0$.

By considering any convergent subsequences, we deduce that $V_k \xrightarrow{K} 0$ and that f_* is the unique cluster point of $\{\tau_k\}_{k\in K}$ and $\{f(\hat{u}^k)\}_{k\in K}$. Hence, $\lim_l \tau_{k(l)-1} = \lim_l f(\hat{u}^{k(l)-1}) = f_*$. Since $f(\hat{u}^{k(l)}) \le \tau_k \le \tau_{k(l+1)-1}$ for $k(l) \le k < k(l+1)$ by Steps 3, 4, and 7, we obtain $\lim_k f(\hat{u}^k) = \lim_k \tau_k = f_*$.

Finally, for the remaining case of $\bar{k} < \infty$, use the monotonicity of $\{\tau_k = f(\hat{u}^k)\}_{k\ge\bar{k}}$ and the relations $\bar{\tau} = f(\bar{u})$, $h(\bar{u}) \le 0$ in the second to last paragraph to get $0 \in \partial e_C(\bar{u}; \bar{\tau})$ and $\bar{u} \in U_*$ from Lemma 2.2; the rest follows as before.

(iv) Use the proof of (iii), getting $\underline{\lim}_k f(\hat{u}^k) \ge f_*$ from Lemma 3.3.

(v) If $\bar{k} < \infty$, the set $\{u \in C : f(u) \le f(\hat{u}^{\bar{k}}), h(u) \le 0\}$ is bounded (such is U_*) and contains $\{\hat{u}^k\}_{k\ge\bar{k}}$. Suppose that $\bar{k} = \infty$. By Theorem 3.10(vi), there is $K' \subset K$ such that $\overline{\lim}_{k\in K'} f(\hat{u}^k) \le f_*$. Hence, for infinitely many k, $\hat{u}^k$ lies in the set $\{u \in C : f(u) \le f_* + 1, h(u) \le h(u^1)_+\}$, which is bounded (such is U_*). Therefore, $\{\hat{u}^k\}$ has a cluster point.

(vi) The set $\{u \in C : h(u) \le h(u^1)_+\}$ is bounded (such is U) and contains $\{\hat{u}^k\}$.

(vii) If $\bar{k} < \infty$, then for $k \ge \bar{k}$, $\hat{u}^k \in U$ implies $f(\bar{u}) = f_* \le f(\hat{u}^k) = \pi(\hat{u}^k; c_k + 1)$; together with Lemma 2.3, this validates our claim below (3.13). Let $k \in K$, $k \ge k'$.

Since (3.13) implies $e_C(\bar{u};\tau_k) \le e_C(\hat{u}^k;\tau_k)$ by Lemma 2.3, (3.14) yields $\langle p^k, \bar{u}-\hat{u}^k\rangle \le \epsilon_k$. Then, using the facts that $\hat{u}^{k+1}-\hat{u}^k = -t_k p^k$ by (2.18) and $v_k = t_k|p^k|^2+\epsilon_k$ by (2.23), we get

$$\begin{aligned}|\hat{u}^{k+1}-\bar{u}|^2 &= |\hat{u}^k-\bar{u}|^2 + 2\langle \hat{u}^{k+1}-\hat{u}^k, \hat{u}^k-\bar{u}\rangle + |\hat{u}^{k+1}-\hat{u}^k|^2\\ &\le |\hat{u}^k-\bar{u}|^2 + 2t_k\epsilon_k + 2t_k^2|p^k|^2 = |\hat{u}^k-\bar{u}|^2 + 2t_k v_k.\end{aligned}$$

Therefore, since $\overline{\lim}_{k\in K} t_k < \infty$, $\sum_{k\in K} v_k < \infty$ by (ii), and $|\hat{u}^{k+1}-\bar{u}|^2 = |\hat{u}^k-\bar{u}|^2$ if $k \notin K$, we deduce from [Pol83, Lem. 2.2.2] that the sequence $\{|\hat{u}^k-\bar{u}|\}$ converges. Thus the sequence $\{\hat{u}^k\}$ is bounded, and using (iii) we may choose $\bar{u} \in U_*$ as a cluster point of $\{\hat{u}^k\}$, in which case the sequence $\{|\hat{u}^k-\bar{u}|\}$ must converge to zero, i.e., $\hat{u}^k \to \bar{u}$.

(viii) Argue as for (ii) to get $\sum_{k\in K} v_k < \infty$. Since $v_k = t_k|p^k|^2+\epsilon_k$ (cf. (2.23)) and $\epsilon_k \ge 0$, we have $\underline{\lim}_{k\in K}|p^k|^2 = 0$ (using $\sum_{k\in K} t_k = \infty$) and $\lim_{k\in K}\epsilon_k = 0$. Thus, there is $\bar{K} \subset K$ such that $\epsilon_k, |p^k| \xrightarrow{\bar{K}} 0$. Let $\bar{u}$ be a cluster point of $\{\hat{u}^k\}_{k\in\bar{K}}$. To see that $\bar{u} \in U_*$, replace K by $\bar{K}$ in the proof of (iii). Hence, this point $\bar{u}$ may be used in the final part of the proof of (vii). □

Remark 3.13. (i) The condition $\epsilon_{\max} = 0$ in Theorem 3.12 means that the linearizations are exact *and* Step 3 is inactive. If we drop this condition in Step 3, so that Step 3 ensures $v_k \ge \kappa_h h_{\hat{u}}^k$ when $h_{\hat{u}}^k > 0$ in the exact case as well, then for $\epsilon_{\max} = 0$, both Theorems 3.12 and 3.10 hold with $\epsilon_f = \epsilon_h = 0$ in the bounds of (3.1).

(ii) Condition (3.13) was used in [SaS05, Prop. 4.3(ii)] with $c_k \equiv 0$. Since in this case, $f_* = \inf_C \pi(\cdot, c_k+1)$ iff $\bar{\mu} \le 1$ (cf. section 2.1), we conclude that at phase 1 ($\bar{k} = \infty$) condition (3.13) with $c_k \equiv 0$ may be expected to hold only if $\bar{\mu} \le 1$. (Also see section 4.4.)

4. Modifications. In this section we consider several useful modifications.

4.1. Alternative descent tests. As in [Kiw06a, section 4.3], at Steps 4 and 5 we may replace the predicted decrease $v_k = t_k|p^k|^2+\epsilon_k$ (cf. (2.23)) by the smaller quantity $w_k := t_k|p^k|^2/2+\epsilon_k$. Then Lemma 2.5(ii) is replaced by the fact that

$$w_k \ge -\epsilon_k \quad\Longleftrightarrow\quad t_k|p^k|^2/4 \ge -\epsilon_k \quad\Longleftrightarrow\quad w_k \ge t_k|p^k|^2/4.$$

Hence, $w_k \ge -\epsilon_k$ at Step 5 implies $w_k \le v_k \le 3w_k$ and $v_k \ge -\epsilon_k$ for the bounds (2.25)–(2.26), whereas for Step 4, the bound (2.27) is replaced by the fact that

$$V_k < (4\epsilon_{\max}/t_k)^{1/2}(1+|\hat{u}^k|) \quad \text{if} \quad w_k < -\epsilon_k.$$

The preceding results extend easily (in the proof of Lemma 3.7, $e_{k+1}(u^{k+1}) > [h_{\hat{u}}^k]_+ - \kappa w_k$ implies $e_{k+1}(u^{k+1}) > [h_{\hat{u}}^k]_+ - \kappa v_k$, whereas in the proofs of Theorems 3.9 and 3.10(i), we have $\sum_{k\in K} v_k \le 3\sum_{k\in K} w_k < \infty$). We add that [SaS05, Alg. 3.1] uses w_k instead of v_k.

As in [Kiw85, p. 227], we may replace the descent test (2.30) by the two-part test

$$h_u^{k+1} \le h_{\hat{u}}^k - \kappa v_k \qquad \text{if } h_{\hat{u}}^k > 0, \tag{4.1a}$$

$$f_u^{k+1} \le f_{\hat{u}}^k - \kappa v_k \quad\text{and}\quad h_u^{k+1} \le 0 \quad \text{if } h_{\hat{u}}^k \le 0. \tag{4.1b}$$

Since (2.30) implies (4.1), the latter test may produce faster convergence. In particular, at phase 2 ($h_{\hat{u}}^k \le 0$) the additional requirement $h_u^{k+1} \le -\kappa v_k$ of (2.30) may

hinder the progress of $\{\hat{u}^k\}$ towards the boundary of the feasible set. The preceding convergence results are not affected (since if (4.1) fails at a null step, then so does (2.30), whereas the requirements of (4.1) suffice for descent steps).

In connection with (4.1b), we add that if $h_{\hat{u}}^1 \le 0$, i.e., the starting point is approximately feasible, then the objective linearizations need not be defined at infeasible points. Specifically, if $h_u^{k+1} > 0$ in (4.1b), then a null step must occur; so we may skip evaluating f_u^{k+1} and choose $J_f^{k+1} \supset \hat{J}_f^k$ at Step 6 (without requiring $J_f^{k+1} \ni k+1$). In the proof of Lemma 3.7, using $v_k = -\check{e}_k(u^{k+1})$ (cf. (2.10)) and replacing (3.10) by

$$e_{k+1}(\cdot) := \begin{cases} f_{k+1}(\cdot) - f_{\hat{u}}^k & \text{if } h_u^{k+1} \le 0, \\ h_{k+1}(\cdot) & \text{otherwise,} \end{cases} \tag{4.2}$$

we see that (4.1b) can be expressed as $e_{k+1}(u^{k+1}) \le -\kappa v_k$ or equivalently by (3.11); this suffices for the proof. Similarly, if $h_u^{k+1} \le 0$, then we may skip finding the subgradient g_h^{k+1} and choose $J_h^{k+1} \supset \hat{J}_h^k$ at Step 6 (omitting $\check{h}_k$ in (2.8) if $J_h^k = \emptyset$).

4.2. Linearization aggregation. To trade off storage and work per iteration for speed of convergence, one may replace selection with aggregation, so that only $\bar{m} \ge 4$ subgradients are stored. To this end, we note that the preceding results remain valid if, for each k, $\check{f}_{k+1}$ and $\check{h}_{k+1}$ are closed convex functions such that $0 \in \partial\phi_k(u^{k+1})$ implies (2.11)–(2.13) for k increased by 1, and

$$\max\{\bar{f}_k(u), f_{k+1}(u)\} \le \check{f}_{k+1}(u) \le f(u) \quad \text{for all } u \in C, \tag{4.3a}$$

$$\max\{\bar{h}_k(u), h_{k+1}(u)\} \le \check{h}_{k+1}(u) \le h(u) \quad \text{for all } u \in C. \tag{4.3b}$$

(This extends some ideas of [CoL93].) The max terms above are needed only after null steps in the proof of Lemma 3.7, $\bar{f}_k$ is not needed if $\nu_k = 0$, and $\bar{h}_k$ is not needed if $\nu_k = 1$. The aggregate linearizations may be treated like the oracle linearizations. Indeed, letting $f_{-j} := \bar{f}_j$, $h_{-j} := \bar{h}_j$ for $j = 1, \dots, k$, to ensure that $\bar{f}_k \le \check{f}_{k+1}$ and $\bar{h}_k \le \check{h}_{k+1}$, we may work with $J_f^{k+1}, J_h^{k+1} \subset \{-k, -k+1, \dots, k+1\}$ in (2.31), replacing the set $\hat{J}_f^k$ or $\hat{J}_h^k$ by $\{-k\}$ when $\hat{J}_f^k$ or $\hat{J}_h^k$ is "too large."

To illustrate, consider the following scheme with *minimal aggregation*. First, suppose $|J_f^k| + |J_h^k| = \bar{m}$. If $|\hat{J}_f^k| + |\hat{J}_h^k| \le \bar{m} - 2$, remove from J_f^k or J_h^k two indices in $J_f^k \setminus \hat{J}_f^k$ or $J_h^k \setminus \hat{J}_h^k$. If $|\hat{J}_f^k| + |\hat{J}_h^k| = \bar{m} - 1$, set $J_f^k := \hat{J}_f^k$, $J_h^k := \hat{J}_h^k$; if $|\hat{J}_h^k| \ge 2$, remove two indices from $\hat{J}_h^k$ and set $J_h^k := \hat{J}_h^k \cup \{-k\}$; otherwise, remove two indices from $\hat{J}_f^k$ and set $J_f^k := \hat{J}_f^k \cup \{-k\}$. If $|\hat{J}_f^k| + |\hat{J}_h^k| = \bar{m}$, remove four indices from $\hat{J}_f^k$ or $\hat{J}_h^k$, and set $J_f^k := \hat{J}_f^k \cup \{-k\}$, $J_h^k := \hat{J}_h^k \cup \{-k\}$. Next, suppose $|J_f^k| + |J_h^k| = \bar{m} - 1$. If $|\hat{J}_f^k| + |\hat{J}_h^k| = \bar{m} - 1$, proceed as in the second case above. If $|\hat{J}_f^k| + |\hat{J}_h^k| \le \bar{m} - 2$, remove from J_f^k or J_h^k one index in $J_f^k \setminus \hat{J}_f^k$ or $J_h^k \setminus \hat{J}_h^k$. At this stage, $|J_f^k| + |J_h^k| \le \bar{m} - 2$; so set $J_f^{k+1} := J_f^k \cup \{k+1\}$, $J_h^{k+1} := J_h^k \cup \{k+1\}$. This scheme employs aggregation only where needed; for $\bar{m} \ge m + 3$, it reduces to selection (cf. Remark 2.7(vii)).

In practice, without storing the points u^j for $j \ge 1$, we may use the representations

$$f_j(\cdot) = f_j(\hat{u}^k) + \langle \nabla f_j, \cdot - \hat{u}^k \rangle \quad \text{and} \quad h_j(\cdot) = h_j(\hat{u}^k) + \langle \nabla h_j, \cdot - \hat{u}^k \rangle,$$

since after a descent step, we can update the linearization values

$$f_j(\hat{u}^{k+1}) = f_j(\hat{u}^k) + \langle \nabla f_j, \hat{u}^{k+1} - \hat{u}^k \rangle \quad \text{for } j \in J_f^{k+1}, \tag{4.4a}$$

$$h_j(\hat{u}^{k+1}) = h_j(\hat{u}^k) + \langle \nabla h_j, \hat{u}^{k+1} - \hat{u}^k \rangle \quad \text{for } j \in J_h^{k+1}. \tag{4.4b}$$

Let us now consider *total aggregation*, in which only $\bar{m} \geq 2$ linearizations need be stored. Define e_1 by (3.10) with $k = 0$ and $\tau_0 := \tau_1$. Let $J_e^1 := \{1\}$. For $k \geq 1$, having linearizations $e_j(\cdot) \leq e(\cdot; \tau_k)$ for $j \in J_e^k$, replace $\check{e}_k$ in (2.8) by the "overall" model

$$\check{e}_k(\cdot) := \max_{j \in J_e^k} e_j(\cdot) \tag{4.5}$$

of $e(\cdot; \tau_k)$; thus we still have $\check{e}_k(\cdot) \leq e(\cdot; \tau_k)$ without maintaining separate models of f and h. Then the optimality condition $0 \in \partial \phi_k(u^{k+1})$ yields the existence of a subgradient $p_e^k \in \partial \check{e}_k(u^{k+1})$ such that p_e^k replaces $\nu_k p_f^k + (1 - \nu^k) p_h^k$ in (2.12) and (2.18). Consequently, using the aggregate linearization

$$\bar{e}_k(\cdot) := \check{e}_k(u^{k+1}) + \langle p_e^k, \cdot - u^{k+1} \rangle \leq \check{e}_k(\cdot) \leq e(\cdot; \tau_k) \tag{4.6}$$

and replacing the definition (2.17) of the linearization $\bar{e}_C^k$ and its expression (2.20) by

$$\bar{e}_C^k(\cdot) := \bar{e}_k(\cdot) + \bar{\imath}_C^k(\cdot) = \check{e}_k(u^{k+1}) + \langle p^k, \cdot - u^{k+1} \rangle \tag{4.7}$$

yields (2.21)–(2.22) and Lemma 2.5 as before. With e_{k+1} given by (3.10), for linearization selection we may use multipliers γ_j^k of the pieces e_j, $j \in J_e^k$, such that

$$(p_e^k, 1) = \sum_{j \in J_e^k} \gamma_j^k (\nabla e_j, 1),\ \gamma_j^k \geq 0,\ \gamma_j^k \big[\check{e}_k(u^{k+1}) - e_j(u^{k+1})\big] = 0,\ j \in J_e^k, \tag{4.8}$$

to choose the set $J_e^{k+1} \supset \hat{J}_e^k \cup \{k+1\}$ with $\hat{J}_e^k := \{j \in J_e^k : \gamma_j^k \neq 0\}$. For aggregation (cf. (4.3)), after a null step the next model $\check{e}_{k+1}$ should satisfy

$$\max\big\{\bar{e}_k(u), e_{k+1}(u)\big\} \leq \check{e}_{k+1}(u) \leq e(u; \tau_k) \quad \text{for all } u \in C, \tag{4.9}$$

and it suffices to choose $J_e^{k+1} \supset \{-k, k+1\}$ with $e_{-k} := \bar{e}_k$. Note that (4.6) and the minorization $e_{k+1}(\cdot) \leq e(\cdot; \tau_k)$ (cf. (3.10)) yield $\check{e}_{k+1}(\cdot) \leq e(\cdot; \tau_k)$. To ensure that $e(\cdot; \tau_k)$ is still minorized by each $e_j(\cdot) = e_j(\hat{u}^k) + \langle \nabla e_j, \cdot - \hat{u}^k \rangle$ after a descent step, since $e(\cdot; \tau_{k+1}) \geq e(\cdot; \tau_k) - (\tau_{k+1} - \tau_k)_+$ (cf. (2.2)), we may update

$$e_j(\hat{u}^{k+1}) := e_j(\hat{u}^k) + \langle \nabla e_j, \hat{u}^{k+1} - \hat{u}^k \rangle - (\tau_{k+1} - \tau_k)_+. \tag{4.10}$$

Similarly, when τ_k increases to τ_k', say, at Steps 3 or 4, the update $e_j(\hat{u}^k) := e_j(\hat{u}^k) - \tau_k' + \tau_k$ provides the minorization $e_j(\cdot) \leq e(\cdot; \tau_k')$.

Although total aggregation needs only $\bar{m} \geq 2$ linearizations, whereas separate aggregation described below (4.3) needs $\bar{m} \geq 4$, in practice this difference is immaterial, since larger values of $\bar{m}$ are required for faster convergence anyway. On the other hand, total aggregation has a serious drawback: its update (4.10), being based on a crude pessimistic estimate, tends to make the linearizations e_j lower than necessary when $\tau_{k+1} \neq \tau_k$. In contrast, separate aggregation is not sensitive to changes of τ_k.

Similar techniques can be applied to the *composite model*

$$\check{e}_k(\cdot) := \max \left\{ \max_{j \in J_f^k} f_j(\cdot) - \tau_k, \max_{j \in J_h^k} h_j(\cdot), \max_{j \in J_e^k} e_j(\cdot) \right\}. \tag{4.11}$$

For instance, (4.9) holds if $J_f^{k+1} \ni k+1$, $J_h^{k+1} \ni k+1$, $J_e^{k+1} \ni -k$, but many other choices are possible.

Remark 4.1. We add that [SaS05, Alg. 3.1] employs the model (4.11) with

$$J_f^k := \{\, j \in J^k : f_u^j - \tau_k \geq h_u^j \,\} \quad \text{and} \quad J_h^k := \{\, j \in J^k : f_u^j - \tau_k < h_u^j \,\} \tag{4.12}$$

for an additional "oracle" set $J^k \subset \{1, \ldots, k\}$; then J^k and J_e^k are reduced if necessary so that $2|J^k| + |J_e^k| \leq \bar{m} - 3$ for a given $\bar{m} \geq 3$, and $J^{k+1} := J^k \cup \{k+1\}$, $J_e^{k+1} := J_e^k \cup \{-k\}$. First, this scheme is quite unusual: although $|J^k|$ "original" linearizations of f and h are maintained ($2|J^k|$ in total), only half of them are selected via (4.12) for the model (4.11), thus reducing the QP size from $2|J^k| + |J_e^k|$ to $|J^k| + |J_e^k|$. (This selection is unnecessary in the sense that even for $J_f^k = J_h^k = J^k$, the model (4.11) still satisfies $\check{e}_k(\cdot) \leq e(\cdot, \tau_k)$.) Second, its storage requirement of $\bar{m} \geq 3$ places it between total aggregation and separate aggregation. Third, this scheme employs the update of (4.10) for $j \in J_e^k$.

4.3. Estimating Lagrange multipliers. Suppose that $f_* > -\infty$, so that the dual optimal set $M := \operatorname{Arg\,max}_{\mathbb{R}_+} q$ is nonempty (cf. section 2.1). For $\bar{\epsilon} \geq 0$, the set of *$\bar{\epsilon}$-optimal dual solutions* is defined by

$$M_{\bar{\epsilon}} := \{\, \mu \in \mathbb{R}_+ : q(\mu) \geq f_* - \bar{\epsilon} \,\}. \tag{4.13}$$

We now develop conditions under which the *Lagrange multiplier estimates*

$$\mu_k := (1 - \nu_k)/\nu_k \tag{4.14}$$

converge to the set $M_{\bar{\epsilon}}$ for a suitable $\bar{\epsilon} \geq 0$, where ν_k is the multiplier of (2.12)–(2.13).

Since $\nu_k \in [0, 1]$ by (2.13), (2.14)–(2.19) yield the sharper version of (2.22):

$$\nu_k \big[f(u) - \tau_k \big] + (1 - \nu_k) h(u) \geq \big[h_{\hat{u}}^k \big]_+ - V_k \big(1 + |u| \big) \quad \text{for all } u \in C. \tag{4.15}$$

If $\nu_k > 0$ (e.g., $V_k < -h(\mathring{u})/(1 + |\mathring{u}|)$), then (4.14) with $\mu_k \in \mathbb{R}_+$ and (4.15) give

$$f(u) + \mu_k h(u) \geq \tau_k - V_k \big(1 + |u| \big)/\nu_k \quad \text{for all } u \in C. \tag{4.16}$$

LEMMA 4.2. (i) *Suppose that $f_* > -\infty$. Let $K' \subset \mathbb{N}$ be such that $V_k \overset{K'}{\longrightarrow} 0$ and*

$$\varliminf_{k \in K'} \tau_k \geq f_* - \epsilon_f - \bar{\mu} \epsilon_h, \tag{4.17}$$

where $\bar{\mu} := \inf_{\mu \in M} \mu$ (cf. section 2.1). Then $\overline{\lim}_{k \in K'} \mu_k < \infty$ and $V_k/\nu_k \overset{K'}{\longrightarrow} 0$. Moreover, the sequence $\{\mu_k\}_{k \in K'}$ converges to the set $M_{\bar{\epsilon}}$ given by (4.13) for $\bar{\epsilon} := \epsilon_f + \bar{\mu} \epsilon_h$.

(ii) *If $f_* > -\infty$, then a set K' satisfying the requirements of* (i) *exists under the assumptions of Theorems* 3.8, 3.9, *or* 3.10 *or those of Theorem* 3.12 *if additionally either* $\inf\{k : h(\hat{u}^k) \leq 0\} < \infty$ *or* $|\hat{u}^k| \not\to \infty$ (*e.g., the optimal set U_* is nonempty and bounded*).

Proof. (i) By (4.17), $\tau_\infty := \varliminf_{k \in K'} \tau_k \geq f_* - \bar{\epsilon}$. If we had $\varliminf_{k \in K'} \nu_k = 0$, for $u = \mathring{u}$, (4.15) would yield in the limit $0 > h(\mathring{u}) \geq 0$, a contradiction. Hence, $\varliminf_{k \in K'} \nu_k > 0$, so that $V_k/\nu_k \overset{K'}{\longrightarrow} 0$ and $\overline{\lim}_{k \in K'} \mu_k < \infty$ by (4.14). Let μ_∞ be any cluster point of $\{\mu_k\}_{k \in K'}$; then $\mu_\infty \in \mathbb{R}_+$. Passing to the limit in (4.16) bounds the Lagrangian values as follows:

$$L(u; \mu_\infty) := f(u) + \mu_\infty h(u) \geq \tau_\infty \quad \text{for all } u \in C.$$

Hence, $q(\mu_\infty) \geq \tau_\infty \geq f_* - \bar{\epsilon}$ implies $\mu_\infty \in M_{\bar{\epsilon}}$ by (4.13). Since μ_∞ was an arbitrary cluster point of $\{\mu_k\}_{k \in K'} \subset \mathbb{R}_+ \cup \{\infty\}$ and $\overline{\lim}_{k \in K'} \mu_k < \infty$, the conclusion follows.

(ii) In Theorem 3.8, $\tau_k = f_{\hat{u}}^{\bar{k}}$ for all $k \geq \bar{k}$ (and we may take $K' = K$). In Theorem 3.9, $\tau_k \to f_{\hat{u}}^\infty \in [f_* - \epsilon_f - \bar{\mu} \epsilon_h, f_*]$ and $\varliminf_{k \in K} V_k = 0$. For the rest, see Theorems 3.10(ii, v) and 3.12(i, iv, v), noting that $|\hat{u}^k| \not\to \infty$ iff $\{\hat{u}^k\}$ has a cluster point. ∎

4.4. Updating the penalty coefficient in the exact case. We first show how to choose the penalty coefficient c_k by using the Lagrange multiplier estimate μ_k of (4.14) to ensure the "convergence" condition (3.13) of Theorem 3.12(vii).

LEMMA 4.3. *Under the assumptions of Theorem* 3.12*, suppose that* $|\hat{u}^k| \not\to \infty$. *Moreover, suppose that for all large* k*, after a descent step, Step* 7 *chooses* $c_{k+1} \geq \max\{\mu_k, c_k\}$ *if* $\mu_k < \infty$, $c_{k+1} \geq c_k$ *otherwise. Then there exists* k' *such that condition* (3.13) *holds for any* $\bar{u} \in U_*$.

Proof. By Theorem 3.12(iv), the assumptions of Lemma 4.2(i) hold for some $K' \subset K$, $\epsilon_f = \epsilon_h = \bar{\epsilon} = 0$; thus, $\{\mu_k\}_{k\in K'}$ converges to $M_0 = M$, and $\underline{\lim}_{k\in K'} \mu_k \geq \bar{\mu} := \inf_{\mu\in M} \mu$ implies $\mu_k \geq \bar{\mu} - 1$ for all large $k \in K'$. Hence, since $\{c_k\}$ is nondecreasing for large k, we have $c_k \geq \bar{\mu} - 1$ for all large k, and the conclusion follows from Theorem 3.12(vii). ∎

Remark 4.4. Variations on the strategy of Lemma 4.3 are possible. For instance, if $\{\hat{u}^k\}$ is bounded (e.g., U is bounded), Step 7 may choose $c_{k+1} \geq \mu_k$ after each descent step when $\mu_k < \infty$; this suffices for the proof of Lemma 4.3 with $K' = K$ by Theorem 3.12(iii).

We shall exploit the following basic property of the exact penalty function (2.1).

LEMMA 4.5. *If* $c \geq \bar{\mu}$, *then* $\pi(u; c) \geq f_* + (c - \bar{\mu})h(u)_+$ *for all* $u \in C$.

Proof. By (2.1), $\pi(u; c) = L(u; \bar{\mu}) + (c-\bar{\mu})h(u)_+ + \bar{\mu}[h(u)_+ - h(u)]$ for each $u \in C$, where $L(u; \bar{\mu}) \geq q(\bar{\mu}) = f_*$ (cf. section 2.1), $\bar{\mu} \geq 0$, and $h(u)_+ \geq h(u)$. ∎

For phase 1 in the exact case (when Step 3 is inactive), the main difficulty lies in ensuring $h(\hat{u}^k) \downarrow 0$. Complementing Theorem 3.12, we now show that it suffices if the penalty parameter c_k majorizes strictly the minimal Lagrange multiplier $\bar{\mu}$ asymptotically, and we give a specific update of c_k, based on a simple idea: increase the penalty coefficient if the constraint violation is large relative to the optimality measure (cf. [Kiw91]).

LEMMA 4.6. *Under the assumptions of Theorem* 3.12*, suppose that* $h(\hat{u}^k) > 0$ *for all* k. *Then we have the following statements*:

(i) *There is* $K' \subset K$ *such that* $V_k \xrightarrow{K'} 0$ *and* $\overline{\lim}_{k\in K'} f(\hat{u}^k) \leq \overline{\lim}_{k\in K'} \tau_k \leq f_*$.

(ii) *If* $c_\infty := \underline{\lim}_k c_k > \bar{\mu}$, *then* $h(\hat{u}^k) \downarrow 0$.

(iii) *Suppose that for all large* k*, after a descent step, Step* 7 *chooses* $c_{k+1} \geq 2c_k$ *if* $h(\hat{u}^{k+1}) > V_k$, $c_{k+1} \geq c_k$ *otherwise,* $c_{k+1} > 0$ *when* $h(\hat{u}^{k+1}) > 0$. *If* $f_* > -\infty$, *then* $h(\hat{u}^k) \downarrow 0$.

(iv) *If* $h(\hat{u}^k) \downarrow 0$, *then* $\underline{\lim}_k \tau_k \geq \underline{\lim}_k f(\hat{u}^k) \geq f_*$, *and* $f(\hat{u}^k) \xrightarrow{K'} f_*$ *in* (i) *above.*

Proof. (i) This follows from Theorem 3.10(vi).

(ii) By (i) and Lemma 4.5, $f_* \geq \underline{\lim}_k \tau_k \geq f_* + (c_\infty - \bar{\mu}) \underline{\lim}_k h(\hat{u}^k)_+$ with $c_\infty > \bar{\mu}$ yields $\underline{\lim}_k h(\hat{u}^k)_+ = 0$. Hence, $h(\hat{u}^k) \downarrow 0$, using $0 < h(\hat{u}^{k+1}) \leq h(\hat{u}^k)$ by (2.34a).

(iii) If $c_\infty := \lim_k c_k < \infty$, then $h(\hat{u}^{k+1}) \leq V_k$ for all large $k \in K$; so by (i), $V_k \xrightarrow{K'} 0$ yields $h(\hat{u}^k) \downarrow 0$. Otherwise, $c_\infty = \infty > \bar{\mu}$ (from $f_* > -\infty$), and (ii) applies.

(iv) Invoke Lemma 3.3 with $\epsilon_f = \epsilon_h = 0$, and use the fact that $\tau_k \geq f(\hat{u}^k)$. ∎

5. Column generation for LP problems. In this section we consider the following primal-dual pair of LP problems:

$$\min\ c\lambda \quad \text{s.t.} \quad A\lambda \geq b,\ \lambda \geq 0, \tag{5.1}$$

$$\max\ ub \quad \text{s.t.} \quad uA \leq c,\ u \geq 0, \tag{5.2}$$

where $c \in \mathbb{R}^n$, $A \in \mathbb{R}^{m\times n}$, $b \in \mathbb{R}^m$. We assume that $c > 0$. Let A_i denote column i of A for $i \in I := \{1\colon n\}$. When the number of columns is huge, problems (5.1)–(5.2)

may be solved by column generation, provided that for each $u \geq 0$, one can solve the *column generation subproblem* of finding $i_u \in \operatorname{Arg\,max}_{i \in I}(uA_i - c_i)$. We show that this subproblem may be solved inexactly when our method is applied to the dual problem (5.2) formulated as (1.1) and that approximate solutions to (5.1) can be recovered at no extra cost.

To ease subsequent notation, let us rewrite the LP problems (5.1)–(5.2) as follows:

$$\max\ \psi_0(\lambda) := -c\lambda \quad \text{s.t.} \quad \psi(\lambda) := A\lambda - b \geq 0,\ \lambda \in \mathbb{R}^n_+, \tag{5.3}$$

$$\min\ f(u) := -ub \quad \text{s.t.} \quad uA \leq c,\ u \in \mathbb{R}^m_+. \tag{5.4}$$

We regard the dual problem (5.4) as (1.1) with $C := \mathbb{R}^m_+$ and the constraint function

$$h(\cdot) := \max_{i \in I}\bigl(\langle A_i, \cdot\rangle - c_i\bigr). \tag{5.5}$$

Since $c > 0$, $\mathring{u} := 0$ may serve as the Slater point. For our method applied to (1.1), we assume that f is evaluated exactly (i.e., $\epsilon_f = 0$ and $f_k = f$), whereas the approximate linearization condition (2.4b) boils down to finding an index $i_k \in I$ such that

$$h_k(\cdot) = \langle A_{i_k}, \cdot\rangle - c_{i_k} \quad \text{with} \quad h_k(u^k) \geq h(u^k) - \epsilon_h. \tag{5.6}$$

By duality, f_* is the common optimal value of (5.3) and (5.4). In view of Lemma 4.2, we assume that $f_* > -\infty$ and let $K' \subset \mathbb{N}$ be the set such that $V_k \xrightarrow{K'} 0$ and (4.17) holds; then $\nu_k > 0$ and $\mu_k := (1 - \nu_k)/\nu_k < \infty$ for large $k \in K'$. We shall show that the corresponding subsequence of the multipliers $\{\mu_k \beta^k_j\}_{j \in J^k_h}$ of (2.28b) solves the primal problem (5.3) approximately; thus, below we consider only $k \in K'$ such that $\nu_k > 0$.

The multipliers $\{\mu_k \beta^k_j\}_{j \in J^k_h}$ define an *approximate primal solution* $\hat{\lambda}^k \in \mathbb{R}^n_+$ via

$$\hat{\lambda}^k_i := \mu_k \sum_{j \in J^k_h : i_j = i} \beta^k_j \quad \text{for each } i \in I.$$

Let $\underline{1} := (1, \dots, 1) \in \mathbb{R}^n$. In this notation, using the form (5.6) of the linearizations h_j in (2.28b) and the fact that $\mu_k \check{h}_k(u^{k+1}) = \mu_k \check{e}_k(u^{k+1})$ (cf. (2.13)) yields the relations

$$\mu_k p^k_h = A\hat{\lambda}^k, \quad \mu_k = \underline{1}\hat{\lambda}^k, \quad \hat{\lambda}^k \geq 0, \quad (u^{k+1}A - c)\hat{\lambda}^k = \mu_k \check{e}_k(u^{k+1}). \tag{5.7}$$

We first derive useful expressions for the primal function values $\psi_0(\hat{\lambda}^k)$ and $\psi(\hat{\lambda}^k)$.

LEMMA 5.1. $\psi_0(\hat{\lambda}^k) = \tau_k + ([h^k_{\hat{u}}]_+ - \epsilon_k - \langle p^k, \hat{u}^k\rangle)/\nu_k$, $\psi(\hat{\lambda}^k) = (p^k - p^k_C)/\nu_k \geq p^k/\nu_k$.

Proof. Since $p^k_f = \nabla f = -b$ (cf. (2.11), (5.4)), $\mu_k p^k_h = A\hat{\lambda}^k$ by (5.7), and $\nu_k \mu_k = 1 - \nu_k$ by (4.14), the definitions of $\psi(\lambda)$ in (5.3) and of p^k in (2.18) give

$$\nu_k \psi(\hat{\lambda}^k) = \nu_k\bigl(A\hat{\lambda}^k - b\bigr) = \nu_k p^k_f + (1 - \nu_k)p^k_h = p^k - p^k_C,$$

where $p^k_C \in \partial i_{\mathbb{R}^m_+}(u^{k+1})$ implies $p^k_C \leq 0$ and $\langle p^k_C, u^{k+1}\rangle = 0$. Next, by (5.7) and (2.18),

$$\begin{aligned} \nu_k c\hat{\lambda}^k + (1 - \nu_k)\check{e}_k(u^{k+1}) &= \langle \nu_k \mu_k p^k_h, u^{k+1}\rangle \\ &= \langle (1 - \nu_k)p^k_h + p^k_C, u^{k+1}\rangle = \langle p^k - \nu_k p^k_f, u^{k+1}\rangle, \end{aligned}$$

where $\nu_k\langle p_f^k, u^{k+1}\rangle = \nu_k \check{f}_k(u^{k+1}) = \nu_k \check{e}_k(u^{k+1}) + \nu_k\tau_k$ by (2.13). Hence,

$$-\nu_k c\hat{\lambda}^k - \nu_k\tau_k = \check{e}_k(u^{k+1}) - \langle p^k, u^{k+1}\rangle = \bar{e}_C^k(0) = \big[h_{\hat{u}}^k\big]_+ - \langle p^k, \hat{u}^k\rangle - \epsilon_k,$$

where we have used (2.20)–(2.21). Dividing by ν_k gives the required expression of $\psi_0(\hat{\lambda}^k) := -c\hat{\lambda}^k$; for $\psi(\hat{\lambda}^k)$, see the first displayed equality above. ∎

In terms of the optimality measure V_k of (2.19), the bounds of Lemma 5.1 imply

$$\hat{\lambda}^k \geq 0 \quad \text{with} \quad \psi_0(\hat{\lambda}^k) \geq \tau_k - V_k/\nu_k, \quad \psi_i(\hat{\lambda}^k) \geq -V_k/\nu_k, \quad i = 1\colon m. \tag{5.8}$$

We now show that $\{\hat{\lambda}^k\}_{k\in K'}$ converges to the set of $\bar{\epsilon}$-*optimal primal solutions*

$$\Lambda_{\bar{\epsilon}} := \big\{\, \lambda \in \mathbb{R}^n_+ : \psi_0(\lambda) \geq f_* - \bar{\epsilon}, \psi(\lambda) \geq 0 \,\big\}, \tag{5.9}$$

where $\bar{\epsilon} := \bar{\mu}\epsilon_h$, with $\bar{\mu}$ being the minimal Lagrange multiplier of (1.1); in our context, we may as well take (a possibly larger) $\bar{\mu} := \underline{1}\bar{\lambda}$ for any primal solution $\bar{\lambda}$ of (5.3).

THEOREM 5.2. *Suppose that $f_* > -\infty$. Let $K' \subset \mathbb{N}$ be such that $V_k \xrightarrow{K'} 0$ and* (4.17) *holds* (*see Lemma* 4.2(ii) *for sufficient conditions*). *Then we have the following statements*:

(i) *The sequence $\{\hat{\lambda}^k\}_{k\in K'}$ is bounded and all its cluster points lie in $\mathbb{R}^n_+$.*

(ii) *Let $\hat{\lambda}^\infty$ be a cluster point of $\{\hat{\lambda}^k\}_{k\in K'}$. Then $\hat{\lambda}^\infty \in \Lambda_{\bar{\epsilon}}$.*

(iii) $d_{\Lambda_{\bar{\epsilon}}}(\hat{\lambda}^k) := \inf_{\lambda\in\Lambda_{\bar{\epsilon}}} |\hat{\lambda}^k - \lambda| \xrightarrow{K'} 0$.

Proof. By Lemma 4.2, $\overline{\lim}_{k\in K'} \mu_k < \infty$ and $V_k/\nu_k \xrightarrow{K'} 0$. Since $\underline{\lim}_{k\in K'} \tau_k \geq f_* - \bar{\epsilon}$ by (4.17), (5.8) yields $\underline{\lim}_{k\in K'} \psi_0(\hat{\lambda}^k) \geq f_* - \bar{\epsilon}$ and $\underline{\lim}_{k\in K'} \min_{i=1}^n \psi_i(\hat{\lambda}^k) \geq 0$.

(i) This follows from $\overline{\lim}_{k\in K'} \underline{1}\hat{\lambda}^k = \overline{\lim}_{k\in K'} \mu_k < \infty$ (cf. (5.7)) and $\hat{\lambda}^k \geq 0$.

(ii) We have $\hat{\lambda}^\infty \geq 0$, $\psi_0(\hat{\lambda}^\infty) \geq f_* - \bar{\epsilon}$, and $\psi(\hat{\lambda}^\infty) \geq 0$ by continuity of ψ_0 and ψ.

(iii) Use (i), (ii), and the continuity of the distance function $d_{\Lambda_{\bar{\epsilon}}}$. ∎

Remark 5.3. (i) By Remark 3.11(ii), we may use $\bar{\epsilon} := \bar{\mu}\epsilon_h^\infty$ for Theorem 5.2.

(ii) By Lemma 3.1(iii) and the proof of Theorem 5.2, if an infinite loop between Steps 1 and 4 occurs, then $V_k \to 0$ yields $d_{\Lambda_{\bar{\epsilon}}}(\hat{\lambda}^k) \to 0$. Similarly, if Step 2 terminates with $V_k = 0$, then $\hat{\lambda}^k \in \Lambda_{\bar{\epsilon}}$. In both cases, we may take $\bar{\epsilon} := \bar{\mu}\epsilon_h^{k(l)}$ by Remark 3.11(ii).

(iii) Given two tolerances $\epsilon_{\rm F}, \epsilon_{\rm tol} > 0$, the method may stop if $h_{\hat{u}}^k \leq \epsilon_{\rm F}$,

$$\psi_0(\hat{\lambda}^k) \geq f(\hat{u}^k) - \epsilon_{\rm tol} \quad \text{and} \quad \psi_i(\hat{\lambda}^k) \geq -\epsilon_{\rm tol}, \quad i = 1\colon m.$$

Then $\psi_0(\hat{\lambda}^k) \geq f_* - \bar{\mu}(\epsilon_h + \epsilon_{\rm F}) - \epsilon_{\rm tol}$ from $f(\hat{u}^k) \geq f_* - \bar{\mu}(\epsilon_h + \epsilon_{\rm F})$; so $\hat{\lambda}^k$ is an approximate solution of (5.3). This stopping criterion will be met when $V_k/\nu_k \leq \epsilon_{\rm tol}$.

We add that our numerical experiments (to be reported elsewhere) on the test problems of [Kiw05, KiL07, SaS05] indicate that our method is quite sensitive to constraint scaling; yet, with proper scaling, it can perform quite well.

Acknowledgments. I would like to thank the Associate Editor, the two anonymous referees, and Claude Lemaréchal for helpful comments.

IMPROVED APPROXIMATION ALGORITHMS FOR WEIGHTED HYPERGRAPH EMBEDDING IN A CYCLE*

HANN-JANG HO† AND SINGLING LEE‡

Abstract. We consider the problem of embedding weighted hyperedges of a hypergraph as paths in a cycle on the same number of vertices, such that the maximum congestion of any physical link of the cycle is minimized. The problem, called weighted hypergraph embedding in a cycle (WHEC), is known to be NP-complete even when each hyperedge is unweighted or each weighted hyperedge contains exactly two vertices. In this paper, we propose an improved rounding algorithm for the WHEC problem to provide a solution with an approximation bound of $1.5(opt + w_{max})$, where opt represents the optimal value of the problem and w_{max} denotes the largest weight of hyperedges. For any fixed $\varepsilon > 0$, we also present a polynomial time algorithm to provide an embedding whose congestion is at most $(1.5 + \varepsilon)$ times the optimum. This improves previous results for the general WHEC problem.

1. Introduction.

The problem of weighted hypergraph embedding in a cycle (WHEC) is to embed m weighted hyperedges of a hypergraph as paths in an n-vertex cycle, such that the maximum congestion of any physical link in the cycle is minimized. Note that each vertex of the hypergraph actually is the same as the vertex in the cycle; i.e., the problem of mapping vertices between hypergraph and cycle is not considered here. The WHEC problem is NP-complete even when each hyperedge is unweighted or each weighted hyperedge contains exactly two vertices [1].

In the first special case when each hyperedge is unweighted, the unweighted version of the WHEC problem has many applications in electronic design automation [2, 3]. Several studies related to the unweighted WHEC problem have been performed. Frank et al. [4] and Gonzalez and Lee [2] proposed linear time algorithms to solve the problem when all hyperedges contain exactly only two vertices. Ganley and Cohoon [5] showed that the unweighted WHEC problem is NP-complete in general but solvable in polynomial time if the maximum congestion is bounded by a constant. Gonzalez [6] proposed two improved approximation algorithms that both generate solutions with maximum congestion at most two times the optimum. Carpenter et al. [7] provided a linear time approximation algorithm which routes the hyperedges in the clockwise direction starting from the lowest numbered vertex to the highest numbered vertex. This algorithm is also guaranteed to find a solution whose value is at most twice the optimal value. Recently, Gu and Wang presented an algorithm to solve the unweighted WHEC problem with the performance ratio 1.8 by a

reembedding technique [8]. Lee and Ho presented an LP-based algorithm to solve the problem with the performance ratio 1.5 [9]. Deng and Li proposed a polynomial time approximation scheme (PTAS) for the unweighted WHEC problem by a randomized rounding approach [10].

In the second special case when each weighted hyperedge contains exactly two vertices, the graph version of the WHEC problem is equivalent to the ring loading problem without demand splitting. When each demand must be entirely routed in either of the two directions, the ring loading problem is NP-complete [11]. Cosares and Saniee presented a polynomial time algorithm that approximates the optimal solution value to within a multiplicative factor of two [11]. Schrijver, Seymour, and Winkler developed an efficient algorithm to generate a solution that exceeds the optimum by at most an additive term of 1.5 times the maximum weight [12]. Khanna proposed a PTAS that computes a solution with at most $(1+\varepsilon)$ times the optimum for any fixed $\varepsilon > 0$ [13].

The WHEC problem has many applications, including minimizing communication congestions in computer networks and parallel computations. These applications focus on minimizing the maximum congestions of multicast transmissions over any physical communication link. For example, in computer networks, the hypergraph embedding problem is equivalent to a multicast congestion problem [16, 17, 18] when each hyperedge is formed as a multicast tree (i.e., Steiner tree). Several studies related to the multicast congestion problem on more general graphs have been performed. Vempala and Vöcking [16] presented a randomized rounding algorithm for approximating multicast congestion to within $O(\log n)$ times the optimum. Carr and Vempala [17] proposed a randomized asymptotic algorithm for the multicast congestion problem to find a solution of congestion $O(opt + \log n)$, where *opt* is the optimal value of the maximum congestion. Jansen and Zhang [18] presented an improved approximation algorithm to overcome the difficulties of an exponential number of variables.

We are concerned with the general WHEC problem. In [1], an LP-based rounding algorithm and a linear time algorithm had been proposed to find a solution with maximum congestion at most two times the optimum. In this paper, we propose an improved (2/3)-rounding algorithm to provide a solution with an approximation bound of $1.5(opt + w_{max})$, where *opt* represents the optimal value of the problem and w_{max} denotes the largest weight of hyperedges. For any fixed $\varepsilon > 0$, we also present a PTAS to provide an embedding whose congestion is at most $(1.5+\varepsilon)$ times the optimum. This improves the previous approximation results [1] for the general WHEC problem.

2. Notation and problem definition. The WHEC problem is to embed the weighted hyperedges of a hypergraph as the paths in a cycle, such that the maximum congestion of any physical link in the cycle is minimized. We denote the cycle as $C = (V, E_c)$, where $V = \{1, 2, \ldots, n\}$ is a set of vertices and $E_c = \{(i, i+1) | 1 \leq i \leq n-1\} \bigcup \{(n, 1)\}$ is a set of physical links. The vertices of the cycle are labelled clockwise by 1 through n, and each edge in the cycle is referred to as an undirected link. A hypergraph $H = (V, E_h)$ with m weighted hyperedges is defined over the same set of vertices V, where $E_h = \{h_1, h_2, \ldots, h_m\}$ is a set of hyperedges. The hyperedge h_i consists of $|h_i|$ vertices with a nonnegative weight w_i for interconnecting these vertices. In particular, these interconnected vertices of hyperedge h_i are represented as an ordered sequence $(v_1^i, v_2^i, \ldots, v_{|h_i|}^i)$, i.e., $v_1^i \leq v_2^i \leq \cdots \leq v_{|h_i|}^i$. For example, a hypergraph $H = \{h_1, h_2, h_3\}$ is embedded in an 8-vertex cycle as shown in Figure 1.

We denote the jth adjacent path of hyperedge h_i as $p(i, j)$, where $p(i, j)$ is a

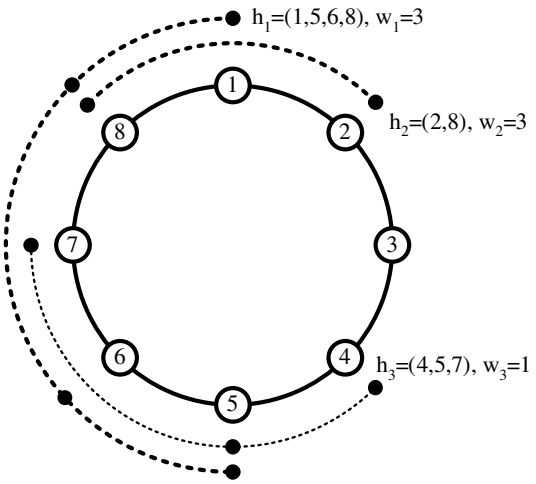

FIG. 1. *A weighted hypergraph* $H = \{h_1, h_2, h_3\}$ *is embedded in an* 8*-vertex cycle. The link* $(8, 1)$ *has the maximum congestion of* 6 *that is an optimal solution.*

clockwise connecting path between v_j^i and v_{j+1}^i in the cycle C, and the last adjacent path $p(i, |h_i|)$ of the hyperedge h_i is connected between $v_{|h_i|}^i$ and v_1^i. Obviously, vertices $v_1^i, v_2^i, \ldots, v_{|h_i|}^i$ in the hyperedge h_i must be connected by at least $|h_i| - 1$ adjacent paths to ensure the connectivity. We define an assignment of adjacent paths to embed the hypergraph H in the cycle C as a set of binary variables $Y = \{y_{p(i,j)} | \forall i \in \{1, 2, \ldots, m\}, j \in \{1, 2, \ldots, |h_i|\}\}$, where $y_{p(i,j)} = 1$ if an adjacent path $p(i, j)$ is embedded in the cycle C, and $y_{p(i,j)} = 0$ otherwise. Therefore, a feasible assignment of adjacent paths can be expressed as $\sum_{1 \le j \le |h_i|} y_{p(i,j)} \ge |h_i| - 1 \; \forall h_i \in E_h$. Moreover, we denote $P(e)$ as a set of adjacent paths that pass through the link $e \in E_c$. Therefore, the WHEC problem can be formally defined as follows.

DEFINITION 2.1. *The problem of minimizing the maximum congestion for WHEC is as follows*: *Given a cycle* $C = (V, E_c)$ *and a weighted hypergraph* $H = (V, E_h)$, *find a feasible assignment* Y *of adjacent paths to embed the hypergraph* H *in the cycle* C *such that the maximum congestion* φ *over any link in* E_c *is minimized. Note that each hyperedge* h_i *is associated with a nonnegative weight* w_i *and the maximum link congestion of an assignment* Y *can be expressed as* $\varphi = \max_{e \in E_c} \{\sum_{p(i,j) \in P(e)} y_{p(i,j)} w_i\}$, *where* $y_{p(i,j)} = 1$ *if the* $p(i, j)$ *is embedded in the cycle* C, *and* $y_{p(i,j)} = 0$ *otherwise.*

3. Mixed integer linear programming. The WHEC problem can be modelled as a mixed integer linear programming (MILP) formulation. We define a set of binary variables $Y = \{y_{p(i,j)} | \forall i \in \{1, 2, \ldots, m\}, j \in \{1, 2, \ldots, |h_i|\}\}$ to represent the assignment of adjacent paths to embed the hypergraph H in the cycle C, where $y_{p(i,j)} = 1$ if an adjacent path $p(i, j)$ is embedded in the cycle C, and $y_{p(i,j)} = 0$ otherwise. Each hyperedge h_i is associated with a nonnegative weight w_i. Our objective is to minimize the maximum congestion φ over all links in E_c. We formulate an MILP model to solve the problem as follows:

$\Phi(Y)$: Minimize φ

Subject to

$$\sum_{1\le j\le |h_i|} y_{p(i,j)} \ge |h_i| - 1 \quad \forall h_i \in E_h, \quad i \in \{1,2,\ldots,m\} \quad \text{(connectivity constraints)},$$

$$\sum_{p(i,j)\in P(e)} y_{p(i,j)} w_i \le \varphi \quad \forall e \in E_c \quad \text{(capacity constraints)},$$

$$y_{p(i,j)} \in \{0,1\} \quad \forall i \in \{1,2,\ldots,m\}, \quad j \in \{1,2,\ldots,|h_i|\} \quad \text{(binary variables)}.$$

There are two classes of constraints in this problem. First, the connectivity constraints mean that each hyperedge $h_i \in E_h$ must be connected by at least $|h_i| - 1$ adjacent paths. Second, the capacity constraints ensure that each physical link $e \in E_c$ can only be embedded with hyperedges at most the maximum congestion φ. Finally, the objective function $\Phi(Y)$ of the MILP is to minimize the maximum congestion φ. Note that φ is a continuous variable since the binary variable $y_{p(i,j)}$ is multiplied by a weight w_i which is a nonnegative real constant.

Suppose that we relax the integer constraints of Y and require only that $0 \le y_{p(i,j)} \le 1$ $\forall i,j$; this linear program is called the LP relaxation of the MILP formulation, and the LP solution immediately provides a lower bound on the minimum congestion. On the other hand, finding a tight upper bound for the MILP formulation presents a difficult challenge. However, the LP-rounding technique can commonly be applied to find an upper bound and generate an approximate solution. Let $\varphi^* = \Phi(Y^*)$ and $\varphi^L = \Phi(Y^L)$ be the optimal solutions of MILP formulation and LP relaxation, respectively. If the solution for the LP-rounding is φ^R, then we have $\varphi^L \le \varphi^* \le \varphi^R$.

The next lemma states that the value of the kth smallest variable in $\{y^L_{p(i,j)} \mid 1 \le j \le |h_i|\}$ is at least $(k-1)/k$ for every hyperedge $h_i \in E_h$. This implies that the value of the second smallest variable is at least $1/2$. Therefore, a $(1/2)$-rounding approach can be applied to generate an approximate solution $\varphi^R = \Phi(Y^R)$, where we assign $y^R_{p(i,j)} = 1$ if $y^L_{p(i,j)} \ge 1/2$, and $y^R_{p(i,j)} = 0$ otherwise. The $(1/2)$-rounding approach always produce a 2-approximated solution for the WHEC problem [1].

LEMMA 3.1. *For every hyperedge $h_i \in E_h$, $|h_i| \ge k$, $i \in \{1,2,\ldots,m\}$, the value of the kth smallest variable in $\{y^L_{p(i,j)} \mid 1 \le j \le |h_i|\}$ is at least $(k-1)/k$.*

Proof. From connectivity constraints, the solution of LP relaxation must ensure that $\sum_{1\le j\le |h_i|} y^L_{p(i,j)} \ge |h_i| - 1$ $\forall y^L_{p(i,j)} \in [0,1]$. In an extreme case, values from the $(k+1)$st smallest variable to the greatest variable are equal to 1, and we need to distribute the value $k-1$ into k smaller variables. We know that the value of the largest element in the k smaller variables is at least $(k-1)/k$. ∎

4. 1.5(opt+w_{max}) approximation. In this section, we apply a $(2/3)$-rounding approach to generate an approximate solution $\varphi^R = \Phi(Y^R)$, where we assign $y^R_{p(i,j)} = 1$ if $y^L_{p(i,j)} \ge 2/3$, and $y^R_{p(i,j)} = 0$ otherwise. Lemma 4.1 states that the maximum congestion of the rounding approach is at most 1.5 times the optimal congestion of the WHEC problem when the value of the smallest LP variable in $\{y^L_{p(i,j)} \mid 1 \le j \le |h_i|\}$ is at most $1/3$; i.e., $\min_{1\le j\le |h_i|}\{y^L_{p(i,j)}\} \le 1/3$ for every hyperedge $h_i \in E_h$, $i \in \{1,2,\ldots,m\}$.

LEMMA 4.1. *The maximum congestion of the $(2/3)$-rounding approach is at most 1.5 times the optimum if $\min_{1\le j\le |h_i|}\{y^L_{p(i,j)}\} \le 1/3$ for every hyperedge $h_i \in E_h$, $i \in \{1,2,\ldots,m\}$.*

Proof. Let $\varphi^R = \Phi(Y^R)$ be the solution of the $(2/3)$-rounding approach. First, we show that $\Phi(Y^R)$ is a feasible solution if the condition of $\min_{1\le j\le |h_i|}\{y^L_{p(i,j)}\} \le 1/3$

$\forall h_i \in E_h$ is satisfied. According to connectivity constraints, any solution to LP relaxation must satisfy that $\sum_{1\le j\le|h_i|} y^L_{p(i,j)} \ge |h_i| - 1$ for every hyperedge $h_i \in E_h$, $i \in \{1, 2, \ldots, m\}$. If the value of the smallest LP variable in $\{y^L_{p(i,j)} \mid 1 \le j \le |h_i|\}$ is at most 1/3, we know that the value of the second smallest LP variable is at least 2/3. This implies that the sum of rounded values $\sum_{1\le j\le|h_i|} y^R_{p(i,j)}$ is at least $|h_i| - 1$ $\forall i \in \{1, 2, \ldots, m\}$. Each hyperedge $h_i \in E_h$ is continuously connected, and hence the solution $\Phi(Y^R)$ is feasible. Next, we show that $\varphi^R \le 1.5\varphi^*$. If $y^R_{p(i,j)}$ is rounded to 1, then $y^L_{p(i,j)}$ has a value at least 2/3. Therefore, we have $y^R_{p(i,j)} \le (3/2)y^L_{p(i,j)}$ $\forall i, j$. From the capacity constraints, we have $\sum_{p(i,j)\in P(e)} y^R_{p(i,j)} w_i \le \varphi^R \le \sum_{p(i,j)\in P(e)} (3/2) y^L_{p(i,j)} w_i \le (3/2)\varphi^L \le (3/2)\varphi^*$ $\forall e \in E_c$. □

When $\min_{1\le j\le|h_i|}\{y^L_{p(i,j)}\} \le 1/3$ $\forall h_i \in E_h$, the (2/3)-rounding approach generates a feasible solution whose value is at most 1.5 times the optimum. However, the solution of the (2/3)-rounding algorithm may be infeasible if the condition is unsatisfied. In this case, we will propose a $1.5(opt + w_{max})$ approximation algorithm on the condition that $\min_{1\le j\le|h_i|}\{y^L_{p(i,j)}\} > 1/3$, $\exists h_i \in E_h$.

From Lemma 3.1, the value of the kth smallest variable in $\{y^L_{p(i,j)} \mid 1 \le j \le |h_i|\}$ is at least $(k-1)/k$ for each hyperedge $h_i \in E_h$. If the (2/3)-rounding algorithm is applied to generate an approximate solution, the third smallest variable and these $|h_i|-3$ larger variables will certainly be rounded to 1. If the condition $\min_{1\le j\le|h_i|}\{y^L_{p(i,j)}\} \le 1/3$ is unsatisfied, values of the first and second smallest variables are both less than 2/3 and will be truncated to 0 by the (2/3)-rounding algorithm. In this case, the hyperedge h_i is disconnected, and we need to round either the first or second smallest variable to 1 for ensuring the connectivity of the hyperedge.

Let D be the set of disconnected hyperedges in the output of the (2/3)-rounding algorithm, i.e., $D = \{h_i | \sum_{1\le j\le|h_i|} y^R_{p(i,j)} = |h_i| - 2, 1 \le i \le m\}$. The problem of rounding selection for the smallest two variables on $h_i \in D$ can be translated into the ring loading problem without demand splitting. The ring loading problem was studied by Cosares and Saniee [11], Schrijver, Seymour, and Winkler [12], Wilfong and Winkler [14], Khanna [13], and Myung [15]. When each demand must be entirely routed in either of the two directions, the ring loading problem is NP-complete. Here we need only to consider the unsplitting subproblem of the ring loading problem. In this case, each separated variable in D must be merged and entirely routed in either of the two directions.

Let $y^L_{g(i,k)}$ be the kth smallest LP variable for the hyperedge h_i, where $g(i,k)$ represents the corresponding adjacent path for the kth smallest variable. If the adjacent path $g(i,2)$ for the second smallest variable is connected around the cycle from vertex s_i to vertex t_i in the clockwise direction, we rearrange the adjacent path $g(i,1)$ for connecting in the other way around the cycle from t_i to s_i. Now we define new variables as $y^M_{g(i,2)} = \frac{3}{2} y^L_{g(i,2)}$ and $y^M_{g(i,1)} = 1 - y^M_{g(i,2)}$. For each disconnected hyperedge $h_i \in D$, we need to round either $y^M_{g(i,1)}$ or $y^M_{g(i,2)}$ to 1 for ensuring the connectivity of the hyperedge h_i. Our objective is to find an optimal rounding assignment of $y^R_{g(i,1)}$ and $y^R_{g(i,2)}$ for each disconnected hyperedge $h_i \in D$ such that the maximum increment of weighted load, denoted as Δ, over any physical link in the cycle is minimized. The next lemma shows that the translation is valid.

LEMMA 4.2. *For each disconnected hyperedge $h_i \in D$, we have $(y^M_{g(i,2)} + y^R_{g(i,2)})w_i \le \frac{3}{2} y^L_{g(i,2)} w_i$ and $(y^M_{g(i,1)} + y^R_{g(i,j)})w_i \le \frac{3}{2} y^L_{g(i,j)} w_i$ $\forall j \ne 2$.*

Proof. Consider a disconnected hyperedge $h_i \in D$ from the output of (2/3)-

rounding algorithm. From Lemma 3.1, the value of the third smallest LP variable $y^L_{g(i,3)}$ of h_i is at least 2/3. Since the hyperedge h_i is disconnected, both the first and second smallest LP variables should be less than 2/3, i.e., $y^L_{g(i,1)} \le y^L_{g(i,2)} < \frac{2}{3}$. Therefore, we have $y^R_{g(i,1)} = 0$, $y^R_{g(i,2)} = 0$, and $y^R_{g(i,j)} = 1\ \forall j \ge 3$. It is trivial that $(y^M_{g(i,2)} + y^R_{g(i,2)})w_i \le \frac{3}{2}y^L_{g(i,2)}w_i$, since we define $y^M_{g(i,2)} = \frac{3}{2}y^L_{g(i,2)}$ and we know that $y^R_{g(i,2)} = 0$. Next, we show that $(y^M_{g(i,1)} + y^R_{g(i,1)})w_i \le \frac{3}{2}y^L_{g(i,1)}w_i$. From the definition, we have $y^M_{g(i,1)} = 1 - \frac{3}{2}y^L_{g(i,2)}$. Since $y^R_{g(i,1)} = 0$ and we know that $y^L_{g(i,1)} + y^L_{g(i,2)} \ge 1$ from Lemma 3.1, we have $(y^M_{g(i,1)}+y^R_{g(i,1)})w_i = (1-\frac{3}{2}y^L_{g(i,2)})w_i \le (1-\frac{3}{2}(1-y^L_{g(i,1)}))w_i < \frac{3}{2}y^L_{g(i,1)}w_i$. Finally, we show that $(y^M_{g(i,1)} + y^R_{g(i,j)})w_i \le \frac{3}{2}y^L_{g(i,j)}w_i$, $3 \le j \le |h_i|$. Since $y^R_{g(i,1)} = 0$, $y^L_{g(i,1)} < \frac{2}{3}$ and we know that $y^L_{g(i,1)} + y^L_{g(i,2)} + y^L_{g(i,3)} \ge 2$ from Lemma 3.1, we have $y^L_{g(i,2)} \ge 2 - y^L_{g(i,1)} - y^L_{g(i,3)} > 2 - \frac{2}{3} - y^L_{g(i,3)} = \frac{4}{3} - y^L_{g(i,3)}$. Then, for $j \ge 3$, we have $y^L_{g(i,2)} \ge \frac{4}{3} - y^L_{g(i,j)}$ since $y^L_{g(i,j)} \ge y^L_{g(i,3)}$. We thus have $(y^M_{g(i,1)} + y^R_{g(i,j)})w_i = (1 - \frac{3}{2}y^L_{g(i,2)} + y^R_{g(i,j)})w_i \le (2 - \frac{3}{2}(\frac{4}{3} - y^L_{g(i,j)}))w_i = \frac{3}{2}y^L_{g(i,j)}w_i$ for any $j \ge 3$. □

Next, we extend the merging and sequential rounding techniques [12, 14] from the ring loading problem to ensure $\sum_{p(i,j)\in P(e)} y^R_{p(i,j)}w_i \le \frac{3}{2}(w_{max}+\sum_{p(i,j)\in P(e)} y^L_{p(i,j)}w_i) \le \frac{3}{2}(opt + w_{max})\ \forall e \in E_c$. Here *opt* represents the optimal value of the problem and w_{max} denotes the largest weight of hyperedges, i.e., $opt = \varphi^*$ and $w_{max} = \max\{w_i \mid 1 \le i \le m\}$. In order to apply the merging and sequential rounding techniques for the unsplitting problem, we represent the notation of adjacent paths $g(i,1)$ and $g(i,2)$ for each disconnected hyperedge $h_i \in D$ in clockwise order around the cycle. Let $s(i,1)$ and $s(i,2)$, respectively, be the first and second adjacent paths of h_i in clockwise order around the cycle (sequencing from vertex 1). Now, given the adjacent paths $s(i,1)$ and $s(i,2)$ with translative variables $y^M_{s(i,1)}$ and $y^M_{s(i,2)}$ for all disconnected hyperedge $h_i \in D$, our objective is to find an optimal rounding assignment of $y^R_{s(i,1)}$ and $y^R_{s(i,2)}$ such that the maximum increment of weighted load over any physical link in the cycle is minimized. Two disconnected hyperedges h_i and h_j are said to be *crossing* if both their two adjacent paths $s(i,1)$, $s(i,2)$ and $s(j,1)$, $s(j,2)$ intersect on at least one physical link. Otherwise, they are said to be *noncrossing*. The next lemma describes how to merge two noncrossing hyperedges into a connected hyperedge without increasing the total load over any physical link.

LEMMA 4.3. *If two disconnected hyperedges are noncrossing, they can be merged into a connected hyperedge without increasing the total load over any physical link.*

Proof. Suppose that two disconnected hyperedges h_i and h_j are noncrossing. Without loss of generality, we assume that their noncrossing adjacent paths are given as Figure 2(a). In this figure, we assume that $a = w_i$, $a_1 = y^M_{s(i,1)}w_i$, $a_2 = y^M_{s(i,2)}w_i$, $b = w_j$, $b_1 = y^M_{s(j,1)}w_j$, and $b_2 = y^M_{s(j,2)}w_j$, respectively. If $y^M_{s(j,2)}w_j \ge (1 - y^M_{s(i,1)})w_i$ (see Figure 2(b)), we output an unsplitting assignment to ensure the connectivity of the hyperedge h_i by setting $y^R_{s(i,1)} = y^M_{s(i,1)} = 1$, $y^R_{s(i,2)} = y^M_{s(i,2)} = 0$, and $D = D - \{h_i\}$. Then we define a new splitting assignment for the hyperedge h_j by setting $y^M_{s(j,1)} = y^M_{s(j,1)} + y^M_{s(i,2)}(w_i/w_j)$ and $y^M_{s(j,2)} = y^M_{s(j,2)} - (1 - y^M_{s(i,1)})(w_i/w_j)$. The new load on each physical link is either unchanged or reduced. And, the new splitting assignment for the hyperedge h_j keeps the same property of $y^M_{s(j,1)} + y^M_{s(j,2)} = 1$. On the other hand, if $y^M_{s(j,2)}w_j < (1-y^M_{s(i,1)})w_i$ (see Figure 2(c)), we output an unsplitting assignment to ensure the connectivity of hyperedge h_j by setting $y^R_{s(j,1)} = y^M_{s(j,1)} = 1$,

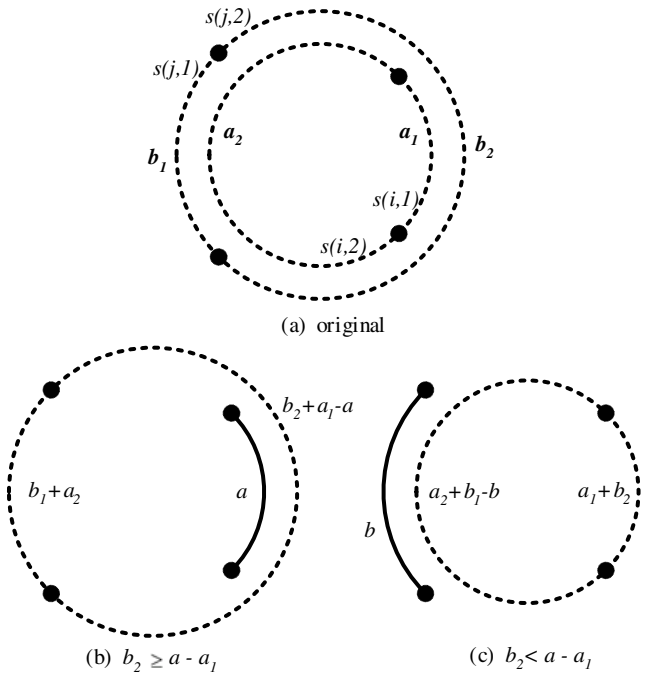

FIG. 2. *Merge two disconnected hyperedges into a connected hyperedge.*

$y^R_{s(j,2)} = y^M_{s(j,2)} = 0$, and $D = D - \{h_j\}$. Similarly, we define a new splitting assignment for the hyperedge h_i by setting $y^M_{s(i,1)} = y^M_{s(i,1)} + y^M_{s(j,2)}(w_j/w_i)$ and $y^M_{s(i,2)} = y^M_{s(i,2)} - (1 - y^M_{s(j,1)})(w_j/w_i)$. In this case, the load on each physical link and the property for the hyperedge h_i are also properly maintained. □

The merging procedure can be performed repeatedly without increasing the maximum load over any physical link; i.e., the maximum load increment Δ in the cycle is zero. Since each time we reduce by one the total number of disconnected hyperedges, this procedure will terminate in at most $|D|$ steps until no two disconnected hyperedges contain a pair of noncrossing adjacent paths. Nevertheless, not all adjacent paths of disconnected hyperedges are noncrossing. Let S be the set of remnant disconnected hyperedges. We perform a sequential rounding technique to round each remnant variable in the clockwise direction around the cycle. In the following algorithm, we combine the (2/3)-rounding, merging, and sequential rounding techniques for ensuring an approximation bound of $1.5(opt + w_{max})$. Here *opt* represents the optimal value of the problem and w_{max} denotes the largest weight of hyperedges, i.e., $w_{max} = \max\{w_i \mid 1 \le i \le m\}$.

ALGORITHM 1. *The improved* (2/3)*-rounding algorithm.*

Step (1). *Solve optimally the LP relaxation of the MILP formulation. Let the optimal solution be* $\Phi(Y^L)$, *where* $Y^L = [y^L_{p(i,j)}]$ *and* $0 \le y^L_{p(i,j)} \le 1$.

Step (2). $\forall i, j, let y^R_{p(i,j)} = 1$ *if* $y^L_{p(i,j)} \ge 2/3$, *and* $y^R_{p(i,j)} = 0$ *otherwise.*

Step (3). *Let* $D = \{h_i \mid \sum_{1 \le j \le |h_i|} y^R_{p(i,j)} = |h_i| - 2, 1 \le i \le m\}$ *be the set of disconnected hyperedges. Let* $g(i,j)$ *denote the adjacent path with the* j*th smallest LP variable for the hyperedge* $h_i \in D$. *Rearrange the adjacent path* $g(i,1)$ *and assign* $y^M_{g(i,2)} = \frac{3}{2} y^L_{g(i,2)}$ *and* $y^M_{g(i,1)} = 1 - y^M_{g(i,2)}$, *respectively.*

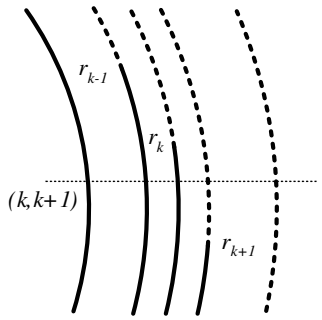

FIG. 3. *The link* $(k, k+1)$ *is crossed by the adjacent paths* $s(r_1, 1)$, $s(r_2, 1), \ldots, s(r_k, 1)$, $s(r_{k+1}, 2)$, $s(r_{k+2}, 2), \ldots, s(r_{|S|}, 2)$.

Step (4). *Given the adjacent paths* $g(i, j)$ *and translative variables* $y^M_{g(i,j)}$ $\forall h_i \in D$, $j \in \{1, 2\}$, *perform the merging procedure on* D *repeatedly until only crossing adjacent paths remain.*

Step (5). *Let* S *be the set of remnant hyperedges. For each hyperedge* $h_i \in S$, *let* $y^M_{s(i,1)}$ *and* $y^M_{s(i,2)}$, *respectively, be the first and second variables of* h_i *in clockwise order. And let* $r_1, r_2, \ldots, r_{|S|}$ *be the labels of hyperedges in* S *in clockwise sequential order.*

Step (6). *Let* $y^R_{s(r_1,1)} = 1$ *and* $y^R_{s(r_1,2)} = 0$ *if* $y^M_{s(r_1,1)} > 0.5$; *otherwise let* $y^R_{s(r_1,1)} = 0$ *and* $y^R_{s(r_1,2)} = 1$.

Step (7). $\forall 2 \le k \le |S|$, *if* $(1-y^M_{s(r_k,1)})w_k + \sum_{i\in\{r_1,\ldots,r_{k-1}\}}(y^R_{s(i,1)} - y^M_{s(i,1)})w_i < w_{max}/2$, *then let* $y^R_{s(r_k,1)} = 1$ *and* $y^R_{s(r_k,2)} = 0$; *otherwise let* $y^R_{s(r_k,1)} = 0$ *and* $y^R_{s(r_k,2)} = 1$. *Due to the complementary nature, we have* $\sum_{i\in\{r_1,\ldots,r_k\}}(y^R_{s(i,1)} - y^M_{s(i,1)})w_i \in [-\frac{w_{max}}{2}, \frac{w_{max}}{2})$ *and* $\sum_{i\in\{r_1,\ldots,r_k\}}(y^R_{s(i,2)} - y^M_{s(i,2)})w_i \in (-\frac{w_{max}}{2}, \frac{w_{max}}{2}]$.

Step (8). *Output the approximate solution* $\varphi^R = \Phi(Y^R)$ *of the maximum congestion.*

THEOREM 4.4. *The improved* (2/3)*-rounding algorithm has an approximation bound of* $1.5(opt + w_{max})$, *where opt represents the optimal value of the problem and* w_{max} *denotes the largest weight of hyperedges.*

Proof. Step (6) ensures that $(y^R_{s(r_1,1)} - y^M_{s(r_1,1)})w_{r_1} \in [-\frac{w_{r_1}}{2}, \frac{w_{r_1}}{2})$ and $(y^R_{s(r_1,2)} - y^M_{s(r_1,2)})w_{r_1} \in (-\frac{w_{r_1}}{2}, \frac{w_{r_1}}{2}]$. By induction, if the partial sum $\sum_{i\in\{r_1,\ldots,r_{k-1}\}}(y^R_{s(i,1)} - y^M_{s(i,1)})w_i$ from r_1 to r_{k-1} is given and places in the interval $[-\frac{w_{max}}{2}, \frac{w_{max}}{2})$, then we define $y^R_{s(k,1)}$ sequentially around the cycle from r_1 to $r_{|S|}$ by Step (7) for ensuring $\sum_{i\in\{r_1,\ldots,r_k\}}(y^R_{s(i,1)} - y^M_{s(i,1)})w_i \in [-\frac{w_{max}}{2}, \frac{w_{max}}{2})$. Due to the complementary nature, we also have $\sum_{i\in\{r_1,\ldots,r_k\}}(y^R_{s(i,2)} - y^M_{s(i,2)})w_i \in (-\frac{w_{max}}{2}, \frac{w_{max}}{2}]$.

For any physical link $(k, k+1) \in E_c$, we assume without loss of generality that it is crossed by two partitions of sequential hyperedges $r_1, r_2, \ldots, r_k$ and $r_{k+1}, r_{k+2}, \ldots, r_{|S|}$, as shown in Figure 3. Therefore, the increment of congestion of the link $(k, k+1)$ is at most $\Delta_k = \sum_{i\in\{r_1,\ldots,r_k\}}(y^R_{s(i,1)} - y^M_{s(i,1)})w_i + \sum_{i\in\{r_{k+1},\ldots,r_{|S|}\}}(y^R_{s(i,2)} - y^M_{s(i,2)})w_i = \sum_{i\in\{r_1,\ldots,r_k\}}(y^R_{s(i,1)} - y^M_{s(i,1)})w_i + \sum_{i\in\{r_1,\ldots,r_{|S|}\}}(y^R_{s(i,2)} - y^M_{s(i,2)})w_i - \sum_{i\in\{r_1,\ldots,r_k\}}(y^R_{s(i,2)} - y^M_{s(i,2)})w_i \le \frac{w_{max}}{2} + \frac{w_{max}}{2} - (-\frac{w_{max}}{2}) = \frac{3}{2}w_{max}$. We thus have $\Delta = \max_k\{\Delta_k\} \le \frac{3}{2}w_{max}$. Therefore, from Lemma 4.1, we have an approximation bound of $1.5(opt + w_{max})$. ∎

5. (1.5+ε) approximation. The improved (2/3)-rounding algorithm generates a feasible solution whose value is at most $1.5(opt+w_{max})$. Clearly, if the optimal value *opt* of maximum congestion is large, the additional term of the maximum weight w_{max} of hyperedges can be translated into a relatively small deviation in value from the optimal solution. However, the value of optimal solution may be near the maximum weight of hyperedges, and the additive error term could be a significant deviation from the optimum. In this section we will apply the PTAS in [13] to show that for any fixed $\varepsilon > 0$, there is a polynomial time algorithm that yields a $(1.5 + \varepsilon)$ approximation.

Let φ^T denote the value of approximate solution of the (1/2)-rounding algorithm [1]. The approximate solution of the (1/2)-rounding algorithm is always feasible, and it ensures that $\varphi^T \leq 2\varphi^*$. On the other hand, if the improved (2/3)-rounding algorithm is applied to generate an approximate solution, we need to round either the first or second smallest variable of a disconnected hyperedge to 1 for ensuring the connectivity. In Algorithm 1, we denote S as the set of these disconnected hyperedges. A hyperedge in S is said to be *heavy* if its weight is at least $\frac{1}{3}\varepsilon\varphi^T$ and *light* otherwise. Let S_H and S_L, respectively, denote the subsets of heavy and light hyperedges in S. The following lemma bounds the total number of heavy hyperedges in S_H.

LEMMA 5.1. *The set S_H contains at most $\frac{3n}{2\varepsilon}$ hyperedges, i.e., $|S_H| \leq \frac{3n}{2\varepsilon}$.*

Proof. Each hyperedge in S_H has weight at least $\frac{1}{3}\varepsilon\varphi^T \leq \frac{2}{3}\varepsilon\varphi^*$. In an ideal case, these hyperedges are routed in one hop and shared out equally among n physical links in the cycle. Obviously, the maximum congestion on any physical link is at least $\frac{2}{3}\varepsilon\varphi^* \frac{|S_H|}{n}$. This gives a lower bound on the maximum congestion for embedding all hyperedges in S_H. Hence we have $\frac{2}{3}\varepsilon\varphi^* \frac{|S_H|}{n} \leq \varphi^*$. Rearranging the term, we get $|S_H| \leq \frac{3n}{2\varepsilon}$. ∎

For every disconnected hyperedge in S_H, we need to choose one of two adjacent paths for ensuring the connectivity. If the longer of the two adjacent paths is selected for connecting a disconnected hyperedge along the cycle, we say that the hyperedge is routed in the long way. The next lemma bounds the total number of heavy hyperedges that could be routed in the long way for any optimal routing.

LEMMA 5.2. *In any optimal routing, at most $3/\varepsilon$ heavy hyperedges are embedded in the long way.*

Proof. Suppose to the contrary that more than $3/\varepsilon$ heavy hyperedges were routed in the long way in the optimal solution. Since the hyperedge must be routed at least $\lceil n/2 \rceil$ physical links in the long way, the total weight induced by those heavy hyperedges in the long way is more than $\lceil n/2 \rceil \times \frac{2}{3}\varepsilon\varphi^* \times 3/\varepsilon \geq n\varphi^*$. By the pigeonhole principle, there must be some links with congestion more than the optimal value $\frac{n\varphi^*}{n} = \varphi^*$, which contradicts the optimality of the optimal routing. ∎

Since the largest weight of hyperedges in S_L is less than $\frac{1}{3}\varepsilon\varphi^T \leq \frac{2}{3}\varepsilon\varphi^*$, we can perform the clockwise sequential rounding algorithm on S_L to generate an approximation with a bound of $\frac{3}{2}w_{max} < \frac{3}{2} \times \frac{2}{3}\varepsilon\varphi^* = \varepsilon\varphi^*$. On the other hand, we need to exhaustively try all possible ways to find the optimal solution for embedding all hyperedges in S_H. Fortunately, the time complexity of the exhaustive search is bounded by a polynomial function of the problem size.

LEMMA 5.3. *For an exhaustive search on S_H, the total number of times for searching is bounded by $k(\frac{en}{2})^k$, where $k = 3/\varepsilon$.*

Proof. Since the set S_H contains at most $\frac{3n}{2\varepsilon}$ hyperedges, we need only to choose at most $3/\varepsilon$ heavy hyperedges from S_H for embedding them in the long way. Let $k = 3/\varepsilon$. The number of choices is bounded by $\sum_{i=0}^{k} \binom{\frac{kn}{2}}{i}$. From the well-known

inequality $\binom{x}{y} \leq (\frac{ex}{y})^y$, we have

$$\sum_{i=0}^{k} \binom{\frac{kn}{2}}{i} \leq \sum_{i=0}^{k} \left(\frac{e \times kn}{2i} \right)^i \leq k \left(\frac{en}{2} \right)^k.$$

Thus, the total running time of exhaustive search on S_H is bounded by a polynomial function of n. □

THEOREM 5.4. *For any fixed $\varepsilon > 0$, there is a polynomial time algorithm whose approximate solution is within $(1.5 + \varepsilon)$ times the optimum for the general WHEC problem.*

6. Conclusion. This paper concerns the problem of WHEC and focuses on the impact of the maximum congestion. We formulate the problem as a MILP and propose an improved (2/3)-rounding algorithm to provide a solution with an approximation bound of $1.5(opt + w_{max})$, where opt represents the optimal value of the WHEC problem and w_{max} denotes the largest weight of hyperedges. If the value of optimal solution is near the maximum weight of hyperedges, then the additive error term w_{max} could be a significant deviation from the optimum. For any fixed $\varepsilon > 0$, we also present a polynomial time approximation algorithm to provide an embedding whose congestion is at most $(1.5 + \varepsilon)$ times the optimum. To our knowledge, this is the best approximation bound known for the general problem of embedding weighted hypergraph in a cycle. However, the main problem with the LP-based approximation is the time required to solve the linear program. To improve the efficiency, it is worthwhile to look into ways of making better use of the congestion information for obtaining a simple heuristic algorithm with a tighter approximation bound.

Acknowledgments. The author thanks the editor and anonymous reviewers for their constructive comments.

ERRATUM: MESH ADAPTIVE DIRECT SEARCH ALGORITHMS FOR CONSTRAINED OPTIMIZATION*

CHARLES AUDET†, A. L. CUSTÓDIO‡, AND J. E. DENNIS, JR.§

Abstract. In [*SIAM J. Optim.*, 17 (2006), pp. 188–217] Audet and Dennis proposed the class of *mesh adaptive direct search* (MADS) *algorithms* for minimization of a nonsmooth function under general nonsmooth constraints. The notation used in the paper evolved since the preliminary versions, and, unfortunately, even though the statement of Proposition 4.2 is correct, it is not compatible with the final notation. The purpose of this note is to show that the proposition is valid.

Key words. mesh adaptive direct search algorithms, constrained optimization, nonsmooth optimization

DOI. 10.1137/060671267

In [1] Audet and Dennis proposed the class of *mesh adaptive direct search* (MADS) *algorithms* for minimization of a nonsmooth function under general nonsmooth constraints. The paper contains a convergence analysis for this class of methods and proposes two variants of an implementable instance called LTMADS.

The proof that LTMADS is indeed an instance of MADS is not compatible with the notation used in the rest of the paper. We restate the proposition and propose a consistent proof.

PROPOSITION 0.1 (Proposition 4.2 of [1]). *At each iteration k, the procedure above yields a D_k and a MADS frame P_k such that*

$$P_k = \{x_k + \Delta_k^m d : d \in D_k\} \subset M_k,$$

where $\Delta_k^m > 0$ is the mesh size parameter, M_k is given by Definition 2.1 of [1], and D_k is a positive spanning set such that for each $d \in D_k$,

- *d can be written as a nonnegative integer combination of the directions in D: $d = Du$ for some vector $u \in \mathbb{N}^{n_D}$ that may depend on the iteration number k;*
- *the distance from the frame center x_k to a frame point $x_k + \Delta_k^m d \in P_k$ is bounded above by a constant times the poll size parameter: $\Delta_k^m \|d\|_\infty \leq \Delta_k^p \max\{\|d'\|_\infty : d' \in D\}$;*
- *limits (as defined in Coope and Price [2]) of convergent subsequences of the normalized sets $\overline{D_k} := \{\frac{d}{\|d\|_\infty} : d \in D_k\}$ are positive spanning sets.*

Proof. In order to construct the set of directions D_k, the algorithm builds matrices at iteration k that should be called L_k, B_k, and B'_k. To ease the presentation, we omit the index k in the proof of the two first bullets. The index k reappears in the proof of the last bullet since this last result involves limits as k goes to infinity.

By the construction in [1], L is a lower triangular $(n-1)\times(n-1)$ matrix where each term on the diagonal is either plus or minus 2^ℓ, and the lower components are randomly chosen from the discrete set $\{-2^\ell+1,-2^\ell+2,\ldots,2^\ell-1\}$, with ℓ an integer that satisfies $2^\ell = 1/\sqrt{\Delta_k^m}$. The rules for updating the mesh size parameter Δ_k^m ensure that $\ell \in \mathbb{N}$. It follows that L is a basis in $\mathbb{R}^{n-1}$ with $|\det(L)| = 2^{\ell(n-1)}$. Let $\{p_1, p_2, \ldots, p_{n-1}\}$ be a random permutation of the set $\{1,2,\ldots,n\}\setminus\{\hat{\imath}\}$, where $\{\hat{\imath}\}$ is defined in [1]. The elements of the matrix B are defined as

$$\begin{array}{ll} B_{p_i,j} = L_{i,j} & \text{for } i,j = 1,2,\ldots,n-1,\\ B_{\hat{\imath},j} = 0 & \text{for } j = 1,2,\ldots,n-1,\\ B_{i,n} = b_i(\ell) & \text{for } i = 1,2,\ldots,n,\end{array}$$

where $b_i(\ell)$ is a vector that depends only on the value of the mesh size parameter and not on the iteration number (see section 4.1 of [1]). It follows that B is a permutation of the rows and the columns of a lower triangular matrix whose diagonal elements are either -2^ℓ or 2^ℓ. Therefore B is a basis in $\mathbb{R}^n$ and $|\det(B)| = 2^{\ell n}$.

The square matrix B' is obtained by permuting the columns of B, and therefore the columns of B' form a basis of $\mathbb{R}^n$. Furthermore, $|\det(B')| = |\det(B)| = 2^{\ell n}$.

One of the proposed versions of LTMADS uses a minimal positive basis at every iteration, and the other variant uses a maximal positive basis at every iteration. The columns of $[B' \;\; -b']$ with $b'_i = \sum_{j\in N} B'_{ij}$ define a minimal positive basis, and the columns of $[B' \;\; -B']$ define a maximal positive basis [3].

Therefore, if $D_k = [B' \;\; -b']$ or if $D_k = [B' \;\; -B']$, then all entries of D_k are integers in the interval $[-n2^\ell, n2^\ell]$ or in the interval $[-2^\ell, 2^\ell]$, respectively. It follows that each column d of D_k can be written as a nonnegative integer combination of the columns of $D = [I \;\; -I]$. Hence, the frame defined by D_k is on the mesh M_k.

Two cases must be considered to show the second bullet. Recall that with LTMADS, the poll size parameter Δ_k^p (see [1]) is defined differently depending on whether minimal or maximal positive bases are used. If the maximal positive basis construction is used, then $\|\Delta_k^m d\|_\infty = \Delta_k^m \|d\|_\infty = \sqrt{\Delta_k^m} = \Delta_k^p$. If the minimal positive basis construction is used, then $\|\Delta_k^m d\|_\infty = \Delta_k^m \|d\|_\infty \le n\sqrt{\Delta_k^m} = \Delta_k^p$. The proof of the second bullet follows by noticing that $\max\{\|d'\|_\infty : d' \in [I \;\; -I]\} = 1$.

To show the third bullet, we will verify that the limit of the normalized sets $\overline{D_k} := \{\frac{d}{\|d\|_\infty} : d \in D_k\}$ forms a positive basis. It suffices to show that the conditions (1a), (1b), and (C1) or (C2) of Coope and Price [2] hold.

- Conditions (1a) and (1b) ensure that the limit of any convergent subsequence of the sequence of bases $\overline{B'_k} := \{\frac{d}{\|d\|_\infty} : d \in B'_k\}$ is also a basis. Condition (1a) requires that $|\det(\overline{B'_k})|$ be bounded below by a positive constant that is independent of k. In our context, $|\det(\overline{B'_k})| = 1$ for all k, and therefore this condition is satisfied. Condition (1b) is also easily satisfied since normalized directions are used. It follows that the limit of $\overline{B'_k}$ is a basis.
- Conditions (C1) and (C2) involve the columns added to each basis B'_k to form a positive basis. In the case of the maximal bases, condition (C1) is easily satisfied. For the minimal bases, (C2) holds since all the structure constants ξ (again following the definition of Coope and Price [2]) satisfy $-1 \le \xi \le -\frac{1}{n}$.

This concludes the proof. ∎
