[3]The fact that a fully-supported problem is one where the RP_m are fully-supported with probability 1, as opposed to *always* fully-supported, is a source of a bit of complication in the proof. On the other hand, requiring always fully-supportedness is too limitative since, e.g., extracting the same constraint m times results in a non-fully-supported P_m.

To establish (10) in a more concrete way, consider one of the sets $S_{\mathcal{I}}$, e.g., the set $S_{\bar{\mathcal{I}}}$ where the support constraints indexes are $1, \ldots, d$. Also let $\widetilde{S}_{\bar{\mathcal{I}}}$ be the set where $\delta^{(d+1)}, \ldots, \delta^{(m)}$ are not violated by the solution generated by $\delta^{(1)}, \ldots, \delta^{(d)}$. It is an intuitive fact that $S_{\bar{\mathcal{I}}}$ and $\widetilde{S}_{\bar{\mathcal{I}}}$ are the same up to a probability 0 set. To streamline the presentation, we accept in the following this fact for granted; however, the interested reader can find full details at the end of this Part 1 of the proof.

We next compute $\mathbb{P}^m\{\widetilde{S}_{\bar{\mathcal{I}}}\}$, which is the same as $\mathbb{P}^m\{S_{\bar{\mathcal{I}}}\}$.

Select fixed values for $\bar{\delta}^{(1)}, \ldots, \bar{\delta}^{(d)}$, and let α be the violation of the solution with these d constraints only. Then, the probability that $\delta^{(d+1)}, \ldots, \delta^{(m)}$ fall in the nonviolated set, that is, $(\bar{\delta}^{(1)}, \ldots, \bar{\delta}^{(d)}, \delta^{(d+1)}, \ldots, \delta^{(m)}) \in \widetilde{S}_{\bar{\mathcal{I}}}$, is $(1-\alpha)^{m-d}$.

Integrating over the domain Δ^d for $(\bar{\delta}^{(1)}, \ldots, \bar{\delta}^{(d)})$, we then have

$$\begin{aligned}
&\mathbb{P}^m\left\{\widetilde{S}_{\bar{\mathcal{I}}}\right\} \\
&= [\text{letting } x^*_{\bar{\mathcal{I}}} \text{ be the solution with constraints } \bar{\delta}^{(1)}, \ldots, \bar{\delta}^{(d)} \text{ only}] \\
&= \int_{\Delta^d} (1-\alpha(x^*_{\bar{\mathcal{I}}}))^{m-d} \mathbb{P}^d(\mathrm{d}\bar{\delta}^{(1)}, \ldots, \mathrm{d}\bar{\delta}^{(d)}) \\
&= \int_0^1 (1-\alpha)^{m-d} F(\mathrm{d}\alpha),
\end{aligned}$$

where the third equality is a change of variables from the domain $(\bar{\delta}^{(1)}, \ldots, \bar{\delta}^{(d)})$ to that of the violation of the corresponding solution.

Since $\mathbb{P}^m\{S_{\bar{\mathcal{I}}}\} = \mathbb{P}^m\{\widetilde{S}_{\bar{\mathcal{I}}}\}$ and this probability is the same for any other set $S_{\mathcal{I}}$, (10) remains proven.

Now turn back to (9). Recalling that the sets $S_{\mathcal{I}}$ form a partition of Δ^m up to a probability 0 set and that $\mathbb{P}^m\{\Delta^m\} = 1$, (10) yields

$$\binom{m}{d} \int_0^1 (1-\alpha)^{m-d} F(\mathrm{d}\alpha) = 1 \quad \forall m \geq d. \tag{11}$$

Expression $F(\alpha) = \alpha^d$ in (9) is indeed a solution of (11) (integration by parts); on the other hand, no other solutions exist since determining an F satisfying (11) is a moment problem for a distribution with finite support, and its solution is unique; see, e.g., Chapter II, section 12.9, Corollary 1 of [26]. Thus, it remains proven that $F(\alpha)$ must have the expression (9).

To conclude the proof of Part 1, consider now the problem with N constraints and partition set $\{(\delta^{(1)}, \ldots, \delta^{(N)}) : \quad V(x^*_N) > \epsilon\}$ by intersecting it with the $\binom{N}{d}$ sets $S_{\mathcal{I}}$ grouping multiextractions such that the d support constraints have the same indexes. We then have

$$\begin{aligned}
&\mathbb{P}^N\{V(x^*_N) > \epsilon\} \\
&= \mathbb{P}^N\big\{ \cup_{\mathcal{I}} \{V(x^*_N) > \epsilon \text{ and } x^*_N \text{ is supported by the constraints} \\
&\qquad \text{with indexes in } \mathcal{I}\}\big\} \\
&= [\mathbb{I}_A \text{ is the indicator function of set } A; \text{ i.e., } \mathbb{I}_A = 1 \text{ over } A, \text{ and } \mathbb{I}_A = 0 \text{ otherwise}] \\
&= \binom{N}{d} \int_{\Delta^d} (1-\alpha(x^*_{\bar{\mathcal{I}}}))^{N-d} \mathbb{I}_{\{\alpha(x^*_{\bar{\mathcal{I}}}) > \epsilon\}} \mathbb{P}^d(\mathrm{d}\bar{\delta}^{(1)}, \ldots, \mathrm{d}\bar{\delta}^{(d)}) \\
&= \binom{N}{d} \int_\epsilon^1 (1-\alpha)^{N-d} \; F(\mathrm{d}\alpha)
\end{aligned}$$

$$
\begin{aligned}
&= [\text{since } F(\mathrm{d}\alpha) = d\alpha^{d-1}\,\mathrm{d}\alpha] \\
&= \binom{N}{d} \int_\epsilon^1 \left[(1-\alpha)^{N-d} d\alpha^{d-1}\right]\,\mathrm{d}\alpha \\
&= [\text{integrating by parts}] \\
&= \binom{N}{d}\left[-\frac{(1-\alpha)^{N-d+1}}{N-d+1} d\alpha^{d-1}\Big|_\epsilon^1 + \int_\epsilon^1 \frac{(1-\alpha)^{N-d+1}}{N-d+1} d(d-1)\alpha^{d-2}\,\mathrm{d}\alpha\right] \\
&= \binom{N}{d-1}\epsilon^{d-1}(1-\epsilon)^{N-d+1} + \binom{N}{d-1}\int_\epsilon^1 (1-\alpha)^{N-d+1}(d-1)\alpha^{d-2}\,\mathrm{d}\alpha \\
&= \cdots \\
&= \binom{N}{d-1}\epsilon^{d-1}(1-\epsilon)^{N-d+1} + \ldots + \binom{N}{1}\epsilon(1-\epsilon)^{N-1} + \binom{N}{1}\int_\epsilon^1 (1-\alpha)^{N-1}\,\mathrm{d}\alpha \\
&= \sum_{i=0}^{d-1}\binom{N}{i}\epsilon^i(1-\epsilon)^{N-i}.
\end{aligned}
$$

Proof of the fact that $S_{\bar{\mathcal{I}}} = \widetilde{S}_{\bar{\mathcal{I}}}$ up to a probability zero set.

$\boldsymbol{S_{\bar{\mathcal{I}}} \subseteq \widetilde{S}_{\bar{\mathcal{I}}}}$: Take a $(\delta^{(1)}, \ldots, \delta^{(m)}) \in S_{\bar{\mathcal{I}}}$ and eliminate a constraint among $\delta^{(d+1)}$, $\ldots, \delta^{(m)}$. Since this constraint is not of support, the solution remains unchanged; moreover, it is easy to see that the first d constraints are still the support constraints for the problem with $m-1$ constraints. If we now remove another constraint among those which are not of support, the conclusion is similarly drawn that the solution remains unchanged and that the first d constraints are still the support constraints for the problem with $m-2$ constraints. Proceeding this way until all constraints but the first d are removed, we obtain that the solution with the sole d support constraints $\delta^{(1)}, \ldots, \delta^{(d)}$ in place is the same as the solution with all m constraints. Since no constraint among $\delta^{(d+1)}, \ldots, \delta^{(m)}$ can be violated by the solution with all m constraints and such a solution is the same as the one with only the first d constraints, it follows that $(\delta^{(1)}, \ldots, \delta^{(m)}) \in \widetilde{S}_{\bar{\mathcal{I}}}$.

$\boldsymbol{\widetilde{S}_{\bar{\mathcal{I}}} \subseteq S_{\bar{\mathcal{I}}}}$ **up to a probability 0 set**: Suppose now that $\delta^{(d+1)}, \ldots, \delta^{(m)}$ are not violated by the solution generated by $\delta^{(1)}, \ldots, \delta^{(d)}$, i.e., $(\delta^{(1)}, \ldots, \delta^{(m)}) \in \widetilde{S}_{\bar{\mathcal{I}}}$. A simple reasoning reveals that $(\delta^{(1)}, \ldots, \delta^{(m)})$ does not belong to any one of sets $S_{\mathcal{I}}$, $\mathcal{I} \neq \bar{\mathcal{I}}$. In fact, adding nonviolated constraints to $\delta^{(1)}, \ldots, \delta^{(d)}$ does not change the solution, and each of the added constraints can be removed back without altering the solution. Therefore, none of the constraints $\delta^{(d+1)}, \ldots, \delta^{(m)}$ can be of support, and hence the multiextraction is not in $S_{\mathcal{I}}$, $\mathcal{I} \neq \bar{\mathcal{I}}$. It follows that $\widetilde{S}_{\bar{\mathcal{I}}}$ is a subset of the complement of $\cup_{\mathcal{I}, \mathcal{I} \neq \bar{\mathcal{I}}} S_{\mathcal{I}}$, which is $S_{\bar{\mathcal{I}}}$ up to a probability 0 set.

PART 2: $\boldsymbol{\mathbb{P}^N\{V(x_N^*) > \epsilon\} \leq \sum_{i=0}^{d-1}\binom{N}{i}\epsilon^i(1-\epsilon)^{N-i}$ FOR EVERY PROBLEM. A non-fully-supported problem admits with nonzero probability randomized instances where the number of support constraints is less than d. A support constraint has to be an active constraint, and the typical reason for a lack of support constraints is that at the optimum the active constraints are less than d; see Figure 4. To carry on a proof along lines akin to those for the fully-supported case, we are well-advised to generalize the notion of solution to that of ball-solution; a ball-solution has always at least d active constraints. For simplicity, we henceforth assume that constraints are not trivial, i.e., $\mathcal{X}_\delta \neq \mathbb{R}^d\ \forall \delta \in \Delta$.

Roughly speaking, given an optimization problem whose solution is x_m^*, its *ball-solution* is a ball centered in x_m^* and whose radius has been enlarged until the ball

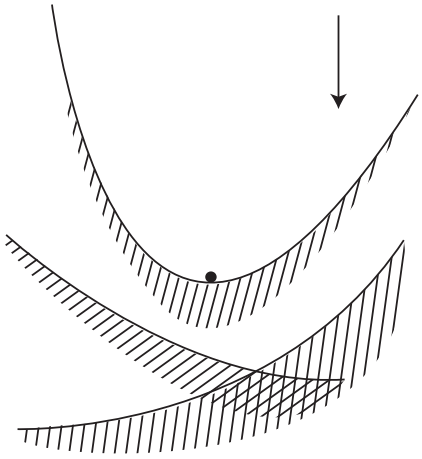

FIG. 4. *A two-dimensional problem with only one active constraint which is of support.*

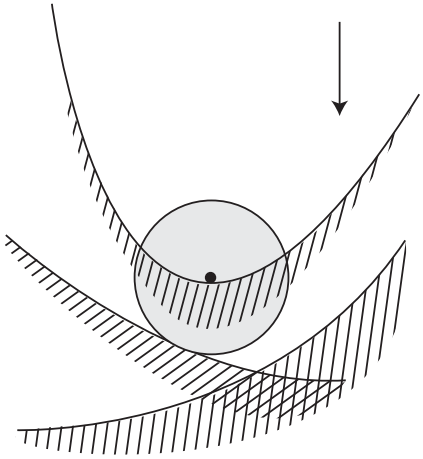

FIG. 5. *Ball-solution.*

touches the frontier of d constraints. See Figure 5 for an example of a ball-solution. The mathematical definition of a ball-solution is as follows.

DEFINITION 4 (ball-solution). *Consider a finite instance P_m of UP with $m \geq d$, and let x_m^* be its solution. The* ball-solution $\mathcal{B}(x_m^*, r_m^*)$ *of P_m is the largest closed ball centered in x_m^* fully contained in the feasibility domain of all constraints, with the exception of at most $d-1$ of them; i.e., $\mathcal{X}_{\delta^{(i)}} \cap \mathcal{B}(x_m^*, r_m^*) = \mathcal{B}(x_m^*, r_m^*)$ for all i's, except at most $d-1$ of them.*

Note also that, when active constraints are d or more, $r_m^* = 0$ and $\mathcal{B}(x_m^*, r_m^*)$ reduces to the standard solution x_m^*. Moreover, a ball-solution $\mathcal{B}(x_m^*, r_m^*)$ need not be contained in $\mathcal{X}$, although its center x_m^* does.

The notion of active constraint can be generalized to balls by saying that a constraint is active for a ball if the ball touches the frontier of the constraint. If in addition the ball is fully contained in the constraint, then the constraint is said to be strictly active. See Figure 6 for a graphical illustration of active and strictly active constraints for a ball, while the precise definition is as follows.

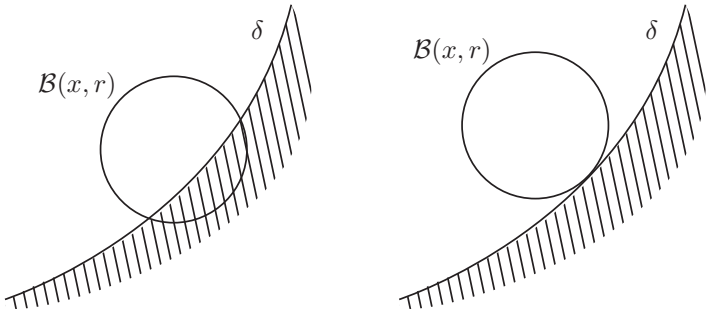

FIG. 6. *Active and strictly active constraints for a ball.*

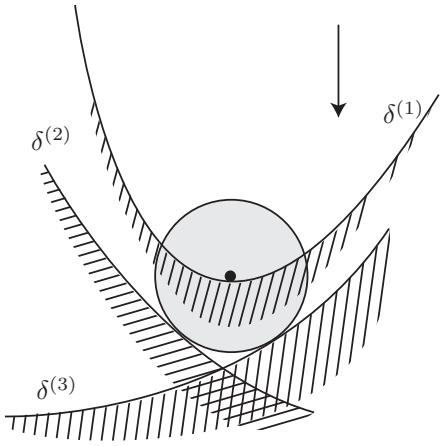

FIG. 7. *Only $\delta^{(1)}$ is a ball-support constraint.*

DEFINITION 5 (active constraint for a ball). *A constraint δ is* active *for a ball $\mathcal{B}(x,r)$ if $\mathcal{X}_\delta \cap \mathcal{B}(x,r) \neq \emptyset$ and $\mathcal{X}_\delta \cap \mathcal{B}(x,r+h) \neq \mathcal{B}(x,r+h)$ $\forall h > 0$. If in addition $\mathcal{X}_\delta \cap \mathcal{B}(x,r) = \mathcal{B}(x,r)$, $\mathcal{X}_\delta$ is said to be* strictly active.

If the ball is a single point, active and strictly active are the same and reduce to the standard notion of active.

By construction, a ball-solution has at least d active constraints. To go back to the track of the proof in Part 1, however, we need d support constraints, not just active constraints. The following definition naturally extends the notion of support constraint to the case of ball-solutions.

DEFINITION 6 (ball-support constraint). *Constraint $\delta^{(r)}$, $r \in \{1,\dots,m\}$, is a* ball-support constraint *for P_m if its removal changes the ball-solution of P_m.*

An active constraint is not necessarily a ball-support constraint, nor does a P_m necessarily have to have d ball-support constraints (see Figure 7, where $\delta^{(2)}$ and $\delta^{(3)}$ are not of support). It is clear that the number of ball-support constraints is less than or equal to d. The case with less than d ball-support constraints is regarded as *degenerate* and needs to be treated separately. We thus split the remaining part of the proof in two sections: Part 2a (fully-ball-supported problems) and Part 2b (degenerate problems). Before proceeding, we are well-advised to give a formal definition of fully-ball-supported problems.

DEFINITION 7 (fully-ball-supported problem). *A finite instance P_m, with $m \geq d$, is fully-ball-supported if the number of ball-support constraints of P_m is d. Problem UP is fully-ball-supported if, for any $m \geq d$, RP_m is fully-ball-supported with probability* 1.

PART 2a: FULLY-BALL-SUPPORTED PROBLEMS. We start by introducing the notion of a constraint violated by a ball: a constraint δ is violated by $\mathcal{B}(x,r)$ if $\mathcal{X}_\delta \cap \mathcal{B}(x,r) \neq \mathcal{B}(x,r)$. The definition of probability of violation then generalizes naturally to the ball case.

DEFINITION 8 (violation probability of a ball). *The* violation probability *of a ball $\mathcal{B}(x,r)$, $x \in \mathcal{X}$, is defined as $V_{\mathcal{B}}(x,r) = \mathbb{P}\{\delta \in \Delta : \mathcal{X}_\delta \cap \mathcal{B}(x,r) \neq \mathcal{B}(x,r)\}$.*

Clearly, for any x, $V_{\mathcal{B}}(x,r) \geq V(x)$. Hence, if $\mathcal{B}(x^*_N, r^*_N)$ is the ball-solution of RP_N, we have

$$\mathbb{P}^N\{V(x^*_N) > \epsilon\} \leq \mathbb{P}^N\{V_{\mathcal{B}}(x^*_N, r^*_N) > \epsilon\}. \tag{12}$$

Below, we show that a result similar to (7) holds for fully-ball-supported problems, namely,

$$\mathbb{P}^N\{V_{\mathcal{B}}(x^*_N, r^*_N) > \epsilon\} = \sum_{i=0}^{d-1} \binom{N}{i} \epsilon^i (1-\epsilon)^{N-i}, \tag{13}$$

and this result together with (12) leads to the thesis

$$\mathbb{P}^N\{V(x^*_N) > \epsilon\} \leq \sum_{i=0}^{d-1} \binom{N}{i} \epsilon^i (1-\epsilon)^{N-i}.$$

The proof of (13) is verbatim the same as the proof of Part 1 provided that one substitutes

- *solution* with *ball-solution*,
- *support constraint* with *ball-support constraint*,
- *violation probability V* with *violation probability of a ball $V_{\mathcal{B}}$*,

with only one exception: the part where we proved that $\boldsymbol{S}_{\bar{\boldsymbol{\mathcal{I}}}} \subseteq \widetilde{\boldsymbol{S}}_{\bar{\boldsymbol{\mathcal{I}}}}$ has to be modified in a way that we spell out in the following.

The first rationale to conclude that "the solution with only the d support constraints $\delta^{(1)}, \ldots, \delta^{(d)}$ in place is the same as the solution with all m constraints" is still valid and leads in our present context to the fact that the ball-solution with only the d ball-support constraints $\delta^{(1)}, \ldots, \delta^{(d)}$ in place is the same as the ball-solution with all m constraints. Instead, the last argument with which we concluded that $\boldsymbol{S}_{\bar{\boldsymbol{\mathcal{I}}}} \subseteq \widetilde{\boldsymbol{S}}_{\bar{\boldsymbol{\mathcal{I}}}}$ is no longer valid since ball-solutions can violate constraints.

To amend it, suppose for the purpose of contradiction that a constraint among $\delta^{(d+1)}, \ldots, \delta^{(m)}$, say, $\delta^{(d+1)}$, is violated by the ball-solution with d constraints. Two cases can occur: (i) the ball-solution has only one strictly active constraint among $\delta^{(1)}, \ldots, \delta^{(d)}$; or (ii) it has more than one. In case (i), $d-1$ constraints among $\delta^{(1)}, \ldots, \delta^{(d)}$ are violated by the ball-solution so that, with the extra $\delta^{(d+1)}$ violated constraint, the number of violated constraints of the ball-solution with m constraints would add up to at least d, and this contradicts the definition of ball-solution. If instead (ii) is true, a simple thought reveals that, with one more constraint $\delta^{(d+1)}$ violated by the ball-solution, the strictly active constraints (which, in this case, are more than one) cannot be of ball-support for the problem with m constraints, and this contradicts the fact that $(\delta^{(1)}, \ldots, \delta^{(m)}) \in S_{\bar{\mathcal{I}}}$.

PART 2b: DEGENERATE PROBLEMS. For not being fully-ball-supported, a finite problem P_m needs to have more than one strictly active constraint, a circumstance which requires that constraints are not "generically" distributed. This observation is at the basis of the rather technical proof of Part 2b, which proceeds along the following steps:

Step 1. A constraint "heating" is introduced; heating scatters constraints around, and the resulting heated problem is shown to be fully-ball-supported; by resorting to the result in Part 2a, conclusions are derived about the violation properties of the heated problem.

Step 2. It is shown that the solution of the original problem is recovered by cooling the heated problem down.

Step 3. The violation properties of the original (nonheated) problem are determined from the violation properties of the heated problem by a limiting process.

Step 1 (*heating*). Let $\Delta' := \Delta \times \mathcal{B}_\rho$, where $\rho > 0$ is the *heating parameter* and $\mathcal{B}_\rho \subset \mathbb{R}^d$ is the closed ball centered in the origin with radius ρ, and let $\mathbb{P}' := \mathbb{P} \times \mathbb{U}$ be the probability in Δ' obtained as the product probability between $\mathbb{P}$ and the uniform probability $\mathbb{U}$ in $\mathcal{B}_\rho$. Each $z \in \mathcal{B}_\rho$ represents a constraint translation, and the heated uncertain program (HUP) is defined as

$$\begin{aligned} \mathrm{HUP}: \min_{x \in \mathcal{X} \subseteq \mathbb{R}^d} & c^T x \\ \text{subject to: } & x \in [\mathcal{X}_\delta + z], \quad (\delta, z) \in \Delta', \end{aligned}$$

where $[\mathcal{X}_\delta + z]$ is set $\mathcal{X}_\delta$ translated by z, and the new uncertain parameter (δ, z) allows for different selections of $\mathcal{X}_\delta$ constraints as well as for any translation z in $\mathcal{B}_\rho$. We show that HUP is fully-ball-supported.

To start with, consider a given deterministic ball $\mathcal{B}(x, r)$. We first prove that the strictly active constraints $\delta' \in \Delta'$ for $\mathcal{B}(x, r)$ form a set of zero-probability $\mathbb{P}'$, and later on from this we shall conclude that HUP is fully-ball-supported.

Let $\delta' = (\delta, z)$, and $\mathbb{I}_A$ indicate the indicator function of set A, and write

$$\begin{aligned} &\mathbb{P}'\{\delta' \text{ is strictly active for } \mathcal{B}(x,r)\} \\ &= \int_{\Delta'} \mathbb{I}_{\{\delta' \text{ is strictly active for } \mathcal{B}(x,r)\}} \mathbb{P}'(\mathrm{d}\delta') \\ &= [\text{by Fubini's theorem [23]}] \\ &= \int_{\Delta} \left[\int_{\mathcal{B}_\rho} \mathbb{I}_{\{(\delta,z) \text{ is strictly active for } \mathcal{B}(x,r)\}} \frac{\mathrm{d}z}{\mathrm{Vol}(\mathcal{B}_\rho)} \right] \mathbb{P}(\mathrm{d}\delta). \end{aligned} \tag{14}$$

The result that

$$\mathbb{P}'\{\delta' \text{ is strictly active for } \mathcal{B}(x,r)\} = 0 \tag{15}$$

is established by showing that the term within square brackets in (14) is null for all δ's.

Fix a δ, and let $C = \{z \in \mathcal{B}_\rho : \mathcal{B}(x,r) \subseteq [\mathcal{X}_\delta + z]\}$ be the set of translations not violating $\mathcal{B}(x,r)$. We show that C is convex and that the set $\{z \in \mathcal{B}_\rho : (\delta, z) \text{ is strictly active for } \mathcal{B}(x,r)\}$ belongs to ∂C, the boundary of C. Since the

boundary of a convex set has zero Lebesgue measure,[4] the desired result that the term within square brackets in (14) is null follows, viz.

$$\int_{\mathcal{B}_\rho} \mathbb{I}_{\{(\delta,z) \text{ is strictly active for } \mathcal{B}(x,r)\}} \frac{\mathrm{d}z}{\mathrm{Vol}(\mathcal{B}_\rho)} = 0. \tag{16}$$

The convexity of C is immediate: let $z_1, z_2 \in C$, that is, $\mathcal{B}(x,r) \subseteq [\mathcal{X}_\delta + z_1]$ and $\mathcal{B}(x,r) \subseteq [\mathcal{X}_\delta + z_2]$, or, equivalently, $\mathcal{B}(x,r) - z_1 \subseteq \mathcal{X}_\delta$ and $\mathcal{B}(x,r) - z_2 \subseteq \mathcal{X}_\delta$. From the convexity of $\mathcal{X}_\delta$, it follows that $\mathcal{B}(x,r) - \alpha z_1 - (1-\alpha) z_2 \subseteq \mathcal{X}_\delta \ \forall \alpha \in [0,1]$; that is, $\alpha z_1 + (1-\alpha) z_2 \in C$ and C is convex.

Consider now an interior point z of C (if any); i.e., there exists a ball centered in z all contained in C. This means that $[\mathcal{X}_\delta + z]$ can be moved around in all directions by a small quantity, and $\mathcal{B}(x,r)$ remains contained in it. It easily follows that (δ, z) cannot be strictly active, and, thus, $\{z \in \mathcal{B}_\rho : (\delta, z) \text{ is strictly active for } \mathcal{B}(x,r)\}$ has to belong to ∂C.

Wrapping up, (16) is established and, substituting in (14), (15) is obtained.

We next prove that (15) entails the fact that HUP is fully-ball-supported.

Consider a finite instance HP_m of HUP with $m \geq d$. One by one, eliminate $m-d$ constraints choosing at any time a constraint among those nonviolated by the ball-solution in such a way that the ball-solution does not change. This is certainly possible because the ball-support constraints are at most d. In the end, we are left with d constraints, say, the first d $\delta'^{(1)}, \ldots, \delta'^{(d)}$. A simple thought reveals that these d constraints are actually of ball-support for HP_m, provided that none of the other $m-d$ constraints that have been removed were strictly active.

Repeat the same above procedure for every m-ple of constraints (that is, for every HP_m generated by HUP), and group together all of the m-ples for which the procedure returns in the end the first d constraints $\delta'^{(1)}, \ldots, \delta'^{(d)}$. Call this group of m-ples G. We shall show that the probability of the m-ples in G such that HP_m is not fully-ball-supported is zero, and from this—by the observation that only a finite number $\binom{m}{d}$ of groups of m-ples can be similarly constructed—the final conclusion that HUP is fully-ball-supported will be secured.

Select fixed values $\bar{\delta}'^{(1)}, \ldots, \bar{\delta}'^{(d)}$ for the first d constraints, and consider the ball-solution $\mathcal{B}$ that these constraints generate. Let the other $m-d$ constraints vary in such a way that the m-ple $\bar{\delta}'^{(1)}, \ldots, \bar{\delta}'^{(d)}, \delta'^{(d+1)}, \ldots, \delta'^{(m)}$ belongs to G. For one such m-ple to correspond to a *non*-fully-ball-supported HP_m, at least one among the $m-d$ constraints $\delta'^{(d+1)}, \ldots, \delta'^{(m)}$ must be strictly active for $\mathcal{B}$, but we have proven in (15) that this happens with probability zero. Integrating over all possible values $\bar{\delta}'^{(1)}, \ldots, \bar{\delta}'^{(d)}$ for the first d constraints, the conclusion is drawn that the *non*-fully-ball-supported HP_m in G have zero probability.

Hence, by the above observation that there are only a finite number $\binom{m}{d}$ of groups and by the fact that $\binom{m}{d}$ times zero is zero, we obtain that HUP is fully-ball-supported.

To conclude Step 1, note that if we suppose to extract N constraints $\delta'^{(1)}, \ldots, \delta'^{(N)}$ from Δ', according to probability $\mathbb{P}'$ and in an independent fashion, and we denote by x'^*_N the corresponding solution, the result of Part 2a can be invoked to establish

[4] This simple fact follows from the observation that a convex set C in $\mathbb{R}^d$ either belongs to a flat of dimension $d-1$—and therefore C has zero $\mathbb{R}^d$ Lebesgue measure—or admits an interior point $\bar{z}$, and every half-line from $\bar{z}$ crosses the boundary of C in only one point (see, e.g., Propositions 1.1.13 and 1.1.14 in [19]).

that

$$(\mathbb{P}')^N\{V'(x'^*_N) > \epsilon\} \leq \sum_{i=0}^{d-1} \binom{N}{i} \epsilon^i (1-\epsilon)^{N-i}, \tag{17}$$

where $V'(x)$ is the probability of violation for the heated problem (i.e., $V'(x) = \mathbb{P}'\{(\delta, z) \in \Delta' : \ x \notin [\mathcal{X}_\delta + z]\}$). Equation (17) is the final result to which we wanted to arrive in this heating Step 1.

Step 2 (*cooling*). Fix a multiextraction $(\bar{\delta}^{(1)}, \ldots, \bar{\delta}^{(N)}) \in \Delta^N$, and consider x^*_N, the solution of the original optimization problem P_N with such constraints. We remark that in all of Step 2 the multiextraction $(\bar{\delta}^{(1)}, \ldots, \bar{\delta}^{(N)})$ is kept fixed and never changed throughout. Consider a closed ball $\mathcal{B}(x_f, r_f)$, $r_f > 0$, in the feasibility domain of P_N, which exists because the feasibility domain of P_N has a nonempty interior. Further, let $\rho_k \downarrow 0$ be a sequence of heating parameters monotonically decreasing to zero (*cooling of the heating parameter*) and such that $\rho_1 < \frac{r_f}{2}$. For all ρ_k, consider the heated versions of $(\bar{\delta}^{(1)}, \ldots, \bar{\delta}^{(N)})$, namely, $((\bar{\delta}^{(1)}, z_k^{(1)}), \ldots, (\bar{\delta}^{(N)}, z_k^{(N)}))$ where $z_k^{(1)}, \ldots, z_k^{(N)} \in \mathcal{B}_{\rho_k}$, and let $x'^*_N(z_k^{(1)}, \ldots, z_k^{(N)})$ be the solution of the heated optimization problem HP_N with heated constraints $(\bar{\delta}^{(1)}, z_k^{(1)}), \ldots, (\bar{\delta}^{(N)}, z_k^{(N)})$. The goal of Step 2 is to prove that

$$\sup_{z_k^{(1)}, \ldots, z_k^{(N)} \in \mathcal{B}_{\rho_k}} \left\| x'^*_N \left(z_k^{(1)}, \ldots, z_k^{(N)} \right) - x^*_N \right\| \longrightarrow 0 \quad \text{as } k \to \infty; \tag{18}$$

that is, the solution of the original problem is recovered by cooling the heated problem down.[5]

For brevity, from now on we omit the arguments $z_k^{(1)}, \ldots, z_k^{(N)}$ and write x'^*_N for $x'^*_N(z_k^{(1)}, \ldots, z_k^{(N)})$.

We first show that

$$\limsup_{k \to \infty} \sup_{z_k^{(1)}, \ldots, z_k^{(N)} \in \mathcal{B}_{\rho_k}} c^T x'^*_N \leq c^T x^*_N. \tag{19}$$

Following Figure 8, consider the convex hull $\mathrm{co}[\mathcal{B}(x_f, r_f) \cup x^*_N]$ generated by the feasibility ball $\mathcal{B}(x_f, r_f)$ and the solution x^*_N of the original problem with constraints $\bar{\delta}^{(1)}, \ldots, \bar{\delta}^{(N)}$. By convexity, $\mathrm{co}[\mathcal{B}(x_f, r_f) \cup x^*_N]$ is feasible for the original problem P_N. Construct the closed ball $\mathcal{B}(x_k, \rho_k) \subset \mathrm{co}[\mathcal{B}(x_f, r_f) \cup x^*_N]$ with radius ρ_k, whose center x_k is as close as possible to x^*_N and lies on the line segment connecting x_f with x^*_N (this ball exists since $\rho_1 < r_f$; the assumed stricter condition that $\rho_1 < \frac{r_f}{2}$ is required in the next construction). Clearly, $x_k \to x^*_N$ as $k \to \infty$. Since x_k is in the feasibility domain of P_N at a distance at least ρ_k from where $\bar{\delta}^{(1)}, \ldots, \bar{\delta}^{(N)}$ are violated, x_k is also in the feasibility domain of every heated problem HP_N with heating parameter ρ_k. Thus,

$$\limsup_{k \to \infty} \sup_{z_k^{(1)}, \ldots, z_k^{(N)} \in \mathcal{B}_{\rho_k}} c^T x'^*_N \leq \limsup_{k \to \infty} c^T x_k = c^T x^*_N;$$

that is, (19) holds.

[5] Although result (18) has an intuitive appeal, its proof is rather technical. The reader not interested in these technical details can jump to Step 3 from here without loss of continuity.

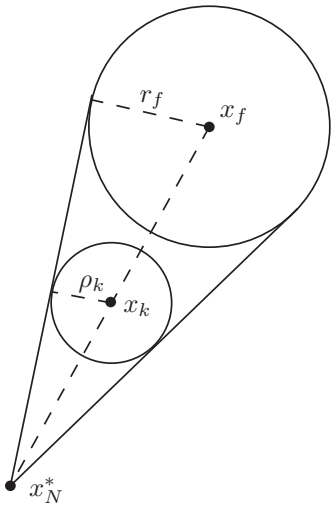

FIG. 8. *Convex hull of* $\mathcal{B}(x_f, r_f)$ *and* x_N^**, and construction of* $\mathcal{B}(x_k, \rho_k)$.

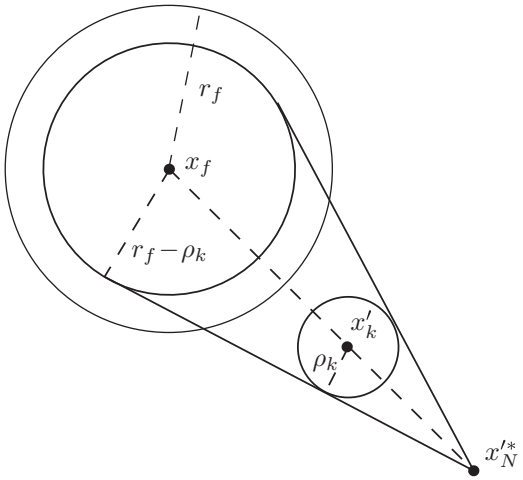

FIG. 9. *Convex hull of* $\mathcal{B}(x_f, r_f - \rho_k)$ *and* x'^*_N*, and construction of* $\mathcal{B}(x'_k, \rho_k)$.

Next, we construct a new convex hull which will allow us to reformulate goal (18) in a different, handier, way. Based on this reformulation, (18) will then be established in light of (19).

The new convex hull is $\mathrm{co}[\mathcal{B}(x_f, r_f - \rho_k) \cup x'^*_N]$; see Figure 9. Note that, for a given k, $\mathcal{B}(x_f, r_f - \rho_k)$ is a fixed ball, while instead x'^*_N depends on the specific choice of $z_k^{(1)}, \ldots, z_k^{(N)} \in \mathcal{B}_{\rho_k}$; this means that there are actually as many convex hulls as choices of $z_k^{(1)}, \ldots, z_k^{(N)}$. Moreover, $\mathrm{co}[\mathcal{B}(x_f, r_f - \rho_k) \cup x'^*_N]$ is feasible for problem HP_N with constraints translated by $z_k^{(1)}, \ldots, z_k^{(N)}$ since $\mathcal{B}(x_f, r_f - \rho_k)$ and x'^*_N are. Construct then the closed ball $\mathcal{B}(x'_k, \rho_k) \subseteq \mathrm{co}[\mathcal{B}(x_f, r_f - \rho_k) \cup x'^*_N]$ with radius ρ_k, whose center x'_k is as close as possible to x'^*_N and lies on the line segment connecting x_f with x'^*_N (this ball exists since $\rho_1 < \frac{r_f}{2}$). Note that x'_k depends on $z_k^{(1)}, \ldots, z_k^{(N)}$, too.

Since x'_k is in the feasibility domain of HP_N with constraints translated by $z_k^{(1)}, \ldots, z_k^{(N)}$ at a distance at least ρ_k from where these translated constraints are violated, x'_k is also in the feasibility domain of P_N.

What is different from the previous convex hull construction is that we cannot here easily conclude that $x'_k \to x'^*_N$ as $k \to \infty$ since x'^*_N is not a fixed point (it depends on $z_k^{(1)}, \ldots, z_k^{(N)} \in \mathcal{B}_{\rho_k}$, a ball that changes with k). We can still, however, secure a result that goes along a similar line, namely, that

$$x'_k = \alpha_k x_f + (1-\alpha_k) x'^*_N, \qquad \text{where } \alpha_k = \frac{\rho_k}{r_f - \rho_k} \longrightarrow 0 \text{ as } k \to \infty, \tag{20}$$

as it results from Figure 9 by a simple proportion argument.[6] Reorganizing terms in this equation, we obtain $x'^*_N - x^*_N = -\frac{\alpha_k}{1-\alpha_k}(x_f - x^*_N) + \frac{1}{1-\alpha_k}(x'_k - x^*_N)$, from which

$$\|x'^*_N - x^*_N\| \leq \frac{\alpha_k}{1-\alpha_k} \|x_f - x^*_N\| + \frac{1}{1-\alpha_k} \|x'_k - x^*_N\| .$$

We are now ready to reformulate goal (18) in a different way.

Note that the norm in (18) is the same as the left-hand side of the latter equation. On the right-hand side, $\|x_f - x^*_N\|$ is a fixed quantity multiplied by scalar $\frac{\alpha_k}{1-\alpha_k}$ which goes to zero. So, this first term vanishes. In the second term, scalar $\frac{1}{1-\alpha_k} \to 1$, and hence (18) is equivalent to

$$\sup_{z_k^{(1)}, \ldots, z_k^{(N)} \in \mathcal{B}_{\rho_k}} \|x'_k - x^*_N\| \longrightarrow 0 \quad \text{as } k \to \infty. \tag{21}$$

The goal of establishing (18) is finally achieved by proving (21) by contradiction.

Suppose that (21) is false; then, for a given $\mu > 0$, we can choose translations $\bar{z}_k^{(1)}, \ldots, \bar{z}_k^{(N)} \in \mathcal{B}_{\rho_k}$, $k = 1, 2, \ldots$, such that

$$\left\| x'_k \left(\bar{z}_k^{(1)}, \ldots, \bar{z}_k^{(N)} \right) - x^*_N \right\| > \mu \quad \forall k,$$

where we have here preferred to explicitly indicate dependence of x'_k on $\bar{z}_k^{(1)}, \ldots, \bar{z}_k^{(N)}$.

Note that $x'_k(\bar{z}_k^{(1)}, \ldots, \bar{z}_k^{(N)})$ is asymptotically superoptimal for problem P_N:

$$\begin{aligned}
&\limsup_{k\to\infty} c^T x'_k \left(\bar{z}_k^{(1)}, \ldots, \bar{z}_k^{(N)} \right) \\
&\leq [\text{using (20) and since } \alpha_k \to 0] \\
&\leq \limsup_{k\to\infty} \sup_{z_k^{(1)}, \ldots, z_k^{(N)}} c^T x'^*_N \\
&\leq [\text{using (19)}] \\
&\leq c^T x^*_N. \qquad (22)
\end{aligned}$$

The line segment connecting $x'_k(\bar{z}_k^{(1)}, \ldots, \bar{z}_k^{(N)})$ with x^*_N intersects the surface of the ball with center x^*_N and radius μ in a point that we name x'^S_k. x'^S_k is still feasible for P_N being a convex combination of x^*_N and $x'_k(\bar{z}_k^{(1)}, \ldots, \bar{z}_k^{(N)})$, both feasible points for P_N. In addition, since $x'_k(\bar{z}_k^{(1)}, \ldots, \bar{z}_k^{(N)})$ is asymptotically superoptimal for P_N (see (22)) and x^*_N is the solution of P_N, x'^S_k is asymptotically superoptimal for P_N, too, i.e., $\limsup_{k\to\infty} c^T x'^S_k \leq c^T x^*_N$. Finally, since x'^S_k belongs to a compact, it admits a convergent subsequence to, say, x'^S_∞, a point which is still feasible for P_N due to

[6] Note that (20) does not imply that $x'_k \to x'^*_N$ since x'^*_N could in principle escape to infinity.

the fact that the feasibility domain of P_N is closed. x'^S_∞ would thus be feasible and superoptimal for P_N, so contradicting the uniqueness of the solution of P_N.

This concludes Step 2.

Step 3 (*drawing the conclusions*). The theorem statement that $\mathbb{P}^N\{V(x^*_N) > \epsilon\} \leq \sum_{i=0}^{d-1} \binom{N}{i}\epsilon^i(1-\epsilon)^{N-i}$ is established in this Step 3 along the following lines: by the convergence result (18) in Step 2, a bad multiextraction $(\bar\delta^{(1)}, \ldots, \bar\delta^{(N)})$ (i.e., one such that $V(x^*_N) > \epsilon$) is shown to generate bad heated multiextractions $((\bar\delta^{(1)}, z_k^{(1)}), \ldots, (\bar\delta^{(N)}, z_k^{(N)}))$ for k large enough; we thus have that the probability of bad multiextractions can be bounded by the probability of bad heated multiextractions; by then using the bound for the probability of bad heated multiextractions derived in Step 1, the thesis follows.

Fix a *bad* multiextraction $(\bar\delta^{(1)}, \ldots, \bar\delta^{(N)}) \in \Delta^N$, and consider x^*_N, the solution of the optimization problem P_N with constraints $\bar\delta^{(1)}, \ldots, \bar\delta^{(N)}$. For an additional constraint $\delta \in \Delta$ to be violated by x^*_N, x^*_N must belong to the complement of $\mathcal{X}_\delta$, i.e., $\mathcal{X}^c_\delta$. Since $\mathcal{X}^c_\delta$ is open, we then have the fact that there exists a small enough ball centered in x^*_N fully contained in $\mathcal{X}^c_\delta$. Thus,

$$\{\delta \in \Delta :\ x^*_N \notin \mathcal{X}_\delta\} = \bigcup_{n=1,2,\ldots} \{\delta \in \Delta :\ \mathcal{B}(x^*_N, 1/n) \subseteq \mathcal{X}^c_\delta\}, \tag{23}$$

and

$$\begin{aligned}
\epsilon &< [\text{since } \left(\bar\delta^{(1)}, \ldots, \bar\delta^{(N)}\right) \text{ is bad}] \\
&< V(x^*_N) \\
&= \mathbb{P}\{\delta \in \Delta :\ x^*_N \notin \mathcal{X}_\delta\} \\
&= [\text{using (23)}] \\
&= \mathbb{P}\Big\{ \bigcup_{n=1,2,\ldots} \{\delta \in \Delta :\ \mathcal{B}(x^*_N, 1/n) \subseteq \mathcal{X}^c_\delta\}\Big\} \\
&= \lim_{n\to\infty} \mathbb{P}\{\delta \in \Delta :\ \mathcal{B}(x^*_N, 1/n) \subseteq \mathcal{X}^c_\delta\},
\end{aligned}$$

from which there exists a $\bar n$ such that

$$\mathbb{P}\{\delta \in \Delta :\ \mathcal{B}(x^*_N, 1/\bar n) \subseteq \mathcal{X}^c_\delta\} > \epsilon. \tag{24}$$

Let us now heat the constraints $\bar\delta^{(1)}, \ldots, \bar\delta^{(N)}$ up by translation parameters $z_k^{(1)}, \ldots, z_k^{(N)} \in \mathcal{B}_{\rho_k}$ and ask the following question: is it true that the heated multiextraction $((\bar\delta^{(1)}, z_k^{(1)}), \ldots, (\bar\delta^{(N)}, z_k^{(N)}))$ is bad for HUP with heating parameter ρ_k? It turns out that the answer is positive for k large enough, a fact that is proven next.

Recall that x'^*_N is the solution with constraints $(\bar\delta^{(1)}, z_k^{(1)}), \ldots, (\bar\delta^{(N)}, z_k^{(N)})$, and define $d_k := \sup_{z_k^{(1)}, \ldots, z_k^{(N)} \in \mathcal{B}_{\rho_k}} \|x'^*_N - x^*_N\|$ which, by (18), goes to 0 as $k \to \infty$. Pick a $\bar k$ such that

$$d_k + \rho_k < 1/\bar n \quad \forall k \geq \bar k.$$

All heated solutions x'^*_N are apart from x^*_N by at most d_k, and all heated constraints $(\delta, z) \in \Delta \times \mathcal{B}_{\rho_k}$ are apart from the corresponding unheated constraint δ by at most ρ_k. Thus, if $k \geq \bar k$, all heated versions of a constraint δ in the set $\{\delta \in \Delta :\ \mathcal{B}(x^*_N, 1/\bar n) \subseteq \mathcal{X}^c_\delta\}$ on the left-hand side of (24) are violated by x'^*_N. That is,

$$\{\delta \in \Delta :\ \mathcal{B}(x^*_N, 1/\bar n) \subseteq \mathcal{X}^c_\delta\} \times \mathcal{B}_{\rho_k} \subseteq \{(\delta, z) \in \Delta \times \mathcal{B}_{\rho_k} :\ x'^*_N \notin [\mathcal{X}_\delta + z]\} \quad \forall k \geq \bar k. \tag{25}$$

Then, for any $z_k^{(1)}, \ldots, z_k^{(N)} \in \mathcal{B}_{\rho_k}$ and for any $k \geq \bar{k}$, we have

$$\begin{aligned} V'(x_N'^*) &= \mathbb{P}'\{(\delta, z) \in \Delta \times \mathcal{B}_{\rho_k} : \ x_N'^* \notin [\mathcal{X}_\delta + z]\} \\ &\geq [\text{using (25)}] \\ &\geq \mathbb{P}'\Big\{\{\delta \in \Delta : \ \mathcal{B}(x_N^*, 1/\bar{n}) \subseteq \mathcal{X}_\delta^c\} \times \mathcal{B}_{\rho_k}\Big\} \\ &= [\text{recalling that } \mathbb{P}' = \mathbb{P} \times \mathbb{U}] \\ &= \mathbb{P}\{\delta \in \Delta : \ \mathcal{B}(x_N^*, 1/\bar{n}) \subseteq \mathcal{X}_\delta^c\} \cdot \mathbb{U}\{\mathcal{B}_{\rho_k}\} \\ &> [\text{since } \mathbb{U}\{\mathcal{B}_{\rho_k}\} = 1 \text{ and using (24)}] \\ &> \epsilon, \end{aligned}$$

i.e., $((\bar{\delta}^{(1)}, z_k^{(1)}), \ldots, (\bar{\delta}^{(N)}, z_k^{(N)}))$ is bad for HUP with heating parameter ρ_k for any $z_k^{(1)}, \ldots, z_k^{(N)} \in \mathcal{B}_{\rho_k}$ when $k \geq \bar{k}$. In turn, this entails that

$$\int_{\mathcal{B}_{\rho_k}^N} \mathbb{I}_{\{V'(x_N'^*) > \epsilon\}} \frac{\mathrm{d}z^N}{\mathrm{Vol}(\mathcal{B}_{\rho_k}^N)} = 1 \quad \forall k \geq \bar{k}. \tag{26}$$

Finally,

$$\begin{aligned} &\sum_{i=0}^{d-1} \binom{N}{i} \epsilon^i (1-\epsilon)^{N-i} \\ &\quad \geq \quad [\text{using (17)}] \\ &\quad \geq \quad (\mathbb{P}')^N\{V'(x_N'^*) > \epsilon\} \\ &\quad = \quad \int_{\Delta^N} \left[\int_{\mathcal{B}_{\rho_k}^N} \mathbb{I}_{\{V'(x_N'^*) > \epsilon\}} \frac{\mathrm{d}z^N}{\mathrm{Vol}(\mathcal{B}_{\rho_k}^N)} \right] \mathbb{P}^N(\mathrm{d}\delta^N) \\ &\quad \geq \quad \int_{\{V(x_N^*) > \epsilon\}} \left[\int_{\mathcal{B}_{\rho_k}^N} \mathbb{I}_{\{V'(x_N'^*) > \epsilon\}} \frac{\mathrm{d}z^N}{\mathrm{Vol}(\mathcal{B}_{\rho_k}^N)} \right] \mathbb{P}^N(\mathrm{d}\delta^N) \\ &\overrightarrow{k \to \infty} [\text{recalling (26) and by the dominated convergence theorem [26]}] \\ &\overrightarrow{k \to \infty} \int_{\{V(x_N^*) > \epsilon\}} \mathbb{P}^N(\mathrm{d}\delta^N) \\ &\quad = \quad \mathbb{P}^N\{V(x_N^*) > \epsilon\}. \end{aligned}$$

This concludes the proof. □

GLOBAL CONVERGENCE OF FILTER METHODS FOR NONLINEAR PROGRAMMING*

ADEMIR A. RIBEIRO†, ELIZABETH W. KARAS†, AND CLÓVIS C. GONZAGA‡

Abstract. We present a general filter algorithm that allows a great deal of freedom in the step computation. Each iteration of the algorithm consists basically in computing a point which is not forbidden by the filter, from the current point. We prove its global convergence, assuming that the step must be efficient, in the sense that, near a feasible nonstationary point, the reduction of the objective function is "large." We show that this condition is reasonable, by presenting two classical ways of performing the step which satisfy it. In the first one, the step is obtained by the inexact restoration method of Martínez and Pilotta. In the second, the step is computed by sequential quadratic programming.

Key words. filter methods, nonlinear programming, global convergence

1. Introduction.

We shall study the nonlinear programming problem

$$(P) \qquad \begin{array}{ll} \text{minimize} & f_0(x) \\ \text{subject to} & f_{\mathcal{E}}(x) = 0 \\ & f_{\mathcal{I}}(x) \leq 0, \end{array}$$

where the index sets $\mathcal{E}$ and $\mathcal{I}$ refer to the equality and inequality constraints, respectively. Let the cardinality of $\mathcal{E} \cup \mathcal{I}$ be m, and assume that the functions $f_i : \mathbb{R}^n \to \mathbb{R}$, $i = 0, 1, \ldots, m$, are continuously differentiable.

A nonlinear programming algorithm must deal with two different (and possibly conflicting) criteria, related respectively to optimality and to feasibility. Optimality is measured by the objective function f_0; feasibility is typically measured by penalization of constraint violation, for instance, by the function $h : \mathbb{R}^n \to \mathbb{R}_+$, given by

$$h(x) = \left\| f^+(x) \right\|, \tag{1.1}$$

where $\| \cdot \|$ is an arbitrary norm and $f^+ : \mathbb{R}^n \to \mathbb{R}^m$ is defined by

$$f_i^+(x) = \begin{cases} f_i(x) & \text{if } \ i \in \mathcal{E}, \\ \max\{0, f_i(x)\} & \text{if } \ i \in \mathcal{I}. \end{cases}$$

Both criteria must be optimized and the algorithm should follow a certain balance between them at every step of the iterative process. Several algorithms for nonlinear programming have been designed in which a merit function is a tool to guarantee global convergence [3, 11, 12, 20, 26].

As an alternative to merit function, Fletcher and Leyffer [7] introduced the so-called *filter* to globalize sequential quadratic programming type methods. Filter methods are based on the concept of dominance, borrowed from multicriteria optimization.

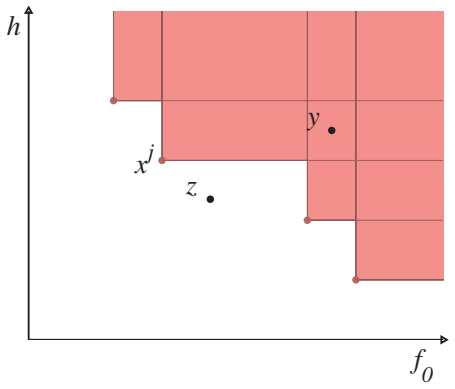

FIG. 1.1. *A filter with four pairs.*

A filter algorithm defines a *forbidden region*, by memorizing pairs $(f_0(x^j), h(x^j))$, chosen conveniently from former iterations and then avoids points dominated by these by the modified Pareto domination rule:

$$y \text{ is dominated by } x \text{ if, and only if, } f_0(y) \geq f_0(x) \text{ and } h(y) \geq h(x).$$

Figure 1.1 shows a filter with four pairs, where we have simplified the notation by using x to represent the pair $(f_0(x), h(x))$. The point y is in the forbidden region and z is not.

The filter methods were also applied to sequential linear programming (SLP). The works of Chin and Fletcher [5] and Fletcher, Leyffer, and Toint [8] present global convergence proofs of the method.

For SQP-filter methods, global convergence has been proved by Fletcher, Leyffer, and Toint [9], assuming that the quadratic subproblems are solved globally. Without this requirement, that is, allowing approximate solutions of the subproblems, Fletcher et al. [6] have also proved convergence to first-order critical points. Their approach uses a composite-step SQP method similar in spirit to the ones pioneered by Byrd [2] and Omojokun [22]. Another SQP-filter algorithm, using line search, was proposed by Wächter and Biegler [28], where global convergence was obtained.

In the context of interior points, Ulbrich, Ulbrich, and Vicente [24] have proposed a globally convergent primal-dual interior-point filter method. However, the filter entries have components that take into account the centrality and complementarity measures arising from interior-point techniques.

The filter was also studied by Gonzaga, Karas, and Vanti [13], in an algorithm that resembles the inexact restoration method of Martínez and Pilotta [19, 20]. By suitable rules for building the filter they prove stationarity of all qualified accumulation points.

The good performance of these methods [7, 29] has motivated their use in other problems, like nonlinear systems of equations [14, 16, 17], unconstrained optimization [15], and nonsmooth convex constrained optimization [18]. This last work, by Karas et al., combines the ideas of the proximal bundle methods [23] with the filter strategy. We can find a survey of filter methods in [10].

Although we know that filter methods may suffer from the Maratos effect, we shall not discuss local convergence issues in this work. Some strategies can be found in [4, 25, 27] to ensure a fast rate of convergence.

In this paper, we propose a general filter algorithm that does not depend on the particular method used for the step computation. The only requirement is that the points generated must be acceptable for the filter and that near a feasible nonstationary point, the reduction of the objective function be large. This efficiency condition, stated below as Hypothesis H3, is the main tool of the global convergence analysis. It is a weaker version of the one introduced by Gonzaga, Karas, and Vanti [13] in their inexact restoration filter method. Under this hypothesis, we prove that every sequence generated by the algorithm has at least one stationary accumulation point. Furthermore, we show how to compute the step in order to fulfill this hypothesis. One way to do this is by inexact restoration, for which H3 was proven in [13]. Another way for computing the step is by a sequential quadratic programming algorithm. We prove in this work that this approach also satisfies the efficiency condition H3.

The paper is organized as follows. Our general filter algorithm and its convergence analysis are described in section 2. In section 3 we present the SQP method for computing the step and prove that Hypothesis H3 is satisfied.

2. The algorithm. In this section we present a general filter algorithm that allows a great deal of freedom in the step computation. Afterwards we state an assumption on the performance of the step, and prove that any sequence generated by the algorithm has a stationary accumulation point. In the next section we show that this condition is reasonable, by presenting a classical way of performing the step, satisfying this condition.

The algorithm constructs a sequence of *filter* sets $F_0 \subset F_1 \subset \cdots \subset F_k$, composed of pairs $(\tilde{f}_0^j, \tilde{h}^j) \in \mathbb{R}^2$. We also mention in the algorithm the sets $\mathcal{F}_k \subset \mathbb{R}^n$, which are formally defined in each step for clarity, but are never actually constructed.

ALGORITHM 2.1. *General filter algorithm model*

Given: $x^0 \in \mathbb{R}^n$, $F_0 = \emptyset$, $\mathcal{F}_0 = \emptyset$, $\alpha \in (0,1)$.

$k = 0$

REPEAT

$(\tilde{f}_0, \tilde{h}) = (f_0(x^k) - \alpha h(x^k),\ (1-\alpha)h(x^k))$.

Set $\bar{F}_k = F_k \bigcup \{(\tilde{f}_0, \tilde{h})\}$ and define

$\bar{\mathcal{F}}_k = \mathcal{F}_k \bigcup \{x \in \mathbb{R}^n \mid f_0(x) \geq \tilde{f}_0, h(x) \geq \tilde{h}\}$.

Step:

IF x^k is stationary, stop with success

ELSE, compute $x^{k+1} \notin \bar{\mathcal{F}}_k$.

Filter update:

IF $f_0(x^{k+1}) < f_0(x^k)$,

$F_{k+1} = F_k, \quad \mathcal{F}_{k+1} = \mathcal{F}_k$ (f_0-iteration: the new entry is discarded)

ELSE,

$F_{k+1} = \bar{F}_k, \quad \mathcal{F}_{k+1} = \bar{\mathcal{F}}_k$ (h-iteration: the new entry becomes permanent)

$k = k + 1$.

At the beginning of each iteration, the pair $(\tilde{f}_0, \tilde{h})$ is temporarily introduced in the filter. After the complete iteration, this entry will become permanent in the filter only if the iteration *does not* produce a decrease in f_0.

Note that the forbidden region was slightly modified by subtracting the expression $\alpha h(x^k)$ from both filter pair components. This prevents the acceptance of trial pairs (f_0, h) arbitrarily close to old iterates $(f_0(x^j), h(x^j))$. Figure 2.1 illustrates the effect of this modification which adds a small margin around the border of region already

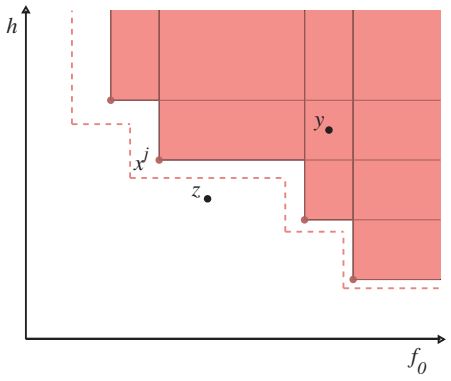

FIG. 2.1. *The filter margin.*

defined by the Pareto domination rule. Now, all points above the dashed line are forbidden.

In order to obtain our global convergence result, we shall assume that the algorithm generates an infinite sequence $(x^k)_{k\in\mathbb{N}}$ in $\mathbb{R}^n$ and the following hypotheses are satisfied.

H1. *All the functions $f_i(\cdot)$, $i = 0, 1, \ldots, m$, are twice continuously differentiable.*

H2. *The sequence $(x^k)_{k\in\mathbb{N}}$ remains in a convex compact domain $X \subset \mathbb{R}^n$.*

H 3. *Given a feasible nonstationary point $\bar{x} \in X$, there exist $M > 0$ and a neighborhood V of $\bar{x}$ such that for any iterate $x^k \in V$,*

$$f_0\left(x^k\right) - f_0\left(x^{k+1}\right) \geq M v_k,$$

where $v_k = \min\{1, \min\{\tilde{h}^j \mid (\tilde{f}_0^j, \tilde{h}^j) \in F_k\}\}$.

The first ones are standard hypotheses, while Hypothesis H3 requires some discussion. With this hypothesis we are assuming that the step must be efficient, in the sense that, near a feasible nonstationary point, the reduction of the objective function is "large." This assumption is a weaker version of the decrease condition introduced by Gonzaga, Karas, and Vanti [13] who used

$$H_k = \min\left\{1, \min\left\{\tilde{h}^j \mid \left(\tilde{f}_0^j, \tilde{h}^j\right) \in F_k, \tilde{f}_0^j \leq f_0\left(x^k\right)\right\}\right\} \tag{2.1}$$

instead of v_k. Figure 2.2 shows the variables v_k and H_k.

We start our analysis with some relations which follow directly from the hypotheses and the construction of the algorithm. In the next section we shall state methods which satisfy Hypothesis H3.

LEMMA 2.2. *Given $k \in \mathbb{N}$, the following statements hold:*

(i) $\mathcal{F}_k \subset \mathcal{F}_{k+1}$ *(Inclusion property).*

(ii) $x^{k+p} \notin \mathcal{F}_{k+1}$ *for all* $p \geq 1$.

(iii) *At least one of the two conditions below occurs:*

1. $f_0(x^{k+1}) < f_0(x^k) - \alpha h(x^k)$,
2. $h(x^{k+1}) < (1-\alpha)h(x^k)$.

(iv) $\tilde{h} > 0$ *for all* $\left(\tilde{f}_0, \tilde{h}\right) \in F_k$.

Proof. The first statement follows directly from the filter update criterion. By (i) and the definition of $\bar{\mathcal{F}}$, we have $\mathcal{F}_{k+1} \subset \mathcal{F}_{k+p} \subset \bar{\mathcal{F}}_{k+p-1}$. Then the second statement follows from $x^{k+p} \notin \bar{\mathcal{F}}_{k+p-1}$. The third one is clear, since $x^{k+1} \notin \bar{\mathcal{F}}_k$. Finally, note

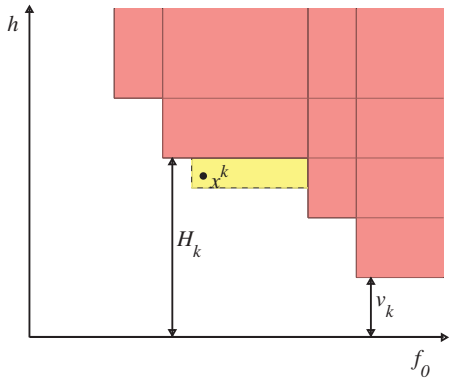

FIG. 2.2. *The filter height v_k and the filter slack H_k.*

that if $h(x^k) = 0$, using (iii), we obtain

$$f_0\left(x^{k+1}\right) < f_0\left(x^k\right) - \alpha h\left(x^k\right) = f_0\left(x^k\right),$$

that is, the iteration k is an f_0-iteration. Thus the pair $(\tilde{f}_0, \tilde{h})$ can be added to the filter only if $h(x^k) > 0$, or equivalently if $\tilde{h} > 0$. This completes the proof. ∎

For the purpose of our analysis, we shall consider

$$\mathcal{K}_a = \left\{k \in \mathbb{N} \mid \left(f_0\left(x^k\right) - \alpha h\left(x^k\right),\ (1-\alpha)h\left(x^k\right)\right) \text{ is added to the filter}\right\}, \tag{2.2}$$

the set of indices of h-iterations. First, we analyze what happens when this set is infinite.

LEMMA 2.3. *If the set $\mathcal{K}_a$ is infinite, then*

$$h\left(x^k\right) \overset{\mathcal{K}_a}{\to} 0.$$

Proof. Given k, we denote $\left(f_0(x^k), h(x^k)\right)$ by $\left(f_0^k, h^k\right)$. Assume by contradiction that, for some $\delta > 0$, the set

$$\mathcal{K} = \left\{k \in \mathcal{K}_a \mid h\left(x^k\right) \geq \delta\right\}$$

is infinite. The continuity of (f_0, h), implied by H1, and the compactness assumption H2 ensure that there exists a convergent subsequence $(f_0^k, h^k)_{k\in\mathcal{K}_1}$, $\mathcal{K}_1 \subset \mathcal{K}$. Therefore, since $\alpha \in (0,1)$, we can take indices $j, k \in \mathcal{K}_1$, $j < k$ such that

$$\left\|\left(f_0^k, h^k\right) - \left(f_0^j, h^j\right)\right\| < \alpha\delta \leq \alpha h(x^j).$$

This means that $x^k \in \bar{\mathcal{F}}_j = \mathcal{F}_{j+1}$, contradicting Lemma 2.2(ii) and completing the proof. ∎

We now prove that the objective function decreases along the iterations, whenever the iterates stay near a nonstationary point.

LEMMA 2.4. *Let $\bar{x} \in X$ be a nonstationary point. Then there exist $\bar{k} \in \mathbb{N}$ and a neighborhood V of $\bar{x}$ such that whenever $k > \bar{k}$ and $x^k \in V$, the iteration k is an f_0-iteration, that is, $k \notin \mathcal{K}_a$.*

Proof. If $\bar{x}$ is a feasible point, then by Hypothesis H3 there exist $M > 0$ and a neighborhood V of $\bar{x}$ such that for all $x^k \in V$,

$$f_0\left(x^k\right) - f_0\left(x^{k+1}\right) \geq M v_k.$$

Using Lemma 2.2(iv), we conclude that $v_k > 0$, consequently $f_0(x^{k+1}) < f_0(x^k)$ and k is an f_0-iteration.

Now, assume that $\bar{x}$ is infeasible and suppose by contradiction that there exists an infinite set $\mathcal{K} \subset \mathcal{K}_a$ such that $x^k \overset{\mathcal{K}}{\to} \bar{x}$. Since h is continuous, we have $h(x^k) \overset{\mathcal{K}}{\to} h(\bar{x})$. On the other hand, Lemma 2.3 ensures that $h(x^k) \overset{\mathcal{K}}{\to} 0$. Thus $h(\bar{x}) = 0$, contradicting that $\bar{x}$ is infeasible and completing the proof. ∎

Our global convergence result is presented in the next theorem.

THEOREM 2.5. *The sequence $(x^k)_{k\in\mathbb{N}}$ has a stationary accumulation point.*

Proof. Let $\mathcal{K}_a$ be the set defined in (2.2). If $\mathcal{K}_a$ is infinite, then by H2 there exist $\mathcal{K}_1 \subset \mathcal{K}_a$ and $\bar{x} \in X$ such that $x^k \overset{\mathcal{K}_1}{\to} \bar{x}$. From Lemma 2.4, $\bar{x}$ must be stationary.

On the other hand, if $\mathcal{K}_a$ is finite, there exists $k_0 \in \mathbb{N}$ such that every iteration $k \geq k_0$ is an f_0-iteration. Thus $(f_0(x^k))_{k\geq k_0}$ is decreasing and by H1 and H2,

$$f_0\left(x^k\right) - f_0\left(x^{k+1}\right) \to 0. \tag{2.3}$$

Moreover, by construction, $F_k = F_{k_0}$ for all $k \geq k_0$. Therefore, the sequence $(v_k)_{k\in\mathbb{N}}$, defined in Hypothesis H3, satisfies

$$v_k = v_{k_0} > 0 \tag{2.4}$$

for all $k \geq k_0$. If the set

$$\mathcal{K}_2 = \left\{k \in \mathbb{N} \mid \alpha h\left(x^k\right) < f_0\left(x^k\right) - f_0\left(x^{k+1}\right)\right\}$$

is infinite, using (2.3), we conclude that $h(x^k) \overset{\mathcal{K}_2}{\to} 0$. Otherwise, Lemma 2.2(iii) ensures that there exists $k_1 \in \mathbb{N}$ such that $h(x^{k+1}) < (1-\alpha)h(x^k)$ for all $k \geq k_1$, which in turn implies that $h(x^k) \to 0$. Anyway, $(x^k)_{k\in\mathbb{N}}$ has a feasible accumulation point $\bar{x}$. Now we prove that this point is stationary. Let $\mathcal{K}$ be a set of indices such that $x^k \overset{\mathcal{K}}{\to} \bar{x}$ and assume by contradiction that $\bar{x}$ is nonstationary. By Hypothesis H3, there exist $k_2 \in \mathbb{N}$ and $M > 0$ such that

$$f_0\left(x^k\right) - f_0\left(x^{k+1}\right) \geq M v_k$$

for all $k \in \mathcal{K}$, $k \geq k_2$. This together with (2.4) contradicts (2.3), completing the proof. ∎

As we have seen above, the hypothesis H3 is crucial for the convergence analysis. It is a very strong assumption and we must show that there exist methods satisfying this condition. One of them is the inexact restoration method of Martínez and Pilotta [20]. Gonzaga, Karas, and Vanti [13] have proved in their inexact restoration filter method a condition that implies our hypothesis.

We now discuss another way of performing the step, satisfying H3. It uses sequential quadratic programming and decomposes the step into its normal and tangential components.

3. Sequential quadratic programming. In this section we present an SQP method based on that proposed by Fletcher et al. [6], which computes the overall step in two phases. First, a feasibility phase aims at reducing the infeasibility measure h, satisfying a linear approximation of the constraints. Then an optimality phase computes a trial point reducing a quadratic model of the objective function in the linearization of the feasible set. We prove that this approach satisfies Hypothesis H3.

The step computation. Given the current iterate x^k and a trust-region radius $\Delta > 0$, we compute the step by solving the quadratic subproblem

$$(QP_k) \qquad \begin{array}{ll} \text{minimize} & m_k\left(x^k + d\right) \\ \text{subject to} & x^k + d \in \mathcal{L}\left(x^k\right) \\ & \|d\| \leq \Delta, \end{array}$$

where

$$m_k\left(x^k + d\right) = f_0\left(x^k\right) + \nabla f_0\left(x^k\right)^T d + \frac{1}{2} d^T B_k d, \tag{3.1}$$

with B_k symmetric, and

$$\mathcal{L}\left(x^k\right) = \left\{x^k + d \in \mathbb{R}^n \mid f_{\mathcal{E}}\left(x^k\right) + A_{\mathcal{E}}\left(x^k\right) d = 0,\ f_{\mathcal{I}}\left(x^k\right) + A_{\mathcal{I}}\left(x^k\right) d \leq 0\right\}. \tag{3.2}$$

The matrix B_k may be chosen as an approximation of the Hessian of some Lagrangian function or any other symmetric matrix, provided that the sequence (B_k) remains uniformly bounded. See the hypothesis H6 below.

The solution of (QP_k) yields a trial point $x^k + d_\Delta$ that will be evaluated by the filter. To be accepted as the new iterate, this point must not be forbidden.

In fact, we will see the step d_Δ as the sum of two components, a feasibility step n^k and a tangential (optimality) step t_Δ. We now discuss each one of these steps.

Feasibility step and compatibility of (QP_k). The feasibility step n^k must satisfy the constraints of (QP_k) and has the purpose of reducing the infeasibility measure h. This can be done, for example, by

$$n^k = P_{\mathcal{L}(x^k)}\left(x^k\right) - x^k,$$

where $P_{\mathcal{L}(x)}(\cdot)$ is the projection onto the set $\mathcal{L}(x)$. However, we do not use this particular choice, but we shall assume a certain efficiency in this phase, given by the following hypothesis.

H 4. *There exist constants $\delta_h > 0$ and $c_n > 0$ such that for all $k \geq 0$ with $h(x^k) \leq \delta_h$, a step n^k can be computed, satisfying*

$$\left\|n^k\right\| \leq c_n h\left(x^k\right).$$

This assumption means that the feasibility step must be reasonably scaled with respect to the constraints. In particular, $n^k = 0$ whenever x^k is feasible. This hypothesis is discussed by Martínez [19], who presents a feasibility algorithm which satisfies it under reasonable conditions, like some regularity of the constraints and the absence of a stationary point $\bar{x}$ for h, with $h(\bar{x}) \neq 0$.

The step n^k is only useful if it is not too close to the trust-region boundary because, otherwise, the tangential step is unlikely to produce a sufficient decrease in the model m_k. We say that the subproblem (QP_k) is *compatible* when $\mathcal{L}(x^k) \neq \emptyset$ and

$$\left\|n^k\right\| \leq \xi\Delta, \tag{3.3}$$

where $\xi \in (0, 1)$ is a constant.

In our analysis, we shall consider

$$z^k = x^k + n^k, \tag{3.4}$$

the point obtained in the feasibility phase. Note that, from (3.1) and (3.4), we have

$$m_k\left(z^k\right) = m_k\left(x^k + n^k\right) = f_0\left(x^k\right) + \nabla f_0\left(x^k\right)^T n^k + \frac{1}{2} {n^k}^T B_k n^k. \tag{3.5}$$

Tangential step. If the subproblem (QP_k) is compatible, we anticipate a satisfactory decrease in the model when performing a tangential step t_Δ, approximate solution of the quadratic problem

$$(TP_k) \qquad \begin{array}{ll} \text{minimize} & \left(\nabla f_0\left(x^k\right) + B_k n^k\right)^T t + \frac{1}{2} t^T B_k t \\ \text{subject to} & A_{\mathcal{E}}\left(x^k\right) t = 0 \\ & f_{\mathcal{I}}\left(x^k\right) + A_{\mathcal{I}}\left(x^k\right)\left(n^k + t\right) \leq 0 \\ & \left\|n^k + t\right\| \leq \Delta. \end{array}$$

This problem is equivalent to (QP_k) with $d = n^k + t$.

Given the current iterate x^k and a trust-region radius $\Delta > 0$, if (QP_k) is compatible, the trial point is

$$x^k + d_\Delta = z^k + t_\Delta,$$

where $z^k = x^k + n^k$ is the point which comes from the feasibility phase and t_Δ is the tangential step.

Restoration procedure. If the subproblem (QP_k) is not compatible, the algorithm calls a *restoration procedure*, whose aim is to obtain a point $x^{k+1} \notin \bar{\mathcal{F}}_k$ with $h(x^{k+1}) < h(x^k)$, where the function h is the infeasibility measure defined by (1.1). This can be done by taking steps of some algorithm for solving the nonsmooth problem

$$\begin{array}{ll} \text{minimize} & h(x) \\ x \in \mathbb{R}^n & \end{array}.$$

We can now summarize the above discussion in the following algorithm for the step computation. After stating the algorithm we shall make some comments about its features.

ALGORITHM 3.1. *Computation of* $x^{k+1} \notin \bar{\mathcal{F}}_k$

Data: $x^k \in \mathbb{R}^n$, the current filter $\bar{\mathcal{F}}_k$, $0 < \Delta_{\min} < \Delta_{\max}$, $\Delta \in [\Delta_{\min}, \Delta_{\max}]$ and $c_p, \xi, \eta, \gamma \in (0,1)$.

IF $\mathcal{L}(x^k) = \emptyset$,
  use the restoration procedure to obtain $x^{k+1} \notin \bar{\mathcal{F}}_k$.
ELSE
  compute a feasibility step n^k such that $x^k + n^k \in \mathcal{L}(x^k)$
  REPEAT (while the point x^{k+1} is not obtained)
    IF $\left\|n^k\right\| > \xi\Delta$,
      use the restoration procedure to obtain $x^{k+1} \notin \bar{\mathcal{F}}_k$.
      determine B_{k+1} symmetric
    ELSE
      compute the tangential step t_Δ as above and define $d_\Delta = n^k + t_\Delta$
      set $ared = f_0(x^k) - f_0(x^k + d_\Delta)$ and $pred = m_k(x^k) - m_k(x^k + d_\Delta)$

IF $\{x^k + d_\Delta \in \bar{\mathcal{F}}_k\}$ OR $\{pred \geq c_p(h(x^k))^2$ AND $ared < \eta\, pred\}$
  $\Delta = \gamma\Delta$
ELSE
  $x^{k+1} = x^k + d_\Delta$
  determine B_{k+1} symmetric
$\Delta_k = \Delta$

Algorithm 3.1 was inspired in the SQP-filter algorithm proposed by Fletcher et al. [6]. However, there exist some differences between them, which we now point out. The first one is that here the step computation is made separately from the main filter algorithm, presented in section 2. This simplifies the study of the step properties and leaves the convergence analysis of the main algorithm in a clean framework. Another difference is in the trust-region radius. Algorithm 3.1 starts with a radius $\Delta \in [\Delta_{\min}, \Delta_{\max}]$, where $\Delta_{\min}, \Delta_{\max} > 0$ are constants. This procedure is not used in [6], making the convergence proofs involved. To overcome some difficulties they impose a condition like

$$\left\|n^k\right\| \leq c\Delta^{1+\mu},$$

where $c > 0$ and $\mu \in (0,1)$, to accept the normal step and to proceed with the tangential step. In our algorithm, this condition is replaced by (3.3); that is,

$$\left\|n^k\right\| \leq \xi\Delta,$$

where $\xi \in (0,1)$ is a constant. This requirement is usual in the composite-step approaches that we are considering.

We mention that the choice of a minimum radius $\Delta_{\min}$ may cause practical disadvantages, like the rejection of many trial points before the progress of the algorithm. On the other hand, it simplifies the analysis and enhances the chance of taking a pure Newton step.

Remarks. At iteration k, we denote by d_Δ the trial step obtained with the trust-region radius $\Delta \geq \Delta_k$. The point x^{k+1} can be computed in two different ways: by means of a restoration procedure or by $x^{k+1} = x^k + d_{\Delta_k}$. We also have two possibilities for rejecting the trial step d_Δ:

$$x^k + d_\Delta \in \bar{\mathcal{F}}_k \tag{3.6}$$

or

$$pred \geq c_p \left(h\left(x^k\right)\right)^2 \quad \text{and} \quad ared < \eta\, pred. \tag{3.7}$$

In both cases the trust-region radius is reduced and a new step is computed. Thus, in order to accept the step d_Δ, it is not enough to pass the filter criterion. It also must ensure a sufficient decrease in the objective function whenever the predicted reduction is more significant than the constraint violation. In particular, if all iterates are feasible, the first inequality in (3.7) will be always true, because $n^k = 0$ in this case. Furthermore, if $ared \geq \eta\, pred$, then $x^k + d_\Delta \notin \bar{\mathcal{F}}_k$. So, the step acceptance criterion reduces to $ared \geq \eta\, pred$, and the algorithm may be viewed as a classical unconstrained trust-region method.

We now prove that Hypothesis H3 is satisfied if Algorithm 2.1 is applied to problem (P) and the step is obtained by Algorithm 3.1. For that, we shall introduce a

function used as a stationarity measure. Given $x, z \in X$ and the set $\mathcal{L}(x)$ defined in (3.2), we denote

$$d^c(x,z) = P_{\mathcal{L}(x)}\left(z - \nabla f_0(x)\right) - z \tag{3.8}$$

the *projected gradient direction* and the function $\varphi : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$, given by

$$\varphi(x,z) = \begin{cases} -\nabla f_0(x)^T \dfrac{d^c(x,z)}{\|d^c(x,z)\|} & \text{if } d^c(x,z) \neq 0, \\ 0 & \text{otherwise,} \end{cases} \tag{3.9}$$

the stationarity measure. According to [13] we have, at a feasible point $\bar{x}$, that the KKT conditions are equivalent to $d^c(\bar{x},\bar{x}) = 0$. Furthermore, if $\bar{x}$ is nonstationary, then $\varphi(\bar{x},\bar{x}) > 0$.

The projected gradient direction given above is based on a direction introduced by Martínez and Svaiter [21] to define a new optimality condition, called *AGP property* (Approximate Gradient Projection), which implies, and is strictly stronger than, the Fritz–John optimality conditions. Unlike the KKT conditions, it is satisfied by local minimizers of nonlinear programming problems, independently of constraint qualifications.

Note. Let us give an interpretation for the direction $d^c(x,z)$ when $z \in \mathcal{L}(x)$ (which is the case in the algorithm). It is an approximation to

$$d_B(z) = P_{\mathcal{L}(x)}\left(z - \nabla f_0(z)\right) - z.$$

This is the projected Cauchy direction defined by Bertsekas [1] for the minimization of $f_0(\cdot)$ in $\mathcal{L}(x)$, and $d_B(z) = 0$ implies that z is stationary for this problem if $z \in \mathcal{L}(x)$. If, in addition, z is feasible for (P) it is also stationary for (P). The direction $d^c(x,z)$ may be a good descent direction for (P) if

$$\frac{\nabla f_0(x)}{\|\nabla f_0(x)\|} \approx \frac{\nabla f_0(z)}{\|\nabla f_0(z)\|},$$

but otherwise it may be meaningless (possibly null). If $d^c(x^k,z^k) \neq 0$, we consider $d_1^c = \frac{d^c(x^k,z^k)}{\|d^c(x^k,z^k)\|}$. To continue our analysis we define the *generalized Cauchy step* given by

$$t^c = \begin{cases} \underset{\lambda \geq 0}{\operatorname{argmin}} \left\{ m_k\left(z^k + \lambda d_1^c\right) \mid \left\| z^k + \lambda d_1^c - x^k \right\| \leq \Delta \right\} & \text{if } d^c\left(x^k, z^k\right) \neq 0, \\ 0 & \text{otherwise,} \end{cases}$$

and we assume the following hypotheses related to Algorithm 3.1.

H5. *If the subproblem (QP_k) is compatible, then the model decrease at the tangential step t_Δ satisfies*

$$m_k\left(z^k\right) - m_k\left(z^k + t_\Delta\right) \geq m_k\left(z^k\right) - m_k\left(z^k + t^c\right).$$

H 6. *The matrices B_k are uniformly bounded, that is, there exists a constant $\beta > 0$ such that $\|B_k\| \leq \beta$ for all $k \geq 0$.*

The assumption H5 says that the tangential step must be at least as good as the generalized Cauchy step t^c. We also consider a very standard condition on the Hessians B_k, stated in Hypothesis H6.

We start our task by evaluating the infeasibility measure before and after the trial step.

LEMMA 3.2. *Suppose that Hypotheses* H1 *and* H2 *hold. There exists a constant* $c_h > 0$ *such that for any* $x^k \in X$ *and* $\Delta > 0$ *so that a trial step* d_Δ *is obtained by Algorithm* 3.1*,*

$$h\left(x^k\right) \leq c_h \Delta \qquad \textit{and} \qquad h\left(x^k + d_\Delta\right) \leq c_h \Delta^2.$$

Proof. It follows from Hypotheses H1 and H2 that there exists a constant $c_h > 0$ such that

$$\|\nabla f_i(x)\| \leq c_h \qquad \text{and} \qquad \left\|\nabla^2 f_i(x)\right\| \leq c_h \tag{3.10}$$

for all $x \in X$ and $i = 1, \ldots, m$. Consider $x^k \in X$ and $\Delta > 0$ so that a trial step d_Δ is obtained by Algorithm 3.1. Thus the feasibility step n^k also was computed by the algorithm. Taking, without loss of generality, the norm $\|\cdot\|_\infty$ in (1.1) and using the fact that $x^k + n^k \in \mathcal{L}(x^k)$, we conclude that

$$h\left(x^k\right) = \left|f_i\left(x^k\right)\right| = \left|-\nabla f_i\left(x^k\right)^T n^k\right|$$

for some $i \in \mathcal{E}$, or

$$h\left(x^k\right) = f_i\left(x^k\right) \leq -\nabla f_i\left(x^k\right)^T n^k$$

for some $i \in \mathcal{I}$. Hence, from the Cauchy–Schwarz inequality, (3.10), and the trust-region boundedness of n^k, we obtain

$$h\left(x^k\right) \leq \left\|\nabla f_i\left(x^k\right)\right\| \left\|n^k\right\| \leq c_h \Delta,$$

proving the first claim in the lemma.

To prove the other inequality, note that by Taylor's theorem and the fact that $x^k + d_\Delta \in \mathcal{L}(x^k)$,

$$f_i\left(x^k + d_\Delta\right) = \frac{1}{2} d_\Delta^T \nabla^2 f_i\left(x^k + \theta_i d_\Delta\right) d_\Delta,$$

for $i \in \mathcal{E}$, and

$$f_i\left(x^k + d_\Delta\right) \leq \frac{1}{2} d_\Delta^T \nabla^2 f_i\left(x^k + \theta_i d_\Delta\right) d_\Delta,$$

for $i \in \mathcal{I}$, where $\theta_i \in (0, 1)$. Because the trust-region radius is bounded, we may assume without loss of generality that the trial points also remain in the compact set X. Thus, from (3.10), the Cauchy–Schwarz inequality and since $\|d_\Delta\| \leq \Delta$,

$$h\left(x^k + d_\Delta\right) \leq c_h \Delta^2,$$

completing the proof. ∎

We next assess the model and the objective function growth in the feasibility step computed by Algorithm 3.1.

LEMMA 3.3. *Suppose that Hypotheses* H1, H2, H4, *and* H6 *hold. Let* δ_h *be the constant given by* H4*. Given a feasible point* $\bar{x} \in X$*, there exist* $N > 0$ *and a neighborhood* V_1 *of* $\bar{x}$ *such that if* $x^k \in V_1$ *and* $z^k = x^k + n^k$*, then*

(i) $h(x^k) \leq \delta_h$.
(ii) $\left|m_k(x^k) - m_k(z^k)\right| \leq N h(x^k)$.
(iii) $\left|f_0(x^k) - f_0(z^k)\right| \leq N h(x^k)$.

In particular, by (i)*, the hypothesis* H4 *is applicable; that is, the step* n^k *can be computed and satisfies* $\|n^k\| \leq c_n h(x^k)$.

Proof. Let c_n and β be the constants given by H4 and H6, respectively. Consider the constant $c_g = \max\{\|\nabla f_0(x)\| \mid x \in X\}$, whose existence is ensured by H1 and H2. Since $h(\bar{x}) = 0$ and h is continuous, there exists a neighborhood V_1 of $\bar{x}$ such that if $x^k \in V_1$, then

$$h\left(x^k\right) \leq \delta_h \qquad \text{and} \qquad \frac{1}{2}\beta c_n^2 \left(h\left(x^k\right)\right)^2 \leq c_g c_n h\left(x^k\right). \tag{3.11}$$

The first inequality in (3.11) proves (i). By (3.5), we have

$$m_k\left(z^k\right) = m_k\left(x^k\right) + \nabla f_0\left(x^k\right)^T n^k + \frac{1}{2} n^{kT} B_k n^k.$$

Using the Cauchy–Schwarz inequality, H4 and H6, we obtain

$$\begin{aligned} |m_k\left(x^k\right) - m_k\left(z^k\right)| &\leq c_g \left\|n^k\right\| + \tfrac{1}{2}\beta \left\|n^k\right\|^2 \\ &\leq c_g c_n h\left(x^k\right) + \tfrac{1}{2}\beta c_n^2 \left(h\left(x^k\right)\right)^2. \end{aligned}$$

From the second inequality in (3.11), it follows that

$$|m_k\left(x^k\right) - m_k\left(z^k\right)| \leq 2 c_g c_n h\left(x^k\right).$$

On the other hand, by Hypotheses H1 and H2, there exists a constant $L > 0$ such that

$$\left|f_0\left(x^k\right) - f_0\left(z^k\right)\right| \leq L \left\|x^k - z^k\right\|.$$

This together with H4 yields

$$\left|f_0\left(x^k\right) - f_0\left(z^k\right)\right| \leq L c_n h\left(x^k\right).$$

Taking $N = \max\{2c_g c_n, L c_n\}$, we complete the proof. ∎

Now we prove that the model and the objective function reductions are large near a feasible nonstationary point, if we ignore the filter. The first lemma looks only at the tangential step, while the second lemma considers the whole step (feasibility and tangential).

LEMMA 3.4. *Suppose that Hypotheses* H1, H2, and H4–H6 *hold. Let* $\bar{x} \in X$ *be a feasible nonstationary point and* $\bar{\eta} \in (0,1)$*. Consider the neighborhood* V_1 *and the constant* $\Delta_{\min}$ *given by Lemma* 3.3 *and Algorithm* 3.1*, respectively. Then there exist constants* $\Delta_\rho \in (0, \Delta_{\min}]$*,* $\tilde{c} > 0$*, and a neighborhood* $V_2 \subset V_1$ *of* $\bar{x}$ *such that whenever* $x^k \in V_2$*,* $z^k = x^k + n^k$*, and a tangential trial step* t_Δ *is obtained by the algorithm, we have*

(i) $m_k(z^k) - m_k(z^k + t_\Delta) \geq \tilde{c}\Delta'$ *for all* Δ, Δ' *such that* $\Delta' \leq \min\{\Delta, \Delta_\rho\}$.

(ii) $f_0(z^k) - f_0(z^k + t_\Delta) \geq \bar{\eta}\left(m_k(z^k) - m_k(z^k + t_\Delta)\right)$ *for all* $\Delta \in (0, \Delta_\rho]$.

Proof. Let $\Delta > 0$ and $\lambda_{\Delta'} = (1 - \xi)\Delta'$, where ξ is given by (3.3) and $\Delta' \leq \Delta$. First, note that the vector d_1^c, defined before H5, satisfies $\|d_1^c\| = 1$. Consequently,

$$\left\|z^k + \lambda_{\Delta'} d_1^c - x^k\right\| = \left\|n^k + \lambda_{\Delta'} d_1^c\right\| \leq \left\|n^k\right\| + \lambda_{\Delta'} \leq \xi\Delta + (1 - \xi)\Delta' \leq \Delta.$$

Using the assumption on the Cauchy point H5, we obtain

$$m_k\left(z^k\right) - m_k\left(z^k + t_\Delta\right) \geq m_k\left(z^k\right) - m_k\left(z^k + t^c\right) \geq m_k\left(z^k\right) - m_k\left(z^k + \lambda_{\Delta'} d_1^c\right).$$

Developing the quadratic model (3.1) in the right-hand side, we conclude that

$$m_k\left(z^k\right) - m_k\left(z^k + t_\Delta\right) \geq \lambda_{\Delta'}\left(-\nabla f_0\left(x^k\right)^T d_1^c - {n^k}^T B_k d_1^c - \frac{1}{2}\lambda_{\Delta'} {d_1^c}^T B_k d_1^c\right).$$

By (3.9), $\varphi(x^k, z^k) = -\nabla f_0(x^k)^T d_1^c$ and by H6, $\|B_k\| \leq \beta$. Hence

$$m_k\left(z^k\right) - m_k\left(z^k + t_\Delta\right) \geq \lambda_{\Delta'}\left(\varphi\left(x^k, z^k\right) - \left\|n^k\right\|\beta - \frac{1}{2}\lambda_{\Delta'}\beta\right). \tag{3.12}$$

Since $\bar{x}$ is feasible nonstationary, the continuous function φ satisfies $\varphi(\bar{x}, \bar{x}) > 0$. Using the fact that $\|n^k\| \leq c_n h(x^k)$ by H4, we conclude that there exist a neighborhood V_2 of $\bar{x}$ and $\Delta_0 \in (0, \Delta_{\min}]$ such that for any $x^k \in V_2$ and $\Delta' \in (0, \Delta_0]$,

$$\varphi\left(x^k, z^k\right) \geq \frac{1}{2}\varphi\left(\bar{x}, \bar{x}\right) \qquad \text{and} \qquad \left\|n^k\right\|\beta + \frac{1}{2}\lambda_{\Delta'}\beta \leq \frac{1}{4}\varphi\left(\bar{x}, \bar{x}\right).$$

Thus, by (3.12), we obtain for $\Delta' \leq \min\{\Delta, \Delta_0\}$,

$$m_k\left(z^k\right) - m_k\left(z^k + t_\Delta\right) \geq \frac{1}{4}\lambda_{\Delta'}\varphi(\bar{x}, \bar{x}) = \frac{1}{4}\left(1 - \xi\right)\varphi\left(\bar{x}, \bar{x}\right)\Delta'.$$

This proves (i) for any $\Delta_\rho \leq \Delta_0$ and $\tilde{c} = \frac{1}{4}(1-\xi)\varphi(\bar{x}, \bar{x})$.

To prove (ii), note that by the mean value theorem,

$$ared_{z^k} \stackrel{\text{def}}{=} f_0\left(z^k\right) - f_0\left(z^k + t_\Delta\right) = -\nabla f_0\left(z^k + \theta t_\Delta\right)^T t_\Delta$$

for some $\theta \in (0, 1)$. On the other hand,

$$pred_{z^k} \stackrel{\text{def}}{=} m_k\left(z^k\right) - m_k\left(z^k + t_\Delta\right) = -\nabla f_0\left(x^k\right)^T t_\Delta - t_\Delta^T B_k n^k - \frac{1}{2} t_\Delta^T B_k t_\Delta.$$

By H1 and H2, we can apply the mean value inequality to ∇f_0 to conclude that there exists a constant $L > 0$ such that

$$\left\|\nabla f_0\left(x^k\right) - \nabla f_0\left(z^k + \theta t_\Delta\right)\right\| \leq L\left\|z^k - x^k + \theta t_\Delta\right\|,$$

so, using the facts that $\|B_k\| \leq \beta$ and $\|t_\Delta\| \leq \Delta$, we obtain

$$\begin{aligned} |ared_{z^k} - pred_{z^k}| &\leq L\left\|z^k - x^k + \theta t_\Delta\right\|\|t_\Delta\| + \beta\left\|n^k\right\|\|t_\Delta\| + \tfrac{1}{2}\beta\|t_\Delta\|^2 \\ &\leq L\left\|n^k\right\|\Delta + L\Delta^2 + \beta\left\|n^k\right\|\Delta + \tfrac{1}{2}\beta\Delta^2 \\ &= (L+\beta)\left\|n^k\right\|\Delta + \left(L + \tfrac{1}{2}\beta\right)\Delta^2. \end{aligned}$$

We can restrict the neighborhood V_2, if necessary, and take $\Delta_\rho \leq \Delta_0$ such that for any $x^k \in V_2$ and $\Delta \in (0, \Delta_\rho]$,

$$\frac{(L+\beta)\left\|n^k\right\|}{\tilde{c}} \leq \frac{1-\bar{\eta}}{2} \qquad \text{and} \qquad \frac{\left(L + \frac{1}{2}\beta\right)\Delta}{\tilde{c}} \leq \frac{1-\bar{\eta}}{2}.$$

Consequently, using (i) with $\Delta' = \Delta$,

$$\left|\frac{ared_{z^k}}{pred_{z^k}} - 1\right| = \left|\frac{ared_{z^k} - pred_{z^k}}{pred_{z^k}}\right| \leq \frac{(L+\beta)\left\|n^k\right\|\Delta + \left(L + \frac{1}{2}\beta\right)\Delta^2}{\tilde{c}\Delta} \leq 1 - \bar{\eta},$$

completing the proof. □

In the next lemma we extend for the whole step the properties of the tangential step near a feasible nonstationary point.

LEMMA 3.5. *Suppose that Hypotheses* H1, H2, and H4–H6 *hold. Let* $\bar{x} \in X$ *be a feasible nonstationary point and* $0 < \eta < 1$. *Consider the constant* γ *given in Algorithm* 3.1, *the neighborhood* V_2 *and the constant* Δ_ρ *given in Lemma* 3.4. *Then there exists a neighborhood* $V_3 \subset V_2$ *of* $\bar{x}$ *such that whenever* $x^k \in V_3$, $z^k = x^k + n^k$, *and a tangential trial step* t_Δ *is obtained by the algorithm, we have for all* $\Delta \in [\gamma^2\Delta_\rho, \Delta_\rho]$,

(i) $m_k(x^k) - m_k(z^k + t_\Delta) \geq \frac{1}{2}\tilde{c}\Delta$,

(ii) $f_0(x^k) - f_0(z^k + t_\Delta) \geq \eta(m_k(x^k) - m_k(z^k + t_\Delta))$.

Proof. Let $\bar{\eta} \in (\eta, 1)$ and $\tau = \frac{\bar{\eta}-\eta}{\bar{\eta}+\eta}$. Consider the constants N and $\tilde{c}$ given by Lemmas 3.3 and 3.4, respectively, and $V_3 \subset V_2$ a neighborhood of $\bar{x}$ such that for all $x \in V_3$,

$$Nh(x) \leq \min\left\{\frac{1}{2}\tilde{c}\gamma^2\Delta_\rho, \tau\bar{\eta}\tilde{c}\gamma^2\Delta_\rho\right\}. \tag{3.13}$$

Hence, if $x^k \in V_3$ and $\Delta \in [\gamma^2\Delta_\rho, \Delta_\rho]$, we can apply Lemma 3.3 to conclude that

$$\left|m_k\left(x^k\right) - m_k\left(z^k\right)\right| \leq Nh\left(x^k\right) \leq \frac{1}{2}\tilde{c}\gamma^2\Delta_\rho \leq \frac{1}{2}\tilde{c}\Delta.$$

It follows from this and Lemma 3.4(i) with $\Delta' = \Delta$ that

$$m_k\left(x^k\right) - m_k\left(z^k + t_\Delta\right) = m_k\left(x^k\right) - m_k\left(z^k\right) + m_k\left(z^k\right) - m_k\left(z^k + t_\Delta\right) \geq \frac{1}{2}\tilde{c}\Delta,$$

proving (i).

(ii) Applying again Lemmas 3.3 and 3.4 together with (3.13), we obtain

$$\left|f_0\left(x^k\right) - f_0\left(z^k\right)\right| \leq Nh\left(x^k\right) \leq \tau\bar{\eta}\tilde{c}\gamma^2\Delta_\rho \leq \tau\bar{\eta}\tilde{c}\Delta \leq \tau\left(f_0\left(z^k\right) - f_0\left(z^k + t_\Delta\right)\right)$$

and

$$m_k\left(x^k\right) - m_k\left(z^k\right) \leq Nh\left(x^k\right) \leq \tau\tilde{c}\gamma^2\Delta_\rho \leq \tau\tilde{c}\Delta \leq \tau\left(m_k\left(z^k\right) - m_k\left(z^k + t_\Delta\right)\right).$$

Consequently,

$$\begin{aligned} f_0\left(x^k\right) - f_0\left(z^k + t_\Delta\right) &= f_0\left(x^k\right) - f_0\left(z^k\right) + f_0\left(z^k\right) - f_0\left(z^k + t_\Delta\right) \\ &\geq (1-\tau)\left(f_0\left(z^k\right) - f_0\left(z^k + t_\Delta\right)\right) \end{aligned} \tag{3.14}$$

and

$$\begin{aligned} m_k\left(x^k\right) - m_k\left(z^k + t_\Delta\right) &= m_k\left(x^k\right) - m_k\left(z^k\right) + m_k\left(z^k\right) - m_k\left(z^k + t_\Delta\right) \\ &\leq (1+\tau)\left(m_k\left(z^k\right) - m_k\left(z^k + t_\Delta\right)\right). \end{aligned} \tag{3.15}$$

Therefore, if $x^k \in V_3$ and $\Delta \in [\gamma^2\Delta_\rho, \Delta_\rho]$, using (3.14), (3.15), and Lemma 3.4(ii), we obtain

$$\begin{aligned} f_0\left(x^k\right) - f_0\left(z^k + t_\Delta\right) &\geq (1-\tau)\bar{\eta}\left(m_k\left(z^k\right) - m_k\left(z^k + t_\Delta\right)\right) \\ &\geq \frac{(1-\tau)\bar{\eta}}{(1+\tau)}\left(m_k\left(x^k\right) - m_k\left(z^k + t_\Delta\right)\right) \\ &= \eta\left(m_k\left(x^k\right) - m_k\left(z^k + t_\Delta\right)\right), \end{aligned}$$

completing the proof. ∎

In the next two results we shall use the *filter slack* H_k, defined in (2.1). First we show that, near a feasible nonstationary point, the rejection of a step is due to a large increase of the infeasibility.

LEMMA 3.6. *Suppose that Hypotheses* H1, H2, and H4–H6 *hold. Let* $\bar{x} \in X$ *be a feasible nonstationary point and consider the constants* γ *and* Δ_ρ *given by Algorithm* 3.1 *and Lemma* 3.4, *respectively, and the neighborhood* V_3 *given by Lemma* 3.5. *Then there exists a neighborhood* $V \subset V_3$ *of* $\bar{x}$ *such that whenever* $x^k \in V$, $z^k = x^k + n^k$, *and a tangential trial step* t_Δ *is obtained by the algorithm, we have*

$$h\left(z^k + t_\Delta\right) \geq H_k$$

for any $\Delta \in [\gamma^2 \Delta_\rho, \Delta_\rho]$ *that was rejected by Algorithm* 3.1.

Proof. Let α, η, N, and $\tilde{c}$ be the constants given by Algorithms 2.1, 3.1 and Lemmas 3.3, 3.4, respectively. Consider $V \subset V_3$ a neighborhood of $\bar{x}$ such that for all $x \in V$,

$$Nh(x) \leq \frac{1}{2}\tilde{c}\gamma^2\Delta_\rho \qquad \text{and} \qquad \alpha h(x) \leq \frac{1}{2}\eta\tilde{c}\gamma^2\Delta_\rho. \tag{3.16}$$

Hence, if $x^k \in V$ and $\Delta \in [\gamma^2\Delta_\rho, \Delta_\rho]$, we can apply Lemma 3.3 to obtain

$$\left|m_k\left(x^k\right) - m_k\left(z^k\right)\right| \leq Nh\left(x^k\right) \leq \frac{1}{2}\tilde{c}\gamma^2\Delta_\rho \leq \frac{1}{2}\tilde{c}\Delta,$$

which together with Lemma 3.4 yields

$$m_k\left(x^k\right) - m_k\left(z^k + t_\Delta\right) \geq \frac{1}{2}\tilde{c}\Delta \geq \frac{1}{2}\tilde{c}\gamma^2\Delta_\rho. \tag{3.17}$$

Using Lemma 3.5, (3.16), and (3.17), we obtain

$$\begin{aligned} f_0\left(x^k\right) - f_0\left(z^k + t_\Delta\right) &\geq \eta\left(m_k\left(x^k\right) - m_k\left(z^k + t_\Delta\right)\right) \\ &\geq \frac{1}{2}\eta\tilde{c}\gamma^2\Delta_\rho \\ &\geq \alpha h\left(x^k\right). \end{aligned}$$

Since $z^k + t_\Delta = x^k + d_\Delta$, it follows that

$$f_0\left(x^k\right) - f_0\left(x^k + d_\Delta\right) \geq \eta\left(m_k\left(x^k\right) - m_k\left(x^k + d_\Delta\right)\right) \tag{3.18}$$

and

$$f_0\left(x^k + d_\Delta\right) \leq f_0\left(x^k\right) - \alpha h\left(x^k\right). \tag{3.19}$$

Therefore, if the trial step d_Δ was rejected by Algorithm 3.1, then $x^k + d_\Delta \in \bar{\mathcal{F}}_k$ because of (3.18). We thus conclude from (3.19) that

$$h\left(z^k + t_\Delta\right) \geq H_k,$$

completing the proof. ∎

We now prove the main result of this section: *Hypothesis* H3 *is satisfied.* Indeed, we give a sufficient condition to ensure H3. As we saw in Theorem 2.5, this hypothesis was crucial in the convergence analysis of section 2.

For the purpose of our analysis, we shall consider the set of restoration iterations

$$\mathcal{K}_r = \left\{k \in \mathbb{N} \mid \mathcal{L}\left(x^k\right) = \emptyset \text{ or } \left\|n^k\right\| > \xi\Delta_k\right\}, \tag{3.20}$$

where $\mathcal{L}(x^k)$ is defined by (3.2). We also assume the following hypothesis.

H7. *Every feasible accumulation point* $\bar{x} \in X$ *of* $(x^k)_{k\in\mathbb{N}}$ *satisfies the Mangasarian–Fromovitz constraint qualification; namely, the gradients* $\nabla f_i(\bar{x})$ *for* $i \in \mathcal{E}$ *are linearly independent, and there exists a direction* $d \in \mathbb{R}^n$ *such that* $A_{\mathcal{E}}(\bar{x})d = 0$ *and* $A_{\bar{\mathcal{I}}}(\bar{x})d < 0$, *where* $\bar{\mathcal{I}} = \{i \in \mathcal{I} \mid f_i(\bar{x}) = 0\}$.

THEOREM 3.7. *Suppose that Algorithm* 2.1 *is applied to problem* (P)*, with the step computed by Algorithm* 3.1*, and that Hypotheses* H1, H2, and H4–H7 *hold. Given a feasible nonstationary point* $\bar{x} \in X$*, there exist* $M > 0$ *and a neighborhood* V *of* $\bar{x}$ *such that if* $x^k \in V$*, then*

$$f_0\left(x^k\right) - f_0\left(x^{k+1}\right) \geq M\sqrt{H_k}.$$

In particular, since $\sqrt{H_k} \geq v_k$*, the hypothesis* H3 *is satisfied.*

Proof. Let $\bar{x}$ be a feasible nonstationary point. Consider the neighborhood V given by Lemma 3.6 and the constant Δ_ρ given by Lemma 3.4. Without loss of generality, we can assume that

$$\Delta_\rho \leq \frac{\gamma^2}{c_h} \min\left\{\frac{\xi}{c_n}, \frac{\tilde{c}}{2N}, \frac{\tilde{c}}{2c_p}, \frac{\eta\tilde{c}}{2\alpha}\right\}, \tag{3.21}$$

where α is the constant given in Algorithm 2.1, ξ, γ, c_p, and η are given in Algorithm 3.1, c_n is given in Hypothesis H4, and c_h, N, and $\tilde{c}$ are given by Lemmas 3.2, 3.3, and 3.4, respectively. By the constraint qualification hypothesis H7, we can assume that if $x^k \in V$, then $\mathcal{L}(x^k) \neq \emptyset$. Thus, Algorithm 3.1 starts with the radius $\Delta \geq \Delta_{\min}$ and ends with $\Delta_k = \gamma^r\Delta$, where r is the number of times that the radius was reduced in the algorithm. We shall consider two cases, respectively, with $\Delta_k \geq \gamma^2\Delta_\rho$ and $\Delta_k < \gamma^2\Delta_\rho$.

First case: $\Delta_k \geq \gamma^2\Delta_\rho$. In this case, using the hypothesis H4 and restricting the neighborhood V, if necessary, we have

$$\left\|n^k\right\| \leq c_n h\left(x^k\right) \leq \xi\gamma^2\Delta_\rho \leq \xi\Delta_k.$$

So, Algorithm 3.1 does not enter the restoration phase during the iteration k, that is, $k \notin \mathcal{K}_r$. Therefore, applying Lemma 3.4(i) with $\Delta' = \gamma^2\Delta_\rho$, we obtain

$$m_k\left(z^k\right) - m_k\left(x^{k+1}\right) = m_k\left(z^k\right) - m_k\left(z^k + t_{\Delta_k}\right) \geq \tilde{c}\gamma^2\Delta_\rho. \tag{3.22}$$

On the other hand, by Lemma 3.3,

$$\left|m_k\left(x^k\right) - m_k\left(z^k\right)\right| \leq Nh\left(x^k\right). \tag{3.23}$$

We can restrict again the neighborhood V, if necessary, so that

$$Nh\left(x^k\right) \leq \frac{1}{2}\tilde{c}\gamma^2\Delta_\rho, \quad c_p\left(h\left(x^k\right)\right)^2 \leq \frac{1}{2}\tilde{c}\gamma^2\Delta_\rho \quad \text{and} \quad h\left(x^k\right) \leq 1. \tag{3.24}$$

By (3.22)–(3.24), we have

$$pred_k \stackrel{\text{def}}{=} m_k\left(x^k\right) - m_k\left(x^{k+1}\right) \geq \frac{1}{2}\tilde{c}\gamma^2\Delta_\rho \geq c_p\left(h\left(x^k\right)\right)^2.$$

Then the mechanism of Algorithm 3.1 and the fact that $H_k \leq 1$ imply that

$$f_0\left(x^k\right) - f_0\left(x^{k+1}\right) \stackrel{\text{def}}{=} ared_k \geq \eta\, pred_k \geq \frac{1}{2}\eta\tilde{c}\gamma^2\Delta_\rho \geq \frac{1}{2}\eta\tilde{c}\gamma^2\Delta_\rho\sqrt{H_k}. \tag{3.25}$$

Second case: now, assume that $\Delta_k < \gamma^2\Delta_\rho$. In this case we shall analyze two possibilities. In the first one, we suppose that $h(x^k + d_\Delta) \geq H_k$ for all $\Delta \leq \gamma\Delta_\rho$ such that the trial step d_Δ has been computed. Let $\tilde{\Delta} = \frac{\Delta_k}{\gamma}$. Since $\Delta_k < \Delta_{\min}$, the trial step $\tilde{d} = d_{\tilde{\Delta}}$ was computed. Furthermore, $h(x^k + \tilde{d}) \geq H_k$ because $\tilde{\Delta} < \gamma\Delta_\rho$. So, using Lemma 3.2 and the definition of H_k, it follows that

$$c_h\Delta_k^2 = c_h\gamma^2\tilde{\Delta}^2 \geq \gamma^2 h\big(x^k + \tilde{d}\big) \geq \gamma^2 H_k \geq \gamma^2 h\left(x^k\right). \tag{3.26}$$

From Hypothesis H4, (3.21), and (3.26), we obtain

$$\left\|n^k\right\| \leq c_n h\left(x^k\right) \leq \frac{c_n c_h}{\gamma^2}\Delta_k^2 \leq \xi\Delta_k,$$

meaning that Algorithm 3.1 does not enter the restoration phase during the iteration k, that is, $k \notin \mathcal{K}_r$. Therefore, by Lemma 3.4(i) with $\Delta' = \Delta_k$, we have

$$m_k\left(z^k\right) - m_k\left(x^{k+1}\right) = m_k\left(z^k\right) - m_k\left(z^k + t_{\Delta_k}\right) \geq \tilde{c}\Delta_k. \tag{3.27}$$

Moreover, (3.23) remains true in this case and together with (3.21) and (3.26) yields

$$\left|m_k\left(x^k\right) - m_k\left(z^k\right)\right| \leq Nh\left(x^k\right) \leq \frac{Nc_h}{\gamma^2}\Delta_k^2 \leq \frac{1}{2}\tilde{c}\Delta_k. \tag{3.28}$$

Combining (3.27) and (3.28), we obtain

$$pred_k = m_k\left(x^k\right) - m_k\left(x^{k+1}\right) \geq \frac{1}{2}\tilde{c}\Delta_k. \tag{3.29}$$

By (3.21), (3.24), and (3.26),

$$pred_k \geq \frac{c_p c_h}{\gamma^2}\Delta_k^2 \geq c_p h\left(x^k\right) \geq c_p\left(h\left(x^k\right)\right)^2.$$

Thus, the mechanism of Algorithm 3.1, (3.26), and (3.29) imply that

$$f_0\left(x^k\right) - f_0\left(x^{k+1}\right) = ared_k \geq \eta\, pred_k \geq \frac{1}{2}\eta\tilde{c}\Delta_k \geq \frac{\eta\tilde{c}\gamma}{2\sqrt{c_h}}\sqrt{H_k}. \tag{3.30}$$

Let us see now the second possibility; that is, there exists $\Delta \leq \gamma\Delta_\rho$ such that $h(x^k + d_\Delta) < H_k$. Let $\hat{\Delta}$ be the first Δ satisfying such a condition. We shall show that $\hat{\Delta} = \Delta_k$. Let $\bar{d} = d_{\bar{\Delta}}$ be the trial step obtained with $\bar{\Delta} = \frac{\hat{\Delta}}{\gamma}$. We claim that

$$h\left(x^k + \bar{d}\right) \geq H_k. \tag{3.31}$$

Indeed, if $\bar{\Delta} \leq \gamma\Delta_\rho$, the definition of $\hat{\Delta}$ ensures the claim. On the other hand, if $\bar{\Delta} > \gamma\Delta_\rho$, then $\bar{\Delta} \in [\gamma^2\Delta_\rho, \Delta_\rho]$ and, applying Lemma 3.6, we have

$$h\left(x^k + \bar{d}\right) = h\left(z^k + t_{\bar{\Delta}}\right) \geq H_k.$$

So, the inequality (3.31) holds. As above, we can therefore prove that

$$c_h\hat{\Delta}^2 \geq \gamma^2 H_k \geq \gamma^2 h\left(x^k\right) \tag{3.32}$$

and

$$pred_{\hat{\Delta}} \stackrel{\text{def}}{=} m_k\left(x^k\right) - m_k\left(z^k + t_{\hat{\Delta}}\right) \geq \frac{1}{2}\tilde{c}\hat{\Delta}. \tag{3.33}$$

Now, by the same reasoning as in the proof of Lemma 3.5(ii), using (3.32) and (3.33), we obtain

$$ared_{\hat{\Delta}} \stackrel{\text{def}}{=} f_0\left(x^k\right) - f_0\left(z^k + t_{\hat{\Delta}}\right) \geq \eta\, pred_{\hat{\Delta}} \geq \frac{1}{2}\eta\tilde{c}\hat{\Delta}, \tag{3.34}$$

which together with (3.21) and (3.32) yields

$$ared_{\hat{\Delta}} > \frac{\alpha c_h}{\gamma^2}\hat{\Delta}^2 \geq \alpha h\left(x^k\right). \tag{3.35}$$

The definition of $\hat{\Delta}$ and (3.35) ensure that $z^k + t_{\hat{\Delta}}$ is accepted by the filter. Therefore, using (3.34), we conclude that $z^k + t_{\hat{\Delta}} = x^{k+1}$. Moreover, (3.32) and (3.34) imply that

$$f_0\left(x^k\right) - f_0\left(z^k + t_{\hat{\Delta}}\right) \geq \frac{1}{2}\eta\tilde{c}\hat{\Delta} \geq \frac{\eta\tilde{c}\gamma}{2\sqrt{c_h}}\sqrt{H_k},$$

that is,

$$f_0\left(x^k\right) - f_0\left(x^{k+1}\right) \geq \frac{\eta\tilde{c}\gamma}{2\sqrt{c_h}}\sqrt{H_k}. \tag{3.36}$$

Since (3.25), (3.30), and (3.36) run out all possibilities, by defining

$$M = \min\left\{\frac{1}{2}\eta\tilde{c}\gamma^2\Delta_\rho, \frac{\eta\tilde{c}\gamma}{2\sqrt{c_h}}\right\},$$

we complete the proof. □

4. Conclusions. In this work we have studied filter methods for nonlinear programming. These methods seem to be a successful strategy for globalizing algorithms without the use of merit functions. Since its appearance in 1997, the filter technique has been applied to many problems, including sequential linear programming (SLP), sequential quadratic programming (SQP), inexact restoration, interior-point methods, nonlinear systems of equations, unconstrained optimization, and nonsmooth convex constrained optimization.

Our purpose here was to present a general globally convergent filter algorithm that leaves the step computation separate from the main algorithm. This technique cleans the convergence analysis and accepts any method for computing the step, as long as this internal algorithm is efficient in the sense that the hypothesis H3 is satisfied. For completeness, we have shown that there are methods which satisfy the referred hypothesis.

Acknowledgment. We thank the referees for their valuable comments and suggestions which very much improved this paper.

PARAMETERIZED MINIMAX PROBLEM: ON LIPSCHITZ-LIKE DEPENDENCE OF THE SOLUTION WITH RESPECT TO THE PARAMETER*

MARC QUINCAMPOIX† AND NADIA ZLATEVA‡

Abstract. We study Lipschitz continuity with respect to the parameter of the set of solutions of a parameterized minimax problem on a product Banach space. We present a sufficient condition, ensuring that the map which to any value of the parameter assigns the set of solutions of the problem (possibly multi-valued, and unbounded) possesses Aubin property.

Key words. parameterized minimax problem, saddle point, set-valued map, Aubin property, pseudo-Lipschitz continuity

AMS subject classifications. 90C31, 90C47, 46N10

DOI. 10.1137/060653718

1. Introduction.

Consider the parameterized minimax problem

$$M(\lambda) \qquad \inf_{x\in K} \sup_{y\in L} f(x,y,\lambda),$$

where $\lambda \in \Lambda$ is a parameter.

Here K and L are nonempty closed subsets of the Banach spaces X and Y, respectively; $\{f(\cdot,\cdot,\lambda) : X \times Y \to \mathbb{R}, \lambda \in \Lambda\}$ is a family of real-valued functions parameterized by $\lambda \in \Lambda$, where Λ is a subset of the Banach space Z.

Saddle point of $f(\cdot,\cdot,\lambda)$ on $K \times L$ is any point $(\overline{x},\overline{y}) \in K \times L$ that satisfies

$$f(\overline{x},y,\lambda) \le f(\overline{x},\overline{y},\lambda) \le f(x,\overline{y},\lambda) \quad \forall x \in K, \quad \forall y \in L.$$

A saddle point $(\overline{x},\overline{y})$ of $f(\cdot,\cdot,\lambda)$ on $K \times L$ can be considered as a solution of the minimax problem $M(\lambda)$ by reason of $(\overline{x},\overline{y}) \in K \times L$ and $f(\overline{x},\overline{y}) = \inf_{x\in K} \sup_{y\in L} f(x,y,\lambda)$. Let us denote the (possibly empty) set of all saddle points of the function $f(\cdot,\cdot,\lambda)$ on $K \times L$ by

$$\mathcal{S}(\lambda) := \{(\overline{x},\overline{y}) \in K\times L : f(\overline{x},y,\lambda) \le f(\overline{x},\overline{y},\lambda) \le f(x,\overline{y},\lambda),\ \forall x \in K,\ \forall y \in L\}. \tag{1.1}$$

That $\mathcal{S}(\lambda)$ is nonempty can be ensured in several cases. For example, if K and L are convex sets, $f(x,y,\lambda)$ is convex and lower semicontinuous in x, concave and upper semicontinuous in y, and there are $x_0 \in K$ and $y_0 \in L$ such that $f(\cdot,y_0,\lambda)$ is inf-compact and $f(x_0,\cdot,\lambda)$ is sup-compact, then $\mathcal{S}(\lambda) \neq \emptyset$ by a minimax result due to Hartung [17], Theorem 1 (see also [3], Theorem 6.2.8). When, moreover, $f(x,y,\lambda)$ is strictly convex in x and strictly concave in y, then $\mathcal{S}(\lambda)$ is a singleton.

In the present work we presume the existence of saddle points for $M(\lambda)$ and focus our attention on studying Lipschitz-like dependence of the solution set $\mathcal{S}(\lambda)$ on the

parameter λ. That is, we find sufficient conditions for Lipschitz-like continuity of the set-valued map

$$\mathcal{S} : \lambda \rightrightarrows \mathcal{S}(\lambda)$$

from Λ to nonempty subsets of $K \times L$.

Of course, when the map $\mathcal{S}$ is single-valued, the Lipschitz continuity is understood in the classical sense. However, the map $\mathcal{S}$ could be multivalued. Moreover, its values $\mathcal{S}(\lambda)$ could be unbounded sets. A notion of Lipschitz-like continuity very appropriate for such a case is due to Aubin [1, 2]:

The multivalued map $S : \Lambda \rightrightarrows X$ has *Aubin property*, or it is *Aubin continuous, near* $(\overline{\lambda}, \overline{x}) \in \operatorname{gph} S$, if there are positive constant κ and neighborhoods U of $\overline{x}$, and V of $\overline{\lambda}$, such that

$$e(S(\lambda) \cap U, S(\mu)) \leq \kappa \|\lambda - \mu\|, \quad \forall \lambda, \mu \in \Lambda \cap V, \tag{1.2}$$

where $e(A, B) := \sup_{x \in A} d(x, B)$ is the *excess* from set A to set B with $e(\emptyset, B) = +\infty$. S is said to be *Aubin continuous* if S is Aubin continuous near any point $(\overline{\lambda}, \overline{x}) \in \operatorname{gph} S$.

For various applications of Aubin continuity in the field of nonlinear analysis and optimization the reader is referred, e.g., to [1, 2, 4, 23]. The Aubin property of a map S near $(\overline{\lambda}, \overline{x})$ is known to be equivalent to the metric regularity of S^{-1} near $(\overline{x}, \overline{\lambda})$ and was originally introduced in [2] under the name of *pseudo-Lipschitz continuity*. For bibliographical details see [23].

Whenever S is locally bounded, Aubin continuity coincides with the classical notion for Lipschitz continuity of set-valued maps [4, 23]

$$e(S(\lambda), S(\mu)) \leq \kappa \|\lambda - \mu\|, \quad \forall \lambda, \mu,$$

but Aubin property works without any boundedness imposed on the values of S. Aubin property is in fact Lipschitzean property localized in the range space, as well as in the domain space.

In the present paper we establish quite general sufficient conditions for Aubin continuity of the saddle point map $\mathcal{S} : \lambda \rightrightarrows \mathcal{S}(\lambda)$ arising from the parameterized minimax problem $M(\lambda)$. Examples illustrating this condition are presented. Several corollaries related to the case of convex-concave smooth data are also sketched.

The paper is organized as follows. In section 2, after a short subsection devoted to preliminaries, we formulate and prove a sufficient condition for Aubin continuity of the solution map $S : \Lambda \rightrightarrows X$ of a parameterized minimization problem

$$P(\lambda) \qquad \inf_{x \in K} f(x, \lambda).$$

Many authors study Lipschitz-like dependence on λ of the solutions of the associated generalized Euler equation

$$0 \in \nabla_x f(x, \lambda) + N_K(x);$$

see [7, 15, 25] and the references therein for recent developments. Here we do not follow that approach, because the map $St : \lambda \rightrightarrows St(\lambda)$, which to any λ assigns the set $St(\lambda)$ of solutions of the generalized Euler equation, does not inherit Aubin continuity property from S (see Example 2.6 for a parameterized problem such that the corresponding S is Aubin continuous while St is not).

In section 3 we present our main result (Theorem 3.2), which is a sufficient condition for Aubin continuity of the saddle point map $\mathcal{S} : \Lambda \rightrightarrows X \times Y$ of a parameterized minimax problem $M(\lambda)$.

It is clear that the results of section 2 are contained in the more general framework of section 3. Nevertheless, we think that presenting the proof of the former simple case will help the understanding of the more technical proof of the latter general case.

Section 4 relates the obtained results to some questions in the field of two-player zero sum differential games.

2. Parameterized minimization problem.

2.1. Preliminaries. As already said, X stands for a Banach space. We denote its norm by $\|\cdot\|$, and its open unit ball by B°. The dual space is denoted by X^*, while for the duality brackets notation $\langle\cdot,\cdot\rangle$ is used.

For $C \subset X$ the *distance function* to C is $d(x,C) := \inf_{c\in C} \|x-c\|$ if $C \neq \emptyset$, and $d(x,C) := +\infty$ if $C = \emptyset$.

Function $f : X \to \mathbb{R}$ is *Gâteaux differentiable* at $\overline{x} \in X$ if there exists $\nabla f(\overline{x}) \in X^*$, called the *Gâteaux derivative* of f at $\overline{x}$, such that for any $h \in X$,

$$\lim_{t\to 0} \frac{f(\overline{x}+th) - f(\overline{x})}{t} = \langle \nabla f(\overline{x}), h\rangle.$$

Also, f is said to be *strictly differentiable* at $\overline{x}$ whenever

$$\lim_{\substack{x\to\overline{x}\\ t\to 0}} \frac{f(x+th) - f(x)}{t} = \langle \nabla f(\overline{x}), h\rangle.$$

Given an open set $U \subset X$ we denote by $C^{1,\alpha}(U)$ the class of all Gâteaux differentiable functions $f : U \to \mathbb{R}$ such that $\nabla f : U \to X^*$ is α-*Hölder* on U, that is, for some constant $L > 0$,

$$\|\nabla f(x) - \nabla f(y)\| \le L\|x-y\|^\alpha, \quad \forall x, y \in U.$$

Let Z be a Banach space, whose norm is also denoted by $\|\cdot\|$. Let S be a *map* from $\Lambda \subset Z$ to X. If not stated otherwise, *map* means *set-valued map*. In order to outline the multivaluedness we write $S : Z \rightrightarrows X$. The *inverse* $S^{-1} : X \rightrightarrows Z$ of S is defined by $\lambda \in S^{-1}(x) \iff x \in S(\lambda)$. The *graph*, *domain*, and *range* sets of S are given by

$$\operatorname{gph} S := \{(\lambda, x) \mid x \in S(\lambda)\}, \quad \operatorname{dom} S := \{\lambda \mid S(\lambda) \neq \emptyset\}, \quad \operatorname{rge} S := \operatorname{dom} S^{-1},$$

respectively.

Any product space $X \times Z$ of Banach spaces X and Z is considered with the supremum norm $\|(x,z)\| := \max\{\|x\|, \|z\|\}$.

2.2. Assumptions. Let $\{f(\cdot,\lambda) : X \to \mathbb{R}, \lambda \in \Lambda\}$ be a family of functions parameterized by $\lambda \in \Lambda \subset Z$. We look for sufficient conditions to ensure Aubin continuity of the solutions of the parameterized family of constrained minimization problems:

$$P(\lambda) \qquad \inf_{x\in K} f(x,\lambda),$$

where K is a given nonempty closed set in X.

For $\lambda \in \Lambda$, the (possibly empty) set of solutions of the minimization problem $P(\lambda)$ is denoted by

$$S(\lambda) := \left\{ \overline{x} \in K : f(\overline{x}, \lambda) = \inf_{x \in K} f(x, \lambda) \right\},$$

and its optimal value by

$$m(\lambda) := \inf_{x \in K} f(x, \lambda).$$

It is well known that even for smooth parameterized problem $P(\lambda)$ the solution $S : \Lambda \rightrightarrows X$ may fail Lipschitz continuity. For example, for $f(x, \lambda) = \frac{1}{4}x^4 - \lambda x$, where $x, \lambda \in \mathbb{R}$, and $K = [-1, 1]$, we see that for $\lambda \in (-1, 1)$ the solution is $S(\lambda) = \{\sqrt[3]{\lambda}\}$, and it is not Lipschitz continuous at $\lambda = 0$ ([7], Example 4.31).

Hence, to establish Lipschitz behavior of S one needs something more than the standard requirements. We now turn to relevant analysis of $P(\lambda)$.

DEFINITION 2.1. *Let X and Z be Banach spaces. Let $U \subset X$, $V \subset Z$ be nonempty. We denote by $\mathfrak{L}^{\alpha,\beta}(U; V)$, $\alpha, \beta \in [0, 1]$, the class of all functions $g : U \times U \times V \to \mathbb{R}$ such that there exists a constant $k_g > 0$ such that for all $x, x' \in U$ and all $\lambda, \lambda' \in V$,*

$$|g(x, x', \lambda) - g(x, x', \lambda')| \leq k_g \|x - x'\|^\alpha \|\lambda - \lambda'\|^\beta.$$

For example, $g \in \mathfrak{L}^{1,1}(U; V)$ means that $g(x, x', \cdot)$ is Lipschitz on V and its best Lipschitz constant $L(x, x')$ satisfies $L(x, x') \leq k\|x - x'\|$ for some positive constant k and all $x, x' \in U$.

With the parameterized family of functions $\{f(\cdot, \lambda), \lambda \in \Lambda\}$ one may associate two difference functions: the function $f_1 : X \times X \times \Lambda \to \mathbb{R}$ defined by

$$f_1(x, x', \lambda) := f(x, \lambda) - f(x', \lambda),$$

and the function $f_2 : \Lambda \times \Lambda \times X \to \mathbb{R}$ defined by

$$f_2(\lambda, \lambda', x) := f(x, \lambda) - f(x, \lambda').$$

The above notions are linked through the following:

PROPOSITION 2.2. *For any $U \subset X$, $V \subset Z$ the function $f_1 \in \mathfrak{L}^{\alpha,\beta}(U; V)$ if and only if $f_2 \in \mathfrak{L}^{\beta,\alpha}(V; U)$.*

Proof. Let $f_1 \in \mathfrak{L}^{\alpha,\beta}(U; V)$. Take any $x, x' \in U$, and any $\lambda, \lambda' \in V$. Since

$$\begin{aligned} f_2(\lambda, \lambda', x) - f_2(\lambda, \lambda', x') &= [f(x, \lambda) - f(x, \lambda')] - [f(x', \lambda) - f(x', \lambda')] \\ &= [f(x, \lambda) - f(x', \lambda)] - [f(x, \lambda') - f(x', \lambda')] \\ &= f_1(x, x', \lambda) - f_1(x, x', \lambda') \leq k_{f_1} \|x - x'\|^\alpha \|\lambda - \lambda'\|^\beta, \end{aligned}$$

one can take $k_{f_2} := k_{f_1}$ to conclude that $f_2 \in \mathfrak{L}^{\beta,\alpha}(V; U)$. The proof of the other direction is similar. ∎

We are ready to present the sufficient condition for Aubin continuity of the solution map.

Given a $(\overline{\lambda}, \overline{x}) \in \operatorname{gph} S$, consider the following local assumption A at $(\overline{\lambda}, \overline{x})$:

$$(A) \quad \begin{cases} \text{there exist neighborhoods } U \text{ of } \overline{x} \text{ and } V \text{ of } \overline{\lambda}, \text{ such that} \\ 1. \quad S(\lambda) \cap U \neq \emptyset \text{ for all } \lambda \in \Lambda \cap V; \\ \text{and there exist constants } c > 0 \text{ and } \alpha \in [0, 1] \text{ such that} \\ 2. \quad f(x, \lambda') \geq m(\lambda') + c d^{1+\alpha}(x, S(\lambda')), \ \forall \lambda, \lambda' \in \Lambda \cap V, \ \forall x \in S(\lambda) \cap U; \\ 3. \quad f_1 \in \mathfrak{L}^{\alpha,1}(K; \Lambda \cap V). \end{cases}$$

By Proposition 2.2 it is clear that assumption $A3$ could be replaced with $f_2 \in \mathfrak{L}^{1,\alpha}(\Lambda \cap V; K)$.

It is clear that $A1$ implies that $m(\lambda)$ is finite for all $\lambda \in \Lambda \cap V$.

In the case $\alpha = 1$, assumption $A2$ can be considered as a relaxed (in x) uniform (in λ') version of the so-called second-order growth condition. One says that the *second-order growth condition* holds for the problem

$$\inf_{x \in K} f(x)$$

in a neighborhood N of the solution set S_0, if there exists a constant $c > 0$ such that

$$f(x) \geq \inf_K f + cd^2(x, S_0), \quad \forall x \in K \cap N. \tag{2.1}$$

This condition is involved in a number of works (see [5, 6, 7, 19, 24]) in order to ensure Lipschitz stability of the solution map S of the constrained minimization problem. Let us recall that S is said to be *Lipschitz stable* or, equivalently, *upper Lipschitz* at a point $\overline{\lambda} \in \Lambda$, if there exist a constant $\kappa > 0$ and a neighborhood V of $\overline{\lambda}$ such that it holds that

$$e(S(\lambda), S(\overline{\lambda})) \leq \kappa \left\|\lambda - \overline{\lambda}\right\|, \quad \forall \lambda \in \Lambda \cap V.$$

Let us note that Lipschitz stability is a point property: it holds for S at a fixed point $\overline{\lambda}$, while Aubin continuity we wish to obtain, is a local property, and it holds uniformly at all points μ in some neighborhood V of the referenced point $\overline{\lambda}$. Obviously, Aubin continuity of S near $(\overline{\lambda}, \overline{x})$ implies Lipschitz stability of $S \cap U$ at $\overline{\lambda}$ while the opposite implication is not always true.

A stronger version of uniform second-order growth condition than $A2$ with $\alpha = 1$ is given in [7], Definition 5.16. It implies single-valuedness and local Lipschitz continuity of S (cf. [7], Theorem 5.17 and Remark 5.19). In contrast, assumption $A2$ does not imply neither single-valuedness nor local boundedness of the solution map S (see Example 2.6).

We would now give a few examples of parameterized families of functions $\{f(\cdot, \lambda), \lambda \in \Lambda\}$ for which A holds, in this way showing the consistency of our main assumption.

Obviously, the compactness of K and lower semicontinuity of $f(\cdot, \lambda)$ on K are sufficient to ensure $A1$ (note that weak compactness and weak lower semicontinuity would do just as well).

$A2$ with $\alpha = 1$ is satisfied at any $(\overline{\lambda}, \overline{x}) \in \operatorname{gph} S$ provided that, for example, $U = X$, $V = Z$, and $K \subset X$ is a nonempty closed convex set, the functions $f(\cdot, \lambda)$ are lower semicontinuous, and uniformly on $\lambda \in \Lambda$ strongly convex on K, that is, for some constant $c > 0$ the inequality

$$f(tx' + (1-t)x'', \lambda) \leq tf(x', \lambda) + (1-t)f(x'', \lambda) - ct(1-t)\|x' - x''\|^2$$

holds for every $t \in [0, 1]$, every $x', x'' \in K$ and every $\lambda \in \Lambda$.

Lemma 2.3 below provides examples of parameterized families of functions satisfying $A3$. However, we need a few more definitions before stating this lemma.

Recall that the *Clarke generalized derivative* of Lipschitz function $f : X \to \mathbb{R}$ at $\overline{x} \in X$ in direction $h \in X$ is

$$f^\circ(\overline{x}; h) := \limsup_{\substack{x \to \overline{x} \\ t \downarrow 0}} \frac{f(x + th) - f(x)}{t},$$

and the *Clarke subdifferential* at $\overline{x}$ is the nonempty w^* compact set

$$\partial f(\overline{x}) := \{x^* \in X^* : \langle x^*, h\rangle \le f^\circ(\overline{x}; h),\ \forall h \in X\};$$

see [12]. It is well known that for any $h \in X$ there exists some $x^* \in \partial f(\overline{x})$ such that

$$\langle x^*, h\rangle = f^\circ(\overline{x}; h).$$

Lipschitz function $f : U \to \mathbb{R}$ is said to be *regular* on an open set $U \subset X$ if for any $h \in X$ and any $\overline{x} \in U$ its *directional derivative*

$$f'(\overline{x}; h) := \lim_{t \downarrow 0} \frac{f(\overline{x} + th) - f(\overline{x})}{t}$$

exists and is equal to $f^\circ(\overline{x}; h)$. Convex continuous functions and strictly differentiable functions are examples of regular functions.

Let $f(x, \lambda)$ be Lipschitz on each variable bivariate function. Denote by $f_x^\circ(\overline{x}, \overline{\lambda}; h)$ and by $f_x'(\overline{x}, \overline{\lambda}; h)$ the generalized derivative and the directional derivative of $f(\cdot, \overline{\lambda})$ at $\overline{x}$ in direction h, respectively. Also, denote by $\partial_x f(\overline{x}, \overline{\lambda})$ the partial Clarke subdifferential of $f(\cdot, \overline{\lambda})$ at $\overline{x}$, and by $\partial_\lambda f(\overline{x}, \overline{\lambda})$ the partial Clarke subdifferential of $f(\overline{x}, \cdot)$ at $\overline{\lambda}$.

LEMMA 2.3. *Let $(\overline{\lambda}, \overline{x}) \in \operatorname{gph} S$ and let $U \subset X$ and $V \subset Z$ be convex neighborhoods of K and $\overline{\lambda}$, respectively. Consider the conditions:*

$$(F1) \qquad \begin{cases} \text{for } \lambda \in \Lambda \cap V,\ f(\cdot, \lambda) \text{ is Lipschitz and regular on } U \text{ and} \\ \partial_x f(x, \cdot) : \Lambda \cap V \to X^* \text{ is a } k\text{-Lipschitz map on } \Lambda \cap V \\ \text{with } k \text{ that does not depend on } x \in U, \end{cases}$$

$$(F2) \qquad \begin{cases} \text{for } x \in K,\ f(x, \cdot) \text{ is Lipschitz and regular on } V \text{ and} \\ \partial_\lambda f(\cdot, \lambda) : K \to Z^* \text{ is a } k\text{-Lipschitz map on } K \\ \text{with } k \text{ that does not depend on } \lambda \in V. \end{cases}$$

If f satisfies $F1$ or $F2$, then $A3$ holds with $\alpha = 1$.

Proof. Let f satisfy $F1$. Fix $x, y \in K$ and $\lambda, \mu \in \Lambda \cap V$. Consider the function $r(t) := f(y + t(x - y), \lambda)$ which is well-defined on an open interval I containing $[0, 1]$. Since the function $f(\cdot, \lambda)$ is assumed to be Lipschitz on U, we have that r is Lipschitz on I. By Rademacher's theorem, for almost all $t \in [0, 1]$ there exists

$$\begin{aligned} r'(t) &= \lim_{s \to 0} \frac{r(t+s) - r(t)}{s} = \lim_{s \downarrow 0} \frac{f(y + t(x-y) + s(x-y), \lambda) - f(y + t(x-y), \lambda)}{s} \\ &= f_x'(y + t(x-y), \lambda; x - y) = f_x^\circ(y + t(x-y), \lambda; x - y). \end{aligned}$$

The last equality holds because $f(\cdot, \lambda)$ is regular on U.

Hence,

$$f(x, \lambda) - f(y, \lambda) = r(1) - r(0) = \int_0^1 r'(t)\, dt = \int_0^1 f_x^\circ(y + t(x-y), \lambda; x - y)\, dt. \tag{2.2}$$

Similarly,

$$f(x, \mu) - f(y, \mu) = \int_0^1 f_x^\circ(y + t(x-y), \mu; x - y)\, dt. \tag{2.3}$$

There exists $x^*_\lambda(t) \in \partial_x f(y + t(x-y), \lambda)$ such that $f^\circ_x(y + t(x-y), \lambda; x-y) = \langle x^*_\lambda(t), x-y\rangle$, so (2.2) becomes

$$f(x,\lambda) - f(y,\lambda) = \int_0^1 \langle x^*_\lambda(t), x-y\rangle \, dt. \tag{2.4}$$

Since $x_\lambda(t) \in \partial_x f(y + t(x-y), \lambda)$ and the multivalued map $\partial_x f(x,\cdot) : \Lambda \cap V \to X^*$ is k–Lipschitz continuous with w^* compact images, there is $x^*_\mu(t) \in \partial_x f(y+t(x-y), \mu)$ such that $\|x^*_\lambda(t) - x^*_\mu(t)\| \le k\|\lambda - \mu\|$. Note that k does not depend on either $t \in [0,1]$ or $x, y \in U$.

Let us use these for estimating $f_1(x,y,\lambda) - f_1(x,y,\mu)$.

From (2.4) we get

$$\begin{aligned} f(x,\lambda) - f(y,\lambda) &= \int_0^1 \langle x^*_\lambda(t) - x^*_\mu(t), x-y\rangle \, dt + \int_0^1 \langle x^*_\mu(t), x-y\rangle \, dt \\ &\le \int_0^1 \|x^*_\lambda(t) - x^*_\mu(t)\| \, \|x-y\| \, dt + \int_0^1 \langle x^*_\mu(t), x-y\rangle \, dt \\ &\le k\|\lambda-\mu\| \, \|x-y\| + \int_0^1 \langle x^*_\mu(t), x-y\rangle \, dt. \end{aligned}$$

Since $x^*_\mu(t) \in \partial_x f(y+t(x-y), \mu)$, it holds that $\langle x^*_\mu(t), x-y\rangle \le f^\circ_x(y+t(x-y), \mu; x-y)$, and by (2.3) we have

$$\int_0^1 \langle x^*_\mu(t), x-y\rangle \, dt \le \int_0^1 f^\circ_x(y + t(x-y), \mu; x-y) \, dt = f(x,\mu) - f(y,\mu).$$

Hence,

$$f(x,\lambda) - f(y,\lambda) \le f(x,\mu) - f(y,\mu) + k\|\lambda-\mu\|\|x-y\|;$$

that is, $f_1(x,y,\lambda) \le f_1(x,y,\mu) + k\|\lambda-\mu\|\|x-y\|$, or

$$f_1(x,y,\lambda) - f_1(x,y,\mu) \le k\|\lambda-\mu\|\|x-y\|,$$

which means that $f_1 \in \mathfrak{L}^{1,1}(K; \Lambda \cap V)$.

If f satisfies $F2$, then by the same reasoning one obtains that $f_2 \in \mathfrak{L}^{1,1}(\Lambda \cap V; K)$ and by Proposition 2.2, $A3$ holds. □

It is interesting to note here that the regularity (in particular, the differentiability) can be asked for the argument x as in $F1$, or for the parameter λ as in $F2$.

It is clear that both $F1$ and $F2$ hold whenever $f \in C^{1,1}(U \times V)$.

2.3. Lipschitz-like continuity of the solution map. Here we prove that given $(\overline{\lambda}, \overline{x}) \in \operatorname{gph} S$, assumption A is sufficient to ensure Aubin continuity of the solution map S near $(\overline{\lambda}, \overline{x})$.

PROPOSITION 2.4. *Assume that X and Z are Banach spaces and consider a family of constraint minimization problems $P(\lambda)$ parameterized by $\lambda \in \Lambda$, a nonempty subset of Z.*

If for some $(\overline{\lambda}, \overline{x}) \in \operatorname{gph} S$ assumption A holds, then

$$e(S(\lambda) \cap U, S(\mu)) \le \frac{k_{f_1}}{c}\|\lambda - \mu\|, \quad \forall \lambda, \mu \in \Lambda \cap V, \tag{2.5}$$

and the solution map S is Aubin continuous near $(\overline{\lambda}, \overline{x}) \in \operatorname{gph} S$.

Proof. Take any $\lambda \in \Lambda \cap V$ and any $x_\lambda \in S(\lambda) \cap U$ (which is a nonempty set thanks to $A1$). By $A2$, for arbitrary $\mu \in \Lambda \cap V$

$$f(x_\lambda, \mu) \geq m(\mu) + cd^{1+\alpha}(x_\lambda, S(\mu)). \tag{2.6}$$

Since by $A1$ the set $S(\mu) \cap U$ is nonempty, for any $\varepsilon > 0$ there exists some $x_\mu^\varepsilon \in S(\mu)$ such that

$$\|x_\lambda - x_\mu^\varepsilon\| \leq d(x_\lambda, S(\mu)) + \varepsilon. \tag{2.7}$$

As $x_\mu^\varepsilon \in S(\mu)$ we have $m(\mu) = f(x_\mu^\varepsilon, \mu)$ and inequality (2.6) reads

$$f(x_\lambda, \mu) \geq f(x_\mu^\varepsilon, \mu) + cd^{1+\alpha}(x_\lambda, S(\mu)). \tag{2.8}$$

Since $x_\lambda \in S(\lambda)$, we have that

$$f(x_\mu^\varepsilon, \lambda) \geq f(x_\lambda, \lambda). \tag{2.9}$$

By adding (2.8) and (2.9) and rearranging, we obtain

$$[f(x_\lambda, \mu) - f(x_\mu^\varepsilon, \mu)] - [f(x_\lambda, \lambda) - f(x_\mu^\varepsilon, \lambda)] \geq cd^{1+\alpha}(x_\lambda, S(\mu)).$$

That is,

$$f_1\left(x_\lambda, x_\mu^\varepsilon, \mu\right) - f_1\left(x_\lambda, x_\mu^\varepsilon, \lambda\right) \geq cd^{1+\alpha}(x_\lambda, S(\mu)). \tag{2.10}$$

Using $A3$, that is, $f_1 \in \mathfrak{L}^{\alpha,1}(K; \Lambda \cap V)$, we estimate the left-hand side of (2.10):

$$f_1\left(x_\lambda, x_\mu^\varepsilon, \mu\right) - f_1\left(x_\lambda, x_\mu^\varepsilon, \lambda\right) \leq k_{f_1}\|x_\lambda - x_\mu^\varepsilon\|^\alpha \|\lambda - \mu\|.$$

Hence, we have that $k_{f_1}\|\lambda - \mu\| \, \|x_\lambda - x_\mu^\varepsilon\|^\alpha \geq cd^{1+\alpha}(x_\lambda, S(\mu))$. From this and (2.7) it follows that

$$k_{f_1}\|\lambda - \mu\|[d(x_\lambda, S(\mu)) + \varepsilon]^\alpha \geq cd^{1+\alpha}(x_\lambda, S(\mu)).$$

Letting $\varepsilon \downarrow 0$ and then dividing by $d^\alpha(x_\lambda, S(\mu)) > 0$ (if $= 0$ the inequality below is trivial), we obtain $k_{f_1}\|\lambda - \mu\| \geq cd(x_\lambda, S(\mu))$, or

$$d(x_\lambda, S(\mu)) \leq \frac{k_{f_1}}{c}\|\lambda - \mu\|.$$

As x_λ was an arbitrary point in $S(\lambda) \cap U$, the latter yields

$$e(S(\lambda) \cap U, S(\mu)) \leq \frac{k_{f_1}}{c}\|\lambda - \mu\|,$$

completing the proof. □

2.4. Examples and corollaries. The following is a basic example of nonsmooth parameterized minimization problem with Lipschitz continuous solution map with unbounded values. We show that it is within the scope of Proposition 2.4.

Example 2.5. Let $K = \mathbb{R}^2$ and

$$f(x_1, x_2, \lambda) := |x_1 - x_2 - \lambda|,$$

$x_1, x_2, \lambda \in \mathbb{R}$. Consider the parameterized family of unconstrained minimization problems over the plane

$$P(\lambda) \qquad \inf_{x_1,x_2} f(x_1, x_2, \lambda).$$

Then the solution map $S : \lambda \rightrightarrows S(\lambda)$ is Lipschitz continuous.

Proof. Obviously, for any $\lambda \in \mathbb{R}$ the solution set consists of a single line, i.e., $S(\lambda) = \{(x_1, x_2) : x_1 - x_2 = \lambda\}$. Moreover, for λ and μ the solution sets $S(\lambda)$ and $S(\mu)$ are parallel lines. The distance between $S(\lambda)$ and $S(\mu)$ is the distance from any point $(\overline{x}_1, \overline{x}_2) \in S(\lambda)$ to the line $x_1 - x_2 = \mu$ which is equal to $\frac{|\overline{x}_1 - \overline{x}_2 - \mu|}{\sqrt{2}} = \frac{|\lambda - \mu|}{\sqrt{2}}$, so the map S is Lipschitz continuous with Lipschitz constant $\frac{1}{\sqrt{2}}$.

Note that the sufficient condition A holds. Indeed

$A1$ holds with $U \equiv \mathbb{R}^2$;

$A2$ holds with $\alpha = 0$, $c = \sqrt{2}$, and $U = \mathbb{R}^2$, $V = \mathbb{R}$;

$A3$ holds because $f_1 \in \mathfrak{L}^{0,1}(\mathbb{R}^2, \mathbb{R})$ with $k_{f_1} = 2$.

The Lipschitz constant provided by Proposition 2.4 is $\frac{k_{f_1}}{c} = \sqrt{2}$. □

The next example shows that studying the generalized Euler equation may sometimes be inadequate for obtaining Aubin continuity of the solution map. This is because the set of the stationary points may be larger than the set of minima.

Example 2.6. Let $K = \mathbb{R}^2$ and

$$f(x_1, x_2, \lambda) := (x_1 + \lambda x_2 - 1)^2 (x_2 + \lambda x_1 + 1)^2,$$

$x_1, x_2, \lambda \in \mathbb{R}$. Consider the parameterized family of unconstrained minimization problems over the plane

$$P(\lambda) \qquad \inf_{x_1,x_2} f(x_1, x_2, \lambda).$$

Then at the point $\overline{\lambda} = 1$ the set of solutions $S(\lambda)$ is smaller than the set of stationary points $St(\lambda) := \{x \in \mathbb{R}^2 : 0 \in \nabla_x f(x, \lambda)\}$. Moreover, the map S is Aubin continuous near any point in his graph while St is not Aubin continuous near the point $(\overline{\lambda}, \overline{x}) \in \operatorname{gph} St$ where $\overline{\lambda} = 1$ and $\overline{x} = (0, 0)$.

Proof. Straightforward computations show that for any $\lambda \in \mathbb{R}$ the solution set

$$S(\lambda) = \{(x_1, x_2) : x_2 + \lambda x_1 = -1, \text{ or } x_1 + \lambda x_2 = 1\}$$

is the union of two lines—the line $p_1(\lambda)$ with equation $x_2 + \lambda x_1 = -1$ and the line $p_2(\lambda)$ with equation $x_1 + \lambda x_2 = 1$. Because of

$$\begin{aligned} \nabla_x f(x, \lambda) = [&2(x_1 + \lambda x_2 - 1)(x_2 + \lambda x_1 + 1)(2\lambda x_1 + (1 + \lambda^2)x_2 + 1 - \lambda), \\ &2(x_1 + \lambda x_2 - 1)(x_2 + \lambda x_1 + 1)((1 + \lambda)^2 x_1 + 2\lambda x_2 + \lambda - 1)], \end{aligned}$$

the set of the stationary points at $\overline{\lambda} = 1$ consists of three parallel lines

$$St(1) = \{(x_1, x_2) : x_1 + x_2 = 1, \text{ or } x_1 + x_2 = -1, \text{ or } x_1 + x_2 = 0\},$$

while for $\lambda \neq 1$, $St(\lambda) \equiv S(\lambda)$.

It is not difficult to see that S is Aubin continuous near an arbitrary point $(\lambda, x) \in \operatorname{gph} S$ (we note, by the way, that S is not Lipschitz continuous). Indeed, fix $\tilde{\lambda} \in \mathbb{R}$ and take $\tilde{x} = (\tilde{x}_1, \tilde{x}_2) \in S(\tilde{\lambda}) = p_1(\tilde{\lambda}) \cup p_2(\tilde{\lambda})$. Obviously, $\tilde{x} \neq 0$.

Take λ such that $|\lambda-\tilde{\lambda}|<1/2$. If $\tilde{x}\in p_1(\tilde{\lambda})$, then

$$d(\tilde{x},S(\lambda))\le d(\tilde{x},p_1(\lambda))=\frac{\left|\left(\lambda-\tilde{\lambda}\right)\tilde{x}_1\right|}{\sqrt{1+\lambda^2}}\le\left|\lambda-\tilde{\lambda}\right|\,|\tilde{x}_1|\,,$$

and if $\tilde{x}\in p_2(\tilde{\lambda})$, then

$$d(\tilde{x},S(\lambda))\le d(\tilde{x},p_2(\lambda))=\frac{\left|\left(\lambda-\overline{\lambda}\right)\tilde{x}_2\right|}{\sqrt{1+\lambda^2}}\le\left|\lambda-\tilde{\lambda}\right|\,|\tilde{x}_2|\,,$$

which yields

$$d(\tilde{x},S(\lambda))\le\left|\lambda-\tilde{\lambda}\right|\max\{|\tilde{x}_1|,|\tilde{x}_2|\}\le\left|\lambda-\tilde{\lambda}\right|\,\|\tilde{x}\|<\|\tilde{x}\|/2.$$

This implies that for all λ such that $|\lambda-\tilde{\lambda}|<1/2$ the intersection of $S(\lambda)$ with the neighborhood $U:=\tilde{x}+\|\tilde{x}\|B^\circ$ is nonempty.

Take $x=(x_1,x_2)\in S(\lambda)\cap U$ and μ such that $|\mu-\tilde{\lambda}|<1/2$. Similarly we get

$$d(x,S(\mu))\le|\lambda-\mu|\,\|x\|\le|\lambda-\mu|\,[\|x-\tilde{x}\|+\|\tilde{x}\|]\le2\|\tilde{x}\|\,|\lambda-\mu|.$$

Hence,

$$e(S(\lambda)\cap U,S(\mu))\le2\|\tilde{x}\|\,|\lambda-\mu|,\quad\forall\lambda,\mu\in\tilde{\lambda}+\frac{1}{2}B^\circ,$$

which means that S is Aubin continuous near $(\tilde{\lambda},\tilde{x})\in\operatorname{gph}S$.

In contrast, St is not Aubin continuous near the point, $(\overline{\lambda},\overline{x})\in\operatorname{gph}St$ where $\overline{\lambda}=1$ and $\overline{x}=(0,0)$. Indeed, if St is Aubin continuous near that point, then $d(\overline{x},St(\lambda))$ tends to zero as λ tends to 1. But the distance

$$d(\overline{x},St(\lambda))=\min\{d(\overline{x},p_1(\lambda)),d(\overline{x},p_2(\lambda))\}=\frac{1}{\sqrt{1+\lambda^2}}$$

tends to $\frac{1}{\sqrt{2}}$ as λ tends to 1, which means that St is not Aubin continuous near $(\overline{\lambda},\overline{x})\in\operatorname{gph}St$. □

As an immediate consequence of Proposition 2.4 we get the following.

COROLLARY 2.7. *Let for the parameterized family of minimization problems $P(\lambda)$ the following assumption hold*

$$(A')\qquad\begin{cases}\text{for all }\lambda\in\Lambda,\ \text{all }x\in K,\ \text{and some }c>0\\ 1.\ S(\lambda)\neq\emptyset;\\ 2.\ f(x,\lambda)\ge m(\lambda)+cd^2(x,S(\lambda));\\ 3.\ f\in C^{1,1}(X\times Z).\end{cases}$$

Then the solution map $S:\Lambda\rightrightarrows X$ is Lipschitz continuous on Λ.

In a Banach space X with separable dual X^* the notion of a second-order subdifferential for a function $f\in C^{1,1}(X)$ is introduced in [16] (see also the previous work [18] for the finite dimensional case). For any $x\in X$ the second-order subdifferential $\partial^2f(x)$ of f at x is a nonempty, convex, and w^* compact set in $\mathcal{L}(X\times X)$ (the Banach space of all bilinear continuous functionals $M:X\times X\to\mathbb{R}$ with the norm $\|M\|:=\sup_{\|h_1\|=\|h_2\|=1}|M[h_1,h_2]|$), which is singleton exactly when f is twice strictly Gâteaux differentiable at x.

Setting a simple condition on the second subdifferential is sufficient to get a family of functions satisfying assumption A' in the above corollary.

Indeed, let X be a Banach space with separable dual. Let in the parameterized family of minimization problems $P(\lambda)$, $f \in C^{1,1}(X \times Z)$, and let the constraint set K be closed and convex. If there exist $c > 0$ with

$$\langle M(y-x), y-x\rangle \geq c\|y-x\|^2 \quad \text{for all } \lambda \in \Lambda,\ x, y \in K,\ M \in \partial^2 f(\cdot,\lambda)(x), \tag{2.11}$$

then the solution map $S : \Lambda \to X$ will be single-valued and Lipschitz continuous on Λ.

It is easily seen that (2.11) implies uniform on $\lambda \in \Lambda$ strong convexity of $f(\cdot,\lambda)$ on K. By this and continuity of $f(\cdot,\lambda)$, for every λ the infimum of $f(\cdot,\lambda)$ is attained at unique $x_\lambda \in K$ and $A'1$ holds.

For any $x \in K$ and $\lambda \in \Lambda$ there exists some $z_\lambda \in K$ and $M_{z_\lambda} \in \partial^2 f(\cdot,\lambda)(z_\lambda)$ with

$$f(x,\lambda) = f(x_\lambda,\lambda) + \langle \nabla_x f(x_\lambda,\lambda), x - x_\lambda\rangle + \frac{1}{2}\langle M_{z_\lambda}(x - x_\lambda), x - x_\lambda\rangle$$

(see [16]). Since x_λ is a minimum point for $f(\cdot,\lambda)$ on K and K is convex, then for all $x \in K$, $\langle \nabla_x f(x_\lambda,\lambda), x - x_\lambda\rangle \geq 0$ and from above equality and (2.11)

$$f(x,\lambda) \geq m(\lambda) + \frac{1}{2}c\|x - x_\lambda\|^2,$$

so $A'2$ holds with $\alpha = 1$.

We will use Corollary 2.7 to obtain existence and Lipschitz continuity of the optimal solution for a linearly perturbed optimization problem, assuming a slightly weaker version (see (2.12) below) of the uniform second-order growth condition (Definition 5.19 in [7]), and $C^{1,1}$ data. In this way we extend [7], Theorem 5.17 (see also [7], Remark 5.19), where C^2 data are assumed.

Recall that the Banach space X has *Radon–Nikodym property* (RNP) if for every bounded set C and every $\varepsilon > 0$, there exists an $x \in C$ that does not belong to the closed convex hull of $C \setminus \{x + \varepsilon B^\circ\}$. All Banach spaces which have separable dual and all reflexive Banach spaces have RNP. In [13], p. 157 there is a long list of equivalent definitions of RNP. A good introductory survey on RNP is [14].

An efficient tool in dealing with minimization problems on Banach space X with RNP is *Stegall's variational principle* [26] (see also [21], Theorem 5.15): Let $C \subset X$ be a non-empty closed and bounded convex set and let $f : C \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous function, bounded below on C, then for every $\varepsilon > 0$, there exists $x^* \in X^*$ with $\|x^*\| \leq \varepsilon$ such that $f + x^*$ attains its strong minimum on C. Let us remind that $x_0 \in C$ is said to be a *strong minimum* for function $g : C \to \mathbb{R} \cup \{+\infty\}$ on the set C if $g(x_0) = \inf_C g$ and $\|x_n - x_0\| \to 0$ whenever $g(x_n) \to g(x_0)$.

Corollary 2.8. *Let the Banach space X have Radon–Nikodym property. Consider a parameterized family of minimization problems $P(\lambda)$, where the parameter space is X^* and $f : X \times X^* \to \mathbb{R}$ is defined by $f(x,\lambda) := f(x) + \langle \lambda, x\rangle$.*

Assume that the constraint set K is closed and convex, $f \in C^{1,1}(X)$, and $S(0)$ is nonempty.

Suppose that there exist neighborhood V of the origin 0 of X^* and a constant $c > 0$ such that for all $\lambda \in V$ and all $x_\lambda \in S(\lambda)$ it holds that

$$f(x,\lambda) \geq f(x_\lambda,\lambda) + c\|x - x_\lambda\|^2, \quad \forall x \in K. \tag{2.12}$$

Then there exists a neighborhood W of the origin 0 of X^* such that $S(\lambda)$ is single-valued and Lipschitz continuous on W.

Proof. From (2.12) it is clear that $S(\lambda)$ contains at most one point for $\lambda \in V$.

We will show that $S(\lambda)$ is nonempty for λ belonging to some neighborhood of 0. Fix $\gamma > 0$ such that $W := 2\gamma B^\circ \subset V$.

Given $\lambda \in \gamma B^\circ$, let ε_k be a sequence of positive numbers less than γ, tending to zero.

Thanks to (2.12) with $\lambda = 0$, $f(\cdot, \lambda)$ is bounded below on K.

If K is bounded we could apply directly Stegall's variational principle for the function $f(\cdot, \lambda) : K \to \mathbb{R}$ and ε_k to find $x_k^* \in X^*$ with $\|x_k^*\| \le \varepsilon_k$ and a strong minimum x_k of $f(\cdot, \lambda) + x_k^*$ on K.

If K is not bounded, a variant of Stegall's variational principle still holds thanks to (2.12). Indeed, (2.12) for $\lambda = 0$ reads

$$f(x) \ge f(x_0) + c\|x - x_0\|^2, \quad \forall x \in K,$$

which yields that for all $x \in K$,

$$\begin{aligned} f(x, \lambda) &\ge f(x_0) + \langle \lambda, x\rangle + c\|x - x_0\|^2 = f(x_0, \lambda) + \langle \lambda, x - x_0\rangle + c\|x - x_0\|^2 \\ &\ge f(x_0, \lambda) + \|x - x_0\|[c\|x - x_0\| - \|\lambda\|] \\ &\ge f(x_0, \lambda) + \|x - x_0\|[c\|x - x_0\| - \gamma]. \end{aligned} \tag{2.13}$$

Set $r := \frac{3\gamma}{c}$. Now, we apply Stegall's variational principle for the function $f(\cdot, \lambda)$ on the closed bounded set $K \cap \{x_0 + rB\}$ and ε_k. Thus, there exists $x_k^* \in X^*$, $\|x_k^*\| < \varepsilon_k$, and a point $x_k \in K \cap \{x_0 + rB\}$ such that $f(\cdot, \lambda) + x_k^*$ attains a strong minimum on $K \cap \{x_0 + rB\}$ at x_k. Moreover, x_k is a strong minimum of $f(\cdot, \lambda) + x_k^*$ on K. Indeed, if we assume that $x \in K$ is such that

$$f(x, \lambda) + \langle x_k^*, x\rangle \le f(x_k, \lambda) + \langle x_k^*, x_k\rangle = \inf_{K \cap \{x_0 + rB\}} f(\cdot, \lambda) + x_k^* \le f(x_0, \lambda) + \langle x_k^*, x_0\rangle,$$

then by (2.13) we will have

$$\|x - x_0\|[c\|x - x_0\| - \gamma] \le \|x_k^*\|\|x - x_0\| \le \varepsilon_k\|x - x_0\| < \gamma\|x - x_0\|,$$

or

$$\|x - x_0\| \le \frac{2\gamma}{c} < r,$$

which means that $x \in x_0 + rB$ and clearly entails $x = x_k$.

However, in both cases for any k we found $x_k^* \in X^*$ with $\|x_k^*\| \le \varepsilon_k$ and unique $x_k \in K$ satisfying

$$f(x) + \langle \lambda + x_k^*, x\rangle \ge f(x_k) + \langle \lambda + x_k^*, x_k\rangle, \quad \forall x \in K.$$

This means that $S(\lambda + x_k^*) = \{x_k\}$ and since $\lambda + x_k^* \in V$, (2.12) reads

$$f(x) + \langle \lambda + x_k^*, x\rangle \ge f(x_k) + \langle \lambda + x_k^*, x_k\rangle + c\|x - x_k\|^2, \quad \forall x \in K. \tag{2.14}$$

Substitute $x = x_n$ and rearrange to obtain

$$f(x_n) - f(x_k) \ge \langle \lambda + x_k^*, x_k - x_n\rangle + c\|x_n - x_k\|^2.$$

Also, swapping k and n we get

$$f(x_k) - f(x_n) \ge \langle \lambda + x_n^*, x_n - x_k\rangle + c\|x_n - x_k\|^2.$$

Adding the above two, we obtain $2c\|x_n - x_k\|^2 \le \langle x_k^* - x_n^*, x_n - x_k\rangle \le (\|x_k^*\| + \|x_n^*\|)\|x_n - x_k\|$. That is, $2c\|x_n - x_k\| \le \varepsilon_k + \varepsilon_n$, which means that x_k is a Cauchy sequence. Let $x_\lambda \in K$ be its limit. Passing to limit in (2.14) we see that $x_\lambda \in S(\lambda)$.

A straightforward application of Corollary 2.7 completes the proof. ∎

3. Parameterized minimax problem. In this section we study the behavior of the saddle points set of a parameterized family of minimax problems.

3.1. Preliminaries and statement of the problem. Let X and Y be Banach spaces, and let $\{f(\cdot,\cdot,\lambda) : X \times Y \to \mathbb{R}, \lambda \in \Lambda\}$ be a family of functions defined on the product space $X \times Y$, parameterized by $\lambda \in \Lambda \subset Z$.

Let us consider the parameterized family of minimax problems

$$M(\lambda) \qquad \inf_{x\in K} \sup_{y\in L} f(x,y,\lambda),$$

where the constraints are nonempty closed sets $K \subset X$ and $L \subset Y$. Denote the optimal value of $M(\lambda)$ by $\mathfrak{m}(\lambda)$ and recall that the (possibly empty) set of saddle points of $f(\cdot,\cdot,\lambda)$ on $K \times L$ is given by (1.1).

For a set $C \subset X \times Y$ we denote by $\pi_X C$ and $\pi_Y C$ the *projections* of C on the spaces X and Y, respectively. More precisely, $x \in \pi_X C$ whenever there exists some $y \in Y$ with $(x,y) \in C$ and $y \in \pi_Y C$ whenever there exists some $x \in X$ with $(x,y) \in C$.

It is well known that the saddle point set is a product set; that is,

$$\mathcal{S}(\lambda) = \pi_X \mathcal{S}(\lambda) \times \pi_Y \mathcal{S}(\lambda). \tag{3.1}$$

To the parameterized family of functions $\{f(\cdot,\cdot,\lambda), \lambda \in \Lambda\}$ one naturally associates three difference functions:

$$\begin{aligned}
\mathfrak{f}_1(x,x',\lambda,y) &:= f(x,y,\lambda) - f(x',y,\lambda),\\
\mathfrak{f}_2(y,y',\lambda,x) &:= f(x,y,\lambda) - f(x,y',\lambda),\\
\mathfrak{f}_3(\lambda,\lambda',x,y) &:= f(x,y,\lambda) - f(x,y,\lambda').
\end{aligned}$$

By analogy with Definition 2.1 we write $\mathfrak{f}_1 \in \mathfrak{L}_W^{\alpha,\beta}(U;V)$ whenever the functions $f_1^y(x,x',\lambda) := \mathfrak{f}_1(x,x',\lambda,y)$ are such that for all $y \in W$, $f_1^y \in \mathfrak{L}^{\alpha,\beta}(U;V)$, and $\sup_{y\in W} k_{f_1^y}$ is finite. We set $k_{\mathfrak{f}_1} := \sup_{y\in W} k_{f_1^y}$.

Easy computations as those done in Proposition 2.2 show that $\mathfrak{f}_1 \in \mathfrak{L}_W^{\alpha,\beta}(U;V)$ exactly when $\mathfrak{f}_3 \in \mathfrak{L}_W^{\beta,\alpha}(V;U)$ and that $\mathfrak{f}_2 \in \mathfrak{L}_U^{\alpha,\beta}(W;V)$ exactly when $\mathfrak{f}_3 \in \mathfrak{L}_U^{\beta,\alpha}(V;W)$.

Now we are ready to state the sufficient condition for Aubin continuity of the saddle points map $\mathcal{S} : \Lambda \rightrightarrows X \times Y$.

Let $(\overline{\lambda},\overline{x},\overline{y}) \in \operatorname{gph}\mathcal{S}$. We set the following local assumption $\mathcal{A}$ at $(\overline{\lambda},\overline{x},\overline{y})$:

$$(\mathcal{A}) \quad \begin{cases}
\text{there exist neighborhoods } U \text{ of } \overline{x},\ W \text{ of } \overline{y}, \text{ and } V \text{ of } \overline{\lambda}, \text{such that}\\
1.\quad \mathcal{S}(\lambda) \cap [U \times W] \neq \emptyset \text{ for all } \lambda \in \Lambda \cap V;\\
\text{and there exist constants } c > 0 \text{ and } \alpha \in [0,1] \text{ such that}\\
2.\quad f(x,y',\lambda') \geq \mathfrak{m}(\lambda') + c d^{1+\alpha}(x, \pi_X \mathcal{S}(\lambda')),\\
\qquad f(x',y,\lambda') \leq \mathfrak{m}(\lambda') - c d^{1+\alpha}(y, \pi_Y \mathcal{S}(\lambda')),\\
\qquad \forall \lambda,\lambda' \in \Lambda \cap V, \forall (x,y) \in \mathcal{S}(\lambda) \cap [U \times W], \forall (x',y') \in \mathcal{S}(\lambda');\\
3.\ \mathfrak{f}_1 \in \mathfrak{L}_{L\cap W}^{\alpha,1}(K;\Lambda\cap V) \text{ and } \mathfrak{f}_2 \in \mathfrak{L}_{K\cap U}^{\alpha,1}(L;\Lambda\cap V).
\end{cases}$$

Clearly, condition $\mathcal{A}3$ could be replaced by

$$\mathfrak{f}_3 \in \mathfrak{L}_{L\cap W}^{1,\alpha}(\Lambda\cap V;K) \cap \mathfrak{L}_{K\cap U}^{1,\alpha}(\Lambda\cap V;L).$$

$\mathcal{A}1$ implies that $\mathfrak{m}(\lambda)$ is finite for $\lambda \in \Lambda \cap V$.

We would show the consistency of our main hypothesis by giving some examples of parameterized families of functions $\{f(\cdot,\cdot,\lambda), \lambda \in \Lambda\}$ for which $\mathcal{A}$ is satisfied.

One gets a parameterized family of functions $\{f(\cdot,\cdot,\lambda), \lambda\in\Lambda\}$ satisfying $\mathcal{A}2$, for example, by assuming that $K \subset X$ and $L \subset Y$ are nonempty closed convex sets; the function $f(\cdot, y, \lambda)$ is lower semicontinuous and uniformly on $(y,\lambda) \in L \times \Lambda$ strongly convex on K, i.e., such that for some constant $c > 0$ the inequality

$$f(tx + (1-t)x', y, \lambda) \le tf(x, y, \lambda) + (1-t)f(x', y, \lambda) - ct(1-t)\|x - x'\|^2$$

holds for every $t \in [0,1]$, every $x, x' \in K$, and every $(y,\lambda) \in L \times \Lambda$; the function $f(x,\cdot,\lambda)$ is upper semicontinuous and uniformly on $(x,\lambda) \in K \times \Lambda$ strongly concave on L, i.e., such that the inequality

$$f(x, ty + (1-t)y', \lambda) \ge tf(x, y, \lambda) + (1-t)f(x, y', \lambda) + ct(1-t)\|y - y'\|^2$$

holds for every $t \in [0,1]$, every $y, y' \in L$, and every $(x,\lambda) \in K \times \Lambda$.

Then it is routine to see that $\mathcal{A}2$ holds at any $(\overline{\lambda}, \overline{x}, \overline{y}) \in \operatorname{gph}\mathcal{S}$ with $\alpha = 1$, $V = Z$, $U = X$, and $W = Y$.

Examples of parameterized families of functions satisfying $\mathcal{A}3$ are given by the following.

LEMMA 3.1. *Let $(\overline{\lambda}, \overline{x}, \overline{y}) \in \operatorname{gph}\mathcal{S}$ and let $U \subset X$, $W \subset Y$ and $V \subset Z$ be convex neighborhoods of K, L, and $\overline{\lambda}$, respectively. Consider the conditions:*

$(\mathcal{F}1)$ $\begin{cases} \text{for any } (y,\lambda) \in L \times [\Lambda \cap V],\ f(\cdot, y, \lambda) \text{ is Lipschitz and regular} \\ \text{function on } U \text{ and } \partial_x f(x, y, \cdot) : \Lambda \cap V \to X^* \text{ is a } k\text{–Lipschitz map on} \\ \Lambda \cap V \text{ with } k \text{ that does not depend on } (x,y) \in K \times L, \end{cases}$

$(\mathcal{F}2)$ $\begin{cases} \text{for any } (x,\lambda) \in K \times [\Lambda \cap V],\ f(x, \cdot, \lambda) \text{ is Lipschitz and regular} \\ \text{function on } W \text{ and } \partial_y f(x, y, \cdot) : \Lambda \cap V \to Y^* \text{ is a } k\text{–Lipschitz map on} \\ \Lambda \cap V \text{ with } k \text{ that does not depend on } (x,y) \in K \times L, \end{cases}$

$(\mathcal{F}3)$ $\begin{cases} \text{for any } (x,y) \in K \times L,\ f(x, y, \cdot) \text{ is Lipschitz and regular} \\ \text{function on } V \text{ and } \partial_\lambda f(\cdot, y, \lambda) : K \to \Lambda^* \text{ is a } k\text{–Lipschitz map on} \\ K \text{ with } k \text{ that does not depend on } (y,\lambda) \in L \times [\Lambda \cap V], \end{cases}$

$(\mathcal{F}4)$ $\begin{cases} \text{for any } (x,y) \in K \times L,\ f(x, y, \cdot) \text{ is Lipschitz and regular} \\ \text{function on } V \text{ and } \partial_\lambda f(x, \cdot, \lambda) : L \to \Lambda^* \text{ is a } k\text{–Lipschitz map on} \\ L \text{ with } k \text{ that does not depend on } (x,\lambda) \in K \times [\Lambda \cap V]. \end{cases}$

If f satisfies $\mathcal{F}1 - \mathcal{F}2$ or $\mathcal{F}3 - \mathcal{F}4$, then $\mathcal{A}3$ holds with $\alpha = 1$.

Proof. We follow the same steps as in the proof of Lemma 2.3.

If f satisfies $\mathcal{F}1$, then $\mathfrak{f}_1 \in \mathfrak{L}^{1,1}_L(K; \Lambda \cap V)$.

If f satisfies $\mathcal{F}2$, then $\mathfrak{f}_2 \in \mathfrak{L}^{1,1}_K(L; \Lambda \cap V)$.

If f satisfies $\mathcal{F}3$, then $\mathfrak{f}_3 \in \mathfrak{L}^{1,1}_L(\Lambda \cap V; K)$.

If f satisfies $\mathcal{F}4$, then $\mathfrak{f}_3 \in \mathfrak{L}^{1,1}_K(\Lambda \cap V; L)$. ∎

Obviously, if $f \in C^{1,1}(U \times W \times V)$, then $\mathcal{F}1$ to $\mathcal{F}4$ hold.

3.2. Lipschitz-like continuity of the saddle point map. Here we will prove that assumption $\mathcal{A}$ is sufficient for Aubin continuity of the saddle point map $\mathcal{S}$. Let us note that the result cannot be derived (or at least not in an obvious manner) from the case of minimization only. Indeed, if $f(x, y, \lambda)$ satisfies assumption $\mathcal{A}$, then the function $f(x,\lambda) := \sup_{y\in L} f(x, y, \lambda)$ satisfies assumption $A2$ but $A3$ for this $f(x,\lambda)$ cannot be derived from $\mathcal{A}3$ since the differences of suprema involved do not yield themselves to rearrangement.

THEOREM 3.2. *Assume that for the parameterized family of minimax problems $M(\lambda)$ the assumption $\mathcal{A}$ holds at some $(\overline{\lambda},\overline{x},\overline{y}) \in \operatorname{gph}\mathcal{S}$. Then for all $\lambda,\mu \in \Lambda \cap V$*

$$e(\mathcal{S}(\lambda)\cap[U\times W],\mathcal{S}(\mu)) \le \frac{2k}{c}\|\lambda-\mu\|, \tag{3.2}$$

where $k := \max\{k_{\mathfrak{f}_1}, k_{\mathfrak{f}_2}\}$, hence the saddle point map $\mathcal{S} : \Lambda \rightrightarrows X \times Y$ is Aubin continuous near $(\overline{\lambda},\overline{x},\overline{y}) \in \operatorname{gph}\mathcal{S}$.

Proof. By $\mathcal{A}1$ for all $\lambda \in \Lambda \cap V$ the set $\mathcal{S}(\lambda)\cap[U\times W]$ is nonempty.

Fix $\lambda \in \Lambda \cap V$ and take some $(x_\lambda, y_\lambda) \in \mathcal{S}(\lambda)\cap[U\times W]$.

Pick any other $\mu \in \Lambda \cap V$.

Since $\mathcal{S}(\mu)$ is a nonempty set we find some $x^\varepsilon_\mu \in \pi_X\mathcal{S}(\mu)$ such that

$$\|x_\lambda - x^\varepsilon_\mu\| \le d(x_\lambda, \pi_X\mathcal{S}(\mu)) + \varepsilon.$$

Similarly, there is $y^\varepsilon_\mu \in \pi_Y\mathcal{S}(\mu)$ such that

$$\|y_\lambda - y^\varepsilon_\mu\| \le d(y_\lambda, \pi_Y\mathcal{S}(\mu)) + \varepsilon.$$

By the product form of the saddle point set, $(x^\varepsilon_\mu, y^\varepsilon_\mu) \in \mathcal{S}(\mu)$. The first inequality of $\mathcal{A}2$ for $(x_\lambda, y_\lambda) \in \mathcal{S}(\lambda)\cap[U\times W]$ and $(x^\varepsilon_\mu, y^\varepsilon_\mu) \in \mathcal{S}(\mu)$ reads

$$f\left(x_\lambda, y^\varepsilon_\mu, \mu\right) \ge \mathfrak{m}(\mu) + cd^{1+\alpha}(x_\lambda, \pi_X\mathcal{S}(\mu)), \tag{3.3}$$

in particular,

$$f\left(x_\lambda, y^\varepsilon_\mu, \mu\right) \ge \mathfrak{m}(\mu), \tag{3.4}$$

while the second inequality of $\mathcal{A}2$ states

$$\mathfrak{m}(\mu) \ge f\left(x^\varepsilon_\mu, y_\lambda, \mu\right) + cd^{1+\alpha}(y_\lambda, \pi_Y\mathcal{S}(\mu)), \tag{3.5}$$

in particular,

$$\mathfrak{m}(\mu) \ge f\left(x^\varepsilon_\mu, y_\lambda, \mu\right). \tag{3.6}$$

Combining (3.3) with (3.6) and (3.4) with (3.5), we get

$$\begin{aligned} f\left(x_\lambda, y^\varepsilon_\mu, \mu\right) &\ge f\left(x^\varepsilon_\mu, y_\lambda, \mu\right) + cd^{1+\alpha}(x_\lambda, \pi_X\mathcal{S}(\mu)),\\ f\left(x_\lambda, y^\varepsilon_\mu, \mu\right) &\ge f\left(x^\varepsilon_\mu, y_\lambda, \mu\right) + cd^{1+\alpha}(y_\lambda, \pi_Y\mathcal{S}(\mu)), \end{aligned}$$

which yields

$$f\left(x_\lambda, y^\varepsilon_\mu, \mu\right) - f\left(x^\varepsilon_\mu, y_\lambda, \mu\right) \ge c[\max\{d(x_\lambda, \pi_X\mathcal{S}(\mu)), d(y_\lambda, \pi_Y\mathcal{S}(\mu))\}]^{1+\alpha}.$$

By the definition of the supremum norm and since $\mathcal{S}(\mu)$ is a product set, it is obvious that

$$\begin{aligned} d((x_\lambda, y_\lambda), \mathcal{S}(\mu)) &= d((x_\lambda, y_\lambda), \pi_X\mathcal{S}(\mu)\times\pi_Y\mathcal{S}(\mu))\\ &= \max\{d(x_\lambda, \pi_X\mathcal{S}(\mu)), d(y_\lambda, \pi_Y\mathcal{S}(\mu))\}, \end{aligned} \tag{3.7}$$

and the above inequality can be rewritten as

$$f\left(x_\lambda, y^\varepsilon_\mu, \mu\right) - f\left(x^\varepsilon_\mu, y_\lambda, \mu\right) \ge cd^{1+\alpha}((x_\lambda, y_\lambda), \mathcal{S}(\mu)).$$

We transform the left-hand side to get

$$f\left(x_\lambda, y_\mu^\varepsilon, \mu\right) - f(x_\lambda, y_\lambda, \mu) + f(x_\lambda, y_\lambda, \mu) - f\left(x_\mu^\varepsilon, y_\lambda, \mu\right) \geq cd^{1+\alpha}((x_\lambda, y_\lambda), \mathcal{S}(\mu)),$$

which is

$$-\mathfrak{f}_2\left(x_\lambda, y_\lambda, y_\mu^\varepsilon, \mu\right) - \mathfrak{f}_1\left(x_\mu^\varepsilon, x_\lambda, y_\lambda, \mu\right) \geq cd^{1+\alpha}((x_\lambda, y_\lambda), \mathcal{S}(\mu)). \tag{3.8}$$

On the other hand, since $(x_\lambda, y_\lambda) \in \mathcal{S}(\lambda)$, the saddle point inequalities give

$$f(x, y_\lambda, \lambda) \geq f(x_\lambda, y_\lambda, \lambda) \geq f(x_\lambda, y, \lambda), \quad \forall x \in K, \forall y \in L.$$

In particular, for $x = x_\mu^\varepsilon \in K$ we have

$$f(x_\mu^\varepsilon, y_\lambda, \lambda) \geq f(x_\lambda, y_\lambda, \lambda),$$

which is

$$\mathfrak{f}_1(x_\mu^\varepsilon, x_\lambda, y_\lambda, \lambda) \geq 0, \tag{3.9}$$

and for $y = y_\mu^\varepsilon \in L$ we get

$$f(x_\lambda, y_\lambda, \lambda) \geq f(x_\lambda, y_\mu^\varepsilon, \lambda),$$

which is

$$\mathfrak{f}_2(x_\lambda, y_\lambda, y_\mu^\varepsilon, \lambda) \geq 0. \tag{3.10}$$

Adding the inequalities (3.8), (3.9), and (3.10) and rearranging we obtain

$$\begin{aligned}\left[\mathfrak{f}_1\left(x_\mu^\varepsilon, x_\lambda, y_\lambda, \lambda\right) - \mathfrak{f}_1\left(x_\mu^\varepsilon, x_\lambda, y_\lambda, \mu\right)\right] + \left[\mathfrak{f}_2\left(x_\lambda, y_\lambda, y_\mu^\varepsilon, \lambda\right) - \mathfrak{f}_2\left(x_\lambda, y_\lambda, y_\mu^\varepsilon, \mu\right)\right] \\ \geq cd^{1+\alpha}((x_\lambda, y_\lambda), \mathcal{S}(\mu)).\end{aligned} \tag{3.11}$$

Since by $\mathcal{A}3$, $\mathfrak{f}_1 \in \mathfrak{L}^{\alpha,1}_{L\cap W}(K; \Lambda \cap V)$, the term in first brackets in (3.11) is estimated by

$$\mathfrak{f}_1\left(x_\mu^\varepsilon, x_\lambda, y_\lambda, \mu\right) - \mathfrak{f}_1\left(x_\mu^\varepsilon, x_\lambda, y_\lambda, \lambda\right) \leq k_{\mathfrak{f}_1}\|x_\mu^\varepsilon - x_\lambda\|^\alpha\|\lambda - \mu\|, \tag{3.12}$$

and since $\mathfrak{f}_2 \in \mathfrak{L}^{\alpha,1}_{K\cap U}(L; \Lambda \cap V)$ the term in second brackets in (3.11) is estimated by

$$\mathfrak{f}_2\left(x_\lambda, y_\lambda, y_\mu^\varepsilon, \lambda\right) - \mathfrak{f}_2\left(x_\lambda, y_\lambda, y_\mu^\varepsilon, \mu\right) \leq k_{\mathfrak{f}_2}\|y_\lambda - y_\mu^\varepsilon\|^\alpha\|\lambda - \mu\|. \tag{3.13}$$

Using (3.13) and (3.12) in (3.11) and setting $k := \max\{k_{\mathfrak{f}_1}, k_{\mathfrak{f}_2}\}$, we get

$$k\|\lambda - \mu\|[\|x_\lambda - x_\mu^\varepsilon\|^\alpha + \|y_\lambda - y_\mu^\varepsilon\|^\alpha] \geq cd^{1+\alpha}((x_\lambda, y_\lambda), \mathcal{S}(\mu)).$$

By the choice of x_μ^ε and y_μ^ε, we have that

$$\begin{aligned}k\|\lambda - \mu\|[(d(x_\lambda, \pi_X\mathcal{S}(\mu)) + \varepsilon)^\alpha + (d(y_\lambda, \pi_Y\mathcal{S}(\mu)) + \varepsilon)^\alpha] \\ \geq cd^{1+\alpha}((x_\lambda, y_\lambda), \mathcal{S}(\mu)).\end{aligned}$$

Passing to limit $\varepsilon \downarrow 0$ we obtain

$$k\|\lambda - \mu\|[d^\alpha(x_\lambda, \pi_X\mathcal{S}(\mu)) + d^\alpha(y_\lambda, \pi_Y\mathcal{S}(\mu))] \geq cd^{1+\alpha}((x_\lambda, y_\lambda), \mathcal{S}(\mu)). \tag{3.14}$$

By (3.7) we get

$$d^\alpha(y_\lambda, \pi_Y\mathcal{S}(\mu)) + d^\alpha(x_\lambda, \pi_X\mathcal{S}(\mu)) \le 2\left[\max\{d(y_\lambda, \pi_Y\mathcal{S}(\mu)), d(x_\lambda, \pi_X\mathcal{S}(\mu))\}\right]^\alpha$$
$$= 2d^\alpha((x_\lambda, y_\lambda), \mathcal{S}(\mu)),$$

and from (3.14) we obtain

$$2k\|\lambda - \mu\| d^\alpha((x_\lambda, y_\lambda), \mathcal{S}(\mu)) \ge c d^{1+\alpha}((x_\lambda, y_\lambda), \mathcal{S}(\mu)).$$

This yields

$$\frac{2k}{c}\|\lambda - \mu\| \ge d((x_\lambda, y_\lambda), \mathcal{S}(\mu)),$$

and since (x_λ, y_λ) was an arbitrary element of $\mathcal{S}(\lambda) \cap [U \times W]$ the latter implies

$$e(\mathcal{S}(\lambda) \cap [U \times W], \mathcal{S}(\mu)) \le \frac{2k}{c}\|\lambda - \mu\|.$$

The proof is completed. □

As an immediate consequence of Theorem 3.2 and Lemma 3.1 one deduces the following.

COROLLARY 3.3. *Let for the parameterized family of minimax problems $M(\lambda)$ the following assumption hold:*

$$(\mathcal{A}') \quad \begin{cases} 1. & \mathcal{S}(\lambda) \ne \emptyset \text{ for any } \lambda \in \Lambda; \\ 2. & \text{for some constant } c > 0 \text{ and all } \lambda \in \Lambda, (x,y) \in \mathcal{S}(\lambda), (x',y') \in K \times L: \\ & f(x', y, \lambda) \ge \mathfrak{m}(\lambda) + c d^2(x', \pi_X\mathcal{S}(\lambda)), \\ & f(x, y', \lambda) \le \mathfrak{m}(\lambda) - c d^2(y', \pi_Y\mathcal{S}(\lambda)); \\ 3. & f \in C^{1,1}(X \times Y \times Z). \end{cases}$$

Then the saddle point map $\mathcal{S} : \Lambda \to X \times Y$ is single-valued and Lipschitz continuous.

As we pointed out after Corollary 2.7 we could deduce the single-valuedness and Lipschitz continuity of the saddle point map $\mathcal{S}$ when X and Y has separable duals, the sets K and L are convex, $f \in C^{1,1}(X \times Y \times Z)$, and there exists a constant $c > 0$ such that for all $\lambda \in \Lambda$, $x, z \in K$, $y, w \in L$,

$$\langle M(z-x), z-x\rangle \ge c\|z-x\|^2, \quad \langle N(w-y), w-y\rangle \le -c\|w-y\|^2$$

for all $M \in \partial^2 f(\cdot, y, \lambda)(x)$ and all $N \in \partial^2 f(x, \cdot, \lambda)(y)$.

4. Lipschitz continuity of the saddle points map in context of two-player zero sum differential games. In this section we briefly consider a differential game for which our result might be of relevance.

In differential games, open-loop strategies are of low interest in many examples. One major reason is that differential games with open-loop strategies do not satisfy, in general, the dynamic programming principle [9, 11, 22]. It is well known now that to solve many problems in differential games (existence of a value, characterization of the game through Hamilton–Jacobi equations), one needs a more general class of strategies which contains the feedback strategies.[1] Such class of strategies is the

[1] It has been shown in [8] that the class of regular feedback is not rich enough to solve differential games at a satisfactory level of generality.

class of nonanticipative strategies introduced by Elliot–Roxin–Varaiya–Kalton (cf. for instance [10]); another possible class of strategies are the positional strategies discussed in [20]. The class of nonanticipative strategies is nice enough to prove the existence of the value, but it is hard to implement for the players. So it is important to know when the nonanticipative strategies giving the value of the game can be reduced to feedback strategies. We will explain in this part how the main result of the paper can lead to a partial answer to this question.

We consider the following differential game with dynamic described by the differential equation:

$$\begin{cases} x'(t) = f(x(t), u(t)), \;\; y'(t) \in g(y(t), v(t)), \\ u(t) \in U, \; v(t) \in V, \end{cases} \tag{4.1}$$

where $f : \mathbb{R}^n \times U \to \mathbb{R}^n$ and $g : \mathbb{R}^n \times V \to \mathbb{R}^n$ are (globally) Lipschitz, $U \subset \mathbb{R}^m$, $V \subset \mathbb{R}^p$ being the control sets of the players. The first player—Ursula, playing with u—wants to minimize a given cost. The goal of the second player—Victor, playing with v—is to maximize the cost

$$J(x_0, y_0, u(\cdot), v(\cdot)) := \int_0^\infty e^{-rt} l(x(t), y(t))\, dt,$$

where $(x(\cdot), y(\cdot))$ is the unique solution starting at $t = 0$ from (x_0, y_0) and $r > 0$ is fixed. Observe that the game is in a separable form, i.e., each player acts in his own dynamics. This is the case, for instance, for pursuit games. Moreover, the integral cost does not depend directly on the control but only on the trajectories.

We work here in the framework of the *nonanticipative strategies* (also called Varaiya–Roxin–Elliot–Kalton strategies). Let

$$\mathcal{U} = L^1([0, +\infty[, U), \;\; \mathcal{V} = L^1([0, +\infty[, V) \tag{4.2}$$

be the sets of time-measurable controls of the first (Ursula) and the second (Victor) player, respectively. We denote $t \mapsto (x(t, x_0, u(t)), y(t, y_0, v(t)))$ the solution of (4.1) starting at $t = 0$ from (x_0, y_0).

DEFINITION 4.1 (nonanticipative strategies). *A map $\alpha : \mathcal{V} \to \mathcal{U}$ is a nonanticipative strategy (for Ursula) if it satisfies the following condition: For any $s \geq 0$, for any $v_1(\cdot)$ and $v_2(\cdot)$ belonging to $\mathcal{V}$ such that $v_1(\cdot)$ and $v_2(\cdot)$ coincide almost everywhere on $[0, s]$, the images $\alpha(v_1(\cdot))$ and $\alpha(v_2(\cdot))$ coincide almost everywhere on $[0, s]$.*

Nonanticipative strategies $\beta : \mathcal{U} \to \mathcal{V}$ (for Victor) are defined in the symmetric way.

Assume now that f and g are continuous and Lipschitz with respect to x and y. Then, we know that the game has a value (cf. [11]), namely,

$$V(x_0, y_0) = \inf_\alpha \sup_{v \in \mathcal{V}} J(x_0, y_0, \alpha(v(\cdot)), v(\cdot)) = \sup_\beta \inf_{u \in \mathcal{U}} J(x_0, y_0, u(\cdot), \beta(u(\cdot))).$$

Let us denote by $R(t)$ the attainable set of the dynamics (4.1) at moment t; i.e.,

$$R(t) = \{(x(t), y(t)) \in \mathbb{R}^n \times \mathbb{R}^n : \exists\, u \in \mathcal{U}, v \in \mathcal{V} \text{ such that}$$
$$(x(\cdot), y(\cdot)) \text{ is the solution of (4.1) starting at } t = 0 \text{ from } (x_0, y_0)\}.$$

Now, suppose that U and V are convex and compact. Saddle point of the function $l(\cdot, \cdot)$ on $R(t)$ will be any point $(\overline{x}, \overline{y}) \in R(t)$ that satisfies

$$l(\overline{x}, y) \leq l(\overline{x}, \overline{y}) \leq l(x, \overline{y}), \quad \forall (x, y) \in R(t),$$

and, because of $e^{-rt} > 0$, the saddle points of $l(\cdot,\cdot)$ on $R(t)$ will be the same as the saddle points of $e^{-rt}l(\cdot,\cdot)$ on $R(t)$.

Let us denote the (possibly empty) set of all saddle points of the function $l(\cdot,\cdot)$ on $R(t)$ by $\mathcal{S}(t) := \{(\overline{x},\overline{y}) \in R(t) : l(\overline{x},y) \le l(\overline{x},\overline{y}) \le l(x,\overline{y}), \quad \forall (x,y) \in R(t)\}$.

Let us suppose that the parameterized by t family of functions $\{e^{-rt}l(\cdot,\cdot), t \in [0,\infty)\}$ satisfies an assumption slightly stronger than assumption $\mathcal{A}$, namely:

$$\begin{cases} 1. \quad \mathcal{S}(t) \neq \emptyset, \ \forall t \ge 0; \\ \text{and there exist constants } k, c > 0 \text{ and } \alpha \in [0,1] \text{ such that} \\ \forall t, t' \ge 0, \forall (x,y) \in \mathcal{S}(t), \forall (x',y') \in \mathcal{S}(t') \text{ it holds :} \\ 2. \quad l(x',y) \ge l(x,y) + ce^{rt}\|x'-x\|^{1+\alpha}, \\ \qquad l(x,y') \le l(x,y) - ce^{rt}\|y'-y\|^{1+\alpha}; \\ 3. \quad |l(x,y) - l(x',y)| \le k\|x-x'\|^{\alpha}, \\ \qquad |l(x,y) - l(x,y')| \le k\|y-y'\|^{\alpha}. \end{cases}$$

This assumption guarantees that for any $t \in [0,\infty)$ the saddle point mapping $\mathcal{S}(t)$ is single-valued and Lipschitz continuous; i.e., for all positive t, the function $e^{-rt}l(\cdot,\cdot)$ has a saddle point $(x(t),y(t))$ on the attainable set $R(t)$ of the dynamics (4.1), which depends in a Lipschitz way on t.

Therefore, if it turns out that so-obtained single valued saddle point mapping is a trajectory $(x(\cdot),y(\cdot))$ of (4.1), then it is an optimal feedback strategy of the game.

For example, under the above assumptions in the case when $m = p = n$ and $f(x,u) = u$, $g(y,v) = v$, the Lipschitz continuity on t of the saddle point map implies that the corresponding controls u and v belong to $\mathcal{U}$ and $\mathcal{V}$, respectively, and, hence, they generate a trajectory of the differential game.

ON BIN PACKING WITH CONFLICTS*

LEAH EPSTEIN† AND ASAF LEVIN‡

Abstract. We consider the offline and online versions of a bin packing problem called BIN PACKING WITH CONFLICTS. Given a set of items $V = \{1, 2, \ldots, n\}$ with sizes $s_1, s_2, \ldots, s_n \in [0, 1]$ and a conflict graph $G = (V, E)$, the goal is to find a partition of the items into independent sets of G, where the total size of items in each independent set is at most 1 so that the number of independent sets in the partition is minimized. This problem is clearly a generalization of both the classical (one-dimensional) bin packing problem where $E = \emptyset$ and of the graph coloring problem where $s_i = 0$ for all $i = 1, 2, \ldots, n$. Since coloring problems on general graphs are hard to approximate, following previous work, we study the problem on specific graph classes. For the offline version, we design improved approximation algorithms for perfect graphs and other special classes of graphs: These are a $\frac{5}{2} = 2.5$-approximation algorithm for perfect graphs; a $\frac{7}{3} \approx 2.33333$-approximation algorithm for a subclass of perfect graphs, which contains interval graphs and chordal graphs; and a $\frac{7}{4} = 1.75$-approximation for algorithm bipartite graphs. For the online problem on interval graphs, we design a 4.7-competitive algorithm and show a lower bound of $\frac{155}{36} \approx 4.30556$ on the competitive ratio of any algorithm. To derive the last lower bound, we introduce the first lower bound on the asymptotic competitive ratio of any online bin packing algorithm with known optimal value, which is $\frac{47}{36} \approx 1.30556$.

1. Introduction.

We consider the following BIN PACKING WITH CONFLICTS problem (BPC) (see [5, 17] and also the information on the bin packing problem given in [4]). Given a set of items $V = \{1, 2, \ldots, n\}$ with sizes $s_1, s_2, \ldots, s_n \in [0, 1]$ and a conflict graph $G = (V, E)$, the goal is to find a partition of the items into independent sets of G where the total size of each independent set is at most 1 so that the number of independent sets in the partition is minimized. This problem is clearly a generalization of both the classical (one-dimensional) bin packing problem where $E = \emptyset$ and of the graph coloring problem where $s_i = 0$ for all $i = 1, 2, \ldots, n$. In an online environment, items arrive one by one to be packed immediately and irrevocably. A new item is introduced by its size, together with all its incident edges in the current conflict graph (i.e., edges which connect it to previously introduced items).

This problem arises in assigning processes or tasks to processors. In this case we are given a set of tasks, where some pairs of tasks are not allowed to execute on the same processor due to efficiency or fault tolerance reasons. The goal is to assign a minimum number of processors to this set of processes given that the makespan is bounded by some constant (see Jansen [16]). Other applications of this problem arise in the area of database replicas storage, school course time tables construction, scheduling communication systems (see de Werra [6]), and, finally, in load balancing the parallel solution of partial differential equations by two-dimensional domain decomposition (see Irani and Leung [15]). We follow earlier work and consider the

BPC on subclasses of perfect graphs. This restriction is motivated by the theoretical hardness of approximating graph coloring on general graphs.

In order to analyze our approximation and online algorithms, we use common criteria, which are the approximation ratio (also called performance guarantee) for offline algorithms, and competitive analysis for online algorithms. For an algorithm $\mathcal{A}$, we denote its cost by $\mathcal{A}$ as well. An optimal offline algorithm that knows the complete sequence of items is denoted by OPT. We consider the absolute approximation (respectively, competitive) ratio that is defined as follows. The absolute approximation (respectively, competitive) ratio of $\mathcal{A}$ is the infimum $\mathcal{R}$ such that, for any input, $\mathcal{A} \leq \mathcal{R} \cdot \mathrm{OPT}$. If the absolute approximation (respectively, competitive) ratio of an offline (respectively, online) algorithm is at most ρ, we say that it is a ρ-approximation (respectively, ρ-competitive). The asymptotic approximation (respectively, competitive) ratio of $\mathcal{A}$ is the infimum $\mathcal{R}$ such that, for any input, $\mathcal{A} \leq \mathcal{R} \cdot \mathrm{OPT} + c$ for some c that is independent of the input. For the offline problem, we restrict ourselves to algorithms that run in polynomial time. Our online algorithm is also a polynomial time algorithm (though this property is not always required in the competitive analysis literature). We focus on the absolute criteria and not on the criteria of asymptotic approximation ratio and asymptotic competitive ratio, since coloring problems are typically studied using these absolute criteria. Note that asymptotic criteria are commonly used for bin packing problems. However, the problem studied here is more similar in nature to coloring problems, even though it is an extension of bin packing. Throughout the paper we omit the adjective "absolute," since this is the only criterion studied here. We let $s(X)$ denote the sum of item sizes in a set X, i.e., $s(X) = \sum_{x \in X} s_x$.

Since the BPC problem generalizes the classical coloring problem that is known to be extremely hard to approximate, we follow earlier studies and consider the BPC problem on the class of perfect graphs for which the coloring problem is polynomially solvable (see [27]). The best previously known approximation algorithm for BPC on perfect graphs is the algorithm of Jansen and Öhring [17] with an approximation ratio of 2.7. In section 3.1, we improve this result and present our 2.5-approximation algorithm for BPC on perfect graphs.

Following Jansen and Öhring [17], we consider the class of graphs for which one can solve in polynomial time the PRECOLORING EXTENSION problem defined as follows. Given an undirected graph $G = (V, E)$ and k distinct vertices $v_1, v_2, \ldots, v_k$, the problem is to find a minimum coloring f of G such that $f(v_i) = i$ for $i = 1, 2, \ldots, k$. This problem is reviewed in [14, 23], and it is known to be polynomially solvable for the following graph classes: interval graphs, forests, split graphs, complements of bipartite graphs, cographs, partial K-trees and complements of Meyniel graphs[1] (see [14] for a review of these results), and it is also polynomially solvable for chordal graphs as shown by Marx [24]. However, it is known to be NP-complete for bipartite graphs [14]. We denote by $\mathcal{C}$ the class of graphs G for which one can solve in polynomial time the precoloring extension problem for any induced subgraph of G (including G itself). That is, $\mathcal{C}$ is closed under the operation of induced subgraph extraction. Jansen and Öhring [17] analyzed the following *algorithm with precoloring* for the case where G belongs to $\mathcal{C}$. Denote the set of large items by $L = \{j : s_j > \frac{1}{2}\}$, and denote by $\chi_I(G)$ the minimum number of colors used by an optimal solution for the precoloring extension problem defined by G. Finally, we define the set of precolored vertices to be L. Compute a feasible coloring of G using $\chi_I(G)$ colors, where,

[1] A graph is Meyniel if every cycle of odd length which is at least five, has at least two chords.

for each pair of items in L, they are assigned different colors. For each color class, apply a bin-packing heuristic such as the first-fit-decreasing (FFD) algorithm. They proved that the resulting algorithm is a $\frac{5}{2}$-approximation algorithm. In section 3.2, we improve this result by presenting a $\frac{7}{3}$-approximation algorithm.

For all $\varepsilon > 0$, Jansen and Öhring [17] also presented a $(2+\varepsilon)$-approximation algorithm for BPC on cographs and partial K-trees. Furthermore, they presented a 2-approximation algorithm for bipartite graphs. A d-inductive graph has the property that the vertices can be assigned distinct numbers $1, \ldots, n$ such that each vertex is adjacent to at most d lower-numbered vertices. Jansen [16] showed an asymptotic fully polynomial time approximation scheme for BPC on d-inductive graphs where d is a constant. This result includes the cases of trees, grid graphs, planar graphs, and graphs with constant treewidth. Oh and Son [26] and McCloskey and Shankar [25] considered BPC on graphs that are a union of cliques, but their results are inferior to the 2.7-approximation algorithm of Jansen and Öhring [17]. Even and Shahar [7] considered BPC on unit circular-arc graphs and presented a 3-approximation algorithm for this case. Since our 2.5-approximation algorithm for perfect graphs can be applied also for unit circular-arc graphs (since it only uses a coloring of an induced subgraph using a minimum number of colors, and the coloring problem is solvable in polynomial time on unit circular-arc graphs), we get an improvement of the 3-approximation algorithm of [7].

The hardness of the approximation of BPC follows from the hardness of standard offline bin packing (with respect to the absolute approximation ratio). It is not hard to see that unless $\mathbf{P} = \mathbf{NP}$, no algorithm can have an absolute approximation ratio of less than $\frac{3}{2}$ (due to a simple reduction from the PARTITION problem, see problem SP12 in [10]). Since standard bin packing is a special case of BPC, where the conflict graph is an independent set, we get that, for all graph classes studied in this paper, BPC is **APX**-hard, and unless $\mathbf{P} = \mathbf{NP}$, cannot be approximated within a factor smaller than $\frac{3}{2}$. Note that for bin packing, already the simple FFD algorithm is a $\frac{3}{2}$-approximation [29]. These hardness results hold for the graph classes we consider, since an empty graph is bipartite and perfect.

Our results. In section 2, we describe the methods applied in this paper. We use weights for our analysis. The weights used throughout the paper have the unique and novel property that weights are assigned not only as a function of the size of items, but also as a function of the location of items in an optimal solution or in an approximate solution. We think that this new technical approach can contribute to the analysis of algorithms for other problems as well.

We use these methods in section 2 to give improved and tight bounds on two algorithms designed in [17]. We show that their algorithm for perfect graphs has performance guarantee of approximately 2.691, and their algorithm with precoloring has performance guarantee of approximately 2.423. These tight results follow from our analysis together with lower bounds on the performance guarantee of these algorithms, given in [17]. Note that these bounds and their proofs resemble the analysis of the Harmonic algorithm [21] (the bounds are one unit higher than the upper bounds for Harmonic). However, neither the algorithms of [17] nor our algorithms use a partition into classes as is done in the Harmonic algorithm. Moreover, such a partition in our case would result in an arbitrarily high approximation ratios.

In section 3, we present our improved new algorithms for the offline case of BPC. In section 3.1, we design an improved algorithm for perfect graphs with performance guarantee of 2.5. Our algorithm is also a 2.5-approximation algorithm for BPC on all

graph classes where one can solve the regular coloring problem (i.e., coloring the vertex set of a graph using a minimum number of colors) in polynomial time. In section 3.2, we design an improved algorithm with precoloring with performance guarantee of $\frac{7}{3}$. In section 3.3, we design a $\frac{7}{4}$-approximation algorithm for bipartite graphs.

In section 4 we discuss *online* algorithms for BPC on interval graphs. We design a simple 4.7-competitive algorithm and show a lower bound of $\frac{155}{36} \approx 4.30556$ on the competitive ratio of any online algorithm. We derive the last lower bound by introducing the first nontrivial lower bound for online bin packing with known optimal value, which is $\frac{47}{36} \approx 1.30556$. We also show an $O(\log n)$ competitive algorithm for bipartite graphs, which is best possible. Both algorithms are adaptations of online algorithms for the standard coloring problem; see [20, 22].

2. Weighting functions and the performance of FFD-based algorithms. In this section, we define weighting functions which are a major tool in the analysis of algorithms for bin packing. The weights defined in this section are later adapted and used for the analysis of our improved algorithms.

The idea of such weights is simple. An item receives a weight according to its size and its packing in some fixed solution. The weights of items are typically not equal to their sizes, but are related to them. The weights are assigned in a way that the cost of an algorithm is close to the total sum of weights. In order to complete the analysis, it is usually necessary to consider the total weight that can be packed into a single bin of an optimal solution.

In this paper, we exploit this method in order to achieve improved algorithms for BPC. Though this method was not applied to BPC before, it was widely used for standard bin packing and many variants of bin packing. This technique was used as early as 1971 by Ullman [31] (see also [19, 21, 28]).

Specifically, we use the following theorem.

THEOREM 1. *Consider an algorithm $\mathcal{A}$ for* BPC. *Let w, w' be two weight measures defined on the input items, $w, w' : I \to \mathbb{R}$. Let $W(I)$ and $W'(I)$ denote the sum of the weights of all input items of I, according to w and w', respectively, and assume that, for every input I, $W'(I) \leq W(I)$. Assume that, for every output of the algorithm, the number of bins used by the algorithm $\mathcal{A}$ is upper bounded by $W'(I) + \tau \cdot \mathrm{OPT}(I)$, where $\mathrm{OPT}(I)$ is the cost of an optimal algorithm on the input I. Denote by W_I the supremum amount of weight that can be packed into a bin of the optimal solution, according to measure w. Then the approximation ratio of $\mathcal{A}$ is upper bounded by $W_I + \tau$.*

Note that w, w' are real functions and are not necessarily nonnegative.

Proof. Given an input I, we have $\mathcal{A} \leq W'(I) + \tau\mathrm{OPT}(I)$. Since an optimal algorithm has $\mathrm{OPT}(I)$ bins, with a weight of at most W_I in each one of them, we get the upper bound $W(I) \leq W_I \cdot \mathrm{OPT}(I)$. Using $W'(I) \leq W(I)$, we get $\mathcal{A} \leq (W_I + \tau)\mathrm{OPT}(I)$, and the theorem follows. □

Typically, this theorem is used with $w = w'$, which satisfies all conditions of the theorem. We will also use it in this paper with $w \neq w'$.

In this section, we define a set of weights which depends solely on the size of items. For an item x such that $s_x > \frac{1}{2}$, we define $weight(x) = 1$. We define the interval $\mathcal{I}_1$ by $\mathcal{I}_1 = (\frac{1}{2}, 1]$. For an item x such that $s_x \leq \frac{1}{2}$, let j be an integer such that $s_x \in \mathcal{I}_j = (\frac{1}{j+1}, \frac{1}{j}]$. We define $weight(x) = s_x + \frac{1}{j(j+1)}$. Note that even though this classification to intervals was used before, the weight function is nonstandard. Typically either all items in an interval receive the same weight or are scaled by a common multiplicative factor (see, e.g., [21, 2]). We note that the weight function

does not round up the size of an item to the next unit fraction, but the weight of an item in an interval $(\frac{1}{j+1}, \frac{1}{j}]$ is never lower than the next unit fraction (i.e., it is larger than $\frac{1}{j}$).

We need to use this special weight function in order to make sure that the amount of weight is large enough, even if the input is partitioned into several classes, each of which is packed separately. On the other hand, we must make sure that the weights are not too large so that the bound on the performance guarantee is not increased artificially. A similar (though different) weight function was used before by Galambos and Woeginger [8]. Their weight function can be used to prove Corollary 6 and Theorem 8 but not the other results of this paper. Therefore, we need to modify the weight function of [8] for our needs.

Given this set of weights, we note that, for an item x of size $s_x \in \mathcal{I}_j$ $(j \geq 2)$, the ratio between its weight and its size is bounded as follows:

$$\frac{j+2}{j+1} \leq \frac{weight(x)}{s_x} < \frac{j+1}{j}.$$

For a set of items X, we denote the sum of the weights of all items in X by $W(X)$. That is, $W(X) = \sum_{x \in X} weight(x)$. We next show that any algorithm which first partitions the input into μ color classes and then applies the FFD algorithm on each color class separately, satisfies the following condition on its cost as a function of the total weight and μ.

LEMMA 2. *Consider a subset of items J which forms an independent set and is packed using FFD. Let Y be the number of bins used for this packing. Then we have $Y \leq W(J) + 1$.*

Proof. Note that, for the above weight function, any bin which contains an item of size in $(\frac{1}{2}, 1]$ has a total weight of the items of at least 1. As stated above, the weight of an item in $\mathcal{I}_j = (\frac{1}{j+1}, \frac{1}{j}]$ is at least $\frac{1}{j+1} + \frac{1}{j(j+1)} = \frac{1}{j}$. Therefore, any bin which contains j items of size in the interval $(\frac{1}{j+1}, \frac{1}{j}]$ has a total weight of at least 1. We can remove such bins from the packing and focus on all other bins, which are called *transition bins*. If no bins are left after the removal, we are done.

A transition bin contains only items whose sizes are at most $\frac{1}{2}$. Note that the last bin ever opened may result in a transition bin, and it contains at least one item. Moreover, let a transition bin be of *type* j (for some $j \geq 2$), if the first item ever packed into it has size in $\mathcal{I}_j$. Next, we argue that there can be at most one transition bin of each possible type. Since the items are packed using FFD, transition bins are created in a sorted order, starting with the smallest type (or largest size). If there are two bins of the same type j, this means that during the time between the packing of the first items in these two bins, all packed items were also of size in the interval $\mathcal{I}_j$. Therefore, the first bin must be assigned j such items before the second transition bin of this type is opened, and thus the first bin is not a transition bin. Let k be the largest type of any transition bin ever opened (i.e., the transition bin with the smallest item). Remove from the packing all items of size at most $\frac{1}{k+1}$. This removal may only decrease the total weight. As stated above, the weight of each remaining item in the transition bins is at least a multiplicative factor of $\frac{k+2}{k+1}$ its size.

Let α be the size of the first item in the last transition bin. As the last transition bin is opened, all other bins have a total size of items which is more than $1 - \alpha$. Let $i_1 < \cdots < i_t < i_{t+1} = k$ be the sorted list of the types of transition bins.

It suffices to show that the total weight of all items in the transition bins is at least t (since there are $t + 1$ transition bins). Let $t' = \min\{\lfloor \frac{k+2}{2} \rfloor, t\}$.

CLAIM 3. *The total weight in the last $t'+1$ transition bins is at least t', and each other bin carries a weight of at least 1.*

Proof. If $t = t' = 0$, we are done. Assume therefore that $t' \geq 1$. In the last $t'+1$ transition bins, we get a total weight of at least

$$t'(1-\alpha)\frac{k+2}{k+1} + \alpha + \frac{1}{k(k+1)} = t'\frac{k+2}{k+1} + \frac{1}{k(k+1)} - \alpha\left(t'\frac{k+2}{k+1} - 1\right)$$
$$\geq t'\frac{k+2}{k+1} + \frac{1}{k(k+1)} - \frac{t'\frac{k+2}{k+1} - 1}{k} = t'\frac{k+2}{k+1}\frac{k-1}{k} + \frac{k+2}{k(k+1)}.$$

The inequality holds, since the coefficient multiplied by α is negative and $\alpha \leq \frac{1}{k}$. We need to show that the weight is at least t', i.e., that

$$t'\left(\frac{k^2+k-2}{k^2+k} - 1\right) + \frac{k+2}{k(k+1)} = \frac{-2t'}{k^2+k} + \frac{k+2}{k^2+k} \geq 0.$$

We get that this holds for $t' \leq \frac{k+2}{2}$, which holds due to the definition of t'.

Consider the second part of the claim. It is enough to consider the first $f = t - \lfloor\frac{k+2}{2}\rfloor$ transition bins, in the case where f is positive. These bins are transition bins of types $i_1, \ldots, i_f$. Consider the bin of type i_{f+1}. Note that $i_{f+1} \leq k - \lfloor\frac{k+2}{2}\rfloor$ since no two transition bins are of the same type, and $i_{f+1} \geq 3$ since $i_f \geq 2$. Let β be the size of the first item in the bin of type i_{f+1}. Let $m = i_{f+1}$. Considering only the items of sizes in $(\frac{1}{m}, \frac{1}{2}]$, we have that each bin out of the first f transition bins has a total size of such items of at least $1-\beta$. However, they also have a total size of items in $(\frac{1}{k+1}, \frac{1}{2}]$ of at least $1-\alpha$. Therefore, the weight of items in each such bin is at least

$$(1-\beta)\frac{m+2}{m+1} + (\beta-\alpha)\frac{k+2}{k+1} = \frac{m+2}{m+1} + \beta\left(\frac{1}{k+1} - \frac{1}{m+1}\right) - \alpha\frac{k+2}{k+1}.$$

We will show that this amount is never smaller than 1. This expression is minimized for maximum values of α, β, and thus we need to show that

$$\left(1 - \frac{1}{m}\right)\cdot\frac{m+2}{m+1} + \left(\frac{1}{m} - \frac{1}{k}\right)\cdot\frac{k+2}{k+1} - 1 \geq 0,$$

which is equivalent to $\frac{k-m}{km}\cdot\frac{k+2}{k+1} \geq \frac{2}{m(m+1)}$. Note that $k - m \geq \frac{k+1}{2}$, $m+1 \geq 4$, and thus $\frac{k-m}{km}\frac{k+2}{k+1}\cdot\frac{m(m+1)}{2} \geq \frac{k+2}{k} > 1$. ∎

This completes the proof of Lemma 2. ∎

In what follows, we consider algorithms for an input I of the following structure, called COLORFFD. The set I is partitioned into ν independent sets. Out of these sets, μ sets (where $\mu \leq \nu$) are packed using FFD. Each other independent set J is packed into a single bin and is assigned a total weight of at least 1.

COROLLARY 4. *Let $\mathcal{B}$ be a* COLORFFD *algorithm. Then $\mathcal{B}$ satisfies $\mathcal{B} \leq W(I) + \mu$.*

We now give a tight analysis of the FFD-based algorithm given in [17] for perfect graphs.

The FFD-based algorithm of [17].
Find a coloring of all items with a minimum number of colors. Use FFD to pack each color class.

It was shown in [17] that the performance guarantee of this algorithm is at most 2.7 and at least $1+\Pi_\infty \approx 2.69103$. The value $\Pi_\infty = \Pi_\infty(1)$ is computed using the well-known sequence $\pi_i = \pi_i(1)$, $i \geq 1$, which often occurs in bin packing. Given a positive integer z, let $\pi_0(z) = z$, $\pi_1(z) = z+1$, and, for $i \geq 1$, $\pi_{i+1}(z) = \pi_i(z)(\pi_i(z)-1)+1$. Then $\Pi_\infty(z) = \sum_{i=1}^{\infty} \frac{1}{\pi_i(z)-1}$. An alternative definition is $\pi_0(z) = z, \pi_{i+1}(z) = (\prod_{j=0}^{i} \pi_j(z))+1$ for $i \geq 1$. The equivalence can be shown by induction. For $i = 1$, by this definition, $\pi_1(z) = z+1$ as required. Assume this is true for a given $i \geq 1$. For $i+1$, we have $\pi_{i+1}(z) = \pi_i(z)(\pi_i(z)-1)+1 = (\pi_i(z))^2 - \pi_i(z)+1 = \pi_i(z)(\prod_{j=0}^{i-1} \pi_j(z)+1) - \pi_i(z) + 1 = (\prod_{j=0}^{i} \pi_j(z)) + 1$.

This sequence with $z = 1$ is known as "Sylvester's sequence" and as "Euclid numbers" (see sequence A000058 in [30]). The sequence is often used for the analysis of bin packing algorithms and the design of lower bound for online variants of the problem; see [2, 21, 32].

The relation of this sequence to bin packing is as follows. Each number $\pi_i(z)$ is the smallest integer such that a bin of size $\frac{1}{z}$ that already contains the items of sizes slightly larger than $\frac{1}{\pi_j(z)}$, for $j = 1, \ldots, i-1$, can accommodate an item that is slightly larger than $\frac{1}{\pi_i(z)}$. Indeed, we can show by induction that $\sum_{i=1}^{k} \frac{1}{\pi_i(z)} = \frac{1}{z} - \frac{1}{\pi_{k+1}(z)-1}$ for all $k \geq 0$. This clearly holds for $k = 0$. Assume that this holds for some value of $k \geq 0$, then $\sum_{i=1}^{k+1} \frac{1}{\pi_i(z)} = \frac{1}{z} - \frac{1}{\pi_{k+1}(z)-1} + \frac{1}{\pi_{k+1}(z)} = \frac{1}{z} - \frac{1}{(\pi_{k+1}(z)-1)(\pi_{k+1}(z))} = \frac{1}{z} - \frac{1}{\pi_{k+2}(z)-1}$.

We are now ready to prove a matching upper bound of $1+\Pi_\infty = 2.691$ for this algorithm. In order to do so, we need to find an upper bound on the total weight which can reside in one bin. The proof is similar to those of [2, 21], however, our weights are defined differently, since these proofs do not hold in our case. We assume that the weight of an item x of size in $\mathcal{I}_1$ is $s_x + \frac{1}{2}$, which may only increase the total weight, since we previously assigned weight 1 to these items.

LEMMA 5. *Consider a set of items J, whose total size is $s(J) \leq \frac{1}{z}$. Then $W(J) - s(J) \leq \Pi_\infty(z) - \frac{1}{z}$, and thus $W(J) \leq \Pi_\infty(z)$.*

Proof. We define the "increase," or modified weight, of an item by its weight minus its size, i.e., $weight'(x) = weight(x) - s_x$. Let $W'(X)$, for a set X, be the sum of the increases of items in X. We need to show that $W'(J) \leq \Pi_\infty(z) - \frac{1}{z}$. Specifically, we show that $\Pi_\infty(z) - \frac{1}{z}$ is the supremum total increase of the items of J.

First, consider the sequence $\pi_i(z)$, using its definition, we get that, for any value of k and small enough $\delta > 0$, the following holds: $\sum_{i=1}^{k} (\frac{1}{\pi_i(z)} + \delta) < \frac{1}{z}$. This means that a set of items of sizes $\frac{1}{\pi_i(z)} + \delta$ for $1 \leq i \leq k$ has a total size of at most $\frac{1}{z}$. Taking $k \to \infty$, we get that the total increase in a bin which contains such items tends to $\sum_{i=1}^{\infty} \frac{1}{\pi_i(z)(\pi_i(z)-1)} = \sum_{i=1}^{\infty} \frac{1}{\pi_{i+1}(z)-1} = \Pi_\infty(z) - \frac{1}{z}$. We call a part of a bin of size $\frac{1}{z}$ a *partial bin*. We will next show that a set of the items of these sizes is the worst case contents of a partial bin, which would prove the claim.

Assume by contradiction that there exists a value $\varepsilon > 0$ and a set of items for which the sum of increases is at least $\Pi_\infty(z) - \frac{1}{z} + \varepsilon$. We prove that if the partial bin contains exactly one item of each interval in the set of intervals $\{\mathcal{I}_{\pi_1(z)-1}, \ldots, \mathcal{I}_{\pi_{i-1}(z)-1}\}$, then it also contains exactly one item of the interval $\mathcal{I}_{\pi_i(z)-1}$.

We have $\frac{1}{z} - \sum_{j=1}^{i-1} \frac{1}{\pi_j(z)} = \frac{1}{\pi_i(z)-1}$ for $i \geq 1$. Therefore, the largest interval from which the next item can come from is $\mathcal{I}_{\pi_i(z)-1}$. Assume that there is no such item. Thus, all other item sizes are from the interval $(0, \frac{1}{\pi_i(z)}]$, and therefore the increase of an item is smaller than a multiplicative factor of $\frac{1}{\pi_i(z)}$ of its size. The total increase is therefore smaller than $\sum_{j=1}^{i-1} \frac{1}{\pi_j(z)(\pi_j(z)-1)} + \frac{1}{\pi_i(z)-1} \cdot \frac{1}{\pi_i(z)} = \sum_{j=1}^{i} \frac{1}{\pi_{i+1}(z)-1} < \Pi_\infty(z) - \frac{1}{z}$. This leads to a contradiction, and therefore, in order to get above $\Pi_\infty(z) - \frac{1}{z}$, there must be an item of size in $(\frac{1}{\pi_i(z)}, \frac{1}{\pi_i(z)-1}]$. We have proved that the partial

bin must contain at least one item of $\mathcal{I}_{\pi_i(z)}$. Note that, by the above argument, the largest item, excluding one item of each interval in $\{\mathcal{I}_{\pi_1(z)-1}, \ldots, \mathcal{I}_{\pi_i(z)-1}\}$, is of size at most $\frac{1}{\pi_{i+1}(z)-1}$, and therefore the partial bin must contain exactly one item from $\mathcal{I}_{\pi_i(z)-1}$. By this claim (applied to $i = 1$), there is exactly one item from $\mathcal{I}_{\pi_1(z)-1}$, and, by induction on i, there is exactly one item from each interval $\mathcal{I}_{\pi_i(z)-1}$ for all $i \geq 1$.

Consider the smallest value of i such that $\frac{1}{\pi_{i+1}(z)-1} < \varepsilon$. The total size of all the items excluding the largest i items, is at most $\frac{1}{\pi_{i+1}(z)-1}$. No matter what these items are, they have an increase of at most their size, that is, of at most $\frac{1}{\pi_{i+1}(z)-1}$. This means that the total increase is at most $\Pi_\infty(z) - \frac{1}{z} + \frac{1}{\pi_{i+1}(z)-1} < \Pi_\infty(z) - \frac{1}{z} + \varepsilon$, which leads to a contradiction. □

COROLLARY 6. *The performance guarantee of the* FFD*-based algorithm* $\mathcal{A}$ *of* [17] *for perfect graphs is* $\Pi_\infty + 1 \approx 2.69103$.

Proof. As [17] supplies an example which achieves this bound (asymptotically), we should prove the upper bound. Since the input is colored optimally, the number of independent sets is exactly $\mu = \chi(G) \leq \mathrm{OPT}$. We have $\mathcal{A} \leq W(I) + \mathrm{OPT}$. However, $W(I) \leq \Pi_\infty \cdot \mathrm{OPT}$, since by Lemma 5, any bin (of size 1) may contain a total weight of at most $\Pi_\infty \approx 1.69103$, and thus $\mathcal{A} \leq (\Pi_\infty + 1) \cdot \mathrm{OPT}$. □

We give a formal definition of *the algorithm with precoloring* of [17], which is used for graphs in class $\mathcal{C}$.

The algorithm with precoloring of [17].
Let $L = \{j : s_j > \frac{1}{2}\}$.
Compute a feasible coloring of the conflict graph using the minimum number of colors needed to color it, such that each pair of items in L is assigned two distinct colors.
Use FFD to pack each color class.

In order to analyze the *algorithm with precoloring*, we need to define a set of weights which does not give very high weights to items in $\mathcal{I}_1 = (\frac{1}{2}, 1]$. We define the weight for $s_x \in \mathcal{I}_1$ to be $weight(x) = s_x + \frac{1}{6}$. This unique definition is possible due to the special treatment of items in $\mathcal{I}_1$.

In order to establish a lemma regarding the sum of weights in an independent set, we modify the type of algorithms we allow to use. Once again, the set I is partitioned into ν independent sets. Each independent set has at most one item of size in $\mathcal{I}_1$. Out of these sets $\mu \leq \nu$ are packed using FFD. Assume that each other independent set J is packed into a single bin and is assigned a total weight of at least 1.

LEMMA 7. *An algorithm* $\mathcal{B}$ *as above satisfies* $\mathcal{B} \leq W(I) + \mu$.

Proof. We consider two types of independent sets. The first type of independent sets are sets which are packed into a single bin. For each such set, we note that the total weight of items in it is at least 1, by definition.

The second type of independent sets are all other such sets, i.e., independent sets which require at least two bins. We need to show that the sum of the weights of items in each such independent set J is at least the number of bins in this set, minus 1. That is, if J is packed into λ bins, then the total weight of the items of J is at least $\lambda - 1$.

Therefore, in order to complete the proof, we note that independent sets where no item of size in $\mathcal{I}_1$ exists do not have a change in weights (compared to Lemma 2), and thus the previous proof holds.

Consider therefore an independent set packed using FFD, which has a single item in $\mathcal{I}_1$. We may assume that this set consists of at least two bins, otherwise the total weight clearly satisfies the property. The item of size in $\mathcal{I}_1$ is the first one to be packed

by FFD. In this proof we consider this single bin to be a transition bin as well. Let k be the type of the last transition bin as in the proof of Lemma 2. We again calculate only the weight of these bins and show that their number exceeds their total weight by at most 1. Note that if we show that the number of transition bins is ℓ and the total weight in these bins is at least $\ell - 1$, then we are done. We denote the size of the first item in the last transition bin by α.

We have six cases, which are $k \geq 6$ and $k = 1, 2, 3, 4$, or 5.

- If $k \geq 6$, we have that the total size y of items in the first transition bin is at least $\frac{5}{6}$, and thus the weight is at least $y + \frac{1}{6} \geq 1$ (since the weight of the large item is its size plus $\frac{1}{6}$, and no weight of an item is smaller than its size). The rest of the transition bins can be considered as in the proof of Lemma 2.
- Otherwise, if there is a single transition bin, we are done.
- Otherwise, if $k = 2$ (and thus there are exactly two transition bins), or if $3 \leq k \leq 5$, and there are two transition bins. This means that the first item assigned to the second transition bin could not be assigned to the first one. Thus, the total sum of item sizes in the two bins is strictly larger than 1. The weight of an item is no smaller than its size, so the total weight in the transition bins is at least 1, which is what needs to be proved for two such bins.
- Otherwise, if $k = 3$, there are at most three transition bins. The case of two transition bins was considered, so we may assume that three transition bins exist. As in the proof of Lemma 2, we lower bound the sum of weights in bins that are not the first or last transition bin using $\frac{k+2}{k+1}(1-\alpha)$. Since $\frac{1}{k+1} \leq \alpha \leq \frac{1}{k}$, this value is strictly smaller than 1. The weight of items in the first transition bin is at least $1 - \alpha + \frac{1}{6}$, and in the last one it is at least $\alpha + \frac{1}{k(k+1)}$. For $k = 3$, this gives a total weight of at least $1 - \alpha + \frac{1}{6} + \frac{5}{4}(1 - \alpha) + \alpha + \frac{1}{12} = \frac{5}{2} - \frac{5\alpha}{4} \geq \frac{25}{12} > 2$.
- Otherwise, if $k = 4$, then there are three or four transition bins. Let t denote the number of transition bins. We get a total weight of at least

$$1 - \alpha + \frac{1}{6} + (t-2)\frac{6}{5}(1-\alpha) + \alpha + \frac{1}{20} \geq \frac{6}{5}(t-2)\left(1 - \frac{1}{4}\right) + \frac{73}{60} = \frac{9}{10}(t-2) + \frac{73}{60} > t - 1,$$

  which holds for $t = 3, 4$.
- Finally, we are left with the case $k = 5$. We denote again by t the number of transition bins (which is at least three and at most five) and get a total weight of at least

$$1-\alpha+\frac{1}{6}+(t-2)\frac{7}{6}(1-\alpha)+\alpha+\frac{1}{30} = \frac{7}{6}(t-2)\left(1 - \frac{1}{5}\right)+\frac{6}{5} = \frac{14}{15}(t-2)+\frac{6}{5} \geq t-1,$$

  which holds for $t = 3, 4, 5$. □

We can now show a tight analysis of the FFD-based *algorithm with precoloring* given in [17]. It was shown in [17] that the performance guarantee of this algorithm is at most 2.5 and at least $\Pi_\infty(3) + 2 \approx 2.4231$.

THEOREM 8. *The performance guarantee of the* FFD*-based algorithm with precoloring* $\mathcal{B}$ *of* [17] *is* $\Pi_\infty(3) + 2 \approx 2.4231$.

Proof. Since in this case $\mu = \chi_I(G) \leq \mathrm{OPT}$, it is left to upper bound the amount of weight that can fit into a single bin and show that it is at most $\Pi_\infty(3)+1 \approx 1.4231$.

Given a packed bin in OPT, we may assume that all items have size at most $\frac{1}{2}$. Otherwise, there is a single item of size $y > \frac{1}{2}$, replace this item with two items of size $\frac{y}{2}$. If $\frac{1}{4} < \frac{y}{2} \leq \frac{1}{3}$, then the weight of each of these two items is $\frac{y}{2} + \frac{1}{12}$, and their total weight equals the weight of the original item. If $\frac{1}{3} < \frac{y}{2} \leq \frac{1}{2}$, then the weight of each of these two items is $\frac{y}{2} + \frac{1}{6}$, and their total weight is even larger than the weight of the original item. Hence, we can assume that all items have size at most $\frac{1}{2}$.

Consider the case where the bin contains no items of size in $\mathcal{I}_2$ or just one such item. Since, for smaller items, the ratio between weight and size is at most $\frac{4}{3}$, we conclude that the total weight is at most $\frac{4}{3}$ in the case of zero items and at most $\frac{25}{18} \approx 1.38889$ in the case of one item. If it contains two such items, then since the remainder of the bin is of size smaller than $\frac{1}{3}$, the difference between the total weight of the additional items in the bin and their total size is at most $\Pi_\infty(3) - \frac{1}{3}$, by Lemma 5. The difference between the total weight of the items in $\mathcal{I}_2$ and their total size is $2 \cdot (\frac{1}{6}) = \frac{1}{3}$. Thus, the total weight of all items is at most the total difference, which is at most $\Pi_\infty(3)$, plus the total size, which gives $\Pi_\infty(3) + 1 \approx 1.4231$. Note that the weights of items of size in $(0, \frac{1}{2}]$ are the same as is used for the proof of Lemma 5, and therefore the usage of that lemma here is correct. □

3. Improved algorithms. In the previous section, we showed better bounds for two variants of the problem, based on previously known algorithms from [17]. Though this already gives an improvement over the previously known bounds, the bounds we have shown are tight bounds, and thus further improvement is possible only using new algorithms, which we now design. To analyze these algorithms, we use weighting in a more complex way.

3.1. Perfect conflict graphs. We design an algorithm which uses a preprocessing phase.

Algorithm. MATCHING PREPROCESSING

1. Define the following bipartite graph. One set of vertices consists of all items of size in $\mathcal{I}_1$. The other set of vertices consists of all other items. An edge (a, b) between the vertices of the items of sizes $s_a > \frac{1}{2}$ and $s_b \leq \frac{1}{2}$ occurs if the two following conditions hold:
   (a) $s_a + s_b \leq 1$.
   (b) $(a, b) \notin E(G)$.
   That is, if these two items can be placed in a bin together. If this edge occurs, we give it the cost $c(a, b) = weight(b)$, where $weight(b)$ is defined as above to be $s_b + \frac{1}{j(j+1)}$, for the integer j such that $s_b \in (\frac{1}{j+1}, \frac{1}{j}]$.
2. Find a maximum cost matching in the bipartite graph.
3. Each pair of matched vertices are removed from G and packed into a bin together.
4. Let G' denote the induced subgraph over the items that were not packed in the preprocessing.
5. Compute a feasible coloring of G' using $\chi(G')$ colors.
6. For each color class, apply the FFD algorithm.

We next analyze this algorithm.

THEOREM 9. *The above algorithm is a* $\frac{5}{2} = 2.5$*-approximation algorithm.*

Proof. The outline of the proof is as follows. We assign weights to items according to an optimal packing and call this weight function $weight_1$, or the reduced weights. Afterwards, we take the total weight of all items, according to $weight_1$, and reassign

it to items, to get the weight function $weight_2$, so that the total weight of all items does not grow, and we will be able to apply Corollary 4 to bound the number of bins packed by the FFD algorithm, as the algorithm is a COLORFFD algorithm for these items. We will analyze the algorithm using $weight_2$ and the optimal packing using $weight_1$. Specifically, we will use Theorem 1 with these two weights functions. In what follows, we use the notation *weight* for the regular weight function (as used in the proofs for perfect graphs in section 2).

Fix an optimal packing, OPT. We next define a reduced weight function that is based on the weight function *weight*, which is defined for perfect graphs in section 2, with some modifications. For a bin in OPT with no items of size in $\mathcal{I}_1$, reduced weights are defined to be equal to weights according to *weight*. For an item of size in $\mathcal{I}_1$, the reduced weight is 1, which is equal to its weight according to *weight*. Given a bin in OPT with an item of size in $\mathcal{I}_1$ which contains additional items, pick an item of largest size in the bin among the items in the bin with size at most $\frac{1}{2}$, and give it a reduced weight zero. All other items in the bin receive reduced weights that are equal to their weights.

We next define a valid matching in the bipartite graph, defined by the algorithm MATCHING PREPROCESSING. Consider the set of items whose reduced weight is zero. Match each such item to the item of size in $\mathcal{I}_1$ that is placed together with it in a bin of OPT. Consider the cost of this matching. This cost is the sum of the weights of the items (according to *weight*) whose reduced weight is zero. Thus the cost of this matching is exactly the total reduction in the weights of items, i.e., the difference between the total weight of all items according to *weight* and the total weight according to $weight_1$.

Let ω be the cost of the matching removed by the algorithm. Then, by the optimality of the removed matching, we conclude that $\sum_{x\in I}(weight(x)-weight_1(x)) \leq \omega$. We reassign weights to items so that an item of size in $(0, \frac{1}{2}]$ that was removed in the matching (by the algorithm) receives weight zero, and any other item receives a weight as defined by the function *weight*. This weight function (after the reassignment) is called $weight_2$. We have

$$\sum_{x\in I} weight_2(x) + \omega = \sum_{x\in I} weight(x) \leq \omega + \sum_{x\in I} weight_1(x).$$

Therefore, the total weight according to $weight_2$ is no larger than the total weight according to $weight_1$. By Theorem 1, we may analyze the algorithm using the weights $weight_2$ and analyze OPT using the weights $weight_1$. Clearly, each of the bins removed by the algorithm in the matching has weight of at least 1, since each of these contains an item of unit weight. Therefore, we can use Corollary 4, since the weights of items that are packed using FFD are the same as before.

Finally, we need to find an upper bound on the largest amount of the weight of items that can be packed into a single bin of OPT, according to $weight_1$. Note that, for every item, its weight according to $weight_1$ is no larger than its weight according to *weight*. Using Theorem 8, we can see that if all item sizes are no larger than $\frac{1}{2}$, the total weight of items that can be packed into one bin has a total weight (according to *weight* and thus also according to $weight_1$) smaller than $\frac{3}{2}$. Consider now a bin with an item of size in $\mathcal{I}_1$. If this is the only item in the bin, then the total weight of all items in this bin is simply 1. Otherwise, let $x_1 \geq \cdots \geq x_t$ be the sorted list of other items in the bin, where x_1 is the item which was assigned a zero weight in $weight_1$.

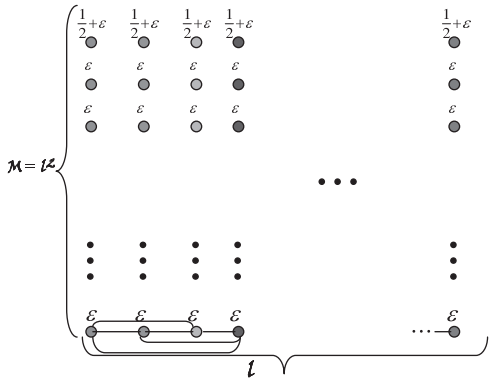

FIG. 1. *The tight example for perfect graphs. The items of each column are packed in one bin by the optimal solution. In the algorithm, the preprocessing step removes the two top items from each column, the remaining items all receive the same color, except for $\ell-1$ items of the last row.*

Let $j \geq 2$ be an integer such that $x_1 \in \mathcal{I}_j$. The total weight, according to $weight_1$, of the large item and items $x_1, \ldots, x_t$ is therefore at most

$$\frac{j+1}{j}\left(\sum_{i=2}^{t} s_{x_i}\right) + 1 \leq 1 + \frac{j+1}{j}\left(1 - \frac{1}{2} - \frac{1}{j+1}\right) = 1 + \frac{j+1}{2j} - \frac{1}{j} = 1 + \frac{j-1}{2j} < \frac{3}{2}.$$

By Corollary 4, the algorithm has an approximation ratio of at most 2.5. □

We next show that our analysis of algorithm MATCHING PREPROCESSING is tight.

PROPOSITION 10. *The approximation ratio of algorithm* MATCHING PREPROCESSING *is at least* 2.5.

Proof. Let M and ℓ be large constants and $\varepsilon = \frac{1}{2M}$. To construct the set of items we do as follows. We use one sequence of ℓ items $a_1, \ldots, a_\ell$ each with size $\frac{1}{2} + \varepsilon$. Furthermore, we have $(M-1)\ell$ additional items $b_{i,j}$, $1 \leq i \leq \ell$, $1 \leq j \leq M-1$, each of size ε. The conflict graph induces a clique with the ℓ items $b_{i,M-1}$ and contains no further edges (see Figure 1).

An optimal solution is given by ℓ independent sets $U_i = \{a_i, b_{i,1}, \ldots, b_{i,M-1}\}$ with total size of exactly one for each set. Thus $\mathrm{OPT} = \ell$.

The preprocessing step finds ℓ pairs, which are $\{a_i, b_{i,1}\}$. Next, a coloring with ℓ colors which is found for the remaining items consists of one independent set, which contains all items $b_{i,j}$ for $1 \leq i \leq \ell$, $2 \leq j \leq M-2$ and additionally contains $b_{1,M-1}$. Each other independent set contains a single item $b_{i,M-1}$ for $2 \leq i \leq \ell$. The number of bins used to color the first independent set is $\lceil \frac{\ell(M-3)+1}{2M} \rceil$, since this is the total size of items. Each other independent set consumes one additional bin, thus in total we get at least $2\ell - 1 + \frac{\ell}{2} - \frac{3\ell}{2M}$ bins. It can be seen that, for $M = \ell^2$ and $\ell >> 1$, the ratio becomes arbitrarily close to $\frac{5}{2}$. □

Remark 11. Algorithm MATCHING PREPROCESSING is a 2.5-approximation algorithm for BPC on any hereditary class of graphs for which one can find in polynomial time a coloring that uses a minimum number of colors.

Remark 11 shows that algorithm MATCHING PREPROCESSING is also a 2.5-approximation algorithm for BPC on unit circular-arc graphs, hence improving the result of [7].

3.2. Conflict graphs that belong to $\mathcal{C}$. In this section, we study an approximation algorithm for the case where the conflict graph G belongs to $\mathcal{C}$. That is, given

an induced subgraph of G, $G' = (V', E')$, and a set of vertices $L' \subseteq V'$, we can find a coloring of G using a minimum number of colors such that each pair of vertices from L' are assigned distinct colors.

We analyze the following algorithm. The weight function $weight$ is defined as in section 2 for items with size at most $\frac{1}{2}$ and for an item x such that $s_x \in \mathcal{I}_1$, $weight(x) = s_x + \frac{1}{6}$. We can use Lemma 7, since our algorithm will follow its conditions.

Algorithm. GREEDY PREPROCESSING

1. **While** there is a set of three items $\{a, b, c\}$ that can fit into one bin (i.e., $s_a + s_b + s_c \leq 1$ and $\{a, b, c\}$ is an independent set of G) such that $weight(a) + weight(b) + weight(c) > 1$ and $s_c \leq s_b \leq s_a \leq \frac{1}{2}$, or two items $\{a, b\}$ that can fit into one bin (i.e., $s_a + s_b \leq 1$ and $\{a, b\}$ is an independent set of G) such that $weight(a) + weight(b) > 1$, **do**, as follows.
   Choose such a set A of maximum total weight. Delete A from G and assign a new bin for the items of A that is dedicated to this set of items.
   Denote by $G' = (V', E')$ the resulting conflict graph induced by the remaining items.
2. Denote the set of large items by $L = \{j \in V' : s_j > \frac{1}{2}\}$, and denote by $\chi_I(G')$ the minimum number of colors used by the optimal solution for the precoloring extension problem defined by G' and the set of precolored vertices L. Compute a feasible coloring of G' using $\chi_I(G')$ colors, where any two items in L are assigned different colors.
3. For each color class, apply the FFD algorithm.

THEOREM 12. *The approximation ratio of the above algorithm is exactly* $\frac{7}{3} \approx 2.33333$.

Proof. Fix an optimal solution OPT. Let $weight$ be the weight function as used in the algorithm. We use Theorem 1 again and apply a method similar to the proof of Theorem 9; however, in the proof here we need only one auxiliary weight function $weight_1$, so the two functions w, w' that are required for the usage of Theorem 1 are equal. We assign weights that are based on the packing of OPT and denote this weight function by $weight_1$ (also called the reduced weights). For an optimal bin which contains no items of size in $\mathcal{I}_1$ and contains no triple of items of total weight strictly larger than 1 with respect to $weight$, we use $weight_1 = weight$ to define the weights of items for all items in the bin. For a bin which contains an item x of size in $\mathcal{I}_1$ but contains no other item y such that $weight(x) + weight(y) > 1$, we again use $weight_1 = weight$ for every item in the bin.

For a bin which contains no items of size in $\mathcal{I}_1$ but contains a triple of items of total weight strictly larger than 1 with respect to $weight$, let a_1, a_2, a_3 be three items with largest weights in the bin ordered according to their weight. Note that $s_{a_1} \in \mathcal{I}_2 \cup \mathcal{I}_3$, since otherwise the sum of weights of the three items cannot exceed 1. We define the reduction value for this bin to be $\Delta = \frac{weight(a_1)+weight(a_2)+weight(a_3)-1}{3}$. The reduction value is used for the definition of weights, according to $weight_1$. For any item b in this bin such that $b \neq a_i$ for $i = 1, 2, 3$, we define $weight_1(b) = weight(b)$. Note that in the preprocessing step, the algorithm removes at least one of a_1, a_2, and a_3, since otherwise if all three items are not removed, then the preprocessing step cannot terminate. Let i' be an index of the item of an item a_i such that $1 \leq i' \leq 3$, and $a_{i'}$ is removed no later than a_j for all $1 \leq j \leq 3$. We define $weight_1(a_{i'}) = weight(a_{i'}) - \Delta$, and, for $i \neq i'$, $weight_1(a_i) = weight(a_i)$.

For a bin which contains an item x of size in $\mathcal{I}_1$ and contains another item y such that $weight(x) + weight(y) > 1$, let y be such an item with maximum weight according

to $weight$. We define the reduction value for this bin to be $\Delta = \frac{weight(x)+weight(y)-1}{3}$. For any item b in the bin for $b \neq x, y$, we define $weight_1(b) = weight(b)$. Note that at least one of x and y is removed in the preprocessing step. If y is removed no later than x, we define $weight_1(y) = weight(y) - \Delta$ and $weight_1(x) = weight(x)$, and otherwise $weight_1(y) = weight(y)$ and $weight_1(x) = weight(x) - \Delta$.

Consider a bin which is removed in the greedy preprocessing step. In order to be able to use Corollary 4, we argue that the total weight of the items in this bin according to $weight_1$ is greater than 1. First note that the total weight of the items according to $weight$ is at least 1. Therefore, if for every item a in this bin $weight_1(a) = weight(a)$, we get that the sum of weights in this bin is strictly larger than 1. We will show that a possible reduction in the weights (i.e., a possible difference between $weight_1$ and $weight$) does not decrease the sum of weights below 1. Let A be the set of (two or three items) in this bin and $\Gamma = \frac{\left(\sum_{a\in A} weight(a)\right)-1}{3}$. For an item $a \in A$, we have $weight_1(a) < weight(a)$ if the following conditions hold. Consider the bin to which a belongs in OPT. Then a value $\Delta(a)$ was computed for this bin such that $weight_1(a) = weight(a) - \Delta(a)$. We get that a is removed in the preprocessing, and at the time of the removal of a, it belongs to a set of items $\mathbf{A}$ of largest weight that is valid for removal in the preprocessing step. Moreover, no item of $\mathbf{A}$ has been already removed at the time that a is being removed. This means that, in the greedy process, we have $\Gamma \geq \Delta(a)$. Thus we have $\sum_{a\in A} weight_1(a) = \sum_{a\in A}[weight(a) - \Delta(a)] \geq \sum_{a\in A} weight(a) - 3\Gamma = 1$. Therefore, each of the bins that were removed by the algorithm in the greedy preprocessing step has weight of at least 1. Therefore, we can use Lemma 7, since the weights of items that are packed using FFD are the same as in section 2.

Finally, we need to analyze the largest amount of weight that can be packed into a single bin of OPT. This analysis is done with respect to $weight_1$. Consider the set of items A in a given bin of OPT.

If all items in A have size at most $\frac{1}{3}$, then for all $a \in A$, $weight_1(a) \leq \frac{4}{3} \cdot s_a$, and thus the total weight of the items in A is at most $\frac{4}{3}$. This covers both the case where there is no reduction in the weight of items in $weight_1$ compared to $weight$ and the case where there is such a reduction for some items.

Next, assume that A has an item x of size in $\mathcal{I}_2$, but all weights in this bin were assigned according to $weight$ (i.e., for all $a \in A$, $weight_1(a) = weight(a)$). This can happen in two cases.

- If A contains an additional item y of size in $\mathcal{I}_2$, then $A = \{x, y\}$. This is so as a third item in the bin would imply a triple whose total weight is strictly more than 1, and hence we will have $weight_1(x) \neq weight(x)$. Therefore, in this case where $A = \{x, y\}$, we get a total weight of
$$s_x + \frac{1}{6} + s_y + \frac{1}{6} \leq 1 + \frac{1}{3} \leq \frac{4}{3}.$$
- Otherwise, for all $y \in A \setminus \{x\}$, we conclude that $s_y \in (0, \frac{1}{3}]$.
  - If all $y \in A \setminus \{x\}$ actually have size in $(0, \frac{1}{4}]$, then $weight_1(y) \leq \frac{5}{4} \cdot s_y$, and the total size of all items in $A \setminus \{x\}$ is at most $1 - s_x$. Together this gives a total weight of at most
$$s_x + \frac{1}{6} + \frac{5}{4} \cdot (1 - s_x) = \frac{17}{12} - \frac{s_x}{4}\ .$$
This value is maximized when s_x is minimized, and therefore the total weight of the items in A is at most $\frac{16}{12} = \frac{4}{3}$.

– Finally, if there is $y \in A$ such that $s_y \in \mathcal{I}_3$, then we conclude that all items of $A \setminus \{x, y\}$ have size in $(0, \frac{1}{6}]$, and thus their weights are at most $\frac{7}{6}$ times their sizes. This is so because a third item of size in $(\frac{1}{6}, \frac{1}{4}]$ in the bin would imply a triple whose total weight is at least $\frac{1}{2}+\frac{1}{3}+\frac{1}{5} > 1$. This triple will force $weight_1(x) < weight(x)$, contradicting our assumption. Therefore, in this case the total weight of the items in A is at most

$$s_x+\frac{1}{6}+s_y+\frac{1}{12}+(1-s_x-s_y)\cdot\frac{7}{6} = \frac{17}{12}-\frac{s_x+s_y}{6} \le \frac{17}{12}-\frac{7}{72} = \frac{95}{72} < \frac{4}{3}.$$

Suppose that A has an item y of size in $\mathcal{I}_1$.

- If $A = \{y\}$, then the total weight is at most $\frac{7}{6}$.
- Otherwise, let $A = \{y, x_1, x_2, \ldots, x_t\}$, where $s_{x_1} \ge \cdots \ge s_{x_t}$ is the sorted list of other items in the bin. Then x_1 is an item of largest weight according to *weight* among $A \setminus \{y\}$. Let $j \ge 2$ be an integer such that $x_1 \in \mathcal{I}_j$. Let

$$\Delta = \frac{weight(y)+weight(x_1)-1}{3} = \frac{s_y+\frac{1}{6}+s_{x_1}+\frac{1}{j(j+1)}-1}{3}$$

be the reduction value of this bin. We have $weight(y)+weight(x_1) = 3\Delta+1$. The total weight (according to $weight_1$) of the items $y, x_1, \ldots, x_t$ is therefore at most

$$\begin{aligned}
&\frac{j+1}{j}\left(\sum_{i=2}^{t} s_{x_i}\right) + weight(y) + weight(x_1) - \Delta \\
&\le \frac{j+1}{j}(1-s_y-s_{x_1}) + 1 + \frac{2}{3}\left(s_y+\frac{1}{6}+s_{x_1}+\frac{1}{j(j+1)}-1\right) \\
&= -\frac{(j+3)(s_y+s_x)}{3j} + \frac{j+1}{j} + \frac{4}{9} + \frac{2}{3j(j+1)}.
\end{aligned}$$

We use $s_y \ge \frac{1}{2}$ and $s_{x_1} \ge \frac{1}{j+1}$ and get total weight of at most

$$-\frac{3(j+3)^2}{18j(j+1)} + \frac{18(j+1)^2+8j(j+1)+12}{18j(j+1)} = \frac{23j^2+26j+3}{18j(j+1)} = \frac{23}{18}+\frac{1}{6j}\,.$$

If $j \ge 3$, we are done. However, if $j = 2$, then all items but y and x_1 are of size strictly smaller than $\frac{1}{6}$, and thus their weights are at most $\frac{7}{6}$ times their sizes. We get a weight of at most

$$\begin{aligned}
\frac{7}{6}(1-s_y-s_{x_1}) + 1 + \frac{2}{3}\left(s_y+\frac{1}{6}+s_{x_1}+\frac{1}{6}-1\right) &= -\frac{s_{x_1}+s_y}{2}+\frac{31}{18} \\
&\le -\frac{5}{12}+\frac{31}{18} = \frac{47}{36} < \frac{4}{3}\,.
\end{aligned}$$

It is left to consider the case where all items in A are no larger than $\frac{1}{2}$, but $weight_1$ is not equivalent to *weight* for this set of items. Such a bin must contain at least one item of size in $\mathcal{I}_2$ (otherwise, this case is already covered). There are two types of such bins. One option is that A has a single item y of size in $\mathcal{I}_2$. The other option is that A has two items y_1, y_2 of size in $\mathcal{I}_2$.

- Consider the first option and assume first that A contains one item of $\mathcal{I}_2$ and does not contain an item of size in $\mathcal{I}_3$. In this case, we can show that the total

weight according to *weight* of the items in A is at most $\frac{4}{3}$. This is so because, in this case, the total weight is at most $s_y + \frac{1}{6} + \frac{5}{4} \cdot (1 - s_y) = \frac{17}{12} - \frac{s_y}{4} \leq \frac{4}{3}$, where the last inequality holds, since $s_y > \frac{1}{3}$.

- Consider the first option and assume that A contains an item of size in $\mathcal{I}_3$. Let y_1, y_2 be the items of sizes in $\mathcal{I}_2$,$\mathcal{I}_3$ (respectively) and assume that $A = \{y_1, y_2, x_1, \ldots, x_t\}$, where $s_{x_1} \geq \cdots \geq s_{x_t}$, so x_1 is an item of largest weight according to *weight* in $A \backslash \{y_1, y_2\}$. Let $j \geq 3$ be an integer such that $s_{x_1} \in \mathcal{I}_j$. Let

$$\begin{aligned}\Delta &= \frac{weight(y_1) + weight(y_2) + weight(x_1) - 1}{3} \\ &= \frac{s_{y_1} + \frac{1}{6} + s_{y_2} + \frac{1}{12} + s_{x_1} + \frac{1}{j(j+1)} - 1}{3}\end{aligned}$$

be the reduction value of this bin. We have $weight(y_1) + weight(y_2) + weight(x_1) = 3\Delta + 1$. The total weight (according to $weight_1$) of the items in A is therefore at most

$$\begin{aligned}&\frac{j+1}{j}\left(\sum_{i=2}^{t} s_{x_i}\right) + weight(y_1) + weight(y_2) + weight(x_1) - \Delta \\ &\leq \frac{j+1}{j}(1 - s_{y_1} - s_{y_2} - s_{x_1}) + 1 \\ &\quad + \frac{2}{3}\left(s_{y_1} + \frac{1}{6} + s_{y_2} + \frac{1}{12} + s_{x_1} + \frac{1}{j(j+1)} - 1\right) \\ &= -\frac{(j+3)(s_{y_1} + s_{y_2} + s_x)}{3j} + \frac{j+1}{j} + \frac{1}{2} + \frac{2}{3j(j+1)}.\end{aligned}$$

We use $s_{y_1} \geq \frac{1}{3}$, $s_{y_2} \geq \frac{1}{4}$, and $s_{x_1} \geq \frac{1}{j+1}$ and get a total weight of at most

$$\begin{aligned}&-\frac{(j+3)(7j+19)}{36j(j+1)} + \frac{36(j+1)^2 + 18j(j+1) + 24}{36j(j+1)} \\ &= -\frac{7j^2 + 40j + 57}{36j(j+1)} + \frac{36j^2 + 72j + 36 + 18j^2 + 18j + 24}{36j(j+1)} = \frac{47}{36} + \frac{1}{12j} \leq \frac{4}{3}.\end{aligned}$$

- Consider the second option. Assume that $A = \{y_1, y_2, x_1, \ldots, x_t\}$, where $s_{x_1} \geq \cdots \geq s_{x_t}$, so x_1 is an item of largest weight according to *weight* in $A \setminus \{y_1, y_2\}$. Let $j \geq 3$ be an integer such that $s_{x_1} \in \mathcal{I}_j$. Let

$$\begin{aligned}\Delta &= \frac{weight(y_1) + weight(y_2) + weight(x_1) - 1}{3} \\ &= \frac{s_{y_1} + \frac{1}{6} + s_{y_2} + \frac{1}{6} + s_{x_1} + \frac{1}{j(j+1)} - 1}{3}\end{aligned}$$

be the reduction value of this bin. We have $weight(y_1) + weight(y_2) + weight(x_1) = 3\Delta + 1$. The total weight (according to $weight_1$) of the items

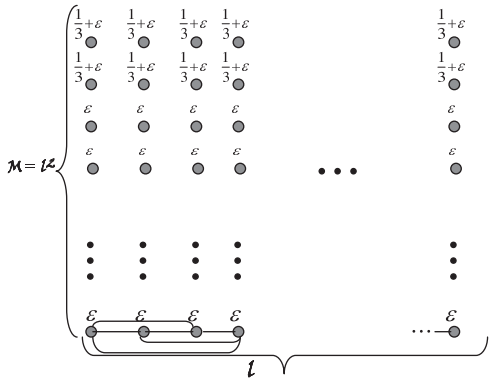

FIG. 2. *The tight example for the class $\mathcal{C}$. The items of each column are packed in one bin by the optimal solution. In the algorithm, the preprocessing step removes the three top items from each column, and the remaining items all receive the same color, except for $\ell - 1$ items of the last row.*

in A is therefore at most

$$\begin{aligned}
&\frac{j+1}{j}\left(\sum_{i=2}^{t} s_{x_i}\right) + weight(y_1) + weight(y_2) + weight(x_1) - \Delta \\
&\leq \frac{j+1}{j}(1 - s_{y_1} - s_{y_2} - s_{x_1}) + 1 \\
&\quad + \frac{2}{3}\left(s_{y_1} + \frac{1}{6} + s_{y_2} + \frac{1}{6} + s_{x_1} + \frac{1}{j(j+1)} - 1\right) \\
&= -\frac{(j+3)(s_{y_1} + s_{y_2} + s_x)}{3j} + \frac{j+1}{j} + \frac{5}{9} + \frac{2}{3j(j+1)}.
\end{aligned}$$

We use $s_{y_1}, s_{y_2} \geq \frac{1}{3}$, and $s_{x_1} \geq \frac{1}{j+1}$ and get a total weight of at most

$$\begin{aligned}
&-\frac{(j+3)(2j+5)}{9j(j+1)} + \frac{9(j+1)^2 + 5j(j+1) + 6}{9j(j+1)} = -\frac{2j^2 + 11j + 15}{9j(j+1)} \\
&+ \frac{9j^2 + 18j + 9 + 5j^2 + 5j + 6}{9j(j+1)} = \frac{4}{3}\,.
\end{aligned}$$

We next show that our analysis of algorithm GREEDY PREPROCESSING is tight. Let M and ℓ be large constants and $\varepsilon = \frac{1}{3M}$. To construct the set of items, we do as follows. We use two sequences of ℓ items each, $a_1, \ldots, a_\ell, b_1, \ldots, b_\ell$, where each of these items has size $\frac{1}{3} + \varepsilon$. Furthermore, we have $(M-2)\ell$ additional items $c_{i,j}$, $1 \leq i \leq \ell$, $1 \leq j \leq M-2$, each of size ε. The conflict graph induces a clique on the ℓ items $c_{i,M-2}$ and contains no further edges (see Figure 2).

An optimal solution is given by ℓ independent sets $U_i = \{a_i, b_i, c_{i,1}, \ldots, c_{i,M-2}\}$ with total size of exactly one for each set. Thus $\mathrm{OPT} = \ell$.

The preprocessing step finds ℓ sets of triples, which are $\{a_i, b_i, c_{i,1}\}$. Next, a coloring with ℓ colors which is found for the remaining items consists of one independent set which contains all items $c_{i,j}$ for $1 \leq i \leq \ell$, $2 \leq j \leq M-3$, and additionally contains $c_{1,M-2}$. Each other independent set contains a single item $c_{i,M-2}$ for $2 \leq i \leq \ell$. The number of bins used to color the first independent set is $\lceil \frac{\ell(M-4)+1}{3M} \rceil$, since $\frac{\ell(M-4)+1}{3M}$ is the total size of these items. Each other independent set consumes one additional

bin, thus in total we get at least $2\ell - 1 + \frac{\ell}{3} - \frac{4\ell}{3M}$ bins. It can be seen that, for $M = \ell^2$ and $\ell >> 1$, the ratio becomes arbitrarily close to $\frac{7}{3}$. □

Consider now alternative algorithms which remove triples in a different way in the first step of the algorithm. That is, instead of picking a triple or pair greedily at each time, it applies a different heuristic. The example actually shows that even if this step is processed optimally (using an exponential time algorithm), that is, if a set of triples and pairs with total maximum weight is removed, still the performance cannot be improved. Therefore, we keep this step simple and do not apply advanced methods (such as local search; see [1]) that allow the removal of a set of triples and pairs of a larger weight.

3.3. Bipartite graphs. In this section, we can assume that $\mathrm{OPT} \geq 2$ and that the conflict graph contains at least one edge. This holds since $\mathrm{OPT} = 1$ means that the conflict graph is empty, and the total size of the items is at most 1. Each one of these properties can be easily checked in polynomial time, and if both conditions hold, the algorithm returns an optimal solution. Moreover, if the conflict graph is empty, the problem reduces to standard bin packing, for which FFD has an approximation ratio of $\frac{3}{2}$ [29]. Since the algorithm presented in this section has an approximation ratio larger than $\frac{3}{2}$, we can assume that the conflict graph contains at least one edge.

In [17], the following simple algorithm was analyzed for graphs which have a nonempty conflict graph.

The algorithm Two-Set (TS) of [17].

Find a coloring of the conflict graph with two colors. Pack each color class using a simple heuristic (Next-Fit, First-Fit (FF), or FFD).

It was shown in [17] that TS is a 2-approximation for all of these suggested heuristics. (Using FFD instead of Next-Fit does not give a better approximation ratio.)

We design an algorithm which gives special treatment to some of the problematic cases and thus get a $\frac{7}{4}$-approximation.

We start with an analysis of the algorithm TS (with FFD), as a function of the value OPT. Let A and B denote the sets of the items of the two colors. Let $\ell(A)$ and $\ell(B)$ denote the numbers of bins packed by FFD for each of the two sets, and let $\mathrm{OPT}(X)$ denote the cost of an optimal solution for a set X. Clearly, we have $s(X) \leq \mathrm{OPT}(X) \leq \mathrm{OPT}$ for $X = A, B$, and also $\mathrm{OPT} \geq s(A) + s(B)$.

As stated above, Simchi-Levi [29] proved that, for any input Y, the solution of FFD on this output satisfies $\mathrm{FFD}(Y) \leq \frac{3}{2}\mathrm{OPT}(Y)$. Therefore, if the size of one of the sets (without loss of generality, the set A) is small enough, namely, this set fits into one bin $s(A) \leq 1$, we get $TS \leq \mathrm{FFD}(B) + 1 \leq \frac{3}{2}\mathrm{OPT} + 1$.

Otherwise, if for both sets, the output of FFD created at least one bin where the smallest item that opens a new bin is in the interval $(0, \frac{1}{3}]$. Then, for each set A and B, all bins but the last one are occupied by more than $\frac{2}{3}$, and the sum of items in the two last bins together is more than 1. We get for $X = A, B$, $s(X) > \frac{2}{3}(\ell(X) - 2) + 1$. Thus $TS \leq \ell(A) + \ell(B) < \frac{3}{2}\mathrm{OPT} + 1$.

Suppose next that both sets A and B do not have a bin opened by an item with size in the interval $(0, \frac{1}{3}]$. Then, we remove all items smaller than $\frac{1}{3}$ from the input. Clearly, the output does not change. Each bin contains an item of size in $(\frac{1}{2}, 1]$ (and possibly one smaller item as well) or two items in the interval $(\frac{1}{3}, \frac{1}{2}]$, except possibly the last bin for each set, that may contain a single item of this last interval. Let Z denote the number of the items of size in $(\frac{1}{2}, 1]$ in $A \cup B$, and let V denote the number of items from $A \cup B$ with size in the interval $(\frac{1}{3}, \frac{1}{2}]$. Therefore,

$TS \le Z + \frac{V-2}{2} + 2 = Z + \frac{V}{2} + 1$. However, for any packing and thus for an optimal one, we have that each bin contains at most one item with size larger than $\frac{1}{2}$, and at most two items with size larger than $\frac{1}{3}$, thus we have $\mathrm{OPT} \ge Z$ and $\mathrm{OPT} \ge \frac{Z+V}{2}$. We get $TS \le \frac{Z+V}{2} + \frac{Z}{2} + 1 \le \frac{3}{2}\mathrm{OPT} + 1$.

We are left with the case where (without loss of generality) the set A contains a bin opened by an item in $(0, \frac{1}{3}]$, and B does not. If A does not contain a bin opened by an item of size in $(0, \frac{1}{4}]$, we can remove all items smaller than $\frac{1}{4}$ from the input and get the same output. Let Z denote again the number of items in $(\frac{1}{2}, 1]$ and V denote the number of items in $(\frac{1}{4}, \frac{1}{2}]$. We now argue that $V \le 3(\mathrm{OPT} - Z) + Z = 3\mathrm{OPT} - 2Z$. This last inequality holds, since a bin with an item larger than $\frac{1}{2}$ can contain at most one item larger than $\frac{1}{4}$, and any other bin can contain at most three such items. Therefore, $TS \le Z + \frac{V-2}{2} + 2 \le Z + \frac{3}{2}\mathrm{OPT} - Z + 1 = \frac{3}{2}\mathrm{OPT} + 1$.

Finally, we need to consider the case where A contains at least one bin opened by an item of size in $(0, \frac{1}{4}]$, and B does not have a bin opened by an item whose size is at most $\frac{1}{3}$. Thus all bins of A but the last one are occupied by more than $\frac{3}{4}$. We get $s(A) > \frac{3}{4}(\ell(A) - 2) + 1$ and $s(B) > \frac{1}{2}\ell(B)$. The last inequality holds for any Any-Fit type algorithm and for FFD in particular. Moreover, note that the packing of B is an optimal one. This can be proved using simple exchange arguments (see [29]). Thus we have $\ell(B) \le \mathrm{OPT}$. We get $\mathrm{OPT} \ge s(A) + s(B) > \frac{3}{4}\ell(A) + \frac{1}{2}\ell(B) - \frac{1}{2}$. Thus $TS < \frac{4}{3}\mathrm{OPT} + \frac{2}{3} + \frac{1}{3}\mathrm{OPT} = \frac{5}{3}\mathrm{OPT} + \frac{2}{3}$. Since both OPT and TS are integers and our last inequality is a strict inequality, we get $TS \le \frac{5}{3}\mathrm{OPT} + \frac{1}{3}$.

We can prove the following lemma.

LEMMA 13. *If* $\mathrm{OPT} \ge 3$ *then the algorithm above satisfies* $TS \le \frac{7}{4}\mathrm{OPT}$*, and this bound is tight when* $\mathrm{OPT} = 4$*.*

Proof. We obtained two bounds, and since TS is integer, we conclude that $TS \le \max\{\lfloor \frac{3}{2}\mathrm{OPT} + 1 \rfloor, \lfloor \frac{5}{3}\mathrm{OPT} + \frac{1}{3} \rfloor\}$. If $\mathrm{OPT} \ge 4$, we get $\frac{3}{2}\mathrm{OPT} + 1 \le \frac{7}{4}\mathrm{OPT}$ and $\lfloor \frac{5}{3}\mathrm{OPT} + \frac{1}{3} \rfloor \le \frac{7}{4}\mathrm{OPT}$. For $\mathrm{OPT} = 3$, we get $TS \le 5 = \frac{5}{3}\mathrm{OPT}$.

To see that this bound is tight, consider the following example. Let $\varepsilon > 0$ be a small number and define the following set of item sizes $A = \{\frac{1}{4} + \varepsilon, \frac{1}{4} + \varepsilon, \frac{1}{4} + \varepsilon, \frac{1}{4} + \varepsilon, \frac{1}{4} - 2\varepsilon, \frac{1}{4} - 2\varepsilon, \frac{1}{4} - 2\varepsilon, \frac{1}{4} - 2\varepsilon\}$, and $B = \{\frac{1}{2} + \varepsilon, \frac{1}{2} + \varepsilon, \frac{1}{2} + \varepsilon, \frac{1}{2} + \varepsilon\}$. Assume that the conflict graph has a single edge between one item of size $\frac{1}{2} + \varepsilon$ and one of the items of size $\frac{1}{4} + \varepsilon$. Then an optimal solution has four bins, each of which has one item of size $\frac{1}{2} + \varepsilon$, one item of size $\frac{1}{4} + \varepsilon$, and one item of size $\frac{1}{4} - 2\varepsilon$. Clearly, the two items which have a conflict do not share a bin. However, assume that the coloring into two colors partitions the items into A and B. Then, $\mathrm{FFD}(A) = 3$ and $\mathrm{FFD}(B) = 4$. Therefore, for this example, $\mathrm{OPT} = 4$, and the algorithm returns a solution that uses seven bins. ∎

Note that if we were considering the asymptotic approximation ratio rather than the absolute approximation ratio, this analysis of TS proves that its asymptotic approximation ratio is at most $\frac{3}{2}$.

As we can see, the only case which is left is $\mathrm{OPT} = 2$, which requires special treatment. This case can be identified by a solution returned by TS of cost 4. Clearly, such solutions can be achieved also for $\mathrm{OPT} = 3$ and $\mathrm{OPT} = 4$. We define an algorithm and prove that it succeeds if $\mathrm{OPT} = 2$. Thus, if it fails, then $\mathrm{OPT} \ge 3$, which means that the original solution already does not violate the approximation ratio $\frac{7}{4}$ which we would like to prove. We call this algorithm MODIFIED TWO-SET (MTS).

If $\mathrm{OPT} = 2$, this means that it is possible to color the input using two colors and pack each independent set into a single bin. If the conflict graph is connected, there is a unique way to color the items, and thus this optimal packing can be achieved.

However, a bipartite disconnected graph has more than one possible coloring with two colors, since the roles of the two colors in each connected component can be swapped. The first step of MTS is to color each connected component using two colors. Let z be the number of components and denote the items of component i by V_i. For each $1 \le i \le z$, this gives two sets A_i and B_i, such that $A_i \cup B_i = V_i$, $A_i \cap B_i = \emptyset$, and $s(A_i) \ge s(B_i)$. Each set in $\{A_i, B_i\}$ contains the vertices of V_i that share one color. Define $p_i = s(A_i) - s(B_i)$ and assume that the values p_i are sorted such that $p_1 \ge p_2 \ge \cdots \ge p_z$. Let $q_i = s(B_i) = s(A_i) - p_i$. Use the sizes p_i to define a scheduling problem on two machines. Run LPT (Longest Processing Time First) on this input. This means that two empty sets of indices $\mathcal{V}_1$ and $\mathcal{V}_2$ are initialized. Then starting from $i = 1$, assign i for $i = 1, \ldots, z$ to the set ($\mathcal{V}_1$ or $\mathcal{V}_2$) whose total sum (of the values p_j, where j is a member of the set) is minimal. Graham [12] defined and analyzed this algorithm for an arbitrary number of machines (subsets). It is not difficult to see that when the algorithm terminates, $|\sum_{i\in\mathcal{V}_1} p_i - \sum_{i\in\mathcal{V}_2} p_i| \le p_1$ holds. For $1 \le i \le z$, we define a coloring using two colors (which are defined by the sets C and D) as follows. If $i \in \mathcal{V}_1$, then MTS assigns the items in A_i to C and the items in B_i to D. Otherwise, it assigns the items in B_i to C and the items in A_i to D. This assignment means that $s(C) = \sum_{i\in\mathcal{V}_1} p_i + \sum_{i=1}^{z} q_i$ and $s(D) = \sum_{i\in\mathcal{V}_2} p_i + \sum_{i=1}^{z} q_i$. Thus we have $|s(C) - s(D)| = |\sum_{i\in\mathcal{V}_1} p_i - \sum_{i\in\mathcal{V}_2} p_i| \le p_1$. Assume (without loss of generality) that $s(C) \ge s(D)$. Since $\mathrm{OPT} = 2$, $s(C) + s(D) \le 2$. Thus $s(D) \le 1$, and all of the items assigned to D fit into a single bin. Let i_1 be the maximum index in $\mathcal{V}_1$. Now remove all items of A_{i_1} (where $s(A_{i_1}) = p_{i_1} + q_{i_1}$) from C. We get a total sum of less than $s(D) \le 1$, and thus the remaining items of C fit into one additional bin. Finally, the items of A_{i_1} need to be packed. If indeed $\mathrm{OPT} = 2$, then the items of A_{i_1} are packed into a single bin in any optimal solution and thus can be packed into a third bin. This gives a total of three bins.

We summarize the action of MODIFIED TWO-SET as follows.

Algorithm. MODIFIED TWO-SET (MTS)

Run TS on the input. If the output consists of four bins, apply the following algorithm, which assumes $\mathrm{OPT} = 2$. If the algorithm does not fail (that is, each one of the three bins it creates is valid, in terms of total size), give its output. Otherwise, give the output of TS as output.

1. Color each connected component of the conflict graph using two colors. Denote the vertices of connected component $1 \le i \le z$ by V_i. Assume that the two independent sets resulting from connected component V_i are A_i,B_i, where $s(A_i) \ge s(B_i)$ and that the sets are sorted so that the values $p_i = s(A_i) - s(B_i)$ are nonincreasing.
2. Apply the algorithm LPT on the values p_i to partition the (indices of the) sets V_i into two subsets $\mathcal{V}_1$ and $\mathcal{V}_2$, where $\sum_{i\in\mathcal{V}_1} p_i \ge \sum_{i\in\mathcal{V}_2} p_i$. Let i_1 be the maximum index in $\mathcal{V}_1$, then $\sum_{i\in\mathcal{V}_1} p_i - \sum_{i\in\mathcal{V}_2} p_i \le p_{i_1}$.
3. Pack all items of $\bigcup_{i\in\mathcal{V}_1} A_i \cup \bigcup_{i\in\mathcal{V}_2} B_i$, except for items of A_{i_1} into one bin.
4. Pack all items of $\bigcup_{i\in\mathcal{V}_2} A_i \cup \bigcup_{i\in\mathcal{V}_1} B_i$ into one bin.
5. Pack all items of A_{i_1} into one bin.

We proved the following theorem.

THEOREM 14. *Algorithm* MTS *has an approximation ratio of exactly* $\frac{7}{4}$.

Proof. We showed that if $\mathrm{OPT} = 2$, the process above succeeds to pack the input into three bins. Otherwise, the theorem follows from Lemma 13. ∎

4. Online algorithms. In this section, we discuss online algorithms for interval graphs.

In the online problem, items arrive one by one. When an item arrives, the following information is revealed to the algorithm: the size of the item, the existing edges in the conflict graph between the new item, and the previous items. The algorithm has to pack the new item before the next item arrives. Once an item is packed in a bin, its location cannot be changed. For interval graphs, an item arrives together with its realization, that is, the coordinates of the interval on the real line, which corresponds to this item.

For many classes of graphs, the online coloring problem is hard to approximate. Note that online coloring is a special case of BPC, where all item sizes are zero.

Consider, e.g., the problem on trees. Gyárfás and Lehel [13] proved a deterministic lower bound of $\Omega(\log n)$ on the online coloring of bipartite graphs on n vertices, which holds already for trees. Lovász, Saks, and Trotter [22] showed an online coloring algorithm which colors such a graph (which is 2 colorable) using $O(\log n)$ colors. This immediately implies an online coloring algorithm for BPC on bipartite graphs, which is optimal up to a constant multiplicative factor on the competitive ratio. This algorithm $\mathcal{A}$ uses the algorithm of [22] to color the conflict graph using C colors. Then the items of each color class are packed independently using some reasonable algorithm for bin packing, e.g., Next-Fit. We get that for each color class i, which contains ℓ_i bins, the total size of items S_i of color class i is more than $\frac{\ell_i - 1}{2}$ (since no two consecutive bins can be combined). We get that

$$\mathcal{A} \leq \sum_{i=1}^{C} \ell_i < \sum_{i=1}^{C} (2S_i + 1) \leq 2\mathrm{OPT} + C \leq O(\log n)\mathrm{OPT} \ .$$

Since the same can be applied for any graph class for which no constant competitive algorithm exists, we focus on a graph class for which such an algorithm exists, namely, interval graphs. Kierstead and Trotter [20] constructed an online coloring algorithm for interval graphs, which uses at most $3\omega - 2$ colors, where ω is the maximum clique size of the graph. They also presented a matching lower bound of $3\omega - 2$ on the number of colors in a coloring of an arbitrary online coloring algorithm.

The main idea of the algorithm of [20] is the creation of "levels." At the time of the arrival of an interval, it is classified into a level as follows. Denote by A_k the union of the sets of intervals which currently belong to all levels $1, \ldots, k$. Intervals are classified so that the largest cardinality clique in A_k is of size k. Thus, A_1 is simply a set of nonintersecting intervals. On the arrival of an interval, the algorithm finds the smallest k such that the new interval can join level k, without violating the rule above. It can be shown that each level can be colored using two colors by an offline algorithm. Since the algorithm defined here is online, such a coloring cannot be found, in general. However, it is shown in [20] that at most three colors are required for each such level, and a coloring using three colors can be found by applying FF on each level (with disjoint sets of colors). Moreover, the first level can always be colored using a single color, and ω is equal exactly to the number of levels. Thus a total number of colors, which is at most $3(\omega - 1) + 1 = 3\omega - 2$, is used.

Note that the chromatic number of interval graphs equals to the size of a maximum clique, which is equivalent in the case of interval graphs to the largest number of intervals that intersect any point (see [18, 11]). The technique above implies a 5-competitive algorithm. We can show that using FF instead of Next-Fit for coloring each class slightly improves this bound.

A combined algorithm for interval graphs.
Use the algorithm of [20] to color the arriving intervals and FF to pack the items of each color.

THEOREM 15. *The combined algorithm has a competitive ratio of* 4.7.

Proof. The proof is similar to the proof of [17] for perfect graphs. We can use the well-known weight function $\hat{w}$ defined for FF already in [9] (see also page 219 in [3]). This weight function is defined as follows:

$$\hat{w}(r) = \begin{cases} \frac{6r}{5} & \text{if } 0 \le r < \frac{1}{6}, \\ \frac{9r}{5} - \frac{1}{10} & \text{if } \frac{1}{6} \le r < \frac{1}{3}, \\ \frac{6r}{5} + \frac{1}{10} & \text{if } \frac{1}{3} \le r < \frac{1}{2}, \\ 1 & \text{if } \frac{1}{2} \le r \le 1. \end{cases}$$

It was shown that, for a set of items J on which FF is applied, we have $\ell(J) \le W(J) + 1$, where $W(J)$ denotes the total weight of items in J and $\ell(J)$ is the number of bins in the packing of J by FF. On the other hand, if we remove the incompatibility constraint (i.e., assume that the conflict graph has no edges) and let OPT' denote an optimal solution for this instance, we have $W(I) \le 1.7\mathrm{OPT}' \le 1.7\mathrm{OPT}$. Let I_j denote the items colored by the algorithm of [20] by color j, and let C denote the number of colors which is used. This algorithm colors the items with at most $3\chi(G) - 2 \le 3\mathrm{OPT} - 2$ colors; therefore $C < 3\mathrm{OPT}$, and thus we get $\mathcal{A} \le \sum_{j=1}^{C} \ell(I_j) < \sum_{j=1}^{C} (W(I_j) + 1) = W(I) + C \le 4.7\mathrm{OPT}$.

Based on the examples of [17, 19] and [20], we can show a sequence of instances whose competitive ratio is arbitrarily close to 4.7. The tight example simply combines the two previously known tight examples. The example of [20] is used as a black box. Given an interval $[x, y]$, we use the fact that it is possible to construct an example, which is a sequence of intervals contained in $[x, y]$, where the size of the largest clique is ω, for a given value of ω, and for which the algorithm of [20] uses the $3\omega - 2$ colors $1, 2, \ldots, 3\omega - 2$.

We fix a value of $\mathrm{OPT} = k + 2$ and a value of $\varepsilon >> \delta > 0$ that is small enough, and we let $\ell = \frac{k}{10}$. The construction is composed of two phases. In the first phase, we repeat the construction of [20] with a maximum clique size $k+1$, where all items that correspond to the vertices which the intervals represent have zero size. We repeat the construction to have $3k$ copies of this construction that use the same set of $3k + 1$ colors. Since the intervals are colored by the algorithm of [20], all structures are all colored in the same way. We call these $3k + 1$ colors $1, 2, \ldots, 3k + 1$.

At the end of the first phase, we call the subintervals of the real line such that each one of them contains a copy of the construction of [20] that uses the color set $\{1, 2, \ldots, 3k + 1\}$, $[x_i, y_i]$ for $1 \le i \le 3k$. Each future interval will completely contain an interval $[x_i, y_i]$ and will not have any overlap with other intervals from the first phase or the second phase.

We next present $3k$ disjoint intervals one by one (i.e., this set of intervals is an independent set of G). Each of these intervals contains exactly one interval $[x_i, y_i]$ of the first phase, and therefore these intervals cannot be colored using colors $1, 2, \ldots, 3k+1$, by the algorithm.

- The first k intervals, which are denoted by $a_{i,p}$ for $i = 1, \ldots, 10$ and $p = 1, \ldots, \ell$, have sizes according to the following: $a_{i,p}$ has size $\frac{1}{6} + \frac{\varepsilon}{3^p} - \delta$ for $1 \le i \le 5$, and otherwise, it has size $\frac{1}{6} - \frac{\varepsilon}{3^{p+1}} - \delta$. These k intervals are

introduced according to the following order:

$$a_{1,1}, a_{2,1}, a_{3,1}, a_{6,1}, a_{7,1}, a_{4,1}, a_{5,1}, a_{8,1}, a_{9,1}, a_{10,1}, a_{1,2}, \ldots .$$

- The next k intervals are denoted by $b_{i,p}$ for $i = 1, \ldots, 10$ and $p = 1, \ldots, \ell$. Their sizes are defined according to the following: the size of $b_{i,p}$ for $1 \le i \le 5$ is $\frac{1}{3} + \frac{\varepsilon}{3^{p-1}} - \delta$, and otherwise, the size of $b_{i,p}$ is $\frac{1}{3} - \frac{\varepsilon}{3^p} - \delta$. These k intervals are introduced in the following order: $b_{1,1}, b_{6,1}, b_{2,1}, b_{7,1}, b_{3,1}, b_{8,1}, b_{4,1}, b_{9,1}, b_{5,1}, b_{10,1}, b_{1,2}, \ldots$.
- The last k intervals are denoted by c_i for $i = 1, 2, \ldots, k$, and each of these has size of $\frac{1}{2} + \delta$.

Note that the coloring algorithm of [20] will color all of the intervals of the second phase using color $3k + 2$, and therefore we need to compute the number of bins that the FF algorithm uses in order to pack all of these items. Applying FF will open ℓ bins of the following type: $\{a_{1,p}, a_{2,p}, a_{3,p}, a_{6,p}, a_{7,p}\}$ for $p = 1, 2, \ldots, \ell$. It will use another ℓ bins of the following type: $\{a_{4,p}, a_{5,p}, a_{8,p}, a_{9,p}, a_{10,p}\}$. There will be another 5ℓ bins each containing $\{b_{i,p}, b_{i+5,p}\}$ for $i = 1, 2, \ldots, 5$ and $p = 1, 2, \ldots, \ell$. Last, the algorithm will pack each of the items c_i separately using another 10ℓ bins. The total number of bins used to pack the second phase intervals is $17\ell = 1.7k$. By adding the $3k + 1$ colors that are used to color the first phase intervals, we get a solution whose cost is $4.7k + 1$ (see Figure 3).

It remains to show that the optimal solution costs $k + 2$. We first show a packing of the second phase intervals using exactly $k + 2$ bins. We use 5ℓ bins each containing $\{a_{i,p}, b_{5+i,p}, c_{5(p-1)+i}\}$ for $i = 1, \ldots, 5$ and $p = 1, \ldots, \ell$. We use another $5\ell - 10$ bins each containing $\{a_{5+i,p-2}, b_{i,p}, c_{5(p+\ell-3)+i}\}$. We use another five bins containing $\{c_{10(\ell-1)+i}, b_{i,1}\}$ for $i = 1, \ldots, 5$, and another five bins containing $\{c_{10(\ell-1)+5+i}, b_{i,2}\}$ for $i = 1, \ldots, 5$. We have another two bins where the first one consists of $\{a_{6,\ell-1}, a_{7,\ell-1}, a_{8,\ell-1}, a_{9,\ell-1}, a_{10,\ell-1}\}$ and the second bin consists of $\{a_{6,\ell}, a_{7,\ell}, a_{8,\ell}, a_{9,\ell}, a_{10,\ell}\}$. Then, for each one of the $3k$ constructions of the first phase, there is a single color out of the list of $k + 2$ colors (or bins) that is used in the coloring of the second phase interval that contains this construction. Therefore, we have a set of $k + 1$ colors that can be used to color the intervals of the first phase construction; these are all the colors except the one that is used for the interval of the second phase. It is possible to complete the coloring of the construction using a set of $k + 1$ colors, as the maximum clique size in each such construction is $k + 1$. Therefore, we are able to color the entire set of intervals using $k + 2$ colors, each of them containing items of total size at most one. Hence, $\mathrm{OPT} = k + 2$. □

We can show that an algorithm of much smaller competitive ratio does not exist.

THEOREM 16. *The competitive ratio of any online algorithm for* BPC *on interval graphs has a competitive ratio of at least* $\frac{155}{36} \approx 4.30556$.

In order to prove this theorem, we prove the following two lemmas.

The proof of the next lemma uses a construction similar to the lower bound given in [20]. In our construction, we prove a lower bound of $3 + c$ on the competitive ratio. We assume that we know the optimal value $\mathrm{OPT} = k$, and thus we are allowed to use a set of at most $(3 + c)k$ bins. The construction is composed of two phases. In the first phase, we introduce intervals such that the corresponding items have size zero. We call the intervals that correspond to these items zero sized intervals, where the size of an interval is unrelated to its length. The *size of an interval* is simply the size of the item that is associated with the vertex in the conflict graph that this interval represents. The maximum cardinality clique among these intervals will be $k - 1$, and

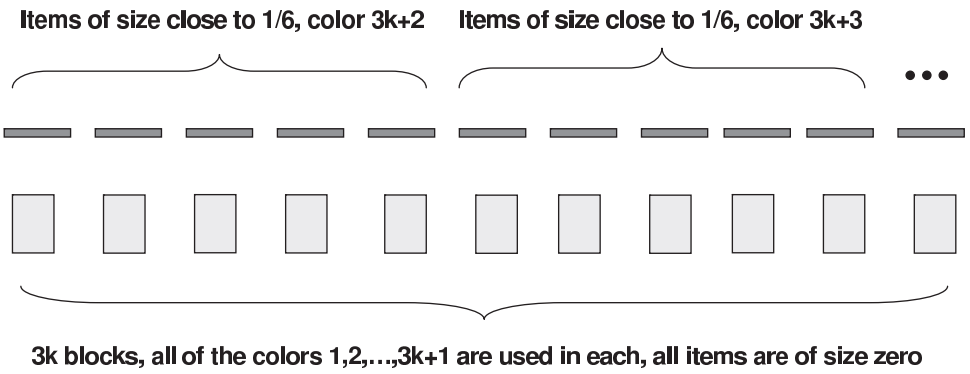

FIG. 3. *A schematic illustration of the behavior of the algorithm in the example of the proof of Theorem* 15. *The large rectangles represent the first part of the input. The thin rectangles represent the additional intervals. Only the first set of such intervals is shown.*

the algorithm is forced to use at least $3k-5$ bins, denoted by $1, 2, \ldots, 3k-5$. This part of the construction follows a similar framework as the lower bound in [20]. The second phase of our construction is similar to the second phase of the tight example in the proof of Theorem 15.

LEMMA 17. *Let c be a lower bound on the asymptotic competitive ratio of any online algorithm for standard bin packing, which knows the value* OPT *in advance. Then the competitive ratio for any online algorithm for* BPC *on interval graphs is at least $3+c$.*

Proof. Our construction is composed of two phases. During the first phase, we *shrink* some parts of the line into single points. We next define the operation of shrinking an interval $[a,b]$ into a point p. Such an operation is performed only if the interval $[a,b]$ and each previously presented interval $[x,y]$ satisfy that either $[x,y] \subseteq [a,b]$ or $[x,y]$ and $[a,b]$ are disjoint. The shrinking operation is a mapping of the real line onto itself such that the points in $[a,b]$ are mapped to $p=a$, a point q such that $q<a$ is mapped to q, and a point $q'>b$ is mapped to $q'-(b-a)$. We note that at the time of the shrinking, each existing interval does not contain p as a (strictly) inner point. The shrinking operation does not affect the sizes of intervals which are not shrunk.

Therefore, every interval presented in the past which is contained in $[a,b]$ is also shrunk into p, and thus such a point inherits a list of colors that such intervals received. These colors cannot be assigned to any interval that contains the point p.

If at some time during the construction, an algorithm uses more than $U = 4\left\lceil \frac{(3+c)k}{4} \right\rceil$ bins, the construction is stopped. Therefore, we assume that the algorithm is initially given U bins, or equivalently, a palette of U colors. As soon as all of these colors are used, the proof is complete, and no further phases are presented. This is just one stopping condition; we may stop the first phase of the sequence earlier as well, after the algorithm used $3k-5$ colors from the set of colors $\{1, 2, \ldots, U\}$. In this case, a second phase is used.

The first phase is composed of at most $k-1$ steps that we define as follows. At the first step of the first phase, we introduce S disjoint (unit length and zero sized) intervals, where $S = U^{3k}X$ and X is fixed later. Since the algorithm is using at most U colors, this means that there exists a set of at least $\frac{S}{U}$ intervals that share the exact same color $\mathbf{c}$. We shrink all intervals into single points. Later steps result in additional points.

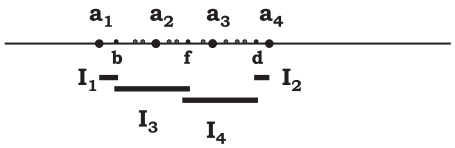

FIG. 4. *The set of intervals in the case that I_1 and I_2 receive the same color.*

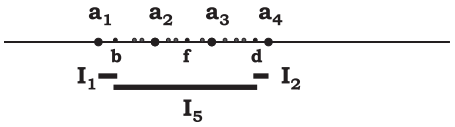

FIG. 5. *The set of intervals in the case that I_1 and I_2 receive distinct colors.*

We now define step $j > 1$ of the first phase. The steps are constructed in a way that, in the beginning of step $j \geq 1$, there is a set of at least $U^{3(k-j)+2}X$ points that contain a given subset of the U colors (which clearly holds after the first step). These points are called *points of interest*. After the first step, all points of interest contain one fixed color.

Note that at all times, there may exist some other points containing some subsets of colors. All of these points are called *void points*.

At the beginning of a step $j > 1$, we partition $U^{3(k-j+1)+2}X$ of the points of interest into consecutive sets of four, $X\frac{U^{3(k-j+1)+2}}{4}$ sets in total. All other points of interest, if they exist, that do not participate in this become void points.

We next define additional intervals, increasing the size of the largest cardinality clique (with respect to the number of intervals, i.e., ignoring sizes) by exactly 1. Given a set of four points of interest a_1, a_2, a_3, a_4 (listed from left to right), let b be a point between a_1 and a_2, which is not a void point, and let d be a point between a_3 and a_4, which is not a void point. Let f be a point between a_2 and a_3, which is not a void point. We introduce the zero sized intervals $I_1 = [a_1, b]$ and $I_2 = [d, a_4]$.

If they both receive the same color, we introduce the zero sized intervals $I_3 = [b, f]$ and $I_4 = [f, d]$. The interval I_3 intersects with a_2 and with I_1. The second interval I_4 intersects I_3, a_3, and I_2; therefore two new colors must be used. In total, three new colors were used (See Figure 4).

If I_1 and I_2 receive distinct colors, we introduce the zero sized interval $I_5 = [b, d]$. Interval I_5 intersects with I_1, I_2, a_2, and a_3, and thus gets a new color. In total, three new colors were used (See Figure 5).

We shrink every such interval $[a_1, a_4]$ into a single point. Each of the new shrunk points received three new colors.

Note that throughout all of the steps of the first phase, we use at most U colors (otherwise, this phase is stopped), and each new shrunk point receives exactly three new colors, since four intervals are introduced only if the first two received the same color, and otherwise, three intervals of three different colors are introduced. However, even though the initial sets of colors are the same for all points of interest, the sets of the three new colors may differ for different sets of four points of interest from the previous step. Since the number of choices of three colors out of at most U colors is $\frac{U^3}{6}$, there are less than $\frac{U^3}{6}$ options to choose a set of three new colors.

We can choose at least $\frac{(XU^{3(k-j+1)+2})/4}{U^3/6} > XU^{3(k-j)+2}$ points having the exact same set of used colors. The points containing these exact sets of colors become the

points of interest of the next step, and the others become void points of the next step. Points that are void points of previous steps and are not contained in shrunk intervals remain void points. Note that the points where the new intervals intersect are points with no previous intervals, and therefore the clique size increases by exactly 1.

The result of each step is therefore an increase of 3 in the number of colors that each point of interest contains, whereas the cardinality of the largest clique increased by 1.

At the end of the $k-1$th step, the first phase where we have a set of zero sized intervals ends, and the online algorithm used at least $3k-5$ colors to color these intervals, since the first step creates points of interest with one color, and each additional step increases the number of colors attributed to points of interest by 3. At this time, the number of points of interest, where each point contains the same set of $3k-5$ colors, is at least XU^2.

Assume that c is a lower bound on the asymptotic competitive ratio of any online algorithm for standard bin packing, which knows the value $\mathrm{OPT} = k$ in advance. This means that, for any $\varepsilon > 0$, there exists a sequence of at most $f(k)$ items (defined by their sizes) such that $\mathrm{OPT} = k$, and the algorithm is forced to use at least $(c-\varepsilon)k$ bins. For example, in the proof of Lemma 18, $f(k) = 3k$. (Note that even if the lower bound construction uses an infinite number of items, we can always use a subsequence of the construction of finite length, which gives a lower bound of $c-\varepsilon$.)

We let $X = f(k) \cdot \binom{U}{3k-5}$. In this way, we create at least $f(k)$ disjoint subintervals of the real line (each of them can be obtained from unshrinking a point of interest), where each contains a set of zero sized intervals such that at least one interval of each range is colored with colors $\{1, 2, \ldots, 3k-5\}$. In the second phase, we will introduce disjoint intervals which contain these subintervals of the real line obtained in the first phase. That is, in the conflict graph, a vertex of an interval of the second phase would be adjacent to a set of vertices such that, for each color in $1, 2, \ldots, 3k-5$, at least one neighbor of the new vertex has this color. Therefore, all colors used in the second phase would be of a larger index.

In the second phase, we consider the lower bound instance of the bin packing problem where OPT is known to the algorithm. If the lower bound construction asks to present an item of size s_i, we present an interval with size s_i that overlaps exactly one subinterval of the real line defined by the first phase (and therefore it cannot be colored with a color from $\{1, 2, \ldots, 3k-5\}$), and it does not intersect any preceding interval of the second phase. In this way, all intervals of the second phase are colored with colors greater than $3k-5$, and since they cannot be packed by the online algorithm using less than $(c-\varepsilon)k$ bins, they use colors $3k-4, \ldots, (3+c-\varepsilon)k-5$ (this is without loss of generality after renaming the colors).

To prove the claim, it suffices to show that $\mathrm{OPT} = k$. To see this, note that each of the first phase construction can be colored using $k-1$ colors (as the maximum clique size in it is $k-1$). Therefore, we consider the optimal solution for the bin packing instance that uses k bins. Then we traverse the first phase constructions one by one and allocate the intervals in the first phase constructions to $k-1$ colors among the existing k colors so that the overlapping interval of the second phase (if there is such one) has a different color. In this way, the total size of items that are allocated to a color is at most one, and we obtain a coloring using k colors that satisfies the conflicts constraints such that the total size of each color class is at most one. ∎

LEMMA 18. *Any online algorithm for standard bin packing, which knows the value* OPT *in advance, has a competitive ratio of at least* $\frac{47}{36} \approx 1.30556$.

Proof. We use a construction similar to the lower bound given by Yao in [33] (see also [32]). The difference is that since we commit on a given value of OPT in advance, we need to pad the sequence with items of size 1 in cases where we would otherwise simply stop the sequence.

Let N be a large integer which is divisible by 6. The input consists of one of the following three inputs:

1. N items of size 0.15, followed by $\frac{5}{6}N$ items of size 1.
2. N items of size 0.15, followed by N items of size 0.34, followed by $\frac{N}{2}$ items of size 1.
3. N items of size 0.15, followed by N items of size 0.34, followed by N items of size 0.51.

It is not difficult to verify that, in all three cases, $\mathrm{OPT} = N$. We use the following variables. For $i = 1, \ldots, 6$, X_i denotes the number of bins with exactly i items of size 0.15, after only these items have arrived. For $i = 0, \ldots, 6$, $0 \le j \le 2$, $i + j > 0$, $X_{i,j}$ denotes the number of bins with exactly i items of size 0.15 and j items of size 0.34, after these two sets of items have arrived. Clearly, if $i \ge 3$, then $X_{i,2} = 0$ and if $i \ge 5$, then $X_{i,j} = 0$ for $j \ne 0$. For convenience, we also let $X_{0,0} = 0$. We define $X_0 = X_{0,1} + X_{0,2}$ to be the number of bins with only (one or two) items of size 0.34. Moreover, we have for $1 \le i \le 6$, $X_i = X_{i,0} + X_{i,1} + X_{i,2}$.

The following equalities must hold due to the amounts of items: $\sum_{i=1}^{6} iX_i = N$ and $\sum_{i=0}^{6} \sum_{j=0}^{2} jX_{i,j} = N$.

Let $\mathcal{R}$ be the competitive ratio of an algorithm. We can compute the cost of the algorithm for each of the three inputs. This cost is at most $\mathcal{R} \cdot N$. The costs are $\sum_{i=1}^{6} X_i + \frac{5}{6}N$, $\sum_{i=0}^{6} X_i + \frac{N}{2}$, since, in these cases, the algorithm must put the large items into new bins, and $X_{0,2} + X_{1,2} + X_{2,1} + X_{2,2} + X_{3,1} + X_4 + X_5 + X_6 + N$. This is true, since the following bins can accommodate an item of size 0.51: bins with no items of size 0.34 and at most three items of size 0.15, bins with one item of each of these sizes, and bins with only one item which is of size 0.34.

We have three inequalities, which we multiply by the coefficients $1, 2, 3$, respectively, and get the following:

$$\begin{aligned} &2X_{0,1} + 5X_{0,2} + 3X_{1,0} + 3X_{1,1} + 6X_{1,2} + 3X_{2,0} + 6X_{2,1} + 6X_{2,2} \\ &+ 3X_{3,0} + 6X_{3,1} + 6X_{4,0} + 6X_{4,1} + 6X_{5,0} + 6X_{6,0} + \frac{29}{6}N \le 6\mathcal{R}N. \end{aligned}$$

We have established the following two equalities: $\sum_{i=1}^{6} iX_i = N$ and $\sum_{i=0}^{6} \sum_{j=0}^{2} jX_{i,j} = N$, which we multiply by the coefficients $1, 2$, respectively. Hence, we get the following:

$$\begin{aligned} &2X_{0,1} + 4X_{0,2} + X_{1,0} + 3X_{1,1} + 5X_{1,2} + 2X_{2,0} + 4X_{2,1} + 6X_{2,2} \\ &+ 3X_{3,0} + 5X_{3,1} + 4X_{4,0} + 6X_{4,1} + 5X_{5,0} + 6X_{6,0} = 3N. \end{aligned}$$

Since all variables are nonnegative, we substitute and get $\frac{29}{6}N + 3N \le 6\mathcal{R}N$, and thus $\mathcal{R} \ge \frac{47}{36}$. ∎

5. Conclusion. We have improved the upper bounds for BPC on perfect graphs, interval graphs (and a few related classes), and bipartite graphs. Most of our results follow from the adaptation of weighting systems to enable an analysis of algorithms for BPC, and new algorithms which carefully remove small subgraphs of items which cause problematic instances. There is still a gap between the inapproximability which

follows from bin packing and the upper bounds. An open problem would be to close this gap.

Another open question is the following. As in [17], we used the absolute approximation ratio to analyze the performance of our algorithms. It can be seen that, using the asymptotic approximation ratio, we can achieve a slightly better upper bound for bipartite graphs. It is unclear whether the same is true for other graph classes, i.e., whether the asymptotic approximation ratio for BPC is strictly lower than the absolute one for some cases.

DYNAMIC CONTROL OF INFEASIBILITY IN EQUALITY CONSTRAINED OPTIMIZATION*

ROBERTO H. BIELSCHOWSKY† AND FRANCISCO A. M. GOMES‡

Abstract. This paper describes a new algorithm for solving nonlinear programming problems with equality constraints. The method introduces the idea of using trust cylinders to keep the infeasibility under control. Each time the trust cylinder is violated, a restoration step is called and the infeasibility level is reduced. The radius of the trust cylinder has a nonincreasing update scheme, so eventually a feasible (and optimal) point is obtained. Global and local convergence of the algorithm are analyzed, as well as its numerical performance. The results suggest that the algorithm is promising.

Key words. nonlinear programming, constrained optimization, large-scale optimization

DOI. 10.1137/070679557

1. Introduction.

We consider the equality constrained optimization problem

$$\begin{aligned} &\text{minimize} && f(x) \\ &\text{subject to} && h(x) = 0, \end{aligned} \tag{1.1}$$

where $f : \mathbb{R}^n \to \mathbb{R}$ and $h : \mathbb{R}^n \to \mathbb{R}^m$ are C^2 functions.

Usual algorithms for solving problem (1.1) alternate normal (or "vertical") steps towards the feasible set $\mathcal{H}_0 = \{x : h(x) = 0\}$ with tangential (or "horizontal") steps towards the dual manifold $\nabla\mathcal{L} = \{x : \nabla L(x, \lambda) = 0\}$, where L is the Lagrangian function. Generally, these steps are obtained from some quadratic model for (1.1). This feature is shared, for example, by the trust region methods proposed by Biegler, Nocedal, and Schmid [4], Byrd, Gilbert, and Nocedal [9], Byrd, Hribar, and Nocedal [10], Dennis and Vicente [15], El-Alem [17], Gomes, Maciel, and Martínez [22], and Lalee, Nocedal, and Plantenga [23].

In this paper, we propose an algorithm that uses normal and tangential trust region models in a more flexible way. Our bet is that, rather than taking one normal and one tangential step per iteration, we might do better if, at some iterations, $\nabla\mathcal{L}$ is pursued with some priority, so several successive horizontal steps are taken before one vertical step is computed. On the other hand, we believe that, in some cases, it is preferable to move closer and closer to $\mathcal{H}_0$, so we systematically force the vertical step. To allow this to occur, we introduce a single mechanism based on what we call *trust cylinders*.

Another feature that distinguishes our method from most of the nonlinear optimization algorithms recently proposed is that, using trust cylinders, we need not rely on a filter (see, for example, [13, Chap. 15]) or on a merit function (see [22]) to obtain global convergence. Instead, we accept the horizontal step if it sufficiently decreases

the Lagrangian function, subject to the condition of staying (dynamically) close to feasibility, in a sense that will be explained in what follows.

Algorithms that generate feasible iterates, without solving $h(x) = 0$ explicitly, go back to the early 1960s, with methods usually classified either as generalized reduced gradient (see [44, 1, 2]) or as projected gradient (PG) [37, 38]. Variations of the PG method, including some strategies to relax feasibility in a controlled way, began to appear at the end of the '60s with the suggestive denomination of sequential gradient-restoration algorithm [29, 30]. See also [32, 35, 36]. More recently, Martínez introduced a new class of algorithms, called *inexact restoration methods* [24, 25, 26, 27, 28], that also controls infeasibility at each iteration.

Our approach has the flavor of a PG algorithm and could be characterized as a relaxed feasible point method, with a *dynamic control of infeasibility* (DCI). We look for a compromise between allowing a large enough horizontal step, in a direction approximately tangent to the restrictions $h(x) = 0$, and keeping infeasibility under control. The main idea is to force each iterate x^k to remain in a trust cylinder defined by

$$\mathcal{C}^k = \{x \in \mathbb{R}^n : \|h(x)\| \leq \rho^k\},$$

where $\|.\|$ denotes the ℓ_2 norm.

The dynamic control of infeasibility is kept defining the "radii" ρ^k of the trust cylinders in such a way that

$$\rho^k = O(\|g_p(x^k)\|), \tag{1.2}$$

where $g_p(x)$ stands for the projected gradient, i.e., the orthogonal projection of the gradient $g(x) = \nabla f(x)$ onto the null space of $\nabla h(x)$, the Jacobian of h. In our case of interest, $g_p(x)$ will be calculated at regular points of h, where $\nabla h(x)$ has full rank. In this situation, the least squares multiplier estimates, $\lambda_{LS}(x)$, are given by

$$\lambda_{LS}(x) = \operatorname{argmin}\{\|\nabla h(x)^T\lambda + g(x)\|\} = -(\nabla h(x)\nabla h(x)^T)^{-1}\nabla h(x)g(x), \tag{1.3}$$

and the resulting projected gradient is

$$g_p(x) = g(x) + \nabla h(x)^T\lambda_{LS}(x). \tag{1.4}$$

Given x^{k-1}, the kth iteration begins with a *restoration step*, if necessary, in order to obtain a point $x_c = x_c^k$ and a radius $\rho = \rho^k$ such that

$$\|h(x_c)\| \leq \rho = O(\|g_p(x_c)\|) \tag{1.5}$$

and

$$\|x_c - x^{k-1}\| = O(\|h(x^{k-1})\|). \tag{1.6}$$

A radius $\rho = \rho^k$ satisfying (1.2) may be defined as $\rho = \nu\, n_p(x_c)\, \rho_{max}$, where

$$n_p(x_c) = \frac{\|g_p(x_c)\|}{\|g(x_c)\| + 1} \tag{1.7}$$

and $10^{-4} \leq \nu \leq 1$ and $\rho_{max} > 0$ are constants.

Given x_c in $\mathcal{C}^k$, the second part of the kth iteration looks for a *horizontal step*, δ_t, that provides a sufficient decrease for a quadratic approximation of f and guarantees

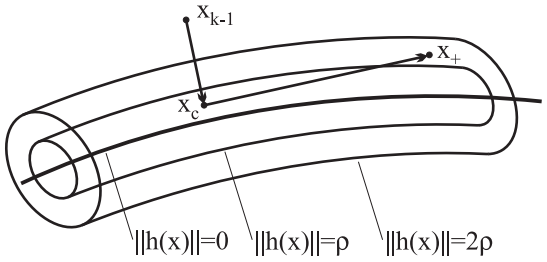

FIG. 1.1. *The step and the trust cylinders.* x_c *satisfies* $\|h(x_c)\| < \rho$, *while* x_+ *satisfies* $\|h(x_+)\| < 2\rho$.

that $x_+ = x_c + \delta_t$ remains in a bigger trust cylinder of radius 2ρ. An optional second order correction δ_{soc} may also be used to reduce the infeasibility, so $x^k = x_c + \delta_t + \delta_{soc}$.

Figure 1.1 sketches the vertical and the horizontal steps of a typical iteration.

An advantage of staying close to the feasible set is that a "good horizontal step" in a level set given by $h(x) = c$ is likely to be close to a "good horizontal step" in the feasible set given by $h(x) = 0$ if c is relatively small.

The parameter $\rho_{max} = \rho^k_{max}$ is nonincreasing and is responsible for the trustability of the trust cylinders. It is decreased every time there is evidence that the reduction of the Lagrangian function obtained in the horizontal step was menaced by a significant increase in the restoration step.

In the next section, we formalize the DCI algorithm. In section 3, a global convergence result for the algorithm is presented, followed by the local convergence theory introduced in section 4. Section 5 contains some preliminary numerical results. Finally, some conclusions and lines for future work are included in section 6.

2. The DCI algorithm. In this section, we depict a typical iteration of our main algorithm. As usual, we use the Lagrangian function, defined as

$$L(x, \lambda) = f(x) + \lambda^T h(x),$$

to evaluate the algorithm behavior. In fact, the control of the trust cylinder radius is also based on the variation of the Lagrangian at x^k_c, given by

$$\Delta L^k_c = L^k_c - L^{k-1}_c,$$

where $L^k_c = L(x^k_c, \lambda^k)$. Since our algorithm divides the step into two components, one vertical and one horizontal, this variation is also split according to

$$\Delta L^k_c = \Delta L^{k-1}_H + \Delta L^k_V, \tag{2.1}$$

where

$$\Delta L^{k-1}_H = L(x^{k-1}, \lambda^{k-1}) - L(x^{k-1}_c, \lambda^{k-1}), \tag{2.2}$$

$$\Delta L^k_V = L(x^k_c, \lambda^k) - L(x^{k-1}, \lambda^{k-1}). \tag{2.3}$$

In the vertical step of the algorithm, we seek a point x_c that satisfies (1.5) and (1.6). Under usual regularity assumptions for $\nabla h(x)$ along the iterations, we can achieve (1.5) and (1.6) with almost every algorithm available for the least squares problem

$$\text{minimize} \quad \|h(x)\|^2. \tag{2.4}$$

Careful line searches in the Cauchy, Gauss–Newton, or Newton directions, or in some combination of them, can be used, for example, to solve problem (2.4). As a matter of fact, algorithms for (2.4) that take steps in the form $d = -M\nabla h(x)^T h(x)$, where M represents a family of uniformly bounded and positive definite matrices, will produce a "sufficiently" fast convergence to a feasible point, and that is what we need to guarantee (1.6). In the implementation of the algorithm, we will give preference to a trust region method. Namely, our restoration step successively solves the linearized least squares problem

$$\begin{aligned} &\text{minimize} && \|h(x) + Ad\|^2 \\ &\text{subject to} && \|d\|_\infty \le \Delta_{VS}, \end{aligned} \tag{2.5}$$

where A is an approximation of $\nabla h(x)$ and $\Delta_{VS} > 0$ is a trust region radius adequately updated in the vertical subproblems.

In the horizontal step we solve the quadratic programming problem

$$\begin{aligned} &\text{minimize} && q(\delta) = g(x_c)^T\delta + \frac{1}{2}\delta^T B\delta \\ &\text{subject to} && \nabla h(x_c)\delta = 0, \\ & && \|\delta\|_\infty \le \Delta, \end{aligned} \tag{2.6}$$

where B is a symmetric approximation of the Hessian of the Lagrangian and $\Delta > 0$ is the trust region radius.

We suppose that, at the beginning of the kth iteration, the previous approximate solution, x^{k-1}, and the Lagrange multipliers estimate, λ^{k-1}, are available. In addition, we also suppose that the following are known: the upper limit for the trust cylinder radius, ρ_{max}; the Lagrangian function at some previous iteration j, $L_{ref} = L(x_c^j, \lambda^j)$; the horizontal variation of the Lagrangian, ΔL_H^{k-1}; and the trust region radii, $\Delta_{VS} \ge \Delta_{min}$ and $\Delta \ge \Delta_{min}$.

ALGORITHM 2.1. *The kth iteration of the DCI method.*

1. *Vertical step:*
1.1. $x_c = x^{k-1}$.
1.2. Choose an approximate value for ρ.
1.3. REPEAT
1.3.1. IF $\|h(x_c)\| > \rho$
1.3.1.1. Find x_c, such that $\|h(x_c)\| \le \rho$.
1.3.2. $g_p \leftarrow g_p(x_c)$; $n_p \leftarrow \|g_p(x_c)\|/(\|g(x_c)\| + 1)$.
1.3.3. Choose $\rho \in [10^{-4} n_p \rho_{max}, n_p \rho_{max}]$.
1.4. UNTIL $\|h(x_c)\| \le \rho$.
1.5. Compute λ_+.
2. *Convergence test:*
2.1. IF $(n_p = 0)$,
2.1.1. QUIT (x_c is a stationary point).
3. *ρ_{max} update:*
3.1. $\Delta L_V^k \leftarrow L(x_c, \lambda_+) - L(x^{k-1}, \lambda^{k-1})$.
3.2. IF $\Delta L_V^k \ge \frac{1}{2}[L_{ref} - L(x^{k-1}, \lambda^{k-1})]$,
3.2.1. $\rho_{max} \leftarrow \rho_{max}/2$.
3.3. IF $\Delta L_V^k > -\frac{1}{2}\Delta L_H^{k-1}$,
3.3.1. $L_{ref} \leftarrow L(x_c, \lambda_+)$.

4. *Horizontal step:*
4.1. REPEAT
4.1.1. Compute the Cauchy step δ_{CP}, solution of
$$\text{minimize} \quad q(\mu g_p)$$
$$\text{subject to} \quad \|\mu g_p\| \le \Delta,\ \mu \in [0,\infty).$$
4.1.2. Compute a trial step δ_t such that
$q(\delta_t) \le q(\delta_{CP})$,
$\|\delta_t\| \le \Delta$, and
$\nabla h(x_c)\,\delta_t = 0$.
4.1.3. Optionally, compute a second order correction δ_{soc}.
4.1.4. $\delta_+ \leftarrow \delta_t + \delta_{soc}$; $x_+ \leftarrow x_c + \delta_+$.
4.1.5. $\Delta L_H^k \leftarrow L(x_+,\lambda_+) - L(x_c,\lambda_+)$; $r \leftarrow \Delta L_H^k / q(\delta_t)$.
4.1.6. IF $(\|h(x_+)\| > 2\rho)$ OR $(r < \eta_1)$,
4.1.6.1. $\Delta \leftarrow \alpha_R \Delta$;
4.1.7. ELSE IF $r > \eta_2$,
4.1.7.1. $\Delta \leftarrow \alpha_I \Delta$.
4.2. UNTIL $(\|h(x_+)\| \le 2\rho)$ AND $(r \ge \eta_1)$.
5. *Approximate solution update:*
5.1. $x^k \leftarrow x_+$; $\lambda^k \leftarrow \lambda_+$; $k \leftarrow k+1$.
5.2. Choose $\Delta \ge \Delta_{min}$.

In Algorithm 2.1, we suppose that the restoration step 1.3.1.1 will always succeed. Obviously, this may not occur, since problem (1.1) may be infeasible. Therefore, some termination criterion needs to be defined to prevent the algorithm from getting stuck on this step.

In step 1.3.2 of the algorithm and in the next section, we assume that n_p is computed according to (1.7). As a matter of fact, all we need for our convergence theory is that $n_p = O(\|g_p(x_c)\|)$, but we decided to use an explicit formula for n_p in order to keep the text more readable. Another choice we made was to define λ_+ as the vector of least squares multipliers (1.3) computed at x_c^k, although other update schemes would work as well.

Most of the constants used in Algorithm 2.1 are explicitly shown above, so the reader does not need to guess the meaning of several obscure Greek letters. We do prefer to write $\|h(x_+)\| > 2\rho$ instead of $\|h(x_+)\| > \zeta\rho$, for example, to make clear that, in steps 4.1.6 and 4.2, we are considering a larger trust cylinder. Naturally, the algorithm will also work if we use $\zeta = 3$, although this modification will slightly affect the proofs of some lemmas presented in the next section. Only Δ_{min}[1] and the four constants that control the behavior of the trust region method used to compute the horizontal step were not specified. These parameters must satisfy $0 < \eta_1 \le 1/2$, $\eta_1 \le \eta_2 < 1$, $0 < \alpha_R < 1$, $\alpha_I \ge 1$, and $\Delta_{min} > 0$. Possible values are $\eta_1 = 10^{-3}$, $\eta_2 = 0.7$, $\alpha_R = 0.25$, $\alpha_I = 2.5$, and $\Delta_{min} = 10^{-5}$.

The following relations, easily derived from steps 1.3 and 4.2 of Algorithm 2.1, will be used frequently in the next two sections and are presented here for convenience:

$$\rho^k \le \rho_{max}^k \|g_p(x_c^k)\|, \tag{2.7}$$

[1]The parameter Δ_{min} plays no role in the global convergence theory of Algorithm 2.1. It is also unnecessary for the local convergence theory if we use the true Lagrangian second order polynomial as the quadratic model $q(\delta)$ or if B is a good approximation of $\nabla^2_{xx}L(x,\lambda)$ in the plane that contains the Cauchy and the quasi-Newton directions, as will become clear in section 4. However, our numerical tests indicate that keeping $\Delta \ge 10^{-5}$ may slightly improve the performance of the algorithm, so we decided to include step 5.2.

$$\rho_{max}^k \leq 10^4 \rho^k \frac{1}{n_p} = 10^4 \rho^k \frac{\|g(x_c^k)\| + 1}{\|g_p(x_c^k)\|}, \tag{2.8}$$

$$\|h(x_c^k)\| \leq \|h(x^{k-1})\| \leq 2\rho^{k-1}. \tag{2.9}$$

The global convergence of DCI will be guaranteed, under reasonable assumptions, by a typical *sufficient decrease* argument for the Lagrangian function evaluated at x_c^k. The variation of the Lagrangian between two successive iterations is given by (2.1). The idea is to prevent the decrease of the Lagrangian obtained at the horizontal step from being destroyed by the restoration. For that, ρ_{max}^k is decreased in step 3 of DCI every time ΔL_V^k is larger than a fraction of the difference between the Lagrangian at the current iteration and a reference value L_{ref} fixed in some previous iteration j. If the increase in ΔL_V^k significantly menaces the decrease in the Lagrangian obtained since iteration j, ρ_{max} is divided by 2 and L_{ref} is updated. L_{ref} is also updated every time $\Delta L_V^k > -\frac{1}{2}\Delta L_H^{k-1}$. The main argument to guarantee global convergence establishes, under suitable assumptions, the existence of *enough normal space*, dynamically calibrated for horizontal steps of reasonable size, in the sense that ρ_{max}^k remains bounded away from zero unless $\liminf(\|g_p(x_c^k)\|) = 0$.

3. Global convergence. The global convergence analysis of the DCI algorithm is based on the following hypotheses.

H1 (differentiability): f and h are C^2.

H2 (compacity): The generated sequences $\{{x_c}^k\}$ and $\{x^k\}$, the Hessian approximations B^k, and the multipliers $\{\lambda^k\}$ remain uniformly bounded.

H3 (regularity and restoration): The restoration never fails, and $Z = \{{x_c}^k\}$ remains far from the singular set of h, in the sense that h is regular in the closure of Z. Equivalently, $\{\|\nabla h({x_c}^k)^T \nabla h({x_c}^k)^{-1}\|\}$ remains uniformly bounded. Also, if the generated sequence $\{{x_c}^k\}$ is infinite, it satisfies

$$\|{x_c}^{k+1} - x^k\| = O(\|h(x^k)\|). \tag{3.1}$$

H4 (second order correction): $\|{\delta_{soc}}^k\| = O(\|{\delta_t}^k\|^2)$.

Supposing that H1 holds, we can assure that the remaining hypotheses will hold if, for example, the feasible set $\mathcal{H}_0$ is compact and regular (i.e., $\nabla h(x)$ is of maximal rank on $\mathcal{H}_0$) and x^0 is feasible. In this case, if we choose an initial ρ_{max}^0 sufficiently small, we can keep $\nabla h(x)$ with maximal rank and assure (3.1) using standard algorithms for restoration, such as the Gauss–Newton method. We could also replace the compacity property of $\mathcal{H}_0$ by adequate properties on f, such as requiring f to satisfy $\lim_{\|x\|\to\infty} f(x) = \infty$. In such situations, H2–H4 can be guaranteed by construction.

From now on we assume that the sequences $\{x_c^k\}$ and $\{x^k\}$ generated by DCI satisfy H1–H4. In addition, when we say that a number is a constant, we mean that it can be used for all k and is associated with these specific sequences generated by DCI.

Denoting by δ_V^k the vertical step and by δ_H^k the horizontal step in the kth iteration, we have

$$\delta_V^k = {x_c}^k - x^{k-1} \quad \text{and} \quad \delta_H^k = x^k - {x_c}^k = {\delta_t}^k + \delta_{soc}^k.$$

Hypotheses H1–H4 allow us to choose a constant $\delta_{max} > 0$ such that, for all k,

$$\|\delta_t^k\| + \|\delta_{soc}^k\| + \|\delta_V^k\| \leq \delta_{max}. \tag{3.2}$$

We can also define a second positive constant ξ_0 such that, for all k, if $\|x-x_c^k\| \le \delta_{max}$, then

$$\|\nabla h_j(x)\| \le \xi_0, \quad j = 1, \ldots, m, \tag{3.3}$$

$$\|\nabla^2 h_j(x)\| \le \xi_0, \quad j = 1, \ldots, m, \tag{3.4}$$

$$\|\nabla f(x)\| \le \xi_0, \tag{3.5}$$

$$\|\nabla^2 f(x)\| \le \xi_0, \tag{3.6}$$

$$\|\nabla h(x_c^k)^T \nabla h(x_c^k)\| \le \xi_0, \tag{3.7}$$

$$\|B^k\| \le \xi_0, \tag{3.8}$$

$$\|\lambda^k\| \le \xi_0, \tag{3.9}$$

$$\|\delta_{soc}^k\| \le \xi_0 \|\delta_t^k\|^2. \tag{3.10}$$

To simplify our notation, we suppose that the constant ξ_0 is large enough so that (3.1) can be rewritten as

$$\|{x_c}^{k+1} - x^k\| \le \xi_0 \|h(x^k)\|. \tag{3.11}$$

The main result of this section, presented in Theorem 3.6, is based on five lemmas. The first gives an upper limit for the increase in the infeasibility produced by the horizontal step.

LEMMA 3.1. *The trial iterate x_+ generated in step* 4.1.4 *of Algorithm* 2.1 *satisfies*

$$\|h(x_+) - h({x_c}^k)\| \le \overline{\xi_0} \|\delta_t\|^2. \tag{3.12}$$

Proof. Since $x_+ = {x_c}^k + \delta_+ = {x_c}^k + \delta_t + \delta_{soc}$, with $\|\delta_+\| \le \delta_{max}$, we can use a Taylor expansion, together with relations (3.4), (3.3), (3.10), and (3.2) and the fact that $\nabla h({x_c}^k){\delta_t}^k = 0$, to show that, for every $j = 1, \ldots, m$,

$$\begin{aligned} |h_j(x_+) - h_j(x_c)| &\le |\nabla h_j(x_c)^T(\delta_t + \delta_{soc})| + \frac{\xi_0}{2}\|\delta_t + \delta_{soc}\|^2 \\ &= |\nabla h_j(x_c)^T \delta_{soc}| + \frac{\xi_0}{2}\|\delta_t + \delta_{soc}\|^2 \\ &\le \xi_0^2 \|\delta_t\|^2 + \xi_0(\|\delta_t\|^2 + \|\delta_{soc}\|^2) \\ &\le (\xi_0^2 + \xi_0 + \xi_0^2 \delta_{max})\|\delta_t\|^2. \end{aligned}$$

Setting $\overline{\xi}_0 = \sqrt{m}(\xi_0^2 + \xi_0 + \xi_0^2 \delta_{max})$, we get the desired result. ∎

The second lemma establishes that, under H1–H4, each iteration succeeds and the Lagrangian is sufficiently decreased.

LEMMA 3.2. *If x_c^k is not a stationary point for* (1.1)*, then x_+ is eventually accepted in step* 4 *of DCI. Moreover, we can define positive constants ξ_1, ξ_2, and ξ_3 such that, for all k,*

$$\begin{aligned} \Delta L_H^k &= L(x^k, \lambda^k) - L(x_c^k, \lambda^k) \\ &\le -\xi_1 \|g_p(x_c^k)\| \min\left\{\xi_2 \|g_p(x_c^k)\|,\, \xi_3 \sqrt{\rho^k}\right\}. \end{aligned} \tag{3.13}$$

Proof. To simplify the notation we will omit here the superscript k. Suppose that x_c is not stationary for (1.1). Let $x_+ = x_c + \delta_+ = x_c + \delta_t + \delta_{soc}$ be a candidate obtained in step 4 of the kth iteration of the DCI algorithm, and let λ_+ be the corresponding multiplier.

Using a Taylor expansion, Lemma 3.1, and relations (3.6), (3.9), (3.5), (3.2), (3.10), and (3.8), we obtain

$$\begin{aligned}\Delta L_H^+ &= L(x_+,\lambda_+) - L(x_c,\lambda_+) = f(x_+) - f(x_c) + \lambda_+^T(h(x_+) - h(x_c)) \\ &\le g(x_c)^T\delta_t + g(x_c)^T\delta_{soc} + \frac{\xi_0}{2}\|\delta_t + \delta_{soc}\|^2 + \xi_0\overline{\xi}_0\|\delta_t\|^2 \\ &\le q(\delta_t) - \frac{1}{2}\delta_t^T B\delta_t + \overline{\xi}_1\|\delta_t\|^2 \\ &\le q(\delta_t) + \overline{\xi}_2\|\delta_t\|^2, \qquad (3.14)\end{aligned}$$

where $\overline{\xi}_1 = \xi_0^2 + \xi_0 + \xi_0^2\delta_{max} + \xi_0\overline{\xi}_0$ and $\overline{\xi}_2 = \xi_0/2 + \overline{\xi}_1$.

Because δ_{CP}, defined in step 4.1.1 of DCI, is a Cauchy step tangent to the constraints, we have (see, for example, [13])

$$\|\delta_{CP}\| \ge \min\left\{\frac{\|g_p(x_c)\|}{\|B\|}, \Delta\right\} \ge \min\left\{\frac{\|g_p(x_c)\|}{\xi_0}, \Delta\right\}$$

and

$$q(\delta_{CP}) \le \frac{1}{2}g(x_c)^T\delta_{CP} \le -\frac{1}{2}\|g_p(x_c)\| \min\left\{\frac{\|g_p(x_c)\|}{\xi_0}, \Delta\right\}. \qquad (3.15)$$

To prove the first part of the lemma, we will show that x_+ is always accepted whenever $\Delta \le \overline{\Delta}$, where

$$\overline{\Delta} = \min\left\{\frac{\|g_p(x_c)\|}{4\overline{\xi}_2}, \sqrt{\frac{\rho}{\overline{\xi}_0}}\right\}. \qquad (3.16)$$

We start by noting that, since $\xi_0 < 4\overline{\xi}_2$,

$$\overline{\Delta} \le \frac{\|g_p(x_c)\|}{\xi_0}. \qquad (3.17)$$

Based on the fact that $\Delta \le \overline{\Delta}$ and on (3.17), the upper limit of $q(\delta_{CP})$ given by (3.15) can be simplified to

$$q(\delta_{CP}) \le -\frac{1}{2}\|g_p(x_c)\|\Delta. \qquad (3.18)$$

Combining the conditions $\|\delta_t\| \le \Delta$ and $q(\delta_t) \le q(\delta_{CP})$, stated in step 4.1.2 of the DCI algorithm, with (3.16) and (3.18), we obtain

$$\overline{\xi}_2\|\delta_t\|^2 \le \overline{\xi}_2\Delta^2 \le \overline{\xi}_2\overline{\Delta}\Delta \le \frac{1}{4}\|g_p(x_c)\|\Delta \le -\frac{1}{2}q(\delta_{CP}) \le -\frac{1}{2}q(\delta_t). \qquad (3.19)$$

Now, from (3.14) and (3.19), we get

$$\Delta L_H^+ \le \frac{1}{2}q(\delta_t) < 0, \qquad (3.20)$$

which implies that

$$r = \frac{\Delta L_H^+}{q(\delta_t)} \ge \frac{1}{2} \ge \eta_1. \qquad (3.21)$$

Since $\Delta \leq \overline{\Delta}$ and $\|h(x_c)\| \leq \rho$, we can use (3.12) and (3.16) to guarantee that

$$\|h(x_+)\| \leq \rho + \overline{\xi}_0 \|\delta_t\|^2 \leq \rho + \overline{\xi}_0 \overline{\Delta}^2 \leq 2\rho.$$

Therefore, both conditions stated in step 4.2 of the algorithm are satisfied, and x_+ is accepted.

To prove the second part of the lemma, let us recall that, each time the step is rejected, Δ is multiplied by α_R, which means that we can assume the accepted trust region radius satisfies $\Delta \geq \alpha_R \overline{\Delta}$, where $0 < \alpha_R < 1$. Combining this with (3.20), the condition $q(\delta_t) \leq q(\delta_{CP})$, (3.15), (3.17), and (3.16), we get

$$\begin{aligned} \Delta L_H^+ \leq \frac{1}{2} q(\delta_t) \leq \frac{1}{2} q(\delta_{CP}) &\leq -\frac{1}{4} \|g_p(x_c)\| \min\left\{ \frac{\|g_p(x_c)\|}{\xi_0}, \Delta \right\} \\ &\leq -\frac{1}{4} \|g_p(x_c)\| \alpha_R \overline{\Delta}. \end{aligned} \tag{3.22}$$

Defining $\xi_1 = \alpha_R/4$, $\xi_2 = 1/(4\overline{\xi}_2)$, and $\xi_3 = 1/\sqrt{\overline{\xi}_0}$, we obtain (3.13) from (3.16) and (3.22). ∎

Our third lemma defines an upper limit for the (possibly positive) vertical variation of the Lagrangian, ΔL_V^{k+1}.

LEMMA 3.3. *There exists a positive constant ξ_4 such that*

$$\Delta L_V^{k+1} \leq \xi_4 \rho_{max}^k \|g_p(x_c^k)\|. \tag{3.23}$$

Proof. Using a Taylor expansion, (3.5), (3.9), (3.11), (2.9), and (2.7), we get, for the vertical variation,

$$\begin{aligned} \Delta L_V^{k+1} &= L(x_c^{k+1}, \lambda^{k+1}) - L(x^k, \lambda^k) \\ &= f(x_c^{k+1}) - f(x^k) + {\lambda^{k+1}}^T h(x_c^{k+1}) - {\lambda^k}^T h(x^k) \\ &\leq \xi_0 \|x_c^{k+1} - x^k\| + \xi_0 \|h(x_c^{k+1})\| + \xi_0 \|h(x^k)\| \\ &\leq (\xi_0^2 + 2\xi_0) \|h(x^k)\| \leq 2(\xi_0^2 + 2\xi_0)\rho^k \leq \xi_4 \rho_{max}^k \|g_p(x_c^k)\|. \end{aligned}$$

Therefore, defining $\xi_4 = 2(\xi_0^2 + 2\xi_0)$, we obtain the desired result. ∎

Our fourth lemma establishes that, between successive iterations without changes in ρ_{max}, the Lagrangian decreases proportionally to the descent in the corresponding horizontal steps.

LEMMA 3.4. *If $\rho_{max}^{k+1} = \rho_{max}^{k+2} = \cdots = \rho_{max}^{k+j}$, for $j \geq 1$, then*

$$L_c^{k+j} - L_c^k = \sum_{i=k+1}^{k+j} \Delta L_c^i \leq \frac{1}{4} \sum_{i=k}^{k+j-1} \Delta L_H^i + r^k, \tag{3.24}$$

where $r^k = \frac{1}{2}[L_{ref}^k - L_c^k]$.

Proof. Let us suppose that L_{ref} does not change between iterations $k+1$ and $k + j_1 - 1$, where $0 < j_1 \leq j + 1$. In this case, by (2.1) and the criterion defined in step 3.3 of the algorithm, we have

$$L_c^{k+j_1-1} - L_c^k = \sum_{i=k+1}^{k+j_1-1} (\Delta L_V^i + \Delta L_H^{i-1}) \leq \frac{1}{2} \sum_{i=k}^{k+j_1-2} \Delta L_H^i. \tag{3.25}$$

On the other hand, if L_{ref} changes at iteration $k+j_1$, then the condition stated in step 3.3 of DCI is satisfied. In this case, using the hypothesis that ρ_{max} stays unchanged at iteration $k+j_1$ (so the inequality in step 3.2 is not satisfied) and the fact that $\Delta L_H^k \leq 0$, for all k, we have

$$\begin{aligned} L_c^{k+j_1} - L_c^k &= \Delta L_V^{k+j_1} + L(x^{k+j_1-1}, \lambda^{k+j_1-1}) - L_{ref}^k + [L_{ref}^k - L_c^k] \\ &\leq \frac{1}{2}(L(x^{k+j_1-1}, \lambda^{k+j_1-1}) - L_{ref}^k) + [L_{ref}^k - L_c^k] \\ &= \frac{1}{2}(\Delta L_H^{k+j_1-1} + L_c^{k+j_1-1} - L_c^k) + \frac{1}{2}[L_{ref}^k - L_c^k] \\ &\leq \frac{1}{4}\sum_{i=k}^{k+j_1-1} \Delta L_H^i + r^k. \end{aligned} \tag{3.26}$$

If $j_1 \geq j$, then (3.25) and (3.26) imply (3.24).

On the other hand, if L_{ref} is updated at iterations $k+j_1, \ldots, k+j_s$, where $0 < j_1 < j_2 < \cdots < j_s \leq j$, then $r^{k+j_1} = r^{k+j_2} = \cdots = r^{k+j_s} = 0$. Therefore, applying the same procedure described above several times and defining $j_0 = 0$, we obtain

$$L_c^{k+j} - L_c^k = \sum_{i=1}^{s}[L_c^{k+j_i} - L_c^{k+j_{i-1}}] + L_c^{k+j} - L_c^{k+j_s} \leq \frac{1}{4}\sum_{i=k}^{k+j-1} \Delta L_H^i + r^k. \qquad \square$$

Our fifth lemma establishes the existence of *enough normal space* in the trust cylinders $\mathcal{C}^k$ to guarantee that the Lagrangian can be sufficiently decreased. The idea supporting this lemma is that (3.13) guarantees, asymptotically, that $\|\Delta L_H^k\|$ is bigger than a fraction of $\sqrt{\rho^k}$, while, on the other hand, $\|\Delta L_V^k\| = O(\rho^k)$ (see the proof of Lemma 3.3). This means that a restoration cannot, asymptotically, destroy the decrease in the Lagrangian achieved at the horizontal step, and this prevents further ρ_{max} updates.

LEMMA 3.5. *If DCI generates an infinite sequence $\{x^k\}$, then the following hold:*

(i) *There are positive constants ξ_5 and ξ_6 such that, whenever*

$$\rho_{max}^k < \min\{\xi_5 \|g_p(x_c^k)\|, \xi_6\}, \tag{3.27}$$

ρ_{max} does not change at iteration $k+1$.

(ii) *Furthermore, if $\liminf \|g_p(x_c^k)\| > 0$, then there exists $k_0 > 0$ such that, for every $k \geq k_0$,*

$$\rho_{max}^k = \rho_{max}^{k_0}. \tag{3.28}$$

(iii) *If the horizontal step and the vector of Lagrange multipliers satisfy*

$$\|x^k - x_c^k\| = O(\|g_p(x_c^k)\|), \tag{3.29}$$

$$\|\lambda^k - \lambda_{LS}(x_c^k)\| = O(\|g_p(x_c^k)\|), \tag{3.30}$$

then (3.28) is satisfied, regardless of the value of $\liminf \|g_p(x_c^k)\|$. In other words, ρ_{max}^k remains bounded away from zero.

Proof. Let us consider the first part of the lemma. To prove that ρ_{max} does not change at iteration $k+1$, we just need to show that $\Delta L_V^{k+1} < -\Delta L_H^k/2$ (see step 3.2 of Algorithm 2.1). From Lemma 3.2, this result is attained whenever

$$\Delta L_V^k < \frac{\xi_1 \xi_2}{2}\|g_p(x_c^k)\|^2 \tag{3.31}$$

and

$$\Delta L_V^k < \frac{\xi_1\xi_3}{2}\sqrt{\rho^k}\|g_p(x_c^k)\|. \tag{3.32}$$

Condition (3.31) can be easily obtained from Lemma 3.3 and (3.27), taking $\xi_5 = \xi_5^a \equiv \xi_1\xi_2/(2\xi_4)$. To obtain (3.32), we need a few more steps. First we use (2.8) and (3.5) to write

$$\sqrt{\rho_{max}^k} \le 10^2\sqrt{\rho^k}\frac{(\xi_0+1)^{1/2}}{\|g_p(x_c^k)\|^{1/2}}. \tag{3.33}$$

Then, taking the square root from both sides of (3.27) and combining the result with (3.33), we get

$$\rho_{max} \le \sqrt{\xi_5}10^{-2}\sqrt{\xi_0+1}\sqrt{\rho^k}. \tag{3.34}$$

Now, defining $\xi_5 = \xi_5^b \equiv 10^{-4}\xi_1^2\xi_2^2/[4\xi_4^2(\xi_0+1)]$ and using Lemma 3.3 and (3.27), we obtain (3.32). The desired result follows from taking $\xi_5 = \min\{\xi_5^a, \xi_5^b\}$.

In order to prove item (ii), let us define $b = \liminf(\|g_p(x_c^k)\|)$ and choose an index $\overline{k}_0$ such that $\|g_p(x_c^k)\| > b/2$ for $k \ge \overline{k}_0$. Then, as we proved above, $\rho_{max}^k \ge \min\{\rho_{max}^{\overline{k}_0}, \xi_5 b/2, \xi_6\}$ for $k > k_0$. Thus, ρ_{max} will never be decreased after a certain iteration k_0, as claimed.

To prove the third part of the lemma, we begin observing that (1.3)–(1.4) and H1–H3 imply that $\lambda_{LS}(x)$ and $g_p(x)$ are well defined and of class C^1 in a compact neighborhood of $\overline{Z}$, the closure of $Z = \{x_c^k\}$. Therefore, $\lambda_{LS}(x)$ and $g_p(x)$ are Lipschitz continuous on the iterates in the sense that

$$\|\lambda_{LS}(x_c^{k+1}) - \lambda_{LS}(x_c^k)\| = O(\|x_c^{k+1} - x_c^k\|) \tag{3.35}$$

and

$$\|g_p(x_c^{k+1}) - g_p(x_c^k)\| = O(\|x_c^{k+1} - x_c^k\|). \tag{3.36}$$

From (3.1), (2.9), (2.7), and (3.29) we get

$$\|x_c^{k+1} - x_c^k\| \le \|x_c^{k+1} - x^k\| + \|x^k - x_c^k\| = O(\|g_p(x_c^k)\|), \tag{3.37}$$

and from (3.36) and (3.37) we obtain

$$\|g_p(x_c^{k+1})\| = O(\|g_p(x_c^k)\|). \tag{3.38}$$

Noticing that

$$L(x_c^{k+1}, \lambda^{k+1}) = L(x_c^{k+1}, \lambda_{LS}(x_c^{k+1})) + [\lambda^{k+1} - \lambda_{LS}(x_c^{k+1})]^T h(x_c^{k+1})$$

and

$$\begin{aligned} L(x^k, \lambda^k) = L(x^k, \lambda_{LS}(x_c^{k+1})) &- [\lambda_{LS}(x_c^{k+1}) - \lambda_{LS}(x_c^k)]^T h(x^k) \\ &-[\lambda_{LS}(x_c^k) - \lambda^k]^T h(x^k), \end{aligned}$$

we get the following decomposition of ΔL_V^{k+1} into a sum of four terms:

$$\begin{aligned}\Delta L_V^{k+1} &= L(x_c^{k+1},\lambda^{k+1}) - L(x^k,\lambda^k)\\ &= [L(x_c^{k+1},\lambda_{LS}(x_c^{k+1})) - L(x^k,\lambda_{LS}(x_c^{k+1}))]\\ &\quad +[\lambda^{k+1}-\lambda_{LS}(x_c^{k+1})]^T h(x_c^{k+1})\\ &\quad +[\lambda_{LS}(x_c^{k+1})-\lambda_{LS}(x_c^k)]^T h(x^k)\\ &\quad +[\lambda_{LS}(x_c^k)-\lambda^k]^T h(x^k).\end{aligned} \tag{3.39}$$

Using a Taylor expansion, (1.4), hypothesis H2, (2.9), (3.1), (3.4)–(3.7), and (3.38), we get

$$\begin{aligned}&L(x_c^{k+1},\lambda_{LS}(x_c^{k+1})) - L(x^k,\lambda_{LS}(x_c^{k+1}))\\ &= g_p(x_c^{k+1})^T(x_c^{k+1}-x^k) + O(\|x_c^{k+1}-x^k\|^2)\\ &= O(\|g_p(x_c^k)\|\rho^k + {\rho^k}^2).\end{aligned} \tag{3.40}$$

Since (2.7) implies that ${\rho^k}^2 \le \rho_{max}^k \|g_p(x_c^k)\|\rho^k$, (3.40) ensures that the first term in the right-hand side of (3.39) is $O(\|g_p(x_c^k)\|\rho^k)$.

From (3.30) and (3.38), we deduce that $\|\lambda^{k+1}-\lambda_{LS}(x_c^{k+1})\|$ and $\|\lambda_{LS}(x_c^k)-\lambda^k\|$ are $O(\|g_p(x_c^k)\|)$. From (3.35) and (3.37), we also obtain $\|\lambda_{LS}(x_c^{k+1})-\lambda_{LS}(x_c^k)\| = O(\|g_p(x_c^k)\|)$. Finally, (2.9) ensures that $\|h(x_c^{k+1})\| \le \|h(x^k)\| \le 2\rho^k$. This implies that the remaining three terms in the right-hand side of (3.39) are also $O(\|g_p(x_c^k)\|\rho^k)$. Together with (2.7), this ensures that there exists $\xi_7 > 0$ such that

$$\Delta L_V^{k+1} \le \xi_7 \rho_{max}^k \|g_p(x_c^k)\|^2. \tag{3.41}$$

Let $\overline{\rho}_{max}$ be defined by

$$\overline{\rho}_{max} = \min\left\{\frac{\xi_1\xi_2}{2\xi_7},\ \frac{10^{-4}}{4\xi_0(\xi_0+1)}\left(\frac{\xi_1\xi_3}{\xi_7}\right)^2\right\}. \tag{3.42}$$

With arguments entirely similar to those used to show (3.31)–(3.32), we can prove, from (3.41) and (3.42), that, if $\rho_{max}^{k_0} < \overline{\rho}_{max}$ and $k \ge k_0$, then $\Delta L_V^{k+1} < -\frac{1}{2}\Delta L_H^k$. Therefore, ρ_{max}^k does not change after k_0. ∎

We say that a point x is stationary for (1.1), i.e., it satisfies the KKT conditions for the problem, if $h(x) = 0$ and $g_p(x) = 0$. The next theorem states that, under H1–H4, the sequence $\{{x_c}^k\}$ generated by the DCI algorithm has stationary points for (1.1) in its accumulation set. Some additional conditions are defined to ensure that every accumulation point is stationary for (1.1).

THEOREM 3.6. *Under H1–H4, either DCI stops at a stationary point for* (1.1)*, in a finite number of iterations, or generates a sequence with stationary points in its accumulation set. In addition, if we impose the horizontal step and the Lagrange multipliers to satisfy* (3.29) *and* (3.30)*, then every accumulation point of* ${x_c}^k$ *is stationary for* (1.1).

Proof. Let us suppose, by contradiction, that $\liminf(\|g_p(x_c^k)\|) = 2b > 0$, and let $\overline{k}_0$ be such that $\|g_p(x_c^k)\|) > b$ for $k \ge \overline{k}_0$. In this case, item (ii) from Lemma 3.5 allows us to choose $k_0 \ge \overline{k}_0$ such that, for every $k \ge k_0$, $\rho_{max}^k = \rho_{max}^{k_0}$. Together with (2.8) and (3.5), this implies that $\rho^k \ge 10^{-4}\rho_{max}^{k_0} b/[2(\xi_0+1)]$.

Now, using (3.24) and (3.13), we can assure that, for $k > k_0$,

$$L(x_c^k, \lambda^k) - L(x_c^{k_0}, \lambda^{k_0}) = \sum_{i=k_0+1}^{k} \Delta L_c^i \leq \frac{1}{4} \sum_{i=k_0}^{k-1} \Delta L_H^i + r^{k_0}$$
$$\leq -(k - k_0)\theta + r^{k_0} \to -\infty,$$

where

$$\theta = \frac{1}{4}\xi_1 b \min\left\{\xi_2 b,\ 10^{-2}\xi_3\sqrt{\frac{b\rho_{max}^{k_0}}{\xi_0 + 1}}\right\} > 0. \tag{3.43}$$

This contradicts H1–H2, imposing $\liminf(\|g_p(x_c^k)\|) = 0$.

For the second part of the theorem, let us assume that (3.29) and (3.30) apply. In this case, Lemma 3.5 ensures that $\rho_{max}^k = \rho_{max}^{k_0}$ for some k_0 and every $k \geq k_0$.

Suppose, by contradiction, that $\|g_p(x_c)^{k_\ell})\| \geq b > 0$ for an infinite subsequence $\{k_\ell\}$. Let n_k be the number of iterations between k_0 and k for some index $k \in \{k_\ell\}$. In this case, using (3.24) and (3.13) again and taking $n_k \to \infty$, we have

$$L(x_c^k, \lambda^k) - L(x_c^{k_0}, \lambda^{k_0}) = \sum_{i=k_0+1}^{k} \Delta L_c^i \leq \frac{1}{4} \sum_{i=k_0}^{k-1} \Delta L_H^i + r^{k_0}$$
$$\leq -n_k\theta + r^{k_0} \to -\infty, \tag{3.44}$$

where θ is given by (3.43). This also contradicts H1–H2, implying that $\|g_p(x_c^{k_\ell})\| \to 0$ for every subsequence of x_c^k. ∎

Theorem 3.6 can equally be proved if we admit inexact solutions for the subproblems associated with Algorithm 2.1, using fairly loose conditions on the residues for accepting the step. For instance, we could relax the condition $\nabla h(x_c)\,\delta_t = 0$ or admit inexact computations of $g_p(x)$ and the solution of the quadratic subproblem (2.4). Although this modification can be interesting for large-scale problems and would not change the proofs significantly, we preferred not to present it in this article, since its details might look rather messy on a first reading. We also believe that the second order correction would play a very interesting role if inexact methods were used.

4. Local convergence. Let $N(M)$ represent the null space of M. Also let $\{x_c^k\}$ and $\{x^k\}$ be sequences generated by Algorithm 2.1, converging to x^*, a "good minimizer" of problem (1.1). By "good minimizer" we mean that $\nabla h(x^*)$ has full row rank, $\nabla f(x^*) = -\nabla h(x^*)^T\lambda^*$ with $\lambda^* = \lambda_{LS}(x^*)$, and there is a constant $\mu_1 > 0$ such that, for $y \in N(\nabla h(x^*))$,

$$\mu_1\|y\|^2 \leq y^T\nabla_{xx}^2 L(x^*, \lambda^*)y. \tag{4.1}$$

In this section, we will restrict our attention to a neighborhood V^* of x^*, where, due to the fact that h is C^2 and $\nabla h(x^*)$ has full row rank, the orthogonal projector onto $N(\nabla h(x))$, i.e., $P(x) = I - \nabla h(x)^T(\nabla h(x)\nabla h(x)^T)^{-1}\nabla h(x)$, is Lipschitz continuous. Sometimes we will use the term δ_c to represent the "full" step taken by the algorithm, i.e., $\delta_c = x_c^{k+1} - x_c^k = \delta_H^k + \delta_V^{k+1}$.

Besides considering hypotheses H1–H4, our analysis of the local convergence of x_c^k and x^k will be based on four additional local assumptions. The first three of these assumptions are used in the proof of Lemma 4.1 and are described below.

A1: $\lambda^k - \lambda_{LS}(x_c^k) = O(\|g_p(x_c^k)\|)$.

A2: B^k is asymptotically uniformly positive definite in the tangent space to the restrictions, which means that, in some neighborhood of x^*, we can redefine μ_1 so that

$$\mu_1\|y\|^2 \leq y^T B^k y \leq \mu_2\|y\|^2 \tag{4.2}$$

for $y \in N(\nabla h(x_c^k))$, where μ_2 is just the constant ξ_0 defined in (3.8).

A3: Let δ_{HN}^k be the minimizer of the quadratic model (2.6) without the trust region constraint. We assume that, whenever δ_{HN}^k is within the trust region ($\|\delta_{HN}^k\| \leq \Delta$), it is the first horizontal step tried by the algorithm. In addition, we also suppose that it satisfies

$$P(x_c^k)(B^k - \nabla_{xx}^2 L(x^*, \lambda^*))\delta_{HN}^k = o(\|\delta_{HN}^k\|).$$

Assumption A1 is not a stringent condition. Usual estimates for the Lagrange multipliers (see, for example, [41]) satisfy $\|\lambda^k - \lambda^*\| = O(\|x_c^k - x^*\|)$, so A1 can be guaranteed by our Lemma 4.2, along with (1.5) and (1.2).

Assumptions A2 and A3 are essentially equivalent to standard conditions for superlinear convergence in two steps of SQP quasi-Newton methods, such as those established by Powell in [34]. These assumptions are satisfied, for example, if we define $B^k = \nabla_{xx} L(x_c^k, \lambda^k)$. In a future paper, we intend to incorporate in our analysis the use of secant reduced Hessian approximation schemes, as well as the inexact solution of the subproblems involved, in such a way that A2 and A3 are satisfied.

From now on, we also suppose that $\delta_{soc} = 0$. This is done only to simplify the exposition. In fact, the arguments presented below are still valid if we consider $\delta_{soc} = O(\|\delta_t\|^2)$.

Since $\nabla h(x)$ and $\nabla_{xx}^2 L(x, \lambda)$ are continuous and $\nabla h(x^*)$ has full row rank, our assumptions imply that there is a constant $\mu_3 > 0$ and a neighborhood V^* of x^* such that, for x, $x_c^k \in V^*$,

$$\mu_3\|\lambda\| \leq \|\nabla h(x)^T \lambda\| \quad \text{for } \lambda \in \mathbb{R}^m, \tag{4.3}$$

$$P(x_c^k)(B^k - \nabla_{xx}^2 L(x_c^k, \lambda_{LS}(x_c^k)))\delta_{HN}^k = o(\|\delta_{HN}^k\|), \quad \text{and} \tag{4.4}$$

$$P(x_c^k)(B^k - \nabla_{xx}^2 L(x_c^k, \lambda^k))\delta_{HN}^k = o(\|\delta_{HN}^k\|). \tag{4.5}$$

Let Z^k be a matrix whose columns form an orthonormal basis for the null space $N(\nabla h(x_c^k))$. We can define the global minimizer of the quadratic model in the tangent space as $\delta_{HN}^k = Z^k \nu^k \in N(\nabla h(x_c^k))$. This point clearly satisfies

$$(Z^k)^T(B^k \delta_{HN}^k + \nabla_x f(x_c^k)) = (Z^k)^T B^k Z^k \nu^k + (Z^k)^T g_p(x_c^k) = 0. \tag{4.6}$$

From (4.2) and the fact that $(Z^k)^T Z^k = I$, matrix $((Z^k)^T B^k Z^k)^{-1}$ satisfies, in the neighborhood V^* and for all $u \in R^{n-m}$,

$$\frac{1}{\mu_2}\|u\|^2 \leq u^T((Z^k)^T B^k Z^k)^{-1} u \leq \frac{1}{\mu_1}\|u\|^2. \tag{4.7}$$

In the next lemma we will prove the eventual acceptance, in Algorithm 2.1, of

$$\delta_{HN}^k = -Z^k \nu^k = -Z^k((Z^k)^T B^k Z^k)^{-1}(Z^k)^T g_p(x_c^k). \tag{4.8}$$

LEMMA 4.1. *δ_{HN}^k is accepted by Algorithm* 2.1 *for k sufficiently large.*

Proof. Combining (4.7) and (4.8), we have that

$$\|\delta_{HN}^k\| \leq \frac{1}{\mu_1}\|g_p(x_c^k)\| \tag{4.9}$$

for $x_c^k \in V^*$. Because the trust region radius satisfies $\Delta \geq \Delta_{min}$ at the beginning of each iteration, assumption A3 and (4.9) imply that, in a suitable V^*, δ_H^+ will be the first horizontal step tried by Algorithm 2.1.

For $\nu \in \mathbb{R}^{n-m}$, the *reduced* polynomial

$$\overline{q}(\nu) = q(Z^k\nu) = ((Z^k)^T g_p(x_c^k))^T\nu + \nu^T((Z^k)^T B^k Z^k)\nu$$

has degree 2, with positive definite quadratic form. Therefore, its minimum, $\overline{q}(\nu^k)$, satisfies (see [13])

$$\begin{aligned} q(\delta_{HN}^k) &= q(Z^k\nu^k) = \overline{q}(\nu^k) \\ &= -\frac{1}{2}((Z^k)^T g_p(x_c^k))^T((Z^k)^T B^k Z^k)^{-1}(Z^k)^T g_p(x_c^k) \\ &\leq -\frac{1}{2\mu_2}\|g_p(x_c^k)\|^2, \end{aligned} \tag{4.10}$$

where the last inequality comes from (4.7).

Now, using a Taylor expansion, the fact that $\delta_{HN}^k = P(x_c^k)\delta_{HN}^k$, (4.5), and (4.9), we get

$$\begin{aligned} \Delta L_H^+ &= L(x_c^k + \delta_{HN}^k, \lambda^k) - L(x_c^k, \lambda^k) \\ &= g_p(x_c^k)^T\delta_{HN}^k + \frac{1}{2}\delta_{HN}^{kT}\nabla_{xx}{}^2 L(x_c^k)\delta_{HN}^k + o(\|\delta_{HN}^k\|^2) \\ &= g_p(x_c^k)^T\delta_{HN}^k + \frac{1}{2}\delta_{HN}^{kT}B^k\delta_{HN}^k + o(\|\delta_{HN}^k\|^2) \\ &= q(\delta_{HN}^k) + o(\|g_p(x_c^k)\|^2). \end{aligned} \tag{4.11}$$

It follows from (4.10)–(4.11) that

$$|r| = \left|\frac{\Delta L_H^+}{q(\delta_{HN}^k)}\right| = 1 + \frac{o(\|g_p(x_c^k)\|^2)}{\|g_p(x_c^k)\|^2/(2\mu_2)} \to 1,$$

so one of the acceptance conditions stated in step 4.2 of Algorithm 2.1 is satisfied for k sufficiently large.

Let us now prove that the other acceptance condition, $\|h(x_c^k + \delta_{HN}^k)\| \leq 2\rho^k$, also holds. From (4.9), assumption A1, and Lemma 3.5, there exists k_0 sufficiently large so that $\rho_{max}^k = \rho_{max}^{k_0} > 0$ for $k \geq k_0$. Therefore, (2.8) and (3.5) guarantee that, for $k \geq k_0$, $\|g_p(x_c^k)\| \leq \beta\rho^k$, where $\beta = 10^4(1+\xi_0)/\rho_{max}^{k_0}$. Together with (3.12) and (4.9), this implies that, for k sufficiently large,

$$\begin{aligned} \|h(x_c^k + \delta_{HN}^k)\| &\leq \|h(x_c^k)\| + \overline{\xi}_0\|\delta_{HN}^k\|^2 \leq \|h(x_c^k)\| + \frac{\overline{\xi}_0}{{\mu_1}^2}\|g_p(x_c^k)\|^2 \\ &\leq \rho^k\left(1 + \beta\frac{\xi_0}{{\mu_1}^2}\|g_p(x_c^k)\|\right). \end{aligned}$$

Since, for k sufficiently large, $\beta\frac{\xi_0}{{\mu_1}^2}\|g_p(x_c^k)\| < 1$, the step δ_{HN}^k will eventually be accepted. ∎

This lemma is based on the fact that $\Delta \geq \Delta_{min}$ at the beginning of an iteration. This condition can be removed if we replace A3 by the following more restrictive assumption:

A3′: Let δ_+ be obtained as a positive linear combination of δ_{CP} and δ_{HN}. Also let δ_+ satisfy

$$P(x_c^k)(B^k - \nabla^2_{xx} L(x^*, \lambda^*))\delta_+ = o(\|\delta_+\|).$$

In this case, we can also prove that δ_+ is accepted whenever x_c^k and x^k are in a suitable neighborhood V^* of x^*. Therefore, there exists k_1 such that Δ^k is not reduced for $k > k_1$, so we can restrict our attention to the case where $\delta_H^k = \delta_{HN}^k$.

Notice that the dynamic control of the infeasibility might force us to compute more than one single vertical step δ_V^+, starting from x^k, if $\|g_p(x^k + \delta_V^+)\|$ is too small.

At the beginning of iteration $k+1$, we have $x_c = x^k$, while the vertical step ends at $x_c = x_c^{k+1}$. In order to avoid unnecessary updates of $\nabla h(x_c^k)$, we state our fourth local assumption:

A4: Each nonzero vertical step $\delta_V^{k+1} = x_c^{k+1} - x^k$ is computed by taking one or more steps in the form

$$\delta_V^+ = -A^T(AA^T)^{-1}h(x_c), \tag{4.12}$$

where A satisfies

$$\|A - \nabla h(x_c)\| = O(\|g_p(x_c^k)\|). \tag{4.13}$$

Vector δ_V^+ given by (4.12) is the usual Gauss–Newton step for solving $h(x) = 0$, with an approximation A for the Jacobian $\nabla h(x_c)$. Using a Taylor expansion, (4.3), (4.12), (4.13), and the continuity of $\nabla h(x)$, it is easy to show that, if $x_c^{k+1} \neq x^k$, then the first vertical step δ_V^+ of iteration $k+1$ satisfies

$$\|\delta_V^+\| = O(\|h(x^k)\|) \quad \text{and} \tag{4.14}$$

$$\|h(x_c^{k+1})\| \leq \|h(x^k + \delta_V^+)\| = o(\|h(x^k)\|). \tag{4.15}$$

As $g_p(x^k)$ becomes small, it is natural to force a restoration after each horizontal step. This can be done, for instance, by choosing ρ^k slightly smaller than $\|h(x^k)\|$. In [11] and [12], Coleman and Conn analyze algorithms that alternate a horizontal step with a single vertical restoration step. Under local assumptions similar to those presented here, these so called horizontal-vertical algorithms are superlinear convergent in two steps. Coleman and Conn also point out in [11] that the restoration step adopted by their methods differs from the usual SQP vertical step, since it is based on $x^k + \delta_H$, while, in the SQP framework, x^k is used to define the vertical subproblem.

One difference between these horizontal-vertical algorithms and ours is that we admit more than one vertical step like (4.12) at each iteration, as mentioned above. Our main result on the local behavior of the algorithm is based on the following lemma that, in a sense, expresses analytically the "good" structure we have in the neighborhood of a "good" KKT point. This approach is similar to the one used by Powell in [34], although his focus was restricted to each sequence generated by an SQP algorithm.

It is well known that the function $\phi(x) = \|h(x)\| + \|g_p(x)\|$ can be used to measure how close $x \in V^*$ is to x^*. However, we need a stronger result. We want to say that, in a vicinity of x^*, $\phi(x)$ is *equivalent* to $\|x - x^*\|$, in the sense that $\|x - x^*\| = \Theta(\phi(x))$, i.e., $\|x - x^*\| = O(\phi(x))$ and $\phi(x) = O(\|x - x^*\|)$.

LEMMA 4.2. *There is a neighborhood V^* of x^*, where*

$$\|x - x^*\| = \Theta(\|h(x)\| + \|g_p(x)\|). \tag{4.16}$$

Proof. We just have to show that

$$\|x - x^*\| = O(\|h(x)\|) + O(\|g_p(x)\|). \tag{4.17}$$

The converse follows trivially from the fact that $h(x)$ and $g_p(x)$ are Lipschitz continuous in V^*.

In [18], Fletcher shows that the SQP method has quadratic convergence to a good minimizer x^*. The same argument can be used to prove that, if δ_x is an SQP step from $x \in V^*$ to $x_+ = x + \delta_x$, where V^* is a suitable neighborhood of x^*, then we have $x_+ - x^* = O(\|x - x^*\|^2)$. It is also easy to show (see equations (10.1.11)–(10.1.13) in [18]) that δ_x satisfies $\delta_x = x_+ - x = O(\|g_p(x)\|) + O(\|h(x)\|)$. From these two relations, it follows that $x - x^* = (x_+ - x^*) - (x_+ - x) = O(\|x_+ - x\|) = O(\|g_p(x)\|) + O(\|h(x)\|)$. ∎

Byrd [7] and Yuan [45] give examples showing that we cannot expect superlinear convergence in one step for x_c^k. However, Byrd [8] points to the possibility of obtaining superlinear convergence in one step for x^k. To understand why this happens, notice that a vertical step that moves from x^k to x_c^{k+1} approaches the feasible set in a "superlinear" way. After that, the horizontal step superlinearly pushes x_c^{k+1} towards the dual manifold $\mathcal{L}^* = \{x \in V^* : g_p(x) = 0\}$, with δ_H^{k+1} tangent to the feasible directions. Therefore, this horizontal step does not destroy the "vertical superlinear approximation." On the other hand, if we start at x_c^k, the superlinear convergence in a single step cannot be guaranteed since the vertical step δ_V^{k+1} usually is not tangent to $\mathcal{L}^*$ and, for this reason, δ_V^{k+1} can partly spoil the good approach to $\mathcal{L}^*$ obtained by δ_H^k.

To close this section, we present our main theorem, showing that the algorithm is 2-step superlinearly convergent. Besides, convergence in one step can also be obtained if we call a restoration at each iteration.

THEOREM 4.3. *Under* H1–H4 *and* A1–A4, *x^k and x_c^k are 2-step superlinearly convergent to x^*. If a restoration is computed at each x^k, then x^k converges superlinearly to x^*.*

Proof. Since $\|x^{k+1} - x^*\| \le \|x^{k+1} - x_c^{k+1}\| + \|x_c^{k+1} - x^*\|$, (4.9) and (4.16) imply that

$$\|x^{k+1} - x^*\| = O(\|x_c^{k+1} - x^*\|). \tag{4.18}$$

In addition, observing that $\|x_c^{k+1} - x^*\| \le \|x^k - x_c^{k+1}\| + \|x^k - x^*\|$ and using (3.1) and (4.16), we have

$$\|x_c^{k+1} - x^*\| = O(\|x^k - x^*\|). \tag{4.19}$$

In order to prove the 2-step superlinear convergence, we shall use the following relations:

$$g_p(x^k) = o(\|x_c^k - x^*\|), \tag{4.20}$$

$$g_p(x_c^{k+1}) = o(\|x_c^{k-1} - x^*\|), \tag{4.21}$$

$$h(x^k) = o(\|x_c^{k-1} - x^*\|), \text{ and} \tag{4.22}$$

$$h(x_c^{k+1}) = o(\|x_c^k - x^*\|). \tag{4.23}$$

Let us show that these relations are valid, starting with (4.20). Using a Taylor expansion along with (1.4), we have, for $x^k \in V^*$,

$$\begin{aligned} \|g_p(x^k)\| &= \|P(x^k)\Gamma^k\| + o(\|\delta_H^k\|) \\ &\le \|(P(x^k) - P(x_c^k))\Gamma^k\| + \|P(x_c^k)\Gamma^k\| + o(\|\delta_H^k\|), \end{aligned} \tag{4.24}$$

where $\Gamma^k = g_p(x_c^k) + \nabla^2_{xx} L(x_c^k, \lambda_{LS}(x_c^k))\delta_H^k$.

The continuity of $P(x)$ in V^* and (4.9) give us

$$\|(P(x^k) - P(x_c^k))\Gamma^k\| = o(\|\Gamma^k\|) = o(\|g_p(x_c^k)\|). \tag{4.25}$$

In addition, (4.4), (4.8), and (4.9) imply that

$$\|P(x_c^k)\Gamma^k\| = \|P(x_c^k)(g_p(x_c^k) + B^k\delta_H^k)\| + o(\|\delta_H^k\|) = o(\|g_p(x_c^k)\|). \tag{4.26}$$

Substituting (4.25) and (4.26) into (4.24) and also considering (4.16), we get (4.20).

To prove (4.23), we need to consider separately two situations. First, let k_i be an infinite subsequence at which no vertical step was made, i.e., $x_c^{k_i+1} = x^{k_i}$. In this case, the dynamic control of the infeasibility, together with (4.20), implies that

$$\|h(x_c^{k_i+1})\| = O(\|g_p(x_c^{k_i+1})\|) = O(\|g_p(x^{k_i})\|) = o(\|x_c^{k_i} - x^*\|). \tag{4.27}$$

Now let us consider an infinite subsequence of iterations k_j at which at least one vertical step δ_V^+ satisfying A4 was made. In this case, (4.15) and (4.16) imply that

$$\|h(x_c^{k_j+1})\| \le \|h(x_c^{k_j} + \delta_V^+)\| = o(\|h(x^{k_j})\|) = o(\|x^{k_j} - x^*\|). \tag{4.28}$$

Equation (4.23) follows directly from (4.18), (4.27), and (4.28).

Combining (3.12), (4.9), (4.16), (4.18), (4.19), and (4.23), we can write

$$\begin{aligned} \|h(x^k)\| &= \|h(x_c^k)\| + O(\|{\delta_H}^k\|^2) = h(x_c^k) + O(\|g_p(x_c^k)\|^2) \\ &= \|h(x_c^k)\| + O(\|x_c^k - x^*\|^2) = o(\|x_c^{k-1} - x^*\|), \end{aligned} \tag{4.29}$$

so (4.22) is proved.

Finally, to obtain (4.21), we use a Taylor expansion, (3.1), (4.18), (4.19), (4.20), and (4.22), so

$$\begin{aligned} \|g_p(x_c^{k+1})\| &= \|g_p(x^k)\| + O(\|x^k - x_c^{k+1}\|) \\ &= \|g_p(x^k)\| + O(\|h(x^k)\|) = o(\|x_c^{k-1} - x^*\|). \end{aligned}$$

The 2-step superlinear convergence of x_c^k and x^k follows from (4.16) and (4.18)–(4.23), since these equations imply that

$$\|x^{k+1} - x^*\| = O(\|g_p(x^{k+1})\| + \|h(x^{k+1})\|) = o(\|x^{k-1} - x^*\|) \text{ and} \tag{4.30}$$

$$\|x_c^{k+1} - x^*\| = O(\|g_p(x_c^{k+1})\| + \|h(x_c^{k+1})\|) = o(\|x_c^{k-1} - x^*\|). \tag{4.31}$$

In order to conclude the proof, let us assume a nonzero restoration step is done at each iteration. Then, (3.12) and (4.15), together with (4.9), (4.16), and (4.19), allow us to improve (4.22), obtaining

$$\|h(x^k)\| = \|h(x_c^k)\| + O(\|g_p(x_c^k)\|^2) = o(\|x^{k-1} - x^*\|). \tag{4.32}$$

Substituting (4.20) and (4.32) into (4.30) and also considering (4.19), we get

$$\begin{aligned} \|x^{k+1} - x^*\| &= O(\|g_p(x^{k+1})\| + \|h(x^{k+1})\|) \\ &= o(\|x_c^{k+1} - x^*\| + \|x^k - x^*\|) = o(\|x^k - x^*\|), \end{aligned}$$

so the desired superlinear convergence of x^k to x^* is attained. ∎

5. Numerical experience. The success of an algorithm is based not only on its theoretical convergence results, but also on its practical behavior. In this section, we present one possible implementation for the DCI algorithm, along with the numerical results obtained by applying it to some problems from the CUTEr collection [21].

We do not claim to have implemented the ultimate version of the algorithm. On the contrary, our implementation is quite simple and should be improved in order to compete with modern commercial codes. Our only purpose is to show that the algorithm can successfully solve medium-sized equality constrained problems. Some hints on how to improve the code are given in the next section.

5.1. A practical implementation of the algorithm. We begin the detailed description of the algorithm by explaining how the vertical and horizontal steps can be implemented. After that, we discuss how to solve the linear systems that appear when computing these steps. Finally, we present a second order correction used to reduce the infeasibility after applying the horizontal step.

5.1.1. Vertical step. Whenever $\|h(x_c)\| > \rho$ at the beginning of an iteration, we need to reduce the infeasibility. Unfortunately, this test is tricky to perform, since ρ depends on $n_p(x_c)$ and this term, in turn, depends on the matrix $\nabla h(x_c)$. Naturally, it would not be wise to compute $\nabla h(x_c)$ just before calling the restoration, as we will need to update this matrix after this step. For this reason, in step 1.2 of Algorithm 2.1, we define an approximate value for ρ, replacing n_p by

$$n_p^a = \frac{|\Delta L_H|}{|f(x^{k-1}) - f(x_c^{k-1})| + \|\delta_t^{k-1}\|}.$$

The restoration is done by applying Powell's *dogleg* method [33] to the constrained linear least squares problem (2.5), replacing x by x_c. Again, the solution of this problem depends on $\nabla h(x_c)$. Therefore, the first time we try to solve (2.5), we use $A = \nabla h(x_c^{k-1})$. If the infeasibility is not sufficiently reduced, we define $A = \nabla h(x_c)$ and recompute the step.

To find an approximate solution for the trust region problem, the dogleg method uses a path consisting of two line segments. The first connects the origin to the Cauchy point, defined as

$$s_{CS} = -\gamma A(x_c)^T h(x_c),$$

where

$$\gamma = \min\left\{ \frac{\Delta_{VS}}{\|A(x_c)^T h(x_c)\|}, \frac{\|A(x_c)^T h(x_c)\|^2}{\|A(x_c)A(x_c)^T h(x_c)\|^2} \right\}.$$

The second line runs from the Cauchy point to the Newton point

$$s_{NS} = -A(x_c)^T (A(x_c)A(x_c)^T)^{-1} h(x_c). \tag{5.1}$$

If $\|s_{NS}\| \leq \Delta_{VS}$, then the Newton point is the solution of the problem. Otherwise, the point of intersection of the dogleg path and the trust region boundary is chosen.

The trust region radius Δ_{VS} used to compute the vertical step is updated using rules similar to those defined for the horizontal step.

Let P_{red} denote the predicted reduction and A_{red} the actual reduction of the infeasibility. The step is rejected if $A_{red}/P_{red} < 10^{-3}$. In this case, Δ_{VS} is divided by 4. On the other hand, if $A_{red}/P_{red} \geq 0.5$, we double Δ_{VS}.

Sometimes it is necessary to apply the dogleg method several times in order to obtain the desired level of infeasibility. To avoid recomputing A frequently, we try to take a new step using the same matrix whenever the dogleg method is able to reduce $\|h(x_c)\|$ by at least 10%. This expedient is used up to four times in a row, after which A is recalculated.

After the restoration, $\nabla h(x_c)$ is available, and we need to choose ρ satisfying the conditions stated in step 1.3.3 of Algorithm 2.1. These conditions are quite loose, so a good scheme for defining the trust cylinder radius can be devised, taking into account some problem characteristics and the values of ρ_{max} and n_p. In our implementation, however, a naive rule was used. If the approximate ρ computed in step 1.2 satisfies $10^{-4} n_p \rho_{max} \leq \rho \leq n_p \rho_{max}$, we keep this value. Otherwise, we simply define

$$\rho = \min\{n_p \rho_{max},\, 0.75\rho_{max}\}.$$

The reduction obtained by the dogleg method may be small depending on the curvature of h. When this happens, we abandon the constrained linear least squares problem and try to apply the Moré and Thuente line search algorithm [31] to the unconstrained nonlinear least squares problem

$$\text{minimize} \quad \|h(x)\|^2, \tag{5.2}$$

using a BFGS approximation for the second order part of the Hessian of the objective function [14].

Since this last approach is more time-consuming than the dogleg method, it is applied only if $\|h(x_c)\|/\|h(x_{k-1})\| < 0.95$ for three successive dogleg steps. Fortunately, this is unlikely to occur, as the dogleg method usually works well.

5.1.2. Horizontal step. The horizontal step of the method consists in solving the quadratic programming problem (2.6). If Z is a matrix that spans the null space of $\nabla h(x_c)$, then it is possible to rewrite (2.6) as the constrained nonlinear programming problem

$$\begin{aligned} &\text{minimize} \quad g(x_c)^T Zv + \frac{1}{2} v^T Z^T B Z v \\ &\text{subject to} \quad \|Zv\|_\infty \leq \Delta, \end{aligned} \tag{5.3}$$

where δ was replaced by Zv.

One should notice that B need not be positive definite; thus we cannot use the dogleg method to solve (5.3), as we did in the vertical step. Instead, we use the Steihaug–Toint method [40, 42], which is an extension of the conjugate gradient (CG) method for nonconvex problems.

Since computing the product of Z times a vector several times would be too costly, we write the Steihaug–Toint algorithm using δ directly, as described by Lalee, Nocedal, and Plantenga in [23].

The method starts by computing the Cauchy step defined in step 4.1.1 of Algorithm 2.1. If this point falls inside the trust region, it is improved by applying successive CG iterations until $q(\delta) \leq 0.01 q(\delta_{CP})$, a direction of negative curvature is found, or the trust region boundary is violated. In the last two cases, a point on the boundary of the trust region is chosen.

5.1.3. Linear systems. In the core of both the vertical and the horizontal steps, we have linear systems involving AA^T. Such systems need to be solved when we compute

- the Newton step (5.1) in the dogleg method;
- the Lagrange multipliers (1.3) and, consequently, the projected gradient (1.4);
- the second order correction (see (5.4));
- the projection of the residual vector onto $N(A)$ in the Steihaug–Toint method.

Two routines are provided for solving these systems. One is based on the sparse Cholesky decomposition of AA^T. The second uses the CG method to generate an approximate solution.

If we choose to work with the Cholesky decomposition, the approximate minimum degree algorithm of Amestoy, Davis, and Duff [3] is used to reorder the rows and columns of AA^T, so the fill-in created during the factorization is minimized. For the CG method, a band preconditioner has been implemented to accelerate the method.

As an attractive alternative, we could use the augmented system approach to solve such systems, since it reduces the fill-in produced by dense rows in A and keeps the condition number of the matrix under control. Direct methods for solving symmetric indefinite augmented systems are presented, for example, in [6, 39], while iterative approaches are introduced in [19, 5], just to cite a few references. We plan to include one or more of these algorithms in our code in the near future.

5.1.4. Second order correction. In DCI, a second order correction can be used to reduce the infeasibility after the horizontal step, as the acceptance of this compound step is more likely to happen. Clearly, $\delta_{soc} = 0$ would be a possibility for the second order correction term. In fact, any $\delta_{soc} = O(\|\delta_t\|^2)$ is acceptable for global convergence purposes. The nonzero natural candidate corresponds to

$$\begin{aligned} \delta_{soc} &= \operatorname{argmin}\{\|\nabla h(x_c)\,\delta + (h(x_c+\delta_t) - h(x_c))\|\} \\ &= -\nabla h(x_c)^T(\nabla h(x_c)\nabla h(x_c)^T)^{-1}(h(x_c+\delta_t) - h(x_c)). \end{aligned} \tag{5.4}$$

If $g_p(x_c) = g(x_c) + \nabla h(x_c)^T\lambda_{LS} = \operatorname{argmin}\{\|\nabla h(x_c)^T\lambda + g(x_c)\|\}$ is obtained from the Cholesky factorization of $\nabla h(x_c)\nabla h(x_c)^T$, the second order correction turns out to be computationally cheap. On the other hand, if we use iterative methods to compute $g_p(x_c)$, it looks reasonable to relax the convergence to g_p so that we can save some time for computing δ_{soc}.

The second order correction is called if, after computing the horizontal step, we have

$$\|h(x_c+\delta_t)\| > \min\{2\rho,\ 2\|h(x_c)\| + 0.5\rho\}$$

or

$$\|h(x_c)\| \le 10^{-5} \ \text{ and } \ \|h(x_c+\delta_t)\| > \max\{10^{-5},\ 2\|h(x_c)\|\}.$$

If the second order correction is refused, it is not calculated again at the same global iteration of Algorithm 2.1.

5.2. Algorithm performance. To analyze the behavior of the algorithm just described, we used a set of 53 medium-sized equality constrained problems extracted from the CUTEr collection [21]. The selected problems are presented in Table 5.1. The number of variables of the problem is given by n, while m is the number of constraints.

Originally, all of the equality constrained problems of the CUTEr library were selected to compose the test set. However, at this moment, the DCI algorithm is not

prepared to handle singular Jacobian matrices, so some of the problems needed to be excluded from the list.

The DCI algorithm was implemented in Fortran 77, and the executable program was generated using the ifort 9.0 compiler, under the Fedora 4 Linux operating system. To evaluate the performance of the new method, it was compared with two freely available nonlinear programming solvers. The first is Lancelot-B, the well-known algorithm distributed along with the GALAHAD library [20]. The second is Ipopt (version 3.3.3) [43], an interior point method that also tackles equality constrained problems quite well. Both codes include a nice interface for solving CUTEr problems.

The tests were performed on a Dell Optiplex GX280 computer, using an Intel Pentium 4 540 processor, with a clock speed of 3.2GHz, 1MB of cache memory, a 800MHz front side bus, and the Intel 915G chipset. Exact first and second derivatives were computed by all of the methods.

The DCI algorithm was designed to declare convergence when both $\|h(x)\| < \epsilon_h$ and $n_p < \epsilon_p$, as well as when $\rho_{max} < \epsilon_r$. However, since Lancelot-B uses the infinity norm in its convergence criteria, we decided to change the first criterion, stopping the algorithm when $\|h(x)\|_\infty < \epsilon_h$ and one of $\|g_p\|_\infty < \epsilon_g$ or $n_p < \epsilon_p$ occurs. Besides, it also terminates if $\|\delta_t\| < \epsilon_d \|x\|$ for 10 successive iterations or if the restoration fails to obtain a feasible point. The constants $\epsilon_h = 10^{-5}$, $\epsilon_g = 10^{-5}$, $\epsilon_p = 10^{-7}$, $\epsilon_r = 10^{-7}$, and $\epsilon_d = 10^{-8}$ were adopted, so the stopping tolerances are compatible with those used in Lancelot-B. The Ipopt stopping tolerances were changed accordingly. Default values were used for the remaining Ipopt parameters. The default settings were also used in Lancelot-B, except for the maximum number of iterations, which was increased to 10000.

Other parameters used in the DCI algorithm are

$$\rho^0_{max} = \max\{10^{-5},\, 5.1\|h(x^0)\|,\, 50\, n_p(x^0)\}, \tag{5.5}$$
$$\Delta^0 = \Delta^0_{VS} = \max\{10\|x^0\|,\, 10^5\},$$

and $\Delta_{min} = 10^{-5}$. For all of the problems presented here, we used the Cholesky decomposition to compute the solution of $(AA^T)s = b$, although, for many of them, it would be preferable to use the preconditioned CG method.

The comparison of the methods was done using the performance profiles defined by Dolan and Moré [16]. To draw the performance profiles for a set S of solvers on a set P of problems, we need to compute, for each problem $p \in P$ and each solver $s \in S$, the performance ratio defined by

$$r_{p,s} = \frac{t_{p,s}}{\min\{t_{p,s} : s \in S\}},$$

where $t_{p,s}$ is the time spent by the solver s to solve problem p. The overall performance of solver s is represented by the function

$$P(t) = \frac{1}{n_p} size\{p \in P : r_{p,s} \leq t\},$$

where n_p is the number of problems considered. In words, $P(t)$ is the fraction of the number of problems that are solved by s within a factor t of the time spent by the fastest solver (for each problem). Plotting $P(t)$, we get a performance profile for a particular solver.

For the 53 equality constrained problems selected, the performance profiles of Lancelot-B, Ipopt, and DCI are shown in Figure 5.1. One can deduce from this figure that the DCI algorithm took less time than Lancelot-B and Ipopt to obtain the solution of 47% of the problems, while Ipopt was the best solver for 45% of the problems, and Lancelot-B took less time in only 9.4% of the cases. Ipopt outperforms DCI for t between 1.5 and 4.5, but, in general, we may say that DCI presented the best performance among the solvers.

DCI and Lancelot-B obtained an optimal solution (i.e., a stationary point for (1.1)) for all of the problems. The Ipopt code, in turn, converged to a point of local infeasibility when solving the LUKVLE16 problem and ran out of memory after spending 2920 seconds searching the solution of the LUKVLE11 problem. For all of the remaining problems, Ipopt also obtained an optimal solution.

To close this section, let us focus our analysis on the behavior of the restoration scheme adopted in DCI, summarized in Figure 5.2. Each point in the figure represents one CUTEr problem. The horizontal coordinate of a point is the percentage of the number of iterations in which only one restoration was done. The vertical coordinate is the percentage of iterations in which more than one restoration was needed. Diagonal lines were included to group the problems by the percentage of iterations with one or more restorations.

The results obtained for the 53 CUTEr problems showed that, on average, the DCI algorithm performed one restoration in 24.3% of the iterations, while it was necessary to perform more than one restoration in only 9.2% of the iterations. Summing the figures, we observe that no restoration was made in about two-thirds of the iterations, on average. Besides, if we consider only the iterations in which more than one restoration was done, the number of restorations was equal to 2 in 62.1% of the cases.

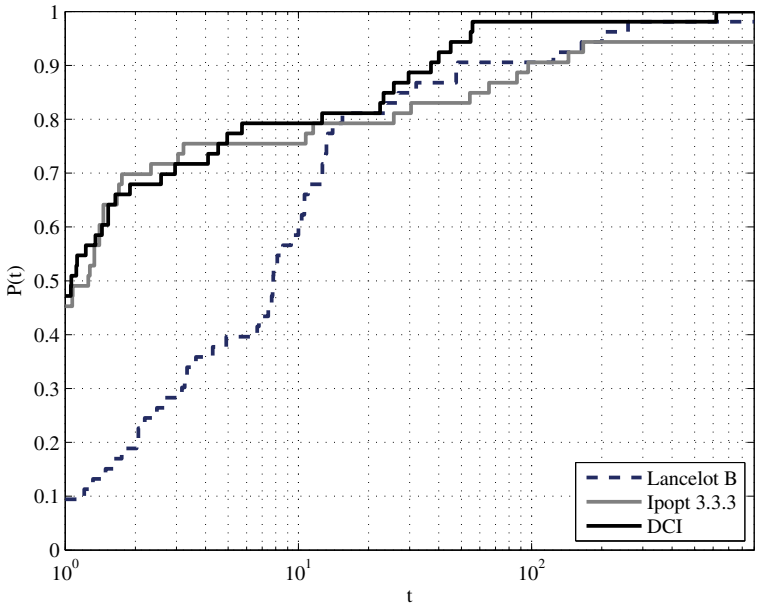

FIG. 5.1. *Performance profiles for* 53 *CUTEr problems.*

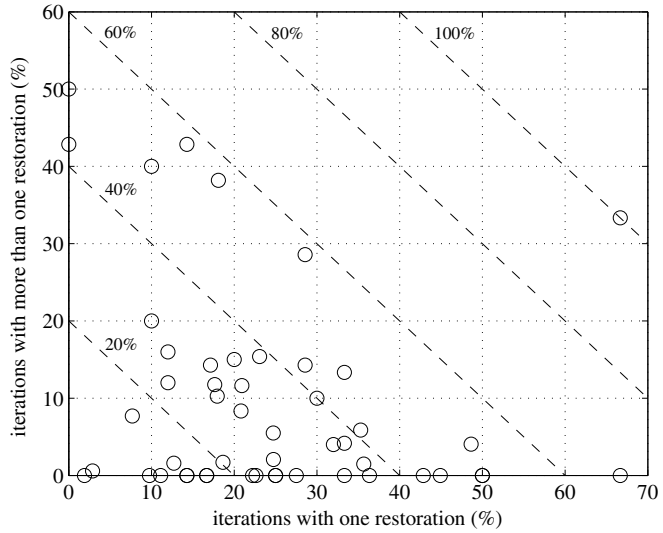

FIG. 5.2. *Percentage of iterations with one or more restorations for the* 53 *CUTEr problems.*

Our experiments with the CUTEr problems also revealed that the choice of an initial value for ρ_{max} is still an open problem. For several problems, a particular value of ρ^0_{max} has led to a much better performance of the algorithm if compared to (5.5). One possible way to circumvent this problem is to use a few iterations of the algorithm only to calibrate this parameter, prior to using the rules for updating it.

6. Conclusions. In this paper, we have presented a new algorithm for solving nonlinear programming problems with equality constraints. The method uses the idea of a trust cylinder to keep the infeasibility under control. The radius of this cylinder is reduced as the algorithm approaches the optimal point. The algorithm is globally convergent in the sense that its accumulation set has stationary points for (1.1). In addition, it is also superlinearly convergent under some mild assumptions.

Our current implementation of the algorithm works well when applied to medium-sized problems, so we believe it worthwhile to investigate its performance for larger problems. Some of the improvements that are to be made to the code after solving large-scale problems include

- the use of an augmented system approach to solve the linear systems;
- the reformulation of the algorithm so that inexact solutions for the linear subroutines are admitted;
- the use of BFGS approximations to the Hessian of the Lagrangian when computing the horizontal step;
- the definition of clever rules for choosing the initial value of ρ_{max}.

Furthermore, we also have plans to extend the algorithm to solve inequality constrained problems.

OPTIMIZATION PROBLEMS WITH SECOND ORDER STOCHASTIC DOMINANCE CONSTRAINTS: DUALITY, COMPACT FORMULATIONS, AND CUT GENERATION METHODS*

GÁBOR RUDOLF† AND ANDRZEJ RUSZCZYŃSKI‡

Abstract. For stochastic optimization problems with second order stochastic dominance constraints we develop a new form of the duality theory featuring measures on the product of the probability space and the real line. We present two formulations involving small numbers of variables and exponentially many constraints: primal and dual. The dual formulation reveals connections between dominance constraints, generalized transportation problems, and the theory of measures with given marginals. Both formulations lead to two classes of cutting plane methods. Finite convergence of both methods is proved in the case of finitely many events. Numerical results for a portfolio problem are provided.

Key words. stochastic programming, stochastic dominance, duality, cutting plane methods

1. Introduction.

Our objective is to develop new approaches to stochastic optimization problems with a constraint in the form of the second order stochastic dominance relation. Such problems, introduced and analyzed in [4, 5], are new models of risk-averse optimization, in which risk aversion is expressed by the stochastic dominance constraint. Due to its specific structure, the constraint poses new theoretical and computational challenges.

The relation of *stochastic dominance* (introduced in statistics in [18, 19] and in economics in [14, 27]) is defined as follows: Let X and Y be random variables on a probability space $(\Omega, \mathcal{F}, P)$ with distribution functions F_X and F_Y, respectively. We say that X *dominates* Y *in the first order* if $F_X(\eta) \leq F_Y(\eta)$ for all $\eta \in \mathrm{R}$, and we denote this relation by $X \succeq_{(1)} Y$. An equivalent condition is that for every nondecreasing function $u(\cdot)$ one has

$$\mathrm{E}[u(X)] \geq \mathrm{E}[u(Y)], \tag{1.1}$$

provided the expected values above are finite.

For two integrable random variables X and Y, we say that X *dominates* Y *in the second order* if $\int_{-\infty}^{\eta} F_X(t)\,dt \leq \int_{-\infty}^{\eta} F_Y(t)\,dt$ for all $\eta \in \mathrm{R}$, and we denote this relation by $X \succeq_{(2)} Y$. An equivalent condition is that for every concave nondecreasing function $u(\cdot)$ condition (1.1) holds true, provided that the expected values on both sides are finite.

We refer the readers to the monographs [21, 32] for a modern view on the stochastic dominance relations and other comparison methods for random outcomes.

†RUTCOR, Rutgers University, 640 Bartholomew Rd., Piscataway, NJ 08854 (grudolf@new-rutcor.rutgers.edu).

‡Department of Management Science and Information Systems, Rutgers University, 94 Rockafeller Rd., Piscataway, NJ 08854 (rusz@business.rutgers.edu).

More generally, for an interval $I \subset \mathrm{R}$ let $X \succeq_{(2,I)} Y$ denote the relation

$$\int_{-\infty}^{\eta} F_X(t)\,dt \le \int_{-\infty}^{\eta} F_Y(t)\,dt \quad \forall\, \eta \in I.$$

It is a relaxation of the second order dominance relation. If the interval I is compact, then this relaxation allows us to overcome technical difficulties in dealing with the second order dominance relation, as discussed in [4, 5]. If the interval I is reduced to one point, then the relation $X \succeq_{(2,I)} Y$ becomes the *integrated chance constraint* of [16].

An alternative representation of the second order dominance relation can be derived by using the *shortfall* of a random variable X from a target $\eta \in \mathrm{R}$, defined as $\max(0, \eta - X)$ (and written compactly as $[\eta - X]_+$). By changing the order of integration one can easily verify that the expected value of the shortfall is given by the formula $\mathrm{E}([\eta - X]_+) = \int_{-\infty}^{\eta} F_X(t)\,dt$. Therefore, we can rewrite the relation $X \succeq_{(2,I)} Y$ in the following form:

$$\mathrm{E}([\eta - X]_+) \le \mathrm{E}([\eta - Y]_+) \quad \forall\, \eta \in I. \tag{1.2}$$

Consider a stochastic model in which our decisions $z \in Z$ affect a random outcome $X = G(z)$. We assume that $z \in Z \subset \mathcal{Z}$, where $\mathcal{Z}$ is a Banach space and Z is a convex closed set. The mapping $G : \mathcal{Z} \to \mathcal{L}_1(\Omega, \mathcal{F}, P)$ is assumed to be continuous and concave in the sense that for P-almost all $\omega \in \Omega$ the function $z \mapsto [G(z)](\omega)$ is concave. Finally, let $f : \mathcal{Z} \to \mathrm{R}$ be a concave objective functional (for example, $f(z) = \mathrm{E}G(z)$). We are interested in the following problem:

$$\begin{array}{ll} \underset{z}{\text{maximize}} & f(z) \\ \text{subject to} & G(z) \succeq_{(2,I)} Y, \\ & z \in Z. \end{array} \tag{1.3}$$

Here $Y \in \mathcal{L}_1(\Omega, \mathcal{F}, P)$ is a benchmark random outcome and I is an interval in R.

As the second order dominance relation carries over to expectations of concave nondecreasing utility functions, no risk-averse decision maker will prefer random outcome Y over random outcome $G(z)$ (if $I = \mathrm{R}$). Therefore, if the benchmark outcome Y represents an "acceptable" risk exposure, the risk exposure of $G(z)$ is even "more acceptable." Furthermore, suppose that the objective functional is monotone (consistent) with respect to the second order stochastic dominance relation, as defined in [24, 25, 26]: $G(z') \succeq_{(2)} G(z) \Rightarrow f(z') \ge f(z)$. For example, we may use $f(z) = \mathrm{E}[G(z)]$ or $f(z)$ being a negative of a coherent measure of risk. If the solution of problem (1.3) is unique, then no other feasible outcome $G(z')$ can strictly dominate the solution $G(z)$ (see [24, 25, 26]). The essence of the approach via stochastic dominance constraints is that the distribution of the outcome $G(z)$ is indirectly shaped by the distribution of the benchmark Y, which may also be an artificially constructed random variable. Reference [23] illustrates this modeling flexibility on an example of a portfolio problem.

The papers [4, 5] provide the optimality and duality theory for problem (1.3) in which Lagrange multipliers associated with the dominance constraints are identified with concave nondecreasing utility functions. In [7] an equivalent inverse form of the second order stochastic dominance constraint was analyzed, and it was shown that it is equivalent to a continuum of conditional (average) value at risk constraints [29].

Moreover, Lagrange multipliers associated with the inverse form of stochastic dominance constraints were identified in [7] with concave rank dependent utility functions of the dual utility theory [34]. In this way, model (1.3) is related to several classical models of risk-averse decision making.

However, an efficient solution of problem (1.3), even in the finite-dimensional linear case, remains a challenge.

In what follows we focus on the stochastic dominance constraint $G(z) \succeq_{(2,I)} Y$ as the novel element in model (1.3), leaving aside considerations about possible objective functionals. We also remark that setting the problem in a Banach space $\mathcal{Z}$ does not lead to any significant technical difficulties, as compared to the finite-dimensional case $\mathcal{Z} = \mathrm{R}^n$. Moreover, we hope to apply our formulation to multistage stochastic optimization problems, with $\mathcal{Z}$ representing the space of policies, which is usually modeled as a subspace of the space of integrable functions (see [30]).

Using (1.2) we obtain a more explicit formulation of (1.3):

$$\begin{aligned} &\underset{z}{\text{maximize}} && f(z) \\ &\text{subject to} && \mathrm{E}([\eta - G(z)]_+) \le \mathrm{E}([\eta - Y]_+) \quad \forall\, \eta \in I, \\ &&& z \in Z. \end{aligned} \tag{1.4}$$

When the functions $f(\cdot)$ and $G(\cdot)$ are affine and the set Z is a convex closed polyhedron, in section 2 we develop a linear programming formulation of problem (1.4). But even in the finite-dimensional case, this problem is difficult to solve because its size grows quadratically with the number of the elementary events considered.

Another approach to (1.4) is the dual method of [5]. It is a specialized nonsmooth optimization algorithm applied to the dual problem, in the space of concave nondecreasing functions playing the role of Lagrange multipliers associated with the dominance constraint. While efficient for some problems, especially portfolio problems of [8], the dual method is rather complicated.

Our objective is to develop new efficient linear programming formulations which exploit the specific structure of the stochastic dominance constraint in cut generation schemes. This results in a significant increase of the size of computationally tractable problems, as well as in a speedup in the solution of smaller instances. Furthermore, for problems with first order stochastic dominance constraints $G(z) \succeq_{(1)} Y$, which are typically much more difficult, due to the potential nonconvexity of the feasible region, model (1.3) serves as a powerful convex relaxation (see [6, 22, 23]). Thus, the speedup also benefits some advanced iterative methods of [23] for problems with first order constraints.

In sections 2 and 3 we present a primal cutting plane method based on formulation (1.4). In section 4 we develop a new version of the duality theory for an extended reformulation of problem (1.4). In section 5 we show how a reduction of the number of variables in the dual problem can be achieved by employing Strassen's theorem about the existence of measures on product spaces with given marginals. This leads to a dual cutting plane method in section 7. Finally, in section 8 we present numerical results, along with performance comparisons of the various methods, for portfolio optimization problems based on real data.

2. A linear representation of the second order stochastic dominance constraint. In order to solve (1.3) it is necessary to represent the relation $\succeq_{(2,I)}$ in a tractable form. The usual approach to achieve this is to introduce *shortfall functions*. In the finite-dimensional case they correspond to slack variables, but in

the infinite-dimensional case we need to introduce an appropriate space of the shortfall functions.

Denote by ℓ the Lebesgue measure on I, and let $\mathcal{B}$ be the σ-algebra of Borel subsets of I. We denote the Banach space of continuous functions on I by $\mathcal{C}(I)$. Let $\mathcal{S}$ be the vector space of all real-valued measurable functions s on $(I\times\Omega, \mathcal{B}\times\mathcal{F}, P\times\ell)$ satisfying the following conditions:

(i) for every $\eta\in I$ the function $s(\eta,\cdot)$ is an element of $\mathcal{L}_1(\Omega,\mathcal{F},P)$;
(ii) for P-almost all $\omega\in\Omega$ the function $s(\cdot,\omega)$ is an element of $\mathcal{C}(I)$;
(iii) the function $\omega\to\max_{\eta\in I}|s(\eta,\omega)|$ is an element of $\mathcal{L}_1(\Omega,\mathcal{F},P)$.

Owing to the Lebesgue theorem, the function $w(\eta)=\int_\Omega s(\eta,\omega)\,dP$ is an element of $\mathcal{C}(I)$. It can be verified directly from the definition that $\mathcal{S}$ is a Banach space with the norm

$$\|s\|=\int_\Omega \max_{\eta\in I}|s(\eta,\omega)|\,dP.$$

Immediately from (1.2) we obtain the following observation.

LEMMA 2.1. *Assume that $X,Y\in\mathcal{L}_1(\Omega,\mathcal{F},P)$. Then $X\succeq_{(2,I)}Y$ if and only if there exists a nonnegative function $s\in\mathcal{S}$ such that*

$$s(\eta,\omega)\ge\eta-X(\omega)\quad\forall\,\eta\in I\quad\forall\,\omega\in\Omega,$$
$$\int_\Omega s(\eta,\omega)\,dP\le\int_\Omega[\eta-Y(\omega)]_+\,dP\quad\forall\,\eta\in I.$$

Let us introduce the notation $v(\eta)=\mathrm{E}([\eta-Y]_+)=\int_\Omega[\eta-Y(\omega)]_+\,dP$ for the shortfalls of the benchmark variable. Applying Lemma 2.1, we can formulate another optimization problem which is equivalent to (1.3):

$$\begin{aligned}
&\underset{z,s}{\text{maximize}} && f(z)\\
&\text{subject to} && \int_\Omega s(\eta,\omega)\,dP\le v(\eta)\quad\forall\,\eta\in I,\\
&&& [G(z)](\omega)+s(\eta,\omega)\ge\eta\quad\forall\eta\in I\quad\forall\,\omega\in\Omega,\\
&&& s\ge 0,\\
&&& z\in Z,\ s\in\mathcal{S}.
\end{aligned}\tag{2.1}$$

If the functional $f(\cdot)$ and the mapping $G(\cdot)$ are affine and the set Z is polyhedral, then problem (2.1) becomes a linear programming problem in Banach spaces. When the distribution of the benchmark outcome is discrete, one can restrict the range of η in (2.1) to the realizations of the benchmark Y.

A potential drawback of the above approach is the introduction of the auxiliary variables $s(\cdot,\cdot)$ indexed by the set $I\times\Omega$. As we shall see in section 8, even in the finite-dimensional case, when $\mathcal{Z}=\mathrm{R}^n$ and the probability space Ω is finite, formulation (2.1) may be impractical to solve.

We now present an alternative representation which does not require additional variables $s(\cdot,\cdot)$. It is an extension of the representation developed in [17] for integrated chance constraints.

THEOREM 2.2. *Assume that $X,Y\in\mathcal{L}_1(\Omega,\mathcal{F},P)$. Then $X\succeq_{(2,I)}Y$ if and only if for all $\eta\in I$ and all events $A\in\mathcal{F}$*

$$\mathrm{E}\left((\eta-X)\,1_A\right)\le v(\eta).$$

Proof. For every event $A \in \mathcal{F}$

$$\mathrm{E}\left((\eta - X)\,1_A\right) \le \mathrm{E}([\eta - X]_+).$$

This inequality becomes an equation if $A = \{X < \eta\}$, and thus

$$\max_{A \in \mathcal{F}} \mathrm{E}\left((\eta - X)\,1_A\right) = \mathrm{E}([\eta - X]_+).$$

The theorem immediately follows from (1.2). □

Using this result we obtain another equivalent formulation of the optimization problem (1.2):

$$\begin{array}{ll} \underset{z}{\text{maximize}} & f(z) \\ \text{subject to} & \displaystyle\int_A \big(\eta - G(z)\big)\,dP \le v(\eta), \quad \forall\, \eta \in I, \quad \forall\, A \in \mathcal{F}, \\ & z \in Z. \end{array} \tag{2.2}$$

Although the auxiliary variables are no longer present, we have introduced an infinite family of constraints indexed by the set $I \times \mathcal{F}$. However, we shall show that the new family of constraints can be efficiently dealt with by a cut generation method.

3. A primal cutting plane method. In this section we assume that $I = \mathrm{R}$ and the probability space Ω is finite, with elementary events $\omega_1, \ldots, \omega_N$ and corresponding probabilities $p_1, \ldots, p_N$. The realizations of the benchmark outcome Y are denoted by $y_1, \ldots, y_D$, and the corresponding benchmark shortfalls are $v_j = \mathrm{E}([y_j - Y]_+)$. We also write $G_i(z)$ for $[G(z)](\omega_i)$.

It is known from [4, 5] that in the case of a discrete benchmark the second order dominance condition $G(z) \succeq_{(2)} Y$ is equivalent to finitely many inequalities:

$$\mathrm{E}([y_j - G(z)]_+) \le v_j, \quad j = 1, \ldots, D. \tag{3.1}$$

We can thus rewrite problem (2.2) as follows:

$$\begin{array}{ll} \underset{z}{\text{maximize}} & f(z) \\ \text{subject to} & \displaystyle\sum_{i \in A} p_i\big(y_j - G_i(z)\big) \le v_j \quad \forall\, j = 1, \ldots, D, \quad \forall\, A \subset \{1, \ldots, N\}, \\ & z \in Z. \end{array} \tag{3.2}$$

The last formulation allows for the construction of a cutting plane method. At iteration k we have a collection of subsets (events) $A_1, \ldots, A_{k-1}$ of $\{1, \ldots, N\}$. We solve a relaxation of (3.2):

$$\begin{array}{ll} \underset{z}{\text{maximize}} & f(z) \\ \text{subject to} & \displaystyle\sum_{i \in A_m} p_i\big(y_j - G_i(z)\big) \le v_j, \quad j = 1, \ldots, D, \quad m = 1, \ldots, k-1, \\ & z \in Z. \end{array} \tag{3.3}$$

If the solution z^k of this problem (which is assumed to exist) satisfies all constraints (3.1), then we stop. Otherwise, we find j^* for which (3.1) is violated, and we define

$$A_k = \{1 \le i \le N : y_{j^*} > G_i(z^k)\}.$$

The iteration index k is increased by one, and we solve (3.3) again.

Since (3.1) is violated,

$$\sum_{i\in A_k} p_i\big(y_{j^*} - G_i(z)\big) > v_{j^*},$$

and thus A_k is different than A_m, $m = 1,\dots,k-1$, used in problem (3.3). As the possible number of sets that can be added is finite, the method must stop at an optimal solution of (3.2). Examples in section 8 suggest that in practice a small number of sets A_k need to be generated in order to find the optimal solution.

4. Lagrangian duality. In this section we derive duality relations for the extended formulation (2.1). Our derivation uses ideas and techniques developed in [5]. The main difference is that we develop duality relations for the formulation (2.1) involving explicit shortfall variables, in contrast to the duality theory of [5], where we focused on the dominance constraint in the nonsmooth formulation (1.4).

The difficulty with formulation (2.1) is that no Slater condition can be formulated for the inequality constraint on the shortfall variables

$$[G(z)](\omega) + s(\eta,\omega) \ge \eta \quad \forall\, \eta \in I \quad \forall\, \omega \in \Omega,$$

because the nonnegative cone in the space $\mathcal{S}$ has no interior. Because of that, we cannot simply apply general duality schemes from [28] or [16]. We need to exploit the special structure of problem (2.1).

At first, we introduce several relevant topological vector spaces. We denote by $\mathbf{rca}(I)$ the space of finite signed measures on I and by $\mathcal{L}_\infty(\Omega,\mathcal{F},P)$ the space of essentially bounded measurable real functions on $(\Omega,\mathcal{F},P)$. Let $\mathcal{M}$ denote the vector space of signed measures on $(I\times\Omega,\mathcal{B}\times\mathcal{F})$ such that for every measure $\lambda\in\mathcal{M}$ the *marginal measures* λ_I and λ_Ω, defined by the equations

$$\lambda_I(B) = \lambda(B\times\Omega), \quad B\in\mathcal{B},$$
$$\lambda_\Omega(A) = \lambda(I\times A), \quad A\in\mathcal{F},$$

satisfy the following conditions:

$$\lambda_I \in \mathbf{rca}(I), \qquad \frac{d\lambda_\Omega}{dP} \in \mathcal{L}_\infty(\Omega,\mathcal{F},P). \tag{4.1}$$

Here we implicitly assume that λ_Ω is absolutely continuous with respect to P.

THEOREM 4.1. *The space $\mathcal{M}$ is the topological dual space to the space $\mathcal{S}$ that is, ℓ is a continuous linear functional on $\mathcal{S}$ if and only if there exists $\lambda\in\mathcal{M}$ such that for all $s\in\mathcal{S}$*

$$\ell(s) = \iint_{I\times\Omega} s(\eta,\omega)\,d\lambda. \tag{4.2}$$

Proof. Fix any $\lambda\in\mathcal{M}$, $\lambda\ge 0$, and consider the linear functional (4.2). Its value can be bounded as follows:

$$|\ell(s)| \le \iint_{I\times\Omega} \max_{\eta\in I}|s(\eta,\omega)|\,d\lambda = \int_\Omega \max_{\eta\in I}|s(\eta,\omega)|\,d\lambda_\Omega$$
$$= \int_\Omega \max_{\eta\in I}|s(\eta,\omega)|\,\frac{d\lambda_\Omega}{dP}(\omega)\,dP \le \Big\|\frac{d\lambda_\Omega}{dP}\Big\|_{\mathcal{L}_\infty}\|s\|.$$

For a general signed measure $\lambda \in \mathcal{M}$ we use its Jordan decomposition into a difference of two nonnegative measures $\lambda = \lambda^+ - \lambda^-$, and we define Ω^+ and Ω^- to be the support sets of λ^+ and λ^-, respectively. Using the last displayed inequality we obtain the estimate

$$\begin{aligned}
|\ell(s)| &\le \left| \iint\limits_{I\times\Omega^+} s(\eta,\omega)\, d\lambda_+ \right| + \left| \iint\limits_{I\times\Omega^-} s(\eta,\omega)\, d\lambda_- \right| \\
&\le \left\| \frac{d\lambda^+_\Omega}{dP} \right\|_{\mathcal{L}_\infty} \int_{\Omega^+} \max_{\eta\in I} |s(\eta,\omega)|\; dP + \left\| \frac{d\lambda^-_\Omega}{dP} \right\|_{\mathcal{L}_\infty} \int_{\Omega^-} \max_{\eta\in I} |s(\eta,\omega)|\; dP \\
&\le \max\left(\left\| \frac{d\lambda^+_\Omega}{dP} \right\|_{\mathcal{L}_\infty}, \left\| \frac{d\lambda^-_\Omega}{dP} \right\|_{\mathcal{L}_\infty} \right) \int_\Omega \max_{\eta\in I} |s(\eta,\omega)|\; dP = \left\| \frac{d\lambda_\Omega}{dP} \right\|_{\mathcal{L}_\infty} \|s\|,
\end{aligned}$$

and we conclude that the linear functional (4.2) is continuous. Thus $\mathcal{S}^* \supset \mathcal{M}$.

To prove the converse inclusion, consider the linear subspace of S:

$$\mathcal{S}_0 = \big\{ s \in \mathcal{S} : s = \varphi\xi,\ \varphi \in \mathcal{C}(I),\ \xi \in \mathcal{L}_1(\Omega,\mathcal{F},P) \big\}.$$

Let $\ell \in \mathcal{S}_0^*$. Fix $A \in \mathcal{F}$, and consider the functional $\varphi \mapsto \ell(\varphi 1_A)$. It is continuous on $\mathcal{C}(I)$. By the Riesz representation theorem, there exists a measure $\mu^\ell_A \in \mathbf{rca}(I)$ such that

$$\ell(\varphi 1_A) = \int_I \varphi(\eta)\, d\mu^\ell_A \quad \forall\, \varphi \in \mathcal{C}(I).$$

Define the measure λ^ℓ on $(I\times\Omega, \mathcal{B}\times\mathcal{F})$ by the formula

$$\lambda^\ell(B\times A) = \mu^\ell_A(B), \quad \forall\, B \in \mathcal{B}, \quad \forall\, A \in \mathcal{F}.$$

Then

$$\ell(\varphi 1_A) = \iint\limits_{I\times\Omega} \varphi(\eta) 1_A(\omega)\, d\lambda^\ell.$$

It follows that for every $s = \varphi\xi$ such that $\varphi \in \mathcal{C}(I)$ and ξ is a step function, i.e., $\xi = \sum_{k=1}^K \alpha_k 1_{A_k}$ with some $\alpha_k \in \mathrm{R}$ and $A_k \in \mathcal{F}$, $k = 1,\dots,K$, the functional ℓ has the form (4.2) with $\lambda = \lambda^\ell$. As the step functions are dense in $\mathcal{L}_1(\Omega,\mathcal{F},P)$, for every $\xi \in \mathcal{L}_1(\Omega,\mathcal{F},P)$ we can find a sequence of step functions $\xi^j \to \xi$, $j \to \infty$. Since ℓ is continuous, we obtain

$$\ell(\varphi\xi) = \lim_{j\to\infty} \ell(\varphi\xi^j) = \lim_{j\to\infty} \iint\limits_{I\times\Omega} \varphi(\eta)\xi_j(\omega)\, d\lambda^\ell = \iint\limits_{I\times\Omega} \varphi(\eta)\xi(\omega)\, d\lambda^\ell,$$

and thus the functional ℓ has the form (4.2) on $\mathcal{S}_0$. Moreover, the marginal measure λ^ℓ_I satisfies the first part of condition (4.1):

$$\lambda^\ell_I(B) = \lambda^\ell(B\times\Omega) = \mu^\ell_\Omega \in \mathbf{rca}(I).$$

Consider now functions $s(\eta,\omega) = \xi(\omega)$ with $\xi \in \mathcal{L}_1(\Omega,\mathcal{F},P)$. As ℓ is continuous, the functional $\xi \mapsto \ell(1\xi)$ must be continuous on $\mathcal{L}_1(\Omega,\mathcal{F},P)$. Since

$$\ell(1\xi) = \iint\limits_{I\times\Omega} \xi(\omega)\, d\lambda^\ell = \int_\Omega \xi(\omega)\, d\lambda^\ell_\Omega,$$

it is necessary that also the second part of (4.1) is satisfied by λ_Ω^ℓ. Thus $\mathcal{S}^* \subset \mathcal{S}_0^* \subset \mathcal{M}$. □

We can now formulate the *Lagrangian* $L : \mathcal{Z} \times \mathcal{S} \times \mathcal{M} \times \mathbf{rca}(I) \to \mathrm{R}$ of the optimization problem (2.1) as follows:

$$L(z,s,\lambda,\mu) = f(z) - \iint\limits_{I\times\Omega} \Big(\eta - [G(z)](\omega) - s(\eta,\omega)\Big)\, d\lambda + \int_I \left(v(\eta) - \int_\Omega s(\eta,\omega)\, dP\right) d\mu.$$

The corresponding *Lagrangian dual function* $L_D : \mathcal{M} \times \mathbf{rca}(I) \to \mathrm{R}$ is given by

$$\begin{aligned} L_D(\lambda,\mu) &= \sup_{s\ge 0,\ z\in Z} L(z,s,\lambda,\mu) \\ &= \sup_{s\ge 0,\ z\in Z} \left\{ f(z) + \iint\limits_{I\times\Omega} s(\eta,\omega)\, d(\lambda - \mu\times P) - \int_I \eta\, d\lambda_I + \int_\Omega [G(z)](\omega)\, d\lambda_\Omega + \int_I v(\omega)\, d\mu \right\}. \end{aligned}$$

By examining the second term of this expression we obtain

(4.3)
$$L_D(\lambda,\mu) = \begin{cases} -\displaystyle\int_I \eta\, d\lambda_I + \int_I v(\eta)\, d\mu + \sup_{z\in Z} \left\{ f(z) + \int_\Omega [G(z)](\omega)\, d\lambda_\Omega \right\} & \text{if } \lambda \le \mu \times P, \\ +\infty & \text{otherwise.} \end{cases}$$

This leads to the following dual problem:

$$\begin{aligned} &\underset{\lambda,\mu}{\text{minimize}} \ -\int_I \eta\, d\lambda_I + \int_I v(\omega)\, d\mu + \sup_{z\in Z} \left\{ f(z) + \int_\Omega [G(z)](\omega)\, d\lambda_\Omega \right\} \\ &\text{subject to } \lambda \le \mu \times P, \\ &\qquad\qquad \lambda \in \mathcal{M}^+, \quad \mu \in \mathbf{rca}^+(I). \end{aligned} \tag{4.4}$$

Here we use $\mathcal{M}^+$ and $\mathbf{rca}^+(I)$ to denote the sets of all nonnegative measures in $\mathcal{M}$ and $\mathbf{rca}(I)$, respectively.

THEOREM 4.2 (weak duality). *Let c_* and c_L denote the optimum values of the original problem* (2.1) *and the Lagrangian dual* (4.4)*, respectively. Then $c_* \le c_L$.*

Proof. Let (z,s) be feasible for (2.1). Then for every $(\lambda,\mu) \in \mathcal{M}^+ \times \mathbf{rca}^+(I)$ we have the inequalities

$$L_D(\lambda,\mu) \ge L(z,s,\lambda,\mu) \ge f(z).$$

Taking the infimum of the left-hand side with respect to (λ,μ) and the supremum of the right-hand side with respect to feasible (z,s), we obtain the assertion. □

In order to prove the strong duality relation we need a constraint qualification condition, introduced in [4, 5].

DEFINITION 4.3. *Problem* (2.1) *satisfies the* uniform dominance condition *if there exists $\tilde z \in Z$ such that*

$$\max_{\eta\in I} \Big\{ \mathrm{E}\big[(\eta - G(\tilde z))_+\big] - v(\eta) \Big\} < 0.$$

THEOREM 4.4 (strong duality). *Assume that problem* (2.1) *satisfies the uniform dominance condition and that it has an optimal solution. Then the dual problem* (4.4) *has an optimal solution and $c_* = c_L$.*

Proof. Due to Theorem 4.2, it is sufficient to find $(\hat{\lambda}, \hat{\mu}) \in \mathcal{M}^+ \times \mathbf{rca}^+(I)$ such that $L_D(\hat{\lambda}, \hat{\mu}) = c_*$.

Let $(\hat{z}, \hat{s})$ be an optimal solution of (2.1). Consider the equivalent problem formulation (1.4). Following [4] we can rewrite it in the abstract form:

$$\begin{aligned} &\underset{z}{\text{maximize}}\ f(z) \\ &\text{subject to } \Gamma(z) \in K, \\ &z \in Z, \end{aligned}$$

where $\Gamma : \mathcal{Z} \to \mathcal{C}(I)$ is a continuous operator defined as

$$[\Gamma(z)](\eta) = v(\eta) - \mathrm{E}([\eta - G(z)]_+), \quad \eta \in I.$$

The set K is the cone of nonnegative functions in $\mathcal{C}(I)$. Observe that the function $z \to \eta - G(z)$ is convex, for almost all $\omega \in \Omega$, and the function $x \to (x)_+$ is convex and nondecreasing. Therefore, the composition $\mathrm{E}[(\eta - G(z))_+]$ is a convex function of z. It follows that the operator Γ is concave with respect to the cone K; that is, for any z_1, z_2 in Z and all $\lambda \in [0, 1]$,

$$\Gamma(\lambda z_1 + (1 - \lambda) z_2) - [\lambda \Gamma(z_1) + (1 - \lambda)\Gamma(z_2)] \in K.$$

As the topological dual space to $\mathcal{C}(I)$ is $\mathbf{rca}(I)$, we can introduce the Lagrangian $\Lambda : \mathcal{Z} \times \mathbf{rca}(I) \to \mathrm{R}$,

$$\Lambda(z, \mu) = f(z) + \int_I [\Gamma(z)](\eta)\, d\mu. \tag{4.5}$$

Let us observe that the uniform dominance condition implies that the following generalized Slater condition is satisfied: There exists a point $\tilde{z} \in Z$ such that $\Gamma(\tilde{z}) \in \operatorname{int} K$. Therefore, we can use the necessary conditions of optimality in Banach spaces (see, e.g., [3, Theorem 3.4]). We conclude that there exists a measure $\hat{\mu} \in \mathbf{rca}^+(I)$ such that

$$\Lambda(\hat{z}, \hat{\mu}) = \max_{z \in Z} \Lambda(z, \hat{\mu}) \tag{4.6}$$

and

$$\int_I \big(v(\eta) - \mathrm{E}([\eta - G(\hat{z})]_+)\big)\, d\hat{\mu} = 0. \tag{4.7}$$

This means that $c_* = f(\hat{z}) = \Lambda(\hat{z}, \hat{\mu})$.

Define the set $U = \big\{(\beta, X, z) \in \mathrm{R} \times \mathcal{L}_1(\Omega, \mathcal{F}, P) \times Z : \beta \le f(z),\ X \le G(z)\big\}$. It follows from (4.6) that $\hat{\beta} = f(\hat{z})$, $\hat{X} = G(\hat{z})$, and $\hat{z}$ are the solution of the convex optimization problem

$$\underset{(\beta, X, z) \in U}{\text{maximize}}\ \beta - \iint_{I \times \Omega} [\eta - X]_+\, dP\, d\hat{\mu}. \tag{4.8}$$

Indeed, the best value of β is $f(z)$, and, due to the monotonicity of the function $x \to -[\eta - x]_+$, the best value of X is $G(z)$. By carrying out the partial maximization with respect to (β, X) we reduce (4.8) to the right-hand side of (4.6).

Consider the function $\varphi : \mathcal{S} \to \mathrm{R}$ defined by

$$\varphi(s) = \iint\limits_{I\times\Omega} \big[s(\eta,\omega)\big]_+ \, dP \, d\hat{\mu}$$

at the point $\hat{s}(\eta,\omega) = \eta - [G(\hat{z})](\omega)$, $\eta \in I$, $\omega \in \Omega$. By virtue of the necessary and sufficient condition of optimality for problem (4.8), there exists a subgradient $\gamma \in \partial\varphi(\hat{s})$ such that $(\hat{\beta}, \hat{X}, \hat{z})$ is also a solution of the problem

$$\underset{(\beta,X,z)\in U}{\text{maximize}} \ \beta + \iint\limits_{I\times\Omega} \gamma(\eta,\omega) X \, dP \, d\hat{\mu}. \tag{4.9}$$

By Strassen's disintegration theorem [33, Theorem 1],

$$\gamma(\eta,\omega) \in \partial\big(\eta - \hat{X}(\omega)\big)_+ = \begin{cases} \{1\} & \text{if } \eta > \hat{X}(\omega), \\ \{0\} & \text{if } \eta < \hat{X}(\omega), \\ [0,1] & \text{if } \eta = \hat{X}(\omega). \end{cases}$$

From the definition of the set U and from the fact that $\gamma(\eta,\omega) \ge 0$, for every value of z the best values of β and X in (4.9) are $f(z)$ and $G(z)$, respectively. It follows that $\hat{z}$ is an optimal solution of the problem

$$\underset{z\in Z}{\text{maximize}} \left\{ f(z) + \iint\limits_{I\times\Omega} \gamma(\eta,\omega) G(z) \, dP \, d\hat{\mu} \right\}.$$

Define the measure $\hat{\lambda}$ as absolutely continuous with respect to $\hat{\mu} \times P$ with the Radon–Nikodym derivative

$$\frac{d\hat{\lambda}}{d(\hat{\mu}\times P)} = \gamma.$$

Since $0 \le \gamma \le 1$, we have $0 \le \hat{\lambda} \le \hat{\mu} \times P$. From (4.3) we obtain

$$\begin{aligned} L_D(\hat{\lambda},\hat{\mu}) &= -\int_I \eta \, d\hat{\lambda}_I(\eta) + \int_I v(\eta) \, d\hat{\mu} + \sup_{z\in Z} \left\{ f(z) + \int_\Omega [G(z)](\omega) \, d\hat{\lambda}_\Omega \right\} \\ &= -\iint\limits_{I\times\Omega} \eta\gamma(\eta,\omega) \, dP \, d\hat{\mu} + \int_I v(\eta) \, d\hat{\mu} + f(\hat{z}) + \iint\limits_{I\times\Omega} [G(\hat{z})](\omega)\gamma(\eta,\omega) \, dP \, d\hat{\mu}. \end{aligned}$$

It follows from the definition of γ that the first and the last term in this expression can be written as

$$\begin{aligned} &-\iint\limits_{I\times\Omega} \eta\gamma(\eta,\omega) \, dP \, d\hat{\mu} + \iint\limits_{I\times\Omega} [G(\hat{z})](\omega)\gamma(\eta,\omega) \, dP \, d\hat{\mu} \\ &\qquad = -\iint\limits_{I\times\Omega} \big(\eta - [G(\hat{z})](\omega)\big)_+ \, dP \, d\hat{\mu} = -\int_I \mathrm{E}\big(\eta - [G(\hat{z})](\omega)\big)_+ \, d\hat{\mu}. \end{aligned}$$

Substituting into the last formula for $L_D(\hat{\lambda}, \hat{\mu})$ we conclude that

$$L_D(\hat{\lambda}, \hat{\mu}) = f(\hat{z}) + \int_I \Big[v(\eta) - \mathrm{E}\big(\eta - [G(\hat{z})](\omega)\big)_+ \Big] \, d\hat{\mu} = f(\hat{z}) = c_*.$$

In the last equation we have used the complementarity condition (4.7). □

Finally, let us observe that the condition $\lambda \leq \mu \times P$ appearing in the dual problem implies that $\lambda_I \leq \mu$. This is of importance for the solution method we describe later in section 7.

5. Reducing the space of Lagrange multipliers. Notice that apart from the condition $\lambda \leq \mu \times p$ the measure $\lambda \in \mathcal{M}$ on the product space $I \times \Omega$ appears in the dual optimization problem (4.4) via its marginal measures λ_I and λ_Ω. We can exploit this fact to achieve a reduction of the space of variables similar to that seen in the case of the primal problem. The main tool for this reduction is Strassen's theorem on the existence of measures with given marginals [33, Theorem 6]. We present here its version in the setting suitable for direct application to our problem.

THEOREM 5.1. *Let $\kappa \in \mathcal{M}^+$, $\beta \in \mathbf{rca}(I)$, and let α be a measure on $(\Omega, \mathcal{F})$. There exists a measure $\lambda \in \mathcal{M}^+$ having marginal measures $\lambda_I = \beta$ and $\lambda_\Omega = \alpha$ and such that $\lambda \leq \kappa$ if and only if*

$$\beta(B) + \alpha(A) \leq \psi + \kappa(B \times A) \quad \forall\, B \in \mathcal{B} \quad \forall\, A \in \mathcal{F},$$

where $\psi = \beta(I) = \alpha(\Omega)$.

Observe that setting $B = I$ we obtain $\alpha(A) \leq \kappa(B \times A)$ for all $A \in \mathcal{F}$. Employing the definition of $\mathcal{M}^+$ we conclude that it is necessary that $d\alpha/dP \in \mathcal{L}_\infty(\Omega, \mathcal{F}, P)$.

Applying Theorem 5.1 to the dual problem (4.4) with $\kappa = \mu \times P$, we obtain the following equivalent formulation of the dual problem:

$$\begin{aligned} \underset{\alpha,\beta,\mu,\psi}{\text{minimize}} \quad & -\int_I \eta \, d\beta + \int_I v \, d\mu + \sup_{z \in Z} \left(f(z) + \int_\Omega [G(z)](\omega) \, d\alpha \right) \\ \text{subject to} \quad & \beta(I) = \psi, \qquad \alpha(\Omega) = \psi, \\ & \beta(B) + \alpha(A) \leq \psi + \mu(B) P(A) \quad \forall\, B \in \mathcal{B} \quad \forall\, A \in \mathcal{F}, \\ & \alpha \geq 0, \quad \frac{d\alpha}{dP} \in \mathcal{L}_\infty(\Omega, \mathcal{F}, P), \quad \beta, \mu \in \mathbf{rca}^+(I). \end{aligned} \tag{5.1}$$

Note that the measure λ on the product space $I \times \Omega$ is eliminated from this formulation, at the cost of introducing new constraints indexed by the family $\mathcal{B} \times \mathcal{F}$. The merits of this trade-off become apparent for problems with discrete distributions, where we propose a column generation method.

6. An implied transportation problem. We now focus again on the finite probability space $\Omega = \{\omega_1, \ldots, \omega_N\}$ with corresponding probabilities $p_1, \ldots, p_N$. The realizations of the benchmark outcome Y are denoted by $y_1, \ldots, y_D$, and the corresponding benchmark shortfalls are $v_j = \mathrm{E}([y_j - Y]_+)$.

We recall for convenience the dual problem (4.4) in this case. The measure λ becomes an array λ_{ij}, $i = 1, \ldots, N$, $j = 1, \ldots, D$. The marginal measures are its row and column sums, respectively. We obtain the following formulation:

$$\begin{aligned} \underset{\lambda,\mu}{\text{minimize}} \quad & -\sum_{j=1}^{D} \sum_{i=1}^{N} \lambda_{ij} y_j + \sum_{j=1}^{D} \mu_j v_j + \sup_{z \in Z} \left\{ f(z) + \sum_{i=1}^{N} \sum_{j=1}^{D} \lambda_{ij} G_i(z) \right\} \\ \text{subject to} \quad & \lambda_{ij} \leq p_i \mu_j, \quad i = 1, \ldots, N, \quad j = 1, \ldots, D, \\ & \lambda \geq 0, \quad \mu \geq 0. \end{aligned} \tag{6.1}$$

Consider the marginal sums

$$\alpha_i = \sum_{j=1}^{D} \lambda_{ij}, \quad i = 1, \dots, N,$$
$$\beta_j = \sum_{i=1}^{N} \lambda_{ij}, \quad j = 1, \dots, D.$$

Vectors $\alpha \geq 0$ and $\beta \geq 0$ are marginal sums of a feasible dual variable λ if and only if the following conditions are satisfied:

(i) for some $\psi \geq 0$ we have $\sum_{i=1}^{N} \alpha_i = \sum_{j=1}^{D} \beta_j = \psi$;

(ii) there exists a transportation flow of value ψ in the network having N source nodes with supplies α, D destination nodes with demands β, and arc capacities equal to $p_i \mu_j$ for every arc (i, j), $i = 1, \dots, N$, $j = 1, \dots, D$.

In the discrete case Strassen's theorem takes on the form of the *maximum flow–minimum cut theorem* [11, 13]: For all $A \subset \{1, \dots, N\}$ and all $B \subset \{1, \dots, D\}$

$$\sum_{i \in A} \alpha_i + \sum_{j \in B} \beta_j - \sum_{i \in A} p_i \sum_{j \in B} \mu_j \leq \psi. \tag{6.2}$$

The dual formulation based on this fact and corresponding to (5.1) is

$$\begin{aligned} \underset{\alpha, \beta, \mu, \psi}{\text{minimize}} \quad & -\sum_{j=1}^{D} y_j \beta_j + \sum_{j=1}^{D} v_j \mu_j + \sup_{z \in Z} \left\{ f(z) + \sum_{i=1}^{N} \alpha_i G_i(z) \right\} \\ \text{subject to} \quad & \sum_{i=1}^{N} \alpha_i = \psi, \qquad \sum_{j=1}^{D} \beta_j = \psi, \\ & \sum_{i \in A} \alpha_i + \sum_{j \in B} \beta_j - \sum_{i \in A} p_i \sum_{j \in B} \mu_j \leq \psi \\ & \qquad \forall\, A \subset \{1, \dots, N\} \quad \forall\, B \subset \{1, \dots, D\} \\ & \alpha \geq 0, \quad \beta \geq 0, \quad \mu \geq 0, \quad \psi \geq 0. \end{aligned} \tag{6.3}$$

In this formulation ND dual variables of (6.1) are replaced by $N + D$ marginal sums, at the cost of introducing 2^{N+D} new constraints, indexed by all possible sets A and B.

If the functions $f(\cdot)$ and $G_i(\cdot)$ are affine and the set Z is defined by linear equations and inequalities, then problem (6.3) becomes a linear programming problem. In a standard way, the term $\sup_{z \in Z} \{f(z) + \sum_{i=1}^{N} \alpha_i G_i(z)\}$ can be replaced by an affine function of α and linear inequalities involving α. All of these manipulations are the same as in linear programming duality theory. We illustrate them for a portfolio example in section 8.

The main difficulty associated with problem (6.3) is the large number of constraints. We show in section 7 a way to overcome this difficulty by generating only a subset of relevant constraints.

7. A dual column generation method. Formulation (6.3) suggests a cutting plane method of the following form: At iteration k we have pairs of sets $A_m \subset \{1, \dots, N\}$ and $B_m \subset \{1, \dots, D\}$, $m = 1, \dots, k-1$. We solve a relaxation of problem

(6.3):

$$\begin{aligned}
&\underset{\alpha,\beta,\mu,\psi}{\text{minimize}} \quad -\sum_{j=1}^{D} y_j\beta_j + \sum_{j=1}^{D} v_j\mu_j + \sup_{z\in Z}\left\{ f(z) + \sum_{i=1}^{N} \alpha_i G_i(z)\right\} \\
&\text{subject to} \quad \sum_{i=1}^{N} \alpha_i = \psi, \qquad \sum_{j=1}^{D} \beta_j = \psi, \\
&\qquad \sum_{i\in A_m} \alpha_i + \sum_{j\in B_m} \beta_j - \sum_{i\in A_m} p_i \sum_{j\in B_m} \mu_j \le \psi, \quad m = 1,\dots,k-1, \\
&\qquad \alpha \ge 0, \quad \beta \ge 0, \quad \mu \ge 0, \quad \psi \ge 0.
\end{aligned} \tag{7.1}$$

The next step is to verify inequalities (6.2) for all possible sets A and B at the optimal solution $(\alpha^k, \beta^k, \mu^k, \psi^k)$. To this end, we find a pair A_k, B_k which solves the problem

$$\underset{\substack{A\subset\{1,\dots,N\}\\ B\subset\{1,\dots,D\}}}{\text{maximize}} \quad -\psi^k + \sum_{i\in A} \alpha_i^k + \sum_{j\in B} \beta_j^k - \sum_{i\in A} p_i \sum_{j\in B} \mu_j^k. \tag{7.2}$$

Defining the complement event $A^c = \{1,\dots,N\} \setminus A$ we observe that the first three terms in (7.2) describe the required inflow to the set of nodes $A^c \cup B$. The last term in (7.2) is the total capacity of the arcs leading to this set, that is, the arcs starting in A and ending in B. It follows that problem (7.2) is a problem of finding a minimal cut in a bipartite graph. It can be solved in a very efficient way by special network algorithms, as described in [1]. One method, which is closely related to our transformation, is the following. We formulate the maximum flow problem:

$$\begin{aligned}
&\underset{\lambda}{\text{maximize}} \quad \sum_{i=1}^{N}\sum_{j=1}^{D} \lambda_{ij} \\
&\text{subject to} \quad \sum_{j=1}^{D} \lambda_{ij} \le \alpha_i^k, \quad i = 1,\dots,N, \qquad (7.3)\\
&\qquad \sum_{i=1}^{N} \lambda_{ij} \le \beta_j^k, \quad j = 1,\dots,D, \qquad (7.4)\\
&\qquad 0 \le \lambda_{ij} \le p_i\mu_j^k, \quad i = 1,\dots,N, \quad j = 1,\dots,D.
\end{aligned}$$

If the flow equals ψ^k, then the optimal solution of (7.1) is also optimal for (6.3). Otherwise, we denote the Lagrange multipliers associated with (7.3) by ζ_i, $i = 1,\dots,N$, and the Lagrange multipliers associated with (7.4) by ξ_j, $j = 1,\dots,D$ (they all are equal to either 0 or 1). We set

$$A_k = \{i : \zeta_i = 0\}, \qquad B_k = \{j : \xi_j = 0\},$$

and we add the pair (A_k, B_k) to the pairs of sets included in (7.1), increase k by 1, and continue.

Observe that if the maximum in (7.2) is positive (and thus the maximum flow in the last displayed problem is smaller than ψ^k), the new cut is different than the cuts already included in problem (7.1). As the number of possible cuts is finite, the method must eventually stop at an optimal solution. In that case the flow in the network gives us the optimal values of the multipliers λ in the dual problem (6.1).

8. Numerical illustration. Let $R_1, \dots, R_n$ be random return rates of assets $1, \dots, n$. We denote the fractions of the initial capital invested in these assets by $z_1, \dots, z_n$. Clearly, the portfolio return rate equals

$$G(z) = R_1 z_1 + \cdots + R_n z_n.$$

The set of possible asset allocations is the simplex

$$Z = \{z \in \mathrm{R}^n : z_1 + \cdots + z_n = 1,\ z_k \geq 0,\ k = 1, \dots, n\},$$

but the approach outlined here easily extends to more general polyhedral sets Z. Finally, let a benchmark random return rate Y be given; for example, Y may represent the return rate of an index or the return rate of the current portfolio. The dominance-constrained portfolio optimization problem takes on the form

$$\begin{aligned} \underset{z}{\text{maximize}}\ & \mathrm{E}\big[R_1 z_1 + \cdots + R_n z_n\big] \\ \text{subject to}\ & R_1 z_1 + \cdots + R_n z_n \succeq_{(2)} Y, \\ & z \in Z. \end{aligned}$$

This model was introduced as an example in [4] and analyzed in [8].

As discussed in the introduction, no risk-averse decision maker will prefer a portfolio with return rate Y over a portfolio with return rate $R_1 z_1 + \cdots + R_n z_n$. Therefore, the risk exposure of the portfolio return rate is "more acceptable" than that of Y. In our model we use the expected value of the portfolio return rate as the objective functional, and thus the entire burden of controlling risk is carried by the stochastic dominance constraint. As the distribution of the returns at the solution is indirectly shaped by the distribution of the benchmark Y, it is essential that Y be "acceptable," for example, the return rate of a broad market index. However, it is easy to additionally incorporate risk-averse objective functionals to our model, such as coherent measures of risk (see [2, 9, 10, 20, 31] and the references therein).

In the discrete distribution case, we denote the return of asset k in event i by r_{ik}, $i = 1, \dots, N$, $k = 1, \dots, n$, the probabilities of the elementary events by p_i, $i = 1, \dots, N$, the realizations of the benchmark returns by y_j, and the benchmark shortfalls by

$$v_j = \sum_{i=1}^{N} p_i (y_j - y_i)_+.$$

We obtain the following problem:

$$\begin{aligned} \underset{z}{\text{maximize}}\quad & \sum_{i=1}^{N} \sum_{k=1}^{n} p_i r_{ik} z_k \\ \text{subject to}\quad & \sum_{i=1}^{N} p_i \left(y_j - \sum_{k=1}^{n} r_{ik} z_k \right)_+ \leq v_j, \quad j = 1, \dots, N, \\ & z \in Z. \end{aligned}$$

The piecewise linear constraint is dealt with by the primal cutting plane method.

TABLE 8.1
Dimensions of the three formulations.

Scenarios	Linear Programming		Primal Formulation		Dual Formulation	
	Variables	Constraints	Variables	Constraints	Variables	Constraints
50	3000	2551	500	1	152	502
100	10500	10101	500	1	302	502
150	23000	22651	500	1	452	502
200	40500	40201	500	1	602	502
500	250500	250001	500	1	1502	502
750	563000	562501	500	1	2252	502
1000	1000500	1000001	500	1	3002	502

The dual problem (6.3) takes on the following form:

$$
\begin{aligned}
\underset{\alpha,\beta,\mu,\psi,\zeta}{\text{minimize}} \quad & -\sum_{j=1}^{N} y_j\beta_j + \sum_{j=1}^{N} v_j\mu_j + \zeta \\
\text{subject to} \quad & \sum_{i=1}^{N} \alpha_i = \psi, \qquad \sum_{j=1}^{N} \beta_j = \psi, \\
& \sum_{i=1}^{N} (p_i + \alpha_i) r_{ik} \le \zeta, \quad k = 1, \ldots, n, \\
& \sum_{i\in A} \alpha_i + \sum_{j\in B} \beta_j - \sum_{i\in A} p_i \sum_{j\in B} \mu_j \le \psi \quad \forall\, A \subset \{1, \ldots, N\} \\
& \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \forall\, B \subset \{1, \ldots, N\} \\
& \alpha \ge 0, \quad \beta \ge 0, \quad \mu \ge 0, \quad \psi \ge 0.
\end{aligned}
$$

The variable ζ in the objective function of this problem represents the term

$$
\begin{aligned}
\sup_{z\in Z} \left\{ f(z) + \sum_{i=1}^{N} \alpha_i G_i(z) \right\} &= \sup_{z\in Z} \left\{ \sum_{i=1}^{N} \sum_{k=1}^{n} p_i r_{ik} z_k + \sum_{i=1}^{N} \sum_{k=1}^{n} \alpha_i r_{ik} z_k \right\} \\
&= \max_{1\le k\le n} \sum_{i=1}^{N} (p_i + \alpha_i) r_{ik}.
\end{aligned}
$$

The constraints involving the sets A and B are dealt with by the dual cutting plane method.

We considered several problem instances of different sizes, obtained from historical data on realizations of joint daily returns of $n = 500$ assets in N days, for seven different values of N ranging from 50 to 1000. We used the returns in each day as equally probable realizations of the n-dimensional random vector R. The benchmark outcome Y was the return rate of the Standard & Poors 500 index. All calculations were carried out on a 2.00 GHz Pentium 4 PC with 1.00 GB of RAM by using the AMPL modeling language [12] and with version 9.1 of the CPLEX solver [15].

Table 8.1 compares the sizes of the three formulations: The straightforward linear programming model (2.1), the primal cutting plane formulation (2.2), and the dual cutting plane formulation (5.1). In the last two cases we report the initial numbers of constraints only, without the cuts indexed by the sets $A \in \mathcal{F}$ and $B \in \mathcal{B}$. The numbers of cuts, which were actually generated in the course of the solution, are reported in

TABLE 8.2
Performance of the three approaches.

Scenarios	Linear Programming		Primal Method			Dual Method		
	CPU	Iterations	CPU	Cuts	Iterations	CPU	Cuts	Iterations
50	3.44	570	0.55	9	9	13.81	68	6883
100	20.23	3161	2.03	33	75	407.26	259	156304
150	372.52	7272	3.49	53	267	9144.25	552	1155166
200	373.63	16666	3.90	61	180	-	-	-
500	-	-	6.59	88	924	-	-	-

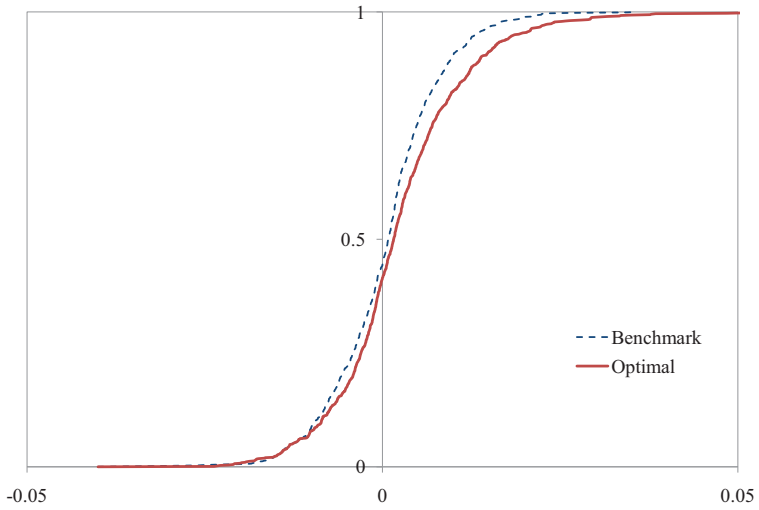

FIG. 8.1. *Cumulative distribution functions of the return rates of the benchmark and optimal portfolios in the* 1000 *scenario example.*

Table 8.2. This table provides also the CPU times of the simplex solver in the three cases and the total numbers of simplex iterations performed.

It can be seen from these results that the primal cut generation method is quite efficient, and it dramatically outperforms the direct linear programming approach. This is consistent with the results of [17] for integrated chance constraints. In fact, the direct linear programming model was too large for our computer for 500 scenarios and more. The dual method is much slower for this problem class, mainly due to minimal differences between many cuts and severe numerical difficulties associated with that. For problems with $N = 200$ scenarios and more, we interrupted the calculation because of excessive time. Apparently, the number of Strassen cuts is too large. However, we still believe that the dual formulation is interesting in its own right and that one day it may find its application.

Finally, Figure 8.1 compares the cumulative distribution functions of the return rates of the benchmark portfolio (the S&P 500 index) and of the solution to the dominance-constrained problem for the case of 1000 scenarios. The optimal portfolio contains only 11 assets, but we can see that they are sufficient to shape the distribution function in a favorable way. Close inspection reveals that the optimal distribution function is not entirely below the benchmark (this would mean first order stochastic

dominance); in the range between -0.02 and -0.015 it is slightly above. However, the expected shortfall (1.2) is always smaller at the solution than at the benchmark. This is in line with the results of [23], where similar examples are presented.

Acknowledgments. The authors are grateful to two anonymous referees for their insightful comments which helped to improve the presentation of this paper.

A MINIMAX THEOREM WITH APPLICATIONS TO MACHINE LEARNING, SIGNAL PROCESSING, AND FINANCE*

SEUNG-JEAN KIM† AND STEPHEN BOYD†

Abstract. This paper concerns a fractional function of the form $x^T a/\sqrt{x^T Bx}$, where B is positive definite. We consider the game of choosing x from a convex set, to maximize the function, and choosing (a, B) from a convex set, to minimize it. We prove the existence of a saddle point and describe an efficient method, based on convex optimization, for computing it. We describe applications in machine learning (robust Fisher linear discriminant analysis), signal processing (robust beamforming and robust matched filtering), and finance (robust portfolio selection). In these applications, x corresponds to some design variables to be chosen, and the pair (a, B) corresponds to the statistical model, which is uncertain.

Key words. convex optimization, minimax theorem, robust optimization

1. Introduction.

This paper concerns a fractional function of the form

$$f(x, a, B) = \frac{x^T a}{\sqrt{x^T Bx}}, \tag{1}$$

where $x, a \in \mathbb{R}^n$ and $B = B^T \in \mathbb{R}^{n\times n}$. We assume that $x \in \mathcal{X} \subseteq \mathbb{R}^n\backslash\{0\}$ and $(a, B) \in \mathcal{U} \subseteq \mathbb{R}^n \times \mathbb{S}^n_{++}$. Here $\mathbb{S}^n_{++}$ denotes the set of $n \times n$ symmetric positive definite matrices.

We list some of the basic properties of the function f. It is (positive) homogeneous (of degree zero) in x: for all $t > 0$,

$$f(tx, a, B) = f(x, a, B).$$

If

$$x^T a \geq 0 \text{ for all } x \in \mathcal{X} \text{ and for all } a, \text{ with } (a, B) \in \mathcal{U}, \tag{2}$$

then for fixed $(a, B) \in \mathcal{U}$, f is quasi-concave in x, and for fixed $x \in \mathcal{X}$, f is quasi-convex in (a, B). This can be seen as follows: for $\gamma \geq 0$, the set

$$\{x \mid f(a, B, x) \geq \gamma\} = \left\{x \;\middle|\; \gamma\sqrt{x^T Bx} \leq x^T a\right\}$$

is convex (since it is a second-order cone in $\mathbb{R}^n$), and the set

$$\{(a, B) \mid f(a, B, x) \leq \gamma\} = \left\{(a, B) \;\middle|\; \gamma\sqrt{x^T Bx} \geq x^T a\right\}$$

is convex (since $\sqrt{x^T Bx}$ is concave in B).

A zero-sum game and related problems. In this paper we consider the zero-sum game of choosing x from a convex set $\mathcal{X}$, to maximize the function, and choosing (a, B) from a convex compact set $\mathcal{U}$, to minimize it. The game is associated with the following two problems:

- max-min problem

$$\begin{array}{ll} \text{maximize} & \inf\limits_{(a,B)\in\mathcal{U}} f(x,a,B) \\ \text{subject to} & x \in \mathcal{X}, \end{array} \tag{3}$$

  with variables $x \in \mathbb{R}^n$,
- min-max problem

$$\begin{array}{ll} \text{minimize} & \sup\limits_{x\in\mathcal{X}} f(x,a,B) \\ \text{subject to} & (a,B) \in \mathcal{U}, \end{array} \tag{4}$$

  with variables $a \in \mathbb{R}^n$ and $B = B^T \in \mathbb{R}^{n\times n}$.

Problems of the form (3) arise in several disciplines including machine learning (robust Fisher linear discriminant analysis), signal processing (robust beamforming and robust matched filtering), and finance (robust portfolio selection). In these applications, x corresponds to some design variables to be chosen, and the pair (a, B) corresponds to the first and second moments of a random vector, say, $\mathbf{Z}$, which are uncertain. We want to choose x so that the combined random variable $x^T\mathbf{Z}$ is well separated from zero. The ratio of the mean of the random variable to the standard deviation $f(x, a, B)$ measures the extent to which the random variable can be well separated from zero. The max-min problem is to find the design variables that are optimal in a worst-case sense, where worst-case means over all possible statistics. The min-max problem is to find the least-favorable statistical model, with the design variables chosen optimally for the statistics.

Minimax properties. The minimax inequality or *weak minimax property*

$$\sup_{x\in\mathcal{X}} \inf_{(a,B)\in\mathcal{U}} f(x,a,B) \le \inf_{(a,B)\in\mathcal{U}} \sup_{x\in\mathcal{X}} f(x,a,B) \tag{5}$$

always holds for any $\mathcal{X} \subseteq \mathbb{R}$ and any $\mathcal{U} \subseteq \mathbb{S}^n_{++}$. The minimax equality or *strong minimax property*

$$\sup_{x\in\mathcal{X}} \inf_{(a,B)\in\mathcal{U}} f(x,a,B) = \inf_{(a,B)\in\mathcal{U}} \sup_{x\in\mathcal{X}} f(x,a,B) \tag{6}$$

holds if $\mathcal{X}$ is convex, $\mathcal{U}$ is convex and compact, and (2) holds, which follows from Sion's quasi-convex–quasi-concave minimax theorem [25].

In this paper we will show that the strong minimax property holds with a weaker assumption than (2):

$$\text{there exists } \bar{x} \in \mathcal{X} \text{ such that } \bar{x}^T a > 0 \text{ for all } a \text{ with } (a, B) \in \mathcal{U}. \tag{7}$$

To state the minimax result, we first describe an equivalent formulation of the min-max problem (4).

PROPOSITION 1. *Suppose that $\mathcal{X}$ is a cone in $\mathbb{R}^n$ that does not contain the origin, with $\mathcal{X} \cup \{0\}$ convex and closed, and $\mathcal{U}$ is a compact subset of $\mathbb{R}^n \times \mathbb{S}^n_{++}$. Suppose further that* (7) *holds. Then, the min-max problem* (4) *is equivalent to*

$$\begin{array}{ll} \textit{minimize} & (a+\lambda)^T B^{-1}(a+\lambda) \\ \textit{subject to} & (a,B) \in \mathcal{U}, \quad \lambda \in \mathcal{X}^*, \end{array} \tag{8}$$

where $a \in \mathbb{R}^n$, $B = B^T \in \mathbb{R}^{n\times n}$, and $\lambda \in \mathbb{R}^n$ are the variables and $\mathcal{X}^*$ is the dual

cone of $\mathcal{X}$ *given by*

$$\mathcal{X}^* = \left\{\lambda \in \mathbb{R}^n \mid \lambda^T x \geq 0 \ \forall x \in \mathcal{X}\right\},$$

in the following sense: if $(a^\star, B^\star, \lambda^\star)$ *solves* (8)*, then* $(a^\star, B^\star)$ *solves* (4)*, and conversely if* $(a^\star, B^\star)$ *solves* (4)*, then there exists* $\lambda^\star \in \mathcal{X}^*$ *such that* $(a^\star, B^\star, \lambda^\star)$ *solves* (8)*. Moreover,*

$$\inf_{(a,B)\in\mathcal{U}} \sup_{x\in\mathcal{X}} f(x,a,B) = \left(\inf_{(a,B)\in\mathcal{U},\ \lambda\in\mathcal{X}^*} (a+\lambda)^T B^{-1}(a+\lambda)\right)^{1/2}.$$

Finally, (8) *always has a solution, and for any solution* $(a^\star, B^\star, \lambda^\star)$*,*

$$a^\star + \lambda^\star \neq 0.$$

The proof is deferred to the appendix.

The dual cone $\mathcal{X}^*$ is always convex. The objective of (8) is convex since a function of the form $f(x,X) = x^T X^{-1} x$, called a matrix fractional function, is convex over $\mathbb{R}^n \times \mathbb{S}^n_{++}$; see, e.g., [7, section 3.1.7]. Therefore, (8) is a convex problem. We conclude that the min-max problem (4) can be reformulated as the convex problem (8).

We can solve the max-min problem (3), using a minimax result for the fractional function $f(x,a,B)$.

THEOREM 1. *Suppose that* $\mathcal{X}$ *is a cone in* $\mathbb{R}^n$ *that does not contain the origin, with* $\mathcal{X} \cup \{0\}$ *convex and closed, and* $\mathcal{U}$ *is a convex compact subset of* $\mathbb{R}^n \times \mathbb{S}^n_{++}$*. Suppose further that* (7) *holds. Let* $(a^\star, B^\star, \lambda^\star)$ *be a solution to the convex problem* (8) *(whose existence is guaranteed in Proposition* 1*). Then,*

$$x^\star = B^{\star -1}(a^\star + \lambda^\star) \in \mathcal{X},$$

and the triple $(x^\star, a^\star, B^\star)$ *satisfies the* saddle-point property

$$f(x,a^\star,B^\star) \leq f(x^\star,a^\star,B^\star) \leq f(x^\star,a,B) \quad \forall x \in \mathcal{X} \quad \forall (a,B) \in \mathcal{U}. \tag{9}$$

The proof is deferred to the appendix.

We show that the assumption (7) is needed for the strong minimax property to hold. Consider $\mathcal{X} = \mathbb{R}^n \backslash \{0\}$ and $\mathcal{U} = \mathcal{B}_1 \times \{I\}$, where $\mathcal{B}_1$ is the Euclidean ball of radius one. Then, all of the assumptions hold except for (7). We have

$$\sup_{x\neq 0} \inf_{(a,B)\in\mathcal{U}} \frac{x^T a}{\sqrt{x^T B x}} = \sup_{x\neq 0} \inf_{a\in\mathcal{B}_1} \frac{x^T a}{\sqrt{x^T x}} = \sup_{x\neq 0} \frac{-\|x\|}{\|x\|} = -1$$

and

$$\inf_{(a,B)\in\mathcal{U}} \sup_{x\neq 0} \frac{x^T a}{\sqrt{x^T B x}} = \inf_{a\in\mathcal{B}_1} \sup_{x\neq 0} \frac{x^T a}{\|x\|} = \inf_{a\in\mathcal{B}_1} \frac{\|x\|\|a\|}{\|x\|} = 0.$$

From a standard result [2, section 2.6] in minimax theory, the saddle-point property (9) means that

$$\begin{aligned} f(x^\star,a^\star,B^\star) &= \sup_{x\in\mathcal{X}} f(x,a^\star,B^\star) \\ &= \inf_{(a,B)\in\mathcal{U}} f(x^\star,a,B) \\ &= \sup_{x\in\mathcal{X}} \inf_{(a,B)\in\mathcal{U}} f(x,a,B) \\ &= \inf_{(a,B)\in\mathcal{U}} \sup_{x\in\mathcal{X}} f(x,a,B). \end{aligned}$$

As a consequence, $x^\star$ solves (3).

More computational results. The max-min problem (3) has a unique solution up to (positive) scaling.

PROPOSITION 2. *Under the assumptions of Theorem* 1, *the max-min problem* (3) *has a unique solution up to (positive) scaling, meaning that for any two solutions* $x^\star$ *and* $y^\star$, *there is a positive number* $\alpha > 0$ *such that* $x^\star = \alpha y^\star$.

The proof is deferred to the appendix.

The convex problem (8) can be reformulated as a standard convex optimization problem. Using the Schur complement technique [7, Appendix 5.5], we can see that

$$(a+\lambda)^T B^{-1}(a+\lambda) \le t$$

if and only if the linear matrix inequality (LMI)

$$\begin{bmatrix} t & (a+\lambda)^T \\ a+\lambda & B \end{bmatrix} \succeq 0$$

holds. (Here $A \succeq 0$ means that A is positive semidefinite.) The convex problem (8) is therefore equivalent to

$$\begin{array}{ll} \text{minimize} & t \\ \text{subject to} & (a,B) \in \mathcal{U}, \quad \lambda \in \mathcal{X}^*, \quad \begin{bmatrix} t & (a+\lambda)^T \\ a+\lambda & B \end{bmatrix} \succeq 0, \end{array}$$

where the variables are $t \in \mathbb{R}$, $a \in \mathbb{R}^n$, $B = B^T \in \mathbb{R}^{n\times n}$, and $\lambda \in \mathbb{R}^n$. When the uncertainty sets $\mathcal{U}$ can be represented by LMIs, this problem is a semidefinite program (SDP). (Several high-quality open-source solvers for SDPs are available, e.g., SeDuMi [26], SDPT3 [27], and DSDP5 [1].) The reader is referred to [6, 29] for more on semidefinite programming and LMIs.

Outline of the paper. In the next section, we give a probabilistic interpretation of the saddle-point property established above. In sections 3–5, we give the applications of the minimax result in machine learning, signal processing, and portfolio selection. We give our conclusions in section 6. The appendix contains the proofs that are omitted from the main text.

2. A probabilistic interpretation.

2.1. Probabilistic linear separation. Suppose $z \sim \mathcal{N}(a,B)$ and $x \in \mathbb{R}^n$. Here, we use $\mathcal{N}(a,B)$ to denote the Gaussian distribution with mean a and covariance B. Then, $x^T z \sim \mathcal{N}(x^T a, x^T B x)$, so

$$\textbf{Prob}\left(x^T z \ge 0\right) = \Phi\left(\frac{x^T a}{\sqrt{x^T B x}}\right), \tag{10}$$

where Φ is the cumulative distribution function of the standard normal distribution.

Theorem 1 with $\mathcal{U} = \{(a,B)\}$ tells us that the right-hand side of (10) is maximized (over $x \in \mathcal{X}$) by $x = B^{-1}(a+\lambda^\star)$, where $\lambda^\star$ solves the convex problem (8) with $\mathcal{U} = \{(a,B)\}$. In other words, $x = B^{-1}(a+\lambda^\star)$ gives the hyperplane through the origin that maximizes the probability of z being on its positive side. The associated maximum probability is $\Phi([(a+\lambda^\star)^T B^{-1}(a+\lambda^\star)]^{1/2})$. Thus, $(a+\lambda^\star)^T B^{-1}(a+\lambda^\star)$ (which is the objective of (8)) can be used to measure the extent to which a hyperplane perpendicular to $x \in \mathcal{X}$ can separate a random signal $z \sim \mathcal{N}(a,B)$ from the origin.

We give another interpretation. Suppose that we know the mean $\mathbf{E}\, z = a$ and the covariance $\mathbf{E}(z-a)(z-a)^T = B$ of z, but its third and higher moments are unknown.

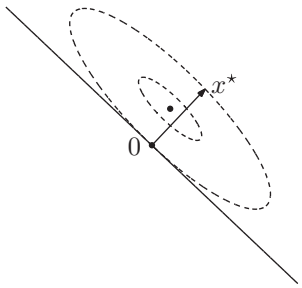

FIG. 1. *Illustration of $x^\star = B^{-1}a$. The center of the two confidence ellipsoids (whose boundaries are shown as dashed line curves) is a, and their shapes are determined by B.*

Here $\mathbf{E}$ denotes the expectation operation. Then, $\mathbf{E}\, x^T z = x^T a$ and $\mathbf{E}(x^T z - x^T a)^2 = x^T B x$, so by the Chebyshev bound, we have

$$\mathbf{Prob}\left(x^T z \geq 0\right) \geq \Psi\left(\frac{x^T a}{\sqrt{x^T B x}}\right), \tag{11}$$

where

$$\Psi(u) = \frac{\max\{u, 0\}^2}{1 + \max\{u, 0\}^2}.$$

This bound is sharp; in other words, there is a distribution for z with mean a and covariance B for which equality holds in (11) [3, 30]. Since Ψ is increasing, this probability is also maximized by $x = B^{-1}(a + \lambda^\star)$. Thus, $x = B^{-1}(a + \lambda^\star)$ gives the hyperplane through the origin and perpendicular to $x \in \mathcal{X}$ that maximizes the Chebyshev lower bound for $\mathbf{Prob}(x^T z \geq 0)$. The maximum value of the Chebyshev lower bound is $p^\star/(1 + p^\star)$, where $p^\star = \left[(a + \lambda^\star)^T B^{-1}(a + \lambda^\star)\right]^{1/2}$. This quantity assesses the maximum extent to which a hyperplane perpendicular to $x \in \mathcal{X}$ can separate from the origin a random signal z, whose first and second moments are known but otherwise arbitrary. This quantity is an increasing function of $p^\star$, so the hyperplane perpendicular to $x \in \mathcal{X}$ that maximally separates from the origin a Gaussian random signal $z \sim \mathcal{N}(a, B)$ also maximally separates, in the sense of the Chebyshev bound, a signal with known mean and covariance.

When $\mathcal{X} = \mathbb{R}^n \backslash \{0\}$, we have $\mathcal{X}^* = 0$, so $x = B^{-1}a$ maximizes the right-hand side of (10). We can give its graphical interpretation. We find the confidence ellipsoid of the Gaussian distribution $\mathcal{N}(a, B)$, whose boundary touches the origin. This ellipsoid is tangential to the hyperplane through the origin and perpendicular to $x = B^{-1}a$. Figure 1 illustrates this interpretation in $\mathbb{R}^2$.

2.2. Robust linear separation. We now assume that the mean and covariance are uncertain but known to belong to a convex compact subset $\mathcal{U}$ of $\mathbb{R}^n \times \mathbb{S}^n_{++}$. We make one assumption: for each $(a, \Sigma) \in \mathcal{U}$, we have $a \neq 0$. In other words, we rule out the possibility that the mean is zero.

Theorem 1 tells us that there exists a triple $(x^\star, a^\star, B^\star)$, with $x^\star \in \mathcal{X}$ and $(a^\star, B^\star) \in \mathcal{U}$, such that

$$\Phi\left(\frac{x^T a^\star}{\sqrt{x^T B^\star x}}\right) \leq \Phi\left(\frac{x^{\star T} a^\star}{\sqrt{x^{\star T} B^\star x^\star}}\right) \leq \Phi\left(\frac{x^{\star T} a}{\sqrt{x^{\star T} B x^\star}}\right) \quad \forall x \in \mathcal{X} \quad \forall (a, B) \in \mathcal{U}. \tag{12}$$

Here we use the fact that Φ is strictly increasing.

From the saddle-point property (12), we can see that $x^\star$ solves

$$\begin{array}{ll} \text{maximize} & \inf\limits_{(a,B)\in\mathcal{U}, z\sim\mathcal{N}(a,B)} \mathbf{Prob}\left(x^T z \geq 0\right) \\ \text{subject to} & x \in \mathcal{X}, \end{array} \tag{13}$$

and the pair $(a^\star, B^\star)$ solves

$$\begin{array}{ll} \text{minimize} & \sup\limits_{x\in\mathcal{X}, z\sim\mathcal{N}(a,B)} \mathbf{Prob}\left(x^T z > 0\right) \\ \text{subject to} & (a,B) \in \mathcal{U}. \end{array} \tag{14}$$

Problem (13) is to find a hyperplane through the origin and perpendicular to $x \in \mathcal{X}$ that separates robustly a normal random variable z on $\mathbb{R}^n$ with uncertain first and second moments belonging to $\mathcal{U}$. Problem (14) is to find the least-favorable model in terms of the separation probability (when the random variable is normal). It follows from (10) that (13) is equivalent to the max-min problem (3), and (14) is equivalent to (4) and hence to the convex problem (8) by Proposition 1. These two problems can be solved using convex optimization.

We close by pointing out that the same results hold with the Chebyshev bound as the separation probability.

3. Robust Fisher discriminant analysis. As another application, we consider a robust classification problem.

3.1. Fisher linear discriminant analysis. In linear discriminant analysis, we want to separate two classes which can be identified with two random variables in $\mathbb{R}^n$. Fisher linear discriminant analysis (FLDA) is a widely used technique for pattern classification, proposed by Fisher in the 1930s. The reader is referred to standard textbooks on statistical learning, e.g., [13], for more on FLDA.

For a (linear) discriminant characterized by $w \in \mathbb{R}^n$, the degree of discrimination is measured by the Fisher discriminant ratio

$$F(w, \mu_+, \mu_-, \Sigma_+, \Sigma_-) = \frac{\left(w^T(\mu_+ - \mu_-)\right)^2}{w^T(\Sigma_+ + \Sigma_-)w},$$

where μ_+ and Σ_+ (μ_+ and Σ_-) denote the mean and covariance, respectively, of examples drawn from the positive (negative) class. A discriminant that maximizes the Fisher discriminant ratio is given by

$$\bar{w} = (\Sigma_+ + \Sigma_-)^{-1}(\mu_+ - \mu_-),$$

which gives the maximum Fisher discriminant ratio

$$\sup_{w\neq 0} F(w, \mu_+, \mu_-, \Sigma_+, \Sigma_-) = (\mu_+ - \mu_-)^T(\Sigma_+ + \Sigma_-)^{-1}(\mu_+ - \mu_-).$$

Once the optimal discriminant is found, we can form the (binary) classifier

$$\phi(x) = \operatorname{sgn}\left(\bar{w}^T x + v\right), \tag{15}$$

where

$$\operatorname{sgn}(z) = \begin{cases} +1, & z > 0, \\ -1, & z \leq 0, \end{cases}$$

and v is the bias or threshold. The classifier picks the outcome, given x, according to the linear boundary between the two binary outcomes (defined by $\bar{w}^T x + v = 0$).

We can give a probabilistic interpretation of FLDA. Suppose that $x \sim \mathcal{N}(\mu_+, \Sigma_+)$ and $y \sim \mathcal{N}(\mu_-, \Sigma_-)$. We want to find w that maximizes $\mathbf{Prob}(w^T x > w^T y)$. Here,

$$x - y \sim \mathcal{N}(\mu_+ - \mu_-, \Sigma_+ + \Sigma_-),$$

so

$$\mathbf{Prob}\left(w^T x > w^T y\right) = \mathbf{Prob}\left(w^T (x-y) > 0\right) = \Phi\left(\frac{w^T(\mu_+ - \mu_-)}{\sqrt{w^T(\Sigma_+ + \Sigma_-)w}}\right).$$

This probability is called the nominal discrimination probability. Evidently, FLDA amounts to maximizing the fractional function

$$f(w, \mu_+ - \mu_-, \Sigma_+ + \Sigma_-) = \frac{w^T(\mu_+ - \mu_-)}{\sqrt{w^T(\Sigma_+ + \Sigma_-)w}}.$$

3.2. Robust Fisher linear discriminant analysis. In FLDA, the problem data or parameters (i.e., the first and second moments of the two random variables) are not known but are estimated from sample data. FLDA can be sensitive to the variation or uncertainty in the problem data, meaning that the discriminant computed from an estimate of the parameters can give very poor discrimination for another set of problem data that is also a reasonable estimate of the parameters. Robust FLDA attempts to systematically alleviate this sensitivity problem by explicitly incorporating a model of data uncertainty in the classification problem and optimizing for the worst-case scenario under this model; see [17] for more on robust FLDA and its extension.

We assume that the problem data μ_+, μ_-, Σ_+, and Σ_- are uncertain but known to belong to a convex compact subset $\mathcal{V}$ of $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{S}^n_{++} \times \mathbb{S}^n_{++}$. We make the following assumption:

$$\text{for each } (\mu_+, \mu_-, \Sigma_+, \Sigma_-) \in \mathcal{V}, \text{ we have } \mu_+ \neq \mu_-. \tag{16}$$

This assumption simply means that for each possible value of the means and covariances, the two classes are distinguishable via FLDA.

The *worst-case analysis problem* of finding the worst-case means and covariances for a given discriminant w can be written as

$$\begin{array}{ll} \text{minimize} & f(w, \mu_+ - \mu_-, \Sigma_+ + \Sigma_-) \\ \text{subject to} & (\mu_+, \mu_-, \Sigma_+, \Sigma_-) \in \mathcal{V}, \end{array} \tag{17}$$

with variables μ_+, μ_-, Σ_+, and Σ_-. Optimal points for this problem, say, $(\mu_+^{\mathrm{wc}}, \mu_-^{\mathrm{wc}}, \Sigma_+^{\mathrm{wc}}, \Sigma_-^{\mathrm{wc}})$, are called the *worst-case means and covariances*, which depend on w. With the worst-case means and covariances, we can compute the *worst-case discrimination probability*

$$\mathbf{P}_{\mathrm{wc}}(w) = \Phi\left(\frac{w^T(\mu_+^{\mathrm{wc}} - \mu_-^{\mathrm{wc}})}{\sqrt{w^T(\Sigma_+^{\mathrm{wc}} + \Sigma_-^{\mathrm{wc}})w}}\right)$$

(over the set $\mathcal{U}$ of possible means and covariances).

The *robust FLDA problem* is to find a discriminant that maximizes the worst-case Fisher discriminant ratio:

$$\begin{array}{ll} \text{maximize} & \inf\limits_{(\mu_+,\mu_-,\Sigma_+,\Sigma_-)\in\mathcal{V}} f(w, \mu_+ - \mu_-, \Sigma_+ + \Sigma_-) \\ \text{subject to} & w \neq 0, \end{array} \tag{18}$$

with variable w. Here we choose a linear discriminant that maximizes the Fisher discrimination ratio, with the worst possible means and covariances that are consistent with our data uncertainty model. Any solution to (18) is called a *robust optimal Fisher discriminant*.

The robust FLDA problem (18) has the form (3) with

$$\mathcal{U} = \{(\mu_+ - \mu_-, \Sigma_+ + \Sigma_-) \in \mathbb{R}^n \times \mathbb{S}^n_{++} \mid (\mu_+, \mu_-, \Sigma_+, \Sigma_-) \in \mathcal{U}\}.$$

In this problem, each element of the set $\mathcal{U}$ is a pair of the mean and covariance of the difference of the two random variables. For this problem, we can see from (16) that assumption (7) holds. The robust FLDA problem can therefore be solved by using the minimax result described above.

3.3. Numerical example. We illustrate the result with a classification problem in $\mathbb{R}^2$. The nominal means and covariances of the two classes are

$$\bar{\mu}_+ = (1, 0), \qquad \bar{\mu}_- = (-1, 0), \qquad \bar{\Sigma}_+ = \bar{\Sigma}_- = I \in \mathbb{R}^{2\times 2}.$$

We assume that only μ_+ is uncertain and lies within the ellipse

$$\mathcal{E} = \left\{\mu_+ \in \mathbb{R}^2 \mid \mu_+ = \bar{\mu}_+ + Pu,\ \|u\| \leq 1\right\},$$

where the matrix P which determines the shape of the ellipse is

$$P = \begin{bmatrix} 0.78 & 0.64 \\ 0.64 & 0.78 \end{bmatrix} \in \mathbb{R}^{2\times 2}.$$

Figure 2 illustrates the setting described above. Here the shaded ellipse corresponds to $\mathcal{E}$, and the dashed line curves are the set of points μ_+ and μ_- that satisfy

$$\left\|{\Sigma_+}^{-1/2}(\mu_+ - \bar{\mu}_+)\right\| = \|\mu_+ - \bar{\mu}_+\| = 1, \qquad \left\|{\Sigma_-}^{-1/2}(\mu_- - \bar{\mu}_-)\right\| = \|\mu_- - \bar{\mu}_-\| = 1.$$

The nominal optimal discriminant which maximizes the Fisher discriminant ratio with the nominal means and covariances is given by $w^{\text{nom}} = (1, 0)$. The robust optimal discriminant w^{rob} is computed using the method described above. Figure 2 shows two linear decision boundaries

$$x^T w^{\text{nom}} = 0, \qquad x^T w^{\text{rob}} = 0$$

determined by the two discriminants. Since the mean of the positive class is uncertain and the uncertainty is significant in a certain direction, the robust discriminant is tilted toward the direction.

Table 1 summarizes the results. Here, $\mathbf{P}_{\text{nom}}$ is the nominal discrimination probability and $\mathbf{P}_{\text{wc}}$ is the worst-case discrimination probability. The nominal optimal discriminant achieves $\mathbf{P}_{\text{nom}} = 0.92$, which corresponds to 92% of correct discrimination without uncertainty. However, with uncertainty present, its nominal discrimination probability degrades rapidly; the worst-case discrimination probability for the nominal optimal discriminant is 78%. The robust optimal discriminant performs well in the presence of uncertainty. It has a worst-case discrimination probability around 83%, 5% higher than that of the nominal optimal discriminant.

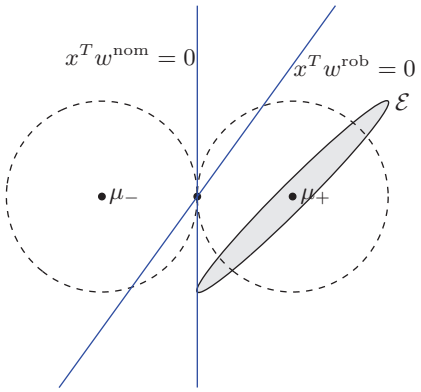

FIG. 2. *A simple example for robust FLDA.*

TABLE 1
Robust discriminant analysis results.

	$\mathbf{P}_{\text{nom}}$	$\mathbf{P}_{\text{wc}}$
Nominal optimal discriminant	0.92	0.78
Robust optimal discriminant	0.87	0.83

4. Robust matched filtering. We consider a signal model of the form

$$y(t) = s(t)a + v(t) \in \mathbb{R}^n,$$

where a is the steering vector, $s(t) \in \{0, 1\}$ is the binary source signal, $y(t) \in \mathbb{R}^n$ is the received signal, and $v(t) \sim \mathcal{N}(0, \Sigma)$ is the noise. We consider the problem of estimating $s(t)$, based on an observed sample of y. In other words, the sample is generated from one of the two possible distributions $\mathcal{N}(0, \Sigma)$ and $\mathcal{N}(a, \Sigma)$, and we are to guess which one.

After reviewing a basic result on optimal detection with the setting described above, we show how the minimax result given above allows us to design a robust detector that takes into account the uncertainty in the model parameters, namely, the steering vector and the noise covariance.

4.1. Matched filtering. A (deterministic) detector is a function ψ from $\mathbb{R}^n$ (the set of possible observed values) into $\{0, 1\}$ (the set of possible signal values or hypotheses). It can be expressed as

$$\psi(y) = \begin{cases} 0, & h(y) < t, \\ 1, & h(y) > t, \end{cases} \tag{19}$$

which thresholds a detection or test statistic, a function of the received signal, $h(y) \in \mathbb{R}$. Here t is the threshold that determines the boundary between the two hypotheses. A detector with a detection statistic of the form $h(y) = w^T y$ is called linear.

The performance of a detector ψ can be summarized by the pair $(P_{\text{fp}}, P_{\text{tp}})$, where

$$P_{\text{fp}} = \mathbf{Prob}(\psi(y) = 1 \mid s(t) = 0)$$

is the *false positive or alarm rate* (the probability that the signal is falsely detected when in fact there is no signal) and

$$P_{\text{tp}} = \mathbf{Prob}(\psi(y) = 1 \mid s(t) = 1)$$

is the *true positive rate* (the probability that the signal is detected correctly). The optimal detector design problem is a bicriterion problem, with objectives $P_{\rm fn}$ and $P_{\rm fp}$. The optimal trade-off curve between $P_{\rm fn}$ and $P_{\rm fp}$ is called the *receiver operating characteristic* (ROC).

The filtered output, with weight vector $w \in \mathbb{R}^n$, is given by

$$w^T y(t) = s(t) w^T a + w^T v(t).$$

The power of the steering vector $w^T a$ (which is deterministic) at the filtered output is given by $(w^T a)^2$, and the power of the undesired signal $w^T v$ at the filtered output is $w^T \Sigma w$. The signal to noise ratio (SNR) is

$$S(w, a, \Sigma) = \frac{\left(w^T a\right)^2}{w^T \Sigma w}.$$

The optimal ROC curve is obtained using a linear detection statistic $h(y) = w^{\star T} y$ with $w^\star$ maximizing

$$f(w, a, \Sigma) = \frac{w^T a}{\sqrt{w^T \Sigma w}},$$

which is the square root of the SNR (SSNR). (See, e.g., [28].) The weight vector that maximizes SSNR is given by $w = \Sigma^{-1} a$. When the covariance is a scaled identity matrix, the matched filter $w = a$ is optimal. Even when Σ is not a scaled identity matrix, the optimal weight vector is called the matched filter.

4.2. Robust matched filtering. Matched filtering is often sensitive to the uncertainty in the input parameters, namely, the steering vector and the noise covariance. Robust matched filtering attempts to alleviate the sensitivity problem by taking into account an uncertainty model in the detection problem. (The reader is referred to the tutorial [15] for more on robust signal detection.)

We assume that the desired signal and covariance matrix are uncertain but known to belong to a convex compact subset $\mathcal{U}$ of $\mathbb{R}^n \times \mathbb{S}^n_{++}$. We make a technical assumption:

$$a \neq 0 \qquad \forall (a, \Sigma) \in \mathcal{U}. \tag{20}$$

In other words, we rule out the possibility that the signal we want to detect is zero.

The *worst-case SSNR analysis problem* of finding a steering vector and a covariance that minimize SSNR for a given weight vector w can be written as

$$\begin{array}{ll} \text{minimize} & f(w, a, \Sigma) \\ \text{subject to} & (a, \Sigma) \in \mathcal{U}, \end{array} \tag{21}$$

with variables a and Σ. The optimal value of this problem is the *worst-case SSNR* (over the uncertainty set $\mathcal{U}$).

The *robust matched-filtering problem* is to find a weight vector that maximizes the worst-case SSNR, which can be cast as

$$\begin{array}{ll} \text{maximize} & \inf\limits_{(a,\Sigma)\in\mathcal{U}} f(x, a, B) \\ \text{subject to} & w \neq 0, \end{array} \tag{22}$$

with variables w. (The thresholding rule $h(y) = w^{\star T} y$ that uses a solution $w^\star$ of this problem as the weight vector yields the robust ROC curve that characterizes limits of performance in the worst-case sense.)

The robust signal detection setting described above is exactly the minimax setting described in the introduction, where a is the steering vector and B is the noise covariance. For this problem, we can see from the compactness of $\mathcal{U}$ and (20) that assumption (7) holds. We can solve the robust matched-filtering problem (22), using the minimax result for the fractional function (1).

We close by pointing out that we can handle convex constraints on the weight vector. For example, in robust beamforming, a special type of robust matched-filtering problem, we often want to choose the weight vector that maximizes the worst-case SSNR, subject to a unit array gain for the desired wave and rejection constraints on interferences [22]. This problem can also be solved using Theorem 1.

4.3. Numerical example. As an illustrative example, we consider the case when $a = (2, 3, 2, 2)$ is fixed (with no uncertainty) and the noise covariance Σ is uncertain and has the form

$$\begin{bmatrix} 1 & - & + & - \\ & 1 & ? & + \\ & & 1 & ? \\ & & & 1 \end{bmatrix}.$$

(Only the upper triangular part is shown because the matrix is symmetric.) Here, "+" means that $\Sigma_{ij} \in [0, 1]$, "−" means that $\Sigma_{ij} \in [-1, 0]$, and "?" means that $\Sigma_{ij} \in [-1, 1]$. Of course we assume $\Sigma \succ 0$. The nominal noise covariance is taken as

$$\bar{\Sigma} = \begin{bmatrix} 1 & -.5 & .5 & -.5 \\ & 1.0 & 0.0 & .5 \\ & & 1.0 & 0.0 \\ & & & 1.0 \end{bmatrix}.$$

Here, the upper-triangular part is shown since the matrix is symmetric. With the nominal covariance, we compute the nominal optimal weight vector or filter.

The least-favorable covariance, found by solving the convex problem (8) corresponding to the problem data above, is given by

$$\Sigma^{\mathrm{lf}} = \begin{bmatrix} 1.00 & 0.00 & .38 & -.12 \\ & 1.00 & .41 & .74 \\ & & 1.00 & .23 \\ & & & 1.00 \end{bmatrix}.$$

With the least-favorable covariance, we compute the robust optimal weight vector or filter.

Table 2 summarizes the results. The nominal optimal filter achieves an SSNR of 5.5 without uncertainty. In the presence of uncertainty, the SSNR achieved by the filter can degrade rapidly; the worst-case SSNR level for the nominal optimal filter is 3.0. The robust filter performs well in the presence of model mismatch; it has the worst-case SSNR of 3.6, which is 20% larger than that of the nominal optimal filter.

5. Worst-case Sharpe ratio maximization. The minimax result has an important application in robust portfolio selection.

5.1. Mean-variance asset allocation. Since the pioneering work of Markowitz [20], mean-variance (MV) analysis has been a topic of extensive research. In MV analysis, the (percentage) returns of risky assets $1, \ldots, n$ over a period are modeled

TABLE 2
Robust matched-filtering results.

	Nominal SSNR	Worst-case SSNR
Nominal optimal filter	5.5	3.0
Robust optimal filter	4.9	3.6

as a random vector $a = (a_1, \ldots, a_n)$ in $\mathbb{R}^n$. The input data or parameters needed for MV analysis are the mean μ and the covariance matrix Σ of a:

$$\mu = \mathbf{E}\, a, \qquad \Sigma = \mathbf{E}\, (a-\mu)(a-\mu)^T.$$

We assume that there is a risk-free asset with deterministic return $\mu_{\rm rf}$ and zero variance.

A portfolio $w \in \mathbb{R}^{n+1}$ is a finite linear combination of the assets. Let w_i denote the amount of asset i held throughout the period. A long position in asset i corresponds to $w_i > 0$, and a short position in asset i corresponds to $w_i < 0$. The return of a portfolio $w = (w_1, \ldots, w_n)$ is a (scalar) random variable $w^T a = \sum_{i=1}^n w_i a_i$, whose mean and volatility (standard deviation) are $\mu^T w$ and $\sqrt{w^T \Sigma w}$, respectively. We assume that an admissible portfolio $w = (w_1, \ldots, w_n)$ is constrained to lie in a convex compact subset $\mathcal{A}$ of $\mathbb{R}^n$. The portfolio budget constraint on w can be expressed, without loss of generality, as $\mathbf{1}^T w = 1$. Here $\mathbf{1}$ is the vector of all ones. The set of admissible portfolios subject to the portfolio budget constraint is given by

$$\mathcal{W} = \left\{ w \mid w \in \mathcal{A},\ \mathbf{1}^T w = 1 \right\}.$$

The performance of an admissible portfolio is often measured by its reward-to-variability or Sharpe ratio (SR):

$$S(w, \mu, \Sigma) = \frac{\mu^T w - \mu_{\rm rf}}{\sqrt{w^T \Sigma w}}.$$

The admissible portfolio that maximizes the ratio over $\mathcal{W}$ is called the *tangency portfolio* (TP). The SR achieved by this portfolio is called the market price of risk. The TP plays an important role in asset pricing theory and practice (see, e.g., [8, 19, 24]).

If the n risky assets with (single period) returns follow $a \sim \mathcal{N}(\mu, \Sigma)$, then

$$w^T a \sim \mathcal{N}\left(w^T \mu, w^T \Sigma w\right),$$

so the probability of outperforming the risk-free return $\mu_{\rm rf}$ is

$$\mathbf{Prob}\left(a^T w > \mu_{\rm rf}\right) = \Phi\left(\frac{\mu^T w - \mu_{\rm rf}}{\sqrt{w^T \Sigma w}}\right).$$

This probability is maximized by the TP.

SR maximization is related to the safety-first approach to portfolio selection [23], through the Chebyshev bound. Suppose $\mathbf{E}\, a = \mu$, $\mathbf{E}\, (a-\mu)^T (a-\mu) = \Sigma$ and otherwise arbitrary. Then, $\mathbf{E}\, a^T w = \mu^T x$ and $\mathbf{E}\, (a^T x - \mu^T x)^2 = w^T \Sigma w$, so it follows from the Chebyshev bound that

$$\mathbf{Prob}\left(a^T w \geq \mu_{\rm rf}\right) \geq \Psi\left(\frac{\mu^T w - \mu_{\rm rf}}{\sqrt{w^T \Sigma w}}\right).$$

In the safety-first approach [23], we want to find a portfolio that maximizes the bound. Since Ψ is increasing, this bound is also maximized by the TP.

5.2. Worst-case SR maximization. The input parameters are estimated with error. Conventional MV allocation is often sensitive to the uncertainty or the estimation error in the parameters, meaning that optimal portfolios computed with an estimate of the parameters can give very poor performance for another set of parameters that is similar and statistically hard to distinguish from the estimate; see, e.g., [4, 5, 14, 21], to name a few. Robust MV portfolio analysis attempts to systematically alleviate the sensitivity problem of conventional MV allocation by explicitly incorporating an uncertainty model on the input data or parameters in a portfolio selection problem and carrying out the analysis for the worst-case scenario under this model. Recent work on robust portfolio optimization includes [9, 10, 11, 12, 18].

In this section, we consider the robust counterpart of the SR maximization problem. The reader is referred to [16] for the importance of this problem in robust MV analysis. In this paper, we focus on the computational aspects of the robust counterpart.

We assume that the expected return μ and covariance Σ of the asset returns are uncertain but known to belong to a convex compact subset $\mathcal{U}$ of $\mathbb{R}^n \times \mathbb{S}^n_{++}$. We also assume there exists an admissible portfolio $\bar{w} \in \mathcal{W}$ of risky assets whose worst-case mean return is greater than the risk-free return:

$$\text{there exists a portfolio } \bar{w} \in \mathcal{W} \text{ such that } \mu^T w > \mu_{\rm rf} \text{ for all } (\mu, \Sigma) \in \mathcal{U}. \tag{23}$$

Worst-case SR maximization. The zero-sum game of choosing w from $\mathcal{W}$, to maximize the SR, and choosing (μ, Σ) from $\mathcal{U}$, to minimize the SR, is associated with the following two problems:

- worst-case SR maximization problem of finding an admissible portfolio w that maximizes the worst-case SR (over the given model $\mathcal{U}$ of uncertainty)

$$\begin{array}{ll} \text{maximize} & \inf\limits_{(\mu,\Sigma)\in\mathcal{U}} S(w, \mu, \Sigma) \\ \text{subject to} & w \in \mathcal{W}, \end{array} \tag{24}$$

- worst-case market price of risk analysis (MPRA) problem of finding the least-favorable statistics (over the uncertainty set $\mathcal{U}$), with portfolio weights chosen optimally for the asset return statistics,

$$\begin{array}{ll} \text{minimize} & \sup\limits_{w\in\mathcal{W}} S(w, \mu, \Sigma) \\ \text{subject to} & (\mu, \Sigma) \in \mathcal{U}. \end{array} \tag{25}$$

The SR is not a fractional function of the form (1), so we cannot apply Theorem 1 directly to the zero-sum game given above. We can get around this difficulty by using the fact that when the domain is restricted to $\mathcal{W}$, the SR has the form (1)

$$\frac{\mu^T w - \mu_{\rm rf}}{\sqrt{w^T \Sigma w}} = \frac{w^T(\mu - \mu_{\rm rf}\mathbf{1})}{\sqrt{w^T \Sigma w}} = f(w, \mu - \mu_{\rm rf}\mathbf{1}, \Sigma) \qquad \forall w \in \mathcal{W}$$

and

$$S(w, \mu, \Sigma) = f(tw, \mu - \mu_{\rm rf}\mathbf{1}, \Sigma), \quad w \in \mathcal{W}, \quad t > 0, \tag{26}$$

whenever $S(w, \mu, \Sigma) > 0$.

The set

$$\mathcal{X} = \mathrm{cl}\,\{tw \in \mathbb{R}^n \mid w \in \mathcal{W},\ t > 0\} \backslash \{0\},$$

where $\operatorname{cl} A$ means the closure of the set A and $A\backslash B$ means the complement of B in A, is a cone in $\mathbb{R}^n$, with $\mathcal{X} \cup \{0\}$ closed and convex. Assumption (23), along with the compactness of $\mathcal{U}$, means that

$$\inf_{(\mu,\Sigma)\in\mathcal{U}} \bar{w}^T(\mu - \mu_{\rm rf}\mathbf{1}) > 0.$$

We can therefore apply Theorem 1 to the zero-sum game of choosing w from $\mathcal{X}$, to maximize $f(x, \mu-\mu_{\rm rf}\mathbf{1}, \Sigma)$, and choosing (μ, Σ) from $\mathcal{U}$, to minimize $f(x, \mu-\mu_{\rm rf}\mathbf{1}, \Sigma)$.

The max-min and min-max problems associated with the game are

- max-min problem

$$\begin{array}{ll} \text{maximize} & \inf\limits_{(\mu,\Sigma)\in\mathcal{U}} f(x, \mu - \mu_{\rm rf}\mathbf{1}, \Sigma) \\ \text{subject to} & x \in \mathcal{X}, \end{array} \tag{27}$$

- min-max problem

$$\begin{array}{ll} \text{minimize} & \sup\limits_{x\in\mathcal{X}} f(x, \mu - \mu_{\rm rf}\mathbf{1}, \Sigma) \\ \text{subject to} & (\mu, \Sigma) \in \mathcal{U}. \end{array} \tag{28}$$

According to Theorem 1, the two problems have the same optimal value:

$$\sup_{x\in\mathcal{X}} \inf_{(\mu,\Sigma)\in\mathcal{U}} f(x, \mu - \mu_{\rm rf}\mathbf{1}, \Sigma) = \inf_{(\mu,\Sigma)\in\mathcal{U}} \sup_{x\in\mathcal{X}} f(x, \mu - \mu_{\rm rf}\mathbf{1}, \Sigma). \tag{29}$$

As a result, the SR satisfies the minimax equality

$$\sup_{w\in\mathcal{W}} \inf_{(\mu,\Sigma)\in\mathcal{U}} S(w, \mu, \Sigma) = \inf_{(\mu,\Sigma)\in\mathcal{U}} \sup_{w\in\mathcal{W}} S(w, \mu, \Sigma),$$

which follows from (26) and (29).

From Proposition 1, we can see that the min-max problem (28) is equivalent to the convex problem

$$\begin{array}{ll} \text{minimize} & (\mu - \mu_{\rm rf}\mathbf{1} + \lambda)^T\Sigma^{-1}(\mu - \mu_{\rm rf}\mathbf{1} + \lambda) \\ \text{subject to} & (\mu, \Sigma) \in \mathcal{U}, \quad \lambda \in \mathcal{W}^{\oplus} \end{array} \tag{30}$$

in which the optimization variables are $\mu \in \mathbb{R}^n$, $\Sigma = \Sigma^T \in \mathbb{R}^{n\times n}$, and $\lambda \in \mathbb{R}^n$. Here $\mathcal{W}^{\oplus}$ is the positive conjugate cone $\mathcal{W}$, which is equal to the dual cone $X^\star$ of $\mathcal{X}$:

$$\mathcal{X}^* = \mathcal{W}^{\oplus} = \left\{\lambda \in \mathbb{R}^n \mid \lambda^T w \geq 0 \ \forall w \in \mathcal{W}\right\}.$$

The convex problem (30) has a solution, say, $(\mu^\star, \Sigma^\star, \lambda^\star)$. Then,

$$x^\star = {\Sigma^\star}^{-1}(\mu^\star - \mu_{\rm rf}\mathbf{1} + \lambda^\star) \in \mathcal{X}$$

is a unique solution of the max-min problem (27) (up to positive scaling). Moreover, the saddle-point property

$$f(x, \mu^\star - \mu_{\rm rf}\mathbf{1}, \Sigma^\star) \leq f(x^\star, \mu^\star - \mu_{\rm rf}\mathbf{1}, \Sigma^\star) \leq f(x^\star, \mu - \mu_{\rm rf}\mathbf{1}, \Sigma), \quad x \in \mathcal{X}, \quad (\mu, \Sigma) \in \mathcal{U}, \tag{31}$$

holds. We can see from (26) that

$$S(w, \mu^\star, \Sigma^\star) \leq S(w^\star, \mu^\star, \Sigma^\star) \leq S(w^\star, \mu, \Sigma) \quad \forall w \in \mathcal{W} \quad \forall (\mu, \Sigma) \in \mathcal{U}. \tag{32}$$

Finally, since $\mathbf{1}^T x \geq 0$ for all $x \in \mathcal{X}$, we have

$$\mathbf{1}^T \Sigma^{\star -1}(\mu^\star - \mu_{\rm rf}\mathbf{1} + \lambda^\star) \geq 0.$$

If $x^\star$ satisfies $\mathbf{1}^T x^\star > 0$, the portfolio

$$w^\star = \left(1/\mathbf{1}^T x^\star\right) x^\star = \frac{1}{\mathbf{1}^T \Sigma^{\star -1}(\mu^\star - \mu_{\rm rf}\mathbf{1} + \lambda^\star)} \Sigma^{\star -1}(\mu^\star - \mu_{\rm rf}\mathbf{1} + \lambda^\star) \tag{33}$$

satisfies the budget constraint and is admissible (i.e., $w^\star \in \mathcal{W}$); i.e., it is a solution to the worst-case SR maximization (24). Moreover, it is the unique solution to the worst-case SR maximization (24). The case of $\mathbf{1}^T x^\star = 0$ may arise when the set $\mathcal{W}$ is unbounded. In this case, the worst-case SR maximization problem (24) has no solution, so the game involving the SR has no saddle point.

Minimax properties of the SR. The results established above are summarized in the following proposition.

PROPOSITION 3. *Suppose that the uncertainty set $\mathcal{U}$ is compact and convex. Suppose further that Assumption* (23) *holds. Let $(\mu^\star, \Sigma^\star, \lambda^\star)$ be a solution to the convex problem* (30). *Then, we have the following:*

(i) *If $\mathbf{1}^T \Sigma^{-1}(\mu - \mu_{\rm rf}\mathbf{1} + \lambda^\star) > 0$, then the triple $(w^\star, \mu^\star, \Sigma^\star)$ with $w^\star$ in* (33) *satisfies the saddle-point property* (32), *and $w^\star$ is the unique solution to the worst-case SR maximization problem* (24).

(ii) *If $\mathbf{1}^T \Sigma^{-1}(\mu - \mu_{\rm rf}\mathbf{1} + \lambda^\star) = 0$, then the optimal value of the worst-case SR maximization problem* (24) *is not achieved by any portfolio in $\mathcal{W}$.*

Moreover, the minimax equality

$$\sup_{w \in \mathcal{W}} \inf_{(\mu,\Sigma) \in \mathcal{U}} S(w, \mu, \Sigma) = \inf_{(\mu,\Sigma) \in \mathcal{U}} \sup_{w \in \mathcal{W}} S(w, \mu, \Sigma)$$

holds regardless of the existence of a solution.

The worst-case MPRA problem (25) is equivalent to the min-max problem (28), which is in turn equivalent to the convex problem (30). This proposition shows that the TP of the least-favorable model $(\mu^\star, \Sigma^\star)$ solves the worst-case SR maximization problem (24). The saddle-point property (32) means that the portfolio $w^\star$ in (33) is the TP of the least-favorable model $(\mu^\star, \Sigma^\star)$. The portfolio is called the *robust TP*.

5.3. Numerical example. We illustrate the result with a synthetic example, with $n = 7$ risky assets. The risk-free return is taken as $\mu_{\rm rf} = 5$.

Setup. The nominal returns $\bar{\mu}_i$ and variances $\bar{\sigma}_i^2$ of the risky assets are taken as

$$\bar{\mu} = [10.3 \;\; 10.5 \;\; 5.5 \;\; 10.5 \;\; 110 \;\; 14.4 \;\; 10.1]^T,$$
$$\bar{\sigma} = [11.3 \;\; 18.1 \;\; 6.8 \;\; 22.7 \;\; 24.0 \;\; 14.7 \;\; 20.9]^T.$$

The nominal correlation matrix $\bar{\Omega}$ is

$$\bar{\Omega} = \begin{bmatrix} 1.00 & .07 & -.12 & .43 & -.11 & .44 & .25 \\ & 1.00 & .73 & -.14 & .39 & .28 & .10 \\ & & 1.00 & .14 & .50 & .52 & -.13 \\ & & & 1.00 & .04 & .35 & .38 \\ & & & & 1.00 & .70 & .04 \\ & & & & & 1.00 & -.09 \\ & & & & & & 1.00 \end{bmatrix}.$$

The nominal covariance is

$$\bar{\Sigma} = \operatorname{diag}(\bar{\sigma})\bar{\Omega}\operatorname{diag}(\bar{\sigma}),$$

where we use $\operatorname{diag}(u_1, \ldots, u_m)$ to denote the diagonal matrix with diagonal entries $u_1, \ldots, u_m$.

The mean uncertainty model used in our study is

$$\begin{aligned} |\mu_i - \bar{\mu}_i| &\le 0.3|\bar{\mu}_i|, \quad i = 1, \ldots, 7, \\ \left|\mathbf{1}^T\mu - \mathbf{1}^T\bar{\mu}\right| &\le 0.15\left|\mathbf{1}^T\bar{\mu}\right|. \end{aligned}$$

These constraints mean that the possible variation in the expected return of each asset is at most 30%, and the possible variation in the expected return of the portfolio $(1/n)\mathbf{1}$ (in which a fraction $1/n$ of the budget is allocated to each asset of the n assets) is at most 15%. The covariance uncertainty model used in our study is

$$\begin{aligned} \left|\Sigma_{ij} - \bar{\Sigma}_{ij}\right| &\le 0.3\left|\bar{\Sigma}_{ij}\right|, \quad i, j = 1, \ldots, 7, \\ \left\|\Sigma - \bar{\Sigma}\right\|_F &\le 0.15\left\|\bar{\Sigma}\right\|_F. \end{aligned}$$

(Here, $\|A\|_F$ denotes the Frobenius norm of A, i.e., $\|A\|_F = (\sum_{i,j=1}^n A_{ij}^2)^{1/2}$.) These constraints mean that the possible variation in each component of the covariance matrix is at most 30% and the possible deviation of the covariance from the nominal covariance is at most 15% in terms of the Frobenius norm.

We consider the case when short selling is allowed in a limited way as follows:

$$w = w_{\text{long}} - w_{\text{short}}, \quad w_{\text{long}}, w_{\text{short}} \succeq 0, \quad \mathbf{1}^T w_{\text{short}} \le \eta \mathbf{1}^T w_{\text{long}}, \tag{34}$$

where η is a positive constant and w_{long} and w_{short} represent the total long and short positions at the beginning of the period, respectively. ($w \succeq 0$ means that w is componentwise nonnegative.) The last constraint limits the total short position to some fraction η of the total long position. In our numerical study, we take $\gamma = 0.3$.

The asset constraint set is given by the cone

$$\mathcal{W} = \left\{ w \in \mathbb{R}^n \mid w = w_{\text{long}} - w_{\text{short}},\ A\begin{bmatrix} w_{\text{long}} \\ w_{\text{short}} \end{bmatrix} \preceq 0 \right\},$$

where

$$A = \begin{bmatrix} -I & 0 \\ 0 & -I \\ -\gamma\mathbf{1}^T & \mathbf{1}^T \end{bmatrix} \in \mathbb{R}^{(2n+1)\times(2n)}.$$

A simple argument based on linear programming duality shows that the dual cone of $\mathcal{X} = \mathcal{W}$ is given by

$$\mathcal{X}^* = \left\{ \lambda \in \mathbb{R}^n \;\middle|\; \text{there exists } y \succeq 0 \text{ such that } A^T y + \begin{bmatrix} \lambda \\ -\lambda \end{bmatrix} = 0 \right\}.$$

Comparison results. We can find the robust TP by applying Theorem 1 to the corresponding problem (27) with the asset allocation constraints and uncertainty model described above. The nominal TP can be found using Theorem 1 with the singleton $\mathcal{U} = \{(\bar{\mu}, \bar{\Sigma})\}$.

TABLE 3
Nominal and worst-case SRs of the nominal and robust TPs.

	Nominal SR	Worst-case SR
Nominal TP	0.74	0.22
Robust TP	0.57	0.36

TABLE 4
Outperformance probability of the nominal and robust TPs.

	$\mathbf{P}_{\mathrm{nom}}$	$\mathbf{P}_{\mathrm{wc}}$
Nominal TP	0.77	0.59
Robust TP	0.71	0.64

Table 3 shows the nominal and worst-case SRs of the nominal optimal and robust optimal allocations. In comparison with the market portfolio, the robust market portfolio shows a relatively small decrease in the SR, in the presence of possible variations in the parameters. The SR of the robust market portfolio decreases about 39% from 0.57 to 0.36, while the SR of the nominal market portfolio decreases about 70% from 0.74 to 0.22.

Table 4 shows the probabilities of outperforming the risk-free asset for the nominal optimal and robust optimal weight allocations, when the asset returns follow a normal distribution. Here, $\mathbf{P}_{\mathrm{nom}}$ is the probability of beating the risk-free asset without uncertainty, called the outperformance probability, and $\mathbf{P}_{\mathrm{wc}}$ is the worst-case probability of outperforming the risk-free asset with uncertainty. The nominal optimal TP achieves $\mathbf{P}_{\mathrm{nom}} = 0.77$, which corresponds to 77% of outperforming the risk-free asset without uncertainty. However, in the presence of uncertainty in the parameters, its performance degrades rapidly; the worst-case outperformance probability for the nominal optimal discriminant is 59%. The robust optimal allocation performs well in the presence of uncertainty in the parameters, with the worst-case outperformance probability 5% higher than that of the nominal optimal allocation.

6. Conclusions. The fractional function $f(x, a, B) = a^T x/\sqrt{x^T B x}$ comes up in many contexts, some of which are discussed above. In this paper, we have established a minimax result for this function and a general computational method, based on convex optimization, for computing a saddle point.

The arguments used to establish the minimax result do not appear to be extensible to other fractional functions that have a similar form. For instance, the extension to a general fractional function of the form

$$g(x, A, B) = \frac{x^T A x}{x^T B x},$$

which is the Rayleigh quotient of the matrix pair $A \in \mathbb{R}^{n\times n}$ and $B \in \mathbb{R}^{n\times n}$ evaluated at $x \in \mathbb{R}^n$, is not possible; see, e.g., [31] for a counterexample. However, the arguments can be extended to the special case when A is a dyad, i.e., $A = aa^T$, with $a \in \mathbb{R}^n$, and $\mathcal{X} = \mathbb{R}^n\backslash\{0\}$. In this case, the minimax equality

$$\sup_{x\neq 0}\inf_{(a,B)\in\mathcal{U}} \frac{\left(x^T a\right)^2}{x^T B x} = \inf_{(a,B)\in\mathcal{U}}\sup_{x\neq 0} \frac{\left(x^T a\right)^2}{x^T B x}$$

holds with assumption (7); see [17] for the proof.

Appendix A. Proofs.

A.1. Proof of Proposition 1. We first show that the optimal value of (8) is positive. We start by noting that

$$\inf_{(a,B)\in\mathcal{U}} \frac{\bar{x}^T a}{\sqrt{\bar{x}^T B \bar{x}}} > 0, \tag{35}$$

with $\bar{x}$ in (7), and

$$\inf_{(a,B)\in\mathcal{U},\lambda\in\mathcal{X}^*} \frac{\bar{x}^T(a+\lambda)}{\sqrt{\bar{x}^T B\bar{x}}} = \inf_{(a,B)\in\mathcal{U}} \inf_{\lambda\in\mathcal{X}^*} \frac{\bar{x}^T(a+\lambda)}{\sqrt{\bar{x}^T B\bar{x}}} = \inf_{(a,B)\in\mathcal{U}} \frac{\bar{x}^T a}{\sqrt{\bar{x}^T B\bar{x}}}. \tag{36}$$

Here, we have used (35) and $\inf_{\lambda\in\mathcal{X}^*} \bar{x}^T\lambda = 0$. By the Cauchy–Schwarz inequality, $x^T(a+\lambda)/\sqrt{x^T Bx}$ is maximized over nonzero x by $x = B^{-1}(a+\lambda)$, so

$$\sup_{x\neq 0} x^T(a+\lambda)/\sqrt{x^T Bx} = \left[(a+\lambda)^T B^{-1}(a+\lambda)\right]^{1/2}.$$

It follows from the minimax inequality (5), (35), and (36) that

$$\begin{aligned}
\inf_{(a,B)\in\mathcal{U},\lambda\in\mathcal{X}^*} \left[(a+\lambda)^T B^{-1}(a+\lambda)\right]^{1/2} &= \inf_{(a,B)\in\mathcal{U},\lambda\in\mathcal{X}^*} \sup_{x\neq 0} \frac{x^T(a+\lambda)}{\sqrt{x^T Bx}} \\
&\geq \sup_{x\neq 0} \inf_{(a,B)\in\mathcal{U},\lambda\in\mathcal{X}^*} \frac{x^T(a+\lambda)}{\sqrt{x^T Bx}} \\
&\geq \inf_{(a,B)\in\mathcal{U},\lambda\in\mathcal{X}^*} \frac{\bar{x}^T(a+\lambda)}{\sqrt{\bar{x}^T B\bar{x}}} \\
&> 0.
\end{aligned}$$

(Here, we use the fact that the weak minimax property for $x^T(a+\lambda)/\sqrt{x^T Bx}$ holds for any $\mathcal{U} \subseteq \mathbb{R}^n \times \mathbb{S}^n_{++}$ and $\mathcal{X} \subseteq \mathbb{R}^n$.)

We next show that (8) has a solution. There is a sequence

$$\left\{ \left(a^{(i)} + \lambda^{(i)}, B^{(i)}\right) \;\middle|\; \left(a^{(i)}, B^{(i)}\right) \in \mathcal{U},\ \lambda^{(i)} \in \mathcal{X}^*,\ i = 1, 2, \dots \right\}$$

such that

$$\lim_{i\to\infty} \left(a^{(i)} + \lambda^{(i)}\right)^T {B^{(i)}}^{-1} \left(a^{(i)} + \lambda^{(i)}\right) = \inf_{(a,B)\in\mathcal{U},\lambda\in\mathcal{X}^*} (a+\lambda)^T B^{-1}(a+\lambda). \tag{37}$$

Since $\mathcal{U}$ is a compact subset of $\mathbb{R}^n \times \mathbb{S}^n_{++}$, we have

$$\sup\left\{\lambda_{\max}\left(B^{-1}\right) \;\middle|\; \text{for all } B \text{ with } (a,B)\in\mathcal{U}\right\} < \infty.$$

(Here $\lambda_{\max}(B)$ is the maximum eigenvalue of B.) Then, $S_1 = \{a^{(i)} + \lambda^{(i)} \in \mathbb{R}^n \mid i = 1, 2, \dots\}$ must be bounded. (Otherwise, there arises a contradiction to (37).) Since $\mathcal{U}$ is compact, the sequence $S_2 = \{(a^{(i)}, B^{(i)}) \in \mathcal{U} \mid i = 1, 2, \dots\}$ is bounded, which along with the boundedness of S_1 means that $S_3 = \{\lambda^{(i)} \in \mathbb{R}^n \mid i = 1, 2, \dots\}$ is also bounded. The bounded sequences S_2 and S_3 have convergent subsequences, which converge to, say, $(a^\star, B^\star)$ and $\lambda^\star$, respectively. Since $\mathcal{U}$ and $\mathcal{X}^*$ are closed, $(a^\star, B^\star) \in \mathcal{U}$ and $\lambda^\star \in \mathcal{X}^*$. The triple $(a^\star, B^\star, \lambda^\star)$ achieves the optimal value of (8). Since the optimal value is positive, $a^\star + \lambda^\star \neq 0$.

The equivalence between (4) and (8) follows from the following implication:

$$\sup_{x\in\mathcal{X}} x^T a > 0 \quad \Longrightarrow \quad \sup_{x\in\mathcal{X}} \frac{x^T a}{\sqrt{x^T B x}} = \inf_{\lambda\in\mathcal{X}^*} \left[(a+\lambda)^T B^{-1}(a+\lambda)\right]^{1/2}. \tag{38}$$

Then, (4) is equivalent to

$$\begin{array}{ll} \text{minimize} & \inf\limits_{\lambda\in\mathcal{X}^*} (a+\lambda)^T B^{-1}(a+\lambda) \\ \text{subject to} & (a,B)\in\mathcal{U}. \end{array}$$

It is now easy to see that (4) is equivalent to (8).

To establish the implication, we show that

$$\sup_{x\in\mathcal{X}} \frac{x^T a}{\sqrt{x^T B x}} = \sup_{x\neq 0} \inf_{\lambda\in\mathcal{X}^*} \frac{x^T(a+\lambda)}{\sqrt{x^T B x}}. \tag{39}$$

First, suppose that $x \in \mathcal{X}$. Then, $\lambda^T x \geq 0$ for any $\lambda \in \mathcal{X}^*$ and $0 \in \mathcal{X}^*$, so $\inf_{\lambda\in\mathcal{X}^*} \lambda^T x = 0$. Thus,

$$\inf_{\lambda\in\mathcal{X}^*} \frac{x^T(a+\lambda)}{\sqrt{x^T B x}} = \frac{x^T a}{\sqrt{x^T B x}}.$$

Next, suppose that $x \notin \mathcal{X}\cup\{0\}$. Note from $\mathcal{X}^{**} = \mathcal{X}\cup\{0\}$ that there exists a nonzero $\bar{\lambda} \in \mathcal{X}^*$, with $\bar{\lambda}^T x < 0$. Then,

$$\inf_{\lambda\in\mathcal{X}^*} \frac{x^T(a+\lambda)}{\sqrt{x^T B x}} \leq \inf_{t>0} \left(\frac{x^T a}{\sqrt{x^T B x}} + \frac{t x^T \bar{\lambda}}{\sqrt{x^T B x}} \right) = -\infty \quad \forall x \notin \mathcal{X}\cup\{0\}.$$

When $\sup_{x\in\mathcal{X}} x^T a > 0$, we have from (39) that

$$\inf_{\lambda\in\mathcal{X}^*} \sup_{x\neq 0} \frac{x^T(a+\lambda)}{\sqrt{x^T B x}} > 0.$$

By the Cauchy–Schwarz inequality,

$$\inf_{\lambda\in\mathcal{X}^*} \sup_{x\neq 0} \frac{x^T(a+\lambda)}{\sqrt{x^T B x}} = \inf_{\lambda\in\mathcal{X}^*} \left[(a+\lambda)^T B^{-1}(a+\lambda)\right]^{1/2} = \left[\inf_{\lambda\in\mathcal{X}^*} (a+\lambda)^T B^{-1}(a+\lambda)\right]^{1/2}.$$

Since $(a+\lambda)^T B^{-1}(a+\lambda)$ is strictly concave in λ, we can see that there is $\lambda^\star$ such that

$$\inf_{\lambda\in\mathcal{X}^*} (a+\lambda)^T B^{-1}(a+\lambda) = (a+\lambda^\star)^T B^{-1}(a+\lambda^\star). \tag{40}$$

Then,

$$\sup_{x\neq 0} \frac{x^T(a+\lambda^\star)}{\sqrt{x^T B x}} = \inf_{\lambda\in\mathcal{X}^*} \sup_{x\neq 0} \frac{x^T(a+\lambda)}{\sqrt{x^T B x}}.$$

As will be seen soon, $x^\star = B^{-1}(a+\lambda^\star)$ satisfies

$$\frac{x^{\star T}(a+\lambda^\star)}{\sqrt{x^{\star T} B x^\star}} = \inf_{\lambda\in\mathcal{X}^*} \frac{x^{\star T}(a+\lambda)}{\sqrt{x^{\star T} B x^\star}}. \tag{41}$$

Therefore,

$$\sup_{x\neq 0}\inf_{\lambda\in\mathcal{X}^*}\frac{x^T(a+\lambda)}{\sqrt{x^TBx}}=\inf_{\lambda\in\mathcal{X}^*}\sup_{x\neq 0}\frac{x^T(a+\lambda)}{\sqrt{x^TBx}}.$$

Taken together, the results established above show that

$$\begin{aligned}\sup_{x\in\mathcal{X}}\frac{x^Ta}{\sqrt{x^TBx}}&=\sup_{x\neq 0}\inf_{\lambda\in\mathcal{X}^*}\frac{x^T(a+\lambda)}{\sqrt{x^TBx}}=\inf_{\lambda\in\mathcal{X}^*}\sup_{x\neq 0}\frac{x^T(a+\lambda)}{\sqrt{x^TBx}}\\&=\inf_{\lambda\in\mathcal{X}^*}\left[(a+\lambda)^TB^{-1}(a+\lambda)\right]^{1/2}.\end{aligned}$$

We complete the proof by establishing (41). To this end, we derive explicitly the optimality condition for $\lambda^\star$ to satisfy (40):

$$2x^{\star T}(\lambda-\lambda^\star)\geq 0\quad\forall\lambda\in\mathcal{X}^*, \tag{42}$$

with $x^\star=B^{\star-1}(a+\lambda^\star)$. (See [7, section 4.2.3].) We now show that $x^\star$ satisfies (41). To this end, we note that $\bar\lambda$ is optimal for (41) if and only if

$$\left\langle\nabla_\lambda\frac{\left(x^{\star T}(a+\lambda)\right)^2}{x^{\star T}Bx^\star}\bigg|_{\bar\lambda},\left(\lambda-\bar\lambda\right)\right\rangle\geq 0\quad\forall\lambda\in\mathcal{X}^*.$$

Here $\nabla_\lambda h(\lambda)|_{\bar\lambda}$ denotes the gradient of h at the point $\bar\lambda$. We can write the optimality condition as

$$2\frac{x^{\star T}\left(a+\bar\lambda\right)}{x^{\star T}\bar Bx^\star}x^{\star T}\left(\lambda-\bar\lambda\right)\geq 0\quad\forall\lambda\in\mathcal{X}^*.$$

Substituting $\bar\lambda=\lambda^\star$ and noting that $(a+\lambda)^{\star T}x^\star/x^{\star T}B^\star x^\star=1$, the optimality condition reduces to (42). Thus, we have shown that $\lambda^\star$ is optimal for (41).

A.2. Proof of Theorem 1. We will establish the following claims:

- $x^\star=B^{\star-1}(a^\star+\lambda^\star)\in\mathcal{X}$.
- $(x^\star,a^\star,\lambda^\star,B^\star)$ satisfies the saddle-point property
(43)
$$\frac{x^T(a^\star+\lambda^\star)}{\sqrt{x^TB^\star x}}\leq\frac{x^{\star T}(a^\star+\lambda^\star)}{\sqrt{x^{\star T}B^\star x^\star}}\leq\frac{x^{\star T}(a+\lambda)}{\sqrt{x^{\star T}Bx^\star}}\ \ \forall x\neq 0\ \ \forall\lambda\in\mathcal{X}^*\ \ \forall(a,B)\in\mathcal{U}.$$
- $x^\star$ and $\lambda^\star$ are orthogonal to each other:
(44)
$$x^{\star T}\lambda^\star=0.$$

The claims of Theorem 1 follow directly from the claims above. By definition of the dual cone, we have $\lambda^{\star T}x\geq 0$ for all $x\in\mathcal{X}$ and $0\in\mathcal{X}^*$. It follows from (43) and (44) that

$$\begin{aligned}\frac{x^Ta^\star}{\sqrt{x^TB^\star x}}&\leq\frac{x^T(a^\star+\lambda^\star)}{\sqrt{x^TB^\star x}}\leq\frac{x^{\star T}(a^\star+\lambda^\star)}{\sqrt{x^{\star T}B^\star x^\star}}=\frac{x^{\star T}a^\star}{\sqrt{x^{\star T}B^\star x^\star}}\\&\leq\frac{x^{\star T}a}{\sqrt{x^{\star T}Bx^\star}}\ \forall x\in\mathcal{X}\ \forall(a,B)\in\mathcal{U}.\end{aligned}$$

The saddle-point property (43) is equivalent to showing that

$$\sup_{x\neq 0} \frac{x^T(a^\star+\lambda^\star)}{\sqrt{x^TB^\star x}} = \frac{x^{\star T}(a^\star+\lambda^\star)}{\sqrt{x^{\star T}B^\star x^\star}} \tag{45}$$

and

$$\inf_{(a,B)\in\mathcal{U},\lambda\in\mathcal{X}^*} \frac{x^{\star T}(a+\lambda)}{\sqrt{x^{\star T}Bx^\star}} = \frac{x^{\star T}(a^\star+\lambda^\star)}{\sqrt{x^{\star T}B^\star x^\star}}. \tag{46}$$

Here, (45) follows from the Cauchy–Schwarz inequality.

We establish (46) by showing an equivalent claim

$$\inf_{(c,B)\in\mathcal{V}} \frac{x^{\star T}c}{\sqrt{x^{\star T}Bx^\star}} = \frac{x^{\star T}c^\star}{\sqrt{x^{\star T}B^\star x^\star}},$$

where

$$c^\star = a^\star+\lambda^\star, \qquad \mathcal{V} = \{(a+\lambda,B)\in\mathbb{R}^n\times\mathbb{S}^n_{++} \mid (a,B)\in\mathcal{U},\ \lambda\in\mathcal{X}^*\}.$$

The set $\mathcal{V}$ is closed and convex.

We know that $(c^\star,B^\star)$ is optimal for the convex problem

$$\begin{array}{ll}\text{minimize} & g(c,B)=c^TB^{-1}c\\ \text{subject to} & (c,B)\in\mathcal{V},\end{array} \tag{47}$$

with variables $c\in\mathbb{R}^n$ and $B=B^T\in\mathbb{R}^{n\times n}$. From the optimality condition of this problem that $(c^\star,B^\star)$ satisfies, we will prove that $(c^\star,B^\star)$ is also optimal for the problem

$$\begin{array}{ll}\text{minimize} & x^{\star T}c/\sqrt{x^{\star T}Bx^\star}\\ \text{subject to} & (c,B)\in\mathcal{V},\end{array} \tag{48}$$

with variables $c\in\mathbb{R}^n$ and $B=B^T\in\mathbb{R}^{n\times n}$. The proof is based on an extension of the arguments used to establish (41).

We derive explicitly the optimality condition for the convex problem (47). The pair $(c^\star,B^\star)$ must satisfy the optimality condition

$$\left\langle \nabla_c g(c,B)|_{(c^\star,B^\star)}, (c-c^\star)\right\rangle + \left\langle \nabla_B g(c,B)|_{(c^\star,B^\star)}, (B-B^\star)\right\rangle \geq 0 \quad \forall (c,B)\in\mathcal{V}$$

(see [7, section 4.2.3]). Here $(\nabla_c f(c,B)|_{(\bar c,\bar B)}, \nabla_B g(c,B)|_{(\bar c,\bar B)})$ denotes the gradient of f at the point (c,B). Using $\nabla_c(c^TB^{-1}c)=2B^{-1}c$, $\nabla_B(c^TB^{-1}c)=-B^{-1}cc^TB^{-1}$, and $\langle X,Y\rangle=\mathbf{Tr}(XY)$ for $X,Y\in\mathbb{S}^n$, where $\mathbf{Tr}$ denotes trace, we can express the optimality condition as

$$2c^{\star T}B^{\star -1}(c-c^\star) - \mathbf{Tr}\, B^{\star -1}c^\star c^{\star T}B^{\star -1}(B-B^\star)\geq 0 \quad \forall (c,B)\in\mathcal{V}$$

or equivalently

$$2x^{\star T}(c-c^\star) - x^{\star T}(B-B^\star)x^\star \geq 0 \quad \forall (c,B)\in\mathcal{V}, \tag{49}$$

with $x^\star = B^{\star -1}c^\star$.

To establish the optimality of $(c^\star, B^\star)$ for (48), we show that a solution of (48) is also a solution to the optimization problem

$$\begin{array}{ll} \text{minimize} & \left(x^{\star T} c\right)^2 / \left(x^{\star T} B x^\star\right) \\ \text{subject to} & (c, B) \in \mathcal{V}, \end{array} \tag{50}$$

with variables $c \in \mathbb{R}^n$ and $B = B^T \in \mathbb{R}^{n \times n}$ and vice versa. To show that (50) is a convex optimization problem, we must show that the objective is a convex function of c and B. To do so, we express the objective as the composition

$$\frac{\left(x^{\star T} c\right)^2}{x^{\star T} B x^\star} = g(H(c, B)),$$

where $g(u, t) = u^2/t$ and H is the function

$$H(c, B) = \left(x^{\star T} c, x^{\star T} B x^\star\right).$$

The function H is linear (as a mapping from c and B into $\mathbb{R}^2$), and the function g is convex (provided $t > 0$, which holds here). Thus, the composition f is a convex function of a and B. (See [7, section 3].)

This equivalence between (48) and (50) follows from

$$x^{\star T} c / \left(x^{\star T} B x^\star\right)^{1/2} > 0 \quad \forall (c, B) \in \mathcal{V},$$

which is a direct consequence of the optimality condition (49):

$$\begin{aligned} 2x^{\star T} c &\geq 2x^{\star T} c^\star + x^{\star T}(B - B^\star)x^\star \\ &= x^{\star T} c^\star + x^{\star T}(c^\star - B^\star x^\star) + x^{\star T} B x^\star \\ &= x^{\star T} B^{\star -1} x^\star + x^{\star T} B x^\star \\ &> 0 \quad \forall (c, B) \in \mathcal{V}. \end{aligned}$$

We now show that $(c^\star, B^\star)$ is optimal for (50) and hence for (48). The optimality condition for (50) is that a pair $(\bar{c}, \bar{B})$ is optimal for (50) if and only if

$$\left\langle \nabla_c \frac{\left(x^{\star T} c\right)^2}{x^{\star T} B x^\star}\bigg|_{(\bar{c}, \bar{B})}, (c - \bar{c}) \right\rangle + \left\langle \nabla_B \frac{\left(x^{\star T} c\right)^2}{x^{\star T} B x^\star}\bigg|_{(\bar{c}, \bar{B})}, \left(B - \bar{B}\right) \right\rangle \geq 0 \quad \forall (c, B) \in \mathcal{V}$$

(see [7, section 4.2.3]). Using

$$\nabla_c \frac{\left(x^{\star T} c\right)^2}{x^{\star T} B x^\star} = 2\frac{c^T x^\star}{x^{\star T} B x^\star} x^\star, \qquad \nabla_B \frac{\left(x^{\star T} c\right)^2}{x^{\star T} B x^\star} = -\frac{\left(c^T x^\star\right)^2}{\left(x^{\star T} B x^\star\right)^2} x^\star x^{\star T},$$

we can write the optimality condition as

$$\begin{aligned} &2\frac{x^{\star T}\bar{c}}{x^{\star T}\bar{B}x^\star} x^{\star T}(c - \bar{c}) - \mathbf{Tr}\, \frac{\left(x^{\star T}\bar{c}\right)^2}{\left(x^{\star T}\bar{B}x^\star\right)^2} x^\star x^{\star T}\left(B - \bar{B}\right) \\ &= 2\frac{x^{\star T}\bar{c}}{x^{\star T}\bar{B}x^\star} x^{\star T}(c - \bar{c}) - \frac{\left(x^{\star T}\bar{c}\right)^2}{\left(x^{\star T}\bar{B}x^\star\right)^2} x^{\star T}\left(B - \bar{B}\right) x^\star \\ &\geq 0 \quad \forall (c, B) \in \mathcal{V}. \end{aligned}$$

Substituting $\bar{c} = c^\star$, $\bar{B} = B^\star$, and noting that $c^{\star T}x^\star / x^{\star T}B^\star x^\star = 1$, the optimality condition reduces to

$$2x^{\star T}(c - c^\star) - x^{\star T}(B - B^\star)x^\star \geq 0 \quad \forall (c, B) \in \mathcal{V},$$

which is precisely (49). Thus, we have shown that $(c^\star, B^\star)$ is optimal for (50), which in turn means that it is also optimal for (48).

We next show by way of contradiction that $x^\star \in \mathcal{X}$. Suppose that $x^\star \notin \mathcal{X}$. Then, it follows from $\mathcal{X}^{**} = \mathcal{X} \cup \{0\}$ that there is $\bar{\lambda} \in \mathcal{X}^*$ such that $\bar{\lambda}^T x^\star < 0$. For any fixed $(\bar{a}, \bar{B})$ in $\mathcal{U}$, we can see from (43) (already established) that

$$\inf_{(a,B)\in\mathcal{U},\ \lambda\in\mathcal{X}^*} \frac{x^{\star T}(a+\lambda)}{\sqrt{x^{\star T}Bx^\star}} \leq \inf_{\lambda\in\mathcal{X}^*} \frac{x^{\star T}(\bar{a}+\lambda)}{\sqrt{x^{\star T}\bar{B}x^\star}} \leq \frac{x^{\star T}\bar{a}}{\sqrt{x^{\star T}\bar{B}x^\star}} + \inf_{t\geq 0} \frac{tx^{\star T}\bar{\lambda}}{\sqrt{x^{\star T}\bar{B}x^\star}} = -\infty.$$

However, this is contradictory to the fact that

$$\frac{x^{\star T}(a^\star + \lambda^\star)}{\sqrt{x^{\star T}B^\star x^\star}} = \inf_{(a,B)\in\mathcal{U},\ \lambda^*\in\mathcal{X}^*} \frac{x^{\star T}(a+\lambda)}{\sqrt{x^{\star T}Bx^\star}}$$

must be finite.

We complete the proof by showing $\lambda^{\star T}x^\star = 0$. Since $0 \in \mathcal{X}^*$, the saddle-point property (43) implies that

$$\frac{x^{\star T}(a^\star + \lambda^\star)}{\sqrt{x^{\star T}B^\star x^\star}} \leq \frac{x^{\star T}a^\star}{\sqrt{x^{\star T}B^\star x^\star}},$$

which means $x^{\star T}\lambda^\star \leq 0$. Since $\lambda \in \mathcal{X}^*$ and $x^\star \in \mathcal{X}$, we also have $x^{\star T}\lambda^\star \geq 0$.

A.3. Proof of Proposition 2. Let γ be the optimal value of (3):

$$\gamma = \sup_{x\in\mathcal{X}} \inf_{(a,B)\in\mathcal{U}} \frac{x^T a}{\sqrt{x^T Bx}}. \tag{51}$$

We can see that for any $x \in \mathcal{X}$, the set $X = \{(\sqrt{x^T Bx}, x^T a) \mid (a, B) \in \mathcal{U}\}$ cannot lie entirely above the line $r = \gamma\sigma$ in the (σ, r) space.

Using the Cauchy–Schwarz inequality, we can show that for any nonzero x and y

$$\frac{1}{2}\left(\sqrt{x^T Bx} + \sqrt{y^T By}\right) \geq \left(\left(\frac{x+y}{2}\right)^T B \left(\frac{x+y}{2}\right)\right)^{1/2}. \tag{52}$$

Here equality holds if and only if x and y are linearly dependent.

Suppose that there are two solutions $x^\star$ and $y^\star$ which are not linearly dependent. Then, the two sets

$$X = \left\{\left(\sqrt{x^{\star T}Bx^\star}, x^{\star T}a\right) \;\middle|\; (a,B) \in \mathcal{U}\right\}, \quad Y = \left\{\left(\sqrt{y^{\star T}By^\star}, y^{\star T}a\right) \;\middle|\; (a,B) \in \mathcal{U}\right\}$$

lie on and above, but cannot lie entirely above, the line $r = \gamma\sigma$ in the (σ, r) space. If $x^\star$ and $y^\star$ are not linearly dependent, then it follows from (52) and the compactness of $\mathcal{U}$ that the set $Z = \{(\sqrt{z^{\star T}Bz^\star}, z^{\star T}a) \mid (a, B) \in \mathcal{U}\}$, with $z^\star = (x^\star + y^\star)/2$, lies entirely above the line $r = \gamma\sigma$. Therefore, we have

$$\inf_{(a,B)\in\mathcal{U}} \frac{z^{\star T}a}{\sqrt{z^{\star T}Bz^\star}} > \gamma,$$

which is contradictory to the definition of γ given in (51).

Acknowledgments. The authors thank Alessandro Magnani, Almir Mutapcic, and Young-Han Kim for helpful comments and suggestions.

TWO ALGORITHMS FOR THE MINIMUM ENCLOSING BALL PROBLEM*

E. ALPER YILDIRIM†

Abstract. Given $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$ and $\epsilon > 0$, we propose and analyze two algorithms for the problem of computing a $(1+\epsilon)$-approximation to the radius of the minimum enclosing ball of $\mathcal{A}$. The first algorithm is closely related to the Frank–Wolfe algorithm with a proper initialization applied to the dual formulation of the minimum enclosing ball problem. We establish that this algorithm converges in $O(1/\epsilon)$ iterations with an overall complexity bound of $O(mn/\epsilon)$ arithmetic operations. In addition, the algorithm returns a "core set" of size $O(1/\epsilon)$, which is independent of both m and n. The latter algorithm is obtained by incorporating "away" steps into the former one at each iteration and achieves the same asymptotic complexity bound as the first one. While the asymptotic bound on the size of the core set returned by the second algorithm also remains the same as the first one, the latter algorithm has the potential to compute even smaller core sets in practice, since, in contrast to the former one, it allows "dropping" points from the working core set at each iteration. Our analysis reveals that the leading terms in the asymptotic complexity analysis are reasonably small. In contrast to the first algorithm, we also establish that the second algorithm asymptotically exhibits linear convergence, which provides further insight into our computational results, indicating that the latter algorithm indeed terminates faster with smaller core sets in comparison with the first one. We also discuss how our algorithms can be extended to compute an approximation to the minimum enclosing ball of more general input sets without sacrificing the iteration complexity and the bound on the core set size. In particular, we establish the existence of a core set of size $O(1/\epsilon)$ for a much wider class of input sets. We adopt the real number model of computation in our analysis.

Key words. minimum enclosing balls, core sets, approximation algorithms

1. Introduction.

Given a finite set of points $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$, we are concerned with the problem of computing an approximation to the minimum enclosing ball of $\mathcal{A}$, which we shall denote by MEB($\mathcal{A}$).

For $c \in \mathbb{R}^n$ and a nonnegative $\rho \in \mathbb{R}$, let $\mathcal{B}_{c,\rho} \subset \mathbb{R}^n$ denote the ball centered at c with radius ρ, i.e.,

$$\mathcal{B}_{c,\rho} := \{x \in \mathbb{R}^n : \|x - c\| \leq \rho\},$$

where $\|\cdot\|$ denotes the Euclidean norm.

Given $\epsilon > 0$, a ball $\mathcal{B}_{c,\rho}$ is said to be a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$) if

$$\mathcal{A} \subset \mathcal{B}_{c,\rho}, \quad \rho \leq (1+\epsilon)\rho_{\mathcal{A}}, \tag{1}$$

where $\mathcal{B}_{c_{\mathcal{A}},\rho_{\mathcal{A}}} := \text{MEB}(\mathcal{A})$.

A subset $\mathcal{X} \subseteq \mathcal{A}$ is said to be an ϵ-core set (or a core set) of $\mathcal{A}$ if

$$\rho_{\mathcal{X}} \leq \rho_{\mathcal{A}} \leq (1+\epsilon)\rho_{\mathcal{X}}, \tag{2}$$

where $\mathcal{B}_{c_{\mathcal{X}},\rho_{\mathcal{X}}} := \text{MEB}(\mathcal{X})$. Small core sets play an important role in designing efficient algorithms for large-scale problems, since they provide a compact representation of

the input set $\mathcal{A}$. If a small ϵ-core set $\mathcal{X}$ is available, then solving the problem on $\mathcal{X}$ already yields a good approximation to MEB($\mathcal{A}$). Since the center $c_{\mathcal{A}}$ of MEB($\mathcal{A}$) lies in the convex hull of $\mathcal{A}$ (cf. section 2), it follows from Carathéodory's theorem that there always exists a 0-core set of size at most $n + 1$.

Minimum enclosing balls have numerous important applications in clustering, nearest neighbor search, data classification, support vector machines, machine learning, facility location, collision detection, computer graphics, and military operations. We refer the reader to [24] and the references therein. In particular, many of these applications give rise to large-scale instances of the MEB problem, and a reasonably small accuracy suffices for such applications.

The minimum enclosing ball problem has a fairly rich literature dating back to at least the 19th century [37]. One of the earliest known solution methods is given by Sylvester [38], which is attributed to Peirce, and later rediscovered by Chrystal [9]. The reader is referred to [6] for a detailed account of the earlier history of this problem. More recent references include [25, 14, 28, 11, 8, 35, 7, 23, 22, 27, 31, 40, 16, 17, 4, 2, 24, 42, 13, 12, 29, 30, 21, 44, 32].

The earliest known algorithm due to Chrystal and Peirce [38, 9] computes the exact minimum enclosing ball of m points in the plane in $O(m^2)$ operations in the worst case. For a fixed dimension n, the minimum enclosing ball of m points can be computed in $O(m)$ operations [27, 40]. However, the dependence on the dimension n is exponential. Bădoiu, Har-Peled, and Indyk [4] established the existence of an ϵ-core set of size $O(1/\epsilon^2)$. Note that the size of the core set is independent of m and n. Based on this result, their algorithm can compute a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$) in $O\left(mn/\epsilon^2 + (1/\epsilon^{10})\log(1/\epsilon)\right)$ operations. Bădoiu and Clarkson [2] and Kumar, Mitchell, and Yıldırım [24] independently discovered the existence of an ϵ-core set of size $O(1/\epsilon)$. As noted in [2], this improved core set result can be combined with the algorithm of [4] to obtain an improved running time of $O\left(mn/\epsilon + 1/\epsilon^5\right)$. The algorithm of [24] achieves a slightly improved complexity bound of $O\left(mn/\epsilon + (1/\epsilon^{4.5})\log(1/\epsilon)\right)$ using second-order cone programming combined with column generation. In addition, Bădoiu and Clarkson [2] proposed another simple algorithm that computes a $(1 + \epsilon)$-approximation in $O(mn/\epsilon^2)$ operations. In another paper, the same authors established a tight upper bound of $\lceil 1/\epsilon \rceil$ on the size of an ϵ-core set [3]. However, their construction is based on the assumption that $n \geq \lfloor 1/\epsilon \rfloor$. The algorithm of Panigrahy [33] computes a $(1 + \epsilon)$-approximation in $O(mn/\epsilon)$ operations. Note that this algorithm has the best known dependence on ϵ, and each of these algorithms is polynomial for fixed ϵ. If ϵ is viewed as part of the input data, the minimum enclosing ball can be formulated as an instance of convex programming problem and can be solved using the ellipsoid method in $O\left(n^3 m \log(1/\epsilon)\right)$ operations [19]. Alternatively, interior-point methods yield an overall complexity bound of $O\left(n^2 m^{3/2} \log(1/\epsilon)\right)$ operations if the problem is formulated as an instance of second-order cone programming [24].

In this paper, we focus on large-scale instances of the minimum enclosing ball problem for which a reasonably small value of ϵ is satisfactory. Throughout this paper, we adopt the real number model of computation [5], i.e., we assume that arithmetic operations with real numbers and comparisons can be done at unit cost. We propose and analyze two algorithms that compute a $(1 + \epsilon)$-approximation to MEB($\mathcal{A}$) for a given $\epsilon > 0$. Our first algorithm is closely related to the Frank–Wolfe algorithm [15] applied to the dual formulation of the problem. At each iteration, the algorithm can only add points to the working core set. The second algorithm is obtained by incorporating "away" steps into each iteration of the first one (see, e.g., [41, 20]). As such, the

latter algorithm has the potential to compute a smaller core set than the former one, since it allows "dropping" points from the working core set at each iteration. A similar algorithm has recently been proposed for the minimum-volume enclosing ellipsoid problem [39]. Both of our algorithms compute a $(1+\epsilon)$-approximation to $\mathrm{MEB}(\mathcal{A})$ in $O(mn/\epsilon)$ operations, which matches the currently best known dependence on ϵ. In addition, each algorithm explicitly computes an ϵ-core set of size $O(1/\epsilon)$. Our analysis reveals that the leading terms in the complexity analysis are reasonably small, which further contributes to the efficiency of our algorithms. Furthermore, we establish that the second algorithm asymptotically exhibits linear convergence. Our computational results indicate that the sizes of the core sets returned by our algorithms are generally much smaller than the corresponding worst-case estimates. Furthermore, as expected, the latter algorithm almost always outperforms the former one both in terms of the running time and the core set size.

We also discuss how our algorithms can be extended to compute an approximate minimum enclosing ball of more general input sets. In particular, we establish that the asymptotic core set size of $O(1/\epsilon)$ extends to a much larger class of input sets.

We first compare our algorithms with the one proposed by Panigrahy [33], which computes a $(1+\epsilon)$-approximation to the minimum enclosing ball of a finite set of points in $O(mn/\epsilon)$ arithmetic operations. Panigrahy's algorithm starts with a ball whose radius is known to be smaller than that of the minimum enclosing ball and maintains an upper bound ζ on the difference between these two radii. At each iteration, the algorithm moves the current ball toward the furthest point from the center until the ball touches that particular point without changing the radius of the ball. After repeating such iterations $O(1/\zeta)$ times, the algorithm either provides a certificate that an approximate solution has been computed or decides that either the radius can be increased or the error bound ζ can be decreased. The whole procedure is then repeated using the new parameters for the radius and the error bound. Similarly to Panigrahy's algorithm, each of our algorithms also constructs a sequence of balls, and our first algorithm moves the center toward the furthest point from the center of the current ball at each iteration. However, the center moves by only a fraction of this distance. Furthermore, the second algorithm also allows us to move the current center away from the closest point in the working core set. Unlike Panigrahy's algorithm, our algorithms construct balls of strictly increasing radii in each iteration, and the radius and the error bound are updated at each iteration. While Panigrahy's algorithm checks the termination criterion after each set of $O(1/\zeta)$ iterations, our algorithms employ a simpler termination criterion in each iteration. This strategy has the potential advantage of earlier termination than that predicted by the theoretical worst-case estimate. Finally, while Panigrahy exclusively works with an input set of finite points with more general enclosing shapes, our algorithms can easily be modified to compute an approximation of the minimum enclosing ball of a much wider class of input sets without sacrificing the core set bound of $O(1/\epsilon)$.

After the first version of this manuscript had been submitted, Clarkson [10] announced several results concerning the convergence properties of the Frank–Wolfe algorithm, which is the main ingredient in both of our algorithms. He studied the problem of maximizing a general concave function over the unit simplex, of which the dual formulation of the minimum enclosing problem is a special case. By giving a general definition of an *additive* ϵ-core set, he established core set results for several variants of the Frank–Wolfe algorithm in a more general setting. Due to the special structure of the objective function in the dual formulation of the minimum enclosing

ball problem, his additive core set definition almost matches with our multiplicative core set definition given by (2). He presented an improved complexity bound of $O(mn/\epsilon)$ for a slightly modified version of the algorithm of [2], which matches the complexity bounds of our algorithms.

On the other hand, he establishes an ϵ-core set size of $O(1/\epsilon^2)$ for the general problem using his Algorithm 1.1, which, apart from the choice of the initial solutions, coincides with our first algorithm that computes a core set of size $O(1/\epsilon)$. He proposes a more sophisticated algorithm (cf. Algorithm 4.2 in [10]), which requires the computation of the optimal solution of a sequence of subproblems restricted to the smaller faces of the unit simplex, to establish the improved core set result of $O(1/\epsilon)$. In addition, he also studies a variant of the Frank–Wolfe algorithm that uses "away" steps (cf. Algorithm 5.1), for which he establishes a core set size of $O(1/\epsilon)$. However, this algorithm differs from our second algorithm, since it again requires the computation of the optimal solution of a sequence of subproblems. In contrast, we establish a core set size of $O(1/\epsilon)$ using much simpler (and lazier) algorithms. We derive explicit small constants inside the asymptotic bounds. Finally, we extend each of our algorithms to much more general input sets and establish the existence of core sets of size $O(1/\epsilon)$. Therefore, while Clarkson's results apply to a more general class of problems, we achieve the same or stronger results using simpler algorithms for the special case of the minimum enclosing ball problem, but we allow more general input sets.

This paper is organized as follows. In the remainder of this section, we define our notation. In section 2, we discuss optimization formulations for the minimum enclosing ball problem. Section 3 presents our first algorithm. The second algorithm is the topic of section 4. We discuss the extensions of our algorithms in section 5. The computational results are presented in section 6. Finally, we conclude the paper with some future research directions in section 7.

1.1. Notation. Vectors are denoted by lowercase Roman letters. For a vector p, p_i denotes its ith component. Inequalities on vectors apply to each component. We reserve e^j for the jth unit vector. Uppercase Roman letters are reserved for matrices. We use $\log(\cdot)$ to denote the natural logarithm. Functions and operators are denoted by uppercase Greek letters. Scalars except for m and n are represented by lowercase Greek letters unless they represent components of a vector or elements of a sequence of scalars, vectors, or matrices. We reserve i, j, and k for such indexing purposes. Uppercase script letters are used for all other objects such as sets, balls, and ellipsoids.

2. Optimization formulations. In this section, we review the optimization formulations of the minimum enclosing ball problem. We remark that most of the material of this section already appears in the earlier literature (see, e.g., [11, 26]). Some results and proofs are included for the sake of completeness.

Let $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$. The minimum enclosing ball of $\mathcal{A}$ can be computed by solving the following optimization problem:

$$(\mathcal{P}_1) \quad \begin{array}{ll} \min_{c,\rho} & \rho \\ \text{subject to} & \\ & \left\|a^i - c\right\| \le \rho, \quad i = 1, \ldots, m, \end{array}$$

where $c \in \mathbb{R}^n$ and $\rho \in \mathbb{R}$ are the decision variables. By squaring the constraints and defining $\gamma := \rho^2$, $(\mathcal{P}_1)$ can be converted into the following optimization problem with

smooth, convex quadratic constraints:

$$\begin{array}{lll} (\mathcal{P}_2) & \min_{c,\gamma} & \gamma \\ & \text{subject to} & \\ & & (a^i)^T a^i - 2(a^i)^T c + c^T c \leq \gamma, \quad i = 1, \ldots, m. \end{array}$$

The Lagrangian dual of $(\mathcal{P}_2)$ is given by

$$\begin{array}{lll} (\mathcal{D}) & \max_u & \Phi(u) := \sum_{i=1}^m u_i (a^i)^T a^i - \left(\sum_{i=1}^m u_i a^i \right)^T \left(\sum_{i=1}^m u_i a^i \right) \\ & \text{subject to} & \\ & & \sum_{i=1}^m u_i = 1, \\ & & u_i \geq 0, \quad i = 1, \ldots, m, \end{array}$$

where $u \in \mathbb{R}^m$ is the decision variable.

Since $(\mathcal{P}_2)$ is a concave maximization problem with linear constraints, it follows from the Karush–Kuhn–Tucker optimality conditions that $(c_{\mathcal{A}}, \gamma_{\mathcal{A}}) \in \mathbb{R}^n \times \mathbb{R}$ is an optimal solution of $(\mathcal{P}_2)$ if and only if there exists $u^* \in \mathbb{R}^m$ such that

$$\sum_{i=1}^m u_i^* = 1, \tag{3a}$$

$$c_{\mathcal{A}} = \sum_{i=1}^m u_i^* a^i, \tag{3b}$$

$$(a^i)^T a^i - 2(a^i)^T c_{\mathcal{A}} + (c_{\mathcal{A}})^T c_{\mathcal{A}} \leq \gamma_{\mathcal{A}}, \quad i = 1, \ldots, m, \tag{3c}$$

$$u_i^* \left((a^i)^T a^i - 2(a^i)^T c_{\mathcal{A}} + (c_{\mathcal{A}})^T c_{\mathcal{A}} - \gamma_{\mathcal{A}} \right) = 0, \quad i = 1, \ldots, m, \tag{3d}$$

$$u^* \geq 0. \tag{3e}$$

A simple manipulation of the optimality conditions reveals that

$$\gamma_{\mathcal{A}} = \Phi(u^*), \tag{4}$$

which implies that $u^* \in \mathbb{R}^m$ is an optimal solution of $(\mathcal{D})$ and that strong duality holds between $(\mathcal{P}_2)$ and $(\mathcal{D})$. Note that the center $c_{\mathcal{A}}$ of the minimum enclosing ball of $\mathcal{A}$ is given by a convex combination of the elements of $\mathcal{A}$ by (3b). In addition, it follows from (3d) that only the components of u^* corresponding to the points on the boundary of MEB($\mathcal{A}$) can have a positive value.

LEMMA 2.1. *Let $\mathcal{A} = \{a^1, \ldots, a^m\}$. The minimum enclosing ball of $\mathcal{A}$ exists and is unique. Let $u^* \in \mathbb{R}^m$ denote the optimal solution of $(\mathcal{D})$. Then, MEB($\mathcal{A}$) $= \mathcal{B}_{c_{\mathcal{A}}, \rho_{\mathcal{A}}}$, where*

$$c_{\mathcal{A}} = \sum_{i=1}^m u_i^* a^i, \quad \rho_{\mathcal{A}} = \sqrt{\Phi(u^*)}. \tag{5}$$

Proof. Note that $\mathcal{A} \subset \mathcal{B}_{0,\rho^u}$, where $\rho^u := \max_{i=1,\ldots,m} \left\| a^i \right\|$. By adding the redundant constraint $\gamma \leq (\rho^u)^2$ to $(\mathcal{P}_2)$, the feasible region becomes a closed and bounded set and the objective function is continuous, which establishes the existence of MEB($\mathcal{A}$). If there were two different minimum enclosing balls, one can then construct a ball of smaller radius that encloses the intersection of the two balls and

hence also $\mathcal{A}$, which is a contradiction. The relationships (5) directly follow from the discussions preceding the lemma. □

By Lemma 2.1, MEB($\mathcal{A}$) can be computed by solving the dual problem ($\mathcal{D}$), which will be the basis of both of our algorithms in this paper. We close this section by the following technical result, which will play an important role in finding a good initial feasible solution in our algorithms. The reader is referred to [18, 4, 12] for the proof of this result.

LEMMA 2.2. *Let $\mathcal{A} = \{a^1, \ldots, a^m\}$, and let MEB($\mathcal{A}$) $= \mathcal{B}_{c_\mathcal{A}, \rho_\mathcal{A}}$. Then, any closed half-space that contains $c_\mathcal{A}$ also contains at least one point $a^j \in \mathcal{A}$ such that $\|a^j - c_\mathcal{A}\| = \rho_\mathcal{A}$.*

3. The first algorithm. Given $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$ and $\epsilon > 0$, we present our first algorithm that computes a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$) in this section.

Algorithm 3.1 The first algorithm that computes a $(1 + \epsilon)$-approximation to MEB($\mathcal{A}$).

Require: Input set of points $\mathcal{A} = \{a^1, \ldots, a^m\} \subset \mathbb{R}^n, \epsilon > 0$.

1: $\alpha \leftarrow \arg\max_{i=1,\ldots,m} \|a^i - a^1\|^2$, $\beta \leftarrow \arg\max_{i=1,\ldots,m} \|a^i - a^\alpha\|^2$;
2: $u_i^0 \leftarrow 0, \quad i = 1, \ldots, m$;
3: $u_\alpha^0 \leftarrow 1/2, \quad u_\beta^0 \leftarrow 1/2$;
4: $\mathcal{X}_0 \leftarrow \{a^\alpha, a^\beta\}$;
5: $c^0 \leftarrow \sum_{i=1}^m u_i^0 a^i$;
6: $\gamma^0 \leftarrow \Phi(u^0)$;
7: $\kappa \leftarrow \arg\max_{i=1,\ldots,m} \|a^i - c^0\|^2$;
8: $\delta_0 \leftarrow \left(\|a^\kappa - c^0\|^2 / \gamma^0\right) - 1$;
9: $k \leftarrow 0$;
10: While $\delta_k > (1+\epsilon)^2 - 1$, do
11: **loop**
12: $\lambda^k \leftarrow \delta_k / [2(1+\delta_k)]$;
13: $k \leftarrow k + 1$;
14: $u^k \leftarrow (1 - \lambda^{k-1}) u^{k-1} + \lambda^{k-1} e^\kappa$;
15: $c^k \leftarrow (1 - \lambda^{k-1}) c^{k-1} + \lambda^{k-1} a^\kappa$;
16: $\mathcal{X}_k \leftarrow \mathcal{X}_{k-1} \cup \{a^\kappa\}$;
17: $\gamma^k \leftarrow \Phi(u^k)$;
18: $\kappa \leftarrow \arg\max_{i=1,\ldots,m} \|a^i - c^k\|^2$;
19: $\delta_k \leftarrow \left(\|a^\kappa - c^k\|^2 / \gamma^k\right) - 1$;
20: **end loop**
21: **Output** $c^k, \mathcal{X}_k, u^k, \sqrt{(1+\delta_k)\gamma^k}$.

We now describe Algorithm 3.1 in more detail. In step 1, the algorithm computes the furthest point $a^\alpha \in \mathcal{A}$ from $a^1 \in \mathcal{A}$ and then computes the furthest point $a^\beta \in \mathcal{A}$ from a^α. Steps 2 and 3 initialize the vector $u^0 \in \mathbb{R}^m$. Note that u^0 is a feasible solution of the dual problem ($\mathcal{D}$). The core set $\mathcal{X}_0$ is initialized at step 4. At each iteration, the algorithm implicitly constructs a "trial" ball with center c^k and radius $(\gamma^k)^{1/2}$. By Lemma 2.1, this ball coincides with MEB($\mathcal{A}$) if and only if u^k is an optimal solution of ($\mathcal{D}$). Otherwise, at least one point in $\mathcal{A}$ lies outside of this ball. Note that δ_k satisfies $\|a^\kappa - c^k\|^2 = (1+\delta_k)\gamma^k$, where $a^\kappa \in \mathcal{A}$ is the furthest point from c^k. It follows that the trial ball encloses $\mathcal{A}$ if its radius is expanded by a factor

of $(1+\delta_k)^{1/2}$, i.e., $\Phi(u^k) \le \Phi(u^*) \le (1+\delta_k)\Phi(u^k)$. Unless the termination criterion is satisfied, the new center c^{k+1} is computed by shifting c^k toward the furthest point a^κ, which is added to the working core set $\mathcal{X}_{k+1}$, and u^{k+1} is updated accordingly to ensure that dual feasibility is maintained. The algorithm continues in an iterative manner by computing a new trial ball corresponding to u^{k+1}.

Algorithm 3.1 is the adaptation of the Frank–Wolfe algorithm to the dual problem $(\mathcal{D})$. At each iteration, the quadratic objective function $\Phi(u)$ of $(\mathcal{D})$ is linearized at the current feasible solution u^k. Since the feasible region of $(\mathcal{D})$ is the unit simplex, the unit vector e^κ, where κ is the index of the furthest point in $\mathcal{A}$ from c^k, solves the linearized subproblem. It is easy to verify that

$$\lambda^k = \arg\max_{\lambda\in[0,1]} \Phi\left((1-\lambda)u^k + \lambda e^\kappa\right).$$

We remark that Algorithm 3.1 uses only the first-order approximation to the objective function Φ. As such, each iteration is fairly cheap, but the number of iterations is usually significantly higher than other algorithms that use second-order information such as interior-point methods. However, such general-purpose algorithms become computationally infeasible for larger problems, since each iteration is usually much more expensive. This observation provides one of our motivations to develop a specialized algorithm for this problem.

3.1. Analysis of the first algorithm. This subsection is devoted to the analysis of Algorithm 3.1.

LEMMA 3.1. *$u^0 \in \mathbb{R}^m$ satisfies $\gamma^0 = \Phi(u^0) \ge (1/3)\Phi(u^*) = (1/3)\gamma_{\mathcal{A}}$, where $u^* \in \mathbb{R}^m$ and $\gamma_{\mathcal{A}}$ are the optimal solution and the optimal value of $(\mathcal{D})$, respectively. Furthermore, $\delta_0 \le 8$.*

Proof. For any vectors $y, z \in \mathbb{R}^n$ and any $\varphi \in \mathbb{R}$, it is easy to verify that

$$\|(1-\varphi)y + \varphi z\|^2 = (1-\varphi)\|y\|^2 + \varphi\|z\|^2 - \varphi(1-\varphi)\|y-z\|^2. \tag{6}$$

Note that

$$\Phi(u^0) = (1/2)\left\|a^\alpha\right\|^2 + (1/2)\left\|a^\beta\right\|^2 - \left\|(1/2)\left(a^\alpha + a^\beta\right)\right\|^2 = (1/4)\left\|a^\alpha - a^\beta\right\|^2, \tag{7}$$

where we used (6) to derive the second equality. The proof is based on establishing that at least one of a^α and a^β is sufficiently away from the center $c_{\mathcal{A}}$ of $\mathrm{MEB}(\mathcal{A})$.

First, suppose that $\left\|a^1 - c_{\mathcal{A}}\right\| \ge (1/\sqrt{3})\rho_{\mathcal{A}}$, where $\rho_{\mathcal{A}}$ is the radius of $\mathrm{MEB}(\mathcal{A})$. Let $\mathcal{H}$ be the hyperplane passing through $c_{\mathcal{A}}$ that is perpendicular to $a^1 - c_{\mathcal{A}}$. Let $\mathcal{H}_+$ denote the closed half-space whose boundary is $\mathcal{H}$ and which does not contain a^1. By Lemma 2.2, $\mathcal{H}_+$ contains a point $a^j \in \mathcal{A}$ such that $\left\|a^j - c_{\mathcal{A}}\right\| = \rho_{\mathcal{A}}$. Therefore, $\left\|a^\alpha - a^1\right\|^2 \ge \left\|a^1 - c_{\mathcal{A}}\right\|^2 + (\rho_{\mathcal{A}})^2 \ge (4/3)\gamma_{\mathcal{A}}$, where $\gamma_{\mathcal{A}} = \Phi(u^*) = (\rho_{\mathcal{A}})^2$ is the optimal value of $(\mathcal{D})$. It follows from (7) that

$$\Phi(u^0) = (1/4)\left\|a^\beta - a^\alpha\right\|^2 \ge (1/4)\left\|a^1 - a^\alpha\right\|^2 \ge (1/3)\Phi(u^*).$$

Suppose now that $\left\|a^1 - c_{\mathcal{A}}\right\| = \theta\rho_{\mathcal{A}}$, where $\theta < 1/\sqrt{3}$. In this case, $\left\|a^1 - a^\alpha\right\| \le \left\|a^1 - c_{\mathcal{A}}\right\| + \|c_{\mathcal{A}} - a^\alpha\|$, which implies that

$$\|c_{\mathcal{A}} - a^\alpha\| \ge \left\|a^1 - a^\alpha\right\| - \left\|a^1 - c_{\mathcal{A}}\right\| \ge (1+\theta^2)^{1/2}\rho_{\mathcal{A}} - \theta\rho_{\mathcal{A}} = [(1+\theta^2)^{1/2} - \theta]\rho_{\mathcal{A}},$$

where we again invoked Lemma 2.2 to obtain a lower bound on $\left\|a^1 - a^\alpha\right\|$. Therefore, one more application of Lemma 2.2 yields

$$\begin{aligned}\Phi(u^0) &= (1/4)\left\|a^\beta - a^\alpha\right\|^2 \\ &\geq (1/4)\left(\left\|a^\alpha - c_{\mathcal{A}}\right\|^2 + (\rho_{\mathcal{A}})^2\right) \\ &\geq (1/4)\left(1+\theta^2+\theta^2 - 2\theta(1+\theta^2)^{1/2}+1\right)\gamma_{\mathcal{A}} \\ &= (1/2)\left(1+\theta^2-\theta(1+\theta^2)^{1/2}\right)\gamma_{\mathcal{A}}.\end{aligned}$$

It is easy to verify that $(1/2)\left(1+\theta^2-\theta(1+\theta^2)^{1/2}\right)$ is a decreasing function of θ. Since $\theta < 1/\sqrt{3}$, it follows that

$$\Phi(u^0) \geq (1/2)\,(1+1/3-2/3)\,\gamma_{\mathcal{A}} = (1/3)\Phi(u^*),$$

which completes the first part of the proof.

Let a^κ be the furthest point in $\mathcal{A}$ from $c^0 = (1/2)(a^\alpha + a^\beta)$. Then,

$$\begin{aligned}\left\|a^\kappa - c^0\right\| &\leq \left\|a^\kappa - a^\alpha\right\| + \left\|a^\alpha - c^0\right\|, \\ &\leq \left\|a^\beta - a^\alpha\right\| + (1/2)\left\|a^\beta - a^\alpha\right\| = (3/2)\left\|a^\beta - a^\alpha\right\|,\end{aligned}$$

where we used the definition of c^0 and the fact that a^β is the furthest point in $\mathcal{A}$ from a^α to derive the second inequality. Therefore, $\delta_0 = (\|a^\kappa - c^0\|^2/\gamma^0) - 1 \leq [4(9/4)(\gamma^0/\gamma^0)] - 1 = 8$, where we used (7). The second part of the assertion follows. □

Lemma 3.1 establishes several properties of the initial feasible solution $u^0 \in \mathbb{R}^m$. The next lemma relates the dual objective function values evaluated at the successive iterates generated by Algorithm 3.1.

LEMMA 3.2. *For each $k = 0, 1, \ldots$, the following relationship is satisfied:*

$$\gamma^{k+1} = \gamma^k\left(1 + \frac{\delta_k^2}{4(1+\delta_k)}\right). \tag{8}$$

Proof. Let a^κ denote the furthest point from c^k. Then, $u^{k+1} = \left(1-\lambda^k\right)u^k + \lambda^k e^\kappa$. Therefore,

$$\begin{aligned}\gamma^{k+1} &= \Phi\left((1-\lambda^k)u^k + \lambda^k e^\kappa\right) \\ &= (1-\lambda^k)\sum_{i=1}^m u_i^k (a^i)^T(a^i) + \lambda^k (a^\kappa)^T(a^\kappa) - \left\|(1-\lambda^k)\left(\sum_{i=1}^m u_i^k a^i\right) + \lambda^k a^\kappa\right\|^2 \\ &= (1-\lambda^k)\left(\sum_{i=1}^m u_i^k (a^i)^T(a^i) - \left\|\sum_{i=1}^m u_i^k a^i\right\|^2\right) + \lambda^k(1-\lambda^k)\left\|\sum_{i=1}^m u_i^k a^i - a^\kappa\right\|^2 \\ &= (1-\lambda^k)\gamma^k + \lambda^k(1-\lambda^k)\left\|a^\kappa - c^k\right\|^2 \\ &= (1-\lambda^k)\gamma^k + \lambda^k(1-\lambda^k)(1+\delta_k)\gamma^k \\ &= \gamma^k\left(1 + \frac{\delta_k^2}{4(1+\delta_k)}\right),\end{aligned}$$

where we used (6) in the third equality, the definitions of c^k and δ_k in the fourth and fifth equalities, respectively, and the definition of λ^k in the last equality. □

We now focus on establishing an upper bound on the number of iterations required to have an iterate u^k with δ_k sufficiently small. To that end, let us define

$$\tau_\nu := \min\left\{k : \delta_k \leq \frac{1}{2^\nu}\right\}, \quad \nu = 0, 1, \ldots . \tag{9}$$

LEMMA 3.3. *τ_ν satisfies the following relationships:*

$$\tau_0 \leq 9, \tag{10a}$$

$$\tau_\nu - \tau_{\nu-1} \leq 12.5(2^\nu) \quad \nu = 1, 2, \ldots . \tag{10b}$$

Proof. Let us first consider τ_0. At each iteration $k < \tau_0$, we have $\delta_k > 1$. By Lemma 3.2,

$$\begin{aligned}\gamma^{k+1} &= \gamma^k\left(1 + \frac{\delta_k^2}{4(1+\delta_k)}\right),\\ &\geq \gamma^k(1 + 1/8),\end{aligned}$$

where we used the fact that $1 + (1/4)(x^2/(1+x))$ is an increasing function of x. Iterating this inequality, we obtain $\gamma^{k+1} \geq (9/8)^{k+1}\gamma^0$. By Lemma 3.1 and the feasibility of u^{k+1}, we have

$$\gamma_{\mathcal{A}} \geq \gamma^{k+1} \geq (9/8)^{k+1}\gamma^0 \geq (9/8)^{k+1}\left(\gamma_{\mathcal{A}}/3\right),$$

which implies that $\tau_0 \leq k + 1 \leq \log(3)/\log(9/8)$ or, equivalently, that $\tau_0 \leq 9$.

Let us now consider $\tau_\nu - \tau_{\nu-1}$ for $\nu = 1, 2, \ldots$. Let $\mu := \tau_{\nu-1}$. At each iteration k with $\delta_k > 1/2^\nu$, we similarly have

$$\gamma^{k+1} = \gamma^k\left(1 + \frac{\delta_k^2}{4(1+\delta_k)}\right) \geq \gamma^k\left(1 + \frac{1}{2^{2+\nu}(2^\nu+1)}\right).$$

At iteration μ, we have $\delta_\mu \leq 1/2^{\nu-1}$. Since the ball centered at c^μ with radius $[(1+\delta_\mu)\gamma^\mu]^{1/2}$ encloses $\mathcal{A}$, it follows that $\gamma^\mu \leq \gamma_{\mathcal{A}} \leq (1+\delta_\mu)\gamma^\mu \leq (1 + (1/2^{\nu-1}))\gamma^\mu$. Together with the repeated application of the inequality above, we have

$$\gamma_{\mathcal{A}} \geq \gamma^{\mu+k} \geq \gamma^\mu\left(1 + \frac{1}{2^{2+\nu}(2^\nu+1)}\right)^k \geq \frac{\gamma_{\mathcal{A}}}{1 + (1/2^{\nu-1})}\left(1 + \frac{1}{2^{2+\nu}(2^\nu+1)}\right)^k,$$

which implies that

$$\begin{aligned}\tau_\nu - \tau_{\nu-1} &\leq \frac{\log\left(1 + \frac{1}{2^{\nu-1}}\right)}{\log\left(1 + \frac{1}{2^{2+\nu}(2^\nu+1)}\right)}\\ &\leq \frac{1}{2^{\nu-1}}\frac{\frac{1}{2^{2+\nu}(2^\nu+1)} + 1}{\frac{1}{2^{2+\nu}(2^\nu+1)}} = \frac{2}{2^\nu} + 8(2^\nu + 1)\\ &\leq 9 + 8(2^\nu) \leq (12.5)2^\nu,\end{aligned}$$

where we used the inequalities $\log(1+x) \leq x$ for $x > -1$ and $\log(1+x) \geq x/(x+1)$ for $x > -1$. ∎

The following lemma establishes an upper bound on the number of iterations to obtain an iterate with $\delta_k \leq \delta$.

LEMMA 3.4. *Let $\delta \in (0,1)$. Algorithm* 3.1 *computes an iterate k satisfying $\delta_k \leq \delta$ in at most $9 + 50/\delta$ iterations.*

Proof. Let σ be an integer such that $1/2^\sigma \leq \delta \leq 2/2^\sigma$. Therefore, after at most τ_σ iterations, Algorithm 3.1 computes an iterate k satisfying $\delta_k \leq \delta$. By Lemma 3.3,

$$\tau_\sigma = \tau_0 + \sum_{\nu=1}^{\sigma} (\tau_\nu - \tau_{\nu-1}) \leq 9 + 12.5 \sum_{\nu=1}^{\sigma} 2^\nu \leq 9 + 25(2^\sigma) \leq 9 + 50/\delta. \qquad \square$$

We now have all of the ingredients to establish the iteration complexity of Algorithm 3.1.

THEOREM 3.1. *Given $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$ and $\epsilon \in (0,1)$, Algorithm* 3.1 *computes a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$) in at most $9 + 25/\epsilon$ iterations.*

Proof. Let u^η denote the final iterate computed by Algorithm 3.1, and let $\gamma^\eta = \Phi(u^\eta)$. Then, the trial ball centered at c^η with radius $[(1+\delta_\eta)\gamma^\eta]^{1/2}$ encloses $\mathcal{A}$. Note that u^η is a feasible solution of $(\mathcal{D})$, and $\delta_\eta \leq (1+\epsilon)^2 - 1$ by the termination criterion. Therefore, $(\gamma^\eta)^{1/2} \leq \rho_{\mathcal{A}} \leq [(1+\delta_\eta)\gamma^\eta]^{1/2} \leq (1+\epsilon)(\gamma^\eta)^{1/2}$, which implies that the ball centered at c^η with radius $[(1+\delta_\eta)\gamma^\eta]^{1/2}$ is a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$).

By Lemma 3.4, Algorithm 3.1 computes such an iterate with $\delta \leq (1+\epsilon)^2 - 1$ in at most $9 + 50/(2\epsilon + \epsilon^2) \leq 9 + 25/\epsilon$ iterations. $\square$

Theorem 3.1 establishes that Algorithm 3.1 converges in $O(1/\epsilon)$ iterations. The next result presents the overall complexity.

THEOREM 3.2. *Given $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$ and $\epsilon \in (0,1)$, Algorithm* 3.1 *computes a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$) in at most $O(mn/\epsilon)$ arithmetic operations.*

Proof. The computation of the initial feasible solution u^0 requires two furthest point computations, which can be performed in $O(mn)$ operations. At each iteration, the dominating work is the computation of the furthest point from the center of the current trial ball, which also requires $O(mn)$ operations (note that γ^k can be updated using (8) in $O(1)$ operations). The result follows from Theorem 3.1. $\square$

We remark that the overall complexity of Algorithm 3.1 is linear in the number of points m and also linear in the dimension n. As such, the worst-case running time asymptotically matches the currently best known bound due to [33]. In particular, Theorem 3.2 suggests that Algorithm 3.1 is especially well-suited for large instances of the minimum enclosing ball problem where a moderately small value of ϵ (such as 10^{-3}) would be satisfactory.

We close this section by establishing that Algorithm 3.1 explicitly computes a core set of size $O(1/\epsilon)$, which also asymptotically matches the currently best known bound.

THEOREM 3.3. *Given $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$ and $\epsilon \in (0,1)$, let η denote the index of the final iterate computed by Algorithm* 3.1. *Then, $\mathcal{X}_\eta \subseteq \mathcal{A}$ is an ϵ-core set of $\mathcal{A}$. Furthermore, $|\mathcal{X}_\eta| = O(1/\epsilon)$.*

Proof. Let u^η denote the final iterate returned by Algorithm 3.1, and let $\gamma^\eta = \Phi(u^\eta)$. Clearly, the restriction of u^η to its positive entries is a feasible solution of the dual formulation of the minimum enclosing ball problem for $\mathcal{X}_\eta$. Therefore, $\gamma^\eta \leq (\rho_{\mathcal{X}_\eta})^2 \leq (\rho_{\mathcal{A}})^2$, where $\rho_{\mathcal{X}_\eta}$ is the radius of MEB($\mathcal{X}_\eta$). However, $\gamma_{\mathcal{A}} = (\rho_{\mathcal{A}})^2 \leq (1+\delta_\eta)\gamma^\eta \leq (1+\epsilon)^2\gamma^\eta$ by Theorem 3.1. Combining these inequalities, we obtain $\rho_{\mathcal{X}_\eta} \leq \rho_{\mathcal{A}} \leq (1+\epsilon)(\gamma^\eta)^{1/2} \leq (1+\epsilon)\rho_{\mathcal{X}_\eta}$ as desired.

Note that $|\mathcal{X}_\eta|$ is precisely equal to the number of positive components of u^η. However, the initial solution u^0 has only two positive components. Each iteration can add at most one positive component to u^k. Therefore, $|\mathcal{X}_\eta| \leq 11 + 25/\epsilon = O(1/\epsilon)$ by Theorem 3.1. $\square$

4. The second algorithm. In this section, we describe our second algorithm, which is a modification of Algorithm 3.1.

Algorithm 4.1 The second algorithm that computes a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$).

Require: Input set of points $\mathcal{A} = \{a^1, \ldots, a^m\} \subset \mathbb{R}^n, \epsilon > 0$.

$\alpha \leftarrow \arg\max_{i=1,\ldots,m} \left\|a^i - a^1\right\|^2, \quad \beta \leftarrow \arg\max_{i=1,\ldots,m} \left\|a^i - a^\alpha\right\|^2;$
$u_i^0 \leftarrow 0, \quad i = 1, \ldots, m;$
$u_\alpha^0 \leftarrow 1/2, \quad u_\beta^0 \leftarrow 1/2;$
$\mathcal{X}_0 \leftarrow \{a^\alpha, a^\beta\};$
$c^0 \leftarrow \sum_{i=1}^m u_i^0 a^i;$
$\gamma^0 \leftarrow \Phi(u^0);$
$\kappa \leftarrow \arg\max_{i=1,\ldots,m} \left\|a^i - c^0\right\|^2, \quad \xi \leftarrow \arg\min_{i:a^i \in \mathcal{X}_0} \left\|a^i - c^0\right\|^2;$
$\delta_0^+ \leftarrow \left(\left\|a^\kappa - c^0\right\|^2 / \gamma^0\right) - 1, \quad \delta_0^- \leftarrow 1 - \left(\left\|a^\xi - c^0\right\|^2 / \gamma^0\right);$
$\delta_0 \leftarrow \max\{\delta_0^+, \delta_0^-\};$
$k \leftarrow 0;$
While $\delta_k > (1+\epsilon)^2 - 1$, do
loop
  if $\delta_k > \delta_k^-$, **then**
    $\lambda^k \leftarrow \delta_k / [2(1+\delta_k)];$
    $k \leftarrow k+1;$
    $u^k \leftarrow (1-\lambda^{k-1})u^{k-1} + \lambda^{k-1} e^\kappa;$
    $c^k \leftarrow (1-\lambda^{k-1})c^{k-1} + \lambda^{k-1} a^\kappa;$
    $\mathcal{X}_k \leftarrow \mathcal{X}_{k-1} \cup \{a^\kappa\};$
  else
    $\lambda^k \leftarrow \min\left\{\frac{\delta_k^-}{2(1-\delta_k^-)}, \frac{u_\xi^k}{1-u_\xi^k}\right\};$
    if $\lambda^k = u_\xi^k/(1-u_\xi^k)$, **then**
      $\mathcal{X}_{k+1} \leftarrow \mathcal{X}_k \backslash \{a^\xi\};$
    else
      $\mathcal{X}_{k+1} \leftarrow \mathcal{X}_k;$
    end if
    $k \leftarrow k+1;$
    $u^k \leftarrow (1+\lambda^{k-1})u^{k-1} - \lambda^{k-1} e^\xi;$
    $c^k \leftarrow (1+\lambda^{k-1})c^{k-1} - \lambda^{k-1} a^\xi;$
  end if
  $\gamma^k \leftarrow \Phi(u^k);$
  $\kappa \leftarrow \arg\max_{i=1,\ldots,m} \left\|a^i - c^k\right\|^2, \quad \xi \leftarrow \arg\min_{i:a^i \in \mathcal{X}_k} \left\|a^i - c^k\right\|^2;$
  $\delta_k^+ \leftarrow \left(\left\|a^\kappa - c^k\right\|^2 / \gamma^k\right) - 1, \quad \delta_k^- \leftarrow 1 - \left(\left\|a^\xi - c^k\right\|^2 / \gamma^k\right);$
  $\delta_k \leftarrow \max\{\delta_k^+, \delta_k^-\};$
end loop
Output $c^k, \mathcal{X}_k, u^k, \sqrt{(1+\delta_k)\gamma^k}$.

Algorithm 4.1 starts off with the same initial solution u^0 as the one computed by Algorithm 3.1. At each iteration, the furthest point in $\mathcal{A}$ from the center c^k of the trial ball is computed as in Algorithm 3.1. In contrast, each iteration of Algorithm 4.1 also includes the computation of the *closest* point to c^k among all points in $\mathcal{X}_k \subseteq \mathcal{A}$.

Geometrically, the parameter δ_k^- is the largest number such that the current ball shrunken by a factor of $(1-\delta)^{1/2}$ does not contain any points in $\mathcal{X}_k$ for any $\delta > \delta_k^-$. Algebraically, the step performed by Algorithm 4.1 in this case corresponds to moving away from the vertex of the unit simplex that minimizes the linear approximation to $\Phi(u)$ at u^k, where the minimization is over the vertices $\{e^j : u_j^k > 0\}$. The feasible solution u^k is updated in different ways based on these two computations. If $\delta_k = \delta_k^+$, then Algorithm 4.1 uses the exact same update as in Algorithm 3.1. Otherwise, the new center c^{k+1} is obtained by moving the current center c^k *away* from the closest point $a^\xi \in \mathcal{X}_k$. Therefore, Algorithm 4.1 is obtained by incorporating "away" steps into Algorithm 3.1. For "away" steps, it is easy to verify that

$$\lambda^k = \arg \max_{\lambda \in \left[0, u_\xi^k/(1-u_\xi^k)\right]} \Phi\left((1+\lambda)u^k - \lambda e^\xi\right). \tag{11}$$

Note that the range of λ is chosen to ensure that the dual feasibility constraint $u^{k+1} \geq 0$ is satisfied.

4.1. Analysis of the second algorithm. The analysis of Algorithm 4.1 is very similar to that of Algorithm 3.1. As in [39], we call iteration k a *plus*-iteration if $\delta_k = \delta_k^+$. If $\delta_k = \delta_k^-$ and $\lambda^k = (\delta_k^-)/[2(1-\delta_k^-)]$, then we call it a *minus*-iteration. The working core set remains unchanged at a minus-iteration. Finally, if $\delta_k = \delta_k^-$ and $\lambda^k = u_\xi^k/(1-u_\xi^k)$, we then call it a *drop*-iteration, since the ξth component of u^k drops to 0 and a^ξ is removed from the working core set.

Our analysis mimics the analysis of [39] for a similar algorithm that computes an approximation to the minimum-volume enclosing ellipsoid of a finite set of points. The next lemma establishes a lower bound on the improvement at each plus- or minus-iteration.

LEMMA 4.1. *At each plus- or minus-iteration,*

$$\gamma^{k+1} \geq \gamma^k \left(1 + \frac{\delta_k^2}{4(1+\delta_k)}\right), \quad k = 0, 1, \ldots. \tag{12}$$

Proof. At a plus-iteration, the result directly follows from Lemma 3.2. At a minus-iteration, a similar application of (6) reveals that

$$\gamma^{k+1} = \Phi\left((1+\lambda^k)u^k - \lambda^k e^\xi\right) = \gamma^k \left(1 + \frac{(\delta_k^-)^2}{4(1-\delta_k^-)}\right).$$

The result easily follows from the observation that

$$\frac{(\delta_k^-)^2}{4(1-\delta_k^-)} \geq \frac{(\delta_k^-)^2}{4(1+\delta_k^-)}$$

and that $\delta_k^- = \delta_k$ at a minus-iteration. ∎

Lemma 4.1 establishes that Algorithm 4.1 makes at least as much improvement as Algorithm 3.1 at each plus- or minus-iteration. At a drop-iteration, it is easy to show that $\gamma^{k+1} \geq \gamma^k$. However, we can no longer find a positive lower bound on $\gamma^{k+1} - \gamma^k \geq 0$. Using similar reasoning as in [39], each drop-iteration can be paired with the most recent plus-iteration k at which u_ξ^k was increased from 0, except for the αth and βth components, which were positive at the initial solution and may be decreased to zero for the first time. Therefore, we can double the iteration count (and add two iterations to account for the initial positive components of u^0) in the

analysis of Algorithm 3.1 to establish that Algorithm 4.1 can compute a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$) in at most twice as many iterations as that required by Algorithm 3.1. Note that this does not affect the asymptotic iteration bound of Algorithm 3.1. Furthermore, each iteration still requires $O(mn)$ operations, which implies that the asymptotic overall complexity of Algorithm 4.1 also remains the same as that of Algorithm 3.1. Finally, the asymptotic bound on the size of the core set is also unaffected. However, we remark that Algorithm 4.1 has the potential to compute even smaller core sets than those returned by Algorithm 3.1 due to the possible inclusion of minus- and drop-iterations. We summarize these results in the following theorem.

THEOREM 4.1. *Given $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$ and $\epsilon \in (0,1)$, Algorithm* 4.1 *computes a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$) in $O(mn/\epsilon)$ operations. Furthermore, upon termination, $\mathcal{X}_\eta \subseteq \mathcal{A}$ is an ϵ-core set and $|\mathcal{X}_\eta| = O(1/\epsilon)$, where η is the index of the final iterate computed by Algorithm* 4.1.

4.2. Linear convergence of the second algorithm. Despite the fact that Algorithm 4.1 appears to be a simple modification of Algorithm 3.1, it turns out that these two algorithms actually exhibit different characteristics. In particular, we establish that Algorithm 4.1 enjoys linear convergence, while a similar rate of convergence cannot, in general, be expected from Algorithm 3.1.

As observed in [41, 20], the search directions of Algorithm 3.1 always point toward the extreme points of the unit simplex. Therefore, the angle between these directions and the gradient of the objective function gets increasingly closer to the right angle in the situation when the optimal solution lies on the boundary of the unit simplex and is not an extreme point. For the minimum enclosing ball problem, an optimal solution of the dual problem will almost always lie in a lower-dimensional face of the unit simplex, except for the trivial cases such as a single input point or an input set sampled from the surface of a ball. It follows that Algorithm 3.1 is, in general, expected to exhibit a sublinear rate of convergence. In fact, this result has been formalized in [41] (see also [20, Theorem 3]) for the Frank–Wolfe algorithm under even stronger assumptions than those satisfied by the dual formulation of the minimum enclosing ball problem.

In an attempt to circumvent this drawback of Algorithm 3.1, Algorithm 4.1 works with an enlarged set of search directions by including those directions pointing away from the extreme points of the unit simplex. Such a general algorithm that incorporates "away" steps into the Frank–Wolfe algorithm was first proposed by Wolfe [41], and its convergence properties have been investigated by several authors. For the general problem of maximizing a concave function over a polytope, Wolfe [41] sketched and Guélat and Marcotte [20] detailed the proof of linear convergence under the assumptions of Lipschitz continuity of the gradient of the objective function, strong concavity of the objective function, and strict complementarity. More recently, Ahipaşaoğlu, Sun, and Todd [1] established the linear convergence of such an algorithm for the problem of maximizing a concave function over the unit simplex under a slightly different set of assumptions. Unfortunately, none of these previous results is directly applicable to our case, since either set of these assumptions implies the uniqueness of the optimal solution, which is not, in general, satisfied by the dual formulation of the minimum enclosing ball problem.

We therefore use an argument similar to that of [1] to establish the linear convergence of Algorithm 4.1. We work with a perturbation of the primal formulation $(\mathcal{P}_2)$ and show that the distance from an optimal primal-dual solution of the perturbed problem to the set of optimal primal-dual solutions of $(\mathcal{P}_2)$ and $(\mathcal{D})$ satisfies

a Lipschitz condition using the stability results of Robinson [34] for general nonlinear programming problems.

Let us define the following perturbation of $(\mathcal{P}_2)$:

$$\begin{array}{lll}(\mathcal{P}(z(u,\delta))) & \min_{c,\gamma} & \gamma \\ & \text{subject to} & \\ & & (a^i)^T a^i - 2(a^i)^T c + c^T c \le \gamma + z_i(u,\delta), \quad i = 1,\dots,m,\end{array}$$

where $u \in \mathbb{R}^m$ lies on the unit simplex, $\delta \ge 0$, and $z(u,\delta)$ is given by

$$z_i(u,\delta) := \begin{cases} \delta\Phi(u) & \text{if } u_i = 0, \\ (a^i)^T a^i - 2(a^i)^T c(u) + c(u)^T c(u) - \Phi(u) & \text{else,} \end{cases} \quad ; \quad i = 1,\dots,m,$$

where

$$c(u) := \sum_{i=1}^m u_i a^i.$$

Let $z^k := z(u^k, \delta_k),\ k = 0, 1, \dots$, where $u^k \in \mathbb{R}^m$ denotes the kth iterate and δ_k is the corresponding measure as computed by Algorithm 4.1. By a definition of δ_k,

$$(a^i)^T a^i - 2(a^i)^T c^k + (c^k)^T c^k - \Phi(u^k) \le \delta_k \Phi(u^k), \quad i = 1,\dots,m,$$

and

$$(a^i)^T a^i - 2(a^i)^T c^k + (c^k)^T c^k - \Phi(u^k) \ge -\delta_k \Phi(u^k), \quad \text{if } u_i^k > 0,$$

which implies that $|z_i^k| \le \delta_k \Phi(u^k)$ for $i = 1,\dots,m$. We remark that the latter inequality above is not necessarily satisfied by the kth iterate computed by Algorithm 3.1. Furthermore,

$$(u^k)^T z^k = \sum_{i:u_i^k > 0} u_i^k (a^i)^T a^i - 2(c^k)^T (c^k) + (c^k)^T c^k - \Phi(u^k) = 0, \tag{13}$$

where we used the definitions of c^k and $\Phi(u)$ together with the fact that u^k lies on the unit simplex. Using the fact that $c(u^k) = c^k$, it follows that $(c^k, \Phi(u^k))$ is a feasible solution of $(\mathcal{P}(z^k))$. The next lemma establishes that $(c^k, \Phi(u^k))$ is actually an optimal solution.

LEMMA 4.2. *For all $k = 0, 1, \dots$, $(c^k, \Phi(u^k))$ is an optimal solution of $(\mathcal{P}(z^k))$.*

Proof. The feasibility of $(c^k, \Phi(u^k))$ follows from the discussions preceding the lemma. Since $(\mathcal{P}(z^k))$ is a convex optimization problem and $(c^k, \Phi(u^k))$ satisfies the optimality conditions along with u^k as the Lagrange multipliers, the result follows. ∎

Let $\Xi(z(u,\delta))$ denote the optimal value of $(\mathcal{P}(z(u,\delta)))$. Note that Ξ is a convex function of $z(u,\delta)$, and if u^* is any Lagrange multiplier corresponding to the optimal solution of $\mathcal{P}(0)$ (equivalently, of $(\mathcal{P}_2)$), then u^* is a subgradient of Ξ at 0. Therefore, for all $k = 0, 1, \dots$,

$$\begin{array}{rcl}\Phi(u^k) = \Xi(z^k) & \ge & \Xi(0) + (u^*)^T z^k \\ & = & \Phi(u^*) + (u^* - u^k)^T z^k \\ & \ge & \Phi(u^*) - \|u^k - u^*\| \|z^k\|,\end{array} \tag{14}$$

where we used Lemma 4.2 and (13).

Let Δ denote the diameter of the input set $\mathcal{A}$, i.e., the maximum distance between any pair of points in $\mathcal{A}$. Since $(1/4)\Delta^2 \leq \Phi(u^*) \leq \Delta^2$, we have, for all k,

$$|z_i^k| \leq \delta_k \Phi(u^k) \leq \delta_k \Phi(u^*) \leq \delta_k \Delta^2,$$

which implies that $\|z^k\| \leq \sqrt{m}\Delta^2\delta_k$.

We will next use the stability results of Robinson [34] to establish an upper bound on $\|u^k - u^*\|$. We need to verify that all of the assumptions are satisfied for the unperturbed problem $(\mathcal{P}(0))$. Since the problem is convex and Slater's constraint qualification is satisfied, the constraints are regular at any feasible solution. Furthermore, let (c^*, γ^*) be the unique optimal solution of $(\mathcal{P}(0))$, and let u^* be any corresponding Lagrange multiplier (i.e., any optimal solution of $(\mathcal{D})$). Then, the Lagrangian function $\mathcal{L} : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^m \to \mathbb{R}$ for the problem $(\mathcal{P}(0))$ is given by

$$\mathcal{L}((c,\gamma),u) = \gamma + \sum_{i=1}^{m} u_i \left((a^i)^T a^i - 2(a^i)^T c + c^T c - \gamma \right).$$

By taking derivatives with respect to the primal variables $(c, \gamma) \in \mathbb{R}^n \times \mathbb{R}$, we obtain

$$\nabla_{(c,\gamma)} \mathcal{L}((c,\gamma),u) = \begin{bmatrix} 0 \\ 1 \end{bmatrix} + \sum_{i=1}^{m} u_i \begin{bmatrix} -2a^i + 2c \\ -1 \end{bmatrix},$$

$$\nabla^2_{(c,\gamma)} \mathcal{L}((c,\gamma),u) = \sum_{i=1}^{m} u_i \begin{bmatrix} 2I & 0 \\ 0 & 0 \end{bmatrix},$$

where $I \in \mathbb{R}^{n \times n}$ denotes the identity matrix. Note that any direction $d \in \mathbb{R}^{n+1}$ orthogonal to the gradient of the objective function of $(\mathcal{P}(0))$ is of the form $d = [(d')^T, 0]^T$, where $d' \in \mathbb{R}^n$. Therefore, for any such direction d,

$$d^T \nabla^2_{(c,\gamma)} \mathcal{L}(c^*, \gamma^*, u^*) d = 2(d')^T d' = 2\|d\|^2,$$

since u^* lies on the unit simplex, which implies that Robinson's second-order sufficient condition is satisfied (see Definition 2.1 in [34]) by the optimal solution (c^*, γ^*) of $(\mathcal{P}(0))$ along with any dual optimal solution u^*. Therefore, by Theorem 4.2 in [34], there exists a dual optimal solution u^* and a positive constant ℓ such that

$$\|u^k - u^*\| \leq \ell \|z^k\| \leq \ell\sqrt{m}\Delta^2\delta_k \tag{15}$$

for all sufficiently small δ_k. Combining this inequality with (14), we obtain

$$\Phi(u^*) - \Phi(u^k) \leq m\ell\Delta^4(\delta_k)^2 \tag{16}$$

for all sufficiently small δ_k.

Suppose now that $\delta_k \leq 1/2$. Since $\Phi(u^k) \leq \Phi(u^*) \leq (1+\delta_k)\Phi(u^k) \leq (3/2)\Phi(u^k)$, it follows that

$$\Phi(u^k) \geq (2/3)\Phi(u^*) \geq (1/6)\Delta^2.$$

At each plus- or minus-iteration, by Lemma 4.1, we obtain

$$\Phi(u^{k+1}) \geq \Phi(u^k)\left(1 + \frac{\delta_k^2}{4(1+\delta_k)}\right) \geq \Phi(u^k) + \frac{\delta_k^2 \Delta^2}{36}. \tag{17}$$

Combining (16) and (17), at each plus- or minus-iteration, we obtain

$$\Phi(u^*) - \Phi(u^{k+1}) \le \Phi(u^*) - \Phi(u^k) - \frac{\delta_k^2 \Delta^2}{36} \le \left(1 - \frac{1}{36m\ell\Delta^2}\right)(\Phi(u^*) - \Phi(u^k)) \tag{18}$$

for all sufficiently small δ_k. This establishes the linear convergence of Algorithm 4.1.

THEOREM 4.2. *Given $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$, Algorithm 4.1 computes iterates u^k such that $\Phi(u^*) - \Phi(u^k)$ is nonincreasing. Asymptotically, this gap is decreased by at least a factor of $(1 - 1/(36m\ell\Delta^2))$ at each plus- or minus-iteration. There exist constants $\bar{\tau}$ and ϑ that depend on the input data such that Algorithm 4.1 computes a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$) in $\bar{\tau} + \vartheta \log(1/\epsilon)$ operations for $\epsilon \in (0, 1)$.*

Proof. Lemma 4.1 and the following discussions imply that $\Phi(u^*) - \Phi(u^k)$ is a nonincreasing sequence. The asymptotic linear convergence follows from (18). Therefore, we need only to establish the last statement.

Let $\tau := \max\{\tau_1, \tau^*\}$, where τ_1 is defined as in (9) and τ^* is the smallest value of k such that the inequality (15) is satisfied. After iteration τ, the sequence $\Phi(u^*) - \Phi(u^k)$ satisfies the relationship (18). By the termination criterion of Algorithm 4.1, it suffices to compute an iterate k_* such that $\Phi(u^{k_*}) \le \Phi(u^*) \le (1+\delta_{k_*})\Phi(u^{k_*}) \le (1+\epsilon)^2\Phi(u^{k_*})$. This implies that the final iterate satisfies $\Phi(u^*) - \Phi(u^{k_*}) \le [(1+\epsilon)^2 - 1]\Phi(u^{k_*})$. Since $\Phi(u^k) \ge (1/6)\Delta^2$ for all $k \ge \tau$, it follows that the termination criterion is satisfied if $\Phi(u^*) - \Phi(u^{k_*}) \le (1/6)[(1+\epsilon)^2 - 1]\Delta^2$. By (18), $\Phi(u^*) - \Phi(u^{k+1}) \le (1 - (1/\bar{\mu}))(\Phi(u^*) - \Phi(u^k)) \le (1 - (1/\bar{\mu}))(\Delta^2 - (1/6)\Delta^2) = (5/6)(1 - (1/\bar{\mu}))\Delta^2$ at each plus- or minus-iteration for all $k \ge \tau$, where $\bar{\mu} := 36m\ell\Delta^2$. Therefore, once Algorithm 4.1 computes iterate τ, we have

$$\Phi(u^*) - \Phi(u^{\tau+\hat{k}}) \le \frac{5}{6}\left(1 - \frac{1}{\bar{\mu}}\right)^{\hat{k}} \Delta^2$$

after $\hat{k}$ plus- or minus-iterations. Therefore, if

$$\frac{5}{6}\left(1 - \frac{1}{\bar{\mu}}\right)^{\hat{k}} \Delta^2 \le \frac{1}{6}(2\epsilon + \epsilon^2)\Delta^2,$$

then the termination criterion is satisfied after $\hat{k}$ plus- or minus-iterations. It follows that $\hat{k}$ satisfies

$$\log 5 + \hat{k} \log\left(1 - \frac{1}{\bar{\mu}}\right) \le \log\epsilon + \log(\epsilon + 2).$$

Using the inequality $\log(1 + x) \le x$ for all $x > -1$, a sufficient condition in order for the above inequality to be satisfied is given by

$$\log 5 - \frac{\hat{k}}{\bar{\mu}} \le \log 2 + \log\epsilon,$$

which implies that $\tau' + \bar{\mu}\log(1/\epsilon)$ plus- or minus-iterations will suffice, where $\tau' = \bar{\mu}\log(5/2)$. By the argument following Lemma 4.1, we can double the iteration count and add two iterations to account for the drop-iterations, which completes the proof. ∎

We remark that Theorem 4.2 establishes a polynomial convergence result for Algorithm 4.1 even if ϵ is part of the input data. In addition, it implies that the

convergence is "fast" once inequality (15) is satisfied. However, the bound on the number of iterations depends on the data as it is not known a priori when the linear convergence will kick in. As such, it does not provide a better global complexity bound than that of Theorem 4.1. Nevertheless, the results of this section will shed some light into the usually better practical performance of Algorithm 4.1 in section 6.

5. Extensions. In this section, we establish that the algorithmic frameworks of sections 3 and 4 can be used to compute an approximation to the minimum enclosing ball of more general input sets. While the cost of each iteration of the corresponding algorithms may depend on the input set, the iteration complexity and the asymptotic size of the core set remain unchanged. Therefore, the existence of an ϵ-core set of size $O(1/\epsilon)$ extends to more general sets including those with uncountably many points.

We remark that the analysis of both of the algorithms heavily relies on the structure of the dual optimization formulation $(\mathcal{D})$ of the minimum enclosing ball problem of a finite set of points. In this section, we argue that the same algorithmic framework can be applied to much more general input sets with minor modifications. We employ similar arguments as in [43], where a Frank–Wolfe-type algorithm for the problem of computing the minimum-volume enclosing ellipsoid of a finite set of ellipsoids is studied. Given a possibly infinite set of points, the primal optimization formulation $(\mathcal{P}_2)$ can be extended to a semi-infinite optimization problem with a linear objective function and infinitely many convex quadratic constraints. The main idea is to approximate the given input set using only a carefully selected finite subset of points and then to refine this approximation by adding more points if necessary. This leads to an approximation of the primal formulation with only a finite number of constraints, and this approximation is refined by adding more constraints. In the dual formulation, we therefore start with a finite number of variables and add more variables if necessary.

Let $\mathcal{A} \subset \mathbb{R}^n$ be an arbitrary compact input set, and let us first consider Lemma 3.1, which establishes the quality of the initial feasible solution computed by each of the two algorithms. The initial working core set $\mathcal{X}_0$ provides the first approximation to the given input set with only two points. Let $\Phi_0(\cdot)$ denote the objective function of the dual formulation of the minimum enclosing ball problem for $\mathcal{X}_0$, and let $\gamma_{\mathcal{A}}$ denote the optimal value of the aforementioned semi-infinite primal formulation. The result of Lemma 3.1 continues to hold, since the proof relies on Lemma 2.2, which remains true for arbitrary compact input sets. The proof of Lemma 2.2 is based on the argument that an enclosing ball of smaller radius can be constructed by moving the center away from the half-space in the direction of the normal vector of the bounding hyperplane if the hypothesis of Lemma 2.2 is not satisfied by that half-space. Therefore, we still have $\Phi_0(u^0) \geq (1/3)\gamma_{\mathcal{A}}$, which implies that the quality of the initial solution is independent of the input set.

Similarly, let $\Phi_k(\cdot)$ denote the objective function of the dual formulation of the minimum enclosing ball problem for $\mathcal{X}_k \subset \mathcal{A}$. At iteration k in each algorithm, $\mathcal{X}_k$ provides the current finite approximation to $\mathcal{A}$. Let $c^k \in \mathbb{R}^n$ denote the current center. Each algorithm computes the furthest point in $\mathcal{A}$ from c^k. In Algorithm 3.1, $\mathcal{X}_{k+1}$ is obtained by adding this point to $\mathcal{X}_k$. Unless the furthest point in $\mathcal{A}$ already belongs to $\mathcal{X}_k$, the dual formulation for $\mathcal{X}_{k+1}$ differs from that for $\mathcal{X}_k$ in only one variable. Therefore, $[(u^k)^T, 0]^T$ is a feasible solution for the new dual formulation that satisfies $\Phi_{k+1}([(u^k)^T, 0]^T) = \Phi_k(u^k)$, which implies that the improvement in each iteration still obeys the relation given by Lemma 3.2, with γ^{k+1} replaced by $\Phi_{k+1}(u^{k+1})$ and γ^k by $\Phi_k(u^k)$. Note that the dimension of u^{k+1} is one more than that of u^k in this case. It follows that the upper bound on the number of iterations required by Algorithm 3.1 to

achieve a prescribed accuracy as well as the bound on the core set remain unchanged for a general compact input set $\mathcal{A} \subset \mathbb{R}^n$.

The preceding argument establishes the same improvement result at a plus-iteration of Algorithm 4.1 for a general input set $\mathcal{A}$. Since $\mathcal{X}_k$ is finite, the computation of the closest point in $\mathcal{X}_k$ is straightforward independently of the input set. At a minus-iteration, the dimension of the dual formulation remains the same. Therefore, Lemma 4.1 still applies. At a drop-iteration, we can reverse the argument employed at a plus-iteration, since the number of dual variables actually decreases in this case. We conclude that the iteration complexity of Algorithm 4.1 and the upper bound on the size of the core set also remain unchanged for a general compact input set $\mathcal{A} \subset \mathbb{R}^n$. On the other hand, our analysis that leads to the linear convergence of Algorithm 4.1 is not likely to be extended to more general input sets, since it explicitly relies on the stability results for nonlinear programming problems with a finite number of constraints.

We give another perspective on the extension of the two algorithms to more general input sets. Let $\mathcal{X}_\eta \subset \mathcal{A}$ denote the finite set computed by either one of the two algorithms upon termination on a general input set $\mathcal{A}$. Then, each algorithm would geometrically behave exactly the same way on the input set $\mathcal{X}_\eta$ as it would on the original input set $\mathcal{A}$. However, the termination criterion is satisfied for the whole set $\mathcal{A}$. Clearly, the set $\mathcal{X}_\eta \subset \mathcal{A}$ is not known a priori and is sequentially generated by each algorithm. Furthermore, the cost of each iteration is likely to be higher for a general input set $\mathcal{A}$ in comparison with that for $\mathcal{X}_\eta$. Therefore, the main work involved in each algorithm is the extraction of the finite set $\mathcal{X}_\eta$ from $\mathcal{A}$.

In order to transform this conceptual algorithmic framework into a practical algorithm, we need to ensure that each operation required by either algorithm can be carried out efficiently for a given input set. Note that both of the algorithms in this paper compute the initial feasible solution in a similar fashion. This computation entails finding the furthest point in the input set from a fixed point. In addition, similar furthest point computations are performed at each iteration of both of the algorithms. Therefore, the extent of input sets which are amenable to these algorithms highly depends on the efficiency with which such computations can be performed.

We now specify several input sets for which similar algorithmic frameworks can be applied.

5.1. Set of balls. Let $\mathcal{A} = \{\mathcal{B}_1, \ldots, \mathcal{B}_m\} \subset \mathbb{R}^n$ be a set of m balls. Given $\mathcal{B}_{c,\rho}$ and $x \in \mathbb{R}^n$, the furthest point in $\mathcal{B}_{c,\rho}$ from x is given by $x^* = c + \rho(c - x)/\|c - x\|$, which can be computed in $O(n)$ operations. Therefore, each iteration of Algorithm 3.1 still requires $O(mn)$ operations, which implies that Algorithm 3.1 computes a $(1+\epsilon)$-approximation to $\mathrm{MEB}(\mathcal{A})$ in $O(mn/\epsilon)$ operations and returns an ϵ-core set of size $O(1/\epsilon)$. In addition to computing the furthest point at each iteration, Algorithm 4.1 also requires the computation of the closest point in a finite set. The size of this set is bounded above by $O(1/\epsilon)$, which implies that each iteration can be performed in $O(mn + n/\epsilon)$ operations. Therefore, Algorithm 4.1 can compute a $(1+\epsilon)$-approximation to $\mathrm{MEB}(\mathcal{A})$ in $O(mn/\epsilon + n/\epsilon^2)$ operations and returns an ϵ-core set of size $O(1/\epsilon)$.

5.2. Set of ellipsoids. Let $\mathcal{A} = \{\mathcal{E}_1, \ldots, \mathcal{E}_m\} \subset \mathbb{R}^n$ be a set of m ellipsoids given by $\mathcal{E}_i := \{x \in \mathbb{R}^n : (x - c^i)^T Q^i (x - c^i) \leq 1\}$, where $c^i \in \mathbb{R}^n$ and $Q^i \in \mathbb{R}^{n \times n}$ is symmetric and positive definite for $i = 1, \ldots, m$. The furthest point in an ellipsoid from a given point can be computed using a tight semidefinite programming relaxation with a fixed number of constraints in $O(n^{O(1)})$ operations in the real number model of com-

putation [43], where $O(1)$ denotes a universal constant greater than three. Therefore, Algorithm 3.1 computes a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$) in $O(mn^{O(1)}/\epsilon)$ operations and returns an ϵ-core set of size $O(1/\epsilon)$. Similarly, Algorithm 4.1 can compute a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$) in $O(mn^{O(1)}/\epsilon + n^{O(1)}/\epsilon^2)$ operations and returns an ϵ-core set of size $O(1/\epsilon)$.

5.3. Set of half ellipsoids. $\mathcal{H}$ is said to be a half ellipsoid if it is given by the intersection of an ellipsoid with a half-space. Let $\mathcal{A} = \{\mathcal{H}_1, \ldots, \mathcal{H}_m\}$, where $\mathcal{H}_i := \{x \in \mathbb{R}^n : (x - c^i)^T Q^i (x - c^i) \leq 1, \quad (f^i)^T x \leq \omega^i\}$, where $c^i \in \mathbb{R}^n$, $f^i \in \mathbb{R}^n, \omega^i \in \mathbb{R}$, and $Q^i \in \mathbb{R}^{n \times n}$ is symmetric and positive definite for $i = 1, \ldots, m$. Sturm and Zhang [36] established that the maximization of any quadratic function over a half ellipsoid can be cast as a semidefinite programming problem with a fixed number of constraints similarly to quadratic optimization over an ellipsoid. Therefore, the asymptotic overall complexity bounds of Algorithms 3.1 and 4.1 are identical to those for the case of a set of ellipsoids. In particular, both algorithms return an ϵ-core set of size $O(1/\epsilon)$.

5.4. Set of intersections of a pair of similar ellipsoids. Two n-dimensional ellipsoids $\mathcal{E}_1$ and $\mathcal{E}_2$ are said to be similar if they both admit a representation using the same semidefinite matrix. This implies that the length and the alignment of the corresponding axes are the same. Let $\mathcal{A} = \{\mathcal{T}_1, \ldots, \mathcal{T}_m\}$, where $\mathcal{T}_i := \{x \in \mathbb{R}^n : (x - c^i)^T Q^i (x - c^i) \leq 1, \quad (x - h^i)^T Q^i (x - h^i) \leq 1\}$, where $c^i \in \mathbb{R}^n, h^i \in \mathbb{R}^n$, and $Q^i \in \mathbb{R}^{n \times n}$ is symmetric and positive definite for $i = 1, \ldots, m$. It follows from the results of [36] that any quadratic optimization problem over the intersection of a pair of similar ellipsoids can be decomposed into two quadratic optimization problems over two half ellipsoids. Therefore, the asymptotic complexity bounds of Algorithms 3.1 and 4.1 are identical to those for the case of a set of half ellipsoids. Similarly, both algorithms return an ϵ-core set of size $O(1/\epsilon)$.

5.5. Further extensions. We have described several classes of more general input sets for which an approximate minimum enclosing ball can be computed in polynomial time (for fixed ϵ) using the appropriate extensions of Algorithms 3.1 and 4.1. Obviously, the results can be extended to input sets that are composed of a combination of elements from each of the above classes. In particular, it is remarkable that the existence of an ϵ-core set of size $O(1/\epsilon)$ extends to much more general classes of input sets including those with uncountably many points.

Similarly to the discussion in [43], the extent of input sets to which similar algorithmic frameworks can be applied largely depends on the efficiency of the furthest point computation required at each iteration of each of the two algorithms. It is well known that the maximization of a convex quadratic function over certain sets (such as polytopes defined by inequalities) is computationally intractable. Therefore, our algorithmic framework does not yield a polynomial-time algorithm for an input set of polytopes. In summary, the discovery of polynomial-time routines for quadratic optimization over other classes of input sets may lead to further efficient generalizations of our algorithms.

6. Computational results. In this section, we report the results of our computational experiments. We implemented Algorithms 3.1 and 4.1 in MATLAB. For the purposes of comparison, we also implemented the first-order algorithm of Bădoiu and Clarkson [2] (henceforth the BC algorithm). Their simple algorithm starts by setting any arbitrary point $a^i \in \mathcal{A}$ as the initial center c^1. At iteration k, let a^{j_k} denote the furthest point from c^k, $k = 1, 2, \ldots$. The center is updated according to the following

relation:

$$c^{k+1} = [1 - 1/(k+1)]c^k + [1/(k+1)]a^{j_k}, \quad k = 1, 2, \ldots .$$

Bădoiu and Clarkson establish that $1/\epsilon^2$ such updates suffice in order to obtain a $(1+\epsilon)$-approximation to MEB($\mathcal{A}$). Note that each iteration requires $O(mn)$ operations, which yields an overall complexity bound of $O(mn/\epsilon^2)$.

Similarly to Algorithms 3.1 and 4.1, it is easy to verify that the BC algorithm also generates a sequence of feasible solutions for the dual formulation of the minimum enclosing ball problem. Therefore, in order to have a fair and meaningful comparison, we employed the same termination criterion that we used for Algorithms 3.1 and 4.1 rather than running the BC update for $1/\epsilon^2$ times.

In contrast with Algorithms 3.1 and 4.1, the objective functions evaluated at the iterates generated by the BC algorithm are not monotonically increasing in general. Therefore, the analysis of the BC algorithm uses entirely different tools [2].

The computational experiments were carried out on a Pentium IV processor with a clock speed of 2.80 GHz and 512 MB RAM running under Linux. We used MATLAB version 7.3.0.298 (R2006b) in our experiments.

We used three data sets in our experiments. The first data set is restricted to instances with $m \gg n$ and was randomly generated as in [1], with sizes (n, m) varying from $(10, 500)$ to $(100, 100000)$. For each fixed (n, m), ten different data sets were generated, and the results are reported in terms of the averages over these data sets in Table 1, which is divided into four sets of columns. The first set of columns reports the size (n, m). The next three sets of columns present the CPU time, core set size, and the number of iterations, respectively. Each one of these three sets is further divided into three columns labeled A1, A2, and BC corresponding to Algorithm 3.1, Algorithm 4.1, and the BC algorithm, respectively. In all of our experiments, we set $\epsilon = 10^{-3}$.

As illustrated by Table 1, each of the three algorithms is capable of quickly computing an approximation to the minimum enclosing ball of the given input set. In particular, all three algorithms terminated under eight minutes even on the largest instances. In terms of CPU time, Algorithm 4.1 has significantly better performance than Algorithm 3.1 and the BC algorithm, both of which have similar running times. All three algorithms computed very small core sets of similar sizes. Algorithm 4.1 always returned the smallest core sets for each input set. The core sets computed by Algorithm 3.1 and the BC algorithm have similar sizes with the former being slightly better than the latter. In terms of the number of iterations, Algorithm 4.1 once again significantly outperforms the other two algorithms. Unlike Algorithm 3.1, the number

of iterations of the BC algorithm seems to be independent of the dimensions of the input set.

A close examination of Table 1 reveals that Algorithm 4.1 resulted in reductions of 73% to 88% in terms of running time and of 74% to 90% in terms of the number of iterations in comparison with the other two algorithms. These results seem to indicate that the linear convergence of Algorithm 4.1 may be responsible for the improved performance. Furthermore, due to allowing points to be dropped from the working core set, the sizes of the core sets computed by Algorithm 4.1 are about 10% to 30% smaller than those returned by the other two algorithms.

The second data set consists of instances with $n \gg m$. In particular, we generated random instances with (n, m) varying from $(10000, 100)$ to $(25000, 1000)$. The averaged results are presented in Table 2, which is organized similarly to Table 1. The results indicate that all three algorithms compute core sets of similar sizes. Algorithm 3.1 and Algorithm 4.1 exhibit similar performances in terms of running time and the number of iterations due to the fact that "away" steps are performed relatively infrequently on such instances. On the other hand, the running time and the number of iterations of the BC algorithm are considerably larger than either of our two algorithms. Once again, note that the number of iterations of the BC algorithm seems to be relatively insensitive to m and n, which suggests a stronger relationship with $1/\epsilon$ in comparison with our algorithms.

The final data set we considered is the vertices of the unit simplex. Bădoiu and Clarkson [3] establish a tight upper bound of $\lceil 1/\epsilon \rceil$ on the size of the core set for such an input set under the assumption that $n \geq \lfloor 1/\epsilon \rfloor$. In an attempt to assess the performances of the three algorithms on such a data set, we considered the vertices of the unit simplex with $n = 1000$ using $\epsilon \in \{1, .1, .01, .001\}$. The results of this experiment are presented in Table 3, which is organized similarly to Table 1.

As illustrated by Table 3, all three algorithms have similar performances on the vertices of the unit simplex in $\mathbb{R}^n$, with $n = 1000$. Note that both the size of the core set and the number of iterations grow proportionally to $1/\epsilon$. These results are in agreement with the tight core set bound of [3]. This example illustrates that the asymptotic bounds on the core set size and the number of iterations for Algorithms 3.1 and 4.1, in general, cannot be improved. However, all three algorithms computed the exact minimum enclosing ball for $\epsilon = 10^{-3}$ (and for any $\epsilon \geq 10^{-3}$). Therefore, this

example illustrates that the upper bound of $\lceil 1/\epsilon \rceil$ on the size of the core set is no longer tight for $n \leq \lfloor 1/\epsilon \rfloor$.

We do not compare our algorithms with other exact or approximate algorithms, since such computational studies have been performed in earlier literature. For instance, it is well known that the minimum enclosing ball problem can be formulated as an instance of second-order cone programming and interior-point methods can achieve very high accuracy (e.g., 10^{-8}) in small- and medium-scale instances. However, each iteration requires the computation and factorization of an $(n+1) \times (n+1)$ matrix, which can be performed in $O(n^3)$ and $O(mn^2)$ operations, respectively [24]. Therefore, such an approach is not computationally feasible for large instances as illustrated by the results of [42, 44]. Similarly, exact algorithms [16] perform well on small- and medium-scale instances, but the performance degrades significantly for large-scale instances [24]. Since our focus is on applications with large-scale instances in which a moderate accuracy suffices, our computational results indicate that our algorithms are capable of solving such instances in a reasonable amount of time.

7. Concluding remarks. In this paper, we proposed and analyzed two algorithms that compute an approximation to the minimum enclosing ball of a given finite set of points. Both algorithms exploit the special structure of the dual formulation of the problem and can geometrically be viewed as generating a sequence of trial balls until a ball with desired properties is computed. Each of the two algorithms is especially well-suited for the large-scale instances of the minimum enclosing ball problem for which a moderate approximation suffices. Both algorithms can compute a small core set whose size depends only on the approximation parameter. The second algorithm asymptotically exhibits linear convergence, which further contributes to its efficiency. We have discussed how our algorithms can be extended to more general input sets without sacrificing the iteration complexity and hence the size of the core set. In particular, we established that several more general classes of input sets admit small and finite core sets. Our computational experiments reveal that both of our algorithms are capable of quickly computing a good approximation to the minimum enclosing ball of a finite set of points. Algorithm 4.1, which is obtained by incorporating "away" steps into Algorithm 3.1, seems to exhibit a significantly better performance than other first-order algorithms. The sizes of the core sets computed by our algorithms are usually fairly small. The example that consists of the vertices of the unit simplex illustrates that our analysis, in general, cannot be improved.

While the discovery of efficient algorithms such as interior-point methods revolutionized convex optimization, the computational cost of each iteration of such algorithms quickly becomes prohibitive as the size of the problems increases. Therefore, it seems desirable to design specialized algorithms for large-scale problems that exploit the underlying special structure of the problem. We have developed two such algorithms for the minimum enclosing ball problem in this paper. We intend to continue our work on developing specialized algorithms for other classes of large-scale structured optimization problems in the near future.

Acknowledgments. I gratefully acknowledge the insightful comments and suggestions by the Associate Editor and two anonymous referees, which contributed significantly to the improvement of the manuscript. In particular, section 4.2 was added based on the comments of an anonymous referee, and the alternative perspective on the extension of the algorithms to more general input sets in section 5 was suggested by another anonymous referee.

IDENTIFICATION AND ELIMINATION OF INTERIOR POINTS FOR THE MINIMUM ENCLOSING BALL PROBLEM*

S. DAMLA AHIPAŞAOĞLU† AND E. ALPER YILDIRIM‡

Abstract. Given $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$, we consider the problem of reducing the input set for the computation of the minimum enclosing ball of $\mathcal{A}$. In this note, given an approximate solution to the minimum enclosing ball problem, we propose a simple procedure to identify and eliminate points in $\mathcal{A}$ that are guaranteed to lie in the interior of the minimum-radius ball enclosing $\mathcal{A}$. Our computational results reveal that incorporating this procedure into two recent algorithms proposed by Yıldırım lead to significant speed-ups in running times especially for randomly generated large-scale problems. We also illustrate that the extra overhead due to the elimination procedure remains at an acceptable level for spherical or almost spherical input sets.

Key words. minimum enclosing balls, input set reduction, approximation algorithms

1. Introduction.

Given $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$, we denote the unique minimum enclosing ball of $\mathcal{A}$ by MEB($\mathcal{A}$), i.e.,

$$\text{MEB}(\mathcal{A}) = \mathcal{B}_{c^*,\rho^*} := \{x \in \mathbb{R}^n : \|x - c^*\| \leq \rho^*\},$$

where $c^* \in \mathbb{R}^n$ is the optimal center, $\rho^* \in \mathbb{R}$ is the optimal radius, and $\|\cdot\|$ denotes the Euclidean norm. Given $\epsilon > 0$, a ball $\mathcal{B}_{c,\rho}$ is said to be a $(1+\epsilon)$-approximate solution to MEB($\mathcal{A}$) if

$$\rho \leq \rho^*, \quad \mathcal{A} \subset \mathcal{B}_{c,(1+\epsilon)\rho}. \tag{1}$$

In this note, given a $(1+\epsilon)$-approximate solution $\mathcal{B}_{c,\rho}$ to MEB($\mathcal{A}$), we propose a simple condition that should be satisfied by each point in $\mathcal{A}$ that lies on the boundary of MEB($\mathcal{A}$). Furthermore, we derive an upper bound on the Euclidean distance between c and c^*.

2. Main result.

LEMMA 2.1. *Given $\mathcal{A} := \{a^1, \ldots, a^m\} \subset \mathbb{R}^n$ and $\epsilon > 0$, let $\mathcal{B}_{c,\rho}$ be a $(1+\epsilon)$-approximate solution to MEB($\mathcal{A}$). Then,*

$$\|c - c^*\| \leq (2\epsilon + \epsilon^2)^{1/2}\rho. \tag{2}$$

Furthermore, each point $a^i \in \mathcal{A}$ on the boundary of MEB($\mathcal{A}$) satisfies

$$\|a^i - c\| \geq (1 - (2\epsilon + \epsilon^2)^{1/2})\rho. \tag{3}$$

Proof. Suppose that $c \neq c^*$. Consider the hyperplane $\mathcal{H}$ passing through c^* perpendicular to $c^* - c$. Let $\mathcal{H}_+$ denote the closed halfspace bounded by $\mathcal{H}$ and not containing c. Then, by [2, Lemma 2.2], there exists a point $a^j \in \mathcal{H}_+ \cap \mathcal{A}$ such that $\|a^j - c^*\| = \rho^*$. Therefore, $\|c - a^j\|^2 \geq \|c - c^*\|^2 + \|c^* - a^j\|^2$, which implies that

$$\begin{aligned}\|c - c^*\|^2 &\leq \|c - a^j\|^2 - \|c^* - a^j\|^2,\\ &\leq (1+\epsilon)^2\rho^2 - (\rho^*)^2,\\ &\leq (1+\epsilon)^2\rho^2 - \rho^2,\\ &= (2\epsilon + \epsilon^2)\rho^2,\end{aligned}$$

where we used (1) to derive the second and third inequalities. This establishes (2).

Let a^i be any point on the boundary of MEB($\mathcal{A}$). Then, $\|a^i - c^*\| \leq \|a^i - c\| + \|c - c^*\|$, which implies that

$$\begin{aligned}\|a^i - c\| &\geq \rho^* - \|c - c^*\|,\\ &\geq \rho - (2\epsilon + \epsilon^2)^{1/2}\rho,\\ &= (1 - (2\epsilon + \epsilon^2)^{1/2})\rho,\end{aligned}$$

where we used (1) and (2) to derive the second inequality. This completes the proof. ∎

3. Computational results. Recently, Yıldırım [2] proposed two first-order algorithms that can compute a $(1+\epsilon)$-approximate solution to the minimum enclosing ball of a finite input set $\mathcal{A}$ of points for any given $\epsilon > 0$. Each algorithm generates a sequence of approximate minimum enclosing balls $\mathcal{B}_{c^k,\rho^k}$, which converge to MEB($\mathcal{A}$) in the limit. Each such ball is a $(1+\epsilon^k)$-approximate solution to MEB($\mathcal{A}$) for a certain $\epsilon^k > 0$, and the algorithm terminates when $\epsilon^k \leq \epsilon$. Both of these algorithms extract a small core set $\mathcal{X} \subseteq \mathcal{A}$ and can be extended to much more general input sets without sacrificing the small core set result.

Lemma 2.1 can be easily incorporated into both of the algorithms in [2] in an attempt to eliminate interior points in $\mathcal{A}$ (with respect to MEB($\mathcal{A}$)) thereby reducing the size of the input set. This elimination procedure does not affect the minimum enclosing ball and may decrease the computational cost of each iteration due to the reduction in the input size.

In order to assess the implications of Lemma 2.1 in practice, we have performed computational tests in which the simple elimination procedure proposed in this note was incorporated into each of the two algorithms in [2]. In our experiments, we checked the boundary condition (3) at an approximate minimum enclosing ball generated throughout either algorithm only if the right-hand side of (3) is sufficiently bounded away from zero. This strategy eliminates the computational cost of checking the boundary condition at an iterate where it would be unlikely to remove a large subset of input points. At iterate k, (3) is checked in our computational experiments only if $1 - (2\epsilon^k + (\epsilon^k)^2)^{1/2} > 0.55$, where 0.55 is a threshold value that was found to work well empirically.

The computational experiments were carried out on a 3.40 GHz Pentium IV processor with 1.0 GB RAM using MATLAB version R2006b on four different data sets. The first two data sets were randomly generated using different procedures outlined below. The last two sets consist of spherical or almost spherical input sets.

3.1. Random input sets. The first data set was randomly generated as in [2] with sizes (n, m) varying from $(10, 500)$ to $(100, 100000)$, while the second one was

generated using the standard normal distribution with the same sizes (n, m). We used $\epsilon = 10^{-3}$ for both data sets. For each fixed (n, m), ten different problem instances were generated for each data set. The computational results are reported in terms of averages over these instances in Table 1 and Table 2, each of which is divided into three sets of columns. The first set of columns reports the size (n, m). The second set of columns presents the results regarding the CPU time and is further divided into two parts, the first of which is devoted to the computational results related to [2, Algorithm 3.1] (an adaptation of the Frank–Wolfe algorithm to the minimum enclosing ball problem), while the second one displays those results using [2, Algorithm 4.1] (an adaptation of the Frank–Wolfe algorithm with *away steps* to the minimum enclosing ball problem). In the first part, A1 and A1E denote the CPU times in seconds using [2, Algorithm 3.1] without and with the elimination procedure, respectively, and speed-up denotes the resulting speed-up factor in running time due to the elimination procedure measured in terms of the ratio of A1 to A1E. Similarly, A2 and A2E denote the CPU times in seconds using [2, Algorithm 4.1] without and with the elimination procedure, respectively, and speed-up denotes the resulting speed-up factor in running time measured in terms of the ratio of A2 to A2E. The last set of columns reports the number of remaining input points upon termination using each algorithm with the elimination procedure.

As illustrated by Table 1 and Table 2, the incorporation of the elimination procedure into each of the two algorithms results in significant savings in running times especially for large instances where $m \gg n$. The procedure described in Lemma 2.1 identifies and eliminates 75% to 99% of the data points in our experiments, and the running times may improve by more than a factor of 19 on some instances. It is also worth noticing that the speed-up factors obtained from Algorithm 3.1 are generally considerably larger than those obtained with Algorithm 4.1. This may be due to the reason that the asymptotical linear convergence property of Algorithm 4.1 [2] already

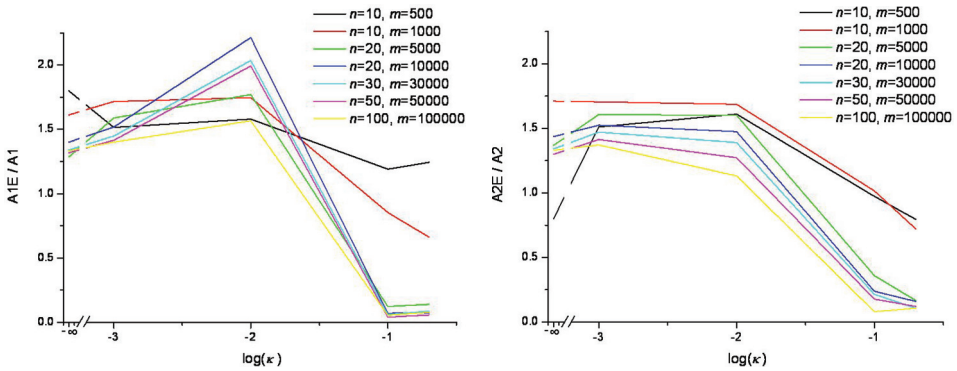

FIG. 1. *Experimental results for almost spherical input sets.*

results in significantly better performance compared to that of Algorithm 3.1, which may not leave much room for further improvement. Finally, we remark that the elimination procedure does not seem to have a noticeable effect on the core set sizes and on the number of iterations for either of the two algorithms.

3.2. Spherical and almost spherical input sets. In an attempt to assess the extent of extra overhead due to the elimination procedure, we considered data sets where all points lie on (or almost on) the unit sphere centered at the origin. An input set $\mathcal{A}$ is said to lie on a κ-approximate unit sphere centered at the origin, denoted by $\mathcal{S}_\kappa$, if $\mathcal{A} \subset \mathcal{S}_\kappa := \{x \in \mathbb{R}^n : 1 - \kappa \leq \|x\| \leq 1 + \kappa\}$. For an input set $\mathcal{A} \subset \mathcal{S}_\kappa$ where $\kappa \geq 0$ is small, the elimination procedure will keep testing input points for removal at each iteration but will be unable to remove a substantial subset of the input set. In the extreme case where $\kappa = 0$, none of the input points can be removed, since there would be no interior point. This extra overhead will necessarily result in an increase in the running time of an algorithm that uses the elimination procedure. We generated random input sets $\mathcal{A} \subset \mathcal{S}_\kappa$, where $\kappa \in \{0, 0.001, 0.01, 0.1, 0.2\}$, with sizes (n, m) varying from $(10, 500)$ to $(100, 100000)$ as in our experiments with the first two data sets. For each choice of experimental parameters, the computational results averaged over ten data sets are illustrated in Figure 1. The horizontal axis in each graph corresponds to κ using the logarithmic scale, while the vertical axis in the graph on the left (on the right) corresponds to the "slow-down" factor measured in terms of the ratio of the running time of Algorithm 3.1 (Algorithm 4.1) with the elimination procedure to the running time of the same algorithm without the elimination. A close examination of these two graphs reveals that the slow-down factors usually remain at an acceptable level especially for the faster Algorithm 4.1. Note that the elimination procedure leads to an extra overhead of at most 70% on all instances for Algorithm 4.1. A comparison of the slow-down and speed-up factors stemming from our experiments seems to justify the use of the elimination procedure, especially since spherical input sets would not likely be encountered in practical applications.

We also tested the two algorithms on data sets which consist of the vertices of the unit simplex where $n \in \{1000, 2500, 5000\}$. Note that each point in such an input set lies on the boundary of the minimum enclosing ball, and it is known that each point should be in the core set if $\epsilon \leq 1/n$ [1]. We tested each of the two algorithms with and without the elimination procedure using $\epsilon = 1/n$. The computational results are reported in Table 3, which is organized in a similar manner to that of Table 1. Note

TABLE 3
Computational results for the vertices of the unit simplex ($\epsilon = 1/n$).

n	m	CPU time					
		A1	A1E	A1E/A1	A2	A2E	A2E/A2
1000	1000	39.5312	53.625	1.357	40.078	54.219	1.352
2500	2500	251.75	336.7188	1.338	252.234	339.391	1.346
5000	5000	988.2812	1301.5312	1.317	983.25	1289.547	1.311

that the increase in the running time of each algorithm due to the inclusion of the elimination procedure is only around 35% for large spherical instances.

4. Concluding remarks. In this paper, we have described a procedure that identifies and eliminates data points that cannot lie on the boundary of the minimum enclosing ball of a finite set of points. This procedure can be easily incorporated into any iterative algorithm that generates a sequence of approximate minimum enclosing balls converging to the minimum enclosing ball of a given input set. Our computational results demonstrate the resulting significant improvements in the practical performance of the two algorithms proposed in [2] especially for randomly generated input sets. The extra overhead of the elimination procedure remains at an acceptable level for spherical or almost spherical input sets.

Furthermore, the same elimination procedure can also be incorporated into algorithms that can compute an approximate minimum enclosing ball of more general input sets such as a set of balls or ellipsoids for which the algorithms in [2] can still be applied. Such input sets can be viewed as an infinite set of points, and condition (3) essentially means that all input points that lie in the interior of a ball of a certain radius centered at the current approximate center c can be safely removed without affecting the optimal solution. In this case, an element of a more general input set (such as a ball or ellipsoid) can be completely removed if the furthest point on that element from the current approximate center c already lies in the interior of the aforementioned ball centered at c, which readily implies that every point on that element should necessarily violate (3). This may lead to considerable savings in the computation of minimum enclosing balls of more general input sets arising from practical applications.

ITERATIVE MINIMIZATION SCHEMES FOR SOLVING THE SINGLE SOURCE LOCALIZATION PROBLEM*

AMIR BECK†, MARC TEBOULLE‡, AND ZAHAR CHIKISHEV§

Abstract. We consider the problem of locating a single radiating source from several noisy measurements using a maximum likelihood (ML) criteria. The resulting optimization problem is nonconvex and nonsmooth, and thus finding its global solution is in principle a hard task. Exploiting the special structure of the objective function, we introduce and analyze two iterative schemes for solving this problem. The first algorithm is a very simple explicit fixed-point-based formula, and the second is based on solving at each iteration a nonlinear least squares problem, which can be solved globally and efficiently after transforming it into an equivalent quadratic minimization problem with a single quadratic constraint. We show that the nonsmoothness of the problem can be avoided by choosing a specific "good" starting point for both algorithms, and we prove the convergence of the two schemes to stationary points. We present empirical results that support the underlying theoretical analysis and suggest that, despite of its nonconvexity, the ML problem can effectively be solved globally using the devised schemes.

Key words. single source location problem, Weiszfield algorithm, nonsmooth and nonconvex minimization, fixed-point methods, nonlinear least squares, generalized trust region, semidefinite relaxation

1. Introduction.

1.1. The source localization problem.

Consider the problem of locating a single radiating source from noisy range measurements collected using a network of passive sensors. More precisely, consider an array of m sensors, and let $\mathbf{a}_j \in \mathbb{R}^n$ denote the coordinates of the jth sensor.[1] Let $\mathbf{x} \in \mathbb{R}^n$ denote the unknown source's coordinate vector, and let $d_j > 0$ be a noisy observation of the range between the source and the jth sensor:

$$d_j = \|\mathbf{x} - \mathbf{a}_j\| + \varepsilon_j, \quad j = 1, \ldots, m, \tag{1.1}$$

where $\boldsymbol{\varepsilon} = (\varepsilon_1, \ldots, \varepsilon_m)^T$ denotes the unknown noise vector. Such observations can be obtained, for example, from the time-of-arrival measurements in a constant-velocity propagation medium. The source localization problem is the following.

The source localization problem: Given the observed range measurements $d_j > 0$, find a "good" approximation of the source $\mathbf{x}$ satisfying (1.1).

[1] In practical applications $n = 2$ or 3.

The source localization problem has received significant attention in the signal processing literature and specifically in the field of mobile phones localization [12, 5, 13]. It is also worth mentioning that the interest in wireless localization problems has increased since the first ruling of the Federal Communications Commission (FCC) for the detection of emergency calls in the United States in 1996 [17]. Currently, a high percentage of Enhanced 911 (E911) calls originate from mobile phones. Due to the unknown location of the wireless E911 calls, these calls do not receive the same quality of emergency assistance that fixed network 911 calls enjoy. To deal with this problem, the FCC issued an order on July 12, 1996, requiring all wireless service providers to report accurate mobile station location information to the E911 operator.

In addition to emergency management, mobile position information is also useful in mobile advertising, asset tracking, fleet management, location-sensitive billing [12], interactive map consultation, and monitoring of the mentally impaired [5].

1.2. The maximum likelihood criteria. In this paper we adopt the maximum-likelihood (ML) approach for solving the source localization problem (1.1); see, e.g., [4]. When $\boldsymbol{\varepsilon}$ follows a Gaussian distribution with a covariance matrix proportional to the identity matrix, the source $\mathbf{x}$ is the ML estimate that is the solution of the problem:

$$\text{(ML):} \quad \min_{\mathbf{x}\in\mathbb{R}^n} \left\{ f(\mathbf{x}) \equiv \sum_{j=1}^{m} (\|\mathbf{x}-\mathbf{a}_j\| - d_j)^2 \right\}. \tag{1.2}$$

Note that, in addition to the statistical interpretation, the latter problem is a least squares problem in the sense that it minimizes the squared sum of the errors.

An alternative approach for estimating the source location $\mathbf{x}$ is by solving the following least squares (LS) problem in the squared domain:

$$\text{(LS):} \quad \min_{\mathbf{x}\in\mathbb{R}^n} \sum_{j=1}^{m} \left(\|\mathbf{x}-\mathbf{a}_j\|^2 - d_j^2\right)^2. \tag{1.3}$$

Despite of its nonconvexity, the LS problem can be solved globally and efficiently by transforming it into a problem of minimizing a quadratic function subject to a single quadratic constraint [1] (more details will be given in section 3.2). However, the LS approach has two major disadvantages compared to the ML approach: first, the LS formulation lacks the statistical interpretation of the ML problem. Second, as demonstrated by the numerical simulations in section 4, the LS estimate provides less accurate solutions than those provided by the the ML approach.

The ML problem, like the LS problem, is nonconvex. However, as opposed to the LS problem for which a global solution can be computed efficiently [1], the ML problem seems to be a difficult problem to solve efficiently. A possible reason for the increased difficulty of the ML problem is its nonsmoothness. One approach for approximating the solution of the ML problem is via semidefinite relaxation (SDR) [4, 1]. We also note that the source localization problem formulated as (ML) can be viewed as a special instance of sensor network localization problems in which several sources are present; see, for example, the recent work in [3]; for this class of problems, semidefinite programming-based algorithms have been developed.

In this paper we depart from the SDR techniques and seek other efficient approaches to solve the ML problem. This is achieved by exploiting the special structure of the objective function which allows us to devise fixed-point-based iterative schemes

for solving the nonsmooth and nonconvex ML problem (1.2). The first scheme admits a very simple explicit iteration formula given by

$$\mathbf{x}^{k+1} = \mathcal{M}_1\left(\mathbf{x}^k, \mathbf{a}\right) \text{ (where } \mathbf{a} \equiv (\mathbf{a}_1, \ldots, \mathbf{a}_m)),$$

while the second iterative scheme is of the form

$$\mathbf{x}^{k+1} \in \operatorname*{argmin}_{\mathbf{x}} \mathcal{M}_2\left(\mathbf{x}, \mathbf{x}^k, \mathbf{a}\right)$$

and requires the solution of an additional subproblem which will be shown to be efficiently solved. The main goals of this paper are to introduce the building mechanism of these two schemes, to develop and analyze their convergence properties, and to demonstrate their computational viability for solving the ML problem (1.2), as well as their effectiveness when compared with the LS and SDR approaches.

1.3. Paper layout. In the next section, we present and analyze the first scheme, which is a simple fixed-point-based method. The second algorithm, which is based on solving a sequence of least squares problems of a similar structure to that of (1.3), is presented and analyzed in section 3. The construction of both methods is motivated by two different interpretations of the well-known Weiszfeld method for the Fermat–Weber location problem [16]. For both schemes, we show that the nonsmoothness of the problem can be avoided by choosing a specific "good" starting point. Empirical results presented in section 4 provide a comparison between the two devised algorithms, as well as a comparison to different approaches such as LS and SDR. In particular, the numerical results suggest that, despite its nonconvexity, the ML problem can, for all practical purposes, be globally solved using the devised methods.

1.4. Notation. Throughout the paper, the following notation is used: vectors are denoted by boldface lowercase letters, e.g., $\mathbf{y}$, and matrices by boldface uppercase letters, e.g., $\mathbf{A}$. The ith component of a vector $\mathbf{y}$ is written as y_i. Given two matrices $\mathbf{A}$ and $\mathbf{B}$, $\mathbf{A} \succ \mathbf{B}$ ($\mathbf{A} \succeq \mathbf{B}$) means that $\mathbf{A} - \mathbf{B}$ is positive definite (semidefinite). The directional derivative of a function $f : \mathbb{R}^n \to \mathbb{R}$ at $\bar{\mathbf{x}}$ in the direction $\mathbf{v}$ is defined (if it exists) by

$$f'(\mathbf{x}; \mathbf{v}) \equiv \lim_{t \to 0^+} \frac{f(\bar{\mathbf{x}} + t\mathbf{v}) - f(\bar{\mathbf{x}})}{t}. \tag{1.4}$$

The α-level set of a function $f : \mathbb{R}^n \to \mathbb{R}$ is defined by $\mathrm{Lev}(f, \alpha) = \{\mathbf{x} \in \mathbb{R}^n : f(\mathbf{x}) \leq \alpha\}$. The collection of m sensors $\{\mathbf{a}_1, \ldots, \mathbf{a}_m\}$ is denoted by $\mathcal{A}$.

2. A simple fixed-point algorithm. In this section we introduce a simple fixed-point algorithm that is designed to solve the ML problem (1.2). The algorithm is inspired by the celebrated Weiszfeld algorithm for the Fermat–Weber problem, which is briefly recalled in section 2.1. In section 2.2 we introduce and analyze the fixed-point scheme designed to solve the ML problem.

2.1. A small detour: Weiszfeld algorithm for the Fermat–Weber problem. As was already mentioned, the ML problem (1.2) is nonconvex and nonsmooth, and thus finding its exact solution is in principle a difficult task. We propose a fixed-point scheme motivated by the celebrated Weiszfeld algorithm [16, 7] for solving the Fermat–Weber location problem:

$$\min_{\mathbf{x}} \left\{ s(\mathbf{x}) \equiv \sum_{j=1}^{m} \omega_j \|\mathbf{x} - \mathbf{a}_j\| \right\}, \tag{2.1}$$

where $\omega_j > 0$ and $\mathbf{a}_j \in \mathbb{R}^n$ for $j = 1, \ldots, m$. Of course, the Fermat–Weber problem is much easier to analyze and solve than the ML problem (1.2) since it is a well-structured nonsmooth convex minimization problem. This problem has been extensively studied in the location theory literature; see, for instance, [11]. Our objective here is to mimic the Weiszfeld algorithm [16] to obtain an algorithm for solving the nonsmooth and nonconvex ML problem (1.2). The Weiszfeld method is a very simple fixed-point scheme that is designed to solve the Fermat–Weber problem. One way to derive it is to write the first order global optimality conditions for the convex problem (2.1)

$$\nabla s(\mathbf{x}) = \sum_{j=1}^{m} \omega_j \frac{\mathbf{x} - \mathbf{a}_j}{\|\mathbf{x} - \mathbf{a}_j\|} = 0 \ \forall \mathbf{x} \notin \mathcal{A}$$

as

$$\mathbf{x} = \frac{\sum_{j=1}^{m} \omega_j \frac{\mathbf{a}_j}{\|\mathbf{x}-\mathbf{a}_j\|}}{\sum_{j=1}^{m} \frac{\omega_j}{\|\mathbf{x}-\mathbf{a}_j\|}},$$

which naturally calls for the iterative scheme

$$\mathbf{x}^{k+1} = \frac{\sum_{j=1}^{m} \omega_j \frac{\mathbf{a}_j}{\|\mathbf{x}^k-\mathbf{a}_j\|}}{\sum_{j=1}^{m} \frac{\omega_j}{\|\mathbf{x}^k-\mathbf{a}_j\|}}. \tag{2.2}$$

For the convergence analysis of the Weiszfeld algorithm (2.2) and modified versions of the algorithm, see, e.g., [10, 15], and references therein.

2.2. The simple fixed-point algorithm: Definition and analysis. Similarly to the Weiszfeld method, our starting point for constructing a fixed-point algorithm to solve the ML problem is by writing the optimality conditions. Assuming that $\mathbf{x} \notin \mathcal{A}$ we have that $\mathbf{x}$ is a stationary point for problem (ML) if and only if

$$\nabla f(\mathbf{x}) = 2 \sum_{j=1}^{m} (\|\mathbf{x} - \mathbf{a}_j\| - d_j) \frac{\mathbf{x} - \mathbf{a}_j}{\|\mathbf{x} - \mathbf{a}_j\|} = \mathbf{0}, \tag{2.3}$$

which can be written as

$$\mathbf{x} = \frac{1}{m} \left\{ \sum_{j=1}^{m} \mathbf{a}_j + \sum_{j=1}^{m} d_j \frac{\mathbf{x} - \mathbf{a}_j}{\|\mathbf{x} - \mathbf{a}_j\|} \right\}.$$

The latter relation calls for the following fixed-point algorithm, which we term the *standard fixed point (SFP) scheme*.

ALGORITHM SFP.

$$\mathbf{x}^{k+1} = \frac{1}{m} \left\{ \sum_{j=1}^{m} \mathbf{a}_j + \sum_{j=1}^{m} d_j \frac{\mathbf{x}^k - \mathbf{a}_j}{\|\mathbf{x}^k - \mathbf{a}_j\|} \right\}, \quad k \geq 0. \tag{2.4}$$

Like in the Weiszfeld algorithm, the SFP scheme is not well defined if $\mathbf{x}^k \in \mathcal{A}$ for some k. In what follows we will show that by carefully selecting the initial vector $\mathbf{x}^0$

we can *guarantee* that the iterates are not in the sensors set $\mathcal{A}$, therefore establishing that the method is well defined. At this juncture, it is interesting to notice that the approach we suggest here for dealing with the points of nonsmoothness that occur at $\mathbf{x}^k \in \mathcal{A}$ is quite different from the common approaches for handling the nonsmoothness. For example, in order to avoid the nondifferentiable points of the Fermat–Weber objective function, several modifications of the Weiszfeld method were proposed; see, e.g., [10, 15], and references therein. However, there do not seem to have been any attempts in the literature to choose good initial starting points to avoid the nonsmoothness difficulty. A constructive procedure for choosing a good starting point for the SFP method will be given at the end of this section.

Before proceeding with the analysis of the SFP method, we record the fact that, much like the Weiszfeld algorithm (see [7]), the SFP scheme is a gradient method with a fixed step size.

PROPOSITION 2.1. *Let* $\{\mathbf{x}^k\}$ *be the sequence generated by the SFP method* (2.4)*, and suppose that* $\mathbf{x}^k \notin \mathcal{A}$ *for all* $k \geq 0$*. Then*

$$\mathbf{x}^{k+1} = \mathbf{x}^k - \frac{1}{2m}\nabla f\left(\mathbf{x}^k\right). \tag{2.5}$$

Proof. The proof follows by a straightforward calculation, using the gradient of f computed in (2.3). ∎

A gradient method does not necessarily converge without additional assumptions (e.g., assuming that ∇f is Lipschitz continuous and/or using a line search [2]). Nevertheless, we show below that scheme (2.4) *does* converge.

By Proposition 2.1 the SFP method can be compactly written as

$$\mathbf{x}^{k+1} = T\left(\mathbf{x}^k\right), \tag{2.6}$$

where $T : \mathbb{R}^n \setminus \mathcal{A} \to \mathbb{R}^n$ is the operator defined by

$$T(\mathbf{x}) = \mathbf{x} - \frac{1}{2m}\nabla f(\mathbf{x}). \tag{2.7}$$

In the convergence analysis of the SFP method, we will also make use of the auxiliary function:

$$h(\mathbf{x}, \mathbf{y}) \equiv \sum_{j=1}^{m} \|\mathbf{x} - \mathbf{a}_j - d_j r_j(\mathbf{y})\|^2 \quad \forall \mathbf{x} \in \mathbb{R}^n, \mathbf{y} \in \mathbb{R}^n \setminus \mathcal{A}, \tag{2.8}$$

where

$$r_j(\mathbf{y}) \equiv \frac{\mathbf{y} - \mathbf{a}_j}{\|\mathbf{y} - \mathbf{a}_j\|}, \quad j = 1, \ldots, m.$$

Note that for every $\mathbf{y} \notin \mathcal{A}$, the following relations hold for every $j = 1, \ldots, m$:

$$\|r_j(\mathbf{y})\| = 1, \tag{2.9}$$

$$(\mathbf{y} - \mathbf{a}_j)^T r_j(\mathbf{y}) = \|\mathbf{y} - \mathbf{a}_j\|. \tag{2.10}$$

In Lemma 2.1 below, we prove several key properties of the auxiliary function h defined in (2.8).

LEMMA 2.1.
(a) $h(\mathbf{x},\mathbf{x}) = f(\mathbf{x})$ *for every* $\mathbf{x} \notin \mathcal{A}$.
(b) $h(\mathbf{x},\mathbf{y}) \geq f(\mathbf{x})$ *for every* $\mathbf{x} \in \mathbb{R}^n, \mathbf{y} \in \mathbb{R}^n \setminus \mathcal{A}$.
(c) *If* $\mathbf{y} \notin \mathcal{A}$, *then*

$$T(\mathbf{y}) = \operatorname*{argmin}_{\mathbf{x}\in\mathbb{R}^n} h(\mathbf{x},\mathbf{y}). \tag{2.11}$$

Proof. (a) For every $\mathbf{x} \notin \mathcal{A}$,

$$\begin{aligned} f(\mathbf{x}) &= \sum_{j=1}^{m} (\|\mathbf{x}-\mathbf{a}_j\| - d_j)^2 \\ &= \sum_{j=1}^{m} (\|\mathbf{x}-\mathbf{a}_j\|^2 - 2d_j\|\mathbf{x}-\mathbf{a}_j\| + d_j^2) \\ &\overset{(2.9),(2.10)}{=} \sum_{j=1}^{m} (\|\mathbf{x}-\mathbf{a}_j\|^2 - 2d_j(\mathbf{x}-\mathbf{a}_j)^T r_j(\mathbf{x}) + d_j^2\|r_j(\mathbf{x})\|^2) = h(\mathbf{x},\mathbf{x}), \end{aligned}$$

where the last equation follows from (2.8).

(b) Using the definition of f and h given in (1.2) and (2.8), respectively, and the fact (2.9), a short computation shows that for every $\mathbf{x} \in \mathbb{R}^n, \mathbf{y} \in \mathbb{R}^n \setminus \mathcal{A}$,

$$\begin{aligned} h(\mathbf{x},\mathbf{y}) - f(\mathbf{x}) &= 2\sum_{j=1}^{m} d_j \left(\|\mathbf{x}-\mathbf{a}_j\| - (\mathbf{x}-\mathbf{a}_j)^T r_j(\mathbf{y})\right) \\ &\geq 0, \end{aligned}$$

where the last inequality follows from the Cauchy–Schwarz inequality and using again (2.9).

(c) For any $\mathbf{y} \in \mathbb{R}^n \setminus \mathcal{A}$, the function $\mathbf{x} \mapsto h(\mathbf{x},\mathbf{y})$ is strictly convex on $\mathbb{R}^n$ and consequently admits a unique minimizer $\mathbf{x}^*$ satisfying

$$\nabla_{\mathbf{x}} h(\mathbf{x}^*,\mathbf{y}) = \mathbf{0}.$$

Using the definition of h given in (2.8), the latter identity can be explicitly written as

$$\sum_{j=1}^{m} (\mathbf{x}^* - \mathbf{a}_j - d_j r_j(\mathbf{y})) = \mathbf{0},$$

which by simple algebraic manipulation can be shown to be equivalent to $\mathbf{x}^* = \mathbf{y} - \frac{1}{2m}\nabla f(\mathbf{y})$, establishing that $\mathbf{x}^* = T(\mathbf{y})$. ∎

Using Lemma 2.1 we are now able to prove the monotonicity property of the operator T with respect to f.

LEMMA 2.2. *Let* $\mathbf{y} \notin \mathcal{A}$. *Then*

$$f(T(\mathbf{y})) \leq f(\mathbf{y}),$$

and equality holds if and only if $T(\mathbf{y}) = \mathbf{y}$.

Proof. By (2.11) and the strict convexity of the function $\mathbf{x} \mapsto h(\mathbf{x},\mathbf{y})$, one has

$$h(T(\mathbf{y}),\mathbf{y}) < h(\mathbf{x},\mathbf{y}) \text{ for every } \mathbf{x} \neq T(\mathbf{y}).$$

In particular, if $T(\mathbf{y}) \neq \mathbf{y}$, then

$$h(T(\mathbf{y}), \mathbf{y}) < h(\mathbf{y}, \mathbf{y}) = f(\mathbf{y}), \tag{2.12}$$

where the last equality follows from Lemma 2.1(a). By Lemma 2.1(b), $h(T(\mathbf{y}), \mathbf{y}) \geq f(T(\mathbf{y}))$, which, combined with (2.12), establishes the desired strict monoton icity. ∎

Theorem 2.1 given below states the basic convergence results for the SFP method. In the proof, we exploit the boundedness of the level sets of the objective function f, which is recorded in the following lemma.

LEMMA 2.3. *The level sets of f are bounded.*

Proof. The proof follows immediately from the fact that $f(\mathbf{x}) \to \infty$ as $\|\mathbf{x}\| \to \infty$. ∎

THEOREM 2.1 (convergence of the SFP method). *Let $\{\mathbf{x}^k\}$ be generated by* (2.4) *such that $\mathbf{x}^0$ satisfies*

$$f\left(\mathbf{x}^0\right) < \min_{j=1,\ldots,m} f(\mathbf{a}_j). \tag{2.13}$$

Then

(a) *$\mathbf{x}^k \notin \mathcal{A}$ for every $k \geq 0$;*

(b) *for every $k \geq 0$, $f(\mathbf{x}^{k+1}) \leq f(\mathbf{x}^k)$, and equality is satisfied if and only if $\mathbf{x}^{k+1} = \mathbf{x}^k$.*

(c) *the sequence of function values $\{f(\mathbf{x}^k)\}$ converges;*

(d) *the sequence $\{\mathbf{x}^k\}$ is bounded;*

(e) *every convergent subsequence $\{\mathbf{x}^{k_l}\}$ satisfies $\mathbf{x}^{k_l+1} - \mathbf{x}^{k_l} \to \mathbf{0}$;*

(f) *any limit point of $\{\mathbf{x}^k\}$ is a stationary point of f.*

Proof. (a) and (b) The proof follows by induction on k using Lemma 2.2.

(c) The proof readily follows from the monotonicity and lower boundedness (by zero) of the sequence $\{f(\mathbf{x}^k)\}$.

(d) By (b), all of the iterates $\mathbf{x}^k$ are in the level set $\mathrm{Lev}(f, f(\mathbf{x}^0))$ which, by Lemma 2.3, establishes the boundedness of the sequence $\{\mathbf{x}^k\}$.

(e) and (f) Let $\{\mathbf{x}^{k_l}\}$ be a convergent subsequence of $\{\mathbf{x}^k\}$ with limit point $\mathbf{x}^*$. Since $f(\mathbf{x}^{k_l}) \leq f(\mathbf{x}^0) < \min_{j=1,\ldots,m} f(\mathbf{a}_j)$, it follows by the continuity of f that $f(\mathbf{x}^*) \leq f(\mathbf{x}^0) < \min_{j=1,\ldots,m} f(\mathbf{a}_j)$, proving that $\mathbf{x}^* \notin \mathcal{A}$. By (2.6)

$$\mathbf{x}^{k_l+1} = T\left(\mathbf{x}^{k_l}\right). \tag{2.14}$$

Therefore, since the subsequence $\{\mathbf{x}^{k_l}\}$ and its limit point $\mathbf{x}^*$ are not in $\mathcal{A}$, by the continuity of ∇f on $\mathbb{R}^n \setminus \mathcal{A}$, we conclude that the subsequence $\{\mathbf{x}^{k_l+1}\}$ converges to a vector $\bar{\mathbf{x}}$ satisfying

$$\bar{\mathbf{x}} = T(\mathbf{x}^*). \tag{2.15}$$

To prove (e), we need to show that $\bar{\mathbf{x}} = \mathbf{x}^*$. Since both $\mathbf{x}^*$ and $\bar{\mathbf{x}}$ are limit points of $\{\mathbf{x}^k\}$ and since the sequence of function values converges (by (c)), then the continuity of f over $\mathbb{R}^n$ implies that $f(\mathbf{x}^*) = f(\bar{\mathbf{x}})$. Invoking Lemma 2.2 for $\mathbf{y} = \mathbf{x}^*$, we conclude that $\bar{\mathbf{x}} = \mathbf{x}^*$, proving claim (e). Part (f) follows from the observation that the equality $\mathbf{x}^* = T(\mathbf{x}^*)$ is equivalent (by the definition of T) to $\nabla f(\mathbf{x}^*) = \mathbf{0}$. ∎

Remark 2.1. It is easy to find a vector $\mathbf{x}^0$ satisfying condition (2.13). For example, Procedure INIT, that will be described at the end of this section, produces a point satisfying (2.13).

Combining claims (c) and (f) of Theorem 2.1, we immediately obtain convergence of the sequence of function values.

COROLLARY 2.1. *Let $\{\mathbf{x}^k\}$ be the sequence generated by the SFP algorithm satisfying* (2.13). *Then $f(\mathbf{x}^k) \to f^*$, where f^* is the function value at a stationary point of f.*

We were able to prove the convergence of the function values of the sequence. The situation is more complicated for the sequence itself, where we were able only to show that all limit points are stationary points. We can prove convergence of the sequence itself if we assume that all stationary points of the objective function are isolated.[2] The proof of this claim strongly relies on the following lemma from [8].

LEMMA 2.4 (see [8, Lemma 4.10]). *Let $\mathbf{x}^*$ be an isolated limit point of a sequence $\{\mathbf{x}^k\}$ in $\mathbb{R}^n$. If $\{\mathbf{x}^k\}$ does not converge, then there is a subsequence $\{\mathbf{x}^{k_l}\}$ which converges to $\mathbf{x}^*$ and an $\epsilon > 0$ such that $\|\mathbf{x}^{k_l+1} - \mathbf{x}^{k_l}\| \geq \epsilon$.*

We can now use the above lemma to prove a convergence result under the assumption that all stationary points of f are isolated.

THEOREM 2.2 (convergence of the sequence). *Let $\{\mathbf{x}^k\}$ be generated by* (2.4) *such that $\mathbf{x}^0$ satisfies* (2.13). *Suppose further that all stationary points of f are isolated. Then the sequence $\{\mathbf{x}^k\}$ converges to a stationary point.*

Proof. Let $\mathbf{x}^*$ be a limit point of $\{\mathbf{x}^k\}$ (its existence follows from the boundedness of the sequence proved in Theorem 2.1(d)). By our assumption $\mathbf{x}^*$ is an isolated point. Suppose in contradiction that the sequence does not converge. Then by Lemma 2.4 there exists a subsequence $\{\mathbf{x}^{k_l}\}$ that converges to $\mathbf{x}^*$ satisfying $\|\mathbf{x}^{k_l+1} - \mathbf{x}^{k_l}\| \geq \epsilon$. However, this is in contradiction to (e) of Theorem 2.1. We thus conclude that $\{\mathbf{x}^k\}$ converges to a stationary point. ∎

The analysis of the SFP method relies on the validity of condition (2.13) on the starting point $\mathbf{x}^0$. We will now show that, thanks to the special structure of the objective function (ML), we can compute such a point through a simple procedure. This is achieved by establishing the following result.

LEMMA 2.5. *Let $\mathcal{A} \equiv \{\mathbf{a}_1, \ldots, \mathbf{a}_m\}$ be the given set of m sensors, and let*

$$g_j(\mathbf{x}) = \sum_{i=1, i\neq j}^{m} (\|\mathbf{x} - \mathbf{a}_i\| - d_i)^2, \quad j = 1, \ldots, m.$$

Then for every $j = 1, \ldots, m$ the following apply:

(i) *If $\nabla g_j(\mathbf{a}_j) \neq \mathbf{0}$, then $f'(\mathbf{a}_j; -\nabla g_j(\mathbf{a}_j)) < 0$. Otherwise, if $\nabla g_j(\mathbf{a}_j) = \mathbf{0}$, then $f'(\mathbf{a}_j; \mathbf{v}) < 0$ for every $\mathbf{v} \neq \mathbf{0}$. In particular, there exists a descent direction from every sensor point.*

(ii) *Every $\bar{\mathbf{x}} \in \mathcal{A}$ is not a local optimum for the ML problem* (1.2).

Proof. (i) For convenience, for every $j = 1, \ldots, m$ we denote

$$f_j(\mathbf{x}) = (\|\mathbf{x} - \mathbf{a}_j\| - d_j)^2 \tag{2.16}$$

so that the objective function of problem (ML) can be written as

$$f(\mathbf{x}) = f_j(\mathbf{x}) + g_j(\mathbf{x}) \tag{2.17}$$

for every $\mathbf{x} \in \mathbb{R}^n$ and $j = 1, \ldots, m$. Note that f is not differentiable for every $\mathbf{x} \in \mathcal{A}$. Nonetheless, the directional derivative of f at $\mathbf{x}$ in the direction $\mathbf{v} \in \mathbb{R}^n$ always exists

[2] We say that $\mathbf{x}^*$ is an isolated stationary point of f, if there are no other stationary points in some neighborhood of $\mathbf{x}^*$.

and is given by

$$f'(\bar{\mathbf{x}};\mathbf{v}) = \begin{cases} \nabla f(\bar{\mathbf{x}})^T\mathbf{v}, & \bar{\mathbf{x}} \notin \mathcal{A}, \\ \nabla g_j(\mathbf{a}_j)^T\mathbf{v} - 2d_j\|\mathbf{v}\|, & \bar{\mathbf{x}} = \mathbf{a}_j. \end{cases} \tag{2.18}$$

Indeed, the above formula for $\bar{\mathbf{x}} \notin \mathcal{A}$ is obvious. In the other case, suppose then that $\bar{\mathbf{x}} = \mathbf{a}_j$ for some $j \in \{1,\ldots,m\}$. Noting that g_j is differentiable at $\mathbf{a}_j$, we have $g_j'(\mathbf{a}_j;\mathbf{v}) = \nabla g_j(\mathbf{a}_j)^T\mathbf{v}$, and using definition (2.16) for f_j, we get $f_j'(\mathbf{a}_j;\mathbf{v}) = -2d_j\|\mathbf{v}\|$, and hence with (2.17), we obtain the desired formula (2.18) for $f'(\mathbf{a}_j;\mathbf{v})$. Finally, if $\nabla g_j(\mathbf{a}_j) \neq \mathbf{0}$, then using (2.18) we have

$$f'(\mathbf{a}_j; -\nabla g_j(\mathbf{a}_j)) = -\|\nabla g_j(\mathbf{a}_j)\|^2 - 2d_j\|\nabla g_j(\mathbf{a}_j)\| < 0.$$

Otherwise, if $\nabla g_j(\mathbf{a}_j) = \mathbf{0}$, then for every $\mathbf{v} \neq \mathbf{0}$ we have

$$f'(\mathbf{a}_j;\mathbf{v}) = -2d_j\|\mathbf{v}\| < 0.$$

(ii) By part (i) there exists a descent direction from every sensor point $\bar{\mathbf{x}} \in \mathcal{A}$. Therefore, none of the sensor points can be a local optimum for problem (ML). ∎

Using the descent directions provided by Lemma 2.5, we can compute a point $\bar{\mathbf{x}}$ satisfying

$$f(\bar{\mathbf{x}}) < \min_{j=1,\ldots,m} f(\mathbf{a}_j)$$

by the following procedure.

PROCEDURE INIT.

1. $t = 1$.
2. **Set** k to be an index for which $f(\mathbf{a}_k) = \min_{j=1,\ldots,m} f(\mathbf{a}_j)$.
3. **Set**

$$\mathbf{v}_0 = \begin{cases} -\nabla g_k(\mathbf{a}_k), & \nabla g_k(\mathbf{a}_k) \neq \mathbf{0}, \\ \mathbf{e}, & \nabla g_k(\mathbf{a}_k) = \mathbf{0}, \end{cases} \tag{2.19}$$

   where $\mathbf{e}$ is the vector of all ones.[3]
4. **While** $f(\mathbf{a}_k + t\mathbf{v}_0) \geq f(\mathbf{a}_k)$, **set** $t = t/2$. **End**
5. The output of the algorithm is $\mathbf{a}_k + t\mathbf{v}_0$.

The validity of this procedure stems from the fact that, by Lemma 2.5, the direction $\mathbf{v}_0$ defined in (2.19) is always a descent direction.

One of the advantages of the SFP scheme is its simplicity. However, the SFP method, being a gradient method, does have the tendency to converge to local minima. In the next section we will present a second and more involved algorithm to solve the ML problem. As we shall see in the numerical examples presented in section 4, the empirical performance of this second iterative scheme is significantly better than that of the SFP, both with respect to the number of required iterations and with respect to the probability of getting stuck in a local/nonglobal point.

3. A sequential weighted least squares algorithm. In this section we study a different method for solving the ML problem (1.2), which we call the sequential weighted least squares (SWLS) algorithm. The SWLS algorithm is also motivated by the construction of the Weiszfeld method, but from a different viewpoint; see section 3.1. Each iteration of the method consists of solving a nonlinear least squares problem, whose solution is found by the approach discussed in section 3.2. The convergence analysis of the SWLS algorithm is given in section 3.3.

[3] We could have chosen any other nonzero vector.

3.1. The SWLS algorithm. To motivate the SWLS algorithm, let us first go back to the Weiszfeld scheme for solving the classical Fermat–Weber location problem, whereby we rewrite the iterative scheme (2.2) in the following equivalent, but different, way:

$$\mathbf{x}^{k+1} = \operatorname*{argmin}_{\mathbf{x}\in\mathbb{R}^n} \left\{ \sum_{j=1}^{m} \omega_j \frac{\|\mathbf{x}-\mathbf{a}_j\|^2}{\|\mathbf{x}^k-\mathbf{a}_j\|} \right\}. \tag{3.1}$$

The strong convexity of the objective function in (3.1) (recall that $\omega_j > 0$ for all j) implies that $\mathbf{x}^{k+1}$ is uniquely defined as a function of $\mathbf{x}^k$. Therefore, the Weiszfeld method (2.2) for solving problem (2.1) can also be written as

$$\mathbf{x}^{k+1} = \operatorname*{argmin}_{\mathbf{x}\in\mathbb{R}^n} q\left(\mathbf{x}, \mathbf{x}^k\right),$$

where

$$q(\mathbf{x},\mathbf{y}) \equiv \sum_{j=1}^{m} \omega_j \frac{\|\mathbf{x}-\mathbf{a}_j\|^2}{\|\mathbf{y}-\mathbf{a}_j\|} \text{ for every } \mathbf{x}\in\mathbb{R}^n, \mathbf{y}\in\mathbb{R}^n\setminus\mathcal{A}.$$

The auxiliary function q was essentially constructed from the objective function s of the Fermat–Weber location problem, by replacing the norm terms $\|\mathbf{x}-\mathbf{a}_j\|$ with $\frac{\|\mathbf{x}-\mathbf{a}_j\|^2}{\|\mathbf{y}-\mathbf{a}_j\|}$, i.e., with $s(\mathbf{x}) = q(\mathbf{x},\mathbf{x})$. Mimicking this observation for the ML problem under study, we will use an auxiliary function in which each norm term $\|\mathbf{x}-\mathbf{a}_j\|$ in the objective function (1.2) is replaced with $\frac{\|\mathbf{x}-\mathbf{a}_j\|^2}{\|\mathbf{y}-\mathbf{a}_j\|}$, resulting in the following auxiliary function:

$$g(\mathbf{x},\mathbf{y}) \equiv \sum_{i=1}^{m} \left(\frac{\|\mathbf{x}-\mathbf{a}_i\|^2}{\|\mathbf{y}-\mathbf{a}_i\|} - d_i \right)^2, \quad \mathbf{x}\in\mathbb{R}^n, \mathbf{y}\in\mathbb{R}^n\setminus\mathcal{A}. \tag{3.2}$$

The general step of the algorithm for solving problem (ML), the SWLS method, is now given by

$$\mathbf{x}^{k+1} \in \operatorname*{argmin}_{\mathbf{x}\in\mathbb{R}^n} g\left(\mathbf{x}, \mathbf{x}^k\right)$$

or more explicitly by the following algorithm.

ALGORITHM SWLS.

$$\mathbf{x}^{k+1} \in \operatorname*{argmin}_{\mathbf{x}\in\mathbb{R}^n} \sum_{j=1}^{m} \left(\frac{\|\mathbf{x}-\mathbf{a}_j\|^2}{\|\mathbf{x}^k-\mathbf{a}_j\|} - d_j \right)^2. \tag{3.3}$$

The name SWLS stems from the fact that at each iteration k we are required to solve the following weighted least squares (WLS) version of the LS problem (1.3):

$$\text{(WLS):} \quad \min_{\mathbf{x}} \sum_{j=1}^{m} \omega_j^k \left(\|\mathbf{x}-\mathbf{c}_j\|^2 - \beta_j^k \right)^2, \tag{3.4}$$

with

$$\mathbf{c}_j = \mathbf{a}_j, \qquad \beta_j^k = d_j \|\mathbf{x}^k - \mathbf{a}_j\|, \qquad \omega_j^k = \frac{1}{\|\mathbf{x}^k - \mathbf{a}_j\|^2}. \tag{3.5}$$

Note that the SWLS algorithm as presented above is not defined for iterations in which $\mathbf{x}^k \in \mathcal{A}$. In our random numerical experiments (cf. section 4) this situation never occurred; i.e., $\mathbf{x}^k$ did not belong to $\mathcal{A}$ for every k. However, from a theoretical point of view this issue must be resolved. Similarly to the methodology advocated in the convergence analysis of the SFP method, our approach for avoiding the sensor points $\mathcal{A}$ is by choosing a "good enough" initial vector. In section 3.3, we introduce a simple condition on the initial vector $\mathbf{x}^0$ under which the algorithm is well defined and proven to converge.

3.2. Solving the WLS subproblem. We will now show how the WLS subproblem (3.4) can be solved globally and efficiently by transforming it into a problem of minimizing a quadratic function subject to a single quadratic constraint. This derivation is a straightforward extension of the solution technique devised in [1] and is briefly described here for completeness.

For a given fixed k (for simplicity we omit the index k below), we first transform (3.4) into a constrained minimization problem:

$$\min_{\mathbf{x}\in\mathbb{R}^n,\alpha\in\mathbb{R}} \left\{ \sum_{j=1}^{m} \omega_j \left(\alpha - 2\mathbf{c}_j^T\mathbf{x} + \|\mathbf{c}_j\|^2 - \beta_j\right)^2 : \|\mathbf{x}\|^2 = \alpha \right\}, \tag{3.6}$$

which can also be written as (using the substitution $\mathbf{y} = (\mathbf{x}^T, \alpha)^T$)

$$\min_{\mathbf{y}\in\mathbb{R}^{n+1}} \left\{ \|\mathbf{A}\mathbf{y} - \mathbf{b}\|^2 : \mathbf{y}^T\mathbf{D}\mathbf{y} + 2\mathbf{f}^T\mathbf{y} = 0 \right\}, \tag{3.7}$$

where

$$\mathbf{A} = \begin{pmatrix} -2\sqrt{\omega_1}\mathbf{c}_1^T & \sqrt{\omega_1} \\ \vdots & \vdots \\ -2\sqrt{\omega_m}\mathbf{c}_m^T & \sqrt{\omega_m} \end{pmatrix}, \quad \mathbf{b} = \begin{pmatrix} \sqrt{\omega_1}\left(\beta_1 - \|\mathbf{c}_1\|^2\right) \\ \vdots \\ \sqrt{\omega_m}\left(\beta_m - \|\mathbf{c}_m\|^2\right) \end{pmatrix}$$

and

$$\mathbf{D} = \begin{pmatrix} \mathbf{I}_n & \mathbf{0}_{n\times 1} \\ \mathbf{0}_{1\times n} & 0 \end{pmatrix}, \quad \mathbf{f} = \begin{pmatrix} 0 \\ -0.5 \end{pmatrix}.$$

Note that (3.7) belongs to the class of problems consisting of minimizing a quadratic function subject to a single quadratic constraint. Problems of this type are called generalized trust region subproblems (GTRS). GTRS problems possess necessary and sufficient optimality conditions from which efficient solution methods can be derived; see, e.g., [6, 9].

The SWLS scheme is of course more involved than the simpler SFP scheme. However, as explained above, the additional computations required in SWLS to solve the subproblem can be done efficiently and are worthwhile, since the SWLS algorithm usually possesses a much larger region of convergence to the global minimum than the SFP scheme, which in turn implies that it has the tendency of avoiding local minima and a greater chance of hitting the global minimum. This will be demonstrated on the numerical examples given in section 4.

TABLE 1
Number of runs (out of 10000*) for which Assumption* 2 *is satisfied for* $\mathbf{x}^0 = \mathbf{x}_{\rm LS}$.

N_σ	10000	10000	9927	6281

3.3. Convergence analysis of the SWLS method. In this section we provide an analysis of the SWLS method. We begin by presenting our underlying assumptions in section 3.3.1, and in section 3.3.2 we prove the convergence results of the method.

3.3.1. Underlying assumptions. The following assumption will be made throughout this section.

Assumption 1. The matrix

$$\mathbf{A} = \begin{pmatrix} 1 & \mathbf{a}_1^T \\ 1 & \mathbf{a}_2^T \\ \vdots & \vdots \\ 1 & \mathbf{a}_m^T \end{pmatrix}$$

is of full column rank.

This assumption is equivalent to saying that $\mathbf{a}_1, \ldots, \mathbf{a}_m$ do not reside in a lower-dimensional affine space (i.e., a line if $n = 2$ and a plane if $n = 3$).

To guarantee the well definiteness of the SWLS algorithm (i.e., $\mathbf{x}^k \notin \mathcal{A}$ for all k), we will make the following assumption on the initial vector $\mathbf{x}^0$.

Assumption 2. $\mathbf{x}^0 \in \mathcal{R}$. where

$$\mathcal{R} := \left\{ \mathbf{x} \in \mathbb{R}^n : f(\mathbf{x}) < \frac{\min_j \{d_j\}^2}{4} \right\}. \tag{3.8}$$

A similar assumption was made for the SFP method (see condition (2.13)). Note that for the true source location $\mathbf{x}_{\rm true}$ one has $f(\mathbf{x}_{\rm true}) = \sum_{j=1}^m \varepsilon_j^2$. Therefore, $\mathbf{x}_{\rm true}$ satisfies Assumption 2 if the errors ε_j are smaller in some sense than the range measurements d_j. This is a very reasonable assumption since in real applications the errors ε_i are often an order of magnitude smaller than d_i. Now, if the initial point $\mathbf{x}^0$ is good enough in the sense that it is close to the true source location, then Assumption 2 will be satisfied. We have observed through numerical experiments that the solution to the LS problem (1.3) often satisfies Assumption 2 as the following example demonstrates.

Example 3.1. Consider the source localization problem with $m = 5$ and $n = 2$. We performed Monte Carlo runs, where in each run the sensor locations $\mathbf{a}_j$ and the source location $\mathbf{x}$ were randomly generated from a uniform distribution over the square $[-20, 20] \times [-20, 20]$. The observed distances d_j are given by (1.1) with ε_j being independently generated from a normal distribution with mean zero and standard deviation σ. In our experiments σ takes on four different values: $1, 10^{-1}, 10^{-2}$, and 10^{-3}. For each σ, N_σ denotes the number of runs for which the condition $f(\mathbf{x}_{\rm LS}) < \frac{\min_j d_j^2}{4}$ holds, and the results are given in Table 1. Clearly, Assumption 2 fails only for high noise levels.

The following simple and important property will be used in our analysis.

LEMMA 3.1. *Let* $\mathbf{x} \in \mathcal{R}$. *Then*

$$\|\mathbf{x} - \mathbf{a}_j\| > d_j/2, \quad j = 1, \ldots, m. \tag{3.9}$$

Proof. Suppose in contradiction that there exists j_0 for which $\|\mathbf{x}-\mathbf{a}_{j_0}\| \le d_{j_0}/2$. Then

$$f(\mathbf{x}) = \sum_{j=1}^{m} (\|\mathbf{x}-\mathbf{a}_j\| - d_j)^2 \ge (\|\mathbf{x}-\mathbf{a}_{j_0}\| - d_{j_0})^2 \ge \frac{d_{j_0}^2}{4} \ge \frac{\min\{d_j\}^2}{4},$$

which contradicts $\mathbf{x} \in \mathcal{R}$. ∎

A direct consequence of Lemma 3.1 is that any element in $\mathcal{R}$ cannot be one of the sensors.

COROLLARY 3.1. *If* $\mathbf{x} \in \mathcal{R}$, *then* $\mathbf{x} \notin \mathcal{A}$.

3.3.2. Convergence analysis of the SWLS method. We begin with the following result which plays a key role in the forthcoming analysis.

LEMMA 3.2. *Let* δ *be a positive number, and let* $t > \delta/2$. *Then*

$$\left(\frac{s^2}{t} - \delta\right)^2 \ge 2(s-\delta)^2 - (t-\delta)^2 \tag{3.10}$$

for every $s > \sqrt{\frac{\delta t}{2}}$, *and equality is satisfied if and only if* $s = t$.

Proof. Rearranging (3.10) one has to prove

$$A(s,t) \equiv \left(\frac{s^2}{t} - \delta\right)^2 - 2(s-\delta)^2 + (t-\delta)^2 \ge 0.$$

Some algebra shows that the expression $A(s,t)$ can be written as follows:

$$A(s,t) = \frac{1}{t}(s-t)^2 \left(\left(\frac{s}{\sqrt{t}} + \sqrt{t}\right)^2 - 2\delta\right). \tag{3.11}$$

Using the conditions $t > \delta/2$ and $s > \sqrt{\frac{\delta t}{2}}$, we obtain

$$\left(\frac{s}{\sqrt{t}} + \sqrt{t}\right)^2 - 2\delta > \left(\sqrt{\frac{\delta}{2}} + \sqrt{\frac{\delta}{2}}\right)^2 - 2\delta = 0. \tag{3.12}$$

Therefore, from (3.11) and (3.12) it readily follows that $A(s,t) \ge 0$ and that equality holds if and only if $s = t$. ∎

Thanks to Lemma 3.2, we establish the next result which is essential in proving the monotonicity of the SWLS method.

LEMMA 3.3. *Let* $\mathbf{y} \in \mathcal{R}$. *Then the function* $g(\mathbf{x},\mathbf{y})$ *given in* (3.2) *is well defined on* $\mathbb{R}^n \times \mathcal{R}$, *and with*

$$\mathbf{z} \in \operatorname*{argmin}_{\mathbf{x}\in\mathbb{R}^n} g(\mathbf{x},\mathbf{y}), \tag{3.13}$$

the following properties hold:

(a) $f(\mathbf{z}) \le f(\mathbf{y})$, *and the equality is satisfied if and only if* $\mathbf{z} = \mathbf{y}$;

(b) $\mathbf{z} \in \mathcal{R}$.

Proof. By Corollary 3.1, any $\mathbf{y} \in \mathcal{R}$ implies $\mathbf{y} \notin \mathcal{A}$, and hence the function g given by (cf. (3.2))

$$g(\mathbf{x},\mathbf{y}) = \sum_{i=1}^{m} \left(\frac{\|\mathbf{x}-\mathbf{a}_i\|^2}{\|\mathbf{y}-\mathbf{a}_i\|} - d_i\right)^2$$

is well defined on $\mathbb{R}^n \times \mathcal{R}$. Now, by (3.13) and $\mathbf{y} \in \mathcal{R}$ we have

$$g(\mathbf{z},\mathbf{y}) \leq g(\mathbf{y},\mathbf{y}) = f(\mathbf{y}) < \frac{\min\{d_j\}^2}{4}. \tag{3.14}$$

In particular,

$$\left(\frac{\|\mathbf{z}-\mathbf{a}_j\|^2}{\|\mathbf{y}-\mathbf{a}_j\|} - d_j\right)^2 < \frac{d_j^2}{4}, \quad j = 1,\ldots,m,$$

from which it follows that

$$\frac{\|\mathbf{z}-\mathbf{a}_j\|^2}{\|\mathbf{y}-\mathbf{a}_j\|} \geq \frac{d_j}{2}, \quad j = 1,\ldots,m. \tag{3.15}$$

Invoking Lemma 3.2, whose conditions are satisfied by (3.15) and Lemma 3.1, we obtain

$$\left(\frac{\|\mathbf{z}-\mathbf{a}_j\|^2}{\|\mathbf{y}-\mathbf{a}_j\|} - d_j\right)^2 \geq 2(\|\mathbf{z}-\mathbf{a}_j\| - d_j)^2 - (\|\mathbf{y}-\mathbf{a}_j\| - d_j)^2.$$

Summing over $j = 1,\ldots,m$, we obtain

$$\sum_{j=1}^m \left(\frac{\|\mathbf{z}-\mathbf{a}_j\|^2}{\|\mathbf{y}-\mathbf{a}_j\|} - d_j\right)^2 \geq 2\sum_{j=1}^m (\|\mathbf{z}-\mathbf{a}_j\| - d_j)^2 - \sum_{j=1}^m (\|\mathbf{y}-\mathbf{a}_j\| - d_j)^2.$$

Therefore, together with (3.14), we get

$$f(\mathbf{y}) \geq g(\mathbf{z},\mathbf{y}) \geq 2f(\mathbf{z}) - f(\mathbf{y}),$$

showing that $f(\mathbf{z}) \leq f(\mathbf{y})$. Now, assume that $f(\mathbf{y}) = f(\mathbf{z})$. Then by Lemma 3.2 it follows that the following set of equalities is satisfied:

$$\|\mathbf{y}-\mathbf{a}_j\| = \|\mathbf{z}-\mathbf{a}_j\|, \quad j = 1,\ldots,m, \tag{3.16}$$

which after squaring and rearranging reads as

$$(\|\mathbf{y}\|^2 - \|\mathbf{z}\|^2) - 2\mathbf{a}_j^T(\mathbf{y}-\mathbf{z}) = 0, \quad j = 1,\ldots,m.$$

Therefore,

$$\begin{pmatrix} 1 & \mathbf{a}_1^T \\ 1 & \mathbf{a}_2^T \\ \vdots & \vdots \\ 1 & \mathbf{a}_m^T \end{pmatrix} \begin{pmatrix} \|\mathbf{y}\|^2 - \|\mathbf{z}\|^2 \\ -2(\mathbf{y}-\mathbf{z}) \end{pmatrix} = 0.$$

Thus, by Assumption 1, $\mathbf{z} = \mathbf{y}$, and the proof of (a) is completed. To prove (b), using (a) and (3.14), we get

$$f(\mathbf{z}) \leq f(\mathbf{y}) < \min_{j=1,\ldots,m} \frac{d_j^2}{4},$$

proving that $\mathbf{z} \in \mathcal{R}$. ∎

We are now ready to prove the main convergence results for the SWLS method.

THEOREM 3.1 (convergence of the SWLS method). *Let $\{\mathbf{x}^k\}$ be the sequence generated by the SWLS method. Suppose that Assumptions* 1 *and* 2 *hold true. Then*

(a) $\mathbf{x}^k \in \mathcal{R}$ *for* $k \geq 0$*;*
(b) *for every* $k \geq 0$, $f(\mathbf{x}^{k+1}) \leq f(\mathbf{x}^k)$ *and equality holds if and only if* $\mathbf{x}^{k+1} = \mathbf{x}^k$*;*
(c) *the sequence of function values* $\{f(\mathbf{x}^k)\}$ *converges;*
(d) *the sequence* $\{\mathbf{x}^k\}$ *is bounded;*
(e) *every convergent subsequence* $\{\mathbf{x}^{k_l}\}$ *satisfies* $\mathbf{x}^{k_l+1} - \mathbf{x}^{k_l} \to \mathbf{0}$*;*
(f) *any limit point of* $\{\mathbf{x}^k\}$ *is a stationary point of* f*.*

Proof. (a) and (b) The proof follows by induction on k using Lemma 3.3.

(c) The proof follows from the fact that $\{f(\mathbf{x}^k)\}$ is bounded below (by zero) and is a nonincreasing sequence.

(d) By (b), all of the iterates $\mathbf{x}^k$ are in the level set $\mathrm{Lev}(f, f(\mathbf{x}^0))$ which, by Lemma 2.3, establishes the boundedness of the sequence $\{\mathbf{x}^k\}$.

(e) Let $\{\mathbf{x}^{k_l}\}$ be a convergent subsequence, and denote its limit by $\mathbf{x}^*$. By claims (a) and (b), we have for every k that

$$f\left(\mathbf{x}^k\right) \leq f\left(\mathbf{x}^0\right) < \min_{j=1,\ldots,m} \frac{d_j^2}{4},$$

which combined with the continuity of f implies $\mathbf{x}^* \in \mathcal{R}$ and hence $\mathbf{x}^* \notin \mathcal{A}$, by Corollary 3.1. Now, recall that

$$\mathbf{x}^{k_l+1} \in \operatorname{argmin} g\left(\mathbf{x}, \mathbf{x}^{k_l}\right).$$

To prove the convergence of $\{\mathbf{x}^{k_l+1}\}$ to $\mathbf{x}^*$, we will show that every subsequence converges to $\mathbf{x}^*$. Let $\{\mathbf{x}^{k_{l_p}+1}\}$ be a convergent subsequence, and denote its limit by $\mathbf{y}^*$. Since

$$\mathbf{x}^{k_{l_p}+1} \in \operatorname*{argmin}_{\mathbf{x}\in\mathbb{R}^n} g\left(\mathbf{x}, \mathbf{x}^{k_{l_p}}\right),$$

the following holds:

$$g\left(\mathbf{x}, \mathbf{x}^{k_{l_p}}\right) \geq g\left(\mathbf{x}^{k_{l_p}+1}, \mathbf{x}^{k_{l_p}}\right) \text{ for every } \mathbf{x} \in \mathbb{R}^n.$$

Taking the limits of both sides in the last inequality and using the continuity of the function f, we have

$$g(\mathbf{x}, \mathbf{x}^*) \geq g(\mathbf{y}^*, \mathbf{x}^*) \text{ for every } \mathbf{x} \in \mathbb{R}^n,$$

and hence

$$\mathbf{y}^* \in \operatorname*{argmin}_{\mathbf{x}\in\mathbb{R}^n} g(\mathbf{x}, \mathbf{x}^*). \tag{3.17}$$

Since the sequence of function values converges, it follows that $f(\mathbf{x}^*) = f(\mathbf{y}^*)$. Invoking Lemma 3.3 with $\mathbf{y} = \mathbf{x}^*$ and $\mathbf{z} = \mathbf{y}^*$, we obtain $\mathbf{x}^* = \mathbf{y}^*$, establishing claim (e).

(f) To prove the claim, note that (3.17) and $\mathbf{x}^* = \mathbf{y}^*$ imply that

$$\mathbf{x}^* \in \operatorname*{argmin}_{\mathbf{x}\in\mathbb{R}^n} g(\mathbf{x}, \mathbf{x}^*).$$

Thus, by the first order optimality conditions we obtain the following:

$$0 = \nabla_{\mathbf{x}} g(\mathbf{x}, \mathbf{x}^*)|_{\mathbf{x}=\mathbf{x}^*} = 4 \sum_{j=1}^{m} \left(\|\mathbf{x}^* - \mathbf{a}_j\| - d_j\right) \frac{\mathbf{x}^* - \mathbf{a}_j}{\|\mathbf{x}^* - \mathbf{a}_j\|} = 2\nabla f(\mathbf{x}^*). \qquad \square$$

As a direct consequence of Theorem 3.1, we obtain the following convergence in function values.

COROLLARY 3.2. *Let $\{\mathbf{x}^k\}$ be the sequence generated by the algorithm. Then $f(\mathbf{x}^k) \to f^*$, where f^* is the function value at some stationary point $\mathbf{x}^*$ of f.*

As was shown for the SFP algorithm, global convergence of the sequence generated by the SWLS algorithm can also be established under the same condition, i.e., assuming that f admits isolated stationary points.

THEOREM 3.2 (convergence of the sequence). *Let $\{\mathbf{x}^k\}$ be generated by* (3.3) *such that Assumptions* 1 *and* 2 *hold. Suppose further that all stationary points of f are isolated. Then the sequence $\{\mathbf{x}^k\}$ converges to a stationary point.*

Proof. The proof is the same as the proof of Theorem 2.2. □

4. Numerical examples. In this section we present numerical simulations illustrating the performance of the SFP and SWLS schemes, as well as numerical comparisons with the LS approach and with the SDR of the ML problem. The simulations were performed in MATLAB, and the semidefinite programs were solved by SeDuMi [14].

Before describing the numerical results, for the reader's convenience, we first recall the SDR proposed in [4], which will be used in our numerical experiments comparisons. The first stage is to rewrite problem (ML) given in (1.2) as

$$\begin{array}{ll} \min_{\mathbf{x},\mathbf{g}} & \sum_{j=1}^{m}(g_j - d_j)^2 \\ \text{s.t.} & g_j^2 = \|\mathbf{x} - \mathbf{a}_j\|^2, \quad j = 1, \ldots, m. \end{array}$$

Making the change of variables

$$\mathbf{G} = \begin{pmatrix} \mathbf{g} \\ 1 \end{pmatrix} \begin{pmatrix} \mathbf{g}^T & 1 \end{pmatrix}, \qquad \mathbf{X} = \begin{pmatrix} \mathbf{x} \\ 1 \end{pmatrix} \begin{pmatrix} \mathbf{x}^T & 1 \end{pmatrix},$$

problem (1.2) becomes

$$\begin{array}{ll} \min_{\mathbf{X},\mathbf{G}} & \sum_{j=1}^{m}(G_{jj} - 2d_j G_{m+1,j} + d_j^2) \\ \text{s.t.} & G_{jj} = \mathrm{Tr}(\mathbf{C}_j \mathbf{X}), \quad j = 1, \ldots, m, \\ & \mathbf{G} \succeq \mathbf{0}, \ \ \mathbf{X} \succeq \mathbf{0}, \\ & G_{m+1,m+1} = X_{n+1,n+1} = 1, \\ & \mathrm{rank}(\mathbf{X}) = \mathrm{rank}(\mathbf{G}) = 1, \end{array}$$

where

$$\mathbf{C}_j = \begin{pmatrix} \mathbf{I} & -\mathbf{a}_j \\ -\mathbf{a}_j^T & \|\mathbf{a}_j\|^2 \end{pmatrix}, \quad j = 1, \ldots, m.$$

Dropping the rank constraints in the above problem, we obtain the desired SDR of problem (1.2). The SDR is not guaranteed to provide an accurate solution to the ML problem, but it can always be considered as an approximation of the ML problem.

In the first example, we show that the SWLS scheme usually possesses a larger region of convergence to the global minimum than the scheme SFP. This last property is further demonstrated in the second example, which compares the SFP and SWLS methods and also demonstrates the superiority of the SWLS scheme. The last example

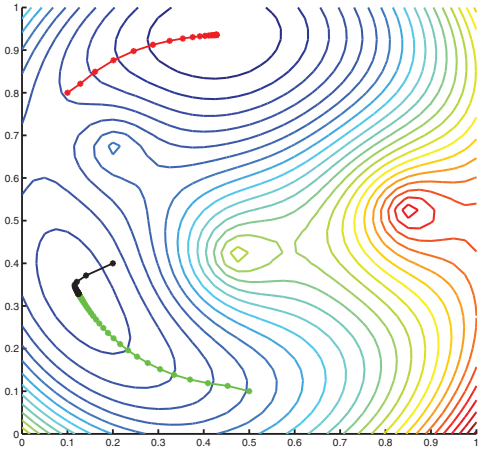

FIG. 1. *The SFP method for three initial points.*

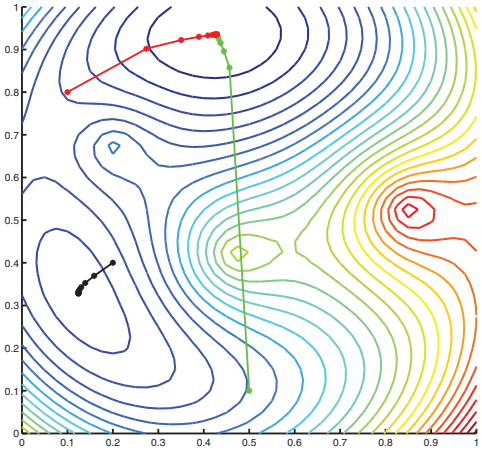

FIG. 2. *The SWLS method for three initial points.*

illustrates the attractiveness of the solution obtained by the SWLS method over the SDR and the LS approaches.

Example 4.1 (region of convergence of the SFP and SWLS methods). In this example we show typical behaviors of the SFP and SWLS methods. Consider an instance of the source localization problem in the plane ($n = 2$) with three sensors ($m = 3$) in the locations (0.466,0.418), (0.846,0.525) and (0.202,0.672). Figures 1 and 2 describe the results produced by the iterative schemes SFP and SWLS, respectively, for three initial trial points. The global minimum is $(0.4285, 0.9355)$, and there exists one additional local minimum at $(0.1244, 0.3284)$. As demonstrated in Figure 2, the SWLS method might converge to a local minimum; however, it seems to have a greater chance than the SFP algorithm to avoid local minima; for example, the SWLS converged to the (relatively far) global minimum from the initial starting point (0.5,0.1), while the SFP converged to the local minimum. We estimated the probability to converge to the global minimum by invoking both methods for 1681 initial starting

TABLE 2
Comparison between the SFP and SWLS methods.

m	#tight	$\#(f(\hat{\mathbf{x}}_{\mathrm{SFP}}) > f(\hat{\mathbf{x}}_{\mathrm{SWLS}}))$	Iter – SFP	Iter – SWLS
3	314	152	207(500.2)	26.2 (5)
4	325	96	124(192.6)	29.9(1.8)
5	259	83	93.6(96.2)	30.9(3.1)
10	278	23	66.5 (35.3)	31.6 (1.3)

points, which are the nodes of a 41×41 grid over the square $[0,1] \times [0,1]$. The SFP method converged to the global minimum in 45.87% of the runs, while the SWLS methods converged to the global minimum in 83.28% of the runs. Thus, the SWLS method has a much wider region of convergence to the global minimum. This was our observation in many other examples that we ran, which suggests that the SWLS method has the tendency to converge to the global minimum.

Remark 4.1. As shown in Proposition 2.1, the SFP scheme is just a gradient method with a fixed step size. Thanks to Lemma 2.5, which as shown in section 2.2 can be used in order to avoid the nonsmoothness, we can of course use more sophisticated smooth unconstrained minimization methods. Indeed, we also tested a gradient method with an Armijo step-size rule and a trust region method [8], which uses second order information. Our observation was that, while these methods usually possess an improved rate of convergence in comparison to the SFP method, they essentially have the same region of convergence to the global minimum as the SFP algorithm.

Example 4.2 (comparison of the SFP and SWLS methods). We performed Monte Carlo runs, where in each run the sensor locations $\mathbf{a}_j$ and the true source location were randomly generated from a uniform distribution over the square $[-1000, 1000] \times [-1000, 1000]$. The observed distances d_j are given by (1.1) with ε_j being generated from a normal distribution with mean zero and standard deviation 20. Both the SFP and SWLS methods were employed with (the same) initial point, which was also uniformly randomly generated from the square $[-1000, 1000] \times [-1000, 1000]$. The stopping rule for both the SWLS and SFP methods was $\|\nabla f(\mathbf{x}^k)\| < 10^{-5}$.

The results of the runs are summarized in Table 2. For each value of m, 1000 realizations were generated. The numbers in the first column are the number of sensors, and in the second column we give the number of runs out of 1000 in which the SDR of the ML problem was tight; that is, the matrix which is the optimal solution of the SDR has rank one. We have also compared the SWLS solution with the SDR solution for these "tight" runs (about a quarter of the runs). In all of these runs, the SWLS and SDR solutions coincided; i.e., the SWLS method produced the exact ML solution. The third column contains the number of runs out of 1000 in which the solution produced by the SFP method was worse than the SWLS method. In all of the remaining runs, the two methods converge to the same point; thus, there were no runs in which the SWLS produced worse results. The last two columns contain the mean and standard deviation of the number of iterations of each of the methods in the form "mean (standard deviation)."

As can be clearly seen from the table, the SWLS method requires much less iterations than the SFP method, and in addition it is more robust in the sense that the number of iterations are more or less constant. In contrast, the standard deviations of the number of iterations of the SFP method are quite large. For example, the huge standard deviation 500.2 in the first row stems from the fact that in some of the runs the SFP algorithm required thousands of iterations!

TABLE 3
Mean squared position error of the SDR, LS and SWLS methods.

σ	SDR	LS	SWLS
$1e-3$	$2.4e-6$	$2.7e-6$	$\mathbf{1.5e-6}$
$1e-2$	$2.2e-4$	$1.6e-4$	$\mathbf{1.3e-4}$
$1e-1$	$2.2e-2$	$1.9e-2$	$\mathbf{1.3e-2}$
$1e+0$	$2.2e+0$	$2.7e+0$	$\mathbf{2.0e+0}$

From the above examples we conclude that the SWLS method does tend to converge to the global minimum. Of course, we can always construct an example in which the method converges to a local minimum (as was demonstrated in Example 4.1), but it seems that for random instances this convergence to a nonglobal solution is not likely.

We should also note that we also compared the SFP and SWLS methods with the initial point chosen as the solution of the LS problem (1.3). For this choice of the initial point, the SFP and SWLS methods always converged to the same location point[4] (which is probably the global minimum); however, with respect to the number of iterations, the SWLS method was still significantly superior to the SFP algorithm. We have also compared the SWLS solution with the SDR solution for the runs in which the SDR solution is tight (about a quarter of the runs (cf. column 1 in Table 2)). In all of these runs, the SWLS and SDR solutions coincided; i.e., the SWLS method produced the exact ML solution.

The last example shows the attractiveness of the SWLS method over the LS and SDR approaches.

Example 4.3 (comparison with the LS and SDR estimates). Here we compare the solution of (1.3) and the solution of the SDR with the SWLS solution. The stopping rule for the SWLS method was $\|\nabla f(\mathbf{x}_k)\| < 10^{-5}$. We generated 100 random instances of the source localization problem with five sensors, where in each run the sensor locations $\mathbf{a}_j$ and the source location $\mathbf{x}$ were randomly generated from a uniform distribution over the square $[-10, 10] \times [-10, 10]$. The observed distances d_j are given by (1.1) with ε_j being independently generated from a normal distribution with mean zero and standard deviation σ. In our experiments σ takes four different values: $1, 10^{-1}, 10^{-2}$, and 10^{-3}. The numbers in the three right columns of Table 3 are the average of the squared position error $\|\hat{\mathbf{x}} - \mathbf{x}\|^2$ over 100 realizations, where $\hat{\mathbf{x}}$ is the solution by the corresponding method. The best result for each possible value of σ is marked in boldface. From the table, it is clear that the SWLS algorithm outperforms the LS and SDR methods for all four values of σ.

A SIMPLIFIED APPROACH TO SEMISMOOTH NEWTON METHODS IN FUNCTION SPACE*

ANTON SCHIELA†

Abstract. We present an alternative approach to the analysis of Newton's method for function space problems involving semismooth Nemyckii operators. The simple main idea is to apply a local continuity result to appropriately chosen finite differences. In this respect it runs in parallel to the theory of Fréchet differentiable Nemyckii operators. This leads to a concise proof of superlinear convergence under relaxed conditions, compared to previous results. Moreover, extensions of this technique allow one to prove sharpened bounds on the rate of convergence and study semismooth Newton methods in the presence of compactness.

Key words. continuity of Nemyckii operators, Newton methods in function space, optimal control

DOI. 10.1137/060674375

1. Introduction. Newton's method is a standard algorithm for solving nonlinear systems of equations and optimization problems, both in finite- and in infinite dimensional normed spaces. For a nonlinear system $G(x) = 0$ classical assumptions in the analysis of Newton's method are Lipschitz continuous differentiability of G in a neighborhood of a solution x_* and invertibility of $G'(x)$. Many nonlinear problems in function space are formulated with the help of a pointwise nonlinear function. The corresponding operators in function space are called *Nemyckii-* or superposition operators. Due to their practical importance Nemyckii operators have been analyzed thoroughly, and many standard results have been established (for a thorough exposition, see [2]), such as continuity and differentiability.

For a large class of problems the requirement of continuous differentiability is too strong, because the pointwise nonlinear functions that appear there are not differentiable in the classical sense, but are only semismooth. In the last few years semismooth Newton methods in function space have been studied (cf., e.g., [8, 14, 12, 13, 6]) with great success, particularly in the field of PDE-constrained optimal control, where control constraints can be modeled by semismooth functions. In [12, 13] Newton methods for problems involving semismooth Nemyckii operators were analyzed, and superlinear convergence was studied in the presence of some smoothing operator that maps L_q to L_p for $q < p$. The corresponding proofs (cf. also [6]) rely on sophisticated splittings of the domain of definition into several subdomains and different estimates there.

Here we consider an alternative approach to the semismoothness of Nemyckii operators, which runs closely in parallel to the corresponding theory for Fréchet differentiability. This approach yields several benefits. First, we can replace global Lipschitz continuity conditions as used in [12] by weaker growth conditions and thus extend the theoretical framework for semismooth Newton methods. Second, the semismoothness of Nemyckii operators can be derived as a simple consequence of a *local* continuity result and Hölder's inequality. Further, we derive sharpened bounds on convergence

rates and analyze semismooth Newton methods in the presence of compactness. Finally, we illustrate our results with a simple example from optimal control.

Although this work contains a couple of new *results* about semismooth Newton methods, this is not its main emphasis. We rather want to point out new and simpler *techniques* for its analysis and its convergence theory. We hope that this makes the theory of semismooth Newton methods more accessible, and that new ideas may emerge in this framework.

2. Theoretical framework and outline. Let X be a normed space, Y a linear space, and $G : X \to Y$ a nonlinear mapping. Consider the equation

$$G(x) = 0, \tag{1}$$

and assume that there is an $x_* \in X$ that solves this equation; i.e., $G(x_*) = 0$.

A minimal approach to Newton's method. Consider Newton's method for the solution of (1), taking a general point of view. For this purpose let $U(x_*)$ be a neighborhood of x_*, and for all $x \in U(x_*)$ let $G'(x)(\cdot) : X \to Y$ be invertible linear operators. They will play *the role* of derivatives of $G(x)$. Let $x_k \in U(x_*)$, and define a Newton step via the update formula

$$x_{k+1} := x_k - G'(x_k)^{-1} G(x_k). \tag{2}$$

The following theorem covers local superlinear convergence of the corresponding Newton iteration. Because existence of x_* is assumed, which is characteristic for semismooth Newton theorems, completeness of X is not required.

THEOREM 2.1. *For the nonlinear equation* (1) *define*

$$\Theta(x) := \frac{\left\| G'(x)^{-1} \big(G'(x)(x - x_*) - (G(x) - G(x_*)) \big) \right\|_X}{\|x - x_*\|_X}. \tag{3}$$

For $x_k \in U(x_*)$ the Newton step (2) *satisfies*

$$\|x_{k+1} - x_*\|_X = \Theta(x_k) \|x_k - x_*\|_X .$$

If the consistency condition $\lim_{x \to x_*} \Theta(x) = 0$ holds, then Newton's method converges locally superlinearly to x_*.

Proof. By our assumptions the Newton step $x_k \to x_{k+1}$ is well defined in $U(x_*)$. By its definition and by $G(x_*) = 0$ we have

$$\begin{aligned} \|x_{k+1} - x_*\|_X &= \left\| x_k - x_* - G'(x_k)^{-1} G(x_k) \right\|_X \\ &= \left\| G'(x_k)^{-1} \big(G'(x_k)(x_k - x_*) - (G(x_k) - G(x_*)) \big) \right\|_X \\ &= \Theta(x_k) \|x_k - x_*\|_X . \end{aligned}$$

If $\lim_{x \to x_*} \Theta(x) = 0$, then there is a ball around x_*, where $\Theta(x) < 0.5$, and

$$\|x_{k+1} - x_*\|_X < 0.5 \|x_k - x_*\|_X .$$

In this case the Newton sequence remains in this ball by induction, converges to x_*, and thus converges superlinearly by definition of the quantity $\Theta(x)$. ∎

Classically, $G'(x)$ is taken as the Fréchet derivative of G at x, which, however, need not exist in many practically relevant cases, such as semismoothness. We will view $G'(x)$ as an *algorithmic construct* rather than an analytic object. Any choice of $G'(x)$ can be used for which the *consistency condition* $\lim_{x \to x_*} \Theta(x) = 0$ holds. This choice is far from being unique.

Baire–Carathéodory functions and their Nemyckii operators. Consider a measurable set $\Omega \subset \mathbb{R}^d$ equipped with a positive measure μ such that $\mu(\Omega) < \infty$, two separable Banach spaces $\mathcal{X}, \mathcal{Y}$ (usually $\mathcal{X}, \mathcal{Y} = \mathbb{R}^n$), and a function

$$\psi : \mathcal{X} \times \Omega \to \mathcal{Y},$$

$$(x, t) \mapsto \psi(x, t).$$

For $1 \le p \le \infty$ consider the Bochner–Lebesgue space $L_p(\Omega, \mathcal{X})$ of p-integrable functions $v : \Omega \to \mathcal{X}$, and denote its norm by $\|\cdot\|_{L_p}$. As usual, $L_\infty(\Omega, \mathcal{X})$ is the space of essentially bounded functions, and for $p = \infty$ we set $p^{-1} = 0$. Let $D \subset L_p(\Omega, \mathcal{X})$. If it is well defined, then the operator

$$\Psi : D \to L_s(\Omega, \mathcal{Y}),$$

$$x \mapsto \Psi(x) : \Psi(x)(t) = \psi(x(t), t) \qquad \text{a.e.}$$

is called the *Nemyckii* operator from D to $L_s(\Omega, \mathcal{Y})$ corresponding to ψ. To be well defined Ψ must necessarily map measurable functions to measurable functions. Note that there are several concepts of measurability in Banach spaces that, however, coincide in separable spaces. As a sufficient condition ψ is usually assumed to be a *Carathéodory* function; i.e., ψ is continuous in x and measurable in t. However, since pointwise limits of measurable functions in separable spaces are measurable (cf., e.g., [9, 21.4]), this class can be extended substantially to functions ψ that are *pointwise limits* of sequences ψ_n of Carathéodory functions. Inserting a measurable function x into Ψ, the sequence of measurable functions $\Psi_n(x)$ converges pointwise to $\Psi(x)$, which is consequently measurable. This is the class of *Baire–Carathéodory* functions (cf. [2])—an extension that is essential for our theory.

So far Ψ is a mapping between spaces of measurable functions. To assert that $\Psi : L_p(\Omega, \mathcal{X}) \to L_s(\Omega, \mathcal{Y})$ we have to impose a *growth condition* on ψ, which reads (cf. [16, section 26.3]) as follows:

$$|\psi(x, t)|_{\mathcal{Y}} \le a(t) + b\,|x|_{\mathcal{X}}^{p/s} \qquad \text{for some } a \in L_s(\Omega, \mathbb{R}), b \in \mathbb{R}. \tag{4}$$

Hence, the behavior of ψ for large x restricts the choice of spaces on which a corresponding Nemyckii operator Ψ can be defined.

Semilinear operator equations. As a convenient framework, consider nonlinear operators $G(x)$ of the following form, which we will call *semilinear* operators:

$$G(x) := \mathrm{T}\,x + F(x). \tag{5}$$

Let us gather our notation introduced so far and fix our theoretical framework by stating the following set of basic assumptions.

Basic Assumptions 2.2. *Let $\Omega \subset \mathbb{R}^d$ be a measurable set, equipped with a positive measure μ with $\mu(\Omega) < \infty$. Let $\mathcal{X}$ and $\mathcal{Y}$ be separable Banach spaces.*

Let X and Y be linear spaces and assume that there are $1 \le p, q \le \infty$ such that $X \subset L_p(\Omega, \mathcal{X})$ and $L_q(\Omega, \mathcal{Y}) \subset Y$. Assume that $(X, \|\cdot\|_{L_p})$ is a normed space.

Let $T : X \to Y$ be a linear operator and $F : L_p(\Omega, \mathcal{X}) \to L_q(\Omega, \mathcal{Y})$ a Nemyckii operator, corresponding to a Carathéodory function $f(x, t)$.

Assume that there is $x_* \in X$ such that $G(x_*) = 0$. Let

$$f'(\cdot, \cdot)(\cdot) : (\mathcal{X} \times \Omega) \times \mathcal{X} \to \mathcal{Y},$$

$$(x, t, v) \mapsto f'(x, t)(v)$$

be a function that is a Baire–Carathéodory function in (x,t) *and linear in* v.

Assume that there is a neighborhood $U(x_*)$ *of* x_* *such that for every* $x \in U(x_*)$ *the corresponding* linear *Nemyckii operator* $F'(x)(\cdot)$ *maps* X *to* Y *and the linear operator* $G'(x) := T + F'(x)$,

$$G'(x)(\cdot) : X \to Y,$$
$$v \mapsto Tv + F'(x)v,$$

has an inverse $G'(x)^{-1} : Y \to X$.

Remark 2.3. In many applications T is a linear differential operator, which is defined on some Sobolev space $X := W^{\sigma,r}(\Omega) \hookrightarrow L_p(\Omega)$. Since we do not need the completeness of X, we are free to equip $W^{\sigma,r}(\Omega)$ with an L_p-norm. This captures the nonlinearity of F best. Y can be chosen as a dual space that contains $L_q(\Omega)$.

In such a setting $G(x) = 0$ may be a semilinear PDE, but our formulation also includes systems of PDEs and algebraic equations, which arise in control-constrained optimal control (cf. section 6 below).

Linearity of T is assumed for simplicity of presentation. Of course, our framework extends straightforwardly to nonlinear operators $T(x)$ that satisfy suitable smoothness conditions such as semismoothness.

Basic Assumptions 2.2 define our framework and assert that $G : X \to Y$, $G'(x) : X \to Y$, and that the Newton steps (2) are well defined on a neighborhood of x_*, but they are not sufficient to show (superlinear) convergence of the corresponding iteration. To this end we have to establish a relation between f and f'. We will do this conveniently in terms of the function

$$\psi_*(x,t;\alpha) := \begin{cases} \dfrac{f'(x,t)(x - x_*(t)) - (f(x,t) - f(x_*(t),t))}{|x - x_*(t)|_{\mathcal{X}}^{\alpha}} & : \quad x \neq x_*(t), \\ 0 & : \quad x = x_*(t), \end{cases} \tag{6}$$

and its limiting behavior at $x = x_*(t)$ for $\alpha \geq 1$. In sections 3 and 5, where we study superlinear convergence of Newton's method, we will assume continuity of $\psi_*(x,t;1)$ at $x_*(t)$ a.e. In section 4 we discuss local boundedness of $\psi_*(x,t;\alpha)$ for $\alpha > 1$ and rates of convergence. We may view these assumptions as *pointwise consistency conditions*.

As a general strategy we will carry over the properties of $\psi_*(x,t;\alpha)$ to its corresponding Nemyckii operator $\Psi_*(x;\alpha)$ in suitable spaces. Then, under a *smoothing* assumption on $G'(x)^{-1}$ we invoke Theorem 2.1 by estimating

$$\begin{aligned} \Theta(x) &:= \frac{\left\| G'(x)^{-1}\big(G'(x)(x - x_*) - (G(x) - G(x_*))\big)\right\|_{L_p}}{\|x - x_*\|_{L_p}} \\ &= \frac{\left\| G'(x)^{-1}\big(F'(x)(x - x_*) - (F(x) - F(x_*))\big)\right\|_{L_p}}{\|x - x_*\|_{L_p}} \end{aligned} \tag{7}$$

and showing consistency in $L_p(\Omega, \mathcal{X})$. Observe that T cancels out by linearity.

Relation to semismoothness. Theorem 2.1 is closely related to a semismooth Newton theorem. Its formulation purely in terms of the domain space makes it independent of the topology of the image space (an *affine covariant* formulation; cf. [4]). In view of (3) the use of operator norms for $G'(x)^{-1}$ recovers known results on semismooth Newton methods, such as [12, Theorem 3.12] or [6, Theorem 1.1].

Although semismooth Newton theorems are very simple, the characterization of semismoothness as an *intrinsic property* of G is involved. A straightforward definition would be via (3) and the requirement $\lim_{x\to x_*}\Theta(x)=0$. However, for fixed x_* there is always some $G'(x)$ such that $\Theta(x)=0$, which renders this definition of semismoothness meaningless. The choice of $G'(x)$ has to be restricted and localized to x. In finite dimensions Rademacher's theorem gives us an appropriate tool to define a set-valued generalized derivative $\partial G(x)$, from which $G'(x)$ has to be chosen. With this restriction a definition via (3) makes sense. However, this construction is not possible anymore for infinite dimensional spaces.

For this reason [12] first chooses a set-valued mapping $\partial G(x)$ from which $G'(x)$ has to be taken, and then defines $\partial G(x)$-semismoothness via this set. For nonlinear Nemyckii operators $F(x)$, [12] defines $\partial F(x)$ pointwise via $\partial f(x,t)$.

If f is semismooth and $f'(x,t)\in\partial f(x,t)$, then $\lim_{x\to x_*(t)}\psi_*(x,t;1)=0$ a.e. If f is γ-order semismooth, then $\psi_*(x,t;1+\gamma)$ is bounded a.e. in Ω. So semismoothness is a particular case in which our results can be applied.

3. Continuity of $\Psi_*(x;1)$ and superlinear convergence. Our first qualitative convergence result is proved in two simple steps. First, we prove a local version of a standard result on continuity of Nemyckii operators (cf., e.g., [16, Proposition 26.7(a)] or [5, Proposition IV.1.1]) for Baire–Carathéodory functions. Second, we apply this result to $\psi_*(x,t;1)$ and conclude superlinear convergence of Newton's method via the Hölder inequality and a smoothing assumption on $G'(x)^{-1}$.

LEMMA 3.1 (local continuity of Nemyckii operators). *Let $\mathcal{X}$, $\mathcal{Y}$ be separable Banach spaces, Ω a measurable subset of $\mathbb{R}^d$, and $\psi:\mathcal{X}\times\Omega\to\mathcal{Y}$ a Baire–Carathéodory function. For each measurable function $x:\Omega\to\mathcal{X}$ let $\Psi(x)$ be the measurable function $t\to\psi(x(t),t)$. Let $x_*\in L_p(\Omega,\mathcal{X})$ be given. Then the following assertion holds: If ψ is continuous with respect to x at $(x_*(t),t)$ for almost all $t\in\Omega$, and Ψ maps $L_p(\Omega,\mathcal{X})$ into $L_s(\Omega,\mathcal{Y})$ for $1\le p,s<\infty$, then Ψ is continuous at x_* in the norm topology.*

Proof. This is a slight modification of a well-known lemma of Krasnoselski, which states global continuity of Ψ for Carathéodory functions ψ. Our proof stays very close to the proof in [5, Proposition IV.1.1], and our weakened assumptions do not cause any additional difficulties compared to the standard case.

Because ψ is a Baire–Carathéodory function, Ψ maps measurable functions to measurable functions. To show its continuity at x_* for $s<\infty$ we consider an arbitrary sequence $\|x_n-x_*\|_{L_p}\to 0$. By picking a suitable subsequence, we may assume w.l.o.g. that $\|x_n-x_*\|_{L_p}^p\le 2^{-n}$ and $x_n(t)\to x_*(t)$ pointwise a.e. (cf., e.g., [9, Theorem 22.31]). Define the function

$$w(x,t):=|\psi(x,t)-\psi(x_*(t),t)|_{\mathcal{Y}}^s,$$

and denote by W the corresponding Nemyckii operator. Inserting the sequence x_n, we conclude that $W(x_n)\to 0$ pointwise a.e. because $\psi(x,t)$ is continuous in x at $(x_*(t),t)$ a.e.

Next we will show $W(x_n)\to 0$ in $L_1(\Omega,\mathbb{R})$ via the convergence theorem of Lebesgue. For this we construct a function $\overline{w}\in L_1(\Omega,\mathbb{R})$ that dominates the sequence $W(x_n)$. Since $W(x)\ge 0$ and $W(x_n)\to 0$ a.e., we can define the measurable sets

$$\Omega_n:=\{t\in\Omega: w(x_n(t),t)\ge w(x_m(t),t)\ \forall m\in\mathbb{N}\}\setminus\left(\bigcup_{1\le k<n}\Omega_k\right).$$

Hence, the function $\overline{x} := \sum_n \chi_{\Omega_n} x_n$ is measurable. Let $\overline{w} := W(\overline{x})$, which is measurable as well. By construction, $\overline{w}(t) = \sup_n w(x_n(t), t)$ a.e. Moreover,

$$\begin{aligned}\int_\Omega |\overline{x}(t) - x_*(t)|_{\mathcal{X}}^p \, dt &\le \int_\Omega \sup_n |x_n(t) - x_*(t)|_{\mathcal{X}}^p \, dt \\ &\le \sum_{n=1}^\infty \|x_n(t) - x_*(t)\|_{L_p}^p \le \sum_{n=1}^\infty 2^{-n} = 1.\end{aligned} \tag{8}$$

Consequently, since $x_* \in L_p(\Omega, \mathcal{X})$, $\overline{x} \in L_p(\Omega, \mathcal{X})$ by the triangle inequality and hence, because $\Psi : L_p(\Omega, \mathcal{X}) \to L_s(\Omega, \mathcal{Y})$, $\overline{w} = W(\overline{x}) \in L_1(\Omega, \mathbb{R})$. Since $\overline{w}$ dominates $W(x_n)$ we can apply the convergence theorem of Lebesgue to obtain $W(x_n) \to 0$ in $L_1(\Omega, \mathbb{R})$. Hence, $\Psi(x_n) \to \Psi(x_*)$ in $L_s(\Omega, \mathcal{Y})$. Because x_n was arbitrary, we conclude continuity of the operator $\Psi : L_p(\Omega, \mathcal{X}) \to L_s(\Omega, \mathcal{Y})$ at x_*. □

Remark 3.2. Let us add some remarks, concerning the indices s and p:

(i) In general one has to verify the growth condition (4) for ψ to assert that Ψ maps $L_p(\Omega, \mathcal{X})$ to $L_s(\Omega, \mathcal{Y})$.

(ii) If $p < \infty$ and $\|\Psi(x)\|_{L_\infty} \le M$ uniformly for all $x \in L_p(\Omega, \mathcal{X})$, then Lemma 3.1 holds for all $s < \infty$ but *not* for $s = \infty$ (except for the case of constant Ψ). This will turn out to be the main reason for the so-called *norm gap* that is observed in the analysis of semismooth Newton methods. The proof of Lemma 3.1 simplifies in this case because we can use the domination function $\overline{w} = (2M)^s$. In section 5 we consider a variant of Lemma 3.1 that shows a weak form of continuity for $s = \infty$.

(iii) The case $p = \infty$ is not covered by Lemma 3.1. However, for $s < \infty$ the proof carries over, replacing (8) by a suitable expression with essential suprema. Then, instead of a growth condition it is sufficient that $\|\Psi(x)\|_{L_\infty} \le M$ uniformly in a neighborhood of $x_* \in L_\infty(\Omega, \mathcal{X})$.
The case $p = s = \infty$ is different in character. Then Ψ is continuous at x_* if continuity of $\psi(x, t)$ at $x_*(t)$ is *uniform* in Ω. This is usually a too strong assumption in the context of semismoothness (cf. Example 3.4 below).

THEOREM 3.3. *Let $G : X \to Y$ be a semilinear operator as defined in* (5)*, and suppose that Basic Assumptions* 2.2 *hold. Assume additionally the following:*

(i) *$\psi_*(x, t; 1)$ as defined in* (6) *is a Baire–Carathéodory function and*

$$\lim_{x \to x_*(t)} \psi_*(x, t; 1) = 0 \quad \text{for almost all } t \in \Omega.$$

The corresponding Nemyckii operator $\Psi_*(x; 1)$ maps $L_p(\Omega, \mathcal{X})$ into $L_s(\Omega, \mathcal{Y})$ with $s < \infty$ and $s^{-1} + p^{-1} = q^{-1}$ (hence $p > q$).

(ii) *$\left\|G'(x)^{-1}\right\|_{L_q(\Omega, \mathcal{Y}) \to L_p(\Omega, \mathcal{X})} \le M$ holds uniformly on a neighborhood of x_*.*

Then Newton's method converges locally superlinearly to x_*.

Proof. By definition of $\psi_*(\cdot, \cdot; 1)$ we have for $x, x_* \in X$

$$F'(x)(x - x_*) - (F(x) - F(x_*)) = \Psi_*(x; 1)|x - x_*|_{\mathcal{X}}, \tag{9}$$

by interpretation of $|\cdot|_{\mathcal{X}} : L_p(\Omega, \mathcal{X}) \to L_p(\Omega, \mathbb{R})$ as a Nemyckii operator. By the Hölder inequality

$$\|\Psi_*(x; 1)|x - x_*|_{\mathcal{X}}\|_{L_q} \le \|\Psi_*(x; 1)\|_{L_s} \|x - x_*\|_{L_p} \quad \text{for } q^{-1} = s^{-1} + p^{-1}.$$

By (i) $\psi_*(x,t;1)$ is continuous at $x_*(t)$ a.e., and we can apply Lemma 3.1 to get $\lim_{x\to x_*}\|\Psi_*(x;1)\|_{L_s}=0$. Now we estimate $\Theta(x)$ as defined in (3), using (ii):

$$\Theta(x)\le\frac{\left\|G'(x)^{-1}\right\|_{L_q\to L_p}\|F'(x)(x-x_*)-(F(x)-F(x_*))\|_{L_q}}{\|x-x_*\|_{L_p}}\le M\|\Psi_*(x;1)\|_{L_s}.$$

Hence, $\lim_{x\to x_*}\Theta(x)=0$, which implies superlinear convergence by Theorem 2.1. ∎

Connection to known results. For semismooth functions [12] studies semismoothness of the corresponding Nemyckii operators under an additional *global Lipschitz condition*, which corresponds to global boundedness of ψ_*. In [6] semismoothness of the max-function is studied. In both works Ω is split into three subdomains whose sizes are carefully balanced. Then the remainder terms are estimated separately.

In our approach via Lemma 3.1 we can relax the global Lipschitz condition and replace it by weaker *growth conditions* (4) on $\psi_*(x,t;1)$. By Proposition A.1 these follow from growth conditions on f' and on *local* Lipschitz constants of f.

From a structural point of view, our approach via Lemma 3.1 parallels completely the study of *local Fréchet differentiability* of Nemyckii operators: replace $f'(x,t)$ by $f'(x_*(t),t)$ in (6) and assume again continuity of $\psi_*(x,t;1)$ at $x_*(t)$ a.e. Then Lemma 3.1 and the Hölder inequality yield local Fréchet differentiability of $F:L_p(\Omega,\mathcal{X})\to L_q(\Omega,\mathcal{Y})$ at x_*. Just as in Theorem 3.3, $p>q$ is necessary and depends on a growth condition for $\psi_*(x,t;1)$. Hence, one technique applied to different remainder terms yields semismoothness or Fréchet differentiability at x_*, respectively. This unifies the treatment of both concepts and clarifies their relation.

Example 3.4. As an illustration consider the following simple class of examples:

$$f(x):=\max(x,\tau)^\sigma,\qquad f'(x):=\begin{cases}0 & : \quad x\le\tau,\\ \sigma x^{\sigma-1} & : \quad \text{otherwise},\end{cases}\qquad \tau\ge 0,\ \sigma\ge 1. \tag{10}$$

Except for special cases f is not differentiable at $x=\tau$ and not globally Lipschitz continuous for $\sigma>1$. For f, f', and $x_*:\Omega\to\mathbb{R}$ we will study $\psi_*(x,t;\alpha)$. Let now $t_0\in\Omega$ and $x_0:=x_*(t_0)$ be fixed. Then by (6),

$$\psi_*(x,t_0;\alpha)=\begin{cases}0 & : \quad x=x_0,\\ \dfrac{-\tau^\sigma+\max(x_0,\tau)^\sigma}{|x-x_0|^\alpha} & : \quad x_0\ne x\le\tau,\\ \dfrac{\sigma x^{\sigma-1}(x-x_0)-x^\sigma+\max(x_0,\tau)^\sigma}{|x-x_0|^\alpha} & : \quad \text{otherwise}.\end{cases} \tag{11}$$

If $\tau>0$ and $x_0\ne\tau$, then $\psi_*(x,t_0;\alpha)$ has a *jump* at $x=\tau$ and is thus not a Carathéodory function, but it is easy to see that it is a Baire–Carathéodory function. We will show now that $\lim_{x\to x_0}\psi_*(x,t_0;1)=0$, regardless of the choice of x_0.

If $x_0\ne\tau$, then f is differentiable in a neighborhood of x_0 and f' is Lipschitz continuous there. If $x_0=\tau$, then the same holds separately for both one-sided neighborhoods of x_0, excluding x_0. In both cases there is $\varepsilon(x_0)>0$ such that we can apply the fundamental theorem of calculus for all $\tilde{x}$ with $|\tilde{x}-x_0|\le\varepsilon$ to obtain

$$|\psi_*(\tilde{x},t_0;1)|\le\int_0^1|f'(\tilde{x})-f'(s\tilde{x}+(1-s)x_0)|\,ds\le L|\tilde{x}-x_0|. \tag{12}$$

Observe that this integral is independent of $f'(x_0)$. Hence, $\lim_{x\to x_0}\psi_*(x,t_0;1)=0$ and $\psi_*(x,t_0;\alpha)$ is bounded for $\alpha\le 2$. If $\sigma=1$, f' is piecewise constant and (12) vanishes, which implies boundedness of $\psi_*(x,t_0;\alpha)$ for all $\alpha\ge 1$.

However, and this is a particular feature of semismoothness, these results *do not hold uniformly* with respect to x_0 (and hence t_0). Because f' has a jump at $x=\tau$, the estimate (12) holds only for $\varepsilon(x_0)<|x_0-\tau|$. Also boundedness of $\psi_*(x,t_0;\alpha)$ depends on the choice of x_0. If x_0 is very close to τ, then this bound is very large, and tends to ∞, if $x_0\to\tau$.

If we consider $\psi_*(x,t;\alpha)$ for a continuous function $x_*:\Omega\to\mathbb{R}$, then this nonuniformity occurs if $x_*(t)=\tau$ for some $t\in\Omega$. As a consequence, L_s bounds for $\Psi_*(x;\alpha)$ depend on the size of the sets for which $x_*(t)$ is close to τ. In section 4 we discuss assumptions (essentially on x_*) that allow us to quantify this effect.

Concerning growth conditions in the case $\sigma>1$, f is locally Lipschitz continuous, and the corresponding local Lipschitz constant satisfies $L(x)\le a+b|x|^{\sigma-1}$ and also $|f'(x)|\le a+b|x|^{\sigma-1}$. Hence, by Proposition A.1, $\Psi_*(\cdot;1)$ maps $L_p(\Omega,\mathbb{R})$ into $L_s(\Omega,\mathbb{R})$ for $p/s\ge\sigma-1$. Thus, for successful application of Theorem 3.3 to an equation $G(x)=Tx+F(x)$, we have to show (ii) for $p/q\ge\sigma$.

If $\sigma=1$, then f is globally Lipschitz continuous. Then ψ_* is uniformly bounded and Theorem 3.3 holds if there is some $p>q$ such that (ii) holds (cf. Remark 3.2). This is the only case covered by previous results [12, 13, 6].

4. Boundedness of $\Psi_*(x;\alpha)$ and rates of convergence. One way of showing boundedness of an integral is limiting the size of the sets where the integrand is large. In the following we will consider an assumption that asserts $\Psi_*(x;\alpha)\in L_s(\Omega,\mathcal{Y})$ based on this principle. Following the ideas of [12], we define the set

$$\Omega_\varepsilon(x):=\left\{t\in\Omega:|\psi_*(x(t),t;\alpha)|_{\mathcal{Y}}>\frac{1}{\varepsilon^{\alpha-1}}\right\}\qquad\text{for }\alpha>1$$

and assume that there are $\rho>0$ and $C<\infty$ such that for its measure $\mu(\Omega_\varepsilon(x))$ the following bounds hold for some $\gamma>0$:

$$\sup_{\|x-x_*\|_{L_p}\le\rho}\mu(\Omega_\varepsilon(x))\le C\varepsilon^\gamma\qquad\forall\varepsilon>0. \tag{13}$$

This assumption means qualitatively that the sets of high nonlinearity are small near x_* (cf. the discussion in Example 3.4). In section 6 this assumption is reformulated as a strict complementarity assumption as known in constrained optimization.

Relations like (13) can be described conveniently in terms of the *distribution function* $\mathcal{S}_v$ of a measurable nonnegative function $v:\Omega\to\mathbb{R}_+$, defined by

$$\mathcal{S}_v(e):=\mu\left(\{t\in\Omega:v(t)>e\}\right).$$

The distribution function measures the size of the sets where v is large. Obviously, $\mathcal{S}$ is positive, monotonically decreasing, and bounded on bounded domains. It has already been useful in the convergence analysis of interior point methods in function space (cf. [11, 10]). We will use it now to obtain sharpened estimates for convergence rates, compared to [12].

LEMMA 4.1 (the distribution function). *Let Ω be a σ-finite measure space and*

$v\colon \Omega \to \mathbb{R}_+$ measurable and nonnegative. Then

$$\int_\Omega v(t)dt = \int_{[0,\infty]} \mathcal{S}_v(e)\, de, \tag{14}$$

$$\mathcal{S}_v(e) = \mathcal{S}_{v^s}(e^s). \tag{15}$$

Let $\varphi : [0,\infty] \to [0,\infty]$ be locally absolutely continuous, strictly monotone (increasing or decreasing), and bijective. Then

$$\int_\Omega v(t)dt = \int_{[0,\infty]} \mathcal{S}_v(\varphi(e))|\varphi'(e)|\, de. \tag{16}$$

Proof. Equation (14) is a special case of [15, Theorem 8.8]. Equation (16) follows from the substitution rule (cf. [15, Theorem 8.1]), which shows that with $\tilde{e} = \varphi(e)$

$$\int_{[0,\infty]} \mathcal{S}_v(\tilde{e})\, d\tilde{e} = \int_{[0,\infty]} \mathcal{S}_v(\varphi(e))|\varphi'(e)|\, de.$$

Equation (15) follows from

$$\mathcal{S}_{v^s}(e^s) = \mu\left(\{t \in \Omega : v(t)^s > e^s\}\right) = \mu\left(\{t \in \Omega : v(t) > e\}\right) = \mathcal{S}_v(e). \qquad \square$$

In terms of the distribution function our assumption (13) reads

$$\mathcal{S}_{|\Psi_*(x;\alpha)|_{\mathcal{Y}}}\left(\varepsilon^{1-\alpha}\right) \le \min\left\{\mu(\Omega); C\varepsilon^\gamma\right\} \qquad \forall \varepsilon > 0. \tag{17}$$

LEMMA 4.2. *If (13) holds for some $1 < \alpha < 1+\gamma s^{-1}$, then there is a neighborhood of x_* in X in which $\Psi_*(x;\alpha)$ is uniformly bounded in $L_s(\Omega, \mathcal{Y})$.*

Proof. By (15) and (17) we have

$$\mathcal{S}_{|\Psi_*(x;\alpha)|_{\mathcal{Y}}^s}\left(\varepsilon^{(1-\alpha)s}\right) = \mathcal{S}_{|\Psi_*(x;\alpha)|_{\mathcal{Y}}}\left(\varepsilon^{1-\alpha}\right) \le \min\left\{\mu(\Omega); C\varepsilon^\gamma\right\}. \tag{18}$$

By (16) with $\varphi(\varepsilon) = \varepsilon^{(1-\alpha)s}$ and thus $\varphi'(\varepsilon) = (1-\alpha)s\varepsilon^{(1-\alpha)s-1}$ we deduce

$$\begin{aligned}
\|\Psi_*(x;\alpha)\|_{L_s}^s &= \int_\Omega |\Psi_*(x;\alpha)|_{\mathcal{Y}}^s\, dt \\
&= \int_{[0,\infty]} \mathcal{S}_{|\Psi_*(x;\alpha)|_{\mathcal{Y}}^s}\left(\varepsilon^{(1-\alpha)s}\right) \left|(1-\alpha)s\varepsilon^{(1-\alpha)s-1}\right| d\varepsilon.
\end{aligned}$$

Inserting (18), we finally obtain for $\gamma + (1-\alpha)s > 0$ and $\alpha > 1$ the boundedness of

$$\begin{aligned}
\|\Psi_*(x;\alpha)\|_{L_s}^s &\le C \int_{[0,\infty]} \min\left\{\mu(\Omega); \varepsilon^\gamma\right\} \varepsilon^{(1-\alpha)s-1} d\varepsilon \\
&= C \int_{[0,\mu(\Omega)]} \varepsilon^{\gamma+(1-\alpha)s-1} d\varepsilon + C \int_{[\mu(\Omega),\infty]} \mu(\Omega)\varepsilon^{(1-\alpha)s-1} d\varepsilon \\
&\le c \lim_{\varepsilon\to 0} \varepsilon^{\gamma+(1-\alpha)s} + C + c \lim_{\varepsilon\to\infty} \varepsilon^{(1-\alpha)s}. \qquad \square
\end{aligned} \tag{19}$$

THEOREM 4.3. *Let $G : X \to Y$ be a semilinear operator as defined in (5), and suppose that Basic Assumptions 2.2 hold. Assume additionally the following:*

(i) $\psi_*(x,t;\alpha)$ *as defined in* (6) *is a Baire–Carathéodory function that satisfies assumption* (13) *for some* α *in the range*

$$1 < \alpha < \alpha_0 := \frac{1+\gamma q^{-1}}{1+\gamma p^{-1}}. \tag{20}$$

(ii) $\left\|G'(x)^{-1}\right\|_{L_q(\Omega,\mathcal{Y})\to L_p(\Omega,\mathcal{X})} \le M$ *holds uniformly on a neighborhood of* x_*.

Then Newton's method converges locally superlinearly to x_* *with the rate* α.

Proof. By definition of $\psi_*(\cdot,\cdot;\alpha)$ we have for $x, x_* \in X$

$$F'(x)(x-x_*) - (F(x)-F(x_*)) = \Psi_*(x;\alpha)|x-x_*|_{\mathcal{X}}^{\alpha}.$$

By the Hölder inequality we obtain for $s^{-1} + \alpha p^{-1} = q^{-1}$

$$\left\|\Psi_*(x;\alpha)|x-x_*|_{\mathcal{X}}^{\alpha}\right\|_{L_q} \le \left\|\Psi_*(x;\alpha)\right\|_{L_s} \left\|x-x_*\right\|_{L_p}^{\alpha}.$$

Application of Lemma 4.2 shows that $\left\|\Psi_*(x;\alpha)\right\|_{L_s}$ is uniformly bounded for $1 < \alpha < 1+\gamma s^{-1}$, which holds due to (20). Now we can estimate $\Theta(x)$ as defined in (3) and use (ii):

$$\begin{aligned}\Theta(x) &\le \frac{\left\|G'(x)^{-1}\right\|_{L_q\to L_p} \left\|F'(x)(x-x_*) - (F(x)-F(x_*))\right\|_{L_q}}{\left\|x-x_*\right\|_{L_p}} \\ &\le M \left\|\Psi_*(x;\alpha)\right\|_{L_s} \left\|x-x_*\right\|_{L_p}^{\alpha-1}.\end{aligned}$$

By Theorem 2.1 this yields local superlinear convergence with the rate α. ∎

Remark 4.4. Under the given restrictions on α, Theorem 4.3 gives us a result as good as we can expect, but often (13) holds for a whole range $\alpha \in [1, \overline{\alpha}]$ with $\overline{\alpha} \ge \alpha_0$. Then Theorem 4.3 holds only for all $\alpha < \alpha_0$. We may interpret this as Newton's method approaching the rate α_0 asymptotically from below, a behavior often called *convergence of order* α_0.

If we *additionally* assume that $\left\|\Psi_*(x;1)\right\|_{L_\infty}$ is uniformly bounded near x_* and $\alpha > \alpha_0$, then we can refine our results slightly. For this we have to use a splitting of Ω similar to that used in [12] or [6]. However, despite a considerably increased technical effort, no substantial improvement on α is possible. We merely obtain the closure of the interval (20).

THEOREM 4.5. *Let* $G : X \to Y$ *be a semilinear operator as defined in* (5), *suppose that Basic Assumptions* 2.2 *hold, and let* $p > q$. *Assume additionally the following:*

(i) $\psi_*(x,t;\alpha)$ *as defined in* (6) *is a Baire–Carathéodory function that satisfies assumption* (13) *for some* α *in the range*

$$\frac{1+\gamma q^{-1}}{1+\gamma p^{-1}} =: \alpha_0 < \alpha \le \frac{p}{q}. \tag{21}$$

(ii) $\left\|G'(x)^{-1}\right\|_{L_q(\Omega,\mathcal{Y})\to L_p(\Omega,\mathcal{X})} \le M$ *holds uniformly on a neighborhood of* x_*.

(iii) $\left\|\Psi_*(x;1)\right\|_{L_\infty}$ *is uniformly bounded in a neighborhood of* x_*.

Then Newton's method converges locally superlinearly to x_* *with the rate* α_0.

Proof. For $x, x_* \in X$ we abbreviate $R(x) := F'(x)(x-x_*) - (F(x)-F(x_*))$ and $\delta x := x - x_*$. Depending on a parameter κ, we divide Ω into two parts. In view of (13) we call Ω_κ the set where $|\Psi_*(x;\alpha)|_{\mathcal{Y}} > \kappa^{1-\alpha}$ and obtain $\mu(\Omega_\kappa) \le C\kappa^{\gamma}$. On Ω_κ we use

the boundedness of $\|\Psi_*(x;1)\|_{L_\infty}$ and the relation $\|v\|_{L_q(S)} \le \mu(S)^{(q^{-1}-p^{-1})} \|v\|_{L_p(S)}$, which holds for $p \ge q$ (cf. [1, Theorem 2.8]). This yields

$$\|R(x)\|_{L_q(\Omega_\kappa)} \le \|\Psi_*(x;1)\|_{L_\infty} \mu(\Omega_\kappa)^{(q^{-1}-p^{-1})} \|\delta x\|_{L_p(\Omega_\kappa)} \le C\kappa^{\gamma(q^{-1}-p^{-1})} \|\delta x\|_{L_p(\Omega)}.$$

Setting $\kappa := \|\delta x\|^\nu_{L_p(\Omega)}$ (with $\nu > 0$ to be chosen later), we conclude

$$\|R(x)\|_{L_q(\Omega_\kappa)} \le C \|\delta x\|^{\nu\gamma(q^{-1}-p^{-1})+1}_{L_p(\Omega)}. \tag{22}$$

On the remaining set $\Omega \setminus \Omega_\kappa$ we apply, as before, the Hölder inequality

$$\|R(x)\|_{L_q(\Omega\setminus\Omega_\kappa)} \le \|\Psi_*(x;\alpha)\|_{L_s(\Omega\setminus\Omega_\kappa)} \|\delta x\|^\alpha_{L_p(\Omega)} \tag{23}$$

with $s^{-1} := q^{-1} - \alpha p^{-1}$. By construction, $|\Psi_*(x;\alpha)|^s \le \kappa^{(1-\alpha)s}$ on $\Omega \setminus \Omega_\kappa$ and hence $\mathcal{S}_{|\Psi_*(x;\alpha)|^s_{\mathcal{Y}}}\left(\varepsilon^{(1-\alpha)s}\right) = 0$ for $\varepsilon < \kappa$. Consequently, just as in the proof of Lemma 4.2, we have the following estimate for $\alpha \ne 1$ and $\gamma + (1-\alpha)s \ne 0$:

$$\begin{aligned}\|\Psi_*(x;\alpha)\|^s_{L_s(\Omega\setminus\Omega_\kappa)} &\le C \int_{[\kappa,\infty]} \min\left\{\mu(\Omega); \varepsilon^\gamma\right\} \varepsilon^{(1-\alpha)s-1} d\varepsilon \\ &\le c\kappa^{\gamma+(1-\alpha)s} + C + c \lim_{\varepsilon\to\infty} \varepsilon^{(1-\alpha)s}.\end{aligned}$$

Hence, for $(1-\alpha)s < 0$, $\gamma + (1-\alpha)s < 0$ and for $\kappa \in [0, \overline{\kappa}]$ with arbitrary $\overline{\kappa} > 0$

$$\|\Psi_*(x;\alpha)\|_{L_s(\Omega\setminus\Omega_\kappa)} \le C(\kappa^{\gamma s^{-1}+1-\alpha} + 1) = C(\overline{\kappa})\kappa^{\gamma s^{-1}+1-\alpha}. \tag{24}$$

Hypothesis (21) ensures that the above inequalities for s^{-1} are valid. By our definition $\kappa := \|\delta x\|^\nu$ with $\nu > 0$, κ remains bounded in the following, since δx is always chosen from a bounded set. Thus we can drop the argument of $C(\overline{\kappa})$. Hence, inserting (24) with $\kappa = \|\delta x\|^\nu_{L_p(\Omega)}$ and $s^{-1} = q^{-1} - \alpha p^{-1}$ into (23), we obtain

$$\|R(x)\|_{L_q(\Omega\setminus\Omega_\kappa)} \le C \|\delta x\|^{\nu(\gamma s^{-1}+1-\alpha)+\alpha}_{L_p(\Omega)} \le C \|\delta x\|^{\nu\gamma(q^{-1}-\alpha p^{-1})-\nu(\alpha-1)+\alpha}_{L_p(\Omega)}. \tag{25}$$

Finally we compute the norm of $R(x)$ on Ω by adding both components:

$$\|R(x)\|^q_{L_q(\Omega)} = \|R(x)\|^q_{L_q(\Omega_\kappa)} + \|R(x)\|^q_{L_q(\Omega\setminus\Omega_\kappa)}.$$

The summands can be estimated by (22) and (25), respectively, and a choice of ν that balances both estimates will provide the sharpest results. Thus, comparing the exponents in (22) and (25), we choose ν such that

$$\nu\gamma(q^{-1} - p^{-1}) + 1 = \nu\gamma(q^{-1} - \alpha p^{-1}) - \nu(\alpha - 1) + \alpha. \tag{26}$$

Solving this linear equation for ν yields $\nu = (\gamma p^{-1} + 1)^{-1}$. Note that α cancels out. Inserting ν into (22), we finally obtain for the contraction $\Theta(x)$

$$\Theta(x) \le \left\|G'(x)^{-1}\right\|_{L_q\to L_p} \frac{\|R(x)\|_{L_q(\Omega)}}{\|\delta x\|_{L_p(\Omega)}} \le C \|\delta x\|^{\alpha_0-1}_{L_p(\Omega)},$$

with α_0 as defined in (21). This shows superlinear convergence with rate α_0. ∎

Relation to known estimates. In [12, Theorem 3.45] the rate of convergence of Newton's method is estimated under assumption (13) for the case of uniformly bounded ψ_*. Translating the notation used there into our framework, the rate of convergence β of Newton's method was estimated in that work by

$$\beta = \min\left\{\alpha_0\,;\,\alpha\cdot\frac{(\alpha-1)/\alpha+\tau}{(\alpha-1)+\tau}\right\},\quad \tau=\gamma(q^{-1}-p^{-1}).$$

Theorems 4.3 and 4.5 show that the second bound can essentially be replaced by α, which is an improvement because $\alpha>1$. Example 3.53 in [12] shows that the rate in Theorem 4.5 can be considered sharp.

5. Newton's method and compactness. Consider again the equation $G(x)=0$, where G is a semilinear operator satisfying (5). In section 3 we used continuity of the Nemyckii operator $\Psi_*(x;1)$ to show local superlinear convergence of Newton's method. By lack of continuity from $L_p(\Omega,\mathcal{X})$ to $L_\infty(\Omega,\mathcal{Y})$ (cf. Remark 3.2(ii)) we encountered a norm gap and needed an $L_q\to L_p$ smoothing property of $G'(x)^{-1}$.

The classical qualitative notion of a smoothing operation is that of a compact operator, and we will now explore its connection to convergence of Newton's method. By the Sobolev embedding theorems, compact embeddings in a space L_q usually imply some continuous embedding into a stronger space L_p (cf. [1]). So our considerations are mainly of theoretical interest, but due to the fundamental role of compactness in analysis this connection is worth investigating.

LEMMA 5.1. *Let $\mathcal{X}$, $\mathcal{Y}$ be separable Banach spaces and Ω a measurable subset of $\mathbb{R}^d$. Let $\psi:\mathcal{X}\times\Omega\to\mathcal{Y}$ be a Baire–Carathéodory function. Assume that there is a constant $M<\infty$ independent of x such that $|\psi(x,t)|_{\mathcal{Y}}\le M$ a.e. in Ω.*

For some $1\le p\le\infty$ let $x_*\in L_p(\Omega,\mathcal{X})$ be given, and let x_n be a sequence of functions that converges to x_* in $L_p(\Omega,\mathcal{X})$. If $\psi(x,t)$ is continuous with respect to x at $(x_*(t),t)$ for almost all $t\in\Omega$, then

$$\lim_{n\to\infty}\int_\Omega |\psi(x_n(t),t)-\psi(x_*(t),t)|_{\mathcal{Y}}^q\,v(t)\,dt=0\quad\forall\,v\in L_1(\Omega,\mathbb{R}),\ \ \forall\,1\le q<\infty. \tag{27}$$

Proof. Since $x_n\to x_*$ in $L_p(\Omega,\mathcal{X})$, by picking a suitable subsequence we may assume that $x_n(t)\to x_*(t)$ a.e. Thus, by continuity of $\psi(x,t)$ in x at $x_*(t)$ a.e. and by continuity of the power function, also $|\psi(x_n(t),t)-\psi(x_*(t),t)|_{\mathcal{Y}}^q\to 0$ a.e. Consequently, for each $v\in L_1(\Omega,\mathbb{R})$ we have

$$|\psi(x_n(t),t)-\psi(x_*(t),t)|_{\mathcal{Y}}^q\,v(t)\to 0\quad\text{ a.e. in }\Omega.$$

Because $|\psi(x,t)|_{\mathcal{Y}}\le M$ for all $x\in\mathcal{X}$ a.e., this sequence is dominated by $(2M)^q v\in L_1(\Omega,\mathbb{R})$, and the convergence theorem of Lebesgue yields (27). ∎

We conclude with a semismooth Newton theorem based on compactness. Just as L_q-L_p continuity of each $G'(x)^{-1}$ was not sufficient in Theorem 3.3 (we needed a uniform bound), compactness of each $G'(x)^{-1}$ is not sufficient in Theorem 5.2.

THEOREM 5.2. *Let $G:X\to Y$ be a semilinear operator as defined in* (5)*, suppose that Basic Assumptions* 2.2 *hold, and let $1<p<\infty$. Assume additionally the following:*

(i) *$\psi_*(x,t;1)$ as defined in* (6) *is a Baire–Carathéodory function, and*

$$\lim_{x\to x_*(t)}\psi_*(x,t;1)=0\quad\text{ for almost all } t\in\Omega.$$

The corresponding Nemyckii operator $\Psi_*(x;1)$ maps $L_p(\Omega,\mathcal{X})$ into $L_\infty(\Omega,\mathcal{Y})$.

(ii) *The linear space Y can be equipped with a norm $\|\cdot\|_Y$ such that $L_p(\Omega,\mathcal{Y})$ is compactly embedded into $(Y,\|\cdot\|_Y)$.*

(iii) $\left\|G'(x)^{-1}\right\|_{Y\to L_p(\Omega,\mathcal{X})} \le M$ *holds uniformly on a neighborhood of x_*.*

Then Newton's method converges locally superlinearly to x_*.

Proof. Let x_n be an arbitrary sequence in X with $\|x_n - x_*\|_{L_p} \to 0$, and define $R(x) := F'(x)(x-x_*) - (F(x) - F(x_*))$. Let p' be defined by $p'^{-1} + p^{-1} = 1$. Then $1 < p' < \infty$ and $L_{p'}(\Omega,\mathcal{Y}^*) = (L_p(\Omega,\mathcal{Y}))^*$. Consider $v \in L_{p'}(\Omega,\mathcal{Y}^*)$. By the Hölder inequality we estimate

$$|\langle R(x_n), v\rangle| \le \| |R(x_n)|_{\mathcal{Y}}\, |v|_{\mathcal{Y}^*} \|_{L_1} \le \|x_n - x_*\|_{L_p}\, \| |\Psi_*(x_n;1)|_{\mathcal{Y}}\, |v|_{\mathcal{Y}^*} \|_{L_{p'}}$$

$$= \|x_n - x_*\|_{L_p} \left(\int_\Omega |\psi_*(x_n(t),t;1)|_{\mathcal{Y}}^{p'}\, |v(t)|_{\mathcal{Y}^*}^{p'}\, dt \right)^{p'^{-1}}.$$

Because $\psi_*(x_*(t),t;1) = 0$ a.e., by Lemma 5.1 the last integral expression converges to 0 for each $|v|_{\mathcal{Y}^*}^{p'} \in L_1(\Omega)$. Thus, division by $\|x_n - x_*\|_{L_p}$ yields

$$r_n := \frac{R(x_n)}{\|x_n - x_*\|_{L_p}} \rightharpoonup 0 \quad \text{in } L_p(\Omega,\mathcal{Y}).$$

By (ii), $r_n \to 0$ in Y, and thus by (iii), $e_n := G'(x_n)^{-1} r_n \to 0$ in $L_p(\Omega,\mathcal{X})$. Hence,

$$\lim_{n\to\infty} \Theta(x_n) = \lim_{n\to\infty} \frac{\left\|G'(x_n)^{-1} R(x_n)\right\|_{L_p}}{\|x_n - x_*\|_{L_p}} = \lim_{n\to\infty} \|e_n\|_{L_p} = 0.$$

Because x_n was arbitrary, this implies superlinear convergence by Theorem 2.1. ∎

Often Y is the dual of some Sobolev space W. If there is a compact embedding $E : W \to L_{p'}$, then its adjoint $E^* : L_p \to Y$ with $p^{-1} + p'^{-1} = 1$ is also a compact embedding, suitable for Theorem 5.2.(ii). For a characterization of compactness in L_p spaces we refer to [1, Theorem 2.21].

6. Application to an optimal control problem. As an illustration and in view of Example 3.4 consider the following optimal control problem:

$$\min \frac{1}{2}\|y - y_d\|_{L_2(\Omega)}^2 + \frac{1}{1/\sigma+1}\int_\Omega |u|^{1/\sigma+1}\, dt \qquad \text{for } \sigma \ge 1$$

$$\text{s.t. } -\Delta y - u = 0, \quad y\big|_{\partial\Omega} = 0, \qquad u \ge \tau^\sigma \qquad \text{for } \tau \ge 0.$$

To compute (u,y) we introduce an adjoint state λ and consider the first-order optimality conditions:

$$\begin{aligned} y - y_d - \Delta\lambda = 0, \quad \lambda\big|_{\partial\Omega} = 0, \\ -\Delta y - \max(\lambda,\tau)^\sigma = 0, \quad y\big|_{\partial\Omega} = 0 \end{aligned} \tag{28}$$

with $u = \max(\lambda,\tau)^\sigma$. This is a semilinear system of equations of the form (5) with $x = (y,\lambda)$. For $\sigma = 1$ its solution in function space by Newton's method has been considered in [6, 12] by a formulation in terms of the control u. The consideration of the system (28) in terms of y and λ is an interesting alternative, which naturally describes algorithms based on the discretization idea of [7].

Constructing a linearization. The nonlinearity in this system is given by the function $f(\lambda) := \max(\lambda, \tau)^\sigma$, which has been considered in Example 3.4. Using f' as defined in (10), we can construct a Jacobian matrix $G'(x)$ to (28), given by

$$G'(x) = \begin{pmatrix} I & -\Delta \\ -\Delta & -f'(\lambda) \end{pmatrix}. \tag{29}$$

Let $x_* = (y_*, \lambda_*)$ be the solution of (28). Computation of the remainder term yields

$$G'(x_* + \delta x)\delta x - (G(x_* + \delta x) - G(x_*)) = \begin{pmatrix} 0 \\ R(\lambda) \end{pmatrix}.$$

Here $R(\lambda)(t) = \psi_*(\lambda(t), t; \alpha)|\lambda(t) - \lambda_*(t)|^\alpha$, with ψ_* defined in (11). The properties of ψ_* at x_* have already been established in Example 3.4. In particular, $\lim_{x\to x_*} \psi_*(x, t; 1) = 0$ and $|\psi_*(x, t; 1)| \le a(t) + b|x|^{\sigma-1}$. Hence, by Theorem 3.3, local superlinear convergence of Newton's method follows if an $L_q - L_p$ *smoothing property* holds for some $p/q \ge \sigma$. If $\sigma = 1$, then we can use either Theorem 3.3 with any $p > q$ or Theorem 5.2.

Solvability and smoothing property of $\mathrm{G'(x)^{-1}}$. Let us not go into the details of invertibility of G' in the case of a block structure as in (29). It is, however, not hard to see that G' inherits a smoothing property of the solution operator of the state equation. One approach is via a general theory for linear saddle point problems as can be found, for example, in [3, Chapter III.4].

Since the nonlinear terms in our system depend on the adjoint state λ only, it is sufficient to consider this component only, setting $x = \lambda$. By duality techniques it can be shown (cf., e.g., [10, Chapter 4]) that a smoothing property holds for $q^{-1} + p^{-1} = 1$ as long as for $-\Delta y = v$ we have $\|y\|_{L_p} \le c\,\|v\|_{L_2}$. We then obtain

$$\begin{pmatrix} \delta y \\ \delta\lambda \end{pmatrix} = G'(x)^{-1} \begin{pmatrix} 0 \\ R(\lambda) \end{pmatrix} \Longrightarrow \|\delta\lambda\|_{L_p} \le C\,\|R\|_{L_q}.$$

In particular, on regular domains $p = \infty$ and $q = 1$ are often obtained by H^2-regularity results for solutions of the state equation. Appropriate spaces for convergence analysis are then $X = (H^2(\Omega), \|\cdot\|_{L_\infty})$ and $Y = X^* \supset L_1(\Omega)$.

Rates of convergence. To study convergence rates we restrict our analysis to the case $\sigma = 1$ for simplicity. Following [12], we assume

$$\mu\left(\{t \in \Omega : 0 < |\lambda_*(t)| < \varepsilon\}\right) \le C\varepsilon^\gamma, \tag{30}$$

a condition that resembles a strengthened strict complementarity condition. If $|\lambda - \lambda_*(t)| < |\lambda_*(t)|$ or $\lambda_*(t) = 0$, then $r = 0$. Otherwise, we have $r < |\lambda_*(t)|$. Hence, for any $1 < \alpha < \infty$

$$\psi_*(\lambda, t; \alpha) \le \frac{|\lambda_*(t)|}{|\lambda - \lambda_*(t)|^\alpha} \le |\lambda_*(t)|^{1-\alpha},$$

and thus finally (30) becomes (13):

$$\mu(\Omega_\varepsilon(\lambda)) := \mu\left(\left\{t \in \Omega : \psi_*(\lambda(t), t; \alpha) < \varepsilon^{1-\alpha}\right\}\right) \le C\varepsilon^\gamma.$$

By Theorem 4.5 we obtain the rate of convergence α as in (21). In particular, for the very common case $\gamma = 1$, $q = 1$, $p = \infty$ we obtain $\alpha = 2$. Thus, Newton's method converges locally quadratically in function space.

Appendix.

PROPOSITION A.1 (a growth condition for $\psi_*(x,t;1)$). *For given $x_* \in L_p(\Omega,\mathcal{X})$, $f(x,t)$, and $f'(x,t)$ let $\psi_*(x,t;1)$ be defined as in* (6). *Define the local Lipschitz constant $L(x,t)$ of f with respect to x at (x,t) by*

$$L(x,t) := \sup_{|x-\tilde{x}|_{\mathcal{X}} \le 1} \frac{|f(x,t) - f(\tilde{x},t)|_{\mathcal{Y}}}{|x-\tilde{x}|_{\mathcal{X}}}.$$

Assume that

$$L(x,t) \le a(t) + b\,|x|_{\mathcal{X}}^{p/s} \qquad \text{for some } a \in L_s(\Omega,\mathbb{R}), b \in \mathbb{R}, \tag{31}$$

$$|f'(x,t)|_{\mathcal{X}\to\mathcal{Y}} \le a(t) + b\,|x|_{\mathcal{X}}^{p/s} \qquad \text{for some } a \in L_s(\Omega,\mathbb{R}), b \in \mathbb{R}. \tag{32}$$

Then $\psi_*(x,t;1)$ satisfies the growth condition (4).

Proof. By the triangle inequality,

$$|\psi_*(x,t;1)|_{\mathcal{Y}} \le \frac{|f'(x,t)(x-x_*(t))|_{\mathcal{Y}}}{|x-x_*(t)|_{\mathcal{X}}} + \frac{|f(x,t)-f(x_*(t),t)|_{\mathcal{Y}}}{|x-x_*(t)|_{\mathcal{X}}}.$$

Taking the operator norm of $f'(x,t)$, by (32) the first part of this sum satisfies (4).

To show the same for the second part we define for $n \in \mathbb{N}$ and $i = 0,\dots,n$ the collinear points $x_i := x \cdot i/n + x_*(t) \cdot (n-i)/n$. For sufficiently large n we can apply (31) to obtain

$$\frac{|f(x,t)-f(x_*(t),t)|_{\mathcal{Y}}}{|x-x_*(t)|_{\mathcal{X}}} \le \frac{\sum_{i=1}^n L(x_i,t)|x_i - x_{i-1}|_{\mathcal{X}}}{|x_0 - x_n|_{\mathcal{X}}} \le a(t) + \frac{b}{n}\sum_{i=1}^n |x_i|_{\mathcal{X}}^{p/s}. \tag{33}$$

Application of the triangle inequality yields

$$|x_i|_{\mathcal{X}}^{p/s} \le \left(|x|_{\mathcal{X}} \cdot \frac{i}{n} + |x_*(t)|_{\mathcal{X}} \cdot \frac{(n-i)}{n}\right)^{p/s} \le \left(\max\{|x|_{\mathcal{X}}, |x_*(t)|_{\mathcal{X}}\}\right)^{p/s}.$$

Inserting this into (33), using $x_* \in L_p(\Omega,\mathcal{X})$, yields the desired estimate. ∎

Often there is a relation $L(x,t) \approx \sup_{|\tilde{x}-x|_{\mathcal{X}}\le 1} |f'(\tilde{x},t)|$. Then one of (31) and (32) is redundant.

Acknowledgments. The author would like to thank Prof. Peter Deuflhard and Dr. Martin Weiser for support and encouragement and for valuable comments concerning this work. Further, the author wants to thank the referees, who contributed to the clarity and accuracy of this paper by a large number of valuable suggestions.

NEW FORMULATIONS FOR OPTIMIZATION UNDER STOCHASTIC DOMINANCE CONSTRAINTS*

JAMES LUEDTKE†

Abstract. Stochastic dominance constraints allow a decision maker to manage risk in an optimization setting by requiring his or her decision to yield a random outcome which stochastically dominates a reference random outcome. We present new integer and linear programming formulations for optimization under first- and second-order stochastic dominance constraints, respectively. These formulations are more compact than existing formulations, and relaxing integrality in the first-order formulation yields a second-order formulation, demonstrating the tightness of this formulation. We also present a specialized branching strategy and heuristics which can be used with the new first-order formulation. Computational tests illustrate the potential benefits of the new formulations.

Key words. stochastic programming, stochastic dominance constraints, risk, probabilistic constraints, integer programming

1. Introduction. Optimization under stochastic dominance constraints is an attractive approach to managing risk in an optimization setting. The idea is to optimize an objective, such as the expected profit, subject to a constraint that a random outcome of interest, such as the actual profit, is preferable in a strong sense than a given reference random outcome. Here, "preferable" is taken to mean that the random outcome we achieve stochastically dominates the reference outcome. A simple example application is to choose investments to maximize the expected return, subject to the constraint that the actual return should stochastically dominate the return from a given index, such as the S&P 500; see, e.g., [7]. Stochastic dominance constraints have also been used in risk modeling in power systems with dispersed generation [10]. In addition, dose-volume restrictions appearing in radiation treatment planning problems [18] can be formulated as a first-order stochastic dominance constraint. Stochastic programming under stochastic dominance constraints has recently been studied in [4, 5, 6, 8, 11, 12, 24, 25, 26].

Let W and Y be random variables with distribution functions F and G. The random variable W dominates Y in the first order, written $W \succeq_{(1)} Y$, if

$$F(\eta) \leq G(\eta) \qquad \forall\, \eta \in \mathbb{R}. \tag{1.1}$$

The random variable W dominates Y in the second order, written $W \succeq_{(2)} Y$, if

$$\mathbb{E}\big[\max\{\eta - W, 0\}\big] \leq \mathbb{E}\big[\max\{\eta - Y, 0\}\big] \qquad \forall\, \eta \in \mathbb{R}. \tag{1.2}$$

If W and Y represent random outcomes for which we prefer larger values, then stochastic dominance of W over Y implies a very strong preference for W. In particular, it is known that (see, e.g., [29]) $W \succeq_{(1)} Y$ if and only if

$$\mathbb{E}[h(W)] \geq \mathbb{E}[h(Y)]$$

for all nondecreasing functions $h : \mathbb{R} \to \mathbb{R}$ for which the above expectations exist and are finite. Thus, if $W \succeq_{(1)} Y$, any rational decision maker would prefer W to Y. In addition, $W \succeq_{(2)} Y$ if and only if

$$\mathbb{E}[h(W)] \geq \mathbb{E}[h(Y)]$$

for all nondecreasing and concave functions $h : \mathbb{R} \to \mathbb{R}$ for which the above expectations exist and are finite. Thus, if $W \succeq_{(2)} Y$, any rational and risk-averse decision maker will prefer W to Y.

In this paper, we present new, computationally attractive formulations for *optimization under stochastic dominance constraints*. Let $X \subseteq \mathbb{R}^n$, and let $f : \mathbb{R}^n \to \mathbb{R}$ represent an objective we want to maximize. Let Y be a given random variable, which we refer to as the *reference random variable*, and let ξ be a random vector taking values in $\mathbb{R}^m$. Finally, let $g : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ be a given mapping which represents a random outcome depending on the decision x and the random vector ξ. We consider the two optimization problems

$$\max_x \left\{ f(x) : x \in X, g(x, \xi) \succeq_{(1)} Y \right\} \tag{FSDP}$$

and

$$\max_x \left\{ f(x) : x \in X, g(x, \xi) \succeq_{(2)} Y \right\}. \tag{SSDP}$$

We will present formulations for these problems for instances when the random vector ξ and reference random variable Y have finite distributions. That is, we assume ξ can take at most N values, and Y can take at most D values. In particular, we have the following.

1. We introduce two new linear formulations for SSDP which have $O(N + D)$ constraints, as opposed to $O(ND)$ constraints in an existing linear formulation. Computational results indicate that this yields significant improvement in solution time for instances in which $N = D$.

2. We introduce a new mixed-integer programming (MIP) formulation for FSDP which also has $O(N + D)$ constraints. In addition, the linear relaxation of this formulation is also a formulation of SSDP. As a result, the linear programming relaxation of this formulation is equivalent to the SSDP relaxation proposed in [24], and is shown to be a tight relaxation of FSDP in [25].

3. We present a specialized branching rule and heuristics for the new FSDP formulation and conduct computational tests which indicate that provably good, and in some cases provably optimal, solutions can be obtained for relatively large instances using this approach.

We do not make any assumptions on the set X or the mapping g in the development of the formulations, but computationally we are interested in the case when X is a polyhedron and $g(x, \xi)$ is affine in x for all possible values of ξ, so that the formulations become linear and linear integer programs, for SSDP and FSDP, respectively.

In [6] it is shown that in some special cases the convex second-order dominance constraint yields the convexification of the nonconvex first-order dominance constraint, and that in all cases, the second-order constraint is a relaxation of the first-order constraint. Our new formulations further illustrate this close connection by showing that relaxing integrality in the new formulation for FSDP yields a formulation for SSDP.

In section 2 we review some basic results about stochastic dominance and present existing formulations for FSDP and SSDP. In section 3 we present the new formula-

tions for SSDP, and in section 4 we present the new formulation for FSDP. In section 5 we present a specialized branching scheme and some heuristics for solving the new formulation of FSDP. In section 6 we present some illustrative computational results, and we close with some concluding remarks in section 7.

2. Review of existing results. For the purpose of developing formulations for FSDP and SSDP, it will be sufficient to present conditions which characterize instances when a random variable W stochastically dominates the reference random variable Y. We will assume the distributions of W and Y are finite and described by

$$\mu\{W = w_i\} = p_i, \qquad i \in \mathcal{N} := \{1, \dots, N\}, \tag{2.1}$$

$$\nu\{Y = y_k\} = q_k, \qquad k \in \mathcal{D} := \{1, \dots, D\}, \tag{2.2}$$

where μ and ν are the probability distributions induced by W and Y, respectively. Furthermore, we assume without loss of generality that $y_1 < y_2 < \cdots < y_D$.

Given a formulation which guarantees W stochastically dominates Y, a formulation for FSDP or SSDP can be obtained by simply enforcing that $g(x, \xi) \geq W$. Then, if ξ has distribution given by $\mathbb{P}\{\xi = \xi^i\} = p_i$ for $i \in \mathcal{N}$ and we add the constraints

$$w_i \leq g(x, \xi^i), \qquad i \in \mathcal{N} \tag{2.3}$$

to the formulation, then we will have $g(x, \xi) \succeq_{(1)} Y$ if and only if $W \succeq_{(1)} Y$, and $g(x, \xi) \succeq_{(2)} Y$ if and only if $W \succeq_{(2)} Y$. Henceforth, we will consider only formulations which guarantee stochastic dominance of W over Y, but based on the relation (2.3), the reader should think of the values w_i as decision variables, whereas the values y_k are fixed.

When the reference random variable Y has finite distribution, the conditions for stochastic dominance can be simplified, as has been observed, for example, in [4, 5]. We let $y_0 \in \mathbb{R}$ be such that $y_0 < y_1$ and introduce the notation $(\cdot)^+ = \max\{0, \cdot\}$.

LEMMA 2.1. *Let W, Y be random variables with distributions given by* (2.1) *and* (2.2). *Then, $W \succeq_{(2)} Y$ if and only if*

$$\mathbb{E}[(y_k - W)^+] \leq \mathbb{E}[(y_k - Y)^+], \qquad k \in \mathcal{D}, \tag{2.4}$$

and $W \succeq_{(1)} Y$ if and only if

$$\mu\{W < y_k\} \leq \nu\{Y \leq y_{k-1}\}, \qquad k \in \mathcal{D}. \tag{2.5}$$

The key simplification is that the infinite sets of inequalities in the definitions (1.1) and (1.2) can be reduced to a finite set when Y has a finite distribution.

Second-order stochastic dominance (SSD) constraints are known to define a convex feasible region [4]. In fact, condition (2.4) can be used to derive a linear formulation (in an extended variable space) for SSD by introducing variables s_{ik} representing the terms $(y_k - w_i)^+$; see, e.g., [4]. Thus, $W \succeq_{(2)} Y$ if and only if there exists $s \in \mathbb{R}_+^{ND}$ such that

$$\begin{aligned} &\sum_{i=1}^{N} p_i s_{ik} \leq \sum_{j=1}^{D} q_j (y_k - y_j)^+, \quad k \in \mathcal{D}, \\ &s_{ik} + w_i \geq y_k, \qquad\qquad\qquad\qquad i \in \mathcal{N}, k \in \mathcal{D}. \end{aligned}$$

We refer to this formulation as SDLP. Note that this formulation introduces ND variables and $(N+1)D$ constraints.

It is possible to use the nonsmooth convex constraints (2.4) directly, yielding a formulation for SSDP that does not introduce auxiliary variables and has $O(D)$ constraints; and specialized methods can be used to solve this formulation; see [5]. The advantage of using a linear formulation is that it can be solved directly by readily available linear programming solvers such as the open source solver CLP [9] or the commercial solver Ilog CPLEX [14]. In addition, if the base problem contains integer restrictions on some of the variables x, then a linear formulation is advantageous because it can be solved as a mixed-integer *linear* program, as opposed to a mixed-integer nonlinear program.

The condition for second-order dominance given in (2.4) can also be interpreted as a collection of D *integrated chance constraints*, as introduced by Klein Haneveld [15]. In [16], Klein Haneveld and van der Vlerk proposed a cutting plane algorithm for solving problems with integrated chance constraints and demonstrated its computational efficiency. Due to (2.4), this approach can also be used for problems with second-order stochastic dominance constraints, as has been observed in [8]. Independently, Rudolf and Ruszczyński [26] proposed a primal cutting plane method and a dual column generation method for optimization problems with SSD constraints, and the primal method is shown to be computationally efficient. In the case of finite distributions, the primal cutting plane method is equivalent to the cutting plane method used for integrated chance constraints in [16].

Condition (2.5) can be used to derive an MIP formulation for a first-order stochastic dominance (FSD) constraint [24, 25]. $W \succeq_{(1)} Y$ if and only if there exists β such that

$$
\begin{aligned}
\sum_{i=1}^{N} p_i \beta_{ik} &\le \sum_{j=1}^{k-1} q_j, \quad && k \in \mathcal{D}, \\
w_i + M_{ik}\beta_{ik} &\ge y_k, && i \in \mathcal{N}, k \in \mathcal{D}, \\
\beta_{ik} &\in \{0,1\}, && i \in \mathcal{N}, k \in \mathcal{D}.
\end{aligned} \tag{2.6}
$$

We refer to this formulation as FDMIP. Here, M_{ik} is sufficiently large to guarantee that if $\beta_{ik} = 1$, then the corresponding constraint (2.6) will be redundant. For example, if other constraints in the model imply $w_i \ge l_i$, then we can take $M_{ik} = y_k - l_i$. Although this formulation was presented in [24, 25], the authors do not recommend using this formulation for computation, since the linear programming relaxation bounds are too weak. Instead, because first-order stochastic dominance implies second-order dominance, any formulation for second-order dominance is a relaxation of first-order dominance, and the authors therefore propose using the problem SSDP as a relaxation for FSDP. Thus, they use the cutting plane algorithm proposed in [26] for solving problem SSDP, which yields bounds for FSDP, and then they improve these bounds using disjunctive cuts [1]. In addition, problem SSDP is used as a basis for heuristics to find feasible solutions for FSDP. It is demonstrated in [25] that the bounds from using SSDP as a relaxation of FSDP are usually good, and that the heuristics are able to obtain good feasible solutions. However, these results do not yield a convergent algorithm for finding an optimal solution to FSDP. As these results are based on solving problem SSDP, an easily implementable and computationally efficient formulation for solving SSDP will also enhance this approach.

3. New formulations for second-order stochastic dominance. When all outcomes are equally likely and $N = D$, a formulation for SSDP based on majorization theory [13, 21] can be derived which introduces $O(N^2)$ variables but only $O(N)$

rows. This has been done implicitly in [6] when proving that in this case the SSD constraint yields the convexification of the FSD constraint, and explicitly in [17] to derive a test for SSD. In this section we present two formulations for second-order dominance between finitely distributed random variables which do not require all outcomes to be equally likely and allow $N \neq D$. The formulations will not be based on the majorization theory, and instead will follow from the following theorem due to Strassen, which we state here in a form that is convenient for our use.

THEOREM 3.1 (see Corollary 1.5.21 in [22]). *Let W and Y be random variables with finite means. Then $W \succeq_{(2)} Y$ if and only if there exists random variables W' and Y', with the same distributions as W and Y, such that almost surely*

$$\mathbb{E}[Y'|W'] \leq W'.$$

THEOREM 3.2. *Let W, Y be random variables with distributions given by* (2.1) *and* (2.2). *Then $W \succeq_{(2)} Y$ if and only if there exists $\pi \in \mathbb{R}_+^{ND}$ which satisfies*

$$\sum_{j=1}^{D} y_j \pi_{ij} \leq w_i, \qquad i \in \mathcal{N}, \tag{3.1}$$

$$\sum_{j=1}^{D} \pi_{ij} = 1, \qquad i \in \mathcal{N}, \tag{3.2}$$

$$\sum_{i=1}^{N} p_i \pi_{ik} = q_k, \qquad k \in \mathcal{D}. \tag{3.3}$$

Proof. First suppose $W \succeq_{(2)} Y$. By Theorem 3.1, there exists random variables W' and Y' (defined, say, on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$) such that $\mathbb{E}[Y'|W'] \leq W'$ and $\mathbb{P}\{W' = w_i\} = p_i$ for $i \in \mathcal{N}$ and $\mathbb{P}\{Y' = y_k\} = q_k$ for $k \in \mathcal{D}$. Define a vector $\pi \in \mathbb{R}^{ND}$ by $\pi_{ik} = \mathbb{P}\{Y' = y_k | W' = w_i\}$ for $i \in \mathcal{N},\ k \in \mathcal{D}$. By definition, $\pi \geq 0$ and $\sum_{k \in \mathcal{D}} \pi_{ik} = 1$ for each $i \in \mathcal{N}$. Also, for each $k \in \mathcal{D}$

$$q_k = \mathbb{P}\{Y' = y_k\} = \sum_{i=1}^{N} \mathbb{P}\{Y' = y_k | W' = w_i\} \mathbb{P}\{W' = w_i\} = \sum_{i=1}^{N} p_i \pi_{ik}.$$

Finally, for each $i \in \mathcal{N}$

$$w_i \geq \mathbb{E}[Y'|W' = w_i] = \sum_{k=1}^{D} y_k \pi_{ik}$$

and hence π satisfies (3.1)–(3.3).

Now suppose there exists $\pi \in \mathbb{R}_+^{ND}$ which satisfies (3.1)–(3.3). Let $\Omega = \{(i,k) : i \in \mathcal{N}, k \in \mathcal{D}\}$, and define the probability measure $\mathbb{P}$ on Ω by $\mathbb{P}\{(i,k)\} = p_i \pi_{ik}$. Note that $\mathbb{P}$ is well defined since by (3.2) $\sum_{k \in \mathcal{D}} \sum_{i \in \mathcal{N}} p_i \pi_{ik} = 1$. Now define W' by $W'\big((i,k)\big) = w_i$ for $i \in \mathcal{N}$, $k \in \mathcal{D}$, and Y' by $Y'\big((i,k)\big) = y_k$ for $i \in \mathcal{N}$, $k \in \mathcal{D}$. Then, $\mathbb{P}\{W' = w_i\} = p_i \sum_{k \in \mathcal{D}} \pi_{ik} = p_i$ by (3.2), and so W' has the same distribution as W. Also, $\mathbb{P}\{Y' = y_k\} = \sum_{i \in \mathcal{N}} p_i \pi_{ik} = q_k$ by (3.3), and so Y' has the same distribution as Y. Finally, for each $i \in \mathcal{N}$,

$$\mathbb{E}[Y'|W' = w_i] = \sum_{k=1}^{D} y_k \pi_{ik} \leq w_i$$

by (3.1). It follows from Theorem 3.1 that $W \succeq_{(2)} Y$. □

To use Theorem 3.2 to obtain a formulation for SSDP, we replace w_i with $g(x, \xi^i)$ so that (3.1) becomes

$$g(x, \xi^i) \geq \sum_{j=1}^{D} y_j \pi_{ij}, \qquad i \in \mathcal{N}, \tag{3.4}$$

and thus obtain our first new formulation for SSDP given by

$$f^*_{\text{SSDP}} = \max_{x,\pi} \left\{ f(x) : \ (3.2),\ (3.3),\ (3.4), x \in X, \pi \in \mathbb{R}^{ND}_+ \right\}. \tag{cSSD1}$$

This formulation, which we refer to as cSSD1, introduces ND variables and $O(N+D)$ linear constraints.

THEOREM 3.3. *Let W, Y be random variables with distributions given by* (2.1) *and* (2.2). *Then $W \succeq_{(2)} Y$ if and only if there exists $\pi \in \mathbb{R}^{ND}_+$ which satisfies* (3.1), (3.2), *and*

$$\sum_{i=1}^{N} p_i \sum_{j=1}^{k-1} (y_k - y_j)\pi_{ij} \leq \sum_{j=1}^{k-1} (y_k - y_j), q_j \qquad k = 2, \ldots, D. \tag{3.5}$$

Proof. First suppose $W \succeq_{(2)} Y$. Then by Theorem 3.2 there exists $\pi \in \mathbb{R}^{ND}_+$ which satisfies (3.1)–(3.3). Then,

$$\sum_{i=1}^{N} p_i \sum_{j=1}^{k-1} (y_k - y_j)\pi_{ij} = \sum_{j=1}^{k-1} (y_k - y_j) \sum_{i=1}^{N} p_i \pi_{ij} = \sum_{j=1}^{k-1} (y_k - y_j) q_j$$

for $k = 2, \ldots, D$ by (3.3) and hence π satisfies (3.5).

Now suppose there exists $\pi \in \mathbb{R}^{ND}_+$ which satisfies (3.1), (3.2), and (3.5). For any $i \in \mathcal{N}$, $k \in \mathcal{D}$, we have

$$\begin{aligned}
(y_k - w_i)^+ &\leq \left(y_k - \sum_{j=1}^{D} y_j \pi_{ij} \right)^+ && \text{by (3.1)} \\
&= \left(\sum_{j=1}^{D} (y_k - y_j)\pi_{ij} \right)^+ && \text{by (3.2)} \\
&\leq \sum_{j=1}^{D} (y_k - y_j)^+ \pi_{ij} = \sum_{j=1}^{k-1} (y_k - y_j)\pi_{ij} && \text{since } \pi \geq 0.
\end{aligned}$$

Thus, for each $k \in \mathcal{D}$,

$$\begin{aligned}
\mathbb{E}[(y_k - W)^+] = \sum_{i=1}^{N} p_i (y_k - w_i)^+ &\leq \sum_{i=1}^{N} p_i \sum_{j=1}^{k-1} (y_k - y_j)\pi_{ij} \\
&\leq \sum_{j=1}^{k-1} (y_k - y_j) q_j = \mathbb{E}[(y_k - Y)^+],
\end{aligned}$$

where the second inequality follows from (3.5). Thus, condition (2.4) in Lemma 2.1 implies that $W \succeq_{(2)} Y$. □

When using the formulation arising from Theorem 3.3, it is beneficial for computational purposes to use an equivalent formulation in which we introduce variables $v \in \mathbb{R}^D$ and replace the constraints in (3.5) with the $2D$ constraints

$$v_j - \sum_{i=1}^{N} p_i \pi_{ij} = 0, \qquad j \in \mathcal{D}, \tag{3.6}$$

$$\sum_{j=1}^{k-1} (y_k - y_j) v_j \leq \sum_{j=1}^{k-1} (y_k - y_j) q_j, \qquad k \in \mathcal{D}. \tag{3.7}$$

Thus, our second formulation for SSDP is given by

$$\text{(cSSD2)} \quad f^*_{\text{SSDP}} = \max_{x,\pi,v} \left\{ f(x) : (3.2), (3.4), (3.6), (3.7), x \in X, \pi \in \mathbb{R}^{ND}_+, v \in \mathbb{R}^D \right\}.$$

The advantage of using (3.6) and (3.7) instead of (3.5) is that this yields a formulation with $O(ND)$ nonzeros, as compared to $O(ND^2)$ nonzeros if we used (3.5). This formulation, which we refer to as cSSD2, introduces $(N+1)D$ new variables and $O(N+D)$ linear constraints.

One motivation for introducing formulation cSSD2 is that we have empirical evidence (section 6) that it performs better than cSSD1, at least when solved with the dual simplex algorithm (as implemented in Ilog CPLEX [14]). cSSD2 is also interesting because a slight generalization of this formulation can be used to compactly model a collection of expected shortfall constraints of the form

$$\mathbb{E}[(y_k - g(x,\xi))^+] \leq L_k, \qquad k \in \mathcal{D}, \tag{3.8}$$

where $y_1 < y_2 < \cdots < y_D$ are given targets and $0 \leq L_1 \leq L_2 \leq \cdots \leq L_D$ are given limits on the expected shortfalls of these targets. Note that if

$$L_k = \mathbb{E}[(y_k - Y)^+], \qquad k \in \mathcal{D}, \tag{3.9}$$

where Y is a random variable with distribution given by (2.2), then the inequalities (3.8) are equivalent to (2.4), and hence (3.8) is satisfied exactly when $W \succeq_{(2)} Y$. If L_k is not defined by a random variable Y as in (3.9), formulation cSSD2 can still be extended to directly model (3.8), provided that $L_1 = 0$, which implies that we require $g(x,\xi) \geq y_1$ with probability 1. All that is required is to replace the term $\sum_{j=1}^{k-1}(y_k - y_j)q_j$ in the right-hand side of (3.5) with L_k.

4. A new formulation for first-order stochastic dominance. As in the case for second-order stochastic dominance, if $N = D$ and all outcomes are equally likely, a formulation for first-order stochastic dominance which introduces N^2 (binary) variables and $O(N)$ constraints has been presented in [17]. Once again, we are able to generalize this to the case in which the probabilities are not necessarily equal and $N \neq D$.

THEOREM 4.1. *Let W, Y be random variables with distributions given by* (2.1) *and* (2.2). *Then $W \succeq_{(1)} Y$ if and only if there exists $\pi \in \{0,1\}^{ND}$ such that (w, π) satisfy* (3.1), (3.2) *and*

$$\sum_{i=1}^{N} p_i \sum_{j=1}^{k-1} \pi_{ij} \leq \sum_{j=1}^{k-1} q_j, \qquad k = 2, \ldots, D. \tag{4.1}$$

Proof. First suppose $W \succeq_{(1)} Y$. Then, by condition (2.5) in Lemma 2.1 we have

$$\mu\{W < y_k\} \leq \nu\{Y \leq y_{k-1}\} = \sum_{i=1}^{k-1} q_i \tag{4.2}$$

for each $k \in \mathcal{D}$. In particular, (4.2) for $k = 1$ implies $\mu\{W \geq y_1\} = 1$, and hence $w_i \geq y_1$ for all $i \in \mathcal{N}$. Now, for each $i \in \mathcal{N}, k \in \mathcal{D}$, let $\pi_{ik} = 1$ if $y_k \leq w_i < y_{k+1}$ and $\pi_{ik} = 0$ otherwise, where we take $y_{D+1} \equiv +\infty$. Then, $\sum_{k=1}^{D} \pi_{ik} = 1$ because $w_i \geq y_1$ for all i, and so π satisfies (3.2). It is also immediate by the definition of π_{ik} that $w_i \geq \sum_{k=1}^{D} y_k \pi_{ik}$ and so π satisfies (3.1). Finally, note that $w_i < y_k$ if and only if $\sum_{j=1}^{k-1} \pi_{ij} = 1$. Thus,

$$\mu\{W < y_k\} = \sum_{i \in \mathcal{N}: w_i < y_k} p_i = \sum_{i=1}^{N} p_i \sum_{j=1}^{k-1} \pi_{ij}.$$

This combined with (4.2) proves that π satisfies (4.1).

Now suppose $\pi \in \{0,1\}^{ND}$ satisfies (3.1), (3.2), and (4.1). Note that by (3.1) and (3.2) if $w_i < y_k$, then $\sum_{j=1}^{k-1} \pi_{ij} = 1$. Thus,

$$\mu\{W < y_k\} = \sum_{i \in \mathcal{N}: w_i < y_k} p_i \leq \sum_{i=1}^{N} p_i \sum_{j=1}^{k-1} \pi_{ij} \leq \sum_{j=1}^{k-1} q_j = \nu\{Y \leq y_{k-1}\},$$

where the second inequality follows from (4.1). It follows that $W \succeq_{(1)} Y$ by condition (2.5) in Lemma 2.1. □

As in the new formulation for second-order stochastic dominance cSSD2, for computational purposes it is beneficial to use the equivalent formulation obtained by introducing variables $v \in \mathbb{R}^D$ and replacing the constraints (4.1) with the constraints

$$v_j - \sum_{i=1}^{N} p_i \pi_{ij} = 0, \qquad j \in \mathcal{D}, \tag{4.3}$$

$$\sum_{j=1}^{k-1} v_j \leq \sum_{j=1}^{k-1} q_j, \qquad k \in \mathcal{D}. \tag{4.4}$$

Thus, taking $w_i = g(x, \xi^i)$, and using (4.3) and (4.4) in place of (4.1), Theorem 4.1 yields the formulation for FSDP given by

$$\text{(cFSD)} \qquad f^*_{\text{FSDP}} = \max_{x,\pi} \left\{ f(x) : \ (3.2), (3.4), (4.3), (4.4), x \in X, \pi \in \{0,1\}^{ND} \right\}.$$

One advantage of formulation cFSD over FDMIP is that the number of constraints is reduced from $O(ND)$ to $O(N + D)$, which means it should be more efficient to solve the linear programming relaxation of cFSD than to solve that of FDMIP. We now consider the relationship between the relaxation of this formulation and *second*-order stochastic dominance.

THEOREM 4.2. *Let W, Y be random variables with distributions given by* (2.1) *and* (2.2). *Then the linear programming relaxation of* cFSD *yields a valid formulation for second-order stochastic dominance. That is, $W \succeq_{(2)} Y$ if and only if there exists $\pi \in \mathbb{R}^{ND}_+$ such that (w, π) satisfy* (3.1), (3.2), *and* (4.1).

Proof. Let $\pi \in \mathbb{R}_+^{ND}$ and (w, π) satisfy (3.1), (3.2), and (4.1). Then,

$$\begin{aligned}\sum_{i=1}^{N} p_i \sum_{j=1}^{k-1} \pi_{ij}(y_k - y_j) &= \sum_{i=1}^{N} p_i \sum_{j=1}^{k-1} \pi_{ij} \sum_{l=j+1}^{k} (y_l - y_{l-1}) \\ &= \sum_{l=2}^{k} (y_l - y_{l-1}) \sum_{i=1}^{N} p_i \sum_{j=1}^{l-1} \pi_{ij} \\ &\le \sum_{l=1}^{k} (y_l - y_{l-1}) \sum_{j=1}^{l-1} q_j \qquad \text{by (4.1)} \\ &= \sum_{j=1}^{k-1} q_j (y_k - y_j),\end{aligned}$$

and hence π also satisfies (3.5), which implies $W \succeq_{(2)} Y$ by Theorem 3.3.

Now suppose $W \succeq_{(2)} Y$. Then by Theorem 3.2 there exists $\pi \in \mathbb{R}_+^{ND}$ which satisfies (3.1)–(3.3). Then, (3.3) implies

$$\sum_{i=1}^{N} p_i \sum_{j=1}^{k-1} \pi_{ik} = \sum_{j=1}^{k-1} \sum_{i=1}^{N} p_i \pi_{ik} = \sum_{j=1}^{k-1} q_j$$

for $k = 2, \ldots, D$ and hence (4.1) holds. ∎

As a result, we obtain another formulation for SSDP, but more importantly we know that the linear programming relaxation of cFSD yields a bound at least as strong as the bound obtained from the SSDP relaxation.

Next, we illustrate the relationship between the formulation cFSD and FDMIP by presenting a derivation of cFSD based on strengthening FDMIP. In FDMIP, if $\beta_{ik} = 0$, then $w_i \ge y_k$. But, because $y_k > y_{k-1} > \cdots > y_1$, then we also know $w_i \ge y_{k-1} > \cdots > y_1$. Thus, we lose nothing by setting $\beta_{i,k-1} = \cdots = \beta_{i1} = 0$. Hence, we can add the inequalities

$$\beta_{ik} \le \beta_{i,k+1}, \qquad i \in \mathcal{N}, k \in \mathcal{D}, \tag{4.5}$$

and maintain a valid formulation. The inequalities (2.6) can then be replaced by

$$w_i - \sum_{k=1}^{D} (\beta_{i,k+1} - \beta_{ik}) y_k \ge 0, \qquad i \in \mathcal{N},$$

which together with inequalities (4.5) ensure that when $\beta_{ik} = 0$, we have $w_i \ge y_k$. We finally obtain the new formulation cFSD by substituting $\pi_{ik} = \beta_{i,k+1} - \beta_{ik}$ for $k \in \mathcal{D}$ and $i \in \mathcal{N}$, where $\beta_{i,D+1} = 1$.

5. Branching and heuristics for FSDP. cFSD yields a mixed-integer programming formulation for FSDP. Moreover, if X is a polyhedron and $g(x, \xi^i)$ are affine in x for each i, then cFSD is a mixed-integer *linear* programming formulation. As has been shown in [25], the optimal value of SSDP yields a good bound on the optimal value of FSDP, and hence the bound obtained from relaxing integrality in cFSD should be good. In addition, because of the compactness of cFSD, this bound can be calculated efficiently. However, we have found that the default settings in the MIP solver we use (Ilog CPLEX 9.0 [14]) do not effectively generate good feasible solutions

for cFSD. In addition, the default branching setting does not help to find feasible solutions or effectively improve the relaxation bounds. In this section we present a specialized branching approach and two heuristics which exploit the structure of this formulation. The computational benefits of these techniques will be demonstrated in section 6.

5.1. Branching for FSDP. Standard variable branching for mixed-integer programming would select a variable π_{ij} which is fractional in the current node relaxation solution, and then branch to create two new nodes, one with π_{ij} fixed to one and one with π_{ij} fixed to zero. However, the constraints (3.1) and (3.2) imply that for a fixed i, the set of variables π_{ij} for $j \in \mathcal{D}$ are essentially selecting which value level y_j the variable w_i should be greater than. In particular, the set of variables $\{\pi_{ij} : j \in \mathcal{D}\}$ is a *special order set of type* 1 (SOS1), that is, at most one of the variables in this set can be positive. As a result, it is natural to consider using an SOS1 branching rule (see, e.g., [2]). In this branching scheme, we select a *set index* $i \in \mathcal{N}$, specifying which special ordered set to branch on, and also choose a *level index* $k \in \{2, \dots, D\}$. Then in the first branch the constraint $\sum_{j<k} \pi_{ij} = 0$ is enforced and in the second branch $\sum_{j<k} \pi_{ij} = 1$ is enforced. In an implementation, the first condition is enforced by changing the upper bound on the variables π_{ij} to zero for $j < k$, and the second condition is enforced by changing the upper bound on the variables π_{ij} to zero for $j \geq k$.

To specify an SOS1 branching rule, we must state how the set and level indices are chosen. Our branching scheme is based on attempting to enforce the feasibility condition (2.5),

$$\mu\{W < y_k\} \leq \nu\{Y \leq y_{k-1}\}, \qquad k \in \mathcal{D}.$$

At each node in which we must branch, we find $k^* = \min\{k \in \mathcal{D} : \mu\{W < y_k\} > \nu\{Y \leq y_{k-1}\}\}$ based on the values of w in the current relaxation solution. Note that if such a k^* does not exist, then we have $W \succeq_{(1)} Y$, so the current solution is feasible. In this case, if π is not integer feasible (which may happen), then we construct an integer feasible solution of the same cost as in the proof of Theorem 4.1, and as a result, branching is not required at this node. We will take k^* to be the level index on which we will branch. Note that (3.1) and (3.2) imply that $w_i \geq y_1$ for all i in any relaxation solution, so that $k^* \geq 2$, making it an eligible branching level index.

We next choose a set index $i \in \mathcal{N}$ such that

$$w_i < y_{k^*}, \tag{5.1}$$

$$\sum_{j<k^*} \pi_{ij} < 1. \tag{5.2}$$

We claim that such an index must exist. Indeed, let $\Omega_{k^*} = \{i \in \mathcal{N} : w_i < y_{k^*}\}$. By the definition of k^* we have $\sum_{i\in\Omega_{k^*}} p_i > \sum_{j=1}^{k-1} q_j$, and so, in particular, $\Omega_{k^*} \neq \emptyset$. If there were no $i \in \Omega_{k^*}$ which also satisfies (5.2), then we would have

$$\sum_{i=1}^{N} p_i \sum_{j=1}^{k^*-1} \pi_{ij} \geq \sum_{i\in\Omega_{k^*}} p_i > \sum_{j=1}^{k^*-1} q_j,$$

violating (4.1). If there are multiple set indices which satisfy (5.1) and (5.2), we choose an index which maximizes the product $(y_{k^*} - w_i)(1 - \sum_{j<k^*} \pi_{ij})$. In the

first branch, we enforce $\sum_{j<k^*} \pi_{ij} = 0$, which by (3.1) forces $w_i \geq y_{k^*}$. Because of (5.1), this will make the current relaxation solution infeasible to this branch, and will promote feasibility of (2.5) at the currently infeasible level k^*. In the second branch, we enforce $\sum_{j<k^*} \pi_{ij} = 1$, which because of (5.2) will make the current relaxation solution infeasible for this branch. The motivation for this choice of set index i is to make progress in both of the branches. The motivation for the choice of level index k^* is that in the first branch progress toward feasibility of (2.5) is made, whereas by selecting k^* as small as possible, reasonable progress is also made in the second branch since this enforces $\pi_{ij} = 0$ for all $j \geq k^*$.

5.2. Heuristics for FSDP. We now present some heuristics we have developed that can be used with formulation cFSD. We first present a simple and efficient heuristic, called the *order-preserving heuristic,* and then present a variant of a diving heuristic which can be integrated with the order-preserving heuristic.

Order-preserving heuristic. Given a solution x^* to a relaxation of cFSD, let $w^* \in \mathbb{R}^N$ be the vector given by $w_i^* = g(x^*, \xi^i)$ for $i \in \mathcal{N}$. The idea behind the order-preserving heuristic is to use w^* as a guide to build a solution $\hat{\pi} \in \{0,1\}^{ND}$ which satisfies (3.2) and (4.1), and then solve the problem with π fixed to $\hat{\pi}$. If this problem is feasible, it yields a feasible solution to cFSD. The heuristic is *order-preserving* because it chooses $\hat{\pi}$ in such a way that if $w_i^* < w_{i'}^*$, then $\sum_{j\in\mathcal{D}} y_j \hat{\pi}_{ij} \leq \sum_{j\in\mathcal{D}} y_j \hat{\pi}_{i'j}$, so that the constraints (3.4) obtained with this $\hat{\pi}$ enforce lower bounds on $g(x, \xi^i)$ which are consistent with the ordering of $w_i^* = g(x^*, \xi^i)$ obtained from the current relaxation solution. The order-preserving heuristic is given in Algorithm 1. The algorithm begins by sorting the values of w^*. Then, in lines 2 to 8 a solution $\hat{\pi}$ is constructed which is feasible to (3.2) and (4.1) by working in this order. To see that $\hat{\pi}$ satisfies (3.2), observe that the algorithm will terminate with $t = N+1$, since when $k = D$, $\sum_{j=1}^{t} p_{i_j} \leq \sum_{j=1}^{D} q_j$ for all $t \leq N$, so the loop on line 4 will terminate only when $t > N$. Since $\{i_1, \ldots, i_N\} = \mathcal{N}$, this implies that for each $i \in \mathcal{N}$, there is some k such that the algorithm sets $\hat{\pi}_{ik} = 1$. The condition $\sum_{j=1}^{t} p_{i_j} \leq \sum_{j=1}^{k} q_j$ in line 4

Algorithm 1. Order-preserving heuristic

Data: $w^* \in \mathbb{R}^N$

1 Sort w^* to obtain $\{i_1, \ldots, i_N\} = \mathcal{N}$ with $w_{i_1}^* \leq w_{i_2}^* \leq \cdots \leq w_{i_N}^*$;
2 Set $t := 1$ and $\hat{\pi}_{ij} := 0$ for all $i \in \mathcal{N}, j \in \mathcal{D}$;
3 **for** $k := 1$ **to** D **do**
4 **while** $t \leq N$ **and** $\sum_{j=1}^{t} p_{i_j} \leq \sum_{j=1}^{k} q_j$ **do**
5 $\hat{\pi}_{i_t k} := 1$;
6 $t := t + 1$;
7 **end**
8 **end**
9 Solve cSSD($\hat{\pi}$) $= \max_x \{f(x) : x \in X, g(x, \xi_i) \geq \sum_{j=1}^{D} \hat{\pi}_{ij} y_j \ i \in \mathcal{N}\}$;
10 **if** cSSD($\hat{\pi}$) *is feasible* **then**
11 Let $\hat{x}$ be the optimal solution to cSSD($\hat{\pi}$);
12 **return** $(\hat{x}, \hat{\pi})$;
13 **end**

ensures that (4.1) holds for $\hat{\pi}$, since it ensures that for each $k \in \mathcal{D}$,

$$\sum_{j=1}^{k} \sum_{i=1}^{N} p_i \hat{\pi}_{ij} = \sum_{j=1}^{t(k)} p_{i_j},$$

where $t(k) = \max\{t : \sum_{j=1}^{t} p_{i_j} \leq \sum_{j=1}^{k} q_j\}$.

The main work done in Algorithm 1 is the sorting of w^* and the solving of cSSD($\hat{\pi}$). Note that this problem is small relative to the original problem cFSD, since the $O(ND)$ variables π are fixed, the constraints (3.2) and (4.1) no longer need to be considered, and the constraints (3.4) reduce to lower bounds on the functions $g(x, \xi^i)$ for $i \in \mathcal{N}$.

Integrated order-preserving and diving heuristic. Diving is a classic heuristic strategy for integer programs which alternates between fixing one or more integer variables based on the current linear programming (LP) relaxation solution and resolving the relaxation. We have developed a variant of the diving heuristic for solving cSSD which we call the *aggressive diving heuristic*. For brevity, we only outline the idea of the heuristic here; for details, we refer the reader to [19]. Within each iteration of the aggressive diving heuristic, the heuristic repeatedly selects the index $i \in \mathcal{N}$ which has minimum value of $w_i^* = g(x^*, \xi^i)$ and has not yet had π_{ij} fixed to one for any $j \in \mathcal{D}$. A variable π_{ik} is then fixed to one, where k is the minimum index such that π_{ik} could feasibly be fixed to one and still satisfy (4.1). This is done until one of the fixings causes inequality (3.4) to be violated by the current solution, that is, until a π_{ik} is fixed to one with $w_i^* < y_k$. Also within an iteration, a similar sequence of fixings is done for indices $i \in \mathcal{N}$ which have *maximum* value of w_i^* until one of the fixings implies (3.4) is violated by the current solution. After these fixings have been done, the LP relaxation is resolved, and the next iteration begins. The heuristic terminates when the current LP relaxation yields a feasible integer solution or is infeasible (where infeasibility would be caused by the lower bounds implied by (3.4) due to the fixed variables). The key advantages of the aggressive diving heuristic are that it fixes multiple variables in each iteration, leading to faster convergence, and that the variables are fixed in such a way that constraints (3.2) and (4.1) will not become violated.

Integration of the order-preserving heuristic with the aggressive diving heuristic is accomplished by calling the order-preserving heuristic during each iteration of the diving heuristic, using the current relaxation solution. If this yields an improved feasible solution, it is saved, but the heuristic still continues the dive until it terminates. At the end, the best feasible solution found over all iterations in the dive is reported.

6. Computational results. We conducted computational experiments to test the new formulations for stochastic dominance. Following [17] and [25], we conducted tests on a portfolio optimization problem with stochastic dominance constraints. In this problem, we wish to choose the fraction of our investment to invest in n different assets. The return of asset j is a random variable given by R_j with $\mathbb{E}[R_j] = r_j$. We are also given a reference random variable Y, and the objective is to maximize the expected return subject to the constraint that the random return we achieve stochastically dominates Y. Thus, the portfolio optimization problems we consider are

$$\max\left\{\sum_{j=1}^{n} r_j x_j : \; x \in X, \; \sum_{j=1}^{n} R_j x_j \succeq_{(k)} Y\right\}, \qquad k = 1, 2, \tag{6.1}$$

where $X = \{x \in \mathbb{R}^n_+ : \sum_{j=1}^n x_j = 1\}$.

We constructed test instances using the daily returns of 435 stocks ($n = 435$) in the S&P 500, for which daily return data was available from January 2002 through March 2007. We take each daily return as an outcome that occurs with equal probability. For each desired number of outcomes N, we constructed three instances by taking the N daily returns immediately preceding March 14 of the years 2005, 2006, and 2007. For example, the instance for the year 2007 with $N = 100$ is obtained by taking the daily returns in the days from November 16, 2006 through March 14, 2007.

For the reference random variable Y, we use the returns that would be obtained by investing an equal fraction in each of the available assets. That is, we take $Y = \sum_{j=1}^n R_j/n$. Hence, if R^i_j is the return that is achieved under outcome i for asset j, then the distribution of Y is given by $\nu\{Y = \sum_{j=1}^n R^i_j/n\} = 1/N$ for $i \in \mathcal{N}$. Note that in this case, the number of outcomes of Y is the same as the number of outcomes of R, i.e., $D = N$. This is an extreme case: in many settings we would expect D to be significantly less than N. However, this extreme case will yield challenging instances for comparing the formulations.

We used CPLEX 9.0 [14] to solve the LP and MIP formulations, and all experiments were done on a computer with two 2.4 GHz processors (although no parallelism is used) and 2.0 GB of memory. The specialized heuristics and branching for FSDP were implemented using callback routines provided by the CPLEX callable library.

6.1. Second-order dominance. We first compared the solution times using the formulations SDLP, cSSD1, and cSSD2 to solve the portfolio optimization problem (6.1) with SSD constraint ($k = 2$ in (6.1)). We tested seven different sizes N and three instances for each size. These linear programs were solved using the dual simplex method (the default CPLEX setting), and a time limit of 100,000 seconds was used. Table 6.1 gives the solution time and number of simplex iterations for each formulation

TABLE 6.1

on each instance. From this table it is clear that when using a commercial LP solver, the new formulations cSSD1 and cSSD2 allow for a much more efficient solution of SSDP. Formulation cSSD1 yields a solution an order of magnitude faster than SDLP, whereas cSSD2 yields a solution roughly two orders of magnitude faster. Both formulations cSSD1 and cSSD2 have $O(N)$ rows as opposed to $O(ND) = O(N^2)$ rows in SDLP, leading to a significantly reduced basis size, so that the time per iteration using these formulations is significantly less. The additional reduction in computation time obtained from formulation cSSD2 can be explained by the large reduction in the number of simplex iterations.

We should stress that because $N = D$ in this test, the relative improvement of cSSD1 and cSSD2 over SDLP is likely the best case. For instances in which D is of much more modest size, such as $D = 10$, we would not expect such an extreme difference.

6.2. First-order dominance. We next present results of the tests on the portfolio optimization problem (6.1) in which a first-order stochastic constraint is enforced ($k = 1$ in (6.1)).

We tested four solution methods for solving FSDP:

(i) FDMIP: Solve FDMIP with default CPLEX settings.

(ii) cFSD: Solve cFSD with default CPLEX settings and CPLEX SOS1 branching.

(iii) cFSD+H: Solve cFSD with CPLEX SOS1 branching and specialized heuristic.

(iv) cFSD+H+B: Solve cFSD with CPLEX, specialized heuristic, and specialized branching.

When solving cFSD with or without the heuristic (but not with the specialized branching), we declare the sets of variables $\{\pi_{ij} : j \in \mathcal{D}\}$ for $i \in \mathcal{N}$ as SOS1, allowing CPLEX to perform its general purpose SOS1 branching, as discussed in section 5.1. We found that this yields better results than having CPLEX perform its default single variable branching. Note that the specialized branching scheme also uses SOS1 branching, but crucially differs from the CPLEX implementation in the selection of the SOS1 set and level on which to branch.

The heuristic used in the last two methods is the aggressive diving heuristic integrated with the order-preserving heuristic. In our implementation, we call the heuristic at every node of depth less than five, at every fifth node for the first 100 nodes, at every 20th node between 100 and 1000 nodes, and at every 100th node thereafter. When the heuristic is used we turn off the CPLEX heuristics and preprocessing. The preprocessing was turned off for implementation convenience, but we found it had little effect for formulation cFSD anyway.

The specialized branching used in the last method is the branching strategy given in section 5.1. For this case, we set the CPLEX branching variable selection to select the most fractional variable since this takes the least time and we do not use CPLEX's choice of branching variable anyway.

We first compare the time required to solve the root linear program relaxations and the resulting lower bound from formulations FDMIP and cFSD. These results are given in Table 6.2. For formulation FDMIP we report the results before and after the addition of CPLEX cuts. The results obtained after the addition of CPLEX cuts are under the FDMIP.C column. For cFSD, we report only the results after the initial relaxation solution, because CPLEX cuts had little effect in this formulation. The columns under the heading "Percent above cFSD UB report the percent by which the

	300	43.5	298.6	732.6	11.12%	8.26%
	350	114.0	320.9	1060.7	10.80%	10.60%
	400	245.7	2010.8	3664.2	11.53%	11.02%

upper bound obtained from the relaxation of FDMIP with or without cuts, exceeds the upper bound obtained from the relaxation of cFSD. It is clear from Table 6.2 that the relaxation of formulation cFSD provides significantly better upper bounds in significantly less time.

We next tested how the different methods performed when run for a time limit of 10,000 seconds. Table 6.3 reports the optimality gap remaining after this time limit. All formulations were able to solve the 2006 instance with $N = 100$ in less than a minute, so this instance is excluded. Using formulation cFSD with the heuristic and specialized branching, 8 of the remaining 20 instances were solved to optimality within the time limit, and for these instances the solution time is reported (these are the instances with "-" in the "Gap" column). From Table 6.3 we observe that even without the use of specialized heuristic or branching formulation cFSD outperforms formulation FDMIP. However, in several instances cFSD fails to find a feasible solution, and in several others the optimality gaps for the feasible solutions found are quite bad. This is remedied to a significant extent by using the specialized heuristic, in which case a feasible solution is found for every instance, and in most cases it is within 2% of the upper bound. If, in addition, we use the specialized branching scheme, the final optimality gaps are reduced even further, with many of the instances being solved to optimality.

Table 6.4 gives more detailed results for the methods based on formulation cFSD for the 2005 instances (results for the other instances yield similar insights and are excluded for brevity). First, for each of these methods, the table indicates the percent by which the final upper bound ("UB" in the table) was below the initial upper bound obtained simply from solving the LP relaxation ("Root UB" in the table). These results indicate that by using CPLEX branching, with or without the specialized heuristic, very little progress is made in improving the upper bound through branching. In contrast, the specialized branching scheme improves the upper bound

considerably. Table 6.4 also reports the percent by which the value of the best feasible solution found ("LB" in the table) is below the best upper bound found over all methods ("Best UB" in the table). These results indicate that the specialized heuristic significantly improves the value of the feasible solutions found, and that integrating the specialized branching with the heuristic often yields even further improvement in solution quality.

7. Concluding remarks. More computational experiments need to be performed to test the effectiveness of the new formulations in different settings. For example, we tested the case in which the number of possible realizations of the reference random variable, D, is large. The case in which D is small should also be tested since this is likely the case when a stochastic dominance constraint is used to model a collection of risk constraints. It would be particularly interesting to test these formulations for radiation treatment planning models with dose-volume constraints. We expect that when D is small it will be possible to significantly increase the number of possible realizations, N, of the random vector appearing in the constraints. Another setting in which to test the new formulations is in two-stage stochastic programming with stochastic dominance constraints, as has been recently studied in [11, 12],

where they use the previous, less compact formulations for the stochastic dominance constraints.

Finally, it will be interesting to study a Monte Carlo sampling based approximation scheme for problems with stochastic dominance constraints that have more general distributions. Results on sample approximations for probabilistic constraints (e.g., [3, 20, 23]) may be applied to yield approximations for FSD constraints in which the random vector ξ appearing in the constraint may have general distribution. It will be interesting to explore whether the specific structure of the FSD constraint can yield results beyond direct application of the results for probabilistic constraints. Similarly, results on sample approximations for optimization problems with expected value constraints (e.g., [27, 28]) may be applied to yield approximations for second-order dominance constraints.

Acknowledgments. The author is grateful to Shabbir Ahmed for his helpful comments on a draft of this paper. The author also thanks Darinka Dentcheva, Andrzej Ruszczyński, and an anonymous referee for pointing out the connection between the SSD formulations presented and Strassen's theorem.

THE CONVEX ENVELOPE OF (N–1)-CONVEX FUNCTIONS*

MATTHIAS JACH†, DENNIS MICHAELS†, AND ROBERT WEISMANTEL†

Abstract. The question of determining strong convex underestimators for nonlinear functions is theoretically and practically of major interest. Unfortunately, results along these lines are quite limited as very few general procedures are at hand that can be applied to general classes of functions. In this paper we show how to reduce the question of determining a convex envelope to lower-dimensional optimization problems when the underlying function is indefinite and (n–1)-convex. Our structural result about this reduction technique enables us to give descriptions for the convex envelope of a variety of two-dimensional functions.

Key words. convex envelopes, (n–1)-convex functions, convex relaxations

AMS subject classifications. 52A27, 52A41

DOI. 10.1137/07069359X

1. Introduction. Many approaches for solving mixed-integer nonlinear optimization problems (MINLP) combine local search methods with algorithms to compute global bounds on convex relaxations of underlying feasible regions (e.g., [5, 2, 16, 1, 4, 13, 14]). Typically, convex relaxations are obtained by replacing all nonconvex terms in the original formulation by convex under- and concave overestimators, respectively. In order to derive strong bounds that allow one to verify the quality of known feasible solutions, tight estimators are necessary: the tighter the estimator, the tighter the bound. By definition, the tightest possible convex under- and concave overestimator of a general nonlinear function are called its envelopes. Despite this necessity of having convex and concave envelopes at hand, very little is known in the literature. The limited availability of formulae for the envelopes is due to the fact that the standard representation of envelopes is a nonconvex optimization problem that is intractable, in general. In the special case when a multivariate function is concave in one variable and convex in all the others, Tawarmalani and Sahinidis showed that the nonconvex optimization problem can be tackled using disjunctive programming techniques [11]. To the best of our knowledge, we are not aware of other general techniques in this direction. Indeed, the majority of results about convex envelopes apply to particular functions only. This includes continuously differentiable univariate functions [5], the product terms given by x_1x_2 [5, 2, 4, 10] and $x_1x_2x_3$ [6, 7], and the bivariate function given by x_1/x_2 [16, 11, 12]. The most involved functions for which the convex envelopes are determined analytically are affine transformations of x_1/x_2. The function $f : [\mathbf{l}, \mathbf{u}] \subseteq \mathbf{R}_{\geq 0} \times \mathbf{R}_{>0} \to \mathbf{R}$, $\mathbf{x} \mapsto x_1/x_2$ is convex in x_1 and x_2, but is not convex in both variables simulaneously, i.e., it is indefinite. Our main theorem applies precisely to functions of this type. It allows us to express the value of the convex envelope of such a function at a given point as an (n–1)-dimensional optimization problem. This result can, in turn, be used to determine new formulae for the convex envelopes of generalizations of the function $\mathbf{x} \mapsto x_1x_2$.

This paper is structured as follows: We begin by introducing the notation and recall some basic results from convex analysis in section 2. Our main result is given in section 3. Section 4 deals with computational aspects for evaluating the convex envelope for (n–1)-convex functions on a box. Section 5 is devoted to three interesting families of bivariate functions.

2. Preliminaries. Throughout this section we consider twice continuously differentiable functions $f : \mathbf{R}^n \to \mathbf{R}$ over a *convex compact* domain $D \subseteq \mathbf{R}^n$.

DEFINITION 2.1. *Let $D \subseteq \mathbf{R}^n$ be a convex compact subset, and let $f : D \to \mathbf{R}$ be a real-valued function.*

(a) *A function $\eta : \mathbf{R}^n \to \mathbf{R} \cup \{\pm\infty\}$ is called an* underestimator *(*overestimator*) of f on D if $\eta(\mathbf{x}) \le f(\mathbf{x})$ ($\eta(\mathbf{x}) \ge f(\mathbf{x})$) for all $\mathbf{x} \in D$. If η is, in addition, convex (concave) on D, then we call η a convex underestimator (concave overestimator).*

(b) *The tightest convex underestimator of f over D is called the* convex envelope*, denoted by $\mathrm{vex}_D[f]$, while the tightest concave overestimator of f over D is called* concave envelope*, denoted by $\mathrm{cave}_D[f]$. The envelopes are defined pointwise:*

$$\begin{aligned}\mathrm{vex}_D[f](\mathbf{x}) = \max\ \{&\eta(\mathbf{x}) \mid \eta : D \to \mathbf{R} \cup \{\pm\infty\} \text{ with}\\ &\eta(\mathbf{x}) \le f(\mathbf{x}) \text{ for all } \mathbf{x} \in D, \text{ and } \eta \text{ convex}\},\\ \mathrm{cave}_D[f](\mathbf{x}) = \min\ \{&\eta(\mathbf{x}) \mid \eta : D \to \mathbf{R} \cup \{\pm\infty\} \text{ with}\\ &\eta(\mathbf{x}) \ge f(\mathbf{x}) \text{ for all } \mathbf{x} \in D, \text{ and } \eta \text{ concave}\}.\end{aligned}$$

In the following, we recall some basic facts from convex analysis that are required for subsequent sections of this paper.

First, we remark that deriving the envelopes for a function is quite hard, in general. To see this, consider the following representation of the convex envelope that is used in [9]:

$$\mathrm{vex}_D[f](\mathbf{x}) = \min\ \{\mu \mid (\mathbf{x}, \mu) \in \mathrm{conv}(\mathrm{epi}_D[f])\}, \tag{2.1}$$

where $\mathrm{epi}_D[f] := \{(\mathbf{x}, \mu) \in \mathbf{R}^{n+1} \mid \mu \ge f(\mathbf{x}),\ \mathbf{x} \in D\}$ denotes the *epigraph* of f on D.

The representation in formula (2.1) implies that evaluating the convex envelope of a function $f : D \subseteq \mathbf{R}^n \to \mathbf{R}$ at a single point $\mathbf{x} \in D$ requires solving the nonlinear optimization problem

$$\begin{aligned}\mathrm{vex}_D[f](\mathbf{x}) &= \min \mu\\ \text{s. t.} \sum_k \lambda_k \mathbf{x}^{\mathbf{k}} &= \mathbf{x},\\ \sum_k \lambda_k f(\mathbf{x}^{\mathbf{k}}) &= \mu,\\ \sum_k \lambda_k &= 1,\\ \lambda_k &\ge 0 \quad \forall\, k,\\ \mathbf{x}^{\mathbf{k}} &\in D \quad \forall\, k.\end{aligned} \tag{2.2}$$

Problem (2.2) is a highly nonconvex optimization model involving two types of variables: the convex multipliers $\lambda_k \in [0, 1]$ and the variable vectors $\mathbf{x}^{\mathbf{k}}$ representing

suitable points in D. By Caratheodory's theorem about the representation of points in a convex set (cf. Theorem 17.1 in [9]), it suffices to consider convex combinations of at most $(n+1)$ points $(\mathbf{x^k}, f(\mathbf{x^k}))$, $\mathbf{x^k} \in D$. In particular, such sets of points can be chosen to be affinely independent; i.e., to be simplices. In our analysis we are interested in special structured simplices given by the following definition.

DEFINITION 2.2. *Let $f : \mathbf{R}^n \to \mathbf{R}$ be a function restricted to a convex compact domain $D \subseteq \mathbf{R}^n$. For a point $\mathbf{x} \in D$, let $\mathbf{x^k} \in D$ and $\lambda_k \in \mathbf{R}_{\geq 0}$, $k = 1, \ldots, t$, with $\sum_{k=1}^{t} \lambda_k = 1$, be an optimal solution to problem* (2.2) *such that the points $(\mathbf{x^k}, f(\mathbf{x^k}))$ are vertices of a simplex S, and $\lambda_k > 0$ for all $k = 1, \ldots, t$, $t \leq n+1$. Then, for $\mathbf{x} \in D$, S is said to be* minimizing *w.r.t. problem* (2.2).

The next proposition is easy to prove.

PROPOSITION 2.3. *Consider a function $f : \mathbf{R}^n \to \mathbf{R}$ on a convex compact domain D. For a given point $\mathbf{x} \in D$, let S be a minimizing simplex w.r.t. problem* (2.2). *Then, each face $S' \subseteq S$ is a minimizing simplex for all points $\mathbf{x}' \in D$ contained in the relative interior of the projection of S' on D.*

Note that for each point contained in the projection of a simplex S as defined above, there is indeed a face S' whose projection contains the point in its relative interior.

In problem (2.2) we can restrict our attention to those points $(\mathbf{x^k}, f(\mathbf{x^k}))$ which are extreme points of $\mathrm{conv}(\mathrm{epi}_D[f])$. For a continuous function $f : D \subseteq \mathbf{R}^n \to \mathbf{R}$ on a convex compact domain D, let

$$\mathcal{G}_D^{\mathrm{vex}}[f] \;:=\; \{\mathbf{x} \mid (\mathbf{x}, \mathrm{vex}_D[f](\mathbf{x})) \text{ is an extreme point of } \mathrm{conv}(\mathrm{epi}_D[f])\}$$

be the *generating set of the convex envelope of f* on D (cf. [11, 12]). The next observation provides a sufficient condition under which a point $\mathbf{x} \in D$ does not belong to the generating set of its convex envelope.

OBSERVATION 1 (cf. Corollary 5 in [12]). *Let $f : \mathbf{R}^n \to \mathbf{R}$ be restricted to a convex compact subset $D \subseteq \mathbf{R}^n$. If there is a line segment $s \subseteq D$ such that $\mathbf{x}$ is contained in the* relative interior *$ri(s)$ and f is concave over $ri(s)$, then $\mathbf{x} \notin \mathcal{G}_D^{\mathrm{vex}}[f]$.*

Tawarmalani and Sahinidis use this observation in [11] to reduce the complexity of problem (2.2) for those functions

$$f :\; D = [\mathbf{l}, \mathbf{u}] \times [v, w] \;\subseteq\; \mathbf{R}^n \times \mathbf{R} \;\to\; \mathbf{R}, \qquad (\mathbf{x}, z) \;\mapsto\; f(\mathbf{x}, z),$$

which are concave in z, but convex whenever z is fixed. The reduction is possible because

$$\mathcal{G}_D^{\mathrm{vex}}[f] \;\subseteq\; \{(\mathbf{x}, v) \mid \mathbf{x} \in [\mathbf{l}, \mathbf{u}]\} \;\cup\; \{(\mathbf{x}, w) \mid \mathbf{x} \in [\mathbf{l}, \mathbf{u}]\}.$$

That is, the convex hull of the epigraph of f over $[\mathbf{l}, \mathbf{u}] \times [v, w]$ is the convex hull of the union of two convex epigraphs restricted to $z = v$ and $z = w$, respectively. Therefore, in problem (2.2) only one-dimensional simplices, i.e., segments, need to be considered.

Example 1. Consider the function $f : \mathbf{R}^2 \to \mathbf{R}$, $(x_1, x_2) \mapsto \frac{x_1}{x_2}$ on a box $D := [\mathbf{l}, \mathbf{u}] \subseteq \mathbf{R}_{\geq 0} \times \mathbf{R}_{>0}$. A description of its convex envelope has been provided in [11]. To obtain this description, problem (2.2) was reformulated as a univariate minimization problem. An analysis of this optimization problem yields a case distinction with expressions for the individual cases. Using the fact that the set of the concave directions is contained in $(\mathbf{R}^2_{\geq 0}) \cup (\mathbf{R}^2_{\leq 0})$ for every $\mathbf{x} \in D$, the description of

the convex envelope can be summarized in the following formula:

$$\begin{aligned}\operatorname{vex}_D[\tfrac{x_1}{x_2}](\mathbf{x}) = \; & \frac{u_1 - x_1}{u_1 - l_1} \frac{l_1}{\max\left(l_2, \frac{u_2 - x_2}{u_1 - x_1}(l_1 - x_1) + x_2, \frac{x_2\sqrt{l_1}(u_1 - l_1)}{(u_1 - x_1)\sqrt{l_1} + (x_1 - l_1)\sqrt{u_1}}\right)} \\ & + \frac{x_1 - l_1}{u_1 - l_1} \frac{u_1}{\min\left(\frac{x_2 - l_2}{x_1 - l_1}(u_1 - x_1) + x_2, u_2, \frac{x_2\sqrt{u_1}(u_1 - l_1)}{(u_1 - x_1)\sqrt{l_1} + (x_1 - l_1)\sqrt{u_1}}\right)}. \end{aligned} \tag{2.3}$$

From the representation in formula (2.3), one can immediately deduce that the graph of $\operatorname{vex}_D[\frac{x_1}{x_2}]$ is the union of segments. The first and second entries in the max- and min-terms correspond to solutions where one endpoint of the segment is given by a vertex of D, whereas taking the third entry in both terms yields the function first given in Theorem 2 of [15].

Our ability to derive a formula for the convex envelope of the function x_1/x_2 relied on the fact that problem (2.2) in this special case can be reduced to a series of optimization problems in lower dimension, each of which can be solved explicitly.

In the next section we will show that this phenomenon carries over to a much broader family of functions.

DEFINITION 2.4. *Let $f : \mathbf{R}^n \to \mathbf{R}$ be a twice differentiable function.*

(a) *f is said to be (strictly) (n–1)-convex if and only if for all $i \in \{1, \ldots, n\}$ the function $f|_{x_i = \bar{x}_i} : \mathbf{R}^{n-1} \to \mathbf{R}$ is (strictly) convex for each fixed value $\bar{x}_i \in \mathbf{R}$.*

(b) *If f is restricted to a convex domain D, then f is called indefinite (on D) if and only if for each $\mathbf{x} \in D$ the Hessian matrix $\mathcal{H}_f(\mathbf{x})$ is indefinite.*

(c) *The set of all concave directions of f at a point $\mathbf{x} \in D$ is denoted by $\gamma_f(\mathbf{x})$, i.e.,*

$$\gamma_f(\mathbf{x}) \; := \; \{\mathbf{y} \in \mathbf{R}^n \mid \mathbf{y}^\top \mathcal{H}_f(\mathbf{x})\mathbf{y} < 0\}.$$

Example 2.

(a) For integers $n \geq 2$, the family of quadratic functions $f_n : \mathbf{R}^n \to \mathbf{R}$ given by $f_n(x) := x^\top J_n x$, where $J_n \in \mathbf{R}^{n \times n}$ with

$$(J_n) \quad := \quad \begin{pmatrix} 2n-3 & -2 & -2 & \cdots & -2 \\ -2 & 2n-3 & -2 & \cdots & -2 \\ \vdots & & \ddots & & \vdots \\ -2 & \ldots\ldots & -2 & 2n-3 & -2 \\ -2 & \ldots\ldots\ldots & & -2 & 2n-3 \end{pmatrix},$$

is (n–1)-convex and indefinite on $\mathbf{R}^n$.

(b) The bivariate functions $f : \mathbf{R}^2 \to \mathbf{R}$ given by $f(x) := \exp(x_1 x_2)$ and $f(x) := x_1^p x_2^q$ (for $p, q \geq 1$) are 1-convex and indefinite on $\mathbf{R}^2_{\geq 0}$.

3. A structural result. It is the purpose of this section to provide a result which characterizes the convex envelope for further important classes of functions. More precisely, we show that for indefinite (n–1)-convex functions restricted to a box $[\mathbf{l}, \mathbf{u}] \subseteq \mathbf{R}^n$, the minimal value of convex combinations in problem (2.2) is already attained when only segments are chosen. To exclude pathological or trivial cases, we assume in the following that the dimension $n \geq 2$ and the box $[\mathbf{l}, \mathbf{u}] \subseteq \mathbf{R}^n$ is full-dimensional.

THEOREM 3.1. *Let $f : \mathbf{R}^n \to \mathbf{R}$ be an (n–1)-convex and indefinite function on $D := [\mathbf{l}, \mathbf{u}]$, and denote by $\mathcal{F}$ the union of all facets of the box D. Then*

(a) *the concave envelope of f over its domain is polyhedral, i.e., its generating set is finite,*

(b) *the convex envelope of f over its domain is given by the function $g : D \to \mathbf{R}$ which maps each vector $\mathbf{x} \in D$ to*

$$g(\mathbf{x}) := \min\{(1-\lambda)f(\mathbf{x}^1) + \lambda f(\mathbf{x}^2) \mid \mathbf{x}^i \in \mathcal{F},\ i = 1,2, \\ (1-\lambda)\mathbf{x}^1 + \lambda\mathbf{x}^2 = \mathbf{x},\ 0 \le \lambda \le 1\}. \tag{3.1}$$

Part (a) of Theorem 3.1 follows from Observation 1. Our proof for part (b) relies on the fact that concave directions are contained in a fixed pair of orthants for each point $\mathbf{x} \in [\mathbf{l}, \mathbf{u}]$. We show this result first.

LEMMA 3.2. *Let $f : D = [\mathbf{l}, \mathbf{u}] \to \mathbf{R}$ be a twice differentiable function, and let the collection $\{\mathcal{O}_1, \ldots, \mathcal{O}_{2^n}\}$ be the system of open orthants of the space $\mathbf{R}^n$. Then, the function f is (n–1)-convex and indefinite if and only if $\gamma_f(\mathbf{x})$ is nonempty for each $\mathbf{x} \in D$ and there exists an index $i \in \{1, \ldots, 2^n\}$ such that*

$$\forall\, \mathbf{x} \in D: \qquad \gamma_f(\mathbf{x}) \subseteq \mathcal{O}_i \cup (-\mathcal{O}_i).$$

Proof. Sufficiency of the condition is clear: If $\gamma_f(.)$ has the described properties, then f is indefinite and (n–1)-convex on D.

On the other hand, let f be indefinite and (n–1)-convex on D, and let $H = \mathcal{H}_f(\mathbf{x})$ be the Hessian matrix of f at an arbitrary point $\mathbf{x} \in D$.

We claim that H has precisely one negative eigenvalue λ_1. H being indefinite has at least one negative eigenvalue λ_1. If there were another nonpositive eigenvalue λ_2 or if λ_1 were not a simple root, then the space spanned by the corresponding eigenvectors would contain lines of concave directions of f intersecting a hyperplane $x_j = 0$ for some $j = 1, \ldots, n$ in a point different from $\mathbf{0}$. This would contradict the (n–1)-convexity.

Hence, λ_1 is the uniquely determined simple negative eigenvalue of H, to which we can assign the eigenvector $\mathbf{v^1}$, which in turn determines a pair $U(\mathbf{x}) := \mathcal{O}_i \cup (-\mathcal{O}_i)$ for some $i \in \{1, \ldots, 2^n\}$. From the argumentation above it follows that $\gamma_f(\mathbf{x}) \subseteq U(\mathbf{x})$.

We will now show that for all other points $\mathbf{x}' \in D$ the set $\gamma_f(\mathbf{x}')$ is contained in the union $U(\mathbf{x})$ just defined, and assume to the contrary that there exists a point $\mathbf{x}' \in D$ such that $\gamma_f(\mathbf{x}') \not\subseteq U(\mathbf{x})$. Furthermore, we consider the following composition $h : \mathbf{R}^n \to \mathbf{R}$, $\mathbf{y} \mapsto h(\mathbf{y}) := \psi(\phi(\mathbf{y}))$, where ϕ maps a point $\mathbf{y} \in D$ to the eigenvector $\mathbf{v^1}(\mathbf{y})$ associated with the negative eigenvalue of $\mathcal{H}_f(\mathbf{y})$ such that $v_1^1(\mathbf{y}) = 1$, and $\psi : \mathbf{R}^n \to \mathbf{R}$ takes the form

$$\psi : \mathbf{v} \quad \mapsto \quad \begin{cases} \min\{|v_2|, \ldots, |v_n|\} & \text{if } \mathbf{v} \in U(\mathbf{x}), \\ -\min\{|v_2|, \ldots, |v_n|\} & \text{otherwise.} \end{cases}$$

It is straightforward to check that both ϕ and ψ are continuous, and hence, h is continuous, too. For ϕ we point to the continuous dependency of the eigenvalues on the entries of a square matrix (see, e.g., [8]).

If $\mathbf{z}_\lambda := (1-\lambda)\mathbf{x} + \lambda\mathbf{x}'$ with $\lambda \in [0,1]$, then, by assumption, $h(\mathbf{z}_1) > 0$ and $h(\mathbf{z}_0) < 0$, and there is a number $\tilde{\lambda} \in (0,1)$ with $h(\mathbf{z}_{\tilde{\lambda}}) = 0$. This means that the eigenvector corresponding to the negative eigenvalue of $\mathcal{H}_f(\mathbf{z}_{\tilde{\lambda}})$ has a zero component and, hence, is contained in some coordinate plane. This is a contradiction to the property of (n–1)-convexity of f. ∎

We are now ready to prove Theorem 3.1.

Proof of Theorem 3.1. (a) Using Observation 1 and the identity $\mathrm{cave}_D[f] = -\mathrm{vex}_D[-f]$, one can easily check that the generating set of $\mathrm{cave}_D[f]$ is given by the set of the vertices of the domain $[\mathbf{l}, \mathbf{u}]$. Thus, $\mathrm{cave}_D[f]$ is polyhedral.

(b) First, note that the function f is indefinite on D. From Observation 1, it follows that the convex envelope of f is generated by points in $\mathcal{F}$ of D only; i.e., $\mathcal{G}_D^{\mathrm{vex}}[f] \subseteq \mathcal{F}$.

Next, we show the correctness of our claim for strictly $(n–1)$-convex functions. For this, assume that the value of $\mathrm{vex}_D[f]$ at a given point $\bar{\mathbf{x}} \in D$ is attained at a nontrivial convex combination of at least three different points $\mathbf{x^i} \in \mathcal{F}$; i.e.,

$$\mathrm{vex}_D[f](\bar{\mathbf{x}}) = \sum_{1 \le i \le k} \lambda_i f(\mathbf{x}^i), \text{ for some } \lambda_i > 0, \sum_{1 \le i \le k} \lambda_i = 1, \sum_{1 \le i \le k} \lambda_i \mathbf{x}^i = \bar{\mathbf{x}}, \ \mathbf{x}^i \in \mathcal{F},$$

with $k \ge 3$. It suffices to deduce a contradiction for a simplex generated by three vertices since, by Proposition 2.3, each triangular face of a minimizing simplex must be minimizing, too. Without loss of generality, we consider the triangle spanned by $\mathbf{x}^1, \mathbf{x}^2$, and $\mathbf{x}^3$. By symmetry, it suffices to investigate the following two cases:

- $\mathbf{x}^1 = (l_1, x_2^1, x_3^1, \dots)$, $\mathbf{x}^2 = (x_1^2, l_2, x_3^2, \dots)$, $\mathbf{x}^3 = (x_1^3, x_2^3, l_3, \dots)$,
- $\mathbf{x}^1 = (l_1, x_2^1, x_3^1, \dots)$, $\mathbf{x}^2 = (u_1, x_2^2, x_3^2, \dots)$, $\mathbf{x}^3 = (x_1^3, l_2, x_3^3, \dots)$.

Consider the difference vectors $\mathbf{d^{1,2}} := \mathbf{x^1} - \mathbf{x^2}$, $\mathbf{d^{2,3}} := \mathbf{x^2} - \mathbf{x^3}$, and $\mathbf{d^{3,1}} := \mathbf{x^3} - \mathbf{x^1}$. If one of the three difference vectors has a zero component, say $\mathbf{d^{1,2}}$, then the direction $\mathbf{d^{1,2}}$ is contained in a coordinate plane. Thus, f is strictly convex on the segment between $\mathbf{x^1}$ and $\mathbf{x^2}$. Otherwise, it is easy to check that two of the three difference vectors, say $\mathbf{d^{1,2}}$ and $\mathbf{d^{2,3}}$, are contained in two different pairs of open orthants. From Lemma 3.2, it follows that f is strictly convex on at least one of the segments between $\mathbf{x^1}$ and $\mathbf{x^2}$ or between $\mathbf{x^2}$ and $\mathbf{x^3}$.

In both cases there exist two vertices $(\mathbf{x^i}, f(\mathbf{x^i}))$ and $(\mathbf{x^j}, f(\mathbf{x^j}))$ of a minimizing simplex such that on the one hand f is strictly convex on the segment between $\mathbf{x^i}$ and $\mathbf{x^j}$, and on the other hand, the segment spanned by $(\mathbf{x^i}, f(\mathbf{x^i}))$ and $(\mathbf{x^j}, f(\mathbf{x^j}))$ is minimizing, again by Proposition 2.3. This is a contradiction. Thus, we conclude that for strictly $(n–1)$-convex functions there are no minimizing simplices with more than two vertices.

If f is not $(n–1)$-convex in the strict sense, then the sequence of strictly $(n–1)$-convex functions $f_m : \mathbf{R}^n \to \mathbf{R}$, given by $f_m(\mathbf{x}) := f(\mathbf{x}) + \frac{1}{m} \sum_{1 \le i \le n} x_i^2$, uniformly converges to f on D in the $\mathcal{C}^2$ norm. By the compactness of D, the functions f_m are indefinite provided that m is sufficiently large. Let

$$\mathrm{vex}_D[f_m](\mathbf{x}) = (1 - \lambda_m) f_m(\mathbf{x}_m^1) + \lambda_m f_m(\mathbf{x}_m^2), \quad \lambda_m \in [0, 1],$$

then, by the compactness of $\mathcal{F} \times \mathcal{F} \times [0, 1]$, there is a convergent subsequence $\{(\mathbf{x}_{m_k}^1, \mathbf{x}_{m_k}^2, \lambda_{m_k})\}_k$, yielding the statement for f. ∎

It is possible to extend Theorem 3.1 slightly to the case when f is indefinite on the interior of $[\mathbf{l}, \mathbf{u}]$. This extension can be shown by applying standard approximation techniques to the proof of Theorem 3.1. In fact, if we replace the box $[\mathbf{l}, \mathbf{u}]$ in Theorem 3.1 and in its proof by the sequence of boxes $[\mathbf{l} + \frac{1}{n}\mathbf{1}, \mathbf{u} - \frac{1}{n}\mathbf{1}]_n$, where $\mathbf{1} = (1, \dots, 1)^\top$, then we obtain the desired extension. Due to this observation we will use the expression *indefinite on* $[\mathbf{l}, \mathbf{u}]$ also in this more general sense.

4. Computing minimizing segments. In this section we will show that determining the value of the convex envelope of an (n–1)-convex indefinite function $f : [\mathbf{l}, \mathbf{u}] \to \mathbf{R}$ at a given point $\mathbf{x}$ is computationally tractable.

We first remark that if the given point $\mathbf{x}$ is contained in a facet of $[\mathbf{l}, \mathbf{u}]$, i.e., $\mathbf{x} \in \mathcal{F}$ (cf. Theorem 3.1), then, since f is convex on each facet, $\mathrm{vex}_{[\mathbf{l},\mathbf{u}]}[f](\mathbf{x}) = f(\mathbf{x})$.

In the following, let $\mathbf{x} \in [\mathbf{l}, \mathbf{u}] \setminus \mathcal{F}$ be given. By Theorem 3.1, we have to find a segment through $\mathbf{x}$ which has endpoints in $\mathcal{F}$ and provides an optimal solution for problem (2.2). We can classify the set of all segments through $\mathbf{x}$ into subsets where each subset consists of all segments connecting the same two facets of $[\mathbf{l}, \mathbf{u}]$.

The idea is to identify a minimizing segment in each class of segments and to determine the overall minimizing segment afterwards. From both a geometric and a computational point of view we distinguish the following two cases: subsets of segments connecting opposite facets of $[\mathbf{l}, \mathbf{u}]$ (*parallel case*) and subsets of segments connecting adjacent facets of $[\mathbf{l}, \mathbf{u}]$ (*nonparallel case*).

First, we consider the parallel case. Here, computing minimizing segments is similar to the case described in [11] where $f : \mathbf{R}^n \to \mathbf{R}$ is assumed to be convex in the first (n–1) variables, but concave in the last variable.

The proof is based on a reformulation technique following the method used in [11].

Observation 2 (parallel case). *Let $f : [\mathbf{l}, \mathbf{u}] \to \mathbf{R}$ be an (n–1)-convex indefinite function. For a given point $\mathbf{x} \in [\mathbf{l}, \mathbf{u}] \setminus \mathcal{F}$, computing a minimizing segment with endpoints in parallel facets gives rise to a convex optimization problem.*

Proof. Let $\mathbf{x} \in [\mathbf{l}, \mathbf{u}] \setminus \mathcal{F}$ be given. Without loss of generality, we consider the set of all segments through $\mathbf{x}$ that connect the two facets of $[\mathbf{l}, \mathbf{u}]$ given by $x_1 = l_1$ and $x_1 = u_1$. Denote by $\mathbf{a}, \mathbf{b}$ the endpoints of such a segment where $a_1 = l_1$ and $b_1 = u_1$. The corresponding subproblem of problem (2.2) reads as

$$\min\ \lambda f(\mathbf{a}) + (1-\lambda) f(\mathbf{b}) \quad \text{s.t.} \quad \lambda \mathbf{a} + (1-\lambda)\mathbf{b} = \mathbf{x}, \quad \mathbf{l} \le \mathbf{a}, \mathbf{b} \le \mathbf{u}. \tag{4.1}$$

The condition $x_1 = \lambda a_1 + (1-\lambda) b_1 = \lambda l_1 + (1-\lambda) u_1$ implies that $\lambda = (u_1 - x_1)/(u_1 - l_1) \in (0, 1)$. Replacing the variable λ in problem (4.1) by the expression $(u_1 - x_1)/(u_1 - l_1)$ results in a convex objective function which is minimized over linear constraints. ∎

If f is assumed to be strictly (n–1)-convex, then an optimal solution to (4.1) of Observation 2 is easily seen to be uniquely determined.

Next, we consider the nonparallel case. As we will see, in this case the underlying optimization problem can be analyzed elegantly using the notion of unimodal functions.

Definition 4.1. *A differentiable function $f : D \to \mathbf{R}$, D convex, is said to be* unimodal *if there are no critical points other than global minima and if the set of all global minima of f on D is convex.*

In order to prepare the general analysis, we first discuss a convex formulation for the minimization problem in the bivariate case.

Lemma 4.2. *Let $f : [\mathbf{l}, \mathbf{u}] \subseteq \mathbf{R}^2 \to \mathbf{R}$ be a 1-convex indefinite function. For a given point $\mathbf{x} \in [\mathbf{l}, \mathbf{u}] \setminus \mathcal{F}$, computing a minimizing segment with endpoints in adjacent facets can be stated as a minimization problem of a unimodal function.*

Proof. Without loss of generality, we consider a 1-convex function on a box $[\mathbf{l}, \mathbf{u}]$, and assume that a given point $\mathbf{x}$ in the interior of $[\mathbf{l}, \mathbf{u}]$ is contained in a segment with endpoints (y, l_2) and (l_1, z). From the conditions $x_1 = \lambda y + (1-\lambda) l_1$ and $x_2 = \lambda l_2 + (1-\lambda) z$, we can deduce the following formulation of the problem of finding

a minimizing segment:

$$\begin{aligned} \min \quad & \phi(\lambda) := \lambda f\left(\frac{1}{\lambda}(x_1-(1-\lambda)l_1), l_2\right) + (1-\lambda) f\left(l_1, \frac{1}{1-\lambda}(x_2-\lambda l_2)\right) \\ \text{s.t.} \quad & \frac{1}{\lambda}(x_1-(1-\lambda)l_1) \in [l_1,u_1],\ \frac{1}{1-\lambda}(x_2-\lambda l_2) \in [l_2,u_2],\ 0<\lambda<1. \end{aligned} \tag{4.2}$$

The function ϕ is convex on the feasible set of (4.2), since the second derivative satisfies

$$\phi''(\lambda) = \frac{(x_1-l_1)^2}{\lambda^3}\frac{\partial^2 f}{\partial x_1^2}\left(\frac{x_1-(1-\lambda)l_1}{\lambda}, l_2\right) + \frac{(x_2-l_2)^2}{(1-\lambda)^3}\frac{\partial^2 f}{\partial x_2^2}\left(l_1, \frac{x_2-\lambda l_2}{1-\lambda}\right) \geq 0.$$

Considering the parameter λ as a function of y via $\lambda = \frac{x_1-l_1}{y-l_1}$, we obtain

$$\frac{\mathrm{d}\phi}{\mathrm{d}y}(\lambda(y)) = -\frac{\mathrm{d}\phi}{\mathrm{d}\lambda}(\lambda)\frac{x_1-l_1}{(y-l_1)^2},$$

and deduce that the parameter λ and the corresponding value of y minimize the segment value simultaneously. Furthermore, we see that except for global minima, the derivative $\frac{\mathrm{d}\phi}{\mathrm{d}y}$ is not equal to 0, and that the segment value between two global minima remains constant, showing the convexity. ∎

We notice that, if f is strictly 1-convex, then its second partial derivatives $\frac{\partial^2 f}{\partial x_1^2}$ and $\frac{\partial^2 f}{\partial x_2^2}$ do not vanish on any nondegenerate interval. Then the same is true for $\phi''(\lambda)$; i.e., ϕ is strictly convex, and the minimal value is attained at a uniquely determined solution.

In the general $(n$–$1)$-convex case, we consider the problem of finding a minimizing segment with endpoints in adjacent facets $F_1,\ F_2$ for a given point $\mathbf{x} \in [\mathbf{l},\mathbf{u}] \setminus \mathcal{F}$. If we let a point $\mathbf{y} \in F_1$ vary as one endpoint of the segment such that the second one $\mathbf{z} \in F_2$ is uniquely determined, then the minimization problem can be stated as

$$\begin{aligned} \min \quad & \phi(\mathbf{y}) := \lambda(\mathbf{y}) f(\mathbf{y}) + (1-\lambda(\mathbf{y})) f(\mathbf{z}(\mathbf{y})) \\ \text{s.t.} \quad & \mathbf{y} \in F_1, \mathbf{z}(\mathbf{y}) \in F_2, \\ & \mathbf{x} = \lambda(\mathbf{y})\mathbf{y} + (1-\lambda(\mathbf{y}))\mathbf{z}(\mathbf{y}). \end{aligned} \tag{4.3}$$

The set of feasible vectors $\mathbf{y}$ is the intersection of the face F_1 and the pointed cone with vertex $\mathbf{x}$ and directions $\{\mathbf{x}-\mathbf{v} \mid \mathbf{v} \text{ is a vertex of } F_2\}$, and hence a convex set.

We are now prepared to prove the following lemma.

LEMMA 4.3 (nonparallel case). *Let $f : [\mathbf{l},\mathbf{u}] \to \mathbf{R}$ be an $(n$–$1)$-convex, indefinite function. The function ϕ defined in* (4.3) *is unimodal on its domain.*

Proof. First, we show that all critical points are global minima. Let $\mathbf{y^0}$ be a critical point and $\mathbf{y^1}$ be another feasible vector in (4.3). If $\lambda(\mathbf{y^0}) = \lambda(\mathbf{y^1})$, then ϕ is convex on the segment $[\mathbf{y^0},\mathbf{y^1}]$ according to Observation 2; therefore, $\phi(\mathbf{y^0}) \leq \phi(\mathbf{y^1})$. In the case of $\lambda(\mathbf{y^0}) \neq \lambda(\mathbf{y^1})$, we consider ϕ on the one-dimensional segment $[\mathbf{y^0},\mathbf{y^1}]$, which, together with the segment $[\mathbf{z}(\mathbf{y^0}),\mathbf{z}(\mathbf{y^1})]$, can be embedded in $\mathbf{R}^2$ yielding a univariate function $\hat{\phi}(y) := \lambda(y)f(y)+(1-\lambda(y))f(z(y))$ on the segment $[y_0,y_1]$, where y_0 and y_1 correspond to $\mathbf{y_0}$ and $\mathbf{y_1}$, respectively. From the discussion of the bivariate case it follows that $\hat{\phi}(y_0) \leq \hat{\phi}(y_1)$ and hence $\phi(\mathbf{y^0}) \leq \phi(\mathbf{y^1})$.

Next, let $\mathbf{y}^0$ and $\mathbf{y}^1$ be two global minima of ϕ. Performing the case distinction $\lambda(\mathbf{y^0}) = \lambda(\mathbf{y^1})$ and $\lambda(\mathbf{y^0}) \neq \lambda(\mathbf{y^1})$ as outlined before allows us to draw the conclusion that the set of global minima of ϕ is convex. ∎

Observation 2 and Lemma 4.3 show that the value of the convex envelope of an (n–1)-convex indefinite function restricted to a box at a given point can be computed using standard numerical solvers. Moreover, once the endpoints $(\mathbf{y}, f(\mathbf{y}))$, $(\mathbf{z}, f(\mathbf{z}))$ of a minimizing segment for $\mathbf{y} \in [\mathbf{l}, \mathbf{u}]$ have been found, the intersection of the subdifferentials of f at $\mathbf{y}$ and $\mathbf{z}$ when f is restricted to the corresponding facets of $[\mathbf{l}, \mathbf{u}]$ yield feasible normals for any supporting hyperplane at $(\mathbf{x}, \mathrm{vex}_{[\mathbf{l},\mathbf{u}]}[f](\mathbf{x}))$.

In the next section we will describe the convex envelopes of some interesting families of bivariate functions by investigating the reduced nonlinear optimization problem (3.1) of Theorem 3.1.

In doing so, we will implicitly make use of the fact that in these cases for a given point $\mathbf{x} \in [\mathbf{l}, \mathbf{u}]$ a segment can be minimizing only if its direction is contained in $\gamma_f(\mathbf{x})$. By Lemma 3.2, for all $\mathbf{x} \in [\mathbf{l}, \mathbf{u}]$, the sets $\gamma_f(\mathbf{x})$ are contained in one fixed pair of orthants. This allows us to restrict our attention to such segments fitting the underlying orthant pattern only. For the purpose of illustration, consider the bivariate functions on $\mathbf{R}^2_{\geq 0}$ given by $f(\mathbf{x}) := \frac{x_1}{x_2}$ (cf. Example 1) and $f(\mathbf{x}) := \exp(x_1 x_2)$ (cf. Example 3). It is easy to check that

$$\gamma_{\frac{x_1}{x_2}}(\mathbf{x}) \subseteq (\mathbf{R}^2_{\geq 0} \cup \mathbf{R}^2_{\leq 0}) \quad \text{and} \quad \gamma_{\exp(x_1 x_2)}(\mathbf{x}) \subseteq (\mathbf{R}_{\geq 0} \times \mathbf{R}_{\leq 0}) \cup (\mathbf{R}_{\leq 0} \times \mathbf{R}_{\geq 0}).$$

In Figure 4.1(a) and (b), different types of segments through a point $\mathbf{x}$ are shown. The solid segments are possible candidates to minimize since they are contained in the pair of orthants predetermined by $\gamma_f(\mathbf{x})$. The dashed segments do not respect the orthant pattern w.r.t. $\gamma_f(\mathbf{x})$, and can be excluded from further consideration.

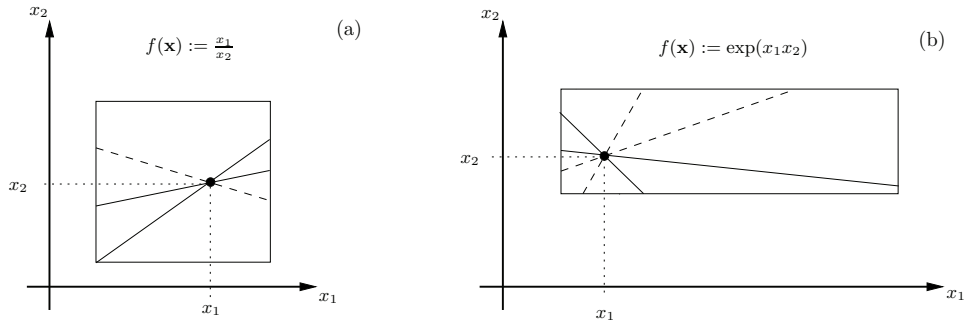

FIG. 4.1. *For the functions given by* $f(\mathbf{x}) := \frac{x_1}{x_2}$ *(cf.* (a) *and Example* 1*) and* $f(\mathbf{x}) := \exp(x_1 x_2)$ *(cf.* (b) *and Example* 3*), the figures show different types of segments connecting points of the facets of the domain* $[\mathbf{l}, \mathbf{u}]$.

5. Application to the bivariate case. Using our results presented in sections 3 and 4, we will investigate three different families of bivariate functions. Each of them can be considered as a generalization of the product term $x_1 x_2$, for which the convex envelope on a box $[\mathbf{l}, \mathbf{u}] \subseteq \mathbf{R}^2$ is well known (cf. [5, 2]):

$$\mathrm{vex}_{[\mathbf{l},\mathbf{u}]}[x_1 x_2](\mathbf{x}) = \max(l_2 x_1 + l_1 x_2 - l_1 l_2, u_2 x_1 + u_1 x_2 - u_1 u_2). \tag{5.1}$$

PROPOSITION 5.1. *Let* $g : \mathbf{R}_{\geq 0} \to \mathbf{R}$ *be a convex and strictly increasing function. Then the function* $f : \mathbf{R}^2_{\geq 0} \to \mathbf{R}$, $\mathbf{x} \mapsto g(x_1 x_2)$, *is* 1*-convex and indefinite. If* f *is*

restricted to a box $[\mathbf{l},\mathbf{u}] \subseteq \mathbf{R}^2_{\geq 0}$*, then on the subset* $R_1 \cup R_2 \subseteq [\mathbf{l},\mathbf{u}]$*, given by*

$$\begin{aligned} R_1 &:= \{(x_1,x_2) \in D \mid l_i x_j \leq -l_j(x_i - l_i) + l_i u_j\}, \\ R_2 &:= \{(x_1,x_2) \in D \mid u_i x_j \geq -u_j(x_i - u_i) + u_i l_j\}, \end{aligned} \tag{5.2}$$

where $l_i u_j \leq u_i l_j$ *for* $(i,j) \in \{(1,2),(2,1)\}$ *(see Figure* 5.1*), we have*

$$\operatorname{vex}_{[\mathbf{l},\mathbf{u}]}[f](\mathbf{x}) = f(\max(l_2 x_1 + l_1 x_2 - l_1 l_2, u_2 x_1 + u_1 x_2 - u_1 u_2)) =: f^*(\mathbf{x}). \tag{5.3}$$

Moreover, for each point $\mathbf{x} \in R_3 := [\mathbf{l},\mathbf{u}] \setminus (R_1 \cup R_2)$*, the relative interior of the projection of the associated minimizing segment is contained in* R_3*, and the endpoints are contained in parallel facets of* $[\mathbf{l},\mathbf{u}]$*.*

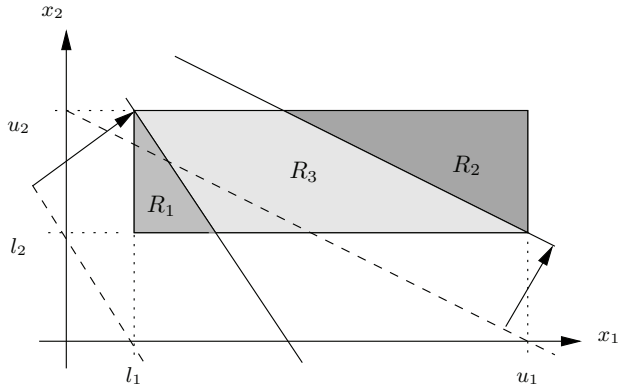

FIG. 5.1. *Subdivision of a box* $[\mathbf{l},\mathbf{u}] \subseteq \mathbf{R}^2_{\geq 0}$ *(with* $l_1 u_2 < u_1 l_2$*) into three regions with respect to different expressions of the convex envelope of functions* $f : \mathbf{R}^2_{\geq 0} \to \mathbf{R}$ *given by* $f(\mathbf{x}) := g(x_1 x_2)$*, where* $g : \mathbf{R}_{\geq 0} \to \mathbf{R}$ *is convex and strictly increasing:* $R_1 := \{\mathbf{x} \in [\mathbf{l},\mathbf{u}] \mid l_1 x_2 \leq -l_2(x_1 - l_1) + l_1 u_2\}$*,* $R_2 := \{\mathbf{x} \in [\mathbf{l},\mathbf{u}] \mid u_1 x_2 \geq -u_2(x_1 - u_1) + u_1 l_2\}$*, and* $R_3 := [\mathbf{l},\mathbf{u}] \setminus (R_1 \cup R_2)$*.*

Proof. A straightforward analysis of the Hessian matrix of f immediately shows the claim of 1-convexity and indefiniteness.

To prove the properties of $f^* : \mathbf{R}^2 \to \mathbf{R}$ as defined in formula (5.3), we first assume that $l_1 u_2 = u_1 l_2$ (i.e., $[\mathbf{l},\mathbf{u}] = R_1 \cup R_2$). Observe that f^* is the composition of the univariate increasing convex function g and the convex envelope of the product term $x_1 x_2$ on $[\mathbf{l},\mathbf{u}]$ (cf. formula (5.1)), and hence a valid convex underestimator of f (cf. [5]). On the other hand, the graph of f^* consists of two families of segments given by the endpoints

$$\begin{aligned} &\big(l_1 + \lambda(u_1 - l_1), l_2,\ f(l_1 + \lambda(u_1 - l_1), l_2)\big), \\ &\qquad \big(l_1, l_2 + \lambda(u_2 - l_2), f(l_1, l_2 + \lambda(u_2 - l_2))\big) \\ &\qquad \text{and} \\ &\big(u_1, l_2 + \mu(u_2 - l_2), f(u_1, l_2 + \mu(u_2 - l_2))\big), \\ &\qquad \big(l_1 + \mu(u_1 - l_1), u_2, f(l_1 + \mu(u_1 - l_1), u_2)\big), \end{aligned} \tag{5.4}$$

where λ, μ range over $[0,1]$. Hence, f^* is also an upper estimate of $\operatorname{vex}_{[\mathbf{l},\mathbf{u}]}[f]$. This proves the correctness of the claim in the special case.

In the general case, we may assume without loss of generality that $l_1 u_2 < u_1 l_2$. Note that R_1 is just a segment if $l_1 = 0$ and $l_2 > 0$. Assume that for a point $\mathbf{x} \in R_1 \cup R_2$

with an associated segment s of a type as described in formula (5.4), there is a segment $\bar{s}$ different from s which yields a lower value at the point $\mathbf{x}$. Then, by increasing l_1 or u_2, or by decreasing u_1 or l_2, we can construct a box $[\bar{\mathbf{l}}, \bar{\mathbf{u}}]$ containing both s and $\bar{s}$ such that $[\bar{\mathbf{l}}, \bar{\mathbf{u}}] = \bar{R}_1 \cup \bar{R}_2$ holds (where $\bar{R}_1$ and $\bar{R}_2$ are given by formula (5.2) using the bounds $\bar{l}_1, \bar{l}_2, \bar{u}_1, \bar{u}_2$). This contradicts the minimality of s w.r.t. $[\bar{\mathbf{l}}, \bar{\mathbf{u}}]$.

Now, let $\mathbf{x} \in R_3 := [\mathbf{l}, \mathbf{u}] \setminus (R_1 \cup R_2)$. Assume first that g is strictly convex and assume further that the relative interior of the projection of an associated minimizing segment $\bar{s}$ is not contained in R_3. By Proposition 2.3, $\bar{s}$ is also minimizing for points in the interior of $R_1 \cup R_2$, but different from those given in formula (5.4). Let $\bar{\mathbf{x}} \in R_1 \cup R_2$ be such a point with a minimizing segment s as defined in formula (5.4). Then the convex hull of s and $\bar{s}$ is a facet of the epigraph of $\mathrm{vex}_{[\mathbf{l},\mathbf{u}]}[f]$. This yields a similar contradiction, as in the proof of Theorem 3.1, or is possible only if $l_1 = l_2 = 0$, but then R_3 was empty.

If R_1 is not a segment, then the minimizing segments associated with points $\mathbf{x} \in R_3$ clearly have the stated property. Otherwise, consider $(l_1^n)_n \to l_1 = 0$ (if $l_2 > 0$) or vice versa. Similarly, the result for functions g that are not necessarily 1-convex in the strict sense follows from an approximation procedure similar to the one used in the proof of Theorem 3.1. □

Example 3. Consider the function $f : \mathbf{R}^2 \to \mathbf{R}$, $\mathbf{x} \mapsto \exp(x_1 x_2)$, restricted to a box $[\mathbf{l}, \mathbf{u}] \subseteq \mathbf{R}^2_{\geq 0}$. Then, by Proposition 5.1, the convex envelope of f on $R_1 \cup R_2$ reads as follows:

$$\mathrm{vex}_{[\mathbf{l},\mathbf{u}]}[\exp(x_1 x_2)] \;=\; \exp(\max(l_2 x_1 + l_1 x_2 - l_1 l_2, u_2 x_1 + u_1 x_2 - u_1 u_2)).$$

For the points $\mathbf{x} \in R_3$, when $l_1 u_2 < u_1 l_2$ (cf. Figure 5.1), it suffices to calculate

$$\min\ \lambda f(a_1, l_2) + (1-\lambda) f(b_1, u_2),$$

where $\lambda = \frac{u_2 - x_2}{u_2 - l_2}$, $l_1 \leq b_1 < a_1 \leq u_1$, and $\lambda a_1 + (1-\lambda) b_1 = x_1$ (see Observation 2). In this example, if the x_1-bounds are neglected, then, using standard analysis means, one can compute that the minimum is attained when

$$\frac{b_1 - a_1}{u_2 - l_2} \;=\; \frac{x_1 - \frac{\ln(l_2/u_2)}{u_2 - l_2}}{x_2 - l_2 - u_2}.$$

If b_1 or a_1 do not respect the bounds, then the endpoints of the segment are shifted such that they are contained in the box $[\mathbf{l}, \mathbf{u}]$.

This results in the following expression:

$$\mathrm{vex}_{[\mathbf{l},\mathbf{u}]}[f](\mathbf{x}) \;=\; \lambda(x_2)\ \exp\big(l_2 g_1(x_1, x_2)\big) + \big(1 - \lambda(x_2)\big)\ \exp\big(u_2 g_2(x_1, x_2)\big)$$

for all $\mathbf{x} \in R_3$, where $\lambda(x_2) := \frac{u_2 - x_2}{u_2 - l_2}$ and

$$g_1(x_1, x_2) \;:=\; \min\left\{u_1,\ \frac{x_1 - l_1}{x_2 - u_2}(l_2 - x_2) + x_1,\ \frac{x_1 - \frac{\ln(l_2/u_2)}{u_2 - l_2}}{x_2 - u_2 - l_2}(l_2 - x_2) + x_1\right\},$$

$$g_2(x_1, x_2) \;:=\; \max\left\{\frac{x_1 - u_1}{x_2 - l_2}(u_2 - x_2) + x_1,\ l_1,\ \frac{x_1 - \frac{\ln(l_2/u_2)}{u_2 - l_2}}{x_2 - u_2 - l_2}(u_2 - x_2) + x_1\right\}.$$

Another generalization is presented in the following proposition.

PROPOSITION 5.2. *Let $f : [\mathbf{l}, \mathbf{u}] \to \mathbf{R}$ be an indefinite function such that $\mathbf{x} \mapsto f(\mathbf{x}) = g(x_1)h(x_2)$, and the functions g, h are nonnegative, convex, and strictly increasing. Assuming $\frac{\mathrm{d}g(l_1)}{\mathrm{d}x_1}h(u_2) < \frac{\mathrm{d}g(u_1)}{\mathrm{d}x_1}h(l_2)$, there are points $v_1, w_1 \in (l_1, u_1)$ such that*

$$\frac{\mathrm{d}g(l_1)}{\mathrm{d}x_1}h(u_2) \;=\; \frac{\mathrm{d}g(y_1)}{\mathrm{d}x_1}h(l_2) \quad \textit{and} \quad \frac{\mathrm{d}g(u_1)}{\mathrm{d}x_1}h(l_2) \;=\; \frac{\mathrm{d}g(z_1)}{\mathrm{d}x_1}h(u_2).$$

Moreover, let $R' \subset [\mathbf{l}, \mathbf{u}]$ be the quadrilateral with vertices (v_1, l_2), (u_1, l_2), (w_1, u_2), (l_1, u_2) as shown in Figure 5.2. Then $\mathrm{vex}_{[\mathbf{l},\mathbf{u}]}[f]$ restricted to R' is given by the union of segments joining points $(y_1, l_2, f(y_1, l_2))$ and $(z_1, u_2, f(z_1, u_2))$, where $v_1 \le y_1 \le u_1$, $l_1 \le z_1 \le w_1$, and $\frac{\mathrm{d}g(y_1)}{\mathrm{d}x_1}h(l_2) = \frac{\mathrm{d}g(z_1)}{\mathrm{d}x_1}h(u_2)$.

For each point $\mathbf{x} \in [\mathbf{l}, \mathbf{u}] \setminus R'$, the relative interior of the projection of the associated minimizing segment is contained in $[\mathbf{l}, \mathbf{u}] \setminus R'$, where the endpoints are contained in orthogonal facets of $[\mathbf{l}, \mathbf{u}]$.

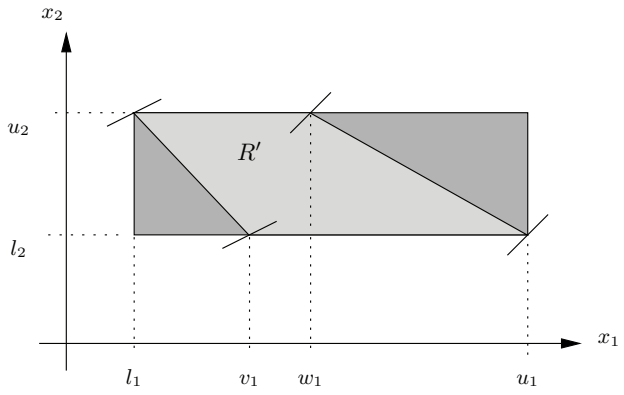

FIG. 5.2. *Subdivision of a box $[\mathbf{l}, \mathbf{u}] \subseteq \mathbf{R}^2_{\ge 0}$ into regions R' and $[\mathbf{l}, \mathbf{u}] \setminus R'$ with respect to different expressions of the convex envelope of functions $f : \mathbf{R}^2_{\ge 0} \to \mathbf{R}$ given by $f(\mathbf{x}) := g(x_1)h(x_2)$, where $g, h : \mathbf{R}_{\ge 0} \to \mathbf{R}$ are convex and strictly increasing. Region R' is a quadrilateral with vertices (l_1, u_2), (u_1, l_2), (v_1, l_2), and (w_1, u_2), where the two pairs of points (l_1, u_2), (v_1, l_2), and (u_1, l_2), (w_1, u_2), respectively, have identical slopes in the direction of the x_1-variable.*

Proof. The first statement follows directly from the properties of f.

Next, let $\mathbf{x} \in R'$, and assume that f is strictly 1-convex on $[\mathbf{l}, \mathbf{u}]$. Then there exist points $(y_1, l_2), (z_1, u_2) \in R'$ with identical slopes

$$\frac{\mathrm{d}g(y_1)}{\mathrm{d}x_1}h(l_2) \;=\; \frac{\mathrm{d}g(z_1)}{\mathrm{d}x_1}h(u_2) \;=:\; m$$

and such that $\mathbf{x}$ is contained in the segment spanned by $(y_1, l_2), (z_1, u_2)$.

We will show that the plane H given by the two tangents at the points $(y_1, l_2, f(y_1, l_2))$ and $(z_1, u_2, f(z_1, u_2))$ with slope m is a valid underestimator of the graph of f on $[\mathbf{l}, \mathbf{u}]$.

Assume to the contrary that there is a point $\hat{\mathbf{x}} \in [\mathbf{l}, \mathbf{u}]$ whose function value of f is smaller than the value given by the plane H. This is equivalent to the fact that there is a point $\tilde{\mathbf{x}}$ in the interior of $[\mathbf{l}, \mathbf{u}]$ with $m = \frac{\mathrm{d}g(\tilde{x_1})}{\mathrm{d}x_1}h(\tilde{x_2})$ whose function value is strictly overestimated by H. We can further assume that the violation among these points is maximal for $\tilde{\mathbf{x}}$.

Now consider the plane H' containing the point $(\tilde{\mathbf{x}}, f(\tilde{\mathbf{x}}))$ obtained from H by shifting it downwards in the direction of the f-axis. Then H' is a valid underestimator of f. By the construction, there is no point $\mathbf{t}$ contained in a facet of $[\mathbf{l}, \mathbf{u}]$ such that $(\mathbf{t}, f(\mathbf{t}))$ is contained in H'. Hence, $(\tilde{\mathbf{x}}, f(\tilde{\mathbf{x}}))$ can be separated by a plane from the graph of f restricted to the facets of $[\mathbf{l}, \mathbf{u}]$. But this contradicts the property that $(\tilde{\mathbf{x}}, f(\tilde{\mathbf{x}}))$ is contained in the convex hull of the graph of f restricted to the facets of $[\mathbf{l}, \mathbf{u}]$. Thus, the plane H is indeed valid for the graph of f proving that the segment given by $(y_1, l_2, f(y_1, l_2))$ and $(z_1, u_2, f(z_1, u_2))$ is minimizing.

The statement for points $\mathbf{x} \in [\mathbf{l}, \mathbf{u}] \setminus R'$ and the case when f is not necessarily strictly 1-convex can be proven with arguments similar to the proof of Proposition 5.1. □

Example 4. For numbers $p, q > 1$, consider the function $f : \mathbf{R}^2 \to \mathbf{R}$, $\mathbf{x} \mapsto x_1^p x_2^q$, on $[\mathbf{l}, \mathbf{u}] \subseteq \mathbf{R}^2_{\geq 0}$. If $pl_1^{p-1}u_2^q < pu_1^{p-1}l_2^q$, then the minimizing segments on R' as defined in Proposition 5.2 (see also Figure 5.2) are given by

$$(y_1, y_2) := \left(\frac{x_1}{\lambda + \mu - \lambda\mu}, l_2 \right) \quad \textit{and} \quad (z_1, z_2) := \left(\frac{\mu x_1}{\lambda + \mu - \lambda\mu}, u_2 \right),$$

where $\lambda := \frac{u_2 - x_2}{u_2 - l_2}$ and $\mu := \left(\frac{l_2}{u_2}\right)^{\frac{q}{p-1}}$.

If $p = q$, then Proposition 5.1 can also be applied to obtain the description for the regions R_1 and R_2 defined in formula (5.2). (Note that by Proposition 5.1, R_1 and R_2 do not overlap with R'.) For points in $[\mathbf{l}, \mathbf{u}] \setminus (R' \cup R_1 \cup R_2)$, the projections of the minimizing segments have a vertex of $[\mathbf{l}, \mathbf{u}]$ as an endpoint.

Next, we focus on the convex and concave envelopes of an arbitrary bivariate quadratic polynomial. We remark that Anstreicher and Burer have recently given a semidefinite representation for the envelopes of this class of functions (see [3]). However, our results developed in sections 3 and 4 enable us to derive explicit formulae via a case distinction.

Example 5. Consider an arbitrary bivariate quadratic polynomial $f : [\mathbf{l}, \mathbf{u}] \subseteq \mathbf{R}^2 \to \mathbf{R}$ defined by $f(\mathbf{x}) := a_{11}x_1^2 + 2a_{12}x_1x_2 + a_{22}x_2^2 + b_1x_1 + b_2x_2 + c$, with all coefficients being real.

If $a_{11}^2 + a_{22}^2 = 0$, then the convex and concave envelopes are generated by the four vertices of $[\mathbf{l}, \mathbf{u}]$ and are, hence, polyhedral. In this case, the formulae of the envelopes are easy to compute.

Let $a_{11}^2 + a_{22}^2 > 0$. Setting $a_{21} := a_{12}$, we obtain the Hessian matrix H_f of f as $H_f(\mathbf{x}) = 2(a_{ij})_{1 \leq i,j \leq 2}$. This leads to the following cases:

- *Case* 1. H_f is positive (negative) (semi-)definite. Then f is convex (concave), and the envelopes are trivial to compute. In the convex case,

$$\mathrm{vex}_{[\mathbf{l},\mathbf{u}]}[f](\mathbf{x}) = f(\mathbf{x}),$$

  and $\mathrm{cave}_{[\mathbf{l},\mathbf{u}]}[f](\mathbf{x})$ is generated by the four vertices of $[\mathbf{l}, \mathbf{u}]$.
- *Case* 2. H_f is indefinite, and $a_{11}a_{22} < 0$. Without loss of generality, let $a_{11} > 0 > a_{22}$. Then, f is convex in x_1 and concave in x_2. For determining a formula for the envelopes we can make use of Observation 2 or the reduction technique introduced in [11].
  First, assume that the eigenvector related to the negative eigenvalue of H_f has entries different in sign. An analysis of the reduced underlying optimization problem (4.1) defined in the proof of Observation 2 shows that the envelopes

can be computed as

$$\begin{aligned}\operatorname{vex}_{[\mathbf{l},\mathbf{u}]}[f](\mathbf{x}) &= \lambda f(y_1,l_2)+(1-\lambda)f(z_1,u_2),\\ \operatorname{cave}_{[\mathbf{l},\mathbf{u}]}[f](\mathbf{x}) &= \mu f(l_1,y_2)+(1-\mu)f(u_1,z_2),\end{aligned}$$

where $\lambda=\frac{u_2-x_2}{u_2-l_2}$, $\mu=\frac{u_1-x_1}{u_1-l_1}$,

$$\begin{aligned}y_1 &= \min\left(\tfrac{a_{12}}{a_{11}}(1-\lambda)(u_2-l_2)+x_1,\ u_1,\ \tfrac{x_1-l_1}{x_2-u_2}(l_2-x_2)+x_1\right),\\ z_1 &= \max\left(\tfrac{a_{12}}{a_{11}}\lambda(l_2-u_2)+x_1,\ \tfrac{x_1-u_1}{x_2-l_2}(u_2-x_2)+x_1,\ l_1\right),\\ y_2 &= \max\left(\tfrac{a_{12}}{a_{22}}(1-\mu)(u_1-l_1)+x_2,\ l_2,\ \tfrac{u_2-x_2}{u_1-x_1}(l_1-x_1)+x_2\right),\\ z_2 &= \min\left(\tfrac{a_{12}}{a_{22}}\mu(l_1-u_1)+x_2,\ \tfrac{x_2-l_2}{x_1-l_1}(u_1-x_1)+x_2,\ u_2\right).\end{aligned}\tag{5.5}$$

If the eigenvector to the negative eigenvalue of H_f does not have entries different in sign, then we can choose $(1,0)$ and $(0,1)$, respectively, as the eigenvectors associated with the positive and negative eigenvalues of H_f, respectively. In this case $a_{12}=0$ holds, so formula (5.5) can be simplified to

$$y_1=z_1=x_1,\quad y_2=z_2=x_2.$$

If $a_{11}a_{22}=0$ and $a_{11}>a_{22}=0$, then f is strictly convex in x_1 and affine in x_2. Hence, the convex envelope is given as in formula (5.5), whereas the concave envelope is polyhedral.

- *Case* 3. H_f is indefinite and $a_{11}a_{22}>0$. We may assume that $a_{11},a_{22}>0$ (otherwise, consider $-f$ and use $\operatorname{vex}_{[\mathbf{l},\mathbf{u}]}[-f](\mathbf{x})=-\operatorname{cave}_{[\mathbf{l},\mathbf{u}]}[f](\mathbf{x})$). Then f is 1-convex, i.e., the concave envelope is polyhedral. For the convex envelope, we assume that the eigenvector to the negative eigenvalue of H_f has entries different in sign (otherwise, consider $f(x_1,l_2+u_2-x_2)$). Moreover, let

$$\tfrac{\partial f}{\partial x_2}(l_1,u_2)(l_2-u_2)+f(l_1,u_2)\ \geq\ \tfrac{\partial f}{\partial x_1}(u_1,l_2)(l_1-u_1)+f(u_1,l_2).$$

Set $\mathbf{v}:=\left(-\sqrt{a_{22}},\sqrt{a_{11}}\right)$. The box $[\mathbf{l},\mathbf{u}]$ can be separated into three regions using the two lines with direction $\mathbf{v}$ through the corner points (l_1,u_2) and (u_1,l_2), respectively (see Figure 5.3). In the regions D_1 and D_2, the convex envelope is given by segments whose projections to $\mathbf{R}^2$ are parallel to the vector $\mathbf{v}$. Thus, on D_1 and D_2, the convex envelope reads as

$$\begin{aligned}\operatorname{vex}_{[\mathbf{l},\mathbf{u}]}[f](\mathbf{x})\,|_{D_1} &= \lambda f(y_1,l_2)+(1-\lambda)f(l_1,z_2),\\ \operatorname{vex}_{[\mathbf{l},\mathbf{u}]}[f](\mathbf{x})\,|_{D_2} &= \mu f(v_1,u_2)+(1-\mu)f(u_1,w_2),\end{aligned}$$

where $\lambda=\frac{x_1-l_1}{y_1-l_1}$, $\mu=\frac{x_1-u_1}{y_1-u_1}$,

$$\begin{aligned}y_1&=-\sqrt{\tfrac{a_{22}}{a_{11}}}(l_2-x_2)+x_1, & z_2&=-\sqrt{\tfrac{a_{11}}{a_{22}}}(l_1-x_1)+x_2,\\ v_1&=-\sqrt{\tfrac{a_{22}}{a_{11}}}(u_2-x_2)+x_1, & w_2&=-\sqrt{\tfrac{a_{11}}{a_{22}}}(u_1-x_1)+x_2.\end{aligned}$$

Validity is seen by expanding these formulae yielding the expressions

$$\begin{aligned}g(x_1,x_2)&=a_{11}x_1^2+2\sqrt{a_{11}a_{22}}x_1x_2+a_{22}x_2^2+(b_1+2l_2(a_{12}-\sqrt{a_{11}a_{22}}))x_1\\ &\quad+(b_2+2l_1(a_{12}-\sqrt{a_{11}a_{22}}))x_2+c-2l_1l_2(a_{12}-\sqrt{a_{11}a_{22}}),\\ h(x_1,x_2)&=a_{11}x_1^2+2\sqrt{a_{11}a_{22}}x_1x_2+a_{22}x_2^2+(b_1+2u_2(a_{12}-\sqrt{a_{11}a_{22}}))x_1\\ &\quad+(b_2+2u_1(a_{12}-\sqrt{a_{11}a_{22}}))x_2+c-2u_1u_2(a_{12}-\sqrt{a_{11}a_{22}}).\end{aligned}$$

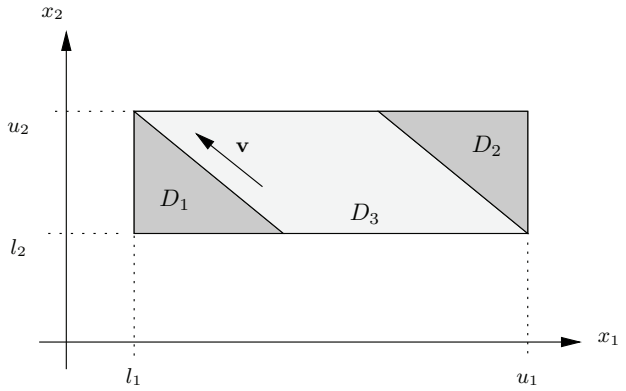

FIG. 5.3. *Subdivision of a box* $[\mathbf{l}, \mathbf{u}] \subseteq \mathbf{R}^2_{\geq 0}$ *into regions* D_1, D_2, *and* D_3 *with respect to different expressions of the convex envelope of a bivariate quadratic polynomial* $a_{11}x_1^2 + 2a_{12}x_1x_2 + a_{22}x_2^2 + b_1x_1 + b_2x_2 + c$ *(with* $a_{11} \geq a_{22} > 0$*) that is* 1*-convex and indefinite. The subdivision is defined by the two lines with direction* $\mathbf{v} = (-\sqrt{a_{22}}, \sqrt{a_{11}})$ *through the corner points* (l_1, u_2) *and* (u_1, l_2)*, respectively.*

The functions g and h are clearly convex on their domains D_1 and D_2, respectively. With an argument as in the proof of Proposition 5.1, the validity follows. Moreover, it can be deduced that in the middle region D_3, the envelope is described by the formulae of Case 2.

6. Conclusions. In this paper we showed that evaluating the value of the convex envelope of an (n–1)-convex indefinite function on a box is a computationally tractable task, provided that the number of variables involved is not too large. However, for deriving analytical formulae based on our structural result (cf. Theorem 3.1), it is required to have strong analytical and geometrical properties at hand. We are not aware of practically relevant families of functions with more than three variables for which we could provide formulae for the envelope following the approach outlined in Examples 1–5. Indeed, this lack of geometric information limits our ability to turn the knowledge of Theorem 3.1 into an analytical formula. Still, Observation 2 and Lemma 4.3 may be applied and can be utilized by a numerical solver for evaluating the value of the convex envelope at a given point and a normal vector of a supporting hyperplane.

Acknowledgment. We greatly appreciate the suggestions of two anonymous referees.

UNIVERSAL CONFIDENCE SETS FOR SOLUTIONS OF OPTIMIZATION PROBLEMS*

SILVIA VOGEL†

Abstract. We consider random approximations to deterministic optimization problems. The objective function and the constraint set can be approximated simultaneously. Relying on concentration-of-measure results we derive universal confidence sets for the constraint set, the optimal value, and the solution set. Special attention is paid to solution sets which are not single-valued. With many statistical estimators being solutions to random optimization problems, the approach can also be employed to derive confidence sets for constrained estimation problems.

Key words. random optimization problems, universal confidence sets, convergence rate, constrained estimation

1. Introduction.

Random approximations of deterministic or random optimization problems come into play if unknown quantities are replaced with estimates or for numerical reasons. One solves the approximate problem and hopes that the solution is a good surrogate for the solution of the true problem. Hence there is the need for methods that help to evaluate the goodness of the surrogate solution.

Usually the approximating problems can be arranged to a sequence $(P_n)_{n\in N}$ which approximates the true problem in a suitable sense. Often n can be regarded as the size of the sample on which the estimates are based. Qualitative stability results, which make assertions on the (semi-)convergence of the constraint sets, the optimal values, and the solution sets, are available for convergence almost surely, in probability and in distribution, cf. [12], [17], [8], [7], [19], [3], and the references therein. Furthermore, there are quantitative results which estimate the distance between the optimal values and/or solutions sets by suitable probability metrics; see [14] for an overview.

Confidence bounds for optimal values and solution sets provide valuable additional information. In parametric statistics confidence sets are standard tools. They contain the true value of a parameter at least with a prescribed probability and should satisfy some quality criteria, e.g., minimal size. In the traditional way they are derived from the distribution of a suitable point estimator, which often turns out to be the solution to an appropriate optimization problem. However, the exact distribution of the estimator for a given sample size n is available only in rare cases. Therefore, usually the limit distribution is used as a surrogate, i.e., one deals with asymptotic confidence sets. As indicated in [12] and [3], qualitative stability results for convergence in distribution can also be employed to derive asymptotic confidence sets.

In this paper we will consider a general method which provides *for each* n a set which covers the true solution at least with the prescribed probability. Hence we speak of *universal* confidence sets. These universal confidence sets have a structure which resembles that of many confidence sets in statistics. They are suitable neighborhoods of the solutions to the approximate problems. However, in order to derive such sets,

†Mathematics and Sciences, Ilmenau Technical University, Weimarer Straße 25, 98693 Ilmenau, Germany (Silvia.Vogel@tu-ilmenau.de).

we do not try to obtain full knowledge about the true distribution of some statistic. Instead we rely on uniform concentration-of-measure results and some assumptions about the true model.

We will also give conditions under which the confidence sets do not only cover the true set, but converge to it in an appropriate sense. Since in general the diameters of the neighborhoods will converge to zero with increasing n, universal confidence sets provide a valuable aid for the decision whether the solution to an approximate problem is good enough or should be improved choosing a larger n.

Confidence bounds for constraint sets and optimal values will be treated in a similar way. Confidence sets for the optimal values can help to assess the quality of the solution to an approximate problem and may be of interest also for model selection. Confidence bounds for constraint sets are of independent interest if sets have to be approximated which are defined by inequality constraints. It is obvious that the method also can be employed for the derivation of confidence sets in statistics if the quantity under consideration can be obtained as solution to an optimization problem.

We adopt ideas from the paper [13]. In [13] Pflug shows how results about uniform convergence in probability, supplemented with known convergence rate and tail behavior, together with a growth condition for the true objective function can be used to derive different kinds of confidence sets. Confidence sets in the sense described above are obtained under the additional assumption that the solution set is single-valued. Furthermore, sufficient conditions for the assumed convergence conditions are discussed in [13].

We will pursue the way proposed in [13] farther, take into account also the approximation of the constraint set, and show how one can proceed if the solution set is not single-valued. The results are formulated in a general way, allowing, e.g., for "relaxed" constraint sets and "κ-optimal" solutions.

We will assume that suitable assertions on the (one-sided) uniform convergence in probability of the objective functions and/or the constraint functions with a convergence rate and tail behavior function are available. Furthermore, we assume some knowledge about the true model, such as a growth condition for the objective function.

Emphasis in this paper is on the concepts in a general form. Three simple examples at the end of the paper are in the first instance meant for illustration. Applications of our results to more complex problems require additional sufficient conditions for the convergence conditions and methods to estimate the parameters of the true model. These topics will be discussed elsewhere.

In order to derive confidence sets for each n, we assume full knowledge about the tail behavior function. If this function is not completely known, the proposed approach can still be employed to derive asymptotic confidence sets.

The paper is organized as follows. In section 2 we introduce the mathematical model and show how universal confidence sets can be derived from suitable convergence results. In section 3 and section 4 we prove the needed convergence assertions for the constraint sets, the optimal values, and the solutions sets. Section 5 contains the examples. The first example is to show how one can deal with the uniform convergence assumptions in a simple case. Approximation of a chance constraint is dealt with in the second example. The third example was chosen to demonstrate the applicability of our results in statistics. We will provide universal confidence bounds for quantiles, allowing for distribution functions which are not continuous.

2. Universal confidence sets. Let (E, d) be a complete separable metric space and $[\Omega, \Sigma, P]$ a complete probability space. We assume that a deterministic optimiza-

tion problem

$$(P_0) \quad \min_{x\in\Gamma_0} f_0(x)$$

is approximated by a sequence of random problems

$$(P_n) \quad \min_{x\in\Gamma_n(\omega)} f_n(x,\omega), \quad n\in N.$$

Additionally to (P_n), for a given $\kappa > 0$, we consider so-called κ-relaxations

$$(P_{n,\kappa}) \quad \min_{x\in\Gamma_{n,\kappa}(\omega)} f_{n,\kappa}(x,\omega), \quad n\in N.$$

The relaxed problems offer the possibility to deal with "relaxed" constraint sets, objective functions and/or solution sets, which are accurate only up to a small parameter that depends on n and κ and tends to zero for each κ if $n\to\infty$. Consequently, the approach can be applied, e.g., to constraint sets and functions which are obtained by Monte Carlo methods (cf. [15], [11]), or to methods which use plug-in estimators, and to ε_n-optimal solutions. Moreover, the relaxed problems are crucial in our approach for the derivation of outer approximations for constraint sets and solution set (see section 3).

The following results will be formulated for $(P_{n,\kappa})$. The problem (P_n) is then regarded as a special case of $(P_{n,\kappa})$ with objective functions and constraint sets that do not depend on κ.

Γ_0 is a nonempty closed subset of E, and the function f_0, which maps into the extended reals $\bar{R}^1 := R^1\cup\{-\infty\}\cup\{+\infty\}$, is a lower semicontinuous function. For each $n\in N$ and $\kappa>0$, $\Gamma_{n,\kappa}|\Omega\to 2^E$ is a closed-valued measurable multifunction, and $f_{n,\kappa}|E\times\Omega\to\bar{R}^1$ is a lower semicontinuous random function, which is supposed to be $(\mathcal{B}(E)\otimes\Sigma,\bar{\mathcal{B}}^1)$ measurable. $\mathcal{B}(E)$ denotes the Borel-σ-field of E and $\bar{\mathcal{B}}^1$ the σ-field which is generated by the Borel sigma field $\mathcal{B}^1$ of R^1 and $\{+\infty\}$, $\{-\infty\}$. Furthermore, we assume that all objective functions are (almost surely) proper functions, i.e., functions with values in $(-\infty,+\infty]$ which are not identically ∞.

The measurability conditions imposed here do not have the weakest form. We use them for sake of simplicity. They are satisfied in many applications and guarantee that all functions of ω needed in the following have the necessary measurability properties. Moreover, the lower semicontinuity assumption of the objective functions $f_{n,\kappa}$ can be dropped. Imposing this condition, however, we can omit some technical details in the proofs.

In the following, the optimal values are denoted by Φ. $\Phi_{n,\kappa}(\omega) := \inf_{x\in\Gamma_{n,\kappa}(\omega)} f_{n,\kappa}(x,\omega)$ is the optimal value for the realization $(P_{n,\kappa}(\omega))$ of the approximate problem, while $\Phi_0 := \inf_{x\in\Gamma_0} f_0(x)$ is the optimal value to (P_0). $\Psi_{n,\kappa}(\omega)$ and Ψ_0 denote the corresponding solution sets.

Our main concern will be with the solution sets Ψ_0 and $\Psi_{n,\kappa}$. We aim at proving assertions of the form

$$(1) \qquad \forall\kappa>0: \sup_{n\ge n_0(\kappa)} P\{\omega:\ \Psi_{n,\kappa}(\omega)\setminus U_{\beta_{n,\kappa}}\Psi_0\neq\emptyset\}\le\mathcal{H}(\kappa)$$

and

$$(2) \qquad \forall\kappa>0: \sup_{n\ge n_0(\kappa)} P\{\omega:\ \Psi_0\setminus U_{\beta_{n,\kappa}}\Psi_{n,\kappa}(\omega)\neq\emptyset\}\le\mathcal{H}(\kappa).$$

Here $(\beta_{n,\kappa})_{n\in N}$ is a sequence of nonnegative numbers which tends to zero for each $\kappa > 0$, and $\mathcal{H}|R^+ \to R^+$ is a function with $\lim_{\kappa\to\infty} \mathcal{H}(\kappa) = 0$. $U_\alpha X$ denotes an open neighborhood of the set X with radius α: $U_\alpha X := \{x \in E : \ d(x, X) < \alpha\}$. $\bar{U}_\alpha X$ means its closure.

In stochastic programming, objective functions and constraint functions which are expectations of random functions are of special interest. If the true, but unknown distribution is replaced with the empirical measure, one often obtains a convergence rate of the form $\tilde{\beta}_{n,\kappa} = \frac{\kappa}{\sqrt{n}}$ for these functions. As we shall see later, the rate $\beta_{n,\kappa}$ which occurs in (1) and (2) is a nondecreasing function of $\tilde{\beta}_{n,\kappa}$. Hence the neighborhoods grow with increasing κ and become smaller with increasing n, cf. section 5. Examples of $\mathcal{H}$ are given in section 5 and [13].

It is desirable that the following assumption (C) is satisfied. Let $\kappa_n(\varepsilon) := \max\{\kappa : \beta_{n,\kappa} \le \varepsilon\}$.

(C) For all $\kappa > 0$ $(\beta_{n,\kappa})_{n\in N}$ converges monotonically to zero, and for all $\varepsilon > 0$ $\lim_{n\to\infty} \kappa_n(\varepsilon) \to \infty$ is satisfied.

If (C) is fulfilled, inequality (1) implies the following property of $(\Psi_n)_{n\in N}$:

For each $\varepsilon > 0$ and an arbitrary compact set $K \subset E$ we have for sufficiently large n,

$$P\{\omega : \ (\Psi_n(\omega) \setminus U_\varepsilon \Psi_0) \cap K \neq \emptyset\} \le P\{\omega : \ \Psi_n(\omega) \setminus U_{\beta_{n,\kappa_n(\varepsilon)}} \Psi_0 \neq \emptyset\} \le \mathcal{H}(\kappa_n(\varepsilon)).$$

Hence the condition

$$\forall \varepsilon > 0 \ \forall \text{ compact } K : \ \lim_{n\to\infty} P\{\omega : \ (\Psi_n(\omega) \setminus U_\varepsilon \Psi_0) \cap K \neq \emptyset\} = 0 \tag{3}$$

holds.

Sequences $(\Psi_n)_{n\in N}$ satisfying condition (3) are called inner approximations in probability to Ψ_0 (cf. [8], [20]). Roughly spoken, inner approximations tend to a subset of Ψ_0 in the particular convergence mode under consideration. For the aims of this paper, convergence in probability is the appropriate mode. In a corresponding way one can show that a sequence which fulfills condition (2) for a sequence $(\beta_{n,\kappa})_{n\in N}$ with the above properties is a so-called outer approximation in probability to Ψ_0. Outer approximations tend to cover Ψ_0. A sequence which is an inner and an outer approximation in probability to Ψ_0 is (Kuratowski–Painlevé)-convergent in probability to Ψ_0.

Because of the relationship to inner and outer approximations in probability, we will call a sequence $(\Psi_{n,\kappa})_{n\in N}$ fulfilling relation (1) an *inner approximation in probability to* Ψ_0 *with convergence rate* $\beta_{n,\kappa}$ *and tail behavior function* $\mathcal{H}$ (in short, an *inner* $(\beta_{n,\kappa}, \mathcal{H})$*-approximation*) and a sequence $(\Psi_{n,\kappa})_{n\in N}$ fulfilling (2) an *outer approximation in probability to* Ψ_0 *with convergence rate* $\beta_{n,\kappa}$ *and tail behavior function* $\mathcal{H}$ (in short, an *outer* $(\beta_{n,\kappa}, \mathcal{H})$*-approximation*). Sequences $(\Psi_{n,\kappa})_{n\in N}$ which are inner and outer $(\beta_{n,\kappa}, \mathcal{H})$-approximations in probability to Ψ_0, such that $(\beta_{n,\kappa})_{n\in N}$ satisfies condition (C), are called $(\beta_{n,\kappa}, \mathcal{H})$*-convergent in probability to* Ψ_0. $(\beta_{n,\kappa}, \mathcal{H})$-convergence in probability is closely related to the normalized convergence investigated in [2].

In order to derive *universal confidence sets to the level* ε_0, i.e., a sequence of random sets $(C_n)_{n\in N}$ with the property $\sup_{n\ge n_0} P\{\omega : \ \Psi_0 \setminus C_n(\omega) \neq \emptyset\} \le \varepsilon_0$, we can proceed as follows.

Suppose that an outer $(\beta_{n,\kappa}, \mathcal{H})$-approximation $(\Psi_{n,\kappa})_{n\in N}$ to Ψ_0 is available and choose to $\varepsilon_0 > 0$ a $\kappa_0 > 0$ such that $\mathcal{H}(\kappa_0) \le \varepsilon_0$. The sets

$$C_n := U_{\beta_{n,\kappa_0}} \Psi_{n,\kappa_0} \tag{4}$$

have the desired property. Of course, one is interested in small confidence sets; hence $(\beta_{n,\kappa})_{n\in N}$ should go to zero as fast as possible and $\mathcal{H}(\kappa)$ should converge to zero as fast as possible if κ tends to infinity.

Unfortunately, under reasonable conditions one obtains inner approximations for the solution set only; see, for instance, the following example.

Example E1. Consider the family of minimization problems $\{\tilde{P}_n,\ n \in N_0\}$ with $E = R^1,\ \Gamma_0 = \Gamma_n = [-1,+1],\ f_0(x) \equiv 0$, and $f_n(x) = \min\{|x|, \frac{1}{n}\}$. Then $(f_n)_{n\in N}$ converges uniformly to f_0, but $\Psi_n = \{0\}$ for all $n \in N$, while $\Psi_0 = [-1,+1]$.

Inner approximations will serve our purpose if all approximating problems (P_n) have solutions which are uniformly bounded and the solution set to the problem (P_0) is single valued, because in this case inner approximations are also outer approximations, and we can proceed as above.

What can be done if the solution set to (P_0) is not single valued? Taking into account that we need knowledge about convergence rates anyway, we can exploit this knowledge to determine suitable relaxing sequences $(\rho_{n,\kappa})_{n\in N}$, which tend to zero for each $\kappa > 0$ and consider $\rho_{n,\kappa}$-optimal solutions, denoted by $\Psi^r_{n,\kappa}$.

The problem, that in general only inner approximations can be obtained, is also apparent for the constraint sets. An example will be considered in section 5.

As mentioned, for reasonable confidence sets one would like to have $\lim_{n\to\infty} \beta^{(i)}_{n,\kappa} = 0$ and $\lim_{\kappa\to\infty} \mathcal{H}_i(\kappa) = 0$ for all sequences $(\beta^{(i)}_{n,\kappa})_{n\in N}$ and functions $\mathcal{H}_i$ which occur in the following. These properties are, however, not needed to prove the results in section 3 and section 4. We only assume throughout the paper that the sequences $(\beta^{(i)}_{n,\kappa})_{n\in N}$ belong to the class B of nonincreasing sequences of positive numbers and the functions $\mathcal{H}_i$ belong to the class H of nonincreasing functions which are defined on R^+ and map into R^+.

3. Approximation of the constraint set. In this section we consider constraint sets, which are given by inequality constraints, and their approximations. Results of that kind are, of course, needed if approximation of the constraint set is inherent in the problem under consideration. Moreover, because of the equations

$$\Psi_0 = \{x \in \Gamma_0 :\ f_0(x) - \Phi_0 \le 0\} \text{ and}$$
$$\Psi_n(\omega) = \{x \in \Gamma_n :\ f_n(x,\omega) - \Phi_n(\omega) \le 0\},$$

the statements can be employed to derive assertions on the behavior of the solution sets, regarding the difference between the true objective function and the optimal value as constraint function. As the optimal values for problems with $\rho_{n,\kappa}$-relaxed constraint sets may depend on κ, the resulting "constraint function" $\tilde{g}_{n,\kappa} := f_n - \Phi_{n,\kappa}$ may depend on κ, too. Furthermore, when applying Theorem 1 below to the solution sets, the multifunctions Q_n, which occur in this theorem, will be interpreted as constraint sets; hence we have to allow that they depend on κ, too.

We assume that the feasibility set Γ_0 in (P_0) can be written as

$$\Gamma_0 = \left\{x :\ g^j_0(x) \le 0,\ j \in J\right\} \cap Q_0,$$

where $J = \{1,\dots,j_M\}$ is a finite index set, the functions $g^j_0 | E \to R^1,\ j \in J$, are lower semicontinuous in all points $x \in E$, and Q_0 is a closed nonempty subset of E. Furthermore, we assume that Γ_0 is nonempty.

For each $\kappa > 0$, the set Q_0 is approximated by a sequence $(Q_{n,\kappa})_{n\in N}$ of closed-valued measurable multifunctions, and the functions $g^j_0,\ j \in J$, are approximated by

sequences $(g^j_{n,\kappa})_{n\in N}$ of functions $g^j_{n,\kappa}|E \to R^1,\ j \in J$, which are $(\mathcal{B}(E)\otimes\Sigma,\mathcal{B}^1)$-measurable. Furthermore, we assume that the functions $g_{n,\kappa}(\cdot,\omega)$ are lower semicontinuous for all $\omega\in\Omega$. Also these measurability and semicontinuity properties could be weakened.

Hence the approximate constraint set $\Gamma_{n,\kappa}$ has the form

$$\Gamma_{n,\kappa}(\omega) = \left\{x \in E :\ g^j_{n,\kappa}(x,\omega) \le 0,\ j \in J\right\} \cap Q_{n,\kappa}(\omega).$$

Under our assumptions $\Gamma_{n,\kappa}$ is a closed-valued measurable multifunction.

If we have $Q_{n,\kappa}(\omega) \equiv Q_0 = E$, we will use the denotation $\hat\Gamma_0$ and $\hat\Gamma_{n,\kappa}$, respectively:

$$\hat\Gamma_0 = \left\{x \in E :\ g^j_0(x) \le 0,\ j \in J\right\}$$

and

$$\hat\Gamma_{n,\kappa}(\omega) := \left\{x \in E :\ g^j_{n,\kappa}(x,\omega) \le 0,\ j \in J\right\}.$$

In the following we employ functions $\nu,\ \mu$, and λ. They are assumed to belong to the set Λ of functions $\tilde\lambda|R^1 \to R^1$ which are right-continuous, nondecreasing, nonconstant, and have the property $\tilde\lambda(0) = 0$. By the superscript $^{-1}$ we denote their inverses: $\tilde\lambda^{-1}(y) := \inf\{x \in R :\ \tilde\lambda(x) \ge y\}$.

THEOREM 1 (inner approximation of the constraint set). *Assume that the following conditions are satisfied:*

(CI1) *There exists a function $\mathcal{H}_1 \in H$ and for all $\kappa > 0$ a sequence $(\beta^{(1)}_{n,\kappa})_{n\in N} \in B$ such that*

$$\sup_{n\in N} P\{\omega :\ Q_{n,\kappa}(\omega) \setminus U_{\beta^{(1)}_{n,\kappa}} Q_0 \ne \emptyset\} \le \mathcal{H}_1(\kappa).$$

(CI2) *There exists a function $\mathcal{H}_2 \in H$ and for all $\kappa > 0$ a sequence $(\beta^{(2)}_{n,\kappa})_{n\in N} \in B$ such that*

$$\sup_{j\in J}\ \sup_{n\in N} P\{\omega :\ \inf_{x\in UQ_0\setminus\Gamma_0} (g^j_{n,\kappa}(x,\omega) - g^j_0(x)) \le -\beta^{(2)}_{n,\kappa}\} \le \mathcal{H}_2(\kappa)$$

for a suitable neighborhood UQ_0.

(CI3) *There exists a function $\nu \in \Lambda$ such that for all $\varepsilon > 0$*

$$U_\varepsilon\Gamma_0 \supset U_{\nu(\varepsilon)}Q_0 \cap U_{\nu(\varepsilon)}\hat\Gamma_0.$$

(CI4) *There exists a function $\mu \in \Lambda$ such that for all $\varepsilon > 0$*

$$\forall\, x \in U_\varepsilon Q_0 \setminus U_\varepsilon\hat\Gamma_0\ \ \exists j \in J :\ g^j_0(x) \ge \mu(\varepsilon).$$

Then for all $\kappa > 0$, $\beta^{(3)}_{n,\kappa} = \max\{\nu^{-1}(\beta^{(1)}_{n,\kappa}), \nu^{-1}(\mu^{-1}(\beta^{(2)}_{n,\kappa}))\}$, and $n_0(\kappa) = \min\{l :\ U_{\nu(\beta^{(3)}_{l,\kappa})}Q_0 \subset UQ_0\}$ the relation $\sup_{n\ge n_0(\kappa)} P\{\omega :\ \Gamma_{n,\kappa}(\omega) \setminus U_{\beta^{(3)}_{n,\kappa}}\Gamma_0 \ne \emptyset\} \le \mathcal{H}_1(\kappa) + j_M\mathcal{H}_2(\kappa)$ holds.

Proof. Assume that for given $\kappa > 0,\ n \ge n_0(\kappa)$, and $\omega \in \Omega$ the relation $\Gamma_{n,\kappa}(\omega) \setminus U_{\beta^{(3)}_{n,\kappa}}\Gamma_0 \ne \emptyset$ holds. Then there is $x_{n,\kappa}(\omega) \in \Gamma_{n,\kappa}(\omega)$ which does not belong to $U_{\beta^{(3)}_{n,\kappa}}\Gamma_0$. Because of (CI3) we have $x_{n,\kappa}(\omega) \notin U_{\nu(\beta^{(3)}_{n,\kappa})}Q_0$ or $x_{n,\kappa}(\omega) \in U_{\nu(\beta^{(3)}_{n,\kappa})}Q_0$ and $x_{n,\kappa}(\omega) \notin U_{\nu(\beta^{(3)}_{n,\kappa})}\hat\Gamma_0$.

In the first case we obtain $Q_{n,\kappa} \backslash U_{\nu(\beta^{(3)}_{n,\kappa})} Q_0 \neq \emptyset$. Hence, because of $\nu(\beta^{(3)}_{n,\kappa}) \geq \beta^{(1)}_{n,\kappa}$, $Q_{n,\kappa}(\omega) \setminus U_{\beta^{(1)}_{n,\kappa}} Q_0 \neq \emptyset$, and we can employ (CI1).

In the second case we obtain by (CI4) for at least one $j \in J$, $g_0^j(x_{n,\kappa}(\omega)) \geq \mu(\nu(\beta^{(3)}_{n,\kappa})) \geq \beta^{(2)}_{n,\kappa}$; hence, because of $U_{\nu(\beta^{(3)}_{n,\kappa})} Q_0 \subset UQ_0$, $\inf_{x \in UQ_0 \setminus \Gamma_0} (g^j_{n,\kappa}(x,\omega) - g_0^j(x)) \leq -\beta^{(2)}_{n,\kappa}$. It remains to employ (CI2). □

Condition (CI1) says that the sequence $(Q_{n,\kappa})_{n \in N}$ is an inner $(\beta^{(1)}_{n,\kappa}, \mathcal{H}_1)$-approximation to Q_0. Condition (CI2) claims—roughly speaking—that the functions $g^j_{n,\kappa}$ outside Γ_0 do not take values that are "essentially" less than the value of g_0^j at the same point. It is a relaxed one-sided version of the uniform concentration-of-measure assumption that was used in [13] for the objective functions. Because of its relationship to a lower semicontinuous approximation in probability (cf. [8], [20]), each sequence $(g^j_{n,\kappa})_{n \in N}$ which satisfies condition (CI2) could be called a *lower semicontinuous approximation in probability to* g_0^j *at* $UQ_0 \setminus \Gamma_0$ *with convergence rate* $\beta^{(2)}_{n,\kappa}$ *and tail behavior function* $\mathcal{H}_2$. (CI2) is a crucial assumption in our approach. Unfortunately, so far there are only a few sufficient conditions which are directly applicable; see, for instance, [13] and the examples at the end of the paper. A general approach for the derivation of sufficient conditions which can serve as a bridge to the concentration-of-measure results for sequences of random variables will be provided elsewhere.

The assumptions (CI3) and (CI4) are conditions about the true model. (CI4) requires that at least one constraint function g_0^j grows outside $\hat{\Gamma}_0$ with a certain rate. This rate can sometimes be derived from the model; see section 5. In general cases it will have to be estimated. Replacing μ with estimates, however, changes the overall convergence rate and will be discussed elsewhere. Condition (CI3) is an assumption about the mutual position and the curvature of Q_0 and $\hat{\Gamma}_0$. It can be dispensed with if $Q_{n,\kappa} \equiv Q_0$ and (CI4) is sharpened to (CI4-W); see Corollary 1 below. (CI2) can then be slightly weakened to (CI2-W). (CI4-W) refers to a function $\tilde{\mu}$ which is determined with respect to the distance to Γ_0, not to $\hat{\Gamma}_0$. $\tilde{\mu}$ will in general be different from μ; compare the following example.

Example E2. Let $E = R^2$, $Q_0 = \{(x,y) : \ y = 2x\}$, $j_M = 1$, and $g_0^1(x,y) = x$. Then $\hat{\Gamma}_0 = (-\infty, 0] \times R^1$ and $\Gamma_0 = \{(x,y) : \ x \leq 0, y = 2x\}$. Consequently we obtain for all $\varepsilon > 0$

$$\forall x \in U_\varepsilon Q_0 \setminus U_\varepsilon \hat{\Gamma}_0 : \ g_0^1(x) \geq \varepsilon, \text{ but}$$
$$\forall x \in Q_0 \setminus U_\varepsilon \Gamma_0 : \ g_0^1(x) \geq \frac{\varepsilon}{\sqrt{5}}.$$

COROLLARY 1. *Assume that* $Q_{n,\kappa} \equiv Q_0$ *holds and the following assumptions are satisfied:*

(CI2-W) *There exists a function* $\mathcal{H}_2 \in H$ *and for all* $\kappa > 0$ *a sequence* $(\beta^{(2)}_{n,\kappa})_{n \in N} \in B$ *such that*

$$\sup_{j \in J} \sup_{n \in N} P\{\omega : \inf_{x \in Q_0 \setminus \Gamma_0} (g^j_{n,\kappa}(x,\omega) - g_0^j(x)) \leq -\beta^{(2)}_{n,\kappa}\} \leq \mathcal{H}_2(\kappa).$$

(CI4-W) *There exists a function* $\tilde{\mu} \in \Lambda$ *such that for all* $\varepsilon > 0$

$$\forall \ x \in Q_0 \setminus U_\varepsilon \Gamma_0 \ \ \exists j \in J : \ g_0^j(x) \geq \tilde{\mu}(\varepsilon).$$

Then for all $\kappa > 0$ *and* $\beta^{(3)}_{n,\kappa} = \tilde{\mu}^{-1}(\beta^{(2)}_{n,\kappa})$ *the relation* $\sup_{n \in N} P\{\omega : \ \Gamma_{n,\kappa}(\omega) \setminus U_{\beta^{(3)}_{n,\kappa}} \Gamma_0 \neq \emptyset\} \leq j_M \mathcal{H}_2(\kappa)$ *holds.*

Proof. Assume that for given $\kappa > 0$, $n \in N$, and $\omega \in \Omega$ the relation $\Gamma_{n,\kappa}(\omega) \setminus U_{\beta^{(3)}_{n,\kappa}}\Gamma_0 \neq \emptyset$ holds. Then there is $x_{n,\kappa}(\omega) \in \Gamma_{n,\kappa}(\omega)$ which does not belong to $U_{\beta^{(3)}_{n,\kappa}}\Gamma_0$. Because of $Q_{n,\kappa} \equiv Q_0$, $x_{n,\kappa}(\omega)$ belongs to Q_0, and we can immediately make use of (CI4-W), which gives $g_0^j(x_{n,\kappa}(\omega)) \geq \tilde{\mu}(\beta^{(3)}_{n,\kappa}) \geq \beta^{(2)}_{n,\kappa}$. Consequently $\inf_{x\in Q_0\setminus\Gamma_0}(g^j_{n,\kappa}(x,\omega) - g_0^j(x)) \leq -\beta^{(2)}_{n,\kappa}$. It remains to employ (CI2-W). □

Later on, Corollary 1 can immediately be applied to obtain results about the approximation of the solution set if the constraint set remains fixed.

Remark 1. Sometimes, concentration-of-measure results are formulated for strict inequalities. Therefore we would like to mention that the conclusion of Theorem 1 does not change if condition (CI2) is replaced by the weaker condition (CI2-S) below and at the same time the stronger condition (CI4-S) is imposed instead of (CI4). This holds correspondingly for further assertions.

(CI2-S) There exists a function $\mathcal{H}_2 \in H$ and for all $\kappa > 0$ a sequence $(\beta^{(2)}_{n,\kappa})_{n\in N} \in B$ such that

$$\sup_{j\in J}\sup_{n\in N} P\{\omega : \inf_{x\in UQ_0\setminus\Gamma_0}(g^j_{n,\kappa}(x,\omega) - g_0^j(x)) < -\beta^{(2)}_{n,\kappa}\} \leq \mathcal{H}_2(\kappa)$$

for a suitable neighborhood UQ_0.

(CI4-S) There exists a function $\mu \in \Lambda$ such that for all $\varepsilon > 0$

$$\forall\, x \in U_\varepsilon Q_0 \setminus U_\varepsilon\hat{\Gamma}_0 \;\; \exists j \in J :\; g_0^j(x) > \mu(\varepsilon).$$

If we want to exploit Theorem 1 for solution sets we have to deal with one constraint function only. Therefore we provide a further specialization of Theorem 1, namely for $j_M = 1$ and $g_0^1 =: g_0$, $g^1_{n,\kappa} =: g_{n,\kappa}$. Additionally, in order to give an example for the function μ in (CI4), we replace (CI4) with a special growth condition (Gr-g_0), which is inspired by the growth condition in [13]. (Gr-g_0) specifies μ as $\mu(\varepsilon) = c_1\varepsilon^{\delta_1}$ for all $\varepsilon > 0$ with $U_\varepsilon Q_0 \subset U_{\theta_1}Q_0$.

COROLLARY 2. *Assume that* (CI1), (CI2), (CI3), *and the following condition* (Gr-g_0) *are satisfied.*

(Gr-g_0) *There exist constants* $c_1 > 0$, $\delta_1 > 0$, *and* $\theta_1 > 0$ *such that*

$$\forall x \in \bar{U}_{\theta_1}Q_0 :\; g_0(x) \geq c_1 \cdot d\big(x,\hat{\Gamma}_0\big)^{\delta_1}.$$

Then for all $\kappa > 0$, $\beta^{(3)}_{n,\kappa} = \max\{\nu^{-1}(\beta^{(1)}_{n,\kappa}), \nu^{-1}((\frac{\beta^{(2)}_{n,\kappa}}{c_1})^{\frac{1}{\delta_1}})\}$, *and* $n_0(\kappa) = \min\{l : U_{\beta^{(3)}_{l,\kappa}}Q_0 \subset \bar{U}_{\theta_1}Q_0 \cap UQ_0\}$ *the relation*

$$\sup_{n\geq n_0(\kappa)} P\{\omega :\; \Gamma_{n,\kappa}(\omega) \setminus U_{\beta^{(3)}_{n,\kappa}}\Gamma_0 \neq \emptyset\} \leq \mathcal{H}_1(\kappa) + \mathcal{H}_2(\kappa)$$

holds.

An important reason for considering constraint functions $g^j_{n,\kappa}$ which depend on κ is the intended application of Theorem 1 to the derivation of assertions about the solution set. If one is interested in the constraint set only, the following special case of Theorem 1 will be applicable in many cases. Often one has inequality constraints and perhaps the intersection with a fixed set Q_0. Usually the functions g_n do not depend on κ, and a convergence rate of the form $\beta^{(2)}_{n,\kappa} = \frac{\kappa}{\gamma_n}$ can be assumed. Then instead of (CI2) the following condition can be used and the growth condition can be given with respect to Γ_0.

(CI2') There exists a function $\mathcal{H}_2 \in H$ and a sequence $(\gamma_n)_{n\in N}$ which tends to ∞ such that for all $\kappa > 0$

$$\sup_{n\in N} P\{\omega :\ \gamma_n \left(\inf_{x\in Q_0\setminus\Gamma_0} (g_n(x,\omega) - g_0(x)\right) \le -\kappa\} \le \mathcal{H}_2(\kappa).$$

(Gr-g_0-Γ_0) There exist constants $c_1 > 0$, $\delta_1 > 0$, and $\theta_1 > 0$ such that

$$\forall x \in Q_0 \cap \bar{U}_{\theta_1}\Gamma_0 :\ g_0(x) \ge c_1 \cdot d(x,\Gamma_0)^{\delta_1}.$$

In this case Corollary 2 can be simplified in the following way:

COROLLARY 3. *Assume that $j_M = 1$ and for all $n \in N$ $g_{n,\kappa} \equiv g_n$ and $Q_{n,\kappa} \equiv Q_0$ holds. Additionally, suppose that* (CI2') *and* (Gr-g_0-Γ_0) *are satisfied. Then for all $\kappa > 0$ and $n_0(\kappa) = \min\{l : \gamma_l \ge (\frac{\kappa}{\theta_1})^{\delta_1}\}$ the relation*

$$\sup_{n\ge n_0(\kappa)} P\left\{\omega :\ \Gamma_n(\omega) \setminus U_{\frac{\kappa}{\gamma_n^{\frac{1}{\delta_1}}}}\Gamma_0 \ne \emptyset\right\} \le \mathcal{H}_2\left(c_1\kappa^{\delta_1}\right)$$

holds.

Proof. Let $\tilde{\kappa} := c_1\kappa^{\delta_1}$. With $\beta^{(2)}_{n,\tilde{\kappa}} = \frac{\tilde{\kappa}}{\gamma_n}$ and $\tilde{\mu}(\varepsilon) = c_1\varepsilon^{\delta_1}$ for $0 < \varepsilon \le \theta_1$ we can apply Corollary 1, taking into account that, additionally, $\beta^{(3)}_{n,\tilde{\kappa}} \le \theta_1$ has to be satisfied. We obtain for $\tilde{\kappa}$, $\beta^{(3)}_{n,\tilde{\kappa}} = (\frac{\tilde{\kappa}}{c_1\gamma_n})^{\frac{1}{\delta_1}} = \frac{\kappa}{\gamma_n^{\frac{1}{\delta_1}}}$, and $n_0(\kappa) = \min\{l : \beta^{(3)}_{l,\tilde{\kappa}} \le \theta_1\} = \min\{l : \gamma_l \ge (\frac{\kappa}{\theta_1})^{\delta_1}\}$ the inequality $\sup_{n\ge n_0(\kappa)} P\{\omega :\ \Gamma_n(\omega) \setminus U_{\beta^{(3)}_{n,\tilde{\kappa}}}\Gamma_0 \ne \emptyset\} \le \mathcal{H}_2(\tilde{\kappa})$, which yields the conclusion. □

As mentioned in the introduction, in general, the sequence $(\Gamma_n)_{n\in N}$ approximates a subset of Γ_0 only. In order to obtain outer approximations, additional assumptions have to be imposed. Qualitative stability theory usually assumes that the condition $\Gamma_0 \subset \mathrm{cl}\{x \in Q_0 :\ g_0^j(x) < 0,\ \forall j \in J\}$ is fulfilled where cl denotes the closure. In order to obtain also a convergence rate and a tail behavior function, we impose a "quantified version" of this assumption with a (negative) growth function μ; see (CO3) in Theorem 2. Unfortunately, a condition of that kind is useless if one intends to employ the result for the solution set, because (CO3) can not be satisfied by $\tilde{g}_0 := f_0 - \Phi_0$.

Hence in Theorem 3 we will provide a second approach which uses "relaxed" inequality constraints. The simple principle can be explained using a modified version of Example E1.

Example E3. Let $E = R^1$, $\Gamma_0 = \Gamma_n = [-1,+1]$, $g_0(x) \equiv 0$, and $g_n(x) = \min\{|x|, \frac{1}{n}\}$. Then $(g_n)_{n\in N}$ converges uniformly to g_0. We consider $\Gamma_0 := \{x \in R^1 : g_0(x) \le 0\}$ and $\Gamma_n := \{x \in R^1 : g_n(x) \le 0\}$. Obviously, $\Gamma_n = \{0\}$ for all $n \in N$, while $\Gamma_0 = [-1,+1]$; i.e., only a subset of Γ_0 is approximated. If we, however, consider the sets $\tilde{\Gamma}_n := \{x \in R^1 :\ g_n(x) \le \frac{1}{n}\}$, which are defined by the "relaxed" inequality constraint $g_n(x) \le \frac{1}{n}$, we see that even $\tilde{\Gamma}_n = \Gamma_0$ holds for all $n \in N$.

Similarly, we weaken the "≤ 0" inequality constraints by "$\le \rho_{n,\kappa}$" with suitably chosen sequences $(\rho_{n,\kappa})_{n\in N}$ of positive reals which satisfy $\lim_{n\to\infty} \rho_{n,\kappa} = 0\ \forall \kappa > 0$.

For the formulation of (CO3) we need the "ε-interior" of Γ_0. Let, for a given $\varepsilon > 0$, $CI(\varepsilon) := \Gamma_0 \setminus U_\varepsilon(E \setminus \Gamma_0)$. $\bar{U}_\varepsilon$ denotes the closure of U_ε. The requirement $\Gamma_0 \subset \bar{U}_\varepsilon CI(\varepsilon)$ is needed since we allow for rather general sets Γ_0.

Condition (CO1) below is the "outer" counterpart to (CI1), and condition (CO2) is the "upper semicontinuous" counterpart to (CI2).

THEOREM 2 (outer approximation of the constraint set (CO3)). *Assume that the following conditions are satisfied:*

(CO1) *There exists a function* $\mathcal{H}_1 \in H$ *and for all* $\kappa > 0$ *a sequence* $(\beta^{(1)}_{n,\kappa})_{n\in N} \in B$ *such that*

$$\sup_{n\in N} P\left\{\omega :\ Q_0 \setminus U_{\beta^{(1)}_{n,\kappa}} Q_{n,\kappa}(\omega) \neq \emptyset\right\} \leq \mathcal{H}_1(\kappa).$$

(CO2) *There exists a function* $\mathcal{H}_2 \in H$ *and for all* $\kappa > 0$ *a sequence* $(\beta^{(2)}_{n,\kappa})_{n\in N} \in B$ *such that*

$$\sup_{j\in J}\ \sup_{n\in N} P\left\{\omega :\ \sup_{x\in\Gamma_0}\left(g^j_{n,\kappa}(x,\omega) - g^j_0(x)\right) \geq \beta^{(2)}_{n,\kappa}\right\} \leq \mathcal{H}_2(\kappa).$$

(CO3) *There exist* $\tilde{\varepsilon} > 0$ *and a function* $\mu \in \Lambda$ *such that for all* $0 < \varepsilon \leq \tilde{\varepsilon}$ $\Gamma_0 \subset \bar{U}_\varepsilon CI(\varepsilon)$ *and*

$$\forall x \in CI(\varepsilon)\ \forall j \in J :\ g^j_0(x) \leq -\mu(\varepsilon).$$

Then for all $\kappa > 0$, $\beta^{(3)}_{n,\kappa} = \max\{\beta^{(1)}_{n,\kappa}, \mu^{-1}(2\beta^{(2)}_{n,\kappa})\}$, *and* $n_0(\kappa) = \min\{l : \beta^{(3)}_{l,\kappa} \leq 2\tilde{\varepsilon}\}$ *the relation*

$$\sup_{n\geq n_0(\kappa)} P\left\{\omega :\ \Gamma_0 \setminus \left(U_{\beta^{(3)}_{n,\kappa}} \hat{\Gamma}_{n,\kappa}(\omega) \cap U_{\beta^{(1)}_{n,\kappa}} Q_{n,\kappa}(\omega)\right) \neq \emptyset\right\} \leq \mathcal{H}_1(\kappa) + j_M \mathcal{H}_2(\kappa)$$

holds.

Proof. Assume that for given $\kappa > 0$, $n \geq n_0(\kappa)$, and $\omega \in \Omega$ the relation $\Gamma_0 \setminus (U_{\beta^{(3)}_{n,\kappa}} \hat{\Gamma}_{n,\kappa}(\omega) \cap U_{\beta^{(1)}_{n,\kappa}} Q_{n,\kappa}(\omega)) \neq \emptyset$ holds. Then there is $x_{n,\kappa}(\omega) \in \Gamma_0$ which does not belong to $U_{\beta^{(3)}_{n,\kappa}} \hat{\Gamma}_{n,\kappa}(\omega) \cap U_{\beta^{(1)}_{n,\kappa}} Q_{n,\kappa}(\omega)$.

If $x_{n,\kappa}(\omega) \notin U_{\beta^{(1)}_{n,\kappa}} Q_{n,\kappa}(\omega)$, we can employ (CO1).

Now suppose that $x_{n,\kappa}(\omega) \notin U_{\beta^{(3)}_{n,\kappa}} \hat{\Gamma}_{n,\kappa}(\omega)$. Because of $\beta^{(3)}_{n,\kappa} \leq 2\tilde{\varepsilon}$ and the first part of condition (CO3), we find $\tilde{x}_{n,\kappa}(\omega) \in CI(\frac{\beta^{(3)}_{n,\kappa}}{2})$ with $\tilde{x}_{n,\kappa}(\omega) \notin \hat{\Gamma}_{n,\kappa}(\omega)$; i.e., $g^{j_0}_{n,\kappa}(\tilde{x}_{n,\kappa}(\omega), \omega) > 0$ for at least one $j_0 \in J$. The second part of (CO3) implies $g^{j_0}_0(\tilde{x}_{n,\kappa}(\omega)) \leq -\mu(\frac{\beta^{(3)}_{n,\kappa}}{2}) \leq -\beta^{(2)}_{n,\kappa}$. It remains to employ (CO2). ∎

Unfortunately, the result is not the "symmetric" counterpart to the statement of Theorem 1. In order to obtain an assertion of the form

$$\sup_{n\geq n_0(\kappa)} P\left\{\omega :\ \Gamma_0 \setminus U_{\beta^{(3)}_{n,\kappa}} \Gamma_{n,\kappa}(\omega) \neq \emptyset\right\} \leq \mathcal{H}(\kappa),$$

we would need functions $\nu_{n,\kappa}$ and conditions similar to (CI3) for each n and κ.

Now we consider $\rho_{n,\kappa}$-relaxed inequality constraints. Let

$$\hat{\Gamma}^r_{n,\kappa}(\omega) := \{x \in E :\ g^j_{n,\kappa}(x,\omega) \leq \rho_{n,\kappa},\ j \in J\}$$

and

$$\Gamma^r_{n,\kappa}(\omega) = \hat{\Gamma}^r_{n,\kappa}(\omega) \cap Q_{n,\kappa}(\omega).$$

THEOREM 3 (outer approximation of the constraint set, relaxation). *Assume that* (CO1) *and* (CO2) *are satisfied. Then for all* $\kappa > 0$ *and* $\rho_{n,\kappa} = \beta^{(2)}_{n,\kappa}$ *the relation*

$$\sup_{n\in N} P\left\{\omega :\ \Gamma_0 \setminus \left(\hat{\Gamma}^r_{n,\kappa}(\omega) \cap U_{\beta^{(1)}_{n,\kappa}} Q_{n,\kappa}(\omega)\right) \neq \emptyset\right\} \leq \mathcal{H}_1(\kappa) + j_M \mathcal{H}_2(\kappa)$$

holds.

Proof. Assume that for given $\kappa > 0$, $n \in N$, and $\omega \in \Omega$ the relation $\Gamma_0 \setminus (\hat{\Gamma}^r_{n,\kappa}(\omega) \cap U_{\beta^{(1)}_{n,\kappa}} Q_{n,\kappa}(\omega)) \neq \emptyset$ is fulfilled. Then there is $x_{n,\kappa}(\omega) \in \Gamma_0$ which does not belong to $\hat{\Gamma}^r_{n,\kappa}(\omega) \cap U_{\beta^{(1)}_{n,\kappa}} Q_{n,\kappa}(\omega)$. Hence $g^j_0(x_{n,\kappa}(\omega)) \leq 0 \ \forall j \in J$ and $x_{n,\kappa}(\omega) \in Q_0$, but either $x_{n,\kappa}(\omega) \notin U_{\beta^{(1)}_{n,\kappa}} Q_{n,\kappa}(\omega)$ or $g^j_{n,\kappa}(x_{n,\kappa}(\omega), \omega) > \beta^{(2)}_{n,\kappa} = \rho_{n,\kappa}$ for at least one $j \in J$.

In the first case we obtain $Q_0 \setminus U_{\beta^{(1)}_{n,\kappa}} Q_{n,\kappa}(\omega) \neq \emptyset$ and employ (CO1).

The second case yields $\sup_{x \in \Gamma_0}(g^j_{n,\kappa}(x, \omega) - g^j_0(x)) \geq \beta^{(2)}_{n,\kappa}$ for at least one $j \in J$, and we make use of (CO2). □

Remark 2. A corresponding result holds if $U_{\beta^{(1)}_{n,\kappa}} Q_{n,\kappa}$ is replaced with $Q_{n,\kappa}$ in condition (CO1) and in the assertion. This observation is of importance if we apply the result to the solution set and have to deal with a constraint set which was obtained via relaxation: The constraint set will then play the role of Q in Theorem 3, and an additional enlargement of $Q_{n,\kappa}$ by a neighborhood should be avoided.

Relaxing the constraints means enlarging the approximating sets. Hence the question arises under what conditions $(\Gamma^r_{n,\kappa})_{n \in N}$ is also an inner approximation. Results of that kind will help to assess the quality of an outer approximation. An inspection of the proof to Theorem 1 shows that with $\rho_{n,\kappa} = \beta^{(2)}_{n,\kappa}$ the following statement can be obtained. The "price" for the relaxation is the additional factor 2 in the definition of $\beta^{(2)}_{n,\kappa}$.

THEOREM 4 (inner approximation of the constraint set, relaxation). *Assume that* (CI1), (CI2), (CI3), *and* (CI4) *are satisfied. Then for all* $\kappa > 0$, $\rho_{n,\kappa} = \beta^{(2)}_{n,\kappa}$, $\beta^{(3)}_{n,\kappa} = \max\{\nu^{-1}(\beta^{(1)}_{n,\kappa}), \nu^{-1}(\mu^{-1}(2\beta^{(2)}_{n,\kappa}))\}$, *and* $n_0(\kappa) = \min\{l : U_{\nu(\beta^{(3)}_{l,\kappa})} Q_0 \subset U Q_0\}$ *the relation*

$$\sup_{n \geq n_0(\kappa)} P\left\{\omega : \Gamma^r_{n,\kappa}(\omega) \setminus U_{\beta^{(3)}_{n,\kappa}} \Gamma_0 \neq \emptyset\right\} \leq \mathcal{H}_1(\kappa) + j_M \mathcal{H}_2(\kappa)$$

holds.

The assertions about inner and outer approximations provided so far can be combined to several convergence statements. As an example, we will summarize what we obtain for only one constraint function under a growth condition. In the following we combine conditions like (CI1) and (CO1). The assumption that in both conditions the same function $\mathcal{H}_1$ and the same sequences $(\beta^{(1)}_{n,\kappa})_{n \in N}$ occur is no restriction. If the original functions or sequences are different we can always take the maximum.

THEOREM 5 (approximation of the constraint set, relaxation). *Assume that* $j_M = 1$, (CI3), *and* (Gr-g_0) *are satisfied. Furthermore, suppose that* (CI1) *and* (CO1) *are fulfilled with the same function* $\mathcal{H}_1 \in H$ *and the same sequences* $(\beta^{(1)}_{n,\kappa})_{n \in N} \in B$, *and* (CI1) *and* (CO2) *are fulfilled with the same function* $\mathcal{H}_2 \in H$ *and the same sequences* $(\beta^{(2)}_{n,\kappa})_{n \in N} \in B$.

Then for all $\kappa > 0$, $\rho_{n,\kappa} = \beta^{(2)}_{n,\kappa}$, $\beta^{(3)}_{n,\kappa} = \max\{\beta^{(1)}_{n,\kappa}, \beta^{(2)}_{n,\kappa}, \nu^{-1}(\beta^{(1)}_{n,\kappa}), \nu^{-1}((\frac{2\beta^{(2)}_{n,\kappa}}{c_1})^{\frac{1}{\delta_1}})\}$, *and* $n_0(\kappa) = \min\{l : U_{\nu(\beta^{(3)}_{l,\kappa})} Q_0 \subset U Q_0\}$ *the relation*

$$\sup_{n \geq n_0(\kappa)} P\left\{\omega : \left(\Gamma^r_{n,\kappa}(\omega) \setminus U_{\beta^{(3)}_{n,\kappa}} \Gamma_0\right) \cup \left(\Gamma_0 \setminus \left(\hat{\Gamma}^r_{n,\kappa}(\omega) \cap Q_{n,\kappa}(\omega)\right)\right) \neq \emptyset\right\} \leq 2\mathcal{H}_1(\kappa) + 2\mathcal{H}_2(\kappa)$$

holds.

Proof. We have

$$P\{\omega:\ (\Gamma^r_{n,\kappa}(\omega)\setminus U_{\beta^{(3)}_{n,\kappa}}\Gamma_0)\cup(\Gamma_0\setminus(\hat\Gamma^r_{n,\kappa}(\omega)\cap Q_{n,\kappa}(\omega))\neq\emptyset\}$$
$$\leq P\{\omega:\ \Gamma^r_{n,\kappa}(\omega)\setminus U_{\beta^{(3)}_{n,\kappa}}\Gamma_0\neq\emptyset\}+P\{\omega:\ \Gamma_0\setminus(\hat\Gamma^r_{n,\kappa}(\omega)\cap Q_{n,\kappa}(\omega))\neq\emptyset\}.$$

The assumptions of Theorem 3 and Theorem 4 are satisfied with $\mu(\varepsilon)=c_1\varepsilon^{\delta_1}$ and $\tilde\beta^{(1)}_{n,\kappa}=\tilde\beta^{(2)}_{n,\kappa}=\beta^{(3)}_{n,\kappa}$. □

Finally, for sake of convenience, we give a special case of Theorem 5 which uses assumptions that correspond to those of Corollary 3. The following condition will be imposed:

(CO2') There exist a function $\mathcal{H}_2\in H$ and a sequence $(\gamma_n)_{n\in N}$, which tends to ∞, such that for all $\kappa>0$

$$\sup_{n\in N}P\left\{\omega:\ \gamma_n\sup_{x\in\Gamma_0}(g_n(x,\omega)-g_0(x))\geq\kappa\right\}\leq\mathcal{H}_2(\kappa).$$

Corollary 4. *Assume that $j_M=1$, for all $n\in N$ $g_{n,\kappa}\equiv g_n$ holds, and* (Gr-g_0-Γ_0) *is satisfied. Additionally, suppose that* (CI2') *and* (CO2') *are fulfilled with the same function $\mathcal{H}_2\in H$ and the same sequences $(\beta^{(2)}_{n,\kappa})_{n\in N}\in B$. Then for all $\kappa>0$, $\Gamma_0=\{x\in Q_0:\ g_0(x)\leq 0\}$, $\Gamma^r_{n,\kappa}(\omega)=\{x\in Q_0:\ g_n(x,\omega))\leq\frac{\kappa}{\sqrt{n}}\}$, $\beta^{(3)}_{n,\kappa}=(\frac{2\kappa}{c_1\gamma_n})^{\frac{1}{\delta_1}}$, and $n_0(\kappa)=\min\{l:\gamma_l\geq\frac{2\kappa}{c_1\theta_1^{\delta_1}}\}$ the relation*

$$\sup_{n\geq n_0(\kappa)}P\left\{\omega:\ \left(\Gamma^r_{n,\kappa}(\omega)\setminus U_{\beta^{(3)}_{n,\kappa}}\Gamma_0\right)\cup\left(\Gamma_0\setminus\Gamma^r_{n,\kappa}(\omega)\right)\neq\emptyset\right\}\leq 2\mathcal{H}_2(\kappa)$$

holds.

Proof. We have

$$P\left\{\omega:\ \left(\Gamma^r_{n,\kappa}(\omega)\setminus U_{\beta^{(3)}_{n,\kappa}}\Gamma_0\right)\cup\left(\Gamma_0\setminus\Gamma^r_{n,\kappa}(\omega)\right)\neq\emptyset\right\}$$
$$\leq P\left\{\omega:\ \Gamma^r_{n,\kappa}(\omega)\setminus U_{\beta^{(3)}_{n,\kappa}}\Gamma_0\neq\emptyset\right\}+P\{\omega:\ \Gamma_0\setminus\Gamma^r_{n,\kappa}(\omega)\neq\emptyset\}.$$

Firstly, assume that for given $\kappa>0$, $n\geq n_0(\kappa)$ and $\omega\in\Omega$ the relation $\Gamma^r_{n,\kappa}(\omega)\setminus U_{\beta^{(3)}_{n,\kappa}}\Gamma_0\neq\emptyset$ is satisfied. Then there is $x_{n,\kappa}(\omega)\in\Gamma^r_{n,\kappa}(\omega)$ which does not belong to $U_{\beta^{(3)}_{n,\kappa}}\Gamma_0$. Because of $n\geq n_0(\kappa)$ we have $\beta^{(3)}_{n,\kappa}\leq\theta_1$. Consequently, by (Gr-$g_0$-$\Gamma_0$), $g_0(x_{n,\kappa}(\omega)\geq c_1(\beta^{(3)}_{n,\kappa})^{\delta_1}=\frac{2\kappa}{\gamma_n}$. Hence $\inf_{x\in Q_o\setminus\Gamma_0}(g_n(x,\omega)-g_0(x))\leq\frac{\kappa}{\gamma_n}-\frac{2\kappa}{\gamma_n}=-\frac{\kappa}{\gamma_n}$, and we can employ (CI2').

Now, assume that for given $\kappa>0$, $n\geq n_0(\kappa)$, and $\omega\in\Omega$ the relation $P\{\omega:\Gamma_0\setminus\Gamma^r_{n,\kappa}(\omega)\neq\emptyset\}$ is satisfied. Then there is $x_{n,\kappa}(\omega)\in\Gamma_0$ which does not belong to $\Gamma^r_{n,\kappa}(\omega)$. Because of $x_{n,\kappa}(\omega)\in Q_0$ we obtain $g_n(x_{n,\kappa}(\omega),\omega)>\frac{\kappa}{\sqrt{n}}$, and finally $\sup_{x\in\Gamma_0}(g_n(x,\omega)-g_0(x))\geq\frac{\kappa}{\gamma_n}$. It remains to employ (CO2'). □

4. Approximation of the optimal values and the solution sets. We turn to the optimal values and the solutions sets of the problems (P_0) and $(P_{n,\kappa})$.

In the following, the constraint sets and their approximations are not supposed to have a special form. Especially, $\Gamma_{n,\kappa}$ can be described by inequality constraints as in section 3, but it can also denote a set originating from a relaxation like $\Gamma^r_{n,\kappa}$.

We do not impose compactness conditions on Γ_0 and $\Gamma_{n,\kappa}$. Instead, for the sake of simplicity, we assume that the original and the approximating problems have a solution.

We start with the consideration of the optimal values. Results of this kind are, among others, needed for assertions about the solution sets. The assertion of Theorem 6 says, roughly speaking, that the optimal values of the approximate problem are greater (in the in-probability sense) than the true optimal value. The denotation "lower approximation" in the theorem is chosen because of the relationship to lower semicontinuity of a function of one variable—in our case the "variable" n.

THEOREM 6 (lower approximation of the optimal value). *Assume that the following conditions are satisfied:*

(VL1) *There exists a function* $\mathcal{H}_1 \in H$ *and for all* $\kappa > 0$ *a sequence* $(\beta_{n,\kappa}^{(1)})_{n\in N} \in B$ *such that*

$$\sup_{n\in N} P\left\{\omega :\ \Gamma_{n,\kappa}(\omega) \setminus U_{\beta_{n,\kappa}^{(1)}}\Gamma_0 \neq \emptyset\right\} \leq \mathcal{H}_1(\kappa).$$

(VL2) *There exists a function* $\mathcal{H}_2 \in H$ *and to all* $\kappa > 0$ *a sequence* $(\beta_{n,\kappa}^{(2)})_{n\in N} \in B$ *such that*

$$\sup_{n\in N} P\left\{\omega :\ \inf_{x\in U\Gamma_0}(f_{n,\kappa}(x,\omega) - f_0(x)) \leq -\beta_{n,\kappa}^{(2)}\right\} \leq \mathcal{H}_2(\kappa)$$

for a suitable neighborhood $U\Gamma_0$.

(VL3) *There exists a function* $\lambda \in \Lambda$ *such that for all* $\varepsilon > 0$

$$\forall\, x \in U_{\lambda(\varepsilon)}\Gamma_0 \cap U\Gamma_0 :\ f_0(x) \geq \Phi_0 - \varepsilon.$$

Then for all $\kappa > 0$, $\beta_{n,\kappa}^{(3)} = \max\{2\lambda^{-1}(\beta_{n,\kappa}^{(1)}), 2\beta_{n,\kappa}^{(2)}\}$, *and* $n_0(\kappa) = \min\{l :\ U_{\lambda(\frac{\beta_{l,\kappa}^{(3)}}{2})}\Gamma_0 \subset U\Gamma_0\}$ *the relation*

$$\sup_{n\geq n_0(\kappa)} P\left\{\omega :\ \Phi_{n,\kappa}(\omega) - \Phi_0 \leq -\beta_{n,\kappa}^{(3)}\right\} \leq \mathcal{H}_1(\kappa) + \mathcal{H}_2(\kappa)$$

holds.

Proof. Assume that for given $\kappa > 0$, $n \geq n_0(\kappa)$, and $\omega \in \Omega$ the relation $\Phi_{n,\kappa}(\omega) \leq \Phi_0 - \beta_{n,\kappa}^{(3)}$ holds. Then there exists $x_{n,\kappa}(\omega) \in \Gamma_{n,\kappa}(\omega)$ such that $f_{n,\kappa}(x_{n,\kappa}(\omega),\omega) = \Phi_{n,\kappa}(\omega) \leq \Phi_0 - \beta_{n,\kappa}^{(3)}$.

Firstly, let $x_{n,\kappa}(\omega) \in U_{\lambda(\frac{\beta_{n,\kappa}^{(3)}}{2})}\Gamma_0$. Then $\inf_{x\in U\Gamma_0}(f_{n,\kappa}(x,\omega) - f_0(x)) \leq f_{n,\kappa}(x_{n,\kappa}(\omega),\omega) - f_0(x_{n,\kappa}(\omega)) \leq \Phi_{n,\kappa}(\omega) - \Phi_0 + \frac{\beta_{n,\kappa}^{(3)}}{2} \leq -\frac{\beta_{n,\kappa}^{(3)}}{2} \leq -\beta_{n,\kappa}^{(2)}$, and we can employ (VL2).

Secondly, if $x_{n,\kappa}(\omega) \notin U_{\lambda(\frac{\beta_{n,\kappa}^{(3)}}{2})}\Gamma_0$, we have $\Gamma_{n,\kappa}(\omega) \setminus U_{\beta_{n,\kappa}^{(1)}}\Gamma_0 \neq \emptyset$. It remains to employ (VL1). □

The proof shows that the following assertion also holds, which applies to the important special case $\Gamma_{n,\kappa} \equiv \Gamma_0$.

COROLLARY 5. *Assume that* $\Gamma_{n,\kappa} \equiv \Gamma_0$ *and the following condition is satisfied:*

(VL2') *There exists a function* $\mathcal{H}_2 \in H$ *and to all* $\kappa > 0$ *a sequence* $(\beta_{n,\kappa}^{(2)})_{n\in N} \in B$ *such that*

$$\sup_{n\in N} P\left\{\omega :\ \inf_{x\in\Gamma_0}(f_{n,\kappa}(x,\omega) - f_0(x)) \leq -\beta_{n,\kappa}^{(2)}\right\} \leq \mathcal{H}_2(\kappa).$$

Then for all $\kappa > 0$ *the relation*

$$\sup_{n\in N} P\left\{\omega :\ \Phi_{n,\kappa}(\omega) - \Phi_0 \leq -\beta_{n,\kappa}^{(2)}\right\} \leq \mathcal{H}_2(\kappa)$$

holds.

In the following we consider the counterpart, so-called upper approximations, and distinguish two cases according to whether

$$\forall \kappa > 0: \sup_{n \geq n_0(\kappa)} P\left\{\omega:\ \Gamma_0 \setminus U_{\beta^{(1)}_{n,\kappa}} \Gamma_{n,\kappa}(\omega) \neq \emptyset\right\} \leq \mathcal{H}_1(\kappa) \text{ or}$$
$$\forall \kappa > 0: \sup_{n \geq n_0(\kappa)} P\left\{\omega:\ \Gamma_0 \setminus \Gamma_{n,\kappa}(\omega) \neq \emptyset\right\} \leq \mathcal{H}_1(\kappa)$$

is imposed. The first case, which is dealt with in Theorem 7, occurs if outer approximations are derived under condition (CO3). The second case, which is considered in Theorem 8, comes into play if $\Gamma_{n,\kappa}$ is obtained via relaxation; compare Remark 2. Recall that minimization is always taken with respect to $\Gamma_{n,\kappa}$. Hence, in Theorem 7 and Theorem 8 we will find different convergence rates.

THEOREM 7 (upper approximation of the optimal value I). *Assume that the following conditions are satisfied:*

(VU1) *There exists a function $\mathcal{H}_1 \in H$ and for all $\kappa > 0$ a sequence $(\beta^{(1)}_{n,\kappa})_{n\in N} \in B$ such that*

$$\sup_{n\in N} P\left\{\omega:\ \Gamma_0 \setminus U_{\beta^{(1)}_{n,\kappa}} \Gamma_{n,\kappa}(\omega) \neq \emptyset\right\} \leq \mathcal{H}_1(\kappa).$$

(VU2) *There exists a function $\mathcal{H}_2 \in H$ and for all $\kappa > 0$ a sequence $(\beta^{(2)}_{n,\kappa})_{n\in N} \in B$ such that*

$$\sup_{n\in N} P\left\{\omega:\ \sup_{x\in U\Psi_0} (f_{n,\kappa}(x,\omega) - f_0(x)) \geq \beta^{(2)}_{n,\kappa}\right\} \leq \mathcal{H}_2(\kappa)$$

for a suitable neighborhood $U\Psi_0$.

(VU3) *There exists a function $\lambda \in \Lambda$ such that for all $\varepsilon > 0$*

$$\forall\, x \in U_{\lambda(\varepsilon)}\Psi_0 \cap U\Psi_0:\ f_0(x) \leq \Phi_0 + \varepsilon.$$

Then for all $\kappa > 0$, $\beta^{(3)}_{n,\kappa} = \max\{2\lambda^{-1}(\beta^{(1)}_{n,\kappa}), 2\beta^{(2)}_{n,\kappa}\}$, and $n_0(\kappa) = \min\{l:\ U_{\lambda(\frac{\beta^{(3)}_{l,\kappa}}{2})}\Psi_0 \subset U\Psi_0\}$ the relation

$$\sup_{n\geq n_0(\kappa)} P\left\{\omega:\ \Phi_{n,\kappa}(\omega) - \Phi_0 \geq \beta^{(3)}_{n,\kappa}\right\} \leq \mathcal{H}_1(\kappa) + \mathcal{H}_2(\kappa)$$

holds.

Proof. Assume that for given $\kappa > 0$, $n \geq n_0(\kappa)$, and $\omega \in \Omega$ the relation $\Phi_{n,\kappa}(\omega) \geq \Phi_0 + \beta^{(3)}_{n,\kappa}$ holds. Then there exists $x_{n,\kappa}(\omega) \in \Gamma_{n,\kappa}(\omega)$ such that $f_{n,\kappa}(x_{n,\kappa}(\omega),\omega) = \Phi_{n,\kappa}(\omega) \geq \Phi_0 + \beta^{(3)}_{n,\kappa}$. To $x_{n,\kappa}(\omega)$ we select $\tilde{x}_{n,\kappa}(\omega) \in \Gamma_{n,\kappa}(\omega)$ such that $d(\tilde{x}_{n,\kappa}(\omega), \Psi_0) = \min_{x\in\Gamma_{n,\kappa}(\omega)} d(x,\Psi_0)$.

Firstly, assume that $\tilde{x}_{n,\kappa}(\omega) \in U_{\lambda(\frac{\beta^{(3)}_{n,\kappa}}{2})}\Psi_0$. Then $f_{n,\kappa}(\tilde{x}_{n,\kappa}(\omega),\omega) \geq \Phi_{n,\kappa}(\omega) \geq \Phi_0 + \beta^{(3)}_{n,\kappa} \geq f_0(\tilde{x}_{n,\kappa}(\omega)) + \frac{\beta^{(3)}_{n,\kappa}}{2}$ and consequently, $\sup_{x\in U\Psi_0}(f_{n,\kappa}(x,\omega) - f_0(x)) \geq \frac{\beta^{(3)}_{n,\kappa}}{2} \geq \beta^{(2)}_{n,\kappa}$. Hence we can make use of (VU2).

If $\tilde{x}_{n,\kappa}(\omega) \notin U_{\lambda(\frac{\beta^{(3)}_{n,\kappa}}{2})}\Psi_0$, we have $\Gamma_0 \setminus U_{\beta^{(1)}_{n,\kappa}} \Gamma_{n,\kappa}(\omega) \neq \emptyset$ and we can employ (VU1). □

If we impose the special upper semicontinuity condition (UCon) for f_0, we obtain the following corollary.

COROLLARY 6 (upper approximation of the optimal value I). *Assume that* (VU1), (VU2), *and the following condition* (UCon) *are satisfied:*

(UCon) *There exist constants* $c_2 > 0$, $\delta_2 > 0$, *and* $\theta_2 > 0$ *such that*

$$\forall x \in \bar{U}_{\theta_2}\Psi_0 : \ f_0(x) \leq \Phi_0 + c_2 d(x, \Psi_0)^{\delta_2}.$$

Then, for all $\kappa > 0$, $\beta_{n,\kappa}^{(3)} = \max\{2c_2(\beta_{n,\kappa}^{(1)})^{\delta_2}, 2\beta_{n,\kappa}^{(2)}\}$, *and* $n_0(\kappa) = \min\{l : \ U_{\lambda_{l,\kappa}}\Psi_0 \subset U\Psi_0 \cap \bar{U}_{\theta_2}\Psi_0\}$ *with* $\lambda_{l,\kappa} = (\frac{\beta_{l,\kappa}^{(3)}}{2c_2})^{\frac{1}{\delta_2}}$ *the relation*

$$\sup_{n \geq n_0(\kappa)} P\left\{\omega : \ \Phi_{n,\kappa}(\omega) - \Phi_0 \geq \beta_{n,\kappa}^{(3)}\right\} \leq \mathcal{H}_1(\kappa) + \mathcal{H}_2(\kappa)$$

holds.

Proof. We employ Theorem 7. Because of (UCon) we can choose $\lambda(\varepsilon) = (\frac{\varepsilon}{c_2})^{\frac{1}{\delta_2}}$ and consequently $\lambda^{-1}(\varepsilon) = c_2\varepsilon^{\delta_2}$. □

A similar corollary can be proved for the lower approximation of the optimal values. We give only the result for the upper approximation because we will use it in the following. Furthermore, the assertions can be supplemented by results similar to Corollary 3 and Corollary 4.

We could also consider a variant of (UCon) which refers to $\hat{\Psi}_0$ instead of Ψ_0. We refrain from giving a corresponding statement because (UCon) requires only f_0 not to vary too much outside Ψ_0. It is in its importance not comparable to a growth condition which requires that f_0 has to grow outside the reference set with a certain rate.

THEOREM 8 (upper approximation of the optimal value II). *Assume that the following conditions are satisfied:*

(VU1-R) *There exists a function* $\mathcal{H}_1 \in H$ *such that*

$$\sup_{n \in N} P\{\omega : \ \Gamma_0 \setminus \Gamma_{n,\kappa}(\omega) \neq \emptyset\} \leq \mathcal{H}_1(\kappa).$$

(VU2-R) *There exists a function* $\mathcal{H}_2 \in H$ *and for all* $\kappa > 0$ *a sequence* $(\beta_{n,\kappa}^{(2)})_{n \in N} \in B$ *such that*

$$\sup_{n \in N} P\left\{\omega : \ \sup_{x \in \Psi_0}(f_{n,\kappa}(x, \omega) - f_0(x)) \geq \beta_{n,\kappa}^{(2)}\right\} \leq \mathcal{H}_2(\kappa).$$

Then for all $\kappa > 0$ *the relation*

$$\sup_{n \in N} P\left\{\omega : \ \Phi_{n,\kappa}(\omega) - \Phi_0 \geq \beta_{n,\kappa}^{(2)}\right\} \leq \mathcal{H}_1(\kappa) + \mathcal{H}_2(\kappa)$$

holds.

Proof. Assume that for given $\kappa > 0$, $n \in N$, and $\omega \in \Omega$ the relation $\Phi_{n,\kappa}(\omega) \geq \Phi_0 + \beta_{n,\kappa}^{(2)}$ holds. Then there exists $x_{n,\kappa}(\omega) \in \Gamma_{n,\kappa}(\omega)$ such that $f_{n,\kappa}(x_{n,\kappa}(\omega), \omega) = \Phi_{n,\kappa}(\omega) \geq \Phi_0 + \beta_{n,\kappa}^{(2)}$. To $x_{n,\kappa}(\omega)$ we select $\tilde{x}_{n,\kappa}(\omega) \in \Gamma_{n,\kappa}(\omega)$ such that $d(\tilde{x}_{n,\kappa}(\omega), \Psi_0) = \min_{x \in \Gamma_{n,\kappa}(\omega)} d(x, \Psi_0)$.

If $\tilde{x}_{n,\kappa}(\omega) \in \Psi_0$ we have

$$f_{n,\kappa}(\tilde{x}_{n,\kappa}(\omega), \omega) \geq \Phi_{n,\kappa}(\omega) \geq \Phi_0 + \beta_{n,\kappa}^{(2)} = f_0(\tilde{x}_{n,\kappa}(\omega)) + \beta_{n,\kappa}^{(2)}$$

and consequently, $\sup_{x \in \Psi_0}(f_{n,\kappa}(x, \omega) - f_0(x)) \geq \beta_{n,\kappa}^{(2)}$. Hence (VU2-R) can be utilized. Otherwise we have $\Gamma_0 \setminus \Gamma_{n,\kappa}(\omega) \neq \emptyset$ and can employ the first assumption. □

Now we turn to the solution sets. We use the abbreviation

$$\hat{\Psi}_0 = \{x \in E :\ f_0(x) \le \Phi_0\}.$$

THEOREM 9 (inner approximation of the solution set). *Assume that* (VL1), (VL2), *and the following assumptions are satisfied:*

(SI3) *There exists a function* $\mathcal{H}_3 \in H$ *and for all* $\kappa > 0$ *a sequence* $(\hat{\beta}^{(2)}_{n,\kappa})_{n\in N} \in B$ *and* $n_0(\kappa)$ *such that*

$$\sup_{n\ge n_0(\kappa)} P\left\{\omega :\ \Phi_{n,\kappa}(\omega) - \Phi_0 \ge \hat{\beta}^{(2)}_{n,\kappa}\right\} \le \mathcal{H}_3(\kappa).$$

(SI4) *There exists a function* $\nu \in \Lambda$ *such that for all* $\varepsilon > 0$

$$U_\varepsilon \Psi_0 \supset U_{\nu(\varepsilon)}\Gamma_0 \cap U_{\nu(\varepsilon)}\hat{\Psi}_0.$$

(SI5) *There exists a function* $\mu \in \Lambda$ *such that for all* $\varepsilon > 0$

$$\forall\, x \in U_\varepsilon\Gamma_0 \setminus U_\varepsilon\hat{\Psi}_0 :\ f_0(x) \ge \Phi_0 + \mu(\varepsilon).$$

Then for all $\kappa > 0$, $\beta^{(3)}_{n,\kappa} = \max\{\nu^{-1}(\beta^{(1)}_{n,\kappa}), \nu^{-1}(\mu^{-1}(\beta^{(2)}_{n,\kappa} + \hat{\beta}^{(2)}_{n,\kappa}))\}$, *and* $n_1(\kappa) = \min\{l \ge n_0(\kappa) :\ U_{\nu(\beta^{(3)}_{l,\kappa})}\Gamma_0 \subset U\Gamma_0\}$ *the relation*

$$\sup_{n\ge n_1(\kappa)} P\left\{\omega :\ \Psi_{n,\kappa}(\omega) \setminus U_{\beta^{(3)}_{n,\kappa}}\Psi_0 \ne \emptyset\right\} \le \mathcal{H}_1(\kappa) + \mathcal{H}_2(\kappa) + \mathcal{H}_3(\kappa)$$

holds.

Proof. Let $\tilde{g}_{n,\kappa}(x,\omega) := f_{n,\kappa}(x,\omega) - \Phi_{n,\kappa}(\omega)$, $\tilde{g}_0(x) := f_0(x) - \Phi_0$. Then $\Psi_{n,\kappa}(\omega) = \Gamma_{n,\kappa}(\omega) \cap \{x \in E :\ \tilde{g}_{n,\kappa}(x,\omega) \le 0\}$ and $\Psi_0 = \Gamma_0 \cap \{x \in E :\ \tilde{g}_0(x) \le 0\}$. Furthermore,

$$\begin{aligned}
&\sup_{n\ge n_0(\kappa)} P\left\{\omega :\ \inf_{x\in U\Gamma_0\setminus\Psi_0} (\tilde{g}_{n,\kappa}(x,\omega) - \tilde{g}_0(x)) \le -\beta^{(2)}_{n,\kappa} - \hat{\beta}^{(2)}_{n,\kappa}\right\}\\
&\le \sup_{n\ge n_0(\kappa)} P\left\{\omega :\ \inf_{x\in U\Gamma_0\setminus\Psi_0} (f_{n,\kappa}(x,\omega) - f_0(x)) \le -\beta^{(2)}_{n,\kappa}\right\}\\
&+ \sup_{n\ge n_0(\kappa)} P\left\{\omega :\ -\Phi_{n,\kappa}(\omega) + \Phi_0 \le -\hat{\beta}^{(2)}_{n,\kappa}\right\} \le \mathcal{H}_2(\kappa) + \mathcal{H}_3(\kappa) =: \tilde{\mathcal{H}}_2(\kappa).
\end{aligned}$$

It remains to apply Theorem 1 with $\tilde{\beta}^{(2)}_{n,\kappa} = \beta^{(2)}_{n,\kappa} + \hat{\beta}^{(2)}_{n,\kappa}$ and $\tilde{\mathcal{H}}_2$. □

When applying our results to problems in decision theory or estimation theory, the most critical assumption is probably (SI4). Fortunately, there are several important applications where some quantities do not vary with n and ν can be avoided or, as in our third example, (SI4) is easy to verify.

We emphasize that we can choose $\nu(\varepsilon) = \varepsilon$ if $\Gamma_{n,\kappa} \equiv \Gamma_0$ and the growth condition is given with respect to Ψ_0.

(SI5-W) There exists a function $\tilde{\mu} \in \Lambda$ such that for all $\varepsilon > 0$

$$\forall\, x \in \Gamma_0 \setminus U_\varepsilon\Psi_0 :\ f_0(x) \ge \Phi_0 + \tilde{\mu}(\varepsilon).$$

This case is considered in [13]. Imposing the special form of $\tilde{\mu}$ in [13], Pflug's result can be derived from Corollary 3.

Furthermore, if $U_{\tilde{\varepsilon}}\Psi_0 \subset \Gamma_0$ for a suitable $\tilde{\varepsilon} > 0$, we can also deal with $\nu(\varepsilon) = \varepsilon$ for all $\varepsilon \leq \tilde{\varepsilon}$.

In the general case, however, if the constraint set and the objective function are approximated simultaneously and the solution lies on the boundary of the constraint set, ν cannot be ignored. Only in rare cases one should have enough information to determine it exactly. One way out are adaptive methods for successive approximation of ν. However, even if one does not succeed in determining ν with satisfactory accuracy, our results still yield assertions on the convergence rate, albeit without a reliable constant. Results of that kind can be used to derive asymptotic confidence sets if a limiting distribution is not available.

The following corollary incorporates sufficient conditions for the needed approximation of the optimal value. It combines Theorem 9 and Corollary 6.

COROLLARY 7 (inner approximation of the solution set). *Assume that* (VL1) *and* (VU1) *are fulfilled with the same function $\mathcal{H}_1$ and the same sequences $(\beta^{(1)}_{n,\kappa})_{n\in N}$, and* (VL2) *and* (VU2) *are fulfilled with the same function $\mathcal{H}_2$ and the same sequences $(\beta^{(2)}_{n,\kappa})_{n\in N}$. Furthermore, suppose that* (SI4), (UCon), *and the following condition are satisfied:*

(Gr-f_0) There exist constants $c_1 > 0$, $\delta_1 > 0$, and $\theta_1 > 0$ such that

$$\forall x \in \bar{U}_{\theta_1}\Gamma_0 :\ f_0(x) - \Phi_0 \geq c_1 \cdot d(x, \hat{\Psi}_0)^{\delta_1}.$$

Then for all $\kappa > 0$, $\beta^{(3)}_{n,\kappa} = \max\{\nu^{-1}(\beta^{(1)}_{n,\kappa}), \nu^{-1}((\frac{\hat{\beta}^{(2)}_{n,\kappa}+\beta^{(2)}_{n,\kappa}}{c_1})^{\frac{1}{\delta_1}})\}$, $\hat{\beta}^{(2)}_{n,\kappa} = \max\{2c_2 (\beta^{(1)}_{n,\kappa})^{\delta_2}, 2\beta^{(2)}_{n,\kappa}\}$, $n_1(\kappa) = \min\{l :\ U_{\beta^{(3)}_{l,\kappa}}\Gamma_0 \subset U\Gamma_0,\ U_{\hat{\lambda}_{l,\kappa}}\Psi_0 \subset U\Psi_0,\ \beta^{(3)}_{l,\kappa} \leq \theta_1,\ \hat{\lambda}_{l,\kappa} \leq \theta_2\}\}$, and $\hat{\lambda}_{n,\kappa} = (\frac{\hat{\beta}^{(2)}_{n,\kappa}}{2c_2})^{\frac{1}{\delta_1}}$ the relation

$$\sup_{n\geq n_1(\kappa)} P\left\{\omega :\ \Psi_{n,\kappa}(\omega) \setminus U_{\beta^{(3)}_{n,\kappa}}\Psi_0 \neq \emptyset\right\} \leq 2\mathcal{H}_1(\kappa) + 2\mathcal{H}_2(\kappa)$$

holds.

Proof. We apply Theorem 9 together with Corollary 6. (SI3) is satisfied with $\hat{\beta}^{(2)}_{n,\kappa}$, $\mathcal{H}_3 = \mathcal{H}_1 + \mathcal{H}_2$, and $\hat{n}_0(\kappa) = \min\{l :\ \hat{\lambda}_{l,\kappa} \leq \theta_2,\ U_{\hat{\lambda}_{l,\kappa}}\Psi_0 \subset U\Psi_0\}$. Theorem 9 with $\mu^{-1}(\varepsilon) = (\frac{\varepsilon}{c_1})^{\frac{1}{\delta_1}}$ yields the conclusion. □

The following condition covers the cases dealt with in Theorem 5 or Corollary 4.

(CK-R) There exists a function $\mathcal{H}_1 \in H$ and for all $\kappa > 0$ a sequence $(\beta^{(1)}_{n,\kappa})_{n\in N} \in B$ such that

$$\sup_{n\in N} P\left\{\omega :\ \left(\Gamma_{n,\kappa}(\omega) \setminus U_{\beta^{(1)}_{n,\kappa}}\Gamma_0\right) \cup (\Gamma_0 \setminus \Gamma_{n,\kappa}(\omega)) \neq \emptyset\right\} \leq \mathcal{H}_1(\kappa).$$

If (CK-R) is satisfied, also (VL1) and (VU1) are fulfilled with $\mathcal{H}_1$ and $\beta^{(1)}_{n,\kappa}$. Consequently, if $\Gamma_{n,\kappa} = \Gamma^r_{n,\kappa}$, we can employ Theorem 5 or Corollary 4 in order to determine a suitable $\rho_{n,\kappa}$ and formulate sufficient conditions for (VL1) and (VU1).

Finally, we consider outer approximations of the solution set via $\rho_{n,\kappa}$-optimal solutions of the approximating problems.

Let

$$\hat{\Psi}^r_{n,\kappa}(\omega) := \{x \in E :\ f_{n,\kappa}(x,\omega) \leq \Phi_{n,\kappa}(\omega) + \rho_{n,\kappa}\}.$$

$\Gamma_{n,\kappa}$ can, e.g., be specified as $U_{\beta^{(1)}_{n,\kappa}}\Gamma_n$ or as $\Gamma^r_{n,\kappa}$.

THEOREM 10 (outer approximation of the solution set, relaxation). *Assume that* (VU1), (VU2), *and the following assumption are satisfied:*

(SO3) *There exists a function* $\mathcal{H}_3 \in H$ *and for all* $\kappa > 0$ *a sequence* $(\hat{\beta}^{(2)}_{n,\kappa})_{n\in N} \in B$ *and* $n_0(\kappa)$ *such that*

$$\sup_{n\geq n_0(\kappa)} P\left\{\omega:\ \Phi_{n,\kappa}(\omega) - \Phi_0 \leq -\hat{\beta}^{(2)}_{n,\kappa}\right\} \leq \mathcal{H}_3(\kappa).$$

Then for all $\kappa > 0$, $\rho_{n,\kappa} = \beta^{(2)}_{n,\kappa} + \hat{\beta}^{(2)}_{n,\kappa}$, *and* $\beta^{(3)}_{n,\kappa} = \max\{\beta^{(1)}_{n,\kappa}, \beta^{(2)}_{n,\kappa} + \hat{\beta}^{(2)}_{n,\kappa}\}$ *the relation*

$$\sup_{n\geq n_0(\kappa)} P\left\{\omega:\ \Psi_0 \setminus (\hat{\Psi}^r_{n,\kappa}(\omega) \cap U_{\beta^{(1)}_{n,\kappa}}\Gamma_{n,\kappa}(\omega)) \neq \emptyset\right\} \leq \mathcal{H}_1(\kappa) + \mathcal{H}_2(\kappa) + \mathcal{H}_3(\kappa)$$

holds.

Proof. Let $n \geq n_0(\kappa)$. We apply Theorem 3 and underline the denotations that correspond to that in Theorem 3. With $\underline{g}_{n,\kappa}(x,\omega) := f_{n,\kappa}(x,\omega) - \Phi_{n,\kappa}(\omega)$ and $\underline{g}_0(x) := f_0(x) - \Phi_0$ we have $\Psi_0 = \{x \in \Gamma_0 :\ \underline{g}_0(x) \leq 0\}$ and $\hat{\Psi}^r_{n,\kappa}(\omega) := \{x \in E :\ \underline{g}_{n,\kappa}(x,\omega) \leq \rho_{n,\kappa}\}$. Furthermore, let $\underline{Q}_{n,\kappa} = \Gamma_{n,\kappa}$, $\hat{\underline{\Gamma}}^r_{n,\kappa} = \hat{\Psi}^r_{n,\kappa}$, $\underline{Q}_0 = \Gamma_0$, and $\hat{\underline{\Gamma}}_0 = \hat{\Psi}_0$.

Because of

$$\begin{aligned}
&P\left\{\omega:\ \inf_{x\in\Psi_0}((f_{n,\kappa}(x,\omega) - \Phi_{n,\kappa}(\omega)) - (f_0(x) - \Phi_0)) \geq \beta^{(2)}_{n,\kappa} + \hat{\beta}^{(2)}_{n,\kappa}\right\}\\
&\leq P\left\{\omega:\ \inf_{x\in\Psi_0}(f_{n,\kappa}(x,\omega) - f_0(x)) \geq \beta^{(2)}_{n,\kappa}\right\} + P\left\{\omega:\ -\Phi_{n,\kappa}(\omega) + \Phi_0 \geq \hat{\beta}^{(2)}_{n,\kappa}\right\}\\
&\leq \mathcal{H}_2(\kappa) + \mathcal{H}_3(\kappa) =: \underline{\mathcal{H}}_2(\kappa)
\end{aligned}$$

condition (CO2) is satisfied with $\underline{\beta}^{(2)}_{n,\kappa} = \beta^{(2)}_{n,\kappa} + \hat{\beta}^{(2)}_{n,\kappa}$ and $\underline{\mathcal{H}}_2$. □

A similar result can be obtained if we impose (VU1-R) and (VU2-R); compare the remark after Theorem 3.

5. Examples.

5.1. Example 5.1—Approximation of the objective functions. Firstly, we will discuss a simple example in order to show how one can deal with the uniform convergence assumption for the objective functions. At the first glance this assumption seems to be rather restrictive. There is, however, a growing number of results from probability theory yielding assertions of that kind; cf. [16], [1], [13]. Nevertheless there is still the need for sufficient conditions for the convergence assumptions. The following example, though very simple, is intended to show how one can proceed in principle also in more involved cases. The approach will be further developed elsewhere.

We assume $E = R^p$ and consider a fixed compact constraint set K and a linear objective function $q(z)^T x$ with $x = (x_1, \ldots, x_p)^T$ $q = (q_1, \ldots, q_p)^T$, and $q_i | R^m \to R^1$. z is the realization of a random vector Z with a given distribution P_Z on the sigma-field of Borel sets of R^m. The range of $q(Z)$ is supposed to be bounded. The problem

$$(P_0) \quad \min_{x\in K} \mathrm{E} q(Z)^T x$$

is approximated, replacing the expectation E with respect to P_Z by the expectation with respect to the empirical distribution based on a sequence $(Z^{(j)})_{j\in N}$ of indepen-

dent random vectors which are distributed according to P_Z:

$$(P_n) \quad \min_{x\in K} \frac{1}{n}\sum_{j=1}^{n} q\big(Z^{(j)}\big)^T x.$$

We assume $\mathrm{E}q(Z) \neq \mathbf{0}$, because otherwise the problem becomes trivial, and abbreviate $m := \max_{i=1,\dots,p} \sup_\omega |q_i(Z(\omega))|$. We consider the sets $K_k = \{x \in K :\ k-1 < ||x|| \leq k\},\ k = 1, 2, \dots$, where $||\cdot||$ denotes the Euclidean norm, and a suitable neighborhood $\bar{U}K$. Let $I_K := \{k :\ K_k \cap \bar{U}K \neq \emptyset\}$. Hence we obtain by Hoeffding's inequality ([4], [1]):

$$\begin{aligned}
&P\left\{\omega :\ \sup_{x\in\bar{U}K} |\frac{1}{n}\sum_{j=1}^{n} q(Z^{(j)}(\omega))^T x - \mathrm{E}q(Z)^T x| \geq \frac{\kappa}{\sqrt{n}}\right\}\\
&\leq \sum_{k\in I_K} P\left\{\omega :\ \sup_{x\in K_k} |\frac{1}{n}\sum_{j=1}^{n} q(Z^{(j)}(\omega))^T x - \mathrm{E}q(Z)^T x| \geq \frac{\kappa}{\sqrt{n}}\right\}\\
&\leq \sum_{k\in I_K} P\left\{\omega :\ \max_{i=1,\dots,p} |\frac{1}{n}\sum_{j=1}^{n} q_i(Z^{(j)}(\omega)) - \mathrm{E}q_i(Z)| \geq \frac{\kappa}{k\sqrt{n}}\right\}\\
&\leq 2p \sum_{k\in I_K} e^{-\frac{\kappa^2}{2k^2m^2}} =: \mathcal{H}_2(\kappa).
\end{aligned}$$

Of course this inequality can be further improved. For example, due to the linearity, it is enough to consider the boundary of K instead of the whole set K. Employing other concentration-of-measure inequalities, the boundedness condition for $q(Z)$ can also be weakened. We give the rough estimation above, because the basic idea of the approach can often be utilized, even if the functions have a more involved form.

In order to derive assertions about the solution set, we can employ Theorem 9 and (in case of a nonunique solution) Theorem 10. (VL1), (VU1), and (VU1-R) are satisfied with $\mathcal{H}_1 \equiv 0$. (VL2), (VU2), and (VU2-R) are fulfilled with $\beta^{(2)}_{n,\kappa} = \frac{\kappa}{\sqrt{n}}$ and $\mathcal{H}_2$. The function ν, which occurs in condition (SI4), can be determined if we assume a special form of K. It remains to investigate the semicontinuity condition (UCon) and the growth condition (Gr-f_0), where we can replace $\bar{U}_{\theta_1}\Gamma_0$ with Γ_0.

We have $f_0(x) - \Phi_0 \leq ||\mathrm{E}q(Z)||d(x, \Psi_0)$; hence (UCon) is satisfied with $c_2 = ||\mathrm{E}q(Z)||$ and $\delta_2 = 1$. (Gr-f_0) refers to the distance to $\hat{\Psi}_0$. To $x \in \Gamma_0$ we find $\hat{x}_0 \in \{x \in R^p :\ \mathrm{E}q(Z)^T x = \Phi_0\}$ such that $|f_0(x) - \Phi_0| = |\mathrm{E}q(Z)^T(x - \hat{x}_0)| = ||\mathrm{E}q(Z)|| \cdot ||x - \hat{x}_0|| = ||\mathrm{E}q(Z)||d(x, \hat{\Psi}_0)$. Consequently (Gr-$f_0$) is satisfied with $c_1 = ||\mathrm{E}q(Z)||$ and $\delta_1 = 1$.

5.2. Example 5.2—Approximation of a probabilistic constraint. Secondly, we consider the approximation of a constraint set which is determined by a probabilistic constraint. Replacing the true probability measure with the empirical measure, we obtain a sequence of approximating constraint functions.

In detail, we assume that the constraint function has the special form

$$g_0(x) = \alpha - P_Z((-\infty, \gamma(x)]) = \alpha - F_Z(\gamma(x)).$$

Z is a real-valued random variable with given distribution P_Z on the σ-field $\mathcal{B}^1$. $\alpha \in (0,1)$ denotes a probability level and $\gamma | E \to R^1$ a given concave function. The inequality constraint $g_0(x) \leq 0$ then reads as $P\{\omega : Z(\omega) \leq \gamma(x)\} \geq \alpha$. We assume that

$$\Gamma_0 = \hat{\Gamma}_0 = \{x \in E : \ g_0(x) \leq 0\} \neq \emptyset.$$

The approximating constraint set has the form

$$\Gamma_n(\omega) = \{x \in E : \ \alpha - F_n(\gamma(x), \omega) \leq 0\}$$

with the empirical distribution function F_n .

In order to fulfill (CI2') and (CO2') we can directly apply the Dvoretzky–Kiefer–Wolfowitz inequality with Massart's bound ([10], [1]), and we obtain $P\{\omega : \sqrt{n} \sup_{x \in R^1} |(\alpha - F_n(\gamma(x), \omega)) - (\alpha - F_Z(\gamma(x))| > \kappa\} \leq 2e^{-2\kappa^2}$.

(CI3) is not needed. In order to fulfill (Gr-g_0), we will impose growth conditions for F_Z and γ.

Assume that, for the given probability level α, the α-quantile q_α of F_Z is unique and consider a compact set $\tilde{K}$ such that $q_\alpha \in \text{int}\tilde{K}$. Furthermore, let $X_{\tilde{K}} := \{x \in E : \gamma(x) \in \tilde{K}\}$ and suppose that the following conditions are satisfied:

(IG) There exist positive constants $c_{1,\gamma}$, $c_{1,F}$, $\delta_{1,\gamma}$, and $\delta_{1,F}$ such that $\forall y \in \tilde{K}$ with $y < q_\alpha$: $\alpha - F_Z(y) > c_{1,F} d(y, q_\alpha)^{\delta_{1,F}}$ and $\forall x \in X_{\tilde{K}}$: $\gamma(x) < q_\alpha - c_{1,\gamma} d(x, \Gamma_0)^{\delta_{1,\gamma}}$.

(Gr-g_0) with $\tilde{K}$ instead of UQ_0 and a strict inequality is then satisfied with $\tilde{c}_1 = c_F (c_{1,\gamma})^{\delta_F}$ and $\tilde{\delta}_1 = \delta_{1,\gamma} \cdot \delta_F$.

If Γ_0 is single-valued, it remains to apply Theorem 1. Otherwise we employ Theorem 2 and assume that the following condition is satisfied:

(OG) There exist positive constants $c_{2,\gamma}$, $c_{2,F}$, $\delta_{2,\gamma}$, and $\delta_{2,F}$ such that $\forall y \in \tilde{K}$ with $y > q_\alpha$: $F_Z(y) - \alpha > c_{2,F} d(y, q_\alpha)^{\delta_{2,F}}$. Furthermore, there exists an $\tilde{\varepsilon} > 0$ such that $CI(\tilde{\varepsilon}) \neq \emptyset$ and $\forall x \in \Gamma_0 \setminus CI(\tilde{\varepsilon}) : \ \gamma(x) > q_\alpha + c_{2,\gamma} d(x, (E \setminus \Gamma_0)^{\delta_{2,\gamma}}$.

Hence, with respect to (CO3) we obtain for all $0 < \varepsilon \leq \tilde{\varepsilon}$ $\Gamma_0 \subset \bar{U}_\varepsilon CI(\varepsilon)$ and $\forall x \in \Gamma_0 \setminus CI(\tilde{\varepsilon}) : \ g_0(x) < -\tilde{c}_2 d(x, E \setminus \Gamma_0)^{\tilde{\delta}_2}$ with $\tilde{c}_2 = c_F (c_{2,\gamma})^{\delta_F}$ and $\tilde{\delta}_2 = \delta_{2,\gamma} \cdot \delta_F$. Thus in Theorem 2 we can choose $\mu(\varepsilon) = \tilde{c}_2 \varepsilon^{\tilde{\delta}_2}$.

Consequently, for all $\kappa \leq \tilde{\varepsilon}$, $\beta^{(3)}_{n,\kappa} = \max\{(\frac{\kappa}{\tilde{c}_1})^{\frac{1}{\tilde{\delta}_1}} n^{-\frac{1}{2\tilde{\delta}_1}}, (2\frac{\kappa}{\tilde{c}_2})^{\frac{1}{\tilde{\delta}_2}} n^{-\frac{1}{2\tilde{\delta}_2}}\}$, and $n_0(\kappa) = \min\{l : \beta^{(3)}_{l,\kappa} \leq 2\tilde{\kappa}, \ \gamma(\Gamma_0 \setminus CI(\frac{\beta^{(3)}_{l,\kappa}}{2})) \subset K\}$ the relation $\sup_{n \geq n_0(\kappa)} P\{\omega : \ (\Gamma_n(\omega) \setminus U_{\beta^{(3)}_{n,\kappa}} \Gamma_0) \cup (\Gamma_0 \setminus (U_{\beta^{(3)}_{n,\kappa}} \Gamma_n(\omega)) \neq \emptyset\} \leq 4e^{-2\kappa^2}$ holds.

5.3. Example 5.3—Quantile estimation. Finally, we consider quantile estimation because here relaxation of the constraint set comes into play in a natural way. Papers dealing with quantile estimation usually assume that the distribution function is strictly increasing in a neighborhood of the quantile (cf. [5], [6]). There are, however, applications where one cannot a priori assume that the lower and the upper quantile coincide.

We consider, as in the foregoing example, a real-valued random variable Z with distribution P_Z and distribution function F_Z. We will, for a fixed $\alpha \in (0,1)$, investigate the lower α-quantile

$$q^l_\alpha := \inf \left\{x \in R^1 : F_Z(x) \geq \alpha\right\}.$$

We consider the constraint set

$$\Gamma_0 := \{x \in R : F_Z(x) \geq \alpha\}$$

and the optimization problem

$$(P_0) \quad \min_{x \in \Gamma_0} x.$$

As F_Z is upper semicontinuous by definition, the set Γ_0 is closed and the minimum q_α^l will be attained.

(P_0) could be approximated replacing F_Z by the empirical distribution function F_n. Unfortunately, the set $\{x \in R^1 : F_n(x) \geq \alpha\}$, in general, does not approximate the whole set Γ_0. In [20] we showed that with a suitable relaxation $\rho_{n,\kappa}$ the solutions to the approximate problems convergence in probability to the desired quantile. Here we can proceed in a similar way; consider the modified constraint set $\Gamma_{n,\kappa}$ with

$$\Gamma_{n,\kappa}(\omega) := \left\{x \in R : F_n(x,\omega) > \alpha - \frac{\kappa}{\sqrt{n}}\right\}$$

and investigate the approximating optimization problems

$$(P_{n,\kappa}) \quad \min_{x \in \Gamma_{n,\kappa}} x.$$

$(P_{n,\kappa})$ has a unique solution, too.

In order to obtain a convergence rate, we need some knowledge about F_Z, e.g., a growth condition.

THEOREM 11 (quantile estimation). *Assume that there exist constants $c > 0$, $\delta > 0$, and $\theta > 0$ such that $\forall\, x \in \bar{U}_\theta \Gamma_0 :\ F_Z(x) < \alpha - cd(x,\Gamma_0)^\delta$. Then for all $\kappa > 0$, $\beta_{n,\kappa}^{(3)} = (\frac{2\kappa}{c})^{\frac{1}{\delta}} n^{-\frac{1}{2\delta}}$, and $n_0(\kappa) = \min\{l : \beta_{l,\kappa}^{(3)} \leq \theta\}$ the relations*

$$\sup_{n \geq n_0(\kappa)} P\{\omega : (\Gamma_{n,\kappa}(\omega) \setminus U_{\beta_{n,\kappa}^{(3)}} \Gamma_0) \cup (\Gamma_0 \setminus \Gamma_{n,\kappa}(\omega)) \neq \emptyset\} \leq 2e^{-2\kappa^2} \text{ and}$$

$$\sup_{n \geq n_0(\kappa)} P\{\omega : (\Psi_{n,\kappa}(\omega) \setminus U_{\beta_{n,\kappa}^{(3)}} \Psi_0) \cup (\Psi_0 \setminus U_{\beta_{n,\kappa}^{(3)}} \Psi_{n,\kappa}(\omega)) \neq \emptyset\} \leq 2e^{-2\kappa^2}$$

hold.

Proof. In order to prove the first assertion, we employ Corollary 4 with strict inequalities; compare Remark 1. Condition (Gr-g_0-Γ_0) is fulfilled by assumption. Due to the Dvoretzky–Kiefer–Wolfowitz inequality with Massart's bound ([10], [1]), "strict" variants of (CI2') and (CO2') are satisfied with $\gamma_n = n^{\frac{1}{2}}$ and $\mathcal{H}_2(\kappa) = e^{-2\kappa^2}$.

The second assertion could be derived via a variant of Theorem 9, which takes into account that the objective function is not approximated. We will instead give a direct proof.

Assume that for given $\kappa > 0$, $n \geq n_0(\kappa)$, and $\omega \in \Omega$ the relation $(\Psi_{n,\kappa}(\omega) \setminus U_{\beta_{n,\kappa}^{(3)}} \Psi_0) \cup (\Psi_0 \setminus U_{\beta_{n,\kappa}^{(3)}} \Psi_{n,\kappa}(\omega)) \neq \emptyset$ holds. Then there are $x_{n,\kappa}(\omega) \in \Psi_{n,\kappa}(\omega)$ and $x_0 \in \Psi_0$ such that either $x_{n,\kappa}(\omega) \leq x_0 - \beta_{n,\kappa}^{(3)}$ or $x_0 \leq x_{n,\kappa} - \beta_{n,\kappa}^{(3)}$ is satisfied. Since the solutions Ψ_0 and $\Psi_{n,\kappa}$ consist of the left boundary points of the constraint sets, we obtain $(\Gamma_{n,\kappa}(\omega) \setminus U_{\beta_{n,\kappa}^{(3)}} \Gamma_0) \cup (\Gamma_0 \setminus \Gamma_{n,\kappa}(\omega)) \neq \emptyset$, and the conclusion follows by the first assertion. □

ON EXTENSION OF FENCHEL DUALITY AND ITS APPLICATION*

LI GUOYIN† AND NG KUNG FU†

Abstract. By considering the epigraphs of conjugate functions, we extend the Fenchel duality, applicable to a (possibly infinite) family of proper lower semicontinuous convex functions on a Banach space. Applications are given in providing fuzzy KKT conditions for semi-infinite programming.

Key words. Fenchel duality, epigraph, Karush–Kuhn–Tucker (KKT) conditions, semi-infinite programming

DOI. 10.1137/080716803

1. Introduction.

The famous Fenchel duality theorem can be stated as follows (cf. [30, Corollary 2.8.5]): For any family of finitely many proper lower semicontinuous convex functions $f_0, f_1, \ldots, f_n$ on a Banach space X, if $\mathrm{dom} f_{i_0} \cap \mathrm{int}\left(\bigcap_{i\neq i_0} \mathrm{dom} f_i\right) \neq \emptyset$ for some $i_0 \in \{0, 1, \ldots, n\}$, then their conjugate functions $f_0^*, f_1^*, \ldots, f_n^*$ satisfy the relation

$$\inf_{x\in X}\left(\sum_{i=0}^{n} f_i(x)\right) = \max\left\{-\sum_{i=0}^{n} f_i^*(x_i^*) : \sum_{i=0}^{n} x_i^* = 0\right\}, \tag{1.1}$$

and, in fact, the following stronger relation holds for any $x^* \in X^*$:

$$\inf_{x\in X}\left\{\sum_{i=0}^{n} f_i(x) - \langle x^*, x\rangle\right\} = \max\left\{-\sum_{i=0}^{n} f_i^*(x_i^*) : \sum_{i=0}^{n} x_i^* = x^*\right\}. \tag{1.2}$$

Background information on the Fenchel duality theory can be found in Rockafellar [28] (see also [1, 2, 16, 27, 30]). This theory is a fundamental tool for establishing penalty results in nonlinear programming (cf. [8]). Moreover, it also plays an important role in the theory of best approximation (cf. [14, 20]), error bound analysis [12], in the study of monotone operators [25], and also in the KKT theory in connection with the following convex programming:

$$\begin{aligned} &\min_{x\in X} && f_0(x) \\ &\text{subject to (s.t.)} && f_i(x) \le 0 \quad (i = 1, \ldots, n). \end{aligned}$$

The Fenchel duality enables us to transform the original problem (primal problem) into an optimization problem on the dual space (dual problem). In some cases, especially in optimal control problems, the dual problems are easier to handle than the original ones (see [13, Example 25.2], [15]). Stimulated by the study of semi-infinite programming problems (see [17, 21] and the references therein), it is both interesting and useful to extend the Fenchel duality applicable to a family $\{f_i\}_{i\in I}$ of proper lower semicontinuous convex functions on a Banach space with the index set

I, which is allowed to be infinite. In this present paper, much of our study is based on the consideration of the epigraphs of the conjugate functions and is motivated by the recent work of Jeyakumar and his collaborators (see [9, 10, 19], for example); we provide characterizations (and sufficient conditions) for the following property: For any $x^* \in X^*$,

$$\begin{aligned}&\inf_{x\in X}\{f(x)-\langle x^*,x\rangle\}\\ &=\max\left\{-\sum_{i\in I}f_i^*(x_i^*):\ x_i^*\in X^* \text{ and } \sum_{i\in I}\langle x_i^*,x\rangle=\langle x^*,x\rangle \text{ for any } x\in X\right\},\end{aligned}$$

where f is the sum function of $\{f_i : i \in I\}$, that is, $f(x) = \sum_{i\in I} f_i(x)$ for all $x \in X$. As an application, we present a fuzzy KKT condition in section 5 for the semi-infinite programming problem.

2. Preliminaries. Throughout this paper, X denotes a Banach space and X^* denotes its topological dual. We use $B(x, \epsilon)$ (resp. $\overline{B}(x, \epsilon)$) to denote the open (resp. closed) ball of X with center x and radius ϵ. For a set A in X, the interior (resp. relative interior, closure, convex hull, affine hull, linear span) of A is denoted by $\mathrm{int}A$ (resp. $\mathrm{ri}A$, $\overline{A}$, $\mathrm{co}A$, $\mathrm{aff}A$, $\mathrm{span}A$) (if A is a subset of X^*, its weak* closure is denoted by $\overline{A}^{w^*}$). Let A be a nonempty subset of X. The indicator function $\delta_A : X \to \mathbb{R}\cup\{+\infty\}$ and the support function $\sigma_A : X^* \to \mathbb{R}\cup\{+\infty\}$ of A are, respectively, defined by

$$\delta_A(x) := \begin{cases} 0 & \text{if} \quad x \in A,\\ +\infty & \text{otherwise,}\end{cases} \tag{2.1}$$

and $\sigma_A(x^*) = \sup_{x\in A}\langle x^*, x\rangle$ for all $x^* \in X^*$. Let $\Gamma(X)$ denote the class of proper lower semicontinuous convex functions on X, $\Gamma_c(X) := \{f \in \Gamma(X) : f$ is continuous and real-valued on $X\}$, and $\Gamma_+(X) := \{f \in \Gamma(X) : f$ is nonnegative on $X\}$. For a proper function f on X, the effective domain and the epigraph are, respectively, defined by $\mathrm{dom}f := \{x \in X : f(x) < +\infty\}$ and $\mathrm{epi}f := \{(x, r) \in X \times \mathbb{R} : f(x) \le r\}$. The subdifferential of f at $x \in X$ is defined by

$$\partial f(x) = \begin{cases} \{x^* \in X^* : \langle x^*, y - x\rangle \le f(y) - f(x) \text{ for all } y \in X\} & \text{if } x \in \mathrm{dom}f,\\ \emptyset & \text{otherwise.}\end{cases} \tag{2.2}$$

More generally, for any $\epsilon \ge 0$, the ϵ-subdifferential of f at $x \in X$ is defined by

$$\partial_\epsilon f(x) = \begin{cases} \{x^* \in X^* : \langle x^*, y - x\rangle \le f(y) - f(x) + \epsilon \text{ for all } y \in X\} & \text{if } x \in \mathrm{dom}f,\\ \emptyset & \text{otherwise.}\end{cases} \tag{2.3}$$

As usual, for a proper function f on X, its conjugate function $f^* : X^* \to \mathbb{R}\cup\{+\infty\}$ is defined by $f^*(x^*) = \sup_{x\in X}\{\langle x^*, x\rangle - f(x)\}$ for all $x^* \in X^*$. In particular, one has

$$(\delta_A)^*(x^*) = \sigma_A(x^*) \text{ for all } x^* \in X^*. \tag{2.4}$$

The definition of f^* entails that $\langle x^*, x\rangle \le f^*(x^*) + f(x)$ (Young's inequality) for any $x \in X$ and $x^* \in X^*$. Moreover, for any $\epsilon \ge 0$ and $x \in \mathrm{dom}f$,

$$x^* \in \partial_\epsilon f(x) \ \Leftrightarrow\ f^*(x^*)+f(x) \le \langle x^*, x\rangle+\epsilon \ \Leftrightarrow\ (x^*, \epsilon+\langle x^*, x\rangle-f(x)) \in \mathrm{epi}f^*. \tag{2.5}$$

In particular, we have the following Young's equality:

$$x^* \in \partial f(x) \ \Leftrightarrow\ \langle x^*, x\rangle = f^*(x^*) + f(x).$$

From the definitions, it is clear that, for any proper lower semicontinuous convex functions f_1, f_2 on X,

$$f_1 \le f_2 \;\Leftrightarrow\; f_1^* \ge f_2^* \;\Leftrightarrow\; \mathrm{epi} f_1^* \subseteq \mathrm{epi} f_2^*. \tag{2.6}$$

Moreover, it is known that $f^* \in \Gamma(X^*)$ for any $f \in \Gamma(X)$ (cf. [30, Theorem 2.3.3]). As usual, $X^* \times \mathbb{R}$ and $(X \times \mathbb{R})^*$ are identified and, for convenience, we use the norms defined by

$$\|(x, \alpha)\| = \max\{\|x\|, |\alpha|\} \text{ for all } (x, \alpha) \in X \times \mathbb{R}$$

and

$$\|(x^*, \alpha)\| = \|x^*\| + |\alpha| \text{ for all } (x^*, \alpha) \in X^* \times \mathbb{R}.$$

If H is a subspace of X, the restrictions and the corresponding norms of the restrictions are defined as follows: $x^*|_H \in H^*$, $(x^*|_H, \alpha) \in H^* \times \mathbb{R} = (H \times \mathbb{R})^*$, $\|x^*\|_H := \sup\{\langle x^*, x\rangle : x \in H, \|x\| \le 1\}$, and

$$\|(x^*|_H, \alpha)\| = \|x^*\|_H + |\alpha|. \tag{2.7}$$

Let I be an index set, and let $\mathcal{F}(I)$ denote the collection of all finite subsets of I (thus $\mathcal{F}(I)$ is a directed set ordered under the inclusion relation). Let $\{a_i : i \in I\} \subseteq \mathbb{R} \cup \{+\infty\}$. We define the sum of $\{a_i : i \in I\}$ by

$$\sum_{i \in I} a_i = \lim_{A \in \mathcal{F}(I)} \sum_{i \in A} a_i,$$

provided that the (unconditional) limit $\lim_{A \in \mathcal{F}(I)} \sum_{i \in A} a_i$ exists as a member of $\mathbb{R} \cup \{+\infty\}$. In particular, if $a_i \ge 0$ for all $i \in I$, then $\sum_{i \in I} a_i$ exists and

$$\sum_{i \in I} a_i = \sup_{A \in \mathcal{F}(I)} \sum_{i \in A} a_i \le +\infty. \tag{2.8}$$

Remark 2.1. Let $\{a_i, b_i, c_i\}_{i \in I} \subseteq \mathbb{R}$ be such that $a_i \le b_i \le c_i$ for all $i \in I$. Suppose that $\sum_{i \in I} a_i$ and $\sum_{i \in I} c_i$ exist in $\mathbb{R}$. Then $\sum_{i \in I} b_i$ also exists in $\mathbb{R}$ (because $0 \le b_i - a_i \le c_i - a_i$ and $\sum_{i \in I}(c_i - a_i) < +\infty$).

Let $\{f_i : i \in I\}$ be a family of extended real-valued functions on X. We define their sum function f as follows: Let $D_f := \{x \in X : \sum_{i \in I} f_i(x) \text{ exists in } \mathbb{R} \cup \{+\infty\}\}$; we define

$$f(x) = \sum_{i \in I} f_i(x) \text{ for all } x \in D_f.$$

In particular, if $f_i \in \Gamma_+(X)$ for all $i \in I$, then $D_f = X$ and

$$\left(\sum_{i \in I} f_i\right)(x) = \sup_{A \in \mathcal{F}(I)} \sum_{i \in A} f_i(x) \text{ for all } x \in X. \tag{2.9}$$

For $x^* \in X^*$ and a family $\{x_i^*\}_{i \in I}$ of elements in X^*, the notation

$$x^* = \sum_{i \in I}^{*} x_i^* \tag{2.10}$$

means that $\langle x^*, h\rangle = \lim_{A\in\mathcal{F}(I)} \sum_{i\in A}\langle x_i^*, h\rangle$ for each $h \in X$. Let $\{A_i\}_{i\in I}$ be a family of the subsets of X^*. The set $\{x^* \in X^* : \exists x_i^* \in A_i$ for all $i \in I$ such that $x^* = \sum_{i\in I}^* x_i^*\}$ will be denoted by $\sum_{i\in I}^* A_i$. It is easy to check that $\sum_{i\in I}^* A_i$ is convex if each A_i is convex and that $\sum_{i\in I}^* A_i = \sum_{i\in I} A_i$ if I is a finite set. Moreover, $\{A_i\}_{i\in I}$ is said to be weak* summable if $\sum_{i\in I}^* x_i^*$ exists in X^* (that is, (2.10) holds for some $x^* \in X^*$) whenever $x_i^* \in A_i$ for each $i \in I$.

Remark 2.2. The above definition is slightly different from [32]: Our notation $\sum_{i\in I}^* A_i$ does not require the family $\{A_i\}_{i\in I}$ to be weak* summable.

A useful relationship between $\mathrm{epi}f^*$ and $\partial_\epsilon f$ is given in the following formula observed by Burachik and Jeyakumar in [9] (we note that, as observed in [3], this formula works even when f is merely a proper function):

(2.11)
$$\mathrm{epi}f^* = \bigcup_{\epsilon\geq 0}\{(x^*, \epsilon + \langle x^*, x\rangle - f(x)) : x^* \in \partial_\epsilon f(x)\} \text{ for all } f \in \Gamma(X),\ x \in \mathrm{dom}f.$$

Throughout this paper, unless explicitly mentioned otherwise, I is an arbitrary index set (that is, the cardinality $|I| \leq +\infty$). For convenience, we list below several known results that will be useful for us.

LEMMA 2.1 (cf. [30]). *Let I be a finite set, and let $\{f, f_i : i \in I\} \subseteq \Gamma(X)$ be such that $f(x) = \sum_{i\in I} f_i(x)$ for all $x \in X$. Then $\mathrm{epi}f^* = \overline{\sum_{i\in I}\mathrm{epi}f_i^*}^{w^*}$, and, moreover, the result can be strengthened to $\mathrm{epi}f^* = \sum_{i\in I}\mathrm{epi}f_i^*$ if there exists $i_0 \in I$ such that $\mathrm{dom}f_{i_0} \cap \mathrm{int}\big(\bigcap_{i\neq i_0}(\mathrm{dom}f_i)\big) \neq \emptyset$.*

Remark 2.3. Let I be a finite set, and let C be a closed convex subset of X. Recall that $\mathrm{sqri}C := \{x \in C : \bigcup_{\lambda\geq 0}\lambda(C - x)$ is a closed subspace$\}$. A weaker generalized interior point regularity condition ensuring $\mathrm{epi}f^* = \sum_{i\in I}\mathrm{epi}f_i^*$ is as follows (cf. [5, 23]): There exists $i_0 \in I$ such that
$$0 \in \mathrm{sqri}\prod_{i\neq i_0}(\mathrm{dom}f_i - \mathrm{dom}f_{i_0}).$$

The following lemma can be found in [20, Lemma 2.3]. We note that it has been also derived in [4, section 4.3] via a different approach.

LEMMA 2.2. *Let $\{f_i : i \in I\} \subseteq \Gamma(X)$. Suppose that there exists $x_0 \in X$ such that $\sup_{i\in I} f_i(x_0) < \infty$. Then*
$$\mathrm{epi}(\sup_{i\in I} f_i)^* = \overline{\mathrm{co}\bigcup_{i\in I}\mathrm{epi}f_i^*}^{w^*},$$
where $\sup_{i\in I} f_i : X \to \mathbb{R}\cup\{+\infty\}$ is defined by $(\sup_{i\in I} f_i)(x) = \sup_{i\in I} f_i(x)$ for all $x \in X$.

Remark 2.4. Let $f \in \Gamma(X)$ and $A := \{x : f(x) \leq 0\} \neq \emptyset$. Then $\delta_A = \sup_{\lambda>0}\lambda f$, and it follows from Lemma 2.2 that

$$\mathrm{epi}(\delta_A)^* = \overline{\mathrm{co}\bigcup_{\lambda>0}\mathrm{epi}(\lambda f)^*}^{w^*} = \overline{\bigcup_{\lambda>0}\mathrm{epi}(\lambda f)^*}^{w^*}, \tag{2.12}$$

where the last equality holds because $\bigcup_{\lambda>0}\mathrm{epi}(\lambda f)^*$ is a convex set.

For continuous functions, the following result in [31] will play an important role.

LEMMA 2.3. *Let $\{f, f_i : i \in I\} \subseteq \Gamma_c(X)$ be such that $f(x) = \sum_{i\in I} f_i(x)$ for all $x \in X$. Then $\{\partial f_i(x)\}_{i\in I}$ is weak* summable, and the following relation holds:*
$$\partial f(x) = \overline{\sum_{i\in I}^*\partial f_i(x)}^{w^*} \qquad \text{for all } x \in X.$$

Moreover, if I is countable, then $\sum_{i\in I}{}^{*}\partial f_i(x)$ is weak closed, and hence*

$$\partial f(x) = \sum_{i\in I}{}^{*}\partial f_i(x) \quad \text{for all } x \in X.$$

3. Strong Fenchel duality and its characterization. In this section, we provide some characterization of the strong Fenchel duality (in the sense that (1.2) holds for all $x^* \in X^*$). To do this, we need the following lemma.

LEMMA 3.1. *Let $\{f, f_i : i \in I\} \subseteq \Gamma(X)$ be such that*

$$f(x) = \sum_{i\in I} f_i(x) \text{ for all } x \in X. \tag{3.1}$$

Then the following inclusion holds:

$$\overline{\sum_{i\in I}{}^{*}\operatorname{epi} f_i^*}^{w^*} \subseteq \operatorname{epi} f^*. \tag{3.2}$$

Proof. Let $(x^*, \alpha) \in \sum_{i\in I}{}^{*}\operatorname{epi} f_i^*$, that is, for each $i \in I$, there exists $(x_i^*, \alpha_i) \in X^* \times \mathbb{R}$, with $f_i^*(x_i^*) \le \alpha_i$ such that

$$\sum_{i\in I}\alpha_i = \alpha \text{ and } \sum_{i\in I}\langle x_i^*, x\rangle = \langle x^*, x\rangle \text{ for all } x \in X. \tag{3.3}$$

Since $\operatorname{epi} f^*$ is weak* closed, to prove (3.2), it suffices to show that $f^*(x^*) \le \alpha$. Let $x \in \operatorname{dom} f$. Note that

$$\langle x_i^*, x\rangle - f_i(x) \le \sup_{z\in X}\{\langle x_i^*, z\rangle - f_i(z)\} = f_i^*(x_i^*) \le \alpha_i. \tag{3.4}$$

Applying Remark 2.1 and making use of (3.1), (3.3), and (3.4), we note that $\sum_{i\in I} f_i^*(x_i^*)$ exists, and

$$\langle x^*, x\rangle - f(x) = \sum_{i\in I}\big(\langle x_i^*, x\rangle - f_i(x)\big) \le \sum_{i\in I} f_i^*(x_i^*) \le \sum_{i\in I}\alpha_i = \alpha.$$

Taking supremum over all x in $\operatorname{dom} f$, this implies that

$$f^*(x^*) = \sup_{x\in\operatorname{dom} f}\big(\langle x^*, x\rangle - f(x)\big) \le \sum_{i\in I} f_i^*(x_i^*) \le \alpha, \tag{3.5}$$

as required to show. This completes the proof. □

The following result is known [9] (see also [11, Corollary 3.4]) for the special case when I is finite.

THEOREM 3.2. *Let $\{f, f_i : i \in I\}$ be as in Lemma 3.1. Then the following statements are equivalent:*

(i)
$$\partial_\epsilon f(x) \subseteq \bigcup\left\{\sum_{i\in I}{}^{*}\partial_{\epsilon_i} f_i(x) : \sum_{i\in I}\epsilon_i = \epsilon, \text{ each } \epsilon_i \ge 0\right\} \text{ for all } \epsilon \ge 0 \text{ and } x \in X. \tag{3.6}$$

(ii) $\partial_\epsilon f(x) = \bigcup\big\{\sum_{i\in I}{}^{*}\partial_{\epsilon_i} f_i(x) : \sum_{i\in I}\epsilon_i = \epsilon, \text{ each } \epsilon_i \ge 0\big\}$ *for all* $\epsilon \ge 0$ *and* $x \in \operatorname{dom} f$.

(iii) $\mathrm{epi} f^* = \sum_{i\in I}{}^* \mathrm{epi} f_i^*$.
(iv) *For any* $x^* \in X^*$,

$$\inf_{x\in X}\{f(x) - \langle x^*, x\rangle\} = \max\left\{-\sum_{i\in I} f_i^*(x_i^*) : \sum_{i\in I}{}^* x_i^* = x^*\right\},$$

that is, $f^*(x^*) = \min\left\{\sum_{i\in I} f_i^*(x_i^*) : \sum_{i\in I}{}^* x_i^* = x^*\right\}$.
Any of the statements (i)–(iv) *implies that*
(v) $\inf_{x\in X} f(x) = \max\left\{-\sum_{i\in I} f_i^*(x_i^*) : \sum_{i\in I}{}^* x_i^* = 0\right\}$.

Proof. First, (v) follows from (iv) by letting $x^* = 0$. Thus, we need only to show the equivalence of (i)–(iv).

[(i) $\Rightarrow$ (ii)] Let $x \in \mathrm{dom} f$, $\epsilon \geq 0$, and $\epsilon_i \geq 0$ be such that $\sum_{i\in I} \epsilon_i = \epsilon$. To prove (i) $\Rightarrow$ (ii), it suffices to show that

$$\sum_{i\in I}{}^* \partial_{\epsilon_i} f_i(x) \subseteq \partial_\epsilon f(x). \tag{3.7}$$

To do this, let $x^* = \sum_{i\in I}{}^* x_i^* \in X^*$, where each $x_i^* \in \partial_{\epsilon_i} f_i(x)$. Then, from Young's inequality and (2.5), we have

$$\langle x_i^*, x\rangle - \epsilon_i \leq f_i^*(x_i^*) + f_i(x) - \epsilon_i \leq \langle x_i^*, x\rangle.$$

Therefore, by Remark 2.1, $\sum_{i\in I}(f_i^*(x_i^*) + f_i(x) - \epsilon_i)$ exists in $\mathbb{R}$ and

$$\sum_{i\in I} f_i^*(x_i^*) + f(x) - \epsilon = \sum_{i\in I}\left(f_i^*(x_i^*) + f_i(x) - \epsilon_i\right) \leq \sum_{i\in I}\langle x_i^*, x\rangle = \langle x^*, x\rangle. \tag{3.8}$$

On the other hand, note that $f^*(x^*) \leq \sum_{i\in I} f_i^*(x_i^*)$ because, for each $z \in \mathrm{dom} f$, one has

$$\langle x^*, z\rangle - f(z) = \sum_{i\in I}\left(\langle x_i^*, z\rangle - f_i(z)\right) \leq \sum_{i\in I} f_i^*(x_i^*). \tag{3.9}$$

Thus, by (3.8),

$$f^*(x^*) + f(x) - \epsilon \leq \sum_{i\in I} f_i^*(x_i^*) + f(x) - \epsilon \leq \langle x^*, x\rangle.$$

Therefore, $x^* \in \partial_\epsilon f(x)$, and (3.7) holds.

[(ii) $\Rightarrow$ (iii)] In view of Lemma 3.1, it suffices to show that $\mathrm{epi} f^* \subseteq \sum_{i\in I}{}^* \mathrm{epi} f_i^*$. To do this, let $(x^*, \alpha) \in \mathrm{epi} f^*$. We have to show that $(x^*, \alpha) \in \sum_{i\in I}{}^* \mathrm{epi} f_i^*$. Take an arbitrary $x \in \mathrm{dom} f$; from (2.11), there exists $\epsilon \geq 0$ such that $x^* \in \partial_\epsilon f(x)$ and $\alpha = \epsilon + \langle x^*, x\rangle - f(x)$. It follows from (ii) that there exist $\epsilon_i \geq 0$ and $x_i^* \in \partial_{\epsilon_i} f_i(x)$ $\big($so $(x_i^*, \alpha_i) \in \mathrm{epi} f_i^*$, where $\alpha_i := \epsilon_i + \langle x_i^*, x\rangle - f_i(x)\big)$ such that $\epsilon = \sum_{i\in I} \epsilon_i$ and $x^* = \sum_{i\in I}{}^* x_i^*$. Thus

$$(x^*, \alpha) = \sum_{i\in I}{}^* (x_i^*, \alpha_i) \in \sum_{i\in I}{}^* \mathrm{epi} f_i^*,$$

as required to show.

[(iii) $\Rightarrow$ (iv)] Let $x^* \in X^*$. Note first that, by (3.9),

$$-f^*(x^*) = \inf_{z\in \mathrm{dom} f}\{f(z) - \langle x^*, z\rangle\} \geq -\sum_{i\in I} f_i^*(x_i^*) \tag{3.10}$$

whenever $\{x_i^* : i \in I\} \subseteq X^*$, with $x^* = \sum_{i\in I}{}^* x_i^*$. Thus, to prove (iv), it remains to show that there exists $x_i^* \in X^*$ $(i \in I)$ such that $x^* = \sum_{i\in I} x_i^*$ and

$$\inf_{z\in \mathrm{dom} f}\{f(z) - \langle x^*, z\rangle\} \le -\sum_{i\in I} f_i^*(x_i^*). \tag{3.11}$$

To do this, we can suppose that $\inf_{z\in\mathrm{dom}f}\{f(z) - \langle x^*, z\rangle\} > -\infty$, that is, $f^*(x^*) < +\infty$. Then $(x^*, f^*(x^*)) \in \mathrm{epi}f^*$. It follows from (iii) that $(x^*, f^*(x^*)) \in \sum_{i\in I}{}^* \mathrm{epi}f_i^*$, that is, there exist $(x_i^*, \alpha_i) \in \mathrm{epi}f_i^*$ $(i \in I)$ such that

$$\sum_{i\in I}{}^* x_i^* = x^* \ \text{ and } \ \sum_{i\in I}\alpha_i = f^*(x^*). \tag{3.12}$$

We claim that $\{x_i^* : i \in I\}$ satisfies (3.11). In fact, since $(x_i^*, \alpha_i) \in \mathrm{epi}f_i^*$ $(i \in I)$, Young's inequality implies that, for any $z \in X$,

$$\langle x_i^*, z\rangle - f_i(z) \le f_i^*(x_i^*) \le \alpha_i \ (i \in I). \tag{3.13}$$

Since $\sum_{i\in I} f_i(z) = f(z) \in \mathbb{R}$ if $z \in \mathrm{dom}f$, it follows from (3.12) and Remark 2.1 that $\sum_{i\in I} f_i^*(x_i^*)$ exists and, for any $z \in \mathrm{dom}f$,

$$\langle x^*, z\rangle - f(z) = \sum_{i\in I}\big(\langle x_i^*, z\rangle - f_i(z)\big) \le \sum_{i\in I} f_i^*(x_i^*) \le \sum_{i\in I}\alpha_i = f^*(x^*).$$

Taking supremum over all $z \in \mathrm{dom}f$, this implies that $f^*(x^*) \le \sum_{i\in I} f_i^*(x_i^*) \le \sum_{i\in I}\alpha_i = f^*(x^*)$. In view of (3.13), this forces that $f_i^*(x_i^*) = \alpha_i$ for all $i \in I$. Therefore, we obtain that

$$\inf_{z\in\mathrm{dom}f}\{f(z) - \langle x^*, z\rangle\} = -f^*(x^*) = -\sum_{i\in I}\alpha_i = -\sum_{i\in I} f_i^*(x_i^*).$$

Thus (3.11) holds as claimed.

[(iv) $\Rightarrow$ (i)] Let $\epsilon \ge 0$, $x \in X$, and $x^* \in \partial_\epsilon f(x)$. By the definition of $f^*(x^*)$, (iv) means that

$$f^*(x^*) = \min\left\{\sum_{i\in I} f_i^*(x_i^*) : \sum_{i\in I}{}^* x_i^* = x^*\right\}.$$

Thus, there exist $x_i^* \in X^*$, with $\sum_{i\in I}{}^* x_i^* = x^*$ such that $f^*(x^*) = \sum_{i\in I} f_i^*(x_i^*)$. Hence

$$f^*(x^*) + f(x) - \langle x^*, x\rangle = \sum_{i\in I}\big(f_i^*(x_i^*) + f_i(x) - \langle x_i^*, x\rangle\big),$$

where $0 \le f_i^*(x_i^*) + f_i(x) - \langle x_i^*, x\rangle$ for all $i \in I$ (by Young's inequality). Since $x^* \in \partial_\epsilon f(x)$ (that is $f^*(x^*) + f(x) - \langle x^*, x\rangle \le \epsilon$), it follows that there exist $\epsilon_i \ge 0$ $(i \in I)$ such that $\sum_{i\in I}\epsilon_i = \epsilon$ and

$$f_i^*(x_i^*) + f_i(x) - \langle x_i^*, x\rangle \le \epsilon_i \quad \text{for all } i \in I.$$

Then $x_i^* \in \partial_{\epsilon_i} f_i(x)$ $(i \in I)$ and $x^* \in \sum_{i\in I}{}^* \partial_{\epsilon_i} f_i(x)$ (as $x^* = \sum_{i\in I}{}^* x_i^*$). Therefore, x^* belongs to the set on the right-hand side of (i). This completes the proof. ∎

Note 3.1. The property (v), sometimes referred as the Fenchel duality, is strictly weaker (even when $|I| = 2$) than the properties (i)–(iv) listed in Theorem 3.2. Examples can be found in [5, pp. 2798–2799] and [26, Example 11.1 and Example 11.3].

COROLLARY 3.3 (an extension of the Fenchel duality). *Let* $\{f_i, h, f : i \in I \cup J\} \subseteq \Gamma(X)$, *with* $I \cap J = \emptyset$, $|J| < +\infty$, *and*

$$h(x) = \sum_{i\in I} f_i(x) \text{ and } f(x) = \sum_{i\in I} f_i(x) + \sum_{j\in J} f_j(x) \text{ for all } x \in X.$$

Suppose that

$$\operatorname{epi} h^* = \sum_{i\in I}^{*} \operatorname{epi} f_i^*, \tag{3.14}$$

and (at least) one of the following conditions holds:

$$\text{(i)}\ \operatorname{dom} h \cap \operatorname{int}\Big(\bigcap_{j\in J} \operatorname{dom} f_j\Big) \neq \emptyset. \tag{3.15}$$

(ii) *There exists* $j_0 \in J$ *such that*

$$\operatorname{int}(\operatorname{dom} h) \cap \operatorname{dom} f_{j_0} \cap \operatorname{int}\Big(\bigcap_{j\in J\setminus\{j_0\}} \operatorname{dom} f_j\Big) \neq \emptyset. \tag{3.16}$$

Then

$$\operatorname{epi} f^* = \sum_{i\in I}^{*} \operatorname{epi} f_i^* + \sum_{j\in J} \operatorname{epi} f_j^*, \tag{3.17}$$

and, in particular, one has

$$\inf_{x\in X} f(x) = \max\left\{ -\sum_{i\in I} f_i^*(x_i^*) - \sum_{j\in J} f_j^*(y_j^*) : \sum_{i\in I}^{*} x_i^* + \sum_{j\in J} y_j^* = 0 \right\}. \tag{3.18}$$

Proof. First, from the implication (iii) $\Rightarrow$ (v) in Theorem 3.2, we need only to show (3.17). Since $\{f_j, h, f\ : j \in J\} \subseteq \Gamma(X)$ and $f = h + \sum_{j\in J} f_j$, Lemma 2.1 implies that

$$\operatorname{epi} f^* = \operatorname{epi} h^* + \sum_{j\in J} \operatorname{epi} f_j^*,$$

provided that (i) or (ii) holds. Consequently, (3.17) holds by (3.14). □

4. Sufficient conditions. This section is devoted to providing sufficient conditions ensuring that, for $\{f_i, f : i \in I\} \subseteq \Gamma(X)$, $\operatorname{epi} f^* = \sum_{i\in I}^{*} \operatorname{epi} f_i^*$ (see Theorem 3.2 (iii)), where

$$f(x) = \sum_{i\in I} f_i(x) \text{ for all } x \in X. \tag{4.1}$$

4.1. Continuous type. Throughout this subsection, we assume that f and each f_i are continuous, that is,

$$\{f_i, f : i \in I\} \subseteq \Gamma_c(X). \tag{4.2}$$

THEOREM 4.1. *Assume* (4.1) *and* (4.2). *Then*

$$\mathrm{epi} f^* = \overline{\sum\nolimits_{i\in I}^{*} \mathrm{epi} f_i^*}^{w^*}. \tag{4.3}$$

Proof. Let $x \in X$. By continuity, each $\partial f_i(x) \neq \emptyset$; take $x_i^* \in \partial f_i(x)$. By Lemma 2.3, there exists $x^* \in \partial f(x)$ such that $x^* = \sum_{i\in I}{}^{*} x_i^*$. Denote $r := \langle x^*, x\rangle - f(x)$ and $r_i = \langle x_i^*, x\rangle - f_i(x)$. It follows from (4.1) that $r = \sum_{i\in I} r_i$. Moreover, by (2.5), each $(x_i^*, r_i) \in \mathrm{epi} f_i^*$, and so $(x^*, r) \in \sum_{i\in I}{}^{*} \mathrm{epi} f_i^*$. Therefore, by Lemma 3.1, $\emptyset \neq \sum_{i\in I}{}^{*} \mathrm{epi} f_i^* \subseteq \mathrm{epi} f^*$. Thus, since $\mathrm{epi} f^*$ is weak* closed, if (4.3) is not true, then there exists $(x^*, \alpha) \in \mathrm{epi} f^* \backslash \overline{\sum_{i\in I}{}^{*} \mathrm{epi} f_i^*}^{w^*}$. Recalling that a linear functional h on X^* is the form $h(x^*) = \langle a, x^*\rangle$ for some $a \in X$ if and only if h is continuous in the weak* topology of X^* (cf. [29, p. 112, Theorem 1], it follows from the separation theorem that there exists $(x_0, r_0) \in X \times \mathbb{R}$ such that

$$\sup\left\{\langle y^*, x_0\rangle + \beta r_0 : \ (y^*, \beta) \in \sum_{i\in I}^{*} \mathrm{epi} f_i^*\right\} < \langle x^*, x_0\rangle + \alpha r_0. \tag{4.4}$$

Considering $\beta > 0$ large, it follows that $r_0 \leq 0$. We claim that $r_0 < 0$. Indeed, if $r_0 = 0$, then (4.4) means $\sup\{\langle y^*, x_0\rangle : (y^*, \beta) \in \sum_{i\in I}{}^{*} \mathrm{epi} f_i^*\} < \langle x^*, x_0\rangle$. Since $x^* \in \mathrm{dom} f^*$ and $\mathrm{Im}\, \partial f$ is norm dense in $\mathrm{dom} f^*$ (cf. [24, Theorem 3.18]), there exist $a^* \in \mathrm{Im}\, \partial f$ (so $a^* \in \partial f(a)$ for some $a \in X$) such that $\sup\left\{\langle y^*, x_0\rangle : \ (y^*, \beta) \in \sum_{i\in I}{}^{*} \mathrm{epi} f_i^*\right\} < \langle a^*, x_0\rangle$. By Lemma 2.3, this implies that

$$\sup\left\{\langle y^*, x_0\rangle : \ (y^*, \beta) \in \sum_{i\in I}^{*} \mathrm{epi} f_i^*\right\} < \langle a_0^*, x_0\rangle \tag{4.5}$$

for some $a_0^* \in \sum_{i\in I}{}^{*} \partial f_i(a)$. Note that a_0^* can be expressed in the form $a_0^* = \sum_{i\in I}{}^{*} a_i^*$, with each $a_i^* \in \partial f_i(a)$. Since each $\langle a_i^*, a\rangle = f_i(a) + f_i^*(a_i^*)$ (Young's equality), it follows from (4.1) that $\langle a_0^*, a\rangle = f(a) + \sum_{i\in I} f_i^*(a_i^*)$, and hence that $(a_0^*, \beta_0) \in \sum_{i\in I}{}^{*} \mathrm{epi} f_i^*$, where $\beta_0 := \langle a_0^*, a\rangle - f(a) \in \mathbb{R}$. But then $\sup\left\{\langle y^*, x_0\rangle : \ (y^*, \beta) \in \sum_{i\in I}{}^{*} \mathrm{epi} f_i^*\right\} \geq \langle a_0^*, x_0\rangle$, contradicting (4.5). Henceforth, without loss of generality, we may assume that $r_0 = -1$. Then (4.4) becomes

$$\sup\left\{\langle y^*, x_0\rangle - \beta : \ (y^*, \beta) \in \sum_{i\in I}^{*} \mathrm{epi} f_i^*\right\} < \langle x^*, x_0\rangle - \alpha. \tag{4.6}$$

Note that $\langle x^*, x_0\rangle - \alpha \leq f(x_0)$ by Young's inequality and the fact that $(x^*, \alpha) \in \mathrm{epi} f^*$, and it follows from (4.6) that

$$\sup\left\{\langle y^*, x_0\rangle - \beta : \ (y^*, \beta) \in \sum_{i\in I}^{*} \mathrm{epi} f_i^*\right\} < f(x_0). \tag{4.7}$$

Moreover, for each $i \in I$, pick $x_i^* \in \partial f_i(x_0)$. Define $x_0^* := \sum_{i\in I}{}^{*} x_i^*$ (this is well-defined by Lemma 2.3). Let $\alpha_0 := \langle x_0^*, x_0\rangle - f(x_0)$. Note from Young's equality that $\langle x_i^*, x_0\rangle =$

$f_i(x_0) + f_i^*(x_0^*)$ for each $i \in I$, and it follows from (4.1) that $\alpha_0 = \sum_{i\in I} f_i^*(x_i^*)$, and hence that $(x_0^*, \alpha_0) = \sum_{i\in I}{}^*(x_i^*, f_i^*(x_i^*)) \in \sum_{i\in I}{}^* \mathrm{epi} f_i^*$. Consequently, by (4.7), $\langle x_0^*, x_0\rangle - \alpha_0 < f(x_0)$, contradicting the definition of α_0. □

If I is countable and if another assumption, namely,

$$\mathrm{dom}\, f^* = \mathrm{Im}\, \partial f \tag{4.8}$$

is added, the following result shows that the set $\sum_{i\in I}{}^* \mathrm{epi} f_i^*$ is weak* closed.

THEOREM 4.2. *Assume* (4.8) *in addition to* (4.1) *and* (4.2)*, and suppose that I is countable. Then* $\mathrm{epi} f^* = \sum_{i\in I}{}^* \mathrm{epi} f_i^*$.

Proof. Noting that $\mathrm{epi} f^* = \mathrm{gph} f^* + \{0\} \times [0, +\infty)$ and,

$$\sum_{i\in I}{}^* \mathrm{epi} f_i^* + \{0\} \times [0, \infty) \subseteq \sum_{i\in I}{}^* \mathrm{epi} f_i^* \tag{4.9}$$

(because $\mathrm{epi} f_i^* + \{0\} \times [0, \infty) = \mathrm{epi} f_i^*$ for each i) and making use of Theorem 4.1, we need only to show that

$$\mathrm{gph} f^* \subseteq \sum_{i\in I}{}^* \mathrm{epi} f_i^*, \tag{4.10}$$

where $\mathrm{gph} f^*$ denotes the graph of f^*. To see (4.10), let $(x^*, \alpha) \in \mathrm{gph} f^*$. Then $x^* \in \mathrm{dom} f^* = \mathrm{Im}\, \partial f$ thanks to (4.8). Hence there exists $x \in X$ such that $x^* \in \partial f(x)$. By Lemma 2.3, x^* can be expressed in the form

$$x^* = \sum_{i\in I}{}^* x_i^*,$$

where each $x_i^* \in \partial f_i(x)$. By Young's equality, $f^*(x^*) = \langle x^*, x\rangle - f(x)$ and each $f_i^*(x_i^*) = \langle x_i^*, x\rangle - f_i(x)$, and it follows from (4.1) that $\sum_{i\in I} f_i^*(x_i^*) = \langle x^*, x\rangle - f(x)$, that is, $\sum_{i\in I} f_i^*(x_i^*) = f^*(x^*) = \alpha$. Therefore, $(x^*, \alpha) = \sum_{i\in I}{}^*(x_i^*, f_i^*(x_i^*)) \in \sum_{i\in I}{}^* \mathrm{epi} f_i^*$. This completes the proof. □

4.2. Nonnegative type. Throughout this subsection, we assume that f and each f_i are nonnegative-valued, that is,

$$\{f_i, f : i \in I\} \subseteq \Gamma_+(X). \tag{4.11}$$

THEOREM 4.3. *Assume* (4.1) *and* (4.11)*. Then*

$$\mathrm{epi} f^* = \overline{\bigcup_{\substack{J\subseteq I,\\ |J|<\infty}} \sum_{i\in J} \mathrm{epi} f_i^*}^{w^*} = \overline{\sum_{i\in I}{}^* \mathrm{epi} f_i^*}^{w^*}. \tag{4.12}$$

Proof. Since each $\mathrm{epi} f_i^*$ is a convex set containing the origin (because $f_i \geq 0$), one has from (2.6) and Lemma 3.1 that

$$\bigcup_{\substack{J\subseteq I,\\ |J|<\infty}} \sum_{i\in J} \mathrm{epi} f_i^* \subseteq \sum_{i\in I}{}^* \mathrm{epi} f_i^* \subseteq \mathrm{epi} f^*,$$

and hence

$$\overline{\bigcup_{\substack{J\subseteq I,\\ |J|<\infty}} \sum_{i\in J} \mathrm{epi} f_i^*}^{w^*} \subseteq \overline{\sum_{i\in I}{}^* \mathrm{epi} f_i^*}^{w^*} \subseteq \mathrm{epi} f^*. \tag{4.13}$$

For each $J \subseteq I$, with $|J| < \infty$, let g_J denote the sum function of $\{f_i : i \in J\}$, namely, $g_J(x) = \sum_{i\in J} f_i(x)$ for all $x \in X$. Since each f_i is nonnegative-valued, we have that, by (4.1) and (2.9),

$$f = \sum_{i\in I} f_i = \sup_{\substack{J\subseteq I,\\ |J|<\infty}} g_J. \tag{4.14}$$

Hence, by Lemma 2.2 (applied to $\{g_J : J \subseteq I, |J| < +\infty\}$) and Lemma 2.1, we have that

$$\operatorname{epi} f^* = \overline{\bigcup_{\substack{J\subseteq I,\\ |J|<\infty}} \operatorname{epi} g_J^*}^{w^*} = \overline{\bigcup_{\substack{J\subseteq I,\\ |J|<\infty}} \overline{\sum_{i\in J} \operatorname{epi} f_i^*}^{w^*}}^{w^*} \tag{4.15}$$

(note that $\bigcup_{\substack{J\subseteq I,\\ |J|<\infty}} \operatorname{epi} g_J^*$ is a convex set since $\operatorname{epi} g_{J_1}^* \subseteq \operatorname{epi} g_{J_2}^*$ if $J_1 \subseteq J_2$). Combining this with (4.13) and (4.15), we see that (4.12) holds because the set on the right-hand side of (4.15) is equal to that on the left-hand side of (4.13) (to see the latter fact, note that, for any $J \subseteq I$, with $|J| < +\infty$, one has

$$\overline{\sum_{i\in J} \operatorname{epi} f_i^*}^{w^*} \subseteq \overline{\bigcup_{\substack{J\subseteq I,\\ |J|<\infty}} \sum_{i\in J} \operatorname{epi} f_i^*}^{w^*},$$

and so

$$\overline{\bigcup_{\substack{J\subseteq I,\\ |J|<\infty}} \overline{\sum_{i\in J} \operatorname{epi} f_i^*}^{w^*}}^{w^*} \subseteq \overline{\bigcup_{\substack{J\subseteq I,\\ |J|<\infty}} \sum_{i\in J} \operatorname{epi} f_i^*}^{w^*}.$$

This completes the proof. □

Next, we seek some sufficient conditions to ensure that the set $\sum_{i\in I}^* \operatorname{epi} f_i^*$ in Theorem 4.3 is weak* closed. It would be convenient for us to introduce some new notation first. Let Y be a Banach space, and let J be a finite set. Let $\{K_i\}_{i\in J}$ be closed convex cones of Y. Following [28], we define $\gamma(K_i; J)$ by

$$\gamma(K_i; J) = \inf\left\{\left\|\sum_{i\in J} y_i\right\| : \sum_{i\in J} \|y_i\| = 1, \text{ each } y_i \in K_i\right\}. \tag{4.16}$$

When $J = \{1, 2\}$ and Y is a Hilbert space, the corresponding value of $\cos^{-1}\gamma(K_i; J)$ is termed as the angle between the closed convex cones K_1 and K_2 (see [7] for a detailed discussion). Given $y^* \in Y^*$ and any subspace Z of Y, $y^*|_Z$ denotes the restriction of y^* to Z and $\|y^*\|_Z$ denotes the corresponding norm of $y^*|_Z$ in Z^*. Furthermore, let $D \subseteq Y^*$; we define $D|_Z := \{y^*|_Z : y^* \in D\}$. Let K be a subset of Y (resp. Y^*), the (negative) polar of K is denoted by K° and is defined by $K^\circ = \{y^* \in Y^* : \langle y^*, y\rangle \le 0$ for all $y \in K\}$) (resp. $K^\circ = \{y \in Y : \langle y^*, y\rangle \le 0$ for all $y^* \in K\}$). From the definition, it is clear that if K_1 and K_2 are two subsets of Y (resp. Y^*) and $K_1 \subseteq K_2$, then $K_2^\circ \subseteq K_1^\circ$.

When H is a subspace of X, $Y = X^* \times \mathbb{R}$, $Z = H \times \mathbb{R}$, and each K_i ($i \in J$) is a weak* closed convex cone of Y, $K_i|_Z$ ($i \in J$) and $\gamma(K_i|_Z; J)$ are, respectively, defined by

$$K_i|_Z = \{(x^*|_H, \alpha) : (x^*, \alpha) \in K_i\} \tag{4.17}$$

and

(4.18)
$$\gamma(K_i|_Z; J) = \inf\left\{\left\|\sum_{i\in J}(x_i^*|_H, \alpha_i)\right\| : \sum_{i\in J}\|(x_i^*|_H, \alpha_i)\| = 1, \text{ each } (x_i^*, \alpha_i) \in K_i\right\}$$

(see (4.16)). If H is finite-dimensional, the infimum in (4.18) is attained and hence can be replaced by minimum.

An important special case (that we shall consider in the next theorem) is as follows: Each f_i is given in the form

$$f_i(x) = \max\{\langle a_i^*, x\rangle + r_i, 0\} + \delta_{C_i}(x), \tag{4.19}$$

where C_i are closed convex subsets of X with $\bigcap_{i\in I} C_i \neq \emptyset$ and $a_i^* \in X^*$ and $r_i \in \mathbb{R}$. Let D_i denote the convex hull of the set $(a_i^*, -r_i) \cup (0,0)$, and let K_i denote the set $\mathrm{epi}\sigma_{C_i}$. Then D_i is a weak* compact set in $X^* \times \mathbb{R}$ containing the origin, and K_i is a weak* closed convex cone in $X^* \times \mathbb{R}$. We observe that

$$\mathrm{co}\{\big(\{a_i^*\} \times [-r_i, \infty)\big) \cup \big(\{0\} \times [0, \infty)\big)\} = \mathrm{co}\{(a_i^*, -r_i) \cup (0,0)\} + \{0\} \times [0, \infty). \tag{4.20}$$

Indeed, let $(x^*, r) \in \mathrm{co}\{\big(\{a_i^*\} \times [-r_i, \infty)\big) \cup \big(\{0\} \times [0, \infty)\big)\}$. There exist $t \in [0,1]$, $\epsilon, \delta \geq 0$ such that $(x^*, r) = t(a_i^*, -r_i + \epsilon) + (1-t)(0, \delta) = t(a_i^*, -r_i) + (0, t\epsilon + (1-t)\delta)$. Note that $t\epsilon + (1-t)\delta \geq 0$. It follows that $(x^*, r) \in \mathrm{co}\{(a_i^*, -r_i) \cup (0,0)\} + \{0\} \times [0, \infty)$, and hence $\mathrm{co}\{\big(\{a_i^*\} \times [-r_i, \infty)\big) \cup \big(\{0\} \times [0, \infty)\big)\} \subseteq \mathrm{co}\{(a_i^*, -r_i) \cup (0,0)\} + \{0\} \times [0, \infty)$. As the converse inclusion can be verified similarly, (4.20) is seen to hold. Consequently, we have that

$$\begin{aligned}
\mathrm{epi} f_i^* &= \mathrm{epi}(\max\{\langle a_i^*, \cdot\rangle + r_i, 0\})^* + \mathrm{epi}(\delta_{C_i})^* \\
&= \mathrm{co}\{\mathrm{epi}(\langle a_i^*, \cdot\rangle + r_i)^* \cup \big(\{0\} \times [0, \infty)\big)\} + \mathrm{epi}(\delta_{C_i})^* \\
&= \mathrm{co}\{\big(\{a_i^*\} \times [-r_i, \infty)\big) \cup \big(\{0\} \times [0, \infty)\big)\} + \mathrm{epi}(\delta_{C_i})^* \\
&= \mathrm{co}\{(a_i^*, -r_i) \cup (0,0)\} + \mathrm{epi}(\delta_{C_i})^* \\
&= D_i + K_i, \qquad (4.21)
\end{aligned}$$

where the first equality follows from (4.19) and Lemma 2.1, the second equality follows from Lemma 2.3, and the fourth equality holds by (4.20) and the fact $\mathrm{epi}(\delta_{C_i})^* = \mathrm{epi}(\delta_{C_i})^* + \{0\} \times [0, +\infty)$. Therefore, the condition (C1) in the following theorem is satisfied if the functions f_i are given in the form (4.19).

THEOREM 4.4. *Let I be a compact metric space. Assume* (4.1), (4.11), *and the following assumptions:*

(C1) *For each $i \in I$, there exist a weak* compact convex set D_i in $X^* \times \mathbb{R}$ containing the origin, and a weak* closed convex cone K_i in $X^* \times \mathbb{R}$ such that*

$$\mathrm{epi} f_i^* = D_i + K_i. \tag{4.22}$$

(C2) $\sum_{i\in I} \mathrm{diam}(D_i) < \infty$, *where* $\mathrm{diam}(D_i)$ *denotes the diameter of D_i ($i \in I$), i.e.,* $\mathrm{diam}(D_i) := \sup\{\|x - y\| : x, y \in D_i\}$.

(C3) *There exist $i_0 \in I$ and a finite-dimensional subspace H of X such that $K_{i_0}^\circ \subseteq Z := H \times \mathbb{R}$ (denote the corresponding dimension of Z by m).*

(C4) *For any $J \subseteq I$ with $|J| = m$, $\gamma(K_i|_Z; J) > 0$.*

(C5) *The set-valued mapping $i \mapsto K_i|_Z$ is upper semicontinuous, i.e., for any $\overline{i} \in I$,*

$$\limsup_{i\to\overline{i}}(K_i|_Z) \subseteq K_{\overline{i}}|_Z,$$

where $\limsup_{i\to\overline{i}}(K_i|_Z) := \{x^* \in Z^* : \exists\ x_i^* \in K_i|_Z$ *such that* $x^* = \lim_{i\to\overline{i}} x_i^*$ *(in the norm of* Z^**)*$\}$. *Then* $\sum_{i\in I}{}^*\mathrm{epi}f_i^*$ *is weak** *closed and*

$$\mathrm{epi}f^* = \sum_{i\in I}{}^*\mathrm{epi}f_i^*. \tag{4.23}$$

Proof. By Theorem 4.3, we need only prove the weak*-closedness assertion. Denote $Y := X \times \mathbb{R}$, and so Y^* is identified with $X^* \times \mathbb{R}$. Denote $A_i := \mathrm{epi}f_i^* \subseteq Y^*$ and $A := \sum_{i\in I}{}^* A_i$. Let $a^* \in \overline{A}^{w^*}$. We have to show that $a^* \in A$. To do this, we take a sequence $\{a_k^*\} \subseteq A$ such that $a_k^* \to a^*$ on $Z := H \times \mathbb{R}$ (thanks to the assumption that H is finite-dimensional and the weak* topology coincides with the norm topology on a finite-dimensional space). For each $k \in \mathbb{N}$, noting that $a_k^* \in A = \sum_{i\in I}{}^* A_i$, there exists a sequence in $\bigcup_{\substack{J\subseteq I,\\ |J|<\infty}} \sum_{i\in J} A_i$ weak* converging (and hence in norm $\|\cdot\|_Z$) to a^*. Thus, there exist a finite subset I_k of I and $a_{i,k}^* \in A_i$ $(i \in I_k)$ such that

$$\left\| a_k^* - \sum_{i\in I_k} a_{i,k}^* \right\|_Z \le \frac{1}{k}. \tag{4.24}$$

Hence

$$\lim_{k\to\infty} \|u_k^* - a^*\|_Z \to 0, \tag{4.25}$$

where $u_k^* := \sum_{i\in I_k} a_{i,k}^*$. Note that $u_k^* \in \sum_{i\in I_k} D_i + \sum_{i\in I_k} K_i$ $\big($by (4.22)$\big)$. Since Z is of dimension m and each K_i is a (convex) cone, it follows from the Carathédory theorem [27, Corollary 17.1.2] that, for each $k \in \mathbb{N}$, there exist $\{i_{1,k}, i_{2,k}, \ldots, i_{m,k}\} \subseteq I_k$, such that

$$u_k^* = \sum_{i\in I_k} \overline{y}_{i,k}^* + \sum_{j=1}^m \overline{z}_{i_{j,k}}^* \text{ on } Z \tag{4.26}$$

for some $\overline{y}_{i,k}^* \in D_i$ $(i \in I_k)$ and $\overline{z}_{i_{j,k}}^* \in K_{i_{j,k}}$ $(1 \le j \le m)$. Let $I' := \bigcup_{k\in\mathbb{N}} I_k$ and set $\overline{y}_{i,k}^* := 0$ for any $i \in I'\backslash I_k$. For each fixed $k \in \mathbb{N}$, it follows from (4.26) that

$$u_k^* = \sum_{i\in I'} \overline{y}_{i,k}^* + \sum_{j=1}^m \overline{z}_{i_{j,k}}^* \text{ on } Z, \tag{4.27}$$

where $\overline{y}_{i,k}^* \in D_i$ for all $i \in I'$ $\big($thanks to the assumption that each D_i contains the origin$\big)$. Next, we show that

$$\{\overline{z}_{i_{j,k}}^*|_Z\}_{k\in\mathbb{N}} \text{ are bounded sequences for all } 1 \le j \le m. \tag{4.28}$$

To prove this, we suppose on the contrary that $\{\overline{z}_{i_{j,k}}^*|_Z\}_{k\in\mathbb{N}}$ is an unbounded sequence for some $j \in \{1, 2, \ldots, m\}$. By passing to a subsequence if necessary, we may assume that

$$\lim_{k\to\infty} \sum_{j=1}^m \|\overline{z}_{i_{j,k}}^*\|_Z \to \infty. \tag{4.29}$$

Dividing by $\sum_{j=1}^m \|\overline{z}^*_{i_{j,k}}\|_Z$ on both sides of (4.27), we obtain

$$\frac{u^*_k}{\sum_{j=1}^m \|\overline{z}^*_{i_{j,k}}\|_Z} = \frac{\sum_{i\in I'} \overline{y}^*_{i,k}}{\sum_{j=1}^m \|\overline{z}^*_{i_{j,k}}\|_Z} + \sum_{j=1}^m \frac{\overline{z}^*_{i_{j,k}}}{\sum_{j=1}^m \|\overline{z}^*_{i_{j,k}}\|_Z} \text{ on } Z. \tag{4.30}$$

Note that $\{\|u^*_k\|_Z\}_{k\in\mathbb{N}}$ is a bounded numerical sequence (since $\|u^*_k - a^*\|_Z \to 0$), and

$$\left\|\sum_{i\in I'} \overline{y}^*_{i,k}\right\|_Z \le \sum_{i\in I'} \|\overline{y}^*_{i,k}\| \le \sum_{i\in I} \operatorname{diam}(D_i) < \infty. \tag{4.31}$$

Moreover, since I is compact, we may assume without loss of generality that $i_{j,k} \to \overline{i}_j$ for some $\overline{i}_j \in I$ $(1 \le j \le m)$ as $k \to \infty$. Considering subsequences if necessary, we may assume that there exists $z^*_j \in X^*$ such that the bounded sequence

$$\frac{\overline{z}^*_{i_{j,k}}}{\sum_{j=1}^m \|\overline{z}^*_{i_{j,k}}\|_Z} \to z^*_j \text{ on } Z \quad (1 \le j \le m) \tag{4.32}$$

(thanks to the fact that Z is finite-dimensional). By (4.32), it is clear that $\sum_{j=1}^m \|z^*_j\|_Z = 1$. Moreover, assumption (C5) entails that each $z^*_j|_Z \in K_{\overline{i}_j}|_Z$. Finally, by passing to the limits in (4.30) and making use of (4.31) and (4.29), we have $\sum_{j=1}^m z^*_j = 0$ on Z. Then $\gamma(K_i|_Z, \{\overline{i}_1, \overline{i}_2, \dots, \overline{i}_m\}) = 0$, contradicting assumption (C4). Therefore, (4.28) is proved.

By the compactness of I again and by passing to subsequences if necessary, we may assume that $i_{j,k} \to \hat{i}_j$ for some $\hat{i}_j \in I$ as $k \to \infty$ $(1 \le j \le m)$. For each j, since Z is finite-dimensional and by (4.28), we may assume that $\overline{z}^*_{i_{j,k}} \to \overline{z}^*_j$ on Z for some $\overline{z}^*_j \in X^*$. By (C5), $\overline{z}^*_j|_Z \in K_{\hat{i}_j}|_Z$, and so there exists $\omega^*_j \in K_{\hat{i}_j}$ such that $\overline{z}^*_j = \omega^*_j$ on Z. Hence, replacing $\overline{z}^*_j$ by ω^*_j if necessary, we may assume without loss of generality that

$$\overline{z}^*_j \in K_{\hat{i}_j} \quad (1 \le j \le m). \tag{4.33}$$

Since $u^*_k \to a^*$ on Z $\big($by (4.25)$\big)$, (4.27) implies that

$$\sum_{i\in I'} \overline{y}^*_{i,k} = u^*_k - \sum_{j=1}^m \overline{z}^*_{i_{j,k}} \to a^* - \sum_{j=1}^m \overline{z}^*_j \text{ on } Z \quad \text{as } k \to \infty. \tag{4.34}$$

Since I' is countable, we may represent I' in the form that $I' = \{i_1, \dots, i_n, \dots\}$, and hence

$$\sum_{n\in\mathbb{N}} \overline{y}^*_{i_n,k} \to a^* - \sum_{j=1}^m \overline{z}^*_j \text{ on } Z \quad \text{as } k \to \infty.$$

Since $\overline{y}^*_{i_1,k} \in D_{i_1}$ and $D_{i_1}|_Z$ is compact, there exists an infinite subset $N_1 \subseteq \mathbb{N}$ such that $\{\overline{y}^*_{i_1,k}\}_{k\in N_1}$ converges to $\overline{y}^*_{i_1}$ on Z for some $\overline{y}^*_{i_1} \in D_{i_1}$. Inductively, we can find a sequence of infinite subsets $N_n \subseteq \mathbb{N}$ such that $N_{n+1} \subseteq N_n$ and, for each $n \in \mathbb{N}$,

$$\{\overline{y}^*_{i_n,k}\}_{k\in N_n} \text{ converges to } \overline{y}^*_{i_n} \text{ on } Z \text{ for some } \overline{y}^*_{i_n} \in D_{i_n}. \tag{4.35}$$

Since $\sum_{n\in\mathbb{N}}\|\overline{y}^*_{i_n}\| \le \sum_{i\in I}\|\overline{y}^*_i\| \le \sum_{i\in I}\mathrm{diam}D_i < +\infty$ (by the assumption (C2)), $\sum_{n\in\mathbb{N}}\overline{y}^*_{i_n}$ exists as an element in X^*, and, in particular,

$$\sum_{n\in\mathbb{N}}\overline{y}^*_{i_n} \in \sum_{n\in\mathbb{N}}{}^* D_{i_n}. \tag{4.36}$$

Similarly, for all $k\in\mathbb{N}$,

$$\sum_{n\in\mathbb{N}}\|\overline{y}^*_{i_n,k}\| \le \sum_{i\in I}\mathrm{diam}D_i < +\infty,$$

and thus, for any $\epsilon>0$, there exists $n_0\in\mathbb{N}$ such that, for all $n'\ge n_0$,

$$\sum_{n>n'}\|\overline{y}^*_{i_n,k}\| \le \sum_{n>n'}\mathrm{diam}(D_{i_n}) \le \epsilon/2 \text{ for all } k\in\mathbb{N}. \tag{4.37}$$

Note that, for any fixed $n'\ge n_0$, (by (4.35) and (4.34)) there exists $k_0\in\mathbb{N}$ (depending on n') such that

$$\|\overline{y}^*_{i_n,k_0} - \overline{y}^*_{i_n}\|_Z \le \frac{\epsilon}{4n'} \text{ for all } n\in\{1,\dots,n'\} \quad \text{and}$$
$$\left\| a^* - \sum_{j=1}^m \overline{z}^*_j - \sum_{n\in\mathbb{N}}\overline{y}^*_{i_n,k_0}\right\|_Z \le \epsilon/4.$$

It follows from (4.37) that, for any $n'\ge n_0$,

$$\begin{aligned}\left\| a^* - \sum_{j=1}^m \overline{z}^*_j - \sum_{n=1}^{n'}\overline{y}^*_{i_n}\right\|_Z &\le \left\| a^* - \sum_{j=1}^m \overline{z}^*_j - \sum_{n\in\mathbb{N}}\overline{y}^*_{i_n,k_0}\right\|_Z \\ &\quad + \sum_{n=1}^{n'}\|\overline{y}^*_{i_n,k_0} - \overline{y}^*_{i_n}\|_Z + \sum_{n>n'}\|\overline{y}^*_{i_n,k_0}\|_Z \\ &\le \epsilon.\end{aligned}$$

Since ϵ is arbitrary, one has

$$a^* = \sum_{j=1}^m \overline{z}^*_j + \sum_{n\in\mathbb{N}}\overline{y}^*_{i_n} \text{ on } Z. \tag{4.38}$$

Then, one has

$$a^* - \sum_{j=1}^m \overline{z}^*_j - \sum_{n\in\mathbb{N}}\overline{y}^*_{i_n} \in Z^\perp. \tag{4.39}$$

From (4.33) and (4.35), we know that each $\overline{z}^*_j \in K_{\hat{i}_j}$ and $\overline{y}_{i_n}\in D_{i_n}$, and it follows from (4.36) that $\sum_{j=1}^m \overline{z}^*_j + \sum_{n\in\mathbb{N}}\overline{y}^*_{i_n} \in \sum_{j=1}^m K_{\hat{i}_j} + \sum_{n\in\mathbb{N}}{}^* D_{i_n}$. Therefore, (4.39) entails that

$$a^* \in \sum_{j=1}^m K_{\hat{i}_j} + \sum_{n\in\mathbb{N}}{}^* D_{i_n} + Z^\perp. \tag{4.40}$$

Note from the bipolar theorem (cf. [30, Theorem 1.1.9]) and assumption (C3) that $Z^\perp \subseteq K_{i_0}$. It follows that $a^* \in \sum_{j=1}^m K_{\hat{i}_j} + \sum_{n\in\mathbb{N}}{}^* D_{i_n} + K_{i_0}$. Since $0 \in D_i \cap K_i$, one has

$$a^* \in \sum_{j=1}^m K_{\hat{i}_j} + \sum_{n\in\mathbb{N}}{}^* D_{i_n} + K_{i_0} = \sum_{n\in\mathbb{N}}{}^* D_{i_n} + \left(\sum_{j=1}^m K_{\hat{i}_j} + K_{i_0}\right) \subseteq \sum_{i\in I}{}^* (D_i + K_i) = A,$$

as required to show. This completes the proof. □

COROLLARY 4.5. *Let I be a compact metric space, and let f_i be given by* (4.19)*. Assume* (4.1), (4.11)*, and the following assumptions:*

(B1) $\sum_{i\in I}(\|a_i^*\| + |r_i|) < \infty$.

(B2) *There exists $i_0 \in I$ such that $H := \operatorname{span}(C_{i_0})$ is of finite dimension. (Denote the corresponding dimension by n.)*

(B3) *For any $J \subseteq I\backslash\{i_0\}$ with $|J| \le n+1$, it holds that*

$$C_{i_0} \cap \left(\bigcap_{i\in J} \operatorname{int}_H C_i\right) \neq \emptyset,$$

where $\operatorname{int}_H C_i := \{x \in C_i :$ *there exists $\epsilon > 0$ s.t. $B(x,\epsilon) \cap H \subseteq C_i$*$\}$.

(B4) *The mapping $i \mapsto C_i \cap H$ is lower semicontinuous, i.e., for any $\overline{i} \in I$,*

$$C_{\overline{i}} \cap H \subseteq \liminf_{i\to\overline{i}} (C_i \cap H).$$

Then the conclusion of Theorem 4.4 *holds.*

Proof. Define $D_i := \operatorname{co}\{(a_i^*, -r_i) \cup (0,0)\}$, and $K_i := \operatorname{epi}\sigma_{C_i}$. Then, as we have mentioned before, assumption (C1) in Theorem 4.4 holds (see (4.21)). Therefore, to finish the proof, it suffices to show that the assumptions (C2)–(C5) in Theorem 4.4 are satisfied. First of all, from condition (B1), we see that $\sum_{i\in I} \operatorname{diam} D_i < \infty$, and hence assumption (C2) holds. To see (C3), noting that $Z^\perp = (\operatorname{span} C_{i_0})^\perp \times \{0\} \subseteq \operatorname{epi}\sigma_{C_{i_0}} = K_{i_0}$, one has $K_{i_0}^\circ \subseteq Z$. Therefore, assumption (C3) holds with $m := n+1$. To see that assumption (C4) holds with $m := n+1$, we proceed by contradiction and suppose that there exists $J_0 \subseteq I$, with $|J_0| = n+1$ such that $\gamma(\operatorname{epi}\sigma_{C_i}|_{H\times\mathbb{R}}; J_0) = 0$. Noting that $H \times \mathbb{R}$ is finite-dimensional, it follows from (4.18) that there exist $(x_i^*, \alpha_i) \in \operatorname{epi}\sigma_{C_i}$ $(i \in J_0)$ such that

$$\sum_{i\in J_0} \left(\|x_i^*\|_H + |\alpha_i|\right) = 1, \tag{4.41}$$

$$\sum_{i\in J_0} x_i^* = 0 \text{ on } H, \quad \text{and} \quad \sum_{i\in J_0} \alpha_i = 0. \tag{4.42}$$

We claim that

$$x_i^* = 0 \text{ on } H \text{ for all } i \in J_0. \tag{4.43}$$

Granting this, we have $0 = \sigma_{C_i\cap H}(x_i^*) \le \sigma_{C_i}(x_i^*) \le \alpha_i$ for all $i \in J_0$. This together with the second equality of (4.42) implies that $\alpha_i = 0$ for all $i \in J_0$. However, this and (4.43) contradict (4.41). To see (4.43), we divide our proof into two cases.

Case 1: $i_0 \notin J_0$,

Case 2: $i_0 \in J_0$.

For Case 1, we note that $J_0 \subseteq I\backslash\{i_0\}$, and it follows from (B3) that $\bigcap_{j\in J_0} \mathrm{int}_H C_i \neq \emptyset$. Thus there exist $x_0 \in X$ and $\epsilon > 0$ such that $x_0 \in \overline{\mathbb{B}}(x_0,\epsilon) \cap H \subseteq C_i$ for all $i \in J_0$. Recalling the fact that $(x_i^*, \alpha_i) \in \mathrm{epi}\sigma_{C_i}$ $(i \in J_0)$ and the definition of $\|\cdot\|_H$, it follows from (4.42) that

$$\begin{aligned}\epsilon \sum_{i\in J_0} \|x_i^*\|_H = \sum_{i\in J_0} \big(\langle x_i^*, x_0\rangle + \epsilon\|x_i^*\|_H\big) &\leq \sum_{i\in J_0} \sup_{x\in\overline{\mathbb{B}}(x_0,\epsilon)\cap H} \langle x_i^*, x\rangle \\ &\leq \sum_{i\in J_0} \sup_{x\in C_i} \langle x_i^*, x\rangle \\ &\leq \sum_{i\in J_0} \alpha_i = 0. \qquad (4.44)\end{aligned}$$

Thus (4.43) holds in this case. For Case 2, one applies (B3) again, and there exist $x_0 \in C_{i_0}$ and $\epsilon > 0$ such that $x_0 \in \overline{\mathbb{B}}(x_0,\epsilon) \cap H \subseteq C_i$ for all $i \in J_0\backslash\{i_0\}$. Hence $\sup_{x\in\overline{B}(x_0,\epsilon)\cap H}\langle x_i^*, x\rangle \leq \sup_{x\in C_i}\langle x_i^*, x\rangle$, that is,

$$\langle x_i^*, x_0\rangle + \epsilon\|x_i^*\|_H = \sup_{x\in\overline{\mathbb{B}}(x_0,\epsilon)\cap H} \langle x_i^*, x\rangle \leq \sigma_{C_i}(x_i^*) \text{ for all } i \in J_0\backslash\{i_0\}. \qquad (4.45)$$

Since $(x_i^*, \alpha_i) \in \mathrm{epi}\sigma_{C_i}$ for all $i \in J_0$ and $x_0 \in C_{i_0}$ (so $\langle x_{i_0}^*, x_0\rangle \leq \alpha_{i_0}$), it follows from (4.42) that

$$\epsilon \sum_{i\in J_0\backslash\{i_0\}} \|x_i^*\|_H = \sum_{i\in J_0} \langle x_i^*, x_0\rangle + \epsilon \sum_{i\in J_0\backslash\{i_0\}} \|x_i^*\|_H \leq \sum_{i\in J_0} \alpha_i = 0.$$

This together with the first equality in (4.42) gives that $x_i^* = 0$ on H for all $i \in J_0$. Thus (4.43) also holds in this case. Finally, for (C5), fix an $\overline{i} \in I$. Consider $i \to \overline{i}$ and $(x_i^*, \alpha_i) \in H^* \times \mathbb{R}$ $(i \in I)$ be such that $(x_i^*, \alpha_i) \in \mathrm{epi}\sigma_{C_i}|_{H\times\mathbb{R}}$, with $(x_i^*, \alpha_i) \to (x^*, \alpha)$ for some $(x^*, \alpha) \in H^* \times \mathbb{R}$. Let $x \in C_{\overline{i}} \cap H$. By (B4) and since H is of finite dimension, there exists a sequence $\{x_i\} \subseteq C_i \cap H$ such that $x_i \to x$. It follows that

$$\langle x^*, x\rangle = \lim_{i\to\overline{i}} \langle x_i^*, x_i\rangle \leq \limsup_{i\to\overline{i}} \sigma_{C_i\cap H}(x_i^*) \leq \lim_{i\to\overline{i}} \alpha_i = \alpha.$$

This implies that $(x^*, \alpha) \in \mathrm{epi}\sigma_{C_{\overline{i}}}|_{H\times\mathbb{R}}$, and hence (C5) in Theorem 4.4 holds. Therefore, the assumptions (C2)–(C5) in Theorem 4.4 hold. This finishes the proof. □

5. Application to the KKT theory. We first establish an ϵ-sum rule involving possibly infinitely many convex functions. In the special case where $I = \emptyset$, the following result has been presented in [18] (see also [30, Corollary 2.6.7]).

THEOREM 5.1. *Let I, J be two index sets with $I \cap J = \emptyset$ and $|J| < \infty$. Let $\{f_i\}_{i\in I} \subseteq \Gamma_+(X)$ and $\{f_j\}_{j\in J} \subseteq \Gamma(X)$. Let $f \in \Gamma(X)$ be such that $f(x) = \sum_{i\in I} f_i(x) + \sum_{j\in J} f_j(x)$ for each $x \in X$. Let $\epsilon \geq 0$ and $x \in X$. Then we have*

$$\partial_\epsilon f(x) \subseteq \bigcap_{\eta>0} \bigcup_{\substack{I'\subseteq I,\\ |I'|<\infty}} \overline{\left\{\sum_{i\in I'} \partial_{\epsilon_i} f_i(x) + \sum_{j\in J} \partial_{\epsilon_j} f_j(x) : \sum_{i\in I'} \epsilon_i + \sum_{j\in J} \epsilon_j \leq \epsilon + \eta\right\}}^{w^*}. \qquad (5.1)$$

Proof. To see the inclusion, let $x^* \in \partial_\epsilon f(x)$, $\eta > 0$, and let V be a weak* neighborhood of 0. It suffices to show that there exist I' with $|I'| < +\infty$, $\epsilon_i, \epsilon_j \geq 0$ $(i \in I', j \in J)$ such that

$$\sum_{i\in I'} \epsilon_i + \sum_{j\in J} \epsilon_j \leq \epsilon + \eta \qquad (5.2)$$

and

$$x^* \in \sum_{i\in I'} \partial_{\epsilon_i} f_i(x) + \sum_{j\in J} \partial_{\epsilon_j} f_j(x) + V. \tag{5.3}$$

Let $h := \sum_{i\in I} f_i$. Note that $h \in \Gamma_+(X)$ (since $f_i \in \Gamma_+(X)$ and $h(x_0) < +\infty$ for all $x_0 \in \mathrm{dom} f$). From Lemma 2.1 (applied to $\{h, f_j : j \in J\}$) and Theorem 4.3, we have

$$\begin{aligned}
\mathrm{epi} f^* = \mathrm{epi}\left(h + \sum_{j\in J} f_j\right)^* &= \overline{\mathrm{epi} h^* + \sum_{j\in J} \mathrm{epi} f_j^*}^{w^*} \\
&= \overline{\overline{\bigcup_{\substack{I'\subseteq I,\\ |I'|<\infty}} \sum_{i\in I'} \mathrm{epi} f_i^*}^{w^*} + \sum_{j\in J} \mathrm{epi} f_j^*}^{w^*} \\
&= \overline{\bigcup_{\substack{I'\subseteq I,\\ |I'|<\infty}} \sum_{i\in I'} \mathrm{epi} f_i^* + \sum_{j\in J} \mathrm{epi} f_j^*}^{w^*}.
\end{aligned}$$

Since $x^* \in \partial_\epsilon f(x)$, it follows from (2.5) and the above expression that

$$(x^*, \epsilon + \langle x^*, x\rangle - f(x)) \in \overline{\bigcup_{\substack{I'\subseteq I,\\ |I'|<\infty}} \sum_{i\in I'} \mathrm{epi} f_i^* + \sum_{j\in J} \mathrm{epi} f_j^*}^{w^*}, \tag{5.4}$$

and hence there exist $I' \subseteq I$ with $|I'| < \infty$, $(x_i^*, r_i) \in \mathrm{epi} f_i^*$ $(i \in I')$, and $(x_j^*, r_j) \in \mathrm{epi} f_j^*$ $(j \in J)$ such that

$$x^* \in \sum_{i\in I'} x_i^* + \sum_{j\in J} x_j^* + V \tag{5.5}$$

and

$$\sum_{i\in I'} r_i + \sum_{j\in J} r_j \le (\epsilon + \eta/2) + \langle x^*, x\rangle - f(x). \tag{5.6}$$

By shrinking V if necessary, we may assume without loss of generality that

$$\left|\left\langle \sum_{i\in I'} x_i^* + \sum_{j\in J} x_j^* - x^*,\ x \right\rangle\right| \le \eta/2. \tag{5.7}$$

For each $k \in I' \cup J$, let $\epsilon_k := f_k^*(x_k^*) + f_k(x) - \langle x_k^*, x\rangle$; then $\epsilon_k \ge 0$ (Young's inequality), and $x_k^* \in \partial_{\epsilon_k} f_k(x)$ (see (2.5)). Thus (5.3) holds by (5.5). It remains to show (5.2). To see this, note that $(x_k^*, r_k) \in \mathrm{epi} f_k^*$, and so $\epsilon_k \le r_k + f_k(x) - \langle x_k^*, x\rangle$ for each $k \in I' \cup J$. Further, $\sum_{i\in I'} f_i(x) + \sum_{j\in J} f_j(x) \le f(x)$ (since f_i are nonnegative for all $i \in I$). It follows from (5.6) that

$$\sum_{k\in I'\cup J} \epsilon_k \le \sum_{k\in I'\cup J} r_k + f(x) - \left\langle \sum_{i\in I'\cup J} x_k^*, x \right\rangle \le \left\langle x^* - \sum_{k\in I'\cup J} x_k^*, x \right\rangle + (\epsilon + \eta/2),$$

and so (5.2) holds by (5.7). This completes the proof. ∎

Let $|I| \leq +\infty$. Consider the following semi-infinite programming

$$\begin{aligned} &\min_{x\in X} \ f_0(x) \\ &\text{s.t.} \ \ f_i(x) \leq 0 \quad (i \in I), \end{aligned} \tag{5.8}$$

where $\{f_0, f_i : i \in I\} \subseteq \Gamma(X)$. We say that x is a feasible point of (5.8) if $f_0(x) < +\infty$ and $f_i(x) \leq 0$ for all $i \in I$. For any $\epsilon \geq 0$, a feasible point $\overline{x}$ of (5.8) is called an ϵ-solution if $f_0(\overline{x}) \leq f_0(x) + \epsilon$ for all feasible points x of (5.8). As an application of the preceding theorem, we have the following fuzzy KKT result for (5.8). In the special case when $\epsilon = 0$, X is reflexive and $\{f_0, f_i : i \in I\} \subseteq \Gamma_c(X)$. The fuzzy KKT condition was first derived by Jeyakumar, Lee, and Dinh in [19]. In the special case when $\epsilon = 0$ and each f_i $(i \in I)$ is epi-closed, this result was also established by Boţ, Csetnek, and Wanka in [3, 6] via the perturbation approach (indeed, [3, 6] gave the corresponding result for a more general problem: The cone constraint problem).

THEOREM 5.2. *Let $\epsilon \geq 0$, and let $\overline{x}$ be an ϵ-solution of* (5.8). *Let U be a weak*-neighborhood of* 0 *and $\eta > 0$. Then there exist a finite subset I' of I and $\{\epsilon_i : i \in \{0\} \cup I'\} \cup \{\lambda_i : i \in I'\} \subseteq [0, +\infty)$ such that*

$$0 \leq \sum_{i\in I'\cup\{0\}} \epsilon_i \leq \epsilon + \eta, \quad -(\epsilon + \eta) \leq \sum_{i\in I'} \lambda_i f_i(\overline{x}) \leq 0, \tag{5.9}$$

and

$$0 \in x_0^* + \sum_{i\in I'} x_i^* + U \tag{5.10}$$

for some

$$x_0^* \in \partial_{\epsilon_0} f_0(\overline{x}) \text{ and } x_i^* \in \partial_{\epsilon_i}(\lambda_i f_i)(\overline{x}) \ (i \in I'). \tag{5.11}$$

Proof. Define $f : X \to \mathbb{R} \cup \{+\infty\}$ by

$$f(x) = f_0(x) + \sum_{i\in I} g_i(x),$$

where $g_i = \delta_{A_i}$ and $A_i := \{x \in X : f_i(x) \leq 0\}$. Then $f(\overline{x}) = f_0(\overline{x}) < +\infty$ and $f \in \Gamma(X)$. Moreover, since $\overline{x}$ is an ϵ-solution of (5.8), one has $f(\overline{x}) \leq f(x) + \epsilon$ for all $x \in X$ so that $0 \in \partial_\epsilon f(\overline{x})$. We assume without loss of generality that the given weak* neighborhood U is convex. Note that each g_i is a nonnegative function $(i \in I)$. From Theorem 5.1 (applied to $\{I, \{0\}, \{g_i\}_{i\in I}, f_0, \epsilon\}$ in place of $\{I, J, \{f_i\}_{i\in I}, \{f_j\}_{j\in J}, \epsilon\}$), there exist a finite subset I' of I and $\{\overline{\epsilon}_i : i \in \{0\} \cup I'\} \subseteq [0, \infty)$ such that

$$\overline{\epsilon}_0 + \sum_{i\in I'} \overline{\epsilon}_i \leq \epsilon + \frac{\eta}{2} \text{ and } 0 \in x_0^* + \sum_{i\in I'} z_i^* + \frac{U}{2} \tag{5.12}$$

for some $x_0^* \in \partial_{\overline{\epsilon}_0} f_0(\overline{x})$ and $z_i^* \in \partial_{\overline{\epsilon}_i} g_i(\overline{x})$ $(i \in I')$. Since $g_i = \delta_{A_i}$, it follows from (2.4) that $g_i^*(z_i^*) = \sup_{a\in A_i} \langle z_i^*, a\rangle \leq \langle z_i^*, \overline{x}\rangle + \overline{\epsilon}_i$. By (2.12) (applied to f_i in place of f), it follows that

$$(z_i^*, \langle z_i^*, \overline{x}\rangle + \overline{\epsilon}_i) \in \overline{\bigcup_{\lambda>0} \operatorname{epi}(\lambda f_i)^*}^{w^*}.$$

Hence, for each $i \in I'$, there exist $\lambda_i > 0$ and $(x_i^*, s_i) \in \mathrm{epi}(\lambda_i f_i)^*$ such that

$$z_i^* \in x_i^* + \frac{U}{2|I'|}, \tag{5.13}$$

$$\langle z_i^* - x_i^*, \overline{x}\rangle < \eta/(4|I'|), \tag{5.14}$$

and

$$|\langle z_i^*, \overline{x}\rangle + \overline{\epsilon}_i - s_i| < \eta/(4|I'|). \tag{5.15}$$

By (2.11) $\big($applied to $\{\lambda_i f_i, \overline{x}\}$ in place of $\{f, x\}\big)$, for each $i \in I'$ there exists $\epsilon_i \geq 0$ such that

$$x_i^* \in \partial_{\epsilon_i}(\lambda_i f_i)(\overline{x}) \text{ and } s_i = \epsilon_i + \langle x_i^*, \overline{x}\rangle - \lambda_i f_i(\overline{x}). \tag{5.16}$$

Thus, letting $\epsilon_0 := \overline{\epsilon}_0$, (5.11) holds. By (5.12) and (5.13), (5.10) also holds. Since each $\epsilon_i \geq 0$ and $f_i(\overline{x}) \leq 0$ $(i \in I')$, we note that

$$\max\left\{\sum_{i\in\{0\}\cup I'} \epsilon_i \ , \ -\sum_{i\in I'} \lambda_i f_i(\overline{x})\right\} \leq \sum_{i\in\{0\}\cup I'} \epsilon_i - \sum_{i\in I'} \lambda_i f_i(\overline{x});$$

thus to prove (5.9), it suffices to show that

$$\sum_{i\in\{0\}\cup I'} \epsilon_i - \sum_{i\in I'} \lambda_i f_i(\overline{x}) \leq \epsilon + \eta. \tag{5.17}$$

To do this, note that, for each $i \in I'$,

$$\epsilon_i - \lambda_i f_i(\overline{x}) = s_i - \langle x_i^*, \overline{x}\rangle = (s_i - \langle z_i^*, \overline{x}\rangle) + \langle z_i^* - x_i^*, \overline{x}\rangle < \left(\overline{\epsilon}_i + \frac{\eta}{4|I'|}\right) + \frac{\eta}{4|I'|}$$

$\big($see (5.14), (5.15), and (5.16)$\big)$. Hence it follows from (5.12) that

$$\epsilon_0 + \sum_{i\in I'} \big(\epsilon_i - (\lambda_i f_i)(\overline{x})\big) < \overline{\epsilon}_0 + \sum_{i\in I} \overline{\epsilon}_i + \eta/2 \leq \epsilon + \eta.$$

Thus (5.17) is true, and the proof is completed. □

Acknowledgments. The authors would like to express their sincere thanks to the anonymous referees for many helpful comments and for pointing out the references [3, 4, 5, 6, 11, 26].

MULTIVARIABLE UTILITY FUNCTIONS*

MARIA B. CHIAROLLA† AND ULRICH G. HAUSSMANN‡

Abstract. Utility functions of several variables are ubiquitous in economics. Their maximization requires inversion of the gradient map. Using convex analysis tools, we provide a representation of an extension of this inverse that accounts for possible constraints. To solve economic equilibrium problems, the utility functions of the agents are frequently aggregated into a representative (agent's) utility function. We establish regularity and inversion properties of such representative utility functions.

Key words. multivariable utility functions, representative agent utility function, convex analysis

1. Introduction. Concave functions appear frequently in economics, e.g., as production functions (translating "input" into "output") and as utility functions (producing an ordering of "preferences"); cf. [1], [2], [3], [7], [8], [9], [10], [11]. In early, simple dynamic utility maximization problems, utility functions depended on one variable—consumption of a single good. But more recently models where preferences depend on the consumption of several goods, cf. [2], or on several variables such as leisure and money supply in addition to consumption, cf. [3], [10], require multivariable utility functions. And of course the variables are constrained—typically the variable x_i lies in an interval. The two main properties of utility functions used in these settings, inversion of the derivative and aggregation of the functions, are well understood in the scalar case, cf. [9], but less so in the multivariable case. It is the purpose of this paper to remedy this situation.

Utility functions are assumed to be strictly increasing, strictly concave, and usually smooth, with "derivative equal to zero at infinity," meaning in the scalar case that $\lim_{x\to\infty} u_x(x) = 0$, where u_x is the derivative of the function. If the feasible set in the utility maximization is bounded as in [11], then conditions at infinity can be dispensed with; however, that excludes the interesting cases. Dana and Pontier [7] present a nice perspective on Arrow–Debreu and Arrow–Radner equilibriums in a dynamic, stochastic economy with exogenous endowment without assumptions on the utility functions at zero or infinity, but in the single variable case. In [5] we study equilibrium in a dynamic, stochastic economy with endogenous endowment consisting in part from the return on labor provided to produce the commodity. And in [4] we study the simpler problem of a static, deterministic economy. Both of these papers work with multivariable utility functions and rely on the present work. Smooth utility

functions of several variables are also considered by Bank and Riedel [2] for a portfolio optimization problem rather than an equilibrium problem, but they do not use a general representation of the extension of the inverse of the gradient of the utility function. Nonsmooth multivariable utility functions are considered in [8] for the problem of maximizing terminal utility derived from a portfolio of financial instruments under transaction costs.

We explain first the inversion result. Let $y^\top$ denote the transpose of y. Consider the problem

$$\max_{x\in A}\{u(x) - y^\top x\} \tag{1.1}$$

for a concave, strictly increasing function u and a convex set A. u may be a production function transforming a quantity x of resources into goods (or cash after the sale of the goods), and y is the price vector of the resources. Given a price y, the manager of the facility wants to determine the resources x required to maximize profit, so he wants to solve (1.1). The solution is $x = (\nabla u)^{-1}(y)$ if $y \in \nabla u(A)$. But what if y is not in this set? Convex analysis treats this problem by extending u to u_A, which is defined to be $-\infty$ off A. Then the solution is $x = (\partial u_A)^{-1}(y) = \partial u_A^*(y)$, where $\partial f(x)$ is the supergradient of a concave function f at x and f^* is the concave conjugate of f. The question then is to find the (effective) domain of ∂u_A^* since (1.1) has a solution when y lies in this domain. In section 3 we show that the mapping ∂u_A^* is single-valued; we call it I^{u_A}. Then we estimate its domain, and we show that $I^{u_A}(y) = (\nabla u)^{-1}(\mathcal{P}_A(y))$, where $\mathcal{P}_A$ is a suitable projection of y onto $\nabla u(A)$, so I^{u_A} is an extension of $(\nabla u)^{-1}$. We study its regularity; the tools are standard results from convex analysis; cf. [12].

In section 3 we allow somewhat general sets A, but in the economic applications A usually has more structure. In the above interpretation each component x_i must lie in the interval of available resources, $x_i \geq 0$ or possibly $x_i \in [0, b_i]$, which can be transformed into $[0, 1]$ by rescaling. In [5] where u is an agent's utility function and $x = (c, l)$, with c a consumption rate and l a leisure rate, $A = [0, \infty) \times [0, 1]$, i.e., we have "box" constraints. This is the setting for aggregation of several utility functions and preference sets treated in section 4.

We sketch now a simple equilibrium problem to indicate the purpose of aggregation of utility functions. We have J agents. Agent j is endowed with ρ^j units of a resource which he can sell at price y. The resource is transformed into consumables; z units of resource produces $v(z)$ units of consumable. The price of a consumable good is one. Agent j obtains utility $u^j(c^j, r^j)$ from consuming c^j units of good and holding r^j units of the resource. His personal set of preferences is described by a set in A^j; now we restrict A^j to be a right parallelepiped; i.e., his preferences are subject to "box" constraints. He wishes to maximize u^j over A^j, subject to a budget constraint $c^j \leq y(\rho^j - r^j)$ or equivalently

$$\max_{(c,r)\in A^j}\{u^j(c, r) - \eta[c + y\, r]\} \quad \text{with solution } (c^j, r^j) = I^{u^j_{A^j}}(\eta(1, y)),$$

where η is a Lagrange multiplier and must satisfy $(1, y)\cdot I^{u^j_{A^j}}(\eta(1, y)) = y\,\rho^j$. Observe that the budget constraint will reduce to an equality at the max. The total amount of resource in the economy is $\sum_{j=1}^J \rho^j := Z$, and the amount of good produced will be $v(z)$, where $z = Z - \sum_j r^j$. *Equilibrium* holds if all of the goods are consumed, i.e., $v(z) = \sum_j c^j$ (market clearing). The question is, Can a price y be found so that equilibrium is obtained?

If there is only one agent in the economy (with utility function u), then the equilibrium problem can be solved as follows: Since market clearing implies $c = v(z),\ r = Z - z$, take y such that $I^{u_A}(\eta(1,y)) = (v(z), Z-z)$, i.e., $\eta(1,y) = \nabla u(v(z), Z-z) = (u_c(v(z), Z-z), u_r(v(z), Z-z))$. z and y are unknown, but the choice of y implies that

$$y = \frac{u_r(v(z), Z-z)}{u_c(v(z), Z-z)}. \tag{1.2}$$

However, if z solves the auxiliary maximization problem

$$\max_{z \le Z}\ u(v(z), Z-z),$$

then the right side of (1.2) is $v'(z)$, and the solution of this maximization problem gives z independent of y; the latter can then be found as $v'(z)$. Then $(c,r) = I^{u_A}(\eta(1,y))$ solves the agent's problem. Market clearing follows from $I^{u_A}(\eta(1,y)) = (v(z), Z-z)$.

Motivated by this result when $J = 1$, we introduce a representative agent with a utility function $u(c, r; \Lambda)$, which is an aggregation of u^j and depends on a parameter $\Lambda = (\lambda_1, \ldots, \lambda_J)$, with $\lambda_j > 0$; cf. (4.1). The properties of this function are less transparent in the multivariable case, but we show that they are sufficient to apply the above process to solve the problem. This (in addition to the characterization of I^{u_A} above) is the main result of the paper and is applied to a static example as above in [4] and to a stochastic dynamic equilibrium model in [5].

In section 2 we summarize our notation. Section 3 contains the result on the extension of the inverse of ∇u. Here we keep A fairly general, but in section 4 we study the properties of the aggregated utility function assuming that each set A^j is a (possibly semi-infinite) right parallelepiped, i.e., a box.

2. Notation. We summarize some notation and results from convex analysis on $\Re^n$ (but in the context of *concave* functions); our reference is [12]. A set is *affine* if it is the translate of a subspace of $\Re^n$, including $\{0\}$ and $\Re^n$. $\operatorname{int}(A)$ denotes the interior of the set A, $\operatorname{cl}(A)$ denotes its closure, $\operatorname{bdy}(A)$ denotes its boundary, $\operatorname{aff}(A)$ denotes its affine hull (smallest affine set containing A), and $\operatorname{ri}(A)$ denotes the relative interior of A, i.e., the interior of A relative to $\operatorname{aff}(A)$. If u is a function $\Re^n \mapsto [-\infty, \infty)$, then the (effective) domain of u is $\operatorname{dom}(u) := \{x : u(x) > -\infty\}$ and $\operatorname{im}(u) := u(\operatorname{dom}(u))$. u is *nondecreasing* if $u(x) \le u(x')$ whenever $x, x' \in \operatorname{dom}(u)$ and $x \le x'$ and where the latter inequality in $\Re^n$ is taken componentwise. u is *strictly increasing* if $u(x) < u(x')$ for such x, x', with $x \ne x'$; i.e., u is strictly increasing in each of its n arguments. The function u is *(strictly) concave* if it is (strictly) concave on $\operatorname{dom}(u)$, which we assume to be nonempty. This makes the function a proper, concave function in the terminology of convex analysis.

The *conjugate* function of the concave function u is defined as

$$u^*(y) := \inf_{x \in \Re^n} \{x^\top y - u(x)\}.$$

Observe that $\bar{u} := -u$ is convex if u is concave and its (convex) conjugate function is

$$\bar{u}^*(y) := \sup_{x \in \Re^n} \{x^\top y - \bar{u}(x)\} = -u^*(-y).$$

This implies that $\operatorname{dom}(\bar{u}^*) := \{y : \bar{u}^*(y) < \infty\} = -\operatorname{dom}(u^*)$.

The *supergradients* of u at x are all $y \in \Re^n$ such that for all z

$$u(z) - u(x) \leq (z - x)^\top y.$$

The set of all supergradients (called the superdifferential) is denoted by $\partial u(x)$, and $\mathrm{dom}(\partial u) := \{x : \partial u(x) \neq \emptyset\}$ is the (effective) domain of ∂u. If we write $\partial_o \bar{u}$ for the subgradient of the convex function $\bar{u}$ (both ∂ and ∂_o are generalized gradients in the sense of Clarke [6]), then $\partial u = -\partial_o(\bar{u})$, so the results for convex functions can be translated to concave functions. We observe that if u is concave, then

$$(x - x')^\top y \leq u(x) - u(x') \leq (x - x')^\top y' \tag{2.1}$$

for all $x \neq x'$ and all $y \in \partial u(x),\ y' \in \partial u(x')$, with strict inequality in the case u is strictly concave. If in addition u is differentiable on $\mathrm{int}(\mathrm{dom}(u))$, then $\partial u = \{\nabla u\}$, the gradient of u, on this set. Note that ∂u is monotone in the terminology of convex analysis and strictly monotone in the case of strict concavity. Note bene (N.b.) for $A \subset \Re^n$ a multivalued function $g : A \mapsto 2^{\Re^n}$ is *monotone* if $(x - x')^\top (y - y') \leq 0$ for all $y \in g(x), y' \in g(x')$, and $x, x' \in A$. It is strictly monotone if the inequality is strict for $x \neq x', y \neq y'$. We have translated monotonicity from the convex setting to the concave by reversing the inequality; hence if $n = 1$ the graph of g is decreasing rather than increasing. Finally when $\partial u = \{\nabla u\}$, we will write $\partial u = \nabla u$.

The *recession cone* of a convex set $A \in \Re^n$ is, cf. Theorem 8.1 of [12]

$$0^+ A := \{z \in \Re^n : A + z \subset A\}.$$

If u is a closed, proper concave function, then $\bar{u}$ is a proper convex function and its *recession function* is, cf. Theorem 8.5 of [12] (n.b. $\mathrm{dom}(\bar{u}) = \mathrm{dom}(u)$),

$$(\bar{u}0^+)(x) := \sup_{z \in \mathrm{dom}(\bar{u})} [\bar{u}(z + x) - \bar{u}(z)] = - \inf_{z \in \mathrm{dom}(u)} [u(z + x) - u(z)].$$

Then Theorem 13.3 of [12] implies that

$$\inf_{y \in \mathrm{dom}(u^*)} y^\top x = - \sup_{y \in \mathrm{dom}(\bar{u}^*)} y^\top x = -(\bar{u}0^+)(x). \tag{2.2}$$

The *normal cone* to A at $x \in A$, denoted by $\mathcal{N}_A(x)$, consists of the outward normals to A at x. It is empty for $x \notin A$ and is $\{0_n\}$ for $x \in \mathrm{int}(A)$. Here 0_n denotes the zero vector in $\Re^n$. Note that $\mathrm{aff}(\mathcal{N}_A(x)) = \mathcal{N}_A(x) - \mathcal{N}_A(x)$ is a subspace. Define

$$\chi_A(x) := \begin{cases} 0 & \text{if } x \in A, \\ \infty & \text{if } x \notin A; \end{cases}$$

it is the indicator function of A. Then $\partial_o \chi_A(x) = \mathcal{N}_A(x)$ for $x \in A$ and is empty for $x \notin A$. Define $u_A(x) := u(x) - \chi_A(x)$, $\Re^n_+ := \{x \in \Re^n : x_i \geq 0,\ i = 1, \ldots, n\}$, and $\Re^n_{++} := \{x \in \Re^n : x_i > 0,\ i = 1, \ldots, n\}$.

We shall have occasion to decompose $\Re^n$ as a direct sum of orthogonal subspaces, $\Re^n = Z \oplus Z^\perp$. Then $x \in \Re^n$ decomposes as $x = z \oplus z^\perp$. We denote by $\partial_z u(x)$ the superdifferential with respect to z of u at x, similarly for $\nabla_z u(x)$. In section 4 the subspaces Z will always be generated by a subset of the standard basis vectors $\vec{e}_1, \ldots, \vec{e}_n$, but in section 3 a rotation may intervene.

3. The inverse. For a positive integer n, consider a function $u : \Re^n \mapsto [-\infty, \infty)$. Henceforth we work under the following assumptions. The smoothness assumptions are very strong relative to the current work in convex analysis, but they are standard in a large part of the mathematical finance and economics literature.

Assumption 1.

(i) u is upper semicontinuous, concave, and nondecreasing, and $\text{int}(\text{dom}(u)) \neq \emptyset$;
(ii) u is continuous on $\text{dom}(u)$;
(iii) u is continuously differentiable on $\text{int}(\text{dom}(u))$.

From (i) it follows that u is a closed, proper concave function. (ii) removes some possible pathologies at any boundary of $\text{dom}(u)$, and (i) and (iii) imply that $\partial u = \nabla u$ on $\text{int}(\text{dom}(u)) \subset \text{dom}(\partial u)$. Typically for us $\text{int}(\text{dom}(u)) = \Re^n$ or $x_o + \Re^n_{++}$ for some $x_o \in \Re^n$.

Assumption 2.

(i) $A \neq \emptyset$, convex, $A \subset \Re^n_+ \cap \text{dom}(u)$, and A is closed relative to $\text{dom}(u)$;
(ii) $\text{dom}(\partial u_A) \subset \text{int}(\text{dom}(u)) \cap A$;
(iii) u is strictly increasing, strictly concave on $\text{dom}(\partial u_A)$.

From Assumption 2(i) it follows that u_A is a closed, proper concave function with $\text{dom}(u_A) = A$. Assumption 2(ii) implies that $\text{ri}(A) = \text{ri}(\text{dom}(u_A)) \subset \text{dom}(\partial u_A) \subset \text{int}(\text{dom}(u))$ and hence Theorem 23.8 of [12] implies $\partial u_A(x) = \partial u(x) - \mathcal{N}_A(x)$ since $\partial_o \chi_A(x) = \mathcal{N}_A(x)$. Furthermore (the last inclusion follows from Assumption 2(ii) again)

$$\text{int}(\text{dom}(u)) \cap A \subset \text{dom}(\partial u) \cap A = \text{dom}(\partial u_A) \subset \text{int}(\text{dom}(u)) \cap A, \tag{3.1}$$

so $\text{dom}(\partial u_A) = \text{int}(\text{dom}(u)) \cap A$ is convex and $\partial u_A(x) = \{\nabla u(x)\} - \mathcal{N}_A(x)$, and hence $\nabla u(x) \in \partial u_A(x)$ on $\text{dom}(\partial u_A)$ with equality on $\text{int}(A)$.

Note that Assumption 2(ii) can often be satisfied by extending u. For example, if $u(x) = \sqrt{x+1}$ on $\text{dom}(u) := [0, \infty) = A$, then (ii) fails, but by extending the effective domain to $\text{dom}(u) := (-1, \infty)$ we assure Assumption 2(ii) without changing the problem (1.1).

Assumption 3. There exists $\mu \in 0^+A$ such that for all $x \in 0^+A$

$$\inf_{z \in \text{dom}(\partial u_A)} \nabla u(z)^\top x \leq \mu^\top x. \tag{3.2}$$

Because ∂u is monotone, Assumption 3 is a growth condition at infinity.

Example 3.1.

(i) $n = 1$ and $u(x) = \ln(x - \varepsilon)$, so $\text{dom}(u) = \text{dom}(\partial u) = (\varepsilon, \infty)$. Take $A = (0, \infty)$ if $\varepsilon = 0$ or $[0, \infty)$; if $\varepsilon < 0$, then Assumptions 1, 2, and 3 are satisfied with $\mu = 0$.
(ii) $n = 2$ and

$$u(x_1, x_2) := \begin{cases} (x_1 - \varepsilon_1)^{\gamma_1}(x_2 - \varepsilon_2)^{\gamma_2} & \text{if } x_i \geq \varepsilon_i,\ i = 1, 2, \\ -\infty & \text{if } x_i < \varepsilon_i, \end{cases}$$

with $\gamma_i > 0$, $\gamma_1 + \gamma_2 < 1$; then $\text{dom}(\partial u) = (\varepsilon_1, \varepsilon_2) + \Re^2_{++} = \text{int}(\text{dom}(u))$, and u satisfies Assumption 1. If

(a) $A = [0, \infty) \times [0, 1]$, then Assumption 2 holds for $\varepsilon_i \leq 0$. Note that $\text{dom}(\partial u_A) = A$ if both $\varepsilon_i < 0$, but $\text{dom}(\partial u_A) = A \cap \Re^2_{++}$ if both $\varepsilon_i = 0$;
(b) $A = [0, \infty) \times \{0\}$ and we require $\varepsilon_2 < 0$, then $\text{dom}(\partial u_A) = A$ if $\varepsilon_1 < 0$, but $\text{dom}(\partial u_A) = A \cap \{x_1 > 0\}$ if $\varepsilon_1 = 0$. Assumption 2 holds. Observe that $\mathcal{N}_A(x) = \{0\} \times \Re$ for $x \in \text{ri}(A)$ and $\mathcal{N}_A(x) = (-\infty, 0] \times \Re$ for $x = (0, 0)$ and is empty otherwise.

In both cases $0^+A = [0,\infty)\times\{0\}$ and Assumption 3 holds with $\mu = 0_2$ since $\gamma_1 < 1, \gamma_2 > 0$.

(iii) For $A = [0,\infty)\times\{0\}$, it is also interesting to consider the case $\gamma_2 = 0$, i.e.,

$$u(x_1,x_2) := \begin{cases} (x_1-\varepsilon_1)^{\gamma_1} & \text{if } x_1 \geq \varepsilon_1, \\ -\infty & \text{if } x_1 < \varepsilon_1, \end{cases}$$

with $0 < \gamma_1 < 1$. Assumption 1 holds with $\mathrm{dom}(\partial u) = (\varepsilon_1,\infty)\times\Re = \mathrm{int}(\mathrm{dom}(u))$. Since $\mathrm{dom}(\partial u_A) = A$ for $\varepsilon_1 < 0$, $\mathrm{dom}(\partial u_A) = (0,\infty)\times\{0\}$ for $\varepsilon_1 = 0$; then Assumption 2 holds. Assumption 3 also holds with $\mu = 0_2$.

(iv) For $\mu_o \geq 0$, $u(x_1,x_2) := \mu_o x_1 - x_1^{-1} + \sqrt{x_2}$ and $A := (0,\infty)\times[0,1)$ satisfy Assumptions 1, 2, and 3 with $\mu = (\mu_o, 0)$.

Later we shall be considering several utility functions which we will want to define on the same space $\Re^n$, but not all of the functions will depend on all n arguments. Example 3.1(iii) above gives such a function.

Recall (3.1) and define

$$\mathcal{R}_{u_A} := \nabla u(A \cap \mathrm{int}(\mathrm{dom}(u))) = \nabla u(\mathrm{dom}(\partial u_A)). \tag{3.3}$$

Notice that as u is strictly increasing on $\mathrm{dom}(\partial u_A)$, then $\mathcal{R}_{u_A} \subset \Re^n_{++}$. Recall that $\nabla u \in \partial u_A$ on $\mathrm{dom}(\partial u_A)$ with equality on $\mathrm{int}(A)$. Although ∇u_A is only defined on $\mathrm{int}(A)$, we extend it as $\mathrm{gr}_A u(x) := \nabla u(x)$ for $x \in \mathrm{dom}(\partial u_A)$. We explain in Remark 3.11 below why this works for us even when $\mathrm{int}(A) = \emptyset$. Since ∇u is strictly monotone on $A \cap \mathrm{int}(\mathrm{dom}(u))$, we should be able to invert $\mathrm{gr}_A u$ on $\mathcal{R}_{u_A}$, but we want to extend this inverse function as far as possible so that it solves (1.1) for as large a selection of y as possible. Note that $(\nabla u)^{-1}$ will usually not be the correct extension; for example, if $n = 1$ additional conditions (the Inada conditions) must be imposed for this to be true.

As u_A is a closed, proper concave function, the conjugate concave function of u_A is again closed, proper, and concave, and is

$$u_A^*(y) = \inf_{x\in\Re^n}\{x^\top y - u_A(x)\} = \inf_{x\in A}\{x^\top y - u(x)\}.$$

PROPOSITION 3.2. *Under Assumptions* 1 *and* 2*, there exists a continuous, monotone function* $I^{u_A} : \mathrm{int}(\mathrm{dom}(u_A^*)) \to \mathrm{dom}(\partial u_A) = \mathrm{dom}(\partial u) \cap A$ *that extends* $(\mathrm{gr}_A u)^{-1}$ *beyond* $\mathcal{R}_{u_A}$ *and solves* (1.1)*.* I^{u_A} *is strictly monotone on* $\mathcal{R}_{u_A}$*. If* ∇u *is* p *times continuously differentiable, then so is* I^{u_A} *on* $\mathrm{int}(\mathcal{R}_{u_A})$*.*

Proof. The solution of (1.1) is

$$I^{u_A}(y) := \arg\min_{x\in\Re^n}\{x^\top y - u_A(x)\} = \{x : y \in \partial u_A(x)\} = \partial u_A^*(y) \tag{3.4}$$

according to Theorem 23.5 and Corollary 23.5.1 of [12]. The strict concavity of u_A on $\mathrm{dom}(\partial u_A)$ and (2.1) implies that I^{u_A} is single-valued, so $\partial u_A^*(y)$ is a singleton and hence a bounded set, and Theorem 23.4 of [12] implies that $\mathrm{dom}(I^{u_A}) = \mathrm{dom}(\partial u_A^*) = \mathrm{int}(\mathrm{dom}(u_A^*))$. Moreover, $y \in \mathcal{R}_{u_A}$ implies that $y = \nabla u(x)$ for some $x \in \mathrm{dom}(\partial u_A)$, i.e., $y \in \partial u_A(x)$ and hence $x \in \partial u_A^*(y) = I^{u_A}(y)$, cf. Corollary 23.5.1 of [12] and we conclude that $I^{u_A} = (\mathrm{gr}_A u)^{-1}$ on $\mathcal{R}_{u_A}$; i.e., I^{u_A} extends the inverse of $\mathrm{gr}_A u$ beyond $\mathcal{R}_{u_A}$, and $\mathrm{im}(I^{u_A}) = \mathrm{dom}(\partial u_A^{**}) = \mathrm{dom}(\partial u_A)$.

Since I^{u_A} is single-valued, then $I^{u_A} = \nabla u_A^*$, and so u_A^* is differentiable on $\mathrm{dom}(I^{u_A})$. Since I^{u_A} is proper and concave, then it is continuous on this set; cf.

Theorem 25.5 of [12]. The concavity of u_A^* implies that $I^{u_A} = \nabla u_A^*$ is monotone. Strict concavity of u on $\mathrm{dom}(\partial u_A)$ implies

$$(x^1 - x^2)^\top (\nabla u(x^1) - \nabla u(x^2)) < 0 \quad \text{for } x^1 \neq x^2 \in \mathrm{dom}(\partial u_A), \quad \text{so}$$
$$(I^{u_A}(y^1) - I^{u_A}(y^2))^\top (y^1 - y^2) < 0 \quad \text{for } y^1 \neq y^2 \in \mathcal{R}_{u_A}. \tag{3.5}$$

It follows that I^{u_A} is strictly monotone on $\mathcal{R}_{u_A}$.

Let us now look at the differentiability of I^{u_A}. If ∇u is differentiable, then the Hessian of u at x, i.e., $H_u(x)$, exists and is negative definite, and hence so is its inverse $(H_u(x))^{-1}$. The inverse function theorem now implies that I^{u_A} is p times continuously differentiable on $\mathrm{int}(\mathcal{R}_{u_A})$ if ∇u is. □

We now find inner and outer estimates for $\mathrm{dom}(I^{u_A})$. Define the polar of a nonempty convex cone K as $K^\circ := \{y : y^\top x \leq 0 \quad \forall x \in K\}$, and observe that $(-K)^\circ = -K^\circ$.

PROPOSITION 3.3. *Under Assumptions* 1, 2, *and* 3,

$$\mu - \mathrm{int}((0^+A)^\circ) \subset \mathrm{dom}(I^{u_A}) \subset -\mathrm{int}((0^+A)^\circ).$$

Proof. For the inner estimate it suffices to show that $\inf_{y \in \mathrm{dom}(u_A^*)} y^\top x \leq \inf_{y \in \mu - (0^+A)^\circ} y^\top x$ since this implies $\mathrm{cl}(\mu - (0^+A)^\circ) \subset \mathrm{cl}(\mathrm{dom}(u_A^*))$, and hence $\mu - \mathrm{int}((0^+A)^\circ) = \mathrm{int}(\mathrm{cl}(\mu - (0^+A)^\circ)) \subset \mathrm{int}(\mathrm{cl}(\mathrm{dom}(u_A^*))) = \mathrm{ri}(\mathrm{dom}(u_A^*)) \subset \mathrm{dom}(\partial u_A^*) = \mathrm{dom}(I^{u_A})$. As $A \subset \Re^n_+$, then 0^+A cannot contain any nontrivial subspace, so Corollary 14.6.1 of [12] implies that $\mathrm{int}((0^+A)^\circ) \neq \emptyset$, and the same must be true for $\mathrm{dom}(u_A^*)$; hence $\mathrm{int}(\mathrm{dom}(u_A^*)) = \mathrm{ri}(\mathrm{dom}(u_A^*))$.

From (2.2) and concavity

$$\inf_{y \in \mathrm{dom}(u_A^*)} y^\top x = \inf_{z \in \mathrm{dom}(u_A)} [u_A(z + x) - u_A(z)] \leq \inf_{\substack{z \in \mathrm{dom}(u_A) \\ y \in \partial u_A(z)}} y^\top x. \tag{3.6}$$

If $x \notin 0^+A = 0^+(\mathrm{ri}(A))$, then the second infimum is $-\infty$ since for some $z \in \mathrm{ri}(A) \subset \mathrm{dom}(u_A)$ we must have $z + x \notin \mathrm{ri}(A)$ and a slight perturbation of z produces $z' \in \mathrm{ri}(A)$ (so $u_A(z') > -\infty$) with $z' + x \notin \mathrm{cl}(A) \supset \mathrm{dom}(u_A)$; hence $u_A(z' + x) = -\infty$.

For $x \in 0^+A$, (3.6) and (3.2) imply

$$\inf_{y \in \mathrm{dom}(u_A^*)} y^\top x \leq \inf_{\substack{z \in \mathrm{dom}(\partial u_A) \\ y \in \partial u_A(z)}} y^\top x \leq \inf_{z \in \mathrm{dom}(\partial u_A)} \nabla u(z)^\top x \leq \mu^\top x.$$

On the other hand, if $x \in 0^+A$, then

$$\inf_{y \in \mu - (0^+A)^\circ} y^\top x = \mu^\top x + \inf_{y \in -(0^+A)^\circ} y^\top x.$$

But $y \in -(0^+A)^\circ \Leftrightarrow y^\top z \leq 0 \quad \forall z \in -(0^+A) \Rightarrow y^\top x \geq 0$. Taking $\lim_{\|y\| \downarrow 0}$ yields $\inf_{y \in -(0^+A)^\circ} y^\top x = 0$, so for all x

$$\inf_{y \in \mathrm{dom}(u_A^*)} y^\top x \leq \inf_{y \in \mu - (0^+A)^\circ} y^\top x$$

and the inner approximation follows.

For the outer approximation, observe that for $z \in 0^+A$ and $y \in \Re^n$

$$\begin{aligned} \sup_{x \in A} \{u(x) - y^\top x\} &\geq \sup_{x \in A + z} \{u(x) - y^\top x\} = \sup_{x \in A} \{u(z + x) - y^\top (z + x)\} \\ &= \sup_{x \in A} \{u(z + x) - y^\top x\} - y^\top z \geq \sup_{x \in A} \{u(x) - y^\top x\} - y^\top z \end{aligned}$$

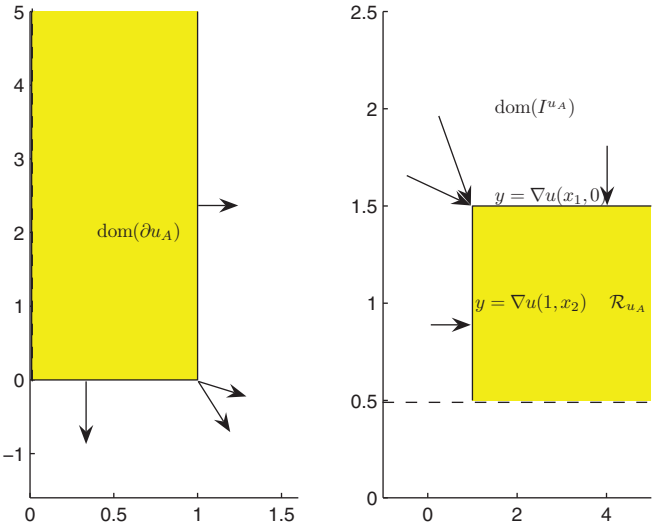

FIG. 1. *A*, $\mathrm{dom}(\partial u_A)$, $\mathrm{dom}(I^{u_A})$, *and* $\mathcal{R}_{u_A}$.

since u is strictly increasing and $0^+A \subset \Re^n_+$. Hence $u^*_A(y) \le u^*_A(y) + y^\top z$, i.e., $y^\top z \ge 0$ for all $z \in 0^+A$ and $y \in \mathrm{dom}(u^*_A)$. But $y \in -(0^+A)^\circ \Leftrightarrow y^\top z \ge 0 \ \ \forall z \in 0^+A$, so $\mathrm{dom}(I^{u_A}) \subset \mathrm{dom}(u^*_A) \subset -(0^+A)^\circ$. The result follows since $\mathrm{dom}(I^{u_A})$ is open; cf. Proposition 3.2. □

Remark 3.4. We observe that if $\mu = 0$, then our estimates are exact, i.e., $\mathrm{dom}(I^{u_A}) = -(0^+A)^\circ$.

Example 3.5. Let $u(x_1, x_2) := 2\sqrt{x_1} + \mu_o x_2 + \frac{x_2}{1+x_2}$ and $A := [0,1] \times [0,\infty)$, so $\mathrm{dom}(\partial u) = (0,\infty) \times (-1,\infty)$, $\mathcal{R}_{u_A} = [1,\infty) \times (\mu_o, \mu_o + 1]$, and $\mathrm{dom}(I^{u_A}) = \{y \in \Re^2 : y_2 > \mu_o\}$. In Figure 1 we have used $\mu_o = 0.5$. In the left panel the shaded region is A, and with the left boundary deleted it is $\mathrm{dom}(\partial u_A)$. The arrows denote outward normals. In the right panel $\mathcal{R}_{u_A}$ is the shaded region, $\mathrm{dom}(I^{u_A})$ is the region above the dashed line, and the arrows represent the projection $\mathcal{P}_{u_A}$; cf. Corollary 3.9.

Remark 3.6. Write $H_u(x)$ for the Hessian of u at x. If u is twice continuously differentiable on $\mathrm{int}(\mathrm{dom}(u))$, then ∇I^{u_A} is a continuous function on $\mathcal{R}_{u_A}$ since $\nabla I^{u_A}(y) = (H_u(I^{u_A}(y)))^{-1}$.

Remark 3.7. Sometimes u will also depend on a parameter, i.e., $u(x,t)$; nevertheless, $\nabla u(x,t)$ will still denote the gradient of u *with respect to* x only. Assumptions 1, 2, and 3 are assumed to hold for each t. For such u with t in an interval $\mathcal{T}$, I^{u_A} is a function of (y,t) and $\mathcal{R}_{u_A}$ also depends on t. If $\nabla u(x,t)$ is continuously differentiable in (x,t), then I^{u_A} is continuously differentiable in $\{(y,t) : y \in \mathrm{int}(\mathcal{R}_{u_A}(t)), t \in \mathrm{int}(\mathcal{T})\}$. This follows again from the implicit function theorem.

Let us give a representation of $I^{u_A}(y)$ as a projection of $\mathrm{dom}(I^{u_A})$ onto $\mathcal{R}_{u_A}$ parallel to a vector in $\mathcal{N}_A(x)$, the set of outward normals to A at x, for some $x \in A$ such that $y = \nabla u(x)$. If A is a polyhedral set, then $\mathcal{N}_A(x)$ is constant on each face, so the projection is particularly simple to identify; cf. Examples 3.5 and 4.8 and Figures 1 and 2.

LEMMA 3.8. *For every* $y \in \mathrm{dom}(I^{u_A})$ *there exists a unique* $x \in \mathrm{dom}(\partial u_A)$ *such that* $y + \vec{n} = \nabla u(x)$ *for some* $\vec{n} \in \mathcal{N}_A(x)$.

Proof. Define the convex function $x \mapsto h^y(x) := x^\top y - u(x)$ so $\partial_o h^y(x) = y - \partial u(x)$. Recall ∂_o denotes the subgradient. Then $\mathrm{dom}(h^y) = \mathrm{dom}(u)$ and Assumptions

1(iii) and 2(ii) and Theorem 23.4 of [12] imply

$$\mathrm{ri}(\mathrm{dom}(h^y)) = \mathrm{int}(\mathrm{dom}(u)) \supset \mathrm{dom}(\partial u_A) \supset \mathrm{ri}(\mathrm{dom}(u_A)) = \mathrm{ri}(A) \neq \emptyset.$$

Hence Theorem 27.4 of [12] yields that $x = I^{u_A}(y)$, cf. (3.4), if and only if there exists $x^* \in \partial_o h^y(x)$ such that $-x^* \in \mathcal{N}_A(x)$. Since $x^* \in \partial_o h^y(x)$, then $y - x^* \in y - \partial_o h^y(x) = \partial u(x)$. But $x = I^{u_A}(y) \in \mathrm{dom}(\partial u_A) \subset \mathrm{int}(\mathrm{dom}(u))$, so $y - x^* = \nabla u(x)$. Hence $y \in \nabla u(x) - \mathcal{N}_A(x)$ for $x = I^{u_A}(y)$.

$I^{u_A}(y)$ is the only such x since $\nabla u(x) - \vec{n} = \nabla u(x') - \vec{n}' = y$ implies

$$[\nabla u(x) - \nabla u(x')]^\top [x - x'] = [\vec{n} - \vec{n}']^\top [x - x'] \geq 0$$

because $x \mapsto \mathcal{N}_A(x) = \partial_o \chi(x)$ is maximal monotone, being the convex subdifferential of a convex function. This contradicts the strict concavity of u on $\mathrm{dom}(\partial u_A)$. □

COROLLARY 3.9. *There exists a projection* $\mathcal{P}_{u_A} : \mathrm{dom}(I^{u_A}) \mapsto \mathcal{R}_{u_A}$ *such that*

$$I^{u_A}(y) = (\nabla u)^{-1}(\mathcal{P}_{u_A}(y)).$$

Proof. The required projection is $\mathcal{P}_{u_A}(y) := \nabla u(x)$ with x given by Lemma 3.8. □

Remark 3.10. Corollary 3.9 implies that $\mathrm{dom}(I^{u_A}) = \bigcup_{x \in A \cap\, Int(\mathrm{dom}(u))} [\nabla u(x) - \mathcal{N}_A(x)]$. If $x \in \mathrm{bdy}(A) \cap \mathrm{dom}(\partial u)$, then $\nabla u(x) \in \mathcal{R}_{u_A} \cap \mathrm{bdy}(\mathcal{R}_{u_A})$ and I^{u_A} extends $(\mathrm{gr}_A u)^{-1}$ across these boundary points of $\mathcal{R}_{u_A}$; cf. Example 3.5 and Figure 1. The other boundary points of $\mathcal{R}_{u_A}$ are not in $\mathcal{R}_{u_A}$ and in fact are on $\mathrm{bdy}(\mathrm{dom}(I^{u_A}))$.

Remark 3.11. Let us explain the situation when $\mathrm{int}(A) = \emptyset$. Consider $x \in \mathrm{ri}(A)$. Then $\Re^n$ decomposes into $\mathcal{N}_A(x)^\perp \oplus \mathcal{N}_A(x)$, with $\mathrm{aff}(A)$ a translation of $\mathcal{N}_A(x)^\perp$. For convenience take $n = 2$, $\mu = 0_2$, $A = [0, \infty) \times \{b\}$, with $b \geq 0$, so $\mathcal{N}_A(x)^\top = \{x : x_2 = 0\}$. For $\max_{x \in A}[u(x) - y^\top x]$ the map of interest is the partial derivative u_{x_1} or, to embed it in $\Re^2$, $(u_{x_1}, 0)$. For any $y \in \Re^2$ with $0 < y_1 < u_{x_1}(0, b)$, the appropriate inverse image projects y into $(y_1, 0)$ and then takes the inverse under $(u_{x_1}, 0)$ to produce $x = ((u_{x_1}(\cdot, b))^{-1}(y_1), b) \in \mathrm{ri}(A)$. On the other hand, $(\nabla u)^{-1}(\mathcal{P}_{u_A}(y))$ projects y into $(y_1, y_2^o) \in \nabla u(A)$ for some y_2^o. Then $(\nabla u)^{-1}(y_1, y_2^o)$ is the same x as above. A similar situation occurs for $y_1 \geq u_{x_1}(0, b)$; either approach maps y into $(0, b)$. It is much more convenient to work with ∇u rather than $(u_{x_1}, 0)$; that is why we defined $\mathrm{gr}_A u$ as the restriction of ∇u to $A \cap \mathrm{int}(\mathrm{dom}(u))$.

DEFINITION 3.12. *If* $\mathrm{cl}(A)$ *is polyhedral, then it has a finite number of nonempty faces of dimension less than* n*, call them* $\bar{\mathcal{C}}_k, k = 1, \ldots, K$*; cf. Theorem* 19.1 *of* [12]*. Define* $\mathcal{C}_k := \mathrm{ri}(\bar{\mathcal{C}}_k), k = 1, \ldots, K$*, and* $\mathcal{C}_0 := \mathrm{int}(A)$*, possibly empty. Then* $\mathcal{C}_0, \ldots, \mathcal{C}_K$ *is a partition of* $\mathrm{cl}(A)$*, cf. Theorem* 18.2 *of* [12]*, and* $\mathcal{C}_1, \ldots, \mathcal{C}_K$ *is a partition of* $\mathrm{bdy}(A)$*. Set* $\mathcal{S}_k := (I^{u_A})^{-1}(\mathcal{C}_k), k = 0, \ldots, K$*. Then* $\mathcal{S}_0 = (I^{u_A})^{-1}(\mathrm{int}(A)) = \nabla u(\mathrm{int}(A)) = \mathrm{int}(\mathcal{R}_{u_A})$*. Write* $\mathrm{bdy}(\mathcal{R}_{u_A}, \mathcal{S}_k)$ *for the boundary between* $\mathcal{R}_{u_A}$ *and* $\mathcal{S}_k$*.*

We now discuss differentiability of I^{u_A} off $\mathcal{R}_{u_A}$.

COROLLARY 3.13. *Assume that* A *is a polyhedron and* ∇u *is continuously differentiable. Then* I^{u_A} *and* $\mathcal{P}_{u_A}$ *are continuously differentiable on* $\mathrm{int}(\mathcal{S}_k)$ *for each* k*. The directional derivative of* I^{u_A} *parallel to the boundary is continuous, but normal to the boundary it is not.*

Proof. $\mathcal{N}_A(x)$ is independent of x for $x \in \mathcal{C}_k$, i.e., $\mathcal{N}_A(x) = \mathcal{N}_A(\mathcal{C}_k)$. Now for $y \in \mathcal{S}_k$ we have an orthogonal decomposition $y = y^\perp \oplus y^o$, with $y^o \in \mathrm{aff}(\mathcal{N}_A(\mathcal{C}_k))$, and similarly for $x \in \mathcal{C}_k$ we have $x = x^\perp \oplus x^o$, with $x^o \in \mathrm{aff}(\mathcal{N}_A(\mathcal{C}_k))$, *same* for all $x \in \mathcal{C}_k$, and $x^\perp \in \mathrm{aff}(\mathcal{N}_A(\mathcal{C}_k))^\perp$, the subspace parallel to $\mathrm{aff}(\mathcal{C}_k)$. This is equivalent

to rotating and reordering the axes so that $\mathrm{aff}(\mathcal{C}_k)$ is parallel to the span of the standard basis vectors $\{e_1, \dots, e_\ell\}$; of course the transformation changes with k. Then $\mathcal{P}_{u_A}(y) = \nabla u(x^\perp \oplus x^o) = \nabla_{x^\perp} u(x^\perp \oplus x^o) \oplus \nabla_{x^o} u(x^\perp \oplus x^o)$ where, $\nabla_{x^\perp}$ denotes the gradient with respect to $x^\perp$ and similarly for ∇_{x^o}. Moreover $\mathcal{P}_{u_A}(y) = y^\perp \oplus \phi(y^\perp)$, where $\phi(y^\perp) = \nabla_{x^o} u(x^\perp(y^\perp) \oplus x^o)$ and $x^\perp(y^\perp)$ is the solution of $y^\perp = \nabla_{x^\perp} u(x^\perp \oplus x^o)$. The Hessian with respect to $x^\perp$ of $u(x^\perp \oplus x^o)$ is negative definite since H_u is. The implicit function theorem now implies the continuous differentiability of $x^\perp$. The continuous differentiability on $\mathrm{int}(\mathcal{S}_k)$ follows since $I^{u_A}(y) = x^\perp(y^\perp) \oplus x^o$.

Since $\nabla I^{u_A}(y) = (H_u(I^{u_A}(y)))^{-1}$, then the directional derivative of $I^{u_A}(\cdot)$ in the direction v at $y \in \mathcal{R}_{u_A}$ (where $I^{u_A} = (\nabla u)^{-1}$) is

$$(I^{u_A})'(y; v) = \Big(H_u(I^{u_A}(y))\Big)^{-1} v.$$

For $y = y^\perp \oplus y^o \in \mathcal{S}_k$ the Jacobian of $\mathcal{P}_{u_A}$ intervenes ($\mathcal{P}_{u_A}$ is just $\mathbf{I}$ on $\mathcal{R}_{u_A}$), so we obtain

$$\begin{aligned}
(I^{u_A})'(y; v) &= \Big(H_u(I^{u_A}(y))\Big)^{-1} \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \nabla\phi(y^\perp) & \mathbf{0} \end{pmatrix} v \\
&= \Big(H_u(I^{u_A}(y))\Big)^{-1} \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ (H_u(I^{u_A}(y)))_{x^o x^\perp}((H_u(I^{u_A}(y)))_{x^\perp x^\perp})^{-1} & \mathbf{0} \end{pmatrix} v \qquad (3.7) \\
&= \begin{pmatrix} ((H_u(I^{u_A}(y)))_{x^\perp x^\perp})^{-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix} v,
\end{aligned}$$

where $(H_u)_{x^\perp x^\perp} := (\frac{\partial}{\partial x^\perp})^2 u$ has dimension $\dim(y^\perp) \times \dim(y^\perp) = \ell \times \ell$, $(H_u)_{x^o x^\perp} := \frac{\partial^2}{\partial x^o \partial x^\perp} u$ has dimension $\dim(y^o) \times \dim(y^\perp) = (n - \ell) \times \ell$, and $\mathbf{I}$, $\mathbf{0}$ are the identity and zero matrices, respectively, of appropriate dimensions. We use the obvious matrix notation for linear transformations mapping $\mathrm{aff}(\mathcal{N}(\mathcal{C}_k))^\perp \oplus \mathrm{aff}(\mathcal{N}_A(\mathcal{C}_k)) \mapsto \mathrm{aff}(\mathcal{N}_A(\mathcal{C}_k))^\perp \oplus \mathrm{aff}(\mathcal{N}(\mathcal{C}_k))$.

Note that $\mathrm{bdy}(\mathcal{R}_{u_A}, \mathcal{S}_k) \subset \mathcal{S}_k \cap \mathcal{R}_{u_A}$, and for $y \in \mathrm{bdy}(\mathcal{R}_{u_A}, \mathcal{S}_k)$, $\mathcal{P}_{u_A}(y) = y$. Then the two versions of $(I^{u_A})'$ agree only if v is orthogonal to $\mathrm{aff}(\mathcal{N}_A(\mathcal{C}_k))$. We conclude that the directional derivatives of I^{u_A} in the directions parallel to $\mathcal{N}_A(\mathcal{C}_k)$ are discontinuous across the boundary.

A similar result holds for the boundaries between $\mathcal{S}_k$ and $\mathcal{S}_j$ since the dimension of $(H_u)_{x^\perp x^\perp}$ decreases when the dimension of $\mathcal{C}_k$ decreases. ∎

This work can be extended to the time-dependent case. Consider a function $u(x, t)$, where $t \in \mathcal{T}$ denotes time. We maintain Assumptions 1, 2, and 3 for each t, and we assume that $A = A(t)$ is polyhedral. We say that it is p times continuously differentiable if the maps $t \mapsto a_k(t)$ are p times continuously differentiable, where the a_k, $k \in \mathcal{K}$, are the generators of $A(t)$ (terminology of section 19 of [12]). The following proposition extends Proposition 3.2, Remark 3.7, and Corollary 3.13. Recall that ∇ refers to the gradient with respect to x only. We write $I^{u_A}(y, t)$ for $I^{u_A(\cdot,t)}(y)$ and similarly for $\mathcal{P}_{u_A}$.

PROPOSITION 3.14. *If $t \mapsto A(t)$ and $(x, t) \mapsto \nabla u(x, t)$ are continuous on $\mathcal{T}$, $\mathrm{int}(\mathrm{dom}(u)) \times \mathcal{T}$, respectively, then so are $I^{u_A}(y, t)$ and $\mathcal{P}_{u_A}(y, t)$ on $\mathrm{dom}(I^{u_A}) := \{(y, t) : y \in \mathrm{dom}(I^{u_A(\cdot,t)}),\ t \in \mathcal{T}\}$. If A and ∇u are continuously differentiable in (x, t), then $I^{u_A}(y, t)$ and $\mathcal{P}_{u_A}(y, t)$ are similarly continuously differentiable on $\{(y, t) : y \in \mathcal{S}_k(t), t \in \mathrm{int}(\mathcal{T})\}$ for each k. The directional derivative with respect to y in the normal direction is discontinuous across the boundary of $\mathcal{S}_k(t)$.*

Proof. From Proposition 3.2 we know that I^{u_A} is continuous in y on each t-section of $\mathrm{dom}(I^{u_A})$. On the other hand, the continuity of ∇u gives that of $t \mapsto \mathcal{R}_{u_A}(t)$, cf.

(3.3), and hence of $(y,t) \mapsto \mathcal{P}_{u_A}(y,t)$, cf. the proof of Corollary 3.13. Moreover $I^{u_A}(y,t)$ is the solution x of $\nabla u(x,t) = \mathcal{P}_{u_A}(y,t)$, so the joint continuity follows from the implicit function theorem.

The piecewise continuous differentiability follows similarly. □

Remark 3.15. We can also compute the time derivative of $I^{u_A(\cdot,t)}(y)$ when A is constant. For $y \in \mathcal{R}_{u_A}(t)$

$$\frac{\partial}{\partial t} I^{u_A(\cdot,t)}(y) = -\Big(H_{u(\cdot,t)}((\nabla u(\cdot,t))^{-1}(y))\Big)^{-1} \frac{\partial}{\partial t} \nabla u(x,t)\Big|_{x=(\nabla u(\cdot,t))^{-1}(y)}. \tag{3.8}$$

For $y \in \mathcal{S}_k(t)$, $y^\perp$ and x^o are constant since A is; moreover $I^{u_A(\cdot,t)}(y) = x = x^\perp \oplus x^o$, with $x^\perp$ solution of $y^\perp = \nabla_{x^\perp} u(x^\perp \oplus x^o, t)$. Then $0 = \nabla_{x^\perp x^\perp} u(x^\perp \oplus x^o, t) \frac{\partial}{\partial t} x^\perp + \frac{\partial}{\partial t} \nabla_{x^\perp} u(x^\perp \oplus x^o, t)$, and hence

$$\frac{\partial}{\partial t} x^\perp = -\Big[\nabla_{x^\perp x^\perp} u(x^\perp \oplus x^o, t)\Big]^{-1} \frac{\partial}{\partial t} \nabla_{x^\perp} u(x^\perp \oplus x^o, t).$$

It follows that

$$\frac{\partial}{\partial t} I^{u_A(\cdot,t)}(y) = -\begin{pmatrix} ((H_{u(\cdot,t)}(I^{u_A(\cdot,t)}(y)))_{x^\perp x^\perp})^{-1} \\ \mathbf{0} \end{pmatrix} \frac{\partial}{\partial t} \nabla_{x^\perp} u(x,t)\Big|_{x=I^{u_A(\cdot,t)}(y)}. \tag{3.9}$$

We conclude that $\frac{\partial}{\partial t} I^{u_A(\cdot,t)}(y)$ is continuous except at the boundaries of $\mathcal{R}_{u_A}(t)$ and each $\mathcal{S}_k(t)$. Moreover $\frac{\partial}{\partial t} I^{u_A(\cdot,t)}(y)$ is orthogonal to $\mathcal{N}_A(I^{u_A(\cdot,t)}(y))$ since, cf. (3.9),

$$(\,\mathbf{0} \quad \mathbf{I}\,) \begin{pmatrix} ((H_{u(\cdot,t)}(I^{u_A(\cdot,t)}(y)))_{x^\perp x^\perp})^{-1} \frac{\partial}{\partial t} \nabla_{x^\perp} u(x,t)\Big|_{x=I^{u_A(\cdot,t)}(y)} \\ 0_{\dim(y^o)} \end{pmatrix} = 0,$$

and this holds *for all* $y \in \Re^+_n$ since $\mathcal{N}_A(I^{u_A(\cdot,t)}(y)) = \{0_n\}$ for $y \in \mathcal{R}_{u_A}(t)$.

4. Aggregate utility function. We now aggregate the actions of several agents into the action of a single representative agent. His utility function must opportunely weight the utility functions of the individual agents in the economy; the factor Λ below will accomplish this. We strengthen Assumption 2 so that A corresponds to "box" constraints.

Assumption 2′.

(i) $A = \prod_{i=1}^n D_i \subset \operatorname{dom}(u)$, $\quad D_i = \begin{cases} [0,\infty) \text{ or } (0,\infty) & \text{if } i \in \mathcal{M}, \\ [0,1] \text{ or } (0,1] & \text{if } i \in \tilde{\mathcal{M}}, \\ \{0\} & \text{if } i \in \mathcal{M}_o, \end{cases}$

$\mathcal{M} \cup \tilde{\mathcal{M}} \cup \mathcal{M}_o = \{1,\dots,n\}$, A closed relative to $\operatorname{dom}(u)$;

(ii) $\operatorname{dom}(\partial u_A) \subset \operatorname{int}(\operatorname{dom}(u)) \cap A$;

(iii) u is strictly increasing, strictly concave on $\operatorname{dom}(\partial u_A)$.

In (i) above the inclusion or exclusion of 0 in D_i is determined by the requirement that A be closed in the relative topology of $\operatorname{dom}(u)$. The more general case where the left end point of D_i is a_i and the right is $b_i > a_i$ is reduced to the above by shifting the origin to a and changing the scale. This will not alter the concavity or regularity of u. $\mathcal{M}$ gives the variables which are unbounded so $0^+A = \prod_{i\in\mathcal{M}} D_i$, $\tilde{\mathcal{M}}$ gives the variables which are bounded, and $\mathcal{M}_o$ gives those variables that do not affect u. Write m for $\operatorname{card}(\mathcal{M}) = \dim(0^+A)$, so if we think of 0^+A as $\Re^m_+ \oplus \{0\}$, then $-(0^+A)^\circ = \Re^m_+ \oplus \Re^{n-m}$.

We will aggregate J utility functions, $u^1, \dots, u^J$; we assume that for each j, u^j and A^j satisfy Assumptions 1, 2′, and 3 with corresponding D_i^j, $\mathcal{M}^j$, $\tilde{\mathcal{M}}^j$, $\mathcal{M}_o^j$, m^j, and μ^j. We may assume that $\bigcap_j \mathcal{M}_o^j = \emptyset$.

For $\Lambda = (\lambda_1, \dots, \lambda_J) \in \Re^J_{++}$ we will define the function $u(x;\Lambda)$ as a supremal convolution on $\Re^n$:

$$u(x;\Lambda) := \sup_{\sum_j x^j = x} \sum_{j=1}^J \lambda_j u^j_{A^j}(x^j), \tag{4.1}$$

where $x^j = (x_1^j, \dots, x_n^j)^\top \in \Re^n$.

We require more notation. Define

$$I^u(y;\Lambda) := \sum_{j=1}^J I^{u^j_{A^j}}\Big(\frac{y}{\lambda_j}\Big), \tag{4.2}$$

and set $\mathcal{D}(\Lambda) := \operatorname{dom}(I^u(\cdot\,;\Lambda)) = \bigcap_j \lambda_j \operatorname{dom}(I^{u^j_{A^j}})$, an open set since $\operatorname{dom}(I^{u^j_{A^j}}) = \operatorname{int}(\operatorname{dom}((u^j_{A^j}))^*)$. Then Proposition 3.3 implies

$$\emptyset \neq \bigcap_j \Big(\lambda_j \mu^j + \Re^{m^j}_{++} \oplus \Re^{n-m^j}\Big) \subset \mathcal{D}(\Lambda) \subset \bigcap_j \Big(\Re^{m^j}_{++} \oplus \Re^{n-m^j}\Big). \tag{4.3}$$

Observe that if $\mu^j = 0$ for all j, then $\mathcal{D}(\Lambda) = \bigcap_j \Big(\Re^{m^j}_{++} \oplus \Re^{n-m^j}\Big)$. Define

$$\mathcal{R}_o(\Lambda) := \Big\{ y \in \mathcal{D}(\Lambda) : \bigcap_{j=1}^J \operatorname{aff}\Big(\mathcal{N}_{A^j}\Big(I^{u^j_{A^j}}\Big(\frac{y}{\lambda_j}\Big)\Big)\Big) = \{0_n\}\Big\}. \tag{4.4}$$

Note that $\mathcal{R}_o(\Lambda) \supset \mathcal{D}(\Lambda) \cap \bigcup_j \lambda_j \operatorname{int}(\mathcal{R}_{u^j_{A^j}})$ (since $\mathcal{N}_{A^j}(x) = \{0_n\}$ for $x \in \operatorname{int}(A^j)$), but the inclusion may be strict. If $\mathcal{M}_o^j \neq \emptyset$, then $\operatorname{int}(\mathcal{R}_{u^j_{A^j}}) = \emptyset$, and if $\mathcal{C}_k^j$ is a vertex of A^j, then $\operatorname{aff}(\mathcal{N}_{A^j}(\mathcal{C}_k^j)) = \Re^n$.

Definition 4.1. *$\mathcal{R}_o$ is* set-continuous *if for $y \in \mathcal{R}_o(\Lambda)$ there exists $\varepsilon > 0$ such that whenever y', Λ' satisfy $\max_j \|\frac{y'}{\lambda'_j} - \frac{y}{\lambda_j}\| < \varepsilon$, then $y' \in \mathcal{R}_o(\Lambda')$.*

Lemma 4.2. *$\mathcal{R}_o(\Lambda) \subset \Re^n_{++}$ is open, and $\mathcal{R}_o$ is set-continuous.*

Proof. Suppose $y \in \mathcal{D}(\Lambda)$ but $y \notin \Re^n_{++}$, so $y_i \leq 0$ for some $i \notin \bigcup_j \mathcal{M}^j$; cf. (4.3). Since u^j is strictly increasing on $\operatorname{dom}(\partial u^j_{A^j})$, then $\mathcal{R}_{u^j_{A^j}} = \nabla u^j(\operatorname{dom}(\partial u^j_{A^j})) \subset \Re^n_{++}$, so $\mathcal{P}_{u^j_{A^j}}$ projects $\frac{y}{\lambda_j}$ into $\Re^n_{++}$. Then $\vec{n}^j$ of Lemma 3.8 can be written as $\vec{n}^j = \sum_{\ell \in \mathcal{L}} \alpha_\ell^j \tilde{e}_\ell^j$, where $\alpha_\ell^j > 0$, $\tilde{e}_\ell^j$ is plus or minus a standard basis vector, and the convex hull of $\{\tilde{e}_\ell : \ell \in \mathcal{L}\}$ generates the convex cone $\mathcal{N}_{A^j}(I^{u^j_{A^j}}(\frac{y}{\lambda_j}))$. Because $\mathcal{P}_{u^j_{A^j}}$ projects $\frac{y}{\lambda_j}$ into $\Re^n_{++}$ and $y_i \leq 0$, then $\vec{e}_i$ is one of the $\tilde{e}_\ell^j$ for all j, and hence $\vec{e}_i \in \mathcal{N}_{A^j}(I^{u^j_{A^j}}(\frac{y}{\lambda_j}))$ for all j. From the definition of $\mathcal{R}_o$ it follows that $y \notin \mathcal{R}_o(\Lambda)$, and hence $\mathcal{R}_o(\Lambda) \subset \Re^n_{++}$.

Next we show that $\mathcal{R}_o(\Lambda)$ is open. $\mathcal{D}(\Lambda)$ is open; take $y \in \mathcal{R}_o(\Lambda)$, and write $\hat{x}^j(\frac{y}{\lambda_j})$ for $I^{u^j_{A^j}}(\frac{y}{\lambda_j})$. Recall that we set $\mathcal{C}_0^j = \operatorname{int}(A^j)$; cf. Definition 3.12. If $\hat{x}^j(\frac{y}{\lambda_j}) \in \operatorname{int}(A^j)$, then so is $\hat{x}^j(\frac{y'}{\lambda_j})$ for y' a sufficiently small pertubation of y; cf. Proposition 3.2. If $\hat{x}^j(\frac{y}{\lambda_j}) \in \mathcal{C}_k^j$, then $\hat{x}^j(\frac{y'}{\lambda_j}) \in \mathcal{C}_k^j$ or $\hat{x}^j(\frac{y'}{\lambda_j}) \in \mathcal{C}_{k'}^j$ with $\operatorname{cl}(\mathcal{C}_{k'}^j) \supset \mathcal{C}_k^j$ since $\mathcal{C}_k^j$ is relatively open (think of $\mathcal{C}_k^j$ as an edge with the end point removed and $\mathcal{C}_{k'}^j$ as the relative interior

of an adjoining face). In the latter case it follows that $\mathcal{N}_{A^j}(\hat{x}^j(\frac{y'}{\lambda_j})) \subset \mathcal{N}_{A^j}(\hat{x}^j(\frac{y}{\lambda_j}))$. In any case $\bigcap_{j=1}^J \operatorname{aff}(\mathcal{N}_{A^j}(I^{u^j_{A^j}}(\frac{y'}{\lambda_j}))) \subset \bigcap_{j=1}^J \operatorname{aff}(\mathcal{N}_{A^j}(I^{u^j_{A^j}}(\frac{y}{\lambda_j}))) = \{0_n\}$, and hence $y' \in \mathcal{R}_o(\Lambda)$.

The set continuity of $\mathcal{R}_o$ is established as in the previous paragraph but with $\frac{y'}{\lambda_j}$ replaced by $\frac{y'}{\lambda'_j}$ since $y \in \mathcal{D}(\Lambda)$ if and only if $\frac{y}{\lambda_j} \in \operatorname{dom}(I^{u^j_{A^j}})$ for all j, and $\operatorname{dom}(I^{u^j_{A^j}})$ is open. □

Recall that $\operatorname{bdy}(A^j)$ decomposes into the relatively open pieces $\mathcal{C}^j_k$, $k > 0$. We will demand a bit more regularity of u^j:

$$\text{if } \mathcal{C}^j_k \cap \operatorname{dom}(\partial u^j) \neq \emptyset, \text{ then } \mathcal{C}^j_k \subset \operatorname{dom}(\partial u^j). \tag{4.5}$$

THEOREM 4.3. *Assume that u^j, $j = 1, \dots, J$, are utility functions satisfying Assumptions 1, 2′, and 3. If (4.5) holds for each j, then the following hold:*

(i) *For each $\Lambda \in \Re^J_{++}$, $u(\cdot\,;\Lambda) : \Re^n \mapsto [-\infty, \infty)$ is a closed, proper, concave, nondecreasing function on $\Re^n$ with $\operatorname{dom}(u(\cdot;\Lambda)) = A := \sum_{j=1}^J A^j$. For each $x \in A$ there exist $\hat{x}^j \in A^j$ such that*

$$x = \sum_j \hat{x}^j, \quad u(x;\Lambda) = \sum_j \lambda_j u^j_{A^j}(\hat{x}^j). \tag{4.6}$$

Moreover $I^u(\cdot\,;\Lambda)$ is the inverse of $\partial u(\cdot\,;\Lambda)$ and is monotone. $u(\cdot\,;\Lambda)$ is strictly concave on $\operatorname{dom}(\partial u(\cdot\,;\Lambda)) = \operatorname{im}(I^u(\cdot\,;\Lambda))$.

(ii) *$\operatorname{im}(I^u(\cdot\,;\Lambda)) = \tilde{A} := \sum_j \operatorname{dom}(\partial u^j_{A^j})$ is convex. For $x \in \tilde{A}$ there exists $y \in (I^u(\cdot\,;\Lambda))^{-1}(x)$ such that*

$$\hat{x}^j = I^{u^j_{A^j}}\left(\frac{y}{\lambda_j}\right). \tag{4.7}$$

(iii) *$u(\cdot;\Lambda)$ is continuously differentiable on $A^u(\Lambda) := I^u(\mathcal{R}_o(\Lambda);\Lambda)$. This set is dense in A. Moreover $(\nabla u(\cdot;\Lambda))^{-1} = I^u(\cdot;\Lambda)$ on $\nabla u(A^u(\Lambda);\Lambda) = \mathcal{R}_o(\Lambda)$, so $I^u(y;\Lambda)$ is a continuous, monotone extension of $(\nabla u(\cdot;\Lambda))^{-1}$, strictly monotone on $\operatorname{cl}(\mathcal{R}_o(\Lambda)) \cap \mathcal{D}(\Lambda)$. $u(\cdot\,;\Lambda)$ is strictly increasing on $A^u(\Lambda)$. For $y \in \mathcal{R}_o(\Lambda)$ we have*

$$\nabla u(I^u(y;\Lambda);\Lambda) = y. \tag{4.8}$$

(iv) *For each $x \in A^u(\Lambda)$,*

$$\nabla u(x;\Lambda) = \lambda_j \nabla u^j(\hat{x}^j) - \vec{n}^j(\hat{x}^j), \quad j = 1, \dots, J, \tag{4.9}$$

where $\vec{n}^j(\hat{x}^j) \in \mathcal{N}_{A^j}(\hat{x}^j)$ and for each $i = 1, \dots, n$ there exists $j(i)$ such that $[\vec{n}^{j(i)}(\hat{x}^{j(i)})]_i = 0$.

(v) *If for each j, $\nabla u^j(x)$ is continuously differentiable, then $\nabla u(x;\Lambda)$ is piecewise continuously differentiable.*

Proof. Define the convex function $f^j := -\lambda_j u^j_{A^j}$. Recall that for a concave function u, $(-u)^*(y) = -u^*(-y)$. From this and (4.3) it follows that

$$\bigcap_j \operatorname{int}\Big(\operatorname{dom}((f^j)^*)\Big) = -\bigcap_j \operatorname{int}\Big(\operatorname{dom}((\lambda_j u^j_{A^j})^*)\Big) \neq \emptyset.$$

It follows from Theorem 16.4 of [12] that u is closed, concave, and proper and (4.6) holds with $\hat{x}^j \in A^j$. Evidently $\operatorname{dom}(u(\cdot\,;\Lambda)) = A$. Since the constraint in (4.1) can be relaxed to $\sum x^j \leq x$, then it follows that u is nondecreasing.

The same theorem also implies

$$u^*(y;\Lambda) = \sum_j (\lambda_j u^j_{A^j})^*(y) = \sum_j \lambda_j u^{j*}_{A^j}\Big(\frac{y}{\lambda_j}\Big).$$

Now Theorem 23.8 of [12] implies that the superdifferential of $u^*(\cdot;\Lambda)$ is

$$\partial u^*(y;\Lambda) = \sum_j \partial(\lambda_j u^j_{A^j})^*(y) = \sum_j \partial u^{j*}_{A^j}\Big(\frac{y}{\lambda_j}\Big) = \sum_j I^{u^j_{A^j}}\Big(\frac{y}{\lambda_j}\Big) = I^u(y;\Lambda); \tag{4.10}$$

cf. (4.2). Thus $\partial u^*(y;\Lambda)$ is single-valued on $\mathcal{D}(\Lambda)$. We can now conclude that the concave function u^* is continuously differentiable, cf. Theorems 25.1 and 25.5 of [12], on $\mathcal{D}(\Lambda) = \operatorname{dom}(I^u) = \operatorname{dom}(\partial u^*)$, and as usual $\partial u^* = (\partial u)^{-1}$; i.e., I^u is the inverse of ∂u. Furthermore as the supergradient of a concave function, I^u is monotone.

Since ∂u^* is single-valued, then $\partial u(x) \cap \partial u(x') = \emptyset$ for $x \neq x'$. As in the proof of Theorem 26.3 of [12], this implies that u is strictly concave on $\operatorname{dom}(\partial u) = \operatorname{im}(I^u)$. That this set is convex will follow from (ii). This establishes (i) of the theorem.

We turn to (ii). Notice that $\tilde{A}$ is convex since, cf. (3.1),

$$\tilde{A} = \sum_j [\operatorname{dom}(\partial u^j) \cap A^j] = \sum_j [A^j \cap \operatorname{int}(\operatorname{dom}(u^j))].$$

As $\operatorname{im}(I^u) \subset \tilde{A}$, cf. (4.2) and Proposition 3.2, it suffices to show the reverse inclusion. In the process we shall establish (4.7). For $x \in \tilde{A}$ we consider the maximization problem whose value is $u(x;\Lambda)$:

$$\begin{cases} \sup\Big\{f(x^1,\dots,x^J) : (x^1,\dots,x^J) \in C, \quad \sum_j x^j = x\Big\}, \\ f(x^1,\dots,x^J) := \sum_{j=1}^J \lambda_j u^j_{A^j}(x^j), \quad C := \prod_{j=1}^J A^j. \end{cases} \tag{4.11}$$

Note that the unique solution is $(\hat{x}^1,\dots,\hat{x}^J)$. Let us first modify the problem to ensure that there is always a feasible solution in $\operatorname{ri}(C)$ so that we can apply some Lagrange multiplier results.

Consider $x \in \tilde{A} \subset A = \sum_j A^j$. If some components of x have certain values, to be made precise below, the constraints in (4.11) will fix the corresponding components of x^j in any decomposition $x = \sum_j x^j$, with $x^j \in A^j$, and hence these components may be removed from (4.11), reducing x to $\bar{x}$ and x^j to $\bar{x}^j$. We will show that for any decomposition $\bar{x} = \sum_j \bar{x}^j$, with $\bar{x}^j \in \bar{A}^j$, there is a decomposition $\bar{x} = \sum_j \tilde{x}^j$, with $\tilde{x}^j \in \operatorname{ri}(\bar{A}^j)$, where $\bar{A}^j$ is the set corresponding to A^j after dropping the fixed components.

We now find the components which will be dropped. Suppose that $x_i = 0$; then for any decomposition $x = \sum_j x^j$, with $x^j \in A^j$, i.e., $x^j_i \in D^j_i$ so $x^j_i \geq 0$, we must have $x^j_i = 0$, and hence there is no maximization in (4.11) over x^j_i, $j = 1,\dots,J$. Moreover if the largest possible value of x_i is finite, i.e., if d^j_i, the right end point of D^j_i, is finite for *all* j, equivalently, $d^j_i \in \{0,1\}$, equivalently, $i \notin \bigcup_j \mathcal{M}^j$, equivalently, $i \in \bigcap_j (\tilde{\mathcal{M}}^j \cup \mathcal{M}^j_o)$, then $0 \leq x_i \leq \sum_j d^j_i = \operatorname{card}\{j : i \in \mathcal{M}^j\}$. Now suppose that for such an i, $x_i = \operatorname{card}\{j : i \in \mathcal{M}^j\}$; then for any decomposition $x = \sum_j x^j$, we must have $x^j_i = d^j_i$; i.e., again in (4.11) there is no maximization over x^j_i, $j = 1,\dots,J$.

We summarize as follows: Set $\mathcal{I}(x) := \{i \in \{1,\dots,n\} : x_i = 0\} \cup \{i \in \bigcap_j (\tilde{\mathcal{M}}^j \cup \mathcal{M}^j_o) : x_i = \sum_j d^j_i\}$, and let $n_o = \operatorname{card}(\mathcal{I}(x))$, where card denotes cardinality. Observe

that $\mathcal{I}(x) = \emptyset$, i.e., $n_o = 0$, if and only if $x \in \text{int}(A)$, and $n_o = n$ if and only if x is an extreme point of A.

Set $\bar{n} = n - n_o$, decompose $\Re^n = \Re^{\bar{n}} \oplus \Re^{n_o}$, and write $x = \bar{x} \oplus x^o$. For any decomposition $x = \sum_j x^j \in \sum_j A^j$ and any $i \in \mathcal{I}(x)$ we have $x_i^{jo} = 0$ if $x_i = 0$ or $x_i^{jo} = d_i^j$ if $x_i = \sum_j d_i^j$, i.e., x^{jo} fixed, so there is no maximization to be done over these components of x^j. Define $\bar{A}^j$ as the orthogonal projection of A^j onto $\Re^{\bar{n}}$. We can then replace the maximization problem by

$$\begin{cases} \sup\left\{f(\bar{x}^1, \ldots, \bar{x}^J) : (\bar{x}^1, \ldots, \bar{x}^J) \in \bar{C}, \quad \sum_{j=1}^J \bar{x}^j = \bar{x}\right\}, \\ f(\bar{x}^1, \ldots, \bar{x}^J) := \sum_{j=1}^J \lambda_j u_{A^j}^j(\bar{x}^j \oplus x^{jo}), \quad \bar{C} := \prod_{j=1}^J \bar{A}^j. \end{cases}$$

We may think of the new problem as having dropped the coordinates in $\mathcal{I}(x)$. If $\hat{x}^j$ decomposes as $\hat{x}^j = \bar{x}^j \oplus x^{jo}$, then $(\bar{x}^1, \ldots, \bar{x}^J) \in \bar{C}$ is feasible for the new problem. For any $i \notin \mathcal{I}(x)$ not all $\bar{x}_i^j$ can be 0, so if any are, we can perturb the $\bar{x}_i^j$ slightly to make them all positive while maintaining the constraint $\sum_j \bar{x}_i^j = \bar{x}_i$. Similarly not all $\bar{x}_i^j$ can be d_i^j, and hence we can perturb the nonzero $\bar{x}_i^j$ (i.e., j such that $i \in \tilde{\mathcal{M}}^j$ since for $i \in \mathcal{M}_o^j$ we must have $\bar{x}_i^j = 0$) so that all are less than one. This provides a feasible solution in $\text{ri}(\bar{C})$. The problem can be put in standard form as follows: $\bar{x} \in \Re^{\bar{n}}$ is fixed; let $f_i(\bar{x}^1, \ldots, \bar{x}^J) := \bar{x}_i - \sum_{j=1}^J \bar{x}_i^j,\ i = 1, \ldots, \bar{n}$. Then $\text{dom}(f_i) = \Re^{\bar{n}J}$. Moreover if $g_j(\bar{x}^1, \ldots, \bar{x}^J) := \lambda_j u_{A^j}^j(\bar{x}^j \oplus x^{jo})$, then the problem is to maximize $\sum_j g_j$ subject to $f_i = 0,\ i = 1, \ldots, \bar{n}$.

Below we will introduce the Lagrange multiplier $\bar{y}$. The following calculations will aid us in identifying it. Observe that $\bigcap_{j=1}^J \text{ri}(\text{dom}(g_j)) = \bigcap_{j=1}^J \text{ri}(\bar{A}^j \oplus \Re^{\bar{n}(J-1)}) = \prod_{j=1}^J \text{ri}(\bar{A}^j) \neq \emptyset$. From this and Theorem 23.8 of [12] follows that

$$\partial\left[\sum_{j=1}^J g_j + \sum_{i=1}^{\bar{n}} \bar{y}_i f_i\right] = \sum_{j=1}^J \partial g_j + \sum_{i=1}^{\bar{n}} \bar{y}_i \partial f_i.$$

We compute

$$\sum_j \partial g_j(\bar{x}^1, \ldots, \bar{x}^J) = \left(\lambda_1 \partial_{\bar{x}^1} u_{A^1}^1(\bar{x}^1 \oplus x^{o1}), \ldots, \lambda_J \partial_{\bar{x}^J} u_{A^J}^J(\bar{x}^J \oplus x^{Jo})\right),$$
$$\sum_{i=1}^{\bar{n}} \bar{y}_i \partial f_i(\bar{x}^1, \ldots, \bar{x}^J) = -\sum_{i=1}^{\bar{n}} \bar{y}_i(\vec{e}_i, \ldots, \vec{e}_i) = -(\bar{y}, \ldots, \bar{y}).$$

Here $\partial_{\bar{x}^j}$ refers to supergradients with respect to $\bar{x}^j \in \Re^{\bar{n}}$.

Now Corollary 28.2.2 and Theorem 28.3 of [12] allow us to infer that there exists a multiplier $\bar{y} \in \Re^{\bar{n}}$ such that $0 \in \partial[\sum_j g_j + \sum_i \bar{y}_i f_i]$; i.e., for every j (recalling $\hat{x}^j = \bar{\hat{x}}^j \oplus \hat{x}^{jo}$)

$$\bar{y} \in \lambda_j \partial_{\bar{x}^j} u_{A^j}^j(\hat{x}^j) = \lambda_j[\partial_{\bar{x}^j} u^j(\hat{x}^j) - \mathcal{N}_{\bar{A}^j}(\bar{\hat{x}}^j)] = \lambda_j \nabla_{\bar{x}^j} u^j(\hat{x}^j) - \lambda_j \mathcal{N}_{\bar{A}^j}(\bar{\hat{x}}^j).$$

Note that $\nabla_{\bar{x}^j}$ refers to the gradient with respect to $\bar{x}^j \in \Re^{\bar{n}}$. The last equality holds by Theorem 25.6 of [12]. Hence for some $\vec{\bar{n}}^j \in \mathcal{N}_{\bar{A}^j}(\bar{\hat{x}}^j)$ we have

$$\frac{\bar{y}}{\lambda_j} + \vec{\bar{n}}^j = \nabla_{\bar{x}^j} u^j(\hat{x}^j).$$

Since $x \in \tilde{A}$, then $x = \sum_j x^j$, with $x^j \in \text{dom}(\partial u_{A^j}^j)$, for some $\{x^j\}$. But $x^{jo} = \hat{x}^{jo}$, so if $n_o > 0$, then both $x^j, \hat{x}^j \in \mathcal{C}_k^j$ for some k. Now (4.5) implies that

$\hat{x}^j \in \mathrm{dom}(\partial u^j_{A^j})$, and hence $\nabla u^j(\hat{x}^j) = \nabla_{\bar{x}^j} u^j(\hat{x}^j) \oplus \nabla_{x^{jo}} u^j(\hat{x}^j)$ exists. In addition, $\mathcal{N}_{A^j}(\hat{x}^j)$ decomposes into $\mathcal{N}_{\bar{A}^j}(\hat{\bar{x}}^j) \oplus \mathcal{N}_o$, where $\mathcal{N}_o$ (same for all j) is an orthant of $\Re^{n_o}$. Since $\nabla_{x^{jo}} u^j(\hat{x}^j) \in \Re^{n_o}$, then $\bigcap_j \lambda_j[\nabla_{x^{jo}} u^j(\hat{x}^j) - \mathcal{N}_o] \neq \emptyset$. Let y^o be a point in this set. If we set $y := \bar{y} \oplus y^o$, then for some $\vec{n}^j_y(\hat{x}^j) \in \mathcal{N}_{A^j}(\hat{x}^j)$,

$$\frac{y}{\lambda_j} + \vec{n}^j_y(\hat{x}^j) = \nabla u^j(\hat{x}^j). \tag{4.12}$$

Lemma 3.8 and Corollary 3.9 imply that $\hat{x}^j = I^{u^j_{A^j}}(\frac{y}{\lambda_j})$, so we have found y such that $I^u(y;\Lambda) = x$; i.e., $y \in (I^u(\cdot;\Lambda))^{-1}(x)$, and (4.7) holds.

We turn to the proof of (iii). Fix Λ. As $\partial u = (\partial u^*)^{-1} = (I^u)^{-1}$ and u is differentiable where ∂u is single valued, then u is differentiable where I^u is one-to-one. We will show that $I^u(\cdot\,;\Lambda)$ is one-to-one on $\mathcal{R}_o(\Lambda) \subset \Re^n_{++}$, cf. Lemma 4.2, by showing that it is strictly monotone on $\mathrm{cl}(\mathcal{R}_o(\Lambda))$. Fix j for now. If $y \in \lambda_j \mathcal{R}_{u^j_{A^j}}$ (cf. (3.3)), then $I^{u^j_{A^j}}(\frac{y}{\lambda_j}) = (\nabla u^j)^{-1}(\frac{y}{\lambda_j})$ is strictly monotone in y.

Recall $\mathcal{S}^j_k = (I^{u^j_{A^j}})^{-1}(\mathcal{C}^j_k)$; we can decompose $\Re^n = \mathrm{aff}(\mathcal{N}_{A^j}(\mathcal{C}^j_k))^\perp \oplus \mathrm{aff}(\mathcal{N}_{A^j}(\mathcal{C}^j_k))$ and accordingly for $y \in \mathcal{S}^j_k$, $y = y^{j\perp} \oplus y^{jo}$, and for $x \in \mathcal{C}^j_k$, $x = x^{j\perp} \oplus x^{jo}$ with x^{jo} depending only on j and k, not on x. We set $\mathcal{J}(\mathcal{C}^j_k) := \{i : x_i = x^{j\perp}_i, x \in \mathcal{C}^j_k\}$, i.e., the set of component indices of $x^{j\perp}$ or of $y^{j\perp}$.

For $y \in \lambda_j \mathcal{S}^j_k$, $I^{u^j_{A^j}}(\frac{y}{\lambda_j}) = (I^{u^j_{A^j}}(\frac{y}{\lambda_j}))^\perp \oplus (I^{u^j_{A^j}}(\frac{y}{\lambda_j}))^o := x^{j\perp}(\frac{y^{j\perp}}{\lambda_j}) \oplus x^{jo} \in \mathcal{C}^j_k$ with x^{jo} constant, i.e., $\mathcal{C}^j_k = \{x^\perp \oplus x^{jo} : x^\perp \in \prod_{i \in \mathcal{J}(C^j_k)} D^j_i\}$, and $x^{j\perp}(\frac{y^{j\perp}}{\lambda_j})$ is the solution of $\nabla_{x^\perp} u^j_{A^j}(x^\perp \oplus x^{jo}) = \frac{y^{j\perp}}{\lambda_j}$. We conclude that for $y \in \lambda_j \mathcal{S}^j_k$, $(I^{u^j_{A^j}}(\frac{y}{\lambda_j}))^\perp$ is constant in y^{jo} and strictly monotone in $y^{j\perp}$ and $(I^{u^j_{A^j}}(\frac{y}{\lambda_j}))^o$ is constant.

If $y \in \mathrm{bdy}(\lambda_j \mathcal{S}^j_k)$ and $y_n \to y$ with $y_n \in \lambda_j \mathcal{S}^j_k$, then $\mathcal{N}_{A^j}(I^{u^j_{A^j}}(\frac{y_n}{\lambda_j})) \subset \mathcal{N}_{A^j}(I^{u^j_{A^j}}(\frac{y}{\lambda_j}))$, i.e., $I^{u^j_{A^j}}(\frac{y_n}{\lambda_j}) \in \mathcal{C}^j_k$, $I^{u^j_{A^j}}(\frac{y}{\lambda_j}) \in \mathcal{C}^j_{k'}$ with $\mathrm{cl}(\mathcal{C}^j_k) \supset \mathcal{C}^j_{k'}$. Since $\mathrm{aff}(\mathcal{N}_{A^j}(I^{u^j_{A^j}}(\frac{y_n}{\lambda_j}))) = \mathrm{aff}(\mathcal{N}_{A^j}(\mathcal{C}^j_k))$ is independent of n, we can use this decomposition, i.e., the decomposition corresponding to $\mathcal{J}(\mathcal{C}^j_k)$. We may take y_n such that $y^{j\perp}_n = y^{j\perp}$. Passing to the limit as $n \to \infty$ allows us to establish the monotonicity properties of $I^{u^j_{A^j}}(\frac{y}{\lambda_j})$ on $\mathrm{cl}(\lambda_j \mathcal{S}^j_k)$.

Recall that $\mathcal{S}^j_0 := \mathrm{int}(\mathcal{R}_{u^j_{A^j}})$, possibly empty; cf. Definition 3.12. For $y \in \mathcal{D}(\Lambda)$, y lies in $\lambda_j \mathcal{S}^j_{k(j)}$ for each j and some selection $k(j) \in \{0, 1, \ldots, K\}$. For $y, y' \in \bigcap_j \mathrm{cl}(\lambda_j \mathcal{S}^j_{k(j)})$, $y \neq y'$, we have

$$\begin{aligned}
(y - y')^\top (I^u(y;\Lambda) - I^u(y';\Lambda)) &= \sum_j (y^{j\perp} - y'^{j\perp})^\top \left(\left(I^{u^j_{A^j}}\left(\frac{y^j}{\lambda_j}\right)\right)^\perp - \left(I^{u^j_{A^j}}\left(\frac{y'^j}{\lambda_j}\right)\right)^\perp \right) \\
&\quad + \sum_j (y^{jo} - y'^{jo})^\top \left(\left(I^{u^j_{A^j}}\left(\frac{y^j}{\lambda_j}\right)\right)^o - \left(I^{u^j_{A^j}}\left(\frac{y'^j}{\lambda_j}\right)\right)^o \right) \\
&= \sum_j (y^{j\perp} - y'^{j\perp})^\top \left(\left(I^{u^j_{A^j}}\left(\frac{y^j}{\lambda_j}\right)\right)^\perp - \left(I^{u^j_{A^j}}\left(\frac{y'^j}{\lambda_j}\right)\right)^\perp \right) \\
&\leq 0.
\end{aligned} \tag{4.13}$$

In fact the last inequality is strict unless $y^{j\perp} - y'^{j\perp} = 0$ for all j because $(I^{u^j_{A^j}}(\frac{y^j}{\lambda_j}))^\perp$ is strictly monotone in $\frac{y^{j\perp}}{\lambda_j}$ on $\mathcal{S}^j_k$.

If $y, y' \in \mathrm{cl}(\mathcal{R}_o(\Lambda)) \cap (\bigcap_j \mathrm{cl}(\lambda_j \mathcal{S}^j_{k(j)}))$, $y \neq y'$, then $y - y' = (y^{j\perp} - y'^{j\perp}) \oplus (y^{jo} - y'^{jo})$ and $(y^{j\perp} - y'^{j\perp})_i = (y - y')_i$ for $i \in \mathcal{J}(\mathcal{C}^j_{k(j)})$. Note we use the *same* decomposition on $\mathrm{bdy}(\mathcal{S}^j_{k(j)})$ as in the interior; cf. the monotonicity argument of $I^{u^j_{A^j}}$ above. On $\mathcal{R}_o(\Lambda)$ we have $\bigcap_j \mathrm{aff}(\mathcal{N}_{A^j}(I^{u^j_{A^j}}(\frac{y}{\lambda_j}))) = \{0_n\}$, i.e., $\sum_j \mathrm{aff}(\mathcal{N}_{A^j}(I^{u^j_{A^j}}(\frac{y}{\lambda_j})))^\perp = \Re^n$, equivalently, $\bigcup_j \mathcal{J}(\mathcal{C}^j_{k(j)}) = \{1, \ldots, n\}$. It follows that if $y^{j\perp} - y'^{j\perp} = 0$ for all j, then $y - y' = 0$, a contradiction, so $I^u(\cdot\,;\Lambda)$ is strictly monotone on $\bigcap_j \mathrm{cl}(\lambda_j \mathcal{S}^j_{k(j)})$. Thus the inequality in (4.13) must be strict.

The argument extends to any y' for which the line segment $[y, y']$ contains a subsegment which lies in $\mathrm{cl}(\mathcal{R}_o(\Lambda))$ because I^u is monotone. To see this, suppose $[y, z]$ is such a subsegment lying in one of the pieces used in the previous paragraph. Then

$$\begin{aligned}
&(y - y')^\top (I^u(y;\Lambda) - I^u(y';\Lambda)) \\
&= \frac{\|y - y'\|}{\|y - z\|}(y - z)^\top (I^u(y;\Lambda) - I^u(z;\Lambda)) + \frac{\|y - y'\|}{\|z - y'\|}(z - y')^\top (I^u(z;\Lambda) - I^u(y';\Lambda)) \\
&< 0
\end{aligned}$$

since the first term on the right is negative and the second is nonpositive.

It follows that $I^u(\cdot;\Lambda)$ is strictly monotone on $\mathrm{cl}(\mathcal{R}_o(\Lambda))$ and only there. Hence $I^u(\cdot\,;\Lambda)$ is one-to-one on $\mathcal{R}_o(\Lambda)$, and so $\partial u(x)$ is single-valued for $x \in I^u(\mathcal{R}_o(\Lambda);\Lambda) = A^u(\Lambda)$ (and only there) and u is continuously differentiable there; cf. Theorem 25.5 of [12]. As the set of points where u is differentiable, $A^u(\Lambda)$ is dense in $\mathrm{int}(\mathrm{dom}(u)) = \mathrm{int}(A)$. Since $\bigcap_j \mathcal{M}^j_o = \emptyset$, then $\mathrm{aff}(A) = \Re^n$, so $\mathrm{int}(A)$ is dense in A; i.e., $A^u(\Lambda)$ is dense in A. As $I^u(\cdot\,;\Lambda)^{-1} = \nabla u(\cdot\,;\Lambda)$ on $I^u(\mathcal{R}_o(\Lambda);\Lambda)$, then (4.8) holds on $\mathcal{R}_o(\Lambda)$.

$\nabla u(\cdot\,;\Lambda) \in \mathcal{R}_o(\Lambda) \subset \Re^n_{++}$, cf. Lemma 4.2, so u is strictly increasing on $A^u(\Lambda)$; cf. (2.1).

Next we prove (iv). Let $x \in A^u(\Lambda)$, $y := (I^u(\cdot\,;\Lambda))^{-1}(x)$, a singleton for $x \in A^u(\Lambda)$, and let $\hat{x}^j$ be given by (4.7); then (4.8) and (4.12) imply

$$\nabla u(x;\Lambda) = \; y = \lambda_j \nabla u^j(\hat{x}^j) - \lambda_j \vec{n}^j_y(\hat{x}^j) \quad \text{for all } j,$$

and hence (4.9) follows. Fix i. If $[\vec{n}^j_y(\hat{x}^j)]_i \neq 0$ for all j, then $\vec{e}_i \in \mathrm{aff}(\mathcal{N}_{A^j}(\hat{x}^j))$ for all j, since $\mathrm{aff}(\mathcal{N}_{A^j}(\hat{x}^j))$ is the subspace spanned by a subset (depending on j) of the standard basis vectors. It follows that $\vec{e}_i \in \bigcap_j \mathrm{aff}(\mathcal{N}_{A^j}(\hat{x}^j))$, a contradiction, since $y \in \mathcal{R}_o(\Lambda)$. Hence for every i there exists j such that $u_{x_i}(x;\Lambda) = \lambda_j u^j_{x_i}(\hat{x}^j)$.

Finally turning to (v), (4.2), Proposition 3.2, and Corollary 3.13 imply that $I^u(\cdot\,;\Lambda)$ is continuously differentiable except on $\bigcup_{k,j} \mathrm{bdy}(\mathcal{S}^j_k)$. By the inverse function theorem $\nabla u(\cdot\,;\Lambda)$ is piecewise continuously differentiable. □

We are able to extend $\nabla u(\cdot;\Lambda)$ to $\tilde{A}$ if we control the behavior of ∇u^j near points on $\mathrm{bdy}(A)$ not in $\mathrm{dom}(\partial u^j)$, i.e., where $\|\nabla u^j\| = \infty$. Of necessity such points (if any) are on $\mathrm{bdy}(\Re^n_{++})$, i.e., constitute some of the faces of $\mathrm{bdy}(A)$; cf. (4.5). The condition is as follows: For every j and bounded sequence $\{x^k\} \subset A^j$,

$$\text{if } \lim_{k\to\infty} u^j_{x_i}(x^k) = \infty \text{ for some } i, \text{ then } \lim_{k\to\infty} x^k_i = 0. \tag{4.14}$$

COROLLARY 4.4. *Assume* (4.14). *Then* $\nabla u(\cdot\,;\Lambda)$ *can be extended continuously to* $\tilde{A}$ *such that on* $\tilde{A}$ *we have* $I^u(\nabla u(x;\Lambda);\Lambda) = x$. *Moreover* (4.8) *holds for* $y \in \mathrm{cl}(\mathcal{R}_o(\Lambda))$ *and* (4.9) *holds on* $\tilde{A}$.

Proof. The extensions of the equations follows by continuity once $\nabla u(\cdot\,;\Lambda)$ has been extended. For $x \in \tilde{A}$ and any sequence $x^k \to x$, $x^k \in A^u(\Lambda)$, there exist $y^k \in \mathcal{R}_o(\Lambda) \subset \Re^n_{++}$ with $x^k = I^u(y^k;\Lambda) = \sum_j I^{u^j_{A^j}}(\frac{y^k}{\lambda_j}) = \sum_j \hat{x}^{k,j}$. Then $\|\hat{x}^{k,j}\| \le \|x\| + 1$ for k sufficiently large. Now $\hat{x}^{k,j} \in \mathcal{C}^j_{l_j}$ is of the form $\hat{x}^{k,j} = \hat{x}^{k,j\perp} \oplus x^{l_j o}$, with $x^{l_j o} \in \operatorname{aff}(\mathcal{N}_{A^j}(\mathcal{C}^j_{l_j}))$, and we can decompose $y^k = y^{k,j\perp} \oplus y^{k,jo}$. By extracting subsequences J times we may assume that l_j is independent of k since the number of faces is finite. Then $\lambda_j \nabla u^j(\hat{x}^{k,j}) = y^k + \vec{n}^j(\hat{x}^{k,j})$ for all j by (4.9). We claim that $\{y^k\}$ is bounded.

Assume that for a subsequence $\|y^k\| \to \infty$. Since $\sum \operatorname{aff}(\mathcal{N}_{A^j}(\mathcal{C}^j_{l_j}))^\perp = \Re^n$, then there exists j_o such that $\|y^{k,j_o\perp}\| \to \infty$, i.e., $y^k_i \to \infty$ for some i such that $\vec{n}^{j_o}_i(\hat{x}^{k,j_o}) = 0$ since $\vec{n}^{j_o}(\hat{x}^{k,j_o}) \in \operatorname{aff}(\mathcal{N}_{A^{j_o}}(\mathcal{C}^{j_o}_{l_{j_o}}))$. Then $u^{j_o}_{x_i}(\hat{x}^{k,j_o}) = y^k_i/\lambda_{j_o} \to \infty$, cf. (4.9), and hence $\hat{x}^{k,j_o}_i \to 0$ by (4.14). For all j we have $\lambda_j u^j_{x_i}(\hat{x}^{k,j}) = y^k_i + \vec{n}^j_i(\hat{x}^{k,j})$, and the geometry implies that $\vec{n}^j_i(\hat{x}^{k,j}) \ge 0$ unless $\hat{x}^{k,j}_i = 0$. Again by taking subsequences, we can arrange that either $\hat{x}^{k,j}_i = 0$ for all k so that $\lim_k \hat{x}^{k,j}_i = 0$ or $\vec{n}^j_i(\hat{x}^{k,j}) \ge 0$ for all k so $u^j_{x_i}(\hat{x}^{k,j}) \ge y^k_i/\lambda_j \to \infty$, and hence again $\lim_k \hat{x}^{k,j}_i = 0$. It follows that $x_i = \lim_k x^k_i = \lim_k \sum_j \hat{x}^{k,j}_i = 0$ so $x \notin \tilde{A} = \sum_j \operatorname{dom}(\partial u^j_{A^j})$ since (4.14) implies that $\{x_i = 0\} \cap \operatorname{dom}(\partial u^{j_o}_{A^{j_o}}) = \emptyset$. This contradiction implies that $\{y^k\}$ is bounded.

We can conclude that $\{y^k\}$ contains convergent subsequences, again denoted by $\{y^k\}$, with limit $y \in \operatorname{cl}(\mathcal{R}_o(\Lambda))$. Hence

$$x = \lim_k x^k = \lim_k I^u(y^k;\Lambda) = \lim_k \sum_j I^{u^j_{A^j}}\Big(\frac{y^k}{\lambda_j}\Big) = \sum_j I^{u^j_{A^j}}\Big(\frac{y}{\lambda_j}\Big) = I^u(y;\Lambda).$$

Moreover this limit is unique since $I^u(\cdot\,;\Lambda)$ is strictly monotone on $\operatorname{cl}(\mathcal{R}_o(\Lambda))$. It follows that $\nabla u(x;\Lambda) := y$ is a continuous extension of ∇u. ∎

We note that Cobb–Douglas utility functions satisfy (4.14), as do functions such that $\operatorname{cl}(A^j) \subset \operatorname{dom}(\partial u^j)$ since the assumption is void in this case.

Remark 4.5. Since $\tilde{A} = \sum_j \operatorname{dom}(\partial u^j_{A^j})$ and $\operatorname{dom}(\partial u^j_{A^j})$ is closed except possibly on some of the $\mathcal{C}^j_k \subset \operatorname{bdy}(\Re^n_{++})$, then $\tilde{A}$ has the same structure. In fact a face (in $\operatorname{bdy}(\Re^n_{++})$) of $\operatorname{cl}(\tilde{A})$ is contained in $\tilde{A}$ if and only if the corresponding face of each $\operatorname{cl}(\operatorname{dom}(\partial u^j_{A^j}))$ is contained in $\operatorname{dom}(\partial u^j_{A^j})$, i.e., for any set $\mathcal{I}_o \subset \{0,1,\dots,n\}$,

$$\{x \in A : x_i = 0,\ i \in \mathcal{I}_o\} \subset \tilde{A} \Leftrightarrow \{x \in A^j : x_i = 0,\ i \in \mathcal{I}_o\} \subset \operatorname{dom}(\partial u^j_{A^j}) \text{ for all } j.$$

Example 4.6. Let us consider a setting which arises in [3]. We take $J = 2$, and we make Assumptions 1, 2′, and 3, with $\mu^j = 0$ in (3.2), and the "Inada" condition, i.e., $\Re^n_{++} = \operatorname{dom}(\partial u^j) \subset \operatorname{dom}(u^j) \subset \Re^n_+$. (If u has the form $u(x^1 \oplus x^2) = g(x^1)$, cf. Example 3.1(iii), we require only that g satisfies this condition.)

We can conclude that

$$\lim_{x \to \operatorname{bdy}(\Re^n_{++})} \|\nabla u^j(x)\| = \infty. \tag{4.15}$$

We see this as follows: For $x_o \in \operatorname{bdy}(\Re^n_{++})$ but $x_o \notin \operatorname{dom}(u^j)$ and for $w \in \Re^n_+$ such that $x_o + w \in \operatorname{dom}(\partial u^j)$, ∇u^j monotone implies

$$\nabla u^j(x_o + \varepsilon w)^\top w(1-\varepsilon) \ge \int_\varepsilon^1 \nabla u^j(x_o + tw)^\top w\, dt = u^j(x_o + w) - u^j(x_o + \varepsilon w) \to +\infty$$

as $\varepsilon \to 0$. If $x_o \in \mathrm{bdy}(\Re^n_{++}) \cap \mathrm{dom}(u^j)$, then $\emptyset = \partial u^j(x_o) = U(x_o) - \mathcal{N}_{\mathrm{dom}(u^j)}(x_o)$, where $U(x_o)$ is the closure of the convex hull of all limits of $\nabla u^j(x_m)$ with $x_m \to x_o$; cf. Theorem 25.6 of [12]. Since $\mathcal{N}_{\mathrm{dom}(u^j)}(x_o) \neq \emptyset$ for $x_o \in \mathrm{dom}(u^j)$, then $U(x_o) = \emptyset$, so $\|\nabla u^j(x_m)\|$ must be unbounded.

We take $n = 3$, with $A^1 = ([0,\infty)^2 \times |0,1]) \cap \mathrm{dom}(u^1)$ and $A^2 = ([0,\infty)^2 \times \{0\}) \cap \mathrm{dom}(u^2)$. A and $\tilde{A}$ are easy to compute, but $A^u(\Lambda)$ is more complicated. Of interest are the pieces of A^j which lie in $\mathrm{dom}(\partial(u^j))$; these are $\mathcal{C}^1_o = \mathrm{int}(A^1)$, $\mathcal{C}^1_1 = \Re^2_{++} \times \{1\}$, and $\mathcal{C}^2_1 = \Re^2_{++} \times \{0\}$. We find $\mathcal{R}_o(\Lambda)$ which is composed of $\lambda_j \mathrm{int}(\mathcal{R}_{u^j_{A^j}})$, $j = 1, 2$, plus sets of the form $\lambda_1 \mathcal{S}^1_{k_1} \cap \lambda_2 \mathcal{S}^2_{k_2}$ with k_1, k_2 such that $\mathcal{N}_{A^1}(\mathcal{C}^1_{k_1})$ is orthogonal to $\mathcal{N}_{A^2}(\mathcal{C}^2_{k_2})$.

Since $\mathcal{M}^j = \{1, 2\}$, $\tilde{\mathcal{M}}^1 = \mathcal{M}^2_o = \{3\}$ and $\tilde{\mathcal{M}}^2 = \mathcal{M}^1_o = \emptyset$, then

$$\begin{aligned} \mathcal{S}^1_0 = \mathcal{R}_{u^1_{A^1}} &= \{y \in \Re^3_{++} : y_3 \geq u^1_{x_3}(x_1(y_1, y_2), x_2(y_1, y_2), 1)\}, \\ \mathcal{R}_{u^2_{A^2}} &= \Re^2_{++} \times \{0\},\ \mathcal{D}(\Lambda) = \Re^2_{++} \times \Re, \end{aligned}$$

where $x_1(y_1, y_2), x_2(y_1, y_2)$ satisfy $(u^1_{x_1}(x_1, x_2, 1), u^1_{x_2}(x_1, x_2, 1)) = (y_1, y_2)$, and

$$\mathcal{S}^1_1 = \{y \in \Re^3 : y_1 > 0,\ y_2 > 0,\ y_3 \leq u^1_{x_3}(x_1(y_1, y_2), x_2(y_1, y_2), 1)\}, \quad \mathcal{S}^2_1 = \Re^2_{++} \times \Re,$$

since $\mathcal{S}^j_k = (I^{u^j_{A^j}})^{-1}(\mathcal{C}^j_k)$. There are no other $\mathcal{S}^j_k$'s. We also have $\mathrm{aff}(\mathcal{N}_{A^1}(\mathcal{C}^1_1)) = \mathrm{aff}(\mathcal{N}_{A^2}(\mathcal{C}^2_1)) = \{(0,0)\} \times \Re$, and hence $\mathcal{R}_o(\Lambda) = \lambda_1 \mathrm{int}(\mathcal{R}_{u^1_{A^1}})$ and $A^u(\Lambda) = I^u(\mathcal{R}_o(\Lambda); \Lambda) = I^{u^1_{A^1}}(\mathrm{int}(\mathcal{R}_{u^1_{A^1}})) + I^{u^2_{A^2}}(\frac{\lambda_1}{\lambda_2} \mathrm{int}(\mathcal{R}_{u^1_{A^1}}))$,

$$\begin{aligned} A^u(\Lambda) &= (0,\infty)^2 \times (0,1) + (0,\infty)^2 \times \{0\} = (0,\infty)^2 \times (0,1), \\ \tilde{A} &= (0,\infty)^2 \times (0,1] + (0,\infty)^2 \times \{0\} = (0,\infty)^2 \times (0,1], \\ A &= [0,\infty)^2 \times [0,1] \cap \mathrm{dom}(u^1) \cap \mathrm{dom}(u^2). \end{aligned}$$

Note that $A^u(\Lambda)$ is all of $(0,\infty)^2 \times (0,1)$ because for x in this set we can solve

$$\begin{aligned} \lambda_1 u^1_{x_1}(\xi_1, \xi_2, x_3) - \lambda_2 u^2_{x_1}(x_1 - \xi_1, x_2 - \xi_2, 0) = 0, \\ \lambda_1 u^1_{x_2}(\xi_1, \xi_2, x_3) - \lambda_2 u^2_{x_2}(x_1 - \xi_1, x_2 - \xi_2, 0) = 0 \end{aligned}$$

for $(\xi_1, \xi_2) \in (0, x_1) \times (0, x_2)$. Then $x = I^u(y; \Lambda)$ for $y = \lambda_1 \nabla u^1(\xi_1, \xi_2, x_3)$.

For $x \in A^u(\Lambda)$, $\hat{x}^1 \in (0,\infty)^2 \times (0,1)$ and $\hat{x}^2 \in (0,\infty)^2 \times \{0\}$ since $\hat{x}^j \in \mathrm{dom}(\partial u^j_{A^j})$ always and $\hat{x}^1_3 = x_3$. Then the normals in (4.9) are $\vec{n}^1(\hat{x}^1) = 0$ and $\vec{n}^2(\hat{x}^2) = (0, 0, n_3)^\top$, and (4.9) becomes

$$\begin{aligned} u_{x_1}(x; \Lambda) &= \lambda_1 u^1_{x_1}(\hat{x}^1) = \lambda_2 u^2_{x_1}(\hat{x}^2), \\ u_{x_2}(x; \Lambda) &= \lambda_1 u^1_{x_2}(\hat{x}^1) = \lambda_2 u^2_{x_2}(\hat{x}^2), \\ u_{x_3}(x; \Lambda) &= \lambda_1 u^1_{x_3}(\hat{x}^1), \end{aligned} \tag{4.16}$$

where we have dropped the uninteresting equality $u_{x_3}(x; \Lambda) = -\vec{n}^2_3(\hat{x}^2)$. The extension given by Corollary 4.4 is obvious.

Example 4.7. Again take $J = 2$, $\mu^j = 0$, $\mathrm{dom}(u^j) = \Re^3_+$, and $\mathrm{dom}(\partial u^j) = \Re^3_{++}$, with $u^2(x) := u^2(x_1, x_2)$ (we are thinking of something like $u^1(x_1, x_2, x_3) = x_1^{\frac{1}{3}} x_2^{\frac{1}{3}} x_3^{\frac{1}{6}}$ and $u^2(x_1, x_2, x_3) = x_1^{\frac{1}{3}} x_2^{\frac{1}{3}}$). We take $A^1 = [0,\infty) \times [0,1] \times [0,\infty)$ and $A^2 = [0,\infty) \times [0,1] \times \{0\}$.

Then $\mathcal{M}^1 = \{0,2\}$, $\mathcal{M}^2 = \{0\}$, $\tilde{\mathcal{M}}^1 = \tilde{\mathcal{M}}^2 = \{1\}$, $\mathcal{M}_o^2 = \{2\}$, and $\mathcal{M}_o^1 = \emptyset$. The pieces of A^1 in $\mathrm{dom}(\partial u^1)$ are $\mathcal{C}_0^1 = \mathrm{int}(A^1)$ and $\mathcal{C}_1^1 = (0,\infty)\times\{1\}\times(0,\infty)$, a face, and for A^2 they are $\mathcal{C}_1^2 = (0,\infty)\times(0,1)\times\{0\}$, a face, and $\mathcal{C}_2^2 = (0,\infty)\times\{1\}\times\{0\}$, an edge. Moreover

$$\mathcal{S}_1^1 = \{(y_1,y_2,y_3) : y_1 = u^1_{x_1}(x_1,1,x_3),\ y_2 \le u^1_{x_2}(x_1,1,x_3),\ y_3 = u^1_{x_3}(x_1,1,x_3), \\ (x_1,x_3)\in\Re^2_{++}\},$$
$$\mathcal{S}_1^2 = \{(y_1,y_2) : y_1 = u^2_{x_1}(x_1,x_2,0),\ y_2 = u^2_{x_2}(x_1,x_2,0),\ (x_1,x_2)\in(0,\infty)\times(0,1)\} \\ \times\Re,$$
$$\mathcal{S}_2^2 = \{(y_1,y_2) : y_1 = u^2_{x_1}(x_1,1,0),\ y_2 \le u^2_{x_2}(x_1,1,0),\ x_1\in(0,\infty)\}\times\Re$$

and $\mathrm{aff}(\mathcal{N}_{A^1}(\mathcal{C}_1^1)) = \{0\}\times\Re\times\{0\}$, $\mathcal{N}_{A^2}(\mathcal{C}_1^2) = \{(0,0)\}\times\Re$, and $\mathrm{aff}(\mathcal{N}_{A^2}(\mathcal{C}_2^2)) = \{0\}\times\Re^2$. Observe that

$$\mathcal{R}_{u^1_{A^1}} = \{(y_1,y_2,y_3) : y_1 = u^1_{x_1}(x_1,1,x_3),\ y_2 \ge u^1_{x_2}(x_1,1,x_3),\ y_3 = u^1_{x_3}(x_1,1,x_3), \\ (x_1,x_3)\in\Re^2_{++}\},$$
$$\mathcal{R}_{u^2_{A^2}} = \{(y_1,y_2) : y_1 = u^2_{x_1}(x_1,x_2,0),\ y_2 = u^2_{x_2}(x_1,x_2,0),\ (x_1,x_2)\in(0,\infty)\times(0,1]\} \\ \times\{0\},$$

and $\mathcal{D}(\Lambda) = \Re_{++}\times\Re\times\Re_{++}$. Thus

$$\mathcal{R}_o(\Lambda) = \lambda_1\mathrm{int}(\mathcal{R}_{u^1_{A^1}}) \cup [\lambda_1\mathcal{S}_1^1 \cap \lambda_2\mathcal{S}_1^2].$$

If $y\in\lambda_1\mathrm{int}(\mathcal{R}_{u^1_{A^1}})$, then $I^{u^1}(\frac{y}{\lambda_1})\in\mathrm{int}(A^1)$, so $I^u(y)\in\mathrm{int}(A^1)+A^2 = (0,\infty)\times(0,2)\times(0,\infty)$. If $y\in\lambda_1\mathcal{S}_1^1\cap\lambda_2\mathcal{S}_1^2$, then $I^{u^1}(\frac{y}{\lambda_1})\in\mathcal{C}_1^1$ and $I^{u^2}(\frac{y}{\lambda_2})\in\mathcal{C}_1^2$, and hence $I^u(y)\in\mathcal{C}_1^1+\mathcal{C}_1^2 = (0,\infty)\times(1,2)\times(0,\infty)$.

Let us show that $A^u(\Lambda) = (0,\infty)\times(0,2)\times(0,\infty)$. For $x\in(0,\infty)\times(0,1]\times(0,\infty)$ we can find $\hat{x}^j$ by solving $\nabla_\xi[\lambda_1u^1(\xi_1,\xi_2,x_3) + \lambda_2u^2(x_1-\xi_1,x_2-\xi_2,0)] = 0$, i.e., $\hat{x}^1 = (\xi_1,\xi_2,x_3)^\top$, $\hat{x}^2 = x-\hat{x}^1$, where

$$\begin{aligned}\lambda_1u^1_{x_1}(\xi_1,\xi_2,x_3) - \lambda_2u^2_{x_1}(x_1-\xi_1,x_2-\xi_2,0) &= 0,\\ \lambda_1u^1_{x_2}(\xi_1,\xi_2,x_3) - \lambda_2u^2_{x_2}(x_1-\xi_1,x_2-\xi_2,0) &= 0,\end{aligned} \tag{4.17}$$

and $(\xi_1,\xi_2)\in(0,x_1)\times(0,x_2)$. For each ξ_2 the intermediate value and implicit function theorems give a continuous function $\xi_1(\xi_2)$ satisfying the first equation. Similarly from the second we obtain $\xi_2(\xi_1)$. Their intersection in the rectangle gives the solution. Then $\hat{x}^1 = (\xi_1,\xi_2,x_3)$ and $x = I^u(y;\Lambda)$ with $y = \lambda_1\nabla u^1(\xi_1,\xi_2,x_3) = \lambda_2\nabla u^2(x_1-\xi_1,x_2-\xi_2,0)$.

For $x\in(0,\infty)\times(1,2]\times(0,\infty)$ the same argument gives a solution $(\xi_1,\xi_2)\in(0,x_1)\times[x_2-1,1]$ if we work with supergradients; i.e., we replace $u^j_{x_2}(\xi_1,1,x_3)$ whenever it occurs by the interval (multivalued function) $(-\infty,u^j_{x_2}(\xi_1,1,x_3))$ (due to the constraint $x_2=1$; cf. the normal in (4.9)). So again $x = I^u(y;\Lambda)$ with $y = \lambda_1\nabla u^1(\xi_1,\xi_2,x_3)$, and I^u maps onto $(0,\infty)\times(0,2)\times(0,\infty)$. Then

$$A = [0,\infty)\times[0,2]\times[0,\infty),\quad \tilde{A} = (0,\infty)\times(0,2]\times(0,\infty),\quad A^u(\Lambda) = \mathrm{int}(A).$$

Observe that $\vec{n}^1(\hat{x}^1) = (0,n_2^1,0)$ where $n_2^1 = 0$ unless $\hat{x}^1\in\mathcal{C}_3^1$; otherwise $\vec{n}^1 = 0$. Moreover $\vec{n}^2(\hat{x}^2) = (0,n_2^2,n_3^2)$ with $n_2^2 = 0$ unless $\hat{x}^2\in\mathcal{C}_2^2$. From (4.17) we see that

$n_2^1 > 0$ if and only if $\lambda_1 u^1_{x_2}(\xi_1, 1, x_3) > \lambda_2 u^2_{x_2}(x_1 - \xi_1, x_2 - 1, 0)$ and $n_2^2 > 0$ if and only if $\lambda_1 u^1_{x_2}(\xi_1, x_2 - 1, x_3) < \lambda_2 u^2_{x_2}(x_1 - \xi_1, 1, 0)$. Here ξ_1 is the solution of (4.17), with $\xi_2 = 1$ in the first case and $\xi_2 = x_2 - 1$ in the second. Note that $n_2^j = 0$ if $x_2 \le 1$.

Theorem 4.3(iv) gives

$$\begin{aligned} u_{x_1}(x;\Lambda) &= \lambda_1 u^1_{x_1}(\hat{x}^1) \quad = \quad \lambda_2 u^2_{x_1}(\hat{x}^2), \\ u_{x_2}(x;\Lambda) &= \lambda_1 u^1_{x_2}(\hat{x}^1) - n_2^1 \quad = \quad \lambda_2 u^2_{x_2}(\hat{x}^2) - n_2^2, \\ u_{x_3}(x;\Lambda) &= \lambda_1 u^1_{x_3}(\hat{x}^1), \end{aligned}$$

where we have dropped the uninformative equality $u_{x_3}(x;\Lambda) = n_3^2 \in \Re$.

Example 4.8. In this example we do not assume the Inada condition at 0, so take $J = 2$ and assume that u^j satisfy Assumptions 1, 2′, and 3 with $\mu^j = 0$ and $A^1 = [0,\infty) \times [0,1]$, $A^2 = [0,\infty) \times \{0\}$. We assume that $\mathrm{dom}(\partial u^j)$ contains $[0,\infty)^2$. Then $n = 2$, $\mathcal{M}^j = \{1\}$, $\tilde{\mathcal{M}}^1 = \mathcal{M}_o^2 = \{2\}$, and $\tilde{\mathcal{M}}^2 = \mathcal{M}_o^1 = \emptyset$.

The sets $\mathcal{C}_k^1$, $k = 1,\dots,5$, are $(0,\infty)\times\{0\}, \{(0,0)\}, \{0\}\times(0,1), \{(0,1)\}, (0,\infty)\times\{1\}$ in order, and $\mathcal{C}_1^2 = (0,\infty)\times\{0\}$ and $\mathcal{C}_2^2 = \{(0,0)\}$. Moreover $\mathcal{R}_{u^1_{A^1}}$ is the subset of $\Re^2_{++}$ with boundaries given by the three curves $\{y = \nabla u^1(\xi,0) : \xi \ge 0\}$, $\{y = \nabla u^1(0,\xi) : \xi \in (0,1)\}$, $\{y = \nabla u^1(\xi,1) : \xi \ge 0\}$, $\mathcal{R}_{u^2_{A^2}} = \{\nabla u^2(\xi,0) : \xi \ge 0\}$ and $\mathcal{D}(\Lambda) = \Re^1_{++} \times \Re$. Figure 1 of [3] shows $\bigcup_k \mathcal{S}_k^1 \cap \Re^2_{++}$.

$$\begin{aligned} \mathcal{S}_1^1 &= \{y \in \Re^2 : y_1 = u^1_{x_1}(\xi,0),\ y_2 \ge u^1_{x_2}(\xi,0),\ \xi > 0\}, \\ \mathcal{S}_2^1 &= \{y \in \Re^2 : y \ge \nabla u^1(0,0)\}, \\ \mathcal{S}_3^1 &= \{y \in \Re^2 : y_1 \ge u^1_{x_1}(0,\xi),\ y_2 = u^1_{x_2}(0,\xi),\ 1 > \xi > 0\}, \\ \mathcal{S}_4^1 &= \{y \in \Re^2 : y_1 \ge u^1_{x_1}(0,1),\ y_2 \le u^1_{x_2}(0,1)\}, \\ \mathcal{S}_5^1 &= \{y \in \Re^2 : y_1 = u^1_{x_1}(\xi,1),\ y_2 \le u^1_{x_2}(\xi,1),\ \xi > 0\}, \\ \mathcal{S}_1^2 &= \{y \in \Re^2 : 0 < y_1 < u^2_{x_1}(0,0)\}, \\ \mathcal{S}_2^2 &= \{y \in \Re^2 : y_1 \ge u^2_{x_1}(0,0)\}. \end{aligned}$$

Now $\mathrm{aff}(\mathcal{N}_{A^1}(\mathcal{C}_2^1)) = \mathrm{aff}(\mathcal{N}_{A^1}(\mathcal{C}_4^1)) = \mathrm{aff}(\mathcal{N}_{A^2}(\mathcal{C}_2^2)) = \Re^2$, $\mathrm{aff}(\mathcal{N}_{A^1}(\mathcal{C}_1^1)) = \mathrm{aff}(\mathcal{N}_{A^1}(\mathcal{C}_5^1))$ $= \mathrm{aff}(\mathcal{N}_{A^2}(\mathcal{C}_1^2)) = \{0\}\times\Re$, and $\mathrm{aff}(\mathcal{N}_{A^1}(\mathcal{C}_3^1)) = \Re\times\{0\}$. Thus

$$\mathcal{R}_o(\Lambda) = \lambda_1 \mathrm{int}(\mathcal{R}_{u^1_{A^1}}) \cup [\lambda_1\mathcal{S}_3^1 \cap \lambda_2\mathcal{S}_1^2].$$

If $y \in \lambda_1 \mathrm{int}(\mathcal{R}_{u^1_{A^1}})$, then $I^{u^1}(\frac{y}{\lambda_1}) \in \mathrm{int}(A^1)$, so $I^u(y) \in \mathrm{int}(A^1) + A^2 = (0,\infty)\times(0,1)$. If $y \in \lambda_1\mathcal{S}_3^1 \cap \lambda_2\mathcal{S}_1^2$, then $I^{u^1}(\frac{y}{\lambda_1}) \in \mathcal{C}_3^1$ and $I^{u^2}(\frac{y}{\lambda_2}) \in \mathcal{C}_1^2$. Hence $I^u(y) \in \mathcal{C}_3^1 + \mathcal{C}_1^2 = (0,\infty)\times(0,1)$, and in fact

$$A^u(\Lambda) = (0,\infty)\times(0,1), \qquad \tilde{A} = A = [0,\infty)\times[0,1].$$

For $x = (x_1,x_2) \in A^u(\Lambda)$, $\hat{x}_2^1 = x_2 \in (0,1)$, so $\vec{n}_2^1(\hat{x}^1) = 0$. Hence

$$\begin{aligned} u_{x_1}(x;\Lambda) &= \lambda_1 u^1_{x_1}(\hat{x}^1) - \vec{n}_1^1(\hat{x}^1) = \lambda_2 u^2_{x_1}(\hat{x}^2) - \vec{n}_1^2(\hat{x}^2), \\ u_{x_2}(x;\Lambda) &= \lambda_1 u^1_{x_2}(\hat{x}^1), \end{aligned}$$

where $\vec{n}_1^j(\hat{x}^j) \le 0$ and is nonzero only if $\hat{x}_1^j = 0$. We have dropped the uninformative equality involving the arbitrary $\vec{n}_2^2(\hat{x}^2)$. Since $\hat{x}_1^1 + \hat{x}_1^2 = x_1 > 0$, then at least one of

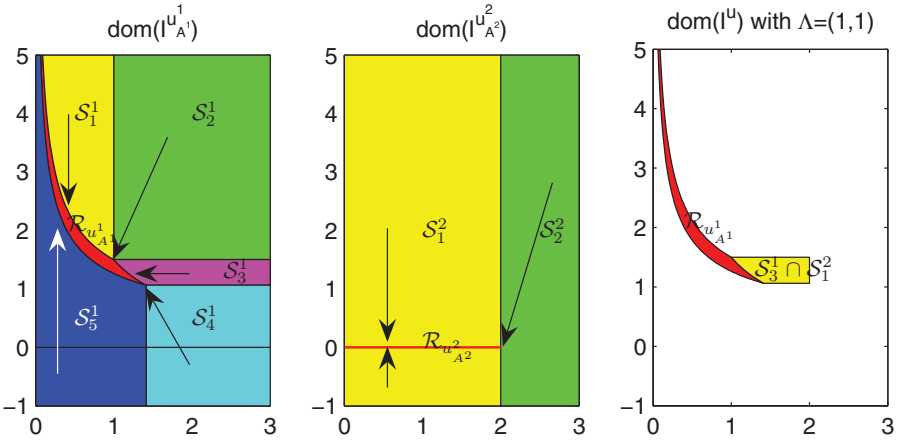

FIG. 2. *The domains of* $I^{u^1_{A^1}}$, $I^{u^2_{A^2}}$, I^u.

$\hat{x}_1^j > 0$. In fact x determines when $\vec{n}_1^j(\hat{x}^j) < 0$ as follows: $\vec{n}_1^1(\hat{x}^1) < 0$ if and only if $\lambda_1 u^1_{x_1}(0, x_2) < \lambda_2 u^2_{x_1}(x_1, 0)$, and $\vec{n}_1^2(\hat{x}^2) < 0$ if and only if $\lambda_1 u^1_{x_1}(x) > \lambda_2 u^2_{x_1}(0, 0)$ (look at $F'(0)$, $F'(x_1)$, where $F(\xi) := \lambda_1 u^1(\xi, x_2) + \lambda_2 u^2(x_1 - \xi, 0)$; cf. the definition of $u(\cdot\,; \Lambda)$).

We have computed some of the sets in the y-space for $u^1(x) := 3(x_1 + 1)^{1/3}\,(x_2 + 1)^{1/2}$ and $u^2(x) = 2(x_1 + \frac{1}{4})^{1/2}$ and plotted them in Figure 2. The arrows correspond to the projections; i.e., they are outward normals to $\mathcal{C}_k^j$. The third panel exhibits $\mathcal{R}_o$ as part of $\mathrm{dom}(I^u)$ when $\Lambda = (1, 1)$.

Remark 4.9. If we replace u^2 in Example 4.8 by $u^2(x_1, x_2) := \mu_1 x_1 - x_1^{-1}$, A^2 by $(0, \infty) \times \{0\}$, then $\mathrm{dom}(I^{u^2_{A^2}}) = \{y \in \Re^2 : y_1 > \mu_1\} = \mathcal{S}_1^2$ and $\mathcal{R}_{u^2_{A^2}} = (\mu_1, \infty) \times \{0\}$. There are no other $\mathcal{S}_k^2$. With $\Lambda = (1, 1)$ again, $\mathrm{dom}(I^u(\cdot\,, \Lambda)) = \{y \in \Re^2 : y_1 > \mu_1\}$ and $\mathcal{R}_o(\Lambda)$ is the intersection of $\mathrm{dom}(I^u(\cdot\,, \Lambda))$ with $\mathcal{R}_o(\Lambda)$ of the third panel of Figure 2, after the lightly shaded part has been extended infinitely to the right. Moreover $A = (0, \infty) \times [0, 1]$, $\tilde{A} = (0, \infty) \times (0, 1]$, and $A^u = (0, \infty) \times (0, 1)$.

SPARSE SOS RELAXATIONS FOR MINIMIZING FUNCTIONS THAT ARE SUMMATIONS OF SMALL POLYNOMIALS*

JIAWANG NIE† AND JAMES DEMMEL‡

Abstract. This paper discusses how to find the global minimum of functions that are summations of small polynomials ("small" means involving a small number of variables). Some sparse sum of squares (SOS) techniques are proposed. We compare their computational complexity and lower bounds with prior SOS relaxations. Under certain conditions, we also discuss how to extract the global minimizers from these sparse relaxations. The proposed methods are especially useful in solving sparse polynomial system and nonlinear least squares problems. Numerical experiments are presented which show that the proposed methods significantly improve the computational performance of prior methods for solving these problems. Lastly, we present applications of this sparsity technique in solving polynomial systems derived from nonlinear differential equations and sensor network localization.

Key words. polynomials, sum of squares (SOS), sparsity, nonlinear least squares, polynomial system, nonlinear differential equations, sensor network localization

1. Introduction.

Global optimization of multivariate polynomial functions contains quite a broad class of optimization problems. It has wide and important applications in science and engineering. Recently, there has been much work on globally minimizing polynomial functions using representation theorems from real algebraic geometry for positive polynomials. The basic idea is to approximate nonnegative polynomials by sum of squares (SOS) polynomials. This approximation is also called *SOS relaxation*, since not every nonnegative polynomial is SOS. Here a polynomial is said to be SOS if it can be written as a sum of squares of other polynomials. The advantage of SOS polynomials is that a polynomial is SOS if and only if a certain semidefinite program (SDP) formed by its coefficients is feasible. Since SDP [29] has efficient numerical methods, we can check whether a polynomial is SOS by solving a particular SDP.

To be more specific, suppose we wish to find the global minimum value f^* of a polynomial function $f(x)$ of vector $x = (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n$. The SOS relaxation finds a lower bound γ for f^* such that the polynomial $f(x) - \gamma$ is SOS. Obviously, $f(x) - \gamma$ being SOS implies that $f(x) - \gamma$ is nonnegative for every real vector x. Hence such a γ is a lower bound. The maximum γ found this way is called the SOS lower bound, which is often denoted by f^*_{sos}. The relation $f^*_{sos} \le f^*$ always holds for every polynomial $f(x)$ (it is possible that $f^*_{sos} = -\infty$). When $f^*_{sos} = f^*$, we say the SOS relaxation is *exact*. We refer to [13, 22, 23] for more details on SOS relaxations for polynomial optimization problems. There are two important issues for applying SOS relaxation in global optimization of polynomial functions: the *quality* and *computational complexity*.

The quality means how good is the SOS lower bound f^*_{sos}. In practice, as observed in [22], many nonnegative polynomials that are not "artificially" constructed are SOS. However, Blekherman [4] pointed out that there are much more nonnegative polynomials than SOS polynomials. But usually SOS relaxation provides very good approximations, although theoretically it can fail with high probability. When SOS relaxation is not exact, i.e., $f^*_{sos} < f^*$, there are methods to fix it by applying modified SOS relaxations. Nie, Demmel, and Sturmfels [20] proposed to use SOS representations of $f(x)-\gamma$ modulo the gradient ideal of $f(x)$, and show that the minimum value f^* can be obtained when f^* is attained at some point. Schweighofer [26] proposes to minimize $f(x)$ over a semialgebraic set called the *gradient tentacle*, and shows that the minimum value f^* can be computed when $f^* > -\infty$ but not attainable. Jibetean and Laurent [10] and Lasserre [14] propose perturbing $f(x)$ by adding a higher degree polynomial with tiny coefficients, and showed that the lower bounds will converge to the minimum value f^*. Recently, Laurent [16] gave a survey on solving polynomial optimization by using semidefinite relaxations. We refer to [10, 14, 16, 20, 26] for related work.

Another important issue for SOS relaxation is the computational complexity. Suppose $f(x)$ has degree $2d$ (it must be even for $f(x)$ to have a finite minimum). Then $f(x)$ has up to $\binom{n+2d}{2d}$ monomials. The condition that $f(x) - \gamma$ being SOS reduces to an SDP the size of whose linear matrix inequality (LMI) is $\binom{n+d}{d}$ with $\binom{n+2d}{2d}$ variables. These numbers can be huge for moderate n and d, say, $n = 2d = 10$. For large scale polynomial optimization problems, the general SOS relaxation is very difficult to implement numerically. Sometimes this complexity makes the applicability of SOS relaxation very limited. We refer to [22, 23] for the connection between SOS relaxation and SDP.

Prior work. There is some work on exploiting sparsity in polynomial optimization when the polynomials are *sparse*. In such situations, sparse SOS relaxations are available and the resulting SDPs have reduced sizes, and hence larger problems can be solved. Here being sparse means that the number of monomials with nonzero coefficients is much smaller than the maximum possible number $\binom{n+2d}{2d}$. Kojima et al. [12] and Parrilo [24] discussed how to exploit sparsity of SOS relaxations in unconstrained polynomial optimization. Kim et al. [11] and Lasserre [15] discussed sparse SOS relaxations for constrained polynomial optimization problems and showed convergence under certain conditions. Waki et al. [28] proposed a heuristic procedure to exploit sparsity for minimizing polynomials by *chordal extension* of the *correlation sparsity pattern graph* (csp graph): the vertices of the csp graph are the variables $x_1, \ldots, x_n$; the edge (x_i, x_j) exists whenever $x_i x_j$ appears in one monomial of $f(x)$. To find one chordal extension, [28] proposed to use the symbolic sparse Cholesky factorization of the csp matrix with minimum degree ordering. If the chordal extension of the csp graph is also sparse, then the sparsity technique in [28] works well. However, if the chordal extension of the csp graph is much less sparse, then that sparsity technique might still be too expensive to be implementable for some practical problems.

Contributions. In many practical applications, the polynomials are not only sparse, but also given with certain sparsity patterns. For instance, the polynomials are often summations of other "small" polynomials, i.e., polynomials involving only a small number of variables. Sometimes, these representations contain useful information that might help us save computations significantly. These sparsity patterns are often ignored in prior work, where these polynomials would be treated using the usual "dense" algorithms. The main contribution of this paper is to propose new

sparse SOS relaxation techniques taking the given sparsity pattern into account, and to show numerical experiments demonstrating their accuracy and speed.

In this paper, we consider the polynomial optimization problem of the form

$$\min_{x\in\mathbb{R}^n} \quad f(x) = \sum_{i=1}^{m} f_i(x_{\Delta_i}), \tag{1.1}$$

where $\Delta_i \subset [n] = \{1, 2, \ldots, n\}$. Here each $f_i(x_{\Delta_i})$ is a polynomial in $x_{\Delta_i} = (x_j | j \in \Delta_i)$. Let $\deg(f_i) = 2d_i$ and $2d = \deg(f) = \max\{2d_1, \ldots, 2d_m\}$ (we assume each f_i has even degree along with f). One basic and natural idea for solving problem (1.1) is to find the maximum γ such that

$$f(x) - \gamma = \sum_{i=1}^{m} s_i(x_{\Delta_i}),$$

where each $s_i(x_{\Delta_i})$ is an SOS polynomial in x_{Δ_i} instead of all the variables $x_1, \ldots, x_n$. Exploiting this sparsity pattern can save significant computation without sacrificing much solution quality for many practical problems. In addition to presenting its numerical implementation, this paper will also discuss the theoretical properties of this sparse SOS relaxation and its variations.

The main distinction of our sparse SOS technique from earlier work like Waki et al. [28] is that we do not use the chordal extension of csp graphs. In the case that the csp graph of $f(x)$ in (1.1) is chordal, our sparsity technique is almost the same as the one in [28]. However, if the csp graph of $f(x)$ is not chordal and its chordal extension is much less sparse, then our sparsity technique is significantly more efficient. If the csp graph of $f(x)$ is not chordal and its chordal extension is also sparse, then our sparsity technique is slightly more efficient while not losing much quality of solution. Furthermore, our sparsity technique can be applied to solve bigger dense polynomial optimization problems which cannot be solved by other existing methods. This is due to the observation that every polynomial $g(x)$ is a summation of monomials whose number of variables is at most the degree $\deg(g)$. So, when $\deg(g)$ is small, like 4 or 6, then the formulation (1.1) is a good sparse model. The numerical computations show that our sparsity technique is usually more efficient than other existing methods in solving problems of the form (1.1).

We remark that for a given polynomial $f(x)$, there is a flexibility to choose the summands $f_i(x_{\Delta_i})$ in (1.1). Sometimes, this flexibility is very useful, since it allows us to choose among various sparse relaxations and select the most efficient one from them. The best choice of $f_i(x_{\Delta_i})$ is usually problem dependent and there is no general rule. However, for practical problems like solving polynomial systems or nonlinear least squares, there are natural choices for $f_i(x_{\Delta_i})$. This is illustrated in section 4 and section 5.

Polynomial optimization problems of the form (1.1) have important practical applications: (i) *Solving polynomial systems:* Many large scale polynomial equations are often sparse, and each equation might involve just a few variables, e.g., the polynomial equations obtained from discretization in nonlinear differential equations. Such polynomial systems can be equivalently transformed to global polynomial optimization problems of the form (1.1). We will show that the proposed sparse SOS relaxation is exact when the polynomial system has at least one real solution. (ii) *Nonlinear least squares:* Many difficult problems in statistics, biology, engineering, or other applications require solving certain nonlinear least squares problems and finding their

global optimal solutions. If each equation is sparse, then sparse polynomial optimization (1.1) is a very natural model and our sparsity technique is very suitable. Sensor network localization is one important application of this kind.

Outline. This paper is organized as follows. Section 2 introduces some notation and background for SOS relaxations, section 3 discusses properties of the sparse SOS relaxation and its variations, section 4 presents some numerical implementations, and section 5 shows applications. Lastly, section 6 draws some conclusions and discusses future work in this area.

2. Preliminaries. This section introduces some notations and backgrounds in SOS relaxation methods for minimizing polynomial functions.

Throughout this paper, we will use the following notation: $\mathbb{R}$ is the field of real numbers; $\mathbb{N}$ is the set of nonnegative integers; $\mathbb{R}^{\Delta_i} = \{(x_{k_1}, \ldots, x_{k_\ell}) : x_{k_j} \in \mathbb{R}\}$ when $\Delta_i = \{k_1, k_2, \ldots, k_\ell\}$; $\mathbb{R}[X]$: the ring of real polynomials in $X = (x_1, x_2, \ldots, x_n)$; $\mathbb{R}[X_{\Delta_i}]$: the ring of real polynomials in $X_{\Delta_i} = (x_k)_{k\in\Delta_i}$; $\sum\mathbb{R}[X]^2$: SOS polynomials in $\mathbb{R}[X]$; $\sum\mathbb{R}[X_{\Delta_i}]^2$: SOS polynomials in $\mathbb{R}[X_{\Delta_i}]$; $\sum\mathbb{R}_N[X]^2$: SOS polynomials in $\mathbb{R}[X]$ with degree at most $2N$; $\sum\mathbb{R}_N[X_{\Delta_i}]^2$: SOS polynomials in $\mathbb{R}[X_{\Delta_i}]$ with degree at most $2N$; $\|x\|_2 = \sqrt{x_1^2 + x_2^2 + \cdots + x_n^2}$; $x^\alpha = x_1^{\alpha_1}x_2^{\alpha_2}\ldots x_n^{\alpha_n}$ for $\alpha \in \mathbb{N}^n$; $\mathrm{supp}(\alpha) = \{i \in [n] : \alpha_i \neq 0\}$; $\mathrm{supp}(f) = \{\alpha \in \mathbb{N}^n :$ the coefficient of x^α in $f(x)$ is nonzero$\}$; $|F|$ denotes the cardinality of set F; A^T denotes the transpose of matrix A; $A \succeq (\succ) 0$ means matrix A is positive semidefinite (definite); $\mathcal{M}_d(y)$ is the moment matrix of order d about $x \in \mathbb{R}^n$; $\mathcal{M}_d^{\Delta_i}(y)$ is the moment matrix of order d about $x_{\Delta_i} \in \mathbb{R}^{\Delta_i}$; $\mathcal{M}_F(y)$ is the moment matrix generated monomials with support F.

2.1. SOS and semidefinite programming (SDP). A polynomial $p(x)$ in $x = (x_1, \ldots, x_n)$ is said to be sum of squares (SOS) if $p(x) = \sum_i p_i^2(x)$ for some polynomials $p_i(x)$. Obviously, if $p(x)$ is SOS, then $p(x)$ is *nonnegative*; i.e., $p(x) \geq 0$ for all $x \in \mathbb{R}^n$. However, the converse is not true. If $p(x)$ is nonnegative, then $p(x)$ is not necessarily SOS. In other words, the set of SOS polynomials (which forms a cone) is properly contained in the set of nonnegative polynomials (which forms a larger cone). The process of approximating nonnegative polynomials by SOS polynomials is called SOS relaxation. For instance, the polynomial

$$\begin{aligned} &x_1^4 + x_2^4 + x_3^4 + x_4^4 - 4x_1x_2x_3x_4 \\ &\quad = \tfrac{1}{3}\Big\{\big(x_1^2 - x_2^2 - x_4^2 + x_3^2\big)^2 + \big(x_1^2 + x_2^2 - x_4^2 - x_3^2\big)^2 + \big(x_1^2 - x_2^2 - x_3^2 + x_4^2\big)^2 \\ &\qquad + 2(x_1x_4 - x_2x_3)^2 + 2(x_1x_2 - x_3x_4)^2 + 2(x_1x_3 - x_2x_4)^2\Big\} \end{aligned}$$

is SOS. This identity immediately implies that

$$x_1^4 + x_2^4 + x_3^4 + x_4^4 - 4x_1x_2x_3x_4 \geq 0, \ \ \forall (x_1, x_2, x_3, x_4) \in \mathbb{R}^4,$$

which is one arithmetic-geometric mean inequality.

The advantage of SOS polynomials over nonnegative polynomials is that it is more tractable to check whether a polynomial is SOS. To test whether a polynomial is SOS is equivalent to testing the feasibility of some SDP [22, 23], which has efficient numerical solvers. To illustrate this, suppose polynomial $p(x)$ has degree $2d$ (SOS polynomials must have even degree). Then $p(x)$ is SOS if and only if [22, 23] there exists a symmetric matrix $W \succeq 0$ such that

$$p(x) = \mathbf{m}_d(x)^T\, W\, \mathbf{m}_d(x),$$

where $\mathbf{m}_d(x)$ is the column vector of monomials up to degree d. For instance,

$$\mathbf{m}_2(x_1, x_2) = \left[1,\, x_1,\, x_2,\, x_1^2,\, x_1x_2,\, x_2^2\right]^T.$$

As is well known, the number of monomials in x up to degree d is $\binom{n+d}{d}$. Thus the size of matrix W is $\binom{n+d}{d}$. This number can be very large. For instance, when $n = d = 10$, $\binom{n+d}{d} \geq 10^5$. However, for fixed d (e.g., $d = 2$), $\binom{n+d}{d}$ is polynomial in n. On the other hand, it is NP-hard (with respect to n) to tell whether a polynomial is nonnegative whenever $2d \geq 4$ (even when d is fixed) [13].

2.2. SOS relaxation in polynomial optimization. Let $f(x) = \sum_\alpha f_\alpha x^\alpha$ be a polynomial in x. Consider the global optimization problem

$$f^* := \min_{x \in \mathbb{R}^n} \quad f(x).$$

This problem is NP-hard when $\deg(f) \geq 4$. The standard SOS relaxation is

$$\begin{aligned} f^*_{sos} := \max \quad & \gamma \\ s.t. \quad & f(x) - \gamma \text{ is SOS.} \end{aligned}$$

Obviously we have that $f^*_{sos} \leq f^*$. In practice, SOS provides very good approximations, and often gives exact global minimum, i.e., $f^*_{sos} = f^*$, even though theoretically there are many more nonnegative polynomials than SOS polynomials [4].

In terms of SDP, the SOS relaxation can also be written as

$$f^*_{sos} := \max \quad \gamma \tag{2.1}$$

$$s.t. \quad f(x) - \gamma = \mathbf{m}_d(x)^T W \mathbf{m}_d(x) \tag{2.2}$$

$$W \succeq 0 \tag{2.3}$$

where $2d = \deg(f)$. The decision variable in the above is (γ, W) instead of x. The above program is convex about (γ, W). A lower bound f^*_{sos} can be computed by solving the resulting SDP. It can be shown [13] that the dual of (2.1)–(2.3) is

$$f^*_{mom} := \min_y \quad \sum_{|\alpha| \leq 2d} f_\alpha y_\alpha \tag{2.4}$$

$$s.t. \quad \mathcal{M}_d(y) \succeq 0 \tag{2.5}$$

$$y_{0,\ldots,0} = 1. \tag{2.6}$$

Here $\mathcal{M}_d(y)$ is the *moment matrix* generated by $y = (y_\alpha)$, a vector indexed by monomials of degree at most $2d$. The rows and columns of moment matrix $\mathcal{M}_d(y)$ are indexed by integer vectors. Each entry of $\mathcal{M}_d(y)$ is defined as

$$\mathcal{M}_d(y)(\alpha, \beta) := y_{\alpha+\beta}, \ \forall |\alpha|, |\beta| \leq d.$$

For instance, when $d = 2$ and $n = 2$, the vector

$$y = [\, y_{0,0},\, y_{1,0},\, y_{0,1},\, y_{2,0},\, y_{1,1},\, y_{0,2},\, y_{3,0},\, y_{2,1},\, y_{1,2},\, y_{0,3},\, y_{4,0},\, y_{3,1},\, y_{2,2},\, y_{1,3},\, y_{0,4}\,]$$

defines moment matrix

$$\mathcal{M}_2(y) = \begin{bmatrix} y_{0,0} & y_{1,0} & y_{0,1} & y_{2,0} & y_{1,1} & y_{0,2} \\ y_{1,0} & y_{2,0} & y_{1,1} & y_{3,0} & y_{2,1} & y_{1,2} \\ y_{0,1} & y_{1,1} & y_{0,2} & y_{2,1} & y_{1,2} & y_{0,3} \\ y_{2,0} & y_{3,0} & y_{2,1} & y_{4,0} & y_{3,1} & y_{2,2} \\ y_{1,1} & y_{2,1} & y_{1,2} & y_{3,1} & y_{2,2} & y_{1,3} \\ y_{0,2} & y_{1,2} & y_{0,3} & y_{2,2} & y_{1,3} & y_{0,4} \end{bmatrix}.$$

For SOS relaxation (2.1)–(2.3) and its dual problem (2.4)–(2.6), strong duality holds [13]; i.e., their optimal values are equal ($f^*_{sos} = f^*_{mom}$). Hence f^*_{mom} is also a lower bound for the global minimum f^* of $f(x)$.

Now let us see how to extract minimizer(s) from optimal solutions to (2.4)–(2.6). Let y^* be one optimal solution. If moment matrix $\mathcal{M}_d(y^*)$ has rank one, then there exists one vector w such that $\mathcal{M}_d(y^*) = ww^T$. Normalize w so that $w_{(0,\dots,0)} = 1$. Set $x^* = w(2 : n+1)$. Then the relation $\mathcal{M}_d(y^*) = ww^T$ immediately implies that $y^* = \mathbf{m}_{2d}(x^*)$, i.e., $y^*_\alpha = (x^*)^\alpha$, so $f^*_{mom} = f(x^*)$. This says that a lower bound of $f(x)$ is attained at one point x^*. So x^* is one global minimizer.

When moment matrix $\mathcal{M}_d(y^*)$ has rank more than one, the process described above does not work. However, if $\mathcal{M}_d(y^*)$ satisfies the so-called *flat extension condition*

$$\operatorname{rank} \mathcal{M}_k(y^*) = \operatorname{rank} \mathcal{M}_{k+1}(y^*)$$

for some $0 \le k \le m-1$, we can extract more than one minimizer (in this case the global solution is not unique). When the flat extension condition is met, it can be shown [7] that there exist distinct vectors $u_1, \dots, u_r$ such that

$$\mathcal{M}_d(y^*) = \lambda_1 \mathbf{m}_d(u_1) \cdot \mathbf{m}_d(u_1)^T + \cdots + \lambda_r \mathbf{m}_d(u_r) \cdot \mathbf{m}_d(u_r)^T$$

for some $\lambda_i > 0$, $\sum_{i=1}^r \lambda_i = 1$. Here $r = \operatorname{rank} \mathcal{M}_d(y^*)$. The set $\{u_1, \dots, u_r\}$ is called an *r-atomic representing support* for moment matrix $\mathcal{M}_d(y^*)$. All the vectors $u_1, \dots, u_r$ can be shown to be global minimizers. They can be computed by solving some particular eigenvalue problem. We refer to [7] for flat extension conditions in moment problems and [9] for extracting minimizers.

2.3. Exploiting sparsity in SOS relaxation. As mentioned in the previous subsections, the size of matrix W in SOS relaxation is $\binom{n+d}{d}$, which can be very large. So SOS relaxation is expensive when either n or d is large. This is true for general dense polynomials. However, if $f(x)$ is sparse, i.e., its support $\mathcal{F} = \operatorname{supp}(f)$ is small, the size of the resulting SDP can be reduced significantly. Without loss of generality, assume $(0, \dots, 0) \in \mathcal{F}$. Then $\operatorname{supp}(f) = \operatorname{supp}(f - \gamma)$ for any number γ.

Suppose $f(x) - \gamma = \sum_i \phi_i(x)^2$ is an SOS decomposition. Then by Theorem 1 in [25] we have

$$\operatorname{supp}(\phi_i) \subset \mathcal{F}^0 := \left(\text{the convex hull of } \frac{1}{2}\mathcal{F}^e \right)$$

where $\mathcal{F}^e = \{\alpha \in \mathcal{F} : \ \alpha \text{ is an even integer vector}\}$. There exists some work [12, 28] on exploiting sparsity further. Here we briefly describe the technique introduced in [28].

For polynomial $f(x)$, define its *csp graph* $G = ([n], E)$ such that $(i, j) \in E$ if and only if $x_i x_j$ appears in some monomial of $f(x)$. Let $\{C_1, C_2, \dots, C_K\}$ be the set of all maximal cliques of graph G. Waki et al. [28] proposed to represent $f(x) - \gamma$ as

$$f(x) - \gamma = \sum_{i=1}^K s_i(x), \quad \text{each } s_i(x) \text{ being SOS } \operatorname{supp}(s_i) \subset C_i.$$

Theoretically, when $f(x) - \gamma$ is SOS, the above representation may not hold (see Example 3.5). It is also difficult to find all the maximal cliques of graph G. Waki

et al. [28] propose to replace $\{C_1, C_2, \ldots, C_K\}$ by the set of all maximal cliques of one *chordal extension* of G. We refer to [3] for properties of chordal graphs. For chordal graphs, there are efficient methods to find all the maximal cliques. Chordal extension is essentially the *sparse symbolic Cholesky factorization*; the sparsity of matrix factors represents the chordal extension. To find the minimum chordal extension requires sparse Cholesky factorization with the smallest number of fill-ins, which is difficult generally. However, some heuristics like minimum degree ordering are usually efficient in practice in finding a good approximation. We refer to [28] for more details on how to get an efficient chordal extension.

We remark that in the worst case the sparse SOS relaxation above might be weaker than the general dense SOS relaxation even when the chordal extension is applied, as shown by Example 3.5.

There is much work in exploiting sparsity in SOS relaxations. We refer to [8, 11, 12, 24, 28] and the references therein.

3. The sparse SOS relaxation. Throughout this paper, we assume $f(x) = \sum_{i=1}^m f_i(x_{\Delta_i})$. Let $\|\Delta\|$ be the maximum cardinality of Δ_i, i.e., $\|\Delta\| = \max_i |\Delta_i|$. We are interested in the case that $\|\Delta\| \ll n$. To find the global minimum f^* of $f(x)$, we propose the following sparse SOS relaxation:

$$\begin{aligned} f_\Delta^* := \max \quad & \gamma \\ s.t. \quad & f(x) - \gamma \in \sum_{i=1}^m \sum \mathbb{R}_d[x_{\Delta_i}]^2. \end{aligned}$$

In terms of SDP, the above SOS relaxation is essentially the same as

$$f_\Delta^* := \max \quad \gamma \tag{3.1}$$

$$s.t. \quad f(x) - \gamma = \sum_{i=1}^m \mathbf{m}_d(x_{\Delta_i})^T W_i \mathbf{m}_d(x_{\Delta_i}), \tag{3.2}$$

$$W_i \succeq 0,\ i = 1, \ldots, m. \tag{3.3}$$

Notice that (3.2) is an identity. Let

$$\mathcal{F}_i = \{\alpha \in \mathbb{N}^n : \mathrm{supp}(\alpha) \subset \Delta_i,\ |\alpha| \le 2d\}, \quad \mathcal{F} = \bigcup \mathcal{F}_i. \tag{3.4}$$

Write $f(x) = \sum_\alpha f_\alpha x^\alpha$. Since $f(x) = \sum_i f_i(x_{\Delta_i})$, $f_\alpha \neq 0$ implies that $\alpha \in \mathcal{F}$. By comparing coefficients of both sides of (3.2), we have equality constraints

$$f_0 - \gamma = \sum_{i=1}^m W_i(0,0), \quad f_\alpha = \sum_{i=1}^m \sum_{\eta+\tau=\alpha} W_i(\eta,\tau),\ \ \forall\, \alpha \neq 0. \tag{3.5}$$

Now we derive the dual problem for (3.1)–(3.3). Notice that constraint (3.2) is equivalent to the equality constraints (3.5). Let $y = (y_\alpha)_{\alpha\in\mathcal{F}}$ be the Lagrange multipliers for equations in (3.5), and U_i be the Lagrange multipliers for inequalities in (3.3). Each U_i is also positive semidefinite. The Lagrange function for problem (3.1)–(3.3) is

$$\begin{aligned} \mathcal{L} &= \gamma + \left(f_0 - \gamma - \sum_i W_i(0,0)\right) y_0 + \sum_{0\neq\alpha\in\mathcal{F}} \left(f_\alpha - \sum_{i=1}^m \sum_{\eta+\tau=\alpha} W_i(\eta,\tau)\right) y_\alpha + \sum_i W_i \bullet U_i \\ &= \gamma(1-y_0) + \sum_{\alpha\in\mathcal{F}} f_\alpha y_\alpha + \sum_{i=1}^m \sum_{\alpha\in\mathcal{F}} \sum_{\eta+\tau=\alpha} W_i(\eta,\tau)\Big(U_i(\eta,\tau) - y_\alpha\Big). \end{aligned}$$

So we can see that

$$\max_{\gamma, W_i} \mathcal{L}(\gamma, W_i, y_\alpha, U_i) = \begin{cases} \sum_\alpha f_\alpha y_\alpha & \text{if } y_0 = 1, U_i = \mathcal{M}_d^{\Delta_i}(y) \succeq 0\,; \\ +\infty & \text{otherwise.} \end{cases}$$

Therefore the dual of (3.1)–(3.3) is

$$f_\Sigma^* := \min \quad \sum_{\alpha \in \mathcal{F}} f_\alpha y_\alpha \tag{3.6}$$

$$s.t. \quad \mathcal{M}_d^{\Delta_i}(y) \succeq 0,\ i = 1, \ldots, m \tag{3.7}$$

$$y_0 = 1. \tag{3.8}$$

3.1. Complexity comparison. Since the dual of the standard or sparse SOS relaxation not only returns the SOS lower bound but also provides the moment matrix to help extract minimizers, we compare the computational complexity of (2.4)–(2.6) and (3.6)–(3.8). The LMI (2.5) is of size $\binom{n+d}{d} = \mathcal{O}(n^d)$ and has $\binom{n+2d}{2d} = \mathcal{O}(n^{2d})$ decision variables. At each step of an interior-point method (e.g., the dual scaling method [2]), the complexity for solving (2.4)–(2.6) is $\mathcal{O}(n^{6d})$. On the other hand, (3.7) has m LMIs, which are of sizes at most $\binom{\|\Delta\|+d}{d} = \mathcal{O}(\|\Delta\|^d)$, and $\mathcal{O}\big(m\binom{\|\Delta\|+2d}{2d}\big) = \mathcal{O}(m\|\Delta\|^{2d})$ decision variables. At each step of interior-point methods, the complexity for solving (3.6)–(3.8) is $\mathcal{O}(m^3\|\Delta\|^{6d})$. When $\|\Delta\|$ is independent of n and $m = \mathcal{O}(n^p)$ with $p < 2d$, then

$$\mathcal{O}\left(m^3\|\Delta\|^{6d}\right) \ll \mathcal{O}\left(n^{6d}\right).$$

Therefore (3.6)–(3.8) is much easier to solve than (2.4)–(2.6).

The complexity of sparse SOS relaxation in [28] depends on the chordal extension of the csp graph. In the worst case, it can be as big as for the general SOS relaxation (2.4)–(2.6). Let Ω be the maximum size of the maximal cliques of the chordal extension. In practice, Ω is often bigger than or equal to $\|\Delta\|$. When $\Omega > \|\Delta\|$, the SOS relaxation (3.6)–(3.8) is usually more efficient.

3.2. Lower bound analysis. Recall that $\mathcal{F}_i = \{\alpha \in \mathbb{N}^n : \text{supp}(\alpha) \subset \Delta_i,\ |\alpha| \le 2d\}$. From the representation (1.1) of $f(x)$, we have

$$\text{supp}(f) \subseteq \bigcup_{i=1}^m \mathcal{F}_i.$$

This leads us to think that the relaxation (3.6)–(3.8) should give reasonable lower bounds, although it might be weaker than the general SOS (see Example 3.5).

THEOREM 3.1. *The optimal values $f_\Sigma^*, f_\Delta^*, f_{sos}^*$, and f^* satisfy the relationship*

$$f_\Sigma^* = f_\Delta^* \le f_{sos}^* \le f^*.$$

Proof. The latter two inequalities are obvious because the feasible region defined by (3.7)–(3.8) contains the one defined by (2.5)–(2.6). To prove the first equality, by the standard duality argument for convex program, it suffices to show that (3.7) admits a strict interior point. Define $\hat{y} = (\hat{y}_\alpha)_{\alpha \in \mathcal{F}}$ as

$$\hat{y}_\alpha := \frac{\int_{\mathbb{R}^n} x^\alpha e^{-\|x\|_2^2}\, dx}{\int_{\mathbb{R}^n} e^{-\|x\|_2^2}\, dx}.$$

For every nonzero vector $\xi = (\xi_\alpha)_{\alpha \in \mathcal{F}_i}$, we have

$$\xi^T M_d^{\Delta_i}(\hat{y})\, \xi = \frac{\int_{\mathbb{R}^n} \left(\sum_{|\alpha| \le d} \xi_\alpha x^\alpha \right)^2 e^{-\|x\|_2^2} dx}{\int_{\mathbb{R}^n} e^{-\|x\|_2^2} dx} > 0.$$

So $M_d^{\Delta_i}(\hat{y}) \succ 0$ for every $1 \le i \le m$. Therefore $\hat{y}$ is an interior point for (3.6)–(3.8), which implies the strong duality $f_\Sigma^* = f_\Delta^*$. ∎

Remark 3.2. Theorem 3.1 implies that the lower bound f_Δ^* given by (3.1)–(3.3) is weaker than the SOS lower bound f_{sos}^*. There are examples such that $f_\Delta^* < f_{sos}^*$ (see Example 3.5). However, in many numerical simulations, the lower bound f_Δ^* is very useful. For randomly generated polynomials, as shown in section 4, it frequently happens that $f_\Delta^* = f_{sos}^*$. On the other hand, under some conditions, we can prove $f_\Delta^* = f_{sos}^*$.

Suppose $\Delta_1, \Delta_2, \ldots, \Delta_m$ satisfy the *running intersection property*:

$$\text{For every } 1 \le i \le m-1,\ \exists\, k \le i \text{ such that } \quad \Delta_{i+1} \cap \left(\bigcup_{j=1}^{i} \Delta_j \right) \subsetneq \Delta_k. \tag{3.9}$$

THEOREM 3.3. *Suppose* (3.6)–(3.8) *has an optimal solution* y^* *such that each* $\mathcal{M}_{d_i}^{\Delta_i}(y^*)$ *has a representing measure* μ_i *on* $\mathbb{R}^{\Delta_i}$. *If condition* (3.9) *holds, then* $f_\Delta^* = f_{sos}^*$.

Proof. For any Δ_i, Δ_j, $\mathcal{M}_d^{\Delta_i \cap \Delta_j}(y^*)$ is a common principle submatrix of $\mathcal{M}_d^{\Delta_i}(y^*)$ and $\mathcal{M}_d^{\Delta_j}(y^*)$. So the marginals of measures μ_i are consistent; i.e., the restrictions of these measures on the common subspaces are the same. By Lemma 6.4 in [15], there exists a measure on $\mathbb{R}^n$ such that μ_i is the marginal of μ with respect to Δ_i for all $i = 1, \ldots, m$. Define vector $\tilde{y}$ such that

$$\mathcal{M}_d(\tilde{y}) = \int_{\mathbb{R}^n} \mathbf{m}_d(x) \mathbf{m}_d(x)^T \mu(dx).$$

Then every $\mathcal{M}_d^{\Delta_i}(y^*)$ is a principle submatrix of $\mathcal{M}_d(\tilde{y})$. So $\tilde{y}_\alpha = y_\alpha^*$ whenever $\mathrm{supp}(\alpha) \subset \Delta_j$ for some j. Since the $f_\alpha \ne 0$ implies $\mathrm{supp}(\alpha) \subset \Delta_j$ for some j, we know the objective value of (3.6) is the same for y^* and $\tilde{y}$. Thus $f_{sos}^* \le f_\Delta^*$. Since $f_{sos}^* \ge f_\Delta^*$, we get $f_{sos}^* = f_\Delta^*$. ∎

Remark 3.4. The running intersection property (3.9) alone is not sufficient to guarantee the equality $f_\Delta^* = f_{sos}^*$, as shown by the following example.

Example 3.5. $f(x) = f_1(x_1, x_2) + f_2(x_2, x_3)$ where $f_1 = x_1^4 + (x_1 x_2 - 1)^2$ and $f_2 = x_2^2 x_3^2 + (x_3^2 - 1)^2$. Solving dense SOS relaxation (2.1)–(2.3) and sparse SOS relaxation (3.1)–(3.3) numerically, we find that

$$f_\Delta^* \approx 5.0 \cdot 10^{-5} \ < \ f_{sos}^* \approx 0.8499.$$

Actually the minimum $f^* \approx 0.8650$. First, solve equation $\nabla f(x) = 0$, and evaluate $f(x)$ on these critical points, and then we find the minimum of these critical values is about 0.8650. So $f^* < 1$. Second, we prove that the minimum f^* is attainable. Let $\{x^{(k)}\}$ be a sequence such that $f(x^{(k)}) \to f^*$ as k goes to infinity. We claim that the sequence $\{x^{(k)}\}$ must be bounded.

Otherwise, suppose $x^{(k)} \to \infty$. Thus at least one of coordinates $x_1^{(k)}$, $x_2^{(k)}$, $x_3^{(k)}$ should go to infinity. If either $x_1^{(k)}$ or $x_3^{(k)}$ goes to infinity, then $f(x^{(k)})$ goes to infinity, which is not possible. So $x_2^{(k)} \to \infty$. Since $\{f(x^{(k)})\}$ is bounded, without loss of generality, we assume $x_1^{(k)} \to a_1$, $x_1^{(k)}x_2^{(k)} \to a_{12}$, $x_2^{(k)}x_3^{(k)} \to a_{23}$, $x_3^{(k)} \to a_3$ for some numbers a_1, a_{12}, a_{23}, a_3. If $a_3 = 1$, then $x_2^{(k)}$ is convergent to a_2, which is not possible. And, if $a_3 \neq 0$, then $x_2^{(k)}x_3^{(k)}$ goes to infinity, which is also not possible. So $a_3 = 0$, and hence

$$f\left(x^{(k)}\right) \geq \left(x_3^2 - 1\right)^2 \to 1 > f^*,$$

which is a contradiction.

So the sequence $\{x^{(k)}\}$ is bounded and has an accumulation point x^*. Then we must have $f(x^*) = f^*$, which means that f^* is attained at some point. From the computation of critical values, we know $f^* \approx 0.8650$. For this polynomial, both the dense and sparse SOS relaxation are not exact: $f_\Delta^* < f_{sos}^* < f^*$, and the method in [28] gives the same lower bound f_Δ^*.

COROLLARY 3.6. *If all f_i are quadratic and condition* (3.9) *holds, then $f_{sos}^* = f_\Delta^*$.*

Proof. When all f_i are quadratic, i.e., $d_i = 1$, the entries of moment matrix $\mathcal{M}_1^{\Delta_i}$ are the first and second order moments. The positive semidefiniteness of $\mathcal{M}_1^{\Delta_i}$ implies $\mathcal{M}_1^{\Delta_i}$ has a representing measure. Then the conclusion is immediately implied by Theorem 3.3. ∎

Remark 3.7. If the running intersection condition (3.9) fails, then Corollary 3.6 is no longer true, as shown by the example below.

Example 3.8. Consider the polynomial $f(x) = f_1(x_1, x_2) + f_2(x_2, x_3) + f_3(x_1, x_3)$ where $f_1 = \frac{1}{2}(x_1^2 + x_2^2) + 2x_1x_2$, $f_2 = \frac{1}{2}(x_2^2 + x_3^2) + 2x_2x_3$, and $f_3 = \frac{1}{2}(x_1^2 + x_3^2) + 2x_1x_3$. In this case

$$\Delta_1 = \{1, 2\}, \quad \Delta_2 = \{2, 3\}, \quad \Delta_3 = \{1, 3\}.$$

The running intersection property (3.9) fails. But we have $f_\Delta^* = -\infty < f_{sos}^* = f^* = 0$.

3.3. Extraction of minimizers. In this subsection, we discuss how to extract minimizer(s) $x^* = (x_1^*, \ldots, x_n^*)$. Suppose $y^* = (y_\alpha^*)_{\alpha \in \mathcal{F}}$ is one optimal solution to (3.6)–(3.8). Let $\delta_i = \{i\}$ for every i. The entries of y^* whose indices are supported in δ_i are

$$y_0^*, y_{e_i}^*, y_{2e_i}^*, \ldots, y_{2de_i}^*,$$

which are the entries of the moment matrix $M_d^{\delta_i}(y^*)$. So coordinate x_i^* can be extracted from moment matrix $M_d^{\delta_i}(y^*)$ if it satisfies the flat extension condition. Let $\mathcal{V}_i$ be the set of all the points that can be extracted from the moment matrix $M_d^{\delta_i}(y^*)$. If $\mathcal{V}_i$ is a singleton, then x_i^* has a unique choice.

The situation is more subtle if some $\mathcal{V}_i$ has cardinality greater than one. Suppose for some $i, j \in [n]$ we have $|\mathcal{V}_i| > 1$ and $|\mathcal{V}_j| > 1$. Can $x_i^* x_j^*$ appear simultaneously in the optimal solution x^* for arbitrarily chosen $x_i^* \in \mathcal{V}_i$, $x_j^* \in \mathcal{V}_j$? The answer is obviously no! For instance, the polynomial

$$\left(x_1^2 - 1\right)^2 + \left(x_2^2 - 1\right)^2 + (x_1 - x_2)^2$$

has only two global minimizers $\pm(1,1)$. We find that $\mathcal{V}_1 = \mathcal{V}_2 = \{1,-1\}$. But obviously $(1,-1)$ and $(-1,1)$ are not global minimizers.

Now what is the rule for matching x_i^* and x_j^* if $|\mathcal{V}_i| > 1$ or $|\mathcal{V}_j| > 1$? So far we have not yet used the information of moment matrix $M_d^{\Delta_i}(y^*)$. If $M_d^{\Delta_i}(y^*)$ also satisfies the flat extension condition, we can extract the tuples $x_{\Delta_i}^* = (x_k^*)_{k\in\Delta_i}$ from $M_d^{\Delta_i}(y^*)$. Let $\mathcal{X}_{\Delta_i}$ be the set of all such tuples that can be extracted from $M_d^{\Delta_i}(y^*)$. One might ask whether $\mathcal{V}_i$ and $\mathcal{X}_{\Delta_i}$ are consistent, that is, does $x_{\Delta_i}^* \in \mathcal{X}_{\Delta_i}$ imply that $x_k^* \in \mathcal{V}_k$ for all $k \in \Delta_i$? Under the flat extension assumption, the answer is yes, which is due to the following theorem.

THEOREM 3.9. *Suppose y^* is one optimal solution to* (3.6)–(3.8) *such that all $M_d^{\Delta_i}(y^*)$ satisfy the flat extension condition. Then for any $x_{\Delta_i}^* \in \mathcal{X}_{\Delta_i}$, it holds that $x_k^* \in \mathcal{V}_k$ for all $k \in \Delta_i$.*

Proof. Let $\mathcal{X}_{\Delta_i} = \{x_{\Delta_i}^{(1)}, x_{\Delta_i}^{(2)}, \ldots, x_{\Delta_i}^{(r)}\}$ be the r-atomic representing support for $\mathcal{M}_d^{\Delta_i}(y^*)$. Then we have decomposition

$$M_d^{\Delta_i}(y^*) = \sum_{\ell=1}^{r} \lambda_\ell \, \mathbf{m}_2\left(x_{\Delta_i}^{(\ell)}\right) \mathbf{m}_2\left(x_{\Delta_i}^{(\ell)}\right)^T$$

for some $\lambda_1, \ldots, \lambda_r > 0, \sum_{\ell=1}^r \lambda_\ell = 1$. Notice that $M_d^{\delta_k}(y^*)$ is a principle submatrix of $M_d^{\Delta_i}(y^*)$. So we also have that for every $k \in \Delta_i$

$$M_d^{\delta_k}(y^*) = \sum_{\ell=1}^{r} \lambda_\ell \, \mathbf{m}_2\left(x_k^{(\ell)}\right) \mathbf{m}_2\left(x_k^{(\ell)}\right)^T.$$

This means that $\{x_k^{(1)}, x_k^{(2)}, \ldots, x_k^{(r)}\}$ is a r-atomic representing support for moment matrix $M_d^{\delta_k}(y^*)$ (some $x_k^{(\ell)}$ might be the same). By the definition of $\mathcal{V}_i$, we have $\{x_k^{(1)}, \ldots, x_k^{(r)}\} \subseteq \mathcal{V}_k$. ∎

THEOREM 3.10. *Suppose y^* is one optimal solution to* (3.6)–(3.8) *such that all $M_d^{\Delta_i}(y^*)$ satisfy the flat extension condition. Then any $x^* = (x_1^*, \ldots, x_n^*)$ with $x_k^* \in \mathcal{V}_k$ and $x_{\Delta_i}^* \in \mathcal{X}_{\Delta_i}$ for all k and i is a global optimal minimizer of $f(x)$.*

Proof. Fix x^* as in the theorem. Since $M_d^{\Delta_i}(y^*)$ satisfies the flat extension condition, we have the decomposition

$$M_d^{\Delta_i}(y^*) = \lambda_{\Delta_i} \mathbf{m}_d(x_{\Delta_i}^*)\mathbf{m}_2(x_{\Delta_i}^*)^T + \hat{M}_{\Delta_i},$$

where $1 \geq \lambda_{\Delta_i} > 0$ and $\hat{M}_{\Delta_i} \succeq 0$. Now let $\lambda = \min_i \lambda_{\Delta_i} > 0$ and

$$M_{\Delta_i} = (\lambda_{\Delta_i} - \lambda)\mathbf{m}_2(x_{\Delta_i}^*)\mathbf{m}_2(x_{\Delta_i}^*)^T + \hat{M}_{\Delta_i} \succeq 0.$$

Notice that $\hat{M}_{\Delta_i}$ and M_{Δ_i} are also moment matrices. Without loss of generality, we can assume $\lambda < 1$, since otherwise each $M_2^{\Delta_i}(y^*)$ has rank one and then x^* is obviously a global minimizer. For every $\alpha \in \mathcal{F}_i$, define $\hat{y}_\alpha = \left(x_{\Delta_i}^*\right)^\alpha$ and $\hat{y} = (\hat{y}_\alpha)_{\alpha\in\mathcal{F}}$. Let $\tilde{y} = (\tilde{y}_\alpha)_{\alpha\in\mathcal{F}}$ be the vector such that $y^* = \lambda\hat{y} + (1-\lambda)\tilde{y}$. Then it holds

$$M_d^{\Delta_i}(y^*) = \lambda M_d^{\Delta_i}(\hat{y}) + (1-\lambda) M_d^{\Delta_i}(\tilde{y}).$$

Obviously vector $\tilde{y}$ is feasible for (3.7)–(3.8) since

$$M_d^{\Delta_i}(\tilde{y}) = \frac{1}{1-\lambda}\left(M_d^{\Delta_i}(y^*) - \lambda M_d^{\Delta_i}(\hat{y})\right) = \frac{1}{1-\lambda} M_{\Delta_i} \succeq 0.$$

Since y^* is optimal, we can see $\sum_{\alpha\in\mathcal{F}} f_\alpha y_\alpha^* \le \sum_{\alpha\in\mathcal{F}} f_\alpha \hat{y}_\alpha$ and $\sum_{\alpha\in\mathcal{F}} f_\alpha y_\alpha^* \le \sum_{\alpha\in\mathcal{F}} f_\alpha \tilde{y}_\alpha$. By linearity, it holds

$$f_\Delta^* = \sum_{\alpha\in\mathcal{F}} f_\alpha y_\alpha^* = \lambda \sum_{\alpha\in\mathcal{F}} f_\alpha \hat{y}_\alpha + (1-\lambda) \sum_{\alpha\in\mathcal{F}} f_\alpha \tilde{y}_\alpha.$$

Therefore, we must have $\sum_{\alpha\in\mathcal{F}} f_\alpha \hat{y}_\alpha = f_\Delta^*$ since $0 < \lambda < 1$. On the other hand, by the definition of $\hat{y}$, we know $f(x^*) = \sum_{\alpha\in\mathcal{F}} f_\alpha \hat{y}_\alpha = f_\Delta^*$. Thus x^* is one point at which the polynomial $f(x)$ attains its lower bound f_Δ^*, which implies that x^* is a global minimizer of $f(x^*)$. □

The algorithm for minimizing $f(x)$ via sparse SOS relaxation (3.1)–(3.3) is as follows.

ALGORITHM 3.11 (Minimizing sum of polynomials).
Input: $n, m, \Delta_i, f_i(x_{\Delta_i})\,(i = 1, \ldots, m)$
Output: $\mathcal{V}_i$ *and* $\mathcal{X}_{\Delta_i}\,(i = 1, \ldots, m)$
Begin
Step 1: *Solve the dual problem* (3.6)–(3.8). *Get the optimal solution* y^*.
Step 2: *For each* $1 \le k \le n$, *find the set* $\mathcal{V}_k$ *of points that can be extracted from* $M_d^{\delta_k}(y^*)$.
Step 3: *For every* k *with* $|\mathcal{V}_k| > 1$, *find the set* $\mathcal{X}_{\Delta_i}$ *from* $M_d^{\Delta_i}(y^*)$ *whenever* $k \in \Delta_i$.
End

As an example, let us illustrate how to solve the global optimization problem

$$\min_{x\in\mathbb{R}^3} \quad \underbrace{\left(x_1^2 - 1\right)^2 + (x_1 - x_2)^4}_{f_1(x_{\Delta_1})} + \underbrace{(x_2 - x_3)^4}_{f_2(x_{\Delta_2})}$$

and find global minimizers. Here $\Delta_1 = \{1, 2\}$ and $\Delta_2 = \{2, 3\}$. Solve the dual problem (3.6)–(3.8) and we get solutions

$$\mathcal{M}_1^{\Delta_1}(y^*) = \mathcal{M}_1^{\Delta_2}(y^*) = \begin{bmatrix} 1 & 0 & 0 & 1 & 1 & 1 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 1 & 1 & 1 \end{bmatrix}.$$

Both $\mathcal{M}_1^{\Delta_1}(y^*)$ and $\mathcal{M}_1^{\Delta_2}(y^*)$ have rank two and satisfy the flat extension condition. Using the technique from [9], we can extract

$$\mathcal{V}_1 = \mathcal{V}_2 = \mathcal{V}_3 = \{-1, 1\}$$

and

$$\mathcal{X}_{\Delta_1} = \left\{ \begin{bmatrix} -1 \\ -1 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \end{bmatrix} \right\}, \quad \mathcal{X}_{\Delta_2} = \left\{ \begin{bmatrix} -1 \\ -1 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \end{bmatrix} \right\}.$$

Since the x_2-component from $\mathcal{X}_{\Delta_1}$ and $\mathcal{X}_{\Delta_2}$ must be the same, we know there are two global minimizers $x^* = \pm(1, 1, 1)$.

3.4. Nonlinear least squares problems. Now we consider the special case that each $f_i(x_{\Delta_i})$ is a square of some polynomial, say, $f_i(x_{\Delta_i}) = g_i^2(x_{\Delta_i})$. Then the global minimization of $f(x) = \sum_i f_i(x_{\Delta_i})$ is equivalent to solving the nonlinear least squares (NLS) problem associated with the polynomial system:

$$g_1(x_{\Delta_1}) = g_2(x_{\Delta_2}) = \cdots = g_m(x_{\Delta_m}) = 0. \tag{3.10}$$

In this situation, the polynomial function is often nonconvex and it is very difficult for general numerical optimization schemes like branch-bound to find the global minimizer of $f(x)$.

THEOREM 3.12. *If the polynomial system* (3.10) *admits a solution, then the sparse SOS relaxation* (3.1)–(3.3) *is exact; i.e.,* $f_\Delta^* = f_{sos}^* = f^*$.

Proof. Obviously $f^* = 0$. And $\gamma = 0$ is a feasible solution to problem (3.1)–(3.3), since $f(x)$ itself is a sparse SOS representation as in (3.2)–(3.3). So $f_\Delta^* \geq 0$, and hence all the inequalities in the Theorem 3.1 become equalities. ∎

Remark 3.13. When the polynomial system (3.10) admits a solution, we necessarily have $f^* = 0$. This might be trivial in some sense. However, the optimal solution y^* to the dual problem (3.6)–(3.8) can help recover the real zeros of polynomial system (3.10), which are absolutely the global minimizers of $f(x)$. See the example below.

Example 3.14. Consider the sparse polynomial system

$$\begin{aligned} 2x_1^2 - 3x_1 + 2x_2 - 1 &= 0, \\ 2x_i^2 + x_{i-1} - 3x_i + 2x_{i+1} - 1 &= 0\,(i = 2, \ldots, n-1), \\ 2x_n^2 + x_{n-1} - 3x_n - 1 &= 0. \end{aligned}$$

This polynomial system is consistent and has at least two real solutions. Set $n = 20$. We apply sparse SOS relaxation (3.1)–(3.3) to solve the least squares problem and get the lower bound $f_\Delta^* \approx -2.0 \cdot 10^{-11}$. Using the optimal dual solution, we obtain two real solutions (only the first four digits are shown):

$\hat{x} = (1.8327,\ -0.1097,\ -0.5929,\ -0.6860,\ -0.7032,\ -0.7064,\ -0.7070,\ -0.7071,\ -0.7071,\ -0.7071,$
$-0.7071,\ -0.7070,\ -0.7068,\ -0.7064,\ -0.7051,\ -0.7015,\ -0.6919,\ -0.6658,\ -0.5960,\ -0.4164)$
$\tilde{x} = (-0.5708,\ -0.6819,\ -0.7025,\ -0.7063,\ -0.7070,\ -0.7071,\ -0.7071,\ -0.7071,\ -0.7071,\ -0.7071,$
$-0.7071,\ -0.7070,\ -0.7068,\ -0.7064,\ -0.7051,\ -0.7015,\ -0.6919,\ -0.6658,\ -0.5960,\ -0.4164).$

3.5. A sparser SOS relaxation. From Theorem 3.12, we know the sparse SOS relaxation (3.1)–(3.3) is exact whenever the polynomial system (3.10) admits a solution, and the optimal dual solution can help recover the real zeros. This fact makes it possible to exploit the sparsity of each $f_i(x_{\Delta_i})$ further. In (3.1)–(3.3), we assume each $f_i(x_{\Delta_i})$ is a dense polynomial. However, if each $f_i(x_{\Delta_i})$ is sparse, we can get a sparser SOS relaxation. It is obvious that

$$\operatorname{supp}(f_i) \subseteq \mathcal{G}_i + \mathcal{G}_i,$$

where $\mathcal{G}_i$ is the convex hull of $\{\alpha \in \mathbb{N}^n : 2\alpha \in \operatorname{supp}(f_i)\}$. This motivates us to propose the sparser SOS relaxation

$$f_{\Delta_s}^* := \max \quad \gamma \tag{3.11}$$

$$s.t. \quad f(x) - \gamma = \sum_{i=1}^{m} \mathbf{m}_{\mathcal{G}_i}(x)^T W_i \mathbf{m}_{\mathcal{G}_i}(x), \tag{3.12}$$

$$W_i \succeq 0,\ i = 1, \ldots, m. \tag{3.13}$$

Here $\mathbf{m}_{\mathcal{G}_i}(x_{\Delta_i})$ is the column vector of all monomials in x with exponents from $\mathcal{G}_i$. The size of matrix W_i is equal to the cardinality of $\mathcal{G}_i$. Similar to (3.1)–(3.3), the dual of (3.11)–(3.13) can be derived to be

$$f^*_{\Sigma_s} := \min \quad \sum_\alpha f_\alpha y_\alpha \tag{3.14}$$

$$s.t. \quad \mathcal{M}_{\mathcal{G}_i}(y) \succeq 0,\ i = 1, \ldots, m, \tag{3.15}$$

$$y_0 = 1. \tag{3.16}$$

Here the sparse moment matrix $\mathcal{M}_{\mathcal{G}_i}(y)$ is indexed by vectors from $\mathcal{G}_i$ and defined as

$$\mathcal{M}_{\mathcal{G}_i}(y)(\alpha, \beta) = y_{\alpha+\beta}$$

for all $\alpha, \beta \in \mathcal{G}_i$.

THEOREM 3.15. *The optimal values $f^*_{\Sigma_s}$, $f^*_{\Delta_s}$, f^*_{Σ}, f^*_{Δ}, f^*_{sos} and f^* satisfy the relationship*

$$f^*_{\Sigma_s} = f^*_{\Delta_s} \le f^*_{\Sigma} = f^*_{\Delta} \le f^*_{sos} \le f^*.$$

Proof. Applying the standard duality theory in convex programming as in the proof of Theorem 3.1, we can get the first equality from the left by proving (3.12)–(3.13) has a strict interior point. Since the relaxation (3.11)–(3.13) is a special case of (3.1)–(3.3), we obtain the first inequality from the left. The other relations follow Theorem 3.1. □

THEOREM 3.16. *Suppose $f_i(x_{\Delta_i}) = g_i^2(x_{\Delta_i})$. If the polynomial system* (3.10) *admits a solution, then the sparse SOS relaxation* (3.11)–(3.13) *is exact, i.e., $f^*_{\Delta_s} = f^*_{sos} = f^*$.*

Proof. The proof is almost the same as for Theorem 3.12. Obviously $f^* = 0$. And $\gamma = 0$ is a feasible solution, since $f(x)$ itself is a sparse SOS representation as in (3.12)–(3.13). So $f^*_{\Delta_s} \ge 0$, and hence all the inequalities in the Theorem 3.15 become equalities. □

Remark 3.17. When the polynomial system (3.10) admits a solution, we must have $f^* = 0$. This lower bound itself might not be interesting. However, the optimal dual solution y^* to (3.14)–(3.16) can help recover the real zeros of polynomial system (3.10), which are absolutely the global minimizers of $f(x)$. This observation is very important and has many applications. See examples in subsection 5.1.

4. Numerical examples. In this section, we present some numerical experiments using sparse SOS relaxations (3.1)–(3.3) and (3.11)–(3.13). First, we use them to solve some test problems from unconstrained optimization. Second, we generate various random polynomials, test the performance of these sparse SOS relaxations, and compare with other methods. All the computations are implemented on a Linux machine with 0.98 GB memory and 1.46 GHz CPU. The SOS relaxations are solved by the software *SeDuMi* [27] using the *YALMIP* [17] interface. Throughout this section, the computation time is in CPU seconds. The accuracy of relaxations is measured by $\frac{|f(\hat{x})-\hat{f}|}{\max\{1,|f(\hat{x})|\}}$, where $\hat{x}$ is one extracted solution and $\hat{f}$ is the computed lower bound.

4.1. Some global optimization test problems. In this subsection, we apply SOS relaxations (3.1)–(3.3) and (3.11)–(3.13) to solve some global optimization test problems from [6, 18, 19]. The relaxation (3.1)–(3.3) is usually applied when each $f_i(\Delta_i)$ is almost dense, and the sparser relaxation (3.11)–(3.13) is usually applied

TABLE 1
The performance of sparse SOS relaxation (3.1)–(3.3).

	Chained singular		Chained wood		Gen. Rosen.

200	3.0e − 10	5.29	3.7e − 10	2.25	1.8e − 7	1.46
300	5.0e − 09	8.01	3.8e − 10	3.19	2.7e − 7	2.24
400	5.0e − 10	11.64	3.9e − 10	4.12	3.6e − 7	2.88
500	4.9e − 09	33.09	3.9e − 10	5.12	4.5e − 7	3.45

when each $f_i(\Delta_i)$ is sparse. All the test functions in this subsection have global minimum $f^* = 0$. So we use the absolute value of the lower bounds f^*_Δ or $f^*_{\Delta_s}$ to measure the accuracy of the relaxation.

First, consider the following test functions.

- The chained singular function [6]:

$$f(x) = \frac{1}{10^5}\sum_{i\in J}\big((\,x_i + 10x_{i+1})^2 + 5(x_{i+2} - x_{i+3})^2 + (x_{i+1} - 2x_{i+2})^4 + 10(x_i - 10x_{i+3})^4\big)$$

  where $J = \{1, 3, 5, \ldots, n-3\}$ and n is a multiple of 4. The factor $\frac{1}{10^5}$ is used to scale the coefficients to avoid numerical troubles.

- The chained wood function [6]

$$f(x) = \sum_{i\in J}\big(\,100\left(x_{i+1} - x_i^2\right)^2 + (1 - x_i)^2 + 90\left(x_{i+3} - x_{i+2}^2\right)^2 + (1 - x_{i+2})^2 + 10(x_{i+1} + x_{i+3} - 2)^2 + 0.1(x_{i+1} - x_{i+3})^2\big)$$

  where $J = \{1, 3, 5, \ldots, n-3\}$ and n is a multiple of 4.

- The generalized Rosenbrock function [19]:

$$f(x) = \sum_{i=2}^{n}\left\{100\left(x_i - x_{i-1}^2\right)^2 + (1 - x_i)^2\right\}.$$

We apply SOS relaxation (3.1)–(3.3) to minimize these polynomial functions. The relaxation (3.1)–(3.3) is solved by the software *SeDuMi* using the *YALMIP* interface. The accuracy and consumed CPU time are in Table 1. The problems are solved from size 100 to 500. For these polynomials, the relaxation (3.1)–(3.3) is almost the same as the one in [28]. This is because the csp graphs of these polynomials are chordal graphs. However, if the csp graphs are sparse but their chordal extensions are much dense, then the relaxation in [28] is very similar to the dense SOS relaxation. In such situations, the relaxation (3.1)–(3.3) might be more suitable. For example, to minimize the sparse polynomial

$$\left(x_1^2 + x_2^2 - 1\right)^2 + \left(x_2^2 + x_3^2 - 1\right)^2 + \cdots + \left(x_{n-1}^2 + x_n^2 - 1\right)^2 + \left(x_n^2 + x_1^2 - 1\right)^2,$$

the chordal extension of the csp graph is the complete graph, and hence the sparse SOS relaxation using chordal extension is the same as the dense SOS relaxation. However, the sparse relaxation (3.1)–(3.3) is very suitable for this problem.

TABLE 2
The performance of sparse SOS relaxation (3.11)–(3.13).

Broyden tridiagonal			Broyden banded			Disc. bound val.		
n	accu.	time	n	accu.	time	n	accu.	time
100	1.2e − 7	2.65	10	3.6e − 11	9.72	10	6.0e − 12	0.92
200	2.3e − 7	2.69	15	2.2e − 10	17.28	20	3.4e − 11	1.57
300	5.0e − 7	3.58	20	1.6e − 10	25.27	25	1.6e − 11	2.28
400	3.0e − 6	4.53	25	1.8e − 10	35.19	30	1.1e − 11	2.47
500	4.1e − 6	5.44	30	4.9e − 10	45.30	35	3.9e − 11	3.00

Second, consider the following test functions.

- Broyden tridiagonal function [18]:

$$f(x) = \sum_{i=1}^{n} \left((3 - 2x_i)x_i - x_{i-1} - 2x_{i+1} + 1\right)^2,$$

  where $x_0 = x_{n+1} = 0$.
- Broyden banded function [18]:

$$f(x) = \sum_{i=1}^{n} \left(x_i \left(2 + 10x_i^2\right) + 1 - \sum_{j \in J_i} (1 + x_j)x_j \right)^2,$$

  where $J_i = \{j : j \neq i, \max(1, i-5) \leq j \leq \min(n, i+1)\}$.
- Discrete boundary value function [6]:

$$f(x) = \sum_{i=1}^{n} \left(2x_i - x_{i-1} - x_{i+1} + \frac{1}{2} h^2 (x_i + t_i + 1)^3 \right)^2,$$

  where $h = \frac{1}{n+1}$, $t_i = ih$, and $x_0 = x_{n+1} = 0$.

These three polynomials have sparse summand polynomial $f^*_{\Delta_i}$. So we apply the sparser SOS relaxation (3.11)–(3.13) and solve it by the software *SeDuMi* using the *YALMIP* interface. The computational results are in Table 2. All the problems are solved quite well in a few seconds.

For the Broyden tridiagonal function, we can also apply the sparse relaxation (3.1)–(3.3) or chordal extension from [28]. They are slightly more expensive. For $n = 500$, the problem can be solved in about ten seconds with similar accuracy. However, for the Broyden banded function and discrete boundary value function, the relaxation (3.1)–(3.3) and the method in [28] are much more expensive. For instance, when n has values 10 or bigger, they are usually difficult to implement due to computer memory restrictions.

We should mention that the Broyden banded function and discrete boundary value function have different representations as sums of small polynomials. For instance, if we expand all the squares, then they are sums of small polynomials which all have only two variables. However, the sparse SOS relaxations based on these new representations are usually too loose and not useful in practice, because they are very likely to be primarily infeasible and often no lower bounds can be obtained.

One interesting observation in Table 2 is that the accuracy for the Broyden tridiagonal function is not as high as for the other two functions. One possible reason is that the global minimizer of Broyden tridiagonal function is not unique and there

TABLE 3
Computational results for quartic polynomials with different sizes.

	$\|\Delta\| = 3$				$\|\Delta\| = 4$			
	CPU seconds			accu	CPU seconds			accu
n	max	avr.	min	max	max	avr.	min	max
20	0.85	0.62	0.54	4.1e − 9	1.46	1.15	0.91	2.4e − 9
40	1.22	1.07	0.91	1.9e − 9	2.86	2.49	2.25	2.9e − 9
60	1.80	1.55	1.45	2.9e − 9	4.43	4.17	3.91	3.1e − 9

100	3.02	2.70	2.33	2.8e − 9	7.85	7.41	7.01	5.0e − 9

are additional numerical troubles caused from extracting minimizers. This illustrates that the computation is more numerically difficult when there are multiple global solutions.

4.2. Randomly generated test problems. In this subsection, we present the computational results for randomly generated polynomials. The aim is to test the performance of the sparse SOS relaxation (3.1)–(3.3) for minimizing random polynomials and compare with other sparse SOS methods. For these randomly generated polynomials, solve the sparse relaxation (3.1)–(3.3) by the software *SeDuMi* using the *YALMIP* interface. Then we get lower bounds f_Δ^* and extract minimizers $\hat{x}$. Since we do not know the true global minimizers in advance, the accuracy of $\hat{x}$ can be measured by $err = \frac{|f(\hat{x})-f_\Delta^*|}{\max\{1,|f(\hat{x})|\}}$. The smaller err is, the more accurate $\hat{x}$ is, since f_Δ^* is a guaranteed lower bound.

4.2.1. Randomly generated sums of small polynomials. In this subsubsection, we randomly generate sparse polynomials $f(x)$ of the form (1.1) and use them to test the performance of the sparse relaxation (3.1)–(3.3). Then the csp graph of $f(x)$ is usually not chordal, and its chordal extension is often much less sparse. So the method in [28] is usually expensive for these polynomials. We let $m = n$ and choose f_i to have the form

$$f_i(x_{\Delta_i}) = \mathbf{m}_d(x_{\Delta_i})^T \cdot A_i \cdot \mathbf{m}_d(x_{\Delta_i}) + b_i^T \mathbf{m}_{2d-1}(x_{\Delta_i}),$$

where Δ_i are chosen to be random subsets of $[n]$ with cardinality at most $\|\Delta\|$. Here $N_i = \binom{|\Delta_i|+d}{d}$, $A_i = nI_{N_i} + BB^T$, $B \in \mathbb{R}^{N_i \times N_i}$, and $b_i \in \mathbb{R}^{\binom{|\Delta_i|+d-1}{d-1}}$ are random. So each A_i is positive definite. This choice guarantees that the global minimizers of $f(x)$ are contained in some compact set.

First, let $2d = 4$ and n be $20, 40, 60, 80, 100$. For each $\|\Delta\|$ (3 or 4) and n, we generate 100 random polynomials in the way described above. For each one, we solve the sparse SOS relaxation (3.1)–(3.3) by the software *SeDuMi* using the *YALMIP* interface, and get the lower bound f_Δ^* and optimal dual solution $\hat{y}$. For all these randomly generated polynomials, the moment matrices $\mathcal{M}_d^{\Delta_i}(\hat{y})$ have numerical rank one. So we can easily extract the minimizer $\hat{x}$. The maximum, average, and minimum of consumed CPU time are in Table 3. For these random polynomials, we just record the maximum error of the extracted minimizers. From Table 3, for $\Delta = 4$, we can find the global minimizer of a quartic sparse polynomial of 100 variables with error $O(10^{-9})$ within about 8 CPU seconds.

Second, let $n = 30$ and $2d$ be $4, 6, 8$. For each $\|\Delta\|$ (3 or 4) and $2d$, we generate 100 random polynomials in the way described in the above. For each one, solve the sparse SOS relaxation (3.1)–(3.3) by the software *SeDuMi* using the *YALMIP* interface,

TABLE 4
Computational results for polynomials of size $n = 30$ with different degrees.

	$\|\Delta\| = 3$				$\|\Delta\| = 4$			
	CPU seconds			err	CPU seconds			err
$2d$	max	avr	min	max	max	avr	min	max
4	1.01	0.87	0.77	2.5e − 9	2.33	1.93	1.65	2.4e − 9
6	3.22	2.96	2.67	1.8e − 9	17.16	14.92	11.71	2.2e − 9
8	13.07	11.44	10.13	1.7e − 8	136.67	119.90	107.28	9.4e − 8

and get the lower bounds f_Δ^* and optimal dual solution $\hat{y}$. Similarly, all moment matrices $\mathcal{M}_d^{\Delta_i}(\hat{y})$ have rank one, and the minimizer $\hat{x}$ can be extracted easily. The maximum, average, and minimum of the consumed CPU time, and the maximum error of extracted minimizers are in Table 4. For $\|\Delta\| = 4$, the global minimizer of such generated polynomials of degree 8 and 30 variables can be found with error $O(10^{-8})$ within about 120 seconds.

We remark that the sparsity technique in [28] is too expensive to be implementable for minimizing these random polynomials generated in the way as above because of computer memory limitations. For these random polynomials, the sparsity technique using chordal extension is almost as expensive as the general dense SOS relaxation. This is because the chordal extensions of csp graphs of these polynomials are usually much more dense than the original csp graphs. However, as we have seen in the above, the SOS relaxation (3.1)–(3.3) is very suitable for these polynomials.

4.2.2. Random sparse polynomials with given chordal extension. In this subsubsection, we generate random sparse polynomials in a similar way as in [28], and compare the performance of our sparse SOS relaxation (3.1)–(3.3) with the one in [28] using chordal extension. Generate a chordal graph randomly such that the size of every maximal clique is at most 6. Let $\{C_1, \ldots, C_m\}$ be the set of maximal cliques. If we choose $\Delta_i = C_i$, then the sparse SOS relaxation (3.1)–(3.3) is the same as the one using chordal extension. Therefore, to make a reasonable comparison, for each C_i, we choose a random subset $\Delta_i \subseteq C_i$. Choose each small polynomial f_i to have the form

$$f_i(x_{\Delta_i}) = \mathbf{m}_d(x_{\Delta_i})^T \cdot A_i \cdot \mathbf{m}_d(x_{\Delta_i}) + b_i^T \mathbf{m}_{2d-1}(x_{\Delta_i}).$$

Here $N_i = \binom{|\Delta_i|+d}{d}$, $A_i = nI_{N_i} + BB^T$, $B \in \mathbb{R}^{N_i \times N_i}$, and $b_i \in \mathbb{R}^{\binom{|\Delta_i|+d-1}{d-1}}$ are random. The global minimizers of $f(x) = \sum_i f_i(x_{\Delta_i})$ generated as above always exist and are contained in some compact set.

For polynomials randomly generated as above, the technique in [28] using chordal extension is a good choice, because there exists one sparse chordal extension of the csp graph. Now we compare the computational results for these two methods.

First, let $2d = 4$ and n be $20, 40, 60, 80, 100$. For each n, generate 50 random polynomials as above. For each of these random polynomials, solve the relaxation (3.1)–(3.3), find a chordal extension of the csp graph of $f(x)$, and then apply the sparse relaxation in [28]. Both relaxations are solved by the software *SeDuMi* using the *YALMIP* interface. Then we extract minimizers $\hat{x}$ from moment matrices. The computational results are in Table 5. For these solved problems, we just record the maximum error of the relaxation. Second, let $n = 30$ and $2d$ be $4, 6, 8$. For each $2d$, generate 50 random polynomials as above. For each one, solve the problem by the relaxation (3.1)–(3.8) and the one in [28] using chordal extension. They are solved by

TABLE 5
Comparison with chordal extension on quartic polynomials.

	Relaxation (3.1)–(3.3)				Relaxation using chordal extension

the software *SeDuMi* using the *YALMIP* interface. The computational results are in Table 6.

From Tables 5 and 6, we observe that for polynomials randomly generated as above the sparse SOS relaxation (3.1)–(3.3) is slightly more computationally efficient than the one using chordal extension. As we can see, for these random polynomials, there is not much difference between the qualities of these two kinds of sparse SOS relaxations. The distinction between their qualities depends on specific problems. Of course, theoretically the sparse relaxation using chordal extension in [28] is at least as tight as the relaxation (3.1)–(3.3).

4.2.3. Random dense polynomials. In this subsubsection, we test the performance of our sparse SOS relaxation on minimizing general dense polynomials. We observe that every polynomial $f(x)$ is a summation of monomials whose number of variables is at most the degree $\deg(f)$. So the sparse SOS relaxation (3.1)–(3.3) is attractive when the degree $2d$ is small like 4. We generate the random dense polynomials as follows:

$$f(x) = \mathbf{m}_d(x)^T \cdot A \cdot \mathbf{m}_d(x) + b^T \mathbf{m}_{2d-1}(x).$$

Here $N = \binom{n+d}{d}$, $A = nI_N + BB^T$, $B \in \mathbb{R}^{N\times N}$ is a random matrix, and $b \in \mathbb{R}^{\binom{n+2d-1}{n}}$ is a random vector. So the global minimizers of $f(x)$ generated this way are contained in some compact set. Note that $f(x)$ is also a summation of small polynomials. Let Δ_i be the subsets of $[n]$ with cardinality $2d$. Then we can write

$$f(x) = \sum_{i=1}^{\binom{n}{2d}} f_i(x_{\Delta_i})$$

for some small polynomials $f_i(x_{\Delta_i})$.

Since $\|\Delta\| = 2d$, which should not be big for the effectiveness of the sparse relaxation (3.1)–(3.3), we test for the case that $2d = 4$. Let n be $16, 17, 18, 19, 20, 21, 22, 23$. For each pair (n, d) of these values, generate 50 random examples as above. For each

random polynomial, solve the sparse relaxation (3.1)–(3.3) by the software *SeDuMi* using the *YALMIP* interface. The consumed CPU time and the accuracy of relaxation are in Table 7. We can see that the obtained solutions are very good within reasonably acceptable time. When $n \geq 24$, the sparse relaxation (3.1)–(3.3) is then also too expensive to be implementable due to computer memory restrictions.

For these randomly generated dense polynomials, the general dense SOS relaxation and sparse SOS relaxations like in [28] are not implementable for $n \geq 16$, due to either computer memory shortage or unacceptable long running time. However, when $2d$ is small like 4, the sparse SOS relaxation (3.1)–(3.3) can solve bigger dense polynomial optimization problems which can not be solved by other methods.

5. Applications. Minimizing a summation of small polynomials arises in various applications. Many big polynomials in applications often come in this form. In such situations, the sparse SOS relaxation (3.1)–(3.3) or (3.11)–(3.13) is very useful. In this section, we show some applications in solving sparse polynomial systems and sensor network localization.

5.1. Solving sparse polynomial system. Suppose we are trying to solve the sparse polynomial system

$$g_1(x_{\Delta_1}) = 0,\, g_2(x_{\Delta_2}) = 0,\, \ldots,\, g_m(x_{\Delta_m}) = 0.$$

In some applications, these equations are redundant or even inconsistent. When the polynomial system does not admit a solution, we want to seek a least squares solution, which is often useful in applications.

This problem can be formulated as finding the global minimizer of the sparse polynomial

$$f^* := \min_{x\in\mathbb{R}^n} f(x) = \sum_{i=1}^{m} g_i^2(x_{\Delta_i}).$$

The polynomial system has a real zero if and only if $f^* = 0$. When $f^* = 0$, the global minimizers are precisely the real zeros of the polynomial system. When $f^* > 0$, the global minimizers are the least squares solutions.

One important sparse polynomial system of the above form is from computing the numerical solutions of nonlinear differential equations. Consider the two-point BVP

$$F(t, x, x', x'') = 0,\;\; x(a) = \alpha,\, x(b) = \beta,$$

where $F(t, x, x', x'')$ is a polynomial function in t, x, x', x''. To find the numerical solution, the central difference approximation with a uniform mesh is often used to discretize the derivatives. Let N be a positive integer and set $h = \frac{b-a}{N+1}$. Then we get

TABLE 8
The performance of (3.11)–(3.13) *solving the equations in Example* 5.1.

N	Eqn. error	$\|x_k - x(t_k)\|_\infty$	$\|x_k - x(t_k)\|_\infty / h^2$	Time

100	1.8628e − 06	8.1425e − 04	8.3062e + 00	8.79

polynomial difference equations

$$F\left(t_k, x_k, \frac{x_{k+1} - x_{k-1}}{2h}, \frac{x_{k-1} - 2x_k + x_{k+1}}{h^2}\right) = 0,\ k = 1, \ldots, N,$$

where $x_0 = \alpha$, $x_{N+1} = \beta$, and $t_k = a + hk$. Every polynomial on the left involves 2 or 3 variables x_{k-1}, x_k, x_{k+1}. So this is a sparse polynomial system. There are several methods for solving this kind of polynomial system, like Newton's method and homotopy methods. Newton's method is very fast, but often require an accurate initial guess. Homotopy methods do not require a "satisfactory" guess and work well for small N, but are expensive to implement for large N. We refer to [1] and the references therein for work in this area. When N is large, this polynomial system is large but sparse. We solve this system by applying the sparse SOS relaxation (3.11)–(3.13) for big N (up to 100 or even bigger).

Example 5.1 ([1]). Consider a basic BVP

$$x'' - 2x^3 = 0,\ \ x(0) = \frac{1}{2},\ x(1) = \frac{1}{3}.$$

The exact solution to this problem is $x(t) = \frac{1}{t+2}$. Now we discretize the differential equation with mesh size $h = \frac{1}{N+1}$, then get the difference equation

$$\begin{aligned} \frac{1}{2} - 2x_1 + x_2 - 2h^2 x_1^3 &= 0, \\ x_{k-1} - 2x_k + x_{k+1} - 2h^2 x_k^3 &= 0,\ k = 2, \ldots, N-1 \\ x_{N-1} - 2x_N + \frac{1}{3} - 2h^2 x_N^3 &= 0. \end{aligned}$$

This is a polynomial system about $x_1, x_2, \ldots, x_N$. We can solve this polynomial system as a nonlinear least squares problem by applying sparse SOS relaxation (3.11)–(3.13). The computational results are in Table 8. The equation error is defined to be the infinity norm of the residuals of the left-hand side of the polynomial system, which measures the quality of how the polynomial systems are solved. The obtained solutions have equation error from $\mathcal{O}(10^{-6})$ to $\mathcal{O}(10^{-7})$. If we want to make them more accurate, they can be used as the initial guesses in Newton's methods for refining. The accuracy of the discretization is defined to be the difference between computed solution x_k and true solution $x(t_k) = \frac{1}{2+t_k}$ where $t_k = \frac{k}{N+1}$. Since the discretization

has error $\mathcal{O}(h^2)$, we expect that $\|x_k - x(t_k)\|_\infty/h^2$ is a constant. When $N \le 40$, we can see that $\|x_k - x(t_k)\|_\infty/h^2$ is almost constant. When $N \ge 50$, *SeDuMi* experienced numerical troubles, and the returned solutions are not as accurate as for the smaller Ns. This explains why $\|x_k - x(t_k)\|_\infty$ and $\|x_k - x(t_k)\|_\infty/h^2$ becomes bigger for $N \ge 50$. Time records the CPU seconds consumed by the SDP solver *SeDuMi*. For $N = 100$, the computation takes less CPU time than for $N = 80$ or $N = 90$. This is because the numerical troubles make *SeDuMi* terminate earlier.

Example 5.2. Consider another BVP

$$x'' + \frac{1}{2}(x+t)^3 = 0, \;\; x(0) = 0, \, x(1) = 0.$$

Now we discretize the differential equation with mesh size $h = \frac{1}{N+1}$ and get the difference equation

$$\begin{aligned} 2x_1 - x_2 + \frac{1}{2}h^2(x_1 + t_1)^3 &= 0, \\ 2x_i - x_{i-1} - x_{i+1} + \frac{1}{2}h^2(x_i + t_i)^3 &= 0, \, i = 2, \dots, N-1, \\ 2x_N - x_{N-1} + \frac{1}{2}h^2(x_N + t_N)^3 &= 0. \end{aligned}$$

This is a polynomial system about $x_1, x_2, \dots, x_N$. We can solve this polynomial system as a nonlinear least squares problem by applying sparse SOS relaxation (3.11)–(3.13). When $N = 30$, we get the following real solution within about 2.5 CPU seconds (only the first four digits are shown):

$$\begin{aligned} &(-0.0159, \, -0.0312, \, -0.0459, \, -0.0600, \, -0.0735, \, -0.0864, \, -0.0985, \, -0.1099, \, -0.1205, \, -0.1302, \\ &\, -0.1391, \, -0.1470, \, -0.1540, \, -0.1599, \, -0.1646, \, -0.1682, \, -0.1705, \, -0.1715, \, -0.1710, \, -0.1689, \\ &\, -0.1651, \, -0.1596, \, -0.1521, \, -0.1425, \, -0.1307, \, -0.1164, \, -0.0995, \, -0.0796, \, -0.0567, \, -0.0302). \end{aligned}$$

For solving polynomial systems arising from BVPs, the sparse SOS method based on chordal extension like in [28] and (3.1)–(3.3) have similar performance, because the csp matrices are banded and the Cholesky factors are sparse. But they are much more expensive than the further sparse SOS relaxation (3.11)–(3.13). This is because (3.11)–(3.13) has further used the sparsity of each small polynomial $g_i(x_{\Delta_i})$ resulting from BVPs.

5.2. Sensor network localization. The *sensor network location* problem is basically described as follows: find a sequence of unknown vectors $x_1, x_2, \dots, x_n \in \mathbb{R}^k (k = 1, 2, \dots)$ (they are called *sensors*) such that distances between these sensors and some other known vectors $a_1, \dots, a_m$ (they are called *anchors*) are equal to some given numbers. Now each x_i itself is a k-dimensional vector. To be more specific, let $\mathcal{A} = \{(i,j) \in [n] \times [n] : \, i < j, \, \|x_i - x_j\|_2 = d_{ij}\}$, and $\mathcal{B} = \{(i,k) \in [n] \times [m] : \, \|x_i - a_k\|_2 = e_{ik}\}$, where d_{ij}, e_{ik} are given distances. Then the sensor network localization problem is to find vectors $x_1, x_2, \dots, x_n$ such that $\|x_i - x_j\|_2 = d_{ij}$ for all $(i,j) \in \mathcal{A}$ and $\|x_i - a_k\|_2 = e_{ik}$ for all $(i,k) \in \mathcal{B}$. Notice that $\mathcal{A}$ and $\mathcal{B}$ give only some partial pairs of distances. $\mathcal{A}$ does not contain all the pairs (i,j) such that $i < j$, and neither does $\mathcal{B}$.

Sensor network localization is also known as the *graph realization problem* or the *distance geometry problem*. Given a graph $G = (V, E)$ along with a real number associated with each edge, graph realization is to assign each vertex a coordinate so that the Euclidean distance between any two adjacent vertices is equal to the real number associated with that edge.

The locations of sensors can be determined from the polynomial system

$$\|x_i - x_j\|_2^2 = d_{ij}^2, \forall\, (i,j) \in \mathcal{A},$$
$$\|x_i - a_k\|_2^2 = e_{ik}^2, \forall\, (i,k) \in \mathcal{B}.$$

Usually solving this polynomial system directly is very expensive. Here we solve this polynomial system as a nonlinear least squares problem. Minimize the quartic polynomial function

$$f(x) := \sum_{(i,j)\in\mathcal{A}} \left(\|x_i - x_j\|_2^2 - d_{ij}^2\right)^2 + \sum_{(i,k)\in\mathcal{B}} \left(\|x_i - a_k\|_2^2 - e_{ik}^2\right)^2, \tag{5.1}$$

where $x = [\,x_1, \ldots, x_n]$. x^* is a solution to sensor network localization problem if and only if x^* is a global minimizer of $f(x)$ such that $f(x^*) = 0$. When x^* is a global minimizer such that $f(x^*) > 0$, the distances $d_{i,j}$ and e_{ik} are not consistent, and x^* is a solution in the least squares sense. This polynomial $f(x)$ is of the form (1.1), and our sparse SOS relaxation (3.1)–(3.3) can be applied to solve the problem.

We randomly generate test problems which are similar to those given in [5]. First, we randomly generate $n = 500$ sensor locations $x_1^*, \ldots, x_n^*$ from the unit square $[-0.5, 0.5] \times [-0.5, 0.5]$. The anchors $\{a_1, a_2, a_3, a_4\}\,(m = 4)$ are chosen to be four fixed points $(\pm 0.45, \pm 0.45)$. Choose edge set $\mathcal{A}$ such that for every sensor x_i^* there are at most 10 sensors $x_j^*\,(j > i)$ with $(i,j) \in \mathcal{A}$ and $\|x_i^* - x_j^*\|_2 \le 0.3$. For every $(i,j) \in \mathcal{A}$, compute the distance $\|x_i^* - x_j^*\|_2 = d_{ij}$. Choose edge $\mathcal{B}$ such that every anchor is connected to all the sensors within distance 0.3. For every $(i,k) \in \mathcal{B}$, compute the distance $\|x_i^* - a_k\|_2 = e_{ik}$. Then we apply sparse SOS relaxation (3.1)–(3.8) to minimize polynomial function (5.1). The accuracy of computed sensor locations $\hat{x}_1, \ldots, \hat{x}_n$ will be measured by the Root Mean Square Distance (RMSD), which is defined as $\text{RMSD} = \left(\frac{1}{n}\sum_{i=1}^n \|\hat{x}_i - x_i^*\|_2^2\right)^{\frac{1}{2}}$. We use *SeDuMi* to solve the sparse SOS relaxation (3.1)–(3.8) on a Linux machine with 1.46 GHz CPU and 0.98GB memory. The problem can be solved within about 18 CPU minutes with accuracy $\mathcal{O}(10^{-6})$.

The sparse SOS method based on chordal extension like in [28] is usually not practical for solving sensor network localization problems, because the corresponding csp matrices usually do not have sparse Cholesky factorizations and the resulting chordal extensions are often too dense to be useful. We refer to [21] for more details about sparse SOS methods for sensor network localization.

6. Conclusions and discussions. This paper proposes sparse SOS relaxations for minimizing polynomial functions that are summations of small polynomials. We discuss various properties of these relaxations and the computational issues. We also present applications of this sparsity technique in solving polynomial equations derived from nonlinear differential equations and sensor network localization. As a special case, this sparsity technique provides a heuristic approach to solve bigger dense polynomial optimization problems.

In order to exploit the sparsity, the polynomial and its SOS representation must be sparse. In many applications, the polynomials are often given with sparsity pattern (1.1), and then the sparsity technique proposed in this paper is very suitable. If the sparsity pattern is not given, one important future work is how to represent the polynomial in a sparse pattern such that the technique proposed in this paper is most efficient. Of course, one simple choice is to consider each monomial as a small polynomial.

The idea of this sparse SOS relaxation can be applied in a similar way to solve constrained polynomial optimization problems, provided the objective and constraint polynomials are also sums of small polynomials. See Kim et al. [11] and Lasserre [15] for related work. To get the global minimum, high order relaxations are usually necessary. Lasserre [15] proved the convergence under the running intersection property. However, unlike the general dense SOS relaxation for minimizing polynomials over compact sets, the convergence might fail when the running intersection property does not hold. As a counterexample, consider the *Minimum Cover Set Problem*. Let $G = (V, E)$ be a graph with vertex set $V = [3]$ and edge set $E = \{(1,2), (1,3), (2,3)\}$. To find the minimum cover set is equivalent to solving

$$\begin{aligned} \min_{x \in \mathbb{R}^3} \quad & f_1(x_{\Delta_1}) + f_2(x_{\Delta_2}) + f_3(x_{\Delta_3}) \\ s.t. \quad & x_1^2 = x_1,\, x_2^2 = x_2,\, x_3^2 = x_3, \\ & x_1 + x_2 \geq 1,\, x_1 + x_3 \geq 1, x_2 + x_3 \geq 1, \end{aligned}$$

where $\Delta_1 = \{1,2\}$, $\Delta_2 = \{1,3\}$, $\Delta_3 = \{2,3\}$ and $f_1(x_{\Delta_1}) = \frac{1}{2}(x_1 + x_2)$, $f_2(x_{\Delta_2}) = \frac{1}{2}(x_1 + x_3)$, $f_3(x_{\Delta_3}) = \frac{1}{2}(x_2 + x_3)$. The running intersection property now fails. However, it can be shown that the global minimum $f^* = 2$ and the lower bounds given by sparse SOS relaxations are at most $\frac{3}{2}$. The sparse SOS relaxations do not converge for this example.

Another important future work is to apply the sparse SOS relaxations in solving big real sparse polynomial systems arising from nonlinear differential equations.

Acknowledgments. The authors wish to thank Bernd Sturmfels and the referees for helpful suggestions to improve this paper.

ON SEMIDEFINITE PROGRAMMING RELAXATIONS OF THE TRAVELING SALESMAN PROBLEM*

ETIENNE DE KLERK†, DMITRII V. PASECHNIK‡, AND RENATA SOTIROV†

Abstract. We consider a new semidefinite programming (SDP) relaxation of the symmetric traveling salesman problem (TSP) that may be obtained via an SDP relaxation of the more general quadratic assignment problem (QAP). We show that the new relaxation dominates the one in [D. Cvetković, M. Cangalović, and V. Kovačević-Vujčić, *Semidefinite programming methods for the symmetric traveling salesman problem*, in Proceedings of the 7th International IPCO Conference on Integer Programming and Combinatorial Optimization, Springer-Verlag, London, UK, 1999, pp. 126–136]. Unlike the bound of Cvetković et al., the new SDP bound is not dominated by the Held–Karp linear programming bound, or vice versa.

Key words. traveling salesman problem, semidefinite programming, quadratic assignment problem, association schemes

1. Introduction.

The quadratic assignment problem (QAP) may be stated in the following form:

$$\min_{X \in \Pi_n} trace\left(AXBX^T\right), \tag{1}$$

where A and B are given symmetric $n \times n$ matrices, and Π_n is the set of $n \times n$ permutation matrices.

It is well known that the QAP contains the symmetric traveling salesman problem (TSP) as a special case. To show this, we denote the complete graph on n vertices with edge lengths (weights) $D_{ij} = D_{ji} > 0$ $(i \neq j)$, by $K_n(D)$, where D is called the matrix of edge lengths (weights). The TSP is to find a Hamiltonian circuit of minimum length in $K_n(D)$. The n vertices are often called *cities*, and the Hamiltonian circuit of minimum length the *optimal tour*.

To see that TSP is a special case of QAP, let C_1 denote the adjacency matrix of $\mathcal{C}_n$ (the standard circuit on n vertices):

$$C_1 := \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 & 1 \\ 1 & 0 & 1 & 0 & \cdots & 0 \\ 0 & 1 & 0 & 1 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \ddots & \\ 0 & & & & 0 & 1 \\ 1 & 0 & \cdots & 0 & 1 & 0 \end{bmatrix}.$$

Now the TSP problem is obtained from the QAP problem (1) by setting $A = \frac{1}{2}D$ and $B = C_1$. To see this, note that every Hamiltonian circuit in a complete graph has

adjacency matrix XC_1X^T for some $X \in \Pi_n$. Thus we may concisely state the TSP as

$$TSP_{opt} := \min_{X \in \Pi_n} trace\left(\frac{1}{2} DXC_1X^T\right). \tag{2}$$

The symmetric TSP is NP-hard in the strong sense [20], and therefore so is the more general QAP. In the special case where the distance function of the TSP instance satisfies the triangle inequality (metric TSP), there is a celebrated 3/2-approximation algorithm due to Christofides [9]. It is a long-standing (since 1975) open problem to improve on the 3/2 constant, since the strongest negative result is that a $(1+1/219)$-approximation algorithm is not possible, unless P=NP [21].

In the case when the distances are Euclidean in fixed dimension (the so-called planar or geometric TSP), the problem allows a polynomial-time approximation scheme [1]. A recent survey of the TSP is given by Schrijver [22, Chapter 58].

Main results and outline of this paper. In this paper we will consider semidefinite programming (SDP) relaxations of the TSP. We will introduce a new SDP relaxation of TSP in section 2, which is motivated by the theory of association schemes. Subsequently, we will show in section 3 that the new SDP relaxation coincides with the SDP relaxation for QAP introduced in [26] when applied to the QAP reformulation of TSP in (2). Then we will show in section 4 that the new SDP relaxation dominates the relaxation due to Cvetković et al. [5]. The relaxation of Cvetković et al. is known to be dominated by the Held–Karp linear programming bound [6, 15], but we show in section 5 that the new SDP bound is not dominated by the Held–Karp bound (or vice versa).

Notation. The space of $p \times q$ real matrices is denoted by $\mathbb{R}^{p\times q}$, the space of $k \times k$ symmetric matrices is denoted by $\mathcal{S}_k$, and the space of $k \times k$ symmetric positive semidefinite matrices by $\mathcal{S}_k^+$. We will sometimes also use the notation $X \succeq 0$ instead of $X \in \mathcal{S}_k^+$, if the order of the matrix is clear from the context. By $\mathrm{diag}(X)$ we mean the n-vector composed of the diagonal entries of $X \in \mathcal{S}_n$.

We use I_n to denote the identity matrix of order n. Similarly, J_n and e_n denote the $n \times n$ all-ones matrix and all ones n-vector, respectively, and $0_{n\times n}$ is the zero matrix of order n. We will omit the subscript if the order is clear from the context.

The *Kronecker product* $A \otimes B$ of matrices $A \in \mathbb{R}^{p\times q}$ and $B \in \mathbb{R}^{r\times s}$ is defined as the $pr \times qs$ matrix composed of pq blocks of size $r \times s$, with block ij given by $A_{ij}B$ $(i = 1, \ldots, p)$, $(j = 1, \ldots, q)$.

The Hadamard (component-wise) product of matrices A and B of the same size will be denoted by $A \circ B$.

2. A new SDP relaxation of TSP. In this section we show that the optimal value of the following semidefinite program provides a lower bound on the length TSP_{opt} of an optimal tour:

$$\left.\begin{array}{rll} \min & \frac{1}{2} trace\left(DX^{(1)}\right) & \\ \text{subject to} & & \\ & X^{(k)} \geq 0, & k = 1, \ldots, d \\ & \sum_{k=1}^{d} X^{(k)} = J - I, & \\ & I + \sum_{k=1}^{d} \cos\left(\frac{2\pi i k}{n}\right) X^{(k)} \succeq 0, & i = 1, \ldots, d \\ & X^{(k)} \in \mathcal{S}^n, & k = 1, \ldots, d, \end{array}\right\}, \tag{3}$$

where $d = \lfloor \frac{1}{2} n \rfloor$ is the diameter of $\mathcal{C}_n$.

Note that this problem involves nonnegative matrix variables $X^{(1)}, \ldots, X^{(d)}$ of order n. The matrix variables $X^{(k)}$ have an interesting interpretation in terms of *association schemes*.

Association schemes. We will give a brief overview of this topic; for an introduction to association schemes, see Chapter 12 in [10], and in the context of SDP, [11].

DEFINITION 2.1 (Asssociation scheme). *Assume that a given set of $n \times n$ matrices $B_0, \ldots, B_t$ has the following properties:*

(1) *B_i is a $0-1$ matrix for all i and $B_0 = I$;*
(2) *$\sum_i B_i = J$;*
(3) *$B_i = B_{i^*}^T$ for some i^*;*
(4) *$B_i B_j = B_j B_i$ for all i, j;*
(5) *$B_i B_j \in span\{B_1, \ldots, B_t\}$.*

Then we refer to $\{B_1, \ldots, B_t\}$ as an association scheme. If the B_i's are also symmetric, then we speak of a symmetric association scheme.

Note that item (4) (commutativity) implies that the matrices $B_1, \ldots, B_t$ share a common set of eigenvectors, and therefore can be simultaneously diagonalized. Note also that an association scheme is a basis of a matrix-$*$ algebra (viewed as a vector space). Moreover, one clearly has

$$trace\left(B_i B_j^T\right) = 0 \text{ if } i \neq j.$$

Since the B_i's share a system of eigenvectors, there is a natural ordering of their eigenvalues with respect to any fixed ordering of the eigenvectors. Thus the last equality may be interpreted as

$$\sum_k \lambda_k(B_i)\lambda_k(B_j) = 0 \text{ if } i \neq j, \tag{4}$$

where the $\lambda_k(B_i)$'s are the eigenvalues of B_i with respect to the fixed ordering.

The association scheme of particular interest to us arises as follows. Given a connected graph $G = (V, E)$ with diameter d, we define $|V| \times |V|$ matrices $A^{(k)}$ $(k = 1, \ldots, d)$ as follows:

$$A_{ij}^{(k)} = \begin{cases} 1 & \text{if } \operatorname{dist}(i,j) = k \\ 0 & \text{else,} \end{cases} \qquad (i, j \in V),$$

where $\operatorname{dist}(i, j)$ is the length of the shortest path from i to j.

Note that $A^{(1)}$ is simply the adjacency matrix of G. Moreover, one clearly has

$$I + \sum_{k=1}^{d} A^{(k)} = J.$$

It is well known that, for $G = \mathcal{C}_n$, the matrices $A^{(k)}$ $(k = 1, \ldots, d \equiv \lfloor n/2 \rfloor)$ together with $A^{(0)} := I$ form an association scheme, since $\mathcal{C}_n$ is a distance regular graph.

It is shown in the Appendix to this paper that for $G = \mathcal{C}_n$, the eigenvalues of the matrix $A^{(k)}$ are

$$\lambda_m\left(A^{(k)}\right) = 2\cos(2\pi mk/n), \quad m = 0, \ldots, n-1,\ k = 1, \ldots, \lfloor (n-1)/2 \rfloor,$$

and, if n is even,

$$\lambda_{n/2}\left(A^{(k)}\right) = \cos(k\pi) = (-1)^k.$$

In particular, we have

$$\lambda_m\big(A^{(k)}\big) = \lambda_k\big(A^{(m)}\big) \qquad k,m = 1,\ldots,\lfloor (n-1)/2 \rfloor. \tag{5}$$

Also note that

$$\lambda_m\big(A^{(k)}\big) = \lambda_{n-m}\big(A^{(k)}\big), \quad k,m = 1,\ldots,\lfloor (n-1)/2 \rfloor, \tag{6}$$

so that each matrix $A^{(k)}$ $(k = 1,\ldots,d)$ has only $1 + \lfloor n/2 \rfloor$ distinct eigenvalues.

Verifying the SDP relaxation (3). We now show that setting $X^{(k)} = A^{(k)}$ $(k = 1,\ldots,d)$ gives a feasible solution of (3). We only need to verify that

$$I + \sum_{k=1}^{d} \cos\left(\frac{2\pi i k}{n}\right) A^{(k)} \succeq 0, \qquad i = 1,\ldots,d.$$

We will show this for odd n, the proof for even n being similar.

Since the $A^{(k)}$'s may be simultaneously diagonalized, the last linear matrix inequality (LMI) is the same as

$$2 + \sum_{k=1}^{d} \lambda_k\big(A^{(i)}\big)\lambda_j\big(A^{(k)}\big) \geq 0, \qquad i,j = 1,\ldots,d,$$

and by using (5) this becomes

$$2 + \sum_{k=1}^{d} \lambda_k\big(A^{(i)}\big)\lambda_k\big(A^{(j)}\big) \geq 0, \qquad i,j = 1,\ldots,d.$$

Since $\lambda_0(A^{(i)}) = 2$ $(i = 1,\ldots,d)$, and using (4), one can easily verify that the last inequality holds. Indeed, one has

$$\begin{aligned}
&2 + \sum_{k=1}^{d} \lambda_k\big(A^{(i)}\big)\lambda_k\big(A^{(j)}\big) \\
&= 2 + \frac{1}{2}\sum_{k=1}^{n-1} \lambda_k\big(A^{(i)}\big)\lambda_k\big(A^{(j)}\big) \quad \text{(by (6))} \\
&= 2 - \frac{1}{2}\lambda_0\big(A^{(i)}\big)\lambda_0\big(A^{(j)}\big) + \frac{1}{2}\sum_{k=0}^{n-1} \lambda_k\big(A^{(i)}\big)\lambda_k\big(A^{(j)}\big) \\
&= \begin{cases} 2 - 2 + 0 = 0 & \text{if } (i \neq j), \text{ by (4)}, \\ 2 - 2 + \frac{1}{2}\sum_{k=0}^{n-1} \big(\lambda_k\big(A^{(i)}\big)\big)^2 \geq 0 & \text{if } (i = j). \end{cases}
\end{aligned}$$

Thus we have established the following result.

THEOREM 2.1. *The optimal value of the SDP problem* (3) *provides a lower bound on the optimal value* TSP_{opt} *of the associated TSP instance.*

3. Relation of (3) to an SDP relaxation of QAP. An SDP relaxation of the QAP problem (1) was introduced in [26], and further studied for specially structured instances in [7].

When applied to the QAP reformulation of TSP in (2), this SDP relaxation takes the form:

$$\left.\begin{array}{rl} \min & \frac{1}{2}trace(C_1 \otimes D)Y \\ \text{subject to} & \\ & trace(((I \otimes (J-I))Y + ((J-I) \otimes I)Y = 0 \\ & trace(Y) - 2e^T y = -n \\ & \begin{pmatrix} 1 & y^T \\ y & Y \end{pmatrix} \succeq 0, \;\; Y \geq 0. \end{array}\right\}. \tag{7}$$

It is easy to verify that this is indeed a relaxation of problem (2), by noting that setting $Y = \mathrm{vec}(X)\mathrm{vec}(X)^T$ and $y = \mathrm{diag}(Y)$ gives a feasible solution if $X \in \Pi_n$.

In this section we will show that the optimal value of the SDP problem (7) actually equals the optimal value of the new SDP relaxation (3). The proof is via the technique of *symmetry reduction*.

Symmetry reduction of the SDP problem (7). Consider the following form of a general SDP problem:

$$p^* := \min_{X \succeq 0, X \geq 0} \{trace(A_0 X) \; : \; trace(A_k X) = b_k, \quad k = 1, \ldots, m\}, \tag{8}$$

where the A_i $(i = 0, \ldots, m)$ are given symmetric matrices.

If we view (7) as an SDP problem in the form (8), the data matrices of problem (7) are

$$\begin{pmatrix} 0 & 0^T \\ 0 & \frac{1}{2}C_1 \otimes D \end{pmatrix}, \begin{pmatrix} 0 & 0^T \\ 0 & I \otimes (J-I) + (J-I) \otimes I, \end{pmatrix}, \begin{pmatrix} 0 & -e^T \\ -e & 2I \end{pmatrix}, \begin{pmatrix} 1 & 0^T \\ 0 & 0 \end{pmatrix}. \tag{9}$$

Definition 3.1. *We define the* automorphism group *of a matrix* $Z \in \mathbb{R}^{k \times k}$ *as*

$$aut(Z) = \{P \in \Pi_k \; : \; PZP^T = Z\}.$$

Symmetry reduction of problem (8) is possible under the assumption that the multiplicative matrix group

$$\mathcal{G} := \bigcap_{i=0}^{m} \mathrm{aut}(A_i)$$

is nontrivial. We call $\mathcal{G}$ the symmetry group of the SDP problem (8).

For the matrices (9), the group $\mathcal{G}$ is given by the matrices

$$\mathcal{G} := \left\{ \begin{pmatrix} 1 & 0^T \\ 0 & P \otimes I \end{pmatrix} \; : \; P \in \mathcal{D}_n \right\}, \tag{10}$$

where $\mathcal{D}_n$ is the (permutation matrix representation of) dihedral group of order n, i.e., the automorphism group of $\mathcal{C}_n$.

The basic idea of symmetry reduction is given by the following result.

Theorem 3.1 (see, e.g., [8]). *If X is a feasible (resp. optimal) solution of the SDP problem* (8) *with symmetry group $\mathcal{G}$, then*

$$\bar{X} := \frac{1}{|\mathcal{G}|} \sum_{P \in \mathcal{G}} P^T X P$$

is also a feasible (resp. optimal) solution of (8).

Thus there exist optimal solutions in the set

$$\mathcal{A}_{\mathcal{G}} := \left\{ \frac{1}{|\mathcal{G}|} \sum_{P \in \mathcal{G}} P^T X P \ : \ X \in \mathbb{R}^{n \times n} \right\}.$$

This set is called the centralizer ring (or commutant) of $\mathcal{G}$ and it is a matrix $*$-algebra. For the group defined in (10), it is straightforward to verify that the centralizer ring is given by

$$\mathcal{A}_{\mathcal{G}} := \left\{ \begin{pmatrix} \alpha & x^T \\ y & C \otimes Z \end{pmatrix} \ \middle| \ \alpha \in \mathbb{R},\ C = C^T \text{ circulant},\ Z \in \mathbb{R}^{n \times n},\ x, y \in \mathbb{R}^{n^2} \right\}, \tag{11}$$

where $x^T = [x_1 e^T \dots x_n e^T]$ and $y^T = [y_1 e^T \dots y_n e^T]$ for some scalars x_i and y_i $(i = 1, \dots, n)$, where $e \in \mathbb{R}^n$ is the all-ones vector, as before.

Thus we may restrict the feasible set of problem (7) to feasible solutions of the form (11).

If we divide y and Y in (7) into blocks

$$y = \left(\left(y^{(1)}\right)^T \cdots \left(y^{(n)}\right)^T \right)^T,$$

and

$$Y = \begin{pmatrix} Y^{(11)} & \dots & Y^{(1n)} \\ \vdots & \ddots & \vdots \\ Y^{(n1)} & \dots & Y^{(nn)} \end{pmatrix},$$

where $y^{(i)} \in \mathbb{R}^n$ and $Y^{(ij)} = Y^{(ji)T} \in \mathbb{R}^{n \times n}$, then feasible solutions of (7) satisfy

$$\begin{pmatrix} 1 & \left(y^{(1)}\right)^T & \dots & \left(y^{(n)}\right)^T \\ y^{(1)} & Y^{(11)} & \dots & Y^{(1n)} \\ \vdots & \vdots & \ddots & \vdots \\ y^{(n)} & Y^{(n1)} & \dots & Y^{(nn)} \end{pmatrix} \succeq 0. \tag{12}$$

Feasible solutions have the following additional structure (see [26] and Theorem 3.1 in [7]):

- $Y^{(ii)}$ $(i = 1, \dots, n)$ is a diagonal matrix;
- $Y^{(ij)}$ $(i \neq j)$ is a matrix with zero diagonal;
- $trace(JY^{(ij)}) = 1$ $(i, j = 1, \dots, n)$;
- $\sum_{i=1}^n Y^{(ij)} = e \left(y^{(j)}\right)^T \quad (j = 1, \dots, n)$;
- $\operatorname{diag}(Y) = y$.

Since $\operatorname{diag}(Y) = y$ for feasible solutions, we have $y^{(i)} = \operatorname{diag}(Y^{(ii)})$ $(i = 1, \dots, n)$. Moreover, since we may also assume the structure (11), we have that

$$y^{(i)} = y_i e \quad (i = 1, \dots, n),$$

for some scalar values y_i. This implies that the diagonal elements of $Y^{(ii)}$ all equal y_i. Since the diagonal elements of $Y^{(ii)}$ sum to 1, we have $y_i = 1/n$ and $\operatorname{diag}(Y^{(ii)}) = (1/n)e$. Thus the condition

$$\begin{pmatrix} 1 & y^T \\ y & Y \end{pmatrix} \succeq 0$$

reduces to

$$Y - \frac{1}{n^2} J \succeq 0$$

by the Shur complement theorem. This is equivalent to

$$(I \otimes Q^*) Y (I \otimes Q) - \frac{1}{n^2} (I \otimes Q^*) J (I \otimes Q) \succeq 0,$$

where Q is the discrete Fourier transform matrix defined in (25) in the Appendix.

Using the properties of the Kronecker product and of Q, we get

$$\begin{pmatrix} Q^*Y^{(11)}Q & \cdots & Q^*Y^{(1n)}Q \\ \vdots & \ddots & \vdots \\ Q^*Y^{(n1)}Q & \cdots & Q^*Y^{(nn)}Q \end{pmatrix} - J \otimes \begin{pmatrix} \frac{1}{n} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 0 \end{pmatrix} \succeq 0.$$

Recall that $Y^{(ii)} = \frac{1}{n} I$ and that we may assume $Y^{(ij)}$ $(i \neq j)$ to be symmetric circulant, say

$$Y^{(ij)} = \sum_{k=1}^{d} x_k^{(ij)} C_k, \quad (i \neq j),$$

where C_k $(k = 1, \ldots, d)$ forms a basis of the symmetric circulant matrices with zero diagonals (see the Appendix for the precise definition). Note that the nonnegativity of $Y^{(ij)}$ is equivalent to $x_k^{(ij)} \geq 0$ $(k = 1, \ldots, d)$. Since $trace(JY^{(ij)}) = 1$, one has

$$\sum_{k=1}^{d} x_k^{(ij)} = \frac{1}{2n} \quad (i \neq j).$$

Since $\sum_{i=1}^{n} Y^{(ij)} = e \left(y^{(j)}\right)^T = \frac{1}{n} J$, one also has

$$\sum_{k=1}^{d} \sum_{i=1}^{n} x_k^{(ij)} C_k = \frac{1}{n} J.$$

By the definition of the C_k's, this implies that

$$\sum_{i=1}^{n} x_k^{(ij)} = \begin{cases} \frac{1}{n} & \text{if } 1 \leq k \leq \lfloor (n-1)/2 \rfloor, \\ \frac{1}{2n} & \text{if } k = n/2 \ (n \text{ even}). \end{cases} \tag{13}$$

Moreover,

$$Q^* Y^{(ij)} Q = \sum_{k=1}^{d} x_k^{(ij)} D_k, \quad (i \neq j),$$

where D_k is the diagonal matrix with the eigenvalues (26) of C_k on its diagonal.

Thus the LMI becomes

$$\begin{pmatrix} \frac{1}{n} I & \cdots & \sum_{k=1}^{d} x_k^{(1n)} D_k \\ \vdots & \ddots & \vdots \\ \sum_{k=1}^{d} x_k^{(1n)} D_k & \cdots & \frac{1}{n} I \end{pmatrix} - J \otimes \begin{pmatrix} \frac{1}{n} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 0 \end{pmatrix} \succeq 0. \tag{14}$$

The left-hand side of this LMI is a block matrix with each block being a diagonal matrix. Thus this matrix has a chordal sparsity structure (n disjoint cliques of size n). We may now use the following lemma to obtain the system of LMI's (3).

LEMMA 3.1 (cf. [14]). *Assume a $nt \times nt$ matrix has the block structure*

$$M := \begin{pmatrix} D^{(11)} & \cdots & D^{(1n)} \\ \vdots & \ddots & \vdots \\ D^{(n1)} & \cdots & D^{(nn)} \end{pmatrix},$$

where $D^{(ij)} \in \mathcal{S}_t$ are diagonal $(i, j = 1, \ldots, n)$. Then $M \succeq 0$ if and only if

$$\begin{pmatrix} D_{ii}^{(11)} & \cdots & D_{ii}^{(1n)} \\ \vdots & \ddots & \vdots \\ D_{ii}^{(n1)} & \cdots & D_{ii}^{(nn)} \end{pmatrix} \succeq 0 \quad i = 1, \ldots, t.$$

Applying the lemma to the LMI (14), and setting

$$X_{ij}^{(k)} = 2n x_k^{(ij)}, \qquad k = 1, \ldots, \lfloor n/2 \rfloor \tag{15}$$

yields the system of LMI's in (3).

Thus we have established the following result.

THEOREM 3.2. *The optimal values of the semidefinite programs* (3) *and* (7) *are equal.*

4. Relation of (3) to an SDP relaxation of Cvetković et al. We will now show that the new SDP relaxation (3) dominates an SDP relaxation (16) due to Cvetković et al. [5]. This latter relaxation is based on the fact that the spectrum of the Hamiltonian circuit $\mathcal{C}_n$ is known. In particular, the smallest eigenvalue of its Laplacian is zero and corresponds to the all ones eigenvector, while the second smallest eigenvalue equals $2 - 2\cos\left(\frac{2\pi}{n}\right)$.

The relaxation takes the form

$$TSP_{opt} \geq \min \frac{1}{2} trace(DX)$$

subject to

$$\left.\begin{aligned} Xe &= 2e, \\ \operatorname{diag}(X) &= 0, \\ 0 \leq X &\leq J, \\ 2I - X + \left(2 - 2\cos\left(\tfrac{2\pi}{n}\right)\right)(J - I) &\succeq 0. \end{aligned}\right\} \tag{16}$$

Note that the matrix variable X corresponds to the adjacency matrix of the minimal length Hamiltonian circuit.

THEOREM 4.1. *The SDP relaxation* (3) *dominates the relaxation* (16).

Proof. Assume that given $X^{(k)} \in \mathcal{S}^n$ $(k = 1, \ldots, d)$ satisfies (3). Then, $\operatorname{diag}(X^{(1)}) = 0$, while (13) and (15) imply

$$X^{(k)}e = 2e \quad (k = 1, \ldots, \lfloor (n-1)/2 \rfloor),$$

and $X^{(n/2)}e = e$ if n is even. In particular, one has $X^{(1)}e = 2e$. It remains to show that

$$2I - X^{(1)} + \left(2 - 2\cos\left(\frac{2\pi}{n}\right)\right)(J - I) \succeq 0,$$

which is the same as showing that

$$2I - X^{(1)} + \left(2 - 2\cos\left(\frac{2\pi}{n}\right)\right)\sum_{k=1}^{d} X^{(k)} \succeq 0, \tag{17}$$

since

$$\sum_{k=1}^{d} X^{(k)} = J - I.$$

We will show that the LMI (17) may be obtained as a nonnegative aggregation of the LMI's

$$I + \sum_{k=1}^{d} X^{(k)} \succeq 0$$

and

$$I + \sum_{k=1}^{d} \cos\left(\frac{2\pi ik}{n}\right) X^{(k)} \succeq 0 \quad (i = 1, \ldots, d).$$

The matrix of coefficients of these LMI's is a $(d+1) \times (d+1)$ matrix, say A, with entries:

$$A_{ij} = \cos\left(\frac{2\pi ij}{n}\right) \quad (i, j = 0, \ldots, d).$$

Since we may rewrite (17) as

$$2I + \left(1 - 2\cos\left(\frac{2\pi}{n}\right)\right) X^{(1)} + \left(2 - 2\cos\left(\frac{2\pi}{n}\right)\right)\sum_{k=2}^{d} X^{(k)} \succeq 0,$$

we need to show that the linear system $Ax = b$ has a nonnegative solution, where

$$b := \left[2, \left(1 - 2\cos\left(\frac{2\pi}{n}\right)\right), \left(2 - 2\cos\left(\frac{2\pi}{n}\right)\right), \ldots, \left(2 - 2\cos\left(\frac{2\pi}{n}\right)\right)\right]^T.$$

One may verify that, for n odd, the system $Ax = b$ has a (unique) solution given by

$$x_i = \frac{4}{n}\begin{cases} d\left(1 - \cos\left(\frac{2\pi}{n}\right)\right) & \text{if } i = 0 \\ \cos\left(\frac{2\pi}{n}\right) - \cos\left(\frac{2\pi i}{n}\right) & \text{for } i = 1, \ldots, d. \end{cases}$$

Note that x is nonnegative, as it should be. If n is even, the solution is

$$x_i = \frac{4}{n}\begin{cases} \frac{(n-1)}{2}\left(1 - \cos\left(\frac{2\pi}{n}\right)\right) & \text{if } i = 0, \\ \cos\left(\frac{2\pi}{n}\right) - \cos\left(\frac{2\pi i}{n}\right) & \text{for } i = 1, \ldots, d-1, \\ \frac{1}{2}\cos\left(\frac{2\pi}{n}\right) - \frac{1}{2}\cos\left(\frac{2\pi i}{n}\right) & \text{for } i = d. \end{cases}$$ □

In the section with numerical examples, we will present instances where the new SDP relaxation (3) is strictly better than (16).

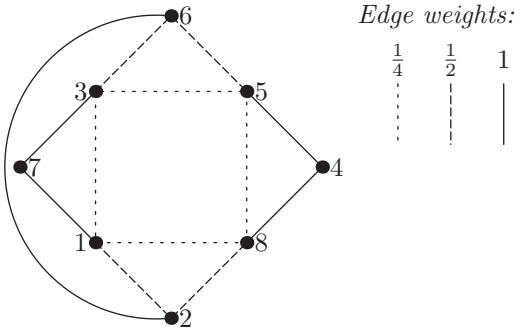

FIG. 1. *The weighted graph used in the proof of Theorem* 5.1.

5. Relation to the Held–Karp bound. One of the best-known linear programming (LP) relaxations of TSP is the LP with subtour elimination constraints:

$$TSP_{opt} \geq \min \frac{1}{2} trace(DX)$$

subject to

$$\left.\begin{array}{r} Xe = 2, \\ \mathrm{diag}(X) = 0, \\ 0 \leq X \leq J, \\ \sum_{i \in \mathcal{I},\, j \notin \mathcal{I}} X_{ij} \geq 2 \quad \forall\, \emptyset \neq \mathcal{I} \subset \{1, \ldots, n\} \end{array}\right\}. \tag{18}$$

This LP relaxation dates back to 1954 and is due to Dantzig, Fulkerson, and Johnson [6]. Its optimal value coincides with the LP bound of Held and Karp [15] (see, e.g., Theorem 21.34 in [16]), and the optimal value of the LP is commonly known as the *Held–Karp bound*.

The last constraints are called *subtour elimination inequalities* and model the fact that $\mathcal{C}_n$ is 2-connected. Although there are exponentially many subtour elimination inequalities, it is well known that the LP (18) may be solved in polynomial time using the ellipsoid method; see, e.g., Schrijver [22], section 58.5.

It was shown by Goemans and Rendl [12] that this LP relaxation dominates the SDP relaxation (16) by Cvetković et al. [5]. The next theorem shows that the LP relaxation (18) does not dominate the new SDP relaxation (3), or vice versa.

THEOREM 5.1. *The LP subtour elimination relaxation* (18) *does not dominate the new SDP relaxation* (3), *or vice versa.*

Proof. Define the 8×8 symmetric matrix $\bar{X}$ as the weighted adjacency matrix of the graph shown in Figure 1.

The matrix $\bar{X}$ satisfies the subtour elimination inequalities, since the minimum cut in the graph in Figure 1 has weight 2.

On the other hand, there does not exist a feasible solution of (3) that satisfies $X^{(1)} = \bar{X}$, as may be shown using SDP duality theory.

Conversely, in section 7 we will provide examples where the optimal value of (18) is strictly greater than the optimal value of (3) (see, e.g., the instances gr17, gr24, and bays24 there). ∎

6. An LMI cut via the number of spanning trees. In addition to the subtour elimination inequalities, there are several families of linear inequalities known for the TSP polytope; for a review, see Naddef [18] and Schrijver [22, Chapter 58].

Of particular interest to us is a valid nonlinear inequality that models the fact that $\mathcal{C}_n$ has n distinct spanning trees. To introduce the inequality we require a general form of the *matrix tree theorem*; see, e.g., Theorem VI.29 in [24] for a proof.

THEOREM 6.1 (Matrix tree theorem). *Let a simple graph $G = (V, E)$ be given and associate with each edge $e \in E$ a real variable x_e. Define the (generalized) Laplacian of G with respect to x as the $|V| \times |V|$ matrix with entries*

$$L(G)(x)_{ij} := \begin{cases} \sum_{e\,:\,e\cap i\neq\emptyset} x_e & \text{if } i = j, \\ -x_e & \text{if } \{i,j\} = e, \\ 0 & \text{else.} \end{cases}$$

Now all principal minors of $L(G)(x)$ of order $|V| - 1$ equal:

$$\sum_T \prod_{e\in T} x_e, \tag{19}$$

where the sum is over all distinct spanning trees T of G.

In particular, if $L(G)(x)$ is the usual Laplacian of a given graph, then $x_e = 1$ for all edges e of the graph, and expression (19) evaluates to the number of spanning trees in the graph.

Thus if X corresponds to the approximation of the adjacency matrix of a minimum tour, then one may require that

$$\det\,(2I - X)_{2:n,2:n} \geq n, \tag{20}$$

where $X_{2:n,2:n}$ denotes the principle submatrix of X obtained by deleting the first row and column.

The inequality (20) may be added to the above SDP relaxations (16) and (3) (with $X = X^{(1)}$), since the set

$$\{Z \succeq 0 \;:\; \det Z \geq n\}$$

is LMI representable; see, e.g., Nemirovski [19, section 3.2].

We know from numerical examples that (20) is not implied by the relaxation of Cvetković et al. (16), but do not know any examples where it is violated by a feasible $X^{(1)}$ of the new relaxation (3). Nevertheless, we have been unable to show that (20) (with $X = X^{(1)}$) is implied by (3).

7. Numerical examples. In Table 1 we give the lower bounds on some small TSPLIB[1] instances for the two SDP relaxations (3) and (16), as well as the LP relaxation with all subtour elimination constraints (18) (the Held–Karp bound). These instances have integer data, and the optimal values of the relaxations were rounded up to obtain the bounds in the table.

The SDP problems were solved by the interior point software CSDP [2] using the Yalmip interface [17] and Matlab 6.5, running on a PC with two 2.1 GHz dual-core processors and 2GB of memory.

Note that the relaxation (3) can indeed be strictly better than (16), as is clear from the gr17, bays24, and bays29 instances. Also, since the LP relaxation (18) gives better bounds than (3) for all four instances, it is worth recalling that this will not happen in general, by Theorem 5.1.

The LMI cut from (20) was already satisfied by the optimal solutions of (16) and (3) for the four instances.

A second set of test problems was generated by considering all facet-defining inequalities for the TSP polytope on 8 nodes; see [3] for a description of these inequalities, as well as the SMAPO project web site.[2]

The facet-defining inequalities are of the form $\frac{1}{2}trace(DX) \geq RHS$ where $D \in \mathcal{S}_n$ has nonnegative integer entries and RHS is an integer. From each inequality, we form a symmetric TSP instance with distance matrix D. Thus the optimal value of the TSP instance is the value RHS. In Table 2 we give the optimal values of the LP relaxation (18) (i.e., the Held–Karp bound), the SDP relaxation of Cvetković et al. (16), and the new SDP relaxation (3) for these instances, as well as the right-hand-side RHS of each inequality $\frac{1}{2}trace(DX) \geq RHS$. For $n = 8$, there are 24 classes of facet-defining inequalities. The members of each class are equal modulo a permutation of the nodes, and we need therefore consider only one representative per class. The first three classes of inequalities are subtour elimination inequalities.

[2] http://www.iwr.uni-heidelberg.de/groups/comopt/software/SMAPO/tsp/

The numbering of the instances in Table 2 coincides with the numbering of the classes of facet-defining inequalities on the SMAPO project web site.

The new SDP bound (3) is only stronger than the Held–Karp bound (18) for the instances 16, 21, and 23 in Table 2, and for the instances 1, 5, 9, 12, 14, 17, 18, 19, and 22 the two bounds coincide. For the remaining 18 instances the Held–Karp bound is better than the SDP bound (3). However, if the bounds are rounded up, the SDP bound (3) is still better for the instances 16, 21 and 23, whereas the two (rounded) bounds are equal for all the other instances. Adding the LMI cut from (20) did not change the optimal values of the SDP relaxations (16) or (3) for any of the instances.

For $n = 9$, there are 192 classes of facet-defining inequalities of the TSP polytope [4]. Here the SDP bound (3) is better than the Held–Karp bound for 23 out of the 192 associated TSP instances. Similar to the $n = 8$ case, when rounding up, the rounded SDP bound remains better in all 23 cases and coincides with the rounded Held–Karp bound in all the remaining cases.

8. Concluding remarks. Wolsey [25] showed that the optimal value of the LP relaxation (18) is at least 2/3 the length of an optimal tour for metric TSP (see also [23]). An interesting question is whether a similar result may be proved for the new SDP relaxation (3).

Finally, the computational perspectives of the SDP relaxation (3) are somewhat limited due to its size. However, since it provides a new polynomial-time convex approximation of TSP with a rich mathematical structure, it is our hope that it may lead to a renewed interest in improving approximation results for metric TSP.

Appendix: Circulant matrices. Our discussion of circulant matrices is condensed from the review paper by Gray [13].

A circulant matrix has the form

$$C = \begin{bmatrix} c_0 & c_1 & c_2 & \cdots & & c_{n-1} \\ c_{n-1} & c_0 & c_1 & & & \\ & c_{n-1} & c_0 & c_1 & & \vdots \\ \vdots & \ddots & \ddots & \ddots & \ddots & \\ & & & & & c_1 \\ c_1 & & \cdots & & c_{n-1} & c_0 \end{bmatrix}. \tag{21}$$

Thus the entries satisfy the relation

$$C_{ij} = c_{(j-i) \mod n}. \tag{22}$$

The matrix C has eigenvalues

$$\lambda_m(C) = c_0 + \sum_{k=1}^{n-1} c_k e^{-2\pi\sqrt{-1}mk/n}, \quad m = 0, \ldots, n-1.$$

If C is symmetric with n odd, this reduces to

$$\lambda_m(C) = c_0 + \sum_{k=1}^{(n-1)/2} 2c_k \cos(2\pi mk/n), \quad m = 0, \ldots, n-1, \tag{23}$$

and when n is even we have

$$\lambda_m(C) = c_0 + \sum_{k=1}^{n/2-1} 2c_k \cos(2\pi mk/n) + c_{n/2}\cos(m\pi), \quad m = 0, \ldots, n-1. \tag{24}$$

The circulant matrices form a commutative matrix $*$-algebra, as do the symmetric circulant matrices. In particular, all circulant matrices share a set of eigenvectors, given by the columns of the *discrete Fourier transform matrix*:

$$Q_{ij} := \frac{1}{\sqrt{n}} e^{-2\pi\sqrt{-1}ij/n}, \quad i,j = 0,\ldots,n-1. \tag{25}$$

One has $Q^*Q = I$, and Q^*CQ is a diagonal matrix for any circulant matrix C. Also note that $Q^*e = \sqrt{n}e$.

We may define a basis $C^{(0)},\ldots,C^{\lfloor n/2\rfloor}$ for the symmetric circulant matrices as follows: to obtain $C^{(i)}$ we set $c_i = c_{n-i} = 1$ in (21) and all other c_j's to zero. (We set $C_0 = 2I$ and also multiply $C_{n/2}$ by 2 if n is even.)

By (23) and (24), the eigenvalues of these basis matrices are

$$\lambda_m(C^{(k)}) = 2\cos(2\pi mk/n), \quad m = 0,\ldots,n-1,\ k = 0,\ldots,\lfloor n/2\rfloor. \tag{26}$$

Also note that

$$\lambda_m(C^{(k)}) = \lambda_{n-m}(C^{(k)}), \quad m = 1,\ldots,\lfloor n/2\rfloor,\ k = 0,\ldots,\lfloor n/2\rfloor$$

so that each matrix $C^{(k)}$ has only $1 + \lfloor n/2\rfloor$ distinct eigenvalues.

Acknowledgments. Etienne de Klerk would like to thank Dragoš Cvetković and Vera Kovačević-Vujčić for past discussions on the SDP relaxation (16). The authors would also like to thank an anonymous referee for suggestions that led to a significant improvement of this paper.

ROBUST STOCHASTIC APPROXIMATION APPROACH TO STOCHASTIC PROGRAMMING*

A. NEMIROVSKI†, A. JUDITSKY‡, G. LAN†, AND A. SHAPIRO†

Abstract. In this paper we consider optimization problems where the objective function is given in a form of the expectation. A basic difficulty of solving such stochastic optimization problems is that the involved multidimensional integrals (expectations) cannot be computed with high accuracy. The aim of this paper is to compare two computational approaches based on Monte Carlo sampling techniques, namely, the stochastic approximation (SA) and the sample average approximation (SAA) methods. Both approaches, the SA and SAA methods, have a long history. Current opinion is that the SAA method can efficiently use a specific (say, linear) structure of the considered problem, while the SA approach is a crude subgradient method, which often performs poorly in practice. We intend to demonstrate that a properly modified SA approach can be competitive and even significantly outperform the SAA method for a certain class of convex stochastic problems. We extend the analysis to the case of convex-concave stochastic saddle point problems and present (in our opinion highly encouraging) results of numerical experiments.

Key words. stochastic approximation, sample average approximation method, stochastic programming, Monte Carlo sampling, complexity, saddle point, minimax problems, mirror descent algorithm

1. Introduction.

In this paper we first consider the following stochastic optimization problem:

$$\min_{x\in X}\big\{f(x)=\mathbb{E}[F(x,\xi)]\big\}, \tag{1.1}$$

and then we deal with an extension of the analysis to stochastic saddle point problems. Here $X\subset\mathbb{R}^n$ is a nonempty bounded closed convex set, ξ is a random vector whose probability distribution P is supported on set $\Xi\subset\mathbb{R}^d$ and $F: X\times\Xi\to\mathbb{R}$. We assume that the expectation

$$\mathbb{E}[F(x,\xi)]=\textstyle\int_{\Xi}F(x,\xi)dP(\xi) \tag{1.2}$$

is well defined and finite valued for every $x\in X$. Moreover, we assume that the expected value function $f(\cdot)$ is *continuous* and *convex* on X. Of course, if for every $\xi\in\Xi$ the function $F(\cdot,\xi)$ is convex on X, then it follows that $f(\cdot)$ is convex. With these assumptions, (1.1) becomes a convex programming problem.

A basic difficulty of solving stochastic optimization problem (1.1) is that the multidimensional integral (expectation) (1.2) cannot be computed with a high accuracy for dimension d, say, greater than five. The aim of this paper is to compare two

computational approaches based on Monte Carlo sampling techniques, namely, the *stochastic approximation* (SA) and the *sample average approximation* (SAA) methods. To this end we make the following assumptions.

(A1) It is possible to generate an independent identically distributed (iid) sample $\xi_1, \xi_2, \ldots$, of realizations of random vector ξ.

(A2) There is a mechanism (an oracle), which, for a given input point $(x, \xi) \in X \times \Xi$ returns *stochastic subgradient*—a vector $\mathsf{G}(x, \xi)$ such that $\mathsf{g}(x) := \mathbb{E}[\mathsf{G}(x, \xi)]$ is well defined and is a subgradient of $f(\cdot)$ at x, i.e., $\mathsf{g}(x) \in \partial f(x)$.

Recall that if $F(\cdot, \xi)$, $\xi \in \Xi$, is convex and $f(\cdot)$ is finite valued in a neighborhood of a point x, then (cf. Strassen [28])

$$\partial f(x) = \mathbb{E}\left[\partial_x F(x, \xi)\right]. \tag{1.3}$$

In that case we can employ a measurable selection $\mathsf{G}(x, \xi) \in \partial_x F(x, \xi)$ as a stochastic subgradient. At this stage, however, this is not important, we shall see later other relevant ways for constructing stochastic subgradients.

Both approaches, the SA and SAA methods, have a long history. The SA method is going back to the pioneering paper by Robbins and Monro [21]. Since then SA algorithms became widely used in stochastic optimization (see, e.g., [3, 6, 7, 20, 22] and references therein) and, due to especially low demand for computer memory, in signal processing . In the classical analysis of the SA algorithm (it apparently goes back to the works [5] and [23]) it is assumed that $f(\cdot)$ is twice continuously differentiable and strongly convex and in the case when the minimizer of f belongs to the interior of X, exhibits asymptotically optimal rate[1] of convergence $\mathbb{E}[f(x_t) - f_*] = O(t^{-1})$ (here x_t is tth iterate and f_* is the minimal value of $f(x)$ over $x \in X$). This algorithm, however, is very sensitive to a choice of the respective stepsizes. Since "asymptotically optimal" stepsize policy can be very bad in the beginning, the algorithm often performs poorly in practice (e.g., [27, section 4.5.3.]).

An important improvement of the SA method was developed by Polyak [18] and Polyak and Juditsky [19], where longer stepsizes were suggested with consequent averaging of the obtained iterates. Under the outlined "classical" assumptions, the resulting algorithm exhibits the same optimal $O(t^{-1})$ asymptotical convergence rate, while using an easy to implement and "robust" stepsize policy. It should be mentioned that the main ingredients of Polyak's scheme—long steps and averaging—were, in a different form, proposed already in Nemirovski and Yudin [15] for the case of problems (1.1) with general-type Lipschitz continuous convex objectives and for convex-concave saddle point problems. The algorithms from [15] exhibit, in a nonasymptotical fashion, the $O(t^{-1/2})$ rate of convergence. It is possible to show that in the general convex case (without assuming smoothness and strong convexity of the objective function), this rate of $O(t^{-1/2})$ is unimprovable. For a summary of early results in this direction, see Nemirovski and Yudin [16].

The SAA approach was used by many authors in various contexts under different names. Its basic idea is rather simple: generate a (random) sample $\xi_1, \ldots, \xi_N$, of size N, and approximate the "true" problem (1.1) by the sample average problem

$$\min_{x \in X} \left\{ \hat{f}_N(x) = N^{-1} \sum_{j=1}^{N} F(x, \xi_j) \right\}. \tag{1.4}$$

[1] Throughout the paper, we speak about convergence in terms of the objective value.

Note that the SAA method is not an algorithm; the obtained SAA problem (1.4) still has to be solved by an appropriate numerical procedure. Recent theoretical studies (cf. [11, 25, 26]) and numerical experiments (see, e.g., [12, 13, 29]) show that the SAA method coupled with a good (deterministic) algorithm could be reasonably efficient for solving certain classes of two-stage stochastic programming problems. On the other hand, classical SA-type numerical procedures typically performed poorly for such problems.

We intend to demonstrate in this paper that a properly modified SA approach can be competitive and even significantly outperform the SAA method for a certain class of stochastic problems. The mirror descent SA method we propose here is a direct descendent of the stochastic mirror descent method of Nemirovski and Yudin [16]. However, the method developed in this paper is more flexible than its "ancestor": the iteration of the method is exactly the prox-step for a chosen prox-function, and the choice of prox-type function is not limited to the norm-type distance-generating functions. Close techniques, based on subgradient averaging, have been proposed in Nesterov [17] and used in [10] to solve the stochastic optimization problem (1.1). Moreover, the results on large deviations of solutions and applications of the mirror descent SA to saddle point problems, to the best of our knowledge, are new.

The rest of this paper is organized as follows. In section 2 we focus on theory of the SA method applied to (1.1). We start with outlining the relevant–to-our-goals part of the classical "$O(t^{-1})$" SA theory (section 2.1), along with its "$O(t^{-1/2})$" modifications (section 2.2). Well-known and simple results presented in these sections pave the road to our main developments carried out in section 2.3. In section 3 we extend the constructions and results of section 2.3 to the case of the convex-concave stochastic saddle point problem. In concluding section 4 we present results (in our opinion, highly encouraging) of numerical experiments with the SA algorithm (sections 2.3 and 3) applied to large-scale stochastic convex minimization and saddle point problems. Section 5 gives a short conclusion for the presented results. Finally, some technical proofs are given in the appendix.

Throughout the paper, we use the following notation. By $\|x\|_p$, we denote the ℓ_p norm of vector $x \in \mathbb{R}^n$, in particular, $\|x\|_2 = \sqrt{x^T x}$ denotes the Euclidean norm, and $\|x\|_\infty = \max\{|x_1|, \ldots, |x_n|\}$. By Π_X, we denote the metric projection operator onto the set X, that is, $\Pi_X(x) = \arg\min_{x' \in X} \|x - x'\|_2$. Note that Π_X is a nonexpanding operator, i.e.,

$$\|\Pi_X(x') - \Pi_X(x)\|_2 \le \|x' - x\|_2 \ \ \forall x', x \in \mathbb{R}^n. \tag{1.5}$$

By $O(1)$, we denote positive absolute constants. The notation $\lfloor a \rfloor$ stands for the largest integer less than or equal to $a \in \mathbb{R}$ and $\lceil a \rceil$ for the smallest integer greater than or equal to $a \in \mathbb{R}$. By $\xi_{[t]} = (\xi_1, \ldots, \xi_t)$, we denote the history of the process $\xi_1, \ldots,$ up to time t. Unless stated otherwise, all relations between random variables are supposed to hold almost surely.

2. Stochastic approximation, basic theory. In this section we discuss theory and implementations of the SA approach to the minimization problem (1.1).

2.1. Classical SA algorithm. The classical SA algorithm solves (1.1) by mimicking the simplest subgradient descent method. That is, for chosen $x_1 \in X$ and a sequence $\gamma_j > 0$, $j = 1, \ldots,$ of stepsizes, it generates the iterates by the formula

$$x_{j+1} = \Pi_X(x_j - \gamma_j \mathsf{G}(x_j, \xi_j)). \tag{2.1}$$

Of course, the crucial question of that approach is how to choose the stepsizes γ_j. Let x_* be an optimal solution of (1.1). Note that since the set X is compact and $f(x)$ is continuous, (1.1) has an optimal solution. Note also that the iterate $x_j = x_j(\xi_{[j-1]})$ is a function of the history $\xi_{[j-1]} = (\xi_1, \ldots, \xi_{j-1})$ of the generated random process and hence is random.

Denote

$$A_j = \tfrac{1}{2}\|x_j - x_*\|_2^2 \quad \text{and} \quad a_j = \mathbb{E}[A_j] = \tfrac{1}{2}\mathbb{E}\left[\|x_j - x_*\|_2^2\right]. \tag{2.2}$$

By using (1.5) and since $x_* \in X$ and hence $\Pi_X(x_*) = x_*$, we can write

$$\begin{aligned} A_{j+1} &= \tfrac{1}{2}\left\|\Pi_X(x_j - \gamma_j \mathsf{G}(x_j, \xi_j)) - x_*\right\|_2^2 \\ &= \tfrac{1}{2}\left\|\Pi_X(x_j - \gamma_j \mathsf{G}(x_j, \xi_j)) - \Pi_X(x_*)\right\|_2^2 \\ &\le \tfrac{1}{2}\left\|x_j - \gamma_j \mathsf{G}(x_j, \xi_j) - x_*\right\|_2^2 \\ &= A_j + \tfrac{1}{2}\gamma_j^2 \|\mathsf{G}(x_j, \xi_j)\|_2^2 - \gamma_j (x_j - x_*)^T \mathsf{G}(x_j, \xi_j). \end{aligned} \tag{2.3}$$

Since $x_j = x_j(\xi_{[j-1]})$ is independent of ξ_j, we have

$$\begin{aligned} \mathbb{E}\left[(x_j - x_*)^T \mathsf{G}(x_j, \xi_j)\right] &= \mathbb{E}\left\{\mathbb{E}\left[(x_j - x_*)^T \mathsf{G}(x_j, \xi_j) \,|\xi_{[j-1]}\right]\right\} \\ &= \mathbb{E}\left\{(x_j - x_*)^T \mathbb{E}\left[\mathsf{G}(x_j, \xi_j) \,|\xi_{[j-1]}\right]\right\} \\ &= \mathbb{E}\left[(x_j - x_*)^T \mathsf{g}(x_j)\right]. \end{aligned} \tag{2.4}$$

Assume now that there is a positive number M such that

$$\mathbb{E}\left[\|\mathsf{G}(x, \xi)\|_2^2\right] \le M^2 \quad \forall x \in X. \tag{2.5}$$

Then, by taking expectation of both sides of (2.3) and using (2.4), we obtain

$$a_{j+1} \le a_j - \gamma_j \mathbb{E}\left[(x_j - x_*)^T \mathsf{g}(x_j)\right] + \tfrac{1}{2}\gamma_j^2 M^2. \tag{2.6}$$

Suppose further that the expectation function $f(x)$ is differentiable and strongly convex on X, i.e., there is constant $c > 0$ such that

$$f(x') \ge f(x) + (x' - x)^T \nabla f(x) + \tfrac{1}{2}c\|x' - x\|_2^2, \quad \forall x', x \in X,$$

or equivalently that

$$(x' - x)^T (\nabla f(x') - \nabla f(x)) \ge c\|x' - x\|_2^2 \quad \forall x', x \in X. \tag{2.7}$$

Note that strong convexity of $f(x)$ implies that the minimizer x_* is unique. By optimality of x_*, we have that

$$(x - x_*)^T \nabla f(x_*) \ge 0 \quad \forall x \in X,$$

which together with (2.7) implies that $(x - x_*)^T \nabla f(x) \ge c\|x - x_*\|_2^2$. In turn, it follows that $(x - x_*)^T g \ge c\|x - x_*\|_2^2$ for all $x \in X$ and $g \in \partial f(x)$, and hence

$$\mathbb{E}\left[(x_j - x_*)^T \mathsf{g}(x_j)\right] \ge c\mathbb{E}\left[\|x_j - x_*\|_2^2\right] = 2ca_j.$$

Therefore, it follows from (2.6) that

$$a_{j+1} \le (1 - 2c\gamma_j)a_j + \tfrac{1}{2}\gamma_j^2 M^2. \tag{2.8}$$

Let us take stepsizes $\gamma_j = \theta/j$ for some constant $\theta > 1/(2c)$. Then, by (2.8), we have

$$a_{j+1} \leq (1 - 2c\theta/j)a_j + \tfrac{1}{2}\theta^2 M^2/j^2.$$

It follows by induction that

$$\mathbb{E}\left[\|x_j - x_*\|_2^2\right] = 2a_j \leq Q(\theta)/j, \tag{2.9}$$

where

$$Q(\theta) = \max\left\{\theta^2 M^2 (2c\theta - 1)^{-1}, \|x_1 - x_*\|_2^2\right\}. \tag{2.10}$$

Suppose further that x_* is an *interior* point of X and $\nabla f(x)$ is Lipschitz continuous, i.e., there is constant $L > 0$ such that

$$\|\nabla f(x') - \nabla f(x)\|_2 \leq L\|x' - x\|_2 \ \ \forall x', x \in X. \tag{2.11}$$

Then

$$f(x) \leq f(x_*) + \tfrac{1}{2}L\|x - x_*\|_2^2, \ \ \forall x \in X, \tag{2.12}$$

and hence

$$\mathbb{E}\big[f(x_j) - f(x_*)\big] \leq \tfrac{1}{2}L\mathbb{E}\left[\|x_j - x_*\|_2^2\right] \leq \tfrac{1}{2}LQ(\theta)/j, \tag{2.13}$$

where $Q(\theta)$ is defined in (2.10).

Under the specified assumptions, it follows from (2.9) and (2.13), respectively, that after t iterations, the expected error of the current solution in terms of the distance to x_* is of order $O(t^{-1/2})$, and the expected error in terms of the objective value is of order $O(t^{-1})$, provided that $\theta > 1/(2c)$. The simple example of $X = \{x : \|x\|_2 \leq 1\}$, $f(x) = \frac{1}{2}cx^T x$, and $\mathsf{G}(x, \xi) = \nabla f(x) + \xi$, with ξ having standard normal distribution $\mathcal{N}(0, I_n)$, demonstrates that the outlined upper bounds on the expected errors are tight within factors independent of t.

We have arrived at the $O(t^{-1})$ rate of convergence in terms of the expected value of the objective mentioned in the Introduction. Note, however, that the result is highly sensitive to a priori information on c. What would happen if the parameter c of strong convexity is overestimated? As a simple example, consider $f(x) = x^2/10$, $X = [-1, 1] \subset \mathbb{R}$, and assume that there is no noise, i.e., $\mathsf{G}(x, \xi) \equiv \nabla f(x)$. Suppose, further that we take $\theta = 1$ (i.e., $\gamma_j = 1/j$), which will be the optimal choice for $c = 1$, while actually here $c = 0.2$. Then the iteration process becomes

$$x_{j+1} = x_j - f'(x_j)/j = \left(1 - \frac{1}{5j}\right) x_j,$$

and hence starting with $x_1 = 1$,

$$\begin{aligned} x_j = \prod_{s=1}^{j-1}\left(1 - \frac{1}{5s}\right) &= \exp\left\{-\sum_{s=1}^{j-1} \ln\left(1 + \frac{1}{5s-1}\right)\right\} > \exp\left\{-\sum_{s=1}^{j-1}\frac{1}{5s-1}\right\} \\ &> \exp\left\{-\left(0.25 + \int_1^{j-1}\frac{1}{5t-1}dt\right)\right\} > \exp\left\{-0.25 + 0.2\ln 1.25 - \frac{1}{5}\ln j\right\} \\ &> 0.8 j^{-1/5}. \end{aligned}$$

That is, the convergence is extremely slow. For example, for $j = 10^9$, the error of the iterated solution is greater than 0.015. On the other hand, for the optimal stepsize factor of $\theta = 1/c = 5$, the optimal solution $x_* = 0$ is found in one iteration.

It could be added that the stepsizes $\gamma_j = \theta/j$ may become completely unacceptable when f loses strong convexity. For example, when $f(x) = x^4$, $X = [-1, 1]$, and there is no noise, these stepsizes result in a disastrously slow convergence: $|x_j| \geq O([\ln(j+1)]^{-1/2})$. The precise statement here is that with $\gamma_j = \theta/j$ and $0 < x_1 \leq \frac{1}{6\sqrt{\theta}}$, we have that $x_j \geq \frac{x_1}{\sqrt{1+32\theta x_1^2[1+\ln(j+1)]}}$ for $j = 1, 2, \ldots$.

We see that in order to make the SA "robust"—applicable to general convex objectives rather than to strongly convex ones—one should replace the classical stepsizes $\gamma_j = O(j^{-1})$, which can be too small to ensure a reasonable rate of convergence even in the "no noise" case, with "much larger" stepsizes. At the same time, a detailed analysis shows that "large" stepsizes poorly suppress noise. As early as in [15] it was realized that in order to resolve the arising difficulty, it makes sense to separate collecting information on the objective from generating approximate solutions. Specifically, we can use large stepsizes, say, $\gamma_j = O(j^{-1/2})$ in (2.1), thus avoiding too slow motion at the cost of making the trajectory "more noisy." In order to suppress, to some extent, this noisiness, we take, as approximate solutions, appropriate averages of the search points x_j rather than these points themselves.

2.2. Robust SA approach. Results of this section go back to Nemirovski and Yudin [15, 16]. Let us look again at the basic relations (2.2), (2.5), and (2.6). By convexity of $f(x)$, we have that $f(x) \geq f(x_t) + (x - x_t)^T \mathsf{g}(x_t)$ for any $x \in X$, and hence

$$\mathbb{E}\big[(x_t - x_*)^T \mathsf{g}(x_t)\big] \geq \mathbb{E}\big[f(x_t) - f(x_*)\big].$$

Together with (2.6), this implies (recall that $a_t = \mathbb{E}\left[\frac{1}{2}\|x_t - x_*\|_2^2\right]$)

$$\gamma_t \mathbb{E}\big[f(x_t) - f(x_*)\big] \leq a_t - a_{t+1} + \tfrac{1}{2}\gamma_t^2 M^2.$$

It follows that whenever $1 \leq i \leq j$, we have

$$\sum_{t=i}^{j} \gamma_t \mathbb{E}\big[f(x_t) - f(x_*)\big] \leq \sum_{t=i}^{j} [a_t - a_{t+1}] + \tfrac{1}{2}M^2 \sum_{t=i}^{j} \gamma_t^2 \leq a_i + \tfrac{1}{2}M^2 \sum_{t=i}^{j} \gamma_t^2, \tag{2.14}$$

and hence, setting $\nu_t = \frac{\gamma_t}{\sum_{\tau=i}^{j} \gamma_\tau}$,

$$\mathbb{E}\left[\sum_{t=i}^{j} \nu_t f(x_t) - f(x_*)\right] \leq \frac{a_i + \frac{1}{2}M^2 \sum_{t=i}^{j} \gamma_t^2}{\sum_{t=i}^{j} \gamma_t}. \tag{2.15}$$

Note that $\nu_t \geq 0$ and $\sum_{t=i}^{j} \nu_t = 1$. Consider the points

$$\tilde{x}_i^j = \sum_{t=i}^{j} \nu_t x_t, \tag{2.16}$$

and let

$$D_X = \max_{x \in X} \|x - x_1\|_2. \tag{2.17}$$

By convexity of X, we have $\tilde{x}_i^j \in X$, and, by convexity of f, we have $f(\tilde{x}_i^j) \leq \sum_{t=i}^j \nu_t f(x_t)$. Thus, by (2.15) and in view of $a_1 \leq D_X^2$ and $a_i \leq 4D_X^2$, $i > 1$, we get

$$\begin{aligned} &\text{(a)} \quad \mathbb{E}\left[f(\tilde{x}_1^j) - f(x_*)\right] \leq \frac{D_X^2 + M^2 \sum_{t=1}^j \gamma_t^2}{2 \sum_{t=1}^j \gamma_t} \quad \text{for} \quad 1 \leq j, \\ &\text{(b)} \quad \mathbb{E}\left[f(\tilde{x}_i^j) - f(x_*)\right] \leq \frac{4D_X^2 + M^2 \sum_{t=i}^j \gamma_t^2}{2 \sum_{t=i}^j \gamma_t} \quad \text{for} \quad 1 < i \leq j. \end{aligned} \tag{2.18}$$

Based on the resulting bounds on the expected inaccuracy of approximate solutions $\tilde{x}_i^j$, we can now develop "reasonable" stepsize policies along with the associated efficiency estimates.

Constant stepsizes and basic efficiency estimate. Assume that the number N of iterations of the method is fixed in advance and that $\gamma_t = \gamma$, $t = 1, \ldots, N$. Then it follows by (2.18(a)) that

$$\mathbb{E}\left[f\left(\tilde{x}_1^N\right) - f(x_*)\right] \leq \frac{D_X^2 + M^2 N \gamma^2}{2N\gamma}. \tag{2.19}$$

Minimizing the right-hand side of (2.19) over $\gamma > 0$, we arrive at the *constant* stepsize policy

$$\gamma_t = \frac{D_X}{M\sqrt{N}}, \quad t = 1, \ldots, N, \tag{2.20}$$

along with the associated efficiency estimate

$$\mathbb{E}\left[f\left(\tilde{x}_1^N\right) - f(x_*)\right] \leq \frac{D_X M}{\sqrt{N}}. \tag{2.21}$$

With the constant stepsize policy (2.20), we also have, for $1 \leq K \leq N$,

$$\mathbb{E}\left[f\left(\tilde{x}_K^N\right) - f(x_*)\right] \leq \frac{D_X M}{\sqrt{N}} \left[\frac{2N}{N - K + 1} + \frac{1}{2}\right]. \tag{2.22}$$

When $K/N \leq 1/2$, the right-hand side of (2.22) coincides, within an absolute constant factor, with the right-hand side of (2.21). Finally, for a constant $\theta > 0$, passing from the stepsizes (2.20) to the stepsizes

$$\gamma_t = \frac{\theta D_X}{M\sqrt{N}}, \quad t = 1, \ldots, N, \tag{2.23}$$

the efficiency estimate becomes

$$\mathbb{E}\left[f\left(\tilde{x}_K^N\right) - f(x_*)\right] \leq \max\left\{\theta, \theta^{-1}\right\} \frac{D_X M}{\sqrt{N}} \left[\frac{2N}{N - K + 1} + \frac{1}{2}\right], \ 1 \leq K \leq N. \tag{2.24}$$

Discussion. We conclude that the expected error in terms of the objective of *Robust SA* algorithm (2.1), (2.16), with constant stepsize policy (2.20), after N iterations is of order $O(N^{-1/2})$ in our setting. Of course, this is worse than the rate $O(N^{-1})$ for the classical SA algorithm as applied to a smooth strongly convex function attaining minimum at a point from the interior of the set X. However, the error bounds (2.21)

and (2.22) are guaranteed independently of any smoothness and/or strong convexity assumptions on f. All that matters is the convexity of f on the convex compact set X and the validity of (2.5). Moreover, scaling the stepsizes by positive constant θ affects the error bound (2.24) *linearly* in $\max\{\theta, \theta^{-1}\}$. This can be compared with a possibly disastrous effect of such scaling in the classical SA algorithm discussed in section 2.1. These observations, in particular the fact that there is no necessity in "fine tuning" the stepsizes to the objective function f, explain the adjective "robust" in the name of the method. Finally, it can be shown that without additional, as compared to convexity and (2.5), assumptions on f, the accuracy bound (2.21) within an absolute constant factor is the best one allowed by statistics (cf. [16]).

Varying stepsizes. When the number of steps is not fixed in advance, it makes sense to replace constant stepsizes with the stepsizes

$$\gamma_t = \frac{\theta D_X}{M\sqrt{t}}, \quad t = 1, 2, \ldots . \tag{2.25}$$

From (2.18(b)) it follows that with this stepsize policy, one has, for $1 \le K \le N$,

$$\mathbb{E}\left[f\left(\tilde{x}_K^N\right) - f(x_*)\right] \le \frac{D_X M}{\sqrt{N}} \left[\frac{2}{\theta}\left(\frac{N}{N-K+1}\right) + \frac{\theta}{2}\sqrt{\frac{N}{K}}\right]. \tag{2.26}$$

Choosing K as a fixed fraction of N, i.e., setting $K = \lceil rN \rceil$, with a fixed $r \in (0,1)$, we get the efficiency estimate

$$\mathbb{E}\left[f\left(\tilde{x}_K^N\right) - f(x_*)\right] \le C(r) \max\left\{\theta, \theta^{-1}\right\} \frac{D_X M}{\sqrt{N}}, \quad N = 1, 2, \ldots, \tag{2.27}$$

with an easily computable factor $C(r)$ depending solely on r. This bound, up to a factor depending solely on r and θ, coincides with the bound (2.21), with the advantage that our new stepsize policy should not be adjusted to a fixed-in-advance number of steps N.

2.3. Mirror descent SA method. On a close inspection, the robust SA algorithm from section 2.2 is intrinsically linked to the Euclidean structure of $\mathbb{R}^n$. This structure plays the central role in the very construction of the method (see (2.1)), the same as in the associated efficiency estimates, like (2.21) (since the quantities D_X, M participating in the estimates are defined in terms of the Euclidean norm, see (2.17) and (2.5)). By these reasons, from now on, we refer to the algorithm from section 2.2 as the (robust) *Euclidean SA* (E-SA). In this section we develop a substantial generalization of the E-SA approach allowing us to adjust, to some extent, the method to the geometry, not necessary Euclidean, of the problem in question. We shall see in the meantime that we can gain a lot, both theoretically and numerically, from such an adjustment. A rudimentary form of the generalization to follow can be found in Nemirovski and Yudin [16], from where the name "mirror descent" originates.

Let $\|\cdot\|$ be a (general) norm on $\mathbb{R}^n$ and $\|x\|_* = \sup_{\|y\|\le 1} y^T x$ be its dual norm. We say that a function $\omega : X \to \mathbb{R}$ is a *distance-generating function* modulus $\alpha > 0$ with respect to $\|\cdot\|$, if ω is convex and continuous on X, the set

$$X^o = \{x \in X : \partial\omega(x) \ne \emptyset\} \tag{2.28}$$

is convex (note that X^o always contains the relative interior of X) and restricted to X^o, ω is continuously differentiable and strongly convex with parameter α with

respect to $\|\cdot\|$, i.e.,

$$(x'-x)^T(\nabla\omega(x')-\nabla\omega(x)) \geq \alpha\|x'-x\|^2 \ \ \forall x', x \in X^o. \tag{2.29}$$

A simple example of a distance-generating function is $\omega(x) = \frac{1}{2}\|x\|_2^2$ (modulus 1 with respect to $\|\cdot\|_2$, $X^o = X$).

Let us define function $V : X^o \times X \to \mathbb{R}_+$ as follows:

$$V(x,z) = \omega(z) - \left[\omega(x) + \nabla\omega(x)^T(z-x)\right]. \tag{2.30}$$

In what follows we shall refer to $V(\cdot,\cdot)$ as *prox-function* associated with distance-generating function $\omega(x)$ (it is also called Bregman distance [4]). Note that $V(x,\cdot)$ is nonnegative and is a strongly convex modulus α with respect to the norm $\|\cdot\|$. Let us define *prox-mapping* $P_x : \mathbb{R}^n \to X^o$, associated with ω and a point $x \in X^o$, viewed as a parameter, as follows:

$$P_x(y) = \arg\min_{z\in X}\left\{y^T(z-x) + V(x,z)\right\}. \tag{2.31}$$

Observe that the minimum in the right-hand side of (2.31) is attained since ω is continuous on X and X is compact, and all the minimizers belong to X^o, whence the minimizer is unique, since $V(x,\cdot)$ is strongly convex on X^o. Thus, the prox-mapping is well defined.

For $\omega(x) = \frac{1}{2}\|x\|_2^2$, we have $P_x(y) = \Pi_X(x-y)$ so that (2.1) is the recurrence

$$x_{j+1} = P_{x_j}(\gamma_j \mathsf{G}(x_j,\xi_j)), \quad x_1 \in X^o. \tag{2.32}$$

Our goal is to demonstrate that the main properties of the recurrence (2.1) (which from now on we call the E-SA recurrence) are inherited by (2.32), *whatever be the underlying distance-generating function* $\omega(x)$.

The statement of the following lemma is a simple consequence of the optimality conditions of the right-hand side of (2.31) (proof of this lemma is given in the appendix).

LEMMA 2.1. *For every $u \in X, x \in X^o$, and $y \in \mathbb{R}^n$, one has*

$$V(P_x(y),u) \leq V(x,u) + y^T(u-x) + \frac{\|y\|_*^2}{2\alpha}. \tag{2.33}$$

Using (2.33) with $x = x_j$, $y = \gamma_j \mathsf{G}(x_j,\xi_j)$, and $u = x_*$, we get

$$\gamma_j(x_j - x_*)^T\mathsf{G}(x_j,\xi_j) \leq V(x_j,x_*) - V(x_{j+1},x_*) + \frac{\gamma_j^2}{2\alpha}\|\mathsf{G}(x_j,\xi_j)\|_*^2. \tag{2.34}$$

Note that with $\omega(x) = \frac{1}{2}\|x\|_2^2$, one has $V(x,z) = \frac{1}{2}\|x-z\|_2^2$, $\alpha = 1$, $\|\cdot\|_* = \|\cdot\|_2$. That is, (2.34) becomes nothing but the relation (2.6), which played a crucial role in all the developments related to the E-SA method. We are about to process, in a completely similar fashion, the relation (2.34) in the case of a general distance-generating function, thus arriving at the mirror descent SA. Specifically, setting

$$\Delta_j = \mathsf{G}(x_j,\xi_j) - \mathsf{g}(x_j), \tag{2.35}$$

we can rewrite (2.34), with j replaced by t, as

$$\gamma_t(x_t - x_*)^T\mathsf{g}(x_t) \leq V(x_t,x_*) - V(x_{t+1},x_*) - \gamma_t\Delta_t^T(x_t - x_*) + \frac{\gamma_t^2}{2\alpha}\|\mathsf{G}(x_t,\xi_t)\|_*^2. \tag{2.36}$$

Summing up over $t = 1, \ldots, j$, and taking into account that $V(x_{j+1}, u) \geq 0$, $u \in X$, we get

$$\sum_{t=1}^{j} \gamma_t (x_t - x_*)^T \mathsf{g}(x_t) \leq V(x_1, x_*) + \sum_{t=1}^{j} \frac{\gamma_t^2}{2\alpha} \|\mathsf{G}(x_t, \xi_t)\|_*^2 - \sum_{t=1}^{j} \gamma_t \Delta_t^T (x_t - x_*). \tag{2.37}$$

Setting $\nu_t = \frac{\gamma_t}{\sum_{i=1}^{j} \gamma_i}$, $t = 1, \ldots, j$, and

$$\tilde{x}_1^j = \sum_{t=1}^{j} \nu_t x_t \tag{2.38}$$

and invoking convexity of $f(\cdot)$, we have

$$\begin{aligned} \sum_{t=1}^{j} \gamma_t (x_t - x_*)^T \mathsf{g}(x_t) &\geq \sum_{t=1}^{j} \gamma_t \left[f(x_t) - f(x_*) \right] \\ &= \left(\sum_{t=1}^{j} \gamma_t \right) \left[\sum_{t=1}^{j} \nu_t f(x_t) - f(x_*) \right] \\ &\geq \left(\sum_{t=1}^{j} \gamma_t \right) \left[f(\tilde{x}_j) - f(x_*) \right], \end{aligned}$$

which combines with (2.37) to imply that

$$f(\tilde{x}_1^j) - f(x_*) \leq \frac{V(x_1, x_*) + \sum_{t=1}^{j} \frac{\gamma_t^2}{2\alpha} \|\mathsf{G}(x_t, \xi_t)\|_*^2 - \sum_{t=1}^{j} \gamma_t \Delta_t^T (x_t - x_*)}{\sum_{t=1}^{j} \gamma_t}. \tag{2.39}$$

Let us suppose, as in the previous section (cf. (2.5)), that we are given a positive number M_* such that

$$\mathbb{E}\left[\|\mathsf{G}(x, \xi)\|_*^2 \right] \leq M_*^2 \ \ \forall x \in X. \tag{2.40}$$

Taking expectations of both sides of (2.39) and noting that (i) x_t is a deterministic function of $\xi_{[t-1]} = (\xi_1, \ldots, \xi_{t-1})$, (ii) conditional on $\xi_{[t-1]}$, the expectation of Δ_t is 0, and (iii) the expectation of $\|\mathsf{G}(x_t, \xi_t)\|_*^2$ does not exceed M_*^2, we obtain

$$\mathbb{E}\left[f(\tilde{x}_1^j) - f(x_*) \right] \leq \frac{\max_{u \in X} V(x_1, u) + (2\alpha)^{-1} M_*^2 \sum_{t=1}^{j} \gamma_t^2}{\sum_{t=1}^{j} \gamma_t}. \tag{2.41}$$

Assume from now on that the method starts with the minimizer of ω:

$$x_1 = \operatorname{argmin}_X \omega(x).$$

Then, from (2.30), it follows that

$$\max_{z \in X} V(x_1, z) \leq D_{\omega, X}^2, \tag{2.42}$$

where

$$D_{\omega, X} := \left[\max_{z \in X} \omega(z) - \min_{z \in X} \omega(z) \right]^{1/2}. \tag{2.43}$$

Consequently, (2.41) implies that

$$\mathbb{E}\left[f(\tilde{x}_1^j) - f(x_*) \right] \leq \frac{D_{\omega, X}^2 + \frac{1}{2\alpha} M_*^2 \sum_{t=1}^{j} \gamma_t^2}{\sum_{t=1}^{j} \gamma_t}. \tag{2.44}$$

Constant stepsize policy. Assuming that the total number of steps N is given in advance and $\gamma_t = \gamma$, $t = 1, \ldots, N$, optimizing the right-hand side of (2.44) over $\gamma > 0$ we arrive at the constant stepsize policy

$$\gamma_t = \frac{\sqrt{2\alpha}D_{\omega,X}}{M_*\sqrt{N}}, \quad t = 1, \ldots, N \tag{2.45}$$

and the associated efficiency estimate

$$\mathbb{E}\left[f\left(\tilde{x}_1^N\right) - f(x_*)\right] \leq D_{\omega,X}M_*\sqrt{\frac{2}{\alpha N}} \tag{2.46}$$

(cf. (2.20), (2.21)). For a constant $\theta > 0$, passing from the stepsizes (2.45) to the stepsizes

$$\gamma_t = \frac{\theta\sqrt{2\alpha}D_{\omega,X}}{M_*\sqrt{N}}, \quad t = 1, \ldots, N, \tag{2.47}$$

the efficiency estimate becomes

$$\mathbb{E}\left[f\left(\tilde{x}_1^N\right) - f(x_*)\right] \leq \max\left\{\theta, \theta^{-1}\right\} D_{\omega,X}M_*\sqrt{\frac{2}{\alpha N}}. \tag{2.48}$$

We refer to the method (2.32), (2.38), and (2.47) as the (robust) *mirror descent SA* algorithm with constant stepsize policy.

Probabilities of large deviations. So far, all our efficiency estimates were upper bounds on the expected nonoptimality, in terms of the objective, of approximate solutions generated by the algorithms. Here we complement these results with bounds on probabilities of large deviations. Observe that by Markov inequality, (2.48) implies that

$$\mathrm{Prob}\left\{f\left(\tilde{x}_1^N\right) - f(x_*) > \varepsilon\right\} \leq \frac{\sqrt{2}\max\left\{\theta, \theta^{-1}\right\} D_{\omega,X}M_*}{\varepsilon\sqrt{\alpha N}} \quad \forall \varepsilon > 0. \tag{2.49}$$

It is possible, however, to obtain much finer bounds on deviation probabilities when imposing more restrictive assumptions on the distribution of $\mathsf{G}(x, \xi)$. Specifically, assume that

$$\mathbb{E}\left[\exp\left\{\|\mathsf{G}(x,\xi)\|_*^2/M_*^2\right\}\right] \leq \exp\{1\} \quad \forall x \in X. \tag{2.50}$$

Note that condition (2.50) is stronger than (2.40). Indeed, if a random variable Y satisfies $\mathbb{E}[\exp\{Y/a\}] \leq \exp\{1\}$ for some $a > 0$, then by Jensen inequality, $\exp\{\mathbb{E}[Y/a]\} \leq \mathbb{E}[\exp\{Y/a\}] \leq \exp\{1\}$, and therefore, $\mathbb{E}[Y] \leq a$. Of course, condition (2.50) holds if $\|\mathsf{G}(x,\xi)\|_* \leq M_*$ for all $(x, \xi) \in X \times \Xi$.

PROPOSITION 2.2. *In the case of* (2.50) *and for the constant stepsizes* (2.47)*, the following holds for any* $\Omega \geq 1$*:*

$$\mathrm{Prob}\left\{f\left(\tilde{x}_1^N\right) - f(x_*) > \frac{\sqrt{2}\max\left\{\theta, \theta^{-1}\right\} M_*D_{\omega,X}(12 + 2\Omega)}{\sqrt{\alpha N}}\right\} \leq 2\exp\{-\Omega\}. \tag{2.51}$$

Proof of this proposition is given in the appendix.

Varying stepsizes. Same as in the case of E-SA, we can modify the mirror descent SA algorithm to allow for time-varying stepsizes and "sliding averages" of the search points x_t in the role of approximate solutions, thus getting rid of the necessity to fix in advance the number of steps. Specifically, consider

$$\begin{aligned}\overline{D}_{\omega,X} &:= \sqrt{2}\sup_{x\in X^o, z\in X}\left[\omega(z)-\omega(x)-(z-x)^T\nabla\omega(x)\right]^{1/2}\\ &= \sup_{x\in X^o, z\in X}\sqrt{2V(x,z)}\end{aligned} \tag{2.52}$$

and assume that $\overline{D}_{\omega,X}$ is finite. This is definitely so when ω is continuously differentiable on the entire X. Note that for the E-SA, that is, with $\omega(x)=\frac{1}{2}\|x\|_2^2$, $\overline{D}_{\omega,X}$ is the Euclidean diameter of X.

In the case of (2.52), setting

$$\tilde{x}_i^j = \frac{\sum_{t=i}^j \gamma_t x_t}{\sum_{t=i}^j \gamma_t}, \tag{2.53}$$

summing up inequalities (2.34) over $K\le t\le N$, and acting exactly as when deriving (2.39), we get for $1\le K\le N$,

$$f\left(\tilde{x}_K^N\right)-f(x_*)\le \frac{V(x_K,x_*)+\sum_{t=K}^N \frac{\gamma_t^2}{2\alpha}\|\mathsf{G}(x_t,\xi_t)\|_*^2-\sum_{t=K}^N\gamma_t\Delta_t^T(x_t-x_*)}{\sum_{t=K}^N\gamma_t}.$$

Noting that $V(x_K,x_*)\le\frac{1}{2}\overline{D}_{\omega,X}^2$ and taking expectations, we arrive at

$$\mathbb{E}\left[f\left(\tilde{x}_K^N\right)-f(x_*)\right]\le\frac{\frac{1}{2}\overline{D}_{\omega,X}^2+\frac{1}{2\alpha}M_*^2\sum_{t=K}^N\gamma_t^2}{\sum_{t=K}^N\gamma_t} \tag{2.54}$$

(cf. (2.44)). It follows that with a decreasing stepsize policy

$$\gamma_t=\frac{\theta\overline{D}_{\omega,X}\sqrt{\alpha}}{M_*\sqrt{t}},\quad t=1,2,\ldots, \tag{2.55}$$

one has for $1\le K\le N$,

$$\mathbb{E}\left[f\left(\tilde{x}_K^N\right)-f(x_*)\right]\le\frac{\overline{D}_{\omega,X}M_*}{\sqrt{\alpha}\sqrt{N}}\left[\frac{2}{\theta}\frac{N}{N-K+1}+\frac{\theta}{2}\sqrt{\frac{N}{K}}\right] \tag{2.56}$$

(cf. (2.26)). In particular, with $K=\lceil rN\rceil$ for a fixed $r\in(0,1)$, we get an efficiency estimate

$$\mathbb{E}\left[f\left(\tilde{x}_K^N\right)-f(x_*)\right]\le C(r)\max\left\{\theta,\theta^{-1}\right\}\frac{\overline{D}_{\omega,X}M_*}{\sqrt{\alpha}\sqrt{N}}, \tag{2.57}$$

completely similar to the estimate (2.27) for the E-SA.

Discussion. Comparing (2.21) to (2.46) and (2.27) to (2.57), we see that for both the Euclidean and the mirror descent robust SA, the expected inaccuracy, in terms of the objective, of the approximate solution built in course of N steps is $O(N^{-1/2})$. A benefit of the mirror descent over the Euclidean algorithm is in the

potential possibility to reduce the constant factor hidden in $O(\cdot)$ by adjusting the norm $\|\cdot\|$ and the distance-generating function $\omega(\cdot)$ to the geometry of the problem.

Example. Let $X = \{x \in \mathbb{R}^n : \sum_{i=1}^n x_i = 1,\ x \geq 0\}$ be a standard simplex. Consider two setups for the mirror descent SA:

— *Euclidean setup*, where $\|\cdot\| = \|\cdot\|_2$ and $\omega(x) = \frac{1}{2}\|x\|_2^2$, and

— ℓ_1*-setup*, where $\|\cdot\| = \|\cdot\|_1$, with $\|\cdot\|_* = \|\cdot\|_\infty$ and ω is the *entropy* function

$$\omega(x) = \sum_{i=1}^n x_i \ln x_i. \tag{2.58}$$

The Euclidean setup leads to the Euclidean robust SA, which is easily implementable (computing the prox-mapping requires $O(n \ln n)$ operations) and guarantees that

$$\mathbb{E}\left[f\left(\tilde{x}_1^N\right) - f(x_*)\right] \leq O(1) \max\left\{\theta, \theta^{-1}\right\} M N^{-1/2}, \tag{2.59}$$

with $M^2 = \sup_{x \in X} \mathbb{E}\left[\|\mathsf{G}(x,\xi)\|_2^2\right]$, provided that the constant M is known and the stepsizes (2.23) are used (see (2.24), (2.17), and note that the Euclidean diameter of X is $\sqrt{2}$).

The ℓ_1-setup corresponds to $X^o = \{x \in X : x > 0\}$, $D_{\omega,X} = \sqrt{\ln n}$, $\alpha = 1$, and $x_1 = \operatorname{argmin}_X \omega = n^{-1}(1, \ldots, 1)^T$ (see appendix). The associated mirror descent SA is easily implementable: the prox-function here is

$$V(x,z) = \sum_{i=1}^n z_i \ln \frac{z_i}{x_i},$$

and the prox-mapping $P_x(y) = \operatorname{argmin}_{z \in X}\left[y^T(z-x) + V(x,z)\right]$ can be computed in $O(n)$ operations according to the explicit formula

$$[P_x(y)]_i = \frac{x_i e^{-y_i}}{\sum_{k=1}^n x_k e^{-y_k}},\ \ i = 1, \ldots, n.$$

The efficiency estimate guaranteed with the ℓ_1-setup is

$$\mathbb{E}\left[f\left(\tilde{x}_1^N\right) - f(x_*)\right] \leq O(1) \max\left\{\theta, \theta^{-1}\right\} \sqrt{\ln n} M_* N^{-1/2}, \tag{2.60}$$

with

$$M_*^2 = \sup_{x \in X} \mathbb{E}\left[\|\mathsf{G}(x,\xi)\|_\infty^2\right],$$

provided that the constant M_* is known and the constant stepsizes (2.47) are used (see (2.48) and (2.40)). To compare (2.60) and (2.59), observe that $M_* \leq M$, and the ratio M_*/M can be as small as $n^{-1/2}$. Thus, the efficiency estimate for the ℓ_1-setup never is much worse than the estimate for the Euclidean setup, and for large n, can be *far better* than the latter estimate:

$$\sqrt{\frac{1}{\ln n}} \leq \frac{M}{\sqrt{\ln n} M_*} \leq \sqrt{\frac{n}{\ln n}},\ N = 1, 2, \ldots,$$

both the upper and the lower bounds being achievable. Thus, when X is a standard simplex of large dimension, we have strong reasons to prefer the ℓ_1-setup to the usual Euclidean one.

Note that $\|\cdot\|_1$-norm can be coupled with "good" distance-generating functions different from the entropy one, e.g., with the function

$$\omega(x) = (\ln n)\sum_{i=1}^{n} |x_i|^{1+\frac{1}{\ln n}}, \quad n \geq 3. \tag{2.61}$$

Whenever $0 \in X$ and $\mathrm{Diam}_{\|\cdot\|_1}(X) \equiv \max_{x,y\in X} \|x-y\|_1$ equal to 1 (these conditions can always be ensured by scaling and shifting X), for the just-outlined setup, one has $\overline{D}_{\omega,X} = O(1)\sqrt{\ln n}$, $\alpha = O(1)$, so that the associated mirror descent robust SA guarantees that with $M_*^2 = \sup_{x\in X} \mathbb{E}\left[\|\mathsf{G}(x,\xi)\|_\infty^2\right]$ and $N \geq 1$,

$$\mathbb{E}\left[f\left(\tilde{x}^N_{\lceil rN\rceil}\right) - f(x_*)\right] \leq C(r)\frac{M_*\sqrt{\ln n}}{\sqrt{N}} \tag{2.62}$$

(see (2.57)), while the efficiency estimate for the Euclidean robust SA is

$$\mathbb{E}\left[f(\tilde{x}^N_{\lceil rN\rceil}) - f(x_*)\right] \leq C(r)\frac{M\,\mathrm{Diam}_{\|\cdot\|_2}(X)}{\sqrt{N}}, \tag{2.63}$$

with

$$M^2 = \sup_{x\in X} \mathbb{E}\left[\|\mathsf{G}(x,\xi)\|_2^2\right] \ \text{ and } \ \mathrm{Diam}_{\|\cdot\|_2}(X) = \max_{x,y\in X} \|x-y\|_2.$$

Ignoring logarithmic in n factors, the second estimate (2.63) can be much better than the first estimate (2.62) only when $\mathrm{Diam}_{\|\cdot\|_2}(X) \ll 1 = \mathrm{Diam}_{\|\cdot\|_1}(X)$, as it is the case, e.g., when X is an Euclidean ball. On the other hand, when X is an $\|\cdot\|_1$-ball or its nonnegative part (which is the simplex), so that the $\|\cdot\|_1$- and $\|\cdot\|_2$-diameters of X are of the same order, the first estimate (2.62) is much more attractive than the estimate (2.63) due to potentially much smaller constant M_*.

Comparison with the SAA approach. We compare now theoretical complexity estimates for the robust mirror descent SA and the SAA methods. Consider the case when (i) $X \subset \mathbb{R}^n$ is contained in the $\|\cdot\|_p$-ball of radius R, $p = 1, 2$, and the SA in question is either the E-SA ($p = 2$), or the SA associated with $\|\cdot\|_1$ and the distance-generating function[2] (2.61), (ii) in SA, the constant stepsize rule (2.45) is used, and (iii) the "light tail" assumption (2.50) takes place.

Given $\varepsilon > 0$, $\delta \in (0, 1/2)$, let us compare the number of steps $N = N_{\mathrm{SA}}$ of SA, which, with probability $\geq 1-\delta$, results in an approximate solution $\tilde{x}_1^N$ such that $f(\tilde{x}_1^N) - f(x_*) \leq \varepsilon$, with the sample size $N = N_{\mathrm{SAA}}$ for the SAA resulting in the same accuracy guarantees. According to Proposition 2.2 we have that $\mathrm{Prob}\left[f(\tilde{x}_1^N) - f(x_*) > \varepsilon\right] \leq \delta$ for

$$N_{\mathrm{SA}} = O(1)\varepsilon^{-2}D_{\omega,X}^2 M_*^2 \ln^2(1/\delta), \tag{2.64}$$

where M_* is the constant from (2.50) and $D_{\omega,X}$ is defined in (2.43). Note that the constant M_* depends on the chosen norm, $D_{\omega,X}^2 = O(1)R^2$ for $p = 2$, and $D_{\omega,X}^2 = O(1)\ln(n)R^2$ for $p = 1$.

This can be compared with the estimate of the sample size (cf. [25, 26])

$$N_{\mathrm{SAA}} = O(1)\varepsilon^{-2}R^2M_*^2\left[\ln(1/\delta) + n\ln\left(RM_*/\varepsilon\right)\right]. \tag{2.65}$$

[2]In the second case, we apply the SA after the variables are scaled to make X the unit $\|\cdot\|_1$-ball.

We see that both SA and SAA methods have logarithmic in δ and quadratic (or nearly so) in $1/\varepsilon$ complexity in terms of the corresponding sample sizes. It should be noted, however, that the SAA method requires solution of the corresponding (deterministic) problem, while the SA approach is based on simple calculations as long as stochastic subgradients could be easily computed.

3. Stochastic saddle point problem. We show in this section how the mirror descent SA algorithm can be modified to solve a convex-concave stochastic saddle point problem. Consider the following minimax (saddle point) problem:

$$\min_{x\in X}\max_{y\in Y}\big\{\phi(x,y)=\mathbb{E}[\Phi(x,y,\xi)]\big\}. \tag{3.1}$$

Here $X\subset\mathbb{R}^n$ and $Y\subset\mathbb{R}^m$ are nonempty bounded closed convex sets, ξ is a random vector whose probability distribution P is supported on set $\Xi\subset\mathbb{R}^d$, and $\Phi: X\times Y\times\Xi\to\mathbb{R}$. We assume that for every $(x,y)\in X\times Y$, the expectation

$$\mathbb{E}[\Phi(x,y,\xi)]=\int_{\Xi}\Phi(x,y,\xi)dP(\xi)$$

is well defined and finite valued and that the expected value function $\phi(x,y)$ is *convex* in $x\in X$ and *concave* in $y\in Y$. It follows that (3.1) is a *convex-concave saddle point* problem. In addition, we assume that $\phi(\cdot,\cdot)$ is *Lipschitz continuous* on $X\times Y$. It is well known that, in the above setting, (3.1) is solvable, i.e., the corresponding "primal" and "dual" optimization problems

$$\min_{x\in X}\left[\max_{y\in Y}\phi(x,y)\right]\quad\text{and}\quad\max_{y\in Y}\left[\min_{x\in X}\phi(x,y)\right],$$

respectively, are solvable with equal optimal values, denoted ϕ^*, and pairs (x^*,y^*) of optimal solutions to the respective problems form the set of saddle points of $\phi(x,y)$ on $X\times Y$.

As in the case of the minimization problem (1.1), we assume that neither the function $\phi(x,y)$ nor its sub/supergradients in x and y are available explicitly. However, we make the following assumption.

(A′2) We have at our disposal an oracle which, given an input of point $(x,y,\xi)\in X\times Y\times\Xi$, returns a *stochastic subgradient*, that is, $(n+m)$-dimensional vector $\mathsf{G}(x,y,\xi)=\begin{bmatrix}\mathsf{G}_x(x,y,\xi)\\ -\mathsf{G}_y(x,y,\xi)\end{bmatrix}$ such that vector

$$\mathsf{g}(x,y)=\begin{bmatrix}\mathsf{g}_x(x,y)\\ -\mathsf{g}_y(x,y)\end{bmatrix}=\begin{bmatrix}\mathbb{E}[\mathsf{G}_x(x,y,\xi)]\\ -\mathbb{E}[\mathsf{G}_y(x,y,\xi)]\end{bmatrix}$$

is well defined, $\mathsf{g}_x(x,y)\in\partial_x\phi(x,y)$, and $-\mathsf{g}_y(x,y)\in\partial_y(-\phi(x,y))$.

For example, if for every $\xi\in\Xi$ the function $\Phi(\cdot,\cdot,\xi)$ is *convex-concave* and the respective subdifferential and integral operators are interchangeable, we ensure (A′2) by setting

$$\mathsf{G}(x,y,\xi)=\begin{bmatrix}\mathsf{G}_x(x,y,\xi)\\ -\mathsf{G}_y(x,y,\xi)\end{bmatrix}\in\begin{bmatrix}\partial_x\Phi(x,y,\xi)\\ \partial_y(-\Phi(x,y,\xi))\end{bmatrix}.$$

Let $\|\cdot\|_x$ be a norm on $\mathbb{R}^n$ and $\|\cdot\|_y$ be a norm on $\mathbb{R}^m$, and let $\|\cdot\|_{*,x}$ and $\|\cdot\|_{*,y}$ stand for the corresponding dual norms. As in section 2.1, the basic assumption we make about the stochastic oracle (aside from its unbiasedness, which we have already postulated) is that we know positive constants $M_{*,x}^2$ and $M_{*,y}^2$ such that

$$\mathbb{E}\left[\|\mathsf{G}_x(u,v,\xi)\|_{*,x}^2\right]\le M_{*,x}^2\ \text{ and }\ \mathbb{E}\left[\|\mathsf{G}_y(u,v,\xi)\|_{*,y}^2\right]\le M_{*,y}^2\ \ \forall(u,v)\in X\times Y. \tag{3.2}$$

3.1. Mirror SA algorithm for saddle point problems. We equip X and Y with distance-generating functions $\omega_x : X \to \mathbb{R}$ modulus α_x with respect to $\|\cdot\|_x$, and $\omega_y : Y \to \mathbb{R}$ modulus α_y with respect to $\|\cdot\|_y$. Let $D_{\omega_x,X}$ and $D_{\omega_y,Y}$ be the respective constants (see definition (2.42)). We equip $\mathbb{R}^n \times \mathbb{R}^m$ with the norm

$$\|(x,y)\| = \sqrt{\tfrac{\alpha_x}{2D^2_{\omega_x,X}}\|x\|_x^2 + \tfrac{\alpha_y}{2D^2_{\omega_y,Y}}\|y\|_y^2}, \tag{3.3}$$

so that the dual norm is

$$\|(\zeta,\eta)\|_* = \sqrt{\tfrac{2D^2_{\omega_x,X}}{\alpha_x}\|\zeta\|_{*,x}^2 + \tfrac{2D^2_{\omega_y,Y}}{\alpha_y}\|\eta\|_{*,y}^2} \tag{3.4}$$

and set

$$M_*^2 = \frac{2D^2_{\omega_x,X}}{\alpha_x}M_{*,x}^2 + \frac{2D^2_{\omega_y,Y}}{\alpha_y}M_{*,y}^2. \tag{3.5}$$

It follows by (3.2) that

$$\mathbb{E}\big[\|\mathsf{G}(x,y,\xi)\|_*^2\big] \le M_*^2. \tag{3.6}$$

We use the notation $z = (x,y)$ and equip the set $Z = X \times Y$ with the distance-generating function

$$\omega(z) = \frac{\omega_x(x)}{2D^2_{\omega_x,X}} + \frac{\omega_y(y)}{2D^2_{\omega_y,Y}}.$$

It is immediately seen that ω indeed is a distance-generating function for Z modulus $\alpha = 1$ with respect to the norm $\|\cdot\|$ and that $Z^o = X^o \times Y^o$ and $D_{\omega,Z} = 1$. In what follows, $V(z,u) : Z^o \times Z \to \mathbb{R}$ and $P_z(\zeta) : \mathbb{R}^{n+m} \to Z^o$ are the prox-function and prox-mapping associated with ω and Z (see (2.30), (2.31)).

We are ready now to present the mirror SA algorithm for saddle point problems. This is the iterative procedure (compare with (2.32))

$$z_{j+1} = P_{z_j}(\gamma_j \mathsf{G}(z_j,\xi_j)), \tag{3.7}$$

where the initial point $z_1 \in Z$ is chosen to be the minimizer of $\omega(z)$ on Z. As before (compare with (2.38)), we define approximate solution $\tilde z_1^j = (\tilde x_1^j, \tilde y_1^j)$ of (3.1) after j iterations as

$$\tilde z_1^j = \frac{\sum_{t=1}^j \gamma_t z_t}{\sum_{t=1}^j \gamma_t}. \tag{3.8}$$

We refer to the procedure (3.7), (3.8) as the *saddle point mirror SA* algorithm.

Let us analyze convergence properties of the algorithm. We measure quality of an approximate solution $\tilde z = (\tilde x, \tilde y)$ by the error

$$\epsilon_\phi(\tilde z) := \left[\max_{y\in Y}\phi(\tilde x, y) - \phi_*\right] + \left[\phi_* - \min_{x\in X}\phi(x,\tilde y)\right] = \max_{y\in Y}\phi(\tilde x, y) - \min_{x\in X}\phi(x,\tilde y).$$

By convexity of $\phi(\cdot, y)$, we have

$$\phi(x_t,y_t) - \phi(x,y_t) \le (x_t - x)^T \mathsf{g}_x(x_t,y_t) \ \ \forall x \in X$$

and by concavity of $\phi(x,\cdot)$,

$$\phi(x_t,y)-\phi(x_t,y_t)\le (y-y_t)^T\mathtt{g}_y(x_t,y_t)\ \ \forall y\in Y$$

so that for all $z=(x,y)\in Z$,

$$\phi(x_t,y)-\phi(x,y_t)\le (x_t-x)^T\mathtt{g}_x(x_t,y_t)+(y-y_t)^T\mathtt{g}_y(x_t,y_t)=(z_t-z)^T\mathtt{g}(z_t).$$

Using once again the convexity-concavity of ϕ, we write

$$\begin{aligned}\epsilon_\phi(\tilde z_1^j)&=\max_{y\in Y}\phi\left(\tilde x_1^j,y\right)-\min_{x\in X}\phi\left(x,\tilde y_1^j\right)\\ &\le\left[\sum_{t=1}^j\gamma_t\right]^{-1}\left[\max_{y\in Y}\sum_{t=1}^j\gamma_t\phi(x_t,y)-\min_{x\in X}\sum_{t=1}^j\gamma_t\phi(x,y_t)\right]\\ &\le\left[\sum_{t=1}^j\gamma_t\right]^{-1}\max_{z\in Z}\sum_{t=1}^j\gamma_t(z_t-z)^T\mathtt{g}(z_t).\end{aligned}\tag{3.9}$$

To bound the right-hand side of (3.9), we use the result of the following lemma (its proof is given in the appendix).

LEMMA 3.1. *In the above setting, for any $j\ge 1$, the following inequality holds:*

$$\mathbb{E}\left[\max_{z\in Z}\sum_{t=1}^j\gamma_t(z_t-z)^T\mathtt{g}(z_t)\right]\le 2+\frac{5}{2}M_*^2\sum_{t=1}^j\gamma_t^2.\tag{3.10}$$

Now to get an error bound for the solution $\tilde z_1^j$, it suffices to substitute inequality (3.10) into (3.9) to obtain

$$\mathbb{E}\left[\epsilon_\phi\left(\tilde z_1^j\right)\right]\le\left[\sum_{t=1}^j\gamma_t\right]^{-1}\left[2+\frac{5}{2}M_*^2\sum_{t=1}^j\gamma_t^2\right].\tag{3.11}$$

Constant stepsizes and basic efficiency estimates. For a fixed number of steps N, with the constant stepsize policy

$$\gamma_t=\frac{2\theta}{M_*\sqrt{5N}},\ \ t=1,\dots,N,\tag{3.12}$$

condition (3.6) and estimate (3.11) imply that

$$\begin{aligned}\epsilon_\phi\left(\tilde z_1^N\right)&\le 2\max\left\{\theta,\theta^{-1}\right\}M_*\sqrt{\tfrac{5}{N}}\\ &=2\max\left\{\theta,\theta^{-1}\right\}\sqrt{\frac{10\left[\alpha_yD^2_{\omega_x,X}M^2_{*,x}+\alpha_xD^2_{\omega_y,Y}M^2_{*,y}\right]}{\alpha_x\alpha_yN}}.\end{aligned}\tag{3.13}$$

Variable stepsizes. Same as in the minimization case, assuming that

$$\begin{aligned}\overline{D}_{\omega,Z}&:=\sqrt{2}\sup_{z\in Z^o,w\in Z}\left[\omega(w)-\omega(z)-(w-z)^T\nabla\omega(z)\right]^{1/2}\\ &=\sqrt{2}\left[\sup_{z\in Z^o,w\in Z}V(z,w)\right]^{1/2}\end{aligned}\tag{3.14}$$

is finite, we can pass from constant stepsizes on a fixed "time horizon" to decreasing stepsize policy

$$\gamma_t = \frac{\theta \overline{D}_{\omega,Z}}{M_* \sqrt{t}}, \quad t = 1, 2, \ldots$$

(compare with (2.55) and take into account that we are in the situation of $\alpha = 1$), and from the averaging of all iterates to the "sliding averaging"

$$\tilde{z}_i^j = \frac{\sum_{t=i}^j \gamma_t z_t}{\sum_{t=i}^j \gamma_t},$$

arriving at the efficiency estimates (compare with (2.56) and (2.57))

$$\begin{aligned} \epsilon\left(\tilde{z}_K^N\right) &\le \frac{\overline{D}_{\omega,Z} M_*}{\sqrt{N}} \left[\frac{2}{\theta} \frac{N}{N-K+1} + \frac{5\theta}{2} \sqrt{\frac{N}{K}}\right], \quad 1 \le K \le N, \\ \epsilon\left(\tilde{z}_{\lceil rN \rceil}^N\right) &\le C(r) \max\left\{\theta, \theta^{-1}\right\} \frac{\overline{D}_{\omega,Z} M_*}{\sqrt{N}}, \qquad r \in (0,1). \end{aligned} \tag{3.15}$$

Probabilities of large deviations. Assume that instead of (3.2), the following stronger assumption holds:

$$\begin{aligned} \mathbb{E}\left[\exp\left\{\|\mathsf{G}_x(u,v,\xi)\|_{*,x}^2 / M_{*,x}^2\right\}\right] &\le \exp\{1\}, \\ \mathbb{E}\left[\exp\left\{\|\mathsf{G}_y(x,y,\xi)\|_{*,y}^2 / M_{*,y}^2\right\}\right] &\le \exp\{1\}. \end{aligned} \tag{3.16}$$

Proposition 3.2. *In the case of* (3.16)*, with the stepsizes given by* (3.12) and (3.6)*, one has, for any* $\Omega > 1$*,*

$$\text{Prob}\left\{\epsilon_\phi\left(\tilde{z}_1^N\right) > \frac{(8+2\Omega)\max\left\{\theta,\theta^{-1}\right\}\sqrt{5} M_*}{\sqrt{N}}\right\} \le 2\exp\{-\Omega\}. \tag{3.17}$$

Proof of this proposition is given in the appendix.

3.2. Application to minimax stochastic problems. Consider the following minimax stochastic problem:

$$\min_{x \in X} \max_{1 \le i \le m} \left\{f_i(x) = \mathbb{E}[F_i(x,\xi)]\right\}, \tag{3.18}$$

where $X \subset \mathbb{R}^n$ is a nonempty bounded closed convex set, ξ is a random vector whose probability distribution P is supported on set $\Xi \subset \mathbb{R}^d$, and $F_i : X \times \Xi \to \mathbb{R}$, $i = 1, \ldots, m$. We assume that the expected value functions $f_i(\cdot)$, $i = 1, \ldots, m$, are well defined, finite valued, *convex*, and *Lipschitz continuous* on X. Then the minimax problem (3.18) can be formulated as the following saddle point problem:

$$\min_{x \in X} \max_{y \in Y} \left\{\phi(x,y) = \sum_{i=1}^m y_i f_i(x)\right\}, \tag{3.19}$$

where $Y = \{y \in \mathbb{R}^m : \sum_{i=1}^m y_i = 1,\ y \ge 0\}$.

Assume that we are able to generate independent realizations $\xi_1, \ldots,$ of random vector ξ, and, for given $x \in X$ and $\xi \in \Xi$, we can compute $F_i(x,\xi)$ and its *stochastic subgradient* $\mathsf{G}_i(x,\xi)$ such that $\mathsf{g}_i(x) = \mathbb{E}[\mathsf{G}_i(x,\xi)]$ is well defined and $\mathsf{g}_i(x) \in \partial f_i(x)$,

$x \in X$, $i = 1, \ldots, m$. In other words, we have a stochastic oracle for the problem (3.19) such that assumption (A′2) holds, with

$$\mathsf{G}(x, y, \xi) = \begin{bmatrix} \sum_{i=1}^m y_i \mathsf{G}_i(x, \xi) \\ -\big(F_1(x, \xi), \ldots, F_m(x, \xi)\big) \end{bmatrix} \tag{3.20}$$

and

$$\mathsf{g}(x, y) = \mathbb{E}[\mathsf{G}(x, y, \xi)] = \begin{bmatrix} \sum_{i=1}^m y_i \mathsf{g}_i(x) \\ -\big(f_1(x), \ldots, f_m(x)\big) \end{bmatrix} \in \begin{bmatrix} \partial_x \phi(x, y) \\ -\partial_y \phi(x, y) \end{bmatrix}. \tag{3.21}$$

Suppose that the set X is equipped with norm $\|\cdot\|_x$, whose dual norm is $\|\cdot\|_{*,x}$, and a distance-generating function ω modulus α_x with respect to $\|\cdot\|_x$, and let $R_x^2 = \frac{D^2_{\omega_x, X}}{\alpha_x}$. We equip the set Y with the norm $\|\cdot\|_y = \|\cdot\|_1$, so that $\|\cdot\|_{*,y} = \|\cdot\|_\infty$, and with the distance-generating function

$$\omega_y(y) = \sum_{i=1}^m y_i \ln y_i$$

and set $R_y^2 = \frac{D^2_{\omega_y, Y}}{\alpha_y} = \ln m$. Next, following (3.3), we set

$$\|(x, y)\| = \sqrt{\frac{\|x\|_x^2}{2R_x^2} + \frac{\|y\|_1^2}{2R_y^2}},$$

and hence

$$\|(\zeta, \eta)\|_* = \sqrt{2R_x^2 \|\zeta\|_{*,x}^2 + 2R_y^2 \|\eta\|_\infty^2}.$$

Let us assume uniform bounds:

$$\max_{1 \le i \le m} \mathbb{E}\left[\|\mathsf{G}_i(x, \xi)\|_{*,x}^2\right] \le M_{*,x}^2, \quad \mathbb{E}\left[\max_{1 \le i \le m} |F_i(x, \xi)|^2\right] \le M_{*,y}^2, \quad i = 1, \ldots, m.$$

Note that

$$\mathbb{E}\left[\|\mathsf{G}(x, y, \xi)\|_*^2\right] = 2R_x^2 \, \mathbb{E}\left[\Big\|\sum_{i=1}^m y_i \mathsf{G}_i(x, \xi)\Big\|_{*,x}^2\right] + 2R_y^2 \, \mathbb{E}\left[\|F(x, \xi)\|_\infty^2\right],$$

and since $y \in Y$,

$$\left\|\sum_{i=1}^m y_i \mathsf{G}_i(x, \xi)\right\|_{*,x}^2 \le \left(\sum_{i=1}^m y_i \|\mathsf{G}_i(x, \xi)\|_{*,x}\right)^2 \le \sum_{i=1}^m y_i \|\mathsf{G}_i(x, \xi)\|_{*,x}^2.$$

It follows that

$$\mathbb{E}\left[\|\mathsf{G}(x, y, \xi)\|_*^2\right] \le M_*^2, \tag{3.22}$$

where

$$M_*^2 = 2R_x^2 M_{*,x}^2 + 2R_y^2 M_{*,y}^2 = 2R_x^2 M_{*,x}^2 + 2M_{*,y}^2 \ln m.$$

Let us now use the saddle point mirror SA algorithm (3.7)–(3.8) with the constant stepsize policy

$$\gamma_t = \frac{2}{M_*\sqrt{5N}}, \quad t = 1, 2, \ldots, N.$$

When substituting the value of M_*, we obtain the following from (3.13):

$$\begin{aligned} \mathbb{E}\left[\epsilon_\phi\left(\tilde{z}_1^N\right)\right] &= \mathbb{E}\left[\max_{y\in Y}\phi\left(\hat{x}_1^N, y\right) - \min_{x\in X}\phi\left(x, \hat{y}_1^N\right)\right] \\ &\le 2M_*\sqrt{\tfrac{5}{N}} \le 2\sqrt{\tfrac{10\left[R_x^2 M_{*,x}^2 + M_{*,x}^2 \ln m\right]}{N}}. \end{aligned} \tag{3.23}$$

Discussion. Looking at the bound (3.23), one can make the following important observation. The error of the saddle point mirror SA algorithm in this case is "almost independent" of the number m of constraints (it grows as $O(\sqrt{\ln m})$ as m increases). The interested reader can easily verify that if an E-SA algorithm were used in the same setting (i.e., the algorithm tuned to the norm $\|\cdot\|_y = \|\cdot\|_2$), the corresponding bound would grow with m much faster (in fact, our error bound would be $O(\sqrt{m})$ in that case).

Note that properties of the saddle point mirror SA can be used to reduce significantly the arithmetic cost of the algorithm implementation. To this end let us look at the definition (3.20) of the stochastic oracle: In order to obtain a realization $\mathsf{G}(x, y, \xi)$, one has to compute m random subgradients $\mathsf{G}_i(x, \xi)$, $i = 1, \ldots, m$, and then their convex combination $\sum_{i=1}^m y_i \mathsf{G}_i(x, \xi)$. Now let η be an independent of ξ and uniformly distributed on $[0, 1]$ random variable, and let $\imath(\eta, y) : [0, 1] \times Y \to \{1, \ldots, m\}$ equal to i when $\sum_{s=1}^{i-1} y_s < \eta \le \sum_{s=1}^{i} y_s$. That is, random variable $\hat{\imath} = \imath(\eta, y)$ takes values $1, \ldots, m$ with probabilities $y_1, \ldots, y_m$. Consider random vector

$$\mathsf{G}(x, y, (\xi, \eta)) = \begin{bmatrix} \mathsf{G}_{\imath(\eta,y)}(x, \xi) \\ -\big(F_1(x, \xi), \ldots, F_m(x, \xi)\big) \end{bmatrix}. \tag{3.24}$$

We refer to $\mathsf{G}(x, y, (\xi, \eta))$ as a *randomized oracle* for problem (3.19), the corresponding random parameter being (ξ, η). By construction, we still have $\mathbb{E}\big[\mathsf{G}(x, y, (\xi, \eta))\big] = \mathsf{g}(x, y)$, where g is defined in (3.21), and, moreover, the same bound (3.22) holds for $\mathbb{E}\big[\|\mathsf{G}(x, y, (\xi, \eta))\|_*^2\big]$. We conclude that the accuracy bound (3.23) holds for the error of the saddle point mirror SA algorithm with randomized oracle. On the other hand, in the latter procedure only one randomized subgradient $\mathsf{G}_{\hat{\imath}}(x, \xi)$ per iteration is computed. This simple idea is further developed in another interesting application of the saddle point mirror SA algorithm to bilinear matrix games, which we discuss next.

3.3. Application to bilinear matrix games. Consider the standard matrix game problem, that is, problem (3.1) with

$$\phi(x, y) = y^T A x + b^T x + c^T y,$$

where $A \in \mathbb{R}^{m\times n}$, and X and Y are the standard simplexes:

$$X = \left\{x \in \mathbb{R}^n : x \ge 0, \sum_{j=1}^n x_j = 1\right\}, \quad Y = \left\{y \in \mathbb{R}^m : y \ge 0, \sum_{i=1}^m y_i = 1\right\}.$$

In the case in question it is natural to equip X (respectively, Y) with the $\|\cdot\|_1$-norm on $\mathbb{R}^n$ (respectively, $\mathbb{R}^m$). We choose entropies as the corresponding distance-generating functions:

$$\omega_x(x) = \sum_{i=1}^n x_i \ln x_i, \quad \omega_y(x) = \sum_{i=1}^m y_i \ln y_i \qquad \left[\Rightarrow \tfrac{D^2_{\omega_x,X}}{\alpha_x} = \ln n, \tfrac{D^2_{\omega_y,Y}}{\alpha_y} = \ln m\right].$$

According to (3.3), we set

$$\|(x,y)\| = \sqrt{\frac{\|x\|_1^2}{2\ln n} + \frac{\|y\|_1^2}{2\ln m}} \Rightarrow \|(\zeta,\eta)\|_* = \sqrt{2\|\zeta\|_\infty^2 \ln n + 2\|\eta\|_\infty^2 \ln m}. \tag{3.25}$$

In order to compute the estimates $\mathsf{G}(x,y,\xi)$ of $\mathsf{g}(x,y) = (b + A^T y, -c - Ax)$, to be used in the saddle point mirror SA iterations (3.7), we use the *randomized oracle*

$$\mathsf{G}(x,y,\xi) = \begin{bmatrix} c + A^{\imath(\xi_1,y)} \\ -b - A_{\imath(\xi_2,x)} \end{bmatrix}, \tag{3.26}$$

where ξ_1 and ξ_2 are independent uniformly distributed on $[0,1]$ random variables and $\hat{j} = \imath(\xi_1, y)$, $\hat{\imath} = \imath(\xi_2, x)$ are defined as in (3.24) (i.e., $\hat{j}$ can take values $1,\dots,m$, with probabilities $y_1,\dots,y_m$ and $\hat{\imath}$ can take values $1,\dots,n$, with probabilities $x_1,\dots,x_n$), and A_j, $[A^i]^T$ are jth column and ith row in A, respectively.

Note that

$$\mathsf{g}(x,y) \equiv \mathbb{E}\left[\mathsf{G}\left(x,y,\left(\hat{j},\hat{\imath}\right)\right)\right] \in \begin{bmatrix} \partial_x \phi(x,y) \\ \partial_y(-\phi(x,y)) \end{bmatrix}. \tag{3.27}$$

Besides this,

$$\begin{array}{ll} |\mathsf{G}(x,y,\xi)_i| \le \max_{1\le j\le m} \|A^j + b\|_\infty, & 1 \le i \le n, \\ |\mathsf{G}(x,y,\xi)_i| \le \max_{1\le j\le n} \|A_j + c\|_\infty, & n+1 \le i \le n+m, \end{array}$$

whence, invoking (3.25), for any $x \in X$, $y \in Y$, and ξ,

$$\|\mathsf{G}(x,y,\xi)\|_*^2 \le M_*^2 = 2\ln n \max_{1\le j\le m} \|A^j + b\|_\infty^2 + 2\ln m \max_{1\le j\le n} \|A_j + c\|_\infty^2. \tag{3.28}$$

The bottom line is that our stochastic gradients along with the just-defined M_* satisfy both (A′2) and (3.16), and therefore with the constant stepsize policy (3.12), we have

$$\mathbb{E}\left[\epsilon_\phi\left(\tilde{z}_1^N\right)\right] = \mathbb{E}\left[\max_{y\in Y} \phi\left(\tilde{x}_1^N, y\right) - \min_{x\in X} \phi\left(x, \tilde{y}_1^N\right)\right] \le 2M_* \sqrt{\frac{5}{N}} \tag{3.29}$$

(cf. (3.13)). In our present situation, Proposition 3.2 in a slightly refined form (for proof, see the appendix) reads as follows.

PROPOSITION 3.3. *With the constant stepsize policy* (3.12)*, for the just-defined algorithm, one has for any* $\Omega \ge 1$*, that*

$$\mathrm{Prob}\left\{\epsilon_\phi\left(\tilde{z}_1^N\right) > 2M_* \sqrt{\tfrac{5}{N}} + \tfrac{4\overline{M}}{\sqrt{N}}\Omega\right\} \le \exp\left\{-\Omega^2/2\right\}, \tag{3.30}$$

where

$$\overline{M} = \max_{1\le j\le m} \|A^j + b\|_\infty + \max_{1\le j\le n} \|A_j + c\|_\infty. \tag{3.31}$$

Discussion. Consider a bilinear matrix game with $n \geq m$, $\ln(m) = O(1)\ln(n)$, and $b = c = 0$ (so that $M_* = O(1)\sqrt{\ln n}\,\overline{M}$ and $\overline{M} = \max_{i,j} |A_{ij}|$; see (3.28), (3.31)). Suppose that we are interested to solve it within a fixed relative accuracy ρ, that is, to ensure that the (perhaps random) approximate solution $\tilde{z}_1^N$, which we get after N iterations, satisfies the error bound

$$\epsilon_\phi(\tilde{z}_N) \leq \rho \max_{1 \leq i,\, j \leq n} |A_{ij}|$$

with probability at least $1 - \delta$. According to (3.30), to this end, one can use the randomized saddle point mirror SA algorithm (3.7), (3.8), (3.26) with stepsizes (3.12), (3.28) and with

$$N = O(1)\frac{\ln n + \ln(1/\delta)}{\rho^2}. \tag{3.32}$$

The computational cost of building $\tilde{z}_1^N$ with this approach is

$$\mathcal{C}(\rho) = O(1)\frac{[\ln n + \ln(1/\delta)]\,[\mathcal{R} + n]}{\rho^2}$$

arithmetic operations, where $\mathcal{R}$ is the arithmetic cost of extracting a column/row from A given the index of this column/row. The total number of rows and columns visited by the algorithm does not exceed the number of steps N as given in (3.32) so that the total number of entries in A used in the course of the entire computation does not exceed

$$M = O(1)\frac{n(\ln n + \ln(1/\delta))}{\rho^2}.$$

When ρ is fixed, $m = O(1)n$ and n is large, M is incomparably less than the total number mn of entries in A. Thus, our algorithm exhibits *sublinear-time behavior*: it produces reliable solutions of prescribed quality to large-scale matrix games by inspecting a negligible, as $n \to \infty$, part of randomly selected data. Note that randomization here is critical.[3] It can be seen that a deterministic algorithm, which is capable to find a solution with (deterministic) relative accuracy $\rho \leq 0.1$, has to "see" in the worst case *at least* $O(1)n$ rows/columns of A.

4. Numerical results. In this section, we report the results of our computational experiments where we compare the performance of the robust mirror descent SA method and the SAA method applied to three stochastic programming problems, namely: a stochastic utility problem, a stochastic max-flow problem, and a network planning problem with random demand. We also present a small simulation study of the performance of randomized mirror SA algorithm for bilinear matrix games.

The algorithms we were testing are the two variants of the robust mirror descent SA. The first variant, the E-SA, is as described in section 2.2; in terms of section 2.3, this is nothing but mirror descent robust SA with Euclidean setup; see the example in section 2.3. The second variant, referred to as the *non-Euclidean* SA (N-SA), is the mirror descent robust SA with ℓ_1-setup; see, the example in section 2.3.

[3] The possibility to solve matrix games in a sublinear-time fashion by a randomized algorithm was discovered by Grigoriadis and Khachiyan [9]. Their "ad hoc" algorithm is similar, although not completely identical to ours, and possesses the same complexity bounds.

TABLE 4.1
Selecting stepsize policy.

[method: N-SA, N:2,000, K:10,000, instance: L1]

	θ			
Policy	0.1	1	5	10
Variable	−7.4733	−7.8865	−7.8789	−7.8547
Constant	−6.9371	−7.8637	−7.9037	−7.8971

These two variants of the SA method are compared with the SAA approach in the following way: fixing an iid. sample (of size N) for the random variable ξ, we apply the three aforementioned methods to obtain approximate solutions for the test problem under consideration, and then the quality of the solutions yielded by these algorithms is evaluated using another iid. sample of size $K >> N$. It should be noted that SAA itself is not an algorithm, and in our experiments, it was coupled with the non-Euclidean restricted memory level (NERML) [2]—a powerful deterministic algorithm for solving the sample average problem (1.4).

4.1. Preliminaries.

Algorithmic schemes. Both E-SA and N-SA were implemented according to the description in section 2.3, the number of steps N being the parameter of a particular experiment. In such an experiment, we generated $\approx \log_2 N$ candidate solutions $\tilde{x}_i^N$, with $N-i+1 = \min[2^k, N]$, $k = 0, 1, \ldots, \lceil \log_2 N \rceil$. We then used an additional sample to estimate the objective at these candidate solutions in order to choose the best of these candidates, specifically, as follows: we used a relatively short sample to choose the two "most promising" of the candidate solutions, and then a large sample (of size $K \gg N$) to identify the best of these two candidates, thus getting the "final" solution. The computational effort required by this simple postprocessing is *not* reflected in the tables to follow.

The stepsizes. At the "pilot stage" of our experimentation, we made a decision on which stepsize policy—(2.47) or (2.55)—to choose and how to identify the underlying parameters M_* and θ. In all our experiments, M_* was estimated by taking the maxima of $\|\mathsf{G}(\cdot,\cdot)\|_*$ over a small (just 100) calls to the stochastic oracle at randomly generated feasible solutions. As about the value of θ and type of the stepsize policy ((2.47) or (2.55)), our choice was based on the results of experimentation with a single test problem (instance L1 of the utility problem, see below); some results of this experimentation are presented in Table 4.1. We have found that the constant stepsize policy (2.47) with $\theta = 0.1$ for the E-SA and $\theta = 5$ for the N-SA slightly outperforms other variants we have considered. This particular policy, combined with the aforementioned scheme for estimating M_*, was used in all subsequent experiments.

Format of test problems. All our test problems are of the form $\min_{x\in X} f(x)$, $f(x) = \mathbb{E}[F(x,\xi)]$, where the domain X either is a standard simplex $\{x \in \mathbb{R}^n : x \geq 0, \sum_i x_i = 1\}$ or can be converted into such a simplex by scaling of the original variables.

Notation in the tables. Below,

- n is the design dimension of an instance,
- N is the sample size (i.e., the number of steps in SA, and the size of the sample used to build the stochastic average in SAA),
- `Obj` is the empirical mean of the random variable $F(x,\xi)$, x being the approximate solution generated by the algorithm in question. The empirical means are taken over a large ($K = 10^4$ elements) dedicated sample,
- `CPU` is the CPU time in seconds.

4.2. A stochastic utility problem. Our first experiment was carried out with the utility model

$$\min_{x\in X}\left\{f(x)=\mathbb{E}\left[\phi\Big(\sum_{i=1}^{n}(i/n+\xi_i)x_i\Big)\right]\right\}, \tag{4.1}$$

where $X=\{x\in\mathbb{R}^n : x\geq 0, \sum_{i=1}^n x_i = 1\}$, $\xi_i \sim \mathcal{N}(0,1)$ are independent and $\phi(\cdot)$ is a piecewise linear convex function given by $\phi(t)=\max\{v_1+s_1t,\ldots,v_m+s_mt\}$, where v_k and s_k are certain constants. In our experiment, we used $m=10$ breakpoints, all located on $[0,1]$. The four instances L1, L2, L3, L4 we dealt with were of dimension varying from 500 to 2,000, each instance—with its own randomly generated function ϕ. All the algorithms were coded in ANSI C, and the experiments were conducted on an Intel PIV 1.6GHz machine with Microsoft windows XP professional.

We run each of the three aforementioned methods with various sample sizes on every one of the instances. The results are reported in Table 4.2.

In order to evaluate stability of the algorithms, we run each of them 100 times; the resulting statistics are shown in Table 4.3. In this relatively time-consuming experiment, we restrict ourselves with a single instance (L2) and just two sample sizes (N = 1,000 and 2,000). In Table 4.3, "Mean" and "Dev" are, respectively, the mean and the deviation, over 100 runs, of the objective value Obj at the resulting approximate solution.

The experiments demonstrate that as far as the quality of approximate solutions is concerned, N-SA outperforms E-SA and is almost as good as SAA. At the same time, the solution time for N-SA is significantly smaller than the one for SAA.

4.3. Stochastic max-flow problem. In the second experiment, we consider simple two-stage stochastic linear programming, namely, a stochastic max-flow problem. The problem is to optimize the capacity expansion of a stochastic network. Let

$G = (N, A)$ be a diagraph with a source node s and a sink node t. Each arc $(i, j) \in A$ has an existing capacity $p_{ij} \geq 0$ and a random implementing/operating level ξ_{ij}. Moreover, there is a common random degrading factor η for all arcs in A. The goal is to determine how much capacity to add to the arcs, subject to a budget constraint, in order to maximize the expected maximum flow from s to t. Denoting by x_{ij} the capacity to be added to arc (i, j), the problem reads

$$\max_x \left\{ f(x) = \mathbb{E}[F(x;\xi,\eta)] : \sum_{(i,j)\in A} c_{ij}x_{ij} \leq b, x_{ij} \geq 0, \quad \forall (i,j) \in A \right\}, \tag{4.2}$$

where c_{ij} is the per unit cost for the capacity to be added, b is the total available budget, and $F(x;\xi,\eta)$ denotes the maximum $s-t$ flow in the network when the capacity of an arc (i, j) is $\eta\xi_{ij}(p_{ij} + x_{ij})$. Note that the above is a maximization rather than a minimization problem.

We assume that the random variables ξ_{ij}, θ are independent and uniformly distributed on $[0, 1]$ and $[0.5, 1]$, respectively, and consider the case of $p_{ij} = 0$, $c_{ij} = 1$ for all $(i, j) \in E$, and $b = 1$. We randomly generated 4 network instances (referred to as F1, F2, F3, and F4) using the network generator GRIDGEN available on DIMACS challenge. The push-relabel algorithm [8] was used to solve the second stage max-flow problem.

In the first test, each algorithm (N-SA, E-SA, SAA) was run once at each test instance; the results are reported in Table 4.4, where m, n stand for the number of nodes, respectively, arcs in G. Similar to the stochastic utility problem, we investigate the stability of the methods by running each of them 100 times. The resulting statistics is presented in Table 4.5, whose columns have exactly the same meaning as in Table 4.3.

This experiment fully supports the conclusions on the methods suggested by the experiments with the utility problem.

4.4. A network planning problem with random demand. In the last experiment, we consider the so-called SSN problem of Sen, Doverspike, and Cosares [24]. This problem arises in telecommunications network design where the owner of the network sells private-line services between pairs of nodes in the network, and the demands are treated as random variables based on the historical demand patterns.

TABLE 4.5
The variability for the stochastic max-flow problem.

		Obj		Avg.	Obj		Avg.	Obj		Avg.
Inst	N	Mean	Dev	CPU	Mean	Dev	CPU	Mean	Dev	CPU
F2	1,000	0.0691	0.0004	3.11	0.0688	0.0006	4.62	0.0694	0.0003	90.15
F2	2,000	0.0694	0.0003	6.07	0.0692	0.0002	6.91	0.0695	0.0003	170.45

The optimization problem is to decide where to add capacity to the network to minimize the expected rate of unsatisfied demands. Since this problem has been studied by several authors (see, e.g., [12, 24]), it could be interesting to compare the results. Another purpose of this experiment is to investigate the behavior of the SA method when the Latin hyperplane sampling (LHS) variance reduction technique (introduced in [14]) is applied.

The problem has been formulated as a two-stage stochastic linear programming as follows:

$$\min_x \left\{ f(x) = \mathbb{E}[F(x,\xi)] : x \geq 0, \sum_i x_i = b \right\}, \tag{4.3}$$

where x is the vector of capacities to be added to the arcs of the network, b (the budget) is the total amount of capacity to be added, ξ denotes the random demand, and $F(x,\xi)$ represents the number of unserved requests, specifically,

$$F(x,\xi) = \min_{s,f} \left\{ \sum_i s_i : \begin{array}{l} \sum_i \sum_{r \in R(i)} A_r f_{ir} \leq x + c \\ \sum_{r \in R(i)} f_{ir} + s_i = \xi^i, \quad \forall i \\ f_{ir} \geq 0, s_i \geq 0, \quad \forall i, r \in R(i) \end{array} \right\}. \tag{4.4}$$

Here,

- $R(i)$ is the set of routes used for traffic i (traffic between the source-sink pair of nodes # i),
- ξ^i is the (random) demand for traffic i,
- A_r are the route-arc incidence vectors (so that jth component of A_r is 1 or 0 depending on whether arc j belongs to the route r),
- c is the vector of current capacities, f_{ir} is the fraction of traffic i transferred via route r, and s is the vector of unsatisfied demands.

In the SSN instance, there are $\dim x = 89$ arcs and $\dim \xi = 86$ source-sink pairs, and components of ξ are independent random variables with known discrete distributions (from 3 to 7 possible values per component), which result in $\approx 10^{70}$ possible demand scenarios.

In the first test with the SSN instance, each of our 3 algorithms was run once without and once with the LHS technique; the results are reported in Table 4.6. We then tested the stability of algorithms by running each of them 100 times; see statistics in Table 4.7. Note that experiments with the SSN problem were conducted on a more powerful computer: Intel Xeon 1.86GHz with Red Hat Enterprize Linux.

As far as comparison of our three algorithms is concerned, the conclusions are in full agreement with those for the utility and the max-flow problem. We also see that for our particular example, the LHS does not yield much of an improvement, especially when a larger sample size is applied. This result seems to be consistent with the observation in [12].

4.5. N-SA versus E-SA. The data in Tables 4.3, 4.4, and 4.6 demonstrate that with the same sample size N, the N-SA somehow outperforms the E-SA in terms of both the quality of approximate solutions and the running time.[4] The difference in solutions' quality, at the first glance, seems slim, and one could think that adjusting the SA algorithm to the "geometry" of the problem in question (in our case, to minimization over a standard simplex) is of minor importance. We, however, do believe that such a conclusion would be wrong. In order to get a better insight, let us come back to the stochastic utility problem. This test problem has an important advantage—we can easily compute the value of the objective $f(x)$ at a given candidate solution x analytically.[5] Moreover, it is easy to minimize $f(x)$ over the simplex—on a closest inspection, this problem reduces to minimizing an easy-to-compute *univariate* convex function so that we can approximate the true optimal value f_* to high accuracy by bisection. Thus, in the case in question, we can compare solutions x generated by various algorithms in terms of their "true inaccuracy" $f(x) - f_*$, and this is the rationale behind our "Gaussian setup." We can now exploit this advantage of the stochastic utility problem for comparing properly N-SA and E-SA. In Table 4.8, we present the true values of the objective $f(\bar{x})$ at the approximate solutions $\bar{x}$ generated by N-SA and E-SA as applied to the instances L1 and L4 of the utility problem (cf. Table 4.3) along with the inaccuracies $f(\bar{x}) - f_*$ and the Monte Carlo estimates $\widehat{f}(\bar{x})$ of $f(\bar{x})$ obtained via 50,000-element samples. We see that the difference in

[4]The difference in running times can be easily explained: with X being a simplex, the prox-mapping for E-SA takes $O(n \ln n)$ operations versus $O(n)$ operations for N-SA.

[5]Indeed, $(\xi_1, \ldots, \xi_n) \sim \mathcal{N}(0, I_n)$, so that the random variable $\xi_x = \sum_i (a_i + \xi_i) x_i$ is normal with easily computable mean and variance, and since ϕ is piecewise linear, the expectation $f(x) = \mathbb{E}[\phi(\xi_x)]$ can be immediately expressed via the error function.

TABLE 4.8
N-SA versus E-SA.

Method	Problem	$\widehat{f}(\bar{x}), f(\bar{x})$	$f(\bar{x}) - f_*$	Time
N-SA, $N = 2{,}000$	L2: $n = 1{,}000$	$-5.9232/-5.9326$	0.0113	5.00
E-SA, $N = 2{,}000$	L2	$-5.8796/-5.8864$	0.0575	6.60
E-SA, $N = 10{,}000$	L2	$-5.9059/-5.9058$	0.0381	39.80
E-SA, $N = 20{,}000$	L2	$-5.9151/-5.9158$	0.0281	74.50
N-SA, $N = 2{,}000$	L4: $n = 5{,}000$	$-5.5855/-5.5867$	0.0199	25.00
E-SA, $N = 2{,}000$	L4	$-5.5467/-5.5469$	0.0597	44.60
E-SA, $N = 10{,}000$	L4	$-5.5810/-5.5812$	0.0254	165.10
E-SA, $N = 20{,}000$	L4	$-5.5901/-5.5902$	0.0164	382.00

the inaccuracy $f(\bar{x}) - f_*$ of the solutions produced by the algorithms is much more significant than is suggested by the data in Table 4.3 (where the actual inaccuracy is "obscured" by the estimation error and summation with f_*). Specifically, at the common for both algorithm sample sizes $N = 2{,}000$, the inaccuracy yielded by N-SA is 3–5 times less than the one for E-SA and in order to compensate for this difference, one should increase the sample size for E-SA (and hence the running time) by factor 5–10. It should be added that in light of theoretical complexity analysis carried out in Example 2.3, the outlined significant difference in performances of N-SA and E-SA is not surprising; the surprising fact is that E-SA works at all.

4.6. Bilinear matrix game. We consider here a bilinear matrix game

$$\min_{x\in X}\max_{y\in Y} y^T A x,$$

where both feasible sets are the standard simplexes in $\mathbb{R}^n$: $Y = X = \{x \in \mathbb{R}^n : \sum_{i=1}^n x_i = 1, x \geq 0\}$. We consider two versions of the randomized mirror SA algorithm (3.7), (3.8) for the saddle point problem. The first algorithm, the E-SA, uses $\frac{1}{2}\|x\|_2^2$ as ω_x, ω_y and $\|\cdot\|_2$ as $\|\cdot\|_x$, $\|\cdot\|_y$. The second algorithm, the N-SA, uses the entropy function (2.58) as ω_x, ω_y and the norm $\|\cdot\|_1$ as $\|\cdot\|_x$, $\|\cdot\|_y$. To compare the two procedures, we compute the corresponding approximate solutions $\tilde{z}_1^N$ and compute the exact values of the error:

$$\epsilon\left(\tilde{z}_1^N\right) = \max_{y\in Y} y^T A\tilde{x}_1^N - \min_{x\in X}\left[\tilde{y}_1^N\right]^T Ax, \quad i = 1, 2.$$

In our experiments we consider symmetric matrices A of two kinds. The matrices of the first family, parameterized by $\alpha > 0$, are given by

$$A_{ij} = \left(\frac{i+j-1}{2n-1}\right)^{\alpha}, \ \ 1 \leq i, j \leq n.$$

The second family of matrices, which are also parameterized by $\alpha > 0$, is given by

$$A_{ij} = \left(\frac{|i-j|+1}{2n-1}\right)^{\alpha}, \ \ 1 \leq i, j \leq n.$$

We use the notations $E_1(\alpha)$ and $E_2(\alpha)$ to refer to the experiments with the matrices of the first and second kind with parameter α. We present in Table 4.9 the results of experiments conducted for the matrices A of size $10^4 \times 10^4$. We made 100 simulation runs in each experiment and present the average error (column Mean), standard

deviation (column Dev) and the average running time (with excluded time to compute the error of the resulting solution). For comparison, we also present the error of the initial solution $\tilde{z}_1 = (x_1, y_1)$.

Our basic observation is as follows: Both N-SA and E-SA succeed to reduce the solution error reasonably fast. The N-SA implementation is preferable as it is more efficient in terms of running time. For comparison, it takes MATLAB from 10 (for the simplest problem) to 35 seconds (for the hardest one) to compute just one answer $\mathtt{g}(x, y) = \begin{bmatrix} A^T y \\ -Ax \end{bmatrix}$ of the deterministic oracle.

5. Conclusions. It is shown that for a certain class of convex stochastic optimization and saddle point problems, robust versions of the SA approach have similar theoretical estimates of computational complexity, in terms of the required sample size, to the SAA method. Numerical experiments, reported in section 4, confirm this conclusion. These results demonstrate that for considered problems, a properly implemented mirror descent SA algorithm produces solutions of comparable accuracy to the SAA method for the same sample size of generated random points. On the other hand, the implementation (computational) time of the SA method is significantly smaller with a factor of up to 30–40 for considered problems. Thus, both theoretical and numerical results suggest that the robust mirror descent SA is a viable alternative to the SAA approach, an alternative which at least deserves testing in particular applications. It is also shown that the robust mirror SA approach can be applied as a randomization algorithm to large-scale deterministic saddle point problems (in particular, to minimax optimization problems and bilinear matrix games) with encouraging results.

6. Appendix. *Proof of Lemma* 2.1. Let $x \in X^o$ and $v = P_x(y)$. Note that $v \in \operatorname{argmin}_{z \in X}[\omega(z) + p^T z]$, where $p = \nabla\omega(x) - y$. Thus, ω is differentiable at v and $v \in$

X^o. As $\nabla_v V(x,v) = \nabla\omega(v) - \nabla\omega(x)$, the optimality conditions for (2.31) imply that

$$(\nabla\omega(v) - \nabla\omega(x) + y)^T(v-u) \le 0 \quad \forall u \in X. \tag{6.1}$$

For $u \in X$, we therefore have

$$\begin{aligned} V(v,u) - V(x,u) &= \big[\omega(u) - \nabla\omega(v)^T(u-v) - \omega(v)\big] \\ &\quad - \big[\omega(u) - \nabla\omega(x)^T(u-x) - \omega(x)\big] \\ &= \nabla\omega(v) - \nabla\omega(x) + y)^T(v-u) + y^T(u-v) \\ &\le y^T(u-v) - V(x,v), \end{aligned}$$

where the last inequality is due to (6.1). By Young's inequality,[6] we have

$$y^T(x-v) \le \frac{\|y\|_*^2}{2\alpha} + \frac{\alpha}{2}\|x-v\|^2,$$

while $V(x,v) \ge \frac{\alpha}{2}\|x-v\|^2$, due to the strong convexity of $V(x,\cdot)$. We get

$$\begin{aligned} V(v,u) - V(x,u) &\le y^T(u-v) - V(x,v) = y^T(u-x) + y^T(x-v) - V(x,v) \\ &\le y^T(u-x) + \frac{\|y\|_*^2}{2\alpha}, \end{aligned}$$

as required in (2.33). □

Entropy as a distance-generating function on the standard simplex. The only property which is not immediately evident is that the entropy $w(x) = \sum_{i=1}^n x_i \ln x_i$ is strongly convex, modulus 1 with respect to $\|\cdot\|_1$-norm, on the standard simplex $X = \big\{x \in \mathbb{R}^n : x \ge 0,\ \sum_{i=1}^n x_i\big\}$. We are in the situation where $X^o = \{x \in X : x > 0\}$ and in order to establish the property in question, it suffices to verify that $h^T\nabla^2\omega(x)h \ge \|h\|_1^2$ for every $x \in X^o$. Here is the computation:

$$\left[\sum_i |h_i|\right]^2 = \left[\sum_i (x_i^{-1/2}|h_i|)x_i^{1/2}\right]^2 \le \left[\sum_i h_i^2 x_i^{-1}\right]\left[\sum_i x_i\right] = \sum_i h_i^2 x_i^{-1} = h^T\nabla^2\omega(x)h,$$

where the inequality follows by Cauchy inequality.

Proof of Lemma 3.1. By (2.33), we have, for any $u \in Z$, that

$$\gamma_t(z_t - u)^T\mathsf{G}(z_t,\xi_t) \le V(z_t,u) - V(z_{t+1},u) + \frac{\gamma_t^2}{2}\|\mathsf{G}(z_t,\xi_t)\|_*^2 \tag{6.2}$$

(recall that we are in the situation of $\alpha = 1$). This relation implies that for every $u \in Z$, one has

$$\gamma_t(z_t - u)^T\mathsf{g}(z_t) \le V(z_t,u) - V(z_{t+1},u) + \frac{\gamma_t^2}{2}\|\mathsf{G}(z_t,\xi_t)\|_*^2 - \gamma_t(z_t-u)^T\Delta_t, \tag{6.3}$$

where $\Delta_t = \mathsf{G}(z_t,\xi_t) - \mathsf{g}(z_t)$. Summing up these inequalities over $t = 1,\dots,j$, we get

$$\sum_{t=1}^j \gamma_t(z_t-u)^T\mathsf{g}(z_t) \le V(z_1,u) - V(z_{t+1},u) + \sum_{t=1}^j \frac{\gamma_t^2}{2}\|\mathsf{G}(z_t,\xi_t)\|_*^2 - \sum_{t=1}^j \gamma_t(z_t-u)^T\Delta_t.$$

Now we need the following simple lemma.

[6] For any $u, v \in \mathbb{R}^n$, we have, by the definition of the dual norm, that $\|u\|_*\|v\| \ge u^T v$, and hence $(\|u\|_*^2/\alpha + \alpha\|v\|^2)/2 \ge \|u\|_*\|v\| \ge u^T v$.

LEMMA 6.1. *Let $\zeta_1, \dots, \zeta_j$ be a sequence of elements of $\mathbb{R}^{n+m}$. Define the sequence v_t, $t = 1, 2, \dots$ in Z^o as follows: $v_1 \in Z^o$ and*

$$v_{t+1} = P_{v_t}(\zeta_t),\ 1 \le t \le j.$$

Then, for any $u \in Z$, the following holds:

$$\sum_{t=1}^{j} \zeta_t^T (v_t - u) \le V(v_1, u) + \tfrac{1}{2} \sum_{t=1}^{j} \|\zeta_t\|_*^2. \tag{6.4}$$

Proof. Using the bound (2.33) of Lemma 2.1 with $y = \zeta_t$ and $x = v_t$ (so that $v_{t+1} = P_{v_t}(\zeta_t)$) and recalling that we are in the situation of $\alpha = 1$, we obtain the following for any $u \in Z$:

$$V(v_{t+1}, u) \le V(v_t, u) + \zeta_t^T (u - v_t) + \tfrac{1}{2} \|\zeta_t\|_*^2.$$

Summing up from $t = 1$ to $t = j$, we conclude that

$$V(v_{j+1}, u) \le V(v_1, u) + \sum_{t=1}^{j} \zeta_t^T (u - v_t) + \tfrac{1}{2} \sum_{t=1}^{j} \|\zeta_t\|_*^2,$$

which implies (6.4) due to $V(v, u) \ge 0$ for any $v \in Z^o, u \in Z$. □

Applying Lemma 6.1 with $v_1 = z_1$, $\zeta_t = -\gamma_t \Delta_t$, we get

$$\sum_{t=1}^{j} \gamma_t \Delta_t^T (u - v_t) \le V(z_1, u) + \frac{1}{2} \sum_{t=1}^{j} \gamma_t^2 \|\Delta_t\|_*^2 \ \ \forall u \in Z. \tag{6.5}$$

Observe that

$$\mathbb{E}\|\Delta_t\|_*^2 \le 4\mathbb{E}\|\mathsf{G}(z_t, \xi_t)\|_*^2 \le 4 \left(\frac{2D_{\omega_x, X}^2}{\alpha_x} M_{*,x}^2 + \frac{2D_{\omega_y, Y}^2}{\alpha_y} M_{*,y}^2 \right) = 4M_*^2$$

so that when taking the expectation of both sides of (6.5), we get

$$\mathbb{E}\left[\sup_{u \in Z} \left\{ \sum_{t=1}^{j} \gamma_t \Delta_t^T (u - v_t) \right\} \right] \le 1 + 2M_*^2 \sum_{t=1}^{j} \gamma_t^2 \tag{6.6}$$

(recall that $V(z_1, \cdot)$ is bounded by 1 on Z). Now we proceed exactly as in section 2.2: we sum up (6.3) from $t = 1$ to j to obtain

$$\begin{aligned} &\sum_{t=1}^{j} \gamma_t (z_t - u)^T \mathsf{g}(z_t) \le V(z_1, u) + \sum_{t=1}^{j} \frac{\gamma_t^2}{2} \|\mathsf{G}(z_t, \xi_t)\|_*^2 - \sum_{t=1}^{j} \gamma_t (z_t - u)^T \Delta_t \\ &= V(z_1, u) + \sum_{t=1}^{j} \frac{\gamma_t^2}{2} \|\mathsf{G}(z_t, \xi_t)\|_*^2 - \sum_{t=1}^{j} \gamma_t (z_t - v_t)^T \Delta_t + \sum_{t=1}^{j} \gamma_t (u - v_t)^T \Delta_t. \end{aligned} \tag{6.7}$$

When taking into account that z_t and v_t are deterministic functions of $\xi_{[t-1]} = (\xi_1, \dots, \xi_{t-1})$ and that the conditional expectation of Δ_t, $\xi_{[t-1]}$ being given, vanishes, we conclude that $\mathbb{E}[(z_t - v_t)^T \Delta_t] = 0$. We take now suprema in $u \in Z$ and then

expectations on both sides of (6.7):

$$\begin{aligned}\mathbb{E}\left[\sup_{u\in Z}\sum_{t=1}^{j}\gamma_t(z_t-u)^T\mathsf{g}(z_t)\right] &\le \sup_{u\in Z}V(z_1,u)+\sum_{t=1}^{j}\frac{\gamma_t^2}{2}\mathbb{E}\|\mathsf{G}(z_t,\xi_t)\|_*^2\\ &\quad+\sup_{u\in Z}\sum_{t=1}^{j}\gamma_t(u-v_t)^T\Delta_t\\ \text{(by (6.6))}\quad &\le 1+\frac{M_*^2}{2}\sum_{t=1}^{j}\gamma_t^2+\left[1+2M_*^2\sum_{t=1}^{j}\gamma_t^2\right]\\ &= 2+\frac{5}{2}M_*^2\sum_{t=1}^{j}\gamma_t^2,\end{aligned}$$

and we arrive at (3.10).

Proof of Propositions 2.2 and 3.2. We provide here the proof of Proposition 3.2 only. The proof of Proposition 2.2 follows the same lines and can be easily reconstructed using the bound (2.39) instead of the relations (6.5) and (6.7) in the proof below.

First of all, with M_* given by (3.6), one has

$$\forall(z\in Z):\mathbb{E}\left[\exp\{\|\mathsf{G}(z,\xi)\|_*^2/M_*^2\}\right]\le\exp\{1\}. \tag{6.8}$$

Indeed, setting $p_x=\frac{2D^2_{\omega_x,X}M^2_{*,x}}{\alpha_x M_*^2}$, $p_y=\frac{2D^2_{\omega_y,Y}M^2_{*,y}}{\alpha_y M_*^2}$, we have $p_x+p_y=1$, whence, invoking (3.4),

$$\mathbb{E}\left[\exp\{\|\mathsf{G}(z,\xi)\|_*^2/M_*^2\}\right]=\mathbb{E}\left[\exp\{p_x\|\mathsf{G}_x(z,\xi)\|_{*,x}^2/M_{*,x}^2+p_y\|\mathsf{G}_y(z,\xi)\|_{*,y}^2/M_{*,y}^2\}\right],$$

and (6.8) follows from (3.16) by the Hölder inequality.

Setting $\Gamma_N=\sum_{t=1}^N\gamma_t$ and using the notation from the proof of Lemma 3.1, relations (3.9), (6.5), and (6.7) combined with the fact that $V(z_1,u)\le 1$ for $u\in Z$, imply that

$$\Gamma_N\epsilon_\phi(\tilde z_N)\le 2+\underbrace{\tfrac12\sum_{t=1}^{N}\gamma_t^2\left[\|\mathsf{G}(z_t,\xi_t)\|_*^2+\|\Delta_t\|_*^2\right]}_{\alpha_N}+\underbrace{\sum_{t=1}^{N}\gamma_t(v_t-z_t)^T\Delta_t}_{\beta_N}. \tag{6.9}$$

Now, from (6.8), it follows straightforwardly that

$$\mathbb{E}\left[\exp\left\{\|\Delta_t\|_*^2/(2M_*)^2\right\}\right]\le\exp\{1\},\quad \mathbb{E}\left[\exp\left\{\|\mathsf{G}(z_t,\xi_t)\|_*^2/M_*^2\right\}\right]\le\exp\{1\}, \tag{6.10}$$

which, in turn, implies that

$$\mathbb{E}[\exp\{\alpha_N/\sigma_\alpha\}]\le\exp\{1\},\quad \sigma_\alpha=\frac{5}{2}M_*^2\sum_{t=1}^{N}\gamma_t^2, \tag{6.11}$$

and therefore, by Markov inequality, for any $\Omega>0$,

$$\mathrm{Prob}\{\alpha_N\ge(1+\Omega)\sigma_\alpha\}\le\exp\{-\Omega\}. \tag{6.12}$$

Indeed, we have by (6.8)

$$\|\mathsf{g}(z_t)\|_*=\|\mathbb{E}[\mathsf{G}(z_t,\xi_t)|\xi_{[t-1]}]\|_*\le\sqrt{\mathbb{E}(\|\mathsf{G}(z_t,\xi_t)\|_*^2|\xi_{[t-1]})}\le M_*$$

and

$$\|\Delta_t\|_*^2 = \|\mathsf{G}(z_t,\xi_t) - \mathsf{g}(z_t)\|_*^2 \le (\|\mathsf{G}(z_t,\xi_t)\|_* + \|\mathsf{g}(z_t)\|_*)^2 \le 2\|\mathsf{G}(z_t,\xi_t)\|_*^2 + 2M_*^2,$$

which implies that

$$\alpha_N \le \sum_{t=1}^N \frac{\gamma_t^2}{2}\left[3\|\mathsf{G}(z_t,\xi_t)\|_*^2 + 2M_*^2\right].$$

Further, by the Hölder inequality, we have the following from (6.8):

$$\mathbb{E}\left[\exp\left\{\frac{\gamma_t^2\left[\frac{3}{2}\|\mathsf{G}(z_t,\xi_t)\|_*^2 + M_*^2\right]}{\frac{5}{2}\gamma_t^2 M_*^2}\right\}\right] \le \exp(1).$$

Observe that if $r_1,\dots,r_i$ are nonnegative random variables such that $\mathbb{E}[\exp\{r_t/\sigma_t\}] \le \exp\{1\}$ for some deterministic $\sigma_t > 0$, then, by convexity of the exponent, $w(s) = \exp\{s\}$ and

$$\mathbb{E}\left[\exp\left\{\frac{\sum_{t\le i} r_t}{\sum_{t\le i}\sigma_t}\right\}\right] \le \mathbb{E}\left[\sum_{t\le i}\frac{\sigma_t}{\sum_{\tau\le i}\sigma_\tau}\exp\{r_t/\sigma_t\}\right] \le \exp\{1\}. \tag{6.13}$$

Now applying (6.13) with $r_t = \gamma_t^2\left[\frac{3}{2}\|\mathsf{G}(z_t,\xi_t)\|_*^2 + M_*^2\right]$ and $\sigma_t = \frac{5}{2}\gamma_t^2 M_*^2$, we obtain (6.11).

Now let $\zeta_t = \gamma_t(v_t - z_t)^T\Delta_t$. Observing that v_t, z_t are deterministic functions of $\xi_{[t-1]}$, while $\mathbb{E}[\Delta_t|\xi_{[t-1]}] = 0$, we see that the sequence $\{\zeta_t\}_{t=1}^N$ of random real variables forms a martingale difference. Besides this, by strong convexity of ω with modulus 1 w.r.t. $\|\cdot\|$ and due to $D_{\omega,Z} \le 1$, we have

$$u \in Z \Rightarrow 1 \ge V(z_1,u) \ge \frac{1}{2}\|u - z_1\|^2,$$

whence the $\|\cdot\|$-diameter of Z does not exceed $2\sqrt{2}$ so that $|\zeta_t| \le 2\sqrt{2}\gamma_t\|\Delta_t\|_*$, and therefore

$$\mathbb{E}\left[\exp\left\{|\zeta_t|^2/\left(32\gamma_t^2M_*^2\right)\right\}|\xi_{[t-1]}\right] \le \exp\{1\}$$

by (6.10). Applying Cramer's deviation bound, we obtain, for any $\Omega > 0$,

$$\text{Prob}\left\{\beta_N > 4\Omega M_*\sqrt{\sum_{t=1}^N \gamma_t^2}\right\} \le \exp\{-\Omega^2/4\}. \tag{6.14}$$

Indeed, for $0 \le \gamma$, setting $\sigma_t = 4\sqrt{2}\gamma_t M_*$ and taking into account that ζ_t is a deterministic function of $\xi_{[t]}$, with $\mathbb{E}[\zeta_t|\xi_{[t-1]}] = 0$ and $\mathbb{E}[\exp\{\zeta_t^2/\sigma_t^2\}|\xi_{[t-1]}] \le \exp\{1\}$, we have

$$\begin{aligned}
&0 < \gamma\sigma_t \le 1 \Rightarrow \quad \left(\text{as } e^x \le x + e^{x^2}\right)\\
&\mathbb{E}[\exp\{\gamma\zeta_t\}|\xi_{[t-1]}] \le \mathbb{E}[\exp\left\{\gamma^2\zeta_t^2\right\}|\xi_{[t-1]}]\\
&\qquad\qquad \le \mathbb{E}\left[\left(\exp\left\{\zeta_t^2/\sigma_t^2\right\}\right)^{\gamma^2\sigma_t^2}|\xi_{[t-1]}\right] \le \exp\left\{\gamma^2\sigma_t^2\right\};\\
&\gamma\sigma_t > 1 \Rightarrow\\
&\mathbb{E}[\exp\{\gamma\zeta_t\}|\xi_{[t-1]}] \le \mathbb{E}\left[\exp\left\{\left[\tfrac{1}{2}\gamma^2\sigma_t^2 + \tfrac{1}{2}\zeta_t^2/\sigma_t^2\right\}|\xi_{[t-1]}\right]\\
&\qquad\qquad \le \exp\left\{\tfrac{1}{2}\gamma^2\sigma_t^2 + \tfrac{1}{2}\right\} \le \exp\left\{\gamma^2\sigma_t^2\right\},
\end{aligned}$$

that is, in both cases, $\mathbb{E}[\exp\{\gamma\zeta_t\}|\xi_{[t-1]}] \le \exp\{\gamma^2\sigma_t^2\}$. Therefore,

$$\mathbb{E}[\exp\{\gamma\beta_i\}] = \mathbb{E}\left[\exp\{\gamma\beta_{i-1}\}\mathbb{E}[\exp\{\gamma\zeta_i\}|\xi_{[i-1]}]\right] \le \exp\left\{\gamma^2\sigma_i^2\right\}\mathbb{E}[\exp\{\gamma\beta_{i-1}\}],$$

whence $\mathbb{E}[\exp\{\gamma\beta_N\}] \le \exp\{\gamma^2\sum_{t=1}^N\sigma_t^2\}$, and thus, by Markov inequality for every $\Omega > 0$, it holds

$$\mathrm{Prob}\left\{\beta_N > \Omega\sqrt{\sum_{t=1}^N\sigma_t^2}\right\} \le \exp\left\{\gamma^2\sum_{t=1}^N\sigma_t^2\right\}\exp\left\{-\gamma\Omega\sqrt{\sum_{t=1}^N\sigma_t^2}\right\}.$$

When choosing $\gamma = \frac{1}{2}\Omega\left(\sum_{t=1}^N\sigma_t^2\right)^{-1/2}$, we arrive at (6.14).

Combining (6.9), (6.10), and (6.14), we get the following for any positive Ω and Θ:

$$\mathrm{Prob}\left\{\Gamma_N\,\epsilon_\phi(\tilde z_t) > 2 + \frac{5}{2}(1+\Omega)M_*^2\sum_{t=1}^N\gamma_t^2 + 4\sqrt{2}\Theta M_*\sqrt{\sum_{t=1}^N\gamma_t^2}\right\} \le \exp\{-\Omega\} + \exp\left\{-\frac{1}{4}\Theta^2\right\}.$$

When setting $\Theta = 2\sqrt{\Omega}$ and substituting (3.12), we obtain (3.17). □

Proof of Proposition 3.3. As in the proof of Proposition 3.2, when setting $\Gamma_N = \sum_{t=1}^N\gamma_t$ and using the relations (3.9), (6.5), and (6.7), combined with the fact that $\|\mathsf{G}(z,\xi_y)\|_* \le M_*$, we obtain

$$\begin{aligned}\Gamma_N\,\epsilon_\phi(\tilde z_N) &\le 2 + \sum_{t=1}^N\frac{\gamma_t^2}{2}\left[\|\mathsf{G}(z_t,\xi_t)\|_*^2 + \|\Delta_t\|_*^2\right] + \sum_{t=1}^N\gamma_t(v_t - z_t)^T\Delta_t \\ &\le 2 + \frac{5}{2}M_*^2\sum_{t=1}^N\gamma_t^2 + \underbrace{\sum_{t=1}^N\gamma_t(v_t - z_t)^T\Delta_t}_{\alpha_N}. \qquad (6.15)\end{aligned}$$

Recall that by definition of Δ_t, $\|\Delta_t\|_* = \|\mathsf{G}(z_t,\xi_t) - \mathsf{g}(z_t)\|_* \le \|\mathsf{G}(z_t,\xi_t)\| + \|\mathsf{g}(z_t)\|_* \le 2M_*$.

Note that $\zeta_t = \gamma_t(v_t - z_t)^T\Delta_t$ is a bounded martingale difference, i.e., $\mathbb{E}(\zeta_t|\xi_{[t-1]}) = 0$ and $|\zeta_t| \le 4\gamma_t\overline{M}$ (here $\overline{M}$ is defined in (3.31)). Then, by Azuma–Hoeffding's inequality [1] for any $\Omega \ge 0$,

$$\mathrm{Prob}\left(\alpha_N > 4\Omega\overline{M}\sqrt{\sum_{t=1}^N\gamma_t^2}\right) \le e^{-\Omega^2/2}. \qquad (6.16)$$

Indeed, let us denote $v_t = (v_t^{(x)}, v_t^{(y)})$ and $\Delta_t = (\Delta_t^{(x)}, \Delta_t^{(y)})$. When taking into account that $\|v_t^{(x)}\|_1 \le 1$, $\|v_t^{(y)}\|_1 \le 1$ and $\|x_t\|_1 \le 1$, $\|y_t\|_1 \le 1$, we conclude that

$$\begin{aligned}|(v_t - z_t)^T\Delta_t| &\le \left|\left(v_t^{(x)} - x_t\right)^T\Delta_t^{(x)}\right| + \left|\left(v_t^{(y)} - y_t\right)^T\Delta_t^{(y)}\right| \\ &\le 2\left\|\Delta_t^{(x)}\right\|_\infty + 2\left\|\Delta_t^{(y)}\right\|_\infty \le 4\max_{1\le j\le m}\|A^j + b\|_\infty + 4\max_{1\le j\le n}\|A_j + c\|_\infty \\ &= 4\overline{M}.\end{aligned}$$

We conclude from (6.15) and (6.16) that

$$\text{Prob}\left(\Gamma_N\,\epsilon_\phi(\tilde{z}_N) > 2 + \frac{5}{2}M_*^2\sum_{t=1}^N\gamma_t^2 + 4\Omega\overline{M}\sqrt{\sum_{t=1}^N\gamma_t^2}\right) \le e^{-\Omega^2/2},$$

and the bound (3.30) of the proposition can be easily obtained by substituting the constant stepsizes γ_t as defined in (3.12). □

SHAPE OPTIMIZATION UNDER UNCERTAINTY—A STOCHASTIC PROGRAMMING PERSPECTIVE*

SERGIO CONTI†, HARALD HELD†, MARTIN PACH†, MARTIN RUMPF‡, AND RÜDIGER SCHULTZ†

Abstract. We present an algorithm for shape optimization under stochastic loading and representative numerical results. Our strategy builds upon a combination of techniques from two-stage stochastic programming and level-set-based shape optimization. In particular, usage of linear elasticity and quadratic objective functions permits us to obtain a computational cost which scales linearly in the number of *linearly independent* applied forces, which often is much smaller than the number of different realizations of the stochastic forces. Numerical computations are performed using a level set method with composite finite elements both in two and in three spatial dimensions.

Key words. two-stage stochastic programming, shape optimization in elasticity, level set method

1. Introduction.

Uncertainty is a prevailing issue in many, if not most, practical shape optimization problems. In the optimization of elastic structures, one usually deals with volume and in particular surface loadings which are not fixed but vary stochastically over time. Decisions on the shape have to be made before the stochastic forcing is applied. Thus, an optimal structure for the expectation of the stochastic loading does not properly reflect the actual stochastic optimization set up. Indeed, one observes a striking similarity with two-stage stochastic programming. Our work received inspiration from this field, and this paper is intended to work out this analogy in the case of shape optimization for linear elastic material laws and stochastic volume and surface loadings.

Optimization under uncertainty depends on information available on the uncertain problem components. At the one end, there are worst-case approaches, as in online or robust optimization [3,14]. These approaches assume that only the ranges of the uncertain parameters are known, without distributional information. At the other end, stochastic optimization deals with models where uncertainty can be captured by a probability distribution. Stochastic optimization has been analyzed in continuous time, as, for example, in stochastic dynamic programming or stochastic control [18,27]. In particular, there exists a rich theory and methodology to treat stochastic uncertainty in (mostly finite-dimensional) mathematical programming models, mainly linear [49], less often linear mixed-integer or nonlinear programming models [12, 46, 55]. In two-stage stochastic programming [16, 33, 47], first-stage decisions must be taken without knowing the realizations of the random data, and then, after observation of

‡Institute for Numerical Simulation, Rheinische Friedrich-Wilhelms-Universität Bonn, Nussallee 15, 53115 Bonn, Germany.

the random data, a second-stage (or recourse) decision is taken. The requirement that the first-stage decision must not depend on the future observation is referred to as nonanticipativity. This notion extends accordingly if the two-stage scheme of alternating decision and observation is expanded into a (finite) multistage scheme. For a recent comprehensive overview we refer to [58]. Related work on nonlinear models can be found in optimal design of structural systems under uncertainty; see [40] and references therein. The essential difference from the present work is that design decisions in these contributions vary in Euclidean spaces, while our design decisions are shapes (open sets) in suitable working domains.

Shape optimization under deterministic loading is a well-developed field, which can be seen as an instance of PDE-constrained infinite-dimensional optimization; see, e.g., the books [4, 15, 54]; a brief review of the points relevant for us is presented below. We are not aware of two- or multistage stochastic programming approaches in shape optimization, or more generally in PDE-constrained optimization. There are, however, recent approaches in shape optimization which generalize the single load assumption. In so-called multiload approaches a fixed (usually small) number of different loading configurations is considered, and optimization refers to this set of configurations; see, e.g., [7, 29, 59] and references therein, as well as [11] for an one-dimensional (1D) model. In these approaches each evaluation of the objective functional requires a separate computation for each of the possible stochastic forces, which renders them infeasible if the set of possible forces is large, as, for example, is the case when one aims at approximating a continuous distribution of forces. A more efficient method was derived for a truss model in [10], where it is shown that optimization of the expected compliance is equivalent to a convex problem and hence efficiently solvable. This, however, is based on additional geometrical assumptions, namely, on considering a fixed *ground structure*, and leaving only the thickness of the bars to be optimized. A robust probabilistic approach for the optimization of beam models is discussed in [1], whereas in [41] structural reliability is discussed for beam geometries with uncertain load magnitude. Worst-case situations in a multiload context have also been considered; see, e.g., [13].

The paper is organized as follows. In section 1.1 we formulate the stochastic shape optimization problem considered in this paper. Then in section 1.2 we review deterministic shape optimization based on a level formulation. Then in section 1.3 we recall finite-dimensional, two-stage stochastic optimization to underline the close similarity of the approach to shape optimization to be discussed here. In section 2 the two-stage shape optimization with stochastic volume and surface loads is introduced the primal and dual stochastic state equations are investigated in section 2.1, and a representation of the stochastic shape gradient is given in section 2.2. A finite element discretization for elastic domains described via level sets is discussed in section 3. In section 3.1 we introduce composite finite elements and suitable multigrid methods to apply them for the efficient solution of the discrete primal and dual problem in section 3.2, whereas in section 3.3 the actual numerical algorithm based on a regularized gradient descent is presented. Finally, in section 4 we discuss various applications in two and three space dimensions and show corresponding numerical results.

1.1. Setup of the shape optimization problem. In shape optimization one seeks the shape $\mathcal{O}$ of a body which optimizes certain response properties. We shall focus here on optimality criteria which depend on the linear elastic response to applied forces. Therefore we start by describing the elastic problem. Given an admissible shape $\mathcal{O} \subset \mathbb{R}^d$ $(d = 2, 3)$ representing the elastic body, the displacement $u : \mathcal{O} \to \mathbb{R}^d$

is determined as the solution of the following system of linear partial differential equations:

$$\begin{aligned} -\operatorname{div}(Ae(u)) &= f(\omega) \quad \text{in } \mathcal{O}\,, \\ u &= 0 \quad \text{on } \Gamma_D\,, \\ (Ae(u))n &= g(\omega) \quad \text{on } \Gamma_N\,, \\ (Ae(u))n &= 0 \quad \text{on } \partial\mathcal{O} \setminus \Gamma_N \setminus \Gamma_D\,. \end{aligned} \tag{1.1}$$

Here, $e(u) = \frac{1}{2}(\nabla u + \nabla u^\top)$ is the linearized strain tensor and $A = (A_{ijkl})_{ijkl}$ the elasticity tensor. We shall for simplicity focus on isotropic materials, where $A_{ijkl} = 2\mu\delta_{ik}\delta_{jl} + \lambda\delta_{ij}\delta_{kl}$, where δ_{ij} denotes the Kronecker symbol and μ, λ the positive Lamé constants of the material. We consider only admissible shapes $\mathcal{O}$ which are subsets of a fixed, bounded working domain $D \subset \mathbb{R}^d$. On $\Gamma_D \subset \partial\mathcal{O}$ we assume homogeneous Dirichlet boundary conditions $u = 0$, and on $\Gamma_N \subset \partial\mathcal{O}$ we assume inhomogeneous Neumann boundary conditions, with $\Gamma_D \cap \Gamma_N = \emptyset$. Both parts of the boundary are kept fixed during the optimization. Precisely, we shall fix a certain open set $\mathcal{O}_* \subset D$, restrict the class of admissible shapes to $\mathcal{O}$ such that $\mathcal{O}_* \subset \mathcal{O} \subset D$, and assume that $\Gamma_D, \Gamma_N \subset \partial\mathcal{O}_* \cap \partial D$. Then necessarily $\Gamma_D, \Gamma_N \subset \partial\mathcal{O}$. Finally, $f(\omega) \in L^2(D;\mathbb{R}^d)$ and $g(\omega) \in L^2(\Gamma_N;\mathbb{R}^d)$ are random volume forces and surface loads, respectively, and ω is a realization on a probability space Ω. Standard results show that for any connected open set $\mathcal{O}$ with Lipschitz boundary and any fixed realization ω, the elasticity problem (1.1) has a unique weak solution $u = u(\mathcal{O},\omega) \in H^1(\mathcal{O};\mathbb{R}^d)$ [19, 39].

The unique solution to (1.1) can be equivalently characterized as the unique minimizer of a corresponding quadratic variational problem. In fact, $u(\mathcal{O},\omega)$ minimizes

$$E(\mathcal{O},u,\omega) := \frac{1}{2}A(\mathcal{O},u,u) - l(\mathcal{O},u,\omega) \quad \text{with} \tag{1.2}$$

$$A(\mathcal{O},\psi,\vartheta) := \int_{\mathcal{O}} A_{ijkl}e_{ij}(\psi)e_{kl}(\vartheta)\,\mathrm{d}x\,, \tag{1.3}$$

$$l(\mathcal{O},\vartheta,\omega) := \int_{\mathcal{O}} f_i(\omega)\vartheta_i\,\mathrm{d}x + \int_{\partial\mathcal{O}} g_i(\omega)\vartheta_i\,\mathrm{d}\mathcal{H}^{d-1} \tag{1.4}$$

among all u in $H^1_{\Gamma_D}(\mathcal{O};\mathbb{R}^d) := \{u \in H^1(\mathcal{O};\mathbb{R}^d) \,|\, u = 0 \text{ on } \Gamma_D \text{ in the sense of traces}\}$; see [19, 26, 39] for details. Here and below, we implicitly sum over repeated Cartesian indices.

As an objective functional $\mathbf{J}$ we consider

$$\mathbf{J}(\mathcal{O},\omega) = J(\mathcal{O},u(\mathcal{O},\omega)) := \int_{\mathcal{O}} j(u(\mathcal{O},\omega))\,dx + \gamma\int_{\partial\mathcal{O}} \mathrm{d}\mathcal{H}^{d-1}, \tag{1.5}$$

where γ is a nonnegative control parameter. The second term measuring surface area serves as a regularization. We assume that $j(\cdot)$ is linear or quadratic and does not depend explicitly on the realization ω.

A shape optimization problem under uncertainty is then formulated as

$$\text{minimize} \quad \{\mathbb{E}_\omega(\mathbf{J}(\mathcal{O},\omega)) \,:\, \mathcal{O} \in \mathcal{U}_{ad}\}, \tag{1.6}$$

where $\mathcal{U}_{ad}$ is the set of admissible shapes, e.g., $\mathcal{U}_{ad} := \{\mathcal{O} \subset D \,:\, \mathcal{O} \text{ open and of finite perimeter } \mathcal{O}_* \subset \mathcal{O}, \operatorname{Per}(\mathcal{O}) < \infty\}$, where $\operatorname{Per}(\mathcal{O}) = \mathrm{d}\mathcal{H}^{d-1}(\partial\mathcal{O})$ and for notational simplicity we write ∂) for the reduced boundary. Here and below, $\mathbb{E}_\omega(\dots)$ represents the expected value with respect to the probability distribution of the random variables $f(\omega)$, $g(\omega)$.

We emphasize that we solve the elasticity problem only in the physical domain $\mathcal{O}$. This differs from common practice in shape optimization, which is based on solving the elasticity problem on D with very small (but still positive) values of the elasticity constants λ and μ on $D \setminus \mathcal{O}$. For existence results in this context we refer to [9] and references therein. Our approach is closer to physical reality but brings some technical difficulties. The surface area term in the definition of the cost functional (1.5) ensures rectifiability of the domain boundary for configurations with finite energy but is not expected to guarantee existence of an optimal design. From a theoretical viewpoint, we are unaware of any result for the existence of solutions for the presently considered shape optimization problem. From a numerical viewpoint, this requires robust techniques to solve elasticity problems on badly shaped domains, which are discussed below. Furthermore, numerically different regularization strategies can be considered.

In the optimization problem (1.6) there is a natural information constraint stating that first, and independently of the realizations of $f(\omega), g(\omega)$, the shape $\mathcal{O}$ has to be selected. Then, after observation of $f(\omega), g(\omega)$, (1.1) determines the displacement field $u = u(\mathcal{O}, \omega)$, leading to the objective value $\mathbf{J}(\mathcal{O}, \omega)$. This manifests the interpretation of (1.6) as a two-stage random optimization problem: In the outer optimization, or first stage, the nonanticipative decision on $\mathcal{O}$ has to be taken. After observation of $f(\omega), g(\omega)$ the second-stage optimization problem is the mentioned variational problem, given $\mathcal{O}$ and ω. This second-stage optimization process is neither associated with further stochastic parameters nor with the optimization of additional material properties. In fact, it consists of the determination of the elastic displacement, which in turn is required for the computation of the elastic energy and the cost functional. Even though there is no additional decision making involved, the variational structure of the elasticity problem we are solving gives an obvious analogy to the second-stage problem in stochastic programming.

1.2. Deterministic level-set-based shape optimization. For the readers' convenience and to introduce notation we here briefly sketch the general procedure in deterministic shape optimization, where the volume and surface forces do not depend on a stochastic realization ω. Furthermore, we give an outline of our level set approach.

To get started, we consider variations $\mathcal{O}_v = (\mathrm{Id} + v)(\mathcal{O})$ of a smooth elastic domain $\mathcal{O}$ for a smooth vector field v defined on the working domain D. The shape derivative [22] of the objective functional $\mathbf{J}$ in the direction v takes the form

$$\begin{aligned}(1.7)\quad \mathbf{J}'(\mathcal{O})(v) &= J_{,\mathcal{O}}(\mathcal{O}, u(\mathcal{O}))(v) + J_{,u}(\mathcal{O}, u(\mathcal{O}))(u'(\mathcal{O})(v)) \\ &= \int_{\partial\mathcal{O}} (v \cdot n)\,(j(u(\mathcal{O})) + \gamma\, h)\ \mathrm{d}\mathcal{H}^{d-1} + \int_{\mathcal{O}} j_{,u}(u(\mathcal{O}))\,(u'(\mathcal{O})(v))\ \mathrm{d}x\,.\end{aligned}$$

Here, h denotes the mean curvature on $\partial\mathcal{O}$, defined as the sum of the principal curvatures, and $u'(\mathcal{O})(v)$ denotes the shape derivative of the elastic displacement defined by $u'(\mathcal{O})(v) = \lim_{t\to 0}[u((\mathrm{Id} + tv)\mathcal{O}) - u(\mathcal{O})]/t$.

In order to avoid the need of a separate evaluation of $u'(\mathcal{O})(v)$ for any infinitesimal domain displacement v, we seek a simpler expression for the $J_{,u}$ term. This is obtained by determining the variation of u with v implicitly, through its definition. Precisely, $u(\mathcal{O})$ was defined as the weak solution of (1.1), i.e.,

$$(1.8)\qquad A(\mathcal{O}, u(\mathcal{O}), \vartheta) = l(\mathcal{O}, \vartheta)$$

for all $\vartheta \in H^1_{\Gamma_D}(\mathcal{O}; \mathbb{R}^d)$. Differentiating this with respect to the variation v of the domain $\mathcal{O}$ (which in this entire discussion is assumed to be sufficiently smooth), we

get

$$A(\mathcal{O}, u'(\mathcal{O})(v), \vartheta) = l_{,\mathcal{O}}(\mathcal{O}, \vartheta)(v) - A_{,\mathcal{O}}(\mathcal{O}, u(\mathcal{O}), \vartheta)(v) \quad \text{with} \tag{1.9}$$

$$A_{,\mathcal{O}}(\mathcal{O}, \psi, \vartheta)(v) = \int_{\partial\mathcal{O}} (v \cdot n) A_{ijkl} e_{ij}(\psi) e_{kl}(\vartheta) \, \mathrm{d}\mathcal{H}^{d-1} , \tag{1.10}$$

$$l_{,\mathcal{O}}(\mathcal{O}, \vartheta)(v) = \int_{\partial\mathcal{O}} (v \cdot n) \, (f_i + g_i \, h + \partial_n g_i) \, \vartheta_i \, \mathrm{d}\mathcal{H}^{d-1}. \tag{1.11}$$

We observe that $J_{,u}(\mathcal{O}, u(\mathcal{O}))(\cdot)$ is a linear bounded functional on $L^2(D; \mathbb{R}^d)$. Therefore we can consider the dual problem and define $p(\mathcal{O}) \in H^1_{\Gamma_D}(D; \mathbb{R}^d)$ to be the solution of

$$A(\mathcal{O}, \vartheta, p(\mathcal{O})) = -J_{,u}(\mathcal{O}, u(\mathcal{O}))(\vartheta) \tag{1.12}$$

for all ϑ in $H^1_{\Gamma_D}(\mathcal{O}; \mathbb{R}^d)$. For the purpose of later reference let us also give a variational interpretation of this dual approach. Equation (1.12) corresponds to the fact that $p(\mathcal{O}) \in H^1_{\Gamma_D}(\mathcal{O}; \mathbb{R}^d)$ minimizes the quadratic functional

$$F(q) = \frac{1}{2} A(\mathcal{O}, q, q) + J_{,u}(\mathcal{O}, u(\mathcal{O}))(q) \tag{1.13}$$

among all $q \in H^1_{\Gamma_D}(\mathcal{O}; \mathbb{R}^d)$. In the strong formulation, we thus ask for a solution p of the system of partial differential equations $-\mathrm{div}\,(Ae(p(\mathcal{O}))) = -j_{,u}(u(\mathcal{O}))$, with $p(\mathcal{O}) = 0$ on Γ_D and $Ae(p(\mathcal{O})) \cdot n = 0$ on $\partial\mathcal{O} \setminus \Gamma_D$. Choosing $\vartheta = u'(\mathcal{O})(v)$ in (1.12) and recalling (1.19), one finally rewrites the shape derivative (1.7) of the objective functional as follows:

$$\begin{aligned} \mathbf{J}'(\mathcal{O})(v) &= J_{,\mathcal{O}}(\mathcal{O}, u(\mathcal{O}))(v) - A(\mathcal{O}, u'(\mathcal{O})(v), p(\mathcal{O})) \\ &= J_{,\mathcal{O}}(\mathcal{O}, u(\mathcal{O}))(v) - l_{,\mathcal{O}}(\mathcal{O}, p(\mathcal{O}))(v) + A_{,\mathcal{O}}(\mathcal{O}, u(\mathcal{O}), p(\mathcal{O}))(v) \\ &= \int_{\partial\mathcal{O}} (v \cdot n) \big[j(u(\mathcal{O})) + \gamma \, h - (f_i + g_i \, h + \partial_n g_i) \, p_i(\mathcal{O}) \\ &\qquad + A_{ijkl} e_{ij}(u(\mathcal{O})) e_{kl}(p(\mathcal{O})) \big] \, \mathrm{d}\mathcal{H}^{d-1} . \end{aligned} \tag{1.14}$$

In order to permit the topology of the domain $\mathcal{O}$ to change, we consider an implicit description of shapes in terms of a level set function $\phi : D \to \mathbb{R}$. In particular, the elastic body is represented by $\mathcal{O} = \{\phi < 0\} := \{x \in D \,|\, \phi(x) < 0\}$, and its boundary $\partial\mathcal{O}$ corresponds to the zero level set of ϕ, i.e., $D \cap \partial\mathcal{O} = \{\phi = 0\}$. Shape optimization and shape analysis for elastic solids via level set methods has been investigated by various authors [9, 23, 36, 52]. In particular, Allaire and coworkers [4–6, 9] have extensively studied a level set modeling of shapes in 2D and 3D structural optimization and compared and combined this approach with homogenization methods. In [8] they recently investigated topological optimization in the context of minimizing the expected elastic stress.

Interface propagation based on level sets was first introduced by Osher and Sethian [43] and since then attracted very much attention due to their enormous flexibility. For a general overview we refer to [42,51]. If a domain boundary $\partial\mathcal{O}$ propagates with speed v, the evolution of the corresponding level set function ϕ is given by the level set equation $\partial_t \phi + |\nabla\phi| \, v \cdot n = 0$, where $n = \frac{\nabla\phi}{|\nabla\phi|}$ is the field of outer normals on the level sets. In fact, the level set equation identifies variations $s = \partial\phi$ of the level set function with variations $v \cdot n$ of the level sets in the direction of the normal

n. Even though hypersurfaces are described in the level set context by functions on the whole domain, suitable implementations lead to efficient numerical algorithms as well [2, 34, 57]. Fairly general shapes can be effectively described and modeled with level sets [38]. Shape sensitive analysis as introduced by Sokolowski and Zolésio [54] can be phrased elegantly in terms of level sets. Let us rewrite the objective functional $\mathbf{J}(\mathcal{O})$ in terms of a level set function ϕ and define

$$\mathcal{J}(\phi) := \mathbf{J}(\{\phi < 0\}). \tag{1.15}$$

Due to the above identification we obtain for the shape derivative of $\mathcal{J}(\phi)$ with respect to a variation s of ϕ (again, working for the moment on smooth domains and away from degeneracies and topological changes)

$$\mathcal{J}'(\phi)(s) = \mathbf{J}'(\{\phi < 0\}) \left(-s\,|\nabla\phi|^{-1} n\right) . \tag{1.16}$$

For the relaxation of the shape functional we now consider a gradient descent

$$\partial_t \phi(t) = -\mathrm{grad}_{\mathcal{G}} \mathcal{J}(\phi)$$

with respect to a metric $\mathcal{G}$ on the space of variations of the level set function ϕ (cf. [45]). This metric ensures smoothness of the descent path and is expected to approximate a regular minimizer from the set of all minimizers. For an overview on optimal design based on level sets and suitable energy descent methods we refer to a recent survey by Burger and Osher [17]. From (1.14) we learn that the support of $\mathbf{J}'(\mathcal{O})(\cdot)$ is contained in $\partial\mathcal{O} \setminus \Gamma_D$. Thus, we take into account a regularized gradient descent based on the metric

$$\mathcal{G}(\zeta, \xi) = \int_D \zeta\xi + \frac{\rho^2}{2} \nabla\zeta \cdot \nabla\xi \,\mathrm{d}x\,, \tag{1.17}$$

which is related to a Gaussian filter with width ρ. For the time discretization, we consider Armijo rule as a step size control, and starting with an initial level set function ϕ^0 we iteratively compute a sequence of level set functions $(\phi^k)_{k=1,\dots}$ given by

$$\mathcal{G}(\phi^{k+1} - \phi^k, \xi) = -\tau \mathcal{J}'(\phi^k)(\xi) \tag{1.18}$$

for all test functions ξ and a sequence of time steps $(\tau^k)_{k=1,\dots}$. In each time step a linear elliptic problem of the type $(\mathrm{Id} - \frac{\rho^2}{2}\Delta)\phi = r$ has to be solved. Alternatively, one might consider a relaxation of shapes described via an evolution of signed distance functions [21,28]. For the spatial discretization we consider piecewise affine continuous finite element functions on the working domain D. Shape relaxations tend to create fine scale structures and complicated domains $\mathcal{O}$. To evaluate the objective functional itself and the shape derivative, the elastic displacement u on $\mathcal{O}$ has to be computed solving the Euler Lagrange equations (1.1) of the inner, elastic minimization subproblem. Here, we apply multilevel composite finite elements introduced by Hackbusch and Sauter [31, 50]. They incorporate the characteristic behavior of the solution on fine scales into the coarse scale shape functions without, necessarily, adding degrees of freedom.

1.3. Two-stage stochastic programming revisited. Before we apply two-stage stochastic programming to our shape optimization problem, let us recall the basic concepts from finite-dimensional stochastic optimization. Consider the random linear program

$$\min \left\{ c^\top x + q^\top y \;:\; Tx + Wy \,=\, z(\omega),\;\; x \in X,\; y \in Y \right\} \tag{1.19}$$

for finite-dimensional polyhedra X and Y in Euclidean space together with the information constraint

$$\text{decide } x \;\mapsto\; \text{observe } \omega \;\mapsto\; \text{decide } y = y(x,\omega).$$

We assume that the minimum exists; possibly making the spaces larger, we can also without loss of generality replace the condition $y \in Y$ by $y \geq 0$ (that is, $y_i \geq 0$ for all i). We also remark that given x and $z(\omega)$ there are multiple solutions y from which we have to select one.

Let us emphasize the two-stage characteristic of this optimization problem. Indeed, rewriting (1.19) yields

$$\begin{aligned} &\min_x \left\{ c^\top x + \min_y \{ q^\top y \,:\, Wy \,=\, z(\omega) - Tx,\; y \in Y \} \;:\; x \in X \right\} \\ &= \min \left\{ c^\top x + \Phi(z(\omega) - Tx) \;:\; x \in X \right\}, \end{aligned} \tag{1.20}$$

where $\Phi(v) := \min\{q^\top y \,:\, Wy = v,\; y \in Y\}$ is the value function of a linear program with parameters on the right-hand side. The cost functional we aim to minimize is $\mathsf{j}(x,\omega) := c^\top x + \Phi(z(\omega) - Tx)$. The representation (1.20) gives rise to understanding the search for a "best" nonanticipative decision x in the initial random optimization problem as the search for a "minimal" member in the family of random variables $\{\mathsf{j}(x,\omega) \;:\; x \in X\}$, where x is seen as an "index" varying in the set X. In a risk-neutral setting, these random variables are ranked by their expectations, leading to the (nonlinear) optimization problem

$$\min\{Q_{\mathbb{E}}(x) \,:=\, \mathbb{E}_\omega\left(\mathsf{j}(x,\omega)\right) \;:\; x \in X\}. \tag{1.21}$$

The straightforward but crucial idea is to detect structural properties and algorithmic possibilities in (1.21) by resorting to the dual of the linear program with value function $\Phi(\cdot)$. Indeed, one observes

$$\begin{aligned} \Phi(v) &= \min\left\{ q^\top y \,:\, Wy = v,\; y \geq 0 \right\} \\ &= \max\left\{ v^\top y \,:\, W^\top y \leq q \right\} = \max_{l=1,\dots,L} d_l^\top v\,, \end{aligned} \tag{1.22}$$

where $\{d_l\}_{l=1,\dots,L}$ denotes the set of vertices of the dual polyhedron $\{y \,:\, W^\top y \leq q\}$, which is assumed compact, and $v = z(\omega) - Tx$. Recalling the cost functional $\mathsf{j}(x,\omega)$, we can rewrite (1.21) and obtain

$$\min\left\{ c^\top x + \sum_{\sigma=1}^{S} \pi_\sigma \max_{l=1,\dots,L} d_l^\top (z_\sigma - Tx) \;\;:\;\; x \in X \right\} \tag{1.23}$$

in the case of a discrete probability distribution with realizations z_σ and probabilities π_σ for $\sigma = 1,\dots,S$. Here, S is the total number of scenarios. Thus, minimizing $Q_{\mathbb{E}}$ amounts to minimizing a piecewise linear convex function over a polyhedron. Let us emphasize that in our concrete setup, the functional to be minimized in (1.23) depends linearly on the random variable z, which can be exploited further in the actual numerical minimization.

Algorithmically, two aspects are important: By its very definition, computing $Q_{\mathbb{E}}(x)$ in (1.21) would amount to solving $\min\{q^\top y \,:\, Wy = z_\sigma - Tx,\; y \geq 0\}$ for all scenarios z_σ with $\sigma = 1,\dots,S$ and this again at any new iteration point x. In

(1.23) this is prevented by using dual information. Here, the situation is particularly comfortable since cutting planes generated in adaptations of bundle methods, see, e.g., [48,53], capture (at least approximately) information on the objective also locally around iteration points. The second aspect is that (sub)gradient information on $Q_{\mathbb{E}}$ is made available by the help of the dual, cf. (1.23).

The facts reviewed above form our guideline for treating shape optimization under uncertainty: Departing from the outlined two-stage model with shape decisions in the first stage and displacements in the second, we will formulate an (infinite-dimensional) counterpart to the expectation problem (1.21). The variational formulation of the elasticity system will provide an inner optimization problem in the spirit of (1.20). As in (1.22) a duality argument will provide information for the shape derivative. In what follows, the domain $\mathcal{O}$ replaces the variable x, the elastic deformation $u(\mathcal{O},\omega)$ the optimal solution y being a minimizer of the above $\Phi(v)$, where v depends on x and $z(\omega)$. Finally, as a counterpart to the cost functional $\mathsf{j}(x,\omega)$ we consider the objective functional $\mathbf{J}(\mathcal{O},\omega)$. Moreover, as above, in each iteration of a descent method linearity of the elasticity PDE will avoid the solution of as many related PDEs as there are scenarios.

2. Two-stage stochastic programming formulation of shape optimization. We now present our stochastic shape optimization scheme, which incorporates the techniques from deterministic shape optimization discussed in section 1.2 and the two-stage stochastic programming reviewed in section 1.3. In our setting, the second stage optimization problem is the variational problem of linearized elasticity, where for a fixed elastic domain $\mathcal{O}$ and random state ω one seeks a displacement u which minimizes the energy $E(\mathcal{O},u,\omega)$ defined in (1.2). In turn, the objective functional can be computed from the domain $\mathcal{O}$ and the displacement u and hence can be seen as a function of $\mathcal{O}$ and the random state ω. We observe the following information constraints:

$$\text{decide } \mathcal{O} \;\mapsto\; \text{observe } \omega \;\mapsto\; \text{compute } u = u(\mathcal{O},\omega)\,.$$

In other words, one first selects a domain $\mathcal{O}$ (like in section 1.3 one decided for some x), then random volume and boundary forces $f(\omega)$ and $g(\omega)$ are applied (the counterpart of the right-hand side $z(\omega)$ in (1.19)), and only at this point the elastic displacement u (the counterpart of the degree of freedom y in (1.19)) and hence the objective functional can be computed. Thus, in analogy to (1.20) we can reformulate the random shape optimization problem in a two-stage optimization manner as follows:

$$\min\left\{\mathbf{J}(\mathcal{O},\omega)\;:\; u(\mathcal{O},\omega) = \operatorname{argmin}_{u\in H^1_{\Gamma_D}(\mathcal{O};\mathbb{R}^d)} E(\mathcal{O},u,\omega)\right\}.$$

As mentioned above, $\mathcal{O}$ has the role of the first-stage and $u(\mathcal{O},\omega)$ of the second-stage decisions. Finally, the stochastic program

$$\min\left\{Q_{\mathbb{E}}(\mathcal{O}) := \mathbb{E}_\omega\left(\mathbf{J}(\mathcal{O},\omega)\right)\;:\; \mathcal{O}\in\mathcal{U}_{ad}\right\} \tag{2.1}$$

arises as the "natural" counterpart to (1.21). Replacing the variational problem in (2.1) by its Euler equation enables us to introduce the (dual or) adjoint system needed to effectively compute gradients of the stochastic objective functional.

2.1. Stochastic primal and dual problem. We start from the analysis of the second-stage problem. As illustrated in section 1.3, in order to determine the shape derivative of the objective function it is convenient to solve both the primal and the

dual elastic problem as a counterpart of (1.22) in two-stage stochastic programming. Precisely, given $\mathcal{O}$ and ω we seek a primal solution $u(\mathcal{O},\omega) \in H^1_{\Gamma_D}(D;\mathbb{R}^d)$ and a dual solution $p(\mathcal{O},\omega) \in H^1_{\Gamma_D}(D;\mathbb{R}^d)$ such that

$$A(\mathcal{O}, u(\mathcal{O},\omega), \vartheta) = l(\mathcal{O},\vartheta,\omega)\,, \tag{2.2}$$

$$A(\mathcal{O}, \vartheta, p(\mathcal{O},\omega)) = -J_{,u}(\mathcal{O}, u(\mathcal{O},\omega))(\vartheta) \tag{2.3}$$

for all $\vartheta \in H^1_{\Gamma_D}(D;\mathbb{R}^d)$. The function $u(\mathcal{O},\omega)$ entering the dual problem is the solution to the primal problem. Let us emphasize that as in (1.22) both the primal and the dual state solve variational problems, in fact (1.2) and (1.13), respectively.

A key simplification in the solution of these equations arises from the general fact that the solution of a linear problem depends linearly on the data. We phrase this fact first in general terms and then discuss the implications in our setting. Let $A_{\mathcal{O}} : H^1_{\Gamma_D} \to H^{-1}_{\Gamma_D}(D;\mathbb{R}^d)$ be the elliptic operator induced by the quadratic form $A(\mathcal{O},\cdot,\cdot)$, in fact $A_{\mathcal{O}}(u)(\vartheta) = A(\mathcal{O},u,\vartheta)$. By the positivity of the elastic coefficients, for any Lipschitz, connected domain $\mathcal{O}$, and under the assumption that $\Gamma_D \subset \partial\mathcal{O}$ has positive $(d-1)$-dimensional measure, the operator $A_{\mathcal{O}}$ is bounded and coercive on the Hilbert space $H^1_{\Gamma_D}(D;\mathbb{R}^d)$ and therefore invertible. This implies that for any $l \in H^{-1}_{\Gamma_D}(D;\mathbb{R}^d)$ one can find a unique solution u to $A_{\mathcal{O}}(u,\vartheta) = l(\vartheta)$, namely, $u = A^{-1}_{\mathcal{O}} l$. Therefore both (2.2) and (2.3) have a unique solution, which depends linearly on the right-hand side.

We now consider the specific case of interest here, namely, the dependence of u and p on ω. The crucial point is that the left-hand side of both equations, i.e., the quadratic form $A(\mathcal{O},\cdot,\cdot)$, does not depend on ω. The right-hand side depends on ω only through f, g, and u, and this dependence is linear. Here, it is important that the integrand j entering the objective function is linear or quadratic. We shall now exploit this fact in order to obtain an efficient algorithm, which does not require us to solve (2.2) and (2.3) for every ω but only for a representative subset (a "basis").

We start from the primal problem (2.2). Since the right-hand side is linear in the forces f and g, and A does not depend on ω, the solution u depends linearly on the forces f and g. In order to make this more explicit, assume that f and g are random combinations of finitely many forces $f^1,\dots,f^K \in L^2(D;\mathbb{R}^d)$ and $g^1,\dots,g^M \in H^1(D;\mathbb{R}^d)$, respectively, i.e.,

$$f(\omega) = \sum_{k=1}^{K} \alpha_k(\omega) f^k, \qquad g(\omega) = \sum_{m=1}^{M} \beta_m(\omega) g^m.$$

Here, the $\alpha_k(\omega)$ and $\beta_m(\omega)$ are stochastic coefficients. For later convenience we assume that $\sum_{k=1}^{K} \alpha_k(\omega) = \sum_{m=1}^{M} \beta_k(\omega) = 1$. (This can always be achieved by a rescaling of the coefficients of f^k's and g^m's such that their corresponding sums are both smaller than 1. Adding two virtual loads equal to zero, we easily can ensure the equality sign.) We assume that ω follows a discrete distribution with scenarios ω_σ and probabilities π_σ, with $\sigma = 1,\dots,S$ ($\sum_{\sigma=1}^{S} \pi_\sigma = 1$); continuous distributions can be recovered in the limit $S \to \infty$. For any pair $(k,m) \in \{1,\dots,K\} \times \{1,\dots,M\}$ let $u^{km}(\mathcal{O})$ be the solution to the elasticity system $(1.1)_{km}$, which is (1.1) with right-hand sides f^k, g^m. Then, for any $\sigma = 1,\dots,S$,

$$\bar{u}(\mathcal{O},\omega_\sigma) \;:=\; \sum_{k=1}^{K}\sum_{m=1}^{M} \alpha_k(\omega_\sigma)\beta_m(\omega_\sigma) u^{km}(\mathcal{O}) \tag{2.4}$$

solves (1.1) for $\omega = \omega_\sigma$. In the numerical implementation, we confine to $K + M$ displacements, where each of them corresponds either to a single volume force or a single boundary force and vanishing components with respect to all other forces. To simplify the presentation, we consider here an overdetermined system of $K\,M$ spanning displacements. This is a substantial algorithmic shortcut, in the case that the discretization parameter of the probability measure S is larger than the sum of the $K + M$ effective base forces.

An analogous argument applies to the dual problem (2.3). We first determine, for each pair $(k, m) \in \{1, \dots, K\} \times \{1, \dots, M\}$, the solution $p^{km}(\mathcal{O})$ of the basis problem

$$A\left(\mathcal{O}, \vartheta, p^{km}(\mathcal{O})\right) = -J_{,u}\left(\mathcal{O}, u^{km}(\mathcal{O})\right)(\vartheta) \text{ for all } \vartheta \in H^1_{\Gamma_D}\left(D; \mathbb{R}^d\right). \tag{2.5}$$

Since j depends linearly or quadratically on u, the dependence of $j_{,u}$ on u is linear (possibly trivial). Therefore (2.4) and the above-introduced normalization implies

$$J_{,u}(\mathcal{O}, \bar{u}(\mathcal{O}, \omega_\sigma))(\vartheta) = \sum_{k=1}^{K} \sum_{m=1}^{M} \alpha_k(\omega_\sigma)\beta_m(\omega_\sigma) J_{,u}(\mathcal{O}, u^{km}(\mathcal{O}))(\vartheta),$$

and linearity of the inverse operator $A^{-1}_{\mathcal{O}}$ gives

$$\bar{p}(\mathcal{O}, \omega_\sigma) = \sum_{k=1}^{K} \sum_{m=1}^{M} \alpha_k(\omega_\sigma)\beta_m(\omega_\sigma) p^{km}(\mathcal{O}). \tag{2.6}$$

Obviously, $\bar{p}(\mathcal{O}, \omega_\sigma)$ is the weak solution $\bar{p}$ of $-\mathrm{div}\,(Ae(\bar{p})) = -j'(\bar{u}(\mathcal{O}, \omega_\sigma))$ on the domain $\mathcal{O}$ with $\bar{p} = 0$ on Γ_D and $Ae(\bar{p}) \cdot n = 0$ on $\partial\mathcal{O} \setminus \Gamma_D$.

2.2. Shape gradient in the stochastic optimization problem. Now, with the primal solution $\bar{u}(\mathcal{O}, \omega_\sigma)$ for a particular realization ω_σ at hand, the stochastic program (2.1) can be rewritten as follows:

$$\begin{aligned} \min \Bigg\{ & \gamma \int_{\partial\mathcal{O}} \mathrm{d}\mathcal{H}^{d-1} + \sum_{\sigma=1}^{S} \pi_\sigma \int_{\mathcal{O}} j(\bar{u}(\mathcal{O}, \omega_\sigma))\, dx \ : \\ & \bar{u}(\mathcal{O}, \omega_\sigma) := \sum_{k=1}^{K} \sum_{m=1}^{M} \alpha_k(\omega_\sigma)\beta_m(\omega_\sigma) u^{km}(\mathcal{O}),\ \sigma = 1, \dots, S \Bigg\}. \end{aligned} \tag{2.7}$$

Using the primal solution for the elastic deformation $\bar{u}(\mathcal{O}, \omega_\sigma)$ and the dual solution $\bar{p}(\mathcal{O}, \omega_\sigma)$ for any realization ω_σ, we deduce the stochastic shape derivative (1.7) of the objective functional $\mathbf{J}(\mathcal{O}, \omega_\sigma)$ and achieve, from (1.14),

$$\begin{aligned} \mathbf{J}'(\mathcal{O}, \omega_\sigma)(v) &= J_{,\mathcal{O}}(\mathcal{O}, \bar{u}(\mathcal{O}, \omega_\sigma))(v) - l_{,\mathcal{O}}(\mathcal{O}, \bar{p}(\mathcal{O}, \omega_\sigma))(v) \\ &\quad + A_{,\mathcal{O}}(\mathcal{O}, \bar{u}(\mathcal{O}, \omega_\sigma), \bar{p}(\mathcal{O}, \omega_\sigma))(v) \\ &= \int_{\partial\mathcal{O}} (v \cdot n)\big(j(\bar{u}(\mathcal{O}, \omega_\sigma)) + \gamma\, h - (f_i(\omega_\sigma) + g_i(\omega_\sigma)\, h + \partial_n g_i)\, \bar{p}_i(\mathcal{O}, \omega_\sigma) \\ &\qquad + A_{ijkl} e_{ij}(\bar{u}(\mathcal{O}, \omega_\sigma)) e_{kl}(\bar{p}(\mathcal{O}, \omega_\sigma))\big)\ \mathrm{d}\mathcal{H}^{d-1}. \end{aligned} \tag{2.8}$$

Finally, the shape derivative of our actual stochastic cost functional, namely, of the expectation of the cost $Q_{\mathbb{E}}(\mathcal{O})$ in the case of S scenarios $(\omega_\sigma)_{\sigma=1,\dots,S}$, is given by

$$Q'_{\mathbb{E}}(\mathcal{O})(v) = \mathbb{E}_\omega\left(\mathbf{J}'(\mathcal{O}, \omega)(v)\right) = \sum_{\sigma=1}^{S} \pi_\sigma J'(\mathcal{O}; \omega_\sigma)(v). \tag{2.9}$$

In the algorithm this shape derivative can be used as a descent direction. Thereby, first the $K\,M$ primal and dual base states are computed. These allow for the efficient evaluation of the effective deformations $\bar{u}(\mathcal{O}, \omega_\sigma)$ and the effective dual states $\bar{p}(\mathcal{O}, \omega_\sigma)$ for a set of S scenarios ω_σ with S usually much larger than $K\,M$.

3. Multiscale finite element implementation. In this section we detail the concrete numerical algorithm and consider a finite element approach for the representation of the level set function ϕ on the working domain D, which implicitly describes the discrete elastic domain $\mathcal{O}$ as the sublevel set of the discrete level set function. The elastic state equations for u^{km} and the corresponding set of dual problems for p^{km} are discretized as well with finite elements. Here, we pick up the composite finite element approach originally proposed by [31] and investigated in the level set context for complicated 3D geometries in [35]. Finally, we will discuss the time step control used in our descent scheme.

3.1. Finite element spaces. Without any restriction we suppose our working domain D to be a hexahedron ($d = 3$) or a rectangle ($d = 2$), respectively. In a first step, a hierarchical grid is generated based on successive subdivision of hexahedrons (resp., rectangles) into 8 (resp., 4) equally sized child hexahedrons (resp., rectangles). Next, each cell of the resulting fine grid is split into 6 tetrahedra (2 triangles) such that a regular simplicial grid $\mathcal{T}_h$ of the domain D is obtained. We denote the simplicial elements of this grid by $T \in \mathcal{T}_h$ and the set of nodes by $\mathcal{N}_h = \{X_i\}_{i \in I_h}$ with a corresponding index set I_h. Let us emphasize that we do not represent this simplicial grid explicitly. Instead access to element data is implicitly encoded in look up tables. Here, h indicates the grid size. Let $\mathcal{V}_h$ be the space of continuous, piecewise affine functions on $\mathcal{T}_h$ with the canonical basis $\{\Phi_i\}_{i \in I_h}$, given by $\Theta_i(X_j) = \delta_{ij}$. In what follows, discrete variables will always be capitalized, whereas continuous ones will be lowercase. Now, we consider a discrete level set function $\Phi(x) = \sum_{i \in I_h} \Phi_i \Theta_i(x)$. As a consequence, the discrete domain $\mathcal{O}_h = \{x \in D \,|\, \Phi(x) < 0\}$ is polygonal. This algorithmic advantage justifies the use of a tetrahedral grid. A solution of the state equation (2.2) and the dual problem (2.3) is defined on the elastic domain only. Here, we explicitly work with a void phase $D \setminus \mathcal{O}$, and, at variance with [6, 9], we do not consider a softer elastic material outside of actual elastic body $\mathcal{O}$ to be optimized. Thus, we have to define suitable finite element spaces on the discrete elastic domain $\mathcal{O}_h$ implicitly described by a level set function $\Phi \in \mathcal{V}_h$. A straightforward mesh generation based on a marching cube-type algorithm [37, 56] leads to badly shaped tetrahedra with a significant impact on the condition number of the linear systems to be solved. Explicit grid generation would require a regular remeshing of the boundary $\partial\mathcal{O}_h$ followed by the actual meshing algorithm in $\mathcal{O}_h \subset \mathbb{R}^d$ [24, 44]. Both steps are fairly complicated in the case of general elastic domains and result in nonhierarchical, unstructured meshes which do not allow for a multilevel algorithm for the discrete PDE problems. To avoid these drawbacks we construct a suitable composite finite element space. In contrast to explicit meshing approaches, the geometry is encoded in the design of the basis functions, which still correspond to grid nodes of the regular underlying grid. In fact, given a basis function $\Theta_i \in \mathcal{V}_h$ whose support intersects the discrete elastic domain $\mathcal{O}_h$, we define the corresponding composite finite element basis function $\Theta_i^{\text{cfe}}(x) = \chi_{\mathcal{O}_h}(x)\Theta_i(x)$, selecting the part of the old basis function contained in the elastic domain [31]. Here, $\chi_{\mathcal{O}_h}$ denotes the characteristic function of the discrete domain $\mathcal{O}_h$. Let us remark that there are also degrees of freedom at nodes outside the actual domain as long as the support of the corresponding basis function interests $\mathcal{O}_h$. Collecting all of these basis functions we obtain the composite

finite element space

$$\mathcal{V}_h^{\mathrm{cfe}} := \{\Theta_i^{\mathrm{cfe}}(x) = \chi_{\mathcal{O}_h}(x)\Theta_i(x) \,|\, \operatorname{supp}\Theta_i \cap \mathcal{O}_h \neq \emptyset\},$$

and the resulting nodal index set I_h^{cfe} is a subset of the index set I_h. Hence, far from the domain boundary the basis functions coincide with the standard basis functions, whereas in the vicinity of the boundary, the standard basis is modified to resolve the domain geometry. Finally, let us incorporate boundary data and define $\mathcal{V}_{h,\Gamma_D}^{\mathrm{cfe}} = (\mathcal{V}_h^{\mathrm{cfe}})^3 \cap H^1_{\Gamma_D}(D;\mathbb{R}^d)$ as the space of discrete vector valued functions which vanish on the Dirichlet boundary Γ_D. For the sake of simplicity, we assume here Γ_D to be resolved on the underlying regular grid. Thus, no special treatment of the Dirichlet boundary condition in the construction of the composite finite elements [32] is required. Indeed, to conserve the Dirichlet boundary condition we furthermore freeze the level set function ϕ in a small neighborhood of the Dirichlet boundary Γ_D and the Neumann boundary Γ_N on which the surface load is applied. Hence, in this region the body still behaves elastic but does not undergo any optimization. As basis functions for the vector valued problem we consider $\Theta_i^{\mathrm{cfe}} e_j$ with $i \in I_h^{\mathrm{cfe}}$ and $1 \leq j \leq d$.

3.2. Discrete primal and dual solutions. Given the composite finite element space $\mathcal{V}_{h,\Gamma_D}^{\mathrm{cfe}}$ we can solve the primal and the dual problem numerically. Explicitly, the discrete primal solutions are defined as the finite element functions $U^{km} \in \mathcal{V}_{h,\Gamma_D}^{\mathrm{cfe}}$ solving

$$A\left(\mathcal{O}_h, U^{km}, \Theta\right) = l^{km}(\mathcal{O}_h, \Theta) \tag{3.1}$$

for all $\Theta \in \mathcal{V}_{h,\Gamma_D}^{\mathrm{cfe}}$, where $l^{km}(\mathcal{O}_h,\Theta) := \int_{\mathcal{O}_h} f_i^k \Theta_i \,\mathrm{d}x + \int_{\partial\mathcal{O}_h} g_i^m \Theta_i \,\mathrm{d}\mathcal{H}^{d-1}$ for $1 \leq k \leq K$ and $1 \leq m \leq M$. The corresponding set of dual solutions are those functions $P^{km} \in \mathcal{V}_{h,\Gamma_D}^{\mathrm{cfe}}$ for which

$$A\left(\mathcal{O}_h, \Theta, P^{km}\right) = -J_{,u}\left(\mathcal{O}_h, U^{km}\right)(\Theta) \tag{3.2}$$

for all $\Theta \in \mathcal{V}_{h,\Gamma_D}^{\mathrm{cfe}}$. For the variation of the cost functional J with respect to the discrete elastic displacement U we obtain $J_{,u}(\mathcal{O}_h, U^{km})(\Theta) = \int_{\mathcal{O}_h} j_{,u}(U^{km})(\Theta)\,\mathrm{d}x$. Due to the assumption that $j(\cdot)$ is a linear or quadratic polynomial, the resulting integrant is at most quadratic and can be integrated exactly using a Gauss quadrature rule. In the case of the compliance cost functional $J(\mathcal{O}, u(\mathcal{O},\omega)) = l^{km}(\mathcal{O}, u^{km}, \omega) + \gamma \int_{\partial\mathcal{O}} \mathrm{d}\mathcal{H}^{d-1}$, we derive as usual from (3.1) the representation $J_{,u}(\mathcal{O}_h, U^{km})(\Theta) = A(\mathcal{O}_h, U^{km}, \Theta) = \int_{\mathcal{O}_h} A_{ijkl} e_{ij}(U^{km}) e_{kl}(\Theta)\,\mathrm{d}x$. The numerical solution of (3.1) and (3.2) both require numerical quadrature for the assembly of the stiffness matrix $(A(\mathcal{O}_h, \Theta_i e_j, \Theta_r e_s))_{i,r\in I_h^{\mathrm{cfe}}, 1\leq j,s\leq d}$ and the right-hand side vectors $(l^{km}(\mathcal{O}_h, \Theta_r e_s))_{r\in I_h^{\mathrm{cfe}}, 1\leq s\leq d}$ and $(-J_{,u}(\mathcal{O}_h, U^{km})(\Theta_r e_s))_{r\in I_h^{\mathrm{cfe}}, 1\leq s\leq d}$, respectively. For this purpose, on simplices of the original mesh which are intersected by the domain boundary $\partial\mathcal{O}_h$ a local, virtual grid is generated. Based on a look up table the cells generated by the marching cube-type method in the construction of the composite finite elements are subdivided into simplices. On these simplices and on the simplices within $\mathcal{O}_h$ not intersected by the domain boundary a one point, center of mass quadrature rule is applied. The evaluation of the boundary integral $\int_{\partial\mathcal{O}_h} g_s^m \Theta_r \,\mathrm{d}\mathcal{H}^{d-1}$ is treated analogously.

As long as the discrete domain $\mathcal{O}_h$ is connected in the following discrete sense, namely, for every node X_i with $i \in I_h^{\mathrm{cfe}}$ there is a chain of nodes $(X_j)_{j=0,\ldots,n}$ with $j \in I_h^{\mathrm{cfe}}$ such that $[X_j, X_{j+1}]$ is an edge of $\mathcal{T}_h$, $X_0 = X_i$, and X_n is a node on Γ_D,

we easily verify that there exist unique solutions U^{km} and P^{km} of (3.1) and (3.2), respectively. The resulting symmetric linear systems of equations are solved with a conjugate gradient method for $d = 2$ and with a multigrid method for $d = 3$. In general a still high condition number for the corresponding linear system of equations on the finest grid level will reflect the badly shaped support of single composite basis functions. Here, in particular the multigrid method leads to convergence rates which are independent of the grid size h and—for a wide range of problems—the geometric complexity of the domain. For the multigrid solver, we first recursively construct coarse grid matrices and right-hand sides. Here, the underlying hierarchical grid induces a canonical projection operator for any grid level to the next finer one generated by the cell subdivision. Let us emphasize that this applies not only for the hierarchical hexahedral grid but analogously for the associated simplicial mesh as well. Based on the projection operator a standard Galerkin projection [30] is applied both for the matrices and the right-hand sides. We then use a multigrid method with V cycles and symmetric Block–Gauß–Seidel iterations as a smoother. Thereby, we gather the 3 spatial components of the solution at a grid node and apply the Gauß–Seidel iterations on the resulting 3×3 blocks. In the applications considered here, 3 pre- and post-smoothing steps in the V cycle turned out to be a reasonable choice. For details on the composite finite element approach and the multigrid method we refer to [35].

3.3. Discrete gradient descent algorithm. The numerical relaxation of the shape functional is based on the time discretized, regularized gradient descent scheme given in (1.18) and applied to the spatially discrete stochastic shape functional

$$Q_{\mathbb{E},h}(\mathcal{O}_h) := \mathbb{E}_\omega\left(\mathcal{J}(\Phi,\omega)\right) = \sum_{\sigma=1}^{S} \pi_\sigma \mathcal{J}(\Phi,\omega_\sigma), \tag{3.3}$$

where the shape functional $\mathcal{J}$ for a discrete level set function Φ is defined in a straightforward way by $\mathcal{J}(\Phi,\omega_\sigma) := \mathbf{J}(\{\Phi < 0\},\omega_\sigma)$ for any realization ω_σ. Here, for the ease of presentation we notationally do not distinguish continuous and discrete shape functionals; in fact, in what follows discrete shape functionals always involve the corresponding discrete solution of the state equation. For an initial level set function $\Phi^0 \in \mathcal{V}_h$ we iteratively compute a sequence of level set functions $(\Phi^k)_{k=1,\dots}$ given by

$$\mathcal{G}\left(\Phi^{k+1} - \Phi^k, \Xi\right) = -\tau \mathbb{E}_\omega\left(\mathcal{J}'\left(\Phi^k,\omega\right)(\Xi)\right) \tag{3.4}$$

for all $\Xi \in \mathcal{V}_h$. Hence, in every time step the vector $(\mathbb{E}_\omega(\mathcal{J}'(\Phi^k,\omega)(\Psi_i)))_{i\in I_h}$ of variations of the expectation of the objective functional $\mathcal{J}$ in all basis directions Ψ_i for $i \in I_h$ has to be evaluated. Furthermore, one has to solve the linear system of equations resulting from a standard finite element discretization of $\mathcal{G}$. As already discussed the time step τ is chosen according to a simple variant of the Armijo step size control. Indeed, given a constant $\beta \in (0,1)$ we accept a time step τ if the condition

$$\mathbb{E}_\omega\left(\mathcal{J}\left(\Phi^{k+1},\omega\right)\right) - \mathbb{E}_\omega\left(\mathcal{J}\left(\Phi^k,\omega\right)\right) \le -\beta\mathcal{G}\left(\Phi^{k+1} - \Phi^k, \Phi^{k+1} - \Phi^k\right)$$

is satisfied; otherwise the timestep is reduced.

Let us now detail the evaluation of $\mathcal{J}'(\Phi)(\Xi)$ in the spatially discrete setting. For any scenario of the stochastic loading ω_σ with $\sigma = 1,\dots,S$ we obtain a discrete effective displacement $\bar{U}(\mathcal{O}_h,\omega_\sigma) \in \mathcal{V}^{\mathrm{cfe}}_{h,\Gamma_D}$ and an effective dual solution $\bar{P}(\mathcal{O}_h,\omega_\sigma) \in \mathcal{V}^{\mathrm{cfe}}_{h,\Gamma_D}$

as the following linear combinations of U^{km} and P^{km} (cf. (2.4), (2.6)), respectively:

$$\bar{U}(\mathcal{O}_h,\omega_\sigma) = \sum_{k=1}^{K}\sum_{m=1}^{M} \alpha_k(\omega_\sigma)\beta_m(\omega_\sigma) U^{km}(\mathcal{O}_h)\,,$$
$$\bar{P}(\mathcal{O}_h,\omega_\sigma) = \sum_{k=1}^{K}\sum_{m=1}^{M} \alpha_k(\omega_\sigma)\beta_m(\omega_\sigma) P^{km}(\mathcal{O}_h)\,.$$

Given the discrete primal solution $\bar{U}(\mathcal{O}_h,\omega_\sigma)$ the variation of the objective functional (cf. (1.5))

$$\mathcal{J}(\Phi,\omega_\sigma) = \int_{\mathcal{O}_h} j\left(\bar{U}(\mathcal{O}_h,\omega_\sigma)\right)\,dx + \gamma\int_{\partial\mathcal{O}_h} \mathrm{d}\mathcal{H}^{d-1}$$

for a particular realization ω_σ of the stochastic loading and a shape domain $\mathcal{O}_h$ implicitly defined by the discrete level set function Φ (that is, $\mathcal{O}_h = \{\Phi < 0\}$) can be computed as follows (cf. (1.16) and (2.8)):

$$\begin{aligned}\mathcal{J}'(\Phi,\omega_\sigma)(\Xi) &= \mathbf{J}'(\mathcal{O}_h,\omega_\sigma)\left(-\Xi\,|\nabla\Phi|^{-1}N\right)\\ &= \int_{\partial\mathcal{O}_h}\left(-\Xi|\nabla\Phi|^{-1}\right)\Big(j\left(\bar{U}(\mathcal{O}_h,\omega_\sigma)\right) + \gamma\,H\\ &\qquad - \left(f_i(\omega_\sigma) + g_i(\omega_\sigma)\,H + \partial_N g_i(\omega_\sigma)\right)\bar{P}_i(\mathcal{O}_h,\omega_\sigma)\\ &\qquad + A_{ijkl}e_{ij}\left(\bar{U}(\mathcal{O}_h,\omega_\sigma)\right)e_{kl}\left(\bar{P}(\mathcal{O}_h,\omega_\sigma)\right)\Big)\,\mathrm{d}\mathcal{H}^{d-1}\,.\end{aligned} \tag{3.5}$$

Here, N denotes the outer normal on $\partial\mathcal{O}_h$ and H a discrete mean curvature function on $\partial\mathcal{O}_h$. As a suitable approximation we consider N and H to be piecewise affine on $\partial\mathcal{O}_h$. The discrete mean curvature vector $H\,N$ is defined on each vertex X on $\partial\mathcal{O}_h$ as the gradient vector of the area functional with respect to the position of the vertex (cf. [25] for the resulting formula and the relation to the continuous mean curvature). For the numerical integration we apply a Gauss quadrature of degree 4. Hence, the integration is exact as long as f and g are (piecewise) affine functions on $\mathbb{R}^d$. Finally, the discrete counterpart of the shape derivative of our actual stochastic cost functional, namely, the expectation of the discrete cost functional $Q_{\mathbb{E},h}(\mathcal{O}_h)$ in the case of S scenarios $(\omega_\sigma)_{\sigma=1,\dots,S}$ (cf. (3.3)), is given by

$$Q'_{\mathbb{E},h}(\mathcal{O}_h)(V) = \mathbb{E}_\omega\left(\mathcal{J}'(\Phi,\omega)(\Xi)\right) = \sum_{\sigma=1}^{S}\pi_\sigma\mathcal{J}'(\Phi,\omega_\sigma)(\Xi)\,, \tag{3.6}$$

where $V = -\Xi|\nabla\Phi|^{-1}N$ is the normal variation corresponding to the variation Ξ of the level set function Φ. In the algorithm this shape derivative can be used as a descent direction. In any step of the considered time-discrete gradient descent (3.4) one has to compute for the current discrete domain $\mathcal{O}_h$ once the $K\,M$ discrete primal base deformations $U^{km}(\mathcal{O}_h)$ and the corresponding discrete dual base states $P^{km}(\mathcal{O}_h)$. From these, we can efficiently compute the effective deformations $\bar{U}(\mathcal{O},\omega_\sigma)$ and the effective dual states $\bar{P}(\mathcal{O},\omega_\sigma)$ for a possibly very large set of scenarios $\{\omega_\sigma\,|\,\sigma = 1,\dots,S\}$, and using (3.5) and (3.6) we then evaluate the stochastic descent direction.

4. Computational results. As discussed above the major characteristic of two-stage stochastic shape optimization investigated here is that one first decides the domain $\mathcal{O}$, and then the stochastic loading is observed. Hence, we expect the resulting

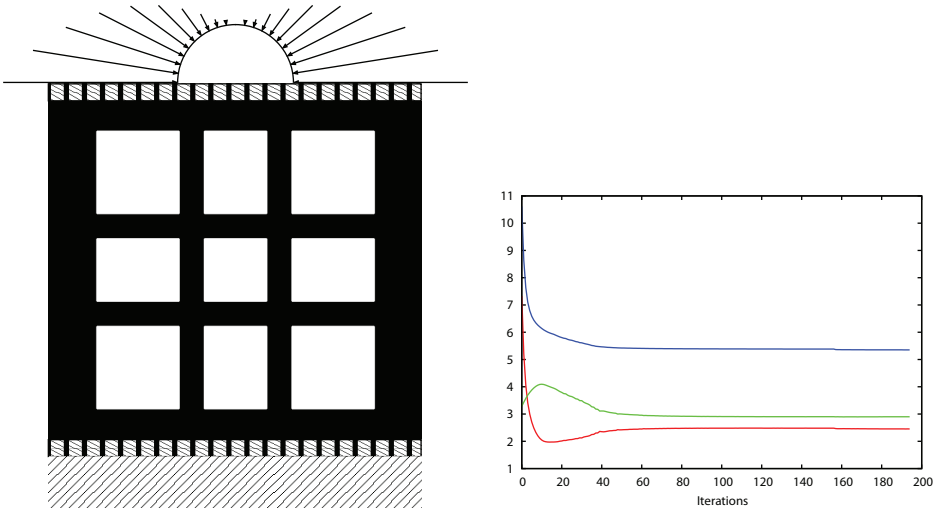

FIG. 4.1. *The initial domain considered in the computation of the optimal shapes in Figures* 4.2 *and* 4.3 *is depicted on the left. On the right the different contributions to the objective function are plotted over the number of iterations. The upper curve shows the robust decay of the objective functional, whereas the lower curve and the middle curve display the evolution and the interplay of the compliance functional and the enclosed volume term, respectively.*

optimal shapes to differ significantly from those obtained in the case of an optimization for the load straightforwardly computed as the expected value of the stochastic loads. In what follows we consider shape optimization applications in two and three dimensions which in particular reflect this consideration. Let us assume a vanishing volume load $f(\omega)$ and Neumann boundary conditions $g(\omega)$ with support Γ_N. As explained above, we assume neither Γ_D nor Γ'_N not to be modified in the actual shape optimization. Indeed, we choose $7h$ as the size of this neighborhood of Γ_D and Γ_N, where the level set function is kept fixed. As the objective function, we take into account a sum of the expectation of the compliance load $\int_{\Gamma_N} g(\omega) \cdot u(\mathcal{O}, \omega)\, \mathrm{d}\mathcal{H}^{d-1}$ and the weighted volume $\eta \int_{\partial\mathcal{O}} \mathrm{d}\mathcal{H}^{d-1}$ of the structure, where η is a positive constant.

4.1. 2D carrier plate. The first application in 2D is a carrier plate, where we optimize the shape of the carrier construction between a floor slap, whose lower boundary is assumed to be the Dirichlet boundary, and the upper plate, on which the loading is applied. Figure 4.1 depicts the initial shape and a sketch of a particular instance of the stochastic loading on the upper plate. Figures 4.2, 4.3, and 4.4 show results obtained by the stochastic optimization algorithm presented here. Each realization of the stochastic load is spatially uniform on the upper plate; realizations only differ by the direction of the force. Hence, two base loads g^1 and g^2 are required to span a load space containing all realizations of the stochastic load. Hence, $m = 2$, whereas S ranges from 2 in Figure 4.2 to 20 in Figure 4.3 to 21 in Figure 4.4. In Figure 4.3 a slightly nonsymmetric set of stochastic scenarios is taken into account, whereas the stochastic load configuration in Figure 4.4 is symmetric. The resulting optimal domains reflect this break of symmetry. Both figures show on the single stochastically optimal shape the von Mises stress distribution for different load scenarios. For the stochastic optimization result in Figure 4.2, we have evaluated the relative error in the stress when refining the underlying grid once. Explicitly, we

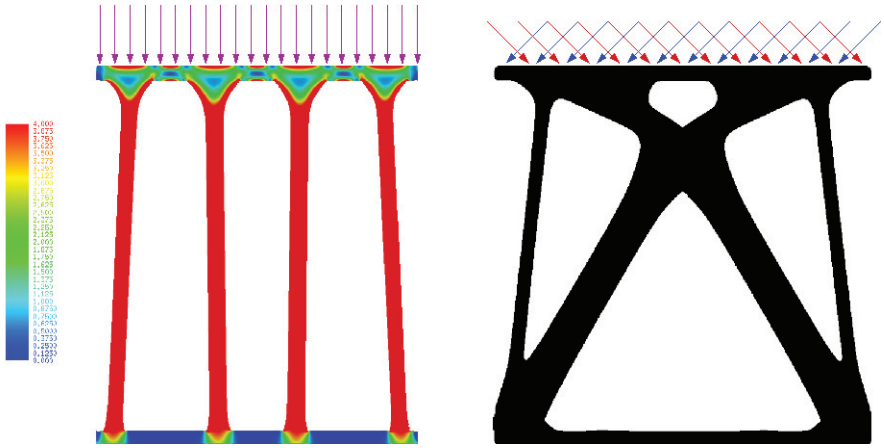

FIG. 4.2. *A direct comparision of two-scale stochastic optimization and deterministic optimization for an averaged load is shown. On the right, a stochastically optimal shape is rendered together with the two underlying load scenarios ω_1 and ω_2 on the upper plate, with surface loads $g(\omega_1)$ and $g(\omega_2)$ both with probability $\frac{1}{2}$. On the left the optimal shape colorcoded with the von Mises stress is drawn for a deterministic load $\frac{1}{2}g(\omega_1) + \frac{1}{2}g(\omega_2)$.*

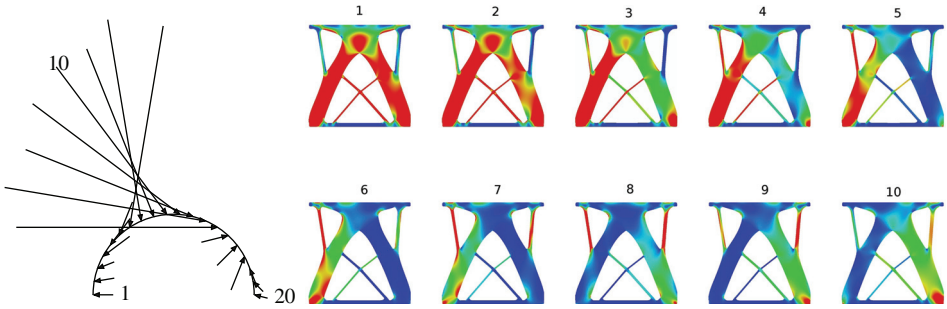

FIG. 4.3. *Stochastic shape optimization based on* 20 *scenarios is depicted. On the left the different loads $g(\omega_\sigma)$ with probabilities π_σ are sketched. Each arrow represents one scenario where the arrow length is determined by the corresponding force intensity weighted with the probability π_σ of the corresponding scenario. On the right the von Mises stress distribution is color coded on the optimal shape for* 10 *out of the* 20 *realizations of the stochastic loading. Due to the nonsymmetric loading configuration the resulting shape is nonsymmetric as well. In particular, the right carrier is significantly thicker than the left one, whereas the connecting diagonal stray pointing up right is thinner than the one point down left.*

obtain a relative error $\int_{\mathcal{O}}[A_{ijkl}e_{ij}(\bar{U}_h(\mathcal{O}) - \bar{U}_{\frac{h}{2}}(\mathcal{O}))]^2\,\mathrm{d}x / \int_{\mathcal{O}}[A_{ijkl}e_{ij}(\bar{U}_h(\mathcal{O}))]^2\,\mathrm{d}x$ of about 0.25 percent. Here, $\bar{U}_h(\mathcal{O})$ is the solution for the grid size $h = 2^{-8}$ and $\bar{U}_{\frac{h}{2}}(\mathcal{O})$ the corresponding solution on grid size $h = 2^{-9}$ for the same discrete domain $\mathcal{O}$.

4.2. 2D cantilever. The second application deals with shape optimization of a 2D cantilever. The initial domain and the optimal shape in the case of deterministic loading are shown in Figure 4.5. Here, the cantilever is fixed on the left side, and a downward pointing force is applied on the right. In Figure 4.6 the dependence of the computed optimal shape on the initial domain is depicted. In Figure 4.7 we focus on the coefficient in front of the volume penalty term and its impact on the optimal shape. A stochastic counterpart is presented in Figure 4.8 with 21 different scenarios

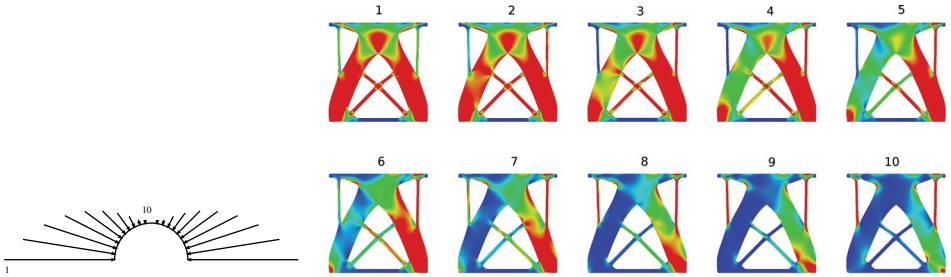

FIG. 4.4. *Results for a symmetric load configuration with* 21 *scenarios, to be contrasted with those reported with a nonsymmetric configuration in Figure* 4.3. *Again on the left the configuration is sketched, and on the right the von Mises stress distribution in plotted in the case of the first* 10 *scenarios.*

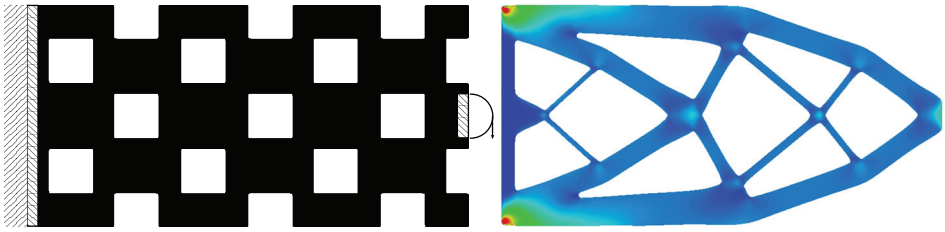

FIG. 4.5. *The initial domain for the computation in the case of a cantilever geometry is rendered on the left. The left boundary is a Dirichlet boundary where the cantilever is attached to a vertical wall. The center part of the right boundary is the support* Γ_N *of the boundary force, which is a deterministic downward-pointing force in this sketch. The resulting optimal shape computed by the proposed level set algorithm is plotted on the right and color coded with the von Mises stress. The corresponding stochastic case is reported in Figure* 4.8.

pulling in different directions. Again the realizations of the stochastic load on the smaller plate on the right are spatially uniform. Thus, the space of realization is 2D, and we can choose $m = 2$.

The subset of the domain Ω, which does not undergo an optimization but is still treated as elastic material, is indicated by the hatched box texture in Figures 4.1 and 4.5. The diameter of the initial domain is 0.9, and the Lamé coefficients in all instances are $\lambda = 40$ and $\mu = 40$. For the parameters in the objective functional we choose $\eta = 8$ in the application in Figures 4.2, 4.3, and 4.4, whereas $\eta = 0.3$ in the case of Figure 4.5. Here, instead of a regularizing surface area term we consider an iterative regularization strategy based on a weaker morphological operator applied during the gradient descent. In all 2D computations the underlying grid is a uniform grid with 257×257 nodes; the discrete primal and dual state equations are solved using a conjugate gradient approach. Furthermore, we take into account $\beta = 0.2$ for the parameter in the Armijo rule and reduce halve the step size as required. Finally, we set $\rho = 6h$ for the computations in Figures 4.3 and 4.4 and $\rho = 4h$ in Figures 4.2 and 4.5, where ρ is the filter parameter in the regularized gradient descent. As mentioned above, we regularize the discrete shape boundary after a couple of iterations applying the morphological operator $D(s)E(2s)D(s)$, where $D(\cdot)$ and $E(\cdot)$ are discrete dilation and erosion operators, respectively. These operators are implemented via a fast marching method [51]. We set $s = 0.5h$ for the width parameter of these operators. Starting from the initial configuration, the decay of the

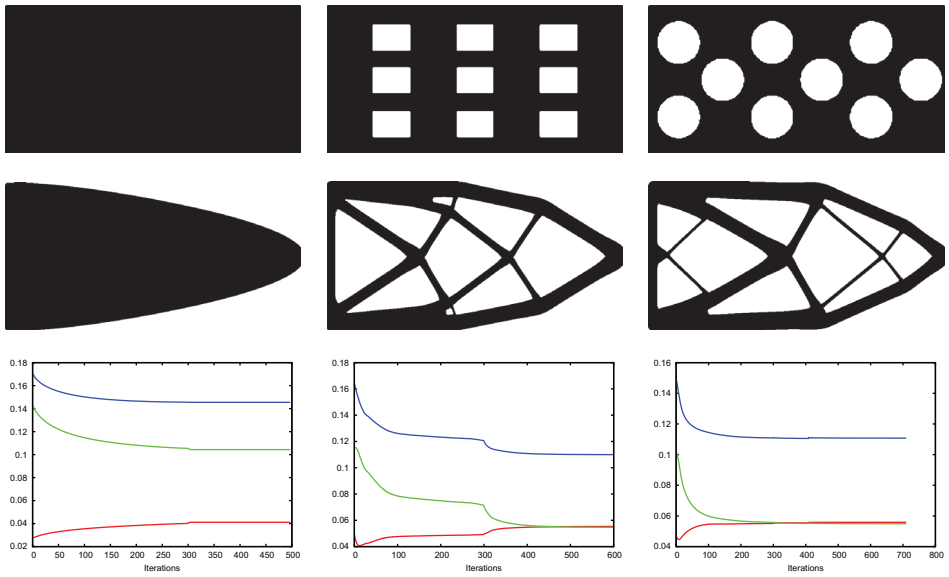

FIG. 4.6. *Results for different initial shapes for the deterministic cantilever computation (see Figure* 4.5*). The top row shows the intial guess. The corresponding optimal shapes and energy plots are depicted in the second and third rows, respectively. In all cases,* η *is fixed to* 0.3*. The middle and right simulation results are obviously local minima with values of the cost functional that are fairly close, as indicated by the error plot.*

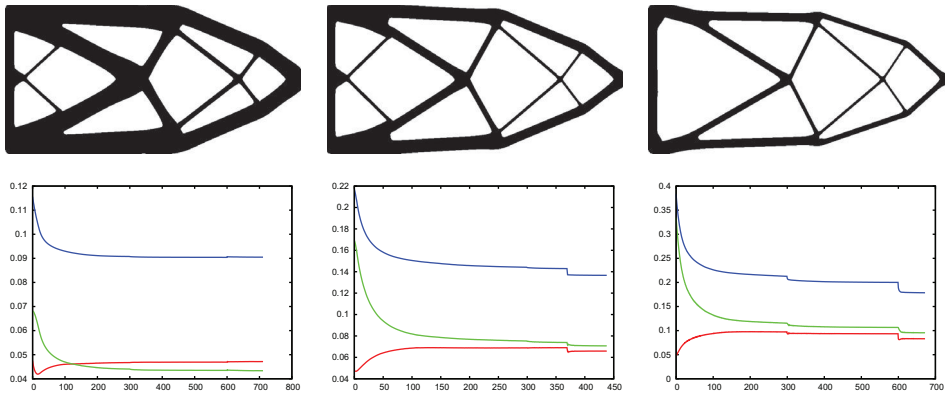

FIG. 4.7. *Results for variations of the volume penalization parameter* η*. In all shown test runs, the initial shape shown in Figure* 4.6 *on the right was used. From left to right, the optimal solutions correspond to the choices* $\eta = 0.2$*,* $\eta = 0.5$*, and* $\eta = 1$*.*

different energy contributions is plotted already on the right-hand side in Figure 4.1. The underlying stochastic scenario is shown in Figure 4.4.

4.3. VSS and EVPI. As stochastic programs are known to be computationally hard to solve, the question arises whether the additional effort pays off compared to solving simpler deterministic problems. There are two common concepts to measure the quality of the stochastic solution: the *value of the stochastic solution* (VSS) and the *expected value of perfect information* (EVPI) (see [16] for details). We computed these two values for the instance shown in Figure 4.2. The optimal objective

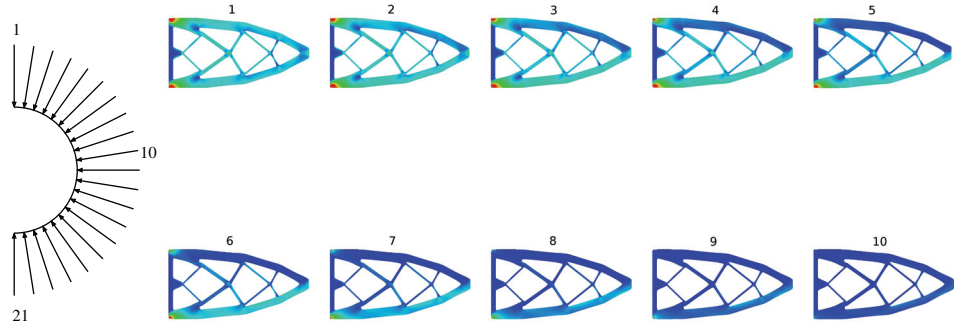

FIG. 4.8. *Stochastic shape optimization in the cantilever case with* 21 *scenarios. The different loads* $g(\omega_\sigma)$ *with probabilities* π_σ *are sketched on the left. The von Mises stress distribution is color coded on the stochastically optimal shape for* 10 *out of the* 21 *scenarios.*

TABLE 4.1

Let $\mathcal{O}_1$ *denote the optimal shape from Figure* 4.3 *and* $\mathcal{O}_2$ *the one from Figure* 4.4. *The table shows the cost functionals arising from the different stochastic loadings shown in Figures* 4.3 *and* 4.4, *respectively, evaluated at* $\mathcal{O}_1$ *and* $\mathcal{O}_2$.

	$\mathcal{O}_1$	$\mathcal{O}_2$
objective from Figure 4.3	4.32398	4.4342
objective from Figure 4.4	5.54182	5.35328

value of the *recourse problem* (2.1) is denoted by RP, and we consider the following deterministic program, which is called the *expected value problem*:

$$\mathrm{EV} := \min \{\mathbf{J}(\mathcal{O}, \bar{\omega}) \ : \ \mathcal{O} \in \mathcal{U}_{ad}\},$$

where $\bar{\omega}$ indicates that all occuring random variables are substituted by their expectations. Let $\mathcal{O}_{\mathrm{EV}} \in \arg\min\{\mathbf{J}(\mathcal{O}, \bar{\omega}) \ : \ \mathcal{O} \in \mathcal{U}_{ad}\}$. Note that in our example, $\mathcal{O}_{\mathrm{EV}}$ is shown in Figure 4.2 on the left. Next, we can define the *expected result of using the EV solution* as $\mathrm{EEV} := \sum_{\sigma=1}^{S} \pi_\sigma \mathbf{J}(\mathcal{O}_{\mathrm{EV}}, \omega_\sigma)$, which finally leads to the VSS given by $\mathrm{VSS} = \mathrm{EEV} - \mathrm{RP}$. For our particular instance, we have $\mathrm{VSS} = 53.68$, or 94 % of the EEV.

To compute the EVPI, we have to compute the so-called *wait-and-see* solution (WS). If $\mathcal{O}_\sigma$ for $\sigma = 1, \ldots, S$ denote the solutions to the many problems

$$\min \{\mathbf{J}(\mathcal{O}, \omega_\sigma) \ : \ \mathcal{O} \in \mathcal{U}_{ad}\}, \quad \sigma = 1, \ldots, S$$

(and there are as many of those as scenarios), then WS is defined to be $\mathrm{WS} := \sum_{\sigma=1}^{S} \pi_\sigma \mathbf{J}(\mathcal{O}_\sigma, \omega_\sigma)$, and $\mathrm{EVPI} := \mathrm{RP} - \mathrm{WS}$. For our instance, we obtained $\mathrm{EVPI} = 0.24$. Finally, we directly compared in Table 4.1 the values of the cost functional on the two different optimal shapes computed by our algorithm shown in Figures 4.3 and 4.4 for both stochastic load scenarios. Even though the shapes visually do not differ too much, a clear preference is demonstrated for the shape optimized with respect to a particular stochastic load configuration.

4.4. 3D cantilever. Finally, we consider a 3D cantilever as a generalization of the problem considered in the first example in 2D. On one side, a disk-shaped plate is fixed on a wall prescribing zero Dirichlet conditions. On the other side, a small rectangular plate opposite to the center of the disk is considered as Neumann boundary loaded with different deterministic and stochastic boundary forces. Figure 4.9 shows

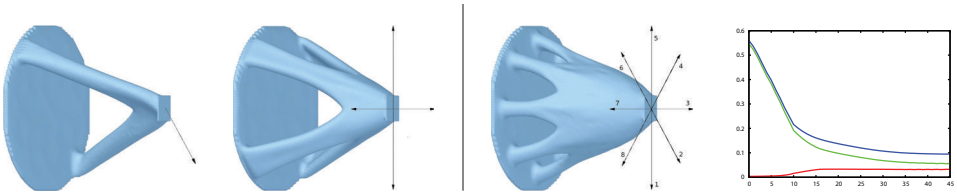

FIG. 4.9. *From left to right the optimal shapes in the deterministic approach and the stochastic optimization approach for one, four, and eight scenarios are shown. The arrows represent the different involved loads $g(\omega_\sigma)$ for varying scenario indices σ. On the right the energy decay is shown for the eight scenario configuration. Again the upper curve represents the total value of the objective functional, the middle one the enclosed volume term, and the lower one the compliance functional.*

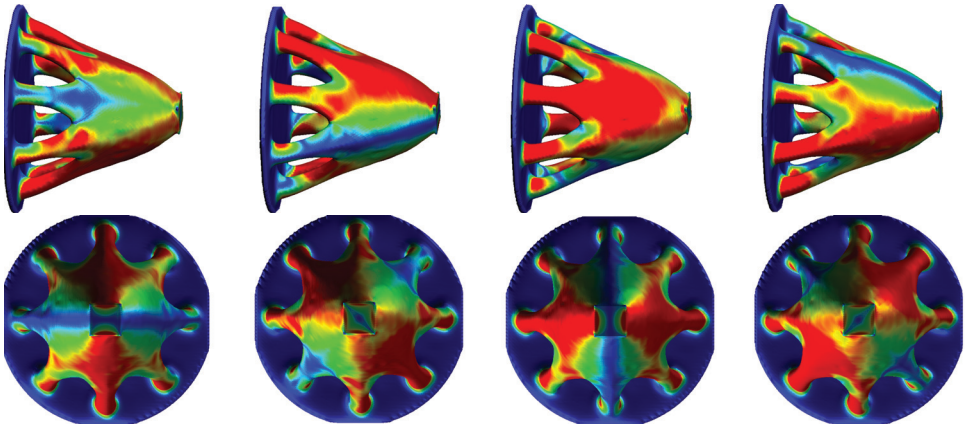

FIG. 4.10. *The optimal design in the case of stochastic shape optimization for the cantilever problem with eight scenerios is depicted. From left to right four scenerios are color coded with the von Mises stress in a consecutive clockwise ordering with respect to the sketch of the loads in Figure* 4.9. *The upper and the lower row show the shape geometry under different perspectives.*

the optimal designs in the case of a single deterministic load and for four and eight stochastic loading scenarios. Furthermore, the energy decay during the numerical relaxation of the shape functional is depicted. As the initial shape we have considered a 3D version of the initial 2D shape shown in Figure 4.1. Figure 4.10 displays a color coding of the von Mises stress distribution on the optimal shape in the stochastic setting with eight equally probable and equally distributed load scenarios.

Here, we choose $\eta = 1$ for the volume penalization parameter, and the elastic behavior is described by the Lame coefficients $\lambda = 40$ and $\mu = 40$ for a structure diameter of the order 1. The parameters involved in the Armijo step control are the same as those in the 2D applications. The underlying grid is a regular grid with 128^3 nodes. The shape optimization is first performed on a 64^3 grid. Then the level set function is prolongated to the next finer grid level. Before the gradient descent of the shape functional is released a morphological smoothing operator $D(s)E(2s)D(s)$ is applied. Here, as in the 2D case $D(s)$ and $E(s)$ represent discrete dilation and erosion operators, implemented based in a fast marching algorithm in 3D. As the width parameter we select $s = 0.45h$. The filter parameter in the regularized gradient descent is $\rho = 2.5h$. A multigrid method for the numerical solution of the discrete primal and dual problem is applied.

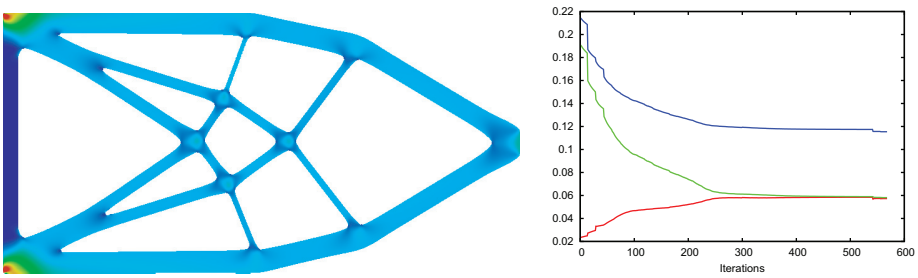

FIG. 4.11. *The optimal shape for a cantilever problem with deterministic loading is computed based on a combined level-set and topogical derivative approach. A relaxation step with respect to the topological derivative is considered in every* 15*th step of a general shape gradient descent method (left). Furthermore, the corresponding energies, i.e., the total value of the objective function, the enclosed volume, and the compliance functional are plotted on the right.*

Outlook. Our approach of using two-stage stochastic optimization with the Lamé equation as a variational problem does not link only stochastic shape optimization to two-stage stochastic programming. Indeed, it offers the flexibility to go beyond expected value optimization and addresses risk aversion. To this end, the expectation in (2.1) is replaced by suitable risk measures such as *expected excess* and *excess probability*. The resulting optimal shapes will significantly depend on the chosen risk measure. Furthermore, we included results on a combination of level-set and topological shape optimization which can be extended to the case of uncertain loadings (cf. Figure 4.11). For a detailed discussion of these issues we refer to a forthcoming publication [20].

ERROR BOUNDS FOR CONVEX POLYNOMIALS*

W. H. YANG†

Abstract. The purpose of this paper is to investigate error bounds for convex polynomials. We prove that for a convex polynomial f in n variables which is not everywhere positive and which is not constant on any affine subspace, either f is a sum of a convex polynomial in fewer variables and a linear form with negative coefficients or the negativity set of f is compact. As an application, we deduce various types of error bounds for unconstrained and polyhedral-constrained convex polynomials.

Key words. error bound, convex polynomial, kernel, recession cone

1. Introduction.

Multivariate polynomial minimization has received much attention over the years thanks to its application in engineering and economics. It has been studied extensively, and there are many works devoted to this subject. The reader is referred to [6, 7, 11, 15, 17] and also the references therein. A popular method for solving the polynomial minimization problem is the sum-of-squares (SOS) method, which was first introduced by Shor [17] and further developed by Nesterov [11], Lasserre [7], and Parrilo [14]. The SOS method is based on semidefinite programming, for which efficient algorithms are now available. Another important approach for polynomial minimization is based on tensor analysis, which involves various computational topics of higher-order tensors, such as tensor decomposition, computation of tensor rank, computation of tensor eigenvalues, and so on. For the interested reader, see [15] for a survey on the state-of-the-art knowledge on this topic.

In this paper, we will study the properties of convex multivariate polynomials (convex polynomials for short), since it is the simplest type of nonlinear and nonquadratic polynomial. As far as we know, Belousov was the first one who used convex analysis to study polynomial minimization. In 1977, Belousov derived some basic properties of convex polynomials in his book [5]. Following a way similar to that proposed by Belousov, Bank and Mandel [1] extended the results in [5] to quasi-convex polynomials. In [4], Belousov and Klatte generalized the Frank–Wolfe-type theorem to convex polynomial systems. The impetus of this manuscript came from Lemmas 1 and 2 in [4]. We will present some further results on convex polynomials using convex analysis. As an application, we derive various error bounds for unconstrained and polyhedral-constrained convex polynomials.

Recently, error bounds have found important applications in various areas in mathematical programming such as sensitivity analysis, convergence analysis of algorithms, and asymptotic analysis. There is plenty of literature on this subject. The reader is referred to the papers [13, 18, 20] and references therein for the theory and applications of error bounds. When considering the polynomial inequality systems, Hölderian error bounds have been demonstrated for these systems in [8, 9, 10, 12, 19].

†School of Mathematical Sciences, Fudan University, Shanghai 200433, People's Republic of China (whyang@fudan.edu.cn).

It is proved in this paper that for an mth-order convex polynomial f, if the negativity set of f is nonempty, then f has a linear error bound. Otherwise, f has a local Hölderian error bound of order $1/m$.

The rest of the paper is organized as follows. In section 2, we introduce some notations and definitions on convex analysis. Some preliminary results on convex polynomials are presented. In section 3, we show that for a convex polynomial f which is not constant on any affine subspace, if the lower level set of f is unbounded, then f can be represented as a sum of a convex polynomial in fewer variables and a linear form with negative coefficients. We also investigate some properties of the kernel of a homogeneous convex polynomial. Finally, in section 4, we identify exactly and establish various types of error bounds for unconstrained and polyhedral-constrained convex polynomials.

2. Definitions and preliminary results. In this section, we give the notations, definitions, and preliminary results which will be used throughout the paper. For a positive integer n, we use $[n]$ to denote the set $\{1,\dots,n\}$. For $x \in \mathbb{R}^n$, x_i ($i \in [n]$) is the ith component of x as usual. The transpose of x is denoted by x^T. For a subspace $L \subset \mathbb{R}^n$, $L^\perp$ denotes the orthogonal complement of L in $\mathbb{R}^n$. The dimension of L is denoted by $\dim(L)$.

For a function $\varphi : \mathbb{R}^n \to \mathbb{R}$, the lower level set of φ is defined by $S_\varphi := \{x \in \mathbb{R}^n : \varphi(x) \le 0\}$. We say that φ has an error bound of order γ if there exists $\tau > 0$ such that

$$d(x, S_\varphi) \le \tau [\varphi(x)]_+^\gamma \quad \forall x \in \mathbb{R}^n,$$

where $[\varphi(x)]_+ = \max\{\varphi(x), 0\}$ and $d(x, S_\varphi)$ denotes the distance from x to S_φ. If φ has an error bound of order 1, we also say φ has a linear error bound. The optimal solution set of φ is denoted by $\operatorname{argmin}_{x\in\mathbb{R}^n}\varphi(x)$.

Let $C \subset \mathbb{R}^n$ be a closed convex set. We use $\mathrm{bd}(C)$ to denote the boundary of C. For $x \in C$, the normal cone of C at x is defined by

$$N_C(x) := \left\{ z \in \mathbb{R}^n : z^T(y - x) \le 0 \ \ \forall y \in C \right\}.$$

Let $N_C^1(x) := \{h \in N_C(x) : \|h\| = 1\}$ denote the set of all unit vectors in $N_C(x)$. The recession cone C^∞ [16] of C is defined by

$$C^\infty := \{d \in \mathbb{R}^n : x + td \in C, \ \ \forall t \ge 0, \ \forall x \in C\}.$$

It is easy to see that C^∞ is a convex cone. For a convex function ψ, by [16, Theorem 8.7], all the nonempty level sets of the form $\{x : \psi(x) \le c\}$, $c \in \mathbb{R}$, have the same recession cone, namely, the recession cone of ψ. Without loss of generality, we use the notation S_ψ^∞ to denote the recession cone of ψ. Let $E = S_\psi^\infty \cap (-S_\psi^\infty)$. Then E is a subspace and is called the constancy space [16, p. 69] of ψ.

LEMMA 2.1 (see [16, p. 69]). *The constancy space E is the largest subspace contained in S_ψ^∞ which satisfies*

$$E = \{z \in \mathbb{R}^n \ : \ \psi(x + \lambda z) = \psi(x), \ \forall x \in \mathbb{R}^n, \ \forall \lambda \in \mathbb{R}\}.$$

For a convex function ψ, we denote the set of subgradients of ψ at $x \in \mathbb{R}^n$ by $\partial\psi(x)$. It is well known that the directional derivative $\psi'(x;h) = \lim_{t\to 0+} \frac{\psi(x+th)-\psi(x)}{t}$ always exists for $x, \ h \in \mathbb{R}^n$, and one has that

$$\psi'(x;h) = \max\left\{\eta^T h : \eta \in \partial\psi(x)\right\}. \tag{2.1}$$

Let $\mathbb{Z}^n_+ = \{\beta = (\beta_1, \ldots, \beta_n) : \beta_i \in \mathbb{Z}, \beta_i \geq 0,\ \forall i \in [n]\}$. For $\beta \in \mathbb{Z}^n_+$, we use x^β to denote the product $x_1^{\beta_1}, \ldots, x_n^{\beta_n}$ for every $x \in \mathbb{R}^n$. Then, for an mth-order polynomial f on $\mathbb{R}^n$, we can write it as $f(x) = \sum_{|\beta|=0}^m a_\beta x^\beta\ \forall x \in \mathbb{R}^n$, where $\beta \in \mathbb{Z}^n_+$, $a_\beta \in \mathbb{R}$, and $|\beta| = \sum_{i=1}^n \beta_i$. In this paper, we always use f_l, $0 \leq l \leq m$, to denote the lth-order homogeneous polynomial corresponding to f, that is, $f_l(x) = \sum_{|\beta|=l} a_\beta x^\beta$, and so

$$f = \sum_{l=0}^m f_l. \tag{2.2}$$

Note that f_0 is the constant term of f. If $f(x) \geq 0$ ($f(x) > 0$) $\forall x \in \mathbb{R}^n$ ($x \neq 0$), we say that f is a positive semidefinite (definite) polynomial. It is easy to see that if f is a convex polynomial and $m \geq 2$, then m is an even integer.

The Taylor series of an mth-order polynomial f can be written as

$$f(x+y) = \sum_{|\beta|=0}^m \frac{D^\beta f(x)}{\beta!} y^\beta \quad \forall x,\ \forall y \in \mathbb{R}^n, \tag{2.3}$$

where $\beta \in \mathbb{Z}^n_+$, $D^\beta f(x) := \frac{\partial^{\beta_1}}{\partial x_1^{\beta_1}}, \ldots, \frac{\partial^{\beta_n}}{\partial x_n^{\beta_n}} f(x)$ and $\beta! = \beta_1!, \ldots, \beta_n!$. Using this notation, we have $(\nabla f(x))^T y = \sum_{|\beta|=1} (D^\beta f(x))^T y^\beta,\ \forall x \in \mathbb{R}^n,\ \forall y \in \mathbb{R}^n$.

Let h be a kth-order homogeneous polynomial ($k \geq 1$). We define the kernel of h by

$$\mathrm{Ker}(h) := \left\{x \in \mathbb{R}^n\ :\ D^\alpha h(x) = 0\ \forall \alpha \in \mathbb{Z}^n_+ \text{ satisfying } |\alpha| = k-1\right\}.$$

It is easy to see that if $x \in \mathrm{Ker}(h)$, then $D^\beta h(x) = 0$ for every $\beta \in \mathbb{Z}^n_+$ satisfying $0 \leq |\beta| \leq k-1$. In particular, $x \in \mathrm{Ker}(h)$ implies $h(x) = 0$. Moreover, $\mathrm{Ker}(h)$ is a linear space. If h is a homogeneous quadratic function, that is, $h(x) = x^T A x$ for some matrix A, then $\mathrm{Ker}(h) = \mathrm{Ker}(A)$.

The following lemma is a well-known result, and we omit the proof.

LEMMA 2.2. *Let $f(x) = \sum_{|\beta|=0}^m a_\beta x^\beta$ be a polynomial defined on $\mathbb{R}^n$. If $f(x) = 0\ \forall x \in \mathbb{R}^n$, then $a_\beta = 0$ for every $\beta \in \mathbb{Z}^n_+$ satisfying $0 \leq |\beta| \leq m$.*

The next two lemmas, which play an important role in this paper are due to Belousov (see [4, Lemmas 1 and 2]).

LEMMA 2.3. *Let f be a convex polynomial. Let $x, y, d \in \mathbb{R}^n$. If $\mu(t) = f(x+td)$ defined on $\mathbb{R}$ is a convex polynomial of order p, then $\nu(t) = f(y+td)$, $t \in \mathbb{R}$, is also a convex polynomial of order p. Further, if $p \geq 1$, then the coefficient associated with the term t^p in $\mu(t)$ and $\nu(t)$ are identical.*

LEMMA 2.4. *Let f be a convex polynomial satisfying $S_f \neq \emptyset$. For $d \neq 0$, $d \in S_f^\infty$ if and only if $f(td) = f(0) + rt,\ \forall t \in \mathbb{R}$, for some $r \leq 0$.*

COROLLARY 2.1. *Let $h : \mathbb{R}^n \to \mathbb{R}$ be a kth-order homogeneous convex polynomial, where $k \geq 2$. Then h is positive semidefinite.*

Proof. Suppose that $h(y) < 0$ for some y. Since $h(ty) = t^k h(y) < 0$ for each $t > 0$, we have $ty \in S_h\ \forall t \geq 0$. From [16, Theorem 8.3], it follows that $y \in S_h^\infty$. By Lemma 2.4, we have that $h(ty) = \beta t$ for some $\beta \leq 0$, which contradicts $h(ty) = t^k h(y)$. ∎

Note that a positive semidefinite homogeneous polynomial is not necessarily a convex polynomial. Let $g : \mathbb{R}^2 \to \mathbb{R}$ be defined by $g(x_1, x_2) = (x_1^2 - x_2^2)^2$. It is easy to see that g is positive semidefinite but not convex.

LEMMA 2.5. *Let h be a kth-order homogeneous polynomial ($k \geq 1$), and let $K \subset \mathbb{R}^n$ be a subspace. Then $h(x+y) = h(x)$, $\forall x \in \mathbb{R}^n$, $\forall y \in K$, if and only if $K \subset \mathrm{Ker}(h)$.*

Proof. Note that $h(x+y) = \sum_{|\beta|=0}^{k} \frac{D^\beta h(y)}{\beta!} x^\beta$ and $h(x) = \sum_{|\beta|=k} \frac{D^\beta h(0)}{\beta!} x^\beta$ $\forall x, y \in \mathbb{R}^n$. By Lemma 2.2, $h(x+y) = h(x)$, $\forall x \in \mathbb{R}^n$, $\forall y \in K \iff D^\beta h(y) = 0$, $\forall y \in K$, for each β satisfying $|\beta| \leq k-1$. Thus, the claim holds. ∎

LEMMA 2.6. *Let h be a kth-order homogeneous convex polynomial. Then* $\mathrm{Ker}(h) = \{x : h(x) = 0\}$, *and h is positive definite on* $(\mathrm{Ker}(h))^\perp$.

Proof. Let $H = \{x : h(x) = 0\}$. We need only to prove $H \subseteq \mathrm{Ker}(h)$. For $y \in H$, we have $g(ty) = 0 = g(0)$ $\forall t \in \mathbb{R}$. From Lemma 2.3, it follows that $g(x+ty) = g(x)$ $\forall x \in \mathbb{R}^n$ and $t \in \mathbb{R}$. By Lemma 2.5, one has that $y \in \mathrm{Ker}(h)$, which implies $H \subseteq \mathrm{Ker}(h)$. By Corollary 2.1, h is nonnegative on $\mathbb{R}^n$. Suppose $h(x) = 0$ for some $x \in (\mathrm{Ker}(h))^\perp$. Then $H \subseteq \mathrm{Ker}(h)$ implies $x \in \mathrm{Ker}(h)$, and therefore $x = 0$. ∎

The next lemma shows that if a polynomial f is constant along a subspace, then it can be transformed into a polynomial with less variables by changing the basis.

LEMMA 2.7. *Let $f(x)$ be an mth-order polynomial on $\mathbb{R}^n$, and let $L \subset \mathbb{R}^n$ be a subspace of dimension p. If $f(x+y) = f(x)$ $\forall x \in \mathbb{R}^n$ and $y \in L^\perp$, then there exists an orthogonal matrix U such that*

$$f(Ux) = g(x_1, \ldots, x_p) \quad \forall x \in \mathbb{R}^n, \tag{2.4}$$

for some polynomial g in p variables.

Proof. Let $f = \sum_{l=0}^{m} f_l$. By Lemma 2.5, we have $L^\perp \subset \cap_{l=1}^{m} \mathrm{Ker}(f_l)$. Let U be the matrix such that the first p columns of U are an orthonormal basis of L and the rest of the columns are an orthonormal basis of $L^\perp$. By (2.3) and $L^\perp \subset \cap_{l=1}^{m} \mathrm{Ker}(f_l)$, it is easy to obtain (2.4). ∎

The following result can be proved by Lemmas 2.1 and 2.7 in a straightforward way.

COROLLARY 2.2. *Let f be a convex polynomial on $\mathbb{R}^n$, and let $E = S_f^\infty \cap (-S_f^\infty)$. Assume that* $\dim(E) = n - p$. *Then there exists an orthogonal matrix U such that*

$$f(Ux) = g(x_1, \ldots, x_p) \quad \forall x \in \mathbb{R}^n,$$

where g is a convex polynomial satisfying $S_g^\infty \cap (-S_g^\infty) = \{0\}$.

3. Properties of convex polynomials. In this section, we will prove that if S_f^∞ is not a linear space, then we can simplify the form of f to the sum of a convex polynomial in fewer variables and a linear form. In view of Corollary 2.2, we always assume that $S_f^\infty \cap (-S_f^\infty) = \{0\}$ for each convex polynomial f in the remainder of the paper.

THEOREM 3.1. *Let $f = \sum_{l=0}^{m} f_l$ be a convex polynomial on $\mathbb{R}^n$. Then*

$$\cap_{l=2}^{m} \mathrm{Ker}(f_l) = S_f^\infty - S_f^\infty. \tag{3.1}$$

Moreover, $\dim(\cap_{l=2}^{m} \mathrm{Ker}(f_l)) \leq 1$.

Proof. Let $z \in \cap_{l=2}^m \operatorname{Ker}(f_l)$. Then $tz \in \cap_{l=2}^m \operatorname{Ker}(f_l)\ \forall t \in \mathbb{R}$, which together with (2.3) implies that

$$\begin{aligned} f(x+tz) &= \sum_{l=0}^{m} \sum_{|\beta|=0}^{l} \frac{D^\beta f_l(tz)}{\beta!} x^\beta \\ &= \sum_{l=2}^{m} \sum_{|\beta|=l} \frac{D^\beta f_l(tz)}{\beta!} x^\beta + \sum_{|\beta|=1} D^\beta f_1(tz) x^\beta + f_1(tz) + f_0 \\ &= \sum_{l=2}^{m} \sum_{|\beta|=l} \frac{D^\beta f_l(0)}{\beta!} x^\beta + \sum_{|\beta|=1} D^\beta f_1(0) x^\beta + t f_1(z) + f_0 \\ &= f(x) + t f_1(z) \quad \forall x \in \mathbb{R}^n, \forall t \in \mathbb{R}. \end{aligned} \tag{3.2}$$

If $f_1(z) \le 0$, then $f(x+tz) \le f(x)\ \forall t \ge 0$, and so $z \in S_f^\infty$. Since $0 \in S_f^\infty$, we have $z = z - 0 \in S_f^\infty - S_f^\infty$. If $f_1(z) \ge 0$, then $-z \in S_f^\infty$, and so $z = 0 - (-z) \in S_f^\infty - S_f^\infty$. Thus, $\cap_{l=2}^m \operatorname{Ker}(f_l) \subseteq S_f^\infty - S_f^\infty$.

For (3.1), it suffices to prove $S_f^\infty \subset \cap_{l=2}^m \operatorname{Ker}(f_l)$. Fix $d \in S_f^\infty$. By Lemmas 2.3 and 2.4, there exists $\delta \le 0$ such that $f(x+td) = f(x) + \delta t$ for every $t \in \mathbb{R}$ and $x \in \mathbb{R}^n$. Then

$$\begin{aligned} f(x) + \delta t = f(x+td) &= \sum_{l=0}^{m} \sum_{|\beta|=0}^{l} \frac{D^\beta f_l(td)}{\beta!} x^\beta = \sum_{l=0}^{m} \sum_{|\beta|=0}^{l} \frac{D^\beta f_l(d)}{\beta!} x^\beta t^{l-|\beta|} \\ &= \sum_{k=0}^{m} \left(\sum_{|\beta|=0}^{m-k} \frac{D^\beta f_{|\beta|+k}(d)}{\beta!} x^\beta \right) t^k \quad \forall t \in \mathbb{R}, \forall x \in \mathbb{R}^n. \end{aligned}$$

Hence, $\sum_{|\beta|=0}^{m-1} \frac{D^\beta f_{|\beta|+1}(d)}{\beta!} x^\beta = \delta$ for every $x \in \mathbb{R}^n$. By Lemma 2.2, we have $\frac{D^\beta f_{|\beta|+1}(d)}{\beta!} = 0$ for each $\beta \in \mathbb{Z}_+^n$ satisfying $1 \le |\beta| \le m-1$, that is, $d \in \cap_{l=2}^m \operatorname{Ker}(f_l)$.

Let $X_\infty := \cap_{l=2}^m \operatorname{Ker}(f_l)$. If $\dim(X_\infty) > 1$, there exist $y,\ z \in X_\infty$ such that $y \ne \lambda z\ \forall \lambda \in \mathbb{R}$. We can find real numbers μ and ν such that $f_1(\mu y + \nu z) = 0$ and $\mu y + \nu z \ne 0$. Since $y,\ z \in X_\infty = \cap_{l=2}^m \operatorname{Ker}(f_l)$, similar to (3.2), we have

$$f(x + \lambda(\mu y + \nu z)) = f(x) + \lambda f_1(\mu y + \nu z) = f(x) \qquad \forall x \in \mathbb{R}^n,\ \forall \lambda \in \mathbb{R}.$$

By Lemma 2.1, $\mu y + \nu z \in S_f^\infty \cap (-S_f^\infty)$, which contradicts to $S_f^\infty \cap (-S_f^\infty) = \{0\}$. ∎

THEOREM 3.2. *Let f be a convex polynomial as in Theorem* 3.1.

(i) *If $S_f^\infty \ne \{0\}$, then there exists an orthogonal matrix U such that*

$$f(Ux) = g(x_1, \dots, x_{n-1}) + r x_n \quad \forall x \in \mathbb{R}^n,$$

where g is a convex polynomial satisfying $S_g^\infty = \{0\}$ and $r < 0$.

(ii) *If $S_f^\infty = \{0\}$, then f is strictly convex, and so* $\operatorname{argmin}_{x \in \mathbb{R}^n} f(x)$ *is a singleton set.*

Proof. (i). Since $S_f^\infty \ne \{0\}$, by Theorem 3.1, there exists $w \in \mathbb{R}^n$, with $\|w\| = 1$ such that

$$\cap_{l=2}^m \operatorname{Ker}(f_l) = S_f^\infty - S_f^\infty = \{tw \ :\ t \in \mathbb{R}\}.$$

Since S_f^∞ is a cone, we can assume that $S_f^\infty = \{tw \,:\, t \geq 0\}$ without loss of generality. By Lemma 2.4, there exists $r \leq 0$ such that $f(x+tw) = f(x) + rt$. If $r = 0$, it is easy to prove $w \in S_f^\infty \cap (-S_f^\infty)$, which is a contradiction. Thus, $r < 0$. Note that

$$f(0) + rt = f(tw) = \sum_{l=0}^{m} \sum_{|\beta|=0}^{l} \frac{D^\beta f_l(0)}{\beta!} w^\beta t^{|\beta|} \quad \forall t \in \mathbb{R}.$$

By Lemma 2.2, one has that $r = \sum_{|\beta|=1} \frac{D^\beta f_1(0)}{\beta!} w^\beta = (\nabla f_1)^T w$. Let $F(x) = f(x) - (\nabla f_1)^T x \; \forall x \in \mathbb{R}^n$. Then F is a convex polynomial. We also have

$$\begin{aligned} F(x+tw) &= f(x+tw) - (\nabla f_1)^T (x+tw) \\ &= f(x) + rt - (\nabla f_1)^T x - t(\nabla f_1)^T w \\ &= F(x) \quad \forall x \in \mathbb{R}^n, \forall t \in \mathbb{R}, \end{aligned}$$

that is, $w \in S_F^\infty \cap (-S_F^\infty)$. Note that for any vector v satisfying $\pm v \notin S_f^\infty$, F is not linear on the line $\{tv : t \in \mathbb{R}\}$. Hence, $S_F^\infty \cap (-S_F^\infty) = \{tw : t \in \mathbb{R}\}$. Let U be an orthogonal matrix such that the last column of U is w. By Corollary 2.2, $F(Ux) = \phi(x_1, \ldots, x_{n-1})$, where ϕ is a convex polynomial. Note that the last component of vector $U^T(\nabla f_1 - rw)$ is zero and $U^T w = e(n)$, where $e(n) = (0, \ldots, 0, 1)$. Thus,

$$\begin{aligned} f(Ux) &= F(Ux) + (\nabla f_1)^T Ux \\ &= \phi(x_1, \ldots, x_{n-1}) + \left[U^T(\nabla f_1 - rw)\right]^T x + rw^T Ux \\ &= g(x_1, \ldots, x_{n-1}) + rx_n \quad \forall x \in \mathbb{R}^n, \end{aligned}$$

for some convex polynomial g. It is easy to see that $S_g^\infty = \{0\}$.

(ii). If f is not strictly convex, there exists $x, y \in \mathbb{R}^n$ $(x \neq y)$ such that f is linear on the segment $S = \{z : z = tx + (1-t)y, 0 \leq t \leq 1\}$. Then, it is easy to prove that f is linear on the line $\{z : z = tx + (1-t)y, t \in \mathbb{R}\}$, and so $y - x \in S_f^\infty$ (or $x - y \in S_f^\infty$) according to Lemma 2.4, which contradicts $S_f^\infty = \{0\}$. □

COROLLARY 3.1. *Let h be a kth-order homogeneous convex polynomial on $\mathbb{R}^n$. Then ∇h is a one-to-one mapping from $\mathbb{R}^n$ onto itself.*

Proof. Note that $S_h = \{0\}$, and so $S_h^\infty = \{0\}$. By Theorem 3.2 (ii), h is strictly convex. It is easy to see that $\lim_{\lambda \to \infty} \frac{f(\lambda y)}{\lambda} = +\infty$ for every $y \neq 0$. Then the claim follows from [16, Theorem 26.6]. □

For a homogeneous convex polynomial h, by Lemma 2.6, it is easy to see that $\mathrm{Ker}(h) = S_h = S_h^\infty$. In what follows, we study the relationship between $\mathrm{Ker}(h)$ and the range of ∇h. Note that we do not assume $S_h^\infty \cap (-S_h^\infty) = \{0\}$.

COROLLARY 3.2. *Let h be a kth-order homogeneous convex polynomial. Then we have $\mathrm{Ker}(h)^\perp = R(\nabla h)$, where $R(\nabla h) = \{z \in \mathbb{R}^n : z = \nabla h(x)$ for some $x \in \mathbb{R}^n\}$.*

Proof. The case $k = 1$ is trivial. Suppose $k \geq 2$. Let L be a subspace such that $L^\perp = \mathrm{Ker}(h)$. We will prove $R(\nabla h) = L$. Suppose $\dim(L) = p$. Let $U = (\alpha(1), \ldots, \alpha(n))$, where $[\alpha(1), \ldots, \alpha(p)]$ is an orthonormal basis for L and $[\alpha(p+1), \ldots, \alpha(n)]$ is an orthonormal basis for $L^\perp$. We define $\zeta(x) = h(Ux) \; \forall x \in \mathbb{R}^n$. By Lemma 2.6, we have $\mathrm{Ker}(\zeta) = \{x : \zeta(x) = 0\}$ and $\mathrm{Ker}(h) = \{y : h(y) = 0\}$, and so $\mathrm{Ker}(h) = U\,\mathrm{Ker}(\zeta)$. By the construction of U and $L^\perp = \mathrm{Ker}(h)$, we have $\mathrm{Ker}(\zeta) = (0, \mathbb{R}^{n-p})^T$. From $\zeta(x) = h(Ux)$, it follows that $\nabla\zeta(x) = U^T \nabla h(Ux)$, and so $R(\nabla\zeta) = U^T R(\nabla h)$. Hence, to show $R(\nabla h) = L$, it suffices to prove $R(\nabla\zeta) = (\mathbb{R}^p, 0)^T$. Let $\psi : \mathbb{R}^p \to \mathbb{R}$ be defined by $\psi(y) = \zeta(y, 0) \; \forall y \in \mathbb{R}^p$. Then ψ is a convex

polynomial and $\mathrm{Ker}(\psi) = 0$, which implies $S_\psi = \{0\}$. By Corollary 3.1, we have $R(\nabla\psi) = \mathbb{R}^p$, and so $R(\nabla\zeta) = (\mathbb{R}^p, 0)^T$. □

The condition that h is convex cannot be removed as the next example shows.

Example 3.1. Let $h : \mathbb{R}^2 \to \mathbb{R}$ be defined by $h(x_1, x_2) = (x_1^2 - x_2^2)^2$. It is easy to verify that $\mathrm{Ker}(h) = \{0\}$. Note that

$$\frac{1}{4}\nabla h(x) = \left(\left(x_1^2 - x_2^2\right) x_1, -\left(x_1^2 - x_2^2\right) x_2\right)^T \quad \forall x \in \mathbb{R}^2.$$

Next we show that $R(\nabla h) \neq \mathbb{R}^2$. If $(x_1^2 - x_2^2)x_1 = -(x_1^2 - x_2^2)x_2$, then $(x_1 - x_2)(x_1 + x_2)^2 = 0$. We obtain that $x_1 = x_2$ or $x_1 = -x_2$, and so $\nabla h(x) = (0, 0)^T$. Hence, $(y_1, y_2)^T \notin R(\nabla h)$ if $y_1 = y_2 \neq 0$.

4. Error bounds for convex polynomials. In this section, for each convex polynomial f, we always assume

$$S_f \neq \emptyset \quad \text{and} \quad S_f^\infty \cap (-S_f^\infty) = \{0\}. \tag{4.1}$$

Then, by Theorem 3.1, S_f^∞ is a ray or equal to $\{0\}$. The next theorem shows that if $S_f^\infty \neq \{0\}$, then f has a linear error bound.

THEOREM 4.1. *Let f be a convex polynomial satisfying $S_f^\infty \neq \{0\}$. Then f is unbounded below, and there exists $\tau > 0$ such that*

$$d(x, S_f) \leq \tau[f(x)]_+ \quad \forall x \in \mathbb{R}^n. \tag{4.2}$$

Proof. By Theorem 3.2(i), there exists an orthogonal matrix U such that $f(Ux) = g(x_1, \ldots, x_{n-1}) + rx_n$ for some $r < 0$. It is obvious that f is unbounded below. Let $\bar{f}(x) = f(Ux)\ \forall x \in \mathbb{R}^n$. Then $US_{\bar{f}} = S_f$. Since Euclidean distance is invariant under orthogonal transformations, we have $d(Ux, S_f) = d(x, S_{\bar{f}})$. Thus, it is equivalent to prove that (4.2) holds for $\bar{f}$. Let $x' = x + te(n)$, where $e(n) = (0, \ldots, 0, 1)$. Since $\frac{\partial \bar{f}}{\partial x_n} = r$, we have that $t \leq -\frac{r}{2}(\bar{f}(x) - \bar{f}(x'))$ if $t > 0$ is sufficiently small. Then (4.2) follows from [13, Lemma 2.3]. □

To deal with the case $S_f^\infty = \{0\}$, we need to study convex polynomials which have no linear term.

THEOREM 4.2. *Let $g = \sum_{l=k}^m g_l$ be a convex polynomial, where $k \geq 2$. Then g_k is a convex polynomial.*

Proof. If g_k is not convex, by [3, Theorem 3.3.7], $\nabla^2 g_k(\bar{x})$ is not positive semidefinite for some $\bar{x} \in \mathbb{R}^n$ (obviously $\bar{x} \neq 0$). Then there exists $v \in \mathbb{R}^n$, which satisfies $v^T \nabla^2 g_k(\bar{x}) v < 0$. Hence, we have

$$v^T \nabla^2 g(t\bar{x}) v = \sum_{l=k}^m v^T \nabla^2 g_l(t\bar{x}) v = \sum_{l=k}^m t^{l-2} v^T \nabla^2 g_l(\bar{x}) v \quad \forall t \in \mathbb{R}.$$

If $t > 0$ is small enough, from $v^T \nabla^2 g_k(\bar{x}) v < 0$, it follows that $v^T \nabla^2 g(t\bar{x}) v < 0$, which shows that $\nabla^2 g(t\bar{x})$ is not positive semidefinite. By [3, Theorem 3.3.7], g is not convex, which is a contradiction. Thus, g_k must be convex. □

Stimulated by the idea of [1, p. 46], in the following we will define subspaces $X_k,\ k = 0, \ldots, \frac{m}{2}$, which satisfy

$$X_{k+1} \subseteq X_k \quad \text{and} \quad X_{\frac{m}{2}} = \{0\}. \tag{4.3}$$

For a convex polynomial $f = \sum_{l=2}^m f_l$, let

$$X_0 = \mathbb{R}^n \quad \text{and} \quad X_k = \cap_{i=1}^k \mathrm{Ker}(f_{2i}) \quad \text{for} \quad k = 1, \ldots, \frac{m}{2}. \tag{4.4}$$

LEMMA 4.1. *For each* $1 \le k \le \frac{m}{2}$*, the following assertions hold:*

(i) *If* $2 \le i \le 2k+1$*, then* $X_k \subseteq \mathrm{Ker}(f_i)$.

(ii) $f_{2k}(x) > 0$ *for every* $x \in X_{k-1} \backslash X_k$.

Proof. We prove (i) by induction. For $k = 1$, we need only to prove $X_1 \subseteq \mathrm{Ker}(f_3)$. Let $\bar{f} : X_1 \to \mathbb{R}$ be the restriction of f on X_1. Then $\bar{f}$ is convex, and $\bar{f}(x) = \sum_{i=3}^{m} f_i(x)\ \forall x \in X_1$. By Theorem 4.2, f_3 is a convex function on X_1, which implies that $f_3(x) = 0\ \forall x \in X_1$. From Lemma 2.6, it follows that $X_1 \subseteq \mathrm{Ker}(f_3)$.

Assume that (i) holds for $k = l-1$, where $2 \le l \le \frac{m}{2}$. Since $X_l \subseteq X_{l-1}$, we have $X_l \subseteq \mathrm{Ker}(f_i)$ for each $2 \le i \le 2l-1$, and $X_l \subseteq \mathrm{Ker}(f_{2l})$ by the definition of X_l. Let $\bar{f} : X_l \to \mathbb{R}$ be the restriction of f on X_l. Then $\bar{f}$ is convex, and $\bar{f}(x) = \sum_{i=2l+1}^{m} f_i(x)\ \forall x \in X_l$. Similar to the proof of $k = 1$, we can prove $X_l \subseteq \mathrm{Ker}(f_{2l+1})$. Then (i) holds for $k = l$.

(ii). Let $g : X_{k-1} \to \mathbb{R}$ be the restriction of f on X_{k-1}. Then g is convex and by (i), $g(x) = \sum_{i=2k}^{m} f_i(x)\ \forall x \in X_{k-1}$. From Theorem 4.2, it follows that f_{2k} is convex on X_{k-1}. If $f_{2k}(x) = 0$ for some $x \in X_{k-1}$, then $x \in \mathrm{Ker}(f_{2k})$ by Lemma 2.6, and so $x \in X_k$. Thus, f_{2k} is positive on $X_{k-1} \backslash X_k$. □

If $d \in X_{\frac{m}{2}}$, then by Lemma 4.1(i), $f(td) = \sum_{l=2}^{m} f_l(td) = 0\ \forall t \in \mathbb{R}$. From Lemma 2.3, it follows that $f(y + td) = f(y),\ \forall y \in \mathbb{R}^n,\ \forall t \in \mathbb{R}$, and so $d \in S_f^\infty \cap (-S_f^\infty)$. By (4.1), we obtain $d = 0$, that is, $X_{\frac{m}{2}} = \{0\}$.

LEMMA 4.2. *Let* $f = \sum_{l=2}^{m} f_l$ *be a convex polynomial. Then* $\mathrm{argmin}_{x \in \mathbb{R}^n} f(x) = \{0\}$*, and so* $S_f^\infty = \{0\}$.

Proof. First, we prove f is nonnegative. Suppose there exists $\bar{x} \in \mathbb{R}^n$ such that $f(\bar{x}) < 0$. If we show that $\bar{x} \in X_{\frac{m}{2}}$, then $\bar{x} = 0$ by (4.3), which is a contradiction. Note that

$$f(t\bar{x}) \le (1-t)f(0) + tf(\bar{x}) < 0 \tag{4.5}$$

for every $0 < t < 1$. If $f_2(\bar{x}) > 0$, then $f(t\bar{x}) = \sum_{l=3}^{m} f_l(\bar{x})t^l + f_2(\bar{x})t^2$ is positive for $t > 0$ sufficiently small, which contradicts (4.5). Thus, $f_2(\bar{x}) \le 0$. By Theorem 4.2, f_2 is a convex polynomial, and so $f_2(\bar{x}) \ge 0$. Thus $f_2(\bar{x}) = 0$, which implies $\bar{x} \in X_1$. Assume that $\bar{x} \in X_{k-1}$, where $2 \le k \le \frac{m}{2}$. Next we prove $\bar{x} \in X_k$. By Lemma 4.1 (i), we have $f(t\bar{x}) = \sum_{l=2k+1}^{m} f_l(\bar{x})t^l + f_{2k}(\bar{x})t^{2k}$. If $f_{2k}(\bar{x}) > 0$, then $f(t\bar{x})$ is positive for $t > 0$ sufficiently small, which contradicts (4.5). Thus, $f_{2k}(\bar{x}) \le 0$. Note that $f(z) = \sum_{l=2k}^{m} f_l(z)\ \forall z \in X_{k-1}$. By Theorem 4.2, f_{2k} is a convex polynomial on X_{k-1}, and so f_{2k} is positive semidefinite on X_{k-1}. Hence, $f_{2k}(\bar{x}) = 0$, which implies $\bar{x} \in X_{k-1} \cap \mathrm{Ker}(f_{2k}) = X_k$. By the proof above, we obtain that $\bar{x} \in X_{\frac{m}{2}}$ and arrive at a contradiction. Thus, f is nonnegative.

If $f(\bar{y}) = 0$ for some $\bar{y} \ne 0$, then $f(t\bar{y}) = 0,\ \forall t \in [0,1]$, from the convexity of f. Since f is a polynomial, it is easy to see that $f(t\bar{y}) = 0\ \forall t \in \mathbb{R}$. From Lemma 2.3, it follows that $\bar{y} \in S_f^\infty \cap (-S_f^\infty)$, which contradicts (4.1).

The claim $S_f^\infty = \{0\}$ follows from the boundness of the set $S_f = \{0\}$. □

The following result shows that a convex polynomial $f = \sum_{l=2}^{m} f_l$ has an error bound of order $\frac{1}{m}$ locally.

THEOREM 4.3. *For a convex polynomial* $f = \sum_{l=2}^{m} f_l$*, there exists* $\kappa > 0$ *such that*

$$\|x\| \le \kappa f(x)^{\frac{1}{m}} \quad \text{if} \quad \|x\| < 1. \tag{4.6}$$

Proof. We prove the claim via a contrapositive argument. If (4.6) does not hold, there exists a sequence $\{x(k)\} \subset \mathbb{R}^n$ satisfying $\|x(k)\| < 1$ and

$$\|x(k)\| > kf(x(k))^{\frac{1}{m}} \qquad \forall\ k \ge 1. \tag{4.7}$$

Since $\{x(k)\}$ is bounded, there exists a subsequence $x(n_k)$ such that $x(n_k) \to y$. By (4.7), we have $\|y\| > kf(y)^{\frac{1}{m}}\ \forall k \geq 1$. Then $f(y) = 0$, and so $y = 0$ according to Lemma 4.2. Let $d(k) = \frac{x(n_k)}{\|x(n_k)\|}$ for each $k \geq 1$. Then $\{d(k)\}$ has a cluster d, with $\|d\| = 1$. Without loss of generality, assume that $d = \lim_{k\to\infty} d(k)$.

Now we prove that $d \in X_k$ for each $k \geq 1$. For each $k \geq 1$, let

$$\sigma_k = k^m \frac{f(\|x(n_k)\|d(k))}{\|x(n_k)\|^m} = k^m \sum_{l=2}^{m} f_l(d(k))\|x(n_k)\|^{i-m}.$$

Then by (4.7), $\sigma_k < 1\ \forall k \geq 1$. If $d \notin X_1$, by Lemma 4.1(ii), we have $f_2(d) > 0$. Hence, $f_2(d(k)) > 0$ for all large enough k. Since $\|d(k)\| = 1$, there exists $M > 0$ such that $|f_i(d(k))| < M\ \forall k \geq 1$ and $2 \leq i \leq m$. Then

$$\sigma_k \geq \frac{k^m}{\|x(n_k)\|^{m-3}} \left(\frac{f_2(d(k))}{\|x(n_k)\|} - M \sum_{i=3}^{m} \|x(n_k)\|^{i-3} \right). \tag{4.8}$$

Since $x(n_k) \to 0$, the right-hand side of (4.8) is unbounded as $k \to \infty$, which is a contradiction. Thus, $d \in X_1$. Assume that $d \in X_{k-1}$, where $2 \leq k \leq \frac{m}{2}$. By Lemma 4.1(i), we have

$$\sigma_k = k^m \sum_{l=2k}^{m} f_l(d(k))\|x(n_k)\|^{l-m}.$$

If $f_{2k}(d) > 0$, similar to the proof above, we can derive a contradiction. Then $d \in X_k$. By induction, we have $d \in X_{\frac{m}{2}}$, and so $d = 0$ by (4.3), which is contradiction. The proof is complete. □

THEOREM 4.4. *Let $f = \sum_{l=0}^{m} f_l$ be a convex polynomial satisfying $S_f^\infty = \{0\}$.*

(i) *If there exists $\bar{x} \in \mathbb{R}^n$ such that $f(\bar{x}) < 0$, then f has a linear error bound.*

(ii) *If f is nonnegative on $\mathbb{R}^n$, then there exists a unique $z \in \mathbb{R}^n$ such that $f(z) = 0$. In particular, there exists $\tau > 0$ such that*

$$\|x - z\| \leq \tau \left(f(x) + f(x)^{\frac{1}{m}} \right) \quad \forall x \in \mathbb{R}^n. \tag{4.9}$$

Proof. (i). Note that $\mathrm{bd}(S_f) = \{x \in \mathbb{R}^n : f(x) = 0\}$. Then $\mathrm{bd}(S_f)$ contains none of the optimal solution set. By the fact that f is a convex function, we have $\|\nabla f(x)\| > 0\ \forall x \in bd(S_f)$. Since $S_f^\infty = \{0\}$, S_f is bounded by [16, Theorem 8.4]. Then there exists $\sigma > 0$ such that $\|\nabla f(x)\| \geq \sigma$ for each $x \in \mathrm{bd}(S_f)$. By [13, Theorem 3.1(iii)], f has a linear error bound.

(ii). Note that $\min_{x\in\mathbb{R}^n} f(x) = 0$. By Theorem 3.2(ii), there exists a unique $z \in \mathbb{R}^n$ such that $f(z) = 0$. Let $g(x) = f(x + z)$. Then $S_g^\infty = \{0\}$. Assume that $g = \sum_{l=0}^{m} g_l$. Since $g(0) = 0$, we have $g_0 = 0$. From $g(0) = \min_x g(x)$, it follows that $\nabla g(0) = g_1 = 0$. Hence, $g = \sum_{l=2}^{m} g_l$, and so (4.6) holds for g.

To prove (4.9), it is equivalent to show that there exists $\tau > 0$ such that

$$\|x\| \leq \tau \left(g(x) + g(x)^{\frac{1}{m}} \right) \quad \forall x \in \mathbb{R}^n. \tag{4.10}$$

For $\delta > 0$, let $C_\delta = \{x : g(x) \leq \delta\}$. Select $\delta > 0$ such that $C_\delta \subset \{x : \|x\| \leq \frac{1}{3}\}$. Let $\bar{g}(x) = g(x) - \delta\ \forall x \in \mathbb{R}^n$. Then $S_{\bar{g}} = C_\delta$. By Theorem 4.1, there exists $\tau_1 > 0$ such that

$$d(x, C_\delta) \leq \tau_1 [\bar{g}(x)]_+ \leq \tau_1 g(x) \quad \forall x \in \mathbb{R}^n. \tag{4.11}$$

If $\|x\| > \frac{2}{3}$, $\|x\| \le d(x, C_\delta) + \frac{1}{3} \le 2d(x, C_\delta)$. Thus, from (4.11), it follows that

$$\|x\| \le 2d(x, C_\delta) \le 2\tau_1 g(x) \quad \forall x \text{ satisfying } \|x\| > \frac{2}{3}. \tag{4.12}$$

Combining (4.6) and (4.12), it is easy to see that (4.10) holds for $\tau = \max\{\kappa, 2\tau_1\}$. □

Remark 4.1. By Theorems 4.1 and 4.4(i), for any convex polynomial f, if f satisfies the Slater condition (i.e., there exists $\bar{x}$ such that $f(\bar{x}) < 0$), then f has a linear error bound.

For a convex polynomial $f = \sum_{l=2}^{m} f_l$ $(m \ge 2)$, let

$$Z_0 = \mathbb{R}^n \quad \text{and} \quad Z_i = \cap_{l=1}^{i} \operatorname{Ker}(f_{m-2l+2}) \quad \text{for} \ \ i = 1, \ldots, \frac{m}{2}.$$

LEMMA 4.3. *For each $0 \le i \le \frac{m}{2} - 1$, let $s_i(x) = \sum_{l=m-2i}^{m} f_l(x)$ $\forall x \in \mathbb{R}^n$. Then for each $1 \le i \le \frac{m}{2} - 1$, the following assertions hold:*

(i) *For $m - 2i + 1 \le l \le m$, we have $Z_i \subset \operatorname{Ker}(f_l)$.*

(ii) *There exist $\tau > 0$ and $\delta > 0$ such that*

$$s_i(x) \ge \tau \|x\|^{m-2i} \quad \forall x \in (Z_{i+1})^\perp \cap V_\delta, \tag{4.13}$$

where $V_\delta := \{x \in \mathbb{R}^n : \|x\| \ge \delta\}$.

Proof. We prove the assertions by induction. Let $i = 1$. For (i), by the definition of Z_1, it suffices to prove $Z_1 \subset \operatorname{Ker}(f_{m-1})$. Let $\bar{f} : Z_1 \to \mathbb{R}$ be the restriction of f on Z_1. Then $\bar{f}(x) = \sum_{l=2}^{m-1} f_l(x)$ $\forall x \in Z_1$, and $\bar{f}$ is a convex polynomial on Z_1. By [1, p. 40 Lemma 1], f_{m-1} is a convex polynomial on Z_1. Since $m - 1$ is odd, f_{m-1} must vanish on Z_1. From Lemma 2.6, it follows that $Z_1 \subset \operatorname{Ker}(f_{m-1})$.

(ii). We use a contrapositive argument. If (4.13) does not hold, then there exists a sequence $\{x(k)\} \subset (Z_2)^\perp$ satisfying $\|x(k)\| \ge k$ such that

$$s_1(x(k)) = f_m(x(k)) + f_{m-1}(x(k)) + f_{m-2}(x(k)) < \frac{1}{k}\|x(k)\|^{m-2}. \tag{4.14}$$

Let $d(k) = \frac{x(k)}{\|x(k)\|} \in (Z_2)^\perp$ for each $k \ge 1$. Then $\{d(k)\}$ has a cluster $d \in (Z_2)^\perp$ satisfying $\|d\| = 1$. Without loss of generality, assume that $d = \lim_{k\to\infty} d(k)$. Dividing (4.14) by $\|x(k)\|^m$ and letting $k \to \infty$, we obtain $f_m(d) \le 0$. By [1, p. 40 Lemma 1], f_m is a convex polynomial, which together with Corollary 2.1 implies that $f_m(d) = 0$, that is, $d \in Z_1$. Let $\bar{f} : Z_1 \to \mathbb{R}$ be the restriction of f on Z_1. Then $\bar{f}$ is a convex polynomial on Z_1, and $\bar{f}(x) = \sum_{l=2}^{m-2} f_l(x)$ $\forall x \in Z_1$. By [1, p. 40 Lemma 1], f_{m-2} is a convex polynomial on Z_1. According to Corollary 2.1, f_{m-2} is nonnegative on Z_1. If we prove $f_{m-2}(d) \le 0$, then $f_{m-2}(d) = 0$, and so $d \in \operatorname{Ker}(f_{m-2})$ by Lemma 2.6. Hence, $d \in Z_1 \cap \operatorname{Ker}(f_{m-2}) = Z_2$. We obtain a contradiction, and so (ii) holds for $i = 1$.

Now we prove $f_{m-2}(d) \le 0$. For $x \in \mathbb{R}^n$, we use x_u (x_v) to denote the projection of x on Z_1 $((Z_1)^\perp)$. By $Z_1 = \operatorname{Ker}(f_m) \subset \operatorname{Ker}(f_{m-1})$ and Lemma 2.5,

$$f_m(x(k)) + f_{m-1}(x(k)) = f_m(x_v(k)) + f_{m-1}(x_v(k)). \tag{4.15}$$

Since f_m is a convex polynomial, by Lemma 2.6, f_m is positive on $(Z_1)^\perp$. Then there exists $\rho > 0$ such that $f_m(x) + f_{m-1}(x) > 0$ $\forall x \in (Z_1)^\perp \cap V_\rho$. If $x_v(k) \in V_\rho$ for infinitely k, then the left-hand side of (4.15) is nonnegative for such k, which

together with (4.14) implies that $f_{m-2}(x(k)) < \frac{1}{k}\|x(k)\|^{m-2}$, that is, $f_{m-2}(d(k)) < \frac{1}{k}$. Letting $k \to \infty$, we obtain $f_{m-2}(d) \le 0$. If $\|x_v(k)\| \le \rho$ for k sufficiently large, then $f_m(x(k)) + f_{m-1}(x(k))$ is bounded. Dividing (4.14) by $\|x(k)\|^{m-2}$ and letting $k \to \infty$, we obtain $f_{m-2}(d) \le 0$ also.

Assume the assertions hold for $i = j-1$, where $2 \le j \le \frac{m}{2}$. Now we prove (i) for $i = j$. We need only to prove $Z_j \subset \mathrm{Ker}(f_{m-2j+1})$. Let $\bar{f} : Z_j \to \mathbb{R}$ be the restriction of f on Z_j. Then $\bar{f}$ is a convex polynomial on Z_j. By the inductive hypothesis and $Z_j \subset \mathrm{Ker}(f_{m-2j+2})$, we have $\bar{f}(x) = \sum_{l=2}^{m-2j+1} f_l(x)\ \forall x \in Z_j$. By [1, p. 40 Lemma 1], f_{m-2j+1} is a convex polynomial on Z_j. Since $m-2j+1$ is odd, f_{m-2j+1} must vanish on Z_j. From Lemma 2.6, it follows that $Z_j \subset \mathrm{Ker}(f_{m-2j+1})$.

For (ii), if (4.13) does not hold, then there exists a sequence $\{x(k)\} \subset (Z_{j+1})^\perp$ satisfying $\|x(k)\| \ge k$ such that

$$s_j(x(k)) = s_{j-1}(x(k)) + f_{m-2j+1}(x(k)) + f_{m-2j}(x(k)) < \frac{1}{k}\|x(k)\|^{m-2j}. \tag{4.16}$$

Let $d(k) = \frac{x(k)}{\|x(k)\|} \in (Z_{j+1})^\perp$ for each $k \ge 1$. As above, we assume that $d = \lim_{k\to\infty} d(k)$. Then $d \in (Z_{j+1})^\perp$, and $\|d\| = 1$. For $x \in \mathbb{R}^n$, let x_u (x_v) be the projection of x on Z_j ($(Z_j)^\perp$). By $Z_j \subset \mathrm{Ker}(f_{m-2j+1})$ and the definition of Z_j, we have

$$s_{j-1}(x(k)) + f_{m-2j+1}(x(k)) = s_{j-1}(x_v(k)) + f_{m-2j+1}(x_v(k)). \tag{4.17}$$

If $\{x_v(k)\}$ is bounded, then $d = \lim_{k\to\infty} x_u(k)/\|x(k)\| \in Z_j$. If $\{x_v(k)\}$ is unbounded, by the inductive hypothesis, (4.13) holds for $i = j-1$, and so there exists $\tau > 0$ such that

$$s_{j-1}(x_v(k)) \ge \tau\|x_v(k)\|^{m-2j+2} \tag{4.18}$$

for infinitely k. By (4.16), (4.17), and (4.18), we deduce that $\lim_{k\to\infty} \frac{\|x_v(k)\|}{\|x(k)\|} = 0$, which implies $d \in Z_j$ also. Similar to the proof of $i = 1$, if we show that $f_{m-2j}(d) \le 0$, then we obtain $d \in Z_j \cap \mathrm{Ker}(f_{m-2j}) = Z_{j+1}$, which is a contradiction.

Now we prove $f_{m-2j}(d) \le 0$. Since (4.13) holds for $i = j-1$, there exists $\rho > 0$ such that $s_{j-1}(x) + f_{m-2j+1}(x) > 0$ for any $x \in (Z_j)^\perp \cap V_\rho$. If $x_v(k) \in V_\rho$ for infinitely k, by (4.16) and (4.17), we have $f_{m-2j}(x(k)) < \frac{1}{k}\|x(k)\|^{m-2j}$ for such k, that is, $f_{m-2j}(d(k)) < \frac{1}{k}$. Letting $k \to \infty$, we obtain $f_{m-2j}(d) \le 0$. If $\|x_v(k)\| \le \rho$ for k sufficiently large, then $s_{j-1}(x(k)) + f_{m-2j+1}(x(k))$ is bounded. Dividing (4.16) by $\|x(k)\|^{m-2j}$ and letting $k \to \infty$, we obtain $f_{m-2j}(d) \le 0$ also. The proof is complete. □

If $d \in Z_{\frac{m}{2}}$, by Lemma 4.3(i) and the definition of $Z_{\frac{m}{2}}$, $f(td) = \sum_{l=2}^{m} f_l(td) = 0\ \forall t \in \mathbb{R}$. From Lemma 2.3, it follows that $f(y + td) = f(y),\ \forall y \in \mathbb{R}^n,\ t \in \mathbb{R}$, and so $d \in S_f^\infty \cap (-S_f^\infty)$. By (4.1), we obtain $d = 0$, that is, $Z_{\frac{m}{2}} = \{0\}$. By Lemma 4.3(ii) and the fact $Z_{\frac{m}{2}} = \{0\}$, there exist $\tau > 0$ and $\delta > 0$ such that

$$f(x) \ge \tau\|x\|^2 \quad \forall x \in V_\delta. \tag{4.19}$$

Combining (4.19) and Lemma 4.2, it is easy to obtain the following stronger result.

COROLLARY 4.1. *Let $f = \sum_{l=2}^{m} f_l$ be a convex polynomial. For any $\delta > 0$, there exists $\tau > 0$ such that*

$$f(x) \ge \tau\|x\|^2 \quad \forall x \in V_\delta.$$

PROPOSITION 4.1. *Let $f = \sum_{l=2}^{m} f_l$ be a convex polynomial. For any $\delta > 0$, there exists $\tau > 0$ such that $\|\nabla f(x)\| \geq \tau \|x\|$ $\forall x \in V_\delta$, where $V_\delta := \{x \in \mathbb{R}^n : \|x\| \geq \delta\}$.*

Proof. Note that $f(0) = f(x) - x^T \nabla f(x) + \frac{1}{2} x^T \nabla^2 f(\xi) x$ for some $\xi \in \mathbb{R}^n$. Since $\nabla^2 f(\xi)$ is positive semidefinite, we have

$$\|x\| \cdot \|\nabla f(x)\| \geq x^T \nabla f(x) \geq f(x) - f(0) \geq \tau \|x\|^2 \quad \forall x \in V_\delta,$$

where the last inequality follows from Corollary 4.1. Thus, the claim is true. ∎

Using the fact $Z_{\frac{m}{2}} = \{0\}$ and a contrapositive argument, we can establish the following result, which generalizes Corollary 3.1 to the nonhomogeneous convex polynomials.

PROPOSITION 4.2. *Let $f = \sum_{l=2}^{m} f_l$ be a convex polynomial. Then ∇f is a one-to-one mapping from $\mathbb{R}^n$ onto itself.*

Proof. By Lemma 4.2, we have $S_f^\infty = \{0\}$, which together with Theorem 3.2(ii) implies that f is strictly convex. If we prove $\lim_{\lambda \to \infty} \frac{f(\lambda y)}{\lambda} = +\infty$ for every $y \neq 0$, then the claim follows from [16, Theorem 26.6]. Suppose the contrary. There exists $\bar{y} \neq 0$ such that

$$\lim_{\lambda \to \infty} \frac{f(\lambda \bar{y})}{\lambda} = \delta \tag{4.20}$$

for some $\delta \geq 0$. We must have $\bar{y} \in Z_1$. Otherwise, $f_m(\bar{y}) > 0$, and so $\lim_{\lambda \to \infty} \frac{f(\lambda \bar{y})}{\lambda} = +\infty$. Suppose $\bar{y} \in Z_{k-1}$, where $2 \leq k \leq \frac{m}{2}$. By Lemma 4.3(i), $f(\lambda \bar{y}) = \sum_{l=2}^{m-2k+2} f_l(\lambda \bar{y})$. We must have $\bar{y} \in Z_k$. Otherwise, we will obtain a contradiction to (4.20). Thus, we arrive at $\bar{y} \in Z_{\frac{m}{2}}$, and so $\bar{y} = 0$, which is a contradiction. ∎

Remark 4.2. For a convex polynomial $f = \sum_{l=2}^{m} f_l$, if $S_f^\infty \cap (-S_f^\infty) = \{0\}$ does not hold, according to Lemma 4.2, S_f^∞ must be a linear space. Thus, by Theorem 3.1, one has that $S_f^\infty = \cap_{l=2}^{m} \mathrm{Ker}(f_l)$. Moreover, using a similar argument of Corollary 3.2, it is easy to prove $(S_f^\infty)^\perp = R(\nabla f)$.

5. Error bounds for polyhedral-constrained convex polynomials. In this section, we consider the error bounds of the following problem:

$$\begin{aligned} &\min f(x) \\ &\text{subject to } x \in P, \end{aligned} \tag{5.1}$$

where f is an mth-order convex polynomial and P is a polyhedral set. Let $P = \{x \in \mathbb{R}^n : (a^i)^T x \leq b^i,\ 1 \leq i \leq k\}$, where $a^i \in \mathbb{R}^n$, $b^i \in \mathbb{R}$ for each $i \in [k]$. Let $S = S_f \cap P \neq \emptyset$. By Lemma 2.4, if $d \in S^\infty \cap (-S^\infty)$, then f is constant along the direction $\pm d$ and $P + td = P$ $\forall t \in \mathbb{R}$. Hence, without loss of generality, we assume that

$$S^\infty \cap (-S^\infty) = \{0\}.$$

First, we will derive a linear error bound under the Slater condition.

$$\text{There exists } x^* \in S \text{ such that } f(x^*) < 0. \tag{5.2}$$

For each $x \in \mathrm{bd}(S)$, we define the index set of x by $I(x) := \{i \in [k] : (a^i)^T x = b^i\}$.

THEOREM 5.1. *If there exists $x^* \in S$ such that $f(x^*) < 0$, then there exists $\tau > 0$ such that*

$$d(x, S) \leq \tau [f(x)]_+ \quad \forall x \in P. \tag{5.3}$$

Proof. Let $F(x) = f(x) + \iota_P(x)$, $\forall x \in \mathbb{R}^n$, where $\iota_P(x) = 0$ $\forall x \in P$ and $\iota_P(x) = +\infty$ $\forall x \notin P$. Then $\partial F(x) = \nabla f(x) + N_P(x)$ for each $x \in P$. Fix $y \in \mathrm{bd}(S)$, which satisfies $f(y) = 0$. By (5.2) and [2, Corollary 3],

$$N_S(y) = N_{S_f}(y) + N_P(y) = \left\{ \lambda \nabla f(y) + \sum_{i \in I(y)} \lambda_i a^i : \lambda \geq 0, \lambda_i \geq 0 \ \forall i \in I(y) \right\}.$$

Hence, $N_S(y) = \{\theta \partial F(y) : \theta \geq 0\}$. If $h \in N_S^1(y)$, then $h = \theta(\nabla f(y) + \sum_{i \in I(y)} \mu_i a^i)$ for some $\theta > 0$ and $\mu_i \geq 0$ $\forall i \in I(y)$. By (2.1), we have

$$\begin{aligned} F'(y;h) &= \max\left\{h^T \xi : \xi \in \partial F(y)\right\} \\ &\geq \theta \left\| \nabla f(y) + \sum_{i \in I(y)} \mu_i a^i \right\|^2 = \left\| \nabla f(y) + \sum_{i \in I(y)} \mu_i a^i \right\|. \end{aligned} \tag{5.4}$$

Now we prove that for each $x \in \mathrm{bd}(S)$ satisfying $f(x) = 0$, the following holds:

$$\left\| \nabla f(x) + \sum_{i \in I(x)} \lambda_i a^i \right\| \geq \frac{1}{\tau} \quad \forall \lambda_i \geq 0, \ i \in I(x). \tag{5.5}$$

Then (5.3) follows from [13, Theorem 3.1(iii)], (5.4), and (5.5). Suppose the contrary. There exist sequences of $\{x^r\}$ and $\{\lambda^r\}$ such that $x^r \in \mathrm{bd}(S)$, $f(x^r) = 0$, $\lambda^r \geq 0$, and

$$\nabla f(x^r) + \sum_{i \in I(x^r)} \lambda_i^r a^i \to 0. \tag{5.6}$$

Since $I(x^r) \subset [k]$ and $[k]$ has finite number of subsets, there is a subsequence $\{y^r\}$ of $\{x^r\}$ such that $I(y^r) = I$ for some index set $I \subset [k]$. Without loss of generality, we may assume that $I(x^r) = I$. Let $L = \{x \in \mathbb{R}^n : (a^i)^T x = b^i \ \forall i \in I\}$. Then $\{x^r\} \subset L$.

Now we show that $\{x^r\}$ is unbounded. Otherwise, $\{x^r\}$ has a cluster, say x^∞. Then $f(x^\infty) = 0$ and $(a^i)^T x^\infty = b^i$ $\forall i \in I$. From (5.6), it follows that $\| \sum_{i \in I(x^r)} \lambda_i^r a^i \|$ is bounded. By Hoffman's error bound we may assume, without loss of generality, that $\{\lambda_i^r\}$, $i \in I$ is bounded. Therefore, by passing to a subsequence if necessary, we can assume that the sequence $\{\lambda_i^r\}$ converges to $\lambda_i^\infty \geq 0$ for each $i \in I$. Then (cf. (5.6))

$$\nabla f(x^\infty) + \sum_{i \in I} \lambda_i^\infty a^i = 0. \tag{5.7}$$

Let $\varphi(x) = f(x) + \sum_{i \in I} \lambda_i^\infty ((a^i)^T x - b^i)$ $\forall x \in \mathbb{R}^n$. Then $\varphi(x^\infty) = 0$ and $\nabla \varphi(x^\infty) = 0$. Since φ is convex, φ attains its global minimum, which is 0, at x^∞. However, by (5.2) and the fact $x^* \in P$, we have $\varphi(x^*) < 0$, a contradiction. Hence, $\{x^r\}$ is unbounded.

If S_f^∞ is a linear space, without loss of generality, we assume that $S_f^\infty = (0, \mathbb{R}^{n-p})^T$ for some $p < n$. For each $x \in \mathbb{R}^n$, let x_u denote the vector of the first p components of x, that is, $x_u = (x_1, \ldots, x_p)$. Then $f(x) = g(x_u)$, where g is a convex polynomial on $\mathbb{R}^p$ satisfying $S_g^\infty = \{0\}$. Thus, S_g is bounded, which implies $\{x_u^r\}$ is bounded. Therefore, $\{x_u^r\}$ has a cluster $z \in \mathbb{R}^p$. Let $x^\infty = (z^T, 0)^T \in \mathbb{R}^n$. Then $f(x^\infty) = 0$. Similar to the proof above, we can assume that the sequence $\{\lambda_i^r\}$ converges to $\lambda_i^\infty \geq 0$ for each $i \in I$. Then (5.7) holds for x^∞ and λ^∞. By the same argument as above, we can derive a contradiction.

Thus, S_f^∞ is not a space. By Theorem 3.1 and Theorem 3.2(i), without loss of generality, we assume that $S_f^\infty = \{x \in \mathbb{R}^n : x_{p+1} \geq 0, x_i = 0 \text{ for } i > p+1\}$ for some $p \leq n-1$ and

$$f(x) = g(x_1, \ldots, x_p) + cx_{p+1},$$

where g is a convex polynomial on $\mathbb{R}^p$ satisfying $S_g^\infty = \{0\}$ and $c < 0$. By Theorem 3.2(ii), g is strictly convex. It is not hard to see that there exist r_1 and r_2 such that $f(\frac{x^{r_1}+x^{r_2}}{2}) < 0$. Let $\bar{f}$ be the restriction of f on L. Then $\bar{f}$ satisfies the Slater condition. By coordinate transformation, if necessary, and using Remark 4.1, $\bar{f}$ has a linear error bound.

Fix $q \in \{x \in L : \bar{f}(x) = 0\}$. Let w be the projection of $\nabla f(q)$ onto L^∞. Then $w \neq 0$. Otherwise, $\bar{f}$ will attain its minimum at q. Note that $\|w\| = \min\{\|\nabla f(q)+\xi\| : \xi \in (L^\infty)^\perp\}$. We also have $N^1_{S_{\bar{f}}}(q) \cap L^\infty = \{w/\|w\|\}$. Since $\bar{f}$ has a linear error bound, by [13, Theorem 3.1(iii)], there exists $\kappa > 0$ such that

$$\kappa < \bar{f}\left(q; \frac{w}{\|w\|}\right) = \frac{w^T \nabla f(q)}{\|w\|} = \|w\| = \min\left\{\|\nabla f(q) + \xi\| : \xi \in (L^\infty)^\perp\right\},$$

which contradicts (5.6) since $(L^\infty)^\perp = \{\sum_{i\in I} \lambda_i a^i : \lambda_i \in \mathbb{R}\}$. The proof is complete. □

THEOREM 5.2. *If f is nonnegative on P, then there exists $\tau > 0$ such that*

$$d(x, S) \leq \tau\left(f(x) + f(x)^{\frac{1}{m}}\right) \quad \forall x \in P. \tag{5.8}$$

Proof. It is easy to see that S is a singleton set. Assume that $S = \{x^*\}$. By KKT condition of problem (5.1), there exist $\lambda_i \geq 0,\ \forall i \in I(x^*)$, such that

$$\nabla f(x^*) + \sum_{i\in I(x^*)} \lambda_i a^i = 0.$$

Let $\varphi(x) = f(x) + \sum_{i\in I(x^*)} \lambda_i((a^i)^T x - b^i)\ \forall x \in \mathbb{R}^n$. Then φ is a convex polynomial and $\nabla\varphi(x^*) = 0$, and so φ attains its minimum at x^*. By Theorem 4.4(ii), (5.8) holds thanks to $\varphi(x) \leq f(x)\ \forall x \in P$. □

Acknowledgments. The author is grateful to the referees for their valuable comments and suggestions in improving the quality of the manuscript.

CALMNESS FOR L-SUBSMOOTH MULTIFUNCTIONS IN BANACH SPACES*

XI YIN ZHENG† AND KUNG FU NG‡

Abstract. Using variational analysis techniques, we study subsmooth multifunctions in Banach spaces. In terms of the normal cones and coderivatives, we provide some characterizations for such multifunctions to be calm. Sharper results are obtained for Asplund spaces. We also present some exact formulas of the modulus of the calmness. As applications, we provide some error bound results on nonconvex inequalities, which improve and generalize the existing error bound results.

Key words. subsmoothness, calmness, metric subregularity, error bound, multifunction

1. Introduction. As an extension of convexity, prox-regularity of a set expresses a variational behavior of "order two" and plays an important role in variational analysis (see [5, 32, 34] and the references therein). Recently, Aussel, Daniilidis, and Thibault [1] considered a variational behavior of "order one" of a set and introduced subsmoothness, extending the notions of the smoothness and the prox-regularity. Motivated by their work, we consider (in section 3) a further weakened notion (called L-subsmooth).

The calmness property plays an important role in many issues in mathematical programming like exact penalty functions, optimality conditions, local error bounds, weak sharp minima, and so on. Recently, many authors studied calmness (cf. [8, 11, 9, 10, 17, 34, 43, 45] and the references therein). Let Y, X be Banach spaces and $M : Y \rightrightarrows X$ a multifunction. For $\bar{y} \in Y$ and $\bar{x} \in M(\bar{y})$, recall that M is calm at $(\bar{y}, \bar{x})$ if there exist $\eta, \delta \in (0, +\infty)$ such that

$$d(x, M(\bar{y})) \le \eta \|y - \bar{y}\| \quad \forall y \in B(\bar{y}, \delta) \text{ and } x \in M(y) \cap B(\bar{x}, \delta), \tag{1.1}$$

where $B(\bar{x}, \delta)$ denotes the open ball with center $\bar{x}$ and radius r. Let $F(x) := \{y \in Y : x \in M(y)\}$ for all $x \in X$. As observed by Henrion and Outrata [10], the calmness of M at $(\bar{y}, \bar{x})$ is equivalent to the condition that there exist $\eta, \delta \in (0, +\infty)$ such that

$$d(x, F^{-1}(\bar{y}) \le \eta d(\bar{y}, F(x)) \quad \forall x \in B(\bar{x}, \delta). \tag{1.2}$$

Following Dontchev and Rockafellar [6], (1.2) means that the generalized equation $\bar{y} \in F(x)$ is metrically subregular at $\bar{x}$. This property provides an estimate on how far a candidate x can be from the solution set of the generalized equation. A stronger property is the following: a multifunction F is said to be metrically regular at $\bar{x}$ for $\bar{y}$

if there exist $\tau, \delta \in (0, +\infty)$ such that

$$d(x, F^{-1}(y)) \le \tau d(y, F(x)) \quad \forall (x, y) \in B(\bar{x}, \delta) \times B(\bar{y}, \delta)). \tag{1.3}$$

Both notions (of the metric regularity and the metric subregularity) have been studied by many authors (see [7, 6, 14, 20, 23, 24, 25, 28, 40, 43] and the references therein). In particular, it is well known (cf. [23, 24, 25, 34]) that if X and Y are finite-dimensional, then F is metrically regular at $\bar{x}$ for $\bar{y}$ if and only if $D^*F(\bar{x}, \bar{y})^{-1}(0) = \{0\}$; moreover

$$\inf\{\tau > 0 : \text{ (1.3) holds}\} = \|D^*F(\bar{x}, \bar{y})^{-1}\|^- = \limsup_{(x,y) \overset{\mathrm{Gr}(F)}{\longrightarrow} (\bar{x}, \bar{y})} \|D^*F(x, y)^{-1}\|^-, \tag{1.4}$$

where $D^*F(x, y)$ is the coderivative of F at (x, y) and $\|D^*F(x, y)^{-1}\|^-$ denotes the inner norm of $D^*F(x, y)^{-1}$ (see section 2 for undefined terms and further notation). The modulus of the calmness of M at $(\bar{y}, \bar{x})$ is denoted by $\eta(M; \bar{y}, \bar{x})$ and defined by

$$\eta(M; \bar{y}, \bar{x}) := \inf\{\eta \in (0, \infty) : \text{ (1.1) holds for some } \delta \in (0, +\infty)\}. \tag{1.5}$$

The case $\eta(M; \bar{y}, \bar{x}) = \infty$ indicates that M is not calm at $(\bar{y}, \bar{x})$ (here and throughout we adopt the convention that the infimum over the empty set is ∞). In terms of the normal cone of $M(\bar{y})$, the derivative, or subdifferential, Henrion and Outrata [9], Henrion, Jourani, and Outrata [11], and Henrion and Jourani [8] gave sufficient conditions for $\eta(M; \bar{y}, \bar{x}) < +\infty$ in some special cases. Recently, in terms of the normal cone and coderivative, the authors [43] considered the case when M is a general closed convex multifunction between Banach spaces and provided some characterizations for $\eta(M; \bar{y}, \bar{x}) < +\infty$. This and (1.4) motivate us to seek some formulas for $\eta(M; \bar{y}, \bar{x})$ in terms of coderivative in the case when M is not necessarily convex. In section 4, for L-subsmooth multifunctions, we establish some such formulas and provide several sufficient and/or necessary conditions for the calmness. In section 5, as an application, we consider error bounds for inequalities. In particular, we extend some existing error bound results from the convex case to the nonconvex case.

2. Preliminaries. Let X be a Banach space. Let X^* and B_X denote the dual space and the closed unit ball of X, respectively.

For a closed subset A of X and $a \in A$, let $T_c(A, a)$ and $T(A, a)$ denote, respectively, the Clarke tangent cone and the contingent (Bouligand) cone of A at a; they are defined by

$$T_c(A, a) := \liminf_{x \overset{A}{\to} a, t \to 0^+} \frac{A - x}{t} \quad \text{and} \quad T(A, a) := \limsup_{t \to 0^+} \frac{A - a}{t},$$

where $x \overset{A}{\to} a$ means that $x \to a$ with $x \in A$. Thus, $v \in T_c(A, a)$ if and only if, for each sequence $\{a_n\}$ in A converging to a and each sequence $\{t_n\}$ in $(0, \infty)$ decreasing to 0, there exists a sequence $\{v_n\}$ in X converging to v such that $a_n + t_n v_n \in A$ for all n, while $v \in T(A, a)$ if and only if there exist a sequence $\{v_n\}$ converging to v and a sequence $\{t_n\}$ in $(0, \infty)$ decreasing to 0 such that $a + t_n v_n \in A$ for all n. We denote by $N_c(A, a)$ the Clarke normal cone of A at a, that is,

$$N_c(A, a) := \{x^* \in X^* : \langle x^*, h\rangle \le 0 \ \ \forall h \in T_c(A, a)\}.$$

For $\varepsilon \ge 0$ and $a \in A$, the nonempty set

$$\hat{N}_\varepsilon(A, a) := \left\{ x^* \in X^* : \limsup_{x \overset{A}{\to} a} \frac{\langle x^*, x - a\rangle}{\|x - a\|} \le \varepsilon \right\}$$

is called the set of Fréchet ε-normals of A at a. When $\varepsilon = 0$, $\hat{N}_\varepsilon(A,a)$ is a convex cone which is called the Fréchet normal cone of A at a and is denoted by $\hat{N}(A,a)$.

Let $N(A,a)$ denote the Mordukhovich normal cone (also known as the limiting or basic normal cone) of A at a, that is,

$$N(A,a) = \limsup_{x \xrightarrow{A} a, \varepsilon \to 0^+} \hat{N}_\varepsilon(A,x).$$

Thus, $x^* \in N(A,a)$ if and only if there exists a sequence $\{(x_n, \varepsilon_n, x_n^*)\}$ in $A \times R_+ \times X^*$ such that $(x_n, \varepsilon_n) \to (a,0)$, $x_n^* \xrightarrow{w^*} x^*$ and $x_n^* \in \hat{N}_{\varepsilon_n}(A, x_n)$ for each $n \in \mathbb{N}$, where $\mathbb{N}$ denotes the set of all natural numbers. It is known that

$$\hat{N}(A,a) \subset N(A,a) \subset N_c(A,a) \tag{2.1}$$

(cf. [24, 25, 26]). It is known that if A is convex, then $T_c(A,a) = T(A,a)$ and

$$N_c(A,a) = \hat{N}(A,a) = \{x^* \in X^* : \ \langle x^*, x\rangle \le \langle x^*, a\rangle \ \ \forall x \in A\}.$$

Recall that a Banach space X is called an Asplund space if every continuous convex function on X is Fréchet differentiable at each point of a dense subset of X (for other definitions and their equivalents, see [31, Definition 1.22 and Corollary 2.35]). It is well known (cf. [31]) that X is an Asplund space if and only if every separable subspace of X has a separable dual space. In the case when X is an Asplund space, Mordukhovich and Shao [26] proved that

$$N_c(A,a) = \mathrm{cl}^*(\mathrm{co}(N(A,a))) \ \text{ and } \ N(A,a) = \limsup_{x \xrightarrow{A} a} \hat{N}(A,x).$$

The following approximate projection result (recently established in [44]) will play an important role in the proofs of our main results.

LEMMA 2.1. *Let be A a nonempty closed subset of a Banach space X and let $\gamma \in (0,\ 1)$. Then for any $x \notin A$ there exist $a \in \mathrm{bd}(A)$ and $a^* \in N_c(A,a)$ with $\|a^*\| = 1$ such that*

$$\gamma\|x - a\| < \min\{d(x,A),\ \langle a^*, x - a\rangle\}.$$

If X is assumed to be an Asplund space, then above a^* can be chosen from $\hat{N}(A,a)$.

For a multifunction F between Banach spaces X and Y, the graph of F is defined by

$$\mathrm{Gr}(F) := \{(x,y) \in X \times Y : \ y \in F(x)\}.$$

As usual, F is said to be closed (resp., convex) if $\mathrm{Gr}(F)$ is a closed (resp., convex) subset of $X \times Y$. Let $(x,y) \in \mathrm{Gr}(F)$. The Clarke tangent and contingent derivatives $D_cF(x,y)$, $DF(x,y)$ of F at (x,y) are defined by

$$\mathrm{Gr}(D_cF(x,y)) = T_c(\mathrm{Gr}(F),(x,y)) \ \text{ and } \ \mathrm{Gr}(DF(x,y)) = T(\mathrm{Gr}(F),(x,y)),$$

respectively. Let $\hat{D}^*F(x,y)$, $D^*F(x,y)$, and $D_c^*F(x,y)$ denote the coderivatives of F at (x,y) associated, respectively, with the Fréchet, Mordukhovich, and Clarke normal structures; they are defined by

$$\hat{D}^*F(x,y)(y^*) := \{x^* \in X^* : \ (x^*, -y^*) \in \hat{N}(\mathrm{Gr}(F),(x,y))\} \quad \forall y^* \in Y^*,$$
$$D^*F(x,y)(y^*) := \{x^* \in X^* : \ (x^*, -y^*) \in N(\mathrm{Gr}(F),(x,y))\} \quad \forall y^* \in Y^*,$$

and

$$D_c^*F(x,y)(y^*) := \{x^* \in X^* :\ (x^*, -y^*) \in N_c(\mathrm{Gr}(F), (x,y))\} \quad \forall y^* \in Y^*.$$

The history of the coderivatives can be found in Mordukhovich's book [24, 25].

Let $G : X \rightrightarrows Y$ be a positively homogeneous multifunction (i.e., $\mathrm{Gr}(G)$ is a cone in $X \times Y$). Following Dontchev, Lewis, and Rockefeller [7], the inner norm of G is defined by $\|G\|^- := \sup_{x\in B_X} \inf_{y\in Gx} \|y\|$. For a cone K in X, let $\|G|_K\|^-$ be defined by $\|G|_K\|^- := \sup_{x\in B_X\cap K} \inf_{y\in Gx} \|y\|$. It is not difficult to verify that

$$\|G^{-1}|_C\|^- = \inf\{\tau > 0 :\ C \cap B_Y \subset \tau G(B_X)\}. \tag{2.2}$$

3. Subsmoothness of multifunctions. Throughout the remainder of this paper, X, Y, and Z denote Banach spaces. If additional conditions are imposed, they will be explicitly specified.

Let A be a subset of X and $a \in A$. Recall (see [5, 32, 34]) that A is prox-regular at a if there exist $\sigma, \delta \in (0, +\infty)$ such that

$$\langle x^* - u^*, x - u\rangle \geq -\sigma\|x - u\|^2$$

whenever $x, u \in B(a,\delta) \cap A$, $x^* \in N_c(A, x) \cap B_{X^*}$, and $u^* \in N_c(A, u) \cap B_{X^*}$. As an interesting extension of the prox-regularity, Aussel, Daniilidis, and Thibault [1] introduced and studied the following subsmoothness and semisubsmoothness: A is said to be

(a) subsmooth at $a \in A$ if for any $\varepsilon > 0$ there exists $\delta > 0$ such that

$$\langle x^* - u^*, x - u\rangle \geq -\varepsilon\|x - u\|$$

whenever $x, u \in B(a,\delta) \cap A$, $x^* \in N_c(A, x) \cap B_{X^*}$, and $u^* \in N_c(A, u) \cap B_{X^*}$;

(b) semisubsmooth at $a \in A$ if

$$\langle x^* - a^*, x - a\rangle \geq -\varepsilon\|x - a\|$$

whenever $x \in B(a,\delta) \cap A$, $x^* \in N_c(A, x) \cap B_{X^*}$, and $a^* \in N_c(A, a) \cap B_{X^*}$.

It is easy to verify that A is subsmooth at $a \in A$ if and only if for any $\varepsilon > 0$ there exists $\delta > 0$ such that

$$\langle u^*, x - u\rangle \leq \varepsilon\|x - u\|$$

whenever $x, u \in B(a,\delta) \cap A$ and $u^* \in N_c(A, u) \cap B_{X^*}$. In the above (b), setting $x^* = 0$, one can define a weaker notion: A satisfies condition (S) at a if for any $\varepsilon > 0$ there exists $\delta > 0$ such that

$$\langle a^*, x - a\rangle \leq \varepsilon\|x - a\| \quad \forall x \in B(a,\delta) \cap A \ \text{ and } \ \forall a^* \in N_c(A, a) \cap B_{X^*}.$$

Clearly, if A satisfies condition (S), then $N_c(A, a) \subset \hat{N}(A, a)$ and so, by (2.1),

$$N_c(A, a) = N(A, a) = \hat{N}(A, a).$$

It is known (and easily verified) that

convexity⇒prox-regularity⇒subsmoothness⇒semisubsmoothness⇒condition (S).

In what follows, let $F : X \rightrightarrows Y$ be a closed multifunction, and let $a \in X$ and $b \in F(a)$.

DEFINITION 3.1. *We say that F is subsmooth (resp., satisfies condition* (S)*) at (a, b) if* $\mathrm{Gr}(F)$ *is subsmooth (resp., satisfies condition* (S)*) at (a, b).*

Now we introduce a few new notions which are weaker than the subsmoothness but stronger than condition (S). They will play an important role in our analysis.

DEFINITION 3.2. *We say that*

(i) *F is L-subsmooth at (a, b) if for any $\varepsilon > 0$ there exists $\delta > 0$ such that*

$$\langle u^*, x - a\rangle + \langle v^*, y - v\rangle \le \varepsilon(\|x - a\| + \|y - v\|) \tag{3.1}$$

whenever $v \in F(a) \cap B(b, \delta)$, $(u^*, v^*) \in N_c(\mathrm{Gr}(F), (a, v)) \cap (B_{X^*} \times B_{Y^*})$, and $(x, y) \in \mathrm{Gr}(F)$ with $\|x - a\| + \|y - b\| < \delta$;

(i′) *F is $\mathcal{L}$-subsmooth at (a, b) if F^{-1} is L-subsmooth at (b, a);*

(ii) *F is weakly L-subsmooth if same as in* (i) *but the Clarke normal cone $N_c(\mathrm{Gr}(F), \cdot)$ is replaced with the Mordukhovich normal cone $N(\mathrm{Gr}(F), \cdot)$;*

(ii′) *F is weakly $\mathcal{L}$-subsmooth at (a, b) if F^{-1} is weakly L-subsmooth at (b, a).*

It is clear that the subsmoothness of F at (a, b) implies both the L-subsmoothness and the $\mathcal{L}$-subsmoothness of F at (a, b) and that the L-subsmoothness implies the weak L-subsmoothness.

Below we provide some sufficient conditions for subsmoothness of multifunctions.

PROPOSITION 3.3. *Suppose that F is defined by $F(x) = g(x) + \Omega$ for all $x \in X$, where $g : X \to Y$ is a smooth function and Ω is a closed subset of Y. Let $(a, b) \in \mathrm{Gr}(F)$. Then the following assertions hold.*

(i) $T_c(\mathrm{Gr}(F), (a, b)) = \{(u, v) \in X \times Y : \ v \in g'(a)(u) + T_c(\Omega, b - g(a))\}$.

(ii) $N_c(\mathrm{Gr}(F), (a, b)) = \{(-(g'(a))^*(y^*), y^*) \in X^* \times Y^* : \ y^* \in N_c(\Omega, b - g(a))\}$.

(iii) *If, in addition, Ω is subsmooth at $b - g(a)$, F is subsmooth at (a, b).*

Proof. (i) Let $(u, v) \in T_c(\mathrm{Gr}(F), (a, b))$ and take sequences $\omega_n \xrightarrow{\Omega} b - g(a)$ and $t_n \downarrow 0$. Then $(a, g(a) + \omega_n) \xrightarrow{\mathrm{Gr}(F)} (a, b)$ and hence there exists a sequence $\{(u_n, v_n)\}$ converging to (u, v) such that for all $n \in \mathbb{N}$,

$$(a, g(a) + \omega_n) + t_n(u_n, v_n) \in \mathrm{Gr}(F),$$

that is, $g(a) + \omega_n + t_n v_n \in g(a + t_n u_n) + \Omega$. This means that

$$\omega_n + t_n \left(v_n - \frac{g(a + t_n u_n) - g(a)}{t_n} \right) \in \Omega \quad \forall n \in \mathbb{N}.$$

Since $v_n - \frac{g(a+t_n u_n)-g(a)}{t_n} \to v - g'(a)(u)$, we obtain that $v - g'(a)(u) \in T_c(\Omega, b - g(a))$. This shows that the set on the left-hand side of (i) is contained in the set on the right-hand side. To prove the converse inclusion, let $u \in X$ and $v \in g'(a)(u) + T_c(\Omega, b - g(a))$; take arbitrary sequences $(x_n, y_n) \xrightarrow{\mathrm{Gr}(F)} (a, b)$ and $t_n \downarrow 0$. Then there exists a sequence $\{\omega_n\}$ in Ω such that $\omega_n = y_n - g(x_n) \to b - g(a)$, and so there exists a sequence $\{\tilde{\omega}_n\}$ in Ω such that $\frac{\tilde{\omega}_n - \omega_n}{t_n} \to v - g'(a)(u)$. By the smoothness of g, it follows that

$$v_n := \frac{g(x_n + t_n u) - g(x_n)}{t_n} + \frac{\tilde{\omega}_n - \omega_n}{t_n} \to v.$$

Note that, for each $n \in \mathbb{N}$,

$$y_n + t_n v_n = g(x_n) + \omega_n + t_n v_n = g(x_n + t_n u) + \tilde{\omega}_n \in F(x_n + t_n u),$$

that is, $(x_n, y_n) + t_n(u, v_n) \in \mathrm{Gr}(F)$. Therefore $(u, v) \in T_c(\mathrm{Gr}(F), (a, b))$. This shows that the converse inclusion holds.

(ii) This follows easily from (i).

(iii) Let $\varepsilon > 0$. Since g is smooth, there exist $M, r \in (0, +\infty)$ such that

$$\|g(x) - g(u)\| \le M\|x - u\| \quad \forall x, u \in B(a, r) \tag{3.2}$$

and

$$\|g(x) - g(u) - g'(u)(x - u)\| \le \frac{\varepsilon}{2}\|x - u\| \quad \forall x, u \in B(a, r). \tag{3.3}$$

By the subsmoothness of Ω at $b - g(a)$, there exists $\delta_1 > 0$ such that

$$\langle z^*, y - z\rangle \le \frac{\varepsilon}{2(1 + M)}\|y - z\| \tag{3.4}$$

whenever $y, z \in \Omega \cap B(b - g(a), \delta_1)$ and $z^* \in N_c(\Omega, z) \cap B_{Y^*}$. By the continuity of g and the definition of F, there exists $\delta \in (0,\ r)$ such that

$$y - g(x) \in \Omega \cap B(b - g(a), \delta_1) \quad \forall (x, y) \in \mathrm{Gr}(F) \cap B((a, b), \delta). \tag{3.5}$$

Let $(x, y), (u, v) \in \mathrm{Gr}(F) \cap B((a, b), \delta)$ and $(u^*, v^*) \in N_c(\mathrm{Gr}(F), (u, v)) \cap (B_{X^*} \times B_{Y^*})$. Then, by (ii), $u^* = -(g'(u))^*(v^*)$ and $v^* \in N_c(\Omega, v - g(u)) \cap B_{Y^*}$. Thanks to (3.5), one can apply (3.4) to $y - g(x), v - g(u)$ in place of y, z and conclude that

$$\langle v^*, y - g(x) - (v - g(u))\rangle \le \frac{\varepsilon}{2(1 + M)}\|y - g(x) - (v - g(u))\|;$$

it follows from (3.3) and (3.2) that

$$\begin{aligned}
\langle (u^*, v^*), (x, y) - (u, v)\rangle &= \langle v^*, -g'(u)(x - u) + y - v\rangle \\
&\le \langle v^*, -(g(x) - g(u)) + y - v\rangle + \frac{\varepsilon\|x - u\|}{2} \\
&\le \frac{\varepsilon}{2(1 + M)}\|y - v - g(x) + g(u)\| + \frac{\varepsilon}{2}\|x - u\| \\
&\le \frac{\varepsilon}{2(1 + M)}\|y - v\| + \left(\frac{\varepsilon M}{2(M + 1)} + \frac{\varepsilon}{2}\right)\|x - u\| \\
&\le \varepsilon(\|x - u\| + \|y - v\|).
\end{aligned}$$

This shows that F is subsmooth at (a, b). The proof is complete.

In the case when $g'(a)$ is surjective, Proposition 3.3 can be strengthened as follows.

PROPOSITION 3.4. *Suppose that $F : X \rightrightarrows Y$ is defined by $F(x) = G(g(x))$ for all $x \in X$, where $g : X \to Z$ is a smooth function and $G : Z \rightrightarrows Y$ is a closed multifunction. Let $(a, b) \in \mathrm{Gr}(F)$. Suppose that $g'(a)$ is surjective and that G is $\mathcal{L}$-subsmooth (resp., subsmooth) at $(g(a), b)$. Then F is $\mathcal{L}$-subsmooth (resp., subsmooth) at (a, b).*

To prove Proposition 3.4, we need the following lemma, which is of some independent interest.

LEMMA 3.5. *Let Θ be a closed subset of Y. Let $g : X \to Y$ be strictly differentiable at $\bar{x} \in g^{-1}(\Theta)$ and suppose that $g'(\bar{x})$ is surjective. Then*

$$T_c(g^{-1}(\Theta), \bar{x}) = (g'(\bar{x}))^{-1}(T_c(\Theta, g(\bar{x}))) \tag{3.6}$$

and

$$N_c(g^{-1}(\Theta),\bar{x}) = g'(\bar{x})^*(N_c(\Theta, g(\bar{x}))). \tag{3.7}$$

Proof. Let $h \in T_c(g^{-1}(\Theta),\bar{x})$ and take any sequences $y_n \overset{\Theta}{\to} g(\bar{x})$ and $t_n \downarrow 0$. By our assumptions on $\bar{x}$, the Lyusternik–Graves theorem (cf. [24, Theorem 1.57]) can be applied and so there exists $\mu \in (0, +\infty)$ such that for all large enough n,

$$d(\bar{x}, g^{-1}(y_n)) \le \mu\|g(\bar{x}) - y_n\|.$$

It follows that there exists $x_n \in g^{-1}(y_n) \subset g^{-1}(\Theta)$ such that $x_n \to \bar{x}$. Since $h \in T_c(g^{-1}(\Theta),\bar{x})$, there exists a sequence $h_n \to h$ such that $x_n + t_n h_n \in g^{-1}(\Theta)$ for all n. On the other hand, the strict differentiability assumption implies that

$$g(x_n + t_n h_n) = y_n + g'(\bar{x})(t_n h_n) + t_n\|h_n\|\alpha_n, \tag{3.8}$$

where $\{\alpha_n\}$ is a sequence in Y converging to 0. Since $g'(\bar{x})$ is surjective, the open mapping theorem implies that there exists a sequence $\{u_n\}$ in X converging to 0 such that $g'(\bar{x})(u_n) = \alpha_n$. Hence $g'(\bar{x})(h_n + \|h_n\|u_n) \to g'(\bar{x})(h)$. Noting (by (3.8)) that

$$y_n + t_n g'(\bar{x})(h_n + \|h_n\|u_n) = g(x_n + t_n h_n) \in \Theta,$$

it follows that $g'(\bar{x})(h) \in T_c(\Theta, g(\bar{x}))$. Therefore,

$$T_c(g^{-1}(\Theta),\bar{x}) \subset (g'(\bar{x}))^{-1}(T_c(\Theta, g(\bar{x}))).$$

Conversely, let $u \in (g'(\bar{x}))^{-1}(T_c(\Theta, g(\bar{x})))$. Then $g'(\bar{x})(u) \in T_c(\Theta, g(\bar{x}))$. To prove (3.6), we have to show that $u \in T_c(g^{-1}(\Theta),\bar{x})$. To do this, let $x_n \overset{g^{-1}(\Theta)}{\longrightarrow} \bar{x}$ and $t_n \searrow 0$. Then $g(x_n) \overset{\Theta}{\to} g(\bar{x})$. Hence, there exists a sequence $v_n \to g'(\bar{x})(u)$ such that $g(x_n) + t_n v_n \in \Theta$ for all n. By the Lyusternik–Graves theorem, we assume without loss of generality that

$$d(x_n + t_n u, g^{-1}(g(x_n) + t_n v_n)) \le \mu\|g(x_n + t_n u) - g(x_n) - t_n v_n\| \tag{3.9}$$

for some $\mu \in (0, +\infty)$ and all $n \in \mathbb{N}$. By the strict differentiability of g at $\bar{x}$,

$$g(x_n + t_n u) - g(x_n) = g'(\bar{x})(t_n u) + o(t_n).$$

This and (3.9) imply that there exists $\tilde{x}_n$ with

$$\tilde{x}_n \in g^{-1}(g(x_n) + t_n v_n) \subset g^{-1}(\Theta)$$

such that

$$\|x_n + t_n u - \tilde{x}_n\| \le 2\mu(t_n\|g'(\bar{x})(u) - v_n\| + \|o(t_n)\|).$$

Then $u_n := \frac{\tilde{x}_n - x_n}{t_n} \to u$ and $x_n + t_n u_n = \tilde{x}_n \in g^{-1}(\Theta)$. This shows that $u \in T_c(g^{-1}(\Theta),\bar{x})$ as required to show. Since $g'(\bar{x})(X) = Y$, (3.7) is immediate from (3.6) and [39, Corollary 2.8.4 (ii)] (applied to $g'(\bar{x}), X, T_c(\Theta, g(\bar{x}))$ in place of A, L, M). The proof is complete.

Remark 3.1. Our formula (3.7) was inspired by Mordukhovich [24, Corollary 1.15] where the same relation was established but for Fréchet normal cones in place of Clarke normal cones. In the literature, study on the calculus of the Clarke tangent cone and

normal cone seems to be quite scarce. Nevertheless, Clarke [4, p. 108, Corollary 1] did prove the same formula but required that $g'(\bar{x})(X) \cap \operatorname{int}(T_c(\Theta, g(\bar{x})) \neq \emptyset$ and that Θ admit a hypertangent vector at $g(\bar{x})$, namely, there exist $v \in Y$ and $r > 0$ such that

$$B(g(\bar{x}), r) \cap \Theta + tB(v, r) \subset \Theta \ \ \forall t \in (0,\ r).$$

For Proposition 3.4, we shall also need the following lemma.

LEMMA 3.6. *Let $g : X \to Z$ be smooth and $a \in X$, and suppose that $g'(a)$ is surjective. Then there exist $l, r \in (0,\ +\infty)$ such that*

$$lB_Z \subset g'(u)(B_X) \ \text{ and } \ l\|z^*\| \leq \|(g'(u))^*(z^*)\| \quad \forall u \in B(a, r) \text{ and } \forall z^* \in Z^*. \tag{3.10}$$

Proof. We need only show that the inclusion in (3.10) holds for some $l, r \in (0,\ +\infty)$ (the inequality then follows easily). By the surjectivity assumption and the open mapping theorem, there exists $l \in (0,\ +\infty)$ such that $2lB_Z \subset g'(a)(B_X)$; by the smoothness of g, there exists $r > 0$ such that $\|g'(u) - g'(a)\| < \frac{l}{2}$ for all $u \in B(a, r)$. Hence,

$$2lB_Z \subset (g'(u) + (g'(a) - g'(u)))(B_X) \subset g'(u)(B_X) + \frac{l}{2}B_Z \quad \forall u \in B(a, r).$$

By the Radstrom cancellation lemma (cf. [42, Lemma 2.3]), this implies that

$$\frac{3l}{2}B_Z \subset \operatorname{cl}(g'(u)(B_X)) \quad \forall u \in B(a, r). \tag{3.11}$$

Since X, Z are Banach spaces and $g'(u)$ is a bounded linear operator from X to Z, $g'(u)(B_X)$ and $\operatorname{cl}(g'(u)(B_X))$ have the same interior (by [15, p. 183, Theorem A.1]). It follows from (3.11) that the inclusion in (3.10) holds. This completes the proof.

Proof of Proposition 3.4. We shall prove only the assertion regarding the $\mathcal{L}$-subsmoothness (the corresponding assertion regarding the subsmoothness can be proved similarly). By the smoothness and surjectivity assumption and Lemma 3.6, there exist $M, l, r \in (0,\ +\infty)$ such that (3.2) and (3.10) hold. Suppose that G is $\mathcal{L}$-subsmooth at $(g(a), b)$. Let $\varepsilon > 0$ and $\sigma := \frac{l\varepsilon}{(l+1)(M+1)}$. Then there exists $\eta > 0$ such that

$$\langle w^*, z - w\rangle + \langle v^*, y - b\rangle \leq \sigma(\|z - w\| + \|y - b\|)$$

for any $w \in G^{-1}(b) \cap B(g(a), \eta)$, $(w^*, v^*) \in N_c(\operatorname{Gr}(G), (w, b)) \cap (B_{Z^*} \times B_{Y^*})$, and $(z, y) \in \operatorname{Gr}(G)$ with $\|z - g(a)\| + \|y - b\| \leq \eta$. On the other hand, the smoothness of g implies that there exists $\delta \in (0,\ r)$ such that

$$\|g(x) - g(u) - g'(u)(x - u)\| \leq \sigma\|x - u\| \quad \forall x, u \in B(a, \delta), \tag{3.12}$$
$$g(B(a, \delta)) \subset B(g(a), \eta),$$

and

$$\|x - a\| + \|y - b\| < \delta \Longrightarrow \|g(x) - g(a)\| + \|y - b\| < \eta.$$

Let $u \in F^{-1}(b) \cap B(a, \delta)$. Then $g(u) \in G^{-1}(b) \cap B(g(a), \eta)$ and hence

$$\langle w^*, g(x) - g(u)\rangle + \langle v^*, y - b\rangle \leq \sigma(\|g(x) - g(u)\| + \|y - b\|) \tag{3.13}$$

for any $(w^*, v^*) \in N_c(\mathrm{Gr}(G), (g(u), b)) \cap (B_{Z^*} \times B_{Y^*})$ and $(x, y) \in \mathrm{Gr}(F)$ with $\|x - a\| + \|y - b\| < \delta$. Let $\tilde{g} : X \times Y \to Z \times Y$ be defined by $\tilde{g}(x, y) = (g(x), y)$ for all $(x, y) \in X \times Y$. Then $\tilde{g}$ is smooth and $\tilde{g}'(u, b)(B_X \times B_Y) = g'(u)(B_X) \times B_Y$; hence $\tilde{g}'(u, b)$ is surjective (by the first equality of (3.10)). Noting that $\mathrm{Gr}(F) = \tilde{g}^{-1}(\mathrm{Gr}(G))$, it follows from Lemma 3.5 that $N_c(\mathrm{Gr}(F), (u, b)) = (\tilde{g}'(u, b))^*(N_c(\mathrm{Gr}(G), (g(u), b)))$. This and the definition of $\tilde{g}$ imply that

$$N_c(\mathrm{Gr}(F), (u, b)) = \{((g'(u))^*(z^*), y^*) : \ (z^*, y^*) \in N_c(\mathrm{Gr}(G), (g(u), b))\}.$$

Now let $(u^*, y^*) \in N_c(\mathrm{Gr}(F), (u, b)) \cap (B_{X^*} \times B_{Y^*})$. Then there exists $z^* \in Z^*$ such that $u^* = (g'(u))^*(z^*)$ and $(z^*, y^*) \in N_c(\mathrm{Gr}(G), (g(u), b))$. It follows from (3.10) that $\|z^*\| \le \frac{1}{l}$. Thus, applying (3.13) (with $\frac{l}{1+l}(z^*, y^*)$ in place of (w^*, v^*)) and making use of (3.2), one has

$$\begin{aligned} \langle z^*, g(x) - g(u)\rangle + \langle y^*, y - b\rangle &\le \frac{\sigma(l+1)}{l}(\|g(x) - g(u)\| + \|y - b\|) \\ &\le \frac{\sigma(l+1)}{l}(M\|x - u\| + \|y - b\|) \end{aligned} \tag{3.14}$$

for any $(x, y) \in \mathrm{Gr}(F)$ with $\|x - a\| + \|y - b\| < \delta$. Moreover, (3.12) entails that for any $x \in B(a, \delta)$,

$$\begin{aligned} -\frac{\sigma}{l}\|x - u\| &\le \langle z^*, g(x) - g(u) - g'(u)(x - u)\rangle \\ &= \langle z^*, g(x) - g(u)\rangle - \langle u^*, x - u\rangle. \end{aligned}$$

This and (3.14) imply that

$$\begin{aligned} \langle u^*, x - u\rangle + \langle y^*, y - b\rangle &\le \frac{\sigma(l+1)(M+1)}{l}(\|x - u\| + \|y - b\|) \\ &= \varepsilon(\|x - u\| + \|y - b\|) \end{aligned}$$

for any $(x, y) \in \mathrm{Gr}(F)$ with $\|x - a\| + \|y - b\| < \delta$. This shows that F is $\mathcal{L}$-subsmooth at (a, b). The proof is complete.

Note that every closed convex multifunction is subsmooth at each point of its graph. The following corollary is immediate from Proposition 3.4.

COROLLARY 3.7. *Suppose that F is defined by $F = G \circ g$, namely, $F(x) = G(g(x))$ for all $x \in X$, where $g : X \to Z$ is a smooth function and $G : Z \rightrightarrows Y$ is a closed convex multifunction. Let $(a, b) \in \mathrm{Gr}(F)$ and suppose that $g'(a)$ is surjective. Then F is subsmooth at (a, b).*

4. Calmness for multifunctions. Throughout this section, let $M : Y \rightrightarrows X$ be a closed multifunction. We also fix (arbitrary) $\bar{y} \in Y$ and $\bar{x} \in M(\bar{y})$.

It is easy to verify that M is calm at $(\bar{y}, \bar{x})$ if and only if there exist $\tau, \delta \in (0, +\infty)$ such that

$$M(y) \cap B(\bar{x}, \delta) \subset M(\bar{y}) + \tau\|y - \bar{y}\|B_X \ \ \forall\ y \text{ close to } \bar{y}. \tag{4.1}$$

Motivated by the notion of linear cover property (cf. [7, 23, 28]), let us say that a multifunction $\Phi : X \rightrightarrows Y$ has the linear cover-like property at $(\bar{x}, \bar{y})$ if there exists $\tau \in (0, +\infty)$ such that for all x close to $\bar{x}$ and $r > 0$

$$\bar{y} \in \Phi(x) + \mathrm{int}(rB_Y) \implies \bar{y} \in \Phi(x + \mathrm{int}(\tau r B_X)). \tag{4.2}$$

In terms of (4.1) and (4.2), the following proposition provides formulas for the calmness modulus $\eta(M;\bar{y},\bar{x})$ (which is defined by (1.5)); we omit its proof as it is immediate from the related definitions.

PROPOSITION 4.1.

$$\begin{aligned}\eta(M;\bar{y},\bar{x}) &= \inf\{\tau>0:\ (4.1)\text{ holds for some }\delta>0\}\\ &= \inf\{\tau>0:\ (4.2)\text{ holds with }\Phi=M^{-1}\ \forall\ r>0\text{ and }\forall\ x\text{ close to }\bar{x}\}.\end{aligned}$$

The remainder of this section is devoted to a study on the duality aspect of the calmness. We divide our discussion into two subsections addressing the necessary conditions and the sufficient conditions for calmness.

4.1. Necessary conditions for calmness. There are two results in this subsection: one is on the Banach space setting and the other on the Asplund spaces.

THEOREM 4.2. *Suppose that there exist* $\eta,\delta\in(0,\ +\infty)$ *such that* (1.1) *holds. Then*

$$\hat{N}(M(\bar{y}),u)\cap B_{X^*}\subset \eta D^*_cM^{-1}(u,\bar{y})(B_{Y^*})\quad\forall u\in M(\bar{y})\cap B(\bar{x},\delta). \tag{4.3}$$

Proof. Let $\mathcal{I}_{\mathrm{Gr}(M^{-1})}$ denote the indicator function of $\mathrm{Gr}(M^{-1})$. Then (1.1) can be rewritten as

$$d(x,M(\bar{y}))\le \mathcal{I}_{\mathrm{Gr}(M^{-1})}(x,y)+\eta\|y-\bar{y}\|\quad\forall(x,y)\in B(\bar{x},\delta)\times B(\bar{y},\delta). \tag{4.4}$$

Let $u\in M(\bar{y})\cap B(\bar{x},\delta)$ and $u^*\in\hat{N}(M(\bar{y}),u)\cap B_{X^*}$. Noting (cf. [24, Corollary 1.96]) that $\hat{N}(M(\bar{y}),u)\cap B_{X^*}=\hat{\partial}d(\cdot,M(\bar{y})))(u)$, it follows that for any $\sigma>0$ there exists $r\in(0,\ \delta)$ such that $B(u,r)\subset B(\bar{x},\delta)$ and

$$\langle u^*,x-u\rangle\le d(x,M(\bar{y}))+\sigma\|x-u\|\quad\forall x\in B(u,r). \tag{4.5}$$

Hence, by (4.4),

$$\langle u^*,x-u\rangle\le \mathcal{I}_{\mathrm{Gr}(M^{-1})}(x,y)+\eta\|y-\bar{y}\|+\sigma\|x-u\|\quad\forall(x,y)\in B(u,r)\times B(\bar{y},\delta),$$

that is, $(u,\bar{y})$ is a local minimizer of ϕ defined by

$$\phi(x,y):=-\langle u^*,x-u\rangle+\mathcal{I}_{\mathrm{Gr}(M^{-1})}(x,y)+\eta\|y-\bar{y}\|+\sigma\|x-u\|\quad\forall(x,y)\in X\times Y.$$

Hence, $(0,0)\in\partial_c\phi(u,\bar{y})$. It follows from [4, Theorem 2.9.8] that

$$(0,0)\in(-u^*,0)+N_c(\mathrm{Gr}(M^{-1}),(u,\bar{y}))+\{0\}\times\eta B_{Y^*}+(\sigma B_{X^*})\times\{0\},$$

that is,

$$(u^*+\sigma x^*_\sigma,-\eta y^*_\sigma)\in N_c(\mathrm{Gr}(M^{-1}),(u,\bar{y}))$$

for some $x^*_\sigma\in B_{X^*}$ and $y^*_\sigma\in B_{Y^*}$. Since B_{Y^*} is weak* compact, without loss of generality we can assume $(u^*+\sigma x^*_\sigma,-\eta y^*_\sigma)\overset{w^*}{\to}(u^*,-\eta v^*)$ for some v^* in B_{Y^*} as $\sigma\to 0^+$. Hence $(u^*,-\eta v^*)\in N_c(\mathrm{Gr}(M^{-1}),(u,\bar{y}))$ (because $N_c(\mathrm{Gr}(M^{-1}),(u,\bar{y}))$ is weak*-closed). This implies that

$$u^*\in D^*_cM^{-1}(u,\bar{y})(\eta v^*)\subset\eta D^*_cM^{-1}(u,\bar{y})(B_{Y^*}).$$

This shows that (4.3) holds. The proof is complete.

When Y, X are Asplund spaces, the conclusion in Theorem 4.2 can be strengthened with $\hat{N}(M(\bar{y}), u)$ and $D_c^* M^{-1}(u, \bar{y})$ replaced, respectively, by $N(M(\bar{y}), u)$ and $D^* M^{-1}(u, \bar{y})$.

THEOREM 4.3. *Suppose that Y, X are Asplund spaces and that there exist $\eta, \delta \in (0, +\infty)$ such that (1.1) holds. Then*

$$N(M(\bar{y}), u) \cap B_{X^*} \subset \eta D^* M^{-1}(u, \bar{y})(B_{Y^*}) \quad \forall u \in M(\bar{y}) \cap B(\bar{x}, \delta). \tag{4.6}$$

Proof. Let $u \in M(\bar{y}) \cap B(\bar{x}, \delta)$ and $u^* \in B_{X^*} \cap N(M(\bar{y}), u)$. Then there exist sequences $\{u_n\}$ in $M(\bar{y}) \cap B(\bar{x}, \delta)$ and $\{u_n^*\}$ in X^* such that

$$u_n \to u, \quad u_n^* \xrightarrow{w^*} u^*, \ \text{ and } \ u_n^* \in \hat{N}(M(\bar{y}), u_n) \quad \forall n \in \mathbb{N}.$$

Similar to the proof of (4.5), there exists $r \in (0, \delta)$ such that $B(u_n, r) \subset B(\bar{x}, \delta)$ and

$$\langle u_n^*, x - u_n \rangle \le d(x, M(\bar{y})) + \frac{1}{n}\|x - u_n\| \quad \forall x \in B(u_n, r).$$

Letting

$$\phi(x, y) := -\langle u_n^*, x - u_n \rangle + \mathcal{I}_{\mathrm{Gr}(M^{-1})}(x, y) + \eta\|y - \bar{y}\| + \frac{1}{n}\|x - u_n\| \quad \forall (x, y) \in X \times Y,$$

from the corresponding part of the proof of Theorem 4.2, it follows that $(u_n, \bar{y})$ is a local minimizer of ϕ. This and [24, Theorem 2.33] imply that there exists $(w_n, y_n) \in \mathrm{Gr}(M^{-1})$ such that $\|w_n - u_n\| + \|y_n - \bar{y}\| < \frac{1}{n}$ and

$$(0, 0) \in (-u_n^*, 0) + \hat{N}(\mathrm{Gr}(M^{-1}), (w_n, y_n)) + \{0\} \times \eta B_{Y^*} + \frac{2}{n}(B_{X^*} \times B_{Y^*}).$$

Therefore, $(w_n, y_n) \to (u, \bar{y})$ and there exist $x_n^* \in B_{X^*}$ and $y_n^*, v_n^* \in B_{Y^*}$ such that

$$\left(u_n^* + \frac{2}{n}x_n^*, -\eta y_n^* - \frac{2}{n}v_n^*\right) \in \hat{N}(\mathrm{Gr}(M^{-1}), (w_n, y_n)).$$

Since B_{Y^*} is sequentially weak*-compact (as Y is an Asplund space), we can assume that $y_n^* \xrightarrow{w^*} y^* \in B_{Y^*}$ as $n \to \infty$. It follows that $(u^*, -\eta y^*) \in N(\mathrm{Gr}(M^{-1}), (u, \bar{y}))$ and so $u^* \in D^* M^{-1}(u, \bar{y})(\eta y^*)$. Therefore, (4.6) holds. The proof is complete.

Remark 4.1. In Asplund spaces, the limiting subdifferential enjoys, like the Clarke subdifferential, the full sum rule, but, on the other hand, the Mordukhovich normal cone is not necessarily weak*-closed. This is why the last part of the proof of Theorem 4.3 differs from that of Theorem 4.2.

4.2. Sufficient conditions for calmness of L-subsmooth multifunctions. Under a suitable L-subsmoothness assumption, we show in the next result that a slightly stronger condition than (4.3) turns out to be sufficient for calmness.

THEOREM 4.4. *Suppose that M is L-subsmooth (resp., weakly L-subsmooth) at $(\bar{y}, \bar{x})$ and that there exist $\eta, \delta \in (0, +\infty)$ such that*

$$N_c(M(\bar{y}), u) \cap B_{X^*} \subset \eta D_c^* M^{-1}(u, \bar{y})(B_{Y^*}) \quad \forall u \in \mathrm{bd}(M(\bar{y})) \cap B(\bar{x}, \delta) \tag{4.7}$$

$$(\textit{resp.}, \ N_c(M(\bar{y}), u) \cap B_{X^*} \subset \eta D^* M^{-1}(u, \bar{y})(B_{Y^*}) \quad \forall u \in \mathrm{bd}(M(\bar{y})) \cap B(\bar{x}, \delta)).$$

Then M is calm at $(\bar{y},\bar{x})$ and, more precisely, for any $\varepsilon \in (0,\ \frac{1}{1+\eta})$ there exists $\delta_\varepsilon > 0$ such that

$$d(x,M(\bar{y})) \le \frac{\eta+(1+\eta)\varepsilon}{1-(1+\eta)\varepsilon}\|y-\bar{y}\| \quad \forall y \in B(\bar{y},\delta_\varepsilon) \text{ and } \forall x \in M(y)\cap B(\bar{x},\delta_\varepsilon). \tag{4.8}$$

Proof. We provide only the proof for the assertion under the L-subsmoothness assumption (the proof for the other part is similar). Let $\varepsilon \in (0,\ \frac{1}{1+\eta})$. Then, by the L-subsmoothness assumption, there exists $\delta_\varepsilon \in (0,\ \frac{\delta}{2})$ such that

$$-\langle v^*, y-\bar{y}\rangle + \langle u^*, x-u\rangle \le \varepsilon(\|y-\bar{y}\|+\|x-u\|) \tag{4.9}$$

whenever $y \in B(\bar{y},2\delta_\varepsilon)$, $x \in M(y)\cap B(\bar{x},2\delta_\varepsilon)$, $u \in M(\bar{y})\cap B(\bar{x},2\delta_\varepsilon)$, $v^* \in B_{Y^*}$, and $u^* \in D_c^*M^{-1}(u,\bar{y})(v^*)\cap B_{X^*}$. To verify (4.8), let $y \in B(\bar{y},\delta_\varepsilon)$ and $x \in M(y)\cap (B(\bar{x},\delta_\varepsilon)\setminus M(\bar{y}))$. Then $d(x,M(\bar{y})) \le \|x-\bar{x}\| < \delta_\varepsilon$. Let

$$\gamma \in \left(\max\left\{\frac{d(x,M(\bar{y}))}{\delta_\varepsilon}, (1+\eta)\varepsilon, \frac{1}{2}\right\},\ 1\right).$$

By Lemma 2.1 there exist $u \in \mathrm{bd}(M(\bar{y}))$ and $u^* \in N_c(M(\bar{y}),u)$ with $\|u^*\| = 1$ such that

$$\gamma\|x-u\| \le \min\{\langle u^*, x-u\rangle, d(x,M(\bar{y}))\}. \tag{4.10}$$

Thus, $\|x-u\| \le \frac{d(x,M(\bar{y}))}{\gamma} < \delta_\varepsilon$. Hence

$$\|u-\bar{x}\| \le \|u-x\| + \|x-\bar{x}\| < 2\delta_\varepsilon < \delta.$$

By (4.7), there exists $v^* \in \eta B_{Y^*}$ such that $u^* \in D_c^*M^{-1}(u,\bar{y})(v^*)$. Applying (4.9) with $(\frac{u^*}{1+\eta}, \frac{v^*}{1+\eta})$ in place of (u^*,v^*), it follows that

$$-\langle v^*, y-\bar{y}\rangle + \langle u^*, x-u\rangle \le (1+\eta)\varepsilon(\|y-\bar{y}\|+\|x-u\|)$$

and so

$$\begin{aligned}\langle u^*, x-u\rangle - (1+\eta)\varepsilon\|x-u\| &\le \langle v^*, y-\bar{y}\rangle + (1+\eta)\varepsilon\|y-\bar{y}\| \\ &\le (\eta+(1+\eta)\varepsilon)\|y-\bar{y}\|.\end{aligned}$$

This and (4.10) imply that

$$(\gamma-(1+\eta)\varepsilon)\|x-u\| \le (\eta+(1+\eta)\varepsilon)\|y-\bar{y}\|$$

and hence

$$d(x,M(\bar{y})) \le \frac{\eta+(1+\eta)\varepsilon}{\gamma-(1+\eta)\varepsilon}\|y-\bar{y}\|$$

(because $u \in M(\bar{y})$). Letting $\gamma \to 1$, it follows that (4.8) holds. The proof is complete.

The following example shows that the L-subsmoothness assumption cannot be dropped in Theorem 4.4.

Example 4.5. Let $X = Y = R$ and let

$$\Omega_1 = \{(s,t) \in R^2 :\ s^2 + (t-1)^2 \le 1 \text{ and } (s-1)^2 + t^2 \le 1\},$$
$$\Omega_2 = \{(s,t) \in R^2 :\ s^2 + (t+1)^2 \le 1 \text{ and } (s-1)^2 + t^2 \le 1\},$$
$$\Omega_3 = \{(s,t) \in R^2 :\ (s+1)^2 + t^2 \le 1 \text{ and } s^2 + (t+1)^2 \le 1\},$$
$$\Omega_4 = \{(s,t) \in R^2 :\ (s+1)^2 + t^2 \le 1 \text{ and } s^2 + (t-1)^2 \le 1\}.$$

Define the multifunction $M : Y \rightrightarrows X$ such that $\mathrm{Gr}(M) = \bigcup_{i=1}^4 \Omega_i$. Then $M(0) = \{0\}$ and so $N_c(M(0), 0) = X^*$. It is easy to verify that $N_c(\mathrm{Gr}(M), (0,0)) = X^* \times Y^*$. Hence

$$N_c(M(0),0) \cap B_{X^*} = B_{X^*} \subset \tau D_c^* M^{-1}(0,0)(B_{Y^*}) = X^* \quad \forall \tau \in (0,\ +\infty).$$

On the other hand, note that

$$\frac{1}{n} \in M\left(\frac{1}{n^2\left(1+\sqrt{1-\frac{1}{n^2}}\right)}\right) \quad \text{and} \quad \frac{d(\frac{1}{n}, M(0))}{\left\|\frac{1}{n^2\left(1+\sqrt{1-\frac{1}{n^2}}\right)} - 0\right\|} \to +\infty.$$

Hence M is not calm at $(0,0)$.

Recall [43] that M is strongly calm at $(\bar{y}, \bar{x})$ if there exist $\eta, \delta \in (0,\ +\infty)$ such that

$$\|x - \bar{x}\| \le \eta \|y - \bar{y}\| \quad \forall y \in B(\bar{y}, \delta) \text{ and } x \in M(y) \cap B(\bar{x}, \delta).$$

It is clear that M is strongly calm at $(\bar{y}, \bar{x})$ if and only if $\bar{x}$ is an isolated point of $M(\bar{y})$ (i.e., $M(\bar{y}) \cap B(\bar{x}, r) = \{\bar{x}\}$ for some $r > 0$) and M is calm at $(\bar{y}, \bar{x})$.

COROLLARY 4.6. *Suppose that M satisfies condition* (S) *at $(\bar{y}, \bar{x})$. Then M is strongly calm at $(\bar{y}, \bar{x})$ if and only if*

$$D_c^* M^{-1}(\bar{x}, \bar{y})(Y^*) = X^*. \tag{4.11}$$

Proof. Suppose that (4.11) holds. Since $D_c^* M^{-1}(\bar{x}, \bar{y})$ is a closed convex multifunction from Y^* to X^*, (4.11) and the Robinson–Ursescu theorem (cf. [33, 36]) imply that there exists $\eta > 1$ such that

$$\frac{1}{\eta} B_{X^*} \subset D_c^* M^{-1}(\bar{x}, \bar{y})(B_{Y^*}) \cap B_{X^*}. \tag{4.12}$$

Hence, by the Hahn–Banach theorem,

$$\frac{1}{\eta}\|u\| \le \max\{\langle u^*, u\rangle :\ u^* \in D_c^* M^{-1}(\bar{x}, \bar{y})(B_{Y^*}) \cap B_{X^*}\} \quad \forall u \in X. \tag{4.13}$$

Consider $\varepsilon \in (0,\ \frac{1}{\eta})$. The condition (S) assumption implies that there exists $\delta > 0$ such that

$$\langle u^*, x - \bar{x}\rangle \le \varepsilon \|x - \bar{x}\| \quad \forall x \in M(\bar{y}) \cap B(\bar{x}, \delta) \text{ and } \forall u^* \in D_c^* M^{-1}(\bar{x}, \bar{y})(B_{Y^*}) \cap B_{X^*}.$$

It follows from (4.13) that $M(\bar{y}) \cap B(\bar{x}, \delta) = \{\bar{x}\}$. This entails that M is L-subsmooth at $(\bar{y}, \bar{x})$ and (4.7) holds (due to the condition (S) assumption and (4.12), respectively). Therefore, Theorem 4.4 can be applied to conclude that M is calm at $(\bar{y}, \bar{x})$.

Conversely, suppose that M is strongly calm at $(\bar{y},\bar{x})$. Then $M(\bar{y})\cap B(\bar{x},r)=\{\bar{x}\}$ for some $r>0$ (so $\hat{N}(M(\bar{y}),\bar{x})=X^*$), and Theorem 4.2 implies that there exist $\eta,\delta\in(0,\,+\infty)$ such that (4.3) holds and so does (4.11). The proof is complete.

COROLLARY 4.7. *Suppose that Y,X are finite-dimensional and that $\mathrm{Gr}(M)$ is Clarke regular at $(\bar{y},\bar{x})$ (i.e., $T_c(\mathrm{Gr}(M),(\bar{y},\bar{x}))=T(\mathrm{Gr}(M),(\bar{y},\bar{x}))$). Then M is strongly calm at $(\bar{y},\bar{x})$ if and only if $D_c^*M^{-1}(\bar{x},\bar{y})(Y^*)=X^*$.*

Proof. By Corollary 4.6, we need only show that M satisfies condition (S) at $(\bar{y},\bar{x})$. To do this, suppose to the contrary that there exist $\varepsilon_0>0$, a sequence $\{(y_n,x_n)\}$ in $\mathrm{Gr}(M)\setminus\{(\bar{y},\bar{x})\}$, and a sequence $\{(v_n^*,u_n^*)\}$ in $N_c(\mathrm{Gr}(M),(\bar{y},\bar{x}))\cap(B_{Y^*}\times B_{X^*})$ such that $(y_n,x_n)\to(\bar{y},\bar{x})$ and

$$\langle v_n^*,y_n-\bar{y}\rangle+\langle u_n^*,x_n-\bar{x}\rangle>\varepsilon_0(\|y_n-\bar{y}\|+\|x_n-\bar{x}\|)\quad\forall n.$$

Since Y,X are finite-dimensional, we can assume that

$$\frac{(y_n-\bar{y},x_n-\bar{x})}{\|y_n-\bar{y}\|+\|x_n-\bar{x}\|}\to(v,u)\ \text{ and }\ (v_n^*,u_n^*)\to(v^*,u^*)$$

for some $(v,u)\in Y\times X$ and $(v^*,u^*)\in Y^*\times X^*$. Then $\langle v^*,v\rangle+\langle u^*,v\rangle\ge\varepsilon_0$, $(v,u)\in T(\mathrm{Gr}(M),(\bar{y},\bar{x}))$, and $(v^*,u^*)\in N_c(\mathrm{Gr}(M),(\bar{y},\bar{x}))$. This contradicts the Clarke regularity assumption. The proof is complete.

When X is an Asplund space, the assumption in Theorem 4.4 can be weakened with $N_c(M(\bar{y}),u)$ replaced by $\hat{N}(M(\bar{y}),u)$.

THEOREM 4.8. *Suppose that X is an Asplund space and that M is L-subsmooth (resp., weakly L-subsmooth) at $(\bar{y},\bar{x})$ and that there exist $\eta,\delta\in(0,\,+\infty)$ such that*

$$\hat{N}(M(\bar{y}),u)\cap B_{X^*}\subset\eta D_c^*M^{-1}(u,\bar{y})(B_{Y^*})\quad\forall u\in M(\bar{y})\cap B(\bar{x},\delta)$$

$$(\textit{resp.},\ \hat{N}(M(\bar{y}),u)\cap B_{X^*}\subset\eta D^*M^{-1}(u,\bar{y})(B_{Y^*})\quad\forall u\in M(\bar{y})\cap B(\bar{x},\delta)).$$

Then for any $\varepsilon>0$ there exists $\delta_\varepsilon>0$ such that (4.8) *holds.*

The proof of Theorem 4.8 is the same as that of Theorem 4.4, but with the Asplund space version of Lemma 2.1 applied in place of the Banach space version.

Making use of (2.2) and the equivalence

$$x^*\in(D_c^*M(\bar{y},u))^{-1}(y^*)\Leftrightarrow -x^*\in D_c^*M^{-1}(u,\bar{y})(-y^*),$$

it is easy from Theorem 4.2 to verify part (i) of the following corollary. Similarly, part (ii) follows from Theorem 4.4.

COROLLARY 4.9. *The following assertions hold.*

(i) $\eta(M;\bar{y},\bar{x})\ge\limsup_{u\in M(\bar{y}),u\to\bar{x}}\|D_c^*M(\bar{y},u)|_{-\hat{N}(M(\bar{y}),u)}\|^-$.

(ii) *If M is L-subsmooth at $(\bar{y},\bar{x})$, then*

$$\eta(M;\bar{y},\bar{x})\le\limsup_{u\in M(\bar{y}),u\to\bar{x}}\|D_c^*M(\bar{y},u)|_{-N_c(M(\bar{y}),u)}\|^-.$$

Similarly, one can use Theorems 4.3 and 4.8 to show the following corollary.

COROLLARY 4.10. *Suppose that Y,X are Asplund spaces. Then the following assertions hold.*

(i) $\eta(M;\bar{y},\bar{x})\ge\limsup_{u\in M(\bar{y}),u\to\bar{x}}\|D^*M(\bar{y},u)|_{-\hat{N}(M(\bar{y}),u)}\|^-$.

(ii) *If M is weakly L-subsmooth at $(\bar{y},\bar{x})$, then the equality in* (i) *holds.*

Note that, in the Asplund space setting, the Fréchet normal cone $\hat{N}(M(\bar{y}),u)$ is used in Theorem 4.8. However, for the general Banach spaces, one needs to use the

Clarke normal cone $N_c(M(\bar{y}),u)$ in Theorem 4.4; we have only the inequality version in Corollary 4.9(ii) while we have the equality version in Corollary 4.10(ii).

The following result concerns "convex-composite" multifunctions. Optimization problems involving convex-composite functions have been extensively studied (for details, see [16, 30, 35, 37] and the references therein).

THEOREM 4.11. *Suppose that M is defined by $M = g^{-1} \circ G$, namely, $M(y) = g^{-1}(G(y))$ for all $y \in Y$, where $G : Y \rightrightarrows Z$ is a closed convex multifunction and $g : X \to Z$ is a smooth function. Let $(\bar{y},\bar{x}) \in \mathrm{Gr}(M)$ and suppose that $g'(\bar{x})$ is surjective. Then the following assertions hold.*

(i) $\eta(M;\bar{y},\bar{x}) = \limsup_{u\in M(\bar{y}),u\to\bar{x}} \|D^*M(\bar{y},u)|_{-N(M(\bar{y}),u)}\|^-$.

(ii) *If there exist $\eta,\delta \in (0,\ +\infty)$ such that*

$$N(M(\bar{y}),u)\cap B_{X^*} \subset \eta D^*M^{-1}(u,\bar{y})(B_{Y^*}) \quad \forall u \in M(\bar{y})\cap B(\bar{x},\delta), \tag{4.14}$$

then for any $\varepsilon > 0$ there exists $\delta_\varepsilon \in (0,\ \delta)$ such that

$$d(x,M(\bar{y})) \le \frac{\eta}{1-\varepsilon}\|y-\bar{y}\| \tag{4.15}$$

whenever $y \in B(\bar{y},\delta_\varepsilon)$ and $x \in M(y)\cap B(\bar{x},\delta_\varepsilon)$.

Proof. By Corollary 3.7, M^{-1} $(= G^{-1}\circ g)$ is subsmooth at $(\bar{x},\bar{y})$ and so is M at $(\bar{y},\bar{x})$. Let $\tilde{g}(y,x) := (y,g(x))$ for all $(y,x) \in Y \times X$. Then it follows from the surjectivity of $g'(\bar{x})$ that $\tilde{g}'(\bar{y},\bar{x})$ is surjective. By Lemma 3.6, take $r > 0$ such that $g'(u)$ and $\tilde{g}'(y,u)$ are surjective for all $(y,u) \in B(\bar{y},r)\times B(\bar{x},r)$. Noting that $M(\bar{y}) = g^{-1}(G(\bar{y}))$ and $\mathrm{Gr}(M) = \tilde{g}^{-1}(\mathrm{Gr}(G))$, it follows from Lemma 3.5 and [24, Theorem 1.17] that

$$\hat{N}(M(\bar{y}),u) = N(M(\bar{y}),u) = N_c(M(\bar{y}),u) \quad \forall u \in M(\bar{y})\cap B(\bar{x},r) \tag{4.16}$$

and

$$\hat{N}(\mathrm{Gr}(M),(y,u)) = N(\mathrm{Gr}(M),(y,u)) = N_c(\mathrm{Gr}(M),(y,u))$$

for all $(y,u) \in \mathrm{Gr}(M)\cap(B(\bar{y},r)\times B(\bar{x},r))$; hence

$$D^*M(\bar{y},u) = D^*_cM(\bar{y},u) \quad \forall u \in M(\bar{y})\cap B(\bar{x},r).$$

Thus (i) follows from Corollary 4.9.

To prove (ii), let $\eta,\delta \in (0,\ +\infty)$ satisfy (4.14). Let $\varepsilon \in (0,\ 1)$. Then, by the subsmoothness of M at $(\bar{y},\bar{x})$, there exists $\delta_\varepsilon \in (0,\ r)$ such that

$$\langle u^*, x-u\rangle - \langle v^*, y-\bar{y}\rangle \le \varepsilon\|x-u\| \tag{4.17}$$

whenever $y \in B(\bar{y},2\delta_\varepsilon)$, $x \in M(y)\cap B(\bar{x},2\delta_\varepsilon)$, $u \in M(\bar{y})\cap B(\bar{x},2\delta_\varepsilon)$, $v^* \in Y^*$, and $u^* \in D^*M^{-1}(u,\bar{y})(v^*)\cap B_{X^*}$. Let $y \in B(\bar{y},\delta_\varepsilon)$ and $x \in B(\bar{x},\delta_\varepsilon)\setminus M(\bar{y})$. We have to show that (4.15) holds. To do this, let $\gamma \in \big(\max\big\{\frac{d(x,M(\bar{y}))}{\delta_\varepsilon},\ \frac{1}{2}\big\},\ 1\big)$ sufficiently close to 1. By Lemma 2.1, as in the corresponding part of the proof of Theorem 4.4, there exist $u \in \mathrm{bd}(M(\bar{y}))\cap B(\bar{x},2\delta_\varepsilon)$ and $u^* \in N_c(M(\bar{y}),u)$ with $\|u^*\| = 1$ such that (4.10) holds. It follows from (4.14) and (4.16) that there exists $v^* \in \eta B_{Y^*}$ such that $u^* \in D^*M^{-1}(u,\bar{y})(v^*)$. By (4.10) and (4.17), one has

$$(\gamma-\varepsilon)\|x-u\| \le \langle u^*, x-u\rangle - \varepsilon\|x-u\| \le \langle v^*, y-\bar{y}\rangle \le \eta\|y-\bar{y}\|$$

and so $(\gamma-\varepsilon)d(x,M(\bar{y}))\le\eta\|y-\bar{y}\|$. Letting $\gamma\to 1$, it follows that (4.15) holds. The proof is complete.

Remark 4.2. Motivated by (1.4), a natural problem is whether the upper limit

$$\limsup_{u\in M(\bar{y}),u\to\bar{x}}\|D_c^*M(\bar{y},u)|_{-N_c(M(\bar{y}),u)}\|^-$$

in Corollaries 4.9 and 4.10 and Theorem 4.11 can be replaced with

$$\|D_c^*M(\bar{y},\bar{x})|_{-N_c(M(\bar{y}),\bar{x})}\|^-.$$

The answer is negative even when M is convex and X,Y are finite-dimensional. Below we give an example of a closed convex multifunction M between two finite-dimensional spaces such that

$$\|D_c^*M(\bar{x},\bar{y})|_{-N_c(M(\bar{y}),\bar{x})}\|^-=0\quad\text{but}\quad\eta(M;\bar{y},\bar{x})=+\infty.$$

Let $S=\{(u,v)\in R^2:\ u^2+v^2\le 1\}$ and $C=\{(u,v)\in R^2:\ v\le 1\}$. Let $M:R\rightrightarrows R^2$ be defined by

$$M(y):=\{x\in C:\ d^2(x,S)\le y\}\quad\forall y\in R.$$

Then M is a closed convex multifunction (because C and S are closed convex sets). Take $\bar{y}=0$ and $\bar{x}=(0,1)$. Then $S=M(\bar{y})$ and $\bar{x}\in M(\bar{y})$. It is clear that

$$d(x,M(\bar{y})=d(x,S)\ \text{ and }\ x\in M(d^2(x,S))\quad\forall x\in C.$$

This shows that M is not calm at $(\bar{y},\bar{x})$, that is, $\eta(M;\bar{y},\bar{x})=+\infty$. Next we show that $\|D_c^*M(\bar{y},\bar{x})|_{-N_c(M(\bar{y}),\bar{x}))}\|^-=0$. It is easy from the convexity of $M(\bar{y})$ to verify that

$$N_c(M(\bar{y}),\bar{x})=N(S,\bar{x})=N(C,\bar{x})=\{0\}\times R_+.$$

Let $t,r\in(0,\ +\infty)$. Then, for any $x\in C$ and $y\in M^{-1}(x)=[d^2(x,S),\ +\infty)$, one has

$$\langle(0,t),x\rangle-r(y-\bar{y})\le\langle(0,t),\bar{x}\rangle.$$

This and the convexity of M imply that $((0,t),-r)\in N_c(\mathrm{Gr}(M^{-1}),(\bar{x},\bar{y}))$ and so $(0,t)\in D_c^*M^{-1}(\bar{x},\bar{y})(r)$. Since t and r are arbitrary in $(0,\ +\infty)$, $N_c(M(\bar{y}),\bar{x})\subset D_c^*M^{-1}(\bar{x},\bar{y})(r)$. This shows that

$$-N_c(M(\bar{y}),\bar{x})\subset(D_c^*M(\bar{y},\bar{x}))^{-1}(-r)\subset(D_c^*M(\bar{y},\bar{x}))^{-1}(rB_{Y^*})\ \ \forall r>0.$$

It follows from (2.2) that $\|D_c^*M(\bar{y},\bar{x})|_{-N_c(M(\bar{y}),\bar{x})}\|^-=0$.

Nevertheless, in the convex-composite case, $\|D_c^*M(\bar{y},\bar{x})|_{-N_c(M(\bar{y}),\bar{x})}\|^-<+\infty$ does imply the calmness of the sublinear multifunction $D_cM(\bar{y},\bar{x})$. First, we provide a result in a general case.

PROPOSITION 4.12. *Suppose that*

$$T_c(M(\bar{y}),\bar{x})\subset D_cM(\bar{y},\bar{x})(0).\tag{4.18}$$

Then

$$\|D_c^*M(\bar{y},\bar{x})|_{-N_c(M(\bar{y}),\bar{x})}\|^-=\inf\{\eta>0:\ d(x,T_c(M(\bar{y}),\bar{x}))\le\eta\|y\|\ \ \forall y\in Y\ \textit{and}\ x\in D_cM(\bar{y},\bar{x})(y))\}.$$

If, in addition, $\|D_c^*M(\bar{y},\bar{x})_{-N_c(M(\bar{y}),\bar{x})}\|^- < +\infty$, *then*

$$T_c(M(\bar{y}),\bar{x}) = D_cM(\bar{y},\bar{x})(0)$$

and so $\eta(D_cM(\bar{y},\bar{x});0,0) = \|D_c^*M(\bar{y},\bar{x})|_{-N_c(M(\bar{y},\bar{x})}\|^-$.

Proof. Let

$$\eta_* := \inf\{\eta > 0 :\ d(x, T_c(M(\bar{y}),\bar{x})) \le \eta\|y\| \ \ \forall y \in Y \text{ and } x \in D_cM(\bar{y},\bar{x})(y))\}.$$

First, we assume that $\eta_* < \infty$. Consider any $\eta \in (\eta_*,\ \infty)$. Then

$$d(x, T_c(M(\bar{y},\bar{x})) \le \eta\|y\| \ \ \forall y \in Y \text{ and } x \in D_cM(\bar{y},\bar{x})(y).$$

It follows that $D_cM(\bar{y},\bar{x})(0) \subset T_c(M(\bar{y}),\bar{x})$. This and (4.18) imply that

$$T_c(M(\bar{y}),\bar{x}) = D_cM(\bar{y},\bar{x})(0).$$

Hence $\eta(D_c(M(\bar{y};\bar{x}),0,0) = \eta_*$. Noting that $D_cM(\bar{y},\bar{x})$ is a closed convex multifunction, it follows from [43, Theorem 4.3] that

$$\|D_c^*M(\bar{y},\bar{x})|_{-N_c(M(\bar{y}),\bar{x})}\|^- = \|D_c^*(D_cM(\bar{y},\bar{x}))(0,0)|_{-N_c(D_cM(\bar{y},\bar{x})(0),0)}\|^- = \eta_*.$$

It remains to show that $\|D_c^*M(\bar{y},\bar{x})|_{-N_c(M(\bar{y}),\bar{x})}\|^- = +\infty$ if $\eta_* = +\infty$. Suppose that $\|D_c^*M(\bar{y},\bar{x})|_{-N_c(M(\bar{y}),\bar{x})}\|^- < +\infty$. We need only show that $\eta_* < +\infty$. Let $x \in X \setminus T_c(M(\bar{y}),\bar{x})$ and $\gamma \in (0,\ 1)$. By Lemma 2.1 there exist

$$z \in T_c(M(\bar{y}),\bar{x}) \ \text{ and } \ z^* \in N_c(T_c(M(\bar{y}),\bar{x}),z)$$

such that

$$\|z^*\| = 1 \ \text{ and } \ \langle z^*, x-z\rangle \ge \gamma\|x-z\|. \tag{4.19}$$

Noting that $T_c(M(\bar{y}),\bar{x})$ is a convex cone, it is easy to verify that

$$N_c(T_c(M(\bar{y}),\bar{x}),z) \subset N_c(T_c(M(\bar{y}),\bar{x}),0) = N_c(M(\bar{y}),\bar{x}).$$

Therefore, $z^* \in N_c(M(\bar{y}),\bar{x})$. Let $\eta \in (\|D_c^*M(\bar{y},\bar{x})|_{-N_c(M(\bar{y}),\bar{x})}\|^-,\ \infty)$. Then there exists $y^* \in D_c^*M(\bar{y},\bar{x})(-z^*)$ such that $\|y^*\| < \eta$. It follows that

$$(y^*,z^*) \in N_c(\mathrm{Gr}(M),(\bar{y},\bar{x})) = N_c(\mathrm{Gr}(D_cM(\bar{y},\bar{x})),(0,0)).$$

Since $\mathrm{Gr}(D_cM(\bar{y},\bar{x}))$ is convex,

$$\langle y^*, y-0\rangle + \langle z^*, x-0\rangle \le 0 \quad \forall (y,x) \in \mathrm{Gr}(D_cM(\bar{y},\bar{x})).$$

Noting that $\langle z^*, z\rangle = 0$ (because $z^* \in N_c(T_c(M(\bar{y}),\bar{x}),z)$ and $T_c(M(\bar{y}),\bar{x})$ is a convex cone), it follows from (4.19) that

$$\gamma d(x, T_c(M(\bar{y}),\bar{x})) \le \gamma\|x-z\| \le -\langle y^*, y\rangle \le \eta\|y\| \quad \forall (y,x) \in \mathrm{Gr}(D_cM(\bar{y},\bar{x})).$$

Letting $\gamma \to 1$, one has

$$d(x, T_c(M(\bar{y}),\bar{x})) \le \eta\|y\| \quad \forall (y,x) \in \mathrm{Gr}(D_cM(\bar{y},\bar{x})).$$

Hence, $\eta_* \le \eta < +\infty$. The proof is complete.

Remark 4.3. If one drops the condition $\|D_c^*M(\bar{y},\bar{x})|_{-N_c(M(\bar{y}),\bar{x})}\|^- < \infty$, it is possible that $T_c(M(\bar{y}),\bar{x}) \neq D_cM(\bar{y},\bar{x})(0)$. For example, let $M : R \rightrightarrows R$ be defined by

$$\mathrm{Gr}(M) := \{(y,x) \in R \times R :\ y^2 + x^2 \leq 1\}.$$

Thus, $M(1) = \{0\}$ and so $T_c(M(1),0) = \{0\}$; but $T_c(\mathrm{Gr}(M),(1,0)) = R_+ \times R$. Hence $D_cM(1,0)(0) = R$. This shows that $T_c(M(1),0) \neq D_cF(1,0)(0)$.

In Proposition 4.12, the assumption (4.18) is a mild one. Indeed, the corresponding assertion for contingent derivative always holds: $T(M(\bar{y}),\bar{x}) \subset DM(\bar{y},\bar{x})(0)$ (which is easy to verify). Thus, (4.18) is satisfied if $\mathrm{Gr}(M)$ is regular at $(\bar{y},\bar{x})$ in the Clarke sense. Hence, (4.18) is satisfied if M (resp., M^{-1}) is subsmooth at $(\bar{y},\bar{x})$ (resp., $(\bar{x},\bar{y})$); in particular, (4.18) is satisfied under the assumption of Theorem 4.11. Hence, the following corollary is immediate from Corollary 3.7 and Proposition 4.12.

COROLLARY 4.13. *Let G, g, M, and $(\bar{y},\bar{x})$ be as in Theorem* 4.11. *Then*

$$\|D^*M(\bar{y},\bar{x})|_{-N(M(\bar{y}),\bar{x})}\|^- = \inf\{\eta > 0 :\ d(x, T(M(\bar{y}),\bar{x})) \leq \eta\|y\| \ \ \forall y \in Y \text{ and } x \in DM(\bar{y},\bar{x})(y))\}.$$

If, in addition, $\|D^*M(\bar{y},\bar{x})_{-N(M(\bar{y}),\bar{x})}\|^- < +\infty$, then

$$\eta(DM(\bar{y},\bar{x});0,0) = \|D^*M(\bar{y},\bar{x})|_{-N(M(\bar{y},\bar{x})}\|^-.$$

In what follows, we consider the multifunction $M : Y \rightrightarrows X$ defined by

$$M(y) := \{x \in X :\ g(x) + y \in \Lambda\} \quad \forall y \in Y, \tag{4.20}$$

where $g : X \to Y$ is a function and Λ is a closed subset of Y.

THEOREM 4.14. *Let M be given by* (4.20) *and $(\bar{y},\bar{x}) \in \mathrm{Gr}(M)$. Suppose that g is smooth and that Λ is subsmooth at $g(\bar{x}) + \bar{y}$. Further suppose that there exist $\eta, \delta \in (0,\ +\infty)$ such that*

$$N_c(M(\bar{y}),u) \cap B_{X^*} \subset \eta(g'(u))^*(N_c(\Lambda, g(u) + \bar{y}) \cap B_{Y^*}) \quad \forall u \in M(\bar{y}) \cap B(\bar{x},\delta).$$

Then M is calm at $(\bar{y},\bar{x})$, and, more precisely, for any $\varepsilon > 0$ there exists $\delta_\varepsilon > 0$ such that

$$d(x, M(\bar{y})) \leq \frac{\eta + (1+\eta)\varepsilon}{1 - (1+\eta)\varepsilon}\|y - \bar{y}\| \quad \forall y \in B(\bar{y},\delta_\varepsilon) \text{ and } \forall x \in M(y) \cap B(\bar{x},\delta_\varepsilon).$$

Proof. Note that $M^{-1}(x) = -g(x) + \Lambda$ for each $x \in X$. It follows from Proposition 3.3(ii) (applied to $M^{-1}, -g$ in place of F, g) that

$$D_c^*M^{-1}(u,\bar{y})(B_{Y^*}) = (g'(u))^*(N_c(\Lambda, g(u) + \bar{y}) \cap B_{Y^*}) \quad \forall u \in M(\bar{y}).$$

Similarly, since Λ is subsmooth at $g(\bar{x}) + \bar{y}$, Proposition 3.3(iii) implies that M^{-1} is subsmooth at $(\bar{x},\bar{y})$ and so is M at $(\bar{y},\bar{x})$. Thus, the assertion of Theorem 4.14 follows from Theorem 4.4. The proof is complete.

Let T be a compact topological space and let $\mathcal{C}(T)$ denote the Banach space of all continuous functions on T equipped with the sup-norm. Let $\psi : X \times T \to R$ be a function and consider the multifunction $M : \mathcal{C}(T) \rightrightarrows X$ defined by

$$M(y) := \{x \in X :\ \psi(x,t) \leq -y(t) \ \ \forall t \in T\} \quad \forall y \in \mathcal{C}(T); \tag{4.21}$$

equivalently one can write (4.21) as

$$M(y) = \{x \in X : \ g(x) + y \in \Lambda\} \quad \forall y \in \mathcal{C}(T),$$

where $g(x) = \psi(x, \cdot)$ and Λ is the convex cone of all nonpositive continuous functions on T. In the special case when $X = R^n$, $T \subset R^m$, and ψ is a continuously differentiable function on $R^n \times R^m$ such that $\psi_1'(x,t)$ is locally Lipschitzian on $R^n \times R^m$, where $\psi_1'(x,t)$ denotes the derivative of $\psi(x,t)$ with respect the first variable x, Henrion and Outrata [10] recently considered the calmness of M defined by (4.21) at $(0, \bar{x}) \in \mathrm{Gr}(M)$. For $x \in M(0)$, let $T(x) := \{t \in T : \ \psi(x,s) \le \psi(x,t) \ \text{ for all } s \in T\}$ and let

$$\mathcal{J} := \{S \in \mathcal{K}(T) : \ \exists x_i \overset{\mathrm{bd}M(0)\setminus\{\bar{x}\}}{\longrightarrow} \bar{x} \ \text{ s.t. } d_H(S, T(x_i)) \to 0\},$$

where $\mathcal{K}(T)$ denotes the family of all compact subsets of T and d_H denotes the Hausdorff distance between compact sets. Henrion and Outrata established the following sufficient condition for calmness (see [10, Theorem 4]).

THEOREM A. *Consider* (4.21) *with* $X = R^n$, $T \subset R^m$, *and* ψ *being a smooth function on* $R^n \times R^m$ *such that* $\psi_1'(x,t)$ *is locally Lipschitzian on* $R^n \times R^m$. *Let* $\bar{x} \in M(0)$ *with* $\psi(\bar{x}, \bar{t}) = 0$ *for some* $\bar{t} \in T$. *Suppose that the following two conditions are satisfied.*

(1) $T(M(0), \bar{x}) = \{h \in R^n : \ \langle \psi_1'(\bar{x}, t), h\rangle \le 0$ *for all* $t \in T(\bar{x})\}$.

(2) *There exists* $\rho > 0$ *such that* $d(0, \mathrm{co}\{\psi_1'(\bar{x}, t) : \ t \in S\}) \ge \rho$ *for all* $S \in \mathcal{J}$.

Then M *is calm at* $(0, \bar{x})$.

Recently, Zheng and Yang [45] proved that the conditions (1) and (2) in Theorem A can be replaced by the following weaker condition: there exist $\eta, \delta \in (0, \ +\infty)$ such that

$$\text{(WC)} \quad N_c(M(0), u) \cap B_{X^*} \subset [0, \ \eta]\mathrm{co}\{\psi_1'(u,t) : \ t \in T(u)\} \quad \forall u \in M(0) \cap B(\bar{x}, \delta).$$

As an application of Theorem 4.14, we can improve and generalize Theorem A to the general Banach space case. To do this, it would be convenient to recall some standard notation. Let $\mathcal{B}(T)$ denote the family of all Borel sets in T and let $\mathrm{rca}(T)$ denote the space of all regular finite real-valued Borel measures on T equipped with the total variation norm $\|\mu\| = |\mu|(T)$ for any $\mu \in \mathrm{rca}(T)$. Recall that a Borel measure μ on T is said to be supported on $A \in \mathcal{B}(T)$ if $\mu(B) = 0$ for all $B \in \mathcal{B}(T)$ with $B \cap A = \emptyset$. Let

$$\mathrm{rca}^+(T) := \{\mu \in \mathrm{rca}(T) : \ \mu(B) \ge 0 \ \ \forall B \in \mathcal{B}(T)\}$$

and

$$\mathrm{rac}_A^+(T) := \{\mu \in \mathrm{rac}^+(T) : \ \mu \text{ is supported on } A\},$$

where $\mathrm{rac}_A^+(T)$ is interpreted as $\{0\}$ if $A = \emptyset$. It is well known, as the Riesz representation theorem, that $C(T)^* = \mathrm{rca}(T)$ and that

$$\mu \in \mathrm{rca}(T) \text{ and } \int_T y(t)d\mu \ge 0 \ \ \forall y \in C^+(T) \Longrightarrow \mu \in \mathrm{rca}^+(T),$$

where $C^+(T)$ denotes the set of all nonnegative continuous functions on T. For $y \in \mathcal{C}(T)$, let $I(y) = \{t \in T : \ y(t) = 0\}$.

PROPOSITION 4.15. *Let X be a general Banach space, T a compact topological space, $\psi(x,t)$ a continuous function on $X \times T$ such that $\psi_1'(x,t)$ is continuous on $X \times T$, and $g : X \to \mathcal{C}(T)$ defined by $g(x) := \psi(x,\cdot)$ for all $x \in X$. Let $M : \mathcal{C}(T) \rightrightarrows X$ be defined by* (4.21) *and let $\bar{x} \in M(0)$. Suppose that there exist $\eta, \delta \in (0, +\infty)$ such that for all $u \in M(0) \cap B(\bar{x}, \delta)$,*

(4.22)

$$N_c(M(0),u) \cap B_{X^*} \subset [0,\ \eta] \left\{ \int_T \psi_1'(u,t)d\mu :\ \mu \in \mathrm{rac}^+_{I(g(u))}(T) \text{ and } \mu(T) \le 1 \right\}.$$

Then M is calm at $(0, \bar{x})$.

Proof. By the assumption on ψ, it is easy to verify that $g'(x) = \psi_1'(x,\cdot)$ for all $x \in X$, and so

$$(g'(x))^*(\mu) = \int_T \psi_1'(x,t)d\mu \quad \forall \mu \in \mathrm{rac}(T) = \mathcal{C}(T)^*.$$

By Theorem 4.14 (applied to $Y = \mathcal{C}(T)$, $\Lambda = -\mathcal{C}^+(T)$, $g(x) = \psi(x,\cdot)$ for all $x \in X$ and $\bar{y} = 0$), we need only show that

$$N(-\mathcal{C}^+(T), -y) = \mathrm{rac}^+_{I(y)}(T) \quad \forall y \in \mathcal{C}^+(T). \tag{4.23}$$

Let $y \in \mathcal{C}^+(T)$ and $\mu \in N(-\mathcal{C}^+(T), -y)$. Since $-\mathcal{C}^+(T)$ is a closed convex cone in $\mathcal{C}(T)$, the Riesz representation theorem implies that

$$\int_T -z(t)d\mu \le \int_T -y(t)d\mu = 0 \quad \forall z \in \mathcal{C}^+(T).$$

It follows that $\mu \in \mathrm{rac}^+(T)$ and $\int_T y(t)d\mu = 0$. This shows that $\mu \in \mathrm{rac}^+_{I(y)}(T)$. Hence, $N(-\mathcal{C}(T), -y) \subset \mathrm{rac}^+_{I(y)}(T)$. Since the reverse inclusion is clear, (4.23) holds. The proof is complete.

Remark 4.4. Note that in the special case when $X = R^n$ and under the assumption of Proposition 4.15,

$$\mathrm{co}\{\psi_1'(u,t) :\ t \in I(g(u))\} = \mathrm{cl}(\mathrm{co}\{\psi_1'(u,t) :\ t \in I(g(u))\})$$

and so

$$\mathrm{co}\{\psi_1'(u,t) :\ t \in I(g(u))\} = \left\{ \int_T \psi_1'(u,t)d\mu :\ \mu \in \mathrm{rac}^+_{I(g(u))}(T) \text{ and } \mu(T) \le 1 \right\}.$$

Thus, (4.22) and (WC) are the same. Hence Proposition 4.15 improves and generalizes Theorem A by Henrion and Outrata. Moreover, Proposition 4.15 does not require that $\psi_1'(x,t)$ is locally Lipschitzian.

5. Application to error bounds for inequality systems. Let $f : X \to R \cup \{+\infty\}$ be a proper lower semicontinuous function and consider the following inequality system:

$$f(x) \le 0. \tag{5.1}$$

Let $f_1, \ldots, f_n : X \to R \cup \{+\infty\}$ be proper lower semicontinuous functions and $f(x) = \max\{f_i(x) :\ i = 1, \ldots, n\}$. Then (5.1) is the following system of finitely many inequalities:

$$f_i(x) \le 0,\ \ i = 1, \ldots, n. \tag{5.2}$$

Recall that inequality (5.1) has a local error bound (or metric regularity) at $\bar{x}$ if there exists $\tau > 0$ such that

$$d(x, S) \le \tau [f(x)]_+ \quad \forall x \text{ close to } \bar{x}, \tag{5.3}$$

where S is the solution set of (5.1) and $[f(x)]_+ = \max\{0, f(x)\}$.

In the case when f (resp., f_i) is convex, many authors studied the error bound issues for (5.1) (resp., (5.2)) (see [12, 13, 18, 19, 21, 38, 39, 41] and the references therein). In particular, in the case when f is convex, it is known (cf. [12, 13, 41]) that (5.1) has a local error bound at a point a of the solution set S if and only if there exist $\tau, \delta \in (0, +\infty)$ such that

$$N(S, z) \cap B_{X^*} \subset [0, \tau] \partial f(z) \quad \forall\, z \in \mathrm{bd}(S) \cap B(a, \delta).$$

Under the condition that X is finite-dimensional and each f_i is convex and smooth, Li [19] proved that inequality system (5.2) has a local error bound at $a \in S$ if and only if

$$N(S, z) = R_+ \mathrm{co}\{f_i'(z) : \ i \in I(z)\} \ \ \forall z \in \mathrm{bd}(S) \text{ close to } a,$$

where $I(z) := \{1 \le i \le n : \ f_i(z) = 0\}$.

As applications of the main results obtained in section 4, we consider local error bounds for (5.1) and (5.2) when f and f_i are not necessarily convex. For the sake of simplicity in presentation, let us assume, in the remainder of this section, that $f : X \to R$ is a local Lipschitz (not necessarily convex) function.

As an extension of the convexity, Ngai, Luc, and Thera [29] introduced the approximate convexity. Recall that a function $f : X \to R$ is said to be approximately convex at $a \in X$ if for any $\varepsilon > 0$ there exists $\delta > 0$ such that

$$f(tx_1 + (1-t)x_2) \le tf(x_1) + (1-t)f(x_2) + \varepsilon t(1-t)\|x_1 - x_2\|$$

for all $x_1, x_2 \in B(a, \delta)$ and $t \in (0, 1)$. Recently, Aussel, Daniilidis, and Thibault [1] proved that a local Lipschitz function $f : X \to R$ is approximately convex at a if and only if for any $\varepsilon > 0$ there exists $\delta > 0$ such that

$$(*) \qquad f(x) - f(u) - \langle u^*, x - u\rangle \ge -\varepsilon\|x - u\| \quad \forall x, u \in B(a, \delta) \text{ and } \forall u^* \in \partial_c f(u).$$

Slightly weakened conditions can be introduced as follows: f is said to be L-subsmooth (resp., weak L-subsmooth) at $a \in X$ if for any $\varepsilon > 0$ there exists $\delta > 0$ such that

$$f(x) - f(u) - \langle u^*, x - u\rangle \ge -\varepsilon\|x - u\|$$

whenever $x \in B(u, \delta)$ and $u \in B(a, \delta)$ with $f(u) = f(a)$, $u^* \in \partial_c f(u)$ (resp., $u^* \in \partial f(u)$).

Let $M : R \rightrightarrows X$ be defined by

$$M(y) := \{x \in X : \ f(x) \le y\} \quad \forall y \in R.$$

Then $\mathrm{Gr}(M^{-1}) = \mathrm{epi}(f)$. Hence,

$$\mathrm{dom}(D_c^* M^{-1}(x, f(x))) = [0, +\infty) \ \text{ and } \ D_c^* M^{-1}(x, f(x))(r) = r\partial_c f(x) \tag{5.4}$$

for all $x \in X$ and $r \in [0, +\infty)$. Note that $N_c(\mathrm{Gr}(M), (t, x)) = \{(0, 0)\}$ for any $x \in X$ and $t > f(x)$ (because $(x, t) \in \mathrm{int}(\mathrm{Gr}(M^{-1}))$). By the local Lipschitz property of

f, it is easy to verify that f is (weak) L-subsmooth at a if and only if M is (weak) L-subsmooth at $(f(a), a)$. Note that $M(0) = S$, and (5.1) has a local error bound at $a \in S$ if and only if M is calm at $(0, a)$. Thus, the following result is immediate from Theorems 4.2 and 4.4.

THEOREM 5.1. *The following assertions hold.*

(i) *If inequality* (5.1) *has a local error bound at* $a \in S$*, then there exist* $\tau, \delta \in (0, +\infty)$ *such that*

$$\hat{N}(S, x) \cap B_{X^*} \subset [0, \tau]\partial_c f(x) \quad \forall x \in S \cap B(a, \delta).$$

(ii) *If* f *is L-subsmooth at* $a \in S$ *and there exist* $\tau, \delta \in (0, +\infty)$ *such that*

$$N_c(S, x) \cap B_{X^*} \subset [0, \tau]\partial_c f(x) \quad \forall x \in \mathrm{bd}(S) \cap B(a, \delta), \tag{5.5}$$

then (5.1) *has a local error bound at* a.

By the same argument but using Theorems 4.3 and 4.8 (in place of Theorems 4.2 and 4.4), we have the following characterization of a local error bound for inequality (5.1) when X is an Asplund space.

THEOREM 5.2. *Suppose that* X *is an Asplund space and that* f *is weakly L-subsmooth at* $a \in S$*. Then inequality* (5.1) *has a local error bound at* $a \in S$ *if and only if there exist* $\tau, \delta \in (0, +\infty)$ *such that*

$$\hat{N}(S, x) \cap B_{X^*} \subset [0, \tau]\partial f(x) \quad \forall x \in \mathrm{bd}(S) \cap B(a, \delta).$$

The next two theorems (Theorems 5.3 and 5.6) concern convex-composite functions.

THEOREM 5.3. *Let* $\phi : Z \to R$ *be a continuous convex function and* $g : X \to Z$ *be a smooth function. Let* $f(x) = \phi(g(x))$ *for all* $x \in X$*. Let* $a \in S$ *and suppose that* $g'(a)$ *is surjective. Then* (5.1) *has a local error bound at* a *if and only if there exist* $\tau, \delta \in (0, +\infty)$ *such that* (5.5) *holds.*

Proof. Let $G : R \rightrightarrows Z$ and $M : R \rightrightarrows X$ be defined by

$$M(y) := \{x \in X : \ f(x) \le y\} \ \text{ and } \ G(y) := \{z \in Z : \ \phi(z) \le y\} \quad \forall y \in R.$$

Then $M(y) = g^{-1}(G(y))$ for all $y \in R$. It follows from Theorem 4.11 and (5.4) that M is calm at $(0, a)$ if and only if that there exist $\tau, \delta \in (0, +\infty)$ such that (5.5) holds. Since M is calm at $(0, a)$ if and only if (5.1) has a local error bound, the proof is complete.

Theorems 5.1–5.3 can be regarded as generalizations of the main result in [41] from the convex case to the nonconvex case. Next we consider local error bounds for inequality system (5.2).

PROPOSITION 5.4. *Let* $f_1, \ldots, f_n : X \to R$ *be smooth (not necessarily convex) functions. Let* $a \in S := \{x \in X : \ f_i(x) \le 0, \ i = 1, \ldots, n\}$ *and suppose that there exists* $\tau \in (0, +\infty)$ *such that*

$$N_c(S, z) \cap B_{X^*} \subset [0, \tau]\mathrm{co}(\{f_i'(z) : \ i \in I(z)\}) \ \forall \ z \in \mathrm{bd}(S) \text{ close to } a.$$

Then (5.2) *has a local error bound at* a.

Proof. Let $f(x) = \max\{f_i(x) : \ i = 1, \ldots, n\}$ for all $x \in X$. Then, by [4, Proposition 2.3.12], one has

$$\partial_c f(u) = \mathrm{co}(\{f_i'(u) : \ i \in I(u)\}) \quad \forall u \in X.$$

By (ii) of Theorem 5.1, we need only show that f is L-subsmooth at a. Since each f_i is smooth on X, for any $\varepsilon > 0$ there exists $\delta > 0$ such that

$$f_i(x_1) - f_i(x_2) - \langle f_i'(x_2), x_1 - x_2\rangle \geq -\varepsilon\|x_1 - x_2\| \quad \forall x_1, x_2 \in B(a,\delta). \tag{5.6}$$

Let $x, u \in B(a,\delta)$ and $u^* \in \partial_c f(u)$. Then there exist $t_i \geq 0$ $(i \in I(u))$ such that $\sum_{i\in I(u)} t_i = 1$ and $u^* = \sum_{i\in I(u)} t_i f_i'(u)$. Hence, it follows from (5.6) that

$$\begin{aligned} f(x) - f(u) - \langle u^*, x - u\rangle &= \sum_{i\in I(u)} t_i(f(x) - f_i(u) - \langle f_i'(u), x - u\rangle) \\ &\geq -\varepsilon\|x - u\|. \end{aligned}$$

This shows that f is approximately convex (and thus L-subsmooth) at a. The proof is complete.

Now we extend Li's result on local error bounds (i.e., the metric regularity) for a system of smooth and convex inequalities to the nonconvex case. First we prove a lemma.

LEMMA 5.5. *Let $f_1, \ldots, f_n : X \to R$ be smooth functions. Let $a \in \mathrm{bd}(S)$ be such that for any $J \subset I(a)$,*

$$0 \in \mathrm{co}\{f_i'(a) :\ i \in J\} \Rightarrow a \text{ is a local minimizer of } \max\{f_i(x) :\ i \in J\}. \tag{5.7}$$

Then there exists $\tau \in (0,\ +\infty)$ such that

$$N_c(S,z) \cap B_{X^*} \subset [0,\ \tau]\mathrm{co}\{f_i'(z) :\ i \in I(z)\}\ \ \forall z \in \mathrm{bd}(S) \text{ close to } a \tag{5.8}$$

if and only if

$$N_c(S,z) = R_+\mathrm{co}(\{f_i'(z) :\ i \in I(z)\})\ \ \forall z \in \mathrm{bd}(S) \text{ close to } a. \tag{5.9}$$

The corresponding result also holds if $N_c(S,z)$ is replaced with $\hat{N}(S,z)$ in (5.8) *and* (5.9).

Proof. We prove only the first assertion (the proof for the last assertion is similar). Since each f_i is smooth, it is easy to verify that

$$R_+\mathrm{co}(\{f_i'(z) :\ i \in I(z)\}) \subset N_c(S,z) \quad \forall z \in \mathrm{bd}(S).$$

We need only show that (5.9) implies that there exists $\tau \in (0,\ +\infty)$ such that (5.8) holds. To do this, suppose to the contrary that there exist a sequence $\{z_k\}$ in $\mathrm{bd}(S)$ and a sequence $\{z_k^*\}$ in X^* such that

$$z_k \to a \text{ and } z_k^* \in N_c(S,z_k) \cap B_{X^*} \setminus [0,\ k]\mathrm{co}\{f_i'(z_k) :\ i \in I(z_k)\}. \tag{5.10}$$

By the continuity of f_i and by considering k large if necessary, we assume without loss of generality that $I(z_k) \subset I(a)$ for each k. Similarly, by (5.9), we may assume that for each k there exist $t_k(i) > 0$ $(i \in I(z_k))$ such that $z_k^* = \sum_{i\in I(z_k)} t_k(i) f_i'(z_k)$. It follows from the Carathéodory theorem (cf. [3, p. 25]) that there exist $J_k \subset I(z_k)$ and $r_k(i) > 0$ such that $\{f_i'(z_k) :\ i \in J_k\}$ is linearly independent and $z_k^* = \sum_{i\in J_k} r_k(i) f_i'(z_k)$. This and (5.10) imply that $\sum_{i\in J_k} r_k(i) > k$. Noting that $J_k \subset \{1, \ldots, n\}$, without loss of generality we can assume that $J_k = J$ for each k and

$$\frac{r_k(i)}{\sum_{j\in J} r_k(j)} \to r_i, \text{ as } k \to \infty \text{ and } i \in J$$

(passing to a subsequence if necessary). Then $J \subset I(z_k) \subset I(a)$ and $\sum_{i\in J} r_i = 1$. Since $z_k^* \in B_{X^*}$, it follows that

$$0 = \lim_{k\to\infty} \frac{z_k^*}{\sum_{j\in J} r_k(j)} = \lim_{k\to\infty} \frac{\sum_{i\in J} r_k(i) f_i'(z_k)}{\sum_{j\in J} r_k(j)} = \sum_{i\in J} r_i f_i'(a) \in \mathrm{co}\{f_i'(a) :\ i \in J\}.$$

This and (5.7) imply that a is a local minimizer of f_J defined by $f_J(x) := \max\{f_i(x) : i \in J\}$. Thus there exists an open neighborhood U of a such that $f_J(x) \geq f_J(a)$ for all $x \in U$. Noting that $f_J(a) = f_J(z_k)$ (as $I(z_k) \subset I(a)$), it follows from (5.10) that z_k is also a local minimizer of f_J for each k large enough. Thus, for each k large enough, $0 \in \mathrm{co}\{f_i'(z_k) :\ i \in J\}$, contradicting the fact that $\{f_i'(z_k) :\ i \in J\}$ is linearly independent.

The following theorem clearly improves and extends Li's result (from the convex and finite-dimensional case to the nonconvex and infinite-dimensional case).

THEOREM 5.6. *Let $f_i(x) = \phi_i(g(x))$ for all $x \in X$ $(i = 1, \ldots, n)$, where $g : X \to Z$ is a smooth mapping, $\phi_i : Z \to R$ is a smooth convex function, and Z is another Banach space. Let $a \in \mathrm{bd}(S)$. Suppose that $g'(a)$ is surjective. Then* (5.2) *has a local error bound at a if and only if*

$$N_c(S, z) = R_+\mathrm{co}(\{f_i'(z) :\ i \in I(z)\}) \ \text{ for } z \in \mathrm{bd}(S) \text{ close to } a.$$

Proof. Note that (5.2) has a local error bound at a if and only if (5.1) also does with $f(x) = \max\{f_i(x) :\ i = 1, \ldots, n\}$ for all $x \in X$, and also note that

$$\partial_c f(x) = \mathrm{co}(\{f_i'(x) :\ i \in I(x)\}) \quad \forall x \in X.$$

By Theorem 5.3 and Lemma 5.5, we need only show that (5.7) holds. To do this, let $J \subset I(a)$ and $0 \in \mathrm{co}\{f_i'(a) :\ i \in J\}$. Then there exist $\lambda_i \geq 0$ with $\sum_{i\in J} \lambda_i = 1$ such that

$$0 = \sum_{i\in J} \lambda_i f_i'(a) = \sum_{i\in J} \lambda_i [g'(a)]^*(\phi_i'(g(a))) = [g'(a)]^* \left(\sum_{i\in J} \lambda_i \phi_i'(g(a)) \right).$$

Noting that $[g'(a)]^*$ is injective (because $g'(a)$ is surjective), it follows that

$$0 = \sum_{i\in J} \lambda_i \phi_i'(g(a)). \tag{5.11}$$

Let $\phi(u) := \max\{\phi_i(u) :\ i \in J\}$ for all $u \in Z$. Then ϕ is a continuous convex function and, by $J \subset I(a)$, $\phi(g(a)) = \phi_i(g(a))$ for all $i \in J$. This and (5.11) imply that $g(a)$ is a global minimizer of ϕ. It follows that a is a global minimizer of $\max\{f_i(x) :\ i \in J\}$. This shows that (5.7) holds.

Acknowledgment. The authors wish to thank the referees for careful reading of the paper and for many valuable comments, which helped to improve our presentation.

ADAPTIVE BARRIER UPDATE STRATEGIES FOR NONLINEAR INTERIOR METHODS*

JORGE NOCEDAL†, ANDREAS WÄCHTER‡, AND RICHARD A. WALTZ†

Abstract. This paper considers strategies for selecting the barrier parameter at every iteration of an interior-point method for nonlinear programming. Numerical experiments suggest that heuristic adaptive choices, such as Mehrotra's probing procedure, outperform monotone strategies that hold the barrier parameter fixed until a barrier optimality test is satisfied. A new adaptive strategy is proposed based on the minimization of a *quality function*. The paper also proposes a globalization framework that ensures the convergence of adaptive interior methods, and examines convergence failures of the Mehrotra predictor-corrector algorithm. The barrier update strategies proposed in this paper are applicable to a wide class of interior methods and are tested in the two distinct algorithmic frameworks provided by the IPOPT and KNITRO software packages.

1. Introduction.

In this paper we describe interior methods for nonlinear programming that update the barrier parameter adaptively, as the iteration progresses. The goal is to design algorithms that are both efficient in practice and that enjoy global convergence guarantees. The adaptive strategies studied in this paper allow the barrier parameter to increase or decrease at every iteration and provide an alternative to the so-called Fiacco–McCormick approach that fixes the barrier parameter until an approximate solution of the barrier problem is computed. Our motivation for this work stems from our belief that robust interior methods for nonlinear programming must be able to react swiftly to changes of scale in the problem and to correct overly aggressive decreases in the barrier parameter.

Adaptive barrier update strategies are well established in interior methods for linear and convex quadratic programming. The most popular approach of this type is Mehrotra's predictor-corrector (MPC) method [22]. It computes, at every iteration, a probing (affine scaling) step that determines a target value of the barrier parameter, and then takes a primal-dual step using this target value. A corrector step is added to better follow the trajectory of the central path to the solution. Mehrotra's method has proved to be very effective for linear and convex quadratic programming, but is not supported by global convergence guarantees. Indeed, as we show in section 7, its reliability is heavily dependent upon an appropriate choice of the starting point.

When solving nonlinear nonconvex programming problems, much caution must be exercised to prevent the iteration from failing. Nonminimizing stationary points can attract the iteration, and aggressive decreases in the barrier parameter can lead to failure. Our numerical experience shows that the direct extension of Mehrotra's

predictor-corrector method to nonlinear programming does not result in a robust method. As we discuss below, the main source of instability is the corrector step. Further adaptive barrier update strategies designed specifically for nonlinear programming include [2, 11, 15, 23, 24, 25].

The global convergence properties of interior methods for nonlinear programming have recently received much attention [4, 8, 11, 17, 20, 23, 24, 26, 32]. Some of these studies focus on the effects of merit functions or filters, and on regularization techniques. With the exception of [11, 23, 24], however, these papers do not consider the numerical or theoretical properties of adaptive barrier update techniques.

The organization of this paper is as follows. After stating the basic nonlinear interior method in section 2, we start our exploration of adaptive barrier updates by examining several established techniques in section 3. In this initial investigation, we do not impose a rigorous globalization scheme on the methods, but simply compare their practical behavior on a standard test set. Motivated by the initial observations of these experiments, we then

- propose (in section 4) a new strategy for choosing the barrier parameter that, in contrast to previously proposed update rules, is not based on heuristics but follows a clear-cut objective, namely, the minimization of a "quality function";
- present two simple frameworks that ensure global convergence for interior methods that use *any* update rule for the barrier parameter (section 5);
- explore the numerical performance of the proposed strategy on standard test sets (section 6); and
- discuss the shortcomings of the Mehrotra corrector step (which can be observed even in the linear case) and propose a remedy (section 7).

To show the generality of our quality function approach, we implement it in the two different algorithmic contexts provided by the IPOPT [27] and KNITRO [6, 28] software packages.

Notation. For any vector z, we denote by Z the diagonal matrix whose diagonal entries are given by z. We let e denote the vector of ones, of appropriate dimension, that is, $e = (1, 1, \ldots, 1)^T$.

2. Primal-dual nonlinear interior methods. The problem under consideration will be written as

$$\min_x \ f(x), \tag{2.1a}$$

$$\text{s.t. } c(x) = 0, \tag{2.1b}$$

$$x \geq 0, \tag{2.1c}$$

where $f : \mathbb{R}^n \to \mathbb{R}$ and $c : \mathbb{R}^n \to \mathbb{R}^m$ are twice continuously differentiable functions. For conciseness we will refer to interior-point methods for nonlinear programming as "nonlinear interior methods." A variety of these methods have been proposed in the last 10 years; they differ mainly in some aspects of the step computation and in the globalization scheme. Most of the nonlinear interior methods are related to the simple primal-dual iteration described next; our discussion of barrier parameter choices will be phrased in the context of this iteration.

We associate with the nonlinear program (2.1) the barrier problem

$$\min_x \ \varphi_\mu(x) \equiv f(x) - \mu \sum_{i=1}^{n} \ln x^{(i)}, \tag{2.2a}$$

$$\text{s.t. } c(x) = 0, \tag{2.2b}$$

where $\mu > 0$ is the barrier parameter. As is well known, the KKT conditions of the barrier problem (2.2) can be written as

$$\nabla f(x) - A(x)^T y - z = 0, \tag{2.3a}$$

$$Xz - \mu e = 0, \tag{2.3b}$$

$$c(x) = 0, \tag{2.3c}$$

where $A(x)$ denotes the Jacobian matrix of the constraint function $c(x)$. Condition (2.3b), the positivity of μ, and the requirement that the log function be well-defined in (2.2a) implicitly requires that

$$x > 0, \qquad z > 0. \tag{2.4}$$

Applying Newton's method to (2.3), in the variables (x, y, z), gives the *primal-dual* system

$$\begin{bmatrix} \nabla^2_{xx}\mathcal{L} & -A(x)^T & -I \\ Z & 0 & X \\ A(x) & 0 & 0 \end{bmatrix} \begin{bmatrix} \Delta x \\ \Delta y \\ \Delta z \end{bmatrix} = - \begin{bmatrix} \nabla f(x) - A(x)^T y - z \\ Xz - \mu e \\ c(x) \end{bmatrix}, \tag{2.5}$$

where $\mathcal{L}$ denotes the Lagrangian of the nonlinear program, that is,

$$\mathcal{L}(x, y, z) = f(x) - y^T c(x) - z^T x. \tag{2.6}$$

After the step $\Delta = (\Delta x, \Delta y, \Delta z)$ has been determined, we compute primal and dual steplengths, α_p and α_d, and define the new iterate (x^+, y^+, z^+) as

$$x^+ = x + \alpha_p \Delta x, \quad y^+ = y + \alpha_d \Delta y, \quad z^+ = z + \alpha_d \Delta z. \tag{2.7}$$

The steplengths are computed in two stages. First we compute

$$\alpha_x^{\max} = \max\{\alpha \in (0, 1] : x + \alpha \Delta x \geq (1 - \tau)x\}, \tag{2.8a}$$

$$\alpha_z^{\max} = \max\{\alpha \in (0, 1] : z + \alpha \Delta z \geq (1 - \tau)z\}, \tag{2.8b}$$

with $\tau \in (0, 1)$ (e.g., $\tau = 0.995$). Next, we perform a backtracking line search to compute the final steplengths

$$\alpha_p \in (0, \alpha_x^{\max}], \qquad \alpha_d \in (0, \alpha_z^{\max}], \tag{2.9}$$

which provide sufficient decrease of a merit function or ensure acceptability by a filter.

The other major ingredient in this simple primal-dual iteration is the procedure for choosing the barrier parameter μ. Two types of barrier update strategies have been studied in the literature: adaptive and monotone. Adaptive strategies [11, 15, 24, 25] allow changes in the barrier parameter at every iteration, and are often efficient in practice, but as already mentioned, they generally do not enjoy global convergence properties. (The analyses presented in [11, 24] provide certain convergence results to stationary points, but these methods do not explicitly aim to decrease the objective function—they only enforce reduction of a measure of stationarity.)

The most important monotone strategy is the so-called Fiacco–McCormick approach that fixes the barrier parameter until an approximate solution of the barrier problem is computed. It has been employed in various nonlinear interior algorithms [3, 5, 14, 16, 27, 29, 31] and has been implemented, for example, in the IPOPT and

KNITRO software packages. The Fiacco–McCormick strategy provides a framework for establishing global convergence [4, 26], but suffers from important limitations. It can be very sensitive to the choice of the initial point, the initial value of the barrier parameter, and the scaling of the problem, and it is often unable to recover quickly when the iterates approach the boundary of the feasible region prematurely. The numerical experience with IPOPT and KNITRO reported below suggests that more dynamic update strategies are needed to improve the efficiency of nonlinear interior methods.

The algorithms considered in this paper guarantee only convergence to first-order stationary points; enforcing convergence to second-order points would require an estimation of the smallest eigenvalue of the reduced Hessian, which is too expensive in the large-scale case. However, the algorithms presented here generate steps that promote convergence to minimizers by ensuring descent properties for the barrier problem.

3. Choosing the barrier parameter. In this section we discuss two adaptive barrier strategies proposed in the literature and compare them numerically with the monotone Fiacco–McCormick approach. These numerical results motivate the techniques presented in the following sections.

Given an iterate (x, y, z), consider an interior method that computes primal-dual search directions by (2.5). The most common approach for choosing the barrier parameter μ is to make it proportional to the current complementarity value, that is,

$$\mu = \sigma \frac{x^T z}{n}, \tag{3.1}$$

where $\sigma > 0$ is a *centering parameter* and n denotes the number of variables. Mehrotra's predictor-corrector (MPC) method [22] for linear programming determines the value of σ using a preliminary step computation (an affine scaling step). We now describe a direct extension of Mehrotra's strategy to the nonlinear programming case.

First, we calculate an affine scaling step

$$\left(\Delta x^{\text{aff}}, \Delta y^{\text{aff}}, \Delta z^{\text{aff}}\right) \tag{3.2}$$

by setting $\mu = 0$ in (2.5), that is,

$$\begin{bmatrix} \nabla^2_{xx}\mathcal{L} & -A(x)^T & -I \\ Z & 0 & X \\ A(x) & 0 & 0 \end{bmatrix} \begin{bmatrix} \Delta x^{\text{aff}} \\ \Delta y^{\text{aff}} \\ \Delta z^{\text{aff}} \end{bmatrix} = - \begin{bmatrix} \nabla f(x) - A(x)^T y - z \\ Xz \\ c(x) \end{bmatrix}. \tag{3.3}$$

We then compute α_x^{aff} and α_z^{aff} to be the largest steplengths in $(0, 1]$ that can be taken along the direction (3.2) before violating the nonnegativity conditions $(x, z) \geq 0$. Explicit formulae for these values are given by (2.8) with $\tau = 1$.

Next, we define μ^{aff} to be the value of complementarity that would be obtained by a full step to the boundary, that is,

$$\mu^{\text{aff}} = \left(x + \alpha_x^{\text{aff}} \Delta x^{\text{aff}}\right)^T \left(z + \alpha_z^{\text{aff}} \Delta z^{\text{aff}}\right) / n, \tag{3.4}$$

and set the centering parameter to be

$$\sigma = \left(\frac{\mu^{\text{aff}}}{x^T z / n}\right)^3. \tag{3.5}$$

This heuristic choice of σ is based on experimentation with linear programming problems and has proved to be effective for convex quadratic programming as well. Note that when good progress is made along the affine scaling direction, we have $\mu^{\text{aff}} \ll x^T z/n$, so the σ obtained from this formula is small. In other cases, σ may be chosen to be greater than 1.

Mehrotra's algorithm also computes a *corrector* step, but we take the view that the corrector is not part of the selection of the barrier parameter, and is simply a mechanism for improving the quality of the step. In section 7 we study the complete MPC algorithm including the corrector step.

Other adaptive procedures of the form (3.1) have been proposed specifically for nonlinear interior methods [11, 15, 24, 25]. The strategy employed in the LOQO software package [25] is particularly noteworthy because of its success in practice. It defines σ as

$$\sigma = 0.1 \min\left(0.05\frac{1-\xi}{\xi}, 2\right)^3, \quad \text{where} \quad \xi = \frac{\min_i \{x^{(i)} z^{(i)}\}}{x^T z/n}. \tag{3.6}$$

Note that ξ measures the deviation of the smallest complementarity product $x^{(i)} z^{(i)}$ from the average. When $\xi = 1$ (all individual products are equal to the average) we have that $\sigma = 0$ and the algorithm takes an aggressive step. The rule (3.6) always chooses $\sigma \leq 0.8$, so that even though the value of μ may increase from one iteration to the next, it will never be chosen to be larger than the current complementarity value $x^T z/n$.

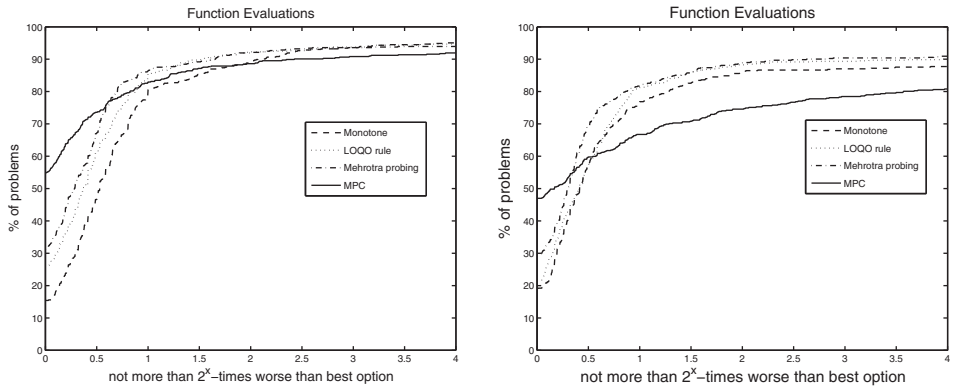
Our first set of numerical experiments compares the effectiveness of the two adaptive strategies mentioned above with the monotone Fiacco–McCormick approach. For these experiments, we use the IPOPT and KNITRO software packages, which have a globalization mechanism for the monotone variant but none for adaptive barrier parameter choices. These codes implement significantly different variations of the simple primal-dual iteration (2.5).

The experiments with KNITRO were done using the default Interior/Direct option (we will refer to this version as KNITRO-DIRECT henceforth), which implements a line search approach that is occasionally safeguarded by a trust region iteration [29]. The trust-region safeguard is needed, for example, to handle negative curvature directions. A merit function is used to promote global convergence, and when an adaptive barrier update rule is used, the penalty parameter associated with the merit function is reset at every iteration.

In our experiments with IPOPT, we go a step further and disable the line search within each iteration and always accept the full fraction-to-the-boundary step with step sizes from (2.8). In this way, we can examine the performance of pure primal-dual steps generated with the adaptive barrier schemes.

The barrier parameter strategies tested in our first set of experiments are as follows:

- LOQO *rule*. The barrier parameter is chosen by (3.1) and (3.6).
- *Mehrotra probing*. At every iteration, the barrier parameter μ is given by (3.1) and (3.5). Since this requires the computation of the affine scaling step (3.2), this strategy is more expensive than the LOQO rule. For KNITRO-DIRECT, in the iterations in which the safeguarding trust region algorithm is invoked (e.g., when the reduced Hessian is not positive definite), the barrier parameter is computed by the LOQO rule instead of Mehrotra probing. This is done because Mehrotra probing is expensive to implement in the trust region algorithm, which uses a conjugate gradient iteration.



(a) KNITRO (b) IPOPT

FIG. 1. *Results for four barrier parameter updating strategies.*

- *MPC.* The complete Mehrotra predictor-corrector algorithm as described later in section 7. As in the Mehrotra probing rule, when KNITRO-DIRECT falls back on the safeguarded trust region algorithm, the barrier parameter is computed using the LOQO rule for efficiency, and no corrector step is used.
- *Monotone.* (Also known as the Fiacco–McCormick approach.) The barrier parameter is fixed, and a series of primal-dual steps is computed, until the optimality conditions for the barrier problem are satisfied to some accuracy. At this point the barrier parameter is decreased. IPOPT and KNITRO implement somewhat different variations of this monotone approach; see [27, 29] for details about the initial value of μ, the rule for decreasing μ, and the form of the barrier stop tests.

For the numerical comparison, we select all the nonlinear programming problems in the CUTEr test set from January 2005 that contain at least one general inequality or bound constraint. We exclude those problems that seem infeasible, unbounded, or are given with initial points at which the model functions cannot be evaluated; see [27]. This gives a total of 599 problems. For all scalable models we use default sizes. Figure 1 reports the number of function evaluations for IPOPT and KNITRO, comparing the performance of the four barrier strategies. All the plots in the paper use the logarithmic performance profiles proposed by Dolan and Moré [10]. To account for the fact that different local solutions might be computed, problems with significantly different final objective function values for successful runs were excluded (for example, for the results in Figure 1, 37 problems we excluded for IPOPT, and 54 for KNITRO).

The results given in Figure 1 indicate that the adaptive strategies outperform the monotone variant, and in particular that Mehrotra probing appears to be the most successful in terms of function evaluations, both in the KNITRO experiment (using steplength control) and in the IPOPT experiment (with no steplength control). Furthermore, the results obtained with IPOPT show that the quality of the pure (unglobalized) steps is good enough to promote convergence in most problems. This observation suggests that the globalization scheme that we propose in section 5 should interfere minimally with the iteration; it should be active only when the algorithms appear to be making no progress.

We also note from Figure 1 that the complete MPC algorithm is very fast on some problems, but is not sufficiently robust. The latter can be seen most clearly in

Figure 1(b) where full MPC steps are taken at every iteration. The reason for the lack of robustness of the MPC strategy will be discussed in section 7, together with a globalization safeguarding procedure.

4. Quality functions. The Mehrotra and LOQO rules rely on the heuristic parameters (3.5) and (3.6). We now consider an approach in which μ is selected using a clear-cut objective, formulated in terms of a *quality function* to be minimized. As before, we assume that $\mu = \sigma \frac{x^T z}{n}$, where the centering parameter $\sigma \geq 0$ is to be determined, and define $\Delta(\sigma)$ to be the solution of the primal-dual equations (2.5) as a function of σ. We also let $\alpha_x^{\max}(\sigma), \alpha_z^{\max}(\sigma)$ denote the steplengths satisfying the fraction to the boundary rule (2.8) for the step $\Delta = \Delta(\sigma)$, and we define the *probing points*

$$x(\sigma) = x + \alpha_x^{\max}(\sigma)\Delta x(\sigma),$$

$$y(\sigma) = y + \alpha_z^{\max}(\sigma)\Delta y(\sigma), \quad z(\sigma) = z + \alpha_z^{\max}(\sigma)\Delta z(\sigma).$$

Our goal is to choose the value of σ that provides significant improvement toward the solution of the nonlinear program (2.1). For example, we could choose σ so as to minimize the following nonlinear quality function based on the KKT error:

$$\begin{aligned} q_N(\sigma) = &\left\|\nabla f(x(\sigma)) - A(x(\sigma))^T y(\sigma) - z(\sigma)\right\|^2 + \|c(x(\sigma))\|^2 \\ &+ \|Z(\sigma)X(\sigma)e\|^2. \end{aligned} \tag{4.1}$$

The evaluation of q_N is, however, expensive since it requires the evaluation of the problem functions and derivatives for every value of σ. We can avoid this expense by using a *linear quality function*. If we assume that f and c are linear functions, we have that (4.1) can be expressed as

$$\begin{aligned} q_L(\sigma) = &(1 - \alpha_z^{\max}(\sigma))^2 \left\|\nabla f(x) - A(x)^T y - z\right\|^2 + (1 - \alpha_x^{\max}(\sigma))^2 \|c(x)\|^2 \\ &+ \|(X + \alpha_x^{\max}(\sigma)\Delta X(\sigma))(Z + \alpha_z^{\max}(\sigma)\Delta Z(\sigma))e\|^2, \end{aligned} \tag{4.2}$$

where $\Delta X(\sigma)$ is the diagonal matrix with $\Delta x(\sigma)$ on the diagonal, and similarly for $\Delta Z(\sigma)$. We point out that by design the function q_L measures the KKT error exactly at the probing points $(x(\sigma), y(\sigma), z(\sigma))$ for linear programming problems.

Note that $\Delta(\sigma) = \Delta(0) + \sigma(\Delta(1) - \Delta(0))$. Therefore, $\Delta(\sigma)$ can be computed easily for any value of σ once the linear system (2.5) has been solved twice to obtain $\Delta(0)$ and $\Delta(1)$. Having computed $\Delta(\sigma)$, the dominant cost in the evaluation of q_L lies in the computation of the maximal steplengths $\alpha_x^{\max}(\sigma), \alpha_z^{\max}(\sigma)$ and the last term in (4.2), which requires a few vector operations.

We have defined the quality function q_L using squared norms to severely penalize any large components in the KKT error. Note that $q_L(\sigma)$ is not a convex function of σ, in general. Moreover, due to the complicated dependence of the steplengths $\alpha_x^{\max}(\sigma), \alpha_z^{\max}(\sigma)$ on the parameter σ, it does not seem possible to obtain an analytic expression for the minimizers of q_L. Nevertheless, we have observed that, in practice, this function is usually unimodal.

Therefore, we implement a one-dimensional search scheme to compute an approximate minimizer of q_L. It uses a golden trisection procedure (see, e.g., [21]), and ignores the fact that q_L may not necessarily be unimodal. We first choose $\sigma^{\min}$ and $\sigma^{\max}$, which define a minimum and maximum limit on the σ value, and

define the two intervals $[\sigma^{\min}, 1]$ and $[1, \sigma^{\max}]$. In our implementation, the value $\sigma^{\min} = \max(\gamma, \mu^{\min} n/x^T z)$, where $\mu^{\min}$ ($= 10^{-9}$ in our implementation) defines a minimal permissible value of the barrier parameter, γ is some small number (say, 10^{-6} or 10^{-8}), and $\sigma^{\max} = 1000$. We first evaluate the quality function for $\sigma = 1$ and for some σ value slightly less than 1 (say 0.99). If $q_L(0.99) \leq q_L(1)$, then we perform our golden trisection procedure in the interval $[\sigma^{\min}, 1]$, otherwise we search in the interval $[1, \sigma^{\max}]$. (It is important that σ be allowed to take on values greater than one so that the algorithm can recover from overly aggressive reductions of the barrier parameter.) Our trisection procedure terminates if either 12 evaluations of the quality functions are performed, or if the search interval $[a, b]$ becomes smaller than $b \times 10^{-2}$.

The expected advantages of the quality function approach are twofold. First, we have defined a procedure that ties the choice of the barrier parameter to a measurable and achievable decrease in the (linearized) KKT error. Therefore, we expect this approach to converge in fewer iterations compared with previously proposed approaches based on heuristic formulas. Second, our choice of the barrier parameter takes into account the fraction to the boundary steplengths (2.8) (the functions (4.1) and (4.2) are based on the steps *after* applying the fraction to the boundary rule). Thus the implicit constraints (2.4) are taken into account in choosing μ. This is similar to the Mehrotra update formulas and should discourage choices of the barrier parameter that generate steps which quickly violate the bounds (2.4) and need to be truncated.

More implementation details are given in section 6. Before presenting our numerical results with the quality function, we study how to guarantee the global convergence of nonlinear interior methods that choose the barrier parameter adaptively.

5. A globalization framework. The adaptive strategies described in section 3 can be seen from the numerical results in that section to be quite robust, even without a rigorous globalization scheme. (We show in the next section this is also the case with the quality function approach.) Yet, since the barrier parameter is allowed to change at every iteration in these algorithms, there is no mechanism that indeed enforces global convergence of the iterates in all cases. In contrast, the monotone barrier strategy employed in the Fiacco–McCormick approach allows us to establish global convergence results by combining two mechanisms. First, the algorithms that minimize a given barrier problem (2.2) use a line search or trust region to enforce a decrease in a merit function (as in KNITRO) or to guarantee acceptability by a filter (as in IPOPT). This ensures that an optimality test for the barrier function is eventually satisfied to some tolerance ϵ. Second, by repeating this minimization process for decreasing values of μ and ϵ that converge to zero, one can establish global convergence results [4, 12] to stationary points of the nonlinear programming problem (2.1).

We now propose two globalization frameworks that monitor the performance of the iterations in reference to a mechanism that enforces global convergence. As long as the adaptive primal-dual steps make sufficient progress towards the solution, the algorithm is free to choose a new value for the barrier parameter at every iteration; here, the barrier parameter can be chosen by *any* desired rule. We call this the *free mode.* However, if the iteration fails to maintain progress, then the algorithm reverts to a *monotone mode*, in which a Fiacco–McCormick strategy is applied. Here, the value of the barrier parameter remains fixed, and a robust globalization technique (e.g., based on a merit function or a filter) is employed to ensure progress for the corresponding barrier problem. Once the barrier problem is approximately minimized,

the barrier parameter is decreased. The monotone mode continues until an iterate is generated that makes sufficient progress for the original problem, at which point the free mode resumes.

We stress that also in the free mode we might want to choose steplengths α_p, α_d that are shorter than the maximal step sizes $\alpha_x^{\max}, \alpha_z^{\max}$, in order to promote convergence to minimizers. In our implementations, we make sure that the steps have descent properties with respect to the barrier problem (2.2) corresponding to the current value of μ, and we perform a line search to enforce progress in a merit function or a filter (without history), both of which are defined with respect to this barrier problem. In this way, we force the algorithm to consider the objective function when determining a new trial point, and not only the norm of the optimality conditions, so that convergence to stationary points that are not minimizers is less likely.

There are various ways to measure whether steps in the free mode make sustained progress toward the solution of the nonlinear program (2.1). We have developed two mechanisms, one based on a measure of KKT error, and the other using a filter based on the value of the objective (2.1a) and a measure of the constraint violation. Both aim to interfere with adaptive steps as little as possible so as not to slow down convergence.

5.1. Nonmonotone decrease of the KKT error. In our first globalization framework, we monitor the KKT error of the original nonlinear program,

$$\Phi(x, y, z) = \left\|\nabla f(x) - A(x)^T y - z\right\|^2 + \|c(x)\|^2 + \|ZXe\|^2. \tag{5.1}$$

We require that this measure be reduced by a factor of $\kappa \in (0, 1)$ over at most a fixed number $l^{\max}$ of iterations, when the algorithm is in the free mode.

Algorithm A: KKT-Error-Based Globalization Framework

Given (x_0, y_0, z_0) with $(x_0, z_0) > 0$, a constant $\kappa \in (0, 1)$ and an integer $l^{\max} \geq 0$.
Set $k \leftarrow 0$.
Repeat
  Choose a target value of the barrier parameter μ_k, based on any rule.
  Compute the primal dual search direction Δ from (2.5).
  Determine step sizes $\alpha_p \in (0, \alpha_x^{\max}]$ and $\alpha_d \in (0, \alpha_z^{\max}]$.
  Compute the new trial iterate $(\tilde{x}_{k+1}, \tilde{y}_{k+1}, \tilde{z}_{k+1})$ from (2.7).
  Compute the KKT error $\tilde{\Phi}_{k+1} \equiv \Phi(\tilde{x}_{k+1}, \tilde{y}_{k+1}, \tilde{z}_{k+1})$.
  Set $M_k = \max\{\Phi_{k-l}, \Phi_{k-l+1}, \ldots, \Phi_k\}$ with $l = \min\{k, l^{\max}\}$.
  If $\tilde{\Phi}_{k+1} \leq \kappa M_k$
    Accept $(\tilde{x}_{k+1}, \tilde{y}_{k+1}, \tilde{z}_{k+1})$ as the new iterate, and set $\Phi_{k+1} \leftarrow \tilde{\Phi}_{k+1}$.
    Set $k \leftarrow k + 1$ and return to the beginning of the loop.
  else
    Start Monotone Mode:
    Starting from $(\tilde{x}_{k+1}, \tilde{y}_{k+1}, \tilde{z}_{k+1})$, and for an initial value $\bar{\mu}$, solve a sequence of barrier problems with a monotonically decreasing sequence of barrier parameters to obtain a new iterate $(x_{k+1}, y_{k+1}, z_{k+1})$ such that
      $\Phi_{k+1} \equiv \Phi(x_{k+1}, y_{k+1}, z_{k+1}) \leq \kappa M_k$.
    Set $k \leftarrow k + 1$ and resume the free mode at the beginning of the loop.
  end if
End (repeat).

In the monotone mode, it is not required to solve each barrier problem to the specified tolerance before checking whether the method can revert to the free mode. Instead, we compute the optimality error $\Phi(x, y, z)$ for all intermediate iterates in the monotone mode, and return to the free mode, as soon as $\Phi(x, y, z) \leq \kappa M_k$.

Typical values for the algorithmic parameters are $\kappa = 0.9999$ and $l^{\max} = 5$. An important issue when switching to the monotone mode is the initialization of the barrier parameter $\bar{\mu}$. This can be chosen, for example, to be some fraction of the current complementarity value. The rule used in our implementations is $\bar{\mu} = 0.8(x_k^T z_k)/n$.

5.2. Two-dimensional filter. In the second globalization method, we make use of a filter that accepts a trial point if it provides sufficient progress in terms of the constraint violation $\theta(x) = \|c(x)\|$ *or* the objective function $f(x)$, compared to the previous iterates generated in the free mode. We let $\mathcal{F}_k \subseteq \{(f, \theta) \in \mathbb{R}^2 : \theta \geq 0\}$ denote the (f, θ) pairs that are not acceptable at the current iteration k. The concept of acceptability by the filter is made precise below.

Algorithm B: Filter-Based Globalization Framework

Given (x_0, y_0, z_0) with $(x_0, z_0) > 0$, and constants $\kappa_1, \kappa_2 > 0$; initialize the filter $\mathcal{F}_0 = \emptyset$.

Set $k \leftarrow 0$.

Repeat

Choose a target value of the barrier parameter μ_k, based on any rule.
Compute the primal dual search direction Δ from (2.5).
Determine step sizes $\alpha_p \in (0, \alpha_x^{\max}]$ and $\alpha_d \in (0, \alpha_z^{\max}]$.
Compute the new trial iterate $(\tilde{x}_{k+1}, \tilde{y}_{k+1}, \tilde{z}_{k+1})$ from (2.7).
Compute the filter margin $\delta_k = \kappa_1 \min\{\kappa_2, \Phi(x_k, y_k, z_k)\}$.
If $(f(\tilde{x}_{k+1}) + \delta_k, \|c(\tilde{x}_{k+1})\| + \delta_k) \notin \mathcal{F}_k$
Accept $(\tilde{x}_{k+1}, \tilde{y}_{k+1}, \tilde{z}_{k+1})$ as the new iterate.
Update the filter $\mathcal{F}_{k+1} = \mathcal{F}_k \cup \{(f, \theta) : f \geq f(\tilde{x}_{k+1}) \text{ and } \theta \geq \|c(\tilde{x}_{k+1})\|\}$.
Set $k \leftarrow k + 1$ and return to the beginning of the loop.
else
Start Monotone Mode:
Starting from $(\tilde{x}_{k+1}, \tilde{y}_{k+1}, \tilde{z}_{k+1})$, and for an initial value $\bar{\mu}$, solve a sequence of barrier problems with a monotonically decreasing sequence of barrier parameters to obtain a new iterate $(x_{k+1}, y_{k+1}, z_{k+1})$ such that
$$(f(x_{k+1}) + \delta_k, \|c(x_{k+1})\| + \delta_k) \notin \mathcal{F}_k.$$
Augment the filter:
$$\mathcal{F}_{k+1} = \mathcal{F}_k \cup \{(f, \theta) : f \geq f(x_{k+1}) \text{ and } \theta \geq \|c(x_{k+1})\|\}.$$
Set $k \leftarrow k + 1$ and resume the free mode at the beginning of the loop.
end if

End (repeat).

Similar to the KKT-error based globalization framework, the monotone mode is terminated as soon as an iterate is encountered that is acceptable to the filter.

We have tested the KKT and filter globalization approaches using IPOPT and KNITRO, and found both to be effective in practice. For the sake of brevity, we report results only for the filter globalization framework in the next section. We set $\kappa_1 = 10^{-5}$ and $\kappa_2 = 1$ for these tests, and we choose $\bar{\mu} = 0.8(x_k^T z_k)/n$ for the barrier parameter when entering the monotone mode.

5.3. Global convergence results. In the following we summarize the theoretical convergence guarantees for the two globalization frameworks presented above.

THEOREM 5.1. *Let $\{(x_k, y_k, z_k)\}$ be the sequence generated by either Algorithm A or Algorithm B, and assume that the monotone mode always terminates successfully. For Algorithm B, further assume that $\{f(x_k)\}$ is bounded below and that $\{\|c(x_k)\|\}$ is bounded above. Then, the KKT error $\Phi(x_k, y_k, z_k)$ converges to zero.*

Proof. Algorithm A: Since this framework ensures that the optimality measure $\Phi_k = \Phi(x_k, y_k z_k)$ is reduced by a factor of $\kappa \in (0, 1)$ in at most every $l^{\max}$ iterations, it is clear that $\Phi_k \to 0$.

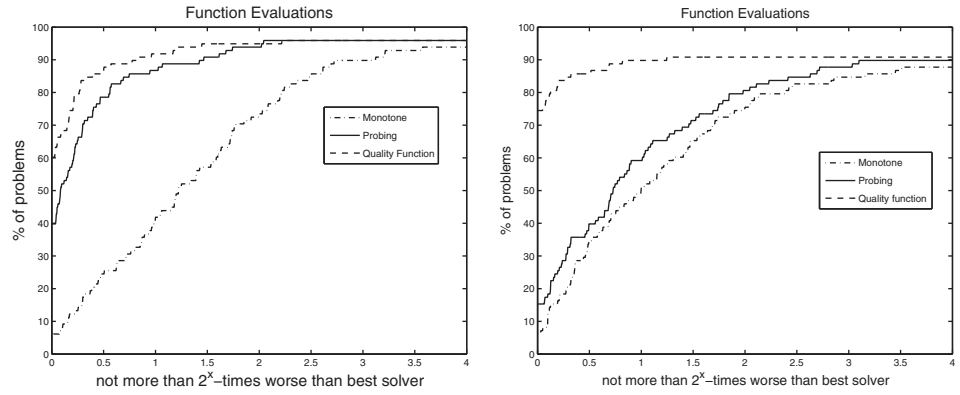
Algorithm B: The proof is by contradiction and is similar to the proof of Lemma 3.3 in [13]. Suppose that there is a subsequence $\{k_j\}$ of iterations in which $\delta_{k_j-1} \geq \epsilon > 0$. Then $f(x_{k_j})$ has to be bounded above, say by f_U, since otherwise we could find a subsequence $\{k_{j_l}\}$ of $\{k_j\}$ with $f(x_{k_{j_l}}) \leq f(x_{k_{j_{l+1}}})$ and $f(x_{k_{j_l}}) \to \infty$ so that the filter update rule would yield $\|c(x_{k_{j_{l+1}}})\| < \|c(x_{k_{j_l}})\| - \delta_{k_{j_l}-1} \leq \|c(x_{k_{j_l}})\| - \epsilon \to -\infty$. Therefore, for each k_j, the area of the region $\mathcal{F}_{k_j} \setminus \mathcal{F}_{k_j-1}$ added to $\mathcal{F}_{k_j-1}$ includes a square of size $\delta^2_{k_j-1} \geq \epsilon^2$ within the set $\bar{\mathcal{F}} = \{(f, \theta) : f_L \leq f \leq f_U \text{ and } 0 \leq \theta \leq \theta_U\}$. Here, f_L denotes a lower bound of $\{f(x_k)\}$ and θ_U an upper bound of $\{\|c(x_k)\|\}$, which exist by assumption. Because of the monotonicity $\mathcal{F}_k \subseteq \mathcal{F}_{k+1}$ of the filter, this leads to a contradiction, since $\bar{\mathcal{F}}$ is finite. ∎

The above result pertains to the cases where the algorithm does not eventually stay in the monotone mode. If it does, the iteration inherits the convergence properties from the underlying Fiacco–McCormick algorithm. In particular, if the nonlinear program (2.1) is infeasible the KKT error cannot converge to zero, and therefore Theorem 5.1 shows that both algorithms must eventually remain in the monotone mode. In that mode, there will be a value of the barrier parameter, say $\bar{\mu}$, for which the corresponding barrier problem is infeasible and cannot be solved to the required convergence tolerance. For KNITRO, it has been shown that the algorithm then generates an infeasible limit point that is a stationary point for the ℓ_2-norm of the constraint violation [4]. For IPOPT, the filter line-search algorithm for that barrier problem will eventually stay in the restoration phase [26]; the current implementation of the restoration phase then minimizes the ℓ_1-norm of the constraint violation. Therefore, if the nonlinear program is infeasible, both algorithms will generate a message indicating that the problem is locally infeasible.

6. Numerical results. We first discuss the choice of norms in the quality function (4.2) and in the optimality measure (5.1). (For consistency, we use the same norms and scaling factors for the individual terms in (4.2) and (5.1).) In IPOPT we use the 2-norm, and each of the three terms is divided by the number of elements in the vectors whose norms are being computed. In KNITRO, we choose the norm and scaling factors to be similar to the terms used in the KNITRO termination test: The first two terms in (4.2) and (5.1) use the infinity-norm, the complementarity term uses the 1-norm divided by n, and we scale these terms using the factors described in [29].

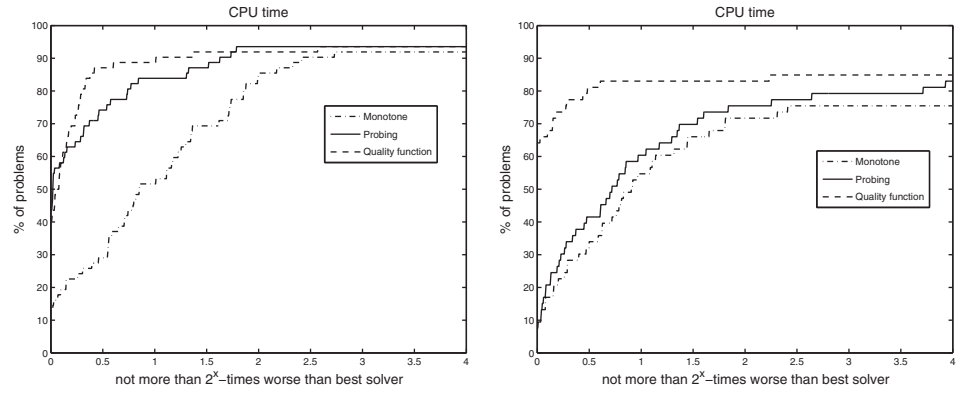
The tests involving IPOPT were run on a Dual-Pentium III, 1GHz machine running Linux. The KNITRO tests were run on a machine with an AMD Athlon XP 3200+ 2.2GHz processor running Linux. For both codes, the maximum number of iterations was set to 3000 and the time limit was set to 1800 CPU seconds. The tests were run using the development versions of IPOPT and KNITRO as of October 2005.

The first results we present are for the linear programming problems in the NETLIB collection, as specified in the CUTEr test set [18]. No preprocessing was



(a) IPOPT (b) KNITRO

FIG. 2. *Function evaluation comparison for the NETLIB test set.*

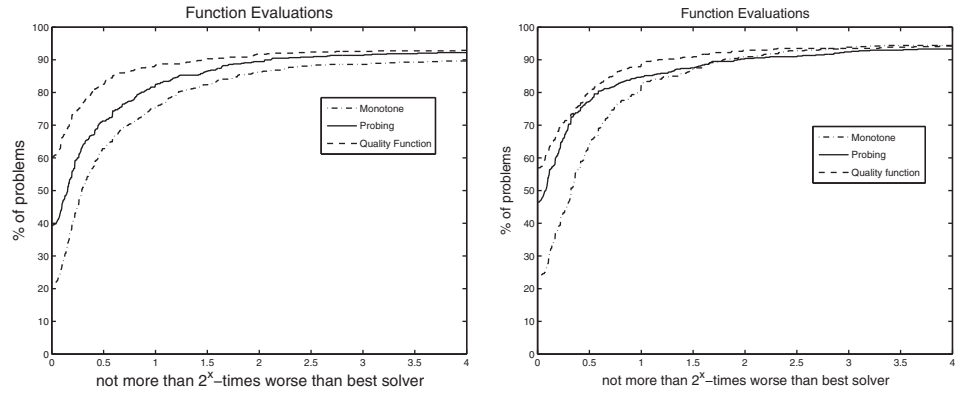


(a) IPOPT (b) KNITRO

FIG. 3. *CPU time comparison for the NETLIB test set.*

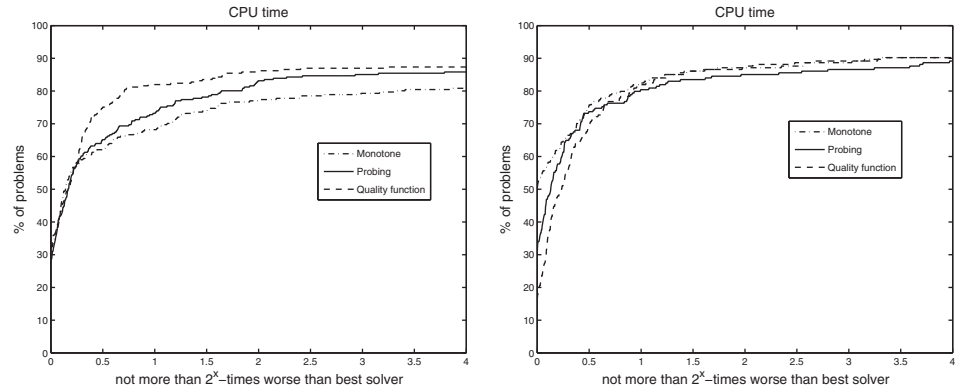
performed, and no initial point strategy was employed (i.e., the default starting point $x_0 = (0, \ldots, 0)$ was used). Figure 2 compares the performance of the quality function approach, in terms of function evaluation count, with two of the strategies described in section 3, namely, the monotone method and the Mehrotra probing heuristic. Figure 3 compares the algorithms in terms of CPU time. Since we are primarily interested in methods with globally convergent frameworks we use the filter based globalization framework described in section 5 for both the Mehrotra probing approach and the quality function approach. The monotone approach is globally convergent on its own. Even though our focus is on nonlinear optimization, linear programming problems are of interest since they allow us to assess the effectiveness of the quality function in a context in which it exactly predicts the KKT error. It is apparent from Figure 2 that the quality function approach is very effective on the NETLIB test set.

The performance (in terms of function evaluations) of the three barrier update strategies on nonlinear programming problems with at least one inequality or bound constraint from the CUTEr collection is reported in Figure 4. The quality function approach again performs significantly better than the monotone method; it also



(a) IPOPT (b) KNITRO

FIG. 4. *Function evaluation comparison for CUTEr test set.*



(a) IPOPT (b) KNITRO

FIG. 5. *CPU time comparison for the CUTEr test set.*

outperforms the Mehrotra probing strategy, which had given the best results in the experiments reported in section 3. The improvements are less pronounced when comparing CPU performance; see Figure 5.

To give more insight into the behavior of the quality function approach, we present in Table 1 data about the value of the centering parameter σ_k chosen by the quality function approach, together with statistics about the globalization strategy employed. The data was collected from the results produced by IPOPT. We compare the probing and quality function approaches. The third column gives the percentage of iterations spent in the monotone mode. The rest of the columns report the percentage of iterations in which σ_k lie in the intervals $[\sigma^{\max}, 10]$, $(10, 1]$, $(1, 10^{-1}]$, etc. The percentage numbers in Table 1 were obtained by computing the average of the percentages for each successfully solved problem.

As we can see, only a small percentage of iterations is spent in the monotone mode, showing that the adaptive mode is the main driving force. Note also that the quality function strategy tends to produce larger values of σ_k than the probing approach.

TABLE 1
Average percentage of iterations in monotone and free mode, producing σ_k in certain ranges.

Method	Testset	%mono	free mode, with σ_k in range							
		mode	≥ 10	≥ 1	$\geq 10^{-1}$	$\geq 10^{-2}$	$\geq 10^{-3}$	$\geq 10^{-4}$	$\geq 10^{-5}$	$< 10^{-5}$
Probing	NETLIB	4.77%	0.00	2.15	72.35	10.18	3.29	1.33	1.44	4.50
Qual. fctn.	NETLIB	3.70%	4.90	11.39	53.41	14.69	3.56	0.63	0.65	7.07

Qual. fctn.	CUTEr	8.39%	4.53	6.98	32.89	22.50	10.57	2.08	2.46	9.59

The performance profiles in Figures 4 and 5 indicate that there are a number of problems that cannot be solved by the quality function approach. We now make some observations about the behavior of the two codes on these problems.

Considering both the NETLIB and CUTEr test sets, there were 38 failures for the KNITRO implementation of the globalized quality function adaptive barrier rule. Of these, 18 problems were solved when the default time or iteration limits were increased; 5 problems (BRANDY, PALMER2, PALMER7A, SAWPATH, SINEALI) terminated at near optimal approximate solutions, but KNITRO could not get enough accuracy in the dual feasibility measure; 2 problems (CRESC132, QCNEW) terminated because of evaluation errors resulting from IEEE exceptions (`NaN`) in the function evaluation; and 1 problem (HS110) terminated with a message of unboundedness at a feasible point with a very large negative value of the objective function. The optimal objective for HS110 is $-9.960\text{e}+39$,[1] whereas by default KNITRO declares unboundedness for a feasible objective value less than the cutoff limit value $-1.0\text{e}+20$. When this limit is changed, KNITRO solves the problem in 4 iterations. In addition, the problem KTMODEL was discovered to have incorrect gradients which caused KNITRO to terminate at an infeasible point. The remaining 11 problems (COSHFUN, DITTERT, DRUGDISE, GREENBEA, GREENBEB, MANNE, NUFFIELD, PILOT-JA, TENBARS2, TENBARS3, ZIGZAG) constitute unresolved failures.

We give some more information about these 11 problems. GREENBEA, GREENBEB, PILOT-JA, NUFFIELD, and ZIGZAG were not solved even when the time limit was increased to three hours. The problems GREENBEA, GREENBEB, and PILOT-JA are linear programs for which KNITRO experiences numerical difficulties (from rank-deficient Jacobians) that cause it to often fallback on steepest descent like steps and converge slowly. KNITRO appears to be very close to the solution in PILOT-JA when it reaches the time limit. The problems COSHFUN, DRUGDISE, TENBARS2, and TENBARS3 were not solved even when the iteration limit was raised to 100,000 (although it appears in all cases that slow progress is still being made when the iteration limit is reached). For the problem DITTERT, KNITRO terminates at an infeasible point but the code is unable to verify whether or not it is an infeasible stationary point. Finally, for the problem MANNE, KNITRO terminated at a feasible point but with a large dual feasibility error.

For the IPOPT code, there were 39 failures for the globalized quality function adaptive barrier rule. Of these, 13 problems were solved if more iterations (100,000) or CPU time (3 hours) were allowed. In 6 problems (A2NNDNIL, A5NNDNIL, CRESC100, EG3, POLAK3, SPIRAL), IPOPT terminated at a point satisfying the local infeasibility criterion; in 2 problems (A2NSDSIL, BRAINPC9) it failed during the restoration phase. For COSHFUN, the memory requirement in the linear solver was exceeded in iteration 10681, and the problems EQC and ROBOT terminated because the search

[1] This is true for problem size N=200 which was the default size for this SIF model at the time of testing.

direction became too small, but in both cases the problem was almost solved. For problem LIN, the objective function value at the (modified) starting point resulted in an IEEE exception (`NaN`).

In the remaining failures, the maximum iteration count or CPU time were exceeded. Problems AVION2, PALMER5E, YORKNET terminated after 100,000 iterations; IPOPT appeared to be cycling with small primal and dual feasibility errors for two of these problems (AVION2 and PALMER5E). For problem PALMER7E, IPOPT still made very small progress after 100,000 iterations, while for problem KT-MODEL the code seemed to diverge (as a result of incorrect gradient information). Finally, the time limit was exceeded for the linear program QAP15 from NETLIB, and for the CUTEr models A5NSDSIL, CRESC132, GAUSSELM, GLIDER, MANNE, NUFFIELD, ORTHREGE, READING8.

7. Corrector steps. The numerical results of section 3 indicate that, when solving nonlinear problems, including the corrector step in Mehrotra's method (the MPC method) is often not beneficial. This is in stark contrast with the experience in linear programming and convex quadratic programming, where the corrector step is known to accelerate the interior-point iteration without degrading its robustness. In this section we study the effect of the corrector step and find that it can also be harmful in the linear programming and quadratic programming cases *if* an initial point strategy is not used. These observations are relevant because in nonlinear programming it is much more difficult to find a good starting point.

Let us begin by considering the linear programming case. There are several ways of viewing the MPC method in this context. One is to consider the step computation as taking place in three stages (see, e.g., [30]). First, the algorithm computes the affine scaling step (3.2) and uses it to determine the target value of the barrier parameter $\mu = \sigma \frac{x^T z}{n}$, where σ is given by (3.5). Next, the algorithm computes a primal-dual step, say Δ^{pd}, from (2.5) using that value of μ. Finally, a corrector step Δ^{corr} is computed by solving (2.5) with the right-hand side given by

$$-\left(0, \Delta X^{\mathrm{aff}} \Delta Z^{\mathrm{aff}} e, 0\right)^T, \tag{7.1}$$

where ΔX^{aff} is the diagonal matrix with diagonal entries given by Δx^{aff}, and similarly for ΔZ^{aff}. The complete MPC step is the sum of the primal-dual and corrector steps. We can compute it by adding the right-hand sides and solving the following system:

$$\begin{bmatrix} \nabla^2_{xx}\mathcal{L} & -A^T(x) & -I \\ Z & 0 & X \\ A(x) & 0 & 0 \end{bmatrix} \begin{bmatrix} \Delta x^{\mathrm{mpc}} \\ \Delta y^{\mathrm{mpc}} \\ \Delta z^{\mathrm{mpc}} \end{bmatrix} = - \begin{bmatrix} \nabla f(x) - A^T(x) y - z \\ Xz - \mu e + \Delta X^{\mathrm{aff}} \Delta Z^{\mathrm{aff}} e \\ c(x) \end{bmatrix}. \tag{7.2}$$

The new iterate (x^+, y^+, z^+) of the MPC method is given by (2.7)–(2.8) with $\Delta = (\Delta x^{\mathrm{mpc}}, \Delta y^{\mathrm{mpc}}, \Delta z^{\mathrm{mpc}})$.

Alternative views of the MPC method are possible by the linearity of the step computation: We can group the right-hand side in (7.2) in different ways and thereby interpret the step as the sum of different components. Yet all these views point out the following inconsistency in the MPC approach.

In the linear programming case, primal and dual feasibility are linear functions and hence vanish at the full affine scaling point, defined by

$$(x, y, z) + \left(\Delta x^{\mathrm{aff}}, \Delta y^{\mathrm{aff}}, \Delta z^{\mathrm{aff}}\right). \tag{7.3}$$

The complementarity term takes on the value

$$\left(X + \Delta X^{\mathrm{aff}}\right)\left(Z + \Delta Z^{\mathrm{aff}}\right) = \Delta X^{\mathrm{aff}} \Delta Z^{\mathrm{aff}}.$$

Therefore the value of the right-hand side vector in (2.5) at the full affine scaling step (7.3) is given by (7.1). Thus the corrector step can be viewed as a modified Newton step taken from the point (7.3) and using the primal-dual matrix evaluated at the current iterate (x, y, z).

The inconsistency in the MPC approach arises because the corrector step, which is designed to improve the full affine scaling step, is applied at the primal-dual point; see Figure 6. In some circumstances, this mismatch can cause poor steps. In particular, we have observed that if the affine scaling step is very long, in the sense that the steplengths (2.8) are very small, and if the corrector step is even larger, then the addition of the corrector step to the primal-dual step (2.7) can significantly increase the complementarity value $x^T z$. This behavior can be sustained and lead to very slow convergence or failure, as shown in Table 2. The results in this table were obtained using PCx [9], an interior-point code for linear programming that implements the MPC method, applied to problem FORPLAN from the NETLIB collection. Practical implementations of the MPC use a procedure for choosing a favorable starting point

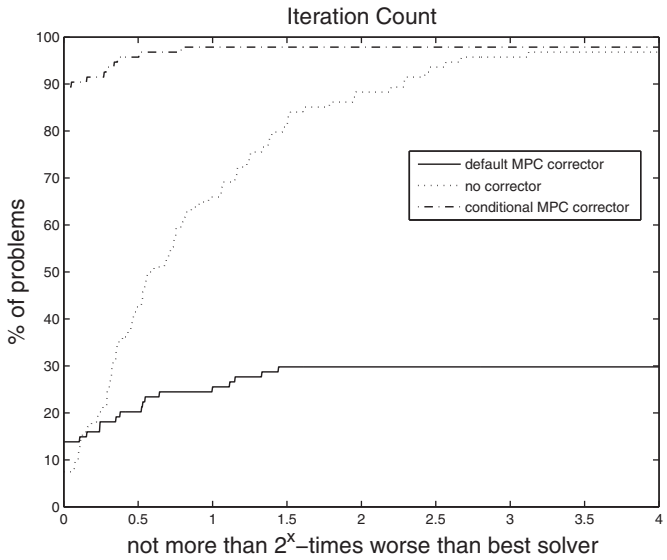

FIG. 7. *Results on the NETLIB test set for three corrector step strategies implemented in PCx. The initial point was set to* $x = e, z = e$.

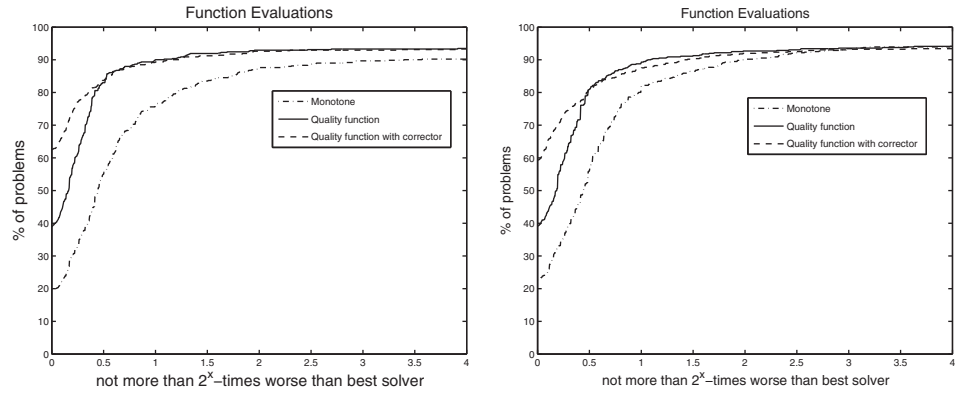
described by Mehrotra [22]. We disabled this initial point strategy for PCx and set the initial point to $x = e, z = e$. Note from Table 2 that the affine scaling and corrector steps appear to grow without bound, and examination of the results shows that the dual variables diverge.

To provide further support to the claim that the corrector step can be harmful, we ran the complete set of test problems (94 in all) in the NETLIB collection. Using the default settings, which includes a strategy for computing a good starting point, PCx solved 90 problems, and terminated very close to the solution in the remaining 4 cases. Next we disabled the initial point strategy and set the initial point to $x = e, z = e$. PCx was now able to solve only 28 problems (and in only 3 additional cases terminated very close to the solution).

We repeated the experiment, using the initial point $x = e, z = e$, but this time removing the corrector step; this corresponds to the algorithm called *Mehrotra probing* in section 3. We also tested a variant that we call *conditional MPC* in which the corrector step is employed in the MPC method only if it does not result in an increase of complementarity by a factor larger than 2. The results, in terms of iterations, are reported in Figure 7. Note the dramatic increase in robustness of both strategies, compared with the MPC algorithm. The conditional MPC strategy is motivated by the observation that harmful effects of the corrector steps manifest themselves in a significant increase in complementarity. The failure of convergence of the MPC method has also been analyzed by Cartis [7].

Finally we compare the monotone and quality function approaches described in section 3 with the conditional MPC approach on the nonlinear programming problems used in that section. The conditional MPC method is now implemented so as to reject corrector steps that increase complementarity (this more conservative approach appears to be more suitable in the nonlinear case). Furthermore, if the conditional MPC step does not pass the merit function or filter acceptance test for the current barrier problem, the corrector step is also rejected, and the backtracking line search



(a) IPOPT (b) KNITRO

FIG. 8. *Results for safeguarded corrector steps.*

for the regular primal-dual step is executed. Finally, no corrector step is computed while the algorithm is in the monotone mode. The results, given in Figure 8, indicate that this conditional MPC method requires fewer function evaluations, and is not less robust, than the other strategies.

8. Conclusion. We have seen in this paper that, both for linear and nonlinear programming, classical barrier update strategies with global convergence guarantees are overly conservative, while strategies that are often fastest in practice are based on heuristic formulas and are not globally convergent. We have presented a new update strategy and shown that it is efficient in practice. Instead of basing the update on a heuristic formula, our approach follows a clearly defined objective, namely, the minimization of a quality function. We further proposed a simple globalization framework that makes use of any nonmonotone barrier parameter strategy.

We have also presented results that show the corrector steps employed in MPC can have harmful effects, even in the linear and quadratic programming cases. These observations were unexpected since the MPC method has become widely used in linear and quadratic programming; our tests show that the reliability of the MPC method depends crucially on heuristics, such as the choice of the initial point. We have shown, however, that the selective use of corrector steps can have beneficial effects in interior point methods.

A question we have not addressed is whether the approach presented in this paper enjoys fast local convergence. We have not specifically introduced features that guarantee superlinear convergence. This could be done by using various techniques proposed in the literature for controlling the asymptotic behavior of the barrier parameter; see, e.g., [19] and the references therein. In particular, we could implement the strategies recently proposed by Armand et al. [1, 2] in conjunction with the quality function approach.

We have not done so because the asymptotic behavior of the method proposed in this paper has proved to be acceptable in practice. In fact, the quality function approach promotes fast local convergence because it chooses the barrier parameter so as to (approximately) minimize the quality function in the region defined by (2.8). One can design a superlinearly convergent algorithm by choosing the barrier parameter so that a step to the region defined by (2.8) decreases the KKT error superlinearly.

Since the quality function is an approximation to the KKT error, and it attempts to minimize it, it is not surprising that the quality function approach tends to yield fast local convergence.

Acknowledgments. We would like to thank Richard Byrd for many valuable suggestions during the course of this work, and the referees for suggesting ways of improving the paper.

AN ADAPTIVE SCALARIZATION METHOD IN MULTIOBJECTIVE OPTIMIZATION*

GABRIELE EICHFELDER†

Abstract. This paper presents a new method for the numerical solution of nonlinear multiobjective optimization problems with an arbitrary partial ordering in the objective space induced by a closed pointed convex cone. This algorithm is based on the well-known scalarization approach by Pascoletti and Serafini and adaptively controls the scalarization parameters using new sensitivity results. The computed image points give a nearly equidistant approximation of the whole Pareto surface. The effectiveness of this new method is demonstrated with various test problems and an applied problem from medicine.

Key words. multicriteria optimization, vector optimization, approximation, sensitivity, scalarization approaches

1. Introduction.

The optimization problems arising nowadays in application areas like engineering, economics, or the sciences are often multiobjective; i.e., several competing objective functions have to be minimized all at once. Those optimization problems have in general not only one best solution but the solution set is very large.

In the last decades the main focus was on finding one minimal solution, e.g., by interactive methods, whereas objective numerical calculations alternate with subjective decisions done by a so-called decision maker (d.m.). Based on much better computer performance it is now possible to represent the whole efficient set. Having an approximation of the whole efficient set available, the d.m. gets a useful insight in the problem structure. Especially in engineering tasks it is interesting to have all design alternatives available [28]. So in this paper we aim to generate an approximation of the efficient set as it is done in many other works, e.g., in [9, 18, 19, 24, 42, 48].

However, the information provided by this approximation depends mainly on the quality of the approximation. Many points are related to a high numerical effort and to too many points which have to be interpreted by the d.m. A sparse approximation neglects large parts of the efficient set. According to different quality criteria as discussed in [47], an approximation is good in the sense of a stinted but representative presentation if the approximation points are evenly spread with equal distances over the whole image of the solution set (see also [19]). Thus our aim is to generate equidistant points in the value space. For this we use a parameter dependent scalarization approach by Pascoletti and Serafini [45] and control the choice of the parameters adaptively.

A common concept for minimality in the multiobjective context is Edgeworth–Pareto- (EP-) minimality based on the natural ordering defined by the ordering cone $\boldsymbol{R}^m_+ := \{x \in \boldsymbol{R}^m \mid x_i \geq 0,\ i = 1, \ldots, m\}$. Using arbitrary partial orderings minimality is defined similarly (see, e.g., [4, 29, 31, 49, 58]). Allowing this, preference structures can be mapped which cannot be formulated explicitly as an objective function; see [55,

Example 4.1]. In decision theory and in economics, arbitrary partial orderings are a well-known tool to model the relative importance of several criteria or to incorporate groups of decision makers, as promoted, for instance, by Wiecek [56]. For example, cones being a superset of the positive orthant can be defined by allowable trade-offs between the objectives or by grouping objectives according to their importance. This provides a more useful representation of the decision makers' preferences than the standard cone because the set of efficient points is reduced by undesired solutions.

For example, in [26, 27] convex polyhedral cones are used for modeling the preferences of a d.m. based on trade-off information facilitating multicriteria decision making. In portfolio optimization [2] polyhedral cones as well as nonfinitely generated cones are considered. Besides, orderings, other than the natural ordering, are important in [20] where a scalar bilevel optimization problem is reformulated as a multiobjective problem. There a nonconvex cone that is the union of two convex cones is used. In [13] a multiobjective optimization problem w.r.t. a cone $K = \boldsymbol{R}^m_+ \times \{0_n\}$ is considered for solving multiobjective bilevel optimization problems. Helbig [24] constructs various cones as a tool for finding EP-minimal points; see also [37, 51]. In addition to that, Wu [57] considers convex cones for a solution concept in fuzzy multiobjective optimization. Hence, multiobjective optimization problems w.r.t. arbitrary partial orderings are essential in decision making and are further an important tool in other areas. Therefore we develop our results w.r.t. more general partial orderings defined by closed pointed convex cones.

In the remainder we proceed as follows: in section 2 we recall the basic concepts in multiobjective optimization. In section 3 we discuss the well-known scalarization approach by Pascoletti and Serafini and we give some properties of this approach. We choose this scalarization because it is very general in the sense that many other scalarizations can be seen as a special case of it; see section 7 and [15]. In section 4 we present our main sensitivity theorem on which we base our new adaptive method in section 5. In section 6 this is applied to some test problems and to a problem in intensity modulated radiotherapy in medicine. We conclude with some remarks on the presented scalarization approach and on the transferability of the given procedure to other scalarization approaches in section 7.

2. Basic notations and concepts. We consider multiobjective optimization problems formally defined by

$$\begin{aligned} &\min_K f(x) = (f_1(x), \dots, f_m(x))^\top \\ &\quad \text{subject to the constraint} \\ &\quad x \in \Omega \subset \boldsymbol{R}^n. \end{aligned} \tag{2.1}$$

Here, K represents the considered partial ordering defined later.

We assume the following:

Assumption 1. Let C be a closed convex cone in $\boldsymbol{R}^p$, $\hat{S} \subset \boldsymbol{R}^n$ a nonempty open subset, and $S \subset \hat{S}$ closed and convex. Let the functions $f\colon \hat{S} \to \boldsymbol{R}^m$, $g\colon \hat{S} \to \boldsymbol{R}^p$, and $h\colon \hat{S} \to \boldsymbol{R}^q$ $(m, n \in \boldsymbol{N},\ p, q \in \boldsymbol{N}_0,\ m \geq 2)$ be continuously differentiable on $\hat{S}$. Let the set $\Omega \subset \boldsymbol{R}^n$, given by $\Omega = \{x \in S \mid g(x) \in C,\ h(x) = 0_q\}$, be compact.

A *convex cone* $C \subset \boldsymbol{R}^p$ is a subset of $\boldsymbol{R}^p$ with the property $\lambda(x + y) \in C$ for all $\lambda \geq 0,\ x, y \in C$. For defining minimality we need a partial ordering "$\leq$" in the image space $\boldsymbol{R}^m$. Here we mean by a partial ordering a binary relation which is reflexive, transitive, and compatible with addition and with nonnegative scalar multiplication. Any partial ordering $\leq$ defines a convex cone K by $K := \{x \in \boldsymbol{R}^m \mid 0_m \leq x\}$ and any convex cone $K \subset \boldsymbol{R}^m$, then called *ordering cone*, defines a partial ordering by

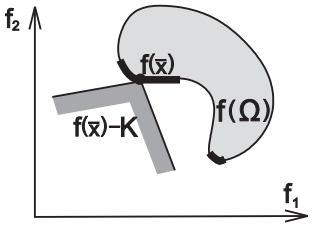

FIG. 2.1. *Illustration of Definition* 2.1 *for* $m = 2$. *The thick part of the boundary of* $f(\Omega)$ *denotes the set* $\mathcal{E}(f(\Omega), K)$.

$\leq_K := \{(x, y) \in \boldsymbol{R}^m \times \boldsymbol{R}^m \mid y - x \in K\}$. For example, the natural ordering is defined by the cone $\boldsymbol{R}^m_+$. The partial ordering is antisymmetric if the related ordering cone is *pointed*, i.e., $K \cap (-K) = \{0_m\}$. Here we consider only partial orderings defined by closed pointed convex cones.

Assumption 2. Let Assumption 1 hold. In addition let $K \subset \boldsymbol{R}^m$ be a closed pointed convex cone.

Minimality is then defined by (see, among others, [29, 31, 49, 58]):

DEFINITION 2.1. *Let* K *be a closed pointed convex cone. A point* $\bar{x} \in \Omega$ *is called* K*-minimal of* (2.1) *if* $(f(\bar{x}) - K) \cap f(\Omega) = \{f(\bar{x})\}$. *Additionally for* $int(K) \neq \emptyset$ *a point* $\bar{x} \in \Omega$ *is called weakly* K*-minimal of* (2.1) *if* $(f(\bar{x}) - int(K)) \cap f(\Omega) = \emptyset$.

For an illustration of this definition see Figure 2.1.

We denote the set of all K-minimal points by $\mathcal{M}(f(\Omega), K)$ and the set of all weakly K-minimal points by $\mathcal{M}_w(f(\Omega), K)$. The set $\mathcal{E}(f(\Omega), K) := \{f(x) \in \boldsymbol{R}^m \mid x \in \mathcal{M}(f(\Omega), K)\}$ is called *efficient set* (see Figure 2.1) and the set $\mathcal{E}_w(f(\Omega), K) := \{f(x) \in \boldsymbol{R}^m \mid x \in \mathcal{M}_w(f(\Omega), K)\}$ *weakly efficient set*. For $K = \boldsymbol{R}^m_+$ the K-minimal points are denoted as *Edgeworth–Pareto (EP)-minimal* points, too.

Later on we need that in the bicriteria case ($m = 2$) every ordering cone is finitely generated. This is stated in the following lemma. The proof is omitted here and the interested reader is referred to [13]. For the definition of a finitely generated cone (or polyhedral cone) see [46, Definition 2.17, 2.18].

LEMMA 2.2. *Let* $K \subset \boldsymbol{R}^2$ *be a closed pointed convex cone with* $K \neq \{0_2\}$. *Then* K *is polyhedral and there is either a* $k \in \boldsymbol{R}^2 \setminus \{0_2\}$ *with* $K = \{\lambda k \mid \lambda \geq 0\}$ *or there are* $l^1, l^2 \in \boldsymbol{R}^2 \setminus \{0_2\}$, l^1, l^2 *linearly independent, and* $\tilde{l}^1, \tilde{l}^2 \in \boldsymbol{R}^2 \setminus \{0_2\}$, $\tilde{l}^1, \tilde{l}^2$ *linearly independent, with*

(2.2)
$$K = \left\{y \in \boldsymbol{R}^2 \mid {l^1}^\top y \geq 0,\ {l^2}^\top y \geq 0\right\} = \left\{y \in \boldsymbol{R}^2 \mid y = \lambda^1 \tilde{l}^1 + \lambda^2 \tilde{l}^2,\ \lambda^1, \lambda^2 \geq 0\right\}.$$

In general, Lemma 2.2 is not true for $m \geq 3$. This is illustrated by the ice-cream cone $\{(x_1, x_2, x_3) \in \boldsymbol{R}^3 \mid x_1 \geq \sqrt{x_2^2 + x_3^2}\}$ which is not polyhedral.

3. Scalarization approach. For determining minimal solutions of the multiobjective optimization problem (2.1) a common approach is the scalarization of the problem. We examine the scalarization problem by Pascoletti and Serafini [45] named (SP(a, r)) which is defined by

(SP(a, r))
$$\begin{array}{c} \min t \\ \text{subject to the constraints} \\ a + t\, r - f(x) \in K, \\ x \in \Omega, \quad t \in \boldsymbol{R} \end{array}$$

for parameters $a, r \in \boldsymbol{R}^m$. Properties of this scalarization approach can be found in [13, 45]. Here we concentrate on some major results only.

THEOREM 3.1.

(a) *Let $\bar{x}$ be a K-minimal point of* (2.1)*, then $(0, \bar{x})$ is a global minimal solution of* (SP(a, r)) *with $a = f(\bar{x})$, $r \in K \setminus \{0_m\}$.*

(b) *Let $(\bar{t}, \bar{x})$ be a global minimal solution of* (SP(a, r))*, then $\bar{x}$ is a weakly K-minimal solution of* (2.1)*.*

Theorem 3.1 is given for global minimal solutions, but the statements can easily be adapted to local minimal solutions (for a continuous function f) too; see [13, 45]. Theorem 3.1 (a) yields that any K-minimal solution of the multiobjective optimization problem can be found by solving the scalar problem (SP(a, r)) for appropriate parameters, even for nonconvex problems. This is not the case for any scalarization approach as, e.g., the weighted sum method [59] shows. In the following Theorems 3.2, 3.3, and 3.5 we even see that it is sufficient to consider only variations of the parameter a in (a subset of) a hyperplane for a fixed chosen parameter $r \in K \setminus \{0_m\}$. Then it is still possible that any minimal solution of the multiobjective optimization can be recovered.

THEOREM 3.2. *Let $\bar{x} \in \mathcal{M}(f(\Omega), K)$ and $r \in K$ be given. We define a hyperplane H by $H = \{y \in \boldsymbol{R}^m \mid b^\top y = \beta\}$ with $b \in \boldsymbol{R}^m \setminus \{0_m\}$, $b^\top r \neq 0$, $\beta \in \boldsymbol{R}$. Then there is a parameter $a \in H$ and some $\bar{t} \in \boldsymbol{R}$ so that $(\bar{t}, \bar{x})$ is a minimal solution of* (SP(a, r))*.*

Proof. We set $\bar{t} = (b^\top f(\bar{x}) - \beta)/(b^\top r)$ and $a = f(\bar{x}) - \bar{t}\, r$. Then $a \in H$ and $(\bar{t}, \bar{x})$ is feasible for (SP(a, r)). We assume $(\bar{t}, \bar{x})$ is not a minimal solution of (SP(a, r)). Then there are $t' \in \boldsymbol{R}$, $t' < \bar{t}$, $x' \in \Omega$, and $k' \in K$ so that $a + t'\, r - f(x') = k'$. Using the definition of the parameter a, this results in $f(\bar{x}) = f(x') + k' + (\bar{t} - t')r$. Since K is a pointed convex cone, $r \in K \setminus \{0_m\}$ and $\bar{t} - t' > 0$ we have $f(\bar{x}) \in f(x') + K \setminus \{0_m\}$ for $x' \in \Omega$ which is a contradiction to $\bar{x}$ K-minimal. ∎

We can restrict the parameter set even further. First we consider the bicriteria case ($m = 2$). Then, according to Lemma 2.2, every closed pointed convex cone is finitely generated. We suppose the cone K is given by (2.2). (The more trivial case $K = \{\lambda k \mid \lambda \geq 0\}$ for some $k \in \boldsymbol{R}^2 \setminus \{0_2\}$ can be handled similarly, but we will not consider this less interesting case here. For more details see [13, pp. 73f]). Next we solve the scalar optimization problems

$$\min_{x \in \Omega} l^{i\top} f(x), \qquad i = 1, 2, \tag{3.1}$$

with minimal solutions $\bar{x}^i$, $i = 1, 2$. Then the points $\bar{x}^i$, $i = 1, 2$, are weakly K-minimal and we can easily show that for every K-minimal point x of (2.1) we have

$$l^{1\top} f\left(\bar{x}^1\right) \leq l^{1\top} f(x) \leq l^{1\top} f\left(\bar{x}^2\right) \quad \text{and} \quad l^{2\top} f\left(\bar{x}^2\right) \leq l^{2\top} f(x) \leq l^{2\top} f\left(\bar{x}^1\right). \tag{3.2}$$

Using (3.2), $l^{1\top} f(\bar{x}^1) = l^{1\top} f(\bar{x}^2)$ implies $l^{1\top} f(x) = l^{1\top} f(\bar{x}^2)$ and, consequently, $f(x) \in f(\bar{x}^2) + K$ for all $x \in \mathcal{M}(f(\Omega), K)$ resulting in $\mathcal{E}(f(\Omega), K) = \{f(\bar{x}^2)\}$. The same, $l^{2\top} f(\bar{x}^2) = l^{2\top} f(\bar{x}^1)$, leads to $\mathcal{E}(f(\Omega), K) = \{f(\bar{x}^1)\}$. Thus, assuming the efficient set does not consist of one point only, we have

$$l^{1\top} f\left(\bar{x}^1\right) < l^{1\top} f\left(\bar{x}^2\right) \quad \text{and} \quad l^{2\top} f\left(\bar{x}^2\right) < l^{2\top} f\left(\bar{x}^1\right). \tag{3.3}$$

If we define the points $\bar{a}^i$, $i = 1, 2$, by a projection of the points $f(\bar{x}^i)$, $i = 1, 2$, in direction $r \in K$ on the hyperplane H, then we get

$$\bar{a}^i := f\left(\bar{x}^i\right) - \bar{t}^i\, r \in H \quad \text{with} \quad \bar{t}^i := \frac{b^\top f\left(\bar{x}^i\right) - \beta}{b^\top r}, \qquad i = 1, 2. \tag{3.4}$$

In the next theorem we see that we can restrict ourselves to the set $H^a := \{y \in \boldsymbol{R}^2 \mid y = \lambda\bar{a}^1 + (1-\lambda)\bar{a}^2,\ \lambda \in [0,1]\}$ for choosing the parameter a.

THEOREM 3.3. *We consider the multiobjective optimization problem* (2.1) *with* $m = 2$ *and* K *as in* (2.2). *Further let* $\bar{a}^i,\ i = 1,2$, *be defined as in* (3.4) *with* $\bar{x}^i$, $i = 1,2$, *minimal solutions of* (3.1) *and assume* $\bar{x} \in \mathcal{M}(f(\Omega), K)$. *Then there is a parameter* $a \in H^a \subset H$ *and some* $\bar{t} \in \boldsymbol{R}$ *so that* $(\bar{t}, \bar{x})$ *is a minimal solution of* (SP(a,r)).

Proof. Notice that $\bar{a}^1, \bar{a}^2 \in H$ and, hence, $H^a \subset H$. According to Theorem 3.2 we have for any $\bar{x} \in \mathcal{M}(f(\Omega), K)$ a parameter $a \in H$ and some $\bar{t} \in \boldsymbol{R}$ so that $(\bar{t}, \bar{x})$ is a minimal solution of (SP(a,r)). This is achieved by $\bar{t} = (b^\top f(\bar{x}) - \beta)/(b^\top r)$ and $a = f(\bar{x}) - \bar{t}\, r$. Hence, it suffices to show $a = \lambda\bar{a}^1 + (1-\lambda)\bar{a}^2$ for some $\lambda \in [0,1]$. Using the definitions of a, $\bar{a}^1$, and $\bar{a}^2$, this equation can be written as

$$f(\bar{x}) - \bar{t}\, r = \lambda \left(f\left(\bar{x}^1\right) - \bar{t}^1\, r\right) + (1-\lambda)\left(f\left(\bar{x}^2\right) - \bar{t}^2\, r\right). \tag{3.5}$$

If the efficient set consists of one point only (and then this point is $f(\bar{x}^1)$ or $f(\bar{x}^2)$) (3.5) is fulfilled for $\lambda = 1$ or $\lambda = 0$. Otherwise, the strict inequalities (3.3) hold. Equation (3.5) can further be written as

$$f(\bar{x}) = \lambda\, f\left(\bar{x}^1\right) + (1-\lambda)\, f\left(\bar{x}^2\right) + \left(\bar{t} - \lambda\, \bar{t}^1 - (1-\lambda)\, \bar{t}^2\right) r, \tag{3.6}$$

and we differentiate the following two cases: $(\bar{t} - \lambda\, \bar{t}^1 - (1-\lambda)\, \bar{t}^2) = \frac{1}{b^\top r}(b^\top(f(\bar{x}) - \lambda\, f(\bar{x}^1) - (1-\lambda)\, f(\bar{x}^2)) \geq 0$ and $(\bar{t} - \lambda\, \bar{t}^1 - (1-\lambda)\, \bar{t}^2) < 0$.

For $\bar{t} - \lambda\, \bar{t}^1 - (1-\lambda)\, \bar{t}^2 \geq 0$ we suppose (3.6) is satisfied for $\lambda < 0$. Applying the linear map l^1 on (3.6) results, together with $r \in K$ and (3.3), in the following:

$$\begin{aligned} l^{1\top} f(\bar{x}) &= \lambda\, l^{1\top} f\left(\bar{x}^1\right) + (1-\lambda)\, l^{1\top} f\left(\bar{x}^2\right) + \underbrace{\left(\bar{t} - \lambda\, \bar{t}^1 - (1-\lambda)\, \bar{t}^2\right)}_{\geq 0} \underbrace{l^{1\top} r}_{\geq 0} \\ &\geq \underbrace{\lambda}_{<0} \underbrace{l^{1\top} f\left(\bar{x}^1\right)}_{<l^{1\top} f(\bar{x}^2)} + (1-\lambda) l^{1\top} f\left(\bar{x}^2\right) \\ &> \lambda\, l^{1\top} f\left(\bar{x}^2\right) + (1-\lambda)\, l^{1\top} f\left(\bar{x}^2\right) = l^{1\top} f\left(\bar{x}^2\right), \end{aligned}$$

which is a contradiction to (3.2).

Instead, assuming (3.6) is satisfied for $\lambda > 1$, we get by applying l^2 on (3.6) together with (3.3)

$$l^{2\top} f(\bar{x}) \geq \lambda\, l^{2\top} f\left(\bar{x}^1\right) + \underbrace{(1-\lambda)}_{<0} \underbrace{l^{2\top} f\left(\bar{x}^2\right)}_{<l^{2\top} f(\bar{x}^1)} > l^{2\top} f\left(\bar{x}^1\right)$$

in contradiction to (3.2). Hence, we have $\lambda \in [0,1]$ for $\bar{t} - \lambda\, \bar{t}^1 - (1-\lambda)\, \bar{t}^2 \geq 0$.

In the same way we show $\lambda \in [0,1]$ for $\bar{t} - \lambda\, \bar{t}^1 - (1-\lambda)\, \bar{t}^2 < 0$, too, and the assertion of the theorem is proven. ∎

A generalization to the case $m \geq 3$ is not possible because then a cone need not be finitely generated as we have seen. Even if the cone is finitely generated, even if it is the positive orthant, the previous results are not true in general for more than two objectives as the following example shows.

Example 3.4. We consider the function $f\colon \boldsymbol{R}^3 \to \boldsymbol{R}^3$ with $f(x) = x$ for all $x \in \boldsymbol{R}^3$ and the set $\Omega = \{x \in \boldsymbol{R}^3 \mid x_1^2 + x_2^2 + x_3^2 \leq 1\}$ representing the unit ball in $\boldsymbol{R}^3$. Let the ordering cone be the natural ordering cone $K = \boldsymbol{R}^3_+$ finitely generated by $l^1 = (1,0,0)^\top$, $l^2 = (0,1,0)^\top$, and $l^3 = (0,0,1)^\top$. The multiobjective optimiz-

ation problem $\min_{x\in\Omega} f(x)$ has the minimal solution set $\mathcal{M}(f(\Omega), \boldsymbol{R}^3_+) = \{x \in \boldsymbol{R}^3 \mid x_1^2 + x_2^2 + x_3^2 = 1,\ x_i \le 0,\ i = 1,2,3\}$. By solving the scalar optimization problems $\min_{x\in\Omega} l^{i\top} f(x),\ i = 1,2,3$ (compare (3.1)), we get the minimal solutions $\bar{x}^1 = (-1,0,0)^\top,\ \bar{x}^2 = (0,-1,0)^\top$, and $\bar{x}^3 = (0,0,-1)^\top$. If we consider now the hyperplane $H = \{y \in \boldsymbol{R}^3 \mid (-1,-1,-1)\cdot y = 1\}$ we have $f(\bar{x}^i) = \bar{x}^i \in H$ for $i = 1,2,3$.

Choosing $r = (1,1,1)^\top$ and determining the points $\bar{a}^i \in H$, $i = 1,2,3$, as in (3.4) results in $\bar{a}^1 = (-1,0,0)^\top,\ \bar{a}^2 = (0,-1,0)^\top,\ \bar{a}^3 = (0,0,-1)^\top$ and, hence, in the set H^a consisting of all convex combinations of the points $\bar{a}^i,\ i = 1,2,3$. In this example the point $\bar{x} = (-1/\sqrt{2}, -1/\sqrt{2}, 0)^\top$ is EP-minimal, but there is no parameter $\bar{a} \in H^a$ such that $\bar{x}$ is a minimal solution of $(\mathrm{SP}(\bar{a}, r))$. For $\bar{a} = -1/(3\sqrt{2})\cdot(1+\sqrt{2}, 1+\sqrt{2}, \sqrt{2}-2)^\top$ and $\bar{t} = (1-\sqrt{2})/3$ the point $(\bar{t}, \bar{x})$ is a minimal solution of $(\mathrm{SP}(\bar{a}, r))$ but it is $\bar{a} \notin H^a$.

Similar considerations have been done in [9, pp. 635f] in connection with the normal boundary intersection method. Nevertheless we want to restrain the set H from which we choose the parameters a for the case of more than two objectives. For this aim we project the set $f(\Omega)$ in the direction r into the set H and determine the set $\tilde{H} := \{y \in H \mid y + t\,r = f(x),\ t \in \boldsymbol{R},\ x \in \Omega\} \subset H$. Of course we would get a stricter limitation by projecting the set $\mathcal{E}(f(\Omega), K)$ instead of $f(\Omega)$, but in general the efficient set is not known in advance. Because the set $\tilde{H} \subset H$ has usually an irregular shape, which complicates a methodic procedure, we embed the set $\tilde{H}$ in the image of an $(m-1)$-dimensional hyperplane under a linear transformation $H^0 \subset \boldsymbol{R}^m$, which we attempt to choose minimally. For doing this we first determine $m-1$ orthogonal vectors $v^1, \dots, v^{m-1}$ spanning the hyperplane H with $\tilde{H} \subset H$. Hence, we have

$$H = \left\{ y \in \boldsymbol{R}^m \mid y = \sum_{i=1}^{m-1} s_i v^i,\ s \in \boldsymbol{R}^{m-1} \right\}. \tag{3.7}$$

Next we solve the following $2(m-1)$ scalar optimization problems

$$\begin{array}{c} \min s_j \\ \text{subject to the constraints} \\ \sum_{i=1}^{m-1} s_i v^i + t\,r = f(x), \\ t \in \boldsymbol{R},\ x \in \Omega,\ s \in \boldsymbol{R}^{m-1}, \end{array} \quad \text{and} \quad \begin{array}{c} \min -s_j \\ \text{subject to the constraints} \\ \sum_{i=1}^{m-1} s_i v^i + t\,r = f(x), \\ t \in \boldsymbol{R},\ x \in \Omega,\ s \in \boldsymbol{R}^{m-1} \end{array} \tag{3.8}$$

for $j \in \{1, \dots, m-1\}$ with minimal solutions $(t^{\min,j}, x^{\min,j}, s^{\min,j})$ and minimal values $s_j^{\min,j}$ and $(t^{\max,j}, x^{\max,j}, s^{\max,j})$ and minimal values $-s_j^{\max,j}$, respectively. These optimization problems are generally nonconvex even if the related multiobjective optimization problem is convex. However, note that it suffices to provide lower bounds for the optimal function values for the following results. Then we obtain the set H^0 by $H^0 := \{y \in \boldsymbol{R}^m \mid y = \sum_{i=1}^{m-1} s_i v^i,\ s_i \in [s_i^{\min,i}, s_i^{\max,i}],\ i = 1, \dots, m-1\}$. The set H^0 includes the set $\tilde{H}$ and is calculated numerically as small as possible.

THEOREM 3.5. *Let $\bar{x} \in \mathcal{M}(f(\Omega), K)$. Then there is a parameter $\bar{a} \in H^0$ and some $\bar{t} \in \boldsymbol{R}$ so that $(\bar{t}, \bar{x})$ is a minimal solution of* $(\mathrm{SP}(\bar{a}, r))$.

Proof. According to the proof of Theorem 3.2 we have for $\bar{t} = (b^\top f(\bar{x}) - \beta)/(b^\top r)$ and $\bar{a} = f(\bar{x}) - \bar{t}\,r$ that $(\bar{t}, \bar{x})$ is a minimal solution of $(\mathrm{SP}(\bar{a}, r))$ with $\bar{a} \in H$. Because $H^0 \subset H$ it suffices to show $\bar{a} \in H^0$. Because $\bar{a} \in H$ there is, according to the representation in (3.7), a vector $\bar{s} \in \boldsymbol{R}^{m-1}$ with $\bar{a} = \sum_{i=1}^{m-1} \bar{s}_i v^i$. Because of $\bar{a} + \bar{t}\,r =$

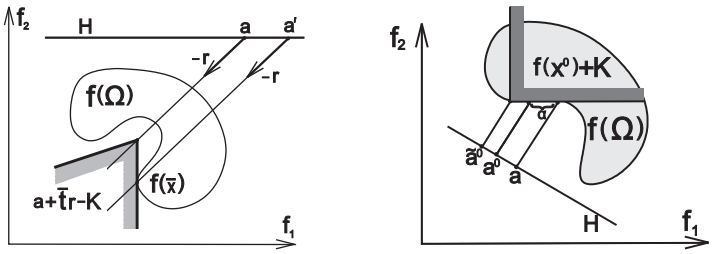

FIG. 3.1. (a) *Visualization of Theorem* 3.6. (b) *Choosing the new parameter in the case* $a^0 + t^0\, r - f(x^0) \neq 0_2$ *and* $\tilde{a}_1^0 < a_1^0$.

$f(\bar{x})$, the point $(\bar{t}, \bar{x}, \bar{s})$ is feasible for the optimization problems (3.8) and thus we have $s_i^{\min,i} \leq \bar{s}_i \leq s_i^{\max,i}$ for $i = 1, \ldots, m-1$. Hence, it follows $\bar{a} \in H^0$. ☐

Thus, it is sufficient to consider only parameters $a \in H^0$ for a fixed $r \in K \setminus \{0_m\}$ to find all K-minimal solutions of the multiobjective optimization problem (2.1).

For our considerations in the next section it will be important that in the minimal solution $(\bar{t}, \bar{x})$ the constraint $a + t\, r - f(x) \in K$ is active; i.e., $a + \bar{t}\, r - f(\bar{x}) = 0_m$. If this is not the case for the choice of a parameter a, we can easily define a new parameter a' for which this property is satisfied (see Figure 3.1(a)).

THEOREM 3.6. *Let the hyperplane* $H = \{y \in \boldsymbol{R}^m \mid b^\top y = \beta\}$ *with* $b \in \boldsymbol{R}^m \setminus \{0_m\}$, $\beta \in \boldsymbol{R}$ *be given. Suppose* $(\bar{t}, \bar{x})$ *is a minimal solution of* $(\mathrm{SP}(a, r))$ *for* $a \in H$, $r \in K$, $b^\top r \neq 0$. *Then there is a* $\bar{k} \in K$ *with* $a + \bar{t}\, r - f(\bar{x}) = \bar{k}$. *However, then there is a point* $a' \in H$ *and some* $t' \in \boldsymbol{R}$ *so that* $(t', \bar{x})$ *is also a minimal solution of* $(\mathrm{SP}(a', r))$ *with* $a' + t'\, r - f(\bar{x}) = 0_m$.

Proof. We set $t' := (b^\top f(\bar{x}) - \beta)/(b^\top r)$ and $a' := a + (\bar{t} - t')\, r - \bar{k} = f(\bar{x}) - t'\, r$. Then $a' \in H$ and $a' + t'\, r - f(\bar{x}) = 0_m$. Next we show that $(t', \bar{x})$ is a minimal solution of $(\mathrm{SP}(a', r))$. Otherwise there is a feasible point $(\hat{t}, \hat{x}) \in \boldsymbol{R} \times \Omega$ with $\hat{t} < t'$ and there is a $\hat{k} \in K$ with $a' + \hat{t}\, r - f(\hat{x}) = \hat{k}$. Together with the definition of a' this leads to $a + (\bar{t} - t' + \hat{t})\, r - f(\hat{x}) = \hat{k} + \bar{k} \in K$. However, then $(\bar{t} - t' + \hat{t}, \hat{x})$ is feasible for $(\mathrm{SP}(a, r))$ with $\bar{t} - t' + \hat{t} < \bar{t}$ in contradiction to $(\bar{t}, \bar{x})$ a minimal solution of $(\mathrm{SP}(a, r))$. ☐

It can also be shown that there is no K-minimal point $\tilde{x}$ for which $\tilde{a} = a + \lambda\,(a' - a)$ for some $\lambda \in]0, 1[$ with $\tilde{a} := f(\tilde{x}) - \tilde{t}\, r$ and $\tilde{t} := (b^\top f(\tilde{x}) - \beta)/(b^\top r)$ [13, Theorem 4.2.12]. Thus the section on the hyperplane H between the parameters a and a' can be neglected. According to Theorem 3.6 we have for the parameter a' not only $a' \in H$ but also $a' + t'\, r = f(\bar{x})$. Hence, for the set H^0 as in Theorem 3.5, it holds $a' \in H^0$.

Under the Assumption 2 it can be shown that if a minimal solution $(\bar{t}, \bar{x})$ of $(\mathrm{SP}(a, r))$ has Lagrange multipliers $(\mu, \nu, \xi) \in K^* \times C^* \times \boldsymbol{R}^q$, then these are also Lagrange multipliers to the point $(t', \bar{x})$ for $(\mathrm{SP}(a', r))$ under the transformation of Theorem 3.6. For the definition of the Lagrange function and the Lagrange multipliers see, for instance, [32, p. 115]. Here, $\mu \in K^*$ is the Lagrange multiplier to the constraint $a + t\, r - f(x) \in K$ (and thus also to $a' + t\, r - f(x) \in K$), $\nu \in C^*$ corresponds to the constraint $g(x) \in C$, and $\xi \in \boldsymbol{R}^q$ to the equality constraint $h(x) = 0_q$.

4. Sensitivity results. The main point of our adaptive parameter control for the parameter dependent scalarization approach $(\mathrm{SP}(a, r))$ is a sensitivity theorem based on theorems by Alt [3, Theorem 5.3, 6.1]. For two reasons we apply these

theorems on a modified version of problem $(\mathrm{SP}(a,r))$ called $(\overline{\mathrm{SP}}(a,r))$:

$$(\overline{\mathrm{SP}}(a,r)) \qquad \begin{array}{c} \min t \\ \text{subject to the constraints} \\ a + t\,r - f(x) = 0_m, \\ t \in \boldsymbol{R},\ x \in \Omega \end{array}$$

with the constraint set $\overline{\Sigma}(a,r) := \{(t,x) \in \boldsymbol{R} \times \boldsymbol{R}^n \mid a + t\,r - f(x) = 0_m,\ x \in \Omega\}$.

First, by getting sensitivity results for the minimal value $t = t(a,r)$ of the problem $(\overline{\mathrm{SP}}(a,r))$ we can at once conclude how a variation of the parameters influences the generated points $f(x(a,r))$ by using the equality constraint $a + t(a,r)\,r - f(x(a,r)) = 0_m$. Second, for applying the sensitivity theorems by Alt directly to the problem $(\mathrm{SP}(a,r))$, for the Hessian of the Lagrange function $\mathcal{L}(t,x,\mu,\nu,\xi,a,r) = t - \mu^\top(a + t\,r - f(x)) - \nu^\top g(x) - \xi^\top h(x)$ w.r.t. the variables (t,x)

$$\nabla^2_{(t,x)}\mathcal{L}(t,x,\mu,\nu,\xi,a,r) = \begin{pmatrix} 0 & 0 \\ 0 & W(x,\mu,\nu,\xi) \end{pmatrix}$$

with $W(x,\mu,\nu,\xi) = \sum_{i=1}^m \mu_i \nabla^2 f_i(x) - \sum_{j=1}^p \nu_j \nabla^2 g_j(x) - \sum_{k=1}^q \xi_k \nabla^2 h_k(x)$ the assumption

$$\left(t, x^\top\right) \nabla^2_{(t,x)}\mathcal{L}(t,x,\mu,\nu,\xi,a,r) \begin{pmatrix} t \\ x \end{pmatrix} \geq \alpha \left\| \begin{pmatrix} t \\ x \end{pmatrix} \right\|^2$$

has to be satisfied for some constant $\alpha > 0$ for all $(t,x) \in \boldsymbol{R}^{n+1}$ with $\nabla h(x)x = 0_q$. This is always contradicted by the points $(t,x) = (t,0_n)$ with $t \neq 0$.

Problem $(\overline{\mathrm{SP}}(a,r))$ is in general nonconvex, even if the original multiobjective optimization problem is convex. However, note that the problem $(\overline{\mathrm{SP}}(a,r))$ is never actually solved. We solve only the problems $(\mathrm{SP}(a,r))$ (which are convex if the original multiobjective optimization problem is convex) and we use the problem $(\overline{\mathrm{SP}}(a,r))$ only for approximating the minimal value and the points $f(x(a,r))$ of the problem $(\mathrm{SP}(a,r))$.

We obtain the connection between the problems $(\mathrm{SP}(a,r))$ and $(\overline{\mathrm{SP}}(a,r))$ by Theorem 3.6: if we solve the problem $(\mathrm{SP}(a,r))$ with a minimal solution $(\bar{t},\bar{x})$ and with $a + \bar{t}\,r - f(\bar{x}) = \bar{k} \in K$, then there always exists a parameter a' and some t' so that $(t',\bar{x})$ is minimal for $(\mathrm{SP}(a',r))$ with $a' + t'\,r - f(\bar{x}) = 0_m$ and then $(t',\bar{x})$ is a minimal solution of $(\overline{\mathrm{SP}}(a',r))$ too. We examine now the dependence of the minimal values of the problem $(\overline{\mathrm{SP}}(a',r))$ on the parameter a' (in Theorem 4.2) and from that we conclude on the (approximated) dependence of the minimal value of the problem $(\mathrm{SP}(a',r))$ on the parameter a' (in section 5.1). Before we come to the main sensitivity result we need the following assumption and the following lemma.

Assumption 3. Let Assumption 2 hold. In addition let the functions f, g, and h be twice continuously differentiable on $\hat{S}$.

LEMMA 4.1. *Let Assumption* 3 *hold. Let* (t^0,x^0) *be a local minimal solution of* $(\overline{\mathrm{SP}}(a^0,r^0))$ *with Lagrange multipliers* $(\mu^0,\nu^0,\xi^0) \in \boldsymbol{R}^m \times C^* \times \boldsymbol{R}^q$. *Assume there exists some constant* $\tilde{\alpha} > 0$ *such that for the matrix* $W(x^0,\mu^0,\nu^0,\xi^0) = \mu^{0\top}\nabla^2 f(x^0) - \nu^{0\top}\nabla^2 g(x^0) - \xi^{0\top}\nabla^2 h(x^0)$ *we have*

$$x^\top W\left(x^0,\mu^0,\nu^0,\xi^0\right) x \geq \tilde{\alpha}\,\|x\|^2 \tag{4.1}$$

for all $x \in \{x \in \boldsymbol{R}^n \mid \nabla h(x^0)x = 0_q,\ \nabla f(x^0)x = r^0\,t \ \text{ for a } t \in \boldsymbol{R}\}$. *Then there exists*

some constant $\alpha > 0$ such that for the Lagrange function $\overline{\mathcal{L}}$ to $(\overline{\mathrm{SP}}(a,r))$ we have

$$\left(t, x^\top\right) \nabla^2_{(t,x)} \overline{\mathcal{L}}\left(t^0, x^0, \mu^0, \nu^0, \xi^0, a^0, r^0\right) \begin{pmatrix} t \\ x \end{pmatrix} \geq \alpha \left\| \begin{pmatrix} t \\ x \end{pmatrix} \right\|^2 \tag{4.2}$$

for all $(t,x) \in \{(t,x) \in \boldsymbol{R} \times \boldsymbol{R}^n \mid \nabla h(x^0)x = 0_q,\ \nabla f(x^0)x = r^0\, t\}$.

Proof. Because (t^0, x^0) is a local minimal solution of $(\overline{\mathrm{SP}}(a^0, r^0))$ with Lagrange multipliers (μ^0, ν^0, ξ^0) we have for the associated Lagrange function

$$\nabla_{(t,x)} \overline{\mathcal{L}}\left(t^0, x^0, \mu^0, \nu^0, \xi^0, a^0, r^0\right)^\top \begin{pmatrix} t - t^0 \\ x - x^0 \end{pmatrix} \geq 0 \text{ for all } t \in \boldsymbol{R},\ x \in S. \tag{4.3}$$

With $\frac{\partial \overline{\mathcal{L}}(t^0, x^0, \mu^0, \nu^0, \xi^0, a^0, r^0)}{\partial t} = 1 - \mu^{0\top} r^0$ and because (4.3) has to be fulfilled for all $t \in \boldsymbol{R}$ we have

$$\mu^{0\top} r^0 = 1 \tag{4.4}$$

and, therefore, $\mu^0 \neq 0_m$, $r^0 \neq 0_m$. Because in $\boldsymbol{R}^n$ and $\boldsymbol{R}^m$, respectively, all norms are equivalent, there exist positive constants M^l, $M^u \in \boldsymbol{R}_+$ and $\tilde{M}^l$, $\tilde{M}^u \in \boldsymbol{R}_+$, respectively, with $M^l \|x\|_2 \leq \|x\| \leq M^u \|x\|_2$ and

$$\tilde{M}^l \left\| \begin{pmatrix} t \\ x \end{pmatrix} \right\|_2 \leq \left\| \begin{pmatrix} t \\ x \end{pmatrix} \right\| \leq \tilde{M}^u \left\| \begin{pmatrix} t \\ x \end{pmatrix} \right\|_2$$

for all $(t,x) \in \boldsymbol{R} \times \boldsymbol{R}^n$. For all $(t,x) \in \boldsymbol{R} \times \boldsymbol{R}^n$ with $\nabla f(x^0)x = r^0\, t$ we have together with (4.4) the equation $\mu^{0\top} \nabla f(x^0)x = t$ and then we get the estimation $|t|^2 = |\mu^{0\top} \nabla f(x^0)x|^2 \leq \|\mu^0\|_2^2 \, \|\nabla f(x^0)\|_2^2 \, \|x\|_2^2$. If we set now

$$\alpha := \frac{\tilde{\alpha}\ \left(M^l\right)^2}{\left(\tilde{M}^u\right)^2\ \left(1 + \|\mu^0\|_2^2 \, \|\nabla f\left(x^0\right)\|_2^2\right)} > 0,$$

we conclude from (4.1) for all $(t,x) \in \{(t,x) \in \boldsymbol{R} \times \boldsymbol{R}^n \mid \nabla h(x^0)x = 0_q,\ \nabla f(x^0)x = r^0\, t\}$

$$\begin{aligned} x^\top W\left(x^0, \mu^0, \nu^0, \xi^0\right) x &\geq \tilde{\alpha}\, \|x\|^2 \geq \tilde{a}\ \left(M^l\right)^2 \|x\|_2^2 \\ &= \alpha\ \left(\tilde{M}^u\right)^2\ \left(1 + \|\mu^0\|_2^2 \, \|\nabla f(x^0)\|_2^2\right)\ \|x\|_2^2 \\ &\geq \alpha\ \left(\tilde{M}^u\right)^2\ \left(\|x\|_2^2 + |t|^2\right) \\ &= \alpha\ \left(\tilde{M}^u\right)^2\ \left\| \begin{pmatrix} t \\ x \end{pmatrix} \right\|_2^2 \geq \alpha \left\| \begin{pmatrix} t \\ x \end{pmatrix} \right\|^2. \end{aligned}$$

With

$$\nabla^2_{(t,x)} \overline{\mathcal{L}}\left(t^0, x^0, \mu^0, \nu^0, \xi^0, a^0, r^0\right) = \begin{pmatrix} 0 & 0 \\ 0 & W\left(x^0, \mu^0, \nu^0, \xi^0\right) \end{pmatrix}$$

the assertion is proven. ∎

The condition (4.2) for all (t,x) of the given set is called strict second-order sufficient condition. If this condition is fulfilled for a regular point, then this is sufficient for strict local minimality of the considered point [41, Theorem 5.2].

THEOREM 4.2. *Let Assumption* 3 *and the assumptions of Lemma* 4.1 *hold. We consider the parametric optimization problem* $(\overline{\mathrm{SP}}(a,r))$ *with the constraint set* $\overline{\Sigma}(a,r)$ *starting with a reference problem* $(\overline{\mathrm{SP}}(a^0,r^0))$ *with a local minimal solution* (t^0,x^0) *and with Lagrange multipliers* $(\mu^0,\nu^0,\xi^0)\in \boldsymbol{R}^m\times C^*\times \boldsymbol{R}^q$.

(i) *Suppose the point* (t^0,x^0) *is regular for the set* $\overline{\Sigma}(a^0,r^0)$, *i.e., we have*

$$0_{m+p+q}\in \mathit{int}\left\{\left(\begin{array}{rcl} r^0\ \left(t-t^0\right) & - & \nabla f\left(x^0\right)\left(x-x^0\right)\\ g\left(x^0\right) & + & \nabla g\left(x^0\right)\left(x-x^0\right)-c\\ & & \nabla h\left(x^0\right)\left(x-x^0\right)\end{array}\right)\ \left|\ \begin{array}{l} c\in C,\\ x\in S,\\ t\in \boldsymbol{R}\end{array}\right.\right\}.$$

(ii) *Assume there exists some* $\zeta>0$ *such that the following holds for all* $p^1,\ p^2\in \zeta\tilde{B}$ *(with* $\tilde{B}$ *the closed unit ball in* $\boldsymbol{R}^{1+n+m+p+q}$*) with* $p^i=(t^{*i},x^{*i},u^i,v^i,w^i)$, $i=1,\,2$: *if* (t^1,x^1) *and* (t^2,x^2), *respectively, are solutions of the quadratic optimization problem*

$$\begin{array}{c}\min J\left(t,x,p^i\right)\\ \textit{subject to the constraints}\\ r^0\ \left(t-t^0\right)-\nabla f\left(x^0\right)\left(x-x^0\right)-u^i=0_m,\\ g\left(x^0\right)+\nabla g\left(x^0\right)\left(x-x^0\right)-v^i\in C,\\ \nabla h\left(x^0\right)\left(x-x^0\right)-w^i=0_q,\\ t\in \boldsymbol{R},\ x\in S,\end{array}$$

$(i=1,2)$ *with* $J(t,x,p^i):=\frac{1}{2}(x-x^0)^\top W(x^0,\mu^0,\nu^0,\xi^0)\,(x-x^0)+(t-t^0)-t^{*i}\,(t-t^0)-(x^{*i})^\top(x-x^0)$, *then the Lagrange multipliers* $(\mu_q^i,\nu_q^i,\xi_q^i)$ *to the solutions* (t^i,x^i), $i=1,\,2$, *are uniquely determined and*

$$\left\|\left(\mu_q^1,\nu_q^1,\xi_q^1\right)-\left(\mu_q^2,\nu_q^2,\xi_q^2\right)\right\|\le c_M\left(\left\|\left(t^1,x^1\right)-\left(t^2,x^2\right)\right\|+\left\|p^1-p^2\right\|\right)$$

with some constant c_M.

Then there exists some $\delta>0$ *and a neighborhood* $N(a^0,r^0)$ *of* (a^0,r^0) *so that the local minimal value function* $\overline{\tau}^\delta(a,r):=\inf\{t\mid (t,x)\in\overline{\Sigma}(a,r)\cap B_\delta(t^0,x^0)\}$ *is differentiable on* $N(a^0,r^0)$ *with the derivative*

$$\nabla_{(a,r)}\overline{\tau}^\delta(a,r)=\nabla_{(a,r)}\overline{\mathcal{L}}\left(\bar{t}(a,r),\bar{x}(a,r),\mu(a,r),\nu(a,r),\xi(a,r),a,r\right).$$

Here $(\bar{t}(a,r),\bar{x}(a,r))$ *denotes the strict local minimal solution of* $(\overline{\mathrm{SP}}(a,r))$ *for* $(a,r)\in N(a^0,r^0)$ *with the unique Lagrange multipliers* $(\mu(a,r),\nu(a,r),\xi(a,r))$. *In addition to that the mapping* $\phi\colon N(a^0,r^0)\to B_\delta(t^0,x^0)\times B_\delta(\mu^0,\nu^0,\xi^0)$ *defined by* $\phi(a,r)=(\bar{t}(a,r),\bar{x}(a,r),\mu(a,r),\nu(a,r),\xi(a,r))$ *is Lipschitzian on* $N(a^0,r^0)$.

Proof. By using Lemma 4.1 it can easily be shown that all premises for applying the Theorems 5.3 and 6.1 by Alt [3] are met. □

Remark 4.3. The condition (ii) of the preceding theorem is always satisfied if we have only equality constraints [3, Theorem 7.1] or, in the case of the natural ordering $C=\boldsymbol{R}^n_+$, if the gradients of the active constraints are linearly independent; compare [16, Theorem 2.1] and [35, Theorem 2].

LEMMA 4.4. *Let the assumptions of Theorem* 4.2 *be satisfied with* $S=\boldsymbol{R}^n$. *Then there is some* $\delta>0$ *and a neighborhood* $N(a^0,r^0)$ *of* (a^0,r^0) *so that for all* $(a,r)\in N(a^0,r^0)$ *the derivatives of the local minimal value function are given by*

$$\begin{aligned}&\nabla_a\overline{\tau}^\delta(a,r)=-\mu(a,r)-\nabla_a\nu(a,r)^\top g(\bar{x}(a,r))\\ \textit{and}\quad &\nabla_r\overline{\tau}^\delta(a,r)=-\bar{t}(a,r)\mu(a,r)-\nabla_r\nu(a,r)^\top g(\bar{x}(a,r)).\end{aligned}$$

Proof. According to Theorem 4.2 there is a neighborhood $N(a^0,r^0)$ of (a^0,r^0) such that for all $(a,r)\in N(a^0,r^0)$ there is a strict minimal solution $(\bar t(a,r),\bar x(a,r))$ with unique Lagrange multipliers $(\mu(a,r),\nu(a,r),\xi(a,r))$. Because of $S=\boldsymbol{R}^n$ we have for the derivative of the Lagrangian $\nabla_{(t,x)}\overline{\mathcal{L}}(\bar t(a,r),\bar x(a,r),\mu(a,r),\nu(a,r),\xi(a,r),a,r)=0_{n+1}$. Then it follows

$$\begin{aligned}0_m &= \nabla_a\begin{pmatrix}\bar t(a,r)\\ \bar x(a,r)\end{pmatrix}^\top \nabla_{(t,x)}\overline{\mathcal{L}}(\bar t(a,r),\bar x(a,r),\mu(a,r),\nu(a,r),\xi(a,r),a,r)\\
&= \nabla_a\bar t(a,r)-\sum_{i=1}^m\mu_i(a,r)\Big(\nabla_a\bar t(a,r)\,r_i-\nabla_a\bar x(a,r)^\top\nabla_x f_i(\bar x(a,r))\Big)\\
&\quad-\sum_{j=1}^p\nu_j(a,r)\nabla_a\bar x(a,r)^\top\nabla_x g_j(\bar x(a,r))-\sum_{k=1}^q\xi_k(a,r)\nabla_a\bar x(a,r)^\top\nabla_x h_k(\bar x(a,r)).\end{aligned}\tag{4.5}$$

According to Theorem 4.2 there exists some $\delta>0$ so that the derivative of the local minimal value function is given by $\nabla_{(a,r)}\overline{\tau}^\delta(a,r)=\nabla_{(a,r)}\overline{\mathcal{L}}(\bar t(a,r),\bar x(a,r),\ \mu(a,r),\ \nu(a,r),\ \xi(a,r),a,r)$. Applying standard rules of differentiation and together with (4.5) we conclude

$$\begin{aligned}\nabla_a\overline{\tau}^\delta(a,r) &= \nabla_a\bar t(a,r)-\sum_{i=1}^m\mu_i(a,r)\Big(e_i+\nabla_a\bar t(a,r)r_i-\ \nabla_a\bar x(a,r)^\top\nabla_x f_i(\bar x(a,r))\Big)\\
&\quad-\sum_{i=1}^m\nabla_a\mu_i(a,r)\underbrace{(a_i+\bar t(a,r)\,r_i-f_i(\bar x(a,r)))}_{=0}\\
&\quad-\sum_{j=1}^p\nu_j(a,r)\nabla_a\bar x(a,r)^\top\nabla_x g_j(\bar x(a,r))-\sum_{j=1}^p\nabla_a\nu_j(a,r)g_j(\bar x(a,r))\\
&\quad-\sum_{k=1}^q\xi_k(a,r)\nabla_a\bar x(a,r)^\top\nabla_x h_k(\bar x(a,r))-\sum_{k=1}^q\nabla_a\xi_k(a,r)\underbrace{h_k(\bar x(a,r))}_{=0}\\
&= -\mu(a,r)-\nabla_a\nu(a,r)^\top g(\bar x(a,r)).\end{aligned}$$

The same for $\nabla_r\overline{\tau}^\delta(a,r)$. ∎

We can use that inactive constraints remain inactive for small parameter changes and then in the case $C=\boldsymbol{R}^p_+$ we conclude (using the arguments in [17, Theorem 3.2.2, Proof of Theorem 3.4.1]) $\nabla_{(a,r)}\nu(a^0,r^0)^\top g(\bar x(a^0,r^0))=0_{2m}$. This results in the following.

COROLLARY 4.5. *Under the assumptions of Lemma* 4.4 *and with* $C=\boldsymbol{R}^p_+$ *it follows*

$$\nabla_{(a,r)}\overline{\tau}^\delta\left(a^0,r^0\right)=-\begin{pmatrix}\mu^0\\ t^0\,\mu^0\end{pmatrix}.$$

Hence, we get in this special case the derivative information via the Lagrange multipliers without additional effort just by solving the problems (SP(a,r)). Otherwise, the derivative of the local minimal value function, being equivalent to the derivative of the Lagrange function, has to be approximated. Under some special additional assumptions as $C=\boldsymbol{R}^p_+,\ K=\boldsymbol{R}^m_+,\ \hat S=S=\boldsymbol{R}^n$, and nondegeneracy the second-order information $\nabla^2_a\tau^\delta(a^0,r^0)=-\nabla_a\mu(a^0,r^0)$ and $\nabla^2_r\tau^\delta(a^0,r^0)=t^0\mu^0(\mu^0)^\top-t^0\nabla_r\mu(a^0,r^0)$ is available [13, Theorem 3.2.4], too.

5. Parameter control and algorithm. In the literature several quality criteria have been discussed for approximations of the efficient set (see [7, 12, 39, 47, 54], and others). Most of them have been developed for evaluating evolutionary algorithms, as, e.g., the quality criteria of measuring the distance of the approximation set to the efficient set. As our approximation points are determined by solving the problems $(\mathrm{SP}(a,r))$ they are at least weakly K-minimal. Here we suppose that a numerical solver is at our disposal which allows us to find global minimal solutions of the considered scalar optimization problems. However, generally numerical methods generate only approximations of a minimal solution if not even only local minimal solutions. Then the distance to the efficient set depends on the numerical solvers used and not on the adaptive parameter control in which we are interested here. Therefore, quality criteria as the distance to the efficient set are not considered in this context.

The most interesting criteria, in the case of scalarization approaches, are the three proposed by Sayin [47] called coverage error, uniformity, and cardinality. In our opinion and with respect to these targets, an approximation possesses a high quality in the sense of a concise but representative approximation if it consists of almost equidistant approximation points.

We want to use the sensitivity results from section 4 to reach the aim of an equidistant approximation, at least locally. We first apply these results for developing a method for determining the parameters a such that we can control the distance between the generated approximation points. This will be used in section 5.2 for locally refining coarse approximations of the efficient set with equidistant points. In section 5.3 we specialize our results to the bicriteria case ($m = 2$), because for two objective functions we do not have to determine a coarse approximation first which is then refined. Instead we can adaptively control the parameter a from the beginning to generate an equidistant approximation of the whole efficient set.

5.1. Parameter control. We start by assuming that we have already solved a so-called reference problem $(\mathrm{SP}(a^0,r))$ with minimal solution (t^0,x^0) with Lagrange multipliers (μ^0,ν^0,ξ^0) and with $a^0 + t^0\, r - f(x^0) = 0_m$. (Otherwise, for $a^0 + t^0\, r - f(x^0) = k \neq 0_m$, we can apply Theorem 3.6 and determine a scalar t' and a parameter a' with $a' + t'\, r - f(x^0) = 0_m$. Then we take the problem $(\mathrm{SP}(a',r))$ as reference problem.) Then (t^0,x^0) is a minimal solution of the modified problem $(\overline{\mathrm{SP}}(a^0,r))$. We further assume that the derivative $\nabla_a \overline{\tau}^\delta(a^0,r)$ of the local minimal value function is known as a consequence of Theorem 4.2.

We will concentrate on a variation of the parameter a. We use the derivative information for a first-order Taylor series approximation (assuming this is possible) of the minimal value t of problem $(\overline{\mathrm{SP}}(a,r))$ depending on the parameter a given by $\bar{t}(a,r) \approx t^0 + \nabla_a \overline{\tau}^\delta(a^0,r)^\top (a - a^0)$. Using the equality constraint $f(\bar{x}(a,r)) = a + \bar{t}(a,r)\, r$ of problem $(\overline{\mathrm{SP}}(a,r))$ we get, together with $f(x^0) = a^0 + t^0\, r$,

$$\begin{aligned} f(\bar{x}(a,r)) &\approx a^0 + \left(a - a^0\right) + \left(t^0 + \nabla_a \overline{\tau}^\delta \left(a^0,r\right)^\top \left(a - a^0\right)\right)\, r \\ &= f\left(x^0\right) + \left(a - a^0\right) + \left(\nabla_a \overline{\tau}^\delta \left(a^0,r\right)^\top \left(a - a^0\right)\right)\, r. \end{aligned}$$

We now use $(\bar{t}(a,r),\bar{x}(a,r))$ (the minimal solution of $(\overline{\mathrm{SP}}(a,r))$) as an approximation of the minimal solution $(t(a,r),x(a,r))$ of $(\mathrm{SP}(a,r))$. We have at least $t(a,r) \leq \bar{t}(a,r)$ and $(\bar{t}(a,r),\bar{x}(a,r))$ feasible for $(\mathrm{SP}(a,r))$. Hence, we get the following local approximation of the generated weakly efficient points of (2.1) depending on the

parameter a:

$$f(x(a,r)) \approx f\left(x^0\right) + \left(a - a^0\right) + \left(\nabla_a \overline{\tau}^\delta \left(a^0, r\right)^\top \left(a - a^0\right)\right) r. \tag{5.1}$$

Our goal is to compute equidistant approximation points and for a predefined distance of $\alpha > 0$ we want to find a new parameter a^1 such that

$$\left\| f\left(x\left(a^0, r\right)\right) - f\left(x\left(a^1, r\right)\right)\right\| = \alpha \tag{5.2}$$

with $f(x(a^0, r)) = f(x^0)$, i.e., such that the new approximation point has a distance of α to the former. In Theorem 3.2 we have seen that it is sufficient to consider parameters a in a hyperplane H. Assuming $a^0 \in H = \{y \in \boldsymbol{R}^m \mid b^\top y = \beta\}$, we choose a direction $v \in \boldsymbol{R}^m$ with $b^\top v = 0$ such that $a^0 + s\,v \in H$ for all $s \in \boldsymbol{R}$. Because we want $a^1 \in H$ we set $a^1 = a^0 + s^1\,v$, $s^1 \in \boldsymbol{R}$, and together with (5.2) and (5.1) this results in

$$\begin{aligned}
\alpha &= \left\| f\left(x\left(a^0, r\right)\right) - f\left(x\left(a^1, r\right)\right)\right\| \\
&\approx \left\| f\left(x^0\right) - \left(f\left(x^0\right) + s^1\,v + s^1 \left(\nabla_a \overline{\tau}^\delta \left(a^0, r\right)^\top v\right) r\right)\right\| \\
&= \left|s^1\right| \left\| v + \left(\nabla_a \overline{\tau}^\delta \left(a^0, r\right)^\top v\right) r\right\|.
\end{aligned}$$

Hence, we choose

$$s^1 := \frac{\alpha}{\left\| v + \left(\nabla_a \overline{\tau}^\delta \left(a^0, r\right)^\top v\right) r\right\|}. \tag{5.3}$$

For the new parameter $a^1 := a^0 + s^1\,v$ (or $a^1 := a^0 - s^1\,v$) we now solve the problem $(\mathrm{SP}(a^1, r))$ with minimal solution (t^1, x^1), and if the quality of our approximations have been good this results in $\|f(x^0) - f(x^1)\| \approx \alpha$.

5.2. General multiobjective case. For the general multiobjective case ($m \geq 2$) we have seen in Theorem 3.5 that it is sufficient to vary the parameter a in the subset H^0 for being able to detect all K-minimal points of the multiobjective optimization problem. We use this information for determining in a first step a coarse approximation of the efficient set. Then, in a second step, this approximation is refined locally with (almost) equidistant points.

The coarse approximation is done using equidistant parameters only. The d.m. can, for instance, define the desired number of points N^i in each direction v^i, $i = 1, \ldots, m-1$, spanning the hyperplane H (see (3.7)). With a distance of $L_i := (s_i^{\max,i} - s_i^{\min,i})/N^i$ this leads to $\prod_{i=1}^{m-1} N^i$ equidistant discretization points. For any of these parameters $a \in H^0$ and for $r \in K$ constant we solve the scalar optimization problem $(\mathrm{SP}(a, r))$ with minimal solution (t^a, x^a) (if one exists) and Lagrange multiplier μ^a to the constraint $a + t\,r - f(x) \in K$.

Based on this coarse approximation the d.m. gets a first overview over the efficient set and can now choose which areas or points are of special interest for doing a refinement now using the results of section 5.1. Let $f(x^0)$ be such a chosen approximation point (with $a^0 + t^0\,r - f(x^0) = 0_m$) and assume a refinement with $\bar{n} \in \boldsymbol{N}$ additional points in every direction should be done. Thus, we search for parameters a with $\|f(x(a)) - f(x^0)\| = \alpha$ for a distance $\alpha > 0$. As the hyperplane H is spanned by

the $m-1$ vectors v^k, $k=1,\dots,m-1$, we set for the new parameters $a=a^0+s\cdot v^k$, $k\in\{1,\dots,m-1\}$, for some $s\in\boldsymbol{R}$. This leads, according to (5.3), to

$$s^k:=\frac{\alpha}{\left\|v+\left(\nabla_a\overline{\tau}^\delta\,(a^0,r)^\top v^k\right)\,r\right\|}.$$

Hence, we get the $2(m-1)$ new parameters $a:=a^0\pm s^k\,v^k$, $k\in\{1,\dots,m-1\}$.

We extend this to a consideration of all $(2\bar{n}+1)^2-1$ parameters a with $a=a^0+\sum_{k=1}^{m-1}l_k\,s^k\,v^k$ for $l_k\in\{-\bar{n},\dots,\bar{n}\}\subset\boldsymbol{Z}$, $k=1,\dots,m-1$, $l:=(l_1,\dots,l_{m-1})\neq 0_{m-1}$, for getting $\bar{n}$ new parameters in every direction. Solving $(\mathrm{SP}(a,r))$ for all these parameters results in a refined approximation with locally equidistant points (around $f(x^0)$).

For the calculation of the values s^k we need the derivative of the local minimal value function which is given in Theorem 4.2. For that, the derivative of the Lagrange function has to be approximated. In the case of $S=\mathbb{R}^n$ this is reduced to an approximation of the derivative of the function ν w.r.t. a. According to Corollary 4.5, in the case of $C=\mathbb{R}^p_+$ the derivative is even immediately given by $\nabla_a\overline{\tau}^\delta(a^0,r)=-\mu^0$. Choosing additionally $K=\mathbb{R}^n_+$ and the hyperplane $H=\{y\in\boldsymbol{R}^m\mid y_m=0\}$, i.e., $b=e_m$, with e_m the mth unit vector in $\boldsymbol{R}^m$, $\beta=0$, and $r=e_m$, then solving the problem $(\mathrm{SP}(a,r))$ for parameters $a=(a_1,\dots,a_{m-1},0)\in H$ is equivalent to solve the problem

$$\begin{gathered}\min f_m(x)\\ \text{subject to the constraints}\\ f_i(x)\le a_i,\qquad i=1,\dots,m-1,\\ x\in\Omega.\end{gathered}$$

This problem is well known as ε-constraint scalarization [21]. Choosing for v^i the unit vectors the problems (3.8) then reduce to $\min_{x\in\Omega}f_i(x)$ and $\max_{x\in\Omega}f_i(x)$ for $i=1,\dots,m-1$, and thus the calculation of the set H^0 (Step 1) is facilitated. Also, the points a', t' to a minimal solution $\bar{x}$ as in Theorem 3.6 are just given by $t'=f_m(\bar{x})$ and $a'=(f_1(\bar{x}),\dots,f_{m-1}(\bar{x}),0)$. Hence, we assume for the given algorithm:

Assumption 4. *Let Assumption* 3 *hold with* $S=\boldsymbol{R}^n$, $K=\mathbb{R}^m_+$, *and* $C=\mathbb{R}^p_+$. *To any choice of parameters* (a,r) *for which we consider the optimization problem* $(\mathrm{SP}(a,r))$ *or* $(\overline{\mathrm{SP}}(a,r))$ *let there exist a minimal solution* $(\bar{t},\bar{x})$ *with Lagrange multipliers* $(\bar{\mu},\bar{\nu},\bar{\xi})\in\boldsymbol{R}^m\times\boldsymbol{R}^p_+\times\boldsymbol{R}^q$ *and let the assumptions of Theorem* 4.2 *in* $(\bar{t},\bar{x})$ *be satisfied.*

This simplifies the algorithm considerably and allows a short representation. For multiobjective optimization problems with arbitrary ordering cones, the ε-constraint reformulation instead of $(\mathrm{SP}(a,r))$ is generally not possible and the determination of the set H^0 is more laborious. Also the calculation of the derivatives $\nabla_a\overline{\tau}^\delta(a,r)$ is more costly if C is not the natural ordering and if S does not equal the whole space (see Lemma 4.4). As the formulation of the general algorithm goes straightforward we restrain here to this common special case.

Algorithm 5.1 (Algorithm for an adaptive parameter control).

Input: Set $r=e_m$, $b=e_m$, $\beta=0$. Choose desired number of discretization points N^i in direction $v^i=e_i$ for $i=1,\dots,m-1$.

Step 1: Solve problem $\min_{x\in\Omega}f_i(x)$ with minimal solution $x^{\min,i}$ and minimal value $f(x^{\min,i})=:a_i^{\min}$ for $i=1,\dots,m-1$, and problem $\max_{x\in\Omega}f_i(x)$ with maximal solution $x^{\max,i}$ and maximal value $f(x^{\max,i})=:a_i^{\max}$ for $i=1,\dots,m-1$.

Step 2: Set $L_i := (a_i^{\max} - a_i^{\min})/N^i$ for $i = 1, \ldots, m-1$ and solve (SP(a, r)) for all $a \in E$ with $E := \{a = (a_1, \ldots, a_{m-1}, 0) \in \boldsymbol{R}^m \mid a_i = a_i^{\min} + L_i/2 + l_i \cdot L_i \text{ for } l_i = 0, \ldots, N^i - 1,\ i = 1, \ldots, m-1\}$ with minimal solution x^a and Lagrange multiplier μ^a to the constraint $a + t\,r - f(x) \in \boldsymbol{R}^m_+$. Determine the set $A := \{x^a \mid x^a$ minimal solution of (SP(a,r)) for $a \in E\}$.

Step 3: Determine the set $D := \{f(x) \mid x \in A\}$ and set $l = 0$.

Input: Choose $y \in D$ with $y = f(x^a)$ and associated Lagrange multiplier μ^a and set $a = (f_1(x^a), \ldots, f_{m-1}(x^a), 0)$. If y is a sufficient good solution, then stop. Otherwise, if additional points in the neighborhood of y are desired, then define a distance $\alpha \in \boldsymbol{R},\ \alpha > 0$, and the number $n^l \in \boldsymbol{N}$ of additional points for each direction and go to step 4.

Step 4: For all $\bar{\iota} = (i_1, \ldots, i_{m-1}) \in \{(i_1, \ldots, i_{m-1}) \in \boldsymbol{Z}^{m-1} \setminus \{(0, \ldots, 0)\} \,|\, i_j = -n^l, \ldots, n^l, \text{ for } j = 1, \ldots, m-1\}$ set

$$a^{\bar{\iota}} := a + \sum_{j=1}^{m-1} i_j \cdot \frac{\alpha}{\sqrt{1 + (\mu_j^a)^2}} \cdot e_j$$

and solve (SP$(a^{\bar{\iota}}, r)$). If there exists a solution $x^{\bar{\iota}}$ with Lagrange multiplier $\mu^{\bar{\iota}}$ set $A := A \cup \{x^{\bar{\iota}}\}$. Set $l := l + 1$ and go to Step 3.

Output: The set D is an approximation of the set of weakly efficient points.

Note that some of the problems considered in Step 2 and Step 4 may be infeasible. Thus in general not all parameters result in approximation points of the efficient set; see also test problem 4 in section 6.1. In [5, 23] conditions are given under which there exist minimal solutions of the problems (SP(a, r)). In detail, we have that for $K = \boldsymbol{R}^m_+$ and a nonempty efficient set there always exists a minimal solution for $a \in \boldsymbol{R}^m,\ r \in \text{int}(\boldsymbol{R}^m_+)$. However, here we have chosen $r = e_m \notin \text{int}(\boldsymbol{R}^m_+)$ for simplicity.

For solving the scalar optimization problems in Steps 1, 2, and 4, an appropriate numerical method has to be used as, e.g., the SQP method. However, using just a local solver can lead to only local minimal solutions of the scalar problems and thus to only locally weakly EP-minimal points of (2.1). As a starting point for a numerical method for solving problem (SP$(a^{\bar{\iota}}, r)$) in Step 4 the point $(f(x^a), x^a)$ can be used.

In Steps 2 and 3 a coarse approximation of the efficient set is calculated and in Step 4 around the special chosen points the refinement is done. Based on this algorithm it is possible to generate local equidistant approximations. With the coarse approximation in Step 2 it is ensured that all parts of the efficient set are covered and that the d.m. gets a survey of the efficient set. Then the method changes to an interactive part where the d.m. has to choose the areas in which a refinement is done.

5.3. Biobjective case. Now we come to the bicriteria case, i.e., $m = 2$. Of course the general Algorithm 5.1 presented in the previous section can be applied for $m = 2$, too. However, in the biobjective case we can use some special properties which do not hold generally for $m \geq 3$. This allows us not only to refine a coarse approximation locally but to determine equidistant approximations of the whole efficient set.

For $m = 2$ we can restrict the parameter set to a line segment H^a (Theorem 3.3). On this line segment we can easily define a total ordering, for instance increasing order w.r.t. the first coordinate. Then, points in the set H^a that are neighbors to each other are neighbors w.r.t. this order, too. This is no longer possible for the set H^0

for $m \geq 3$. As we have to know which points are neighbors to a point already found for using sensitivity information and for controlling the distance between the points, we start with a coarse approximation in the general case (section 5.2). However, since we are considering the biobjective case, we can use the special structure of H^a for adaptively determining the parameter a from the beginning without a previous coarse approximation. The result is an (almost) equidistant approximation of the efficient curve.

In the following we choose the parameters a in increasing order w.r.t. the first coordinate i.e., $a_1^0 \leq a_1^1 \leq \cdots \leq a_1^l \leq a_1^{l+1} \leq \cdots$ assuming we have $b_2 \neq 0$ for the hyperplane H. We choose $v \in \boldsymbol{R}^2$ with $b^\top v = 0$ such that we have $a^0 + s\,v \in H$ for $s \in \boldsymbol{R}$ and for $a^0 \in H$. Further, let $v_1 > 0$. We assume again we have already solved a reference problem (SP(a^0, r)) with a minimal solution (t^0, x^0). For $a^0 + t^0\,r - f(x^0) = 0_2$ we choose the next parameter a^1 by $a^1 = a^0 + s^1\,v$ with $s^1 > 0$ as in (5.3). Then, we have $a_1^1 > a_1^0$. For the case $a^0 + t^0\,r - f(x^0) = k^0 \neq 0_2$ we calculate $\tilde{a}^0$ as described in the proof of Theorem 3.6 by $\tilde{a}^0 = f(x^0) - \tilde{t}^0\,r$ and $\tilde{t}^0 = (b^\top f(x^0) - \beta)/(b^\top r)$. Then $\tilde{a}^0 + \tilde{t}^0\,r - f(x^0) = 0_2$.

In the case of $\tilde{a}_1^0 \geq a_1^0$ we set $a^1 := \tilde{a}^0 + s^1\,v$ (i.e., $a_1^1 > a_1^0$). For the ordering cone $K = \boldsymbol{R}_+^2$ we can show by an easy calculation using the fact that $a^0 + t^0\,r - f(x^0) = k^0$ with $k^0 \in \partial\boldsymbol{R}_+^2 \setminus \{0_2\}$ (see [45], but it is also a direct conclusion of the proof of Theorem 3.1 (b)) that $\tilde{a}_1^0 \geq a_1^0$ if and only if $\big(k_1^0 = 0,\ k_2^0 > 0$ and $\frac{r_1 b_2}{b^\top r} > 0\big)$ or $(k_1^0 > 0,\ k_2^0 = 0$ and $\frac{r_2 b_2}{b^\top r} < 0)$.

For the case $\tilde{a}_1^0 < a_1^0$ special considerations have to be made as it is not desirable to continue with the parameter $\tilde{a}^0$ instead of a^0 as we are looking for parameters with increasing first coordinate. In that case we still use the parameter a^0 for determining a^1. We can no longer assume $f(x(a,r)) = a + t(a,r)\,r$ as we have $f(x^0) = a^0 + t^0\,r - k^0$ with $k^0 \neq 0_2$. However, we can presume that the constraint $a + t\,r - f(x) \in K$ remains inactive and thus in view of $a^0 + t^0\,r = f(x^0) + k^0$ we set $a + t\,r = f(x^0) + k^0 + s\,k^0$ for some $s > 0$. For $s := \alpha/\|k^0\|$ we have a distance of $\alpha > 0$ between the points $a + t\,r$ and $a^0 + t^0\,r$, see Figure 3.1(b). Thus, we set the new parameter as

$$a^1 := f\left(x^0\right) + (1+s)\,k^0 - t\,r \tag{5.4}$$

with $s = \alpha/\|k^0\|$ and with some $t \in \boldsymbol{R}$. As we still demand $a \in H$ we choose $t = \frac{b^\top\left(f(x^0) + (1+s)\,k^0\right) - \beta}{b^\top r}$. Using the definition of $\tilde{a}^0$ we get $a^1 = \tilde{a}^0 + (1+s)(k^0 - \frac{b^\top k^0}{b^\top r} r)$. Because we have $b^\top a^1 = \beta$, the vector a^1 is actually an element of the hyperplane H. Again by an easy calculation, we can show that $a_1^1 \geq a_1^0$ for a_1 as in (5.4) and $s \geq 0$; i.e., the next parameter is chosen with increasing first coordinate.

By repeating the described steps for finding the next parameters $a^2, a^3, \ldots$ we can adaptively determine an almost equidistant approximation $f(x^0), f(x^1), \ldots$ of the efficient set of (2.1). However, it can happen that $\|f(x^l) - f(x^{l-1})\| \gg \alpha$ or $\|f(x^l) - f(x^{l-1})\| \ll \alpha$. This can be due to a strong varying curvature of the efficient set (see, e.g., [10, test problem CTP2]), especially if the distance α is not chosen appropriately small. It can also be due to gaps in the efficient set, i.e., nonconnected parts, see test problem 3 in section 6.1. In practice the efficient set of the examined multiobjective optimization problems is very often smooth (see, e.g., the application problem given in section 6.2 or in [6, 30, 36]). Nevertheless, if the distance between consecutive points is too large a refinement strategy as in Step 4 in Algorithm 5.1 can be applied subsequently. Too small distances can be eliminated afterwards just by reducing the approximation set.

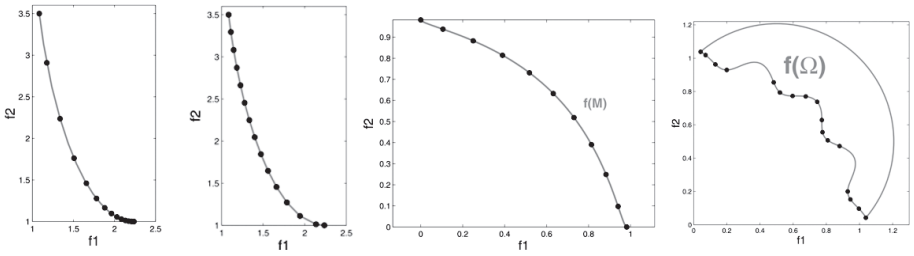

FIG. 6.1. (a) *Efficient set and approximation points of test problem* 1 *with weighted sum method and* (b) *with adaptive parameter control.* (c) *Efficient set and approximation points of test problem* 2. (d) *Image set and approximation points of test problem* 3.

6. Numerical results. In the following we apply the proposed methods on some test problems and on an application in intensity modulated radiotherapy.

6.1. Test problems. We start by considering some test problems which demonstrate the main properties of the proposed methods. It is shown that equidistant approximations are generated and that nonconvex problems as well as problems with a nonconnected efficient set or more than two objectives are covered.

Test problem 1: Comparison with the weighted sum method. The following test problem is chosen to show the advantage of the new method compared to the well-known habitual weighted sum method with which by a variation of the weights approximations of the efficient set can also be generated. For the bicriteria case the scalarization $\min_{x\in\Omega} w_1 f_1(x) + w_2 f_2(x)$ with weights $w_1, w_2 \in [0,1],\ w_1 + w_2 = 1$, is considered. Applying this scalarization to the test problem

$$\min_{\boldsymbol{R}^2_+} \begin{pmatrix} \sqrt{1+x_1^2} \\ x_1^2 - 4x_1 + x_2 + 5 \end{pmatrix}$$
$$\text{subject to the constraints}$$
$$x_1^2 - 4x_1 + x_2 + 5 \le 3.5,$$
$$x_1 \ge 0,\ x_2 \ge 0,$$

choosing uniformly distributed weights leads to the approximation shown in Figure 6.1(a). This approximation has an uneven distribution and thus a low uniformity and a high coverage error. A much better result again with 15 points is gained by applying the procedure of section 5.3 with a hyperplane $H = \{y \in \boldsymbol{R}^2 \mid (1,1)y = 2.5\}$, $r = (1,0)^\top$, and a predefined distance of $\alpha = 0.2$ between the approximation points, see Figure 6.1(b).

Test problem 2: Nonconvex set. The following example by van Veldhuizen [54, p. 545], see also [11, 33], has a nonconvex image. Letting $n \in \boldsymbol{N}$ be a parameter the problem is defined as follows:

$$\min_{\boldsymbol{R}^2_+} \begin{pmatrix} 1 - \exp\left(-\sum_{i=1}^{n}\left(x_i - \frac{1}{\sqrt{n}}\right)^2\right) \\ 1 - \exp\left(-\sum_{i=1}^{n}\left(x_i + \frac{1}{\sqrt{n}}\right)^2\right) \end{pmatrix}$$
$$\text{subject to the constraints}$$
$$x_i \in [-4,4] \quad \text{for all } i = 1,\dots,n.$$

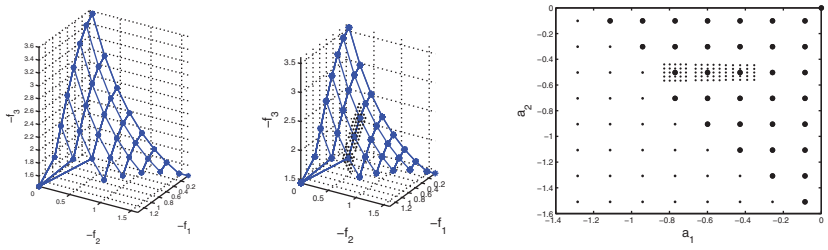

FIG. 6.2. *Test problem* 4: (a) *coarse approximation,* (b) *refined approximation, and* (c) *parameter set.*

We observe that by using the weighted sum method not all EP-minimal points can be found. For $n = 40$ we get with $r = (1,1)^\top$, $b = (1,0)^\top$, $\beta = 1.2$, $\alpha = 0.15$, and the procedure of section 5.3 the approximation shown in Figure 6.1(c). The connected line shows the efficient set of test problem 2 denoted as $f(M) := f(\mathcal{M}(f(\Omega), \boldsymbol{R}^2_+))$.

Test problem 3: Nonconnected efficient set. In the following problem by Tanaka [52] the image set $f(\Omega)$ is nonconvex, too, and additionally the efficient set is nonconnected (in a topological meaning):

$$\min_{\boldsymbol{R}^2_+} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$$
$$\text{subject to the constraints}$$
$$x_1^2 + x_2^2 - 1 - 0.1\cos\left(16\arctan\left(\tfrac{x_1}{x_2}\right)\right) \geq 0,$$
$$(x_1 - 0.5)^2 + (x_2 - 0.5)^2 \leq 0.5,$$
$$x_1, x_2 \in [0, \pi].$$

We have $f(\Omega) = \Omega$. By choosing $r = (1,2)^\top$, $b = (1,1)^\top$, $\beta = 0.5$, $\alpha = 0.08$, and with the procedure of section 5.3 we get the approximation of Figure 6.1(d). Here the difficulty is that by solving the scalar optimization problems (SP(a,r)) global solutions have to be found and thus, by using only a local method as the SQP method only local EP-minimal points instead of global solutions of (2.1) are guaranteed.

Test problem 4: Three objectives. This test problem with a nonconvex image set is a modified version of a problem in [38]. For the ordering cone $K = \boldsymbol{R}^3_+$ we consider

$$\min_{\boldsymbol{R}^3_+} \begin{pmatrix} -x_1 \\ -x_2 \\ -x_3^2 \end{pmatrix}$$
$$\text{subject to the constraints}$$
$$-\cos(x_1) - \exp(-x_2) + x_3 \leq 0,$$
$$0 \leq x_1 \leq \pi,\ x_2 \geq 0,\ x_3 \geq 1.2.$$

We use Algorithm 5.1 with $N^1 = N^2 = 8$ for a coarse approximation. The result after Steps 1–3 is given in Figure 6.2(a). Note that the negative of the objective function values is drawn and that the approximation points are connected with lines.

In the input step of the algorithm we choose the three points $y \in D$ for which $y_1 \leq -0.4$ and $-0.6 \leq y_2 \leq -0.4$ holds. We do a refinement with $n^1 = 2$ and $\alpha = 0.06$. This

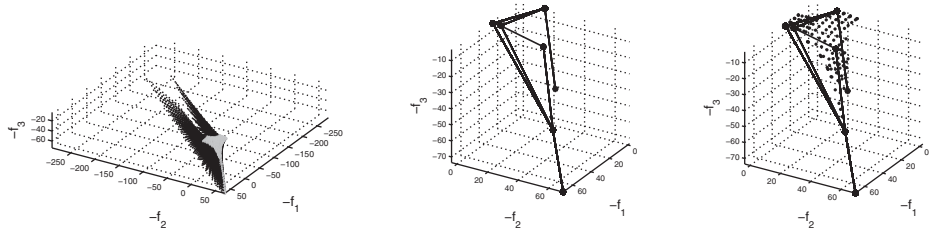

FIG. 6.3. *Test problem* 5: (a) *image set in dark color and efficient set in grey,* (b) *coarse approximation with the approximation points connected with lines, and* (c) *refined approximation.*

results in the refined approximation of the efficient set of Figure 6.2(b). In the course of the algorithm several scalar optimization problems (SP(a, r)) to parameters $a = (a_1, a_2, 0)$ are solved. These parameters are plotted as points (a_1, a_2) in Figure 6.2(c) as dots. To the parameters represented by the smallest dots, no minimal solution of the problem (SP(a, r)) exists. Around three parameters one can see the parameters of the refinement step (Step 4 of the algorithm), and it can well be seen that the distance between the refinement parameters differs depending on the sensitivity information delivered by the Lagrange multipliers (corresponding to the steepness of the efficient set).

Test problem 5: Comet problem. This problem [11, p. 9]

$$\min_{\boldsymbol{R}^3_+} \begin{pmatrix} (1+x_3)\left(x_1^3x_2^2 - 10x_1 - 4x_2\right) \\ (1+x_3)\left(x_1^3x_2^2 - 10x_1 + 4x_2\right) \\ 3(1+x_3)x_1^2 \end{pmatrix}$$
$$\text{subject to the constraints}$$
$$1 \le x_1 \le 3.5,\ -2 \le x_2 \le 2,\ 0 \le x_3 \le 1$$

with the set of K-minimal points $\mathcal{M}(f(\Omega), \boldsymbol{R}^3_+) = \{x \in \boldsymbol{R}^3 \mid 1 \le x_1 \le 3.5,\ -2 \le x_1^3x_2 \le 2,\ x_3 = 0\}$ has its name because of the image of the efficient set with a short broad and a long small area (see Figure 6.3(a)). A first coarse approximation for $N^1 = N^2 = 12$ delivers only a few approximation points (Figure 6.3(b)), but by doing a refinement according to Step 4 of Algorithm 5.1 with $n^1 = 3$, $\alpha = 4$ for all points with no other point with a distance of less than 5 in the neighborhood, an approximation with a high quality is finally achieved (Figure 6.3(c)).

6.2. Application in IMRT. We have also examined a problem in intensity modulated radiotherapy (IMRT) in medical engineering. Here, a patient with, e.g., a prostate tumor has to be irradiated to destroy the tumor. An optimal irradiation plan which is represented by an optimal intensity profile $x \in \mathbb{R}^{400}$ to 400 separate controllable beamlets B_i, $i = 1, \ldots, 400$ has to be found. We assume the beam geometry to be fixed. The problem is that the healthy surrounding organs should be damaged as little as possible while in each cell of the tumor a minimal curative dose has to be reached [1, 8, 40, 43].

Hence, this problem is a multiobjective optimization problem which has formerly been solved by just summing up the objective functions to one single scalar-valued objective using a weighted sum approach. Thereby, the difficulty is that the weights have no medical interpretation and that the physician has to find a good irradiation plan by a laborious trial and error process [40]. Using instead a multiobjective

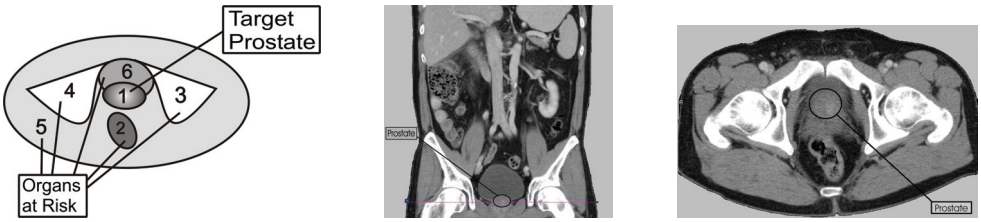

FIG. 6.4. (a) *Schematic axial body cut.* (b) *Coronar and axial CT-cut.*[1]

optimization approach with an approximation of the whole efficient set [22, 40, 43] simplifies this procedure and improves the results significantly and is, therefore, now actually applied. Thereby, a high quality approximation with equidistant points is demanded [40].

The number of objective functions depends on the number of different healthy tissues surrounding the tumor. In our example, the treatment planning for a prostate tumor, one is especially concerned about the bladder (V_6) and the rectum (V_2), while it has to be ensured that the doses in the remaining tissues as left (V_3) and right (V_4) hip bone and surrounding unspecified tissue (V_5) remain below an upper level (for the location of the organs see Figure 6.4(a)).

For evaluating and comparing the radiation stress in the several organs the concept of the equivalent uniform dose by Niemierko [44] based on p-norms is used. Therefore, the relevant part of the patient's body is mapped with the help of a computer tomography (CT), see Figure 6.4(b), and according to the thickness of the slices dissected in cubes, the so-called voxels. Then, using a clustering method [40, 50], whereas voxels with equal radiation exposure are collected, the high number of 435 501 voxels is reduced to 11 877 clusters c_j, $j = 1, \ldots, 11\,877$, which are allocated to the seven volumes $V_0, \ldots, V_6$ by a physician.

Volumes V_0 and V_1 describe the tumor (the so-called target-tissue) while V_1 is the boost-tissue, which is tumor tissue that has to be irradiated especially high. Thus, depending on the volume V_k, the number of voxels $N(V_k)$ in this organ, the number of voxels $N(c_j)$ in cluster c_j, and the dose limit U_k, the radiation stress is evaluated by

$$\mathrm{EUD}_k(x) := \frac{1}{U_k}\left(\frac{1}{N(V_k)}\sum_{\{j|c_j\in V_k\}} N(c_j)\cdot(P_j x)^{p_k}\right)^{\frac{1}{p_k}} - 1, \qquad k = 2, \ldots, 6.$$

The vector P_j denotes the jth row of the matrix $P = (P_{ji})_{j=1,\ldots,11\,877, i=1,\ldots,400}$ which describes the emission by the beamlet B_i ($i = 1, \ldots, 400$) in the cluster c_j ($j = 1, \ldots, 11\,877$) at one radiation unit.[2] For the intensity profile $x \in \boldsymbol{R}^{400}$, $P_j x$ denotes the irradiation dose in the cluster c_j caused by the beamlets B_i, $i = 1, \ldots, 400$. The parameter $p_k \in [1, \infty[$, which represents the physiology of the organ, is determined statistically and is given, like the other parameters, in Table 6.1.

The irradiation stress should remain below a critical value which results in the constraints $U_k(\mathrm{EUD}_k(x) + 1) \le Q_k$, $k = 2, \ldots, 6$, which can be restated as

$$\sum_{\{j|c_j\in V_k\}} N(c_j)(P_j x)^{p_k} \le Q_k^{p_k}\, N(V_k), \quad k = 2, \ldots, 6.$$

TABLE 6.1
Critical values for the organs at risk.

	number of organ (k)	p_k	U_k	Q_k	$N(V_k)$
rectum	2	3.0	30	36	6 459
left hip-bone	3	2.0	35	42	3 749
right hip-bone	4	2.0	35	42	4 177
remaining tissue	5	1.1	25	35	400 291
bladder	6	3.0	35	42	4 901

TABLE 6.2
Critical values for the tumor tissues.

	number of organ (k)	L_k	δ_k	ε_k
target-tissue	0	67	0.11	0.11
boost-tissue	1	72	0.07	0.07

The radiation stress in the tumor tissues V_0 and V_1 is considered w.r.t. each single cluster, as it is important to destroy each single cancer cell. For homogeneity reasons this results in the constraints

$$\begin{aligned} L_0(1-\varepsilon_0) \le P_j x \le L_0(1+\delta_0), \qquad & \forall j \text{ with } c_j \in V_0 \\ \text{and } \; L_1(1-\varepsilon_1) \le P_j x \le L_1(1+\delta_1), \qquad & \forall j \text{ with } c_j \in V_1, \end{aligned}$$

with constants $L_0,\ L_1,\ \varepsilon_0, \varepsilon_1, \delta_0$ and δ_1 given in Table 6.2. Volume V_0 consists of 8 593 clusters while V_1 has 302 clusters. Including nonnegativity constraints for the beamlet intensity, this results in the feasible set

$$\begin{aligned} \Omega = \{x \in \mathbb{R}^{400}_+ \mid \; & U_k(\mathrm{EUD}_k(x)+1) \le Q_k, \qquad k = 2,\dots,6, \\ & L_0(1-\varepsilon_0) \le P_j x \le L_0(1+\delta_0), \qquad \forall j \text{ with } c_j \in V_0, \\ & L_1(1-\varepsilon_1) \le P_j x \le L_1(1+\delta_1), \qquad \forall j \text{ with } c_j \in V_1\} \end{aligned}$$

with 17 795 constraints.

The objectives are a minimization of the dose stress in the rectum (V_2) and in the bladder (V_6) as these two healthy organs always have the highest irradiation stress and a stress reduction for the rectum deteriorates the level for the bladder and vice versa. This leads to the biobjective optimization problem

$$\begin{gathered} \min_{\boldsymbol{R}^2_+} \begin{pmatrix} f_1(x) \\ f_2(x) \end{pmatrix} = \begin{pmatrix} \mathrm{EUD}_6(x) \\ \mathrm{EUD}_2(x) \end{pmatrix} \\ \text{subject to the constraint} \\ x \in \Omega. \end{gathered}$$

We apply the procedure of section 5.3 with $r = (1,1)^\top$, $\alpha = 0.04$, and $H = \{y \in \boldsymbol{R}^2 \mid y_1 = 0\}$, and we get that only parameters $a \in H^a$ with $H^a = \{y \in \boldsymbol{R}^2 \mid y_1 = 0,\ y_2 = \lambda \cdot 0.1841 + (1-\lambda)\cdot(-0.2197),\ \lambda \in [0,1]\}$ have to be considered. The approximation given in Figure 6.5(a) with 10 approximation points (connected with lines) is generated. These points as well as the distances δ^i between consecutive approximation points are listed in Table 6.3.

Based on these results the physician can choose a treatment plan by weighting the damage to the bladder and the rectum against each other. Besides he can choose an interesting plan and refine around it by using the strategy as in Step 4 of Algorithm 5.1. Further he can choose a point y determined by interpolation between the

approximation points and solve problem (SP(a,r)) to the correspondent parameters, see [53], to get a new approximation point.

As it turned out that the treatment success depends also on the irradiation homogeneity, this objective can be added to the former two objective functions. Thereby the homogeneity of the irradiation is measured by

$$H(x) := \sqrt{\frac{\sum\limits_{\{j|c_j\in V_0\}} N(c_j)\,(P_j x - L_0)^2 + \sum\limits_{\{j|c_j\in V_1\}} N(c_j)\,(P_j x - L_1)^2}{N(V_0)+N(V_1)}}$$

with $N(V_0) = 13\,238$ and $N(V_1) = 2686$. This results in the multiobjective optimization problem

$$\min_{\boldsymbol{R}^3_+} \begin{pmatrix} f_1(x) \\ f_2(x) \\ f_3(x) \end{pmatrix} = \begin{pmatrix} \mathrm{EUD}_6(x) \\ \mathrm{EUD}_2(x) \\ H(x) \end{pmatrix}$$
$$\text{subject to the constraint}$$
$$x \in \Omega.$$

We have solved this problem using Algorithm 5.1 with $N^1 = N^2 = 3$. In Step 1 we get $a_1^{\min} = 0.0158$, $a_1^{\max} = 0.2000$, $a_2^{\min} = -0.0141$, and $a_2^{\max} = 0.2000$. This results in $L_1 = 0.0614$, $L_2 = 0.0714$ and thus in the parameter set $E := \{a \in \mathbb{R}^3 \mid a_1 \in \{0.0465,\ 0.1079,\ 0.1693\},\ a_2 \in \{0.0216,\ 0.0929,\ 0.1643\},\ a_3 = 0\}$. For solving the related scalar optimization problems we use the SQP procedure implemented in Matlab with 600 iterations and a restart after 150 iteration steps. We do not get a solution for the parameter $a = (0.0465, 0.0216, 0)$. We assume a physician chooses certain points and we do a refinement around these points with $n^1 = 1$ and $\alpha = 0.07$.

This results in the refined approximation shown in Figure 6.5(b). The determined parameters $a = (a_1, a_2, 0)$ according to Steps 2 and 4 are shown in Figure 6.5(c) as points (a_1, a_2).

If we choose, e.g., the approximation point $(0.0465, 0.1643, 0.2294)$ of the efficient set and calculate the distances between that point and the surrounding refinement points, we get the following 12 distances: $0.0697, 0.0801, 0.0795, 0.0814, 0.0880, 0.0679$, 0.0736, 0.0624, 0.0663, 0.0687, 0.0640, and 0.0712 with a rounded average value of 0.0727.

A more detailed and more technical description of this problem can be found in [13, 14, 40].

7. Outlook. Here we have developed an adaptive parameter control for the Pascoletti–Serafini scalarization. We have chosen this scalarization because it is not only suitable also for finding K-minimal points with $K \neq \boldsymbol{R}^m_+$, but it is also a very general method. Many other scalarization approaches such as the weighted Chebyshev norm, the ε-constraint method (see p. 1707 and [14]), the Polak method [34], or the normal boundary intersection (NBI) method [9] can be seen as a special case of this method (see [15]), and thus the presented results can be applied there too.

Acknowledgments. The author wishes to thank Prof. Dr. J. Jahn for his supervision, comments, and suggestions. Further, the author is grateful to PD Dr. K.-H. Küfer for providing the medical example and to the referees for their valuable comments and suggestions.

APPROXIMATIONS OF STOCHASTIC OPTIMIZATION PROBLEMS SUBJECT TO MEASURABILITY CONSTRAINTS*

PIERRE CARPENTIER†, JEAN-PHILIPPE CHANCELIER‡, AND MICHEL DE LARA‡

Abstract. Motivated by the numerical resolution of stochastic optimization problems subject to measurability constraints, we focus upon the issue of discretization. There exist indeed two components to be discretized for such problems, namely, the random variable modelling uncertainties (noise) and the σ-field modelling the knowledge (information) according to which decisions are taken. There is no reason to bind these two discretizations, which are a priori unrelated. In this setting, we present conditions under which the discretized problems converge to the original one. The focus is put on the convergence notions ensuring the quality of the approximation; we illustrate their importance by means of a counterexample based on the Monte Carlo approximation.

Key words. stochastic programming, measurability constraints, discretization

1. Introduction.

Let $\big(\Omega, \mathcal{A}, \mathbb{P}\big)$ be a probability space, and let $\big(\Xi, \mathcal{B}_\Xi\big)$ and $\big(U, \mathcal{B}_U\big)$ be $\mathbb{R}^n$ and $\mathbb{R}^p$, respectively, with their associated Borel σ-fields. Given a random variable $\boldsymbol{\xi}$ with values in Ξ and a subfield $\mathcal{F}$ of $\mathcal{A}$, which, respectively, represent the noise and the observation, we are concerned with the following stochastic optimization problem:

$$V\big(\boldsymbol{\xi}, \mathcal{F}\big) := \min_{\boldsymbol{u} \in L^2(\Omega, \mathcal{A}, \mathbb{P}; U)} \mathbb{E}\big[j(\boldsymbol{u}, \boldsymbol{\xi})\big] \tag{1.1a}$$

$$\text{subject to} \quad \boldsymbol{u} \text{ is } \mathcal{F}\text{-measurable}\,. \tag{1.1b}$$

Here $j : U \times \Xi \to \mathbb{R}$ (technical assumptions given later), and $\mathbb{E}$ is the mathematical expectation under probability $\mathbb{P}$. *The random variables, defined over* $\big(\Omega, \mathcal{A}, \mathbb{P}\big)$*, will be denoted using bold characters (e.g.,* $\boldsymbol{\xi} \in L^2(\Omega, \mathcal{A}, \mathbb{P}; \Xi)$*), whereas their realizations will be denoted using normal characters (e.g.,* $\xi \in \Xi$*).*

Remark. Problem (1.1) can be easily extended to the sequential control case with direct observation of the noises. Then $\boldsymbol{u} = (\boldsymbol{u_0}, \ldots, \boldsymbol{u_{T-1}})$, each $\boldsymbol{u_t}$ being measurable with respect to a subfield $\mathcal{F}_t$ of $\sigma\big(\boldsymbol{\xi}_0, \ldots, \boldsymbol{\xi}_t\big)$, which is the σ-field generated by the noises prior to t. Practical instances are multistage stochastic programming problems:

$$\min_{(\boldsymbol{u}, \boldsymbol{x})} \mathbb{E}\left[\sum_{t=0}^{T-1} L_{t+1}\big(\boldsymbol{x}_t, \boldsymbol{u}_t, \boldsymbol{\xi}_{t+1}\big) + K\big(\boldsymbol{x}_T\big)\right] \tag{1.2a}$$

$$\text{subject to} \quad \begin{cases} \boldsymbol{x}_0 & = f_0\big(\boldsymbol{\xi}_0\big), \\ \boldsymbol{x}_{t+1} & = f_{t+1}\big(\boldsymbol{x}_t, \boldsymbol{u}_t, \boldsymbol{\xi}_{t+1}\big), \end{cases} \tag{1.2b}$$

$$\boldsymbol{u}_t \text{ is } \mathcal{F}_t\text{-measurable.} \tag{1.2c}$$

Formulation (1.1) has the advantage to clearly distinguish the respective roles of the noise $\boldsymbol{\xi}$ and of the information $\mathcal{F}$. However, in practical situations, the subfield $\mathcal{F}$ is often generated by an observation function h which depends on the noise

$$\mathcal{F} = \sigma\big(h(\boldsymbol{\xi})\big)$$

so that the distinction is not always obvious.

Two polar cases are worth mentioning.

- The *full information* case corresponds to $\mathcal{F} = \mathcal{A}$. In this case, under technical assumptions ensuring the interchange of minimization and expectation (see [15, Theorem 14.60]), problem (1.1) becomes

$$\mathbb{E}\big[\min_{u\in U} j(u, \boldsymbol{\xi})\big].$$

  Once the noise $\boldsymbol{\xi}$ is discretized by a random variable $\boldsymbol{\xi}_n$, the approximate solution is given by $\min_{u\in U} j(u, \boldsymbol{\xi}_n)$, which returns a $\boldsymbol{\xi}_n$-measurable solution and thus an $\mathcal{A}$-measurable one.
- The *open-loop* case arises when $\mathcal{F} = \{\emptyset, \Omega\}$. In this case, the problem is of deterministic nature provided that $\mathbb{E}\big[j(u, \boldsymbol{\xi})\big]$ and its gradient are readily available for each $u \in U$. Otherwise, a standard way to get around the difficulty of computing an expectation is to use samples of $\boldsymbol{\xi}$. A first approach, known as *sample average approximation* (SAA), consists of replacing the expectation to be minimized by a Monte Carlo approximation (see [8]). Another possibility is to use the stochastic gradient method (see [14]).

In the last two cases, one has to deal with only *one* stochastic approximation. However, in the general case, *two* different components of the problem have to be taken into account in order to discretize problem (1.1):

1. The σ-field $\mathcal{F}$ in (1.1b) must be approximated by a finite object $\mathcal{F}_n$ in order to deal with tractable constraints.
2. The expectation in (1.1a) must be approximated in order to be computable, the noise $\boldsymbol{\xi}$ being thus replaced with a finitely valued random variable $\boldsymbol{\xi}_n$.

As already mentioned, the subfield $\mathcal{F}$ is often, e.g., in the stochastic programming framework, given by $\mathcal{F} = \sigma\big(h(\boldsymbol{\xi})\big)$ so that most discretization schemes aim at deducing the discretization of $\mathcal{F}$ from the discretization of $\boldsymbol{\xi}$. In this way, the discretization $\boldsymbol{\xi}_n$ of $\boldsymbol{\xi}$ induces a discretization $\mathcal{F}_n = \sigma\big(h(\boldsymbol{\xi}_n)\big)$. This last discretization scheme may fail to satisfactorily approximate problem (1.1) so that additional conditions have to be added in order to overcome the difficulty (see Pennanen's approach in section 4 for further details). Nevertheless, in the general framework of problem (1.1), we observe that the discretizations of the noise and the information are *a priori unrelated* in the sense that there is no reason for one of these approximations to be deduced from the other. We will follow this way of proceeding in this paper, thus obtaining different perspectives both from the theoretical and the practical point of view.

The noise discretization—related to the convergence of measures and random variables—is somewhat "traditional" in probability theory, whereas the information discretization is not so well-known. Let us recall some results about the space $\mathcal{A}^\star$ of the subfields of $\mathcal{A}$ (see [11] and [7] for further details). The *strong convergence*[1] topology

[1] Although being termed as "strong," this topology actually corresponds to a pointwise convergence notion. We follow here the terminology given by Kudo [11]. Note that there exist "stronger" convergence notions for σ-fields, such as the *uniform convergence* topology given by Boylan [5].

on $\mathcal{A}^\star$ is the coarsest topology such that the conditional expectation is continuous with respect to the σ-field:

$$\mathcal{F}_n \xrightarrow[n\to+\infty]{\text{strong}} \mathcal{F} \Longleftrightarrow \forall f \in L^1(\Omega,\mathcal{A},\mathbb{P};\mathbb{R}), \lim_{n\to+\infty} \|\mathbb{E}[f \mid \mathcal{F}_n] - \mathbb{E}[f \mid \mathcal{F}]\|_{L^1} = 0.$$

Note that this definition depends on the probability $\mathbb{P}$. The main properties of $\mathcal{A}^\star$ equipped with the strong convergence topology are the following.

P_1 The strong convergence topology on $\mathcal{A}^\star$ is metrizable.

P_2 The set of σ-fields generated by finite partitions of Ω is dense in $\mathcal{A}^\star$.

P_3 If $\boldsymbol{y}_n \longrightarrow \boldsymbol{y}$ in probability and $\sigma(\boldsymbol{y}_n) \subset \sigma(\boldsymbol{y})$, then $\sigma(\boldsymbol{y}_n)$ strongly converges to $\sigma(\boldsymbol{y})$.

According to [13, Theorem 2.3.1], the notion of strong convergence of σ-fields, given using $L^1(\Omega,\mathcal{A},\mathbb{P};\mathbb{R})$, can be equivalently defined using $L^r(\Omega,\mathcal{F},\mathbb{P};U)$ for $r \in [1,+\infty)$.

PROPOSITION 1.1. *Let $r \in [1,+\infty)$. The two following statements are equivalent.*

- $\mathcal{F}_n \xrightarrow[n\to+\infty]{\text{strong}} \mathcal{F}$.
- $\forall f \in L^r(\Omega,\mathcal{A},\mathbb{P};U), \lim_{n\to+\infty} \|\mathbb{E}[f \mid \mathcal{F}_n] - \mathbb{E}[f \mid \mathcal{F}]\|_{L^r} = 0$.

In this paper, we present in section 2 a convergence result for approximations of problem (1.1). Contrary to the two polar cases of full or null information, the *functional* $J(\boldsymbol{u},\boldsymbol{\xi}) := \mathbb{E}\big[j(\boldsymbol{u},\boldsymbol{\xi})\big]$ now plays a central role. The continuity of J turns out to be crucial for convergence, and we enlighten the importance of the convergence notions related to the discretization of both the observation and the noise that are used in the approximation. In section 3, we illustrate by an example in what relaxing these notions may lead to failures. Ultimately, we review in section 4 the convergence results obtained in [17], [3], [12], and [10] about the same problem.

2. Convergence theorem. We go back to the initial problem (1.1). The framework of the study is the following.

- The underlying probability space is $(\Omega,\mathcal{A},\mathbb{P})$, and we consider $\mathcal{F}$ a subfield of $\mathcal{A}$.
- The control variable $\boldsymbol{u}$ belongs to the subset $\Delta(\mathcal{F})$ of the $\mathcal{F}$-measurable random variables and is moreover subject to pointwise constraints

  $$\Delta(\mathcal{F}) := \left\{\boldsymbol{u} \in L^r(\Omega,\mathcal{A},\mathbb{P};U),\ \boldsymbol{u} \text{ is } \mathcal{F}\text{-measurable and } \boldsymbol{u}(\omega) \in U^{\text{ad}}\ \mathbb{P}\text{ a.s.}\right\},$$

  U^{ad} being a closed convex subset of U. Here $1 \le r < +\infty$ and $L^r(\Omega,\mathcal{A},\mathbb{P};U)$ is equipped with the topology induced by the norm.
- The random variable $\boldsymbol{\xi}$ belongs to $L^q(\Omega,\mathcal{A},\mathbb{P};\Xi)$, where $1 \le q < +\infty$, equipped with the topology induced by the norm.
- The cost function J, defined on $L^r(\Omega,\mathcal{A},\mathbb{P};U) \times L^q(\Omega,\mathcal{A},\mathbb{P};\Xi)$, is given by

  $$J(\boldsymbol{u},\boldsymbol{\xi}) := \mathbb{E}\big[j(\boldsymbol{u},\boldsymbol{\xi})\big].$$

  Here j is a normal integrand on $U \times \Xi$, J being the associated integral functional (see [15, Chapter 14]).

Using these notations, we want to compute the optimal value $V(\boldsymbol{\xi},\mathcal{F})$ of problem (1.1):

$$V(\boldsymbol{\xi},\mathcal{F}) := \min_{\boldsymbol{u}\in\Delta(\mathcal{F})} J(\boldsymbol{u},\boldsymbol{\xi}). \tag{2.1}$$

Remark. There is no additional difficulty in incorporating in $\Delta(\mathcal{F})$ more general pointwise constraints such as $\boldsymbol{u}(\omega) \in U^{\text{ad}}(\omega)$ $\mathbb{P}$ a.s., U^{ad} being a measurable set-valued mapping whose values are closed and convex.

To approximate problem (2.1), we choose a sequence $\{\mathcal{F}_n\}_{n\in\mathbb{N}}$ of subfields of $\mathcal{A}$ and a sequence $\{\boldsymbol{\xi}_n\}_{n\in\mathbb{N}}$ of random variables in $L^q(\Omega,\mathcal{A},\mathbb{P};\Xi)$, and we consider the following approximated problem:

$$V\big(\boldsymbol{\xi}_n,\mathcal{F}_n\big) := \min_{\boldsymbol{u}\in\Delta(\mathcal{F}_n)} J\big(\boldsymbol{u},\boldsymbol{\xi}_n\big). \tag{2.2}$$

The next theorem emphasizes the role of adequate convergence notions, with rather strong assumptions ($\boldsymbol{H_3}$) on the criterion (weaker assumptions may be found in a companion paper [6]).

THEOREM 2.1. *Under the assumptions*

$\boldsymbol{H_1}$ *the sequence* $\{\mathcal{F}_n\}_{n\in\mathbb{N}}$ *strongly converges to* $\mathcal{F}$*, and* $\mathcal{F}_n\subset\mathcal{F}$*;*

$\boldsymbol{H_2}$ *the sequence* $\{\boldsymbol{\xi}_n\}_{n\in\mathbb{N}}$ *converges in norm to* $\boldsymbol{\xi}$ *in* $L^q(\Omega,\mathcal{A},\mathbb{P};\Xi)$*;*

$\boldsymbol{H_3}$ *the normal integrand* j *is such that*

$$\forall(u,u')\in U^2\ \forall(\xi,\xi')\in\Xi^2,\ |j(u,\xi)-j(u',\xi')|\le\alpha\,\|u-u'\|_U^r+\beta\,\|\xi-\xi'\|_\Xi^q\,,$$

the convergence of the approximated optimal costs holds true:

$$\lim_{n\to+\infty} V\big(\boldsymbol{\xi}_n,\mathcal{F}_n\big) = V\big(\boldsymbol{\xi},\mathcal{F}\big). \tag{2.3}$$

Proof.

Step 1 ($\limsup_{n\to+\infty} V\big(\boldsymbol{\xi}_n,\mathcal{F}_n\big)\le V\big(\boldsymbol{\xi},\mathcal{F}\big)$).

For any $\boldsymbol{u}\in\Delta(\mathcal{F})$, we define $\boldsymbol{u}_n=\mathbb{E}\left[\boldsymbol{u}\mid\mathcal{F}_n\right]$. Note that $\boldsymbol{u}=\mathbb{E}\left[\boldsymbol{u}\mid\mathcal{F}\right]$ $\mathbb{P}$ almost surely. Using assumption $\boldsymbol{H_1}$ and Proposition 1.1, we obtain the convergence of the sequence $\{\boldsymbol{u}_n\}_{n\in\mathbb{N}}$ to $\boldsymbol{u}$ in $L^r(\Omega,\mathcal{A},\mathbb{P};U)$. This implies that the set-valued mapping Δ is lower semicontinuous (see [2, Definition 1.4.2]). From assumption $\boldsymbol{H_3}$, we then deduce that the integral functional J is continuous and therefore upper semicontinuous. Using [2, Theorem 1.4.16], we conclude that the marginal function V is also upper semicontinuous:

$$\limsup_{n\to+\infty} V(\boldsymbol{\xi}_n,\mathcal{F}_n)\le V(\boldsymbol{\xi},\mathcal{F}). \tag{2.4}$$

Step 2 ($\liminf_{n\to+\infty} V\big(\boldsymbol{\xi}_n,\mathcal{F}_n\big)\ge V\big(\boldsymbol{\xi},\mathcal{F}\big)$).

Starting from

$$J(\boldsymbol{u},\boldsymbol{\xi}_n)=J(\boldsymbol{u},\boldsymbol{\xi})+\big(J(\boldsymbol{u},\boldsymbol{\xi}_n)-J(\boldsymbol{u},\boldsymbol{\xi})\big),$$

we obtain by minimization over $\Delta(\mathcal{F}_n)$

$$\begin{aligned}\min_{\boldsymbol{u}\in\Delta(\mathcal{F}_n)} J(\boldsymbol{u},\boldsymbol{\xi}_n) &\ge \min_{\boldsymbol{u}\in\Delta(\mathcal{F}_n)} J(\boldsymbol{u},\boldsymbol{\xi}) + \min_{\boldsymbol{u}\in\Delta(\mathcal{F}_n)} \Big(J(\boldsymbol{u},\boldsymbol{\xi}_n)-J(\boldsymbol{u},\boldsymbol{\xi})\Big)\\ &\ge \min_{\boldsymbol{u}\in\Delta(\mathcal{F})} J(\boldsymbol{u},\boldsymbol{\xi}) + \min_{\boldsymbol{u}\in\Delta(\mathcal{F})} \Big(J(\boldsymbol{u},\boldsymbol{\xi}_n)-J(\boldsymbol{u},\boldsymbol{\xi})\Big),\end{aligned}$$

the last inequality being true because $\mathcal{F}_n\subset\mathcal{F}$ implies $\Delta(\mathcal{F}_n)\subset\Delta(\mathcal{F})$. We thus obtain

$$V(\boldsymbol{\xi}_n,\mathcal{F}_n)\ge V(\boldsymbol{\xi},\mathcal{F})+\min_{\boldsymbol{u}\in\Delta(\mathcal{F})}\Big(J(\boldsymbol{u},\boldsymbol{\xi}_n)-J(\boldsymbol{u},\boldsymbol{\xi})\Big). \tag{2.5}$$

From assumptions $\boldsymbol{H_2}$ and $\boldsymbol{H_3}$, the last term in (2.5) converges to 0 as n goes to infinity, which proves that V is lower semicontinuous:

$$\liminf_{n\to+\infty} V(\boldsymbol{\xi}_n,\mathcal{F}_n)\ge V(\boldsymbol{\xi},\mathcal{F}). \tag{2.6}$$

Gathering (2.4) and (2.6) leads to the result. ∎

From the numerical point of view, problem (2.2) is a tractable approximation of problem (2.1) provided that the range of $\boldsymbol{\xi}_n$ is finite and that $\mathcal{F}_n$ is generated by a finite partition of Ω. Indeed, let

- $\big(\Omega_n^{(1)},\dots,\Omega_n^{(n)}\big)$ be a partition of Ω generating the σ-field $\mathcal{F}_n$, $u_n^{(i)}$ denoting the (constant) value of an $\mathcal{F}_n$-measurable control $\boldsymbol{u}$ on the subset $\Omega_n^{(i)}$,
- $\big(\mho_n^{(1)},\dots,\mho_n^{(n)}\big)$ be a partition of Ω generated by $\boldsymbol{\xi}_n$, $\xi_n^{(l)}$ denoting the (constant) value of the random variable $\boldsymbol{\xi}_n$ on the subset $\mho_n^{(l)}$.

Problem (2.2) is then equivalent to

$$\min_{(u_n^{(1)},\dots,u_n^{(n)})\in U^{\mathrm{ad}}\times\cdots\times U^{\mathrm{ad}}} \sum_{i=1}^{n}\sum_{l=1}^{n} \mathbb{P}\big(\Omega_n^{(i)}\cap\mho_n^{(l)}\big)\; j\big(u_n^{(i)},\xi_n^{(l)}\big), \tag{2.7}$$

whose numerical solution is obtained using classical optimization techniques.

Let us now comment on the assumptions made in Theorem 2.1.

- First of all, the *uniform continuity* assumption $\boldsymbol{H_3}$ made on j is a very strong technical one, which allows for an elementary proof. It can be alleviated using the tools of *epi-convergence*. We do not elaborate on that particular point (see [6] for a comprehensive report) and concentrate on assumptions concerning the convergence notions used in the problem approximation.
- Assumption $\boldsymbol{H_1}$ appears as a reasonable trade-off between two requirements. On the one hand, the strong convergence topology is the coarsest topology such that the conditional expectation is continuous. This is a minimal requirement for approximating $\mathbb{E}\big[j(\boldsymbol{u},\boldsymbol{\xi})\mid\mathcal{F}\big]$, so that it seems that the topology cannot be weakened. On the other hand, the subset of σ-fields generated by a finite partition of Ω is dense in the space $\mathcal{A}^\star$ for the strong convergence topology. This is a desirable feature as far as numerical approximation is concerned, which is no longer verified for more sophisticated topologies as, for instance, the uniform convergence topology defined by Boylan in [5] (see also [3] for a comparison between strong and uniform convergence topologies). Note moreover that $\mathcal{F}_n\subset\mathcal{F}$ is not obvious: When $\mathcal{F}=\sigma\big(h(\boldsymbol{\xi})\big)$, the last inclusion is not automatically satisfied for $\mathcal{F}_n=\sigma\big(h(\boldsymbol{\xi}_n)\big)$.
- Assumption $\boldsymbol{H_2}$ is again a bit strong because the convergence in probability of the sequence $\{\boldsymbol{\xi}_n\}_{n\in\mathbb{N}}$ is in fact sufficient to prove the theorem (see [6]). But the key point here is that the convergence in distribution is insufficient to ensure the result. Indeed, a continuity property on J with respect to $\boldsymbol{\xi}$ cannot be obtained by the *convergence in distribution*, as shown by the following example:
  - $\big(\Omega,\mathcal{A},\mathbb{P}\big)=\big([-1,1],\mathcal{B}_{[-1,1]},\mu\big)$, μ is the uniform distribution on $[-1,1]$ and $U=\Xi=\Omega$.
  - $j(u,\xi)=u\xi$.
  - $\boldsymbol{\xi}_n(\omega)=\begin{cases}(-1)^n & \text{if } \omega\geq 0,\\ (-1)^{n+1} & \text{otherwise,}\end{cases}\qquad \boldsymbol{u}(\omega)=\begin{cases}+1 & \text{if } \omega\geq 0,\\ -1 & \text{otherwise.}\end{cases}$
  - Being stationary in distribution, the sequence $\{\boldsymbol{\xi}_n\}_{n\in\mathbb{N}}$ is converging in distribution, whereas $J\big(\boldsymbol{u},\boldsymbol{\xi}_n\big)=(-1)^n$.

  The discretization process thus requires a stronger convergence notion than Monte Carlo. It is a major difference with the open-loop case, for which it is well-known that the SAA method requires only a notion of convergence in distribution (see, e.g., [8] and [16]).

In the next section, we focus on that particular point and illustrate, on the one hand, in what relaxing assumption $\boldsymbol{H_2}$ may alter the optimal solution and, on the other hand, in what deducing the discretization of $\mathcal{F}$ from the discretization of $\boldsymbol{\xi}$ may conflict with assumption $\boldsymbol{H_1}$.

3. Counterexample. We present here an example illustrating how convergence notions matter in order to accurately discretize problem (1.1). The example, originally designed by Systems & Optimization Working Group (SOWG),[2] has already been used several times, for instance, in [3] to illustrate why using a naive Monte Carlo fails to provide the optimal solution or in [19] (see also [18]) to show that even a sophisticated tool as the Fortet–Mourier metric between probability measures cannot by itself control the error when discretizing a stochastic optimal control problem. Although based on the same example,[3] the purpose is here different: We lower only the convergence requirement made on the approximations of $\boldsymbol{\xi}$ in Theorem 2.1, which leads to suboptimality.

3.1. Formulation and exact solution. We consider a dynamical system incorporating two time steps and only one decision variable. The initial state $\boldsymbol{x}$ is a random variable on $[-1,1]$ with uniform distribution. The final state of the system is defined as

$$\boldsymbol{z} := \boldsymbol{x} + \boldsymbol{u} + \boldsymbol{w}, \tag{3.1a}$$

$\boldsymbol{w}$ being another uniformly distributed random variable on $[-1,1]$ independent of $\boldsymbol{x}$ and the control $\boldsymbol{u}$ being a random variable measurable with respect to the initial state $\boldsymbol{x}$. Let $\epsilon > 0$, and consider the following problem:

$$\min_{\boldsymbol{u} \text{ is } \sigma(\boldsymbol{x})\text{-measurable}} \mathbb{E}\left[\epsilon \boldsymbol{u}^2 + \boldsymbol{z}^2\right]. \tag{3.1b}$$

The probability space associated with problem (3.1) is $\big([-1,1]^2, \mathcal{B}_{[-1,1]^2}, \mu\big)$, where $\mathcal{B}_{[-1,1]^2}$ is the Borel σ-field on $[-1,1]^2$ and μ is the product of two independent uniform probability distributions on $[-1,1]$. The random variables $\boldsymbol{x}$ and $\boldsymbol{w}$ are the two components of the identity application $\mathrm{Id}_{[-1,1]^2}$ on $[-1,1]^2$, the real-valued control variable $\boldsymbol{u}$ being defined on $[-1,1]^2$. Here $j(u,\xi) = \epsilon u^2 + (x+u+w)^2$ with $\xi = (x,w)$, and problem (3.1) is equivalent to

$$\min_{\boldsymbol{u} \text{ is } \sigma(\boldsymbol{x})\text{-measurable}} \int_{[-1,1]^2} \Big(\epsilon\big(\boldsymbol{u}(x,w)\big)^2 + \big(x + \boldsymbol{u}(x,w) + w\big)^2\Big)\mu\big(\mathrm{d}x\mathrm{d}w\big). \tag{3.2}$$

This problem is a Markovian stochastic optimal control problem which can be solved using dynamic programming. Introducing the Bellman functions

$$V_1(z) := z^2 \quad , \quad V_0(x) := \min_{u \in \mathbb{R}} \mathbb{E}\left[\epsilon u^2 + V_1(x + u + \boldsymbol{w})\right],$$

we obtain the optimal feedback law $u^\sharp$ and the associated optimal cost $J^\sharp := \mathbb{E}\left[V_0(\boldsymbol{x})\right]$:

$$\boldsymbol{u}^\sharp(x) = -\frac{x}{1+\epsilon}, \quad J^\sharp = \frac{1}{3}\left(1 + \frac{\epsilon}{1+\epsilon}\right). \tag{3.3}$$

[2] See Acknowledgments.

[3] Which thus provides the same conclusions.

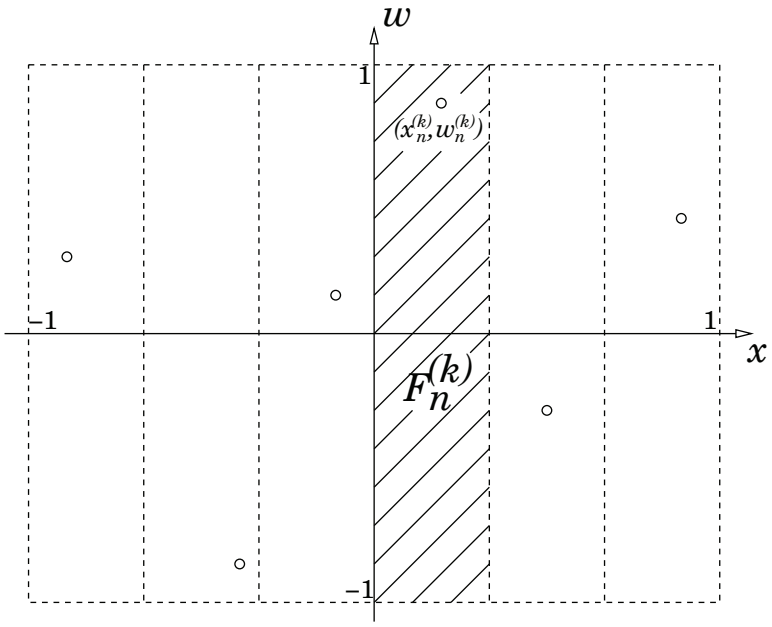

FIG. 3.1. *Partition of* $[-1,1]^2$ *and associated sample.*

3.2. Monte Carlo sampling fails.

3.2.1. Discretization. Let $\{\zeta_n\}_{n\in\mathbb{N}^*}$ be a deterministic sequence of elements in $[-1,1]^2$, with $\zeta_n = \big(\zeta_{n,1}, \zeta_{n,2}\big)$, and let μ_n be the empirical probability distribution associated with $(\zeta_1, \ldots, \zeta_n)$:

$$\mu_n := \frac{1}{n}\sum_{k=1}^{n} \delta_{\zeta_k},$$

where δ denotes the Dirac measure. We assume that the sequence $\{\mu_n\}_{n\in\mathbb{N}^*}$ of empirical probability distributions *weakly converges* to the probability measure μ (see [4]).

Remark. Such a sequence $\{\zeta_n\}_{n\in\mathbb{N}^*}$ is usually obtained as the realization of an infinite Monte carlo sample $\{\boldsymbol{\zeta}_n\}_{n\in\mathbb{N}^*}$ of i.i.d. random variables on $[-1,1]^2$ with distribution μ. The weak convergence assumption is then, almost surely, a consequence of the Glivenko–Cantelli theorem.

Let $n \in \mathbb{N}^\star$; for any $k \in \{1, \ldots, n\}$, we define

$$\big(x_n^{(k)}\ ,\ w_n^{(k)}\big) := \left(\frac{2k-1}{n} - 1 + \frac{\zeta_{k,1}}{n},\ \zeta_{k,2}\right) \tag{3.4}$$

and

$$I_n^{(k)} := \left(\frac{2k-2}{n} - 1, \frac{2k}{n} - 1\right] \quad , \quad F_n^{(k)} := I_n^{(k)} \times [-1,1]. \tag{3.5}$$

By construction, $\big(F_n^{(1)}, \ldots, F_n^{(n)}\big)$ is a partition of $[-1,1]^2$, made of vertical stripes as in Figure 3.1, and $\big(x_n^{(k)}, w_n^{(k)}\big) \in F_n^{(k)}\ \forall k \in \{1, \ldots, n\}$.

We are now ready to discretize problem (3.2).

Random variables. Let $q_n : [-1,1]^2 \to [-1,1]^2$ be the function defined by

$$q_n\big(x,w\big) := \sum_{k=1}^{n} \big(x_n^{(k)}, w_n^{(k)}\big)\mathbb{I}_{F_n^{(k)}}\big(x,w\big);$$

that is, $q_n\big(x,w\big) = \big(x_n^{(k)}, w_n^{(k)}\big)$ if $\big(x,w\big) \in F_n^{(k)}$. We define the sequence $\{\boldsymbol{x}_n, \boldsymbol{w}_n\}_{n\in\mathbb{N}^*}$ of random variables by

$$\big(\boldsymbol{x}_n, \boldsymbol{w}_n\big) := q_n\big(\boldsymbol{x}, \boldsymbol{w}\big). \tag{3.6}$$

According to this definition, the discretized random variable $\big(\boldsymbol{x}_n, \boldsymbol{w}_n\big)$ is constant over each subset $F_n^{(k)}$.

LEMMA 3.1. *The sequence* $\{\boldsymbol{x}_n, \boldsymbol{w}_n\}_{n\in\mathbb{N}^*}$ converges in distribution *to* $\big(\boldsymbol{x}, \boldsymbol{w}\big)$ *as* $n \to +\infty$.

Proof. Consider the empirical distribution function F_n of $\big(\boldsymbol{x}_n, \boldsymbol{w}_n\big)$:

$$F_n\big(x,w\big) = \frac{1}{n}\sum_{k=1}^{n} \mathbb{I}_{[-1,x]\times[-1,w]}\big(x_n^{(k)}, w_n^{(k)}\big).$$

For a given $x \in [-1,1]$ and $n \in \mathbb{N}^*$, let k_0 be the index such that $x \in I_n^{(k_0)}$ (see (3.5)) and let ν_0 be equal to 0 if $x \leq x_n^{(k_0)}$ and equal to 1 otherwise. Then

$$\begin{aligned} F_n\big(x,w\big) &= \frac{1}{n}\sum_{k=1}^{k_0-1} \mathbb{I}_{[-1,w]}\big(w_n^{(k)}\big) + \frac{\nu_0}{n}\mathbb{I}_{[-1,w]}\big(w_n^{(k_0)}\big) \\ &= \frac{k_0-1}{n}\left(\frac{1}{k_0-1}\sum_{k=1}^{k_0-1} \mathbb{I}_{[-1,w]}\big(w_n^{(k)}\big)\right) + \frac{\nu_0}{n}\mathbb{I}_{[-1,w]}\big(w_n^{(k_0)}\big). \end{aligned}$$

The index k_0 goes to infinity as n goes to infinity (for any $x > -1$). We thus conclude that $F_n\big(x,w\big)$ converges to $F\big(x,w\big) = \frac{(1+x)(1+w)}{4}$, the distribution function of μ, the uniform probability on the square $[-1,1]^2$. ∎

Remark. Carrying on the previous remark, $\{\boldsymbol{x}_n, \boldsymbol{w}_n\}_{n\in\mathbb{N}^*}$ is usually a sequence of random variables based on the realization $\{\zeta_n\}_{n\in\mathbb{N}^*}$ of an i.i.d. sample. From Lemma 3.1, the sequence of associated probability distributions converges to μ: This is precisely the condition required in [8] in order to ensure convergence when discretizing an open-loop stochastic optimization problem.

Information. Since $\boldsymbol{x}$ is the first component of $\mathrm{Id}_{[-1,1]^2}$, the subfield $\sigma(\boldsymbol{x})$ of $\mathcal{B}_{[-1,1]^2}$ generated by the random variable $\boldsymbol{x}$ is

$$\mathcal{F} = \mathcal{B}_{[-1,1]} \otimes \{\emptyset, [-1,1]\}.$$

For a given $n \in \mathbb{N}^\star$, we approximate $\mathcal{F}$ by the σ-field $\mathcal{F}_n$ generated by the partition $\big(F_n^{(1)}, \ldots, F_n^{(n)}\big)$:

$$\mathcal{F}_n = \sigma\big(F_n^{(1)}, \ldots, F_n^{(n)}\big). \tag{3.7}$$

From the definition of the subsets $F_n^{(k)}$, the inclusion $\mathcal{F}_n \subset \mathcal{F}$ holds. Note that the approximated information constraint "$\boldsymbol{u}$ is $\mathcal{F}_n$-measurable" is equivalent to "$\boldsymbol{u}$ is

constant over each subset $F_n^{(k)}$," that is, constant on each vertical stripe of Figure 3.1. Such a control variable $\boldsymbol{u}$ is thus parameterized by the values $u_n^{(k)}$ taken on each subset $F_n^{(k)}$:

$$\boldsymbol{u}\big(x,w\big) = \sum_{k=1}^{n} u_n^{(k)} \mathbb{I}_{F_n^{(k)}}\big(x,w\big).$$

Notice that $\mathbb{I}_{F_n^{(k)}}\big(x,w\big)$ does not depend upon w, and therefore $\boldsymbol{u}\big(x,w\big)$ depends only upon x.

LEMMA 3.2. *The sequence* $\{\mathcal{F}_n\}_{n\in\mathbb{N}^*}$ strongly converges *to* $\mathcal{F}$ *as* $n \to +\infty$.

Proof. Since the values $x_n^{(k)}$, $k = 1, \ldots, n$, defined by (3.4) and taken by the random variable $\boldsymbol{x}_n$ are two-by-two distinct, then $\mathcal{F}_n = \sigma\big(\boldsymbol{x}_n\big)$. Following property $\boldsymbol{P_3}$, it is sufficient to show that $\boldsymbol{x}_n \longrightarrow \boldsymbol{x}$ in probability. This last convergence is obvious from the definition of $x_n^{(k)}$. □

3.2.2. Approximated solution. Approximating problem (3.2) consists in replacing $\mathcal{F}$ and $\big(\boldsymbol{x},\boldsymbol{w}\big)$ by their discretized versions $\mathcal{F}_n$ and $\big(\boldsymbol{x}_n,\boldsymbol{w}_n\big)$, respectively. The resulting function to be minimized is constant over each F_n^k so that the general form (2.7) for the approximated problem specializes in

$$\min_{\left(u_n^{(1)},\ldots,u_n^{(n)}\right)\in\mathbb{R}^n} \quad \sum_{k=1}^{n} \mathbb{P}\big(F_n^{(k)}\big)\left(\epsilon\big(u_n^{(k)}\big)^2 + \big(x_n^{(k)} + u_n^{(k)} + w_n^{(k)}\big)^2\right). \tag{3.8}$$

This optimization problem is of a deterministic nature and can be handled using standard optimization procedures. Since $\mathbb{P}\big(F_n^{(k)}\big) > 0$ (indeed equal to $\frac{1}{n}$), problem (3.8) splits into n independent subproblems shaped as

$$\min_{u_n^{(k)}\in\mathbb{R}} \quad \epsilon\big(u_n^{(k)}\big)^2 + \big(x_n^{(k)} + u_n^{(k)} + w_n^{(k)}\big)^2.$$

The optimal solution of this quadratic minimization problem is

$$\widehat{u}_n^{(k)} = -\frac{x_n^{(k)} + w_n^{(k)}}{1+\epsilon}, \tag{3.9}$$

and the associated optimal control variable $\widehat{\boldsymbol{u}}_{\boldsymbol{n}}$ is

$$\widehat{\boldsymbol{u}}_{\boldsymbol{n}}\big(x,w\big) = -\sum_{k=1}^{n} \frac{x_n^{(k)} + w_n^{(k)}}{1+\epsilon} \mathbb{I}_{F_n^{(k)}}\big(x,w\big)\ .$$

By construction the approximated feedback law $\widehat{\boldsymbol{u}}_{\boldsymbol{n}}$ is $\mathcal{F}_n$-measurable. From $\mathcal{F}_n \subset \mathcal{F}$, we deduce that $\widehat{\boldsymbol{u}}_{\boldsymbol{n}}$, as well as $\boldsymbol{u}^\sharp$, satisfies the measurability constraint of problem (3.2). We can compare the cost $\widehat{J}_n$ induced by $\widehat{\boldsymbol{u}}_{\boldsymbol{n}}$, namely,

$$\widehat{J}_n := \mathbb{E}\left[\epsilon\widehat{\boldsymbol{u}}_{\boldsymbol{n}}{}^2 + (\boldsymbol{x} + \widehat{\boldsymbol{u}}_{\boldsymbol{n}} + \boldsymbol{w})^2\right], \tag{3.10}$$

to the true optimal cost $J^\sharp$ in order to evaluate the quality of the approximation, that is, the optimality loss induced by $\widehat{\boldsymbol{u}}_{\boldsymbol{n}}$ with respect to $\boldsymbol{u}^\sharp$.

LEMMA 3.3. *The sequence* $\big\{\widehat{J}_n\big\}_{n\in\mathbb{N}}$ *is such that* $\lim_{n\to+\infty} \widehat{J}_n = \frac{2}{3}$.

Proof. We have

$$\widehat{J}_n = \int_{[-1,1]^2} \Big(\epsilon\big(\widehat{\boldsymbol{u}}_{\boldsymbol{n}}(x,w)\big)^2 + \big(x + \widehat{\boldsymbol{u}}_{\boldsymbol{n}}(x,w) + w\big)^2\Big)\mu\big(\mathrm{d}x\mathrm{d}w\big)$$
$$= \sum_{k=1}^{n} \int_{F_n^{(k)}} \left(\epsilon\left(\frac{x_n^{(k)} + w_n^{(k)}}{1+\epsilon}\right)^2 + \left(x + w - \frac{x_n^{(k)} + w_n^{(k)}}{1+\epsilon}\right)^2\right)\mu\big(\mathrm{d}x\mathrm{d}w\big).$$

Developing the last quadratic term in the previous expression leads to[4]

$$\widehat{J}_n = \frac{2}{3} + \frac{1}{n}\sum_{k=1}^{n} \frac{\big(x_n^{(k)} + w_n^{(k)}\big)^2}{1+\epsilon} - 2\sum_{k=1}^{n}\left(\frac{x_n^{(k)} + w_n^{(k)}}{1+\epsilon}\right)\int_{F_n^{(k)}} \big(x+w\big)\mu\big(\mathrm{d}x\mathrm{d}w\big)$$
$$= \frac{2}{3} + \frac{1}{n}\sum_{k=1}^{n} \frac{\big(x_n^{(k)} + w_n^{(k)}\big)^2}{1+\epsilon} - \frac{2}{n}\sum_{k=1}^{n}\left(\frac{2k-1}{n} - 1\right)\left(\frac{x_n^{(k)} + w_n^{(k)}}{1+\epsilon}\right).$$

Using the convergence in distribution of $\big(\boldsymbol{x}_n, \boldsymbol{w}_n\big)_{n\in\mathbb{N}^*}$ to $\big(\boldsymbol{x}, \boldsymbol{w}\big)$ as $n \to +\infty$ (see Lemma 3.1) and the inequalities $\left|x_n^{(k)} - \left(\frac{2k-1}{n} - 1\right)\right| \leq \frac{1}{n}$ for every k, we obtain that the sum of the last two terms in the previous equality goes to zero as n goes to infinity and hence the result. ∎

From the expression (3.3) of the true optimal cost $J^\sharp$, we deduce that the following inequality holds true for any $\epsilon > 0$:

$$\lim_{n\to+\infty} \widehat{J}_n > J^\sharp.$$

We thus conclude that the proposed discretization scheme fails to asymptotically give the optimal solution of the problem.

Remark. It is easy to verify that the optimal cost $\widetilde{J}_n$ of problem (3.8) is such that

$$\lim_{n\to+\infty} \widetilde{J}_n = \frac{2}{3}\left(\frac{\epsilon}{1+\epsilon}\right).$$

Once again, this limit is different from $J^\sharp$ and goes to zero as ϵ goes to zero. This is another illustration that problem (3.8) is not a valid approximation of problem (3.2). Although the *criterion* in (3.8) looks like a good approximation of the one in (3.2), the two corresponding *optimization problems* are definitely different. As a matter of fact, the "min" operator in (3.8) leads to solutions $\widehat{u}_n^{(k)} = -\frac{x_n^{(k)} + w_n^{(k)}}{1+\epsilon}$ depending on both $x_n^{(k)}$ and $w_n^{(k)}$. The computation of $\widetilde{J}_n$ therefore corresponds to the numerical integration of (3.2) using the feedback law $\widetilde{\boldsymbol{u}}(x,w) = -\frac{x+w}{1+\epsilon}$ which is not $\sigma(\boldsymbol{x})$-measurable and hence the gap with $J^\sharp$.

3.2.3. What has gone wrong. The discretization scheme we have devised in the above example is such that each subproblem derived from (3.8) is optimized using a *unique* sample of the random variable. The kth optimal control value $\widehat{u}_n^{(k)}$ depends on the corresponding first step noise value $x_n^{(k)}$ (which is in adequation with the constraint "$\boldsymbol{u}$ is $\sigma(\boldsymbol{x})$-measurable") and also depends on the second step noise

[4]Remember that $\mathbb{P}(F_n^{(k)}) = \frac{1}{n}$.

value $w_n^{(k)}$ (so that the control law is in some sense anticipative). In the following equivalent form of problem (3.1)

$$\mathbb{E}\Big[\min_{u\in\mathbb{R}} \mathbb{E}\big[\epsilon u^2 + (\boldsymbol{x}+u+\boldsymbol{w})^2 \mid \boldsymbol{x}\big]\Big],$$

our discretization scheme is close to approximating the inner conditional expectation using a single sample of $\boldsymbol{w}$, namely, a really poor way to compute such an expectation.

Let us revisit the assumptions of Theorem 2.1 in view of our example.

- Assumption $\boldsymbol{H_1}$ about the σ-fields is fulfilled.
- Assumption $\boldsymbol{H_3}$ is not exactly satisfied by the cost function j, but it is easy to check that the continuity properties of J required inside the proof are satisfied provided that the control remains bounded.
- Assumption $\boldsymbol{H_2}$ is not fulfilled because the convergence notion available in the example is significantly weaker than the one required by the theorem. More precisely, in our example, the convergence of the sequence $\{\boldsymbol{x}_n, \boldsymbol{w}_n\}_{n\in\mathbb{N}^*}$ towards $\big(\boldsymbol{x}, \boldsymbol{w}\big)$ *does not hold in probability.* Indeed, let $\tau > 0$ be given. Consider the norm $\|(x,w)\| = \sup\{|x|, |w|\}$ on $[-1,1]^2$, and let A_n be the subset of $[-1,1]^2$ defined by

$$A_n := \big\{(x,w)\in[-1,1]^2,\ \ \big\|\big(\boldsymbol{x}_n,\boldsymbol{w}_n\big)(x,w) - \big(\boldsymbol{x},\boldsymbol{w}\big)(x,w)\big\| \le \tau\big\}.$$

Since $(\boldsymbol{x},\boldsymbol{w}) = \mathrm{Id}_{[-1,1]^2}$ and since $(\boldsymbol{x}_n,\boldsymbol{w}_n)$ is constant over each $F_n^{(k)}$, the subset A_n can be expressed as the disjoint union of n subsets $A_n^{(k)}$, with

$$A_n^{(k)} := A_n \cap F_n^{(k)} = \Big\{(x,w)\in F_n^{(k)},\ \ \sup\Big\{\Big|x_n^{(k)} - x\Big|, \Big|w_n^{(k)} - w\Big|\Big\} \le \tau\Big\}.$$

From the definition of $F_n^{(k)}$ and A_n, the subset $A_n^{(k)}$ is included in a $\frac{2}{n}\times 2\tau$ rectangle. We thus obtain $\mu\big(A_n^{(k)}\big) \le \frac{\tau}{n}$ and then $\mu\big(A_n\big) \le \tau$ by summation. This demonstrates that

$$\mu\left(\big\|\big(\boldsymbol{x}_n,\boldsymbol{w}_n\big) - \big(\boldsymbol{x},\boldsymbol{w}\big)\big\| > \tau\right) \ge 1-\tau.$$

What has gone wrong in our example is now clear: Although the discretizations of the noise and the information are a priori unrelated, we have chosen to bind them in a very specific way; however, with this particular binding, one of the assumptions of the theorem, namely, $\boldsymbol{H_2}$, is not fulfilled.

Remark. Note, however, that the convergence notions used in the example may lead to a positive convergence result if the approximations of $\mathcal{F}$ and $\boldsymbol{\xi}$ are implemented in a nested manner (see Barty's approach in section 4).

3.2.4. A better discretization scheme. We ultimately illustrate in what a direct application of Theorem 2.1, and thus the use of a stronger convergence notion for the noise, leads to a positive result for our example. The information discretization previously chosen remains unchanged since it satisfies assumption $\boldsymbol{H_1}$ and leads to the vertical stripes $F_n^{(k)}$. In order to discretize the noise $\boldsymbol{\xi}$, we appeal to the theory of quantization (see, e.g., [9]) and introduce the Voronoi cells $C_n^{(k)}$ around the centroids $(x_n^{(k)}, w_n^{(k)})$ (see Figure 3.2). The discretized random variable $\big(\boldsymbol{x}_n,\boldsymbol{w}_n\big)$ is accordingly defined by

$$\big(\boldsymbol{x}_n,\boldsymbol{w}_n\big)(x,w) := \sum_{k=1}^{n} \big(x_n^{(k)}, w_n^{(k)}\big)\mathbb{I}_{C_n^{(k)}}(x,w).$$

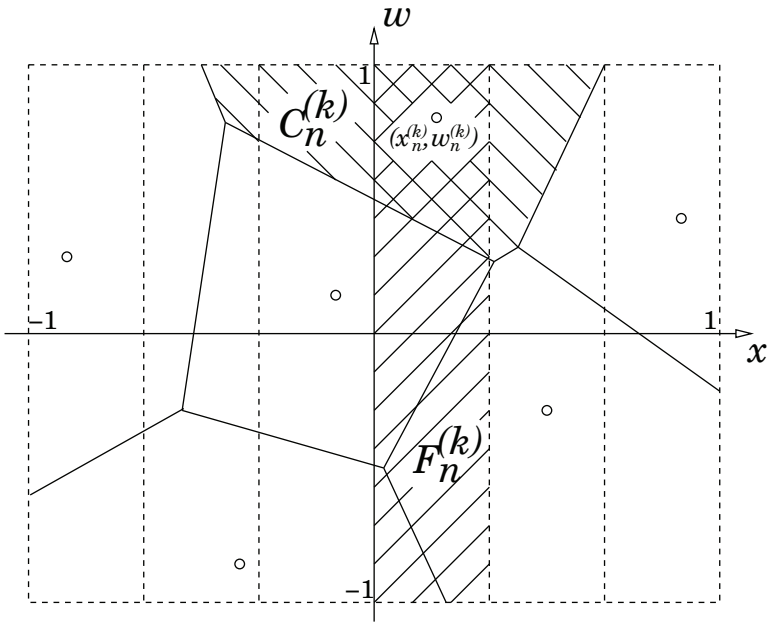

FIG. 3.2. *Noise discretization induced by Voronoi tessellation.*

The optimal Voronoi tessellation is based on the L^2 norm. We suppose that the diameter of the cells goes to zero as n goes to infinity so that assumption $\boldsymbol{H_2}$ is fulfilled. The approximated problem (2.7) to be solved again splits into n open-loop subproblems. Denoting by $\pi_{k,l} = \mathbb{P}(F_n^{(k)} \cap C_n^{(l)})$ the probability weight of the subset $F_n^{(k)} \cap C_n^{(l)}$, the kth subproblem writes

$$\min_{u_n^{(k)} \in \mathbb{R}} \sum_{l=1}^{n} \pi_{k,l} \left(\epsilon \big(u_n^{(k)}\big)^2 + \big(x_n^{(l)} + u_n^{(k)} + w_n^{(l)}\big)^2 \right). \tag{3.11}$$

It is clear that for a fixed k the number of nonempty subsets $F_n^{(k)} \cap C_n^{(l)}$ goes to infinity with n so that each optimal value $\widehat{u}_n^{(k)}$ is computed using a large (in fact asymptotically infinite) number of samples $(x_n^{(l)}, w_n^{(l)})$. This drastic difference with the approximation scheme given in section 3.2.1, where each optimal value $\widehat{u}_n^{(k)}$ is computed using one sample, explains the success of the last approximation.

Remark. A distinctive feature of the last discretization scheme is that a sample $(x_n^{(l)}, w_n^{(l)})$ may enter the computation of several control values $\widehat{u}_n^{(k)}$.

3.3. $\boldsymbol{\mathcal{F}_n = \sigma\big(h(\xi_n)\big)}$ fails. In the example given in section 3.1, the information subfield $\mathcal{F}$ is generated by a function h depending on the noise $\boldsymbol{\xi} = (\boldsymbol{x}, \boldsymbol{w})$, namely,

$$\mathcal{F} = \sigma\big(h(\boldsymbol{\xi})\big),$$

with $h(x, w) = x$. As already explained in section 1, it is possible in this case to deduce a discretization $\widetilde{\mathcal{F}}_n$ of $\mathcal{F}$ from the discretization $\boldsymbol{\xi}_n$ of $\boldsymbol{\xi}$ by

$$\widetilde{\mathcal{F}}_n = \sigma\big(h(\boldsymbol{\xi}_n)\big).$$

Going back to the discretization scheme of section 3.2.1, it is easy to figure out that the information discretization based on the vertical stripes $F_n^{(k)}$, that is,

$$\mathcal{F}_n = \sigma\big(F_n^{(1)}, \ldots, F_n^{(n)}\big),$$

is such that $\mathcal{F}_n = \widetilde{\mathcal{F}}_n$. In this case, the noise discretization induces a discretization of the information such that assumption $\boldsymbol{H_1}$ is satisfied: The pitfall is definitely the convergence notion used for approximating the noise.

Considering now the discretization scheme given in section 3.2.4, the approximated subfield $\mathcal{F}_n$ is the same as in section 3.2.1. The subfield $\widetilde{\mathcal{F}}_n$ deduced from the noise discretization $(\boldsymbol{x}_n, \boldsymbol{w}_n)$ is such that

$$\widetilde{\mathcal{F}}_n \subset \sigma\big(C_n^{(1)}, \ldots, C_n^{(n)}\big).$$

Assuming that the first coordinates of the centroids $(x_n^{(k)}, w_n^{(k)})$ are distinct one from each other,[5] the previous inclusion is in fact an equality. Then $\widetilde{\mathcal{F}}_n \not\subseteq \mathcal{F}$. Moreover we have $\widetilde{\mathcal{F}}_n \xrightarrow{\text{strong}} \mathcal{A}$ rather than $\mathcal{F}$. The subfield $\widetilde{\mathcal{F}}_n$ deduced from the noise discretization is thus not a good candidate for approximating problem (3.2), unless additional conditions are specified as in Pennanen's approach (see section 4 for further details).

4. Discussion about related works. We have proposed an approximation scheme in which the discretization of the noise and the discretization of the information are done separately. It is interesting to compare this approach with others also taking into account the whole discretization process (noise and information) for stochastic optimal control problems.

Barty's approach. In his Ph.D. thesis (in French), K. Barty proves the convergence of a discretization scheme for problem (1.1). The result he gives (see [3, Theorem IV.28]) makes use of the same notions of convergence as those used in section 3 for the counterexample, both for the σ-field and the random variable. Its approach involves two consecutive steps.

(i) The σ-field $\mathcal{F}$ is approximated by a σ-field $\mathcal{F}_k \subset \mathcal{F}$ which is generated by a finite partition $\mathcal{P}_k = \{\Omega_1, \ldots, \Omega_k\}$ of Ω, and problem (1.1) is replaced by

$$V\big(\boldsymbol{\xi}, \mathcal{F}_k\big) = \min_{\boldsymbol{u} \text{ is } \mathcal{F}_k\text{-measurable}} \mathbb{E}\big[j(\boldsymbol{u}, \boldsymbol{\xi})\big]. \tag{4.1}$$

The optimal value $V\big(\boldsymbol{\xi}, \mathcal{F}_k\big)$ of (4.1) converges with k towards the optimal value $V\big(\boldsymbol{\xi}, \mathcal{F}\big)$ of (1.1) as $\mathcal{F}_k$ strongly converges to $\mathcal{F}$ (see [3, Theorem IV.21]). Note that an $\mathcal{F}_k$-measurable random variable $\boldsymbol{u}$ is constant over each subset Ω_l constituting $\mathcal{P}_k$: Such a random variable $\boldsymbol{u}$ is characterized by a vector $\big(u_1, \ldots, u_k\big) \in U^k$, and the minimization in (see 4.1) is thus performed over a finite dimensional space.

(ii) For a given index k, the random variable $\boldsymbol{\xi}$ is approximated by a finitely valued random variable $\boldsymbol{\xi}_n$ and problem (4.1) is replaced by

$$V\big(\boldsymbol{\xi}_n, \mathcal{F}_k\big) = \min_{\boldsymbol{u} \text{ is } \mathcal{F}_k\text{-measurable}} \mathbb{E}\big[j(\boldsymbol{u}, \boldsymbol{\xi}_n)\big]. \tag{4.2}$$

[5] A property which does not conflict with the L^2 convergence.

The optimal value $V(\boldsymbol{\xi}_n, \mathcal{F}_k)$ of (4.2) converges with n toward the optimal value $V(\boldsymbol{\xi}, \mathcal{F}_k)$ of (4.1) as $\boldsymbol{\xi}_n$ converges in distribution toward $\boldsymbol{\xi}$ (see [3, Theorem IV.26]). Note that this step involves only open-loop problems, which are approximated using the traditional Monte Carlo approach.

In this approach, the global discretization error $\left|V(\boldsymbol{\xi}, \mathcal{F}) - V(\boldsymbol{\xi}_n, \mathcal{F}_k)\right|$ is bounded from above by the sum of two terms:

- $\left|V(\boldsymbol{\xi}, \mathcal{F}) - V(\boldsymbol{\xi}, \mathcal{F}_k)\right|$. *Information structure discretization error*,
- $\left|V(\boldsymbol{\xi}, \mathcal{F}_k) - V(\boldsymbol{\xi}_n, \mathcal{F}_k)\right|$. *Mean computation discretization error*.

Apart from the convergence result itself, this approach enlightens the fact that it is not sufficient to properly deal with the last term (Monte Carlo) in order to obtain a "good" approximation of problem (1.1).

The main difference is thus that problem (1.1) is approximated in a nested manner in Barty's approach, whereas we *simultaneously* approximate the σ-field and the random variable.

Pennanen's approach. In [12], Pennanen adresses a stochastic optimization problem very similar to problem (1.1). He assumes that the observation $\boldsymbol{y}$ is a function[6] of the noise $\boldsymbol{\xi}$:

$$\boldsymbol{y} = h(\boldsymbol{\xi}).$$

Then the problem can be formulated on the probability space $(\Xi, \mathcal{B}_\Xi, \mu)$, μ being the probability distribution of ξ, rather than on the probability space $(\Omega, \mathcal{A}, \mathbb{P})$. Pennanen chooses a quantification operator q_n on Ξ, leading to an approximated random variable $\boldsymbol{\xi}_n$,

$$\boldsymbol{\xi}_n = q_n(\boldsymbol{\xi}),$$

and then deduces the information quantization from the noise quantization by setting

$$\boldsymbol{y}_n = h(\boldsymbol{\xi}_n) = h \circ q_n(\boldsymbol{\xi}).$$

Now there is no reason for the quantified observation $\boldsymbol{y}_n$ to be measurable with respect to the initial observation $\boldsymbol{y}$. In order to overcome the difficulty, Pennanen assumes that, in terms of subfields of $\mathcal{B}_\Xi$, the following inclusion holds:

$$\sigma(h \circ q_n) \subset \sigma(h). \tag{4.3}$$

Note that condition (4.3) means that if two samples ξ and ξ' of $\boldsymbol{\xi}$ lead to identical observations, so do the quantified noises $q_n(\xi)$ and $q_n(\xi')$. In the dynamic framework of problem (1.2), this assumption implies that the sampled trajectories of the noise are organized in a scenario tree.

The main difference is thus that the approximation of the σ-field is intimately related to the approximation of the random variable in Pennanen's approach, requiring the additional assumption (4.3), whereas these two approximations are designed *separately* in our approach.[7]

[6] An assumption which can be made without loss of generality.

[7] Note, however, that Pennanen's approach is also designed to handle extended-real-valued functions.

Heitsch's approach. In [10], Heitsch, Römisch and Strugarek address a linear multistage stochastic optimization problem subject to nonanticipative constraints. Denoting, respectively, by $\boldsymbol{\xi} = \left(\boldsymbol{\xi}_1, \ldots, \boldsymbol{\xi}_T\right) \in L^q(\Omega, \mathcal{A}, \mathbb{P}; \Xi)$ and by $\boldsymbol{u} = \left(\boldsymbol{u}_1, \ldots, \boldsymbol{u}_T\right) \in L^r(\Omega, \mathcal{A}, \mathbb{P}; U)$ the noise and the decision stochastic processes, the nonanticipativity constraints "$\boldsymbol{u}_t$ is $\sigma(\boldsymbol{\xi}_1, \ldots, \boldsymbol{\xi}_t)$-measurable" are summarized in the compact form $\boldsymbol{u} \in \mathcal{U}(\boldsymbol{\xi})$ so that the optimization problem writes

$$v(\boldsymbol{\xi}) := \min_{\boldsymbol{u} \in \mathcal{U}(\boldsymbol{\xi})} J(\boldsymbol{u}, \boldsymbol{\xi}).$$

The main result [10, Theorem 2.1] states that, under technical assumptions, there exist positive constants L, α, and δ such that the following majoration

$$\left|v(\boldsymbol{\xi}) - v(\boldsymbol{\xi}^{'})\right| \leq L\Big(\left\|\boldsymbol{\xi} - \boldsymbol{\xi}^{'}\right\|_{L^q} + D_\alpha\big(\boldsymbol{\xi}, \boldsymbol{\xi}^{'}\big)\Big) \tag{4.4}$$

holds for all noise processes $\boldsymbol{\xi}^{'}$ such that $\|\boldsymbol{\xi} - \boldsymbol{\xi}^{'}\|_{L^q} \leq \delta$. Here D_α is a given function measuring the distance between the filtrations of $\boldsymbol{\xi}$ and its approximation $\boldsymbol{\xi}^{'}$.

The last result seems to be very similar to the one given in section 2. It, however, differs significantly on the two following points.

- Only one discretization is considered in [10], namely, the noise discretization. The consequence of this discretization is then measured (using function D_α) in terms of information. General conditions ensuring that the term $D_\alpha(\boldsymbol{\xi}, \boldsymbol{\xi}^{'})$ is close to zero are, however, not given in the main theorem of [10].
- According to the authors, the filtration distance D_α is related to the uniform convergence topology on σ-fields. Such a distance allows for a Lipschitz-like result (4.4) which makes sense[8] but presents the drawback that finite partitions are not dense in the space $\mathcal{A}^\star$ equipped with the uniform convergence topology. Approximating information does not appear to be the main purpose in [10], as illustrated by the example in [10, Example 2.7], where the distance D_α is used to reduce an existing scenario tree rather than to approximate a σ-field.

The main difference is thus that [10] essentially presents a stability result, whereas we are concerned with a convergence result.

5. Conclusion. Approximating a stochastic optimization problem somewhat naturally leads to discretizing the underlying noise or its probability distribution. This procedure has been examined by various authors who have given appropriate conditions for convergence (see [8], [16], and [1]).

In our present work, we provide a framework to deal with the approximation of stochastic optimization problems *subject to measurability constraints*. By means of a simple example, we show how the standard Monte Carlo approximation may fail, although it is generally adapted to the situation without measurability constraints. We also point out that deducing an information discretization uncautiously from the noise discretization may also lead to wrong results. Our main contribution consists in treating separately noise and information discretization, providing appropriate separate sufficient conditions to obtain convergence.

[8] Whereas the distance associated with the strong convergence topology is in fact *arbitrary* and thus not well-suited for a Lipschitz property.

Acknowledgments. This paper is based on earlier work by the SOWG (École Nationale des Ponts et Chaussées); we particularly thank Kengy Barty, Guy Cohen, Anes Dallagi, and Cyrille Strugarek. We also want to thank Professor Roger J.-B. Wets for his kind advice on this work.

STRONG DUALITY FOR THE CDT SUBPROBLEM: A NECESSARY AND SUFFICIENT CONDITION*

WENBAO AI† AND SHUZHONG ZHANG‡

Abstract. In this paper, we consider the problem of minimizing a nonconvex quadratic function, subject to two quadratic inequality constraints. As an application, such a quadratic program plays an important role in the trust region method for nonlinear optimization; such a problem is known as the Celis, Dennis, and Tapia (CDT) subproblem in the literature. The Lagrangian dual of the CDT subproblem is a semidefinite program (SDP), hence convex and solvable. However, a positive duality gap may exist between the CDT subproblem and its Lagrangian dual because the CDT subproblem itself is nonconvex. In this paper, we present a necessary and sufficient condition to characterize when the CDT subproblem and its Lagrangian dual admits no duality gap (i.e., the strong duality holds). This necessary and sufficient condition is easy verifiable and involves only one (any) optimal solution of the SDP relaxation for the CDT subproblem. Moreover, the condition reveals that it is actually rare to render a positive duality gap for the CDT subproblems in general. Moreover, if the strong duality holds, then an optimal solution for the CDT problem can be retrieved from an optimal solution of the SDP relaxation, by means of a matrix rank-one decomposition procedure. The same analysis is extended to the framework where the necessary and sufficient condition is presented in terms of the Lagrangian multipliers at a KKT point. Furthermore, we show that the condition is numerically easy to work with approximatively.

Key words. quadratically constrained quadratic programming, strong Lagrangian duality, Celis, Dennis, and Tapia subproblem, semidefinite program relaxation

1. Introduction.

In this paper, we consider the following nonconvex quadratic optimization problem:

$$(QP) \quad \begin{array}{ll} \text{minimize} & q_0(x) = x^T Q_0 x - 2b_0^T x \\ \text{subject to} & q_i(x) = x^T Q_i x - 2b_i^T x + c_i \le 0, \quad i = 1, \ldots, m. \end{array}$$

In case $m = 1$ and $Q_1 \succ 0$, the problem is known as the *trust region subproblem*, since in the trust region approach to unconstrained optimization, such problems need to be solved repeatedly. In this context, the problem has been thoroughly studied. (For general information on the trust region method, see [6]). It is known that the trust region subproblem can be easily solved. A connection between the solution methods for the trust region subproblem and semidefinite programming (SDP) was established by Sturm and Zhang in [11]. By using a matrix rank-one decomposition procedure, Sturm and Zhang [11] showed that if $m = 1$, then the SDP relaxation of (QP) is tight, and an optimal solution for (QP) can be obtained from an optimal solution of its SDP relaxation. Furthermore, Ye and Zhang [13] showed that if $m = 2$

and certain additional conditions are satisfied, then the SDP relaxation for (QP) can still be tight in many cases. In fact, the quadratic program (QP) with $m = 2$ has its own history as an extended trust region subproblem. In 1985, Celis, Dennis and Tapia (CDT) [3] proposed a trust region method for constrained optimization, in which (QP) with $m = 2$ plays the role as a model for validating a trust region step. In this particular context, $Q_1 \succ 0$ and $Q_2 \succeq 0$, and the extended trust region subproblem is also referred to as the CDT subproblem. A number of papers have been devoted to studying the structure and the solution algorithms for the CDT subproblem; see, e.g., [4, 5, 9, 10, 11, 13, 14, 15, 16].

A remarkable property which makes the CDT subproblem interesting and intriguing is that at a global optimal solution, the Hessian matrix of the Lagrangian function may not necessarily be positive semidefinite; however, it can have at most one negative eigenvalue (see Yuan [14]). In fact, it is quite rare to encounter examples where the Hessian of the Lagrangian function indeed has a negative eigenvalue at optimum. In 1991, Yuan [15] suggested an algorithm for the CDT subproblem under the assumption that the objective function is convex, and, in 1992, Zhang [16] proposed an algorithm for the CDT subproblem under the assumption that the optimal Lagranian Hessian matrix is positive semidefinite. Chen and Yuan [5] presented a sufficient condition (termed as *Property* $\mathcal{J}$ in [5]) under which the Lagrangian function of the CDT subproblem will have a positive semidefinite Hessian at optimal point. Recently, Beck and Eldar [1] used the complex valued SDP (thus relaxed) approach to come up with a similar sufficient condition to guarantee the nonnegativity of the Hessian matrix of the Lagrangian function at optimum. Beck and Eldar [1] reported that in their experiments on randomly generated instances, their sufficient condition was satisfied for an overwhelming majority of the random instances.

The current paper is concerned with the CDT-type quadratic programs. In particular, we shall present a verifiable condition which indicates whether or not the SDP relaxation for the quadratic program is tight. Since the Lagrangian dual of a general quadratically constrained quadratic program is the dual of its SDP relaxation (see Chapter 13 of [12]), our result is equivalent to a necessary and sufficient condition for the strong duality to hold for this class of nonconvex quadratic programs. Our condition involves only the information of an optimal SDP solution, or alternatively, the information of a given KKT point. The paper is organized as follows. In section 2, we shall formally establish the equivalence between the nonnegativity of the Hessian matrix of the Lagrangian function (of (QP)) at an arbitrary optimal solution and the fact that the SDP relaxation is tight. Section 3 is devoted to a specific problem related to the rank-one decomposition of a positive semidefinite matrix. This technical result is interesting in its own right, and it is used in section 4 to derive a *necessary and sufficient* condition to check whether or not the SDP relaxation is indeed tight. Because the dual of the SDP relaxation coincides with the Lagrangian dual of (QP), a tight SDP relaxation manifests that the strong duality holds for (QP). Our necessary and sufficient condition is different from the other two sufficient conditions previously studied in [5] and [1]. In nonlinear programming, it is customary to use terminologies such as the Lagrangian multipliers or the KKT conditions. For this reason, we shall present our results in section 5 both as an easy verifiable condition based on an optimal solution of the SDP relaxation or, alternatively, as an easy verifiable condition based on a KKT point in terms of the Lagrangian function and multipliers. An example is given in section 6 to show that the information carried by the KKT solutions may not be useful for the optimal solution of the CDT problem when the strong duality fails. In section 7, we propose a numerical implementation of the necessary and sufficient

condition. Our simulation results show that the condition is indeed numerically stable and easy to work with.

Throughout the paper, $\mathcal{S}^{n\times n}$ denotes the set of real $n\times n$ symmetric matrices; $\mathcal{S}^{n\times n}_{+}$ denotes the set of real $n\times n$ positive semidefinite matrices; $\mathcal{S}^{n\times n}_{++}$ denotes the set of real $n\times n$ positive definite matrices; for $A, B\in\mathcal{S}^{n\times n}$, $A\bullet B := \operatorname{tr} AB$ denotes the matrix inner-product between A and B.

2. Convex Lagrangian function and the strong duality. In the literature, there are mainly two ways to solve a general quadratically constrained quadratic program (QP): Either use the Lagrangian function with some appropriately chosen multipliers or base the solution method on the SDP relaxation. In the latter case, the method works well if the SDP relaxation is tight, while, in the former case, the method works well if the Hessian of the Lagrangian function is positive semidefinite. It is therefore natural to believe that these two properties must be essentially identical. In this section, we shall formally prove this point. The result is useful for our subsequent analysis.

First of all, following [11], we use the notation

$$M(q_0) := \begin{bmatrix} 0 & -b_0^T \\ -b_0 & Q_0 \end{bmatrix},\ M(q_i) := \begin{bmatrix} c_i & -b_i^T \\ -b_i & Q_i \end{bmatrix},\ \text{for } i=1,\dots,m.$$

Then, (QP) is equivalently written as

$$\begin{aligned} (QP)\quad \text{minimize}\quad & M(q_0)\bullet \begin{bmatrix} t \\ x \end{bmatrix}\begin{bmatrix} t \\ x \end{bmatrix}^T = x^TQ_0x - 2b_0^Txt \\ \text{subject to}\quad & M(q_i)\bullet \begin{bmatrix} t \\ x \end{bmatrix}\begin{bmatrix} t \\ x \end{bmatrix}^T = x^TQ_ix - 2b_i^Txt + c_it^2 \le 0, \quad i=1,\dots,m \\ & t^2 = 1. \end{aligned}$$

The so-called SDP relaxation of (QP) is

$$\begin{aligned} (SP)\quad \text{minimize}\quad & M(q_0)\bullet X \\ \text{subject to}\quad & M(q_i)\bullet X \le 0, \quad i=1,\dots,m \\ & I_{00}\bullet X = 1 \\ & X \succeq 0, \end{aligned}$$

where $I_{00} = \begin{bmatrix} 1 & 0 \\ 0 & \mathbf{0} \end{bmatrix} \in \mathcal{S}^{(n+1)\times(n+1)}$. The dual problem of (SP) is

$$\begin{aligned} (SD)\quad \text{maximize}\quad & y_0 \\ \text{subject to}\quad & Z = M(q_0) - y_0I_{00} + \textstyle\sum_{i=1}^m y_iM(q_i) \succeq 0 \\ & y_i \ge 0, i=1,\dots,m. \end{aligned}$$

Note that (SD) is also the Lagrangian dual problem for (QP) (see [12]). The following well-known facts regarding the relationship between (SP) and (SD) are either straightforward or well known:

(1) (SP) satisfies the Slater condition if the original problem (QP) satisfies the Slater condition.
(2) (SD) satisfies the Slater condition if at least one of the matrices Q_i's, $i = 0,1,\dots,m$, is positive definite.
(3) If both (SP) and (SD) satisfy the Slater condition, then (SP) and (SD) have attainable optimal solutions. Moreover, a primal-dual feasible pair X and

$(Z, y_0, y_1, \ldots, y_m)$ are optimal if and only if they satisfy the complementary conditions:

$$XZ = 0, \quad y_i M(q_i) \bullet X = 0, \quad i = 1, \ldots, m.$$

Throughout this paper, we assume that $Q_1 \succ 0$ and that (QP) satisfied the Slater condition. Hence, (QP), (SP), and (SD) all have optimal solutions, which we shall denote, respectively, by x^*, $\hat{X}$, and $(\hat{Z}, \hat{y_0}, \hat{y_1}, \ldots, \hat{y_m})$, and their optimal values, respectively, by $v(QP)$, $v(SP)$, and $v(SD)$.

Clearly, $v(SP) \leq v(QP)$ since (SP) is a relaxation of (QP), and $v(SP) = v(SD)$ since both (SP) and (SD) satisfy the Slater condition. Therefore, the strong duality holds for (QP) if and only if the SDP relaxation for (QP) is tight; i.e., $v(SP) = v(QP)$. It is helpful to keep in mind that $\hat{Z}$ can also be rewritten as

$$\hat{Z} = \begin{bmatrix} -\hat{y}_0 + \sum_{i=1}^m \hat{y}_i c_i & -b_0^T - \sum_{i=1}^m \hat{y}_i b_i^T \\ -b_0 - \sum_{i=1}^m \hat{y}_i b_i & Q_0 + \sum_{i=1}^m \hat{y}_i Q_i \end{bmatrix}.$$

On the other hand, the Lagrangian function for (QP), with y_i being the multiplier for the constraint $q_i(x) \leq 0$, $i = 1, \ldots, m$, is given as

$$L(x; y) := q_0(x) + \sum_{i=1}^m y_i q_i(x).$$

Clearly, since the function is quadratic in x for any fixed multiplier y, its Hessian matrix is $\nabla^2_{xx} L(x; y) = Q_0 + \sum_{i=1}^m y_i Q_i$.

THEOREM 2.1. *$v(SP) = v(QP) \iff \nabla^2_{xx} L(x; y) = Q_0 + \sum_{i=1}^m y_i Q_i \succeq 0$, where y is the Lagrangian multiplier for an optimal solution of (QP).*

Proof. "$\Longrightarrow$": For any minimizer x^* of the original problem (QP), the matrix $X^* := \begin{bmatrix} 1 \\ x^* \end{bmatrix} \begin{bmatrix} 1 \\ x^* \end{bmatrix}^T$ is also an optimal solution for (SP). So the primal-dual optimal pair X^* and $(\hat{Z}, \hat{y})$ satisfy complementary conditions, where $(\hat{Z}, \hat{y})$ is optimal to (SD), i.e.,

$$\hat{Z} X^* = 0, \quad \hat{y}_i M(q_i) \bullet X^* = 0, \quad i = 1, \ldots, m. \tag{2.1}$$

Since $\hat{Z} \succeq 0$, the relation $\hat{Z} X^* = 0$ is equivalent to $\hat{Z} \begin{bmatrix} 1 \\ x^* \end{bmatrix} = 0$, which implies that

$$\left(Q_0 + \sum_{i=1}^m \hat{y}_i Q_i \right) x^* = b_0 + \sum_{i=1}^m \hat{y}_i b_i.$$

Also, since $q_i(x^*) = M(q_i) \bullet X^*$, it follows from (2.1) that $\hat{y}_i q_i(x^*) = 0$, $i = 1, \ldots, m$. Therefore, x^* and $\hat{y}$ satisfy the KKT condition, and $\hat{y}$ is the corresponding Lagrangian multiplier with the Hessian matrix being

$$\nabla^2_{xx} \left(q_0(x) + \sum_{i=1}^m \hat{y}_i q_i(x) \right) \Bigg|_{x = x^*} = Q_0 + \sum_{i=1}^m \hat{y}_i Q_i = \hat{Z} \succeq 0.$$

"$\Longleftarrow$": Suppose that the original problem (QP) has an optimal solution x^*, with a positive semidefinite Lagrangian Hessian matrix $Q_0 + \sum_{i=1}^m y_i^* Q_i$. Then x^* and

$y_1^*, \ldots, y_m^*$ satisfy the following KKT condition:

$$\left(Q_0 + \sum_{i=1}^m y_i^* Q_i\right) x^* = b_0 + \sum_{i=1}^m y_i^* b_i, \quad y_i^* q_i(x^*) = 0, \quad y_i^* \geq 0, i = 1, \ldots, m.$$

Let

$$\left\{ \begin{array}{l} X^* := \left[\begin{array}{c} 1 \\ x^* \end{array} \right] \left[\begin{array}{c} 1 \\ x^* \end{array} \right]^T, \quad y_0^* := q_0(x^*), \\ \text{and } Z^* := M(q_0) - y_0^* I_{00} + \sum_{i=1}^m y_i^* M(q_i). \end{array} \right. \tag{2.2}$$

Next, we aim to show that X^* and (y^*, Z^*) are, in fact, optimal to (SP) and (SD). To this end, we need only to verify that $Z^* \succeq 0$ and $Z^* X^* = 0$.

Let the Lagrangian function be

$$L(x; y^*) = q_0(x) + \sum_{i=1}^m y_i^* q_i(x). \tag{2.3}$$

By the Taylor expansion at x^* and the KKT optimality condition, we have

$$\begin{aligned} L(x; y^*) &= L(x^*; y^*) + (x - x^*)^T \left(Q_0 + \sum_{i=1}^m y_i^* Q_i\right)(x - x^*) \\ &\geq L(x^*; y^*) = q_0(x^*) = y_0^* \end{aligned} \tag{2.4}$$

for any x, which implies that x^* is a global minimizer of $L(x; y^*)$. Consider any $(n+1)$-dimensional vector $\left[\begin{smallmatrix} t \\ x \end{smallmatrix}\right]$. If $t \neq 0$, then it follows from (2.2), (2.3), and (2.4) that

$$\begin{aligned} \left[\begin{array}{c} t \\ x \end{array} \right]^T Z^* \left[\begin{array}{c} t \\ x \end{array} \right] &= \left(M(q_0) - y_0^* I_{00} + \sum_{i=1}^m y_i^* M(q_i) \right) \bullet \left[\begin{array}{c} t \\ x \end{array} \right] \left[\begin{array}{c} t \\ x \end{array} \right]^T \\ &= t^2 \left(q_0(x/t) + \sum_{i=1}^m y_i^* q_i(x/t) - y_0^* \right) \\ &= t^2 \left(L(x/t; y^*) - y_0^* \right) \geq 0. \end{aligned}$$

If $t = 0$, then

$$\left[\begin{array}{c} t \\ x \end{array} \right]^T Z^* \left[\begin{array}{c} t \\ x \end{array} \right] = x^T \left(Q_0 + \sum_{i=1}^m y_i^* Q_i \right) x \geq 0.$$

Therefore, $Z^* \succeq 0$. Moreover,

$$Z^* \bullet X^* = \left[\begin{array}{c} 1 \\ x^* \end{array} \right]^T Z^* \left[\begin{array}{c} 1 \\ x^* \end{array} \right] = L(x^*; y^*) - y_0^* = 0,$$

which, together with $Z^* \succeq 0$ and $X^* \succeq 0$, implies that $Z^* X^* = 0$. □

Theorem 2.1 implies that once an optimal solution for (QP) admits a Lagrangian multiplier (vector) with nonnegative Hessian matrix, then $v(QP) = v(SP)$, which in

turn implies that *every* optimal solution admits a Lagrangian multiplier with nonnegative Hessian matrix. We formalize the statement as follows.

COROLLARY 2.2. *If at one optimal solution of* (QP) *there is a Lagrangian multiplier with a nonnegative Hessian matrix, then it follows that at any optimal solution of* (QP)*, there is a Lagrangian multiplier with a nonnegative Hessian matrix.*

We note that Theorem 2.1 can actually be used to bridge an easy provable fact to a less obvious one. For instance, it is relatively easy to show that if $m = 1$, then the Hessian of the Lagrangian function is nonnegative (e.g., Theorem 7.2.1 in [6]). Hence we can conclude $v(QP) = v(SP) = v(SD)$ in this case, simply using Theorem 2.1. On the other hand, if $m = 2$ and (QP) is homogeneous (i.e., $b_0 = b_1 = b_2 = 0$), then Ye and Zhang (section 2.2 of [13]) showed that $v(QP) = v(SP)$. A less obvious fact is that the Lagrangian function always has a nonnegative Hessian matrix in this case.

3. A new matrix rank-one decomposition procedure. Sturm and Zhang [11] proposed a simple (polynomial-time) procedure to compute the following matrix rank-one decomposition problem: Given $X \in \mathcal{S}_+^{n\times n}$ and $A \in \mathcal{S}^{n\times n}$, find $x_j \in \Re^n$, $j = 1, \ldots, r$, where $r = \text{rank}(A)$ such that $X = \sum_{j=1}^r x_j x_j^T$ and $x_j^T A x_j = A \bullet X/r$, $j = 1, \ldots, r$. Huang and Zhang [8] extended the result to the case where the matrices in questions are all Hermitian.

The aim of this section is to study a further extension of such rank-one decomposition in the real symmetric case. Our result will then be applied in the next section to enable a method for (QP) when $m = 2$. Let $x_1 \in \Re^n$ and $X \in \mathcal{S}_+^{n\times n}$. As a convention, we shall call matrix X to be *rank-one decomposable* at x_1 if there exist other $r - 1$ vectors $x_2, \ldots, x_r$ such that $X = x_1x_1^T + x_2x_2^T + \cdots + x_rx_r^T$, where $r = \text{rank}(X)$. To find out when X is a matrix rank-one decomposable at a given vector, we first note the following lemma.

LEMMA 3.1. *Suppose that* $X \in \mathcal{S}_+^{n\times n}$*, with* $\text{rank}(X) = r$ *and* $X = x_1x_1^T + x_2x_2^T + \cdots + x_rx_r^T$*. Let* $X_r = [x_1, \ldots, x_r]$*. Then,* $X = y_1y_1^T + y_2y_2^T + \cdots + y_ry_r^T$ *holds if and only if there exists an orthonormal matrix* $P \in \Re^{r\times r}$ *such that* $Y_r = X_rP$ *where* $Y_r = [y_1, \ldots, y_r]$.

Proof. The sufficiency is obvious. To show the necessity of the condition, let us suppose $X = X_rX_r^T = Y_rY_r^T$ and consider $P = X_r^TY_r(Y_r^TY_r)^{-1}$. Clearly,

$$P^TP = (Y_r^TY_r)^{-1}Y_r^TX_rX_r^TY_r(Y_r^TY_r)^{-1} = (Y_r^TY_r)^{-1}Y_r^TY_rY_r^TY_r(Y_r^TY_r)^{-1} = I_r.$$

Hence P is an orthonormal matrix. At the same time,

$$X_rP = X_rX_r^TY_r(Y_r^TY_r)^{-1} = Y_rY_r^TY_r(Y_r^TY_r)^{-1} = Y_r. \qquad \square$$

Since for any given unit vector one can always construct an orthonormal matrix with this unit vector as the first column, this leads to the following characterization of the rank-one decomposability at a given vector.

PROPOSITION 3.2. *Suppose that* $X \in \mathcal{S}_+^{n\times n}$*, with* $\text{rank}(X) = r$ *and* $X = x_1x_1^T + x_2x_2^T + \cdots + x_rx_r^T$*. Let* $X_r = [x_1, \ldots, x_r]$*. Then,* X *is rank-one decomposable at* $y \in \Re^n$ *if and only if there is* $u \in \Re^r$*, with* $\|u\| = 1$ *and* $y = X_ru$*.*

The next result plays an important role in this paper.

LEMMA 3.3. *Let* $A_1, A_2 \in \mathcal{S}^{n\times n}$*. Suppose that* $X = x_1x_1^T + x_2x_2^T + \cdots + x_rx_r^T$*, where* $r \geq 3$*. If*

$$\begin{aligned} &A_1 \bullet x_1x_1^T = A_1 \bullet x_2x_2^T = \delta_1, \\ &(A_2 \bullet x_1x_1^T - \delta_2)(A_2 \bullet x_2x_2^T - \delta_2) < 0, \end{aligned} \tag{3.1}$$

then in the real-number computation sense (viz. the computational model of Blum, Shub, and Smale [2]*, which we shall abbreviate as the BBS model hereafter), one can find in polynomial-time a vector* $y \in \Re^n$ *such that* X *is rank-one decomposable at* y *and*

$$\begin{aligned} A_1 \bullet yy^T &= \delta_1, \\ A_2 \bullet yy^T &= \delta_2. \end{aligned} \tag{3.2}$$

Proof. Without loss of generality, we assume that

$$A_2 \bullet x_1x_1^T - \delta_2 > 0 \text{ and } A_2 \bullet x_2x_2^T - \delta_2 < 0. \tag{3.3}$$

For given real values α_i, $i = 1, 2, 3$, with $(\alpha_1, \alpha_2, \alpha_3) \neq 0$, define

$$y = \frac{\alpha_1 x_1 + \alpha_2 x_2 + \alpha_3 x_3}{\sqrt{\alpha_1^2 + \alpha_2^2 + \alpha_3^2}}. \tag{3.4}$$

By Proposition 3.2, X is rank-one decomposable at y. Let us substitute (3.4) into (3.2) and consider the following system of equations with respect to the unknown real variables α_1, α_2, and α_3:

$$\begin{aligned} 0 = {} & \alpha_3^2(A_1 \bullet x_3x_3^T - \delta_1) + 2\alpha_1\alpha_2 A_1 \bullet x_1x_2^T \\ & + 2\alpha_1\alpha_3 A_1 \bullet x_1x_3^T + 2\alpha_2\alpha_3 A_1 \bullet x_2x_3^T, \end{aligned} \tag{3.5}$$

$$\begin{aligned} 0 = {} & \alpha_1^2(A_2 \bullet x_1x_1^T - \delta_2) + \alpha_2^2(A_2 \bullet x_2x_2^T - \delta_2) + \alpha_3^2(A_2 \bullet x_3x_3^T - \delta_2) \\ & + 2\alpha_1\alpha_2 A_2 \bullet x_1x_2^T + 2\alpha_1\alpha_3 A_2 \bullet x_1x_3^T + 2\alpha_2\alpha_3 A_2 \bullet x_2x_3^T. \end{aligned} \tag{3.6}$$

In fact, it follows from Finsler's lemma [7] that (3.5) and (3.6) admit a real-valued solution $(\alpha_1, \alpha_2, \alpha_3)$. However, Finsler's lemma is a pure existence result. Below we shall construct such solutions. We proceed by considering two cases.

Case 1. $A_1 \bullet x_1x_2^T = 0$.

We choose $\alpha_1 = 1$ and $\alpha_3 = 0$. Then (3.5) is trivially satisfied for any values of α_2, and (3.6) can be rewritten as follows:

$$(A_2 \bullet x_1x_1^T - \delta_2) + \alpha_2^2(A_2 \bullet x_2x_2^T - \delta_2) + 2\alpha_2 A_2 \bullet x_1x_2^T = 0,$$

which is a quadratic equation in α_2 and must have two distinct real roots because of (3.3); one is positive, and another is negative. Let $\bar{\alpha}_2$ be one of the roots. Then $(\alpha_1, \alpha_2, \alpha_3) = (1, \bar{\alpha}_2, 0)$ is a solution for (3.5) and (3.6).

Case 2. $A_1 \bullet x_1x_2^T \neq 0$.

We choose $\alpha_3 = 1$. Then (3.5) and (3.6) become

$$0 = 2\alpha_2\left(\alpha_1 A_1 \bullet x_1x_2^T + A_1 \bullet x_2x_3^T\right) + 2\alpha_1 A_1 \bullet x_1x_3^T + (A_1 \bullet x_3x_3^T - \delta_1), \tag{3.7}$$

$$\begin{aligned} 0 = {} & \alpha_1^2(A_2 \bullet x_1x_1^T - \delta_2) + \alpha_2^2(A_2 \bullet x_2x_2^T - \delta_2) + 2\alpha_1\alpha_2 A_2 \bullet x_1x_2^T \\ & + 2\alpha_1 A_2 \bullet x_1x_3^T + 2\alpha_2 A_2 \bullet x_2x_3^T + (A_2 \bullet x_3x_3^T - \delta_2). \end{aligned} \tag{3.8}$$

Solving (3.7) yields

$$\alpha_2 = -\frac{2\alpha_1 A_1 \bullet x_1x_3^T + (A_1 \bullet x_3x_3^T - \delta_1)}{2(\alpha_1 A_1 \bullet x_1x_2^T + A_1 \bullet x_2x_3^T)} \triangleq p(\alpha_1). \tag{3.9}$$

Moreover, let us denote

$$\begin{aligned} g(\alpha_1, \alpha_2) := {} & \alpha_1^2(A_2 \bullet x_1x_1^T - \delta_2) + \alpha_2^2(A_2 \bullet x_2x_2^T - \delta_2) + 2\alpha_1\alpha_2 A_2 \bullet x_1x_2^T \\ & + 2\alpha_1 A_2 \bullet x_1x_3^T + 2\alpha_2 A_2 \bullet x_2x_3^T + (A_2 \bullet x_3x_3^T - \delta_2) \end{aligned} \tag{3.10}$$

and define

$$t_1 := -\frac{A_1 \bullet x_2 x_3^T}{A_1 \bullet x_1 x_2^T}.$$

We consider the following two possible subcases.

Case 2.1. $\det \begin{bmatrix} 2A_1 \bullet x_1 x_3^T & A_1 \bullet x_3 x_3^T - \delta_1 \\ A_1 \bullet x_1 x_2^T & A_1 \bullet x_2 x_3^T \end{bmatrix} \neq 0.$

Since

$$\begin{aligned} &\left(2\alpha_1 A_1 \bullet x_1 x_3^T + (A_1 \bullet x_3 x_3^T - \delta_1)\right)\big|_{\alpha_1 = t_1} \\ &= -\det \begin{bmatrix} 2A_1 \bullet x_1 x_3^T & A_1 \bullet x_3 x_3^T - \delta_1 \\ A_1 \bullet x_1 x_2^T & A_1 \bullet x_2 x_3^T \end{bmatrix} \Big/ A_1 \bullet x_1 x_2^T \neq 0, \end{aligned}$$

the function $p(\alpha_1)$ has the properties that

$$\lim_{\alpha_1 \to t_1} p(\alpha_1) = \infty \tag{3.11}$$

and

$$\lim_{\alpha_1 \to \infty} p(\alpha_1) = -\frac{A_1 \bullet x_1 x_3^T}{A_1 \bullet x_1 x_2^T}. \tag{3.12}$$

Substituting (3.9) into (3.10), we obtain an equation in α_1:

$$\begin{aligned} g(\alpha_1, p(\alpha_1)) := {} & \alpha_1^2 (A_2 \bullet x_1 x_1^T - \delta_2) + p(\alpha_1)^2 (A_2 \bullet x_2 x_2^T - \delta_2) + 2\alpha_1 p(\alpha_1) A_2 \bullet x_1 x_2^T \\ & + 2\alpha_1 A_2 \bullet x_1 x_3^T + 2p(\alpha_1) A_2 \bullet x_2 x_3^T + (A_2 \bullet x_3 x_3^T - \delta_2) \\ = {} & 0, \end{aligned}$$

which is essentially a quartic polynomial equation in α_1. Since

$$\lim_{\alpha_1 \to t_1} g(\alpha_1, p(\alpha_1)) = -\infty$$

and

$$\lim_{\alpha_1 \to \infty} g(\alpha_1, p(\alpha_1)) = +\infty$$

due to (3.3), (3.11), and (3.12), it follows that $g(\alpha_1, p(\alpha_1))$ has at least one real root $\bar{\alpha}_1$ in the interval $(t_1, +\infty)$. Moreover, such root can be found by solving a quartic polynomial equation with the standard root-finding formula, which can be regarded as a constant operation in the BSS computational model. Substituting back, we derive $(\bar{\alpha}_1, p_1(\bar{\alpha}_1), 1)$ as a solution for (3.5) and (3.6).

Case 2.2. $\det \begin{bmatrix} 2A_1 \bullet x_1 x_3^T & A_1 \bullet x_3 x_3^T - \delta_1 \\ A_1 \bullet x_1 x_2^T & A_1 \bullet x_2 x_3^T \end{bmatrix} = 0.$

The above implies that there exists k such that

$$(2A_1 \bullet x_1 x_3^T, A_1 \bullet x_3 x_3^T - \delta_1) = k(A_1 \bullet x_1 x_2^T, A_1 \bullet x_2 x_3^T).$$

Thus (3.7) becomes

$$(\alpha_1 A_1 \bullet x_1 x_2^T + A_1 \bullet x_2 x_3^T)(2\alpha_2 + k) = 0,$$

for which the roots are

$$\alpha_1 = -\frac{A_1 \bullet x_2 x_3^T}{A_1 \bullet x_1 x_2^T} =: t_1, \quad \alpha_2 \text{ arbitrary}$$

and

$$\alpha_2 = -k/2 =: t_2, \quad \alpha_1 \text{ arbitrary.}$$

Substituting them back into (3.8), it suffices to solve either $g(t_1, \alpha_2) = 0$ or $g(\alpha_1, t_2) = 0$, which are quadratic equations in α_2 and α_1, respectively. If $g(t_1, \alpha_2)$ has a real root $\bar{\alpha}_2$, then $(t_1, \bar{\alpha}_2, 1)$ is a solution to (3.5) and (3.6); otherwise, we have

$$g(t_1, \alpha_2) < 0 \text{ for all } \alpha_2$$

as $\lim_{\alpha_2 \to +\infty} g(t_1, \alpha_2) = -\infty$ due to (3.3). In particular,

$$g(t_1, t_2) < 0.$$

Thus $g(\alpha_1, t_2)$ has a real root $\bar{\alpha}_1$ for α_1 on the interval $(t_1, +\infty)$ as $\lim_{\alpha_1 \to +\infty} g(\alpha_1, t_2) = +\infty$ due to (3.3). Then $(\bar{\alpha}_1, t_2, 1)$ is a solution to (3.5) and (3.6). □

Remark that in Lemma 3.3, we require that $r = 3$. This condition cannot be removed. Consider the following example:

$$A_1 = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}, A_2 = \begin{bmatrix} -1 & 1 \\ 1 & 1 \end{bmatrix}, X = x_1 x_1^T + x_2 x_2^T = \begin{bmatrix} 1 \\ -1 \end{bmatrix} [1, -1] + \begin{bmatrix} 1 \\ 1 \end{bmatrix} [1, 1].$$

Clearly,

$$A_1 \bullet x_1 x_1^T = A_1 \bullet x_2 x_2^T = 0,$$
$$A_2 \bullet x_1 x_1^T = -2 < 0, A_2 \bullet x_2 x_2^T = 2 > 0.$$

However, for any nonzero $x \in \Re^2$, $A_1 \bullet x x^T = 0$ if and only if x is either parallel to x_1 or to x_2, which implies that there is no nontrivial x satisfying both $A_1 \bullet x x^T = 0$ and $A_2 \bullet x x^T = 0$ simultaneously.

Using the above lemma, we now show the following theorem.

THEOREM 3.4. *Let $A_1, A_2 \in \mathcal{S}^{n \times n}$ and $X \in \mathcal{S}_+^{n \times n}$, with*

$$A_1 \bullet X = \delta_1, \quad A_2 \bullet X = \delta_2.$$

If $r := \text{rank}(X) \geq 3$, then in polynomial-time (real-number computation), one finds a rank-one decomposition for X:

$$X = x_1 x_1^T + x_2 x_2^T + \cdots + x_r x_r^T$$

such that

$$A_1 \bullet x_i x_i^T = \delta_1 / r \text{ for } i = 1, \ldots, r,$$
$$A_2 \bullet x_i x_i^T = \delta_2 / r \text{ for } i = 1, \ldots, r-2.$$

Proof. We shall achieve the desired decomposition by the following steps. Initially, we set $X_0 := \emptyset$ and $X_1 := X$. By Lemma 2.2 of [13], one finds a rank-one decomposition for X_1:

$$X_1 = x_1 x_1^T + x_2 x_2^T + \cdots + x_r x_r^T$$

such that $A_1 \bullet x_i x_i^T = \delta_1/r$ for $i = 1, \ldots, r$. Introduce an index set

$$I_0 := \{i \mid A_2 \bullet x_i x_i^T = \delta_2/r, i = 1, \ldots, r\}$$

and then update X_0 and X_1 by setting

$$X_0 := X_0 + \sum_{i \in I_0} x_i x_i^T, \quad X_1 := X_1 - \sum_{i \in I_0} x_i x_i^T.$$

If $\text{rank}(X_1) < 3$, then the procedure is completed; otherwise, i.e., $\text{rank}(X_1) \geq 3$, using Lemma 3.3, we find y for which X_1 is rank-one decomposable at y such that

$$A_1 \bullet yy^T = \delta_1/r, \quad A_2 \bullet yy^T = \delta_2/r.$$

Update X_0 and X_1 by letting

$$X_0 := X_0 + yy^T, \quad X_1 := X_1 - yy^T.$$

In this case, $\text{rank}(X_1)$ is reduced by 1. Repeat the above procedure until $\text{rank}(X_1) < 3$. □

4. Strong duality: A necessary and sufficient condition. In this section, we consider (QP) with $m = 2$, which shall be denoted $(QP)_2$ hereafter. Without loss of generality, we assume $q_1(x) = x^T x - 1$; i.e.,

$$\begin{array}{lll} (QP)_2 & \text{minimize} & q_0(x) = x^T Q_0 x - 2b_0^T x \\ & \text{subject to} & q_1(x) = x^T x - 1 \leq 0 \\ & & q_2(x) = x^T Q_2 x - 2b_2^T x + c_2 \leq 0. \end{array}$$

The above problem is slightly more general than the CDT subproblem in that Q_2 above can be indefinite. The central issue to be considered here is when the corresponding SDP relaxation for $(QP)_2$ is tight, which is shown in section 2 to be equivalent to a strong Lagrangian duality (alternatively, it is also equivalent to the fact that the Lagrangian function has a positive semidefinite Hessian matrix at optimum due to Theorem 2.1). As before, we assume throughout the discussion that the Slater condition is satisfied by $(QP)_2$.

Let $(SP)_2$ be the SDP relxation for $(QP)_2$ and $(SD)_2$ be the dual of $(SP)_2$; that is,

$$\begin{array}{lll} (SP)_2 & \text{minimize} & M(q_0) \bullet X \\ & \text{subject to} & M(q_1) \bullet X \leq 0 \\ & & M(q_2) \bullet X \leq 0 \\ & & I_{00} \bullet X = 1 \\ & & X \succeq 0, \end{array}$$

where

$$M(q_0) := \begin{bmatrix} 0 & -b_0^T \\ -b_0 & Q_0 \end{bmatrix}, M(q_1) := \begin{bmatrix} -1 & 0 \\ 0 & I_n \end{bmatrix},$$
$$M(q_2) := \begin{bmatrix} c_2 & -b_2^T \\ -b_2 & Q_2 \end{bmatrix}, I_{00} := \begin{bmatrix} 1 & 0 \\ 0 & O_n \end{bmatrix}.$$

As we observed earlier, $(SD)_2$ is also the Lagrangian dual of $(QP)_2$. Let $\hat{X}$ and $(\hat{Z}, \hat{y}_0, \hat{y}_1, \hat{y}_2)$ be a pair of optimal solutions to $(SP)_2$ and to $(SD)_2$, respectively. It turns out that the following property of $\hat{X}$ and $(\hat{Z}, \hat{y}_0, \hat{y}_1, \hat{y}_2)$ is important, which we shall call *Property* $\mathcal{I}$ for ease of reference.

DEFINITION 4.1. *For* $\hat{X}$ *and* $(\hat{Z}, \hat{y}_0, \hat{y}_1, \hat{y}_2)$*, a given pair of optimal solutions for* $(SP)_2$ *and* $(SD)_2$*, respectively, we say that this pair has Property* $\mathcal{I}$ *if:*

(1) $\hat{y}_1\hat{y}_2 \neq 0$*;*
(2) $\operatorname{rank}(\hat{Z}) = n - 1$*;*
(3) $\operatorname{rank}(\hat{X}) = 2$*, and there is a rank-one decomposition of* $\hat{X}$*,* $\hat{X} = \hat{x}_1\hat{x}_1^T + \hat{x}_2\hat{x}_2^T$*, such that* $M(q_1) \bullet \hat{x}_i\hat{x}_i^T = 0$*,* $i = 1, 2$*, and* $(M(q_2) \bullet \hat{x}_1\hat{x}_1^T)(M(q_2) \bullet \hat{x}_2\hat{x}_2^T) < 0$*.*

We remark here that it is easy to verify Property $\mathcal{I}$, once $(SP)_2$ and $(SD)_2$ are solved. The first two conditions being straightforward, the last one, due to Proposition 3.2, can be reduced to verifying the condition on a single parameter satisfying a quadratic equation (any 2-by-2 orthonormal matrix can be completely characterized by polar coordinates in a single parameter).

THEOREM 4.2. *Consider* $(QP)_2$ *where the Slater condition is satisfied. Suppose that* $\hat{X}$ *and* $(\hat{Z}, \hat{y}_0, \hat{y}_1, \hat{y}_2)$ *are a pair of optimal solutions for its SDP relaxation problem* $(SP)_2$ *and the dual* $(SD)_2$*, respectively. Then,* $v((SP)_2) < v((QP)_2)$ *holds if and only if the pair* $\hat{X}$ *and* $(\hat{Z}, \hat{y}_0, \hat{y}_1, \hat{y}_2)$ *has Property* $\mathcal{I}$*.*

Proof. We shall complete the proof in two parts. They are, *Part* 1: If Property $\mathcal{I}$ does not hold, then the SDP relaxation is tight; and *Part* 2: If Property $\mathcal{I}$ holds, then the relaxation must not be tight.

In *Part* 1, we enumerate four exhaustive (but not mutually exclusive) possibilities, to be denoted by *Part* 1.i, with $i = 1, 2, 3, 4$.

Part 1.1. $\hat{y}_1\hat{y}_2 = 0$.

The proof that the SDP relaxation is tight in this case can be found in Ye and Zhang [13].

Part 1.2. $\hat{y}_1\hat{y}_2 \neq 0$ and $\operatorname{rank}(\hat{X}) \neq 2$.

$\hat{y}_1\hat{y}_2 \neq 0$ implies by the complementary conditions that

$$\hat{Z}\hat{X} = 0, \quad M(q_1) \bullet \hat{X} = 0, \quad M(q_2) \bullet \hat{X} = 0.$$

Let $r := \operatorname{rank}(\hat{X})$. Obviously, $r > 0$ since $I_{00} \bullet \hat{X} = 1$, and if $r = 1$, then the theorem is already true. Therefore, we need only to consider the nontrivial case $r \geq 3$. By Theorem 3.4, there is a rank-one decomposition of $\hat{X}$ satisfying

$$\begin{aligned} &X = x_1x_1^T + x_2x_2^T + \cdots + x_rx_r^T \\ &M(q_1) \bullet x_ix_i^T = 0, \text{ for } i = 1, \ldots, r \\ &M(q_2) \bullet x_ix_i^T = 0, \text{ for } i = 1, \ldots, r-2. \end{aligned}$$

Thus $x_1x_1^T/t_1^2$ satisfies the complementary conditions hence optimal to $(SP)_2$. This implies that x_1/t_1 is a homogenized optimal solution to (QP), where t_1 denotes the first element of x_1, which must be nonzero because $M(q_1) \bullet x_1x_1^T = 0$, $x_1 \neq 0$, and $Q_1 \succ 0$.

Part 1.3. $\hat{y}_1\hat{y}_2 \neq 0$ and $\operatorname{rank}(\hat{X}) = 2$, and $M(q_2) \bullet \hat{x}_1\hat{x}_1^T = M(q_2) \bullet \hat{x}_2\hat{x}_2^T = 0$.

In this case, both $\hat{x}_1\hat{x}_1^T/\hat{t}_1^2$ and $\hat{x}_2\hat{x}_2^T/\hat{t}_2^2$ are optimal to $(SP)_2$. Thus both $\hat{x}_1/\hat{t}_1$ and $\hat{x}_2/\hat{t}_2$ are optimal solutions for $(QP)_2$, where $\hat{t}_1$ and $\hat{t}_2$ are the first elements of $\hat{x}_1$ and $\hat{x}_2$, respectively, which are both nonzero as argued before.

Part 1.4. $\hat{y}_1\hat{y}_2 \neq 0$ and $\operatorname{rank}(\hat{X}) = 2$, $\left(M(q_2) \bullet \hat{x}_1\hat{x}_1^T\right)\left(M(q_2) \bullet \hat{x}_2\hat{x}_2^T\right) < 0$, and $\operatorname{rank}(\hat{Z}) \neq n - 1$.

Since $\operatorname{rank}(\hat{Z})+\operatorname{rank}(\hat{X}) \le n+1$ and $\operatorname{rank}(\hat{X}) = 2$, it follows that $\operatorname{rank}(\hat{Z}) \le n-1$, and therefore, in this particular case, $\operatorname{rank}(\hat{Z}) < n-1$. Now $\hat{X}+\hat{Z}$ is singular and both $\hat{X}$ and $\hat{Z}$ are positive semidefinite, so there must be a nontrivial y in the intersection of the null spaces of $\hat{X}$ and $\hat{Z}$. Let

$$X := \hat{X} + yy^T = \hat{x}_1\hat{x}_1^T + \hat{x}_2\hat{x}_2^T + yy^T.$$

Obviously, $\operatorname{rank}(X) = 3$ and $\hat{Z}X = 0$. Since

$$M(q_1) \bullet \hat{x}_1\hat{x}_1^T = M(q_1) \bullet \hat{x}_1\hat{x}_1^T = 0, \tag{4.1}$$

$$(M(q_2) \bullet \hat{x}_1\hat{x}_1^T)(M(q_2) \bullet \hat{x}_1\hat{x}_1^T) < 0. \tag{4.2}$$

By applying Lemma 3.3, we obtain x such that X is rank-one decomposable at x and that

$$M(q_1) \bullet xx^T = 0, \quad M(q_2) \bullet xx^T = 0.$$

Since x is in the range space of X, it must be in the null space of $\hat{Z}$. That is, $\hat{Z} \bullet xx^T = 0$, implying that xx^T/t^2 is an optimal solution to $(SP)_2$ and x/t is an optimal solution to $(QP)_2$, where t is the first component of x (which must be nonzero as argued before).

This concludes *Part* 1.

Next we proceed to *Part* 2, in which we shall prove that if Property $\mathcal{I}$ holds, then there is definitely a gap between $(QP)_2$ and $(SP)_2$, i.e., $v((SP)_2) < v((QP)_2)$. To see why this is true, we use a contradiction argument. Suppose that Property $\mathcal{I}$ holds, while $v((SP)_2) = v((QP)_2)$. Let x^* be an optimal solution of $(QP)_2$ (we extend the dimension of x^* to be $(n+1)$-dimensional by putting 1 in the first component). Then, since $v((SP)_2) = v((QP)_2)$, $x^*(x^*)^T$ must be an optimal solution to $(SP)_2$. Consequently, $x^*(x^*)^T$ and $(\hat{Z}, \hat{y}_0, \hat{y}_1, \hat{y}_2)$ must satisfy the complementarity condition; i.e.,

$$\hat{Z}x^*(x^*)^T = 0, \quad M(q_1) \bullet x^*(x^*)^T = 0, \quad M(q_2) \bullet x^*(x^*)^T = 0. \tag{4.3}$$

This implies that x^* must be in the null space of $\hat{Z}$, which is two-dimensional in this case. In other words, it must be a linear combination of $\hat{x}_1$ and $\hat{x}_2$. Let us assume that there are two numbers α and β such that

$$x^* = \alpha\hat{x}_1 + \beta\hat{x}_2. \tag{4.4}$$

Substituting (4.4) into the equations $M(q_1) \bullet x^*(x^*)^T = 0$ and $M(q_2) \bullet x^*(x^*)^T = 0$ and noting (4.1) and (4.2), we obtain

$$\alpha\beta\hat{x}_1^T M(q_1)\hat{x}_2 = 0, \tag{4.5}$$

$$\alpha^2 M(q_2) \bullet \hat{x}_1\hat{x}_1^T + 2\alpha\beta M(q_2) \bullet \hat{x}_1\hat{x}_2^T + \beta^2 M(q_2) \bullet \hat{x}_2\hat{x}_2^T = 0. \tag{4.6}$$

Due to (4.2), neither α nor β can be zero. (For example, if $\alpha = 0$, then by (4.6) and (4.2), it necessarily follows that $\beta = 0$ and vice versa). Thus, from (4.5), it follows that $\hat{x}_1^T M(q_1)\hat{x}_2 = 0$. Let $\hat{x}_1 = (t_1, u^T)^T$ and $\hat{x}_2 = (t_2, v^T)^T$, where $u, v \in \Re^n$. We have $0 = M(q_1) \bullet \hat{x}_1\hat{x}_1^T = t_1^2 - \|u\|^2$ and $0 = M(q_1) \bullet \hat{x}_2\hat{x}_2^T = t_2^2 - \|v\|^2$. Now, $\hat{x}_1^T M(q_1)\hat{x}_2 = 0$ leads to $0 = t_1t_2 - u^Tv$, and so $(u^Tv)^2 = \|u\|^2\|v\|^2$. By the Cauchy–Schwartz inequality, this is only possible when u is a multiple of v. Consequently, $\hat{x}_1$ and $\hat{x}_2$ must be linearly dependent, a contradiction to the fact that $2 = \operatorname{rank}(\hat{X}) = \hat{x}_1\hat{x}_1^T + \hat{x}_2\hat{x}_2^T$. ∎

5. The Lagrangian function and the KKT condition. It is intuitively clear that the Lagrangian function must be related to the SDP relaxation, as Theorem 2.1 has already indicated, primarily due to the fact that the Lagrangian dual of quadratically constrained quadratic program (QP) is identical to the dual of its SDP relaxation. It is, however, useful to translate Property $\mathcal{I}$ using the terms of the Lagrangian function and the KKT conditions explicitly due to its relevance in the nonlinear programming community.

First, let us formally introduce an analog of Property $\mathcal{I}$ in the context of Lagrangian multipliers.

DEFINITION 5.1. *For given Lagrangian multipliers λ and μ for the quadratic program $(QP)_2$, we say that they have Property $\mathcal{I}'$ if*

(1) $\lambda > 0$ *and* $\mu > 0$*;*
(2) $H(\lambda,\mu) = Q_0 + \lambda I + \mu Q_2 \succeq 0$ *and* $\operatorname{rank}(H(\lambda,\mu)) = n-1$*;*
(3) *The system of linear equations $H(\lambda,\mu)x = b_0 + \mu b_2$ has two solutions x_1 and x_2 satisfying $x_i^T x_i = 1$, $i = 1, 2$, and $q_2(x_1)q_2(x_2) < 0$.*

THEOREM 5.2. *Suppose that $(QP)_2$ satisfies the Slater condition. Then, $(QP)_2$ has no strong duality if and only if there exist multipliers λ and μ such that Property $\mathcal{I}'$ holds.*

Proof. The Slater condition for $(QP)_2$ implies $v((SP)_2) = v((SD)_2) = v((QD)_2)$, where $(QD)_2$ denotes the dual problem of $(QP)_2$. Therefore, "$(QP)_2$ has no strong duality" is equivalent to "$v((SP)_2) < v((QP)_2)$." By Theorem 4.2, it is again equivalent to "Property $\mathcal{I}$ holds." What remains to show is that Property $\mathcal{I}$ holds if and only if the above Property $\mathcal{I}'$ holds. To put things in perspective, we restate Property $\mathcal{I}$ as follows: There exist three numbers y_0, λ, μ and two linearly independent $(n+1)$-dimensional vectors $\hat{x}_1 = [t_1, x_1^T]^T$ and $\hat{x}_2 = [t_2, x_2^T]^T$ such that

$$
\begin{cases}
x_1^T x_1 - t_1^2 = x_2^T x_2 - t_2^2 = 0, \\
M(q_2) \bullet \hat{x}_1\hat{x}_1^T + M(q_2) \bullet \hat{x}_2\hat{x}_2^T = 0, \\
(M(q_2) \bullet \hat{x}_1\hat{x}_1^T)(M(q_2) \bullet \hat{x}_2\hat{x}_2^T) < 0, \\
t_1^2 + t_2^2 = 1, \\
(\lambda,\mu) > 0, \\
Z := M(q_0) - y_0 I_{00} + \lambda M(q_1) + \mu M(q_2) \succeq 0, \\
\operatorname{rank}(Z) = n-1, \\
Z\hat{x}_1 = Z\hat{x}_2 = 0.
\end{cases} \tag{5.1}
$$

"Property $\mathcal{I} \Longrightarrow$ Property $\mathcal{I}'$".

First we note that from the sixth equation in (5.1), we may write Z as

$$
Z = \begin{bmatrix} -y_0 + \lambda + \mu c_2 & -b_0^T - \mu b_2^T \\ -b_0 - \mu b_2 & Q_0 + \lambda I + \mu Q_2 \end{bmatrix}. \tag{5.2}
$$

By $x_1^T x_1 - t_1^2 = x_2^T x_2 - t_2^2 = 0$ and the linear independence of $\hat{x}_1$ and $\hat{x}_2$, we have $t_1 t_2 \neq 0$. Let

$$
\bar{x}_1 := x_1/t_1,\ \bar{x}_2 := x_2/t_2.
$$

By (5.1), it immediately follows that $\bar{x}_1$ and $\bar{x}_2$ must satisfy the following:

$$\begin{array}{l}
\|\bar{x}_1\| = \|\bar{x}_2\| = 1, \\
q_2(\bar{x}_1)q_2(\bar{x}_2) < 0, \\
(\lambda, \mu) > 0, \\
Q_0 + \lambda I + \mu Q_2 \succeq 0, \\
(Q_0 + \lambda I + \mu Q_2)\bar{x}_i = b_0 + \mu b_2,\ i = 1, 2, \\
\bar{x}_1, \bar{x}_2 \text{ are linearly indepedent.}
\end{array}$$

It now remains only to check if $\mathrm{rank}(Q_0 + \lambda I + \mu Q_2) = n - 1$. By using $Z\hat{x}_1$=0 and (5.2), we have

$$\left[\begin{array}{c} -y_0 + \lambda + \mu c_2 \\ -b_0 - \mu b_2 \end{array} \right] = - \left[\begin{array}{c} -b_0^T - \mu b_2^T \\ Q_0 + \lambda I + \mu Q_2 \end{array} \right] \bar{x}_1,$$

which implies that

$$\begin{aligned}
n - 1 = \mathrm{rank}(Z) &= \mathrm{rank} \left(\left[\begin{array}{cc} -y_0 + \lambda + \mu c_2 & -b_0^T - \mu b_2^T \\ -b_0 - \mu b_2 & Q_0 + \lambda I + \mu Q_2 \end{array} \right] \right) \\
&= \mathrm{rank} \left(\left[\begin{array}{c} -b_0^T - \mu b_2^T \\ Q_0 + \lambda I + \mu Q_2 \end{array} \right] \right) = \mathrm{rank}(Q_0 + \lambda I + \mu Q_2).
\end{aligned}$$

"Property $\mathcal{I}'$ $\Longrightarrow$ Property $\mathcal{I}$".

Let us assume, without loss of generality, that $q_2(x_1) < 0, q_2(x_2) > 0$, and let us define

$$\begin{array}{l}
y_0 := q_0(x_1) + \lambda q_1(x_1) + \mu q_2(x_1), \\
t_1 := \sqrt{\dfrac{-q_2(x_2)}{q_2(x_1) - q_2(x_2)}}, \\
t_2 := \sqrt{\dfrac{q_2(x_1)}{q_2(x_1) - q_2(x_2)}}, \\
\hat{x}_1 := t_1 \left[\begin{array}{c} 1 \\ x_1 \end{array} \right], \\
\hat{x}_2 := t_2 \left[\begin{array}{c} 1 \\ x_2 \end{array} \right], \\
Z := M(q_0) - y_0 I_{00} + \lambda M(q_1) + \mu M(q_2).
\end{array}$$

Then, it can be straightforwardly checked that

$$\begin{array}{l}
M(q_1) \bullet \hat{x}_1\hat{x}_1^T = M(q_1) \bullet \hat{x}_2\hat{x}_2^T = 0, \\
M(q_2) \bullet \hat{x}_1\hat{x}_1^T + M(q_2) \bullet \hat{x}_2\hat{x}_2^T = 0, \\
M(q_2) \bullet \hat{x}_1\hat{x}_1^T < 0,\ M(q_2) \bullet \hat{x}_2\hat{x}_2^T > 0, \\
t_1^2 + t_2^2 = 1, \\
(\lambda, \mu) > 0.
\end{array}$$

To complete the proof, one needs only to show that $Z \succeq 0$, $Z\hat{x}_1 = Z\hat{x}_2 = 0$, and $\mathrm{rank}(Z) = n - 1$.

Consider the Lagrangian function

$$L(x;\lambda,\mu) := q_0(x) + \lambda q_1(x) + \mu q_2(x),$$

whose Hessian matrix $H(\lambda,\mu) = Q_0 + \lambda I + \mu Q_2$ is semidefinite, due to (2) of Property $\mathcal{I}'$. This implies that $L(x;\lambda,\mu)$ is a convex quadratic function in x. Furthermore, (2) and (3) of Property $\mathcal{I}'$ imply that the minimizers of $L(x;\lambda,\mu)$ consist of all the points on the straight line connecting x_1 and x_2. Consequently,

$$y_0 = L(x_1;\lambda,\mu) = L(x_2;\lambda,\mu) = \min_{x\in\Re^n} L(x;\lambda,\mu).$$

Consider any $(n+1)$-dimensional vector $(t, x^T)^T$, where $t \in \Re^1$ and $x \in \Re^n$. If $t = 0$, then

$$\begin{aligned}\begin{bmatrix} t \\ x \end{bmatrix}^T Z \begin{bmatrix} t \\ x \end{bmatrix} &= \begin{bmatrix} 0 \\ x \end{bmatrix}^T \begin{bmatrix} -y_0 + \lambda + \mu c_2 & -b_0^T - \mu b_2^T \\ -b_0 - \mu b_2 & Q_0 + \lambda I + \mu Q_2 \end{bmatrix} \begin{bmatrix} 0 \\ x \end{bmatrix} \\ &= x^T(Q_0 + \lambda I + \mu Q_2)x \geq 0.\end{aligned}$$

Otherwise, if $t \neq 0$, then

$$\begin{aligned}\begin{bmatrix} t \\ x \end{bmatrix}^T Z \begin{bmatrix} t \\ x \end{bmatrix} &= \begin{bmatrix} t \\ x \end{bmatrix}^T (M(q_0) - y_0 I_{00} + \lambda M(q_1) + \mu M(q_2)) \begin{bmatrix} t \\ x \end{bmatrix} \\ &= t^2 q_0(x/t) - t^2 y_0 + \lambda t^2 q_1(x/t) + \mu t^2 q_2(x/t) = t^2(L(x/t;\lambda,\mu) - y_0) \\ &\geq t^2(L(x_1;\lambda,\mu) - L(x_1;\lambda,\mu)) = 0.\end{aligned}$$

Moreover, $\hat{x}_1^T Z \hat{x}_1 = t_1^2(L(x_1;\lambda,\mu) - y_0) = 0$ and $\hat{x}_2^T Z \hat{x}_2 = t_2^2(L(x_2;\lambda,\mu) - y_0) = t_2^2(L(x_2;\lambda,\mu) - L(x_1;\lambda,\mu)) = 0$. Therefore, $Z\hat{x}_1 = 0$ and $Z\hat{x}_2 = 0$ because $Z \succeq 0$. Since $\hat{x}_1$ and $\hat{x}_2$ are linearly independent, it follows that $\operatorname{rank}(Z) \leq n-1$. On the other hand, $\operatorname{rank}(Z) \geq \operatorname{rank}(H(\lambda,\mu)) = n-1$, leading to $\operatorname{rank}(Z) = n-1$. □

Property $\mathcal{I}'$ is closely related to Property $\mathcal{J}$ studied in Chen and Yuan [5] for the CDT subproblem. Since Chen and Yuan [5] considered the CDT subproblem, they considered problem $(QP)_2$ with an additional condition that $Q_2 \succeq 0$. To put things in perspective, their Property $\mathcal{J}$ can be stated as follows.

DEFINITION 5.3. *For given Lagrangian multipliers λ and μ for the quadratic program $(QP)_2$, we say that they have Property $\mathcal{J}$ if*

(1) *$\lambda > 0$ and $\mu > 0$;*
(2) *$H(\lambda,\mu) = Q_0 + \lambda I + \mu Q_2 \succeq 0$ and $\operatorname{rank}(H(\lambda,\mu)) = n-1$;*
(3) *The following "surrogate" problem*

$$(P)_{\frac{\lambda}{\lambda+\mu}} \quad \begin{aligned} &\textit{minimize} && q_0(x) \\ &\textit{subject to} && \frac{\lambda}{\lambda+\mu} q_1(x) + \frac{\mu}{\lambda+\mu} q_2(x) \leq 0 \end{aligned}$$

has two solutions x_1 and x_2 satisfying

$$H(\lambda,\mu)x = b_0 + \mu b_2,$$

and $x_1^T x_1 < 1$ and $x_2^T x_2 > 1$.

The above Property $\mathcal{J}$ (see [5]) is based on the idea of surrogate representation of the constraints, hence different from ours. Moreover, Chen and Yuan in (see [5]) proved just only that if $(QP)_2$ with $Q_2 \succeq 0$ has no strong duality, then Property $\mathcal{J}$

holds, in other words, the converse proposition cannot be proved so far. However, the appearances of Property $\mathcal{J}$ and Property $\mathcal{I}'$ are quite similar indeed. Despite the similar appearances, below we shall show that they are not identical in all circumstances. Before our discussion, we shall first remark that the existence of multipliers satisfying Property $\mathcal{J}$ cannot be directly verified, while Property $\mathcal{I}$ can be checked in polynomial-time by solving a pair of SDP problems.

PROPOSITION 5.4. *If $Q_2 \succeq 0$, then Property $\mathcal{J}$ is equivalent to Property $\mathcal{I}'$. If $Q_2 \not\succeq 0$, then Property $\mathcal{J}$ is not identical to Property $\mathcal{I}'$, the latter being a necessary and sufficient condition for $(QP)_2$ to admit a gap with its SDP relaxation.*

Proof. First consider the situation when $Q_2 \succeq 0$. We shall prove in this case that Property $\mathcal{J}$ leads to Property $\mathcal{I}'$.

Restricting the quadratic function $\frac{\lambda}{\lambda+\mu}q_1(x) + \frac{\mu}{\lambda+\mu}q_2(x)$ on the line connecting x_1 and x_2, we obtain a univariate function

$$g(t) := \frac{\lambda}{\lambda+\mu}q_1((1-t)x_1 + tx_2) + \frac{\mu}{\lambda+\mu}q_2((1-t)x_1 + tx_2), \quad t \in \Re.$$

Since $\frac{\lambda}{\lambda+\mu}q_1(x) + \frac{\mu}{\lambda+\mu}q_2(x)$ is strictly convex and quadratic, we have

$$g(t) \begin{cases} = 0, & \text{if } t = 0 \text{ and } 1; \\ < 0, & \text{if } 0 < t < 1; \\ > 0, & \text{else.} \end{cases} \tag{5.3}$$

Similarly, $h(t) := q_1((1-t)x_1 + tx_2) = \|(1-t)x_1 + tx_2\|^2$ is also a strictly convex quadratic function of t. Therefore, $h(0) < 0$ and $h(1) > 0$ lead to the existence of two numbers $t_1 \in (-\infty, 0)$ and $t_2 \in (0, 1)$ such that $h(t_1) = h(t_2) = 0$. Denote $x_3 = (1-t_1)x_1 + t_1x_2$ and $x_4 = (1-t_2)x_1 + t_2x_2$. Based on (5.3), we have

$$q_1(x_3) = q_1(x_4) = 0, q_2(x_3) > 0, q_2(x_4) < 0,$$

which means that Property $\mathcal{I}'$ holds.

Now consider the case where $Q_2 \not\succeq 0$. We shall prove our assertion by the following example:

$$\begin{aligned} \text{minimize} \quad & q_0(x) = x_1^2 - 3x_1 \\ \text{subject to} \quad & q_1(x) = x_1^2 + x_2^2 - 1 \le 0, \\ & q_2(x) = -x_1^2 - x_2^2 + 2x_1 \le 0, \end{aligned}$$

where $x = (x_1, x_2)^T$. It is easy to see that the two circles $q_1(x) = 0$ and $q_2(x) = 0$ intersect at two points: P_1 with coordinates $(\frac{1}{2}, \frac{\sqrt{3}}{2})$ and P_2 with coordinates $(\frac{1}{2}, -\frac{\sqrt{3}}{2})$. It is easy to see that P_1 and P_2 are two unique optimal solutions for this problem, for which the corresponding multipliers are $\lambda = \mu = 1$, with the corresponding Hessian matrix of the Lagrangian function being

$$H(\lambda, \mu) = Q_0 + \lambda Q_1 + \mu Q_2 = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix},$$

which is positive semidefinite with rank $n-1$ ($n = 2$). So, this problem has optimal solutions with positive semidefinite Lagrangian Hessian matrices. The KKT points satisfy

$$\begin{cases} 1x_1 = \frac{1}{2}, \\ 0x_2 = 0, \end{cases}$$

which lie on the line connecting P_1 and P_2. In this case, however, by Theorem 5.2 we know that Property $\mathcal{I}'$ is violated. We shall see below that Property $\mathcal{J}$ still holds nevertheless. Choose, for instance, $x^{(1)} = (\frac{1}{2}, 0)^T$, $x^{(2)} = (\frac{1}{2}, 1)^T$, and $\lambda = \mu = 1$. We have $\frac{\lambda}{\lambda+\mu} q_1(x) + \frac{\mu}{\lambda+\mu} q_2(x) = 0$ for $x = x^{(1)}$ and $x = x^{(2)}$, and $\|x^{(1)}\| < 1$ and $\|x^{(2)}\| > 1$. After checking the conditions, we see that Property $\mathcal{J}$ is indeed satisfied in this case; however, Property $\mathcal{I}'$ is violated as we have observed. ∎

Another related result is due to Beck and Eldar [1]. Their approach is based on a comparison between the real and the complex valued SDP relaxations. They showed that if the dimension of the null space of $H(\lambda, \mu)$ is not equal to 1, or equivalently, $\operatorname{rank}(H(\lambda, \mu)) \neq n-1$, then the SDP relaxation is tight. In the context of Theorem 5.2, this is clear, since this sufficient condition guarantees that Property $\mathcal{I}'$ does not hold, and hence the SDP relaxation must be tight.

Since, in Property $\mathcal{I}'$ of Theorem 5.2, the constraint $q_2(x) \leq 0$ plays a role only in the last part, the following corollary is immediate.

Consider

$$\begin{array}{lll} (Q(\rho))_2 & \text{minimize} & q_0(x) = x^T Q_0 x - 2b_0^T x \\ & \text{subject to} & q_1(x) = x^T x - 1 \leq 0 \\ & & q_2(x) - \rho \leq 0, \end{array}$$

where ρ is a parameter.

COROLLARY 5.5. *Suppose that Property $\mathcal{I}'$ holds for $(QP)_2$ with x_1 and x_2 being the two solutions in* (3) *of Property $\mathcal{I}'$ satisfying $q_2(x_1) < 0 < q_2(x_2)$. Then for any $\rho \in (q_2(x_1), q_2(x_2))$, problem $(Q(\rho))_2$ will not have a positive semidefinite Hessian for its Lagrangian function at any optimal solution.*

6. The optimal line of the dual problem. As shown in the previous sections, if Property $\mathcal{I}'$ holds for a CDT subproblem, then there exists a gap between the optimal values of the primal and the dual problems. In the case of Property $\mathcal{I}'$, we obtain two dual optimal solutions x_1 and x_2, one of which is feasible for the primal problem, say, x_1. It can be easily proved that each point of the entire line connecting x_1 and x_2 is also an optimal solution to the dual problem. Let us call this line *the optimal line of the dual problem*. Naturally, we may wish to minimize the original quadratic function along this line to obtain a better approximate solution than x_1 for the primal problem. It is tempting to conjecture that this will always lead to an improvement. However, below we shall give an example to show that this approach may not yield a solution with any quality assurance.

Example 6.1.

$$\begin{array}{ll} \text{minimize} & q_0(x_1, x_2) = x_1(p - x_1) \\ \text{subject to} & q_1(x_1, x_2) = x_1^2 + x_2^2 \leq \dfrac{17}{16} p^2, \\ & q_2(x_1, x_2) = (x_1 - 2p)^2 + (x_2 - p)^2 \leq \dfrac{73}{16} p^2, \end{array}$$

where p is a positive parameter. The global optimal solution for this problem is $x^* \approx \begin{bmatrix} -0.1359p \\ 1.0218p \end{bmatrix}$, which is one of two intersection points of the circles $q_1(x_1, x_2) = 0$ and $q_2(x_1, x_2) = 0$, and the corresponding optimal value is $v^* \approx -0.1544p^2$. The system $(Q_0 + \lambda Q_1 + \mu Q_2)x = b_0 + \mu b_2$ is in this case

$$\begin{aligned} (-2 + 2\lambda + 2\mu)x_1 &= (4\mu - 1)p \\ (2\lambda + 2\mu)x_2 &= 2\mu p. \end{aligned}$$

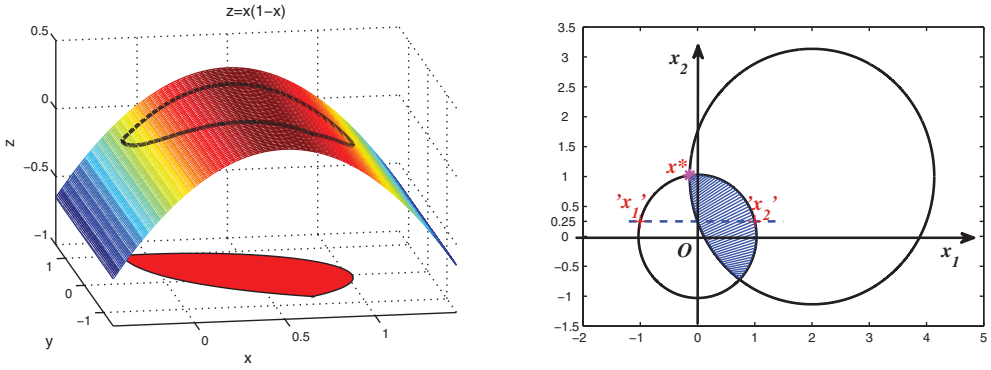

FIG. 6.1. *The graph of* $z = x_1(1 - x_1)$ *(on the left) and the feasible domain (on the right) at* $p = 1$.

One easily verifies that Property $\mathcal{I}'$ holds at $(\lambda, \mu) = (0.75, 0.25)$, and the solutions "$x_1$" and "$x_2$" in (3) of Property $\mathcal{I}'$ are $\begin{bmatrix} p \\ 0.25p \end{bmatrix}$ and $\begin{bmatrix} -p \\ 0.25p \end{bmatrix}$, respectively (see Figure 6.1). The optimal value of the SDP relaxation $(SP)_2$ is $y_0 = -0.75p^2$, and the gap between y_0 and v^* is $v^* - y_0 \approx 0.5926p^2$. The line segment that connects "x_1" and "x_2" and is contained in the feasible domain can be expressed by

$$\left\{ \begin{bmatrix} tp \\ 0.25p \end{bmatrix} \,\middle|\, 0 \le t \le 1 \right\}.$$

On this line segment, the optimal value of $q_0(x_1, x_2)$ is identically 0 for any p, which can be attained at the point "x_2." This shows that there cannot be any bound, in neither absolute nor relative sense of error measurements, regarding the quality of the solution obtained by the heuristic method of searching along the line segment. It remains to be a challenge to solve $(QP)_2$ efficiently, if, after solving its SDP relaxation, it turns out that Property $\mathcal{I}$ indeed holds, although numerical experiments in [1] suggest that this is highly unlikely for randomly generated instances.

7. Testing Property $\mathcal{I}$ numerically. In its direct form, Property $\mathcal{I}$ requires the knowledge of an exact solution for the SDP relaxation. As is well known, in general, it is impossible to solve an SDP problem exactly. It is therefore natural to test its predictive power if one uses the necessary and sufficient condition involving Property $\mathcal{I}$ in an approximative sense. In other words, if we use an ε_1-approximation solution of the SDP relaxation, then a similarly relaxed Property $\mathcal{I}$ can be verified, leading to the conclusion whether or not the original CDT subproblem satisfies the strong duality within an ε_2 error tolerance. The question is, How does the approximation work in practice?

First, we need to relax the requirement on the optimal solution. Applying an SDP solver (such as SeDuMi) to solve the SDP relaxation will return with a solution $\bar{X} \succeq 0$ and a dual solution $(\bar{Z}, \bar{y}_0, \bar{y}_1, \bar{y}_2)$, with $\bar{Z} \succeq 0$. Of course, these solutions might, however, violate the equality and inequality constraints of the primal-dual feasibility requirements, say, by an amount no more than ε_1. Then, to purify the ranks of $\bar{X}$ and $\bar{Z}$, we may operate a spectral decomposition on $\bar{X}$ and $\bar{Z}$: $\bar{X} = Q_1^T \Lambda_1 Q_1$ and $\bar{Z} = Q_2^T \Lambda_2 Q_2$, where Q_i is orthonormal and $\Lambda_i = \mathrm{diag}(\lambda_{i1}, \ldots, \lambda_{in})$, with $\lambda_{ij} \ge 0$,

$j = 1, \ldots, n$, $i = 1, 2$. Introduce

$$\hat{\lambda}_{ij} := \begin{cases} \lambda_{ij}, & \text{if } \lambda_{ij} \geq \varepsilon_2, \\ 0, & \text{if } \lambda_{ij} < \varepsilon_2, \end{cases}$$

for $j = 1, \ldots, n$, $i = 1, 2$, and let us purify the solutions by using

$$\hat{X} := Q_1^T \mathrm{diag}(\hat{\lambda}_{11}, \ldots, \hat{\lambda}_{1n}) Q_1 \text{ and } \hat{Z} := Q_2^T \mathrm{diag}(\hat{\lambda}_{21}, \ldots, \hat{\lambda}_{2n}) Q_2$$

instead of $\bar{X}$ and $\bar{Z}$, while keeping $\hat{y}_i := \bar{y}_i$, $i = 0, 1, 2$. We call $\hat{X}$ and $(\hat{Z}, \hat{y}_0, \hat{y}_1, \hat{y}_2)$ to be *a pair of purified* $(\varepsilon_1, \varepsilon_2)$*-approximate optimal solutions.*

DEFINITION 7.1. *Suppose that* $\hat{X}$ *and* $(\hat{Z}, \hat{y}_0, \hat{y}_1, \hat{y}_2)$ *are a pair of purified* $(\varepsilon_1, \varepsilon_2)$*-approximate optimal solutions for* $(SP)_2$ *and* $(SD)_2$*, respectively. We say this pair has Property* $\mathcal{I}(\varepsilon_2)$ *if*

(1) $\hat{y}_1 > \varepsilon_2$ *and* $\hat{y}_2 > \varepsilon_2$*;*
(2) $\mathrm{rank}(\hat{Z}) = n - 1$*;*
(3) $\mathrm{rank}(\hat{X}) = 2$*, and there is a rank-one decomposition of* $\hat{X}$*,* $\hat{X} = \hat{x}_1 \hat{x}_1^T + \hat{x}_2 \hat{x}_2^T$*, such that* $M(q_1) \bullet \hat{x}_i \hat{x}_i^T = M(q_1) \bullet \hat{X}/2$*,* $i = 1, 2$*, and* $M(q_2) \bullet \hat{x}_1 \hat{x}_1^T < -\varepsilon_2$ *and* $M(q_2) \bullet \hat{x}_2 \hat{x}_2^T > \varepsilon_2$*.*

Below we shall introduce a polynomial-time procedure to test the strong duality for the CDT problem, based on the ε_1-optimal SDP relaxation solution Property $\mathcal{I}(\varepsilon_2)$ and the matrix decomposition technique.

ALGORITHM 7.2. *Input* ε_2*,* $M(q_0)$*,* $M(q_1)$*, and* $M(q_2)$*.*

Step 1. *Let* $\hat{X}$ *and* $(\hat{Z}, \hat{y}_0, \hat{y}_1, \hat{y}_2)$ *be the purified* $(\varepsilon_1, \varepsilon_2)$*-approximate solutions for* $(SP)_2$ *and its dual.*

Step 2. *Test whether or not Property* $\mathcal{I}(\varepsilon_2)$ *is satisfied by checking Definition* 7.1*, which runs in polynomial-time.*

Step 3. *If Property* $\mathcal{I}(\varepsilon_2)$ *is violated, then use the matrix decomposition technique presented in the previous sections to obtain an approximate solution to the original CDT problem; otherwise, get an approximate solution by searching along the optimal line of the dual problem.*

We now use SeDuMi to test this procedure by numerical simulations. Throughout our tests, we let $\varepsilon_2 = 10^{-4}$ and ε_1 be set as the default precision of SeDuMi. For a given positive integer n, our MATLAB code would generate two $(n+1) \times (n+1)$ matrices $M(q_0)$ and $M(q_2)$, of which the upper triangular part (including diagonal) of the entries are uniformly generated random numbers on the interval $[-50, 50]$ (the lower part takes the values by symmetry). In order to guarantee that $(SP)_2$ have an interior feasible solution, we first solve

$$\begin{array}{ll} \text{minimize} & M(q_2) \bullet X \\ \text{subject to} & M(q_1) \bullet X \leq 0, \\ & I_{00} \bullet X = 1, \\ & X \succeq 0. \end{array}$$

Let f^* denote its optimal value. If $f^* > -10^{-4}$, we decrease the first entry (the (1,1)th position) of $M(q_2)$ by the amount $f^* + 10^{-4}$. This ensures that the Slater condition is satisfied. We apply Algorithm 7.2 on 90 randomly generated instances. The numerical results are summarized in Tables 1, 2, and 3, where "n" denotes the dimension of the CDT problem, "Value 1" is equal to $M(q_0) \bullet \bar{X}$, i.e., the ε_1-optimal value of the SDP relaxation solution returned by SeDuMi, "Value 2" denotes the objective value of the feasible solution for the CDT problem generated by Algorithm 7.2, and "Gap"

indicates the difference between "Value 1" and "Value 2" (Gap = Value 2 − Value 1), which reflects the eventual performance of Algorithm 7.2. Finally, "Rank" indicates the rank of $\hat{X}$, and at the column "$\mathcal{I}(\varepsilon_2)$," the symbol "V" denotes that Property $\mathcal{I}(\varepsilon_2)$ is *violated* and "H" signifies that Property $\mathcal{I}(\epsilon_2)$ *holds*.

Among 90 runs summarized in Tables 1 through 3, there are 87 instances violating Property $\mathcal{I}(\varepsilon_2)$ and only 3 cases holding Property $\mathcal{I}(\varepsilon_2)$. For all these 87 instances, the gaps between "Value 1" and "Value 2" are far less than the tolerance ε_2, which show that Algorithm 7.2 is indeed effective. Furthermore, the rank of the purified solution $\hat{X}$ for the 87 instances are all actually one, meaning that the eigenvector of $\hat{X}$ is the approximate optimal solution for the original CDT problem. We also made a test for two different values of the dimension: $n = 5$ and $n = 50$. Tables 2 and 3 show that it is less likely for Property $\mathcal{I}(\varepsilon_2)$ to hold for the larger n.

APPROXIMATE PRIMAL SOLUTIONS AND RATE ANALYSIS FOR DUAL SUBGRADIENT METHODS*

ANGELIA NEDIĆ† AND ASUMAN OZDAGLAR‡

Abstract. In this paper, we study methods for generating approximate primal solutions as a byproduct of subgradient methods applied to the Lagrangian dual of a primal convex (possibly nondifferentiable) constrained optimization problem. Our work is motivated by constrained primal problems with a favorable dual problem structure that leads to efficient implementation of dual subgradient methods, such as the recent resource allocation problems in large-scale networks. For such problems, we propose and analyze dual subgradient methods that use averaging schemes to generate approximate primal optimal solutions. These algorithms use a constant stepsize in view of its simplicity and practical significance. We provide estimates on the primal infeasibility and primal suboptimality of the generated approximate primal solutions. These estimates are given per iteration, thus providing a basis for analyzing the trade-offs between the desired level of error and the selection of the stepsize value. Our analysis relies on the Slater condition and the inherited boundedness properties of the dual problem under this condition. It also relies on the boundedness of subgradients, which is ensured by assuming the compactness of the constraint set.

Key words. subgradient methods, averaging, approximate primal solutions, convergence rate estimates

1. Introduction.

Lagrangian relaxation and duality have been effective tools for solving large-scale convex optimization problems and for systematically providing lower bounds on the optimal value of nonconvex (continuous and discrete) optimization problems. Subgradient methods have played a key role in this framework providing computationally efficient means to obtain near-optimal dual solutions and bounds on the optimal value of the original optimization problem. Most remarkably, in networking applications, over the last few years, subgradient methods have been used with great success in developing decentralized cross-layer resource allocation mechanisms (see Low and Lapsley [18], Shakkottai and Srikant [30], and Srikant [33] for more on this subject).

Subgradient methods for solving nondifferentiable problems have been studied extensively starting with Polyak [26] and Ermoliev [9]. Their convergence properties under various stepsize rules have been established, for example, in Shor [32], Demyanov and Vasilyev [8], Polyak [27], Hiriart-Urruty and Lemaréchal [10], Bertsekas [4], and Bertsekas, Nedić, and Ozdaglar [5]. Nonasymptotic convergence rate estimates have been provided in the seminal work of Nemirovskii and Yudin [23], [24], and more recently in Ben-Tal, Margalit, and Nemirovski [2], Ben-Tal and Nemirovski [3], and Nesterov [25]. Numerous extensions and implementations including parallel and incremental versions have been proposed and analyzed (for example, see Ben-Tal, Margalit, and Nemirovski [2], Ben-Tal and Nemirovski [3], Kiwiel and Lindberg [13],

Zhao, Luh, and Wang [35], Nedić and Bertsekas [20], [21], and Nedić, Bertsekas, and Borkar [22]).

Our development in this paper is motivated by problems with a favorable dual structure, so that solving the problem using dual subgradient methods leads to efficient implementations.[1] For such problems, we develop methods that exploit the subgradient information generated in the dual space directly to construct approximate primal solutions with explicit error estimates. Our methods use an *averaging scheme* that constructs primal solutions by forming running averages of the primal iterates generated when evaluating the subgradient of the dual function. We provide convergence rate estimates for the infeasibility and error estimates on suboptimality of the generated approximate primal solutions.

Averaging schemes for generating primal solutions have been studied in a number of earlier works. Primal-averaging was first proposed and analyzed within a primal-dual subgradient method by Nemirovskii and Yudin [23]. Subsequently, a related primal-averaging scheme based on subgradient information generated by a dual subgradient method has been proposed for linear (primal) optimization problems by Shor [32] and applied to a scheduling problem by Zhurbenko et al. [36]. Shor's ideas have been further developed and computationally tested by Larsson and Liu [14]. Sherali and Choi [31] have extended these results to allow for more general averaging schemes (i.e., more general choices of the weights for convex combinations) and a wider class of stepsize choices. More recently, Larsson, Patriksson, and Strömberg generalized these results in a series of papers (see [15], [16], [17]) to convex constrained optimization problems and demonstrated promising applications of these schemes in the context of traffic equilibrium and road pricing. Sen and Sherali [29] have studied a more complex scheme combining a subgradient method and an auxiliary penalty problem to recover primal solutions. A dual subgradient method producing primal solutions, the volume algorithm, for linear problems has been proposed by Barahona and Anbil [1]. They have reported experimental results for several problems including set partitioning, set covering, and max-cut, but have not analyzed the convergence properties of the algorithm. Kiwiel, Larsson, and Lindberg [12] have studied the convergence of primal-averaging in dual subgradient methods using a target-level based stepsize. Recently, Nesterov [25] has proposed a subgradient algorithm using averaging and provided convergence rate estimates assuming the availability of a bound on the Euclidean norm of an optimal solution. Nesterov's algorithm generates a solution to a convex minimization problem, and it is not a primal-recovery scheme. More recently, Ruszczyński [28] has proposed a new subgradient method that uses averaging to identify both an optimal solution of a convex minimization problem and a subgradient that appears in the optimality condition.

Among the papers cited above, our work is most closely related to the primal-recovery algorithms of Shor [32], Sherali and Choi [31], Larsson, Patriksson, and Strömberg [15], [16], [17], and Kiwiel, Larsson, and Lindberg [12]. The focus of these works is on exact recovery methods for primal solutions and the convergence properties for diminishing stepsize rules (with divergent sum).[2] In contrast, our focus in this paper is on methods generating approximate primal solutions for general

[1] Section 2.2 illustrates a motivating example of a network resource allocation problem, where the use of dual subgradient methods leads to *decentralized resource allocation policies* for communication networks.

[2] The exception is the paper [12], where a target-level based stepsize (i.e., a modification of Polyak's stepsize [26]) has been considered.

(possibly nondifferentiable) convex constrained optimization problems and providing convergence rate guarantees. We consider subgradient methods that use a constant stepsize, mainly because of its practical importance and simplicity for implementations. We provide convergence rate estimates for the approximate solutions under the Slater constraint qualification, including estimates for the amount of feasibility violation, and upper and lower bounds for the primal objective function. Moreover, our estimates are per iteration and illustrate the trade-offs between the approximate solution error and the stepsize value.

This paper is organized as follows: In section 2, we define the primal and dual problems, and provide an explicit bound on the level sets of the dual function under Slater condition. In section 3, we consider a subgradient method with a constant stepsize and study its properties under Slater. In section 4, we introduce approximate primal solutions generated through averaging and provide bounds on their feasibility violation and primal cost values. In section 5, we consider an alternative to the basic subgradient method based on the boundedness properties of the dual optimal solution set under the Slater condition, and we provide error estimates for the generated approximate primal solutions. We conclude in section 6 by summarizing our work and providing some comments.

2. Primal and dual problems. In this section, we formulate the primal and dual problems of interest. We provide a motivating example for the use of dual subgradient methods and give some preliminary results that we use in the subsequent development. We start by introducing the notation and the basic terminology that we use throughout this paper.

2.1. Notation and terminology. We consider the n-dimensional vector space $\mathbb{R}^n$ and the m-dimensional vector space $\mathbb{R}^m$. We view a vector as a column vector, and we denote by $x'y$ the inner product of two vectors x and y. We use $\|y\|$ to denote the standard Euclidean norm, $\|y\| = \sqrt{y'y}$. Occasionally, we also use the standard 1-norm and ∞-norm denoted, respectively, by $\|y\|_1$ and $\|y\|_\infty$, i.e., $\|y\|_1 = \sum_i |y_i|$ and $\|y\|_\infty = \max_i |y_i|$. We write $dist(\bar{y}, Y)$ to denote the standard Euclidean distance of a vector $\bar{y}$ from a set Y, i.e.,

$$dist(\bar{y}, Y) = \inf_{y \in Y} \|\bar{y} - y\|.$$

For a vector $u \in \mathbb{R}^m$, we write u^+ to denote the projection of u on the nonnegative orthant in $\mathbb{R}^m$; i.e., u^+ is the componentwise maximum of the vector u and the zero vector:

$$u^+ = (\max\{0, u_1\}, \ldots, \max\{0, u_m\})' \quad \text{for } u = (u_1, \ldots, u_m)'.$$

For a concave function $q : \mathbb{R}^m \to [-\infty, \infty]$, we denote the domain of q by $\mathrm{dom}(q)$, where

$$\mathrm{dom}(q) = \{\mu \in \mathbb{R}^m \mid q(\mu) > -\infty\}.$$

We use the notion of a subgradient of a concave function $q(\mu)$. In particular, a subgradient $s_{\bar{\mu}}$ of a concave function $q(\mu)$ at a given vector $\bar{\mu} \in \mathrm{dom}(q)$ provides a linear overestimate of the function $q(\mu)$ for all $\mu \in \mathrm{dom}(q)$. We use this as the subgradient defining property: *$s_{\bar{\mu}} \in \mathbb{R}^m$ is a subgradient of a concave function $q(\mu)$ at a given vector $\bar{\mu} \in \mathrm{dom}(q)$* if the following relation holds:

$$q(\bar{\mu}) + s'_{\bar{\mu}}(\mu - \bar{\mu}) \geq q(\mu) \qquad \text{for all } \mu \in \mathrm{dom}(q). \tag{1}$$

The set of all subgradients of q at $\bar{\mu}$ is denoted by $\partial q(\bar{\mu})$.

In this paper, we focus on the following constrained optimization problem:

$$\begin{aligned} &\text{minimize} && f(x) \\ &\text{subject to} && g(x) \leq 0, \\ &&& x \in X, \end{aligned} \tag{2}$$

where $f : \mathbb{R}^n \to \mathbb{R}$ is a convex function, $g = (g_1, \ldots, g_m)'$ and each $g_j : \mathbb{R}^n \to \mathbb{R}$ is a convex function, and $X \subset \mathbb{R}^n$ is a nonempty closed convex set. We refer to this as the *primal problem*. We denote the primal optimal value by f^*, and throughout this paper, we assume that the value f^* is finite.

To generate approximate solutions to the primal problem in (2), we consider solving its dual using subgradient methods. Here, the *dual problem* is the one arising from the Lagrangian relaxation of the inequality constraints $g(x) \leq 0$, and it is given by

$$\begin{aligned} &\text{maximize} && q(\mu) \\ &\text{subject to} && \mu \geq 0, \\ &&& \mu \in \mathbb{R}^m, \end{aligned} \tag{3}$$

where q is the dual function defined by

$$q(\mu) = \inf_{x \in X} \{f(x) + \mu' g(x)\}. \tag{4}$$

We often refer to a vector $\mu \in \mathbb{R}^m$ with $\mu \geq 0$ as a *multiplier*. We denote the dual optimal value by q^* and the dual optimal set by M^*. We say that there is *zero duality gap* if the optimal values of the primal and the dual problems are equal, i.e., $f^* = q^*$.

We assume that the minimization problem associated with the evaluation of the dual function $q(\mu)$ has a solution for every $\mu \geq 0$. This is the case, for instance, when the set X is compact (since f and $g_j's$ are continuous due to being convex over $\mathbb{R}^n$). Furthermore, we assume that the minimization problem in (4) is simple enough so that it either has a closed form solution or can be solved efficiently. For example, this is the case when the functions f and g_j's are affine or affine plus norm-square term (i.e., $c\|x\|^2 + a'x + b$), and the set X is a nonnegative orthant or a box in $\mathbb{R}^n$. Many practical problems of interest, such as those arising in network optimization (see section 2.2), often have this structure.

In our subsequent development, we consider subgradient methods as applied to the dual problem given by (3) and (4). Due to the form of the dual function q, the subgradients of q at a vector μ are related to the primal vectors x_μ attaining the minimum in (4). Specifically, the set $\partial q(\mu)$ of subgradients of q at a given $\mu \geq 0$ is given by

$$\partial q(\mu) = \operatorname{conv}\left(\{g(x_\mu) \mid x_\mu \in X_\mu\}\right), \qquad X_\mu = \{x_\mu \in X \mid q(\mu) = f(x_\mu) + \mu' g(x_\mu)\}, \tag{5}$$

where $\operatorname{conv}(Y)$ denotes the convex hull of a set Y.

Before proceeding with our analysis, we discuss an example that motivates the subsequent development of dual subgradient methods.

2.2. Motivating example. Here, we describe the canonical utility-based network resource allocation problem and briefly discuss how dual subgradient methods lead to decentralized policies that can be used over a network. This approach was

proposed in the seminal work of Kelly, Maulloo, and Tan [11] and further developed by Low and Lapsley [18], Shakkottai and Srikant [30], and Srikant [33].

Consider a network that consists of a set $\mathcal{S} = \{1, \ldots, S\}$ of sources and a set $\mathcal{L} = \{1, \ldots, L\}$ of undirected links, where a link l has capacity c_l. Let $\mathcal{L}(i) \subset \mathcal{L}$ denote the set of links used by source i. The application requirements of source i are represented by a concave increasing utility function $u_i : [0, \infty) \to [0, \infty)$; i.e., each source i gains a utility $u_i(x_i)$ when it sends data at a rate x_i. We further assume that rate x_i is constrained to lie in the interval $I_i = [0, M_i]$ for all $i \in \mathcal{S}$, where the scalar M_i denotes the maximum allowed rate for source i. Let $\mathcal{S}(l) = \{i \in \mathcal{S} \mid l \in \mathcal{L}(i)\}$ denote the set of sources that use link l. The goal of the *network utility maximization problem* is to allocate the source rates as the optimal solution of the problem

$$\begin{aligned} &\text{maximize} \sum_{i \in \mathcal{S}} u_i(x_i) && (6)\\ &\text{subject to} \sum_{i \in \mathcal{S}(l)} x_i \le c_l \quad \text{for all } l \in \mathcal{L}, \\ &x_i \in I_i \quad \text{for all } i \in \mathcal{S}. && (7) \end{aligned}$$

Solving problem (6) directly by applying existing subgradient methods requires coordination among sources and therefore may be impractical for real networks. This is because in real networks, such as the Internet, there is no central entity that has access to both the source utility functions and the capacity of all the links in the network. The utility function $u_i(x_i)$ is known only by source i, while the link capacities may be known only by "network providers." At the same time, in view of the separable structure of the objective and constraint functions, the dual problem can be evaluated exactly while using decentralized information. In particular, the dual problem of (6) is given by (3), where the dual function takes the form

$$\begin{aligned} q(\mu) &= \max_{x_i \in I_i,\ i \in \mathcal{S}} \sum_{i \in \mathcal{S}} u_i(x_i) - \sum_{l \in \mathcal{L}} \mu_l \left(\sum_{i \in \mathcal{S}(l)} x_i - c_l \right) \\ &= \max_{x_i \in I_i,\ i \in \mathcal{S}} \sum_{i \in \mathcal{S}} \left(u_i(x_i) - x_i \sum_{l \in \mathcal{L}(i)} \mu_l \right) + \sum_{l \in \mathcal{L}} \mu_l c_l. \end{aligned}$$

Since the optimization problem on the right-hand side of the preceding relation is separable in the variables x_i, the problem decomposes into subproblems for each source i. Letting $\mu_i = \sum_{l \in \mathcal{L}(i)} \mu_l$ for each i (i.e., μ_i is the sum of the multipliers corresponding to the links used by source i), we can write the dual function as

$$q(\mu) = \sum_{i \in \mathcal{S}} \max_{x_i \in I_i} \{u_i(x_i) - x_i \mu_i\} + \sum_{l \in \mathcal{L}} \mu_l c_l.$$

Hence, to evaluate the dual function, each source i needs to solve the one-dimensional optimization problem $\max_{x_i \in I_i} \{u_i(x_i) - x_i \mu_i\}$. This involves only its own utility function u_i and the value μ_i, which is available to source i in practical networks (through a direct feedback mechanism from its destination).

This favorable structure of the dual problem has motivated much interest in using dual subgradient methods to solve the network utility maximization problem in an iterative decentralized manner (see Chiang et al. [6]). Other problems where

the dual problem has a structure that allows exact evaluation of the dual function using local information include the problem of processor speed control considered by Mutapcic et al. [19], and the traffic equilibrium and road pricing problems considered by Larsson, Patriksson, and Strömberg [15], [16], [17].

2.3. Slater condition and boundedness of the multiplier sets. In this section, we consider sets of the form $\{\mu \geq 0 \mid q(\mu) \geq q(\bar{\mu})\}$ for a fixed $\bar{\mu} \geq 0$, which are obtained by intersecting the nonnegative orthant in $\mathbb{R}^m$ and (upper) level sets of the concave dual function q. We show that these sets are bounded when the primal problem satisfies the standard Slater constraint qualification, formally given in the following.

Assumption 1 (Slater condition). There exists a vector $\bar{x} \in X$ such that

$$g_j(\bar{x}) < 0 \qquad \text{for all } j = 1, \ldots, m.$$

We refer to a vector $\bar{x}$ satisfying the Slater condition as *a Slater vector*.

Under the assumption that f^* is finite, it is well known that the Slater condition is sufficient for a zero duality gap as well as for the existence of a dual optimal solution (see, for example, Bertsekas [4] or Bertsekas, Nedić, and Ozdaglar [5]). Furthermore, the dual optimal set is bounded (see Hiriart-Urruty and Lemaréchal [10]). This property of the dual optimal set under the Slater condition has been observed and used as early as in Uzawa's analysis of the Arrow–Hurwicz gradient method in [34]. This property will be key in our subsequent development and analysis.

The following proposition extends the result on the optimal dual set boundedness under the Slater condition. In particular, it shows that the Slater condition also guarantees the boundedness of the (level) sets $\{\mu \geq 0 \mid q(\mu) \geq q(\bar{\mu})\}$.

LEMMA 1. *Let the Slater condition hold (cf. Assumption* 1*). Then, the set $Q_{\bar{\mu}}$ is bounded and, in particular, we have*

$$\max_{\mu \in Q_{\bar{\mu}}} \|\mu\| \leq \frac{1}{\gamma} \left(f(\bar{x}) - q(\bar{\mu})\right),$$

where $\gamma = \min_{1 \leq j \leq m}\{-g_j(\bar{x})\}$ and $\bar{x}$ is a Slater vector.

Proof. We have, for any $\mu \in Q_{\bar{\mu}}$,

$$q(\bar{\mu}) \leq q(\mu) = \inf_{x \in X} \{f(x) + \mu' g(x)\} \leq f(\bar{x}) + \mu' g(\bar{x}) = f(\bar{x}) + \sum_{j=1}^{m} \mu_j g_j(\bar{x}),$$

implying that

$$-\sum_{j=1}^{m} \mu_j g_j(\bar{x}) \leq f(\bar{x}) - q(\bar{\mu}).$$

Because $g_j(\bar{x}) < 0$ and $\mu_j \geq 0$ for all j, it follows that

$$\min_{1 \leq j \leq m}\{-g_j(\bar{x})\} \sum_{j=1}^{m} \mu_j \leq -\sum_{j=1}^{m} \mu_j g_j(\bar{x}) \leq f(\bar{x}) - q(\bar{\mu}).$$

Therefore,

$$\sum_{j=1}^{m} \mu_j \leq \frac{f(\bar{x}) - q(\bar{\mu})}{\min_{1 \leq j \leq m}\{-g_j(\bar{x})\}}.$$

Since $\mu \geq 0$, we have $\|\mu\| \leq \sum_{j=1}^{m} \mu_j$ and the estimate follows. ∎

It follows from the preceding lemma that under the Slater condition, the dual optimal set M^* is nonempty. In particular, by noting that $M^* = \{\mu \geq 0 \mid q(\mu) \geq q^*\}$ and by using Lemma 1, we see that

$$\max_{\mu^* \in M^*} \|\mu^*\| \leq \frac{1}{\gamma} \left(f(\bar{x}) - q^*\right), \tag{8}$$

with $\gamma = \min_{1 \leq j \leq m}\{-g_j(\bar{x})\}$.

In practice, the dual optimal value q^* is not readily available. However, having a dual function value $q(\tilde{\mu})$ for some $\tilde{\mu} \geq 0$, we can still provide a bound on the norm of the dual optimal solutions. In particular, since $q^* \geq q(\tilde{\mu})$, from relation (8) we obtain the following bound:

$$\max_{\mu^* \in M^*} \|\mu^*\| \leq \frac{1}{\gamma} \left(f(\bar{x}) - q(\tilde{\mu})\right).$$

Furthermore, having any multiplier sequence $\{\mu_k\}$, we can use the dual function values $q(\mu_k)$ to generate a sequence of (possibly improving) upper bounds on the dual optimal solution norms $\|\mu^*\|$. Formally, since $q^* \geq \max_{0 \leq i \leq k} q(\mu_i)$, from relation (8) we have

$$\max_{\mu^* \in M^*} \|\mu^*\| \leq \frac{1}{\gamma} \left(f(\bar{x}) - \max_{0 \leq i \leq k} q(\mu_i)\right) \qquad \text{for all } k \geq 0.$$

Note that these bounds are nonincreasing in k. These bounds have important implications in the development and analysis of subgradient methods since they allow us to "locate dual optimal solutions" by using only a Slater vector $\bar{x}$ and a multiplier sequence $\{\mu_k\}$ generated by a subgradient method.

Such bounds play a key role in our subsequent development. In particular, we use these bounds to provide error estimates of our approximate solutions as well as to design a dual algorithm that projects on a set containing the dual optimal solution.

3. Subgradient method. To solve the dual problem, we consider the classical subgradient algorithm with a constant stepsize:

$$\mu_{k+1} = [\mu_k + \alpha g_k]^+ \qquad \text{for } k = 0, 1, \ldots, \tag{9}$$

where the vector $\mu_0 \geq 0$ is an initial iterate and the scalar $\alpha > 0$ is a stepsize. The vector g_k is a subgradient of q at μ_k given by

$$g_k = g(x_k), \qquad x_k \in \operatorname*{argmin}_{x \in X}\{f(x) + \mu_k' g(x)\} \qquad \text{for all } k \geq 0; \tag{10}$$

see (5).

Our choice of the constant stepsize is primarily motivated by its practical importance and, in particular, because in practice the stepsize typically stays bounded away from zero. Furthermore, the error estimates for this stepsize can be explicitly written in terms of the problem parameters that are often available. Also, when implementing a subgradient method with a constant stepsize rule, the stepsize length α is the only parameter that a user has to select, which is often preferred to more complex stepsize choices involving several stepsize parameters without a good guidance on their selection.

3.1. Basic relations. In this section, we establish some basic relations that hold for a sequence $\{\mu_k\}$ obtained by the subgradient algorithm of (9). These properties are important in our construction of approximate primal solutions and, in particular, in our analysis of the error estimates of these solutions.

We start with a lemma providing some basic relations that hold under minimal assumptions. The relations given in this lemma have been known and used in various ways to analyze subgradient approaches (for example, see Shor [32], Polyak [27], Demyanov and Vasilyev [8], Correa and Lemaréchal [7], Nedić and Bertsekas [20], [21]). The proofs are provided here for completeness.

LEMMA 2 (basic iterate relation). *Let the sequence $\{\mu_k\}$ be generated by the subgradient algorithm* (9). *We then have the following:*

(a) *For any $\mu \geq 0$,*

$$\|\mu_{k+1} - \mu\|^2 \leq \|\mu_k - \mu\|^2 - 2\alpha\,(q(\mu) - q(\mu_k)) + \alpha^2\|g_k\|^2 \qquad \text{for all } k \geq 0.$$

(b) *When the optimal solution set M^* is nonempty, there holds*

$$dist^2(\mu_{k+1}, M^*) \leq dist^2(\mu_k, M^*) - 2\alpha\,(q^* - q(\mu_k)) + \alpha^2\|g_k\|^2 \qquad \text{for all } k \geq 0,$$

where $dist(y, Y)$ denotes the Euclidean distance from a vector y to a set Y.

Proof. (a) By using the nonexpansive property of the projection operation, from relation (9) we obtain, for any $\mu \geq 0$ and all k,

$$\|\mu_{k+1} - \mu\|^2 = \left\|[\mu_k + \alpha g_k]^+ - \mu\right\|^2 \leq \|\mu_k + \alpha g_k - \mu\|^2.$$

Therefore,

$$\|\mu_{k+1} - \mu\|^2 \leq \|\mu_k - \mu\|^2 + 2\alpha g_k'(\mu_k - \mu) + \alpha^2\|g_k\|^2 \qquad \text{for all } k.$$

Since g_k is a subgradient of q at μ_k (cf. (1)), we have

$$g_k'(\mu - \mu_k) \geq q(\mu) - q(\mu_k),$$

implying that

$$g_k'(\mu_k - \mu) \leq -\,(q(\mu) - q(\mu_k)).$$

Hence, for any $\mu \geq 0$,

$$\|\mu_{k+1} - \mu\|^2 \leq \|\mu_k - \mu\|^2 - 2\alpha\,(q(\mu) - q(\mu_k)) + \alpha^2\|g_k\|^2 \qquad \text{for all } k.$$

(b) By using the preceding relation with $\mu = \mu^*$ for any optimal solution μ^*, we obtain

$$\|\mu_{k+1} - \mu^*\|^2 \leq \|\mu_k - \mu^*\|^2 - 2\alpha\,(q^* - q(\mu_k)) + \alpha^2\|g_k\|^2 \qquad \text{for all } k \geq 0.$$

The desired relation follows by taking the infimum over all $\mu^* \in M^*$ in both sides of the preceding relation. ∎

3.2. Bounded multipliers. Here, we show that the multiplier sequence $\{\mu_k\}$ produced by the subgradient algorithm is bounded under the Slater condition and the bounded subgradient assumption. We formally state the latter requirement in the following assumption.

Assumption 2 (bounded set X). The constraint set X in problem (2) is bounded.

Under this assumption, due to the convexity of the constraint functions g_j over $\mathbb{R}^n$, each g_j is continuous over $\mathbb{R}^n$. Thus, $\max_{x\in X}\|g(x)\|$ is finite and provides an upper bound on the norms of the subgradients g_k, i.e.,

$$\|g_k\| \le L \qquad \text{for all } k \ge 0, \qquad \text{with } \ L = \max_{x\in X}\|g(x)\|.$$

In the following lemma, we establish the boundedness of the multiplier sequence. In this, we use the boundedness of the dual sets $\{\mu \ge 0 \mid q(\mu) \ge q(\bar{\mu})\}$ (cf. Lemma 1) and the basic relation for the sequence $\{\mu_k\}$ of Lemma 2(a).

LEMMA 3 (bounded multipliers). *Let the multiplier sequence $\{\mu_k\}$ be generated by the subgradient algorithm of* (9)*. Also, let the Slater condition and the bounded set assumption hold (cf. Assumptions* 1 *and* 2*). Then, the sequence $\{\mu_k\}$ is bounded and, in particular, we have*

$$\|\mu_k\| \le \frac{2}{\gamma}\,(f(\bar{x}) - q^*) + \max\left\{\|\mu_0\|, \frac{1}{\gamma}\,(f(\bar{x}) - q^*) + \frac{\alpha L^2}{2\gamma} + \alpha L\right\},$$

where $\gamma = \min_{1\le j\le m}\{-g_j(\bar{x})\}$, $\bar{x}$ is a Slater vector, L is the subgradient norm bound, and $\alpha > 0$ is the stepsize.

Proof. Under the Slater condition the optimal dual set M^* is nonempty. Consider the set Q_α defined by

$$Q_\alpha = \left\{\mu \ge 0 \mid q(\mu) \ge q^* - \frac{\alpha L^2}{2}\right\},$$

which is nonempty in view of $M^* \subset Q_\alpha$. We fix an arbitrary $\mu^* \in M^*$, and we first prove that, for all $k \ge 0$,

$$\|\mu_k - \mu^*\| \le \max\left\{\|\mu_0 - \mu^*\|, \frac{1}{\gamma}\,(f(\bar{x}) - q^*) + \frac{\alpha L^2}{2\gamma} + \|\mu^*\| + \alpha L\right\}, \tag{11}$$

where $\gamma = \min_{1\le j\le m}\{-g_j(\bar{x})\}$ and L is the bound on the subgradient norms $\|g_k\|$. Then, we use Lemma 1 to prove the desired estimate.

We show that relation (11) holds by induction on k. Note that the relation holds for $k = 0$. Assume now that it holds for some $k > 0$, i.e.,

$$\|\mu_k - \mu^*\| \le \max\left\{\|\mu_0 - \mu^*\|, \frac{1}{\gamma}\,(f(\bar{x}) - q^*) + \frac{\alpha L^2}{2\gamma} + \|\mu^*\| + \alpha L\right\} \text{ for some } k > 0. \tag{12}$$

We now consider two cases: $q(\mu_k) \ge q^* - \alpha L^2/2$ and $q(\mu_k) < q^* - \alpha L^2/2$.

Case 1. $q(\mu_k) \ge q^* - \alpha L^2/2$. By using the definition of the iterate μ_{k+1} in (9) and the subgradient boundedness, we obtain

$$\|\mu_{k+1} - \mu^*\| \le \|\mu_k + \alpha g_k - \mu^*\| \le \|\mu_k\| + \|\mu^*\| + \alpha L.$$

Since $q(\mu_k) \geq q^* - \alpha L^2/2$, it follows that $\mu_k \in Q_\alpha$. According to Lemma 1, the set Q_α is bounded and, in particular, $\|\mu\| \leq \frac{1}{\gamma}\left(f(\bar{x}) - q^* + \alpha L^2/2\right)$ for all $\mu \in Q_\alpha$. Therefore

$$\|\mu_k\| \leq \frac{1}{\gamma}\left(f(\bar{x}) - q^*\right) + \frac{\alpha L^2}{2\gamma}.$$

By combining the preceding two relations, we obtain

$$\|\mu_{k+1} - \mu^*\| \leq \frac{1}{\gamma}\left(f(\bar{x}) - q^*\right) + \frac{\alpha L^2}{2\gamma} + \|\mu^*\| + \alpha L,$$

thus showing that the estimate in (11) holds for $k+1$.

Case 2. $q(\mu_k) < q^* - \alpha L^2/2$. By using Lemma 2(a) with $\mu = \mu^*$, we obtain

$$\|\mu_{k+1} - \mu^*\|^2 \leq \|\mu_k - \mu^*\|^2 - 2\alpha\left(q^* - q(\mu_k)\right) + \alpha^2\|g_k\|^2.$$

By using the subgradient boundedness, we further obtain

$$\|\mu_{k+1} - \mu^*\|^2 \leq \|\mu_k - \mu^*\|^2 - 2\alpha\left(q^* - q(\mu_k) - \frac{\alpha L^2}{2}\right).$$

Since $q(\mu_k) < q^* - \alpha L^2/2$, it follows that $q^* - q(\mu_k) - \alpha L^2/2 > 0$, which when combined with the preceding relation yields

$$\|\mu_{k+1} - \mu^*\| < \|\mu_k - \mu^*\|.$$

By the induction hypothesis (cf. (12)), it follows that the estimate in (11) holds for $k+1$ as well. Hence, the estimate in (11) holds for all $k \geq 0$.

From (11) we obtain, for all $k \geq 0$,

$$\|\mu_k\| \leq \|\mu_k - \mu^*\| + \|\mu^*\| \leq \max\left\{\|\mu_0 - \mu^*\|, \frac{1}{\gamma}\left(f(\bar{x}) - q^*\right) + \frac{\alpha L^2}{2\gamma} + \|\mu^*\| + \alpha L\right\} + \|\mu^*\|.$$

By using $\|\mu_0 - \mu^*\| \leq \|\mu_0\| + \|\mu^*\|$, we further have, for all $k \geq 0$,

$$\begin{aligned}\|\mu_k\| &\leq \max\left\{\|\mu_0\| + \|\mu^*\|, \frac{1}{\gamma}\left(f(\bar{x}) - q^*\right) + \frac{\alpha L^2}{2\gamma} + \|\mu^*\| + \alpha L\right\} + \|\mu^*\| \\ &= 2\|\mu^*\| + \max\left\{\|\mu_0\|, \frac{1}{\gamma}\left(f(\bar{x}) - q^*\right) + \frac{\alpha L^2}{2\gamma} + \alpha L\right\}.\end{aligned}$$

Since $M^* = \{\mu \geq 0 \mid q(\mu) \geq q^*\}$, according to Lemma 1 we have the following bound on the dual optimal solutions:

$$\max_{\mu^* \in M^*} \|\mu^*\| \leq \frac{1}{\gamma}\left(f(\bar{x}) - q^*\right),$$

implying that, for all $k \geq 0$,

$$\|\mu_k\| \leq \frac{2}{\gamma}\left(f(\bar{x}) - q^*\right) + \max\left\{\|\mu_0\|, \frac{1}{\gamma}\left(f(\bar{x}) - q^*\right) + \frac{\alpha L^2}{2\gamma} + \alpha L\right\}. \qquad \square$$

The error estimate of Lemma 3 depends explicitly on the dual optimal value q^*. In practice, the value q^* is not readily available. However, since $q^* \geq q(\mu_0)$, by replacing q^* with $q(\mu_0)$, we have obtain the following norm bound for the multiplier sequence:

$$\|\mu_k\| \leq \frac{2}{\gamma}\left(f(\bar{x}) - q(\mu_0)\right) + \max\left\{\|\mu_0\|, \frac{1}{\gamma}\left(f(\bar{x}) - q(\mu_0)\right) + \frac{\alpha L^2}{2\gamma} + \alpha L\right\},$$

where $\gamma = \min_{1\leq j\leq m}\{-g_j(\bar{x})\}$. Note that this bound depends on the algorithm parameters and problem data only. Specifically, it involves the initial iterate μ_0 of the subgradient method, the stepsize α, the vector $\bar{x}$ satisfying the Slater condition, and the subgradient norm bound L. In some practical applications, such as those in network optimization, such data is readily available. One may think of optimizing this bound with respect to the Slater vector $\bar{x}$. This might be an interesting and challenging problem on its own. However, this is outside the scope of our paper.

4. Approximate primal solutions. In this section, we provide approximate primal solutions by considering the running averages of the primal sequence $\{x_k\}$ generated as a byproduct of the subgradient method (cf. (10)). Intuitively, one would expect that, by averaging, the primal cost and the amount of constraint violation of primal infeasible vectors can be reduced due to the convexity of the cost and the constraint functions. It turns out that the benefits of averaging are far more reaching than merely cost and infeasibility reduction. We show here that under the Slater condition, we can also provide upper bounds for the number of subgradient iterations needed to generate a primal solution within a given level of constraint violation. We also derive upper and lower bounds on the gap from the optimal primal value. These bounds depend on some assumptions and prior information such as a Slater vector and a bound on subgradient norms.

We now introduce the notation that we use in our averaging scheme throughout the rest of this paper. We consider the multiplier sequence $\{\mu_k\}$ generated by the subgradient algorithm of (9), and the corresponding sequence of primal vectors $\{x_k\} \subset X$ that provide the subgradients g_k in the algorithm, i.e.,

$$g_k = g(x_k), \qquad x_k \in \operatorname*{argmin}_{x\in X}\{f(x) + \mu_k' g(x)\} \qquad \text{for all } k \geq 0$$

(cf. (10)). We define $\hat{x}_k$ as the average of the vectors $x_0, \ldots, x_{k-1}$, i.e.,

$$\hat{x}_k = \frac{1}{k}\sum_{i=0}^{k-1} x_i \qquad \text{for all } k \geq 1. \tag{13}$$

The average vectors $\hat{x}_k$ lie in the set X because X is convex and $x_i \in X$ for all i. However, these vectors need not satisfy the primal inequality constraints $g_j(x) \leq 0$, $j = 1, \ldots, m$, and therefore, they can be primal infeasible.

In the rest of this section, we study some basic properties of the average vectors $\hat{x}_k$. Using these properties and the Slater condition, we provide estimates for the primal optimal value and the feasibility violation at each iteration of the subgradient method.

4.1. Basic properties of the averaged primal sequence. In this section, we provide upper and lower bounds on the primal cost of the running averages $\hat{x}_k$. We also provide an upper and a lower bound on the amount of feasibility violation of these vectors. These bounds are given per iteration, as seen in the following.

PROPOSITION 1. *Let the multiplier sequence $\{\mu_k\}$ be generated by the subgradient method of* (9)*. Let the vectors $\hat{x}_k$ for $k \geq 1$ be the averages given by* (13)*. Then, for all $k \geq 1$, the following hold:*

(a) *An upper bound on the amount of constraint violation of the vector $\hat{x}_k$ is given by*

$$\left\|g(\hat{x}_k)^+\right\| \leq \frac{\|\mu_k\|}{k\alpha}.$$

(b) *An upper bound on the primal cost of the vector $\hat{x}_k$ is given by*

$$f(\hat{x}_k) \leq q^* + \frac{\|\mu_0\|^2}{2k\alpha} + \frac{\alpha}{2k}\sum_{i=0}^{k-1}\|g(x_i)\|^2.$$

(c) *A lower bound on the primal cost of the vector $\hat{x}_k$ is given by*

$$f(\hat{x}_k) \geq q^* - \|\mu^*\|\|g(\hat{x}_k)^+\|,$$

where μ^* is a dual optimal solution.

Proof. (a) By using the definition of the iterate μ_{k+1} in (9), we obtain

$$\mu_k + \alpha g_k \leq [\mu_k + \alpha g_k]^+ = \mu_{k+1} \qquad \text{for all } k \geq 0.$$

Since $g_k = g(x_k)$ with $x_k \in X$, it follows that

$$\alpha g(x_k) \leq \mu_{k+1} - \mu_k \qquad \text{for all } k \geq 0.$$

Therefore,

$$\sum_{i=0}^{k-1} \alpha g(x_i) \leq \mu_k - \mu_0 \leq \mu_k \qquad \text{for all } k \geq 1,$$

where the last inequality in the preceding relation follows from $\mu_0 \geq 0$. Since $x_k \in X$ for all k, by the convexity of X, we have $\hat{x}_k \in X$ for all k. Hence, by the convexity of each of the functions g_j, it follows that

$$g(\hat{x}_k) \leq \frac{1}{k}\sum_{i=0}^{k-1} g(x_i) = \frac{1}{k\alpha}\sum_{i=0}^{k-1}\alpha g(x_i) \leq \frac{\mu_k}{k\alpha} \qquad \text{for all } k \geq 1.$$

Because $\mu_k \geq 0$ for all k, we have $g(\hat{x}_k)^+ \leq \mu_k/(k\alpha)$ for all $k \geq 1$, and, therefore,

$$\|g(\hat{x}_k)^+\| \leq \frac{\|\mu_k\|}{k\alpha} \qquad \text{for all } k \geq 1.$$

(b) By the convexity of the primal cost $f(x)$ and the definition of x_k as a minimizer of the Lagrangian function $f(x) + \mu_k' g(x)$ over $x \in X$ (cf. (10)), we have

$$f(\hat{x}_k) \leq \frac{1}{k}\sum_{i=0}^{k-1} f(x_i) = \frac{1}{k}\sum_{i=0}^{k-1}\{f(x_i) + \mu_i' g(x_i)\} - \frac{1}{k}\sum_{i=0}^{k-1}\mu_i' g(x_i).$$

Since $q(\mu_i) = f(x_i) + \mu_i' g(x_i)$ and $q(\mu_i) \leq q^*$ for all i, it follows that, for all $k \geq 1$,

$$f(\hat{x}_k) \leq \frac{1}{k}\sum_{i=0}^{k-1} q(\mu_i) - \frac{1}{k}\sum_{i=0}^{k-1}\mu_i' g(x_i) \leq q^* - \frac{1}{k}\sum_{i=0}^{k-1}\mu_i' g(x_i). \tag{14}$$

From the definition of the algorithm in (9), by using the nonexpansive property of the projection, and the facts $0 \in \{\mu \in \mathbb{R}^m \mid \mu \geq 0\}$ and $g_i = g(x_i)$, we obtain

$$\|\mu_{i+1}\|^2 \leq \|\mu_i\|^2 + 2\alpha\mu_i' g(x_i) + \alpha^2\|g(x_i)\|^2 \qquad \text{for all } i \geq 0,$$

implying that

$$-\mu_i' g(x_i) \leq \frac{\|\mu_i\|^2 - \|\mu_{i+1}\|^2 + \alpha^2 \|g(x_i)\|^2}{2\alpha} \qquad \text{for all } i \geq 0.$$

By summing over $i = 0, \ldots, k-1$ for $k \geq 1$, we have

$$-\frac{1}{k} \sum_{i=0}^{k-1} \mu_i' g(x_i) \leq \frac{\|\mu_0\|^2 - \|\mu_k\|^2}{2k\alpha} + \frac{\alpha}{2k} \sum_{i=0}^{k-1} \|g(x_i)\|^2 \qquad \text{for all } k \geq 1.$$

Combining the preceding relation and (14), we further have

$$f(\hat{x}_k) \leq q^* + \frac{\|\mu_0\|^2 - \|\mu_k\|^2}{2k\alpha} + \frac{\alpha}{2k} \sum_{i=0}^{k-1} \|g(x_i)\|^2 \qquad \text{for all } k \geq 1,$$

implying the desired estimate.

(c) Given a dual optimal solution μ^*, we have

$$f(\hat{x}_k) = f(\hat{x}_k) + (\mu^*)' g(\hat{x}_k) - (\mu^*)' g(\hat{x}_k) \geq q(\mu^*) - (\mu^*)' g(\hat{x}_k).$$

Because $\mu^* \geq 0$ and $g(\hat{x}_k)^+ \geq g(\hat{x}_k)$, we further have

$$-(\mu^*)' g(\hat{x}_k) \geq -(\mu^*)' g(\hat{x}_k)^+ \geq -\|\mu^*\| \|g(\hat{x}_k)^+\|.$$

From the preceding two relations and the fact $q(\mu^*) = q^*$, it follows that

$$f(\hat{x}_k) \geq q^* - \|\mu^*\| \|g(\hat{x}_k)^+\|. \qquad \square$$

An immediate consequence of Proposition 1(a) is that the maximum violation $\|g(\hat{x}_k)^+\|_\infty$ of constraints $g_j(x)$, $j = 1, \ldots, m$, at $x = \hat{x}_k$ is bounded by the same bound. In particular, we have

$$\max_{1 \leq j \leq m} g_j(\hat{x}_k)^+ \leq \frac{\|\mu_k\|}{k\alpha} \qquad \text{for all } k \geq 1,$$

which follows from the proposition in view of the relation $\|y\|_\infty \leq \|y\|$ for any y.

We note that the results of Proposition 1 in parts (a) and (c) show how the amount of feasibility violation $\|g(\hat{x}_k)^+\|$ affects the lower estimate of $f(\hat{x}_k)$. Furthermore, we note that the results of Proposition 1 indicate that the bounds on the feasibility violation and the primal value $f(\hat{x}_k)$ are readily available provided that we have bounds on the multiplier norms $\|\mu_k\|$, optimal solution norms $\|\mu^*\|$, and subgradient norms $\|g(x_k)\|$. This is precisely what we use in the next section to establish our estimates.

Let us also note that the bounds on the primal cost of Proposition 1 in parts (b) and (c) hold for a more general subgradient algorithm than the algorithm of (9). In particular, the result in part (c) is independent of the algorithm that is used to generate the multiplier sequence $\{\mu_k\}$. The proof of the result in part (c) relies on the nonexpansive property of the projection operation and the fact that the zero vector belongs to the projection set $\{\mu \in \mathbb{R}^m \mid \mu \geq 0\}$. Therefore, the results in parts (b) and (c) hold when we use a more general subgradient algorithm of the following form:

$$\mu_{k+1} = \mathcal{P}_D[\mu_k + \alpha g_k] \qquad \text{for } k \geq 1,$$

where $D \subseteq \{\mu \in \mathbb{R}^m \mid \mu \geq 0\}$ is a closed convex set containing the zero vector. We study a subgradient algorithm of this form in section 5 and establish similar error estimates.

Finally, bounds similar to those of Proposition 1 can be established for a multiplier sequence $\{\mu_k\}$ generated by a subgradient algorithm that uses a general (nonequal) stepsize sequence. In particular, given a stepsize sequence $\{\alpha_k\}$ and an initial iterate $\mu_0 \geq 0$, consider the subgradient method

$$\mu_{k+1} = [\mu_k + \alpha_k g_k]^+ \qquad \text{for } k = 0, 1, \ldots, \tag{15}$$

where g_k is given by

$$g_k = g(x_k), \qquad x_k \in \operatorname*{argmin}_{x \in X}\{f(x) + \mu_k' g(x)\} \qquad \text{for all } k \geq 0.$$

Define $\tilde{x}_k$ as the convex combination of the vectors $x_0, \ldots, x_{k-1}$ with weights $\alpha_0, \ldots \alpha_{k-1}$,

$$\tilde{x}_k = \frac{\sum_{i=0}^{k-1} \alpha_i x_i}{\sum_{i=0}^{k-1} \alpha_i}. \tag{16}$$

Following a similar analysis to that of Proposition 1, we establish the following estimates for the weighted-average vectors $\tilde{x}_k$.

PROPOSITION 2. *Let the multiplier sequence $\{\mu_k\}$ be generated by the subgradient method of* (15)*. Let the vectors $\tilde{x}_k$ for $k \geq 1$ be the averages given by* (16)*. Then, for all $k \geq 1$, the following hold:*

(a) *An upper bound on the amount of constraint violation of the vector $\tilde{x}_k$ is given by*

$$\|g(\tilde{x}_k)^+\| \leq \frac{\|\mu_k\|}{\sum_{i=0}^{k-1} \alpha_i}.$$

(b) *An upper bound on the primal cost of the vector $\tilde{x}_k$ is given by*

$$f(\tilde{x}_k) \leq q^* + \frac{\|\mu_0\|^2}{2\sum_{i=0}^{k-1} \alpha_i} + \frac{\sum_{i=0}^{k-1} \alpha_i^2 \|g(x_i)\|^2}{2\sum_{i=0}^{k-1} \alpha_i}.$$

(c) *A lower bound on the primal cost of the vector $\tilde{x}_k$ is given by*

$$f(\tilde{x}_k) \geq q^* - \|\mu^*\| \|g(\tilde{x}_k)^+\|,$$

where μ^* is a dual optimal solution.

4.2. Properties of the averaged primal sequence under Slater. Here, we strengthen the relations of Proposition 1 under the Slater condition and the boundedness of the set X. Our main result is given in the following proposition.

PROPOSITION 3. *Let the sequence $\{\mu_k\}$ be generated by the subgradient algorithm* (9)*. Let the Slater condition and the bounded set assumption hold (cf. Assumptions* 1 *and* 2*). Also, let*

$$B^* = \frac{2}{\gamma}\left(f(\bar{x}) - q^*\right) + \max\left\{\|\mu_0\|, \frac{1}{\gamma}\left(f(\bar{x}) - q^*\right) + \frac{\alpha L^2}{2\gamma} + \alpha L\right\}. \tag{17}$$

Let the vectors $\hat{x}_k$ for $k \geq 1$ be the averages given by (13)*. Then, the following hold for all $k \geq 1$:*

(a) *An upper bound on the amount of constraint violation of the vector $\hat{x}_k$ is given by*

$$\|g(\hat{x}_k)^+\| \leq \frac{B^*}{k\alpha}.$$

(b) *An upper bound on the primal cost of the vector $\hat{x}_k$ is given by*

$$f(\hat{x}_k) \leq f^* + \frac{\|\mu_0\|^2}{2k\alpha} + \frac{\alpha L^2}{2}.$$

(c) *A lower bound on the primal cost of the vector $\hat{x}_k$ is given by*

$$f(\hat{x}_k) \geq f^* - \frac{1}{\gamma}\,[\,f(\bar{x}) - q^*\,]\,\|g(\hat{x}_k)^+\|.$$

Proof. (a) Under the assumptions, by Lemma 3 we have

$$\|\mu_k\| \leq \frac{2}{\gamma}\,(f(\bar{x}) - q^*) + \max\left\{\|\mu_0\|, \frac{1}{\gamma}\,(f(\bar{x}) - q^*) + \frac{\alpha L^2}{2\gamma} + \alpha L\right\} \qquad \text{for all } k \geq 0.$$

By the definition of B^* in (17), the preceding relation is equivalent to

$$\|\mu_k\| \leq B^* \qquad \text{for all } k \geq 0. \tag{18}$$

By using Proposition 1(a), we obtain

$$\|g(\hat{x}_k)^+\| \leq \frac{\|\mu_k\|}{k\alpha} \leq \frac{B^*}{k\alpha} \qquad \text{for all } k \geq 1.$$

(b) From Proposition 1(b), we obtain

$$f(\hat{x}_k) \leq q^* + \frac{\|\mu_0\|^2}{2k\alpha} + \frac{\alpha}{2k}\sum_{i=0}^{k-1}\|g(x_i)\|^2 \qquad \text{for all } k \geq 1.$$

Under the Slater condition, there is zero duality gap, i.e., $q^* = f^*$. Furthermore, the subgradients are bounded by a scalar L (cf. Assumption 2), so that

$$f(\hat{x}_k) \leq f^* + \frac{\|\mu_0\|^2}{2k\alpha} + \frac{\alpha L^2}{2} \qquad \text{for all } k \geq 1.$$

(c) Under the Slater condition, a dual optimal solution exists and there is zero duality gap, i.e., $q^* = f^*$. Thus, by Proposition 1(c), for any dual solution μ^* we have

$$f(\hat{x}_k) \geq f^* - \|\mu^*\|\|g(\hat{x}_k)^+\| \qquad \text{for all } k \geq 1.$$

By using Lemma 1 with $\bar{\mu} = \mu^*$, we see that the dual set is bounded and, in particular, $\|\mu^*\| \leq \frac{1}{\gamma}(f(\bar{x}) - q^*)$ for all dual optimal vectors μ^*. Hence,

$$f(\hat{x}_k) \geq f^* - \frac{1}{\gamma}\,[\,f(\bar{x}) - q^*\,]\,\|g(\hat{x}_k)^+\| \qquad \text{for all } k \geq 1. \qquad \square$$

It seems reasonable to choose the initial iterate as $\mu_0 = 0$, as suggested by the upper bound for $f(\hat{x}_k)$ in part (b) of Proposition 3. In this case, the bound B^* in part (a) of Proposition 3, with $q^* = f^*$, reduces to

$$B^* = \frac{3}{\gamma}\,[f(\bar{x}) - f^*] + \frac{\alpha L^2}{2\gamma} + \alpha L \qquad \text{for } k \geq 1, \tag{19}$$

while the estimate in part (b) reduces to

$$f(\hat{x}_k) \leq f^* + \frac{\alpha L^2}{2} \qquad \text{for all } k \geq 1. \tag{20}$$

Using the preceding two relations, one can estimate the order of the number of iterations needed to achieve an ϵ-feasible and ϵ-optimal solution.[3] In particular, to achieve the ϵ-optimality, from (20) the stepsize should satisfy $\alpha \leq 2\epsilon/L^2$. Assuming for the sake of simplicity that the term $\frac{1}{\gamma}\,[f(\bar{x}) - f^*]$ is dominant in (19), to obtain ϵ-feasibility, the number of iterations k should satisfy $k \geq \frac{[f(\bar{x})-f^*]\,L^2}{c\gamma\epsilon^2}$, where c is some constant independent of ϵ. Thus, to achieve ϵ-feasible and ϵ-optimal solution, the number of iterations is of the order $1/\epsilon^2$, which is typical for subgradient methods.

The results can alternatively be interpreted for a fixed stepsize value α. In this case, by Proposition 3(a), the amount of feasibility violation $\|g(\hat{x}_k)^+\|$ of the vector $\hat{x}_k$ diminishes to zero as the number of subgradient iterations k increases. By combining the results in (a)–(c), we see that the limits of the function values $f(\hat{x}_k)$, as $k \to \infty$, are within the range $\big[f^*, f^* + \alpha L^2/2\big]$.

Finally, we note that a more practical bound than the bound B^* in Proposition 3 can be obtained by using $\max_{0\leq i\leq k} q(\mu_i)$ as an approximation of the optimal value $f^* = q^*$.

5. Modified subgradient method under Slater. In this section, we consider a modified version of the subgradient method under the Slater assumption. The motivation is coming from the fact that under the Slater assumption, the set of dual optimal solutions is bounded (cf. Lemma 1). Therefore, it is of interest to consider a subgradient method in which dual iterates are projected onto a bounded superset of the dual optimal solution set. We consider such algorithms and generate primal solutions using averaging as described in section 4. Also, we provide estimates for the amount of constraint violation and cost of the average primal sequence. Our goal is to compare these estimates with the error estimates obtained for the "ordinary" subgradient method in section 4.

Formally, we consider subgradient methods of the following form:

$$\mu_{k+1} = \mathcal{P}_D\,[\mu_k + \alpha g_k], \tag{21}$$

where the set D is a compact convex set containing the set of dual optimal solutions (to be discussed shortly) and $\mathcal{P}_D$ denotes the projection on the set D. The vector $\mu_0 \in D$ is an arbitrary initial iterate and the scalar $\alpha > 0$ is a constant stepsize. The vector g_k is a subgradient of q at μ_k given by

$$g_k = g(x_k), \qquad x_k \in \operatorname*{argmin}_{x\in X}\{f(x) + \mu_k' g(x)\} \qquad \text{for all } k \geq 0$$

(see (5)).

Under the Slater condition, the dual optimal set M^* is nonempty and bounded, and a bound on the norms of the dual optimal solutions is given by

$$\sum_{j=1}^{m} \mu_j^* \leq \frac{1}{\gamma}(f(\bar{x}) - q^*) \qquad \text{for all } \mu^* \in M^*,$$

[3]We thank an anonymous referee for this insight.

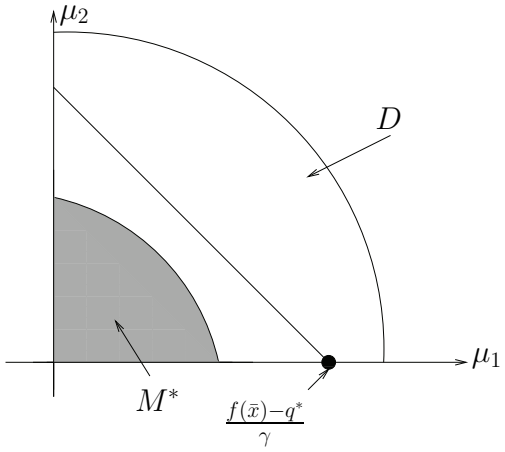

FIG. 1. *The dual optimal set M^* and the set D, which is considered in the modified subgradient method.*

with $\gamma = \min_{1\le j\le m}\{-g_j(\bar{x})\}$ (cf. Lemma 1). Thus, having the dual value $\tilde{q} = q(\tilde{\mu})$ for some $\tilde{\mu} \ge 0$, since $q^* \ge \tilde{q}$, we obtain

$$\sum_{j=1}^{m} \mu_j^* \le \frac{1}{\gamma}(f(\bar{x}) - \tilde{q}) \qquad \text{for all } \mu^* \in M^*. \tag{22}$$

This motivates the following choice for the set D:

$$D = \left\{ \mu \ge 0 \;\middle|\; \|\mu\| \le \frac{f(\bar{x}) - \tilde{q}}{\gamma} + r \right\}, \tag{23}$$

with a scalar $r > 0$. Clearly, the set D is compact and convex, and it contains the set of dual optimal solutions in view of relation (22) and the fact $\|y\| \le \|y\|_1$ for any vector y (the illustration of the set D is provided in Figure 1).

Similar to section 4, we provide near-feasible and near-optimal primal vectors by averaging the vectors from the sequence $\{x_k\}$. In particular, we define $\hat{x}_k$ as the average of the vectors $x_0, \ldots, x_{k-1}$, i.e.,

$$\hat{x}_k = \frac{1}{k}\sum_{i=0}^{k-1} x_i \qquad \text{for all } k \ge 1. \tag{24}$$

In the next proposition, we provide per-iterate bounds for the constraint violation and primal cost values of the average vectors $\hat{x}_k$.

PROPOSITION 4. *Let the Slater condition and the bounded set assumption hold (cf. Assumptions* 1 *and* 2*). Let the dual sequence $\{\mu_k\}$ be generated by the modified subgradient method of* (21)*. Let $\{\hat{x}_k\}$ be the average sequence defined in* (24)*. Then, for all $k \ge 1$, we have the following:*

(a) *An upper bound on the amount of constraint violation of the vector $\hat{x}_k$ is given by*

$$\|g(\hat{x}_k)^+\| \le \frac{2}{k\alpha r}\left(\frac{f(\bar{x}) - \tilde{q}}{\gamma} + r\right)^2 + \frac{\alpha L^2}{2r}.$$

(b) *An upper bound on the primal cost of the vector $\hat{x}_k$ is given by*

$$f(\hat{x}_k) \leq f^* + \frac{\|\mu_0\|^2}{2k\alpha} + \frac{\alpha L^2}{2}.$$

(c) *A lower bound on the primal cost of the vector $\hat{x}_k$ is given by*

$$f(\hat{x}_k) \geq f^* - \left(\frac{f(\bar{x}) - \tilde{q}}{\gamma}\right) \|g(\hat{x}_k)^+\|.$$

Here, the scalars $r > 0$ and $\tilde{q}$ with $\tilde{q} \leq q^*$ are those from the definition of the set D in (23).

Proof. (a) Using the definition of the iterate μ_{k+1} in (21) and the nonexpansive property of projection on a closed convex set, we obtain, for all $\mu \in D$ and all $i \geq 0$,

$$\begin{aligned}\|\mu_{i+1} - \mu\|^2 &= \|\mathcal{P}_D\,[\mu_i + \alpha g_i] - \mu\|^2 \\ &\leq \|\mu_i + \alpha g_i - \mu\|^2 \\ &\leq \|\mu_i - \mu\|^2 + 2\alpha g_i'(\mu_i - \mu) + \alpha^2\|g_i\|^2 \\ &\leq \|\mu_i - \mu\|^2 + 2\alpha g_i'(\mu_i - \mu) + \alpha^2 L^2.\end{aligned}$$

Therefore, for any $\mu \in D$,

$$g_i'(\mu - \mu_i) \leq \frac{\|\mu_i - \mu\|^2 - \|\mu_{i+1} - \mu\|^2}{2\alpha} + \frac{\alpha L^2}{2} \qquad \text{for all } i \geq 0. \tag{25}$$

Since g_i is a subgradient of the dual function q at μ_i, using the subgradient inequality (cf. (1)), we obtain, for any dual optimal solution μ^*,

$$g_i'(\mu_i - \mu^*) \leq q(\mu_i) - q(\mu^*) \leq 0 \qquad \text{for all } i \geq 0,$$

where the last inequality follows from the optimality of μ^* and the feasibility of each $\mu_i \in D$ (i.e., $\mu_i \geq 0$). We then have, for all $\mu \in D$ and all $i \geq 0$,

$$g_i'(\mu - \mu^*) = g_i'(\mu - \mu^* - \mu_i + \mu_i) = g_i'(\mu - \mu_i) + g_i'(\mu_i - \mu^*) \leq g_i'(\mu - \mu_i).$$

From the preceding relation and (25), we obtain, for any $\mu \in D$,

$$g_i'(\mu - \mu^*) \leq \frac{\|\mu_i - \mu\|^2 - \|\mu_{i+1} - \mu\|^2}{2\alpha} + \frac{\alpha L^2}{2} \qquad \text{for all } i \geq 0.$$

Summing over $i = 0, \ldots, k-1$ for $k \geq 1$, we obtain, for any $\mu \in D$ and $k \geq 1$,

$$\sum_{i=0}^{k-1} g_i'(\mu - \mu^*) \leq \frac{\|\mu_0 - \mu\|^2 - \|\mu_k - \mu\|^2}{2\alpha} + \frac{\alpha k L^2}{2} \leq \frac{\|\mu_0 - \mu\|^2}{2\alpha} + \frac{\alpha k L^2}{2}.$$

Therefore, for any $k \geq 1$,

$$\max_{\mu \in D} \left\{\sum_{i=0}^{k-1} g_i'(\mu - \mu^*)\right\} \leq \frac{1}{2\alpha} \max_{\mu \in D} \|\mu_0 - \mu\|^2 + \frac{\alpha k L^2}{2}. \tag{26}$$

We now provide a lower estimate on the left-hand side of the preceding relation. Let $k \geq 1$ be arbitrary and, for simplicity, we suppress the explicit dependence on k by letting

$$s = \sum_{i=0}^{k-1} g_i. \tag{27}$$

Let s^+ be the componentwise maximum of s and the zero vector; i.e., the jth entry of the vector s^+ is given by $s_j^+ = \max\{s_j, 0\}$. If $s^+ = 0$, then the bound in part (a) of this proposition trivially holds. Thus, assume that $s^+ \neq 0$ and define a vector $\bar{\mu}$ as follows:

$$\bar{\mu} = \mu^* + r\,\frac{s^+}{\|s^+\|}.$$

Note that $\bar{\mu} \geq 0$ since $\mu^* \geq 0$, $s^+ \geq 0$, and $r > 0$. By Lemma 1, the dual optimal solution set is bounded and, in particular, $\|\mu^*\| \leq \frac{f(\bar{x})-q^*}{\gamma}$. Furthermore, since $\tilde{q} \leq q^*$, it follows that $\|\mu^*\| \leq \frac{f(\bar{x})-\tilde{q}}{\gamma}$ for any dual solution μ^*. Therefore, by the definition of the vector $\bar{\mu}$, we have

$$\|\bar{\mu}\| \leq \|\mu^*\| + r \leq \frac{f(\bar{x}) - \tilde{q}}{\gamma} + r, \tag{28}$$

implying that $\bar{\mu} \in D$. Using the definition of the vector s in (27) and relation (26), we obtain

$$s'(\bar{\mu} - \mu^*) = \sum_{i=0}^{k-1} g_i'(\bar{\mu} - \mu^*) \leq \max_{\mu \in D} \left\{ \sum_{i=0}^{k-1} g_i'(\mu - \mu^*) \right\} \leq \frac{1}{2\alpha} \max_{\mu \in D} \|\mu_0 - \mu\|^2 + \frac{\alpha k L^2}{2}.$$

Since $\bar{\mu} - \mu^* = r\frac{s^+}{\|s^+\|}$, we have $s'(\bar{\mu} - \mu^*) = r\|s^+\|$. Thus, by the definition of s in (27) and the fact $g_i = g(x_i)$, we have

$$s'(\bar{\mu} - \mu^*) = r \left\| \left[\sum_{i=0}^{k-1} g(x_i) \right]^+ \right\|.$$

Combining the preceding two relations, it follows that

$$\left\| \left[\sum_{i=0}^{k-1} g(x_i) \right]^+ \right\| \leq \frac{1}{2\alpha r} \max_{\mu \in D} \|\mu_0 - \mu\|^2 + \frac{\alpha k L^2}{2r}.$$

Dividing both sides of this relation by k, and using the convexity of the functions g_j in $g = (g_1, \ldots, g_m)$ and the definition of the average primal vector $\hat{x}_k$, we obtain

$$\|g(\hat{x}_k)^+\| \leq \frac{1}{k} \left\| \left[\sum_{i=0}^{k-1} g(x_i) \right]^+ \right\| \leq \frac{1}{2k\alpha r} \max_{\mu \in D} \|\mu_0 - \mu\|^2 + \frac{\alpha L^2}{2r}. \tag{29}$$

Since $\mu_0 \in D$, we have

$$\max_{\mu \in D} \|\mu_0 - \mu\|^2 \leq \max_{\mu \in D} (\|\mu_0\| + \|\mu\|)^2 \leq 4 \max_{\mu \in D} \|\mu\|^2.$$

By using the definition of the set D of (23), we have

$$\max_{\mu\in D}\|\mu\| \leq \frac{f(\bar{x})-\tilde{q}}{\gamma}+r.$$

By substituting the preceding two estimates in relation (29), we obtain

$$\|g(\hat{x}_k)^+\| \leq \frac{2}{k\alpha r}\left(\frac{f(\bar{x})-\tilde{q}}{\gamma}+r\right)^2+\frac{\alpha L^2}{2r}.$$

(b) The proof follows from an identical argument to that used in the proof of Proposition 1(b), and therefore is omitted.

(c) The result follows from an identical argument to that used in the proof of Proposition 1(c) and the bound on the dual optimal solution set that follows in view of the Slater condition (cf. Assumption 1 and Lemma 1 with $\bar{\mu}=\mu^*$). □

We note here that the subgradient method of (21) with the set D given in (23) couples the computation of multipliers. In some applications, it might be desirable to accommodate distributed computation models whereby the multiplier components μ_j^* are processed in a distributed manner among a set of processors or agents. To accommodate such computations, one may modify the subgradient method of (21) by replacing the set D of (23) with the following set:

$$D_\infty=\left\{\mu\geq 0 \;\middle|\; \|\mu\|_\infty \leq \frac{f(\bar{x})-\tilde{q}}{\gamma}+r\right\}.$$

It can be seen that the results of Proposition 4 also hold for this choice of the projection set. In particular, this can be seen by following the same line of argument as in the proof of Proposition 4 and by using the following relation:

$$\|\bar{\mu}\|_\infty \leq \|\mu^*\|+r \leq \frac{f(\bar{x})-\tilde{q}}{\gamma}+r$$

(cf. (28) and the fact $\|y\|_\infty \leq \|y\|$ for any vector y).

We next consider selecting the parameter r, which is used in the definition of the set D, such that the right-hand side of the bound in part (a) of Proposition 4 is minimized at each iteration k. Given some $k\geq 1$, we choose r as the optimal solution of the problem

$$\min_{r>0}\left\{\frac{2}{k\alpha r}\left(\frac{f(\bar{x})-\tilde{q}}{\gamma}+r\right)^2+\frac{\alpha L^2}{2r}\right\}.$$

It can be seen that the optimal solution of the preceding problem, denoted by $r^*(k)$, is given by

$$r^*(k)=\sqrt{\left(\frac{f(\bar{x})-\tilde{q}}{\gamma}\right)^2+\frac{\alpha^2L^2k}{4}} \qquad \text{for } k\geq 1. \tag{30}$$

Consider now an algorithm where the dual iterates are obtained by

$$\mu_{i+1}=\mathcal{P}_{D_k}\left[\mu_i+\alpha g_k\right] \qquad \text{for each } i\geq 0,$$

with $\mu_0 \in D_0$ and the set D_k given by

$$D_k = \left\{ \mu \geq 0 \mid \|\mu\| \leq \frac{f(\bar{x}) - \tilde{q}}{\gamma} + r^*(k) \right\},$$

where $r^*(k)$ is given by (30). Hence, at each iteration i, the algorithm projects onto the set D_k, which contains the set of dual optimal solutions M^*.

Substituting $r^*(k)$ in the bound of Proposition 4(a), we can see that

$$\begin{aligned} \|g(\hat{x}_k)^+\| &\leq \frac{4}{k\alpha} \left(\frac{f(\bar{x}) - \tilde{q}}{\gamma} + \sqrt{\left(\frac{f(\bar{x}) - \tilde{q}}{\gamma} \right)^2 + \frac{\alpha^2 L^2 k}{4}} \right) \\ &\leq \frac{4}{k\alpha} \left(\frac{2(f(\bar{x}) - \tilde{q})}{\gamma} + \frac{\alpha L \sqrt{k}}{2} \right) \\ &= \frac{8}{k\alpha} \left(\frac{f(\bar{x}) - \tilde{q}}{\gamma} \right) + \frac{2L}{\sqrt{k}}. \end{aligned}$$

The preceding discussion combined with Proposition 4(a) immediately yields the following result.

PROPOSITION 5. *Let the Slater condition and the bounded set assumption hold (cf. Assumptions* 1 *and* 2*). Given some $k \geq 1$, define the set D_k as*

$$D_k = \left\{ \mu \geq 0 \;\middle|\; \|\mu\|_2 \leq \frac{f(\bar{x}) - \tilde{q}}{\gamma} + \sqrt{\left(\frac{f(\bar{x}) - \tilde{q}}{\gamma} \right)^2 + \frac{\alpha^2 L^2 k}{4}} \right\}. \tag{31}$$

Let the dual sequence $\{\mu_i\}$ be generated by the following modified subgradient method: let $\mu_0 \in D_k$, and for each $i \geq 0$ the dual iterate μ_i is obtained by

$$\mu_{i+1} = \mathcal{P}_{D_k} \left[\mu_i + \alpha g_i \right].$$

Then, an upper bound on the amount of feasibility violation of the vector $\hat{x}_k$ is given by

$$\|g(\hat{x}_k)^+\| \leq \frac{8}{k\alpha} \left(\frac{f(\bar{x}) - \tilde{q}}{\gamma} \right) + \frac{2L}{\sqrt{k}}. \tag{32}$$

This result shows that at a given k, the error estimate provided in (32) can be achieved if we use a modified subgradient method where each dual iterate is projected on the set D_k defined in (31). Given a prespecified accuracy for the amount of feasibility violation, this bound can be used to select the stepsize value and the set D_k. Furthermore, using the estimate (32) in Proposition 4(c), we can obtain a lower bound on the cost $f(\hat{x}_k)$.

We now compare the feasibility violation bound of Proposition 3(a) for the ordinary subgradient method with the result of Proposition 5 for the modified subgradient method. As we will see, depending on the values of γ, L, and the estimate $\tilde{q}$, each of these bounds can be better or worse than the other one. For the sake of comparison, let us assume that $\tilde{q}$ is the same in both bounds. Then, by Proposition 5(a) and by using $q^* \geq \tilde{q}$ in the definition of the bound B^* in (17), we obtain, for all $k \geq 1$,

$$\|g(\hat{x}_k)^+\| \leq \frac{2}{k\alpha\gamma} \left(f(\bar{x}) - \tilde{q} \right) + \frac{1}{k\alpha} \max \left\{ \|\mu_0\|, \frac{1}{\gamma} \left(f(\bar{x}) - \tilde{q} \right) + \frac{\alpha L^2}{2\gamma} + \alpha L \right\}. \tag{33}$$

This bound, as compared to that of Proposition 5, is better when k is very large, since the feasibility violation decreases in the order of $1/k$, while in Proposition 5, it decreases in the order of $1/\sqrt{k}$. However, initially, the feasibility violation in (33) for the ordinary subgradient method can be worse because it depends on the initial iterate μ_0. Suppose that the initial iterate is $\mu_0 = 0$. Then, the bound in (33) reduces to

$$\|g(\hat{x}_k)^+\| \leq \frac{3}{k\alpha\gamma}\,[\,f(\bar{x}) - \tilde{q}\,] + \frac{1}{k}\left(\frac{L^2}{2\gamma} + L\right).$$

Even in this case, initially, this bound can be worse than that of Proposition 5 because the bound depends inversely on γ which can be very small (recall $\gamma = \min_{1\leq j\leq m}\{-g_j(\bar{x})\}$ with a Slater vector $\bar{x}$). To complement our theoretical analysis, we need to perform some numerical experiments to further study and compare these algorithms.

6. Conclusions. In this paper, we have studied the application of dual subgradient algorithms for generating primal near-feasible and near-optimal optimal solutions. We have proposed and analyzed two such algorithms under Slater condition. Both of the proposed algorithms use projections to generate a dual sequence and an averaging scheme to produce approximate primal vectors. The algorithms employ the same averaging scheme in the primal space. However, they operate on different sets when projecting in the dual space. One algorithm uses the projections on the nonnegative orthant, while the other algorithm uses the projections on nested compact convex sets that change with each iteration but always contain the dual optimal solutions. Nevertheless, both algorithms produce primal vectors whose infeasibility diminishes to zero and function values in the limit stay within the interval $[f^*, f^* + \alpha L/2]$.

Let us note that, in general, one may consider solving the dual problem to generate a good approximate "dual solution" (with a method more efficient than the subgradient method with a constant step), and then proceed with our algorithm with averaging. This can be advantageous since $x(\mu_k)$ for μ_k far from an optimum can be less informative than those closer to an optimum.[4]

Our comparison of the two methods is purely based on our *theoretical analysis*, which need not reflect the real behavior of these algorithms for practical implementations. Our future goal is to numerically test and evaluate these algorithms in order to gain deeper insights into their behavior.

Acknowledgments. We thank Robert Freund and Pablo Parrilo for useful comments and discussions. Also, we thank Vladimir Norkin and the two anonymous referees for valuable comments and suggestions.

ON MULTIVARIATE DISCRETE MOMENT PROBLEMS: GENERALIZATION OF THE BIVARIATE MIN ALGORITHM FOR HIGHER DIMENSIONS*

GERGELY MÁDI-NAGY†

Abstract. The objective of the multivariate discrete moment problem (MDMP) is to find the minimum and/or maximum of the expected value of a function of a random vector with a discrete finite support where the probability distribution is unknown, but some of the moments are given. The moments may be binomial, power, or of a more general type. The MDMP can be formulated as a linear programming problem with a very ill-conditioned coefficient matrix. Hence, the LP problem can be solved with difficulty or cannot be solved at all. The central results of the field of the MDMP concern the structure of the dual feasible bases. These bases, on one hand, provide us with bounds without any numerical difficulties. On the other hand, they can be used as an initial basis of the dual simplex method. That results in shorter running time and better numerical stability because the first phase can be skipped. This paper introduces a new type of MDMP, where the bivariate moments up to a certain order m consisting of the first variable and further univariate moments up to the order m_j, $j = 1, \dots, s$, are given. Then we generalize the bivariate Min Algorithm of Mádi-Nagy and Prékopa [*Math. Oper. Res.*, 29 (2004), pp. 229–258] for higher dimensions, which gives numerous dual feasible bases of the MDMP. By the aid of this, on one hand, we can give useful bounds for MDMPs with higher dimensional random vectors even if the usual solvers cannot give acceptable results. On the other hand, applying our algorithm for the binomial MDMP, we can give better bounds for probabilities of Boolean functions of event sequences than the recent bounds in the literature. These results are illustrated by numerical examples.

1. Introduction.

1.1. Moment problems. The classical moment problem was introduced in 1894–1895 by Stieltjes [38] (see Kjeldsen [18]). The problem is about trying to invert the mapping that takes a measure P on $I \subset \mathbb{R}$ to the sequences of moments μ_k, $k = 1, 2, 3, \dots$, where the kth, so-called power, moments are defined as

$$\mu_k = \int_I z^k dP.$$

In what follows, we will use the notation μ_0 for $k = 0$, but we know $\mu_0 = 1$. More general moments than the power moments can be defined if we consider the sequence of functions $u_k(z)$, $k = 0, 1, 2, \dots$, which are assumed to be measurable and integrable functions on I. Then the generalized moment sequence with respect to $\{u_k(z)\}$ is

$$\int_I u_k(z) dP, \qquad k = 0, 1, \dots.$$

Sometimes the moment problem is based on these general moments, but typically power moments are used. The questions of the classical moment problem can be the following. Given a sequence of numbers μ_k, $k = 1, 2, 3, \ldots$,

(a) does there exist a probability measure on I with the moments μ_k, $k = 1, 2, 3, \ldots$?
(b) is this probability measure uniquely determined by the moments μ_k, $k = 1, 2, 3, \ldots$?
(c) how can one describe all probability measures on I with the moments μ_k, $k = 1, 2, 3, \ldots$?

Depending on the set I, classical results can be found in Hamburger [12], [13], Hausdorff [14], [15], and Riesz [36]. Akhiezer [1] gives a comprehensive survey of that field.

The truncated variation of the classical moment problem studies the properties of measures with fixed first k moments (for a finite k) or with finite set of moments. Beside the classical questions (existence, uniqueness of the measure P) the following bounding problem arises. Given the moments μ_k, $k = 1, \ldots, m$, or any finite collection of the moments, what are the possible lower and upper bounds for

$$\int_I f(z)dP,$$

where f is a given real function on I and P is unknown, but P has to have the given moments? Let X be a random variable with support I. Assume that the expected values of X^k, $k = 1, \ldots, m$, are given finite values, but the distribution of X is not known. Then the *bounding moment problem* can be formulated as

$$\begin{aligned} &\inf(\sup)\ E[f(X)] = \int_I f(z)dP \\ &\text{subject to} \\ &E[X^k] = \int_I z^k dP = \mu_k, \quad k = 0, 1, \ldots, m, \end{aligned} \tag{1.1}$$

where the probability measure P is unknown, and I, f, μ_k, $k = 0, 1, \ldots, m$, are given. Bounding problems related to moments were first considered by Bienaymé [2], Chebyshev [6], [7], and Markov [23]. The bounding moment problem frequently appears in the literature as Chebyshev-type inequalities. A good summary of these results can be found in Krein and Nudelman [19]. For historical background, see Kjeldsen [18] and Prékopa and Alexe [33].

At the end of the 1980s, Prékopa [25], [26], [27] and Samuels and Studden [37] independently introduced and studied the *univariate discrete moment problem (DMP)*, where $I = \{z_0, z_1, \ldots, z_n\}$ is a discrete finite set. Samuels and Studden use the classical approach and determine the solutions in closed form whenever possible; however, their method is applicable only to small size problems. Prékopa invented a linear programming methodology, presented briefly below. It turns out that in the special case of the DMP, linear programming techniques provide us with more general and simpler algorithmic solutions than the classical ones. Moreover, it allows for an efficient solution of large size moment problems as well as for finding closed form sharp bounds.

The DMP has (at least) three useful properties. The first one is that it uses the discrete property of the support I beside the moment information. Hence, it can give tighter bounds than the classical moment problems. The second one is that the

DMP can be formulated as a linear programming (LP) problem. Let us designate the (unknown) probability distribution of X in the following way:

$$p_i = P(X = z_i), \qquad i = 0, 1, \ldots, n,$$

and let $f(z_i) = f_i$. Then

$$E[f(X)] = f_0 p_0 + f_1 p_1 + \cdots + f_n p_n$$

and

$$E[X^k] = z_0^k p_0 + z_1^k p_1 + \cdots + z_n^k p_n, \qquad k = 0, 1, \ldots, m.$$

The LP corresponding to the DMP is

$$\begin{array}{lrrrcl} \min(\max) & f_0 p_0 & +f_1 p_1 & +\cdots & +f_n p_n & \\ \text{subject to} & & & & & \\ & p_0 & +p_1 & +\cdots & +p_n & = \mu_0 (= 1), \\ & z_0 p_0 & +z_1 p_1 & +\cdots & +z_n p_n & = \mu_1, \\ & z_0^2 p_0 & +z_1^2 p_1 & +\cdots & +z_n^2 p_n & = \mu_2, \\ & & & & & \vdots \\ & z_0^m p_0 & +z_1^m p_1 & +\cdots & +z_n^m p_n & = \mu_m, \\ & p_0, & p_1, & \ldots & p_n & \geq 0, \end{array} \tag{1.2}$$

where the unknown variables are p_i, $i = 0, 1, \ldots, n$. The support $I = \{z_0, z_1, \ldots, z_n\}$, the values of the function $f(z)$, $z \in I$, and the moments μ_k, $k = 0, 1, \ldots, m$, are given. Since the coefficient matrix of (1.2) is an ill-conditioned Vandermonde matrix, the problem usually cannot be solved by general solution methods. However, under some conditions of the function f, Prékopa [27] developed a numerically stable dual method for the solution. This method is based on theorems which give the subscript structures of columns of all dual feasible bases. By the aid of the known dual feasible bases, closed form bounds in terms of the moments can also be given; see Boros and Prékopa [3].

The third useful property is that the optimal solution of the so-called binomial moment problem can give sharp Bonferroni-type bounds and other probability bounds, as well. The kth binomial moment of a random variable X with the support $I \subset \mathbb{N}$ is defined as

$$E\left[\binom{X}{k}\right].$$

Let $A_1, A_2, \ldots, A_n$ be arbitrary events. Let the random variable X with the support $\{0, 1, \ldots, n\}$ be the number of those events which occur. Then the binomial moments of X equals the following (see, e.g., Prékopa [29, p. 182]):

$$E\left[\binom{X}{k}\right] = S_k = \sum_{0 \leq i_1 < i_2 < \cdots < i_k \leq n} P(A_{i_1} \cap A_{i_2} \cap \cdots \cap A_{i_k}), \tag{1.3}$$

$k = 1, 2, \ldots$, and also $E[\binom{X}{0}] = S_0 = 1$. The binomial moment problem has the following form:

$$
\begin{array}{lrlll}
\min(\max) & f_0p_0 & +f_1p_1 \quad +\cdots & +f_np_n & \\
\text{subject to} & & & & \\
& p_0 & +p_1 \quad +\cdots & +p_n & = S_0(=1), \\
& \binom{0}{1}p_0 & +\binom{1}{1}p_1 \quad +\cdots & +\binom{n}{1}p_n & = S_1, \\
& \binom{0}{2}p_0 & +\binom{1}{2}p_1 \quad +\cdots & +\binom{n}{2}p_n & = S_2, \\
& & & & \vdots \\
& \binom{0}{m}p_0 & +\binom{1}{m}p_1 \quad +\cdots & +\binom{n}{m}p_n & = S_m, \\
& p_0, & p_1, \quad \ldots & p_n & \geq 0.
\end{array} \tag{1.4}
$$

If we would like to give bounds for the probability of the union or intersection of all the n events, then we have to consider

$$
f(z) = \begin{cases} 0 \text{ if } z = 0, \\ 1 \text{ otherwise} \end{cases} \quad \text{or } f(z) = \begin{cases} 1 \text{ if } z = s, \\ 0 \text{ otherwise,} \end{cases} \tag{1.5}
$$

respectively. If in problem (1.2) we assume that $\{z_0, z_1, \ldots, z_n\} = \{0, 1, \ldots n\}$, then problems (1.2) and (1.4) can be transformed into each other by simple nonsingular transformations (see Prékopa [25]). This means that the matrices of the equality constraints can be transformed into each other by a nonsingular square matrix and its inverse, respectively. This fact implies that *a basis in problem* (1.2) *is dual feasible if and only if it is dual feasible in* (1.4). Hence, the dual method of Prékopa [27] can be applied as well as closed form bounds can be given for the binomial DMP, too. If we consider the first function in (1.5), then sharp Bonferroni-type bounds can be given for the union of events in terms of $S_0, S_1, \ldots, S_m$; see Prékopa [26], [28], [29] and Boros and Prékopa [3].

1.2. The multivariate discrete moment problem. The multivariate discrete moment problem (MDMP) has been introduced by Prékopa [28] and also discussed in papers by Prékopa [30], [32], Mádi-Nagy and Prékopa [21], and Mádi-Nagy [20]. The MDMP can be formulated as follows. Let $\boldsymbol{X} = (X_1, \ldots, X_s)$ be a random vector and assume that the support of X_j is a known finite set $Z_j = \{z_{j0}, \ldots, z_{jn_j}\}$, consisting of distinct elements, $j = 1, \ldots, s$. A certain set of the following moments will be considered.

DEFINITION 1.1. *The* $(\alpha_1, \ldots, \alpha_s)$-order power moment *of the random vector* $(X_1, \ldots, X_s)$ *is defined as*

$$
\mu_{\alpha_1 \ldots \alpha_s} = E\left[X_1^{\alpha_1} \cdots X_s^{\alpha_s}\right],
$$

where $\alpha_1, \ldots, \alpha_s$ *are nonnegative integers. The sum* $\alpha_1 + \cdots + \alpha_s$ *will be called the* total order of the moment.

We use the following notation for the (unknown) distribution of $\boldsymbol{X}$:

$$
p_{i_1 \ldots i_s} = P(X_1 = z_{1i_1}, \ldots, X_s = z_{si_s}), \qquad 0 \leq i_j \leq n_j,\ j = 1, \ldots, s. \tag{1.6}
$$

Then the moments can be written in the form

$$
\mu_{\alpha_1 \ldots \alpha_s} = \sum_{i_1=0}^{n_1} \cdots \sum_{i_s=0}^{n_s} z_{1i_1}^{\alpha_1} \cdots z_{si_s}^{\alpha_s} p_{i_1 \ldots i_s}.
$$

Let $Z = Z_1 \times \cdots \times Z_s$ and $f(\boldsymbol{z})$, $\boldsymbol{z} \in Z$, be a function. Let

$$
f_{i_1 \ldots i_s} = f(z_{1i_1}, \ldots, z_{si_s}).
$$

The (power) MDMP is to give bounds for

$$E[f(X_1,\dots,X_s)],$$

where distribution of X (i.e., (1.6)) is unknown, but known are the moments

$$\mu_{\alpha_1\dots\alpha_s} \text{ for } (\alpha_1\dots\alpha_s)\in H.$$

We can formulate the problem by the following LP:

$$\begin{aligned} &\min(\max)\ \sum_{i_1=0}^{n_1}\cdots\sum_{i_s=0}^{n_s} f_{i_1\dots i_s}p_{i_1\dots i_s} \\ &\text{subject to} \\ &\sum_{i_1=0}^{n_1}\cdots\sum_{i_s=0}^{n_s} z_{1i_1}^{\alpha_1}\cdots z_{si_s}^{\alpha_s}p_{i_1\dots i_s}=\mu_{\alpha_1\dots\alpha_s} \\ &\text{for } (\alpha_1\dots\alpha_s)\in H, \\ &p_{i_1\dots i_s}\ge 0 \text{ for all } i_1,\dots,i_s. \end{aligned} \tag{1.7}$$

In problem (1.7) $p_{i_1\dots i_s}$, $0\le i_j\le n_j$, $j=1,\dots,s$, are the unknown variables; all other parameters (i.e., the function f and the moments) are given. Regarding the set H, in the literature the following are considered. In Prékopa [30], [32]

$$H=\{(\alpha_1,\dots,\alpha_s)|\ 0\le\alpha_j,\ \alpha_j \text{ integer}, \alpha_1+\cdots+\alpha_s\le m,\ j=1,\dots,s\}, \tag{1.8}$$

where m is a given nonnegative integer, and

$$H=\{(\alpha_1\dots\alpha_s)|\ 0\le\alpha_j\le m_j, \alpha_j \text{ integer},\ j=1,\dots,s\}, \tag{1.9}$$

where m_j, $j=1,\dots,s$, are given nonnegative integers. In Mádi-Nagy and Prékopa [21] and Mádi-Nagy [20]

$$\begin{aligned} &H=\{(\alpha_1,\dots,\alpha_s)|\ 0\le\alpha_j,\ \alpha_j \text{ integer}, \alpha_1+\cdots+\alpha_s\le m,\ j=1,\dots,s; \\ &\text{or } \alpha_j=0,\ j=1,\dots,k-1,k+1,\dots,s,\ m\le\alpha_k\le m_k,\ k=1,\dots,s\} \end{aligned} \tag{1.10}$$

was considered.

The MDMP, beside arising in a natural way, can be applied in several other fields, e.g., bounding expected utilities (Prékopa and Mádi-Nagy [35]), solving generalized s-dimensional transportation problems (Hou and Prékopa [16]) and approximating values of multivariate generating functions (Mádi-Nagy and Prékopa [22]). One of the most popular applications is to bound probabilities of Boolean functions of events. These results are based on the binomial MDMP. Let us introduce the notion of cross-binomial moments.

DEFINITION 1.2. *The* $(\alpha_1,\dots,\alpha_s)$-order cross-binomial moment *of the random vector* $(X_1,\dots,X_s)$*, with the support* $Z\subset\mathbb{N}^s$*, is defined as*

$$S_{\alpha_1\dots\alpha_s}=E\left[\binom{X_1}{\alpha_1}\cdots\binom{X_s}{\alpha_s}\right],$$

where $\alpha_1,\dots,\alpha_s$ *are nonnegative integers. The sum* $\alpha_1+\cdots+\alpha_s$ *will be called* the total order of the moment.

Assume that we have n arbitrary events. We can subdivide them into s subsequences. Let the jth subsequence be designated as $A_{j1},\dots,A_{jn_j}$, $j=1,\dots,s$.

Certainly, $n_1 + \cdots + n_s = n$. Let the random variable X_j with the support $Z_j = \{0, 1, \ldots, n_j\}$ be the number of events that occur in the jth sequence, $j = 1, \ldots, s$. In case of event sequences

$$E\left[\binom{X_1}{\alpha_1}\cdots\binom{X_s}{\alpha_s}\right] = \sum_{\substack{1\le i_{j1}<\cdots<i_{j\alpha_j}\le n_j,\\ j=1,\ldots,s}} P[A_{1i_{11}}\cap\cdots\cap A_{1i_{1\alpha_1}}\cap\cdots\cap A_{si_{s1}}\cap\cdots\cap A_{si_{s\alpha_s}}],$$

in accordance with the notation $S_{\alpha_1\ldots\alpha_s}$ of Definition 1.2. The binomial MDMP can be formulated by the following LP:

$$\begin{aligned} &\min(\max)\ \sum_{i_1=0}^{n_1}\cdots\sum_{i_s=0}^{n_s} f_{i_1\ldots i_s}p_{i_1\ldots i_s} \\ &\text{subject to} \\ &\sum_{i_1=0}^{n_1}\cdots\sum_{i_s=0}^{n_s}\binom{i_1}{\alpha_1}\cdots\binom{i_s}{\alpha_s}p_{i_1\ldots i_s} = S_{\alpha_1\ldots\alpha_s} \\ &\quad\text{for } (\alpha_1\ldots\alpha_s)\in H, \\ &p_{i_1\ldots i_s}\ge 0 \text{ for all } i_1,\ldots,i_s. \end{aligned} \tag{1.11}$$

If we would like to give bounds for the probability of the union or intersection of all the n events, then we have to consider

$$f(z_1,\ldots,z_s) = \begin{cases} 0 \text{ if } (z_1,\ldots,z_s) = (0,\ldots,0), \\ 1 \text{ otherwise} \end{cases} \tag{1.12}$$

or

$$f(z_1,\ldots,z_s) = \begin{cases} 1 \text{ if } (z_1,\ldots,z_s) = (n_1,\ldots,n_j), \\ 0 \text{ otherwise,} \end{cases} \tag{1.13}$$

respectively. If we assume in problem (1.7) that $Z_j = \{0, 1, \ldots, n_j\}$, $j = 1, \ldots, s$, then in the case of the set H (1.10) and (1.8), problems (1.7) and (1.11) can be transformed into each other by simple nonsingular transformations, similar to in the univariate case. Hence, *the dual feasible basis columns in the binomial MDMP and in its transformed power MDMP pair are the same*. The binomial MDMP gives a useful tool to approximate the unknown probabilities, e.g., in network reliability calculation (Habib and Szántai [11]) as well as in probabilistic constrained stochastic programming models (Prékopa [31], Fábián and Szőke [8]). It can also be a good alternative to the bounding techniques of Bukszár and Prékopa [4] and Bukszár and Szántai [5]. This type of probability bound is also useful in developing variance reduction Monte-Carlo simulation algorithms for estimating the exact probability values (Szántai [39], [40]).

Unfortunately, in case of the MDMP we cannot give all the dual feasible structures under any assumption on the function f; hence, we cannot generalize the numerically stable dual method of DMP for the multivariate case. However, under some circumstances, we can give some dual feasible bases which can be used as an initial basis in the dual method. This means, on one hand, that we can skip the first phase in the execution of the dual algorithm, which results in shorter running time and better numerical stability. On the other hand, the objective function value corresponding to a dual feasible basic solution yields a bound for the optimum value of problem (1.7). Hence, if we know a large variety of dual feasible bases, then the best bounds corresponding to those bases can give a good approximation to the optimum value

without any numerical difficulties. In case of (1.9) we know enough dual feasible bases for the approximation, but *in the case of* (1.10) *(and* (1.8)*)* a large number of dual feasible bases are known *only in the bivariate case (*i.e.*,* $s = 2$*).*

The main result of this paper is that we generalize the dual feasible basis structures corresponding to the bivariate case of the set H (1.10), for higher dimensions. We follow a similar way as in the Min and Max Algorithms of Mádi-Nagy and Prékopa [21], but we define a new set of H:

$$
\begin{aligned}
H \quad = \quad & \{(\alpha_1, 0, \ldots, 0, \alpha_j, 0, \ldots, 0) |\ 0 \le \alpha_1, \alpha_j,\ \alpha_1, \alpha_j \text{ integer},\ \alpha_1 + \alpha_j \le m, \\
& j = 2, \ldots, s; \} \\
& \cup \{(0, \ldots, 0, \alpha_j, 0, \ldots, 0) |\ m + 1 \le \alpha_j \le m_j,\ \alpha_j \text{ integer},\ \ j = 1, \ldots, s\}.
\end{aligned} \tag{1.14}
$$

It is easy to see that, in the bivariate case, set (1.14) and set (1.10) are the same. The choice of (1.14) allows us to give a large variety of dual feasible bases of higher dimensional MDMPs under some assumptions on the function f. *In case of* H (1.14) *the power and the binomial MDMP can be transformed into each other by simple nonsingular transformations, which means that the given dual feasible bases can be used in the binomial MDMP, too.* The advantage of a large set of directly given dual feasible bases is twofold. On one hand, we can give good bounds without numerical difficulties even if regular solvers cannot give any useful results. On the other hand, in case of the binomial MDMP, we can take binomial moments (i.e., sums of probabilities of intersections of events) of many subsets of the events into account. Hence, the dual feasible bases of the binomial MDMP can yield better bounds than the bounding methods based on the information of the individual probabilities of the intersection of events, e.g., the method of Bukszár and Prékopa [4]. These advantages will be illustrated by numerical examples.

Our bounding technique of the MDMP is based on multivariate Lagrange interpolation. In section 3 we give a multivariate Lagrange polynomial with prescribed degrees of the variables that approximates the function values of $f(z_1, \ldots, z_s)$, $(z_1, \ldots, z_s) \in Z$ from below or above under some assumptions on the function f.

This paper is organized as follows. In section 2 we present the connection between the MDMP and the multivariate Lagrange interpolation; in section 3 we prove a theorem on multivariate Lagrange interpolation corresponding to our new MDMP. In section 4 we give several dual feasible bases as well as bounds of the MDMP with the set H (1.14). In section 5 numerical examples are presented.

2. The MDMP and the multivariate Lagrange interpolation. In case of univariate Lagrange interpolation concerning arbitrary distinct points $z_0, \ldots, z_n \in \mathbb{R}$ a unique interpolation polynomial of degree n can be given. The multivariate case is much more difficult. On one hand, it is difficult to identify the geometric distribution of the interpolation points for which we can give a (unique) multivariate Lagrange polynomial with prescribed degrees of the variables. On the other hand, it is also difficult to give an appropriate reminder formula.

Regarding the degrees of the Lagrange polynomial we give the following definition.

DEFINITION 2.1. *Let* $H = \{(\alpha_1, \ldots, \alpha_s)\}$ *be a finite set of* s*-tuples of nonnegative integers* $(\alpha_1, \ldots, \alpha_s)$*, and* $\boldsymbol{z} = (z_1, \ldots z_s) \in \mathbb{R}^s$*. We say that* $p(\boldsymbol{z})$ is an H-type polynomial *if its variables have the degrees from the set* H*, i.e.,*

$$
p(\boldsymbol{z}) = \sum_{(\alpha_1, \ldots, \alpha_s) \in H} c_{\alpha_1 \cdots \alpha_s} z_1^{\alpha_1} \cdots z_s^{\alpha_s}, \tag{2.1}
$$

where all $c_{\alpha_1 \cdots \alpha_s}$ *are real.*

On the geometric distributions of the interpolation points we can give the following definition.

DEFINITION 2.2. *Let $U = \{\boldsymbol{u}_1, \dots, \boldsymbol{u}_M\}$ be a set of distinct points in $\mathbb{R}^s$ and $H = \{(\alpha_1, \dots, \alpha_s)\}$ a finite set of s-tuples of nonnegative integers $(\alpha_1, \dots, \alpha_s)$. We say that the set U admits an H-type Lagrange interpolation if for any real function $f(\boldsymbol{z})$, $\boldsymbol{z} \in U$, there exists an H-type polynomial $p(\boldsymbol{z})$, such that*

$$p(\boldsymbol{u}_i) = f(\boldsymbol{u}_i), \qquad i = 1, \dots, M. \tag{2.2}$$

In the literature of multivariate Lagrange interpolation the notion of poised set of points is usual; see, e.g., Definition 1.1 in Gasca and Sauer [9]. Regarding this, Definition 2.2 is equivalent to the notion that the set of points U is *poised* in the linear space of H-type Lagrange polynomials. However, in this paper our definition is more appropriate because, in contrast with other papers on interpolation, we do not deal explicitly with the linear space of polynomials.

The problem of H-type Lagrange interpolation in case of set H (1.8) and (1.9) was discussed in several papers. A good survey on this topic with results can be found in Gasca and Sauer [9]; an earlier historical background is presented in Gasca and Sauer [10]. The case of the set H (1.10) was first investigated in Mádi-Nagy and Prékopa [21]. The results of our case (1.14) will be presented in the following section.

Regarding the connection between the MDMP and the multivariate Lagrange interpolation we should consider the following. Let us use the following notation for the compact matrix form of (1.7), for a given set H:

$$\begin{array}{rl} & \min(\max) \quad \boldsymbol{f}^T\boldsymbol{p} \\ \text{subject to} & \\ & \begin{array}{rcl} A\boldsymbol{p} & = & \boldsymbol{b}, \\ \boldsymbol{p} & \geq & \boldsymbol{0}. \end{array} \end{array} \tag{2.3}$$

DEFINITION 2.3. *Let $\boldsymbol{b}(z_1, \dots, z_s)$ be defined in a similar way as $\boldsymbol{b}$, but we remove the expectation and replace z_j for X_j, $j = 1, \dots, s$; i.e., if we consider a component of the vector $\boldsymbol{b}$, which can be written as $\mu_{\alpha_1 \cdots \alpha_s} = E[X_1^{\alpha_1} \cdots X_s^{\alpha_s}]$ $((\alpha_1, \dots \alpha_s) \in H)$, then the corresponding component of the vector $\boldsymbol{b}(z_1, \dots, z_s)$ will be $z_1^{\alpha_1} \cdots z_s^{\alpha_s}$.*

THEOREM 2.1. *Let us consider a basis B of problem (2.3). Note that the term "basis" as well as the symbol B mean a matrix and, at the same time, the collection of its column vectors. Let I be the set of subscripts corresponding to the columns of B, i.e.,*

$$I = \{(i_1, \dots, i_s) |\ a_{i_1 \cdots i_s} \in B\}, \tag{2.4}$$

where $a_{i_1 \cdots i_s}$ indicates the column of the coefficient matrix A corresponding to the point $(z_{1i_1}, \dots, z_{si_s})$. If we consider the set of distinct points in $\mathbb{R}^s$

$$U = \{(z_{1i_1}, \dots, z_{si_s}) |\ (i_1, \dots, i_s) \in I\}, \tag{2.5}$$

then

$$L_I(z_1, \dots, z_s) \quad = \quad \boldsymbol{f}_B^T B^{-1} \boldsymbol{b}(z_1, \dots, z_s) \tag{2.6}$$

is the unique H-type Lagrange polynomial corresponding to the set U.

Proof. The proof of fitting the interpolation points is yielded by substitution. The uniqueness follows from the fact that if the vector $\boldsymbol{c}$ consists of the corresponding

coefficients of an H-type Lagrange polynomial fitting the set U, then it should be the solution of

$$\boldsymbol{c}^T B = \boldsymbol{f}_B^T. \tag{2.7}$$

Indeed, the only solution of (2.7) is $\boldsymbol{c}^T = \boldsymbol{f}_B^T B^{-1}$. □

THEOREM 2.2. *Let V_{min} (V_{max}) designate the minimum (maximum) value in problem* (2.3). *Further let B_1 (B_2) designate a dual feasible basis, i.e.,*

$$\begin{aligned} &\boldsymbol{f}_{B_1}^T {B_1}^{-1} \boldsymbol{a}_{i_1 \cdots i_s} \le f_{i_1 \cdots i_s} \text{ for all } (z_{i_1}, \ldots, z_{i_s}) \in Z, \\ &(\boldsymbol{f}_{B_2}^T {B_2}^{-1} \boldsymbol{a}_{i_1 \cdots i_s} \ge f_{i_1 \cdots i_s} \text{ for all } (z_{i_1}, \ldots, z_{i_s}) \in Z), \end{aligned} \tag{2.8}$$

for the minimization (maximization) problem. Relation (2.8) *is called the condition of optimality of the minimization (maximization) problem* (2.3). *Then*

$$\boldsymbol{f}_{B_1}^T \boldsymbol{p}_{B_1} \le V_{min} \le E\left[f(X_1, \ldots, X_s)\right] \le V_{max} \le \boldsymbol{f}_{B_2}^T \boldsymbol{p}_{B_2}. \tag{2.9}$$

If B_1 (B_2) is an optimal basis in the minimization (maximization) problem, then the first (last) inequality holds with equality sign. We say that V_{min} and V_{max} are the sharp lower and upper bounds, respectively, for the expectation of $f(X_1, \ldots, X_s)$.

Proof. The theorem follows from the basic results of linear programming theory. □

By the aid of dual feasible bases we can give a special multivariate Lagrange interpolation that approximates the function values of $f(z_1, \ldots, z_s)$ from below (above) in case of the min (max) problem of (2.3).

THEOREM 2.3. *If the basis B is dual feasible in the minimization (maximization) problem and the subscript set I is defined as in* (2.4), *then*

$$\begin{aligned} &f(z_1, \ldots, z_s) \ge L_I(z_1, \ldots, z_s) \text{ for all } (z_1, \ldots, z_s) \in Z, \\ &(f(z_1, \ldots, z_s) \le L_I(z_1, \ldots, z_s) \text{ for all } (z_1, \ldots, z_s) \in Z), \end{aligned} \tag{2.10}$$

where equality holds in case of $(z_1, \ldots, z_s) \in U$ of (2.5). *Regarding $E[f(X_1, \ldots, X_s)]$ we have the following bound:*

$$\begin{aligned} &E[f(X_1, \ldots, X_s)] \ge E[L_I(X_1, \ldots, X_s)], \\ &(E[f(X_1, \ldots, X_s)] \le E[L_I(X_1, \ldots, X_s)]). \end{aligned} \tag{2.11}$$

If the basis is also primal feasible, then it is optimal and, thus, the obtained bound is sharp.

Proof. The inequality (2.10) follows from (2.6) and (2.8). The bound (2.11) can be obtained if we replace $(X_1, \ldots, X_s)$ for $(z_1, \ldots, z_s)$ and take the expectations in (2.10). □

THEOREM 2.4. *Assume that $L_I(\boldsymbol{z})$ is an H-type Lagrange polynomial corresponding to the points Z_I and inequality* (2.10) *is satisfied. If the columns in the* min *(*max*) problem* (2.3) *corresponding to the interpolation points Z_I are linearly independent, then they form a dual feasible basis.*

Proof. Let B_1 (B_2) be the matrix that consists of the columns corresponding to the points of Z_I. Since B_1 (B_2) is basis, (2.10) is equivalent to the condition of optimality (2.8). Thus, B_1 (B_2) is dual feasible in the min (max) problem (2.3). □

In the following section we give a formula of an H-type Lagrange polynomial and its remainder, where the set H is the type of (1.14). We fix only the subscript set I of the interpolation points, which means that we can get several sets

$$Z_I = \{(z_{1i_1}, \ldots, z_{si_s}) |\ (i_1, \ldots, i_s) \in I\} \tag{2.12}$$

that admit an H-type Lagrange interpolation. Indeed, if we change the order of the elements in the sequence $\{z_{j0},\dots,z_{jn_j}\}$ (or, equivalently, we change the subscripts of the elements within the sets Z_j), $j=1,\dots,s$, then the set of interpolation points Z_I will be different.

The coefficients of the Lagrange polynomial will be given in terms of the multivariate divided differences of the function f. Hence, we give the following definition.

DEFINITION 2.4. *Let $f(z),\ z\in\{z_0,\dots,z_n\}$, be a univariate discrete function, where $z_0,\dots,z_n$ are distinct real numbers,*

$$[z_i;f]:=f(z_i),\ \textit{where } z_i\in\{z_0,\dots,z_n\}.$$

The kth order (univariate) divided differences *($k\geq 1$) are defined recursively:*

$$[z_i,\dots,z_{i+k};f]=\frac{[z_{i+1},\dots,z_{i+k};f]-[z_i,\dots,z_{i+k-1};f]}{z_{i+k}-z_i},\ \text{where } z_i\in\{z_0,\dots,z_n\}.$$

DEFINITION 2.5. *Let $f(\boldsymbol{z}),\ \boldsymbol{z}\in Z=Z_1\times\cdots\times Z_s$, be a multivariate discrete function and take the subset*

$$\begin{aligned} Z_{I_1\dots I_s} &= \{z_{1i},\ i\in I_1\}\times\cdots\times\{z_{si},\ i\in I_s\}\\ &= Z_{1I_1}\times\cdots\times Z_{sI_s}, \end{aligned} \tag{2.13}$$

*where $|I_j|=k_j+1,\ j=1,\dots,s$. Then we can define the $(k_1,\dots,k_s)$-*order (multivariate) divided difference of *f on the set* (2.13) *in an iterative way. First we take the k_1th divided difference with respect to the first variable, then the k_2th divided difference with respect to the second variable, etc. These operations can be executed in any order even in a mixed manner, the result always being the same. Let*

$$[z_{1i},\ i\in I_1;\cdots;z_{si},\ i\in I_s;f] \tag{2.14}$$

designate the $(k_1,\dots,k_s)$-order divided difference. The sum $k_1+\cdots+k_s$ is called the total order of the divided difference.

In order to make the definition easier to understand we present the following example.

Example 2.1.

$$[z_{10},z_{11};z_{20},z_{21};f]=\left[z_{20},z_{21};\frac{f(z_{11},z_2)-f(z_{10},z_2)}{z_{11}-z_{10}}\right]$$

$$=\frac{\frac{f(z_{11},z_{21})-f(z_{10},z_{21})}{z_{11}-z_{10}}-\frac{f(z_{11},z_{20})-f(z_{10},z_{20})}{z_{11}-z_{10}}}{z_{21}-z_{20}}.$$

3. A theorem on multivariate Lagrange interpolation. Let $f(\boldsymbol{z})$, $\boldsymbol{z}\in Z=Z_1\times\cdots\times Z_s$, where $Z_j=\{z_{j0},\dots,z_{jn_j}\}$ consists of distinct real values, $j=1,\dots,s$. In this section we present an H-type Lagrange polynomial and its remainder on the interpolation points $Z_I=\{(z_{1i_1},\dots,z_{si_s})|\ (i_1,\dots,i_s)\in I\}$, where the set H is defined by (1.14) and

$$I=\left(\bigcup_{j=1}^{s}I_j\right)\cup\left(\bigcup_{j=1}^{s}J_j\right), \tag{3.1}$$

where

$$I_1 = \{(i_1, 0, \dots, 0) |\ 0 \le i_1 \le m-1,\ \text{integers}\}, \tag{3.2}$$

$$I_j = \{(i_1, 0, \dots, 0, i_j, 0, \dots, 0) |\ 0 \le i_1,\ 1 \le i_j \le m-1,\ \text{integers},\ i_1 + i_j \le m\},\quad j = 2, \dots, s,$$

and

$$\begin{aligned} &J_j = \{(0, \dots, 0, i_j, 0, \dots, 0) |\ i_j \in K_j\},\\ &K_j = \{k_j^{(1)}, \dots, k_j^{(|K_j|)}\} \subset \{m, m+1, \dots, n_j\},\\ &|K_j| = mj + 1 - m,\ j = 1, \dots, s. \end{aligned} \tag{3.3}$$

In what follows we will use the notations

$$\begin{aligned} Z_{ji} &= \{z_{j0}, \dots, z_{ji}\},\\ Z'_{ji} &= \{z_{j0}, \dots, z_{ji}, z_j\},\\ &\quad i = 0, \dots, n_j,\ j = 1, \dots, s, \end{aligned}$$

and

$$\begin{aligned} K_{ji} &= \{k_j^{(1)}, \dots, k_j^{(i)}\},\\ Z_{jK_{ji}} &= \{z_{jk_j^{(1)}}, \dots, z_{jk_j^{(i)}}\},\\ &\quad i = 1, \dots, |K_j|,\ j = 1, \dots, s,\\ Z_{jK_j} &= Z_{jK_{j|K_j|}},\ j = 1, \dots, s. \end{aligned}$$

We assign the Lagrange polynomial, given by its Newton form

$$\begin{aligned} &L_I(z_1, \dots, z_s)\\ &= \sum_{i_1=0}^{m-1} [Z_{1i_1}; Z_{20}; \cdots; Z_{s0}; f] \prod_{k=0}^{i_1-1} (z_1 - z_{1k})\\ &+ \sum_{j=2}^{s} \sum_{\substack{i_1+i_j \le m\\ 1 \le i_j \le m-1}} \left[Z_{1i_1}; Z_{20}; \cdots; Z_{(j-1)0}; Z_{ji_j}; Z_{(j+1)0}; Z_{s0}; f\right]\\ &\qquad \times \prod_{k=0}^{i_1-1} (z_1 - z_{1k}) \prod_{k=0}^{i_j-1} (z_j - z_{jk})\\ &+ \sum_{j=1}^{s} \sum_{i=1}^{|K_j|} \left[Z_{10}; \cdots; Z_{(j-1)0}; Z_{j(m-1)} \cup Z_{jK_{ji}}; Z_{(j+1)0}; \cdots; Z_{s0}; f\right]\\ &\qquad \times \prod_{\substack{k \in \{0, \dots, m-1\} \cup K_{j(i-1)}\\ k \ne i_j - 1}} (z_j - z_{jk}), \end{aligned} \tag{3.4}$$

where, by definition, $\prod_{k=0}^{i_j-1} (z_j - z_{jk}) = 1$, for $i_j = 0$, and $K_{j0} = \emptyset$.

In (3.4) the function f is not necessarily restricted to the set Z as its domain of definition; it may be defined on any subset of $\mathbb{R}^s$ that contains Z.

Next, we define the residual function:

$$R_I(z_1, \dots, z_s) = R_{1I}(z_1, \dots, z_s) + R_{2I}(z_1, \dots, z_s) + R_{3I}(z_1, \dots, z_s), \tag{3.5}$$

where

$$
\begin{aligned}
&R_{1I}(z_1,\dots,z_s)\\
&=\sum_{j=1}^{s}\left[z_{10};\cdots;z_{(j-1)0};Z_{j(m-1)}\cup Z_{jK_j}\cup\{z_j\};z_{(j+1)0};\cdots;z_{s0};f\right]\\
&\qquad\times\prod_{k\in\{0,\dots,m-1\}\cup K_j}(z_j-z_{jk})
\end{aligned}
\tag{3.6}
$$

and

$$
\begin{aligned}
&R_{2I}(z_1,\dots,z_s)\\
&=\sum_{j=2}^{s}\Bigg(\sum_{\substack{i_1+i_j=m\\0\le i_1,i_j\le m-1}}\left[Z'_{1i_1};Z_{20};\cdots;Z_{(j-1)0};Z_{ji_j};Z_{(j+1)0};\cdots;Z_{s0};f\right]\\
&\qquad\times\prod_{l=0}^{i_1}(z_1-z_{1l})\prod_{k=0}^{i_j-1}(z_j-z_{jk})\\
&\qquad+[Z'_{10};Z_{20};\cdots;Z_{(j-1)0};Z'_{j(m-1)};Z_{(j+1)0};\cdots;Z_{s0};f]\\
&\qquad\times(z_1-z_{10})\prod_{k=0}^{m-1}(z_j-z_{jk})\Bigg)
\end{aligned}
\tag{3.7}
$$

and

$$
\begin{aligned}
&R_{3I}(z_1,\dots,z_s)\\
&=\sum_{h=2}^{s-1}\sum_{j=h+1}^{s}\left[z_1;\cdots;z_{h-1};Z'_{h0};Z_{(h+1)0};\cdots;Z_{(j-1)0};Z'_{j0};Z_{(j+1)0};\cdots;Z_{s0};f\right]\\
&\qquad\times(z_h-z_{h0})(z_j-z_{j0}).
\end{aligned}
\tag{3.8}
$$

We prove the following theorem.

THEOREM 3.1. *Consider the H-type Lagrange polynomial* (3.4)*, corresponding to the points Z_I. For any $\boldsymbol{z}=(z_1,\dots,z_s)$ for which the function f is defined, we have the equality*

$$
L_I(z_1,\dots,z_s)+R_I(z_1,\dots,z_s)=f(z_1,\dots,z_s).
\tag{3.9}
$$

Proof. For the sake of simplicity we assume that $m_j\le n_j$, $j=1,\dots,s$. The proof of the general case needs only slight modification. Now we consider the following lemma.

LEMMA 3.2. *We have the equality*

$$
\begin{aligned}
&L_I(z_1,\dots,z_s)+R_{1I}(z_1,\dots,z_s)\\
&=\sum_{i_1=0}^{m-1}[Z_{1i_1};Z_{20};\cdots;Z_{s0};f]\prod_{k=0}^{i_1-1}(z_1-z_{1k})\\
&+\sum_{j=2}^{s}\sum_{\substack{i_1+i_j\le m\\1\le i_j\le m-1}}\left[Z_{1i_1};Z_{20};\cdots;Z_{(j-1)0};Z_{ji_j};Z_{(j+1)0};Z_{s0};f\right]\\
&\times\prod_{l=0}^{i_1-1}(z_1-z_{1l})\prod_{k=0}^{i_j-1}(z_j-z_{jk})\\
&+\sum_{j=1}^{s}[Z_{10};\cdots;Z_{(j-1)0};Z'_{j(m-1)};Z_{(j+1)0};\cdots;Z_{s0};f]\prod_{k=0}^{m-1}(z_j-z_{jk}).
\end{aligned}
\tag{3.10}
$$

Proof of Lemma 3.2. The proof is the same as that of Lemma 3.2 in Mádi-Nagy and Prékopa [21]. □

LEMMA 3.3.

$$
\begin{aligned}
&L_I(z_1,\dots,z_s)+R_{1I}(z_1,\dots,z_s)+R_{2I}(z_1,\dots,z_s)\\
&=[z_1;Z_{20};\cdots;Z_{s0};f]\\
&+\sum_{j=2}^{s}\left[z_1;Z_{20};\cdots;Z_{(j-1)0};Z'_{j0};Z_{(j+1)0};\cdots;Z_{s0};f\right](z_j-z_{j0}).
\end{aligned}
\tag{3.11}
$$

Proof of Lemma 3.3. Let us look at the terms of (3.7) and (3.11) as univariate functions of z_1. Adding up the first term of (3.10) and the case of $j=1$ in the third term of (3.10) we get the first term of (3.11); i.e.,

$$
\sum_{i_1=0}^{m-1}[Z_{1i_1};Z_{20};\cdots;Z_{s0};f]\prod_{k=0}^{i_1-1}(z_1-z_{1k})+[Z'_{1(m-1)};Z_{20};\cdots;Z_{s0};f]\prod_{k=0}^{m-1}(z_1-z_{1k})
$$

$$
=[z_1;Z_{20};\cdots;Z_{s0};f]. \tag{3.12}
$$

Let us consider the terms of the second sum of (3.10) for a given value of j and i_j. Adding them to the terms of the first part of the sum of (3.7) with the same value of j and i_j we have

$$
\sum_{i_1\le m-i_j}\left[Z_{1i_1};Z_{20};\cdots;Z_{(j-1)0};Z_{ji_j};Z_{(j+1)0};Z_{s0};f\right]\prod_{k=0}^{i_j-1}(z_j-z_{jk})\prod_{l=0}^{i_1-1}(z_1-z_{1l})
$$

$$
+[Z'_{1(m-i_j)};Z_{20};\cdots;Z_{(j-1)0};Z_{ji_j};Z_{(j+1)0};\cdots;Z_{s0};f]\prod_{k=0}^{i_j-1}(z_j-z_{jk})\prod_{l=0}^{m-i_j}(z_1-z_{1l})
$$

$$
=\left[z_1;Z_{20};\cdots;Z_{(j-1)0};Z_{ji_j};Z_{(j+1)0};\cdots;Z_{s0};f\right]\prod_{k=0}^{i_j-1}(z_j-z_{jk}). \tag{3.13}
$$

Adding up all terms of (3.10) and (3.7) corresponding to a given $2\le j\le s$, by the use of the result (3.13) we have

$$
\sum_{i_j=1}^{m-1}\left[z_1;Z_{20};\cdots;Z_{(j-1)0};Z_{ji_j};Z_{(j+1)0};\cdots;Z_{s0};f\right]\prod_{k=0}^{i_j-1}(z_j-z_{jk})
$$

$$
+[Z_{10};\cdots;Z_{(j-1)0};Z'_{j(m-1)};Z_{(j+1)0};\cdots;Z_{s0};f]\prod_{k=0}^{m-1}(z_j-z_{jk})
$$

$$
+[Z'_{10};Z_{20};\cdots;Z_{(j-1)0};Z'_{j(m-1)};Z_{(j+1)0};\cdots;Z_{s0};f](z_1-z_{10})\prod_{k=0}^{m-1}(z_j-z_{jk})
$$

$$
\begin{aligned}
&= \sum_{i_j=1}^{m-1} \left[z_1; Z_{20}; \cdots; Z_{(j-1)0}; Z_{ji_j}; Z_{(j+1)0}; \cdots; Z_{s0}; f\right] \prod_{k=0}^{i_j-1} (z_j - z_{jk}) \\
&+ \left[z_1; Z_{20}; \cdots; Z_{(j-1)0}; Z'_{j(m-1)}; Z_{(j+1)0}; \cdots; Z_{s0}; f\right] \prod_{k=0}^{m-1} (z_j - z_{jk}) .
\end{aligned} \tag{3.14}
$$

Considering (3.14) as a function of z_j we get that this sum equals

$$
\left[z_1; Z_{20}; \cdots; Z_{(j-1)0}; Z'_{j0}; Z_{(j+1)0}; \cdots; Z_{s0}; f\right] (z_j - z_{j0}) . \tag{3.15}
$$

Adding up (3.12) and the terms (3.15) for $j = 2, \ldots, s$ we get (3.11). Thus, the lemma is proven. □

Proof of Theorem 3.1. We prove that

$$
\begin{aligned}
&(L_I(z_1, \ldots, z_s) + R_{1I}(z_1, \ldots, z_s) + R_{2I}(z_1, \ldots, z_s)) + R_{3I}(z_1, \ldots, z_s) \\
&= f(z_1, \ldots, z_s),
\end{aligned}
$$

where the brackets emphasize that we will use (3.11). Let us choose the $h = 2$ case in the sum of (3.8) and add it to (3.11). Considering them as univariate functions of z_2 the result is

$$
\begin{aligned}
&\sum_{j=3}^{s} \left[z_1; Z'_{20}; Z_{30}; \cdots; Z_{(j-1)0}; Z'_{j0}; Z_{(j+1)0}; \cdots; Z_{s0}; f\right] (z_2 - z_{20}) (z_j - z_{j0}) \\
&+ [z_1; Z_{20}; \cdots; Z_{s0}; f] + \sum_{j=2}^{s} \left[z_1; Z_{20}; \cdots; Z_{(j-1)0}; Z'_{j0}; Z_{(j+1)0}; \cdots; Z_{s0}; f\right] (z_j - z_{j0}) \\
&= ([z_1; Z_{20}; \cdots; Z_{s0}; f] + [z_1; Z'_{20}; Z_{30}; \cdots; Z_{s0}; f] (z_2 - z_{20})) \\
&+ \left(\sum_{j=3}^{s} \left[z_1; Z_{20}; \cdots; Z_{(j-1)0}; Z'_{j0}; Z_{(j+1)0}; \cdots; Z_{s0}; f\right] (z_j - z_{j0}) \right. \\
&\left. + \sum_{j=3}^{s} \left[z_1; Z'_{20}; Z_{30}; \cdots; Z_{(j-1)0}; Z'_{j0}; Z_{(j+1)0}; \cdots; Z_{s0}; f\right] (z_2 - z_{20}) (z_j - z_{j0}) \right)
\end{aligned}
$$

$$
\begin{aligned}
&= [z_1; z_2; Z_{30}; \cdots; Z_{s0}; f] \\
&+ \sum_{j=3}^{s} \left[z_1; z_2; Z_{30}; \cdots; Z_{(j-1)0}; Z'_{j0}; Z_{(j+1)0}; \cdots; Z_{s0}; f\right] (z_j - z_{j0}) .
\end{aligned} \tag{3.16}
$$

Adding the $h = 3$ case in the sum of (3.8) to (3.16) we get a similar formula with z_3 in the places of the third variable. Finally, after choosing all the cases $h = 2, 3, \ldots, s-1$ in (3.8) and adding them in this order to (3.16) we have

$$
[z_1; z_2; \cdots, z_{s-1}; Z_{s0}; f] + \sum_{j=s}^{s} [z_1; z_2; \cdots; z_{s-1}; Z'_{s0}; f] (z_j - z_{j0}) .
$$

Considering this as the function of z_s, the result is

$$[z_1; z_2; \cdots, z_{s-1}; z_s; f] = f(z_1, \ldots, z_s).$$

Thus, the theorem is proven. □

THEOREM 3.4. *The H-type Lagrange polynomial* (3.4) *of the function f corresponding to the points Z_I is unique (for a given set Z). Furthermore, the set of columns B of A in problem* (2.3)*, corresponding to the subscript set I, forms a basis of A.*

Proof. The formula (3.4) gives a Lagrange polynomial on Z_I for any function f on the set Z. This means that we can obtain the coefficients of the H-type Lagrange polynomial in case of *any* function $f(\boldsymbol{z})$, $\boldsymbol{z} \in Z$. Let the matrix B consist of the columns corresponding to the points of Z_I. The coefficient vector $\boldsymbol{c}_f$ of the Lagrange polynomial corresponding to the function f is the solution of the equation

$$\boldsymbol{c}_f^T B = \boldsymbol{f}_B^T. \tag{3.17}$$

Since we have Lagrange interpolation for *any* f, (3.17) has a solution $\boldsymbol{c}_f$ in case of any vector $\boldsymbol{f}_B$. From this follows that the square matrix B is nonsingular, hence *the columns corresponding to the points of Z_I form a basis.* Thus, the second assertion is proven. Then the uniqueness is the corollary of Theorem 2.1. □

4. Bounds for the MDMP with the set H (1.14). The problem in the title of this section is the following LP:

$$\begin{aligned}
&\min(\max) \sum_{i_1=0}^{n_1} \cdots \sum_{i_s=0}^{n_s} f_{i_1 \ldots i_s} p_{i_1 \ldots i_s} \\
&\text{subject to} \\
&\sum_{i_1=0}^{n_1} \cdots \sum_{i_s=0}^{n_s} z_{1i_1}^{\alpha_1} z_{ji_j}^{\alpha_j} p_{i_1 \ldots i_s} = \mu_{\alpha_1 0 \ldots 0 \alpha_j 0 \ldots 0} \\
&\quad \text{for } \alpha_1, \alpha_j \geq 0,\ \alpha_1 + \alpha_j \leq m,\ j = 2, \ldots, s; \\
&\sum_{i_1=0}^{n_1} \cdots \sum_{i_s=0}^{n_s} z_{ji_j}^{\alpha_j} p_{i_1 \ldots i_s} = \mu_{0 \ldots 0 \alpha_j 0 \ldots 0} \\
&\quad \text{for } m+1 \leq \alpha_j \leq m_j,\ j = 1, \ldots, s; \\
&p_{i_1 \ldots i_s} \geq 0 \text{ for all } i_1, \ldots, i_s.
\end{aligned} \tag{4.1}$$

In the following theorems let us designate the coefficient matrix of (4.1) by A, the right-hand side vector by $\boldsymbol{b}$, and the coefficient vector of the objective function by $\boldsymbol{f}$, in agreement with (2.3).

We present several dual feasible bases for the min problem of (4.1), which give lower bounds for the objective function. As at the numerical examples we shall see, the best bounds, among the given ones, are usually close to the values of the sharp bounds. This means that we can give good bounds without using LP solvers, which work numerically unstably because of the Vandermonde systems in the coefficient matrix.

First of all, we should introduce some assumptions. They are as follows.

Assumption 1. The function $f(\boldsymbol{z})$, $\boldsymbol{z} \in Z$,

(a) has nonnegative univariate divided differences of order $m_j + 1$ regarding z_j, $j = 1, \ldots, s$,

(b) has nonnegative bivariate divided differences of order $m + 1$,

(c) has nonnegative mixed second order divided differences.

If $f(\boldsymbol{z}),\ \boldsymbol{z} \in Z$, is derived from a function $\overline{f}(\boldsymbol{z})$ defined in $\overline{Z} = [z_{10}, z_{1n_1}] \times \cdots \times [z_{s0}, z_{sn_s}]$ by taking $f(\boldsymbol{z}) = \overline{f}(\boldsymbol{z}),\ \boldsymbol{z} \in Z$, and $\overline{f}(\boldsymbol{z})$ has continuous, nonnegative derivatives of order $(k_1, \dots, k_s)$ in the interior of $\overline{Z}$, then all divided differences of $f(\boldsymbol{z}),\ \boldsymbol{z} \in Z$, of order $(k_1, \dots, k_s)$ are nonnegative. For further results in this respect, see Popoviciu [24]. This fact helps one find out whether a function satisfies Assumption 4. If in the assumption we require nonpositivity, then we shall see that the following bases will be dual feasible for the max problem and will give upper bounds for (4.1).

We introduce four different structures for K_j, defined in (3.4), as follows:

$$\begin{array}{cll} & |K_j| \text{ even} & |K_j| \text{ odd} \\ \min & u^{(j)}, u^{(j)}+1, \dots, v^{(j)}, v^{(j)}+1 & m, u^{(j)}, u^{(j)}+1, \dots, v^{(j)}, v^{(j)}+1 \\ \max & m, u^{(j)}, u^{(j)}+1, \dots, v^{(j)}, v^{(j)}+1, n_j & u^{(j)}, u^{(j)}+1, \dots, v^{(j)}, v^{(j)}+1, n_j; \end{array} \tag{4.2}$$

i.e., K_j (consists of distinct elements of the subset of $\{m, \dots, n_j\}$) is a set of pairs of consecutive elements completed by m and n_j depending on its parity and its (min or max) type.

As regards the ordering of the elements in the sets $Z_1, \dots, Z_s$, we mention separately in each theorem of this section what our assumption is about.

THEOREM 4.1. *Let $z_{j0} < z_{j1} < \cdots < z_{jn_j},\ j = 1, \dots, s$. Suppose that K_j follows the min structure of* (4.2)*, $j = 1, \dots, s$.*

Under Assumption 4*, $L_I(z_1, \dots, z_s)$, defined by* (3.4)*, is a unique H-type Lagrange polynomial on Z_I and satisfies the relations*

$$f(z_1, \dots, z_s) \geq L_I(z_1, \dots, z_s),\ (z_1, \dots, z_s) \in Z. \tag{4.3}$$

The set of columns B of A in problem (4.1)*, with the subscript set I, is a dual feasible basis in the minimization problem* (4.1)*, and*

$$E[f(X_1, \dots, X_s)] \geq E[L_I(X_1, \dots, X_s)]. \tag{4.4}$$

If B is also a primal feasible basis in problem (4.1)*, then the inequality* (4.4) *is sharp.*

Proof. We have only to prove (4.3). The proof of the other parts of the theorem is straightforward from Theorems 3.4, 2.4, and 2.3.

In order to prove (4.3) it is sufficient to show that

$$R_I(z_1, \dots, z_s) \geq 0 \text{ for all } (z_1, \dots, z_s) \in Z. \tag{4.5}$$

In fact, we show that all terms in the sum $R_I(z_1, \dots, z_s)$ are nonnegative. Considering any term in $R_{1I}(z_1, \dots, z_s)$ the first factor of the product is a divided difference, which is nonnegative because of Assumption 4, while the last part is

$$\prod_{k \in \{0, \dots, m-1\} \cup K_j} (z_j - z_{jk}) > 0 \text{ for } z_j \notin \{z_{j0}, \dots, z_{j(m-1)}\} \cup Z_{jK_j} \tag{4.6}$$

because there are even numbers of negative factors, due to the special structure of K_j. If $z_j \in \{z_{j0}, \dots, z_{j(m-1)}\} \cup Z_{jK_j}$, the above product is 0. This means that any term of $R_{1I}(z_1, \dots, z_s)$ is nonnegative. Considering a term of the sum $R_{2I}(z_1, \dots, z_s)$ or $R_{3I}(z_1, \dots, z_s)$ the first factor of the product is a divided difference, which is nonnegative because of Assumption 4. In the other part of the product at least one of the factors is zero or all factors are positive because of the ordering of Z_j's.

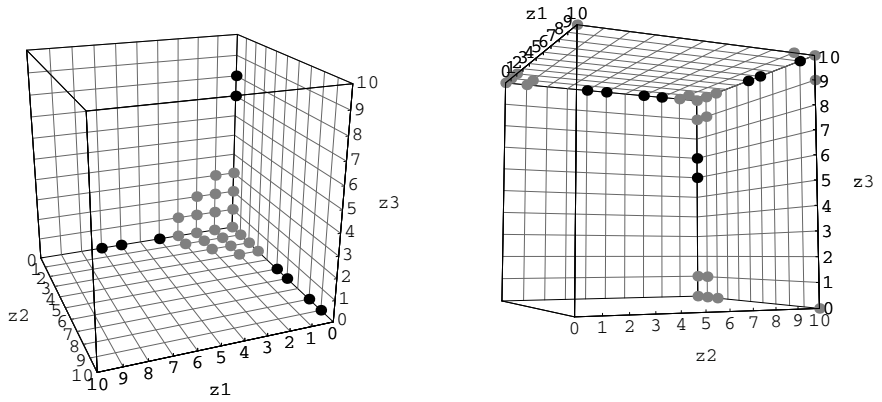

FIG. 1. *Assume* $Z_j = \{0, \dots, 10\}$, $j = 1, 2, 3$, $m = 4$, $m_1 = 7$, $m_2 = 8$, $m_3 = 6$. (a): *Dual feasible basis corresponding to Theorem* 4.1, *where* $K_1 = \{4, 6, 7\}$, $K_2 = \{5, 6, 8, 9\}$, $K_3 = \{7, 8\}$. (b): *Dual feasible basis of the Min Algorithm, where* $(z_{10}, z_{11}, z_{12}, z_{13}) = (0, 1, 10, 2)$, $(z_{j0}, z_{j1}, z_{j2}, z_{j3}) = (10, 0, 9, 1)$, $j = 2, 3$, $K_1 = \{6, 7, 10\}$ *(*$Z_{1K_1} = \{5, 6, 9\}$*)*, $K_2 = \{6, 7, 9, 10\}$ *(*$Z_{2K_2} = \{4, 5, 7, 8\}$*)*, $K_3 = \{8, 9\}$ *(*$Z_{3K_3} = \{6, 7\}$*). Elements of* $\bigcup_{j=1}^{s} I_j$ *are colored by gray while elements of* $\bigcup_{j=1}^{s} J_j$*'s are black.*

This means that all factors of the product are nonnegative and hence the term is nonnegative as well. All terms of $R_I(z_1, \dots, z_s)$ are nonnegative, hence the sum of them, i.e., $R_I(z_1, \dots, z_s)$, is also nonnegative on Z. Thus, the theorem is proven. □

The basis of Theorem 4.1 is illustrated in Figure 1(a).

In the following algorithm we will consider more orders of the elements of the set Z_j in the sequence $(z_{j0}, \dots, z_{jn_j})$, $j = 1, \dots, s$, for which all terms of $R_I(z_1, \dots, z_s)$ are nonnegative. Note that transposing the elements of the sequence $(z_{j0}, \dots, z_{jn_j})$ is equivalent to exchanging subscripts of the elements; however, the proof of the validity of the algorithm is based on the orders of the elements. At each order of the elements, the set of interpolation points Z_I as well as the corresponding dual feasible basis are different, which means that we can give more lower bounds on (4.1) by the objective function value of the dual feasible basis corresponding to Z_I.

Min Algorithm.

At first we assume, without loss of generality, that $Z_j = \{0, 1, \dots, n_j\}$, $j = 1, \dots, s$.

Step 0. Let

$$z_{20} = z_{30} = \cdots = z_{s0} = 0 \tag{4.7}$$

or

$$z_{20} = n_2, z_{30} = n_3, \dots, z_{s0} = n_s. \tag{4.8}$$

If (4.7) holds, then let $0 \le q_1 \le m$ be an even number, else (if (4.8) holds) let $0 \le q_1 \le m$ be an odd number. $L := (0, 1, \dots, (m-1)-q_1)$, $U := (n_1, n_1-1, \dots, n_1-(q_1-1))$, $V^0 := \{\text{arbitrary merger of the sequences } L, U\} = (v^0, v^1, \dots, v^{m-1})$.

$$(z_{10}, \dots, z_{1(m-1)}) := V^0.$$

Let $j = 2$. Goto Step 1.

Step 1. Initialize $t = 0$. If (4.7) holds, then let $l_0 = 1$ and $u_0 = n_j$, else let $l_0 = 0$ and $u_0 = n_j - 1$. Goto Step 2.

Step 2. Let $V^t = \{v^0, v^1, \dots, v^{m-1-t}\}$, $H^t = \{h^1, \dots, h^t\}$. If $v^{m-1-t} \in L$, then let $h^{t+1} = l^t$, $l^{t+1} = l^t + 1$, $u^{t+1} = u^t$, and if $v^{m-1-t} \in U$, then let $h^{t+1} = u^t$, $u^{t+1} = u^t - 1$, $l^{t+1} = l^t$. Set $t \leftarrow t+1$. If $t = m$, then goto Step 3, else repeat Step 2.

Step 3. Let

$$(z_{j1}, \dots, z_{j(m-1)}) = H^{m-1}.$$

Set $j \leftarrow j + 1$. If $j = s + 1$, then goto Step 4, else goto Step 1.

Step 4. Let $0, 1, \dots, r_j, n_j, \dots, n_j - (m - r_j - 2)$ be the numbers used to construct $z_{j0}, z_{j1}, \dots, z_{j(m-1)}$. Then let

$$(z_{jm}, z_{j(m+1)}, \dots, z_{jn_j}) = (r_j + 1, r_j + 2, \dots, n_j - (m - r_j - 1)) \tag{4.9}$$

as ordered sets, $j = 1, \dots, s$. Note that these subsets of the sets Z_j, $j = 1, \dots, s$, remain intact. If $m - r_j - 1$ is even, then K_j should follow a minimum structure in (4.2), and if $m - r_j - 1$ is odd, then K_j should follow a maximum structure. Stop, we have completed the construction of the dual feasible basis related to the subscript set I.

In the general case, where Z_j is not necessarily $\{0, 1, \dots, n_j\}$, $j = 1, \dots, s$, we do the following. First we order the elements in each Z_j in increasing order. Then we establish one-to-one correspondences between the elements of Z_j and the elements of the ordered set $(0, 1, \dots, n_j)$. After that, we carry out the Min Algorithm to find a dual feasible basis, using the sets $\{0, 1, \dots, n_j\}$, $j = 1, \dots, s$. Finally, we create the set Z_I, by the use of the above mentioned one-to-one correspondences.

THEOREM 4.2. *Let the elements of the sequence* $(z_{j0}, \dots, z_{jn_j})$, $j = 1, \dots, s$, *be in one of the orders of the Min Algorithm, and also let* K_j *follow the* min *(*max*) structure if* $m - r_j - 1$ *is even (odd) in the Min Algorithm,* $j = 1, \dots, s$.

Under Assumption 4, $L_I(z_1, \dots, z_s)$, *defined by* (3.4), *is a unique* H*-type Lagrange polynomial on* Z_I *and satisfies the relations*

$$f(z_1, \dots, z_s) \geq L_I(z_1, \dots, z_s), \qquad (z_1, \dots, z_s) \in Z. \tag{4.10}$$

The set of columns B *of* A *in problem* (4.1), *with the subscript set* I, *is a dual feasible basis in the minimization problem* (4.1), *and*

$$E[f(X_1, \dots, X_s)] \geq E[L_I(X_1, \dots, X_s)]. \tag{4.11}$$

If B *is also a primal feasible basis in problem* (4.1), *then the inequality* (4.11) *is sharp.*

Proof. We have only to prove that $R_I(z_1, \dots, z_s) \geq 0$ for all $(z_1, \dots, z_s) \in Z$ and then we can follow the proof of Theorem 4.1. We can restrict ourselves to the case $Z_j = \{0, 1, \dots, n_j\}$, $j = 1, \dots, s$, because in the following inequalities only the orders of the elements play a role.

First, let us consider $R_{3I}(z_1, \dots, z_s)$ of (3.8). All divided differences are nonnegative, and the set of the second parts of the products equals

$$(z_h - z_{h0})(z_j - z_{j0}), \qquad 2 \leq h < j \leq s. \tag{4.12}$$

These products can be nonnegative if and only if both factors are nonnegative or both factors are nonpositive. Because we have pairs for all $2 \leq h < j \leq s$ this means that

either all factors $(z_j - z_{j0})$, $2 \le j \le s$, are nonnegative, or all of them are nonpositive. The first case is provided by (4.7) while the second by (4.8). Hence, $R_{3I}(\boldsymbol{z}) \ge 0$, $\boldsymbol{z} \in Z$.

If we consider $R_{2I}(z_1, \ldots, z_s)$ of (3.7), we will see that the factors of products after the nonnegative divided differences are associated with the following arrays:

$$\begin{array}{cccccccc} z_{10} & z_{11} & z_{12} & \cdots & z_{1(m-2)} & z_{1(m-1)} & & z_{j0} \\ z_{10} & z_{11} & z_{12} & \cdots & z_{1(m-2)} & & z_{j0} & z_{j1} \\ & & & & \vdots & & & \\ z_{10} & z_{11} & z_{j0} & \cdots & z_{j(m-4)} & z_{j(m-3)} & & z_{j(m-2)} \\ z_{10} & z_{j0} & z_{j1} & \cdots & z_{j(m-3)} & z_{j(m-2)} & & z_{j(m-1)} \end{array} \tag{4.13}$$

$$j = 2, \ldots, s.$$

A sufficient condition for the nonnegativity of all products in (3.7) is that

$$|\{i|\ 0 \le i \le i_1,\ z_{1i} > z_1\}| + |\{i|\ 0 \le i \le i_j,\ z_{ji} > z_j\}| = \text{even number} \tag{4.14}$$

for every $0 \le i_j \le m-1$ integers satisfying $i_1 + i_j = m-1$, and for all $(z_1, z_j) \in Z_1 \times Z_j$, $j = 2, \ldots, s$. The first m elements of the first row in (4.13) are the elements of V^0; the $m+1$st element of the same row is z_{j0}. In Step 0 the parity of q_1 provides that (4.14) is satisfied for the product of (3.7) corresponding to the first row of (4.13). The elements of V^t, z_{j0}, H^t, in that order, constitute the tth row of tableau (4.13). In Steps 1 and 2 we define the following element h^{t+1} such that (4.14) is still satisfied for the product of (3.7) corresponding to the $t+1$st row of (4.13). From this follows that $R_{2I}(\boldsymbol{z}) \ge 0$, $\boldsymbol{z} \in Z$.

Regarding $R_{1I}(z_1, \ldots, z_s)$ the divided differences are nonnegative in terms of (3.6). Hence, after the assignments (4.9) we have only to choose the subscript sets K_j such that

$$\prod_{k \in \{0, \ldots, m-1\} \cup K_j} (z_j - z_{jk}) \ge 0, \qquad \boldsymbol{z} \in Z,$$

for $j = 1, \ldots, s$. For each j the products

$$\prod_{k=0}^{m-1} (z_j - z_{jk}),\ (z_1, \ldots, z_s) \in Z \tag{4.15}$$

are nonnegative (nonpositive) if $m - r_j - 1$ is even (odd). (Note that $r_2 = \cdots = r_s$ by construction.) Then the choice of K_j (with assignment (4.9)), $j = 1, \ldots, s$, provides that $R_{1I}(\boldsymbol{z}) \ge 0$ for all $\boldsymbol{z} \in Z$.

Thus, $R_I(\boldsymbol{z}) = R_{1I}(\boldsymbol{z}) + R_{2I}(\boldsymbol{z}) + R_{3I}(\boldsymbol{z}) \ge 0$ for all $\boldsymbol{z} \in Z$. □

The basis of the algorithm is illustrated in Figure 1(b).

The above algorithm allows for the construction of a variety of dual feasible bases. However, we do not have a simple criterion, like in the dual method, to decide which of the bases, that we can obtain by the above Min Algorithm, would improve on the bound (on the value of the objective function). Hence, in order to give the best bound for $E[f(X_1, \ldots, X_s)]$ we have to calculate the objective function values for all dual feasible bases yielded by the Min Algorithm and then choose the highest value from among them. For a given order of $(z_{j0}, \ldots, z_{js})$, $j = 1, \ldots, s$, we can find the

best sets K_j, $j = 1, \ldots, s$, independently. The argument of this can be found in Mádi-Nagy [20].

Numerical experiments show that this method produces very good results much faster than the execution of the dual algorithm. Its other main advantage is that it is not sensitive to the numerical difficulties that arise from the bad numerical property of the matrix A.

5. Numerical examples. In the following we consider three numerical examples. In the first one we give bounds for the expected value of a three-variate utility function by the aid of the Min Algorithm of section 4 and we also give the sharp bounds calculated by the LP solver CPLEX (www.ilog.com). The method of the Min Algorithm is written in Wolfram's Mathematica (www.wolfram.com). This means that its running times are not really comparable with the running times of the dual method of CPLEX; however, we give these results, too. Because of the numerical instability of the MDMP, CPLEX sometimes cannot give appropriate results (it reports infeasibility; however, the problem is feasible by construction). These cases are indicated by "−" sign in the tables. We can conclude that our Min Algorithm yields useful bounds without numerical difficulties even if the CPLEX cannot give the right answer.

In the last two examples we give bounds for the union of events by the application of the Min Algorithm for the binomial MDMP (1.11). Comparing the results to the cherry tree bounds of Bukszár and Prékopa [4] and the bounds of univariate and bivariate MDMPs, the bounds of our Min Algorithm turn out to be the best.

Example 5.1. In this example we solve a problem similar to Example 4.2 in Prékopa and Mádi-Nagy [35]. Consider the utility function

$$u(z_1, z_2, z_3) = \log\left[(e^{\alpha_1 z_1 + a_1} - 1)(e^{\alpha_2 z_2 + a_2} - 1)(e^{\alpha_3 z_3 + a_3} - 1) - 1\right], \quad (z_1, z_2, z_3) \in Z, \tag{5.1}$$

where Z is specialized as follows:

$$Z = (0, 1, 2, 3, 4, 5, 6, 7, 8, 9) \times (0, 1, 2, 3, 4, 5, 6, 7, 8, 9) \times (0, 1, 2, 3, 4, 5, 6, 7, 8, 9).$$

Let the parameters be $\alpha_1 = 1.75,\ \alpha_2 = 1.25,\ \alpha_3 = 0.75,\ a_1 = 3,\ a_2 = 2,\ a_3 = 1$. In the cited paper it was proven that the even (odd) order derivatives of the function are nonpositive (nonnegative). We use our Min Algorithm for the MDMP (1.7) with set H (1.14) to give an upper bound for the expected utility

$$E[u(X_1, X_2, X_3)]. \tag{5.2}$$

Since the even order divided differences of the function $-u(z_1, z_2, z_3)$ on Z are nonnegative, we can apply the Min Algorithm to give a lower bound for $E[-u(X_1, X_2, X_3)]$ that yields, indeed, an upper bound for (5.2).

Regarding the moments taken into account they are generated from the distribution of (X_1, X_2, X_3), defined by

$$X_1 = \min(X + Y_1, 9),$$

$$X_2 = \min(X + Y_2, 9),$$

$$X_3 = \min(X + Y_3, 9),$$

where X, Y_1, Y_2, Y_3 have independent Poisson distributions with parameters $1, 2, 2.5, 3$, respectively. Note that X_1, X_2, X_3 are stochastically dependent.

We calculate the bounds for several values of the parameters m, m_1, m_2, m_3 of the set H (1.14). We also give the sharp upper bounds calculated by the dual method of CPLEX (where it is possible). In order to see the closeness of our (not sharp) upper bounds we also calculate the minimum of the objective function value. That gives the possibility to compare the difference between our upper bound and the dual maximum to the gap between the sharp upper and lower bounds. The results are summarized below.

m	m_1	m_2	m_3	Upper bound	CPU	Dual max	CPU	Dual min	CPU
3	3	3	3	18.586715186	0.14	18.557668477	0.08	18.510511279	0.11
3	5	5	5	18.549493662	0.41	18.546562878	0.05	18.539798360	0.40
3	7	7	7	18.543584031	0.69	18.543580944	0.11	18.542882716	0.69
3	9	9	9	18.543304428	0.36	–	–	–	–

m	m_1	m_2	m_3	Upper bound	CPU	Dual max	CPU	Dual min	CPU
5	5	5	5	18.562168728	1.50	18.546562667	0.14	18.539911300	0.65
5	7	7	7	18.543588614	2.61	18.543580474	0.44	18.542921460	1.16
5	9	9	9	18.543304428	2.31	–	–	–	–

We can see that our bounds are very close to the sharp bounds except cases $m = m_1 = \cdots = m_3 = 3$ and $m = m_1 = \cdots = m_3 = 5$. On the other hand, we can give better approximation taking the marginal moments up to the order 9 into account, despite the fact that CPLEX cannot solve the MDMP.

We also check whether we do not lose too much information using the set H (1.14) instead of the set H (1.10) (set H (1.14) is a subset of H (1.10)). The sharp bounds for set H (1.10) are summarized below.

m	m_1	m_2	m_3	Dual max	CPU	Dual min	CPU
3	3	3	3	18.557668337	0.28	1.8510552138	0.12
3	5	5	5	18.546562783	0.53	1.8539798515	0.42
3	7	7	7	18.543580810	1.54	1.8542882927	0.11
3	9	9	9	–	–	–	–

m	m_1	m_2	m_3	Dual max	CPU	Dual min	CPU
5	5	5	5	18.546560902	2.13	1.8539941923	1.52
5	7	7	7	18.543579438	6.62	1.8542948216	3.69
5	9	9	9	–	–	–	–

We can conclude that these bounds are not significantly better. Hence, we do not lose as much as we can gain on the structure of the set H (1.14), which makes the Min Algorithm applicable for higher dimensions.

Example 5.2. In this example we shall give upper bounds for the probability of the union of events of the following two systems. In both systems there are 12 events $A_1, A_2, \ldots, A_{12}$, and 16 outcomes, $x_1, x_2, \ldots x_{16}$ with probabilities $P(x_1), P(x_2), \ldots, P(x_{16})$, respectively. The events of System I are defined by the matrix $R^I = (r^I_{ij})$, where $r^I_{ij} = 1$, if $x_i \in A_j$; otherwise $r^I_{ij} = 0$. The events of System II are defined by the matrix R^{II}, similarly. (The matrices R^I and R^{II} were randomly

generated with different densities.)

$$R^I = \begin{pmatrix} 0&0&0&0&0&0&1&0&0&0&0&1\\ 0&0&1&0&1&0&0&0&0&0&1&0\\ 0&0&1&0&0&0&0&0&0&0&0&0\\ 0&1&0&0&1&1&0&0&0&0&0&0\\ 1&1&0&1&0&0&0&1&0&1&0&0\\ 0&1&0&0&1&1&0&1&0&0&0&1\\ 0&0&1&1&0&0&0&0&0&0&0&0\\ 0&0&0&0&1&0&0&0&0&0&0&0\\ 1&0&0&0&0&0&0&0&0&1&1&0\\ 1&0&0&0&0&1&0&0&1&1&0&1\\ 0&0&1&0&0&1&0&0&0&0&1&0\\ 0&0&1&1&0&1&1&0&0&0&0&1\\ 0&1&0&0&0&1&1&0&0&1&1&0\\ 1&0&0&0&1&0&0&1&0&0&1&0\\ 0&1&0&0&0&1&0&0&0&1&0&0\\ 0&0&0&0&0&0&0&0&0&0&0&0 \end{pmatrix}, \; R^{II} = \begin{pmatrix} 1&1&0&1&1&1&0&1&1&1&1&0\\ 0&1&1&0&1&1&0&0&1&0&1&0\\ 1&0&1&1&0&1&1&1&1&1&1&0\\ 1&1&1&0&1&1&1&0&1&1&1&1\\ 1&1&1&1&1&1&1&0&1&1&1&1\\ 1&1&1&1&1&1&1&1&0&0&1&1\\ 1&1&1&1&1&1&1&1&1&1&1&1\\ 1&1&1&0&0&1&1&1&0&1&1&1\\ 1&1&1&1&1&1&1&1&1&1&1&1\\ 1&1&1&1&1&1&0&1&0&1&1&1\\ 1&1&1&1&1&0&1&1&1&1&0&1\\ 1&1&0&1&0&1&0&1&0&1&1&1\\ 1&1&1&1&1&1&1&1&1&1&1&1\\ 1&1&1&0&1&1&1&1&1&1&1&1\\ 1&1&1&1&1&0&0&1&0&1&1&0\\ 0&0&0&0&0&0&0&0&0&0&0&0 \end{pmatrix}. \tag{5.3}$$

It is easy to see that at least one event occurs at each outcome except x_{16}. From this

$$P(\cup A_i) = 1 - P(x_{16}).$$

Regarding the probability of the outcomes we consider the following three cases.

	$P(x_1)$	$P(x_2)$	$P(x_3)$	$P(x_4)$	$P(x_5)$	$P(x_6)$	$P(x_7)$	$P(x_8)$
Case 1:	0.023	0.034	0.045	0.056	0.067	0.078	0.067	0.056
Case 2:	0.012	0.022	0.023	0.033	0.034	0.044	0.045	0.055
Case 3:	0.0329	0.1076	0.0599	0.1108	0.042	0.0055	0.0508	0.1142

(5.4)

	$P(x_9)$	$P(x_{10})$	$P(x_{11})$	$P(x_{12})$	$P(x_{13})$	$P(x_{14})$	$P(x_{15})$	$P(x_{16})$
Case 1:	0.045	0.038	0.011	0.022	0.033	0.044	0.055	0.326
Case 2:	0.056	0.066	0.067	0.077	0.078	0.088	0.089	0.211
Case 3:	0.048	0.0235	0.0676	0.0295	0.0441	0.1265	0.1058	0.0313

We use several bounding techniques depending on the known information about the systems. On one hand, we give the (sharp) upper bounds of the univariate binomial moment problem of (1.4) with the first function f in (1.5), based on the information on S_1, S_2, S_3. We use the dual method of Prékopa [27].

On the other hand, we subdivide the sequence of $\{A_1, A_2, \ldots, A_{12}\}$ into subsequences

$$\{A_1, A_2, \ldots, A_6\},\ \{A_7, A_8, \ldots, A_{12}\} \tag{5.5}$$

and then into subsequences

$$\{A_1, A_2, A_3, A_4\},\ \{A_5, A_6, A_7, A_8\},\ \{A_9, A_{10}, A_{11}, A_{12}\} \tag{5.6}$$

and then into

$$\{A_1, A_2, A_3\},\ \{A_4, A_5, A_6\},\ \{A_7, A_8, A_9\},\ \{A_{10}, A_{11}, A_{12}\}. \tag{5.7}$$

We consider the multivariate binomial moment problem (1.11) with the function f in (1.12) with the appropriate sets H (1.14), respectively. Prékopa [30] has shown that the even (odd) order divided differences of f in (1.12) are nonpositive (nonnegative). This means that in cases where $m+1$ and m_j+1, $j = 1, \ldots, s$ (where s is the number of subsequences), are even we can give upper bounds by the application of the Min

TABLE 1
Results of System I.

	Univariate S_1, S_2, S_3	(5.5) $m = 3$, $m_1 = 3$, $m_2 = 3$	(5.6) $m = 3$, $m_1 = 3$, $m_2 = 3$, $m_3 = 3$	(5.7) $m = 3$, $m_1 = m_2 = 3$, $m_3 = m_4 = 3$	Cherry tree bound

Algorithm for $-f(\boldsymbol{z})$. In this example we use the Min Algorithm with parameters $m = 3$, $m_j = 3$, $j = 1, \ldots, s$.

Finally, we give the so-called cherry tree bounds of Bukszár and Prékopa [4]. These bounds are based on the knowledge of the individual probabilities of the occurrences of the events, of the intersections of pairs of events, and of the intersections of three events. These bounds are always at least as good as the Hunter–Worsley second order bounds (see Hunter [17]).

The results for System I and System II are summarized in Tables 1 and 2, respectively. Comparing the bounds, we can see that we get the best bound in case of the subsequences (5.7).

Regarding the order of the columns in Tables 1 and 2, we took more and more information on the system into account; i.e., in case of the univariate binomial moments we just considered the sums of probabilities of events, intersections of pairs of events, and triples of events. In the case of multivariate binomial moments we considered the sums of those probabilities of smaller groups of the events; i.e., we separated the sums of the univariate moments into subsums. Finally, in the case of cherry trees we used individual probabilities. This would imply that we should get better and better bounds. However, the bounds of our paper as well as the cherry tree bounds are not sharp; that is why it could happen that *the Min Algorithm gave better bounds, using less information, than the cherry tree bounds of Bukszár and Prékopa* [4].

The numerical results confirm that our method yields a new effective tool for bounding the probability of the union of events based on the knowledge of probabilities of the intersection up to three events. On the other hand, we can see that the bivariate bounds corresponding to the subsequences (5.5) are much weaker than the bounds corresponding to the binomial MDMPs of higher dimensions. *Since our generalization of the bivariate Min Algorithm gives the possibility of taking more detailed information into account, it can give substantially better bounds.*

Example 5.3. We shall also give upper bounds for the probability of the union of events. There are 20 events $A_1, A_2, \dots, A_{20}$, and 16 outcomes, $x_1, x_2, \dots, x_{16}$ with probabilities $P(x_1), P(x_2), \dots, P(x_{16})$, respectively. The events of the system are defined by the matrix $R = (r_{ij})$, where $r_{ij} = 1$, if $x_i \in A_j$; otherwise $r_{ij} = 0$.

$$R = \begin{pmatrix}
1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 \\
0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\
1 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 \\
1 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 \\
1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 & 1 \\
1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 1 \\
1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\
1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 \\
0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix}. \tag{5.8}$$

The matrix R is taken from System 1 of Example 2 in Prékopa and Gao [34], but we use the probabilities of outcomes of (5.4) instead of their probabilities because in their system the probability of the union is nearly 1. We consider the univariate binomial DMP for S_1, S_2, S_3 and for $S_1, \dots, S_5$. We also give the results of the multivariate binomial DMP (1.11) with the function f in (1.12) with the appropriate sets H (1.14). We consider the subdivisions

$$\{A_1, \dots, A_7\},\ \{A_8, \dots, A_{14}\},\ \{A_{15}, \dots, A_{20}\}, \tag{5.9}$$

with $m = m_j = 5$ $(j = 1, 2, 3)$, and

$$\{A_1, \dots, A_5\},\ \{A_6, \dots, A_{10}\},\ \{A_{11}, \dots, A_{15}\},\ \{A_{16}, \dots, A_{20}\}, \tag{5.10}$$

with $m = m_j = 5$ $(j = 1, 2, 3, 4)$. (The MDMPs with third order binomial moments yield trivial bounds.) We also give the cherry tree bounds. The results are summarized in Table 3. Among the third order bounds once the univariate binomial DMP bound, once the cherry tree bound was the best, however, none of them were useful. However, *using moments up to the order* 5 *our binomial MDMP, with subdivision* (5.10)*, yields the best (in these cases the sharp) bounds.*

SMOOTH OPTIMIZATION APPROACH FOR SPARSE COVARIANCE SELECTION*

ZHAOSONG LU†

Abstract. In this paper we first study a smooth optimization approach for solving a class of nonsmooth *strictly* concave maximization problems whose objective functions admit smooth convex minimization reformulations. In particular, we apply Nesterov's smooth optimization technique [Y. E. Nesterov, *Dokl. Akad. Nauk SSSR*, 269 (1983), pp. 543–547; Y. E. Nesterov, *Math. Programming*, 103 (2005), pp. 127–152] to their dual counterparts that are smooth convex problems. It is shown that the resulting approach has $\mathcal{O}(1/\sqrt{\epsilon})$ iteration complexity for finding an ϵ-optimal solution to both primal and dual problems. We then discuss the application of this approach to sparse covariance selection that is approximately solved as an l_1-norm penalized maximum likelihood estimation problem, and also propose a variant of this approach which has substantially outperformed the latter one in our computational experiments. We finally compare the performance of these approaches with other first-order methods, namely, Nesterov's $\mathcal{O}(1/\epsilon)$ smooth approximation scheme and block-coordinate descent method studied in [A. d'Aspremont, O. Banerjee, and L. El Ghaoui, *SIAM J. Matrix Anal. Appl.*, 30 (2008), pp. 56–66; J. Friedman, T. Hastie, and R. Tibshirani, *Biostatistics*, 9 (2008), pp. 432–441] for sparse covariance selection on a set of randomly generated instances. It shows that our smooth optimization approach substantially outperforms the first method above, and moreover, its variant substantially outperforms both methods above.

Key words. sparse covariance selection, nonsmooth strictly concave maximization, smooth minimization

1. Introduction.

In [19, 21], Nesterov proposed an efficient smooth optimization method for solving convex programming problems of the form

$$\min\{f(u) : u \in U\}, \tag{1}$$

where f is a convex function with Lipschitz continuous gradient, and U is a closed convex set. It is shown that his method has $\mathcal{O}(1/\sqrt{\epsilon})$ iteration complexity bound, where $\epsilon > 0$ is the absolute precision of the final objective function value. A proximal-point-type algorithm for (1) having the same complexity as above has also been proposed more recently by Auslender and Teboulle [2].

Motivated by [10], we are particularly interested in studying the use of a smooth optimization approach for solving a class of nonsmooth *strictly* concave maximization problems whose objective functions admit smooth convex minimization reformulations in this paper. Our key idea is to apply Nesterov's smooth optimization technique [19, 21] to their dual counterparts that are smooth convex problems. It is shown that the resulting approach has $\mathcal{O}(1/\sqrt{\epsilon})$ iteration complexity for finding an ϵ-optimal solution to both primal and dual problems.

One interesting application of the above approach is for sparse covariance selection. Given a set of random variables with Gaussian distribution for which the

†Department of Mathematics, Simon Fraser University, Burnaby, BC, V5A 1S6, Canada (zhaosong@sfu.ca). This author was supported in part by NSERC Discovery Grant and SFU President's Research Grant.

true covariance matrix is unknown, covariance selection is a procedure used to estimate true covariance from a sample covariance matrix by maximizing its likelihood while imposing a certain sparsity on the inverse of the covariance estimation (e.g., see [11]). Therefore, it can be applied to determine a robust estimate of the true variance matrix, and simultaneously to discover the sparse structure in the underlying model. Despite its popularity in numerous real-world applications (e.g., see [3, 10, 25] and the references therein), sparse covariance selection itself is a challenging NP-hard combinatorial optimization problem. By an argument that is often used in regression techniques such as LASSO [23], Yuan and Lin [25] and d'Aspremont et al. [10] (see also [3]) showed that it can be approximately solved as an l_1-norm penalized maximum likelihood estimation problem. Moreover, the authors of [10] studied two efficient first-order methods for solving this problem, that is, Nesterov's smooth approximation scheme and block-coordinate descent method. It was shown in [10] that their first method has $\mathcal{O}(1/\epsilon)$ iteration complexity for finding an ϵ-optimal solution. For their second method, each iterate requires solving a box constrained quadratic programming, and it has a local linear convergence rate. However, its global iteration complexity for finding an ϵ-optimal solution is theoretically unknown. After the first release of our paper, Friedman, Hastie, and Tibshirani [16] studied a slight variant of the block-coordinate descent method proposed in [10]. At each iteration of their method, a coordinate descent approach is applied to solve a lasso (l_1-regularized) least-squares problem, which is the dual of the box constrained quadratic programming appearing in the block-coordinate descent method [10]. In contrast with these methods, the smooth optimization approach proposed in this paper has a more attractive iteration complexity that is $\mathcal{O}(1/\sqrt{\epsilon})$ for finding an ϵ-optimal solution. In addition, we propose a variant of the smooth optimization approach which has substantially outperformed the latter one in our computational experiments. We also compare the performance of our approaches with their methods for sparse covariance selection on a set of randomly generated instances. It shows that our smooth optimization approach substantially outperforms their first method above (i.e., Nesterov's smooth approximation scheme) and, moreover, its variant substantially outperforms their methods [10, 16] mentioned above.

The paper is organized as follows. In section 2, we introduce a class of nonsmooth concave maximization problems in which we are interested and propose a smooth optimization approach to them. In section 3, we briefly introduce sparse covariance selection and show that it can be approximately solved as an l_1-norm penalized maximum likelihood estimation problem. We also discuss the application of the smooth optimization approach for solving this problem and propose a variant of this approach. In section 4, we compare the performance of our smooth optimization approach and its variant with two other first-order methods studied in [10, 16] for sparse covariance selection on a set of randomly generated instances. Finally, we present some concluding remarks in section 5.

1.1. Notation. In this paper, all vector spaces are assumed to be finite-dimensional. The space of symmetric $n \times n$ matrices will be denoted by $\mathcal{S}^n$. If $X \in \mathcal{S}^n$ is positive semidefinite, we write $X \succeq 0$. Also, we write $X \preceq Y$ to mean $Y - X \succeq 0$. The cone of positive semidefinite (resp., definite) matrices is denoted by $\mathcal{S}^n_+$ (resp., $\mathcal{S}^n_{++}$). Given matrices X and Y in $\Re^{p\times q}$, the standard inner product is defined by $\langle X, Y\rangle := \mathrm{Tr}(XY^T)$, where $\mathrm{Tr}(\cdot)$ denotes the trace of a matrix. $\|\cdot\|$ denotes the Euclidean norm and its associated operator norm unless it is explicitly stated otherwise. The Frobenius norm of a real matrix X is defined as $\|X\|_F := \sqrt{\mathrm{Tr}(XX^T)}$.

We denote by e the vector of all ones, and by I the identity matrix. Their dimensions should be clear from the context. For a real matrix X, we denote by $\mathrm{Card}(X)$ the cardinality of X, that is, the number of nonzero entries of X, and denote by $|X|$ the absolute value of X, that is, $|X|_{ij} = |X_{ij}|$ for all i, j. The determinant and the minimal (resp., maximal) eigenvalue of a real symmetric matrix X are denoted by $\det X$ and $\lambda_{\min}(X)$ (resp., $\lambda_{\max}(X)$), respectively. For an n-dimensional vector w, $\mathrm{diag}(w)$ denotes the diagonal matrix whose ith diagonal element is w_i for $i = 1, \ldots, n$. We denote by $\mathcal{Z}_+$ the set of all nonnegative integers.

Let the space $\mathcal{F}$ be endowed with an arbitrary norm $\|\cdot\|$. The dual space of $\mathcal{F}$, denoted by $\mathcal{F}^*$, is the normed real vector space consisting of all linear functionals of $s : \mathcal{F} \to \Re$, endowed with the dual norm $\|\cdot\|^*$ defined as

$$\|s\|^* := \max_u \{\langle s, u\rangle : \ \|u\| \le 1\} \quad \forall s \in \mathcal{F}^*,$$

where $\langle s, u\rangle := s(u)$ is the value of the linear functional s at u. Finally, given an operator $\mathcal{A} : \mathcal{F} \to \mathcal{F}^*$, we define

$$\mathcal{A}[H, H] := \langle \mathcal{A}H, H\rangle$$

for any $H \in \mathcal{F}$.

2. Smooth optimization approach. In this section, we consider a class of concave nonsmooth maximization problems:

$$\max_{x \in X} \{g(x) := \min_{u \in U} \phi(x, u)\}, \tag{2}$$

where X and U are nonempty convex compact sets in finite-dimensional real vector spaces $\mathcal{E}$ and $\mathcal{F}$, respectively, and $\phi(x, u) : X \times U \to \Re$ is a continuous function which is *strictly* concave in $x \in X$ for every fixed $u \in U$, and convex differentiable in $u \in U$ for every fixed $x \in X$. Therefore, for any $u \in U$, the function

$$f(u) := \max_{x \in X} \phi(x, u) \tag{3}$$

is well-defined. We also easily conclude that $f(u)$ is convex differentiable on U, and its gradient is given by

$$\nabla f(u) = \nabla_u \phi(x(u), u) \ \ \forall u \in U, \tag{4}$$

where $x(u)$ denotes the unique solution of (3).

Let the space $\mathcal{F}$ be endowed with an arbitrary norm $\|\cdot\|$. We further assume that $\nabla f(u)$ is Lipschitz continuous on U with respect to $\|\cdot\|$, i.e., there exists some $L > 0$ such that

$$\|\nabla f(u) - \nabla f(\tilde{u})\|^* \le L\|u - \tilde{u}\| \quad \forall u, \tilde{u} \in U.$$

Under the above assumptions, we easily observe that (i) problem (2) and its dual, that is,

$$\min_u \{f(u) : \ u \in U\}, \tag{5}$$

are both solvable and have the same optimal value; and (ii) the dual problem (5) can be suitably solved by Nesterov's smooth minimization approach [19, 21].

Denote by $d(u)$ a prox-function of the set U. We assume that $d(u)$ is continuous and strongly convex on U with modulus $\sigma > 0$. Let u_0 be the center of the set U defined as

$$u_0 = \arg\min\{d(u) : \ u \in U\}. \tag{6}$$

Without loss of generality assume that $d(u_0) = 0$. We now describe Nesterov's smooth minimization approach [19, 21] for solving the dual problem (5), and we will show that it simultaneously solves the nonsmooth concave maximization problem (2).

SMOOTH MINIMIZATION ALGORITHM.

Let $u_0 \in U$ be given in (6). Set $x_{-1} = 0$ and $k = 0$.

(1) Compute $\nabla f(u_k)$ and $x(u_k)$. Set $x_k = \frac{k}{k+2}x_{k-1} + \frac{2}{k+2}x(u_k)$.

(2) Find $u_k^{sd} \in \mathrm{Argmin}\big\{\langle \nabla f(u_k), u - u_k\rangle + \frac{L}{2}\|u - u_k\|^2 : \ u \in U\big\}$.

(3) Find $u_k^{ag} = \mathrm{argmin}\big\{\frac{L}{\sigma}d(u) + \sum_{i=0}^{k}\frac{i+1}{2}[f(u_i) + \langle \nabla f(u_i), u - u_i\rangle] : \ u \in U\big\}$.

(4) Set $u_{k+1} = \frac{2}{k+3}u_k^{ag} + \frac{k+1}{k+3}u_k^{sd}$.

(5) Set $k \leftarrow k + 1$ and go to step 1.

end

The following property of the above algorithm is established in Theorem 2 of Nesterov [21].

THEOREM 2.1. *Let the sequence $\{(u_k, u_k^{sd})\}_{k=0}^{\infty} \subseteq U \times U$ be generated by the smooth minimization algorithm. Then for any $k \geq 0$ we have*

$$\frac{(k+1)(k+2)}{4}f(u_k^{sd}) \leq \min\left\{\frac{L}{\sigma}d(u) + \sum_{i=0}^{k}\frac{i+1}{2}[f(u_i) + \langle \nabla f(u_i), u - u_i\rangle] : \ u \in U\right\}. \tag{7}$$

We are ready to establish the main convergence result of the smooth minimization algorithm for solving the nonsmooth concave maximization problem (2) and its dual (5). Its proof is a generalization of the one given in a more special context in [21].

THEOREM 2.2. *After k iterations, the smooth minimization algorithm generates a pair of approximate solutions (u_k^{sd}, x_k) to problem* (2) *and its dual* (5)*, respectively, which satisfy the following inequality:*

$$0 \leq f(u_k^{sd}) - g(x_k) \leq \frac{4LD}{\sigma(k+1)(k+2)}. \tag{8}$$

Thus if the termination criterion $f(u_k^{sd}) - g(x_k) \leq \epsilon$ is applied, the iteration complexity of finding an ϵ-optimal solution to problem (2) *and its dual* (5) *by the smooth minimization algorithm does not exceed $2\sqrt{LD/(\sigma\epsilon)}$, where*

$$D = \max\{d(u) : \ u \in U\}. \tag{9}$$

Proof. In view of (3), (4), and the notation $x(u)$, we have

$$f(u_i) + \langle \nabla f(u_i), u - u_i\rangle = \phi(x(u_i), u_i) + \langle \nabla_u \phi(x(u_i), u_i), u - u_i\rangle. \tag{10}$$

Invoking the fact that the function $\phi(x, \cdot)$ is convex on U for every fixed $x \in X$, we obtain

$$\phi(x(u_i), u_i) + \langle \nabla_u \phi(x(u_i), u_i), u - u_i\rangle \leq \phi(x(u_i), u). \tag{11}$$

Notice that $x_{-1} = 0$, and $x_k = \frac{k}{k+2}x_{k-1} + \frac{2}{k+2}x(u_k)$ for any $k \geq 0$, which imply

$$x_k = \sum_{i=0}^{k} \frac{2(i+1)}{(k+1)(k+2)} x(u_i). \tag{12}$$

Using (10), (11), (12), and the fact that the function $\phi(\cdot, u)$ is concave on X for every fixed $u \in U$, we have

$$\begin{aligned}\sum_{i=0}^{k}(i+1)[f(u_i) + \langle \nabla f(u_i), u - u_i\rangle] &\leq \sum_{i=0}^{k}(i+1)\phi(x(u_i), u) \\ &\leq \frac{1}{2}(k+1)(k+2)\phi(x_k, u)\end{aligned}$$

for all $u \in U$. It follows from this relation, (7), (9), and (2) that

$$\begin{aligned}f(u_k^{sd}) &\leq \frac{4LD}{\sigma(k+1)(k+2)} \\ &\quad + \min_u \left\{ \sum_{i=0}^{k} \frac{2(i+1)}{(k+1)(k+2)}[f(u_i) + \langle \nabla f(u_i), u - u_i\rangle] : \ u \in U \right\} \\ &\leq \frac{4LD}{\sigma(k+1)(k+2)} + \min_{u \in U} \phi(x_k, u) = \frac{4LD}{\sigma(k+1)(k+2)} + g(x_k),\end{aligned}$$

and hence the inequality (8) holds. The remaining conclusion directly follows from (8). ∎

Remark. We shall mention that Nesterov [20] developed the excessive gap technique for solving problem (2) and its dual (5) in a special context, which enjoys the same iteration complexity as the smooth minimization algorithm described above. In addition, it is not hard to observe that the technique proposed in [20] can be extended to solve problem (2) and its dual (5) in the aforementioned general framework, provided that the subproblem

$$\min_{u \in U} \phi(x, u) + \mu d(u) \tag{13}$$

can be suitably solved for any given $\mu > 0$ and $x \in X$. The computation of each iterate of Nesterov's excessive gap technique [20] is similar to that of the smooth minimization algorithm except that the former method requires solving a prox subproblem in the form of (13), but the latter one needs to solve the prox subproblem described in step 3 above. When the function $\phi(x, \cdot)$ is affine for every fixed $x \in X$, these two prox subproblems have the same form, and thus the computational cost of Nesterov's excessive gap technique [20] is almost the same as that of the smooth minimization algorithm; however, for a more general function $\phi(\cdot, \cdot)$, the computational cost of the former method can be more expensive than that of the latter method.

The following results will be used to develop a variant of the smooth minimization algorithm for sparse covariance selection in subsection 3.4.

LEMMA 2.3. *Problem* (2) *has a unique optimal solution, denoted by* x^*. *Moreover, for any* $u^* \in \mathrm{Argmin}\{f(u) : \ u \in U\}$, *we have*

$$x^* = \arg\max_{x \in X} \phi(x, u^*). \tag{14}$$

Proof. We clearly know that problem (2) has an optimal solution. To prove its uniqueness, it suffices to show that $g(x)$ is strictly concave on X. Indeed, since $X \times U$ is a convex compact set and $\phi(x,u)$ is continuous on $X \times U$, it follows that for any $t \in (0,1)$, $x^1 \neq x^2 \in X$, there exist some $\tilde{u} \in U$ such that

$$\phi(tx^1 + (1-t)x^2, \tilde{u}) = \min_{u \in U} \phi(tx^1 + (1-t)x^2, u).$$

Recall that $\phi(\cdot, u)$ is strictly concave on X for every fixed $u \in U$. Therefore, we have

$$\begin{aligned}\phi(tx^1 + (1-t)x^2, \tilde{u}) &> t\phi(x^1, \tilde{u}) + (1-t)\phi(x^2, \tilde{u}),\\ &\geq t \min\nolimits_{u \in U} \phi(x^1, u) + (1-t) \min\nolimits_{u \in U} \phi(x^2, u),\end{aligned}$$

which together with (2) implies that

$$g(tx^1 + (1-t)x^2) > tg(x^1) + (1-t)g(x^2)$$

for any $t \in (0,1)$, $x^1 \neq x^2 \in X$, and hence $g(x)$ is strictly concave on X as desired.

Note that x^* is the optimal solution of problem (2). We clearly know that for any $u^* \in \mathrm{Argmin}\{f(u) : u \in U\}$, (u^*, x^*) is a saddle point for problem (2), that is,

$$\phi(x^*, u) \geq \phi(x^*, u^*) \geq \phi(x, u^*) \quad \forall (x,u) \in X \times U,$$

and hence we have

$$x^* \in \mathrm{Arg}\max_{x \in X} \phi(x, u^*).$$

This, together with the fact that $\phi(\cdot, u^*)$ is strictly concave on X, immediately yields (14). ∎

THEOREM 2.4. *Let x^* be the unique optimal solution of (2), and let f^* be the optimal value of problems (2) and (5). Assume that the sequences $\{u_k\}_{k=0}^{\infty}$ and $\{x(u_k)\}_{k=0}^{\infty}$ are generated by the smooth minimization algorithm. Then the following statements hold:*

(1) *$f(u_k) \to f^*$, $x(u_k) \to x^*$ as $k \to \infty$;*

(2) *$f(u_k) - g(x(u_k)) \to 0$ as $k \to \infty$.*

Proof. Recall from the smooth minimization algorithm that

$$u_{k+1} = \left(2u_k^{ag} + (k+1)u_k^{sd}\right)/(k+3) \ \ \forall k \geq 0.$$

Since $u_k^{sd}, u_k^{ag} \in U$ for all $k \geq 0$, and U is a compact set, we have $u_{k+1} - u_k^{sd} \to 0$ as $k \to \infty$. Notice that $f(u)$ is continuous on the compact set U, and hence it is uniformly continuous on U. Then we further have $f(u_{k+1}) - f(u_k^{sd}) \to 0$ as $k \to \infty$. Also, it follows from Theorem 2.2 that $f(u_k^{sd}) \to f^*$ as $k \to \infty$. Therefore, we conclude that $f(u_k) \to f^*$ as $k \to \infty$.

Note that X is a compact set, and $x(u_k) \subseteq X$ for all $k \geq 0$. To prove that $x(u_k) \to x^*$ as $k \to \infty$, it suffices to show that every convergent subsequence of $\{x(u_k)\}_{k=0}^{\infty}$ converges to x^* as $k \to \infty$. Indeed, assume that $\{x(u_{n_k})\}_{k=0}^{\infty}$ is an arbitrary convergent subsequence, and $x(u_{n_k}) \to \tilde{x}^*$ as $k \to \infty$ for some $\tilde{x}^* \in X$. Without loss of generality, assume that the sequence $\{u_{n_k}\}_{k=0}^{\infty} \to \tilde{u}^*$ as $k \to \infty$ for some $\tilde{u}^* \in U$ (otherwise, one can consider any convergent subsequence of $\{u_{n_k}\}_{k=0}^{\infty}$). Using the result that $f(u_k) \to f^*$, we obtain that

$$\phi\left(x(u_{n_k}), u_{n_k}\right) = f(u_{n_k}) \to f^* \quad \text{as } k \to \infty.$$

Upon letting $k \to \infty$ and using the continuity of $\phi(\cdot,\cdot)$, we have $\phi(\tilde{x}^*, \tilde{u}^*) = f(\tilde{u}^*) = f^*$. Hence, it follows that

$$\tilde{u}^* \in \operatorname{Arg}\min_{u \in U} f(u), \quad \tilde{x}^* = \arg\max_{x \in X} \phi(x, \tilde{u}^*),$$

which together with Lemma 2.3 implies that $\tilde{x}^* = x^*$. Hence, as desired, $x(u_{n_k}) \to x^*$ as $k \to \infty$.

As shown in Lemma 2.3, the function $g(x)$ is continuous on X. This result, together with statement 1, immediately implies that statement 2 holds. □

3. Sparse covariance selection. In this section, we discuss the application of the smooth optimization approach proposed in section 2 to sparse covariance selection. More specifically, we briefly introduce sparse covariance selection in subsection 3.1 and show that it can be approximately solved as an l_1-norm penalized maximum likelihood estimation problem in subsection 3.2. In subsection 3.3, we address some implementation details of the smooth optimization approach for solving this problem and propose a variant of this approach in subsection 3.4.

3.1. Introduction of sparse covariance selection. In this subsection, we briefly introduce sparse covariance selection. For more details, see d'Aspremont, Banerjee, and El Ghaoui [10] and the references therein.

Given n variables with a Gaussian distribution $\mathcal{N}(0, C)$ for which the true covariance matrix C is unknown, we are interested in estimating C from a sample covariance matrix Σ by maximizing its likelihood while imposing a certain number of components in the inverse of the estimation of C to zero. This problem is commonly known as *sparse covariance selection* (see [11]). Since zeros in the inverse of covariance matrix correspond to conditional independence in the model, sparse covariance selection can be used to determine a robust estimate of the covariance matrix, and simultaneously discover the sparse structure in the underlying graphical model.

Several approaches have been proposed for sparse covariance selection in literature. For example, Bilmes [4] proposed a method based on choosing statistical dependencies according to conditional mutual information computed from training data. The recent works [18, 12] involve identifying the Gaussian graphical models that are best supported by the data and any available prior information on the covariance matrix. Given a sample covariance matrix $\Sigma \in \mathcal{S}_+^n$, d'Aspremont et al. [10] recently formulated sparse covariance selection as the following estimation problem:

$$\begin{array}{ll} \max_X & \log\det X - \langle \Sigma, X\rangle - \rho \mathrm{Card}(X) \\ \text{s.t.} & \tilde{\alpha} I \preceq X \preceq \tilde{\beta} I, \end{array} \tag{15}$$

where $\rho > 0$ is a parameter controlling the trade-off between likelihood and cardinality, and $0 \le \tilde{\alpha} < \tilde{\beta} \le \infty$ are the fixed bounds on the eigenvalues of the solution. For some specific choices of ρ, the formulation (15) has been used for model selection in [1, 5], and applied to speech recognition and gene network analysis (see [4, 13]).

Note that the estimation problem (15) itself is an NP-hard combinatorial problem because of the penalty term $\mathrm{Card}(X)$. To overcome the computational difficulty, d'Aspremont et al. [10] used an argument that is often used in regression techniques (e.g., see [23, 6, 14]), where sparsity of the solution is concerned, to relax $\mathrm{Card}(X)$ to $e^T|X|e$, and obtained the following l_1-norm penalized maximum likelihood estimation

problem:

$$\begin{array}{ll} \max_X & \log\det X - \langle \Sigma, X\rangle - \rho e^T|X|e \\ \text{s.t.} & \tilde{\alpha} I \preceq X \preceq \tilde{\beta} I. \end{array} \tag{16}$$

Recently, Yuan and Lin [25] proposed a similar estimation problem for sparse covariance selection given as follows:

$$\begin{array}{ll} \max_X & \log\det X - \langle \Sigma, X\rangle - \rho \sum_{i\neq j} |X_{ij}| \\ \text{s.t.} & \tilde{\alpha} I \preceq X \preceq \tilde{\beta} I, \end{array} \tag{17}$$

with $\tilde{\alpha} = 0$ and $\tilde{\beta} = \infty$. They showed that problem (17) can be suitably solved by the interior point algorithm developed in Vandenberghe, Boyd, and Wu [24]. A few other approaches have also been studied for sparse covariance selection by solving some related maximum likelihood estimation problems in the literature. For example, Huang, Liu, and Pourahmadi [17] proposed an iterative (heuristic) algorithm to minimize a nonconvex penalized likelihood. Dahl et al. [8, 7] applied Newton's method, the coordinate steepest descent method, and the conjugate gradient method for the problems for which the conditional independence structure is partially known.

As shown in d'Aspremont et al. [10] (see also [3]) and Yuan and Lin [25], the l_1-norm penalized maximum likelihood estimation problems (16) and (17) are capable of discovering effectively the sparse structure or, equivalently, the conditional independence in the underlying graphical model. Also, it is not hard to see that the estimation problem (17) becomes a special case of problem (16) if replacing Σ by $\Sigma + \rho I$ in (17). For these reasons, in the remainder of this paper we focus on problem (16) only.

3.2. Nonsmooth strictly concave maximization reformulation. In this subsection, we show that problem (16) can be reformulated as a nonsmooth strictly concave maximization problem of the form (2).

Recall from subsection 3.1 that $\Sigma \in \mathcal{S}^n_+$, and keep in mind that the notation $|\cdot|$, $\|\cdot\|$, and $\|\cdot\|_F$ is defined in subsection 1.1. We first provide some tighter bounds on the optimal solution of problem (16) for the case where $\tilde{\alpha} = 0$ and $\tilde{\beta} = \infty$.

PROPOSITION 3.1. *Assume that $\tilde{\alpha} = 0$ and $\tilde{\beta} = \infty$. Let $X^* \in \mathcal{S}^n_{++}$ be the unique optimal solution of problem* (16)*. Then we have $\alpha I \preceq X^* \preceq \beta I$, where*

$$\alpha = \frac{1}{\|\Sigma\| + n\rho}, \quad \beta = \min\left\{\frac{n - \alpha \mathrm{Tr}(\Sigma)}{\rho}, \eta\right\} \tag{18}$$

with

$$\eta = \begin{cases} \min\left\{e^T|\Sigma^{-1}|e, (n - \rho\sqrt{n}\alpha)\|\Sigma^{-1}\| - (n-1)\alpha\right\} & \text{if } \Sigma \text{ is invertible;} \\ 2e^T|(\Sigma + \frac{\rho}{2}I)^{-1}|e - \mathrm{Tr}((\Sigma + \frac{\rho}{2}I)^{-1}) & \text{otherwise.} \end{cases}$$

Proof. Let

$$\mathcal{U} := \{U \in \mathcal{S}^n : \ |U_{ij}| \leq 1 \quad \forall ij\} \tag{19}$$

and

$$L(X, U) = \log\det X - \langle \Sigma + \rho U, X\rangle \quad \forall (X, U) \in \mathcal{S}^n_{++} \times \mathcal{U}. \tag{20}$$

Note that $X^* \in \mathcal{S}^n_{++}$ is the optimal solution of problem (16). It can be easily shown that there exist some $U^* \in \mathcal{U}$ such that (X^*, U^*) is a saddle point of $L(\cdot,\cdot)$ on $\mathcal{S}^n_{++} \times \mathcal{U}$, that is,

$$X^* = \arg\min_{X \in \mathcal{S}^n_{++}} L(X, U^*), \quad U^* \in \operatorname{Arg}\min_{U \in \mathcal{U}} L(X^*, U).$$

The above relations along with (19) and (20) immediately yield

$$X^*(\Sigma + \rho U^*) = I, \quad \langle X^*, U^* \rangle = e^T |X^*| e. \tag{21}$$

Hence, we have

$$X^* = (\Sigma + \rho U^*)^{-1} \succeq \frac{1}{\|\Sigma\| + \rho \|U^*\|} I,$$

which together with (19) and the fact $U^* \in \mathcal{U}$ implies that $X^* \succeq \frac{1}{\|\Sigma\| + n\rho} I$. Thus, as desired, $X^* \succeq \alpha I$, where α is given in (18).

We next bound X^* from above. In view of (21), we have

$$\langle X^*, \Sigma \rangle + \rho e^T |X^*| e = n, \tag{22}$$

which together with the relation $X^* \succeq \alpha I$ implies that

$$e^T |X^*| e \le \frac{n - \alpha \mathrm{Tr}(\Sigma)}{\rho}. \tag{23}$$

Now let $X(t) := (\Sigma + t\rho I)^{-1}$ for $t \in (0,1)$. By concavity of $\log\det(\cdot)$, one can easily see that $X(t)$ maximizes the function $\log\det(\cdot) - \langle \Sigma + t\rho I, \cdot \rangle$ over $\mathcal{S}^n_{++}$. Using this observation and the definition of X^*, we can have

$$\log\det X^* - \langle \Sigma + t\rho I, X^* \rangle \le \log\det X(t) - \langle \Sigma + t\rho I, X(t) \rangle,$$

$$\log\det X(t) - \langle \Sigma, X(t) \rangle - \rho e^T |X(t)| e \le \log\det X^* - \langle \Sigma, X^* \rangle - \rho e^T |X^*| e.$$

Adding the above two inequalities upon some algebraic simplification, we obtain that

$$e^T |X^*| e - t\mathrm{Tr}(X^*) \le e^T |X(t)| e - t\mathrm{Tr}(X(t)),$$

and hence

$$e^T |X^*| e \le \frac{e^T |X(t)| e - t\mathrm{Tr}(X(t))}{1 - t} \quad \forall t \in (0,1). \tag{24}$$

If Σ is invertible, upon letting $t \downarrow 0$ on both sides of (24), we have

$$e^T |X^*| e \le e^T |\Sigma^{-1}| e.$$

Otherwise, letting $t = 1/2$ in (24), we obtain

$$e^T |X^*| e \le 2e^T \left| \left(\Sigma + \frac{\rho}{2} I \right)^{-1} \right| e - \mathrm{Tr}\left(\left(\Sigma + \frac{\rho}{2} I \right)^{-1} \right).$$

Combining the above two inequalities and (23), we have

$$\|X^*\| \le \|X^*\|_F \le e^T |X^*| e \le \min\left\{ \frac{n - \alpha \mathrm{Tr}(\Sigma)}{\rho}, \gamma \right\}, \tag{25}$$

where

$$\gamma = \begin{cases} e^T|\Sigma^{-1}|e & \text{if } \Sigma \text{ is invertible;} \\ 2e^T|(\Sigma + \frac{\rho}{2}I)^{-1}|e - \mathrm{Tr}((\Sigma + \frac{\rho}{2}I)^{-1}) & \text{otherwise.} \end{cases}$$

Further, using the relation $X^* \succeq \alpha I$, we obtain that

$$e^T|X^*|e \geq \|X^*\|_F \geq \sqrt{n}\alpha,$$

which together with (22) implies that

$$\mathrm{Tr}(X^*\Sigma) \leq n - \rho\sqrt{n}\alpha.$$

This inequality, along with the relation $X^* \succeq \alpha I$, yields

$$\lambda_{\min}(\Sigma)((n-1)\alpha + \|X^*\|) \leq \mathrm{Tr}(X^*\Sigma) \leq n - \rho\sqrt{n}\alpha.$$

Hence if Σ is invertible, we further have

$$\|X^*\| \leq (n - \rho\sqrt{n}\alpha)\|\Sigma^{-1}\| - (n-1)\alpha.$$

This together with (25) implies that $X^* \preceq \beta I$, where β is given in (18). □

Remark. Some bounds on X^* were also derived in d'Aspremont, Banerjee, and El Ghaoui [10]. In contrast with their bounds, our bounds given in (18) are tighter. Moreover, our approach for deriving the above bounds can be generalized to handle the case where $\tilde{\alpha} > 0$ and $\tilde{\beta} = \infty$, but their approach cannot. Indeed, if $\tilde{\alpha} > 0$ and $\tilde{\beta} = \infty$, we can set $\alpha = \tilde{\alpha}$ and replace the above $X(t)$ by the optimal solution of

$$\begin{array}{ll} \max_X & \log\det X - \langle \Sigma + \rho I, X\rangle \\ \text{s.t.} & \tilde{\alpha} I \preceq X, \end{array}$$

which has a closed-form expression. By following a similar derivation as above, one can obtain a positive scalar β such that $X^* \preceq \beta I$. In addition, for the case where $\tilde{\alpha} = 0$ and $0 < \tilde{\beta} < \infty$, one can set $\beta = \tilde{\beta}$ and easily show that $X^* \geq \alpha I$, where $\alpha = \beta e^{-\beta(\mathrm{Tr}(\Sigma)+n\rho)}$.

From the above discussion, we conclude that problem (16) is equivalent to the following problem:

$$\begin{array}{ll} \max_X & \log\det X - \langle \Sigma, X\rangle - \rho e^T|X|e \\ \text{s.t.} & \alpha I \preceq X \preceq \beta I \end{array} \tag{26}$$

for some $0 < \alpha < \beta < \infty$.

We further observe that problem (26) can be rewritten as

$$\max_{X\in\mathcal{X}} \min_{U\in\mathcal{U}} \ \log\det X - \langle \Sigma + \rho U, X\rangle, \tag{27}$$

where $\mathcal{U}$ is defined in (19), and $\mathcal{X}$ is defined as follows:

$$\mathcal{X} := \{X \in \mathcal{S}^n : \ \alpha I \preceq X \preceq \beta I\}. \tag{28}$$

Therefore, we conclude that problem (16) is equivalent to (27). For the remainder of the paper, we will focus on problem (27) only.

3.3. Smooth optimization method for sparse covariance selection. In this subsection, we describe the implementation details of the smooth minimization algorithm proposed in section 2 for solving problem (27). We also compare the complexity of this algorithm with interior point methods, and two other first-order methods studied in d'Aspremont et al. [10], that is, Nesterov's smooth approximation scheme and block-coordinate descent method.

We first observe that the sets $\mathcal{X}$ and $\mathcal{U}$ both lie in the space $\mathcal{S}^n$, where $\mathcal{X}$ and $\mathcal{U}$ are defined in (28) and (19), respectively. Let $\mathcal{S}^n$ be endowed with the Frobenius norm, and let $\tilde{d}(X) = \log\det X$ for $X \in \mathcal{X}$. Then for any $X \in \mathcal{X}$, we have

$$\nabla^2 \tilde{d}(X)[H,H] = -\mathrm{Tr}(X^{-1}HX^{-1}H) \le -\beta^{-2}\|H\|_F^2$$

for all $H \in \mathcal{S}^n$, and hence, $\tilde{d}(X)$ is strongly concave on $\mathcal{X}$ with modulus β^{-2}. Using this result and Theorem 1 of [21], we immediately conclude that $\nabla f(U)$ is Lipschitz continuous with constant $L = \rho^2\beta^2$ on $\mathcal{U}$, where

$$f(U) := \max_{X\in\mathcal{X}} \log\det X - \langle \Sigma + \rho U, X\rangle \quad \forall U \in \mathcal{U}. \tag{29}$$

Denote the unique optimal solution of problem (29) by $X(U)$. For any $U \in \mathcal{U}$, we can compute $X(U)$, $f(U)$, and $\nabla f(U)$ as follows.

Let $\Sigma + \rho U = Q\mathrm{diag}(\gamma)Q^T$ be an eigenvalue decomposition of $\Sigma + \rho U$ such that $QQ^T = I$. For $i = 1,\dots,n$, let

$$\lambda_i = \begin{cases} \min\{\max\{1/\gamma_i, \alpha\}, \beta\} & \text{if } \gamma_i > 0; \\ \beta & \text{otherwise.} \end{cases}$$

It is not hard to show that

$$X(U) = Q\mathrm{diag}(\lambda)Q^T, \quad f(U) = -\gamma^T\lambda + \sum_{i=1}^n \log\lambda_i, \quad \nabla f(U) = -\rho X(U). \tag{30}$$

From the above discussion, we see that problem (27) has exactly the same form as (2) and also satisfies all assumptions imposed on problem (2). Therefore, it can be suitably solved by the smooth minimization algorithm proposed in section 2. The implementation details of this algorithm for problem (27) are described as follows.

Given $U_0 \in \mathcal{U}$, let $d(U) = \|U - U_0\|_F^2/2$ be the proximal function on $\mathcal{U}$, which is strongly convex function with modulus $\sigma = 1$. For our specific choice of the norm and $d(U)$, we clearly see that steps 2 and 3 of the smooth minimization algorithm can be solved as a problem of the form

$$V = \arg\min_{U\in\mathcal{U}} \langle G, U\rangle + \|U\|_F^2/2$$

for some $G \in \mathcal{S}^n$. In view of (19), we see that

$$V_{ij} = \max\{\min\{-G_{ij}, 1\}, -1\}, \quad i,j = 1,\dots,n.$$

In addition, for any $X \in \mathcal{X}$, we define

$$g(X) := \log\det X - \langle \Sigma, X\rangle - \rho e^T|X|e. \tag{31}$$

For the ease of comparison with its latter variant, we now present a complete version of the aforementioned smooth minimization algorithm for solving problem (27) and its dual.

SMOOTH MINIMIZATION ALGORITHM FOR COVARIANCE SELECTION (SMACS).
Let $\epsilon > 0$ and $U_0 \in \mathcal{U}$ be given. Set $X_{-1} = 0$, $L = \rho^2\beta^2$, $\sigma = 1$, and $k = 0$.
(1) Compute $\nabla f(U_k)$ and $X(U_k)$. Set $X_k = \frac{k}{k+2}X_{k-1} + \frac{2}{k+2}X(U_k)$.
(2) Find $U_k^{sd} = \mathrm{argmin}\left\{\langle \nabla f(U_k), U - U_k\rangle + \frac{L}{2}\|U - U_k\|_F^2 : U \in \mathcal{U}\right\}$.
(3) Find $U_k^{ag} = \mathrm{argmin}\{\frac{L}{2\sigma}\|U - U_0\|_F^2 + \sum_{i=0}^{k}\frac{i+1}{2}[f(U_i) + \langle \nabla f(U_i), U - U_i\rangle] : U \in \mathcal{U}\}$.
(4) Set $U_{k+1} = \frac{2}{k+3}U_k^{ag} + \frac{k+1}{k+3}U_k^{sd}$.
(5) Set $k \leftarrow k + 1$. Go to step 1 until $f(U_k^{sd}) - g(X_k) \le \epsilon$.
end

The iteration complexity of the above algorithm for solving problem (27) is established in the following theorem.

THEOREM 3.2. *The iteration complexity performed by the algorithm SMACS for finding an ϵ-optimal solution to problem* (27) *and its dual does not exceed* $\sqrt{2}\rho\beta \max_{U\in\mathcal{U}}\|U - U_0\|_F/\sqrt{\epsilon}$, *and moreover, if* $U_0 = 0$, *it does not exceed* $\sqrt{2}\rho\beta n/\sqrt{\epsilon}$.

Proof. From the above discussion, we know that $L = \rho^2\beta^2$, $D = \max_{U\in\mathcal{U}}\|U - U_0\|_F^2/2$, and $\sigma = 1$, which together with Theorem 2.2 immediately implies that the first part of the statement holds. Further, if $U_0 = 0$, we easily obtain from (19) that $D = \max_{U\in\mathcal{U}}\|U\|_F^2/2 = n^2/2$. The second part of the statement directly follows from this result and Theorem 2.2. ∎

Remark. By the definition of $\mathcal{U}$ (see (19)), we can easily show that $\min_{U_0\in\mathcal{U}}\max_{U\in\mathcal{U}}\|U - U_0\|_F$ has a unique minimizer $U_0 = 0$. This result together with Theorem 3.2 implies that the initial point $U_0 = 0$ gives the optimal worst-case iteration complexity for the algorithm SMACS.

Alternatively, d'Aspremont et al. [10] applied Nesterov's smooth approximation scheme [21] to solve problem (27). More specifically, let $\epsilon > 0$ be the desired accuracy, and let

$$\hat{d}(U) = \|U\|_F^2/2, \quad \hat{D} = \max_{U\in\mathcal{U}}\hat{d}(U) = n^2/2.$$

As shown in [21], the nonsmooth function $g(X)$ defined in (31) is uniformly approximated by the smooth function

$$g_\epsilon(X) = \min_{U\in\mathcal{U}} \log\det X - \langle \Sigma + \rho U, X\rangle - \frac{\epsilon}{2\hat{D}}\hat{d}(U)$$

on $\mathcal{X}$ with the error at most by $\epsilon/2$, and, moreover, the function $g_\epsilon(X)$ has a Lipschitz continuous gradient on $\mathcal{X}$ with some constant $L(\epsilon) > 0$. Nesterov's smooth optimization technique [19, 21] is then applied to solve the perturbed problem $\max_{X\in\mathcal{X}} g_\epsilon(X)$, and problem (27) is accordingly solved. It was shown in [10] that the iteration complexity of this approach for finding an ϵ-optimal solution to problem (27) does not exceed

$$\frac{2\sqrt{2}\rho\beta n^{1.5}\log\kappa}{\epsilon} + \kappa\sqrt{\frac{n\log\kappa}{\epsilon}}, \tag{32}$$

where $\kappa := \beta/\alpha$.

In view of (32) and Theorem 3.2, we conclude that the smooth optimization approach improves upon Nesterov's smooth approximation scheme at least by a factor of $\mathcal{O}(\sqrt{n}\log\kappa/\sqrt{\epsilon})$ in terms of the iteration complexity for solving problem (27). Moreover, the computational cost per iteration of the former approach is at least as cheap as that of the latter one.

d'Aspremont et al. [10] also studied a block-coordinate descent method for solving problem (16) with $\tilde{\alpha} = 0$ and $\tilde{\beta} = \infty$. Each iterate of this method requires computing the inverse of an $(n-1) \times (n-1)$ matrix and solving a box constrained quadratic programming with $n-1$ variables. As mentioned in section 3 of [10], this method has a local linear convergence rate. However, its global iteration complexity for finding an ϵ-optimal solution is theoretically unknown. Moreover, this method is not suitable for solving problem (16) with $\tilde{\alpha} > 0$ or $\tilde{\beta} < \infty$.

In addition, we observe that problem (26) (also (16)) can be reformulated as a constrained smooth convex problem that has an explicit $\mathcal{O}(n^2)$-logarithmically homogeneous self-concordant barrier function. Thus, it can be suitably solved by interior point methods (see Nesterov and Nemirovskii [22] and Vandenberghe, Boyd, and Wu [24]). The worst-case iteration complexity of interior point methods for finding an ϵ-optimal solution to (26) is $\mathcal{O}(n \log(\epsilon_0/\epsilon))$, where ϵ_0 is an initial gap. Each iterate of interior point methods requires $\mathcal{O}(n^6)$ arithmetic cost for assembling and solving a typically dense Newton system with $\mathcal{O}(n^2)$ variables. Thus, the total worst-case arithmetic cost of interior point methods for finding an ϵ-optimal solution to (26) is $\mathcal{O}(n^7 \log(\epsilon_0/\epsilon))$. In contrast to interior point methods, the algorithm SMACS requires $\mathcal{O}(n^3)$ arithmetic cost per iteration dominated by eigenvalue decomposition and matrix multiplication of $n \times n$ matrices. Based on this observation and Theorem 3.2, we conclude that the overall worst-case arithmetic cost of the algorithm SMACS for finding an ϵ-optimal solution to (26) is $\mathcal{O}(\rho\beta n^4/\sqrt{\epsilon})$, which is substantially superior to that of interior point methods, provided that $\rho\beta$ is not too large and ϵ is not too small.

3.4. Variant of the smooth minimization algorithm. As discussed in subsection 3.3, the algorithm SMACS has a nice theoretical complexity in contrast with interior point methods, Nesterov's smooth approximation scheme, and the block-coordinate descent method. However, its practical performance is still not very attractive (see section 4). To enhance the computational performance, we propose a variant of the algorithm SMACS for solving problem (27) in this subsection.

Our first concern of the algorithm SMACS is that the eigenvalue decomposition of two $n \times n$ matrices is required per iteration. Indeed, the eigenvalue decomposition of $\Sigma + \rho U_k$ and $\Sigma + \rho U_k^{sd}$ is needed at steps 1 and 5 to compute $\nabla f(U_k)$ and $f(U_k^{sd})$, respectively. We also know that the eigenvalue decomposition is one of major computations for the algorithm SMACS. To reduce the computational cost, we now propose a new termination criterion other than $f(U_k^{sd}) - g(X_k) \le \epsilon$ that is used in the algorithm SMACS. In view of Theorem 2.4, we know that

$$f(U_k) - g(X(U_k)) \to 0 \text{ as } k \to \infty.$$

Thus, $f(U_k) - g(X(U_k)) \le \epsilon$ can be used as an alternative termination criterion. Moreover, it follows from (30) that the quantity $f(U_k) - g(X(U_k))$ is readily available in step 1 of the algorithm SMACS with almost no additional cost. We easily see that the algorithm SMACS with this new termination criterion would require only one eigenvalue decomposition per iteration. Despite this clear advantage, we shall mention that the iteration complexity of the resulting algorithm is unfortunately unknown. Nevertheless, in practice we have found that the number of iterations performed by the algorithm SMACS with the above two different termination criteria are almost same. Thus, $f(u_k) - g(x(u_k)) \le \epsilon$ is a useful practical termination criterion.

For sparse covariance selection, the penalty parameter ρ is usually small, but the parameter β can be fairly large. In view of Theorem 3.2, we know that the iteration

complexity of the algorithm SMACS for solving problem (27) is proportional to β. Therefore, when β is too large, the complexity and practical performance of this algorithm become unattractive. To overcome this drawback, we will propose one strategy to dynamically update β.

Let X^* be the unique optimal solution of problem (27). For any $\hat{\beta} \in [\lambda_{\max}(X^*), \beta]$, we easily observe that X^* is also the unique optimal solution to the following problem:

$$(P_{\hat{\beta}}) \qquad \max_{X \in \mathcal{X}_{\hat{\beta}}} \min_{U \in \mathcal{U}} \log\det X - \langle \Sigma + \rho U, X\rangle, \tag{33}$$

where $\mathcal{U}$ is defined in (19) and $\mathcal{X}_{\hat{\beta}}$ is given by

$$\mathcal{X}_{\hat{\beta}} := \{X : \ \alpha I \preceq X \preceq \hat{\beta} I\}.$$

In view of Theorem 3.2, the iteration complexity of the algorithm SMACS for problem (33) is lower than that for problem (27), provided $\hat{\beta} \in [\lambda_{\max}(X^*), \beta)$. Hence, ideally we set $\hat{\beta} = \lambda_{\max}(X^*)$, which would give the lowest iteration complexity, but unfortunately $\lambda_{\max}(X^*)$ is unknown. However, we can generate a sequence $\{\hat{\beta}_k\}_{k=0}^{\infty}$ that asymptotically approaches $\lambda_{\max}(X^*)$ as the algorithm progresses. Indeed, in view of Theorem 2.4, we know that $X(U_k) \to X^*$ as $k \to \infty$, and we obtain that

$$\lambda_{\max}(X(U_k)) \to \lambda_{\max}(X^*) \text{ as } k \to \infty.$$

Therefore, we see that $\{\lambda_{\max}(X(U_k))\}_{k=0}^{\infty}$ can be used to generate a sequence $\{\hat{\beta}_k\}_{k=0}^{\infty}$ that asymptotically approaches $\lambda_{\max}(X^*)$. We next propose a strategy to generate such a sequence $\{\hat{\beta}_k\}_{k=0}^{\infty}$.

For convenience of presentation, we introduce some new notation. Given any $U \in \mathcal{U}$ and $\hat{\beta} \in [\alpha, \beta]$, we define

$$X_{\hat{\beta}}(U) := \arg\max_{X \in \mathcal{X}_{\hat{\beta}}} \log\det X - \langle \Sigma + \rho U, X\rangle, \tag{34}$$

$$f_{\hat{\beta}}(U) := \max_{X \in \mathcal{X}_{\hat{\beta}}} \log\det X - \langle \Sigma + \rho U, X\rangle. \tag{35}$$

Definition 1. *Given any $U \in \mathcal{U}$ and $\hat{\beta} \in [\alpha, \beta]$, $X_{\hat{\beta}}(U)$ is called "active" if $\lambda_{\max}(X_{\hat{\beta}}(U)) = \hat{\beta}$ and $\hat{\beta} < \beta$; otherwise it is called "inactive."*

Let ς_1, $\varsigma_2 > 1$, and $\varsigma_3 \in (0, 1)$ be given and fixed. Assume that $U_k \in \mathcal{U}$ and $\hat{\beta}_k \in [\alpha, \beta]$ are given at the beginning of the kth iteration for some $k \geq 0$. We now describe the strategy for generating the next iterate U_{k+1} and $\hat{\beta}_{k+1}$ by considering the following three different cases:

(1) If $X_{\hat{\beta}_k}(U_k)$ is active, find the smallest $s \in \mathcal{Z}_+$ such that $X_{\bar{\beta}}(U_k)$ is inactive, where $\bar{\beta} = \min\{\varsigma_1^s \hat{\beta}_k, \beta\}$. Set $\hat{\beta}_{k+1} = \bar{\beta}$, and apply the algorithm SMACS for problem $(P_{\hat{\beta}_{k+1}})$ starting with the point U_k and set its next iterate to be U_{k+1}.

(2) If $X_{\hat{\beta}_k}(U_k)$ is inactive and $\lambda_{\max}(X_{\hat{\beta}_k}(U_k)) \leq \varsigma_3 \hat{\beta}_k$, set $\hat{\beta}_{k+1} = \max\{\min\{\varsigma_2 \lambda_{\max}(X_{\hat{\beta}_k}(U_k)), \beta\}, \alpha\}$. Apply the algorithm SMACS for problem $(P_{\hat{\beta}_{k+1}})$ starting with the point U_k, and set its next iterate to be U_{k+1}.

(3) If $X_{\hat{\beta}_k}(U_k)$ is inactive and $\lambda_{\max}(X_{\hat{\beta}_k}(U_k)) > \varsigma_3 \hat{\beta}_k$, set $\hat{\beta}_{k+1} = \hat{\beta}_k$. Continue the algorithm SMACS for problem $(P_{\hat{\beta}_k})$, and set its next iterate to be U_{k+1}.

For the sequences $\{U_k\}_{k=0}^{\infty}$ and $\{\hat{\beta}_k\}_{k=0}^{\infty}$ recursively generated above, we observe that the sequence $\{X_{\hat{\beta}_{k+1}}(U_k)\}_{k=0}^{\infty}$ is always inactive. This together with (34), (35), (29), and the fact that $\hat{\beta}_k \le \beta$ for $k \ge 0$ implies that

$$f(U_k) = f_{\hat{\beta}_{k+1}}(U_k), \quad \nabla f(U_k) = \nabla f_{\hat{\beta}_{k+1}}(U_k) \ \ \forall k \ge 0. \tag{36}$$

Therefore, the new termination criterion $f(U_k) - g(X(U_k)) \le \epsilon$ can be replaced by

$$f_{\hat{\beta}_{k+1}}(U_k) - g(X_{\hat{\beta}_{k+1}}(U_k)) \le \epsilon \tag{37}$$

accordingly.

We now incorporate into the algorithm SMACS the new termination criterion (37) and the aforementioned strategy for generating a sequence $\{\hat{\beta}_k\}_{k=0}^{\infty}$ that asymptotically approaches $\lambda_{\max}(X^*)$, and we obtain a variant of the algorithm SMACS for solving problem (27). For convenience of presentation, we omit the subscript k from $\hat{\beta}_k$.

VARIANT OF THE SMOOTH MINIMIZATION ALGORITHM FOR COVARIANCE SELECTION (VSMACS).

Let $\epsilon > 0$, ς_1, $\varsigma_2 > 1$, and $\varsigma_3 \in (0,1)$ be given. Choose a $U_0 \in \mathcal{U}$. Set $\hat{\beta} = \beta$, $L = \rho^2\beta^2$, $\sigma = 1$, and $k = 0$.

(1) Compute $X_{\hat{\beta}}(U_k)$ according to (30).
  (1a) If $X_{\hat{\beta}}(U_k)$ is active, find the smallest $s \in \mathcal{Z}_+$ such that $X_{\bar{\beta}}(U_k)$ is inactive, where $\bar{\beta} = \min\{\varsigma_1^s\hat{\beta}, \beta\}$. Set $k = 0$, $U_0 = U_k$, $\hat{\beta} = \bar{\beta}$, $L = \rho^2\hat{\beta}^2$, and go to step 2.
  (1b) If $X_{\hat{\beta}}(U_k)$ is inactive and $\lambda_{\max}(X_{\hat{\beta}}(U_k)) \le \varsigma_3\hat{\beta}$, set $k = 0$, $U_0 = U_k$, $\hat{\beta} = \max\{\min\{\varsigma_2\lambda_{\max}(X_{\hat{\beta}}(U_k)), \beta\}, \alpha\}$, and $L = \rho^2\hat{\beta}^2$.
(2) If $f_{\hat{\beta}}(U_k) - g(X_{\hat{\beta}}(U_k)) \le \epsilon$, terminate. Otherwise, compute $\nabla f_{\hat{\beta}}(U_k)$ according to (30).
(3) Find $U_k^{sd} = \operatorname{argmin}\{\langle \nabla f_{\hat{\beta}}(U_k), U - U_k\rangle + \frac{L}{2}\|U - U_k\|_F^2 : \ U \in \mathcal{U}\}$.
(4) Find $U_k^{ag} = \operatorname{argmin}\{\frac{L}{2\sigma}\|U - U_0\|_F^2 + \sum_{i=0}^{k}\frac{i+1}{2}[f_{\hat{\beta}}(U_i) + \langle \nabla f_{\hat{\beta}}(U_i), U - U_i\rangle] : U \in \mathcal{U}\}$.
(5) Set $U_{k+1} = \frac{2}{k+3}U_k^{ag} + \frac{k+1}{k+3}U_k^{sd}$.
(6) Set $k \leftarrow k+1$, and go to step 1.

end

We next establish some preliminary convergence properties of the above algorithm.

PROPOSITION 3.3. *For the algorithm VSMACS, the following properties hold:*

(1) *Suppose that the algorithm VSMACS terminates at some iterate* $(X_{\hat{\beta}}(U_k), U_k)$. *Then* $(X_{\hat{\beta}}(U_k), U_k)$ *is an* ϵ*-optimal solution to problem* (27) *and its dual.*
(2) *Suppose that* $\hat{\beta}$ *is updated only for a finite number of times. Then the algorithm VSMACS terminates in a finite number of iterations and produces an* ϵ*-optimal solution to problem* (27) *and its dual.*

Proof. For the final iterate $(X_{\hat{\beta}}(U_k), U_k)$, we clearly know that $f_{\hat{\beta}}(U_k) - g(X_{\hat{\beta}}(U_k)) \le \epsilon$, and $X_{\hat{\beta}}(U_k)$ is inactive. As shown in (36), $f(U_k) = f_{\hat{\beta}}(U_k)$. Hence, we have $f(U_k) - g(X_{\hat{\beta}}(U_k)) \le \epsilon$. We also know that $U_k \in \mathcal{U}$, and $X_{\hat{\beta}}(U_k) \in \mathcal{X}$ due to $\hat{\beta} \in [\alpha, \beta]$. Thus, statement 1 immediately follows. After the last update of $\hat{\beta}$, the algorithm VSMACS behaves exactly like the algorithm SMACS as applied to solve problem $(P_{\hat{\beta}})$ except with the termination criterion $f(U_k) - g(X_{\hat{\beta}}(U_k)) \le \epsilon$. Thus, it

follows from statement 1 and Theorem 2.4 that statement 2 holds. Thus, it follows from statement 1 and Theorem 2.4 that statement 2 holds. □

4. Computational results. In this section, we compare the performance of the smooth minimization approach and its variant proposed in this paper with other first-order methods studied in [10, 16], that is, Nesterov's smooth approximation scheme and block-coordinate descent method for solving problem (16) (or, equivalently, (27)) on a set of randomly generated instances.

All instances used in this section were randomly generated in the same manner as described in d'Aspremont et al. [10]. First, we generate a sparse invertible matrix $A \in \mathcal{S}^n$ with positive diagonal entries and a density prescribed by ϱ. We then generate the matrix $B \in \mathcal{S}^n$ by

$$B = A^{-1} + \tau V,$$

where $V \in \mathcal{S}^n$ is an independent and identically distributed uniform random matrix, and τ is a small positive number. Finally, we obtain the following randomly generated sample covariance matrix:

$$\Sigma = B - \min\{\lambda_{\min}(B) - \vartheta, 0\}I,$$

where ϑ is a small positive number. In particular, we set $\varrho = 0.01$, $\tau = 0.15$, and $\vartheta = 1.0e-4$ for generating all instances.

As discussed in section 3.3, our smooth minimization approach has much better worst-case iteration complexity than Nesterov's smooth approximation scheme studied in d'Aspremont et al. [10] for problem (27). However, it is unknown how their practical performance differs from each other. In the first experiment, we compare the practical performance of our smooth minimization approach and its variant with Nesterov's smooth approximation scheme studied in d'Aspremont et al. [10] for problem (27) with $\alpha = 0.1$, $\beta = 10$, and $\rho = 0.5$. For convenience of presentation, we label these three first-order methods as SM, VSM, and NSA, respectively. The codes for them are written in MATLAB. More specifically, the code for NSA follows the algorithm presented in d'Aspremont et al. [10], and the codes for SM and VSM are written in accordance with the algorithms SMACS and VSMACS, respectively. Moreover, we set $\varsigma_1 = \varsigma_2 = 1.05$ and $\varsigma_3 = 0.95$ for the algorithm VSMACS. These three methods terminate once the duality gap is less than $\epsilon = 0.1$. All computations are performed on an Intel Xeon 2.66 GHz machine with Red Hat Linux version 8.

The performance of the methods NSA, SM, and VSM for the randomly generated instances are presented in Table 1. The row size n of each sample covariance matrix Σ is given in column one. The numbers of iterations of NSA, SM, and VSM are given in columns two to four, the objective function values are given in columns five to seven, and the CPU times (in seconds) are given in the last three columns, respectively. From Table 1, we conclude that (i) the method SM, namely, the smooth minimization approach, outperforms substantially the method NSA, that is, Nesterov's smooth approximation scheme; and (ii) the method VSM, namely, the variant of the smooth minimization approach, substantially outperforms the other two methods. In addition, we see from this experiment that Nesterov's smooth minimization approach [19] is generally more appealing than his smooth approximation scheme [21] whenever the problem can be solved as an equivalent smooth problem. Nevertheless, we shall mention that the latter approach has a much wider field of application (e.g., see [21]), where the former approach cannot be applied.

TABLE 1
Comparison of NSA, SM and VSM.

Problem	Iter			Obj			Time		
n	NSA	SM	VSM	NSA	SM	VSM	NSA	SM	VSM
50	3657	457	20	−76.399	−76.399	−76.393	49.0	2.7	0.1
100	7629	920	27	−186.717	−186.720	−186.714	900.4	38.4	0.4

200	27499	2294	102	−511.246	−511.245	−511.242	26172.5	698.8	9.2
250	45122	3060	128	−3793.255	−3793.256	−3793.257	87298.9	1767.9	19.8
300	54734	3881	161	−3187.163	−3187.171	−3187.172	184798.1	3994.0	45.5
350	64641	4634	182	−2756.717	−2756.734	−2756.734	351460.7	7613.9	83.6
400	74839	5308	176	−3490.640	−3490.667	−3490.667	614237.1	13536.7	116.9

From the above experiment, we have already seen that the method VSM outperforms substantially two other first-order methods, namely, SM and NSA for solving problem (27). In the second experiment, we compare the performance of the method VSM with the block-coordinate descent methods studied in d'Aspremont et al. [10] and Friedman, Hastie, and Tibshirani [16] on relatively large-scale instances. For convenience of presentation, we label these two methods BCD1 and BCD2, respectively. The method BCD2 was developed very recently and is a slight variant of the method BCD1. In particular, each iterate of BCD1 solves a box constrained quadratic programming by means of interior point methods, but each iterate of BCD2 applies a coordinate descent approach to solving a lasso (l_1-regularized) least-squares problem, which is the dual of the box constrained quadratic programming appearing in BCD1. It is worth mentioning that the methods BCD1 and BCD2 are only applicable for solving problem (16) with $\tilde{\alpha} = 0$ and $\tilde{\beta} = \infty$. Thus, we only compare their performance with our method VSM for problem (16) with such $\tilde{\alpha}$ and $\tilde{\beta}$. As shown in subsection 3.2, problem (16) with $\tilde{\alpha} = 0$ and $\tilde{\beta} = \infty$ is equivalent to problem (27) with α and β given in (18), and hence it can be solved by applying the method VSM to the latter problem instead.

The code for the method BCD1 was written in MATLAB by d'Aspremont and El Ghaoui [9], while the code for BCD2 was written in Fortran 90 by Friedman, Hastie, and Tibshirani [15]. The methods BCD1 and VSM terminate once the duality gap is less than $\epsilon = 0.1$. The original code [15] for BCD2 uses the average absolute change in the approximate solution as the termination criterion. In particular, the average absolute change in the approximate solution is evaluated at the end of each cycle consisting of n block-coordinate descent iterations, and their code terminates once it is below a given accuracy (see [16, p. 6] for details). According to our computational experience, we found that with such a criterion BCD2 is extremely hard to terminate for relatively large-scale instances (say $n = 300$) unless a maximum number of iterations is set. Obviously, it is not easy to choose a suitable maximum number of iterations for BCD2. Thus, to be as fair as possible to BCD1 and VSM, we simply replace their termination criterion detailed in [15] for BCD2 by the one with the duality gap less than $\epsilon = 0.1$. In other words, the duality gap is computed at the end of each cycle consisting of n block-coordinate descent iterations, and BCD2 terminates once it is below $\epsilon = 0.1$. It is worth remarking that the cost for computing a duality gap is $\mathcal{O}(n^3)$ since the inverse of an $n \times n$ symmetric matrix is needed. Thus, it is reasonable to compute the duality gap once every n iterations rather than each iteration.

All computations are performed on an Intel Xeon 2.66 GHz machine with Red Hat Linux version 8. The performance of the methods BCD1, BCD2, and VSM for the randomly generated instances are presented in Table 2. The row size n of each sample covariance matrix Σ is given in column one. The numbers of iterations of BCD1, BCD2, and VSM are given in columns two to four, the objective function values are given in columns five to eight, and the CPU times (in seconds) are given in the last three columns, respectively. From Table 2, we conclude that both BCD2 and VSM substantially outperform BCD1. We also observe that our method VSM outperforms BCD2 for almost all instances except two relatively small-scale instances.

In the above experimentation, we compared the performance of BCD2 and VSM for $\epsilon = 0.1$. We next compare their performance on the same instances as above and apply the same termination criterion as above except that we set $\epsilon = 0.01$ and an upper bound of 20 hours computation time (or 72,000 seconds) per instance for both codes. The performance of the methods BCD2 and VSM is presented in Table 3. The row size n of each sample covariance matrix Σ is given in column one. The numbers of iterations of BCD2 and VSM are given in columns two to three, the objective function

values are given in columns four to five, and the CPU times (in seconds) are given in the last two columns, respectively. It shall be mentioned that BCD2 and VSM are both feasible methods, and, moreover, (16) and (27) are maximization problems. Therefore for these two methods, the larger the objective function value, the better. From Table 3, we observe that up to accuracy $\epsilon = 0.01$, the method BCD2 cannot solve almost all instances within 20 hours except the first three relatively small-scale ones, but our method VSM does solve each of these instances in less than one hour and produces better objective function values for almost all instances except the first three relatively small-scale ones. Also, it is interesting to observe that the number of iterations for VSM nearly doubles as the accuracy parameter ϵ increases by one digit, which is even better than the theoretical estimate, which is $\sqrt{10}$ according to Theorem 3.2.

5. Concluding remarks. In this paper, we proposed a smooth optimization approach for solving a class of nonsmooth strictly concave maximization problems. We also discussed the application of this approach to sparse covariance selection and proposed a variant of this approach. The computational results showed that the variant of the smooth optimization approach substantially outperforms the latter one, as well as two other first-order methods studied in d'Aspremont et al. [10] and Friedman et al. [16].

As discussed in subsection 3.3, problem (27) has the same form as (2) and satisfies all assumptions imposed on problem (2). Moreover, its associated objective function $\phi(X, U) = \log\det X - \langle \Sigma + \rho U, X\rangle$ is affine with respect to U for every fixed $X \in \mathcal{S}^n_{++}$. In view of these facts along with the remarks made in section 2, one can observe that problem (27) can be suitably solved by Nesterov's excessive gap technique [20]. Since the iterate complexity and the computational cost per iterate of this technique is the same as those of the algorithm SMACS, we expect that the computational performance of these two methods for solving (27) is similar. It would be interesting to implement Nesterov's excessive gap technique [20] and its variant (that is, the one in a similar fashion to the algorithm VSMACS) and compare their computational performance with SMACS and VSMACS, respectively.

Though the variant of the smooth optimization approach outperforms substantially the smooth optimization approach, we are currently only able to establish some preliminary convergence properties for it. A possible direction leading to a thorough proof of its convergence would be to show that the updates on $\hat{\beta}$ in the algorithm VSMACS can occur only for a finite number of times. Given that VSMACS is a nonmonotone algorithm, it is, however, highly challenging to analyze the behavior of the sequences $\{U_k\}$ and $\{X_{\hat{\beta}}(U_k)\}$ and hence the total number of updates on $\hat{\beta}$. Interestingly, we observed in our implementation that when $\hat{\beta} > \lambda_{\max}(X^*)$, the sequence $\{X_{\hat{\beta}}(U_k)\}$ generated by the algorithm VSMACS satisfies $\lambda_{\max}(X_{\hat{\beta}}(U_k)) \in [\lambda_{\max}(X^*), \hat{\beta})$, where X^* is the optimal solution of problem (27). Nevertheless, it remains completely open whether or not this holds in general. In addition, the ideas used in the variant of the smooth optimization approach are interesting in their own right even when viewed as some heuristics. They could also be used to enhance the practical performance of Nesterov's first-order methods [19, 21] for solving some general min-max problems.

The codes for the variant of the smooth minimization approach are written in MATLAB and C, which are available online at www.math.sfu.ca/∼zhaosong. The C code for this method can solve large-scale problems more efficiently, provided the LAPACK package is suitably installed. We will plan to extend these codes for solving

more general problems of the form

$$\begin{aligned} \max_X \quad & \log\det X - \langle \Sigma, X\rangle - \sum_{ij} \omega_{ij}|X_{ij}| \\ \text{s.t.} \quad & \tilde{\alpha} I \preceq X \preceq \tilde{\beta} I, \\ & X_{ij} = 0 \quad \forall (i,j) \in \Omega \end{aligned}$$

for some set Ω, where $\omega_{ij} = \omega_{ji} \geq 0$ for all $i, j = 1, \ldots, n$, and $0 \leq \tilde{\alpha} < \tilde{\beta} \leq \infty$ are some fixed bounds on the eigenvalues of the solution.

Acknowledgments. The author would like to thank Prof. Alexandre d'Aspremont for a careful discussion on the iteration complexity of Nesterov's smooth approximation scheme for sparse covariance selection given in [10]. Also, the author is in debt to two anonymous referees for numerous insightful comments and suggestions, which have greatly improved the paper.

CONVERGENCE ANALYSIS OF GENERALIZED ITERATIVELY REWEIGHTED LEAST SQUARES ALGORITHMS ON CONVEX FUNCTION SPACES*

NICOLAI BISSANTZ†, LUTZ DÜMBGEN‡, AXEL MUNK§, AND BERND STRATMANN†

Yehuda Vardi passed away unexpectedly on Jan. 13th, 2005, and we would like to dedicate this work to his memory.

Abstract. The computation of robust regression estimates often relies on minimization of a convex functional on a convex set. In this paper we discuss a general technique for a large class of convex functionals to compute the minimizers iteratively, which is closely related to majorization-minimization algorithms. Our approach is based on a quadratic approximation of the functional to be minimized and includes the iteratively reweighted least squares algorithm as a special case. We prove convergence on convex function spaces for general coercive and convex functionals F and derive geometric convergence in certain unconstrained settings. The algorithm is applied to total variation (TV) penalized quantile regression and is compared with a step size corrected Newton–Raphson algorithm. It is found that typically in the first steps the iteratively reweighted least squares algorithm performs significantly better, whereas the Newton type method outpaces the former only after many iterations. Finally, in the setting of bivariate regression with unimodality constraints we illustrate how this algorithm allows one to utilize highly efficient algorithms for special quadratic programs in more complex settings.

1. Introduction.

The computation of robust parametric and nonparametric regression estimators often requires the minimization of (convex) functionals on a set $\mathcal{C}$ which is determined by a priori information on the model underlying the data. For example, $\mathcal{C}$ can be a linear finite-dimensional space (linear model) or the set of isotonic vectors $m = (m_1, \ldots, m_d) \in \mathbb{R}^d$, $m_1 \le \ldots \le m_d$, with $d \le n$. To this end the functional

$$F^{(\rho)}(m) = \sum_{i=1}^{n} \rho(r_i(m)) \tag{1}$$

has to be minimized over $\mathcal{C} \subset \mathbb{R}^d$. Here $r_1, \ldots, r_n$ denote the (model-dependent) residuals of n data pairs (X_i, Y_i), $1 \le i \le n$, and ρ a given loss function [17]. Taking

$\rho(z) = z^2/2$ gives the ordinary least squares problem, while

$$\rho(z) = 2|z| \cdot \begin{cases} p & z \geq 0 \\ 1-p & z < 0 \end{cases} \tag{2}$$

with $0 < p < 1$ yields quantile regression [21, 30]. Other functions are Huber's [16] loss function

$$\rho(z) = \begin{cases} z^2/2 & |z| \leq \gamma \\ \gamma|z| - \gamma^2/2 & |z| > \gamma \end{cases}$$

or the logistic loss function $\rho(z) = \gamma^z \log(\cosh(z/\gamma))$ [7] for some $\gamma > 0$. An important extension of (1) are functionals

$$F(m) = F^{(\rho)}(m) + \lambda P(m)\ , \quad \lambda \geq 0, \tag{3}$$

where $P(m)$ denotes a penalizing term such as, for instance, the discrete total variation semi-norm of $m \in \mathbb{R}^d$,

$$P(m) = \sum_{j=1}^{d-1} |m_j - m_{j+1}|\ ; \tag{4}$$

see [23, 22] or [27]. In this paper a generalization of the iteratively reweighted least squares (IRLS) algorithm—therefore named GIRLS—is considered for minimization of a functional F as in (3) over any convex subset $\mathcal{C}$ of $\mathbb{R}^d$. This allows us to extend the IRLS algorithm, for example, to situations where $\mathcal{C}$ is defined as the space of monotone (or k-modal) vectors or to the problem of nonparametric regression estimates with total variation semi-norm penalization of its discrete derivative.

The general idea of the IRLS algorithm (and variants of it) is to approximate the functional F in a first step by smooth functionals F_δ such that $F_\delta \to F$ pointwise as $\delta \searrow 0$. The collection $(F_\delta)_{\delta>0}$ will be called a regularization of F (cf. Def. 1). In a second step, for each given base point $f \in \mathcal{C}$ the functional F_δ will be approximated by $G_\delta(f, .)$ (cf. Def. 2). Here $G_\delta : \mathcal{C} \times \mathbb{R}^d \to \mathbb{R}$ is a functional which is chosen such that a quick and numerically stable minimization can be performed. The resulting minimizer will serve as an approximation for the minimizer m_δ^* of F_δ and hence for a minimizer m^* of F. In particular, if it is possible to choose G_δ as a polynomial of degree two, the well-known IRLS algorithm may result [25, 28, 10].

The **GIRLS algorithm** can be summarized schematically as follows:

Preliminary Step: Determine a regularization $(F_\delta)_{\delta>0}$ of F and corresponding smooth approximations G_δ, $\delta > 0$.

Step 1: Initialize $\delta > 0$ and $m_\delta^{(0)} \in \mathcal{C}$.

Step 2: Repeat the following procedure until δ is sufficiently small: Compute

$$m_\delta^{(k)} := \operatorname*{argmin}_{m \in \mathcal{C}} G_\delta(m_\delta^{(k-1)}, m) \qquad \text{for } k = 1, 2, 3, \ldots \tag{5}$$

and terminate this iteration for a proper $k = k(\delta)$. Then replace $(\delta, m_\delta^{(0)})$ with $(\delta/2, m_\delta^{(k(\delta))})$.

Output: The final $m_\delta^{(k(\delta))}$ is our approximate minimizer of F over $\mathcal{C}$.

A more detailed description of this algorithm, including pseudocode and an explicit rule for $k(\delta)$ is provided in section 3.2.

The IRLS and related algorithms are based on the idea of majorizing functionals by a sequence of quadratic approximations and subsequent minimization. These have been treated extensively in the literature, e.g., [24, 19, 42, 29, 9, 18, 36, 37], and the

references therein. However, in most cases convergence is only shown for $\mathcal{C} = \mathbb{R}^d$. This simplifies proofs notably, since the minimizers can be represented as zeros of the derivatives of the functional. For arbitrary convex $\mathcal{C}$, however, the minimizers are no longer represented solely by such equality constraints, instead inequalities occur. Notable exceptions for general convex $\mathcal{C}$ are in [13], where however, the convergence results are restricted to a special class of functionals, requiring, e.g., $F(m) = O(\|m\|)$, or [39], who show convergence on convex polyhedral sets under the assumption that F is two times differentiable. Our findings generalize these results to the case of $\mathcal{C}$ being an arbitrary convex closed set as well as to more general functionals which are only required to be coercive and convex. This appears to be close to the weakest possible set of assumptions required for a general proof of convergence. Our proof adopts various arguments from convex analysis.

It is interesting to note that in the numerical literature the IRLS algorithm is denoted as the Weiszfeld algorithm [40, 41] who suggested this algorithm to solve the Fermat-Steiner-Weber problem [40, 41, 24, 19], which is known to the statistical community as the computation of the spatial median (as mentioned in [5, 6, 11]).

The remainder of this paper is organized as follows. First, we motivate the GIRLS algorithm for the special case of L^1-regression in section 2. Then we present the GIRLS algorithm in a general framework and prove various results about its convergence in section 3. Its convergence to the minimizer m^*_δ and hence to m^* as $\delta \searrow 0$ will be shown under very general assumptions (Theorem 2). Furthermore, in Theorem 5 we prove geometric, or, more precisely, at least Q-linear convergence of the sequence $(m_k)_k$ to m^*_δ under slightly stronger conditions (cf. [39] and [3]), and guidance is provided on the choice of the number of iterates in (5) and the regularization parameter δ. Finally, we show in Theorem 3 that any convex and coercive functional F can be regularized by a sequence F_δ s.t. each F_δ admits a quadratic approximation G_δ from above.

We stress that an advantage of the GIRLS approach is flexibility in the choice of F_δ and G_δ. This choice can be driven by various aspects, such as computational efficiency or rate of convergence (cf. Theorem 3). In this paper we emphasize the possibility to make use of efficient algorithms already available for the minimization of G_δ, such as the pool adjacent violators algorithm (PAVA) for isotonic weighted least squares approximation (see [33] for a comprehensive treatment). This is illustrated in section 4, where we describe the construction of F_δ and G_δ in some specific cases explicitly. In section 5 we discuss two numerical examples. In the first example we investigate in detail numerical performance of the GIRLS algorithm for the case of total variation (TV) penalized quantile regression. To this end the GIRLS algorithm is compared with a step size corrected Newton–Raphson algorithm. It is found that typically it outperforms the latter one in the first iteration steps significantly, in particular when the initial value is far from the optimum. This finding coincides with other numerical experiments, e.g., when applying the algorithms to L^1-penalized Poisson regression.

In the second example we apply the GIRLS algorithm to a two-dimensional TV minimization where we impose an additional unimodality constraint in one direction. We show that the GIRLS algorithm allows us to include the PAVA for the univariate unimodal subproblem, which is in general not possible for regression with two- or higher dimensional predictor. Note also that PAVA type methods are not available in general if an additional penalization term as in (3) is added. Again, the GIRLS algorithm offers a possibility to include them in each updating step.

In summary, the main advantage of the GIRLS algorithm is twofold. First, it is simple to perform and offers great flexibility for the choice of the approximating functionals G_δ. Second, it allows us to combine various restrictions and minimization

criteria (such as monotonicity constraints and roughness penalties). For such complex minimization problems, simple and quick algorithms such as PAVA or Newton type algorithms are not available in general, and more complicated and time consuming algorithms such as quadratic programming or interior point methods become necessary. Here the GIRLS algorithm represents a feasible alternative because it typically requires in each updating step the computation of minimizers (e.g., a weighted L^2 solution), which can be obtained easily. Further, our numerical experiments have shown that a rather small number of updating steps give already satisfactory results and the GIRLS algorithm outperfoms competitors in the first iterations, which is in accordance with previous numerical findings (see, e.g., [39]). Hence, as a practical rule of thumb, we find that the GIRLS algorithm is very simple to implement and provides a quick improvement of an initial value by a few iterations. It can be improved additionally by performing subsequent iterations by other, more sophisticated, optimization algorithms.

2. L^1-regression with the GIRLS algorithm. As a motivating example consider the L^1 linear regression problem for observations $(X_1, Y_1), (X_2, Y_2), \ldots, (X_n, Y_n)$ in $\mathbb{R}^d \times \mathbb{R}$. Assuming that Y_i equals $X_i^\top m$ plus a random error, the goal is to compute

$$m := \operatorname*{argmin}_{m \in \mathbb{R}^d} \sum_{i=1}^{n} |Y_i - X_i^\top m| = \operatorname*{argmin}_{m \in \mathbb{R}^d} F(m), \tag{6}$$

an estimator of the unknown parameter vector $m \in \mathbb{R}^d$. Iteratively reweighted least squares is based on the idea that, in a first step, the L^1-norm F, being a convex functional, will be approximated (regularized) by a family of smooth convex functionals F_δ, $\delta > 0$, e.g.,

$$F_\delta(m) = \sum_{i=1}^{n} h_\delta \left(Y_i - X_i^\top m \right),$$

where

$$h_\delta(z) = [z^2 + \delta]^{1/2}. \tag{7}$$

The regularization of a nonsmooth functional as in (6) by (7) is well known, of course (see, e.g., [38]). It is supposed that minimization of F_δ is numerically better tractable than minimization of the original functional F in in (6). Then $m_\delta := \operatorname{argmin}_{m \in \mathbb{R}^d} F_\delta(m)$ will be an approximation of m (cf. Theorem 1). In order to compute m_δ the following recursion formula is iterated:

$$m_\delta^{(k+1)} = \operatorname*{argmin}_{m \in \mathbb{R}^d} \sum_{i=1}^{n} \frac{(Y_i - X_i^\top m)^2}{h_\delta(Y_i - X_i^\top m_\delta^{(k)})}. \tag{8}$$

Note that in each updating step the computation of $m_\delta^{(k+1)}$ means solving a simple diagonally reweighted least squares minimization problem, which can easily be done by using standard methods such as, e.g., Householder QR decomposition. As a starting value $m_\delta^{(0)}$ any (reasonable) choice, e.g., the least squares estimator, may serve.

It is instructive to indicate a proof for this simple case. The basic idea is to approximate $h_\delta(z)$ from above for any given real number r by a quadratic function $g_\delta(r, z) = c(r) + a(r)z^2/2$ of z such that $g_\delta(r, \cdot) \geq h_\delta$ and $g_\delta(r, r) = h_\delta(r)$. This can

be achieved indeed with

$$g_\delta(r,z) \;=\; h_\delta(r) + h_\delta(r)^{-1}(z^2 - r^2)/2; \tag{9}$$

see also Lemma 1 in section 4. The intrinsic reason is that h_δ is an even convex function whose second derivative h_δ'' is nonincreasing on $[0,\infty)$. Thus $m_\delta^{(k+1)}$ in (8) is the minimizer of

$$G_\delta(m_\delta^{(k)}, m) \;:=\; \sum_{i=1}^n g_\delta\left(Y_i - X_i^\top m_\delta^{(k)}, Y_i - X_i^\top m\right)$$

over all $m \in \mathbb{R}^d$. Note that F_δ as well as $G_\delta(m_\delta^{(k)}, \cdot)$ are convex functions such that $F_\delta(m) \le G_\delta(m_\delta^{(k)}, m)$ with equality for $m = m_\delta^{(k)}$, and their gradients satisfy

$$\nabla F_\delta(m_\delta^{(k)}) = \nabla G_\delta(m_\delta^{(k)}, m_\delta^{(k)}).$$

Here and in the following the gradient of G_δ is defined with respect to the second argument. Thus

$$F_\delta(m_\delta^{(k+1)}) \le G_\delta(m_\delta^{(k)}, m_\delta^{(k+1)}) \le G_\delta(m_\delta^{(k)}, m_\delta^{(k)}) = F_\delta(m_\delta^{(k)}),$$

and the second inequality in the latter display is strict if, and only if, $m_\delta^{(k)}$ differs from the solution m_δ. Consequently, $F_\delta(m_\delta^{(k)})$ is either strictly decreasing in k, or $m_\delta^{(k)} = m_\delta$ for sufficiently large k. This fact was established by [25] for the particular problem (6). Convergence of $m_\delta^{(k)}$ to m_δ as $k \to \infty$ follows from our general Theorem 2 below.

3. The GIRLS algorithm.

3.1. Main theorem and convergence analysis. Returning to the general setting, we always assume that our target functional $F : \mathbb{R}^d \to \mathbb{R}$ is convex and coercive, i.e., $F(x) \to \infty$ as $\|x\| \to \infty$. Moreover, let $\mathcal{C} \subset \mathbb{R}^d$ be closed and convex. This entails that the set

$$M^* := \operatorname*{argmin}_{m \in \mathcal{C}} F(m)$$

is a nonvoid, compact, and convex subset of $\mathcal{C}$. Now the first step is to approximate F by a family of strictly convex and smooth functionals F_δ, $\delta > 0$, converging pointwise to F as $\delta \searrow 0$. This is summarized in the following definition.

DEFINITION 1. *A functional $F_\delta : \mathbb{R}^d \to \mathbb{R}$ is called* regular*, if F_δ is strictly convex, continuously differentiable, and coercive. A* regularization of F *consists of regular functionals F_δ, $\delta > 0$, such that F_δ converges pointwise to F as $\delta \searrow 0$.*

Theorem 4 below shows that there exists always a regularization $(F_\delta)_{\delta>0}$ for F. It follows from strict convexity and coercivity of F_δ that it has a unique minimizer

$$m_\delta^* := \operatorname*{argmin}_{m \in \mathcal{C}} F_\delta(m),$$

which serves as an approximation to M^*. The next theorem provides an exact formulation of this fact.

THEOREM 1 (approximation of M^*). *Let $F : \mathbb{R}^d \to \mathbb{R}$ be a convex and coercive functional, and let $(F_\delta)_{\delta>0}$ be a regularization of F. Then, as $\delta \searrow 0$,*

$$\left.\begin{matrix} F_\delta(m_\delta^*) \\ F(m_\delta^*) \end{matrix}\right\} \to \min_{x\in\mathcal{C}} F(x) \quad \text{and} \quad d(m_\delta^*, M^*) := \inf_{y\in M^*} \|m_\delta^* - y\| \to 0.$$

Before proving Theorem 1 we summarize some well-known facts about convex functionals (see [34]), which we utilize in the subsequent proofs. A convex functional on $\mathbb{R}^d$ is automatically continuous. If a sequence of convex functionals on $\mathbb{R}^d$ converges pointwise, then the convergence is uniform on arbitrary bounded sets. Finally, if $H : \mathbb{R}^d \to \mathbb{R}$ is convex and differentiable, and if $\mathcal{C} \subset \mathbb{R}^d$ is closed and convex, then $f \in \mathcal{C}$ minimizes H over $\mathcal{C}$ if, and only if,

$$\nabla H(f)^\top (m - f) \geq 0 \quad \text{for all } m \in \mathcal{C}. \tag{10}$$

Proof of Theorem 1. For any set $S \subset \mathbb{R}^d$ let $\|F - F_\delta\|_S$ be the supremum norm of $F - F_\delta$ over S. Since M^* is compact, for any fixed $\epsilon > 0$, the set $B_\epsilon := \{m \in \mathcal{C} : d(m, M^*) \leq \epsilon\}$ is compact, too. Thus $\|F - F_\delta\|_{B_\epsilon}$ tends to zero as $\delta \searrow 0$. In particular, for sufficiently small $\delta > 0$,

$$\min_{m\in\mathcal{C}\,:\, d(m,M^*)=\epsilon} F_\delta(m) > \max_{m\in M^*} F_\delta(m). \tag{11}$$

To verify (11), first note that it holds with F in place of F_δ, by definition of M^*. Since $F_\delta \to F$ uniformly on B_ϵ, (11) holds for sufficiently small $\delta > 0$. But (11) implies that $F_\delta(m_o) > \min_{m\in M^*} F_\delta(m)$ for any $m_o \in \mathcal{C} \setminus B_\epsilon$, and hence $m_\delta^* \in B_\epsilon$. Let m_* be the metric projection of m_o onto M^* and write $m_o = m_* + tv$ for some unit vector $v \in \mathbb{R}^d$ and a scalar $t > \epsilon$. Then it follows from convexity of the function $t \mapsto F_\delta(m_* + tv)$ that

$$\begin{aligned} F_\delta(m_o) - \min_{m\in M^*} F_\delta(m) &\geq F_\delta(m_* + tv) - F_\delta(m_*) \\ &\geq (t/\epsilon)(F_\delta(m_* + \epsilon v) - F_\delta(m_*)) \\ &> 0 \end{aligned}$$

in case of (11). These considerations show already that $d(m_\delta^*, M^*) \to 0$ as $\delta \searrow 0$. Note also that in case of $m_\delta^* \in B_\epsilon$,

$$|F_\delta(m_\delta^*) - F(m_\delta^*)| \leq \|F - F_\delta\|_{B_\epsilon}, \tag{12}$$

and

$$F(m_\delta^*) - \min_{x\in\mathcal{C}} F(x) \leq \max_{x,y\in B_\epsilon\,:\,\|x-y\|\leq\epsilon} \big|F(y) - F(x)\big|.$$

Finally, the r.h.s. of the latter inequality tends to 0 as $\epsilon \searrow 0$, by compactness of M^* and continuity of F. These findings show that both $F(m_\delta^*)$ and $F_\delta(m_\delta^*)$ tend to $\min_{x\in\mathcal{C}} F(x)$ as $\delta \searrow 0$. □

The second step is to determine m_δ^* via approximations $G_\delta(f, \cdot)$ of F_δ for various $f \in \mathcal{C}$ as in (5). The following definition summarizes our assumptions on G_δ.

DEFINITION 2. *Let $F_\delta : \mathbb{R}^d \to \mathbb{R}$ be a regular functional. Another functional $G_\delta : \mathcal{C} \times \mathbb{R}^d \to \mathbb{R}$ is called a* smooth approximation of F_δ from above, *if it is continuous in both arguments and satisfies the following additional properties for arbitrary $f \in \mathcal{C}$:*

(i) $G_\delta(f,\cdot)$ *is strictly convex and continuously differentiable,*
(ii) $G_\delta(f,m) \geq F_\delta(m)$ *for all* $m \in \mathbb{R}^d$ *with equality for* $m = f$.

The functional G_δ *is called a* quadratic approximation of F_δ from above *if, in addition,* $G_\delta(f,\cdot)$ *is always a polynomial of order two, i.e.,*

$$G_\delta(f,m) = F_\delta(f) + \nabla F_\delta(f)^\top (m-f) + 2^{-1}(m-f)^\top B(f)(m-f) \tag{13}$$

for some symmetric, positive definite matrix $B(f) \in \mathbb{R}^{d\times d}$.

The next theorem is the main result of this paper.

THEOREM 2 (convergence of the GIRLS algorithm). *Let* $\mathcal{C} \subset \mathbb{R}^d$ *be a closed convex set and* $F_\delta : \mathbb{R}^d \to \mathbb{R}$ *be a regular functional which can be smoothly approximated from above by* G_δ. *Then the GIRLS algorithm, defined by* (5) *with an arbitrary starting point* $m_\delta^{(0)} \in \mathcal{C}$, *yields a sequence* $(m_\delta^{(k)})_{k=0}^\infty$ *converging to* m_δ^*.

Proof. At first we prove that $F_\delta(m_\delta^{(k)})$ is decreasing in k. It follows from Property (ii) in Definition 2 that the gradients $\nabla F_\delta(m)$ and $\nabla G_\delta(m_\delta^{(k)}, m)$ (defined with respect to the second argument) coincide for $m = m_\delta^{(k)}$. Thus it follows from the characterization (10), applied to $H = G_\delta(m_\delta^{(k)},\cdot)$ and $H = F_\delta$, respectively, that $m_\delta^{(k+1)} = m_\delta^{(k)}$ if, and only if, $m_\delta^{(k)} = m_\delta^*$. Otherwise the minimizer $m_\delta^{(k+1)}$ of $G_\delta(m_\delta^{(k)},\cdot)$ over $\mathcal{C}$ differs from $m_\delta^{(k)}$, whence Property (ii) in Definition 2 entails

$$F_\delta(m_\delta^{(k+1)}) \leq G_\delta(m_\delta^{(k)}, m_\delta^{(k+1)}) < G_\delta(m_\delta^{(k)}, m_\delta^{(k)}) = F_\delta(m_\delta^{(k)}).$$

By monotonicity of $(F_\delta(m_\delta^{(k)}))_k$, all points $m_\delta^{(k)}$ lie in the set $\{m \in \mathcal{C} : F_\delta(m) \leq F_\delta(m_\delta^{(0)})\}$, which is compact by continuity and coercivity of F_δ. Hence it is sufficient to show that any limit point m_o equals m_δ^*. Now, take an arbitrary convergent subsequence $(m_\delta^{(k_\ell)})_\ell$ with limit m_o. For any $v \in \mathcal{C}$,

$$\begin{aligned} F_\delta\left(m_\delta^{(k_\ell+1)}\right) &\leq G_\delta\left(m_\delta^{(k_\ell)}, m_\delta^{(k_\ell+1)}\right) \\ &\leq G_\delta\left(m_\delta^{(k_\ell)}, v\right) \\ &\to G_\delta(m_o, v) \quad \text{as } \ell \to \infty, \end{aligned}$$

by continuity of G_δ. But

$$\lim_{\ell\to\infty} F_\delta\left(m_\delta^{(k_\ell+1)}\right) \geq \lim_{\ell\to\infty} F_\delta\left(m_\delta^{(k_{\ell+1})}\right) = F_\delta(m_o) = G_\delta(m_o, m_o).$$

Thus $G_\delta(m_o, m_o) \leq G_\delta(m_o, v)$ for all $v \in \mathcal{C}$; i.e., m_o is the unique minimizer of $G_\delta(m_o,\cdot)$. As argued above, this entails that $m_o = m_\delta^*$. □

The next theorem states that convex and coercive functionals F can always be regularized and approximated quadratically from above. Hence GIRLS is, in principle, always applicable.

THEOREM 3 (regularization and approximation of F). *Let* $F : \mathbb{R}^d \to \mathbb{R}$ *be a convex and coercive functional. Then there exists a regularization* $(F_\delta)_{\delta>0}$ *of* F *such that each* F_δ *admits a quadratic approximation* G_δ *from above.*

In order to prove Theorem 3, we require the following result.

THEOREM 4. *Let* F *be a nonnegative, coercive, convex functional on* $\mathbb{R}^d$. *Then there are strictly convex and infinitely often differentiable functionals* $F_\delta \geq F$, $\delta > 0$, *such that* $F_\delta \to F$ *pointwise as* $\delta \searrow 0$.

Proof. Let $K(x) := 1\{\|x\| < 1\}C \exp\bigl(-(1-\|x\|^2)^{-1}\bigr)$, where C is chosen such that K integrates to one. This is a well-known example of an infinitely differentiable, nonnegative, even kernel function with compact support $\{x : \|x\| \le 1\}$. For $\delta > 0$ we define $K_\delta(x) := \delta^{-1}K(\delta^{-1}x)$ and

$$F_\delta(x) := \int F(y)K_\delta(x-y)\,\mathrm{d}y = \int F(x+\delta z)K(z)\,\mathrm{d}z.$$

It is well known that F_δ is infinitely often differentiable with limit F pointwise (cf. [35]. It is also inherits convexity from F, because for $x, y \in \mathbb{R}^d$ and $\lambda \in (0,1)$,

$$\begin{aligned} F_\delta((1-\lambda)x+\lambda y) &= \int F_\delta\bigl((1-\lambda)(x+\delta z)+\lambda(y+\delta z)\bigr)K(z)\,\mathrm{d}z \\ &\le \int \bigl((1-\lambda)F(x+\delta z)+\lambda F(y+\delta z)\bigr)K(z)\,\mathrm{d}z \\ &= (1-\lambda)F_\delta(x)+\lambda F_\delta(y). \end{aligned}$$

Moreover, since K is even,

$$F_\delta(x) = \int \frac{F(x+\delta z)+F(x-\delta z)}{2}K(z)\,\mathrm{d}z \ge \int F(x)K(z)\,\mathrm{d}z = F(x),$$

again by convexity of F. Finally, if F_δ fails to be strictly convex, we may add to F_δ the strictly convex function $x \mapsto \delta\|x\|^2$. □

We mention that the construction of F_δ given here is mainly for theoretical purposes, and may in practice be difficult to evaluate numerically due to the high dimensionality of the integral.

Proof of Theorem 3. Let $(F_\delta)_{\delta>0}$ be a regularization of F such that D^2F_δ is positive definite everywhere; cf. Theorem 4 and its proof. It may happen that $\limsup_{\|m\|\to\infty} F_\delta(m)/\|m\|^2 = \infty$, rendering quadratic approximation of F_δ from above impossible. Thus we modify the functions F_δ as follows: Let

$$c_\delta := \max_{\|m\|\le\delta^{-1}} \lambda_{\max}(D^2F_\delta(m))$$

with $\lambda_{\max}(A)$ denoting the largest eigenvalue of a symmetric matrix $A \in \mathbb{R}^{d\times d}$. Starting from the representation

$$F_\delta(m) = F_\delta(0) + \nabla F_\delta(0)^\top m + \int_0^1 m^\top D^2F_\delta(tm)m\,(1-t)\,dt,$$

we define

$$\tilde{F}_\delta(m) := F_\delta(0) + \nabla F_\delta(0)^\top m + \int_0^1 m^\top \min(D^2F_\delta(tm), c_\delta I)m\,(1-t)\,dt.$$

Here $\min(A, c_\delta I) \in \mathbb{R}^{d\times d}$ is obtained from the spectral representation of A by replacing each eigenvalue $\lambda_i(A)$ with $\min(\lambda_i(A), c_\delta)$. Note that $\tilde{F}_\delta$ is twice continuously differentiable with $\tilde{F}_\delta(0) = F_\delta(0)$, $\nabla\tilde{F}_\delta(0) = \nabla F_\delta(0)$, and $D^2\tilde{F}_\delta = \min(D^2F_\delta, c_\delta I)$. The Hessian matrix is positive definite with largest eigenvalue never exceeding c_δ. In addition, $\tilde{F}_\delta = F_\delta$ on $\{m : \|m\| \le \delta^{-1}\}$. Thus for sufficiently small $\delta > 0$, $\tilde{F}_\delta$ is regular, and a quadratic approximation of $\tilde{F}_\delta$ from above is given by

$$G_\delta(f,m) := \tilde{F}_\delta(f) + \nabla\tilde{F}_\delta(f)^\top(m-f) + c_\delta\|m-f\|^2/2. \qquad \square$$

Remark 1. In Definition 1 we assume that F_δ is strictly convex. This property is only required for notational convenience, because it guarantees uniqueness of the minimizer m_δ^*. A careful inspection of the proof of Theorem 1 shows, however, that convergence continues to hold if strict convexity is replaced with convexity. Only the assertion $d(m_\delta^*, M^*) \to 0$ has to be replaced by

$$\sup_{x \in M_\delta^*} \inf_{y \in M^*} \|x - y\| \to 0,$$

where $M_\delta^* := \operatorname{argmin}_{m \in \mathcal{C}} F_\delta(m)$. An analogous modification holds for Theorem 2.

We close the section with the following result, which shows under additional regularity conditions on F_δ and $\mathcal{C}$ geometric, or, more precisely, at least Q-linear convergence of the GIRLS algorithm (cf. [3, Theorem 4.1], for a related result).

THEOREM 5 (geometric convergence of the GIRLS algorithm). *Let $F_\delta : \mathbb{R}^d \to \mathbb{R}$ be coercive and twice continuously differentiable with positive definite Hessian matrix $D^2F(m_\delta^*) =: A$. Further let $G_\delta : \mathbb{R}^d \times \mathbb{R}^d$ be a quadratic approximation of F_δ from above with Hessian matrix $B(m_\delta^*) =: B$ as in* (13). *Then the GIRLS algorithm yields a sequence $(m_\delta^{(k)})_{k=0}^\infty$ converging to $m_\delta^* = \operatorname{argmin}_{\mathcal{C}} F_\delta$ such that*

$$\limsup_{k \to \infty} \frac{\|m_\delta^{(k+1)} - m_\delta^*\|_A}{\|m_\delta^{(k)} - m_\delta^*\|_A} \;\le\; 1 - \lambda_{\min}\left(B^{-1}A\right) \in [0, 1).$$

Here $\|v\|_A := (v^\top A v)^{1/2}$, and $\lambda_{\min}(B^{-1}A) \in (0, 1]$ denotes the smallest eigenvalue of $B^{-1}A$.

Proof. According to Theorem 2, $\lim_{k\to\infty} m_\delta^{(k)} = m_\delta^*$. Since $\mathcal{C} = \mathbb{R}^d$, $\nabla F_\delta(m_\delta^*) = 0$ and

$$\begin{aligned} m_\delta^{(k+1)} &= m_\delta^{(k)} - B(m_\delta^{(k)})^{-1} \nabla F_\delta(m_\delta^{(k)}) \\ &= m_\delta^{(k)} - B(m_\delta^{(k)})^{-1} \int_0^1 D^2 F_\delta\left((1-t)m_\delta^* + t m_\delta^{(k)}\right)(m_\delta^{(k)} - m_\delta^*)\,\mathrm{d}t \\ &= m_\delta^{(k)} - B^{-1}A(m_\delta^{(k)} - m_\delta^*) + o\Big(\|m_\delta^{(k)} - m_\delta^*\|\Big). \end{aligned}$$

Thus

$$\frac{\|m_\delta^{(k+1)} - m_\delta^*\|_A}{\|m_\delta^{(k)} - m_\delta^*\|_A} = \frac{\|(I - B^{-1}A)(m_\delta^{(k)} - m_\delta^*)\|_A}{\|m_\delta^{(k)} - m_\delta^*\|_A} + o(1),$$

and for any vector $v \in \mathbb{R}^d$,

$$\begin{aligned} \frac{\|(I - B^{-1}A)v\|_A^2}{\|v\|_A^2} &= \frac{v^\top (I - AB^{-1})A(I - B^{-1}A)v}{v^\top A v} \\ &= \frac{w^\top A^{-1/2}(I - AB^{-1})A(I - B^{-1}A)A^{-1/2}w}{\|w\|^2} \quad (\text{with } w := A^{1/2}v) \\ &= \frac{w^\top C^2 w}{\|w\|^2} \quad (\text{with } C := I - A^{1/2}B^{-1}A^{1/2}) \\ &\le \lambda_{\max}(C^2). \end{aligned}$$

It follows from property (ii) of G_δ in Definition 2 that $B - A$ is nonnegative definite, which implies that $\lambda_i(B^{-1}A) = \lambda_i(A^{1/2}B^{-1}A^{1/2}) \in (0, 1]$. This entails that C is nonnegative definite with $\lambda_{\max}(C^2) = \lambda_{\max}(C)^2 = (1 - \lambda_{\min}(B^{-1}A))^2$. ∎

TABLE 1
Generalized iteratively reweighted least squares algorithm (GIRLS).

Algorithm $m_\star \leftarrow$ **GIRLS**$(F, (F_\delta, G_\delta)_{\delta>0}, \delta_o, \delta_{\min}, m_o, \epsilon, k_{\max})$
$\delta \leftarrow \delta_o$
$m_\star \leftarrow m_o$
while $\delta \geq \delta_{\min}$ **do**
  $m_{\text{new}} \leftarrow \operatorname{argmin}_{m\in\mathcal{C}} G_\delta(m_\star, m)$
  $k \leftarrow 0$
  while $F(m_{\text{new}})/F(m_\star) < 1-\epsilon$ **and** $k < k_{\max}$ **do**
    $m_\star \leftarrow m_{\text{new}}$
    $m_{\text{new}} \leftarrow \operatorname{argmin}_{m\in\mathcal{C}} G_\delta(m_\star, m)$
    $k \leftarrow k+1$
  end while
  $\delta \leftarrow \delta/2$
end while.

3.2. Pseudocode, proper choice of δ, and the number of iterations. In practical applications the points m_δ^* are never calculated exactly. Instead after finitely many, say $k(\delta)$, iterations of (5) the iteration is terminated and the regularization parameter δ is decreased, e.g., replaced with $\delta/2$. An obvious question is how to choose these iteration numbers $k(\delta)$. We found empirically in most cases that for a fixed parameter $\delta > 0$, the values $F(m_\delta^{(k)})$ are decreasing for $k \leq k_o(\delta)$ and increasing in $k \geq k_o(\delta)$ for some fixed $k_o(\delta) \in \mathbb{N}$. Hence in case of a strictly positive target function F we may take

$$k(\delta) := \min\left(\left\{k \in \mathbb{N}_0 : F(m_\delta^{(k+1)})/F(m_\delta^{(k)}) \geq 1-\epsilon\right\} \cup \{k_{\max}\}\right) \tag{14}$$

for a small constant $\epsilon > 0$ and a large maximal number $k_{\max}$. In the examples discussed subsequently, we found that for $\epsilon = 10^{-5}$ and $k_{\max} = 100$, the number $k(\delta)$ was never larger than 30, which seems to compensate for the fact that the sequence $m_\delta^{(k)}$ converges only geometrically. This is similar to numerical findings with an implementation of an algorithm by [25, section 5] for the median and various parametric regression models.

Having determined $k(\delta)$ and $m_\delta^{(k(\delta))}$ for one particular $\delta > 0$, we define $m_{\delta/2}^{(0)} := m_\delta^{(k(\delta))}$ and repeat the same procedure with $\delta/2$ in place of δ, provided that $k(\delta) > 0$. We proceed until $\delta/2$ would be smaller than a certain threshold $\delta_{\min}$. Pseudocode for this algorithm is displayed in Table 1. Input parameters are F, its regularization $(F_\delta, G_\delta)_{\delta>0}$ augmented with smooth aproximations from above, a starting value $\delta_o > 0$ and a lower threshold $\delta_{\min} \in (0, \delta_o)$ for δ, a starting point $m_o \in \mathcal{C}$, and a threshold $\epsilon > 0$, as well as a maximal iteration number $k_{\max}$ for the inner while-loop.

4. Regularization and quadratic approximation for different types of regression problems. In the subsequent data examples the target functional $F(m)$ is always of type (1) or (3), i.e.,

$$F(m) = \sum_{i=1}^{n} \rho(r_i(m)) + \lambda P(m) \tag{15}$$

with $\lambda \geq 0$, where each residual $r_i(m)$ is an affine linear functional of $m \in \mathbb{R}^d$. Here each summand of F is regularized and approximated separately. We will start with an auxiliary result justifying the quadratic approximation (9).

LEMMA 1. *Let $h : \mathbb{R} \to \mathbb{R}$ be even and twice differentiable such that h'' is nonnegative and nonincreasing on $[0, \infty)$. For $r, z \in \mathbb{R}$ define*

$$g(r, z) := h(r) + (h'(r)/r)(z^2 - r^2)/2,$$

where $h'(0)/0 := h''(0)$. Then $g(r, z) \geq h(z)$ with equality if $z = \pm r$.

Proof. One verifies easily that $g(r, z)$ is even in both arguments with $g(r, r) = h(r)$. Thus it suffices to show that $g(r, z) \geq h(z)$ for any $r, z \geq 0$. Now,

$$\begin{aligned} g(r, z) - h(z) &= g(r, z) - h(r) - (h(z) - h(r)) \\ &= (h'(r)/r)(z^2 - r^2)/2 - h'(r)(z - r) - \int_r^z (h'(t) - h'(r))\, dt \\ &= (h'(r)/r)(z - r)^2/2 - \int_r^z (h'(t) - h'(r))\, dt \\ &= \int_r^z \left(\tilde{h}(r, 0) - \tilde{h}(r, t)\right)(t - r)\, dt \\ &= \int_{\min(r,z)}^{\max(r,z)} \left(\tilde{h}(r, 0) - \tilde{h}(r, t)\right)|t - r|\, dt, \end{aligned} \tag{16}$$

where $\tilde{h}(r, t) := (h'(t) - h'(r))/(t - r)$ for $t \neq r$, and $\tilde{h}(r, r) := h''(r)$. One can deduce easily from h'' being nonincreasing on $[0, \infty)$ that $\tilde{h}(r, \cdot)$ has the same property. Thus the integrand of (16) is nonnegative. ∎

Let us first describe how to approximate ρ itself in three special cases. After this we will discuss several penalizations P in (15). Finally we comment on isotonic regression, an example with $\mathcal{C} \neq \mathbb{R}^d$.

Quantile regression. Let $\rho(z)$ be given by (2). This may be rewritten as

$$\rho(z) = |z| + (2p - 1)z.$$

Hence we utilize the functions h_δ and g_δ from (7) and (9), which yields the regularization

$$z \mapsto h_\delta(z) + (2p - 1)z,$$

and by means of Lemma 1 the quadratic approximation

$$z \mapsto g_\delta(r, z) + (2p - 1)z = c_\delta(r) + h_\delta(r)^{-1} z^2/2 + (2p - 1)z$$

of $z \mapsto \rho(z)$, where $c_\delta(r)$ is an irrelevant constant.

***L*^{q}–regression.** Let $\rho(z) := |z|^q$ for some $q \in [1, \infty)$. If $1 \leq q < 2$, one may generalize definitions (7) and (9) immediately as follows:

$$\begin{aligned} h_\delta(z) &:= (z^2 + \delta)^{q/2}, \\ g_\delta(r, z) &:= h_\delta(r) + q(r^2 + \delta)^{1-q}(z^2 - r^2)/2 \\ &= c_\delta(r) + q(r^2 + \delta)^{1-q} z^2/2. \end{aligned}$$

Again it follows from Lemma 1 that $g_\delta(r, z) \geq h_\delta(z)$ with equality for $z = \pm r$.

In case of $q > 2$, the second derivative of $z \mapsto |z|^q$ is increasing in $|z|$ and unbounded, and hence Lemma 1 cannot be applied directly. To circumvent this problem, one could redefine

$$h_\delta(z) := \begin{cases} |z|^q & \text{if } |z| \leq \delta^{-1} \\ a_\delta + b_\delta |z| + q(q - 1)\delta^{2-q} z^2/2 & \text{otherwise} \end{cases}$$

with constants a_δ, b_δ such that h_δ is twice continuously differentiable, and then use the quadratic approximation

$$g_\delta(r,z) \;:=\; h_\delta(r) + h'_\delta(r)(z-r) + q(q-1)\delta^{2-q}(z-r)^2/2.$$

Logistic regression. For data sets with a covariable X and a dichotomous response $Y \in \{0,1\}$, maximum likelihood estimation of $M(X) := \log[P(Y=1\,|\,X)/P(Y=0\,|\,X)]$ involves "residuals" $z = (1/2 - Y)M(X)$ and

$$\rho(z) := h(z) + z \quad \text{with} \quad h(z) := \log[e^z + e^{-z}].$$

Note that h satisfies the conditions of Lemma 1 with $h'(r) = \tanh(r)$ and $h''(r) = 1 - \tanh(r)^2$. Thus regularization is superfluous, while quadratic approximation is straightforward. In this case, the well-known IRLS algorithm results ([28]).

Roughness penalties. Let us start with two particular examples for $P(m)$. For given real numbers $x_1 < x_2 < \cdots < x_d$ let M be a function on $[x_1, x_d]$ and $m := (M(x_j))_{j=1}^d$. Then let

$$\mathrm{TV}^{(0)}(m) := \sum_{j=1}^{d-1} |m_j - m_{j+1}|,$$
$$\mathrm{TV}^{(1)}(m) := \sum_{j=2}^{d-1} |\Delta_j m| \quad \text{with} \quad \Delta_j m := \frac{m_{j+1}-m_j}{x_{j+1}-x_j} - \frac{m_j - m_{j-1}}{x_j - x_{j-1}}.$$

If M is continuous and piecewise linear with knots in $\{x_1, \ldots, x_d\}$, then $\mathrm{TV}^{(0)}(m)$ and $\mathrm{TV}^{(1)}(m)$ are the total variation of M and its first derivative, respectively. One could also think about smoother functions M and approximate the total variation of its second or higher order derivative by suitable divided differences of m.

Generally, let $P(m)$ be a sum of several functionals of the form

$$m \mapsto |v^\top m|$$

with a given vector $v \in \mathbb{R}^d \setminus \{0\}$. For instance, $\mathrm{TV}^{(0)}(m)$ involves

$$v_i = v_i^{(j)} := \begin{cases} 1 & \text{if } i = j, \\ -1 & \text{if } i = j+1, \\ 0 & \text{else} \end{cases}$$

for $1 \le j < d$, while $\mathrm{TV}^{(1)}(m)$ involves

$$v_i = v_i^{(j)} := \begin{cases} (x_j - x_{j-1})^{-1} & \text{if } i = j-1, \\ -(x_j - x_{j-1})^{-1} - (x_{j+1} - x_j)^{-1} & \text{if } i = j, \\ (x_{j+1} - x_j)^{-1} & \text{if } i = j+1, \\ 0 & \text{else,} \end{cases}$$

for $1 < j < d$. Now an obvious strategy is to regularize $m \mapsto |v^\top m|$ by $m \mapsto h_\delta(v^\top m)$ and approximate this quadratically by

$$m \mapsto g_\delta(v^\top f, v^\top m) = c_\delta(v^\top f) + h_\delta(v^\top f)^{-1}\left(v^\top m\right)^2/2.$$

Often it is desirable to work with quadratic approximations $G(f,\cdot)$ whose Hessian matrix $B(f)$ is diagonal. For that purpose one can modify the quadratic term $Q(m) := \left(v^\top m\right)^2$ as follows:

$$\begin{aligned} Q(m) &= \left(v^\top f\right)^2 + 2f^\top vv^\top(m-f) + \left(v^\top(m-f)\right)^2 \\ &\le \left(v^\top f\right)^2 + 2f^\top vv^\top(m-f) + \|v\|^2 \sum_{i:v_i\neq 0} (m_i - f_i)^2 \\ &= c(v,f) - 2w(v,f)^\top m + \|v\|^2 \sum_{i:v_i\neq 0} m_i^2 \end{aligned}$$

for some irrelevant constant $c(v,f)$ and $w(v,f)_i := 1_{v_i\neq 0}\|v\|^2 f_i - v^\top f v_i$.

Isotonic regression. In some applications one seeks to minimize a functional such as (15) over all vectors in $\mathcal{C}_\nearrow := \{m \in \mathbb{R}^d : m_1 \le \cdots \le m_d\}$. In the simplest case, $d = n$ and $\rho(r_i(m)) = (Y_i - m_i)^q$ for some $q \in [1,\infty]$, where $q = \infty$ corresponds to supremum norm of $Y - m$. For this special case it is well known (see [2]) that an explicit solution exists only for $q = 1, 2, \infty$. In general, via regularization and suitable quadratic approximation from above, each updating step of the GIRLS algorithm involves minimization of

$$G_\delta(f,m) \;=\; C(f) + \sum_{i=1}^d w_i(f)(m_i - b_i(f))^2$$

over all vectors $m \in \mathcal{C}_\nearrow$ with certain weights $w_i(f) > 0$, an irrelevant constant $C(f)$, and certain numbers $b_i(f)$. This minimization problem can be solved explicitly by means of the PAVA ([33]).

5. Numerical examples. In this section we discuss the numerical performance of the GIRLS algorithm in practical applications. Our first example is about quantile regression and shows that GIRLS outperforms a Newton–Raphson type algorithm, at least in the first iterations. In the second example we consider a unimodal regression problem. For ordinary isotonic regression in one-dimensional settings, PAVA is known to be highly efficient (cf., e.g., [33]) in the sense of producing an exact solution in $O(d)$ steps. Replacing the isotonicity constraint on m with a penalty term $\mathrm{TV}^{(0)}(m)$ leads to minimization problems which can be solved efficiently with the closely related "taut string algorithm" (cf. [8]). However, analogous problems in multidimensional regression settings, or using $\mathrm{TV}^{(k)}(m)$ with $k \ge 1$, are computationally more involved. We mention, e.g., [15] for a reformulation as a bilateral contact problem and a rather involved solution by a two-level iterative method requiring a semi-smooth Newton method and a primal dual active set algorithm. GIRLS offers a different strategy: PAVA can be applied after approximating the target functional suitably by a quadratic program; hence, we can also understand GIRLS as a linking device to apply efficient special purpose algorithms for quadratic programs such as PAVA to corresponding nonquadratic and/or constrained problems.

Example 1 (estimation of smooth quantile functions). We applied the GIRLS algorithm and a competitor to a dataset containing the income (X) and the expenditure for food (Y) in the year 1973 for 7125 households in Great Britain (Family Expenditure Survey 1968–1983). This dataset has also been analyzed by [14]. In order to enhance the visual quality, we reduced these data to a random subset of size $n = 2000$. Moreover, since the empirical distributions of both variables are

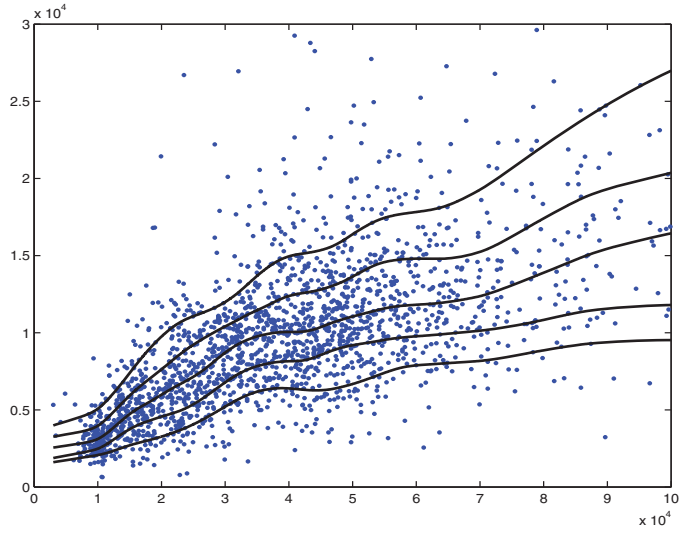

FIG. 1. *Quantile curves for food expenditure data.*

strongly skewed to the right, we plotted only the 1936 pairs (X_i, Y_i) in the range $[0, 10^5] \times [0, 3 \cdot 10^4]$. Figure 1 shows the data together with estimated p–quantile curves M_p for $p = 0.1, 0.25, 0.5, 0.75, 0.9$. Here we used the functional

$$F(m) \;=\; \sum_{i=1}^{n} \rho(Y_i - m_{C(i)}) + \lambda \, \mathrm{TV}^{(1)}(m)$$

on $\mathbb{R}^d$ with ρ given by (2), where $x_1 < x_2 < \cdots < x_d$ are the $d = 1945$ different X–values in the sample, $m_j = M_p(x_j)$, $X_i = x_{C(i)}$, and F was regularized as discussed in the last section. The tuning parameter λ was chosen to be $2 \cdot 10^6$ by visual inspection.

We now turn to the numerical performance of the GIRLS algorithm and compare it to a Newton–Raphson algorithm (robustified with a standard step-size correction as in [12]). In the first step we compare the performance of the two algorithms in the particular setting of our data example; the second step will consist of a small simulation study with artificial data. All computations were performed with Matlab on a 1.86Ghz Pentium-processor with 1GB Ram. As starting value of the iterations we used the polynomial regression p-quantile of order 1, and the tuning parameter δ was selected in a data-driven way from this starting value as the smaller of the median of its absolute residuals, and the median of its first order differences, in both cases divided by 1000. In the first step, we compared the computational efficiency of the GIRLS and the Newton–Raphson algorithm applied to quantile regression with the family expenditure data. To this end we recorded the computing times and number of iterations required for determination of the 25%-quantile curve by GIRLS and the Newton–Raphson algorithm, where we stopped the iterations as soon as the relative improvement of the function $F(m)$ between two subsequent iterations fell below a threshold parameter $\varepsilon = 10^{-12}$. Whereas GIRLS required $5.0s$ CPU time and 59 iterations to find the solution, the Newton–Raphson algorithm turned out to be significantly more expensive with $46.4s$ CPU time and 425 iterations. We also performed the same computations for a wide range of threshold parameters $\varepsilon = 10^{-6} \ldots 10^{-24}$, without significant change in the relative computational expense of the two methods.

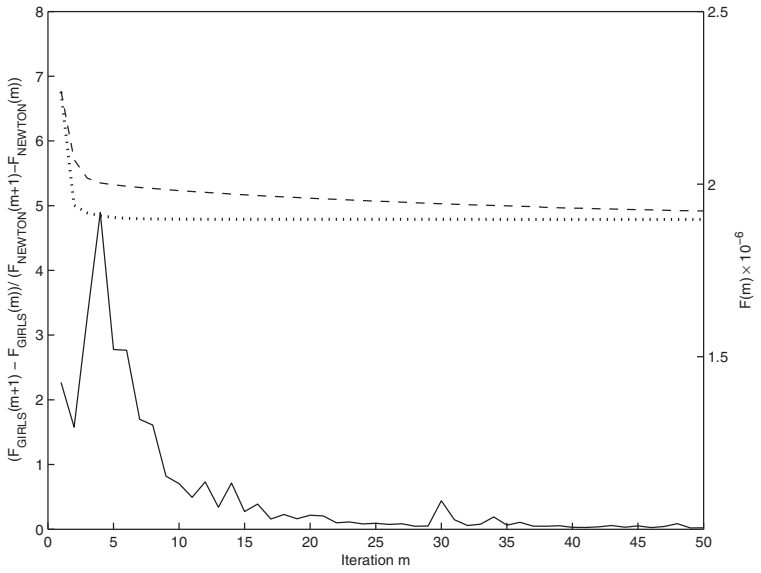

FIG. 2. *Mean performance of GIRLS and a Newton–Raphson-algorithm. The dashed and dotted curves show the mean value of the function $F(m)$ in dependence of the iteration number m for the Newton–Raphson algorithm and GIRLS, respectively, and the solid curve the stepwise rate of improvement $(F_{\mathrm{GIRLS}}(m+1) - F_{\mathrm{GIRLS}}(m)) / (F_{\mathrm{NEWTON}}(m+1) - F_{\mathrm{NEWTON}}(m))$ of $F(m)$ by the two methods. Here, a value larger than 1 indicates that in the mth iteration $F(m)$ decreased more for GIRLS than for the Newton–Raphson-algorithm.*

In the second step of our analysis we performed 100 simulations of the quantile regression problem with (artificial) regression data from the model

$$Y_i = \sin\left(X_i \cdot \frac{\pi}{2}\right) + \varepsilon_i,\ i = 1, \ldots, 1000.$$

Here, $X_i \sim U[0,1]$ are uniformly distributed, independent design variables, and $\varepsilon_i \sim N(0, 0.01)$ i.i.d. noise terms. We used both GIRLS and the Newton–Raphson method to estimate the 25%-quantile curve of the data by determining the minimizer of the function $F(m)$. From visual inspection of a pilot simulation, we chose the tuning parameter $\lambda = 2 \cdot 10^4$ for the subsequent simulations.

Figure 2 compares the mean performance of the GIRLS algorithm with the performance of the Newton–Raphson-method with step-size correction. The two curves in the top show the value of the function $F(m)$ in dependence of the iteration number m, and the bottom curve represents the mean improvement (in the simulations) of the solution, measured by the decrease of the target function $F(m)$. From the figure, we conclude that the first steps of GIRLS are significantly more efficient than for the Newton–Raphson method, whereas the latter catches up after approximately the 8^{th} iteration.

In summary, in the computations with the penalized quantile regression problem, GIRLS outperformed the Newton–Raphson method for the family expenditure data. Moreover, in our simulation we found GIRLS to improve the solution much faster than the Newton–Raphson method in the first ≈ 8 iterations. Only if the initial value of the Newton algorithm has been chosen very close to the true minimizer M^*, we found the performance of the Newton algorithm to be superior. Hence, for practical purposes it seems be advisable to combine both algorithms such that GIRLS will be

used at least as an initial algorithm which efficiently provides a good initial value for a subsequently performed Newton-type algorithm. Moreover, if both GIRLS and the Newton–Raphson method are available, it may be useful to compute both a GIRLS and a Newton step, with subsequent selection of the better one.

Example 2 (GIRLS as a device to utilize efficient algorithms for special quadratic programs in more complex settings). In our second example we will briefly illustrate the flexibility of the GIRLS algorithm to combine several constraints. Precisely, we combine unimodality constraints with TV penalization. Ordinary isotonic regression and hence unimodal regression involves the solution of a weighted least squares problem, and efficient algorithms, the PAVA in particular, are available. If we add a TV penalty, the problem is no longer a quadratic program, and PAVA is not applicable directly. By replacing the problem to be solved by a sequence of quadratic programs, GIRLS makes it possible again to apply PAVA for unimodal regression with TV penalization. To this end consider a two-dimensional regression problem where Y_{ij} are observations to be fitted by $m = (m_{ij})_{i,j}$, $i = 1, \dots, m$, $j = 1, \dots, n$. We want to minimize the sum $F(m)$ of the quadratic cost functional

$$\|Y - m\|^2 = \sum_{ij} (Y_{ij} - m_{ij})^2,$$

and the total variation penalty $\lambda \operatorname{TV}(m)$, where $\lambda > 0$ and

$$\operatorname{TV}(m) := \sum_{i=1}^{m} \sum_{j=1}^{n} |m_{i+1,j} - m_{ij}| + \sum_{i=1}^{m} \sum_{j=1}^{n} |m_{i,j+1} - m_{ij}|.$$

For the regularization F_δ and quadratic approximation $G_\delta(f, \cdot)$, the least squares term is kept unchanged, while each summand $|m_{(a)} - m_{(b)}|$ of $\operatorname{TV}(m)$ is treated as described in section 4: First we regularize it by $h_\delta(m_{(a)} - m_{(b)})$. Then as a first quadratic approximation we may use

$$g_\delta(f_{(a)} - f_{(b)}, m_{(a)} - m_{(b)}) = C_{\delta,(a),(b)}(f) + \frac{(m_{(a)} - m_{(b)})^2}{2h_\delta(f_{(a)} - f_{(b)})}.$$

For our purposes it turns out to be more suitable to replace the enumerator $(m_{(a)} - m_{(b)})^2$ with

$$2\Big(m_{(a)} - \frac{f_{(a)} + f_{(b)}}{2}\Big)^2 + 2\Big(m_{(b)} - \frac{f_{(a)} + f_{(b)}}{2}\Big)^2,$$

which is never less than $(m_{(a)} - m_{(b)})^2$ with equality for $m = f$. The advantages of this latter quadratic approximation are computational simplicity and feasibility of isotonic (and hence unimodal) least squares algorithms. This allows us, e.g., to impose in addition unimodality in vertical direction. Hence, simply in each step for each vertical line the unimodal regression is calculated by means of some standard variation of the PAVA.

Acknowledgments. The authors are thankful to the associate editor and three anonymous referees for their constructive criticism that helped to improve this paper significantly. Moreover, they would like to thank G. Jongbloed and O. Scherzer for helpful comments. The third author is indebted to Y. Vardi for interesting discussions on a previous version of this paper. Parts of this paper were written while

L. Dümbgen was visiting Göttingen University as lecturer within the PhD Program "Applied Statistics and Empirical Methods," and while N. Bissantz was visiting the University of Bern.

ON THE IMPLEMENTATION OF INTERIOR POINT DECOMPOSITION ALGORITHMS FOR TWO-STAGE STOCHASTIC CONIC PROGRAMS*

SANJAY MEHROTRA† AND M. GÖKHAN ÖZEVIN‡

Abstract. In this paper we develop a practical primal interior decomposition algorithm for two-stage stochastic programming problems. The framework of this algorithm is similar to the framework in [S. Mehrotra and M. G. Özevin, "Decomposition based interior point methods for two-stage stochastic convex quadratic programs with recourse," to appear in *Oper. Res.*; S. Mehrotra and M. G. Özevin, *SIAM J. Optim.*, 18 (2007), pp. 206–222] and [G. Zhao, *Math. Program.*, 90 (2001), pp. 507–536], however, their algorithm is altered in a simple yet fundamental way to achieve practical performance. In particular, this new algorithm weighs the log-barrier terms in the second stage problems differently from the theoretical algorithms analyzed in [S. Mehrotra and M. G. Özevin, *Oper. Res.*, to appear], [S. Mehrotra and M. G. Özevin, *SIAM J. Optim.*, 18 (2007), pp. 206–222], and [G. Zhao, *Math. Program.*, 90 (2001), pp. 507–536]. We give a method for generating a suitable starting point; a method for selecting a good starting barrier parameter; a heuristic for first stage step-length calculation without performing line searches; and a method for adaptive addition of new scenarios over the course of the algorithm. The decomposition algorithm is implemented to solve two-stage stochastic conic programs with recourse whose underlying cones are Cartesian products of linear, second order, and semidefinite cones. The performance of primal decomposition method is studied on a set of randomly generated test problems as well as a two-stage stochastic programming extension of the Markowitz portfolio selection model. The computational results show that an efficient and stable implementation of the primal decomposition method is possible. These results also show that in problems with a large number of scenarios, the adaptive addition of scenarios can yield computational savings of up to 80%.

1. Introduction.

We consider the two-stage stochastic conic programming (TSSCP) problem in the form

$$\begin{aligned} &\max b^T x - \frac{1}{2} x^T G x + \rho(x) \\ &\text{s.t. } Dx = d, \\ &\qquad Ax + s_1 = c, \\ &\qquad s_1 \in \mathcal{K}_1, \end{aligned} \tag{1.1}$$

where

$$\rho(x) := \sum_{i=1}^{K} \pi_i \rho_i(x) \tag{1.2}$$

and

$$\begin{aligned} \rho_i(x) := \max\ & f_i^T y_i - \frac{1}{2} y_i^T H_i y_i \\ \text{s.t.}\ & R_i y_i + U_i x = z_i, \\ & W_i y_i + T_i x + s_{2,i} = h_i, \\ & s_{2,i} \in \mathcal{K}_{2,i}. \end{aligned} \tag{1.3}$$

The symmetric cones $\mathcal{K}_1$ and $\mathcal{K}_{2,i}$ are Cartesian products of nonnegative orthant, second order cones and the cones of positive semidefinite matrices. By $\mathcal{K}_1^+$ and $\mathcal{K}_{2,i}^+$ we represent the interior of these cones. The size of these cones in the first stage and second stage problems may be different. The columns of submatrices of A, W_i, and T_i corresponding to the semidefinite cones are vectorizations of symmetric matrices. In other words, the cone of semidefinite matrices are considered as a set of vectors to comply with the above standard form of TSSCP. The matrices G and H_i are symmetric positive semidefinite.

Faybusovich [6, 7] presented a unified description of interior point algorithms for linear, second order cones and semidefinite programming using the theory of Euclidean Jordan algebra. We also describe our interior decomposition algorithms using the Jordan algebra operations. For a brief introduction of Jordan algebra operations, see [1, 27, 28].

Let us define the following feasibility sets:

$$\begin{aligned} &\mathcal{F}^0 := \{(x, s_1) \mid Dx = d, Ax + s_1 = b,\ s_1 \in \mathcal{K}_1\}, \\ &\mathcal{F}_{2,i}(x) := \{(y_i, s_{2,i}) \mid R_i y_i + U_i x = z_i, W_i y_i + s_{2,i} = h_i - T_i x,\ s_{2,i} \in \mathcal{K}_{2,i}\}, \\ &\mathcal{F}_i^1 := \{(x, s_1) \mid \mathcal{F}_{2,i}(x) \neq \emptyset\}, \\ &\mathcal{F}^1 := \{\cap_{i=1}^K \mathcal{F}_i^1\} \cap \mathcal{F}^0, \\ &\mathcal{F} := \{(x, s_1) \times (y_1, s_{2,1}, \ldots, y_K, s_{2,K}) \mid Dx = d, Ax + s_1 = b, \\ &\qquad s_1 \in \mathcal{K}_1;\ R_i y_i + U_i x = z_i, W_i y_i + s_{2,i} = h_i - T_i x,\ s_{2,i} \in \mathcal{K}_{2,i}\}. \end{aligned}$$

Here $\mathcal{F}_{2,i}(x)$ is the second stage feasibility set parameterized by the first stage decision vector x, $\mathcal{F}^1$ is the set of first stage feasible solutions for which all second stage problems are also feasible, and $\mathcal{F}$ is the set of feasible solutions for the extensive formulation of TSSCP.

Mehrotra and Özevin [18] presented a decomposition-based primal interior algorithm for the two-stage stochastic semidefinite programming problem with recourse. In their setting the first stage cone $\mathcal{K}_1$ and the second stage cones $\mathcal{K}_{2,i}$ are $p \times p$ and $r \times r$ symmetric positive semidefinite matrices, respectively. Mehrotra and Özevin [18] show that starting from a well-centered first stage solution (starting barrier parameter μ^0) a short-step path-following interior point algorithm working on the first stage variables requires $O(\sqrt{p + rK}) \ln(\mu^0/\mu^*)$ first stage interior point iterations to obtain a well-centered solution for barrier parameter μ^*, where K is the number of scenarios. Their analysis extends the earlier results of Zhao [31] for the two-stage linear stochastic programming problems and the results of Mehrotra and Özevin [17] for the quadratic case. The work of Zhao [31] and Mehrotra and Özevin [17, 18] provides a framework for implementing primal interior decomposition algorithms for two-stage stochastic programming problems. Several simplifying assumptions were made by Zhao [31] and Mehrotra and Özevin [17, 18] while analyzing their algorithms. The

purpose of this paper is to develop a more practical primal interior decomposition algorithm for two-stage stochastic conic programs.

The basic steps of a primal interior decomposition algorithm are as follows.

ALGORITHM 1. A BASIC PRIMAL INTERIOR DECOMPOSITION FRAMEWORK.

Initialization.

Let x^1 be a starting point, $\mu^1 > 0$ a starting barrier parameter, and μ^* the desired termination value of the barrier parameter. Also, let $\beta > 0, \zeta \in (0,1)$, and $\theta > 0$ be suitable scalar parameters.

Step 1.

Step 1.1. Solve all second stage centering problems for the current x and μ.

Step 1.2. Using the second stage solutions, compute the first stage Newton direction.

Step 1.3. Compute the local norm $\delta(\mu, x)$ of the Newton direction Δx as a measure of distance from the current point x to the first stage μ-center.

Step 1.4. Update first stage solution as $x := x + \theta \Delta x$. If $\delta(\mu, x) \leq \beta$, go to Step 2; otherwise go to Step 1.1.

Step 2. If $\mu \leq \mu^*$ (or some other termination criterion is satisfied) stop; otherwise reduce $\mu = \zeta\mu$ and go to Step 1.1.

Note that a variant of Algorithm 1 that reduces μ rapidly (long-step variant) may iterate several times in the loop Step 1.1–Step 1.4 after reducing the value of μ in Step 2. In the short-step method this loop is executed only once, but this method reduces μ slowly. The iterates in the loop Step 1.1–Step 1.4 are called the inner iterations of Algorithm 1. These iterations constitute most of the work in Algorithm 1. Theoretical values for parameters β, ζ, θ, and the choice of $\delta(\mu, x)$ are given in [31, 17, 18] in the context of proving polynomial time convergence of short-step and long-step methods.

This paper develops a different primal interior decomposition algorithm from the one analyzed in [31, 17, 18]. While the algorithm analyzed in [31, 17, 18] has a better worst-case theoretical complexity than the one proposed in this paper, computational experience suggests that the new proposed algorithm gives better performance in practice. The proposed algorithm differs from the algorithms in [31, 17, 18] in Step 1.1. In particular, it defines the second stage centering problems differently. We will present this algorithm and compare it with the algorithms in [31, 17, 18] in section 2. We have some probabilistic/heuristic justifications for the superior performance of the proposed algorithm, which we intend to document elsewhere.

In the primal decomposition framework (for algorithms in [31, 17, 18], as well as the new algorithm) we need to address several issues to develop practical efficient implementations. These issues are the following:

(i) (Initialization.) We need to find a suitable feasible first stage solution and ensure the feasibility of all second stage problems corresponding to this solution. If TSSCP satisfies a full recourse assumption, i.e., all second stage problems are feasible for all first stage solutions, then feasibility of second stage is not an issue. However, this assumption may not hold in general.

(ii) (Steps 1.1, 1.2.) The assumption of the availability of exact solutions of the second stage centering problems in [31, 17, 18] considerably simplifies the convergence analysis. However, solving second stage problems exactly is not possible. The practical implications of working with inexact solutions on first stage iterations and algorithmic robustness are not clear.

(iii) (Step 1.3.) It is not clear how closely the algorithm should follow the first stage central path (value of parameter β) for it to be practical and robust. Following the central path too closely would unnecessarily increase computational efforts, whereas if we ignore the central path the algorithm may not converge.

(iv) (Step 1.4.) The theoretical analysis assumes taking fixed steps along the Newton direction. This is conservative since taking larger steps give faster convergence. We need to find a good way to select the first stage step-length θ without performing line searches. Performing a line search over the barrier objective (defined in section 2) is not practical since an evaluation of this function for a given μ and x requires solutions of all second stage problems, which is equivalent to computing a new first stage Newton direction.

(v) (Step 2.) A practical value of ζ.

(vi) (Adaptive addition of scenarios.) The primal decomposition interior point methods for two-stage stochastic programming are appealing because the computation of the first stage Newton direction decomposes across second stage scenarios. This naturally allows the possibility of increasing the number of second stage scenarios as the algorithm progresses. The analysis in [31, 17, 18] is for a fixed number of scenarios. Note that adding a significant number of new scenarios modifies the recourse function and changes the first stage central path. A theoretical analysis of this change is challenging. However, adding scenarios adaptively as the algorithm progresses has the potential of saving computational efforts, especially when the number of scenarios is very large. How can adaptive addition of scenarios be implemented in practice?

(vii) (Warm-start.) Is it possible to use solutions from previously solved second stage problems to warm-start new related second stage problems? There are two situations where a warm-start might be possible. The first possibility is when x and/or μ changes in Steps 1.4 and 2 in a preexisting scenario. The second possibility is when scenarios are added adaptively, and a centered solution of a new scenario is desired for the current x and μ.

In stochastic programming we have the additional issue of determining the number of scenarios (when the uncertain parameters have continuous distribution, or have a huge finite support) required to ensure a desired quality of solution. This is achieved through generating lower and upper bounds, and a statistical analysis around these bounds. Methods for generating such bounds are discussed in Linderoth, Shapiro, and Wright [12] and are beyond the scope of this paper. In this paper we will assume that the problem has a given large number of scenarios.

Within the context of the proposed practical algorithm we provide resolution of (i)–(vii) to various extents. We give numerical results for the proposed implementation strategies. Computational results are presented in sections 4–7. These results are obtained on an extension of the classical Markowitz portfolio optimization problem and a set of randomly generated conic programming test problems that have linear, second order, and semidefinite cones. The test problems are described in section 3. Section 4 focuses on various algorithmic parameters and line search in the primal decomposition algorithm. Section 5 presents results on various characteristics of the algorithm exhibited by the problems we solved. Section 6 develops a methodology for adaptive addition of scenarios, and section 7 discusses results obtained using scenario addition and warm-start during scenario addition. The computational results were obtained using MATLAB version 6.5.1 on an IBM T42 using Pentium M 1.7 GHz with 1 GB of RAM. The entire code is written using MATLAB's internal libraries.

2. Primal interior decomposition algorithms. In this section we describe the algorithm we have found to work better in practice. We compare this algorithm with the algorithms presented and analyzed in Zhao [31] and Mehrotra and Özevin [17, 18]. The algorithm of [31, 17, 18] is described in section 2.1. In section 2.2 we describe the proposed practical algorithm, and in section 2.3 we compare the two algorithms computationally.

2.1. Zhao [31], Mehrotra and Özevin [17, 18] primal decomposition algorithm. In [31, 17, 18] the authors redefine the recourse function in (1.2) as

$$\rho(x) := \sum_{i=1}^{K} \bar{\rho}_i(x),$$

where

$$\begin{aligned} \bar{\rho}_i(x) := \max\ & \bar{f}_i^T y_i - \frac{1}{2} y_i^T \bar{H}_i y_i \\ \text{s.t. } & (y_i, s_{2,i}) \in \mathcal{F}_{2,i}(x), \end{aligned} \tag{2.1}$$

$\bar{f}_i = \pi_i f_i$, and $\bar{H}_i = \pi_i H_i$. They consider the log-barrier problem associated with (2.1):

$$\begin{aligned} \bar{\rho}_i(\mu, x) := \max\ & \bar{f}_i^T y_i - \frac{1}{2} y_i^T \bar{H}_i y_i + \mu \ln\det(s_{2,i}) \\ \text{s.t.} & (y_i, s_{2,i}) \in \mathcal{F}_{2,i}(x). \end{aligned} \tag{2.2}$$

The first stage log-barrier problem in [31, 17, 18] is defined as

$$\begin{aligned} \max\ & \bar{\eta}(\mu, x) := b^T x - \frac{1}{2} x^T G x + \bar{\rho}(\mu, x) + \mu \ln\det(s_1) \\ \text{s.t. } & (x, s_1) \in \mathcal{F}^1, \end{aligned} \tag{2.3}$$

where

$$\bar{\rho}(\mu, x) := \sum_{i=1}^{K} \bar{\rho}_i(\mu, x).$$

For a given x and μ, the optimality conditions for (2.2) are

$$\begin{aligned} & R_i y_i + U_i x = z_i, \\ & W_i y_i + T_i x + s_{2,i} = h_i, \\ & W_i^T \bar{\lambda}_i + R_i^T \bar{\gamma}_i + \bar{H}_i y_i = \bar{f}_i, \\ & P(\bar{\lambda}_i^{1/2}) s_{2,i} = \mu \iota_{2,i}, \\ & \bar{\lambda}_i \in \mathcal{K}_{2,i}^+,\ s_{2,i} \in \mathcal{K}_{2,i}^+. \end{aligned} \tag{2.4}$$

Let $x(\mu) := \text{argmax}\{\bar{\eta}(\mu, x)\}$ for a given $\mu > 0$. We refer to $x(\mu)$ as the first stage μ-center and to the trajectory $\{x(\mu),\ \mu > 0\}$ as the first stage central path. We denote the unique solution of (2.4) for any given $x \in \mathcal{F}_i^1$ and $\mu > 0$ by $(y_i(\mu, x),\ s_{2,i}(\mu, x),\ \bar{\lambda}_i(\mu, x),\ \bar{\gamma}_i(\mu, x)),\ i = 1, \ldots, K$, and call this solution the second

stage μ-center. The μ-centers for different values of μ form the second stage central path for a given x as μ decreases from ∞ to zero.

A brief summary of the key Jordan algebra operations is as follows. In (2.4) the matrix $P(\lambda_i^{1/2})$ is the *Jordan quadratic presentation* of the vector $\lambda_i^{1/2}$ and $\iota_{2,i}$ is the *identity solution* of the cone $\mathcal{K}_{2,i}$ [6, 7]. The vector $\lambda_i^{1/2}$ is the *square root* (in the Jordan algebra sense) of the dual multiplier λ_i, that is, $\lambda_i^{1/2}$ is a unique vector such that $\lambda_i = P(\lambda_i^{1/2})\iota$. For any given symmetric cone $\mathcal{K}$ and a given $\lambda \in \mathcal{K}$, the *identity solution* ι of $\mathcal{K}$ is a unique element of $\mathcal{K}$ such that $L(\lambda)\iota = \lambda$ for all $\lambda \in \mathcal{K}$, where $L(\lambda)$ is the multiplication by λ linear operator of the cone $\mathcal{K}$. Furthermore, the vector λ^{-1} is the unique inverse of $\mathcal{K}^+$ such that $P(\lambda)\lambda^{-1} = \lambda$. The vector $\lambda^{1/2}$ is the *square root* of $\lambda \in \mathcal{K}$ such that $L(\lambda^{1/2})\lambda^{1/2} = \lambda$. The gradient and Hessian of the function $\ln\det(\lambda)$ has the form

$$\nabla \ln\det(\lambda) = \lambda^{-1},\ \lambda \in \mathcal{K}^+,$$
$$\nabla^2 \ln\det(\lambda) = -P(\lambda^{-1}),\ \lambda \in \mathcal{K}^+.$$

The form of $P(\lambda)$ in case of primitive symmetric cones as well as Cartesian products of primitives are given in [27]. The gradient and Hessian of the barrier objective $\bar{\eta}(\mu, x)$ are calculated as follows:

$$\nabla\bar{\eta}(\mu,x) = b - Gx + \sum_{i=1}^{K}(T_i^T\bar{\lambda}_i(\mu,x) + U_i^T\bar{\gamma}_i(\mu,x)) - \mu A^T s_1^{-1}, \tag{2.5}$$

$$\nabla^2\bar{\eta}(\mu,x) = -G + \sum_{i=1}^{K}(T_i^T\nabla\bar{\lambda}_i(\mu,x) + U_i^T\nabla\bar{\gamma}_i(\mu,x)) - \mu A^T P(s_1^{-1})A. \tag{2.6}$$

The quantities $\nabla\bar{\lambda}(\cdot)$, and $\nabla\bar{\gamma}_i(\cdot)$ are calculated as follows. Differentiating the optimality conditions (2.4) with respect to x, we obtain

$$\begin{aligned} &R_i\nabla y_i = -U_i,\\ &W_i\nabla y_i + \nabla s_{2,i} = -T_i,\\ &W_i^T\nabla\bar{\lambda}_i + R_i^T\nabla\bar{\gamma}_i + \bar{H}_i\nabla y_i = 0,\\ &P(\bar{\lambda}_i^{1/2})\nabla s_{2,i} + P(s_{2,i}^{1/2})\nabla\bar{\lambda}_i = 0. \end{aligned} \tag{2.7}$$

Solving (2.7), we get

$$\begin{aligned} &\nabla\bar{\gamma}_i = (R_iZ_i^{-1}R_i^T)^{-1}(U_i - R_iZ_i^{-1}W_i^TQ_iT_i),\\ &\nabla y_i = -Z_i^{-1}(R_i^T\nabla\bar{\gamma}_i + W_i^TQ_iT_i),\\ &\nabla s_{2,i} = -(T_i + W_i\nabla y_i),\\ &\nabla\bar{\lambda}_i = -Q_i\nabla s_{2,i}, \end{aligned} \tag{2.8}$$

where

$$Q_i := (P(s_{2,i}^{1/2}))^{-1}P(\bar{\lambda}_i^{1/2}) \text{ and } Z_i := W_i^TQ_iW_i + \bar{H}_i.$$

For a fixed μ, the solution $(x(\mu), s_1(\mu); y_i(\mu,\ x(\mu)), s_{2,i}(\mu,\ x(\mu)),\ i = 1,\dots,K)$ of (2.2)–(2.3) is the same as the maximizer of the log-barrier function

$$b^Tx - \frac{1}{2}x^TGx + \sum_{i=1}^{K}\left(\bar{f}_iy_i - \frac{1}{2}y_i^T\bar{H}_iy_i\right) + \mu\ln\det(s_1) + \mu\sum_{i=1}^{K}\ln\det(s_{2,i}) \tag{2.9}$$

over the set $\mathcal{F}$.

In the basic primal decomposition framework (Algorithm 1) the first stage Newton direction Δx (Step 1.2) is the optimal solution of

$$\begin{aligned} &\max \nabla\bar{\eta}(x)^T\Delta x + \frac{1}{2}\Delta x^T\nabla^2\bar{\eta}(x)\Delta x \\ &\text{s.t.} \quad D\Delta x = 0. \end{aligned} \tag{2.10}$$

In Step 1.3, the local norm of the Newton step calculated at x is given by

$$\delta(\mu, x) = \sqrt{-\frac{1}{\mu}\Delta x^T\nabla^2\bar{\eta}(\mu, x)\Delta x}.$$

For two-stage stochastic semidefinite programs Mehrotra and Özevin [18] show that the log-barrier recourse function $\bar{\eta}(\mu, x)$ is a strongly μ-self-concordant function and forms a strongly self-concordant family. This is used to establish convergence for short- and long-step path-following algorithms as discussed in the introduction.

2.2. A practical primal decomposition algorithm. We now describe a more practical primal decomposition algorithm within the framework of Algorithm 1. In this algorithm we work directly with the form of the second stage problem (1.3) without scaling the second stage objectives as is done in (2.1). Let us consider the log-barrier problem associated with (1.3):

$$\begin{aligned} \rho_i(\mu, x) := \ &\max f_i^T y_i - \frac{1}{2}y_i^T H_i y_i + \mu \ln\det(s_{2,i}) \\ &\text{s.t.} \ \ (y_i, s_{2,i}) \in \mathcal{F}_{2,i}(x). \end{aligned} \tag{2.11}$$

The first stage log-barrier problem is now defined as

$$\begin{aligned} &\max \eta(\mu, x) := b^T x - \frac{1}{2}x^T G x + \mu \ln\det(s_1) + \rho(\mu, x) \\ &\text{s.t.} \quad x \in \mathcal{F}^1, \end{aligned} \tag{2.12}$$

where

$$\rho(\mu, x) := \sum_{i=1}^{K} \pi_i \rho_i(\mu, x). \tag{2.13}$$

We can show that for a fixed μ, the solutions $(x(\mu), s_1(\mu); y_i(\mu, x(\mu)), s_{2,i}(\mu, x(\mu)),$ $i = 1, \ldots, K)$ of (2.11)–(2.12) are the same as the maximizer of the log-barrier function

$$b^T x - \frac{1}{2}x^T G x + \sum_{i=1}^{K} \pi_i \left(f_i y_i - \frac{1}{2}y_i^T H_i y_i \right) + \mu \ln\det(s_1) + \mu \sum_{i=1}^{K} \pi_i \ln\det(s_{2,i}) \tag{2.14}$$

over $\mathcal{F}$.

Note that in contrast to (2.9), in (2.14) the second stage log-barrier terms are scaled with the corresponding probabilities. Hence, when solving the second stage problems to compute the Newton direction for a given x, solutions are computed for a smaller value of μ (scaled by π_i). We do not have an obvious analogue of the result that $\bar{\eta}(\mu, x)$ is a strongly μ-self-concordant function for the function $\eta(x, \mu)$. An inferior worst-case theoretical bound is proved in Mehrotra and Özevin [19]. However, a probabilistic analysis in Mehrotra [16] shows that a better convergence result

(possibly independent of the number of scenarios) is possible under a probabilistic self-concordance assumption.

The algebraic development of the computation of Newton direction for (2.12) is similar to the development for (2.3). For a given x and μ, the optimality conditions of (2.11) are

$$\begin{aligned} & R_i y_i + U_i x = z_i, \\ & W_i y_i + T_i x + s_{2,i} = h_i, \\ & W_i^T \lambda_i + R_i^T \gamma_i + H_i y_i = f_i, \\ & P(\lambda_i^{1/2}) s_{2,i} = \mu \iota_{2,i}, \\ & \lambda_i \in \mathcal{K}_{2,i}^+, \ s_{2,i} \in \mathcal{K}_{2,i}^+, \end{aligned} \tag{2.15}$$

where $\iota_{2,i}$ is defined as before. The gradient and Hessian of the barrier objective $\eta(\mu, x)$ are calculated as follows:

$$\nabla \eta(\mu, x) = b - Gx - \sum_{i=1}^{K} \pi_i (T_i^T \lambda_i(\mu, x) + U_i^T \gamma_i(\mu, x)) - \mu A^T s_1^{-1}, \tag{2.16}$$

$$\nabla^2 \eta(\mu, x) = -G - \sum_{i=1}^{K} \pi_i (T_i^T \nabla \lambda_i(\mu, x) + U_i^T \nabla \gamma_i(\mu, x)) - \mu A^T P(s_1^{-1}) A. \tag{2.17}$$

In the basic primal decomposition framework (Algorithm 1) the first stage Newton direction (Step 1.2) is the optimal solution of

$$\begin{aligned} \max \ & \nabla \eta(x)^T \Delta x + \frac{1}{2} \Delta x^T \nabla^2 \eta(x) \Delta x \\ \text{s.t.} \quad & D \Delta x = 0, \end{aligned} \tag{2.18}$$

which can be calculated by solving the KKT system associated with (2.18):

$$\begin{aligned} & \nabla^2 \eta(x) \Delta x - D^T \tau = -\nabla \eta(x) \\ & D \Delta x = 0. \end{aligned} \tag{2.19}$$

In Step 1.3, the local norm of the Newton step calculated at x becomes

$$\delta(\mu, x) = \sqrt{-\frac{1}{\mu} \Delta x^T \nabla^2 \eta(\mu, x) \Delta x}.$$

2.3. Performance comparison of basic primal decomposition algorithms. The computations of Newton direction in sections 2.1 and 2.2 were implemented using the same starting point, parameter settings, and subroutines. These settings are discussed in the next section in the context of the algorithm in section 2.2. We ensured that same relative precision is achieved when solving the second stage KKT systems (2.4) and (2.15) to compute the second stage solutions in their respective problems. Table 1 gives results on a set of 100 scenario test problems. These problems are described in section 3.2. Columns "Itr." give the number of inner iterations in both algorithms, and columns "Convergence" indicate if convergence to eight digits of accuracy was achieved for these problems when the algorithms terminate. A failure to converge to a solution with eight digits of accuracy is indicated by "No." Various reasons for this failure are explained in section 4.2. Superiority of the algorithm in section 2.2 is obvious.

TABLE 1
Comparison of theoretical and practical algorithms ($\beta = 1$, $\nu = 1$, $\zeta = 0.1$; using line search).

3. Test problems. We studied the performance of our decomposition algorithm on randomly generated two-stage stochastic conic programs and a specific stochastic programming problem arising from a two-stage extension of the classical Markowitz's mean-variance model. We now describe the generation of these test problems.

3.1. An application from finance: Two-stage extension of Markowitz's mean-variance model. The seminal mean-variance model of Markowitz [14] provides a quantitative framework for establishing a balance of the risk and return characteristics of various asset classes. In this model, return on the portfolio is measured by the expected value of the portfolio return, and the associated risk is quantified by the variance of the portfolio return.

Consider a portfolio that invests in n assets over a single period. Denote by $x \in \mathbb{R}^n$ the portfolio vector, and by $\tilde{r} \in \mathbb{R}^n$ the random vector of asset returns over a given horizon. The mean-variance setting assumes that $\tilde{r}$ has a multivariate normal distribution with mean $\bar{r}$ and covariance Q. The corresponding mean-variance problem is given by $\min\{w^T Q w : \bar{r}^T w \geq \rho, e^T w = 1\}$. By minimizing the portfolio variance by varying the level of expected return ρ we can derive the so-called mean-variance efficient frontier.

We formulate a two-stage extension of the static single-period Markowitz model to address these issues. Let us first introduce some notation in preparation to formulating this model. This model can be viewed as an alternative to the robust optimization model proposed by Goldfarb and Iyengar [9] in incorporating uncertainty in the covariance matrix. The current time is denoted by t_1. At time t_1 after having observed the return vector r_0 the investor forms a portfolio and at time $t_2 > t_1$ he can revise his portfolio. The revised portfolio is kept until t_3. The problem is to decide a portfolio at time t_1 in anticipation of its revision at time t_2. The evolution of the asset return vector and the covariance matrix is approximated with K scenarios, which we index by $i = 1, \ldots, K$.

We define the following decision variables and parameters:

- w_1 := vector of first stage portfolio positions,
- r_1 := vector of asset returns in the first period,
- $\bar{r}_1$:= expected asset returns in the first period,
- $\bar{r}_1^{min}$:= lower bound for the expected asset returns in the first period,
- Q_1 := covariance of asset returns in the first period,
- $w_{2,i}$:= vector of second stage portfolio positions under scenario i,
- $r_{2,i}$:= vector of asset returns in the second period under scenario i,
- $\bar{r}_{2,i}$:= expected asset returns in the second period under scenario i,
- $\bar{r}_{2,i}^{min}$:= minimum required return at the end of the second period under scenario i,
- $Q_{2,i}$:= covariance of asset returns in the second period under scenario i.

We have the following two-stage extension of the basic mean-variance model:

$$\begin{aligned}
&\min {w_1}^T Q_1 w_1 + \sum_{i=1}^{K} \frac{1}{K} w_{2,i}^T Q_{2,i} w_{2,i} \\
&\text{s.t. } \bar{r}_1^T w_1 \geq \bar{r}_1^{min}, \\
&\quad e^T w_1 = 1, \\
&\quad \bar{r}_{2,i}^T w_{2,i} \geq \bar{r}_{2,i}^{min},\ i = 1, \ldots, K, \\
&\quad e^T w_{2,i} = 1,\ i = 1, \ldots, K, \\
&\quad \|w_1 - w_{2,i}\| \leq \tau_{2,i},\ i = 1, \ldots, K. \qquad (3.1)
\end{aligned}$$

In the above model, the magnitude of the variation between first and second stage solutions is bounded by the constraints (3.1). In practice an investor would avoid large changes between the optimal first and second stage portfolio positions since such changes can lead to prohibitive amounts of transaction costs. Moreover, limiting the variation between the first and second period portfolio positions would make first period optimal portfolio composition less sensitive to perturbations in the problem parameters. Alternatively, the model may be viewed as a way of finding a "centroid" solution when multiple estimates of r and Q exist. In both respects, one may prefer our model to the single-period robust portfolio optimization model introduced in Goldfarb and Iyengar [9], since robust models tend to be pessimistic.

For the test problems generated for this paper we use a multivariate GARCH model to describe the return process:

$$\begin{aligned}
r_t &= \phi_0 + \phi_1 r_{t-1} + \epsilon_t,\ \epsilon_t \sim N(0, Q_t), \\
Q_t &= C + A * H_{t-1} + B * Q_{t-1}, \qquad (3.2)
\end{aligned}$$

where the symbol $*$ denotes the Hadamard product of two matrices and $H_t = [\epsilon_{i,t}\ \epsilon_{j,t}]_{i,j=1,\ldots,n}$.

We randomly generated the model parameters ϕ_0, ϕ_1, A, C, and B, as well as the starting asset returns vector r_1 and covariance Q_1. The matrices A, B, and C are generated as symmetric positive semidefinite matrices to ensure that the forecasted conditional covariance matrices Q_t are positive semidefinite [11]. We calibrated the probability distributions from which we sample A, B, and C such that the forecasted asset returns in general fall into the $[0.5, 1.5]$ range, volatilities vary around 10%, and correlations take values between -0.5 and 0.5. These parameter ranges allow us to generate problems that are realistic, but also have significant volatility to test the algorithm.

We generate scenarios $(\bar{r}_{2,i}, Q_{2,i})$ using an n-dimensional Sobol' sequence [5, 8], where n is the number assets in the portfolio. To obtain a set of K samples, $(\epsilon_{1,1}, \ldots, \epsilon_{1,K})$, of the residual vector ϵ_1, we start by generating the K n-dimensional Sobol' points $(S_1, \ldots, S_K)$. Then we set $\epsilon_{1,i} = Q_1^{1/2} \Phi^{-1}(S_i), i = 1, \ldots, K$, where Φ is the cumulative normal distribution function. Finally, we generate $(r_{2,i}, Q_{2,i})$ using the following relationships:

$$\begin{aligned}
r_{2,i} &= \phi_0 + \phi_1 (r_1 + \epsilon_{1,i}), \\
Q_{2,i} &= C + A * H_{1,i} + B * Q_1,\ i = 1, \ldots, K.
\end{aligned}$$

To generate the minimum required expected asset returns $\bar{r}_1^{min}$ and $\bar{r}_{2,i}^{min}$ we assume that the investor wants to beat a fixed-weight strategy $\bar{w}$. We randomly generate the vector $\bar{w}$ and then set $\bar{r}_1^{min} = r_1\bar{w}$ and $\bar{r}_{2,i}^{min} = r_{2,i}\bar{w},\ i = 1, \ldots, K$. In this paper, we report results on instances of this model for $n = 20$, 30, and 40 and for different values of $\tau_{2,i}$. The computational results in section 7 indicate that smaller values of $\tau_{2,i}$ tend to generate second stage problems with which warm-start is harder.

3.2. Generation of the random test problems. While two-stage conic extensions of Markowitz model provide an important application example, a more systematic study on the algorithmic behavior is possible on random test problems. We generate these test problems by taking discrete approximations of the following continuous stochastic program:

$$\begin{aligned} \max\ \eta(x) := b^T x + \rho(x) \\ \text{s.t.}\quad Dx = d, \\ Ax + s_1 = c, \\ \|x\|_2 \le \tau_1 \\ s_1 \in \mathcal{K}_1, \end{aligned} \tag{3.3}$$

where

$$\rho(x) := E(\rho(x, \tilde{\omega})), \tag{3.4}$$

and for each realization $\omega \in \Omega$ of the random variable $\tilde{\omega}$

$$\begin{aligned} \rho(x, \omega) := \max\ & f_\omega^T y_\omega \\ \text{s.t.}\ & R_\omega y_\omega + U_\omega x = z_\omega, \\ & W_\omega y_\omega + T_\omega x + s_{2,\omega} = h_\omega, \\ & \|y_\omega\|_2 \le \tau_2 \\ & s_{2,\omega} \in \mathcal{K}_{2,\omega}. \end{aligned} \tag{3.5}$$

In our test problems the first and second stage cones $\mathcal{K}_1$ and $\mathcal{K}_{2,i}$ both consist of a linear, a second order, and two semidefinite cones. The 2-norm inequality constraint in (3.3)–(3.5) gives an additional second order cone. The data D, A, b for the first stage problems uses a random variable with uniform distribution to generate entries in $[-L, L]$. We ensure that D has full row rank and that A has full column rank. We then set $d = D\tilde{x}$ and $c = A\tilde{x} + \iota_1$, where $\tilde{x}$ is generated using a random variable with uniform distribution over $[0, L]^t$, and ι_1 is the *identity element* of the cone $\mathcal{K}_1$. This ensures that the first stage has a feasible interior solution. The problem data $W(\omega)$ and $T(\omega)$ consist of 4 blocks corresponding to the 4 primitive blocks that make up $\mathcal{K}_{2,\omega}$. We assume that t entries in $f(\omega), R(\omega), U(\omega)$ and in each block of the second stage problem data $W(\omega)$ and $T(\omega)$ are random. We start by randomly generating the vector f^0 and the matrices R^0, U^0, W^0, and T^0 whose entries are generated from a uniform distribution over $[-L, L]$. The data f^0, R^0, U^0, W^0, and T^0 are used as a base, which is further randomized to get the second stage scenarios. This is done as follows.

In order to generate second stage scenarios we discretize the continuous probability distribution of $\tilde{\omega}$ using a quasi–Monte Carlo technique. $\tilde{\omega}$ is taken to be a uniform

t-dimensional random vector in $[-L, L]$. In particular, we use a t-dimensional Sobol' sequence to discretize $\tilde{\omega}$ and generate scenarios as follows. Let $(S_1, \ldots, S_N)$ be the Sobol' sequence approximating the t-dimensional uniform distribution. To construct N second stage problems we generate N samples, $\omega_1, \ldots, \omega_N$, of the random vector $\tilde{\omega}$ from this Sobol' sequence using N points. We set $\omega_i = p_{\%} * L * (1 - 2S_i),\ i = 1, \ldots, N$. To obtain the second stage scenario data f_i, R_i, U_i, W_i, and T_i, t elements are randomized in every block (each block corresponding to a cone) of f^0, R^0, U^0, W^0, and T^0 by adding entries of ω_i. Here $p_{\%}$ is the randomization (measured as %) of the base data. A larger value of $p_{\%}$ gives a greater randomization of the base data. Next, we generate a random vector $\tilde{y}$ of the same size as the second stage variable y_ω and set $z_i = R_i\tilde{y} + U_i\tilde{x}$ and $h_i = W_i\tilde{y} + T_i\tilde{x} + \iota_{2,i}$. We choose an appropriate value of τ_1 and $\tau_{2,i}$ to ensure that the feasible sets are bounded. This ensures the feasibility of TSSCP. In (3.3) and (3.5) 2-norm constraints on x and y_ω are given separately for clarity; however, in the rest of the paper they are considered as a second order cone block in A, W_i, T_i and their slacks will be included as a second order cone block in s_1 and $s_{2,i}$, respectively.

Table 2 gives problems generated using the above-described method. For all problems, $L = 2.5$ is used. This table gives information on the number of equality constraints (Equality(F,S)), the size of linear cones (LINC(F,S)), the size of second order cones in the first and second stage problems (SOC(F,S)), the size of semidefinite cones (SDC), and the dimension of variables x and y_i in each of the problems. The suffix (F,S) indicates information in a column for first and second stage problems. The cone information is given for each cone. For example, $[16, 25][16, 25]$ in the Problem MCR2 row indicates two semidefinite constraints in each of first and second stage problems. The size of the first stage semidefinite cone is 4×4 and the size of the second stage semidefinite cone is 5×5. Problems MCR1–MCR6 are generated by taking a reasonable amount of randomness in the second stage ($p_{\%} = 5\%$), Problems MCL1–MCL6 are generated by taking a large amount of randomness ($p_{\%} = 50\%$), and Problems MCH1–MCH6 are generated by taking a huge amount of randomness ($p_{\%} = 500\%$). For all of these problems the size of first and second stage cones are equal and the dimension of the Sobol' sequence is two ($t = 2$). In each second stage problems, two elements f_i, R_i, U_i and two elements in each block of W_i and T_i (totaling 22 elements) are perturbed using the two elements of ω_i. The 2-norm constraint is not randomized.

Problems MCL13–MCL63 have dimensions similar to those of problems MCL1–MCL6; however, these problems were generated using a 33-dimensional Sobol' sequence ($t = 33$) and setting $p_{\%} = 50\%$. Three-dimensional subvectors of the 33-dimensional Sobol' points (altogether 11 distinct subvectors) are used to perturb three elements of f_i, R_i, U_i and three elements in each block of W_i and T_i. Thus these problems are expected to be random in a different way than MCL1–MCL6.

Problems MCRS1–MCRS6 have increasing size of the second stage cone and decision variables y_i. Here Problem MCRS1 is identical to Problem MCR2. Problems MCRF1–MCRF6 have increasing size of the first stage cone and decision variable x. Here Problem MCRF1 is identical to Problem MCR2. These problems were generated using a 2-dimensional Sobol' sequence ($t = 2$) and setting $p_{\%} = 5\%$. When referring to the randomly generated problems we use `name`–N, where N indicates the number of second stage scenarios in the instance.

4. Implementing the primal interior decomposition algorithm. In this section we discuss a practical implementation of primal interior decomposition algo-

TABLE 2
Description of the random test problems.

rithms. This implementation uses the knowledge that the underlying problem is a stochastic program. The central idea is to estimate the properties of a large-scale stochastic problem with the help of problems with few scenarios. This information is used to devise implementation heuristics. In the rest of this paper we assume that the probabilities π_i (weights) in the TSSCP (1.1)–(1.3) are $1/K$.

4.1. Initialization. We need an interior starting point that is feasible for the first stage, and for which all second stage problems have feasible interior solutions. For this purpose we consider the feasibility barrier centering problem

$$\max_{(x,s_1)\in\mathcal{F}^0, s_1\in\mathcal{K}_1^+} \ln\det(s_1)$$

and its KKT conditions

$$\begin{aligned} & Dx = d, \\ & Ax + s_1 = c, \\ & D^T\tau + A^T\upsilon = 0, \\ & P(s_1^{1/2})\upsilon = \iota_1, \\ & s_1, \upsilon \in \mathcal{K}_1^+. \end{aligned} \tag{4.1}$$

Equations (4.1) are solved to a desirable accuracy. An infeasible primal-dual interior point method based on the description in [27, 28] is used. If such a solution is not found within a desirable accuracy, then the problem is "infeasible." Otherwise, the iterate at which the primal-dual algorithm terminates is taken as a solution. Some details of this implementation are given in section 4.2. The properties of interior point methods ensure that if an interior feasible solution is available, then the infeasible primal-dual interior method will provide such a solution [23, 10]. The solution of (4.1) may not provide a starting point for which all second stage problems are feasible if the problem does not have full recourse. We use an artificial variable (y_i^a) for the second stage problem to ensure a full recourse. The second stage problems with the artificial variable take the form

$$\begin{aligned} \max\ & f_i^T y_i - \frac{1}{2} y_i^T H_i y_i - M y_i^a \\ \text{s.t. } & R_i y_i + U_i x = z_i, \\ & W_i y_i + T_i x + s_{2,i} - y_i^a \iota_{2,i} = h_i, \\ & y_i^a \geq 0, s_{2,i} \in \mathcal{K}_{2,i}, \end{aligned} \tag{4.2}$$

where M is a sufficiently large constant to ensure that $y_i^a \to 0$, as a solution of TSSCP is approached. It is easy to construct a feasible solution of (4.2), which is taken as a starting point for the centering problem (2.11) defined for (4.2).

We still have the problem of identifying a proper value of M. We achieve this in the preprocessing phase. We experiment with an approximation of the original large-scale problem with a small number of scenarios (e.g., $N = 100$) with different values of M, which is taken as a multiple of the infinite norm of the problem data. The smallest value of M that successfully reduces y_i^a below 10^{-10} for all sampled problems is multiplied by a constant for later use. This constant is 10 for the experiments reported in this paper. This strategy allows us to work with values of M that are not unnecessarily large. Taking very large values of M may cause numerical difficulties. Although this approach is heuristic it has worked successfully in all our computations. One may think about adjusting the value of M dynamically over the course of the algorithm.

4.1.1. Initial warm-start. When solving different small sampled problems in the beginning, the first stage solution from the first sampled problem is used to warm-start all subsequent problems.

4.1.2. Selection of the starting barrier parameter. Starting with a μ that is too small may take too many inner iterations to reach the initial centered point, whereas choosing an unnecessarily large starting μ increases the number of outer iterations. We use information from the preprocessing phase to identify a suitable

starting μ. When solving a sampled problem we identify the value of μ that gives only a single digit of accuracy in this problem. Solving this problem to optimality also gives us the magnitude of the optimal objective. Let us denote the objective identified in this step by $\hat{o}$. We let $\hat{\mu}^1 = \hat{o}/\hat{\nu}$, where $\hat{\nu}$ is the order of the first stage cone $\mathcal{K}_1$. This value of $\hat{\mu}^1$ is expected to correspond to a solution with zero to one digit of accuracy in the objective value, which can be verified by building a confidence interval around the barrier function value. Next we try different values of μ $(0.1\hat{\mu}^1, 10\hat{\mu}^1)$ as the starting μ, and record the number of inner iterations required to solve the problem. We select a value of μ that requires the least number of inner iterations to get an optimal solution starting from that value. The corresponding solution is used to start the main algorithm for TSSCP.

4.2. Solution of the second stage centering problems. Each inner iteration of our algorithm solves second stage centering problems defined after updating x and/or μ. It is neither necessary nor possible to exactly solve second stage centering problems. In the following, (4.3) ensures sufficient feasibility in the solution, and (4.4) ensures proximity (controlled by the parameter ν) to the central path:

$$\|R_i y_i + U_i x - z_i\| \leq \texttt{tol}_{feas},\ \|W_i y_i + T_i x + s_{2,i} - h_i\| \leq \texttt{tol}_{feas},$$

$$\|W_i^T \lambda_i + R_i^T \gamma_i + H_i y_i - f_i\| \leq \texttt{tol}_{feas}, \tag{4.3}$$

$$\|P(\lambda_i^{1/2}) s_{2,i} - \mu\iota\| \leq \nu\mu. \tag{4.4}$$

We start from the solution of the second stage problem available at the end of the previous iteration. These starting points are no longer feasible or centered. We employ an infeasible primal-dual interior point method to solve the second stage centering problems. The primal-dual method implements the Nesterov–Todd [22, 29] scaling to symmetrize the KKT system and take steps along the Newton direction for recentering. A second stage line search is performed for computing the step-length as follows.

If a full Newton step (length 1) is feasible, we give priority to restoring primal and dual feasibility and take this step. When a full Newton step is not feasible, we choose a step-length that minimizes $\|\xi\| := \|\xi_{feas}, \xi_{cent}\|$, where $(\xi_{feas} = R_i y_i + U_i x - z_i, W_i y_i + T_i x + s_{2,i} - h_i, W_i^T \lambda_i + R_i^T \gamma_i + H_i y_i - f_i)$ is the vector of primal and dual infeasibilities, and $\xi_{cent} = (P(\lambda_i^{1/2}) s_{2,i} - \mu\iota)$ is the residual vector in the complementarity condition (4.4). The derivative of $\|\xi\|^2$ is a third order polynomial in the step-length, which has one or three real roots. Let ϱ denote the maximum step-length that we can take without violating the conic constraints on the primal slack $s_{2,i}$ and on the dual multipliers (λ_i) associated with the primal constraints. If there are no real roots less than ϱ, ϱ is the optimal step-length. If there is only one real root less than ϱ, it is the optimal step-length. If all three roots are real and less than ϱ, either the smallest or the largest root is the optimal step-length. When ϱ is the optimal step-length we take a slightly shorter step $(0.9^*\varrho)$ to ensure that primal and dual iterates stay far away from the boundary. In the results reported in this paper no attempts are made to take different steps along primal and dual directions, and a predictor-corrector strategy is not used.

Table 3 gives computational results for Problem MCR3 with 100 second stage scenarios using $\zeta = 0.1$ and different combinations of β and ν. The first number in each cell of this table gives the number of outer iterations required in our implementation. The second number gives the average number of second stage Newton step calculations

TABLE 3

Number of inner iterations and average iterations for recentering second stage problems for Problem MCR3-100 using accurate (3 digits) line search.

5	- -	- -	- -	- -

(total number of second stage Newton steps over all the scenarios/total number of calls to the second stage problems) for each call to the second stage problem. We use $\texttt{tol}_{feas} = 10^{-9}$ in condition (4.3). Note that the average number of second stage Newton iterations is close to one for the values of ν in the range 0.01 to 10, and the number of outer iterations is also insensitive to the accuracy of the second stage problem solutions. The values of β used for results in this table are chosen to ensure closeness to the first stage central path. Larger values of β do not produce stable performance, as seen from the results reported in Tables 3 and 4. For these results the algorithm is terminated when the relative improvement in the objective value at two successive major iterations is less than eight digits. It usually corresponds to a value of μ between 10^{-7} to 10^{-8}. The number of inner iterations taken by the algorithm is given in Table 3 if a problem is successfully solved to eight digits of accuracy. For all runs reported in Table 3 we used a relatively accurate line search to avoid any misinterpretations. In all the runs performing a line search, the search is terminated when we have three digits of accuracy in the step-length parameter. The iteration counts are indicated by "–" when the implementation fails to achieve eight digits of precision. There are several reasons for this failure. For some problems the Cholesky factorization method in MATLAB becomes unstable. For other problems the solution does not have eight digits of accuracy, even though the change in the objective between two successive major iterations is less than eight digits. This may be due to the fact that for $\beta = 5$ the neighborhood of the central path may be too wide to correctly measure termination based on either relative improvement or the barrier parameter value criterion.

When warm-starting from the previous solution, typically only one (occasionally two) second stage iteration is required. Furthermore, the number of inner iterations of the primal decomposition algorithm remain unchanged for ν in a very large range. Computationally we observe that typically the termination conditions (4.4) are satisfied for much smaller values of $\texttt{tol}_{feas}$ since Newton steps are very effective from a warm-start solution. Furthermore, from Table 3 we observe that the average number of iterations required to recenter the second stage grows only slightly for smaller values of ν.

4.3. First stage centering and barrier reduction rate. Tables 4, 7, and 8 give computational results for Problem MCR3-100 for $\nu = 1$, and using different combinations of β and ζ with exact and inexact line search. The results in Table 4 show that the total number of inner iterations increase for large values of ζ (μ is

TABLE 4
Number of inner iterations and average inner iterations per outer iteration for Problem MCR3-100 using accurate (3 digits) line search.

$\nu = 1$	ζ			
β	0.05	0.1	0.25	0.5

3	- -	20 2.43	26 2.00	26 1.04
5	- -	- -	25 1.92	25 1.00

decreased slowly). Also when μ is reduced too aggressively the total number of inner iterations tends to increase, indicating that recentering becomes more difficult in this case. In our experiments the choices $\zeta = 0.1$ and $\beta = 1$ give good results for all the problems.

4.4. First stage step-length. The analysis of long-step primal interior point algorithms, such as the one given in [18, 21, 31] is based on taking fixed-length steps along the Newton direction. The choice of this step-length is given as $\theta = (1+\delta)^{-1}$, where δ is the local norm of the Newton direction, as explained in sections 2.1 and 2.2. This step-length is usually very conservative, and there is a need to develop a step-length selection strategy that is more efficient. The strategy of taking a constant step to the boundary, which works well for the primal-dual algorithms [13, 15], is not always stable in the current setting. Also, in practice we cannot perform an elaborate line search with backtracking, since each barrier function evaluation (or its derivative evaluation) requires solution of all second stage scenarios. This is almost equal to the cost of computing the first stage direction afresh. Hence, we need a heuristic that avoids unnecessary barrier function evaluations while not increasing the total number of inner iterations significantly.

The following step-length selection strategy has worked well in our computational experiments: $\theta = \min\{\alpha(1+\delta)^{-1}, 1, 0.9\varrho\}$, where ϱ is the maximum step to the boundary of the feasible set, and α is a scalar constant. We take this step and check the value of barrier function at the new point. This evaluation of the barrier function is combined with the computation of the new Newton direction if the step is accepted. Hence, there is no efficiency loss in this function evaluation. We ensure that the barrier function has reduced sufficiently at the new point, which is almost always the case. In a few rare occasions, when the barrier function is not reduced sufficiently, we can backtrack by aggressively reducing α. In our computations when this happened we simply set $\alpha = 1$; i.e., in this case we take $\theta = (1+\delta)^{-1}$. This has always reduced the barrier function to a desirable amount. The use of the parameter α is justified through empirical observations, which indicate that when an iterate is close to the boundary, the optimum step-length is a multiple of $(1+\delta)^{-1}$. Such results are shown in Table 5 for problem MCR4-100. We use $\alpha = 4$ in our actual computations. The results in Table 6 show that the choice of parameter α is important in reducing the total number of inner iterations. Note that the number of inner iterations are slightly larger for both small and large values of α. This is because for a small value of α the step is conservative, while for a large value of α the step is

27	1.00E-08	0.51	1.13	0.6	1.18

usually so large that we take 0.9ϱ as a step-length instead of $\alpha(1+\delta)^{-1}$. Reasons for failure indicated in these tables are similar to those discussed before. While analyzing 100 scenario problems of different size and randomness we find that the heuristic step-length strategy performs well, taking within 10–20% of the number of inner iterations required by an implementation using "exact" line search. The "exact" line search is performed using bisection method, and it is terminated when the interval of uncertainty is reduced to 10^{-3}. The worst offenders (about 25% worse) were problems MCRF14–MCRF6 (see Table 10) suggesting that further refinements may provide improvements.

5. Basic behavior of the primal decomposition algorithm.

5.1. Comparison with a direct method. Since we can formulate TSSCP as a large conic programming problem (extensive formulation), one can use a primal-dual interior point method for solving the extensive formulation. SeDuMi [26] is a popular solver that can be used to directly solve the extensive formulations of the problem we generate. Table 9 gives a comparison of the total number of iterations taken by the primal decomposition algorithm (for $\alpha = 4, \beta = 1, \zeta = 0.1, \nu = 1$) and those taken by SeDuMi 1.05 [26] for an extensive formulation of the problem. In order to compare the performance of primal decomposition algorithm with that of SeDuMi, it is more appropriate to consider the number of inner iterations taken by the primal decomposition algorithm with the number of iterations taken by SeDuMi to achieve the same accuracy in the solution. SeDuMi implements Mehrotra's predictor-corrector method.

The work required to compute one predictor step in SeDuMi is roughly equivalent to computing a Newton direction in an inner iteration of the primal decomposition algorithm. A comparison of CPU times would be misleading for a variety of reasons. These codes are written using different linear algebra libraries (SeDuMi uses its C code, while we depend on MATLAB). Because MATLAB is an interpreted language, it must interpret every line in a for-loop every time it goes through it, and this makes MATLAB very slow in handling loops. Furthermore, when solving problems we generate scenarios on the fly, while SeDuMi reads an extensive formulation, generating and writing to a text file that is readable by SeDuMi which is memory intensive. We were unable to feed larger problems to SeDuMi for this reason. For the problems

that were solved by both SeDuMi and the primal decomposition algorithm, results indicate that both algorithms correctly achieve eight digits of accuracy. SeDuMi took 10–30% fewer iterations. Recall that the corrector step in the predictor-corrector method reduces the total number of iterations by 20–50%. Hence, it appears that for a "Newton" step–based algorithm the total number of iterations taken by the primal decomposition algorithm is comparable.

5.2. Performance with increasing problem size. Table 10 gives the number of iterations required by the primal decomposition method with increasing size of cones in the problem (called *problem size* for short). The problems with increasing second stage size are MCRS1–MCRS6, and those with increasing first stage size are MCRF1–MCRF6. These results show that the number of inner iterations are not significantly affected by the second stage problem size, whereas the number of inner iterations show an early upward trend but become stable as the first stage problem size grows. This indicates that the complexity of the algorithm depends on the first stage problem size; however, the iteration growth is not very rapid, which is generally the case with interior point methods.

TABLE 11

Number of inner iterations as problem randomness increases ($\zeta = 0.1$, $\beta = 1$, $\nu = 1$, and $\alpha = 4$). (Results for problems MCR1-100 to MCR6-100 are given in Table 6.)

5.3. Performance of the algorithm with increasing randomness. We generated problems with increasing amount of randomness in the problem data by varying the value of $p_{\%}$. Recall that for Problems MCR1–MCR6 $p_{\%} = 5\%$, for Problems MCL1–MCL6 $p_{\%} = 50\%$, and for Problems MCH1–MCH6 $p_{\%} = 500\%$. We also generated problems MCL13–MCL63 where the dimension of the underlying random variable is 33 and $p_{\%} = 50\%$. Results for 100-scenario instances of these problems are given in Table 11. When comparing the number of inner iterations for these problems with those for problems MCR1–MCR6 (see Table 6) no significant trend is observed with increasing randomness. From these results we infer that the number of inner iterations required by the algorithm is not dependent on the randomness in the problem data.

5.4. Performance of the algorithm with increasing number of scenarios. In Table 12 we give the number of inner iterations taken when solving Problems MCR3 and MCR4 with an increasing number scenarios. Implementation details for problems with larger than 100 scenarios are discussed in section 7. A comparison of these results shows no increasing trend in the required number of inner iterations with increasing number of scenarios.

6. Adaptive scenario addition heuristic. The primal decomposition algorithm naturally allows adaptive addition of scenarios as the algorithm progresses. It is important to explore this possibility since adaptive addition of scenario may lead to significant computational savings. Recall that when the number of scenarios is fixed (no adaptive scenario addition) we move along a fixed first stage central path as μ is reduced. However, in the adaptive algorithm the first stage central path changes when new scenarios are added. As the results in section 7 show, we need to be careful while adding scenarios adaptively. This is because if a large number of scenarios are added for a small value of the barrier parameter, the change in the primal central path caused by this scenario addition may result in a poorly conditioned problem. This, in turn, may require significantly more inner iterations to recenter and could even cause numerical breakdowns.

In this section we develop a heuristic that addresses this issue. The key idea behind our heuristic is to add the number of scenarios in such a way that adding scenarios and reducing the value of barrier parameter in the algorithm have a similar impact on displacement of the first stage center. For this purpose we devise methods for estimating the change in the barrier objective value caused by scenario addition, and also suggest ways to measure the change in the barrier objective resulting from reducing μ. The assumptions made while developing this heuristic are justified through empirical evidence.

We add new scenarios when μ is reduced in Step 2 of Algorithm 1. Our heuristic aims to maintain

$$|\eta_{N_k}(\mu^k, x_{N_k}(\mu^k)) - \eta_{N_{k-1}}(\mu^k, x_{N_{k-1}}(\mu^k))| \approx \Delta\eta_{N_k}(\mu^k),$$

where $\eta_{N_k}(\mu^k, x_{N_k}(\mu^k))$ is the optimum objective of the sample-average log-barrier problem with N_k samples for $\mu = \mu^k$ and

$$\Delta\eta_{N_k}(\mu^k) := \eta_{N_k}(\mu^k, x_{N_k}(\mu^k)) - \eta_{N_k}(\mu^k, x_{N_k}(\mu^{k-1})). \tag{6.1}$$

Note that the sample-average function is a random variable when scenarios are generated randomly (Monte Carlo). We represent the corresponding random variable by $\hat{\eta}_N(\cdot,\cdot)$. Every randomly generated batch of N-samples yields a different realization $\eta_N(\cdot,\cdot)$ of $\hat{\eta}_N(\cdot,\cdot)$.

A justification of the heuristic idea is as follows. In the adaptive implementation of our algorithm, at the beginning of the kth outer iteration we decrease the barrier parameter from μ^{k-1} to $\mu^k = \zeta\mu^{k-1}$, and we simultaneously increase the number of scenarios from N^{k-1} to N^k. In general, both of these actions may increase the distance of current point x to the central path. Decreasing μ moves away the μ-center, whereas increasing the number of scenarios may change the central path. Since experimentally we know that it takes only a few iterations to recenter after decreasing μ in the case where the number of scenarios is fixed, by keeping the impact of adding to the number of scenarios of the same order as the impact of decreasing μ, we expect that the number of iterations required to converge to the new center with added scenarios will be of the same order.

6.1. Confidence interval estimation. Various estimations required to build our heuristic are motivated by the following theorem from Shapiro [25].

THEOREM 6.1. *Consider the stochastic program* $\inf_{x\in X}\int_\Omega g(x,\omega)P(d\omega)$ *and let* z^* *be its optimal objective. Let* $\hat{z}_N$ *denote the optimal objective of the sample average problem* $\inf_{x\in X} N^{-1}\sum_{i=1}^N g(x,\omega^i)$*, where* ω^i *are independent. Suppose* X *satisfies the following conditions:*

(i) $g(x,\cdot)$ *is measurable for all* $x \in X$*;*

(ii) *there exists some function* $f:\ \Omega \to \mathbb{R}$ *such that* $\int_\Omega |f(\omega)|^2 P(d\omega) < \infty$*, and*

$$|g(x_1,\omega) - g(x_2,\omega)| \le f(\omega)|x_1 - x_2|$$

for all $x_1, x_2 \in X$*;*

(iii) *for some* $\bar{x} \in X$, $\int_\Omega g(\bar{x},\omega)dP(\omega) < \infty$*, and* $E\{g(x,\omega)\} = \int_\Omega g(x,\omega)dP(\omega)$ *has a unique minimizer* $x^* \in X$*. Then* $\sqrt{N}(\hat{z}_N - z^*)$ *converges in distribution to normal distribution* $\Phi(0, \mathrm{Var}[g(x^*,\xi)])$*, where* $\mathrm{Var}[g(x^*,\omega)] = \int_\Omega g(x^*,\omega)^2 dP(\omega) - E\{g(x^*,\omega)\}^2$.

Recall that since the log-barrier recourse function $\eta_N(\mu,x)$ is concave in x, it has a unique maximizer. Thus it satisfies the uniqueness condition in (iii) of Theorem 6.1. Furthermore, since concave functions are Lipschitz continuous in the interior

of their domain, condition (ii) of Theorem 6.1 is also satisfied. The assumption that first and second stage problems are feasible and bounded ensures the remaining regularity conditions in Theorem 6.1. Hence, when the random variable governing the stochastic program has a continuous distribution and the second stage problems are generated using Monte Carlo sampling, Theorem 6.1 applies. In this case, we have $\mathrm{Var}[\hat{\eta}_N(\mu, x_N(\mu))] = \sigma^2(\mu, x(\mu))/N$, where $\sigma^2(\mu, x(\mu)) = \mathrm{Var}[\rho(\mu, x(\mu), \tilde{\omega})]$ [8]. Here, $\rho(\cdot, \cdot, \tilde{\omega})$ is the log-barrier counterpart of $\rho(\cdot, \tilde{\omega})$ in (3.4). Note also that we used the observation that the randomness of $\hat{\eta}_N(\mu, x_N(\mu))$ is due to the log-barrier recourse function. Theorem 6.1 shows that $\sqrt{N}(\hat{\eta}_N(\mu, x_N(\mu)) - \eta(\mu, x(\mu)))$ converges in distribution to a normal random variable with a mean of zero and variance of $\sigma^2(\mu, x(\mu))$.

For any batch of N samples, this result provides a statistical bound on $|\eta_N(\mu, x_N(\mu)) - \eta(\mu, x(\mu))|$ that holds with a certain confidence:

$$|\eta_N(\mu, x_N(\mu)) - \eta(\mu, x(\mu))| \mathrel{\widetilde{\leq}} z_\alpha \frac{s_N(\mu, x_N(\mu))}{\sqrt{N}}.$$

Here $s_N^2(\mu, x_N(\mu))$ is an N-sample approximation of the sample variance estimator of $\sigma^2(\mu, x(\mu))$, and the value of z_α provides the level of confidence we want in the bound. In particular, z_α satisfies $P\{\Phi(0,1) \leq z_\alpha\} = 1 - \alpha$. The statistical and approximate nature of this bound is indicated by using the symbol $\widetilde{\leq}$.

We use a quasi–Monte Carlo (QMC) (Sobol' sequence) technique instead of Monte Carlo to generate second stage samples since it is known that better variance convergence rates are possible by using QMC techniques. For example, the empirical results in Glasserman [8] and our own experiments suggest that a Sobol' sequence gives much faster convergence than a Monte Carlo sampling. Unfortunately, the convergence rate theory for these techniques is not yet fully developed in the stochastic programming setting. For example, we do not know the asymptotic distribution of $\hat{\eta}_N(\mu, x_N(\mu)) - \eta(\mu, x(\mu))$ for scenarios generated using a Sobol' sequence, and whether an analogue of Theorem 6.1 holds. Heuristically, we expect that when scenarios are generated using a Sobol' sequence,

$$|\eta_N(\mu, x_N(\mu)) - \eta(\mu, x_N(\mu))| \mathrel{\widetilde{\leq}} z_\alpha RMS_N(\mu, x_N(\mu)),$$

where $RMS_N(\mu, x_N(\mu))$ represents the "root-mean-square" error of $\hat{\eta}_N(\mu, x_N(\mu))$, and z_α provides a confidence interval as before. The root-mean-square error is calculated by randomizing the Sobol' sequence as follows.

Let S_i represent the Sobol' sequence used to generate the second stage scenarios. To generate the jth set of N scenarios we generate a random (Monte Carlo) vector U_j, uniformly distributed over the unit hypercube of appropriate dimension, and generate a new sequence: $\tilde{S_i}^j = (S_i + U_j) \bmod 1,\ i = 1, \ldots, N$. The problem corresponding to $\tilde{S_i}^j$ is generated as described in section 3.2. This process is repeated for $j = 1, \ldots, m$ to generate m random problems each having N scenarios. Let $\eta_{N(j)}(\mu, x_{N(j)}(\mu))$ denote the log-barrier objective of the jth problem for a given μ and $x_{N(j)}(\mu)$. Now

$$RMS_N(\mu, x_N(\mu)) := \sqrt{\frac{1}{m-1}\sum_{j=1}^{m}(\eta_{N(j)}(\mu, x_{N(j)}(\mu)) - \bar{\eta}_N)^2}, \quad \text{where} \tag{6.2}$$

$$\bar{\eta}_N := \frac{1}{m}\sum_{j=1}^{m}\eta_{N(j)}(\mu, x_{N(j)}(\mu)).$$

Calculation of $RMS_N(\mu, x_N(\mu))$ for large N requires significant work, which is not practical in an algorithmic setting. However, in QMC we expect RMS to decrease by $O(1/N^\kappa)$, where $1 \geq \kappa > 0.5$ [8, Chapter 5]. Note that for Monte Carlo $\kappa = 0.5$. The knowledge of κ can allow us to approximate $RMS_N(\mu, x_N(\mu))$ for large N by scaling $RMS_{N'}(\mu, x_{N'}(\mu))$ calculated for some small value N'. However, even this computation may be expensive, since computation of $RMS_{N'}(\mu, x)$ requires several (m) replications of problems with small sample size. With this in mind in our implementation we perform the computation of κ once off-line, while we further approximate the computation of $RMS_N(\mu, x_N(\mu))$ by taking the (possibly biased) estimation

$$RMS_N(\mu, x_N(\mu)) \approx \hat{\sigma}_N(\mu, x_N(\mu))/N^\kappa,$$

where

(6.3)

$$\hat{\sigma}_N^2(\mu, x_N(\mu)) := \frac{1}{N-1}\sum_{i=1}^{N}(\rho_i(\mu, x_N(\mu)) - \bar{\rho}_N)^2, \text{ where } \bar{\rho}_N := \frac{1}{N}\sum_{i=1}^{N}\rho_i(\mu, x_N(\mu)).$$

Note that as a consequence of this approximation we now have

$$|\eta_N(\mu, x_N(\mu)) - \eta(\mu, x(\mu))| \lesssim z_\alpha \hat{\sigma}_N(\mu, x_N(\mu))/N^\kappa,$$

which is similar to the approximation for the Monte Carlo case except that we now have a tighter inequality due to $1/N^\kappa$. With the above discussion the problem of estimating a bound on $|\hat{\eta}_N(\mu, x_N(\mu)) - \eta(\mu, x(\mu))|$ is now reduced to the problem of estimating $\hat{\sigma}_N^2(\mu, x(\mu))$ and κ. The discussion in section 6.2 shows that good approximations of $\hat{\sigma}_N(\mu, x_N(\mu))$ are available cheaply because of the empirically observed properties of the primal central path. Fortunately very accurate values of κ are not required since the adaptive scenario generation heuristic allows a lot of flexibility. The calculation of κ is discussed in section 6.3.

6.2. Empirical observations on the first stage central path and the variance of second stage barrier objectives. We empirically observe that $\hat{\sigma}_N(\mu, \cdot)$ does not change significantly with μ at solutions on (or near) the first stage central path. Furthermore, it also does not change significantly with increasing value of N. Hence, it is sufficient to compute $\hat{\sigma}_N(\mu, \cdot)$ for a large value of μ and a small sample size N' at $x_{N'}(\mu)$. These empirical observations are illustrated in Table 13. Results in this table are obtained from 100, 1,000, and 10,000 scenario approximations of problem MCR3. We solved each of these problems using the primal decomposition method. We calculated $\hat{\sigma}_N(\mu^k, \hat{x}_N(\mu^k))$ as defined in (6.3) at the approximate first stage μ-center $\hat{x}_N(\mu^k)$ in every outer iteration k of the primal decomposition algorithm.

In the above experiment for each outer iteration k, we also calculated the changes in the value of η_N to observe its behavior. From the results in Table 13 we observe that $\Delta\eta_N(\mu^k)$ scales proportionally to μ and does not change significantly as N increases. This suggests that it is sufficient to solve the sample average approximation to a low accuracy (zero or one digit) to estimate $\hat{\sigma}_{N'}(\mu, \cdot)$, and $\Delta\eta_N(\mu)$ for any μ. Note that this last property is due to the form of the objective in (2.12) (due to the weighting of the second stage barrier term by π_i), and it is not obviously shared by the objective function in (2.3), where the "contribution" of the barrier grows as more scenarios are added.

6.3. Estimating convergence rate of the root-mean-square error. For problem MCR3 we experimented with $N = 10$, 50, 250, 1,000, and 5,000 scenario approximations of the TSSCP. We generated $m = 100$ batches of 5,000 samples. We identified $\hat{x}^1_{10}(0.001)$, an approximate first stage μ-center of the first 10 scenario problem for $\mu = 0.001$, and then solved all the second stage problems in all batches setting $x = \hat{x}^1_{10}(0.001)$ and $\mu = 0.001$. Let $i(j)$ be the index of the ith sample in the jth set with N samples. For $j = 1, \ldots, 100$ and N= 10, 50, 250, 1,000, and 5,000 we calculated

$$\eta_{N(j)}(0.001, \hat{x}_{10}(0.001)) = b^T x - \frac{1}{2}x^T G x + \mu \ln\det(s_1) + \frac{1}{N}\sum_{i(j)=1}^{N} \rho_{i(j)}(\mu, x)\Bigg|_{\mu=0.001,\ x=\hat{x}^1_{10}(0.001)}.$$

Using these values we obtained the root-mean-square error $RMS_N(0.001, \hat{x}^1_{100}(0.001))$ for $N = 10$, 50, 250, 1,000, and 5,000. Table 14 gives the root-mean-square errors for Problem MCR3 calculated in this way. An average convergence rate of $\kappa = 0.84$ is observed. Note that a different choice of x may give a slightly different rate of convergence, and also one may think about building a confidence interval for the rate of convergence. We have not done this in our experiments, since a crude estimate is sufficient for us. In our numerical experiments on adaptive scenario addition, we used $\kappa = 0.85$ for all randomly generated problems, and $\kappa = 0.7$ for all Markowitz problems. The dimension of the Sobol' sequence used to generate Markowitz problems is greater (20 to 40 vs. 2 or 33 in the randomly generated problems), potentially resulting in a slower convergence rate.

TABLE 14
Number of scenarios vs. RMS.

N	$RMS_N(0.001, \hat{x}^1_{10}(0.001))$
10	2.254958E-01
50	5.581944E-02

1,000	4.230485E-03
5,000	1.309438E-03

6.4. A heuristic for adaptive scenario addition. Let μ^3 be the value of barrier parameter after three major iterations in the preprocessing phase and let $\hat{x}(\mu^3)$ be a sufficiently well-centered first stage solution for $\mu = \mu^3$. From the discussion in section 6.1 it follows that

$$\begin{aligned}
&|\eta_{N_k}(\mu^k, \hat{x}_{N_k}(\mu^k)) - \eta_{N_{k-1}}(\mu^k, \hat{x}_{N_{k-1}}(\mu^k))| \\
&= |\eta_{N_k}(\mu^k, \hat{x}_{N_k}(\mu^k)) - \eta(\mu^k, x(\mu^k)) + \eta(\mu^k, x(\mu^k)) - \eta_{N_{k-1}}(\mu^k, \hat{x}_{N_{k-1}}(\mu^k))| \\
&\lessapprox z_\alpha \left(\frac{\hat{\sigma}_{N_k}(\mu^k, \hat{x}_{N_k})}{N_k^\kappa} + \frac{\hat{\sigma}_{N_{k-1}}(\mu^k, \hat{x}_{N_{k-1}})}{N_{k-1}^\kappa} \right) \\
&\lessapprox z_\alpha \left(1 + \left(\frac{N^{k-1}}{N^k} \right)^\kappa \right) \frac{\hat{\sigma}_{N'}(\mu^3, \hat{x}(\mu^3))}{N_{k-1}^\kappa} \\
&\lessapprox 2 z_\alpha \frac{\hat{\sigma}_{N'}(\mu^3, \hat{x}(\mu^3))}{N_{k-1}^\kappa}.
\end{aligned}$$

We may now choose N_k such that

$$2 z_\alpha \frac{\hat{\sigma}_{N'}(\mu, \cdot)}{N_{k-1}^\kappa} = \Delta\eta_{N_k}(\mu^k). \tag{6.4}$$

Note that the heuristic calculation in (6.4) gives an estimation of the number of scenarios at iteration $(k-1)$ in anticipation of the impact of reduction in the barrier parameter. Hence, the heuristic anticipates the future and loads sufficiently many scenarios in the current outer iteration so that the central path does not change dramatically when we load new scenarios in the next outer iteration. In our computations we set $N' = 100$ and used $\Delta\eta_{N_k}(\mu^k) \approx \Delta\eta_{100}(\mu^3)\frac{\mu^k}{\mu^3}$.

7. Computational results on adaptive scenario addition and warm-start. After adding new scenarios we need to solve the corresponding second stage centering problem for the current value of x and μ. In order to exploit the solutions of the scenarios that are already in the problem, we may look for a scenario that is close to the scenario to be added. One possibility is to look for a scenario that is close in terms of problem data to the new scenario. A solution from the neighboring scenario may provide a good starting point. The Sobol' sequences that we used to generate our scenarios do not provide this neighborhood information a priori. Therefore, for each Sobol' point S_k we heuristically identified a neighboring point among the points $S_1, \ldots, S_{k-1}$. We then used the final iterate from this neighboring scenario for the current value of x and μ as a starting solution for the new scenario. Let us denote this warm-start strategy as Warm-Start-1.

Our experience with Warm-Start-1 has been mixed. For easy problems, e.g., when the second stage problems have only linear constraints and linear objectives, we

observed that the strategy of using a solution from a nearby scenario works. However, for more difficult conic problems Warm-Start-1 exacerbates the performance. For these problems starting from a well-centered point of a near by scenario, especially at small values of μ, Newton iterations were not able to absorb the infeasibility within a practical number of iterations. In general, our experience is that such warm-starts with conic and semidefinite problems are harder for the same amount of perturbation in the problem data.

We also experimented with an alternative approach (Warm-Start-2), which was more stable in the current setting. In this approach, once we complete the final inner iteration of the first outer iteration, we also solve all the second stage problems that are yet not included in the problem, for the starting $\mu = \mu^1$ and the latest first stage solution $x = x(\mu^1)$. For $\mu = \mu^1$, the warm-start is very efficient and each second stage problem can be solved within a few iterations. We store all these second stage solutions for later use. When a new scenario is added in a subsequent outer iteration k ($k > 1$), we warm-start its solution from the iterate stored for this scenario in the first outer iteration. We proceed in two steps: In the first step, we solve the new problem for $\mu = \mu^1$ and $x = x(\mu^k)$ and in the second step we reduce μ from μ^1 to μ^k.

7.1. Discussion of randomly generated problems. Tables 15–20 present computational results for problems MCR3-10,000, MCL3-10,000, MCH3-10,000, and MCL33-10,000. Run 1 in these tables corresponds to an implementation where all scenarios are loaded from the beginning, Run 2 uses the scenario addition heuristic of section 6 with $z_\alpha = 1.96$, Run 3 delays addition of these scenarios one major iteration forward, and Run 4 delays addition of scenarios two major iterations forward. Run 5 and Run 6 on MCR3-10,000 are identical to Run 1 and Run 2, except that the algorithm is terminated with a larger value of μ. These runs are included because for MCR3-10,000, using the information from $\hat{\sigma}_{N'}(\mu, \cdot)$, we estimate that a 10,000-scenario problem can produce a "statistical accuracy" (i.e., have a confidence interval that ensures that the objective is accurate to that degree) of about four digits. This accuracy is achieved for $\mu = 10^{-4}$. Although the additional major iterations solve the optimization problem more accurately, they do not improve the quality of the stochastic programming solution. To get an additional digit of "statistical" accuracy in the stochastic programs, we will require between 100,000 to one million scenarios. Solving problems of such sizes is not possible in the MATLAB environment. In Tables 15–26 row "# inner itr" gives the number of first stage Newton direction calculations"; row "# new sce add itr" gives the number of second stage centering iterations needed to add new scenarios while adaptively adding scenarios; row "# 2nd stage recenter itr" gives the total number of second stage centering iterations; row "# 2nd stage rectr calls" gives the total number of second stage calls for centering; row "avg new sce add itr" gives the average number of second stage iterations required to add a new scenario while adaptively adding scenarios; and row "avg recenter itrs" gives the average number of second stage Newton iterations per call.

We make the following observations based on results in Tables 15–16 for Problem MCR3-10,000. Table 16 gives relevant statistics on algorithm performance. First, we observe that a well-designed heuristic is necessary for gaining efficiency for adaptive scenario addition. Note that for Problem MCR3-10,000 Run 3 required significantly more iterations and time than Run 2. Run 4, which was more aggressive in delaying scenario addition, could not even solve the problems. In this run at $\mu = 10^{-4}$, after additional scenarios were loaded, the algorithm failed to recenter within 50 inner iterations and terminated. There are only four digits of accuracy in the solution at

TABLE 15

this value of μ. Second, the warm-start for the existing scenario (after an update of x and/or μ) was effective. However, the addition of a new scenario took relatively more iterations. The computational savings in Run 2 over Run 1 are about 40%. This is because about half of the iterations in Run 2 are done with all the scenarios. When comparing the CPU times of Run 5 and Run 6 we observe that the CPU time savings are about 55%. Run 7, which aggressively delays scenario addition, performs worse than Run 6.

When analyzing the results in Tables 17–22 for Problems MCL3-10,000 and MCH3-10,000, we find a repeat of the above observations. Although Run 4 managed to optimize Problem MCL3-10,000, it took about 60% more time compared to Run 1. Run 4 for Problem MCH3-10,000 was just as efficient as Run 2. Note that more scenarios are added sooner for Problems MCL3-1,000 and MCH3-10,000 since they have larger values of $\hat{\sigma}_{N'}(\mu, \cdot)$. Interestingly, for these problems delaying scenario addition by one or two major iterations did not cause the algorithm to fail although it increased the number of inner iterations. We think this may be because for a larger value of μ it is easier to recover proximity to the first stage central path. However, for a smaller value of μ the recovery to the central path is harder since in this case the iterates are closer to the boundary of the first stage feasible set.

We observe that the average number of inner iterations taken when adding new scenarios in Run 1 increase slightly from MCR3-10,000 to MCL3-10,000 to MCH3-10,000. This shows that the ability to warm-start for an existing scenario depends on the value of $\sigma_{\hat{N}'}(\mu, \cdot)$. As $\sigma_{\hat{N}'}(\mu, \cdot)$ decreases, for a fixed number of scenarios the distance between a given scenario and its closest neighbor decreases. The same is true if the number of scenarios were to increase. In both cases, the quality of final iterates of neighboring scenarios as starting point increases.

7.2. Discussion on two-stage stochastic Markowitz problems. We solved the two-stage Markowitz problem with 20, 30, and 40 securities setting $\tau_{2,i} = 0.05$ and

a 40-security instance of the problem setting $\tau_{2,i} = 0.25$. Decreasing the upper bound $\tau_{2,i}$ on the variation of the portfolio decomposition makes the two-stage Markowitz problem increasingly harder and eventually infeasible.

In Table 24 we report results for the $\tau_{2,i} = 0.05$ case. We performed two runs for each problem. In Run 1, we loaded all scenarios from the beginning and in Run 2 we added them adaptively following the strategies given in Table 23. For all problems, Run 2 uses the scenario addition heuristic of section 6 with $z_\alpha = 1.96$. With $\tau_{2,i} = 0.05$, strategy Warm-Start-1 was not stable. This is similar to the experience described in the previous section. Therefore, we performed addition of scenarios according to strategy Warm-Start-2. Since scenario additions require about 7 second stage iterations and the algorithm converges to optimality taking considerably fewer inner iterations than on the randomly generated test problems, here the adaptive scenario addition does not yield significant computational savings.

In Table 26, we report results for $\tau_{2,i} = 0.25$, where strategy Warm-Start-1 worked successfully. Our experience in this case was positively different. In Run 1 we loaded all scenarios in the first outer iteration. In Run 2 scenarios are added adaptively as discussed in section 6 with $z_\alpha = 1.96$. In Runs 3, 4, and 5 we added scenarios by warm-starting from the final iterate of a neighboring scenario at latest value of μ. Run 4 delays addition of scenarios one major iteration forward. Run 5 is very aggressive and delays addition of scenarios to the final two outer iterations. In Run 2 computational savings over Run 1 are about 30%. Due to more efficient addition of scenarios, savings in Run 3 increase by about 40%. Finally, Run 5 achieves 80% computational savings over Run 1. Also, note that even in Run 5, addition of scenarios was absorbed without taking additional inner iterations. All runs achieved optimality after 15 inner iterations. We estimate that with $\tau_{2,i} = 0.25$, a 15,000-scenario instance of the two-stage Markowitz problem with 40 securities can produce a "statistical accuracy" of

about four digits. So, the relative easiness of the second stage problems are not because scenarios are closer to each other in terms of problem data. We think that the reason lies in the geometric simplicity of the problem that allows absorption of infeasibilities easily even when starting from neighboring scenario solutions for small values of μ.

Recall that the objective of the two-stage Markowitz problem is a concave quadratic function. We remark that our implementation successfully handled these quadratic terms without any numerical issues.

In summary, our experience suggests that adaptive addition of scenarios can be a very effective way of achieving computational savings, particularly when warm-starting the second stage problems from a nearby scenario is possible. However, it is also important to balance scenario addition with changes in the barrier function along the central path.

8. Conclusions. We have given a practical primal decomposition algorithm that follows the primal central path in the first stage. At each iteration, using approximate primal and dual solutions of the second stage barrier problems, it generates gradient and Hessian information for the first stage problem and takes a step along the Newton direction in the primal space. Several problems inherent in the context of primal algorithms were resolved using a preprocessing phase, and heuristics were developed for line search and scenario addition. These heuristics are based on empirically observed properties of the central path. A rigorous theoretical justification of these observed properties is a topic of future research.

Numerical experiments were conducted on a set of randomly generated problems and a two-stage extension of Markowitz's basic portfolio optimization model. Numerical experience suggests that we can solve the second stage centering problem approximately without compromising the performance of the decomposition algorithm. This experience also suggests that we need to follow the primal central path closely to develop stable implementations. Our results show that significant computational savings are possible for primal decomposition algorithms by adaptive addition of scenarios. These computational savings increase if it is possible to warm-start the solution of newly added second stage centering problems from the solution of a neighboring problem. The possibility of using primal predictor-corrector methods and integrating warm-starts with scenario generation may further improve the performance of primal decomposition methods and should be explored in the future.

It is possible to conceive other ways of adding scenarios in the adaptive scenario addition strategy. One example of such a strategy is a linear growth strategy where an equal number of scenarios are added in each major iteration. While a linear growth strategy is simple, and possibly useful, it is not consistent with what one would expect from the convergence rate of quasi–Monte Carlo methods. A linear growth strategy adds more scenarios in the early outer iterations, which is inefficient. In fact, it is easy to argue that with the linear growth strategy the maximum amount of computational savings cannot be more than 50% assuming that the average number of second stage Newton iterations per call is unchanged. Our goal here is to demonstrate that greater improvements in solution times are possible. The results on delayed addition of scenarios are used to demonstrate the importance of developing a strategy with a "reasonable" theoretical foundation.

A USE OF CONJUGATE GRADIENT DIRECTION FOR THE CONVEX OPTIMIZATION PROBLEM OVER THE FIXED POINT SET OF A NONEXPANSIVE MAPPING*

HIDEAKI IIDUKA† AND ISAO YAMADA‡

Abstract. In this paper, we discuss the convex optimization problem over the fixed point set of a nonexpansive mapping. The main objective of the paper is to accelerate the hybrid steepest descent method for the problem. To this goal, we present a new iterative scheme that utilizes the conjugate gradient direction. Its convergence to the solution is guaranteed under certain assumptions. In order to demonstrate the effectiveness, performance, and convergence of our proposed algorithm, we present numerical comparisons of the algorithm with the existing algorithm.

Key words. convex optimization problem, nonexpansive mapping, fixed point, hybrid steepest descent method, conjugate gradient direction

1. Introduction.

Let H be a real Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and its induced norm $\| \cdot \|$. It is well known that the standard *smooth convex optimization problem* [10, 24, 33, 45], given a convex, Fréchet differentiable function $f\colon H \to \mathbb{R}$ and a closed convex subset C of H,

$$\text{find a point } x^* \in C \text{ such that } f(x^*) = \min_{x \in C} f(x), \tag{1.1}$$

can be formulated equivalently as the *variational inequality problem* [23, 24, 36, 45] over C:

$$\text{find } x^* \in C \text{ such that } \langle v - x^*, \nabla f(x^*) \rangle \geq 0 \text{ for all } v \in C, \tag{1.2}$$

where $\nabla f\colon H \to H$ is the gradient of f. The simplest iterative scheme for (1.1) is the well-known *projected gradient method* [17]: $x_1 \in C$ and $x_{n+1} = P_C(x_n - \mu \nabla f(x_n))$ for every $n \in \mathbb{N}$, where P_C is the *metric projection* from H onto C (see section 2) and μ is a positive real number. This method requires repetitive use of P_C, although the closed form expression of P_C is not always known in many situations. To help resolve this problem, the following *hybrid steepest descent method* [42, 43, 44] for (1.2) when C is equal to the *fixed point set* $\mathrm{Fix}(T) := \{x \in H : T(x) = x\}$ of a *nonexpansive* mapping T [2, 3, 15, 16, 32, 37, 38] has been established: $x_1 \in H$ and

$$x_{n+1} = T(x_n - \mu \alpha_n \nabla f(x_n)) \text{ for every } n \in \mathbb{N}, \tag{1.3}$$

where $\mu > 0$, $(\alpha_n)_{n \in \mathbb{N}} \subset (0, 1]$ is a slowly diminishing constant sequence, and $\nabla f\colon H \to H$ is *strongly monotone* and *Lipschitz continuous* (see section 2). By the nonexpansivity of P_C, the method (1.3) is the same as the projected gradient method when

$T := P_C$ and $\alpha_n := 1$ $(n \in \mathbb{N})$. The projected gradient and hybrid steepest descent methods converge strongly to the uniquely existing solution of (1.2) when $C = \mathrm{Fix}(T)$ [42, 43, 44]. Recently, the method (1.3) has been applied successfully to signal processing, inverse problems, and so on [34, 35, 44]. Other algorithms for solving the problem (1.2) have been proposed in [5] and [22]. In [5], an effective scheme for solving the signal recovery problem has been proposed, and this method converges strongly to the solution without using a diminishing constant sequence. In [22], the problem which contains (1.2) and an iterative algorithm for this problem have been presented.

In the case where $C = H = \mathbb{R}^N$, iterative procedures for (1.1) [1, 6, 7, 8, 11, 12, 13, 14, 19, 20, 21, 25, 26, 27, 28, 29, 30, 31, 39, 40, 46] have a long history and have been studied extensively, for example, the *Newton method*, the *quasi-Newton methods*, the *steepest descent method*, and the *conjugate gradient methods*. These have the common form

$$x_{n+1} = x_n + \alpha_n d_n, \tag{1.4}$$

where $x_n \in \mathbb{R}^N$ is the nth approximation to the solution, $\alpha_n > 0$ is a step size, and $d_n \in \mathbb{R}^N$ is a search direction. The Newton method and the quasi-Newton methods are known as fast convergent iterative methods for solving (1.1) when $C = \mathbb{R}^N$. To compute the search direction, the Newton method requires us to solve the Newton equation $\nabla^2 f(x_n) d_n = -\nabla f(x_n)$ $(n \in \mathbb{N})$, that is, to invert the Hessian $\nabla^2 f(x_n)$. If $\nabla^2 f(x_n)$ is positive definite, then the solution d_n of this equation satisfies the descent condition, that is, $\langle d_n, \nabla f(x_n)\rangle < 0$ $(n \in \mathbb{N})$. Even when the objective function f does not have its positive definite Hessian, $\nabla^2 f(x_n)$ or $\nabla^2 f(x_n)^{-1}$ is often replaced by a simpler, positive definite matrix to define a simpler search direction. Such a method is called the quasi-Newton method. In particular, the Davidon–Fletcher–Powell and Broyden–Fletcher–Goldfarb–Shanno methods have been used as effective algorithms for solving (1.1) when $C = \mathbb{R}^N$. The steepest descent method does not need any matrix inversion because this method always utilizes the steepest descent direction $d_n = -\nabla f(x_n)$ $(n \in \mathbb{N})$. Acceleration of the steepest descent method has been of great interest. Much research along this direction covers, for example, the conjugate gradient methods [1, 7, 8, 13, 14, 19, 29, 30, 31, 46], the *three-term-recurrence method* [27], and the *memory gradient methods* [6, 25, 26]. In particular, the conjugate gradient methods have been used widely as an efficient accelerated version of the most gradient methods. We define the conjugate gradient direction as follows:

$$d_n = -\nabla f(x_n) + \beta_n d_{n-1}, \tag{1.5}$$

where $\beta_n \in \mathbb{R}$. Many design schemes for β_n have been developed, for example, the Fletcher–Reeves formula $\beta_n^{\mathrm{FR}} = \|\nabla f(x_n)\|^2/\|\nabla f(x_{n-1})\|^2$ [13, 1, 7, 14], the Polak–Ribière–Polyak formula $\beta_n^{\mathrm{PRP}} = \langle \nabla f(x_n), y_{n-1}\rangle/\|\nabla f(x_{n-1})\|^2$ [29, 30, 14], the Hestenes–Stiefel formula $\beta_n^{\mathrm{HS}} = \langle \nabla f(x_n), y_{n-1}\rangle/\langle d_{n-1}, y_{n-1}\rangle$ [19, 14], and the Dai–Yuan formula $\beta_n^{\mathrm{DY}} = \|\nabla f(x_n)\|^2/\langle d_{n-1}, y_{n-1}\rangle$ [8], where $y_n := \nabla f(x_{n+1}) - \nabla f(x_n)$. The FR method [1, 7, 14] and the DY method [8] determine β_n in such a way that the descent condition is satisfied.

The goal of this paper is to accelerate the hybrid steepest descent method (1.3). To achieve this goal, we present a new iterative scheme (Algorithm 3.4) by combining two ideas: One is the hybrid steepest descent method (1.3) for the variational inequality problem over the fixed point set of a nonexpansive mapping, and the other is the conjugate gradient method (1.4) and (1.5) for the unconstrained optimization problem.

The rest of this paper is divided into four sections. In section 2, we state preliminaries on fixed points, nonexpansive mapping, metric projection, convexity, continuity, and monotone operator. In section 3, we propose an iterative algorithm (Algorithm 3.4) that utilizes a new search direction. In section 4, we apply our method to the convex optimization problem and present convergence analysis (Theorem 4.1) under some assumptions. In section 5, to demonstrate the effectiveness, performance, and convergence of the proposed algorithm, we present numerical comparisons of the algorithm with the hybrid steepest descent method (1.3).

2. Preliminaries.

2.1. Convexity and monotonicity. A function $f\colon H \to \mathbb{R}$ is said to be *convex* if for any $x, y \in H$ and for any $\lambda \in [0,1]$, $f(\lambda x + (1-\lambda)y) \le \lambda f(x) + (1-\lambda)f(y)$. In particular, a convex function $f\colon H \to \mathbb{R}$ is said to be *strongly convex* with $\alpha > 0$ (α-strongly convex) if $f(\lambda x + (1-\lambda)y) \le \lambda f(x) + (1-\lambda)f(y) - (\alpha\lambda(1-\lambda)/2)\|x-y\|^2$ for all $x, y \in H$ and for all $\lambda \in [0,1]$. For example, $f(x) := (1/2)\langle x, Q(x)\rangle + \langle b, x\rangle$ ($x \in H$) is α-strongly convex, where $b \in H$ and $Q\colon H \to H$ is a self-adjoint, bounded, linear operator satisfying $\langle x, Q(x)\rangle \ge \alpha\|x\|^2$ for some $\alpha > 0$ and for all $x \in H$ (for details, see Example 3.2 of this paper). In particular, if Q is the identity mapping on H, then f is 1-strongly convex.

An operator $A\colon H \to H$ is said to be *monotone* if $\langle x-y, A(x)-A(y)\rangle \ge 0$ for all $x, y \in H$. $A\colon H \to H$ is called an *α-strongly monotone* operator if $\langle x-y, A(x)-A(y)\rangle \ge \alpha\|x-y\|^2$ for all $x, y \in H$.

Suppose that $f\colon H \to \mathbb{R}$ is a continuously Fréchet differentiable function. Then f is convex if and only if the gradient ∇f is monotone [4, 20, 21]. It is also known [20, 21] that f is α-strongly convex if and only if ∇f is α-strongly monotone. Let $f\colon \mathbb{R}^N \to \mathbb{R}$ be a twice continuously differentiable function. Then f is convex if and only if, for all $x \in \mathbb{R}^N$, the Hessian $\nabla^2 f(x)$ is positive semidefinite on $\mathbb{R}^N$ [4, 20, 21]. It is also known [11, 20, 21] that f is α-strongly convex if and only if, for all $x \in \mathbb{R}^N$, the matrix $\nabla^2 f(x) - \alpha E$ is positive semidefinite, that is, $\langle y, \nabla^2 f(x)(y)\rangle \ge \alpha\|y\|^2$ for all $y \in \mathbb{R}^N$.

2.2. Nonexpansive mapping and fixed point. A mapping $T\colon H \to H$ is said to be *Lipschitz continuous* with $L > 0$ (L-Lipschitz continuous) if $\|T(x) - T(y)\| \le L\|x-y\|$ for all $x, y \in H$. When $T\colon H \to H$ is 1-Lipschitz continuous, T is said to be *nonexpansive*. It is well known that the *fixed point set* $\mathrm{Fix}(T) := \{x \in H\colon T(x) = x\}$ of a nonexpansive mapping T is closed and convex [2, 16, 38]. $T\colon H \to H$ is called a *firmly nonexpansive* mapping if for all $x, y \in H$, $\|T(x)-T(y)\|^2 \le \langle x-y, T(x)-T(y)\rangle$. Given a nonempty, closed convex subset C of H, the mapping that assigns every point $x \in H$ to its unique nearest point in C is called the *metric projection* onto C and is denoted by P_C, that is, $\|x - P_C(x)\| = \inf_{y\in C}\|x-y\|$. The metric projection P_C is a typical example of firmly nonexpansive mapping satisfying $\mathrm{Fix}(P_C) = C$. Some closed convex set C, for example, a linear variety, a closed ball, a closed cone, and a closed polytope, is simple in the sense that the closed form expression of P_C is known, which implies that P_C can be computed within a finite number of arithmetic operations [2, 9, 41].

To prove the main theorem of this paper, we need the following lemma.

LEMMA 2.1 (see [42, 44]). *Let $T\colon H \to H$ be a nonexpansive mapping and $f\colon H \to \mathbb{R}$ a continuously Fréchet differentiable function. Suppose that $\nabla f\colon H \to H$ is α-strongly monotone and L-Lipschitz continuous and $\mu \in (0, 2\alpha/L^2)$. Define $T^\lambda(x) :=$*

$T(x - \mu\lambda\nabla f(x))$ for all $x \in H$, where $\lambda \in [0,1]$. Then for all $x, y \in H$,

$$\|T^{\lambda}(x) - T^{\lambda}(y)\| \leq (1 - \lambda\tau)\|x - y\|,$$

where $\tau := 1 - \sqrt{1 - \mu(2\alpha - \mu L^2)} \in (0, 1]$.

3. Optimization over the fixed point set of a nonexpansive mapping. In this paper, we consider the following constrained optimization problem.

PROBLEM 3.1. *Assume that*

(A1) *$T\colon H \to H$ is a nonexpansive mapping with $\mathrm{Fix}(T) \neq \emptyset$;*

(A2) *$f\colon H \to \mathbb{R}$ is continuously Fréchet differentiable;*

(A3) *$\nabla f\colon H \to H$ is α-strongly monotone and L-Lipschitz continuous.*

Our objective is to

$$\text{find a point } x^* \in \mathrm{Fix}(T) \text{ such that } f(x^*) = \min_{x \in \mathrm{Fix}(T)} f(x).$$

Note that under the assumptions (A1), (A2), and (A3), the existence and the uniqueness of the minimizer $x^* \in \mathrm{Fix}(T)$ of f over $\mathrm{Fix}(T)$ is guaranteed [42]. A well-known example of a convex function satisfying the assumptions (A2) and (A3) is the following.

Example 3.2 (see [42]). Let $b \in H$ and $Q\colon H \to H$ be a self-adjoint, bounded, linear operator and strongly positive; that is, there exists $\alpha > 0$ such that $\langle x, Q(x)\rangle \geq \alpha\|x\|^2$ for all $x \in H$. Define a quadratic function $f\colon H \to \mathbb{R}$ by

$$f(x) := \frac{1}{2}\langle x, Q(x)\rangle + \langle b, x\rangle \text{ for all } x \in H.$$

Then $\nabla f(\cdot) = Q(\cdot) + b$ is α-strongly monotone and $\|Q\|$-Lipschitz continuous, where $\|Q\| := \sup_{x \neq 0} |\langle x, Q(x)\rangle| \|x\|^{-2}$.

Remark 3.3. When H is finite dimensional, the above operator Q coincides with a positive definite matrix. Then, for all $x \in \mathbb{R}^N$, $\nabla^2 f(x) = Q$ and $\lambda_{\min}\|x\|^2 \leq \langle x, Q(x)\rangle \leq \lambda_{\max}\|x\|^2$, where $\lambda_{\min}$ and $\lambda_{\max}$ are, respectively, the minimum and maximum eigenvalues of Q. Hence $\alpha = \lambda_{\min} \leq \lambda_{\max} = \|Q\|$.

For Problem 3.1, we present an algorithm using a conjugate gradient direction.

ALGORITHM 3.4. *Let $f\colon H \to \mathbb{R}$ and $T\colon H \to H$ satisfy the conditions* (A1), (A2), *and* (A3) *in Problem* 3.1.

Step 0. *Take $\mu > 0$. Choose $x_1 \in H$ and $\alpha_1 \in (0, 1]$ arbitrarily, and set $d_1 := -\nabla f(x_1)$ and $n := 1$.*

Step 1. *Given $x_n \in H$ and $d_n \in H$, choose $\alpha_n \in (0, 1]$ (see Theorem* 4.1*) and define $x_{n+1} \in H$ by*

$$x_{n+1} := T(x_n + \mu\alpha_n d_n). \tag{3.1}$$

Step 2. *Choose $\beta_{n+1} \in [0, \infty)$ (see Theorem* 4.1*), and update the search direction as*

$$d_{n+1} := -\nabla f(x_{n+1}) + \beta_{n+1} d_n. \tag{3.2}$$

Put $n := n + 1$, and go to Step 1.

In the case where T is the identity mapping on H and $\mu := 1$, Algorithm 3.4 coincides with the conjugate gradient method for the unconstrained optimization problem. By (3.1) and (3.2), we can see that the search direction d_n is defined by combining the ideas of the hybrid steepest descent method (1.3) and the conjugate gradient method (1.5).

4. Convergence theorem for the iterative algorithm. We present convergence analysis on Algorithm 3.4.

THEOREM 4.1. *Suppose that* $\mu \in (0, 2\alpha/L^2)$, *and* $(\alpha_n)_{n\in\mathbb{N}} \subset (0,1]$ *and* $(\beta_n)_{n\geq 2} \subset [0,\infty)$ *satisfy* (i) $\lim_{n\to\infty} \alpha_n = 0$, (ii) $\sum_{n=1}^{\infty} \alpha_n = \infty$, (iii) $\sum_{n=1}^{\infty} |\alpha_{n+1} - \alpha_n| < \infty$, (iv) $\alpha_n/\alpha_{n+1} \leq \sigma$ *for some* $\sigma \geq 1$ *and for every* $n \in \mathbb{N}$, *and* (v) $\lim_{n\to\infty} \beta_n = 0$ (an example of satisfying (i)–(v) is $\alpha_n := 1/(n+1)^{\rho}$ and $\beta_{n+1} := 1/(n+1)^{\gamma}$ $(n \in \mathbb{N}, \rho \in (0,1]$, and $\gamma > 0)$). *If* $(\nabla f(x_n))_{n\in\mathbb{N}}$ *is bounded, the sequence* $(x_n)_{n\in\mathbb{N}}$ *generated by Algorithm* 3.4 *satisfies the following:*

(a) $(x_n)_{n\in\mathbb{N}}$ *and* $(d_n)_{n\in\mathbb{N}}$ *are bounded. Moreover,* $\lim_{n\to\infty} \|x_{n+1} - T(x_n)\| = 0$.
(b) $\lim_{n\to\infty} \|x_{n+1} - x_n\| = 0$ *and* $\lim_{n\to\infty} \|x_n - T(x_n)\| = 0$.
(c) *The sequence* $(x_n)_{n\in\mathbb{N}}$ *converges strongly to the uniquely existing solution of Problem* 3.1.

Proof. (a) We shall prove that $(d_n)_{n\in\mathbb{N}}$ in Algorithm 3.4 is bounded. By the condition (v), there exists $m_1 \in \mathbb{N}$ such that $\beta_n \leq 1/2$ for all $n \geq m_1$. Put $K_1 := \sup\{\|\nabla f(x_n)\| : n \in \mathbb{N}\} < \infty$ and $K_2 := \max\{K_1, \|d_{m_1}\|\}$. It is obvious from the definition of K_2 that $\|d_{m_1}\| \leq 2K_2$. From (3.2), we have

$$\|d_{n+1}\| \leq \|\nabla f(x_{n+1})\| + \beta_{n+1}\|d_n\| \leq K_2 + \frac{1}{2}\|d_n\| \tag{4.1}$$

for all $n \geq m_1$. Suppose that $\|d_n\| \leq 2K_2$ for some $n \geq m_1$. Then, by (4.1), we get $\|d_{n+1}\| \leq 2K_2$. By induction, we obtain $\|d_n\| \leq 2K_2$ for all $n \geq m_1$, and hence $(d_n)_{n\in\mathbb{N}}$ is bounded.

Let $x^* \in \mathrm{Fix}(T)$ be the solution of Problem 3.1, and let $\tau \in (0,1]$ be as in Lemma 2.1. Put $K_3 := \sup\{\|\beta_{n+1}d_n - \nabla f(x^*)\| : n \in \mathbb{N}\} < \infty$ and $K := \max\{\|\nabla f(x^*)\|, K_3\}$. Then, by Lemma 2.1, for every $n \geq 2$, we have

$$\begin{aligned}
\|x_{n+1} - x^*\| &= \|T(x_n + \mu\alpha_n d_n) - T(x^*)\| \\
&\leq \|(x_n + \mu\alpha_n(-\nabla f(x_n) + \beta_n d_{n-1})) - x^*\| \\
&= \|(x_n - \mu\alpha_n\nabla f(x_n)) - (x^* - \mu\alpha_n\nabla f(x^*)) \\
&\qquad + \mu\alpha_n(\beta_n d_{n-1} - \nabla f(x^*))\| \\
&\leq \|(x_n - \mu\alpha_n\nabla f(x_n)) - (x^* - \mu\alpha_n\nabla f(x^*))\| \\
&\qquad + \mu\alpha_n\|\beta_n d_{n-1} - \nabla f(x^*)\| \\
&\leq (1 - \tau\alpha_n)\|x_n - x^*\| + \left(\frac{\mu K}{\tau}\right)\tau\alpha_n.
\end{aligned}$$

By $x_2 = T(x_1 - \mu\alpha_1\nabla f(x_1))$ and the definition of K, the inequality above holds for $n = 1$. Therefore, by induction, we obtain

$$\|x_n - x^*\| \leq \max\left\{\|x_1 - x^*\|, \frac{\mu K}{\tau}\right\} \text{ for every } n \in \mathbb{N};$$

that is, $(x_n)_{n\in\mathbb{N}}$ is bounded.

By (3.1) and the nonexpansivity of T, we have $\limsup_{n\to\infty} \|x_{n+1} - T(x_n)\| \leq \mu \limsup_{n\to\infty} \alpha_n\|d_n\|$. The condition (i) and the boundedness of $(d_n)_{n\in\mathbb{N}}$ imply

$$\lim_{n\to\infty} \|x_{n+1} - T(x_n)\| = 0. \tag{4.2}$$

(b) We shall prove $\lim_{n\to\infty} \|x_{n+1} - x_n\| = 0$. Put $z_n := x_n + \mu\alpha_n d_n$ $(n \in \mathbb{N})$, $M_1 := \sup\{|\langle z_n - z_{n-1}, \nabla f(x_{n-1})\rangle| : n \geq 2\} < \infty$, $M_2 := \sup\{|\langle z_n - z_{n-1}, d_{n-1}\rangle|/\tau :$

$n \geq 2\} < \infty$, $M_3 := \sup\{\sigma|\langle z_n - z_{n-1}, d_{n-2}\rangle|/\tau : n \geq 3\} < \infty$, and $M := \max\{M_1, M_2, M_3\}$. It follows from (3.1), (3.2), Lemma 2.1, the nonexpansivity of T, and the condition (iv) that

$$\begin{aligned}
\|x_{n+1} - x_n\|^2 &= \|T(x_n + \mu\alpha_n d_n) - T(x_{n-1} + \mu\alpha_{n-1}d_{n-1})\|^2 \\
&\leq \|(x_n + \mu\alpha_n d_n) - (x_{n-1} + \mu\alpha_{n-1}d_{n-1})\|^2 \\
&= \|(x_n + \mu\alpha_n(-\nabla f(x_n) + \beta_n d_{n-1})) \\
&\qquad - (x_{n-1} - \mu\alpha_n\nabla f(x_{n-1})) - \mu\alpha_n\nabla f(x_{n-1}) - \mu\alpha_{n-1}d_{n-1}\|^2 \\
&= \|(x_n - \mu\alpha_n\nabla f(x_n)) - (x_{n-1} - \mu\alpha_n\nabla f(x_{n-1})) \\
&\qquad + \mu(\alpha_n\beta_n d_{n-1} - \alpha_n\nabla f(x_{n-1}) - \alpha_{n-1}d_{n-1})\|^2 \\
&\leq \|(x_n - \mu\alpha_n\nabla f(x_n)) - (x_{n-1} - \mu\alpha_n\nabla f(x_{n-1}))\|^2 \\
&\qquad + 2\mu\langle\alpha_n\beta_n d_{n-1} - \alpha_n\nabla f(x_{n-1}) - \alpha_{n-1}d_{n-1}, z_n - z_{n-1}\rangle \\
&\leq (1 - \tau\alpha_n)^2\|x_n - x_{n-1}\|^2 + 2\mu\langle\alpha_n\beta_n d_{n-1} - \alpha_n\nabla f(x_{n-1}) \\
&\qquad - \alpha_{n-1}(-\nabla f(x_{n-1}) + \beta_{n-1}d_{n-2}), z_n - z_{n-1}\rangle \\
&\leq (1 - \tau\alpha_n)\|x_n - x_{n-1}\|^2 + 2\mu(\alpha_{n-1} - \alpha_n)\langle z_n - z_{n-1}, \nabla f(x_{n-1})\rangle \\
&\qquad + 2\mu\alpha_n\beta_n\langle z_n - z_{n-1}, d_{n-1}\rangle + 2\mu\alpha_{n-1}\beta_{n-1}\langle z_n - z_{n-1}, -d_{n-2}\rangle \\
&\leq (1 - \tau\alpha_n)\|x_n - x_{n-1}\|^2 + 2\mu M|\alpha_{n-1} - \alpha_n| \\
&\qquad + 2\mu M\tau\alpha_n\beta_n + 2\mu M\tau\frac{\alpha_{n-1}}{\sigma}\beta_{n-1} \\
&\leq (1 - \tau\alpha_n)\|x_n - x_{n-1}\|^2 + 2\mu M|\alpha_{n-1} - \alpha_n| \\
&\qquad + 2\mu M\tau\alpha_n\beta_n + 2\mu M\tau\alpha_n\beta_{n-1}
\end{aligned}$$

for every $n \geq 3$. By the condition (v), for any $\varepsilon > 0$, there exists $n_1 \in \mathbb{N}$ such that $\beta_n \leq \varepsilon/4$ for all $n \geq n_1$. For all $n \geq n_1 + 1$, we have

$$\begin{aligned}
\|x_{n+1} - x_n\|^2 \leq (1 - \tau\alpha_n)\|x_n - x_{n-1}\|^2 &+ 2\mu M|\alpha_{n-1} - \alpha_n| \\
&+ \mu M\varepsilon(1 - (1 - \tau\alpha_n)).
\end{aligned}$$

So, we obtain that for all $n, m \geq n_1$,

$$\begin{aligned}
\|x_{n+m+1} - x_{n+m}\|^2 &\leq (1 - \tau\alpha_{n+m})\|x_{n+m} - x_{n+m-1}\|^2 + 2\mu M|\alpha_{n+m} - \alpha_{n+m-1}| \\
&\qquad + \mu M\varepsilon(1 - (1 - \tau\alpha_{n+m})) \\
&\leq (1 - \tau\alpha_{n+m})\{(1 - \tau\alpha_{n+m-1})\|x_{n+m-1} - x_{n+m-2}\|^2 \\
&\qquad + 2\mu M|\alpha_{n+m-1} - \alpha_{n+m-2}| + \mu M\varepsilon(1 - (1 - \tau\alpha_{n+m-1}))\} \\
&\qquad + 2\mu M|\alpha_{n+m} - \alpha_{n+m-1}| + \mu M\varepsilon(1 - (1 - \tau\alpha_{n+m})) \\
&\leq (1 - \tau\alpha_{n+m})(1 - \tau\alpha_{n+m-1})\|x_{n+m-1} - x_{n+m-2}\|^2 \\
&\qquad + 2\mu M(|\alpha_{n+m} - \alpha_{n+m-1}| + |\alpha_{n+m-1} - \alpha_{n+m-2}|) \\
&\qquad + \mu M\varepsilon\{1 - (1 - \tau\alpha_{n+m})(1 - \tau\alpha_{n+m-1})\} \\
&\leq \prod_{k=m}^{n+m-1}(1 - \tau\alpha_{k+1})\|x_{m+1} - x_m\|^2 + 2\mu M\sum_{k=m}^{n+m-1}|\alpha_{k+1} - \alpha_k| \\
&\qquad + \mu M\varepsilon\left(1 - \prod_{k=m}^{n+m-1}(1 - \tau\alpha_{k+1})\right).
\end{aligned}$$

Since the condition (ii) implies $\prod_{k=m}^{\infty}(1-\tau\alpha_{k+1})=0$, we have

$$\begin{aligned}\limsup_{n\to\infty}\|x_{n+1}-x_n\|^2 &= \limsup_{n\to\infty}\|x_{n+m+1}-x_{n+m}\|^2\\ &\le 2\mu M\limsup_{n\to\infty}\sum_{k=m}^{n+m-1}|\alpha_{k+1}-\alpha_k|+\mu M\varepsilon\end{aligned}$$

for every $m\ge n_1$. From the condition (iii), we obtain $\limsup_{n\to\infty}\|x_{n+1}-x_n\|^2\le \mu M\varepsilon$ for arbitrarily small $\varepsilon>0$, and hence

$$\lim_{n\to\infty}\|x_{n+1}-x_n\|=0. \tag{4.3}$$

Now, by (4.2) and (4.3), we have

$$\lim_{n\to\infty}\|x_n-T(x_n)\|=0. \tag{4.4}$$

(c) The first step is to show $\limsup_{n\to\infty}\langle x^*-x_n,\nabla f(x^*)\rangle\le 0$. Choose a subsequence $(x_{n_i})_{i\in\mathbb{N}}$ of $(x_n)_{n\in\mathbb{N}}$ such that

$$\limsup_{n\to\infty}\langle x^*-x_n,\nabla f(x^*)\rangle=\lim_{i\to\infty}\langle x^*-x_{n_i},\nabla f(x^*)\rangle.$$

Boundedness of $(x_{n_i})_{i\in\mathbb{N}}$ implies the existences of a subsequence $(x_{n_{i_j}})_{j\in\mathbb{N}}$ of $(x_{n_i})_{i\in\mathbb{N}}$ and a point $\hat{x}\in H$ such that $\lim_{j\to\infty}\langle x_{n_{i_j}},w\rangle=\langle\hat{x},w\rangle$ $(w\in H)$. We may assume without loss of generality that $\lim_{i\to\infty}\langle x_{n_i},w\rangle=\langle\hat{x},w\rangle$ $(w\in H)$. Assume $\hat{x}\ne T(\hat{x})$. By (4.4) and the nonexpansivity of T, we have a contradiction:

$$\begin{aligned}\liminf_{i\to\infty}\|x_{n_i}-\hat{x}\| &< \liminf_{i\to\infty}\|x_{n_i}-T(\hat{x})\| = \liminf_{i\to\infty}\|x_{n_i}-T(x_{n_i})+T(x_{n_i})-T(\hat{x})\|\\ &= \liminf_{i\to\infty}\|T(x_{n_i})-T(\hat{x})\|\le\liminf_{i\to\infty}\|x_{n_i}-\hat{x}\|.\end{aligned}$$

This implies $\hat{x}\in\mathrm{Fix}(T)$. Since $x^*\in\mathrm{Fix}(T)$ satisfies $\langle v-x^*,\nabla f(x^*)\rangle\ge 0$ $(v\in\mathrm{Fix}(T))$, we get

$$\begin{aligned}\limsup_{n\to\infty}\langle x^*-x_n,\nabla f(x^*)\rangle &= \lim_{i\to\infty}\langle x^*-x_{n_i},\nabla f(x^*)\rangle\\ &= \langle x^*-\hat{x},\nabla f(x^*)\rangle\le 0.\end{aligned}$$

Moreover, by the condition (v) and the boundedness of $(z_n)_{n\in\mathbb{N}}$ and $(d_n)_{n\in\mathbb{N}}$, we have

$$\limsup_{n\to\infty}\beta_n\langle z_n-x^*,d_{n-1}\rangle\le\limsup_{n\to\infty}\beta_n\|z_n-x^*\|\|d_{n-1}\|\le 0.$$

These facts and the condition (i) guarantee that, for any $\varepsilon>0$, there exists $m_0\in\mathbb{N}$ such that

$$\frac{\mu^2\alpha_n}{\tau}\langle d_n,-\nabla f(x^*)\rangle\le\frac{\varepsilon}{6},\ \frac{\mu}{\tau}\langle x^*-x_n,\nabla f(x^*)\rangle\le\frac{\varepsilon}{6}\ \text{and}\ \frac{\mu\beta_n}{\tau}\langle z_n-x^*,d_{n-1}\rangle\le\frac{\varepsilon}{6} \tag{4.5}$$

for all $n\ge m_0$.

Finally, we shall prove that $(x_n)_{n\in\mathbb{N}}$ converges strongly to the solution x^*. It holds from (3.1), (3.2), the nonexpansivity of T, and Lemma 2.1 that

$$\begin{aligned}
\|x_{n+1}-x^*\|^2 &= \|T(x_n+\mu\alpha_n d_n)-T(x^*)\|^2\\
&\le \|x_n+\mu\alpha_n(-\nabla f(x_n)+\beta_n d_{n-1})-x^*\|^2\\
&= \|(x_n-\mu\alpha_n\nabla f(x_n))-(x^*-\mu\alpha_n\nabla f(x^*))\\
&\qquad +\mu\alpha_n\beta_n d_{n-1}-\mu\alpha_n\nabla f(x^*)\|^2\\
&\le \|(x_n-\mu\alpha_n\nabla f(x_n))-(x^*-\mu\alpha_n\nabla f(x^*))\|^2\\
&\qquad +2\alpha_n\langle (x_n+\mu\alpha_n d_n)-x^*, \mu\beta_n d_{n-1}-\mu\nabla f(x^*)\rangle\\
&\le (1-\tau\alpha_n)\|x_n-x^*\|^2+2\tau\alpha_n\left\{\frac{\mu\beta_n}{\tau}\langle z_n-x^*, d_{n-1}\rangle\right.\\
&\qquad \left.+\frac{\mu}{\tau}\langle x^*-x_n,\nabla f(x^*)\rangle+\frac{\mu^2\alpha_n}{\tau}\langle d_n,-\nabla f(x^*)\rangle\right\}
\end{aligned}$$

for every $n\ge 2$. So, by (4.5), we have

$$\|x_{n+1}-x^*\|^2\le(1-\tau\alpha_n)\|x_n-x^*\|^2+\varepsilon\tau\alpha_n$$

for all $n\ge m_0$. By induction, we get

$$\|x_{n+1}-x^*\|^2\le\prod_{k=m_0}^{n}(1-\tau\alpha_k)\|x_{m_0}-x^*\|^2+\varepsilon\left(1-\prod_{k=m_0}^{n}(1-\tau\alpha_k)\right)$$

for all $n\ge m_0$. Thus, it follows from the condition (ii) that

$$\limsup_{n\to\infty}\|x_{n+1}-x^*\|^2\le\varepsilon.$$

Since $\varepsilon>0$ is arbitrary, we obtain $\limsup_{n\to\infty}\|x_{n+1}-x^*\|^2\le 0$ and hence $\lim_{n\to\infty}\|x_{n+1}-x^*\|^2=0$. This implies that the sequence $(x_n)_{n\in\mathbb{N}}$ converges strongly to the uniquely existing solution x^*. □

Remark 4.2. In convergence analysis [1, 7, 8, 14, 31, 46] for the conjugate gradient methods for unconstrained optimization problems, it is commonly assumed that the step size α_n satisfies the following well-known *Wolfe conditions* [39, 40]: $f(x_n)-f(x_n+\alpha_n d_n)\ge-\delta_1\alpha_n\langle d_n,\nabla f(x_n)\rangle$, $\langle d_n,\nabla f(x_n+\alpha_n d_n)\rangle\ge\delta_2\langle d_n,\nabla f(x_n)\rangle$, where $0<\delta_1<\delta_2<1$. In Theorem 4.1 on Algorithm 3.4 for Problem 3.1, the conditions (i)–(v) are assumed.

5. Numerical examples. In order to demonstrate the effectiveness, performance, and convergence of Algorithm 3.4, we first discuss Problem 3.1 for Example 3.2, where $Q\in\mathbb{R}^{64\times 64}$ is a positive definite matrix which is given in [18] and $b:=(-1,-2,\dots,-64)^T\in\mathbb{R}^{64}$.

PROBLEM 5.1. *Consider the following optimization problem:*

$$\textit{minimize } f(x):=\frac{1}{2}\langle x,Q(x)\rangle+\langle b,x\rangle \textit{ subject to } x\in C:=C_1\cap C_2,$$

where $C_1:=\{x\in\mathbb{R}^{64}\colon\|x\|^2\le 1\}$ *and* $C_2:=\{x\in\mathbb{R}^{64}\colon\|x-(1,1,0,\dots,0)^T\|^2\le 1\}$.

The matrix Q has $\lambda_{\min}\approx 8.5539\times 10^{-2}$ and $\lambda_{\max}\approx 9.9251\times 10$. The global minimizer $-Q^{-1}(b)\approx(24.4697,-23.8379,\dots,620.9782)^T\in\mathbb{R}^{64}$ of f is not in C, and

the exact solution of Problem 5.1 cannot be described because of the definitions of Q [18] and $C := C_1 \cap C_2$. We use $x_1 := (-0.5, -0.5, \ldots, -0.5)^T \in \mathbb{R}^{64}$, $\alpha_n := 1/\sqrt{n+1}$, and $\beta_{n+1} := 1/(n+1)^a$ $(n \in \mathbb{N},\ a > 0)$. From the definition of C_i $(i = 1, 2)$, we note that the exact computation of $P_{C_1 \cap C_2}$ is not necessarily easy, while the computations of P_{C_1} and P_{C_2} are tractable. So, we define a mapping $T\colon\ \mathbb{R}^{64} \to \mathbb{R}^{64}$ by $T(x) := (1/2)P_{C_1}(x) + (1/2)P_{C_2}(x)$ for all $x \in \mathbb{R}^{64}$. Then T is a nonexpansive mapping with $\mathrm{Fix}(T) = C := C_1 \cap C_2 \neq \emptyset$ and the computation of T is not hard [42].

Algorithm 3.4 requires us to choose $\mu \in (0, 2\lambda_{\min}/\lambda_{\max}^2)$ by Theorem 4.1. Even if $\mu \geq 2\lambda_{\min}/\lambda_{\max}^2$, by $\alpha_n := 1/\sqrt{n+1}$ $(n \in \mathbb{N})$, there exists $k_1 \in \mathbb{N}$ such that $\mu\alpha_n < 2\lambda_{\min}/\lambda_{\max}^2$ for all $n \geq k_1$. Moreover, Theorem 4.1 guarantees that Algorithm 3.4 with an initial point $x_{k_1} \in \mathbb{R}^{64}$ converges to the solution of Problem 5.1. Since the approximations of $\lambda_{\min}$ and $\lambda_{\max}$ are given, we have $2\lambda_{\min}/\lambda_{\max}^2 \approx 1.7367 \times 10^{-5}$, and hence $\mu := 10^{-5}$. Then the required iterations of Algorithm 3.4 versus the hybrid steepest descent method (HSDM) [42, 43, 44] are presented in Figure 1. Figure 1 shows that the values $\|x_n - T(x_n)\|$ $(n \in \mathbb{N})$ generated by Algorithm 3.4 when $a = 0.1, 0.01, 0.001$ and HSDM converge to 0; that is, the proposed method and HSDM converge to a point in $\mathrm{Fix}(T) = C$. At the same time, it can be observed from Figure 1 that, as compared with HSDM, Algorithm 3.4 succeeds in reducing the value of f, and Algorithm 3.4 has faster convergence than HSDM. It is also seen from Figure 1 that HSDM and Algorithm 3.4 when $a = 0.001$ converge to the same point. When a sequence $(\beta_{n+1})_{n\in\mathbb{N}}$ is a very slowly diminishing constant sequence $(a = 0.01, 0.001)$, Algorithm 3.4 has fast convergence. Figure 2 shows the behavior of $\|x_n - T(x_n)\|$ and $f(x_n)$ $(n = 1, 2, \ldots, 1000)$ for the methods when $\mu := 1$. It is seen from Figure 2 that by a large μ, $f(x_n)$ $(n = 1, 2, \ldots, 10)$ is severely decreasing, and $f(x_n)$ and $\|x_n - T(x_n)\|$ $(n = 11, 12, \ldots, 1000)$ stay about the same. The case when $\mu := 10^{-2}$ is presented in Figure 3. Figure 3 shows that, as compared with Figure 1 $(\mu := 10^{-5})$, HSDM and Algorithm 3.4 when $a = 0.1$ have faster convergence than the methods when $a = 0.01, 0.001$. By the discussions above, if we use $\mu \in (0, 2\lambda_{\min}/\lambda_{\max}^2)$ (see Lemma 2.1 and Theorem 4.1), then Algorithm 3.4 with a small $a > 0$ has fast convergence.

Next, we consider the case where Q is the identity matrix E and $b := (-1, -2, \ldots, -64)^T \in \mathbb{R}^{64}$: Minimize $f(x) := (1/2)\|x\|^2 + \langle b, x\rangle$ subject to $x \in C := C_1 \cap C_2$. In this case, the global minimizer of f is $-b = (1, 2, \ldots, 64)^T \notin C$. We use $\mu := 10^{-3}$ and suppose that $(\alpha_n)_{n\in\mathbb{N}}$ and $(\beta_{n+1})_{n\in\mathbb{N}}$ are the same as in the discussion above. Convergence to the solution in Problem 5.1 and the required iterations of the methods are provided in Figure 4. It can be observed from Figure 4 that HSDM has faster convergence than the proposed algorithm. In particular, for a small $a > 0$, the required iterations are large. In general, a use of the conjugate gradient method for the unconstrained optimization problem is the most effective when the ratio of the minimum and maximum eigenvalues of Q is small. In the case where $Q = E$, that is, the ratio $\lambda_{\min}/\lambda_{\max} = 1$, HSDM is very effective as compared with other methods. From Figure 4, we note that HSDM and Algorithm 3.4 when $a = 0.01$ converge to the same point.

Finally, we discuss the case where Q is a diagonal matrix which has eigenvalues $1, 2, \ldots, 64$ and $b := (0, 0, \ldots, 0)^T \in \mathbb{R}^{64}$ and consider the following: Minimize $f(x) := (1/2)\langle x, Q(x)\rangle$ subject to $x \in C := C_3 \cap C_4$, where $C_3 := \{x \in \mathbb{R}^{64}\colon \|x\|^2 \leq 4\}$ and $C_4 := \{x \in \mathbb{R}^{64}\colon \|x - (2, 0, 0, \ldots, 0)^T\|^2 \leq 1\}$. In this case, $x^* := (1, 0, 0, \ldots, 0)^T \in \{x \in C\colon f(x) = \min_{y\in C} f(y)\}$. Define $T(x) := (1/2)P_{C_3}(x) + (1/2)P_{C_4}(x)$ $(x \in \mathbb{R}^{64})$. We use $\mu := 10^{-4} < 2\lambda_{\min}/\lambda_{\max}^2$ and suppose that $(\alpha_n)_{n\in\mathbb{N}}$ and $(\beta_{n+1})_{n\in\mathbb{N}}$ are the

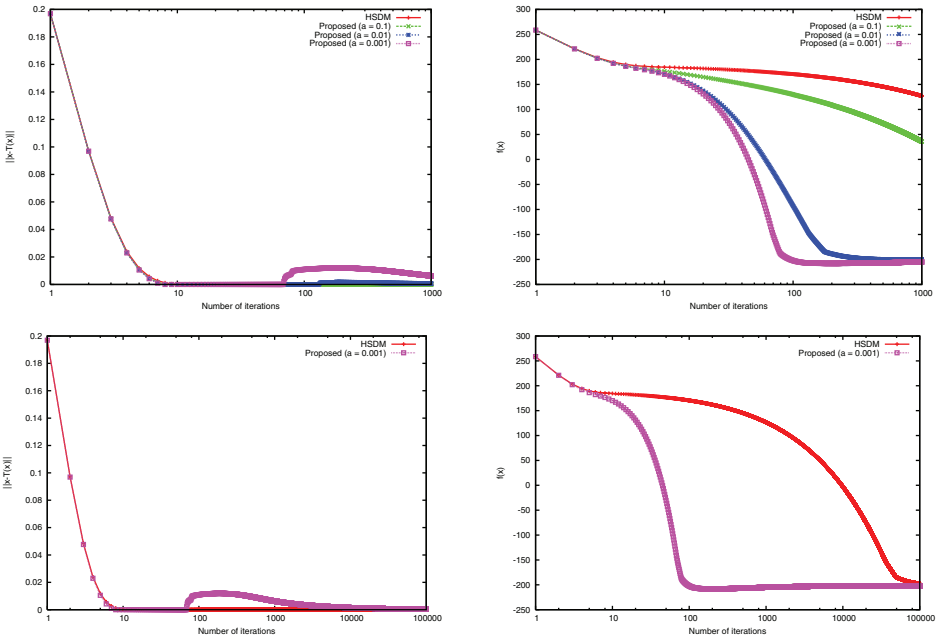

FIG. 1. *Convergence for the methods to the solution when Q is a positive definite matrix which is given in* [18], $\beta_{n+1} := 1/(n+1)^a$ $(a = 0, 1, 0.01, 0.001)$, *and* $\mu := 10^{-5}$.

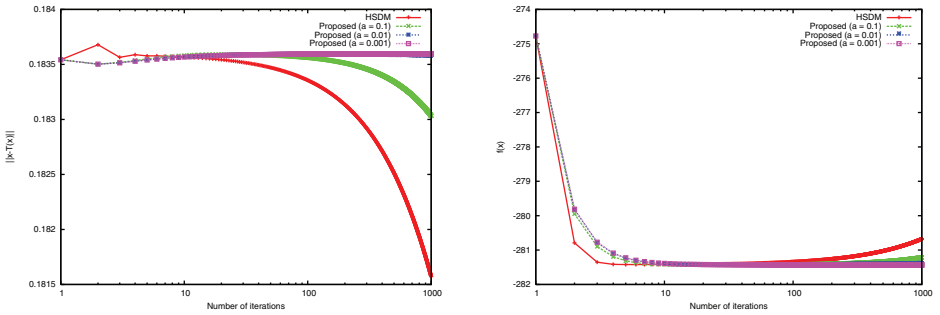

FIG. 2. *Behavior of the methods when Q is a positive definite matrix which is given in* [18], $\beta_{n+1} := 1/(n+1)^a$ $(a = 0, 1, 0.01, 0.001)$, *and* $\mu := 1$.

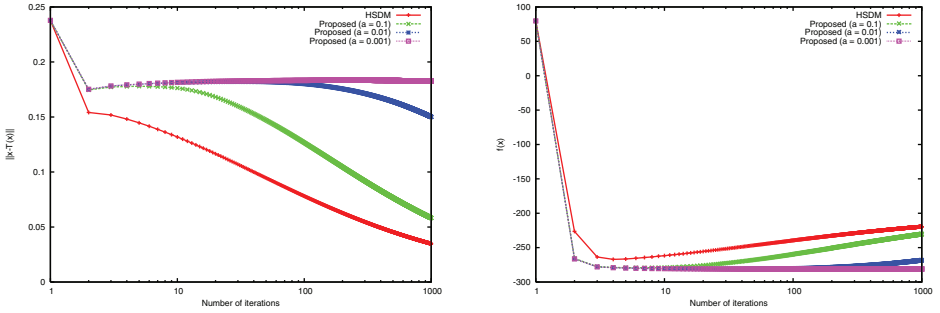

FIG. 3. *Behavior of the methods when Q is a positive definite matrix which is given in* [18], $\beta_{n+1} := 1/(n+1)^a$ $(a = 0, 1, 0.01, 0.001)$, *and* $\mu := 10^{-2}$.

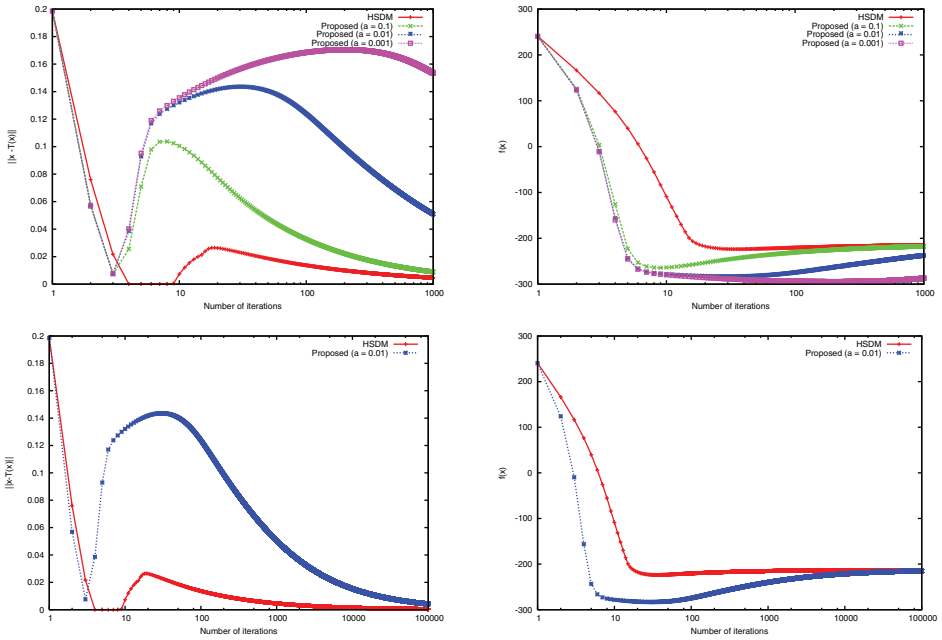

FIG. 4. *Convergence for the methods to the solution when Q is the identity matrix, $\beta_{n+1} := 1/(n+1)^a$ $(a = 0, 1, 0.01, 0.001)$, and $\mu := 10^{-3}$.*

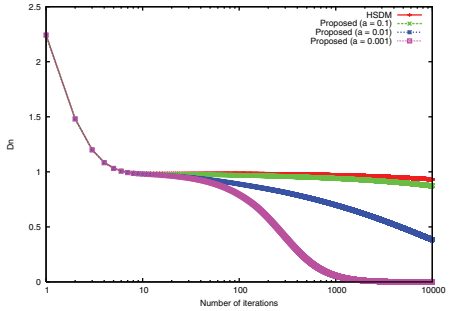

FIG. 5. *Behavior of $D_n := \|x_n - x^*\|^2$ $(n \in \mathbb{N}$, $\{x^*\} = \arg\min_{x \in \mathrm{Fix}(T)} f(x))$ for the methods when Q is a diagonal matrix which has eigenvalues $1, 2, \ldots, 64$, $\beta_{n+1} := 1/(n+1)^a$ $(a = 0, 1, 0.01, 0.001)$, and $\mu := 10^{-4}$.*

same as in the first discussion. The required iterations of the proposed method versus HSDM and the behavior of $D_n := \|x_n - x^*\|^2$ $(n \in \mathbb{N})$ are presented in Figure 5. From Figure 5, our method has faster convergence than HSDM and, in particular, Algorithm 3.4 when $a = 0.001$ succeeds in reducing severely the value D_n $(n \in \mathbb{N})$.

AN INVITATION TO TAME OPTIMIZATION*

A. D. IOFFE†

Abstract. The word "tame" is used in the title in the same context as in expressions like "convex optimization," "nonsmooth optimization," etc.—as a reference to the class of objects involved in the formulation of optimization problems. Definable and tame functions and mappings associated with various o-minimal structures (e.g. semilinear, semialgebraic, globally subanalytic, and others) have a number of remarkable properties which make them an attractive domain for various applications. This relates both to the power of results that can be obtained and the power of available analytic techniques. The paper surveys certain ideas and recent results, some new, which have been or (hopefully) can be productively used in studies relating to variational analysis and nonsmooth optimization.

Key words. variational analysis, optimization, o-minimal structure, definable sets, functions and mappings, critical value, optimal control, semismooth mapping

1. Introduction.

The progress in variational analysis in the last quarter of the 20th century resulted in a complete reshaping of some chapters of analysis and optimization theory. I first of all mean the nonsmooth analysis per se, the theory of nonconvex subdifferentials that extended all rules of differential and convex subdifferential calculus as far as to lower semicontinuous functions and set-valued mappings.

However, it was recognized from the outset that the classes of all lower semicontinuous and even all (locally) Lipschitz functions are often unnecessarily broad and the general theory does not give any answer for which functions and sets one or another result indeed gives useful information. As a most striking example, I shall mention that the limiting subdifferential of a generic Lipschitz function with Lipschitz constant one is identically equal to the unit ball [6], so for a typical Lipschitz function no useful information of its behavior can be obtained from its subdifferential mapping.

Therefore, a search for suitable classes of functions that can be effectively used in one or another context has been one of the leading themes in variational analysis since the very beginning. It is enough to mention semismooth functions [12], prox-regular functions [28], composite and amenable functions [28], etc. More recently, an understanding that sets, functions, and mappings that usually appear in applications have some distinctive structural features which, taken into consideration, may substantially facilitate analysis has been gradually becoming a driving idea. The successful use of convex semialgebraic sets associated with linear matrix inequalities in numerical convex optimization [26] is probably the most impressive demonstration of this trend. Recent concepts of active sets, $\mathcal{U}$-Lagrangians, and some others [24, 22] reviving at a very new technical level an old heuristic idea of the "ravine method" of Gelfand and Zetlin [13] is another important example.

The results presented in the paper suggest that the classes of tame and, especially, definable functions may offer an appropriate domain on which the machinery of variational analysis works with full efficiency. The boundaries of the class have

†Department of Mathematica, Technion, Haifa 32000, Israel (ioffe@math.technion.ac.il).

not been yet fully established, but what is already known shows that it encompasses an enormous variety of functions, sets, and mappings. Functions of this class are uniquely defined by their subdifferential mappings (up to an additive constant for each connected component of the graph). In a nutshell they can be characterized as "pathology free" objects. The meaning of this expression will be gradually clarified in the course of our discussions. We shall just give here a few illuminating examples.

A tame function need not be continuous. But the discontinuities it may have can only be of the "first" type with unilateral limits (perhaps infinite) along tame bounded curves always existing. A tame set need not be a manifold, but it can always be decomposed into a locally finite collection of manifolds which fit each other in a nice way. A tame set-valued mapping has tame selections without any additional topological assumptions. And, what is especially valuable—the class is closed with respect to practically all operations used in variational analysis: Boolean, topological, linear, structural, and most analytical (as composition or differentiation of mappings), including, e.g., partial minimization—a feature especially important for optimization. Finally, elements of the class have distinctive and recognizable structural properties which tremendously facilitate working with them.

Definable and tame sets, functions, and mappings are a product of model theory and algebraic geometry; they are the main concepts of the theory of so-called "o-minimal structures" that has been actively developing during last 20–25 years [8, 10]. Many results of the theory cannot be proved by means of analysis. This, however, is not a real obstacle for using them which is often (if not typically) simple and extremely convenient. The paper is a sort of a survey of some very recent results relating to optimization theory and heavily relying on o-minimality. However, it also contains some new results and proofs.

To the best of my knowledge, the first study in which o-minimality was directly applied to optimization is the 2002 paper by Graña Drammond and Peterzil [14]. They showed that under certain assumptions (of which analyticity of the data was the key, opening the possibility to apply o-minimality) central path trajectories in problems of semidefinite programming converge. We shall briefly describe their result in the next section in which we give definitions of o-minimal structures and tame and definable objects (sets, functions, and mappings) they generate and talk about them in some detail. For more substantial information we can refer to [8, 10, 32]. In the third section we show that the main maps of variational analysis, such as various subdifferentials, slopes, and moduli of metric regularity and surjection (as functions of a point of the graph) are definable or tame, provided so is the original mapping. These two sections can be viewed as an extended introduction. The main content of the paper is sections 4–10.

In the fourth section we present an extension of Sard's theorem to (as far as) tame set-valued mappings, recently proved in [18]. Sard (or Morse–Sard) theorem is among the very central (and technically difficult) results of analysis playing an important part in differential topology, dynamical systems, and singularity theory. It says that the set of critical values of a sufficiently smooth mapping between finite dimensional spaces has Lebesgue measure zero. It might have valuable applications also in optimization theory (especially in stability and sensitivity analysis). There were indeed a few (see, e.g., [29]), but, basically, this has not happened, mainly because of the strong smoothness requirements of the Sard theorem which are known to be sharp. It turns out that, with a natural extension of the concept of critical value based on the metric regularity/openness-at-a-linear-rate dichotomy of variational analysis, the extension of Sard theorem to tame set-valued mappings is possible. In the fifth section we

apply the Sard theorem of section 4 to get some good properties of mathematical programming problems with definable or tame data (normality of the feasible set for a typical right-hand side, finiteness of the number of critical values in a normal problem).

In the sixth section we prove a set-valued extension of the famous Łojasiewicz inequality describing a behavior of a real analytic function near a critical point. In 1998 Kurdyka extended Łojasiewicz's theorem to continuously differentiable definable functions [21] and recently a further extension to lower semicontinuous definable functions in terms of Clarke's generalized gradients was obtained by Bolte-Daniilidis-Lewis in [4]. The non-smooth extension of the Sard theorem plays a central part in our proof and actually leads to its noticeable simplification.

In the seventh section we apply the result of section 6 to get a nonsmooth extension of another famous theorem of Łojasiewicz [23] saying that bounded trajectories of gradient descent of a real analytic function have bounded length. Earlier extensions of this theorem were obtained in [21] for C^1 definable functions and in [3] for definable lower C^2 functions. We consider arbitrary lower semicontinuous definable functions and prove that bounded curves of maximal slope (a concept introduced in 1980 by DeGiorgi–Marino–Tosques [9] as an appropriate extension of trajectories of gradient descent) have bounded length. Again an application of the set-valued Sard theorem is an important element of the argument.

Then in the eighth section we give a simplified proof of a recent result of [5] about semismoothness of locally Lipschitz definable functions. Recall that semismoothness is the property that guarantees superlinear convergence of the Newton method. The problem with this concept was that no sufficiently universal sufficient criteria were known that made the problem of recognizing semismoothness rather complicated. The theorem of [5] basically fills the gap.

In the ninth section we prove a certain "definable" extension of Lyapunov's theorem on vector measures. Namely, it is shown that the integral of a set-valued mapping (that is the collection of integrals of its summable selections) coincides with the "definable" integral (the collection of integrals of tame selections), provided the set-valued mapping is tame.

Finally, in the tenth section we apply the obtained definable extension of Lyapunov's theorem to a class of optimal control problems which contains in particular optimal control of systems guided by linear (nonstationary) equations. This class of problems plays also an important part in mathematical economics (e.g., the famous Aumann–Perles problem [1] belongs to this class). The main result we present here shows that if the data of the problem (e.g., the integrand) are definable, then the problem contains a piecewise continuous optimal control (a very desirable property), provided a certain optimal control exists.

2. Definable and tame functions and sets. There is a sort of hierarchy of classes of tame sets, functions, and maps. In each case it is usually sufficient to describe the collection of sets and then define a corresponding class of functions and mappings by their graphs being elements of the class of sets. The simplest class is formed by so-called semilinear sets (functions, mappings). A semilinear set in $\mathbb{R}^n$ is defined as a finite union of open polyhedra. An open polyhedron is the intersection of a finite number of affine sets and open half-spaces:

$$P = \{x \in \mathbb{R}^n : \ a_i \cdot x = \alpha_i, \ i = 1, \dots, k; \ \langle a_i, x\rangle < \alpha_i, \ i = k+1, \dots, m\}.$$

The dimension of (a nonempty polyhedron) P is $n - \operatorname{rank}(a_1, \dots, a_k)$. A closed polyhedron is clearly a semilinear set (union of all its open faces), so a closed semilinear

set can be defined as a finite union of closed polyhedra. One can easily check that the collection of semilinear sets in $\mathbb{R}^n$ is closed under Boolean operations (union, intersection, complement) and the image and preimage of a semilinear set under a linear (or affine) mapping is also a semilinear set.

A function or a map is called semilinear (sometimes piecewise linear) if its graph is a semilinear set. Another easily verifiable property of a semilinear mapping is that its domain can be decomposed in a finite union of polyhedra such that the restriction of the mapping to each of them is an affine mapping. The latter can be viewed as another definition of semilinear mappings and functions.

The class of semilinear sets, functions, and mappings is of course sufficiently narrow. A much richer collection of tame objects is provided by *semialgebraic* sets, mappings, and functions. A set in $\mathbb{R}^n$ is semialgebraic if it is a finite union of sets of the form

$$\{x \in \mathbb{R}^n : \ p_i(x) = 0, \ i = 1, \dots, k; \ p_i(x) < 0, \ i = k+1, \dots, m\}, \tag{2.1}$$

where all p_i are polynomials. An important for optimization class of convex semialgebraic sets are sets of solutions of a linear-matrix inequalities

$$\sum_{i=1}^{n} x_i A_i \succcurlyeq 0,$$

where A_i are square (symmetric) matrices and $\succcurlyeq$ means positive semidefiniteness. Semialgebraic functions and sets, as their semilinear counterparts, enjoy a number of remarkable properties:

(i) *the class of semialgebraic sets is closed with respect to Boolean operators; a Cartesian product of semialgebraic sets is a semialgebraic set;*

(ii) *the closure and the interior of a semialgebraic set is a semialgebraic set;*

(iii) *semialgebraic subsets of* $\mathbb{R}$ *are precisely finite unions of points and open intervals (hence the same as semilinear);*

(iv) *the projection of a semialgebraic subset of* $\mathbb{R}^n$ *onto* $\mathbb{R}^{n-1}$*, e.g.,*

$$(x_1, \dots, x_n) \to (x_1, \dots, x_{n-1})$$

is a semialgebraic set.

The last of these statements, unlike in the semilinear case, is a deep fact known as the Tarski–Seidenberg theorem. The proofs of the other three are much simpler (although the closedness property in (ii) is a consequence of Tarski–Seidenberg theorem).

The key question behind the further developments is whether there are broader classes of functions and sets for which these (and some other related properties) hold. It turns out that the answer is positive. It is given in terms of so-called *o-minimal structures.*[1]

The latter is a system $\mathcal{S} = \{\mathcal{S}_n\}$, with $\mathcal{S}_n$ being a collection of subsets of $\mathbb{R}^n$ containing all semialgebraic subsets, satisfying (i)–(iv) if we replace there "semialgebraic" by "elements of $\mathcal{S}$." The o-minimal structure of semialgebraic sets is usually

[1] To be more precise we talk here about what is formally defined as an o-minimal structure over $(\mathbb{R}, +, \cdot)$. This means that we consider the subsets of $\mathbb{R}^n$ and make full use of the ring structure of reals. O-minimal structures over other rings can also be considered. On the other hand, semilinear sets are an o-minimal structure which makes no use of the multiplicative structure of reals.

denoted $\mathcal{S}_{alg}$. If we add level and sublevel sets of restrictions of analytic functions to balls, we get the structure $\mathcal{S}_{an}$ of so-called globally subanalytic sets, etc. We refer to [8, 10] for details.

If we have an o-minimal structure, its elements are called *definable sets* (with a reference to the o-minimal structure if necessary). Functions and mappings whose graphs are definable sets are also called definable.

Given an o-minimal structure, we can be sure that

(a) *if $f(x,y)$ is a definable function, then so is $\varphi(x) = \inf_y f(x,y)$;*

(b) *a composition of definable mappings is a definable mapping;*

(c) *the image and preimage of a definable set under a definable mapping are definable sets.*

The three properties we have just stated heavily rely on (iv), the definable counterpart of the Tarski–Seidenberg theorem. To better understand ramifications of the latter, we notice that as an immediate implication of (iv), we get definability of any set $\{x \in P : \exists y \in Q,\ (x,y) \in S\}$, provided P, Q, and S are definable sets in the corresponding spaces. It follows that also $\{x \in P : \forall y \in Q,\ (x,y) \in S\}$ is a definable set as its complement is the union of the complement of P and the set $\{x \in P : \exists y \in Q,\ (x,y) \notin S\}$. Thus, if we have a finite collection of definable sets, then any set obtained from them with the help of a finite chain of quantifiers is also definable.

A consequence of (a)–(c) very useful in any optimization context is that

(d) *if Q is a definable set, then the distance function $d(x,Q)$ is also definable.*

Indeed, the function $\varphi(x,u) = \|u - x\|$ is semialgebraic, and hence definable as well as $\delta_Q(x)$, the indicator of Q; hence $d(x,Q) = \inf_u(\|x-u\| + \delta_Q(u))$ is a definable function by (a),(b).

In case we are interested only in local results and what happens near the infinity is of a limited interest, the following formal definition of tameness is justified: a set is called *tame* (with respect to a certain o-minimal structure) if its intersection with any ball is definable. A function or (set-valued) mapping is *tame* if its graph is tame.

Thus, for instance, the function $\sin t$, not definable in any o-minimal structure (since the nonempty preimage of a point is a countable set), is a tame function with respect to the o-minimal structure $\mathcal{S}_{an}$ of globally subanalytic sets. However, the function $\sin t^{-1}$ is not tame on $(0,1)$.

It is appropriate to note here that *a projection of a tame set may fail to be tame as well as composition of tame mappings* unless the external map is coercive (that is such that preimages of bounded sets are bounded). In particular, the sum of two tame functions may fail to be tame.[2]

Here are some fundamental properties of definable objects.

THEOREM 2.1 (monotonicity theorem). *Let f be a definable function on a real interval (a,b), where $-\infty \le a < b \le \infty$. Then there is a finite number of points $a = t_0 < t_1 < \ldots < t_k < b = t_{k+1}$ such that on every interval (t_i, t_{i+1}) f is continuous and either strictly monotone or constant.*

As an immediate consequence of this theorem we get that a bounded definable trajectory in $\mathbb{R}^n$ defined on an open interval $(0,T)$ converges when, e.g., $t \to 0$. We

[2]An alternative definition void of this inconvenience would be, e.g., a mapping is tame if its restriction to any ball is definable. However, such a definition would also be problematic because in this case (a) the inverse to a tame mapping may not be tame and (b) there would be less tame mappings. Hopefully, future developments will clarify which localization of definability is more convenient, at least for the needs of optimization theory.

shall have a couple of chances to see the power of this seemingly simple result. In particular, this is the key argument in the proof of convergence of the central path in nonlinear semidefinite programming in the quoted paper [14].

We shall briefly explain the idea of the proof in a somewhat more general situation of the problem

$$\text{minimize } f(x), \quad \text{s.t. } g(x,u) \le 0,\ \forall u \in U,$$

where $x \in \mathbb{R}^n$ and $U \subset \mathbb{R}^m$ is a compact set. The functions f and $g(\cdot, u)$ are assumed convex continuous. Continuation methods for solving such problems (under the strict feasibility, or Slater assumption that there is an x such that $\sup_{u\in U} g(x,u) < 0$) consist in solving auxiliary problems

$$\text{minimize } f(x) + \mu\beta(x),$$

where $\beta(x)$ is a barrier function (finite for strictly feasible x and equal to ∞ otherwise) and studying the behavior of its solution $x(\mu)$ as $\mu \to 0$. The barrier function is usually strictly convex, so there may be only one solution $x(\mu)$ for every μ. Theory of convex programming provides conditions that guarantee that $x(\mu)$ (the central path) is well-defined and bounded. The question is when $x(\mu)$ converges as $\mu \to 0$. It turns out that, even for problems of linear programming, the proof of convergence needs methods of algebraic geometry [16]. Monotonicity theorem allows one to easily solve the problem under tameness/definability assumptions. Namely, if *U is a definable set, the functions f and g are tame, and β is definable, all in the same o-minimal structure, then the central path (if it is defined for small μ and bounded) converges.*[3]

THEOREM 2.2 (definable selection theorem). *Let $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ be a set-valued mapping with a definable graph. Let* dom $F = \{x :\ F(x) \neq \emptyset\}$ *stand for the domain of F. Then there is a single-valued definable mapping φ from $\mathbb{R}^n$ into $\mathbb{R}^m$, defined at least on* dom F*, such that $\varphi(t) \in F(t)$ for all $t \in$* dom F.

Again it is worth paying attention to how easily the selection problem (very painful in many situations) is solved in the realm of definable objects.

THEOREM 2.3 (stratification theorem [11]). (a) *Let $Q \in \mathbb{R}^n$ be a definable set. Then Q admits a C^k-Whitney stratification for any k: there is a finite partition*[4] *of Q into C^k manifolds M_i such that*

- *if $M_j \cap \mathrm{cl} M_i \neq \emptyset$, then $M_j \subset \mathrm{cl} M_i \backslash M_i$;*
- *if $x \in M_j$ and $x_k \in M_i$ converge to x as $k \to \infty$, then $T_x M_j$, the tangent space to M_j at x, is contained in the lower limit of $T_{x_k} M_i$.*

(b) *If F is a definable mapping from $\mathbb{R}^n$ into $\mathbb{R}^m$, then for any k there is a C^k-Whitney stratification (M_i) of* dom F *such that the restriction of F to every M_i is k times continuously differentiable.*

This is the most fundamental structural characterization of definable sets. Of course a set which admits even a C^∞ stratification may not be definable. So the important element of the theorem is the possibility to get strata that are both definable and having the desirable order of smoothness.

3. Variational analysis and tameness. Let us consider first an extended-real-valued function f on $\mathbb{R}^n$. The set dom $f = \{x :\ |f(x)| < \infty\}$ is the *domain* of f and the set epi $f = \{(x,\alpha) \in \mathbb{R}^n \times R :\ \alpha \ge f(x)\}$ is the *epigraph* of f. The

[3] In [14] this argument was actually applied to the structure $\mathcal{S}_{\text{an exp}}$ and real analytic f and g.

[4] Note that the standard definition of Whitney stratification involves locally finite partitions.

function is lower semicontinuous if its epigraph is closed. The function $\bar f$ defined by epi $\bar f = \mathrm{cl}(\mathrm{epi}\ f)$ is called the *lower closure* of f. If f is definable (tame), then so is $\bar f$.

Recall that the *proximal* and the *Fréchet* subdifferentials of f at x are defined, respectively, by

$$\partial_p f(x) = \{y :\ \liminf_{\|h\|\to 0} \|h\|^{-2}\big(f(x+h) - f(x) - \langle y, h\rangle\big) > -\infty\},$$

and

$$\partial_F f(x) = \{y :\ \liminf_{\|h\|\to 0} \|h\|^{-1}\big(f(x+h) - f(x) - \langle y, h\rangle\big) \ge 0\}$$

for sufficiently small h.

Along with the two subdifferential set-valued mappings $x \mapsto \partial_p f(x)$ and $x \mapsto \partial_F f(x)$, we can also consider the corresponding *subjets* which are the sets

$$[\partial_p f] = \{(x, \alpha, y) :\ y \in \partial_p f(x),\ \alpha = f(x)\}$$

and

$$[\partial_F f] = \{(x, \alpha, y) :\ y \in \partial_F f(x),\ \alpha = f(x)\}.$$

A remarkable fact is that the closures of the two subjets coincide. The *limiting* subdifferential $\partial f(x)$ is the set-valued mapping defined by the condition: $y \in \partial f(x)$ if and only if $(x, f(x), y)$ belongs to the closure of the just defined subjets. Finally, if f satisfies the Lipschitz condition, then $\partial_c f(x) = \mathrm{conv}\ \partial f(x)$ is the *Clarke* subdifferential (or generalized gradient) of f at x. The limiting and Clarke subjets are defined in the same way as the subjets for the first two subdifferentials.

Observe that for a continuously differentiable function, the Fréchet, limiting, and Clarke subgradients coincide and contain a unique element—the derivative of the function. If, in addition, the function is twice differentiable at the point, then the proximal subdifferential coincides with the other three. Likewise, if f is a convex function, all four subdifferentials coincide and are equal to the subdifferential of the function in the sense of convex analysis. We refer to [28] for the basic facts concerning finite dimensional subdifferential calculi.

Another important characteristic of a local behavior of a function (which actually makes sense even for functions on arbitrary metric spaces) is the *slope* of f at x:

$$|\nabla f|(x) = \limsup_{h\to 0,\ h\ne 0} \|h\|^{-1}(f(x) - f(x+h))^+$$

(where $\alpha^+ = \max\{\alpha, 0\}$) which is the maximal "speed" of decrease of function from x. The connection between slopes and subdifferentials is determined by the following inequalities:

$$\inf\{\|y\| :\ y \in \partial_F f(x)\} \ge |\nabla f|(x) \ge \inf\{\|y\| :\ y \in \partial f(x)\}$$

(see [17] for details). In particular, if f is differentiable at x, then $|\nabla f|(x)$ is equal to the norm of the gradient of f at x; if f is convex, then the slope is equal to the distance from $\partial f(x)$ to zero.

Proposition 3.1. (a) *If F is a definable mapping $\mathbb{R}^n \to \mathbb{R}^m$, then its Fréchet derivative is a definable mapping (into the space of linear operators);*

(b) *If f is a definable function, then so are the four subdifferential mappings and the slope function $|\nabla f|$;*

(c) *If f is a tame function, then each of the four subjets is a tame set.*

(For the case of the generalized gradient we assume that f is locally Lipschitz.[5]*)*

Proof. We first observe the following: let $\varphi(x,h)$ be a definable function of two variables (of different dimensions in general). Then the function

$$\psi(x) = \liminf_{\substack{h\to 0\\ h\neq 0}} \varphi(x,h)$$

is also definable since

$$\psi(x) = \sup_{\varepsilon>0} \inf_{0<\|h\|<\varepsilon} \varphi(x,h).$$

Clearly, the same is true also for

$$\limsup_{\substack{h\to 0\\ h\neq 0}} \varphi(x,h).$$

Now to prove (a) we take

$$\varphi(x,A,h) = \|h\|^{-1}\|F(x+h) - F(x) - Ah\|$$

and notice that the graph of F' is the zero level set of the function $\rho(x,y)$ equal to the upper limit of $\varphi(x,y,h)$ when $0 \neq h \to 0$.

Likewise to prove (b), we take

$$\varphi_r(x,y,h) = \|h\|^{-r}(f(x+h) - f(x) - \langle y,h\rangle)$$

with $r=2$ for proximal subdifferentials and $r=1$ for Fréchet subdifferentials and

$$\varphi(x,h) = \|h\|^{-1}(f(x) - f(x+h))^+$$

for slopes. If now

$$\psi_r(x,y) = \liminf_{\substack{h\to 0\\ h\neq 0}} \varphi_r(x,y,h),$$

then

$$\text{Graph } \partial_p f = \{(x,y):\ \psi_2(x,y) > -\infty\};\ \text{Graph } \partial_F f = \{(x,y):\ \psi_1(x,y) > -\infty\}$$

and, of course,

$$|\nabla f|(x) = \limsup_{\substack{h\to 0\\ h\neq 0}} \varphi(x,h).$$

As long as we know that $\partial_p f$ and ∂f are definable maps, it is an easy matter to show that the corresponding subjets are definable sets. Consider, for instance, the case of the Fréchet subdifferential. Set

$$Q = \{(x,\alpha,z,y):\ \alpha = f(x),\ y \in \partial_F f(z)\} = (\text{Graph } f) \times (\text{Graph } (\partial_F f)).$$

[5] Although the result is valid without the assumption if we use Rockafellar's representation formula for the generalized gradient.

Then $[\partial_F f]$ is the projection of the set $Q \cap \{(x,\alpha,z,y) : \ z = x\}$ to the space of (x,α,y).

Finally, the graph of ∂f is by definition $\{(x,y) : (x,f(x),y) \in \mathrm{cl}[\partial_F f]\}$, that is to say, the preimage of the definable set $\mathrm{cl}[\partial_F f]$ under the definable mapping $(x,y) \to (x,f(x),y)\}$, hence a definable set.

To prove (c), we first consider the case of a bounded f. Then the restriction of f to any open ball is a definable function (as the graph of the restriction is the intersection of the graph of f with a bounded definable set). Hence the subdifferentials and the corresponding subjets of the restriction are definable, so the subjets of the function are tame sets.

Let now f be an arbitrary lower semicontinuous tame function. For any N set

$$B_N = \{(x,\alpha,y) : \ \max\{\|x\|,|\alpha|,\|y\|\} \le N\}, \quad f^K(x) = \min\{K, \max\{f(x),-K\}\}.$$

Then, e.g., $[\partial_F f^{2N}] \cap B_N = [\partial_F f] \cap B_N$ (as is easy to verify) and the same equality holds for the proximal subdifferential. This completes the proof of the proposition. □

Remarks. 1. The derivative or subdifferential of a tame function may not be a tame mapping: consider for instance the function $f(x) = x^{-1} - \sin x^{-1}$ on $(0,\infty)$.

2. We do not need in this paper coderivatives and derivatives of set-valued mappings as well as tangent and normal cones, all playing an important role in variational analysis. Similar properties (definability or tameness) can be also established for them.

We shall next consider the property of metric regularity, one of the central in variational analysis. Recall that F is called *metrically regular* near $(\bar{x},\bar{y}) \in \mathrm{Graph}\ F$ if there is a positive K such that

$$d(x, F^{-1}(y)) \le K d(y, F(x))$$

for all (x,y) sufficiently close to $(\bar{x},\bar{y})$. The lower bound $\mathrm{reg}F(\overline{x}|\overline{y})$ of such K is called *modulus of metric regularity* of F near $(\bar{x},\bar{y})$. F is called *open at a linear rate* near $(\bar{x},\bar{y})$ if there is an $r > 0$ such that

$$B(y,rt) \subset F(B(x,t))$$

if $(x,y) \in \mathrm{Graph}\ F$ are sufficiently close to $(\bar{x},\bar{y})$ and $t > 0$ is sufficiently small. The upper bound $\mathrm{sur}F(\overline{x}|\overline{y})$ of such r is called the *modulus of surjection* of F near $(\bar{x},\bar{y})$. A well-known and important fact is that

$$\mathrm{sur}F(\overline{x}|\overline{y}) \cdot \mathrm{reg}F(\overline{x}|\overline{y}) = 1. \tag{3.1}$$

If we agree to set $0 \cdot \infty = 1$, the property is valid unconditionally. Another useful and rather elementary fact is that

$$\mathrm{sur}(F \circ H)(x|z) \le \|H'(x)\| \mathrm{sur}F(H(x)|z) \tag{3.2}$$

if $H : \mathbb{R}^k \to \mathbb{R}^n$ is continuously differentiable at x.

Finally, we give two formulas that allow to compute the modulus of surjection (metric regularity) for a set-valued mapping $F : \ \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ with closed graph (hence upper semicontinuous). The first (which is in principle valid in arbitrary Banach spaces) is given in terms of slopes:

$$\mathrm{sur}F(\overline{x}|\overline{y}) = \liminf_{\substack{(x,y) \to F\ (\overline{x},\overline{y}) \\ y \notin F(x)}} |\nabla d(y, F(\cdot))|(x) \tag{3.3}$$

(see [17], Theorem 2.2b). Here $(x,y) \to_F (\overline{x},\overline{y})$ means that $x \to \overline{x}$, $y \to \overline{y}$, and $d(y,F(x)) \to 0$.

The second formula, often more convenient for practical calculation, is finite dimensional:

$$\mathrm{sur}F(\overline{x},\overline{y}) = \inf\{\|x^*\| :\ x^* \in D^*F(\bar{x},\bar{y})(y^*),\ \|y^*\| = 1\} \tag{3.4}$$

(see, e.g., [28], Theorem 9.43). Here $D^*F(x,y)$ is the limiting coderivative of F at (x,y).[6]

PROPOSITION 3.2. *If F is definable (tame) set-valued mapping, then so are the functions $(x,y) \to \mathrm{reg}F(x|y)$ and $(x,y) \to \mathrm{sur}F(x,y)$.*

Proof. We shall prove only the "definable" part of the proposition. The "tame" part will then be immediate as the definitions of the moduli deal with bounded portions of the graph. On the other hand, as long as we consider only definable mappings, it is sufficient, according to (3.1), to establish the definability property only for one of the moduli. So we shall talk about modulus of metric regularity of a definable set-valued mapping.

For such a mapping the function $\varphi(x,y) = d(x,F^{-1}(y))$ is definable as its epigraph is the closure of the projection onto the (x,y,α)-space of the set

$$\{(x,y,u,\alpha) :\ \alpha \geq \|x-u\|,\ (u,y) \in \mathrm{Graph}\ F\}.$$

Similar argument shows that also the function $d(y,F(x))$ is definable.

Setting

$$\varphi(u,v) = \begin{cases} \dfrac{d(u,F^{-1}(v))}{d(v,F(u))}, & \text{if } v \notin F(u); \\ 0, & \text{if } v \in F(u) \end{cases}$$

and

$$\psi(x,y,u,v,\varepsilon) = \begin{cases} 0, & \text{if } \|x-u\| < \varepsilon,\ \|y-v\| < \varepsilon, \\ -\infty & \text{otherwise,} \end{cases}$$

we see that

$$\mathrm{reg}F(x|y) = \lim_{\varepsilon \to 0} \sup_{u,v} (\varphi(u,v) + \psi(x,y,u,v,\varepsilon))$$

is a definable function. □

Remark. If F is single valued, we usually write $\mathrm{sur}F(x)$ and $\mathrm{reg}F(x)$ rather than $\mathrm{sur}F(x|F(x))$ and $\mathrm{reg}F(x|F(x))$. The functions $x \to \mathrm{sur}F(x)$ and $x \to \mathrm{reg}F(x)$ are definable if so is F. However if F is only tame, the functions may not be tame: tameness is preserved only by the sets $\{(x,y,\alpha) :\ y = F(x), \alpha = \mathrm{sur}F(x)\}$ and $\{(x,y,\alpha) : y = F(x), \alpha = \mathrm{reg}F(x)\}$.

4. A nonsmooth extension of the Sard theorem. Let $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$, and let $y \in F(x)$. We say that (x,y) is a *critical point* of F if $\mathrm{sur}F(x|y) = 0$. If F is single-valued and continuously differentiable at x, this definition reduces to the

[6] This is the set-valued mapping which with every y^* associates the set of x^* such that $(x^*,-y^*)$ belongs to the limiting normal cone for the graph of F at (x,y). The latter is the limiting subdifferential of the indicator of Graph F (which is the function equal to zero on Graph F and $+\infty$ outside of Graph F). We shall not use the formula in the sequel.

standard concept of a critical (or singular) point: x is critical if $F'(x)$ maps $\mathbb{R}^n$ not to the whole of $\mathbb{R}^m$. We say that $y \in \mathbb{R}^m$ is a *critical value* of F if there is an $x \in \mathbb{R}^n$ such that (x, y) is a critical point of F. The famous Sard theorem (see, e.g., [15]) says that the collection of critical values of a C^k-mapping $F : \mathbb{R}^n \to \mathbb{R}^m$ has Lebesgue measure zero, provided $k > \max\{n - m, 0\}$. The theorem basically says that only for a very meager collection of right-hand side vectors y, the set of solutions of the equation $F(x) = y$ may sharply react to small changes of y. We refer to [32] for applications of the Sard theorem and discussions of some recent developments.

Sard's theorem is a sharp result. The first counterexample of a continuously differentiable function on $\mathbb{R}^2$ whose set of critical values contains an open interval was suggested by Whitney [31] even before the Sard theorem was proved in 1942. The final results due to Bates [2] and Norton [27] say that the conclusion of the theorem is still valid for $C^{n-m,1}$ mappings (having Lipschitz continuous $(n-m)$th derivative) but not for mappings of the Hölder classes $C^{n-m,\alpha}$ with $\alpha < 1$.

The following general result, however, holds true [18].

THEOREM 4.1. *Let $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ $(n \geq m)$ be a set-valued mapping whose graph is locally closed. Assume that* Graph F *admits a C^k-Whitney stratification with $k > \dim(\text{Graph } F) - m$.*[7] *Then the collection of critical values of F has m-dimensional Lebesgue measure zero. In particular, if the graph of F is a definable set in a certain o-minimal structure, then the set of critical values of F is also a definable subset of $\mathbb{R}^m$ whose dimension is strictly smaller than m.*

The proof of the theorem relies on the Sard theorem and is relatively simple. We omit it mainly because it requires introducing rather many technical details involving manifolds. The basic idea of the proof is to show that every critical point of the mapping (in the sense of variational analysis, just defined) is a critical point (in the classical sense) of the restriction of the mapping to the stratum (of the Whitney stratification) to which the point belongs and then to use the Sard theorem. It is worth noting that the inclusion can be strict: Consider for instance the set-valued mapping $\mathbb{R} \rightrightarrows \mathbb{R}$ whose graph is the set $\{(x, y) : \ |x| = |y|\}$. Then zero is a regular value of it in the sense of variational analysis but, for any stratification, a critical value of the union of the restrictions of the projection $(x, y) \to y$ to the strata.

5. Typical normality of optimization problems. Consider the standard minimization problem with finite number of equality and inequality constraints:

$$\mathbf{P}(a) \qquad \left.\begin{array}{ll} \textit{minimize} & f_0(x) \\ \textit{subject to} & f_i(x) \leq \alpha_i,\ i = 1, \dots, k; \\ & f_i(x) = \alpha_i,\ i = k+1, \dots, m. \end{array}\right\}$$

Here $x \in \mathbb{R}^n$ and $a = (\alpha_1, \dots, \alpha_m) \in \mathbb{R}^m$. We denote by $\mathcal{F}(a)$ the set of *feasible* vectors for $\mathbf{P}(a)$. A vector $x \in \mathcal{F}(a)$ is called *normal* for $\mathbf{P}(a)$ if the following condition is satisfied: For no nonzero vector $l = (\lambda_1, \dots, \lambda_m)$ such that $\lambda_i \geq 0$ for $i = 1, \dots, k$ and $\lambda_i(f_i(x) - \alpha_i) = 0$ for all indices $i = 1, \dots, m$, zero belongs to $\partial(\lambda_1 f_1 + \dots + \lambda_m f_m)(x)$. (In the case when all f_i are continuously differentiable, this is the famous *Mangasarian–Fromowitz condition*.) An $x \in \mathcal{F}(a)$ that is not normal is called *abnormal*.

We say that $\mathbf{P}(a)$ is a *normal problem* if every feasible $x \in \mathcal{F}(a)$ is a normal vector for $\mathbf{P}(a)$.

[7] It is natural to define $\dim(\text{Graph } F)$ as the maximal dimension of the strata. Clearly, this does not depend on the specific stratification.

THEOREM 5.1. *Assume that all functions f_i are locally Lipschitz and definable in a certain o-minimal structure. Then the collection of the right-hand side vectors a for which the problem* P(a) *is not normal is a definable set of dimesion strictly smaller than m.*

Proof. We view $\mathcal{F}$ as a set-valued mapping from $\mathbb{R}^m$ into $\mathbb{R}^n$. This is obviously a definable set-valued mapping and so is its inverse $\mathcal{F}^{-1}$ which associates with every $x \in \mathbb{R}^n$ the collection of $a \in \mathbb{R}^m$ such that $x \in \mathcal{F}(a)$. By the definable Sard theorem (Theorem 4.1), the set of critical values of $\mathcal{F}^{-1}$ is a definable set of dimension strictly smaller than m. So to prove the theorem we need to verify that a is a critical value if and only if $\mathbf{P}(a)$ is not a normal problem.

Set $F(x) = (f_1(x), \dots, f_m(x))$. Set further

$$K = \{y = (\eta_1, \dots, \eta_m) \in \mathbb{R}^m : \eta_i \geq 0,\ i = 1, \dots, k;\ \eta_i = 0,\ i = k+1, \dots, m\}.$$

Then $\mathcal{F}^{-1}(x) = F(x) + K$. We have for any $a \in \mathbb{R}^m$

$$\begin{aligned} d(y, F(x)+K) &= \inf\{\|y - F(x) - w\| :\ w \in K\} \\ &= \inf\{\sup_{\|l\|\leq 1} \langle l, y - F(x) - w\rangle :\ w \in K\} \\ &= \sup_{\|l\|\leq 1} \inf\{\langle l, y - F(x) - w\rangle :\ w \in K\} \\ &= \sup\{\langle l, y - F(x)\rangle :\ \|l\| \leq 1,\ l \in K^\circ\}. \end{aligned} \tag{5.1}$$

Here $K^\circ = \{l :\ \langle l, y\rangle \leq 0,\ \forall\, y \in K\}$ is the polar of K.

By definition $\overline{a}$ is a critical value of $\mathcal{F}^{-1}$ if and only if there is an $\overline{x} \in \mathcal{F}(\overline{a})$ such that $\mathrm{sur}\mathcal{F}^{-1}(\overline{x}|\overline{a}) = 0$. By (3.3) this means that for any $\varepsilon > 0$ there is a pair (x, a) arbitrarily close to $(\overline{x}, \overline{a})$ and with $a \notin F(x)+K$ such that $|\nabla d(a, F(\cdot)+K)|(x) < \varepsilon/2$.

Let $l(x, y)$ be the l for which the last supremum in (5.1), for the given x and y, is attained. As $a \neq F(x)$, we have $\|l(x, a)\| = 1$ and, clearly $\langle l(x, a), y - F(x)\rangle \geq 0$. Furthermore, for any u sufficiently close to x

$$\varepsilon \geq |\nabla d(a, F(\cdot) + K)|(x) \geq \frac{\langle l(x, a), F(x) - F(u)\rangle}{\|x - u\|}.$$

It follows that the function $u \to \langle l(x, a), F(u)\rangle + \varepsilon\|u - x\|$ attains a local minimum at x. Hence

$$0 \in \partial(l(x, a) \circ F)(x) + \varepsilon B. \tag{5.2}$$

We may assume that $l(x, a)$ converges to some l as we choose ever smaller ε and (x, a) closer to $(\overline{x}, \overline{a})$. Clearly $\|l\| = 1,\ l \in K^\circ$, and $\langle l, F(\overline{x}) - \overline{a}\rangle \geq 0$. As $\overline{a} - F(\overline{x}) \in K$, the latter two relations imply that $\langle l, F(\overline{x}) - \overline{a}\rangle = 0$. Finally, from (5.2) taking into account that F is Lipschitz near $\overline{x}$ we get that $0 \in \partial(l \circ F)(\overline{x})$. □

Theorem 5.1 applies rather to the constraints of the problem. In [19] a similar problem will be considered in a more general context of constraint systems. The second result, also from [19], deals with critical values of the problem itself. Recall that the first order necessary optimality conditions in P(a) at $x \in \mathcal{F}(a)$ is the existence of a nonzero set of multipliers $\lambda_0, \lambda_1, \dots, \lambda_n$ satisfying

$$\lambda_i \geq 0,\ \lambda_i(f_i(x) - \alpha_i) = 0,\ i = 0, 1, \dots, k;\ 0 \in \partial(\lambda_0 f_0 + \lambda_1 f_1 + \cdots + \lambda_n f_n). \tag{5.3}$$

We shall say that x is a *critical point* of P(a) if (5.3) holds for some nonzero set of multipliers. We shall further say that α is a *critical value* of P(a) if $f_0(x) = \alpha$ for some critical point x of P(a). The following theorem will be proved in [19].

THEOREM 5.2. *Assume that the functions $f_0, f_1, \dots, f_n$ are locally Lipschitz and definable in a certain o-minimal structure. Assume further that* P(a) *is a normal problem. Then the set of critical values of* P(a) *is finite.*

Of course, if $\mathbf{P}(a)$ is normal and (5.1) holds, then $\lambda_0 > 0$.

6. A set-valued Łojasiewicz inequality. In 1965 Łojasiewicz proved that a bounded trajectory of the gradient dynamic system

$$\dot{x} = -\nabla f(x)$$

is finite and converges to a critical point of f if f is a real analytic function. The proof was based on the inequality obtained by Łojasiewicz for real analytic functions a few years earlier: If f is a real analytic function and x is a critical point of f, then there is an $\alpha \in (0,1)$ such that in a neighborhood of x

$$\|\nabla f(u)\| \geq |f(u) - f(x)|^{\alpha}.$$

(The inequality is of course trivial if x is not a critical point.)

In 1998 Kurdyka [21] extended the Łojasiewicz inequality to continuously differentiable functions definable in an o-minimal structure. Kurdyka's result is stated as follows. Let f be a C^1 function on a bounded open set $U \subset \mathbb{R}^n$ which is definable in some o-minimal structure. Suppose that $f(x) > 0 = \inf_U f$ for all $x \in U$. Then there is a $\rho > 0$ and a strictly increasing definable function ψ on $(0, \infty)$ such that for all $x \in U$ with $f(x) < \rho$ we have[8]

$$\|\nabla(\psi \circ f)(x)\| \geq 1. \tag{6.1}$$

Finally, very recently Bolte–Daniilidis–Lewis–Shiota [4] extended the last theorem to arbitrary lower semicontinuous definable functions by proving that a more general version of (6.1) with $\psi'(f(x))\|y\|$ in the left-hand side, where y stands for an arbitrary element of $\partial_c f(x)$.

The theorem below is a Kurdyka-type result for set-valued mappings into $\mathbb{R}$.

THEOREM 6.1. *Let $F : \mathbb{R}^n \rightrightarrows \mathbb{R}$ be a tame set-valued mapping with closed graph, and let U be a bounded open definable set. Take a $\tau \in \mathbb{R}$ and assume that $(\tau, \tau+\delta) \cap F(U) \neq \emptyset$ for any $\delta > 0$. Then there are $\rho > 0$ and a nonnegative continuous function $\psi(t)$ defined at least on $[\tau, \tau + \rho)$ which is continuously differentiable and strictly increasing on $(\tau, \tau + \rho)$ and such that the inequality*

$$\operatorname{sur}(\psi \circ F)(x|\psi(\tau + h)) \geq 1$$

holds for all $x \in U$ and all $h \in (0, \rho)$ such that $\tau + h \in F(x)$.

Proof. Fix a certain $T > 0$. The intersection of the graph of F with $U \times (0, T)$ is a definable set by definition of tameness. Let

$$\varphi(t) = \inf\{\operatorname{sur} F(x|t) : \ x \in U, \ t \in F(x)\}, \quad t \in (0, T).$$

It follows from Proposition 3.2 that φ is a definable function. By the monotonicity theorem (Theorem 2.1) the limit $r = \lim_{t \to 0} \varphi(t)$ exists.

[8] The proof that (6.1) implies the Łojasiewicz inequality for real-analytic functions is based on a highly nontrivial property of subanalytic functions, the so-called Puiseux expansion. We refer to [21] for explanations.

If $r > 0$, then $\psi(t) = kt$ with $k > r^{-1}$ is the desired function. So we assume that $r = 0$ in the rest of the proof.

By the monotonicity theorem (Theorem 2.1), there is a $\delta > 0$ such that either $\varphi(t) \equiv 0$ on $(0, \delta)$ or φ is a strictly increasing, positive, and continuously differentiable function. In the first case, we would have that for any $t \in (0, \delta)$ there is an x in the closure of U such that $\mathrm{sur}F(x|t) = 0$. This would mean that every $t \in (0, \delta)$ is a critical value of F. But the latter contradicts to Theorem 4.1. Thus φ is a continuously differentiable positive and strictly increasing function on $(0, \delta)$ going to zero as $t \to 0$.

To prove the theorem it is enough to verify that $\eta(t) = [\varphi(t)]^{-1}$ is summable on $(0, \rho)$ for some positive ρ. Indeed, in this case

$$\psi(t) = \int_0^t \frac{1}{\varphi(\xi)} d\xi$$

satisfies $\psi'(t)\varphi(t) \equiv 1$ on some interval $(0, \rho)$ and $\mathrm{sur}(\psi \circ F)(x|t)) = \psi'(t)\mathrm{sur}F(x|t) \geq \psi'(t)\varphi(t) \geq 1$ which is immediate from the definition of the modulus of surjection.

Consider the set-valued mapping $\Phi : (0, \delta) \mapsto \mathbb{R}^n$ defined by

$$t \mapsto \{x : \ x \in U, \ t \in F(x), \ 2\varphi(t) \geq \mathrm{sur}F(x|t)\}.$$

This is a definable mapping with nonempty values. By the definable choice theorem (Theorem 2.2) there is a definable selection $x(t)$ for Φ. Applying the monotonicity theorem (and taking again a smaller δ if necessary) we can be sure that $x(t)$ is continuously differentiable on $(0, \delta)$.

As U is a bounded set, it follows from the monotonicity theorem (applied to each component of $x(t)$) that $x(t)$ has a finite length. Set $H(t) = F(x(t))$. We also have $t \in H(t)$ for all positive t close to zero. This means that $\mathrm{sur}H(t|t) \geq 1$ for such t.

On the other hand, as $x(t)$ is continuously differentiable,

$$\mathrm{sur}H(t|t) \leq \|\dot{x}(t)\|\mathrm{sur}F(x(t)|t) \leq 2\varphi(t)\|\dot{x}(t)\|$$

(see (3.2)), so that

$$\int_0^\delta \frac{1}{\varphi(t)} dt \leq 2 \int_0^\delta \|\dot{x}(t)\| dt < \infty$$

as desired. □

COROLLARY 6.2. *Let f be a lower semicontinuous function on $\mathbb{R}^n$, and let U be an open bounded subset of $\mathbb{R}^n$. If f is tame in some o-minimal structure and U is a definable set in the same structure, then for any $\tau \in \mathbb{R}$ there are $\rho > 0$ and a nonnegative continuous function $\psi(t)$ defined at least on $[\tau, \tau+\rho)$ which is continuously differentiable and strictly increasing on $(\tau, \tau + \rho)$ and such that the inequality*

$$|\nabla(\psi \circ f)|(x) \geq 1$$

holds for all $x \in U$ such that $0 < f(x) - \tau < \rho$.

Proof. Consider the set-valued mapping $F(x) = \{\alpha \in \mathbb{R} : \ \alpha \geq f(x)\}$, that is, the mapping whose graph is epi f. As f is lower semicontinuous, the graph of F is closed and we can apply the theorem. Fix a certain $\overline{x} \in \mathrm{dom}\ f$ and let $\overline{y} = f(\overline{x}) \in F(\overline{x})$. If $y \notin F(\overline{x})$, then the distance from y to $F(x)$ for all x sufficiently close to $\overline{x}$ is

$f(x) - y$. Therefore by (3.3) $\mathrm{sur}F(\overline{x}|\overline{y}) \le |\nabla f|(\overline{x})$. This inequality holds for all $(\bar{x}, \bar{y}) \in \mathrm{Graph}\, F$, so the application of the theorem proves the claim. □

The corollary also follows from the mentioned result of [4]; moreover, we do not claim that the function ψ is definable. The advantage of Theorem 6.1 and the corollary is simplicity of the proof which does not rely either on the results of [21][9] or any advanced results on definable functions, beyond those quoted in section 3. We shall apply the corollary in the next section to extend Łojasiewicz's gradient descent theorem to slopes of lower semicontinuous definable functions.

7. Curves of maximal slope. As we mentioned in the beginning of the previous section, one of the most important applications of the Łojasiewicz inequality was his proof that bounded trajectories of gradient descent of real analytic functions have bounded length. Kurdyka showed in [21] that the same is true for continuously differentiable definable functions, and recently Bolte–Daniilidis–Lewis [3] established that a similar property is shared by trajectories of subgradient descent of definable "lower C^2-functions."[10]

Here we show that the property can be further extended to arbitrary lower semicontinuous functions. The key to this extension is the concept of a curve of maximal slope introduced by DeGiorgi–Marino–Tosques in [9]. Namely, given an extended-real-valued function f on $\mathbb{R}^n$ (the original definition actually applies to functions on metric spaces), a curve γ in $\mathbb{R}^n$ is called a *curve of maximal slope for* f if there is a parameterization $u(t)$ for γ such that

(i) $u(0) \in \mathrm{dom}\, f$ and $(f \circ u)(t)$ does not increase with t;

(ii) $u(t)$ is absolutely continuous and $\|u'(t)\| = |\nabla f|(u(t))$ for almost every $t \in (0, T)$;

(iii) $f \circ u$ is absolutely continuous and $(f \circ u)'(t) = -[|\nabla f|(u(t)]^2$ almost everywhere on $(0, T)$.

We leave aside the question about the existence of curves of maximal slope and refer to [9, 25] for the basic existence theorems. In the nutshell, curves exist for any initial $u(0)$, provided the slope function $|\nabla f|(x)$ behaves sufficiently well. In particular, if f is a continuously differentiable function, then curves of maximal slope for f are precisely trajectories of the antigradient equation $\dot{x} = -\nabla f(x)$; if f is a convex or, more generally, lower C^1 function, then curves of maximal slope are precisely trajectories of the antisubgradient inclusion $\dot{x} \in -\partial f(x)$ (see, e.g., [25], Theorem 1.11).

Our purpose is to prove the following theorem.

THEOREM 7.1. *Let f be a definable lower semicontinuous function on $\mathbb{R}^n$, and let U be an open and bounded subset of $\mathbb{R}^n$. Then there is a number N such that the length of any curve of maximal slope for f lying in U does not exceed N.*

Proof. The proof below is basically a readjustment of that of [21] for our more general setting.

1. To begin with, we observe the following. Let γ be a curve of maximal slope for f, and let φ be a strictly increasing continuously differentiable function on a certain interval containing the values of $f(x)$ for $x \in \gamma$. Then γ is a curve of maximal slope

[9] The idea to study the mapping Φ has been borrowed from [21] but the method of the subsequent analysis is different here.

[10] A lower C^k, $k \ge 1$, function is defined as a function that can be locally represented by difference of a convex and C^k function. We observe that for lower C^k functions the four subdifferentials mentioned in section 3 are identically equal if $k \ge 2$, and for $k = 1$ the same is true for Fréchet, limiting and Clarke subdifferentials.

for $\varphi \circ f$. Indeed, let $u(t)$ be a parameterization of γ satisfying (i)–(iii). Then, as

$$|\nabla(\varphi \circ f)|(x) = \varphi'(t)|\nabla f|(x),$$

the function $v(\tau) = u(t(\tau))$ with $\tau(t)$ defined by

$$\frac{d\tau}{dt} = \big(\varphi'(f(u(t))\big)^{-1}$$

is a parameterization of γ showing that (i)–(iii) holds for $\varphi \circ f$; that is, γ is also a curve of maximal slope for $\varphi \circ f$.

As the first consequence of this observation, we may assume that f is bounded on U: Otherwise we can replace f by, say, $\varphi \circ f$, where $\varphi(t) = t/\sqrt{1+t^2}$.

2. Set

$$\varphi(s) = \inf\{|\nabla f|(x) : \ x \in U, \ f(x) = s\}.$$

Again we see that φ is a definable function. So the monotonicity theorem implies that, up to a finite number of points, the domain of φ is the union of finitely many, say k open intervals (α_i, β_i) such that φ is continuous and either strictly monotone or constant on each of them. Let c_i be the lower bound of φ on the ith interval. We observe that $\varphi(f(s))$ is strictly positive on each interval. This is obvious if $c_i > 0$. But if $c_i = 0$ for some i, then φ cannot be constant on the interval because of Theorem 4.1 (as in the proof of Theorem 5.1).

3. Let now γ be a curve of maximal slope and $u(t)$ a corresponding parameterization of γ. Then $f(u(t))$ does not increase with t. In principle, $f(u(t))$ can be constant on finitely many intervals on which it is equal to a critical value of f (that is to s such that $\varphi(s) = 0$) and $u(t)$ is constant. But we can eliminate such intervals by reparameterizing γ in an obvious way and assume that $f(u(t))$ is strictly decreasing. Define ξ_i and η_i by $f(u(\xi_i)) = \beta_i$, $f(u(\eta_i)) = \alpha_i$, and let l_i stand for the length of the piece of γ between $u(\xi_i)$ and $u(\eta_i)$. We have

$$l_i = \int_{\xi_i}^{\eta_i} \|u'(t)\|dt = \int_{\xi_i}^{\eta_i} |\nabla f|(u(t))dt \le \Big((\eta_i - \xi_i)\int_{\xi_i}^{\eta_i} |\nabla f|(u(t))^2 dt\Big)^{1/2}.$$

We also have (in view of (iii))

$$\int_{\xi_i}^{\eta_i} |\nabla f|(u(t))^2 dt = f(u(\xi_i)) - f(u(\eta_i)) = \beta_i - \alpha_i.$$

If $c_i > 0$, then $l_i \ge c_i(\eta_i - \xi_i)$ which, combined with the two inequalities above gives

$$l_i \le \frac{\beta_i - \alpha_i}{c_i}.$$

4. If, on the other hand $c_i = 0$, then by Corollary 6.2 (assuming, to be certain, that φ is strictly increasing on (α_i, β_i)) we shall find a function $\psi_i(s)$ which is defined and continuous on $[\alpha_i, \alpha_i + \rho)$ for some $\rho > 0$ continuously differentiable and strictly increasing on $(\alpha_i, \alpha_i + \rho)$ and such that $|\nabla(\psi_i \circ f)|(u(t)) \ge 1$ if $x \in U$ and $0 < f(x) - \alpha_i < \rho$. As $\varphi(s)$ is strictly increasing on (α_i, β_i), so that $|\nabla f|(x) \ge \varphi(\alpha_i + \rho) > 0$ if $\beta_i > f(x) \ge \alpha_i + \rho$, we can extend ψ_i to a continuous function on the entire segment

$[\alpha_i, \beta_i]$ continuously differentiable and strictly increasing in the interior of the segment with the inequality $|\nabla(\psi \circ f)|(x) \geq 1$ being valid for all $x \in U$ with $\alpha_i < f(x) < \beta_i$.

Then, as we have seen in the beginning of the proof, the piece of γ corresponding to the values of $u(t)$ for $t \in (\xi_i, \eta_i)$ is a curve of maximal slope for $\psi_i \circ f$. As the slope of the function is not smaller than one for all values of f between α_i and β_i, we get as above that $l_i \leq \psi_i(\beta_i) - \psi_i(\alpha_i)$.

If we now denote by I the collection of indices for which $c_i > 0$, then we conclude that the length of the curve does not exceed

$$N = \sum_{i \in I} \frac{\beta_i - \alpha_i}{c_i} + \sum_{i \in \{1,\dots,k\} \setminus I} (\psi_i(\beta_i) - \psi_i(\alpha_i)),$$

which completes the proof as α_i, β_i, c_i, and ψ_i are determined by f and do not depend on the choice of γ. □

8. Semismoothness of tame mappings. A mapping $F : \mathbb{R}^n \to \mathbb{R}^m$ is called semismooth near $\overline{x}$ if it satisfies the Lipschitz condition near $\overline{x}$ and for each x of the neighborhood it is differentiable along every direction and

$$\|F'(x + h; h) - F'(x; h)\| = o(\|h\|).$$

The latter amounts to

$$r(t) = t^{-1} \max_{d \in S^{n-1}} \|F'(x + td; d) - F'(x; d)\| \to 0$$

as $t \to 0$.

The role of the semismoothness property introduced in 1977 by Mifflin is determined by the fact that it guarantees superlinear convergence of the Newton method. We refer to [12] for details.

THEOREM 8.1 ([5]). *A locally Lipschitz tame mapping $F : \mathbb{R}^n \to \mathbb{R}^m$ is semismooth near every point of its domain.*

LEMMA 8.2. *Let $\varphi(t)$ and $\psi(t)$ be defined on a certain interval $(0, T)$ and have the following properties:*

(a) $\varphi(0) = \psi(0) = 0$;

(b) *both functions are definable in a certain o-minimal structure;*

(c) $\psi'(t) > 0$ *for* $t > 0$ *sufficiently close to zero. Then*

$$\lim_{t \to 0} \frac{\varphi(t)}{\psi(t)} = r \;\Rightarrow\; \lim_{t \to 0} \frac{\varphi'(t)}{\psi'(t)} = r.$$

Proof. Fix a $\delta > 0$ and consider the functions $\eta_{\mp}(t) = \varphi(t) - (r \pm \delta)\psi(t)$. Clearly $\eta_{\pm}(0) = 0$ and there is an $\varepsilon > 0$ such that $\eta_-(t) < 0$ and $\eta_+(t) > 0$ for $t \in (0, \varepsilon)$. It follows that any neighborhood of zero must contain points at which $\eta'_-(t) < 0$ and points at which $\eta'_+(t) > 0$. Applying the monotonicity lemma to $\eta'_{\pm}$ and taking a smaller ε , if necessary, we can be sure that the inequalities hold for all $t \in (0, \varepsilon)$ and, consequently,

$$\left| \frac{\varphi'(t)}{\psi'(t)} - r \right| \leq \delta, \ \forall\, t \in (0, \varepsilon),$$

and the lemma follows. □

Proof of the theorem. Fix an $h \in S^{n-1}$. The mapping $t \to F(x+th) - F(x)$ is definable and Lipschitz in a neighborhood of zero, so applying the monotonicity lemma to each of its components, we conclude that the directional derivative $F'(x;h)$ exists for all x of the domain of F and all $h \in S^{n-1}$.

To prove the theorem we have to show that, given an x in the domain of F, the quantity $F'(x+th;h) - F'(x;h) \to 0$ uniformly for $h \in S^{n-1}$ as $t \to +0$. Assuming the contrary, we shall find, using the definable choice theorem, an $\varepsilon > 0$ and a definable mapping $h : (0,\varepsilon) \mapsto S^{n-1}$ such that

$$\|F'(x+th(t);h(t)) - F'(x;h(t))\| \geq \alpha > 0 \tag{8.1}$$

for all sufficiently small t. Then $h(t)$ converge to some $h \in S^{n-1}$ as $t \to 0$, so that $th(t) = th + \xi(t)$, where $\|\xi(t)\| = o(t)$ and $\xi(t)$ is obviously a definable mapping. By Lemma 8.2, $\xi'(t) \to 0$ as $t \to 0$.

The mapping $t \to F(x+th(t))$ is definable as a composition of definable mappings. We can therefore assume (taking a smaller ε, if necessary) that it is differentiable for all $t \in (0,\varepsilon)$ We claim that

$$\lim_{t\to 0} \frac{d}{dt} F(x+th(t)) = F'(x;h) \tag{8.2}$$

Indeed, let K be the Lipschitz constant of F in a neighborhood of x. Then

$$t^{-1}\|F(x+th(t)) - F(x+th)\| \leq Kt^{-1}\|\xi(t)\| \to 0$$

as $t \to 0$, so that

$$\lim_{t\to 0} t^{-1}(F(x+th(t)) - F(x)) = F'(x;h),$$

which, together with the lemma implies (8.2).

On the other hand, for $t \in (0,\varepsilon)$ we have

$$\frac{d}{dt} F(x+th(t)) = F'(x+th(t); h+\xi'(t)).$$

As $F(z;\cdot)$ is Lipschitz continuous with constant K for all z of a neighborhood of x, it follows that $\|F'(x,h(t)) - F'(x;h)\| \to 0$ and

$$F'(x+th(t); h+\xi'(t)) - F'(x+th(t);h(t)) \to 0$$

as $t \to 0$ which together with (8.2) leads to a contradiction with (8.1). □

9. Definable Lyapunov theorem. The famous Lyapunov theorem on vector measures says that the image set of a finite nonatomic $\mathbb{R}^n$-valued measure is a convex compact subset of $\mathbb{R}^n$. A particular case of this theorem is the following well-known result having important applications in optimal control theory: *If $F : [0,T] \rightrightarrows \mathbb{R}^n$ is a measurable set-valued mapping with closed values and there is a summable $r(t)$ on $[0,T]$ such that for almost every t the norm of every element of $F(t)$ does not exceed $r(t)$, then the integral $\int_0^T F(t)dt$ is a convex compact set.* (Here as usual the integral of a set-valued mapping is defined as a set of integrals of its summable selections.) As a consequence of this latter result, we get that the integral of any measurable set-valued mapping into $\mathbb{R}^n$ is either an empty set or a convex set.

Now let $\mathcal{S}$ be a certain o-minimal structure. We denote by

$$(\mathcal{S})\int_0^T F(t)dt$$

the collection of integrals of all definable (in $\mathcal{S}$) selections of F (which are piecewise continuous, hence measurable). Let us agree to call this set the *definable* or $\mathcal{S}$*-integral* of F.

THEOREM 9.1. *Suppose that $F : [0,T] \rightrightarrows \mathbb{R}^n$ is a set-valued mapping with closed values which is definable in a certain o-minimal structure $\mathcal{S}$. Then*

$$(\mathcal{S})\int_0^T F(t)dt = \int_0^T F(t)dt.$$

Proof. We first observe that the $\mathcal{S}$-integral is a subset of the standard integral, so that only the opposite inclusion needs proof. We note next that $(\mathcal{S})\int F(t)dt$ is nonempty if so is $\int F(t)dt$. Indeed, let the latter integral be nonempty, that is there is a summable selection $x(t)$ of F. The function $\rho(t) = \min\{\|x\| : x \in F(t)\}$ is then definable and summable, so the set-valued mapping $F_0(t) = \{x \in F(t) : \ \|x\| \le \rho(t)\}$ is also definable, $F_0(t) \neq \emptyset$ almost everywhere and any definable selection of F_0 is summable. Finally, we can assume of course that $T = 1$. With these three points in mind, we start the proof.

In what follows we set

$$\Phi = \int_0^1 F(t)dt$$

and assume that $\Phi \neq \emptyset$.

1. By the Lyapunov theorem Φ is a convex set. We shall prove the theorem using induction by the dimension of Φ. First we prove the theorem for the case $\dim \Phi = 0$. This is immediate from the above remark that the $\mathcal{S}$-integral is nonempty if so is Φ. Indeed, if the dimension of Φ is zero, then, being a convex set, Φ must be a singleton. This may happen only if $F(t)$ is single-valued up to a set of measure zero and therefore the integral of any of its definable selections must coincide with the unique element of Φ.

2. Assume that the theorem is valid for closed-valued definable mappings into $\mathbb{R}^k$ with $k < n$ (or equivalently, for closed-valued definable mappings with $\dim \Phi = k < n$). We claim that the theorem is true if it is true under the additional boundedness assumption: $0 \in F(t)$ almost everywhere and there is an $N > 0$ such that for almost every t the norm of any $x \in F(t)$ does not exceed N.

Indeed, given F, let F_N be defined by

$$F_N(t) = (F(t) - z(t)) \bigcap NB,$$

where $z(t)$ is any definable and summable selection of F and B stands for the unit ball, and let

$$\Psi_N = \int_0^1 F_N(t)dt, \quad \Psi = \bigcup \Psi_N.$$

Let z be the integral of $z(t)$. By the Lyapunov theorem, (Ψ_N) is a nondecreasing sequence of convex closed bounded sets, so Ψ is convex. Clearly, $\Psi \subset \Phi - z$. There

is no loss of generality in assuming that $z = 0$, which we shall do in the discussion to follow. We intend to show that $\Phi \setminus \Psi \subset (\mathcal{S}) \int F(t)dt$ which is of course sufficient to prove the claim since, according to our assumption, every element of Ψ belongs to $(\mathcal{S}) \int F_N dt$ for some N.

Suppose $\overline{x} \in \Phi \setminus \Psi$. Then $\overline{x}$ can be separated from Ψ by a nonzero vector, that is, there is a $p \in \mathbb{R}^n$ such that $\langle p, \overline{x} \rangle \geq \langle p, x \rangle$ for all $x \in \Psi$. Set $F_p(t) = \{x \in F(t) : \langle p, x \rangle = m_p(t)\}$ and $\Phi_p = \int F_p(t)dt$, where

$$m_p(t) = \sup\{\langle p, x \rangle : \ x \in F(t)\}.$$

Then $m_p(t)$ is a definable function and therefore F_p is a definable mapping with closed values (which in principle can be empty). We claim that

$$\langle p, \overline{x} \rangle = \int_0^1 m_p(t)dt. \tag{9.1}$$

Clearly $\langle p, \overline{x} \rangle \leq \int m_p(t)dt$. Assuming that $\langle p, \overline{x} \rangle < \int m_p(t)dt$, we would be able to find a $w \in \Phi$ and an $\varepsilon > 0$ such that $\langle p, w \rangle \geq \langle p, x \rangle + \varepsilon$ for any $x \in \Psi$. This would mean that

$$\int_0^1 m_p(t) \geq \int_0^1 \max\{\langle p, x \rangle : \ x \in F_N(t)\}dt + \varepsilon, \quad \forall\, N,$$

which is certainly untrue as the maximum under the integral pointwise and non-decreasingly converges to $m_p(t)$ as $N \to \infty$. So (9.1) indeed holds.

Let now $\overline{x}(t)$ be a selection of Φ whose integral is $\overline{x}$. By (9.1) we necessarily have $\langle p, \overline{x}(t) \rangle = m_p(t)$ almost everywhere, which means that the supremum in the definition of m_p is attained for almost every t and the projection of the graph of F_p onto $[0, 1]$ is a set of full measure. As F_p is definable, the projection is also a definable set and, as it has full measure, it must coincide with $[0, 1]$ up to finitely many points. This means, in turn, that the supremum in the definition of m_p is actually attained for all t except for a finite number of points. Thus we have $\overline{x} \in \Phi_p$. But the dimension of Φ_p must be strictly smaller than n, so by the induction assumption $\overline{x} \in (\mathcal{S}) \int F_p(t)dt$.

3. So we assume henceforth that there is an $N > 0$ such that for almost every t we have $\|x\| \leq N$ for all $x \in F(t)$. In this case by the Lyapunov theorem Φ is a convex compact set. Repeating the induction arguments of the previous step, we can easily conclude that every boundary point of Φ belongs to $(\mathcal{S}) \int F(t)dt$, so we have to show that this is true for all interior points of Φ.

So let $\overline{x} \in \operatorname{int} \Phi$. Choose $n + 1$ affinely independent points $x_1, \ldots, x_{n+1}$ on the boundary of Φ such that $\overline{x}$ belongs to the interior of their convex hull and let $r > 0$ be such that $B(\overline{x}, r) \subset \operatorname{conv}\{x_1, \ldots, x_{n+1}\}$. Being boundary points, $x_i \in (\mathcal{S}) \int F(t)dt$, so there are definable selections $x_i(t)$ of F whose integrals give x_i. Applying the monotonicity theorem to each component of every $x_i(t)$, we can find finitely many points $0 = \tau_0 < \tau_1 < \ldots < \tau_m = 1$ such that every $x_i(t)$ is continuous on each interval (τ_j, τ_{j+1}) with each component function of every $x_i(t)$ being either constant or strictly monotone on each interval. Adding more points, if necessary, we can be sure that $\|x_i(\tau_j + 0) - x_i(\tau_{j+1} - 0)\| < \varepsilon$ for a chosen positive ε. (Here $x(\tau + 0) = \lim_{t \searrow \tau} x(t)$ and $x(\tau - 0) = \lim_{t \nearrow \tau} x(t)$.)

We denote by $\Sigma_n = \{a = (\alpha_1, \ldots, \alpha_{n+1}) : \ \alpha_i \geq 0, \ \sum \alpha_i = 1\}$ the standard n-simplex and for any $j \in \{1, \ldots, m\}$ and any $a \in \Sigma_n$ split (τ_j, τ_{j+1}) into n consecutive intervals $\Delta_{ij} = \Delta_{ij}(a)$ such that $|\Delta_{ij}| = \alpha_i |\Delta_j|$ (where $|\cdot|$ stands for the length of an

interval). In other words,

$$\Delta_{ij} = (\tau_j + (\alpha_0 + \cdots + \alpha_{i-1})(\tau_{j+1} - \tau_i), \tau_j + (\alpha_0 + \cdots + \alpha_i)(\tau_{j+1} - \tau_i))$$

(where $\alpha_0 = 0$).

Finally we define ξ_{ij} as the arithmetic mean of the values of $x_i(t)$ at the ends of Δ_j (or to be more precise of the limits of $x_i(t)$ when t tends to the ends of Δ_j from within the interval) and set

$$\Delta_i(a) = \bigcup_j \Delta_{ij}(a); \quad u_i(t,a) = \begin{cases} x_i(t), & \text{if } t \in \Delta_i(a)\ , \\ 0, & \text{otherwise.} \end{cases}$$

We have $\|\xi_{ij} - x_i(t)\| < \varepsilon/2$ if $t \in (\tau_j, \tau_{j+1})$, that is

$$\|\xi_{ij}(\tau_{j+1} - \tau_j) - \int_{\tau_j}^{\tau_{j+1}} x_i(t)dt\| < \frac{\varepsilon}{2}(\tau_{j+1} - \tau_j),$$

so that

$$\|\xi_{ij}|\Delta_{ij}| - \alpha_i \int_{\tau_j}^{\tau_{j+1}} x_i(t)dt\| < \alpha_i \frac{\varepsilon}{2}(\tau_{j+1} - \tau_j).$$

On the other hand,

$$\|\xi_{ij}|\Delta_{ij}| - \int_{\Delta_{ij}} x_i(t)dt\| < \frac{\varepsilon}{2}|\Delta_{ij}| = \alpha_i \frac{\varepsilon}{2}(\tau_{j+1} - \tau_j),$$

and by comparing the last two inequalities, we get

$$\| \int_0^1 u_i(t,a)dt - \alpha_i x_i\| = \| \int_0^1 u_i(t,a)dt - \alpha_i \int_0^1 x_i(t)dt\| < \alpha_i \varepsilon.$$

As all $x_i(t)$ are continuous on every (τ_j, τ_{j+1}), it follows from the definition of Δ_{ij} that integrals of $u_i(t,a)$ depend continuously on a. Consider the following two mappings from Σ_n into $\mathbb{R}^n$:

$$\varphi(a) = \sum_{i=1}^n \alpha_i x_i, \qquad \psi(a) = \sum_{i=1}^n \int_0^1 u_i(t,a)dt.$$

The first is just a linear homeomorphism of Σ_n onto conv $\{x_1, \ldots, x_{n+1}\}$ (recall that $x_1, \ldots, x_{n+1}$ are affinely independent). The second mapping is continuous, and as follows from the last inequality $\|\varphi(a) - \psi(a)\| < \varepsilon$ for all $a \in \Sigma_n$. The latter can be rewritten as $\|(\psi \circ \varphi^{-1})(x) - x\| < \varepsilon$ for all $x \in$ conv $\{x_1, \ldots, x_{n+1}\}$.

It remains to recall that $\varepsilon < r/2$ and $B(\overline{x}, r) \subset$ conv $\{x_1, \ldots, x_{n+1}\}$. Now take an $w \in B(\overline{x}, r/2)$ and consider the mapping $x \mapsto F_w(x) = F(x) - w$, where we set $F = \psi \circ \varphi^{-1}$. Then for any x with $\|x - \overline{x}\| = r$ we have

$$\langle x - \overline{x}, F_w(x)\rangle = r^2 + \langle x - \overline{x}, F(x) - x\rangle + \langle x - \overline{x}, \overline{x} - w\rangle > 0,$$

so by the Borsuk antipodal theorem there is an $x \in B(\overline{x}, r)$ such that $F(x) = w$. Thus the ball $B(\overline{x}, r/2)$ is covered by the image of conv $\{x_1, \ldots, x_{n+1}\}$ under $\psi \circ \varphi^{-1}$. In other words, there is an $a \in \Sigma_n$ such that $\overline{x} = \psi(a)$. Setting $u_i(t) = u_i(t,a)$ and

$$u(t) = \sum_{i=1}^n u_i(t)dt,$$

we easily observe that $u(t)$ is a definable selection of F (as its graph is the union of finitely many definable pieces of graphs of $x_i(t)$) and the integral of $u(t)$ over $[0,1]$ is $\overline{x}$. This completes the proof of the theorem. ∎

10. A class of variational problems. Most general existence theorems in calculus of variations and optimal control, going back to Tonelli, give existence of absolutely continuous solutions. Proofs of existence in "friendlier" classes of functions usually need some additional analytic properties of the data (e.g., positive definiteness of certain second order derivatives). We refer to [7, 30] for details and related discussions.

In this concluding section we apply the definable Lyapunov Theorem 9.1 to prove the existence of piecewise smooth solutions in a class of variational problem. In the simplest form problems of this class are stated as follows:

$$\text{minimize} \quad \int_0^T f(t,u(t))dt, \text{ s.t. } \int_0^T u(t)dt = a. \tag{10.1}$$

The problem, with all simplicity of its formulation, represents a wide array of variational and optimal control problems, including state-linear problems of optimal control (see, e.g., [20]) or many variational problems arising in mathematical economics for economies with a measure space of agents (e.g., the famous Aumann–Perles problem [1] and its various extensions).

We shall consider the problem under the assumption that the integrand is a definable function. The immediate gain we shall get from Theorem 9.1 is the existence of definable (hence, piecewise smooth) solutions. Namely, Theorem 9.1 implies the following result.

THEOREM 10.1. *Suppose the integrand f in* (10.1) *is a definable (in a certain o-minimal structure) extended-real-valued function. Then the value of the problem coincides with its value if we restrict the problem to the class of definable (in the same o-minimal structure) controls $u(t)$.*

Moreover, if the problem has a solution, then it has also a definable solution.

Proof. Indeed, consider the mapping

$$\varphi(t,u) = \begin{pmatrix} f(t,u) \\ u \end{pmatrix}$$

from $[0,T] \times \mathbb{R}^n$ into $\mathbb{R}^n$. (Strictly speaking, φ is a set-valued mapping which is single-valued on its domain, defined as above when $f(t,u) < \infty$ and equal to $\emptyset$ if $f(t,u) = \infty$.) If f is definable, then so is φ. So if a $u(t)$ is such that

$$\int_0^T u(t)dt = a, \quad \int_0^T f(t,u(t))dt = \alpha,$$

then Theorem 9.1, applied to the set-valued mapping $F(t) = \varphi(t,\mathbb{R}^n)$, guarantees the existence of a definable $v(t)$ such that

$$\int_0^T v(t)dt = a, \quad \int_0^T f(t,v(t))dt = \alpha,$$

and the theorem follows. □

Combining Theorem 10.1 with the existence theorem for (10.1) ([20], Theorem 10.3.1), we arrive at the following conclusion. Set

$$S^*(p) = \int_0^T f^*(t,p)dt,$$

where $f^*(t,p)$ is the Fenchel transform of the function $u \to f(t,u)$.

THEOREM 10.2. *Assume that f is definable in a certain o-minimal structure and lower semicontinuous in u. Set*

$$S(x) = \sup_p (p \cdot x - S^*(p)),$$

and let $\bar{p} \in \partial S(a)$. If $a \in \mathrm{ri}(\mathrm{dom}\ S)$ and $\bar{p} \in \mathrm{int}\ (\mathrm{dom}\ S^*)$, then (10.1) *has a definable solution.*

Thus, under the conditions of the last theorem, the problem has a piecewise smooth optimal control.

Acknowledgments. I am thankful to A. S. Lewis and the referees for careful reading and useful remarks.

A POLYNOMIAL PREDICTOR-CORRECTOR TRUST-REGION ALGORITHM FOR LINEAR PROGRAMMING*

GUANGHUI LAN†, RENATO D. C. MONTEIRO†, AND TAKASHI TSUCHIYA‡

Abstract. In this paper we present a scaling-invariant, interior-point, predictor-corrector type algorithm for linear programming (LP) whose iteration-complexity is polynomially bounded by the dimension and the logarithm of a certain condition number of the LP constraint matrix. At the predictor stage, the algorithm either takes the step along the standard affine scaling (AS) direction or a new trust-region type direction, whose construction depends on a scaling-invariant bipartition of the variables determined by the AS direction. This contrasts with the layered least squares direction introduced in S. Vavasis and Y. Ye [*Math. Program.*, 74 (1996), pp. 79–120], whose construction depends on multiple-layered partitions of the variables that are not scaling-invariant. Moreover, it is shown that the overall arithmetic complexity of the algorithm (weakly) depends on the right-hand side and the cost of the LP in view of the work involved in the computation of the trust region steps.

1. Introduction.

We consider the linear programming (LP) problem

$$\begin{array}{ll} \text{minimize}_x & c^T x \\ \text{subject to} & Ax = b,\ x \geq 0 \end{array} \tag{1}$$

and its associated dual problem

$$\begin{array}{ll} \text{maximize}_{(y,s)} & b^T y \\ \text{subject to} & A^T y + s = c,\ s \geq 0, \end{array} \tag{2}$$

where $A \in \Re^{m\times n}, c \in \Re^n$, and $b \in \Re^m$ are given, and the vectors $x, s \in \Re^n$, and $y \in \Re^m$ are the unknown variables.

Karmarkar in his seminal paper [4] proposed the first polynomially convergent interior-point method with an $\mathcal{O}(nL)$ iteration-complexity bound, where L is the size of the LP instance (1). The first path-following interior-point algorithm was proposed by Renegar in his breakthrough paper [17]. Renegar's method closely follows the primal central path and exhibits an $\mathcal{O}(\sqrt{n}L)$ iteration-complexity bound. The first path-following algorithm that simultaneously generates iterates in both the primal and dual spaces has been proposed by Kojima, Mizuno, and Yoshise [5] and Tanabe [19], based on ideas suggested by Megiddo [7]. In contrast to Renegar's algorithm, Kojima et al.'s algorithm has an $\mathcal{O}(nL)$ iteration-complexity bound. A primal-dual path-following with an $\mathcal{O}(\sqrt{n}L)$ iteration-complexity bound was subsequently obtained by

Kojima, Mizuno, and Yoshise [6] and Monteiro and Adler [11, 12] independently. Following these developments, many other primal-dual interior-point algorithms for linear programming have been proposed.

An outstanding open problem in optimization is whether there exists a strongly polynomial algorithm for linear programming, that is one whose complexity is bounded by a polynomial of m and n only. A major effort in this direction is due to Tardos [20] who developed a polynomial-time algorithm whose complexity is bounded by a polynomial of m, n, and L_A, where L_A denotes the size of A. Such an algorithm gives a strongly polynomial method for the important class of linear programming problems where the entries of A are either 1, -1, or 0, e.g., LP formulations of network flow problems. Tardos' algorithm consists of solving a sequence of "low-sized" LP problems by a standard polynomially convergent LP method and using their solutions to obtain the solution of the original LP problem.

The development of a method which works entirely in the context of the original LP problem and whose complexity is also bounded by a polynomial of m, n, and L_A is due to Vavasis and Ye [28]. Their method is a primal-dual, path-following, interior-point algorithm similar to the ones mentioned above except that it uses once in a while a crucial step, namely the least layered square (LLS) direction. They showed that their method has an $O(n^{3.5}(\log \bar{\chi}_A + \log n))$ iteration-complexity bound, where $\bar{\chi}_A$ is a condition number associated with A having the property that $\log \bar{\chi}_A = O(L_A)$. The number $\bar{\chi}_A$ was first introduced implicitly by Dikin [2] in the study of primal affine scaling (AS) algorithms, and was later studied by several researchers including Vanderbei and Lagarias [27], Todd [21], and Stewart [18]. Properties of $\bar{\chi}_A$ are studied in [3, 25, 26].

The complexity analysis of Vavasis and Ye's algorithm is based on the notion of crossover event, a combinatorial event concerning the central path. Intuitively, a crossover event occurs between two variables when one of them is larger than the other at a point in the central path and then becomes smaller asymptotically as the optimal solution set is approached. Vavasis and Ye showed that there can be at most $n(n-1)/2$ crossover events and that a distinct crossover event occurs every $O(n^{1.5}(\log \bar{\chi}_A + \log n))$ iterations, from which they deduced the overall $O(n^{3.5}(\log \bar{\chi}_A + \log n))$ iteration-complexity bound. In [10], an LP instance is given where the number of crossover events is $\Theta(n^2)$.

One difficulty of Vavasis and Ye's method is that it requires the explicit knowledge of $\bar{\chi}_A$ in order to determine a partition of the variables into layers used in the computation of the LLS step. This difficulty was remedied in a variant proposed by Megiddo, Mizuno, and Tsuchiya [8] which does not require the explicit knowledge of the number $\bar{\chi}_A$. They observed that at most n types of partitions arise as $\bar{\chi}_A$ varies from 1 to ∞, and that one of these can be used to compute the LLS step. Based on this idea, they developed a variant which computes the LLS steps for all these partitions and picks the one that yields the greatest duality gap reduction at the current iteration. Another approach that also remedies the above difficulty was proposed by Monteiro and Tsuchiya [14]. Their algorithm computes only one LLS step per iteration without any explicit knowledge of $\bar{\chi}_A$. This method is a predictor-corrector type algorithm like the one described in [9] except that at the predictor stage it takes a step along either the primal-dual AS step or the LLS step. In contrast to the LLS step used in Vavasis and Ye's algorithm, the partition of variables used for computing the LLS step is constructed from the information provided by the AS direction and hence does not require any knowledge on $\bar{\chi}_A$. Both of these variants ([8], [14]) have exactly the same overall complexity as Vavasis and Ye's algorithm.

Another disadvantage associated with Vavasis and Ye's algorithm, as well as its variants in [8] and [14], is that they are not scaling-invariant under the change of variables $(x, y, s) = (D\tilde{x}, \tilde{y}, D^{-1}\tilde{s})$, where D is a positive diagonal matrix. Hence, when these algorithms are applied to the scaled pair of LP problems, the number of iterations performed by it generally changes and is now bounded by $O(n^{3.5}\log(\bar{\chi}_{AD} + n))$, as AD is the coefficient matrix for the scaled pair of LP problems. On the other hand, using the notion of crossover events, LLS steps and a few other nontrivial ideas, Monteiro and Tsuchiya [15] have shown that, for the Mizuno-Todd-Ye predictor-corrector (MTY P-C) algorithm, the number of iterations needed to approximately traverse the central path from μ_0 to μ_f is bounded by $\mathcal{O}(n^{3.5}\log(\bar{\chi}_A^* + n) + T(\mu_0/\mu_f))$, where $\bar{\chi}_A^*$ is the infimum of $\bar{\chi}_{AD}$ as D varies over the set of positive diagonal matrices and $T(t) \equiv \min\{n^2\log(\log t), \log t\}$ for all $t > 0$. The condition number $\bar{\chi}_A^*$ is clearly scaling-invariant and the ratio $\bar{\chi}_A^*/\bar{\chi}_A$, as a function of A, can be arbitrarily small (see [15]). Hence, while the iteration-complexity obtained in [15] for the MTY P-C algorithm has the extra term $T(\mu_0/\mu_f)$, its first term can be considerably smaller than the bound obtained by Vavasis and Ye. Also note that, as μ_0/μ_f grows to ∞, the iteration-complexity bound obtained in [15] is smaller than the classical iteration-complexity bound of $\mathcal{O}(\sqrt{n}\log(\mu_0/\mu_f))$ established in [9] for the MTY P-C algorithm.

An interesting open problem is whether one can develop a scaling-invariant interior-point algorithm for linear programming whose iteration-complexity and arithmetic-complexity are bounded by a polynomial of n and $\log\bar{\chi}_A^*$. In this paper, we partially answer the above question by presenting a predictor-corrector type algorithm, referred to as the predictor-corrector trust-region (PC-TR) algorithm, which has $\mathcal{O}(n^{3.5}\log(\bar{\chi}_A^* + n))$ iteration-complexity bound. It is a predictor-corrector algorithm similar to the one developed in [9] except that, at the predictor stage, it takes a step along either the AS direction or a trust-region (TR) type step. Unlike the LLS direction used in the predictor-corrector algorithm of [14], the TR direction depends on a scaling-invariant bipartition of the variables and hence it is a scaling-invariant direction. Its iteration can be briefly described as follows. First, the AS direction is computed and a test involving this direction is performed to determine whether the TR step is needed. If the TR direction is not needed, a step along the AS direction, followed by a standard corrector step, is taken as usual. Otherwise, the AS direction determines a scaling-invariant bipartition of the variables which allows to construct a pair of primal and dual trust region subproblems whose optimal solutions yield the TR direction. Then the algorithm takes a step along either the AS or the TR direction whichever yields the largest duality gap reduction. Moreover, we show that the overall arithmetic complexity of the PC-TR algorithm (weakly) depends also on b and c due to work involved in the computation of the trust region steps.

The organization of the paper is as follows. Section 2 consists of six subsections. In subsection 2.1, we review the notion of the primal-dual central path and its associated two norm neighborhoods. Subsection 2.2 introduces the notion of the condition number $\bar{\chi}_A$ of a matrix A and describes the properties of $\bar{\chi}_A$ that will be useful in our analysis. Subsection 2.3 reviews the AS step and the corrector (or centrality) step which are the basic ingredients of several well-known, interior-point algorithms. Subsection 2.4 motivates and formally introduces the TR step. Subsection 2.5 describes an interior-point algorithm based on these TR steps, which we refer to as the predictor-corrector trust-region (PC-TR) algorithm, and states one of main results of this paper which gives an upper bound on the iteration-complexity of the PC-TR algorithm. Subsection 2.6 introduces a variant of the PC-TR algorithm with the same iteration-complexity as the latter one and discusses a procedure for computing the TR

steps used by this variant. It also states the other main result of this paper regarding the overall arithmetic complexity of the above variant of the PC-TR algorithm. Section 3, which consists of three subsections, introduces some basic tools which are used in our convergence analysis. Subsection 3.1 discusses the notion of crossover events. Subsection 3.2 introduces the LLS direction and states an approximation result that provides an estimation of the closeness between the AS direction and the LLS direction. Subsection 3.3 reviews an important result, which basically provides sufficient conditions for the occurrence of crossover events. Section 4 is dedicated to the proof of the main result stated in subsection 2.5. Section 5 provides the proof of the other main result stated in subsection 2.6 regarding the arithmetic complexity of the variant of the PC-TR algorithm. Finally, the Appendix gives the proof of an important lemma used in subsection 2.4 to motivate the definition of the TR step.

The following notation is used throughout our paper. We denote the vector of all ones by e. Its dimension is always clear from the context. The symbols $\Re^n$, $\Re^n_+$, and $\Re^n_{++}$ denote the n-dimensional Euclidean space, the nonnegative orthant of $\Re^n$, and the positive orthant of $\Re^n$, respectively. The set of all $m \times n$ matrices with real entries is denoted by $\Re^{m\times n}$. If J is a finite index set, then $|J|$ denotes its cardinality, that is the number of elements of J. For $J \subseteq \{1,\ldots,n\}$ and $w \in \Re^n$, we let w_J denote the subvector $[w_i]_{i\in J}$; moreover, if E is an $m \times n$ matrix, then E_J denotes the $m \times |J|$ submatrix of E corresponding to J. For a vector $w \in \Re^n$, we let $\max(w)$ and $\min(w)$ denote the largest and the smallest component of w, respectively; $\mathrm{Diag}(w)$ denote the diagonal matrix whose ith diagonal element is w_i for $i = 1,\ldots,n$; and for an arbitrary $\alpha \in \Re$, w^α denote the vector $[\mathrm{Diag}(w)]^\alpha e$ whenever it is well-defined. For two vectors $u, v \in \Re^n$, uv denotes their Hadamard product, i.e., the vector in $\Re^n$ whose ith component is $u_i v_i$. The Euclidean norm, the 1-norm, and the ∞-norm are denoted by $\|\cdot\|$, $\|\cdot\|_1$, and $\|\cdot\|_\infty$, respectively. For a matrix E, $\mathrm{Im}(E)$ denotes the subspace generated by the columns of E, and $\mathrm{Ker}(E)$ denotes the subspace orthogonal to the rows of E. The superscript ^{T} denotes transpose.

2. The problem and algorithm. In this section we propose a predictor-corrector, primal-dual, interior-point algorithm with trust-region steps for solving linear programming (1) and (2). We also present the main convergence results for the algorithm. One result establishes a polynomial iteration-complexity bound, namely, $O(n^{3.5}\log(\bar\chi_A^* + n + \varepsilon_0^{-1}))$, where ε_0 is a constant and $\bar\chi_A^*$ is a certain scaling-invariant condition number associated with the constraint matrix A, and the other result establishes a polynomial arithmetic complexity bound for the algorithm.

2.1. The central path. In this subsection we introduce the pair of primal and dual linear programs and the assumptions used in our development. We also describe the associated primal-dual central path and its corresponding two-norm neighborhoods.

Given $A \in \Re^{m\times n}$, $c \in \Re^n$, and $b \in \Re^m$, consider the pairs of linear programs (1) and (2), where $x \in \Re^n$ and $(y,s) \in \Re^m \times \Re^n$ are their respective variables. The set of strictly feasible solutions for these problems are

$$\mathcal{P}^{++} \equiv \{x \in \Re^n : Ax = b,\ x > 0\},$$
$$\mathcal{D}^{++} \equiv \{(y,s) \in \Re^{m\times n} : A^T y + s = c,\ s > 0\},$$

respectively. Throughout the paper we make the following assumptions on the pair of problems (1) and (2).

A.1 $\mathcal{P}^{++}$ and $\mathcal{D}^{++}$ are nonempty.

A.2 The rows of A are linearly independent.

Under the above assumptions, it is well known that for any $\nu > 0$ the system,

$$xs = \nu e, \tag{3}$$

$$Ax = b, \quad x > 0, \tag{4}$$

$$A^T y + s = c, \quad s > 0, \tag{5}$$

has a unique solution (x, y, s), which we denote by $(x(\nu), y(\nu), s(\nu))$. The central path is the set consisting of all these solutions as ν varies in $(0, \infty)$. As ν converges to zero, the path $(x(\nu), y(\nu), s(\nu))$ converges to a primal-dual optimal solution (x^*, y^*, s^*) for problems (1) and (2). Given a point $w = (x, y, s) \in \mathcal{P}^{++} \times \mathcal{D}^{++}$, its duality gap and its normalized duality gap are defined as $x^T s$ and $\mu = \mu(x, s) \equiv x^T s/n$, respectively, and the point $(x(\mu), y(\mu), s(\mu))$ is said to be the central point associated with w. Note that $(x(\mu), y(\mu), s(\mu))$ also has normalized duality gap μ. We define the proximity measure of a point $w = (x, y, s) \in \mathcal{P}^{++} \times \mathcal{D}^{++}$ with respect to the central path by

$$\eta(w) \equiv \|xs/\mu - e\|.$$

Clearly, $\eta(w) = 0$ if and only if $w = (x(\mu), y(\mu), s(\mu))$, or equivalently w coincides with its associated central point. The two-norm neighborhood of the central path with opening $\beta > 0$ is defined as

$$\mathcal{N}(\beta) \equiv \{w = (x, y, s) \in \mathcal{P}^{++} \times \mathcal{D}^{++} : \eta(w) \le \beta\}.$$

Finally, for any point $w = (x, y, s) \in \mathcal{P}^{++} \times \mathcal{D}^{++}$, we define

$$\delta(w) \equiv s^{1/2} x^{-1/2} \in \Re^n. \tag{6}$$

The following propositions provide important estimates which are used throughout our analysis.

PROPOSITION 2.1. *For every $0 < \nu_1 \le \nu_2$, we have*

$$s(\nu_1) \le n s(\nu_2) \quad \text{and} \quad x(\nu_1) \le n x(\nu_2). \tag{7}$$

Proof. Please refer to Lemma 16 of Vavasis and Ye [28]. □

PROPOSITION 2.2. *Let $w = (x, y, s) \in \mathcal{N}(\beta)$ for some $\beta \in (0, 1)$ be given and define $\delta \equiv \delta(w)$. Let $w(\mu) = (x(\mu), y(\mu), s(\mu))$ be the central point associated with w. Then:*

$$\frac{1-\beta}{(1+\beta)^{1/2}}\,\delta \le \frac{s(\mu)}{\sqrt{\mu}} \le \frac{(1+\beta)^{1/2}}{1-\beta}\,\delta.$$

Proof. This result is summarized in Proposition 2.1 in [14]. □

2.2. Condition number. In this subsection we define a certain condition number associated with the constraint matrix A and state the properties of $\bar{\chi}_A$ which will play an important role in our analysis.

Let $\mathcal{D}$ denote the set of all positive definite $n \times n$ diagonal matrices and define

$$\bar{\chi}_A \equiv \sup\Big\{ \|A^T (A\tilde{D}A^T)^{-1} A\tilde{D}\| \ : \tilde{D} \in \mathcal{D} \Big\}$$

$$= \sup\Big\{ \tfrac{\|A^T y\|}{\|c\|} : y = \operatorname{argmin}_{\tilde{y} \in \Re^n} \|\tilde{D}^{1/2}(A^T \tilde{y} - c)\| \text{ for some } 0 \ne c \in \Re^n \text{ and } \tilde{D} \in \mathcal{D} \Big\}. \tag{8}$$

The parameter $\bar{\chi}_A$ plays a fundamental role in the complexity analysis of algorithms for linear programming and least square problems (see [28] and references therein). Its finiteness has been firstly established by Dikin and Zorkalcev [2]. Other authors have also given alternative derivations of the finiteness of $\bar{\chi}_A$ (see, for example, Stewart [18], Todd [21], and Vanderbei and Lagarias [27]).

We summarize in the next proposition a few important facts about the parameter $\bar{\chi}_A$.

PROPOSITION 2.3. *Let $A \in \Re^{m\times n}$ with full row rank be given. Then, the following statements hold:*

(a) $\bar{\chi}_{GA} = \bar{\chi}_A$ *for any nonsingular matrix* $G \in \Re^{m\times m}$;

(b) $\bar{\chi}_A = \max\{\|G^{-1}A\| : G \in \mathcal{G}\}$ *where* $\mathcal{G}$ *denotes the set of all* $m\times m$ *nonsingular submatrices of* A;

(c) *if the* $m \times m$ *identity matrix is a submatrix of* A *and* $\tilde{A}$ *is an* $r \times n$ *submatrix of* A, *then* $\|\tilde{G}^{-1}\tilde{A}\| \le \bar{\chi}_A$ *for every* $r \times r$ *nonsingular submatrix* $\tilde{G}$ *of* $\tilde{A}$.

Proof. Statement (a) readily follows from the definition (8). The inequality $\bar{\chi}_A \ge \max\{\|G^{-1}A\| : G \in \mathcal{G}\}$ is established in Lemma 3 of [28] while the proof of the reverse inequality is given in [21] (see also Theorem 1 of [22]). Hence, (b) holds. A proof of (c) can be found in [14]. □

The condition number $\bar{\chi}_A^*$, defined by taking the infimum of the condition number $\bar{\chi}_{AD}$ as D varies over the set of positive diagonal matrices, that is, $\bar{\chi}_A^* \equiv \inf\{\bar{\chi}_{AD} : D \in \mathcal{D}\}$, also plays an important role in the convergence analysis for our algorithm. Note that by definition, $\bar{\chi}_A^*$ is a scaling-invariant quantity.

2.3. Predictor-corrector step. In this subsection we describe the well-known predictor-corrector (P-C) iteration which is used by several interior-point algorithms (see for example Mizuno et al. [9]). We also describe the properties of this iteration which will be used in our analysis.

The P-C iteration consists of two steps, namely the predictor (or AS) step and the corrector (or centrality) step. The search direction used by either step from a current point in $(x, y, s) \in \mathcal{P}^{++} \times \mathcal{D}^{++}$ is the solution of the following linear system of equations

$$\begin{aligned} S\Delta x + X\Delta s &= \sigma\mu e - xs, \\ A\Delta x &= 0, \\ A^T\Delta y + \Delta s &= 0, \end{aligned} \tag{9}$$

where $\mu = \mu(x, s)$ and $\sigma \in \Re$ is a prespecified parameter, commonly referred to as the centrality parameter. When $\sigma = 0$, we denote the solution of (9) by $(\Delta x^{\mathrm{a}}, \Delta y^{\mathrm{a}}, \Delta s^{\mathrm{a}})$ and refer to it as the primal-dual affine scaling direction at w; it is the direction used in the predictor step of the P-C iteration. When $\sigma = 1$, we denote the solution of (9) by $(\Delta x^{\mathrm{c}}, \Delta y^{\mathrm{c}}, \Delta s^{\mathrm{c}})$ and refer to it as the corrector direction at w; it is the direction used in the corrector step of the P-C iteration.

We are now ready to describe the entire predictor-corrector iteration. Suppose that a constant $\beta \in (0, 1/4]$ and a point $w = (x, y, s) \in \mathcal{N}(\beta)$ is given. The P-C iteration generates another point $(x^+, y^+, s^+) \in \mathcal{N}(\beta)$ as follows. It first moves along the direction $(\Delta x^{\mathrm{a}}, \Delta y^{\mathrm{a}}, \Delta s^{\mathrm{a}})$ until it hits the boundary of the enlarged neighborhood $\mathcal{N}(2\beta)$. More specifically, it computes the point $w^{\mathrm{a}} = (x^{\mathrm{a}}, y^{\mathrm{a}}, s^{\mathrm{a}}) \equiv (x, y, s) + \alpha_{\mathrm{a}}(\Delta x^{\mathrm{a}}, \Delta y^{\mathrm{a}}, \Delta s^{\mathrm{a}})$ where

$$\alpha_{\mathrm{a}} \equiv \sup\{\alpha \in [0, 1] : (x, y, s) + \alpha(\Delta x^{\mathrm{a}}, \Delta y^{\mathrm{a}}, \Delta s^{\mathrm{a}}) \in \mathcal{N}(2\beta)\}. \tag{10}$$

Next, the P-C iteration generates a point inside the smaller neighborhood $\mathcal{N}(\beta)$ by taking a unit step along the corrector direction $(\Delta x^{\rm c}, \Delta y^{\rm c}, \Delta s^{\rm c})$ at the point $w^{\rm a}$; that is, it computes the point $(x^+, y^+, s^+) \equiv (x^{\rm a}, y^{\rm a}, s^{\rm a}) + (\Delta x^{\rm c}, \Delta y^{\rm c}, \Delta s^{\rm c}) \in \mathcal{N}(\beta)$. The successive repetition of this iteration leads to the so-called Mizuno–Todd–Ye (MTY) predictor-corrector algorithm (see [9]).

Our method is very similar to the algorithm of [9] except that it sometimes replaces the AS step by the trust-region step described in the next subsection. The insertion of the trust region step in the above MTY predictor-corrector algorithm guarantees that the modified method has the finite termination property. The trust-region step is taken only when it yields a point with a smaller duality gap than the one obtained from the AS step as described above.

In the remaining part of this subsection, we discuss some properties of the P-C iteration and the primal-dual AS direction. For a proof of the next two propositions, we refer the reader to [9].

PROPOSITION 2.4 (predictor step). *Suppose that $w = (x, y, s) \in \mathcal{N}(\beta)$ for some constant $\beta \in (0, 1/2]$. Let $\Delta w^{\rm a} = (\Delta x^{\rm a}, \Delta y^{\rm a}, \Delta s^{\rm a})$ denote the affine scaling direction at $w^{\rm a}$ and let $\alpha_{\rm a}$ be the step-size computed according to* (10)*. Then the following statements hold:*

(a) *the point $w + \alpha \Delta w^{\rm a}$ has normalized duality gap $\mu(\alpha) = (1-\alpha)\mu$ for all $\alpha \in \Re$;*

(b) *$\alpha_{\rm a} \geq \sqrt{\beta/n}$ and hence $\mu(\alpha_{\rm a})/\mu \leq 1 - \sqrt{\beta/n}$.*

PROPOSITION 2.5 (corrector step). *Suppose that $w = (x, y, s) \in \mathcal{N}(2\beta)$ for some constant $\beta \in (0, 1/4]$ and let $(\Delta x^{\rm c}, \Delta y^{\rm c}, \Delta s^{\rm c})$ denote the corrector step at w. Then, $w + \Delta w^{\rm c} \in \mathcal{N}(\beta)$. Moreover, the (normalized) duality gap of $w + \Delta w^{\rm c}$ is the same as that of w.*

For the sake of future usage, we mention the following alternative characterization of the primal-dual AS direction whose verification is straightforward:

$$\Delta x^{\rm a} \equiv \mathrm{argmin}_{p \in \Re^n} \left\{ \|\delta(x+p)\|^2 : Ap = 0 \right\}, \tag{11}$$

$$(\Delta y^{\rm a}, \Delta s^{\rm a}) \equiv \mathrm{argmin}_{(r,q) \in \Re^m \times \Re^n} \left\{ \|\delta^{-1}(s+q)\|^2 : A^T r + q = 0 \right\}, \tag{12}$$

where $\delta \equiv \delta(w)$. For a search direction $(\Delta x, \Delta y, \Delta s)$ at a point (x, y, s), the quantity

$$\begin{aligned} (Rx(w), Rs(w)) &\equiv \left(\frac{\delta(x+\Delta x)}{\sqrt{\mu}}, \frac{\delta^{-1}(s+\Delta s)}{\sqrt{\mu}} \right) \\ &= \left(\frac{x^{1/2}s^{1/2} + \delta \Delta x}{\sqrt{\mu}}, \frac{x^{1/2}s^{1/2} + \delta^{-1}\Delta s}{\sqrt{\mu}} \right) \end{aligned} \tag{13}$$

appears quite often in our analysis. We refer to it as the *residual* of $(\Delta x, \Delta y, \Delta s)$. Note that if $(Rx^{\rm a}(w), Rs^{\rm a}(w))$ is the residual of $(\Delta x^{\rm a}, \Delta y^{\rm a}, \Delta s^{\rm a})$, then

$$Rx^{\rm a}(w) = -\frac{1}{\sqrt{\mu}} \delta^{-1} \Delta s^{\rm a}, \quad Rs^{\rm a}(w) = -\frac{1}{\sqrt{\mu}} \delta \Delta x^{\rm a}, \tag{14}$$

and

$$Rx^{\rm a}(w) + Rs^{\rm a}(w) = \frac{x^{1/2}s^{1/2}}{\sqrt{\mu}}, \tag{15}$$

due to the fact that $(\Delta x^{\rm a}, \Delta y^{\rm a}, \Delta s^{\rm a})$ satisfies the first equation in (9) with $\sigma = 0$. The following quantity is used in the test to determine when the trust-region step should be used in place of the AS step:

$$\varepsilon_\infty^{\rm a}(w) \equiv \max_i \left\{ \min \left\{ |Rx_i^{\rm a}(w)|, |Rs_i^{\rm a}(w)| \right\} \right\}. \tag{16}$$

We end this section by providing some estimates involving the residual of the AS direction.

LEMMA 2.6. *Suppose that $w = (x, y, s) \in \mathcal{N}(\beta)$ for some $\beta \in (0, 1/4]$. Then, for all $i = 1, \ldots, n$, we have*

$$\max\{|Rx_i^{\mathrm{a}}(w)|, |Rs_i^{\mathrm{a}}(w)|\} \geq \frac{\sqrt{1-\beta}}{2} \geq \frac{1}{4}.$$

Proof. Assume for a contradiction that for some $i \in \{1, \ldots, n\}$, $\max\{|Rx_i^{\mathrm{a}}(w)|, |Rs_i^{\mathrm{a}}(w)|\} < \sqrt{1-\beta}/2$. Then, using (15), we obtain the following contradiction:

$$\frac{x_i^{1/2} s_i^{1/2}}{\sqrt{\mu}} = Rx_i^{\mathrm{a}}(w) + Rs_i^{\mathrm{a}}(w) \leq |Rx_i^{\mathrm{a}}(w)| + |Rs_i^{\mathrm{a}}(w)| < \sqrt{1-\beta} \leq \frac{x_i^{1/2} s_i^{1/2}}{\sqrt{\mu}}. \qquad \square$$

2.4. Trust region step. In this subsection we introduce a new type of search step, namely, the trust-region (TR) step, and describe some properties about it.

The definition of the TR step is motivated by the following result regarding the duality gap reduction obtained by moving along a search direction satisfying certain conditions. This result can be viewed as a generalization of Lemma 4.6 in [14], and its proof is given in the Appendix.

LEMMA 2.7. *Let $w \in \mathcal{N}(\beta)$ with $\beta \in (0, 1/2]$ and a direction $\Delta w = (\Delta x, \Delta y, \Delta s)$ satisfying $A\Delta x = 0$ and $A^T \Delta y + \Delta s = 0$ be given. Then, for any positive scalar γ satisfying*

$$\left(4\sqrt{2} + \sqrt{2(1+\beta)}\right)\gamma \leq \frac{\beta - 2\beta^2}{1 + 2\beta} \tag{17}$$

and for any bipartition (B, N) of $\{1, 2, \ldots, n\}$, the condition

$$\max\left\{\frac{\|\delta_B \Delta x_B\|}{\sqrt{\mu}}, \frac{\|\delta_N^{-1} \Delta s_N\|}{\sqrt{\mu}}\right\} \leq \gamma \tag{18}$$

implies that

$$\frac{\mu(w + \alpha_\tau \Delta w)}{\mu(w)} \leq \frac{\sqrt{1+\beta} + \gamma}{2\gamma} \max\{\|Rx_N\|, \|Rs_B\|\}, \tag{19}$$

where $\alpha_\tau \equiv \sup\{\alpha \in [0, 1] : w + \alpha \Delta w \in \mathcal{N}(2\beta)\}$ and $(Rx(w), Rs(w))$ is defined in (13).

A trivial application of Lemma 2.7 is as follows. Let (B, N) be the AS-bipartition at w, i.e.,

$$\begin{aligned} B = B(w) &\equiv \{i : |Rs_i^a(w)| \leq |Rx_i^a(w)|\}, \\ N = N(w) &\equiv \{i : |Rs_i^a(w)| > |Rx_i^a(w)|\}. \end{aligned} \tag{20}$$

and let

$$\varepsilon_2^{\mathrm{a}}(w) := \max\{\|Rx_N^a\|, \|Rs_B^a\|\}. \tag{21}$$

Then, in view of Lemma 2.7 and identity (14), the condition $\varepsilon_2^{\mathrm{a}}(w) \leq \gamma$ implies that

$$\frac{\mu(w + \alpha \Delta w^{\mathrm{a}})}{\mu(w)} \leq \frac{\sqrt{1+\beta} + \gamma}{2\gamma} \varepsilon_2^{\mathrm{a}}(w),$$

showing that the smaller the quantity $\varepsilon_2^{\mathrm{a}}(w)$ is, the larger the reduction of the duality gap will be, as it moves from w along the AS direction $\Delta w^{\mathrm{a}}(w)$.

However, a more interesting application of Lemma 2.7 is towards deriving a new scaling-invariant search direction, which we refer to as the trust-region direction (see the definition below). This direction is the one which minimizes the right-hand side of (19) subject to the condition (18) when $(B, N) = (B(w), N(w))$. To define this direction, set $(B, N) = (B(w), N(w))$ and consider the two subproblems:

$$\begin{array}{ll} \text{minimize} & \|\delta_N(x_N + \Delta x_N)\| \\ \text{subject to} & \|\delta_B \Delta x_B\|/\sqrt{\mu} \le \gamma_p \\ & A\Delta x = 0 \end{array} \tag{22}$$

and

$$\begin{array}{ll} \text{minimize} & \|\delta_B^{-1}(s_B + \Delta s_B)\| \\ \text{subject to} & \|\delta_N^{-1}\Delta s_N\|/\sqrt{\mu} \le \gamma_d \\ & A^T\Delta y + \Delta s = 0 \end{array} . \tag{23}$$

DEFINITION. *Given $w \in \mathcal{N}(\beta)$ and positive scalars γ_p and γ_d, let $\Delta x^\tau(w;\gamma_p)$ and $(\Delta y^\tau(w;\gamma_d), \Delta s^\tau(w;\gamma_d))$ denote optimal solutions of subproblems* (22) *and* (23)*, respectively. The direction $\Delta w^\tau(w;\gamma_p,\gamma_d) \equiv (\Delta x^\tau(w;\gamma_p), \Delta y^\tau(w;\gamma_d), \Delta s^\tau(w;\gamma_d))$ is then referred to as a trust-region direction at w with radius pair (γ_p,γ_d).*

We now make a few observations regarding the above definition. First, it can be easily shown that both subproblems (22) and (23) must have optimal solutions although their optimal solutions are not necessarily unique. We will refer to any pair of optimal solutions of subproblems (22) and (23) as a trust-region step corresponding to the triple $(w;\gamma_p,\gamma_d)$. Second, if $\varepsilon_2^{\mathrm{a}}(w) \le \min\{\gamma_p,\gamma_d\}$, then the quantity $\varepsilon_2^\tau(w;\gamma_p,\gamma_d)$ defined as

$$\varepsilon_2^\tau(w;\gamma_p,\gamma_d) := \max\left\{\|Rx_N^\tau(w)\|, \|Rs_B^\tau(w)\|\right\}, \tag{24}$$

where $(Rx^\tau(w), Rs^\tau(w))$ denotes the residual pair for the the TR direction $\Delta w^\tau(w;\gamma_p,\gamma_d)$, satisfies $\varepsilon_2^\tau(w;\gamma_p,\gamma_p) \le \varepsilon_2^{\mathrm{a}}(w)$. In other words, whenever the AS direction is a reasonably good direction in the sense that $\varepsilon_2^{\mathrm{a}}(w)$ is sufficiently small, then the TR step is likely to be an even better direction in that it makes the right-hand side of (19) smaller. Third, even though our definition of a TR step does not uniquely characterize it, one can easily modify the definition to make it uniquely defined in the following way. Without loss of generality, we consider only the primal direction, which previously was defined as an optimal solution of (22). This clearly implies that Δx_N^τ is uniquely defined. Now, minimizing the quantity $\|\delta_B\Delta x_B\|$ under the condition that $A\Delta x = 0$ and $\Delta x_N = \Delta x_N^\tau$ uniquely determines the component Δx_B, and hence the whole primal TR step. We note, however, that our analysis does not require that the TR step be uniquely determined and in fact works for any pair of optimal solutions of (22) and (23).

2.5. Main algorithm and the convergence results. In this subsection, we describe our algorithm, namely, the predictor-corrector trust-region (PC-TR) algorithm, to solve the linear programming problem (1) and (2), and then state the main result of this paper which guarantees the convergence of the method in a strong sense. More specifically, this result states that the outer iteration-complexity bound for our method depends only on n and the scaling-invariant condition number $\bar{\chi}_A^*$.

We start by stating our predictor-corrector trust-region algorithm.

PC-TR Algorithm:

Let $0 < \beta \le 1/4$ and $\gamma > 0$ satisfying (17), $w^0 \in \mathcal{N}(\beta)$ and a scalar $\varepsilon_0 \in (0, \gamma/3]$ be given.
Set $\mu_0 \equiv \mu(w^0)$ and $k = 0$.

1) Set $w = w^k$, compute the AS step $\Delta w^{\rm a}$ at w and the residual $\varepsilon_2^{\rm a}(w)$ as defined in (21);
2) If $\varepsilon_2^{\rm a}(w) > \varepsilon_0$, then set $w \leftarrow w + \alpha_a \Delta w^{\rm a}$, where α_a is defined as in (10) and go to 6);
3) Otherwise, compute the TR step $\Delta w^\tau = \Delta w^\tau(w; \gamma_p, \gamma_d)$, for scalars $\gamma_p, \gamma_d \in [\gamma/2, 2\gamma]$;
4) Let $w^\tau = w + \alpha_\tau \Delta w^\tau$, where $\alpha_\tau \equiv \sup\{\alpha \in [0,1] : w + \alpha \Delta w^\tau \in \mathcal{N}(2\beta)\}$;
5) If $\mu(w^\tau) < (1 - \alpha_{\rm a})\mu$, then set $w \leftarrow w^\tau$, or else set $w \leftarrow w + \alpha_{\rm a} \Delta w^{\rm a}$;
6) If $\mu(w) = 0$, then **stop**;
7) Compute the corrector step $\Delta w^{\rm c}$ at w and set $w \leftarrow w + \Delta w^{\rm c}$;
8) Set $w^{k+1} = w$, increment k by 1 and go to 1).

End

We now make a few comments about the above algorithm. In the main body of the algorithm, step 2 followed by step 7 is a standard predictor-corrector iteration of the type described in subsection 2.3. This iteration is always performed in those iterations for which $\varepsilon_2^{\rm a}(w) > \varepsilon_0(w)$. In order to save computation time, the TR step is computed only in those iterations for which the current iterate w satisfies $\varepsilon_2^{\rm a}(w) \le \varepsilon_0$. In these iterations, the algorithm performs either a standard predictor-corrector iteration or a TR-corrector iteration depending on which of the two iterations gives the lower reduction of the duality gap. This test is performed in step 5 since the term $(1-\alpha_{\rm a})\mu$ is the normalized duality gap obtained when the AS step is taken (see Proposition 2.4(a)).

For the sake of future reference, we note that (17) and the assumption that $\beta \in (0, 1/4]$ imply that

$$\gamma \le \frac{1}{20}, \quad \varepsilon_0 \le \frac{\gamma}{3} \le \frac{1}{60}. \tag{25}$$

We refer to an iteration where the TR step is computed as a *TR-iteration*. The following result is immediate from Lemma 2.7 and the definition of a TR-iteration.

PROPOSITION 2.8. *Let w be an iterate of the PC-TR algorithm and assume that the next iterate w^+ after w is obtained by means of a TR-iteration. Then,*

$$\frac{\mu(w^+)}{\mu(w)} \le \frac{\sqrt{1+\beta}+\gamma}{2\gamma}\varepsilon_2^\tau(w;\gamma_p,\gamma_d) \le \frac{\sqrt{1+\beta}+\gamma}{2\gamma}\varepsilon_2^{\rm a}(w) \le \frac{\sqrt{1+\beta}+\gamma}{2\gamma}\varepsilon_0 \le \frac{1}{4}. \tag{26}$$

Proof. First note that if the iteration from w is a TR-iteration, then we have $\varepsilon_2^{\rm a}(w) \le \varepsilon_0 \le \gamma/3 \le \min\{\gamma_p, \gamma_d\}$. The first three inequalities in (26) follow from Lemma 2.7, the previous observation, and the second observation after (23). Moreover, the last inequality in (26) follows from (25) and the fact that $\beta \le 1/4$. ∎

We have the following convergence result for the above algorithm.

THEOREM 2.9. *The PC-TR algorithm described above finds a primal-dual optimal solution $w = (x^*, s^*, y^*)$ of (1) and (2) in at most $\mathcal{O}(n^{3.5}\log(\bar{\chi}_A^* + n + \varepsilon_0^{-1}))$ iterations, of which $\mathcal{O}(n^3 \log(\bar{\chi}_A^* + n + \varepsilon_0^{-1})/\log \varepsilon_0^{-1})$ are TR-iterations. In particular, if $\varepsilon_0^{-1} = \mathcal{O}((n + \bar{\chi}_A^*)^\kappa)$ for some constant $\kappa > 0$, then the total number of iterations is bounded*

by $\mathcal{O}(n^{3.5}\log(\bar{\chi}_A^* + n))$. *Also, if* $\varepsilon_0^{-1} = \Omega((n+\bar{\chi}_A^*)^\kappa)$ *for some constant* $\kappa > 0$, *then the number of TR-iterations is bounded by* $\mathcal{O}(n^3)$.

Note that the PC-TR algorithm is scaling-invariant; i.e., if the change of variables $(x, y, s) = (D\tilde{x}, \tilde{y}, D^{-1}\tilde{s})$ for some $D \in \mathcal{D}$ is performed on the pair of problems (1) and (2) and the PC-TR algorithm is applied to the new dual pair of scaled problems, then the sequence of iterates $\tilde{w}^k$ generated satisfies $(x^k, y^k, s^k) = (D\tilde{x}^k, \tilde{y}^k, D^{-1}\tilde{s}^k)$ for all $k \geq 1$, as long as the initial iterate $\tilde{w}^0 \in \mathcal{N}(\beta)$ in the $\tilde{w}$-space satisfies $(x^0, y^0, s^0) = (D\tilde{x}^0, \tilde{y}^0, D^{-1}\tilde{s}^0)$. For this reason, the PC-TR algorithm should have an iteration-complexity bound which does not depend on the scaled space where the sequence of iterates is generated. Indeed, the iteration-complexity bound stated in Theorem 2.9 is scaling-invariant since the condition number $\bar{\chi}_A^*$ is too. It is worth noting that the PC-TR algorithm is also scaling-invariant with respect to a more strict notion of scaling invariance described in Tunçel [24], which corresponds to choosing the set $\mathcal{D}$ in the above defintion as the full automorphism group of R_+^n. Note that the latter set is larger than the set of positive diagonal maps since it contains the permutation maps, and hence it leads to a stronger notion of scaling invariance.

We note also that, to prove Theorem 2.9, it suffices to show that the the number of iterations of the PC-TR algorithm applied to (1) and (2) is bounded by $O(n^{3.5}\log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$. Indeed, since in the D-scaled space, the iterates can also be viewed as being generated by the PC-TR algorithm (started from a different point), then its complexity is also bounded by

$$O(n^{3.5}\log(\bar{\chi}_{AD} + n + \varepsilon_0^{-1})), \tag{27}$$

and hence by the infimum of (27) over all $D \in \mathcal{D}$, that is, by $O(n^{3.5}\log(\bar{\chi}_A^* + n + \varepsilon_0^{-1}))$.

Finally, Theorem 2.9 does not deal with the overall arithmetic complexity of the PC-TR algorithm. This issue will be dealt with in the next subsection and section 5, where we discuss the arithmetic complexity involved in the computation of a TR step for a suitable variant of the PC-TR algorithm. Roughly speaking, we will derive a bound on the number of arithmetic operations required to compute a TR step which depends on the ratio between the current duality gap and the initial duality gap. This implies that the overall arithmetic complexity obtained in this paper for the above variant of the PC-TR algorithm depends (weakly) on b and c, though its number of iterations just depends on A as shown in Theorem 2.13.

2.6. Computing the TR step. In this subsection, we present an algorithm to compute the TR step and derive the arithmetic complexity for the PC-TR algorithm.

For the sake of simplicity, we focus our discussion on the computation of the primal TR direction. We start by introducing a search direction that is closely related to the optimal solution of (22). Given a scalar $\lambda > 0$ and $w \in \mathcal{P}^{++} \times \mathcal{D}^{++}$, consider the following direction defined as

$$\Delta x(\lambda) := \operatorname{argmin}\left\{\|\delta_N(x_N + \Delta x_N)\|^2 + \lambda\|\delta_B \Delta x_B\|^2 : A\Delta x = 0\right\}, \tag{28}$$

where $\delta \equiv \delta(w)$ and $(B, N) \equiv (B(w), N(w))$. Note that this direction is well-defined in the sense that the above optimization problem has a unique optimal solution. Now, let $\psi_p : \Re_{++} \to \Re_+$ denote the mapping given by

$$\psi_p(\lambda) \equiv \frac{\|\delta_B \Delta x_B(\lambda)\|}{\sqrt{\mu}}, \tag{29}$$

where $\mu \equiv \mu(w)$.

The following technical result can be proved regarding the functions $\Delta x(\lambda)$ and $\psi_p(\lambda)$. Note that in the discussion below, we denote the derivatives of $\Delta x(\lambda)$ and $\psi_p(\lambda)$ as $\Delta x'(\lambda)$ and $\psi_p'(\lambda)$, respectively.

LEMMA 2.10. *The following statements hold:*

(a) *The limits* $\Delta x(0) \equiv \lim_{\lambda\to 0^+} \Delta x(\lambda)$ *and* $\psi_p(0) \equiv \lim_{\lambda\to 0^+} \psi_p(\lambda)$ *exist and are given by*

$$\Delta x_N(0) = \operatorname{argmin}\left\{\|\delta_N(x_N + \Delta x_N)\|^2 : A_N \Delta x_N \in \operatorname{Im}(A_B)\right\}, \tag{30}$$

$$\Delta x_B(0) = \operatorname{argmin}\left\{\|\delta_B \Delta x_B\|^2 : A_B \Delta x_B = -A_N \Delta x_N(0)\right\}, \tag{31}$$

$$\psi_p(0) = \|\delta_B \Delta x_B(0)\|/\sqrt{\mu}. \tag{32}$$

(b) *The limit* $\Delta x_B'(0) \equiv \lim_{\lambda\to 0^+} \Delta x_B'(\lambda)$ *exists. Moreover, if* $\psi_p(0) \neq 0$, *then* $\psi_p'(0) \equiv \lim_{\lambda\to 0^+} \psi_p'(\lambda)$ *also exists;*

(c) *If* $\psi_p(0) \neq 0$, *then the function* $\psi_p(\cdot)$ *is strictly convex, strictly decreasing, and* $\lim_{\lambda\to\infty} \psi_p(\lambda) = 0$; *otherwise, if* $\psi_p(0) = 0$, *then the function* $\psi_p(\cdot)$ *is identically zero.*

(d) *If* $0 < \lambda_1 \le \lambda_2$, *then* $\psi_p(\lambda_1)/\psi_p(\lambda_2) \le \lambda_2/\lambda_1$ *(with the convention that* $0/0 = 0$*).*

We note that, in view of Lemma 2.10, the functions $\Delta x(\lambda)$ and $\psi_p(\lambda)$ can be extended to $\lambda = 0$ and their extensions are continuously differentiable at $\lambda = 0$. The following result relates the direction $\Delta x(\lambda)$ above to the primal TR direction, i.e., the optimal solutions of (22).

LEMMA 2.11. *The following statements hold:*

(a) *For any* $\lambda > 0$, $\Delta x(\lambda)$ *is an optimal solution of* (22) *with* $\gamma_p = \psi_p(\lambda)$;

(b) $\Delta x(0)$ *is an optimal solution of* (22) *for any* $\gamma_p \ge \psi_p(0)$.

Proof. (a) Using the fact that $\Delta x(\lambda)$ satisfies the optimality conditions for (28), we easily see that it also satisfies the optimality conditions, and hence is an optimal solution, of (22) with $\gamma_p = \psi_p(\lambda)$.

(b) In view of Lemma 2.10, we can pass the optimality conditions of (28) to the limit as $\lambda \downarrow 0$ to conclude that $A\Delta x(0) = 0$ and $\delta_N^2(x_N + \Delta x_N(0)) \in \operatorname{Im}(A^T)$. This together with (29) and the assumption that $\gamma_p \ge \psi_p(0)$ imply that $\Delta x(0)$ satisfies the optimality conditions, and hence is an optimal solution, of (22). ∎

Using the above results, the primal TR direction required by the algorithm can be computed as follows. Recall that the goal is to find an optimal solution of (22) for some $\gamma_p \in [\gamma/2, 2\gamma]$. We start by computing $\Delta x(0)$ and then $\psi_p(0)$. If $\psi_p(0) \le 2\gamma$, then by Lemma 2.11(b), we conclude that $\Delta x(0)$ is an optimal solution of (22) with $\gamma_p = 2\gamma$, and hence can be chosen as the required TR direction. Otherwise, if $\psi_p(0) > 2\gamma$, we search for some $\lambda_p > 0$ such that

$$\gamma/2 \le \psi_p(\lambda_p) \le 2\gamma, \tag{33}$$

which always exists in view of Lemma 2.10(c) and the fact that $\psi_p(0) > 2\gamma$.

Now, to find some $\lambda_p > 0$ satisfying (33), it suffices to determine $0 < \lambda_l \le \lambda_u$ such that

$$\psi_p(\lambda_l) \ge \gamma \ge \psi_p(\lambda_u), \tag{34}$$

$$\lambda_u/\lambda_l \le 2. \tag{35}$$

In such a case, any scalar $\lambda_p \in [\lambda_l, \lambda_u]$ satisfies (33). Indeed, by Lemma 2.10(d), we have

$$\frac{\gamma}{2} \le \frac{\lambda_l}{\lambda_u}\gamma \le \frac{\lambda_l}{\lambda_p}\psi_p(\lambda_l) \le \psi_p(\lambda_p) \le \frac{\lambda_u}{\lambda_p}\psi_p(\lambda_u) \le \frac{\lambda_u}{\lambda_l}\gamma \le 2\gamma.$$

Assuming that initial λ_l and λ_u satisfying (34) are given, a standard bisection procedure on the $(\log\lambda)$-space can then be used to determine scalars λ_l and λ_u satisfying both (34) and (35). An iteration of this bisection scheme updates λ_l or λ_u as follows. First, compute $\tilde{\lambda}$ such that $\log\tilde{\lambda} = (\log\lambda_l + \log\lambda_u)/2$, that is $\tilde{\lambda} = (\lambda_l\lambda_u)^{1/2}$. Second, if $\psi_p(\tilde{\lambda}) > \gamma$, λ_l is updated to $\tilde{\lambda}$; otherwise λ_u is updated to $\tilde{\lambda}$. It is clear that each iteration of this bisection scheme always preserves condition (34) and halves the length of the interval $[\log\lambda_l, \log\lambda_u]$. Hence, it eventually finds a pair (λ_l, λ_u) satisfying (34) and (35) in $\mathcal{O}(\log(\log(\lambda_u/\lambda_l)))$ bisection iterations, where λ_l and λ_u are the initial values of these scalars at the start of the procedure.

It remains to describe how to choose initial scalars $0 < \lambda_l \le \lambda_u$ such that (34) holds. We first focus our attention on the description of λ_l. Since $\psi_p(\lambda)$ is convex, we have $\psi_p(\lambda) \ge \psi_p(0) + \psi_p'(0)\lambda$ for every $\lambda > 0$. Hence, choosing λ_l to be the root of the linear equation $\psi_p(0) + \psi_p'(0)\lambda = \gamma$, i.e.,

$$\lambda_l = \frac{\psi_p(0) - \gamma}{|\psi_p'(0)|},$$

we conclude that $\psi_p(\lambda_l) \ge \gamma$.

The following lemma provides the needed information to obtain a lower bound on λ_l. We observe that, in spite of the notation, the quantities $\psi_p(0)$ and $\psi_p'(0)$ depend on the point $w \in \mathcal{P}^{++} \times \mathcal{D}^{++}$.

LEMMA 2.12. *Let w_0 denote the initial iterate of the PC-TR algorithm and set $\mu_0 = \mu(w_0)$. Then, for any $w \in \mathcal{N}(\beta)$ such that $\mu := \mu(w) \le \mu_0$, we have*

$$\frac{\psi_p(0)}{|\psi_p'(0)|} \ge \frac{(1-\beta)^8\mu^2}{n^4(1+\beta)^4\mu_0^2\,\bar{\chi}^2_{A\delta_0^{-1}}}. \tag{36}$$

Using the above result, a lower bound on λ_l can be obtained by observing that, under the assumption that $\psi_p(0) \ge 2\gamma$, we have

$$\lambda_l = \frac{\psi_p(0) - \gamma}{|\psi_p'(0)|} \ge \frac{\psi_p(0)}{2\,|\psi_p'(0)|} \ge \frac{(1-\beta)^8\mu^2}{2\,n^4\,(1+\beta)^4\mu_0^2\,\bar{\chi}^2_{A\delta_0^{-1}}}. \tag{37}$$

We now discuss how to choose the initial scalar λ_u satisfying (34). In contrast to the choice of λ_l, there is no clear way of choosing λ_u for an arbitrary curve $\psi_p(\lambda)$. Fortunately, the PC-TR algorithm stated in the previous subsection can be slightly modified so as to compute the TR step only when the condition $\psi_p(1) \le \gamma$ (in addition to the previously required condition that $\varepsilon_2^{\mathrm{a}}(w) > \varepsilon_0$) is satisfied. Hence, we may always choose the initial λ_u to be 1. In view of our discussion above, we conclude that the computation of a TR step in this variant of the PC-TR algorithm requires $\mathcal{O}\left(\log\log\lambda_l^{-1}\right)$ bisection steps, which is bounded by

$$\mathcal{O}\left[\log\left(\log\bar{\chi}_{A\delta_0^{-1}} + \log\frac{\mu_0}{\mu}\right)\right] \tag{38}$$

bisection steps, in view of (37).

We will now precisely discuss the variant of the PC-TR algorithm mentioned in the previous paragraph. First, we mention that the whole discussion of this subsection up to this point also applies to the computation of the dual TR direction, with the dual auxiliary direction

$$\begin{aligned}(\Delta y(\lambda), \Delta s(\lambda)) := \operatorname{argmin}\{&\|\delta_B^{-1}(s_B + \Delta s_B)\|^2 \\ &+ \lambda\|\delta_N^{-1}\Delta s_N\|^2 : A^T\Delta y + \Delta s = 0\}\end{aligned} \tag{39}$$

replacing $\Delta x(\lambda)$ and the dual curve

$$\psi_d(\lambda) \equiv \frac{\|\delta_N^{-1}\Delta s_N(\lambda)\|}{\sqrt{\mu}} \tag{40}$$

replacing $\psi_p(\lambda)$. We then have the following convergence result about a certain variant of the PC-TR algorithm.

THEOREM 2.13. *Consider the variant of the PC-TR algorithm where step* 2) *is replaced by the following step:*

2') *If* $\varepsilon_2^{\mathrm{a}}(w) > \varepsilon_0$ *and* $\max\{\psi_p(1), \psi_d(1)\} > \gamma/18$, *then set* $w \leftarrow w + \alpha_a \Delta w^{\mathrm{a}}$, *where* α_a *is defined as in* (10) *and go to* 6);

Then, the conclusions of Theorem 2.9 *also hold for the resulting variant of the PC-TR algorithm.*

We will now briefly discuss the arithmetic complexity of the above variant. We will see later in section 4 that the bisection procedure to compute a TR step takes

$$T(\mu; w_0) \equiv \mathcal{O}\left[n^3 + n\,\log\left(\log \bar{\chi}_{A\delta_0^{-1}} + \log(\mu_0/\mu)\right)\right] \tag{41}$$

arithmetic operations, since the procedure requires $\mathcal{O}[\log(\log \bar{\chi}_{A\delta_0^{-1}} + \log(\mu_0/\mu))]$ evaluations of the curves $\psi_p(\lambda)$ and $\psi_d(\lambda)$ with the first evaluation of either curve taking $\mathcal{O}(n^3)$ arithmetic operations and subsequent ones taking only $\mathcal{O}(n)$ arithmetic operations.

The above observation together with Theorem 2.13 yields the following arithmetic complexity result for the above PC-TR variant.

THEOREM 2.14. *The number of arithmetic operations performed by the variant of the PC-TR algorithm stated in Theorem* 2.13 *to find an iterate* w *such that* $\mu(w) \leq \mu_f$ *is bounded by*

$$\mathcal{O}\left[\frac{n^3\,\log(\bar{\chi}_A^* + n + \varepsilon_0^{-1})}{\log \varepsilon_0^{-1}}\, T(\mu_f, w_0) + n^{6.5}\,\log(\bar{\chi}_A^* + n + \varepsilon_0^{-1})\right],$$

where $T(\cdot,\cdot)$ *is defined in* (41). *In particular, if* $\varepsilon_0^{-1} = \Theta((n + \bar{\chi}_A^*)^\kappa)$ *for some* $\kappa > 0$, *the above arithmetic complexity bound reduces to*

$$\mathcal{O}\left[n^{6.5}\log(\bar{\chi}_A^* + n) + n^4 \log\left(\log \bar{\chi}_{A\delta_0^{-1}} + \log(\mu_0/\mu_f)\right)\right].$$

3. Basic tools. In this section we introduce the basic tools that will be used in the proof of Theorem 2.9. The analysis heavily relies on the notion of layered least squares(LLS) directions and crossover events due to Vavasis and Ye [28]. Subsection 3.1 below gives the definition of a crossover event which is slightly different than the one used in [28] and discusses some of its properties. Subsection 3.2 defines the layered least squares directions that will be used in the complexity analysis and also states an approximation result that provides an estimation of the closeness between the LLS direction with respect to a partition J of $\{1, \ldots, n\}$ and the AS direction. Subsection 3.3 reviews from a different perspective an important result from [28], namely Lemma 17 of [28], that essentially guarantees the occurrence of crossover events. Since this result is stated in terms of the residual of an LLS step, the use of the approximation result of subsection 3.2 between the AS and LLS steps allows us to obtain a similar result stated in terms of the residual of the AS direction.

3.1. Crossover events. In this subsection we discuss the notion of crossover event which plays a fundamental role in our convergence analysis.

DEFINITION. *For two indices $i, j \in \{1, \ldots, n\}$ and a constant $\mathcal{C} \geq 1$, a $\mathcal{C}$-crossover event for the pair (i, j) is said to occur on the interval $(\nu', \nu]$ if*

$$\begin{aligned} &\text{there exists } \nu_0 \in (\nu', \nu] \text{ such that } \frac{s_j(\nu_0)}{s_i(\nu_0)} \leq \mathcal{C}, \\ &\text{and, } \frac{s_j(\tilde{\nu})}{s_i(\tilde{\nu})} > \mathcal{C} \text{ for all } \tilde{\nu} \leq \nu'. \end{aligned} \tag{42}$$

Moreover, the interval $(\nu', \nu]$ is said to contain a $\mathcal{C}$-crossover event if (42) holds for some pair (i, j).

Hence, the notion of a crossover event is independent of any algorithm and is a property of the central path only. Note that in view of (3), condition (42) can be reformulated into an equivalent condition involving only the primal variable. For our purposes, we will use only (42).

We have the following simple but crucial result about crossover events.

PROPOSITION 3.1. *Let $\mathcal{C} > 0$ be a given constant. There can be at most $n(n-1)/2$ disjoint intervals of the form $(\nu', \nu]$ containing $\mathcal{C}$-crossover events.*

The notion of $\mathcal{C}$-crossover events can be used to define the notion of $\mathcal{C}$-crossover events between two iterates of the PC-TR algorithm as follows. We say that a $\mathcal{C}$-crossover event occurs between two iterates w^k and w^l, $k < l$, generated by the PC-TR algorithm if the interval $(\mu(w^l), \mu(w^k)]$ contains a $\mathcal{C}$-crossover event. Note that in view of Proposition 3.1, there can be at most $n(n-1)/2$ intervals of this type. We will show in the remaining part of this paper that there exists a constant $\mathcal{C} > 0$ with the following property: for any index k, there exists an index $l > k$ such that $l - k = \mathcal{O}(n^{1.5} \log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$ and a $\mathcal{C}$-crossover event occurs between the iterates w^k and w^l of the PC-TR algorithm. Proposition 3.1 and a simple argument then show that the PC-TR algorithm must terminate within $\mathcal{O}(n^{3.5} \log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$ iterations.

3.2. The layered least squares step. In this subsection we describe another type of direction, namely the layered least squares (LLS) step, which is very important in the analysis of our algorithm. This step was first introduced by Vavasis and Ye in [28]. We also describe two ordered partitions of the index set $\{1, \ldots, n\}$ that are crucial in the definition of the LLS directions.

Let $w = (x, y, s) \in \mathcal{P}^{++} \times \mathcal{D}^{++}$ and a partition $(J_1, \ldots, J_p)$ of the index set $\{1, \ldots, n\}$ be given and define $\delta \equiv \delta(w)$. The primal LLS direction $\Delta x^{\rm ll} = (\Delta x^{\rm ll}_{J_1}, \ldots, \Delta x^{\rm ll}_{J_p})$ at w with the respect to J is defined recursively according to the order $\Delta x^{\rm ll}_{J_p}, \ldots, \Delta x^{\rm ll}_{J_1}$ as follows. Assume that the components $\Delta x^{\rm ll}_{J_p}, \ldots, \Delta x^{\rm ll}_{J_{k+1}}$ have been determined. Let $\Pi_{J_k} : \Re^n \to \Re^{J_k}$ denote the projection map defined as $\Pi_{J_k}(u) = u_{J_k}$ for all $u \in \Re^n$. Then $\Delta x^{\rm ll}_{J_k} \equiv \Pi_{J_k}(L^x_k)$ where L^x_k is given by

$$\begin{aligned} L^x_k &\equiv \operatorname{Argmin}_{u \in \Re^n} \left\{ \|\delta_{J_k}(x_{J_k} + u_{J_k})\|^2 : u \in L^x_{k-1} \right\} \\ &= \operatorname{Argmin}_{u \in \Re^n} \Big\{ \|\delta_{J_k}(x_{J_k} + u_{J_k})\|^2 : u \in \operatorname{Ker}(A), \\ &\qquad\qquad u_{J_i} = \Delta x^{\rm ll}_{J_i} \ \text{ for all } i = k+1, \ldots, p \Big\}, \end{aligned} \tag{43}$$

with the convention that $L^x_0 = \operatorname{Ker}(A)$. The slack component $\Delta s^{\rm ll} = (\Delta s^{\rm ll}_{J_1}, \ldots, \Delta s^{\rm ll}_{J_p})$ of the dual LLS direction $(\Delta y^{\rm ll}, \Delta s^{\rm ll})$ at w with the respect to J is defined recursively

as follows. Assume that the components $\Delta s^{\rm ll}_{J_1}, \ldots, \Delta s^{\rm ll}_{J_{k-1}}$ have been determined. Then $\Delta s^{\rm ll}_{J_k} \equiv \Pi_{J_k}(L^s_k)$ where L^s_k is given by

$$
\begin{aligned}
L^s_k &\equiv \mathrm{Argmin}_{v\in\Re^n} \left\{ \|\delta^{-1}_{J_k}(s_{J_k} + v_{J_k})\|^2 : v \in L^s_{k-1} \right\} \\
&= \mathrm{Argmin}_{v\in\Re^n} \Big\{ \|\delta^{-1}_{J_k}(s_{J_k} + v_{J_k})\|^2 : v \in \mathrm{Im}(A^T), \\
&\qquad\qquad v_{J_i} = \Delta s^{\rm ll}_{J_i} \ \text{ for all } i = 1, \ldots, k-1 \Big\},
\end{aligned} \tag{44}
$$

with the convention that $L^s_0 = \mathrm{Im}(A^T)$. Finally, once $\Delta s^{\rm ll}$ has been determined, the component $\Delta y^{\rm ll}$ is determined from the relation $A^T \Delta y^{\rm ll} + \Delta s^{\rm ll} = 0$.

Note that (11) and (12) imply that the AS direction is a special LLS direction, namely the one with respect to the only partition in which $p = 1$. Clearly, the LLS direction at a given $w \in \mathcal{P}^{++} \times \mathcal{D}^{++}$ depends on the partition $J = (J_1, \ldots, J_p)$ used.

A partition $J = (J_1, \ldots, J_p)$ of $\{1, \ldots, n\}$ is said to be *ordered* with respect to a fixed vector $z \in \Re^n_{++}$ if $\max(z_{J_i}) \le \min(z_{J_{i+1}})$ for all $i = 1, \ldots, p-1$. In such a case, we define the gap of J with respect to z as

$$
\mathrm{gap}(z, J) \ := \ \min_{1\le i\le p-1} \left\{ \frac{\min(z_{J_{i+1}})}{\max(z_{J_i})} \right\} \ge 1,
$$

with the convention that $\mathrm{gap}(z, J) = \infty$ if $p = 1$. We say that a partition J is ordered at $w \in \mathcal{P}^{++} \times \mathcal{D}^{++}$ if it is ordered with respect to $z = \delta(w)$, in which case we denote the quantity $\mathrm{gap}(\delta(w), J)$ simply by $\mathrm{gap}(w, J)$. For partition $J = (J_1, \ldots, J_p)$ and a point $w \in \mathcal{P}^{++} \times \mathcal{D}^{++}$, the spread of the layer J_k with respect to w is defined as

$$
\mathrm{spr}(w, J_k) \equiv \frac{\max(\delta_{J_k}(w))}{\min(\delta_{J_k}(w))}, \quad \forall k = 1, \ldots, p.
$$

We now state how the AS direction can be well approximated by suitable LLS steps. Lemma 3.2, whose proof can be found in [14], essentially states that the larger the gap of J is, the closer the AS direction and the LLS direction with respect to J will be to one another.

LEMMA 3.2. *Let $w = (x, y, s) \in \mathcal{P}^{++} \times \mathcal{D}^{++}$ and an ordered partition $J = (J_1, \ldots, J_p)$ at w be given. Define $\delta \equiv \delta(w)$ and let $\Delta w^{\rm a} = (\Delta x^{\rm a}, \Delta y^{\rm a}, \Delta s^{\rm a})$ and $\Delta w^{\rm ll} = (\Delta x^{\rm ll}, \Delta y^{\rm ll}, \Delta s^{\rm ll})$ denote the AS direction at w and the LLS direction at w with respect to J, respectively. If $\mathrm{gap}(w, J) \ge 4\, p\, \bar{\chi}_A$, then*

$$
\max \left\{ \ \left\| Rx^{\rm a}(w) - Rx^{\rm ll}(w) \right\|_\infty , \ \left\| Rs^{\rm a}(w) - Rs^{\rm ll}(w) \right\|_\infty \ \right\} \ \le \ \frac{12\sqrt{n}\ \bar{\chi}_A}{\mathrm{gap}(w, J)},
$$

where $(Rx^{\rm a}(w), Rs^{\rm a}(w))$ and $(Rx^{\rm ll}(w), Rs^{\rm ll}(w))$ denote the residual pairs for the AS direction $\Delta w^{\rm a}$ and the LLS direction $\Delta w^{\rm ll}$, respectively.

In the remainder of this subsection, we describe the two important LLS directions in the analysis of our algorithm that differs in the definition of ordered partitions. The first ordered partition is due to Vavasis and Ye [28]. Given a point $w \in \mathcal{P}^{++} \times \mathcal{D}^{++}$ and a parameter $\bar{g} \ge 1$, this partition, which we refer to as the *VY partition*, is defined as follows. Let $(i_1, \ldots, i_n)$ be an ordering of $\{1, \ldots, n\}$ such that $\delta_{i_1} \le \ldots \le \delta_{i_n}$, where $\delta = \delta(w)$. For $k = 2, \ldots, n$, let $r_k \equiv \delta_{i_k}/\delta_{i_{k-1}}$ and define $r_1 \equiv \infty$. Let $k_1 < \ldots < k_p$ be all the indices k such that $r_k > \bar{g}$. The VY $\bar{g}$-partition J is then defined as $J = (J_1, \ldots, J_p)$, where $J_q \equiv \{i_{k_q}, i_{k_q+1}, \ldots, i_{k_{q+1}-1}\}$ for all $q = 1, \ldots, p$. More generally, given a subset $I \subset \{1, \ldots, n\}$, we can similarly define the *VY $\bar{g}$-partition* of

I at w by taking an ordering $(i_1, \ldots, i_m)$ of I satisfying $\delta_{i_1} \leq \ldots \leq \delta_{i_m}$ where $m = |I|$, defining the ratios $r_1, \ldots, r_m$ as above, and proceeding exactly as in the construction above to obtain the partition $J = (J_1, \ldots, J_p)$ of I.

It is easy to see that the following result holds for the partition J described in the previous paragraph.

PROPOSITION 3.3. *Given a subset $I \subseteq \{1, \ldots, n\}$, a point $w \in \mathcal{P}^{++} \times \mathcal{D}^{++}$, and a constant $\bar{g} \geq 1$, the VY $\bar{g}$-partition $J = (J_1, \ldots, J_p)$ of I at w satisfies* $\mathrm{gap}(w, J) > \bar{g}$ *and* $\mathrm{spr}(w, J_q) \leq \bar{g}^{|J_q|} \leq \bar{g}^n$ *for all* $q = 1, \ldots, p$.

The second-ordered partition, which is used heavily in our analysis, was introduced by Monteiro and Tsuchiya [14]. Given a point $w \in \mathcal{P}^{++} \times \mathcal{D}^{++}$. First, we compute the bipartition (B, N) of $\{1, \ldots, n\}$ according to (20). Next, an order $(i_1, \ldots, i_n)$ of the index variables is chosen such that $\delta_{i_1} \leq \ldots \leq \delta_{i_n}$. Then, the first block of consecutive indices in the n-tuple $(i_1, \ldots, i_n)$ lying in the same set B or N are placed in the first layer $\mathcal{J}_1$, the next block of consecutive indices lying in the other set is placed in $\mathcal{J}_2$, and so on. As an example assume that $(i_1, i_2, i_3, i_4, i_5, i_6, i_7) \in B \times B \times N \times B \times B \times N \times N$. In this case, we have $\mathcal{J}_1 = \{i_1, i_2\}$, $\mathcal{J}_2 = \{i_3\}$, $\mathcal{J}_3 = \{i_4, i_5\}$, and $\mathcal{J}_4 = \{i_6, i_7\}$. A partition obtained according to the above construction is clearly ordered at w. We refer to it as an *ordered AS-partition*, and denote it by $\mathcal{J} = \mathcal{J}(w)$.

Note that an ordered AS-partition is not uniquely determined since there can be more than one n-tuple $(i_1, \ldots, i_n)$ satisfying $\delta_{i_1} \leq \ldots \leq \delta_{i_n}$. This situation happens exactly when there are two or more indices i with the same value for δ_i. If these tying indices do not all belong to the same set B or N, then there will be more than one way to generate an ordered AS-partition $\mathcal{J}$.

We say that the bipartition (B, N) is *regular* if there do not exist $i \in B$ and $j \in N$ such that $\delta_i = \delta_j$. Observe that there exists a unique ordered AS-partition if and only if (B, N) is regular. When (B, N) is not regular, our algorithm avoids the computation of an ordered AS-partition and hence of any LLS direction with respect to such a partition.

3.3. Relation between crossover events, the AS step, and the LLS step. In this subsection, we state some variants of Lemma 17 of Vavasis and Ye [28]. Specifically, we present two estimates on the number of iterations needed to guarantee the occurrence of a crossover event. While the first estimate essentially depends on the size of the residual of the LLS step and the step-size at the initial iterate, the second one depends only on the size of the residual of the AS direction at the initial iterate. Lemma 3.4 is a restatement of Lemma 17 of of Vavasis and Ye [28]. Its proof can be found in Lemma 3.4 of Monteiro and Tsuchiya [14].

LEMMA 3.4. *Let $w = (x, y, s) \in \mathcal{N}(\beta)$ for some $\beta \in (0, 1)$ and an ordered partition $J = (J_1, \ldots, J_p)$ at w be given. Let $\delta \equiv \delta(w)$, $\mu = \mu(w)$, and $(Rx^{\mathrm{ll}}(w), Rs^{\mathrm{ll}}(w))$ denote the residual of the LLS direction $(\Delta x^{\mathrm{ll}}, \Delta y^{\mathrm{ll}}, \Delta s^{\mathrm{ll}})$ at w with respect to J. Then, for any $q = 1, \ldots, p$ and any constant*

$$\mathcal{C}_q \geq (1 + \beta)\, \mathrm{spr}(w, J_q)/(1 - \beta)^2$$

and for any $\mu' \in (0, \mu)$ such that

$$\frac{\mu'}{\mu} \leq \frac{\|Rx^{\mathrm{ll}}_{J_q}(w)\|_\infty \|Rs^{\mathrm{ll}}_{J_q}(w)\|_\infty}{n^3 \mathcal{C}_q^2 \bar{\chi}_A^2},$$

the interval $(\mu', \mu]$ contains a $\mathcal{C}_q$-crossover event.

The following lemma is the immediate consequence of Lemma 3.4 and an adaption from Lemma 3.5 of Monteiro and Tsuchiya [14].

LEMMA 3.5. *Let $w = (x, y, s) \in \mathcal{N}(\beta)$ for some $\beta \in (0, 1/4]$ and an ordered partition $J = (J_1, \ldots, J_p)$ at w be given. Define $\delta \equiv \delta(w)$ and $\mu = \mu(w)$, and let $(Rx^{\rm ll}(w), Rs^{\rm ll}(w))$ denote the residual of the LLS direction $(\Delta x^{\rm ll}, \Delta y^{\rm ll}, \Delta s^{\rm ll})$ at w with respect to J. Then, for every $q \in \{1, \ldots, p\}$ and every*

$$\mathcal{C}_q \geq (1+\beta)\mathrm{spr}(w, J_q)/(1-\beta)^2, \tag{45}$$

the following statements hold:

(a) *the PC-TR algorithm (or its variant) started from the point w will generate an iterate $\hat{w}$ with a $\mathcal{C}_q$-crossover event occurring between w and $\hat{w}$ in $\mathcal{O}(\sqrt{n}\,\Phi)$ iterations, where*

$$\Phi \equiv \log(\bar{\chi}_A + n) + \log \mathcal{C}_q + \log\left(\frac{\mu_+/\mu}{\|Rx^{\rm ll}_{J_q}(w)\|_\infty \|Rs^{\rm ll}_{J_q}(w)\|_\infty}\right) \tag{46}$$

and μ_+ is the normalized duality gap attained immediately after the first iteration. Moreover, steps 3 through 5 of the PC-TR algorithm (or its variant), and hence computation of the TR step, is performed in only

$$\mathcal{O}(\Phi/\log(\varepsilon_0^{-1})) \tag{47}$$

of these iterations.

(b) *if, in addition,*

$$\mathrm{gap}(w, J) \geq \max\left\{4\, n\bar{\chi}_A\,,\ \frac{24\sqrt{n}\bar{\chi}_A}{\varepsilon^{\rm a}_{J_q}}\right\} \tag{48}$$

where $\varepsilon^{\rm a}_{J_q} \equiv \min\left\{\|Rx^{\rm a}_{J_q}(w)\|_\infty\,,\ \|Rs^{\rm a}_{J_q}(w)\|_\infty\right\}$, then

$$\Phi = \mathcal{O}\left(\log(\bar{\chi}_A + n) + \log \mathcal{C}_q + \log(\varepsilon^{\rm a}_{J_q})^{-1}\right). \tag{49}$$

Proof. The proofs of the first part of statement (a) and the whole statement (b) are given in Lemma 3.5 of [14]. It remains to prove the latter part of statement (a). We refer to an iteration of the PC-TR algorithm as a TR-iteration whenever the TR direction is computed. Let N_0 be the number of TR-iterations performed before reaching the first iterate $\hat{w}$ such that a $\mathcal{C}_q$-crossover event occurs between w and $\hat{w}$. We will show that N_0 is bounded by (47). Indeed, let $\tilde{w}$ denote the iterate obtained immediately after the (N_0-1)-th TR-iteration. Then, in view of Lemma 3.4, we have

$$\frac{\mu(\tilde{w})}{\mu(w)} > \frac{\|Rx^{\rm ll}_{J_q}(w)\|_\infty \|Rs^{\rm ll}_{J_q}(w)\|_\infty}{n^3 \mathcal{C}_q^2 \bar{\chi}_A^2}. \tag{50}$$

Since the duality gap is reduced by a factor of μ_+/μ in the first iteration, and by a factor of at least $\left((\sqrt{1+\beta}+\gamma)/(2\gamma)\right)\varepsilon_0$ in subsequent TR-iterations, due to relation (26), we conclude that

$$\begin{aligned}\log\left(\frac{\mu_+}{\mu}\right) + (N_0 - 2)\log\left(\frac{\sqrt{1+\beta}+\gamma}{2\gamma}\ \varepsilon_0\right) &\geq \log\frac{\mu(\tilde{w})}{\mu(w)} \\ &> \log\left[\frac{\|Rx^{\rm ll}_{J_q}(w)\|_\infty \|Rs^{\rm ll}_{J_q}(w)\|_\infty}{n^3 \mathcal{C}_q^2 \bar{\chi}_A^2}\right],\end{aligned}$$

which clearly implies that N_0 is bounded by (47). ∎

4. Convergence analysis of the PC-TR algorithm. In this section, we will provide the proofs of Theorems 2.9 and 2.13.

Lemma 3.5 gives a good idea of the effort that will be undertaken in this section, namely, to show that there exists a universal constant $\mathcal{C} = \mathcal{C}(\varepsilon_0) > 0$ with the property that, for each iterate w of the PC-TR algorithm, or its variant, there exists an ordered partition $J = (J_1, \ldots, J_p)$ and an index $q = 1, \ldots, p$ such that $\mathcal{C} \geq (1+\beta)\mathrm{spr}(w, J_q)/(1-\beta)^2$ and the quantity Φ defined in (46) with $\mathcal{C}_q = \mathcal{C}$ is bounded by $\mathcal{O}(n \log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$. In view of Lemma 3.5(a), we would then conclude that a $\mathcal{C}$-crossover event occurs every time $\mathcal{O}(n^{1.5} \log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$ iterations of the PC-TR algorithm is performed. Proposition 3.1 together with the previous fact would then imply that the PC-TR algorithm, or its variant, terminates in $\mathcal{O}(n^{3.5} \log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$ iterations.

We start by introducing the aforementioned constant $\mathcal{C} = \mathcal{C}(\varepsilon_0)$ and another global constant used in this section. Let

$$\bar{g}(\varepsilon_0) \equiv \frac{24\, n \bar{\chi}_A}{\varepsilon_0}, \qquad \mathcal{C}(\varepsilon_0) \equiv \frac{(1+\beta)}{(1-\beta)^2} [\bar{g}(\varepsilon_0)]^n. \tag{51}$$

The proof of the above claim will be broken into three cases, namely: (i) $\varepsilon_2^{\mathrm{a}}(w) \geq \varepsilon_0$; (ii) $\mathrm{gap}(w, \mathcal{J}) \leq \bar{g}(\varepsilon_0)$; and (iii) $\mathrm{gap}(w, \mathcal{J}) \geq \bar{g}(\varepsilon_0)$ and $\varepsilon_2^{\mathrm{a}}(w) \leq \varepsilon_0$, where $\varepsilon_2^{\mathrm{a}}(w)$ is given by (21), $\mathcal{J}$ is the AS-partition at w, and $\mathrm{gap}(w, \mathcal{J})$ is defined in subsection 3.2. The first result below considers the case (i).

LEMMA 4.1. *Suppose that $w \in \mathcal{N}(\beta)$ for some $\beta \in (0, 1/4]$ and that $\varepsilon_2^{\mathrm{a}}(w) \geq \varepsilon_0$ for some constant $\varepsilon_0 > 0$. Then PC-TR algorithm, or its variant, started from the point w will generate an iterate $\hat{w}$ with a $\mathcal{C}(\varepsilon_0)$-crossover event occurring between w and $\hat{w}$ in $\mathcal{O}(n^{1.5} \log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$ iterations, of which $\mathcal{O}(n \log(\bar{\chi}_A + n + \varepsilon_0^{-1}) / \log \varepsilon_0^{-1})$ are TR-iterations.*

Proof. The assumption that $\varepsilon_2^{\mathrm{a}}(w) \geq \varepsilon_0$ implies $\varepsilon_\infty^{\mathrm{a}}(w) \geq \varepsilon_0/\sqrt{n}$, and hence, in view of definition (16), there exists an index $i = 1, \ldots, n$ such that $\min\{|Rx_i^{\mathrm{a}}(w)|, |Rs_i^{\mathrm{a}}(w)|\} \geq \varepsilon_0/\sqrt{n}$. Now let $J = (J_1, \ldots, J_p)$ be a VY $\bar{g}(\varepsilon_0)$-partition at w and let J_q be the layer containing the index i above. Clearly, we have

$$\varepsilon_{J_q}^{\mathrm{a}} \equiv \min\left\{\|Rx_{J_q}^{\mathrm{a}}(w)\|_\infty, \|Rs_{J_q}^{\mathrm{a}}(w)\|_\infty\right\} \geq \varepsilon_0/\sqrt{n}. \tag{52}$$

Using the above inequality, the fact that $\mathrm{gap}(w, J) \geq \bar{g}(\varepsilon_0)$ and (51), we easily see that (48) holds. Since by Proposition 3.3 the spread of every layer of a VY $\bar{g}(\varepsilon_0)$-partition at w is bounded above by $\bar{g}(\varepsilon_0)^n$, we conclude that $\mathrm{spr}(w, J_q) \leq \bar{g}^n$, and hence that the constant $\mathcal{C}(\varepsilon_0)$ defined in (51) satisfies (45) with $\mathcal{C}_q = \mathcal{C}(\varepsilon_0)$. We then conclude from Lemma 3.5(b) that $\Phi = \mathcal{O}(n^{1.5} \log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$ in view of (52), (51), and the fact that $\log(\mathcal{C}_q) = \mathcal{O}(n \log \bar{g}(\varepsilon_0)) = \mathcal{O}(n \log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$. The conclusion of the lemma now follows from the previous observation and Lemma 3.5(a). ∎

The next result takes care of case (ii), namely the case in which $\mathrm{gap}(w, \mathcal{J}) \leq \bar{g}(\varepsilon_0)$.

LEMMA 4.2. *Suppose that $w \in \mathcal{N}(\beta)$ for some $\beta \in (0, 1/4]$. Let $\bar{g}(\varepsilon_0)$ and $\mathcal{C}(\varepsilon_0)$ be the constants defined in (51). Let $\mathcal{J} = (\mathcal{J}_1, \ldots, \mathcal{J}_r)$ be an ordered AS-partition at w and assume that $\mathrm{gap}(w, \mathcal{J}) \leq \bar{g}(\varepsilon_0)$. Then, the PC-TR algorithm, or its variant, started from the point w will generate an iterate $\hat{w}$ with a $\mathcal{C}(\varepsilon_0)$-crossover event occurring between w and $\hat{w}$ in $\mathcal{O}(n^{1.5} \log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$ iterations, of which $\mathcal{O}(n \log(\bar{\chi}_A + n + \varepsilon_0^{-1}) / \log \varepsilon_0^{-1})$ are TR-iterations.*

Proof. Assume that $\mathrm{gap}(w, \mathcal{J}) \leq \bar{g}(\varepsilon_0)$ and let $J = (J_1, \ldots, J_p)$ be a VY $\bar{g}(\varepsilon_0)$-partition at w. Using the assumption that $\mathrm{gap}(w, \mathcal{J}) \leq \bar{g}(\varepsilon_0)$, it is easy to see that

there exist two indices i, j of different types, say $i \in B(w)$ and $j \in N(w)$, both lying in some layer J_q of J. By Lemma 2.6 and the definition of $(B(w), N(w))$ given in (20), it follows that $|Rx_i^{\mathrm{a}}(w)| \geq 1/4$ and $|Rs_j^{\mathrm{a}}(w)| \geq 1/4$, and hence that

$$\varepsilon_{J_q}^{\mathrm{a}} \equiv \min\left\{\|Rx_{J_q}^{\mathrm{a}}(w)\|_\infty\,,\ \|Rs_{J_q}^{\mathrm{a}}(w)\|_\infty\right\} \geq \frac{1}{4}. \tag{53}$$

Using this inequality and the fact that $\mathrm{gap}(w, J) \geq \bar{g}(\varepsilon_0) \geq 96\bar{\chi}_A n$, where the last inequality is due to (51) and (25), we easily see that (48) holds. Since by Proposition 3.3 the spread of every layer of a VY $\bar{g}(\varepsilon_0)$–partition at w is bounded above by $\bar{g}(\varepsilon_0)^n$, we conclude that $\mathrm{spr}(w, J_q) \leq \bar{g}^n$, and hence that (45) holds with $\mathcal{C}_q = \mathcal{C}(\varepsilon_0)$ in view of (51). The result now follows from Lemma 3.5 by noting that the quantity Φ in (49) with $\mathcal{C}_q = \mathcal{C}(\varepsilon_0)$ is bounded by $\mathcal{O}(n^{1.5}\log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$ in view of (51) and (53). □

From now on, we consider case (iii), namely the case in which $\mathrm{gap}(w, \mathcal{J}) \geq \bar{g}(\varepsilon_0)$ and $\varepsilon_2^{\mathrm{a}}(w) \leq \varepsilon_0$.

We start by stating a technical result whose proof is given in Lemma 4.3 of [14] and holds for any $\bar{g}(\varepsilon_0) \geq 96n\bar{\chi}_A$, hence for our specific choice of $\bar{g}(\varepsilon_0)$ given in (51), in view of (25).

LEMMA 4.3. *Suppose that $w \in \mathcal{N}(\beta)$ for some $\beta \in (0, 1/4]$. Let $\bar{g}(\varepsilon_0)$ and $\mathcal{C}(\varepsilon_0)$ be the constants defined in* (51). *Let $\mathcal{J} = (\mathcal{J}_1, \ldots, \mathcal{J}_r)$ denote the AS-partition at w and assume that $\mathrm{gap}(w, \mathcal{J}) \geq \bar{g}(\varepsilon_0)$. Let $(Rx^{\mathrm{l}}(w), Rs^{\mathrm{l}}(w))$ denote the residual of the LLS direction at w with respect to $\mathcal{J}$. Let*

$$\hat{\Phi} \equiv n\log\left(\bar{\chi}_A + n + \varepsilon_0^{-1}\right) + \log\left(\frac{\mu_+/\mu}{\varepsilon_\infty^{\mathrm{l}}(w)}\right), \tag{54}$$

μ_+ is the normalized duality gap attained immediately after the first iteration,

$$\varepsilon_\infty^{\mathrm{l}}(w) \equiv \max\left\{\left\|Rx_N^{\mathrm{l}}(w)\right\|_\infty, \left\|Rs_B^{\mathrm{l}}(w)\right\|_\infty\right\} \tag{55}$$

and $(B, N) \equiv (B(w), N(w))$. Then, the PC-TR algorithm started from the point w will generate an iterate $\hat{w}$ with a $\mathcal{C}(\varepsilon_0)$-crossover event occurring between w and $\hat{w}$ in $\mathcal{O}(\sqrt{n}\,\hat{\Phi})$ iterations, of which $\mathcal{O}(\hat{\Phi}/\log\varepsilon_0^{-1})$ are TR-iterations.

Our goal now will be to estimate, under the conditions of case (iii), the second logarithm that appears in the iteration-complexity bound (54). In this estimation procedure, it is important to show that the first iteration from w is a TR-iteration. This will always be the case for the PC-TR algorithm since a TR-iteration occurs in this algorithm if and only if $\varepsilon_2^{\mathrm{a}}(w) \leq \varepsilon_0$ and case (iii) assumes this condition. On the other hand, for the variant, TR-iteration occurs if and only if, in addition to $\varepsilon_2^{\mathrm{a}}(w) \leq \varepsilon_0$, we also have $\max\{\psi_p(1), \psi_d(1)\} \leq \gamma$, where the curves $\psi_p(\cdot)$ and $\psi_d(\cdot)$ are defined in (29) and (40). The next two results show that the latter condition also holds under case (iii).

Given $F \in \Re^{m\times n}$, $h \in \Re^m$, and a scaling vector $z \in \Re^n_{++}$, consider the projection $p^0 \in \Re^n$ given by

$$p^0 \equiv \mathrm{argmin}_{p\in\Re^n}\left\{\|h - p\|^2 : FZp = 0\right\}, \tag{56}$$

where $Z \equiv \mathrm{Diag}(z)$. For a given ordered partition $J = (J_1, \ldots, J_l)$, Lemma 4.4 shows that if $\mathrm{gap}(z, J)$ is large, then the projection matrix onto $\mathrm{Ker}(F\,\mathrm{Diag}(z))$ can be well approximated by a block diagonal matrix where each block is a projection matrix

associated with some layer J_k of J. This fact was first established in [23] and an alternative proof can be found in [13]. The proof of a slightly stronger version of the variant stated below can be found in [16].

LEMMA 4.4. *Let $F \in \Re^{m\times n}$, $h \in \Re^m$, $z \in \Re^n_{++}$, and an ordered partition $J = (J_1, \ldots, J_l)$ of $\{1, \ldots, n\}$ with respect to z be given. Define $p^0 \in \Re^n$ as in* (56) *and $\tilde{p}^0 \in \Re^n$ as*

$$\tilde{p}^0_{J_k} \equiv \operatorname{argmin}_{\tilde{p}_{J_k}\in\Re^{J_k}} \left\{ \|\tilde{p}_{J_k} - h_{J_k}\|^2 : F_{J_k} Z_{J_k} \tilde{p}_{J_k} \in \operatorname{Im}(F_{\bar{J}_k}) \right\}, \tag{57}$$

for every $k = 1, \ldots, l$, where $\bar{J}_k \equiv J_{k+1} \cup \ldots \cup J_l$. Then,

$$\|p^0 - \tilde{p}^0\|_\infty \le K(3 + 2K)\|h\|, \tag{58}$$

where $K \equiv \bar{\chi}_F/\operatorname{gap}(z, J)$.

Using this approximation result, we are now able to prove the result mentioned just after Lemma 4.3.

LEMMA 4.5. *Assume that $w \in \mathcal{P}^{++} \times \mathcal{D}^{++}$ and that $\operatorname{gap}(w, \mathcal{J}) \ge \bar{g}(\varepsilon_0)$ for some $\varepsilon_0 \in (0, 12n]$, where $\mathcal{J} = (\mathcal{J}_1, \ldots, \mathcal{J}_r)$ denotes the ordered AS-partition at w. Then, the curves $\psi_p(\cdot)$ and $\psi_d(\cdot)$ defined in* (29) *and* (40)*, respectively, satisfy $\max\{\psi_p(1), \psi_d(1)\} \le \varepsilon_0/6$.*

Proof. We will show only the inequality $\psi_p(1) \le \varepsilon_0/6$. The proof of the inequality $\psi_d(1) \le \varepsilon_0/6$ is similar. Consider the projections p^0 and $\tilde{p}^0$ defined in Lemma 4.4 with $F = A$, $h = (h_B, h_N) \equiv (0, \delta_N x_N)$, $z = \delta^{-1}$, and $J = (\mathcal{J}_r, \ldots, \mathcal{J}_1)$, where $\delta \equiv \delta(w)$. It is easy to see that the constant K of Lemma 4.4 is exactly equal to $\bar{\chi}_A/\operatorname{gap}(w, \mathcal{J})$. It then follows from relation (51) and the assumptions $\operatorname{gap}(w, \mathcal{J}) \ge \bar{g}(\varepsilon_0)$ and $\varepsilon_0 \le 12n$ that $K \le \varepsilon_0/(24n) \le 1/2$. Using these two inequalities, the conclusion of Lemma 4.4 and the fact that $\|h\| \le \|\delta x\| = \sqrt{x^T s} = \sqrt{n\mu}$, we then obtain

$$\frac{1}{\sqrt{\mu}}\|p^0_B - \tilde{p}^0_B\| \le \frac{\sqrt{n}}{\sqrt{\mu}}\|p^0_B - \tilde{p}^0_B\|_\infty \le nK(3 + 2K) \le 4nK \le \varepsilon_0/6. \tag{59}$$

Moreover, definition (28) clearly implies that $p^0 = \delta\Delta x(1)$, where we recall that $\Delta x(1)$ is the optimal solution of (28) with $\lambda_p = 1$. Using the fact that $h_{J_k} = 0$ for every $J_k \subset B$ and the definition (57), we easily see that $\tilde{p}^0_{J_k} = 0$ for every $J_k \subset B$ and hence that $\tilde{p}^0_B = 0$. The last two observations together with (59) and (29) then imply that

$$\psi_p(1) = \frac{1}{\sqrt{\mu}}\|\delta_B \Delta x_B(1)\| = \frac{1}{\sqrt{\mu}}\|p^0_B\| = \frac{1}{\sqrt{\mu}}\|p^0_B - \tilde{p}^0_B\| \le \varepsilon_0/6. \qquad \square$$

The following result follows an immediate consequence of Lemma 4.5.

LEMMA 4.6. *Assume that w is an iterate of the PC-TR variant such that $\varepsilon^{\mathrm{a}}_2(w) \le \varepsilon_0$ and $\operatorname{gap}(w, \mathcal{J}) \ge \bar{g}(\varepsilon_0)$. Then, the iteration of the PC-TR variant from w is a TR-iteration.*

Proof. In view of Lemma 4.5 and the assumptions that $\operatorname{gap}(w, \mathcal{J}) \ge \bar{g}(\varepsilon_0)$ and $\varepsilon_0 \le \gamma/3$, we conclude that $\max\{\psi_p(1), \psi_d(1)\} \le \gamma/18$. This inequality, together with the assumption $\varepsilon^{\mathrm{a}}_2(w) \le \varepsilon_0$, implies that the iteration of the PC-TR variant from w is a TR-iteration (see the statement of Theorem 2.13). $\square$

When a TR-iteration is performed, it follows from relation (26) that the duality gap is reduced by a factor bounded by $\mathcal{O}(\varepsilon^\tau_2(w; \gamma_p, \gamma_d))$. The following result shows that this factor is indeed $\mathcal{O}(\sqrt{n}\varepsilon^{\mathrm{l}}_\infty(w))$, where $\varepsilon^{\mathrm{l}}_\infty(w)$ is defined in (55), thereby giving the necessary means to bound the second logarithm which appears in (54).

LEMMA 4.7. *Suppose that* $w \in \mathcal{P}^{++} \times \mathcal{D}^{++}$ *is such that* $\varepsilon_2^{\mathrm{a}}(w) \leq \varepsilon_0$. *Let* $\Delta w^l = (\Delta x^l, \Delta y^l, \Delta s^l)$ *denote the LLS direction at* w *with respect to the AS-partition* $\mathcal{J} = (\mathcal{J}_1, \ldots, \mathcal{J}_r)$ *and assume that* $\mathrm{gap}(\mathcal{J}) \geq \bar{g}(\varepsilon_0)$. *Then, we have*

$$\max\left\{\frac{\|\delta_B \Delta x_B^l\|}{\sqrt{\mu}}, \frac{\|\delta_N^{-1} \Delta s_N^l\|}{\sqrt{\mu}}\right\} \leq \frac{3\varepsilon_0}{2}. \tag{60}$$

Moreover, if in addition $\varepsilon_0 \leq \gamma/3$, *then*

$$\varepsilon_2^{\tau}(w; \gamma_p, \gamma_d) \leq \sqrt{n}\varepsilon_{\infty}^{\mathrm{l}}(w) \tag{61}$$

for any $\gamma_p, \gamma_d \geq \gamma/2$, *where* $\varepsilon_{\infty}^{\mathrm{l}}(w)$ *and* $\varepsilon_2^{\tau}(w; \gamma_p, \gamma_d)$ *are defined in* (55) *and* (24), *respectively.*

Proof. Clearly, by definitions (9) and (43) we have $A\Delta x^l = 0$. Moreover, from the triangle inequality for norms, Theorem 3.2, relations (14), (21) and (51) and the assumptions that $\mathrm{gap}(w, \mathcal{J}) \geq \bar{g}(\varepsilon_0)$ and $\varepsilon_2^{\mathrm{a}}(w) \leq \varepsilon_0$, we conclude that

$$\begin{aligned}\frac{\|\delta_B \Delta x_B^l\|}{\sqrt{\mu}} \leq \frac{\|\delta_B \Delta x_B^{\mathrm{a}}\|}{\sqrt{\mu}} + \frac{\|\delta_B(\Delta x_B^l - \Delta x_B^{\mathrm{a}})\|}{\sqrt{\mu}} &\leq \|Rs_B^a\| + \sqrt{n}\,\|Rx^l - Rx^a\|_{\infty} \\ &\leq \varepsilon_2^{\mathrm{a}}(w) + \frac{12n\bar{\chi}_A}{\mathrm{gap}(w, \mathcal{J})} \leq \varepsilon_0 + \frac{12n\bar{\chi}_A}{\bar{g}(\varepsilon_0)} \leq \varepsilon_0 + \frac{\varepsilon_0}{2} \leq \frac{3\varepsilon_0}{2}.\end{aligned}$$

In a similar manner, we can also show that $\|\delta_N^{-1}\Delta s_N^l\|/\sqrt{\mu} \leq 3\varepsilon_0/2$, showing that (60) holds.

Assume now that $\varepsilon_0 \leq \gamma/3$ also holds. In view of (60), it follows that Δx_B^l and Δs_N^l are feasible for subproblems (22) and (23), respectively, whenever $\gamma_p, \gamma_d \geq \gamma/2$. Hence, we conclude that $\|Rx_N^{\tau}\| \leq \|Rx_N^l\|$ and $\|Rs_B^{\tau}\| \leq \|Rs_B^l\|$, from which it follows that

$$\varepsilon_2^{\tau}(w; \gamma_p, \gamma_d) := \max\{\|Rx_N^{\tau}\|, \|Rs_B^{\tau}\|\} \leq \sqrt{n}\max\{\|Rx_N^l\|_{\infty}, \|Rs_B^l\|_{\infty}\} = \sqrt{n}\varepsilon_{\infty}^{\mathrm{l}}(w). \quad \square$$

We are now ready to prove Theorems 2.9 and 2.13.

Proof of Theorems 2.9 *and* 2.13. Let $\mathcal{C}$ and $\bar{g}(\varepsilon_0)$ be the constant defined in (51). We claim that the PC-TR algorithm started from any $w \in \mathcal{N}(\beta)$ generates an iterate $\hat{w}$ with a $\mathcal{C}(\varepsilon_0)$-crossover event occurring between w and $\hat{w}$ in $\mathcal{O}(n^{1.5}\log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$ iteration, of which $\mathcal{O}(n\log(\bar{\chi}_A + n + \varepsilon_0^{-1})/\log\varepsilon_0^{-1})$ are TR-iterations. Since by Proposition 3.1 there can be at most $n(n+1)/2$ $\mathcal{C}(\varepsilon_0)$-crossover events, we conclude that the PC-TR algorithm must ultimately terminate in $\mathcal{O}(n^{3.5}\log(\bar{\chi}_A + n + \varepsilon_0^{-1}))$ iterations, of which $\mathcal{O}(n^3\log(\bar{\chi}_A + n + \varepsilon_0^{-1})/\log\varepsilon_0^{-1})$ are TR-iterations. Let $\mathcal{J} = (\mathcal{J}_1, \ldots, \mathcal{J}_r)$ denote an AS-partition at w. We split the proof into one of the following three possible cases: (1) $\varepsilon_2^{\mathrm{a}}(w) \geq \varepsilon_0$; (2) $\mathrm{gap}(\mathcal{J}) \leq \bar{g}(\varepsilon_0)$; and (3) $\varepsilon_2^{\mathrm{a}}(w) \leq \varepsilon_0$ and $\mathrm{gap}(\mathcal{J}) \geq \bar{g}(\varepsilon_0)$. The claim clearly holds for the first two cases due to Lemmas 4.1 and 4.2. Moreover, Lemma 4.3 implies that the claim also holds in the third case as long as we can show that the quantity $(\mu_+/\mu)/\varepsilon_{\infty}^{\mathrm{l}}(w)$ appearing in (54) is $\mathcal{O}(\sqrt{n})$. Indeed, assume that $\varepsilon_{\infty}^{\mathrm{a}}(w) \leq \varepsilon_0$ and $\mathrm{gap}(\mathcal{J}) \geq \bar{g}(\varepsilon_0)$. Then, the iteration from w for both the PC-TR algorithm and its variant is a TR-iteration in view of Lemma 4.6. Then, it follows from Proposition 2.8 and Lemma 4.7 that $(\mu_+/\mu)/\varepsilon_{\infty}^{\mathrm{l}}(w) = \mathcal{O}(\sqrt{n})$. $\square$

5. Arithmetic complexity for the PC-TR variant. In this section, we will provide the details of the several claims made on subsection 2.6 and prove the main result stated in that subsection, namely Theorem 2.14.

We start by noting that the results stated in subsection 2.6 remain invariant if elementary row operations are applied to the rows of A. Indeed, the condition that $A\Delta x(\lambda) = 0$ can be replaced by the condition that $\Delta x(\lambda)$ is in the null space of A, which remains invariant when the elementary row operations are performed on A. In this section, we will therefore freely perform elementary row operations to bring A to a more convenient form.

Let $w \in \mathcal{P}^{++} \times \mathcal{D}^{++}$ be given. By placing the columns with indices in $B \equiv B(w)$ before the ones with indices in $N \equiv N(w)$, it is easy to see that there exists a sequence of elementary row operations which brings A to a matrix of the form

$$\begin{pmatrix} B & E \\ 0 & N \end{pmatrix}, \tag{62}$$

where $B \in \Re^{r_b \times |B|}$ and $N \in \Re^{r_n \times |N|}$ are full row rank matrices with $r_b \equiv \mathrm{rank}(A_B)$ and $r_n \equiv m - r_b$. By performing further elementary row operations, we may assume that A contains an $m \times m$ identity matrix, or equivalently, after permuting columns of A if necessary, the matrices B, N, and E have the form

$$B = [\ \tilde{B} \quad I\ ], \quad N = [\ I \quad \tilde{N}\ ], \quad E = [\ 0 \quad \tilde{E}\ ], \tag{63}$$

and hence, A has the form

$$A = \begin{pmatrix} \tilde{B} & I & 0 & \tilde{E} \\ 0 & 0 & I & \tilde{N} \end{pmatrix}, \tag{64}$$

where $\tilde{B} \in \Re^{r_b \times (|B| - r_b)}$, $\tilde{N} \in \Re^{r_n \times (|N| - r_n)}$, and $\tilde{E} \in \Re^{r_b \times (|N| - r_n)}$. Note that, by abuse of notation, we still denote the above matrix by A.

The following result, which is only used in the proof of Lemma 2.12, strongly uses the fact that A has the form (64). We observe however that the weaker form (62) of A is sufficient to establish the other results of subsection 2.6.

LEMMA 5.1. *For any positive diagonal $n \times n$ matrix D, there exists a matrix $W \in \Re^{|B| \times |N|}$ such that $E = BW$ and $\|D_B^{-1} W D_N\| \leq \bar{\chi}_{AD}$, where B and E are given by* (63).

Proof. We first prove the result for $D = I$. In this case, we choose W as

$$W = \begin{pmatrix} 0 & 0 \\ 0 & \tilde{E} \end{pmatrix}.$$

It is easy to see that $E = BW$ and that $\|W\| = \|\tilde{E}\| \leq \bar{\chi}_A$, where the last inequality follows as a consequence of Proposition 2.3(c).

Assume now that D is an arbitrary $n \times n$ positive diagonal matrix and let D_I denote the diagonal submatrix of D corresponding to the identity matrix of A. Also, let D_b and D_n denote the diagonal submatrices of D_I corresponding to the first $|B|$ columns and the last $|N|$ columns of the identity matrix of A, respectively. Then, the matrix given by

$$\hat{A} \equiv D_I^{-1} A D = \begin{pmatrix} D_b^{-1} B D_B & D_b^{-1} E D_N \\ 0 & D_n^{-1} N D_N \end{pmatrix}$$

also contains an $m \times m$ identity matrix. Applying the result shown in the first paragraph of this proof to the matrix $\hat{A}$, we conclude that there exists a matrix

$\hat{W}$ such that $\|\hat{W}\| \le \bar{\chi}_{\hat{A}} = \bar{\chi}_{AD}$ and $(D_b^{-1}BD_B)\hat{W} = D_b^{-1}ED_N$, or equivalently $B(D_B\hat{W}D_N^{-1}) = E$. The result now follows by letting $W = D_B\hat{W}D_N^{-1}$. ∎

The following lemma establishes some technical results about the direction $\Delta x(\lambda)$ defined in (28). Its proof is based on techniques developed in [23].

LEMMA 5.2. *Let $\Delta x(\cdot)$ be the curve defined as in* (28) *and let $\Delta x'(\cdot)$ denote its derivative. Then:*

$$\Delta x_B(0) \equiv \lim_{\lambda\to 0^+} \Delta x_B(\lambda) = \Delta_B^{-2}B^T(B\Delta_B^{-2}B^T)^{-1}H\Delta_N x_N; \tag{65}$$

$$\Delta x_N(0) \equiv \lim_{\lambda\to 0^+} \Delta x_N(\lambda) = -\Delta_N^{-1}P_{N\Delta_N^{-1}}x_N; \tag{66}$$

$$\Delta x'_B(0) \equiv \lim_{\lambda\to 0^+} \Delta x'_B(\lambda) = \Delta_B^{-2}B^T(B\Delta_B^{-2}B^T)^{-1}HH^T(B\Delta_B^{-2}B^T)^{-1}H\Delta_N x_N; \tag{67}$$

where $\Delta_B \equiv \mathrm{Diag}\{\delta_B\}$, $\Delta_N \equiv \mathrm{Diag}\{\delta_N\}$, $H \equiv E\Delta_N^{-1}P_{N\Delta_N^{-1}}$, and $P_{N\Delta_N^{-1}}$ denote the projection matrix onto the null space of $N\Delta_N^{-1}$.

Proof. Defining $D_\lambda \equiv \mathrm{Diag}\{\sqrt{\lambda}\delta_B, \delta_N\}$, we can easily see from (28) that $D_\lambda\Delta x(\lambda)$ is the projection of the vector $(0, \delta_N x_N)$ onto the null space of AD_λ^{-1}. Hence, for any $\lambda > 0$ we have

$$\Delta x_B(\lambda) = \lambda^{-1}\Delta_B^{-2}A_B^T(AD_\lambda^{-2}A^T)^{-1}A_N x_N, \tag{68}$$

$$\Delta x_N(\lambda) = \Delta_N^{-2}A_N^T(AD_\lambda^{-2}A^T)^{-1}A_N x_N - x_N. \tag{69}$$

Using (62) and the definition of D_λ, we have

$$\begin{aligned} AD_\lambda^{-2}A^T &= \begin{pmatrix} B & E \\ 0 & N \end{pmatrix}\begin{pmatrix} \lambda^{-1}\Delta_B^{-2} & 0 \\ 0 & \Delta_N^{-2} \end{pmatrix}\begin{pmatrix} B^T & 0 \\ E^T & N^T \end{pmatrix} \\ &= \begin{pmatrix} \lambda^{-1}B\Delta_B^{-2}B^T + E\Delta_N^{-2}E^T & E\Delta_N^{-2}N^T \\ N\Delta_N^{-2}E^T & N\Delta_N^{-2}N^T \end{pmatrix} \\ &= \begin{pmatrix} \lambda^{-1}R_{BB} + R_{EE} & R_{EN} \\ R_{EN}^T & R_{NN} \end{pmatrix}, \end{aligned}$$

where

$$R_{BB} \equiv B\Delta_B^{-2}B^T,\ \ R_{NN} \equiv N\Delta_N^{-2}N^T,\ \ R_{EE} \equiv E\Delta_N^{-2}E^T,\ \ R_{EN} \equiv E\Delta_N^{-2}N^T. \tag{70}$$

Using the standard way to compute the inverse of a 2×2 block matrix (see, for example, page 71–72 of [1]), it is easy to verify that

$$\left(AD_\lambda^{-2}A^T\right)^{-1} = \begin{pmatrix} U_\lambda & V_\lambda \\ V_\lambda^T & Z_\lambda \end{pmatrix},$$

where

$$U_\lambda = (\lambda^{-1}R_{BB} + R_{EE} - R_{EN}R_{NN}^{-1}R_{EN}^T)^{-1}, \tag{71}$$

$$V_\lambda = -U_\lambda R_{EN}R_{NN}^{-1}, \tag{72}$$

$$Z_\lambda = (R_{NN} - R_{EN}^T(\lambda^{-1}R_{BB} + R_{EE})^{-1}R_{EN})^{-1}. \tag{73}$$

Note that, by (70), we have

$$\begin{aligned} R_{EE} - R_{EN}R_{NN}^{-1}R_{EN}^T &= E\Delta_N^{-1}(I - \Delta_N^{-1}N^T(N\Delta_N^{-2}N^T)^{-1}N\Delta_N^{-1})\Delta_N^{-1}E^T \\ &= E\Delta_N^{-1}P_{N\Delta_N^{-1}}\Delta_N^{-1}E^T = HH^T. \end{aligned}$$

where we recall $H = E\Delta_N^{-1}P_{N\Delta_N^{-1}}$ and $P_{N\Delta_N^{-1}}$ denotes the projection matrix onto the null space of $N\Delta_N^{-1}$. Hence, by (71), we have

$$U_\lambda = (\lambda^{-1}R_{BB} + HH^T)^{-1} = \lambda(R_{BB} + \lambda HH^T)^{-1}. \tag{74}$$

Also, by (62) and (72), we have

$$\left(AD_\lambda^{-2}A^T\right)^{-1}A_N = \begin{pmatrix} U_\lambda E + V_\lambda N \\ V_\lambda^T E + Z_\lambda N \end{pmatrix} = \begin{pmatrix} U_\lambda(E - R_{EN}R_{NN}^{-1}N) \\ -R_{NN}^{-1}R_{EN}^T U_\lambda^T E + Z_\lambda N \end{pmatrix}. \tag{75}$$

Hence, using relations (68), (70), (74), and (75) and the definition of H, we obtain

$$\begin{aligned}
\Delta x_B(\lambda) &= \lambda^{-1}\Delta_B^{-2}B^T U_\lambda(E - R_{EN}R_{NN}^{-1}N)x_N \\
&= \lambda^{-1}\Delta_B^{-2}B^T U_\lambda E\Delta_N^{-1}\left(I - \Delta_N^{-1}N^T(N\Delta_N^{-2}N^T)^{-1}N\Delta_N^{-1}\right)\Delta_N x_N \\
&= \lambda^{-1}\Delta_B^{-2}B^T U_\lambda E\Delta_N^{-1}P_{ND_N^{-1}}\Delta_N x_N \;=\; \Delta_B^{-2}B^T(R_{BB} + \lambda HH^T)^{-1}H\Delta_N x_N,
\end{aligned} \tag{76}$$

from which we can easily see that (65) and (67) hold. Now, using relations (74) and (73), we easily see that

$$\lim_{\lambda\to 0^+} U_\lambda = 0, \quad \lim_{\lambda\to 0^+} Z_\lambda = R_{NN}^{-1}.$$

Relation (66) now follows from the last conclusion and relations (69) and (75). ∎

We need one more technical result before giving the proofs of the results of subsection 2.6.

LEMMA 5.3. *Let $G \in \Re^{p\times q}$ and $g \in \Re^q$ be given. Then, $(GG^T)Gg = 0$ if and only if $Gg = 0$.*

Proof. The assumption $(GG^T)Gg = 0$ clearly implies that $\|G^TGg\|^2 = 0$, and hence that $G^TGg = 0$. Also, the latter condition implies that $\|Gg\|^2 = 0$, or equivalently, $Gg = 0$. ∎

We are now ready to prove Lemma 2.10, Lemma 2.12, and Theorem 2.14 stated in subsection 2.6.

Proof of Lemma 2.10. We first prove statements (a) and (b). The existence and characterizations of the two limits $\Delta x(0) \equiv \lim_{\lambda\to 0^+}\Delta x(\lambda)$ and $\Delta x'_B(0) \equiv \lim_{\lambda\to 0^+}\Delta x'_B(\lambda)$ were established in Lemma 5.2. The alternative characterization given by (30) and (31) of the limit $\Delta x(0) \equiv \lim_{\lambda\to 0^+}\Delta x(\lambda)$ can be easily proved by showing that $\Delta x_B(0)$ and $\Delta x_N(0)$ satisfy the optimality conditions, and hence are optimal solutions of (30) and (31), respectively. Now, relation (32) follows immediately from (29). Moreover, differentiating (29) with respect to λ, we conclude that

$$\psi'_p(\lambda) = \frac{[\delta_B\Delta x_B(\lambda)]^T[\delta_B\Delta x'_B(\lambda)]}{\sqrt{\mu}\|\delta_B\Delta x_B(\lambda)\|} = \frac{[\delta_B\Delta x_B(\lambda)]^T[\delta_B\Delta x'_B(\lambda)]}{\mu\psi_p(\lambda)}. \tag{77}$$

Hence, under the the condition that $\psi_p(0) \neq 0$, the limit $\psi'_p(0) \equiv \lim_{\lambda\to 0^+}\psi'_p(\lambda)$ exists and is equal to the right-hand side of (77) with $\lambda = 0$.

We now outline the proof of statement (c). Using definition (29) and relation (76) we conclude that

$$\begin{aligned}
\mu\psi_p(\lambda)^2 &= x_N^T\Delta_N H^T(R_{BB} + \lambda HH^T)^{-1}R_{BB}(R_{BB} + \lambda HH^T)^{-1}H\Delta_N x_N \\
&= x_N^T\Delta_N H^T R_{BB}^{-1/2}(I + \lambda R_{BB}^{-1/2}HH^TR_{BB}^{-1/2})^{-2}R_{BB}^{-1/2}H\Delta_N x_N, \\
&= \|(I + \lambda\tilde{H})^{-1}\tilde{g}\|^2,
\end{aligned} \tag{78}$$

where $\mu \equiv \mu(w)$, $\tilde{H} \equiv R_{BB}^{-1/2} H H^T R_{BB}^{-1/2}$, and $\tilde{g} \equiv R_{BB}^{-1/2} H \Delta_N x_N$. The above formula for $\psi_p(\cdot)$ allows us to express it in terms of the eigenvalues and eigenvector of the positive semidefinite matrix $\tilde{H}$, and the resulting expression easily reveals that (i) $\tilde{H}\tilde{g} = 0$ if and only if $\psi_p(\cdot)$ is identically constant, and (ii) $\tilde{H}\tilde{g} \neq 0$ if and only if $\psi_p(\cdot)$ is strictly decreasing and strictly convex over the interval $(0, \infty)$. Moreover, if case (i) occurs, it follows from Lemma 5.3 with $G = R_{BB}^{-1/2} H$ and $g = \Delta_N x_N$ that $0 = Gg = R_{BB}^{-1/2} H \Delta_N x_N$, and hence that $H \Delta_N x_N = 0$. In view of (65), this implies that $\Delta x_B(0) = 0$, and hence that $\psi_p(0) = 0$. We have thus shown that $\psi_p(\cdot)$ is indeed identically zero when case (i) occurs.

We now show statement d). Let $0 < \lambda_1 \leq \lambda_2$ be given. By (78), we have

$$\frac{\psi_p^2(\lambda_1)}{\psi_p^2(\lambda_2)} = \frac{\tilde{g}^T(\lambda_1 \tilde{H} + I)^{-2}\tilde{g}}{\tilde{g}^T(\lambda_2 \tilde{H} + I)^{-2}\tilde{g}} = \frac{u^T \tilde{M} u}{u^T u},$$

where $u \equiv (\lambda_2 \tilde{H} + I)^{-1}\tilde{g}$ and $\tilde{M} = (\lambda_2 \tilde{H} + I)(\lambda_1 \tilde{H} + I)^{-2}(\lambda_2 \tilde{H} + I)$. Using the fact that $0 < \lambda_1 \leq \lambda_2$, we easily see that the largest eigenvalue of $\tilde{M}$, and hence $\psi_p^2(\lambda_1)/\psi_p^2(\lambda_2)$ is bounded by $(\lambda_2/\lambda_1)^2$. ∎

Proof of Lemma 2.12. First observe that, by (29), (77), and the Cauchy–Schwarz inequality, we have

$$\frac{|\psi_p'(0)|}{\psi_p(0)} = \frac{\left|[\delta_B \Delta x_B(0)]^T [\delta_B \Delta x_B'(0)]\right|}{\|\delta_B \Delta x_B(0)\|^2} \leq \frac{\|\delta_B \Delta x_B'(0)\|}{\|\delta_B \Delta x_B(0)\|}. \tag{79}$$

We will now use the formulas developed in Lemma 5.2 to bound the above ratio from above. Letting $\Delta_B \equiv \mathrm{Diag}(\delta_B)$ and $\Delta_N \equiv \mathrm{Diag}(\delta_N)$, we have that the matrix H defined in Lemma 5.2 can be written as

$$H \equiv E \Delta_N^{-1} P_{N\Delta_N^{-1}} = B \Delta_B^{-1} (\Delta_B W \Delta_N^{-1} P_{N\Delta_N^{-1}}) = B \Delta_B^{-1} M,$$

where $M \equiv \Delta_B W \Delta_N^{-1} P_{N\Delta_N^{-1}}$ and W is a matrix as in Lemma 5.1. Using this expression for H and relations (65) and (67), we then obtain

$$\begin{aligned}
\delta_B \Delta x_B'(0) &= \Delta_B^{-1} B^T (B \Delta_B^{-2} B^T)^{-1} H H^T (B \Delta_B^{-2} B^T)^{-1} H \Delta_N x_N \\
&= \Delta_B^{-1} B^T (B \Delta_B^{-2} B^T)^{-1} \left(B \Delta_B^{-1} M\right) \left(M^T \Delta_B^{-1} B^T\right) (B \Delta_B^{-2} B^T)^{-1} H \Delta_N x_N \\
&= [\Delta_B^{-1} B^T (B \Delta_B^{-2} B^T)^{-1} B \Delta_B^{-1}] (M M^T) [\delta_B \Delta x_B(0)].
\end{aligned}$$

Using the fact that the matrix inside the first bracket in the right-hand side of the above inequality is a projection matrix and Lemma 5.1, we then conclude that

$$\begin{aligned}
\frac{\|\delta_B \Delta x_B'(0)\|}{\|\delta_B \Delta x_B(0)\|} &\leq \|M\|^2 = \|\Delta_B W \Delta_N^{-1} P_{N D_N^{-1}}\|^2 \leq \|\Delta_B W \Delta_N^{-1}\|^2 \\
&\leq \|\delta_B (\delta_0)_B^{-1}\|_\infty^2 \|(\Delta_0)_B W (\Delta_0)_N^{-1}\|^2 \|\delta_N^{-1}(\delta_0)_N\|_\infty^2 \\
&\leq [\bar{\chi}_{A\Delta_0^{-1}}]^2 \|\delta_B (\delta_0)_B^{-1}\|_\infty^2 \|\delta_N^{-1}(\delta_0)_N\|_\infty^2, \qquad (80)
\end{aligned}$$

where $\delta_0 \equiv \delta(w_0)$ and $\Delta_0 \equiv \mathrm{Diag}(\delta_0)$. Moreover, using the fact that $\mu \leq \mu_0$ together with Propositions 2.1 and 2.2, we conclude that

$$\|\delta_B (\delta_0)_B^{-1}\|_\infty \leq \frac{1+\beta}{(1-\beta)^2} \sqrt{\frac{\mu_0}{\mu}} \left\| \frac{s(\mu)}{s(\mu_0)} \right\|_\infty \leq \frac{(1+\beta)n}{(1-\beta)^2} \sqrt{\frac{\mu_0}{\mu}}, \tag{81}$$

$$\|\delta_N^{-1}(\delta_0)_N\|_\infty \le \frac{1+\beta}{(1-\beta)^2}\sqrt{\frac{\mu}{\mu_0}}\left\|\frac{s_N(\mu_0)}{s_N(\mu)}\right\|_\infty$$

$$\le \frac{1+\beta}{(1-\beta)^2}\sqrt{\frac{\mu_0}{\mu}}\left\|\frac{x_N(\mu)}{x_N(\mu_0)}\right\|_\infty \le \frac{(1+\beta)n}{(1-\beta)^2}\sqrt{\frac{\mu_0}{\mu}}. \tag{82}$$

Inequality (36) now follows by combining the estimates (79), (80), (81), and (82). ∎

Proof of Theorem 2.14. Recall that our goal is to prove that the arithmetic complexity of computing a TR direction during a TR-iteration is bounded by (41). It suffices to examine just the computation of the primal TR direction since the argument for the dual TR direction is analogous. We have seen in the proof of Lemma 2.10 that $\psi_p(\lambda)$ can be expressed as $\psi_p(\lambda) = \|(I+\lambda\tilde{H})^{-1}\tilde{g}\|/\sqrt{\mu}$, where $\tilde{H} \in \Re^{|B|\times|B|}$ and $\tilde{g} \in \Re^{|B|}$ can be computed in $\mathcal{O}(n^3)$ arithmetic operations. It is well known that we can compute an orthogonal matrix Q such that the matrix $T \equiv Q^T\tilde{H}Q$ is tridiagonal in $\mathcal{O}(n^3)$ arithmetic operations. Moreover, using the fact that orthogonal matrices preserve vector lengths, we easily see that $\psi_p(\lambda) = \|(I+\lambda T)^{-1}Q^T\tilde{g}\|/\sqrt{\mu}$. Hence, for any fixed $\lambda > 0$, the fact that T is tridiagonal implies that $\psi_p(\lambda)$ can be computed in $\mathcal{O}(n)$ arithmetic operations. We have thus shown that the arithmetic complexity to compute a TR direction during a TR iteration is bounded by (41). ∎

6. Conclusion. In this paper, we have developed a predictor-corrector, trust-region algorithm for linear programming whose iteration-complexity just depends on $\bar{\chi}_A^*$. The overall arithmetic complexity of the algorithm is not independent of b and/or c, due to work involved in the computation of the trust region steps. An interesting and challenging open question is whether the arithmetic complexity of the PC-TR algorithm, or a variant of it, has an arithmetic complexity that does not depend on b and c.

Appendix. The objective of this section is to provide a proof of Lemma 2.7.

First, we state a technical result whose proof is given in Lemma 4.4 of Monteiro and Tsuchiya [14].

LEMMA A.1. *Let $w = (x,y,s) \in \mathcal{P}^{++} \times \mathcal{D}^{++}$ be given and assume that $\|xs - \nu e\| \le \tau\nu$ for some constants $\tau \in (0,1)$ and $\nu > 0$. Then, $(1-\tau/\sqrt{n})\nu \le \mu(w) \le (1+\tau/\sqrt{n})\nu$ and $w \in \mathcal{N}(\tau/(1-\tau))$.*

We are now ready to prove Lemma 2.7.

Proof of Lemma 2.7. Define $v(\alpha) \equiv (x+\alpha\Delta x)(s+\alpha\Delta s)$ for all $\alpha \in \Re$. We claim that

$$\|v(\alpha) - (1-\alpha)\mu e\| \le \frac{2\beta}{1+2\beta}(1-\alpha)\mu \quad \forall\, 0 \le \alpha \le 1-\bar{\alpha}, \tag{83}$$

where $\mu \equiv \mu(w)$,

$$\varepsilon_2(w) \equiv \max\{\|Rx_N\|, \|Rs_B\|\}, \qquad \bar{\alpha} \equiv \frac{\sqrt{1+\beta}+\gamma}{4\gamma}\varepsilon_2(w). \tag{84}$$

Using this claim, the result can be proved as follows. By Lemma A.1 with $w = w + \alpha\Delta w$, $\nu = (1-\alpha)\mu$ and $\tau = 2\beta/(1+2\beta)$, we conclude from the claim that for any $0 \le \alpha \le 1-\bar{\alpha}$, we have $w + \alpha\Delta w \in \mathcal{N}(2\beta)$ and

$$\mu(w+\alpha\Delta w) \le \left(1 + \frac{2\beta}{\sqrt{n}(1+2\beta)}\right)(1-\alpha)\mu \le 2(1-\alpha)\mu. \tag{85}$$

By the definition of α_τ, we then conclude that $\alpha_\tau \ge 1-\bar{\alpha}$. Setting $\alpha = 1-\bar{\alpha}$ in (85) and using the fact that $\alpha_\tau \ge 1-\bar{\alpha}$ and $\mu(w+\alpha\Delta w)$ is a decreasing (affine) function

of α, we obtain

$$\frac{\mu(w+\alpha_\tau \Delta w)}{\mu(w)} \leq \frac{\sqrt{1+\beta}+\gamma}{2\gamma}\varepsilon_2(w),$$

that is, the result holds.

In the remaining part of the proof, we show that (83) holds. It is easy to see that

$$\begin{aligned} v(\alpha)-(1-\alpha)\mu e &= (x+\alpha\Delta x)(s+\alpha\Delta s)-(1-\alpha)\mu e \\ &= (1-\alpha)(xs-\mu e)+\alpha h^1+\alpha(1-\alpha)h^2+\alpha^2 h^3, \end{aligned} \tag{86}$$

where h^1, h^2, and h^3 are vectors in $\Re^n$ defined as

$$\begin{pmatrix} h^1_B \\ h^1_N \end{pmatrix} \equiv \begin{pmatrix} x_B(s_B+\Delta s_B) \\ s_N(x_N+\Delta x_N) \end{pmatrix} = \mu \begin{pmatrix} w_B p_B \\ w_N p_N \end{pmatrix}, \tag{87}$$

$$\begin{pmatrix} h^2_B \\ h^2_N \end{pmatrix} \equiv \begin{pmatrix} s_B \Delta x_B \\ x_N \Delta s_N \end{pmatrix} = \mu \begin{pmatrix} w_B q_B \\ w_N q_N \end{pmatrix}, \tag{88}$$

$$\begin{pmatrix} h^3_B \\ h^3_N \end{pmatrix} \equiv \begin{pmatrix} \Delta x_B(s_B+\Delta s_B) \\ \Delta s_N(x_N+\Delta x_N) \end{pmatrix} = \mu \begin{pmatrix} p_B q_B \\ p_N q_N \end{pmatrix}. \tag{89}$$

Here, the vectors p, q, and w appearing in the second alternative expressions for h^1, h^2, and h^3 are defined as

$$\begin{pmatrix} p_B \\ p_N \end{pmatrix} \equiv \begin{pmatrix} Rs_B(w) \\ Rx_N(w) \end{pmatrix}, \qquad \begin{pmatrix} q_B \\ q_N \end{pmatrix} \equiv \begin{pmatrix} \Delta_B \Delta x_B/\sqrt{\mu} \\ \Delta_N^{-1}\Delta s_N/\sqrt{\mu} \end{pmatrix}, \qquad w \equiv \frac{x^{1/2}s^{1/2}}{\sqrt{\mu}}.$$

Clearly, in view of (84), (18), and the fact that $w \in \mathcal{N}(\beta)$, we have

$$\|p\|_\infty \leq \varepsilon_2(w), \ \ \|p\| \leq \sqrt{2}\varepsilon_2(w), \quad \|q\| \leq \sqrt{2}\gamma, \ \ \|w\|_\infty \leq \sqrt{1+\beta}, \ \ \|w\| = \sqrt{n}. \tag{90}$$

Using (87), (88), (89), and (90), we obtain

$$\begin{aligned} \|h^1\| \leq \mu\|w\|_\infty \|p\| &\leq \mu\sqrt{2(1+\beta)}\varepsilon_2(w), \\ \|h^2\| \leq \mu\|w\|_\infty \|q\| &\leq \mu\sqrt{2(1+\beta)}\gamma, \\ \|h^3\| \leq \mu\|p\|_\infty \|q\| &\leq \mu\sqrt{2}\gamma\varepsilon_2(w). \end{aligned}$$

Using (86), the triangle inequality for norms, the three estimates above and relations (84) and (17), we then obtain

$$\begin{aligned} \|v(\alpha)-(1-\alpha)\mu e\| &\leq (1-\alpha)\|xs-\mu e\|+\alpha\|h^1\|+\alpha(1-\alpha)\|h^2\|+\alpha^2\|h^3\| \\ &\leq (1-\alpha)\left(\|xs-\mu e\|+\|h^2\|\right)+\|h^1\|+\|h^3\| \\ &\leq \left[(1-\alpha)\left(\beta+\sqrt{2(1+\beta)}\,\gamma\right)+\left(\sqrt{2(1+\beta)}+\sqrt{2}\,\gamma\right)\varepsilon_2(w)\right]\mu \\ &\leq \left[(1-\alpha)\left(\beta+\sqrt{2(1+\beta)}\,\gamma\right)+4\sqrt{2}\gamma\bar{\alpha}\right]\mu \\ &\leq \left[\left(\beta+\sqrt{2(1+\beta)}\,\gamma\right)+4\sqrt{2}\gamma\right](1-\alpha)\mu \\ &\leq \frac{2\beta}{1+2\beta}(1-\alpha)\mu, \end{aligned}$$

for all $0 \leq \alpha \leq 1-\bar{\alpha}$. ∎

A NEW CLASS OF MINIMUM NORM DUALITY THEOREMS*

ACHIYA DAX†

Abstract. In this paper we derive new duality results on the width and the length of symmetrical convex bodies. Let K be a symmetrical convex body in R^m and let $\|\cdot\|$ be some (arbitrary) norm on R^m. The width of K is obtained by searching for the smallest "sandwich" (or "slab") that contains K. It is shown that the dual problem has the following form: Find the largest diameter of a norm ball that is contained in K. Indeed, the diameter of a maximal norm ball equals the width of the smallest sandwich. Moreover, the solutions of the two problems obey certain alignment relations. The length of K is found by searching the largest "sandwich" that contains K. The last problem is closely related to the "maximal chord problem" whose optimal value is called the "diameter" of K. In this case the dual problem is to find the smallest norm ball that contains K. It is proved that the diameter of the smallest norm ball equals the diameter (the length) of K, and that primal and dual solutions satisfy certain alignment relations. Part of the results remain valid for more general convex sets.

Key words. minimum norm duality theorems, dual norm, alignment relations, norm balls, symmetrical convex bodies, depth, width, length, diameter, nearest supporting hyperplane, the smallest sandwich problem, the largest sandwich problem

1. Introduction.

The minimum norm duality (MND) theorem considers the distance between a point $\mathbf{z}$ and a closed convex set Y. It says that the shortest distance from $\mathbf{z}$ to Y is equal to the maximum of the distances from $\mathbf{z}$ to any hyperplane separating $\mathbf{z}$ and Y. (See Figure 1.) This fundamental observation gives rise to several useful duality relations in best approximation problems, linear least norm problems, and theorems of the alternative. As far as we know, the first statement of the MND theorem is due to Nirenberg [21], who established this assertion in any normed linear space by applying the Hahn–Banach theorem. The name "MND theorem" was coined by Luenberger [19], who also derived the "alignment" relation between primal and dual solutions.

Recently Dax [8] extended the MND theorem to consider the distance between two convex sets. Roughly speaking the new theorem says that the shortest distance between the two sets is equal to the maximal "separation" between the sets, where the term "separation" refers to the distance between a pair of parallel hyperplanes that separates the two sets. (See Figure 2.)

Another extension of the MND theorem is proposed by Briec [5], who considers the case when $\mathbf{z}$ is an interior point of Y. This theorem says that the shortest distance from $\mathbf{z}$ to any supporting hyperplane of Y is equal to the "depth" of $\mathbf{z}$. (See Figure 4.) The depth of $\mathbf{z}$ is defined as the shortest distance from $\mathbf{z}$ to any boundary point of Y. In other words, the depth of $\mathbf{z}$ is equal to the radius of the largest norm ball that is centered at $\mathbf{z}$ and contained in Y.

In this paper we establish a new class of duality theorems, one that considers the "width" and the "length" of a convex body. Let K be a convex body in R^m. That

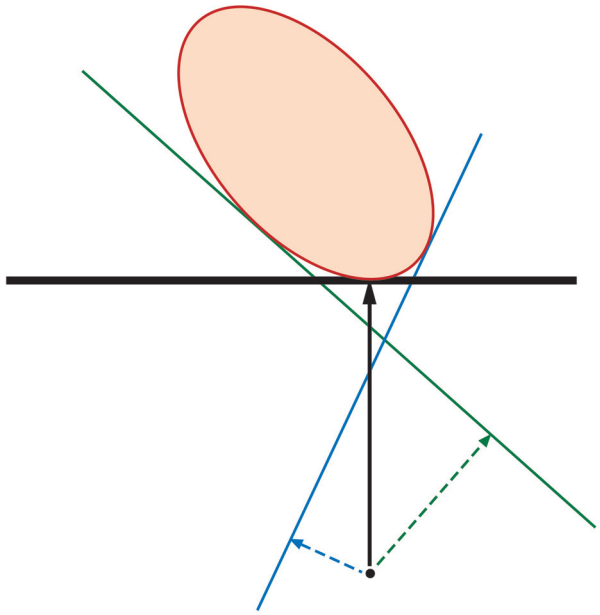

FIG. 1. *The Nirenberg–Luenberger MND theorem.*

is, K is a closed bounded convex set that contains interior points. Let $\|\cdot\|$ be some (arbitrary) norm on R^m and let $\|\cdot\|'$ denote the corresponding dual norm. Then for any nonzero vector $\mathbf{a} \in R^m$ there exists a pair of points, $\mathbf{y}_1 \in K$ and $\mathbf{y}_2 \in K$, such that

$$\mathbf{a}^T\mathbf{y}_1 = \inf_{\mathbf{x}\in K} \mathbf{a}^T\mathbf{x} \quad \text{and} \quad \mathbf{a}^T\mathbf{y}_2 = \sup_{\mathbf{x}\in K} \mathbf{a}^T\mathbf{x}. \tag{1.1}$$

Consequently K is "sandwiched" between the parallel hyperplanes

$$H_1 = \left\{ \mathbf{x} \,\middle|\, \mathbf{a}^T\mathbf{x} = \mathbf{a}^T\mathbf{y}_1 \right\} \quad \text{and} \quad H_2 = \left\{ \mathbf{x} \,\middle|\, \mathbf{a}^T\mathbf{x} = \mathbf{a}^T\mathbf{y}_2 \right\}. \tag{1.2}$$

The distance between a pair of parallel hyperplanes of this form is defined as

$$\inf \left\{ \|\mathbf{x}_1 - \mathbf{x}_2\| \,\middle|\, \mathbf{x}_1 \in H_1,\, \mathbf{x}_2 \in H_2 \right\}.$$

Using this definition one can show that the width function

$$\omega(\mathbf{a}) = (\mathbf{a}^T\mathbf{y}_2 - \mathbf{a}^T\mathbf{y}_1)/\|\mathbf{a}\|' \tag{1.3}$$

measures the distance between the two hyperplanes in (1.2). See section 2. The set

$$S(\mathbf{a}, K) = \left\{ \mathbf{x} \,\middle|\, \inf_{\mathbf{x}\in K} \mathbf{a}^T\mathbf{x} \le \mathbf{a}^T\mathbf{x} \le \sup_{\mathbf{x}\in K} \mathbf{a}^T\mathbf{x} \right\}$$

is said to be a "sandwich" (or "slab") of K, and $\omega(\mathbf{a})$ provides the "width" of this sandwich. The smallest sandwich of K is constructed, therefore, by a vector $\mathbf{a}$ for which $\omega(\mathbf{a})$ attains the smallest possible value. Similarly, the largest sandwich of K is constructed by a vector $\mathbf{a}$ for which $\omega(\mathbf{a})$ attains the largest possible value. The

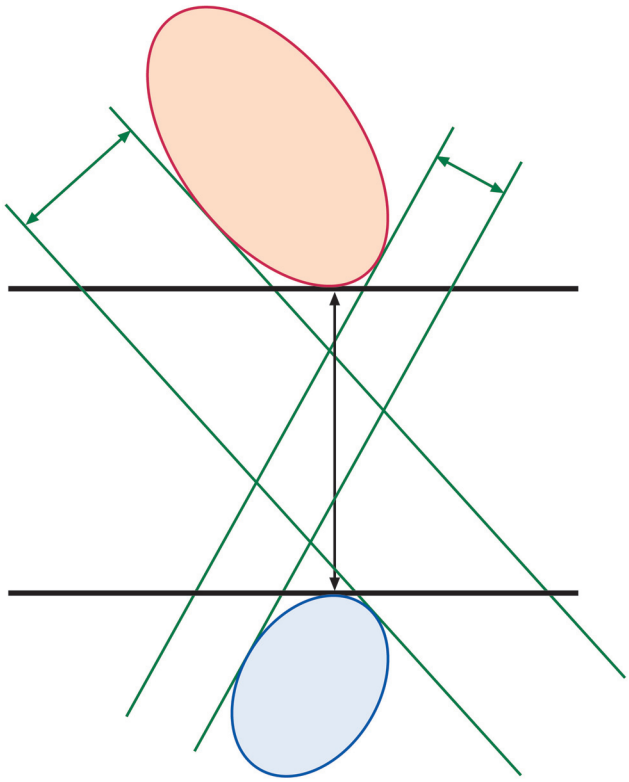

FIG. 2. *Dax MND theorem.*

smallest value of $\omega(\mathbf{a})$ is called the "width" of K. The largest value of $\omega(\mathbf{a})$ is called the "length" of K.

The paper explores the duality properties that characterize the smallest and largest sandwiches of K. The strongest duality results require K to be a symmetrical convex body, for which there exists a point $\mathbf{c} \in K$ with the following property: For any $\mathbf{x} \in K$ the point $\mathbf{y} = 2\mathbf{c} - \mathbf{x}$ belongs to K. The point $\mathbf{c}$ is called the "center of symmetry" of K, or simply the "center" of K. The point $\mathbf{y} = 2\mathbf{c} - \mathbf{x}$ is called the "symmetrical image" of $\mathbf{x}$.

The plan of our paper is as follows. It starts with a brief overview of the basic alignment relations on a norm ball. (See Figure 3.) These relations provide the tools for proving our duality results. The third section considers the nearest hyperplane problem, giving a new simple proof to the Briec theorem [5]. The "opposite" problem is to find a supporting hyperplane of K which is the farthest away from a given point of K. (See Figures 5 and 6.) This problem is discussed in section 4. The duality features that characterize the smallest possible sandwich are derived in section 5. It is shown there that the dual problem has the following form: Find the largest norm ball that is contained in K. (See Figure 7.) The largest possible sandwich is considered in section 6. In this case the dual problem is to find the smallest norm ball that contains K. (See Figure 8.) The duality results that we prove require K to be a symmetrical convex body. Yet, as section 7 shows, part of the results remain valid without symmetry.

2. Alignment relations on a norm ball. Here and henceforth $\|\cdot\|$ denotes some (arbitrary) norm on R^m and $\|\cdot\|'$ denotes the corresponding dual norm. Recall that the dual norm is defined by the rule

$$\|\mathbf{v}\|' = \sup_{\mathbf{u}\in U} \mathbf{u}^T\mathbf{v}, \tag{2.1}$$

where

$$U = \{\, \mathbf{x} \mid \|\mathbf{x}\| \le 1 \,\} \tag{2.2}$$

denotes the unit norm ball in R^m. Recall also that two nonzero vectors $\mathbf{u} \in R^m$ and $\mathbf{v} \in R^m$ are aligned if they satisfy

$$\mathbf{u}^T\mathbf{v} = \|\mathbf{u}\| \cdot \|\mathbf{v}\|'. \tag{2.3}$$

In this case the supremum in (2.1) is obtained for the unit vector $\mathbf{u}^* = \mathbf{u}/\|\mathbf{u}\|$. Moreover, since U is a compact set, there exists a vector $\mathbf{u}^* \in U$ that solves the problem

$$\begin{aligned} &\text{maximize} && \mathbf{u}^T\mathbf{v} \\ &\text{subject to} && \mathbf{u} \in U, \end{aligned}$$

and this vector satisfies $\|\mathbf{u}^*\| = 1$ and $(\mathbf{u}^*)^T\mathbf{v} = \|\mathbf{v}\|'$. That is, the vectors $\mathbf{u}^*$ and $\mathbf{v}$ are aligned and the hyperplane

$$H = \{\, \mathbf{x} \mid \mathbf{v}^T\mathbf{x} = \mathbf{v}^T\mathbf{u}^* \,\}$$

supports U at $\mathbf{u}^*$. See Figure 3.

Similar alignment relations exist on any norm ball in R^m. Let

$$B = \{\, \mathbf{x} \mid \|\mathbf{x} - \mathbf{z}\| \le r \,\}$$

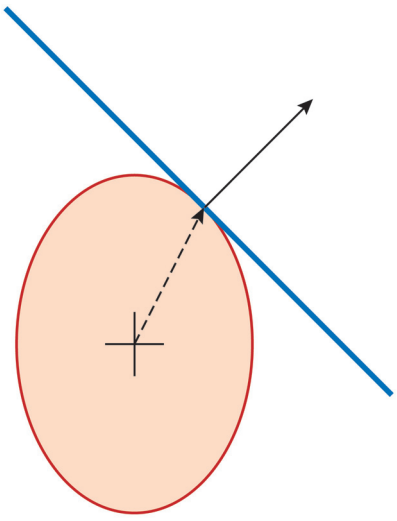

FIG. 3. *Alignment relations on a norm ball.*

be a norm ball of radius r that is centered at some point $\mathbf{z} \in R^m$. Then for any vector $\mathbf{a} \in R^m$, $\mathbf{a} \neq \mathbf{0}$, there exists a boundary point of B, say $\mathbf{y}_1$, such that

$$\mathbf{a}^T\mathbf{y}_1 = \sup_{\mathbf{x}\in B} \mathbf{a}^T\mathbf{x}, \tag{2.4}$$

and

$$H_1 = \{\, \mathbf{x} \mid \mathbf{a}^T\mathbf{x} = \mathbf{a}^T\mathbf{y}_1 \,\}$$

is a supporting hyperplane of B at $\mathbf{y}_1$. A further consequence of (2.4) is that the vectors $\mathbf{u} = \mathbf{y}_1 - \mathbf{z}$ and $\mathbf{a}$ are aligned, and that $\|\mathbf{u}\| = r$. In other words,

$$\mathbf{u}^T\mathbf{a} = \|\mathbf{u}\| \cdot \|\mathbf{a}\|' = r\|\mathbf{a}\|'. \tag{2.5}$$

Recall that the distance between $\mathbf{z}$ and H_1 is defined as

$$d(\mathbf{z}, H_1) = \inf\{\, \|\mathbf{x} - \mathbf{z}\| \mid \mathbf{x} \in H_1 \,\}.$$

Therefore, since H_1 is a supporting hyperplane of B, this distance equals r and satisfies

$$\operatorname{dist}(\mathbf{z}, H_1) = r = \mathbf{a}^T\mathbf{u}/\|\mathbf{a}\|' = (\mathbf{a}^T\mathbf{y}_1 - \mathbf{a}^T\mathbf{z})/\|\mathbf{a}\|'.$$

The last observation can be generalized in two ways. Let

$$H_\alpha = \{\, \mathbf{x} \mid \mathbf{a}^T\mathbf{x} = \alpha \,\}$$

be a hyperplane in R^m. Then the distance between $\mathbf{z}$ and H_α satisfies the following rule:

$$\operatorname{dist}(\mathbf{z}, H_\alpha) = (\alpha - \mathbf{a}^T\mathbf{z})/\|\mathbf{a}\|' \quad \text{when} \quad \mathbf{a}^T\mathbf{z} \leq \alpha,$$

and

$$\operatorname{dist}(\mathbf{z}, H_\alpha) = (\mathbf{a}^T\mathbf{z} - \alpha)/\|\mathbf{a}\|' \quad \text{when} \quad \mathbf{a}^T\mathbf{z} \geq \alpha.$$

Moreover, let

$$H_\beta = \{\, \mathbf{x} \mid \mathbf{a}^T\mathbf{x} = \beta \,\}$$

be some other hyperplane that is parallel to H_α and satisfies $\beta > \alpha$. Then for any point $\mathbf{x} \in H_\beta$

$$\operatorname{dist}(\mathbf{x}, H_\alpha) = (\mathbf{a}^T\mathbf{x} - \alpha)/\|\mathbf{a}\|' = (\beta - \alpha)/\|\mathbf{a}\|'.$$

Consequently

$$\operatorname{dist}(H_\beta, H_\alpha) = (\beta - \alpha)/\|\mathbf{a}\|', \tag{2.6}$$

which proves (1.3).

Another consequence that stems from (2.5) is related to the width of the sandwich $S(\mathbf{a}, B)$. Using the symmetry of B with respect to $\mathbf{z}$, one can verify that the point

$$\mathbf{y}_2 = \mathbf{z} - \mathbf{u} = 2\mathbf{z} - \mathbf{y}_1,$$

which is the "symmetrical image" of $\mathbf{y}_1$, satisfies

$$(-\mathbf{a})^T\mathbf{y}_2 = \sup_{\mathbf{x}\in B}(-\mathbf{a})^T\mathbf{x}.$$

The last equality means that the hyperplane

$$H_2 = \left\{\, \mathbf{x} \;\middle|\; (-\mathbf{a})^T\mathbf{x} = (-\mathbf{a})^T\mathbf{y}_2 \,\right\} = \left\{\, \mathbf{x} \;\middle|\; \mathbf{a}^T\mathbf{x} = \mathbf{a}^T\mathbf{y}_2 \,\right\}$$

supports B at $\mathbf{y}_2$, and that

$$\mathbf{a}^T\mathbf{y}_2 = \inf_{\mathbf{x}\in B}\mathbf{a}^T\mathbf{x}.$$

Therefore, since H_1 and H_2 are parallel hyperplanes,

$$\operatorname{dist}(H_1, H_2) = (\mathbf{a}^T\mathbf{y}_1 - \mathbf{a}^T\mathbf{y}_2)/\|\mathbf{a}\|' = 2\mathbf{u}^T\mathbf{a}/\|\mathbf{a}\|' = 2r,$$

where the last equality comes from (2.5). In other words, for any norm ball, B, and any vector $\mathbf{a} \in R^m$, $\mathbf{a} \neq \mathbf{0}$, the width of the sandwich $S(\mathbf{a}, B)$ equals the diameter of B.

3. The nearest supporting hyperplane. Let X be a closed convex set in R^m with nonempty interior and nonempty boundary. A hyperplane $H = \{\mathbf{x} \mid \mathbf{a}^T\mathbf{x} = \alpha\}$ is said to be a supporting hyperplane of X if $\mathbf{a} \neq \mathbf{0}$ and $\alpha = \sup_{\mathbf{x}\in X}\mathbf{a}^T\mathbf{x}$ attains a finite value. If, in addition, there exists a boundary point $\mathbf{y} \in X$ such that

$$\mathbf{a}^T\mathbf{y} = \alpha = \sup_{\mathbf{x}\in X}\mathbf{a}^T\mathbf{x},$$

then H is said to be a supporting hyperplane of X at $\mathbf{y}$. Let $\mathbf{z}$ be a given interior point of X. Then, as we have seen, the distance between $\mathbf{z}$ and H equals $(\alpha - \mathbf{a}^T\mathbf{z})/\|\mathbf{a}\|'$. The nearest supporting hyperplane is defined, therefore, by a vector $\mathbf{a} \in R^m$, $\mathbf{a} \neq \mathbf{0}$, that solves the minimization problem

$$\text{minimize} \quad \nu(\mathbf{a}) = \left(\sup_{\mathbf{x}\in X}\mathbf{a}^T\mathbf{x} - \mathbf{a}^T\mathbf{z}\right)/\|\mathbf{a}\|',$$

or

$$\begin{aligned} &\text{minimize} && \xi(\mathbf{a}) = \sup_{\mathbf{x}\in X}\mathbf{a}^T\mathbf{x} - \mathbf{a}^T\mathbf{z} \\ &\text{subject to} && \|\mathbf{a}\|' = 1. \end{aligned} \tag{3.1}$$

Below we will show that (3.1) is closely related to the problem of calculating the "depth" of $\mathbf{z}$, which is the radius of the largest norm ball that is centered in $\mathbf{z}$ and contained in X.

The formal definition of the "depth" function is

$$\operatorname{depth}(\mathbf{z}) = \inf\left\{\, \|\mathbf{y} - \mathbf{z}\| \;\middle|\; \mathbf{y} \in \tilde{X} \,\right\},$$

where $\tilde{X}$ denotes the boundary of X. Since X is a closed set, $\tilde{X} \subseteq X$ and there exists a point $\mathbf{y}^* \in \tilde{X}$ such that

$$\operatorname{depth}(\mathbf{z}) = \|\mathbf{y}^* - \mathbf{z}\|.$$

In other words, $\mathbf{y}^*$ solves the depth problem

$$\begin{aligned} &\text{minimize} && \rho(\mathbf{y}) = \|\mathbf{y} - \mathbf{z}\| \\ &\text{subject to} && \mathbf{y} \in \tilde{X}, \end{aligned} \tag{3.2}$$

and

$$B_{\mathbf{z}}^* = \left\{ \mathbf{x} \;\middle|\; \|\mathbf{x} - \mathbf{z}\| \leq \text{depth}(\mathbf{z}) \right\}$$

is the largest norm ball that is centered in $\mathbf{z}$ and contained in X.

Recall that for any boundary point $\mathbf{y} \in \tilde{X}$ one can find a hyperplane H that supports X at $\mathbf{y}$; see, e.g., [8]. Thus, in particular, there exists a vector $\mathbf{a}^* \in R^m$, $\|\mathbf{a}^*\|' = 1$, for which the hyperplane

$$H^* = \left\{ \mathbf{x} \;\middle|\; (\mathbf{a}^*)^T \mathbf{x} = (\mathbf{a}^*)^T \mathbf{y}^* \right\}$$

supports X at $\mathbf{y}^*$. That is,

$$(\mathbf{a}^*)^T \mathbf{y}^* = \sup_{\mathbf{x} \in X} (\mathbf{a}^*)^T \mathbf{x}. \tag{3.3}$$

Observe also that H^* is a supporting hyperplane of $B_{\mathbf{z}}^*$ at $\mathbf{y}^*$. One consequence of this observation is that the vectors $\mathbf{u} = \mathbf{y}^* - \mathbf{z}$ and $\mathbf{a}^*$ are aligned. That is,

$$\mathbf{u}^T \mathbf{a}^* = \|\mathbf{u}\| \, \|\mathbf{a}^*\|'. \tag{3.4}$$

A second consequence is that the distance between $\mathbf{z}$ and H^* equals depth($\mathbf{z}$).

On the other hand, the distance between $\mathbf{z}$ and any other supporting hyperplane of X exceeds depth($\mathbf{z}$), since $B_{\mathbf{z}}^*$ is contained in the "negative half-space" of that hyperplane. The last observation means that H^* solves the nearest hyperplane problem. Moreover, any other supporting hyperplane of X that solves this problem is forced to be a supporting hyperplane of $B_{\mathbf{z}}^*$ at some boundary point of $B_{\mathbf{z}}^*$. The next statement summarizes our findings.

THEOREM 1. *The nearest hyperplane problem* (3.1) *and the depth problem* (3.2) *are solvable and share the same optimal value, which is depth*($\mathbf{z}$). *Let* $\mathbf{y}^*$ *solve* (3.2)*; then there exists a vector* $\mathbf{a}^* \in R^m$ *for which the corresponding supporting hyperplane of* X *satisfies* (3.3)–(3.4) *and solves* (3.1). *Conversely, let* $\mathbf{a}^*$ *define a supporting hyperplane* H^* *of* X *that solves* (3.1). *Then* H^* *is also a supporting hyperplane of* $B_{\mathbf{z}}^*$ *at some boundary point,* $\mathbf{y}^*$*, of* $B_{\mathbf{z}}^*$. *Moreover, in both cases the vectors* $\mathbf{u} = \mathbf{y}^* - \mathbf{z}$ *and* $\mathbf{a}^*$ *are aligned.*

Theorem 1 is essentially the Briec theorem in R^m. The original proof in [5] uses the Edelheit separation theorem and the Nirenberg–Luenberger MND theorem. The current proof replaces these theorems with simple geometric arguments.

An important consequence of Theorem 1 is that searching for a point which maximizes depth($\mathbf{z}$) is equivalent to searching for a point which is farthest from any supporting hyperplane of X. Note also that both (3.1) and (3.2) may have more than one solution. Yet, as we have seen, any solution of one problem is related to a certain solution of the other problem. Methods for solving the nearest hyperplane problem are discussed in [5], [9], and [27]. In the next section we derive analogous results for the farthest supporting hyperplane.

4. The farthest supporting hyperplane. Here X denotes a convex body in R^m and $\mathbf{z}$ is a given interior point of X. Let $\mathbf{a}$ be some nonzero vector in R^m, and

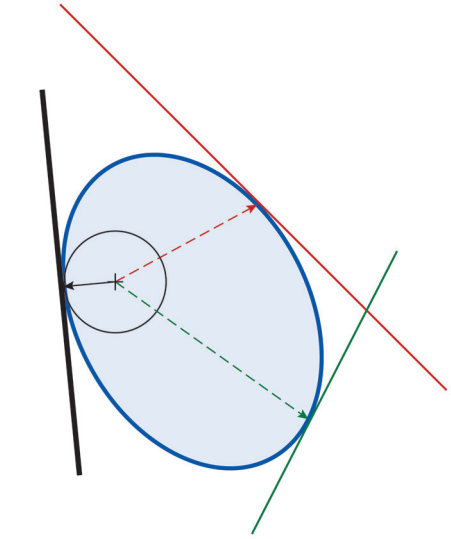

FIG. 4. *The nearest supporting hyperplane (Briec theorem).*

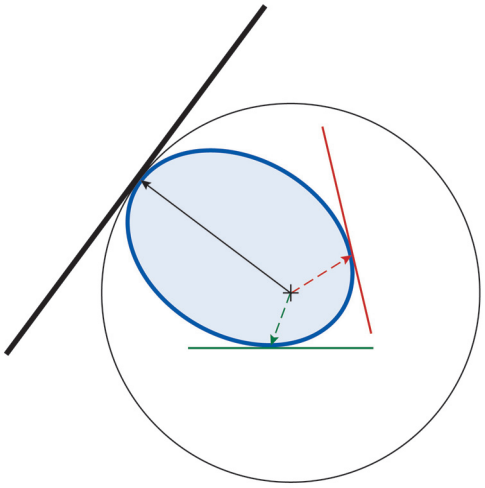

FIG. 5. *The farthest supporting hyperplane and the farthest point.*

let $H = \{\mathbf{x} \mid \mathbf{a}^T\mathbf{x} = \alpha\}$ denote the corresponding supporting hyperplane of X. Then, as we have seen,

$$\alpha = \sup_{\mathbf{x}\in X} \mathbf{a}^T\mathbf{x},$$

and the distance between $\mathbf{z}$ and H equals $(\alpha - \mathbf{a}^T\mathbf{z})/\|\mathbf{a}\|'$. The problem of calculating a supporting hyperplane of X whose distance from $\mathbf{z}$ is maximal can be posed, therefore, as

$$\text{maximize} \quad \varphi(\mathbf{a}) = \Big(\sup_{\mathbf{x}\in X} \mathbf{a}^T\mathbf{x} - \mathbf{a}^T\mathbf{z}\Big)/\|\mathbf{a}\|'$$

or

$$\begin{aligned} &\text{maximize} \quad \psi(\mathbf{a}) = \sup_{\mathbf{x}\in X} \mathbf{a}^T\mathbf{x} - \mathbf{a}^T\mathbf{z} \\ &\text{subject to} \quad \|\mathbf{a}\|' = 1. \end{aligned} \tag{4.1}$$

Below we will show that this problem is related to the "radius" of $\mathbf{z}$, which is the radius of the smallest norm ball that is centered at $\mathbf{z}$ and contains X.

The formal definition of the "radius" function is

$$\text{radius}(\mathbf{z}) = \sup\left\{ \|\mathbf{y} - \mathbf{z}\| \;\middle|\; \mathbf{y} \in X \right\}.$$

Since X is a convex body, there exists a point, $\hat{\mathbf{y}} \in X$, such that

$$\text{radius}(\mathbf{z}) = \|\hat{\mathbf{y}} - \mathbf{z}\|.$$

In other words, $\hat{\mathbf{y}}$ solves the radius problem

$$\begin{aligned} &\text{maximize} \quad \rho(\mathbf{y}) = \|\mathbf{y} - \mathbf{z}\| \\ &\text{subject to} \quad \mathbf{y} \in X. \end{aligned} \tag{4.2}$$

It is also easy to verify that $\hat{\mathbf{y}}$ is a boundary point of X, and that

$$\hat{B}_{\mathbf{z}} = \left\{ \mathbf{x} \;\middle|\; \|\mathbf{x} - \mathbf{z}\| \le \text{radius}(\mathbf{z}) \right\}$$

is the smallest norm ball that is centered at $\mathbf{z}$ and contains X. Consequently there exists a vector $\hat{\mathbf{a}} \in R^m$, $\|\hat{\mathbf{a}}\|' = 1$, for which the hyperplane

$$\hat{H} = \left\{ \mathbf{x} \;\middle|\; \hat{\mathbf{a}}^T\mathbf{x} = \hat{\mathbf{a}}^T\hat{\mathbf{y}} \right\}$$

supports $\hat{B}_{\mathbf{z}}$ at $\hat{\mathbf{y}}$. Therefore, since $\hat{B}_{\mathbf{z}}$ contains X,

$$\hat{\mathbf{a}}^T\hat{\mathbf{y}} = \sup_{\mathbf{x}\in\hat{B}_{\mathbf{z}}} \hat{\mathbf{a}}^T\mathbf{x} = \sup_{\mathbf{x}\in X} \hat{\mathbf{a}}^T\mathbf{x}, \tag{4.3}$$

which means that $\hat{H}$ is also a supporting hyperplane of X at $\hat{\mathbf{y}}$. The distance between $\mathbf{z}$ and $\hat{H}$ is, clearly, radius($\mathbf{z}$). On the other hand, let $\tilde{H}$ be another hyperplane that supports X at some point $\tilde{\mathbf{y}} \in X$. Then, since $\tilde{\mathbf{y}} \in \hat{B}_{\mathbf{z}}$, the distance between $\mathbf{z}$ and $\tilde{H}$ does not exceed radius($\mathbf{z}$). These observations bring us to the following conclusions.

THEOREM 2. *The farthest hyperplane problem* (4.1) *and the radius problem* (4.2) *are solvable and share the same optimal value, which is radius*($\mathbf{z}$). *Let* $\hat{\mathbf{y}}$ *solve* (4.2)*; then there exists a vector* $\hat{\mathbf{a}} \in R^m$ *that solves* (4.1) *and satisfies* (4.3). *Conversely, let* $\hat{\mathbf{a}} \in R^m$ *solve* (4.1)*; then there exists a boundary point,* $\hat{\mathbf{y}} \in X$*, which is also a boundary point of* $\hat{B}_{\mathbf{z}}$*, that solves* (4.2) *and satisfies* (4.3). *Moreover, in both cases the vectors* $\mathbf{u} = \hat{\mathbf{y}} - \mathbf{z}$ *and* $\hat{\mathbf{a}}$ *are aligned. That is,*

$$\mathbf{u}^T\hat{\mathbf{a}} = \|\mathbf{u}\| \cdot \|\hat{\mathbf{a}}\|' = \|\hat{\mathbf{y}} - \mathbf{z}\|.$$

Methods for solving the farthest hyperplane problem are discussed in [9]. One consequence of Theorem 2 is that searching for a point which minimizes radius($\mathbf{z}$) is equivalent to searching for a point that has the smallest distance to its farthest supporting hyperplane. Note also that Theorem 2 remains valid when X is an arbitrary compact set in R^m and $\mathbf{z}$ is an arbitrary point of R^m. Yet in this case the objective function of (4.1) may attain negative values and the terms "supporting hyperplane" or "farthest hyperplane problem" are not quite appropriate.

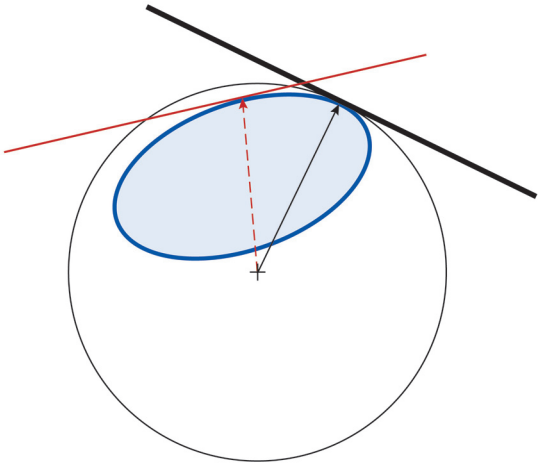

FIG. 6. *The farthest supporting hyperplane and the farthest point.*

5. The smallest sandwich problem. Let K denote a symmetrical convex body in R^m. As mentioned in the introduction, the width function (1.3) measures the distance between a pair of parallel supporting hyperplanes that "sandwich" K. The smallest sandwich problem is, therefore, to find a vector $\mathbf{a} \in R^m$, $\mathbf{a} \neq \mathbf{0}$, that solves the problem

$$\text{minimize} \quad w(\mathbf{a}) = \Big(\sup_{\mathbf{x}\in K} \mathbf{a}^T\mathbf{x} - \inf_{\mathbf{x}\in K} \mathbf{a}^T\mathbf{x} \Big) / \|\mathbf{a}\|'$$

or

$$\begin{aligned} &\text{minimize} && \sigma(\mathbf{a}) = \sup_{\mathbf{x}\in K} \mathbf{a}^T\mathbf{x} - \inf_{\mathbf{x}\in K} \mathbf{a}^T\mathbf{x} \\ &\text{subject to} && \|\mathbf{a}\|' = 1. \end{aligned} \tag{5.1}$$

The aim of this section is to show that the dual problem of (5.1) has the form

$$\begin{aligned} &\text{maximize} && \eta(\mathbf{z}) = 2\,\text{depth}(\mathbf{z}) \\ &\text{subject to} && \mathbf{z} \in K. \end{aligned} \tag{5.2}$$

Recall that

$$\text{depth}(\mathbf{z}) = \inf_{\mathbf{x}\in \tilde{K}} \|\mathbf{x} - \mathbf{z}\|, \tag{5.3}$$

where $\tilde{K}$ denotes the boundary of K. Thus $\eta(\mathbf{z})$ is the diameter of the largest norm ball that is centered at $\mathbf{z}$ and contained in K. Maximizing $\eta(\mathbf{z})$ over K means, therefore, that we search for the largest possible diameter of a norm ball that is contained in K. (See Figure 7.)

Let $\mathbf{z}$ be some interior point of K. Then the width function of the norm ball

$$B_{\mathbf{z}} = \big\{ \mathbf{x} \;\big|\; \|\mathbf{x} - \mathbf{z}\| \leq \text{depth}(\mathbf{z}) \big\}$$

has a constant value, which is $\eta(\mathbf{z})$. In other words, for any vector $\mathbf{a} \in R^m$, $\|\mathbf{a}\|' = 1$, the width of the sandwich $S(\mathbf{a}, B_{\mathbf{z}})$ equals $\eta(\mathbf{z})$. On the other hand, since $B_{\mathbf{z}}$ is contained in K, the width of $S(\mathbf{a}, B_{\mathbf{z}})$ is smaller than the width of $S(\mathbf{a}, K)$. That is,

$$\eta(\mathbf{z}) \leq \sigma(\mathbf{a}). \tag{5.4}$$

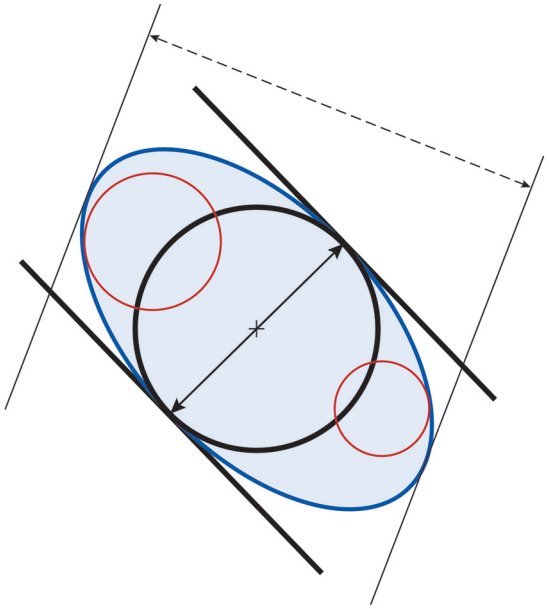

FIG. 7. *The width of the smallest sandwich equals the diameter of the largest norm ball.*

The symmetry of K implies the existence of a "center point," $\mathbf{c}$, that has the following property: For any $\mathbf{x} \in K$ the point $2\mathbf{c} - \mathbf{x}$ (the "symmetrical image" of $\mathbf{x}$) belongs to K. Thus, in particular, for any interior point $\mathbf{z}$ the symmetrical image of $B_{\mathbf{z}}$ is contained in K. Now the convexity of K implies that the norm ball

$$\{\, \mathbf{x} \mid \|\mathbf{x} - \mathbf{c}\| \leq \operatorname{depth}(\mathbf{z}) \,\}$$

is contained in K, so

$$\eta(\mathbf{z}) \leq \eta(\mathbf{c}). \tag{5.5}$$

The last inequality means that $\mathbf{c}$ solves (5.2). That is, the norm ball

$$B_{\mathbf{c}} = \{\, \mathbf{x} \mid \|\mathbf{x} - \mathbf{c}\| \leq \operatorname{depth}(\mathbf{c}) \,\}$$

has the largest possible radius. Yet, as Figure 9 shows, $\mathbf{c}$ is not necessarily the only solution of (5.2).

Let $\tilde{B}_{\mathbf{c}}$ denote the boundary of $B_{\mathbf{c}}$. Then, as we have seen in section 3, there exist a boundary point $\mathbf{y}^* \in \tilde{B}_{\mathbf{c}} \cap \tilde{K}$ and a vector $\mathbf{a}^*$, $\|\mathbf{a}^*\|' = 1$, such that

$$(\mathbf{a}^*)^T \mathbf{y}^* = \sup_{\mathbf{x} \in K} (\mathbf{a}^*)^T \mathbf{x},$$

the hyperplane $H^* = \{\mathbf{x} \mid (\mathbf{a}^*)^T \mathbf{x} = (\mathbf{a}^*)^T \mathbf{y}^*\}$ supports both K and $B_{\mathbf{c}}$ at $\mathbf{y}^*$, and the vectors $\mathbf{u} = \mathbf{y}^* - \mathbf{c}$ and $\mathbf{a}^*$ are aligned. Let the vector $\mathbf{v}^* = 2\mathbf{c} - \mathbf{y}^*$ denote the symmetrical image of $\mathbf{y}^*$. Then, clearly, $\mathbf{v}^* \in \tilde{B}_{\mathbf{c}} \cap \tilde{K}$ and

$$(\mathbf{a}^*)^T \mathbf{v}^* = \inf_{\mathbf{x} \in K} (\mathbf{a}^*)^T \mathbf{x}.$$

These observations mean that $S(\mathbf{a}^*, K) = S(\mathbf{a}^*, B_{\mathbf{c}})$ and $\sigma(\mathbf{a}^*) = \eta(\mathbf{c})$, while (5.4) implies that $\mathbf{a}^*$ solves (5.1).

Finally we extend the above relations to any pair of primal-dual solutions. Let $\hat{\mathbf{a}} \in R^m$ solve (5.1) and let $\hat{\mathbf{z}} \in R^m$ solve (5.2). Then, as we have seen,

$$\eta(\hat{\mathbf{z}}) = \eta(\mathbf{c}) = \sigma(\hat{\mathbf{a}}).$$

Furthermore, since the norm ball

$$B_{\hat{\mathbf{z}}} = \left\{ \mathbf{x} \;\middle|\; \|\mathbf{x} - \hat{\mathbf{z}}\| \le \operatorname{depth}(\hat{\mathbf{z}}) \right\}$$

is contained in K, the sandwich $S(\hat{\mathbf{a}}, B_{\hat{\mathbf{z}}})$ is contained in $S(\hat{\mathbf{a}}, K)$. Yet the optimality of $\hat{\mathbf{a}}$ and $\hat{\mathbf{z}}$ indicates that the two sandwiches have the same width and, therefore, coincide. That is, $S(\hat{\mathbf{a}}, B_{\hat{\mathbf{z}}}) = S(\hat{\mathbf{a}}, K)$. The last equality implies the existence of a common boundary point, $\hat{\mathbf{y}} \in \tilde{B}_{\hat{\mathbf{z}}} \cap \tilde{K}$, such that

$$\hat{\mathbf{a}}^T \hat{\mathbf{y}} = \sup_{\mathbf{x} \in B_{\hat{\mathbf{z}}}} \hat{\mathbf{a}}^T \mathbf{x} = \sup_{\mathbf{x} \in K} \hat{\mathbf{a}}^T \mathbf{x}, \tag{5.6}$$

and the vectors $\hat{\mathbf{u}} = \hat{\mathbf{y}} - \hat{\mathbf{z}}$ and $\hat{\mathbf{a}}$ are aligned. Moreover, since $\hat{\mathbf{z}}$ serves as a "center of symmetry" for $B_{\hat{\mathbf{z}}}$, the point $\hat{\mathbf{v}} = 2\hat{\mathbf{z}} - \hat{\mathbf{y}}$ belongs to $\tilde{B}_{\hat{\mathbf{z}}} \cap \tilde{K}$ and satisfies

$$\hat{\mathbf{a}}^T \hat{\mathbf{v}} = \inf_{\mathbf{x} \in B_{\hat{\mathbf{z}}}} \hat{\mathbf{a}}^T \mathbf{x} = \inf_{\mathbf{x} \in K} \hat{\mathbf{a}}^T \mathbf{x}. \tag{5.7}$$

The next theorem summarizes our conclusions.

THEOREM 3. *The dual of the smallest sandwich problem* (5.1) *is the maximal norm ball problem* (5.2)*, and both problems are solvable. In particular, the center of symmetry,* $\mathbf{c}$*, solves* (5.2)*. Let* $\hat{\mathbf{a}}$ *and* $\hat{\mathbf{z}}$ *be any pair of primal-dual solutions. Then* $\eta(\hat{\mathbf{z}}) = \eta(\mathbf{c}) = \sigma(\hat{\mathbf{a}})$ *and* $S(\hat{\mathbf{a}}, B_{\hat{\mathbf{z}}}) = S(\hat{\mathbf{a}}, K)$*. Furthermore, there exist common boundary points,* $\hat{\mathbf{y}}$ *and* $\hat{\mathbf{v}} = 2\hat{\mathbf{z}} - \hat{\mathbf{y}}$*, that belong to* $\tilde{B}_{\hat{\mathbf{z}}} \cap \tilde{K}$ *and satisfy* (5.6) *and* (5.7)*, respectively. That is, the two points lie on opposite sides of* $S(\hat{\mathbf{a}}, K)$*. The vectors* $\hat{\mathbf{u}} = \hat{\mathbf{z}} - \hat{\mathbf{y}}$ *and* $\hat{\mathbf{a}}$ *are aligned. That is,*

$$\hat{\mathbf{u}}^T \hat{\mathbf{a}} = \|\hat{\mathbf{u}}\| \cdot \|\hat{\mathbf{a}}\|' = \operatorname{depth}(\mathbf{c}). \tag{5.8}$$

The proof of Theorem 3 does not rely on the assumption that K is a bounded set. This brings us to the following conclusion.

COROLLARY 4. *Let* X *be a symmetrical closed convex set in* R^m*, with nonempty interior and nonempty boundary. Then the claims of Theorem* 3 *remain valid when* X *replaces* K*. (Note that* X *may have more than one center of symmetry.)*

6. The largest sandwich problem. As before K denotes a symmetrical convex body in R^m, and $\mathbf{z}$ denotes an arbitrary point in R^m. The radius function of K is defined as

$$\operatorname{radius}(\mathbf{z}) = \sup_{\mathbf{x} \in K} \|\mathbf{x} - \mathbf{z}\|,$$

and

$$B_{\mathbf{z}} = \left\{ \mathbf{x} \;\middle|\; \|\mathbf{x} - \mathbf{z}\| \le \operatorname{radius}(\mathbf{z}) \right\}$$

is the smallest norm ball that is centered in $\mathbf{z}$ and contains K. The smallest norm ball that contains K can be found, therefore, by solving the problem

$$\text{minimize} \quad \tau(\mathbf{z}) = 2 \operatorname{radius}(\mathbf{z}), \tag{6.1}$$

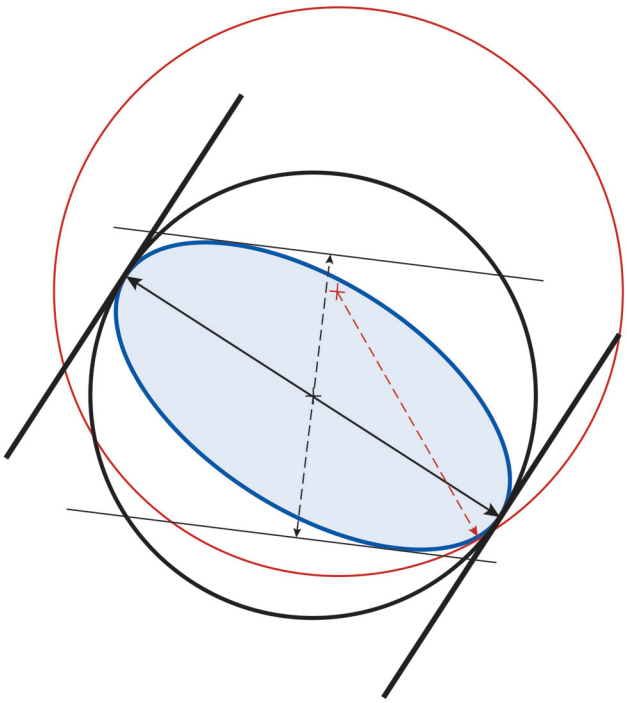

FIG. 8. *The width of the largest sandwich equals the diameter of the smallest norm ball.*

whose optimal value provides the smallest diameter of a norm ball that contains K. In this section we prove that the dual problem of (6.1) is the largest sandwich problem

$$\begin{aligned} &\text{maximize} && \sigma(\mathbf{a}) = \sup_{\mathbf{x}\in K} \mathbf{a}^T\mathbf{x} - \inf_{\mathbf{x}\in K} \mathbf{a}^T\mathbf{x} \\ &\text{subject to} && \|\mathbf{a}\|' = 1. \end{aligned} \tag{6.2}$$

Recall that $\sigma(\mathbf{a})$ equals the width of the sandwich $S(\mathbf{a}, K)$, while $\tau(\mathbf{z})$ equals the width of the sandwich $S(\mathbf{a}, B_{\mathbf{z}})$. Therefore, since K is contained in $B_{\mathbf{z}}$, the inequality

$$\sigma(\mathbf{a}) \le \tau(\mathbf{z}) \tag{6.3}$$

holds for all $\mathbf{a} \in R^m$, $\|\mathbf{a}\|' = 1$, and $\mathbf{z} \in R^m$. Thus to prove duality we need to find a pair of points, $\mathbf{a}^*$ and $\mathbf{z}^*$ say, such that $\|\mathbf{a}^*\|' = 1$ and

$$\sigma(\mathbf{a}^*) = \tau(\mathbf{z}^*). \tag{6.4}$$

For this purpose we consider the norm ball

$$B_{\mathbf{c}} = \left\{ \mathbf{x} \;\middle|\; \|\mathbf{x} - \mathbf{c}\| \le \text{radius}(\mathbf{c}) \right\}, \tag{6.5}$$

where $\mathbf{c}$ denotes the center of K. Then $B_{\mathbf{c}}$ is the smallest norm ball that is centered in $\mathbf{c}$ and contains K. Also, since K is a compact set, there exists a point $\tilde{\mathbf{y}} \in K$ such that

$$\|\tilde{\mathbf{y}} - \mathbf{c}\| = \text{radius}(\mathbf{c}).$$

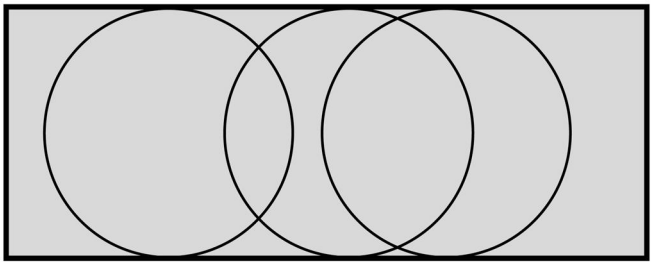

FIG. 9. *Nonuniqueness of the largest norm ball inside a convex body.*

Let $\tilde{K}$ and $\tilde{B}_{\mathbf{c}}$ denote the boundaries of K and $B_{\mathbf{c}}$, respectively. Then, clearly, $\tilde{\mathbf{y}} \in \tilde{K} \cap \tilde{B}_{\mathbf{c}}$. In other words, $\tilde{\mathbf{y}}$ is a boundary point of both K and $B_{\mathbf{c}}$. Hence there exists a vector $\tilde{\mathbf{a}} \in R^m$, $\|\tilde{\mathbf{a}}\|' = 1$, such that

$$\tilde{\mathbf{a}}^T \tilde{\mathbf{y}} = \sup_{\mathbf{x} \in B_{\mathbf{c}}} \tilde{\mathbf{a}}^T \mathbf{x} = \sup_{\mathbf{x} \in K} \tilde{\mathbf{a}}^T \mathbf{x}$$

and

$$\tilde{H} = \left\{ \mathbf{x} \;\middle|\; \tilde{\mathbf{a}}^T \mathbf{x} = \tilde{\mathbf{a}}^T \tilde{\mathbf{y}} \right\}$$

is a supporting hyperplane of both $B_{\mathbf{c}}$ and K at $\tilde{\mathbf{y}}$. Moreover, define

$$\tilde{\mathbf{u}} = \tilde{\mathbf{y}} - \mathbf{c};$$

then the vectors $\tilde{\mathbf{u}}$ and $\tilde{\mathbf{a}}$ are aligned. Let the point

$$\hat{\mathbf{y}} = \mathbf{c} - \tilde{\mathbf{u}} = 2\mathbf{c} - \tilde{\mathbf{y}}$$

denote the "symmetrical image" of $\tilde{\mathbf{y}}$. Then, clearly, $\hat{\mathbf{y}} \in \tilde{B}_{\mathbf{c}} \cap \tilde{K}$. That is, $\hat{\mathbf{y}}$ is a boundary point of both $B_{\mathbf{c}}$ and K. A further consequence of the symmetry of K and $B_{\mathbf{c}}$ with respect to $\mathbf{c}$ is that the hyperplane

$$\hat{H} = \left\{ \mathbf{x} \;\middle|\; (-\tilde{\mathbf{a}})^T \mathbf{x} = (-\tilde{\mathbf{a}})^T \hat{\mathbf{y}} \right\}$$

supports both $B_{\mathbf{c}}$ and K at $\hat{\mathbf{y}}$. The last observation implies the relations

$$\tilde{\mathbf{a}}^T \hat{\mathbf{y}} = \inf_{\mathbf{x} \in B_{\mathbf{c}}} \tilde{\mathbf{a}}^T \mathbf{x} = \inf_{\mathbf{x} \in K} \tilde{\mathbf{a}}^T \mathbf{x},$$

$$S(\tilde{\mathbf{a}}, K) = S(\tilde{\mathbf{a}}, B_{\mathbf{c}}),$$

and

$$\sigma(\tilde{\mathbf{a}}) = \tau(\mathbf{c}),$$

which proves (6.4). The geometric interpretation of this result is quite simple: The width of the largest sandwich equals the diameter of the smallest norm ball that contains K. See Figure 8. Note that the chord vector $\tilde{\mathbf{v}} = \tilde{\mathbf{y}} - \hat{\mathbf{y}} = 2\tilde{u}$ and $\tilde{a}$ are aligned. Below we will show that any solution of (6.2) satisfies similar relations with $B_{\mathbf{c}}$. The nonuniqueness of the solutions is illustrated in Figures 9–11.

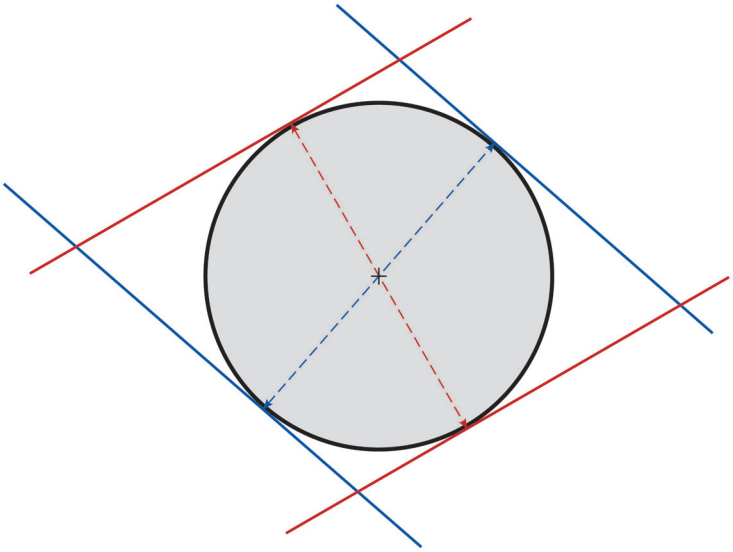

FIG. 10. *Nonuniqueness of the largest/smallest sandwich.*

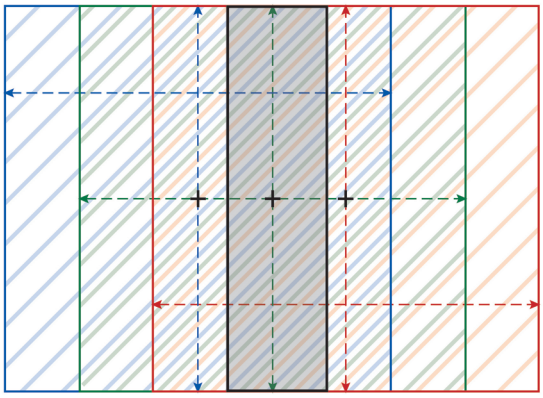

FIG. 11. *Nonuniqueness of the smallest norm ball that contains a convex body.*

Let $\mathbf{a}^* \in R^m$, $\|\mathbf{a}^*\|' = 1$, be some other solution of (6.2). Then, clearly, $S(\mathbf{a}^*, K)$ is contained in $S(\mathbf{a}^*, B_{\mathbf{c}})$. On the other hand, since $\mathbf{a}^*$ solves (6.2), $\sigma(\mathbf{a}^*) = \tau(\mathbf{c})$, so the two sandwiches have the same width and, therefore, coincide. That is,

$$S(\mathbf{a}^*, K) = S(\mathbf{a}^*, B_{\mathbf{c}}). \tag{6.6}$$

The last equality implies the existence of a common boundary point, $\mathbf{y}^* \in \tilde{K} \cap \tilde{B}_{\mathbf{c}}$, such that

$$(\mathbf{a}^*)^T \mathbf{y}^* = \sup_{\mathbf{x} \in B_{\mathbf{c}}} (\mathbf{a}^*)^T \mathbf{x} = \sup_{\mathbf{x} \in K} (\mathbf{a}^*)^T \mathbf{x}. \tag{6.7}$$

In other words, the hyperplane

$$H^* = \{\, \mathbf{x} \mid (\mathbf{a}^*)^T\mathbf{x} = (\mathbf{a}^*)^T\mathbf{y}^* \,\}$$

supports both $B_{\mathbf{c}}$ and K at $\mathbf{y}^*$. Define

$$\mathbf{u}^* = \mathbf{y}^* - \mathbf{c},$$

and let

$$\mathbf{y}^{**} = \mathbf{c} - \mathbf{u}^* = 2\mathbf{c} - \mathbf{y}^*$$

denote the symmetrical image of $\mathbf{y}^*$ with respect to $\mathbf{c}$. Then, as we have seen, the vectors $\mathbf{u}^*$ and $\mathbf{a}^*$ are aligned, $\mathbf{y}^{**} \in \tilde{K} \cap \tilde{B}_{\mathbf{c}}$, and the hyperplane

$$H^{**} = \{\, \mathbf{x} \mid (-\mathbf{a}^*)^T\mathbf{x} = (-\mathbf{a}^*)^T\mathbf{y}^{**} \,\}$$

supports both K and $B_{\mathbf{c}}$ at $\mathbf{y}^{**}$. That is,

$$(\mathbf{a}^*)^T\mathbf{y}^{**} = \inf_{\mathbf{x}\in B_{\mathbf{c}}} (\mathbf{a}^*)^T\mathbf{x} = \inf_{\mathbf{x}\in K} (\mathbf{a}^*)^T\mathbf{x}. \tag{6.8}$$

The next theorem summarizes our conclusions.

THEOREM 5. *The dual of the smallest norm ball problem* (6.1) *is the largest sandwich problem* (6.2)*, and both problems are solvable. In particular, the center of symmetry,* $\mathbf{c}$*, solves* (6.1) *and* $B_{\mathbf{c}}$ *has the smallest possible radius of all the norm balls that contain* K*. Moreover, let* $\mathbf{a}^* \in R^m$*,* $\|\mathbf{a}^*\|' = 1$*, be any solution of* (6.2)*. Then*

$$\sigma(\mathbf{a}^*) = \tau(\mathbf{c}), \tag{6.9}$$

$$S(\mathbf{a}^*, B_{\mathbf{c}}) = S(\mathbf{a}^*, K), \tag{6.10}$$

and there exists a pair of boundary points $\mathbf{y}^*$ *and* $\mathbf{y}^{**} = 2\mathbf{c} - \mathbf{y}^*$ *that belong to* $\tilde{B}_{\mathbf{c}} \cap \tilde{K}$*, but lie on opposite sides of* $S(\mathbf{a}^*, K)$*, and satisfy* (6.7)–(6.8)*. The vectors* $\mathbf{u}^* = \mathbf{y}^* - \mathbf{c}$ *and* $\mathbf{a}^*$ *are aligned. That is,*

$$(\mathbf{u}^*)^T\mathbf{a}^* = \|\mathbf{u}^*\| \cdot \|\mathbf{a}^*\|'. \tag{6.11}$$

COROLLARY 6. *The points* $\mathbf{y}^*$ *and* $\mathbf{y}^{**}$ *solve the maximal chord problem*

$$\begin{aligned} &\textit{maximize} \quad d(\mathbf{x}, \mathbf{y}) = \|\mathbf{x} - \mathbf{y}\| \\ &\textit{subject to} \quad \mathbf{x} \in K \quad \textit{and} \quad \mathbf{y} \in K. \end{aligned} \tag{6.12}$$

Conversely, let the points $\mathbf{x}^*$ *and* $\mathbf{y}^*$ *solve* (6.12)*. Then there exists a vector* $\mathbf{a}^* \in R^m$*,* $\|\mathbf{a}^*\|' = 1$*, that solves* (6.2)*, for which the points* $\mathbf{y}^*$ *and* $\mathbf{y}^{**} = 2\mathbf{c} - \mathbf{y}^*$ *satisfy the relations mentioned in Theorem* 5*. The optimal value of* (6.12) *is called the diameter of* K*. So the diameter of* K *equals the diameter of* $B_{\mathbf{c}}$*.*

7. Nonsymmetrical convex bodies. The duality properties revealed in Theorems 3 and 5 rely on the symmetry of K. The question raised in this section is which properties hold without the symmetry assumption. Let G be an arbitrary convex body in R^m which is not symmetrical. Then in this section G replaces K. The discussion below is divided into two parts. The first one considers the largest sandwich that contains G. The second part considers the smallest sandwich that contains G.

7.1. The nonsymmetrical largest sandwich problem. We shall start by considering the links between the smallest diameter problem

$$\begin{aligned} &\text{minimize} && \tau(\mathbf{z}) = 2\,\text{radius}(\mathbf{z}) \\ &\text{subject to} && \mathbf{z} \in G, \end{aligned} \tag{7.1}$$

the largest sandwich problem

$$\begin{aligned} &\text{maximize} && \sigma(\mathbf{a}) = \sup_{\mathbf{x}\in G} \mathbf{a}^T\mathbf{x} - \inf_{\mathbf{x}\in G} \mathbf{a}^T\mathbf{x} \\ &\text{subject to} && \|\mathbf{a}\|' = 1, \end{aligned} \tag{7.2}$$

and the longest chord problem

$$\begin{aligned} &\text{maximize} && d(\mathbf{x},\mathbf{y}) = \|\mathbf{x}-\mathbf{y}\| \\ &\text{subject to} && \mathbf{x} \in G \ \text{ and } \ \mathbf{y} \in G. \end{aligned} \tag{7.3}$$

As before, for any $\mathbf{z} \in R^m$

$$\text{radius}(\mathbf{z}) = \sup_{\mathbf{x}\in G} \|\mathbf{x}-\mathbf{z}\|, \tag{7.4}$$

and

$$B_{\mathbf{z}} = \left\{ \mathbf{x} \;\middle|\; \|\mathbf{x}-\mathbf{z}\| \le \text{radius}(\mathbf{z}) \right\} \tag{7.5}$$

is the smallest norm ball that is centered in $\mathbf{z}$ and contains G. Using the compactness of G and the continuity of the objective functions it is easy to verify that the above three problems are solvable. Below we derive some useful relations between the solutions of these problems.

Recall that for any $\mathbf{a} \in R^m$, $\|\mathbf{a}\|' = 1$, and any $\mathbf{z} \in R^m$, the width of the sandwich $S(\mathbf{a}, B_{\mathbf{z}})$ equals $\tau(\mathbf{z})$. Therefore, since $S(\mathbf{a}, G)$ is contained in $S(\mathbf{a}, B_{\mathbf{z}})$,

$$\sigma(\mathbf{a}) \le \tau(\mathbf{z}). \tag{7.6}$$

However, unlike the symmetrical case, here the optimal value of (7.1) can be strictly larger than the optimal value of (7.2). Take, for example, an equilateral triangle. This type of relation is sometimes called "weak duality."

Since G is a compact set, there exists a pair of points in G, $\mathbf{y}_1$ and $\mathbf{y}_2$ say, such that

$$\inf_{\mathbf{x}\in G} \mathbf{a}^T\mathbf{x} = \mathbf{a}^T\mathbf{y}_1 \quad \text{and} \quad \sup_{\mathbf{x}\in G} \mathbf{a}^T\mathbf{x} = \mathbf{a}^T\mathbf{y}_2, \tag{7.7}$$

and the sandwich $S(\mathbf{a}, G)$ is constructed by the hyperplanes

$$H_1 = \left\{ \mathbf{x} \;\middle|\; \mathbf{a}^T\mathbf{x} = \mathbf{a}^T\mathbf{y}_1 \right\} \quad \text{and} \quad H_2 = \left\{ \mathbf{x} \;\middle|\; \mathbf{a}^T\mathbf{x} = \mathbf{a}^T\mathbf{y}_2 \right\}. \tag{7.8}$$

Note also that the width of this sandwich satisfies

$$\sigma(\mathbf{a}) = \inf \left\{ \|\mathbf{x}_1 - \mathbf{x}_2\| \;\middle|\; \mathbf{x}_1 \in H_1,\, \mathbf{x}_2 \in H_2 \right\} \le \|\mathbf{y}_1 - \mathbf{y}_2\|. \tag{7.9}$$

Let the points $\mathbf{y}_1^*$ and $\mathbf{y}_2^*$ solve the longest chord problem (7.3), and let

$$\delta = \|\mathbf{y}_2^* - \mathbf{y}_1^*\| \tag{7.10}$$

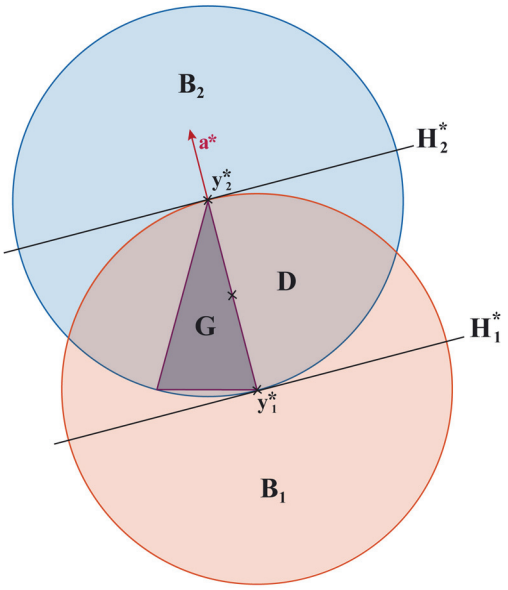

FIG. 12. *A longest chord touches a maximal sandwich.*

denote the optimal value of this problem. Then, clearly,

$$\sigma(\mathbf{a}) \le \|\mathbf{y}_1 - \mathbf{y}_2\| \le \delta.$$

Thus any vector $\mathbf{a}^* \in R^m$, $\|\mathbf{a}^*\|' = 1$, that satisfies

$$\sigma(\mathbf{a}^*) = \delta \tag{7.11}$$

solves the largest sandwich problem (7.2). Furthermore, as we are about to show, there exists a certain solution vector, $\mathbf{a}^*$, that is aligned to the optimal chord

$$\mathbf{u}^* = \mathbf{y}_2^* - \mathbf{y}_1^* \tag{7.12}$$

and satisfies (7.11).

To prove these assertions we introduce the sets

$$B_1 = \left\{ \mathbf{x} \;\middle|\; \|\mathbf{x} - \mathbf{y}_1^*\| \le \delta \right\}, \quad B_2 = \left\{ \mathbf{x} \;\middle|\; \|\mathbf{x} - \mathbf{y}_2^*\| \le \delta \right\}, \quad \text{and} \quad D = B_1 \cap B_2.$$

See Figure 12. Then D is a symmetrical convex body whose center of symmetry lies at the point $(\mathbf{y}_1^* + \mathbf{y}_2^*)/2$. Note also that D contains G, and that $\mathbf{y}_2^*$ is a boundary point of G, D, and B_1. Consequently there exists a vector $\mathbf{a}^* \in R^m$, $\|\mathbf{a}^*\|' = 1$, such that

$$(\mathbf{a}^*)^T\mathbf{y}_2^* = \sup_{\mathbf{x}\in B_1} (\mathbf{a}^*)^T\mathbf{x} = \sup_{\mathbf{x}\in D} (\mathbf{a}^*)^T\mathbf{x} = \sup_{\mathbf{x}\in G} (\mathbf{a}^*)^T\mathbf{x}, \tag{7.13}$$

and

$$H_2^* = \left\{ \mathbf{x} \;\middle|\; (\mathbf{a}^*)^T\mathbf{x} = (\mathbf{a}^*)^T\mathbf{y}_2^* \right\}$$

is a supporting hyperplane of the sets B_1, D, and G, at the point $\mathbf{y}_2^*$. Observe also that the vectors $\mathbf{u}^*$ and $\mathbf{a}^*$ are aligned:

$$(\mathbf{u}^*)^T(\mathbf{a}^*) = \|\mathbf{u}^*\| \cdot \|\mathbf{a}^*\|' = \|\mathbf{u}^*\|. \tag{7.14}$$

Similarly $\mathbf{y}_1^*$ is a boundary point of the sets B_2, D, and G. Hence the symmetry of D and the fact that $\mathbf{y}_1^*$ is the symmetrical image of $\mathbf{y}_2^*$ imply that

$$H_1^* = \left\{ \mathbf{x} \;\middle|\; (-\mathbf{a}^*)^T\mathbf{x} = (-\mathbf{a}^*)^T\mathbf{y}_1^* \right\}$$

is a supporting hyperplane of the sets B_2, D, and G, at the point $\mathbf{y}_1^*$. That is,

$$(-\mathbf{a}^*)^T\mathbf{y}_1^* = \sup_{\mathbf{x}\in B_2} (-\mathbf{a}^*)^T\mathbf{x} = \sup_{\mathbf{x}\in D} (-\mathbf{a}^*)^T\mathbf{x} = \sup_{\mathbf{x}\in G} (-\mathbf{a}^*)^T\mathbf{x} \tag{7.15}$$

and

$$(\mathbf{a}^*)^T\mathbf{y}_1^* = \inf_{\mathbf{x}\in G} (\mathbf{a}^*)^T\mathbf{x}. \tag{7.16}$$

Combining (7.12)–(7.16) gives

$$\begin{aligned}\sigma(\mathbf{a}^*) &= \sup_{\mathbf{x}\in G} (\mathbf{a}^*)^T\mathbf{x} - \inf_{\mathbf{x}\in G} (\mathbf{a}^*)^T\mathbf{x} = (\mathbf{a}^*)^T\mathbf{y}_2^* - (\mathbf{a}^*)^T\mathbf{y}_1 \\ &= (\mathbf{a}^*)^T(\mathbf{y}_2^* - \mathbf{y}_1^*) = (\mathbf{a}^*)^T\mathbf{u}^* = \|\mathbf{u}^*\|,\end{aligned}$$

which proves (7.11). The next theorem summarizes our findings. See Figure 12.

THEOREM 7. *The dual of the smallest norm ball problem* (7.1) *is the largest sandwich problem* (7.2)*, and both problems are solvable. Yet, unlike the symmetrical case, here the optimal primal value may exceed the optimal dual value. The longest chord problem* (7.3) *is also solvable and its optimal value equals that of* (7.2)*. In other words, the "diameter" of* G *equals the "length" of* G*. More precisely, let the points* $\mathbf{y}_1^*$ *and* $\mathbf{y}_2^*$ *solve* (7.3)*; then there exists a vector* $\mathbf{a}^* \in R^m$*,* $\|\mathbf{a}^*\|' = 1$*, that solves* (7.2) *and satisfies* (7.11)–(7.16)*. Thus, in particular, the vectors* $\mathbf{u}^* = \mathbf{y}_2^* - \mathbf{y}_1^*$ *and* $\mathbf{a}^*$ *are aligned.*

Theorem 7 raises the question of whether the converse claim is also true. Let $\hat{\mathbf{a}} \in R^m$, $\|\hat{\mathbf{a}}\|' = 1$, be some other solution of (7.2). Then, as we have seen, there exists a pair of boundary points of G, $\hat{\mathbf{y}}_1$ and $\hat{\mathbf{y}}_2$ say, such that

$$\hat{\mathbf{a}}^T\hat{\mathbf{y}}_1 = \inf_{\mathbf{x}\in G} \hat{\mathbf{a}}^T\mathbf{x} \quad \text{and} \quad \hat{\mathbf{a}}^T\hat{\mathbf{y}}_2 = \sup_{\mathbf{x}\in G} \hat{\mathbf{a}}^T\mathbf{x}. \tag{7.17}$$

Hence the sandwich $S(\hat{\mathbf{a}}, G)$ is constructed by the hyperplanes

$$\hat{H}_1 = \left\{ \mathbf{x} \;\middle|\; \hat{\mathbf{a}}^T\mathbf{x} = \hat{\mathbf{a}}^T\hat{\mathbf{y}}_1 \right\} \quad \text{and} \quad \hat{H}_2 = \left\{ \mathbf{x} \;\middle|\; \hat{\mathbf{a}}^T\mathbf{x} = \hat{\mathbf{a}}^T\hat{\mathbf{y}}_2 \right\}, \tag{7.18}$$

and the width of this sandwich satisfies

$$\sigma(\hat{\mathbf{a}}) = \inf \left\{ \|\mathbf{x}_1 - \mathbf{x}_2\| \;\middle|\; \mathbf{x}_1 \in \hat{H}_1,\, \mathbf{x}_2 \in \hat{H}_2 \right\} \le \|\hat{\mathbf{y}}_1 - \hat{\mathbf{y}}_2\| \le \delta. \tag{7.19}$$

See Figure 13. On the other hand, since $\hat{\mathbf{a}}$ solves (7.2), $\sigma(\hat{\mathbf{a}}) = \delta$. Hence the inequalities in (7.19) imply that

$$\|\hat{\mathbf{y}}_1 - \hat{\mathbf{y}}_2\| = \delta. \tag{7.20}$$

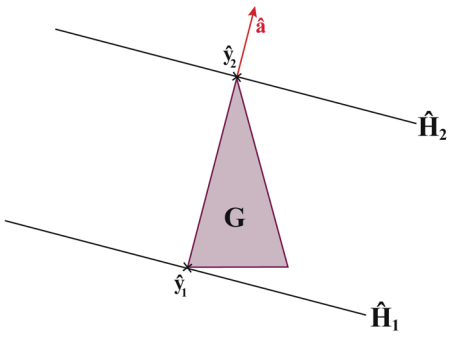

FIG. 13. *A maximal sandwich touches a longest chord.*

In other words, the contact points $\hat{\mathbf{y}}_1$ and $\hat{\mathbf{y}}_2$ solve (7.3). Moreover, since the hyperplane $\hat{H}_2$ supports the norm ball $\hat{B}_1 = \{\mathbf{x} \mid \|\mathbf{x} - \hat{\mathbf{y}}_1\| \le \delta\}$ at $\hat{\mathbf{y}}_2$, the vectors $\hat{\mathbf{u}} = \hat{\mathbf{y}}_2 - \hat{\mathbf{y}}_1$ and $\hat{\mathbf{a}}$ are aligned:

$$\hat{\mathbf{u}}^T \hat{\mathbf{a}} = \|\hat{\mathbf{u}}\| \cdot \|\hat{\mathbf{a}}\|' = \|\hat{\mathbf{u}}\|. \tag{7.21}$$

This proves the following results. See Figure 13.

THEOREM 8. *Let the vector* $\hat{\mathbf{a}} \in R^m$, $\|\hat{\mathbf{a}}\|' = 1$, *solve* (7.2). *Then there exists a pair of points,* $\hat{\mathbf{y}}_1$ *and* $\hat{\mathbf{y}}_2$ *say, that satisfy* (7.17)–(7.21) *and solve the longest chord problem* (7.3). *Moreover, the vectors* $\hat{\mathbf{u}} = \hat{\mathbf{y}}_2 - \hat{\mathbf{y}}_1$ *and* $\hat{\mathbf{a}}$ *are aligned.*

It is also interesting to compare (7.1) with the unconstrained problem

$$\text{minimize} \quad \tau(\mathbf{z}) = 2\,\text{radius}(\mathbf{z}), \tag{7.22}$$

whose solution points may reside outside G. The last feature is easily seen by considering the smallest ℓ_∞ norm ball. See Figure 11. On the other hand, when using the Euclidean norm any solution of (7.22) lies in G. These observations raise the question of whether any solution of (7.1) also solves (7.22). Yet the answer is left beyond the scope of this paper.

7.2. The nonsymmetrical smallest sandwich problem. The smallest sandwich that contains G is obtained by solving the problem

$$\begin{aligned} &\text{minimize} && \sigma(\mathbf{a}) = \sup_{\mathbf{x}\in G} \mathbf{a}^T\mathbf{x} - \inf_{\mathbf{x}\in G} \mathbf{a}^T\mathbf{x} \\ &\text{subject to} && \|\mathbf{a}\|' = 1. \end{aligned} \tag{7.23}$$

The compactness of the sets G and $\{\mathbf{a} \mid \|\mathbf{a}\|' = 1\}$ and the continuity of the objective function ensure the existence of a vector $\mathbf{a}^* \in R^m$, $\|\mathbf{a}^*\|' = 1$, that solves (7.23). However, as Figure 10 shows, the solution is not necessarily unique. Let $\tilde{G}$ and $\mathring{G}$ denote the boundary and the interior of G, respectively. The discussion in section 5 suggests that the dual of (7.23) is the maximal norm ball problem

$$\begin{aligned} &\text{maximize} && \eta(\mathbf{z}) = 2\,\text{depth}(\mathbf{z}) \\ &\text{subject to} && \mathbf{z} \in G, \end{aligned} \tag{7.24}$$

where

$$\text{depth}(\mathbf{z}) = \inf_{\mathbf{x}\in\tilde{G}} \|\mathbf{x} - \mathbf{z}\|, \tag{7.25}$$

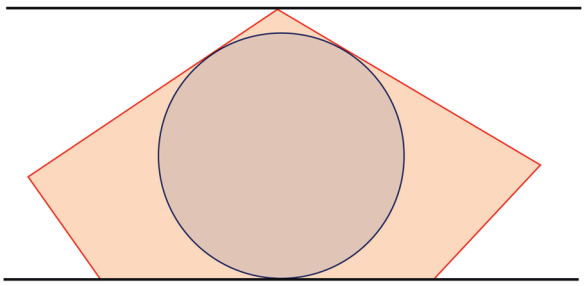

FIG. 14. *The touching conjecture: A maximal norm ball touches a minimal sandwich and vice versa.*

and

$$B_{\mathbf{z}} = \{\, \mathbf{x} \mid \|\mathbf{x} - \mathbf{z}\| \leq \text{depth}(\mathbf{z}) \,\} \tag{7.26}$$

is the largest norm ball that is centered in $\mathbf{z}$ and contained in G. As before, the compactness of G and the continuity of the objective function imply the existence of an interior point, $\mathbf{z}^*$ say, that solves (7.24). Yet, as Figure 9 shows, there may be many solutions.

Recall that for any pair of vectors, $\mathbf{z} \in G$ and $\mathbf{a} \in R^m$, $\|\mathbf{a}\|' = 1$, the width of the sandwich $S(\mathbf{a}, B_{\mathbf{z}})$ equals $\eta(\mathbf{z})$. On the other hand, since $B_{\mathbf{z}}$ is contained in G, the width of $S(\mathbf{a}, B_{\mathbf{z}})$ is smaller than the width of $S(\mathbf{a}, G)$. That is,

$$\eta(\mathbf{z}) \leq \sigma(\mathbf{a}). \tag{7.27}$$

The last inequality invites the question of whether the optimal values of (7.23) and (7.24) are always equal. However, there are many examples of convex sets for which the solution points satisfy a strict inequality of the form

$$\eta(\mathbf{z}^*) < \sigma(\mathbf{a}^*). \tag{7.28}$$

Take, for example, a triangle. Thus again we see that the lack of symmetry may result in "weak duality" relations.

It is also easy to verify that any interior point $\mathbf{z}^* \in \mathring{G}$ that solves the maximal norm ball problem (7.24) has the following property: The maximal norm ball

$$B_{\mathbf{z}^*} = \{\, \mathbf{x} \mid \|\mathbf{x} - \mathbf{z}^*\| \leq \text{depth}(\mathbf{z}^*) \,\} \tag{7.29}$$

"touches" $\widetilde{G}$ in more that one point. Let $\tilde{\mathbf{y}}$ be one of the "touching points." Then $\tilde{\mathbf{y}}$ is a boundary point of both $B_{\mathbf{z}^*}$ and G. Moreover, as we have seen, there exists a vector $\tilde{\mathbf{a}} \in R^m$, $\|\tilde{\mathbf{a}}\|' = 1$, such that

$$\tilde{H} = \{\, \mathbf{x} \mid \tilde{\mathbf{a}}^T\mathbf{x} = \tilde{\mathbf{a}}^T\tilde{\mathbf{y}} \,\}$$

is a supporting hyperplane of both G and $B_{\mathbf{z}^*}$ at the point $\tilde{\mathbf{y}}$, and the vectors $\tilde{\mathbf{y}} - \mathbf{z}^*$ and $\tilde{\mathbf{a}}$ are aligned. In other words, any "touching point," $\tilde{\mathbf{y}}$, is related to a certain "touching sandwich," $S(\tilde{\mathbf{a}}, G)$. There are many examples of convex sets in R^2 and R^3 in which one of the "touching sandwiches," $S(\tilde{\mathbf{a}}, G)$, has the smallest possible width. See Figure 14. These empirical observations bring us to make the following "touching conjecture": A maximal norm ball (inside G) always touches a minimal sandwich. Conversely, any minimal sandwich of G touches a maximal norm ball. However, the validity of these assertions remains an open question.

8. Concluding remarks. Recall that any unit norm ball of the form (2.2) defines an "equilibrated" convex body. That is, a symmetrical convex body with center at the origin. The converse is also true: Any equilibrated convex body defines a norm; see [16]. Thus any symmetrical convex body is essentially a "shifted" unit norm ball of some norm. Hence, from this point of view, Theorems 3 and 5 characterize the duality relations between two arbitrary norms on R^m.

The new MND theorems, together with the old ones, constitute an elegant collection of geometric problems that visually illustrate the basic principles of duality. See Figures 1–8. Being MND theorems, the new theorems have some analogy with the old ones. However, the geometry of the new problems is quite different, and there is no direct way to conclude the new theorems from the old ones. So the new theorems contribute a substantial extension to the range of problems that can be handled via the MND methodology.

The appeal of the MND methodology stems from a number of reasons. First, as noted above, it has a simple geometric interpretation that visually illustrates the links between the primal problem and the dual one. Second, it allows the freedom to use any norm in R^m. Third, the alignment relations add important insight into the nature of primal-dual problems. In particular, when using a smooth strictly convex norm, there are explicit rules for retrieving a primal solution from a dual one, and vice versa, e.g., [8], [10], [19]. Fourth, in spite of their simplicity, the MND theorems apply to a large family of problems. See [8] for a recent survey of such problems.

A recent discussion in [9] considers methods for solving the related duality problems, regarding two types of polyhedral convex sets. The first one is a polyhedron, which is defined as the intersection of n given half-spaces in R^m. The second set is a polytope, which is defined as the convex hull of ℓ given points in R^m. Then, as shown in [9], the nearest hyperplane problem is easy to solve on a polyhedron and difficult to solve on a polytope. Yet in the farthest hyperplane problem the situation is reversed. This problem is easy to solve on a polytope and difficult to solve on a polyhedron. A similar situation characterizes the solutions of the smallest sandwich problem and the largest sandwich problem. The need for calculating a norm ball, usually an ellipsoid, that lies inside (or contains) a given polyhedral convex set arises in several applications; see, e.g., [2], [4].

The new theorems are valid in any finite dimensional real Hilbert space H, with inner product $\langle \mathbf{x}, \mathbf{y} \rangle$. The modification of the current proof to handle this setting is rather simple: R^m is replaced by H, the Euclidean inner product $\mathbf{x}^T\mathbf{y}$ is replaced by $\langle \mathbf{x}, \mathbf{y} \rangle$, the Euclidean norm is replaced by $\|\mathbf{x}\| = (\langle \mathbf{x}, \mathbf{x} \rangle)^{1/2}$, and so forth. Using the geometric Hahn–Banach theorem one can prove the Nirenberg–Luenberger MND theorem in any real (or complex) normed linear space; see, e.g., [11], [12], [18], [19], [21]. This observation suggests that the new MND theorems remain valid in such setting. However, we have good reasons to keep the paper in the R^m setting. First, the restriction to R^m simplifies the presentation and helps to focus on the main ideas. Second, there is vast literature on properties of convex bodies, including closely related issues such as "width," "length," and "diameter" of convex bodies, and most of the discussions are carried out in R^m. See, for example, [1], [2], [4], [6], [13], [14], [17], [20], [22], [24], [26], [27], [28], [29], and the references therein.

PARETO SUBDIFFERENTIAL CALCULUS FOR CONVEX VECTOR MAPPINGS AND APPLICATIONS TO VECTOR OPTIMIZATION*

MOUNIR EL MAGHRI† AND MOHAMED LAGHDIR†

Abstract. This paper deals with the subdifferential of convex analysis defined in the Pareto sense, from a point of view of nonvacuity, characterizations, and calculus rules and their applications to the vector optimization, the convex maps being vector-valued in a finite- or infinite-dimensional ordered vector space. Subdifferentiability is characterized under conditions of Attouch–Brézis type. Formulations by derivatives, when they exist, are provided. Concerning the calculus rules, the first main result gives the gap between the Pareto subdifferential and the ordinary one, allowing thus the computation of the one from the other. Next, as central results, Pareto subdifferentials of the sum and/or composition of two convex vector mappings are developed. The formulas are obtained under Moreau–Rockafellar or Attouch–Brézis-type conditions, revealing, strangely, the presence of the ordinary subdifferential. These formulas actually allow the extension of the indicator function technique to the vector case, so that Pareto optimality (efficiency) conditions are easily derived and weakened with qualification conditions of the Attouch–Brézis kind. Finally, the gap between efficient and optimal sets is also deduced.

1. Introduction.

The notion of the subdifferential defined in the Pareto sense is important for dealing with vector optimization problems (VOPs). There are globally two kinds of solutions for these problems: usual optimum and Pareto optimum, also called efficient point. It is well known that the ordinary optimum for vector problems does not often exist, so it is said to be a rather strongly efficient solution in Pareto language. Thus, for vector mappings, the subdifferential defined in the Pareto sense is naturally more required in the context of vector optimization than a subdifferential defined in the usual sense. We agree to call them, respectively, Pareto subdifferential and strong subdifferential. To be sometimes more precise, since among the Pareto concepts there is the proper or weak notion, we also talk about proper or weak subdifferential of vector mappings.

In this paper, we study several properties of the Pareto subdifferential of convex analysis that have not been considered previously in the literature and give their first direct applications to the constrained convex vector optimization. Only the proper and weak concepts of Pareto are considered; the other concepts remain open issues for future research. For a reason of enlarging the scope of this work, we assume the convex vector mappings taking values in (partially) ordered topological vector spaces. All the obtained results are important also in the finite-dimensional case, and the reader which is not familiar with the infinite-dimensional spaces may consider everywhere all the spaces as real finite-dimensional vector spaces with the range spaces all ordered by the natural componentwise partial order. We nevertheless didn't fail to state in this setting, whenever it is necessary, each result or comment being able to be formulated in simpler terms.

The paper is organized as follows. Section 2 describes the different notions of vector subdifferential underlining their preliminary connections with the efficient sets. Section 3 is divided into three subsections. Subsection 3.1 presents the scalarization of these sets straightforwardly from the well-known one of the efficient sets. Scalarization principle is revealed in our investigations to be fundamental in the obtention of the most essential properties of these vector subdifferentials. In subsection 3.2, the Pareto subdifferentiability and the regular subdifferentiability are characterized under the well-known Attouch–Brézis and Moreau–Rockafellar conditions, respectively; the regular subdifferentiability concept due to Raffin [23] being revealed to be a key hypothesis for the obtention of our main results. As immediate result, we obtain the Pareto subdifferential in terms of the strong one. This relationship expresses, in fact, the gap between the two concepts allowing their mutual computation. Subsection 3.3 concerns the formulations of these sets by means of (directional or Gâteaux) derivatives when they exist. Section 4 represents the central part in this work for both theory and application. It is devoted to calculus rules of the Pareto subdifferentials for the sum and/or composition of two convex vector mappings. The obtained formulas are original and hold under the weak conditions of the Moreau–Rockafellar or Attouch–Brézis types. Let us point out the strange but indispensable appearance of the strong subdifferential, otherwise the formulas would not hold in general. This presence turns out to be rather favorable in applications: In the last section dealing with the constrained vector optimization, the extension of the penalty indicator function to the vector case is realized, in the sense that both necessary and sufficient efficiency conditions of the Kuhn–Tucker type are easily derived under only the weak qualification conditions of the Attouch–Brézis type; also, a certain gap between the efficient and the optimal sets is deduced.

The first studies of the vector subdifferential seem to appear in strong form due, respectively, to Raffin [23], Valadier [32], and Zowe [35], while the Pareto subdifferential was first considered by Sawaragi and Tanino [25] and next appeared in [26]. Concerning the chain rules, the first results concerned the sum operation due to Théra [29] for the strong subdifferential, Lin [18] and Taa [27] for the weak one. Their main results concerning us are described in detail as soon as it is required in the text.

2. Elements of vector convex analysis. Throughout the paper, we shall work with the following spaces and sets:

- X, Y, Z (real) topological vector spaces, with Y and Z separated;
- X^*, Y^*, Z^* their respective topological duals paired in duality by $\langle ., . \rangle$;
- Y_+ a nonempty proper[1] convex cone (resp. Z_+) of Y (resp. of Z), $\operatorname{int} Y_+$ its topological interior (resp. $\operatorname{int} Z_+$) sometimes will be required to be nonempty;
- $l(Y_+) = Y_+ \sqcap -Y_+$ (resp. $l(Z_+)$) the lineality of Y_+ (resp. Z_+), when it is null, the cone is said to be pointed;
- Y_+^* (resp. Z_+^*) the polar cone of Y_+ (resp. Z_+), which is the set of nonnegative forms $\lambda \in Y^*$, i.e., $\lambda(Y_+) \subseteq \mathbb{R}_+$;
- $(Y_+^*)^\circ$ (resp. $(Z_+^*)^\circ$) the strict polar cone of Y_+ (resp. Z_+), which is the set of positive forms $\lambda \in Y^*$, i.e., $\lambda(Y_+ \setminus l(Y_+)) \subseteq \mathbb{R}_+ \setminus \{0\}$, obviously, $(Y_+^*)^\circ \subseteq Y_+^* \setminus \{0\}$ since $Y_+ + Y_+ \setminus l(Y_+) \subseteq Y_+ \setminus l(Y_+)$;
- $L(X, Y)$ the space of linear continuous operators from X to Y;
- $L_+(Y, Z)$ the set of nonnegative operators $A \in L(Y, Z)$, i.e., $A(Y_+) \subseteq Z_+$;

[1] That is, not a linear subspace so that it cannot coincide with its lineality.

- $L^{-1}(X,Y)$ (resp. $L_+^{-1}(Y,Z)$) the set of invertible operators $A \in L(X,Y)$ (resp. $\in L_+(Y,Z)$).

The convex cone Y_+ (resp. Z_+) induces in Y (resp. in Z) preorder relations:

$$\begin{array}{lllll} y \leq_{Y_+} y' & \Longleftrightarrow & y' \geq_{Y_+} y & \Longleftrightarrow & y' - y \in Y_+, \\ y <_{Y_+} y' & \Longleftrightarrow & y' >_{Y_+} y & \Longleftrightarrow & y' - y \in \operatorname{int} Y_+, \\ y \lneq_{Y_+} y' & \Longleftrightarrow & y' \gneq_{Y_+} y & \Longleftrightarrow & y' - y \in Y_+ \setminus l(Y_+). \end{array}$$

We adjoin to Y (resp. Z) an abstract maximal element denoted $+\infty$ so that $y \leq_{Y_+} +\infty$ for all $y \in Y \sqcup \{+\infty\}$ on which we consider the operations $y+(+\infty) = +\infty$ and $\alpha \cdot (+\infty) = +\infty$ for all $\alpha \in \mathbb{R}_+ \setminus \{0\}$ by adopting the convention $0 \cdot (+\infty) = 0$.

Let us notice the following well-known properties on some fundamental relations between a cone and its polar.

PROPOSITION 2.1.

(1) *If Y is locally convex and Y_+ is closed, then*
$\exists y \in Y,\ \forall \lambda \in Y_+^* \setminus \{0\},\ \langle \lambda, y\rangle \geq 0 \Longrightarrow y \in Y_+$.

(2) *If, in addition, Y_+ is pointed, then*
$\exists y \in Y,\ \forall \lambda \in Y_+^* \setminus \{0\},\ \langle \lambda, y\rangle = 0 \Longrightarrow y = 0$.

(3) *If $\operatorname{int} Y_+ \neq \emptyset$, then*
$\forall \lambda \in Y_+^* \setminus \{0\},\ \forall y \in \operatorname{int} Y_+,\ \langle \lambda, y\rangle > 0$.

(4) *In particular,*
$\forall \lambda \in Y_+^* \setminus \{0\},\ \exists y_\lambda \in \operatorname{int} Y_+ : \langle \lambda, y_\lambda\rangle = 1$.

We recall that property (1) is obtained via contradiction by strict separation theorem (see [2, pp. 122] or [5, pp. 11–12], e.g.) knowing that Y_+ is a nonempty closed convex set.[2] Assertion (2) is a direct consequence of assertion (1) using that Y_+ is pointed. Property (3) is an application of the well-known property that a linear form is null if only if it is null on an open set.[3] Assertion (4) is obviously deduced from (3).

Also, we shall work with the following vector mappings:

- $F : X \to Y \sqcup \{+\infty\}$ is said to be
  - Y_+-convex, if

$$\forall x, x' \in X,\ \ \forall \alpha \in [0,1],\ \ F(\alpha x + (1-\alpha)x') \leq_{Y_+} \alpha F(x) + (1-\alpha)F(x');$$

  - sequentially Y_+-l.s.c at $\bar{x} \in X$, if

$$\forall y \leq_{Y_+} F(\bar{x}),\ \ \forall (x^n) \to \bar{x},\ \ \exists (y^n) \to y :\ \ y^n \leq_{Y_+} F(x^n),\ \ \forall n \in \mathbb{N};$$

  - proper, if its effective domain

$$\operatorname{dom} F = \{x \in X :\ F(x) \in Y\} \neq \emptyset.$$

- $G : Y \to Z \sqcup \{+\infty\}$ is said to be (Y_+, Z_+)-nondecreasing, if

$$y \leq_{Y_+} y' \quad \Longrightarrow \quad G(y) \leq_{Z_+} G(y').$$

[2] If $y \notin Y_+$, we can strictly separate it from Y_+, i.e., $\exists \lambda \in Y^* \setminus \{0\}$, $\exists \alpha > 0 : \langle \lambda, y\rangle < \alpha < \langle \lambda, y'\rangle$ $(\forall y' \in Y_+)$. Taking successively $y' = 0$ and $y' = ny''$, with $n \in \mathbb{N}^*$ and $y'' \in Y_+$, we obtain $\langle \lambda, y\rangle < 0$ and $\langle \lambda, y''\rangle > \frac{\alpha}{n}$. Letting $n \nearrow +\infty$, we get $\lambda \in Y_+^* \setminus \{0\}$ in contradiction with $\langle \lambda, y\rangle < 0$.

[3] Let $\lambda \in Y^*$ such that $\lambda(O) = \{0\}$ for some open set $O \subset Y$. Let $y_0 \in O$, then there exists V a neighborhood of 0 such that $y_0 + V \subset O$. For each $y \in Y$, the continuity at 0 of the mapping $\alpha \mapsto \alpha y$ implies the existence of $\alpha \in \mathbb{R}$, with $\alpha y \in V$. But $\langle \lambda, y\rangle = \frac{1}{\alpha}\langle \lambda, y_0 + \alpha y\rangle - \frac{1}{\alpha}\langle \lambda, y_0\rangle = 0$.

▶ $G \circ F : X \to Z \sqcup \{+\infty\}$ the composite vector mapping is defined by

$$G \circ F(x) = \begin{cases} G(F(x)) & \text{if } x \in \operatorname{dom} F, \\ +\infty & \text{else.} \end{cases}$$

It is immediate that

- $\operatorname{dom}(G \circ F) = F^{-1}(\operatorname{dom} G) \sqcap \operatorname{dom} F$.
- F is Y_+-convex $\Longrightarrow \operatorname{dom} F$ is a convex set.
- G is (Y_+, Z_+)-nondecreasing Z_+-convex and F is Y_+-convex $\Longrightarrow G \circ F$ is Z_+-convex.

We agree to denote the sets of such mappings in analogy with the scalar case:

▶ $\Gamma(X, Y)$ the set of proper Y_+-convex mappings from X to $Y \sqcup \{+\infty\}$,

▶ $\Gamma_0(X, Y)$ the set of sequentially Y_+-l.s.c mappings $F \in \Gamma(X, Y)$,

so that $\Gamma(X, \mathbb{R})$ reduces to $\Gamma(X)$, the set of proper convex functionals. In the same way, a functional $(Y_+, \mathbb{R}_+)$-nondecreasing is usually said to be Y_+-nondecreasing. While $\Gamma_0(X, \mathbb{R})$ reduces to $\Gamma_0(X)$, the set of l.s.c functionals in $\Gamma(X)$ if X is metrizable (in particular, a Fréchet space, i.e., complete metrizable space). Indeed, the vector lower semicontinuity concept due to Combari, Laghdir, and Thibault [11] is not other in the setting of metrizable variable and value spaces than a sequential characterization of the concept introduced by Penot and Théra [21]. Hence, sequential $\mathbb{R}_+$-l.s.c is no more than the classical l.s.c if X is metrizable. Sequential $\mathbb{R}^r_+$-l.s.c of $F = (f_1, \ldots, f_r)$, then, by definition, also becomes equivalent to l.s.c of each component f_i in such a space X. In general, the sequential cone l.s.c concept easily implies that each y-sublevel set ($y \in Y$) and the epigraph of F, respectively, defined by

$$Y_+\text{-Lev}(F; y) = \{x \in X : \ F(x) \leq_{Y_+} y\},$$
$$Y_+\text{-Epi } F = \{(x, y) \in X \times Y : \ F(x) \leq_{Y_+} y\}$$

are closed if Y_+ is closed; the converse being false, in general, even for finite-dimensional image spaces equipped with closed order cones (see example in [11] or [21]). It has been noted in [11] that sequential continuity (at a point in the effective domain) is equivalent to sequential Y_+-l.s.c and $-Y_+$-l.s.c (at this point) if the preorder Y_+ is normal, i.e., if there exists a base of neighborhoods V of the origin such that the order intervals

$$[a, b] = \{y \in Y : \ a \leq_{Y_+} y \leq_{Y_+} b\} \subset V \qquad \text{if} \quad a, b \in V.$$

Consider now the VOP associated with the vector map $F : X \supseteq S \to Y \sqcup \{+\infty\}$:

$$\text{VOP:} \qquad \operatorname*{Min}_{x \in S} F(x).$$

There are four kinds of solutions for VOP: a point $\bar{x} \in S \sqcap \operatorname{dom} F$ is said to be

- ▶ optimal or strongly efficient, if $\forall x \in S, \ F(\bar{x}) \leq_{Y_+} F(x)$;
- ▶ Pareto or efficient, if $\nexists x \in S, \ F(x) \lesssim_{Y_+} F(\bar{x})$;
- ▶ weak Pareto or weakly efficient, if $\nexists x \in S, \ F(x) <_{Y_+} F(\bar{x})$;
- ▶ proper Pareto or (Henig) properly efficient, if

$\exists \hat{Y}_+ \subsetneq Y$ a convex cone, with $Y_+ \setminus l(Y_+) \subseteq \operatorname{int} \hat{Y}_+, \ \nexists x \in S, \ F(x) \lesssim_{\hat{Y}_+} F(\bar{x})$.

The weak concept obviously supposes in the image space a nonempty interior preorder cone, while the proper concept supposes generally in counterpart a pointed

preorder cone. The efficient set and the strongly, properly, and weakly efficient sets for VOP will be denoted, respectively, by $E_e(F,S)$, $E_s(F,S)$, $E_p(F,S)$, and $E_w(F,S)$. To unify the presentation, we will denote by $E_\sigma(F,S)$ the set of σ-efficient points depending on the choice of $\sigma \in \{s,p,e,w\}$. By using the well-known property that $\operatorname{int} Y_+ \subseteq Y_+ \setminus l(Y_+)$, it is immediate that

$$E_p(F,S) \subseteq E_e(F,S) \subseteq E_w(F,S). \tag{2.1}$$

When $\dim Y = 1$, all these sets coincide with the ordinary optimal set $E_s(F,S)$. However, in vector optimization, i.e., $\dim Y \neq 1$, it does not often happen that

$$E_s(F,S) \neq \emptyset.$$

But if this situation occurs, one can easily show that $E_e(F,S) \subseteq E_s(F,S)$. The reverse inclusion $E_s(F,S) \subseteq E_e(F,S)$ being always satisfied, one therefore has

$$E_s(F,S) \neq \emptyset \Rightarrow E_s(F,S) = E_e(F,S).$$

The subdifferential of a vector mapping, when it is associated with a VOP, leads in connection with the different efficient sets to consider four concepts, namely, the strong, weak, efficient, and proper, defined, respectively, for $F : X \to Y \sqcup \{+\infty\}$ and $\bar{x} \in \operatorname{dom} F$ as follows:

- $\partial^s F(\bar{x}) = \{A \in L(X,Y) : \quad \forall x \in X,\ F(x) - F(\bar{x}) \geq_{Y_+} A(x-\bar{x})\}.$
- $\partial^w F(\bar{x}) = \{A \in L(X,Y) : \quad \nexists x \in X,\ F(x) - F(\bar{x}) <_{Y_+} A(x-\bar{x})\}.$
- $\partial^e F(\bar{x}) = \{A \in L(X,Y) : \quad \nexists x \in X,\ F(x) - F(\bar{x}) \lneq_{Y_+} A(x-\bar{x})\}.$
- $\partial^p F(\bar{x}) = \{A \in L(X,Y) : \quad \exists \hat{Y}_+ \subsetneq Y$ a convex cone that satisfies $Y_+ \setminus l(Y_+) \subseteq \operatorname{int} \hat{Y}_+,\ \nexists x \in X,\ F(x) - F(\bar{x}) \lneq_{\hat{Y}_+} A(x-\bar{x})\}.$

The notation $\partial^\sigma F(\bar{x})$ will also be used to stand for the σ-subdifferential according to the choice of $\sigma \in \{s,p,e,w\}$. By convention, we take $\partial^\sigma F(\bar{x}) = \emptyset$ if $\bar{x} \notin \operatorname{dom} F$. The σ-subdifferential, with $\sigma = s$ (resp. $\sigma \in \{e,w\}$) seems to first appear in [23] (resp. in [25]). All these definitions are justified by the importance of the following immediate property:

$$\bar{x} \in E_\sigma(F,X) \quad \Longleftrightarrow \quad 0 \in \partial^\sigma F(\bar{x}). \tag{2.2}$$

Similarly to inclusions (2.1), it is easily shown that

$$\partial^p F(\bar{x}) \subseteq \partial^e F(\bar{x}) \subseteq \partial^w F(\bar{x}), \tag{2.3}$$

while inclusion $\partial^s F(\bar{x}) \subseteq \partial^e F(\bar{x})$ is straightforward. If $(Y_+^*)^\circ \neq \emptyset$, we also have $\partial^s F(\bar{x}) \subseteq \partial^p F(\bar{x})$; see (3.3)–(3.4). But $\partial^s F(\bar{x}) \neq \emptyset \not\Rightarrow \partial^s F(\bar{x}) = \partial^e F(\bar{x})$ unlike the efficient sets. Indeed, let $X = \mathbb{R}$, $Y = \mathbb{R}^2$, $Y_+ = \mathbb{R}^2_+$, and $F(x) = (0,-x)$ if $x \geq 0$, $= (-x,-x)$ if $x < 0$. We have $(-1,0) \in \partial^e F(0)$, but $(-1,0) \notin \partial^s F(0) = [-1,0] \times \{-1\}$.

In scalar case ($Y = \mathbb{R}$, $Y_+ = \mathbb{R}_+$), all these sets coincide with the classical subdifferential of convex analysis ($\partial^s F$), usually denoted by ∂F.

3. Scalarization, σ-subdifferentiability, and relations with derivatives.

3.1. Characterization via scalarization. For $\lambda \in Y_+^* \setminus \{0\}$, the scalar function $\lambda \circ F : X \to \mathbb{R} \sqcup \{+\infty\}$ is defined by

$$\lambda \circ F(x) = \begin{cases} \langle \lambda, F(x) \rangle & \text{if } x \in \operatorname{dom} F, \\ +\infty & \text{else.} \end{cases}$$

For $\lambda = 0$, we take by convention $\lambda \circ F = 0$. Note that, $\forall\ \lambda \in Y_+^* \setminus \{0\}$,

- $\operatorname{dom}(\lambda \circ F) = \operatorname{dom} F$.
- F is Y_+-convex $\Longrightarrow \lambda \circ F$ is convex.
- F is sequentially Y_+-l.s.c $\Longrightarrow \lambda \circ F$ is l.s.c (see [11, Proposition 3.7]).

We unify the notation of the polar cones too by putting, for instance, for Y_+:

$$Y_+^\sigma = \begin{cases} Y_+^* \setminus \{0\} & \text{if } \sigma = w, \\ (Y_+^*)^\circ & \text{if } \sigma = p. \end{cases}$$

Then, recall the fundamental VOP scalarization principle whose proof in infinite-dimensional spaces can be found in Luc [19, pp. 91–92]. But we will give here an improved version by Bonnel [8]. Comparatively, the proof is direct and clearly simplified for the weak concept. For the proper one, the reflexivity assumption on Y, in fact not required, has been replaced by Y separated. It also seems that the essential assumption Y_+ is pointed, is only forgotten in [19].

THEOREM 3.1. *Let $F : X \supseteq S \to Y \sqcup \{+\infty\}$. Then,*

$$E_s(F,S) \subseteq \bigsqcap_{\lambda \in Y_+^* \setminus \{0\}} \operatorname*{argmin}_{x \in S} \langle \lambda, F(x) \rangle, \tag{3.1}$$

with equality if Y is locally convex and Y_+ is closed. For $\sigma \in \{p, w\}$,

$$E_\sigma(F,S) \supseteq \bigsqcup_{\lambda \in Y_+^\sigma} \operatorname*{argmin}_{x \in S} \langle \lambda, F(x) \rangle, \tag{3.2}$$

with equality if F is Y_+-convex and S is convex, with Y_+ pointed as $\sigma = p$.

Proof. The direct inclusion in (3.1) is straightforward, while the reverse one uses only Proposition 2.1(1).

Let us show the inclusion in (3.2).

Case $\sigma = p$. Let $\lambda \in Y_+^p$ and $\bar{x} \in \operatorname{argmin}_{x \in S} \langle \lambda, F(x) \rangle$. The pointed convex cone

$$\hat{Y}_+ = \{y \in Y :\ \langle \lambda, y \rangle > 0\} \sqcup \{0\}$$

obviously satisfies $\hat{Y}_+ \neq Y$ and $Y_+ \setminus l(Y_+) \subseteq \operatorname{int} \hat{Y}_+$. If $\bar{x} \notin E_p(F,S)$, there would exist $x \in S$ such that $F(x) \precneqq_{\hat{Y}_+} F(\bar{x})$, i.e., $F(\bar{x}) - F(x) \in \hat{Y}_+ \setminus \{0\}$, and hence, $\langle \lambda, F(\bar{x}) - F(x) \rangle > 0$ contradicting the choice of $\bar{x}$.

Case $\sigma = w$. Consider the convex cone $\widetilde{Y}_+ = \operatorname{int} Y_+ \sqcup \{0\}$. With the property that $\operatorname{int} Y_+ \subseteq Y_+ \setminus l(Y_+)$, we can see that $\widetilde{Y}_+$ is pointed. Moreover, by Proposition 2.1(3), we have that $Y_+^w \subseteq \widetilde{Y}_+^p$. Inclusion (3.2) showed for $\sigma = p$, when applied to $\widetilde{Y}_+$, gets $\bigsqcup_{\lambda \in Y_+^w} \operatorname{argmin}_{x \in S} \langle \lambda, F(x) \rangle \subseteq E_p(F,S,\widetilde{Y}_+)$ the p-efficient set with respect to $\widetilde{Y}_+$. But in view of (2.1), $E_p(F,S,\widetilde{Y}_+) \subseteq E_e(F,S,\widetilde{Y}_+) = E_w(F,S)$; the last equality being trivially true by the fact that $\widetilde{Y}_+$ is pointed.

Let us show now the reverse inclusion for (3.2).

Case $\sigma = w$. Let $\bar{x} \in E_w(F,S)$, then, by definition, $(F(\bar{x}) - \operatorname{int} Y_+) \sqcap F(S) = \emptyset$. Using the well-known property that $Y_+ + \operatorname{int} Y_+ \subseteq \operatorname{int} Y_+$, $(F(\bar{x}) - \operatorname{int} Y_+) \sqcap (F(S) + Y_+) = \emptyset$ holds too. Since F is Y_+-convex and S is convex, then the set $F(S) + Y_+$ is convex. So, by separation theorem, there exists $\lambda \in Y^* \setminus \{0\}$ such that

$$\forall x \in S,\ \forall y \in Y_+,\ \forall y' \in \operatorname{int} Y_+, \quad \langle \lambda, F(\bar{x}) - y' \rangle \leq \langle \lambda, F(x) + y \rangle.$$

Letting $y' \to 0$ and taking $y = 0$, we obtain $\bar{x} \in \operatorname{argmin}_{x \in S} \langle \lambda, F(x) \rangle$. Taking now $x = \bar{x}$ and $y = 0$, we see that $\langle \lambda, y' \rangle \geq 0\ \forall\ y' \in \operatorname{int} Y_+$. The well-known property $\operatorname{cl}(\operatorname{int} Y_+) = \operatorname{cl} Y_+$ ("cl" stands for the topological closure) shows that the last inequality extends to $y' \in Y_+$, i.e., $\lambda \in Y_+^w$.

Case $\sigma = p$. Let $\bar{x} \in E_p(F,S)$, then there exists $\hat{Y}_+ \subsetneq Y$ a convex cone such that $Y_+ \setminus \{0\} \subseteq \operatorname{int} \hat{Y}_+$ (Y_+ is now supposed pointed) and $\bar{x} \in E_e(F,S,\hat{Y}_+)$. In view of (2.1), $\bar{x} \in E_w(F,S,\hat{Y}_+)$ too. Moreover, F being Y_+-convex and $Y_+ \setminus \{0\} \subseteq \operatorname{int} \hat{Y}_+$, obviously F remains $\hat{Y}_+$-convex. So reverse inclusion (3.2) showed, for $\sigma = w$, may be applied with $\hat{Y}_+$, deducing thus $\lambda \in \hat{Y}_+^* \setminus \{0\}$ such that $\bar{x} \in \operatorname{argmin}_{x \in S} \langle \lambda, F(x) \rangle$. It remains to show that $\lambda \in Y_+^p$. If it was not the case, as $Y_+ \setminus \{0\} \subseteq \operatorname{int} \hat{Y}_+$, we therefore could find $y \in Y_+ \setminus \{0\}$ such that $\langle \lambda, y \rangle = 0$, contradicting Proposition 2.1(3). ∎

The next result characterizes scalarly the σ-subdifferential for $\sigma \in \{s,p,w\}$ and will be crucial for the basic results of this paper.

THEOREM 3.2. *Let $F : X \to Y \sqcup \{+\infty\}$. Then, $\forall \bar{x} \in X$,*

$$\partial^s F(\bar{x}) \subseteq \bigsqcap_{\lambda \in Y_+^* \setminus \{0\}} \{A \in L(X,Y) :\ \lambda \circ A \in \partial(\lambda \circ F)(\bar{x})\}, \tag{3.3}$$

with equality if Y is locally convex and Y_+ is closed. For $\sigma \in \{p,w\}$, $\forall \bar{x} \in X$,

$$\partial^\sigma F(\bar{x}) \supseteq \bigsqcup_{\lambda \in Y_+^\sigma} \{A \in L(X,Y) :\ \lambda \circ A \in \partial(\lambda \circ F)(\bar{x})\}, \tag{3.4}$$

with equality if F is Y_+-convex, with Y_+ pointed as $\sigma = p$.

Proof. It is clear that, for $\bar{x} \notin \operatorname{dom} F$, all the previous sets are empty. Hence it suffices to consider $\bar{x} \in \operatorname{dom} F$ and to see as in (2.2) that

$$A \in \partial^\sigma F(\bar{x}) \quad \Longleftrightarrow \quad A \in L(X,Y) :\ \bar{x} \in E_\sigma(F - A, X) \tag{3.5}$$

and then to apply scalarization formulas (3.1)–(3.2). ∎

In the finite-dimensional space $Y = \mathbb{R}^r$ equipped with its natural order $Y_+ = \mathbb{R}^r_+$, the strong subdifferential reduces by the very definition to

$$\partial^s (f_1, \ldots, f_r)(\bar{x}) = \partial f_1(\bar{x}) \times \cdots \times \partial f_r(\bar{x}). \tag{3.6}$$

The equality in (3.4) was already proved by Taa [27] for w-subdifferentials of set-valued maps in Banach spaces using a direct scalarizing proof. It was also proved for the e-subdifferential by Sawaragi, Nakayama, and Tanino [26] in finite-dimensional spaces with an additional hypothesis on a Fenchel-type conjugate map of F.

3.2. σ-subdifferentiability and regular subdifferentiability. The vector mapping $F : X \to Y \sqcup \{+\infty\}$ is said to be at $\bar{x} \in \operatorname{dom} F$:

▶ subdifferentiable (resp. strongly, properly, or weakly subdifferentiable) if

$$\partial^\sigma F(\bar{x}) \neq \emptyset$$

for $\sigma = e$ (resp., $\sigma = s, p, w$). In brief, σ-subdifferentiable when $\sigma \in \{e, s, p, w\}$;

▶ regular subdifferentiable, if

$$\partial(\lambda \circ F)(\bar{x}) = \lambda \circ \partial^s F(\bar{x}) \qquad \forall \lambda \in Y_+^*,$$

where it is understood that the set $\lambda \circ \partial^s F(\bar{x}) := \{\lambda \circ A : A \in \partial^s F(\bar{x})\}$.

This property, due to Raffin [23], essentially reposes upon the inclusion "$\subseteq$", the reverse one "$\supseteq$" being trivial. The absence of the word "strongly" in this definition will be justified next. Afterwards, it is normal that the subdifferential regularity supposes a priori a nonempty strong subdifferential, that is why, by definition, it includes the value $\lambda = 0$. But, in most cases, we will just need the following weaker concepts, depending on the choice of $\sigma \in \{p, w\}$ in which the strong subdifferentiability is anyway not necessary: $F : X \to Y \sqcup \{+\infty\}$ will be said to be at $\bar{x} \in \operatorname{dom} F$

▶ σ-regular subdifferentiable, with $\sigma \in \{p, w\}$, if

$$\partial(\lambda \circ F)(\bar{x}) = \lambda \circ \partial^s F(\bar{x}) \qquad \forall \lambda \in Y_+^\sigma.$$

From scalarization Theorem 3.2, we establish first the σ-subdifferentiability for $\sigma \in \{p, e, w\}$ under recent conditions similar to those of the scalar case.

PROPOSITION 3.1. *Let X be a Fréchet space and $F \in \Gamma(X, Y)$ be such that at $\bar{x} \in \operatorname{dom} F$, the following Attouch–Brézis qualification condition is fulfilled:*

$$\mathbb{R}_+[\operatorname{dom} F - \bar{x}] \quad \textit{is a closed vector subspace of } X.$$

Then, for $\sigma \in \{p, w\}$,

$$\partial^\sigma F(\bar{x}) \neq \emptyset \qquad \textit{iff} \qquad \exists \lambda \in Y_+^\sigma : \lambda \circ F \textit{ is l.s.c at } \bar{x},$$

where the necessary condition demands Y_+ to be pointed [4] *as $\sigma = p$.*

Proof. We use the following result recently established by Laghdir [15].[5]

LEMMA 3.1. *Let X be a Fréchet space and $f \in \Gamma(X)$ be such that at $\bar{x} \in \operatorname{dom} f$, $\mathbb{R}_+[\operatorname{dom} f - \bar{x}]$ is a closed vector subspace of X. Then $\partial f(\bar{x}) \neq \emptyset$ iff f is l.s.c at $\bar{x}$.*

Assume that F satisfies the general hypotheses of Proposition 3.1. Then it is clear that, for any fixed $\lambda \in Y_+^\sigma$, the functional $\lambda \circ F$ also satisfies the general hypotheses of the lemma. If $\lambda \circ F$ is l.s.c at $\bar{x}$, we therefore can apply Lemma 3.1 and deduce the existence of $x_\lambda^* \in \partial(\lambda \circ F)(\bar{x})$. But $\lambda \in Y_+^\sigma$, with $\sigma = p$ (resp. $\sigma = w$) implies, by definition (resp. by Proposition 2.1(4)), the existence of $y_\lambda \in Y_+ \setminus l(Y_+)$ (resp. $y_\lambda \in \operatorname{int} Y_+$) such that $\langle \lambda, y_\lambda \rangle = 1$. Let $A_\lambda : X \to Y$ be defined by

$$A_\lambda(x) = \langle x_\lambda^*, x \rangle \, y_\lambda. \tag{3.7}$$

[4] With Y_+ pointed, following the equality in (3.4) of Theorem 3.2, if $Y_+^p = \emptyset$, then $\partial^p F(\bar{x}) = \emptyset$.

[5] This result improves the well-known Attouch–Brézis theorem [3] about the subdifferentiability of a scalar function, in a sense that l.s.c is not required more than at the point in question, in which case, obviously, the condition becomes necessary and sufficient. In fact, necessity even holds in a topological vector space and without a qualification condition in Lemma 3.1 as well as Proposition 3.1. Note also that if $\bar{x} \in \operatorname{int} \operatorname{dom} f$, then $\mathbb{R}_+[\operatorname{dom} f - \bar{x}] = X$, in particular, if f is continuous at $\bar{x}$.

Then $A_\lambda \in L(X,Y)$ and $\lambda \circ A_\lambda = x^*_\lambda \in \partial(\lambda \circ F)(\bar{x})$. It follows by Theorem 3.2(3.4) that $A_\lambda \in \partial^\sigma F(\bar{x})$, and the sufficient condition is proved. The necessary condition is obtained easily using again Theorem 3.2 and Lemma 3.1. □

While until now, strong subdifferentiability requires conditions slightly stronger. Recently, Zălinescu [34] extended the strong subdifferentiability of $F \in \Gamma(X,Y)$ at $\bar{x} \in \text{core}(\text{dom}\, F) := \{x \in \text{dom}\, F : \forall x' \in X, \exists \alpha > 0,\ x + [-\alpha,\alpha]x' \subseteq \text{dom}\, F\}$ (the algebraic interior) established by Valadier [32, Theorem 6 and Remark 6] in real linear spaces X and Y, with Y an order complete vector lattice and Y_+ pointed, to $\bar{x} \in \text{ri}(\text{dom}\, F) := \{x \in \text{dom}\, F : \forall x' \in \text{dom}\, F, \exists \alpha > 0,\ x + \alpha(x - x') \in \text{dom}\, F\}$ (the relative interior). Well before, Zowe [35] extended some results of Valadier [32] from order complete vector lattices to separated locally convex topological vector spaces ordered by closed convex cones and established the strong subdifferentiability of $F \in \Gamma(X,Y)$ under the three following conditions:

(H_1) X is a reflexive Banach space,

(H_2) F is continuous at $\bar{x} \in \text{int}\, \text{dom}\, F$,

(H_3) $\text{int}\, Y^*_+ \neq \emptyset$.

He also proved that if, furthermore, the following condition is realized:

(H_4) all order intervals $[a,b]$ are relatively weakly compact in Y,

then F is even regular subdifferentiable at $\bar{x}$. Moreover, he showed next that hypotheses (H_3) and (H_4) can be replaced by the following condition:

(H_5) Y is semireflexive and Y_+ has a weakly compact base lying in a closed hyperplane not running through 0.

Recall that a nonempty convex subset $B \subseteq Y_+$ not containing 0 is called a base of Y_+, if each $y \in Y_+ \setminus \{0\}$ has a unique representation $y = \alpha b$, where $b \in B$ and $\alpha > 0$.

The (σ-)regular subdifferentiability concept will reveal to be crucial in what follows. So, we suggest making on it some commentaries surely in some special cases of helpful interest. In the infinite-dimensional case, we have, for instance, the following processes.

Remark 1. Hypothesis (H_2) holds, for example, if $F \in \Gamma_0(X,Y)$, where Y is a Fréchet space equipped with a closed pointed and normal preorder Y_+ (Théra [29]). Recall that a point of continuity is trivially necessarily in the interior of the effective domain. On the other hand, it has been observed in [35] that it is easy to construct closed pointed convex cones Y_+ satisfying (H_5): $Y_+ = \bigsqcup_{\alpha \geq 0} \alpha B$, with B a convex weakly compact subset of a closed hyperplane in Y not containing 0.

In finite dimension, (H_5) is always fulfilled, and (H_2) may be weakened. Let us see this in the two following remarks.

Remark 2. In finite dimension, a cone has a compact base iff it is closed and pointed (see [19], e.g.). But following Peressini–Borwein (see again [19]), a base in a vector space is always of the form

$$B = \{y \in Y_+ :\ \langle \lambda, y \rangle = 1\}$$

for some λ in the algebraic strict polar cone of Y_+. This means that every mapping of $\Gamma(X, \mathbb{R}^r)$ in the setting of a reflexive Banach space X and a preorder Y_+ closed pointed is, at every point of continuity, regular subdifferentiable.

Remark 3. When $Y_+ = \mathbb{R}^r_+$, we have $Y^*_+ = \mathbb{R}^r_+$ and $(Y^*_+)^\circ = \text{int}\, \mathbb{R}^r_+$. So, by (3.6), subdifferential regularity (resp. σ-regularity for $\sigma = w, p$) of $F = (f_1, \ldots, f_r)$ becomes exactly a well-known chain rule of convex analysis: $\forall (\lambda_1, \ldots, \lambda_r) \geq 0$ (resp. $\gneq 0, > 0$),

$$\partial \left(\sum_{i=1}^r \lambda_i f_i \right) (\bar{x}) = \sum_{i=1}^r \lambda_i \partial f_i(\bar{x}).$$

The formula holds with the respective λ_is under the well-known Moreau–Rockafellar qualification condition [20, 24]:

$$(MR)\quad \begin{cases} f_i \in \Gamma(X) \quad (i = 1 \cdots r),\ X \text{ locally convex}, \\ (r-1) \text{ functions } f_i \text{ are finite and continuous at a point of} \\ \text{the effective domain of the other one}, \end{cases}$$

provided that all the f_is are subdifferentiable at $\bar{x}$ (resp. every one or none of them is it at $\bar{x}$ as $\sigma = w$ and for all $\bar{x} \in X$ as $\sigma = p$). For the latter, the formula even holds under the following weaker qualification condition of the Attouch–Brézis kind [11, pp. 139–140]:

$$(AB)\quad \begin{cases} f_i \in \Gamma_0(X) \quad (i = 1 \cdots r),\ X \text{ a Fréchet space}, \\ \mathbb{R}_+[\Delta X^r - \prod_{i=1}^r \operatorname{dom} f_i] \quad \text{is a closed vector subspace of } X^r, \end{cases}$$

where $X^r = X \times \cdots \times X$ (r times) and $\Delta X^r = \{(x, \ldots, x) \in X^r\}$. The (AB)-type conditions have the advantage to be in some sense weaker, with those of (MR) easy to check.

The σ-regular subdifferentiability appears first to be of great interest for finding the gap between vector and scalar concepts, a well-known question in vector analysis. Indeed, for the vector subdifferentials, we obtain the following relationships.

THEOREM 3.3. *Let $F \in \Gamma(X, Y)$ be σ-regular subdifferentiable at $\bar{x}$, $\sigma \in \{p, w\}$ and Y_+ be pointed as $\sigma = p$. Then,*

$$\partial^\sigma F(\bar{x}) = \partial^s F(\bar{x}) + Z_\sigma(X, Y), \tag{3.8}$$

where $Z_\sigma(X, Y) = \{A \in L(X, Y) :\ \exists\ \lambda \in Y_+^\sigma,\ \lambda \circ A = 0\}$ is the set of σ-zerolike linear continuous operators ($A \sim_\sigma 0$), which represents here the gap between $\partial^\sigma F$ and $\partial^s F$.

Proof. By equality in (3.4) and σ-regular subdifferentiability, we have

$$\begin{aligned} A \in \partial^\sigma F(\bar{x}) &\Leftrightarrow A \in L(X, Y),\ \exists \lambda \in Y_+^\sigma :\ \lambda \circ A \in \partial(\lambda \circ F)(\bar{x}) = \lambda \circ \partial^s F(\bar{x}) \\ &\Leftrightarrow A \in L(X, Y),\ \exists B \in \partial^s F(\bar{x}),\ \exists \lambda \in Y_+^\sigma :\ \lambda \circ (A - B) = 0 \\ &\Leftrightarrow \exists B \in \partial^s F(\bar{x}) :\ A - B \in Z_\sigma(X, Y) \\ &\Leftrightarrow A \in \partial^s F(\bar{x}) + Z_\sigma(X, Y). \qquad \square \end{aligned}$$

As $Z_\sigma(X, Y) = -Z_\sigma(X, Y)$, this set may be replaced in (3.8) by its opposite.

In the finite-dimensional case $Y = \mathbb{R}^r$ and $Y_+ = \mathbb{R}^r_+$, we have that $Y_+^w = \mathbb{R}^r_+ \setminus \{0\}$ and $Y_+^p = \operatorname{int} \mathbb{R}^r_+$. So, a matrix $A = (A_1, \ldots, A_r) \in \mathbb{R}^{r \times n}$ is in $Z_w(\mathbb{R}^n, \mathbb{R}^r)$ (resp. in $Z_p(\mathbb{R}^n, \mathbb{R}^r)$) if there exists a vector λ of r nonnegative components λ_i not all equal to zero (resp. all positive) such that $A^T\lambda = \sum_{i=1}^r \lambda_i A_i = 0$. The set $Z_p(\mathbb{R}^n, \mathbb{R}^r)$ of p-zerolike matrices has already been evoked in [26, pp. 204], where the authors claim, for $F \in \Gamma(\mathbb{R}^n, \mathbb{R}^r)$, that[6]

$$\bar{x} \in E_p(F, \mathbb{R}^n) \quad \Leftrightarrow \quad \exists A \sim_p 0 :\ A \in \partial^s F(\bar{x}) \quad \Leftrightarrow \quad \exists A \sim_p 0 :\ \bar{x} \in E_s(F - A, \mathbb{R}^n).$$

The second relation being trivial from (3.5). While in comparison with (3.8), the first relation can be viewed by (2.2) as

$$0 \in \partial^p F(\bar{x}) \quad \Longleftrightarrow \quad 0 \in \partial^s F(\bar{x}) + Z_p(\mathbb{R}^n, \mathbb{R}^r).$$

[6] We just wonder if this result does not require a certain regularity on F, since it is announced without proof.

Remark 4. As predicted, let us underline that, in general spaces, for instance, Y is locally convex equipped with a closed pointed preorder Y_+, we effectively cannot talk about σ-subdifferential regularity for $\sigma \in \{p, e, w\}$. In fact, for all $\lambda \in Y_+^*$, $\partial(\lambda \circ F)(\bar{x}) = \lambda \circ \partial^\sigma F(\bar{x})$ for $\sigma \in \{p, e, w\}$ would imply in view of the equality in (3.3) that $\partial^\sigma F(\bar{x}) \subseteq \partial^s F(\bar{x})$. With the respective reverse inclusions, the subdifferentials of Pareto type would coincide with the strong one, and the function would be regular subdifferentiable too. This may be in contradiction with Theorem 3.3, and this justifies the absence of the word "strongly" in the regular subdifferentiability appellation.

3.3. Characterizations via derivatives. Let us recall the most popular notions of derivatives for vector mappings. $F : X \to Y \sqcup \{+\infty\}$ is said to be, at $\bar{x} \in \operatorname{dom} F$,

- directionally differentiable, in brief, D-differentiable, if $\forall d \in X$,
$$\lim_{t \searrow 0^+} \frac{F(\bar{x} + td) - F(\bar{x})}{t} = l(d) \in Y,$$
we denote $F'(\bar{x}; d) = l(d)$ the directional derivative of F at $\bar{x}$ in the direction d;
- Gâteaux differentiable, in brief, G-differentiable, if $\exists A \in L(X,Y)$, $\forall d \in X$,
$$F'(\bar{x}; d) = \lim_{t \to 0} \frac{F(\bar{x} + td) - F(\bar{x})}{t} = A(d),$$
we denote $F'_G(\bar{x}) = A$ the Gâteaux derivative of F at $\bar{x}$;
- Fréchet differentiable, in brief, F-differentiable, if $\exists A \in L(X, Y)$,
$$\lim_{h \to 0} \frac{F(\bar{x} + h) - F(\bar{x}) - A(h)}{\|h\|} = 0,$$
we denote $F'(\bar{x}) = A$ the Fréchet derivative of F at $\bar{x}$; here, X being, of course, normed.

Obviously,

- F-differentiable at $\bar{x} \Longrightarrow$ G-differentiable at $\bar{x} \Longrightarrow$ D-differentiable at $\bar{x}$.
- In this case, $F'(\bar{x}) = F'_G(\bar{x}) = F'(\bar{x}; \cdot)$.

For a finite-dimensional image space, the D-differentiability of $F = (f_1, \dots, f_r)$ is, of course, equivalent to D-differentiability of functionals f_is. But, it is well known that every proper convex functional always admits directional derivatives in all direction at any point of subdifferentiability. So the D-differentiability of F holds under the conditions of Lemma 3.1 and, in particular, at every point of $\operatorname{int} \operatorname{dom} F = \prod_{i=1}^r \operatorname{int} \operatorname{dom} f_i$, where F is sequentially $\mathbb{R}^r_+$-l.s.c or, strongly again, at every point of the continuity of F. For the case of infinite-dimensional image spaces, the D-differentiability of $F \in \Gamma(X, Y)$ was established in [35] under hypotheses (H_2)–(H_3) and the preorder normality assumption.

We express now the σ-subdifferentials in terms of the derivatives when they exist.

PROPOSITION 3.2. *Let Y be locally convex, Y_+ be closed, pointed as $\sigma = p$, and $F \in \Gamma(X, Y)$ be D-differentiable at $\bar{x}$. Then,*

$$\begin{aligned}
\partial^s F(\bar{x}) &= \{A \in L(X,Y) : \quad \forall d \in X,\ F'(\bar{x}; d) \geq_{Y_+} A(d)\},\\
\partial^w F(\bar{x}) &= \{A \in L(X,Y) : \quad \nexists d \in X,\ F'(\bar{x}; d) <_{Y_+} A(d)\},\\
\partial^p F(\bar{x}) &= \{A \in L(X,Y) : \quad \exists \hat{Y}_+ \subsetneq Y \text{ a convex cone that satisfies}\\
&\qquad Y_+ \setminus \{0\} \subseteq \operatorname{int} \hat{Y}_+,\ \nexists d \in X,\ F'(\bar{x}; d) \lneq_{\hat{Y}_+} A(d)\}.
\end{aligned}$$

Proof. We shall prove that, for $\sigma \in \{s, p, w\}$,

$$A \in \partial^\sigma F(\bar{x}) \iff A \in L(X,Y) :\ 0 \in E_\sigma(F'(\bar{x};\cdot) - A, X), \tag{3.9}$$

which, by the very definitions of σ-efficient sets, show the proposition. To this, observe first that, for all $\lambda \in Y_+^*$, by continuity of λ, for all $d \in X$,

$$\lambda \circ F'(\bar{x};d) = \lim_{t \searrow 0^+} \frac{\lambda \circ F(\bar{x}+td) - \lambda \circ F(\bar{x})}{t} = (\lambda \circ F)'(\bar{x};d). \tag{3.10}$$

On the other hand, by Theorem 3.2, to say $A \in \partial^\sigma F(\bar{x})$ for $\sigma = s$ (resp. $\sigma \in \{p, w\}$) is equivalent to saying that $\lambda \circ A \in \partial(\lambda \circ F)(\bar{x})\ \forall\ \lambda \in Y_+^* \setminus \{0\}$ (resp. for some $\lambda \in Y_+^\sigma$), with $A \in L(X,Y)$. As $\lambda \circ F \in \Gamma(X)$ is D-differentiable at $\bar{x}$, then we have

$$\partial(\lambda \circ F)(\bar{x}) = \{x^* \in X^* :\ \forall d \in X,\ (\lambda \circ F)'(\bar{x};d) \geq \langle x^*, d\rangle\}.$$

So $A \in \partial^\sigma F(\bar{x})$ is also equivalent to $\lambda \circ F'(\bar{x};d) \geq \lambda \circ A(d)\ \forall\ d \in X$ or equivalently, $0 \in \operatorname{argmin}_{d \in X} \langle \lambda, F'(\bar{x};d) - A(d)\rangle$, with the respective σs and λs. Property (3.9) thus follows from scalarization Theorem 3.1, since for $\sigma \in \{p, w\}$, $F'(\bar{x};\cdot)$ is well Y_+-convex. More precisely, as shown in what follows.

LEMMA 3.2. *With the same hypotheses as Proposition* 3.2*, vector function* $d \mapsto F'(\bar{x};d)$ *is positively homogeneous* Y_+*-subadditive, i.e.,* $\forall \alpha \in \mathbb{R}_+,\ \forall d_1,\ d_2 \in X$*,*

$$\begin{aligned} &F'(\bar{x};\alpha d_1) = \alpha F'(\bar{x};d_1),\\ &F'(\bar{x};d_1+d_2) \leq_{Y_+} F'(\bar{x};d_1) + F'(\bar{x};d_2). \end{aligned}$$

Proof of Lemma 3.2. Homogeneous positivity is immediate from the definition of $F'(\bar{x};d)$. While subadditivity, it follows from the one of $(\lambda \circ F)'(\bar{x};.)$, relation (3.10), and Proposition 2.1(1). ∎

PROPOSITION 3.3. *Let* Y *be locally convex,* Y_+ *be closed pointed, and* $F \in \Gamma(X,Y)$ *be both D-differentiable, p-regular subdifferentiable, and s-subdifferentiable at* $\bar{x}$*. Then,* $\forall d \in X$*,*

$$\begin{aligned} F'(\bar{x};d) &= \operatorname*{MAX_s}_{A \in \partial^s F(\bar{x})} A(d),\\ F'(\bar{x};d) &\in \operatorname*{MAX}_{\sigma\ A \in \partial^\sigma F(\bar{x})} A(d) \qquad \text{for } \sigma \in \{p, w\}, \end{aligned}$$

where $\operatorname{MAX}_{\sigma\, x \in D} G(x) = G(E_\sigma(-G, D))$ *denotes the set*[7] *of* σ*-maximal values of a vector mapping* G *over a subset* D*.*

Proof. For $\sigma = s$, taking into account the first result of Proposition 3.2, we have to prove that, for any fixed $d \in X$, there exists $A \in \partial^s F(\bar{x})$ such that $A(d) = F'(\bar{x};d)$. If we proceed by contradiction, it would mean that $F'(\bar{x};d) - A(d) \in Y_+ \setminus \{0\}$ for every $A \in \partial^s F(\bar{x})$. Picking $\lambda \in (Y_+^*)^\circ$, we would have

$$\langle \lambda, F'(\bar{x};d) - A(d)\rangle > 0 \qquad \forall A \in \partial^s F(\bar{x}). \tag{3.11}$$

Since $\lambda \circ F \in \Gamma(X)$ is subdifferentiable at $\bar{x}$ (see (3.3)), it holds that

$$(\lambda \circ F)'(\bar{x};d) = \max_{x^* \in \partial(\lambda \circ F)(\bar{x})} \langle x^*, d\rangle.$$

[7] It is easy to see that the set of strong maximal values $\operatorname{MAX}_{s\, x \in D} G(x)$ is a singleton if the preorder is pointed. So, we consider it a vector instead of a set.

Let $x^* \in \partial(\lambda \circ F)(\bar{x})$ be such that $(\lambda \circ F)'(\bar{x}; d) = \langle x^*, d\rangle$ realizing this maximum. Let $A^* \in \partial^s F(\bar{x})$ be given by p-regular subdifferentiability such that $x^* = \lambda \circ A^*$. Then, with (3.10), $\lambda \circ F'(\bar{x}; d) = (\lambda \circ F)'(\bar{x}; d) = \lambda \circ A^*(d)$ so in contradiction with (3.11). Case $\sigma \in \{p, w\}$ follows easily by contradiction too, using both the previous result and the two last formulas of Proposition 3.2. □

PROPOSITION 3.4. *Let Y be locally convex, Y_+ be closed, and $F \in \Gamma(X, Y)$.*

(1) *If F is G-differentiable at $\bar{x}$, with Y_+ pointed as $\sigma = p$, then*

$$\partial^s F(\bar{x}) = \{F'_G(\bar{x})\},$$
$$\partial^\sigma F(\bar{x}) = \{F'_G(\bar{x})\} + Z_\sigma(X, Y) \qquad \text{for } \sigma \in \{p, w\}.$$

(2) *Conversely, if F is both D-differentiable and p-regular subdifferentiable at $\bar{x}$, with Y_+ pointed, and $\partial^s F(\bar{x}) = \{A\}$, then F is G-differentiable at $\bar{x}$ and $F'_G(\bar{x}) = A$.*

Proof. (1) Case $\sigma = s$ is directly coming from G-differentiability and Proposition 3.2. For $\sigma \in \{p, w\}$, let us prove first the following lemma.

LEMMA 3.3. *In Y locally convex with Y_+ closed, vector mapping $F \in \Gamma(X, Y)$, which is G-differentiable at $\bar{x}$, is regular subdifferentiable at this point.*

Proof of Lemma 3.3. Similarly to (3.10), we have that $(\lambda \circ F)'_G(\bar{x}) = \lambda \circ F'_G(\bar{x})$ for each $\lambda \in Y_+^*$, so functional $\lambda \circ F \in \Gamma(X)$ is G-differentiable at $\bar{x}$. Hence $\partial(\lambda \circ F)(\bar{x}) = \{(\lambda \circ F)'_G(\bar{x})\} = \lambda \circ \{F'_G(\bar{x})\} = \lambda \circ \partial^s F(\bar{x})$. □

If F is regular subdifferentiable, then it is obviously a w-regular one. If $Y_+^p = \emptyset$, then $\partial^p F(\bar{x})$ and $Z_p(X, Y)$ are empty; otherwise, F is also p-regular subdifferentiable. The result of assertion (1) for $\sigma \in \{p, w\}$ then follows from Theorem 3.3.

(2) This assertion is an immediate consequence of Proposition 3.3. □

Propositions 3.2 and 3.3 were proved for $\sigma = s$ by Valadier [32] in the setting of normal order complete vector lattices with continuity hypothesis (H_2), while Proposition 3.4, it was again shown for $\sigma = s$ by Zowe [35] in the more general setting of ordered separated locally convex topological vector spaces using the order normality assumption and hypotheses (H_1) to (H_4).

We end the section by the following corollaries.

COROLLARY 3.1. *Let Y be locally convex, Y_+ be closed, and pointed as $\sigma = p$, $F \in \Gamma(X, Y)$, and $\sigma \in \{p, w\}$.*

(1) *If F is σ-regular subdifferentiable at $\bar{x}$, then*

$$\partial^\sigma F(\bar{x}) = \bigsqcup_{A \in \partial^s F(\bar{x})} \partial^\sigma A(x) \qquad \forall x \in X.$$

(2) *If F is, in particular, G-differentiable at $\bar{x}$, then*

$$\partial^\sigma F(\bar{x}) = \partial^\sigma (F'_G(\bar{x}))(x) \qquad \forall x \in X.$$

(3) *In particular, one has*

$$Z_\sigma(X, Y) = \partial^\sigma 0(x) \qquad \forall x \in X.$$

Indeed, since a continuous linear operator A is G-differentiable and $A'_G(x) = A \ \forall\ x \in X$, then according to Theorem 3.3 and Proposition 3.4(1), we have that $\partial^\sigma F(\bar{x}) = \bigsqcup_{A \in \partial^s F(\bar{x})} \{A\} + Z_\sigma(X, Y) = \bigsqcup_{A \in \partial^s F(\bar{x})} \partial^\sigma A(x) \quad (\forall x \in X)$.

4. σ-subdifferential calculus rules. We are concerned in this section with the subdifferential calculus of the sum and/or the composition of convex vector mappings.

4.1. Addition. In literature, one may find some calculus rules about the sum of two convex vector mappings. The following formula was established by Théra [29] in the setting of a normal order complete vector topological space Y, where one of the functions is supposed to be continuous over a separated locally convex space X:

$$\partial^s(F+G)(\bar{x}) = \partial^s F(\bar{x}) + \partial^s G(\bar{x}).$$

In the more general setting of Banach spaces partially ordered, a similar result was proved in the case $\sigma = w$ by Lin [18] and Taa [27] for convex set-valued maps under a Slater-type qualification condition:

$$\partial^w(F+G)(\bar{x}) \subset \partial^w F(\bar{x}) + \partial^w G(\bar{x}).$$

Let us emphasize that unlike the extended scalar concept, i.e., $\sigma = s$, for which the reverse inclusion is trivial, in fact, with Pareto concepts, this converse cannot hold. Look at this with this simple example of very regular vector mappings: Let $F,\ G \in L(\mathbb{R}^2, \mathbb{R}^2)$ be defined by $F(x_1, x_2) = (x_1, 0)$ and $G(x_1, x_2) = (0, x_2)$. At $\bar{x} = (0,0)$, $F'(0,0) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$, $G'(0,0) = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, and $(F+G)'(0,0) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$. But $A = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$ is a matrix which verifies $\langle \lambda, A - F'(0,0)\rangle = 0$, with $\lambda = (1,0)$ or equivalently, by taking natural order $\mathbb{R}^2_+$, $A \in F'(0,0) + Z_w(\mathbb{R}^2, \mathbb{R}^2) = \partial^w F(0,0)$ according to Proposition 3.4(1). In a similar way, by taking $\lambda = (0,1)$, we verify that the matrix $-A \in \partial^w G(0,0)$. Hence, the matrix $0 = A - A \in \partial^w F(0,0) + \partial^w G(0,0)$. However, $0 \notin \partial^w(F+G)(0,0)$, since otherwise, by the Proposition 3.4(1) again, we obtain, for some $\lambda \in \mathbb{R}^2_+ \setminus \{0\}$, contradiction $0 = \langle \lambda, (F+G)'(0,0)\rangle = \lambda$. Thus

$$\partial^w F(0,0) + \partial^w G(0,0) \not\subset \partial^w(F+G)(0,0).$$

In fact, the presence of the strong subdifferential establishes the desired equality.

THEOREM 4.1. *Let $F,\ G : X \to Y \sqcup \{+\infty\}$, and $\sigma \in \{p, w\}$. Then, $\forall \bar{x} \in X$,*

$$\partial^\sigma(F+G)(\bar{x}) \supseteq \partial^\sigma F(\bar{x}) + \partial^s G(\bar{x}).$$

Assume now that G is σ-regular subdifferentiable at $\bar{x}$, Y_+ is pointed as $\sigma = p$, and one of the two following qualification conditions is satisfied:

$$(MR)_1 \quad \begin{cases} F,\ G \in \Gamma(X,Y),\ X \text{ locally convex}, \\ \text{one of the two functions is finite and continuous} \\ \text{at some point of the effective domain of the other one.} \end{cases}$$

$$(AB)_1 \quad \begin{cases} F,\ G \in \Gamma_0(X,Y),\ X \text{ Fréchet space}, \\ \mathbb{R}_+[\operatorname{dom} F - \operatorname{dom} G] \quad \text{is a closed vector subspace of } X. \end{cases}$$

Then,

$$\partial^\sigma(F+G)(\bar{x}) = \partial^\sigma F(\bar{x}) + \partial^s G(\bar{x}).$$

Proof. Let us prove the first inclusion for $\sigma = w$. Let $A \in \partial^w F(\bar{x})$, $B \in \partial^s G(\bar{x})$. We proceed by contradiction: If $A + B \notin \partial^w(F+G)(\bar{x})$, we would have

$$F(x_0) + G(x_0) - F(\bar{x}) - G(\bar{x}) - A(x_0 - \bar{x}) - B(x_0 - \bar{x}) \in -\operatorname{int} Y_+$$

for some $x_0 \in \operatorname{dom}(F+G) = \operatorname{dom} F \sqcap \operatorname{dom} G$. Then since $B \in \partial^s G(\bar{x})$, we would have

$$-G(x_0) + G(\bar{x}) + B(x_0 - \bar{x}) \in -Y_+.$$

Adding term by term and taking into account the fact that $-Y_+ - \operatorname{int} Y_+ \subseteq -\operatorname{int} Y_+$, we would obtain

$$F(x_0) - F(\bar{x}) - A(x_0 - \bar{x}) \in -\operatorname{int} Y_+,$$

which would contradict $A \in \partial^w F(\bar{x})$. Case $\sigma = p$ is obtained similarly by using now the fact that $-\operatorname{int} \hat{Y}_+ \subseteq -\hat{Y}_+ \setminus l(\hat{Y}_+)$ and $-\hat{Y}_+ \setminus l(\hat{Y}_+) - \hat{Y}_+ \setminus l(\hat{Y}_+) \subseteq -\hat{Y}_+ \setminus l(\hat{Y}_+)$; $\hat{Y}_+$ being given by the p-subdifferential definition.

We show the reverse inclusion by scalarization for $\sigma \in \{p, w\}$ simultaneously. So let $A \in \partial^\sigma(F+G)(\bar{x})$, then, by Theorem 3.2, there exists $\lambda \in Y_+^\sigma$ such that

$$\lambda \circ A \in \partial[\lambda \circ (F+G)](\bar{x}) = \partial(\lambda \circ F + \lambda \circ G)(\bar{x}).$$

Following condition $(MR)_1$ or $(AB)_1$, scalar functions $\lambda \circ F$ and $\lambda \circ G$, then satisfy exactly the qualification hypothesis of Moreau–Rockafellar or Attouch–Brézis. Hence, the subdifferential addition formula for functionals $\lambda \circ F$ and $\lambda \circ G$ applies, and, with the σ-regular subdifferentiability assumption on G, we therefore obtain

$$\partial(\lambda \circ F + \lambda \circ G)(\bar{x}) = \partial(\lambda \circ F)(\bar{x}) + \partial(\lambda \circ G)(\bar{x}) = \partial(\lambda \circ F)(\bar{x}) + \lambda \circ \partial^s G(\bar{x}).$$

Thus we deduce $B \in \partial^s G(\bar{x})$ such that $\lambda \circ (A - B) \in \partial(\lambda \circ F)(\bar{x})$ which shows, again by Theorem 3.2, that $A - B \in \partial^\sigma F(\bar{x})$ or equivalently $A \in \partial^\sigma F(\bar{x}) + \partial^s G(\bar{x})$. □

Using Lemma 3.3 and Proposition 3.4(1), we easily obtain the following corollary.

COROLLARY 4.1. *Let X and Y be locally convex, Y_+ be closed, pointed as $\sigma = p$, $F \in \Gamma(X, Y)$, $A \in L(X, Y)$, and $\sigma \in \{p, w\}$. Then, $\forall \bar{x} \in X$,*

$$\partial^\sigma(F + A)(\bar{x}) = \partial^\sigma F(\bar{x}) + A.$$

In finite-dimensional image space, according to Remark 3, Theorem 4.1 becomes the following.

COROLLARY 4.2. *Let X be locally convex, f_i, $g_i \in \Gamma(X)$ $(i = 1 \cdot\cdot\, r)$, and consider the following hypotheses:*

(MR) *$(r-1)$ g_is are finite and continuous at a point of domain of the other one.*

(AB) *The g_is are l.s.c, $\mathbb{R}_+[\Delta X^r - \prod_{i=1}^r \operatorname{dom} g_i]$ is a closed vector subspace of X^r.*

$(MR)_1$ *All the g_is are finite and continuous at some point of $\prod_{i=1}^r \operatorname{dom} f_i$.*

$(MR)'_1$ *All the f_is are finite and continuous at some point of $\prod_{i=1}^r \operatorname{dom} g_i$.*

$(AB)_1$ *The f_is, g_is are l.s.c, $\mathbb{R}_+[\prod_{i=1}^r \operatorname{dom} f_i - \prod_{i=1}^r \operatorname{dom} g_i]$ is closed vector subspace.*

If one of conditions $(MR)_1$, $\big[(MR)'_1$ and $(MR)\big]$, $\big[(MR)'_1$ and (AB), with X Fréchet$\big]$, $\big[(AB)_1$ and (MR), with X Fréchet$\big]$, or $\big[(AB)_1$ and (AB), with X Fréchet$\big]$ is satisfied, then, $\forall \bar{x} \in X$,

$$\partial^p(f_1 + g_1, \ldots, f_r + g_r)(\bar{x}) = \partial^p(f_1, \ldots, f_r)(\bar{x}) + \prod_{i=1}^r \partial g_i(\bar{x}).$$

If, in addition to condition $(MR)_1$, $\big[(MR)'_1$ and $(MR)\big]$, or $\big[(AB)_1$ and (MR), with X Fréchet$\big]$, every one or none of the g_is is subdifferentiable at $\bar{x}$, then

$$\partial^w(f_1 + g_1, \ldots, f_r + g_r)(\bar{x}) = \partial^w(f_1, \ldots, f_r)(\bar{x}) + \prod_{i=1}^r \partial g_i(\bar{x}).$$

4.2. Composition. We present in this subsection several results concerning the σ-subdifferential calculus of the composite of two convex vector mappings. The main one of them is the following.

THEOREM 4.2. *Let $F : X \to Y \sqcup \{+\infty\}$, $G : Y \to Z \sqcup \{+\infty\}$, and $\sigma \in \{p, w\}$. Then, $\forall \bar{x} \in X$,*

$$\partial^\sigma (G \circ F)(\bar{x}) \supseteq \bigsqcup_{A \in \partial^s G(F(\bar{x}))} \partial^\sigma (A \circ F)(\bar{x}).$$

Assume now that G is (Y_+, Z_+)-nondecreasing and σ-regular subdifferentiable at $F(\bar{x})$, Z_+ is pointed as $\sigma = p$, and one of the two following qualification conditions is satisfied:

$$(MR)_2 \quad \begin{cases} F \in \Gamma(X, Y),\ G \in \Gamma(Y, Z),\ X \text{ and } Y \text{ locally convex}, \\ G \text{ is finite and continuous at some point of } \operatorname{Im} F := F(\operatorname{dom} F). \end{cases}$$

$$(AB)_2 \quad \begin{cases} F \in \Gamma_0(X, Y),\ G \in \Gamma_0(Y, Z),\ X \text{ and } Y \text{ Fréchet spaces}, \\ \mathbb{R}_+[\operatorname{dom} G - \operatorname{Im} F] \text{ is a closed vector subspace of } Y. \end{cases}$$

Then,

$$\partial^\sigma (G \circ F)(\bar{x}) = \bigsqcup_{A \in \partial^s G(F(\bar{x}))} \partial^\sigma (A \circ F)(\bar{x}).$$

Proof. Let us prove the first inclusion for $\sigma = w$. Let $B \in \partial^w (A \circ F)(\bar{x})$ for some $A \in \partial^s G(F(\bar{x}))$. We proceed by contradiction: If $B \notin \partial^w (G \circ F)(\bar{x})$, we would have

$$G \circ F(x_0) - G \circ F(\bar{x}) - B(x_0 - \bar{x}) \in -\operatorname{int} Z_+$$

for some $x_0 \in \operatorname{dom}(G \circ F) = F^{-1}(\operatorname{dom} G) \sqcap \operatorname{dom} F$. But $A \in \partial^s G(F(\bar{x}))$ would imply

$$-G \circ F(x_0) + G \circ F(\bar{x}) + A \circ F(x_0) - A \circ F(\bar{x}) \in -Z_+.$$

Adding term by term, by using that $-Z_+ - \operatorname{int} Z_+ \subseteq -\operatorname{int} Z_+$, we would obtain

$$A \circ F(x_0) - A \circ F(\bar{x}) - B(x_0 - \bar{x}) \in -\operatorname{int} Z_+,$$

which would contradict $B \in \partial^w (A \circ F)(\bar{x})$. The case of $\sigma = p$ is similarly obtained by the same arguments as for Theorem 4.1.

To show the reverse inclusion, we proceed by scalarization. To this end, we need the following subdifferential formula of a scalar composite recently proved by Combari, Laghdir, and Thibault [11], obtained well before by Lemaire [16] in the setting of Banach spaces under the Moreau–Rockafellar-type hypothesis.

LEMMA 4.1. *Let $F : X \to Y \sqcup \{+\infty\}$ and $g : Y \to \mathbb{R} \sqcup \{+\infty\}$ be a functional Y_+-nondecreasing such that one of the two following qualification conditions holds:*

$$(MR)_2 \quad \begin{cases} F \in \Gamma(X, Y),\ g \in \Gamma(Y),\ X \text{ and } Y \text{ locally convex}, \\ g \text{ is finite and continuous at some point of } \operatorname{Im} F. \end{cases}$$

$$(AB)_2 \quad \begin{cases} F \in \Gamma_0(X, Y),\ g \in \Gamma_0(Y),\ X \text{ and } Y \text{ Fréchet spaces}, \\ \mathbb{R}_+[\operatorname{dom} g - \operatorname{Im} F] \text{ is a closed vector subspace of } Y. \end{cases}$$

Then, $\forall \bar{x} \in X$,

$$\partial(g \circ F)(\bar{x}) = \bigsqcup_{\lambda \in \partial g(F(\bar{x}))} \partial(\lambda \circ F)(\bar{x}).$$

We come back to Theorem 4.2. Let $B \in \partial^\sigma(G \circ F)(\bar{x})$, then, by Theorem 3.2,

$$\mu \circ B \in \partial(\mu \circ G \circ F)(\bar{x}) \quad \text{for some} \quad \mu \in Z_+^\sigma.$$

It is easy to see that F and $\mu \circ G$ satisfies the conditions of Lemma 4.1. Hence,

$$\partial(\mu \circ G \circ F)(\bar{x}) = \bigsqcup_{\lambda \in \partial(\mu \circ G)(F(\bar{x}))} \partial(\lambda \circ F)(\bar{x}).$$

So, by σ-regular subdifferentiability of G, we deduce the existence of $A \in \partial^s G(F(\bar{x}))$ such that $\mu \circ B \in \partial(\mu \circ A \circ F)(\bar{x})$. Let us observe that

$$A \in \partial^s G(F(\bar{x})), \quad G \text{ is } (Y_+, Z_+)\text{-nondecreasing} \quad \Longrightarrow \quad A \in L_+(Y, Z),$$

since, in fact, $A \in L(Y, Z)$ and $0 \leq_{Z_+} G(F(\bar{x})) - G(F(\bar{x}) - y) \leq_{Z_+} A(y)\ \forall\ y \in Y_+$. Consequently, $A \circ F \in \Gamma(X, Z)$ and then, by Theorem 3.2, $B \in \partial^\sigma(A \circ F)(\bar{x})$. □

We continue with some specializations of Theorem 4.2.

COROLLARY 4.3. *Let Z be locally convex, $G \in \Gamma(Y, Z)$ be (Y_+, Z_+)-nondecreasing σ-regular subdifferentiable at $A(\bar{x})$, $\sigma \in \{p, w\}$, Z_+ be closed, pointed as $\sigma = p$. Then,*

$$\begin{aligned} \partial^\sigma(G \circ A)(\bar{x}) &= \partial^s G(A(\bar{x})) \circ A + Z_\sigma(X, Z) && \forall A \in L(X, Y), \\ &= \partial^\sigma G(A(\bar{x})) \circ A && \forall A \in L^{-1}(X, Y), \end{aligned}$$

respectively, if

(i) *X, Y are locally convex and G is finite and continuous at some point of* $\operatorname{Im} A$*, or X, Y are Fréchet spaces, G is sequentially Z_+-l.s.c and $\mathbb{R}_+[\operatorname{dom} G - \operatorname{Im} A]$ is a closed vector subspace of Y,*

respectively,

(ii) *X, Y are locally convex and G is finite and continuous at some point of Y, or X, Y are Fréchet spaces and G is sequentially Z_+-l.s.c.*

Proof. The first formula is obtained via Theorem 4.2 and Proposition 3.4. Indeed,

$$\begin{aligned} \partial^\sigma(G \circ A)(\bar{x}) = \bigsqcup_{B \in \partial^s G(A(\bar{x}))} \partial^\sigma(B \circ A)(\bar{x}) &= \bigsqcup_{B \in \partial^s G(A(\bar{x}))} B \circ A + Z_\sigma(X, Z) \\ &= \partial^s G(A(\bar{x})) \circ A + Z_\sigma(X, Z). \end{aligned}$$

The second formula requires the following relation, which may be easily obtained by definition of the σ-zerolike sets using the fact that A is invertible:

$$Z_\sigma(Y, Z) \circ A = Z_\sigma(X, Z).$$

Indeed, because $\operatorname{Im} A = Y$, the first formula still holds under condition (ii), so with Theorem 3.3, $\partial^\sigma(G \circ A)(\bar{x}) = [\partial^s G(A(\bar{x})) + Z_\sigma(Y, Z)] \circ A = \partial^\sigma G(A(\bar{x})) \circ A$. □

The following result may be viewed as a vector extension of the subdifferential regularity in the sense of Pareto.

PROPOSITION 4.1. *Let $F \in \Gamma(X, Y)$ be regular subdifferentiable at $\bar{x}$, $\sigma \in \{p, w\}$ and Z_+ be pointed as $\sigma = p$. Then,*

$$\begin{aligned} \partial^\sigma(A \circ F)(\bar{x}) &= A \circ \partial^s F(\bar{x}) + Z_\sigma(X, Z) && \forall A \in L_+(Y, Z), \\ &= A \circ \partial^\sigma F(\bar{x}) && \forall A \in L_+^{-1}(Y, Z), \end{aligned}$$

where the last equality demands Y_+ to be pointed as $\sigma = p$.

Proof. We already pointed out that $F \in \Gamma(X,Y)$ and $A \in L_+(Y,Z)$ imply that $A \circ F \in \Gamma(X,Z)$. On the other hand, let $\mu \in Z_+^\sigma$, then $\lambda = \mu \circ A \in Y^*$ and $\lambda(Y_+) = \mu(A(Y_+)) \subseteq \mu(Z_+) \subseteq \mathbb{R}_+$, i.e., $\lambda \in Y_+^*$. Hence, by Theorem 3.2 and the regular subdifferentiability assumption, we have that

$$\begin{aligned} B \in \partial^\sigma(A \circ F)(\bar{x}) &\Leftrightarrow B \in L(X,Z), \exists \mu \in Z_+^\sigma : \mu \circ B \in \partial(\mu \circ A \circ F)(\bar{x}) = \lambda \circ \partial^s F(\bar{x}) \\ &\Leftrightarrow B \in L(X,Z), \exists C \in \partial^s F(\bar{x}), \exists \mu \in Z_+^\sigma : \mu \circ (B - A \circ C) = 0 \\ &\Leftrightarrow \exists C \in \partial^s F(\bar{x}) : B - A \circ C \in Z_\sigma(X,Z) \\ &\Leftrightarrow B \in A \circ \partial^s F(\bar{x}) + Z_\sigma(X,Z). \end{aligned}$$

If, furthermore, A is invertible, then we easily have like for Corollary 4.3 that

$$A \circ Z_\sigma(X,Y) = Z_\sigma(X,Z).$$

The proof ends by applying Theorem 3.3. □

Remark 5. We already justified in Remark 4 that σ-subdifferential regularity for $\sigma \in \{p,e,w\}$ cannot generally hold, and this does not contradict Proposition 4.1 since any $A \in L(Y,\mathbb{R})$ cannot be invertible except for the trivial case where $Y = \mathbb{R}$ too.

In finite-dimensional image space, according to Remark 3, Theorem 4.2 becomes the following.

COROLLARY 4.4. *Let X, Y be locally convex, $F \in \Gamma(X,Y)$, $g_i \in \Gamma(Y)$ $(i = 1 \cdots r)$ be Y_+-nondecreasing and consider the following hypotheses:*

- (MR) *$(r-1)$ g_is are finite and continuous at a point of domain of the other one.*
- (AB) *The g_is l.s.c, $\mathbb{R}_+[\Delta Y^r - \prod_{i=1}^r \operatorname{dom} g_i]$ closed vector subspace of Y^r.*
- $(MR)_2$ *All the g_is are finite and continuous at some point of $\operatorname{Im} F$.*
- $(AB)_2$ *The g_is l.s.c, F sequentially Y_+-l.s.c, $\mathbb{R}_+[\prod_{i=1}^r \operatorname{dom} g_i - \operatorname{Im} F]$ closed vector subspace.*

If one of conditions $(MR)_2$, $\big[(AB)_2$ and (MR), with X, Y Fréchet$\big]$ or $\big[(AB)_2$ and (AB), with X, Y Fréchet$\big]$ is satisfied, then, $\forall \bar{x} \in X$,

$$\partial^p(g_1 \circ F, \ldots, g_r \circ F)(\bar{x}) = \bigsqcup_{\substack{\lambda_i \in \partial g_i(F(\bar{x})) \\ i=1\cdots r}} \partial^p(\lambda_1 \circ F, \ldots, \lambda_r \circ F)(\bar{x}).$$

If, in addition to condition $(MR)_2$ or $\big[(AB)_2$ and (MR), with X, Y Fréchet$\big]$, every one or none of the g_is is subdifferentiable at $F(\bar{x})$, then

$$\partial^w(g_1 \circ F, \ldots, g_r \circ F)(\bar{x}) = \bigsqcup_{\substack{\lambda_i \in \partial g_i(F(\bar{x})) \\ i=1\cdots r}} \partial^w(\lambda_1 \circ F, \ldots, \lambda_r \circ F)(\bar{x}).$$

4.3. Addition/composition. In what follows, we establish a formula concerning the σ-subdifferential of the sum of a vector mapping with a vector composite.

THEOREM 4.3. *Let $F : X \to Y \sqcup \{+\infty\}$, $G : X \to Z \sqcup \{+\infty\}$, $H : Z \to Y \sqcup \{+\infty\}$, and $\sigma \in \{p,w\}$. Then, $\forall \bar{x} \in X$,*

$$\partial^\sigma(F + H \circ G)(\bar{x}) \supseteq \bigsqcup_{A \in \partial^s H(G(\bar{x}))} \partial^\sigma(F + A \circ G)(\bar{x}).$$

Assume now that H is (Z_+, Y_+)-nondecreasing and σ-regular subdifferentiable at $G(\bar{x})$, Y_+ is pointed as $\sigma = p$, and one of the two following qualification conditions is satisfied:

$$(MR)_3 \quad \begin{cases} F \in \Gamma(X,Y),\ G \in \Gamma(X,Z),\ H \in \Gamma(Z,Y),\ X \text{ and } Z \text{ locally convex}, \\ H \text{ is finite and continuous at some point of } G(\operatorname{dom} F \sqcap \operatorname{dom} G). \end{cases}$$

$$(AB)_3 \quad \begin{cases} F \in \Gamma_0(X,Y),\ G \in \Gamma_0(X,Z),\ H \in \Gamma_0(Z,Y),\ X \text{ and } Z \text{ Fréchet spaces}, \\ \mathbb{R}_+[\operatorname{dom} H - G(\operatorname{dom} F \sqcap \operatorname{dom} G)] \text{ is a closed vector subspace of } Z. \end{cases}$$

Then,

$$\partial^\sigma(F + H \circ G)(\bar{x}) = \bigsqcup_{A \in \partial^s H(G(\bar{x}))} \partial^\sigma(F + A \circ G)(\bar{x}).$$

The proof is obtained identically to Theorem 4.2 using, instead of Lemma 4.1, the following result due to Combari, Laghdir, and Thibault [11].

LEMMA 4.2. *Let $f : X \to \mathbb{R} \sqcup \{+\infty\}$, $G : X \to Z \sqcup \{+\infty\}$, and $h : Z \to \mathbb{R} \sqcup \{+\infty\}$ be a functional Z_+-nondecreasing such that one of the two following conditions holds:*

$$(MR)_3 \quad \begin{cases} f \in \Gamma(X),\ G \in \Gamma(X,Z),\ h \in \Gamma(Z),\ X \text{ and } Z \text{ locally convex}, \\ h \text{ is finite and continuous at some point of } G(\operatorname{dom} f \sqcap \operatorname{dom} G). \end{cases}$$

$$(AB)_3 \quad \begin{cases} f \in \Gamma_0(X),\ G \in \Gamma_0(X,Z),\ h \in \Gamma_0(Z),\ X \text{ and } Z \text{ Fréchet spaces}, \\ \mathbb{R}_+[\operatorname{dom} h - G(\operatorname{dom} f \sqcap \operatorname{dom} G)] \text{ is a closed vector subspace of } Z. \end{cases}$$

Then, $\forall \bar{x} \in X$,

$$\partial(f + h \circ G)(\bar{x}) = \bigsqcup_{\mu \in \partial h(G(\bar{x}))} \partial(f + \mu \circ G)(\bar{x}).$$

Though popular, the (MR)- and (AB)-type conditions are by their simplicity and feasibility, there exist other weaker interior point conditions ensuring the previous formula, as the following Azé- [4] type condition recently established in [13]:

$$\begin{cases} f \in \Gamma(X),\ G \in \Gamma(X,Z),\ h \in \Gamma(Z),\ X \text{ and } Z \text{ locally convex}, \\ \text{for each neighborhood } V \text{ of } 0 \text{ in } X,\ \text{there exists } \alpha \in \mathbb{R} \text{ such that} \\ 0 \in \operatorname{int}_E[\operatorname{Lev}(h;\alpha) - G(\operatorname{Lev}(f;\alpha) \sqcap \operatorname{dom} G \sqcap \alpha V)], \end{cases}$$

where int_E stands for the topological interior in $E := \operatorname{Vect}[\operatorname{dom} h - G(\operatorname{dom} f \sqcap \operatorname{dom} G)]$, $\operatorname{Vect}(S)$ means vector space generated by a set S, and the symbol Lev refers to $\mathbb{R}_+$-Lev. Weaker again in a sense, another class of qualification conditions, called of closedness-type, is introduced recently by Boţ, Grad, and Wanka [9, 10]. Main among them is

$$\begin{cases} f \in \Gamma_0(X),\ h \in \Gamma_0(Z),\ X \text{ and } Z \text{ separated locally convex}, \\ G \in \Gamma(X,Z) \text{ star } Z_+\text{-l.s.c},\ Z_+ \text{ closed},\ [G(\operatorname{dom} f) + Z_+] \sqcap \operatorname{dom} h \neq \emptyset, \\ \bigsqcup_{\mu \in \operatorname{dom} h^*}(0, h^*(\mu)) + \operatorname{Epi}(f + \mu \circ G)^* \ \text{ is closed}, \end{cases}$$

where h^* stands for the Fenchel conjugate of h (idem for $(f + \mu \circ G)^*$), Epi refers to $\mathbb{R}_+$-Epi, and star Z_+-l.s.c means l.s.c of $\mu \circ G$ for each $\mu \in Z_+^*$. Star and sequential Z_+-l.s.c was relaxed in [10] and [12], respectively, to Z_+-Epi-closedness (Z_+-Epi G closed),

in another variant of the above condition and in the (AB) condition of Lemma 4.2, respectively. The interior point conditions turn out to be globally easily extensible to vector maps, while the closedness ones seem well to require a separate study.

We end this section by the following corollary.

COROLLARY 4.5. *Assume, in addition to the assumptions of Theorem* 4.3*, that F or G is finite and continuous at a point of the effective domain of the other one.*

(1) *If F is σ-regular subdifferentiable at $\bar{x}$, then*

$$\partial^\sigma(F + H \circ G)(\bar{x}) = \partial^s F(\bar{x}) + \bigsqcup_{A \in \partial^s H(G(\bar{x}))} \partial^\sigma(A \circ G)(\bar{x}).$$

(2) *If G is regular subdifferentiable at $\bar{x}$, then*

$$\partial^\sigma(F + H \circ G)(\bar{x}) = \partial^\sigma F(\bar{x}) + \bigsqcup_{A \in \partial^s H(G(\bar{x}))} \partial^s(A \circ G)(\bar{x}).$$

Proof. According to Theorem 4.3, it remains to apply the sum calculus rule for $\partial^\sigma(F + A \circ G)(\bar{x})$ knowing that $A \in L_+(Z, Y)$ and $A \circ G \in \Gamma(X, Y)$ (see the proof of Theorem 4.2). Indeed, Theorem 4.1 directly applies for $F + A \circ G$, taking into account for assertion (2) the following property.

LEMMA 4.3. *With G regular subdifferentiable at $\bar{x}$ and $A \in L_+(Z, Y)$, $A \circ G$ is also regular subdifferentiable at $\bar{x}$.*

Proof of Lemma 4.3. By the regular subdifferentiability of G at $\bar{x}$, we have that $\partial(\lambda \circ A \circ G)(\bar{x}) = \lambda \circ A \circ \partial^s G(\bar{x})$ for any $\lambda \in Y_+^*$ and $A \in L_+(Z, Y)$ since $\lambda \circ A \in Z_+^*$. Also, we easily prove that $A \circ \partial^s G(\bar{x}) \subseteq \partial^s(A \circ G)(\bar{x})$. So $\partial(\lambda \circ A \circ G)(\bar{x}) \subseteq \lambda \circ \partial^s(A \circ G)(\bar{x})$. The reverse inclusion being trivial, the lemma is therefore proved. □

5. Applications to constrained VOPs.

5.1. Vector σ-efficiency conditions for convex VOPs. One main objective in this subsection is to realize the extension of the indicator function technique to the vector case in a way similar to the scalar case, so that necessary and sufficient efficiency conditions under vector forms for a constrained convex VOP may easily be derived from the subdifferential formulas previously obtained. First, the constrained problem

$$\text{VOP:} \qquad \operatorname*{Min}_{x \in S} F(x)$$

may effectively be penalized by the vector indicator function defined for the nonempty set $S \subseteq X$ by

$$\begin{aligned} \delta_S^v : X &\to Y \sqcup \{+\infty\} \\ x &\mapsto \delta_S^v(x) = \begin{cases} 0 & \text{if } x \in S, \\ +\infty & \text{else,} \end{cases} \end{aligned}$$

so that it becomes equivalent to the unconstrained vector problem

$$\operatorname*{Min}_{x \in X} F(x) + \delta_S^v(x)$$

in the following senses.

LEMMA 5.1. *Let $F : X \to Y \sqcup \{+\infty\}$. Then, for $\sigma \in \{s, p, e, w\}$,*
(1) $E_\sigma(F, S) = E_\sigma(F + \delta^v_S, X)$.
(2) $\mathrm{MIN}_\sigma F(S) = \mathrm{MIN}_\sigma(F + \delta^v_S)(X)$.

Proof. Case $\sigma = s$ is easily proved like the scalar case and cases $\sigma \in \{e, p\}$ like $\sigma = w$. Thus, it is enough to show the lemma for $\sigma = w$.

(1) Let $\bar{x} \in E_w(F, S)$, then by definition, $\bar{x} \in S \sqcap \mathrm{dom}\, F = \mathrm{dom}(F + \delta^v_S)$. If $\bar{x} \notin E_w(F + \delta^v_S, X)$, then it would exist $x \in X$ such that $F(x) + \delta^v_S(x) <_{Y_+} F(\bar{x})$, which would imply $x \in S \sqcap \mathrm{dom}\, F$ contradicting $\bar{x} \in E_w(F, S)$. Conversely, let $\bar{x} \in E_w(F + \delta^v_S, X)$, then $\bar{x} \in S \sqcap \mathrm{dom}\, F$. If we suppose that $\bar{x} \notin E_w(F, S)$, then it would exist $x \in S$ such that $F(x) <_{Y_+} F(\bar{x})$, that is, $F(x) + \delta^v_S(x) <_{Y_+} F(\bar{x}) + \delta^v_S(\bar{x})$ contradicting $\bar{x} \in E_w(F + \delta^v_S, X)$. Assertion (1) is therefore proved.

(2) By definition, $\mathrm{MIN}_\sigma F(S) = F(E_\sigma(F, S))$. As $E_w(F, S) \subseteq S$, with (1), it follows that $F(E_w(F, S)) = (F + \delta^v_S)(E_w(F, S)) = (F + \delta^v_S)(E_w(F + \delta^v_S, X))$. ∎

The vector indicator function appears to possess properties like the scalar one. Define for that the normal cone at $\bar{x} \in S$ in a vector sense:

$$N^v_S(\bar{x}) = \{A \in L(X, Y) :\ \forall x \in S,\ A(x - \bar{x}) \leq_{Y_+} 0\}.$$

LEMMA 5.2. *$\delta^v_S \in \Gamma_0(X, Y)$ if S is convex closed. Furthermore, $\forall \bar{x} \in S$,*

$$\partial^s \delta^v_S(\bar{x}) = N^v_S(\bar{x}).$$

In particular, $\delta^v_{-Z_+} \in \Gamma_0(Z, Y)$ if Z_+ is closed and is always (Z_+, Y_+)-nondecreasing. Moreover, if Y_+ is pointed, then, $\forall \bar{z} \in -Z_+$,

$$\partial^s \delta^v_{-Z_+}(\bar{z}) = \{A \in L_+(Z, Y) :\ A(\bar{z}) = 0\}.$$

Proof. The s-subdifferential expression is immediate from the very definitions.

The properness of δ^v_S is immediate, since $\mathrm{dom}\, \delta^v_S = S \neq \emptyset$. Its Y_+-convexity follows easily from the convexity of S and Y_+, more precisely, from its epigraph given by

$$Y_+\text{-Epi}\ \delta^v_S = \{(x, y) \in X \times Y :\ \delta^v_S(x) \leq_{Y_+} y\} = S \times Y_+.$$

While comes the sequential Y_+-l.s.c from the closedness of S. Indeed, let $\bar{x} \in X$, $y \leq_{Y_+} \delta^v_S(\bar{x})$, and $(x^n) \to \bar{x}$ be given. Does $(y^n) \to y$ exist such that $y^n \leq_{Y_+} \delta^v_S(x^n)$ $(\forall n)$? Two cases are distinguished: $\bar{x} \in S$ and $\bar{x} \notin S$. If $\bar{x} \in S$, then it suffices to take $y^n = y$ for all n. If $\bar{x} \in X \setminus S$ which is an open set, then $(x^n) \subset X \setminus S$ for all n large enough. We therefore can take $y^n = y$ for all the n large enough and $= 0$ for the other n. This proves well the sequential Y_+-l.s.c of δ^v_S.

Let us show now that $\delta^v_{-Z_+}$ is (Z_+, Y_+)-nondecreasing. Being given $z_1 \leq_{Z_+} z_2$, do we have $\delta^v_{-Z_+}(z_1) \leq_{Y_+} \delta^v_{-Z_+}(z_2)$? This amounts to showing that if $z_2 \in -Z_+$, then $z_1 \in -Z_+$. But, $z_1 = z_1 - z_2 + z_2 \in -Z_+ - Z_+ \subseteq -Z_+$.

Let us express now its s-subdifferential. One already has $\partial^s \delta^v_{-Z_+}(\bar{z}) = N^v_{-Z_+}(\bar{z})$. By definition, $A \in N^v_{-Z_+}(\bar{z})$ is equivalent to $A \in L(Z, Y)$ and $A(z - \bar{z}) \leq_{Y_+} 0\ \forall\ z \in -Z_+$. Because $\bar{z} \in -Z_+$, by taking successively $z = 0$ and $z = 2\bar{z}$, we get $A(\bar{z}) = 0$. Consequently, $A(z) \geq_{Y_+} 0\ \forall\ z \in Z_+$, i.e., $A \in L_+(Z, Y)$. The reverse inclusion is immediate, since $A(z - \bar{z}) = A(z) \leq_{Y_+} 0\ \forall\ z \in -Z_+$. ∎

The vector indicator function reveals mostly to satisfy the following important property.

LEMMA 5.3. *δ_S^v is regular (resp. p-regular) subdifferentiable on S if* $\operatorname{int} Y_+ \neq \emptyset$ *(resp. if $Y_+^p \neq \emptyset$). In fact, for $\sigma = w$ (resp. $\sigma = p$), $\forall \bar{x} \in S$,*

$$N_S(\bar{x}) = \lambda \circ N_S^v(\bar{x}) \qquad \forall \lambda \in Y_+^\sigma,$$

where $N_S(\bar{x}) = \{x^* \in X : \forall x \in S, \langle x^*, x - \bar{x}\rangle \leq 0\}$ is the usual normal cone to S at $\bar{x}$.

Proof. Let us show first the relation between the vector normal cone and the ordinary one. Let $A \in N_S^v(\bar{x})$ and $\lambda \in Y_+^\sigma$, then $\langle \lambda \circ A, x - \bar{x}\rangle = \langle \lambda, A(x - \bar{x})\rangle \leq 0$ $(\forall x \in S)$. Thus, $\lambda \circ N_S^v(\bar{x}) \subseteq N_S(\bar{x})$. Conversely, let $x^* \in N_S(\bar{x})$ and $\lambda \in Y_+^\sigma$, then we define, exactly as in (3.7), $A_\lambda : X \to Y$ by $A_\lambda(x) = \langle x^*, x\rangle\ y_\lambda$ for some $y_\lambda \in \operatorname{int} Y_+$ if $\sigma = w$ and $y_\lambda \in Y_+ \setminus l(Y_+)$ if $\sigma = p$ so that $A_\lambda \in L(X, Y)$ and $\lambda \circ A_\lambda = x^*$. On the other hand, $A_\lambda(x - \bar{x}) = \langle x^*, x - \bar{x}\rangle y_\lambda \in -Y_+$ $(\forall x \in S)$, i.e., $A_\lambda \in N_S^v(\bar{x})$. Consequently, $N_S(\bar{x}) \subseteq \lambda \circ N_S^v(\bar{x})$.

Let us prove now the regular (resp. p-regular) subdifferentiability of δ_S^v over S. Indeed, by considering the scalar indicator function $\delta_S : X \to \mathbb{R} \sqcup \{+\infty\}$ defined by $\delta_S(x) = 0$ if $x \in S$ and $+\infty$ otherwise, we observe that $\lambda \circ \delta_S^v = \delta_S\ \forall\ \lambda \in Y_+^* \setminus \{0\}$. Hence, for all $\bar{x} \in S$ and $\lambda \in Y_+^\sigma$,

$$\partial(\lambda \circ \delta_S^v)(\bar{x}) = \partial\delta_S(\bar{x}) = N_S(\bar{x}) = \lambda \circ N_S^v(\bar{x}) = \lambda \circ \partial^s \delta_S^v(\bar{x}).$$

This proves the σ-regular subdifferentiability following the hypotheses depending on $\sigma \in \{p, w\}$. But δ_S^v being s-subdifferentiable on S, the above equality remains valid for $\lambda = 0$. This means (taking $\sigma = w$) that δ_S^v is regular subdifferentiable on S. ∎

We are now ready to state the vector σ-efficiency conditions in terms of the Lagrange–Kuhn–Tucker (operator) multiplier and the (vector) normal cone for the following general convex vector mathematical programming problem:

$$\text{VOP:} \qquad \text{Min } F(x) \quad \begin{cases} G(x) \in -Z_+, \\ x \in C, \end{cases}$$

where feasible set $S = \{x \in X : G(x) \in -Z_+\} \sqcap C$, with C a closed convex set.

The Lagrangian map associated to this VOP may be defined as vector function $\mathcal{L} : X \times L_+(Z, Y) \to Y \sqcup \{+\infty\}$ given by

$$\mathcal{L}(x, \Lambda) = F(x) + \Lambda \circ G(x).$$

THEOREM 5.1. *Let $F : X \to Y \sqcup \{+\infty\}$ and $G : X \to Z \sqcup \{+\infty\}$ be such that one of the two following qualification conditions is satisfied:*

$$(MR)_4 \quad \begin{cases} F \in \Gamma(X, Y),\ G \in \Gamma(X, Z),\ X \text{ and } Z \text{ locally convex}, \\ \delta^v_{-Z_+} \text{ is finite and continuous at a point of } G(C \sqcap \operatorname{dom} F \sqcap \operatorname{dom} G). \end{cases}$$

$$(AB)_4 \quad \begin{cases} F \in \Gamma_0(X, Y),\ G \in \Gamma_0(X, Z),\ Z_+ \text{ closed},\ X \text{ and } Z \text{ Fréchet spaces}, \\ \mathbb{R}_+[Z_+ + G(C \sqcap \operatorname{dom} F \sqcap \operatorname{dom} G)] \text{ is a closed vector subspace of } Z. \end{cases}$$

Then, with Y_+ pointed, for $\sigma \in \{p, w\}$,

$$\bar{x} \in E_\sigma(F, S) \iff \begin{cases} G(\bar{x}) \in -Z_+, \\ \exists \bar{\Lambda} \in L_+(Z, Y) :\ \bar{\Lambda}(G(\bar{x})) = 0, \\ 0 \in \partial^\sigma(F + \bar{\Lambda} \circ G + \delta_C^v)(\bar{x}),\ \textit{i.e.,}\ \bar{x} \in E_\sigma(\mathcal{L}(., \bar{\Lambda}), C). \end{cases}$$

Proof. Taking into account that $\delta^v_S = \delta^v_{-Z_+} \circ G + \delta^v_C$, by Lemma 5.1 and relation (2.2), we can write that

$$\bar{x} \text{ is } \sigma\text{-efficient for VOP} \iff 0 \in \partial^\sigma(F + \delta^v_{-Z_+} \circ G + \delta^v_C)(\bar{x}).$$

Next we easily verify that all the hypotheses of Theorem 4.3 are satisfied with $F + \delta^v_C$, G, and $\delta^v_{-Z_+}$ underlining that $F + \delta^v_C$ is well sequentially Y_+-l.s.c as a sum of such maps (see [11]). With Lemmas 5.2 and 5.3 and that $\bar{x} \in S \sqcap \operatorname{dom} F$, we thus obtain that

$$\partial^\sigma(F + \delta^v_C + \delta^v_{-Z_+} \circ G)(\bar{x}) = \bigsqcup_{\substack{\bar{\Lambda} \in L_+(Z,Y) \\ \bar{\Lambda}(G(\bar{x}))=0}} \partial^\sigma(F + \delta^v_C + \bar{\Lambda} \circ G)(\bar{x}).$$

Significance $\bar{x} \in E_\sigma(\mathcal{L}(.,\bar{\Lambda}), C)$ is a consequence of (2.2) and Lemma 5.1. ∎

Remark 6. The condition in $(MR)_4$ is not other than the Slater-type condition "$\exists a \in C \sqcap \operatorname{dom} F \sqcap \operatorname{dom} G : G(a) \in -\operatorname{int} Z_+$," which, in turn, is a particular case of the condition in $(AB)_4$. Indeed, it easily implies that $\mathbb{R}_+[Z_+ + G(C \sqcap \operatorname{dom} F \sqcap \operatorname{dom} G)] = Z$ (see [11]). However, it is, in most cases, easier to check when $\operatorname{int} Z_+ \neq \emptyset$. Theorem 5.1 has been obtained under the Slater condition by several authors using different methods; see, e.g., [17] for the (Benson) proper concept and [1, 27] for the weak one.

COROLLARY 5.1. *If in addition to the assumptions of Theorem* 5.1*, F and G are finite and continuous at some point of C, F (and resp. G) is σ-regular (resp. regular) subdifferentiable at $\bar{x}$ and $\sigma \in \{p, w\}$, then*

$$\bar{x} \in E_\sigma(F,S) \iff \begin{cases} G(\bar{x}) \in -Z_+, \\ \exists \bar{\Lambda} \in L_+(Z,Y) : \ \bar{\Lambda}(G(\bar{x})) = 0, \\ 0 \in \partial^\sigma F(\bar{x}) + \bar{\Lambda} \circ \partial^s G(\bar{x}) + N^v_C(\bar{x}). \end{cases}$$

Proof. It suffices to apply to Theorem 5.1, Theorem 4.1 two times successively followed by Proposition 4.1, and finally Theorem 3.3 and Lemma 5.2 to obtain

$$\begin{aligned} 0 \in \partial^\sigma(F + \bar{\Lambda} \circ G + \delta^v_C)(\bar{x}) &= \partial^\sigma(\bar{\Lambda} \circ G)(\bar{x}) + \partial^s F(\bar{x}) + \partial^s \delta^v_C(\bar{x}) \\ &= \bar{\Lambda} \circ \partial^s G(\bar{x}) + Z_\sigma(X,Y) + \partial^s F(\bar{x}) + \partial^s \delta^v_C(\bar{x}) \\ &= \partial^\sigma F(\bar{x}) + \bar{\Lambda} \circ \partial^s G(\bar{x}) + N^v_C(\bar{x}). \end{aligned}$$ ∎

Remark 7. If space Y (resp. Z) is finite-dimensional endowed with the natural order, then the σ-regular (resp. regular) subdifferentiability assumption on F (resp. on G) in Corollary 5.1 may be omitted, since condition (MR) of Remark 3 is satisfied, and, as $\partial^\sigma(F + \bar{\Lambda} \circ G + \delta^v_C)(\bar{x}) \neq \emptyset$, mappings F and G are sensed to be s-subdifferentiable at $\bar{x}$, i.e., their components are subdifferentiable at this point.

5.2. Gap between weakly or properly and strongly efficient sets. We end up the paper with another application to VOPs. We already presented the gap between the efficient and optimal sets associated to unconstrained VOPs. In what follows, similar results are also derived for constrained VOPs via combinations of several basic results.

THEOREM 5.2. *Let S be convex closed in X locally convex, $F \in \Gamma(X,Y)$ be σ-regular subdifferentiable at $\bar{x}$, $\sigma \in \{p, w\}$, Y_+ be pointed as $\sigma = p$, and one of the three following conditions be satisfied:*

$(MR)_5$ $\left\{ \begin{array}{l} F \text{ is finite and continuous at a point of } S, \text{ or } \operatorname{dom} F \sqcap \operatorname{int} S \neq \emptyset, \text{ or,} \end{array} \right.$

$(AB)_5$ $\left\{ \begin{array}{l} F \text{ sequentially } Y_+\text{-l.s.c}, \ X \text{ Fréchet space}, \\ \mathbb{R}_+[S - \operatorname{dom} F] \quad \text{is a closed vector subspace of } X. \end{array} \right.$

Then,

$$\bar{x} \in E_\sigma(F,S) \quad \Longleftrightarrow \quad \exists A \sim_\sigma 0 \ : \ \bar{x} \in E_s(F-A,S).$$

Proof. Let us show the nontrivial direct implication. According to Lemma 5.1, Theorem 4.1, Theorem 3.3, and finally, relation (3.5), we have that

$$\begin{aligned}\bar{x} \in E_\sigma(F,S) = E_\sigma(F+\delta_S^v,X) &\Leftrightarrow 0 \in \partial^\sigma(F+\delta_S^v)(\bar{x}) = \partial^s F(\bar{x}) + Z_\sigma(X,Y) + \partial^s \delta_S^v(\bar{x}) \\ &\Leftrightarrow \exists A \sim_\sigma 0 : \ A \in \partial^s F(\bar{x}) + \partial^s \delta_S^v(\bar{x}) \subseteq \partial^s(F+\delta_S^v)(\bar{x}) \\ &\Rightarrow \exists A \sim_\sigma 0 : \ \bar{x} \in E_s(F-A+\delta_S^v,X) = E_s(F-A,S).\end{aligned}$$

The reverse implication follows straightforwardly by the definition of the s-efficient set and the σ-zerolike operator one, and, by scalarization, Theorem 3.1. ∎

Remark 8. For the same reasons as in Remark 7, if in Theorem 5.2, the range space is finite-dimensional endowed with the natural order and the first condition in $(MR)_5$ is fulfilled, then the σ-regular subdifferentiability assumption on F may be omitted. Since, for $\sigma = p$, F becomes p-regular subdifferentiable everywhere in its domain (see Remark 3), the result of this theorem then may rather be written in this case as

$$E_p(F,S) = \bigsqcup_{A \sim_p 0} E_s(F-A,S).$$

Conclusion. All the well-known results, in scalar case, coincide with our results. The unique additional assumption, namely σ-regular subdifferentiability, obviously holds in this case: $\partial(\alpha f)(x) = \alpha \partial f(x) \ \forall \ \alpha \in \mathbb{R}_+^\sigma = \mathbb{R}_+ \setminus \{0\} = \operatorname{int} \mathbb{R}_+$.

Further research avenues may interest some other subdifferential operations such as maximum of functions, marginal function, infimal convolution, etc., and the applications that may engender. Also, a particular attention to the Pareto concept ($\sigma = e$) and/or the strong ordinary notion ($\sigma = s$), which certainly will contribute more in multicriteria optimization, may be the subject of future investigations.

Acknowledgments. The authors are grateful to the reviewers for their valuable reports and their judicious remarks and suggestions.

CONVEXITY IN SEMIALGEBRAIC GEOMETRY AND POLYNOMIAL OPTIMIZATION*

JEAN B. LASSERRE†

Abstract. We review several (and provide new) results on the theory of moments, sums of squares, and basic semialgebraic sets when convexity is present. In particular, we show that, under convexity, the hierarchy of semidefinite relaxations for polynomial optimization simplifies and has finite convergence, a highly desirable feature as convex problems are in principle easier to solve. In addition, if a basic semialgebraic set $\mathbf{K}$ is convex but its defining polynomials are not, we provide two algebraic *certificates* of convexity which can be checked numerically. The second is simpler and holds if a sufficient (and almost necessary) condition is satisfied; it also provides a new condition for $\mathbf{K}$ to have semidefinite representation. For this we use (and extend) some of the recent results from the author and Helton and Nie [*Math. Program.*, to appear]. Finally, we show that, when restricting to a certain class of convex polynomials, the celebrated Jensen's inequality in convex analysis can be extended to linear functionals that are not necessarily probability measures.

Key words. convex polynomials, sums of squares, basic semialgebraic sets, convex sets, Jensen inequality, semidefinite programming

1. Introduction.

Motivation. This paper is a contribution to the new emerging field of convex semialgebraic geometry, and its purpose is threefold: First, we show that the moment approach for global polynomial optimization proposed in [13], and based on semidefinite programming (SDP), is consistent as it simplifies and/or has better convergence properties when solving convex problems. In other words, the SDP moment approach somehow "recognizes" convexity, a highly desirable feature for a general purpose method because, in principle, convex problems should be easier to solve.

We next review some recent results (and provide a new one) on the representation of convex basic semialgebraic sets by linear matrix inequalities which show how convexity permits to derive relatively simple and *explicit* semidefinite representations. In doing so, we also provide a *certificate* of convexity for $\mathbf{K}$ when its defining polynomials are not convex.

Finally, we consider the important Jensen's inequality in convex analysis. When restricting its application to a class of convex polynomials, we provide an extension to a class of linear functionals that are not necessarily probability measures.

To do so, we use (and sometimes extend) some recent results of the author [16, 17] and Helton and Nie [6]. We hope to convince the reader that convex semialgebraic geometry is, indeed, a very specific subarea of real algebraic geometry which should deserve more attention from both the optimization and real algebraic geometry research communities.

Background. I. Relatively recent results in the theory of moments and its dual theory of positive polynomials have been proved useful in polynomial optimization as they provide the basis of a specific convergent numerical approximation scheme. Namely, one can define a hierarchy of semidefinite relaxations (in short SDP relaxations) of the original optimization problem whose associated monotone sequence of optimal values converges to the global optimum. For a more detailed account of this approach, the interested reader is referred to, e.g., Lasserre [13, 14], Parrilo [21], Schweighofer [29], and the many references therein.

Remarkably, practice seems to reveal that convergence is often fast and even finite. However, the size of the SDP relaxations grows rapidly with the rank in the hierarchy; typically the rth SDP relaxation in the hierarchy has $O(n^{2r})$ variables and semidefinite matrices of $O(n^r)$ sizes (where n is the number of variables in the original problem). On the other hand, it is well-known that a large class of convex optimization problems can be solved efficiently; see, e.g., Ben-Tal and Nemirovski [1]. Therefore, as the SDP-based moment approach is dedicated to solving difficult nonconvex (most of the time NP-hard) problems, it should have the highly desirable feature to somehow *recognize* "easy" problems like convex ones. That is, when applied to such easy problems, it should show some significant improvement or a particular nice behavior not necessarily valid in the general case. Notice that this is *not* the case of the moment approach based on linear programming (LP) described in [14, 15] for which only asymptotic (and *not* finite) convergence occurs in general (and especially for convex problems), a rather annoying feature. However, for SDP relaxations, some results of [17] already show that, indeed, convexity helps as one provides specialized representation results for convex polynomials that are nonnegative on a basic semialgebraic set.

II. Next, in view of the potential of semidefinite programming techniques, an important issue is the characterization of convex sets that are semidefinite representable (in short called SDr). An SDr set $\mathbf{K} \subset \mathbb{R}^n$ is the projection of a set defined by linear matrix inequalities. That is,

$$\mathbf{K} := \left\{ x \in \mathbb{R}^n \,:\, \exists\, y \in \mathbb{R}^s \text{ such that (s.t.)} \quad A_0 + \sum_{i=1}^{n} x_i\, A_i + \sum_{j=1}^{s} y_j\, B_j \succeq 0 \right\}$$

for some real symmetric matrices (A_i, B_j) (and where $A \succeq 0$ stands for A is positive semidefinite). For more details, the interested reader is referred to Ben Tal and Nemirovski [1], Lewis, Parrilo, and Ramana [19], and Parrilo [22] and more recently, Chua and Tuncel [2], Helton and Nie [6, 7], Henrion [8], and Lasserre [16]. For compact basic semialgebraic sets

$$\mathbf{K} := \{x \in \mathbb{R}^n \,:\, g_j(x) \geq 0, \quad j = 1, \ldots, m\}, \tag{1.1}$$

recent results of Helton and Nie [6, 7] and the author [16] provide sufficient conditions on the defining polynomials $(g_j) \subset \mathbb{R}[X]$ for the convex hull $\mathrm{co}\,(\mathbf{K})$ ($\equiv \mathbf{K}$ if $\mathbf{K}$ is convex) to be SDr. Again, an interesting issue is to analyze whether convexity of $\mathbf{K}$ (with or without concavity of the defining polynomials (g_j)) provides some additional insights and/or simplifications. Another interesting issue is how to detect whether a basic semialgebraic set $\mathbf{K}$ is convex or, equivalently, how to obtain an algebraic *certificate* of convexity of $\mathbf{K}$ from its defining polynomials (g_j). By certificate we mean a mathematical statement that obviously implies convexity of $\mathbf{K}$, can be checked numerically, and does not require infinitely many tests. So far, and to the best of our knowledge, such a certificate does not exist.

III. The celebrated Jensen's inequality is an important result in convex analysis which states that $E_\mu(f(x)) \geq f(E_\mu(x))$ for a convex function $f : \mathbb{R}^n \to \mathbb{R}$ and a probability measure μ with $E_\mu(x) < \infty$. A third goal of this paper is to analyze whether, when restricted to a certain class of convex polynomials, Jensen's inequality can be extended to a class of linear functionals larger than the class of probability measures.

Contribution. Concerning issue I, we first recall two previous results proved in [17]: (a) the cone of convex sums of squares (SOS) is dense (for the l_1-norm of coefficients) in the cone of nonnegative convex polynomials, and (b) a convex positivstellensatz holds for convex polynomials nonnegative on $\mathbf{K}$ (a specialization of Putinar's positivstellensatz). We then analyze the role of convexity for the polynomial optimization problem

$$\mathbf{P}: \quad f^* = \min_x \{ f(x) : x \in \mathbf{K} \}, \tag{1.2}$$

with $\mathbf{K}$ as in (1.1), and show that, indeed, convexity helps and makes the SDP relaxations more efficient. In particular, when $\mathbf{K}$ is convex and Slater's condition[1] holds, by using some recent results of Helton and Nie [6], we show the following.

(i) If the polynomials f and $(-g_j)$ are all convex and $\nabla^2 f$ is positive definite (and so f is strictly convex) on $\mathbf{K}$, then the hierarchy of SDP relaxations has *finite* convergence.

(ii) If f and $(-g_j)$ are all SOS-convex (i.e., their Hessian is an SOS matrix polynomial), then $\mathbf{P}$ reduces to solving a *single* SDP whose index in the hierarchy is readily available.

Concerning II, under certain sufficient conditions on the (g_j) (typically some second-order positive curvature conditions) Helton and Nie [6, 7] have proved that $\mathrm{co}\,(\mathbf{K})$ (or $\mathbf{K}$ if convex) has a semidefinite representation that uses the Schmüdgen or Putinar SOS representation of polynomials positive on $\mathbf{K}$; see [6, 17]. Yet, in general its dimension depends on an unknown degree parameter in the Schmüdgen (or Putinar) SOS representation. Our contribution is to provide a new sufficient condition for the existence of a semidefinite representation when $\mathbf{K}$ is compact with nonempty interior and its boundary satisfies some nondegeneracy assumption. It translates the geometric property of convexity of $\mathbf{K}$ into an SOS Putinar representation of some appropriate polynomial obtained from each g_j. When satisfied, this representation provides an algebraic certificate of convexity for $\mathbf{K}$ and it is almost necessary in the sense that it always holds true when relaxed by an arbitrary $\epsilon > 0$. It also contains as special cases Helton and Nie [6] sufficient conditions of SOS convexity or strict convexity on $\partial\mathbf{K}$ of the $-g_j$'s and leads to an explicit semidefinite representation of $\mathbf{K}$. We also provide a more general algebraic certificate based on Stengle's positivstellensatz, but more complex and heavy to implement and so not very practical. In practice, both certificates are obtained by solving a semidefinite program. Therefore, because of unavoidable numerical inaccuracies, the certificate is valid only up to machine precision.

Concerning III, we prove that, when restricting its application to the subclass of SOS-convex polynomials, Jensen's inequality can be extended to all linear functionals $L_{\mathbf{y}}$ (with $L_{\mathbf{y}}(1) = 1$) in the dual cone of SOS polynomials and, hence, *not* necessarily probability measures.

Some of the results already obtained in [6, 16] and in the present paper strongly suggest that the class of SOS-convex polynomials introduced in Helton and Nie [6] is particularly nice and should deserve more attention.

[1] Slater's condition holds for $\mathbf{K}$ in (1.1) if for some $x_0 \in \mathbf{K}$, $g_j(x_0) > 0$, $j = 1, \ldots, m$.

2. Notation, definitions, and preliminary results. Let $\mathbb{R}[X]$ be the ring of real polynomials in the variables $X = (X_1, \ldots, X_n)$, and let $\Sigma^2[X] \subset \mathbb{R}[X]$ be the subset of SOS polynomials. Let $\mathbb{R}[X]_d \subset \mathbb{R}[X]$ be the set of polynomials of degree at most d, which forms a vector space of dimension $s(d) = \binom{n+d}{d}$. If $f \in \mathbb{R}[X]_d$, write $f(X) = \sum_{\alpha \in \mathbb{N}^n} f_\alpha X^\alpha$ in the usual canonical basis (X^α), and denote by $\mathbf{f} = (f_\alpha) \in \mathbb{R}^{s(d)}$ its vector of coefficients. Also, write $\|f\|_1 \,(= \|\mathbf{f}\|_1 := \sum_\alpha |f_\alpha|)$ the l_1-norm of f. Finally, denote by $\Sigma^2[X]_d \subset \Sigma^2[X]$ the subset of SOS polynomials of degree at most $2d$.

We use the notation X for the variable of a polynomial $X \mapsto f(X)$ and x when x is a point of $\mathbb{R}^n$ as, for instance, in $\{x \in \mathbb{R}^n \,:\, f(x) \geq 0\}$.

Moment matrix. With $\mathbf{y} = (y_\alpha)$ being a sequence indexed in the canonical basis (X^α) of $\mathbb{R}[X]$, let $L_{\mathbf{y}} : \mathbb{R}[X] \to \mathbb{R}$ be the linear functional

$$f \quad \left(= \sum_\alpha f_\alpha \, X^\alpha \right) \quad \mapsto \quad L_{\mathbf{y}}(f) \,=\, \sum_\alpha f_\alpha \, y_\alpha,$$

and let $M_d(\mathbf{y})$ be the symmetric matrix with rows and columns indexed in the canonical basis (X^α) and defined by

$$M_d(\mathbf{y})(\alpha, \beta) \,:=\, L_{\mathbf{y}}\left(X^{\alpha+\beta}\right) \,=\, y_{\alpha+\beta}, \quad \alpha, \beta \in \mathbb{N}^n_d,$$

with $\mathbb{N}^n_d := \{\alpha \in \mathbb{N}^n \,:\, |\alpha| \,(= \sum_i \alpha_i) \leq d\}$.

Localizing matrix. Similarly, with $\mathbf{y} = (y_\alpha)$ and $g \in \mathbb{R}[X]$ written

$$X \mapsto g(X) \,=\, \sum_{\gamma \in \mathbb{N}^n} g_\gamma \, X^\gamma,$$

let $M_d(g\,\mathbf{y})$ be the symmetric matrix with rows and columns indexed in the canonical basis (X^α) and defined by

$$M_d(g\,\mathbf{y})(\alpha, \beta) \,:=\, L_{\mathbf{y}}\left(g(X)\, X^{\alpha+\beta}\right) \,=\, \sum_\gamma g_\gamma \, y_{\alpha+\beta+\gamma}$$

for every $\alpha, \beta \in \mathbb{N}^n_d$.

Putinar positivstellensatz. Let $Q(g) \subset \mathbb{R}[X]$ be the quadratic module generated by the polynomials $(g_j) \subset \mathbb{R}[X]$, that is,

$$Q(g) \,:=\, \left\{ \sigma_0 + \sum_{j=1}^m \sigma_j \, g_j \,:\quad (\sigma_j) \subset \Sigma^2[X] \right\}. \tag{2.1}$$

ASSUMPTION 2.1. *$\mathbf{K} \subset \mathbb{R}^n$ is a compact basic semialgebraic set defined as in* (1.1)*, and the quadratic polynomial $X \mapsto M - \|X\|^2$ belongs to $Q(g)$.*

Assumption 2.1 is not very restrictive. For instance, it holds if every g_j is affine (i.e., $\mathbf{K}$ is a convex polytope) or if the level set $\{x \,:\, g_j(x) \geq 0\}$ is compact for some $j \in \{1, \ldots, m\}$. In addition, if $M - \|x\| \geq 0$ for all $x \in \mathbf{K}$, then it suffices to add the redundant quadratic constraint $M^2 - \|x\|^2 \geq 0$ to the definition (1.1) of $\mathbf{K}$ and Assumption 2.1 will hold true.

THEOREM 2.2 (Putinar's positivstellensatz [24]). *Let Assumption* 2.1 *hold. If* $f \in \mathbb{R}[X]$ *is (strictly) positive on* $\mathbf{K}$*, then* $f \in Q(g)$*. That is,*

$$f = \sigma_0 + \sum_{j=1}^{m} \sigma_j\, g_j \tag{2.2}$$

for some SOS polynomials $(\sigma_j) \subset \Sigma^2[X]$.

2.1. A hierarchy of semidefinite relaxations (SDP relaxations). Let $\mathbf{P}$ be the optimization problem (1.2) with $\mathbf{K}$ as in (1.1), and let $r_j = \lceil (\deg g_j)/2 \rceil$, $j = 1, \ldots, m$. With $f \in \mathbb{R}[X]$ and $2r \geq \max[\deg f,\ \max_j 2r_j]$, consider the hierarchy of semidefinite relaxations $(\mathbf{Q}_r)$ defined by

$$\mathbf{Q}_r : \quad \begin{cases} \inf\limits_{\mathbf{y}} & L_{\mathbf{y}}(f) \\ \text{s.t.} & M_r(\mathbf{y}) \succeq 0, \\ & M_{r-r_j}(g_j\, \mathbf{y}) \succeq 0, \qquad j = 1, \ldots, m, \\ & y_0 = 1, \end{cases} \tag{2.3}$$

with optimal value denoted by $\inf \mathbf{Q}_r$. One says that $\mathbf{Q}_r$ is solvable if it has an optimal solution (in which case one writes $\inf \mathbf{Q}_r = \min \mathbf{Q}_r$). The dual of $\mathbf{Q}_r$ reads

$$\mathbf{Q}_r^* : \quad \begin{cases} \sup & \lambda \\ \text{s.t.} & f - \lambda = \sigma_0 + \sum\limits_{j=1}^{m} \sigma_j\, g_j, \\ & \sigma_j \in \Sigma^2[X], \quad j = 0, 1, \ldots, m, \\ & \deg \sigma_0,\ \deg \sigma_j + \deg g_j \leq 2r, \quad j = 1, \ldots, m, \end{cases} \tag{2.4}$$

with optimal value denoted by $\sup \mathbf{Q}_r^*$ (or $\max \mathbf{Q}_r^*$ if the sup is attained).

By weak duality $\sup \mathbf{Q}_r^* \leq \inf \mathbf{Q}_r$ for every $r \in \mathbb{N}$ and under Assumption 2.1, $\inf \mathbf{Q}_r \uparrow f^*$ as $r \to \infty$. For a more detailed account see, e.g., [13].

2.2. Convexity and SOS convexity. We first briefly recall basic facts on a multivariate convex function. If $C \subseteq \mathbb{R}^n$ is a nonempty convex set, a function $f : C \to \mathbb{R}$ is convex on C if and only if

$$f(\lambda x + (1-\lambda)y) \leq \lambda f(x) + (1-\lambda) f(y) \qquad \forall\, \lambda \in (0,1),\ x, y \in C.$$

Similarly, f is strictly convex on C if and only if the above inequality is strict for every $x, y \in C$, $x \neq y$, and all $\lambda \in (0,1)$.

If $C \subseteq \mathbb{R}^n$ is an open convex set and f is twice differentiable on C, then f is convex on C if and only if its Hessian $\nabla^2 f$ is positive semidefinite on C (denoted $\nabla^2 f \succeq 0$ on C). Finally, if $\nabla^2 f$ is positive definite on C (denoted $\nabla^2 f \succ 0$ on C), then f is strictly convex on C.

SOS convexity. Helton and Nie [6] have introduced the following interesting subclass of convex polynomials, called SOS-convex polynomials.

DEFINITION 2.3 (Helton and Nie [6]). *A polynomial* $f \in \mathbb{R}[X]_{2d}$ *is said to be SOS-convex if* $\nabla^2 f$ *is SOS; that is,* $\nabla^2 f = LL^T$ *for some real matrix polynomial* $L \in \mathbb{R}[X]^{n \times s}$ *(for some* $s \in \mathbb{N}$*).*

As noted in [6], an important feature of SOS convexity is that it can be checked numerically by solving an SDP. They have also proved the following important property.

LEMMA 2.4 (Helton and Nie [6, Lemma 7]). *If a symmetric matrix polynomial $P \in \mathbb{R}[X]^{r\times r}$ is SOS, then, for any $u \in \mathbb{R}^n$, the double integral*

$$X \mapsto \quad F(X,u) := \int_0^1 \int_0^t P(u + s(X-u))\, ds\, dt$$

is also a symmetric SOS matrix polynomial in $\mathbb{R}[X]^{r\times r}$.

See also the following.

LEMMA 2.5 (Helton and Nie [6, Lemma 8]). *For a polynomial $f \in \mathbb{R}[X]$ and every $x, u \in \mathbb{R}^n$,*

$$f(x) = f(u) + \nabla f(u)^T(x-u) + (x-u)^T \underbrace{\int_0^1 \int_0^t \nabla^2 f(u + s(x-u))dsdt}_{F(x,u)} (x-u).$$

So if f is SOS-convex and $f(u) = 0, \nabla f(u) = 0$, then f is an SOS polynomial.

2.3. An extension of Jensen's inequality. Recall that if μ is a probability measure on $\mathbb{R}^n$ with $E_\mu(x) < \infty$, Jensen's inequality states that if $f \in L_1(\mu)$ and f is convex, then

$$E_\mu(f(x)) \;\geq\; f(E_\mu(x)),$$

a very useful property in many applications.

We now provide an extension of Jensen's inequality when one restricts its application to the class of SOS-convex polynomials. Namely, we may consider the linear functionals $L_{\mathbf{y}} : \mathbb{R}[X]_{2d} \to \mathbb{R}$ in the dual cone of $\Sigma^2[X]_d$, that is, vectors $\mathbf{y} = (y_\alpha)$ such that $M_d(\mathbf{y}) \succeq 0$ and $y_0 = L_{\mathbf{y}}(1) = 1$; hence, $\mathbf{y}$ is *not* necessarily the (truncated) moment sequence of some probability measure μ. Crucial in the proof is Lemma 2.4 of Helton and Nie [6].

THEOREM 2.6. *Let $f \in \mathbb{R}[X]_{2d}$ be SOS-convex, and let $\mathbf{y} = (y_\alpha)_{\alpha\in\mathbb{N}^n_{2d}}$ satisfy $y_0 = 1$ and $M_d(\mathbf{y}) \succeq 0$. Then*

$$L_{\mathbf{y}}(f(X)) \;\geq\; f(L_{\mathbf{y}}(X)), \tag{2.5}$$

where $L_{\mathbf{y}}(X) = (L_{\mathbf{y}}(X_1), \ldots, L_{\mathbf{y}}(X_n))$.

Proof. Let $z \in \mathbb{R}^n$ be fixed and arbitrary, and consider the polynomial $X \mapsto f(X) - f(z)$. Then

$$f(X) - f(z) \;=\; \langle \nabla f(z), X - z\rangle + \langle (X-z), F(X)(X-z)\rangle, \tag{2.6}$$

with $F : \mathbb{R}^n \to \mathbb{R}[X]^{n\times n}$ being the matrix polynomial

$$X \mapsto \quad F(X) := \int_0^1 \int_0^t \nabla^2 f(z + s(X-z))\, ds\, dt.$$

As f is SOS-convex, by Lemma 2.4, F is an SOS matrix polynomial and so the polynomial $X \mapsto \Delta(X) := \langle (X-z), F(X)(X-z)\rangle$ is SOS, i.e., $\Delta \in \Sigma^2[X]$. Then applying $L_{\mathbf{y}}$ to the polynomial $X \mapsto f(X) - f(z)$ and using (2.6) yields (recall that $y_0 = 1$)

$$\begin{aligned} L_{\mathbf{y}}(f(X)) - f(z) &= \langle \nabla f(z), L_{\mathbf{y}}(X) - z\rangle + L_{\mathbf{y}}(\Delta(X)) \\ &\geq \langle \nabla f(z), L_{\mathbf{y}}(X) - z\rangle \quad [\text{because } L_{\mathbf{y}}(\Delta(X)) \geq 0]. \end{aligned}$$

As $z \in \mathbb{R}^n$ was arbitrary, taking $z := L_{\mathbf{y}}(X)\,(= (L_{\mathbf{y}}(X_1), \ldots, L_{\mathbf{y}}(X_n)))$ yields the desired result. □

As a consequence we also get the following corollary.

COROLLARY 2.7. *Let f be a convex univariate polynomial, $g \in \mathbb{R}[X]$ (and so $f \circ g \in \mathbb{R}[X]$). Let $d := \lceil (\deg f \circ g)/2 \rceil$, and let $\mathbf{y} = (y_\alpha)_{\alpha \in \mathbb{N}^n_{2d}}$ be such that $y_0 = 1$ and $M_d(\mathbf{y}) \succeq 0$. Then*

$$L_{\mathbf{y}}[\, f(g(X))\,] \;\geq\; f(L_{\mathbf{y}}[\, g(X)\,]). \tag{2.7}$$

Proof. Again, let $z \in \mathbb{R}$ be fixed and arbitrary, and consider the univariate polynomial $Y \mapsto f(Y) - f(z)$ so that (2.6) holds. That is,

$$f(Y) - f(z) \;=\; f'(z)\,(Y - z) + F(Y)(Y - z)^2,$$

with $F : \mathbb{R} \to \mathbb{R}[Y]$ being the univariate polynomial

$$Y \mapsto \quad F(Y) \;:=\; \int_0^1 \int_0^t f''(z + s(Y - z))\, ds\, dt.$$

As f is convex, $f'' \geq 0$, and so the univariate polynomial $Y \mapsto F(Y)(Y - z)^2$ is nonnegative and, being univariate, is SOS. Therefore, with $Y := g(X)$,

$$f(g(X)) - f(z) \;=\; f'(z)\,(g(X) - z) + F(g(X))(g(X) - z)^2,$$

and so

$$\begin{aligned} L_{\mathbf{y}}[\, f(g(X))] - f(z) &= f'(z)\,(L_{\mathbf{y}}[\, g(X)\,] - z) + L_{\mathbf{y}}\left[\, F(g(X))\,(g(X) - z)^2\,\right] \\ &\geq f'(z)(L_{\mathbf{y}}[\, g(X)\,] - z), \end{aligned}$$

and taking $z := L_{\mathbf{y}}[g(X)]$ yields the desired result. □

Hence, the class of SOS-convex polynomials has the very interesting property of extending Jensen's inequality to some linear functionals that are not necessarily coming from a probability measure.

3. Semidefinite relaxations in the convex case.

3.1. A convex positivstellensatz. Let $\mathbf{K}$ be as in (1.1), and define $Q_c(g) \subset \mathbb{R}[X]$ to be the set

$$Q_c(g) \;:=\; \left\{ \sigma_0 + \sum_{j=1}^m \lambda_j\, g_j \;:\quad \lambda \in \mathbb{R}^m_+ ;\; \sigma_0 \in \Sigma^2[X],\; \sigma_0 \text{ convex} \right\} \subset Q(g). \tag{3.1}$$

The set $Q_c(g)$ is a specialization of $Q(g)$ in (2.1) to the convex case, in that the weights asociated with the g_j's are nonnegative scalars, i.e., SOS polynomials of degree 0, and the SOS polynomial σ_0 is convex. In particular, every $f \in Q_c(g)$ is nonnegative on $\mathbf{K}$. Let $\mathcal{F}_{\mathbf{K}} \subset \mathbb{R}[X]$ be the convex cone of convex polynomials nonnegative on $\mathbf{K}$.

THEOREM 3.1 (Lasserre [17]). *Let $\mathbf{K}$ be as in* (1.1), *Slater's condition hold, and g_j be concave for every $j = 1, \ldots, m$.*

Then, with $Q_c(g)$ as in (3.1), *the set $Q_c(g) \cap \mathcal{F}_{\mathbf{K}}$ is dense in $\mathcal{F}_{\mathbf{K}}$ for the l_1-norm $\|\cdot\|_1$. In particular, if $\mathbf{K} = \mathbb{R}^n$ (so that $\mathcal{F}_{\mathbb{R}^n} =: \mathcal{F}$ is now the set of nonnegative convex polynomials), then $\Sigma^2[X] \cap \mathcal{F}$ is dense in $\mathcal{F}$.*

Theorem 3.1 states that if f is convex and nonnegative on $\mathbf{K}$ (including the case $\mathbf{K} \equiv \mathbb{R}^n$), then one may approximate f by a sequence $\{f_{\epsilon r}\} \subset Q_c(g) \cap \mathcal{F}_{\mathbf{K}}$ with $\|f - f_{\epsilon r}\|_1 \to 0$ as $\epsilon \to 0$ (and $r \to \infty$). For instance, with $r_0 := \lfloor (\deg f)/2 \rfloor + 1$,

$$
\begin{aligned}
&X \mapsto f_{\epsilon r}(X) := f + \epsilon(\theta_{r_0}(X) + \theta_r(X)), \quad \text{with} \\
&X \mapsto \theta_r(X) := 1 + \sum_{k=1}^{r} \sum_{i=1}^{n} \frac{X_i^{2k}}{k!}, \qquad r \geq r_\epsilon,
\end{aligned} \tag{3.2}
$$

for some r_ϵ; see Lasserre [17] for details. Observe that Theorem 3.1 provides f with a *certificate* of nonnegativity on $\mathbf{K}$. Indeed, let $x \in \mathbf{K}$ be fixed arbitrary. Then as $f_{\epsilon r} \in Q_c(g)$ one has $f_{\epsilon r}(x) \geq 0$. Letting $\epsilon \downarrow 0$ yields $0 \leq \lim_{\epsilon \to 0} f_{\epsilon r}(x) = f(x)$. As $x \in \mathbf{K}$ was arbitrary, $f \geq 0$ on $\mathbf{K}$.

Theorem 3.1 is a convex (weak) version of Theorem 2.2 (Putinar's positivstellensatz) where one replaces the quadratic module $Q(g)$ with its subset $Q_c(g)$. We call it a *weak* version of Theorem 2.2 because it invokes a density result (i.e., $f_{\epsilon r} \in Q_c(g)$, whereas f might not be an element of $Q_c(g)$). Notice that f is allowed to be nonnegative (instead of strictly positive) on $\mathbf{K}$ and $\mathbf{K}$ need *not* be compact; recall that extending Theorem 2.2 to noncompact basic semialgebraic sets $\mathbf{K}$ and to polynomials f nonnegative on $\mathbf{K}$ is hopeless in general; see Scheiderer [26].

COROLLARY 3.2. *Let* $\mathbf{K}$ *be as in* (1.1), $f \in \mathbb{R}[X]$ *with* $f^* := \min_x\{f(x) : x \in \mathbf{K}\}$, *and let* $d := \max[\lceil (\deg f)/2 \rceil, \max_j \lceil (\deg g_j)/2 \rceil]$. *Consider the simplified SDP relaxation*

$$
\widehat{\mathbf{Q}}: \quad \begin{cases} \inf\limits_{\mathbf{y}} & L_{\mathbf{y}}(f) \\ s.t. & M_d(\mathbf{y}) \succeq 0, \\ & L_{\mathbf{y}}(g_j) \geq 0, \qquad j = 1, \ldots, m, \\ & y_0 = 1 \end{cases} \tag{3.3}
$$

and its dual

$$
\widehat{\mathbf{Q}}^*: \quad \begin{cases} \sup\limits_{\gamma, \sigma_0, \lambda} & \gamma \\ s.t. & f - \gamma = \sigma_0 + \sum\limits_{j=1}^{m} \lambda_j g_j, \\ & \sigma_0 \in \Sigma^2[X]_d;\ \lambda_j \geq 0, \quad j = 1, \ldots, m. \end{cases} \tag{3.4}
$$

(a) *If* $f - f^* \in Q_c(g)$, *then the SDP relaxation* $\widehat{\mathbf{Q}}$ *and its dual* $\widehat{\mathbf{Q}}^*$ *are exact.*

(b) *If* $f, -g_j \in \mathbb{R}[X]$ *are convex,* $j = 1, \ldots, m$, *and if* $\mathbf{y}$ *is an optimal solution of* $\widehat{\mathbf{Q}}$ *which satisfies*

$$
\operatorname{rank} M_d(\mathbf{y}) = \operatorname{rank} M_{d-1}(\mathbf{y}), \tag{3.5}
$$

then $\widehat{\mathbf{Q}}$ *is exact and* $x^* := (L_{\mathbf{y}}(X_i)) \in \mathbf{K}$ *is a (global) minimizer of* f *on* $\mathbf{K}$.

Proof. (a) If $f - f^* \in Q_c(g)$, i.e., if $f - f^* = \sigma_0 + \sum_{j=1}^m \lambda_j g_j$, with $\sigma_0 \in \Sigma^2[X]_d$ and $\lambda \in \mathbb{R}^m_+$, the triplet (f^*, σ_0, λ) is a feasible solution of $\widehat{\mathbf{Q}}^*$ with value f^*. Therefore, as $\sup \widehat{\mathbf{Q}}^* \leq \inf \widehat{\mathbf{Q}} \leq f^*$, the SDP relaxation $\widehat{\mathbf{Q}}$ and its dual $\widehat{\mathbf{Q}}^*$ are exact. In fact, (f^*, σ_0, λ) is an optimal solution of $\widehat{\mathbf{Q}}^*$.

(b) If $\mathbf{y}$ satisfies the rank condition (3.5), then by the *flat extension* theorem of Curto and Fialkow [4], $\mathbf{y}$ is the (truncated) moment sequence of an atomic probability measure μ on $\mathbb{R}^n$, say, $\mu = \sum_{k=1}^s \lambda_k \delta_{x(k)}$ with $s = \operatorname{rank} M_d(\mathbf{y})$, $0 < \lambda_k \leq 1$,

$\sum_k \lambda_k = 1$, and $\delta_{x(k)}$ being the Dirac measure at $x(k) \in \mathbb{R}^n$, $k = 1, \ldots, s$. Let $x^* := \sum_k \lambda_k x(k) = (L_{\mathbf{y}}(X_i)) \in \mathbb{R}^n$. Then $f^* \geq L_{\mathbf{y}}(f)$ and by convexity of f, $L_{\mathbf{y}}(f) = \sum_k \lambda_k f(x(k)) \geq f(\sum_k \lambda_k x(k)) = f(x^*)$. Similarly, by convexity of $-g_j$, $0 \leq L_{\mathbf{y}}(g_j) = \sum_k \lambda_k g_j(x(k)) \leq g_j(\sum_k \lambda_k x(k)) = g_j(x^*)$, $j = 1, \ldots, m$. Therefore, $x^* \in \mathbf{K}$ and as $f(x^*) \leq f^*$, x^* is a global minimizer of f on $\mathbf{K}$. □

Notice that $\mathbf{K}$ in Corollary 3.2 need not be compact. Also, Corollary 3.2(b) has practical value because in general one does not know whether $f - f^* \in Q_c(g)$ (despite that, in the convex case, $f - f^* \in \mathcal{F}_{\mathbf{K}}$ and $Q_c(g) \cap \mathcal{F}_{\mathbf{K}}$ is dense in $\mathcal{F}_{\mathbf{K}}$). However, one may still solve $\widehat{\mathbf{Q}}$ and check whether the rank condition (3.5) is satisfied. If, in solving $\widehat{\mathbf{Q}}_r$, the rank condition (3.5) is not satisfied, then other sufficient conditions can be exploited as we next see.

3.2. The SOS-convex case. Part (a) of the following result is already contained in Lasserre [17, Corollary 2.5].

THEOREM 3.3. *Let $\mathbf{K}$ be as in* (1.1) *and Slater's condition hold. Let $f \in \mathbb{R}[X]$ be such that $f^* := \inf_x\{f(x) : x \in \mathbf{K}\} = f(x^*)$ for some $x^* \in \mathbf{K}$. If f is SOS-convex and $-g_j$ is SOS-convex for every $j = 1, \ldots, m$, then*

(a) $f - f^* \in Q_c(g)$;

(b) *the simplified SDP relaxation $\widehat{\mathbf{Q}}$ in* (3.3) *and its dual* (3.4) *are exact and solvable. If $\mathbf{y}$ is an optimal solution of $\widehat{\mathbf{Q}}$, then $x^* := (L_{\mathbf{y}}(X_i)) \in \mathbf{K}$ is a global minimizer of f on $\mathbf{K}$.*

Proof. (a) is proved in [17, Corollary 2.5]. (b) That $\widehat{\mathbf{Q}}$ is exact follows from (a) and Corollary 3.2(a). Hence, it is solvable (e.g., take $\mathbf{y}$ to be the moment sequence associated with the Dirac measure at a global minimizer $x^* \in \mathbf{K}$). So let $\mathbf{y}$ be an optimal solution of $\widehat{\mathbf{Q}}$, hence, with $f^* = L_{\mathbf{y}}(f)$. As $-g_j$ is SOS-convex for every j, then by Theorem 2.6, $0 \leq L_{\mathbf{y}}(g_j) \leq g_j(x^*)$ with $x^* := (L_{\mathbf{y}}(X_i))$, and so $x^* \in \mathbf{K}$. Similarly, as f is SOS-convex, we also have $f^* = L_{\mathbf{y}}(f) \geq f(x^*)$ which proves that $f(x^*) = f^*$ and x^* is a global minimizer of f on $\mathbf{K}$. Finally, as by (a) $f - f^* \in Q_c(g)$, then $\widehat{\mathbf{Q}}^*$ is exact and solvable. □

(Again notice that $\mathbf{K}$ in Theorem 3.3 need not be compact.) So the class of SOS-convex polynomials is particularly interesting. Not only Jensen's inequality can be extended to some linear functionals that are not coming from a probability measure but also one may also solve SOS-convex optimization problems $\mathbf{P}$ in (1.2) (i.e., with f and $\mathbf{K}$ defined with SOS-convex polynomials) by solving the single semidefinite program (3.3).

Notice that a self-concordant[2] logarithmic barrier function exists for (3.3), whereas the logarithmic barrier function with barrier parameter μ,

$$x \mapsto \phi_\mu(x) := \mu\, f(x) - \sum_{j=1}^{m} \ln\,(g_j(x)), \tag{3.6}$$

associated with $\mathbf{P}$, is not self-concordant in general. Therefore, despite the fact that (3.3) involves additional variables (a lifting), solving (3.3) via an interior point method might be more efficient than solving $\mathbf{P}$ by using the logarithmic barrier function (3.6) with no lifting. In addition, all SOS-convex polynomials nonnegative on $\mathbf{K}$, and which attain their minimum on $\mathbf{K}$ belong to $Q_c(g)$, a very specific version of Putinar positivstellensatz (as f is only nonnegative and $\mathbf{K}$ need not be compact).

[2]The self-concordance property introduced in [20] is fundamental in the design and efficiency of interior point methods for convex programming.

3.3. The strictly convex case. If f or some of the $-g_j$'s are not SOS-convex but $\nabla^2 f \succ 0$ (so that f is strictly convex) and $-g_j$ is convex for every $j = 1, \ldots, m$, then, inspired by a nice argument from Helton and Nie [6] for the existence of a semidefinite representation of convex sets, one obtains the following result.

THEOREM 3.4. *Let* $\mathbf{K}$ *be as in* (1.1)*, and let Assumption* 2.1 *and Slater's condition hold. Assume that* $f, -g_j \in \mathbb{R}[X]$ *are convex,* $j = 1, \ldots, m$*, with* $\nabla^2 f \succ 0$ *on* $\mathbf{K}$.

Then the hierarchy of SDP relaxations defined in (2.3) *has finite convergence. That is,* $f^* = \sup \mathbf{Q}_r^* = \inf \mathbf{Q}_r$ *for some index* r*. In addition,* $\mathbf{Q}_r$ *and* $\mathbf{Q}_r^*$ *are solvable so that* $f^* = \max \mathbf{Q}^* = \min \mathbf{Q}_r$.

Proof. Let $x^* \in \mathbf{K}$ be a global minimizer (i.e., $f^* = f(x^*)$). As Slater's condition holds, there exists a vector of Karush–Kuhn–Tucker (KKT) multipliers $\lambda \in \mathbb{R}^m_+$ such that the (convex) Lagrangian $L_f \in \mathbb{R}[X]$ defined by

$$X \mapsto L_f(X) \,:=\, f(X) - f^* - \sum_{j=1}^m \lambda_j \, g_j(X) \tag{3.7}$$

has a global minimum at $x^* \in \mathbf{K}$, i.e., $\nabla L_f(x^*) = 0$. In addition, $\lambda_j g_j(x^*) = 0$ for every $j = 1, \ldots, m$ and $L_f(x^*) = 0$. Then, by Lemma 2.5,

$$L_f(X) \,=\, \langle (X - x^*), F(X, x^*)(X - x^*) \rangle$$

with

$$F(X, x^*) \,:=\, \left(\int_0^1 \int_0^t \nabla^2 L_f(x^* + s(X - x^*)) \, ds \, dt \right).$$

Next, let I_n be the $n \times n$ identity matrix. As $\nabla^2 f \succ 0$ on $\mathbf{K}$, continuity of the (strictly positive) smallest eigenvalue of $\nabla^2 f$ and compactness of $\mathbf{K}$ yield that $\nabla^2 f \succeq \delta I_n$ on $\mathbf{K}$ for some $\delta > 0$. Next, as $-g_j$ is convex for every j and in view of the definition (3.7) of L_f, $\nabla^2 L_f \succeq \nabla^2 f \succeq \delta I_n$ on $\mathbf{K}$. Hence, for every $\xi \in \mathbb{R}^n$, $\xi^T F(x, x^*) \xi \geq \delta \int_0^1 \int_0^t \xi^T \xi \, ds dt = \frac{\delta}{2} \xi^T \xi$, and so $F(x, x^*) \succeq \frac{\delta}{2} I_n$ for every $x \in \mathbf{K}$. Therefore, by the matrix polynomial version of Putinar positivstellensatz,

$$F(X, x^*) \,=\, F_0(X) + \sum_{j=1}^m F_j(X) \, g_j(X)$$

for some real SOS matrix polynomials $X \mapsto F_j(X) = L_j(X) L_j(X)^T$ (for some appppropriate $L_j \in \mathbb{R}[X]^{n \times p_j}$), $j = 0, \ldots, m$. See Helton and Nie [6], Kojima and Maramatsu [10], and Hol and Scherer [11]. But then

$$X \mapsto \langle (X - x^*), F_j(X, x^*)(X - x^*) \rangle \,=\, \sigma_j(X) \in \Sigma^2[X], \qquad j = 0, \ldots, m,$$

and so

$$\begin{aligned} f(X) - f^* &= L_f(X) + \sum_{j=1}^m \lambda_j g_j(X) \\ &= \sigma_0(X) + \sum_{j=1}^m (\lambda_j + \sigma_j(X)) \, g_j(X). \end{aligned}$$

Let $2s$ be the maximum degree of the SOS polynomials (σ_j). Then $(f^*, \{\sigma_j + \lambda_j\})$ is a feasible solution of the SDP relaxation $\mathbf{Q}_r^*$ in (2.4) with $r := s + \max_j r_j$. Therefore, as

$\sup \mathbf{Q}_r^* \leq \inf \mathbf{Q}_r \leq f^*$, the SDP relaxations $\mathbf{Q}_r$ and $\mathbf{Q}_r^*$ are exact, finite convergence occurs, and $\mathbf{Q}_r^*$ is solvable. But this also implies that $\mathbf{Q}_r$ is solvable (take $\mathbf{y}$ to be the moment sequence of the Dirac measure δ_{x^*} at any global minimizer $x^* \in \mathbf{K}$). □

When compared to Theorem 3.3 for the SOS-convex case, in the strictly convex case the simplified SDP relaxation $\widehat{\mathbf{Q}}$ in (3.3) is not guaranteed to be exact. However, finite convergence still occurs for the SDP relaxations $(\mathbf{Q}_r)$ in (2.3).

Remark 3.5. It is worth emphasizing that in general the hierarchy of LP relaxations (as opposed to SDP relaxations) defined in [15] and based on Krivine's representation [12, 30] and Handelman [**?**] for polynomials positive on $\mathbf{K}$ *cannot* have finite convergence, especially in the convex case! For more details, the interested reader is referred to [14, 15]. Therefore and despite the fact that LP software packages can solve LP problems of very large size, using LP relaxations does not seem a good idea even for solving a convex polynomial optimization problem.

4. Convexity and semidefinite representation of convex sets. We now consider the semidefinite representation of convex sets. First, recall the following result.

THEOREM 4.1 (Lasserre [16]). *Let* $\mathbf{K}$ *in* (1.1) *be compact with* g_j *concave,* $j = 1, \ldots, m$, *and assume that Slater's condition holds. If the Lagrangian polynomial* L_f *in* (3.7) *associated with every linear polynomial* $f \in \mathbb{R}[X]$ *is SOS, then, with* $d := \max_j \lceil (\deg g_j)/2 \rceil$, *the set*

$$\Omega := \left\{ (x, \mathbf{y}) \in \mathbb{R}^n \times \mathbb{R}^{s(2d)} \; : \; \begin{cases} M_d(\mathbf{y}) \succeq 0, \\ L_{\mathbf{y}}(g_j) \geq 0, \quad j = 1, \ldots, m, \\ L_{\mathbf{y}}(X_i) = x_i, \quad i = 1, \ldots, n, \\ y_0 = 1 \end{cases} \right\} \tag{4.1}$$

is a semidefinite representation of $\mathbf{K}$.

Next, Helton and Nie [6, 7] have provided several interesting second-order positive curvature (sufficient and necessary) conditions on the defining polynomials (g_j) for $\mathbf{K}$ (or its convex hull co $(\mathbf{K})$) to be an SDr set. In particular (recall that $r_j = \lceil (\deg g_j)/2 \rceil$ for every $j = 1, \ldots, m$), see the following theorem.

THEOREM 4.2 (Helton and Nie [6]). *Let* $\mathbf{K}$ *in* (1.1) *be convex and Asssumption* 2.1 *hold, and assume that Slater's condition holds and* g_j *is concave on* $\mathbf{K}$, $j = 1, \ldots, m$.

(a) *If* $-g_j$ *is SOS-convex for every* $j = 1, \ldots, m$, *then, for every linear* $f \in \mathbb{R}[X]$, *the associated Lagrangian* L_f (3.7) *is SOS and the set* Ω *in* (4.1) *is a semidefinite representation of* $\mathbf{K}$.

(b) *If every* $-g_j$ *is either SOS-convex or satisfies* $-\nabla^2 g_i \succ 0$ *on* $\mathbf{K} \cap \{x \; : \; g_j(x) = 0\}$, *then there exists* $r \in \mathbb{N}$ *such that the set*

$$\Omega := \left\{ (x, \mathbf{y}) \in \mathbb{R}^n \times \mathbb{R}^{s(2r)} \; : \; \begin{cases} M_r(\mathbf{y}) \succeq 0 \\ M_{r-r_j}(g_j \mathbf{y}) \succeq 0, \quad j = 1, \ldots, m \\ L_{\mathbf{y}}(X_i) = x_i, \quad i = 1, \ldots, n \\ y_0 = 1 \end{cases} \right\} \tag{4.2}$$

is a semidefinite representation of $\mathbf{K}$.

See [6, Theorems 6 and 9]. This follows from the fact that the Hessian $\nabla^2 L_f$ associated with a linear $f \in \mathbb{R}[X]$ has a Putinar representation in terms of SOS matrix polynomials and with degree of the weights bounded uniformly in f. In principle, the degree parameter d in Theorem 4.2(b) may be computed by solving a hierarchy of semidefinite programs. Some other (more technical) weaker second-order positive

curvature sufficient conditions (merely for the existence of a semidefinite representation) are also provided in [6, 7], but the semidefinite representation is not explicit anymore in terms of the defining polynomials (g_j). Notice that if $\mathbf{K}$ is compact but Assumption 2.1 does not hold, then one still obtains a semidefinite representation for $\mathbf{K}$ but more complicated as it is now based on Schmüdgen's representation [27] instead of Putinar's representation; see [6, Theorem 5].

We next provide a sufficient condition in the case where $\mathbf{K}$ is convex but its defining polynomials $(-g_j)$ are *not* necessarily convex. Among its distinguishing features, it is checkable numerically, contains Theorem 4.2 as a special case, and leads to the explicit semidefinite representation (4.2) of $\mathbf{K}$.

4.1. Algebraic certificate of convexity. We first present the following characterization of convexity when $\mathbf{K}$ is closed, satisfies a nondegeneracy assumption on its boundary, and Slater's condition holds.

LEMMA 4.3. *Let $\mathbf{K}$ be as in* (1.1) *(hence, closed), let Slater's condition hold, and assume that for every $j = 1, \ldots, m$, $\nabla g_j(y) \neq 0$ if $y \in \mathbf{K}$ and $g_j(y) = 0$. Then $\mathbf{K}$ is convex if and only if for every $j = 1, \ldots, m$,*

$$\langle \nabla g_j(y), x - y \rangle \geq 0 \qquad \forall x \in \mathbf{K} \text{ and } \forall\, y \in \mathbf{K} \text{ with } g_j(y) = 0. \tag{4.3}$$

Proof. The *only if* part is obvious. Indeed, if $\langle \nabla g_j(y), x - y \rangle < 0$ for some $x \in \mathbf{K}$ and $y \in \mathbf{K}$ with $g_j(y) = 0$, then there is some $\overline{t} > 0$ such that $g_j(y + t(x - y)) < 0$ for all $t \in (0, \overline{t})$, and so the point $x' := tx + (1 - t)y$ does not belong to $\mathbf{K}$, which in turn implies that $\mathbf{K}$ is not convex.

For the *if* part, (4.3) implies that at, every point of the boundary, there exists a supporting hyperplane for $\mathbf{K}$. As $\mathbf{K}$ is closed with nonempty interior, the result follows from [28, Theorem 1.3.3][3]. □

The nondegeneracy assumption is crucial as demonstrated in the following simple example kindly provided by an anonymous referee.

Example 4.1. Consider the nonconvex set $\mathbf{K} \subset \mathbb{R}^2$ defined by

$$\mathbf{K} := \left\{ x \in \mathbb{R}^2 \,:\, \left(1 - x_1^2 + x_2^2\right)^3 \geq 0,\ 10 - x_1^2 - x_2^2 \geq 0 \right\}.$$

Then it is straightforward to see that (4.3) is satisfied. This is because ∇g_1 vanishes on the piece of boundary determined by $g_1(x) = 0$.

Next, using the above characterization (4.3), we provide an algebraic certificate of convexity.

COROLLARY 4.4 (algebraic certificate of convexity). *Let $\mathbf{K}$ be as in* (1.1), *let Slater's condition hold, and assume that for every $j = 1, \ldots, m$, $\nabla g_j(y) \neq 0$ if $y \in \mathbf{K}$ and $g_j(y) = 0$. Then $\mathbf{K}$ is convex if and only if for every $j = 1, \ldots, m$,*

$$h_j(X, Y)\langle \nabla g_j(Y), X - Y \rangle \,=\, \langle \nabla g_j(Y), X - Y \rangle^{2l} + \theta_j(X, Y) + \varphi_j(X, Y) g_j(Y) \tag{4.4}$$

for some integer $l \in \mathbb{N}$, some polynomial $\varphi_j \in \mathbb{R}[X, Y]$, and some polynomials h_j, θ_j in the preordering[4] of $\mathbb{R}[X, Y]$ generated by the family of polynomials $(g_k(X), g_p(Y))$, $k, p \in \{1, \ldots, m\}$, $p \neq j$.

Proof. By Lemma 4.3, $\mathbf{K}$ is convex if and only if, for every $j = 1, \ldots, m$, the polynomial $(X, Y) \mapsto \langle \nabla g_j(Y), X - Y \rangle$ is nonnegative on the set Ω_j defined by

$$\Omega_j \,:=\, \{(x, y) \in \mathbf{K} \times \mathbf{K} \,:\, g_j(y) = 0\}. \tag{4.5}$$

[3] The author is grateful to L. Tuncel for providing us with [28].

[4] The preordering of $\mathbb{R}[X]$ generated by a family $(g_1, \ldots, g_m) \subset \mathbb{R}[X]$ is the set of polynomials $\{p \,:\, p = \sum_{J \subseteq \{1, \ldots, m\}} \sigma_J (\prod_{j \in J} g_j)$, with $\sigma_J \in \Sigma^2[X]\}$.

Equivalently, $\mathbf{K}$ is convex if and only if for every $j = 1, \ldots, m$

$$\emptyset = \{(x,y) \in \mathbb{R}^n : (x,y) \in \mathbf{K} \times \mathbf{K}; \quad g_j(y) = 0; \\ \langle \nabla g_j(y), x - y \rangle \leq 0; \langle \nabla g_j(y), x - y \rangle \neq 0\}.$$

Then (4.4) follows from Stengle's positivstellensatz [25, Theorem 4.4.2, p. 92]. □

Observe that Corollary 4.4 provides an algebraic certificate of convexity when $\mathbf{K}$ is closed with nonempty interior and a nondegeneracy assumption holds on its boundary. If one fixes an a priori bound s on $l \in \mathbb{N}$ and on the degree of h_j, θ_j, and φ_j, then checking whether (4.4) holds reduces to solving a semidefinite program. If $\mathbf{K}$ is convex, by increasing s, eventually one would obtain such a certificate if one could solve semidefinite programs exactly. In practice and because of unavoidable numerical inaccuracies, one obtains only a numerical approximation of the optimal value and so a certificate valid *up to machine precision* only.

However, implementing such a procedure is extremely costly because one has potentially 2×2^m unknown SOS polynomials to define h_j and θ_j in (4.4)! Therefore, it is highly desirable to provide a less costly certificate but with no guarantee to hold for every $\mathbf{K}$ as in Corollary 4.4.

In particular, one considers only compact sets $\mathbf{K}$. Indeed, if $\mathbf{K}$ is compact, one has the following result (recall that $g_0 \equiv 1$).

LEMMA 4.5. *Let $\mathbf{K}$ be convex, and let Assumption 2.1 and Slater's condition hold. Assume that for every $j = 1, \ldots, m$, $\nabla g_j(y) \neq 0$ if $y \in \mathbf{K}$ and $g_j(y) = 0$. Then for every $\epsilon > 0$ and every $j = 1, \ldots, m$*

$$\langle \nabla g_j(Y), X - Y \rangle + \epsilon = \sum_{k=0}^{m} \sigma_{jk}(X,Y)\, g_k(X) + \sum_{k=0, k\neq j}^{m} \psi_{jk}(X,Y)\, g_k(Y) \\ + \psi_j(X,Y)\, g_j(Y) \tag{4.6}$$

for some SOS polynomials (σ_{jk}) and $(\psi_{jk})_{k\neq j} \subset \Sigma^2[X,Y]$ and some polynomial $\psi_j \in \mathbb{R}[X,Y]$.

Proof. By Lemma 4.3, for every $j = 1, \ldots, m$ and every $x, y \in \mathbf{K}$ such that $g_j(y) = 0$, (4.3) holds, and, therefore, for every $j = 1, \ldots, m$,

$$\langle \nabla g_j(y), x - y \rangle + \epsilon > 0 \qquad \forall (x,y) \in \Omega_j, \tag{4.7}$$

where Ω_j has been defined in (4.5). As $\mathbf{K}$ satisfies Assumption 2.1, then so does Ω_j for every $j = 1, \ldots, m$. Hence, (4.6) follows from (4.7) and Theorem 2.2. □

Therefore, inspired by Lemma 4.5, we introduce the following condition.

ASSUMPTION 4.6 (certificate of convexity). *For every $j = 1, \ldots, m$, (4.6) holds with $\epsilon = 0$. Then let $d_j \in \mathbb{N}$ be such that $2d_j$ is larger than the maximum degree of the polynomials $\sigma_{jk} g_k, \psi_{jk} g_k, \psi_j g_j \in \mathbb{R}[X,Y]$ in (4.6), $j = 1, \ldots, m$.*

When $\mathbf{K}$ is closed (and not necessarily compact), Slater's condition holds and the nondegeneracy assumption on the boundary holds (i.e., $\nabla g_j(y) \neq 0$ if $y \in \mathbf{K}$ and $g_j(y) = 0$). Assumption 4.6 is, indeed, a certificate of convexity because then (4.3) holds for every $x, y \in \mathbf{K}$ with $g_j(y) = 0$, and, by Lemma 4.3, $\mathbf{K}$ is convex. It translates the geometric property of convexity of $\mathbf{K}$ into an algebraic SOS Putinar representation of the polynomial $(X,Y) \mapsto \langle \nabla g_j(Y), X - Y \rangle$ nonnegative on Ω_j, $j = 1, \ldots, m$. On the other hand, if $\mathbf{K}$ is convex and Assumption 2.1, Slater's condition, and the nondegeneracy assumption all hold, then Assumption 4.6 is almost necessary as, by Lemma 4.5, (4.6) holds with $\epsilon > 0$ arbitrary.

With d_j fixed a priori, checking whether (4.6) holds with $\epsilon = 0$ can be done numerically. (However, again it provides a certificate of convexity valid *up to machine precision* only.) For instance, for every $j = 1, \ldots, m$, it suffices to solve the semidefinite program (recall that $r_k = \lceil (\deg g_k)/2 \rceil$, $k = 1 \ldots, m$)

$$
\begin{cases}
\rho_j := \min\limits_{\mathbf{z}} \; L_{\mathbf{z}}(\langle \nabla g_j(Y), X - Y \rangle) \\
\text{s.t.} \quad M_{d_j}(\mathbf{z}) \succeq 0, \\
\qquad M_{d_j - r_k}(g_k(X)\,\mathbf{z}) \succeq 0, \quad k = 1, \ldots, m, \\
\qquad M_{d_j - r_k}(g_k(Y)\,\mathbf{z}) \succeq 0, \quad k = 1, \ldots, m;\; k \neq j, \\
\qquad M_{d_j - r_j}(g_j(Y)\,\mathbf{z}) \;=\; 0, \\
\qquad y_0 = 1.
\end{cases} \tag{4.8}
$$

If $\rho_j = 0$ for every $j = 1, \ldots, m$, then Assumption 4.6 holds. This is in contrast to the PP-BDR property defined in [17] that cannot be checked numerically as it involves infinitely many linear polynomials f.

Remark 4.7. Observe that the usual rank condition (3.5) used as a stopping criterion to detect whether (4.8) is exact (i.e., $\rho_1 = 0$) cannot be satisfied in solving (4.8) with primal dual interior point methods (as in the SDP solvers used by GloptiPoly) because one tries to find an optimal solution $\mathbf{z}^*$ in the *relative interior* of the feasible set of (4.8), and this gives maximum rank to the moment matrix $M_{d_j}(\mathbf{z}^*)$. Therefore, in the context of (4.8), if, indeed, $\rho_j = 0$, then $\mathbf{z}^*$ corresponds to the moment vector of some probability measure μ supported on the set of points $(x, x) \in \mathbf{K} \times \mathbf{K}$ that satisfy $g_j(x) = 0$ (as, indeed, $L_{\mathbf{z}^*}(\langle \nabla g_j(Y), X - Y \rangle) = 0 = \rho_j$). Therefore, $\rho_j = 0$ as d_j increases, but the rank of $M_{d_j}(\mathbf{z}^*)$ does not stabilize because μ is not finitely supported. In particular, a good candidate $\mathbf{z}^*$ for an optimal solution is the moment vector of the probability measure uniformly distributed on the set $\{(x, x) \in \mathbf{K} \times \mathbf{K} \,:\, g_j(x) = 0\}$.

Alternatively, if $\rho_j \approx 0$ and the dual of (4.8) has an optimal solution $(\sigma_{jk}, \psi_{jk}, \psi_j)$, then in some cases one may check if (4.6) holds exactly after appropriate rounding of coefficients of the solution. But in general obtaining an exact certificate (i.e., $\rho_j = 0$ in the primal or (4.6) with $\epsilon = 0$ in the dual) numerically is hopeless.

Example 4.2. Consider the following simple illustrative example in $\mathbb{R}^2$:

$$
\mathbf{K} := \left\{ x \in \mathbb{R}^2 \,:\, x_1 x_2 - 1/4 \geq 0;\; 0.5 - (x_1 - 0.5)^2 - (x_2 - 0.5)^2 \geq 0 \right\}. \tag{4.9}
$$

Obviously, $\mathbf{K}$ is convex but its defining polynomial $x \mapsto g_1(x) := x_1 x_2 - 1/4$ is not concave, whereas $x \mapsto g_2(x) := 0.5 - (x_1 - 0.5)^2 - (x_2 - 0.5)^2$ is.

With $d_1 = 3$, solving (4.8) using GloptiPoly 3[5] yields the optimal value $\rho_1 \approx -4.58.10^{-11}$ which, in view of the machine precision for the SDP solvers used in GloptiPoly, could be considered to be zero, but of course with no guarantee. However, and according to Remark 4.7, we could check that (again up to machine precision) for every $\alpha \in \mathbb{N}^n$ with $|\alpha| \leq 2d_j$, $z^*_{\alpha,\alpha} = z^*_{2\alpha,0}$ and $z^*_{\alpha,0} = z^*_{0,\alpha}$. In addition, because of symmetry, $z_{\alpha,\beta} = z_{\alpha',\beta'}$ whenever $\alpha'_1 = \alpha_2$ and $\alpha'_2 = \alpha_1$ (and similarly for β and β'). Indeed, for moments of order 1 we have $z^*_{\alpha,\beta} = (0.5707, 0.5707, 0.5707, 0.5707)$ and for moments of order 2,

$$
z^*_{\alpha,\beta} = (0.4090, 0.25, 0.4090, 0.25, 0.4090, 0.25, 0.4090, 0.4090, 0.25, 0.4090).
$$

[5] GloptiPoly 3 (a Matlab-based public software) is an extension of GloptiPoly [9] to solve the generalized problem of moments described in [18]. For more details see www.laas.fr/∼henrion/software/.

For $j = 2$ there is no test to perform because $-g_2$ being quadratic and convex yields

$$\langle \nabla g_2(Y), X - Y \rangle \;=\; g_2(X) - g_2(Y) + \underbrace{(X-Y)^T \left(-\nabla^2 g_2(Y)\right)(X-Y)}_{SOS} \tag{4.10}$$

which is in the form (4.6) with $d_2 = 1$.

We next show the role of Assumption 4.6 in obtaining a semidefinite representation of $\mathbf{K}$.

THEOREM 4.8. *Let Assumption* 2.1 *and Slater's condition hold. Moreover, assume that for every* $j = 1, \ldots, m$, $\nabla g_j(y) \neq 0$ *whenever* $y \in \mathbf{K}$ *and* $g_j(y) = 0$. *If Assumption* 4.6 *holds, then* $\mathbf{K}$ *is convex and* Ω *in* (4.2) *with* $d := \max_j d_j$ *is a semidefinite representation of* $\mathbf{K}$.

Proof. That $\mathbf{K}$ is convex follows from Lemma 4.3. We next prove that the PP-BDR property defined in Lasserre [16] holds for $\mathbf{K}$. Let $f \in \mathbb{R}[X]$ be a linear polynomial with coefficient vector $\mathbf{f} \in \mathbb{R}^n$ (i.e., $X \mapsto f(X) = \mathbf{f}^T X$), and consider the optimization problem $\mathbf{P}: \min\{\mathbf{f}^T x \;:\; x \in \mathbf{K}\}$. As $\mathbf{K}$ is compact, let $x^* \in \mathbf{K}$ be a global minimizer of f. The Fritz John optimality conditions state that there exists $0 \neq \lambda \in \mathbb{R}^{m+1}_+$ such that

$$\lambda_0 \, \mathbf{f} = \sum_{j=1}^{m} \lambda_j \, \nabla g_j(x^*); \quad \lambda_j \, g_j(x^*) = 0 \quad \forall j = 1, \ldots, m. \tag{4.11}$$

(See, e.g., [3].) We first prove by contradiction that if Slater's condition and the nondegeneracy assumption hold, then $\lambda_0 > 0$. Suppose that $\lambda_0 = 0$ and let $J := \{j \in \{1, \ldots, m\} \;:\; \lambda_j > 0\}$; hence, J is nonempty as $\lambda \neq 0$. With $x_0 \in \mathbf{K}$ such that $g_j(x_0) > 0$ (as Slater's condition holds, one such x_0 exists), let $B(x_0, \rho) := \{z \;:\; \|z - x_0\| \leq \rho\}$. For ρ sufficiently small, $B(x_0, \rho) \subset \mathbf{K}$ and $g_j(z) > 0$ for all $z \in B(x_0, \rho)$ and every $j = 1, \ldots, m$. Then by (4.11) and $\lambda_0 = 0$,

$$0 = \sum_{j=1}^{m} \lambda_j \, \langle \nabla g_j(x^*), z - x^* \rangle \qquad \forall z \in B(x_0, \rho),$$

which in turn implies (by nonnegativity of each term in the above sum)

$$\langle \nabla g_j(x^*), z - x^* \rangle = 0 \qquad \forall z \in B(x_0, \rho), \; j \in J.$$

But this clearly implies $\nabla g_j(x^*) = 0$ for every $j \in J$, in contradiction with the nondegeneracy assumption. Hence, $\lambda_0 > 0$ and, by homogeneity, we may and will take $\lambda_0 = 1$.

Therefore, letting $Y := x^*$ in (4.6), the polynomial $X \mapsto f(X) - f^*$ can be written

$$\begin{aligned}
\mathbf{f}^T X - f^* &= \sum_{j=1}^{m} \lambda_j \, [\, \langle \nabla g_j(x^*), X - x^* \rangle \,] \\
&= \sum_{j=1}^{m} \lambda_j \left[\sum_{k=0}^{m} \sigma_{jk}(X, x^*) \, g_k(X) + \sum_{k=0, k \neq j}^{m} \psi_{jk}(X, x^*) \, g_k(x^*) \right. \\
&\qquad \left. + \, \psi_j(X, x^*) \, g_j(x^*) \right],
\end{aligned}$$

where we have used (4.6) with $Y = x^*$ and $\epsilon = 0$. Next, observe that

$$\begin{aligned} X \mapsto \sigma_{jk}(X, x^*) \in \Sigma^2[X] \qquad & [\text{as } \sigma_{jk} \in \Sigma^2[X, Y]], \\ X \mapsto \psi_{jk}(X, x^*)\, g_k(x^*) \in \Sigma^2[X] \qquad & [\text{as } \psi_{jk} \in \Sigma^2[X, Y] \text{ and } g_j(x^*) \geq 0], \\ \lambda_j g_j(x^*) = 0, \qquad & j = 1, \ldots, m. \end{aligned}$$

So as $\lambda \in \mathbb{R}^m_+$,

$$X \mapsto \mathbf{f}^T X - f^* \;=\; \Delta_0(X) + \sum_{j=1}^m \Delta_j(X)\, g_j(X) \tag{4.12}$$

for SOS polynomials $(\Delta_j)_{j=0}^m \subset \Sigma^2[X]$ defined by

$$\begin{aligned} X \mapsto \Delta_0(X) &= \sum_{j=1}^m \lambda_j \left(\sum_{k=0, k\neq j}^m \psi_{jk}(X, x^*)\, g_k(x^*) \right), \\ X \mapsto \Delta_j(X) &= \sum_{l=1}^m \lambda_l\, \sigma_{lj}(X, x^*), \qquad j = 1, \ldots, m. \end{aligned}$$

Write every affine polynomial $f \in \mathbb{R}[X]$ as $\mathbf{f}^T X + f_0$ for some $\mathbf{f} \in \mathbb{R}^n$ and $f_0 = f(0)$. If f is nonnegative on $\mathbf{K}$, then from (4.12),

$$\begin{aligned} f(X) \;=\; \mathbf{f}^T X - f^* + f^* + f_0 &= f^* + f_0 + \Delta_0(X) + \sum_{j=1}^m \Delta_j(X)\, g_j(X) \\ &= \widehat{\Delta}_0(X) + \sum_{j=1}^m \Delta_j(X)\, g_j(X) \qquad \forall X, \end{aligned}$$

with $\widehat{\Delta}_0 \in \Sigma^2[X]$ (because $f^* + f_0 \geq 0$), and so the PP-BDR property holds for $\mathbf{K}$ with order d. By [16, Theorem 2], $\mathbf{K}$ is SDr with the semidefinite representation (4.2). ∎

We next show that the two sufficient conditions of strict convexity and SOS convexity of Helton and Nie [6] in Theorem 4.2 both imply that Assumption 4.6 holds, and so Theorem 4.8 contains Theorem 4.2 as a special case.

COROLLARY 4.9. *Let* $\mathbf{K}$ *in* (1.1) *be convex and both Assumption* 2.1 *and Slater's condition hold. Assume that either* $-g_j$ *is SOS-convex or* $-g_j$ *is convex on* $\mathbf{K}$ *and* $-\nabla^2 g_j \succ 0$ *on* $\mathbf{K} \cap \{x \,:\, g_j(x) = 0\}$ *for every* $j = 1, \ldots, m$. *Then Assumption* 4.6 *holds and so Theorem* 4.8 *applies.*

Proof. By Lemma 2.5, for every $j = 1, \ldots, m$, write

$$\begin{aligned} (X, Y) \quad &\mapsto \quad g_j(X) - g(Y) - \langle \nabla g_j(Y), X - Y \rangle \\ &= \left\langle (X - Y), \underbrace{\left(\int_0^1 \int_0^t \nabla^2 g_j(Y + s(X - Y))\, ds dt \right)}_{F_j(X,Y)} (X - Y) \right\rangle. \end{aligned}$$

If $-\nabla^2 g_j \succ 0$ on $y \in \mathbf{K}$ with $g_j(y) = 0$, then from the proof of [6, Lemma 19], $-F_j(x, y) \succ 0$ for all $x, y \in \mathbf{K}$ with $g_j(y) = 0$. In other words, $-F_j(x, y) \succeq \delta I_n$ on

Ω_j (defined in (4.5)) for some $\delta > 0$. Therefore, by the matrix polynomial version of Putinar positivstellensatz in [6, Theorem 29],

$$-F_j(X,Y) = \sum_{k=0}^{m} \widehat{\sigma}_{jk}(X,Y)g_k(X) + \sum_{k=0,k\neq j}^{m} \widehat{\psi}_{jk}(X,Y)g_k(Y) + \widehat{\psi}_j(X,Y)g_j(Y) \tag{4.13}$$

for some SOS matrix polynomials $(\widehat{\sigma}_{jk}(X,Y))$, $(\widehat{\psi}_{jk}(X,Y))$ and some matrix polynomial $\widehat{\psi}_j(X,Y)$.

On the other hand, if $-g_j$ is SOS-convex, then by Lemma 2.4, $-F_j(X,Y)$ is SOS and, therefore, (4.13) also holds (take $\widehat{\sigma}_{jk} \equiv 0$ for all $k \neq 0$, and $\widehat{\psi}_{jk} \equiv 0$ for all k and $\widehat{\psi}_j \equiv 0$). But then

$$\begin{aligned}
g_j(X) - g(Y) - \langle \nabla g_j(Y), X - Y\rangle &= \langle (X-Y), F_j(X,Y)(X-Y)\rangle \\
&= -\sum_{k=0}^{m} \langle (X-Y), \widehat{\sigma}_{jk}(X,Y)(X-Y)\rangle\, g_k(X) \\
&\quad - \sum_{k=0,k\neq j}^{m} \Big\langle (X-Y), \widehat{\psi}_{jk}(X,Y)(X-Y)\Big\rangle\, g_k(Y) \\
&\quad - \Big\langle (X-Y), \widehat{\psi}_j(X,Y)(X-Y)\Big\rangle\, g_j(Y) \\
&= -\sum_{k=0}^{m} \sigma_{jk}(X,Y)\, g_k(X) \\
&\quad - \sum_{k=0,k\neq j}^{m} \psi_{jk}(X,Y)\, g_k(Y) - \psi_j(X,Y)\, g_j(Y)
\end{aligned}$$

for all X, Y, for some SOS polynomials $\sigma_{jk}, \psi_{jk} \in \mathbb{R}[X,Y]$, and some polynomial $\psi_j \in \mathbb{R}[X,Y]$. Equivalently,

$$\begin{aligned}
\langle \nabla g_j(Y), X - Y\rangle &= g_j(X) - g_j(Y) + \sum_{k=0}^{m} \sigma_{jk}(X,Y)\, g_k(X) \\
&\quad + \sum_{k=0,k\neq j}^{m} \psi_{jk}(X,Y)\, g_k(Y) + \psi_j(X,Y)\, g_j(Y) \\
&= \sum_{k=0}^{m} \sigma'_{jk}(X,Y)\, g_k(X) + \sum_{k=0,k\neq j}^{m} \psi_{jk}(X,Y)\, g_k(Y) \\
&\quad + \psi'_j(X,Y)\, g_j(Y)
\end{aligned}$$

for some SOS polynomials $\sigma'_{jk}, \psi_{jk} \in \Sigma^2[X,Y]$ and some polynomial $\psi'_j \in \mathbb{R}[X,Y]$. In other words, Assumption 4.6 holds, which concludes the proof. □

Hence, if each $-g_j$ is SOS-convex or convex on $\mathbf{K}$ with $-\nabla^2 g_j \succ 0$ on $\mathbf{K} \cap \{x : g_j(x) = 0\}$, one obtains a numerical scheme to obtain the parameter d in Theorem 4.8 as well as the semidefinite representation (4.2) of $\mathbf{K}$. Solve the semidefinite programs (4.8) with degree parameter d_j. Eventually, $\rho_j = 0$ for every $j = 1, \ldots, m$.

Example 4.3. Consider the convex set $\mathbf{K}$ in (4.9) of Example 4.2 for which the defining polynomial g_1 of $\mathbf{K}$ is not concave. We have seen that Assumption 4.6 holds

(up to $\rho_1 \approx 10^{-11}$, close to machine precision) and $\max[d_1, d_2] = 3$. By Theorem 4.8, if ρ_1 would be exactly 0, the set

$$\Omega := \left\{ (x, \mathbf{y}) \in \mathbb{R}^n \times \mathbb{R}^{s(6)} \; : \; \begin{cases} M_3(\mathbf{y}) & \succeq 0, \\ M_2(g_j\,\mathbf{y}) & \geq 0, \quad j = 1, 2, \\ L_{\mathbf{y}}(X_i) & = x_i, \quad i = 1, 2, \\ y_0 & = 1 \end{cases} \right. \tag{4.14}$$

would be a semidefinite representation of $\mathbf{K}$.

At least in practice, for every linear polynomial $f \in \mathbb{R}[X]$, minimizing $L_{\mathbf{y}}(f)$ over Ω yields the desired optimal value $f^* := \min_{x \in \mathbf{K}} f(x)$, up to $\rho_1 \approx -10^{-11}$.

Indeed, let $f \in \mathbb{R}[X]$ be $\mathbf{f}^T X$ for some vector $\mathbf{f} \in \mathbb{R}^n$. In minimizing f over $\mathbf{K}$, one has $\mathbf{f} = \lambda_1 \nabla g_1(x^*) + \lambda_2 \nabla g_2(x^*)$ for some $\lambda \in \mathbb{R}^2_+$, some $x^* \in \mathbf{K}$ with $\lambda_i g_i(x^*) = 0$, $i = 1, 2$, and $f^* = \lambda_1 \langle \nabla g_1(x^*), x^* \rangle + \lambda_2 \langle \nabla g_2(x^*), x^* \rangle = \min_{x \in \mathbf{K}} \mathbf{f}^T x$. Let x be as in (4.14), arbitrary. Then

$$\mathbf{f}^T x - f^* \; = \; L_{\mathbf{y}}(f(X) - f^*) \; = \; \sum_{i=1}^{2} \lambda_i L_{\mathbf{y}}(\langle \nabla g_i(x^*), X - x^* \rangle).$$

If $\lambda_1 > 0$ so that $g_1(x^*) = 0$, use (4.12) to obtain

$$L_{\mathbf{y}}(\langle \nabla g_1(x^*), X - x^* \rangle) = L_{\mathbf{y}} \left(\rho_1 + \Delta_0(X) + \sum_{j=1}^{2} \Delta_j(X) g_j(X) \right) \geq \rho_1,$$

because $L_{\mathbf{y}}(\Delta_0) \geq 0$ follows from $M_3(\mathbf{y}) \succeq 0$, and $L_{\mathbf{y}}(\Delta_j g_j) \geq 0$, $j = 1, 2$, follows from $M_2(g_1\mathbf{y}), M_2(g_2\mathbf{y}) \succeq 0$. If $\lambda_2 > 0$ so that $g_2(x^*) = 0$, then from (4.10)

$$L_{\mathbf{y}}(\langle \nabla g_2(x^*), X - x^* \rangle) \; = \; L_{\mathbf{y}} \left(g_2(X) - \left\langle (X - x^*), \nabla^2 g_2(x^*)(X - x^*) \right\rangle \right) \geq 0,$$

because $L_{\mathbf{y}}(g_2) \geq 0$ follows from $M_2(g_2\mathbf{y}) \succeq 0$ whereas the second term is nonnegative as $\langle (X - x^*), -\nabla^2 g_2(x^*)(X - x^*) \rangle$ is SOS and $M_3(\mathbf{y}) \succeq 0$. Hence, $\mathbf{f}^T x - f^* \geq \lambda_1 \rho_1$. On the other hand, from $\mathbf{K} \subseteq \{x \; : \; (x, y) \in \Omega\}$, one finally obtains the desired result

$$f^* + \lambda_1 \rho_1 \; \leq \min \{ \mathbf{f}^T x \; : \; (x, y) \in \Omega \} \; \leq \; f^*.$$

5. Conclusion. As well-known, convexity is a highly desirable property in optimization. We have shown that it also has important specific consequences in polynomial optimization. For instance, for polynomial optimization problems with SOS-convex or strictly convex polynomial data, the basic SDP relaxations of the moment approach [13] *recognize* convexity and finite convergence occurs. Similarly, the set $\mathbf{K}$ has a semidefinite representation, explicit in terms of the defining polynomials (g_j).

The class of SOS-convex polynomials introduced in Helton and Nie [6] is particularly interesting because the semidefinite constraint to handle the semidefinite relaxation involves only the Hankel-like moment matrix which does *not* depend on the problem data! Hence, one might envision a dedicated SDP solver that would take into account this peculiarity as Hankel-like or Toeplitz-like matrices enjoy very specific properties. Moreover, if restricted to this class of polynomials, Jensen's inequality can be extended to linear functionals in the dual cone of SOS polynomials (hence, not necessarily probability measures).

Therefore, a topic of further research is to evaluate how *large* is the subclass of SOS-convex polynomials in the class of convex polynomials and, if possible, to also provide simple sufficient conditions for SOS convexity.

Acknowledgments. The author wishes to thank L. Tuncel and Y. Nesterov for helpful discussions on various characterizations of convex sets, and also two anonymous referees for several corrections as well as suggestions and remarks to improve a first version of this paper.
