#### Abstract

X-ray crystallographic studies on $\pi$-allylpalladium complexes coordinated with a chiral phosphine-olefin ligand (-)-1b demonstrate that the phosphine ligand shows a larger trans-influence than the $\pi$-bound olefin. The palladium/chiral phosphine-olefin complex efficiently catalyzed asymmetric allylic alkylation of 1,3-diphenyl-2-propenyl acetate with $96 \%$ enantioselectivity.

## 1. Introduction

The development of new chiral ligands for transition metals is of high importance in the advancement of asymmetric catalysis. Historically, for the late transition metals, the use of phosphorus- and/or nitrogen-based chiral ligands has been most extensively investigated. ${ }^{1}$ Many of the effective ligands in this class are bidentate, as in the case of binap ${ }^{2}$ and bisoxazolines. ${ }^{3}$ In addition to bisphosphine or dinitrogen ligands, $\mathrm{P}, \mathrm{N}$-bidentate chiral ligands have also been well-described (e.g., phosphinooxazolines). ${ }^{4}$ As conceptually novel chiral ligands, a series of chiral dienes were recently introduced, ${ }^{5,6}$ and they showed their high effectiveness in various rhodiumcatalyzed asymmetric processes, exhibiting superiority to conventional chiral bisphosphine ligands in some cases.

Although these dienes demonstrate that a good chiral environment can be created by the use of a framework based on substituted olefins, phosphine-olefin hybrid chiral ligands have been rarely studied to date. In fact, until recently, only one report by Grützmacher had addressed this issue, achieving $86 \%$ ee in the iridium-catalyzed asymmetric hydrogenation of an imine. ${ }^{7}$ Unfortunately, however, these ligands possess another chirality derived from menthol and it is this that is pri-

[^0]marily responsible for the stereochemical outcome of the catalytic reaction.

More recently, we have developed new chiral phos-phine-olefins 1 and demonstrated that these ligands are highly effective for the rhodium-catalyzed asymmetric 1,4 -addition of arylboronic acids to maleimides. ${ }^{8}$ Herein we report that these ligands can also be used in the context of palladium-catalyzed asymmetric processes. Structural features of the palladium complexes by X-ray crystallographic analysis are also described.

## 2. Results and discussion

As shown in Scheme 1, the synthesis of $\mathbf{1}$ begins with known compound ( $\pm$ )-2. ${ }^{9}$ Thus, Swern oxidation of alcohol $( \pm)$-2, followed by ketalization and phosphine oxide introduction, gives $( \pm)$-3, which can be resolved by chiral HPLC on a Chiralcel OD-H column to give each enantiomer of $\mathbf{3}$. The removal of the ketal protection, followed by triflation, affords enantiopure enol triflate (-)-4. Grignard cross-coupling of $(-)-4$, and then reduction with silane, completes the synthesis of $(-)$ $(1 S, 4 R, 7 S)-1 \mathbf{a}(\mathrm{R}=\mathrm{Bn})$ and $(-)-(1 S, 4 R, 7 S)-\mathbf{1 b} \quad(\mathrm{R}=$ Ph). ${ }^{8}$

Treatment of ligand (-)-1b with $\left[\mathrm{PdCl}\left(\eta^{3}-\mathrm{C}_{3} \mathrm{H}_{5}\right)\right]_{2}$ (1.0 equiv Pd ) in chloroform in the presence of $\mathrm{NH}_{4} \mathrm{PF}_{6}$ at room temperature generated $\left[\mathrm{Pd}\left(\eta^{3}-\mathrm{C}_{3} \mathrm{H}_{5}\right)((-)\right.$ 1b) $\mathrm{PF}_{6} 5$ (Scheme 2). from dichloromethane/hexane afforded single crystals suitable for X-ray analysis. The crystal structure of complex $\mathbf{5}$ is illustrated in Figure 1 and its data summarized in Tables 1 and 2.

Figure 1. ORTEP illustration of $\left[\operatorname{Pd}\left(\eta^{3}-\mathrm{C}_{3} \mathrm{H}_{5}\right)((-)-\mathbf{1 b})\right] \mathrm{PF}_{6} 5$ with thermal ellipsoids drawn at the $50 \%$ probability level (hydrogens and $\mathrm{PF}_{6}$ are omitted for clarity).

Knowing that a mixture of $(-) \mathbf{- 1 b}$ and $\left[\operatorname{PdCl}\left(\eta^{3}-\mathrm{C}_{3} \mathrm{H}_{5}\right)\right]_{2}$ gives a $\mathrm{Pd} /(-) \mathbf{- 1 b}$ complex, we carried out the asymmetric allylic alkylation of 1,3-diphenyl-2-propenyl acetate with dimethyl malonate under $\mathrm{Pd} / \mathbf{1}$ catalysis (Scheme 3). We have determined that the use of benzyl-substituted ligand ( - )-1a gives the alkylation product in $96 \%$ yield with $81 \%$ ee $(S)$, whereas the use of phenylsubstituted ligand ( - )-1b affords it in $87 \%$ yield with $96 \%$ ee $(S)$.

Scheme 3.

To analyze this reaction in more detail, we synthesized a $\mathrm{Pd} /(-)-1 \mathrm{~b}$ complex bearing an $\eta^{3}$-1,3-diphenyl-2-propenyl moiety as shown in Scheme 4. This complex turned out to be a mixture of two diastereomers in solution (ratio $=56: 44$ in chloroform), but upon recrystallization from dichloromethane/hexane, crystals of one diastereomer were obtained and analyzed by X-ray crystallography (Fig. 2, Tables 1 and 2). It is worth noting that the $\operatorname{Pd}(1)-\mathrm{C}(3)$ bond length is longer than the $\operatorname{Pd}(1)-\mathrm{C}(1)$ bond length $[2.291(4) \AA$ vs $2.122(6) \AA$ A $]$, indicating that the phosphine ligand [trans to $\mathrm{C}(3)$ ] shows larger

trans-influence than the $\pi$-bound olefin ligand [trans to $\mathrm{C}(1)] .{ }^{10}$ This trend was also observed in complex 5 $[2.200(3) \AA$ vs $2.149(3) \AA]$, which should have smaller impact of the steric factor to take into account. By analogy with the analysis in the literature, ${ }^{11}$ a nucleophile would preferentially attack $\mathrm{C}(3)$ from outside, leading to an ( $S$ )-product (Fig. 3), which is consistent with the experimental outcome in Scheme 3. Assuming that this is what happened in the catalytic reaction, the diastereomer shown in Figure 2 would be the more reactive one out of the two diastereomeric $\operatorname{Pd}\left(\eta^{3}-\mathrm{PhCHCHCHPh}\right)$ $(-)-\mathbf{1 b}$ intermediates existing in solution, thus affording
the alkylation product with high enantiomeric excess in ( $S$ )-configuration.

## 3. Conclusions

We have demonstrated that palladium/chiral phos-phine-olefin complexes can effectively catalyze asymmetric allylic alkylation reactions. Through X-ray crystallographic analysis of $\operatorname{Pd}\left(\eta^{3}\right.$-allyl) ( - )-1b complexes, we have also confirmed the difference between phosphines and $\pi$-bound olefins in transition-metal complexes; specifically, phosphines show larger transinfluence than $\pi$-bound olefins.

## 4. Experimental

### 4.1. General

All air- and moisture-sensitive manipulations were carried out with standard Schlenk techniques under nitrogen or in a glove box under argon. THF and $\mathrm{Et}_{2} \mathrm{O}$ were purified by passing through a neutral alumina column under nitrogen. Benzene was distilled over benzophenone ketyl under nitrogen. Dichloromethane was distilled over $\mathrm{CaH}_{2}$ under nitrogen. EtOH was distilled over magnesium turnings under nitrogen. DMSO was distilled over $\mathrm{CaH}_{2}$ under vacuum. $\mathrm{Et}_{3} \mathrm{~N}$ was distilled over KOH under vacuum. 4.2.1. ( $\pm$ )-Spiro[7-diphenylphosphinylbicyclo[2.2.1]hep-tane-2,2'-[1,3]dioxolane] ( $\mathbf{\pm}$ )-3. DMSO $\quad(3.98 \mathrm{~mL}$, 56.1 mmol ) was slowly added to a solution of oxalyl chloride $(2.45 \mathrm{~mL}, \quad 28.1 \mathrm{mmol})$ in dichloromethane $(60 \mathrm{~mL})$ at $-78^{\circ} \mathrm{C}$, and the resulting mixture stirred for 30 min at $-78^{\circ} \mathrm{C}$. A solution of $( \pm)-2(4.77 \mathrm{~g}$, 25.0 mmol ) in dichloromethane ( 45 mL ) was added to this mixture slowly over 3 h , and $\mathrm{Et}_{3} \mathrm{~N}(15.6 \mathrm{~mL}$, $112 \mathrm{mmol})$ then added dropwise. The reaction mixture was stirred for 1 h at room temperature, and then quenched with water ( 60 mL ). After extraction with dichloromethane, the organic layer was washed successively with HCl ( 60 mL ; 1.0 M aqueous), $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ( 60 mL ; saturated aqueous), and then NaCl (saturated aqueous). The organic phase thus obtained was dried over $\mathrm{MgSO}_{4}$, filtered, and concentrated under vacuum. The residue was chromatographed on silica gel with hexane $/ \mathrm{Et}_{2} \mathrm{O}=2 / 1$ to afford a colorless oil ( 4.54 g , 24.0 mmol ; $96 \%$ yield).

A mixture of this oil ( $4.54 \mathrm{~g}, 24.0 \mathrm{mmol}$ ), p-toluenesulfonic acid ( $457 \mathrm{mg}, 2.40 \mathrm{mmol}$; monohydrate), and ethylene glycol ( $13.4 \mathrm{~mL}, 0.24 \mathrm{~mol}$ ) in benzene ( 50 mL ) was refluxed for 17 h with a Dean-Stark trap. After cooling to room temperature, the mixture was poured into water and extracted with EtOAc. The organic layer was washed with NaCl (saturated aqueous), dried over $\mathrm{MgSO}_{4}$, filtered, and concentrated under vacuum. The residue was chromatographed on silica gel with hexane $/ \mathrm{Et}_{2} \mathrm{O}=5 / 1$ to afford a colorless oil $(5.25 \mathrm{~g}$, 22.5 mmol ; $94 \%$ yield).
$t-\mathrm{BuLi}(27.0 \mathrm{~mL}, 40.0 \mathrm{mmol} ; 1.48 \mathrm{M}$ solution in pentane) was added to a solution of this oil $(3.73 \mathrm{~g}, 16.0 \mathrm{mmol})$ in THF ( 320 mL ) at $-60^{\circ} \mathrm{C}$ slowly over 40 min , and the resulting mixture stirred for 30 min at $-60^{\circ} \mathrm{C}$. Chlorodiphenylphosphine ( $3.45 \mathrm{~mL}, 19.2 \mathrm{mmol}$ ) was then added dropwise. After stirring for 15 min at $-60^{\circ} \mathrm{C}$, the reaction was quenched with water $(0.96 \mathrm{~mL})$, and the solvent removed under vacuum at room temperature. The residue was dissolved in acetone ( 80 mL ), and $\mathrm{H}_{2} \mathrm{O}_{2}$ ( $4.5 \mathrm{~mL} ; 30 \mathrm{wt} \%$ aqueous) then added to it. The reaction mixture was stirred for 15 min at room temperature, and $\mathrm{MnO}_{2}(260 \mathrm{mg}, 2.99 \mathrm{mmol})$ then added. After stirring for 16 h at room temperature, the precipitate was removed by filtration, and the remaining solution concentrated under vacuum. The residue was extracted with EtOAc, dried over $\mathrm{MgSO}_{4}$, filtered, and concentrated under vacuum. This was chromatographed on silica gel with $\mathrm{EtOAc} / \mathrm{MeOH}=20 / 1$ to afford $( \pm)-3$ as a white solid $(3.60 \mathrm{~g}, 10.2 \mathrm{mmol} ; 63 \%$ yield $) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta$ 7.82-7.72 (m, 4H), 7.50-7.40 (m, 6H), $3.86(\mathrm{dt}$, $J_{\mathrm{HH}}=7.3$ and 5.1 Hz 1 H$), 3.78\left(\mathrm{q}, J_{\mathrm{HH}}=7.3 \mathrm{~Hz}, 1 \mathrm{H}\right)$, $3.63\left(\mathrm{dt}, J_{\mathrm{HH}}=7.3\right.$ and $\left.5.1 \mathrm{~Hz}, 1 \mathrm{H}\right), 3.20\left(\mathrm{q}, J_{\mathrm{HH}}=\right.$ $7.3 \mathrm{~Hz}, 1 \mathrm{H}), 2.83-2.80(\mathrm{~m}, 2 \mathrm{H}), 2.43(\mathrm{~s}, 1 \mathrm{H}), 2.30(\mathrm{~s}$, $1 \mathrm{H}), 1.88-1.78(\mathrm{~m}, 1 \mathrm{H}), 1.76-1.66(\mathrm{~m}, 1 \mathrm{H}), 1.54-1.42$ $(\mathrm{m}, 3 \mathrm{H}) \cdot{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta 135.9\left(\mathrm{~d},{ }^{1} J_{\mathrm{CP}}=98.7 \mathrm{~Hz}\right)$, $134.1\left(\mathrm{~d},{ }^{1} J_{\mathrm{CP}}=98.7 \mathrm{~Hz}\right), 131.1\left(\mathrm{~d},{ }^{2} J_{\mathrm{CP}}=9.3 \mathrm{~Hz}\right), 131.0$ $\left(\mathrm{d},{ }^{4} J_{\mathrm{CP}}=2.6 \mathrm{~Hz}\right), 130.9\left(\mathrm{~d},{ }^{4} J_{\mathrm{CP}}=2.5 \mathrm{~Hz}\right), 130.7(\mathrm{~d}$, $\left.{ }^{2} J_{\mathrm{CP}}=8.8 \mathrm{~Hz}\right), \quad 128.3\left(\mathrm{~d},{ }^{3} J_{\mathrm{CP}}=10.9 \mathrm{~Hz}\right), 128.0(\mathrm{~d}$, $\left.{ }^{3} J_{\mathrm{CP}}=11.4 \mathrm{~Hz}\right), \quad 115.0,63.8,63.6,50.6\left(\mathrm{~d},{ }^{1} J_{\mathrm{CP}}=\right.$
