Max-Planck-Institut für Kohlenforschung, Abt. Strahlenchemie, Mülheim-Ruhr

and Department of Chemistry, Boston College, Chestnut Hill, Mass.

(Received in UK 22 March 1968; accepted for publication 15 April 1968)

1.5-Cyclooctadiene-iron tricarbonyl (I) has been reported as a liquid $(n_D^{2O} = 1.5765)$ produced photochemically¹⁾ or thermally²⁾ from Fe(CO)₅ and 1.5-cyclooctadiene (II), and as an unstable solid melting just below room temperature obtained from refluxing II with Fe₃(CO)₁₂ in benzene³⁾. I has also been described in a footnote⁴⁾ as yellow crystals, m.p. 61-63°C, prepared from II and Fe₂(CO)₉. Recently the Mössbauer parameters of I have been reported⁵⁾ without any data on its preparation.

The well known isomerization of II to 1,3-cyclooctadiene (III) with catalytic amounts of iron carbonyls⁶⁾ has caused some doubts⁷⁾ as to whether II or III is coordinated in the reported compounds. Therefore in connection with systematic studies of iron carbonyl complexes⁸⁾ we have re-investigated this system.

Illumination of Fe(CO) $_5$ and II yields 1,5-cyclooctadiene-iron tetracarbonyl (IV) as an unstable oil $(n_D^{2O}\ 1.575)$ when only ~ 1/3 of the Fe(CO) $_5$ is reacted. IV can be recrystallized from pentane at -120°C. Structure IV is supported by the degradation with $Ce(NH_4)_2(NO_3)_6$ (V) in $C_2H_5OH^9$) to II (Table I), the analytical (all reported compounds gave satisfactory elemental analyses) and IR data (Table I), the mass spectrum^{1O)} showing peaks at m/e 276, 248, 220, 192, 164 ([M-(CO) $_1$] $^+$; n = O - 4), 110 (butadiene-Fe $^+$) and 108 (II $^+$), and the NMR spectrum¹¹⁾ with multiplets (m) at 4.53 τ (2 H), 6.8 τ (2 H) and 7.9 τ (8 H) indicating an uncoordinated double bond.

Extended irradiation of Fe(CO)₅ and II, however, yields 1,5-cyclooctadieneiron tricarbonyl (I) as stable orange crystals, m.p. 90-90.5° (from pentane); 3192 No. 28

[NMR: m 6.6 τ (4 H) and m 8.0 τ (8 H)]. IV obviously is the primary product in this photoreaction.

Decomposition of IV on standing leads to 1,5-cyclooctadiene-bis(iron tetracarbonyl) (VI), yellow crystals, m.p. 85-88°C, which form $\text{Fe}_3(\text{CO})_{12}$ on slow heating > 77°C. VI (main product) and I are formed in the reaction of II with $\text{Fe}_2(\text{CO})_9$; the melting point of a 1:1 mixture of I and VI is 67.5-68.5°. The conformation of the ring system in VI [NMR: m 6.3 τ (4 H), m 7.3 τ (4 H) and m 8.2 τ (4 H)] and IV is under current investigation.

[1] and [2] are possible pathways from IV to VI. [2] was demonstrated experimentally; however, a simultaneous reaction [1] cannot be ruled out.

[1] IV +
$$Fe_2(CO)_9$$
 \longrightarrow VI + $Fe(CO)_5$

[2]
$$2 \text{ IV} \longrightarrow \text{VI} + \text{II}$$

According to [1] the predominant formation of VI over IV even in the presence of a large excess of II would require an activation of the uncoordinated double bond in IV compared with II. There is no evidence from the NMR for an interaction of $Fe(CO)_4$ with the free double bond in IV. An analogy to [2] is the formation of butadiene-bis(iron tetracarbonyl) from butadiene-iron tetracarbonyl¹².

1,3-Cyclooctadiene-iron tricarbonyl (VII) [NMR: $q 5.24 \tau (2 H)$, m 7.0 τ (2 H), m 8.2 τ (4 H) and m 8.9 τ (4 H)] can be easily obtained in crystalline form (m.p. $36.5-37^{\circ}$ C) from the photochemical reaction of Fe(CO)₅ and 1,3-cyclo-octadiene. VII seems to be thermally less stable than I: this may be due to conformational strain resulting when the conjugated double bonds are forced into one plane by coordination⁷).

We are grateful to Dr.R.Rienäcker for samples of the pure cyclooctadienes, to Dr.D.Henneberg for the mass spectrometric data and to Miss D.Frischke for measuring the NMR spectra.
