(Received in UK 10 October 1973; accepted for publication 29 October 1973)

There has been considerable interest in the stereochemical dependence of two and three-bond phosphorus-proton coupling constants.^{1, 2} Recently it has been reported that the corresponding phosphorus-carbon coupling constants, ${}^{2}J(PCC)^{3}$, ${}^{2}J(POC)^{4}$, ${}^{2}J(PNC)^{5}$, ${}^{3}J(PCCC)^{6}$, and ${}^{3}J(POCC)^{7}$ are also markedly stereochemically dependent. We now present preliminary results on the threebond coupling ${}^{3}J(PNCC)$.

Aminophosphorus compounds of type $\underline{1}$ provide a good substrate for investigating the conformational dependence of ${}^{3}J(PNCC)$ since at low temperature all four methyl groups are diastereotopic due to molecular asymmetry combined with slow rotation around the PN bond.², ⁸ The low temperature ${}^{13}C$ nmr data for some compounds of this type are given in Table I. In the aminophosphines $\underline{1a}$ and $\underline{1b}$, ${}^{3}J(PNCC)$ shows a very marked conformational dependence as the value for one methyl group is 23 Hz compared with 0-7 Hz for the other three methyl groups. The range of ${}^{3}J(PNCC)$ values is much smaller in the corresponding sulphides ($\underline{2a}$ and $\underline{2b}$), though a stereochemical effect is evident. Although the signs of the coupling constants cannot readily be determined

¹³C Chemical Shifts $(\delta)^a$ and ³¹P ---¹³C Coupling Constants (J) in Table I. Aminophosphorus Compounds.

^a Relative to internal TMS.

^b Data obtained in $CDC\ell_3$ solution. ^c Data obtained in $CD_2C\ell_2$ solution.

d Chlorine exchange appears to become rapid above ambient temperature, inverting configuration at phosphorus and rendering all four methyl groups isochronous.

since ${}^{4}J(PNCCH)$ is close to zero, some relative sign information may be obtained by observing the spectra at higher temperature where rotation around the PN bond is fast on the NMR time-scale. Thus it appears from the time averaged J value for Me(A) and Me(B) in <u>la</u> at 55° that the individual coupling constants have the same sign for these two carbon nuclei in different isopropyl groups.

The ${}^{31}\text{PN}{}^{13}\text{C}$ coupling constants for the anisochronous methine carbon atoms are also reported in Table I. In the aminophosphines <u>la</u> and <u>lb</u> these ${}^{2}\text{J}(\text{PNC})$ couplings clearly differ in sign as the time-averaged value obtained at 55° is approximately equal to half the difference between the two lowtemperature values. Simonnin <u>et</u>. <u>al</u>. have previously reported⁵ similar results for the methyl carbon atoms in chloro-N,N-dimethylaminophenylphosphine, C₆H₅ $P(C\ell)NMe_2$ (<u>3</u>). It is interesting that in the phosphine sulphides <u>2a</u> and <u>2b</u>, ${}^{2}\text{J}(\text{PNC})$ is very small for both methine carbon nuclei.

It has been suggested that a large positive value for ${}^{3}J(PNCH)$ and ${}^{2}J(PNC)$ in <u>3</u> is associated with the N-methyl group <u>cis</u> to the phosphorus lone pair.^{2, 5} Indeed, it appears that a proximate lone pair of electrons usually makes a positive contribution to reduced coupling constants by a "through space" effect.⁹ Thus the large value of ${}^{3}J(PNCC)$ observed for Me(B) in <u>la</u> and <u>lb</u> could result from a preferred molecular conformation that places this methyl group close to the phosphorus lone pair.

<u>Acknowledgment</u>: We are grateful to the Science Research Council for an allocation of time on the Bruker HX-90E spectrometer at P.C.M.U., Harwell.
