(Received in UK 7 November 1975; accepted for publication 13 November 1975)

Attack on halogen by tervalent phosphorus has been commonly observed and these compounds have been widely used as debrominating agents.¹ Attack on halogen by phosphide anions is rare² and we are aware of only one example of debromination, that of 1,2-dibromoethane to give ethylene.³ In view of this a similar debromination of vinyl dibromides seemed likely.

Aguiar has investigated the reactions of diphenylphosphide with 1,2dichloroalkenes⁴ and obtained the corresponding diphosphines (1). We have now shown that similar reactions with 1,2-dibromoalkenes follow a quite

<u>cis</u> ClCH = CHCl + $2Ph_2PLi \longrightarrow \underline{cis} Ph_2PCH = CHPPh_2 + 2L1Cl (1)$ different route involving initial attack on halogen, presumably due to the greater polarisability of bromine than chlorine.

The addition of 1,2-dibromoethylene (2a; 64% <u>cis</u>:36% <u>trans</u> by nmr) to a refluxing solution of an equimolar quantity of lithium diphenylphosphide in THF gave, after 2 hours, acetylene. A similar reaction with two mole equiva-

BrCR¹ = CR²Br + Ph₂PLi \longrightarrow R¹C = CR² (2a) R¹ = R² = H (2b) R¹ = Ph, R² = H (2c) R¹ = R² = Ph

lents of phosphide gave acetylene and after oxidation with hydrogen peroxide and chromatography on silica gel, <u>trans</u>-1,2-vinylenebis(diphenylphosphine) dioxide $(3)^4$ in small yield.

Analogous reactions with 1,2-dibromostyrene (2b; 29% <u>cis</u>:71% <u>trans</u> by nmr)⁵ and 1,2-dibromostilbene (2c) gave the corresponding acetylenes (see Table). Appreciable amounts of unreacted dibromides were recovered from reactions with one mole equivalent of phosphide; in the reaction with dibromostilbene, (1,2diphenylvinyl)diphenylphosphine oxide (4) was also isolated after chromatography.

(3)
$$\begin{array}{c} Ph_2P = 0 \\ H = 0 \\ \end{array} \begin{array}{c} Ph_2 P = 0 \\ PPh_2 \end{array} \qquad Ph = 0 \\ H = 0 \\ \end{array} \begin{array}{c} Ph \\ Ph \\ H = 0 \\ \end{array} \begin{array}{c} Ph \\ Ph \\ Ph \\ H \\ \end{array} \begin{array}{c} C = 0 \\ PPh_2 \end{array} \begin{array}{c} Ph \\ (4) \\ Ph \\ Ph \\ H \\ \end{array}$$

Reaction of dibromides (2a), (2b) and (2c) with one and two mole equivalents of lithium diphenylarsenide gave the corresponding acetylene (see Table) TABLE: Percentage Yields of Acetylenes from Debromination Reactions

Dibromide	Lithium diphenylphosphide		Lithium diphenylarsenide	
	one mole	two mole	one mole	two mole
BrCH=CHBr	50	80 37	33	46
BrCPh=CHBr	1	37	2)) ((
BrCPh=CPhBr	19	33	32	54

The recovery of dibromide and the lower yields obtained from reactions with an equimolar quantity of phosphide or arsenide suggest a 1:2 stoichiometric requirement for the reaction and hence the mechanism shown in the scheme.

 $Ph_0X \xrightarrow{\frown} BrCR^1 = CR^2Br \longrightarrow R^1C \equiv CR^2 + Br^- + Ph_0XBr \xrightarrow{Ph_2X} Ph_0XXPPh_0 + Br^-$

Attempts to gain information about the stereochemistry of the debromination were unsuccessful due to the rapid <u>cis</u> to <u>trans</u> isomerisation of the dibromides under the reaction conditions.⁶

The yields of phenyl acetylene and tolan are probably reduced by further reaction with phosphide⁷ and arsenide⁸. This was confirmed in the case of 1,2-dibromostilbene by the isolation of (4). Volatility and a relative low reactivity towards nucleophiles presumably excludes this reaction for acetylene, although smaller steric effects apparently allow some substitution at carbon in this case.

We thank the N. Ireland Department of Education for a grant and David Stevens for some experiments.
