

A CONVENIENT METHOD FOR MIXING  $^1\text{H}$  AND  $^{13}\text{C}$  LANTHANIDE INDUCED SHIFT (LIS) CALCULATIONS. A TECHNIQUE FOR FACILITATING  $^{13}\text{C}$  ASSIGNMENTS

(Received in USA 26 January 1976; received in UK for publication 16 April 1976)

Although  $^1\text{H}$  LIS data can generally be correlated by the McConnell-Robertson pseudo contact shift equation,<sup>1</sup> similar studies with  $^{13}\text{C}$  data have met with mixed success presumably due to significant contact shift contributions,<sup>2</sup> and, in several cases, to an insufficient number of LIS data to define the lanthanide shift reagent (LSR)-substrate geometry.<sup>3</sup>

We wish to report a novel approach for the treatment of LSR data for  $^{13}\text{C}$  assignments which builds upon our previously described method<sup>4</sup> for determining LSR-substrate geometries from  $^1\text{H}$  shift data. The method depends on a computer program which uses LIS ratios to determine the best position of the lanthanide with respect to a substrate framework, by minimizing the shift ratio function  $\sum_{i < j} (R_{\text{obs},i,j} - R_{\text{calc},i,j})^2$ ; nmr assignments, i.e. the association of LIS's with particular nuclear positions, are made as an integral part of the optimization process. Although the shift ratio  $R_{i,j}$  is a function of the lanthanide position and the *i*th and *j*th nuclear positions, the scale constant *K* disappears from the ratio and the method provides a simple means for mixing  $^{13}\text{C}$

$$R_{\text{calc},i,j} = \frac{\text{LIS}_{\text{calc},i}}{\text{LIS}_{\text{calc},j}} = \frac{K(3\cos^2\theta_i - 1)/r_i^3}{K(3\cos^2\theta_j - 1)/r_j^3}; \quad R_{\text{obs},i,j} = \frac{\text{LIS}_{\text{obs},i}}{\text{LIS}_{\text{obs},j}}$$

and  $^1\text{H}$  data (as  $^{13}\text{C}/^{13}\text{C}$  LIS and  $^1\text{H}/^1\text{H}$  LIS ratios) in the same calculation.

The use of the method will be demonstrated for compounds 1 and 2.

Compound 1.  $^1\text{H}$  and  $^{13}\text{C}$  shifted spectra were recorded with  $\text{Yb}(\text{FOD})_3$ . Because of severe overlap in the  $^1\text{H}$ -LSR spectra, accurate lanthanide induced shifts could be obtained for only three of the nine bicyclic proton resonances. Although these three data are insufficient to reliably determine the LSR-substrate geometry, our ratio method allows them to be combined with the seven  $^{13}\text{C}$ -LIS data, and the Yb position determined from the mixed  $^1\text{H}$ - $^{13}\text{C}$  ratio calculations provides excellent agreement between the observed and calculated data (Table 1). The Yb...O distance is 2.99 Å, the Yb...O=C angle is  $137^\circ$  and the ratio  $(\sum_{i<j} |R_{\text{obs},i,j} - R_{\text{calc},i,j}| / \sum_{i<j} R_{\text{obs},i,j})$  and shift

$(\sum_i |LIS_{\text{obs},i} - LIS_{\text{calc},i}| / \sum_i LIS_{\text{obs},i})$  residuals are, respectively, 0.019 and 0.010.

The program automatically makes  $^{13}\text{C}$  assignments (Table 1) in the process of optimizing the lanthanide position, and the assignments were entirely consistent with those made on the basis of chemical shift and model compound studies on compound 1.<sup>5</sup> It should be noted that  $\text{C}_5$  and  $\text{C}_8$  could not be uniquely assigned with this method because the carbons are symmetrically disposed with respect to the Yb...O=C plane.

TABLE 1.  $\text{Yb}(\text{FOD})_3$   $^1\text{H}$  and  $^{13}\text{C}$  LIS DATA FOR COMPOUND 1

	$\delta$ (ppm)	LIS (Hz)		Assignments	
		Obsd.	Calcd.	Possible	Correct
$^1\text{H}$	2.72	2063	2071	$\text{H}_1, \text{H}_4, \text{H}_6$	$\text{H}_4$
	3.75	891	882	$\text{H}_1, \text{H}_4, \text{H}_6$	$\text{H}_1$
	4.35	860	862	$\text{H}_1, \text{H}_4, \text{H}_6$	$\text{H}_6$
$^{13}\text{C}$	174.3	--- <sup>a</sup>		$\text{C}_3$	$\text{C}_3$
	72.1	479	492	$\text{C}_6, \text{C}_1$	$\text{C}_6$
	53.5	644	627	$\text{C}_1, \text{C}_6$	$\text{C}_1$

	23.9	560	553	$\text{C}_8, \text{C}_5, \text{C}_7$	$\text{C}_8$
	19.8	456	463	$\text{C}_7, \text{C}_8, \text{C}_5$	$\text{C}_7$

<sup>a</sup> The carbonyl carbon resonance could not be detected following addition of LSR.

Compound 2: Obvious assignments were made from the  $^1\text{H}$ ,  $^{13}\text{C}$  and  $^{13}\text{C}$  off-resonance decoupled spectra on the basis of chemical shifts and couplings. In the  $^{13}\text{C}$  spectrum, for example, the assignments for  $\text{C}_2$  and  $\text{C}_{14}$  are clear, and the decoupled spectrum differentiates  $\text{C}_6$  and  $\text{C}_1$  from  $\text{C}_5$  and  $\text{C}_9$  as it does  $\text{C}_{10}$ ,  $\text{C}_{13}$  and  $\text{C}_{11}$ ,  $\text{C}_{12}$  from  $\text{C}_7$ ,  $\text{C}_8$  (Table 2). The  $^{13}\text{C}$  and  $^1\text{H}$  LSR-shifted spectra were recorded with  $\text{Eu}(\text{DPM})_3$  and  $\text{Yb}(\text{DPM})_3$  and the Yb/Eu LIS ratios used to identify contact shifted carbons: e.g.  $\text{C}_5$  in the case of  $\text{Eu}(\text{DPM})_3$ .<sup>6,7</sup>

An LSR-substrate geometry fit and  $^{13}\text{C}$  assignment calculation were performed with the twelve  $^1\text{H}$  and ten  $^{13}\text{C}$  data giving ratio and shift residuals of 0.080 and 0.078 respectively, and a Eu...O distance of 2.46 Å and Eu...O=C angle of 147°. The number of possible  $^{13}\text{C}$  assignments was

36.05	111.83	t	4.06	$\text{C}_5, \text{C}_9$	$\text{C}_9$

(a) The twelve proton data were taken from ref. 4 and are not included in the table. (b) The Eu...O distance was 2.46 Å. Proton only calculations gave an O...Eu distance of 2.44 Å with ratio and shift residuals of 0.060 and 0.048. (c) The carbonyl carbon resonance could not be detected following addition of the LSR.

limited to those possibilities consistent with the off-resonance and chemical shift data<sup>8</sup> (16 total combinations). The method uniquely assigns resonances

to  $C_1$ ,  $C_6$ ,  $C_{10}$ ,  $C_{11}$ ,  $C_{12}$ , and  $C_{13}$ , and, more importantly, it also assigns the ipso-carbons,  $C_7$  and  $C_8$ . LSR calculations with LIS ratios are equivalent to computations which compare observed and calculated shifts<sup>1,2</sup>, with the added advantage that LIS data from different nuclei can be readily mixed in the same analysis.<sup>9</sup> Although  $n$  shifts for a given nucleus can afford  $n(n-1)/2$  ratios, it is important to realize that the ratio method generates no additional data. Specification of the three lanthanide coordinates and two  $K$  values in a  $^{13}C$ - $^1H$  analysis requires a minimum of five LIS data which result in three, unique  $K$ -less ratios.

6.  $Eu(DPM)_3$  data are used here for demonstration purposes. A number of groups<sup>7</sup> have noted that Eu causes the largest contact shift contribution of the available lanthanides. The corresponding calculations using  $Yb(DPM)_3$  data gave a O...Yb distance of 2.92 Å, a C=O...Yb angle of 143° and residuals of 0.102 (ratio) and 0.077 (shift). These calculations included  $C_5$  but we were unable to accurately determine shifts for  $C_7$  and  $C_8$  due to broadening and intensity problems. In this, and other cases, the use of Eu data has advantages if contact shifted nuclei can be identified.

8. Allowing indiscriminate assignments solely on the basis of agreement of observed and calculated values can lead to incorrect results. For example, the Yb observed/calculated shifts for  $C_{13}$  and  $C_{11}$ , respectively 277.4/269.4 and 269.0/278.7, suggest that the assignments be switched. Similarly, for  $C_1$  and  $C_9$  the Yb data are 460.2/478.2, 454.6/506.2, and the Eu data are 123.7/117.2 and 111.8/122.2. However, initial chemical shifts and off-resonance decoupling data show that the initial assignments are correct.
9. The mixed calculations have also been successfully used for  $^{13}C$  assignments in camphor, norcamphor, phenaleneone, a series of methoxy naphthalenes and 6-exo-phenoxy-2-benzyl-3-oxo-2-azabicyclo[2.2.1] heptane.
