

A STEREOSELECTIVE SYNTHESIS OF DISUBSTITUTED TRANS-ALKENES BY THE REACTION OF
TRANS-ALKENYL TRIALKYLALUMINATES WITH ALKYL HALIDES AND SULFONATES

(Received in USA 13 January 1976; received in UK for publication 27 April 1976)

A markedly rate-enhancing effect of polar solvents, such as tetrahydrofuran (THF), has been noted recently in the coupling of aryllithiums¹ or alkenyllithiums² with alkyl halides. Although the latter reaction provides a stereospecific route to alkenes, the synthesis of the requisite stereo-defined alkenyllithium via lithiation of alkenyl halides which, in turn, requires the stereoselective preparation of the halides is often cumbersome. To alleviate this difficulty, the direct use of stereo-defined alkenylaluminums³ or alkenylborons⁴ readily obtainable via the respective hydrometallation in the alkenyl-alkyl coupling has been explored.⁵

We now report that trans-alkenyltrialkylaluminates (1) prepared by the reaction of alkynes with diisobutylaluminum hydride (DIBALH), followed by treatment with an equimolar amount of n-butyllithium, react with certain alkyl halides to produce the corresponding trans-alkenes (>98% trans), thereby providing a simple one-pot procedure for the stereoselective preparation of trans-alkenes.

The stereochemistry of the products has been established by a combination of ¹H and ¹³C NMR, IR (≈970 cm⁻¹) and GLC. As shown in Table 1, this reaction proceeds well with more reactive halides and sulfonates, such as methyl iodide, allyl bromide, propargyl bromide, benzyl iodide

and α -chloromethyl methyl ether. Primary alkyl iodides and sulfonates give the desired coupling products in somewhat lower yields.

Table 1. Stereoselective Synthesis of trans-Alkenes

| Acetylene (RC \equiv CH) | R ¹ X | Reaction Conditions ^a | | Yield ^b (%) of $\begin{array}{c} \text{R} \quad \text{H} \\ \diagdown \quad / \\ \text{C}=\text{C} \\ / \quad \diagdown \\ \text{H} \quad \text{R}^1 \end{array}$ |
|----------------------------|-------------------------------------|----------------------------------|------------------|---|
| | | Solvent | Time (hr) | |
| 1-Heptyne | Methyl iodide | THF | 24 | 65 |
| 1-Heptyne | <u>n</u> -Propyl mesylate | THF | 24 | 44 |
| 1-Hexyne | <u>n</u> -Octyl mesylate | hexane | 24 | 41 |
| 1-Hexyne | <u>n</u> -Octyl iodide | THF | 110 ^c | 49 |
| 1-Hexyne | Allyl bromide | THF | 3 | 73 (60) |
| <u>tert</u> -Butylethylene | Allyl bromide | hexane-THF | 3 | 79 (65) |
| 1-Hexyne | Propargyl bromide | THF | 6 | 60 ^d |
| 1-Hexyne | Benzyl iodide | THF | 18 ^e | 51 |
| 1-Hexyne | Benzyl bromide | THF | 12 ^c | 46 |
| 1-Hexyne | α -Chloromethyl methyl ether | THF | 1 | 51 |

^aHydroalumination was carried out at 50-55° for 2-4 hr in hexane. n-Butyllithium in hexane was added at 25°. The reaction of 1 with R¹X was carried out in the solvent specified at 25°, unless otherwise mentioned.

^bBy GLC. The numbers in parentheses are isolated yields. The stereoisomeric purity in each case established by GLC, ¹H NMR and/or ¹³C NMR is \geq 98%.

^cUnder reflux. ^dtrans-1,2,4-Nonatriene was formed exclusively. ^e40°.

Interestingly, the reactions with tert-alkyl halides are rapid, but appear to follow considerably different reaction paths. For example, the reaction of 1 (R=n-C₄H₉-) with 1-methyl-

1-chlorocyclohexane yielded within 1 hour at 0° 1-methyl-1-n-butylcyclohexane (19%) and 1-methyl-1-isobutylcyclohexane (17%) along with 1-methylcyclohexane (40%) and methylcyclohexane (15%) without producing the desired 1-methyl-1-hexenylcyclohexane.

The transfer of the n-butyl or isobutyl group of 1 in preference to the alkenyl group appears unprecedented.⁶ It seems difficult to rationalize the results in terms of any ionic two-electron transfer process. The relative transferability is consistent with a free-radical process. However, no homo-coupled product has been detected. The one-electron transfer mechanism involving 2 within a solvent cage seems to accommodate the experimental observations, although this point needs to be established by further studies.

The reaction of an alkenyltrialkylaluminum similar to 1 with aldehydes or carbon dioxide has previously been interpreted in terms of the predissociation of the ate complex into the corresponding alkenyllithium and trialkylalane.^{6a} While such a mechanism cannot be ruled out on a rigorous basis, our attempt to promote the hypothetical dissociation reaction by the addition of an equimolar amount of n-butyllithium to 1 in hexane-ether mixture at 25° did not cause any noticeable change other than the well-documented slow reaction of n-butyllithium with ether.⁷ Thus, the NMR features of both n-butyllithium ($\delta = -1.2$ ppm for 2 α -hydrogens) and 1 ($\delta = 6.2 - 6.3$ ppm for 2 alkenyl hydrogens) remain unchanged on mixing. It is therefore likely that 1 is directly involved in the carbon-carbon bond-forming process.
