<u>Summary.</u> MINDO/3 calculations indicate that tetracyclo  $[5.5.1.0^{4,13}0^{10,13}]$  tridecahexaene  $(\underline{1a})$  is nonplanar ( $D_2$  symmetry) in its ground state with pronounced bond alternance.

Recently it was proposed that a central tetracoordinate carbon atom enclosed by a [12] annulene ( $\underline{1}$ ) should have a planar shape [1]. It was argued that the energetically unfavourable HOMO ( $a_{2u}$ ) at the planar central atom is stabilized by interaction with the LUMO of a 12  $\pi$  system [2].

To test this proposal we have carried out MINDO/3 calculations [3] on  $\underline{1}\underline{a}$ , the corresponding dianion  $\underline{1}\underline{b}$  and dication  $\underline{1}\underline{c}$  and the analogous [14]annulenes  $\underline{2}$  and  $\underline{3}$  by minimizing the total energy with respect to all geometrical parameters.

The total energy of  $\underline{1}\underline{a}$ ,  $\underline{1}\underline{b}$  and  $\underline{1}\underline{c}$  under various geometrical constraints was studied in detail. For the neutral species  $\underline{1}\underline{a}$  it was found that the structure of Towest energy belongs to point group  $D_2$ . The angles and bond lengths of  $\underline{1}\underline{a}$  together with the structural parameters of the ionic counterparts  $\underline{1}\underline{v}$  and  $\underline{1}\underline{c}$  are collected in Figure 1. From Table 1 it is seen that the two structures with a planar central atom are much higher in energy; the energy difference between  $D_2$  and  $D_{2h}$  is 49.09 kcal/mol, the  $D_{4h}$  triplet conformation is separated by 59.61 kcal/mol from the structure of lowest energy. This result is anticipated if one compares the energy calculated for the structural deformation  $T_{d} \rightarrow D_{4h}$  of methane (80-100 kcal/mol) [2] [5] [6] [7] with resonance energies calculated for annulenes [8]. Inspection of Figure 1 shows a marked bond alternation of the peripheral ring in the  $D_{2h}$  and  $D_2$  structure of  $\underline{1}\underline{a}$ .

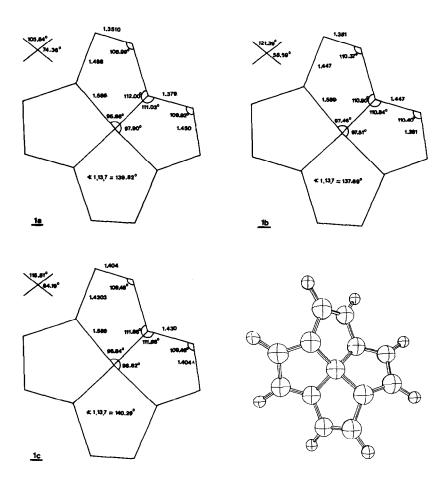

Figure 1. Bond lengths and bond angles of <u>la</u>, <u>lb</u> and <u>lc</u> together with perspective view of <u>la</u>

In Table 2 we have listed the calculated net charges of the carbon atoms. While in both planar forms  $D_{2h}$  and  $D_{4h}$  there is a strong negative charge at the central atom, there is no charge separation between the central unit and the surrounding moiety in the structure of lowest energy,  $D_2$ .

To study geometrical preferences as a function of the occupation numbers of the frontier orbitals and to simulate the effect of electron-donating and electron-withdrawing substituents at the molecular periphery, we also performed calculations on the charged species  $\underline{1}\underline{b}$  and  $\underline{1}\underline{c}$ . Once again the D<sub>2</sub> structure emerges as the one of lowest energy; in  $\underline{1}\underline{b}$  D<sub>4h</sub> and D<sub>2</sub> are separated by 46.93 kcal/mol, while the energy difference in case of the dication  $\underline{1}\underline{c}$  amounts to 44.40 kcal/mol. A comparison between the structures  $\underline{1}\underline{a}$ ,  $\underline{1}\underline{b}$  and  $\underline{1}\underline{c}$  shows that the bond localization is less marked in the two charged systems; both planar structures  $\underline{1}\underline{b}$  and  $\underline{1}\underline{c}$  belong to the point group D<sub>4h</sub>. Inspection of Table 2 leads to the surprisingly result, that the central atom carries more negative charge in the cationic compound  $\underline{1}\underline{c}$  than in  $\underline{1}\underline{b}$ . A common aspect of the three systems  $\underline{1a}$ ,  $\underline{1b}$  and  $\underline{1c}$  is the remarkable tendency to avoid a planar conformation of the central carbon atom and distribute the strain energy over all carbon centers. This leads to highly directed " $\pi$ -orbitals" at C<sub>1</sub>, C<sub>4</sub>, C<sub>7</sub> and C<sub>10</sub> as shown below. The sum of all carbon-carbon angles at these centers reaches a value of 348.22<sup>0</sup> in  $\underline{1a}$ and 345.17<sup>0</sup>/349.95<sup>0</sup> in  $\underline{1b}/\underline{1c}$  respectively. This sum is in between the value of 328.41<sup>0</sup> for sp<sup>3</sup> hybridization and 360<sup>0</sup> for sp<sup>2</sup> hybridization.

The tendency to maintain a tetrahedral carbon atom at the center in  $\frac{2}{2}$  and  $\frac{3}{2}$  is more pronounced than in  $\frac{1}{2}$  due to the greater flexibility of the systems. Once again our calculations predict a strong bond localization for both structures leading to a pair of unequivalent five- and six-membered rings around the nonplanar central atom.

This study indicates that the various synthetic attempts [1] [9] towards a compound like  $\frac{1}{2}$  to  $\frac{3}{2}$  with a planar tetracoordinated central atom will lead at most to energetically unfavourable olefinic ring systems.

## Table 1

Heats of formation ( $\Delta H_f$  in kcal/mol) of <u>la</u>, <u>lb</u> and <u>lc</u>

System	Point Group	Spin Multiplicity	∆H <sub>f</sub> (kcal/mol)
	D <sub>4h</sub>	Triplet	262.08
<u>1</u> a	D <sub>2h</sub>	Singlet	251.57
	D <sub>2</sub>	Singlet	202.48
Ĩ₽	D <sub>4h</sub>	Singlet	314.16
	D <sub>2</sub>	Singlet	267.23
<u>1c</u>	D <sub>4h</sub>	Singlet	654.06
	D <sub>2</sub>	Singlet	609.65
