## TRIMETHYLSILYL IODIDE. PREPARATION FROM AND CATALYTIC BEHAVIOR WITH PHENYLSELENOTRIMETHYLSILANE

## Michael R. Detty

Abstract - Trimethylsilyl iodide (TMSI) and diphenyldiselenide are produced by the addition of iodine to phenylselenotrimethylsilane. TMSI generated in this manner cleaves a variety of C-O bonds and catalyzes 1,2 and 1,4 additions of phenylselenotrimethylsilane to various carbonyl compounds.

Trimethylsilyl iodide is a useful reagent for effecting a variety of transformations in organic synthesis including dealkylations of ethers, <sup>1</sup> esters, <sup>2</sup> carbamates, <sup>3</sup> and ketals, <sup>4</sup> deoxygenations of sulfoxides and N-oxides, <sup>5</sup> and conversion of alcohols into the corresponding iodides. The sensitivity of the reagent to moisture has prompted a number of methods for the <u>in situ</u> generation of trimethylsilyl iodide. <sup>1b,7</sup> We wish to report a facile synthesis of the reagent that is adaptable for both preparative runs and in situ generation.

The addition of iodine to phenylselenotrimethylsilane  $(1)^{8}$  gives a mildly exothermic reaction in which diphenyldiselenide and trimethylsilyl iodide (2)

-SeSi(CH<sub>3</sub>)<sub>3</sub> + 1/2 I<sub>2</sub> 
$$\rightarrow$$
 1/2 -SeSe-

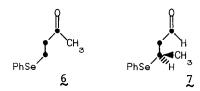

are produced as the only detectable products (eq 1). Presumably, a molecule of iodine reacts with a molecule of 1 to give 2 and phenylselenenyl iodide. The latter species must react rapidly with a second molecule of 1 to give 2 or disproportionate to iodine and diphenyldiselenide. The trimethylsilyl iodide can be isolated in 80-90% yield as an air- and light-sensitive, colorless oil (bp 103-107°) or can be generated in situ in a variety of solvents including methylene chloride, chloroform, and carbon tetrachloride. The major advantage of this method of preparation of 2 is that quantities of the reagent can be prepared within 6 h in 60-70% overall yield in 3 steps from diphenyldiselenide, trimethylsilyl chloride, sodium, and iodine.

Table I contains several examples of C-O bond cleavage by trimethylsilyl iodide generated in situ by this method.  $^{12}$  In a typical procedure, the substrate

and 1.05 molar equivalents of 1 are treated with 0.50 molar equivalent of iodine in 3 mL of solvent per mmol of substrate. No iodine color is visible. Workup consists of a thorough washing of the reaction mixture with sodium bicarbonate solution. The diphenyldiselenide can be removed by fractional crystallization, chromatography, or, for volatile products, as a distillation pot residue. The slight excess of 1 employed may well act as a hydrogen iodide scavenger to give benzeneselenol and trimethylsilyl iodide.

Presumably, the C-O cleavages occur by nucleophilic attack by iodide on a carbon of a silyl dialkyl onium species, such as 3, following initial electrophilic attack of silicon on oxygen. 1,7 We felt that the electrophilic nature of 2 might be further exploited synthetically as a catalyst for the 1,4-additions of phenylselenotrimethylsilane to enones (via 4) and for 1,2-additions to aldehydes and ketones (via 5). Regeneration of the catalyst would occur by nucleophilic attack of iodide ion on 1 to give phenylselenide anion and 2. The 1,2-addition of 2 to aldehydes and the 1,4-addition of 2 to enones have been reported perhaps indicating the intermediacy of 4 and 5.

When the substrates in Table II were treated with 2.5 mole% of iodine and 1.05 equivalents of 1, a mildly exothermic reaction ensued to give the indicated products within 15 min. Benzaldehyde and p-methoxybenzaldehyde showed 90% conversion to the 1,2-adducts shown. Addition of water returned the aldehydes quantitatively. Methyl vinyl ketone gave essentially complete conversion to a 68:32 mixture of the E and Z adducts indicated and small amounts (~5%) of the hydrolysis product 6. Hydrolysis of the reaction mixture gave 6 in 90% yield. Crotonaldehyde was somewhat unusual in that a 3:1 mixture of both the 1,4-adducts and the 1,2-adduct was obtained. The E and Z isomers appeared to be present in nearly equal amounts. Hydrolysis of the adducts gave 7 in 70% yield and crotonaldehyde in 20% yield. Identical results were obtained by adding 5 mole% of 2 directly to a solution of substrate and 1. Similarly, the addition of 5 mole% of potassium iodide and 18-crown-6 to an equimolar solution of methyl vinyl ketone and 1 in THF gave complete reaction within 0.5 h at room temperature to give a 72:28 mixture of the E and Z 1,4-adducts.

An interesting comparison can be made between 1 and phenylthiotrimethylslane (8) and methylthiotrimethylsilane (9). 17 Although 1 reacts readily with iodine, 8 and 2 give no detectable reaction after 24 h. Similarly, potassium iodide is a poor catalyst for initiating the 1,2- and 1,4-additions of 8 to aldehydes and enones. This is perhaps indicative that the silicon-sulfur bond is significantly stronger than the silicon-selenium bond.
