A NEW SYNTHETIC METHOD OF  $\alpha$ -AMINO ACIDS FROM  $\alpha$ -METHOXYURETHANES<sup>1</sup>

\* Tatsuya Shono, Yoshihiro Matsumura, and Kenji Tsubata Department of Synthetic Chemistry, Faculty of Engineering, Kyoto University, Yoshida, Sakyo, Kyoto 606, Japan

Reaction of a-methoxyurethanes with phenylisocyanide gave the corresponding amides of  $\alpha$ -amino acid in reasonable yields.

As a part of our continuing study<sup>2</sup> on the synthetic application of  $\alpha$ -methoxyurethanes (2) being easily obtainable by the anodic oxidation of urethanes (1) in methanol.<sup>3</sup> we have found that in the presence of a Lewis acid catalyst, phenylisocyanide reacts with 2 to afford  $\alpha$ -amino acid derivatives 3 (Scheme 1). A recent communication<sup>4</sup> describing the synthesis of  $\alpha$ -amino cyanides from  $\alpha$ -methoxyamides and trimethylsilylcyanide prompted us to report our results.

The synthesis of valine is shown below as a typical example. To a stirred solution of titanium tetrachloride (5 mmol) in methylene chloride (10 ml) was added a solution of 2 ( $R^1 = H$ ,  $R^2 = i-Pr$ ) (5 mmol) in methylene chloride (3 ml) at - 70 °C. After the reaction mixture was stirred for 5 minutes, phenylisocyanide (6.8 mmol) was added, and the reaction was completed after the reaction mixture was allowed to stand for 3 hr at - 70 °C. Then, diluted hydrochloric acid was added into the reaction mixture and the organic layer was extracted with methylene chloride. Isolation of 3 ( $R^2 = H$ ,  $R^2 = i-Pr$ ) was achieved by column chromatography (82% yield). The conversion of 3 to 4 was accomplished as follows. Hydrolysis of 3  $(R^1 = H,$  $R^2 = i-Pr$ ) by refluxing it in 47% hydrobromic acid for 4 hr afforded  $d$ , *l*-valine in a 63% yield. Other results are summarized in Table I.<sup>5</sup>

Since a variety of  $\alpha$ -methoxyurethanes can easily be synthesized by the anodic oxidation of urethanes, the synthesis of other essential amino acids is achievable by this method.
