UNPRECEDENTED REARRANGEMENTS VIA ALLENES AS  $\pi\text{-}\text{PARTICIPANTS}$  IN  $\alpha\text{-}\text{ACYLIMINIUM}$  ION CYCLISATIONS  $^1$ 

Peter M.M. Nossın and W.Nico Speckamp<sup>\*</sup>, Laboratory of Organic Chemistry, University of Amsterdam, Nieuwe Achtergracht 129, 1018 WS Amsterdam, The Netherlands.

Abstract: Upon HCOOH reaction of ethoxylactams <u>la-ld</u> the terminally unsubstituted allenes <u>la</u> and <u>ld</u> underwent a [3,3] sigmatropic rearrangement. The dimethyl allenes <u>lb</u> and <u>lc</u> afforded only products from an  $\alpha$ -acyliminium ion cyclisation.

Cationic  $\pi$ -cyclisation of  $\alpha$ -acyliminium ions has been applied in the synthesis of various heterocyclic systems<sup>2</sup>. Generally the formation of sixmembered rings is favored although minor variations in the electronic bias of the  $\pi$ -moiety severely influence the mode of ring closure<sup>3</sup>. Aiming at the development of novel methods for selective formation of heterocyclic rings of different sizes the allenic bond has been investigated in its behaviour towards  $\alpha$ -acyliminium ions. Terminal allenes have been shown to possess sufficient reactivity as m-nucleophiles in cationic cyclisation reactions<sup>4</sup>. HCOOH treatment (18 hr, r.t.) of ethoxylactam la<sup>5</sup>, obtained in the usual manner by NaBH,/H<sup>+</sup> reduction and acid work-up (HC1-EtOH)<sup>6</sup> of the corresponding imide, yielded a mixture of 4 formates 2a-5a in an estimated ratio of 2:1:1:2 (<sup>1</sup>H-NMR), which after hydrolysis (K<sub>2</sub>CO<sub>2</sub>, MeOH, H<sub>2</sub>O) easily could be separated by column chromatography (combined yield The expected  $C_6$  epimeric alcohols <u>2b</u> and <u>3b</u> (Scheme I) were isolated as 96%). a non-separable crystalline fraction (47%) in which the epimer ratio mounted to 7:2. In addition alcohol 4b was obtained as a minor product (15%), m.p. 102.5-106.0°C (EtOAc - hexane).

Quite unexpectedly the other major isomer proved to be the ringopened product <u>5b</u> possessing an unusual diene structure. Yield: 34%, m.p. <u>5b</u>: 66.5-68.0°C (dipe). (250 MHz) <sup>1</sup>H-NMR  $\delta$ (CDCl<sub>3</sub>): 6.34 (d of d, J = 11.9 and 17.9 Hz, 1H, C<u>H</u> =  $\begin{array}{l} \mathrm{CH}_2\); \ 5.29 \ (\mathrm{d}, \ \mathrm{J}_{\mathrm{trans}} = 17.9 \ \mathrm{Hz}, \ \mathrm{1H}, \ \mathrm{CH} = \mathrm{CH}_2\); \ 5.17 \ (\mathrm{d}, \ \mathrm{J}_{\mathrm{cis}} = 11.9 \ \mathrm{Hz}, \ \mathrm{1H}, \ \mathrm{CH} = \mathrm{CH}_2; \\ 5.20 \ \mathrm{and} \ 4.94 \ (2 \ \mathrm{broad} \ \mathrm{s}, \ 2\mathrm{H}, \ \mathrm{C} = \mathrm{CH}_2\); \ 5.04 \ \mathrm{and} \ 4.21 \ (2 \ \mathrm{xd}, \ \mathrm{J} = 10.4 \ \mathrm{Hz}, \ 2\mathrm{H}, \ \underline{\mathrm{sec}} - \mathrm{NC}_1\); \\ \mathrm{NC}_1\); \ 4.57 \ (\mathrm{d} \ \mathrm{of} \ \mathrm{d}, \ \mathrm{J} = 3.7 \ \mathrm{and} \ 8.2 \ \mathrm{Hz}, \ \mathrm{1H}, \ \underline{\mathrm{tert}} - \mathrm{NC}_1\); \ 2.60 - 1.70 \ (\mathrm{m}, \ 4\mathrm{H}). \ \mathrm{UV}(\mathrm{EtOH}): \\ \lambda_{\mathrm{max}} = 204 \ \mathrm{nm} \ (\varepsilon = 11.600); \ \lambda_{\mathrm{max}} = 216 \ \mathrm{nm} \ (\varepsilon = 11.000) \ \mathrm{and} \ \lambda_{\mathrm{max}} = 222 \ \mathrm{nm} \ (\varepsilon = 10.900). \\ \mathrm{Its \ structure \ was \ also \ verified \ chemically \ upon \ prolonged \ reaction \ with \ \mathrm{K}_2^{\mathrm{CO}}_3^{\mathrm{aq}} \\ \mathrm{of} \ \underline{5b}, \ \mathrm{which \ produced \ amide} \ \underline{5c} \ \mathrm{with} \ \mathrm{loss \ of \ formaldehyde; \ m.p. \ 52.5 - 56.0^{\circ}\mathrm{C} \ (\mathrm{dipe}). \end{array}$ 

<u>4a</u> X=OCH <u>4b</u> X=H

The formation of <u>5a</u> can be rationalized by either assuming an anchimeric assistance of the amide nitrogen in the fragmentation of <u>A</u><sup>8</sup> (Scheme II) or via a direct [3.3] sigmatropic rearrangement of the  $\alpha$ -acyliminium ion <u>B</u>. Eventually the process depicted in <u>B</u> could be followed by a ring closure via the alternate primary acyliminium ion <u>C</u>, which formally opens a second cyclisation pathway (Scheme II). Until recently examples of the 2-aza-Cope rearrangement <u>B</u> were unknown<sup>9</sup>.

6b R=Me

5b  $R = CH_2OH$ 

5c R = H

7b X=H

By carrying out the cyclisation in different solvent combinations the ratio of (5/2+3+4) could be influenced to a considerable extent (Table). However, we were not able to promote exclusive formation of 5a. Also the submission of either 2, 3, 4 or 5 (a and b) to the conditions of its formation did not indicate a possible conversion of cyclic compounds into acyclic dienes and

## TABLE: Cyclisation of Ethoxylactam la

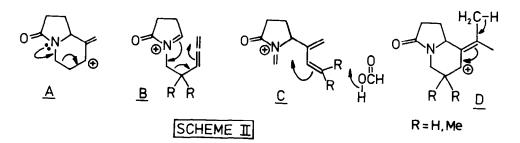

Acid	temp.(°C)	<u>time_(hr</u> )	product_ratio <sup>a</sup>
нсоон	r.t.	18	35/65

a) estimated ratio ringopened/ringclosed (5/2 + 3 + 4) as determined by  ${}^{1}_{\text{H} \cdots \text{NMR}}$ . Accuracy ca 5%.

vice versa. Therefore it seems likely that both types of compounds are formed irreversibly via separate pathways. To investigate this phenomenon a number of structurally related allenes were selected. While HCOOH-cyclisation (18 hr, r.t.) of  $\underline{1b}^5$  and  $\underline{1c}^5$  proceeded quantitatively the products formed possessed the cyclic diene structures <u>6a</u> and <u>6b</u>. Thus instead of the fragmentation route to the acyclic diene an alternative pathway is followed which is depicted in  $\underline{D}$  (Scheme II). Loss of a proton from the gem-dimethyl group supposedly is of lower energy in both the cyclisation and fragmentation routes. Therefore the latter process could only be expected in case the terminal carbon atom of the allene function is not possessing  $\beta$ -hydrogens. The obvious target compound  $\underline{1d}^5$  upon HCOOH-treatment at r.t. (18 hr) afforded a 4:1 mixture of the pyrrolizidines

7a and 7b in 94% yield.

The characterisation of  $\underline{7a}$  rests upon the following <sup>1</sup>H- and <sup>13</sup>C-NMR data:  $\underline{7a}$  oil: (100 MHz) <sup>1</sup>H-NMR  $\delta(CDCl_3)$ : 7.98 (s, 1H, OC<u>H</u>); 5.28 and 5.19 (2 x t, J = 2 Hz, 2H,  $C = C\underline{H}_2$ ); 4.52 (t, J = 7 Hz, 1H,  $\underline{H}_{4a}$ ); 3.99 (m, 1H, deshielded  $\underline{H}_7$ ); 3.38 (d of d, J = 8.5 and 1.5 Hz, 1H,  $\underline{H}_6$ ); 3.13 (d of d, J = 12 and 8.5 Hz, 1H,  $\underline{H}_7$ ); 1.55 and 1.48 (2 x s, 6H, C<u>H</u><sub>3</sub>); 2.90 - 0.85 (m, 4H). (250 MHz) <sup>13</sup>C-NMR  $\delta(CDCl_3)$ : 175.04 (C<sub>2</sub>); 159.83 (O<u>C</u>H); 149.63 (C<sub>5</sub>); 111.10 (C<sub>8</sub>); 84.57 (C<sub>9</sub>); 64.13 (C<sub>4a</sub>); 53.25 (C<sub>7</sub>); 43.46 and 33.65 (C<sub>3</sub> and C<sub>6</sub>); 27.06 (C<sub>4</sub>); 23.86 and 23.78 (C<sub>10</sub> and C<sub>10</sub>,). The relative stereochemistry at C<sub>4a</sub> and C<sub>6</sub> could not be established. The formation of <u>7a</u> and <u>7b</u> can be rationalized on the basis of a process in which fragmentation and ring closure are successive steps (<u>B + C</u>, Scheme II).

Apparently the fragmentation is the preferred route because in the final cyclisation a relatively stable tertiary  $C^{\oplus}$ -ion can be formed. Further investigation on this novel aspect of allene chemistry is in progress.
