

THE REGIOSELECTIVE S → C AND S → N ALLYLIC
 REARRANGEMENT OF S-ALLYLTHIOIMIDATE

Y. Tamaru, M. Kagotani, and Z. Yoshida*

Department of Synthetic Chemistry, Kyoto University,
 Yoshida, Kyoto 606, Japan

Summary. *The regioselective S → C and S → N allylic rearrangements of S-allylthioimidates are realized by thermolysis (160~200°C) or palladium (II) catalysis (1~10 mol% in refluxing THF), respectively.*

In these years the regio- and stereoselective C-C bond forming reactions have been devised making use of the characteristic behavior of the thioamide group.¹ In addition to these, thioamide has been recognized as a versatile synthon by the development of the various high yield transformation methods to other functional groups (e.g., ketones,² amines,³ enamines,⁴ ketene S,N-⁵ and S,S-acetals,⁶ etc.). Compared with the tertiary thioamide, however, the chemistry of the secondary thioamide has been less disclosed.^{7,8} Herein we report some interesting behavior of S-allylthioimidate (2) which is readily prepared by the allylation of thioamides: 2 undergoes selectively the S → C (the carbon α to the thiocarbonyl group) rearrangement to provide the C-allylated secondary thioamide or the S → N rearrangement to provide the N-allylated tertiary thioamide⁹ by the selection of conditions.

S-Allyl-N-methylthiopropionylimidate (2b), upon heating as neat liquid at 160°C for 1 h under argon, provided the S → C allylic migration product, N-methyl-2-methylthio-4-butenoylamide (3b), in 95% yield (entry 2, Table I).¹⁰

Scheme I

Any other products, which might stem from the olefin isomerization to provide S-propenylthioimide¹¹ or S → N allylic rearrangement^{9, 12} to provide N-allyl-N-methylthiopropionamide, were not detectable. The present thermal S → C allylic migration seems to be general as judged by the results summarized in Table I, which covers various types of S-allylthioimides. The complete inversion of allylic portion of S-crotyl to C-methallyl (entries 6 and 8, Table I) suggests that the S → C migration involves two sequential reactions, i.e., isomerization of 2 to ketene S,N-acetal (5) and the thio-Claisen rearrangement of 5 (Scheme I). Unfortunately no diastereoselectivity resulted and 3f was obtained as a diastomeric mixture (1:1) (entry 6, Table I).^{1f, 1g} As being general in these types of rearrangements,¹³ the reactions forming the bonds between the tertiary and the secondary carbons required the higher temperatures and longer reaction times (entries 7 and 8, Table I). No reaction took place in the reaction between the tertiary carbons (entry 9, Table I).

Making marked contrast to these, in the presence of PdCl₂ (2 mol%, THF reflux for 16 h), 2e rearranged to provide a mixture of C- and N-allylated thioamides (3e and 4e, respectively) in a ratio of 81:19 (entry 2, Table II). Under the same conditions except for the absence of PdCl₂, 2e was recovered completely. These results clearly indicate that PdCl₂ catalyzes both the S → N rearrangement (probably caused by the coordination of PdCl₂ to the sulfur atom of 2)⁹ and the isomerization of 2 to ketene S,N-acetal 5 (probably caused by the coordination of PdCl₂ to the nitrogen atom of 2). In order to achieve the selective S → N allylic rearrangement, we examined the reactions taking the HSAB principle¹⁴ as a guide. This proved to work nicely and the striking improvement of the ratio of the S → N to the S → C rearrangements was observed by replacing PdCl₂ with the softer Lewis acid, Pd(OAc)₂ (entry 3, Table II). In a practical sense, the substitution of N-phenyl for N-CH₃, which might correspond to making the nitrogen atom the harder Lewis base, is profitable. The results of the palladium catalyzed S → N allylic rearrangement, together with those of the corresponding thermal S → C rearrangement, are summarized in Table II, which demonstrates the migration of 2 proceeds highly selectively either in a S → C or in a S → N fashion depending on the conditions.

The ease of the present reaction may be augmented in the following experiments, with which the selective S → C and S → N allylic rearrangements are performed: For the S → C rearrangement (entry 7, Table II), thioimide (2l) is heated as neat liquid at 200°C for 1 h under argon (as a matter of convenience by using a Kugelrohr apparatus under slightly reduced pressures). The reaction mixture is directly subjected to a column purification (silica gel, benzene as an eluent) to provide N-phenyl-2-allyl-thiopentanoylamide (3l) in 76% yield; mp. 68.5 °C (from benzene-hexane). ¹H NMR (in CCl₄, TMS)

1) For the structures of 2, 3, and 4, see Scheme I.

2) See the experimental part in the text.

3) Yield refers to the (combined) isolated yield of 3 (and/or 4). All new compounds showed satisfactory spectral and analytical data.

4) 3f is obtained as a diastereomeric mixture (1 : 1).

5) Starting material (2i) is recovered completely.

6) Ratio is determined by means of VPC and/or ¹H NMR.

7) Yield is based on the 71% conversion.

δ 0.9~2.0 (m, 7 H), 2.1~2.7 (m, 3 H), 4.9~5.2 (m, 2 H), 5.5~6.0 (m, 1 H), 7.0~7.7 (m, 5 H), and 8.95 (br.s, 1 H). IR (KBr disk, in cm^{-1}) 3230(s), 1595(m), 1535(s), 1495(m), 1420(s), 1320(s), 915(m), 765(m), and 700(m). Mass (m/e, relative int.) 233(1), 191(29), 190(29), 170(47), and 77(100). For the S \rightarrow N rearrangement (entry 8, Table II), a solution of 21 (1 mmol) and $\text{PdCl}_2(\text{PhCN})_2$ (0.01 mmol) in dry THF (5 ml) is refluxed for 6 h under argon. After the evaporation of THF, the residue is directly subjected to a column purification (silica gel, benzene) to give N-phenyl-N-allyl-thiopentanoylamide (41) in 80% yield; bp. 150°C/1.5 mmHg. ^1H NMR (CCl_4 , TMS) δ 0.8~1.9 (m, 7 H), 2.43 (t, J = 7 Hz, 2 H), 4.8~5.3 (m, 4 H, containing δ 4.9, d, J = 7 Hz, 2 H), 5.7~6.4 (m, 1 H), and 7.1~7.6 (m, 5 H). IR (neat film, cm^{-1}) 1640(w), 1490(s), 1440(s), 1400(s), 1235(m), 1070(m), 960(w), 925(m), and 700(s). Mass (m/e, relative int.) 233 (10), 218(22), 160(100), and 104(54).
