

ELECTROGENERATED ACID AS A POWERFUL CATALYST FOR TRANSFORMATION OF EPOXIDES
 TO KETONES AND ACETONIDES

Summary: Electrochemical Transformation of epoxides 1 to ketones 2 and acetonides 3 were achieved by using an electrogenerated acid-catalyst. A combination of $M(\text{ClO}_4)_n$ [M; Li, Na, Mg, n = 1, 2] with polar aprotic solvents [CH_2Cl_2 , $\text{ClCH}_2\text{CH}_2\text{Cl}$, THF, CH_3COCH_3 , AcOEt, $(\text{MeO})_2\text{CO}$] is useful for the electrochemical transformation.

Much attention has been paid to the electrochemical techniques as a potential tool in synthetic chemistry. Electrolysis procedure can be frequently employed for oxidation and reduction of organic compounds. However, very little is known about the acid-catalyzed reaction in an anodic process although several electrochemical reactions in $\text{MeCN-LiClO}_4\text{-Pt}$ ¹⁾ and MeOH-LiClO_4 or $\text{Et}_4\text{NClO}_4\text{-Pt}$ systems ²⁾ have been explained in terms of an acid-catalysis. We describe here a practical method for the transformation of epoxides 1 to ketones 2 and acetonides 3 promoted by a powerful electrogenerated acid. During our study, an electron-transfer chain reaction for an electrochemical ring opening of some epoxides has been proposed. ³⁾ In contrast to this, the present electrochemical transformation of epoxides 1 to ketones 2 is an electrogenerated acid-catalyzed reaction.

A typical electrolysis condition is as follows; A mixture of 1a (0.2 mmol) and LiClO_4 (1.0 mmol) dissolved in CH_2Cl_2 (7.5 ml) - THF (0.5 ml) ⁴⁾ was electrolyzed under a constant current (10 mA for 1 min, 0.03 F/mol) at room temperature using platinum foils as electrodes in an undivided cell, affording 2a (91%) and 8-benzyloxy-2,6-dimethyloct-1-en-3-ol (4a) (8%). The electrochemical transformation of 1 to 2 is characterized by the following facts; (1) The reaction completes by passing a very small amount of electricity (0.02 - 0.1 F/mol), (2) Without electrolysis no 2a was detected and 1a was recovered, (3) By electrolysis in a divided cell 2a was obtained only from an anolyte and 1a was completely recovered from a

catholyte, (4) Ketone 2a was obtained in good yield (91%) even when 1a was allowed to react in a preelectrolyzed solution, ⁵⁾ (5) Presence of pyridine (1 eq) in the preelectrolyzed solution inhibited the conversion and no 2a was detected, (6) In the prolonged electrolysis, a dark gray lithium metal deposited on the cathode and a check of pH revealed that the electrolysis solution was acidic, (7) The electrolysis gave higher yield and selectivity than those of the usual acid-catalysis (Table 2). These experimental results strongly suggest that the electrochemical conversion is an electrogenerated acid-catalyzed reaction rather than an electron-transfer chain reaction. ^{3),6)}

The mechanism on the generation of the electrogenerated acid is not uncovered yet. However, it is plausible that oxidation of a trace amount of water existing in the electrolysis solution would generate a naked acid in an unbuffered condition which is therefore extremely strong in aprotic solvents. ⁷⁾

The effect of electrolytes is important. Perchlorates such as LiClO_4 (91%, 0.02 F/mol), NaClO_4 (90%, 0.04 F/mol), and $\text{Mg}(\text{ClO}_4)_2$ (79%, 0.04 F/mol in THF) significantly promoted the conversion. Use of Et_4NClO_4 provided 2a in a good yield (89%) but it required more electricity (0.5 F/mol in CH_2Cl_2). Interestingly, use of Et_4NOt s in CH_2Cl_2 led to the preferential formation of 4a (57%) although the current efficiency was unsatisfactory (3.1 F/mol). In contrast, both Et_4NBr and $\text{CF}_3\text{CO}_2\text{Li}$ did not give the desired ketones. Use of Et_4NBr in CH_2Cl_2 resulted in a recovery of 1a even after 3.7 F/mol of electricity was passed. On electrolyzing 1a with $\text{CF}_3\text{CO}_2\text{Li}$, debenzoylation took place in part, affording benzaldehyde (21%) and 6,7-epoxy-3,7-dimethyloctan-1-ol (19%) along with the recovered 1a (70%) after 4.5 F/mol.

Aprotic solvents such as CH_2Cl_2 (91%), $\text{ClCH}_2\text{CH}_2\text{Cl}$ (95%), THF (85%), Me_2CO (75%), and AcOEt (76%) are useful for the purpose. However, use of MeCN (simply distilled once over P_2O_5) and MeOH (treated with Mg and distilled) did not promote the electrochemical reaction.

Similarly, the electrochemical conversion of 1 into acetonides 3 was performed by electrolyzing 1 in a distilled acetone containing LiClO_4 or $\text{Mg}(\text{ClO}_4)_2$ at room temperature. Particularly noteworthy is the fact that the electrochemical acetonidation can be performed by use of a trace amount of LiClO_4 (1% mol eq to 1c) and a catalytic amount of electricity (0.1 F/mol). The selectivity of the acetonidation is strictly controlled by the concentration of LiClO_4 ; [Acetonide 3c (%) : Ketone 2c (%) (LiClO_4 mol eq to 1)], 87:5 (0.01), 76:15 (0.2), 61:28 (2.0), 51:40 (12)]. Ketone 2c increased with the concentration of LiClO_4 presumably because in the high concentration of the salt the intermediate carbenium ion would be significantly associated with LiClO_4 as proposed by Pocker, ⁸⁾ thus retarding nucleophilic attack of acetone. As an electrolyte, LiClO_4 (87%, 0.1 F/mol), NaClO_4 (84%, 0.16 F/mol), $\text{Mg}(\text{ClO}_4)_2$ (90% 0.1 F/mol), and LiBF_4 (81%, 0.1 F/mol) were effective. However, Et_4NClO_4 gave poor yield and current efficiency (37%, 1.7 F/mol) and the use of Et_4NBr or Et_4NOt s resulted recovery of 1c even after 2.0 F/mol of electricity was passed.

The electrolysis of the corresponding diol of 1c in LiClO_4 - acetone provided 3c (85%, 0.3 F/mol) although the current efficiency was lower than that of epoxide 1c (0.1 F/mol). In contrast to this, cyclohexene oxide gave cyclohexene diol (91%) as a sole product which could not be converted to the corresponding acetonide even when 1 F/mol of electricity was passed. This result suggests that acyclic diols also can be transformed into acetonides by the present electrolytic method.

The results of the electrochemical rearrangement of epoxides 1 to ketones 2 and acetonides 3 are summarized in Table 1. Acyclic ω -epoxyisoprenoids 1a-1f were converted to 2a-2f and 3a-3f in satisfactory yields. Functional groups involved in 1 (OH, OAc, SO₂Ph, CHO, and C=C and C≡C bonds) did not change in the electrolysis conditions. Epoxides 1h derived from isosafrole provided 1-(3,4-methylenedioxyphenyl)propan-2-one (2h) (82%), a synthetic precursor of α -methyl dopa.⁹ Similarly, menthene oxide 1i gave a mixture of menthone and isomenthone (72%). Although epoxide 1j of a long chain fatty acid (erucic acid) is less reactive, it could be converted to the corresponding ketone 2j (82%) and acetonide 3j (84%). Electrolysis of 1k proceeded very slowly (1.22 F/mol), affording triphenylmethyl phenyl ketone 2k (30%) along with benzophenone (69%). In contrast, the reaction of 1k in a preelectrolyzed solution provided 2k in 97% yield (After 2.53 F/mol, 1k was added to the preelectrolyzed solution and stood for 2.5 h.).

The result of the electrochemical rearrangement (1 \rightarrow 2) apparently demonstrates usefulness of the electrolysis method (Table 2) in comparison with the conventional chemical acid-catalyzed reaction. On the contrary to the electrolysis, the action of BF₃ etherate in benzene which is one of the most widely employed reagents for the epoxide ring opening induced
