

DIRADICALS IN THE VINYL-CYCLOPROPANE REARRANGEMENT OF
 BICYCLO[3.1.0]HEXANE DERIVATIVES

G.W. Klumpp and M. Schakel

Scheikundig Laboratorium der Vrije Universiteit, Amsterdam, The Netherlands

Abstract Product ratios and their insensitivity to steric effects indicate the title reactions to occur through diradicals with limited rotational freedom.

The mechanism of the thermal vinylcyclopropane rearrangement is still a matter of controversy.¹ The absence of steric effects that might be caused by substituents R of differing size has led us to suggest that diradicals 3a-c are intermediates in the rearrangement of 1 via 2 to 4 (see Scheme 1).²

a: R = D; b: R = Me; c: R = *cyclo*-C₃H₅; 500°C; 1-2 sec

Scheme 1

In order to narrow down the scope of such behaviour we have studied the thermolyses of 5 (Scheme 2). Diradicals 8 derived from these substrates are less stable than 3 and therefore concerted rearrangement might take over and manifest itself by substituent dependent stereoselectivity. For further reference 6b and 10 were studied, too. The results are given in Table 1.

At 325-350°C 5a-c rearrange to a 20:1 mixture of 7a-c and 9a-c (see entries 1-3). Geometric isomerisation to 6a-c is the fastest reaction of 5a-c; 7a-c arise from 6a-c by homo-[1,5] hydrogen shift. It was proven³ that under the conditions of thermolysis the latter reaction quantitatively removes 6a-c. The minor products 9a-c must therefore be formed from 5a-c. At 500°C 9b was also obtained from 6b (see entry 5). The value *endo/exo* was the same as observed for 5b (entry 4), indicating that at 500°C 5 and 6 interconvert rapidly and that the Curtin-Hammett principle applies. In order to supplement our earlier work the system of Scheme 1 was extended by using the *trans*-divinylcyclopropane 10 as the starting material. At 325°C (1-2 sec) the main product was 1b resulting from geometric isomerisation of 10 to 2b followed by Cope-rearrangement. It was accompanied by a very small amount⁴ of 4b in an *endo/exo* ratio that was closer to one than

the one observed with $\underline{1b} \rightleftharpoons \underline{2b}$ at 500°C (see entries 6 and 7). Most probably reactions at 500°C are under Curtin-Hammett control, whereas at 325°C equilibrium between $\underline{2b}$ and $\underline{10}$ is not established due to the irreversible conversion of $\underline{2b}$ to $\underline{1b}$.

a: R = D; b: R = Me; c: R = i-Pr; 325-350°; 1h

Scheme 2

Table I Thermolysis products of $\underline{1b}$, $\underline{5a-c}$, $\underline{6b}$ and $\underline{10^a}$

Entry	Substrate	Temp. °C	time	Products	%	endo/exo
1	$\underline{5a}$	350	1h	$\underline{7a}$	95	-
				$\underline{9a}$	5	2.5/1
2	$\underline{5b}$	350	1h	$\underline{7b}$	95	-
				$\underline{9b}$	5	2.6/1
3	$\underline{5c}$	325	1h	$\underline{7c}$	95	-
				$\underline{9c}$	5	3.8/1
4	$\underline{5b}$	500	1-2 sec	$\underline{7b}$	75	-
				$\underline{9b}$	25	2.1/1
5	$\underline{6b}$	500	1-2 sec	$\underline{7b}$	92	-
				$\underline{9b}$	8	2.0/1
6	$\underline{10}$	325	1-2 sec ^b	$\underline{1b}$	>99.5	-
				$\underline{4b}$	<0.5	1/1.2
7	$\underline{1b}$	500	1-2 sec	$\underline{4b}$	100	1/2.3

a: Entries 1-3: carried out in the gas phase in evacuated ampoules; entries 4-7: carried out in a flow system, as described elsewhere.⁵

b: Under these conditions $\underline{1b}$ is stable

The near invariance of the stereoselectivity of the rearrangement $5a-c \rightarrow 9a-c$ when R is changed from deuterium to isopropyl (Table 1, entries 1-3) indicates transition states which are little susceptible to the size of R. Diradicals 8 which would close to *endo*- and *exo*- 9 via reactant-like transition states satisfy this condition. Product formation via competing concerted [1,3] carbon shifts is expected to show a decrease of *endo*/*exo* upon increase of the size of R (the *sr* transition state leading to *endo*- 9 being more sensitive to steric hindrance by R than the *ar* transition state leading to *exo*- 9)⁶

The moderate, yet nearly substituent-independent stereoselectivity of $8a-c$ is in line with the principle of least nuclear motion (PLNM). In Scheme 3 the operation of the PLNM is illustrated for the formation of $9b$ from two conformations, A and B, of $8b$. Assuming that $k_{\text{PLNM}} : k$ of both A and B be greater than 1 the values of *endo*/*exo* (Table 1, entries 1-3) indicate that the mole fraction of 9 formed from $8A$ must be greater than 0.5 for any ratio $(k_{\text{PLNM}} : k)_A : (k_{\text{PLNM}} : k)_B$.⁷ Thus it appears that the majority of diradicals $8A$ arising from 5 collapse to 9 before they can complete a rotation of more than 90° . [Homolysis of 5 with *anti*-clockwise internal rotation (of the diradicals as depicted in Scheme 3) is not expected to yield 9 but to result in geometric isomerisation, exclusively].^{8,9} The partial conservation of optical activity observed for the rearrangement of (+)-(1S,2S)-*trans*-1-(*trans*-1-propenyl)-2-methylcyclopropane (11) by Andrews and Baldwin¹⁰ has led these authors to propose that the four possible modes of concerted [1,3] carbon shift compete in this reaction.

Conformations A and B of diradicals involved in vinylcyclopropane rearrangements. A and B are viewed down the C^1C^2 bond axis shown in the starting cyclopropane. For the sake of clarity the circle denoting the rear atom in conventional Newman representation is omitted. The circle between H and X portrays the 2p orbital on C^3 .

However, their results can also be accommodated by a scheme analogous to the one proposed for 5. In fact, the ratio of products that can be ascribed to PLNM controlled ring closure of diradicals A and B is very similar for 5b [(endo-9b) : (exo-9b)]_{350°} = 2.6] and 11 [(3S,4S-cis-12) : 3R,4S-trans-12]_{296.5°} = 2.75]. PLNM controlled five-membered ring formation competitive with internal rotation has been implied for orthogonal 2,2'-bis(allylmethane) formed on thermolysis of 1,3-dimethylene cyclopentane.¹¹

7. $\gamma_A = \frac{(m+1)(n^{-1}-N)}{(N+1)(n^{-1}-m)}$, γ_A = mole fraction of product derived from A;
 $m = (k_{\text{PLNM}} : k)_A$; $n = (k_{\text{PLNM}} : k)_B$; $N = ([\text{endo-9}] : [\text{exo-9}])_{\text{overall}}$.
8. *Anti*-clockwise rotation moves CHMe to its maximal distance from CHX (see Scheme 3).
Right after passing through this conformation overlap propitious to 1,3-closure starts to develop rapidly while CHMe and CHX are still far away from each other. Evidence suggesting that closure of 1,3-diradicals is fast compared with bond rotation is discussed in ref.1.
9. Another path to geometric isomerisation is provided by diradicals substituted *trans,trans* in their allylic side chain.
