ABSTRACT: New tetracyclic derivatives (3a, b, 5, 8) similar to protoberberines, but containing a lactam structural element and other hetero atoms besides the bridgehead nitrogen in rings B and C, were prepared by cycloaddition of 6,7-dimethoxy-2H-1,3-benzothiazine (1a) with *o*-substituted aromatic carboxylic acid derivatives (2a, b, 4), and from 4-methyl-6,7-dimethoxy-2H-1,3-benzothiazine (1b) with 3,5-dinitrobenzoyl chloride.

Cyclic imines are easily acylated with acyl halides or anhydrides, and the resulting adducts may be used in the synthesis of heterocyclic compounds.³⁻⁶ Treatment of salicyl chloride (2a)⁷ or thiosalicyl chloride (2b) (prepared from salicylic acid or thiosalicylic acid and oxalyl chloride) with 6,7-dimethoxy-2H-1,3-benzothiazine (1a)⁸ afforded the corresponding 1,3-benzoxazin-4-one (3a, 83%, mp 175-176 °C) or 1,3-benzothiazin-4-ones (3b, 77%, mp 175-176 °C).

Heating anthranilic acid with thionyl chloride produced an unstable sulfinamide anhydride,^{9,10} which was treated with 6,7-dimethoxy-2H-1,3-benzothiazine (1a) in dry benzene at room temperature. In this reaction, via cycloaddition of an iminoketene-type intermediate followed by spontaneous dehydrogenation, compound 5 (69%, mp 255-257 °C) was formed. N-Aroylenamine-type enamines containing an electron-deficient aromatic ring undergo facile thermal cyclization to give the corresponding lactams.¹¹ Acylation of 4-methyl-6,7-dimethoxy-2H-1,3-benzothiazine (1b)⁸ with 3,5-dinitrobenzoyl chloride (6) in the presence of TEA yielded the enamide 7 (89%, mp 159-161 °C), which was thermally cyclized upon refluxing in benzene to afford 8 (94%, mp 259-261 °C).

All spectroscopic data (Tables 1 and 2) are in full agreement with the postulated structures. The amide-I IR band appears between 1670 and 1640 cm^{-1} . The singlet of the isolated H-14 atom appears in the spectra of 3a, b and is missing from that of 5. Instead of this signal, the H-13 line is present in the spectrum of 8, considerably shifted downfield due to the anisotropy of the coplanar nitro group.^{12a} The H-4 singlet is not sensitive to structural changes far from this hydrogen, while H-1 is more shielded in 3b than in 3a and in 8, and is strongly deshielded in 5, lying near the lone pair of N-13 in the same plane.^{12b} The H-9,

10, 11 and 12 shifts show the expected values, considering the substituents on C-12a, and in the case of **8** on C-10 and 12 too.

The 6-methylene protons are equivalent in **5** and **8**, proving the planar structure of the ring skeleton. These hydrogens in compounds **3a,b** are non-equivalent; the shift-difference is small for **3a** and significantly larger for **3b** (0.18 and 1.50 ppm, respectively). This behaviour can very probably be explained by the different conformations of the two flexible heterorings.

Compound **3a** has a preferred conformation, with the thiazine ring in a near-boat form, in which the dihedral angles of the C₆-H_{6a} or C₆-H_{6b} and C=O bonds are about 85° and 25°, and the distance between the tetrasubstituted benzene ring and H-6_a is $\sim 3.8 \text{ \AA}$ (Fig. 1).

Fig.1.

Fig.2.

By inversion of the thiazine ring, **3b** takes on another form (Fig. 2), which dominates in the conformational equilibrium; in this, the 6-methylene protons mutually change their positions and H-6_a is coplanar with the carbonyl group (the C_{6a}-H, C=O dihedral angle is ca. 0°). At the same time, the dihedral angle of the C_{6a}-H and C=O bonds is about 105°. This position lead to a significantly increased shielding of H-6_a and a large opposite effect on H-6_b, due to the anisotropy of the carbonyl group.^{12c} Consequently, instead of the close lines of an

^atwo overlapping lines

AB multiplet as for 3a, for 3b an AX multiplet appears with an appreciable distance between the A and X doublets.

Both presumed conformers have a flat skeleton, and by assuming the arrangement illustrated in Fig. 2, 3b can avoid the steric hindrance between H-1 and the sulfur atom (this effect is smaller in 3a, due to the smaller atomic radius of the oxygen).

The structures of 3a,b, 5 and 8 are confirmed by the ^{13}C NMR shifts: The signals of the methylene carbon C-6, the C-8 carbonyl, the two methoxy-substituted atoms C-2 and 3, other quaternary C-14a, 4a, 8a and 12a and the protonated aromatic carbons C-1, 4, 9, 10, 11 and 12 are identifiable in the expected shift-regions. C-14 is more shielded in 3b than in 3a, as a consequence of the different α -effects of the sulfur and oxygen atoms.^{12d} This signal appears at 152.6 ppm, in the interval characteristic of azomethine carbons.^{12e}

The fact that no significant differences are observable in the shifts of the skeletal carbons (especially in the shifts of C-14, 14a and 1) suggests that the butterfly-wing-like form having the oxazinone or thioxazinone ring in the inverse with H-14 in the quasi-equatorial position plays only an unimportant role in the conformational equilibrium (the other inverse of this ring, with a quasi-axial H-14, is present in the postulated conformers). Such a structure should cause shielding on C-14, 14a and 1, due to a steric compression shift.¹³
