

1-BROMOBICYCLO[1.1.0]BUTANES AND STRONG BASES:
PRODUCTS AND MECHANISM [†]

Summary: Treatment of the bromobicyclo[1.1.0]butanes 4a - c with LDA led to the formation of the 1,2,3-butatrienes 6 which were isomerized by excess base to the alkynes 8. Reaction of [¹²C]4c with LDA afforded [³⁻¹²C]8d, indicating that bicyclo[1.1.0]but-1(3)-ene 5 was not an intermediate.

1-Halobicyclo[1.1.0]butanes of type 1 with a bridge between C-2 and C-4 eliminate hydrogen halide when treated with a strong base, affording the bicyclo[1.1.0]but-1(3)-ene derivatives 2 as short-lived intermediates. At low temperature (< 0°C), 2 could be trapped by nucleophiles (thiolates, amides, organolithium compounds) or by reactive 1,3-dienes ¹⁾. Above 20°C, tricyclo-[4.1.0.0^{2,7}]hept-1(7)-ene (2, n = 3) has been shown to isomerize to 1,2,3-cycloheptatriene (3, n = 3) ²⁾ in a formally orbital symmetry "forbidden" process ³⁾. 1-Halobicyclo[1.1.0]butanes 4 without the bridge between C-2 and C-4 might behave differently when exposed to a strong base. Although the formation of 5 seems reasonable, the rearrangement of 5 to 6 is not hampered by orbital symmetry restrictions. Therefore, 5 could evade all trapping efforts by a fast isomerization to 6.

To test this point experimentally, the 1-bromobicyclo[1.1.0]butanes 4a-c were synthesized by the elegant method of Skattebøl and Baird ⁴⁾ from the dibromocyclopropanes 7a-c and methyl lithium. The NMR data of 4a-c are collected in Table 1. When the bromides 4a-c were mixed with 3-5 equiv. of lithium diisopropylamide (LDA) in ether at -20°C, aqueous workup after 2-5 hours afforded in yields of 30-50% 8a, a 1:6 mixture of 8b and c, and, respectively, 8d. The structures of 8a-d are based on their ¹H and ¹³C NMR spectra, which had been recorded previously ⁵⁾. It was easy to

demonstrate that the alkynes **8** were formed by isomerization of the butatrienes **6**, caused by the excess of LDA. After dropwise addition of one equiv. of a solution of LDA to a solution of **4a** or of **4c** in ether at -20°C , the ^1H NMR spectra of the solutions showed intense signals of **6a** ⁶⁾ or of **6c** ⁷⁾, which disappeared quickly, when base addition was continued.

To find out, if the assumed intermediates **5a** and **c** could be trapped, mixtures of **4a** or **4c** and lithium thiophenolate or 2,5-dimethylfuran were treated with an excess of LDA at -20°C . However, no products containing the bicyclo[1.1.0]butane structure were isolated, leaving the question on the intermediacy of **5** unanswered.

To reach a decision on this point, $[1-^{12}\text{C}]\text{4c}$ was synthesized from $[1-^{12}\text{C}]\text{7c}$. For this purpose, commercially available $^{12}\text{C}\text{DCl}_3$ (^{12}C content $\geq 99.95\%$) was converted to $^{12}\text{CDBr}_3$ by anhydrous AlBr_3 in 71% yield ⁸⁾. Reaction of $^{12}\text{CDBr}_3$ with 1-chloro-3-methylbut-2-ene in CH_2Cl_2 with conc.

NaOH under phase-transfer conditions furnished a 72% yield of $[1-^{12}\text{C}]\underline{7c}$, from which $[1-^{12}\text{C}]\underline{4c}$ was obtained in 34% yield by reaction with methyllithium in ether. The ^{13}C NMR spectrum of $[1-^{12}\text{C}]\underline{4c}$ indicated that the ^{13}C proportion of C^1 was below ^{13}C NMR detection: the singlet of the ^{13}C NMR spectrum of $\underline{4c}$ at δ 28.9 was not observed in the spectrum of $[1-^{12}\text{C}]\underline{4c}$.

Mixing $[1-^{12}\text{C}]\underline{4c}$ with 4 equiv. of LDA at -20°C followed by aqueous workup produced a sample of the alkyne $\underline{8d}$, the ^{13}C NMR spectrum of which gave a clear answer to the posed question: the signal of the olefinic C^3 (at δ 105.4 in the ^{13}C NMR spectrum of $\underline{8d}$) was completely absent in the spectrum of the sample, showing that $[3-^{12}\text{C}]\underline{8d}$ was the only product. This result immediately eliminated $\underline{5c}$ as an intermediate. In this molecule, the bicyclo[1.1.0]butane side-bonds $\text{C}^1\text{-C}^2$ and $\text{C}^2\text{-C}^3$ are equivalent, as are the bonds $\text{C}^1\text{-C}^4$ and $\text{C}^3\text{-C}^4$. Neglecting kinetic isotope effects, cleavage of opposite side bonds ($\text{C}^1\text{-C}^2/\text{C}^3\text{-C}^4$ and, respectively, $\text{C}^2\text{-C}^3/\text{C}^1\text{-C}^4$) should occur with equal probability, leading to a 1:1 mixture of $[2-^{12}\text{C}]\underline{6c}$ and $[3-^{12}\text{C}]\underline{6c}$, and, after base-induced isomerization, finally to a 1:1 mixture of $[2-^{12}\text{C}]\underline{8d}$ and $[3-^{12}\text{C}]\underline{8d}$.

As $\underline{5c}$ is not an intermediate in the hydrogen bromide elimination of $\underline{4c}$, and as $\underline{4c}$, in the absence of electrophilic catalysts, is stable at the reaction temperature, a possible candidate for rearrangement seems to be the lithiated species $\underline{9c}$. Lithium bromide elimination from $\underline{9c}$ is then accompanied by cleavage of the bonds $\text{C}^2\text{-C}^3$ and $\text{C}^1\text{-C}^4$ in a concerted, but not necessarily in a synchronous fashion⁹⁾. The high regioselectivity of bond breaking of the bicyclo[1.1.0]butane framework of $\underline{9c}$ is, however, not fully understood. The mechanistic alternative of single electron transfer (SET) from LDA to $\underline{4c}$ followed by ring opening of the radical anion of $\underline{4c}$ appears to be less attractive, because no evidence of SET was obtained in previous investigations, when halides of type $\underline{1}$ were treated with LDA¹⁾.

Table 1. NMR data of 4a-c, 6c and 8d

<u>4a</u>	^1H NMR (CCl_4) δ 1.10 (broadened s, 2 H), 1.80 (tt, $J = 3$ Hz and $J = 1$ Hz, 1 H), 1.99 (d, $J = 3$ Hz, each line broadened by small coupling, 2 H); ^{13}C NMR (CDCl_3) δ 6.6 (d), 15.1 (s), 38.7 (t).
<u>4b</u>	^1H NMR (CCl_4) δ 1.05 (broadened s, 1 H), 1.15 (m, 4 H), 1.58 (d, $J = 3$ Hz, each line broadened by small coupling, 1 H), 1.93 (d, $J = 3$ Hz, each line broadened by small coupling, 1 H); ^{13}C NMR (C_6D_6) δ 12.3 (d), 14.0 (q), 23.9 (s), 36.2 (t), 43.8 (d).
<u>4c</u>	^1H NMR see Lit. ⁴); ^{13}C NMR (C_6D_6) δ 14.0 (q), 17.9 (d), 23.0 (q), 28.9 (s), 37.3 (t), 51.8 (s).
<u>6c</u>	^1H NMR see Lit. ⁷); ^{13}C NMR (CDCl_3) δ 24.5 (q), 85.4 (t), 117.8 (s), 156.5 (s), 166.2 (s).
<u>8d</u>	^1H NMR see Lit. ^{5e}); ^{13}C NMR (C_6D_6) δ 20.8 (q), 24.5 (q), 80.0 (d), 81.9 (s), 105.4 (d), 149.6 (s).
