

SYNTHESIS OF ORELLANINE, THE LETHAL POISON OF A TOADSTOOL

Eckehard V. Dehmlow* and Hans-Joachim Schulz

Fakultät für Chemie, Universität Bielefeld, D-4800 Bielefeld 1, Germany

Abstract: A ten step synthesis of the structure of orellanine, 3,3',4,4'-hydroxy-2,2'-bipyridyl-bis-N-oxide (1a), is described which proves the identity of the natural product.

The mushroom Cortinarius orellanus Fries was considered edible until 1952, when a mass poisoning of 135 persons (including 19 deaths) in Poland caused attention. Analysis of the incident was complicated by the latency period of 3 to 20 days between consumption of the toadstools and the appearance of symptoms¹. The first separation of the poisonous principle, named orellanine, led to a mixture apparently². Antkowiak and Gessner³ isolated a single compound to which they assign the structure of 3,3',4,4'-tetrahydroxy-2,2'-bipyridyl-bis-N-oxide (1a). Decomposition of 1a on heating gives oxygen⁴ and non-toxic orelline (2a). Moser et al. seem to have isolated 1a as well⁵. Although the nephrotoxicity of this compound and other bipyridyls is well established⁶, recent work from another group implies that the C. orellanus toxins might be peptides⁷. In view of the unusual structure, a synthesis of 1a seemed desirable.

Several synthetic routes towards 1b were attempted in vain. All experiments were futile in particular which used substituted bipyridyls as early intermediates. Ultimately, the process shown in the scheme was developed. The chlorination 3 → 4 (15% H₂O₂ in concentrated HCl) was executed in 82% yield⁸. 38% 5 was obtained from 4 in a Schiemann reaction⁹. Oxidation of 5 with acetic anhydride/30% H₂O₂ gave 54% of 6¹⁰. Nitration (100% HNO₃/100% H₂SO₄ containing 10% SO₃) of 6 led 42% 7 and 2% of 2-chloro-3-fluoro-6-nitro-

pyridine-N-oxide (11). The structure of 7 as a 4-nitro compound becomes apparent from the NMR signals of the isomers 7 and 11 (Table 1). Selective substitution by a molar amount of methoxide in methanol at room temperature gave 8 (84%), whereas the action of two equivalents of methoxide yielded 9 which could also be obtained from 8 in a stepwise manner. The attempted isolation of 9 resulted in a violent decomposition sometimes, and therefore the immediate PCl_3 reduction of raw 9 to 10 is preferred (62% from 7).

The bipyridyl coupling was achieved with the help of the nickel(0)-triphenylphosphine complex using the method of Tiecco et al.¹¹. 10 was added to the freshly prepared complex in DMF and stirred at 50°C for 4 hours. 2b was obtained in 25% yield. It exhibits the expected MS and NMR signals¹². Oxidation of 2b ($\text{Ac}_2\text{O}/\text{H}_2\text{O}_2$) gave 1b in 41% yield. Interestingly, the mass spectrum of 1b¹³ shows the loss of the two oxygen atoms in separate steps so that the [1.5] oxygen shift mechanism proposed for 1a⁴ cannot apply here.

Refluxing 2b or 1b in 33% HBr/HOAc for 4 h yielded 46% 2a or ca. 30% 1a, respectively. Comparison of physical data of these compounds with the published ones (Table 2) established the identity of the natural product¹⁴.

Constant support by Fonds der Chemischen Industrie is acknowledged.
