**Abstract:** The enantioselective reduction of acetophenone by the borane-chiral amine complexes  $\text{BH}_3 \cdot \underline{1a}$  -  $\text{BH}_3 \cdot \underline{1d}$  affords 1-phenyl-1-ethanol with o.y. up to 42%.

In the enantioselective reduction of prochiral ketones the use of chirally modified metal hydrides has extensively been studied. Especially lithium aluminum hydride modified by optically active alcohols or amines give high enantioselective reductions.<sup>1</sup> Although borane-achiral amine complexes have been intensively investigated as reducing agents for functional groups such as alkenes, carbonyls and imines,<sup>2</sup> only a few reports exist on the use of borane-chiral amine complexes; the most successful complexes have proven to be the ones with the following amines: (S)- $\alpha$ -methylbenzylamine,<sup>3</sup> (S)-1,2-diphenylethylamine,<sup>4</sup> (S)-valinol<sup>5</sup> and (S)-2-amino-3-methyl-1,1-diphenylbutan-1-ol<sup>6</sup> which reduce acetophenone in an o.y. of 21%,<sup>3b</sup> 25%,<sup>4</sup> 49%<sup>5</sup> and 94%,<sup>6</sup> respectively.

In our investigations of the applicability of some novel chiral amines (1) and chiral lithium amides (2)<sup>7</sup> in stereoselective synthesis we have investigated the potentiality of  $\text{BH}_3 \cdot \underline{1}$  to reduce acetophenone in an enantioselective way. The  $\text{BH}_3 \cdot \underline{1}$  complexes were made by

- |          |                      |                        |
|----------|----------------------|------------------------|
| <u>a</u> | Ar = phenyl          | . R = H                |
| <u>b</u> | Ar = 2-pyridyl       | . R = H                |
| <u>c</u> | Ar = O-methoxyphenyl | . R = H                |
| <u>d</u> | Ar = phenyl          | . R = OCH <sub>3</sub> |

ligand exchange on treating a solution of 1 with  $\text{BH}_3 \cdot \text{THF}$  in THF ( $\text{BH}_3$  coordinates more strongly with amines than with ethers). It was not possible to isolate the  $\text{BH}_3 \cdot \underline{1}$  complexes in pure form due to decomposition and therefore they were used *in situ*.<sup>8</sup> Although  $\text{BH}_3$ -amine complexes, such as  $\text{BH}_3 \cdot \text{N}(\text{CH}_3)_3$  and  $\text{BH}_3 \cdot \text{pyridine}$ <sup>9</sup> do not reduce acetophenone in THF as

solvent, the  $\text{BH}_3 \cdot \underline{1a}$  complex reduces it with an o.y. of 18% (Table, run 1). This difference can be explained by the assumption that in  $\text{BH}_3 \cdot \underline{1a}$  the  $\text{BH}_3$  is more loosely complexed to  $\underline{1a}$  than it is to trimethylamine and pyridine in  $\text{BH}_3 \cdot \text{N}(\text{CH}_3)_3$  and  $\text{BH}_3 \cdot \text{pyridine}$ , respectively (attributed to a steric repulsion of the  $\text{BH}_3$  group with the phenylgroups of  $\underline{1a}$  as shown in a CPK model of  $\text{BH}_3 \cdot \underline{1a}$ ). This makes the complexation of  $\text{BH}_3$  with the carbonylgroup of

Table: Reduction of acetophenone to (S)-1-phenyl-1-ethanol by  $\text{BH}_3 \cdot \underline{1}$  complexes<sup>a</sup> in the presence of  $\text{BF}_3 \cdot \text{OEt}_2$  (THF solution)

| 8              | <u>1b</u> | 66                    | 0                     |

<sup>a</sup> Ratio acetophenone: $\text{BH}_3 \cdot \underline{1}$ : $\text{BF}_3 \cdot \text{OEt}_2$  is 1:2:1.

<sup>b</sup> Chemical yields not optimized.

<sup>c</sup> Optical yields calculated on basis of the highest value reported. in literature:  $[\alpha]_D^{23} = -52.5$  (c 2.3,  $\text{CH}_2\text{Cl}_2$ ); reference 6a.

<sup>d</sup> Without  $\text{BF}_3 \cdot \text{OEt}_2$ .

<sup>e</sup> Ratio acetophenone: $\text{BH}_3 \cdot \underline{1a}$ : $\text{BF}_3 \cdot \text{OEt}_2$  is 1:1:1.

<sup>f</sup> Still 10% of acetophenone present in the crude reaction mixture.

<sup>g</sup> Ratio acetophenone: $\text{BH}_3 \cdot \underline{1a}$ : $\text{BF}_3 \cdot \text{OEt}_2$  is 1:4:2:1.

<sup>h</sup>  $\text{Et}_2\text{O}$  as solvent.

acetophenone to compete effectively with that of amine  $\underline{1a}$ , allowing the reduction to take place (the latter complexation is proposed as the first step in the uncatalyzed  $\text{BH}_3$  reduction<sup>10</sup>).

On addition of  $\text{BF}_3 \cdot \text{OEt}_2$  to the reaction mixture (which causes a stronger polarization of the carbonyl bond<sup>11</sup>) an o.y. of 42% was obtained (Table, run 2). This result compares favourably with that obtained with the  $\text{BH}_3 \cdot (\text{S})\text{-}\alpha\text{-methylbenzylamine}$  complex (o.y. 14%).<sup>3b</sup> When the reaction was performed with an additional two equivalents of  $\text{BH}_3 \cdot \text{THF}$  the optical yield was hardly lowered (runs 2 and 4). This implies that the rate of reduction with  $\text{BH}_3 \cdot \underline{1a}$  is considerably faster than with  $\text{BH}_3 \cdot \text{THF}$  as reducing agent. Using diethylether instead of THF as solvent did not alter the enantioselectivity (o.y. 42%, run 5), which differs from the results found for other borane.chiral amine complexes.<sup>3b</sup>

The replacements of ligand 1a by an amine with an additional methoxy group (ligands 1c and 1d) did not increase the optical yield (38% and 41%, respectively; runs 6 and 7).<sup>13</sup> This contrasts sharply with the effect observed for the corresponding lithium amides (2a-2d) in the  $n\text{BuLi}$  addition to benzaldehyde.<sup>7a</sup> The difference can be explained by the fact that in the former case the boron atom is coordinatively saturated after complexation with the amine, leaving no capacity for an additional internal ligation with the methoxy group. The complexes  $\text{BH}_3 \cdot \underline{1a}$ ,  $\text{BH}_3 \cdot \underline{1c}$  and  $\text{BH}_3 \cdot \underline{1d}$  are sterically very similar and as a consequence the same degree of enantioselectivity is to be expected. The fact that  $\text{BH}_3 \cdot \underline{1b}$  gave no optical induction (run 8) is understandable when the assumption is made that  $\text{BH}_3$  has a preference for complexation with

the aromatic nitrogen rather than with the aliphatic nitrogen atom of 1b which may bring the  $\text{BH}_3$  moiety too far away from the chiral environment in order to cause enantioselectivity. The preference of the  $\text{BH}_3$  group for complexation with the pyridine nitrogen is in agreement with the already mentioned steric repulsion between the  $\text{BH}_3$  and the two phenyl groups in complex  $\text{BH}_3 \cdot \underline{1a}$ .<sup>14</sup>

It is worthwhile to note that in all experiments the amines 1a-1d could be recovered easily in >90% yield without any loss of optical activity.

11. This stronger polarization may have as consequence that the reduction can take place by a direct nucleophilic attack of the  $\text{BH}_3$ .amine to the carbonyl bond. See e.g. U. Nagai, T. Shishito, R. Chiba and M. Mitsuhashi, Tetrahedron, 1965, **21**, 1701.
12. When 1 eq. of  $\text{BH}_3$ .1a instead of 2 eq. was used (see runs 2 and 3) the same o.y. was found but the reaction mixture still contained 10% of unreacted acetophenone; hence in all other runs 2 equivalents of  $\text{BH}_3$ .1 were used.
13. The  $\text{BH}_3$ .1c and  $\text{BH}_3$ .1d complexes can both exist as a diastereomeric pair because a new chiral center (the nitrogen atom) is created. The effect of this extra chiral center has not been investigated because separation of the diastereomers will be very difficult due to the observed instability of this type of complexes in the solid phase.
14. Attempts to reduce acetophenone by reagents derived from 1e with 1 eq. as well as with 2 eq. of  $\text{BH}_3$  failed under conditions where (S)-valinol with  $\text{BH}_3$  gives complete reaction with acetophenone.<sup>5</sup> Even addition of 1 eq. of  $\text{BF}_3$ .OEt<sub>2</sub> did not lead to reaction.
