NUCLEOPHILIC ADDITION OF 2-INDOLYLACYL ANION EQUIVALENTS TO N-ALKYLPYRIDINIUM SALTS

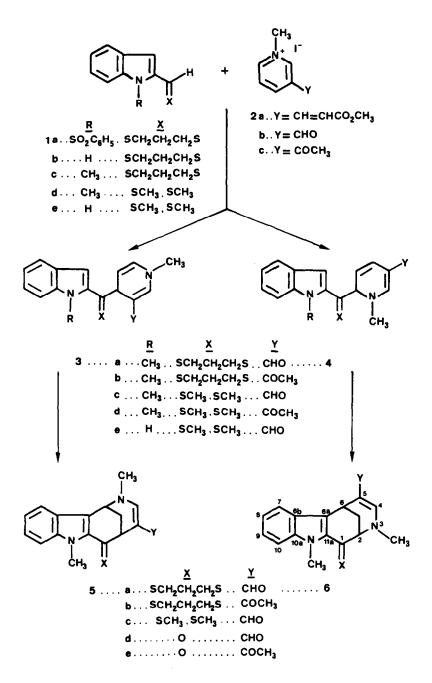

M.-Lluïsa Bennasar^{*}, Ester Zulaica, Antoni Torrens, Angel Pérez, and Joan Bosch^{*} Laboratory of Organic Chemistry, Faculty of Pharmacy, University of Barcelona, Barcelona 08028, Spain

The reactions of the anions derived from dithianes la-c and bis(methylthio)acetals ld,e with <u>N</u>-alkylpyridinium salts 2a-c are reported.

The addition of stabilized carbon nucleophiles to <u>N</u>-alkylpyridinium salts has proved to be a useful method of forming carbon-carbon bonds to give substituted dihydropyridines, which can be further elaborated into complex polycyclic alkaloid systems.¹ In this context, we have recently reported² that the use of the lithium enolates of 1-, 2-, and 3-indoleacetic esters as nucleophiles in the above reaction allows, after acid cyclization of the resulting 1,4-dihydropyridines, the straightforward construction of suitably functionalized tetracyclic ABCD ring substructures of C-mavacurine, <u>Strychnos</u>, and akuammiline alkaloids, respectively.

We are interested in the extension of the above addition-cyclization sequence to 2-indolylacyl anion equivalents in order to evaluate if it could constitute a synthetic way of constructing the tetracyclic 6-oxo-1,5-methanoazocino[4,3-<u>b</u>]indole system present in some 2-acylindole alkaloids.³ To our knowledge the addition of this kind of nucleophiles to pyridinium salts has not previously been studied. This Letter deals with our initial results in this field operating with the anions derived from (dithianyl)indoles **la-c** and bis(methylthio)acetals **ld,e** as starting nucleophiles.

Our first experiments were not encouraging since, after addition of the anions derived from \mathbf{la}^4 and \mathbf{lb}^4 to pyridinium salts $\mathbf{2a}$ or $\mathbf{2b}$ (THF, -30 °C, 1.5 h) and further acidic treatment ($\mathbf{C}_6^{H_6}$ -HCl, -50 °C to rt, 3 h), the starting dithianes were recovered unchanged. However, the use of the same set of conditions from (dithianyl)indole \mathbf{lc}^5 and pyridinium salts $\mathbf{2b}$ or $\mathbf{2c}$ afforded tetracycles $\mathbf{6a}^6$ and $\mathbf{6b}^9$ in 35% and 23% yields, respectively.¹⁰ The expected <u>Strychnos</u>-type tetracyclic systems 5 were not detected. When the acidic treatment was omitted in the reaction with $\mathbf{2b}$, the 1,2-dihydropyridine $\mathbf{4a}^{11}$ (δ C-2 69.3), which was further cyclized to $\mathbf{6a}$, was isolated in 30% yield. These results imply that the addition has taken place at the α -position of the pyridinium salt and that the equilibration of the kinetic products (1,2-dihydropyridines $\mathbf{4a}$,b) to the expected 1,4-dihydropyridines $\mathbf{3a}$,b does not occur. The different behaviour of the dithiane anions here employed as compared with that of the enolates of methyl indole-2-acetates² can be explained by considering both the harder character, which induces only attack at the α -position, and the lower stability,

that disfavours the equilibration, of the former.

Taking into account that open-chain dithioacetals have a softer nucleophilic character than cyclic ones,¹² it could be expected that the use of bis(methylthio)acetals $1d_{,e}^{13}$ increased the ability of the corresponding anions to attack at the γ -position of the pyri-

dinium ring. In fact, exposure of the anion derived from ld to salt 2b under the usual conditions gave a 1:1 mixture of the unstable 1,4- and 1,2-dihydropyridines $3c^{14}$ (δ C-4 38.9) and $4c^{15}$ (SC-2 68.9) in 15% yield, thus pointing out that the γ -attack had occurred to some extent. However, rather surprisingly, when the addition was followed by cyclization (C_6H_6- HCl, rt, 3 h), without isolating the intermediate dihydropyridines, a 1:5 mixture of the unnatural-type tetracycles $6c^{16}$ and $6d^{17}$ (formed by deprotection of 6c) was obtained in 20% yield. In accordance with this result, all attempts to separately cyclize the isolated 1,4dihydropyridine 3c, even under milder conditions (AcOH), resulted in decomposition. A similar result was obtained when the addition-cyclization sequence was effected from dithioacetal 1d and pyridinium salt 2c:¹⁰ tetracycle $6e^{18}$ was obtained in 16% yield.

In contrast, the dianion derived from the N-unsubstituted indole le reacted with salt 2b to give, although in low yield (7%), 1,2-dihydropyridine $4e^{19}$ (δ C-2 67.8) as the only isolable product which decomposed during the cyclization attempts.
