Key Words: Intramolecular reductive coupling; desulfurization of thioenol ethers; axial chirality; carbene addition

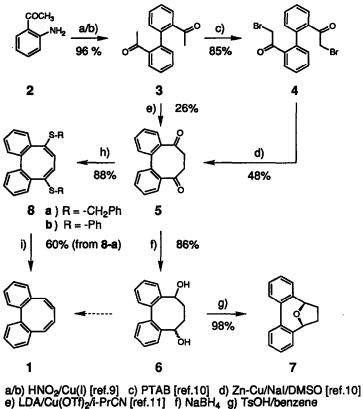

Abstract: 9,10,11,12-Tetrahydrodibenzo[a,c]cyclooctene-9,12-diol (6) is found to be reluctant to double bond forming elimination. It gives a bridged ether (7) instead. The corresponding diketone (5) reacts with benzyl mercaptan to provide the bis-thioenol ether (8-a). The latter, upon treatment with Raney nickel, gives the desired title diene 1. An alternative approach to 1, based on repeated carbene addition to phenanthrene, is also presented.

The efficient synthesis and the properties of $o \cdot o'$ -bridged biphenyls continue to be of interest to many areas of chemistry^{2,3}. The seemingly simple title hydrocarbon 1, although known for nearly three decades⁴, has only recently been resolved into its atropisomers (R)-1 and (S)-1⁵. The chiral features of these antipodes, which are protected against racemization by an inversion barrier of $\Delta G^{\neq} = 30$ kcal/mol, have not yet been exploited. In connection with our continuing studies of highly strained bicyclobutanes⁶ we have demonstrated that the diene 1 undergoes a photo-Diels-Alder reaction with 4-methyl-3H-1,2,4-triazol-3,5(4H)-dione (MTAD). Thermally, 1 is inert towards the dienophile. Further studies on these lines are greatly hampered by the inefficiency of preparations of 1 according to literature procedures^{44,7b}.

One of the first syntheses reported for 1 starts from the photoadduct of maleic anhydride and phenanthrene⁴⁴. It implies an oxidative bis-decarboxylation and a disallowed thermal ring opening. The method has been extended to derivatives of both maleic anhydride and phenanthrene^{24,8}, but global yields are invariably low (1-6%). A somewhat better method was described by Wong and Sondheimer⁷⁶. It starts from 2,2'-bis(bromomethyl)-1,1'-biphenyl and avoids the disallowed ring opening. This method also has been extended to derivatives of the parent system²⁴. Global yields are in the range of 5-9%. In the present communication, we wish to report on a five-step synthesis of 1 which starts from the commercially available 2-aminoacetophenone 2. The eight-membered ring is set up by intramolecular reductive coupling⁷⁴. The target diene 1 is obtained by this synthesis in 21% overall yield including the separation of the enantiomers (+)-1 and (-)-1. Brief mention will be made at the end of this communication. It gives 1 in 14-16% yield.

For the initial biaryl formation $(2 \rightarrow 3)$ we have chosen reductive coupling of the diazonium salt derived from 2. The method had been shown to be very efficient in the analogous synthesis of diphenic acid⁹ and proceeded in higher yield (96%) than the classical Ullmann reaction performed with the corresponding iodide (59%)¹⁰. The subsequent double bromination with phenyltrimethylammonium performide (PTAB) $(3 \rightarrow 4)$ as well as the zinc-copper promoted reductive cyclization providing the diketone 5, are known reactions¹⁰. The ring closure, with its modest 48% yield, is the weakest step in our synthesis. Our efforts to convert the diketone 3 directly into 5 by intramolecular oxidative coupling following Kobayashi's procedure¹¹ met with limited success. This procedure gave 5 in 26% yield only, and therefore does not present any advantage over the path via the dibromide 4.

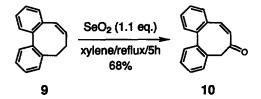

h) RSH/BF₃/AcOH [ref.14] i) Raney-Ni/acetone [ref.14]

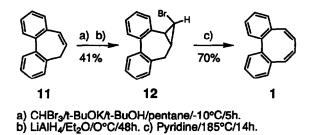

Initially, we had planned to reduce the diketone 5 into its diol 6 (mixture of stereomers) and to reach the target diene 1 by standard elimination procedures. As expected, the reduction step $(5 \rightarrow 6)$ did not provide any problems. The difficulties started when the final elimination $(6 \rightarrow 1)$ was attempted. Most of the classical methods (e.g. TsOH/benzene) when applied to the diol 6, gave the bridged ether 7 as the main product^{12,13}.

We could not find methods transforming 6 or 7 in acceptable yield into the desired diene 1. In order to overcome these difficulties, we resorted to a desulfurization method which had been used successfully in steroid chemistry¹⁴. The diketone 5 was found to react with two equivalents of benzyl mercaptan in the presence of BF₃ as a catalyst, to give the double thioenol ether 8-a in 88% yield^{12,15}. Thiophenol reacts in

analogous fashion to give 8-b(86% yield)¹². Compounds 8-a or 8-b were readily desulfurized by treatment with Raney nickel in acetone to give the desired diene 1 in yields of 60% and 58% respectively¹⁶. This last step gives as a by-product the known 9,10-dihydro-dibenzo[a,c]cyclooctene 9⁵ in 15-20% yield. Careful tic monitoring of the disappearance of starting material is required during the desulfurization in order to minimize this undesired overreduction. Compound 1 was separated into its antipodes by medium pressure chromatography on swollen microcrystalline triacetylcellulose (TAC)⁵ with methanol/water (95/5) as eluent. This final chromatographic step results also in the separation from 9. The compounds are eluted in the order (+)-9, (+)-1, (-)-9, and (-)-1. It must be mentioned however that compounds 1 and 9 have very similar retention times on ordinary silicagel columns. If one aims only at the isolation of racemic 1, it is advantageous to first reflux the crude 1/9 mixture in p-xylene for 5h with selenium dioxide. This leaves 1 unchanged but converts 9 into the ketone 10¹². Final medium-pressure chromatography on silica gel with hexane/ether (95/5) as eluent gives pure 1.

In addition to the synthesis described above, we have examined an entirely different approach towards 1 and wish to report briefly on that finding. Several laboratories^{2a,17} had shown that phenanthrene can be readily expanded into 5H-dibenzo[a,c]cycloheptene 11. The three step process consists of the addition of a dihalocarbene to phenanthrene with subsequent cyclopropyl-allyl rearrangement and reduction. Reported yields for 11 range from 45-60%. We found that the dibromocarbene adduct of 11 undergoes selective reduction with LiAlH₄ (Et₂O/0^oC/48h) to give the *endo*-bromocyclopropane derivative $12^{12,18}$ in 47% yield. It is accompanied by the corresponding fully reduced cyclopropane derivative (14%). Heating of 12 in dry pyridine in a sealed Pyrex tube (185^oC, 15h) results in the formation of 1 in 70% yield based on 12. Note that a pyridinium salt resulting from a substitution path is obtained if this reaction is run at too low temperature (<175^oC). This carbene route towards 1 is clearly a viable alternative to the other approaches.

Acknowledgments. The authors wish to express their gratitude to Mrs. P. Millasson for technical help. Financial support was provided by the Swiss National Science Foundation (grant no. 20-32645.91).
