## Dihydrofurans from $\alpha$ -Diazoketones: Facile Rearrangement of Donor-Acceptor Cyclopropanes

Elizabeth A. Lund, Isaac A. Kennedy and Alex G. Fallis\*

Ottawa-Carleton Chemistry Institute, Department of Chemistry, University of Ottawa, 10 Marie Curie, Ottawa, Ont. Canada, K1N 6N5

Abstract: The direct synthesis of dihydrofurans 7, 11, and 23-25 from  $\alpha$ -diazoketones 3, 8, and 20-22 is described. The cyclopropane intermediates generated upon treatment of the  $\alpha$ -diazoketones with metal catalysts in the presence of ethyl vinyl ether rearranged spontaneously. Sensitized irradiation of 3 afforded 7 plus cyclobutanone 5 while direct photolysis gave the cyclobutanones 5, and 26-28.

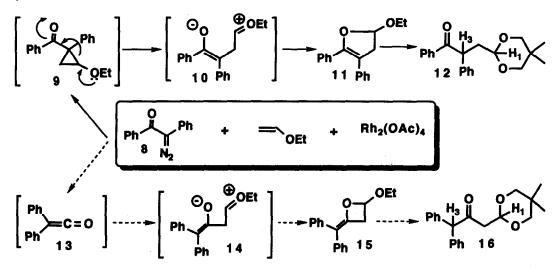

In connection with a synthetic approach we are developing<sup>1</sup> to the potent anti-tumor agent taxol,<sup>2,3</sup>  $\alpha$ diazoketone 3 was prepared from Hagemann's ester (1) by the reduction, oxidation, conjugate addition, enolate trapping-diazo transfer sequence illustrated. Treatment of 3 with Rh<sub>2</sub>(OAc)<sub>4</sub> (2 mol %, 21 °C) in the presence of excess ethyl vinyl ether afforded neither the expected cyclopropylcyclohexanone 4 nor the cyclobutanone 5 that would have arisen from Wolff rearrangement followed by conventional [2 + 2] cycloaddition. Instead, a new compound was isolated that contained two tertiary vinyl carbons (<sup>13</sup>C NMR  $\delta$  102.4, 148.3 ppm), an acetal carbon ( $\delta$  104.6) and an attached proton (<sup>1</sup>H NMR  $\delta$  5.45 ppm). These features were consistent with both the oxetane structure 6 and the dihydrofuran system 7 which could have arisen from ring opening-rearrangement of

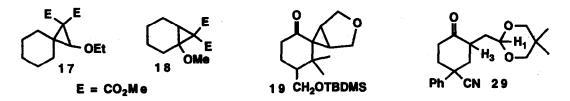

(a) DIBAL, C<sub>6</sub>H<sub>8</sub>, 0<sup>o</sup>C, 2h, 96%; (b) DDQ, dioxane, 25<sup>o</sup>C, 24h, 92%; (c) TBDMSCI, imidazole, DMF, 24h, 95%; (d) Me<sub>2</sub>CuLi, ether, 0<sup>o</sup>C, 1.5h, HCO<sub>2</sub>Et, 0.5h; (e) Et<sub>3</sub>N, TsN<sub>3</sub>, CH<sub>2</sub>Cl<sub>2</sub>, -15<sup>o</sup> to +21<sup>o</sup>C, 2h, KOH(aq), 15min, 20% from 2 DIBAL = Diisobutylaluminium hydride; DDQ = 2,3-Dichloro-5,6-dicyanoquinone; DMF = Dimethylformamide; TBDMSCI = t-Butyldimethylsilylchloride.

the intermediate cyclopropyl ketone 4. In spite of the visual difference between these ring systems various NMR experiments were inconclusive and standard hydrolytic and oxidative cleavage reactions gave mixtures. Thus establishing the structure unambiguously with only one compound available required acid catalyzed hydrolysis and *in situ* trapping of the resulting keto-aldehyde.

Discrete ketene carbonyl cycloadditions are rare. The two previously reported cases involved strong electron withdrawing groups in the ketene (the reaction of bis(trifluoromethyl)ketene with vinyl benzoate)<sup>4</sup> or sterically hindered ethers (diethylketene with the silyl enol ether of pinacolone).<sup>5</sup> In addition, *ab initio* molecular orbital calculations considered alkene addition to the ketene carbonyl to be energetically disfavoured relative to cyclobutanone formation.<sup>6</sup>

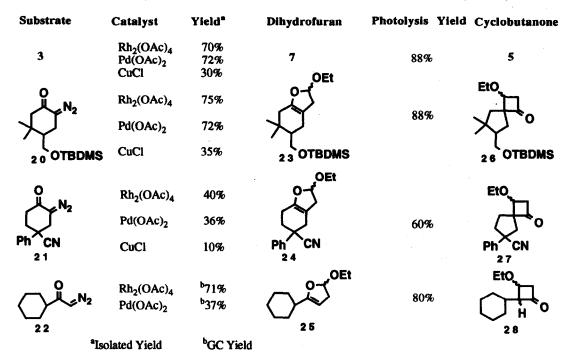

Direct pathways to the dihydrofuran 11 or the oxetane 15 from the diphenyl diazoketone  $8^7$  are feasible after initial reaction of the carbenoid intermediate. Both of these products may arise from the intermediacy of 1,3zwitterions such as 10 and 14 which posses both enolate and oxacarbenium character. Generally cyclopropanes with single electron donating and electron withdrawing groups (e.g., 1-ethoxy-2-carboethoxycyclopropane) are stable at room temperature and require more forcing conditions for rearrangement. Thus, direct rearrangement usually requires either two donor or two acceptor groups. The ease with which the initial cyclopropane undergoes a 1,3-sigmatropic shift is therefore both substituent and substrate dependent.<sup>8</sup> For example, the spirosystem 17 may be isolated, but the related cyclopropane 18 was not detected when dimethyl diazomalonate reacted in the presence of copper.<sup>9</sup> Other methoxy cyclopropanes also rearranged more readily than the corresponding ethoxy substituted isomers.<sup>10</sup> However, the reaction conditions markedly influence the course of diazo rearrangements, particularly solvent polarity (pentane versus  $CH_2Cl_2$ )<sup>11</sup> and the catalyst ( $Rh_2(OAc)_4$  versus  $Rh_2(OPiv)_4$ ).<sup>12</sup> Cyclopropanated 2,3-dihydrofurans were the presumed intermediates generated from cyclic diazo-B-diketones in the presence of furans and rhodium carboxylate salts.<sup>13</sup> In the case of **3**, the major product from the reaction with ethyl vinyl ether was independent of the catalyst. Reaction with Pd(OAc)<sub>2</sub> or CuCl afforded the acetal product in isolated yields of 72% and 30% respectively, while the cyclopropyketone 19 was isolated in 65% yield with Rh<sub>2</sub>(OAc)<sub>4</sub> and 2,5-dihydrofuran.

The cyclic  $\alpha$ -diazoketones 20, 21 and the acyclic systems 8 and 22 displayed similar behaviour with ethyl vinyl ether and metal catalysts to afford acetals 23-28 and 11 whose dihydrofuran structures were established as follows. Treatment of 11 with *p*-toluenesulfonic acid in the presence of 3,3-dimethyl-1,3propanediol generated a keto-acetal that, on the basis of its NMR features, was assigned structure 12 rather than the isomer 16. (H<sub>1</sub>  $\delta$  4.92 coupled to both the adjacent methylene protons plus H<sub>3</sub>, a relationship that does not occur in 16)<sup>14</sup> Compound 29 derived from 24 displayed similar characteristics.<sup>15</sup>

## Table: Metal Catalyzed and Direct Photochemical Reactions in Ethyl Vinyl Ether

The use of benzophenone as a triplet sensitizer during the photolysis of  $\alpha$ -diazo ketones is known to promote cyclopropane formation,<sup>16</sup> although a large excess of sensitizer is required.<sup>17</sup> It was hoped these mild conditions would allow detection of the cyclopropane. Benzophenone (10 equiv.) sensitized photolysis of 3 failed to provide the cyclopropane 4. A mixture of cyclobutanone 5 (30%) and dihydrofuran 7 (25%) was formed instead. This result was surprising since Wolff rearrangement is considered to arise only from the singlet carbene.<sup>17,18</sup> Upon direct irradiation, no acetals could be detected and clean conversion to the cyclobutanones 5

26. 27. and 28 from [2 + 2] cycloaddition to the ketene double bond was observed. Decomposition of 8 under various conditions (Rh2(OAc)4 nentane:ethyl vinyl ether, 30:1, 0 °C; Rh2(OPiy)4 nentane:ethyl vinyl ether, 30:1,  $0 \, {}^{\circ}C)^{11,12}$  known to promote cyclopropanation also afforded 11 as the major product. A similar result was obtained with Rh<sub>2</sub>(OAc)<sub>4</sub> in ethyl vinyl ether at -78 °C.<sup>19</sup>

The formation of these dihydrofurans could be considered concerted 1.3-dipolar cycloadditions but this has been shown to be unlikely in metal catalyzed systems.<sup>20</sup> Rather cycloproparation of enol ethers, followed by rearrangement, has been established as the preferred pathway, 10.21-23 This is consistent with the behaviour of the  $\alpha$ -diazoketones above, although the mild conditions (21 °C or less) for the rearrangement are noteworthy.

In summary, spontaneous dihydrofuran formation from  $\alpha$ -diazoketones usually requires diactivated cvclopropyl carbonyl systems. This mild route from cvclic  $\alpha$ -diazoketones via monoactivated cvclopropyl ketones provides an attractive sequence to generate compounds for further synthetic manipulation in view of the widespread occurrence of five-membered oxygen-containing heterocyclic ring systems in nature.<sup>24</sup>

- Cyclopropanation is favoured by non polar solvents (pentane)<sup>11</sup> and catalysts such as Rh<sub>2</sub>(OPiv)<sub>4</sub>.<sup>12</sup> At (19) temperatures below 0 °C the pentane solution became heterogeneous and the results were inconclusive. The polarity of ethyl vinyl ether appears to encourage rearrangement since GC-MS analysis of the total reaction at -78 °C (diethyl ether) indicated the presence of a minor component (-10%) consistent with the cyclopropane 9 but it could not be isolated and rigorously identified.
