**Abstract:** An efficient synthesis of various model compounds **4a-e** for the tricyclic core of popolophuanone **E** (**1**), a novel marine natural product, was accomplished; the method features highly regioselective annulation of the phenols **5a-e** with the 2,3-dichloro-1,4-benzoquinones **7**, **7c-e**. Preliminary studies definitely demonstrated the feasibility of our designed synthetic strategy for **1** (the phenolic subunit **I** + the quinone subunit **II** → **1**). Popolophuanone **E** (**1**) isolated from the Pohnpei marine sponge *Dysidea* sp. by Scheuer *et al.* in 1993, is a potent inhibitor of topoisomerase-II and exhibits a highly selective cytotoxicity against human non-small cell lung cancer cells.<sup>2</sup> The gross structure of **1** was revealed by means of extensive spectroscopic studies to have a unique 3,7,8-trihydroxydibenzofuran-1,4-dione nucleus which possesses two identical *cis*-fused decalin moieties the same as in arenarol (**2**).<sup>2,4</sup> Scheuer *et al.* proposed that **1** might be produced *in vivo* by oxidative dimerization of the as-yet-unreported 6'-hydroxyarenarol (**3**).<sup>2,5</sup> Its remarkable biological properties and unique structural features make **1** an exceptionally intriguing and timely target for total synthesis. We embarked on a project directed at the total synthesis of optically active **1** and its congeners with the aim of exploring the structure-activity relationships. Our synthetic strategy for **1** was designed as shown in **Scheme 1**, which features the biogenetic-type annulation of the phenolic subunit **I** with the quinone subunit **II** to regioselectively

construct the 3,7,8-trihydroxydibenzofuran-1,4-dione skeleton representing the tricyclic core of **1** as the key step. We wish to report here an efficient synthesis of 2-substituted- and 2,6-disubstituted-3,7,8-trihydroxydibenzofuran-1,4-dione derivatives **4a-e** as model compounds for **1**, demonstrating the feasibility of our designed synthetic strategy.

At first, we pursued the synthesis of the model compound **4a** as shown in **Scheme 2**. In our preliminary studies, the known 2-methoxy-3-methyl-1,4-benzoquinone (**6**)<sup>7</sup> was first employed as **II** for the annulation with commercially available 3,4-dimethoxyphenol (**5a**) corresponding to **I**. However, neither the coupling products nor the cyclization products were found in the reaction mixture probably due to the poor electrophilicity of **6**. After experimentation, the 2,3-dichloro-1,4-benzoquinone **7** was found to behave as **II**. This compound **7**, mp 107-111°C, was readily prepared from **6** in one step by dichlorination.<sup>8</sup> The crucial regioselective annulation of **5a** with **7** to construct the requisite dibenzofuran-1,4-dione **9a** turned out to be effected by a two-step sequence.<sup>9</sup> Thus, the initial coupling reaction of **5a** with **7** in the presence of sodium hydride in tetrahydrofuran at -78°C followed by warming to -35°C proceeded smoothly to afford the C-substituted product **8a**,<sup>10</sup> mp 110-111°C, as a single regioisomer in 67% yield. The structure of **8a** was unambiguously established as depicted by its X-ray diffraction analysis.<sup>11</sup> Subsequent ring closure was carried out by exposure of **8a** to Amberlite® IRA-900 (OH<sup>-</sup> form)<sup>12</sup> in chloroform at 0°C, leading to formation of **9a**, mp 217-218°C(dec), in 72% yield. The final phase remaining to complete the synthesis of **4a** was the full deprotection of the three methyl groups in **9a**.<sup>13</sup> Treatment of **9a** with aluminum chloride in refluxing dichloromethane afforded monomethyl ether **10a**, mp 212-215°C(dec), which was further allowed to react with boron tribromide in refluxing dichloromethane, giving rise to **4a**,<sup>14</sup> mp >300°C.

With completion of the synthesis of **4a**, the explored synthetic scheme was next applied to the synthesis of various model compounds **4b-e** possessing two identical methyl, *n*-butyl, cyclohexymethyl, and *cis*-decalin-1-ylmethyl groups at the C-2 and C-6 positions, respectively (**Schemes 2** and **3**). Towards this end, preparation of the phenols **5b-e** and the 2,3-dichloro-1,4-benzoquinones **7c-e** was first attempted. Hydrogenation of the benzoquinone **6** followed by monomethylation furnished **5b**, mp 105-106°C. The other phenols **5c-e** were accessible from commercially available 3,4-dimethoxyphenol (**11**) via a four-step sequence

involving protection of **11** as its methoxymethyl (MOM) ether, coupling reaction<sup>15</sup> of the aryl lithium *in situ* generated from **12** with various types of the aldehydes,<sup>16</sup> reductive removal of the secondary hydroxy group in **13c-e**, and final deprotection of the MOM group in **14c-e**. On the other hand, the 2,3-dichloro-1,4-benzoquinones **7c-e** were prepared in five steps from the known 3-methoxy-1-(methoxymethoxy)benzene (**16**).<sup>15</sup> Thus, **16** was converted to the phenols **19c-e** *via* alcohols **17c-e** and MOM ethers **18c-e** by a reaction sequence similar to that described for the preparation of **22c-e** from **12**. Further conversion of **19c-e** to **7c-e** was carried out by sequential oxidation with salcomine<sup>17</sup> and dichlorination<sup>18</sup> of the resulting 1,4-benzoquinones **20c-e**.

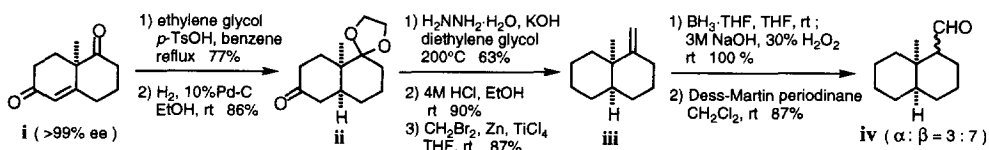

With the requisite phenols **5b-e** and 2,3-dichloro-1,4-benzoquinones **7**, **7c-e** in hand, we next focused our attention on construction of the dibenzofuran-1,4-diones **9b** and **22c-e** (Schemes 2 and 3). By employing a reaction sequence similar to that described for the preparation of **9a** from **5a** and **7**, the requisite dibenzofuran-1,4-diones **9b**, mp 182-183.5°C, and **22c-e** (**22c**: mp 101-103°C, **22d**: mp 133-135°C, **22e**: mp 251-253.5°C) were prepared from **5b-e** and **7**, **7c-e** in good yields (74-97%, 2 steps) *via* the coupling products **8b** and **21c-e**. It is noteworthy that the entire crucial two-step annulation (**5b+7**→**8b**→**9b**, **5c+7c**→**21c**→**22c**, **5d+7d**→**21d**→**22d**, and **5e+7e**→**21e**→**22e**) took place with a high regioselectivity similar to that of **5a** with **7** (**5a+7**→**8a**→**9a**). Complete removal of the three methyl groups in **9b** and **22c,d** according to the same procedure as described for **9a** afforded the requisite model compounds **4b-d**<sup>14</sup> (**4b**: mp >300°C, **4c**: mp 258-262°C(dec), **4d**: mp 286-289°C) *via* monomethyl ethers **10b**, mp 262-266°C(dec),

and **23c,d** (**23c**: mp 224-226°C, **23d**: mp 242-244.5°C(dec) ). In the case of **22e**, full deprotection was effected upon treatment with boron tribromide in refluxing dichloromethane, directly providing the model compound **4e**,<sup>14</sup> mp >300°C, in good yield.

In summary, we have succeeded in developing an efficient synthetic pathway to various model compounds **4a-e** for the 3,7,8-trihydroxydibenzofuran-1,4-dione system of **1**.<sup>19</sup> The key feature of the synthesis consists of highly regioselective annulation of the phenols **5a-e** with the 2,3-dichloro-1,4-benzoquinones **7**, **7c-e** to construct the dibenzofuran-1,4-dione systems **9a-b** and **22c-e** representing the tricyclic core of **1**. Our successful synthesis of **4a-e** obviously suggests that the total synthesis of **1** would be accomplished by employing the proposed synthetic strategy (*vide supra*). Studies on the total synthesis of optically active **1** are in progress and will be reported shortly.
