A NOVEL MODIFICATION OF THE RITTER REACTION USING TRIMETHYLSILYL CYANIDE

H. G. Chen, O. P. Goel,* S. Kesten, J. Knobelsdorf Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, MI 48105

Abstract: A new modification of the Ritter reaction using trimethylsilyl cyanide (Me₃SiCN) is described, which converts alcohols to their corresponding formamides in high yields using a convenient procedure. The reaction conditions and mechanism are discussed. In some cases, new formamides are synthesized which cannot be prepared by the classical Ritter reaction. Copyright © 1996 Elsevier Science Ltd

The Ritter reaction I provides a useful method to convert alcohols or alkenes to amides by reaction with nitriles in the presence of sulfuric acid. The known reaction pathway involves the protonation of an appropriate alcohol or alkene generating a carbocation, which adds to the nitrile, followed by hydrolysis to the corresponding amide.

During the synthesis of an important tachykinin NK₃ antagonist and its analogs,² we needed multigram quantities of a key intermediate (2). The classical Ritter reaction³ of N-benzyl-4-hydroxy-4-phenylpiperidine (1) with NaCN, and concentrated sulfuric acid in acetic acid as solvent, gave the alkene (3) as major product (80%) instead of the expected formamide (2) (17%)⁴ (Scheme 1). However, reaction with acetonitrile under the same conditions gave the expected acetamide (4) in 95% yield. In view of this, we thought to try a more nucleophilic 'HCN' equivalent, such as trimethylsilyl cyanide (Me₃SiCN), in the Ritter type conversion of (1) to (2). This gave us the desired formamide (2) in good yield (70%). The alkene (3) under the same conditions was recovered with little formation of formamide product ((2): (3) = 6: 94). A thorough literature search showed no previous example of Me₃SiCN used in the Ritter type reaction. This encouraged us to further study this reagent in this novel application.

| 15 | Ph OH | no reaction | | 0 |
| 16 | Ph OH | no reaction | | 0 |

^{*} All structures are consistent with ¹H NMR, ¹³C NMR, IR, MS and elemental analysis.

The reaction reported herein, involves a slow addition of concentrated sulfuric acid to a mixture of an alcohol and trimethylsityl cyanide. Since the reaction with sulfuric acid is highly exothermic, the mixture of alcohol and Me₃SiCN is usually cooled in an ice bath under inert atmosphere. The reaction mixture is then warmed to ambient temperature. After the reaction is complete, the mixture is neutralized with NaOH, and the formamide product is purified by recrystallization or chromatography. The results are compiled in Table 1. These results show that better yields are obtained with substituents which stabilize the carbocation intermediate (entries 2, 5). Rearrangement products are observed (entry 12, 13), which also implies a carbocation intermediate in the reaction pathway. Secondary alcohols (entries 13, 14) give lower yields than tertiary alcohols, while no reaction is observed with primary alcohols (entries 15, 16). Pure silylated alcohols (ROSiMe₃) also give the expected formamides (entry 9).

The best ratio of the reactants was determined, and the results are listed in Table 2. A large excess of Me_3SiCN and sulfuric acid does not increase the yield. We found the optimum ratio is alcohol: $Me_3SiCN: H_2SO_4 = 1:2:3$. When solid alcohols are used, the reaction mixture may become too thick to stir. In this situation, HOAc may be added as a solvent, and this does not lower the yields.⁵

Table 2

| Table 2 | | | | | | |
|-------------------------|------------------------|----------------------------------|---|----------------------------|--|--|
| Ph OH CO ₂ H | + Me ₃ SiCN | + H ₂ SO ₄ | | Ph NHCHO CO ₂ H | | |
| mmols | mmols | mmols | | yield% | | |
| 10 | 50 | 115 | | 94 | | |
| 10 | 50 | 60 | | 94 | | |
| 10 | 40 | 50 | | 93 | | |
| 10 | 30 | 40 | | 95 | | |
| 10 | 20 | 30 | • | 95 | | |
| 10 | 10 | 20 | | 79 | | |

The mechanism of the reaction is proposed in Scheme 2. The protonation of the alcohol OH group with H_2SO_4 , followed by loss of water gives the carbocation (6). Me₃SiCN reacts quickly with the carbocation to form intermediate (7), which is then hydrolyzed to the formamide (8).

General Procedure: To a mixture of alcohol (10 mmol) and trimethylsilyl cyanide (20 mmol), cooled to - 15°C in an ice-salt bath, under nitrogen, is added concentrated sulfuric acid (30 mmol) dropwise with vigorous stirring (caution: highly exothermic). After the addition, the cold bath is removed and the mixture is stirred at ambient temperature for 18 hrs. The mixture is then poured onto ice, and neutralized with 50% NaOH solution to pH ~ 7. The aqueous is extracted with tBuOMe or CHCl₃, and the combined organic extracts are washed with brine, and dried over MgSO₄. The crude product is purified by recrystallization (solid) or flash chromatography (oil).

In summary, we have developed a novel modification for the Ritter reaction using Me_3SiCN , which provides a convenient and useful way to convert tertiary and secondary alcohols to the corresponding formamides. The ease of handling of Me_3SiCN would also facilitate in the rapid synthesis of combinatorial libraries of formamides. Further study of the reagent with alkenes and other functional groups is currently on-going in our laboratory.
