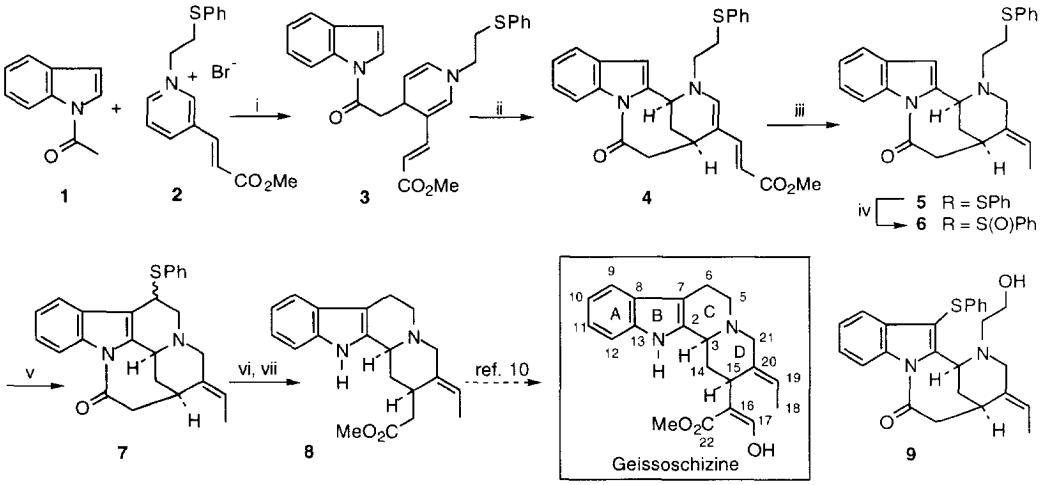
Laboratory of Organic Chemistry, Faculty of Pharmacy, University of Barcelona, 08028-Barcelona, Spain

Abstract: A stereocontrolled synthesis of (±)-geissoschizine, involving the addition of the enolate derived from 1-acetylindole to pyridinium salt **2**, cyclization of the resultant 1,4-dihydropyridine, stereoselective elaboration of the *E*-ethylidene substituent, closure of C ring by Pummerer reaction, and methanolysis of the resulting pentacyclic lactam, is reported.

Geissoschizine, a pivotal early intermediate in indole alkaloid biosynthesis, has received considerable attention from the synthetic standpoint.[1] However, most of the reported syntheses of this alkaloid suffer from some stereochemical problems, as they usually lead to C-3/C-15 *trans* indoloquinolizidine derivatives and/or to the unnatural *Z* configuration (or *Z*/*E* mixtures) for the ethylidene double bond. Consequently, additional steps to promote epimerization at C-3 and/or *Z*–*E* isomerization are required.[2]

We present here a concise, stereocontrolled synthesis of (±)-geissoschizine, in which the required C-3/C-15 *cis*-relationship is secured from the bridgehead character of these carbons in the intermediates **4**-**7**, which embody an extra seven-membered bridged ring that acts as an element of stereochemical control. (Scheme 1). On the other hand, the *E*-configurated ethylidene substituent is stereoselectively formed taking advantage of the β-(tetrahydropyridyl)acrylate moiety of tetracycle **4**. Interestingly, the C-16/C-22 two-carbon fragment of the final intermediate **8** comes from the acetyl group of the starting *N*-substituted indole **1**. The synthesis is based on the general methodology for indole alkaloid synthesis involving the nucleophilic addition of indole-containing enolates to *N*-alkylpyridinium salts, with subsequent elaboration of the resulting 1,4-dihydropyridines.[3]

Interaction of the enolate derived from acetylindole **1** with pyridinium salt **2**, followed by acid-induced cyclization of the resulting 1,4-dihydropyridine **3** in the presence of lithium iodide,[4] led to tetracycle **4**,[5] which was stereoselectively elaborated into the (*E*)-ethylidene derivative **5** (30% yield) by the known[6] one-pot sequence consisting of treatment with refluxing aqueous HCl and subsequent sodium borohydride reduction. Sulfide **5** was then chemoselectively oxidized at the sulfur atom with *m*-CPBA to give sulfoxide **6** (80% yield) as a mixture of stereoisomers. Pummerer cyclization[7] of amino sulfoxides **6** was effected with trimethylsilyl triflate in the presence of diisopropylethylamine to give a 3:1 epimeric mixture of pentacyclic sulfides **7**[8] in 64% yield.[9] The opening of the seven-membered lactam ring by methanolysis, followed by desulfurization, gave the known indoloquinolizidine **8** (50% overall yield from **7**), which had previously been converted into (±)-geissoschizine.[10]



Scheme 1. *Reagents and Conditions:* i) LDA, THF; ii) TsOH-C_6H_6, LiI, THF, rt, 1.5 h; iii) 2.5 N HCl, 100 °C, 2 h, then $NaBH_4$, MeOH, 0 °C, 1 h; iv) TFA (1 eq), then *m*-CPBA, -70 °C, 15 min; v) TMSOTf, DIPEA, CH_2Cl_2, rt, 1.5 h; vi) MeONa (1.5 eq), 4:1 MeOH-THF, rt, 3 h; vii) Bu_3SnH, AIBN, C_6H_6, reflux, 4 h.
