Novel cyclo-dimerization of 1-*tert*-butoxycarbonyl-3-alkenylindole derivatives

Ikuo Kawasaki, Masami Terano, Erika Yada, Miwa Kawai, Masayuki Yamashita and Shunsaku Ohta*

Kyoto Pharmaceutical University, Misasagi Yamashinaku, Kyoto 607-8414, Japan Received 12 November 2004; revised 10 December 2004; accepted 10 December 2004 Available online 8 January 2005

Abstract—Reaction of 1-*tert*-butoxycarbonyl-3-cyclopentylidenemethyl-1*H*-indole with an excess of trifluoroacetic acid in dichloromethane at room temperature gave a cyclic dimer, 13-cyclopentyl-6,7,12,13-tetrahydrospiro[5*H*-cyclohepta[1,2-*b*:4,5-*b*']diindole-6,1'-cyclopentane] in 73% yield as the sole product through a novel cyclo-dimerization process. Structure of the cyclic dimer derived from 5-bromo-1-*t*-butoxycarbonyl-3-cyclopentylidenemethyl-1*H*-indole was elucidated by X-ray crystallographic analysis. © 2004 Elsevier Ltd. 1. Introduction

A number of bisindole alkaloids have been isolated from various genera of marine sponges, and they have become an important focus of scientific attention because of the high degree of their biological activity and their unique structure.^{1,2} Of remarkable importance is the fact that bisindoles often exhibit more potent biological activity than the monomeric units.³ For these reasons, over the past several years, some efforts have been devoted towards the development of new synthetic methods for this type of natural products.4 Among them, bisindole alkaloid caulersin 1, isolated from an alga Caulerpa serrulata in 1997, has been known as the first member constructed from the unique cyclohepta[1,2b:4,5-b']diindole skeleton (Fig. 1).5 Total synthesis of 1 was achieved through several steps of reactions involving cyclization for the construction of the central seven-membered ring system by Fresneda et al.⁶ and Bergman and co-workers.⁷ In this paper, we would like to present a novel cyclo-dimerization of 1-tert-butoxycarbonyl-3-alkenylindole derivatives by treatment with an excess of trifluoroacetic acid (TFA) to give cyclohepta[1,2-b:4,5-b']diindoles.

Figure 1. Structure of caulersin.

2. Results and discussion

In the course of our continuous research⁸ for synthesis of bioactive imidazole–indole alkaloids such as tubastrindoles⁹ and cycloaplysinopsins, ¹⁰ we prepared a 2',2'-disubstituted 1-tert-butoxycarbonyl-3-alkenyl-1Hindole as a model monomer from 1-Boc-3-formylindole 2¹¹ by treating with cyclopentyltriphenylphosphonium bromide as shown in Scheme 1.12 The alkenylindole 3a was then treated with an excess of TFA in dichloromethane (DCM) for removing the Boc group;¹³ however, the unexpected cyclodimer 4a was obtained in 73% yield after chromatographic purification (Scheme 1).14 The cyclodimer 4a gave an M⁺ peak in its HREIMS at m/z 394.2405, which corresponded to the molecular formula $C_{28}H_{30}N_2$. Two broad peaks at 7.75 and 7.81 ppm in the ¹H NMR spectrum, and a strong absorption band at 3438 cm⁻¹ in the IR spectrum suggested the presence of the two NH protons of the indole rings. In the

¹H-¹H COSY spectrum, CH(13)-CH(14)-CH₂(15, 18) and one CH₂(7) attached to two quaternary carbons were revealed. These spectral data and HMBC experiment led to the indicated structure of the obtained product **4a** to have a seven-membered ring between two indole moieties as depicted in Scheme 1. ¹⁵

In general, 3-alkenylindoles have been well known as substrates for [4+2] cycloaddition reaction to six-membered ring systems^{16,17} and dimerization reactions to cyclopent[*b*]indole compounds having a five-membered ring systems,¹⁸ respectively. To our best knowledge, the present reaction is the first example of cyclo-dimerization reaction from 3-alkenylindoles to construct a seven-membered ring skeleton such as the cyclohepta-[1,2-*b*:4,5-*b*']diindole.

Then, we examined the reaction solvents for preparing the cyclodimer (Table 1). It was found that the reaction of **3a** in DCM gave the best result (73%; entry 1). The reaction in toluene gave **4a** in only 36% yield together with a by-product **5** (15% yield, entry 3), whose structure was determined by HMBC experiment as shown in Figure 2. Isolation of the mono-Boc compound **5** might

suggest that removal of the remaining second Boc group from the relatively hindered 12-position by action of TFA should be the final step of this cyclo-dimerization process. On the other hand, treatment of 3a with TFA in THF gave no reaction (entry 4). Treatment of Nunsubstituted 3-cyclopentylidenemethylindole **3b** under the same reaction conditions as entry 1 afforded only a complex mixture and no cyclodimer 4a (entry 5), and this result suggested that the presence of a Boc group at the 1-position should be an important factor to promote the present cyclo-dimerization reaction. Furthermore, reaction with CF₃CO₂D instead of TFA was performed, and it was found that deuterium was incorporated at the 14-position (55%) and the 7-position (24%) in the product 4a, respectively. From these facts, we propose a reaction mechanism as shown in Scheme 2. Removal of the 1-Boc group may be the first step of this reaction to give the active intermediate 6,

then the dimer 7 might be provided by the reaction of 6 with the 1-Boc indole 3a. The mono-*N*-Boc-cyclohepta[1,2-*b*:4,5-*b*']diindole 5 is furnished by the '7-*endo*'-type ring closure of 7 followed by aromatization.

Next, we prepared several 1-Boc-3-alkenylindole derivatives, ¹⁹ and the results of their reaction with TFA are summarized in Table 2. The reaction of **3c** and **3d** in DCM proceeded better than in CHCl₃ to give the corresponding cyclodimers **4b** and **4c** (entries 1–4). Unfortunately, treatment of 2',2'-diphenylated and unsubstituted alkenylindoles **3e** and **3f** gave only complex mixtures (entries 5 and 6); however, use of the 2'-monophenylated compound **3g** provided a mixture of *syn* and *anti* 13-benzyl-6-phenylcyclohepta[1,2-*b*:4,5-*b*']-diindoles (**4d** and **4e**) in 77% yield (entry 7). Although formation of a cyclic dimer, cyclopent[*b*]indole, was

^c Total yield of **4d** and **4e**.

known by treatment of methyl 3-(1*H*-indol-3-yl)-2-propenoate **8** with HCl,²⁰ in our experiment with TFA only removal of the 1-Boc group was observed in the reaction of the corresponding 1-Boc indole **3j** to give the NH indole **8** in 76% yield (entry 10). The cyclo-dimerization reaction of 3-cyclopentylidenemethylindole having bromo and methoxy groups at the 5-position smoothly proceeded to give crystalline cyclodimers **4f** (mp 278–279 °C) and **4g** (mp 139–140 °C) in good to moderate yields (82% and 59%) (entries 8 and 9), and the structure of the former **4f** could be elucidated by X-ray crystallographic analysis as shown in Figure 3.²¹

As a conclusion, we have found a novel cyclo-dimerization of 1-tert-butoxycarbonyl-3-alkenylindole derivatives to give the cyclohepta[1,2-b:4,5-b']diindoles. Further investigation and applications of this reaction are under way, and the results of these studies will be reported elsewhere in due course.

- 14. Preparation of **4a** as a typical experiment: TFA (0.3 mL, 3.9 mmol) was added to a stirred solution of **3a** (89 mg, 0.3 mmol) in DCM (3.0 mL) under N₂ at 0 °C. After stirring for 1 h at 0 °C, the cooling bath was removed and the reaction mixture was stirred at room temperature for 24 h. The reaction mixture was neutralized by addition of satd NaHCO₃ aq and the products were extracted with CHCl₃ (30 mL × 3). The organic layer was dried over anhydrous sodium sulfate and evaporated to give an oily residue, which was purified by silica gel column chromatography (*n*-hexane to AcOEt/*n*-hexane = 1/8) to give pure **4a** (43 mg, 73%) as a pale yellow solid. Analytical sample was obtained by recrystallization from isopropyl ether (mp 239–240 °C).
