Abstract—A method for the synthesis of 3,3-disubstituted oxindole derivatives is described. This involves the base-mediated addition of malonate esters to 3-halo-3-alkyloxindoles. The addition is tolerant of a range of alkyl substituents at position 3 of the oxindole. Addition to an aryl chloro-oxindole is also described. © 2007 Elsevier Ltd. All rights reserved.

Oxindoles are ubiquitous in their presence in nature as well as in pharmaceutically relevant substances.¹ Methods for functionalization of the oxindole nucleus are thus of value in medicinal chemistry and natural product synthesis.

During the course of our studies on the synthesis of alkaloid natural products we sought a convenient preparation of functionalized 3,3-disubstituted oxindoles. To this end we envisioned the formation of 1 via alkylation of a highly reactive electrophilic *o*-azaxylylene intermediate 2 with a suitable nucleophile precursor such as malonate ester 3 (Scheme 1). Compound 2 can in turn be conveniently generated in situ from 3-halo-3-oxindole 4 by base-mediated dehydrohalogenation.

Since the first reports of Hinman and Baumann² in 1964, the potential of 3-bromo-oxindoles as electrophiles has been realized to only a limited extent.³ We sought to expand the scope of these electrophiles by employing malonate nucleophiles for the formation of a carbon–carbon bond at C-3 of the oxindole.

We initially chose bromooxindole 5 as a test substrate. On screening a number of bases employing dimethyl malonate as the pro-nucleophile, we discovered that amidine and phosphazene bases promoted the alkylation in high yield (Table 1). We decided to employ

1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) in our subsequent studies due to its ready availability.

We were able to achieve smooth additions of malonate esters to a variety of 3-bromo-3-alkyloxindoles to generate 3,3-disubstituted oxindoles under mild reaction conditions (Table 2). In addition to dimethyl malonate, diethyl, and dibenzyl malonates delivered the corresponding alkylated products efficiently (entries 4 and 5). A 3-aryl-3-chloro-oxindole could also be employed as the electrophilic component in the reaction (entry 3).

A representative procedure is as follows: Bromo-oxindole 5 (48.2 mg, 0.1144 mmol) was dissolved in THF (1 mL) in the presence of dimethyl malonate (0.3432 mmol, 39μ L). The solution was cooled to -78 °C and DBU (0.3432 mmol, 51 µL) was added dropwise. The reaction mixture was then allowed to warm to 23 °C and quenched by the addition of saturated aqueous NH₄Cl (1 mL), diluted with water (30 mL) and extracted with EtOAc (3 × 20 mL). The combined extracts were washed with brine (1 × 30 mL), dried (Na₂SO₄) and concentrated under reduced pressure to yield a residue that was purified by silica gel chromatography (1:1 hexanes–EtOAc) to yield adduct **6**⁴ as a colorless oil (46.7 mg, 87% yield).

In summary, we have expanded the scope and utility of 3-halooxindoles as electrophiles and have demonstrated their ability to undergo the addition of malonates under mild conditions to generate 3,3-disubstituted oxindoles. We anticipate the utility of this transformation to access biologically relevant oxindoles.
