Diones

ABSTRACT

α-Chloro-1,2-diones and α-fluoro-1,2-diones were prepared from the corresponding α-chloroaldimines by a sequence of reactions involving cyanation to α-cyanoenamines, α-halogenation to form α-chloro- or α-fluoroimidoyl cyanides and addition of organolithium reagents across the nitrile moiety, followed by acidic hydrolysis. All steps are straightforward and occur without side reactions finally leading to regiospecifically chlorinated and fluorinated 1,2-diones in good yields.

1,2-Dicarbonyl compounds have found widespread applications in the synthesis of several heterocyclic compounds[1] and many good synthetic approaches for substituted 1,2-diketones have been described.[2] Also halogenated 1,2-diones are useful in pharmaceutical and agrochemical development,[3] although their regiospecific synthesis remained problematic.[4] α-Chloro-1,2-diones have found application in the synthesis of chlorinated (2-amino)-4-acylthiazoles[5] and 3,4-dihydroxythiophenes[6] while α-fluoro-1,2-diones are building blocks for fluorinated (bicyclic) pyrazines,[7] tetrahydrofurans,[8] and imidazoles.[9] The synthesis and reactivity of α-chlorinated and α-brominated imidoyl cyanides have been extensively discussed in previous papers[10,11] but until now α-fluorinated imidoyl cyanides remained unknown. As a part of our investigations in the chemistry of α-fluorinated imines,[12] the synthesis and reactivity of fluorinated imidoyl cyanides, which constitute a promising new class of building blocks for the synthesis of fluorinated azaheterocyclic compounds,[13] were studied. It is known that the addition of organolithium compounds across the nitrile function of N,N-disubstituted α-cyanoenamines **1** leads to adducts[14] which can be hydrolyzed into 1,2-diones **3** (Scheme 1).[15] On the other hand, tautomerizable α-cyanoenamines **2** (R^1 = H; R^2 = alkyl) react with organolithium compounds[16] or Grignard reagents[17] to give deprotonation at nitrogen followed by elimination of cyanide to afford ketenimines **4**. We report now on the selective addition of organolithium compounds across the nitrile function of α-chloroimidoyl cyanides **9** and α-fluoroimidoyl cyanides **10**, thereby not affecting the α-halogen. The resulting halogenated 1,2-diimines **11** and **13** are hydrolyzed toward regiospecifically α-halogenated 1,2-diketones, an interesting class of trifunctional building blocks.

α-Cyanoenamines **8** were prepared from aldehydes **5** via imination to aldimines **6**, α-chlorination to form chloroaldimines **7**,[18] and cyanation resulting in α-cyanoenamines **8**.[19] The obtained compounds **8** were well chlorinated at the α-position in quantitative yield using *N*-chlorosuccinimide in carbon tetrachloride (Scheme 2).[10,11] Fluorination of α-cyanoenamines **8** was performed with *N*-fluorobenzenesulfonimide (NFSI) or 1-chloromethyl-4-fluoro-1,4-diazoniabicyclo[2.2.2]octane bistetrafluoroborate (Selectfluor) as fluorination reagents in acetonitrile at room temperature to afford α-fluoroimidoyl cyanides for the first time.[20] Selectfluor was the reagent of choice because the workup of the reaction mixture was less complicated due to the lower solubility of Selectfluor in organic solvents during extraction, resulting in an easier purification by distil-

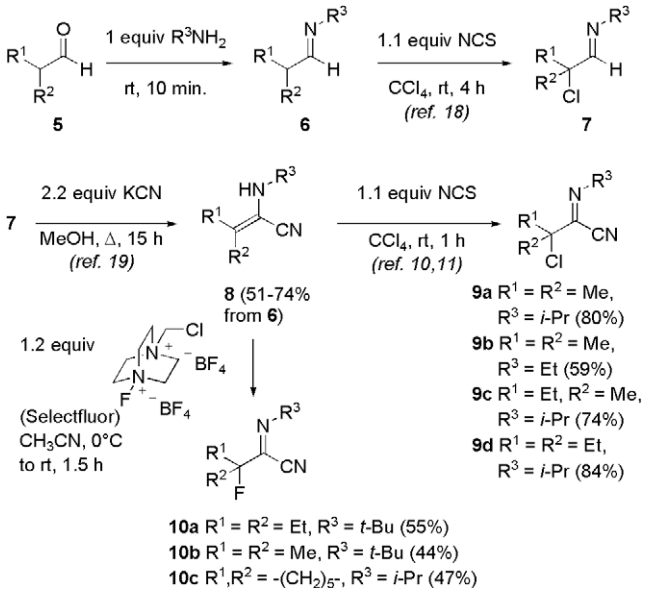
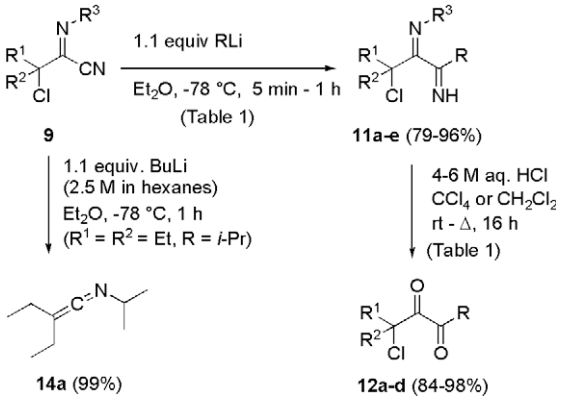


Scheme 2. Synthesis of α-cyanoenamines **8** followed by chlorination or fluorination to α-halogenated imidoyl cyanides **9** and **10**.



Scheme 3. Reaction of α-chloroimidoyl cyanides **9** with organolithium compounds and subsequent hydrolysis.

lation. Although α-fluoroimidoyl cyanides **10** were obtained in high yields, the purification by distillation resulted in some product decomposition and consequently in lower isolated yields.

Reaction of α-chloroimidoyl cyanides **9** with methyllithium (lithium bromide complex) or phenyllithium (1.8 M in Bu_2O) in diethyl ether at −78 °C afforded α-chloro-1,2-diimines **11** after careful aqueous workup at 0 °C (Scheme 3, Table 1).[21] If the reaction was performed at –20 °C only decomposition products were formed. Surprisingly, the use of butyllithium at −78 °C did not result in the selective addition of butyllithium across the nitrile function but yielded ketenimine **14a**[17] through a chlorine–metal exchange and expulsion of cyanide. A possible explanation for the different behaviors between BuLi and MeLi or PhLi is that BuLi is more basic and reactive than MeLi and PhLi. Consequently BuLi is more prone to induce a lithium halogen exchange. Methyllithium and phenyllithium did not attack the chlorine at −78 °C. The labile 1,2-diimines **11**, bearing an unsubstituted and a substituted nitrogen atom, were fully characterized by spectrometric methods (^{1}H NMR, ^{13}C NMR, IR, GC–MS). In some cases *E*/*Z* isomerism of these imines was observed. Upon hydrolysis with aqueous hydrochloric acid at room temperature in a two-phase system with carbon tetrachloride, these chlorinated 1,2-diimines **11a–d** were almost quantitatively converted into the corresponding α-chloro-1,2-diones **12a–c**.[22] The hydrolysis of phenyldiimine **11e** into 1,2-dione **12d** required more concentrated acid at reflux temperature. The present methodology allows the regiospecific synthesis of 1,2-diones, chlorinated at the α-position. This sequence of reactions leads to an interesting class of trifunctional compounds **12**, the chemistry of which has been only scarcely unraveled.[23]

Analogously, α-fluoroimidoyl cyanide **10a** was treated with 1.1 equiv of methyllithium (1.6 M in Et_2O) (Table 2). However, this reaction at room temperature in diethyl ether only gave traces of diimine **13a**. The major product found was ketenimine **14b**[17] that was formed by a fluorine–metal exchange and expulsion of cyanide (entry 1). Lowering the temperature to 0 °C did favor the attack at the nitrile but did not exclude the lithium fluorine exchange (entry 2). Also the aggregation of organolithium compounds is important for their reactivity, and is highly solvent dependent. In hexane, organolithium compounds are more aggregated and less reactive, compared to etheral solutions. Indeed we observed that MeLi in hexane (at 0 °C) was less reactive for attack at the α-fluorine and

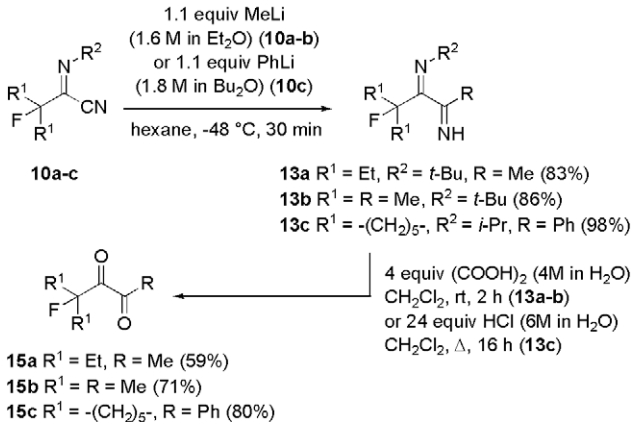
[a] Compounds **11** were isolated as pure liquids (purity > 95%), which were used as such in the next reaction step.
[b] Compounds **12a–c** were obtained from **11a–d** by hydrolysis with 10 mol equiv 4 M HCl in the presence of CCl_4 during 16 h at room temperature.
[c] Compound **12d** was obtained from **11e** by hydrolysis with 24 mol equiv 6 M HCl in the presence of CH_2Cl_2 during 16 h at reflux.



Scheme 4. Reaction of α-fluoroimidoyl cyanides **10** with organolithium compounds and subsequent hydrolysis.

led to less ketenimine byproduct, in comparison to MeLi in diethyl ether (entry 3). At −78 °C the reaction could not be driven to completion (entries 4 and 5). Finally, at −48 °C the reaction of **10a** and 1.1 equiv methyllithium in hexane led to a selective addition of methyllithium across the nitrile function resulting in diimine **13a** in 83% isolated yield and complete conversion (entry 6).[24] α-Fluoroimidoyl cyanides **10a-b** did not react with Grignard reagents, for example, *i*-PrMgBr or *s*-BuMgBr, possibly due to the sterical hindrance of the *N*-*tert*-butyl substituent.

Upon hydrolysis using aqueous oxalic acid at room temperature in a two-phase system with dichloromethane, fluorinated 1,2-diimines **13a–b** were converted into new α-fluorinated 1,2-diones **15a–b**.[25] The hydrolysis of phenyldiimine **13c** required more concentrated acid at reflux temperature (Scheme 4).

In conclusion, a new synthetic pathway for the regiospecific synthesis of 1,2-diones, chlorinated or fluorinated at the α-position, was developed. This class of compounds with potential as building blocks in organic chemistry, was synthesized via the selective attack of organolithium compounds across α-chloro- and new α-fluoroimidoyl cyanides resulting in novel α-halogenated 1,2-diimines followed by aqueous hydrolysis.

20. *Fluorination of α-cyanoenamines* **8**: The fluorination procedure is exemplified for the synthesis of (2*E*)-2-(*tert*-butylimino)-3-ethyl-3-fluoropentanenitrile **10a**. In a flame-dried 100 mL flask, a solution of 2.00 g (11.11 mmol) of 2-(*tert*-butylamino)-3-ethylpent-2-enenitrile **8e** in 50 mL of acetonitrile was cooled to 0 °C and was treated portionwise with 3.94 g (13.33 mmol; 1.2 equiv) of Selectfluor. The mixture was allowed to warm up to room temperature and stirred for 1.5 h. The reaction mixture was poured in 50 mL of water and extracted with 3 × 50 mL of dichloromethane. The combined organic phases were dried over $MgSO_4$ and the solvents were evaporated in vacuo after filtration of the drying agents. The residual oil was distilled to yield 1.21 g (6.11 mmol, 55%) of pure (2*E*)-2-(*tert*-butylimino)-3-ethyl-3-fluoropentanenitrile **10a** (bp 80 °C, 19 mmHg) as a colorless oil. ^{1}H NMR ($CDCl_3$, 300 MHz): δ 0.91 (6H, t, J = 7.4 Hz, 2 × CH_3); 1.43 (9H, s, 3 × CH_3); 1.89 (2H, dq, J = 17.1 Hz, 7.4 Hz, CH_2); 1.91 (2H, dq, J = 24.3 Hz, 7.4 Hz, CH_2). ^{19}F NMR ($CDCl_3$, 282 MHz): δ −162.3 (1F, t × t, J = 24.3 Hz, 17.1 Hz). ^{13}C NMR ($CDCl_3$, 75 MHz): δ 6.9 (d, J = 5.8 Hz); 29.0; 29.5 (d, J = 23.1 Hz); 58.6; 99.9 (d, J = 180.0 Hz); 110.5; 141.1 (d, J = 33.5 Hz). IR (ATR, cm^{-1}): ν = 2975; 2942; 2886; 2218 (CN); 1641 (C=N); 1462; 1366; 1240; 1210; 1160; 1092; 1040; 955; 912; 860. GC–MS (EI) m/z (%): 198 (M^+, 1); 183 (M^+–CH_3, 14); 155 (4); 143 (4); 124 (8); 114 (17); 69 (5); 57 ($^+C(CH_3)_3$; 100); 41 (19).
21. *Reaction of α-chloroimidoyl cyanides with organolithium compounds*: The general procedure is exemplified for the synthesis of *N*-[(3*E*)-2-chloro-4-imino-2-methylpentan-3-ylidene]propan-2-amine **11a**. A solution of 5.17 g (0.03 mol) of (2*E*)-3-chloro-3-methyl-2-(propan-2-ylimino)butanenitrile **9a** in 40 mL of freshly distilled diethyl ether was cooled to −78 °C and was treated dropwise, while stirring under nitrogen, with 22 mL of 1.5 M methyllithium–lithium bromide complex (0.033 mol) in diethyl ether. After stirring for 5 min at −78 °C, the cooling bath was removed and stirring was continued for 15 min. The reaction mixture was then poured into 100 mL of iced water, to which 10 mL of 2 M sodium hydroxide solution was added, and the organic phase was isolated. The aqueous phase was extracted with diethyl ether and the combined organic extracts were dried (K_2CO_3). Filtration of the drying agent and evaporation of the solvent in vacuo afforded compound **11a** (4.90 g, 87%) as a light yellow oil (purity > 96%; ^{1}H NMR). These labile 1,2-diimines **11** were used immediately in the next hydrolysis step. *N*-[(3*E*)-2-Chloro-4-imino-2-methylpentan-3-ylidene]isopropylamine **11a**. ^{1}H NMR ($CDCl_3$, 60 MHz): δ 1.08 (6H, d, J = 6 Hz, NCH(CH_3)$_2$); 1.77 (6H, s, (CH_3)$_2$CCl); 2.20 (3H, s, CH_3C=N); 3.48 (1H, septet, J = 6 Hz, NCH); NH invisible. ^{13}C NMR ($CDCl_3$, 20 MHz): δ 23.6; 28.8; 30.9; 53.1; 68.8; 168.3; 176.6. IR (NaCl, cm^{-1}): ν = 1628–1650 (C=N). GC–MS (EI) m/z (%): 188/190 (M^+, 0.5); 173/175 (3); 153 (3); 152 (3); 146/148

22. *Hydrolysis of α-chloro-1,2-diimines* **11** *into α-chloro-1,2-diones* **12**: The procedure is exemplified by the conversion of **11a** into **12a**. A solution of 5.65 (0.03 mol) of 3-chloro-1,2-diimine **11a** in 50 mL of carbon tetrachloride was treated with 75 mL of 4 M hydrochloric acid (0.3 mol). The two-phase system was vigorously stirred during 16 h at room temperature after which the organic phase was separated, washed with brine, and dried ($MgSO_4$). Evaporation in vacuo of the solvent from the filtrate afforded 4.27 g (96%) of pure 4-chloro-4-methylpentane-2,3-dione **12a**, bp 44–46 °C (18 mmHg). ^{1}H NMR ($CDCl_3$, 60 MHz): δ 1.83 (6H, s, $(CH_3)_2CCl$); 2.42 (3H, s, $CH_3C{=}O$). ^{13}C NMR ($CDCl_3$, 20 MHz): δ 26.7; 28.7; 68.6; 196.5; 199.1. IR (NaCl, cm^{-1}): ν = 1725 (C=O); 1720 (C=O). GC–MS (EI) m/z (%): 148 (M^+, 0.5); 113 (M^+-Cl, 0.5); 77/79 ($(CH_3)_2CCl^+$, 10); 70 (33); 57 (2); 43 (CH_3CO^+, 100); 42 (10); 41 (18). Anal. Calcd for $C_6H_9ClO_2$: C, 48.5; H, 6.1; Cl, 23.9. Found: C, 48.4; H, 6.1; Cl, 23.7.

23. For some leading references on 1,2-diones, halogenated at the α-position with respect to the carbonyls, see for instance: Wegmann, J.; Dahn, H. *Helv. Chim. Acta* **1946**, *29*, 1247; Wanzlick, H.-W.; Sucrow, W. *Chem. Ber.* **1958**, *91*, 2727; Hamer, N. K. *Tetrahedron Lett.* **1986**, *27*, 2167.

24. *Reaction of α-fluoroimidoyl cyanides* **10** *with organolithium compounds*: The procedure is analogous to the reaction of α-chloroimidoyl cyanides **9** with organolithium compounds. α-Fluoroimidoyl cyanides **10** were dissolved in hexane and treated with a methyllithium solution (1.6 M in Et_2O) at −48 °C (acetonitrile/N_2 bath) for 30 min. Careful aqueous workup (0 °C) yielded compounds **13** (83–63%) as a yellow oil (purity > 95%; ^{1}H NMR). These labile 1,2-diimines **13** were used immediately in the next hydrolysis step. *N*-[(3*E*)-4-Ethyl-4-fluoro-2-iminohexan-3-ylidene]-*tert*-butylamine **13a**. Yield 83%. ^{1}H NMR ($CDCl_3$, 300 MHz): δ 0.92 (6H, t, J = 7.4 Hz, $(CH_2CH_3)_2$); 1.24 (9H, s, $NC(CH_3)_3$); 1.67–2.05 (4H, m, $(CH_2CH_3)_2$); 2.20 (3H, s, $CH_3C{=}N$); NH invisible. ^{19}F NMR ($CDCl_3$, 282 MHz): −168.3 (1F, s(br), CF, $\delta_{E\text{-isomer}}$); 169.3 (1F, ttd, J = 34.9 Hz, 13.4 Hz, 7.7 Hz, CF, $\delta_{Z\text{-isomer}}$). ^{13}C NMR ($CDCl_3$, 75 MHz): $\delta_{E\text{-isomer}}$ 7.4; 7.5; 28.4; 30.5; 30.5; 56.4; 102.1 (d, J = 174.2 Hz); 166.5 (d, J = 35.8 Hz); 181.4; $\delta_{Z\text{-isomer}}$ 7.4; 7.5; 28.4; 30.5; 30.5; 56.9; 103.3 (d, J = 171.9 Hz); 165.1 (d, J = 34.6 Hz); 179.8. IR (NaCl, cm^{-1}): ν = 2971; 2941; 2884; 1672; 1634 (C=N); 1524; 1460; 1362; 1213; 1119; 1056; 948; 896; 835. GC–MS (EI) m/z (%): 214 (M^+, 1); 199 (M^+-Me, 1); 179 ($M^+-HF-Me$, 1); 172 ($Et_2CFC{\equiv}N^+$-*t*-Bu, 10); 157 (4); 125 (2); 116 ($Et_2CFC{\equiv}NH^+$, 1); 97 (3); 89 (Et_2CF^+, 5); 69 (23); 57 (Me_3C^+, 100); 42 ($MeC{\equiv}NH^+$, 14); 41 (16).

25. *Hydrolysis of α-fluoro-1,2-diimines* **13** *into α-fluoro-1,2-diones* **15**: α-Fluoro-1,2-diimines **13** were dissolved in dichloromethane and treated with 4 equiv of oxalic acid (4 M in H_2O). The two-phase system was vigorously stirred during 2 h at room temperature. Aqueous workup, isolation of the organic phase, drying (Mg_2SO_4) and evaporation of the solvent gave after distillation compounds **15** (59–71%) as yellow oil. 4-Ethyl-4-fluorohexane-2,3-dione **15a**. Yield 59%. Bp 65 °C (25 mmHg). ^{1}H NMR ($CDCl_3$, 300 MHz): δ 0.93 (6H, t, J = 7.7 Hz, 2 × CH_3); 1.95 (2H, dq, J = 17.1 Hz, 7.7 Hz, CH_2); 2.02 (2H, dq, J = 27.6 Hz, 7.7 Hz, CH_2); 2.36 (3H, s, CH_3). ^{19}F NMR ($CDCl_3$, 282 MHz): δ −170.4 (1F, tt, J = 27.6 Hz, 17.1 Hz). ^{13}C NMR ($CDCl_3$, 75 MHz): δ 7.5 (d, J = 5.8 Hz); 25.5; 29.2 (d, J = 23.1 Hz); 103.2 (d, J = 183.5 Hz); 199.7; 201.9 (d, J = 32.3 Hz). IR (ATR, cm^{-1}): ν = 2979; 2943; 2887; 1717 (C=O); 1462; 1356; 1245; 1160; 1041; 950; 870. GC–MS (EI) m/z (%): 160 (M^+, 4); 134 (2); 115 (3); 98 (15); 88 (10); 69 (51); 59 (10); 43 (CH_3CO^+, 100).
