One-pot catalytic C–C double bond cleavage of α , β -enones aided by alkyl group-immobilized silica spheres

Dong Hun Lee, Eun-Ae Jo, Jung-Woo Park, Chul-Ho Jun *

C–H bond activation by transition-metal catalysts is of current interest in organic synthesis in terms of atom economy.^{[1](#page-2-0)} We have successfully developed a Rh(I)-catalyzed C–H bond activation using 2-aminopyridine derivatives or benzylamine as a chelating auxiliary to induce facile cyclometallation[.2](#page-2-0) In the course of our studies on chelation-assisted C–H bond activation, the Rh(I)-catalyzed hydroiminoacylation of an alkyne with an allylamine or an aldehyde, followed by retro-Mannich type fragmentation of the resulting α , β -unsaturated ketimine was found.^{[3,4](#page-2-0)} We have also developed a C–C double bond cleavage of α , β -enone using amine and acid to produce ketones after hydrolysis step.^{[5](#page-2-0)} For example, the reaction of 4-phenyl-but-3-en-2-one (1a), 3,3-dimethyl-1-butene (3a), and cyclohexylamine (2, 200 mol % based upon 1a) was carried out at 130 °C for 4 h in the presence of the catalyst system of $(Ph_3P)_3RhCl$ (4), 2-amino-3-picoline (5), and benzoic acid (6) to give acetone and ketimine 7, which was hydrolyzed separately by acidic H₂O giving the corresponding ketone $9a$ in a 49% isolated yield (Scheme 1a). This reaction requires greater than 100 mol % of cyclohexylamine based on the starting α , β -enone, and a further hydrolysis step for the resulting ketimine 7 to liberate ketone (9a). To decrease the amount of 2 used and to eliminate the separate hydrolysis step, H_2O can be added as a reactant to hydrolyze the in situ generated ketimine 7 resulting in the formation of 9a directly (Scheme 1b). A proposed mechanism for this one-pot reaction is depicted in [Scheme 2](#page-1-0). Cyclohexylamine 2 undergoes conjugate addition to the α , β -enone 1a, and the subsequent retro-Mannich type fragmentation of the resulting β -aminoketone **A** generates a mixture of aldimine B and ketone 8. Since aldimine is not much susceptible for hydrolysis compared with ketimine,

abstract

Catalytic C–C double bond cleavage of α , β -enones with a 1-alkene and H₂O was carried out in the presence of a $(\text{Ph}_3\text{P})_3$ RhCl catalyst, 2-amino-3-picoline, cyclohexylamine, benzoic acid, and alkyl groupimmobilized silica spheres. Upon completion of the reaction, the corresponding ketones were obtained without needing a further hydrolysis step. In this reaction, alkyl group-immobilized silica spheres act as a water reservoir for hydrolysis of an intermediate ketimine and as a phase divider between the organic solution and H_2O .

 $cy_{\sim}N$

the aldimine survives even in the presence of $H₂O$ during the reaction. Therefore, the aldimine B undergoes hydroiminoacylation with 1-alkene (3a) mediated by the cocatalyst system of $(Ph_3P)_3RhCl$ (4) and 2-amino-3-picoline (5) to afford ketimine 7. This type of transimination/hydroiminoacylation protocol has been utilized in the efficient conversion of aldimine to ketimine.^{[6](#page-2-0)} Now the ketimine **7** is readily hydrolyzed by additional H_2O giving ketone 9a with regeneration of cyclohexylamine (2), which can be involved in the catalytic cycle. Based on this it can be said that without additional H_2O no catalytic reaction takes place since cyclohexylamine cannot be regenerated.

However, addition of $H₂O$ afforded a very low yield of 9a (33%) isolated yield, Scheme 1b) from the reaction of 1a with 3a and

H₂O (100 mol %) in the presence of **2** (50 mol %), **4** (3 mol %), **5** (20 mol %), and $6(15 \text{ mol} \text{ %})^7$ $6(15 \text{ mol} \text{ %})^7$ To overcome this problem, it is necessary to separate the H_2O and organic solution phase (Fig. 1). Herein, we wish to report the efficient one-pot amine-assisted C– C double bond cleavage of α , β -enones aided by alkyl group-immobilized silica spheres. Since the alkyl group-immobilized silica spheres act as both a phase separator and a reservoir for water, the activity of the transition-metal catalyst is maintained even in the presence of water, and a separate hydrolysis step is avoided.

Recently, some organometallic catalytic reactions in aqueous phase have been studied based on the heterogeneous system.⁸ We have developed a new method for the surface-fabrication of the high density long chain alkyl group-grafted silica, which can be used as a divider between the organic reaction media and $H₂O$ absorbed on the silica[.9](#page-3-0) Using this protocol, octadecyl group-functionalized silica spheres 11a (loading rate of octadecyl group = 0.40 mmol $\rm g^{-1})^{10}$ $\rm g^{-1})^{10}$ $\rm g^{-1})^{10}$ were prepared by the reaction of silanol group on the surface of silica ball $(10 \mu m)$ in diameter, 11.67 nm pore size, purchased from Kromasil) with octadecyltrimethallylsilane (10a) in the presence of a $Sc(OTf)_3$ catalyst (OTf = trifluoromethylsulfonate) at room temperature (Scheme 3a). To prove the effect of 11a, the catalytic reaction of **1a, 3a, and H**₂O (100 mol %) with the catalyst system of $(\text{Ph}_3\text{P})_3\text{RhCl}$ (4), 2-amino-3-picolone (5), cyclohexylamine (2), and benzoic acid (6) was carried out in the presence of 11a for 4 h to give the corresponding ketone 9a in a 92% isolated yield without any further hydrolysis step.¹¹

For comparison, other alkyl group-immobilized silica spheres with different alkyl group loading rates were applied to this reaction under the identical reaction conditions: reaction of 1a with 3a at 130 °C for 4 h affording **9a** (Table 1). Among these modified silica additives, 11a (loading rate of 0.45 mmol g^{-1}) exhibited better reactivity than $\bf 11b$ (0.71 mmol $\rm g^{-1}$), and $\bf 11c$ (1.06 mmol $\rm g^{-1}$), prepared from octadecylmethyl-dimethallylsilane (10b) and octadecyldimethylmethallyl-silane (10c), respectively (entries 2 and 3). Interestingly, when the reaction of 1a with 3a was conducted

 $^{\rm a}$ 11a–SiMe₃ and TMS-coated silica spheres were prepared by the reaction of 11a or untreated silica spheres with 1,1,1,3,3,3-hexamethyldisilazane, respectively.

using 11a–SiMe₃, in which the residual silanol groups on 11a were fully capped with trimethylsilyl groups by treatment of 11a with 1,1,1,3,3,3-hexamethyldisilazane, 12 12 12 compound 9a was obtained in a low isolated yield (20%) (entry 4), which suggests that the residual silanol groups on 11a are essential for the in situ hydrolysis

Table 2

^a Isolated yield. The yields in parentheses are determined by GC.

step. Although the reason for this result is not clear, but we speculate that H_2O bound on the surface of silanol groups readily interacts with ketimine 7 to be hydrolyzed in organic solution as shown in [Figure 1.](#page-1-0) However, if silanol group on the silica surface is completely covered with hydrophobic SiMe_3 or octadecylmethylsilyl groups, there is no room for H_2O on the silica surface, and H_2O may smear into the interior of the silica network. This fact was also confirmed by the use of exclusive TMS-coated silica spheres (loading rate: 1.3 mmol g $^{-1}$), prepared by treatment of silica spheres with 1,1,1,3,3,3-hexamethyldisilazane. With this TMS-coated silica spheres, only a 30% yield of 9a was isolated (entry 5). When silica spheres untreated with alkylating reagents were used, only a 49% isolated yield of 9a was obtained (entry 6). It is known that transition-metal phosphine complexes can react with silanol groups on the silica surface to generate inactive metal catalysts due to the formation of $P(V)$ species of the ligand phosphine.^{[13](#page-3-0)}

The reactions of various α , β -enones (1) with olefins (3) are summarized in Table 2. The reaction of 4-phenyl-but-3-en-2-one (1a), 1 hexene (3b), and H_2O was carried out at 130 °C for 4 h in the presence of 4 (3 mol %), 5 (30 mol %), 2 (50 mol %), and 6 (15 mol %) using the octadecyl group-immobilized silica spheres (11a) to afford 1-phenylheptan-1-one (9b) in an 89% isolated yield. Under identical reaction conditions without 11a, the reaction of 1a and 3b produced a 41% isolated yield of 9b (Table 2, entry 1). Similar results were observed in the reactions of other 1-alkenes ($3c-g$), as fairly good yields of the corresponding isolated ketones ($9c-g$) were obtained with 11a (Table 2, entries 2–6); only low yields of the products were obtained in the absence of C_{18} -immobilized silica 11a. When other substituted α , β -enones (**1b** and **1c**) were applied to the reaction with **3a**, different reactivities were observed depending on the substrate (Table 2, entries 7 and 8). The reaction of 3-penten-2-one (1b) with **3a** proceeded to give an 82% GC yield of **9h** after 45 min using the identical catalytic system; however, the reaction of trans-chalcone (1c) with 3a was sluggish, requiring 14 h to get a similar GC yield (89%) of corresponding ketone 9a. These results about different reactivity based on the substituent of substrate imply that the rate-determining step is probably the cleavage of double bond which proceeds by the addition of cyclohexylamine followed by retro-Mannich type fragmentation.

In conclusion, we have demonstrated the one-pot catalytic C–C double bond cleavage of α , β -enone using alkyl group-immobilized silica spheres and a catalyst system consisting of Rh(I) complex, 2-amino-3-picoline, cyclohexylamine, and benzoic acid. In this reaction alkyl group-immobilized silica spheres act as a water reservoir for hydrolysis of the ketimine and a phase divider for the organic solution and H_2O on the silica. This one-pot catalytic reaction system is simple and efficient, and practical. Further applications of this one-pot catalytic system with functional group-immobilized silica are currently being investigated.
