(Received in USA 20 December 1966; accepted for publication 21 March 1967)

Abstract—IR and UV spectra show that both 5-aminoisoxazolin-3-ones and 2-alkyl-5-aminoisoxazolin-3-ones exist largely in a dipolar form, whereas the 3-hydroxyisoxazole structure for 5-aminoisoxazolin-3-ones is favoured when internal salt formation is feasible.

Spectroscopic evidence shows that 3-aminoisoxazolin-5-ones are present either in the 2H or in the 4H form or both. Alkylation of 3-aminoisoxazolin-5-ones in MeOH—K₂CO₃ gives the 2-alkyl derivative, whereas alkylation of the silver salt gives both 2-alkyl and 4-alkyl derivatives.

IR spectra show that 2-dialkylaminoalkyl-3-aminoisoxazolin-5-ones are intramolecularly hydrogen bonded.

IN RECENT years the structure of isoxazolin-3-ones and isoxazolin-5-ones has been fully investigated by means of physico-chemical methods: \(^{1-8}\) in most cases the structures assigned were based on the IR and UV spectra. In 1961\(^{9.10}\) the synthesis of 5-aminoisoxazolin-3-ones(I) and 3-aminoisoxazolin-5-ones(II and III)\(^{11}\) was reported and later a study on their structures, based on the IR spectra, was presented.\(^{10.12a}\) In the present paper we report and discuss the UV and IR spectra of a further group of aminoisoxazolinones and 2-alkyl-aminoisoxazolinones, whose physical constants and elemental analysis are reported in Table 1. The alkylation of 3-aminoisoxazolin-5-ones will also be discussed and a novel C₄-alkylation reported.

5-Aminoisoxazolin-3-ones

Preparation of 5-aminoisoxazolin-3-ones (Compds 1-10). 5-Aminoisoxazolin-3-ones were prepared from the appropriate cyanoacetate and hydroxylamine, in presence of EtONa as described by Bauer. 9. 12b Compounds 5, 6 and 9 were similarly obtained by substituting methylhydroxylamine for hydroxylamine. These same products could also be prepared by alkylation of compounds 1, 2 and 3 with MeI and K_2CO_3 in methanol. We have therefore accordingly assigned the above reported structures of 2-alkyl derivatives to the remaining compounds (7, 8 and 10), which were obtained by treatment of compounds 1, 2 and 3 with an alkyl halide in methanol, in presence of potassium carbonate.

UV and IR spectra of 5-aminoisoxazolin-3-ones. In Table 2 we have reported the UV maxima and the most important bands present in the IR spectra (either in KBr or in solution) of compounds 1-10.

UV spectra. The compounds were examined in ethanol and in acid and basic ethanol solution: solubility reasons inhibited the use of less polar solvents such as cyclohexane. In neutral and acid ethanol solution the average log ε for all the compounds was 4.25 ± 0.01 . 4-Alkyl-5-aminoisoxazolin-3-ones (Nos. 1 and 2) present in ethanol a

maximum at 246 mµ which shifts to 251 mµ in HCl ethanol. The corresponding 2-alkyl derivatives (Nos. 5 and 6) have a maximum at 250 mµ which shifts to about 259 mµ in acid solution.

4-Diethylaminoethyl-5-aminoisoxazolin-3-one (No. 4) as well as 3-methoxy-4-ethyl-5-aminoisoxazole¹³ present a maximum at 238 mµ. The 4-aryl- derivatives show

^{13 3-}Methoxy-4-ethyl-5-aminoisoxazole was obtained, together with some N-methyl derivative (No. 6), by treatment of compound 1 with diazomethane.

Isoxazoles—I 4399

the expected bathochromic shift: 4-phenyl-5-aminoisoxazolin-3-one absorbs at 252 m μ (251 m μ in HCl-EtOH); 2-alkylation (Nos. 9 and 10) shifts the maximum to 257 m μ .

IR spectra. In the solid state the 5-aminoisoxazolin-3-ones (Nos. 1, 2 and 3) exhibit the complex pattern already reported by Bauer^{10.12} who assigned the $1630 \, \mathrm{cm}^{-1}$ band to the NH₂ scissoring mode and the strong broad band at about $1575 \, \mathrm{cm}^{-1}$ to the C=C and C=N ring vibration. 4-Diethylaminoethyl-5-aminoisoxazolin-3-one presents a different spectrum with two strong bands at $1680 \, \mathrm{cm}^{-1}$ and $1470 \, \mathrm{cm}^{-1}$ (broad) (Fig. 1D). 2-Alkylation does not seem to change very much the $6 \, \mu$ region of the IR spectrum of the parent compound: here also a medium band is present at ca. $1640 \, \mathrm{cm}^{-1}$ and a very strong one is present at about $1575 \, \mathrm{cm}^{-1}$ (Fig. 1B). The IR spectra of all the compounds which could be dissolved in dichloromethane (Nos. 5–10) showed, in this solvent, two bands at $3500 \, \mathrm{and} \, 3400 \, \mathrm{cm}^{-1}$ which can be assigned to the NH₂ stretching mode: in the $6 \, \mu$ region a single large and very strong band was present at about $1650 \, \mathrm{cm}^{-1}$.

DISCUSSION

According to Bauer^{10, 12} 5-aminoisoxazolin-3-ones are best depicted by a resonance hybrid of structures IV and V, V being the largest contributing structure.

This representation accounts for the absence of the band at about 1670 cm⁻¹ (CO lactam stretching) which had been previously found^{6.8} to be present in the spectra of simple isoxazolin-3-ones such as 2.4.5-trialkylisoxazolin-3-ones.

The 3-OH tautomer structure VI cannot, however, be ruled out and it has been in fact favoured by Quilico^{6b} and Katritzky⁸ in the case of 5-alkylisoxazolin-3-ones.

According to our data there is no conflict between these hypotheses and we will here present the evidence that in the case of 5-aminoisoxazolin-3-ones, and owing to the presence of an amino group which can stabilize the positive charge, the contributing structure V of the resonance hybrid IV-V, represents these compounds. We will show also that in certain cases the tautomer 3-hydroxy-5-amino-isoxazole structure VI can become favoured.

The strongest argument in favour of the dipolar structure V is to be found in the spectra of 2-alkyl-5-aminoisoxazolin-3- ones. In fact while the 6μ region (CO and ring modes) of the spectrum of the model compound 3-hydroxy-4-ethyl-5-methyl-isoxazole (VII) greatly differs from the one of 2,5-dimethyl-4-ethylisoxazolin-3-one (VIII), $^{6.8}$ as it is to be expected since 2-alkylation involves a change from a 3-hydroxy-isoxazole to a isoxazolin-3-one structure, no large difference is found between the spectra of 5-aminoisoxazolin-3-ones and their 2-alkyl derivative (e.g. 1 and 5; 2 and 6). The presence in the spectra (solid state) of 2-alkyl-5-aminoisoxazolin-3-ones of strong broad bands at about 1640 and 1580 cm⁻¹, that are also present in the spectra of the

parent 5-aminoisoxazolin-3-ones and which have been assigned to ring vibrations, should be especially noted.

The similarity of the spectra and the absence of a CO γ-lactam band can be explained by assigning to 5-aminoisoxazolin-3-ones and to their 2-alkyl derivatives (in the solid state) the analogues hybrid structures IV-V and IX-X, a great weight being given in both cases to the dipolar contributing forms (V and X).

The alkyl derivatives were also examined as dichloromethane or chloroform solutions: in the 3 μ region the presence of the 3500 and 3400 cm $^{-1}$ bands (NH $_2$ stretching modes) clearly demonstrated that these compounds are present in the amino rather than the imino form. In the 6 μ region, only a single very strong and large band at about 1650 cm $^{-1}$ is left and therefore, in dichloromethane solution, a distinction between IX and X is not feasible. Some information can however be gained from the UV spectra. In acid solution, where the dipolar form should be less favoured, the UV maximum shifts to longer wavelengths and this fact suggests that in ethanol solution X is a contributing form. 14

The large contribution of V rather than VI to the structure of 5-aminoisoxazolin-3-ones (Nos. 1, 2, 3) has been further substantiated by the preparation of the 4-diethylaminoethyl derivative (No. 4) to which the 3-hydroxy-isoxazole (VI) or better the internal salt like structure XI has been assigned on the following grounds. The

$$Et_{2}-N-(CH_{2})_{2}-O$$

$$(+) NH_{2} O$$

$$XI$$

product is insoluble in aprotic solvents but soluble in water and gives a very strong FeCl₃ reaction which is an index of an high enol content. The 3 μ region of the IR spectrum presents a weak broad band at 2500–2300 cm⁻¹ which is indicative of a salt like structure (XI), in accord with the solubility behaviour. The 6 μ region presents only two bands¹⁵ at 1680 cm⁻¹ and 1470 cm⁻¹ and it resembles closely the 6 μ region of both 3-hydroxy-4-ethyl-5-methylisoxazole (VII)⁶ and 4-ethyl-5-amino-

¹⁴ The bathochromic shift (comps 7, 9, 10) in alkaline solution is probably due to the 2.4-dialkyl-3-hydroxy-5-imino-isoxazoline tautomer structure.

¹⁵ The 1570 cm⁻¹ (ring vibration) band, which we have related to the dipolar structures V and X, is no longer present.

oxazolin-3-one sodium salt¹⁵ (Fig. 1 C). Furthermore the 3-hydroxyisoxazole rather than the dipolar (V) structure is in better accord with the UV spectrum.^{16a}

CONCLUSIONS

The dipolar structure X is assigned to 2-alkyl-5-aminoisoxazolin-3-ones. 5-Aminoisoxazolin-3-ones are also present in the dipolar (V) rather than the 3-hydroxyisoxazole structure (VI), unless the latter is stabilized by salt formation. 166

5-Aminoisoxazolin-5-ones

Structure and spectra. Considerable UV and IR spectroscopic data on isoxazolin-5-ones has already been reported and interpreted 1.3.5.17 and it can confidently be used to assign the correct structure to the new compounds of this class. We will therefore present jointly the synthesis and the structural proofs of compounds Nos. 11-22 (reported in Table 1) which will be divided in four sub-groups.

(a) 3-Amino-4-R-isoxazolin-5-ones. Compounds 11, 12 and 13 to which structure XII should have been assigned according to Bauer¹⁰ (cf. however¹²) were obtained by condensation of the appropriate ethyl cyanoacetate with hydroxylamine.⁹ The IR spectrum (dichloromethane solution) showed the presence of a NH₂ group, in accord with previous findings¹⁰ and it was eventually used to distinguish between the tautomer formulae XII and XIII.¹⁸ According to the IR spectra, compound 11, in dichloromethane solution, is present in large part in the 4H form (XII); compound 13 is instead present in the 2H form (XIII), whereas the spectrum of compound 12 shows the presence of both the 2H and 4H forms.

In ethanol solution the equilibrium shifts toward the 2H form. In fact the position of the absorption maximum of the UV spectra of the three compounds require that in ethanol all these compounds be present in part in the 2H form (XIII): from the

$$R'$$
 NH_2
 NH

16 a Cf. the spectrum of 3-methoxy-4-ethyl-5-aminoisoxazole and the spectra of 4-alkyl-5-aminoisoxazolin-3-ones in alkaline solution;

^h The NMR spectra have previously⁸ been used to confirm the 3-OH structure of isoxazolin-3-ones; in the case of 5-aminoisoxazolin-3-ones, however, the same solvents (CCl₄ or CDCl₃) could not be used owing to solubility reasons and we had to employ acetone-d₆ where structure VI should be favoured by hydrogen bonding.

The NMR spectrum in this solvent of 4-ethyl-5-aminoisoxazolin-3-one shows the presence of an NH₂ group (2 protons at $3.80~\tau$) in accord with the IR spectrum in KBr. Another rather broad signal is present at $0.10~\tau$ and is due to one proton which readily exchanges with water. The value of the chemical shift does not allow a clear-cut distinction between formulae IV-V and V.

- 2-Methyl-5-aminosoxazolin-3-ones such as 2-methyl-4-ethyl-5-aminoisoxazolin-3-one present in DMSO- d_6 a peak at 2:34 τ (2 protons; NH₂) and a peak at 6:82 τ (3 protons; N—CH₃) as expected.
- ¹⁷ A. R. Katritzky and J. M. Lagowsky, Advances in Heterocyclic Chemistry Vol. II (Edited by A. R. Katritzky) p. 36. Academic Press, New York, N.Y. (1963).
- 18 It is known³ that an isoxazolin-5-one of structure XII should present a CO band at about 1790 cm⁻¹ (β.y-unsaturated-y-lactone), whereas an isoxazolin-5-one of formula XIII should present a CO band at about 1750-1730 cm⁻¹ (α,β-unsaturated-y-lactone).

Isoxazoles—I 4403

values of the extinction coefficient (cf. also compounds 17-20) it is also clear that the 2H form (XIII) is indeed largely preferred. 19a

(b) 2-Alkyl-3-amino-4-R-isoxazolin-5-ones. Condensation of ethyl ethylcyanoacetate with methylhydroxylamine afforded the isoxazolone No. 17 which was found to be an isomer of No. 5 and to which the structure II (R = Me; R' = Et) was accordingly assigned. The structure was confirmed by the IR spectrum (CH₂Cl₂) which showed the presence of an $\alpha.\beta$ -unsaturated- γ -lactone type carbonyl band (1740 cm⁻¹). The UV spectrum presented, in comparison with the spectrum of the 2H parent compound No. 11, the expected bathochromic shift and the larger extinction coefficient.

This same product could also be obtained by alkylation of compound 11 with methyl iodide in methanol solution, in the presence of potassium carbonate. This procedure was applied to different 3-amino-4-R-isoxazolin-5-ones (Nos. 11, 12, 13) and to the compounds in this way obtained (No. 17-20) the structure of 2-alkyl derivatives II was accordingly assigned. 19h

(c) 3-Amino-4,4-dialkylisoxazolin-5-ones. When alkylation of 3-amino-4-ethylisoxazolin-5-one with benzyl bromide was performed on the sodium salt dissolved in dimethylformamide the yields were somewhat lower and a by product could be isolated by chromatography.²⁰ Its UV spectrum (No. 15) presented only the low benzenoid band and this strongly suggested formula III (R' = Et; R" = Ph—CH₂). Moreover the IR spectrum presented, in dichloromethane solution, two bands at 3500 and 3400 cm⁻¹ (free NH₂ stretching bands) and a strong band at about 1780 cm⁻¹ (CO stretching mode in a 4H-isoxazolin-5-one³) which could only be explained by assuming that the isoxazolone had been C-alkylated to give a compound having formula III. An isoxazolinone of formula III (R' = R'' = Et) was obtained by direct synthesis. Condensation of ethyl diethylcyanoacetate with hydroxylamine and sodium ethylate gave a 4.4-diethyl-aminoisoxazolinone to which the structure of 3-amino-4,4diethylisoxazolin-5-one (III; $R' = R'' = C_2H_5$) rather than 5-imino-4,4-diethylisoxazolin-3-one was assigned since, beside showing no UV absorption, in dichloromethane solution were present the typical bands due to a free NH₂ (3500 and 3400 cm⁻¹) and a CO band at 1790 cm⁻¹. Since the spectra of compounds Nos. 15 and 16 were very close, the structure III previously assigned to No. 15 was confirmed and consequently the occurrence of a C-alkylation reaction in the isoxazolinone field was also proved.21

When the silver salt of 3-amino-4-ethylisoxazolin-5-one was treated with benzyl bromide in acetonitrile. C-alkylation and N-alkylation products were formed in

The NMR spectrum of compound 13 shows only the presence of 5-phenyl protons (2·3 2·7 τ , multiplet), 2NH₂ protons (3·4 τ) and a broad band (1 proton) at about 0·2 τ . Compound 13 is therefore in the 2H form.

The NMR spectrum of 2-methyl-3-aminoisoxazolin-5-ones such as 2-methyl-3-amino-4-ethylisoxazolin-5-one presents the expected peaks at 3·67 τ (2 protons; NH₂) and 6·87 τ (3 protons; N—CH₃). The UV and IR spectra are strictly similar to the one of compound 17 and support these conclusions.

¹⁹ a The NMR spectra are in accord with these findings. In acetone-d_n solution compound 11 presents a triplet centered at 6·37 τ (integration value 0·60 protons). Accordingly, in this solvent, approximately 60% of the 4H form, which gives rise to this signal, is present.

This by-product was eventually found by TLC to be formed in limited yields also when the general procedure was employed.

²¹ Although partial C-alkylation of 5-pyrazolones, particularly with benzyl halides.²² is a long known fact.^{23, 24} only 0- and N-alkylation of isoxazolin-5-ones had been until now reported.^{25, 26a, 26b}

comparable amounts, although the total yield was lower owing to the formation of some tars.²⁷ Moreover, the use of a silver salt allowed the isolation in limited yields of a C-alkylation product (No. 14) also when a less reactive alkyl halide, such as methyl iodide, was used.²⁸

(d) 2-Dialkylaminoalkyl-3-aminoisoxazolin-5-ones. Alkylation of 3-aminoisoxazolin-5-ones with dialkylaminochloroethane or dialkylaminochloropropane in methanol, in presence of K_2CO_3 , afforded a dialkylamino alkyl derivative which could not be a C_4 derivative because it had a UV absorption at 255 m μ and a band at 1730 cm⁻¹, already assigned (see 2-alkyl-3-aminoisoxazol-5-ones) to a CO carbonyl in a 2H-isoxazolin-5-one. Since the IR spectrum lacked the typical 3500 and 3400 cm⁻¹ bands due to a free NH₂ (only one band being present at 3480 cm⁻¹) it was at first thought it could be a 3-alkylamino derivative but the synthetic procedure suggested the structure of 2-R derivative (II; R = dialkylaminoalkyl). That this was indeed the case was demonstrated by means of a straightforward synthesis of 2-diethylaminoethyl-3-amino-4-phenylisoxazolin-5-one (compound No. 22).

3-Amino-4-phenylisoxazolin-5-one (No. 13) was treated at room temperature with an excess of 1,2-dibromoethane and K₂CO₃ in methanol to give 2-(2-bromoethyl) 3-amino-4-phenylisoxazolin-5-one which showed the expected IR spectrum of a 2-alkyl-3-aminoisoxazolin-5-one and, more important of all, the 3500 and 3400 cm⁻¹ bands (free NH₂) were clearly present. This compound was next treated with an excess of diethylamine: bromine substitution occurred easily and the desired 2-diethylaminoethyl-3-amino-4-phenylisoxazolin-5-one was isolated in good yield and found to be identical (TLC, IR and mixed m.p.) with the alkylation product of 3-amino-4-phenylisoxazolin-5-one with diethylaminochloroethane (compd. No. 22).

The IR spectrum³⁰ of 2-dialkylaminoalkyl-3-aminoisoxazolin-5-ones present the expected 1730 cm⁻¹ band (see Section b), but, as we have already remarked, only one band is present, in dichloromethane solution, in the 3 μ region, at 3470 cm⁻¹. However in deuterochloroform³¹ a broad and strong absorption band, superimposed on the CH₂ and CH₃ stretching bands, was present at about 2850 cm⁻¹ in the case of compound 21 and at 2800–2700 cm⁻¹ for compound 22. The features of these spectra can be explained by assuming the formation of an intramolecular hydrogen bond between the NH₂ group and the dialkylamino group. Similar intramolecular bonds between a β amide group and a tertiary nitrogen have been recently studied³² and it

²⁷ The oily forerun of the chromatographic columns contained probably the O-alkyl derivative, but, being outside the scope of this work, was not investigated further.

²⁸ These results apparently contradict Kornblum's rule. ²⁹ which would predict the formation of O- or N-, rather than C-alkyl derivatives. It is, however, possible that in this case the solvent plays a determinant role.

²⁹ N. Kornblum, R. A. Sunbey, R. K. Blackwood and D. C. Iffland, J. Am. Chem. Soc. 77, 6269 (1955).

³⁰ The UV spectrum does not differ from the spectra of other 2-alkyl derivatives and needs no comment.

³¹ Deuterochloroform was used because of its good solvent properties accompanied by a low absorption at 3 µ.

³² W. Barbieri and L. Bernardi, Tetrahedron 21, 2453 (1965).

was shown that in those cases in place of the typical 3520 and 3420 cm⁻¹ bands (symmetric and antisymmetric amide NH₂ stretching modes), a sharp band was present at 3480 cm⁻¹, accompanied by a broad strong band at about 3200 cm⁻¹. In the present case the association band occurs at lower wavelengths and this could be related to the size of the ring formed in the intramolecular hydrogen bond.³³

EXPERIMENTAL35

M.ps are uncorrected. The IR spectra were recorded on a Perkin-Elmer M 21 spectrometer fitted with NaCl optics or with a Perkin-Elmer M 237 double grating spectrometer. Samples were prepared as solutions in different solvents and examined in 1 mm cells with NaCl windows and as dispersions in pressed KBr discs

4-Diethylaminoethyl-5-aminoisoxazolin-3-one (No. 4)

Diethylaminochloroethane HCl³⁶ (33 g) was dissolved in EtOH (80 ml) and treated first with EtONa (1 equiv) and next with ethyl cyanoacetate. One equiv EtONa was slowly added to the suspension and at the end the mixture was refluxed for 2 hr. The solvent was eliminated in racuo, the residue was treated with dil HCl (1·3 equiv) and the soln was extracted first with ether and again, after basification with K₂CO₃, with ether. The second ether extract was distilled and 16·5 g of ethyl 3-diethylaminoethylcyanoacetate were collected, b.p. 92-95° at 0·5 mm Hg. (Found: N. 13·5. C_{1.1}H₂₀N₂O₂ requires: N. 13·2°_a), and condensed in MeOH with 1·1 equivs of NH₂OH·HCl and 2·2 equivs of MeONa at 60° for 5 hr After elimination of the solvent the residue was dissolved in H₂O (30 ml) and 1·1 equivs of H₂SO₄ was added. The soln was percolated through Dowes 50 W (H cycle) and discarded. The resin was eluted with dil NH₄OH: evaporation of the solvent left an oil which crystallized from EtOH MeOH to give compound No. 4 (7·5 g).

Diethylaminoethyl-malondiamide

- (a) A soln of compound No. 4 (1·3 g) in MeOH (65 ml) was treated with H₂ and Pd C (0·2 g) at room temp and atm press. After 1 hr the absorption was complete; the soln was filtered and diethylaminoethylmalondiamide separated on concentration (0·66 g), m.p. 154 ·156 . (Found: N, 20·8. C₉H₁₀N₃O₂ requires: N. 20·8 °₉.)
- (b) Ethyl diethylaminoethylcyanoacetate (3 g) in 95" $_{0}$ EtOH (5 ml) was saturated with HCl gas, refluxed for 2 hr and kept overnight at room temp. Some ether and pulverized K_2CO_3 were added and after 6 hr the ether was decanted and evaporated. The oily residue (2·8 g) was treated overnight with NH₄OH (30 ml), with stirring. After evaporation of the solvent, the residue was crystallized from EtOH to give the same compound (1·7 g) that was obtained according to (a).

2-Methyl-4-ethyl-5-aminoisoxazolin-3-one (No. 5)

- (a) Methylhydroxylamine. HCl was treated overnight in EtOH and at room temp with 1 equiv EtONa and 0.9 equiv ethyl ethylcyanoacetate, followed by another equiv EtONa. The soln was next heated at 60 for 3 hr and later the solvent was eliminated in vacuo. The residue was treated with cold water and crystallized from AcOEt-pet, ether to give compound No. 5 (75°, yield).³⁷
- (b)4-Ethyl-5-aminoisoxazolin-3-one was treated in MeOH with K₂CO₃ (1·2 equivs) and MeI (1·2 equivs) at reflux temp for 6 hr. The solvent was eliminated and the residue was treated as in (a) to give compound No. 5 in 70°, yield
- 33 It is known³⁴ that the Δ (OH) of an intramolecular association band increases on going from 1.2 to 1.4 and 1.5 diols (i.e from a 5- to an 8- member ring formed in the intramolecular bond); the largest shifts seem to be associated with 7 and 8-member rings.
- ³⁴ W. F. Baitinger and P. von R. Schleyer, 14th Meeting of American Chemical Society. New York, 8-13 September (1963); Abstracts 36 Q.
- 35 Only representative procedures are reported.
- 36 D. S. Breslow, R. S. Yost, H. G. Walker and C. R. Hauser, J. Am. Chem. Soc. 66, 1921 (1944).
- ³⁷ A further crop (about 10%) can be obtained by saturating with CO₂ the water washings.

3-Methoxy-4-ethyl-5-aminoisoxazole

4-Ethyl-5-aminoisoxazolin-3-one (2 g) in CH₂Cl₂ (50 ml) and MeOH (10 ml) was treated with a slight excess of diazomethane. The solvent was eliminated and the residue was crystallized from benzene-pet-ether to give the N-methyl derivative No. 4 (0.5 g). The mother liquors were chromatographed on silica gel: 3-methoxy-4-ethyl-5-aminoisoxazole was isolated by elution with benzene and distillation at 80° (oil bath) and 0.2 mm Hg (0.8 g). (Found: OCH₃, 21.1. C₆H₁₀N₂O₂ requires: OCH₃, 21.8 %)

2-(3-Dimethylaminopropyl)4-ethyl-5-aminoisoxazolin-3-one (No. 8)

- 4-Ethyl-5-aminoisoxazolin-3-one in MeOH was treated at 70° for 4 hr with 3-dimethylaminopropylchloride (1·2 equivs) and K₂CO₃ (2·2 equivs). The soln was filtered and the solvent eliminated in vacuo. The residue was dissolved in AcOEt and washed with a saturated soln of Na₂CO₃. Evaporation of the solvent and crystallization from AcOEt-Et₂O afforded compound No. 7 (50% yield).
- 2-Benzyl-3-amino-4-ethylisoxazolin-5-one (No. 20) and 3-amino-4-ethylisoxazolin-5-one (No. 15) (a) An aqueous soln of the Na salt of 3-amino-4-ethylisoxazolin-5-one was treated with 1 equiv AgNO₃. The precipitated Ag salt (5·8 g), dried at 60°, ³⁸ was suspended in MeCN (60 ml) and treated at reflux with benzyl bromide (1·05 equivs) for 8 hr. The solvent was evaporated in vacuo and the residue was taken up in AcOEt. On concentration and addition of ether 3-amino-4-benzyl-4-ethylisoxazolin-5-one (No. 15) separated as white prisms (0·55 g). The residue was chromatographed on silica gel (ether as eluent): the 4-benzyl derivative (No. 15) was eluted first (0·2 g), whereas the following fractions afforded 2-benzyl-3-amino-4-ethylisoxazolin-5-one (No. 20) (1·95 g).
- (b) A DMF solution of the sodium salt of No. I was treated at 90° for 4 hr with benzyl bromide. The solvent was distilled off in vacuo and the residue was chromatographed on silica gel: a first fraction gave by crystallization (AcOEt -Et₂O) compound No. 15 (about 8° yield) and the following fractions afforded compound No 20 (about 70° yield).
- (c) A MeOH soln of 3-amino-4-ethylisoxazolin-5-one was treated with benzyl bromide and K₂CO₃ at reflux temp for 3 hr. After elimination of the solvent and crystallization from EtOH-ether, compound No. 20 was obtained in 80% yield. The mother liquors were analysed by TLC and same compound No. 15 was found to be present (estimated yield: 4%).
- 3-Amino-4-methyl-4-butylisoxazolin-5-one (No. 14) and 2-methyl-3-amino-4-butylisoxazolin-5-one (No. 18)

 The Ag salt (5 g) of 3-amino-4-butylisoxazolin-5-one was treated in MeCN with MeI according to the procedure reported for the preparation of compound 15. The 4-methyl derivative (0.16 g; compound No. 14) and the 2-methyl derivative (1.05 g; compound No. 18) were obtained by chromatography on silica gel and crystallization from benzene-ether

3-Amino-4.4-diethylisoxazolin-5-one (No. 16)

Ethyl diethylcyanoacetate (8:5 g) was treated overnight in EtOH at room temp with 1 equiv EtONa and the suspension was next heated at 60° for 4 hr. The solvent was evaporated in vacuo, the residue was dissolved in water and extracted with ether. The ether extracts were discarded and the water layer was acidified to pH 4 with H₂SO₄: compound No. 16 slowly separated and was recrystallized from AcOEt (2:2 g).³⁹

2-Methyt-3-amino-4-ethylisoxazolin-5-one (No. 17)

- (a) Methylhydroxylamine hydrochloride (9·1 g) dissolved in EtOH (60 ml) was treated with one equiv EtONa and ethyl ethylcyanoacetate (14·2 g) was next added. The soln was refluxed for 2 hr, the solvent evaporated in vacuo and the residue was treated first with ether and next with hot AcOEt. Compound No. 17 (5 g) separated on cooling from AcOEt soln.
- (b) This same compound (80%; yield) was obtained by treating 3-amino-4-ethylisoxazolin-5-one (5:12 g) in MeOH (50 ml) with K_2CO_3 (3:2 g) and MeI (6:25 g) at reflux temp for 3 hr and subsequently working up the soln as reported in (a).
- 2-Diethylaminoethyl-3-amino-4-phenylisoxazolin-5-one (No. 22)
 - (a) A soln of 3-amino-4-phenylisoxazolin-5-one (4 g) in MeOH (40 ml) was treated at reflux temp for

³⁸ The salt decomposes explosively when heated at about 150°.

³⁹ If only I equiv of EtONa is used the same compound is formed but in lower yields.

Isoxazoles—I 4407

4 hr with diethylaminoethylchloride. HCl³⁶ (49 g) and K₂CO₃ (4·2 g). After elimination of the solvent the residue was crystallized from AcOEt to give No. 22 in 70% yield.

(b) A soln of 3-amino-4-phenylisoxazolin-5-one (1 g) in MeOH (5 ml) was treated with 1.2-dibromoethane (2.9 g) and K₂CO₃ (0.45 g) at room temp for 90 hr. The soln was filtered, the solvent was evaporated in vacuo and the residue crystallized from MeOH to give 2-(2-bromoethyl) 3-amino-4-phenylisoxazolin-5-one (0.8 g), m.p. 199-200°. (Found: Br, 28.8. C₁₁H₁₁BrN₂O₂ requires: Br, 29.1%.)

2-(2-Bromoethyl) 3-amino-4-phenylisoxazolin-5-one (0-8 g) was treated at 80° for 4 h with Et₂NH (15 ml). The solvent was evaporated and the residue was treated with dil HCl and AcOEt: the acid soln was basified with NH₃ and extracted with AcOEt. Evaporation of this AcOEt extract gave a residue (0-5 g) which was crystallized from AcOEt to give a product that was found identical with No. 22 prepared according to (a).
