(Received in UK 24 June 1986)

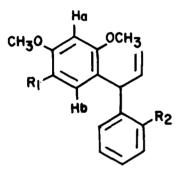

Abstract- Latifolin (1), the major constituent of <u>D.latifolia</u> gave trans 1-(2,4-dimethoxy-3-hydroxypheny1)-2-(2-hydroxypheny1) cyclopropane as the sole photo di- $\pi$ -methane rearrangement product. In contrast, its simpler analogues, 3-(2,4,5-trimethoxypheny1)\_3-pheny1 prop-1-ene(3) and 3-(2,4-dimethoxypheny1) -3-pheny1 prop-1-ene(4), gave 1:1 mixture of cis and trans cyclopropanes. Dye-sensitized photooxidation of latifolin(1) and dihydrolatifolin (16) gave novel xanthan derivatives(15) and (17) involving a crucial step of photooxidative demethylation followed by cyclisation. Similar reaction of the closely related propane 12 gave, interestingly the benzofuran 20. The propene 22, lacking free hydroxyl or double bond, gave only the quinone 23 indicating that quinones are intermediates in the above oxidations. The allyl alcohol 24, having similar feature, undergoes oxidation to the corresponding aldehyde 26 and the benzophenone 28 but not to a quinone.

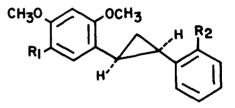

Latifolin (1), the major constituent of the heartwood of <u>Dalbergia latifolia</u> is an important neoflavonoid. Its dimethyl ether 2 was shown in a preliminary report<sup>1</sup> to undergo a facile photorearrangement, known under the general name of di- $\pi$ -methane rearrangement<sup>2,3</sup>. We report here a detailed investigation of this rearrangement with latifolin itself and some of its simpler synthetic analogues. The isolation and characterisation of several novel photooxidation products of latifolin and some related compounds are also reported in this paper. <u>RESULTS AND DISCUSSION</u>

Latifolin 1, on irradiation with UV-light filtered through pyrex gave a single photoproduct. Its IR spectrum showed a strong peak at 1031 cm<sup>-1</sup> (cyclopropane) in addition to two hydroxyl peaks at 3500 and 3580 cm<sup>-1</sup>.Its <sup>1</sup>H NMR spectrum exhibited two singlets at § 4.01 and 4.10 equivalent to six protons of two methoxyl groups, in addition to two multiplets centred at § 1.25 and 1.93 as expected of cyclopropanic protons. Its mass spectrum indicated that it is isomeric with latifolin itself. On the basis of these spectral data it was assigned the structure 1-(2,4-dimethoxy-3-hydroxyphenyl)-2-(2-hydroxyphenyl) cyclopropane (5). This was further confirmed when on methylation it gave the tetramethoxy compound 6 identical with the product reported earlier from the photorearrangement of latifolin dimethyl ether 2. The assignment of trans stereochemistry earlier<sup>1</sup> to 6 was based on spectroscopic grounds. Hence 5 also should have trans orientation.

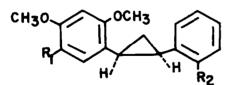

Photoirradiation of the simpler analogue, 3-(2,4,5-trimethoxyphenyl)-3-

phenyl prep-1-ene (3), under the same conditions gave a mixture of two closely related cyclopropanic compounds (TLC) which could be separated by repeated column chromatography on alumina to a higher melting  $(93-94^{\circ})$  and a lower melting  $(69-71^{\circ})$  compounds. Since both had the same molecular weight (MS) they must be isomeric dis and trans cyclopropane compounds. The higher melting isomer was assigned the trans configuration 7 as the chemical shifts of the aromatic protons in the <sup>1</sup>H NMR spectrum of this compound were more deshielded than these of the corresponding protons of the lower melting isomer. Such effects have been observed earlier<sup>5</sup>. The lower melting isomer (m.p.69-71°) should therefore have the dis configuration. <sup>1</sup>H NMR spectrum of the reaction mixture taken before separation exhibited two sets of peaks for each type of protons. Comparison of the area under the peaks of aromatic protons at  $\delta$  6.18 and 6.20 to H<sub>a</sub> and H<sub>b</sub> of the dis isomer 8 and at  $\delta$  6.35 and 6.42 due to correspending protons of the trans isomer 7 showed that the mixture consists of approximately equal amounts of dis and trans cyclopropanes.

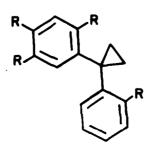

I, R<sub>1</sub>=R<sub>2</sub>=OH 2, R<sub>1</sub>=R<sub>2</sub>=OCH<sub>3</sub> 3, R<sub>1</sub>=OCH<sub>3</sub>,R<sub>2</sub>=H 4, R<sub>1</sub>=R<sub>2</sub>=H 5, R<sub>1</sub> = R<sub>2</sub>= OH 6, R<sub>1</sub> = R<sub>2</sub> = OCH<sub>3</sub> 7, R<sub>1</sub> = OCH<sub>3</sub>, R<sub>2</sub>=H 9, R<sub>1</sub> = R<sub>2</sub> =H

4818

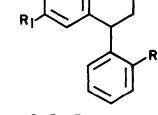

Similarly irradiation of 3-(2,4-dimethexyphenyl)-3-phenyl prop-1-ene( $\underline{4}$ ) yielded a viscous liquid which was found to be a mixture of two compounds having very close  $R_g$  values on  $AgNO_3$  imprognated TLC plate. From <sup>1</sup>H NMR and MS spectra this also appeared to be a 1:1 mixture of cis and trans isomers of cyclepropane derivatives 2 and 10. It was not possible to separate this mixture.

Thus, unlike latifolim (1) and its dimethyl ether 2 the di-77 -methane rearrangement of simpler analogues gave both cis and trans isomers.

Attempted photochemical rearrangement of 1,1-diaryl cycleprepanes, as possible intermediates in di- $\pi$ -methane rearrangement, examined with 1,1diphenyl cycleprepane<sup>6</sup> (13) and its higher analogue <u>14</u> showed that such small ring systems do not undergo any change under these conditions. The required cyclepropanes <u>13</u> and <u>14</u> were synthesised from the corresponding 1,1-diaryl ethylenes <u>11</u> and <u>12</u> by Simmon-Smith reaction<sup>8</sup>.

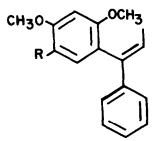

The Co-occurrence of latifolin<sup>9</sup> with a number of exyheterocyclic and other exidation products prompted us to explore the possibility of photochemical exidation reactions of latifolin.

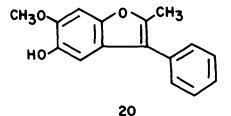

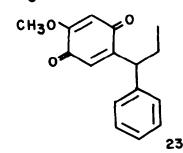

15, R=-CH=CH<sub>2</sub> 17, R=-CH<sub>2</sub>CH<sub>3</sub>

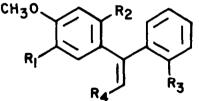

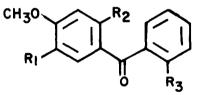

19, R=OH 21, R=OCH3

Latifolin (1) on photoirradiation in  $CCl_A$  in the presence of rese-bengal gave a new product which could be characterised as the xanthan derivatives 15. H NMR spectrum of this product displayed the presence of one methoxyl group at 83.8 and one D<sub>0</sub>0 exchangable proton at 8 5.25. The absence of the methexyl peak at 8 3.9 and the OH peak at 8 5.7 originally present in the <sup>1</sup>H NMR spectrum of latifolin indicated that these sites were involved in the formation of the heterocyclic ring in 15. In a docoupling experiment, irradition of the multiplet centred at S 5.9 caused the doublet of the proton controd at S 4.45 collapse to a singlet and simultaneously the multiplet of -CH=CH\_ protons changed to a doublet. Similarly on irradiation of the doublet situation at  $\delta$  4.45, the multiplet of -CH=CH\_ proton collapsed to a double doublet thus showing that the ethylene side chain of 1 is intact in 15 and is not involved in the cyclisation. The mass spectrum of <u>15</u> exhibited a molecular ion peak at m/z 254 together with peaks at 253 (M<sup>+</sup>-H) and at 227 (M<sup>+</sup>-C<sub>2</sub>H<sub>3</sub>) corresponding to the loss of the benzylic proton and the side chain -CH=CH\_ respectively from the molecular ion. From these data the new product could be assigned the structure 3-methexy-4-hydrexy-6-vinyl xanthan (15). Dihydrelatifolin (16) en dye-sensitized photoexidation also gave a new product 17 having similar structure. Comparison of the <sup>1</sup>H NMR spectrum of <u>16</u> and the photoproduct <u>17</u> revealed again the absence of one methoxyl and one hydroxyl group present in 16. Its mass spectrum which exhibited molecular ion peak at m/z 256 alongwith ether peaks at 255 ( $M^+$ -H) and 227 ( $M^+$ -C<sub>2</sub>H<sub>R</sub>), is in agreement with the cyclised structure 3-methoxy-4-hydroxy-6-ethyl xanthan(17). The fermation of 15 and 17 from latifolin(1) and dihydrolatifolin (16) in these dye-sensitized photoexidations apparently involves a crucial step of exidative demethylation followed by cyclisation with the free hydroxyl group of the second ring. A free OH group in ring A para to the methexy group is essential to start this reaction as latifolin dimethyl ether 2 and dihydrelatifolin dimethyl ether 18 failed to underge any change when subjected to similar photoexidation.

24,  $R_1 = R_3 = H$ ,  $R_2 = 0H$ ,  $R_4 = CH_2OH$ 25,  $R_1 = R_2 = R_3 = 0CH_3$ ,  $R_4 = CH_2OH$ 26,  $R_1 = R_3 = H$ ,  $R_2 = 0H$ ,  $R_4 = CHO$ 27,  $R_1 = R_2 = R_3 = 0CH_3$ ,  $R_4 = CHO$ 

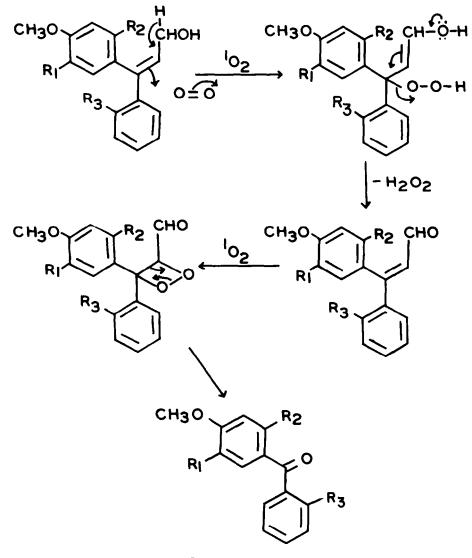

28, R<sub>1</sub> = R<sub>3</sub>=H,R<sub>2</sub>=OH 29, R<sub>1</sub> = R<sub>2</sub>=R<sub>3</sub>=OCH<sub>3</sub>

In order to throw more light on this novel reaction, we studied the photoexidation of the closely related propentl compound <u>19</u> lacking a hydrexyl group in the second ring. Surprisingly it gave a new interesting product which could be assigned the structure <u>20</u> as its <sup>1</sup>H NMR spectrum exhibited on methexyl ( $\delta$  3.9), one hydrexyl ( $\delta$  5.75, D<sub>2</sub>O exchangable) and a methyl group as shown by a new singlet at  $\delta$  2.45. Comparison of this spectrum with that of the starting material revealed that the methexyl peak at  $\delta$  3.5 and the doublet due to the side chain methyl group of <u>19</u> is absent indicating their involvement

4820

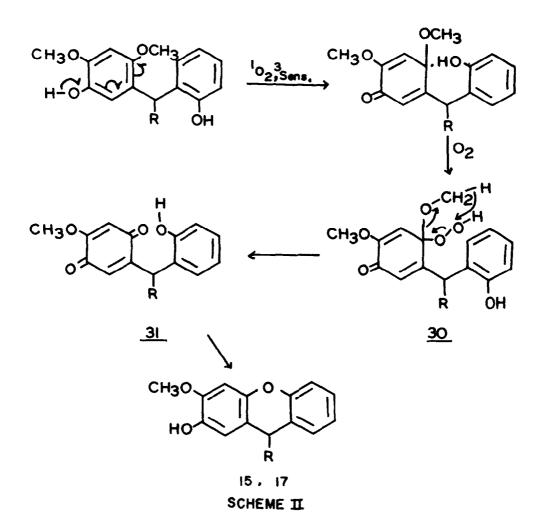

in the formation of the new product 20. Its mass spectrum gave a molecular ion peak at m/z 254 but did not show  $M^+-(-CH=CH_2)$  peak as in <u>15</u> or  $M^+-(CH_2CH_3)$  peak as in <u>17</u>. Instead this spectrum showed a strong peak at m/z 211 indicating less of  $C_2H_3O$  unit as expected from a 2-methyl benzefuran derivative. On this basis it was assigned the structure as 2-methyl-3-phenyl-5-hydroxy-6-methexy benzefuran (<u>20</u>). The complete methyl ether, 3-(2,4,5-trimethoxyphenyl)-3-phenyl prop-2-ene (<u>21</u>) again did not undergo any photochemical change under similar conditions.

SCHEME I

Apparently the first step in the formation of the benzofuran 20, is again oxidative demethylation. However, the quinonoid intermediate, lacking a hydroxyl group in ring B, involved the propene side chain instead, in this process, finally yielding 20.

Indeed the first step in above photooxidations is oxidative densthylation of the partial methyl other of the para quinol system in ring A, as 3-(2, 4dimethoxy-5-hydroxyphenyl)-3-phenyl propane (22), prepared by hydrogenation of propenyl compound <u>19</u>, gave on similar photoexidation the quinone <u>23</u> which could not underge further cyclisation as it lacked features like or the hydroxy group in ring B or a propenyl double bend. The structure of <u>23</u> was confirmed by its mass spectrum ( $M^+$ ,256) and <sup>1</sup>H NMR spectrum which exhibited the presence of one methoxyl group (§ 3.8) and two shielded aromatic protons (§ 5.95 and 6.6) and the absence of one methoxyl peak at § 3.7 as well as one D<sub>2</sub>O exchangeble OH peak at § 5.25 originally present in <sup>1</sup>H NMR spectrum of <u>22</u>. Scheme II and III depicts the pessible mechanism of these oxidative demethylation and cyclisations

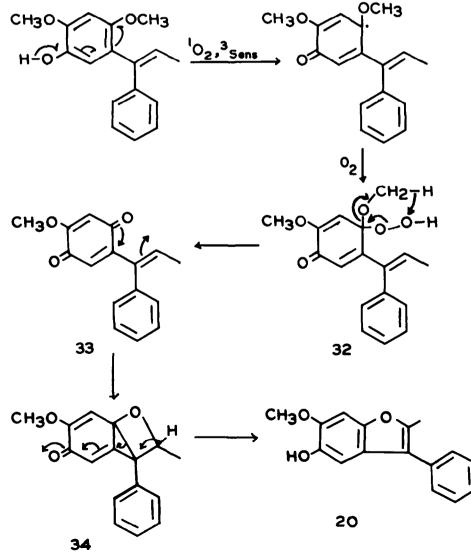

The primary requirement in these exidative demethylations is a para quinol partial methyl ether system as present in 1,16,19 and 22. A free phenolic group alone is not sufficient to give the quineme intermediate. The cinnamyl alcohol 24 having one phenolic group was tried next to see whether a side chain allylic hydroxyl group can participate in this cyclisation. It did not give any cyclised product, instead it gave the substituted cinnamaldehyde 26 by exidation through hydroperexide intermediates for exidations of elefins<sup>11</sup> and allyl alcohols<sup>12</sup> have been proposed earlier. The benzophenene 28 is formed by further exidation of 26. Similarly the fully methylated cinnamyl alcohol 25 also gave the cinnamaldehyde 27 and the benzophenene 29.

The mechanism of dyo-sensitized photoexidative denethylation of para quinol partial methyl others have been described earlier by Saits et al.<sup>13</sup> whe postulated the agency of both singlet exygen and excited triplet sensitizer for the initiating step of hydrogen abstraction from the phonol. The combination of resulting radical with the triplet exygen followed by elimination of HCHO from the complex finally yields the para quinene. Similar quineneid intermediates must be forming in the present cases also as evident from the isolation of 23. However, the cyclisation of the quinoneid intermediates to the xanthans 15 and 17 is rather nevel and its mechanism is not very clear.

The mechanism for the formation of the benzofuran <u>20</u>, through the quinome intermediate <u>33</u> and <u>34</u>, is envisaged in Scheme III. Mechanism involving similar intermediates have been pestulated earlier<sup>14</sup> for light induced conversion of menosubstituted benzoquinenes to benzofurans.

Oxidation of latifolin with free radical initiator like  $K_3[(Fe(CN)_6]$  following the procedure of Sarkanen and Willis<sup>15</sup> gave a yellew dimeric product mp.200<sup>°</sup>(d), (M<sup>+</sup>,506) and not the xanthan<sup>15</sup> showing that singlet exygen and excited triplet sensitizer play a specific role in these dye-sensitized photo-exidative cyclisations excluding the possibility of exclusive involvement of free radicals.

SCHEME III

#### EXPERIMENTAL PROCEDURES

Melting points are uncorrected. IR spectra were recorded on a Perkin Elmer-457 Spectrephotometer. UV spectra were recorded in ethanol solution on a Varian 634 Spectrephotometer. <sup>1</sup>H NMR spectra were recorded on a Varian EM-360 (60 MHz) spectremeter. Chemical shifts are reported in ppm S scale relative to TMS as internal standard. MS spectra were obtained on a Zeel JMS-D300 mass spectremeter.

#### Irradiation of Latifolin (1)

Latifolin (1, 300 mg) in benzene (300 ml) was irradiated with light from a high pressure moreury lamp filtered through pyrex for 6 hours. The residue obtained after removal of solvent was purified by chromatography over silica gel using benzene as eluant when it gave the cyclopropane 5 (175 mg) which crystallised from ethanel as colourless cubes, m.p.111-12<sup>0</sup> (Found: C,70.9; H,6.3;  $C_{17}H_{18}O_4$  requires C,71.3; H,6.3%). MS: m/z 286 (M<sup>+</sup>). <sup>1</sup>H NMR (CDCl<sub>3</sub>): S 1.00-1.50 (2H,m -CH<sub>2</sub>- of cyclopropane ring); 1.71-2.16 (2H,m,benzylic); 4.01 (3H,s,OCH<sub>3</sub>), 4.10 (3H,s,OCH<sub>3</sub>); 5.3 (1H,s,Ar-OH,D<sub>2</sub>O exchangable); 5.8 (1H,s,Ar-OH,D<sub>2</sub>O exchangable); 6.66 (1H,s,aromatic); 6.75 (1H,s,aromatic); 6.9-7.3 (4H,m, aromatic);  $A_{max}$ 

On methylation 5 gave the tetramethexy compound 6, mp.91°, identical with the product obtained by the photorearrangement of latifolin dimethyl ether (2)  $(1it^{1} mp.92-93^{\circ})$ .

# Irradiation of 3-(2.4.5-trimethexyphenyl)-3-phenyl prep-1-ene (3)

 $3-(2,4,5-\text{trimethexyphenyl})-3-\text{phenyl propene}^4$  (3, 300 mg) was photolysed as above when it yielded a mixture (TLC) of two very closely related compounds. These were separated by repeated column chromategraphy on alumina followed by crystallisation from hexane when it gave 7 (m.p.93-94°) (Found: C,76.1; H,7.1;  $C_{18}H_{20}O_3$  requires C,76.1; H,7.0%). MS: m/z 284 (M<sup>+</sup>). <sup>1</sup>H NMR (CDCl<sub>3</sub>):  $\delta$ 1.06-1.41 (2H,m,-CH<sub>2</sub>-); 1.86-2.50 (2H,m,benzylic); 3.70,3.75 (9H,s,3XOCH<sub>3</sub>); 6.35 (1H,s,H<sub>a</sub> or H<sub>b</sub>); 6.42 (1H,s,H<sub>b</sub> or H<sub>a</sub>); 7.10 (5H,m,arematic).

Repeated crystallisation from hexane of the residue from mother liquer gave 8 (50 mg), m.p.69-71<sup>®</sup> (Found: C,76.4; H,7.3;  $C_{18}H_{20}O_3$  requires C,76.1; H,7.0). MS: m/z 284 (M<sup>+</sup>). <sup>1</sup>H NMR (CDCl<sub>3</sub>): S 1.05-1.42 (2H,m,-CH<sub>2</sub>-); 1.85-2.50 (2Hm,benzylic); 3.45, 3.53 and 3.56 (9H,3s,3xOCH<sub>3</sub>); 6.18 (1H,s,H<sub>a</sub> or H<sub>b</sub>); 6.20 (1H,s,H<sub>b</sub> or H<sub>a</sub>); 6.91 (5H,m,aromatic).

# Irradiation of 3-(2.4-dimethexyphenyl)-3-phenyl propene (4)

3-(2,4-dimethexyphenyl)-3-phenyl propene<sup>4</sup> (4,500 mg) was photolysed as described earlier when it gave a mixture. On  $AgNO_3$  impregnated TLC plates it gave two spots corresponding to cis 10 and trans 9 isomers which could not be separated. The mixture gave the following spectral data. MS: m/z 254 (M<sup>+</sup>);  $\lambda_{max}^{KBr}$  1032 cm<sup>-1</sup> (cyclopropane). <sup>1</sup>H NMR (CCl<sub>4</sub>): S 1.25 (2H,m,-CH<sub>2</sub>-); 1.90 (2H,m, benzylic); 3.60, 3.68 (6H,s,2XOCH<sub>3</sub> for cis isomer); 3.76 and 3.81 (6H,s, 2XOCH<sub>3</sub> for trans isomer); 6.40 (2H,m,H<sub>a</sub> and H<sub>c</sub>); 6.80-7.25 (6H,m,H<sub>b</sub> and arematic).

# Synthesis of 1-(2.4.5-trimethexyphenyl)-1-(2-methexyphenyl cyclopromane (13)

To a stirred suspension of Zn-Cu couple (3.9 g) and catalytic amount of cuprous iodide in dry other (400 ml), was added mothylone iodide (4 g) and 1-(2,4,5-trimethexyphenyl)-1-(2-mothoxyphenyl) othylone<sup>7</sup> (11, 4.5 g). The reaction mixture was gently refluxed for 24 hr. and then cooled and filtered. The filtrate was washed with NaHCO<sub>3</sub>, brine and dried. The selvent was removed and the residue purified by column chromatography over silica gel using hexane as the eluant when it gave 14 which crystallised from hexane as colourless

plates, m.p.120-22°. (Found: C,72.1; H,6.6.C<sub>19</sub>H<sub>22</sub>O<sub>4</sub> requires C,72.6; H,7.0%). CHCl<sub>3</sub> 1034 cm<sup>-1</sup> (cycleprepane). MS: m/z 314 (M<sup>+</sup>), <sup>1</sup>H NMR (CDCl<sub>3</sub>):  $\delta$ 1.12 (4H, \$, 2x-CH\_-); 3.75, 3.81 and 3.90 (12H, s, 4xOCH\_2); 6.43 (1H, s, arematic); 6.7-7.3 (5H,m,aromatic).

#### Photoexidation of Latifolin (1)

Latifolin (1, 200 mg) in CCl<sub>4</sub> (200 ml) containing a suspension of rose bengal (100 mg) adsorbed on silica gel (2 g) was irradiated with light from tungsten lamps (600 W) while a gentle stream of air was bubbled through the solution to keep the suspension stirred. After 24 hrs. (TLC), the solution was filtered and selvent removed under reduced pressure. The residue was chromategraphed over silica gel using hexane and benzene as eluants. Hexane-benzene (1:1) eluate (250 ml) on evaporation afforded 15 which crystallised from methanel as light needles (100 mg), mp. 80-81 (Found: C,75.7; H,5.3. C16<sup>H</sup>14<sup>O</sup>3 requires C,75.9; H,5.5%). MS: m/z 254 (M<sup>+</sup>), 253 (M<sup>+</sup>-H), 227 (M<sup>+</sup>-C<sub>2</sub>H<sub>3</sub>). <sup>1</sup>H NMR (CDC1<sub>3</sub>): δ 3.8 (3H, s, OCH<sub>3</sub>); 4.45 (1H, s, J=8Hz, -c-CH=CH<sub>2</sub>); 4.9 (1H, =,-CH=CH\_); 5.2 (1H,m,-CH=CH\_); 5.25 (1H,s,-OH,D\_0 exchangeble); 5.9 (1H,m,--CH-CH=CH\_); 6.5 (1H,s, aromatic), 6.65 (1H,s, aromatic); 7.1 (4H, m, aromatic).

### Phetooxidation of dihydrelatifolin (16)

Dihydrelatifolin (16, 200 mg) in CCl<sub>4</sub> (200 ml) was photoexidised as above. After 24 hrs, the reaction mixture was worked up as usual and the residue chromatographed over silica gel using hexane and benzene as eluants. Hexanebenzene (1:1, 250 ml) eluate yielded 17 as viscous liquid (120 mg) which was further purified by preparative TLC followed by distillation under vacuum (0.1 mm Hg) at 190° (bath) when it was obtained as a colourless liquid (Found: C,74.7; H,5.9. C<sub>16</sub>H<sub>16</sub>O<sub>3</sub> requires C,75.0; H,6.3%). MS: m/z 256 (M<sup>+</sup>), 255 (M<sup>+</sup>-H), 227 (M<sup>+</sup>-C<sub>2</sub>H<sub>5</sub>). <sup>1</sup>H NNR (CDC1<sub>3</sub>): δ 0.7 (3H,t,-CH<sub>2</sub>CH<sub>3</sub>); 1.7 (2H,m,-CH<sub>2</sub>CH<sub>3</sub>); 3.8 (3H,s,OCH<sub>3</sub>); 3.82 (1H,t,-CHCH<sub>2</sub>CH<sub>3</sub>); 5.2 (1H,s,-OH,D<sub>2</sub>O exchangeble); 6.6 (1H,s, aromatic); 6.7 (1H,s,aromatic); 7.0 (4H,m,aromatic).

Photoexidation of 3-(2.4-dimethexy-5-hydroxymhenyl)-3-mhenyl mrem-2-ene (19) 3-(2,4-dimethoxy-5-hydroxymhenyl)-3-mhenylprop-2-ene<sup>10</sup> (19,200 mg) in CCl. (200 ml) was photoexidised as above. After 48 hrs. the reaction was worked up as usual and the residue chromatographed ever silica gel when it gave 20 which crystallised from methanel as colourless plates (125 mg), m.p.121°C (Found: C,75.1; H,5.2.  $C_{16}H_{14}O_3$  requires C,75.6; H,5.5%). MS: m/z 254 (M<sup>+</sup>), 239 (M<sup>+</sup>-CH<sub>3</sub>), 211 (M<sup>+</sup>-C<sub>2</sub>H<sub>3</sub>O). <sup>1</sup>H NMR (CDCl<sub>3</sub>):  $\delta$  2.45 (3H,s,=C-CH<sub>3</sub>); 3.9 (3H,s, OCH<sub>3</sub>); 5.75 (1H,s,OH,D<sub>0</sub>O exchangable); 6.9 & 7.0 (2H,2s,para aromatic protons); 7.4 (5H,m,aromatic).

### <u>Hydrogenation of 3-(2.4-dimethexy-5-hydroxyphenyl)-3-phenyl prop\_2-ene (19)</u>

A selution of 3-(2,4-dimethoxy-5-hydroxyphenyl)-3-phenyl prop-2-ene (19, 1 g ) in ethyl alcohol (200 ml) containing Pd/C (10%, 100 mg) was stirred in  $H_{\rho}$  gas until one mole of the gas was absorbed. The reaction mixture was then filtered and the solvent removed to furnish 22 which crystallised from methanol as colourless needles (800 mg), mp. 58°. (Found: C,74.6; H,7.2. C17H2003 requires C,75.0; H,7.4%). MS: m/z 272 (M<sup>+</sup>). <sup>1</sup>H NMR (CDC13): 80.82 (3H, t, -CH<sub>2</sub>CH<sub>3</sub>); 1.93 (2H, m, -CHCH<sub>2</sub>CH<sub>3</sub>); 3.7 (3H, \*, OCH<sub>3</sub>); 3.8 (3H, \*, OCH<sub>3</sub>); 4.2 (1H,t,-CH\_CH\_CH\_); 5.25 (1H,s,OH,D\_O exchangeble); 6.5 & 6.9 (2H,2s,para aromatic protons); 7.5 (5H,m,arematic).

#### Photooxidation of 22

3-(2,4-dimethexy-5-hydroxyphenyl)-3-phenyl prepane (22, 200 mg)in CCl. (200 ml) was photooxidised as earlier for 48 hrs. when the reaction appeared to be complete. Removal of solvent from the filtrate and chromatography of

the residue over silica gel yielded 23 which crystallised from methanol as yellow needles (140 mg), mp. 152° (Found: C,74.7; H,6.6.6.  $C_{16}H_{16}O_{3}$  requires C,75.0; H,6.3%). MS: m/z 256 (M<sup>+</sup>-CH<sub>3</sub>), 228 (M<sup>+</sup>-CO), 227 (M<sup>+</sup>-CH<sub>2</sub>CH<sub>3</sub>). <sup>1</sup>H NMR (CDCl<sub>3</sub>): 8 0.9 (3H,t,-CH<sub>2</sub>CH<sub>3</sub>); 1.9 (2H,m,-CH<sub>2</sub>CH<sub>3</sub>); 3.8 (3H,s,OCH<sub>3</sub>); 4.1 (1H,t,-CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub>); 5.95 & 6.6 (2H,2s,para arematic protons; 7.3 (5H,m,arematic).

# Photoexidation of 3-(2-hydroxy-4-methoxyshenvi)-3-phonvi allvi alcohol (24)

 $3-(2-hydroxy-4-methexyphenyl)-3-phenyl allyl alcohol<sup>4</sup> (24, 550 mg) in CCl<sub>4</sub> (500 ml) was photoexidised as earlier for 48 hrs. The reaction mixture was worked up and the residue chromatographed ever silica gel eluting the column with benzene when it gave the benzephenene 28 which crystallised from methanol as colourless needles, (Found: C,74.1; H,5.9. C<sub>14</sub>H<sub>12</sub>O<sub>3</sub> requires C,73.7; H,5.3%). MS: m/z 228 (M<sup>+</sup>). <sup>1</sup>H NMR (CDCl<sub>3</sub>): <math>\delta$  3.8 (3H,s,OCH<sub>3</sub>); 6.5 (1H,s,OH,D<sub>2</sub>O exchangable), 7.4-7.6 (8H,m,arematic pretens).

Further elution with benzene (200 ml) gave <u>26</u> as viscous liquid MS: m/z 254 (M<sup>+</sup>). <sup>1</sup>H NMR (CDCl<sub>3</sub>):  $\delta$  3.8 (3H,s,OCH<sub>3</sub>), 6.6 (1H,d,- $\dot{c}$ =CHCHO); 7.5-7.7 (8H,m,aromatic); 9.7 (1H,d,- $\dot{c}$ =CHCHO).

# Photoexidation of 3-(2.4.5-trimethexyphenvl)-3-(2-methexy phenvl) allyl alcohel (25)

3-(2,4,5-trimethexyphenyl)-3-(2-methexyphenyl) allyl alcohol<sup>4</sup> (25, 500 mg) in CCl<sub>4</sub> (500 ml) was photooxidised as earlier for 48 hrs. Chromatography of the mixture over silica gel using benzene as eluant gave 27 as pale yellow pewder (TLC pure) from methanol. mp.107-8<sup>9</sup> (Found: C,69.2; H,5.9. C<sub>19</sub>H<sub>20</sub>O<sub>5</sub> requires C,69.5; H,6.1%). MS: m/z 328 (M<sup>+</sup>). <sup>1</sup>H NMR (CDCl<sub>3</sub>); S 3.20 (3H,s,OCH<sub>3</sub>), 3.8 (12H,m,4xOCH<sub>3</sub>) 6.5 (1H,d,-C=CHCHO), 6.7 (1H,s,arematic); 6.8 (1H,s,arematic); 7.0 (4H,m,arematic); 9.45 (1H,d,-C=CHCHO).

Further elution with benzene yielded 29 which crystallised as light yellew prisms from methanol, mp.92-3° (Found: C,67.1; H,6.4, $C_{17}H_{18}O_5$  requires C,67.5; H,6.0%). MS: m/z 302 (M<sup>+</sup>). <sup>1</sup>H NMR (CDCl<sub>3</sub>): § 3.8 (12H,m,4xOCH<sub>3</sub>); 6.65 (1H,s,aromatic); 6.75 (1H,s,aromatic); 7.05 (4H,m,aromatic).
