

CORRELATION ANALYSIS OF STABILITY CONSTANTS OF COMPLEXES
FORMED BETWEEN ALKALI METAL CATIONS AND MACROCYCLES

Bo-Long Poh

(Received in UK 18 December 1990)

Abstract: The stability constants K_a of 1:1 complexes formed between alkali metal cations and macrocycles are correlated by the equation $\log K_a = m|R_c - R_m| + b$ where R_c and R_m are the radii of the macrocycle cavity and the alkali metal cations respectively, m and b are constants for a given macrocycle.

Introduction. Complexation between alkali metal cations and synthetic macrocycles have been extensively investigated. The stability constants K_a of many such complexes (usually of 1:1 host to guest stoichiometry) have been determined.¹ The $\log K_a$ values are usually plotted against the radii R_m of the alkali metal cations. The plots are usually curve shaped, with a maximum at a radius equalling to the radius R_c of the macrocycle cavity. Such plots are of little use for correlating stability constants. In this paper, a better and more useful method of correlating the $\log K_a$ data is presented.

Method. Two assumptions (justified by the good correlation results shown later) are made concerning the formation of 1:1 complexes between the alkali metal cations and a given macrocycle. First, the macrocycle maintains the same cavity size in complexing with the different alkali metal cations. Second, two metal cations, one larger and the other smaller, than the macrocycle cavity by the same amount (that is, same $|R_c - R_m|$ absolute value) give complexes of equal stability. These two assumptions lead to the following equation

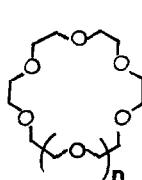

$$\log K_a = m|R_c - R_m| + b \quad (1)$$

where m and b are constants for a given macrocycle host.

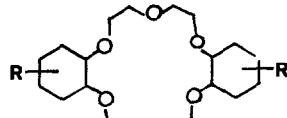

Since the exact value of R_c is not known, R_c is varied until the best correlation between $\log K_a$ and $|R_c - R_m|$ is obtained.

Results and Discussion. The $\log K_a$ values of 116 complexation equilibria involving 104 macrocycles were correlated using equation 1. A summary of the correlation results is given in Table I and the details of the correlations in Table II. Table III and IV contain the R_m and $\log K_a$ values used in the correlations. Some representative plots are shown in Figure 1.

^a The numbering corresponds to that in Table II. ^b Not used in the correlationbecause of uncertainty in the value. ^c 22°C. ^d Average log K_a value is used

whenever more than one value is listed in all the data taken from ref. 1.

The macrocycles are divided into two groups: (1) the ligating atoms are part of the macrocyclic ring structure (A1 to A28); (2) some or all of the ligating atoms are not part of the macrocyclic ring structure (B1 to B79). The first group of macrocycles give good correlations (Table I). There is not a single correlation (out of a total of forty) with a correlation coefficient $r < 0.90$ and a confidence level less than 95%. Some of the macrocycles in the second group have methyl substituents attached to their ligating atoms. These methyl groups may give rise to steric hindrance if they point into the cavity and resulting in poorer correlations. However, the results (Table I) show that steric effect is probably not serious because, on the whole, good correlations are still obtained. Only six correlations have $r < 0.90$ (no. 80, 82, 101, 110, 116 and 117) and two with a confidence level less than 95% (no. 82, 116). It is difficult to state with certainty the reason(s) for these few poorer correlations. Steric factor is unlikely to be the reason for the poor correlation obtained for no. 82 (Table II) since the macrocycle B42 is very similar to B43 which gives a satisfactory correlation in no. 83. Sometimes the accuracy of the experimental log K_a values could be a contributing factor. For example, the earlier log K_a value for Rb⁺ in no. 43 was given by Cram and coworkers² as 3.23 instead of their more recent value of 3.38 (Table IV, no. 43). If the earlier log K_a value for Rb⁺ were used, a poorer correlation for no. 43 is obtained ($R_c = 1.33$ Å, $n = 5$, $r = 0.921$, $m = -1.12$, $b = 3.59$, $Sd = 0.08$ and confidence level = 98.5%).

^a The references are given in Table IV. ^b Using the correlation lines given in Table II;

the Rm value for NH₄⁺ is 1.43 Å (ref. 22). ^c The numbering corresponds to that in

Table II. ^d Calculated values in parentheses.

Steric factor is expected to be significant in the case of the functionalized calixarenes (C1 - C5) since some of the flexible chains attached to the ligating oxygen atoms point into the cavity defined by the ligating oxygen atoms.^{3,4} The reported log K_a data⁵ of these macrocycles are poorly correlated by equation 1.

When the cavity size adopted by the macrocycle for complexation is larger than the size of the largest alkali metal cation Cs⁺ and the first assumption given earlier is still valid, the correlation equation becomes

$$\log K_a = mR_m + b \quad (2)$$

Three of the complexation equilibria (no. 49, 63 and 75) are better correlated by equation 2.

The NH₄⁺ cation is not included in the correlation because, unlike the alkali metal cations, it uses four hydrogen atoms instead of the central charged nitrogen atom to coordinate to its ligating atoms. The log K_a values for the NH₄⁺ complexes calculated from the correlation lines in Table II are given in Table V. The differences between the observed and calculated values are higher than the standard deviations of the estimate in Table II.

The other two metal cations, Ag⁺ and Tl⁺, are also not included in the correlations because they are soft cations, unlike the alkali metal cations which are hard.⁶ They generally deviate from the correlation lines of the alkali metal cations, as shown by a comparison of their observed and calculated log K_a values (Table VI).

Table VI. Comparison of Observed^a and Calculated^b Log K_a Values for Ag⁺ and Tl⁺ Complexes

| No. ^c | Log K _a (Ag ⁺) | Log K _a (Tl ⁺) | No. ^c | Log K _a (Ag ⁺) | Log K _a (Tl ⁺) |
|------------------|---------------------------------------|---------------------------------------|------------------|---------------------------------------|---------------------------------------|
| 1 | 3.62(3.89) ^d | 4.6; 5.26(5.48) | 14 | 4.04(5.05) | 3.86(4.38) |
| 2 | 4.58(5.02) | | 15 | 4.45(4.99) | 2.4(4.80) |
| 3 | 1.55(1.28) | 2.27(1.61) | 25 | 14.0(11.3) | |
| 5 | 7.10(6.29) | 7.13(5.49) | 26 | 18.6(12.7) | |
| 6 | 2.46(2.89) | | 27 | 8.9(13.4) | 12.3(7.93) |
| 7 | 1.7(1.57) | 1.8(1.65) | 29 | 12.1(10.8) | 10.1(8.4) |
| 10 | | 4.60(4.93) | 33 | 11.8(10.5) | 7.9(6.9) |
| 13 | | 5.70(4.74) | 118 | 3.90(2.29) | 4.06(5.72) |

^a The references are given in Table IV. ^b Using the correlation lines given in Table II; the R_m values for Ag⁺ and Tl⁺ are 1.15 and 1.50 Å respectively.¹ ^c The numbering corresponds to that in Table II. ^d Calculated values in parentheses.

Conclusion. The stability constants of 1:1 complexes formed between alkali metal cations and macrocycles are satisfactorily correlated by equation 1 when the macrocycles do not have flexible chains that will interfere with their cavity size defined by the ligating atoms.
