Abstract—The azocino[4,3-*b*]indole system, tricyclic substructure of the indole alkaloids apparicine and ervaticine, is efficiently assembled by ring-closing metathesis of 2-allyl-3-(allylaminomethyl)indoles. The metathesis sites are introduced into the indole nucleus by reductive amination of a 3-formyl derivative with allylamine, followed by α -lithiation with subsequent electrophilic trapping with acrolein. © 2006 Elsevier Ltd. 1. Introduction

Ruthenium-catalyzed ring-closing metathesis (RCM)¹ has emerged as a powerful tool for the construction of a great variety of carbo- and heterocycles from acyclic precursors.² In particular, the RCM methodology has turned out to be very useful for the synthesis of medium-sized rings,³ which is generally problematic due to disfavored entropic factors and transannular interactions. Our interest in the development of indole annulation methodologies led us to consider RCM reactions of indole-containing dienes^{4,5} for the efficient construction of medium-sized indolo 2,3-fused carbo- and azacycles, which are common structural arrangements in many natural and synthetic bioactive compounds.⁶ In this paper we report a direct synthetic approach to the azocino[4,3-*b*]indole system **I** by RCM of appropriate 2,3-dialkenylindoles incorporating a nitrogen atom in the tether linking the two double bonds (Scheme 1). It should be noted that **I** constitutes the tricyclic substructure of apparicine,⁷ an

2. Results and discussion

We set out to explore the feasibility of the protocol using model RCM precursors unfunctionalized at the benzylic indole α -position, such as 2-allyl-3-(allylaminomethyl)indoles **3**.¹⁰ For the preparation of these substrates, a fast formylation–reductive amination sequence starting from the known 2-allylindole **1**¹¹ was envisaged (Scheme 2). A strong electron-withdrawing benzenesulfonyl group was placed at the indole nitrogen to guarantee the stability of the proposed gramine-type intermediates. Thus, Friedel–Crafts reaction of **1** with Cl₂CHOMe in the presence of TiCl₄ gave the aldehyde **2** (90%), which was subjected to reductive amination with allylamine, followed by reaction of the resulting secondary amine with (*t*-BuOCO)₂O or TsCl. In this manner, the required RCM substrates **3a** or **3b**, bearing different

protecting groups at the aliphatic nitrogen, were obtained in 65% overall yield from **2**. Satisfactorily, ring closure of the *N*-Boc diene **3a** took place in refluxing dichloromethane in the presence of the first generation Grubbs catalyst to give the azocino[4,3-*b*]indole **4a** in 60% yield. The *N*-tosyl derivative **3b** proved to be a better substrate as it led to **4b** in a higher yield (89%).

With model azocino[4,3-*b*]indoles in hand, we sought to elaborate C-6 functionalized derivatives simply by extending the chemistry outlined above to an *O*-protected 2-(1-hydroxyallyl)indole. To this end, we selected silyl ether **6**, which was easily prepared from aldehyde **5**,¹² by reaction with vinylmagnesium bromide followed by protection of the resulting alcohol with *tert*-butyldimethylsilyl chloride (63% overall yield, Scheme 3). Disappointingly, we were not able to introduce the formyl group needed for the reductive amination step since **6** gave only a complex mixture upon subjection to the above Friedel–Crafts protocol.

Scheme 3. Reagents and conditions: (a) $\text{BrMgCH}=\text{CH}_2$, THF, -78°C –rt, overnight; (b) TBDMSCl, DMF, imidazole, 55°C , overnight, 63%.

This unsuccessful result prompted us to change the order of the synthetic steps. Functionalization at the 2-position of a properly 3-substituted indole by α -metalation followed by electrophilic trapping seemed to be the logical solution. With this aim, we focused our attention on 3-(aminomethyl)indoles **8** and **9**, which were available from indole-3-carbaldehyde **7**¹³ through reductive amination techniques, using tosylamine or, as above, allylamine followed by acylation (Scheme 4). Unfortunately, treatment of these substrates with either LDA, *sec*-BuLi or *tert*-BuLi in THF under a variety of experimental conditions, followed by addition of DMF, HCOOMe, or acrolein led to the recovery of the starting product.

Scheme 4. Reagents and conditions: (a) TsNH_2 , toluene, reflux, 24 h, then NaBH_4 , MeOH, rt, 24 h, 70%; (b) allylamine, $\text{NaBH}(\text{OAc})_3$, AcOH, rt, overnight; (c) $(t\text{-BuOCO})_2\text{O}$, 4:1 MeOH– Et_3N , reflux, 4 h, 68% (**9a**) or TsCl , Et_3N , CH_2Cl_2 , rt, overnight 67% (**9b**).

We reasoned that the replacement of the indole protecting group by a methoxymethyl (MOM) group could facilitate the α -lithiation, despite a probable reduction in stability of

some synthetic intermediates due to the lower electron-withdrawing character of this moiety. Thus, we turned to aldehyde **10**¹⁴ (Scheme 5), which was converted into the allylaminomethyl derivatives **11** under the usual conditions. As the tosyl compound **11b** partially decomposed under chromatographic purification, we decided to continue the synthesis only with the more stable *N*-Boc derivative **11a**, which could be isolated in a reproducible 72% yield.

Scheme 5. Reagents and conditions: (a) allylamine, $\text{NaBH}(\text{OAc})_3$, AcOH, rt, overnight; (b) $(t\text{-BuOCO})_2\text{O}$, 4:1 MeOH– Et_3N , reflux, 4 h, 72% (**11a**) or TsCl , Et_3N , CH_2Cl_2 , rt, overnight (**11b**); (c) *t*-BuLi, THF, -78°C , 2 h, then acrolein, -78°C , 3.5 h, 79%; (d) MnO_2 , CH_2Cl_2 , rt, 60 h, 64%; (e) TBDMSCl, DMF, imidazole, 55°C , overnight, 64%; (f) $(\text{PCy}_3)_2(\text{Cl})_2\text{Ru}=\text{CHPh}$, CH_2Cl_2 , reflux, overnight, 85% (**15**) or $(\text{Im})(\text{PCy}_3)(\text{Cl})_2\text{Ru}=\text{CHPh}$, CH_2Cl_2 , rt, overnight, 86% (**16**); (g) H_2 , Pd/C, MeOH, 12 h, 80% (**17**), 82% (**18**).

We were pleased to find that the desired α -lithiation did take place from **11a** upon treatment with *tert*-BuLi in THF at -78°C . After quenching with acrolein, the unstable alcohol **12** was isolated (79%) and immediately protected as the *tert*-butyldimethylsilyl ether **13** (64%) or, alternatively, oxidized with MnO_2 (64%) to the ketone **14**. Satisfactorily, when **13** was subjected to the previously used RCM conditions (first generation Grubbs catalyst in refluxing dichloromethane) the expected tricyclic compound **15** was obtained in good yield (85%). However, no cyclization was observed from ketone **14** under the above protocol, probably due to the presence of an electron-poor double bond, and only dimeric products coming from intermolecular metathesis reactions were formed. This problem was circumvented simply by using the more efficient second generation Grubbs catalyst at room temperature, leading to tricyclic ketone **16** in 86% yield. Finally, the saturated forms of the eight-membered heterocycles **17** and **18** were obtained by catalytic hydrogenation over Pd/C.

3. Conclusion

We have developed a new synthetic route to the azocino[4,3-*b*]indole system^{15,16} relying on RCM of 2-allyl-3-(allylaminomethyl)indoles. The efficiency of the cyclization

combined with the easy preparation of the dienic precursors from simple indolic derivatives make this strategy attractive for the construction of medium-sized indolo 2,3-fused carbo- and azacycles, which are scaffolds found in many bioactive compounds.

4.1. General methods

All nonaqueous reactions were performed under an argon atmosphere. All solvents were dried by standard methods. Reaction courses and product mixtures were routinely monitored by TLC on silica gel (precoated F₂₅₄ Merck plates). Drying of organic extracts was carried out over anhydrous Na₂SO₄. The solvents were evaporated under reduced pressure with a rotary evaporator. Flash chromatography was carried out on SiO₂ (silica gel 60, SDS, 0.04–0.06 mm). Melting points are uncorrected. Unless otherwise indicated, NMR spectra were recorded in CDCl₃ at 300 MHz (¹H) or 75.4 MHz (¹³C) using Me₄Si as an internal reference.

4.1.1. 2-Allyl-1-(phenylsulfonyl)-3-indolecarbaldehyde (2). 2-Allylindole **1**¹¹ (0.7 g, 2.3 mmol) in CH₂Cl₂ (6 mL) was added to a solution of TiCl₄ (0.51 mL, 4.7 mmol) and Cl₂CHOCH₃ (0.4 mL, 4.7 mmol) in CH₂Cl₂ (6 mL) at –78 °C, and the resulting mixture was stirred at –78 °C for 2 h. The reaction mixture was diluted with H₂O, basified with 10% aqueous Na₂CO₃, and extracted with CH₂Cl₂. The organic extracts were dried and concentrated and the residue was purified by flash chromatography (9:1 hexanes–AcOEt) to give aldehyde **2**: 0.69 g (90%); ¹H NMR δ 4.22 (m, 2H), 5.05 (dm, *J*=17.0, 1.1 Hz, 1H), 5.12 (dm, *J*=10.0, 1.1 Hz, 1H), 6.05 (m, 1H), 7.34–7.65 (m, 5H), 7.86 (m, 2H), 8.17 (m, 1H), 8.22 (m, 1H), 10.26 (s, 1H); ¹³C NMR δ 29.5 (CH₂), 114.3 (CH), 117.6 (CH₂), 119.5 (C), 121.4 (CH), 125.1 (CH), 125.6 (CH), 126.0 (C), 126.6 (2CH), 129.4 (2CH), 134.2 (CH), 134.4 (CH), 135.9 (C), 138.4 (C), 148.8 (C), 185.6 (CO).
