**Abstract.** We compute the anomalous dimensions of a set of composite operators which involve derivatives at four loops in  $\overline{\text{MS}}$  in  $\phi^4$  theory as a function of the operator moment  $n$ . These operators are similar to the twist-2 operators which arise in QCD in the operator product expansion in deep inelastic scattering. By regarding their inverse Mellin transform as being equivalent to the DGLAP splitting functions we explore to what extent taking a restricted set of operator moments can give a good approximation to the *exact* four loop result.

## 1 Introduction

The scalar field theory with a  $\phi^4$  interaction has been widely studied for a variety of problems. For instance, it underlies the physics of the anti-ferromagnetic phase transition in statistical physics and also is the starting point for the Higgs mechanism of the standard model in particle physics. From another viewpoint it has been used as a toy model in four dimensions to examine fundamental ideas in quantum field theory. One such example is understanding perturbation theory at high orders. (For a review of these points see, for example, [1].) In particular the fundamental functions of the renormalization group like the  $\beta$ -function are known to five loops in the  $\overline{\text{MS}}$  scheme, [2, 3]. In other field theories of interest in particle physics such as gauge theories four loop results have only become available in the last few years. For instance the four loop  $\beta$ -functions of QED and QCD, which describes the strong interactions, were computed in [4, 5] respectively.

Such calculations are necessary in QCD primarily because it is asymptotically free and therefore it describes the physics of high energy collisions involving quarks. As these deep inelastic experiments are becoming increasingly more accurate the theoretical input must be refined accordingly. Therefore current perturbative calculations in QCD have been focussed on the contribution of the anomalous dimensions and coefficient functions of the twist-2 flavour non-singlet and singlet operators that arise in the operator product expansion. These were originally computed at one and two loops in [6, 7] as a function of the moment of the operator  $n$ . Recently the first few moments of the three loop dimensions were determined in [8, 9]. How-

ever, the programme is not yet complete as one requires the explicit  $n$ -dependence at three loops. This is required in order to compute the DGLAP splitting functions, [10], which are given by the inverse Mellin transform with respect to  $n$ . In [9] an approximate fitting procedure was developed to obtain these functions. This was achieved by using general information on the (expected) form of the function in Bjorken  $x$ , which is the variable conjugate to  $n$  with  $0 \leq x \leq 1$ . Also the information from the explicit exact result for the first few moments was used to constrain the fitting parameters. In the absence of a full  $n$ -dependent result for the operator dimensions this strategy has to suffice for present. Clearly there are several potential problems in such an exercise. For example, the first few moments would only be expected to give a fairly accurate approximation to the splitting functions in the bulk of the  $x$ -range. However, the low  $x$  region which is presently of physical interest would not be well covered since there the higher moments give important contributions. So it would be useful to understand to what extent such a fitting procedure can be relied upon.

Whilst the complete calculation in QCD will be a formidable computational task one could at least address this and other issues in a toy model. This is the primary motivation for this paper. We will compute the anomalous dimensions of the analogous operators in  $\phi^4$  theory to four loops in the coupling constant expansion in the  $\overline{\text{MS}}$  scheme. Although this would appear to be one order beyond that currently of interest in QCD, it turns out that due to the form of the model there can be no one loop contribution. We view this theory as a toy for several reasons. First, the nature of the interaction is simpler than in

a non-abelian gauge theory and hence there will be substantially fewer diagrams to consider and also no tensorial complication in the numerator of the Feynman diagrams which occurs when one has fermion and derivative couplings. Consequently although we do not expect the results to be as involved as those which will undoubtedly occur when the full QCD result is realised, those functions of  $n$ , such as finite sums in  $n$ , which will occur will at least mimic analogous structures. Indeed as will be seen, it is these forms which will drive the strategy of the fitting procedure. As we will obtain the full 4-loop results as a function of  $n$  we will be in a position to investigate and gain insight into the approximation procedure for the splitting functions.

This leads us to our second reason why we will regard our work as a laboratory for testing ideas. Clearly unlike QCD  $\phi^4$  theory in four spacetime dimensions is not asymptotically free and therefore it does not make sense to think of the high energy limit describing particle collisions. However we stress that the aim is a *mathematical* one to endeavour to understand the relation of functions of the operator moment  $n$  to their Mellin transform which in  $\phi^4$  we will regard as being on the same footing as the DGLAP functions. In this situation asymptotic freedom plays a minimal role. Finally, our second motivation for this study is in relation to understanding the content of the operator product expansion of  $\phi^4$  in  $d$ -dimensions. As noted earlier the model relates to the perturbation theory of the Heisenberg model which equivalently, in the sense of critical phenomena, can be described by the  $O(N)$  non-linear  $\sigma$  model in  $d = (2 + \epsilon)$  dimensions. (See, for example, [1].) The operator product expansion in that model has received wide attention in recent years both perturbatively and in the  $1/N$  expansion, [11]. Therefore the computation of the anomalous dimension of a set of operators involving derivatives or gradients at high order in the related  $\phi^4$  theory is important for providing at least a cross check on future perturbative calculations in this area.

The paper is organised as follows. In Sect. 2, we review basic features of the renormalization of composite operators in quantum field theories and then perform the two and three loop computations for the anomalous dimensions of the operators in question. This calculation is extended to the fourth order in Sect. 3 where we also discuss the technical details of the determination of the divergent part of some of the underlying Feynman integrals. These results are then used to deduce the corresponding splitting functions in Sect. 4 where the approximate fitting procedure is analysed. Our conclusions are given in Sect. 5 and intermediate results in the four loop calculations are given in an appendix.

## 2 Preliminaries

We begin our discussion by reviewing the background to the computation of anomalous dimensions of composite operators. We will concentrate on one particular set of

operators in this paper,

$$\mathcal{O}_n = \phi(x)\partial_{\mu_1}\dots\partial_{\mu_n}\phi(x) - \text{traces} \quad (2.1)$$

which are twist-2 from the phenomenology point of view and symmetric and traceless. The field  $\phi$  is the basic field of the  $\phi^4$  theory which has the lagrangian

$$L = \frac{1}{2}(\partial\phi)^2 - \frac{g}{24}(\phi^2)^2 \quad (2.2)$$

where  $g$  is the coupling constant which is dimensionless in 4-dimensions. As we will be applying standard techniques of renormalization such as dimensional regularization in  $d = 4 - 2\epsilon$  dimensions and using the modified minimal subtraction scheme, ( $\overline{\text{MS}}$ ), we must derive the momentum space version of the operator. Its divergent structure is deduced from the divergence structure of 2-point Green's functions where  $\mathcal{O}_n$  has been inserted. Therefore we write

$$\int \frac{d^d x}{(2\pi)^d} \mathcal{O}_n = \int \frac{d^d p}{(2\pi)^d} \tilde{\phi}(-p)T_n(p)_{\mu_1\dots\mu_n}\tilde{\phi}(p) \quad (2.3)$$

where  $T_n(p)_{\mu_1\dots\mu_n}$  is a symmetric traceless tensor. It is more convenient to swamp the Lorentz indices by contracting with a constant vector  $\Delta_\mu$  and define the object

$$T_n(p, \Delta) = T_n(p)_{\mu_1\dots\mu_n}\Delta^{\mu_1}\dots\Delta^{\mu_n} \quad (2.4)$$

Given the fact that  $T_n(p)$  is traceless one can derive the form of  $T_n(p, \Delta)$ . However, in higher order calculations we will exploit the first two terms in the construction of recurrence relations for subintegrals. Therefore we record,

$$\begin{aligned} T_n(p, \Delta) &= (\Delta p)^n - \frac{n(n-1)}{4(n+d-3)}p^2\Delta^2(\Delta p)^{n-2} \\ &+ O((\Delta^2)^2(\Delta p)^{n-4}) \end{aligned} \quad (2.5)$$

In QCD calculations [6–9] the constant vector is usually taken to be a null vector in which case (2.5) terminates at the first term.

The anomalous dimension we are aiming to compute is  $\gamma_n(g)$ . In terms of renormalization constants this is defined to be

$$\gamma_n(g) = M^2 \frac{\partial}{\partial M^2} \ln(Z_1^{-1}Z_{\mathcal{O}}) \quad (2.6)$$

where  $M$  is the mass scale introduced to ensure  $g$  remains dimensionless in  $d$ -dimensions. The renormalization constant  $Z_1^{1/2}$  corresponds to the renormalization of the field  $\phi$  and is known at five loops in the more general theory with an internal  $O(N)$  symmetry [3]. The lower order calculations were performed in [2]. In our notation defining

$$\gamma(g) = 2\gamma_\phi(g) = M^2 \frac{\partial}{\partial M^2} \ln Z_1 \quad (2.7)$$

then, for  $N = 1$ ,

$$\gamma(g) = \frac{1}{6}g^2 - \frac{1}{8}g^3 + \frac{65}{81}g^4 \quad (2.8)$$

**Fig. 1.** Two and three loop graphs contributing to  $\gamma_n(g)$

The remaining renormalization constant  $Z_{\mathcal{O}}$  defines the renormalization group function  $\gamma_{\mathcal{O}}(g)$  via

$$\gamma_{\mathcal{O}}(g) = M^2 \frac{\partial}{\partial M^2} \ln Z_{\mathcal{O}} \quad (2.9)$$

which corresponds to the renormalization of the operator insertion in the one particle irreducible 2-point Green's function. From the nature of the quartic interaction  $\gamma_{\mathcal{O}}(g)$  will have the  $O(g^2)$  term as the first non-zero contribution. In the analogous calculation in QCD we note that the twist-2 operators are physical operators and therefore their anomalous dimensions are gauge independent. However the renormalization group functions corresponding to  $\gamma(g)$  and  $\gamma_{\mathcal{O}}(g)$  are each gauge dependent. Therefore although there is no gauge symmetry in  $\phi^4$  it is  $\gamma_n(g)$  which we will regard as being on the same footing as the gauge independent dimensions in QCD.

We now detail the computation of the two and three loop contributions to (2.9). These results will play an important role in the four loop calculation where they will enter multiplied by vertex counterterms for example. Although strictly it is their  $\epsilon$ -expansion to  $O(\epsilon)$  and  $O(1)$  respectively for two and three loops which we will need it is in fact possible to compute the relevant integrals exactly as a function of  $d$ . The two loop contribution to (2.9) arises from the first graph of Fig. 1 where the line with a dot on it represents the insertion of the operator  $T_n(p, \Delta)$ . There is a flow of momenta  $p$  through the external legs of the Green's function. As we are interested only in the ultraviolet divergence of the graphs we compute with massless propagators which in turn allows us to exploit massless integration techniques such as uniqueness [12,13]. However for the lower order cases one needs only to apply, for instance, the elementary chain rule of [12]. Therefore the exact result for the *value* the 2-loop graph of Fig. 1 is

$$\nu(1, 1, 2\mu - 2)\nu_{0nn}(2 - \mu, 2, 3\mu - 4 + n) \quad (2.10)$$

where  $d = 2\mu = 4 - 2\epsilon$ ,

$$\begin{aligned} \nu(\alpha, \beta, \gamma) &= \pi^\mu a(\alpha)a(\beta)a(\gamma), \\ \nu_{mnp}(\alpha, \beta, \gamma) &= \pi^\mu a_m(\alpha)a_n(\beta)a_p(\gamma) \end{aligned} \quad (2.11)$$

$a(\alpha) = \Gamma(\mu - \alpha)/\Gamma(\alpha)$  and  $a_n(\alpha) = \Gamma(\mu - \alpha + n)/\Gamma(\alpha)$ . The  $p$  and  $\Delta$  dependence is easy to reconstruct from the integral dimension. Performing the  $\epsilon$ -expansion of (2.10) and including the symmetry factor of  $1/2$  gives the contribution to (2.9) as

$$\frac{g^2}{2n(n+1)\epsilon} \quad (2.12)$$

The three loop calculation requires the calculation of the second graph of Fig. 1. As there are two graphs with the same topology we have included both in the same diagram with their respective names,  $E1$  and  $E2$ . Again it is straightforward to compute each integral exactly using the chain rule of [12] and we find that their values are

$$E1 = (\nu(1, 1, 2\mu - 2))^2 \nu_{n0n}(2, 4 - 2\mu, 4\mu - 6 + n) \quad (2.13)$$

$$E2 = \nu(1, 1, 2\mu - 2)\nu_{n0n}(2, 1, 2\mu - 3 + n) \nu_{n0n}(5 - 2\mu, 1, 4\mu - 6 + n) \quad (2.14)$$

However each graph has at least one subgraph divergence arising when either one or both loops can be enclosed by a box. The divergence arising from these subgraphs are cancelled by multiplying the two loop graphs of Fig. 1 by the relevant (vertex) counterterm. In this and the four loop case we include in our expressions for the final value of the divergent part of the graphs the subtraction of these subgraph divergences. (Further background to this procedure is well documented in, for example, [14].) However it is appropriate to record that for  $E2$  the subtraction is

$$a^2(1)a_n(2)a_n(3\mu - 4 + n)/\epsilon \quad (2.15)$$

Hence the full  $\overline{\text{MS}}$  contributions to (2.9) at  $O(g^3)$  are

$$E1 = -\frac{1}{3n(n+1)\epsilon^2} + \frac{(2n^2 - 1)}{3n^2(n+1)^2\epsilon} \quad (2.16)$$

$$E2 = -\frac{1}{6n(n+1)\epsilon^2} + \left( -\frac{S_1(n)}{3n(n+1)} + \frac{(4n^2 + 2n - 1)}{6n^2(n+1)^2} \right) \frac{1}{\epsilon} \quad (2.17)$$

where the finite sums  $S_l(n)$  are defined as  $S_l(n) = \sum_{j=1}^n 1/j^l$ . With these values we deduce that

$$\begin{aligned} \gamma_{\mathcal{O}}(g) &= \frac{1}{n(n+1)}g^2 + \left( \frac{2S_1(n)}{n(n+1)} - \frac{(10n^2 + 4n - 3)}{2n^2(n+1)^2} \right) g^3 \end{aligned} \quad (2.18)$$

### 3 Four loop calculation

We now turn to the renormalization of the operator at the four loop level. There are four basic topologies to be considered which are illustrated in Fig. 2. As in Fig. 1 we have indicated the location of the operator insertion by a dot and denoted the corresponding graph by the symbol beside each insertion. Of these four topologies sets  $C$  and  $D$  represent integrals whose divergence structure and subgraph subtractions can be computed directly by elementary chain integrals involving (2.11) and we will not discuss them further. Likewise integral  $A2$  is trivial to compute. The remaining graphs required some ingenuity and we detail the techniques for several as an aid to the

Fig. 2. Four loop graphs contributing to  $\gamma_n(g)$

Fig. 3. Intermediate steps in the calculation of  $A_1$

interested reader and a potential method for future similar problems.

First, we consider the integral  $A_1$  and detail its calculation. It can quickly be reduced to the 2-loop integral illustrated in the first graph of Fig. 3 where the factor arising from the integrations is

$$\frac{a_n(1+3\epsilon)(a(1))^3}{4\epsilon^2(1-2\epsilon)(n+1-5\epsilon)a(1+\epsilon)a_n(1+4\epsilon)} \quad (3.1)$$

In Fig. 3 we denote the power of the propagator beside each line if it is not unity and the location of the numerator  $(\Delta y)^n$  by the symbol  $(n)$  and an arrow on the line beside the propagator involving  $y$ . We have used the coordinate space representation of the integrals so that the variables of integration are the location of the vertices and *not* the flow of momentum around a loop, [12]. On dimensional grounds the value of this integral is

$$A_1(\epsilon, n) \frac{(\Delta p)^n}{p^2} \left( \frac{M^2}{p^2} \right)^{3\epsilon} \quad (3.2)$$

and the aim is to deduce  $A_1(\epsilon, n)$  to the term linear in  $\epsilon$ . This is because (3.1) is  $O(1/\epsilon^2)$ . The first step is to relate  $A_1(\epsilon, n)$  to an integral with all exponents unity or  $O(\epsilon)$

which is achieved by the integration by parts rule given in [12,15]. The result is the set of integrals on the right side of the first equation of Fig. 3. The three terms with a line missing are easy to compute exactly and give the contribution to  $A_1(\epsilon, n)$  of

$$\frac{a(1)a(1+\epsilon)a_n(1+2\epsilon)}{6\epsilon(n+1-4\epsilon)a_n(1+3\epsilon)} \left[ \frac{a_n(1)}{(n-\epsilon)a_n(1+2\epsilon)} - \frac{a(1)}{(1-3\epsilon)a(1+2\epsilon)} \right] \quad (3.3)$$

The remaining two diagrams have similar structure. If we denote by  $b_1(\epsilon, n)$  the value of the first graph on the right side of Fig. 3 then we can obtain a recurrence relation for  $b_1(\epsilon, n)$  with respect to  $n$  which can be solved. One way of achieving this is to consider the integral without the  $\Delta$  contraction and decompose the numerator structure  $y_{\mu_1} \dots y_{\mu_n}$  into a sum of symmetric and traceless objects  $y_{(\mu_1 \dots \mu_r)}$  defined in [13]. As such objects are independent the resulting integral must be a sum of the set  $y_{(\mu_1 \dots \mu_r)}$  with  $r \leq n$  where the balance of indices is made up by including the appropriate number of  $\eta_{\mu\nu}$  tensors. Their coefficients are functions of  $n$  with the leading term corresponding to  $b_1(\epsilon, n)$ . This is deduced by eliminating the next to leading order term between the equations obtained by first contracting with  $\Delta_{\mu_1} \dots \Delta_{\mu_n}$  and applying the differential operator  $x_\mu \partial / \partial \Delta^\mu$  and second by contracting with, say,  $\eta^{\mu n-1 \mu n}$ . This results in the relation

$$b_1(\epsilon, n) = r_n [b_1(\epsilon, n-1) + c_1(\epsilon, n-1)] \quad (3.4)$$

where  $c_1(\epsilon, n)$  is defined in the second equation of Fig. 3 and

$$r_n = \frac{(n+\mu-2)}{(n+2\mu-3)} \quad (3.5)$$

Clearly the solution to (3.4) is

$$b_1(\epsilon, n) = b_1(\epsilon, 0) \left( \prod_{i=1}^n r_i \right) + \sum_{k=1}^n c_1(\epsilon, k-1) \left( \prod_{i=k}^n r_i \right) \quad (3.6)$$

The integral  $b_1(\epsilon, 0)$  has been computed explicitly in [16] and has the value

$$b_1(\epsilon, 0) = \frac{(1-5\epsilon)a^2(1)a(1+\epsilon)}{3\epsilon^2(1-3\epsilon)^2(1-4\epsilon)a(1+3\epsilon)} \quad (3.7)$$

in our notation. For  $c_1(\epsilon, n)$  the second term is

$$\frac{1}{\frac{3(n-\epsilon)(1-3\epsilon)(n+1-3\epsilon)(n+1-4\epsilon)}{a(1)a(1+\epsilon)a_n(1)}} \cdot \frac{a_n(1)}{a_n(1+3\epsilon)} \quad (3.8)$$

whilst the first and third are similar in form where, for example, it is simple to derive the integral representation

for the first graph of the second equation of Fig. 3 as

$$\frac{1}{3(1-2\epsilon)(1-3\epsilon)} \frac{\Gamma(1+3\epsilon)}{\Gamma(1+\epsilon)} \int_0^1 ds s^{-\epsilon}(1-s)^{1-2\epsilon} \int_0^1 dt t^{1-3\epsilon}(1-t)^{-\epsilon}[1-st]^n \quad (3.9)$$

Since we are only interested in the divergent part of  $A1$  it is straightforward to expand the integral in powers of  $\epsilon$  to the  $O(\epsilon)$  term and obtain for it alone

$$\begin{aligned} & \int_0^1 ds s^{-\epsilon}(1-s)^{1-2\epsilon} \int_0^1 dt t^{1-3\epsilon}(1-t)^{-\epsilon}[1-st]^n \\ &= \frac{1}{(n+1)} - \frac{S_1(n+2)}{(n+1)(n+2)} \\ &+ \frac{\epsilon}{(n+1)} \left[ 3 + S_1(n+2) + \frac{3S_1(n+2)}{(n+2)} - \frac{2S_1^2(n+2)}{(n+2)} \right. \\ &\left. - \frac{5S_2(n+2)}{(n+2)} \right] + O(\epsilon^2) \end{aligned} \quad (3.10)$$

Hence we have

$$\begin{aligned} b_1(\epsilon, n) &= \frac{(1-2\epsilon)(1-5\epsilon)}{3\epsilon^2(1-3\epsilon)^2(1-4\epsilon)(n+1-2\epsilon)} \\ &\frac{a_n(1)a^2(1+\epsilon)a(1)}{a(1+3\epsilon)a_n(1+\epsilon)} \\ &+ \frac{1}{3(n+1)} \left[ 2 - S_2(n+1) - \frac{S_1(n+1)}{(n+1)} \right] \end{aligned} \quad (3.11)$$

Assembling all the relevant contributions and factors like (3.1) and expanding in powers of  $\epsilon$  we deduce that the divergent part of  $A1$  itself is

$$\begin{aligned} & \frac{1}{8n(n+1)\epsilon^3} + \frac{1}{\epsilon^2} \left( \frac{S_1(n)}{4n(n+1)} + \frac{(5n^2+11n+1)}{8n^2(n+1)^2} \right) \\ &+ \frac{1}{\epsilon} \left( \frac{(2S_2(n)+S_1^2(n))}{4n(n+1)} + \frac{(5n^2+11n+1)S_1(n)}{4n^2(n+1)^2} \right. \\ &\left. + \frac{(19n^4+68n^3+85n^2+12n+1)}{8n^3(n+1)^3} \right) + O(1) \end{aligned} \quad (3.12)$$

Performing the simple operation of subtraction of subgraph divergences yields the result for  $A1$  which we have recorded in (A.1).

Another technique was also used to compute several of the other graphs of Fig. 2 and we detail this for graph  $B1$ . After performing the two elementary loop integrations we obtain a simple two loop graph. Rather than considering this graph we examine the more general graph illustrated in Fig. 4 where we have introduced an extra parameter  $a$  and the (analytic) regularization  $\delta$ . Denoting the value of this graph by  $B_1(\epsilon, a, \delta)$  we record that for the problem in hand we require  $B_1(\epsilon, 1, 0)$ . The presence of a general  $a$  and  $\delta$  will allow us more freedom in using various calculational techniques such as uniqueness to obtain expressions to determine the coefficients in the power series.

Fig. 4. Intermediate integrals in the calculation of  $B1$

The first step is to apply the operator  $\Delta_\mu \partial / \partial p^\mu$  to the diagram to yield the two graphs  $I_1$  and  $I_2$  of Fig. 4 where

$$B_1(\epsilon, a, \delta) = \frac{1}{(3+a)\epsilon} [a\epsilon I_1 + (1-\delta)I_2] \quad (3.13)$$

Whilst the former is finite with respect to  $\epsilon$  the second is divergent. It is determined by integrating by parts on the integral with the same exponent structure on each line except that 1 is subtracted from the top right line and added to the bottom right. Substituting the result of this operation into (3.13) we obtain

$$B_1(\epsilon, a, \delta) = \frac{1}{(3+a)\epsilon} [(1-\delta)J_2(\epsilon, a, \delta) + F(\epsilon, a, \delta)] \quad (3.14)$$

where  $J_2$  is integral given in Fig. 4 and  $F(\epsilon, a, \delta)$  represents the sum of the remaining graphs which are finite with respect to  $\epsilon$ . As  $J_2(\epsilon, a, \delta)$  is a set of elementary chain integrals all that remains is the calculation of  $F(\epsilon, 1, 0)$  whose  $O(\epsilon)$  term is needed due to the pole in  $\epsilon$  in (3.14). This is achieved by expanding in powers of  $a$  and  $\epsilon$

$$F(\epsilon, a, \delta) = f_0 + (f_1 + af_2)\epsilon + O(\epsilon^2) \quad (3.15)$$

and then determining the constant coefficients  $f_i$ . Rewriting  $F(\epsilon, a, \delta)$  from (3.14) as

$$\begin{aligned} F(\epsilon, a, \delta) &= (3+a)\epsilon B_1(\epsilon, a, \delta) - (1-\delta)J_2(\epsilon, a, \delta) \\ &\equiv D(\epsilon, a, \delta) \end{aligned} \quad (3.16)$$

then it can be evaluated for special cases of  $a$  to give

$$F(\epsilon, 1, 0) = 2D(\epsilon, 0, 0) - D(\epsilon, -1, 0) \quad (3.17)$$

In the explicit evaluation of the integrals, however, there is a potential problem when using uniqueness to integrate the right triangle of  $B_1(\epsilon, -1, 0)$ . To avoid the appearance of factors such as  $\Gamma(0)$  in both numerator and denominator one needs the temporary regulator  $\delta$  and so (3.17) ought to be replaced by

$$F(\epsilon, 1, 0) = [2D(\epsilon, 0, \delta) - D(\epsilon, -1, \delta)]_{\delta \rightarrow 0} \quad (3.18)$$

As an aid we record the results of these intermediate steps as

$$J_2(\epsilon, 1, 0) = \frac{a(1)a(1+\epsilon)a_n(1+\epsilon)a_1(2)}{a(2\epsilon)a_{n+1}(1+2\epsilon)}$$

$$D(\epsilon, 0, 0) = \frac{a^3(1)}{a(\epsilon)} \left( \frac{a_n(1+2\epsilon)}{a_{n+1}(1+3\epsilon)} - \frac{a_n(1+\epsilon)}{a_{n+1}(1+2\epsilon)} \right)$$

$$D(\epsilon, -1, 0) = \frac{a_n(1+\epsilon)}{(1-\epsilon)(n+1-3\epsilon)^2 a_n(1+2\epsilon)} \quad (3.19)$$

With these expressions it is a simple exercise to verify that the result (A.4) is finally obtained for graph B1.

We have used either of these algebraic techniques outlined here to evaluate the remaining divergent parts of the integrals. For completeness the results for each are recorded in the appendix where the subgraph divergences have been removed. In several of the results the additional finite sum  $K_l(n) = \sum_{j=1}^n (-1)^{j+1}/j^l$  occurs. In (A.6), for instance, it arises in the computation of an intermediate two loop integral where the exponents on the lines diagonally opposite each other are 2 and  $1-\epsilon$  respectively and the central line has zero exponent but an  $(n)$  insertion. However, its  $\epsilon$ -expansion is elementary to compute using the rule for chains after the application of the binomial expansion. Also in the graph A3 after completing the first two elementary loop integrals one is left with a two loop integral multiplied by  $1/\epsilon$ . This integral, which is finite with respect to  $\epsilon$ , has been evaluated explicitly in [17] and involves  $K_2(n)$ .

Finally it is a simple exercise to assemble all the contributions to the four loop result and allowing for the symmetry factors of the graphs which are given in Table 1, we find the  $O(g^4)$  term of (2.18) is

$$\begin{aligned} & \frac{3S_2(n)}{n(n+1)} + \frac{S_1^2(n)}{n^2(n+1)^2} - \frac{(89n^2 + 53n - 18)S_1(n)}{6n^2(n+1)^2} \\ & - \frac{(n^2 + n - 4)K_2(n)}{n^2(n+1)^2} \\ & + \frac{(265n^4 + 280n^3 - 36n^2 - 39n + 33)}{12n^3(n+1)^3} \end{aligned} \quad (3.20)$$

We summarize the results of this and the previous section by recording our 4-loop  $\overline{\text{MS}}$  value for  $\gamma_n(g)$  as

$$\begin{aligned} \gamma_n(g) = & -\frac{(n-2)(n+3)}{6n(n+1)}g^2 + \left( \frac{2S_1(n)}{n(n+1)} \right. \\ & \left. + \frac{(n^4 + 2n^3 - 39n^2 - 16n + 12)}{8n^2(n+1)^2} \right) g^3 \\ & + \left( \frac{3S_2(n)}{n(n+1)} + \frac{2S_1^2(n)}{n(n+1)} - \frac{(89n^2 + 53n - 18)S_1(n)}{6n^2(n+1)^2} \right. \\ & \left. - \frac{(n^2 + n - 4)K_2(n)}{n^2(n+1)^2} \right) \\ & + \left. \frac{(265n^4 + 280n^3 - 36n^2 - 39n + 33)}{12n^3(n+1)^3} - \frac{65}{81} \right) g^4 \end{aligned} \quad (3.21)$$

One non-trivial check on this result is that it vanishes for  $n=2$ . In that case the original operator corresponds to the energy momentum tensor which is conserved in the quantum theory. It is well established that the anomalous dimension of non-anomalous conserved physical currents vanish to all orders in perturbation theory. (See, for example, [18].)

## 4 Mellin transform

We now apply the results of the previous sections to the problem outlined in the introduction. Again we emphasise that the aim of the exercise is to investigate the mathematics underlying the fitting to the Mellin transform of the anomalous dimensions given only knowledge of the first few moments. In QCD it is this transform which corresponds to the DGLAP splitting functions, [10]. These are a measure of the probability that a parton decomposes into other partons ie quarks and gluons. The variable conjugate to the moment  $n$  is Bjorken  $x$  which represents the momentum fraction carried by the parton in the nucleon. Therefore it is restricted to lie in the unit interval. Though in general the domain of  $x$  is the half-line. To approximate the three loop splitting functions in QCD the authors of [9] took a set of trial functions of  $x$  whose properties were consistent with expected general behaviour of the splitting functions in the unit interval and fixed the unknown coefficients using the available exact 3-loop moments. For example, for the non-singlet case these expressions are known for  $n=2, 4, 6, 8$  and 10. Of course such an exercise is unnecessary if the full  $n$ -dependent result was available. In [9] as a prelude to exploring the third order correction the two loop result was examined. That had the advantage of knowledge of the exact result of the operator dimension for all  $n$  and hence the splitting functions for all  $x$ . One disadvantage is that the second order result has a simpler structure of functions of  $x$  than those which would arise at next order. Also in this second order case the result is unlikely to be unambiguous as only a few moments are sufficient to isolate which of the set of trial functions play the important role in, say, the small  $x$  behaviour.

Having summarized the status of the QCD calculation we can use our results at four loops in  $\phi^4$  to try and gain a more detailed insight into improvements to the fitting. First, some elementary remarks are in order. It is important to note that we are not claiming there is a parton interpretation in  $\phi^4$  theory. The lack of asymptotic freedom counts against this. Second, although the QCD calculations are at third order and we have computed  $\gamma_n(g)$  to four loops, it is in effect a third order calculation since there is no one loop contribution. Therefore it is this fourth order result which we will regard as being on the same footing as the three loop QCD result although we are not claiming that it has as complex a form. We begin by defining the Mellin transform of a function  $f(x)$  as

$$\mathcal{M}[f(x)] = \int_0^1 dx x^{n-1} f(x) \quad (4.1)$$

where we restrict the function to exist on the unit interval. In QCD the operator dimension is gauge independent though the field dimension and the renormalization of the bare operator are gauge dependent. As there is no gauge symmetry in  $\phi^4$  theory rather than take the full dimension  $\gamma_n(g)$  we concentrate on the part  $\gamma_O(g)$ . This is justified by the fact that  $\gamma(g)$  is  $n$ -independent and therefore its contribution to the  $x$ -dependence will be purely  $\gamma(g)\delta(1-x)$

**Table 1.** Symmetry factors for each graph defined in Fig. 2

Graph	A1	A2	A3	B1	B2	B3	C1	C2	C3	D1	D2	D3
Factor	1	1/4	1/2	1	1/2	1/4	1/8	1/2	1/4	1/6	1/6	1/4

**Fig. 5.** Two loop splitting function

**Fig. 6.** Three loop splitting function

Fig. 7. Four loop splitting function

which is uninteresting for our study. With the definition (4.1) it is straightforward to verify that the splitting functions are given by

$$P(g, x) = \sum_{n=2}^{\infty} P_n(x) g^n \quad (4.2)$$

where

$$P_2(x) = (1 - x) \quad (4.3)$$

$$P_3(x) = -2x \ln(x) - 2(1 - x) \ln(1 - x) - \frac{1}{2}(1 - x)(3 \ln(x) + 10) \quad (4.4)$$

$$\begin{aligned} P_4(x) = & 8(1 - x) \text{Li}_3(-x) - 4(1 - x) \ln(x) \text{Li}_2(-x) \\ & - 3(1 - x) \psi''(1) \\ & - 4x \ln(x) \psi'(1) + \frac{2}{3} x \ln^3(x) \\ & + 9(1 + x) \ln(x) \ln(1 + x) \\ & + 9(1 + x) \text{Li}_2(-x) - 2(1 - x) \text{Li}_2(x) \\ & - 4x \text{Li}_2(x) \\ & + (1 - x) \ln(x) \ln(1 - x) + 2(1 - x) \ln^2(1 - x) \\ & + \frac{89}{6} (1 - x) \ln(1 - x) \\ & + 13x \psi'(1) + 3(1 - x) \psi'(1) + \frac{93}{4} (1 - x) \\ & + \frac{23}{2} \ln(x) + \frac{11}{8} \ln^2(x) - \frac{27}{8} x \ln^2(x) \\ & + \frac{9}{2} x \ln(x) \end{aligned} \quad (4.5)$$

In these expressions  $\text{Li}_n(x)$  is the polylogarithm function whose properties are well known, [19], and  $\psi(x)$  is the logarithmic derivative of the Euler  $\Gamma$ -function. To gain

some idea into the form of these functions we have plotted them in Figs. 5–7.

As a preliminary to the four loop analysis we first summarize the method for the three loop case since the two loop example is clearly trivial. The basic idea is to postulate a basis set of trial functions of  $x$  with arbitrary coefficients. These are fixed by using (4.1) to obtain a function of  $n$  which can be evaluated for the first few moments and compared with the analogous value of (2.18). Once the coefficients have been fixed one can compare the approximate function with the exact result to see how well it covers the function in the unit interval. It is worth pointing out that the trial set of functions ought to contain a few which have logarithmic dependence given the nature of the exact result and its form in Fig. 6. Therefore some guidance on how good the fit is, is that it should be better than taking a trial set which gives a polynomial in  $x$  of the appropriate degree. Given this criterion we discovered that the set

$$\{ 1, x, \ln(x), \ln(1 - x), x \ln(1 - x) \} \quad (4.6)$$

gave a very good approximation. We have plotted this approximation with the exact result in Fig. 8 where the straight line is the exact result and the dots represent the approximation. Interestingly the discrepancy at  $x = 0$  is about 0.12. Clearly to achieve this accuracy we have used only five moments. However, comparing the functions of (4.6) with the exact function one observes that  $x \ln x$  is absent. This illustrates a potential pitfall in fitting approximations to exact results. One feature of the three loop case to emerge was the necessity of having functions in the trial set which reproduced some of the functions of  $x$  which appeared in the exact result. We repeated this exercise with a variety of sets either with fewer functions

**Fig. 8.** Approximation to the three loop splitting function

**Fig. 9.** Approximation to the four loop splitting function with first trial set

and therefore fewer moments or replaced several of the entries in (4.6) with other functions. However the result of Fig. 8 represents the best fit.

We have repeated this analysis for the 4-loop case. From the form of the exact result it turns out to be a harder exercise especially in covering the small  $x$  region well. Again with the criterion that a fit must be better than a polynomial, we managed to gain reasonable approximations with two trial sets. To achieve this we needed to extend the set to seven elements and include higher

powers of the logarithm. Even with this, however, an answer as accurate as three loops could not be achieved. These sets were

$$\{ 1, x, \ln(x), \ln^2(x), \text{Li}_2(x), \ln(x)\text{Li}_2(x), x \ln(x) \} \quad (4.7)$$

$$\{ 1, x, \ln(x), \ln^2(x), \text{Li}_2(x), \ln(x)\text{Li}_2(x), \text{Li}_2(-x) \} \quad (4.8)$$

and we have plotted each beside the exact results respectively in Figs 9 and 10. Although set (4.8) appears to deviate in the middle  $x$  range it is clearly more accurate for small  $x$  than (4.7). This is due to the alternating form

**Fig. 10.** Approximation to the four loop splitting function with second trial set

of the expansion of the dilogarithm for small  $x$ . The respective discrepancies at  $x = 0$  from the exact and approximate answers were 2.5 and 0.5.

## 5 Conclusions

We have constructed the  $\overline{\text{MS}}$  4-loop anomalous dimensions for a set of twist-2 operators which are analogous to operators which occur in the operator product expansion used in deep inelastic scattering in QCD. In the course of examining the inverse Mellin transform for the four loop case we found that it was important to isolate those functions of  $x$  and include them in the fit that reproduced similar forms to the basic finite sums that appear in the exact answer. In the absence of a full exact answer for QCD it would therefore seem to us that one could endeavour to improve the fits of the anomalous dimensions, [9], in the low  $x$ -region by trying to deduce the type of finite sums which would occur at three loops. An insight into this could be obtained by generalizing some of the series that already occur in the exact two loop results. For instance, the sums  $S_l(n)$  occur at  $l$ -loops for  $l = 1$  and 2 and it would appear odd if  $S_3(n)$  did not occur in the 3-loop result. Therefore another structure to study might arise from generalizing those finite sums which only occur in the two loop result. The other feature which we observed in our analysis was that to maintain the accuracy one would require several more exact moments for the anomalous dimensions.

## A Values for 4-loop integrals

In this section we record the values of the divergent parts of the integrals which arise in the computation of the 4-loop anomalous dimension in  $\overline{\text{MS}}$ . The label refers to the diagrams of Fig. 2 though the values given here correspond to those with the subgraph divergences removed. We found

$$\begin{aligned}
 A1 = & \frac{1}{24n(n+1)\epsilon^3} \\
 & + \left( \frac{S_1(n)}{12n(n+1)} - \frac{(7n^2 + 5n - 1)}{24n^2(n+1)^2} \right) \frac{1}{\epsilon^2} \\
 & + \left( -\frac{S_2(n)}{6n(n+1)} + \frac{S_1^2(n)}{12n(n+1)} \right. \\
 & \left. - \frac{(7n^2 + 5n - 1)S_1(n)}{12n^2(n+1)^2} \right. \\
 & \left. + \frac{(25n^4 + 36n^3 + 7n^2 - 4n + 1)}{24n^3(n+1)^3} \right) \frac{1}{\epsilon}
 \end{aligned} \tag{A.1}$$

$$\begin{aligned}
 A2 = & \frac{1}{12n(n+1)\epsilon^3} - \frac{(5n^2 + 3n - 1)}{12n^2(n+1)^2\epsilon^2} \\
 & + \frac{(9n^4 + 8n^3 - 3n^2 - 2n + 1)}{12n^3(n+1)^3\epsilon}
 \end{aligned} \tag{A.2}$$

$$A3 = \frac{K_2(n)}{n^2(n+1)^2\epsilon} \tag{A.3}$$

$$\begin{aligned}
B1 &= \frac{1}{24n(n+1)\epsilon^3} \\
&+ \left( \frac{S_1(n)}{12n(n+1)} - \frac{(7n^2+5n-1)}{24n^2(n+1)^2} \right) \frac{1}{\epsilon^2} \\
&+ \left( \frac{S_2(n)}{3n(n+1)} + \frac{S_1^2(n)}{12n(n+1)} - \frac{(7n^2+5n-1)S_1(n)}{12n^2(n+1)^2} \right. \\
&\quad \left. + \frac{(25n^4+36n^3+7n^2-4n+1)}{24n^3(n+1)^3} \right) \frac{1}{\epsilon} \quad (\text{A.4})
\end{aligned}$$

$$\begin{aligned}
B2 &= \frac{1}{8n(n+1)\epsilon^3} \\
&+ \frac{1}{\epsilon^2} \left( \frac{S_1(n)}{12n(n+1)} - \frac{(11n^2+5n-3)}{24n^2(n+1)^2} \right) \\
&+ \left( \frac{S_2(n)}{12n(n+1)} - \frac{S_1^2(n)}{6n(n+1)} - \frac{S_1(n)(n^2-n-1)}{12n^2(n+1)^2} \right. \\
&\quad \left. + \frac{(13n^4+4n^3-11n^2-2n+3)}{24n^3(n+1)^3} \right) \frac{1}{\epsilon} \quad (\text{A.5})
\end{aligned}$$

$$\begin{aligned}
B3 &= \frac{1}{12n(n+1)\epsilon^3} \\
&+ \left( \frac{S_1(n)}{6n(n+1)} - \frac{(4n^2+2n-1)}{12n^2(n+1)^2} \right) \frac{1}{\epsilon^2} \\
&+ \left( \frac{S_2(n)}{6n(n+1)} + \frac{S_1^2(n)}{6n(n+1)} - \frac{S_1(n)(4n^2+2n-1)}{6n^2(n+1)^2} \right. \\
&\quad \left. - \frac{K_2(n)}{2n(n+1)} + \frac{(4n^4-5n^2-n+1)}{12n^3(n+1)^3} \right) \frac{1}{\epsilon} \quad (\text{A.6})
\end{aligned}$$

$$\begin{aligned}
C1 &= \frac{1}{4n(n+1)\epsilon^3} - \frac{(2n^2-1)}{4n^2(n+1)^2\epsilon^2} \\
&- \frac{(4n^3+3n^2-n-1)}{4n^3(n+1)^3\epsilon} \quad (\text{A.7})
\end{aligned}$$

$$\begin{aligned}
C2 = C3 &= \frac{1}{12n(n+1)\epsilon^3} \\
&+ \left( \frac{S_1(n)}{6n(n+1)} - \frac{(4n^2+2n-1)}{12n^2(n+1)^2} \right) \frac{1}{\epsilon^2} \\
&+ \left( \frac{S_2(n)}{6n(n+1)} + \frac{S_1^2(n)}{6n(n+1)} - \frac{S_1(n)(4n^2+2n-1)}{6n^2(n+1)^2} \right. \\
&\quad \left. + \frac{(4n^4-5n^2-n+1)}{12n^3(n+1)^3} \right) \frac{1}{\epsilon} \quad (\text{A.8})
\end{aligned}$$

$$D1 = \frac{1}{16n(n+1)\epsilon^2} - \frac{(13n^2+9n-2)}{32n^2(n+1)^2\epsilon} \quad (\text{A.9})$$

$$\begin{aligned}
D2 &= \frac{1}{16n(n+1)\epsilon^2} \\
&+ \left( \frac{S_1(n)}{8n(n+1)} - \frac{(3n+2)(3n+1)}{32n^2(n+1)^2} \right) \frac{1}{\epsilon} \quad (\text{A.10})
\end{aligned}$$

$$D3 = -\frac{1}{8n^2(n+1)^2\epsilon^2} - \frac{(n^2-n-1)}{4n^3(n+1)^3\epsilon} \quad (\text{A.11})$$
