THE TOP QUARK

Revised April 2000 by M. Mangano (CERN) and T. Trippe (LBNL).

A. Introduction: The top quark is the $Q = 2/3$, $T_3 = +1/2$ member of the weak-isospin doublet containing the bottom quark (see our review on the "Standard Model of Electroweak Interactions" for more information). This note summarizes its currently measured properties, and provides a discussion of the experimental and theoretical issues involved in the determination of its parameters (mass, production cross section, decay branching ratios, *etc.*); it also comments on prospects for future improvements.

B. Top quark production at the Tevatron: All direct measurements of top quark production and decay have been made by the CDF and DØ experiments at the Fermilab Tevatron collider in $p\overline{p}$ collisions at $\sqrt{s} = 1.8$ TeV. Here top quarks are produced dominantly in pairs from the QCD processes $q\overline{q} \rightarrow t\overline{t}$ and $gg \rightarrow t\overline{t}$. At this energy, the production cross section in these channels is expected to be approximately 5 pb for $m_t = 175$ GeV/c^2, with a 90% contribution from $q\overline{q}$ annihilation. Smaller contributions are expected from electroweak single-top production mechanisms, namely $q\overline{q}' \rightarrow W^* \rightarrow t\overline{b}$ and $qg \rightarrow q't\overline{b}$, the latter mediated by virtual-W exchange ("W-gluon fusion"). The combined rate from these processes is approximately 2.5 pb at $m_t = 175$ GeV/c^2 (see Ref. 1 and references therein). The expected contribution of these channels is further reduced relative to the dominant pair-production mechanisms because of larger backgrounds and poor detection efficiency.

With a mass above the Wb threshold, the decay width of the top quark is expected to be dominated by the two-body channel $t \to Wb$. Neglecting terms of order m_b^2/m_t^2, α_s^2 and those of order $(\alpha_s/\pi)m_W^2/m_t^2$, this is predicted in the Standard Model to be [2]:

$$\Gamma_t = \frac{G_F m_t^3}{8\pi\sqrt{2}}\left(1-\frac{M_W^2}{m_t^2}\right)^2\left(1+2\frac{M_W^2}{m_t^2}\right)\left[1-\frac{2\alpha_s}{3\pi}\left(\frac{2\pi^2}{3}-\frac{5}{2}\right)\right]. \quad (1)$$

The use of G_F in this equation accounts for the largest part of the one-loop electroweak radiative corrections, providing an expression accurate to better than 2%. The width increases with mass, going for example from 1.02 GeV/c^2 at m_t = 160 GeV/c^2 to 1.56 GeV/c^2 at m_t = 180 GeV/c^2 (we used $\alpha_S(\mathrm{M_Z}) = 0.118$). With such a correspondingly short lifetime, the top quark is expected to decay before top-flavored hadrons or $t\bar{t}$-quarkonium bound states can form [3]. Recently, the order α_s^2 QCD corrections to Γ_t have also been calculated [4], thereby improving the overall theoretical accuracy to better than 1%.

In top decay, the Ws and Wd final states are expected to be suppressed relative to Wb by the square of the CKM matrix elements V_{ts} and V_{td}, whose values can be estimated under the assumption of unitarity of the three-generation CKM matrix to be less than 0.043 and 0.014, respectively (see our review "The Cabibbo-Kobayashi-Maskawa Mixing Matrix" in the current edition for more information). Typical final states for the leading pair-production process therefore belong to three classes:

A. $t\bar{t} \to W\,b\,W\,\bar{b} \to q\,\bar{q}'\,b\,q''\,\bar{q}'''\,\bar{b}$,

B. $t\bar{t} \to W\,b\,W\,\bar{b} \to q\,\bar{q}'\,b\,\ell\,\bar{\nu}_\ell\,\bar{b} + \bar{\ell}\,\nu_\ell\,b\,q\,\bar{q}'\,\bar{b}$,

C. $t\bar{t} \to W\,b\,W\,\bar{b} \to \bar{\ell}\,\nu_\ell\,b\,\ell'\,\bar{\nu}_{\ell'}\,\bar{b}$,

where A, B, and C are referred to as the all-jets, lepton + jets, and dilepton channels, respectively.

The final state quarks can emit radiation and eventually evolve into jets of hadrons. The precise number of jets reconstructed by the detectors varies event by event, as it depends on the decay kinematics, as well as on the precise definition of jet used in the analysis. (Additional gluon radiation can also be emitted from the initial states.) The transverse momenta of the neutrinos are reconstructed via the large imbalance in detected transverse momentum of the event (missing E_T).

The observation of $t\bar{t}$ pairs has been reported in all of the above decay modes. As discussed below, the production and decay properties of the top quark extracted from the above three decay channels are all consistent with each other within experimental uncertainty. In particular, the $t \to Wb$ decay mode is supported through the reconstruction of the $W \to jj$ invariant mass in the $\ell\bar{\nu}_\ell b\bar{b}jj$ final state [5].

The extraction of top-quark properties from Tevatron data requires a good understanding of the production and decay mechanisms of the top, as well as of the large background processes. Because only leading order QCD calculations are available for most of the relevant processes (W+3 and 4 jets, or WW+2 jets), theoretical estimates of the backgrounds have large uncertainties. While this limitation affects estimates of the overall $t\bar{t}$ production rates, it is believed that the LO determination of the event kinematics and of the fraction of W + multi-jet events containing b quarks is relatively accurate. In particular, for the background one expects the E_T spectrum of jets to fall rather steeply, the jet direction to peak at small angles to the beams, and the fraction of events with b quarks to be of the order of a few percent. On the contrary, for the top signal, the b fraction is $\sim$ 100% and the jets are rather energetic, since they come from the decay of a massive object. It is therefore possible to improve the S/B ratio either by requiring the presence of a b quark, or by selecting very energetic and central kinematic configurations.

A detailed study of control samples with features similar to those of the relevant backgrounds, but free from possible top contamination, is required to provide a reliable check on background estimates.

C. Measured top properties: Current measurements of top properties are based on the full Run I integrated luminosity of 109 pb^{-1} for CDF and 125 pb^{-1} for DØ. DØ and CDF determine the $t\bar{t}$ cross section $\sigma_{t\bar{t}}$ from their number of observed top candidates, estimated background, $t\bar{t}$ acceptance, and integrated luminosity, assuming the Standard-Model decay $t \to Wb$ with unity branching ratio. Table 1 shows the measured cross sections from DØ and CDF along with the range of theoretical expectations, evaluated at the m_t values used by the experiments in calculating their acceptances. The DØ results have been updated in conference proceedings [7] to adjust to the current DØ value of the top mass. The CDF results have been updated in conference proceedings [16] to include improvements in their Monte Carlo determination of secondary-vertex tagging efficiency, calibration of the background estimate of the heavy-flavor fraction in inclusive W+jets events, and an updated total luminosity. This has brought the CDF cross section into better agreement with theoretical expectations. The agreement of both DØ and CDF $t\bar{t}$ cross sections with theory supports the hypothesis that the excess of events over background in all of these channels can be attributed to $t\bar{t}$ production.

More precise measurements of the top production cross section will test current understanding of the production mechanisms [9–12]. This is important for the extrapolation to higher energies of colliders such as the LHC, where the larger expected cross section will permit more extensive studies [17]. Discrepancies in rate between theory and data, even at the Tevatron, would be quite exciting, and might indicate the presence of exotic production or decay channels, as predicted in certain models. Such new sources of top would lead to a modification of kinematic distributions such as the invariant mass of the top pair or the transverse momentum of the top quark. Studies by CDF of the former [18] and of the latter [19] distributions, show no deviation from expected QCD behavior. DØ [20] also finds these kinematic distributions consistent with Standard Model expectations.

The top mass has been measured in the lepton + jets and dilepton channels by both DØ and CDF, and in the

Table 1: Cross section for $t\bar{t}$ production in $p\bar{p}$ collisions at $\sqrt{s} = 1.8$ TeV from DØ ($m_t = 172.1$ GeV/c^2), CDF ($m_t = 175$ GeV/c^2), and theory.

all-jets channel by CDF. At present, the most precise measurements come from the lepton + jets channel, with four or more jets and large missing E_T. In this channel, each event is subjected to a two-constraint kinematic fit to the hypothesis $t\bar{t} \to W^+ b\, W^- \bar{b} \to \ell\, \nu_\ell\, q\, \bar{q}'\, b\, \bar{b}$, assuming that the four highest E_T jets are the quarks from $t\bar{t}$ decay. The shape of the distribution of fitted top masses from these events is compared to templates expected from a mixture of background and signal distributions for a series of assumed top masses. This comparison yields values of the likelihood as a function of top mass, from which a best value of the top mass and its uncertainty can be obtained. The results are shown in Table 2. The systematic uncertainty (second uncertainty shown) is comparable to the statistical uncertainty, and is primarily due to uncertainties in the jet energy scale and in the Monte Carlo modeling.

Less precise determinations of the top mass come from the dilepton channel with two or more jets and large missing E_T, and from the all-jets channel. In the dilepton channel, a kinematically constrained fit is not possible because there are two missing neutrinos, so experiments must use other mass estimators than the reconstructed top mass. In principle, any quantity which is correlated with the top mass can be used as such an estimator. The DØ method uses the fact that if a value for m_t is assumed, the $t\bar{t}$ system can be reconstructed (up to a four-fold ambiguity). They compare the resulting kinematic configurations to expectations from $t\bar{t}$ production, and obtain an m_t-dependent weight curve for each event, which they histogram in five bins to obtain four shape-sensitive quantities as their multidimensional mass estimator. This method yields a significant increase in precision over one-dimensional estimators. CDF has employed a similar method, thereby reducing their previous systematic uncertainty in the $\ell\ell$ + jets channel by a factor of two. DØ and CDF obtain the top mass and uncertainty from these mass estimators using the same type of template likelihood method as for the lepton + jets channel. CDF also measures the mass in the all-jets channel using events with six or more jets, at least one of which is tagged as a b jet through the detection of a secondary vertex.

Table 2: Top mass measurements from DØ and CDF.

* PDG uses this Top Averaging Group result as its best value

As seen in Table 2, all results are in good agreement with a unique mass for the top quark, giving further support to the hypothesis that these events are due to $t\bar{t}$ production. The Top Averaging Group, a joint CDF/DØ working group, produced the combined CDF/DØ average top mass in Table 2, taking into account correlations between systematic uncertainties in different measurements. They assume that the uncertainty in jet energy scale is completely correlated within CDF and within DØ but uncorrelated between the two experiments, and that the signal model and Monte Carlo generator uncertainties are completely correlated between all measurements. The uncertainties from uranium noise and multiple interactions relate only to DØ and are assumed completely correlated between their two measurements. The uncertainty on the background model is taken to be completely correlated between the CDF and the DØ ℓ+jets measurements, and similarly for the $\ell\ell$ measurements. The Particle Data Group uses this combined top mass, $m_t = 174.3 \pm 5.1$ GeV/c^2 (statistical and systematic uncertainties combined in quadrature), as our PDG best value.

Given the experimental technique used to extract the top mass, these mass values should be taken as representing the top *pole mass* (see our review "Note on Quark Masses" in the current edition for more information).

With a smaller uncertainty on the top mass, and with improved measurements of other electroweak parameters, it will be possible to get important constraints on the value of the Higgs mass. Current global fits performed within the Standard Model and its minimal supersymmetric extension provide indications for a relatively light Higgs (see the review "H^0 Indirect Mass Limits from Electroweak Analysis" in the Particle Listings of the current edition for more information).

Other properties of top decays are being studied. CDF reports a direct measurement of the $t \to Wb$ branching ratio [25]. Their preliminary result, obtained by comparing the number of events with 0, 1 and 2 tagged b jets and using the known b-tagging efficiency, is: $R = \mathrm{B}(t \to Wb)/\sum_{q=d,s,b}\mathrm{B}(t \to Wq) = 0.99 \pm 0.29$ where statistical and systematic uncertainties are included, or as a lower limit, $R > 0.58$ at 95% CL. Assuming that non-W decays of top can be neglected, that only three generations of fermions exist, and that the CKM matrix is unitary, they extract a CKM matrix-element $|V_{tb}| = 0.99 \pm 0.15$ or $|V_{tb}| > 0.76$ at 95% CL. A more direct measurement of the Wtb coupling constant will be possible when enough data are accumulated to detect the less frequent single-top production processes, such as $q\overline{q}' \to W^* \to t\overline{b}$ (a.k.a. s-channel W exchange) and $qb \to q't$ via W exchange (a.k.a. Wg fusion). The cross sections for these processes are proportional to $|V_{tb}|^2$, and there is no assumption needed on the number of families or the unitarity of the CKM matrix in the extraction of $|V_{tb}|$. Preliminary CDF results [19] give 95% CL limits of 15.8 and 15.4 pb for the single-top production rates in the s-channel and Wg-fusion channels, respectively. Comparison with the expected Standard Model rates of 0.73 ± 0.10 pb and 1.70 ± 0.30 pb, respectively, shows that far better statistics will be required before significant measurements can be achieved. For the prospects of these measurements at the LHC, see [17].

Both CDF and DØ have searched for non-Standard Model top decays [26,27], particularly those expected in supersymmetric models. These studies search for $t \to H^+b$, followed by $H^+ \to \tau\nu$ or $c\overline{s}$. The $t \to H^+b$ branching ratio is a minimum at $\tan\beta = \sqrt{m_t/m_b} \simeq 6$ and is large in the region of either $\tan\beta \ll 6$ or $\tan\beta \gg 6$. In the former range $H^+ \to c\overline{s}$ is the dominant decay, while $H^+ \to \tau\nu$ dominates in the latter range. These studies are based either on direct searches for these final states, or on top disappearance. In the standard lepton + jets or dilepton cross section analyses, the charged Higgs decays are not detected as efficiently as $t \to W^{\pm}b$, primarily because the selection criteria are optimized for the standard decays, and because of the absence of energetic isolated leptons in the Higgs decays. With a significant $t \to H^+b$ contribution, this would give rise to measured cross sections lower than the prediction from the Standard Model (assuming that non-Standard contributions to $t\overline{t}$ production are negligible). More details, and the results of these studies, can be found in the review "Search for Higgs bosons" and in the "H^+ Mass Limits" section of the Higgs Particle Listings of the current edition.

CDF reports a search for flavor changing neutral current (FCNC) decays of the top quark $t \to q\gamma$ and $t \to qZ$ [28], for which the Standard Model predicts such small rates that their observation here would indicate new physics. They assume that one top decays via FCNC while the other decays via Wb. For the $t \to q\gamma$ search, they examine two signatures, depending on whether the W decays leptonically or hadronically. For leptonic W decay, the signature is $\gamma\ell$ and missing E_T and two or more jets, while for hadronic W decay, it is γ plus four or more jets, one with a secondary vertex b tag. They observe one event ($\mu\gamma$) with an expected background of less than half an event, giving an upper limit on the top branching ratio of $\mathrm{B}(t \to q\gamma) < 3.2\%$ at 95% CL.

For the $t \to qZ$ FCNC search, they look for $Z \to \mu\mu$ or ee and $W \to$ hadrons, giving a Z + four jets signature. They observe one $\mu\mu$ event with an expected background of 1.2 events, giving an upper limit on the top branching ratio of $\mathrm{B}(t \to qZ) < 33\%$ at 95% CL. Both the γ and Z limits are non-background subtracted (i.e. conservative) estimates.

Indirect constraints on FCNC couplings of the top quark can be obtained from single-top production in e^+e^- collisions, via the process $e^+e^- \to \gamma, Z^* \to t\overline{q}$ and its charge-conjugate ($q = u, c$). Limits on the cross-section for this reaction have been obtained by DELPHI [29] using LEP2 data at energies between 183 and 189 GeV. When interpreted in terms of top decay branching ratios [30,17], these limits lead to a bound of $\mathrm{B}(t \to qZ) < 22\%$ at 95% CL, which is stronger than the direct CDF limit.

Studies of the decay angular distributions allow a direct analysis of the V–A nature of the Wtb coupling, and provide information on the relative coupling of longitudinal and transverse W bosons to the top quark. In the Standard Model, the fraction of decays to longitudinally polarized W bosons is expected to be $\mathcal{F}_0^{\rm SM} = x/(1+x)$, $x = m_t^2/2M_W^2$ ($\mathcal{F}_0^{\rm SM} \sim 70\%$ for $m_t = 175$ GeV/c^2). Deviations from this value would bring into question the validity of the Higgs mechanism of spontaneous symmetry breaking. CDF has recently measured $\mathcal{F}_0^{\rm SM} = 0.91 \pm 0.37_{\rm stat} \pm 0.13_{\rm syst}$ [31], in agreement with the expectations.

DØ has studied $t\overline{t}$ spin correlation [32]. Top quark pairs produced at the Tevatron are expected to be unpolarized but to have correlated spins. Since top quarks decay before hadronizing, their spins are transmitted to their decay daughters. Spin correlation is studied by analyzing the joint decay angular distribution of one t daughter and one $\overline{t}$ daughter. The sensitivity to top spin is greatest when the daughters are charged leptons or d-type quarks, in which case, the joint distribution is

$$\frac{1}{\sigma}\frac{d^2\sigma}{d(cos\theta_+)d(cos\theta_-)} = \frac{1 + \kappa cos\theta_+ cos\theta_-}{4}, \qquad (2)$$

where θ_+ and θ_- are the angles of the daughters in the top rest frames with respect to a particular quantization axis, the optimal off-diagonal basis [33]. In this basis, the Standard Model predicts maximum correlation with $\kappa = 0.88$ at the Tevatron. DØ analyzes their six dilepton events and obtains a likelihood as a function of κ which weakly favors the Standard Model ($\kappa = 0.88$) over no correlation ($\kappa = 0$) or anticorrelation ($\kappa = -1$, as would be expected for $t\overline{t}$ produced via an intermediate scalar). They quote a limit $\kappa > -0.25$ at 68% CL. With improved statistics, an observation of $t\overline{t}$ spin correlation could yield a lower limit on $|V_{tb}|$, independent of the assumption of three quark families [34].

t-Quark Mass in $p\bar{p}$ Collisions

The *t* quark has been observed. Its mass is sufficiently high that decay is expected to occur before hadronization. OUR EVALUATION is an AVERAGE which incorporates correlations between systematic errors of the five different measurements. The average was done by a joint CDF/DØ working group and is reported in DEMORTIER 99, an FNAL Technical Memo. They report 174.3 ± 3.2 ± 4.0 GeV, which yields "OUR EVALUATION" when statistical and systematic errors are combined.

For earlier search limits see the *Review of Particle Physics*, Phys. Rev. **D54**,1 (1996).

[1] Result is based on 109 ± 7 pb^{-1} of data at $\sqrt{s}$ = 1.8 TeV.
[2] Result is based on 125 ± 7 pb^{-1} of data at $\sqrt{s}$ = 1.8 TeV.
[3] The updated systematic error is listed. See ABE 99B.
[4] ABE 97R result is based on the first observation of all hadronic decays of $t\bar{t}$ pairs. Single *b*-quark tagging with jet-shape variable constraints was used to select signal enriched multi-jet events. The updated systematic error is listed. See ABE 99B.
[5] ABBOTT 99G result is obtained by combining the D0 result m_t (GeV) = 168.4 ± 12.3 ± 3.6 from 6 di-lepton events (see also ABBOTT 98D) and m_t (GeV) = 173.3 ± 5.6 ± 5.5 from lepton+jet events (ABBOTT 98F).

[6] ABE 99B result is obtained by combining the CDF results of m_t (GeV)=167.4±10.3±4.8 from 8 dilepton events, m_t (GeV)=175.9 ± 4.8 ± 5.3 from lepton+jet events (ABE 98E), and m_t (GeV)=186.0 ± 10.0 ± 5.7 from all-jet events (ABE 97R). The systematic errors in the latter two measurements are changed in this paper.

[7] BHAT 98B result is obtained by combining the DØ results of m_t(GeV)=168.4 ± 12.3 ± 3.6 from 6 dilepton events and m_t(GeV)=173.3 ± 5.6 ± 5.5 from 77 lepton+jet events.

[8] BHAT 98B result is obtained by combining the DØ results from dilepton and lepton+jet events, and the CDF results (ABE 99B) from dilepton, lepton+jet events, and all-jet events.

Indirect t-Quark Mass from Standard Model Electroweak Fit

"OUR EVALUATION" below is from the fit to electroweak data described in the "Electroweak Model and Constraints on New Physics" section of this Review. This fit result does not include direct measurements of m_t.

The RVUE values are based on the data described in the footnotes. RVUE's published before 1994 and superseded analyses are now omitted. For more complete listings of earlier results, see the 1994 edition (Physical Review **D50** 1173 (1994)).

[9] FIELD 99 result is from the two-parameter fit with free m_t and m_H, yielding also m_H= $47.2^{+29.8}_{-24.5}$ GeV. Only the lepton and charm-jet asymmetry data are used together with the direct measurement constraint m_t= 173.8 ± 5.0 GeV, and $1/\alpha(m_Z)$= 128.896.

[10] DEBOER 97B result is from the five-parameter fit which varies m_Z, m_t, m_H, α_s, and $\alpha(m_Z)$ under the contraints: m_t=175 ± 6 GeV, $1/\alpha(m_Z)$=128.896 ± 0.09. They found m_H=141^{+140}_{-77} GeV and $\alpha_s(m_Z)$=0.1197 ± 0.0031.

[11] ELLIS 96C result is a the two-parameter fit with free m_t and m_H, yielding also m_H=65^{+117}_{-37} GeV.

[12] ERLER 95 result is from fit with free m_t and $\alpha_s(m_Z)$, yielding $\alpha_s(m_Z)$ = 0.127(5)(2).

[13] MATSUMOTO 95 result is from fit with free m_t to Z parameters, M_W, and low-energy neutral-current data. The second error is for $m_H = 300^{+700}_{-240}$ GeV, the third error is for $\alpha_s(m_Z)$ = 0.116 ± 0.005, the fourth error is for $\delta\alpha_{\rm had}$ = 0.0283 ± 0.0007.

[14] ABREU 94 value is for $\alpha_s(m_Z)$ constrained to 0.123 ± 0.005. The second error corresponds to $m_H = 300^{+700}_{-240}$ GeV.

[15] ACCIARRI 94 value is for $\alpha_s(m_Z)$ constrained to 0.124 ± 0.006. The second error corresponds to $m_H = 300^{+700}_{-240}$ GeV.

[16] AKERS 94 result is from fit with free α_s. The second error corresponds to m_H=300^{+700}_{-240} GeV. The 95%CL limit is m_t <210 GeV.

[17] ARROYO 94 measures the ratio of the neutral-current and charged-current deep inelastic scattering of ν_μ on an iron target. By assuming the SM electroweak correction, they obtain $1-m_W^2/m_Z^2$ = 0.2218 ± 0.0059, yielding the quoted m_t value. The second error corresponds to $m_H = 300^{+700}_{-240}$ GeV.

[18] BUSKULIC 94 result is from fit with free α_s. The second error is from m_H=300^{+700}_{-240} GeV.

[19] ELLIS 94B result is fit to electroweak data available in spring 1994, including the 1994 A_{LR} data from SLD. m_t and m_H are two free parameters of the fit for $\alpha_s(m_Z)$ = 0.118 ± 0.007 yielding m_t above, and $m_H = 35^{+70}_{-22}$ GeV. ELLIS 94B also give results for fits including constraints from CDF's direct measurement of m_t and CDF's and DØ 's production cross-section measurements. Fits excluding the A_{LR} data from SLD are also given.

[20] GURTU 94 result is from fit with free m_t and $\alpha_s(m_Z)$, yielding m_t above and $\alpha_s(m_Z)$ = 0.125 ± $0.005^{+0.003}_{-0.001}$. The second errors correspond to $m_H = 300^{+700}_{-240}$ GeV. Uses LEP, M_W, νN, and SLD electroweak data available in spring 1994.

[21] MONTAGNA 94 result is from fit with free m_t and $\alpha_s(m_Z)$, yielding m_t above and $\alpha_s(m_Z)$ = 0.124. The second errors correspond to $m_H = 300^{+700}_{-240}$ GeV. Errors in $\alpha(m_Z)$ and m_b are taken into account in the fit. Uses LEP, SLC, and M_W/M_Z data available in spring 1994.

[22] NOVIKOV 94B result is from fit with free m_t and $\alpha_s(m_Z)$, yielding m_t above and $\alpha_s(m_Z)$ = 0.125 ± 0.005 ± 0.002. The second errors correspond to $m_H = 300^{+700}_{-240}$ GeV. Uses LEP and CDF electroweak data available in spring 1994.

[23] ALITTI 92B assume m_H = 100 GeV. The 95%CL limit is m_t < 250 GeV for m_H < 1 TeV.

t DECAY MODES

	Mode			Fraction (Γ_i/Γ)	Confidence level
Γ_1	$W b$				
Γ_2	$\ell \nu_\ell$ anything		[a,b]	(9.4±2.4) %	
Γ_3	$\tau \nu_\tau b$				
Γ_4	$\gamma q(q=u,c)$		[c]	< 3.2 %	95%
	$\Delta T = 1$ weak neutral current (T1) modes				
Γ_5	$Z q(q=u,c)$	T1	[d]	< 33 %	95%

[a] ℓ means e or μ decay mode, not the sum over them.

[b] Assumes lepton universality and W-decay acceptance.

[c] This limit is for $\Gamma(t \to \gamma q)/\Gamma(t \to W b)$.

[d] This limit is for $\Gamma(t \to Z q)/\Gamma(t \to W b)$.

t BRANCHING RATIOS

$\Gamma(\ell\nu_\ell \text{anything})/\Gamma_{\rm total}$ — Γ_2/Γ

> 34	95	[10] ALBAJAR	88	UA1	CC: e or μ + jets

[1] AFFOLDER 00 looked for b' that decays in to $b+Z$. The signal searched for is $bbZZ$ events where one Z decays into e^+e^- or $\mu^+\mu^-$ and the other Z decays hadronically. The bound assumes B($b' \to bZ$)= 100%. Between 100 GeV and 199 GeV, the 95%CL upper bound on $\sigma(b' \to \bar{b}') \times B^2(b' \to bZ)$ is also given (see their Fig. 2).

[2] ABACHI 95F bound on the top-quark also applies to b' and t' quarks that decay predominantly into W. See FROGGATT 97.

[3] ABE 98N looked for $Z \to e^+e^-$ decays with displaced vertices. Quoted limit assumes B($b' \to bZ$)=1 and $c\tau_{b'}$=1 cm. The limit is lower than 96 GeV (m_Z+m_b) if $c\tau>$ 22 cm or $c\tau<$ 0.009 cm. See their Fig. 4.

[4] ABACHI 97D searched for b' that decays mainly via FCNC. They obtained 95%CL upper bounds on B($b'\bar{b}' \to \gamma+$ 3 jets) and B($b'\bar{b}' \to 2\gamma+$ 2 jets), which can be interpreted as the lower mass bound $m_{b'} > m_Z+m_b$.

[5] MUKHOPADHYAYA 93 analyze CDF dilepton data of ABE 92G in terms of a new quark decaying via flavor-changing neutral current. The above limit assumes B($b' \to b\ell^+\ell^-$)=1%. For an exotic quark decaying only via virtual Z [B($b\ell^+\ell^-$) = 3%], the limit is 85 GeV.

[6] ABE 92 dilepton analysis limit of >85 GeV at CL=95% also applies to b' quarks, as discussed in ABE 90B.

[7] ABE 90B exclude the region 28–72 GeV.

[8] AKESSON 90 searched for events having an electron with p_T > 12 GeV, missing momentum > 15 GeV, and a jet with E_T > 10 GeV, $|\eta|$ < 2.2, and excluded $m_{b'}$ between 30 and 69 GeV.

[9] For the reduction of the limit due to non-charged-current decay modes, see Fig. 19 of ALBAJAR 90B.

[10] ALBAJAR 88 study events at E_{cm} = 546 and 630 GeV with a muon or isolated electron, accompanied by one or more jets and find agreement with Monte Carlo predictions for the production of charm and bottom, without the need for a new quark. The lower mass limit is obtained by using a conservative estimate for the $b'\bar{b}'$ production cross section and by assuming that it cannot be produced in W decays. The value quoted here is revised using the full $O(\alpha_s^3)$ cross section of ALTARELLI 88.

MASS LIMITS for b' (4^{th} Generation) Quark or Hadron in e^+e^- Collisions

Search for hadrons containing a fourth-generation $-1/3$ quark denoted b'.

The last column specifies the assumption for the decay mode (CC denotes the conventional charged-current decay) and the event signature which is looked for.

>19		[28] ALTHOFF	84I	TASS	Aplanarity

[11] DECAMP 90F looked for isolated charged particles, for isolated photons, and for four-jet final states. The modes $b' \to bg$ for B($b' \to bg$) > 65% $b' \to b\gamma$ for B($b' \to b\gamma$) > 5% are excluded. Charged Higgs decay were not discussed.

[12] ADRIANI 93G search for vector quarkonium states near Z and give limit on quarkonium-Z mixing parameter δm^2 <(10–30) GeV^2 (95%CL) for the mass 88–94.5 GeV. Using Richardson potential, a 1S ($b'\bar{b}'$) state is excluded for the mass range 87.7–94.7 GeV. This range depends on the potential choice.

[13] ABREU 90D assumed $m_{H^-} < m_{b'} - 3$ GeV.

[14] Superseded by ABREU 91F.

[15] AKRAWY 90B search was restricted to data near the Z peak at E_{cm} = 91.26 GeV at LEP. The excluded region is between 23.6 and 41.4 GeV if no H^+ decays exist. For charged Higgs decays the excluded regions are between (m_{H^+} + 1.5 GeV) and 45.5 GeV.

[16] AKRAWY 90J search for isolated photons in hadronic Z decay and derive B($Z \to b'\bar{b}'$)·B($b' \to \gamma X$)/B($Z \to$ hadrons) < 2.2×10^{-3}. Mass limit assumes B($b' \to \gamma X$) > 10%.

[17] ABE 89E search at E_{cm} = 56–57 GeV at TRISTAN for multihadron events with a spherical shape (using thrust and acoplanarity) or containing isolated leptons.

[18] ABE 89G search was at E_{cm} = 55–60.8 GeV at TRISTAN.

[19] If the photonic decay mode is large (B($b' \to b\gamma$) > 25%), the ABRAMS 89C limit is 45.4 GeV. The limit for for Higgs decay ($b' \to cH^-$, $H^- \to \bar{c}s$) is 45.2 GeV.

[20] ADACHI 89C search was at E_{cm} = 56.5–60.8 GeV at TRISTAN using multi-hadron events accompanying muons.

[21] ADACHI 89C also gives limits for any mixture of CC and bg decays.

[22] ENO 89 search at E_{cm} = 50–60.8 at TRISTAN.

[23] ENO 89 considers arbitrary mixture of the charged current, bg, and $b\gamma$ decays.

[24] IGARASHI 88 searches for leptons in low-thrust events and gives $\Delta R(b')$ < 0.26 (95% CL) assuming charged current decay, which translates to $m_{b'}$ > 24.4 GeV.

[25] SAGAWA 88 set limit σ(top) < 6.1 pb at CL=95% for top-flavored hadron production from event shape analyses at E_{cm} = 52 GeV. By using the quark parton model cross-section formula near threshold, the above limit leads to lower mass bounds of 23.8 GeV for charge $-1/3$ quarks.

[26] ADEVA 86 give 95%CL upper bound on an excess of the normalized cross section, ΔR, as a function of the minimum c.m. energy (see their figure 3). Production of a pair of 1/3 charge quarks is excluded up to E_{cm} = 45.4 GeV.

[27] ALTHOFF 84C narrow state search sets limit $\Gamma(e^+e^-)$B(hadrons) <2.4 keV CL = 95% and heavy charge 1/3 quark pair production m >21 GeV, CL = 95%.

[28] ALTHOFF 84I exclude heavy quark pair production for 7 <m <19 GeV (1/3 charge) using aplanarity distributions (CL = 95%).

Free Quark Searches

FREE QUARK SEARCHES

The basis for much of the theory of particle scattering and hadron spectroscopy is the construction of the hadrons from a set of fractionally charged constituents (quarks). A central but unproven hypothesis of this theory, Quantum Chromodynamics, is that quarks cannot be observed as free particles but are confined to mesons and baryons.

Experiments show that it is at best difficult to "unglue" quarks. Accelerator searches at increasing energies have produced no evidence for free quarks, while only a few cosmic-ray and matter searches have produced uncorroborated events.

This compilation is only a guide to the literature, since the quoted experimental limits are often only indicative. Reviews can be found in Refs. 1-3.

Quark Flux — Accelerator Searches

The definition of FLUX depends on the experiment

(a) is the ratio of measured free quarks to predicted free quarks if there is no "confinement."
(b) is the probability of fractional charge on nuclear fragments. Energy is in GeV/nucleon.
(c) is the 90%CL upper limit on fractionally-charged particles produced per interaction.
(d) is quarks per collision.
(e) is inclusive quark-production cross-section ratio to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$.
(f) is quark flux per charged particle.
(g) is the flux per ν-event.
(h) is quark yield per π^- yield.
(i) is 2-body exclusive quark-production cross-section ratio to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$.

[10] HUENTRUP 96 quote 95% CL limits for production of fragments with charge differing by as much as ±1/3 (in units of e) for charge $6 \leq Z \leq 10$.

[11] BUSKULIC 93C limits for inclusive quark production are more conservative if the ALEPH hadronic fragmentation function is assumed.

[12] CECCHINI 93 limit at 90%CL for $23/3 \leq Z \leq 40/3$, for 16A GeV O, 14.5A Si, and 200A S incident on Cu target. Other limits are 2.3×10^{-4} for $17/3 \leq Z \leq 20/3$ and 1.2×10^{-4} for $20/3 \leq Z \leq 23/3$.

[13] GHOSH 92 reports measurement of spallation fragment charge based on ionization in emulsion. Out of 650 measured tracks, 2 were consistent with charge $5e/3$, and 4 with $7e/3$.

[14] Hadronic quark.

[15] Leptonic quark.

[16] HE 91 limits are for charges of the form $N\pm1/3$ from 23/3 to 38/3, and correspond to cross-section limits of 380μb (Pb) and 320μb (Cu).

[17] The limits apply to projectile fragment charges of 17, 19, 20, 22, 23 in units of $e/3$.

[18] The limits apply to projectile fragment charges of 16, 17, 19, 20, 22, 23 in units of $e/3$.

[19] Flux limits and mass range depend on charge.

[20] Bound to nuclei.

[21] Quark lifetimes $> 1 \times 10^{-8}$ s.

[22] One candidate m <0.17 GeV.

Quark Flux — Cosmic Ray Searches

Shielding values followed with an asterisk indicate altitude in km. Shielding values not followed with an asterisk indicate sea level in kg/cm^2.

[23] Distribution in celestial sphere was described as anisotropic.

[24] With telescope axis at zenith angle 40° to the south.

[25] Leptonic quarks.

[26] Lifetime $> 10^{-8}$ s; charge ±0.70, 0.68, 0.42; and mass >4.4, 4.8, and 20 GeV, respectively.

[27] Time delayed air shower search.

[28] Prompt air shower search.

[29] Also $e/4$ and $e/6$ charges.

[30] No events in subsequent experiments.

Quark Density — Matter Searches

For a review, see SMITH 89.

LIGHT UNFLAVORED MESONS
$(S = C = B = 0)$

For $I = 1$ (π, b, ρ, a): $u\overline{d}$, $(u\overline{u}-d\overline{d})/\sqrt{2}$, $d\overline{u}$;
for $I = 0$ (η, η', h, h', ω, ϕ, f, f'): $c_1(u\overline{u} + d\overline{d}) + c_2(s\overline{s})$

PSEUDOSCALAR-MESON DECAY CONSTANTS

Revised April 2000 by M. Suzuki (LBNL).

Charged mesons

The decay constant f_P for a charged pseudoscalar meson P is defined by

$$\langle 0|A_\mu(0)|P(\mathbf{q})\rangle = i f_P\, q_\mu \ , \tag{1}$$

where A_μ is the axial-vector part of the charged weak current after a Cabibbo-Kobayashi-Maskawa mixing-matrix element $V_{qq'}$ has been removed. The state vector is normalized by $\langle P(\mathbf{q})|P(\mathbf{q}')\rangle = (2\pi)^3\, 2E_q\, \delta(\mathbf{q}-\mathbf{q}')$, and its phase is chosen to make f_P real and positive. Note, however, that in many theoretical papers our $f_P/\sqrt{2}$ is denoted by f_P.

In determining f_P experimentally, radiative corrections must be taken into account. Since the photon-loop correction introduces an infrared divergence that is canceled by soft-photon emission, we can determine f_P only from the combined rate for $P^\pm \to \ell^\pm\nu_\ell$ and $P^\pm \to \ell^\pm\nu_\ell\gamma$. This rate is given by

$$\Gamma\left(P \to \ell\nu_\ell + \ell\nu_\ell\gamma\right) = \frac{G_F^2|V_{qq'}{}^2|}{8\pi} f_P^2\, m_\ell^2\, m_P \left(1-\frac{m_\ell^2}{m_P^2}\right)^2 \left[1+\mathcal{O}(\alpha)\right] \ . \tag{2}$$

Here m_ℓ and m_P are the masses of the lepton and meson. Radiative corrections include inner bremsstrahlung, which is independent of the structure of the meson [1-3], and also a structure-dependent term [4,5]. After radiative corrections are made, there are ambiguities in extracting f_P from experimental measurements. In fact, the definition of f_P is no longer unique.

It is desirable to define f_P such that it depends only on the properties of the pseudoscalar meson, not on the final decay products. The short-distance corrections to the fundamental electroweak constants like $G_F|V_{qq'}|$ should be separated out. Following Marciano and Sirlin [6], we define f_P with the following form for the $\mathcal{O}(\alpha)$ corrections:

$$1+\mathcal{O}(\alpha) = \left[1+\frac{2\alpha}{\pi}\ln\left(\frac{m_Z}{m_\rho}\right)\right]\left[1+\frac{\alpha}{\pi}F(x)\right] \times\left\{1-\frac{\alpha}{\pi}\left[\frac{3}{2}\ln\left(\frac{m_\rho}{m_P}\right)+C_1+C_2\frac{m_\ell^2}{m_\rho^2}\ln\left(\frac{m_\rho^2}{m_\ell^2}\right)+C_3\frac{m_\ell^2}{m_\rho^2}+\ldots\right]\right\} , \tag{3}$$

where m_ρ and m_Z are the masses of the ρ meson and Z boson. Here

$$F(x) = 3\ln x + \frac{13-19x^2}{8(1-x^2)} - \frac{8-5x^2}{2(1-x^2)^2}\,x^2\ln x - 2\left(\frac{1+x^2}{1-x^2}\ln x + 1\right)\ln(1-x^2) + 2\left(\frac{1+x^2}{1-x^2}\right)L(1-x^2) \ ,$$

with

$$x \equiv m_\ell/m_P \ , \qquad L(z) \equiv \int_0^z \frac{\ln(1-t)}{t}\,dt \ . \tag{4}$$

The first bracket in the expression for $1+\mathcal{O}(\alpha)$ is the short-distance electroweak correction. A quarter of $(2\alpha/\pi)\ln(m_Z/m_\rho)$ is subject to the QCD correction $(1-\alpha_s/\pi)$, which leads to a reduction of the total short-distance correction of 0.00033 from the electroweak contribution alone [6]. The second bracket together with the term $-(3\alpha/2\pi)\ln(m_\rho/m_P)$ in the third bracket corresponds to the radiative corrections to the point-like pion decay ($\Lambda_{\text{cutoff}} \approx m_\rho$) [2]. The rest of the corrections in the third bracket are expanded in powers of m_ℓ/m_ρ. The expansion coefficients C_1, C_2, and C_3 depend on the hadronic structure of the pseudoscalar meson and in most cases cannot be computed accurately. In particular, C_1 absorbs the uncertainty in the matching energy scale between short- and long-distance strong interactions and thus is the main source of uncertainty in determining f_{π^+} accurately.

With the experimental value for the decay $\pi^+ \to \mu^+\nu_\mu + \mu^+\nu_\mu\gamma$, one obtains

$$f_{\pi^+} = 130.7 \pm 0.1 \pm 0.36 \text{ MeV} \ , \tag{5}$$

where the first error comes from the experimental uncertainty on $|V_{ud}|$ and the second comes from the uncertainty on C_1 ($= 0 \pm 0.24$) [6]. Similarly, one obtains from the decay $K^+ \to \mu^+\nu_\mu + \mu^+\nu_\mu\gamma$ the decay constant

$$f_{K^+} = 159.8 \pm 1.4 \pm 0.44 \text{ MeV} \ , \tag{6}$$

where the first error is due to the uncertainty on $|V_{us}|$.

For the heavy pseudoscalar mesons, uncertainties in the experimental values for the decay rates are much larger than the radiative corrections. For the D^+, a value (as opposed to an upper limit) has been obtained for the first time:

$$f_{D^+} = 300^{+180+80}_{-150-40} \text{ MeV} \ , \tag{7}$$

but it is based on only one $D^+ \to \mu^+\nu_\mu$ event [7]. For the D_s^+, the decay constant has been obtained from both the $D_s^+ \to \mu^+\nu_\mu$ and the $D_s^+ \to \tau^+\nu_\tau$ branching fractions. There are altogether six reported values ranging from about 200 to 450 MeV, but the errors are getting smaller; the best and most recent value, from 182 $D_s^+ \to \mu^+\nu_\mu$ events, gives [8]

$$f_{D_s^+} = 280 \pm 19 \pm 28 \pm 34 \text{ MeV} \ . \tag{8}$$

(See the measurements of the $D_s^+ \to \ell^+\nu_\ell$ modes in the Particle Listings for the numbers quoted by individual experiments.)

There have been many attempts to extract f_P from spectroscopy and nonleptonic decays using theoretical models. Since it is difficult to estimate uncertainties for them, we have listed here only values of decay constants that are obtained directly from the observation of $P^\pm \to \ell^\pm\nu_\ell$.

Light neutral mesons

The decay constants for the light neutral pseudoscalar mesons π^0, η, and η' are defined by

$$\sqrt{2}\ \langle 0|A^a_\mu(0)|P(q)\rangle = i\, f^a_P\, q_\mu \qquad (9)$$

where A^a_μ is a neutral axial-vector current [9,10]. Restricting ourselves to the three light flavors, the index $a = 0, 3, 8$ refers to the usual set of Gell-Mann matrices, including the flavor singlet. In case of exact isospin symmetry (which is for most applications a very good approximation) we have only one decay constant for the π^0 meson ($f^3_{\pi^0} \equiv f_{\pi^0}$) and two decay constants each for η and η' (f^8_η, f^0_η, and $f^8_{\eta'}$, $f^0_{\eta'}$).

In the limit of $m_P \to 0$, the Adler-Bell-Jackiw anomaly [11,12] determines the matrix elements of the two-photon decay $P \to \gamma\gamma$ through the decay constants f^a_P. In the case of f_{π^0}, the extrapolation to $m_\pi \neq 0$ gives only a tiny effect, and the value of f_{π^0} can be extracted from the $\pi^0 \to \gamma\gamma$ decay width. The experimental uncertainty in the π^0 lifetime dominates in the uncertainty of f_{π^0}:

$$f_{\pi^0} = 130 \pm 5\ \text{MeV}\ . \qquad (10)$$

This value is compatible with $f_{\pi^\pm}$, as it is expected from isospin symmetry.

The four decay constants of the η-η' system cannot be extracted from the two-photon decay widths alone. Also, the extrapolation to $m_{\eta(\eta')} \neq 0$ may give a larger effect here, and therefore the dominance of the Adler-Bell-Jackiw anomaly is perhaps questionable. Thus, an assessment of the values of the η and η' decay constants requires additional theoretical and phenomenological input about flavor symmetry breaking and η-η' mixing; see Ref. 13 for a review. Most analyses find similar values for the octet decay constants: $f^8_\eta \simeq 1.2\, f_\pi$ and $f^8_{\eta'} \simeq -0.45\, f_\pi$. The situation concerning the singlet decay constants, f^0_P, is less clear.

$\pi^{\pm}$

$I^G(J^P) = 1^-(0^-)$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** (1988).

$\pi^{\pm}$ MASS

The most accurate charged pion mass measurements are based upon x-ray wavelength measurements for transitions in π^--mesonic atoms. The observed line is the blend of three components, corresponding to different K-shell occupancies. JECKELMANN 94 revisits the occupancy question, with the conclusion that two sets of occupancy ratios, resulting in two different pion masses (Solutions A and B), are equally probable. We choose the higher Solution B since only this solution is consistent with a positive mass-squared for the muon neutrino, given the precise muon momentum measurements now available (DAUM 91, ASSAMAGAN 94, and ASSAMAGAN 96) for the decay of pions at rest. Earlier mass determinations with pi-mesonic atoms may have used incorrect K-shell screening corrections.

Measurements with an error of > 0.005 MeV have been omitted from this Listing.

[1] LENZ 98 reslut does not suffer K-electron configuration uncertainties as does JECKELMANN 94.

[2] JECKELMANN 94 Solution B (dominant 2-electron K-shell occupancy), chosen for consistency with positive $m^2_{\nu_\mu}$.

[3] ASSAMAGAN 96 measures the μ^+ momentum p_μ in $\pi^+ \to \mu^+ \nu_\mu$ decay at rest to be 29.79200 ± 0.00011 MeV/c. Combined with the μ^+ mass and the assumption $m_{\nu_\mu} = 0$, this gives the π^+ mass above; if $m_{\nu_\mu} > 0$, m_{π^+} given above is a lower limit. Combined instead with m_μ and (assuming *CPT*) the π^- mass of JECKELMANN 94, p_μ gives an upper limit on m_{ν_μ} (see the ν_μ).

[4] JECKELMANN 94 Solution A (small 2-electron K-shell occupancy) in combination with either the DAUM 91 or ASSAMAGAN 94 pion decay muon momentum measurement yields a significantly negative $m^2_{\nu_\mu}$. It is accordingly not used in our fits.

[5] The DAUM 91 value includes the ABELA 84 result. The value is based on a measurement of the μ^+ momentum for π^+ decay at rest, $p_\mu = 29.79179 \pm 0.00053$ MeV, uses $m_\mu = 105.658389 \pm 0.000034$ MeV, and assumes that $m_{\nu_\mu} = 0$. The last assumption means that in fact the value is a lower limit.

[6] JECKELMANN 86B gives $m_\pi/m_e = 273.12677(71)$. We use $m_e = 0.51099906(15)$ MeV from COHEN 87. The authors note that two solutions for the probability distribution of K-shell occupancy fit equally well, and use other data to choose the lower of the two possible $\pi^\pm$ masses.

[7] These values are scaled with a new wavelength-energy conversion factor $V\lambda = 1.23984244(37) \times 10^{-6}$ eV m from COHEN 87. The LU 80 screening correction relies upon a theoretical calculation of inner-shell refilling rates.

[8] This MARUSHENKO 76 value used at the authors' request to use the accepted set of calibration γ energies. Error increased from 0.0017 MeV to include QED calculation error of 0.0017 MeV (12 ppm).

Γ_{10}	$\mu^- e^+ e^+ \nu$	*LF*		< 1.6 $\times 10^{-6}$	90%

[a] Measurements of $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$ always include decays with γ's, and measurements of $\Gamma(e^+\nu_e\gamma)$ and $\Gamma(\mu^+\nu_\mu\gamma)$ never include low-energy γ's. Therefore, since no clean separation is possible, we consider the modes with γ's to be subreactions of the modes without them, and let $[\Gamma(e^+\nu_e) + \Gamma(\mu^+\nu_\mu)]/\Gamma_{\text{total}} = 100\%$.

[b] See the Particle Listings below for the energy limits used in this measurement; low-energy γ's are not included.

[c] Derived from an analysis of neutrino-oscillation experiments.

$\pi^{\pm} \to \ell^{\pm}\nu\gamma$ AND $K^{\pm} \to \ell^{\pm}\nu\gamma$ FORM FACTORS

Written by H.S. Pruys (Zürich University).

In the radiative decays $\pi^{\pm} \to \ell^{\pm}\nu\gamma$ and $K^{\pm} \to \ell^{\pm}\nu\gamma$, where ℓ is an e or a μ and γ is a real or virtual photon (e^+e^- pair), both the vector and the axial-vector weak hadronic currents contribute to the decay amplitude. Each current gives a structure-dependent term (SD_V and SD_A) from virtual hadronic states, and the axial-vector current also gives a contribution from inner bremsstrahlung (IB) from the lepton and meson. The IB amplitudes are determined by the meson decay constants f_π and f_K [1]. The SD_V and SD_A amplitudes are parameterized in terms of the vector form factor F_V and the axial-vector form factors F_A and R [1–4]:

$$M(\mathrm{SD}_V) = \frac{-eG_F V_{qq'}}{\sqrt{2}\, m_P} \epsilon^\mu \ell^\nu F_V \epsilon_{\mu\nu\sigma\tau} k^\sigma q^\tau ,$$

$$M(\mathrm{SD}_A) = \frac{-ie\, G_F V_{qq'}}{\sqrt{2}\, m_P} \epsilon^\mu \ell^\nu \{F_A [(s-t)g_{\mu\nu} - q_\mu k_\nu] + R\, t\, g_{\mu\nu}\} . \quad (1)$$

Here $V_{qq'}$ is the Cabibbo-Kobayashi-Maskawa mixing-matrix element; ϵ^μ is the polarization vector of the photon (or the effective vertex, $\epsilon^\mu = (e/t)\overline{u}(p_-)\gamma^\mu v(p_+)$, of the e^+e^- pair); $\ell^\nu = \overline{u}(p_\nu)\gamma^\nu(1-\gamma_5)v(p_\ell)$ is the lepton-neutrino current; q and k are the meson and photon four-momenta, with $s = q \cdot k$ and $t = k^2 (= (p_+ + p_-)^2)$; and P stands for π or K. In the analysis of data, the s and t dependence of the form factors is neglected, which is a good approximation for pions [2] but not for kaons [4]. The pion vector form factor F_V^π is related via CVC to the π^0 lifetime, $|F_V^\pi| = (1/\alpha)\sqrt{2\Gamma_{\pi^0}/\pi m_{\pi^0}}$ [1]. PCAC relates R to the electromagnetic radius of the meson [2,4], $R^P = \frac{1}{3} m_P f_P \langle r_P^2 \rangle$. The calculation of the other form factors, F_A^π, F_V^K, and F_A^K, is model dependent [1,4].

When the photon is real, the partial decay rate can be given analytically [1,5]:

$$\frac{d^2\Gamma_{P\to\ell\nu\gamma}}{dxdy} = \frac{d^2(\Gamma_{\mathrm{IB}} + \Gamma_{\mathrm{SD}} + \Gamma_{\mathrm{INT}})}{dxdy} , \quad (2)$$

where $\Gamma_{\mathrm{IB}}, \Gamma_{\mathrm{SD}}$, and Γ_{INT} are the contributions from inner bremsstrahlung, structure-dependent radiation, and their interference, and the Γ_{SD} term is given by

$$\frac{d^2\Gamma_{\mathrm{SD}}}{dxdy} = \frac{\alpha}{8\pi}\Gamma_{P\to\ell\nu} \frac{1}{r(1-r)^2}\left(\frac{m_P}{f_P}\right)^2 \times \left[(F_V+F_A)^2\, \mathrm{SD}^+ + (F_V-F_A)^2\, \mathrm{SD}^-\right] . \quad (3)$$

Here

$$\mathrm{SD}^+ = (x+y-1-r)\left[(x+y-1)(1-x) - r\right] ,$$
$$\mathrm{SD}^- = (1-y+r)\left[(1-x)(1-y) + r\right] , \quad (4)$$

where $x = 2E_\gamma/m_P$, $y = 2E_\ell/m_P$, and $r = (m_\ell/m_P)^2$.

In $\pi^{\pm} \to e^{\pm}\nu\gamma$ and $K^{\pm} \to e^{\pm}\nu\gamma$ decays, the interference terms are small, and thus only the absolute values $|F_A + F_V|$ and $|F_A - F_V|$ can be obtained. In $K^{\pm} \to \mu^{\pm}\nu\gamma$ decay, the interference term is important, and thus the signs of F_V and F_A can be obtained. In $\pi^{\pm} \to \mu^{\pm}\nu\gamma$ decay, bremsstrahlung completely dominates. In $\pi^{\pm} \to e^{\pm}\nu e^+e^-$ and $K^{\pm} \to \ell^{\pm}\nu e^+e^-$ decays, all three form factors, F_V, F_A, and R, can be determined.

We give the $\pi^{\pm}$ form factors F_V, F_A, and R in the Listings below. In the $K^{\pm}$ Listings, we give the sum $F_A + F_V$ and difference $F_A - F_V$.

The electroweak decays of the pseudoscalar mesons are investigated to learn something about the unknown hadronic structure of these mesons, assuming a standard $V-A$ structure of the weak leptonic current. The experiments are quite difficult, and it is not meaningful to analyse the results using parameters for both the hadronic structure (decay constants, form factors) and the leptonic weak current (*e.g.*, to add pseudoscalar or tensor couplings to the $V-A$ coupling). Deviations from the $V-A$ interactions are much better studied in purely leptonic systems such as muon decay.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 =$ 1.9 for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\left<\delta x_i \delta x_j\right>/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

π^0 ELECTROMAGNETIC FORM FACTOR

The amplitude for the process $\pi^0 \to e^+e^-\gamma$ contains a form factor F(x) at the $\pi^0\gamma\gamma$ vertex, where $x = [m_{e^+e^-}/m_{\pi^0}]^2$. The parameter a in the linear expansion F(x) = 1 + ax is listed below.

All the measurements except that of BEHREND 91 are in the time-like region of momentum transfer.

LINEAR COEFFICIENT OF π^0 ELECTROMAGNETIC FORM FACTOR

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT

−0.24 ±0.16	3071	SAMIOS	61	HBC	No radiation corr.

[15] BEHREND 91 estimates that their systematic error is of the same order of magnitude as their statistical error, and so we have included a systematic error of this magnitude. The value of a is obtained by extrapolation from the region of large space-like momentum transfer assuming vector dominance.

[16] TUPPER 83 is a theoretical analysis of FISCHER 78 including 2-photon exchange in the corrections.

[17] The FISCHER 78 error is statistical only. The result without radiation corrections is +0.05 ± 0.03.

[a] See the "Note on the Decay Width $\Gamma(\eta \to \gamma\gamma)$" in our 1994 edition, Phys. Rev. **D50**, 1 August 1994, Part I, p. 1451.

[b] C parity forbids this to occur as a single-photon process.

CONSTRAINED FIT INFORMATION

An overall fit to a decay rate and 16 branching ratios uses 42 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 32.8$ for 34 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

0.56 ±0.16	56	WEINSTEIN	83	CBAL	$e^+e^- \to e^+e^-\eta$
1.00 ±0.22		[1] BEMPORAD	67	CNTR	Primakoff effect

[1] BEMPORAD 67 gives $\Gamma(2\gamma) = 1.21 \pm 0.26$ keV assuming $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.314$. Bemporad private communication gives $\Gamma(2\gamma)^2/\Gamma(\text{total}) = 0.380 \pm 0.083$. We evaluate this using $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.38 \pm 0.01$. Not included in average because the uncertainty resulting from the separation of the coulomb and nuclear amplitudes has apparently been underestimated.

[1] Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
[2] Average and spread of 4 variants ("up" and "down") of KAMINSKI 97B 3-channel model.
[3] Uses data from BEIER 72B, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91B. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
[4] Demonstrates explicitly that $f_0(400\text{–}1200)$ and $f_0(1370)$ are two different poles.
[5] Coupled channel analysis of $\overline{p}p \to 3\pi^0$, $\pi^0\eta\eta$ and $\pi^0\pi^0\eta$ on sheet II.
[6] Coupled channel analysis of $\overline{p}p \to 3\pi^0$, $\pi^0\eta\eta$ and $\pi^0\pi^0\eta$ on sheet III.
[7] Analysis of data from FALVARD 88.
[8] Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.
[9] Analysis of data from OCHS 73, GRAYER 74, and ROSSELET 77.
[10] Analysis of data from OCHS 73, GRAYER 74, BECKER 79, and CASON 83.
[11] Uses data from PROTOPOPESCU 73, HYAMS 73, HYAMS 75, GRAYER 74, ESTABROOKS 74, ESTABROOKS 75, FROGGATT 77, CORDEN 79, BISWAS 81.
[12] Analysis of data from APEL 73, GRAYER 74, CASON 76, PAWLICKI 77. Includes spread and errors of 4 solutions.
[13] Analysis of data from BATON 70, BENSINGER 71, COLTON 71, BAILLON 72, PROTOPOPESCU 73, and WALKER 67.

$\rho(770)$

$I^G(J^{PC}) = 1^+(1^{--})$

THE $\rho(770)$

Updated March 2000 by S. Eidelman (Novosibirsk).

Determination of the parameters of the $\rho(770)$ is beset with many difficulties because of its large width. In physical region fits, the line shape does not correspond to a relativistic Breit-Wigner function with a P-wave width, but requires some additional shape parameter. This dependence on parameterization was demonstrated long ago by PISUT 68. Bose-Einstein correlations are another source of shifts in the $\rho(770)$ line shape, particularly in multiparticle final state systems (LAFFERTY 93).

The same model dependence afflicts any other source of resonance parameters, such as the energy dependence of the phase shift δ_1^1, or the pole position. It is, therefore, not surprising that a study of $\rho(770)$ dominance in the decays of the η and η' reveals the need for specific dynamical effects, in addition to the $\rho(770)$ pole (BENAYOUN 93, ABELE 97B). Recently, BENAYOUN 98 compared the predictions of different Vector Meson Dominance (VMD)-based models with the data on the $e^+e^- \to \pi^+\pi^-$ cross section below 1 GeV, as well as with the phase and near-threshold behavior of the time-like pion form factor. They showed that only the model based on hidden local symmetry (HLS) is able to account consistently for all low-energy information, if one also requires a point-like coupling $\gamma\pi^+\pi^-$, which is excluded by common VMD but predicted by HLS.

The cleanest determination of the $\rho(770)$ mass and width comes from the e^+e^- annihilation and τ-lepton decays. BARATE 97M showed that the charged $\rho(770)$ parameters measured from τ-lepton decays are consistent with those of the neutral one determined from e^+e^- data of BARKOV 85. This conclusion is qualitatively supported by the high statistics study of ANDERSON 00. However, model-independent comparison of the two-pion mass spectrum in τ decays and the $e^+e^- \to \pi^+\pi^-$ cross section gives indications of discrepancies between the overall normalization: τ data are about 3% higher than e^+e^- data (ANDERSON 99, EIDELMAN 99). This effect is too big to be explained by isospin violation (ALEMANY 98).

$\rho(770)$ MASS

We no longer list S-wave Breit-Wigner fits, or data with high combinatorial background.

$\rho(770)$ RANGE PARAMETER

The range parameter R enters an energy-dependent correction to the width, of the form $(1 + q_r^2\ R^2)\ /\ (1 + q^2\ R^2)$, where q is the momentum of one of the pions in the $\pi\pi$ rest system. At resonance, $q = q_r$.

	$\rho(770)^0$ decays		
Γ_6	$\pi^+\pi^-$	~ 100 %	
Γ_7	$\pi^+\pi^-\gamma$	(9.9 ±1.6) × 10^{-3}	
Γ_8	$\pi^0\gamma$	(6.8 ±1.7) × 10^{-4}	
Γ_9	$\eta\gamma$	(2.4 $^{+0.8}_{-0.9}$) × 10^{-4}	S=1.6
Γ_{10}	$\mu^+\mu^-$	[a] (4.60±0.28) × 10^{-5}	
Γ_{11}	e^+e^-	[a] (4.49±0.22) × 10^{-5}	
Γ_{12}	$\pi^+\pi^-\pi^0$	< 1.2 × 10^{-4}	CL=90%
Γ_{13}	$\pi^+\pi^-\pi^+\pi^-$	(1.8 ±0.9) × 10^{-5}	
Γ_{14}	$\pi^+\pi^-\pi^0\pi^0$	< 4 × 10^{-5}	CL=90%

[a] The e^+e^- branching fraction is from $e^+e^- \to \pi^+\pi^-$ experiments only. The $\omega\rho$ interference is then due to $\omega\rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \to \mu^+\mu^-) = \Gamma(\rho^0 \to e^+e^-) \times 0.99785$.

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 10 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 10.7$ for 8 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i \delta p_j\rangle/(\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Γ	15	−15
	x_2	x_3

	Mode	Rate (MeV)	Scale factor
Γ_2	$\pi^\pm\pi^0$	150.2 ±2.4	
Γ_3	$\pi^\pm\gamma$	0.068±0.007	2.3

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and a branching ratio uses 10 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 9.9$ for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i \delta p_j\rangle/(\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 20 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 =$ 10.3 for 17 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i\delta x_j\rangle/(\delta x_i\cdot\delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[a] *C* parity forbids this to occur as a single-photon process.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, 2 combinations of partial widths obtained from integrated cross section, and 16 branching ratios uses 48 measurements and one constraint to determine 7 parameters. The overall fit has a $\chi^2 = 35.6$ for 42 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i\delta p_j\rangle/(\delta p_i\cdot\delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[1] Assuming $\Gamma(f_0)$= 40 MeV.
[2] From a narrow pole fit taking into account $f_0(980)$ and $f_0(1200)$ intermediate mechanisms.
[3] From the combined fit of the photon spectra in the reactions $e^+e^- \to \pi^+\pi^-\gamma$, $\pi^0\pi^0\gamma$.
[4] Supersedes BARBERIS 99 and BARBERIS 99B
[5] T-matrix pole.
[6] In the "narrow resonance" approximation.
[7] Using the "broad resonance" formulae of ACHASOV 97C.
[8] From invariant mass fit.
[9] On sheet II in a 2 pole solution. The other pole is found on sheet III at (1039–93i) MeV.
[10] On sheet II in a 2 pole solution. The other pole is found on sheet III at (963-29i) MeV.
[11] Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
[12] At high $|t|$.
[13] At low $|t|$.
[14] On sheet II in a 4-pole solution, the other poles are found on sheet III at (953–55i) MeV and on sheet IV at (938–35i) MeV.
[15] Combined fit of ALDE 95B, ANISOVICH 94, AMSLER 94D.
[16] On sheet II in a 2 pole solution. The other pole is found on sheet III at (996–103i) MeV.
[17] From sheet II pole position.
[18] On sheet II in a 2 pole solution. The other pole is found on sheet III at (797–185i) MeV and can be interpreted as a shadow pole.
[19] On sheet II in a 2 pole solution. The other pole is found on sheet III at (978–28i) MeV.
[20] From coupled channel analysis.
[21] Coupled channel analysis with finite width corrections.
[22] Included in AGUILAR-BENITEZ 78 fit.

$f_0(980)$ WIDTH

Width determination very model dependent. Peak width in $\pi\pi$ is about 50 MeV, but decay width can be much larger.

CONSTRAINED FIT INFORMATION

An overall fit to 15 branching ratios uses 42 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 38.2$ for 35 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i \delta x_j\rangle/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

<3	90	AKHMETSHIN 98	CMD2	$e^+e^- \to \pi^+\pi^-\gamma\gamma$

[16] Using $\Gamma_{e^+e^-}$ = 1.32 ± 0.04 keV.
[17] Using $B(\phi \to e^+e^-)=(2.99 \pm 0.08) \times 10^{-4}$.
[18] Using $\Gamma(\phi)$= 4.1 Mev. If interference between the $\rho\pi$ and 3π modes is neglected, the fraction of the $\rho\pi$ is more than 80% at the 90% confidence level.
[19] Neglecting interference between resonance and continuum.
[20] Recalculated by us using $B(\phi \to e^+e^-)= (2.99 \pm 0.08) \times 10^{-4}$.
[21] Using $B(\phi \to e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ and $B(\eta \to 3\pi^0)= (32.2 \pm 0.4) \times 10^{-2}$.
[22] From $\pi^+\pi^-\pi^0$ decay mode of η.
[23] From 2γ decay mode of η.
[24] From $3\pi^0$ decay mode of η.
[25] From the $\eta \to 2\gamma$ decay and using $B(\phi \to e^+e^-) =(2.99 \pm 0.08) \times 10^{-4}$.
[26] Using various decay modes of the η from ACHASOV 98F, ACHASOV 00, and ACHASOV 00B and $B(\phi \to e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.
[27] From the $\eta \to \pi^+\pi^-\pi^0$ decay and $B(\phi \to e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.
[28] From $\pi^+\pi^-\pi^0$ decay mode of η and using $B(\phi \to e^+e^-)= (2.99 \pm 0.08) \times 10^{-4}$.
[29] Reanalysis of DRUZHININ 84, DOLINSKY 89, and DOLINSKY 91 taking into account a triangle anomaly contribution.
[30] For $E_\gamma > 20$ MeV and assuming that $B(\phi(1020) \to f_0(980)\gamma)$ is neglibible. Supersedes AKHMETSHIN 97C.
[31] For $E_\gamma > 20$ MeV and assuming that $B(\phi(1020) \to f_0(980)\gamma)$ is negligible.
[32] Supersedes AKHMETSHIN 97C.
[33] Using total width 4.2 MeV. They detect 3π mode and observe significant interference with ω tail. This is accounted for in the result quoted above.
[34] From the $\pi^0 \to 2\gamma$ decay and using $B(\phi \to e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.
[35] Using the value $B(\eta' \to \eta\pi^+\pi^-)= (43.7 \pm 1.5) \times 10^{-2}$ and $B(\eta \to \gamma\gamma)= (39.25 \pm 0.31) \times 10^{-2}$.
[36] Using the value $B(\phi \to \eta\gamma) = (1.26 \pm 0.06) \times 10^{-2}$.
[37] From the combined fit of the photon spectra in the reactions $e^+e^- \to \pi^+\pi^-\gamma$, $\pi^0\pi^0\gamma$.
[38] Assuming that the $\pi^0\pi^0\gamma$ final state is completely determined by the $f_0\gamma$ mechanism, neglecting the decay $B(\phi \to K\overline{K}\gamma)$ and using $B(f_0 \to \pi^+\pi^-)= 2B(f_0 \to \pi^0\pi^0)$.
[39] For $E_\gamma > 20$ MeV. Supersedes AKHMETSHIN 97C.
[40] Neglecting other intermediate mechanisms ($\rho\pi$, $\sigma\gamma$).
[41] A narrow pole fit taking into account $f_0(980)$ and $f_0(1200)$ intermediate mechanisms.
[42] For destructive interference with the Bremsstrahlung process
[43] For constructive interference with the Bremsstrahlung process
[44] Superseded by AKHMETSHIN 00B.
[45] For E_γ > 20 MeV.

$\pi^+\pi^-\pi^0$ / $\rho\pi$ AMPLITUDE RATIO a_1 IN DECAY OF $\phi \to \pi^+\pi^-\pi^0$

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
$-0.16 < a_1 < 0.11$	90	[46] AKHMETSHIN 98	CMD2	$e^+e^- \to \pi^+\pi^-\gamma\gamma$

[46] Dalitz plot analysis of 9735 events taking into account interference between the contact and $\rho\pi$ terms and assuming zero phase for the contact term.

$a_1(1260)$

$I^G(J^{PC}) = 1^-(1^{++})$

THE $a_1(1260)$

Updated March 2000 by S. Eidelman (Novosibirsk).

The main experimental data on the $a_1(1260)$ may be grouped into two classes:

(1) Hadronic Production: This comprises diffractive production with incident π^- (DAUM 80, 81B) and charge-exchange production with low-energy π^- (DANKOWYCH 81, ANDO 92). The 1980's experiments explain the $I^G LJ^P = 1^+ S0^+$ data using a phenomenological amplitude consisting of a rescattered Deck amplitude, plus a direct resonance-production term. They agree on a mass of about 1270 MeV and a width of 300–380 MeV. ANDO 92 finds rather lower values for the mass (1121 MeV) and width (239 MeV), in a partial-wave analysis based on the isobar model of the $\pi^+\pi^-\pi^0$ system. However, in this analysis, only Breit-Wigner terms were considered. Recently, BARBERIS 98B studied central production of the $\pi^+\pi^-\pi^0$ system, and observed the $a_1(1260)$ meson with a mass of 1240 MeV and a width of about 400 MeV.

(2) τ Decay: Various experiments reported good data on $\tau \rightarrow a_1(1260)\nu_\tau \rightarrow \rho\pi\nu_\tau$ (RUCKSTUHL 86, SCHMIDKE 86, ALBRECHT 86B, BAND 87, ACKERSTAFF 97R, ABREU 98G, and ASNER 00). They are somewhat inconsistent concerning the $a_1(1260)$ mass, which can, however, be attributed to model-dependent systematic uncertainties (BOWLER 86, ALBRECHT 93C, ACKERSTAFF 97R). They all find a width greater than 400 MeV.

The discrepancies between the hadronic and τ decay results have stimulated several reanalyses. BASDEVANT 77, 78 used the early diffractive dissociation and τ-decay data, and showed that they could be well reproduced with an a_1 resonance mass of 1180 ± 50 MeV and width of 400 ± 50 MeV. Later, BOWLER 86, TORNQVIST 87, ISGUR 89, and IVANOV 91 have studied the process $\tau \rightarrow 3\pi\nu_\tau$. Despite quite different approaches, they all found a good overall description of the τ-decay data with an $a_1(1260)$ mass near 1230 MeV, consistent with the hadronic data. However, their widths remain significantly larger (400–600 MeV) than those extracted from diffractive-hadronic data. This is also the case with the later OPAL experiment (ACKERSTAFF 97R). In the high statistics analysis of ACKERSTAFF 97R, the models of ISGUR 89 and KUHN 90 are used to fit distributions of the 3π invariant mass, as well as the 2π invariant mass projections of the Dalitz plot. Neither model is found to provide a completely satisfactory description of the data. Another recent high statistics analysis of ABREU 98G obtains a good description of the $\tau \rightarrow 3\pi$ data using the model of FEINDT 90, which includes the a_1' meson, a radial excitation of the $a_1(1260)$ meson, with a mass of 1700 MeV and a width of 300 MeV. A similar signal has been observed by AMELIN 95B in the D and S waves of the $\rho\pi$ state, as well as by GOUZ 92 in the $f_1(1285)\pi$ state. The existence of such a resonance is also suggested by the very big data sample of ASNER 00, which shows an excess of events at high 3π mass. Their data are better described by the a_1' contribution, though at a level below that reported by ABREU 98G. Since the statistical significance of the a_1' contribution is 2–3σ only, they conclude that more data is needed to establish the existence of the a_1'.

ASNER 00 has also performed an analysis of the substructures in the Dalitz plot, and found significant contributions of the a_1 decay to $\sigma\pi$, $f_0(1370)\pi$, and $f_2(1270)\pi$. The contribution of the $a_1 \rightarrow \sigma\pi$ at a similar level has independently been observed in $e^+e^- \rightarrow 4\pi$ annihilation (AKHMETSHIN 99E), where the $2\pi^+2\pi^-$ final state was shown to be dominated by the $a_1(1260)\pi$ mechanism. Note that the existence of isoscalar contributions to the two-pion state, in addition to the isovector one ($\rho\pi$), will influence the ratio $B(a_1^- \rightarrow \pi^-\pi^+\pi^-)/B(a_1^- \rightarrow \pi^-\pi^0\pi^0)$, which should be equal to 1 for the pure $\rho\pi$ state.

BOWLER 88 showed that good fits to both the hadronic and the τ-decay data could be obtained with a width of about

400 MeV. However, applying the same type of analysis to the ANDO 92 data, the low mass and narrow width they obtained with the Breit-Wigner PWA do not change appreciably.

CONDO 93 found no evidence for charge-exchange photoproduction of the $a_1(1260)$ (but found a clear signal of $a_2(1320)$ photoproduction). They show that it is consistent with either an extremely large $a_1(1260)$ hadronic width, or with a small radiative width to $\pi\gamma$, which could be accommodated if the a_1 mass is somewhat below 1260 MeV.

0.003±0.003		[33] LONGACRE	82	RVUE	

[33] Uses multichannel Aitchison-Bowler model (BOWLER 75). Uses data from GAVILLET 77, DAUM 80, and DANKOWYCH 81.
[34] From a fit to the Dalitz plot.
[35] Assuming for $\rho(1450)$ mass and width of 1370 and 386 MeV respectively.
[36] Assuming for σ mass and width of 860 and 880 MeV respectively.
[37] Assuming for $f_0(1370)$ mass and width of 1186 and 350 MeV respectively.
[38] Assuming for $f_2(1270)$ mass and width of 1275 and 185 MeV respectively.
[39] From a fit to the 3π mass spectrum including the $K\overline{K}^*(892)$ threshold.
[40] Assuming for $\pi(1300)$ mass and width of 1300 and 400 MeV respectively. From a fit to the Dalitz plot.
[41] Assuming $\pi(1300) \to \rho\pi$ decay.
[42] Assuming $\pi(1300) \to \sigma\pi$ decay.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 4 partial widths, a combination of partial widths obtained from integrated cross sections, and 6 branching ratios uses 41 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 73.5$ for 34 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i \delta p_j\rangle/(\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\Gamma(\gamma\gamma)$ — Γ_7

The value of this width depends on the theoretical model used. Unitarised models with scalars give values clustering around ≃ 2.6 keV; without an *S*-wave contribution, values are systematically higher (typically around 3 keV).

<1.7	90	VOROBYEV	88 ND	$e^+e^- \to \pi^0\pi^0$

[18] From a partial-wave analysis of data using a K-matrix formalism with 5 poles.
[19] Using a unitarized model with a 300 - 500 keV wide scalar at 1100 MeV.
[20] Using the unitarized model of LYTH 85.
[21] Error includes spread of different solutions. Data of MARK2 and CRYSTAL BALL used in the analysis. Authors report strong correlations with $\gamma\gamma$ width of $f_0(1370)$: $\Gamma(f_2)$ + 1/4 $\Gamma(f^0)$ = 3.6 ± 0.3 KeV.
[22] Radiative corrections modify the partial widths; for instance the COURAU 84 value becomes 2.66 ± 0.21 in the calculation of LANDRO 86.
[23] Using the MENNESSIER 83 model.
[24] Superseded by BOYER 90.
[25] If helicity = 2 assumption is not made.
[26] Using mass, width and B($f_2(1270) \to 2\pi$) from PDG 78.

$f_2(1270)$ $\Gamma(i)\Gamma(\gamma\gamma)/\Gamma(\text{total})$

$\Gamma(K\overline{K}) \times \Gamma(\gamma\gamma)/\Gamma_{total}$ — $\Gamma_3\Gamma_7/\Gamma$

VALUE (keV)	DOCUMENT ID	TECN	COMMENT

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 =$ 24.7 for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_7	−17			
x_8	−8	−95		
x_9	46	−9	−4	
x_{11}	−36	−4	−2	−34
	x_1	x_7	x_8	x_9

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 18 measurements and one constraint to determine 4 parameters. The overall fit has a χ^2 = 9.3 for 15 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

SCALAR MESONS

Written April 2000 by S. Spanier (SLAC) and N.A. Törnqvist (Helsinki).

Introduction: In contrast to the vector and tensor mesons, the identification of the scalar mesons is a long-standing puzzle. The number of publications since our last issue indicates great activity in that field. Scalar resonances are difficult to resolve because of their large decay widths causing a strong overlap between resonances and background, and at the same time, several decay channels open up within a short mass interval. In addition, especially the $\overline{K}K$ and $\eta\eta$ thresholds produce important sharp cusps in the energy dependence of the resonant amplitude. Furthermore, one expects non-$\overline{q}q$ scalar objects, like glueballs and multiquark states, in the mass range below 1800 MeV.

Scalars are produced, for example, in $\overline{p}p$ annihilation (high statistics), πN scattering on polarized/unpolarized targets, central production, J/ψ decays, D- and K-meson decays, $\gamma\gamma$ formation, and ϕ radiative decays. Experiments are accompanied by the development of theoretical models for the reaction amplitudes, which are based on common fundamental principles of two-body unitarity, analyticity, Lorentz invariance, and chiral- and flavor-symmetry using different techniques (K-matrix formalism, N/D-method, Dalitz Tuan ansatz, unitarized quark models with coupled channels, effective chiral field theories like the linear sigma model, etc.).

The mass and width of a resonance are found from the position of the nearest pole in the T matrix (or equivalently, in the S matrix) at an unphysical sheet of the complex energy plane: $(E - i\frac{\Gamma}{2})$. It is important to realize that only in the case of well-separated resonances, far away from the opening of decay channels, does the naive Breit-Wigner parameterization (or K-matrix pole parameterization) agree with the T-matrix pole position in the amplitude.

In this note, we discuss all light scalars organized in the listings under the entries ($I = 1/2$) $K^*(1430)$, ($I = 1$) $a_0(980)$, $a_0(1450)$, and ($I = 0$) σ or $f_0(400\text{–}1200)$, $f_0(980)$, $f_0(1370)$, and $f_0(1500)$. This list is minimal and does not necessarily exhaust the list of actual resonances. The ($I = 2$) $\pi\pi$ and ($I = 3/2$) $K\pi$ phase shifts do not exhibit any resonant behavior.

See also our notes in previous issues for further comments on *e.g.*, scattering lengths and older papers.

The $I = 1/2$ States: The $K^*(1430)$ (ASTON 88) is perhaps the least controversial of the light scalar mesons. The $K\pi$ phase shift rises smoothly from the threshold, passes 90° at 1350 MeV, and continues to rise to about 170° at 1600 MeV, the first important inelastic threshold $K\eta'(958)$. Thus, it behaves like a single broad, nearly elastic resonance. ABELE 98, analyzing the $\overline{K}K\pi$ channel of $\overline{p}p$ annihilation at rest, finds the T-matrix pole parameters, $m \approx 1430$ MeV and $\Gamma \approx 290$ MeV, while the K-matrix pole of the same data is about 1340 MeV. This agrees with the LASS (ASTON 88) determination.

It should, however, be noted that several authors (BLACK 98, 99, DELBOURGO 98, ISHIDA 99, OLLER 99,99C, BEVEREN 99) have introduced a light "$\kappa(900)$" meson, which in the model interferes destructively with a large background. This makes the existence of a such light state very model dependent.

The $I = 1$ States: Two isovector states are known, the established $a_0(980)$ and the $a_0(1450)$ found by the Crystal Barrel experiment (AMSLER 94D). Independently of any model about the nature of the $a_0(980)$, the $\overline{K}K$ component in the wave function of this state must be large: the $a_0(980)$ lies close to the opening of the $\overline{K}K$ channel to which it couples strongly. This gives an important cusp-like behavior in the resonant amplitude. Hence, its mass and width parameters are strongly distorted. To reveal its true coupling constants, a coupled channel model with energy-dependent widths and mass shift contributions must be applied.

In our previous editions, the relative coupling $\overline{K}K/\pi\eta$ was only determined indirectly from $f_1(1285)$ (CORDEN 78, DEFOIX 72) or $\eta(1410)$ decays (BAI 90C, BOLTON 92B, AMSLER 95C), or from the line shape observed in the $\pi\eta$ decay mode (FLATTE 76, AMSLER 94D, BUGG 94, JANSSEN 95). From the analysis of $\pi\pi\eta$ and $\overline{K}K\pi$ final states of $\overline{p}p$ annihilation at rest, a relative production ratio $B(\overline{p}p \to \pi a_0; a_0 \to \overline{K}K)/B(\overline{p}p \to \pi a_0; a_0 \to \pi\eta) = 0.23 \pm 0.05$ is obtained by (ABELE 98). Tuning of the couplings in a coupled channel formula to reproduce the production ratio for the integrated mass distributions gives a relative branching ratio $\Gamma(\overline{K}K)/\Gamma(\pi\eta) = 1.03 \pm 0.14$. The analysis of the $\overline{p}p$ annihilation data also found that the width determined from the T-matrix pole is 92 ± 8 MeV, while the observed width of the peak in the $\pi\eta$ mass spectrum is about 45 MeV. In all measurements listed in our table, the mass position agrees on a value near 980 MeV, but the width takes values between 50 and 300 MeV due to the different applied models.

The $a_0(1450)$ is seen by the Crystal Barrel experiment in its $\pi\eta$, $\overline{K}K$, and $\pi\eta'(958)$ decay modes. The relative couplings to the different final states are found to be close to SU(3)-flavor predictions for an ordinary $\overline{q}q$ meson. The OBELIX experiment (BERTIN 98B) finds two solutions in the $K_S K^{\pm}\pi^{\mp}$ final state of the $\overline{p}p$ annihilation, one at 1480 MeV and one with a mass value close to that of $a_2(1320)$, which is preferred by their fit, and by the low angular momentum in the production. The broad structure at about 1300 MeV observed in $\pi N \to \overline{K}KN$ reactions needs further confirmation in existence and isospin assignment.

The $I = 0$ States: The $I = 0\,J^{PC} = 0^{++}$ sector is the most complex one, both experimentally and theoretically. The data have been obtained from $\pi\pi$, $\overline{K}K$, $\eta\eta$, 4π, and $\eta\eta'(958)$ systems produced in S wave. From the high-statistics data sets collected from $\overline{p}p$ annihilation at rest into $\pi^0 f_0$, where the f_0 decays into the channels mentioned above, one concludes that at least four poles are needed in the mass range from the $\pi\pi$ threshold to about 1600 MeV. The claimed isoscalar resonances are found under separate entries σ or $f_0(400\text{–}1200)$, $f_0(980)$, $f_0(1370)$, and $f_0(1500)$.

Below 1100 MeV, the important data come from the $\pi\pi$ and $\overline{K}K$ final states. Information on the $\pi\pi$ S-wave phase shift $\delta^I_J = \delta^0_0$ was already extracted 20 years ago from the πN scattering with unpolarized (GRAYER 74) and polarized targets (BECKER 79), and near threshold from the K_{e4}-decay (ROSSELET 77). The $\pi\pi$ S-wave inelasticity is not accurately known, and the reported $\pi\pi \to \overline{K}K$ cross sections (WETZEL 76, POLYCHRONAKOS 79, COHEN 80, and ETKIN 82B) may have large uncertainties. The πN data (GRAYER 74, BECKER 79) have been reanalyzed in combination with the $\overline{p}p$ annihilation data (KAMINSKI 97). Two out of four relevant solutions are found, with the S-wave phase shift rising slower than the P wave [$\rho(770)$], which is used as a reference. One of these corresponds to the well-known "down" solution of GRAYER 74. The other "up" solution shows a decrease of the modulus in the mass interval between 800–980 MeV. Both solutions exhibit a sudden drop in the modulus and inelasticity at 1 GeV, due to the appearance of $f_0(980)$, which is very close to the opening of the $\overline{K}K$ threshold. The phase shift δ^0_0 rises smoothly up to this point, where it jumps by 120° (in the "up") or 140° (in the "down") solution to reach 230°, and then both continue to rise slowly.

SVEC 97 suggests the existence of a narrow state at 750 MeV, with a small width of 100 to 200 MeV in his analysis of the πN(polarized) data, from 600 to 900 MeV. Such a solution is also found by (KAMINSKI 97) using the CERN-Munich (-Cracow) data considering both the π- and $a_1(1260)$-exchange in the reaction amplitudes. However, they show that unitarity is violated for this solution. Therefore, a narrow, light f_0 state below 900 MeV is excluded (KAMINSKI 97, 00). Also, the

$2\pi^0$ invariant mass spectra of the $\bar{p}p$ annihilation at rest (AMSLER 95, ABELE 96), and the central collision (ALDE 97), do not show a narrow resonance below 900 MeV, and these data are consistently described with the standard "down" solution (GRAYER 74, KAMINSKI 97), which allows for the existence of the broad ($\Gamma \approx 500$ MeV) σ listed under f_0(400–1200). The σ is difficult to establish experimentally without models. It is expected to be very broad, and so can be easily distorted by large background from contact terms, crossed channel exchanges, the f_0((1370), and other dynamical features. Further information on this object is expected from the analysis of three body decays of the D meson, *e.g.*, $D \to \sigma\pi \to 3\pi$ (E791 experiment).

The $f_0(980)$ interferes destructively with the background leading to a dip in the $\pi\pi$ spectrum at the $\overline{K}K$ threshold. It changes from a dip into a peak structure in the $\pi^0\pi^0$ invariant mass spectrum of the reaction $\pi^- p \to \pi^0\pi^0 n$ (ACHASOV 98E), with increasing four-momentum transfer to the $\pi^0\pi^0$ system, which means increasing the a_1-exchange contribution in the amplitude, while the π-exchange decreases.

A meson resonance very well studied experimentally, is the $f_0(1500)$, seen by the Crystal Barrel experiment in five decay modes: $\pi\pi$, $\overline{K}K$, $\eta\eta$, $\eta\eta'(958)$, and 4π (AMSLER 95D, ABELE 96, and ABELE 98). Due to its interference with the $f_0(1370)$, the peak attributed to $f_0(1500)$ can appear shifted in mass to 1590 MeV, where it was observed by the GAMS Collaboration (BINON 83) in the $\eta\eta$ mass spectrum. For the dynamics in the resonant amplitude, they applied a sum of Breit-Wigner functions. In the central production (ANTINORI 95), a peak at a mass of 1450 MeV, having a width of 60 MeV, can be interpreted as the coherent sum of $f_0(1370)$ and $f_0(1500)$. The $\bar{p}p$ and $\bar{n}p/\bar{p}n$ reactions show a single enhancement at 1400 MeV in the invariant 4π mass (GASPERO 93, ADAMO 93, AMSLER 94, and ABELE 96). In the $5\pi^0$ channel (ABELE 96), this structure was resolved into $f_0(1500)$ and $f_0(1370)$, where the latter was found at somewhat lower mass at around 1300 MeV. An additional scalar had to be introduced in the reanalysis of the reaction $J/\psi(1S) \to \gamma 4\pi$ with a mass above 1700 MeV (BUGG 95). According to these investigations, the $f_0(1500)$ decay proceeds dominantly via $\sigma\sigma \to 4\pi$, where σ denotes the $\pi\pi$ S wave below the $\overline{K}K$ threshold. The $\overline{K}K$ decay of $f_0(1500)$ is suppressed (ABELE 98).

The determination of the $\pi\pi$ coupling of $f_0(1370)$ is aggravated by the strong overlap with the broad background from the f_0(400–1200). Since it does not show up prominently in the 2π spectra, its mass and width are difficult to determine. As mentioned under the $I = 1$ states section, data on $\pi\pi \to \overline{K}K$ show an enhancement in the scalar partial wave at around 1300 MeV (WETZEL 76, COHEN 80, POLYCHRONAKOS 79, COSTA 80, and LONGACRE 86). According to the phase shift, the resonance is found at about 1400 MeV (COHEN 80), while a reanalysis (BUGG 96) claims a trend towards lower mass. The recent three-channel approach (KAMINSKI 99) supports the Crystal Barrel findings, and yields a broad $f_0(1370)$ with a mass above 1400 MeV and a narrow $f_0(1500)$. Here, the $f_0(1370)$ couples more strongly to $\pi\pi$ than to $\overline{K}K$. The $f_0(1370)$ appears explicitly as $\eta\eta$ resonance in the $\pi^0\eta\eta$ final state of the $\bar{p}p$ annihilation at rest (AMSLER 95D). Further information about the $\overline{K}K$ decay of scalars are most welcome, in particular those that can clearly distinguish the $I = 0$ from the $I = 1$ system.

For numerical estimates of coupling constants of the lightest scalars to two pseudoscalars, see ACHASOV 89E,G,I, KAMINSKI 99, AKHMETSHIN 99C. For example, from these estimates, the $f_0(980)$ coupling to $K\overline{K}$ is much larger than its coupling to $\pi\pi$, which is an important constraint to model builders.

Interpretation: Almost every model on scalar states agrees that the $K^*(1430)$ is the quark model $s\bar{u}$ or $s\bar{d}$ state.

If one uses the naive quark model (which may be too naive because of lack of chiral symmetry constraints), it is natural to assume the $f_0(1370)$, $a_0(1450)$, and the $K^*(1430)$ are in the same SU(3) flavor nonet being the $(\bar{u}u + \bar{d}d)$, $u\bar{d}$ and $u\bar{s}$ state, respectively. In this picture, the choice of the ninth member of the nonet is ambiguous. The controversially discussed candidates are $f_0(1500)$ and $f_0(1710)$ (assuming $J = 0$). Compared to the above states, the $f_0(1500)$ is very narrow. Thus, it is unlikely to be their isoscalar partner. It is also too light to be the first radial excitation. Allowing for a gluonic admixture, one can come to an arrangement among these states. See our note on "Non-$\bar{q}q$ states."

The $f_0(980)$ and $a_0(980)$ are often interpreted as being multiquark states (JAFFE 77), $\overline{K}K$ bound states (WEINSTEIN 90), or vacuum scalars (CLOSE 93A). These pictures are supported by the two-photon widths of these states, which are smaller than expected for naive $\bar{q}q$ mesons neglecting the large $\overline{K}K$ components in the wave function (BARNES 85, LI 91). The results from SND (ACHASOV 98I) reveal a much higher branching ratio for radiative $\phi \to \gamma f_0$ decays than expected for naive $\bar{q}q$ mesons, but also for $\overline{K}K$ molecules (CLOSE 93B).

On the other hand, the states $f_0(980)$ and $a_0(980)$ may form a low-mass state nonet with the σ as a central ingredient, and the $K^*(1430)$ (or "$\kappa(900)$"). Attempts have been made to start directly from chiral symmetry or chiral Lagrangians (SCADRON 99, OLLER 98, 99, HANNAH 99, IGI 99, ISHIDA 99, and TORNQVIST 99), which all predict the existence of the σ meson near 500 MeV. Hence, *e.g.*, in the chiral linear sigma model, the σ is the $(\bar{u}u + \bar{d}d)$ state, and at the same time, also the chiral partner of the π. Hence, an experimental proof of its existence has become very important.

In the unitarized quark model with coupled channels, six of the light scalars are understood as different manifestations of bare quark model $\bar{q}q$ states (TORNQVIST 82,95,96, BEVEREN 86). The σ, $f_0(980)$, $f_0(1370)$, $a_0(980)$, $a_0(1450)$, and $K^*(1430)$ are described as unitarized remnants of strongly shifted and mixed $\bar{q}q$ 1^3P_0 states using six parameters. The $f_0(980)$ and $f_0(1370)$, as well as $a_0(980)$ and $a_0(1450)$, are two manifestations of the same $\bar{q}q$ state.

QCD sum rule techniques (ELIAS 99) generally find that the lightest scalars are nearly decoupled from $q\overline{q}$, which would suggest a non-$q\overline{q}$ structure. But this is also consistent with them being unitarized remnants of $q\overline{q}$ surrounded by large "clouds" of light mesons (forming part of the $q\overline{q}$ sea).

Other detailed models exist, which arrive at different groupings of the observed resonances. Further publications discussing the light scalar resonances are (see also our previous issues): AU 87, MORGAN 93, ZOU 94B, JANSSEN 95, KLEMPT 95, ANISOVICH 98, LOCHER 98, ACHASOV 98D, NARISON 98, and MINKOWSKI 99.

$\eta(1440)$

$I^G(J^{PC}) = 0^+(0^{-+})$

See also the mini-review under non-$q\overline{q}$ candidates. (See the index for the page number.)

THE $\eta(1440)$, $f_1(1420)$, AND $f_1(1510)$

Written April 2000 by M. Aguilar-Benitez (CIEMAT, Madrid), C. Amsler (Zürich), and A. Masoni (INFN Cagliari).

The first observation of $\eta(1440)$ was made in $p\overline{p}$ annihilation at rest into $\eta(1440)\pi^+\pi^-$, $\eta(1440) \to K\overline{K}\pi$ (BAILLON 67). This state was reported to decay through $a_0(980)\pi$ and $K^*(892)\overline{K}$ with roughly equal contributions. The $\eta(1440)$ has also been observed in radiative $J/\psi(1S)$ decay to $K\overline{K}\pi$ (SCHARRE 80, EDWARDS 82E, AUGUSTIN 90).

The $f_1(1420)$, decaying to $K^*\overline{K}$, was reported in π^-p reactions at 4 GeV/c (DIONISI 80). However, later analyses found that the 1400–1500 MeV region is far more complex. In π^-p experiments, (CHUNG 85, REEVES 86, BIRMAN 88) reported 0^{-+} with a dominant $a_0(980)\pi$ contribution to $K\overline{K}\pi$. The π^-p data of RATH 89 at 21 GeV/c suggest the presence of two pseudoscalars decaying to $K\overline{K}\pi$, one around 1410 MeV decaying through $a_0(980)\pi$, and the other around 1470 MeV, decaying to $K^*\overline{K}$. A reanalysis of the MARK III data in radiative $J/\psi(1S)$ decay to $K\overline{K}\pi$ (BAI 90C) also claims the existence of two pseudoscalars in the 1400–1500 MeV range, the lower mass state decaying through $a_0(980)\pi$, and the higher mass state decaying via $K^*\overline{K}$. In addition, $f_1(1420)$ is observed to decay into $K^*\overline{K}$.

In $\pi^-p \to \eta\pi\pi n$ charge-exchange reactions at 8–9 GeV/c, the $\eta\pi\pi$ mass spectrum is dominated by $\eta(1440)$ and $\eta(1295)$ (ANDO 86, FUKUI 91C), and at 100 GeV/c, ALDE 97B reports $\eta(1295)$ and $\eta(1440)$ decaying to $\eta\pi^0\pi^0$ with a weak $f_1(1285)$ signal, and no evidence for $f_1(1420)$.

An experiment in $\overline{p}p$ annihilation at rest into $K\overline{K}3\pi$ (BERTIN 95) reports two pseudoscalars with decay properties similar to BAI 90C, although the lower state shows, apart from $a_0(980)\pi$, a large contribution from the direct decay $\eta(1440) \to K\overline{K}\pi$.

The result of BERTIN 95 was supported by further $\overline{p}p$ data from the same experiment (BERTIN 97, CICALO 99). In particular, the data of CICALO 99 provided a decisive evidence for the presence of two pseudoscalar states.

We note that the data from AUGUSTIN 92 also suggest two states, but their intermediate states, $a_0(980)\pi$ and $K^*\overline{K}$, are reversed relative to BAI 90C.

Actually the interpretation of AUGUSTIN 92 is disfavored for several reasons: first, it disagrees with all the other $K\overline{K}3\pi$ results reporting two pseudoscalar states (they all agree in assigning the $K^*(892)\overline{K}$ decay mode to the higher mass pseudoscalar); second, it also disagrees with the $\eta\pi\pi$ results, because if the high mass pseudoscalar decays into $a_0(980)\pi$, then this state (and not the one at lower mass) should be seen in $\eta\pi\pi$ (see below).

In $J/\psi(1S)$ radiative decay, the $\eta(1440)$ decays to $K\overline{K}\pi$ through $a_0(980)\pi$, and hence a signal is also expected in the $\eta\pi\pi$ mass spectrum. This has indeed been observed by MARK III in $\eta\pi^+\pi^-$ (BOLTON 92B), which report a mass of 1400 MeV, in line with the existence of a low mass pseudoscalar, in the $\eta(1440)$ structure, decaying to $a_0(980)\pi$. This state is also observed in $\overline{p}p$ annihilation at rest into $\eta\pi^+\pi^-\pi^0\pi^0$, where it decays to $\eta\pi\pi$ (AMSLER 95F). The intermediate $a_0(980)\pi$ accounts for roughly half of the $\eta\pi\pi$ signal, in agreement with MARK III (BOLTON 92B) and DM2 (AUGUSTIN 90). However, ALDE 97B reports only a very small contribution due to $a_0(980)\pi$.

There is now a fairly consistent picture for the existence of two pseudoscalars. We call them η_L and η_H. The first one decays mainly through $a_0(980)\pi$ or direct $K\overline{K}\pi$. The second one decays mainly to $K^*(892)\overline{K}$. The η_L is seen both in $K\overline{K}\pi$ and $\eta\pi\pi$ experiments. The η_H is seen only in $K\overline{K}\pi$ experiments. The simultaneous observation of two pseudoscalars is reported in three production mechanisms by four different experiments: π^-p (RATH 89); radiative $J/\psi(1S)$ decay (BAI 90C, AUGUSTIN 92); and $\overline{p}p$ annihilation at rest (BERTIN 95, BERTIN 97, CICALO 99). All of them give values for the masses, widths and decay modes (with the exception of AUGUSTIN 92 quoted above) in reasonable agreement.

A recent paper reports only one pseudoscalar state seen in $J/\psi(1S)$ decay to $K\overline{K}\pi$ (BAI 98C), but its statistics are poorer, by a factor six, with respect to MARK III on the same final state (BAI 90C), and by more than an order of magnitude with respect to $\overline{p}p$ data (BERTIN 95, BERTIN 97, CICALO 99). It is, therefore, not surprising that their analysis is not capable to discriminate between the two states.

One of these two pseudoscalars could be the first radial excitation of the η', with the $\eta(1295)$ being the first radial excitation of the η. Ideal mixing, suggested by the $\eta(1295)$ and $\pi(1300)$ mass degeneracy, would then imply that the second isoscalar in the nonet is mainly $s\overline{s}$, and hence, couples to $K^*\overline{K}$, in agreement with observations for the upper $\eta(1440)$ state.

Also its width matches the expected width for the radially excited $\eta^{s\overline{s}}$ (CLOSE 97, BARNES 97).

This scheme then favors an exotic interpretation of the lower state, perhaps gluonium mixed with $q\overline{q}$ (CLOSE 97B) or a bound state of gluinos (FARRAR 96). The gluonium interpretation is, however, not favored by lattice gauge theories, which predict the 0^{-+} state above 2 GeV (BALI 93).

Axial (1^{++}) mesons are not observed in $\overline{p}p$ annihilation at rest in liquid hydrogen, which proceeds dominantly through S-wave annihilation. However, in gaseous hydrogen, P-wave annihilation is enhanced and, indeed, BERTIN 97 reports $f_1(1420)$ decaying to $K^*\overline{K}$, while confirming their earlier evidence for two pseudoscalars (BERTIN 95).

In $\gamma\gamma$ fusion from e^+e^- annihilations, a signal around 1420 MeV is seen in single-tag events (GIDAL 87B, AIHARA 88B, BEHREND 89, HILL 89), where one of the two photons is off-shell. However, it is totally absent in the untagged events where both photons are real. This points to a spin 1 object, which is not produced by two real (massless) photons (Yang-Landau theorem). The 2γ decay also implies $C = +1$. For the parity, AIHARA 88C and BEHREND 89 both find angular distributions with positive parity preferred, but negative parity cannot be excluded.

The $f_1(1420)$, decaying in $K\overline{K}\pi$, is definitely seen in pp central production at 300 and 450 GeV/c, together with $f_1(1285)$. The latter decays via $a_0(980)\pi$, and the former only via $K^*\overline{K}$, while $\eta(1440)$ is absent (ARMSTRONG 89, BARBERIS 97C). The $K_S K_S \pi^0$ decay mode of $f_1(1420)$ establishes unambiguously C=+1. On the other hand, there is no evidence for any state decaying to $\eta\pi\pi$ around 1400 MeV, and hence, the $\eta\pi\pi$ mode of $f_1(1420)$ is suppressed (ARMSTRONG 91B).

We now turn to the experimental evidence for $f_1(1510)$. Two states, $f_1(1420)$ and $f_1(1510)$, decaying to $K^*\overline{K}$, compete for the $s\overline{s}$ assignment in the 1^{++} nonet. The $f_1(1510)$ was seen in $K^- p \rightarrow \Lambda K\overline{K}\pi$ at 4 GeV/c (GAVILLET 82), and at 11 GeV/c (ASTON 88C). Evidence is also reported in $\pi^- p$ at 8 GeV/c, based on the phase motion of the 1^{++} $K^*\overline{K}$ wave (BIRMAN 88).

The absence of $f_1(1420)$ in $K^- p$ (ASTON 88C) argues against $f_1(1420)$ being the $s\overline{s}$ member of the 1^{++} nonet. However, $f_1(1420)$ has been reported in $K^- p$, but not in $\pi^- p$ (BITYUKOV 84) while two experiments do not observe $f_1(1510)$ in $K^- p$ (BITYUKOV 84, KING 91). It is also not seen in radiative $J/\psi(1S)$ decay (BAI 90C, AUGUSTIN 92), central collisions (BARBERIS 97C), or in $\gamma\gamma$ collisions (AIHARA 88C), although, surprisingly for an $s\overline{s}$ state, a signal is reported in 4π decays (BAUER 93B). These facts led to the conclusion that $f_1(1510)$ is not well established, and that its assignment as $s\overline{s}$ member of the 1^{++} nonet is premature (CLOSE 97D). The Particle Data Group has removed this state from the Summary Table. Assigning, instead, the $f_1(1420)$ to the 1^{++} nonet, one finds a nonet mixing angle of $\sim 50°$ (CLOSE 97D). This is derived from the mass formula, and from $f_1(1285)$ radiative decays to $\phi\gamma$ (BITYUKOV 88) and $\rho\gamma$ (AMELIN 95).

Arguments favoring $f_1(1420)$ being a hybrid $q\overline{q}g$ meson or a four-quark state are put forward by ISHIDA 89 and CALDWELL 90, respectively, while LONGACRE 90 argues that this particle is a molecular state formed by the π orbiting in a P-wave around an S-wave $K\overline{K}$ state.

Summarizing, there is rather convincing evidence for $f_1(1420)$, mostly produced in central collisions and decaying to $K^*\overline{K}$, and for $\eta(1440)$, mostly produced in radiative $J/\psi(1S)$ decay and $\overline{p}p$ annihilation at rest, and decaying to $K^*\overline{K}$ and $a_0(980)\pi$. Confusion remains as to which states are observed in $\pi^- p$ interactions. The $f_1(1510)$ is not well established.

Furthermore, there are fairly strong experimental indications for the presence of two pseudoscalars in the $\eta(1440)$ structure

The available information has led the Particle Data Group to split the $K\overline{K}\pi$ entry for $\eta(1440)$ into $a_0(980)\pi$ and $K^*\overline{K}$.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 2 partial widths, a combination of partial widths obtained from integrated cross sections, and 3 branching ratios uses 14 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 11.4$ for 10 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Seen in the amplitude analysis of the $3\pi^0$ system produced in $\overline{p}p \to 4\pi^0$. Possibly seen in the study of the hadronic structure in decay $\tau \to 3\pi\nu_\tau$ (ABREU 98G). Needs confirmation.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 6 measurements and one constraint to determine 4 parameters. The overall fit has a χ^2 = 1.9 for 3 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i \delta x_j\rangle/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[15] Width errors enlarged by us to $4\Gamma/\sqrt{N}$; see the note with the $K^*(892)$ mass.
[16] Uses same data as HYAMS 75 and BECKER 79.
[17] From a phase shift solution containing a $f_2'(1525)$ width two times larger than the $K\overline{K}$ result.
[18] From phase-shift analysis. Error takes account of spread of different phase-shift solutions.

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 10 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 =$ 14.7 for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\left\langle\delta x_i\delta x_j\right\rangle/(\delta x_i\cdot\delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\rho(1700)$

$I^G(J^{PC}) = 1^+(1^{--})$

THE $\rho(1450)$ AND THE $\rho(1700)$

Updated March 2000 by S. Eidelman (Novosibirsk) and J. Hernandez (Valencia).

In our 1988 edition, we replaced the $\rho(1600)$ entry with two new ones, the $\rho(1450)$ and the $\rho(1700)$, because there was emerging evidence that the 1600-MeV region actually contains two ρ-like resonances. ERKAL 86 had pointed out this possibility with a theoretical analysis on the consistency of 2π and 4π electromagnetic form factors and the $\pi\pi$ scattering length. DONNACHIE 87, with a full analysis of data on the 2π and 4π final states in e^+e^- annihilation and photoproduction reactions, had also argued that in order to obtain a consistent picture, two resonances were necessary. The existence of $\rho(1450)$ was supported by the analysis of $\eta\rho^0$ mass spectra obtained in photoproduction and e^+e^- annihilation (DONNACHIE 87B), as well as that of $e^+e^- \rightarrow \omega\pi$ (DONNACHIE 91).

The analysis of DONNACHIE 87 was further extended by CLEGG 88, 94 to include new data on 4π systems produced in e^+e^- annihilation, and in τ decays (τ decays to 4π and e^+e^- annihilation to 4π can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two ρ-like states, and from the tail of the $\rho(770)$ decaying into two-body states. While specific conclusions on $\rho(1450) \rightarrow 4\pi$ were obtained, little could be said about the $\rho(1700)$.

An analysis by CLEGG 90 of 6π mass spectra from e^+e^- annihilation and from diffractive photoproduction provides evidence for two ρ mesons at about 2.1 and 1.8 GeV that decay strongly into 6π states. While the former is a candidate for a new resonance ($\rho(2150)$), the latter could be a manifestation of the $\rho(1700)$ distorted by threshold effects.

Independent evidence for two 1^- states is provided by KILLIAN 80 in 4π electroproduction at $\langle Q^2 \rangle = 1$ (GeV/c)^2, and by FUKUI 88 in a high-statistics sample of the $\eta\pi\pi$ system in $\pi^- p$ charge exchange.

This scenario with two overlapping resonances is supported by other data. BISELLO 89 measured the pion form factor in the interval 1.35–2.4 GeV and observed a deep minimum around 1.6 GeV. The best fit was obtained with the hypothesis of ρ-like resonances at 1420 and 1770 MeV, with widths of about 250 MeV. ANTONELLI 88 found that the $e^+e^- \rightarrow \eta\pi^+\pi^-$ cross section is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of DONNACHIE 87 and BISELLO 89. These results can be considered as a confirmation of the $\rho(1450)$.

Decisive evidence for the $\pi\pi$ decay mode of both $\rho(1450)$ and $\rho(1700)$ came from recent results in $\overline{p}p$ annihilation at rest (ABELE 97). It was shown that these resonances also possess a $K\overline{K}$ decay mode (ABELE 98, BERTIN 98B, ABELE 99D). High statistics studies of the decays $\tau \rightarrow \pi\pi\nu_\tau$ (BARATE 97M, URHEIM 97), and $\tau \rightarrow 4\pi\nu_\tau$ (EDWARDS 00), also require the ρ(1450), but are not sensitive to the ρ(1700), because it is too close to the τ mass.

The structure of these ρ states is not yet completely clear. BARNES 97 and CLOSE 97C claim that ρ(1450) has a mass consistent with radial 2S, but its decays show characteristics of hybrids, and suggest that this state may be a 2S-hybrid mixture. DONNACHIE 99 argues that hybrid states could have a 4π decay mode dominated by the $a_1\pi$. Such behavior has recently been observed by AKHMETSHIN 99E in $e^+e^- \to 4\pi$ in the energy range 1.05–1.38 GeV, and by EDWARDS 00 in $\tau \to 4\pi$ decays. More data should be collected to clarify the nature of the ρ states, particularly in the energy range above 1.6 GeV.

We also list under the ρ(1450) the φπ state with $J^{PC} = 1^{--}$ or C(1480) observed by BITYUKOV 87. While ACHASOV 96B shows that it may be a threshold effect, CLEGG 88 and LANDSBERG 92 suggest two independent vector states with this decay mode. Note, however, that C(1480) in its φπ decay mode was not confirmed by e^+e^- (DOLINSKY 91, BISELLO 91C) and $\overline{p}p$ (ABELE 97H) experiments.

Several observations on the ωπ system in the 1200-MeV region (FRENKIEL 72, COSME 76, BARBER 80C, ASTON 80C, ATKINSON 84C, BRAU 88, AMSLER 93B) may be interpreted in terms of either $J^P = 1^-$ $\rho(770) \to \omega\pi$ production (LAYSSAC 71), or $J^P = 1^+$ $b_1(1235)$ production (BRAU 88, AMSLER 93B). We argue that no special entry for a ρ(1250) is needed. The LASS amplitude analysis (ASTON 91B) showing evidence for ρ(1270) is preliminary and needs confirmation. For completeness, the relevant observations are listed under the ρ(1450).

$f_0(1710)$ $\quad I^G(J^{PC}) = 0^+(0^{++})$

THE $f_0(1710)$

Updated April 2000 by M. Doser (CERN).

The $f_0(1710)$ is seen in the radiative decay $J/\psi(1S) \to \gamma f_0(1710)$; therefore $C = +1$. It decays into $\eta\eta$ and $K^0_S K^0_S$, which implies $I^G J^{PC} = 0^+(even)^{++}$. The spin of the $f_0(1710)$ has been controversial, but evidence for spin 0 has accumulated recently in all production modes.

An analysis of radiative J/ψ decays at BES into $\pi^+\pi^-\pi^+\pi^-$ (BAI 00) clearly favors spin 0. Combined amplitude analyses of the K^+K^-, $K^0_S K^0_S$ and $\pi^+\pi^-$ systems produced in $J/\psi(1S)$ radiative decay by MARK III (CHEN 91 and more recently DUNWOODIE 97) find a large spin-0 component, and at the same time reproduce known parameters of the $f_2(1270)$ and $f'_2(1525)$. In addition, a recent reanalysis (BUGG 95) of the 4π channel from MARK III, allowing both $\rho\rho$ and two $\pi\pi$ S-waves, also finds a 0^{++} assignment for the $f_0(1710)$. Earlier analyses of this final state (BISELLO 89B, BALTRUSAITIS 86B) found only pseudoscalar activity in the $f_0(1710)$ region, but considered only the process $J/\psi \to \gamma\rho\rho$. Similarly, earlier analyses of the K^+K^- system based on less statistics (BALTRUSAITIS 87, BAI 96) found a spin of 2 for the $f_0(1710)$.

A similar situation is present in central production, with earlier analyses favoring spin 2 over spin 0 (ARMSTRONG 89D). More recent analyses with greater statistics by BARBERIS 99 (K^+K^-,$K^0_S K^0_S$), BARBERIS 99B ($\pi^+\pi^-$), and FRENCH 99 (K^+K^-) however clearly indicate spin 0, and exclude spin 2. Generally, analyses preferring spin 2 concentrate on angular distributions in the $f_0(1710)$ region, and do not include possible interferences or distortion due to the nearby $f'_2(1525)$.

The $f_0(1710)$ is also observed in $K\overline{K}$ (FALVARD 88) in $J/\psi(1S) \to \omega K\overline{K}$ and $J/\psi(1S) \to \phi K\overline{K}$, but with no spin-parity analysis, as well as in $\eta\eta$ in radiative J/ψ decays (EDWARDS 82). It is also clearly seen in 300-GeV/c pp central production in both K^+K^- and $K^0_S K^0_S$ (ARMSTRONG 89D). Mass and width are determined via a fit to non-interfering Breit-Wigners over a polynomial background, which leads to large systematic errors for the width. ARMSTRONG 93C also sees a broad peak in $\eta\eta$ at 1747 MeV, which may be the $f_0(1710)$.

This resonance is not observed in the hypercharge-exchange reactions $K^-p \to K^0_S K^0_S \Lambda$ (ASTON 88D) and $K^-p \to K^0_S K^0_S Y^*$ (BOLONKIN 86); these non-observations are explained by a spin of 0 (LINDENBAUM 92). A possible observation in $\gamma\gamma$ collisions leading to $K^0_S K^0_S$ (BRACCINI 99, but no spin determination), and a non-observation in $\gamma\gamma \to \pi^+\pi^-$ (BARATE 00E) is consistent with a large $\overline{s}s$ component.

[5] OAKDEN 94 makes an amplitude analysis of LEAR data on $\overline{p}p \to \pi\pi$ using a method based on Barrelet zeros. This is solution A. The amplitude analysis of HASAN 94 includes earlier data as well, and assume that the data can be parametrized in terms of towers of nearly degenerate resonances on the leading Regge trajectory. See also KLOET 96 and MARTIN 97 who make related analyses.
[6] From solution B of amplitude analysis of data on $\overline{p}p \to \pi\pi$.
[7] $I(J^P) = 0(2^+)$ from simultaneous analysis of $p\overline{p} \to \pi^-\pi^+$ and $\pi^0\pi^0$.
[8] $I^G(J^P) = 0^+(2^+)$ from partial-wave amplitude analysis.

$f_J(2220)$

$I^G(J^{PC}) = 0^+(2^{++} \text{ or } 4^{++})$

OMITTED FROM SUMMARY TABLE

THE $f_J(2220)$

Updated April 2000 by M. Doser (CERN).

This state has been observed in $J/\psi(1S)$ radiative decay into $K\overline{K}$ (K^+K^- and $K_S^0 K_S^0$ modes seen (BALTRUSAITIS 86D, BAI 96B)). An upper limit from DM2 for these modes (AUGUSTIN 88) is at the level at which observation is claimed. There are also indications for further decay modes ($\pi^+\pi^-$ and $\overline{p}p$ (BAI 96B) and $\pi^0\pi^0$ (BAI 98H)) in the same production process, although again at the level at which previous upper limits had been obtained (BALTRUSAITIS 86D). This was also seen in $\eta\eta$ (ALDE 86B), $K_S^0 K_S^0$ (ASTON 88D), and K^+K^- (ALDE 88 F), albeit with very low statistics. Its J^{PC} is determined from the angular distributions of these observations.

It is not seen in Υ radiative decays (BARU 89), B inclusive decays (BEHRENDS 84), nor in $\gamma\gamma$ (GODANG 97, ALAM 98C), which is not surprising, since if it were a glueball, its two-photon width would be expected to be small. It is also not seen in formation in $\overline{p}p \to K^+K^-$ (BARDIN 87, SCULLI 87), in $\overline{p}p \to K_S K_S$ (BARNES 93, EVANGELISTA 97), $\overline{p}p \to \phi\phi$ (EVANGELISTA 98), nor in $\overline{p}p \to \pi^+\pi^-$ (HASAN 96). The upper limit in $\overline{p}p$ formation can be related to the claimed decay into $\overline{p}p$ to give a lower limit for the process $J/\psi \to \gamma f_J(2220)$ of $\sim 2.3 \times 10^{-3}$ (GODFREY 99). Such a signal should be visible in the inclusive photon spectrum (BLOOM 85). The limit also leads to the surprising conclusion that the reported two-body final states constitute only a small fraction of all decay modes of the $f_J(2220)$. Observation of further decay modes and confirmation of the $\overline{p}p$ decay would be very desirable.

[9] Not seen by GRAF 91.
[10] Not seen by CHIBA 88, ANGELOPOULOS 86, ADIELS 86.
[11] They looked for radiative transitions to bound $p\overline{p}$ states, mono-energetic γ rays detected.
[12] Observed widths consistent with experimental resolution.
[13] Not seen by ADIELS 86.
[14] From analysis of difference of π^- and π^+ spectra.
[15] Not seen by CHIBA 88, ANGELOPOULOS 86.
[16] From a phenomenological analysis of ASTERIX data.
[17] Produced backwards.
[18] Using preliminary Crystal Barrel data.
[19] $I(J^P) = 1(1^-)$ from a mass dependent partial-wave analysis taking solution A.
[20] From reanalysis of data from JASTRZEMBSKI 81.
[21] Not seen by BUSENITZ 89.
[22] From energy dependence of 5π cross section. $I^G = 1^-$ from observation of $\omega\rho$ decay. $P = +$ and $J > 1$. $a_2(1320)\pi\pi$ also seen.

23 $I = 0$ favored, $J = 0$ or 1, seen in total $\overline{p}p$ total cross section. Primarily from annihilation reactions. Not seen in $\overline{p}d$ total and annihilation cross sections.

24 Narrow bump seen in total $\overline{p}p$, $\overline{p}d$ cross sections. Isospin uncertain. Not seen in $\overline{p}p$ charge exchange by ALSTON-GARNJOST 75, CHALOUPKA 76. Integrated cross section three times larger than BRUCKNER 77.

25 Narrow bump seen in total $\overline{p}p$, $\overline{p}d$ cross sections. Isospin uncertain. Not seen in $\overline{p}p$ charge exchange by ALSTON-GARNJOST 75, CHALOUPKA 76. Integrated cross section three times larger than BRUCKNER 77. Not seen by CLOUGH 84.

26 From energy dependence of far backward elastic scattering. Some indication of additional structure.

27 From energy dependence of far backward elastic scattering. Some indication of additional structure.

28 Not seen by ALBERI 79 with comparable statistics.

29 Seen as a bump in the $\overline{p}p \rightarrow K^0_S K^0_L$ cross section with $J^{PC} = 1^{--}$.

30 Isospin 1 favored.

31 From a fit to the $I^G(J^{PC}) = 1^+(4^{++})$ $f_2(1270)\pi$ wave.

32 From a fit to the $I^G(J^{PC}) = 0^+(3^{++})$ $\pi^0\pi^0\eta$ wave.

33 Not seen by AJALTOUNI 82, ARMSTRONG 79, BUZZO 97.

34 From a fit to the $I^G(J^{PC}) = 0^+(2^{++})$ $\pi^0\pi^0\eta$ wave.

35 Not seen by BIONTA 80, CARROLL 80, HAMILTON 80, BANKS 81, CHUNG 81, BARNETT 83.

36 From a fit to the $I^G(J^{PC}) = 0^+(2^{-+})$ $\pi^0\pi^0\eta$ wave.

37 Neutron spectator. See also $np\overline{p}\pi^-(p)$ channel following.

38 From a fit to the $I^G(J^{PC}) = 1^+(3^{++})$ $f_2(1270)\pi$ wave.

39 Proton spectator. See also $p\overline{p}n(n)$ channel above.

40 $I(J^P) = 1(3^-)$ from a mass dependent partial-wave analysis taking solution A.

41 From a fit to the $I^G(J^{PC}) = 1^+(2^{++})$ $f_2(1270)\pi$ wave.

42 From a fit to the $I^G(J^{PC}) = 1^+(1^{++})$ $f_2(1270)\pi$ wave.

43 $I(J^P) = 1(3^-)$ from amplitude analysis assuming one-pion exchange.

44 From a fit to the $I^G(J^{PC}) = 0^+(1^{++})$ $\pi^0\pi^0\eta$ wave.

45 Seen in final state $\omega\pi^+\pi^-$.

46 $I(J^P) = 0(2^+)$ from amplitude analysis assuming one-pion exchange.

47 ALLES-BORELLI 67B see neutral mode only $\pi^+\pi^-\pi^0$.

48 $I(J^P) = 0(4^+)$ from a mass dependent partial-wave analysis taking solution A.

49 From a fit to the $I^G(J^{PC}) = 0^+(3^{++})$ $\pi^0\pi^0\eta$ wave.

50 From a fit to the $I^G(J^{PC}) = 0^+(4^{++})$ $\pi^0\pi^0\eta$ wave.

51 Supersedes CARBONELL 93.

52 $I(J^P) = 0(4^+)$ from amplitude analysis assuming one-pion exchange.

53 $I(J^P) = 1(5^-)$ from amplitude analysis assuming one-pion exchange.

54 $I(J^P) = 1(5^-)$ from amplitude analysis of $\overline{p}p \rightarrow \pi\pi$.

55 I=0,1 $J^P = 5^-$ from Barrelet-zero analysis.

56 Decays to $\overline{N}N$ and $\overline{N}N\pi$. Not seen by BARNETT 83.

57 Decays to $4\pi^+4\pi^-$.

$X(1900\text{–}3600)$

OMITTED FROM SUMMARY TABLE

THE $X(1900\text{–}3600)$ REGION

This high-mass region is covered nearly continuously with evidence for peaks of various widths and decay modes. As no satisfactory grouping into particles is yet possible, we list together in order of increasing mass all the $Y = 0$ bumps above 1900 MeV that are coupled neither to $\overline{N}N$ nor to e^+e^-.

$X(1900\text{–}3600)$ MASSES AND WIDTHS

We do not use the following data for averages, fits, limits, etc.

THE CHARGED KAON MASS

Revised 1994 by T.G. Trippe, (LBNL).

The average of the six charged kaon mass measurements which we use in the Particle Listings is

$$m_{K^\pm} = 493.677 \pm 0.013 \text{ MeV (S = 2.4)} , \qquad (1)$$

where the error has been increased by the scale factor S. The large scale factor indicates a serious disagreement between different input data. The average before scaling the error is

$$m_{K^\pm} = 493.677 \pm 0.005 \text{ MeV} ,$$
$$\chi^2 = 22.9 \text{ for 5 D.F., Prob. } = 0.04\% , \qquad (2)$$

where the high χ^2 and correspondingly low χ^2 probability further quantify the disagreement.

The main disagreement is between the two most recent and precise results,

$$m_{K^\pm} = 493.696 \pm 0.007 \text{ MeV} \qquad \text{DENISOV 91}$$
$$m_{K^\pm} = 493.636 \pm 0.011 \text{ MeV (S = 1.5)} \quad \text{GALL 88}$$
$$\text{Average} = 493.679 \pm 0.006 \text{ MeV}$$
$$\chi^2 = 21.2 \text{ for 1 D.F., Prob. } = 0.0004\% , \quad (3)$$

both of which are measurements of x-ray energies from kaonic atoms. Comparing the average in Eq. (3) with the overall average in Eq. (2), it is clear that DENISOV 91 and GALL 88 dominate the overall average, and that their disagreement is responsible for most of the high χ^2.

The GALL 88 measurement was made using four different kaonic atom transitions, K^- Pb ($9 \to 8$), K^- Pb ($11 \to 10$), K^- W ($9 \to 8$), and K^- W ($11 \to 10$). The $m_{K^\pm}$ values they obtain from each of these transitions is shown in the Particle Listings and in Fig. 1. Their K^- Pb ($9 \to 8$) $m_{K^\pm}$is below and somewhat inconsistent with their other three transitions. The average of their four measurements is

$$m_{K^\pm} = 493.636 \pm 0.007 ,$$
$$\chi^2 = 7.0 \text{ for 3 D.F., Prob. } = 7.2\% . \qquad (4)$$

This is a low but acceptable χ^2 probability so, to be conservative, GALL 88 scaled up the error on their average by S=1.5 to obtain their published error ± 0.011 shown in Eq. (3) above and used in the Particle Listings average.

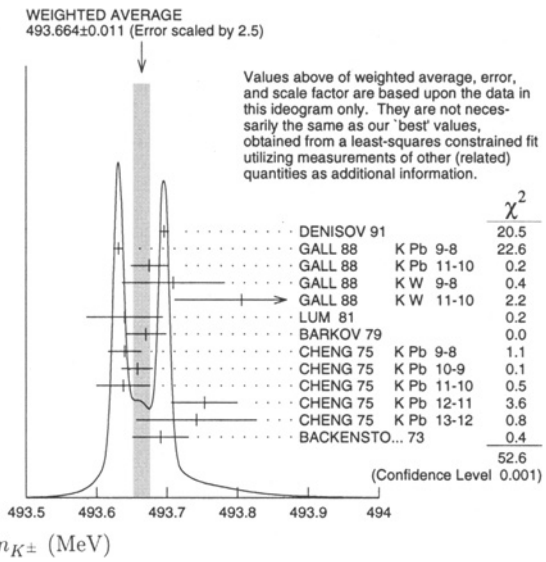

Figure 1: Ideogram of $m_{K^\pm}$ mass measurements. GALL 88 and CHENG 75 measurements are shown separately for each transition they measured.

The ideogram in Fig. 1 shows that the DENISOV 91 measurement and the GALL 88 K^- Pb ($9 \to 8$) measurement yield two well-separated peaks. One might suspect the GALL 88 K^- Pb ($9 \to 8$) measurement since it is responsible both for the internal inconsistency in the GALL 88 measurements and the disagreement with DENISOV 91.

To see if the disagreement could result from a systematic problem with the K^- Pb ($9 \to 8$) transition, we have separated the CHENG 75 data, which also used K^- Pb, into its separate transitions. Figure 1 shows that the CHENG 75 and GALL 88 K^- Pb ($9 \to 8$) values are consistent, suggesting the possibility of a common effect such as contaminant nuclear γ rays near the K^- Pb ($9 \to 8$) transition energy, although the CHENG 75 errors are too large to make a strong conclusion. The average of all 13 measurements has a χ^2 of 52.6 as shown in Fig. 1 and the first line of Table 1, yielding an unacceptable χ^2 probability of 0.00005%. The second line of Table 1 excludes both the GALL 88 and CHENG 75 measurements of the K^- Pb ($9 \to 8$) transition and yields a χ^2 probability of 43%. The third [fourth] line of Table 1 excludes only the GALL 88 K^- Pb ($9 \to 8$) [DENISOV 91] measurement and yields a χ^2 probability of 20% [8.6%]. Table 1 shows that removing both measurements of the K^- Pb ($9 \to 8$) transition produces the most consistent set of data, but that excluding only the GALL 88 K^- Pb ($9 \to 8$) transition or DENISOV 91 also produces acceptable probabilities.

Yu.M. Ivanov, representing DENISOV 91, has estimated corrections needed for the older experiments because of improved ^{192}Ir and ^{198}Au calibration γ-ray energies. He estimates that CHENG 75 and BACKENSTOSS 73 $m_{K^\pm}$ values could be

Table 1: $m_{K^{\pm}}$ averages for some combinations of Fig. 1 data.

$m_{K^{\pm}}$ (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.664 ± 0.004	52.6	12	0.00005	all 13 measurements
493.690 ± 0.006	10.1	10	43	no K^- Pb(9→8)
493.687 ± 0.006	14.6	11	20	no GALL 88 K^- Pb(9→8)
493.642 ± 0.006	17.8	11	8.6	no DENISOV 91

raised by about 15 keV and 22 keV, respectively. With these estimated corrections, Table 1 becomes Table 2. The last line of Table 2 shows that if such corrections are assumed, then GALL 88 K^- Pb ($9 \rightarrow 8$) is inconsistent with the rest of the data even when DENISOV 91 is excluded. Yu.M. Ivanov warns that these are rough estimates. Accordingly, we do not use Table 2 to reject the GALL 88 K^- Pb ($9 \rightarrow 8$) transition, but we note that a future reanalysis of the CHENG 75 data could be useful because it might provide supporting evidence for such a rejection.

Table 2: $m_{K^{\pm}}$ averages for some combinations of Fig. 1 data after raising CHENG 75 and BACKENSTOSS 73 values by 0.015 and 0.022 MeV respectively.

$m_{K^{\pm}}$ (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.666 ± 0.004	53.9	12	0.00003	all 13 measurements
493.693 ± 0.006	9.0	10	53	no K^- Pb(9→8)
493.690 ± 0.006	11.5	11	40	no GALL 88 K^- Pb(9→8)
493.645 ± 0.006	23.0	11	1.8	no DENISOV 91

The GALL 88 measurement uses a Ge semiconductor spectrometer which has a resolution of about 1 keV, so they run the risk of some contaminant nuclear γ rays. Studies of γ rays following stopped π^- and Σ^- absorption in nucleii (unpublished) do not show any evidence for contaminants according to GALL 88 spokesperson, B.L. Roberts. The DENISOV 91 measurement uses a crystal diffraction spectrometer with a resolution of 6.3 eV for radiation at 22.1 keV to measure the 4f-3d transition in K^- ^{12}C. The high resolution and the light nucleus reduce the probability for overlap by contaminant γ rays, compared with the measurement of GALL 88. The DENISOV 91 measurement is supported by their high-precision measurement of the 4d-2p transition energy in π^- ^{12}C, which is good agreement with the calculated energy.

While we suspect that the GALL 88 K^- Pb ($9 \rightarrow 8$) measurements could be the problem, we are unable to find clear grounds for rejecting it. Therefore, we retain their measurement in the average and accept the large scale factor until further information can be obtained from new measurements and/or from reanalysis of GALL 88 and CHENG 75 data.

We thank B.L. Roberts (Boston Univ.) and Yu.M. Ivanov (Petersburg Nuclear Physics Inst.) for their extensive help in understanding this problem.

RARE KAON DECAYS

(Revised April 2000 by L. Littenberg, BNL and G. Valencia, Iowa State University)

A. Introduction: There are several useful reviews on rare kaon decays and related topics [1–11]. The current activity in rare kaon decays can be divided roughly into four categories:

1. Searches for explicit violations of the Standard Model
2. Measurements of Standard Model parameters
3. Searches for CP violation
4. Studies of strong interactions at low energy.

The paradigm of Category 1 is the lepton flavor violating decay $K_L \to \mu e$. Category 2 includes processes such as $K^+ \to \pi^+\nu\overline{\nu}$, which is sensitive to $|V_{td}|$. Much of the interest in Category 3 is focussed on the decays $K_L \to \pi^0\ell\overline{\ell}$, where $\ell \equiv e, \mu, \nu$. Category 4 includes reactions like $K^+ \to \pi^+\ell^+\ell^-$ which constitute a testing ground for the ideas of chiral perturbation theory. Other reactions of this type are $K_L \to \pi^0\gamma\gamma$, which also scales a CP-conserving background to CP violation in $K_L \to \pi^0\ell^+\ell^-$ and $K_L \to \gamma\ell^+\ell^-$, which could possibly shed light on long distance contributions to $K_L \to \mu^+\mu^-$.

B. Explicit violations of the Standard Model: Most of the activity here is in searches for lepton flavor violation (LFV). This is motivated by the fact that many extensions of the minimal Standard Model violate lepton flavor and by the potential to access very high energy scales. For example, the tree-level exchange of a LFV vector boson of mass M_X that couples to left-handed fermions with electroweak strength and without mixing angles yields $\text{B}(K_L \to \mu e) = 4.7 \times 10^{-12}(148\ \text{TeV}/M_X)^4$ [5]. This simple dimensional analysis may be used to read from Table 1 that the reaction $K_L \to \mu e$ is already probing scales of over 100 TeV. Table 1 summarizes the present experimental situation vis a vis LFV, along with the expected near-future progress. The decays $K_L \to \mu^{\pm}e^{\mp}$ and $K^+ \to \pi^+e^{\mp}\mu^{\pm}$ (or $K_L \to \pi^0e^{\mp}\mu^{\pm}$) provide complementary information on potential family number violating interactions since the former is sensitive to parity-odd couplings and the latter is sensitive to parity-even couplings. Related searches in μ and τ process are discussed in our section "Tests of Conservation Laws".

Table 1: Searches for lepton flavor violation in K decay

Mode	90% CL upper limit	Exp't	Yr./Ref.	(Near-) future aim
$K^+ \to \pi^+e\mu$	4.8×10^{-11}*	BNL-865	99/12	9×10^{-12} (BNL-865)
$K_L \to \mu e$	4.7×10^{-12}	BNL-871	98/13	
$K_L \to \pi^0e\mu$	3.2×10^{-9}	FNAL-799	94/14	5×10^{-11} (KTeV)

*preliminary

Another forbidden decay currently being pursued is $K^+ \to \pi^+X^0$, where X^0 is a very light, noninteracting particle (*e.g.* hyperphoton, axion, familon, *etc.*). The 90% CL upper limit on this process was recently improved to 1.1×10^{-10} [15]. Data already collected by BNL-787 are expected to yield a further factor ~ 2 in sensitivity to this process.

C. Measurements of Standard Model parameters: Until 1997, searches for $K^+ \to \pi^+\nu\overline{\nu}$ were motivated by the possibility of observing non-SM physics because the sensitivity attained was far short of the SM prediction for this decay [16] and long-distance contributions were known to be negligible [2]. However, BNL-787 has attained the sensitivity at which the observation of an event can no longer be unambiguously attributed to non-SM physics. In 1997 BNL-787 observed a single candidate event and has recently released the results of further running in which no further events were seen, yielding a branching ratio of $(1.5^{+3.4}_{-1.2}) \times 10^{-10}$ [15]. Further data already collected are expected to increase the sensitivity by approximately a factor 2, and there are plans for an upgrade to the experiment to collect roughly an order of magnitude more sensitivity [17]. This reaction is now interesting from the point of view of constraining SM parameters. The branching ratio can be written in terms of the very well-measured rate of K_{e3} as [2]:

$$\text{B}(K^+ \to \pi^+\nu\overline{\nu}) = \frac{\alpha^2\text{B}(K^+ \to \pi^o e^+\nu)}{V_{us}^2 2\pi^2 \sin^4\theta_W} \times \sum_{l=e,\mu,\tau} |V_{cs}^*V_{cd}X_{NL}^{\ell} + V_{ts}^*V_{td}X(m_t)|^2 \quad (1)$$

to eliminate the *a priori* unknown hadronic matrix element. Isospin breaking corrections to the ratio of matrix elements reduce this rate by 10% [18]. In Eq. (1) the Inami-Lim function $X(m_t)$ is of order 1 [19], and X^{ℓ}_{NL} is several hundred times smaller. This form exhibits the strong dependence of this branching ratio on $|V_{td}|$. QCD corrections, which are contained in X^{ℓ}_{NL}, are relatively small and now known [10] to $\leq$ 10%. Evaluating the constants in Eq. (1) with m_t = 175 GeV, one can cast this result in terms of the CKM parameters A, ρ and η (see our Section on "The Cabibbo-Kobayashi-Maskawa mixing matrix") [10]

$$\mathrm{B}(K^+ \to \pi^+\nu\overline{\nu}) \approx 1.0 \times 10^{-10} A^4[\eta^2 + (\rho_o - \rho)^2] \qquad (2)$$

where $\rho_o \equiv 1 + (\frac{2}{3}X^{e}_{NL} + \frac{1}{3}X^{\tau}_{NL})/(A^2 V^4_{us} X(m_t)) \approx 1.4$. Thus, $\mathrm{B}(K^+ \to \pi^+\nu\overline{\nu})$ determines a circle in the ρ, η plane with center $(\rho_o, 0)$ and radius $\approx \frac{1}{A^2}\sqrt{\frac{\mathrm{B}(K^+\to\pi^+\nu\overline{\nu})}{1.0\times10^{-10}}}$.

The decay $K_L \to \mu^+\mu^-$ also has a short distance contribution sensitive to the CKM parameter ρ. For m_t = 175 GeV it is given by [10]:

$$\mathrm{B}_{\mathrm{SD}}(K_L \to \mu^+\mu^-) \approx 1.7 \times 10^{-9} A^4(\rho'_o - \rho)^2 \qquad (3)$$

where ρ'_o depends on the charm quark mass and is around 1.2. This decay, however, is dominated by a long-distance contribution from a two-photon intermediate state. The absorptive (imaginary) part of the long-distance component is calculated in terms of the measured rate for $K_L \to \gamma\gamma$ to be $\mathrm{B}_{\mathrm{abs}}(K_L \to \mu^+\mu^-) = (7.07 \pm 0.18) \times 10^{-9}$; and it almost completely saturates the observed rate $\mathrm{B}(K_L \to \mu^+\mu^-) = (7.18 \pm 0.17) \times 10^{-9}$ [20]. The difference between the observed rate and the absorptive component can be attributed to the (coherent) sum of the short-distance amplitude and the real part of the long-distance amplitude. In order to use this mode to constrain ρ it is, therefore, necessary to know the real part of the long-distance contribution. Unlike the absorptive part, the real part of the long-distance contribution cannot be derived from the measured rate for $K_L \to \gamma\gamma$. At present, it is not possible to compute this long-distance component reliably and, therefore, it is not possible to constrain ρ from this mode in a model independent way [21]. Several models exist to estimate this long-distance component [22,23] that are sufficient to place rough bounds on new physics from the measured rate for $K_L \to \mu^+\mu^-$ [24]. The decay $K_L \to e^+e^-$ is completely dominated by long distance physics and is easier to estimate. The result, $B(K_L \to e^+e^-) \sim 9 \times 10^{-12}$ [21,23], is in good agreement with the recent measurement [25]. It is expected that studies of the reactions $K_L \to \ell^+\ell^-\gamma$, and $K_L \to \ell^+\ell^-\ell'^+\ell'^-$ for $\ell, \ell' = e$ or μ, currently under active study by the KTeV and NA48 experiments, will improve our understanding of the long distance effects in $K_L \to \mu^+\mu^-$ (the current data is parameterized in terms of α^*_K, discussed on page 25 of the K^0_L Particle Properties Listing in our 1999 WWW update).

D. Searches for direct CP violation: The mode $K_L \to \pi^0\nu\overline{\nu}$ is dominantly CP-violating and free of hadronic uncertainties [2,26]. The Standard Model predicts a branching ratio $(3.0 \pm 1.3) \times 10^{-11}$; for m_t = 175 GeV it is given approximately by [10]:

$$\mathrm{B}(K_L \to \pi^0\nu\overline{\nu}) \approx 4.1 \times 10^{-10} A^4\eta^2 \ . \qquad (4)$$

The current upper bound is $\mathrm{B}(K_L \to \pi^0\nu\overline{\nu}) \leq 5.9 \times 10^{-7}$ [27] and KTeV (FNAL799II) is expected to place a bound of order 10^{-8} [28]. The 90% CL bound on $K^+ \to \pi^+\nu\overline{\nu}$ provides a nearly model independent bound $B(K_L \to \pi^0\nu\overline{\nu}) < 3 \times 10^{-9}$ [29]. A KEK experiment to reach the 10^{-10}/event level is in preparation [30]. The BNL-926 [31] proposal aims to make a $\sim$ 15% measurement of $\mathrm{B}(K_L \to \pi^0\nu\overline{\nu})$. There is also a Fermilab EOI [32] with comparable goals.

There has been much recent theoretical work on possible contributions to ϵ'/ϵ and rare K decays within a generic supersymmetric extension of the Standard Model with R parity conservation and minimal particle content [24,33]. These conclude that contributions to rare decays much larger than those of the Standard Model are possible without violating current phenomenological constraints.

The decay $K_L \to \pi^0e^+e^-$ also has sensitivity to the product $A^4\eta^2$. It has a direct CP-violating component that for m_t = 175 GeV is given by [10]:

$$\mathrm{B}_{\mathrm{dir}}(K_L \to \pi^0e^+e^-) \approx 6.7 \times 10^{-11} A^4\eta^2 \ . \qquad (5)$$

However, like $K_L \to \mu^+\mu^-$ this mode suffers from large theoretical uncertainties due to long distance strong interaction effects. It has an indirect CP-violating component given by:

$$\mathrm{B}_{\mathrm{ind}}(K_L \to \pi^0e^+e^-) = |\epsilon|^2 \frac{\tau_{K_L}}{\tau_{K_S}} \mathrm{B}(K_S \to \pi^0e^+e^-) \ , \qquad (6)$$

that has been estimated to be less than 10^{-12} [34], but that will not be known precisely until a measurement of $K_S \to \pi^0e^+e^-$ is available [4,35]. There is also a CP-conserving component dominated by a two-photon intermediate state that cannot be computed reliably at present. This component has an absorptive part that can be, in principle, determined from a detailed analysis of $K_L \to \pi^0\gamma\gamma$.

To understand the rate and the shape of the distribution $d\Gamma/dm_{\gamma\gamma}$ in $K_L \to \pi^0\gamma\gamma$ within chiral perturbation theory it is necessary to go beyond leading order. The measured rate and spectrum can be accommodated naturally, for example, by allowing only one of the free parameters that occur, a_V, to vary [36]. There is new data on this decay from KTeV [37] and a fit to the distribution has given $a_V = -0.72 \pm 0.05 \pm 0.06$. This value suggests that the absorptive part of the CP-conserving contribution to $K_L \to \pi^0e^+e^-$ could be comparable to the direct CP-violating component [37,35]. The related process, $K_L \to \pi^0\gamma e^+e^-$, is potentially an additional background in some region of phase space [38]. This process has recently been observed with a branching ratio of $(2.42 \pm 0.38_{stat} \pm 0.11_{sys}) \times 10^{-8}$ [39]. Finally, BNL-845 observed a potential background to $K_L \to \pi^0 e^+ e^-$ from the decay $K_L \to \gamma\gamma e^+ e^-$ [40]. This has recently been confirmed with a 500-fold larger sample by FNAL-799 [41], which measured additional kinematic quantities. It has been estimated that this background will enter at the level of 10^{-11} [42], comparable to the signal level. Because of this, the observation of $K_L \to \pi^0 e^+ e^-$ will depend on background subtraction with good statistics.

The current 90% CL preliminary upper bound for the process $K_L \to \pi^0 e^+ e^-$ is 5.64×10^{-10} [41]. For the closely related muonic process, the corresponding upper bound is $B(K_L \to \pi^0 \mu^+ \mu^-) \leq 3.8 \times 10^{-10}$ [43]. KTeV expects to reach a sensitivity of roughly 10^{-11} for both reactions [28].

***E. Other long distance dominated modes*:**

The decays $K^+ \to \pi^+ \ell^+ \ell^-$ ($\ell = e$ or μ) are described by leading order chiral perturbation theory in terms of one parameter, ω^+ [44]. It now appears that this parameterization is not sufficient to account for both the rate and the detailed shape of the spectrum in $K^+ \to \pi^+ e^+ e^-$ [45] An analysis beyond leading order in chiral perturbation theory can accommodate both the rate and the spectrum [46], at the cost of introducing at least one new parameter.

Γ_{43}	$\pi^+\gamma$		[f]		

[a] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[b] See the Particle Listings below for the energy limits used in this measurement.

[c] Direct-emission branching fraction.

[d] Structure-dependent part.

[e] Derived from an analysis of neutrino-oscillation experiments.

[f] Violates angular-momentum conservation.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life, 2 decay rate, and 20 branching ratios uses 60 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2=78.1$ for 53 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i\delta p_j\rangle/(\delta p_i\cdot\delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i\equiv\Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[25] LUCAS 73B gives $N(K_{\mu 3}) = 554 \pm 7.6\%$, $N(K_{e3}) = 786 \pm 3.1\%$. We divide.
[26] CHIANG 72 $\Gamma(\pi^0\mu^+\nu_\mu)/\Gamma(\pi^0 e^+\nu_e)$ is statistically independent of CHIANG 72 $\Gamma(\pi^0\mu^+\nu_\mu)/\Gamma_{total}$ and $\Gamma(\pi^0 e^+\nu_e)/\Gamma_{total}$.
[27] From CALLAHAN 66B we use only the $K_{\mu 3}/K_{e3}$ ratio and do not include in the fit the ratios $K_{\mu 3}/(\pi\pi^+\pi^0)$ and $K_{e3}/(\pi\pi^+\pi^0)$, since they show large disagreements with the rest of the data.
[28] HEINTZE 77 value from fit to λ_0. Assumes μ-e universality.
[29] BRAUN 75 value is from form factor fit. Assumes μ-e universality.
[30] HAIDT 71 is a reanalysis of EICHTEN 68. Only individual ratios included in fit (see $\Gamma(\pi^0\mu^+\nu_\mu)/\Gamma(\pi^+\pi^+\pi^-)$ and $\Gamma(\pi^0 e^+\nu_e)/\Gamma(\pi^+\pi^+\pi^-)$).

$[\Gamma(\pi^+\pi^0)+\Gamma(\pi^0\mu^+\nu_\mu)]/\Gamma_{total}$ — $(\Gamma_3+\Gamma_6)/\Gamma$

We combine these two modes for experiments measuring them in xenon bubble chamber because of difficulties of separating them there.

1.2 ±0.8		BELLOTTI	67	HLBC	+	$E(\gamma)$ >30 MeV

[46] BARMIN 91 quotes branching ratio $\Gamma(K \to e\pi^0\nu\gamma)/\Gamma_{all}$. The measured normalization is $[\Gamma(K \to e\pi^0\nu) + \Gamma(K \to \pi^+\pi^+\pi^-)]$. For comparison with other experiments we used $\Gamma(K \to e\pi^0\nu)/\Gamma_{all} = 0.0482$ to calculate the values quoted here.

[47] $\cos\theta(e\gamma)$ between 0.6 and 0.9.

[48] Both ROMANO 71 values are for $\cos\theta(e\gamma)$ between 0.6 and 0.9. Second value is for comparison with second LJUNG 73 value. We use lowest $E(\gamma)$ cut for Summary Table value. See ROMANO 71 for E_γ dependence.

[49] First LJUNG 73 value is for $\cos\theta(e\gamma) < 0.9$, second value is for $\cos\theta(e\gamma)$ between 0.6 and 0.9 for comparison with ROMANO 71.

[68] AOKI 94 measures $\xi P_\mu = -0.9996 \pm 0.0030 \pm 0.0048$. The above limit is obtained by summing the statistical and systematic errors in quadrature, normalizing to the physically significant region ($|\xi P_\mu| < 1$) and assuming that ξ=1, its maximum value.

[69] Assumes ξ=1.

DALITZ PLOT PARAMETERS FOR $K \rightarrow 3\pi$ DECAYS

Revised 1999 by T.G. Trippe (LBNL).

The Dalitz plot distribution for $K^{\pm} \rightarrow \pi^{\pm}\pi^{\pm}\pi^{\mp}$, $K^{\pm} \rightarrow \pi^0\pi^0\pi^{\pm}$, and $K^0_L \rightarrow \pi^+\pi^-\pi^0$ can be parameterized by a series expansion such as that introduced by Weinberg [1]. We use the form

$$\left|M\right|^2 \propto 1 + g\frac{(s_3 - s_0)}{am^2_{\pi^+}} + h\left[\frac{s_3 - s_0}{m^2_{\pi^+}}\right]^2 + j\ \frac{(s_2 - s_1)}{m^2_{\pi^+}} + k\left[\frac{s_2 - s_1}{m^2_{\pi^+}}\right]^2 + f\ \frac{(s_2 - s_1)}{m^2_{\pi^+}}\frac{(s_3 - s_0)}{m^2_{\pi^+}} + \cdots \ , \qquad (1)$$

where $m^2_{\pi^+}$ has been introduced to make the coefficients g, h, j, and k dimensionless, and

$$s_i = (P_K - P_i)^2 = (m_K - m_i)^2 - 2m_K T_i \ , \ i = 1,2,3,$$

$$s_0 = \frac{1}{3}\sum_i s_i = \frac{1}{3}(m^2_K + m^2_1 + m^2_2 + m^2_3)$$

Here the P_i are four-vectors, m_i and T_i are the mass and kinetic energy of the i^{th} pion, and the index 3 is used for the odd pion.

The coefficient g is a measure of the slope in the variable s_3 (or T_3) of the Dalitz plot, while h and k measure the quadratic dependence on s_3 and $(s_2 - s_1)$, respectively. The coefficient j is related to the asymmetry of the plot and must be zero if CP invariance holds. Note also that if CP is good, g, h, and k must be the same for $K^+ \rightarrow \pi^+\pi^+\pi^-$ as for $K^- \rightarrow \pi^-\pi^-\pi^+$.

Since different experiments use different forms for $\left|M\right|^2$, in order to compare the experiments we have converted to g, h, j, and k whatever coefficients have been measured. Where such conversions have been done, the measured coefficient a_y, a_t, a_u, or a_v is given in the comment at the right. For definitions of these coefficients, details of this conversion, and discussion of the data, see the April 1982 version of this note [2].

LINEAR COEFFICIENT g FOR $K^{\pm} \rightarrow \pi^{\pm}\pi^0\pi^0$

Unless otherwise stated, all experiments include terms quadratic in $(s_3 - s_0) / m^2_{\pi^+}$. See note above on "Dalitz Plot Parameters for $K \rightarrow 3\pi$ Decays."

See BATUSOV 98 for a discussion of the discrepancy between their result and others, especially BOLOTOV 86. At this time we have no way to resolve the discrepancy so we depend on the large scale factor as a warning.

$K^{\pm}_{\ell 3}$ AND $K^0_{\ell 3}$ FORM FACTORS

Written by T.G. Trippe (LBNL).

Assuming that only the vector current contributes to $K \rightarrow \pi \ell \nu$ decays, we write the matrix element as

$$M \propto f_+(t) \left[(P_K + P_\pi)_\mu \bar{\ell}\gamma_\mu(1+\gamma_5)\nu\right] + f_-(t) \left[m_\ell \bar{\ell}(1+\gamma_5)\nu\right] , \quad (1)$$

where P_K and P_π are the four-momenta of the K and π mesons, m_ℓ is the lepton mass, and f_+ and f_- are dimensionless form factors which can depend only on $t = (P_K - P_\pi)^2$, the square of the four-momentum transfer to the leptons. If time-reversal invariance holds, f_+ and f_- are relatively real. $K_{\mu 3}$ experiments measure f_+ and f_-, while K_{e3} experiments are sensitive only to f_+ because the small electron mass makes the f_- term negligible.

(a) $K_{\mu 3}$ experiments. Analyses of $K_{\mu 3}$ data frequently assume a linear dependence of f_+ and f_- on t, *i.e.*,

$$f_\pm(t) = f_\pm(0)\left[1 + \lambda_\pm (t/m_\pi^2)\right] \quad (2)$$

Most $K_{\mu 3}$ data are adequately described by Eq. (2) for f_+ and a constant f_- (*i.e.*, $\lambda_- = 0$). There are two equivalent parametrizations commonly used in these analyses:

(1) $\lambda_+, \xi(0)$ parametrization. Analyses of $K_{\mu 3}$ data often introduce the ratio of the two form factors

$$\xi(t) = f_-(t)/f_+(t) \ . \quad (3)$$

The $K_{\mu 3}$ decay distribution is then described by the two parameters λ_+ and $\xi(0)$ (assuming time reversal invariance and $\lambda_- = 0$). These parameters can be determined by three different methods:

Method A. By studying the Dalitz plot or the pion spectrum of $K_{\mu 3}$ decay. The Dalitz plot density is (see, *e.g.*, Chounet *et al.* [1]):

$$\rho(E_\pi, E_\mu) \propto f_+^2(t)\left[A + B\xi(t) + C\xi(t)^2\right] ,$$

where

$$A = m_K\left(2E_\mu E_\nu - m_K E'_\pi\right) + m_\mu^2\left(\frac{1}{4}E'_\pi - E_\nu\right) ,$$

$$B = m_\mu^2\left(E_\nu - \frac{1}{2}E'_\pi\right) ,$$

$$C = \frac{1}{4}m_\mu^2 E'_\pi ,$$

$$E'_\pi = E_\pi^{\max} - E_\pi = \left(m_K^2 + m_\pi^2 - m_\mu^2\right)/2m_K - E_\pi \ . \quad (4)$$

Here E_π, E_μ, and E_ν are, respectively, the pion, muon, and neutrino energies in the kaon center of mass. The density ρ is fit to the data to determine the values of $\lambda_+, \xi(0)$, and their correlation.

Method B. By measuring the $K_{\mu 3}/K_{e3}$ branching ratio and comparing it with the theoretical ratio (see, *e.g.*, Fearing *et al.* [2]) as given in terms of λ_+ and $\xi(0)$, assuming μ-e universality:

$$\Gamma(K^{\pm}_{\mu 3})/\Gamma(K^{\pm}_{e3}) = 0.6457 + 1.4115\lambda_+ + 0.1264\xi(0) + 0.0192\xi(0)^2 + 0.0080\lambda_+\xi(0) ,$$

$$\Gamma(K^0_{\mu 3})/\Gamma(K^0_{e3}) = 0.6452 + 1.3162\lambda_+ + 0.1264\xi(0) + 0.0186\xi(0)^2 + 0.0064\lambda_+\xi(0) \ . \quad (5)$$

This cannot determine λ_+ and $\xi(0)$ simultaneously but simply fixes a relationship between them.

Method C. By measuring the muon polarization in $K_{\mu 3}$ decay. In the rest frame of the K, the μ is expected to be polarized in the direction $\mathbf{A}$ with $\mathbf{P} = \mathbf{A}/\left|\mathbf{A}\right|$, where $\mathbf{A}$ is given (Cabibbo and Maksymowicz [3]) by

$$\mathbf{A} = a_1(\xi)\mathbf{p}_\mu - a_2(\xi)\left[\frac{\mathbf{p}_\mu}{m_\mu}\left(m_K - E_\pi + \frac{\mathbf{p}_\pi \cdot \mathbf{p}_\mu}{\left|\mathbf{p}_\mu\right|^2}(E_\mu - m_\mu)\right) + \mathbf{p}_\pi\right] + m_K \mathrm{Im}\xi(t)(\mathbf{p}_\pi \times \mathbf{p}_\mu) \ . \quad (6)$$

If time-reversal invariance holds, ξ is real, and thus there is no polarization perpendicular to the K-decay plane. Polarization experiments measure the weighted average of $\xi(t)$ over the t range of the experiment, where the weighting accounts for the variation with t of the sensitivity to $\xi(t)$.

(2) λ_+, λ_0 parametrization. Most of the more recent $K_{\mu 3}$ analyses have parameterized in terms of the form factors f_+ and f_0 which are associated with vector and scalar exchange, respectively, to the lepton pair. f_0 is related to f_+ and f_- by

$$f_0(t) = f_+(t) + \left[t/(m_K^2 - m_\pi^2)\right] f_-(t) \ . \quad (7)$$

Here $f_0(0)$ must equal $f_+(0)$ unless $f_-(t)$ diverges at $t = 0$. The earlier assumption that f_+ is linear in t and f_- is constant leads to f_0 linear in t:

$$f_0(t) = f_0(0)\left[1 + \lambda_0 (t/m_\pi^2)\right] \ . \quad (8)$$

With the assumption that $f_0(0) = f_+(0)$, the two parametrizations, $(\lambda_+, \xi(0))$ and (λ_+, λ_0) are equivalent as long as correlation information is retained. (λ_+, λ_0) correlations tend to be less strong than $(\lambda_+, \xi(0))$ correlations.

The experimental results for $\xi(0)$ and its correlation with λ_+ are listed in the $K^{\pm}$ and K^0_L sections of the Particle Listings in section ξ_A, ξ_B, or ξ_C depending on whether method A, B, or C discussed above was used. The corresponding values of λ_+ are also listed.

Because recent experiments tend to use the (λ_+, λ_0) parametrization, we include a subsection for λ_0 results. Wherever possible we have converted $\xi(0)$ results into λ_0 results and vice versa.

See the 1982 version of this note [4] for additional discussion of the $K^0_{\mu 3}$ parameters, correlations, and conversion between parametrizations, and also for a comparison of the experimental results.

(b) K_{e3} experiments. Analysis of K_{e3} data is simpler than that of $K_{\mu 3}$ because the second term of the matrix element assuming a pure vector current [Eq. (1) above] can be neglected. Here f_+ is usually assumed to be linear in t, and the linear coefficient λ_+ of Eq. (2) is determined.

If we remove the assumption of a pure vector current, then the matrix element for the decay, in addition to the terms in Eq. (1), would contain

$$+2m_K f_S \bar{\ell}(1+\gamma_5)\nu$$
$$+(2f_T/m_K)(P_K)_\lambda (P_\pi)_\mu \bar{\ell}\, \sigma_{\lambda\mu}(1+\gamma_5)\nu \ , \qquad (9)$$

where f_S is the scalar form factor, and f_T is the tensor form factor. In the case of the K_{e3} decays where the f_- term can be neglected, experiments have yielded limits on $|f_S/f_+|$ and $|f_T/f_+|$.

$K^{\pm}_{\ell 3}$ FORM FACTORS

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.

f_S and f_T refer to the scalar and tensor term.

$f_0 = f_+ + f_- t/(m^2_K - m^2_\pi)$.

λ_+, λ_-, and λ_0 are the linear expansion coefficients of f_+, f_-, and f_0.

λ_+ refers to the $K^{\pm}_{\mu 3}$ value except in the $K^{\pm}_{e3}$ sections.

$d\xi(0)/d\lambda_+$ is the correlation between $\xi(0)$ and λ_+ in $K^{\pm}_{\mu 3}$.

$d\lambda_0/d\lambda_+$ is the correlation between λ_0 and λ_+ in $K^{\pm}_{\mu 3}$.

t = momentum transfer to the π in units of m^2_π.

DP = Dalitz plot analysis.

PI = π spectrum analysis.

MU = μ spectrum analysis.

POL= μ polarization analysis.

BR = $K^{\pm}_{\mu 3}/K^{\pm}_{e3}$ branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN $K^{\pm}_{e3}$ DECAY)

For radiative correction of $K^{\pm}_{e3}$ Dalitz plot, see GINSBERG 67 and BECHERRAWY 70.

+1.8 ±0.6		76	BROWN 62B	XEBC	+	DP+BR, $\lambda_+=0$

[85] ARNOLD 74 figure 4 was used to obtain ξ_A and $d\xi(0)/d\lambda_+$.

[86] MERLAN 74 figure 5 was used to obtain $d\xi(0)/d\lambda_+$.

[87] BRAUN 73C gives $\xi(t) = -0.34 \pm 0.20$, $d\xi(t)/d\lambda_+ = -14$ for $\lambda_+ = 0.027$, $t = 6.6$. We calculate above $\xi(0)$ and $d\xi(0)/d\lambda_+$ for their $\lambda_+ = 0.025 \pm 0.017$.

[88] ANKENBRANDT 72 figure 3 was used to obtain $d\xi(0)/d\lambda_+$.

[89] CHIANG 72 figure 10 was used to obtain $d\xi(0)/d\lambda_+$. Fit had $\lambda_- = \lambda_+$ but would not change for $\lambda_- = 0$. L.Pondrom, (private communication 74).

[90] HAIDT 71 table 8 (Dalitz plot analysis) gives $d\xi(0)/d\lambda_+ = (-1.1+0.5)/(0.050-0.029) = -29$, error raised from 0.50 to agree with $d\xi(0) = 0.20$ for fixed λ_+.

[91] KIJEWSKI 69 figure 17 was used to obtain $d\xi(0)/d\lambda_+$ and errors.

[92] CALLAHAN 66 table 1 (π analysis) gives $d\xi(0)/d\lambda_+ = (0.72-0.05)/(0-0.04) = -17$, error raised from 0.80 to agree with $d\xi(0) = 0.37$ for fixed λ_+. t unknown.

[93] JENSEN 64 gives $\lambda^\mu_+ = \lambda^e_+ = -0.020 \pm 0.027$. $d\xi(0)/d\lambda_+$ unknown. Includes SHAKLEE 64 $\xi_B(K_{\mu 3}/K_{e3})$.

$\xi_B = f_-/f_+$ (determined from $K^{\pm}_{\mu 3}/K^{\pm}_{e3}$)

The $K^{\pm}_{\mu 3}/K^{\pm}_{e3}$ branching ratio fixes a relationship between $\xi(0)$ and λ_+. We quote the author's $\xi(0)$ and associated λ_+ but do not average because the λ_+ values differ. The fit result and scale factor given below are not obtained from these ξ_B values. Instead they are obtained directly from the fitted $K^{\pm}_{\mu 3}/K^{\pm}_{e3}$ ratio $\Gamma(\pi^0 \mu^+ \nu_\mu)/\Gamma(\pi^0 e^+ \nu_e)$, with the exception of HEINTZE 77. The parameter ξ is redundant with λ_0 below and is not put into the Meson Summary Table.

+0.062±0.024	0.0	3000	[111] ARTEMOV	97	SPEC	−	DP
−0.017±0.011			[112] BRAUN	74	HLBC	+	$K_{\mu 3}/K_{e3}$ vs. t

[105] ARTEMOV 97B does not give $d\lambda_0/d\lambda_+$ so we take it to be zero.
[106] HEINTZE 77 uses $\lambda_+ = 0.029 \pm 0.003$. $d\lambda_0/d\lambda_+$ estimated by us.
[107] λ_0 value is for $\lambda_+ = 0.03$ calculated by us from $\xi(0)$ and $d\xi(0)/d\lambda_+$.
[108] MERLAN 74 λ_0 and $d\lambda_0/d\lambda_+$ were calculated by us from ξ_A, λ^{μ}_+, and $d\xi(0)/d\lambda_+$. Their figure 6 gives $\lambda_0 = -0.025 \pm 0.012$ and no $d\lambda_0/d\lambda_+$.
[109] This value and error are taken from BRAUN 75 but correspond to the BRAUN 73C λ^{μ}_+ result. $d\lambda_0/d\lambda_+$ is from BRAUN 73C $d\xi(0)/d\lambda_+$ in ξ_A above.
[110] λ_0 calculated by us from $\xi(0)$, λ^{μ}_+, and $d\xi(0)/d\lambda_+$.
[111] ARTEMOV 97 does not give $d\lambda_0/d\lambda_+$ so we take it to be zero. Superseded by ARTEMOV 97B.
[112] BRAUN 74 is a combined $K_{\mu 3}$-K_{e3} result. It is not independent of BRAUN 73C ($K_{\mu 3}$) and BRAUN 73B (K_{e3}) form factor results.

DECAY FORM FACTORS FOR $K^{\pm} \rightarrow \pi^+\pi^- e^{\pm}\nu_e$

Given in ROSSELET 77, BEIER 73, and BASILE 71C.

DECAY FORM FACTOR FOR $K^{\pm} \rightarrow \pi^0\pi^0 e^{\pm}\nu$

Given in BOLOTOV 86B and BARMIN 88B.

$K^{\pm} \to \ell^{\pm} \nu \gamma$ FORM FACTORS

For definitions of the axial-vector F_A and vector F_V form factor, see the "Note on $\pi^{\pm} \to \ell^{\pm} \nu \gamma$ and $K^{\pm} \to \ell^{\pm} \nu \gamma$ Form Factors" in the $\pi^{\pm}$ section. In the kaon literature, often different definitions $a_K = F_A/m_K$ and $v_K = F_V/m_K$ are used.

$F_A + F_V$, SUM OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR $K \to e \nu_e \gamma$

T-VIOLATION PARAMETER IN K^0-$\overline{K}^0$ MIXING

The asymmetry $A_T = \frac{\Gamma(\overline{K}^0 \to K^0) - \Gamma(K^0 \to \overline{K}^0)}{\Gamma(\overline{K}^0 \to K^0) + \Gamma(K^0 \to \overline{K}^0)}$ must vanish if *T* invariance holds.

ASYMMETRY A_T IN K^0-$\overline{K}^0$ MIXING

VALUE (units 10^{-3})	*EVTS*	*DOCUMENT ID*		*TECN*
6.6±1.3±1.0	640k	[1] ANGELOPO...	98E	CPLR

[1] ANGELOPOULOS 98E measures the asymmetry $A_T = [\Gamma(\overline{K}^0_{t=0} \to e^+\pi^-\nu_{t=\tau}) - \Gamma(K^0_{t=0} \to e^-\pi^+\overline{\nu}_{t=\tau})]/[\Gamma(\overline{K}^0_{t=0} \to e^+\pi^-\nu_{t=\tau}) + \Gamma(K^0_{t=0} \to e^-\pi^+\overline{\nu}_{t=\tau})]$ as a function of the neutral-kaon eigentime τ. The initial strangeness of the neutral kaon is tagged by the charge of the accompanying charged kaon in the reactions $p\overline{p} \to K^-\pi^+K^0$ and $p\overline{p} \to K^+\pi^-\overline{K}^0$. The strangeness at the time of the decay is tagged by the lepton charge. The reported result is the average value of A_T over the interval $1\tau_S < \tau < 20\tau_S$.

CPT INVARIANCE TESTS IN NEUTRAL KAON DECAY

Written September 1999 by P. Bloch, CERN.

The time evolution of a neutral kaon state state is described by

$$\frac{d}{dt}\Psi = -i\Lambda\Psi \ , \quad \Lambda \equiv M - \frac{i}{2}\Gamma \qquad (1)$$

where M and Γ are Hermitian 2×2 matrices known as the mass and decay matrices. The corresponding eigenvalues are $\lambda_{L,S} = m_{L,S} - \frac{i}{2}\gamma_{L,S}$. *CPT* invariance requires the diagonal elements of Λ to be equal. The *CPT*-violation complex parameter Δ is defined as

$$\Delta = \frac{\Lambda_{\overline{K}^0\overline{K}^0} - \Lambda_{K^0K^0}}{2(\lambda_L - \lambda_S)} = \Delta_{\|}\exp\Big(i\phi_{SW}\Big) + \Delta_{\perp}\exp\Big(i(\phi_{SW} + \frac{\pi}{2})\Big) \qquad (2)$$

where we have introduced the projections $\Delta_{\|}$ and $\Delta_{\perp}$ respectively parallel and perpendicular to the superweak direction $\phi_{SW} = \tan^{-1}(2\Delta m/\Delta\gamma)$. These projections are linked to the mass and width difference between K^0 and $\overline{K}^0$:

$$\Delta_{\|} = \frac{1}{4}\frac{\gamma_{K^0} - \gamma_{\overline{K}^0}}{\sqrt{\Delta m^2 + \left(\frac{\Delta\gamma}{2}\right)^2}} \ , \ \Delta_{\perp} = \frac{1}{2}\frac{m_{K^0} - m_{\overline{K}^0}}{\sqrt{\Delta m^2 + \left(\frac{\Delta\gamma}{2}\right)^2}} \ . \qquad (3)$$

Re(Δ) can be directly measured by studying the time evolution of the strangeness content of initially pure K^0 and $\overline{K}^0$ states, for example through the asymmetry

$$A_{CPT} = \frac{P[\overline{K}^0 \to \overline{K}^0(t)] - P[K^0 \to K^0(t)]}{P[\overline{K}^0 \to \overline{K}^0(t)] + P[K^0 \to K^0(t)]} = 4\text{Re}(\Delta) \qquad (4)$$

where $P[a \to b(t)]$ is the probability that the pure initial state a is seen as state b at proper time t. This method has been used by tagging the initial strangeness with strong interactions and the final strangeness with the semileptonic decay (a more appropriate combination of semileptonic rates allows to be independent of any direct CPT violation in the decay itself) and yields today's best value of Re(Δ), compatible with zero with an error of $\sim 3 \times 10^{-4}$.

As an alternative it has been proposed to compare the semileptonic charge asymmetries for K_L and K_S

$$\delta_{L,S} = \frac{R(K_{L,S} \to \pi^-\ell^+\nu) - R(K_{L,S} \to \pi^+\ell^-\overline{\nu})}{R(K_{L,S} \to \pi^-\ell^+\nu) + R(K_{L,S} \to \pi^+\ell^-\overline{\nu})} ,$$

$$\delta_S - \delta_L = 4\mathrm{Re}(\Delta) . \quad (5)$$

δ_L has been accurately measured and δ_S should be measured in the near future with tagged K_S at ϕ factories. Note however that Eq. (5) assumes CPT invariance in the $\Delta S = -\Delta Q$ semileptonic decay amplitude.

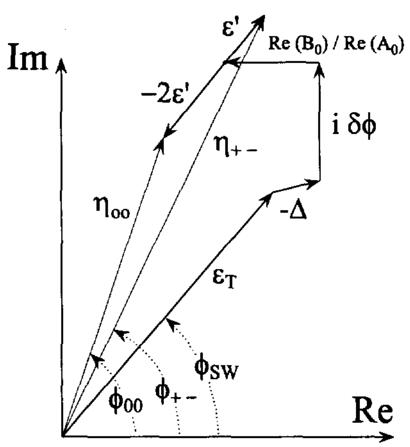

Figure 1: CP- and CPT-violation parameters in 2π decay.

$\Delta_\perp$ can be obtained from the measurement of the $\pi\pi$ decays CP-violation parameters η_{+-} and η_{00}. Figure 1 shows the various contributions to $\eta_{\pi\pi}$ [1]. The T-violation parameter ϵ_T

$$\epsilon_T = i\frac{|\Lambda_{K^0\overline{K}^0}|^2 - |\Lambda_{\overline{K}^0K^0}|^2}{\Delta\gamma(\lambda_L - \lambda_S)} \quad (6)$$

has been defined in such a way that it is exactly aligned along the superweak direction [‡]. A_I (resp. B_I) is the CPT-conserving (resp. violating) decay amplitude for the $\pi\pi$ Isospin I state, ε' is the direct CP/CPT-violation parameter $[\varepsilon' = 1/3(\eta_{+-} - \eta_{00})]$ and $\delta\phi = \frac{1}{2}\left[\varphi_\Gamma - \arg(A_0^*\overline{A}_0)\right]$ is the phase difference between the $I = 0$ component of the decay amplitude and the matrix element $\Gamma_{K^0\overline{K}^0}$. From Fig. 1 one obtains

$$\Delta_\perp = |\eta_{+-}|(\phi_{SW} - \frac{2}{3}\phi_{+-} - \frac{1}{3}\phi_{00}) - \frac{\mathrm{Re}(B_0)}{\mathrm{Re}(A_0)}\sin(\phi_{SW}) + \delta\phi\ \cos(\phi_{SW}) . \quad (7)$$

The present accuracy on the term $|\eta_{+-}|(\phi_{SW} - \frac{2}{3}\phi_{+-} - \frac{1}{3}\phi_{00})$ is 2.6×10^{-5}. $\delta\phi$ gets contributions from CP violation in semileptonic and 3π decays [2,3] and can only be neglected at the present time if one assumes that η_{000} is not significantly larger than η_{+-0}. Furthermore, B_0 is not directly measured, so additional assumptions (for example, CPT conservation in the decay which implies $B_0 = 0$) or a combination with other measurements are necessary to obtain $\Delta_\perp$.

If one assumes unitarity, one can measure Im(Δ) using the Bell-Steinberger relation which relates K_S and K_L decay amplitudes into all final states f:

$$\mathrm{Re}(\epsilon_T) - i\mathrm{Im}(\Delta) = \frac{1}{2(i\Delta m + \frac{1}{2}(\gamma_L + \gamma_S))} \times \sum A_{fL}A^*_{fS} . \quad (8)$$

Since the $\pi\pi$ amplitudes dominate, the result relies also strongly on the $\phi_{\pi\pi}$ phase measurements. The advantage is that B_0 does not enter. Using all available data, one obtains a value of Im(Δ) compatible with zero with a precision of 5×10^{-5}. The precision here is also limited by the poor measurement of η_{000}.

The results on Re(Δ) and Im(Δ) can be combined to obtain $\Delta_\parallel$ and $\Delta_\perp$ and therefore the K^0–$\overline{K}^0$ mass and width difference shown in Fig. 2. The current accuracy is a few 10^{-18} GeV for both.

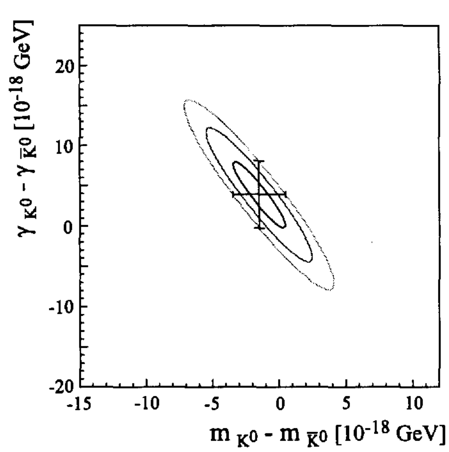

Figure 2: K^0–$\overline{K}^0$ mass vs width difference.

If one assumes that CPT is conserved in the decays ($\gamma_{K^0} = \gamma_{\overline{K}^0}$, $\Delta_\parallel = 0$, $B_I = 0$), the phase of Δ is known, and the $\Delta_\perp$ and Bell-Steinberger methods are identical. Assuming in addition $\eta_{+-0} = \eta_{000}$, one in this case obtains a limit for $|m_{K^0} - m_{\overline{K}^0}|$ of 4.4×10^{-19} GeV (90%CL).

Footnotes and References

[‡] Many authors have a different definition of the T-violation parameter, $\epsilon = (\Lambda_{\overline{K}^0K^0} - \Lambda_{K^0\overline{K}^0})/(2(\lambda_L - \lambda_S))$. ϵ is not exactly aligned with the superweak direction. The two definitions can be related through $\epsilon = \epsilon_T + i\delta\phi$.

CPT-VIOLATION PARAMETERS IN K^0-$\overline{K}^0$ MIXING

If CP-violating interactions include a T conserving part then

$$|K_S\rangle = [|K_1\rangle+(\epsilon+\Delta)|K_2\rangle]/\sqrt{1+|\epsilon+\Delta|^2}$$
$$|K_L\rangle = [|K_2\rangle+(\epsilon-\Delta)|K_1\rangle]/\sqrt{1+|\epsilon-\Delta|^2}$$

where

$$|K_1\rangle = [|K^0\rangle + |\overline{K}^0\rangle]/\sqrt{2}$$
$$|K_2\rangle = [|K^0\rangle - |\overline{K}^0\rangle]/\sqrt{2}$$

and

$$|\overline{K}^0\rangle = CP|K^0\rangle.$$

The parameter Δ specifies the CPT-violating part.

Estimates of Δ are given below assuming the validity of the $\Delta S=\Delta Q$ rule. See also THOMSON 95 for a test of CPT-symmetry conservation in K^0 decays using the Bell-Steinberger relation.

0.872 ±0.009	20000	[5,6] HILL	68	DBC	
0.866 ±0.016		[5] ALFF-...	66B	OSPK	
0.843 ±0.013	5000	[5] KIRSCH	66	HBC	

[1] CARITHERS 75 value is for $m_{K^0_L} - m_{K^0_S}$ $\Delta m = 0.5301 \pm 0.0013$. The Δm dependence of the total decay rate (inverse mean life) is $\Gamma(K^0_S) = [(1.122 \pm 0.004)+0.16(\Delta m - 0.5348)/\Delta m]10^{10}$/s, or, in terms of meanlife $\tau_S = 0.8913 \pm 0.0032 - 0.238(\Delta m - 0.5348)$ where Δm and τ_S are in units of $10^{10}\hbar s^{-1}$ and 10^{-10}s respectively.
[2] HILL 68 has been changed by the authors from the published value (0.865 ± 0.009) because of a correction in the shift due to η_{+-}. SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.
[3] ARONSON 82 find that K^0_S mean life may depend on the kaon energy.
[4] FACKLER 73 does not include systematic errors.
[5] Pre-1971 experiments are excluded from the average because of disagreement with later more precise experiments.
[6] HILL 68 has been changed by the authors from the published value (0.865 ± 0.009) because of a correction in the shift due to η_{+-}. SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

K^0_S DECAY MODES

	Mode		Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Γ_1	$\pi^+\pi^-$		(68.61±0.28) %	S=1.2
Γ_2	$\pi^0\pi^0$		(31.39±0.28) %	S=1.2
Γ_3	$\pi^+\pi^-\gamma$	[a,b]	(1.78±0.05) × 10^{-3}	
Γ_4	$\gamma\gamma$		(2.4 ±0.9) × 10^{-6}	
Γ_5	$\pi^+\pi^-\pi^0$		(3.2 $^{+1.2}_{-1.0}$) × 10^{-7}	
Γ_6	$3\pi^0$		< 1.4 × 10^{-5}	CL=90%
Γ_7	$\pi^\pm e^\mp \nu_e$	[c]	(7.2 ±1.4) × 10^{-4}	
Γ_8	$\pi^\pm \mu^\mp \nu_\mu$	[c]		
	$\Delta S = 1$ weak neutral current (S1) modes			
Γ_9	$\mu^+\mu^-$	S1	< 3.2 × 10^{-7}	CL=90%
Γ_{10}	e^+e^-	S1	< 1.4 × 10^{-7}	CL=90%
Γ_{11}	$\pi^0 e^+ e^-$	S1	< 1.1 × 10^{-6}	CL=90%

[a] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.
[b] See the Particle Listings below for the energy limits used in this measurement.
[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 17 measurements and one constraint to determine 2 parameters. The overall fit has a χ^2 = 16.5 for 16 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i \delta x_j\rangle/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CP VIOLATION IN $K_S \to 3\pi$

Written 1996 by T. Nakada (Paul Scherrer Institute) and L. Wolfenstein (Carnegie-Mellon University).

The possible final states for the decay $K^0 \to \pi^+\pi^-\pi^0$ have isospin $I = 0$, 1, 2, and 3. The $I = 0$ and $I = 2$ states have $CP = +1$ and K_S can decay into them without violating CP symmetry, but they are expected to be strongly suppressed by centrifugal barrier effects. The $I = 1$ and $I = 3$ states, which have no centrifugal barrier, have $CP = -1$ so that the K_S decay to these requires CP violation.

In order to see CP violation in $K_S \to \pi^+\pi^-\pi^0$, it is necessary to observe the interference between K_S and K_L decay, which determines the amplitude ratio

$$\eta_{+-0} = \frac{A(K_S \to \pi^+\pi^-\pi^0)}{A(K_L \to \pi^+\pi^-\pi^0)} \ . \tag{1}$$

If η_{+-0} is obtained from an integration over the whole Dalitz plot, there is no contribution from the $I = 0$ and $I = 2$ final states and a nonzero value of η_{+-0} is entirely due to CP violation.

Only $I = 1$ and $I = 3$ states, which are $CP = -1$, are allowed for $K^0 \to \pi^0\pi^0\pi^0$ decays and the decay of K_S into $3\pi^0$ is an unambiguous sign of CP violation. Similarly to η_{+-0}, η_{000} is defined as

$$\eta_{000} = \frac{A(K_S \to \pi^0\pi^0\pi^0)}{A(K_L \to \pi^0\pi^0\pi^0)} \ . \tag{2}$$

If one assumes that CPT invariance holds and that there are no transitions to $I = 3$ (or to nonsymmetric $I = 1$ states), it can be shown that

$$\eta_{+-0} = \eta_{000}$$
$$= \epsilon + i\frac{\text{Im } a_1}{\text{Re } a_1} \ . \tag{3}$$

With the Wu-Yang phase convention, a_1 is the weak decay amplitude for K^0 into $I = 1$ final states; ϵ is determined from CP violation in $K_L \to 2\pi$ decays. The real parts of η_{+-0} and η_{000} are equal to Re(ϵ). Since currently-known upper limits on $|\eta_{+-0}|$ and $|\eta_{000}|$ are much larger than $|\epsilon|$, they can be interpreted as upper limits on Im(η_{+-0}) and Im(η_{000}) and so as limits on the CP-violating phase of the decay amplitude a_1.

CP-VIOLATION PARAMETERS IN K^0_S DECAY

$\text{Im}(\eta_{+-0})^2 = \Gamma(K^0_S \to \pi^+\pi^-\pi^0,\ CP\text{-violating}) / \Gamma(K^0_L \to \pi^+\pi^-\pi^0)$

CPT assumed valid (i.e. Re(η_{+-0}) $\simeq$ 0).

[28] BARMIN 85 find Re(η_{+-0}) = (0.05 ± 0.17) and Im(η_{+-0}) = (0.15 ± 0.33). Includes events of BALDO-CEOLIN 75.

[29] These authors find Re(A) = 2.75 ± 0.65, above value at Re(A) = 0.

$\text{Im}(\eta_{+-0}) = \text{Im}(A(K^0_S \to \pi^+\pi^-\pi^0,\ CP\text{-violating}) / A(K^0_L \to \pi^+\pi^-\pi^0))$

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
$\mathbf{-0.002\pm0.009^{+0.002}_{-0.001}}$	500k	[30] ADLER	97B	CPLR	
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$-0.002\pm0.018\pm0.003$	137k	[31] ADLER	96D	CPLR	Sup. by ADLER 97B
$-0.015\pm0.017\pm0.025$	272k	[32] ZOU	94	SPEC	

[30] ADLER 97B also find Re(η_{+-0}) = $-0.002 \pm 0.007^{+0.004}_{-0.001}$. See also ANGELOPOULOS 98C.

[31] The ADLER 96D fit also yields Re(η_{+-0}) = 0.006 ± 0.013 ± 0.001 with a correlation +0.66 between real and imaginary parts. Their results correspond to $|\eta_{+-0}| < 0.037$ with 90% CL.

[32] ZOU 94 use theoretical constraint Re(η_{+-0}) = Re(ϵ) = 0.0016. Without this constraint they find Im(η_{+-0}) = 0.019 ± 0.061 and Re(η_{+-0}) = 0.019 ± 0.027.

$\text{Im}(\eta_{000})^2 = \Gamma(K^0_S \to 3\pi^0) / \Gamma(K^0_L \to 3\pi^0)$

CPT assumed valid (i.e. Re(η_{000}) $\simeq$ 0). This limit determines branching ratio $\Gamma(3\pi^0)/\Gamma_{\rm total}$ above.

VALUE	CL%	EVTS	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •						
<0.1	90	632	[33] BARMIN	83	HLBC	
<0.28	90		[34] GJESDAL	74B	SPEC	Indirect meas.
<1.2	90	22	BARMIN	73	HLBC	

[33] BARMIN 83 find Re(η_{000}) = (−0.08 ± 0.18) and Im(η_{000}) = (−0.05 ± 0.27). Assuming *CPT* invariance they obtain the limit quoted above.

[34] GJESDAL 74B uses $K2\pi$, $K_{\mu3}$, and K_{e3} decay results, unitarity, and *CPT*. Calculates $|(\eta_{000})| = 0.26 \pm 0.20$. We convert to upper limit.

$\text{Im}(\eta_{000}) = \text{Im}(A(K^0_S \to \pi^0\pi^0\pi^0)/A(K^0_L \to \pi^0\pi^0\pi^0))$

$K^0_S \to \pi^0\pi^0\pi^0$ violates *CP* conservation, in contrast to $K^0_S \to \pi^+\pi^-\pi^0$ which has a *CP*-conserving part.

VALUE	EVTS	DOCUMENT ID		TECN
−0.05±0.12±0.05	17300	[35] ANGELOPO...	98B	CPLR

[35] ANGELOPOULOS 98B assumes Re(η_{000}) = Re(ϵ) = 1.635×10^{-3}. Without assuming *CPT* invariance, they obtain Re(η_{000}) = 0.18 ± 0.14 ± 0.06 and Im(η_{000}) = 0.15 ± 0.20 ± 0.03.

K^0_L

$I(J^P) = \frac{1}{2}(0^-)$

$m_{K^0_L} - m_{K^0_S}$

For earlier measurements, beginning with GOOD 61 and FITCH 61, see our 1986 edition, Physics Letters **170B** 132 (1986).

OUR FIT is described in the note on "Fits for K^0_L *CP*-Violation Parameters" in the K^0_L Particle Listings.

[1] Uses $\overline{K}^0_{e3}$ and K^0_{e3} strangeness tagging at production and decay.

[2] Fits Δm and ϕ_{+-} simultaneously. GIBBONS 93C systematic error is from B. Winstein via private communtication.

[3] These two experiments have a common systematic error due to the uncertainty in the momentum scale, as pointed out in WAHL 89.

[4] ADLER 96C is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value above.

[5] GIBBONS 93 value assume $\phi_{+-} = \phi_{00} = \phi_{SW} = (43.7 \pm 0.2)°$.

[6] ARONSON 82 find that Δm may depend on the kaon energy.

[7] ARONSON 70 and CARNEGIE 71 use K^0_S mean life $= (0.862 \pm 0.006) \times 10^{-10}$ s. We have not attempted to adjust these values for the subsequent change in the K^0_S mean life or in η_{+-}.

Γ_{33}	$e^\pm e^\pm\mu^\mp\mu^\mp$	LF [a]	$< 6.1 \times 10^{-9}$	CL=90%
Γ_{34}	$\pi^0\mu^\pm e^\mp$	LF [a]	$< 6.2 \times 10^{-9}$	CL=90%

[a] The value is for the sum of the charge states or particle/antiparticle states indicated.

[b] See the Particle Listings below for the energy limits used in this measurement.

[c] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[d] Allowed by higher-order electroweak interactions.

[e] Violates *CP* in leading order. Test of direct *CP* violation since the indirect *CP*-violating and *CP*-conserving contributions are expected to be suppressed.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life, 4 decay rate, and 12 branching ratios uses 46 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 40.5$ for 39 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i \delta p_j\rangle/(\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	−19						
x_3	−37	−28					
x_6	−49	−28	−36				
x_9	−7	21	−5	−5

• • • We do not use the following data for averages, fits, limits, etc. • • •					
2.5 ±0.3	98	[9] JAMES	71	HBC	Assumes *CP*
3.26±0.77	18	ANDERSON	65	HBC	
1.4 ±0.4	14	FRANZINI	65	HBC	

In the fit this rate is well determined by the mean life and the branching ratio $\Gamma(\pi^+\pi^-\pi^0)/\left[\Gamma(\pi^+\pi^-\pi^0) + \Gamma(\pi^\pm\mu^\mp\nu_\mu) + \Gamma(\pi^\pm e^\mp\nu_e)\right]$. For this reason the discrepancy between the $\Gamma(\pi^+\pi^-\pi^0)$ measurements does not affect the scale factor of the overall fit.

[9] JAMES 72 is a final measurement and includes JAMES 71.

[65] Quadratic dependence required by some experiments. (See sections on "QUADRATIC COEFFICIENT *h*" and "QUADRATIC COEFFICIENT *k*" below.) Correlations prevent us from averaging results of fits not including *g*, *h*, and *k* terms.
[66] BISI 74 value comes from quadratic fit with quad. term consistent with zero. *g* error is thus larger than if linear fit were used.
[67] BUCHANAN 70 result revised by BUCHANAN 75 to include radiative correlations and to use more reliable K^0_L momentum spectrum of second experiment (had same beam).

VALUE (units 10^{-3})	EVTS	DOCUMENT ID		TECN
$-3.3\pm1.1\pm0.7$	5M	[69] SOMALWAR	92	E731

[69] SOMALWAR 92 chose m_{π^+} as normalization to make it compatible with the Particle Data Group $K^0_L \to \pi^+\pi^-\pi^0$ definitions.

K^0_L FORM FACTORS

For discussion, see note on form factors in the $K^\pm$ section of the Particle Listings above.

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.

f_S and f_T refer to the scalar and tensor term.

$f_0 = f_+ + f_- t/(m_K^2 - m_\pi^2)$.

λ_+, λ_-, and λ_0 are the linear expansion coefficients of f_+, f_-, and f_0.

λ_+ refers to the $K^0_{\mu 3}$ value except in the K^0_{e3} sections.

$d\xi(0)/d\lambda_+$ is the correlation between $\xi(0)$ and λ_+ in $K^0_{\mu 3}$.

$d\lambda_0/d\lambda_+$ is the correlation between λ_0 and λ_+ in $K^0_{\mu 3}$.

t = momentum transfer to the π in units of m_π^2.

DP = Dalitz plot analysis.

PI = π spectrum analysis.

MU = μ spectrum analysis.

POL= μ polarization analysis.

BR = $K^0_{\mu 3}/K^0_{e3}$ branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN K^0_{e3} DECAY)

For radiative correction of K^0_{e3} DP, see GINSBERG 67 and BECHERRAWY 70.

[71] BIRULEV 81 error, $d\xi(0)/d\lambda_+$ calculated by us from λ_0, λ_+. $d\lambda_0/d\lambda_+ = 0$ used.

[72] HILL 79 and CHO 80 calculated by us from λ_0, λ_+, and $d\lambda_0/d\lambda_+$.

[73] BUCHANAN 75 is calculated by us from λ_0, λ_+ and $d\lambda_0/d\lambda_+$ because their appendix A value -0.20 ± 22 assumes $\xi(t)$ constant, i.e. $\lambda_- = \lambda_+$.

[74] DONALDSON 74B gives $\xi = -0.11 \pm 0.02$ not including systematics. Above error and $d\xi(0)/d\lambda_+$ were calculated by us from λ_0 and λ_+ errors (which include systematics) and $d\lambda_0/d\lambda_+$.

[75] PEACH 73 gives $\xi(0) = -0.95 \pm 0.45$ for $\lambda_+ = \lambda_- = 0.025$. The above value is for $\lambda_- = 0$. K.Peach, private communication (1974).

[76] ALBROW 72 fit has λ_- free, gets $\lambda_- = -0.030 \pm 0.060$ or $\Lambda = +0.15^{+0.17}_{-0.11}$.

[77] CARPENTER 66 $\xi(0)$ is for $\lambda_+ = 0$. $d\xi(0)/d\lambda_+$ is from figure 9.

[78] CHIEN 70 errors are statistical only. $d\xi(0)/d\lambda_+$ from figure 4. DALLY 72 is a reanalysis of CHIEN 70. The DALLY 72 result is not compatible with assumption $\lambda_- = 0$ so not included in our fit. The nonzero λ_- value and the relatively large λ_+ value found by DALLY 72 come mainly from a single low t bin (figures 1,2). The (f_+,ξ) correlation was ignored. We estimate from figure 2 that fixing $\lambda_- = 0$ would give $\xi(0) = -1.4 \pm 0.3$ and would add 10 to χ^2. $d\xi(0)/d\lambda_+$ is not given.

[79] BASILE 70 is incompatible with all other results. Authors suggest that efficiency estimates might be responsible.

$\xi_b = f_-/f_+$ (determined from $K^0_{\mu 3}/K^0_{e3}$)

The $K^0_{\mu 3}/K^0_{e3}$ branching ratio fixes a relationship between $\xi(0)$ and λ_+. We quote the author's $\xi(0)$ and associated λ_+ but do not average because the λ_+ values differ. The fit result and scale factor given below are not obtained from these ξ_b values. Instead they are obtained directly from the authors $K^0_{\mu 3}/K^0_{e3}$ branching ratio via the fitted $K^0_{\mu 3}/K^0_{e3}$ ratio $(\Gamma(\pi^\pm\mu^\mp\nu_\mu)/\Gamma(\pi^\pm e^\mp \nu_e))$. The parameter ξ is redundant with λ_0 below and is not put into the Meson Summary Table.

[80] EVANS 73 replaces EVANS 69.

$\xi_C = f_-/f_+$ (determined from μ polarization in $K^0_{\mu3}$)

The μ polarization is a measure of $\xi(t)$. No assumptions on λ_{+-} necessary, t (weighted by sensitivity to $\xi(t)$) should be specified. In λ_+, $\xi(0)$ parametrization this is $\xi(0)$ for $\lambda_+ = 0$. $d\xi/d\lambda = \xi t$. For radiative correction to μ polarization in $K^0_{\mu3}$, see GINSBERG 73. The parameter ξ is redundant with λ_0 below and is not put into the Meson Summary Table.

[87] BIRULEV 81 gives $d\lambda_0/d\lambda_+ = -1.5$, giving an unreasonably narrow error ellipse which dominates all other results. We use $d\lambda_0/d\lambda_+ = 0$.

[88] λ_0 value is for $\lambda_+ = 0.03$ calculated by us from $\xi(0)$ and $d\xi(0)/d\lambda_+$.

[89] BUCHANAN 75 value is from their appendix A and uses only $K_{\mu3}$ data. $d\lambda_0/d\lambda_+$ was obtained by private communication, C.Buchanan, 1976.

[90] DONALDSON 74B $d\lambda_0/d\lambda_+$ obtained from figure 18.

[91] PEACH 73 assumes $\lambda_+ = 0.025$. Calculated by us from $\xi(0)$ and $d\xi(0)/d\lambda_+$.

[92] ALBROW 72 λ_0 is calculated by us from ξ_A, λ_+ and $d\xi(0)/d\lambda_+$. They give $\lambda_0 = -0.043 \pm 0.039$ for $\lambda_- = 0$. We use our larger calculated error.

[93] CHO 80 BR result not independent of their Dalitz plot result.

[94] Fit for λ_0 does not include this value but instead includes the $K_{\mu3}/K_{e3}$ result from this experiment.

[95] DALLY 72 gives $f_0 = 1.20 \pm 0.35$, $\lambda_0 = -0.080 \pm 0.272$, $\lambda_0{}' = -0.006 \pm 0.045$, but with a different definition of λ_0. Our quoted λ_0 is his λ_0/f_0. We cannot calculate true λ_0 error without his (λ_0, f_0) correlations. See also note on DALLY 72 in section ξ_A.

[96] BASILE 70 λ_0 is for $\lambda_+ = 0$. Calculated by us from ξ_A with $d\xi(0)/d\lambda_+ = 0$. BASILE 70 is incompatible with all other results. Authors suggest that efficiency estimates might be responsible.

DECAY FORM FACTORS FOR $K^0_L \to \pi^\pm\pi^0e^\mp\nu_e$

Given in MAKOFF 93.

FITS FOR K^0_L *CP*-VIOLATION PARAMETERS

Revised April 2000 by T.G. Trippe (LBNL).

In recent years, K^0_L CP-violation experiments have improved our knowledge of CP-violation parameters and their consistency with the expectations of CPT invariance and unitarity. For definitions of K^0_L CP-violation parameters and a brief discussion of the theory, see the article "CP Violation" by L. Wolfenstein in Section 12 of this *Review*.

This note describes our two fits for the CP-violation parameters in $K^0_L \to \pi^+\pi^-$ and $\pi^0\pi^0$ decay, one for the phases ϕ_{+-} and ϕ_{00}, and another for the amplitudes $|\eta_{+-}|$ and $|\eta_{00}|$.

Fit to ϕ_{+-}, ϕ_{00}, $\Delta\phi$, Δm, and τ_S data: We perform a joint fit to the data on ϕ_{+-}, ϕ_{00}, the phase difference $\Delta\phi = \phi_{00} - \phi_{+-}$, the $K^0_L - K^0_S$ mass difference Δm, and the K^0_S mean life τ_S, including the effects of correlations. Measurements of ϕ_{+-} and ϕ_{00} are highly correlated with Δm and τ_S. Some measurements of τ_S are correlated with Δm. The correlations are given in the footnotes of the ϕ_{+-} and ϕ_{00} sections of the K^0_L Particle Listings and the τ_S section of the K^0_S Particle listings. In editions of the Review prior to 1996, we adjusted the experimental values of ϕ_{+-} and ϕ_{00} to account for correlations with Δm and τ_S but did not include the effects of these correlations when evaluating Δm and τ_S. In 1996, we introduced a joint fit including these correlations. In this fit, the ϕ_{+-} measurements have a strong influence on the fitted value of Δm. This is because the CERN NA31 vacuum regeneration experiments (CAROSI 90 [1] and GEWENIGER 74B [2]), the Fermilab E773/E731 regenerator experiments (SCHWINGENHEUER 95 [3] and GIBBONS 93 [4]), and the CPLEAR $K^0 - \overline{K}^0$ asymmetry experiment (APOSTOLAKIS 99C [5]) have very different dependences of ϕ_{+-} on Δm, as can be seen from their diagonal bands in Fig. 1.

The region where the ϕ_{+-} bands from these experiments cross gives a powerful measurement of Δm which decreases the fitted Δm value relative to our pre-1996 average Δm and earlier measurements such as CULLEN 70 [6], GEWENIGER 74C [7], and GJESDAL 74 [8]. This decrease brings the Δm-dependent ϕ_{+-} measurements into good agreement with each other and with ϕ(superweak), where

$$\phi(\text{superweak}) = \tan^{-1}\left(\frac{2\Delta m}{\Delta\Gamma}\right) = \tan^{-1}\left(\frac{2\Delta m \tau_S \tau_L}{\hbar(\tau_L - \tau_S)}\right) . \quad (1)$$

The (ϕ_{+-}, τ_S) correlations influence the τ_S fit result in a similar manner, as can be seen in Fig. 2. The influence of the ϕ_{+-} experiments is not as great on τ_S as it is on Δm because the indirect measurements of τ_S derived from the diagonal crossing bands in Fig. 2 are not as precise as the direct measurements of τ_S from E773 (SCHWINGENHEUER 95 [3]), E731 (GIBBONS 93 [4]), and NA31 (BERTANZA 97 [9]).

In Fig. 1 [Fig. 2] the slope of the diagonal ϕ_{+-} bands shows the Δm $[\tau_S]$ dependence; the unseen τ_S $[\Delta m]$ dependent term is evaluated using the fitted τ_S $[\Delta m]$. The vertical half-width σ_ϕ of each band is the ϕ_{+-} error for fixed Δm $[\tau_S]$ and includes the systematic error due to the error in the fitted τ_S $[\Delta m]$.

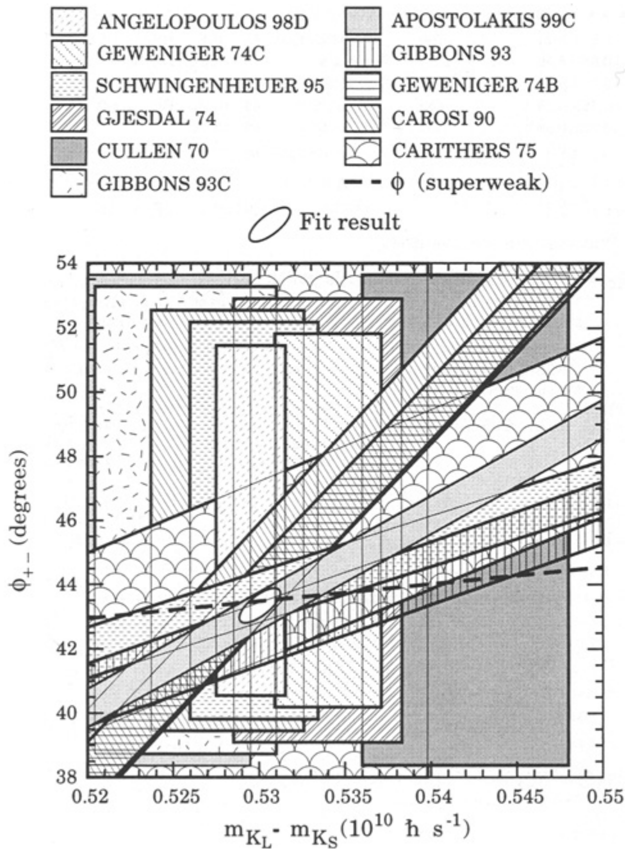

Figure 1: ϕ_{+-} vs Δm. Δm measurements appear as vertical bands spanning $\Delta m \pm 1\sigma$, some of which are cut near the top to aid the eye. The ϕ_{+-} measurements appear as diagonal bands spanning $\phi_{+-} \pm \sigma_\phi$. The dashed line shows ϕ(superweak). The ellipse shows the 1σ contour of the fit result. See Table 1 for data references.

Table 2 gives the resulting fit values for the parameters and Table 3 gives the correlation matrix. The resulting ϕ_{+-} is in good agreement with ϕ(superweak) $= 43.49 \pm 0.07°$ obtained from Eq. (1) using Δm and τ_S from Table 2.

The χ^2 is 16.0 for 20 degrees of freedom, indicating good agreement of the input data. Nevertheless, there has been criticism that Fermilab E773 (SCHWINGENHEUER 95 [3]) and E731 (GIBBONS 93 [4]) measure $\phi_{+-} - \phi_f$ and calculate the regeneration phase ϕ_f from the power law momentum dependence of the regeneration amplitude using analyticity and dispersion relations. In the E731 result, a systematic error of ± 0.5 degrees for departures from a pure power-law is included. For the E773 result, they modeled a variety of effects that do distort the amplitude from a pure power law and ascribed a $\pm 0.35°$ systematic error from uncertainties in these effects. Even so, the E731 result remains valid within its quoted errors. KLEINKNECHT 94 [16] and KLEINKNECHT 95 [17] argue that these systematic errors should be around 3°, primarily

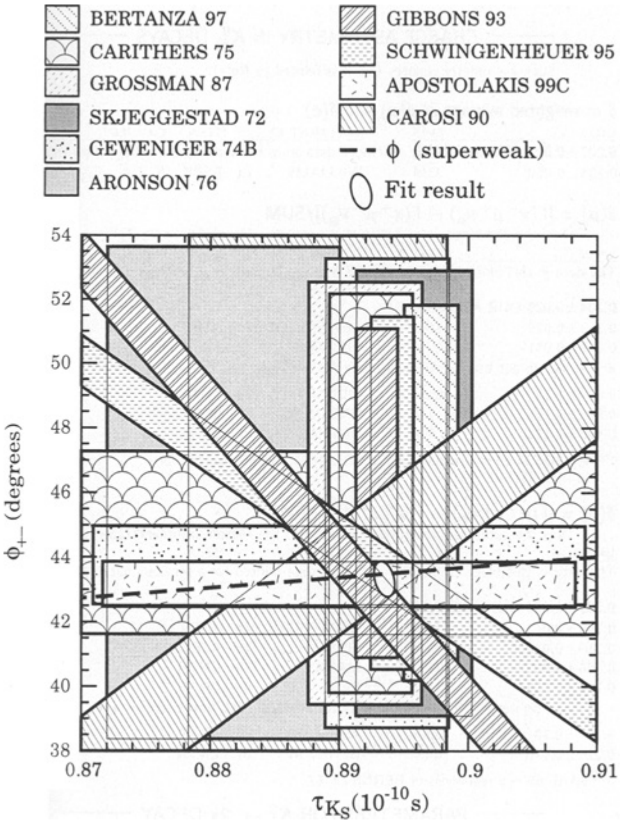

Figure 2: ϕ_{+-} vs τ_S. τ_S measurements appear as vertical bands spanning $\tau_S \pm 1\sigma$, some of which are cut near the top to aid the eye. The ϕ_{+-} measurements appear as diagonal bands spanning $\phi_{+-} \pm \sigma_\phi$. The dashed line shows ϕ(superweak). The ellipse shows the fit result's 1σ contour. See Table 1 for data references.

because of the absence of data on the momentum dependence of the regeneration amplitude above 160 GeV/c. BRIERE 95 [18] and BRIERE 95C [19] reply that the current understanding of regeneration is sufficient to allow a precise and reliable correction for the region above 160 GeV/c. The question is one of judgement about the reliability of the assumptions used. In the absence of any contradictory evidence, we choose to accept the judgement of the E731/E773 experimenters in setting their systematic errors.

Fit for ϵ'/ϵ, $|\eta_{+-}|$, $|\eta_{00}|$, and $B(K_L \to \pi\pi)$

We list measurements of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$ and ϵ'/ϵ. Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from measurements of the K^0_L and K^0_S lifetimes (τ_L, τ_S) and branching ratios (B) to $\pi\pi$, using the relations

$$|\eta_{+-}| = \left[\frac{B(K^0_L \to \pi^+\pi^-)}{\tau_L} \; \frac{\tau_S}{B(K^0_S \to \pi^+\pi^-)}\right]^{1/2} , \quad (2a)$$

$$|\eta_{00}| = \left[\frac{B(K^0_L \to \pi^0\pi^0)}{\tau_L} \; \frac{\tau_S}{B(K^0_S \to \pi^0\pi^0)}\right]^{1/2} . \quad (2b)$$

Table 1: References and location of input data for Fig. 1 and Fig. 2. Unless otherwise indicated by a footnote, a check (√) indicates that the data can be found in the ϕ_{+-} or Δm sections of the K_L Particle Listings, or the τ_S section of the K_S Particle Listings, according to the column headers.

† from $\tau_S(\Delta m)$ in τ_S Particle Listings.

Table 2: Results of the fit for ϕ_{+-}, ϕ_{00}, $\phi_{00} - \phi_{+-}$, Δm, and τ_S. The fit has $\chi^2 = 16.0$ for 20 degrees of freedom (24 measurements −5 parameters +1 constraint).

Quantity	Fit Result
ϕ_{+-}	$43.3 \pm 0.5°$
Δm	$(0.5300 \pm 0.0012) \times 10^{10}\hbar\ s^{-1}$
τ_S	$(0.8935 \pm 0.0008) \times 10^{-10}$s
ϕ_{00}	$43.2 \pm 1.0°$
$\Delta\phi$	$-0.1 \pm 0.8°$

Table 3: Correlation matrix for the fitted parameters.

	ϕ_{+-}	Δm	τ_S	ϕ_{00}	$\Delta\phi$
ϕ_{+-}	1.00	0.71	−0.30	0.54	−0.02
Δm	0.71	1.00	−0.19	0.43	0.04
τ_S	−0.30	−0.19	1.00	−0.14	0.04
ϕ_{00}	0.54	0.43	−0.14	1.00	0.83
$\Delta\phi$	−0.02	0.04	0.04	0.83	1.00

For historical reasons the branching ratio fits and the *CP*-violation fits are done separately, but we want to include the influence of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ measurements on $B(K^0_L \to \pi^+\pi^-)$ and $B(K^0_L \to \pi^0\pi^0)$ and vice versa. We approximate a global fit to all of these measurements by first performing two independent fits: 1) BRFIT, a fit to the K^0_L branching ratios, rates, and mean life, and 2) ETAFIT, a fit to the $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{+-}/\eta_{00}|$, and ϵ'/ϵ measurements. The results from fit 1, along with the K^0_S values from this edition are used to compute values of $|\eta_{+-}|$ and $|\eta_{00}|$ which are included as measurements in the $|\eta_{00}|$ and $|\eta_{+-}|$ sections with a document ID of BRFIT 00. Thus the fit values of $|\eta_{+-}|$ and $|\eta_{00}|$ given in this edition include both the direct measurements and the results from the branching ratio fit.

The process is reversed in order to include the direct $|\eta|$ measurements in the branching ratio fit. The results from fit 2 above (before including BRFIT 00 values) are used along with the K^0_L and K^0_S mean lives and the $K^0_S \to \pi\pi$ branching fractions to compute the K^0_L branching ratios $\Gamma(K^0_L \to \pi^+\pi^-)/\Gamma(\text{total})$ and $\Gamma(K^0_L \to \pi^0\pi^0)/\Gamma(K^0_L \to \pi^+\pi^-)$. These branching ratio values are included as measurements in the branching ratio section with a document ID of ETAFIT 00. Thus the K^0_L branching ratio fit values in this edition include the results of direct measurements of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ. A more detailed discussion of these fits is given in the 1990 edition of this *Review* [20].

— PARAMETERS FOR $K^0_L \to 2\pi$ DECAY —

$$\eta_{+-} = A(K^0_L \to \pi^+\pi^-) / A(K^0_S \to \pi^+\pi^-)$$
$$\eta_{00} = A(K^0_L \to \pi^0\pi^0) / A(K^0_S \to \pi^0\pi^0)$$

The fitted values of $|\eta_{+-}|$ and $|\eta_{00}|$ given below are the results of a fit to $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and Re(ϵ'/ϵ). Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from the fitted values of the $K^0_L \to \pi\pi$ and $K^0_S \to \pi\pi$ branching ratios and the K^0_L and K^0_S lifetimes. This information is included as data in the $|\eta_{+-}|$ and $|\eta_{00}|$ sections with a Document ID "BRFIT." See the note "Fits for K^0_L *CP*-Violation Parameters" above for details.

$|\eta_{00}| = |A(K^0_L \to 2\pi^0) / A(K^0_S \to 2\pi^0)|$

2.95 ±0.63	[101] CHOLLET	70	OSPK	Cu reg., 4γ's

[99] This BRFIT value is computed from fitted values of the K^0_L and K^0_S lifetimes and branching fractions to $\pi\pi$. See the discussion in the note "Fits for K^0_L *CP*-Violation Parameters."

[100] Error is statistical only.

[101] CHOLLET 70 gives $|\eta_{00}|$ = (1.23 ± 0.24)×(regeneration amplitude, 2 GeV/c Cu)/10000mb. WOLFF 71 gives $|\eta_{00}|$ = (1.13 ± 0.12)×(regeneration amplitude, 2 GeV/c Cu)/10000mb. We compute both $|\eta_{00}|$ values for (regeneration amplitude, 2 GeV/c Cu) = 24 ± 2mb. This regeneration amplitude results from averaging over FAISSNER 69, extrapolated using optical-model calculations of Bohm et al., Physics Letters **27B** 594 (1968) and the data of BALATS 71. (From H. Faissner, private communication).

$|\eta_{+-}| = |A(K^0_L \to \pi^+\pi^-) / A(K^0_S \to \pi^+\pi^-)|$

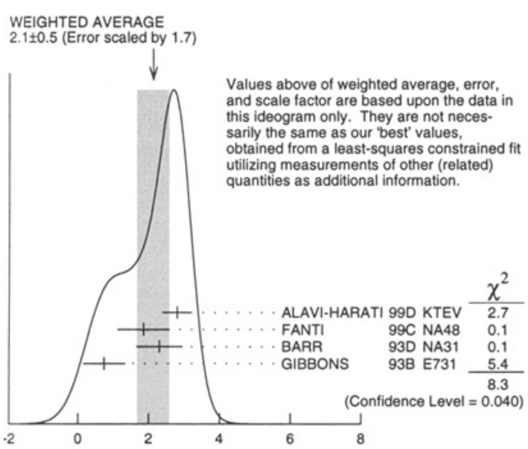
[108] These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements. They enter the average in this section but enter the fit via the $|\eta_{00}/\eta_{+-}|$ section only.

[109] This is the combined results from BARR 93D and BURKHARDT 88, taking into account their common systematic uncertainty.

[110] These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements.



$\epsilon'/\epsilon \approx \mathrm{Re}(\epsilon'/\epsilon) = (1-|\eta_{00}/\eta_{+-}|)/3$

ϕ_{+-}, PHASE of η_{+-}

The dependence of the phase on Δm and τ_S is given for each experiment in the comments below, where Δm is the $K^0_L - K^0_S$ mass difference in units $10^{10}\ \hbar s^{-1}$ and τ_S is the K_S mean life in units 10^{-10} s. For the "used" data, we have evaluated these mass dependences using our 2000 values, $\Delta m = 0.5300 \pm 0.0012$, $\tau_S = 0.8935 \pm 0.0008$ to obtain the values quoted below. We also give the regeneration phase ϕ_f in the comments below.

OUR FIT is described in the note on "Fits for K^0_L CP-Violation Parameters" in the K^0_L Particle Listings.

47.7 ±2.0 ±0.9		[113,122] KARLSSON	90 E731	

[111] APOSTOLAKIS 99C report $(43.19 \pm 0.53 \pm 0.28)^\circ + 300\,[\Delta m - 0.5301]^\circ$.

[112] SCHWINGENHEUER 95 reports $\phi_{+-} = 43.53 \pm 0.76 + 173[\Delta m - 0.5282] - 275[\tau_S - 0.8926]$.

[113] These experiments measure $\phi_{+-} - \phi_f$ and calculate the regeneration phase from the power law momentum dependence of the regeneration amplitude using analyticity and dispersion relations. SCHWINGENHEUER 95 [GIBBONS 93] includes a systematic error of 0.35° [0.5°] for uncertainties in their modeling of the regeneration amplitude. See the discussion of these systematic errors, including criticism that they could be underestimated, in the note on "C violation in K^0_L decay."

[114] GIBBONS 93 measures $\phi_{+-} - \phi_f$ and calculates the regeneration phase ϕ_f from the power law momentum dependence of the regeneration amplitude using analyticity. An error of 0.6° is included for possible uncertainties in the regeneration phase. They find $\phi_{+-} = 42.21 \pm 0.9 + 189\,[\Delta m - 0.5257] - 460\,[\tau_S - 0.8922]^\circ$, as given in SCHWINGENHEUER 95, footnote 8. GIBBONS 93 reports ϕ_{+-} $(42.2 \pm 1.4)^\circ$

[115] CAROSI 90 $\phi_{+-} = 46.9 \pm 1.4 \pm 0.7 + 579\,[\Delta m - 0.5351] + 303\,[\tau_S - 0.8922]^\circ$.

[116] CARITHERS 75 $\phi_{+-} = (45.5 \pm 2.8) + 224[\Delta m - 0.5348]^\circ$. $\phi_f = -40.9 \pm 2.6^\circ$.

[117] GEWENIGER 74B $\phi_{+-} = (49.4 \pm 1.0) + 565[\Delta m - 0.540]^\circ$.

[118] ADLER 96C fit gives $(43.82 \pm 0.41)^\circ + 339(\Delta m - 0.5307)^\circ - 252(\tau_S - 0.8922)^\circ$.

[119] ADLER 96C is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value in the 1996 edition of this Review (Physical Review **D54** 1 (1996)).

[120] ADLER 95B report $42.7^\circ \pm 0.9^\circ \pm 0.6^\circ + 316[\Delta m - 0.5274]^\circ + 30[\tau_S - 0.8926]^\circ$.

[121] ADLER 92B quote separately two systematic errors: ±0.4 from their experiment and ±1.0 degrees due to the uncertainty in the value of Δm.

[122] KARLSSON 90 systematic error does not include regeneration phase uncertainty.

ϕ_{00}, PHASE OF η_{00}

See comment in ϕ_{+-} header above for treatment of Δm and τ_S dependence.

OUR FIT is described in the note on "Fits for K^0_L CP-Violation Parameters" in the K^0_L Particle Listings.

VALUE (°)	DOCUMENT ID	TECN	COMMENT

VALUE	CL%	EVTS	DOCUMENT ID		TECN
<0.3	90	3671	[130] RAMBERG	93B	E731

[130] RAMBERG 93B limit on $|\epsilon'_{+-\gamma}|/\epsilon$ assumes than any difference between η_{+-} and $\eta_{+-\gamma}$ is due to direct CP violation.

$\Delta S = \Delta Q$ IN K^0 DECAYS

The relative amount of $\Delta S \neq \Delta Q$ component present is measured by the parameter x, defined as

$$x = A(\overline{K}^0 \to \pi^-\ell^+\nu)/A(K^0 \to \pi^-\ell^+\nu)\ .$$

We list Re$\{x\}$ and Im$\{x\}$ for K_{e3} and $K_{\mu3}$ combined.

$x = A(\overline{K}^0 \to \pi^-\ell^+\nu)/A(K^0 \to \pi^-\ell^+\nu) = A(\Delta S{=}{-}\Delta Q)/A(\Delta S{=}\Delta Q)$

$K^*(892)^0$ mass (MeV)

[2] Inclusive reaction. Complicated background and phase-space effects.
[3] Mass errors enlarged by us to $\Gamma/\sqrt{N}$. See note.
[4] Number of events in peak reevaluated by us.
[5] From a partial wave amplitude analysis.
[6] From pole extrapolation.

$K^*(892)$ MASSES AND MASS DIFFERENCES

Unrealistically small errors have been reported by some experiments. We use simple "realistic" tests for the minimum errors on the determination of a mass and width from a sample of N events:

$$\delta_{\min}(m) = \frac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4\frac{\Gamma}{\sqrt{N}} . \qquad (1)$$

We consistently increase unrealistic errors before averaging. For a detailed discussion, see the 1971 edition of this Note.

$m_{K^*(892)^0} - m_{K^*(892)^\pm}$

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 7.8$ for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i \delta p_j\rangle/(\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 31 measurements and one constraint to determine 8 parameters. The overall fit has a χ^2 = 20.2 for 24 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i \delta p_j\rangle/(\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 =$ 2.9 for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$K_2(1770)$

$I(J^P) = \frac{1}{2}(2^-)$

THE $K_2(1770)$ AND THE $K_2(1820)$

A partial-wave analysis of the $K^-\omega$ system based on about 100,000 $K^-p \to K^-\omega p$ events (ASTON 93) gives evidence for two $q\bar{q}$ D-wave states near 1.8 GeV. A previous analysis based on about 200,000 diffractively produced $K^-p \to K^-\pi^+\pi^-p$ events (DAUM 81) gave evidence for two $J^P = 2^-$ states in this region, with masses ~ 1780 MeV and ~ 1840 MeV and widths ~ 200 MeV, in good agreement with the results of ASTON 93. In contrast, the masses obtained using a single resonance do not agree well: ASTON 93 obtains 1728 ± 7 MeV, while DAUM 81 estimates ~ 1820 MeV. We conclude that there are indeed two K_2 resonances here.

We list under the $K_2(1770)$ other measurements that do not resolve the two-resonance structure of the enhancement.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 4 measurements and one constraint to determine 4 parameters. The overall fit has a χ^2 = 0.0 for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i \delta x_j\rangle/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CHARMED MESONS
($C = \pm1$)

$D^+ = c\overline{d}$, $D^0 = c\overline{u}$, $\overline{D}^0 = \overline{c}\,u$, $D^- = \overline{c}\,d$, similarly for D^*'s

D MESONS

Revised January 2000 by P.R. Burchat (Stanford University).

The new experimental results on D mesons reported in this edition are mostly from the CLEO-II experiment at the CESR e^+e^- storage ring and from the fixed-target experiment E791 at Fermilab. The CLEO experiment has measured the D^+, D^0, and D_s^+ lifetimes, and E791 has measured the D^0 and D_s^+ lifetimes. The measured ratio of D_s^+ to D^0 lifetimes is now significantly greater than unity: $\tau(D_s^+)/\tau(D^0) = 1.20 \pm 0.02$.

The E791 experiment has obtained the first directly measured limit on the decay-width difference $\Delta\Gamma$ for the mass eigenstates of the neutral D system, looking for a difference in decay rates between the CP-even decay $D^0 \to K^+K^-$ and the CP-mixed decay $D^0 \to K^-\pi^+$. The CERN experiment ALEPH and CLEO have made new searches for neutral D mixing in the "wrong-sign" decay $D^0 \to K^+\pi^-$; no evidence for mixing has been found. CLEO has reduced the uncertainty on the measurement of the doubly Cabibbo-suppressed decay rate $\Gamma(D^0 \to K^+\pi^-)$ by about a factor of three.

The CERN experiment BEATRICE has measured form factors for the semileptonic decay $D^+ \to \overline{K}^*(892)^0\ell^+\nu_\ell$, and E791 has measured form factors both for this decay and for $D_s^+ \to \phi\ell^+\nu_\ell$. The CERN experiment OPAL has measured the semileptonic branching fraction for charm hadrons produced in $Z \to c\overline{c}$. The Fermilab experiment CDF has set limits on semileptonic decay rates involving K resonances above the $K^*(892)$. The BEPC experiment BES has observed one $D^+ \to \mu^+\nu_\mu$ event, and CLEO has improved a measurement of the D_s^+ leptonic decay constant.

CLEO has now measured the important $D^0 \to K^-\pi^+$ branching fraction using three different methods, and has also measured D^+ and D_s^+ branching fractions involving η and η' mesons. An E791 search for 24 rare or forbidden decays to dilepton final states yielded no evidence for new physics.

$D^{\pm}$

$I(J^P) = \frac{1}{2}(0^-)$

$D^{\pm}$ MASS

The fit includes $D^{\pm}$, D^0, $D_s^{\pm}$, $D^{*\pm}$, D^{*0}, and $D_s^{*\pm}$ mass and mass difference measurements.

Γ_{165} A dummy mode used by the fit. (33 ± 5) %

[a] This is a weighted average of $D^{\pm}$ (44%) and D^0 (56%) branching fractions. See "D^+ and $D^0 \to$ (η anything) / (total D^+ and D^0)" under "D^+ Branching Ratios" in these Particle Listings.

[b] This value averages the e^+ and μ^+ branching fractions, after making a small phase-space adjustment to the μ^+ fraction to be able to use it as an e^+ fraction; hence our ℓ^+ here is really an e^+.

[c] An ℓ indicates an e or a μ mode, not a sum over these modes.

[d] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[e] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.

[f] This mode is not a useful test for a ΔC=1 weak neutral current because both quarks must change flavor in this decay.

[g] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 32 branching ratios uses 54 measurements and one constraint to determine 20 parameters. The overall fit has a $\chi^2 = 20.8$ for 35 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i \delta x_j\rangle/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

<0.057	90		[21] AGUILAR-...	87F	HYBR	πp, pp 360, 400 GeV

[20] BAI 91 finds that a fraction $0.79^{+0.15}_{-0.17}{}^{+0.09}_{-0.03}$ of combined D^+ and D^0 decays to $\overline{K}\pi e^+\nu_e$ (24 events) are $\overline{K}^*(892)e^+\nu_e$.

[21] AGUILAR-BENITEZ 87F computes the branching fraction using topological normalization.

$\Gamma(\overline{K}^*(892)^0 \ell^+ \nu_\ell)/\Gamma_{total}$ — Γ_{24}/Γ

We average our $\overline{K}^{*0} e^+\nu_e$ and $\overline{K}^{*0}\mu^+\nu_\mu$ branching fractions, after multiplying the latter by a phase-space factor of 1.05 to be able to use it with the $\overline{K}^{*0} e^+\nu_e$ fraction. Hence our ℓ^+ here is really an e^+.

[35] SCHINDLER 81 (MARK-2) measures $\sigma(e^+e^-\to\psi(3770))$ × branching fraction to be 0.14 ± 0.03 nb. We use the MARK-3 (ADLER 88C) value of σ = 4.2 ± 0.6 ± 0.3 nb.
[36] PERUZZI 77 (MARK-1) measures $\sigma(e^+e^-\to\psi(3770))$ × branching fraction to be 0.14 ± 0.05 nb. We use the MARK-3 (ADLER 88C) value of σ = 4.2 ± 0.6 ± 0.3 nb.

$\Gamma(\overline{K}^0\pi^+)/\Gamma(K^-\pi^+\pi^+)$ — Γ_{36}/Γ_{37}

It is generally assumed for modes such as $D^+\to\overline{K}^0\pi^+$ that
$$\Gamma(D^+\to\overline{K}^0\pi^+)=2\Gamma(D^+\to K^0_S\pi^+);$$
it is the latter Γ that is actually measured. BIGI 95 points out that interference between Cabibbo-allowed and doubly Cabibbo-suppressed amplitudes, where both occur, could invalidate this assumption by a few percent.

Hadronic modes with a $K\overline{K}$ pair

$\Gamma(K^+\overline{K}^0)/\Gamma(\overline{K}^0\pi^+)$ — Γ_{115}/Γ_{36}

It is generally assumed for modes such as $D^+ \to \overline{K}^0\pi^+$ that

$$\Gamma(D^+ \to \overline{K}^0\pi^+) = 2\Gamma(D^+ \to K^0_S\pi^+);$$

it is the latter Γ that is actually measured. BIGI 95 points out that interference between Cabibbo-allowed and doubly Cabibbo-suppressed amplitudes, where both occur, could invalidate this assumption by a few percent.

$D^{\pm}$ PRODUCTION CROSS SECTION AT $\psi(3770)$

A compilation of the cross sections for the direct production of $D^{\pm}$ mesons at or near the $\psi(3770)$ peak in e^+e^- production.

VALUE (nanobarns)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
4.2 ±0.6 ±0.3	[72] ADLER	88C	MRK3	e^+e^- 3.768 GeV
5.5 ±1.0	[73] PARTRIDGE	84	CBAL	e^+e^- 3.771 GeV
6.00±0.72±1.02	[74] SCHINDLER	80	MRK2	e^+e^- 3.771 GeV
9.1 ±2.0	[75] PERUZZI	77	MRK1	e^+e^- 3.774 GeV

[72] This measurement compares events with one detected D to those with two detected D mesons, to determine the the absolute cross section. ADLER 88C measure the ratio of cross sections (neutral to charged) to be 1.36 ± 0.23 ± 0.14. This measurement does not include the decays of the $\psi(3770)$ not associated with charmed particle production.

[73] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. PARTRIDGE 84 measures 6.4 ± 1.15 nb for the cross section. We take the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and we assume that the $\psi(3770)$ is an isosinglet to evaluate the cross sections. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

[74] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. SCHINDLER 80 assume the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and that the $\psi(3770)$ is an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

[75] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. The phase space division of neutral and charged D mesons in $\psi(3770)$ decay is taken to be 1.33, and $\psi(3770)$ is assumed to be an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction. We exclude this measurement from the average because of uncertainties in the contamination from τ lepton pairs. Also see RAPIDIS 77.

[1] PERUZZI 77 and SCHINDLER 81 errors do not include the 0.13% uncertainty in the absolute SPEAR energy calibration. TRILLING 81 uses the high precision $J/\psi(1S)$ and $\psi(2S)$ measurements of ZHOLENTZ 80 to determine this uncertainty and combines the PERUZZI 77 and SCHINDLER 81 results to obtain the value quoted. TRILLING 81 enters the fit in the $D^{\pm}$ mass, and PERUZZI 77 and SCHINDLER 81 enter in the $m_{D^{\pm}} - m_{D^0}$, below.

[2] Error does not include possible systematic mass scale shift, estimated to be less than 5 MeV.

$m_{D^{\pm}} - m_{D^0}$

The fit includes $D^{\pm}$, D^0, $D_s^{\pm}$, $D^{*\pm}$, D^{*0}, and $D_s^{*\pm}$ mass and mass difference measurements.

$|m_{D_1^0} - m_{D_2^0}|$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson. To calculate the following limits, we use $\Delta m = [2r/(1-r)]^{1/2}\hbar/4.126\times10^{-13}$ s, where r is the experimental D^0-$\overline{D}^0$ mixing ratio.

<21	90	[7,9] ANJOS	88C	E691	Photoproduction

[5] This GODANG 00 limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ (via $\overline{D}^0))/\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0-$\overline{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0 \to K^+\pi^-$ and $\overline{D}^0 \to K^+\pi^-$ is assumed to be small.

[6] AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows CP violation in this term.

[7] This limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ or $K^+\pi^-\pi^+\pi^-$ (via $\overline{D}^0))/\Gamma(K^-\pi^+$ or $K^-\pi^+\pi^+\pi^-)$ near the end of the D^0 Listings. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from D^0-$\overline{D}^0$ mixing.

[8] This limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\ell^-\overline{\nu}_\ell$(via $\overline{D}^0))/\Gamma(K^-\ell^+\nu_\ell)$ given near the end of the D^0 Listings.

[9] ANJOS 88C assumes no interference between doubly Cabibbo-suppressed and mixing amplitudes. When interference is allowed, the limit degrades by about a factor of two.

$(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma_{D^0}$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson. AITALA 99E uses a difference in directly measured decay rates to obtain its limit. The other experiments infer the limits here from limits on mixing, using $\Delta\Gamma/\Gamma = [8r/(1+r)]^{1/2}$, where r is the experimental D^0-$\overline{D}^0$ mixing ratio. See the footnotes to the entries below.

$\|\Delta\Gamma\|/\Gamma < 0.17$	90	[13,15] ANJOS	88C	E691	Photoproduction

[10] This GODANG 00 limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ (via $\overline{D}^0))/\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0-$\overline{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The phase between $D^0 \to K^+\pi^-$ and $\overline{D}^0 \to K^+\pi^-$ is assumed to be small.

[11] AITALA 99E measures $\Delta\Gamma = 2[\Gamma(D^0 \to K^+K^-) - \Gamma(D^0 \to K^-\pi^+)] = +0.04 \pm 0.14 \pm 0.05$ ps^{-1} and thus gets 90%-confidence-level limits $-0.20 < \Delta\Gamma < +0.28$ ps^{-1}.

[12] AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows CP violation in this term.

[13] This limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ or $K^+\pi^-\pi^+\pi^-$ (via $\overline{D}^0))/\Gamma(K^-\pi^+$ or $K^-\pi^+\pi^+\pi^-)$ near the end of the D^0 Listings. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from D^0-$\overline{D}^0$ mixing.

[14] This limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\ell^-\overline{\nu}_\ell$(via $\overline{D}^0))/\Gamma(K^-\ell^+\nu_\ell)$ given near the end of the D^0 Listings.

[15] ANJOS 88C assumes no interference between doubly Cabibbo-suppressed and mixing amplitudes. When interference is allowed, the limit degrades by about a factor of two.

D^0 DECAY MODES

$\overline{D}^0$ modes are charge conjugates of the modes below.

	Mode		Fraction (Γ_i/Γ)	Scale factor/ Confidence level

[a] This is a weighted average of $D^\pm$ (44%) and D^0 (56%) branching fractions. See "D^+ and $D^0\to$ (η anything) / (total D^+ and D^0)" under "D^+ Branching Ratios" in these Particle Listings.

[b] This value averages the e^+ and μ^+ branching fractions, after making a small phase-space adjustment to the μ^+ fraction to be able to use it as an e^+ fraction; hence our ℓ^+ here is really an e^+.

[c] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[d] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.

[e] The experiments on the division of this charge mode amongst its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.

[f] However, these upper limits are in serious disagreement with values obtained in another experiment.

[g] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

[h] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 51 branching ratios uses 122 measurements and one constraint to determine 28 parameters. The overall fit has a $\chi^2 = 64.5$ for 95 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i\delta x_j\rangle/(\delta x_i\cdot\delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Semileptonic modes

$\Gamma(K^- \ell^+ \nu_\ell)/\Gamma_{\text{total}}$ Γ_7/Γ

We average our $K^- e^+ \nu_e$ and $K^- \mu^+ \nu_\mu$ branching fractions, after multiplying the latter by a phase-space factor of 1.03 to be able to use it with the $K^- e^+ \nu_e$ fraction. Hence our ℓ^+ here is really an e^+.

[19] BEAN 93C uses $K^- \mu^+ \nu_\mu$ as well as $K^- e^+ \nu_e$ events and makes a small phase-space adjustment to the number of the μ^+ events to use them as e^+ events. A pole mass of 2.00 ± 0.12 ± 0.18 GeV/c^2 is obtained from the q^2 dependence of the decay rate.

[20] CRAWFORD 91B uses $K^- e^+ \nu_e$ and $K^- \mu^+ \nu_\mu$ candidates to measure a pole mass of $2.1^{+0.4}_{-0.2}{}^{+0.3}_{-0.2}$ GeV/c^2 from the q^2 dependence of the decay rate.

[21] ANJOS 89F measures a pole mass of $2.1^{+0.4}_{-0.2}$ ± 0.2 GeV/c^2 from the q^2 dependence of the decay rate.

$\Gamma(K^- \mu^+ \nu_\mu)/\Gamma(K^- \pi^+)$ Γ_9/Γ_{19}

• • • We do not use the following data for averages, fits, limits, etc. • • •					
0.0381±0.0015±0.0016	1165	[39] ARTUSO	98	CLE2	e^+e^- at $\Upsilon(4S)$
0.0369±0.0011±0.0016		[40] COAN	98	CLE2	
0.0391±0.0008±0.0017	4208	[35,41] AKERIB	93	CLE2	$e^+e^- \approx \Upsilon(4S)$

[34] This combines the CLEO results of ARTUSO 98, COAN 98, and AKERIB 93.

[35] ABACHI 88, DECAMP 91J, AKERIB 93, ALBRECHT 94F, and BARATE 97C use $D^*(2010)^+ \to D^0\pi^+$ decays. The π^+ is both slow and of low p_T with respect to the event thrust axis or nearest jet ($\approx D^{*+}$ direction). The excess number of such π^+'s over background gives the number of $D^*(2010)^+ \to D^0\pi^+$ events, and the fraction with $D^0 \to K^-\pi^+$ gives the $D^0 \to K^-\pi^+$ branching fraction.

[36] ALBRECHT 94 uses D^0 mesons from $\overline{B}^0 \to D^{*+}\ell^-\overline{\nu}_\ell$ decays. This is a different set of events than used by ALBRECHT 94F.

[37] SCHINDLER 81 (MARK-2) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.24 ± 0.02 nb. We use the MARK-3 (ADLER 88C) value of σ = 5.8 ± 0.5 ± 0.6 nb.

[38] PERUZZI 77 (MARK-1) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.25 ± 0.05 nb. We use the MARK-3 (ADLER 88C) value of σ = 5.8 ± 0.5 ± 0.6 nb.

[39] ARTUSO 98, following ALBRECHT 94, uses D^0 mesons from $\overline{B}^0 \to D^*(2010)^+ X \ell^- \overline{\nu}_\ell$ decays. Our average uses the CLEO average of this value with the values of COAN 98 and AKERIB 93.

[40] COAN 98 assumes that $\Gamma(\overline{B} \to \overline{D} X \ell^+ \nu)/\Gamma(\overline{B} \to X \ell^+ \nu) = 1.0 - 3|V_{ub}/V_{cb}|^2 - 0.010 \pm 0.005$, the last term accounting for $\overline{B} \to D_s^+ K X \ell^- \overline{\nu}$. COAN 98 is included in the CLEO average in ARTUSO 98.

[41] This AKERIB 93 value does not include radiative corrections; with them, the value is 0.0395 ± 0.0008 ± 0.0017. AKERIB 93 is included in the CLEO average in ARTUSO 98.

0.075 ±0.006 OUR AVERAGE Error includes scale factor of 1.3. See the ideogram below.					
0.079 ±0.015 ±0.009		[48] ALBRECHT	94	ARG	$e^+e^- \approx \Upsilon(4S)$
0.0680±0.0027±0.0057	1430	[49] ALBRECHT	94F	ARG	$e^+e^- \approx \Upsilon(4S)$
0.091 ±0.008 ±0.008	992	ADLER	88C	MRK3	e^+e^- 3.77 GeV
0.117 ±0.025	185	[50] SCHINDLER	81	MRK2	e^+e^- 3.771 GeV
0.062 ±0.019	44	[51] PERUZZI	77	MRK1	e^+e^- 3.77 GeV

[48] ALBRECHT 94 uses D^0 mesons from $\overline{B}^0 \to D^{*+}\ell^-\overline{\nu}_\ell$ decays. This is a different set of events than used by ALBRECHT 94F.

[49] See the footnote on the ALBRECHT 94F measurement of $\Gamma(K^-\pi^+)/\Gamma_{total}$ for the method used.

[50] SCHINDLER 81 (MARK-2) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.68 ± 0.11 nb. We use the MARK-3 (ADLER 88C) value of σ = 5.8 ± 0.5 ± 0.6 nb.

[51] PERUZZI 77 (MARK-1) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.36 ± 0.10 nb. We use the MARK-3 (ADLER 88C) value of σ = 5.8 ± 0.5 ± 0.6 nb.

Rare or forbidden modes

$\Gamma(K^+\ell^-\overline{\nu}_\ell\,(\text{via}\,\overline{D}^0))/\Gamma(K^-\ell^+\nu_\ell)$ Γ_{157}/Γ_7

This is a D^0-$\overline{D}^0$ mixing limit without the complications of possible doubly-Cabibbo-suppressed decays that occur when using hadronic modes. For the limits on $|m_{D^0_1} - m_{D^0_2}|$ and $(\Gamma_{D^0_1} - \Gamma_{D^0_2})/\Gamma_{D^0}$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
<0.005	90	[88] AITALA 96C	E791	π^- nucleus, 500 GeV

[88] AITALA 96C uses $D^{*+} \to D^0\pi^+$ (and charge conjugate) decays to identify the charm at production and $D^0 \to K^-\ell^+\nu_\ell$ (and charge conjugate) decays to identify the charm at decay.

$\Gamma(K^+\pi^-)/\Gamma(K^-\pi^+)$ Γ_{158}/Γ_{19}

The $D^0 \to K^+\pi^-$ decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by $D^0 \to \overline{D}^0$ mixing followed by $\overline{D}^0 \to K^+\pi^-$ decay. The experiments here use the charge of the pion in $D^*(2010)^\pm \to (D^0 \text{ or } \overline{D}^0)\,\pi^\pm$ decay to tell whether a D^0 or a $\overline{D}^0$ was born. Some of the experiments can use the decay-time information to disentangle the two modes. Here, we list the DCS branching ratio; in the next data block we give the limits on the mixing ratio.

Some early limits have been omitted from this Listing; see our 1998 (EPJ **C3** 1) edition.

<0.014	90		[92] ALBRECHT 87K	ARG	e^+e^- 10 GeV

[89] This GODANG 00 result assumes no D^0-$\overline{D}^0$ mixing; the DCS ratio becomes $0.0048 \pm 0.0012 \pm 0.0004$ when mixing is allowed.

[90] This AITALA 98 result assumes no D^0-$\overline{D}^0$ mixing; the DCS ratio becomes $0.0090^{+0.0120}_{-0.0109} \pm 0.0044$ when mixing is allowed.

[91] BARATE 98W gets $0.0177^{+0.0060}_{-0.0056} \pm 0.0031$ for the DCS ratio when mixing is allowed, assuming no interference between the DCS and mixing amplitudes.

[92] CINABRO 94, AMMAR 91, and ALBRECHT 87K cannot distinguish between doubly Cabibbo-suppressed decay and D^0-$\overline{D}^0$ mixing.

[93] ANJOS 88C allows mixing but assumes no interference between the DCS and mixing amplitudes. When interference is allowed, the limit degrades to 0.049.

$\Gamma(K^+\pi^-\,(\text{via}\,\overline{D}^0))/\Gamma(K^-\pi^+)$ Γ_{159}/Γ_{19}

This is a D^0-$\overline{D}^0$ mixing limit. The experiments here (1) use the charge of the pion in $D^*(2010)^\pm \to (D^0 \text{ or } \overline{D}^0)\,\pi^\pm$ decay to tell whether a D^0 or a $\overline{D}^0$ was born; and (2) use the decay-time distribution to disentangle doubly Cabibbo-suppressed decay and mixing. For the limits on $|m_{D^0_1} - m_{D^0_2}|$ and $(\Gamma_{D^0_1} - \Gamma_{D^0_2})/\Gamma_{D^0}$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

This is a D^0-$\overline{D}^0$ mixing limit. For the limits on $|m_{D^0_1} - m_{D^0_2}|$ and $(\Gamma_{D^0_1} - \Gamma_{D^0_2})/\Gamma_{D^0}$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
<0.0085	90	[101] AITALA 98	E791	π^- nucleus, 500 GeV

[101] AITALA 98 uses decay-time information to distinguish doubly Cabibbo-suppressed decays from D^0-$\overline{D}^0$ mixing. The fit allows interference between the two amplitudes, and also allows CP violation in this term. The central value obtained is $0.0039^{+0.0036}_{-0.0032} \pm 0.0016$. When interference is disallowed, the result becomes $0.0021 \pm 0.0009 \pm 0.0002$.

$\Gamma(\mu^- \text{anything}\,(\text{via}\,\overline{D}^0))/\Gamma(\mu^+ \text{anything})$ Γ_{163}/Γ_2

This is a D^0-$\overline{D}^0$ mixing limit. See the somewhat better limits above.

[119] This GODANG 00 result assumes no D^0-$\overline{D}^0$ mixing; it becomes $-0.01^{+0.16}_{-0.17} \pm 0.01$ when mixing is allowed.

D^0 PRODUCTION CROSS SECTION AT $\psi(3770)$

A compilation of the cross sections for the direct production of D^0 mesons at or near the $\psi(3770)$ peak in e^+e^- production.

VALUE (nanobarns)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
5.8 ±0.5 ±0.6	[120] ADLER	88C	MRK3	e^+e^- 3.768 GeV
7.3 ±1.3	[121] PARTRIDGE	84	CBAL	e^+e^- 3.771 GeV
8.00±0.95±1.21	[122] SCHINDLER	80	MRK2	e^+e^- 3.771 GeV
11.5 ±2.5	[123] PERUZZI	77	MRK1	e^+e^- 3.774 GeV

[120] This measurement compares events with one detected D to those with two detected D mesons, to determine the the absolute cross section. ADLER 88C find the ratio of cross sections (neutral to charged) to be 1.36 ± 0.23 ± 0.14.

[121] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. PARTRIDGE 84 measures 6.4 ± 1.15 nb for the cross section. We take the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and we assume that the $\psi(3770)$ is an isosinglet to evaluate the cross sections. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

[122] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. SCHINDLER 80 assume the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and that the $\psi(3770)$ is an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

[123] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. The phase space division of neutral and charged D mesons in $\psi(3770)$ decay is taken to be 1.33, and $\psi(3770)$ is assumed to be an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction. We exclude this measurement from the average because of uncertainties in the contamination from τ lepton pairs. Also see RAPIDIS 77.

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 3 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 = 0.5$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i \delta x_j\rangle/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CHARMED, STRANGE MESONS
($C = S = \pm 1$)

$D_s^+ = c\bar{s}$, $D_s^- = \bar{c}s$, similarly for D_s^*'s

$D_s^{\pm}$

was $F^{\pm}$

$I(J^P) = 0(0^-)$

The angular distributions of the decays of the ϕ and $\overline{K}^*(892)^0$ in the $\phi\pi^+$ and $K^+\overline{K}^*(892)^0$ modes strongly indicate that the spin is zero. The parity given is that expected of a $c\bar{s}$ ground state.

$D_s^{\pm}$ MASS

The fit includes $D^{\pm}$, D^0, $D_s^{\pm}$, $D^{*\pm}$, D^{*0}, and $D_s^{*\pm}$ mass and mass difference measurements. Measurements of the $D_s^{\pm}$ mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted altogether.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT

[a] For now, we average together measurements of the $X e^+\nu_e$ and $X\mu^+\nu_\mu$ branching fractions. This is the *average*, not the *sum*.

[b] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[c] This branching fraction includes all the decay modes of the final-state resonance.

[d] This value includes only K^+K^- decays of the $f_0(1710)$, because branching fractions of this resonance are not known.

[e] This value includes only $\pi^+\pi^-$ decays of the $f_0(1500)$, because branching fractions of this resonance are not known.

[f] This mode is not a useful test for a ΔC=1 weak neutral current because both quarks must change flavor in this decay.

[g] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 15 branching ratios uses 24 measurements and one constraint to determine 10 parameters. The overall fit has a $\chi^2 = 17.5$ for 15 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\left<\delta x_i \delta x_j\right>/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

• • • We do not use the following data for averages, fits, limits, etc. • • •					
$0.015^{+0.013}_{-0.006}{}^{+0.003}_{-0.002}$	3	[7] BAI	95	BES	$e^+e^- \rightarrow D_s^+D_s^-$
$0.004^{+0.0018}_{-0.0014}{}^{+0.0020}_{-0.0019}$	8	[8] AOKI	93	WA75	π^- emulsion 350 GeV
<0.03	0	[9] AUBERT	83	SPEC	μ^+Fe, 250 GeV

[7] BAI 95 uses one actual $D_s^+ \rightarrow \mu^+\nu_\mu$ event together with two $D_s^+ \rightarrow \tau^+\nu_\tau$ events and assumes μ-τ universality. This value of $\Gamma(\mu^+\nu_\mu)/\Gamma_{total}$ gives a pseudoscalar decay constant of $(430^{+150}_{-130} \pm 40)$ MeV.

[8] AOKI 93 assumes the ratio of production cross sections of the D_s^+ and D^0 is 0.27. The value of $\Gamma(\mu^+\nu_\mu)/\Gamma_{total}$ gives a pseudoscalar decay constant $f_{D_s} = (232 \pm 45 \pm 52)$ MeV.

[9] AUBERT 83 assume that the $D_s^\pm$ production rate is 20% of total charm production rate.

$\Gamma(\mu^+\nu_\mu)/\Gamma(\phi\pi^+)$ — Γ_7/Γ_{15}

0.033 ±0.011		30	[28] DERRICK 85B	HRS	e^+e^- 29 GeV

[23] ARTUSO 96 uses partially reconstructed $\overline{B}^0 \to D^{*+}D_s^{*-}$ decays to get a model-independent value for $\Gamma(D_s^- \to \phi\pi^-)/\Gamma(D^0 \to K^-\pi^+)$ of 0.92 ± 0.20 ± 0.11.

[24] BAI 95C uses $e^+e^- \to D_s^+D_s^-$ events in which one or both of the $D_s^{\pm}$ are observed to obtain the first model-independent measurement of the $D_s^+ \to \phi\pi^+$ branching fraction, without assumptions about $\sigma(D_s^{\pm})$. However, with only two "doubly-tagged" events, the statistical error is too large for the result to be competitive with indirect measurements. ADLER 90B used the same method to set a limit.

[25] BUTLER 94, FRABETTI 93G, ALBRECHT 91, ALEXANDER 90B, and ANJOS 90B measure the ratio $\Gamma(D_s^+ \to \phi\ell^+\nu_\ell)/\Gamma(D_s^+ \to \phi\pi^+)$, where ℓ = e and/or μ, and then use a theoretical calculation of the ratio of widths $\Gamma(D_s^+ \to \phi\ell^+\nu_\ell)/\Gamma(D^+ \to \overline{K}^{*0}\ell^+\nu)$. Not everyone uses the same value for this ratio.

[26] The two MUHEIM 94 values here are model-dependent calculations based on distinct data sets. The first uses measurements of the $D_2^*(2460)^0$ and $D_{s1}(2536)^+$, the second uses B-decay factorization and $\Gamma(D_s^+ \to \mu^+\nu_\mu)/\Gamma(D_s^+ \to \phi\ell^+\nu_\ell)$. A third calculation using the semileptonic width of $D_s^+ \to \phi\ell^+\nu_\ell$ is not independent of other results listed here. Note also the upper limit, based on the sum of established D_s^+ branching ratios.

[27] ALVAREZ 90C relies on the Lund model to estimate the ratio of D_s^+ to D^+ cross sections.

[28] Values based on crude estimates of the $D_s^{\pm}$ production level. DERRICK 85B errors are statistical only.

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 1 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 =$ 0.0 for 0 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\left<\delta x_i \delta x_j\right>/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

BOTTOM MESONS
$(B = \pm 1)$

$B^+ = u\overline{b}$, $B^0 = d\overline{b}$, $\overline{B}^0 = \overline{d}b$, $B^- = \overline{u}b$, similarly for B^*'s

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the $B^\pm$ section, but because of their importance we have created two new sections: "$B^\pm/B^0$ Admixture" for $\Upsilon(4S)$ results and "$B^\pm/B^0/B^0_s/b$-baryon Admixture" for results at higher energies. Most inclusive decay branching fractions are found in the Admixture sections. B^0-$\overline{B}^0$ mixing data are found in the B^0 section, while B^0_s-$\overline{B}^0_s$ mixing data and B-$\overline{B}$ mixing data for a B^0/B^0_s admixture are found in the B^0_s section. CP-violation data are found in the B^0 section. b-baryons are found near the end of the Baryon section.

The organization of the B sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

[Production and Decay of b-flavored Hadrons]
- $B^\pm$
  - mass, mean life
  - branching fractions
- B^0
  - mass, mean life
  - branching fractions
  - polarization in B^0 decay
  - [B-$\overline{B}$ Mixing]
  - B^0-$\overline{B}^0$ mixing
  - [CP Violation in B Decay]
  - CP violation
- $B^\pm$ B^0 Admixture
  - branching fractions
- $B^\pm/B^0/B^0_s/b$-baryon Admixture
  - mean life
  - production fractions
  - branching fractions
- B^*
  - mass
- $B^*_J(5732)$
  - mass, width
- B^0_s
  - mass, mean life
  - branching fractions
  - polarizaton in B^0_s decay
  - B^0_s-$\overline{B}^0_s$ mixing
  - B-$\overline{B}$ mixing (admixture of B^0, B^0_s)
- B^*_s
  - mass
- $B^*_{sJ}(5850)$
  - mass, width
- $B^\pm_c$
  - mass, mean life
  - branching fractions

At end of Baryon Listings:
- Λ_b
  - mass, mean life
  - branching fractions
- Ξ^0_b, Ξ^-_b
  - mean life
- b-baryon Admixture
  - mean life
  - branching fractions

PRODUCTION AND DECAY OF b-FLAVORED HADRONS

Updated March 2000 by L. Gibbons (Cornell University, Ithaca) and K. Honscheid (Ohio State University, Columbus).

This year, we opened a new chapter in B physics. A new generation of experiments, BABAR, BELLE, Hera-B, and CLEO III, saw first collisions and started to accumulate B-meson decays. The next Fermilab collider run will start soon. The long-awaited B-factory era has begun.

There is great hope these experiments will provide us with precise measurements of fundamental parameters of the Standard Model, in particular the weak-mixing angles and phase of the Cabibbo-Kobayashi-Maskawa matrix, and with it an improved understanding of CP violation and maybe even a glimpse at new physics.

While the underlying decay of the heavy quark is governed by the weak interaction, it is the strong force that is responsible for the formation of the hadrons that are observed by experimenters. Although this complicates the extraction of the the Standard Model parameters from the experimental data, it also means that decays of B mesons provide an important laboratory to test our understanding of the strong interaction.

Arguably the most exciting development since the last edition of this review is the progress in b-quark processes for which amplitudes beyond the tree level play a major role. The long sought after $B^0 \to \pi^+\pi^-$ decays have finally been observed. Many other $b \to u$ and gluonic penguin transitions have been measured. In addition to branching fractions, limits on CP asymmetries have been measured for several modes. The results on rare hadronic B decays have also been used to probe possible values of the angle γ of the CKM triangle. First attempts to measure another CKM angle, $\sin(2\beta)$, have been reported by OPAL, CDF, and ALEPH.

For $b \to c$ transitions, the CLEO Collaboration used a sample of more than 18 million B decays to update branching fractions for many exclusive hadronic decay channels. New results on semileptonic decays have been reported by CLEO and the LEP Collaborations. Lifetime measurements improve steadily and now have reached a precision of a few percent.

Heavy-flavor physics is a very dynamic field, and in this brief review it is impossible to do justice to all recent theoretical and experimental developments. We will highlight a few new results but otherwise refer the interested reader to several excellent reviews [1–3].

Production and spectroscopy: Elementary particles are characterized by their masses, lifetimes, and internal quantum numbers. The bound states with a $\overline{b}$ quark and a u or d antiquark are referred to as the B_d ($\overline{B}^0$) and the B_u (B^+) mesons, respectively. The first excitation is called the B^* meson. B^{**} is the generic name for the four orbitally excited ($L = 1$) B-meson states that correspond to the P-wave mesons in the charm system, D^{**}. Mesons containing an s or a c quark are denoted B_s and B_c, respectively.

Experimental studies of b decay are performed at the $\Upsilon(4S)$ resonance near production threshold, as well as at higher energies in proton-antiproton collisions and Z decays. Most new results from CLEO are based on a sample of $\approx 9.7 \times 10^6$ $B\overline{B}$ events. At the Tevatron, CDF in particular has made significant contributions with 100 pb^{-1} of data. Operating at the Z resonance, each of the four LEP Collaborations recorded slightly under a million $b\bar{b}$ events, while the SLD experiment collected about 0.1 million $b\bar{b}$ events.

For quantitative studies of B decays, the initial composition of the data sample must be known. The $\Upsilon(4S)$ resonance decays only to $B^0\overline{B}^0$ and B^+B^- pairs, while at high-energy collider experiments, heavier states such as B_s or B_c mesons and b-flavored baryons are produced as well. The current experimental limit for non-$B\overline{B}$ decays of the $\Upsilon(4S)$ is less than 4% at the 95% confidence level [4]. CLEO has measured the ratio of charged to neutral $\Upsilon(4S)$ decays using exclusive $B \to \psi K^{(*)}$ decays. Assuming isospin invariance and $\tau_{B^+}/\tau_{B^0} = 1.066 \pm 0.024$ they found [5]

$$\frac{f_+}{f_0} = \frac{\mathrm{B}(\Upsilon(4S) \to B^+B^-)}{\mathrm{B}(\Upsilon(4S) \to B^0\overline{B}^0)} = 1.044 \pm 0.069^{+0.043}_{-0.045} \ . \quad (1)$$

This is consistent with equal production of B^+B^- and $B^0\overline{B}^0$ pairs, and unless explicitly stated otherwise, we will assume $f_+/f_0 = 1$. This assumption is further supported by the near equality of the B^+ and B^0 masses. Again using exclusive $B \to J/\psi K^{(*)}$ decays, CLEO determined these masses to $m(B^0) = 5.2791 \pm 0.0007 \pm 0.0003$ GeV/c^2 and $m(B^+) = 5.2791 \pm 0.0004 \pm 0.0004$ GeV/c^2, respectively [6].

At high-energy collider experiments, b quarks hadronize as $\overline{B}^0$, B^-, $\overline{B}^0_s$, and B_c^- mesons, or as baryons containing b quarks.

Over the last few years, there have been significant improvements in our understanding of the b-hadron sample composition. Table 1 summarizes the results showing the fractions f_d, f_u, f_s, and $f_{\rm baryon}$ of B^0, B^+, B^0_s, and b baryons in an unbiased sample of weakly decaying b hadrons produced at the Z resonance and in $p\bar{p}$ collisions. A detailed account can be found elsewhere in this Review [7].

Table 1: Fractions of weakly decaying b-hadron species in $Z \to b\bar{b}$ decay and in $p\bar{p}$ collisions at $\sqrt{(s)} = 1.8$ TeV.

b hadron	Fraction [%]
B^-, $\overline{B}^0$	38.9 ± 1.3
$\overline{B}^0_s$	10.7 ± 1.4
b baryons	11.6 ± 2.0

To date, the existence of the b-flavored mesons (B^-, $\overline{B}^0$, B_s, B_c, and various excitations), as well as the Λ_b baryon has been established. The current world average of the B^*-B mass difference is 45.78 ± 0.35 MeV/c^2. Using exclusive hadronic decays such as $B^0_s \to J/\psi\phi$ and $\Lambda_b \to J/\psi\Lambda$, the masses of these states are now known with the precision of a few MeV. The current world averages of the B_s and the Λ_b mass are 5.3696 ± 0.0024 GeV/c^2 and 5.624 ± 0.009 GeV/c^2, respectively. Clear evidence for the B_c, the last weakly decaying bottom meson, has been published by CDF [8]. They reconstruct the semileptonic decay $B_c \to J/\psi \ell X$, and extract a B_c mass of $6.40 \pm 0.39 \pm 0.13$ GeV/c^2.

First indications of Ξ_b production have been presented by the LEP Collaborations [9–10].

Excited B-meson states have been observed by CLEO, CUSB, LEP, and CDF. Evidence for B^{**} production has been presented by CDF and the LEP experiments [11]. Inclusively reconstructing a bottom hadron candidate combined with a charged pion from the primary vertex, they see the B^{**} as a broad resonance around 5.697 ± 0.009 GeV/c^2 in the $M(B\pi) \equiv M(B)$ mass distribution [12]. Due to the inclusive approach, the mass resolution is limited to about 40 MeV, which makes it very difficult to identify the narrow states, B_1 and B_2^*, separately. The LEP experiments have also provided evidence for excited B_s^{**} states.

Lifetimes: Precise lifetimes are key in extracting the weak parameters that are important for understanding the role of the CKM matrix in CP violation, such as the determination of V_{cb} and $B_s\overline{B}_s$ mixing measurements. In the naive spectator model, the heavy quark can decay only via the external spectator mechanism, and thus the lifetimes of all mesons and baryons containing b quarks would be equal. Nonspectator effects, such as the interference between contributing amplitudes, modify this simple picture and give rise to a lifetime hierarchy for b-flavored hadrons similar to the one in the charm sector. However, since the lifetime differences are expected to scale as $1/m_Q^2$, where m_Q is the mass of the heavy quark, the variation in the b system should be significantly smaller, of order 10% or less [14]. For the b system we expect

$$\tau(B^-) \geq \tau(\overline{B}^0) \approx \tau(B_s) > \tau(\Lambda_b^0) \gg \tau(B_c) \ . \quad (2)$$

In the B_c, both quarks can decay weakly, resulting in its much shorter lifetime. Measurements of lifetimes for the various b-flavored hadrons thus provide a means to determine the importance of non-spectator mechanisms in the b sector.

Over the past years, the field has matured, and advanced algorithms based on impact parameter or decay length measurements exploit the potential of silicon vertex detectors. However, in order to reach the precision necessary to test theoretical predictions, the results from different experiments need to be averaged. This is a challenging task that requires detailed knowledge of common systematic uncertainties, and correlations between the results from different experiments. The average lifetimes for b-flavored hadrons given in this edition have been determined by the LEP B Lifetimes Working Group [15]. The papers used in this calculation are listed in the appropriate sections. A detailed description of the procedures and the treatment of correlated and uncorrelated errors can be found in [16]. The new world average b-hadron lifetimes are summarized in Table 2.

The first measurement of the B_c lifetime comes from the CDF Collaboration [8]. Lifetime measurements have reached a level of precision that the average b-hadron lifetime result becomes sensitive to the composition of the data sample. The result listed in Table 2 takes into account correlations between different experiments and analysis techniques, but does not correct for differences due to different admixtures of b-flavored hadrons. For inclusive lifetime measurements, the size of this effect can be estimated by dividing the available results into three sets. LEP measurements based on the identification of a lepton from the b decay yield $\tau_{b\ \text{hadron}} = 1.537 \pm 0.020\ \text{ps}^{-1}$ [17–19]. The average b-hadron lifetime based on inclusive secondary vertex techniques is $\tau_{b\ \text{hadron}} = 1.577 \pm 0.016\ \text{ps}^{-1}$ [18,20–24]. Finally, CDF [25] used J/ψ mesons to tag the b vertex resulting in $\tau_{b\text{-hadron}} = 1.533 \pm 0.015^{+0.035}_{-0.031}\ \text{ps}^{-1}$. Contrary to what is observed, the average b lifetime determined from a sample of semileptonic decays is expected to be larger than the lifetime extracted from inclusive decays. Given the precision of the measurements, however, the discrepancy is not yet significant. The resulting average b lifetime is listed in Table 2.

Table 2: Summary of inclusive and exclusive b-hadron lifetime measurements.

Particle	Lifetime [ps]
B^0	1.548 ± 0.032
B^+	1.653 ± 0.028
B_s	1.493 ± 0.062
B_c	$0.46^{+0.18}_{-0.16} \pm 0.03$
b baryon	1.208 ± 0.051
b hadron	1.564 ± 0.014

For comparison with theory, lifetime ratios are preferred. Experimentally we find [15]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.062 \pm 0.029\,, \quad \frac{\tau_{B_s}}{\tau_{B^0}} = 0.964 \pm 0.045\,, \quad \frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.780 \pm 0.037\,, \tag{3}$$

while theory makes the following predictions [26]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1 + 0.05\left(\frac{f_B}{200\ \text{MeV}}\right)^2\,, \quad \frac{\tau_{B_s}}{\tau_{B^0}} = 1 \pm 0.01\,, \quad \frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.9\,. \tag{4}$$

In conclusion, the pattern of measured B-meson lifetimes follows the theoretical expectations, and non-spectator effects are observed to be small. The short B_c lifetime has been predicted correctly. However, the Λ_b-baryon lifetime is unexpectedly short. As has been noted by several authors, the observed value of the Λ_b lifetime is quite difficult to accommodate theoretically [27–33]. This apparent breakdown of the heavy-quark expansion for inclusive, non-leptonic B decays could be caused by violations of local quark-hadron duality. Neubert, however, argues that this conclusion is premature because a reliable field-theoretical calculation is still lacking. Exploring a reasonable parameter space for the unknown hadronic matrix elements, he demonstrated that within the experimental errors, theory can accommodate the measured lifetime ratios [1]. A recent calculation based on QCD sum rules [34] arrives at a similar conclusion allowing $\tau_{\Lambda_b}/\tau_{B^0} = 0.79$–$0.87$. An initial lattice study [35], on the other hand, finds $\tau_{\Lambda_b}/\tau_{B^0} = 0.91$–$0.93$.

Similar to the kaon system, neutral B mesons contain short- and long-lived components. The lifetime difference is, of course, significantly smaller, and recent experimental limits at 95% C.L. are

$$\frac{\Delta\Gamma_d}{\Gamma_d} < 0.82 \text{ and } \frac{\Delta\Gamma_s}{\Gamma_s} < 0.65\,. \tag{5}$$

These results are based on a comparison of direct δm measurements with χ_d measurements for B_d [36] and a combination [37] of the various B_s proper time measurements. A more restrictive limit for the B_s system can be obtained if one assumes $\Gamma_{B_s} = \Gamma_{B_d}$.

Semileptonic B decays: Measurements of semileptonic B decays are important to determine the weak couplings $|V_{cb}|$ and $|V_{ub}|$. In addition, these decays can be used to probe the dynamics of heavy quark decay. The leptonic current can be calculated exactly, while corrections due to the strong interaction are restricted to the $b \to c$ and $b \to u$ vertices, respectively.

Experimentally, semileptonic decays have the advantage of large branching ratios and the characteristic signature of the energetic charged lepton. The neutrino, however, escapes undetected so a full reconstruction of the decaying B meson is impossible. Various techniques which take advantage of production at threshold or the hermiticity of the detector have been developed by the ARGUS, CLEO, and LEP experiments to overcome this difficulty.

Several different approaches have been used to measure the inclusive semileptonic rate $B \to X\ell\nu_\ell$. These are measurements of the inclusive single lepton momentum spectrum, measurements of dilepton events using charge and angular correlations first pioneered by ARGUS [38], measurements of leptons opposite a b-tagged jet at the Z, and measurements of the separate B^- and $\overline{B}^0$ branching ratios by using events which contain a lepton and a reconstructed B meson. The double-tagged methods (lepton–lepton) have the smallest model dependence, and only the dilepton results from the the $\Upsilon(4S)$ are used. The LEP averages [39] are based primarily on single lepton measurements, which rely on modeling of the semileptonic decays. The uncertainties involved in such modeling are, by their nature, ill-defined and difficult to quantify. The average LEP [39] and the $\Upsilon(4S)$ [40] rates are listed in Table 3. Differences in B_{sl} measured at the $\Upsilon(4S)$ and the Z are expected due to the different admixture of b-flavored hadrons. Given the short Λ_b lifetime, the LEP value should be lower than the $\Upsilon(4S)$ result. Previous LEP determinations of $B \to X\ell\nu_\ell$ have been markedly higher than the $\Upsilon(4S)$ measurements. The current LEP measurements are now in much better agreement with expectations relative to the $\Upsilon(4S)$ rate.

A few new results on the branching fractions of exclusive semileptonic B decays have been reported. The current world averages are listed in Table 3. It is interesting to compare the inclusive semileptonic branching fraction to the sum of branching fractions for exclusive modes, which agree at the 1σ level. The exclusive modes measured are consistent with saturating the inclusive rate.

The makeup of the non-D and D^* components of the B semileptonic process is a critical component in the determination of b lifetimes, B mixing, $|V_{cb}|$, and $|V_{ub}|$. It has been known for some time that the D^{**} excited states do not appear to account for the difference between the $D+D^*$ rates and the inclusive rate [41,42]. A recent inclusive $B \to D^*\pi\ell\nu_\ell X$ study by DELPHI [43] adds information regarding the breakdown into the $D^*\pi$ and $D\pi$ contributions. Unfortunately, we still lack information regarding detailed makeup of, and the hadronic mass spectrum for, this component.

Table 3: Inclusive and exclusive semileptonic branching fractions of B mesons. $\mathrm{B}(\overline{B} \to X_u\ell^-\overline{\nu}_\ell) = 0.15 \pm 0.1\%$ [44] has been included in the sum of the exclusive branching fractions.

Mode		Branching fraction [%]
$\overline{B} \to X\ell^-\overline{\nu}_\ell(\Upsilon(4S))$		$10.49 \pm 0.17 \pm 0.43$
$b \to X\ell^-\overline{\nu}_\ell(Z)$		$10.58 \pm 0.07 \pm 0.17$
$\overline{B} \to D\ell^-\overline{\nu}_\ell$		2.13 ± 0.22
$\overline{B} \to D^*\ell^-\overline{\nu}_\ell$		5.05 ± 0.25
$\overline{B} \to D^{(*)}\pi\ell^-\overline{\nu}_\ell$		2.26 ± 0.44
with $\overline{B} \to D_1^0(2420)\ell^-\overline{\nu}_\ell X$	0.74 ± 0.16	
$\overline{B} \to D_2^{*0}(2460)\ell^-\overline{\nu}_\ell X$	< 0.65 90% CL	
$\Sigma \mathrm{B}_{\mathrm{exclusive}}$		9.59 ± 0.56

Dynamics of semileptonic B decay and $|V_{cb}|$: Since leptons are not sensitive to the strong interaction, the amplitude for a semileptonic B decay can be factorized into two parts, a leptonic and a hadronic current. The leptonic factor can be calculated exactly, while the hadronic part is parameterized by form factors. A simple example is the transition $B \to D\ell\nu_\ell$. The differential decay rate in this case is given by

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2}{24\pi^3}|V_{cb}^2|P_D^3 f_+^2(q^2) \qquad (6)$$

where q^2 is the mass of the virtual W ($\ell\nu_\ell$), P_D is the D momentum and $f_+(q^2)$ is the single vector form factor which gives the probability that the final state quarks will form a D meson. Since the leptons are very light, the corresponding $f_-(q^2)$ form factor can be neglected. For $B \to D^*\ell\nu_\ell$ decays, in the limit of zero lepton mass there are three form factors which correspond to the three possible partial waves of the $B \to D^*\widehat{W}$ system (here $\widehat{W}$ is the virtual W boson, which becomes the lepton-antineutrino pair). Currently, form factors cannot be predicted by theory and need to be determined experimentally. Over the last years, however, it has been appreciated that there is a symmetry of QCD that is useful in understanding systems containing one heavy quark. This symmetry arises when the quark becomes sufficiently heavy to make its mass irrelevant to the nonperturbative dynamics of the light quarks. This allows the heavy quark degrees of freedom to be treated in isolation from the light quark degrees of freedom. This is analogous to the canonical treatment of hydrogenic atoms, in which the spin and other properties of the nucleus can be neglected. The behavior and electronic structure of the atom are determined by the light electronic degrees of freedom. Heavy quark effective theory (HQET) was created by Isgur and Wise [45], who define a single universal form factor, $\xi(v \cdot v')$, known as the Isgur-Wise function. In this function, v and v' are the four velocities of the initial and final state heavy mesons. The Isgur-Wise function cannot be calculated from first principles, but unlike the hadronic form factors mentioned above, it is universal to leading order. In the heavy quark limit, it is the same for all heavy meson to heavy meson transitions, and the four form factors parameterizing $B \to D^*\ell\nu_\ell$ and $B \to D\ell\nu_\ell$ decays can be related to this single function ξ.

In this framework the differential semileptonic decay rates as functions of $w = v_B \cdot v_{D^{(*)}} = (m_B^2 + m_{D^{(*)}}^2 - q^2)/2m_Bm_{D^{(*)}}$ are given by [1]

$$\begin{aligned}\frac{d\Gamma(\overline{B} \to D^*\ell\overline{\nu}_\ell)}{dw} &= \frac{G_F^2M_B^5}{48\pi^3}r_*^3(1-r_*)^2\sqrt{w^2-1}(w+1)^2 \\ &\times\left[1+\frac{4w}{w+1}\frac{1-2wr_*+r_*^2}{(1-r_*)^2}\right]|V_{cb}|^2\mathcal{F}^2(w) \\ \frac{d\Gamma(\overline{B} \to D\ell\overline{\nu}_\ell)}{dw} &= \frac{G_F^2M_B^5}{48\pi^3}r^3(1+r)^2(w^2-1)^{3/2}|V_{cb}|^2\mathcal{G}^2(w) \quad (7)\end{aligned}$$

where $r_{(*)} = M_{D^{(*)}}/M_B$ and q^2 is the invariant momentum transfer. For $m_Q \to \infty$, the two form factors $\mathcal{F}(w)$ and $\mathcal{G}(w)$ coincide with the Isgur-Wise function $\xi(w)$.

Both CLEO [46] and ALEPH [47] have measured the differential decay rate distributions and extracted the ratio $\mathcal{G}(w)/\mathcal{F}(w)$ which is expected to be close to unity. The data are compatible with a universal form factor $\xi(w)$.

CLEO has also performed a direct measurement of the three form factors that are used to parameterize $B \to D^*\ell\nu_\ell$ decays [48]. These are usually expressed in terms of form factor ratios [49]. $R_1(w) = h_V(w)/h_{A_1}(w)$ and $R_2(w) = h_{A_2}(w)/h_{A_1}(w)$ where $h_V(w)$, $h_{A_1}(w)$ and $h_{A_2}(w)$ are the standard three HQET form factors in the zero lepton mass limit (see Ref. 49 and references therein). At zero recoil, *i.e.* $w = 1$, CLEO finds $R_1(1) = 1.18 \pm 0.30 \pm 0.12$ and $R_2(1) = 0.71 \pm 0.2 \pm 0.07$. While the errors are still large, this is in good agreement with a theoretical prediction of $R_1(1) = 1.3 \pm 0.1$ and $R_2(1) = 0.8 \pm 0.2$ [1].

The universal form factor $\xi(w)$ describes the overlap of wave functions of the light degrees of freedom in the initial and final heavy meson. At zero recoil, *i.e.*, when the two mesons move with the same velocity, the overlap is perfect and the form factor is absolutely normalized, $\xi(1) = 1$. In principle, all that experimentalists have to do to extract a model-independent value for $|V_{cb}|$ is to measure $d\Gamma(B \to D^{(*)}\ell\nu_\ell)/dw$ for $w \to 1$. However, in the real, world the b and c quarks are not infinitely heavy, so corrections to the limiting case have to be calculated.

The evaluation of $\mathcal{F}(1)$ and $\mathcal{G}(1)$ remains a topic of some theoretical controversy [1,50–54]. A middle ground could be characterized as

$$\mathcal{F}(1) = 0.92 \pm 0.05 \; , \quad \mathcal{G}(1) = 1.00 \pm 0.07 \; . \qquad (8)$$

The calculations of $\mathcal{F}(1)$ and $\mathcal{G}(1)$ most commonly accepted have relied upon some of the OPE techniques, and in fact these results are correlated at some level with the inclusive rate calculations. Concerns about duality violation, for example, enter these determinations as well. Other, "exclusive approaches" (see Ref. 54 and references therein) yield results similar to the values quoted and are free from duality uncertainties. However, they rely on modelling to estimate exclusive matrix elements, for which uncertainties are very difficult to quantify. Recently, there has been a prototype lattice determination that obtained an $\mathcal{F}(1)$ value only very slightly higher than the above with a preliminary uncertainty of 3.3%. These results are encouraging, and are free of the intimate correlation with the inclusive calculations. To fully understand the uncertainties, an unquenched calculation is needed.

Measurements of $\mathcal{F}(1)|V_{cb}|$ have been performed by the ALEPH, ARGUS, CLEO, DELPHI, and OPAL experiments. Because the differential decay rate actually vanishes at zero recoil, experimentally the decay rate must be measured as a function of w and extrapolated to zero. This requires a parameterization of the shape of the form factor $\mathcal{F}(w)$. Initial measurements used a linear parameterization and fit the slope and $\mathcal{F}(1)|V_{cb}|$ simultaneously. $\mathcal{F}(w)$ must have a positive curvature, so this linear parameterization results in an intercept that is biased low by about 2.6% [55]. More recent determinations [47,56–58] have used dispersion relation calculations [59,60] that relate the curvature to the slope. In either case, the slope and intercept parameters are highly correlated and require simultaneous averaging [61].

$|V_{cb}|$ from exclusive $D{*}\ell\nu_\ell$ determinations and from inclusive determinations (discussed below) are summarized in Table 4. The various averages are in good agreement. Because of the correlations between slope and $\mathcal{F}(1)|V_{cb}|$, and the different meanings of the slopes in the linear and dispersion-relation-based parameterizations, the older CLEO [62] and ARGUS [63] $D^*\ell\nu$ measurements, based on the linear parameterization, have not here been averaged with the LEP results [47,57–58], based on the dispersion-relation parameterization. Determinations of $|V_{cb}|$ based on the $B \to D\ell\nu_\ell$ process [47,56] give consistent results, but with a factor of two larger uncertainty.

Heavy Quark Symmetry (HQS) has also allowed remarkable precision in the calculation of the semileptonic width $\Gamma(B \to X_c\ell\nu_\ell)$. The operator product expansion (OPE) of the width in terms of the (inverse) heavy quark mass and in α_s appears free of $1/m_b$ corrections, and at $1/m_b^2$ is given by [66]

Table 4: Current determinations of $|V_{cb}|$. The inclusive branching fractions have been adjusted for a $1.5 \pm 1.0\%$ $b \to u$ component relative to $b \to c$ [44]. The uncertainties are experimental followed by theoretical.

Mode	$\lvert V_{cb}\rvert$
$\overline{B} \to D^*\ell^-\overline{\nu}_\ell$ [64]	$0.0367 \pm 0.0023 \pm 0.0018$
	(Dispersion relation $\mathcal{F}(w)$ parameterization)
$\overline{B} \to D^*\ell^-\overline{\nu}_\ell$ [65]	$0.0392 \pm 0.0030 \pm 0.0019$
	(Linear $\mathcal{F}(w)$ parameterization (+ bias correction))
$\Gamma(b \to c\ell\nu_\ell)$	$0.0408 \pm 0.0005 \pm 0.0025$
	(B^0, B^+, B_s, and b-baryon admixture at the Z)
$\Gamma(B \to X_c\ell\nu_\ell)$	$0.0400 \pm 0.0010 \pm 0.0024$
	(B^0, B^+ admixture at the $\Upsilon(4S)$)

$$\Gamma_{SL}(B) = \frac{G_F^2 m_b^5 |V_{cb}|^2}{192\pi^3} \times \left[z_0 \left(1 - \frac{\mu_\pi^2 - \mu_G^2}{2m_b^2}\right) - 2\left(1 - \frac{m_c^2}{m_b^2}\right)^4 \frac{\mu_G^2}{m_b^2} - \frac{2\alpha_S}{3\pi} z_0^{(1)} + \ldots \right] . \quad (9)$$

At $1/m_b^2$, three nonperturbative parameters enter the expansion of the differential decay rate: μ_π^2 (or, closely related λ_1), which is related to the average kinetic energy of the b quark in the meson; μ_G^2 (or λ_2), which is related to the hyperfine splitting and can be determined from the B–B^* mass difference; and $\overline{\Lambda}$, which relates the quark mass to the meson mass. This last enters implicitly since the b quark mass, not the B meson mass has been used. The parameters z_0 and $z_0^{(1)}$ are known phase space factors that depend on m_c^2/m_b^2. Bigi [51] suggests an uncertainty of approximately 6% on $|V_{cb}|$ from such a calculation. Various calculations [67–68] are consistent with a central value

$$|V_{cb}| = 0.0411 \sqrt{\frac{\mathcal{B}(B \to X_c\ell\nu)}{0.105}} \sqrt{\frac{1.55 \text{ ps}}{\tau_B}} \left(1 - 0.024 \frac{\mu_\pi^2 - 0.5\text{GeV}^2}{0.2\text{GeV}^2}\right) . \qquad (10)$$

Combined with the semileptonic branching fractions at the $\Upsilon(4S)$ and the Z quoted above, one obtains the inclusive determinations of $|V_{cb}|$ listed in Table 4. These agree with the exclusive determinations.

The validity of the OPE-based calculation rests upon the assumption of quark–hadron duality. The uncertainty induced from this assumption is unknown. While expected to be small [69–71], there has been a suggestion that the assumption could mask corrections of order $1/m_b$ [72]. A 5% effect, for example, cannot be ruled out at this time.

Moments of the inclusive lepton [73] and hadron mass [74–76] spectra can be used both to determine the nonperturbative parameters and to test the OPE/HQS framework at the $1/m_b^2$ level. A preliminary moment analysis by CLEO [77] suggests that the parameters derived from the leptonic moments may be inconsistent with those from the hadronic moments. A variety of explanations for this exist: an experimental problem, slow convergence of the $1/m$ expansion for the higher moments, or more fundamentally, duality violation. Further investigation is required.

Semileptonic $b \to u$ transitions: The simplest diagram for a rare B decay is obtained by replacing the $b \to c$ spectator diagram with a CKM suppressed $b \to u$ transition. These decays probe the small CKM matrix element V_{ub}, the magnitude of which sets bounds on the combination $\rho^2 + \eta^2$ in the Wolfenstein parameterization of the CKM matrix [78]. As with V_{cb}, extraction of V_{ub} has been attempted using both inclusive and exclusive semileptonic B decays. An accurate method of determining V_{ub} has been somewhat elusive. With exclusive techniques, the heavy-to-light $b \to u$ transition has no theoretical analogue to the zero recoil ($w = 1$) point in the heavy-to-heavy $b \to c$ transition of $B \to D^* \ell \nu$. Rather than calculating a correction of order 10% to the unit form factor expected for a heavy-to-heavy transition at $w = 1$ (in the infinite mass limit), the absolute normalization of the form factors must be predicted. This normalization dominates the uncertainty in exclusive determinations of V_{ub}.

There have been two exclusive V_{ub} analyses by the CLEO Collaboration: a simultaneous measurement of the $B \to \pi \ell \nu_\ell$ and the $B \to \rho \ell \nu_\ell$ transitions [79], and a second measurement of the $B \to \rho \ell \nu_\ell$ rate [80]. The results of the two analyses are largely statistically independent, and their results have been combined, with correlated uncertainties accounted for, to obtain $|V_{ub}| = (3.25 \pm 0.14^{+0.21}_{-0.29} \pm 0.55) \times 10^{-3}$, where the final error is the uncertainty from the form factors. New calculations based on light cone sum rules [81–83] and lattice calculations [84,85,86] promise to result in uncertainties in the 10% to 15% range soon. Uncertainties below 10% will require either unquenched lattice calculations or accurate measurements of the rate for $B \to K^* \ell^+ \ell^-$, which would allow one to extract $|V_{ub}|/|V_{cs}|$ from a double ratio of B and D decays [87].

In principle, the fully inclusive rate can be calculated reliably enough (barring an unexpectedly large violation of quark-hadron duality) to determine $|V_{ub}|$ with an accuracy under 10% [51]. Realizing this accuracy is extremely difficult in practice because the ferocious background from $b \to c \ell \nu_\ell$ decays forces experiments to limit measurement to a restricted region of the total phase space. Restriction of the theoretical rate to the restricted region can introduce large uncertainties in the calculation that can be difficult to quantify.

The published inclusive analyses at the $\Upsilon(4S)$ [88] have focused on leptons in the endpoint region of the single lepton spectrum, which are kinematically incompatible with coming from a $b \to c$ transition. Models were used to estimate the rate into the endpoint, from which $|V_{ub}/V_{cb}| = (0.08 \pm 0.02)$ is obtained. The error is dominated by the theoretical uncertainty, which has been very difficult to quantify. Because the endpoint region extends beyond the partonic endpoint and the size of the endpoint is of order $\Lambda_{\rm QCD}$, an infinite series of terms in the OPE rate calculation become equally important [89]. While the leading singularities can be resummed into a structure function [90,91], the structure function is unknown.

Another method for extracting $|V_{ub}|$ from the endpoint has been proposed [92] based on earlier suggestions [90,91] that involve comparison of the endpoint lepton spectrum to the photon spectrum in $b \to s\gamma$. These decays share the same structure function, and the comparison results in a large cancellation of the theoretical uncertainties. In principle, this technique could lead to a determination of $|V_{ub}|$ with an uncertainty under 10%.

Over the past several years, the ALEPH [93], DELPHI [94], and L3 [95] experiments have attempted inclusive measurements of the $b \to u \ell \nu_\ell$ rate. The approaches are disparate, but tend to be sensitive to $b \to u \ell \nu$ primarily when the mass of the hadronic system (m_{X_u}) is in the region $m_{X_u} \lesssim M_D$. They are sensitive to a significantly larger portion of the phase space than the endpoint analyses, but at the cost of very large backgrounds from $b \to c \ell \nu_\ell$ decays (signal:background ratios of order 1:10). The branching fractions obtained are listed in Table 5. An average by the LEP Heavy Flavour Group [37] results in $|V_{ub}| = 4.04^{+0.41}_{-0.46}(\text{exp})^{+0.43}_{-0.48}(b \to c)^{+0.24}_{-0.25}(b \to u) \pm 0.02(\tau_b) \pm 0.19(\text{HQS})$. A note of caution, however. While observation of these decays at LEP is an experimental tour de force, the aggressive systematic errors assigned to unknown aspects of $b \to c \ell \nu_\ell$ and $b \to u \ell \nu_\ell$ processes remain a topic of discussion in the community. Among the concerns: the large uncertainties in the makeup of the non-D and D^* components of the background and the need for modeling of the $b \to u \ell \nu_\ell$ decays to correct for the smearing and nonuniform efficiency over the phase space of the decay.

A new proposal [89] to measure $|V_{ub}|$ inclusively in a restricted region of q^2 has promise. As mentioned above, measurements in the lepton endpoint region suffer from significant theoretical uncertainties from unknown structure functions. Analyses restricted to the hadronic mass range $m_{X_u} < \sqrt{\Lambda m_b}$ are affected by similar uncertainties, so the level appears to be much reduced [96,97], about 10%. The proposed method offers suppression of $b \to c \ell \nu_\ell$ background without introducing such uncertainties.

So far, the various determinations of $|V_{ub}|$ have produced consistent results. However, with the many theoretical and experimental difficulties with the measurements to date, the authors agree with the conservative assessment of the current uncertainties presented in the CKM review [98].

Table 5: Inclusive semileptonic branching fractions for $b \to u \ell \nu_\ell$ measured at LEP.

Experiment	Branching Fraction $[10^{-3}]$
ALEPH [93]	$1.73 \pm 0.55 \pm 0.55$
DELPHI [94]	$1.57 \pm 0.35 \pm 0.55$
L3 [95]	$3.3 \pm 1.0 \pm 1.7$

Hadronic B decays: In hadronic decays of B mesons, the underlying weak transition of the b quark is overshadowed by strong interaction effects caused by the surrounding cloud of light quarks and gluons. While this complicates the extraction of CKM matrix elements from experimental results, it also turns the B meson into an excellent laboratory to study perturbative and non-perturbative QCD, hadronization, and Final State Interaction (FSI) effects.

The precision of the experimental data has steadily improved over the past years. In 1997 CLEO updated most branching fractions for exclusive $B \to (n\pi)^- D^{(*)}$ and $B \to J/\psi K^{(*)}$ transitions. Tighter limits on color suppressed decays such as $\overline{B} \to D^0\pi^0$ have been presented [99]. Updated measurements of the polarization in $B \to J/\psi K^*$ resolved an outstanding discrepancy between theory and experiment [100]. Angular distributions have been studied for other B decays with two vector mesons in the final state including $B \to D^*\rho$, $B \to D^*D^*$, and $B \to D^*D_s^*$. CLEO found the relative phases of the helicity amplitudes in $B \to D^*\rho^-$ decays to be non-zero [101], implying that FSI effects may play a role in B decays after all. $B^0 \to D^{*+}D^{*-}$ decays have been observed with a branching fraction of $(9.9^{+4.2}_{-3.3} \pm 1.2) \times 10^{-4}$, providing unambiguous evidence for Cabibbo–suppressed $b \to c\bar{c}d$ transitions [102,103].

Gronau and Wyler [104] first suggested that decays of the type $B \to DK$ can be used to extract the angle γ of the CKM unitarity triangle, $\gamma \approx \arg(V_{ub})$. The first example of such a Cabibbo–suppressed mode has been observed by CLEO [105]:

$$\frac{\mathrm{B}(B^- \to D^0K^-)}{\mathrm{B}(B^- \to D^0\pi^-)} = 0.055 \pm 0.014 \pm 0.005 \; . \qquad (11)$$

Measurements of exclusive hadronic B decays have reached sufficient precision to challenge our understanding of the dynamics of these decays. It has been suggested that in analogy to semileptonic decays, two-body hadronic decays of B mesons can be expressed as the product of two independent hadronic currents, one describing the formation of a charm meson and the other the hadronization of the remaining $\overline{u}d$ (or $\overline{c}s$) system from the virtual W^-. Qualitatively, for a B decay with a large energy release, the $\overline{u}d$ pair, which is produced as a color singlet, travels fast enough to leave the interaction region without influencing the second hadron formed from the c quark and the spectator antiquark. The assumption that the amplitude can be expressed as the product of two hadronic currents is called "factorization" in this paper. By comparing exclusive hadronic B decays to the corresponding semileptonic modes the factorization hypothesis has been experimentally confirmed for certain $b \to c$ decays with large energy release [100]. An example is given by the longitudinal polarization of ρ mesons in $B \to D^*\rho$ decays, which was recently updated by the CLEO Collaboration [101]. Their result of $\Gamma_L/\Gamma = 0.878 \pm 0.034 \pm 0.040$ agrees well with the factorization expectation, 0.85–0.88 [106–109].

For internal spectator decays, the validity of the factorization hypothesis is also questionable and requires experimental verification. The naive color transparency argument used in the previous sections is not applicable to decays such as $B \to J/\psi K$, and there is no corresponding semileptonic decay for comparison. For internal spectator decays, one can only compare experimental observables to quantities predicted by models based on factorization. Two such quantities are the production ratio

$$\mathcal{R} = \frac{\mathrm{B}(B \to J/\psi K^*)}{\mathrm{B}(B \to J/\psi K)} \qquad (12)$$

and the amount of longitudinal polarization Γ_L/Γ in $B \to J/\psi K^*$ decays. The CLEO Collaboration published new data on $B \to$ charmonium transitions [110].

$$\mathcal{R} = 1.45 \pm 0.20 \pm 0.17 \; , \; \Gamma_L/\Gamma = 0.52 \pm 0.07 \pm 0.04 \; , \qquad (13)$$

are now consistent with factorization-based models.

In the decays of charm mesons, the effect of color suppression is obscured by the effects of FSI or reduced by nonfactorizable effects. Because of the larger mass of the b quark, a more consistent pattern of color-suppression is expected in the B system, and current experimental results seem to support that color-suppression is operative in hadronic decays of B mesons. Besides $B \to$ charmonium transitions, no other color-suppressed decay has been observed experimentally [99]. The current upper limit on $\mathrm{B}(\overline{B}^0 \to D^0\pi^0)$ is 0.012% at 90% C.L.

By comparing hadronic B^- and $\overline{B}^0$ decays, the relative contributions from external and internal spectator decays have been disentangled. For all decay modes studied, the B^- branching fraction was found to be larger than the corresponding $\overline{B}^0$ branching ratio, indicating constructive interference between the external and internal spectator amplitudes. In the BSW model [111], the two amplitudes are proportional to effective coefficients, a_1 and a_2, respectively. A least squares fit using experimental results and a model by Neubert *et al.* [112] gives

$$a_2/a_1 = 0.22 \pm 0.04 \pm 0.06 \; , \qquad (14)$$

where we have ignored uncertainties in the theoretical predictions. The second error is due to the uncertainty in the B-meson production fractions (f_+, f_0) and lifetimes (τ_+, τ_0) that enter into the determination of a_2/a_1 in the combination $(f_+\tau_+/f_0\tau_0)$. As this ratio increases, the value of a_2/a_1 decreases. Varying $(f_+\tau_+/f_0\tau_0)$ in the allowed experimental range excludes a negative value of a_2/a_1. Other uncertainties in the magnitude of the decay constants f_D and f_{D^*}, as well as in the hadronic form factors, can change the magnitude of a_2/a_1, but not its sign.

The magnitude of a_2 determined from this fit to the ratio of B^- and B^0 branching fractions is consistent with the value of $|a_2|$ determined from the fit to the $B \to J/\psi X$ decay modes, which only proceed via the color suppressed amplitude. The coefficient a_1 also shows little or no process dependency.

The observation that the coefficients a_1 and a_2 have the same relative sign in B^- decay came as a surprise, since destructive interference was observed in hadronic charm decay. The sign of a_2 disagrees with the theoretical extrapolation from the fit to charm meson decays using the BSW model. It also disagrees with the expectation from the $1/N_c$ rule [113]. The result may be consistent with the expectation of perturbative QCD [114]. B. Stech proposed that the observed interference pattern in charged B and D decay can be understood in terms of the running strong coupling constant α_s [115]. A solution based on PQCD factorization theorems has been suggested by B. Tseng and H.N. Li [116].

Although constructive interference has been observed in all the B^- modes studied so far, these comprise only a small fraction of the total hadronic rate. It is conceivable that higher-multiplicity B^- decays demonstrate a very different behavior.

It is intriguing that $|a_1|$ determined from the $B \to D^{(*)}\pi$, $D^{(*)}\rho$ modes agrees well with the value of a_1 extracted from $B \to DD_s$ decays. The observation of color-suppressed decays such as $\overline{B}^0 \to D^0\pi^0$ would give another measure of $|a_2|$ complementary to that obtained from $B \to$ charmonium decays.

In summary, experimental results on exclusive B decay match very nicely with theoretical expectations. Unlike charm, the b quark appears to be heavy enough so that corrections due to the strong interaction are small. Factorization and color-suppression are at work. An intriguing pattern of constructive interference in charged B decays has been observed.

Inclusive hadronic decays: Over the last years, inclusive B decays have become an area of intensive studies, experimentally as well as theoretically. Since the hadronization process to specific final state mesons is not involved in inclusive calculations, the theoretical results and predictions are generally believed to be more reliable.

CLEO and the LEP Collaborations presented new measurements of inclusive $b \to c$ transitions that can be used to extract n_c, the number of charm quarks produced per b decay. Naively we expect $n_c = 115\%$, with the additional 15% coming from the fragmentation of the W boson to $\bar{c}s$. This expectation can be verified experimentally by adding all inclusive $b \to c$ branching fractions. Using CLEO and DELPHI results, we can perform the calculation shown in Table 6. Modes with 2 charm quarks in the final state are counted twice. For the unobserved $B \to \eta_c X$ decay, we take the experimental upper limit. B_s mesons and b baryons produced at the Z, but not at the $\Upsilon(4S)$, cause the increase in D_s and Λ_c production rates seen by LEP. To first order, however, this should not affect the charm yield, as it should be compensated by reduced branching fractions for D mesons. This reduction is not reflected in the current data, but the errors in the D branching fractions are still large. In addition, there are significant uncertainties in the D_s and Λ_c absolute branching fractions.

New measurements of the multiplicity of charm quarks per b decay have also been reported by ALEPH and OPAL [117]. Combining this with the DELPHI results yields a new correlated average of $n_c = 1.151 \pm 0.022 \pm 0.022 \pm 0.051$, where the errors are statistical, systematic and due to the uncertainties in charm branching fractions [118]. There is now good agreement between the results from the $\Upsilon(4S)$ and the Z^0.

Table 6: Charm yield per B decay.

Channel	Branching fraction [%] $\Upsilon(4S)$ [100]	Branching fraction [%] LEP (DELPHI) [119]
$B \to D^0 X$	63.6 ± 3.0	60.05 ± 4.29
$+$ $B \to D^+ X$	23.5 ± 2.7	23.01 ± 2.13
$+$ $B \to D_s^+ X$	12.1 ± 1.7	16.65 ± 4.50
$+$ $B \to \Lambda_c^+ X$	2.9 ± 2.0	8.90 ± 3.0
$+$ $B \to \Xi_c^{+,0} X$	2.0 ± 1.0	4.00 ± 1.60
$+$ $2\times$ $B \to J/\psi_{\rm direct} X$	0.8 ± 0.08	
$+$ $2\times$ $B \to \psi(2S)_{\rm direct} X$	0.35 ± 0.05	
$+$ $2\times$ $B \to \chi_{c1} X$	0.37 ± 0.07	
$+$ $2\times$ $B \to \chi_{c2} X$	0.25 ± 0.1	
$+$ $2\times$ $B \to \eta_c X$	< 0.9 (90%C.L.)	
$+$ $2\times$ $b \to (c\bar{c}) X$		2.00 ± 0.65
n_c	110 ± 5	115.1 ± 7.4

The $b \to c\bar{c}s$ transition: It was previously assumed that the conventional $b \to c\bar{u}d \to DX$ and $b \to c\bar{c}s \to DD_sX$ mechanisms account for all D-meson production in B decay. Buchalla *et al.* [120] suggested that a significant fraction of D mesons could also arise from $b \to c\bar{c}s$ transitions with light quark pair production at the upper vertex, *i.e.* $b \to c\bar{c}s \to D\overline{D}X_s$. The two mechanisms can be distinguished by the different final states they produce. In the first case the final state includes only D mesons, whereas in the second case two D mesons can be produced, one of which has to be a $\overline{D}$.

Table 7: CLEO results on $B \to DDK$ decays.

Mode	Branching fraction
$B(\overline{B}^0 \to D^{*+}\overline{D}^0 K^-)$	$0.45^{+0.25}_{-0.19} \pm 0.08\%$
$B(B^- \to D^{*0}\overline{D}^0 K^-)$	$0.54^{+0.33}_{-0.24} \pm 0.12\%$
$B(\overline{B}^0 \to D^{*+}\overline{D}^{*0} K^-)$	$1.30^{+0.61}_{-0.47} \pm 0.27\%$
$B(B^- \to D^{*0}\overline{D}^{*0} K^-)$	$1.45^{+0.78}_{-0.58} \pm 0.36\%$

Two routes to search for this addition to $\Gamma(b \to c\bar{c}s)$ have been pursued experimentally. In an exclusive search for $B \to D\overline{D}K$ decays, CLEO required the final state to include a D and a $\overline{D}$ meson. Statistically significant signals are observed for several $D^{(*)}\overline{D}^{(*)}$ combinations. The preliminary CLEO results are listed in Table 7 [121]. While the observation of these decays proves the existence of $\overline{D}$-meson production at the upper vertex, a more inclusive measurement is needed to estimate the overall magnitude of this effect. A recent CLEO analysis exploits the fact that the flavor of the final state D-meson tags the decay mechanism. High momentum leptons ($p_\ell >$ 1.4 GeV/c) are used to classify the flavor of the decaying B meson. $b \to c\bar{u}d$ transitions lead to $D\ell^+$ combinations, while the observation of $\overline{D}\ell^+$ identifies the new $b \to c\bar{c}s$ mechanism. Angular correlations are used to remove combinations with both particles coming from the same B meson. CLEO finds [122]

$$\frac{\Gamma(\overline{B} \to \overline{D}X)}{\Gamma(\overline{B} \to DX)} = 0.100 \pm 0.026 \pm 0.016 \ , \qquad (15)$$

which implies

$$B(\overline{B} \to \overline{D}X) = 0.079 \pm 0.022\,. \quad (16)$$

We can now calculate $n_{cc} = B(b \to c\overline{c}s)$. n_{cc} is related to n_c, the number of charm quarks produced per b decay

$$n_c = 1 + n_{cc} - n_{B\to \text{no charm}}\,. \quad (17)$$

Using the data listed in Table 6 and the above result, we find

$$n_{cc} = (23.9 \pm 3.0)\%\,. \quad (18)$$

The contribution from $B \to \Xi_c^0 X$ was reduced by 1/3 to take into account the fraction that is not produced by the $b \to c\overline{c}s$ subprocess, but by $b \to c\overline{u}d + s\overline{s}$ quark pair production.

This result is consistent with theoretical predictions, $n_{cc} = 22 \pm 6\%$ [28,123]. $b \to D\overline{D}X$ decays have also been observed at LEP and at the SLC. ALEPH [102] finds

$$B(B \to D^0\overline{D}^0X + D^0D^{\mp}X) = 0.078^{+0.02\,+0.017+0.005}_{-0.018-0.015-0.004}\,, \quad (19)$$

where the last error reflects the uncertainty in D meson branching fractions. DELPHI and SLD look for double charm decays of b hadrons by selecting events that are consistent with having two decay vertices. They find $n_{2c} = (13.6 \pm 4.2)\%$ [124] and $n_{2c} = (16.2 \pm 1.9 \pm 4.2)\%$ [125], respectively. n_{2c} does not include $B \to$Charmonium production. Taking this into account we find that these results are consistent with n_{cc}. DELPHI used a b-tagging technique to measure the inclusive charmless B branching fraction to 0.033 ± 0.021. Subtracting charmonium production allows them to set an upper limit on charmless b decays of 3.7% at 95% CL [124].

Charm Counting and the Semileptonic Branching Fraction: The charm yield per B meson decay is related to an intriguing puzzle in B physics: the experimental value for the semileptonic branching ratio of B mesons, $B(B \to X\ell\nu) = 10.49 \pm 0.17 \pm 0.43\%$ ($\Upsilon(4S)$), is significantly below the theoretical lower bound B > 12.5% from QCD calculations within the parton model [126]. Since the semileptonic and hadronic widths are connected via

$$1/\tau = \Gamma = \Gamma_{\text{Semileptonic}} + \Gamma_{\text{Hadronic}}$$

an enhanced hadronic rate is necessary to accommodate the low semileptonic branching fraction. The hadronic width, which can be expressed as

$$\Gamma_{\text{Hadronic}} = \Gamma(b \to c\overline{c}s) + \Gamma(b \to c\overline{u}d) + \Gamma(b \to sg\ + \text{no charm})$$

is constraint by another experimental quantity, n_c, the average number of charm quarks produced per b decay.

For years it has been difficult to accommodate the experimental results with the theoretical preference for a larger values for B_{sl}, n_c and n_{cc}. Additional confusion has been caused by an apparent discrepancy between LEP (Z^0) and CLEO ($\Upsilon(4S)$) results. The latter issue, however, has been resolved with both the LEP average for B_{sl} and n_c coming down. There is now good agreement between the experiments. Several explanations of this n_c/B_{sl} discrepancy have been proposed:

1. enhancement of $b \to c\overline{c}s$ due to large QCD corrections or a breakdown of local duality;
2. enhancement of $b \to c\overline{u}d$ due to non-perturbative effects;
3. enhancement of $b \to sg$ and/or $b \to dg$ due to New Physics;
4. systematic problem in the experimental results;

or the problem could be caused by some combination of the above.

Arguably the most intriguing solution to this puzzle would be an enhanced $b \to sg$ rate but as we will see in the next section, new results from CLEO and LEP show no indication for New Physics and place tight limits on this process.

$B(b \to c\overline{u}d)$ has been calculated to next-to-leading order. Bagan *et al.* [127] find:

$$r_{ud} = \frac{B(b \to c\overline{u}d)}{B(b \to c\ell\nu)} = 4.0 \pm 0.4 \to B(b \to c\overline{u}d)_{\text{Theory}} = 41 \pm 4\%$$

which compares well with the experimental value of 43±6% [100] but the errors are still too large to completely rule out an enhanced $b \to c\overline{u}d$ rate.

The theoretically preferred solution calls for an enhancement of the $b \to c\overline{c}s$ channel [127,28]. Increasing the $b \to c\overline{c}s$ component, however, would increase the average number of c quarks produced per b quark decay as well as n_{cc}, the number of b decays with 2 charm quarks in the final state. This is not supported by the data, in particular the value of n_c appears to be too low at the few σ-level. Systematic problems with D meson branching fractions have been pointed out as potential solution [128] but new results from ALEPH [129] and CLEO [130] on $B(D^0 \to K^-\pi^+)$ make this less likely.

After years of experimental and theoretical efforts the missing charm/B_{sl} problem has begun to fade away. The discrepancy between experiments at the $\Upsilon(4S)$ and the Z^0 has been resolved. More data are needed to either resolve this issue or to demonstrate that the problem persists.

Rare B decays: All B-meson decays that do not occur through the usual $b \to c$ transition are known as rare B decays. These include both tree level semileptonic and hadronic $b \to u$ decays that are suppressed by the small CKM matrix element V_{ub}, as well as higher order processes such as electromagnetic and gluonic penguin decays. Branching fractions are typically around 10^{-5}, for exclusive channels, and sophisticated background suppression techniques are essential for these analyses.

Arguably the most exciting new experimental results since the last edition of this review are in the field of rare B decays. For many charmless B-decay modes the addition of new data and the refinement of analysis techniques allowed CLEO to observe signals where previously there have been upper limits. For other channels new tighter upper limits have been published.

Hadronic b → u transitions: Using almost 20 million charged and neutral B decays, CLEO successfully reconstructed a handful of exclusive hadronic $B^0 \to \pi^+\pi^-$ decays [131]. As can be seen in Table 8, the branching fraction for this mode is about a factor of 4 smaller than the rate of $B \to K\pi$ transitions. This is not good news for CP-violation studies. Not only is the branching fraction very small, but in addition the analysis will be complicated by "penguin pollution."

A theoretically clean method to determine the sum of the angles $\beta + \gamma$ of the unitarity triangle has been proposed by Snyder and Quinn [136]. They suggest that a sample of 10^3 $B \to \rho\pi$ decays, together with a Dalitz plot analysis, allow a measurement of $\beta+\gamma$ to about 6°. CLEO has recently measured the branching fraction for these modes [132]

$$B(B^+ \to \rho^0\pi^+) = (1.5 \pm 0.5 \pm 0.4) \times 10^{-5} \quad (20)$$

$$B(B^0 \to \rho^\pm\pi^\mp) = (3.5^{+1.1}_{-1.0} \pm 0.5) \times 10^{-5} \quad (21)$$

but it will take a while before a sufficiently large data sample will be available.

Table 8: Summary of CLEO results on $B \to \pi\pi, K\pi$, and KK branching fractions. The branching fractions and the 90% C.L. upper limits are given in units of 10^{-5}. Using the notation of Gronau *et al.* [137], the third column indicates the dominant amplitudes for each decay (T, C, P, E denote tree, color suppressed, penguin, and exchange amplitudes and the unprimed (primed) amplitudes refer to $\bar{b} \to \bar{u}u\bar{d}$ ($\bar{b} \to \bar{u}u\bar{s}$) transitions, respectively.)

Mode ($B \to$)	B	Amplitude	Theoretical expectation
$\pi^+\pi^-$	$0.43^{+0.16}_{-0.14} \pm 0.05$	$-(T+P)$	0.8–2.6
$\pi^+\pi^0$	< 1.3	$-(T+C)/\sqrt{(2)}$	0.4–2.0
$\pi^0\pi^0$	< 0.93	$-(C-P)/\sqrt{(2)}$	0.006–0.1
$K^+\pi^-$	$1.72^{+0.25}_{-0.24} \pm 0.12$	$-(T'+P')$	0.7–2.4
$K^+\pi^0$	$1.16^{+0.30+0.14}_{-0.27-0.13}$	$-(T'+C'+P')/\sqrt{(2)}$	0.3–1.3
$K^0\pi^-$	$1.82^{+0.46}_{-0.40} \pm 0.16$	P'	0.8–1.5
$K^0\pi^0$	$1.46^{+0.59+0.24}_{-0.51-0.33}$	$-(C'-P')/\sqrt{(2)}$	0.3–0.8
K^+K^-	< 0.19	E	—
K^+K^0	< 0.51	P	0.07–0.13
K^0K^0	< 1.7	P	0.07–0.12

Electromagnetic penguin decays: The observation of the decay $B \to K^*(892)\gamma$, reported in 1993 by the CLEO II experiment, provided first evidence for the one-loop penguin diagram [138]. Using a larger data sample, the analysis was re-done in 1999 [139] yielding a total of 125 events and

$$B(B^0 \to K^{*0}\gamma) = (4.55^{+0.72}_{-0.68} \pm 0.34) \times 10^{-5}\ , \quad (22)$$

$$B(B^+ \to K^{*+}\gamma) = (3.76^{+0.89}_{-0.83} \pm 0.28) \times 10^{-5}\ . \quad (23)$$

The decay $B \to K_2^*(1430)\gamma$ was seen with a branching fraction of $(1.66^{+0.59}_{-0.53} \pm 0.13) \times 10^{-5}$. No evidence for the decays $B \to \rho\gamma$ and $B \to \omega\gamma$ was found. The current upper limit for the ratio $B(B \to (\rho/\omega)\gamma)/B(B \to K^*\gamma)$ is 0.32 at 90% CL. The limit on the ratio of branching fractions implies that $|V_{td}/V_{ts}| < 0.75$ at 90% CL.

The observed branching fractions were used to constrain a large class of Standard Model extensions [140]. However, due to the uncertainties in the hadronization, only the inclusive $b \to s\gamma$ rate can be reliably compared with theoretical calculations. This rate can be measured from the endpoint of the inclusive photon spectrum in B decay. CLEO [141] found

$$B(b \to s\gamma) = (3.15 \pm 0.35 \pm 0.41) \times 10^{-4}\,(\text{CLEO})\ , \quad (24)$$

to be compared to the Standard Model rate [142–144] of

$$B(b \to s\gamma)_{SM} = (3.28 \pm 0.33) \times 10^{-4}\ . \quad (25)$$

ALEPH used a lifetime tagged sample of $Z \to b\bar{b}$ events to search for high-energy photons in the hemisphere opposite to the tag. This allows them to measure the photon spectrum from B decays which ultimately leads to [145]

$$B(b \to s\gamma) = (3.11 \pm 0.80 \pm 0.72) \times 10^{-4}\,(\text{ALEPH}). \quad (26)$$

Our theoretical understanding of inclusive $b \to s\gamma$ transitions has been significantly enhanced by two new calculations that now include all terms to next-to-leading order [142–144]. The expected Standard Model rate, while slightly larger now, is still consistent with both the CLEO and ALEPH results. The substantially reduced uncertainties result in tighter constraints on new physics such as double Higgs models [146].

Gluonic penguin decays: A larger total rate is expected for gluonic penguins, the counterpart of $b \to s\gamma$ with the photon replaced by a gluon.

Experimentally, it is a major challenge to measure the inclusive $b \to sg$ rate. The virtual gluon hadronizes as a $q\bar{q}$ pair without leaving a characteristic signature in the detector. CLEO extended D–ℓ correlation measurements described in the section on hadronic B decays to obtain the flavor specific decay rate $\Gamma(\overline{B} \to DX)_{\text{lower vertex}}/\Gamma_{\text{total}}$. This quantity should be 1 minus corrections for charmonium production, $b \to u$ transitions, $B \to$ baryons, and D_s production at the lower vertex. Most importantly, the $b \to sg$ rate must also be subtracted. To remove uncertainties due to $B(D^0 \to K^-\pi^+)$, CLEO normalizes to $\Gamma(\overline{B} \to DX\ell\nu_\ell)/\Gamma(\overline{B} \to X\ell\nu_\ell)$. Their preliminary result is

$$\frac{\Gamma(\overline{B} \to DX)_{\text{lower vertex}}/\Gamma_{\text{total}}}{\Gamma(\overline{B} \to DX\ell\nu_\ell)/\Gamma(\overline{B} \to X\ell\nu_\ell)} = 0.901 \pm 0.034 \pm 0.014 \quad (27)$$

whereas $0.903 \pm 0.018 - (b \to sg)$ was expected. This corresponds to an upper limit of $B(b \to sg) < 6.8\%$ at 90% CL [122]. DELPHI [147] studied the p_T spectrum of charged kaons in B decays and found a model-dependent limit $B(b \to sg) < 5\%$ (95% C.L.). These results agree well with the Standard Model prediction of $B(\overline{B} \to \text{no charm}) = (1.6 \pm 0.8)\%$ [148], and there is little experimental support for new physics and an enhanced $b \to sg$ rate [149]. However, experimental uncertainties are still large, and it is too early to draw final conclusions.

Exclusive decays such as $B \to K^+\pi^-$ are suppressed at tree level and are expected to proceed via loop processes. CLEO studied these decay modes, and all 4 $K\pi$ combinations have been observed [131]. The results are listed in Table 8.

[a] An ℓ indicates an e or a μ mode, not a sum over these modes.

[b] B^0 and B_s^0 contributions not separated. Limit is on weighted average of the two decay rates.

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

B^0 BRANCHING RATIOS

For branching ratios in which the charge of the decaying B is not determined, see the $B^\pm$ section.

[31] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[32] BUSKULIC 97 assumes fraction (B^+) = fraction $(B^0) = (37.8 \pm 2.2)\%$ and PDG 96 values for B lifetime and branching ratio of D^* and D decays.

[33] FULTON 91 assumes assuming equal production of B^0 and B^+ at the $\Upsilon(4S)$ and uses Mark III D and D^* branching ratios.

[34] ALBRECHT 89J reports $0.018 \pm 0.006 \pm 0.005$. We rescale using the method described in STONE 94 but with the updated PDG 94 $B(D^0 \to K^-\pi^+)$.

[35] ATHANAS 97 uses missing energy and missing momentum to reconstruct neutrino.

[36] ACKERSTAFF 97G assumes fraction (B^+) = fraction $(B^0) = (37.8 \pm 2.2)\%$ and PDG 96 values for B lifetime and branching ratio of D^* and D decays.

[37] BUSKULIC 97 assumes fraction (B^+) = fraction $(B^0) = (37.8 \pm 2.2)\%$ and PDG 96 values for B lifetime and D^* and D branching fractions.

[38] ABREU 96P result is the average of two methods using exclusive and partial D^* reconstruction.

[39] BARISH 95 use $B(D^0 \to K^-\pi^+) = (3.91 \pm 0.08 \pm 0.17)\%$ and $B(D^{*+} \to D^0\pi^+) = (68.1 \pm 1.0 \pm 1.3)\%$.

[40] ALBRECHT 94 assumes $B(D^{*+} \to D^0\pi^+) = 68.1 \pm 1.0 \pm 1.3\%$. Uses partial reconstruction of D^{*+} and is independent of D^0 branching ratios.

[41] ALBRECHT 93 reports $0.052 \pm 0.005 \pm 0.006$. We rescale using the method described in STONE 94 but with the updated PDG 94 $B(D^0 \to K^-\pi^+)$. We have taken their average e and μ value. They also obtain $\alpha = 2{*}\Gamma^0/(\Gamma^- + \Gamma^+) - 1 = 1.1 \pm 0.4 \pm 0.2$, $A_{AF} = 3/4{*}(\Gamma^- - \Gamma^+)/\Gamma = 0.2 \pm 0.08 \pm 0.06$ and a value of $|V_{cb}| = 0.036$–0.045 depending on model assumptions.

[42] We have taken average of the the BORTOLETTO 89B values for electrons and muons, $0.046 \pm 0.005 \pm 0.007$. We rescale using the method described in STONE 94 but with the updated PDG 94 $B(D^0 \to K^-\pi^+)$. The measurement suggests a D^* polarization parameter value $\alpha = 0.65 \pm 0.66 \pm 0.25$.

[43] BUSKULIC 95N assumes fraction (B^+) = fraction $(B^0) = 38.2 \pm 1.3 \pm 2.2\%$ and $\tau_{B^0} = 1.58 \pm 0.06$ ps. $\Gamma(D^{*-}\ell^+\nu_\ell)/\text{total} = [5.18 - 0.13(\text{fraction}(B^0) - 38.2) - 1.5(\tau_{B^0} - 1.58)]\%$.

[44] Combining $\overline{D}^{*0}\ell^+\nu_\ell$ and $\overline{D}^{*-}\ell^+\nu_\ell$ SANGHERA 93 test $V-A$ structure and fit the decay angular distributions to obtain $A_{FB} = 3/4{*}(\Gamma^- - \Gamma^+)/\Gamma = 0.14 \pm 0.06 \pm 0.03$. Assuming a value of V_{cb}, they measure V, A_1, and A_2, the three form factors for the $D^*\ell\nu_\ell$ decay, where results are slightly dependent on model assumptions.

[45] ANTREASYAN 90B is average over B and $\overline{D}^*(2010)$ charge states.

[46] The measurement of ALBRECHT 89C suggests a D^* polarization γ_L/γ_T of 0.85 ± 0.45. or $\alpha = 0.7 \pm 0.9$.

[47] ALBRECHT 89J is ALBRECHT 87J value rescaled using $B(D^*(2010)^- \to D^0\pi^-) = 0.57 \pm 0.04 \pm 0.04$. Superseded by ALBRECHT 93.

[48] ALBRECHT 87J assume μ-e universality, the $B(\Upsilon(4S) \to B^0\overline{B}^0) = 0.45$, the $B(D^0 \to K^-\pi^+) = (0.042 \pm 0.004 \pm 0.004)$, and the $B(D^*(2010)^- \to D^0\pi^-) = 0.49 \pm 0.08$. Superseded by ALBRECHT 89J.

$\Gamma(\rho^-\ell^+\nu_\ell)/\Gamma_{\text{total}}$ — Γ_4/Γ

ℓ = e or μ, not sum over e and μ modes.

$2.57\pm0.29^{+0.53}_{-0.62}$		[49] BEHRENS	00	CLE2	$e^+e^- \to \Upsilon(4S)$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$2.5 \pm0.4\ ^{+0.7}_{-0.9}$		[50] ALEXANDER	96T	CLE2	Repl. by BEHRENS 00
<4.1	90	[51] BEAN	93B	CLE2	$e^+e^- \to \Upsilon(4S)$

[49] BEHRENS 00 reports systematic errors $^{+0.33}_{-0.46} \pm 0.41$, where the second error is theoretical model dependence. We combine these in quadrature.

[50] ALEXANDER 96T gives systematic errors $^{+0.5}_{-0.7} \pm 0.5$ where the second error reflects the estimated model dependence. We combine these in quadrature. Assumes isospin symmetry: $\Gamma(B^0 \to \rho^-\ell^+\nu_\ell) = 2 \times \Gamma(B^+ \to \rho^0\ell^+\nu_\ell) \sim 2 \times \Gamma(B^+ \to \omega\ell^+\nu_\ell)$.

[51] BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine $\Gamma(\rho^0\ell^+\nu_\ell)$ and $\Gamma(\omega\ell^+\nu_\ell)$ with this result, they obtain a limit $<(1.6$–$2.7) \times 10^{-4}$ at 90% CL for $B^+ \to (\omega$ or $\rho^0)\ell^+\nu_\ell$. The range corresponds to the ISGW, WSB, and KS models. An upper limit on $|V_{ub}/V_{cb}| < 0.08$–0.13 at 90% CL is derived as well.

0.07 ±0.05		5	[64] BEHRENDS 83	CLEO	$e^+e^- \to \Upsilon(4S)$

[61] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[62] BORTOLETTO 92 assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D. The product branching fraction into $D_0^*(2340)\pi$ followed by $D_0^*(2340) \to D^0\pi$ is < 0.0001 at 90% CL and into $D_2^*(2460)$ followed by $D_2^*(2460) \to D^0\pi$ is < 0.0004 at 90% CL.

[63] BEBEK 87 assume the $\Upsilon(4S)$ decays 43% to $B^0\overline{B}^0$. We rescale to 50%. $B(D^0 \to K^-\pi^+) = (4.2 \pm 0.4 \pm 0.4)$% and $B(D^0 \to K^-\pi^+\pi^+\pi^-) = (9.1 \pm 0.8 \pm 0.8)$% were used.

[64] Corrected by us using assumptions: $B(D^0 \to K^-\pi^+) = (0.042 \pm 0.006)$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 50\%$. The product branching ratio is $B(B^0 \to \overline{D}^0\pi^+\pi^-)B(\overline{D}^0 \to K^+\pi^-) = (0.39 \pm 0.26) \times 10^{-2}$.

[65] BRANDENBURG 98 assume equal production of B^+ and B^0 at $\Upsilon(4S)$ and use the D^* reconstruction technique. The first error is their experiment's error and the second error is the systematic error from the PDG 96 value of $B(D^* \to D\pi)$.

[66] ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEO II $B(D^*(2010)^+ \to D^0\pi^+)$ and absolute $B(D^0 \to K^-\pi^+)$ and the PDG 1992 $B(D^0 \to K^-\pi^+\pi^0)/B(D^0 \to K^-\pi^+)$ and $B(D^0 \to K^-\pi^+\pi^+\pi^-)/B(D^0 \to K^-\pi^+)$.

[67] BORTOLETTO 92 reports $0.0040 \pm 0.0010 \pm 0.0007$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[68] ALBRECHT 90J reports $0.0028 \pm 0.0009 \pm 0.0006$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[69] BEBEK 87 reports $0.0028^{+0.0015}_{-0.0012}{}^{+0.0010}_{-0.0006}$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92 and ALBRECHT 90J.

[70] Assumes $B(Z \to b\overline{b}) = 0.217$ and 38% B_d production fraction.

[71] ALBRECHT 87C use PDG 86 branching ratios for D and $D^*(2010)$ and assume $B(\Upsilon(4S) \to B^+B^-) = 55\%$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 45\%$. Superseded by ALBRECHT 90J.

[72] ALBRECHT 86F uses pseudomass that is independent of D^0 and D^+ branching ratios.

[73] Assumes $B(D^*(2010)^+ \to D^0\pi^+) = 0.60^{+0.08}_{-0.15}$. Assumes $B(\Upsilon(4S) \to B^0\overline{B}^0) = 0.40 \pm 0.02$ Does not depend on D branching ratios.

0.0101±0.0041±0.0001		26	[88] ALBRECHT	90J	ARG	$e^+e^- \to \Upsilon(4S)$
• • • We do not use the following data for averages, fits, limits, etc. • • •						
0.033 ±0.009 ±0.016		27	[89] ALBRECHT	87C	ARG	$e^+e^- \to \Upsilon(4S)$
<0.042	90		[90] BEBEK	87	CLEO	$e^+e^- \to \Upsilon(4S)$

[85] ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEO II $B(D^*(2010)^+ \to D^0\pi^+)$ and absolute $B(D^0 \to K^-\pi^+)$ and the PDG 1992 $B(D^0 \to K^-\pi^+\pi^0)/B(D^0 \to K^-\pi^+)$ and $B(D^0 \to K^-\pi^+\pi^+\pi^-)/B(D^0 \to K^-\pi^+)$.

[86] The three pion mass is required to be between 1.0 and 1.6 GeV consistent with an a_1 meson. (If this channel is dominated by a_1^+, the branching ratio for $\overline{D}^{*-}a_1^+$ is twice that for $\overline{D}^{*-}\pi^+\pi^+\pi^-$.)

[87] BORTOLETTO 92 reports $0.0159 \pm 0.0028 \pm 0.0037$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[88] ALBRECHT 90J reports $0.012 \pm 0.003 \pm 0.004$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[89] ALBRECHT 87C use PDG 86 branching ratios for D and $D^*(2010)$ and assume $B(\Upsilon(4S) \to B^+B^-) = 55\%$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 45\%$. Superseded by ALBRECHT 90J.

[90] BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.

0.0041 ±0.0018	5	[175] ALAM	86 CLEO	Repl. by BEBEK 87

[165] ABE 98O reports $[B(B^0 \to J/\psi(1S)K^*(892)^0)]/[B(B^+ \to J/\psi(1S)K^+)] = 1.76 \pm 0.14 \pm 0.15$. We multiply by our best value $B(B^+ \to J/\psi(1S)K^+) = (9.9 \pm 1.0) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[166] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[167] BORTOLETTO 92 reports $0.0011 \pm 0.0005 \pm 0.0003$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[168] ALBRECHT 90J reports $0.0011 \pm 0.0005 \pm 0.0002$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[169] BEBEK 87 reports $0.0035 \pm 0.0016 \pm 0.0003$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BORTOLETTO 92 to use the same assumptions.

[170] ABE 96H assumes that $B(B^+ \to J/\psi K^+) = (1.02 \pm 0.14) \times 10^{-3}$.

[171] The neutral and charged B events together are predominantly longitudinally polarized, $\Gamma_L/\Gamma = 0.080 \pm 0.08 \pm 0.05$. This can be compared with a prediction using HQET, 0.73 (KRAMER 92). This polarization indicates that the $B \to \psi K^*$ decay is dominated by the $CP = -1$ CP eigenstate. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[172] ALBRECHT 94G measures the polarization in the vector-vector decay to be predominantly longitudinal, $\Gamma_T/\Gamma = 0.03 \pm 0.16 \pm 0.15$ making the neutral decay a CP eigenstate when the K^{*0} decays through $K_S^0\pi^0$.

[173] ALBAJAR 91E assumes B_d^0 production fraction of 36%.

[174] ALBRECHT 87D assume $B^+B^-/B^0\overline{B}^0$ ratio is 55/45. Superseded by ALBRECHT 90J.

[175] ALAM 86 assumes $B^\pm/B^0$ ratio is 60/40. The observation of the decay $B^+ \to J/\psi K^*(892)^+$ (HAAS 85) has been retracted in this paper.

B^0–$\overline{B}^0$ MIXING

Written March 2000 by O. Schneider (Univ. of Lausanne)

Formalism in quantum mechanics

There are two neutral B^0–$\overline{B}^0$ meson systems, B_d–$\overline{B}_d$ and B_s–$\overline{B}_s$ (generically denoted B_q–$\overline{B}_q$, $q = s, d$), which exhibit the phenomenon of particle-antiparticle mixing [1]. Such a system is produced in one of its two possible states of well-defined flavor: $|B^0\rangle$ ($\overline{b}q$) or $|\overline{B}^0\rangle$ ($b\overline{q}$). Due to flavor-changing interactions, this initial state evolves into a time-dependent quantum superposition of the two flavor states, $a(t)|B^0\rangle + b(t)|\overline{B}^0\rangle$, satisfying the equation

$$i\frac{\partial}{\partial t}\begin{pmatrix} a(t) \\ b(t) \end{pmatrix} = \left(\mathbf{M} - \tfrac{i}{2}\mathbf{\Gamma}\right)\begin{pmatrix} a(t) \\ b(t) \end{pmatrix}, \qquad (1)$$

where $\mathbf{M}$ and $\mathbf{\Gamma}$, known as the mass and decay matrices, describe the dispersive and absorptive parts of B^0–$\overline{B}^0$ mixing. These matrices are hermitian, and CPT invariance requires $M_{11} = M_{22} \equiv M$ and $\Gamma_{11} = \Gamma_{22} \equiv \Gamma$, where M and Γ are the mass and decay width of the B^0 and $\overline{B}^0$ flavor states.

The two eigenstates of the effective hamiltonian matrix $(\mathbf{M} - \frac{i}{2}\mathbf{\Gamma})$ are given by

$$|B_{\pm}\rangle = p|B^0\rangle \pm q|\overline{B}^0\rangle, \qquad (2)$$

and correspond to the eigenvalues

$$\lambda_{\pm} = \left(M - \tfrac{i}{2}\Gamma\right) \pm \frac{q}{p}\left(M_{12} - \tfrac{i}{2}\Gamma_{12}\right), \qquad (3)$$

where

$$\frac{q}{p} = \sqrt{\frac{M_{12}^* - \frac{i}{2}\Gamma_{12}^*}{M_{12} - \frac{i}{2}\Gamma_{12}}}. \qquad (4)$$

We choose a convention where $\mathrm{Re}(q/p) > 0$ and $CP|B^0\rangle = |\overline{B}^0\rangle$.

An alternative notation is

$$|B_{\pm}\rangle = \frac{(1+\epsilon)|B^0\rangle \pm (1-\epsilon)|\overline{B}^0\rangle}{\sqrt{2(1+|\epsilon|^2)}} \quad \text{with} \quad \frac{1-\epsilon}{1+\epsilon} = \frac{q}{p}. \qquad (5)$$

The time dependence of these eigenstates of well-defined masses $M_{\pm} = \mathrm{Re}(\lambda_{\pm})$ and widths $\Gamma_{\pm} = -2\,\mathrm{Im}(\lambda_{\pm})$ is given by the phases $e^{-i\lambda_\pm t} = e^{-iM_\pm t} e^{-\frac{1}{2}\Gamma_\pm t}$: the evolution of a pure $|B^0\rangle$ or $|\overline{B}^0\rangle$ state at $t = 0$ is thus given by

$$|B^0(t)\rangle = g_+(t)\,|B^0\rangle + \frac{q}{p}\,g_-(t)\,|\overline{B}^0\rangle\,, \tag{6}$$

$$|\overline{B}^0(t)\rangle = g_+(t)\,|\overline{B}^0\rangle + \frac{p}{q}\,g_-(t)\,|B^0\rangle\,, \tag{7}$$

where

$$g_\pm(t) = \frac{1}{2}\left(e^{-i\lambda_+ t} \pm e^{-i\lambda_- t}\right)\,. \tag{8}$$

This means that the flavor states oscillate into each other with time-dependent probabilities proportional to

$$|g_\pm(t)|^2 = \frac{e^{-\Gamma t}}{2}\left[\cosh\left(\frac{\Delta\Gamma}{2}\,t\right) \pm \cos(\Delta m\, t)\right]\,, \tag{9}$$

where

$$\Delta m = |M_+ - M_-|\,, \quad \Delta\Gamma = |\Gamma_+ - \Gamma_-|\,. \tag{10}$$

Time-integrated mixing probabilities are only well defined when considering decays to flavor-specific final states, *i.e.* final states f such that the instantaneous decay amplitudes $A_{\overline{f}} = \langle \overline{f}|H|B^0\rangle$ and $\overline{A}_f = \langle f|H|\overline{B}^0\rangle$, where H is the weak interaction hamiltonian, are both zero. Due to mixing, a produced B^0 can decay to the final state $\overline{f}$ (mixed event) in addition to the final state f (unmixed event). Restricting the sample to these two decay channels, the time-integrated mixing probability is given by

$$\chi_f^{B^0\to\overline{B}^0} = \frac{\int_0^\infty |\langle \overline{f}|H|B^0(t)\rangle|^2 dt}{\int_0^\infty |\langle \overline{f}|H|B^0(t)\rangle|^2 dt + \int_0^\infty |\langle f|H|B^0(t)\rangle|^2 dt}$$

$$= \frac{|\xi_f|^2 (x^2+y^2)}{|\xi_f|^2(x^2+y^2) + 2 + x^2 - y^2}\,, \tag{11}$$

where we have defined $\xi_f = \dfrac{q}{p}\dfrac{\overline{A}_f}{A_f}$ and

$$x = \frac{\Delta m}{\Gamma}\,, \quad y = \frac{\Delta\Gamma}{2\Gamma}\,. \tag{12}$$

The mixing probability $\chi_f^{\overline{B}^0\to B^0}$ for the case of a produced $\overline{B}^0$ is obtained by replacing ξ_f with $1/\xi_f$ in Eq. (11). It is different from $\chi_f^{B^0\to\overline{B}^0}$ if $|\xi_f|^2 \neq 1$, a condition reflecting non-invariance under the CP transformation. CP violation in the decay amplitudes is discussed elsewhere [2] and we assume $|\overline{A}_{\overline{f}}| = |A_f|$ from now on. The deviation of $|q/p|^2$ from 1, namely the quantity

$$1 - \left|\frac{q}{p}\right|^2 = \frac{4\,\mathrm{Re}(\epsilon)}{1+|\epsilon|^2} + \mathcal{O}\left(\left(\frac{\mathrm{Re}(\epsilon)}{1+|\epsilon|^2}\right)^2\right)\,, \tag{13}$$

describes CP violation in B^0–$\overline{B}^0$ mixing. As can be seen from Eq. (4), this can occur only if $M_{12} \neq 0$, $\Gamma_{12} \neq 0$ and if the phase difference between M_{12} and Γ_{12} is different from 0 or π.

In the absence of CP violation, $|q/p|^2 = 1$, $\mathrm{Re}(\epsilon) = 0$, the mass eigenstates are also CP eigenstates,

$$CP\,|B_\pm\rangle = \pm|B_\pm\rangle\,, \tag{14}$$

the phases $\varphi_{M_{12}} = \arg(M_{12})$ and $\varphi_{\Gamma_{12}} = \arg(\Gamma_{12})$ satisfy

$$\sin(\varphi_{M_{12}} - \varphi_{\Gamma_{12}}) = 0\,, \tag{15}$$

the mass and decay width differences reduce to

$$\Delta m = 2\,|M_{12}|\,, \quad \Delta\Gamma = 2\,|\Gamma_{12}|\,, \tag{16}$$

and the time-integrated mixing probabilities $\chi_f^{B^0\to\overline{B}^0}$ and $\chi_f^{\overline{B}^0\to B^0}$ become both equal to

$$\chi = \frac{x^2+y^2}{2(x^2+1)}\,. \tag{17}$$

Standard Model predictions and phenomenology

In the Standard Model, the transitions $B_q^0 \to \overline{B}_q^0$ and $\overline{B}_q^0 \to B_q^0$ are due to the weak interaction. They are described, at the lowest order, by the box diagrams involving two W bosons and two up-type quarks, as is the case for K^0–$\overline{K}^0$ mixing. However, the long range interactions arising from intermediate virtual states are negligible for the neutral B meson systems, because the large B mass is away from the region of hadronic resonances. The calculation of the dispersive and absorptive parts of the box diagrams yields the following predictions for the off-diagonal element of the mass and decay matrices [3],

$$M_{12} = -\frac{G_F^2 m_W^2 \eta_B m_{B_q} B_{B_q} f_{B_q}^2}{12\pi^2}\, S_0(m_t^2/m_W^2)\,(V_{tq}^* V_{tb})^2 \tag{18}$$

$$\Gamma_{12} = \frac{G_F^2 m_b^2 \eta'_B m_{B_q} B_{B_q} f_{B_q}^2}{8\pi} \times \left[(V_{tq}^* V_{tb})^2 + V_{tq}^* V_{tb} V_{cq}^* V_{cb}\, \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right) + (V_{cq}^* V_{cb})^2\, \mathcal{O}\left(\frac{m_c^4}{m_b^4}\right)\right] \tag{19}$$

where G_F is the Fermi constant, m_W the W mass, m_i the mass of quark i, and where $m_{B_q} = M$, f_{B_q} and B_{B_q} are the B_q^0 mass, decay constant and bag parameter. The known function $S_0(x_t)$ can be approximated very well with $0.784\,x_t^{0.76}$ [4] and V_{ij} are the elements of the CKM matrix [5]. The QCD corrections η_B and η'_B are of order unity. The only non negligible contributions to M_{12} are from top-top diagrams. The phases of M_{12} and Γ_{12} satisfy

$$\varphi_{M_{12}} - \varphi_{\Gamma_{12}} = \pi + \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right) \tag{20}$$

implying that the mass eigenstates have mass and width differences of opposite signs. This means that, like in the K^0–$\overline{K}^0$ system, the "heavy" state with mass $M_{\rm heavy} = \max(M_+, M_-)$ has a smaller decay width than that of the "light" state with mass $M_{\rm light} = \min(M_+, M_-)$. We thus redefine

$$\Delta m = M_{\rm heavy} - M_{\rm light}\,, \quad \Delta\Gamma = \Gamma_{\rm light} - \Gamma_{\rm heavy}\,, \tag{21}$$

where Δm is positive by definition and $\Delta\Gamma$ is expected to be positive in the Standard Model.

Furthermore, since Γ_{12} is, like M_{12}, dominated by the top-top diagrams, the quantity

$$\left|\frac{\Gamma_{12}}{M_{12}}\right| \simeq \frac{3\pi}{2}\frac{m_b^2}{m_W^2}\frac{1}{S_0(m_t^2/m_W^2)} \sim \mathcal{O}\left(\frac{m_b^2}{m_t^2}\right) \tag{22}$$

is small, and a power expansion of $|q/p|^2$ yields

$$\left|\frac{q}{p}\right|^2 = 1 + \left|\frac{\Gamma_{12}}{M_{12}}\right| \sin(\varphi_{M_{12}} - \varphi_{\Gamma_{12}}) + \mathcal{O}\left(\left|\frac{\Gamma_{12}}{M_{12}}\right|^2\right) . \quad (23)$$

Therefore, considering both Eqs. (20) and (22), the CP-violating parameter

$$1 - \left|\frac{q}{p}\right|^2 \simeq \mathrm{Im}\left(\frac{\Gamma_{12}}{M_{12}}\right) \quad (24)$$

is expected to be tiny: $\sim \mathcal{O}(10^{-3})$ for the B_d–$\overline{B}_d$ system and $\lesssim \mathcal{O}(10^{-4})$ for the B_s–$\overline{B}_s$ system [6].

In the approximation of negligible CP violation in the mixing, the ratio $\Delta\Gamma/\Delta m$ is equal to the small quantity $|\Gamma_{12}/M_{12}|$ of Eq. (22); it is hence independent of CKM matrix elements, *i.e.* the same for the B_d–$\overline{B}_d$ and B_s–$\overline{B}_s$ systems. It can be calculated with lattice QCD techniques; typical results are $\sim 5\times10^{-3}$ with quoted uncertainties of 30% at least. Given the current experimental knowledge (discussed below) on the mixing parameter x,

$$\begin{cases} x_d = 0.73 \pm 0.03 & (B_d\text{–}\overline{B}_d \text{ system}) \\ x_s \gtrsim 20 \text{ at 95\% CL} & (B_s\text{–}\overline{B}_s \text{ system}) \end{cases} , \quad (25)$$

the Standard Model thus predicts that $\Delta\Gamma/\Gamma$ is very small for the B_d–$\overline{B}_d$ system (below 1%), but may be quite large for the B_s–$\overline{B}_s$ system (up to $\sim$ 20%). This width difference is caused by the existence of final states to which both the B^0_q and $\overline{B}^0_q$ mesons can decay. Such decays involve $b \to c\bar{c}q$ quark-level transitions, which are Cabibbo-suppressed if $q = d$ and Cabibbo-allowed if $q = s$. If the final states common to B^0_s and $\overline{B}^0_s$ are predominantly CP-even as discussed in Ref. 7, then the B_s–$\overline{B}_s$ mass eigenstate with the largest decay width corresponds to the CP-even eigenstate. Taking Eq. (21) into account, one thus expects $\Gamma_{\text{light}} = \Gamma_+$ and

$$\Delta m_s = M_- - M_+ > 0 , \quad \Delta\Gamma_s = \Gamma_+ - \Gamma_- > 0 . \quad (26)$$

Experimental issues and methods for oscillation analyses

Time-integrated measurements of B^0–$\overline{B}^0$ mixing were published for the first time in 1987 by UA1 [8] and ARGUS [9], and since then by many different experiments. These are typically based on counting same-sign and opposite-sign lepton pairs from the semileptonic decay of the produced $b\bar{b}$ pairs. At high energy colliders, such analyses cannot easily separate the B_d and B_s contributions, therefore experiments at $\Upsilon(4S)$ machines are best suited to measure χ_d.

However, better sensitivity is obtained from time-dependent analyses aimed at the direct measurement of the oscillation frequencies Δm_d and Δm_s, from the proper time distributions of B_d or B_s candidates identified through their decay in (mostly) flavor-specific modes and suitably tagged as mixed or unmixed. This is particularly true for the B_s–$\overline{B}_s$ system where the large value of x_s implies maximal mixing, *i.e.* $\chi_s \simeq 1/2$. In such analyses, performed at high-energy colliders, the neutral B mesons are either partially reconstructed from a charm meson, or selected from a lepton with high transverse momentum with respect to the b jet, or selected from a reconstructed displaced vertex. The proper time $t = \frac{m_B}{p}L$ is measured from the distance L between the production vertex and the B decay vertex, as measured with a silicon vertex detector, and from an estimate of the B momentum p.

The statistical significance $\mathcal{S}$ of an oscillation signal can be approximated as [10]

$$\mathcal{S} \approx \sqrt{N/2}\, f_{\text{sig}}\,(1-2\eta)\, e^{-(\Delta m\, \sigma_t)^2/2} , \quad (27)$$

where N and f_{sig} are the number of candidates and the fraction of signal in the selected sample, η is the mistag probability, and σ_t is the proper time resolution. The quantity $\mathcal{S}$ decreases very quickly as Δm increases; this dependence is controlled by σ_t, which is therefore a critical parameter for Δm_s analyses. The proper time resolution $\sigma_t \sim \frac{m_B}{\langle p\rangle}\sigma_L \oplus t\frac{\sigma_p}{p}$ includes a constant contribution due to the decay length resolution σ_L (typically 0.1–0.3 ps), and a term due to the relative momentum resolution $\frac{\sigma_p}{p}$ (typically 10–20% for partially reconstructed decays), which increases with proper time.

In order to tag a B candidate as mixed or unmixed, it is necessary to determine its flavor state both at production (initial state) and at decay (final state). The initial and final state mistag probabilities, η_i and η_f, degrade $\mathcal{S}$ by a total factor $(1-2\eta) = (1-2\eta_i)(1-2\eta_f)$. In inclusive lepton analyses, the final state is tagged by the charge of the lepton from $b \to \ell^-$ decays; the biggest contribution to η_f is then due to $\bar{b} \to \bar{c} \to \ell^-$ decays. Alternatively, the charge of a reconstructed charm meson (D^{*-} from B^0_d or D^-_s from B^0_s), or that of a kaon thought to come from a $b \to c \to s$ decay [11], can be used. For fully inclusive analyses based on topological vertexing, final state tagging techniques include jet charge [12] and charge dipole methods [11].

The initial state tags are somewhat less dependent on the procedure used to select B candidates. They can be divided in two groups: the ones that tag the initial charge of the $\bar{b}$ quark contained in the B candidate itself (same-side tag), and the ones that tag the initial charge of the other b quark produced in the event (opposite-side tag). On the same side, the charge of a track from the primary vertex is correlated with the production state of the B if that track is a decay product of a B^{**} state or the first particle in the fragmentation chain [13,14]. Jet charge techniques work on both sides. Finally, the charge of a lepton from $b \to \ell^-$ or of a kaon from $b \to c \to s$ can be used as opposite side tags, keeping in mind that their performance depends on integrated mixing. At SLC, the beam polarization produced a sizeable forward-backward asymmetry in the $Z \to b\bar{b}$ decays and provided another very interesting and effective initial state tag based on the polar angle of the B candidate [11]. Initial state tags have also been combined to reach $\eta_i \sim$ 26% at LEP [14,15] or even 16% at SLD [11] with full efficiency. The equivalent figure at CDF is currently $\sim 40\%$ [16].

In the absence of experimental evidence for a width difference, and since $\Delta\Gamma/\Delta m$ is predicted to be very small, oscillation analyses typically neglect $\Delta\Gamma$ and describe the data with the physics functions $\Gamma e^{-\Gamma t}(1 \pm \cos\Delta m t)/2$. As can be seen from Eq. (9), a non zero value of $\Delta\Gamma$ would effectively reduce the oscillation amplitude with a small time-dependent factor that would be very difficult to distinguish from time resolution effects. Whereas measurements of Δm_d are usually extracted from the data using a maximum likelihood fit, no significant B_s–$\overline{B}_s$ oscillations have been seen so far, and all B_s analyses set lower limits on Δm_s. The original technique used to set such limits was to study the likelihood as a function of Δm_s. However, these limits turned out to be difficult to combine. A method was therefore developed [10], in which a B_s oscillation amplitude $\mathcal{A}$ is measured at each fixed value of Δm_s, using a maximum likelihood fit based on the functions $\Gamma_s e^{-\Gamma_s t}(1 \pm \mathcal{A}\cos\Delta m_s t)/2$. To a very good approximation, the statistical uncertainty on $\mathcal{A}$ is Gaussian and equal to $1/S$ [10]. Measurements of $\mathcal{A}$ performed at a given value of Δm_s can be averaged easily. If $\Delta m_s = \Delta m_s^{\rm true}$, one expects $\mathcal{A} = 1$ within the total uncertainty $\sigma_{\mathcal{A}}$; however, if Δm_s is far from its true value, a measurement consistent with $\mathcal{A} = 0$ is expected. A value of Δm_s can be excluded at 95% CL if $\mathcal{A} + 1.645\,\sigma_{\mathcal{A}} \leq 1$. If $\Delta m_s^{\rm true}$ is very large, one expects $\mathcal{A} = 0$, and all values of Δm_s such that $1.645\,\sigma_{\mathcal{A}}(\Delta m_s) < 1$ are expected to be excluded at 95% CL. Because of the proper time resolution, the quantity $\sigma_{\mathcal{A}}(\Delta m_s)$ is an increasing function of Δm_s and one therefore expects to be able to exclude individual Δm_s values up to $\Delta m_s^{\rm sens}$, where $\Delta m_s^{\rm sens}$, called here the sensitivity of the analysis, is defined by $1.645\,\sigma_{\mathcal{A}}(\Delta m_s^{\rm sens}) = 1$.

B_d mixing studies

Many B_d–$\overline{B}_d$ oscillations analyses have been performed by the ALEPH [17,12], CDF [13,18], DELPHI [19], L3 [20], OPAL [21] and SLD [11] collaborations. Although a variety of different techniques have been used, the Δm_d results have remarkably similar precision. The systematic uncertainties are not negligible; they are often dominated by sample composition, mistag probability, or b-hadron lifetime contributions. Before being combined, the measurements are adjusted on the basis of a common set of input values, including the b-hadron lifetimes and fractions published in this *Review*. Some measurements are statistically correlated. Systematic correlations arise both from common physics sources (fragmentation fractions, lifetimes, branching ratios of b hadrons), and from purely experimental or algorithmic effects (efficiency, resolution, tagging, background description). Combining all published measurements [17,13,19,20,21] and accounting for all identified correlations as described in Ref. 22 yields $\Delta m_d = 0.478 \pm 0.012({\rm stat}) \pm 0.013({\rm syst})\ {\rm ps}^{-1}$.

On the other hand, ARGUS and CLEO have published time-integrated measurements based on semileptonic decays [23,24], which average to $\chi_d^{\Upsilon(4S)} = 0.156 \pm 0.024$. The width difference $\Delta\Gamma_d$ could in principle be extracted from the measured value of Γ_d, and the above averages for Δm_d and χ_d (see Eqs. (12) and (17)). The results are however compatible with $\Delta\Gamma_d = 0$, and their precision is still insufficient to provide an interesting constraint. Neglecting $\Delta\Gamma_d$ and using the measured B_d lifetime, the Δm_d and χ_d results are combined to yield the world average

$$\Delta m_d = 0.472 \pm 0.017\ {\rm ps}^{-1} \tag{28}$$

or, equivalently,

$$\chi_d = 0.174 \pm 0.009\,. \tag{29}$$

Evidence for CP violation in B_d mixing has been searched for, both with semileptonic and inclusive B_d decays, in samples where the initial flavor state is tagged. In the semileptonic case, where the final state tag is also available, the following asymmetry

$$\begin{aligned}&\frac{N(\overline{B}{}_d^0(t) \to \ell^+\nu_\ell X) - N(B_d^0(t) \to \ell^-\overline{\nu}_\ell X)}{N(\overline{B}{}_d^0(t) \to \ell^+\nu_\ell X) + N(B_d^0(t) \to \ell^-\overline{\nu}_\ell X)}\\ &= a_{CP} \simeq 1 - |q/p|_d^2 \simeq \frac{4{\rm Re}(\epsilon_d)}{1+|\epsilon_d|^2}\end{aligned} \tag{30}$$

has been measured, either in time-integrated analyses at CLEO [24] and CDF [25], or in more recent and sensitive time-dependent analyses at LEP [26,27,28]. In the inclusive case, also investigated at LEP [29,27,30], no final state tag is used, and the asymmetry [31]

$$\begin{aligned}&\frac{N(B_d^0(t) \to {\rm all}) - N(\overline{B}{}_d^0(t) \to {\rm all})}{N(B_d^0(t) \to {\rm all}) + N(\overline{B}{}_d^0(t) \to {\rm all})}\\ &\simeq a_{CP}\left[\frac{x_d}{2}\sin(\Delta m_d\, t) - \sin^2\left(\frac{\Delta m_d\, t}{2}\right)\right]\end{aligned} \tag{31}$$

must be measured as a function of the proper time to extract information on CP violation. In all cases asymmetries compatible with zero have been found, with a precision limited by the available statistics. A simple average of all published and preliminary results [24–30] neglecting small possible statistical correlations and assuming half of the systematics to be correlated, is $a_{CP} = -0.017 \pm 0.016$, a result which does not yet constrain the Standard Model.

The Δm_d result of Eq. (28) provides an estimate of $|M_{12}|$ and can be used, together with Eqs. (16) and (18), to extract the modulus of the CKM matrix element V_{td} within the Standard Model [32]. The main experimental uncertainties on the resulting estimate of $|V_{td}|$ come from m_t and Δm_d; however, these are at present completely dominated by the 15–20% uncertainty usually quoted on the hadronic matrix element $f_{B_d}\sqrt{B_{B_d}} \sim 200$ MeV obtained from lattice QCD calculations [33].

B_s mixing studies

B_s–$\overline{B}_s$ oscillation has been the subject of many recent studies from ALEPH [14], CDF [34], DELPHI [35,15], OPAL [36] and SLD [37]. No oscillation signal has been found so far. The

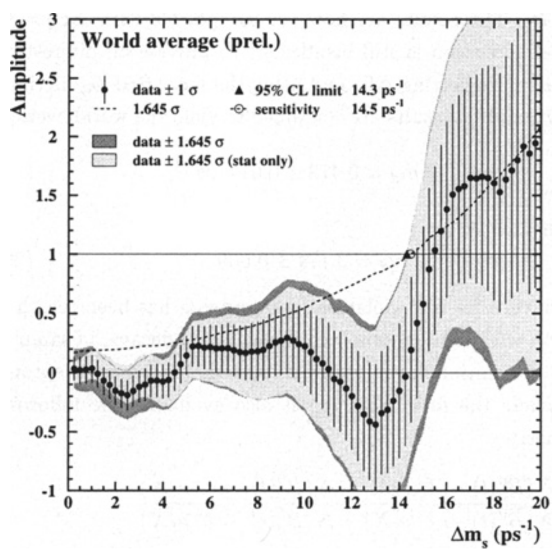

Figure 1: Combined measurements of the B_s oscillation amplitude as a function of Δm_s [22], including all preliminary results available at the end of 1999. The measurements are dominated by statistical uncertainties. Neighboring points are statistically correlated.

most sensitive analyses appear to be the ones based on inclusive lepton samples, and on samples where a lepton and a D_s meson have been reconstructed in the same jet. All results are limited by the available statistics. These are combined to yield the amplitudes $\mathcal{A}$ shown in Fig. 1 as a function of Δm_s [22].

As before, the individual results have been adjusted to common physics inputs, and all known correlations have been accounted for; furthermore, the sensitivities of the inclusive analyses, which depend directly through Eq. (27) on the assumed fraction f_s of B_s mesons in an unbiased sample of weakly-decaying b hadrons, have been rescaled to a common value of $f_s = 0.100 \pm 0.012$ [22]. The combined sensitivity for 95% CL exclusion of Δm_s values is found to be 14.5 ps^{-1}. All values of Δm_s below 14.3 ps^{-1} are excluded at 95% CL, and no deviation from $\mathcal{A} = 0$ is seen in Fig. 1 that would indicate the observation of a signal.

Some Δm_s analyses are still preliminary [15,37]. Using only published results, the combined Δm_s result is

$$\Delta m_s > 10.6 \text{ ps}^{-1} \quad \text{at 95\% CL}\,, \tag{32}$$

with a sensitivity of 12.1 ps^{-1}.

The information on $|V_{ts}|$ obtained, in the framework of the Standard Model, from the combined limit is hampered by the hadronic uncertainty, as in the B_d case. However, many uncertainties cancel in the frequency ratio

$$\frac{\Delta m_s}{\Delta m_d} = \frac{m_{B_s}}{m_{B_d}}\,\xi^2 \left|\frac{V_{ts}}{V_{td}}\right|^2 , \tag{33}$$

where $\xi = (f_{B_s}\sqrt{B_{B_s}})/(f_{B_d}\sqrt{B_{B_d}})$, of order unity, is currently estimated from lattice QCD with a 5–6% uncertainty [33]. The CKM matrix can be constrained using the experimental results on Δm_d, Δm_s, $|V_{ub}/V_{cb}|$ and ϵ_K, together with theoretical inputs and unitarity conditions [32]. Given the information available from $|V_{ub}/V_{cb}|$ and ϵ_K measurements, the constraint from our knowledge on the ratio $\Delta m_d/\Delta m_s$ is presently more effective in limiting the position of the apex of the CKM unitarity triangle than the one obtained from the Δm_d measurements alone, due to the reduced hadronic uncertainty in Eq. (33). We note also that the Standard Model would not easily accommodate values of Δm_s above ~ 25 ps^{-1}.

Information on $\Delta\Gamma_s$ can be obtained by studying the proper time distribution of untagged data samples enriched in B_s mesons [38]. In the case of an inclusive B_s selection [39] or a semileptonic B_s decay selection [40,41], both the short- and long-lived components are present, and the proper time distribution is a superposition of two exponentials with decay constants $\Gamma_s \pm \Delta\Gamma_s/2$. In principle, this provides sensitivity to both Γ_s and $(\Delta\Gamma_s/\Gamma_s)^2$. Ignoring $\Delta\Gamma_s$ and fitting for a single exponential leads to an estimate of Γ_s with a relative bias proportional to $(\Delta\Gamma_s/\Gamma_s)^2$. An alternative approach, which is directly sensitive to first order in $\Delta\Gamma_s/\Gamma_s$, is to determine the lifetime of B_s candidates decaying to CP eigenstates; measurements already exist for $B_s^0 \to J/\psi\phi$ [42] and $B_s^0 \to D_s^{(*)+}D_s^{(*)-}$ [43], which are mostly CP-even states [7]. An estimate of $\Delta\Gamma_s/\Gamma_s$ has also been obtained directly from a measurement of the $B_s^0 \to D_s^{(*)+}D_s^{(*)-}$ branching ratio [43], under the assumption that these decays practically account for all the CP-even final states.

Present data is not precise enough to efficiently constrain both Γ_s and $\Delta\Gamma_s/\Gamma_s$; since the B_s and B_d lifetimes are predicted to be equal within less than a percent [44], an expectation compatible with the current experimental data [45], the constraint $\Gamma_s = \Gamma_d$ can also be used to extract $\Delta\Gamma_s/\Gamma_s$. Applying the combination procedure described in Ref. 22 on the published B_s lifetime results [40,42,46] yields

$$\Delta\Gamma_s/\Gamma_s < 0.65 \quad \text{at 95\% CL} \tag{34}$$

without external constraint, or

$$\Delta\Gamma_s/\Gamma_s < 0.33 \quad \text{at 95\% CL} \tag{35}$$

when constraining $1/\Gamma_s$ to the measured B_d lifetime. These results are not yet precise enough to test Standard Model predictions.

Average b-hadron mixing and b-hadron production fractions

Let f_u, f_d, f_s and f_{baryon} be the B_u, B_d, B_s and b-baryon fractions composing an unbiased sample of weakly-decaying b hadrons produced in high energy colliders. LEP experiments have measured $f_s \times \text{BR}(B_s^0 \to D_s^- \ell^+ \nu_\ell X)$ [47], $\text{BR}(b \to \Lambda_b^0) \times \text{BR}(\Lambda_b^0 \to \Lambda_c^+ \ell^- \overline{\nu}_\ell X)$ [48] and $\text{BR}(b \to \Xi_b^-) \times \text{BR}(\Xi_b^- \to \Xi^- \ell^- \overline{\nu}_\ell X)$ [49] from partially reconstructed final states including a lepton, f_{baryon} from protons identified in b events [50], and the production rate of charged b hadrons [51]. The various b hadron fractions have also been measured at CDF from electron-charm final states [52]. All the published results have been combined following the procedure and assumptions described in Ref. 22, to yield $f_u = f_d = (38.4 \pm 1.8)\%$, $f_s = (11.7 \pm 3.0)\%$ and $f_{\text{baryon}} = (11.5 \pm 2.0)\%$ under the constraints

$$f_u = f_d \quad \text{and} \quad f_u + f_d + f_s + f_{\text{baryon}} = 1 \,. \tag{36}$$

Time-integrated mixing analyses performed with lepton pairs from $b\bar{b}$ events produced at high energy colliders measure the quantity

$$\overline{\chi} = f'_d \chi_d + f'_s \chi_s \,, \tag{37}$$

where f'_d and f'_s are the fractions of B_d and B_s hadrons in a sample of semileptonic b-hadron decays. Assuming that all b hadrons have the same semileptonic decay width implies $f'_q = f_q/(\Gamma_q \tau_b)$ $(q = s, d)$, where τ_b is the average b-hadron lifetime. Hence $\overline{\chi}$ measurements can be used to improve our knowledge on the fractions f_u, f_d, f_s and f_{baryon}.

Combining the above estimates of these fractions with the average $\overline{\chi} = 0.118 \pm 0.005$ (published in this *Review*), χ_d from Eq. (29) and $\chi_s = \frac{1}{2}$ yields, under the constraints of Eq. (36),

$$f_u = f_d = (38.9 \pm 1.3)\% \,, \tag{38}$$

$$f_s = (10.7 \pm 1.4)\% \,, \tag{39}$$

$$f_{\text{baryon}} = (11.6 \pm 2.0)\% \,, \tag{40}$$

showing that mixing information substantially reduces the uncertainty on f_s. These results and the averages quoted in Eqs. (28) and (29) for χ_d and Δm_d have been obtained in a consistent way by the B oscillations working group [22], taking into account the fact that many individual measurements of Δm_d depend on the assumed values for the b-hadron fractions.

Summary and prospects

B^0–$\overline{B}^0$ mixing has been a field of intense study in the last few years. The mass difference in the B_d–$\overline{B}_d$ system is very well measured (with an accuracy of $\sim 3.5\%$) but, despite an impressive theoretical effort, the hadronic uncertainty still limits the precision of the extracted estimate of $|V_{td}|$. The mass difference in the B_s–$\overline{B}_s$ system is much larger and still unmeasured. However, the current experimental lower limit on Δm_s already provides, together with Δm_d, a significant constraint on the CKM matrix within the Standard Model. No strong experimental evidence exists yet for the rather large decay width difference expected in the B_s–$\overline{B}_s$ system. It is interesting to recall that the ratio $\Delta\Gamma_s/\Delta m_s$ does not depend on CKM matrix elements in the Standard Model (see Eq. (22)), and that a measurement of either Δm_s or $\Delta\Gamma_s$ could be turned into a Standard Model prediction of the other one.

The LEP and SLD experiments have still not finalized all their B_s oscillation analyses, but a measurement of Δm_s from data collected at the Z pole becomes unlikely. In the near future, the most promising prospects for B_s mixing are from Run II at the Tevatron, where both Δm_s and $\Delta\Gamma_s$ are expected to be measured; CDF will be able to observe B_s oscillations for values of Δm_s up to ~ 40 ps^{-1} [53], well above the current Standard Model prediction.

CP violation in B mixing, which has not been seen yet, as well as the phases involved in B mixing, will be further investigated with the large statistics that will become available both at the B factories and at the Tevatron.

B mixing may not have delivered all its secrets yet, because it is one of the phenomena where new physics might very well reveal itself (for example new particles involved in the box diagrams). Theoretical calculations in lattice QCD are becoming more reliable and further progress in reducing hadronic uncertainties is expected. In the long term, a stringent check of the consistency, within the Standard Model, of the B_d and B_s mixing measurements with all other measured observables in B physics (including CP asymmetries in B decays) will be possible, allowing to place limits on new physics or, better, discover new physics.

B^0-$\overline{B}^0$ MIXING PARAMETERS

For a discussion of B^0-$\overline{B}^0$ mixing see the note on "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings above.

χ_d is a measure of the time-integrated B^0-$\overline{B}^0$ mixing probability that a produced $B^0(\overline{B}^0)$ decays as a $\overline{B}^0(B^0)$. Mixing violates $\Delta B \neq 2$ rule.

$$\chi_d = \frac{x_d^2}{2(1+x_d^2)}$$

$$x_d = \frac{\Delta m_{B^0}}{\Gamma_{B^0}} = (m_{B^0_H} - m_{B^0_L})\,\tau_{B^0}\,,$$

where H, L stand for heavy and light states of two B^0 CP eigenstates and $\tau_{B^0} = \frac{1}{0.5(\Gamma_{B^0_H}+\Gamma_{B^0_L})}$.

χ_d

This B^0-$\overline{B}^0$ mixing parameter is the probability (integrated over time) that a produced B^0 (or $\overline{B}^0$) decays as a $\overline{B}^0$ (or B^0), e.g. for inclusive lepton decays

$$\chi_d = \Gamma(B^0 \to \ell^- X \text{ (via } \overline{B}^0))/\Gamma(B^0 \to \ell^\pm X)$$
$$= \Gamma(\overline{B}^0 \to \ell^+ X \text{ (via } B^0))/\Gamma(\overline{B}^0 \to \ell^\pm X)$$

Where experiments have measured the parameter $r = \chi/(1-\chi)$, we have converted to χ. Mixing violates the $\Delta B \neq 2$ rule.

Note that the measurement of χ at energies higher than the $\Upsilon(4S)$ have not separated χ_d from χ_s where the subscripts indicate $B^0(\overline{b}d)$ or $B^0_s(\overline{b}s)$. They are listed in the B^0_s-$\overline{B}^0_s$ MIXING section.

The experiments at $\Upsilon(4S)$ make an assumption about the $B^0\overline{B}^0$ fraction and about the ratio of the $B^\pm$ and B^0 semileptonic branching ratios (usually that it equals one).

OUR EVALUATION, provided by the LEP B Oscillation Working Group, includes χ_d calculated from Δm_{B^0} and τ_{B^0}.

<0.27	90	[322] AVERY	84	CLEO	$e^+e^- \to \Upsilon(4S)$

[314] ALBRECHT 94 reports r=0.194 ± 0.062 ± 0.054. We convert to χ for comparison. Uses tagged events (lepton + pion from D^*).

[315] BARTELT 93 analysis performed using tagged events (lepton+pion from D^*). Using dilepton events they obtain $0.157 \pm 0.016^{+0.033}_{-0.028}$.

[316] ALBRECHT 92L is a combined measurement employing several lepton-based techniques. It uses all previous ARGUS data in addition to new data and therefore supersedes ALBRECHT 87I. A value of r = 20.6 ± 7.0% is directly measured. The value can be used to measure $x = \Delta M/\Gamma = 0.72 \pm 0.15$ for the B_d meson. Assumes $f_{+-}/f_0 = 1.0 \pm 0.05$ and uses $\tau_{B^\pm}/\tau_{B^0} = (0.95 \pm 0.14)\ (f_{+-}/f_0)$.

[317] Uses $D^{*+}K^\pm$ correlations.

[318] Uses $(D^{*+}\ell^-)\ K^\pm$ correlations.

[319] These experiments see a combination of B_s and B_d mesons.

[320] ALBRECHT 87I is inclusive measurement with like-sign dileptons, with tagged B decays plus leptons, and one fully reconstructed event. Measures r=0.21 ± 0.08. We convert to χ for comparison. Superseded by ALBRECHT 92L.

[321] BEAN 87B measured r < 0.24; we converted to χ.

[322] Same-sign dilepton events. Limit assumes semileptonic BR for B^+ and B^0 equal. If $B^0/B^\pm$ ratio <0.58, no limit exists. The limit was corrected in BEAN 87B from r < 0.30 to r < 0.37. We converted this limit to χ.

$\Delta m_{B^0} = m_{B^0_H} - m_{B^0_L}$

$\Delta m_{B^0_s}$ is a measure of 2π times the B^0-$\overline{B}^0$ oscillation frequency in time-dependent mixing experiments.

The second "OUR EVALUATION" (0.478 ± 0.018) is an average of the data listed below performed by the LEP B Oscillation Working Group as described in our "Review of B-$\overline{B}$ Mixing" in the B^0 Section of these Listings. The averaging procedure takes into account correlations between the measurements.

The first "OUR EVALUATION" (0.472 ± 0.017), also provided by the LEP B Oscillation Working Group, includes Δm_d calculated from χ_d measured at $\Upsilon(4S)$.

CP VIOLATION IN B DECAY – STANDARD MODEL PREDICTIONS

Revised January 2000 by H. Quinn (SLAC) and A.I. Sanda (Nagoya University).

With the commissioning of the asymmetric B Factories at KEKB and PEP II, and of CESR III and with the completion of the main ring injector at Fermilab, we are headed into an exciting time for the study of CP violation in B meson decays. This review outlines the basic ideas of such studies. For the most part, we follow the discussions given in Refs. [1–3].

Time evolution of neutral B meson states

Neutral B mesons, like neutral K mesons, have mass eigenstates which are not flavor eigenstates. This subject is reviewed separately [4]. Here we give some formulae to establish the notation used in this review. The mass eigenstates are given by:

$$|B_1\rangle = p|B^0\rangle + q|\overline{B}^0\rangle \ ,$$
$$|B_2\rangle = p|B^0\rangle - q|\overline{B}^0\rangle \ , \qquad (1)$$

where B^0 and $\overline{B}^0$ are flavor eigenstates containing the $\bar{b}$ and b quarks respectively. The ratio

$$\frac{q}{p} = +\sqrt{\frac{M_{12}^* - \frac{i}{2}\Gamma_{12}^*}{M_{12} - \frac{i}{2}\Gamma_{12}}} \ . \qquad (2)$$

Here, the CP operator is defined so that $CP|B^0\rangle = |\overline{B}^0\rangle$, and CPT symmetry is assumed. We define $M_{12} = \overline{M}_{12}e^{i\xi}$, where the phase ξ is restricted to $-\frac{1}{2}\pi < \xi < \frac{1}{2}\pi$, and $\overline{M}_{12}$ is taken to be real but not necessarily positive; and similarly (with a different phase) for Γ_{12}. The convention used here is that the real part of q/p is positive.

The differences in the eigenvalues $\Delta M = M_2 - M_1$ and $\Delta\Gamma = \Gamma_1 - \Gamma_2$ are given by

$$\begin{aligned} \Delta M &= -2\mathrm{Re}\left(\frac{q}{p}(M_{12} - \frac{i}{2}\Gamma_{12})\right) \\ &\simeq -2\overline{M}_{12} \\ \Delta\Gamma &= -4\mathrm{Im}\left(\frac{q}{p}(M_{12} - \frac{i}{2}\Gamma_{12})\right) \\ &\simeq 2\overline{\Gamma}_{12}\cos\zeta \ . \end{aligned} \qquad (3)$$

Here we denoted $\dfrac{\Gamma_{12}}{M_{12}} = re^{i\zeta}$. As we expect $r \sim 10^{-3}$ in the Standard Model for B_d, we kept only the leading order term in r. In the Standard Model, with these conventions and given that all models give a positive value for the parameter B_B, ΔM is positive, so that B_2 is heavier than B_1; this is unlikely to be tested soon. (Note that a common alternative convention is to name the two states B_L and B_H for light and heavy respectively; then the sign of q/p becomes the quantity to be tested.)

This review focuses on the B_d system, but also mentions some possibly interesting studies for CP violation in B_s decays, which may be pursued at hadron colliders. Much of the discussion here can be applied directly for B_s decays with the appropriate replacement of the spectator quark type.

The time evolution of states starting out at time $t = 0$ as pure B^0 or $\overline{B}^0$ is given by:

$$\begin{aligned} |B^0(t)\rangle &= g_+(t)|B^0\rangle + \frac{q}{p}g_-(t)|\overline{B}^0\rangle \\ |\overline{B}^0(t)\rangle &= g_+(t)|\overline{B}^0\rangle + \frac{p}{q}g_-(t)|B^0\rangle, \end{aligned} \qquad (4)$$

where

$$g_\pm(t) = \frac{1}{2}e^{-iM_1t}e^{-\frac{1}{2}\Gamma_1 t}\left[1 \pm e^{-i\Delta Mt}e^{\frac{1}{2}\Delta\Gamma t}\right] \ . \qquad (5)$$

We define

$$\begin{aligned} A(f) &= \langle f|H|B^0\rangle \ , \\ \overline{A}(f) &= \langle f|H|\overline{B}^0\rangle \ , \\ \overline{\rho}(f) &= \frac{\overline{A}(f)}{A(f)} = \rho(f)^{-1} \ , \end{aligned} \qquad (6)$$

where f is a final state that is possible for both B^0 and $\overline{B}^0$ decays. The time-dependent decay rates are thus given by

$$\begin{aligned} &\Gamma(B^0(t) \to f) \\ &\propto e^{-\Gamma_1 t}|A(f)|^2\Big[K_+(t) + K_-(t)\left|\frac{q}{p}\right|^2 |\overline{\rho}(f)|^2 \\ &+ 2\mathrm{Re}\Big[L^*(t)\left(\frac{q}{p}\right)\overline{\rho}(f)\Big]\Big] \ , \end{aligned} \qquad (7)$$

$$\begin{aligned} &\Gamma(\overline{B}^0(t) \to f) \\ &\propto e^{-\Gamma_1 t}|\overline{A}(f)|^2\Big[K_+(t) + K_-(t)\left|\frac{p}{q}\right|^2 |\rho(f)|^2 \\ &+ 2\mathrm{Re}\left[L^*(t)\left(\frac{p}{q}\right)\rho(f)\right]\Big], \end{aligned} \qquad (8)$$

where

$$\begin{aligned} |g_\pm(t)|^2 &= \frac{1}{4}e^{-\Gamma_1 t}K_\pm(t) \ , \\ g_-(t)g_+^*(t) &= \frac{1}{4}e^{-\Gamma_1 t}L^*(t) \ , \\ K_\pm(t) &= 1 + e^{\Delta\Gamma t} \pm 2e^{\frac{1}{2}\Delta\Gamma t}\cos\Delta Mt \ , \\ L^*(t) &= 1 - e^{\Delta\Gamma t} + 2ie^{\frac{1}{2}\Delta\Gamma t}\sin\,\Delta Mt \ . \end{aligned} \qquad (9)$$

For the case of B_d decays the quantity $\Delta\Gamma/\Gamma$ is small and is usually dropped, for B_s decays it may be significant [6] and hence is retained in Eqs. 4–8.

Three classes of CP violation in B decays

When two amplitudes with different phase-structure contribute to a B decay, they may interfere and produce CP-violating effects [5]. There are three distinct types of CP violation: (1) CP violation from nonvanishing relative phase between the mass and the width parts of the mixing matrix which gives $|q/p| \neq 1$, often called "indirect;" (2) Direct CP violation, which is any effect that indicates two decay amplitudes have different weak phases (those arising from Lagrangian couplings), in particular it occurs whenever $|\rho(f)| \neq 1$; (3) Interference between a decays with and without mixing which can occur for decays to CP eigenstates whenever $\mathrm{Arg}((q/p)\overline{\rho}(f)) \neq 0$. This can occur even for modes where both the other types do not, *i.e.* $|q/p|,\ |\rho(f)| = 1$.

(1) Indirect CP violation

In the next few years, experiments will accumulate a large number of semileptonic B decays. Any asymmetry in the wrong-sign semileptonic decays (or in any other wrong-flavor decays) is a clean sign of indirect CP violation.

The semileptonic asymmetry for the wrong sign B_q decay, where $q = d$ or s, is given by

$$a_{SL}(B_q) = \frac{\Gamma(\overline{B}_q(t) \to \ell^+ X) - \Gamma(B_q(t) \to \ell^- X)}{\Gamma(\overline{B}_q(t) \to \ell^+ X) + \Gamma(B_q(t) \to \ell^- X)}$$
$$= \frac{|p/q|^2 - |q/p|^2}{|p/q|^2 + |q/p|^2} = r_{B_q} \sin\zeta_{B_q} \ , \qquad (10)$$

where we kept only the leading order term in r_{B_q}. Within the context of the Standard Model, if hadronic rescattering effects are small then $\sin\zeta_{B_q}$ is small because M_{12} and Γ_{12} acquire their phases from the same combination of CKM matrix elements. Since this asymmetry is tiny in the Standard Model, this may be a fruitful area to search for physics beyond the Standard Model.

(2) Direct CP violation

Direct CP violation is the name given to CP violation that arises because there is a difference between the weak phases of any two decay amplitudes for a single decay. Weak phases are those that arise because of a complex coupling constant in the Lagrangian. Note that a single weak phase from a complex coupling constant is never physically meaningful because it can generally be removed by redefining some field by a phase. Only the differences between the phases of couplings which cannot be changed by such redefinitions are physically meaningful. The strong and electromagnetic couplings can always be defined to be real but, as Kobayashi and Maskawa first observed, in the three generation Standard Model one cannot remove all the phases from the CKM matrix by any choice of field redefinitions [7].

There are two distinct ways to observe direct CP-violation effects in B decays:

• $|\overline{A}_{\overline{f}}/A_f| \neq 1$ leading to rate asymmetries for CP-conjugate decays. Here, two amplitudes with different weak phases must contribute to the same decay; they must also have different strong phases, that is, the phases that arise because of absorptive parts (often called final-state interaction effects). When the final state f has different flavor content than its CP conjugate, this gives a rate asymmetry that is directly observable. The asymmetry is given by

$$a = \frac{2A_1A_2\sin(\xi_1 - \xi_2)\sin(\delta_1 - \delta_2)}{A_1^2 + A_2^2 + 2A_1A_2\cos(\xi_1 - \xi_2)\cos(\delta_1 - \delta_2)} \ , \qquad (11)$$

where the A_i are the magnitudes, the ξ_i are the weak phases, and the δ_i are the strong phases of the two amplitudes contributing to A_f. The impact of direct CP violation of this type in decays of neutral B's to flavor eigenstates is discussed below.

• Any difference (other than an overall sign) between the CP asymmetries for decays of B_d mesons to flavor eigenstates, or between those of neutral B_s mesons, is an evidence of direct CP violation. As is shown below, such asymmetries arise whenever the decay weak phase is not canceled by the mixing weak phase, hence any two different results imply that there is a difference between the weak phases of the amplitudes for the two decays. Only if the asymmetries are the same can one choose a phase convention which ascribes all CP-violating phases to the mixing amplitude. For example, the expected asymmetries for the $B \to J/\psi K_S$ and $B \to \pi\pi$ decays are different (whether or not penguin graphs add additional direct CP-violating effects of the type $|\overline{A}_{\overline{f}}/A_f| \neq 1$ in the latter channel) because the dominant decay amplitudes have different weak phases in the Standard Model.

(3) Decays of B^0 and $\overline{B}^0$ to CP eigenstates

In decays to CP eigenstates, the time-dependent asymmetry is given by

$$a_f(t) = \frac{\Gamma(\overline{B}^0(t) \to f) - \Gamma(B^0(t) \to f)}{\Gamma(\overline{B}^0(t) \to f) + \Gamma(B^0(t) \to f)} \ . \qquad (12)$$

Asymmetry is generated if: (i) both $A(B \to f)$ and $A(\overline{B} \to f)$ are nonzero; and (ii) the mixing weak phase in $\frac{q}{p}$ is different from the weak decay phase in $\overline{\rho}(f)$. To the leading order in r, the Standard Model predicts

$$q/p = \frac{V_{tb}^* V_{td}}{V_{tb} V_{td}^*} = e^{-i2\phi_{\text{mixing}}} \ . \qquad (13)$$

If there is only one amplitude (or two with the same weak phase) contributing to $A(B \to f)$ and $A(\overline{B} \to f)$ then $|\overline{\rho}(f)| = 1$ and the relationship between the measured asymmetry and the Kobayshi-Maskawa phases is cleanly predicted by

$$a_f(t) = \mathrm{Im}\left(\frac{q}{p}\overline{\rho}(f)\right)\sin\Delta Mt$$
$$= -\eta_f \sin 2(\phi_{\text{mixing}} + \phi_{\text{decay}})\sin\Delta Mt \ . \qquad (14)$$

Here we have used the fact that in such cases we can write $\overline{\rho}(f) = \eta_f e^{-i2\phi_{\text{decay}}}$ where $\eta_f = \pm$ is the CP eigenvalue of the state f. The weak phases ϕ_{mixing} and ϕ_{decay} are parameterization dependent quantities, but the combination $\phi_{\text{mixing}} + \phi_{\text{decay}}$ is parameterization independent. This is CP violation due to the interference between decays with and without mixing. Note that a single measurement of $\sin(2\phi)$ yields four ambiguous solutions for ϕ.

When more than one amplitude with different weak phases contribute to a decay to a CP eigenstate there can also be direct CP violation effects $|\lambda_f = (q/p)\,\rho(f)| \neq 1$ and the asymmetry takes the more complicated form

$$a_f(t) = \frac{(|\lambda_f|^2 - 1)\cos(\Delta M t) + 2\mathrm{Im}\lambda_f \sin(\Delta M t)}{(1 + |\lambda_f|^2)} \;. \qquad (15)$$

The quantity λ_f involves the ratio of the two amplitudes that contribute to A_f as well as their relative strong phases and hence introduces the uncertainties of hadronic physics into the relationship between the measured asymmetry and the K–M phases. However in certain cases such channels can be useful in resolving the ambiguities mentioned above. If $\cos(2\phi)$ can be measured as well as $\sin(\phi)$ only a two-fold ambiguity remains. This can be resolved only by knowledge of the sign of certain strong phase shifts [8].

When a B meson decays to a CP self-conjugate set of quarks the final state is in general a mixture of CP even and CP odd states, which contribute opposite sign and hence partially canceling asymmetries. In two special cases, namely the decay to two spin zero particles, or one spin zero and one non-zero spin particle there is a unique CP eigenvalue because there is only one possible relative angular momentum between the two final state particles. Quasi-two-body modes involving two particles with non-zero spin can sometimes be resolved into contributions of definite CP by angular analysis of the decays of the "final-state" particles [9].

There can also be a direct CP violation in these channels from the interference of two contributions to the same decay amplitude, $|\rho(f)| \neq 1$. This introduces dependence on the relative strengths of the two amplitude contributions and on their relative strong phases. Since these cannot be reliably calculated at present, this complicates the attempt to relate the measured asymmetry to the phases of CKM matrix elements.

Standard Model predictions for CP-violating asymmetries

• ***Unitarity Triangles***

The requirement that the CKM matrix be unitary leads to a number of relationships among its entries. The constraints that the product of row i with the complex conjugate of row j is zero are generically referred to as "unitarity triangles" because they each take the form of a sum of three complex numbers equal to zero and hence can be represented by triangles in the complex plane. There are six such relationships, (see for example Ref. 10); the most commonly studied is that with all angles of the same order of magnitude, given by the relationship

$$V_{ud}V_{ub}^* + V_{cd}V_{cb}^* + V_{td}V_{tb}^* = 0 \;. \qquad (16)$$

This relation can be represented as a triangle on the complex plane, as shown in Fig. 1, where the signs of all three angles are also defined. When the sides are scaled by $|V_{cd}V_{cb}^*|$, the apex of the triangle is the point ρ, η, where these parameters are defined by the Wolfenstein parameterization of the CKM matrix [11]. If $\eta = 0$, the CKM matrix is real and there is no CP violation in the Standard Model.

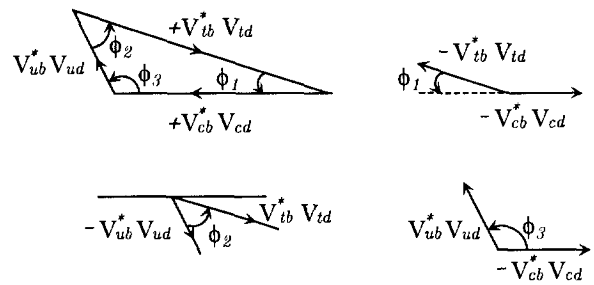

Figure 1: Angles of the unitarity triangle are related to the Kobayashi-Maskawa phases of the CKM matrix. The right-hand rule gives the positive direction of the angle between two vectors. This figure was reproduced from Ref. 1 with permission from Cambridge University Press.

The angles of the triangle are

$$\phi_1 = \pi - \arg\left(\frac{-V_{tb}^* V_{td}}{-V_{cb}^* V_{cd}}\right) = \beta \;,$$

$$\phi_2 = \arg\left(\frac{V_{tb}^* V_{td}}{-V_{ub}^* V_{ud}}\right) = \alpha \;,$$

$$\phi_3 = \arg\left(\frac{V_{ub}^* V_{ud}}{-V_{cb}^* V_{cd}}\right) = \gamma \;. \qquad (17)$$

Two naming conventions for these angles are commonly used in the literature [12,13]; we provide the translation dictionary in Eq. (17), but use the ϕ_i notation in the remainder of this review, where ϕ_i is the angle opposite the side $V_{ib}^* V_{id}$ of the unitarity triangle and i represents the i-th up-type quark. As defined here, for consistency with the measured value of ϵ_K, these angles are all positive in the Standard Model, thus a determination of the sign of these angles constitutes a test of the Standard Model [14].

There are two other independent angles of the Standard Model which appear in other triangles. These are denoted

$$\chi = \arg\left(\frac{-V_{cs}^* V_{cb}}{V_{ts}^* V_{tb}}\right) = \beta_s$$

$$\chi' = \arg\left(\frac{-V_{ud}^* V_{us}}{V_{cd}^* V_{cs}}\right) = -\beta_K \;. \qquad (18)$$

Again there are two naming conventions in common usage so we give both. These angles are of order λ^2 and λ^4 respectively [15], where $\lambda = V_{us}$. The first of them is the phase of the B_s mixing and thus is in principle measurable, though it will not be easy to achieve a result significantly different from zero for such a small angle. The angle χ' will be even more difficult to measure. Meaningful standard model tests can be defined which use the measured value of λ coupled with χ and any two of the three ϕ_i [16].

A major aim of CP-violation studies of B decays is to make enough independent measurements of the sides and angles that this unitarity triangle is overdetermined, and thereby check the validity of the Standard Model predictions that relate various measurements to aspects of this triangle. Constraints can be made on the basis of present data on the B-meson mixing and lifetime, and on the ratio of charmless decays to decays with charm (V_{ub}/V_{cb}), and on ϵ in K decays [17]. These constraints have been discussed in many places in the literature; for a recent summary of the measurements involved, see Ref. [18]. Note, however, that any given "Standard Model allowed range" cannot be interpreted as a statistically-based error range. The ranges of allowed values depend on matrix element estimates. Improved methods to calculate such quantities, and understand the uncertainties in them, are needed to further sharpen tests of the Standard Model. Recent progress in lattice simulation using dynamical fermions seems encouraging [19]. It can be hoped that reliable computations of f_B, B_B, and B_K will be completed in the next few years. This will reduce the theoretical uncertainties in the relationships between measured mixing effects and the magnitudes of CKM parameters.

In the Standard Model there are only two independent phases in this triangle since, by definition, the three angles add up to π. The literature often discusses tests of whether the angles add up to π; but this really means tests of whether relationships between different measurements, predicted in terms of the two independent parameters in the Standard Model, hold true. For example, many models that go beyond the Standard Model predict an additional contribution to the mixing matrix. Any change in phase of M_{12} will change the measured asymmetries so that ϕ_1(measured) $\to \phi_1 - \phi_{\rm new}$ and ϕ_2(measured) $\to \phi_2 + \phi_{\rm new}$. Thus the requirement that the sum of the three angles must add up to π is not sensitive to $\phi_{\rm new}$ [20]. However, the angles as determined from the sides of the triangle would, in general, no longer coincide with those measured from asymmetries. It is equally important to check the asymmetries in channels for which the Standard model predicts very small or vanishing asymmetries. A new mixing contribution which changes the phase of M_{12} will generate significant asymmetries in such channels. In the Standard Model the CKM matrix must be unitary, this leads to relationships among its entries.

• ***Standard Model decay amplitudes***

In the Standard Model, there are two classes of quark-level diagrams that contribute to hadronic B decays, as shown in Fig. 2. Tree diagrams are those where the W produces an additional quark-antiquark pair. Penguin diagrams are loop diagrams where the W reconnects to the same quark line. Penguin diagrams can further be classified by the nature of the particle emitted from the loop: gluonic or QCD penguins if it is a gluon, and electroweak penguins if it is a photon or a Z boson. In addition, one can label penguin diagrams by the flavor of the up-type quark in the loop; for any process all three flavor types contribute. For some processes, there are additional annihilation-type diagrams; these always contribute to the same CKM structure as the corresponding trees. For a detailed discussion of the status of calculations based on these diagrams, or rather on the more complete operator product approach which also includes higher order QCD corrections see, for example, Ref. 21. Note that the distinction between tree and penguin contributions is a heuristic one, the separation of contributions by the operator that enters is more precise.

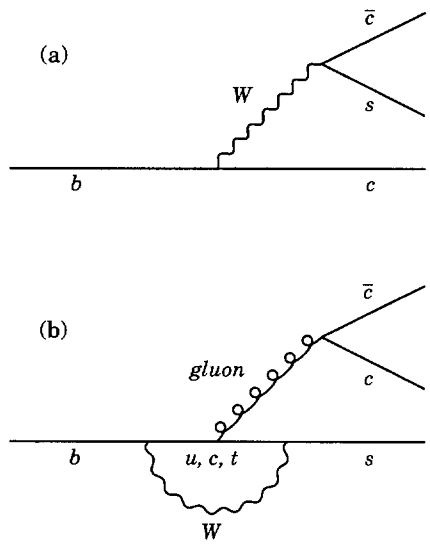

Figure 2: Quark level processes for the example of $b \to c\bar{c}s$. (a) Tree diagram; (b) Penguin diagram. In the case of electroweak penguin contributions, the gluon is replaced by a Z or a γ.

To explore possible CP violations, it is useful to tabulate all possible decays by the CKM structure of the various amplitudes. Let us first consider decays $b \to q\bar{q}'s$. The CKM factors for the diagrams for such decays are given in Table 1. Here we have used the fact that, for all such decays, the contribution to the amplitude from penguin graphs has the structure

$$A_P(q\bar{q}s) = V_{tb}V_{ts}^*P_t + V_{cb}V_{cs}^*P_c + V_{ub}V_{us}^*P_u \ , \qquad (19)$$

where the P_i quantities are the amplitudes described by the loop diagram with a flavor i quark apart from the explicitly shown CKM factor (*i.e.*, including strong phases). These are actually divergent quantities, so it is convenient to use a Standard Model unitarity relationship, $V_{tb}V_{ts}^* + V_{cb}V_{cs}^* + V_{ub}V_{us}^* = 0$, to regroup them in the following way

$$A_P(q\bar{q}s) = V_{cb}V_{cs}^*(P_c - P_t) + V_{ub}V_{us}^*(P_u - P_t) \ , \qquad (20)$$

or, equivalently,

$$A_P(q\bar{q}s) = V_{tb}V_{ts}^*(P_t - P_c) + V_{ub}V_{us}^*(P_u - P_c) \ . \qquad (21)$$

The first term is of order λ^2, whereas the second is of order λ^4, and can be ignored in most instances. For modes with $q' \neq q$, there are no penguin contributions. Note also that for the $q\bar{q} = u\bar{u}, d\bar{d}$ cases, the QCD penguin graphs contribute only to the isospin zero combinations, whereas tree graphs contribute only for $u\overline{u}$ and hence have both $\Delta I = 0$ and $\Delta I = 1$ parts, as do electroweak penguins.

The CKM coefficients for $b \to q\overline{q}'d$ are listed in Table 2. A similar exercise to that described above for the penguins yields

$$A_P(q\overline{q}d) = V_{tb}V_{td}^*(P_t - P_c) + V_{ub}V_{ud}^*(P_u - P_c) \ . \qquad (22)$$

Here the two CKM contributions are of the same order of magnitude λ^3, so both must be considered. This grouping is generally preferred over the alternative, because the second term here is somewhat smaller than the first term; it has no top-quark contribution and would vanish if the up and charm quarks were degenerate. In early literature it was often dropped, but, particularly for modes where there is no tree contribution, its effect in generating direct CP violation may be important [22]. Here the $q\overline{q} = u\overline{u}, d\overline{d}$ cases in the penguin graph contribute only to the isospin zero combinations, yielding $\Delta I = 1/2$ for the three-quark combination, whereas tree graphs and electroweak penguins have both $\Delta I = 1/2$ and $\Delta I = 3/2$ parts. For $q\overline{q} = c\overline{c}$, isospin does not distinguish between tree and penguin contributions.

Modes with direct CP violation

The largest direct CP violation is expected when there are two comparable magnitude contributions with different weak phases. Modes where the tree graphs are Cabibbo suppressed, compared to the penguins or modes with two comparable penguin contributions, are thus the best candidates. As can be seen from the tables and expressions for penguin contributions above, there are many possible modes to study. Because strong phases cannot usually be predicted, there is no clean prediction as to which modes will show the largest direct CP-violation effects. One interesting suggestion is to study three-body modes with more than one resonance in the same kinematic region. Then the different amplitudes can have very different, possibly known, strong phase structure because of the resonance (Breit-Wigner) phases [23].

Over the past two years, new information has become available from the CLEO Collaboration which suggests that penguin contributions, at least for some modes, are larger than initial estimates suggested. This is seen by using SU(3) and comparing $B \to K\pi$ and $B \to \pi\pi$ decays. To get an order of

Table 1: $B \to q\overline{q}s$ decay modes

Quark process	Leading term	Secondary term	Sample B_d modes	B_d angle	Sample B_s modes	B_s angle
$b \to c\overline{c}s$	$V_{cb}V_{cs}^* = A\lambda^2$ tree + penguin$(c-t)$	$V_{ub}V_{us}^* = A\lambda^4(\rho - i\eta)$ penguin only$(u-t)$	$J/\psi\ K_S$	β	$J/\psi\eta$ $D_s\overline{D}_s$	0

magnitude picture, we ignore such details as Clebsch-Gordan coefficients and assume that top penguins dominate the penguin contributions. Thus, we identify the tree and penguin contributions, minus their CKM coefficients, as T and P, the same for both modes. Writing $A_{T,P}(K\pi)$ for the tree and penguin contributions to the $K\pi$ amplitude, and similarly for $\pi\pi$ from the Tables, we see that $|A^T(K\pi)/A^T(\pi\pi)| = \mathcal{O}(\lambda)$. Thus, if the tree graph matrix elements were to dominate both decays, we would expect $\mathrm{Br}(B \to K\pi)/\mathrm{Br}(B \to \pi\pi) \sim \mathcal{O}(\lambda^2)$. Naively, this was expected, since the ratio of tree to penguin contribution was estimated to be $\frac{P}{T} = \frac{\alpha_S}{12\pi}\log\frac{m_t^2}{m_b^2} \sim \mathcal{O}(0.02)$. Experimentally, this is not so [24]; in fact, the $K\pi$ branching ratio is larger. This indicates that $A^P(K\pi) \sim A^T(\pi\pi)$, which suggests that $\frac{P}{T} = \mathcal{O}(\lambda)$ or larger, considerably bigger than expected. Note that this is one way that new physics could be hidden in modes with $|\rho(f)| \neq 1$; any new physics contribution can always be written as a sum of two terms with the weak phases of the two Standard Model terms (for example in Eq. (22)), and thus, when added to the Standard Model contributions, appears only as a change in the sizes of P and T from that expected in the Standard Model. However, we cannot calculate these relative sizes well enough to identify such an effect with confidence.

From the point of view of looking for direct CP-violation effects, a large P/T is good news. The largest asymmetry is expected when the interfering amplitudes have comparable magnitudes. This may be so in $B \to K\pi$ decay (or the penguin contribution may even be larger than the tree). There is no reason for the strong phases to be equal (although they could both be small). Therefore, $B^\pm \to K^\pm\pi$ is a likely hunting ground for direct CP violation. (Note there is no gluonic penguin contribution to charged $B \to \pi\pi$, and hence, no significant CP violation expected in the Standard Model.) However, as we will see below, a large P/T complicates the relationship between the measured asymmetry in neutral B decays to $\pi^+\pi^-$ and KM phases.

Studies of CP eigenstates

• $\boldsymbol{f = J/\psi K_S}$

The asymmetry in the Golden Mode $B \to J/\psi K_S$ [25] will be measured soon. Since, using Eq. (20), the dominant penguin contribution has the same weak phase as the tree graph, and the remaining term is tiny, there is effectively only one weak phase in the decay amplitude. Hence, in the asymmetry, all dependence on the amplitudes cancel. With about 1% uncertainty,

$$\frac{q}{p}\bar{\rho}(J/\psi K_S) \simeq -\frac{V_{tb}^* V_{td}}{V_{tb} V_{td}^*} \cdot \frac{V_{cb} V_{cs}^*}{V_{cb}^* V_{cs}} \cdot \frac{V_{cs} V_{cd}^*}{V_{cs}^* V_{cd}} \equiv -e^{-2i\phi_1} , \quad (23)$$

where the last factor arises from the K^0-$\overline{K}^0$ mixing amplitude and appears because of the K_S in the final state. The asymmetry is thus given by

$$a_{J/\psi K_S} = \sin(2\phi_1)\sin \Delta M t , \quad (24)$$

where the angle ϕ_1 is defined in Fig. 1. Given current constraints a large positive value for $\sin(2\phi_1)$ will be strongly suggestive that the KM ansatz for CP violation is at least one of the sources of this interesting phenomenon.

• $\boldsymbol{B^0 \to \pi^+\pi^-}$

The tree and penguin terms appear at the same order in λ (see Eq. (22) and Table 2.) If penguin decays were negligible the asymmetry would directly measure $\sin(2\phi_2)$. Given the enhanced penguin contribution seen from comparing $\pi\pi$ and $K\pi$ decays, the penguins cannot be ignored, and a treatment that does not assume $|\rho(f)| = 1$ must be made.

If all six modes of $B^+ \to \pi^+\pi^0$, $B^0 \to \pi^+\pi^-$, $B^0 \to \pi^0\pi^0$ and their charge conjugates can be measured with sufficient accuracy, ϕ_2 can be extracted using an isospin analysis [26], up to small corrections from electroweak penguins. However, the branching ratio for the charged modes is less than 10^{-5} [24], and that for the more difficult to measure $B^0 \to \pi^0\pi^0$ is expected to be even smaller. Therefore, further ingenuity is needed to get at this angle cleanly. A future possibility is to study the Dalitz plot of $B \to 3\pi$ decays [27].

Further Measurements

As Tables 1 and 2 suggest there are many more CP-eigenstate modes that are interesting to study, both for B_d and similarly for B_s decays. The latter states are not accessible for the B factories operating at the $\Upsilon(4S)$ resonance, but may be studied at hadronic colliders. The CDF result on the asymmetry in the $J/\psi K_S$ mode is an indication of the capabilities of such facilities for B physics [29]. Upgrades of the Fermilab detectors are in progress and proposals for new detectors with the capability to achieve fast triggers for a larger variety of purely hadronic modes are under development, promising some future improvement in this capability.

In addition to CP-eigenstate modes there are many additional modes for which particular studies have been proposed, in particular those focussed on extracting ϕ_3 (γ). Modes such as DK, DK^* and D^*K where the D mesons decay to CP eigenstates provide theoretically clean extraction of this parameter but have small branching ratios [30]. Other approaches involve the more copious $K\pi$ modes but rely on the use of isospin and SU(3) (U-spin) symmetries, so have larger theoretical uncertainties [31]. This is an active area of current theoretical work.

For a recent review of how predictions for CP-violating effects are affected by Beyond Standard Model effects see Ref. 28. There are also many ways to search for new physics effects in B decays that do not involve just the CP-violation effects. For example searches for isospin breaking effects in $K\pi$ modes have recently been suggested as a likely method to isolate such effects [32].

CP VIOLATION PARAMETERS

$\mathrm{Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2)$

CP Impurity in B^0_d system. It is obtained from either $a_{\ell\ell}$, the charge asymmetry in like-sign dilepton events or a_{cp}, the time-dependent asymmetry of inclusive B^0 and $\overline{B}^0$ decays.

<0.045	[344] BARTELT	93	CLE2	$e^+e^- \rightarrow \Upsilon(4S)$

[342] Data analyzed using the time-dependent asymmetry of inclusive B^0 decay. The production flavor of B^0 mesons is determined using both the jet charge and the charge of secondary vertex in the opposite hemisphere.

[343] ACKERSTAFF 97U assumes *CPT* and is based on measuring the charge asymmetry in a sample of B^0 decays defined by lepton and Q_{hem} tags. If *CPT* is not invoked, $\mathrm{Re}(\epsilon_B) = -0.006 \pm 0.010 \pm 0.006$ is found. The indirect *CPT* violation parameter is determined to $\mathrm{Im}(\delta B) = -0.020 \pm 0.016 \pm 0.006$.

[344] BARTELT 93 finds $a_{\ell\ell} = 0.031 \pm 0.096 \pm 0.032$ which corresponds to $|a_{\ell\ell}| < 0.18$, which yields the above $|\mathrm{Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2|$.

$\sin(2\beta)$

For a discussion of *CP* violation, see the note on "*CP* Violation in *B* Decay Standard Model Predictions" in the B^0 Particle Listings above. $\sin(2\beta)$ is a measure of the *CP*-violating amplitude in the $B^0_d \rightarrow J/\psi(1S) K^0_S$.

1.8 ±1.1 ±0.3	[347] ABE	98U	CDF	Repl. by AFFOLDER 00C

[345] AFFOLDER 00C uses about 400 $B^0 \rightarrow J/\psi(1S) K^0_S$ events. The production flavor of B^0 was determined using three tagging algorithms: a same-side tag, a jet-charge tag, and a soft-lepton tag.

[346] ACKERSTAFF 98Z uses 24 candidates for $B^0_d \rightarrow J/\psi(1S) K^0_S$ decay. A combination of jet-charge and vertex-charge techniques were used to tag the B^0_d production flavor.

[347] ABE 98U uses 198 ± 17 $B^0_d \rightarrow J/\psi(1S) K^0$ events. The production flavor of B^0 was determined using the same side tagging technique.

$B^{\pm}/B^0$ ADMIXTURE

B DECAY MODES

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $B(\Upsilon(4S) \to B\overline{B}) = 100\%$.

For inclusive branching fractions, *e.g.*, $B \to D^{\pm}$ anything, the treatment of multiple D's in the final state must be defined. One possiblity would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections.

$\overline{B}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

	Mode		Fraction (Γ_i/Γ)	Scale factor/ Confidence level
	Semileptonic and leptonic modes			
Γ_1	$B \to e^+ \nu_e$ anything	[a]	(10.41±0.29) %	S=1.2

[a] These values are model dependent. See 'Note on Semileptonic Decays' in the B^+ Particle Listings.

[b] An ℓ indicates an e or a μ mode, not a sum over these modes.

[c] D^{**} stands for the sum of the $D(1\,^1P_1)$, $D(1\,^3P_0)$, $D(1\,^3P_1)$, $D(1\,^3P_2)$, $D(2\,^1S_0)$, and $D(2\,^1S_1)$ resonances.

[d] The value is for the sum of the charge states or particle/antiparticle states indicated.

[e] $D^{(*)}\overline{D}^{(*)}$ stands for the sum of $D^*\overline{D}^*$, $D^*\overline{D}$, $D\overline{D}^*$, and $D\overline{D}$.

[f] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

$B^{\pm}/B^0$ ADMIXTURE BRANCHING RATIOS

$\Gamma(\ell^+\nu_\ell\,\text{anything})/\Gamma_{\text{total}}$ — Γ_4/Γ

These branching fraction values are model dependent. See the note on "Semileptonic Decays of B Mesons at the beginning of the B^+ Particle Listings.

VALUE	DOCUMENT ID		TECN	COMMENT
0.1045±0.0021 OUR AVERAGE	Includes data from the 2 datablocks that follow this one.			
0.108 ±0.002 ±0.0056	[1] HENDERSON	92	CLEO	$e^+e^- \to \Upsilon(4S)$

[1] HENDERSON 92 measurement employs e and μ. The systematic error contains 0.004 in quadrature from model dependence. The authors average a variation of the Isgur, Scora, Grinstein, and Wise model with that of the Altarelli-Cabibbo-Corbò-Maiani-Martinelli model for semileptonic decays to correct the acceptance.

$\Gamma(e^+\nu_e\,\text{anything})/\Gamma_{\text{total}}$ — Γ_1/Γ

These branching fraction values are model dependent. See the note on "Semileptonic Decays of B Mesons at the beginning of the B^+ Particle Listings.

[2] BARISH 96B analysis performed using tagged semileptonic decays of the B. This technique is almost model independent for the lepton branching ratio.

[3] ALBRECHT 93H analysis performed using tagged semileptonic decays of the B. This technique is almost model independent for the lepton branching ratio.

[4] YANAGISAWA 91 also measures an average semileptonic branching ratio at the $\Upsilon(5S)$ of 9.6–10.5% depending on assumptions about the relative production of different B meson species.

[5] ALBRECHT 90H uses the model of ALTARELLI 82 to correct over all lepton momenta. 0.099 ± 0.006 is obtained using ISGUR 89B.

[6] Using data above $p(e)$ = 2.4 GeV, WACHS 89 determine $\sigma(B \to e\nu\text{up})/\sigma(B \to e\nu\text{charm}) < 0.065$ at 90% CL.

[7] Ratio $\sigma(b \to e\nu\text{up})/\sigma(b \to e\nu\text{charm}) < 0.055$ at CL = 90%.

$\Gamma(\mu^+\nu_\mu\,\text{anything})/\Gamma_{\text{total}}$ — Γ_3/Γ

These branching fraction values are model dependent. See the note on "Semileptonic Decays of B Mesons at the beginning of the B^+ Particle Listings.

[24] ALBRECHT 94C find $\Gamma(b \to c)/\Gamma(b \to \text{all}) = 0.99 \pm 0.02 \pm 0.04$.

[25] BARTELT 93B (CLEO II) measures an excess of $107 \pm 15 \pm 11$ leptons in the lepton momentum interval 2.3–2.6 GeV/c which is attributed to $b \to u\ell\nu_\ell$. This corresponds to a model-dependent partial branching ratio ΔB_{ub} between $(1.15 \pm 0.16 \pm 0.15) \times 10^{-4}$, as evaluated using the KS model (KOERNER 88), and $(1.54 \pm 0.22 \pm 0.20) \times 10^{-4}$ using the ACCMM model (ARTUSO 93). The corresponding values of $|V_{ub}|/|V_{cb}|$ are 0.056 ± 0.006 and 0.076 ± 0.008, respectively.

[26] ALBRECHT 91C result supersedes ALBRECHT 90. Two events are fully reconstructed providing evidence for the $b \to u$ transition. Using the model of ALTARELLI 82, they obtain $|V_{ub}/V_{cb}| = 0.11 \pm 0.012$ from 77 leptons in the 2.3–2.6 GeV momentum range.

[27] FULTON 90 observe 76 ± 20 excess e and μ (lepton) events in the momentum interval p = 2.4–2.6 GeV signaling the presence of the $b \to u$ transition. The average branching ratio, $(1.8 \pm 0.4 \pm 0.3) \times 10^{-4}$, corresponds to a model-dependent measurement of approximately $|V_{ub}/V_{cb}| = 0.1$ using $B(b \to c\ell\nu) = 10.2 \pm 0.2 \pm 0.7\%$.

[28] ALBRECHT 90 observes 41 ± 10 excess e and μ (lepton) events in the momentum interval p = 2.3–2.6 GeV signaling the presence of the $b \to u$ transition. The events correspond to a model-dependent measurement of $|V_{ub}/V_{cb}| = 0.10 \pm 0.01$.

[29] The quoted possible limits range from 0.018 to 0.04 for the ratio, depending on which model or momentum range is chosen. We select the most conservative limit they have calculated. This corresponds to a limit on $|V_{ub}|/|V_{cb}| < 0.20$. While the endpoint technique employed is more robust than their previous results in CHEN 84, these results do not provide a numerical improvement in the limit.

[45] GIBBONS 97B reports $B(B \to D^*(2010)^+\text{anything}) = 0.239 \pm 0.015 \pm 0.014 \pm 0.009$ using CLEO measured D and D^* branching fractions. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[46] ALBRECHT 96D reports $B(B \to D^*(2010)^+\text{anything})$ 0.196 ± 0.019 using CLEO measured $B(D^*(2010)^+ \to D^0\pi^+) = 0.681 \pm 0.01 \pm 0.013$, $B(D^0 \to K^-\pi^+) = 0.0401 \pm 0.0014$, $B(D^0 \to K^-\pi^+\pi^+\pi^-) = 0.081 \pm 0.005$., We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[47] BORTOLETTO 92 reports $B(B \to D^*(2010)^+\text{anything}) = 0.25 \pm 0.03 \pm 0.04$ using MARK II $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$ and $B(D^0 \to K^-\pi^+) = 0.042 \pm 0.008$. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[48] ALBRECHT 91H reports $0.348 \pm 0.060 \pm 0.035$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.55 \pm 0.04$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Uses the PDG 90 $B(D^0 \to K^-\pi^+) = 0.0371 \pm 0.0025$.

[49] BORTOLETTO 87 uses old MARK III (BALTRUSAITIS 86E) branching ratios $B(D^0 \to K^-\pi^+) = 0.056 \pm 0.004 \pm 0.003$ and also assumes $B(D^*(2010)^+ \to D^0\pi^+) = 0.60^{+0.08}_{-0.15}$. The product branching ratio for $B(B \to D^*(2010)^+)\, B(D^*(2010)^+ \to D^0\pi^+)$ is $0.13 \pm 0.02 \pm 0.012$. Superseded by BORTOLETTO 92.

[50] $V-A$ momentum spectrum used to extrapolate below $p = 1$ GeV. We correct the value assuming $B(D^0 \to K^-\pi^+) = 0.042 \pm 0.006$ and $B(D^{*+} \to D^0\pi^+) = 0.6^{+0.08}_{-0.15}$. The product branching fraction is $B(B \to D^{*+}X) \cdot B(D^{*+} \to \pi^+ D^0) \cdot B(D^0 \to K^-\pi^+) = (68 \pm 15 \pm 9) \times 10^{-4}$.

1.1 ±0.21±0.23	46	[69] HAAS	85	CLEO	Repl. by ALAM 86

[64] BALEST 95B reports $1.12 \pm 0.04 \pm 0.06$ for $B(J/\psi(1S) \to e^+e^-) = 0.0599 \pm 0.0025$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.. They measure $J/\psi(1S) \to e^+e^-$ and $\mu^+\mu^-$ and use PDG 1994 values for the branching fractions. The rescaling is the same for either mode so we use e^+e^-.

[65] MASCHMANN 90 reports $1.12 \pm 0.33 \pm 0.25$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[66] ALBRECHT 87D reports $1.07 \pm 0.16 \pm 0.22$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.93 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. ALBRECHT 87D find the branching ratio for J/ψ not from $\psi(2S)$ to be 0.0081 ± 0.0023.

[67] ALAM 86 reports $1.09 \pm 0.16 \pm 0.21$ for $B(J/\psi(1S) \to \mu^+\mu^-) = 0.074 \pm 0.012$. We rescale to our best value $B(J/\psi(1S) \to \mu^+\mu^-) = (5.88 \pm 0.10) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[68] Statistical and systematic errors were added in quadrature. ALBRECHT 85H also report a CL = 90% limit of 0.007 for $B \to J/\psi(1S) + X$ where m_X <1 GeV.

[69] Dimuon and dielectron events used.

$\Gamma(J/\psi(1S) \text{(direct) anything})/\Gamma_{total}$ — Γ_{37}/Γ

VALUE	DOCUMENT ID		TECN	COMMENT
0.0080±0.0008	[70] BALEST	95B	CLE2	$e^+e^- \to \Upsilon(4S)$

[70] BALEST 95B assume PDG 1994 values for sub mode branching ratios. $J/\psi(1S)$ mesons are reconstructed in $J/\psi(1S) \to e^+e^-$ and $J/\psi(1S) \to \mu^+\mu^-$. The $B \to J/\psi(1S)X$ branching ratio contains $J/\psi(1S)$ mesons directly from B decays and also from feeddown through $\psi(2S) \to J/\psi(1S)$, $\chi_{c1}(1P) \to J/\psi(1S)$, or $\chi_{c2}(1P) \to J/\psi(1S)$. Using the measured inclusive rates, BALEST 95B corrects for the feeddown and finds the $B \to J/\psi(1S)$ (direct) X branching ratio.

[77] ALBRECHT 93I value is not independent of the sum of $B \to K^+$anything and $B \to K^-$ anything ALBRECHT 94C values.

[78] Assuming $\Upsilon(4S) \to B\overline{B}$, a total of $3.38 \pm 0.34 \pm 0.68$ kaons per $\Upsilon(4S)$ decay is found (the second error is systematic). In the context of the standard B-decay model, this leads to a value for (b-quark $\to$ c-quark)/(b-quark $\to$ all) of $1.09 \pm 0.33 \pm 0.13$.

[79] GIANNINI 82 at CESR-CUSB observed 1.58 ± 0.35 K^0 per hadronic event much higher than 0.82 ± 0.10 below threshold. Consistent with predominant $b \to cX$ decay.

0.076±0.014	[114] ALBRECHT 89K	ARG	$e^+e^- \to \Upsilon(4S)$

[113] ALBRECHT 92O result is from simultaneous analysis of p and Λ yields, $p\overline{p}$ and $\Lambda\overline{p}$ correlations, and various lepton-baryon and lepton-baryon-antibaryon correlations. Supersedes ALBRECHT 89K.

[114] ALBRECHT 89K obtain this result by adding their their measurements (5.5 ± 1.6)% for direct protons and $(4.2 \pm 0.5 \pm 0.6)$% for inclusive Λ production. They then assume (5.5 ± 1.6)% for neutron production and add it in also. Since each B decay has two baryons, they divide by 2 to obtain (7.6 ± 1.4)%.

$B^{\pm}/B^0/B^0_s/b$-baryon ADMIXTURE

$B^{\pm}/B^0/B^0_s/b$-baryon ADMIXTURE MEAN LIFE

Each measurement of the B mean life is an average over an admixture of various bottom mesons and baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different B mean life.

"OUR EVALUATION" is an average of the data listed below performed by the LEP B Lifetime Working Group as described in our review "Production and Decay of b-flavored Hadrons" in the $B^{\pm}$ Section of these Listings. The averaging procedure takes into account correlations between the measurements and asymmetric lifetime errors, but ignores the small differences due to different techniques.

[1] Measured using inclusive $J/\psi(1S)\to\mu^+\mu^-$ vertex.

[2] ACCIARRI 98 uses inclusively reconstructed secondary vertex and lepton impact parameter.

[3] ACKERSTAFF 97F uses inclusively reconstructed secondary vertices.

[4] BUSKULIC 96F analyzed using 3D impact parameter.

[5] ABE,K 95B uses an inclusive topological technique.

[6] ABREU 94L uses charged particle impact parameters. Their result from inclusively reconstructed secondary vertices is superseded by ABREU 96E.

[7] ACTON 93L and ADRIANI 93K analyzed using lepton (e and μ) impact parameter at Z.

[8] BUSKULIC 93O analyzed using dipole method.

[9] Combines ABREU 96E secondary vertex result with ABREU 94L impact parameter result.

[10] From proper time distribution of $b\to J/\psi(1S)$anything.

[11] ABE 93J analyzed using $J/\psi(1S)\to\mu\mu$ vertices.

[12] ABREU 93D data analyzed using $D/D^*\ell$anything event vertices.

[13] ABREU 93G data analyzed using charged and neutral vertices.

[14] ACTON 93C analysed using $D/D^*\ell$anything event vertices.

[15] ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave $(12.7\pm0.4\pm1.2)\times10^{-13}$ s for an admixture of B species weighted by production fraction and mean charge multiplicity, while muon tracks gave $(13.0\pm1.0\pm0.8)\times10^{-13}$ s for an admixture weighted by production fraction and semileptonic branching fraction.

[16] ACTON 92 is combined result of muon and electron impact parameter analyses.

[17] BUSKULIC 92F uses the lepton impact parameter distribution for data from the 1991 run.

[18] BUSKULIC 92G use $J/\psi(1S)$ tags to measure the average b lifetime. This is comparable to other methods only if the $J/\psi(1S)$ branching fractions of the different b-flavored hadrons are in the same ratio.

[19] Using $Z\to e^+X$ or μ^+X, ADEVA 91H determined the average lifetime for an admixture of B hadrons from the impact parameter distribution of the lepton.

[20] Using $Z\to J/\psi(1S)X$, $J/\psi(1S)\to\ell^+\ell^-$, ALEXANDER 91G determined the average lifetime for an admixture of B hadrons from the decay point of the $J/\psi(1S)$.

[21] Using $Z\to eX$ or μX, DECAMP 91C determines the average lifetime for an admixture of B hadrons from the signed impact parameter distribution of the lepton.

[22] HAGEMANN 90 uses electrons and muons in an impact parameter analysis.

[23] LYONS 90 combine the results of the B lifetime measuresments of ONG 89, BRAUNSCHWEIG 89B, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life, and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.

[24] We have combined an overall scale error of 15% in quadrature with the systematic error of ±0.7 to obtain ±2.1 systematic error.

[25] Statistical and systematic errors were combined by BROM 87.

$\overline{b}$ PRODUCTION FRACTIONS AND DECAY MODES

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LEP, Tevatron, $Sp\overline{p}S$) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LEP and at the Tevatron.

For inclusive branching fractions, *e.g.*, $B \to D^{\pm}$anything, the treatment of multiple D's in the final state must be defined. One possiblity would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections.

The modes below are listed for a $\overline{b}$ initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

	Mode		Fraction (Γ_i/Γ)	Scale factor/ Confidence level
	PRODUCTION FRACTIONS			

The production fractions for weakly decaying b-hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the LEP B Oscillation Working Group as described in the note "Production and Decay of b-Flavored Hadrons" in the $B^{\pm}$ Particle Listings. Values assume

$$B(\overline{b} \to B^+) = B(\overline{b} \to B^0)$$
$$B(\overline{b} \to B^+) + B(\overline{b} \to B^0) + B(\overline{b} \to B^0_s) + B(b \to b\text{-baryon}) = 100\ \%.$$

The notation for production fractions varies in the literature (f_d, d_{B^0}, $f(b \to \overline{B}^0)$, $Br(b \to \overline{B}^0)$). We use our own branching fraction notation here, $B(\overline{b} \to B^0)$.

0.105 ±0.006 ±0.005	42 AKERS	93B	OPAL	Repl. by ABBIENDI 00E

[35] ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z \to b\bar{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.
[36] ACCIARRI 00 result obtained from a combined fit of $R_b = \Gamma(Z \to b\bar{b})/\Gamma(Z \to \text{hadrons})$ and $B(b \to \ell\nu X)$, using double-tagging method.
[37] ACCIARRI 96C result obtained by a fit to the single lepton spectrum.
[38] Assumes Standard Model value for R_B.
[39] ABREU 95D give systematic errors ±0.0019 (model) and 0.0012 (R_c). We combine these in quadrature.
[40] BUSKULIC 94G uses e and μ events. This value is from a global fit to the lepton p and p_T (relative to jet) spectra which also determines the b and c production fractions, the fragmentation functions, and the forward-backward asymmetries. This branching ratio depends primarily on the ratio of dileptons to single leptons at high p_T, but the lower p_T portion of the lepton spectrum is included in the global fit to reduce the model dependence. The model dependence is ±0.0026 and is included in the systematic error.
[41] ABREU 93C event count includes ee events. Combining ee, $\mu\mu$, and $e\mu$ events, they obtain 0.100 ± 0.007 ± 0.007.
[42] AKERS 93B analysis performed using single and dilepton events.

0.077 ±0.004 ±0.007	[73] AKERS	93B OPAL	Repl. by ABBIENDI 00E

[70] ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z \to b\bar{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.
[71] ABREU 95D give systematic errors ±0.0033 (model) and 0.0032 (R_c). We combine these in quadrature. This result is from the same global fit as their $\Gamma(\bar{b} \to \ell^+\nu_\ell X)$ data.
[72] BUSKULIC 94G uses e and μ events. This value is from the same global fit as their $\Gamma(\bar{b} \to \ell^+\nu_\ell\text{anything})/\Gamma_{\text{total}}$ data.
[73] AKERS 93B analysis performed using single and dilepton events.

[1] u, d, s flavor averaged.

[2] These papers report E_γ in the B^* center of mass. The $m_{B^*} - m_B$ is 0.2 MeV higher. E_{cm} = 10.61–10.7 GeV. Admixture of B^0 and B^+ mesons, but not B_s.

[3] LEE-FRANZINI 90 value is for an admixture of B^0 and B^+. They measure 46.7 ± 0.4 ± 0.2 MeV for an admixture of B^0, B^+, and B_s, and use the shape of the photon line to separate the above value.

[4] HAN 85 is for E_{cm} = 10.6–11.2 GeV, giving an admixture of B^0, B^+, and B_s.

5713± 2		[3] ACCIARRI 99N	L3	$e^+e^- \to Z$

[1] BARATE 98L uses fully reconstructed B mesons to search for B^{**} production in the $B\pi^{\pm}$ system. In the framework of heavy quark symmetry (HQS), they also measured the mass of B^*_2 to be $5739^{+8}_{-11}{}^{+6}_{-4}$ MeV/c^2 and the relative production rate of B($b \to B^*_2 \to B^{(*)}\pi$)/B($b \to B_{u,d}$) = $(31 \pm 9^{+6}_{-5})$%.

[2] Using $m_{B\pi} - m_B = 424 \pm 4 \pm 10$ MeV.

[3] ACCIARRI 99N uses inclusive reconstructed B mesons to search for B^{**} production in the $B^{(*)}\pi^{\pm}$ system. In the framework of HQET, they measured the mass of B^*_1 and B^*_2 to be 5670 ± 10 ± 13 MeV and 5768 ± 5 ± 6 with the B($b \to B^{**}$)= $(32 \pm 3 \pm 6) \times 10^{-2}$. They also reported the evidence for the existence of an excited B-meson state or mixture of states in the region 5.9–6.0 GeV.

B^0_s MEAN LIFE

"OUR EVALUATION" is an average of the data listed below performed by the LEP B Lifetimes Working Group as described in our review "Production and Decay of b-flavored Hadrons" in the $B^\pm$ Section of the Listings. The averaging procedure takes into account correlations between the measurements and asymmetric lifetime errors.

[3] Measured using $D^-_s \ell^+$ vertices.
[4] Measured using fully reconstructed $B_s \to J/\psi(1S)\phi$ decay.
[5] ACKERSTAFF 98F use fully reconstructed $D^-_s \to \phi\pi^-$ and $D^-_s \to K^{*0}K^-$ in the inclusive B^0_s decay.
[6] Measured using D_s hadron vertices.
[7] Measured using $\phi\ell$ vertices.
[8] Measured using inclusive D_s vertices.
[9] Combined results from $D^-_s \ell^+$ and D_s hadron.
[10] ABE 96N uses 58 ± 12 exclusive $B_s \to J/\psi(1S)\phi$ events.
[11] Combined result for the four ABREU 96F methods.
[12] Exclusive reconstruction of $B_s \to \psi\phi$.
[13] ABREU 94E uses the flight-distance distribution of D_s vertices, ϕ-lepton vertices, and $D_s\mu$ vertices.

$|\Delta\Gamma_{B^0_s}|/\Gamma_{B^0_s}$

$\Gamma_{B^0_s}$ and $|\Delta\Gamma_{B^0_s}|$ are the decay rate average and difference between two B^0_s CP eigenstates.

The first "OUR EVALUATION," < 0.33 (CL=95%), also provided by the LEP B Oscillation Working Group, including the assumption of $\Gamma_s = \frac{1}{\tau_{B_d}}$.

The second "OUR EVALUATION," < 0.65 (CL=95%), is an average of all available B_s semi-leptonic lifetime measurements with the $\Delta\Gamma_{B^0_s}/\Gamma_s$ analyses performed by the LEP B Oscillation Working Group as described in our "Review on B-$\overline{B}$ Mixing" in the B^0 Section of these Listings.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
<0.65 (CL = 95%) OUR EVALUATION					
<0.33 (CL = 95%) OUR EVALUATION					
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<0.83	95	[14] ABE	99D	CDF	$p\overline{p}$ at 1.8 TeV
<0.67	95	[15] ACCIARRI	98S	L3	$e^+e^- \to Z$

[14] ABE 99D assumes $\tau_{B^0_s} = 1.55 \pm 0.05$ ps.
[15] ACCIARRI 98S assumes $\tau_{B^0_s} = 1.49 \pm 0.06$ ps and PDG 98 values of b production fraction.

B^0_s DECAY MODES

These branching fractions all scale with $B(\overline{b} \to B^0_s)$, the LEP B^0_s production fraction. The first four were evaluated using $B(\overline{b} \to B^0_s) = (10.7 \pm 1.4)\%$ and the rest assume $B(\overline{b} \to B^0_s) = 12\%$.

The branching fraction $B(B^0_s \to D^-_s \ell^+ \nu_\ell \text{anything})$ is not a pure measurement since the measured product branching fraction $B(\overline{b} \to B^0_s) \times B(B^0_s \to D^-_s \ell^+ \nu_\ell \text{anything})$ was used to determine $B(\overline{b} \to B^0_s)$, as described in the note on "Production and Decay of b-Flavored Hadrons."

	Mode		Fraction (Γ_i/Γ)	Confidence level
Γ_1	D^-_s anything		(92 ±31) %

[a] Not a pure measurement. See note at head of B^0_s Decay Modes.
[b] The value is for the sum of the charge states or particle/antiparticle states indicated.

B_s^0 BRANCHING RATIOS

$\Gamma(D_s^-\text{ anything})/\Gamma_{total}$ — Γ_1/Γ

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
0.92±0.31 OUR AVERAGE				
0.81 ±0.24 ±0.22	90	[16] BUSKULIC	96E ALEP	$e^+e^- \to Z$
1.56 ±0.58 ±0.44	147	[17] ACTON	92N OPAL	$e^+e^- \to Z$

[16] BUSKULIC 96E separate $c\overline{c}$ and $b\overline{b}$ sources of D_s^+ mesons using a lifetime tag, subtract generic $\overline{b} \to W^+ \to D_s^+$ events, and obtain $B(\overline{b} \to B_s^0) \times B(B_s^0 \to D_s^-\text{anything}) = 0.088 \pm 0.020 \pm 0.020$ assuming $B(D_s \to \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$ and PDG 1994 values for the relative partial widths to other D_s channels. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$.

[17] ACTON 92N assume that excess of 147 ± 48 D_s^0 events over that expected from B^0, B^+, and $c\overline{c}$ is all from B_s^0 decay. The product branching fraction is measured to be $B(\overline{b} \to B_s^0)B(B_s^0 \to D_s^-\text{anything})\times B(D_s^- \to \phi\pi^-) = (5.9 \pm 1.9 \pm 1.1) \times 10^{-3}$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$.

$\Gamma(D_s^-\ell^+\nu_\ell\text{anything})/\Gamma_{total}$ — Γ_2/Γ

The values and averages in this section serve only to show what values result if one assumes our $B(\overline{b} \to B_s^0)$. They cannot be thought of as measurements since the underlying product branching fractions were also used to determinine $B(\overline{b} \to B_s^0)$ as described in the note on "Production and Decay of b-Flavored Hadrons."

0.13 ±0.04 ±0.04	27	[21] BUSKULIC	92E ALEP	$e^+e^- \to Z$

[18] BUSKULIC 95O use $D_s\ell$ correlations. The measured product branching ratio is $B(\overline{b} \to B_s) \times B(B_s \to D_s^-\ell^+\nu_\ell\text{anything}) = (0.82 \pm 0.09^{+0.13}_{-0.14})\%$ assuming $B(D_s \to \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$ and PDG 1994 values for the relative partial widths to the six other D_s channels used in this analysis. Combined with results from $\Upsilon(4S)$ experiments this can be used to extract $B(\overline{b} \to B_s) = (11.0 \pm 1.2^{+2.5}_{-2.6})\%$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$.

[19] ABREU 92M measured muons only and obtained product branching ratio $B(Z \to b \text{ or } \overline{b}) \times B(\overline{b} \to B_s) \times B(B_s \to D_s\mu^+\nu_\mu\text{anything}) \times B(D_s \to \phi\pi) = (18 \pm 8) \times 10^{-5}$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$. We use $B(Z \to b \text{ or } \overline{b}) = 2B(Z \to b\overline{b}) = 2\times(0.2212 \pm 0.0019)$.

[20] ACTON 92N is measured using $D_s \to \phi\pi^+$ and $K^*(892)^0K^+$ events. The product branching fraction measured is measured to be $B(\overline{b} \to B_s^0)B(B_s^0 \to D_s^-\ell^+\nu_\ell\text{anything}) \times B(D_s^- \to \phi\pi^-) = (3.9 \pm 1.1 \pm 0.8) \times 10^{-4}$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$.

[21] BUSKULIC 92E is measured using $D_s \to \phi\pi^+$ and $K^*(892)^0K^+$ events. They use 2.7 ± 0.7% for the $\phi\pi^+$ branching fraction. The average product branching fraction is measured to be $B(\overline{b} \to B_s^0)B(B_s^0 \to D_s^-\ell^+\nu_\ell\text{anything}) = 0.020 \pm 0.0055^{+0.005}_{-0.006}$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$. Superseded by BUSKULIC 95O.

B^0_s-$\overline{B}^0_s$ MIXING

For a discussion of B^0_s-$\overline{B}^0_s$ mixing see the note on "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings above.

χ_s is a measure of the time-integrated B^0_s-$\overline{B}^0_s$ mixing probability that produced $B^0_s(\overline{B}^0_s)$ decays as a $\overline{B}^0_s(B^0_s)$. Mixing violates $\Delta B \neq 2$ rule.

$$\chi_s = \frac{x_s^2}{2(1+x_s^2)}$$

$$x_s = \frac{\Delta m_{B^0_s}}{\Gamma_{B^0_s}} = (m_{B^0_{sH}} - m_{B^0_{sL}})\,\tau_{B^0_s},$$

where H, L stand for heavy and light states of two B^0_s CP eigenstates and

$$\tau_{B^0_s} = \frac{1}{0.5(\Gamma_{B^0_{sH}} + \Gamma_{B^0_{sL}})}.$$

χ_B at high energy

This is a B-$\overline{B}$ mixing measurement for an admixture of B^0 and B^0_s at high energy.

$\chi_B = f'_d\chi_d + f'_s\chi_s$

where f'_d and f'_s are the branching ratio times production fractions of B^0_d and B^0_s mesons relative to all b-flavored hadrons which decay weakly. Mixing violates $\Delta B \neq 2$ rule.

[46] ACCIARRI 99D uses maximum-likelihood fits to extract χ_b as well as the A^b_{FB} in $Z \to b\overline{b}$ events containing prompt leptons.
[47] Uses di-muon events.
[48] ALEXANDER 96 uses a maximum likelihood fit to simultaneously extract χ as well as the forward-backward asymmetries in $e^+e^- \to Z \to b\overline{b}$ and $c\overline{c}$.
[49] This ABREU 94J result is from 5182 $\ell\ell$ and 279 $\Lambda\ell$ events. The systematic error includes 0.004 for model dependence.
[50] BUSKULIC 94G data analyzed using ee, $e\mu$, and $\mu\mu$ events.
[51] BUSKULIC 92B uses a jet charge technique combined with electrons and muons.
[52] ABE 91G measurement of χ is done with $e\mu$ and ee events.
[53] ALBAJAR 91D measurement of χ is done with dimuons.
[54] UENO 96 extracted χ from the energy dependence of the forward-backward asymmetry.
[55] ABREU 94F uses the average electric charge sum of the jets recoiling against a b-quark jet tagged by a high p_T muon. The result is for $\overline{\chi} = f_d\chi_d + 0.9 f_s\chi_s$.
[56] This ABREU 94J result combines $\ell\ell$, $\Lambda\ell$, and jet-charge ℓ (ABREU 94F) analyses. It is for $\overline{\chi} = f_d\chi_d + 0.96 f_s\chi_s$.
[57] ALBAJAR 94 uses dimuon events. Not independent of ALBAJAR 91D.
[58] ABREU 93C data analyzed using ee, $e\mu$, and $\mu\mu$ events.
[59] AKERS 93B analysis performed using dilepton events.
[60] ACTON 92C uses electrons and muons. Superseded by AKERS 93B.
[61] ADEVA 92C uses electrons and muons.
[62] DECAMP 91 done with opposite and like-sign dileptons. Superseded by BUSKULIC 92B.
[63] ADEVA 90P measurement uses ee, $\mu\mu$, and $e\mu$ events from 118k events at the Z. Superseded by ADEVA 92C.
[64] These experiments are not in the average because the combination of B_s and B_d mesons which they see could differ from those at higher energy.
[65] The WEIR 90 measurement supersedes the limit obtained in SCHAAD 85. The 90% CL are 0.06 and 0.38.
[66] ALBAJAR 87C measured $\chi = (\overline{B}^0 \to B^0 \to \mu^+ X)$ divided by the average production weighted semileptonic branching fraction for B hadrons at 546 and 630 GeV.
[67] Limit is average probability for hadron containing B quark to produce a positive lepton.

$\Delta m_{B^0_s} = m_{B^0_{sH}} - m_{B^0_{sL}}$

$\Delta m_{B^0_s}$ is a measure of 2π times the B^0_s-$\overline{B}^0_s$ oscillation frequency in time-dependent mixing experiments.

"OUR EVALUATION" is an average of the data listed below performed by the LEP B Oscillation Working Group as described in our "Review of B-$\overline{B}$ Mixing" in the B^0 Section of these Listings. The averaging procedure takes into account correlations between the measurements.

[68] Uses ℓ-Q_{hem} and ℓ-ℓ.
[69] ABE 99J uses ϕ ℓ-ℓ correlation.
[70] BARATE 99J uses combination of an inclusive lepton and D^-_s-based analyses.
[71] ADAM 97 combines results from D_s ℓ-Q_{hem}, ℓ-Q_{hem}, and ℓ-ℓ.

[72] ABE 99D assumes $\tau_{B^0_s}$= 1.55 ± 0.05 ps and $\Delta\Gamma/\Delta m$= (5.6 ± 2.6) × 10^{-3}.

[73] BARATE 98C combines results from $D_s h$-$\ell/Q_{\rm hem}$, $D_s h$-K in the same side, $D_s \ell$-$\ell/Q_{\rm hem}$ and $D_s \ell$-K in the same side.

[74] Uses ℓ-$Q_{\rm hem}$.

[75] Uses ℓ-ℓ.

[76] BUSKULIC 96M uses D_s lepton correlations and lepton, kaon, and jet charge tags.

[77] BUSKULIC 95J uses ℓ-$Q_{\rm hem}$. They find Δm_s > 5.6 [> 6.1] for f_s=10% [12%]. We interpolate to our central value f_s=10.5%.

$x_s = \Delta m_{B^0_s}/\Gamma_{B^0_s}$

This is derived by the LEP B Oscillation Working Group from the results on $\Delta m_{B^0_s}$ and "OUR EVALUATION" of the B^0_s mean lifetime.

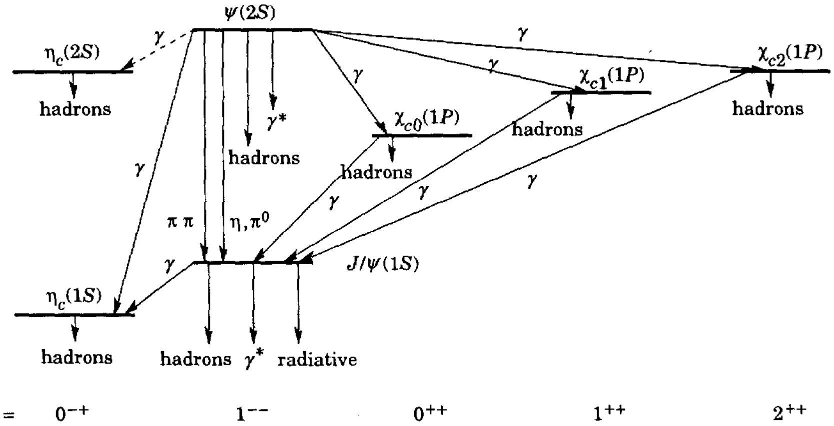
THE CHARMONIUM SYSTEM



The current state of knowledge of the charmonium system and transitions, as interpreted by the charmonium model. Uncertain states and transitions are indicated by dashed lines. The notation γ^* refers to decay processes involving intermediate virtual photons, including decays to e^+e^- and $\mu^+\mu^-$.

$4.0^{+3.5}_{-3.2}$	BAGLIN 89	SPEC	$\bar{p}p \to K^+K^-K^+K^-$

[9] The quoted branching ratios use $B(J/\psi(1S) \to \gamma\eta_c(1S)) = 0.0127 \pm 0.0036$. Where relevant, the error in this branching ratio is treated as a common systematic in computing averages.
[10] We are assuming $B(a_0(980) \to \eta\pi) > 0.5$.
[11] Average from $K^+K^-\pi^0$ and $K^\pm K^0$'s$\pi^\mp$ decay channels.
[12] Estimated using $B(\psi(2S) \to \gamma\eta_c(1S)) = 0.0028 \pm 0.0006$.

[59] Assuming $\Gamma(f_1(1285) \to \eta\pi\pi)/\Gamma_{total} = 0.5 \pm 0.18$.
[60] Obtained summing the sequential decay channels
$B(J/\psi \to \gamma f_1(1285), f_1(1285) \to \pi\pi\pi\pi) = (1.44 \pm 0.39 \pm 0.27) \times 10^{-4}$;
$B(J/\psi \to \gamma f_1(1285), f_1(1285) \to a_0(980)\pi, a_0(980) \to \eta\pi) = (3.90 \pm 0.42 \pm 0.87) \times 10^{-4}$;
$B(J/\psi \to \gamma f_1(1285), f_1(1285) \to a_0(980)\pi, a_0(980) \to K\overline{K}) = (0.66 \pm 0.26 \pm 0.29) \times 10^{-4}$;
$B(J/\psi \to \gamma f_1(1285), f_1(1285) \to \gamma\rho^0) = (0.25 \pm 0.07 \pm 0.03) \times 10^{-4}$.
[61] Using $B(f_1(1285) \to a_0(980)\pi) = 0.37$, and including unknown branching ratio for $a_0(980) \to \eta\pi$.

CONSTRAINED FIT INFORMATION

An overall fit to 10 branching ratios uses 17 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 9.0$ for 10 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\left<\delta x_i \delta x_j\right>/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\psi(2S)$ $\Gamma(i)\Gamma(e^+e^-)/\Gamma$(total)

This combination of a partial width with the partial width into e^+e^- and with the total width is obtained from the integrated cross section into channel$_i$ in the e^+e^- annihilation. We list only data that have not been used to determine the partial width $\Gamma(i)$ or the branching ratio $\Gamma(i)$/total.

[8] Includes cascade decay into $J/\psi(1S)$.
[9] Included in Γ(hadrons)/Γ_{total}.
[10] From an overall fit assuming equal partial widths for e^+e^- and $\mu^+\mu^-$. For a measurement of the ratio see the entry $\Gamma(\mu^+\mu^-)/\Gamma(e^+e^-)$ below. Includes LUTH 75, HILGER 75, BURMESTER 77.
[11] Using $B(J/\psi \to e^+e^-) = 0.0599 \pm 0.0025$ and $B(\psi(2S) \to J/\psi(1S)$anything$) = 0.57 \pm 0.04$. Not an independent measurement, see GU 99.
[12] Restated by us using $B(\psi(2S) \to J/\psi(1S)$anything$) = 0.55$.

[13] The ABRAMS 75B measurement of Γ_6/Γ_5 and the TANENBAUM 76 result for Γ_6/Γ_7 are not independent. The TANENBAUM 76 result is used in the fit because it includes more accurate corrections for angular distributions.
[14] Using $B(J/\psi \to e^+e^-) = 0.0599 \pm 0.0025$ and $B(\psi(2S) \to J/\psi(1S)\text{anything}) = 0.57 \pm 0.04$.
[15] Using data from ARMSTRONG 97.
[16] Not independent of the TANENBAUM 76 result for Γ_6/Γ_7.
[17] Ignoring the $J/\psi(1S)\eta$ and $J/\psi(1S)\gamma\gamma$ decays.
[18] Using $B(J/\psi(1S) \to \mu^+\mu^-) = 0.0597 \pm 0.0025$.
[19] Low statistics data removed from average.

$I^G(J^{PC}) = 0^-(2^{--})$

OMITTED FROM SUMMARY TABLE

Quantum numbers are not established.

Seen in $\pi^\pm$Li interactions by ANTONIAZZI 94 as a peak in the invariant mass of the $J/\psi(1S)\pi^+\pi^-$ system. Possibly seen also in pLi interactions. Interpretation as a $^3D_2$ (2^{--}) charmonium state favored. Not seen by BAI 98E in e^+e^- interactions. Needs confirmation.

$b\bar{b}$ MESONS

WIDTH DETERMINATIONS OF THE Υ STATES

As is the case for the $J/\psi(1S)$ and $\psi(2S)$, the full widths of the $b\bar{b}$ states $\Upsilon(1S)$, $\Upsilon(2S)$, and $\Upsilon(3S)$ are not directly measurable, since they are much narrower than the energy resolution of the e^+e^- storage rings where these states are produced. The common indirect method to determine Γ starts from

$$\Gamma = \Gamma_{\ell\ell}/B_{\ell\ell} \ , \qquad (1)$$

where $\Gamma_{\ell\ell}$ is one leptonic partial width and $B_{\ell\ell}$ is the corresponding branching fraction ($\ell = e$, μ, or τ). One then assumes e-μ-τ universality and uses

$$\Gamma_{\ell\ell} = \Gamma_{ee}$$

$$B_{\ell\ell} = \text{average of } B_{ee},\ B_{\mu\mu},\text{ and } B_{\tau\tau} \ . \qquad (2)$$

The electronic partial width Γ_{ee} is also not directly measurable at e^+e^- storage rings, only in the combination $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$, where $\Gamma_{\rm had}$ is the hadronic partial width and

$$\Gamma_{\rm had} + 3\Gamma_{ee} = \Gamma \ . \qquad (3)$$

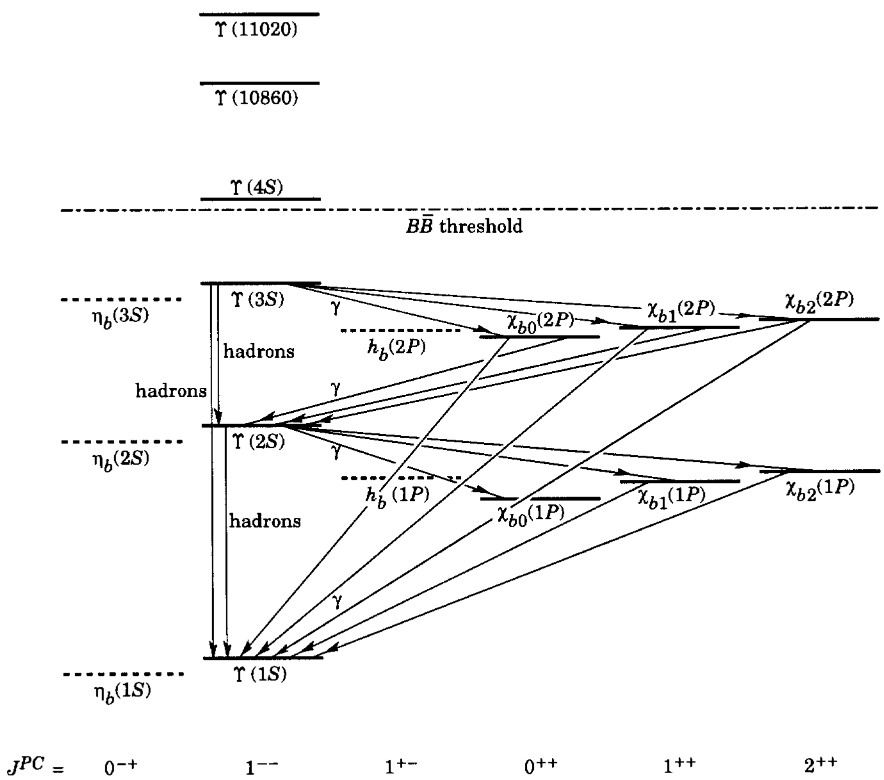
This combination is obtained experimentally from the energy-integrated hadronic cross section

$$\int_{\rm resonance} \sigma(e^+e^- \to \Upsilon \to \text{hadrons})dE$$

$$= \frac{6\pi^2}{M^2}\frac{\Gamma_{ee}\Gamma_{\rm had}}{\Gamma}C_r = \frac{6\pi^2}{M^2}\frac{\Gamma_{ee}^{(0)}\Gamma_{\rm had}}{\Gamma}C_r^{(0)} \ , \qquad (4)$$

where M is the Υ mass, and C_r and $C_r^{(0)}$ are radiative correction factors. C_r is used for obtaining Γ_{ee} as defined in Eq. (1), and contains corrections from all orders of QED for describing $(b\bar{b}) \to e^+e^-$. The lowest order QED value $\Gamma_{ee}^{(0)}$, relevant for comparison with potential-model calculations, is defined by the lowest order QED graph (Born term) alone, and is about 7% lower than Γ_{ee}.

THE BOTTOMONIUM SYSTEM



The level scheme of the $b\bar{b}$ states showing experimentally established states with solid lines. Singlet states are called η_b and h_b, triplet states Υ and χ_{bJ}. In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. *E.g.*, $h_b(2P)$ means 2^1P_1 with $n = 2$, $L = 1$, $S = 0$, $J = 1$, $PC = +-$. If found, D-wave states would be called $\eta_b(nD)$ and $\Upsilon_J(nD)$, with $J = 1,2,3$ and $n = 1,2,3,4,\cdots$. For the χ_b states, the spins of only the $\chi_{b2}(1P)$ and $\chi_{b1}(1P)$ have been experimentally established. The spins of the other χ_b are given as the preferred values, based on the quarkonium models. The figure also shows the observed hadronic and radiative transitions.

The Listings give experimental results on B_{ee}, $B_{\mu\mu}$, $B_{\tau\tau}$, and $\Gamma_{ee}\Gamma_{\text{had}}/\Gamma$. The entries of the last quantity have been re-evaluated consistently using the correction procedure of KURAEV 85.The partial width Γ_{ee} is obtained from the average values for $\Gamma_{ee}\Gamma_{\text{had}}/\Gamma$ and $B_{\ell\ell}$ using

$$\Gamma_{ee} = \frac{\Gamma_{ee}\Gamma_{\text{had}}}{\Gamma(1-3B_{\ell\ell})} . \quad (5)$$

The total width Γ is then obtained from Eq. (1). We do not list Γ_{ee} and Γ values of individual experiments. The Γ_{ee} values in the Meson Summary Table are also those defined in Eq. (1).

$\chi_{b0}(1P)$

$I^G(J^{PC}) = 0^+(0^{++})$
J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

NON-$q\overline{q}$ CANDIDATES

We include here mini-reviews and reference lists on gluonium and other non-$q\overline{q}$ candidates. See also $N\overline{N}$(1100–3600) for possible bound states.

NON-$q\overline{q}$ MESONS

Written March 2000 by C. Amsler (University of Zürich)

See also $N\overline{N}(1100-3600)$ for possible multiquark states.

The constituent quark model describes the observed meson spectrum as bound $q\overline{q}$ states grouped into SU(3) flavor nonets. The self-coupling of gluons in QCD suggests that additional mesons made of bound gluons (glueballs) or $q\overline{q}$-pairs with an excited gluon (hybrids) may exist. Multiquark color singlet states like $qq\overline{q}\overline{q}$ or $qqq\overline{q}\overline{q}\overline{q}$ have also been predicted (JAFFE 77). Among the signatures naively expected for glueballs are (i) no place in $q\overline{q}$ nonets, (ii) enhanced production in gluon rich channels such as central production and radiative $J/\psi(1S)$ decay, (iii) decay branching fractions incompatible with SU(3) predictions for $q\overline{q}$ states, and (iv) reduced $\gamma\gamma$ couplings. However, mixing effects with isoscalar $q\overline{q}$ mesons (AMSLER 96, ANISOVICH 97, WEINGARTEN 97,CLOSE 97B) and decay form factors (BARNES 97) may obscure these simple signatures.

Lattice calculations (BALI 93, SEXTON 95, MORNINGSTAR 99), QCD sum rules, flux tube and constituent glue models agree that the lightest glueballs have quantum numbers $J^{PC} = 0^{++}$ and 2^{++} (for a review see SWANSON 97). On the lattice, the scale parameter (estimated from the string tension in heavy quark mesons) gives by extrapolation to zero lattice spacing a mass of 1611 ± 163 MeV for the ground state (0^{++}) glueball, while the first excited state (2^{++}) has a mass of 2232 ± 310 MeV (MICHAEL 97). Hence the low mass glueballs lie in the same mass region as ordinary isoscalar $q\overline{q}$ states, that is in the mass range of the $1^3P_0(0^{++})$, $2^3P_2, 3^3P_2$, and $1^3F_2(2^{++})$ $q\overline{q}$ states. The 0^{-+} state and exotic glueballs (with non-$q\overline{q}$ quantum numbers like 0^{--}, 0^{+-}, 1^{-+}, 2^{+-}, *etc.*) are expected above 2 GeV (BALI 93).

The lattice calculations assume that the quark masses are infinite and therefore neglect $q\overline{q}$ loops. However, one expects that glueballs will mix with nearby $q\overline{q}$ states of the same quantum numbers. The effect of $q\overline{q}$ loops on the glueball mass is not clear and the size of the $q\overline{q}$ admixture in the glueball wavefunction is not predicted by lattice calculations. However, the presence of a glueball mixed with $q\overline{q}$ would still lead to a supernumerary isoscalar in the SU(3) classification of $q\overline{q}$ mesons.

For earlier experimental searches we refer to the Notes in the 1996 and 1998 issues of this Review. See also the review on exotic mesons by LANDSBERG 99.

We first deal with non-$q\overline{q}$ candidates in the scalar sector. Five isoscalar resonances are well established: the very broad $f_0(400-1200)$ (or σ), the $f_0(980)$, the broad $f_0(1370)$, and the comparatively narrow $f_0(1500)$ and $f_0(1710)$ (see the Note on "Scalar Mesons" and also AMSLER 98). The $f_0(1500)$ was observed in many experiments, *e.g.*, in pion induced reactions π^-p (BINON 83, AMELIN 96B), in $\overline{p}p$ annihilations (AMSLER 95B, 95C, BERTIN 97C), in central collisions (REYES 98, BARBERIS 99, BELLAZZINI 99), in J/ψ radiative decays (BUGG 95) and in D_s decays (FRABETTI 97D). The $f_0(1710)$, with controversial spin (0 or 2), was recently shown to have spin 0 (DUNWOODIE 97, BARBERIS 99, FRENCH 99) and to decay mainly into $K\overline{K}$ (BARBERIS 99, 99B, 99D). This points to a mostly $s\overline{s}$ structure, although no signal was reported in $K^-p \to K_SK_S\Lambda$ interactions, but the data sample was rather small (ASTON 88D). In $\gamma\gamma$ collisions leading to K_SK_S (BRACCINI 99) a signal is observed at the $f_0(1710)$ mass (although its spin cannot be determined) but $f_0(1500)$ is absent, while in $\gamma\gamma$ collisions leading to $\pi^+\pi^-$ neither $f_0(1710)$ nor $f_0(1500)$ are observed (BARATE 00E). The production rate for $f_0(1710)$ and the absence of $f_0(1500)$ in both $K\overline{K}$ and $\pi\pi$ favor the former to be mainly $s\overline{s}$ and the latter to have a small coupling to $\gamma\gamma$ at most compatible with an $s\overline{s}$ state (AMSLER 99).

On the other hand, the $K\overline{K}$ decay branching ratio of $f_0(1500)$ is small compared to $\pi\pi$ (ABELE 96B, 98, BARBERIS 99D) indicating that this state cannot be dominantly $s\overline{s}$. Since $f_0(1370)$ does not couple strongly to $s\overline{s}$ either (BARBERIS 99D), $f_0(1370)$ or $f_0(1500)$ appear to be supernumerary. Note that $f_0(1370)$ and $f_0(1500)$ have rather different decay patterns. The former decays to $\sigma\sigma$ and $\rho\rho$, while the latter does not decay to $\rho\rho$ (BUGG 95, THOMA 99). The narrow width of $f_0(1500)$ and its enhanced production at low transverse momentum transfer in central collisions (CLOSE 97, 98B) favor $f_0(1500)$ to be non-$q\overline{q}$. In AMSLER 96 the ground state scalar nonet is made of $a_0(1450)$, $f_0(1370)$, $K_0^*(1430)$ and the at the time missing $s\overline{s}$ state which could now be identified as $f_0(1710)$. The isoscalars $f_0(1370)$ and $f_0(1710)$ contain a small fraction of glue while $f_0(1500)$ is mostly gluonic. Alternative, less straightforward, mixing schemes have been proposed (TORNQVIST 96, ANISOVICH 97, BOGLIONE 97, WEINGARTEN 97, MINKOWSKI 99).

The $a_0(980)$ and $f_0(980)$ could be four-quark states (JAFFE 77) or $K\overline{K}$ molecular states (WEINSTEIN 90, LOCHER 98) due to their strong affinity for $K\overline{K}$, in spite of their masses being very close to threshold. For $q\overline{q}$ states the expected $\gamma\gamma$ widths (OLLER 97B, DELBOURGO 99) are not significantly larger than for molecular states (BARNES 85). A better filter might be radiative $\phi(1020)$ decay to $a_0(980)$ and $f_0(980)$. Recent data (ACHASOV 98B, 98I, AKHMETSHIN 99C) favor these mesons to be four-quark states (ACHASOV 97C), although not everybody agrees (MALTMAN 99B, DELBOURGO 99). Also, the $f_0(980)$ is strongly produced in D_s^+ decay (FRABETTI 97), suggesting a large $s\overline{s}$ component, while hadronic Z^0 decay favors in contrast a large $u\overline{u}+d\overline{d}$ component (ACKERSTAFF 98Q).

We now turn to the 2^{++} sector. The isoscalar $1^3P_2(2^{++})$ $q\overline{q}$ mesons, $f_2(1270)$, and $f_2'(1525)$, are well known. Above the $f_2'(1525)$ none of the reported isoscalars can be definitely assigned to the 2^3P_2, 3^3P_2, or 1^3F_2 nonets and therefore the identification of the 2^{++} glueball is premature. Three states appear to be solid. The $f_2(1565)$ observed in $\overline{p}p$ annihilation at rest (MAY 90, BERTIN 98) is perhaps the same state as $f_2(1640)$ reported to decay into $\omega\omega$ (ALDE 90, BAKER 99) and 4π (ADAMO 92). This could be one of the 2^3P_2 isoscalars or a nucleon-antinucleon resonance. The rather broad $f_2(1950)$ is observed by several experiments, *e.g.*, in central production (BARBERIS 97B) and in $\overline{p}p$ annihilation in flight (ABELE 99B). Finally, a broad structure (of perhaps several states) decaying to $\phi\phi$ was reported around 2300 MeV in π^-N reactions (BOOTH 86, ETKIN 88) in $\overline{p}p$ annihilation in flight (EVANGELISTA 98) and in central collisions (BARBERIS 98).

The evidence for a narrow meson, $f_J(2220)$ (possibly a tensor), is fading with new formation data in $\overline{p}p$ annihilation (KISIEL 99, see the Note under the $f_J(2220)$ section). The measured partial width to $\overline{p}p$ in radiative J/ψ decay (BAI 96B) is too large and inconsistent with the upper limit from $\overline{p}p$ annihilation into $\pi\pi$ (AMSLER 99). However, the suprisingly large $\phi\phi$ cross section in $\overline{p}p$ just above threshold (EVANGELISTA 98) could be due to the production of the 2^{++} glueball. In fact, the broad enhancement was reanalyzed by PALANO 99. The dominating contribution was found to be 2^{++}, resonating at a mass of 2231 MeV with a width of 70 MeV, in accord with earlier observations in π^-N reactions (BOOTH 86, ETKIN 88).

Let us now deal with hybrid states. Hybrids may be viewed as $q\overline{q}$ mesons with a vibrating gluon flux tube. In contrast to glueballs, they can have isospin 0 and 1. The mass spectrum of hybrids with exotic (non-$q\overline{q}$) quantum numbers was predicted by ISGUR 85 while CLOSE 95 also deals with non-exotic quantum numbers. The ground state hybrids with quantum numbers (0^{-+}, 1^{-+}, 1^{--}, and 2^{-+}) are expected around 1.7 to 1.9 GeV. Lattice calculations predict that the hybrid with exotic quantum numbers 1^{-+} lies at a mass of 1.9 ± 0.2 GeV (LACOCK 97, BERNARD 97). Most hybrids are rather broad but some can be as narrow as 100 MeV (PAGE 99). They prefer to decay into a pair of S- and P-wave mesons.

A $J^{PC} = 1^{-+}$ exotic meson with a mass of 1370 MeV and a width of 385 MeV was reported in $\pi^-p \rightarrow \eta\pi^-p$ (THOMPSON 97, CHUNG 99). This state, called $\hat{\rho}(1405)$ in our previous edition, has now been renamed $\pi_1(1400)$. It was observed as an interference between the angular momentum $L = 1$ and $L = 2$ $\eta\pi$ amplitudes, leading to a forward/backward asymmetry in the $\eta\pi$ angular distribution. This state was reported earlier in π^-p reactions (ALDE 88B) but ambiguous solutions in the partial wave analysis were pointed out by PROKOSHKIN 95B, 95C. A resonating 1^{-+} contribution to the $\eta\pi$ P-wave is also required in the Dalitz plot analysis of $\overline{p}n$ annihilation into $\pi^-\pi^0\eta$ (ABELE 98B) and in $\overline{p}p$ annihilation into $\pi^0\pi^0\eta$ (ABELE 99). The mass of 1400 MeV and the width of 310 MeV (ABELE 98B) are consistent with THOMPSON 97.

Another 1^{-+} state at 1593 MeV with a width of 168 MeV, $\pi_1(1600)$, decaying into $\rho\pi$ was reported in the reaction $\pi^-p \rightarrow \pi^-\rho^0n$ (ADAMS 98B). It was observed earlier in the decay modes $\rho\pi$, $\eta'\pi$, and $b_1(1235)\pi$, but not $\eta\pi$ (GOUZ 92). A strong enhancement in the 1^{-+} $\eta'\pi$ wave, compared to $\eta\pi$, was reported at this mass by BELADIDZE 93. DONNACHIE 98 suggest that a Deck generated $\eta\pi$ background from final state rescattering in $\pi_1(1600)$ decay could mimick $\pi_1(1400)$. However, this mechanism is absent in $\overline{p}p$ annihilation. The $\eta\pi\pi$ data require $\pi_1(1400)$ and cannot accommodate a state at 1600 MeV (DUENNWEBER 99).

Hence we now have evidence for two 1^{-+} exotics, $\pi_1(1400)$ and $\pi_1(1600)$, while the flux tube model and the lattice concur to predict a mass of about 1.9 GeV, where a signal had been reported earlier (LEE 94). As isovectors, $\pi_1(1400)$ and $\pi_1(1600)$ cannot be glueballs. The coupling to $\eta\pi$ of the former points to a four-quark state while the strong $\eta'\pi$ coupling of the latter is favored for hybrid states (CLOSE 87B). Its mass is not far below the lattice prediction.

Finally, 0^{-+}, 1^{--}, and 2^{-+} hybrids were also reported. The $\pi(1800)$ decays mostly to a pair of S- and P-wave mesons (AMELIN 95B), in line with expectations for a 0^{-+} hybrid meson, although recent data contradict this, indicating a strong $\rho\omega$ decay mode (ZAITSEV 97). This meson is also rather narrow if interpreted as the second radial excitation of the the pion. The evidence for 1^{--} hybrids required in e^+e^- annihilation and in τ decays has been discussed by DONNACHIE 99. A candidate for the 2^{-+} hybrid, the $\eta_2(1870)$, was reported in $\gamma\gamma$ interactions (KARCH 92), in $\overline{p}p$ annihilation (ADOMEIT 96) and in central production (BARBERIS 97B). The near degeneracy of $\eta_2(1645)$ and $\pi_2(1670)$ suggests ideal mixing in the 2^{-+} $q\overline{q}$ nonet and hence the second isoscalar should be mainly $s\overline{s}$. However, $\eta_2(1870)$ decays mainly to $a_2(1320)\pi$ and $f_2(1270)\pi$ (ADOMEIT 96) with a relative rate compatible with a hybrid state (CLOSE 95).

p MASS

The mass is known much more precisely in u (atomic mass units) than in MeV; see the footnote. The conversion from u to MeV, 1 u = 931.494013±0.000037 MeV/c^2 (MOHR 99, the 1998 CODATA value), involves the relatively poorly known electronic charge.

VALUE (MeV)	DOCUMENT ID		TECN	COMMENT
938.271998±0.000038	[1] MOHR	99	RVUE	1998 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •

[1] The mass is known much more precisely in u: m = 1.00727646688 ± 0.00000000013 u.
[2] The mass is known much more precisely in u: m = 1.007276470 ± 0.000000012 u.

$|m_p - m_{\overline{p}}|/m_p$

A test of CPT invariance. Note that the $\overline{p}/p$ charge-to-mass ratio, given below, is much better determined.

VALUE	DOCUMENT ID		TECN	COMMENT
<5 × 10^{-7}	[3] TORII	99	SPEC	$\overline{p}e^-$He atom

[3] TORII 99 uses the more-precisely-known constraint on the $\overline{p}$ charge-to-mass ratio of GABRIELSE 95 (see below) to get this result. This is not independent of the TORII 99 value for $|q_p+q_{\overline{p}}|/e$, below.

$\overline{p}/p$ CHARGE-TO-MASS RATIO, $|\frac{q_{\overline{p}}}{m_{\overline{p}}}|/(\frac{q_p}{m_p})$

A test of CPT invariance. Listed here are measurements involving the *inertial* masses. For a discussion of what may be inferred about the ratio of $\overline{p}$ and p *gravitational* masses, see ERICSON 90; they obtain an upper bound of 10^{-6}–10^{-7} for violation of the equivalence principle for $\overline{p}$'s.

p PARTIAL MEAN LIVES

The "partial mean life" limits tabulated here are the limits on τ/B_j, where τ is the total mean life for the proton and B_j is the branching fraction for the mode in question.

Decaying particle: p = proton, n = bound neutron. The same event may appear under more than one partial decay mode. Background estimates may be accurate to a factor of two.

Antilepton + meson

[47] The SUZUKI 93B limit applies to any of $\nu_e\nu_e\overline{\nu}_e$, $\nu_\mu\nu_\mu\overline{\nu}_\mu$, or $\nu_\tau\nu_\tau\overline{\nu}_\tau$.

[48] GLICENSTEIN 97 uses Kamioka data and the idea that the disappearance of the neutron's magnetic moment should produce radiation.

[49] The first BERGER 91B limit is for $n \to \nu_e\nu_e\overline{\nu}_e$, the second is for $n \to \nu_\mu\nu_\mu\overline{\nu}_\mu$.

n

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ∗∗∗∗

We have omitted some results that have been superseded by later experiments. See our earlier editions.

n MASS

The mass is known much more precisely in u (atomic mass units) than in MeV; see the footnotes. The conversion from u to MeV, 1 u = 931.494013±0.000037 MeV/c^2 (MOHR 99, the 1998 CODATA value), involves the relatively poorly known electronic charge.

VALUE (MeV)	DOCUMENT ID		TECN	COMMENT
939.565330±0.000038	[1] MOHR	99	RVUE	1998 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •				
939.565331±0.000037	[2] KESSLER	99	SPEC	$np \to d\gamma$
939.56565 ±0.00028	[3,4] DIFILIPPO	94	TRAP	Penning trap

939.5731 ±0.0027	[4] COHEN	73	RVUE	1973 CODATA value

[1] The mass is known much more precisely in u: $m = 1.00866491578 \pm 0.00000000055$ u.

[2] We use the 1998 CODATA u-to-MeV conversion factor (see the heading above) to get this mass in MeV from the much more precisely measured KESSLER 99 value of $1.00866491637 \pm 0.00000000082$ u.

[3] The mass is known much more precisely in u: $m = 1.0086649235 \pm 0.0000000023$ u. We use the 1986 CODATA conversion factor to get the mass in MeV.

[4] These determinations are not independent of the $m_n - m_p$ measurements below.

[5] The mass is known much more precisely in u: $m = 1.008664904 \pm 0.000000014$ u.

[6] The mass is known much more precisely in u: $m = 1.008664919 \pm 0.000000014$ u.

$\overline{n}$ MASS

[16] The GAEHLER 82 error ± 22 gives the 90% CL limits about the the value -15.

LIMIT ON $n\overline{n}$ OSCILLATIONS

Mean Time for $n\overline{n}$ Transition in Vacuum

A test of ΔB=2 baryon number nonconservation. MOHAPATRA 80 and MOHAPATRA 89 discuss the theoretical motivations for looking for $n\overline{n}$ oscillations. DOVER 83 and DOVER 85 give phenomenological analyses. The best limits come from looking for the decay of neutrons bound in nuclei. However, these analyses require model-dependent corrections for nuclear effects. See KABIR 83, DOVER 89, and ALBERICO 91 for discussions. Direct searches for $n \rightarrow \overline{n}$ transitions using reactor neutrons are cleaner but give somewhat poorer limits. We include limits for both free and bound neutrons in the Summary Table.

[18] NORMAN 96 gets this limit by attributing SAGE and GALLEX counting rates to the charge-nonconserving transition ^{71}Ga $\rightarrow$ ^{71}Ge+neutrals rather than to solar-neutrino reactions.

BARYON DECAY PARAMETERS

Written 1996 by E.D. Commins (University of California, Berkeley).

Baryon semileptonic decays

The typical spin-1/2 baryon semileptonic decay is described by a matrix element, the hadronic part of which may be written as:

$$\overline{B}_f \left[f_1(q^2)\gamma_\lambda + i\, f_2(q^2)\sigma_{\lambda\mu}q^\mu + g_1(q^2)\gamma_\lambda\gamma_5 + g_3(q^2)\gamma_5 q_\lambda \right] B_i \,. \tag{1}$$

Here B_i and $\overline{B}_f$ are spinors describing the initial and final baryons, and $q = p_i - p_f$, while the terms in f_1, f_2, g_1, and g_3 account for vector, induced tensor ("weak magnetism"), axial vector, and induced pseudoscalar contributions [1]. Second-class current contributions are ignored here. In the limit of zero momentum transfer, f_1 reduces to the vector coupling constant g_V, and g_1 reduces to the axial-vector coupling constant g_A. The latter coefficients are related by Cabibbo's theory [2], generalized to six quarks (and three mixing angles) by Kobayashi and Maskawa [3]. The g_3 term is negligible for transitions in which an $e^\pm$ is emitted, and gives a very small correction, which can be estimated by PCAC [4], for $\mu^\pm$ modes. Recoil effects include weak magnetism, and are taken into account adequately by considering terms of first order in

$$\delta = \frac{m_i - m_f}{m_i + m_f} \,, \tag{2}$$

where m_i and m_f are the masses of the initial and final baryons.

The experimental quantities of interest are the total decay rate, the lepton-neutrino angular correlation, the asymmetry coefficients in the decay of a polarized initial baryon, and the polarization of the decay baryon in its own rest frame for an unpolarized initial baryon. Formulae for these quantities are derived by standard means [5] and are analogous to formulae for nuclear beta decay [6]. We use the notation of Ref. 6 in the Listings for neutron beta decay. For comparison with experiments at higher q^2, it is necessary to modify the form factors at $q^2 = 0$ by a "dipole" q^2 dependence, and for high-precision comparisons to apply appropriate radiative corrections [7].

The ratio g_A/g_V may be written as

$$g_A/g_V = |\,g_A/g_V\,|\,e^{i\phi_{AV}} \,. \tag{3}$$

The presence of a "triple correlation" term in the transition probability, proportional to $\mathrm{Im}(g_A/g_V)$ and of the form

$$\boldsymbol{\sigma}_i\cdot(\mathbf{p}_\ell \times \mathbf{p}_\nu) \tag{4}$$

for initial baryon polarization or

$$\boldsymbol{\sigma}_f \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \tag{5}$$

for final baryon polarization, would indicate failure of time-reversal invariance. The phase angle ϕ has been measured precisely only in neutron decay (and in ^{19}Ne nuclear beta decay), and the results are consistent with T invariance.

Hyperon nonleptonic decays

The amplitude for a spin-1/2 hyperon decaying into a spin-1/2 baryon and a spin-0 meson may be written in the form

$$M = G_F\, m_\pi^2 \cdot \overline{B}_f\,(A - B\gamma_5)\, B_i \ , \tag{6}$$

where A and B are constants [1]. The transition rate is proportional to

$$R = 1 + \gamma\,\widehat{\omega}_f \cdot \widehat{\omega}_i + (1-\gamma)(\widehat{\omega}_f \cdot \widehat{\mathbf{n}})(\widehat{\omega}_i \cdot \widehat{\mathbf{n}})$$
$$+ \alpha(\widehat{\omega}_f \cdot \widehat{\mathbf{n}} + \widehat{\omega}_i \cdot \widehat{\mathbf{n}}) + \beta\widehat{\mathbf{n}} \cdot (\widehat{\omega}_f \times \widehat{\omega}_i) \ , \tag{7}$$

where $\widehat{\mathbf{n}}$ is a unit vector in the direction of the final baryon momentum, and $\widehat{\omega}_i$ and $\widehat{\omega}_f$ are unit vectors in the directions of the initial and final baryon spins. (The sign of the last term in the above equation was incorrect in our 1988 and 1990 editions.) The parameters α, β, and γ are defined as

$$\alpha = 2\,\mathrm{Re}(s^* p)/(|\,s\,|^2 + |\,p\,|^2) \ ,$$
$$\beta = 2\,\mathrm{Im}(s^* p)/(|\,s\,|^2 + |\,p\,|^2) \ ,$$
$$\gamma = (|\,s\,|^2 - |\,p\,|^2)/(|\,s\,|^2 + |\,p\,|^2) \ , \tag{8}$$

where $s = A$ and $p = |\,\mathbf{p}_f\,|\,B/(E_f + m_f)$; here E_f and $\mathbf{p}_f$ are the energy and momentum of the final baryon. The parameters α, β, and γ satisfy

$$\alpha^2 + \beta^2 + \gamma^2 = 1 \ . \tag{9}$$

If the hyperon polarization is $\mathbf{P}_Y$, the polarization $\mathbf{P}_B$ of the decay baryons is

$$\mathbf{P}_B = \frac{(\alpha + \mathbf{P}_Y \cdot \widehat{\mathbf{n}})\widehat{\mathbf{n}} + \beta(\mathbf{P}_Y \times \widehat{\mathbf{n}}) + \gamma\widehat{\mathbf{n}} \times (\mathbf{P}_Y \times \widehat{\mathbf{n}})}{1 + \alpha\mathbf{P}_Y \cdot \widehat{\mathbf{n}}} \ . \tag{10}$$

Here $\mathbf{P}_B$ is defined in the rest system of the baryon, obtained by a Lorentz transformation along $\widehat{\mathbf{n}}$ from the hyperon rest frame, in which $\widehat{\mathbf{n}}$ and $\mathbf{P}_Y$ are defined.

An additional useful parameter ϕ is defined by

$$\beta = (1 - \alpha^2)^{1/2} \sin\phi \ . \tag{11}$$

In the Listings, we compile α and ϕ for each decay, since these quantities are most closely related to experiment and are essentially uncorrelated. When necessary, we have changed the signs of reported values to agree with our sign conventions. In the Baryon Summary Table, we give α, ϕ, and Δ (defined below) with errors, and also give the value of γ without error.

Time-reversal invariance requires, in the absence of final-state interactions, that s and p be relatively real, and therefore that $\beta = 0$. However, for the decays discussed here, the final-state interaction is strong. Thus

$$s = |\,s\,|\,e^{i\delta_s} \text{ and } p = |\,p\,|\,e^{i\delta_p} \ , \tag{12}$$

where δ_s and δ_p are the pion-baryon s- and p-wave strong interaction phase shifts. We then have

$$\beta = \frac{-2\,|\,s\,|\,|\,p\,|}{|\,s\,|^2 + |\,p\,|^2} \sin(\delta_s - \delta_p) \ . \tag{13}$$

One also defines $\Delta = -\tan^{-1}(\beta/\alpha)$. If T invariance holds, $\Delta = \delta_s - \delta_p$. For $\Lambda \to p\pi^-$ decay, the value of Δ may be compared with the s- and p-wave phase shifts in low-energy $\pi^- p$ scattering, and the results are consistent with T invariance.

Radiative hyperon decays

For the radiative decay of a polarized spin-1/2 hyperon, $B_i \to B_f\gamma$, the angular distribution of the direction $\widehat{p}$ of the final spin-1/2 baryon in the hyperon rest frame is

$$\frac{d\Gamma_\gamma}{d\Omega} = \frac{\Gamma_\gamma}{4\pi}\,(1 + \alpha_\gamma \widehat{p} \cdot \mathbf{P}_i) \ , \tag{14}$$

where $\mathbf{P}_i$ is the hyperon polarization and the asymmetry parameter α_γ is

$$\alpha_\gamma = \frac{2\mathrm{Re}\,[g_1'(0) f_M^*(0)]}{|g_1'(0)|^2 + |f_M(0)|^2} \ . \tag{15}$$

Here $f_M = \dfrac{(m_i - m_f)}{(m_i + m_f)}\,[(m_i + m_f) f_2' - f_1']$, where $f_1'(q^2)$, $f_2'(q^2)$, and $g_1'(q^2)$ are the $\Delta Q = 0$ analogs of the $|\Delta Q| = 1$ form factors defined above.

N AND Δ RESONANCES

Revised January 2000 by R.L. Workman (George Washington University, Virginia Campus).

I. Introduction

The excited states of the nucleon have been studied in a large number of formation and production experiments. The conventional (*i.e.*, Breit-Wigner) masses, pole positions, widths, and elasticities of the N and Δ resonances in the Baryon Summary Table come largely from partial-wave analyses of πN total, elastic, and charge-exchange scattering data. Partial-wave analyses have also been performed on much smaller data sets to get $N\eta$, ΛK, and ΣK branching fractions. Other branching fractions come from isobar-model analyses of $\pi N \to N\pi\pi$ data. Finally, many $N\gamma$ branching fractions have been determined from photoproduction experiments (see Sec. III).

Table 1 lists all the N and Δ entries in the Baryon Listings and gives our evaluation of the status of each, both overall and channel by channel. Only the "established" resonances (overall status 3 or 4 stars) appear in the Baryon Summary Table. We generally consider a resonance to be established only if it has been seen in at least two independent analyses of elastic scattering and if the relevant partial-wave amplitudes do not behave erratically or have large errors.

No new elastic partial-wave analyses have been published since our last edition. Preliminary new results from the Virginia Tech group were reported at MENU 99 [1]; this reference also reports recent studies of the πN sigma term, scattering lengths, and possible isospin-breaking effects. Two extensions of an earlier [2] multi-channel analysis have appeared since our last edition. The first [3] extracted pole positions and residues for the $N(1535)$ and $N(1650)$. The second [4] added $\gamma N \to N\pi$ multipoles to the previous set of $\pi N \to N\pi$, $\pi N \to N\eta$ and $\gamma N \to N\eta$ data and amplitudes.

The interested reader will find further discussions in the proceedings of three recent conferences [1,5,6], and in two older reviews [7,8].

II. Against Breit-Wigner parameters — a pole-emic

Written December 1997 by G. Höhler (University of Karlsruhe).

(1) All theoretical approaches to the resonance phenomenon have in common that the variation of a partial-wave amplitude $T(W)$, where W is the total c.m. energy, is related to a nearly bound state of the projectile-target system (see *e.g.*, Refs. [9–13]). In πN scattering, this state is an excited state of the nucleon (= isobar). The nearly bound state is described in the framework of S-matrix theory by a pole of the S-matrix element at $W_p = M - i\Gamma/2$ in the lower half of the complex W-plane, close to the real axis; M and Γ are called the mass and width of the resonance. The location of the resonance pole is the same for all reactions to which the resonance couples.

Table 1. The status of the N and Δ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

Particle	$L_{2I\cdot 2J}$	Overall status	Status as seen in —

**** Existence is certain, and properties are at least fairly well explored.
*** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, *etc.* are not well determined.
** Evidence of existence is only fair.
* Evidence of existence is poor.

In the inelastic region, a resonance is associated with a cluster of poles on different Riemann sheets. If one of these poles is located near the real axis and sufficiently far from branch points, it will be strongly dominant. If one of the final-state particles itself has a strong decay, one also has to consider branch points in the lower half plane that belong to thresholds for two-particle final states (see *e.g.*, Refs. [14,15]).

(2) If the formation of an unstable intermediate particle occurs in a scattering process, one expects *a time-delay between the arrival of the incident wave packet and its departure from the collision region.* Goldberger and Watson [16], starting from earlier work by Wigner, derived for elastic scattering the time-delay Q. Expressed in terms of the amplitude $T(W)$, it is $Q = 2\,Sp(W)$, where $Sp(W) = |dT/dW|$ is the *speed* with which the complex vector T traverses the Argand diagram. If the background can be neglected, a resonance pole leads to a peak of $Sp(W)$ at $W = M$ (see the cited books and Refs. [17–19]).

(3) It is an old tradition that authors of partial-wave analyses determine *conventional resonance parameters* from fits to generalized Breit-Wigner formulas. Each group has its own prescription for the treatment of analyticity, the choice of the background, and other details, so the model-dependence is much larger than in the determination of pole parameters. A serious shortcoming is the poor or missing information on inelastic channels. The conventional parameters are the "mass" m, the "width" $\Gamma(W)$ at $W = m$, and the branching ratios. Following are some problems with these parametrizations.

(a) The conventional $\Delta(1232)$ parameters come from a fit to the P33 partial wave. It is well known from the Chew-Low plot and dispersion relations [20] that this partial wave has a *large background from the nucleon pole term.* The pole position, $1210 - 50\,i$ MeV, belongs to the Δ-resonance, whereas the conventional parameters, $m = 1232$ MeV and $\Gamma(m) = 120$ MeV, belong to the Δ *together with the large background in* πN *scattering.*

(b) The $N(1535)\,S_{11}$ is *the only 4-star resonance that does not show a signal in the speed plot.* The signal is probably part of the large peak due to the threshold for η production [21]. In this case, poles in other Riemann sheets are expected to give contributions of comparable magnitude. One of these poles produces the threshold cusp [14]. In the 1960's, this problem was treated in many papers (see Ref. 21). In calculations that rely on the conventional mass of 1535 MeV, one cannot see that one has to study a combined resonance plus threshold-cusp phenomenon.

A similar situation of poles in different sheets arises in $\pi\pi$ scattering near the $K\overline{K}$ threshold. See remarks in footnotes to our $f_0(980)$ Listing.

(c) Around 1440 MeV, the VPI group found *two poles in the* P_{11} *amplitude in different Riemann sheets* [22]. This was interpreted, by other authors, as evidence for the existence of two nearly degenerate P_{11} resonances, in conflict with the constituent quark model. Cutkosky pointed out that the branch point for $\Delta\pi$ decay is located near the poles, so the poles belong to the same resonance. This was confirmed by a new calculation [23], which also led to conventional parameters of $m = 1471$ MeV and $\Gamma(m) = 545$ MeV, which are *much different from the pole parameters,* $1370 - 114\,i$ and $1360 - 120\,i$ MeV. The speed plot confirms that the formation of the unstable particle $N(1440)\,P_{11}$ occurs at a considerably lower energy than expected from the conventional parameters.

Conclusion: In contrast to the conventional parameters, the pole positions and speed plots have a well-defined relation to S-matrix theory. They also give more information on the resonances and thresholds and can be used for predictions on other reactions that couple to the excited states.

III. Electromagnetic interactions

Revised January 2000 by R.L. Workman (George Washington University, Virginia Campus).

Nearly all the entries in the Listings concerning electromagnetic properties of the N and Δ resonances are $N\gamma$ couplings. These couplings, the helicity amplitudes $A_{1/2}$ and $A_{3/2}$, have been obtained in partial-wave analyses of single-pion photoproduction, η photoproduction, and Compton scattering. Most photoproduction analyses have taken the existence, masses, and widths of the resonances from the $\pi N \to \pi N$ analyses, and have only determined the $N\gamma$ couplings. This approach is only applicable to resonances with a significant $N\pi$ coupling. A brief description of the various methods of analysis of photoproduction data may be found in our 1992 edition [24].

Our Listings omit a number of analyses that are now obsolete. Most of the older results may be found in our 1982 edition [25]. The errors quoted for the couplings in the Listings are calculated in different ways in different analyses and therefore should be used with care. In general, the systematic differences between the analyses caused by using different parameterization schemes are probably more indicative of the true uncertainties than are the quoted errors.

Probably the most reliable analyses, for most resonances, are ARAI 80, CRAWFORD 80, AWAJI 81, FUJII 81, CRAWFORD 83, and ARNDT 96. Several special cases are discussed separately below. The errors we give are a combination of the stated statistical errors on the analyses and the systematic differences between them. The analyses are given equal weight, except ARNDT 96 is weighted, rather arbitrarily, by a factor of two because its data set is at least 50% larger than those of the other analyses and contains many new high-quality measurements. The $\Delta(1232)$ and $N(1535)$ are special cases, discussed below.

The Baryon Summary Table gives $N\gamma$ branching fractions for those resonances whose couplings are considered to be reasonably well established. The $N\gamma$ partial width Γ_γ is given in terms of the helicity amplitudes $A_{1/2}$ and $A_{3/2}$ by

$$\Gamma_\gamma = \frac{k^2}{\pi}\frac{2M_N}{(2J+1)M_R}\left[|A_{1/2}|^2 + |A_{3/2}|^2\right] \quad . \qquad (1)$$

Here M_N and M_R are the nucleon and resonance masses, J is the resonance spin, and k is the photon c.m. decay momentum.

New results for $\Delta(1232) \to p\gamma$: Recent studies of the $\Delta(1232)$ have focussed on the problem of separating background from resonance, and on the $E2/M1$ ratio at nonzero values of Q^2. The electric quadrupole ($E2$) and magnetic dipole ($M1$) amplitudes are related to our helicity amplitudes by

$$A_{1/2} = -\frac{1}{2}(M1 + 3E2) \quad \text{and} \quad A_{3/2} = -\frac{\sqrt{3}}{2}(M1 - E2) \ . \ (2)$$

Problems associated with the $E2/M1$ ratio at $Q^2 = 0$ [26] were discussed in our 1998 Review [27].

The $E2/M1$ ratio has been given at $Q^2 = 2.8$ and 4.0 $(\mathrm{GeV/c})^2$, based on analyses of Jefferson Lab $p(e,e'p)\pi^0$ data [28], and at 3.2 $(\mathrm{GeV/c})^2$, based on a re-analysis of older DESY measurements [29]. Results are not yet stable, and depend upon the method employed. This is particularly evident in analyses of the DESY measurements, which have resulted in $E2/M1$ ratios differing in both sign and magnitude [28,30,31].

Results for the $E2/M1$ ratio at $Q^2 = 2.8$ and 4.0 $(\mathrm{GeV/c})^2$ are 0.039 ± 0.029 and 0.04 ± 0.031 from Ref. 30, compared to $-0.020 \pm 0.012 \pm 0.005$ and $-0.031 \pm 0.012 \pm 0.005$ from Ref. 28. Notice the difference in sign. There is general agreement that the ratio remains small relative to the perturbative QCD expectation that $E2/M1$ should approach unity.

The method [32] used in Ref. 30 gives values for the $Q^2 = 0$ $N\gamma$ amplitudes, $A_{1/2}$ and $A_{3/2}$, that are about 30% smaller (in magnitude) than our previous estimates. While this shift improves agreement with quark models, there is no consensus on its validity [26].

The ratio of scalar quadrupole and magnetic dipole amplitudes (S_{1+}/M_{1+}) is also problematic. A previous fit [33] to the DESY measurements gave $0.07\pm0.02\pm0.03$ at Q^2=3.2 $(\mathrm{GeV/c})^2$. This disagrees with a recent fit [28] to the Jefferson Lab data, $-0.112 \pm 0.013 \pm 0.01$ and $-0.148 \pm 0.013 \pm 0.01$ at Q^2=2.8 and 4.0 $(\mathrm{GeV/c})^2$, and with a fit [30] to both DESY and Jefferson Lab data sets, -0.049 ± 0.029, -0.099 ± 0.041, and -0.085 ± 0.021 at Q^2=2.8, 3.2, and 4.0 $(\mathrm{GeV/c})^2$.

New results for $p\eta$: Fits to η-photoproduction data have given $N\gamma$ amplitudes for the $N(1535)$ that are substantially larger than those extracted from fits to π-photoproduction data (see the 1998 Review [27] for details). More recent analyses [34,35] have considered the sensitivity of this reaction to contributions from the $N(1520)$. The ratio of $N(1520) \to N\gamma$ amplitudes, $A_{3/2}/A_{1/2}$, was found to be $-2.5 \pm 0.5 \pm 0.4$ in Ref. 34 and -2.1 ± 0.2 in Ref. 35. Results inferred from π-photoproduction are about a factor of three larger in magnitude (see the Particle Listings). The η-photoproduction result is particularly surprising, as the $N(1520)$ has a very clean resonance signature in π photoproduction.

Recent $p(e,e'p)\eta$ cross-section measurements [36] have been fitted to extract the $N(1535)$ transition amplitude. Values for $A_{1/2}$ are 0.050 ± 0.007 $\mathrm{GeV}^{-1/2}$ at 2.4 $(\mathrm{GeV/c})^2$ and 0.035 ± 0.005 $\mathrm{GeV}^{-1/2}$ at 3.6 $(\mathrm{GeV/c})^2$. These are in qualitative agreement with the results of Ref. 37.

New results for $p\eta'$: A fit to SAPHIR total and differential cross sections has been made [38], assuming resonance dominance and taking only S- and P-wave multipoles. The extracted resonance parameters are $S_{11}(M,\Gamma) = (1897 \pm 50^{+30}_{-2}, 396 \pm 115^{+35}_{-45})$ MeV and $P_{11}(M,\Gamma) = (1986 \pm 26^{+10}_{-30}, 296 \pm 100^{+60}_{-10})$ MeV. Other reaction mechanisms have been proposed [39], and more definitive statements will require the measurement of polarization observables.

New results for $\boldsymbol{\Lambda K^+}$: Recent measurements of $\gamma p \to \Lambda K^+$ total cross sections from SAPHIR [40] suggest a broad structure around 1900 MeV. An analysis [41] of these and associated differential cross-section and recoil-polarization data suggests the influence of a broad D_{13} state. The fitted resonance parameters are $D_{13}(M,\Gamma) = (1895, 372)$ MeV. The choice of a D_{13} state was based on agreement with quark-model predictions, and further polarization measurements are needed to support this claim.

IV. Non-qqq baryon candidates

Revised January 2000 by R.L. Workman (George Washington University, Virginia Campus).

The standard quark-model assignments for baryons are outlined in Sec. 13.3, "Baryons: qqq states." Just as with mesons (see the "Note on Non-$q\bar{q}$ mesons"), there have been suggestions that non-qqq baryons might exist, such as hybrid ($qqqg$) baryons and unstable meson-nucleon bound states [42] (see the "Note on the $\Lambda(1405)$").

If non-qqq states exist, they will be more difficult to verify than hybrid mesons: Hybrid baryons would not have the clean signature of exotic quantum numbers. They should also mix with ordinary qqq states. Their identification will be based on (a) characteristics of their formation and decay, and (b) an over-population of expected qqq states.

Most investigations have focused on the properties of the lightest predicted hybrids. If the first hybrid state lies below 2 GeV, as is suggested by bag-model calculations [43,44,45], it may already exist in our Listings. (However, some estimates put the lightest state well above 2 GeV [46].) At present, there are actually not enough known resonances to fill the known multiplets. If an existing resonance is identified as a hybrid, yet another ordinary qqq state must be found.

The Roper resonance, the $N(1440)\,P_{11}$, has been a hybrid candidate based upon its quantum numbers [43,47] and difficulties with its mass and electromagnetic couplings. If so, this would alter our interpretation of the low-lying P_{11}, P_{13}, P_{31}, and P_{33} resonances [43,48]. In Ref. 48, both the $N(1440)\,P_{11}$ and $\Delta(1600)\,P_{33}$ are hybrid candidates, and $N(1540)\,P_{13}$ and $\Delta(1550)\,P_{31}$ states are predicted. One-star P_{13} and P_{31} states were listed in our 1990 Review [49] but were then removed.

Both photoproduction [48,50,51] and electroproduction [51,52] have been considered in the search for a unique hybrid signature. In Ref. 53, QCD counting rules were used to reveal a characteristic of hybrid electroproduction at high Q^2. If the $N(1440)$ is a hybrid, its transverse form factor is expected to fall asymptotically $O(1/Q^2)$ faster than for a pure qqq state. However, mixing between qqq and $qqqg$ states will make this identification difficult.

A number of recent experiments have searched for pentaquark ($qqqq\bar{q}$) resonances and H dibaryons ($uuddss$ states). Narrow structures found in proton-nucleus scattering [54] have been attributed to $qqqs\bar{s}$ states, an association based on anomalously large branching fractions to strange-particle channels. The H-dibaryon experiments, while finding possible candidates [55], have generally quoted upper limits [56] for exotic resonance production. Searches for narrow dibaryons in the nucleon-nucleon interactions are also continuing [57].

Finally, there has been a report [58] of resonances lying below the $\Delta(1232)$. A very weak signal was found using the reaction $pp \to \pi^+ p X^0$. An earlier search [59] for isospin-3/2 states, using $pp \to nX^{++}$, found a null result in the mass range between M_N and $M_N + M_\pi$. At present, there appears to be no evidence for such low-mass states from other reactions.

N(1440) FOOTNOTES

[1] BAKER 79 finds a coupling of the N(1440) to the $N\eta$ channel near (but slightly below) threshold.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] ARNDT 95 also finds a second-sheet pole with real part = 1383 MeV, −2×imaginary part = 210 MeV, and residue with modulus 92 MeV and phase = −54°.

[5] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[6] ARNDT 91 (Soln SM90) also finds a second-sheet pole with real part = 1413 MeV, −2 × imaginary part = 256 MeV, and residue = (78−153i) MeV.

[7] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[8] An alternative which cannot be distinguished from this is to have a P_{13} resonance with M = 1530 MeV, Γ = 79 MeV, and elasticity = +0.271.

[9] LONGACRE 77 considers this coupling to be well determined.

[10] WADA 84 is inconsistent with other analyses; see the Note on N and Δ Resonances.

[11] Converted to our conventions using M = 1486 MeV, Γ = 613 MeV from NOELLE 78.

$N(1520)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	50–60 %
Γ_2	$N\eta$	
Γ_3	$N\pi\pi$	40–50 %
Γ_4	$\Delta\pi$	15–25 %
Γ_5	$\Delta(1232)\pi$, S-wave	5–12 %
Γ_6	$\Delta(1232)\pi$, D-wave	10–14 %
Γ_7	$N\rho$	15–25 %
Γ_8	$N\rho$, S=1/2, D-wave	
Γ_9	$N\rho$, S=3/2, S-wave	
Γ_{10}	$N\rho$, S=3/2, D-wave	
Γ_{11}	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	<8 %
Γ_{12}	$p\gamma$	0.46–0.56 %
Γ_{13}	$p\gamma$, helicity=1/2	0.001–0.034 %
Γ_{14}	$p\gamma$, helicity=3/2	0.44–0.53 %
Γ_{15}	$n\gamma$	0.30–0.53 %
Γ_{16}	$n\gamma$, helicity=1/2	0.04–0.10 %
Γ_{17}	$n\gamma$, helicity=3/2	0.25–0.45 %

$N(1520)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] LONGACRE 77 considers this coupling to be well determined.

[6] MUKHOPADHYAY 98 uses an effective Lagrangian approach to analyze η photoproduction data. The *ratio* of the $A_{3/2}$ and $A_{1/2}$ amplitudes is determined, with less model dependence than the amplitudes themselves, to be $A_{3/2}/A_{1/2} = -2.5 \pm 0.5 \pm 0.4$.

[7] Converted to our conventions using $M = 1528$ MeV, $\Gamma = 187$ MeV from NOELLE 78.

N(1535) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	35–55 %
Γ_2	$N\eta$	30–55 %
Γ_3	$N\pi\pi$	1–10 %
Γ_4	$\Delta\pi$	<1 %
Γ_5	$\Delta(1232)\pi$, D-wave	
Γ_6	$N\rho$	<4 %
Γ_7	$N\rho$, S=1/2, S-wave	
Γ_8	$N\rho$, S=3/2, D-wave	
Γ_9	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	<3 %
Γ_{10}	$N(1440)\pi$	<7 %
Γ_{11}	$p\gamma$	0.15–0.35 %
Γ_{12}	$p\gamma$, helicity=1/2	0.15–0.35 %
Γ_{13}	$n\gamma$	0.004–0.29 %
Γ_{14}	$n\gamma$, helicity=1/2	0.004–0.29 %

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)\ S_{31}$ coupling to $\Delta(1232)\pi$.

$N(1535)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] KRUSCHE 97 fits with the mass fixed at 1544 MeV.

[4] ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.

[5] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[6] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[7] The best value ARMSTRONG 99B obtains is $\simeq$ 0.55; this assumes S_{11} dominance in the reaction $p(e, e'p)\,\eta$ at Q^2= 4 (GeV/c)^2.

[8] BENMERROUCHE 91 uses an effective Lagrangian approach to analyze η photoproduction data.

[9] Converted to our conventions using M = 1548 MeV, Γ = 73 MeV from NOELLE 78.

$N(1650)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	55–90 %
Γ_2	$N\eta$	3–10 %
Γ_3	ΛK	3–11 %
Γ_4	ΣK	
Γ_5	$N\pi\pi$	10–20 %
Γ_6	$\Delta\pi$	1–7 %
Γ_7	$\Delta(1232)\pi$, D-wave	
Γ_8	$N\rho$	4–12 %
Γ_9	$N\rho$, S=1/2, S-wave	
Γ_{10}	$N\rho$, S=3/2, D-wave	
Γ_{11}	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	<4 %
Γ_{12}	$N(1440)\pi$	<5 %
Γ_{13}	$p\gamma$	0.04–0.18 %
Γ_{14}	$p\gamma$, helicity=1/2	0.04–0.18 %
Γ_{15}	$n\gamma$	0.003–0.17 %
Γ_{16}	$n\gamma$, helicity=1/2	0.003–0.17 %

$N(1650)$ FOOTNOTES

[1] ARNDT 95 finds two distinct states.

[2] BATINIC 95 finds two distinct states. This second resonance was associated with the $N(2090)$ S_{11}.

[3] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.

[4] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[5] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[6] ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.

[7] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[8] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[9] BAKER 79 fixed this coupling during fitting, but the negative sign relative to the $N(1535)$ is well determined.

[10] The overall phase of BAKER 78 couplings has been changed to agree with previous conventions. Superseded by SAXON 80.

[11] The range given for DEANS 75 is from the four best solutions.

[12] LONGACRE 77 considers this coupling to be well determined.

N(1675) FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] SAXON 80 finds the coupling phase is near 90°.

[6] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \rightarrow \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

[7] LONGACRE 77 considers this coupling to be well determined.

[8] A Breit-Wigner fit to the HERNDON 75 IPWA.

N(1680) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	60–70 %
Γ_2	$N\eta$	
Γ_3	ΛK	
Γ_4	ΣK	
Γ_5	$N\pi\pi$	30–40 %
Γ_6	$\Delta\pi$	5–15 %
Γ_7	$\Delta(1232)\pi$, P-wave	6–14 %
Γ_8	$\Delta(1232)\pi$, F-wave	<2 %
Γ_9	$N\rho$	3–15 %
Γ_{10}	$N\rho$, S=1/2, F-wave	
Γ_{11}	$N\rho$, S=3/2, P-wave	<12 %
Γ_{12}	$N\rho$, S=3/2, F-wave	1–5 %
Γ_{13}	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	5–20 %
Γ_{14}	$p\gamma$	0.21–0.32 %
Γ_{15}	$p\gamma$, helicity=1/2	0.001–0.011 %
Γ_{16}	$p\gamma$, helicity=3/2	0.20–0.32 %
Γ_{17}	$n\gamma$	0.021–0.046 %
Γ_{18}	$n\gamma$, helicity=1/2	0.004–0.029 %
Γ_{19}	$n\gamma$, helicity=3/2	0.01–0.024 %

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$(\Gamma_i\Gamma_f)^{1/2}/\Gamma_{total}$ in $N\pi \to N(1680) \to \Delta(1232)\pi$, P-wave — $(\Gamma_1\Gamma_7)^{1/2}/\Gamma$

N(1680) FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[5] The parametrization used may be double counting.
[6] The range given is from 3 of 4 best solutions; not present in solution 1. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.
[7] LONGACRE 77 considers this coupling to be well determined.
[8] A Breit-Wigner fit to the HERNDON 75 IPWA.

$N(1700)$ FOOTNOTES

[1] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] The overall phase of BAKER 78 couplings has been changed to agree with previous conventions.

[7] The range given is from the four best solutions.

$N(1710)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	10–20 %
Γ_2	$N\eta$	
Γ_3	ΛK	5–25 %
Γ_4	ΣK	
Γ_5	$N\pi\pi$	40–90 %
Γ_6	$\Delta\pi$	15–40 %
Γ_7	$\Delta(1232)\pi$, P-wave	
Γ_8	$N\rho$	5–25 %
Γ_9	$N\rho$, S=1/2, P-wave	
Γ_{10}	$N\rho$, S=3/2, P-wave	
Γ_{11}	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	10–40 %
Γ_{12}	$p\gamma$	0.002–0.05%
Γ_{13}	$p\gamma$, helicity=1/2	0.002–0.05%
Γ_{14}	$n\gamma$	0.0–0.02%
Γ_{15}	$n\gamma$, helicity=1/2	0.0–0.02%

$N(1710)$ FOOTNOTES

[1] BATINIC 95 finds a second state with a 6 MeV mass difference.
[2] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.
[3] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[4] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[5] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[6] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[7] The overall phase of BAKER 78 couplings has been changed to agree with previous conventions.
[8] The range given for DEANS 75 is from the four best solutions.

N(1720) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	10–20 %
Γ_2	$N\eta$	
Γ_3	ΛK	1–15 %
Γ_4	ΣK	
Γ_5	$N\pi\pi$	>70 %
Γ_6	$\Delta\pi$	
Γ_7	$\Delta(1232)\pi$, P-wave	
Γ_8	$N\rho$	70–85 %
Γ_9	$N\rho$, S=1/2, P-wave	
Γ_{10}	$N\rho$, S=3/2, P-wave	
Γ_{11}	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	
Γ_{12}	$p\gamma$	0.003–0.10 %
Γ_{13}	$p\gamma$, helicity=1/2	0.003–0.08 %
Γ_{14}	$p\gamma$, helicity=3/2	0.001–0.03 %
Γ_{15}	$n\gamma$	0.002–0.39 %
Γ_{16}	$n\gamma$, helicity=1/2	0.0–0.002 %
Γ_{17}	$n\gamma$, helicity=3/2	0.001–0.39 %

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)\ S_{31}$ coupling to $\Delta(1232)\pi$.

N(1720) FOOTNOTES

[1] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] The overall phase of BAKER 78 copulings has been changed to agree with previous conventions.

[7] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

OMITTED FROM SUMMARY TABLE

There is some evidence for two resonances in this wave between 1800 and 2200 MeV (see CUTKOSKY 80). However, the solution of HOEHLER 79 is quite different.

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** (1982).

$N(2080)$ FOOTNOTES

[1] CUTKOSKY 80 finds a lower mass D_{13} resonance, as well as one in this region. Both are listed here.

[2] The range given for DEANS 75 is from the four best solutions. Disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

$N(2190)$ FOOTNOTES

[1] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[2] The range given for DEANS 75 is from the four best solutions. Disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

N(~ 3000 Region) Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-1/2 resonances found in partial-wave analyses.

Our 1982 edition had an $N(3245)$, an $N(3690)$, and an $N(3755)$, each a narrow peak seen in a production experiment. Since nothing has been heard from them since the 1960's, we declare them to be dead. There was also an $N(3030)$, deduced from total cross-section and 180° elastic cross-section measurements; it is the KOCH 80 $L_{1,15}$ state below.

4.7 to 6.7	NEFKENS	78	$\pi^+ p \to \pi^+ p\gamma$ (UCLA data)

Δ(1232) FOOTNOTES

[1] Using $\pi^{\pm} d$ as well, PEDRONI 78 determine $(M^- - M^{++}) + (M^0 - M^+)/3$ = 4.6 ± 0.2 MeV.
[2] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[3] This VASAN 76B value is from fits to the coulomb-barrier-corrected CARTER 73 phase shift.
[4] This VASAN 76B value is from fits to the CARTER 73 nuclear phase shift without coulomb barrier corrections.
[5] Converted to our conventions using M = 1232 MeV, Γ = 110 MeV from NOELLE 78.
[6] This ARNDT 97 value is very sensitive to the database being fitted. The result is from a fit to the full pion photoproduction database, apart from the BLANPIED 97 cross-section measurements.

$\Delta(1600)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

[6] LONGACRE 77 considers this coupling to be well determined.

[7] WADA 84 is inconsistent with other analyses — see the Note on N and Δ Resonances.

$\Delta(1620)$ FOOTNOTES

[1] CHEW 80 reports two S_{31} resonances at somewhat higher masses than other analyses. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] LONGACRE 77 considers this coupling to be well determined.

Δ(1700) FOOTNOTES

[1] Problems with CHEW 80 are discussed in section 2.1.11 of HOEHLER 83.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[6] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.
[7] LONGACRE 77 considers this coupling to be well determined.

Δ(1900) FOOTNOTES

[1] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[2] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[3] The value given is from solution 1; the resonance is not present in solutions 2, 3, or 4.

$\Delta(1910)$ FOOTNOTES

[1] CHEW 80 reports four resonances in the P_{31} wave — see also the $\Delta(1750)$. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] The range given for DEANS 75 is from the four best solutions.

[5] Evidence for this coupling is weak; see NOVOSELLER 78. This coupling assumes the mass is near 1820 MeV.

$\Delta(1930)$ FOOTNOTES

[1] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[2] The range given for DEANS 75 is from the four best solutions.

$\Delta(1950)$ FOOTNOTES

[1] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[3] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[4] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

[5] A Breit-Wigner fit to the HERNDON 75 IPWA; the phase is near −60°.

[6] A Breit-Wigner fit to the NOVOSELLER 78B IPWA; the phase is near −60°.

[7] A Breit-Wigner fit to the HERNDON 75 IPWA; the phase is near 120°.

[8] A Breit-Wigner fit to the NOVOSELLER 78B IPWA; the phase is near 120°.

$\Delta(\sim 3000$ Region) Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-3/2 resonances found in partial-wave analyses.

Our 1982 edition also had a $\Delta(2850)$ and a $\Delta(3230)$. The evidence for them was deduced from total cross-section and 180° elastic cross-section measurements. The $\Delta(2850)$ has been resolved into the $\Delta(2750)$ $I_{3,13}$ and $\Delta(2950)$ $K_{3,15}$. The $\Delta(3230)$ is perhaps related to the $K_{3,13}$ of HENDRY 78 and to the $L_{3,17}$ of KOCH 80.

[1] We assume CPT invariance: this is the $\overline{\Lambda}$ mass as measured by HARTOUNI 94. See below for the fractional mass difference, testing CPT.
[2] The SCHMIDT 65 masses have been reevaluated using our April 1973 proton and $K^\pm$ and $\pi^\pm$ masses. P. Schmidt, private communication (1974).
[3] The mass has been raised 35 keV to take into account a 46 keV increase in the proton mass and an 11 keV decrease in the $\pi^\pm$ mass (note added Reviews of Modern Physics **39** 1 (1967)).

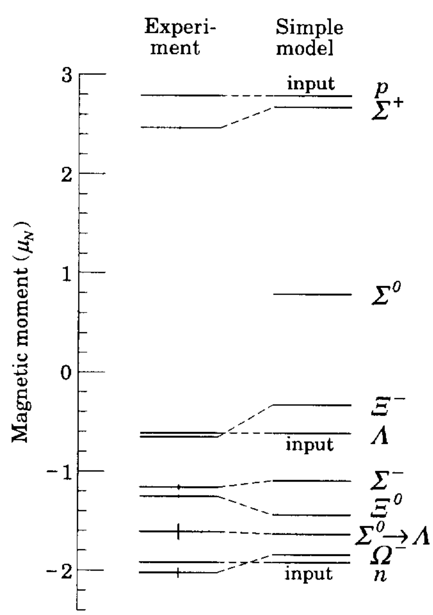
BARYON MAGNETIC MOMENTS

Written 1994 by C.G. Wohl (LBNL).

The figure shows the measured magnetic moments of the stable baryons. It also shows the predictions of the simplest quark model, using the measured p, n, and Λ moments as input. In this model, the moments are [1]



$$\mu_p = (4\mu_u - \mu_d)/3 \qquad \mu_n = (4\mu_d - \mu_u)/3$$
$$\mu_{\Sigma^+} = (4\mu_u - \mu_s)/3 \qquad \mu_{\Sigma^-} = (4\mu_d - \mu_s)/3$$
$$\mu_{\Xi^0} = (4\mu_s - \mu_u)/3 \qquad \mu_{\Xi^-} = (4\mu_s - \mu_d)/3$$
$$\mu_\Lambda = \mu_s \qquad \mu_{\Sigma^0} = (2\mu_u + 2\mu_d - \mu_s)/3$$
$$\mu_{\Omega^-} = 3\mu_s$$

and the $\Sigma^0 \to \Lambda$ transition moment is

$$\mu_{\Sigma^0\Lambda} = (\mu_d - \mu_u)/\sqrt{3}\ .$$

The quark moments that result from this model are $\mu_u = +1.852\,\mu_N$, $\mu_d = -0.972\,\mu_N$, and $\mu_s = -0.613\,\mu_N$. The corresponding effective quark masses, taking the quarks to be Dirac point particles, where $\mu = q\hbar/2m$, are 338, 322, and 510 MeV. As the figure shows, the model gives a good first approximation to the experimental moments. For efforts to make a better model, we refer to the literature [2].

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 20 measurements and one constraint to determine 5 parameters. The overall fit has a χ^2 = 10.5 for 16 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i \delta x_j\rangle/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[7] Changed by us from $\Gamma(pe^-\overline{\nu}_e)/\Gamma(N\pi)$ assuming the authors used $\Gamma(p\pi^-)/\Gamma_{total}$ = 2/3.
[8] Changed by us from $\Gamma(pe^-\overline{\nu}_e)/\Gamma(N\pi)$ because $\Gamma(pe^-\nu)/\Gamma(p\pi^-)$ is the directly measured quantity.

$\Gamma(p\mu^-\overline{\nu}_\mu)/\Gamma(N\pi)$ — $\Gamma_6/(\Gamma_1+\Gamma_2)$

[11] The tabulated result assumes the weak-magnetism coupling $w \equiv g_w(0)/g_v(0)$ to be 0.97, as given by the CVC hypothesis and as assumed by the other listed measurements. However, DWORKIN 90 *measures* w to be 0.15 ± 0.30, and then $g_A/g_V = -0.731 \pm 0.016$.

[12] This experiment measures only the absolute value of g_A/g_V.

Λ AND Σ RESONANCES

Introduction: There are no new results at all on Λ and Σ resonances. The field remains at a standstill and will only be revived if a kaon factory is built. What follows is a much abbreviated version of the note on Λ and Σ Resonances from our 1990 edition. In particular, see that edition for some representative Argand plots from partial-wave analyses.

Table 1 is an attempt to evaluate the status, both overall and channel by channel, of each Λ and Σ resonance in the Particle Listings. The evaluations are of course partly subjective. A blank indicates there is no evidence at all: either the relevant couplings are small or the resonance does not really exist. The main Baryon Summary Table includes only the established resonances (overall status 3 or 4 stars). A number of the 1- and 2-star entries may eventually disappear, but there are certainly many resonances yet to be discovered underlying the established ones.

Sign conventions for resonance couplings: In terms of the isospin-0 and -1 elastic scattering amplitudes A_0 and A_1, the amplitude for $K^- p \rightarrow \overline{K}^0 n$ scattering is $\pm(A_1 - A_0)/2$, where the sign depends on conventions used in conjunction with the Clebsch-Gordan coefficients (such as, is the baryon or the meson the "first" particle). If this reaction is partial-wave analyzed and if the overall phase is chosen so that, say, the $\Sigma(1775)D_{15}$ amplitude at resonance points along the positive imaginary axis (points "up"), then any Σ at resonance will point "up" and any Λ at resonance will point "down" (along the negative imaginary axis). Thus the phase at resonance determines the isospin. The above ignores background amplitudes in the resonating partial waves.

That is the basic idea. In a similar but somewhat more complicated way, the phases of the $\overline{K}N \rightarrow \Lambda\pi$ and $\overline{K}N \rightarrow \Sigma\pi$ amplitudes for a resonating wave help determine the SU(3) multiplet to which the resonance belongs. Again, a convention has to be adopted for some overall arbitrary phases: which way is "up"? Our convention is that of Levi-Setti [1] and is shown in Fig. 1, which also compares experimental results with theoretical predictions for the signs of several resonances. In the Listings, a + or − sign in front of a measurement of an inelastic resonance coupling indicates the sign (the *absence* of a sign means that the sign is not determined, *not* that it is positive). For more details, see Appendix II of our 1982 edition [2].

Errors on masses and widths: The errors quoted on resonance parameters from partial-wave analyses are often only statistical, and the parameters can change by more than these errors when a different parametrization of the waves is used. Furthermore, the different analyses use more or less the same data, so it is not really appropriate to treat the different determinations of the resonance parameters as independent or to average them together. In any case, the spread of the masses, widths, and branching fractions from the different analyses is certainly a better indication of the uncertainties than are the quoted errors. In the Baryon Summary Table, we usually give a range reflecting the spread of the values rather than a particular value with error.

For three states, the $\Lambda(1520)$, the $\Lambda(1820)$, and the $\Sigma(1775)$, there is enough information to make an overall fit to the various branching fractions. It is then necessary to use the quoted errors, but the errors obtained from the fit should not be taken seriously.

Production experiments: Partial-wave analyses of course separate partial waves, whereas a peak in a cross section or an invariant mass distribution usually cannot be disentangled from background and analyzed for its quantum numbers; and more than one resonance may be contributing to the peak. Results from partial-wave analyses and from production experiments are generally kept separate in the Listings, and in the Baryon Summary Table results from production experiments

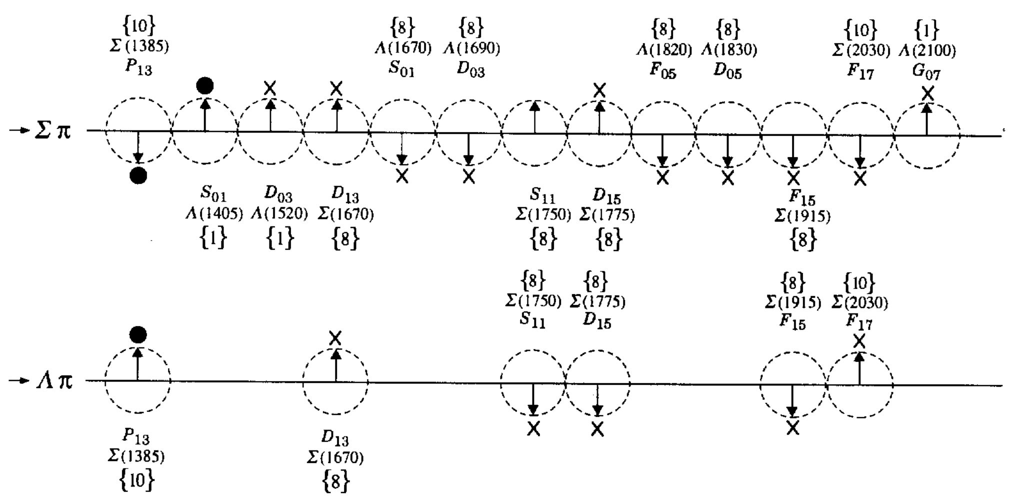

Figure 1. The signs of the imaginary parts of resonating amplitudes in the $\overline{K}N \rightarrow \Lambda\pi$ and $\Sigma\pi$ channels. The signs of the $\Sigma(1385)$ and $\Lambda(1405)$, marked with a •, are set by convention, and then the others are determined relative to them. The signs required by the SU(3) assignments of the resonances are shown with an arrow, and the experimentally determined signs are shown with an ×.

Table 1. The status of the Λ and Σ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

****	Existence is certain, and properties are at least fairly well explored.
***	Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, *etc.* are not well determined.
**	Evidence of existence is only fair.
*	Evidence of existence is poor.

are used only for the low-mass states. The $\Sigma(1385)$ and $\Lambda(1405)$ of course lie below the $\overline{K}N$ threshold and nearly everything about them is learned from production experiments; and production and formation experiments agree quite well in the case of $\Lambda(1520)$ and results have been combined. There is some disagreement between production and formation experiments in the 1600–1700 MeV region: see the note on the $\Sigma(1670)$.

$\Lambda(1405)$ S_{01}

$I(J^P) = 0(\frac{1}{2}^-)$ Status: ****

THE $\Lambda(1405)$

Revised March 1998 by R.H. Dalitz (Oxford University).

It is generally accepted that the $\Lambda(1405)$ is a well-established $J^P = 1/2^-$ resonance. It is assigned to the lowest $L = 1$ supermultiplet of the 3-quark system and paired with the $J^P = 3/2^-$ $\Lambda(1520)$. Lying about 30 MeV below the $N\overline{K}$ threshold, the $\Lambda(1405)$ can be observed directly only as a resonance bump in the $(\Sigma\pi)^0$ subsystem in final states of production experiments. It was first reported by ALSTON 61B in the reaction $K^-p \rightarrow \Sigma\pi\pi\pi$ at 1.15 GeV/c and has since been seen in at least eight other experiments. However, only two of them had enough events for a detailed analysis: THOMAS 73, with about 400 $\Sigma^{\pm}\pi^{\mp}$ events from $\pi^-p \rightarrow K^0(\Sigma\pi)^0$ at 1.69 GeV/c; and HEMINGWAY 85, with 766 $\Sigma^+\pi^-$ and 1106 $\Sigma^-\pi^+$ events from $K^-p \rightarrow (\Sigma\pi\pi)^+\pi^-$ at 4.2 GeV/c, after the selections $1600 \leq M(\Sigma\pi\pi)^+ \leq 1720$ MeV and momentum transfer ≤ 1.0 (GeV/c)^2 to purify the $\Lambda(1405) \rightarrow (\Sigma\pi)^0$ sample. These experiments agree on a mass of about 1395–1400 MeV and a width of about 60 MeV. (Hemingway's mass of 1391 ± 1 MeV is from his best, but unacceptably poor, Breit-Wigner fit.)

The Byers-Fenster tests on these data allow any spin and either parity: neither J nor P has yet been determined *directly.* The early indications for $J^P = 1/2^-$ came from finding Re $A_{I=0}$ to be large and negative in a constant-scattering-length analysis of low-energy $N\overline{K}$ reaction data (see KIM 65, SAKITT 65, and earlier references cited therein). The first multichannel energy-dependent K-matrix analysis (KIM 67) strengthened the case for a resonance around 1400–1420 MeV strongly coupled to the $I = 0$ S-wave $N\overline{K}$ system.

THOMAS 73 and HEMINGWAY 85 both found the $\Lambda(1405)$ bump to be asymmetric and not well fitted by a Breit-Wigner resonance function with constant parameters. The asymmetry involves a rapid fall in intensity as the $N\overline{K}$ threshold energy is approached from below. This is readily understood as due to a strong coupling of the $\Lambda(1405)$ to the S-wave $N\overline{K}$ channel (see DALITZ 81). This striking S-shaped cusp behavior at a new threshold is characteristic of S-wave coupling; the other below-threshold hyperon, the $\Sigma(1385)$, has no such threshold distortion because its $N\overline{K}$ coupling is P-wave. For the $\Lambda(1405)$, this asymmetry is the *sole direct evidence* that $J^P = 1/2^-$.

Following the early work cited above, a considerable literature has developed on proper procedures for phenomenological extrapolation below the $N\overline{K}$ threshold, partly in order to strengthen the evidence for the spin-parity of the $\Lambda(1405)$, and partly to provide an estimate for the amplitude $f(N\overline{K})$ in the unphysical domain below the $N\overline{K}$ threshold; the latter is needed for the evaluation of the dispersion relation for $N\overline{K}$ and NK forward scattering amplitudes. For recent reviews, see MILLER 84 and BARRETT 89. In most recent work, the $(\Sigma\pi)^0$ production spectrum is included in the data fitted (see, *e.g.*, CHAO 73, MARTIN 81).

It is now accepted that the data can be fitted only with an S-wave pole in the reaction amplitudes below $N\overline{K}$ threshold (see, however, FINK 90), but there is still controversy about the physical origin of this pole (for a review, see DALITZ 81 and DALITZ 82). Two extreme possibilities are: (a) an $L = 1$ SU(3)-singlet *uds* state coupled with the S-wave meson-baryon systems; or (b) an unstable $N\overline{K}$ bound state, analogous to the (stable) deuteron in the NN system. The problem with (a) is that the $\Lambda(1405)$ mass is so much lower than that of its partner, the $\Lambda(1520)$. This requires, in the QCD-inspired quark model, rather large spin-orbit couplings, whether or not one uses relativistic kinetic energies. CAPSTICK 86 and CAPSTICK 89 conclude that a proper QCD calculation leads only to small energy splittings, whereas LEINWEBER 90, using QCD sum rules, obtains a good fit to this splitting.

On the other hand, the problem with (b) is that then another $J^P = 1/2^- \Lambda$ is needed to replace the $\Lambda(1405)$ in the $L = 1$ supermultiplet, and it would have to lie close to the $\Lambda(1520)$, a region already well explored by $N\overline{K}$ experiments without result. Intermediate structures are possible; for example, the cloudy bag model allows the configurations (a) and (b) to mix and finds the intensity of (a) in the $\Lambda(1405)$ to be only 14% (VEIT 84, VEIT 85, JENNINGS 86). Such models naturally predict a second $1/2^- \ \Lambda$ close to the $\Lambda(1520)$.

The determination of the mass and width of the resonance from $(\Sigma\pi)^0$ data is usually based on the "Watson approximation," which states that the production rate $R(\Sigma\pi)$ of the $(\Sigma\pi)^0$ state has a mass dependence proportional to $(\sin^2\delta_{\Sigma\pi})/q$, q being the $\Sigma\pi$ c.m. momentum, in a $\Sigma\pi$ mass range where $\delta_{\Sigma\pi}$ is not far from $\pi/2$ and only the $\Sigma\pi$ channel is open, *i.e.*, between the $\Sigma\pi$ and the $N\overline{K}$ thresholds. Then $q\,R(\Sigma\pi)$ is proportional to $\sin^2\delta_{\Sigma\pi}$, and the mass M may be defined as the energy at which $\sin^2\delta_{\Sigma\pi} = 1$. The width Γ may be determined from the rate at which $\delta_{\Sigma\pi}$ goes through $\pi/2$, or from the FWHM; this is a matter of convention.

This determination of M and Γ from the data suffers from the following defects:

(i) The determination of $\sin^2\delta_{\Sigma\pi}$ requires that $R(\Sigma\pi)$ be scaled to give $\sin^2\delta_{\Sigma\pi} = 1$ at the peak for the best fit to the data; *i.e.*, the bump must be *assumed* to arise from a resonance. However, this assumption is supported by the analysis of the low-energy $N\overline{K}$ data and its extrapolation below threshold.

(ii) Owing to the nearby $N\overline{K}$ threshold, the shape of the best fit to the $M(\Sigma\pi)$ bump is uncertain. For energies below this threshold at $E_{N\overline{K}}$, the general form for $\delta_{\Sigma\pi}$ is

$$q\cot\delta_{\Sigma\pi} = \frac{1+\kappa\alpha}{\gamma+\kappa(\alpha\gamma-\beta^2)} \ . \qquad (1)$$

Here α, β, and γ are the (generally energy-dependent) NN, $N\Sigma$, and $\Sigma\Sigma$ elements of the $I = 0$ S-wave K-matrix for the $(\Sigma\pi, N\overline{K})$ system, and κ is the magnitude of the (imaginary) c.m. momentum k_K for the $N\overline{K}$ system below threshold. The elements α, β, γ are real functions of E; they have no branch cuts at the $\Sigma\pi$ and $N\overline{K}$ thresholds, but they are permitted to have poles in E along the real E axis. The resonance asymmetry arises from the effect of κ on $\delta_{\Sigma\pi}$. We note that $\delta_{\Sigma\pi} = \pi/2$ when $\kappa = -1/\alpha$.

Accepting this close connection of $\delta_{\Sigma\pi}$ with the low-energy $N\overline{K}$ data, it is natural to analyze the two sets of data together (*e.g.*, MARTIN 81), and there is now a large body of accurate $N\overline{K}$ data for laboratory momenta between 100 and 300 MeV/c (see MILLER 84). The two sets of data span c.m. energies from 1370 MeV to 1490 MeV, and the K-matrix elements will not be energy independent over such a broad range. For the $I = 0$ channels, a linear energy dependence for K^{-1} has been adopted routinely ever since the work of KIM 67, and it is essential when fitting the $q\,R(\Sigma\pi)$ and $N\overline{K}$ data together. However, $q\,R(\Sigma\pi)$ is not always well fitted in this procedure; the value obtained for the $\Lambda(1405)$ mass M varies a good deal with the type of fit, not a surprising result when the $\Sigma\pi$ mass spectrum below the pK^- threshold contributes only nine data points in a total of about 200. The value of M obtained from an overall fit is not necessarily much better than from one using only the $q\,R(\Sigma\pi)$ data; and M may be a function of the representation—K-matrix, K^{-1}-matrix, relativistic-separable or nonseparable potentials, *etc.*— used in fitting over the full energy range. DALITZ 91 fitted the $q\,R(\Sigma^+\pi^-)$ Hemingway data with each of the first three representations just mentioned, constrained to the $I = 0$ $N\overline{K}$ threshold scattering length from low-energy $N\overline{K}$ data. The (nonseparable) meson-exchange potentials of MÜLLER-GROELING 90, fitted to the low-energy $N\overline{K}$ (and NK) data, predicted an unstable $N\overline{K}$ bound state with mass and width compatible with the $\Lambda(1405)$.

From the measurement of $2p \to 1s$ x rays from kaonic-hydrogen, the energy-level shift ΔE and width Γ of its 1s state can give us two further constraints on the $(\Sigma\pi, N\overline{K})$ system, at an energy roughly midway between those from the low-energy hydrogen bubble chamber studies and those from $q\,R(\Sigma\pi)$ observations below the pK^- threshold. IWASAKI 97 have reported the first convincing observation of this x ray, with a good initial estimate:

$$\Delta E - i\Gamma/2 = (-323 \pm 63 \pm 11) - i(204 \pm 104 \pm 50) \text{ eV} \ . \quad (2)$$

The errors here encompass about half of the predictions made following the various analyses and/or models for the in-flight K^-p and sub-threshold $q\,R(\Sigma\pi)$ data. Better measurements will be needed to discriminate between the analyses and predictions. Now that ΔE is known with some certainty, we can anticipate much-improved data on kaonic-hydrogen, perhaps from the DAΦNE storage ring at Frascati, information vital for our quantitative understanding of the $(\Sigma\pi, N\overline{K})$ system in this region. This will lead to better knowledge of kaonic coupling strengths and to more reliable dispersion-theoretic arguments concerning strange-particle processes.

The present status of the $\Lambda(1405)$ thus depends heavily on theoretical arguments, a somewhat unsatisfactory basis for a four-star rating. Nevertheless, there is no known reason to doubt its existence or quantum numbers. The 3-quark model for baryons has been broadly successful in accounting for all of the $L^P = 1^-$ excited baryonic states (CAPSTICK 89), apart from the relatively large mass separation between the $\Lambda(1405)$ and $\Lambda(1520)$. Quark model builders have no reservations about accepting the $\Lambda(1405)$ as a 3-quark state. However, calculations with broken-chiral-symmetric models, which combine internal 3-quark configurations with external meson-baryon states (*e.g.*, VEIT 85, KAISER 95) end up with descriptions of the $\Lambda(1405)$ dominated by the meson-baryon terms in the wavefunctions. Models using meson-baryon potentials readily fit its mass, and give ΔE negative, as is found empirically. The problem is not so much one of "either (a) or (b)," but rather how to achieve "both (a) and (b)." Theoreticians have not yet been able to deal with the full coupled-channels system, with qqq and $qqqq\bar{q}$ configurations (at the least) being treated on the same footing. On the experimental side, better statistics are needed, both above and below the pK^- threshold. To disentangle the physics, the $I = 1$ channels also need more attention. For example, low-energy pK_L^0 interactions have not been studied at all in the last 25 years.

$\Lambda(1520)\ D_{03}$

$I(J^P) = 0(\frac{3}{2}^-)$ Status: ∗∗∗∗

Discovered by FERRO-LUZZI 62; the elaboration in WATSON 63 is the classic paper on the Breit-Wigner analysis of a multichannel resonance.

The measurements of the mass, width, and elasticity published before 1975 are now obsolete and have been omitted. They were last listed in our 1982 edition Physics Letters **111B** (1982).

Production and formation experiments agree quite well, so they are listed together here.

CONSTRAINED FIT INFORMATION

An overall fit to 9 branching ratios uses 24 measurements and one constraint to determine 6 parameters. The overall fit has a $\chi^2 =$ 16.5 for 19 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i \delta x_j\rangle/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\Gamma(\Sigma(1385)\pi(\to \Lambda\pi\pi))/\Gamma(\Lambda\pi\pi)$ — Γ_5/Γ_3

The $\Lambda\pi\pi$ mode is largely due to $\Sigma(1385)\pi$. Only the values of $(\Sigma(1385)\pi)$ / $(\Lambda 2\pi)$ given by MAST 73B and CORDEN 75 are based on real 3-body partial-wave analyses. The discrepancy between the two results is essentially due to the different hypotheses made concerning the shape of the $(\pi\pi)_{S\text{-wave}}$ state.

Λ(1520) FOOTNOTES

[1] From the best-resolution sample of $\Lambda\pi\pi$ events only.
[2] The $\overline{K}N \to \Sigma\pi$ amplitude at resonance is $+0.46 \pm 0.01$.
[3] Assumes $\Gamma(N\overline{K})/\Gamma_{total} = 0.46 \pm 0.02$.
[4] Both $\Sigma(1385)\pi$ DS_{03} and $\Sigma(\pi\pi)$ DP_{03} contribute.
[5] The central bin (1514–1524 MeV) gives 0.74 ± 0.10; other bins are lower by 2-to-5 standard deviations.
[6] Much of the $\Sigma\pi\pi$ decay proceeds via $\Sigma(1385)\pi$.
[7] Assumes $\Gamma(N\overline{K})/\Gamma_{total} = 0.46$.
[8] Calculated from $\Gamma(\Lambda\gamma)/\Gamma_{total}$, assuming SU(3). Needed to constrain the sum of all the branching ratios to be unity.

38	CARROLL	76	DPWA	Isospin-0 total σ

$\Lambda(1690)$ DECAY MODES

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\overline{K}$	20–30 %
Γ_2	$\Sigma\pi$	20–40 %
Γ_3	$\Lambda\pi\pi$	~ 25 %
Γ_4	$\Sigma\pi\pi$	~ 20 %
Γ_5	$\Lambda\eta$	
Γ_6	$\Sigma(1385)\pi$, S-wave	

The above branching fractions are our estimates, not fits or averages.

$\Lambda(1690)$ BRANCHING RATIOS

The sum of all the quoted branching ratios is more than 1.0. The two-body ratios are from partial-wave analyses, and thus probably are more reliable than the three-body ratios, which are determined from bumps in cross sections. Of the latter, the $\Sigma\pi\pi$ bump looks more significant. (The error given for the $\Lambda\pi\pi$ ratio looks unreasonably small.) Hardly any of the $\Sigma\pi\pi$ decay can be via $\Sigma(1385)$, for then seven times as much $\Lambda\pi\pi$ decay would be required. See "Sign conventions for resonance couplings" in the Note on Λ and Σ Resonances.

$\Lambda(1690)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit. Another D_{03} Λ at 1966 MeV is also suggested by MARTIN 77, but is very uncertain.

[2] BARTLEY 68 uses only cross-section data. The enhancement is not seen by PREVOST 71.

$\Lambda(1820)$ F_{05}

$I(J^P) = 0(\frac{5}{2}^+)$ Status: ∗∗∗∗

This resonance is the cornerstone for all partial-wave analyses in this region. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** (1982).

Most of the quoted errors are statistical only; the systematic errors due to the particular parametrizations used in the partial-wave analyses are not included. For this reason we do not calculate weighted averages for the mass and width.

$\Lambda(1820)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] There is a suggestion of a bump, enough to be consistent with what is expected from $\Sigma(1385) \to \Sigma\pi$ decay.
[3] The published sign has been changed to be in accord with the baryon-first convention.

$I(J^P) = 0(?^?)$ Status: ∗

OMITTED FROM SUMMARY TABLE

We list here all the ambiguous resonance possibilities with a mass around 2 GeV. The proposed quantum numbers are D_3 (BARBARO-GALTIERI 70 in $\Sigma\pi$), D_3+F_5, P_3+D_5, or P_1+D_3 (BRANDSTETTER 72 in $\Lambda\omega$), and S_1 (CAMERON 78B in $N\overline{K}^*$). The first two of the above analyses should now be considered obsolete. See also NAKKASYAN 75.

$I(J^P) = 0(\frac{7}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

In LITCHFIELD 71, need for the state rests solely on a possibly inconsistent polarization measurement at 1.784 GeV/c. HEMINGWAY 75 does not require this state. GOPAL 77 does not need it in either $N\overline{K}$ or $\Sigma\pi$. With new $K^- n$ angular distributions included, DECLAIS 77 sees it. However, this and other new data are included in GOPAL 80 and the state is not required. BACCARI 77 weakly supports it.

Λ(2100) G_{07}

$I(J^P) = 0(\frac{7}{2}^-)$ Status: ****

Discovered by COOL 66 and by WOHL 66. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and in invariant-mass distributions around 2100 MeV used to be listed in a separate entry immediately following. It may be found in our 1986 edition Physics Letters **170B** (1986).

$\Lambda(2100)$ FOOTNOTES

[1] The NAKKASYAN 75 values are from the two best solutions found. Each has the $\Lambda(2100)$ and one additional resonance (P_3 or F_5).

[2] Note that the three for BACCARI 77 entries are for three different waves.

[3] The published sign has been changed to be in accord with the baryon-first convention. The upper limit on the G_3 wave is 0.03.

$\Lambda(2110)$ FOOTNOTES

[1] Found in one of two best solutions.

[2] The published error of 0.6 was a misprint.

[3] The CAMERON 78 upper limit on F-wave decay is 0.03. The sign here has been changed to be in accord with the baryon-first convention.

[4] The published sign has been changed to be in accord with the baryon-first convention. The CAMERON 78B upper limits on the P_3 and F_3 waves are each 0.03.

$\Lambda(2325)$ D_{03}

$I(J^P) = 0(\frac{3}{2}^-)$ Status: *

OMITTED FROM SUMMARY TABLE

BACCARI 77 finds this state with either $J^P = 3/2^-$ or $3/2^+$ in a energy-dependent partial-wave analyses of $K^-p \to \Lambda\omega$ from 2070 to 2436 MeV. A subsequent semi-energy-independent analysis from threshold to 2436 MeV selects $3/2^-$. DEBELLEFON 78 (same group) also sees this state in an energy-dependent partial-wave analysis of $K^-p \to \overline{K}N$ data, and finds $J^P = 3/2^-$ or $3/2^+$. They again prefer $J^P = 3/2^-$, but only on the basis of model-dependent considerations.

$\Lambda(2350)$ H_{09}

$I(J^P) = 0(\frac{9}{2}^+)$ Status: ∗∗∗

DAUM 68 favors $J^P = 7/2^-$ or $9/2^+$. BRICMAN 70 favors $9/2^+$. LASINSKI 71 suggests three states in this region using a Pomeron + resonances model. There are now also three formation experiments from the College de France-Saclay group, DEBELLEFON 77, BACCARI 77, and DEBELLEFON 78, which find $9/2^+$ in energy-dependent partial-wave analyses of $\overline{K}N \to \Sigma\pi$, $\Lambda\omega$, and $N\overline{K}$.

Γ_8	$p e^+ e^-$	$S1$	< 7 × 10^{-6}	

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 14 measurements and one constraint to determine 3 parameters. The overall fit has a χ^2 = 7.7 for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\left\langle\delta x_i \delta x_j\right\rangle/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	−100	
x_3	12	−14
	x_1	x_2

Σ^+ BRANCHING RATIOS

Σ^0

$I(J^P) = 1(\frac{1}{2}^+)$ Status: ∗∗∗∗

COURANT 63 and ALFF-STEINBERGER 65, using $\Sigma^0 \to \Lambda e^+ e^-$ decays (Dalitz decays), determined the Σ^0 parity to be positive, given that $J = 1/2$ and that certain very reasonable assumptions about form factors are true. The results of experiments involving the Primakoff effect, from which the Σ^0 mean life and $\Sigma^0 \to \Lambda$ transition magnetic moment come (see below), strongly support $J = 1/2$.

Σ^0 MASS

The fit uses Σ^+, Σ^0, Σ^-, and Λ mass and mass-difference measurements.

Σ^0 MEAN LIFE

These lifetimes are deduced from measurements of the cross sections for the Primakoff process $\Lambda \to \Sigma^0$ in nuclear Coulomb fields. An alternative expression of the same information is the Σ^0-Λ transition magnetic moment given in the following section. The relation is $(\mu_{\Sigma\Lambda}/\mu_N)^2\ \tau = 1.92951 \times 10^{-19}$ s (see DEVLIN 86).

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 5 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 4.2$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i \delta x_j\rangle/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CHARMED BARYONS
$(C = +1)$

$\Lambda_c^+ = udc$, $\Sigma_c^{++} = uuc$, $\Sigma_c^+ = udc$, $\Sigma_c^0 = ddc$,
$\Xi_c^+ = usc$, $\Xi_c^0 = dsc$, $\Omega_c^0 = ssc$

CHARMED BARYONS

Revised April 2000 by C.G. Wohl (LBNL).

There are now ten (!) known charmed baryons, each with one c quark. Figure 1(a) shows the mass spectrum, and for comparison Fig. 1(b) shows the spectrum of the lightest strange baryons. The Λ_c and Σ_c spectra ought to look much like the Λ and Σ spectra, since a Λ_c or a Σ_c is obtained from a Λ or a Σ by changing the s quark to a c quark. However, a Ξ or an Ω has more than one s quark, only *one* of which is changed to a c quark to make a Ξ_c or an Ω_c. Thus the Ξ_c and Ω_c spectra ought to be richer than the Ξ or Ω spectra.

Before discussing the observed spectra, we review the theory of SU(4) multiplets, which tells us what charmed baryons we should expect to find; this is essential, because the spin-parity assignments given in Fig. 1(a) have not been measured but have been assigned in accord with expectations of the theory.

SU(4) multiplets—Baryons made from u, d, s, and c quarks belong to SU(4) multiplets. The multiplet numerology, analogous to $3\times3\times3 = 10+8_1+8_2+1$ for the subset of baryons made from just u, d, and s quarks, is $4\times4\times4 = 20 + 20'_1 + 20'_2 + \bar{4}$. Figure 2(a) shows the $20'$-plet whose bottom level is an SU(3) octet, such as the octet that includes the nucleon. Figure 2(b) shows the 20-plet whose bottom level is an SU(3) decuplet, such as the decuplet that includes the $\Delta(1232)$. One level up in each multiplet are the baryons with one c quark. The $\bar{4}$ multiplet (not shown), an inverted tetrahedron, contains a Λ, a Λ_c^+, a Ξ_c^+, and a Ξ_c^0 (states at the centers of the four faces of the $20'$-plet). All the baryons in a given multiplet have the same spin and parity. Each N or Δ or SU(3)-singlet-Λ resonance calls for another $20'$- or 20- or $\bar{4}$-plet, respectively.

The flavor symmetries shown in Fig. 2 are of course very badly broken, but the figure is the simplest way to see what charmed baryons should exist. For example, from Fig. 2(a), we expect to find, in the same $J^P = 1/2^+$ $20'$-plet as the nucleon, a Λ_c, a Σ_c, *two* Ξ_c's, and an Ω_c. Note that this Ω_c is not in the same SU(4) multiplet as the famous $J^P = 3/2^+$ Ω^-.

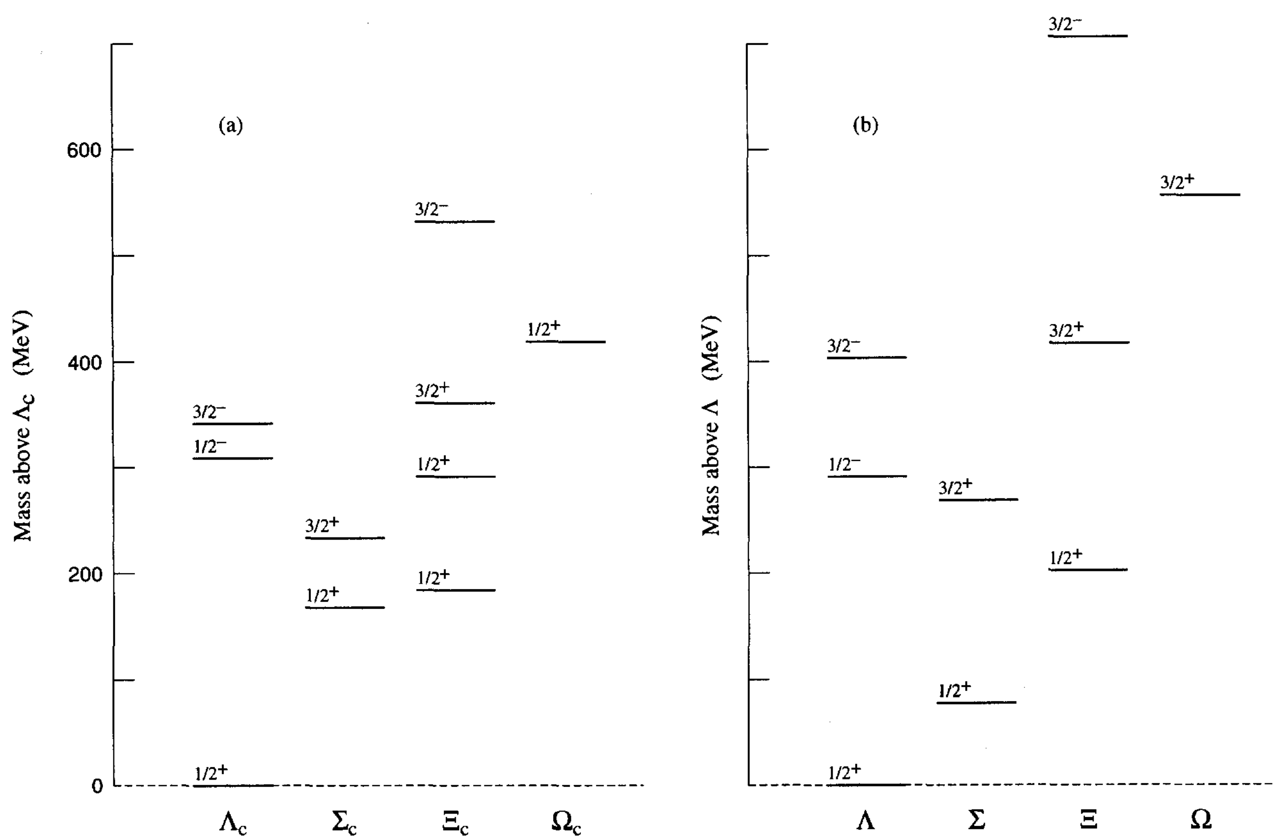

Figure 1. (a) The known charmed baryons, and (b) the lightest strange baryons. The baseline masses are $m(\Lambda_c) = 2284.9$ MeV and $m(\Lambda) = 1115.7$ MeV. Isospin splittings are not shown. Note that there are two $J^P = 1/2^+$ Ξ_c states, and that the Ω_c does not have $J = 3/2$. In fact, none of the J^P values of the charmed baryons has been measured (except perhaps for the $1/2^+ \Lambda_c$), but they are all very likely as shown—see the discussion.

($C = +1$)

$\Lambda_c^+ = udc$, $\Sigma_c^{++} = uuc$, $\Sigma_c^+ = udc$, $\Sigma_c^0 = ddc$,
$\Xi_c^+ = usc$, $\Xi_c^0 = dsc$, $\Omega_c^0 = ssc$

CHARMED BARYONS

Revised April 2000 by C.G. Wohl (LBNL).

There are now ten (!) known charmed baryons, each with one c quark. Figure 1(a) shows the mass spectrum, and for comparison Fig. 1(b) shows the spectrum of the lightest strange baryons. The Λ_c and Σ_c spectra ought to look much like the Λ and Σ spectra, since a Λ_c or a Σ_c is obtained from a Λ or a Σ by changing the s quark to a c quark. However, a Ξ or an Ω has more than one s quark, only *one* of which is changed to a c quark to make a Ξ_c or an Ω_c. Thus the Ξ_c and Ω_c spectra ought to be richer than the Ξ or Ω spectra.

Before discussing the observed spectra, we review the theory of SU(4) multiplets, which tells us what charmed baryons we should expect to find; this is essential, because the spin-parity assignments given in Fig. 1(a) have not been measured but have been assigned in accord with expectations of the theory.

SU(4) multiplets—Baryons made from u, d, s, and c quarks belong to SU(4) multiplets. The multiplet numerology, analogous to $3\times3\times3 = 10+8_1+8_2+1$ for the subset of baryons made from just u, d, and s quarks, is $4\times4\times4 = 20 + 20'_1 + 20'_2 + \bar{4}$. Figure 2(a) shows the 20′-plet whose bottom level is an SU(3) octet, such as the octet that includes the nucleon. Figure 2(b) shows the 20-plet whose bottom level is an SU(3) decuplet, such as the decuplet that includes the $\Delta(1232)$. One level up in each multiplet are the baryons with one c quark. The $\bar{4}$ multiplet (not shown), an inverted tetrahedron, contains a Λ, a Λ_c^+, a Ξ_c^+, and a Ξ_c^0 (states at the centers of the four faces of the 20′-plet). All the baryons in a given multiplet have the same spin and parity. Each N or Δ or SU(3)-singlet-Λ resonance calls for another 20′- or 20- or $\bar{4}$-plet, respectively.

The flavor symmetries shown in Fig. 2 are of course very badly broken, but the figure is the simplest way to see what charmed baryons should exist. For example, from Fig. 2(a), we expect to find, in the same $J^P = 1/2^+$ 20′-plet as the nucleon, a Λ_c, a Σ_c, *two* Ξ_c's, and an Ω_c. Note that this Ω_c is not in the same SU(4) multiplet as the famous $J^P = 3/2^+$ Ω^-.

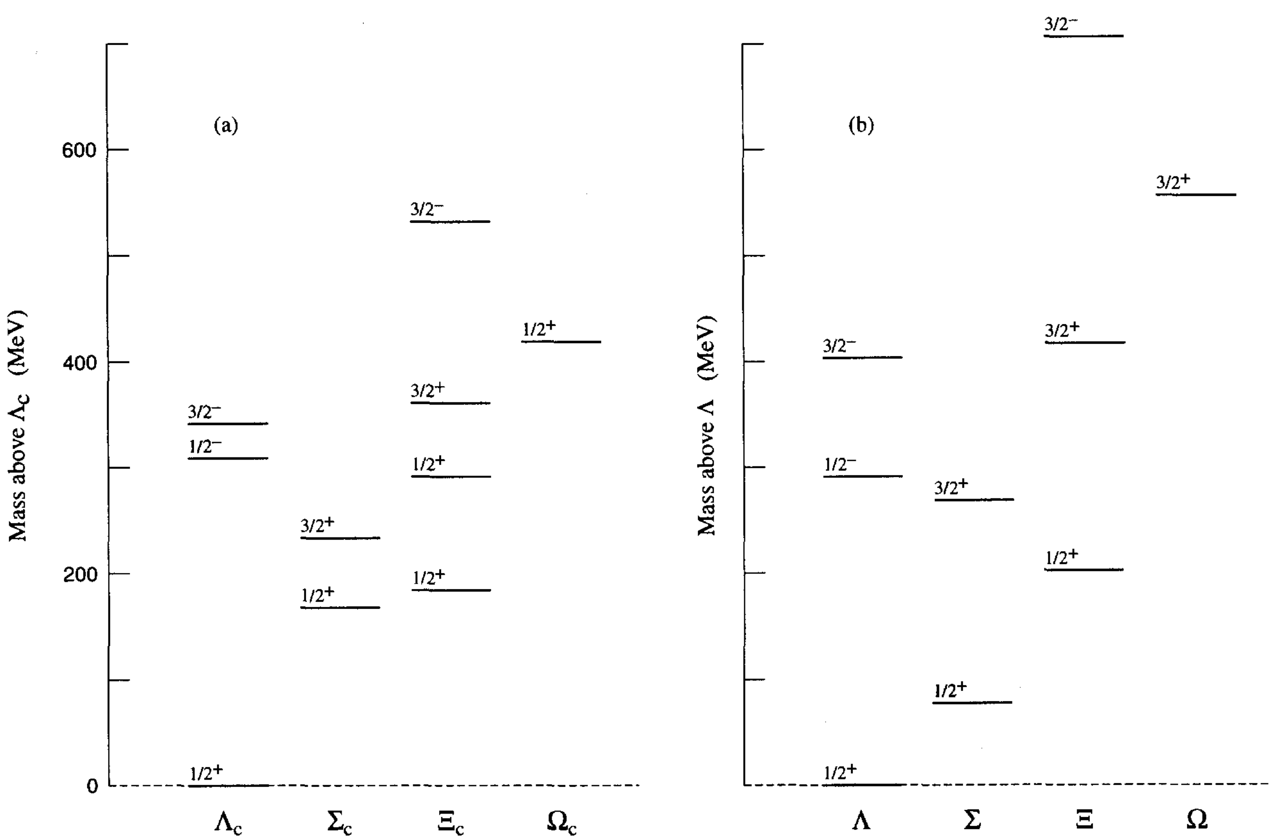

Figure 1. (a) The known charmed baryons, and (b) the lightest strange baryons. The baseline masses are $m(\Lambda_c) = 2284.9$ MeV and $m(\Lambda) = 1115.7$ MeV. Isospin splittings are not shown. Note that there are two $J^P = 1/2^+$ Ξ_c states, and that the Ω_c does not have $J = 3/2$. In fact, none of the J^P values of the charmed baryons has been measured (except perhaps for the $1/2^+\Lambda_c$), but they are all very likely as shown—see the discussion.

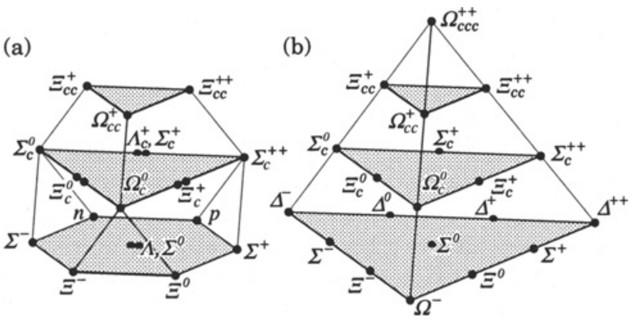

Figure 2: SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) octet on the lowest level. (b) The 20-plet with an SU(3) decuplet on the lowest level.

Figure 3 shows in more detail the middle level of the 20′-plet of Fig. 2(a); it splits apart into two SU(3) multiplets, a $\bar{3}$ and a 6. The states of the $\bar{3}$ are antisymmetric under the interchange of the two light quarks (the u, d, and s quarks), whereas the states of the 6 are symmetric under this interchange. We use a prime to distinguish the Ξ_c in the 6 from the one in the $\bar{3}$.

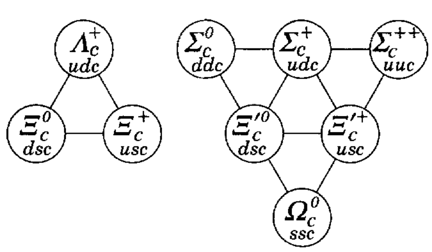

Figure 3: The SU(3) multiplets on the second level of the SU(4) multiplet of Fig. 2(a).

The observed spectra—(1) The parity of the lowest Λ_c is defined to be positive (as are the parities of the p, n, and Λ); and the limited evidence about its spin is consistent with $J = 1/2$. Otherwise, however, none of the J^P quantum numbers in Fig. 1(a) has been measured. Models using spin-spin and spin-orbit interactions between the quarks, with parameters determined using a few of the masses as input, lead to the J^P assignments shown.† There are no surprises: the $J^P = 1/2^+$ states come first, then the $J^P = 3/2^+$ states ...

(2) There is, however, strong evidence that at least some of the J^P assignments in Fig. 1(a) are correct. As is well known, the successive mass differences between the $J^P = 3/2^+$ $\Delta(1232)^-$, $\Sigma(1385)^-$, $\Xi(1535)^-$, and Ω^-, those particles along the lower left edge of the 20-plet in Fig. 2(b), should be, according to SU(3), and nearly are equal; see the $J^P = 3/2^+$ states in Fig. 1(b). Similarly, the mass differences between the $J^P = 1/2^+$ $\Sigma_c(2455)^0$, $\Xi_c'^0$, and Ω_c^0,‡ the particles along the left edge of Fig. 3(b), should be equal—assuming, of course, that they *do* all have the same J^P. And the observed differences are 126.6 ± 3.3 MeV and 125.2 ± 5.1 MeV—perfect, within errors. In fact, the mass difference between the presumed $J^P = 3/2^+$ $\Sigma_c(2520)^0$ and $\Xi_c(2645)^0$ is the same, 127.0 ± 2.3 MeV, which would put the $3/2^+$ Ω_c^0 at about 2772 MeV (= 487 MeV on Fig. 1(a)).

(3) Other evidence comes from the decay of the $\Lambda_c(2593)$. The only allowed strong decay is $\Lambda_c(2593)^+ \rightarrow \Lambda_c^+\pi\pi$, and this appears to be dominated by the submode $\Sigma_c(2455)\pi$, despite little available phase space for the latter (the 'Q' is about 2 MeV, the c.m. decay momentum about 20 MeV/c). Thus the decay is almost certainly s-wave, which, assuming that the $\Sigma_c(2455)$ does indeed have $J^P = 1/2^+$, makes $J^P = 1/2^-$ for the $\Lambda_c(2593)$.

(4) The heavier c baryons, such as the $J^P = 1/2^-$ and $3/2^-$ Λ_c's, have much narrower widths than do their strange counterparts, such as the $\Lambda(1405)$ and $\Lambda(1520)$. The clean Λ_c spectrum has in fact been taken to settle the decades-long discussion about the nature of the $\Lambda(1405)$—true 3-quark state or mere $\overline{K}N$ threshold effect?—unambiguously in favor of the first interpretation; which is not to say that the proximity of the $\overline{K}N$ threshold has no effect on the $\Lambda(1405)$.

Footnotes:

† This is not the place to discuss the details of the models, nor to attempt a guide to the literature. See the discovery papers of the various charmed baryons for references to the models that lead to the quantum-number assignments.

‡ A reminder about the Particle Data Group naming scheme: A particle that decays strongly has its mass as part of its name; otherwise it doesn't. Thus $\Sigma(1385)$ and $\Sigma_c(2455)$ but Ω^- and Ξ_c'.

Λ_c^+

$I(J^P) = 0(\frac{1}{2}^+)$ Status: ****

The parity of the Λ_c^+ is defined to be positive (as are the parities of the proton, neutron, and Λ). The spin J has not actually been measured yet. Results of an analysis of $pK^-\pi^+$ decays (JEZABEK 92) are consistent with the expected $J = 1/2$. The quark content is udc.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in earlier editions.

Λ_c^+ MASS

Measurements with an error greater than 5 MeV or that are otherwise obsolete have been omitted.

The fit also includes Σ_c–Λ_c^+ and Λ_c^{*+}–Λ_c^+ mass-difference measurements.

Λ_c^+ DECAY MODES

Nearly all branching fractions of the Λ_c^+ are measured relative to the $pK^-\pi^+$ mode, but there are no model-independent measurements of this branching fraction. We explain how we arrive at our value of B($\Lambda_c^+ \to pK^-\pi^+$) in a Note at the beginning of the branching-ratio measurements, below. When this branching fraction is eventually well determined, all the other branching fractions will slide up or down proportionally as the true value differs from the value we use here.

[a] See the "Note on Λ_c^+ Branching Fractions" below.

[b] This branching fraction includes all the decay modes of the final-state resonance.

[c] An ℓ indicates an e or a μ mode, not a sum over these modes.

[d] The value is for the sum of the charge states or particle/antiparticle states indicated.

Λ_c^+ BRANCHING FRACTIONS

Revised 2000 by P.R. Burchat (Stanford University).

Most Λ_c^+ branching fractions are measured relative to the decay mode $\Lambda_c^+ \to pK^-\pi^+$. However, there are no model-independent measurements of the absolute branching fraction for $\Lambda_c^+ \to pK^-\pi^+$. Here we describe the measurements that have been used to extract B($\Lambda_c^+ \to pK^-\pi^+$), the model-dependence of the results, and the method we have used to average the results.

ARGUS (ALBRECHT 88C) and CLEO (CRAWFORD 92) measure $B(\overline{B} \to \Lambda_c^+ X) \times B(\Lambda_c^+ \to pK^-\pi^+)$ to be $(0.30 \pm 0.12 \pm 0.06)\%$ and $(0.273 \pm 0.051 \pm 0.039)\%$. Under the assumptions that decays of $\overline{B}$ mesons to baryons are dominated by $\overline{B} \to \Lambda_c^+ X$ and that $\Lambda_c^+ X$ final states other than $\Lambda_c^+ \overline{N} X$ can be neglected, they also measure $B(\overline{B} \to \Lambda_c^+ X)$ to be $(6.8 \pm 0.5 \pm 0.3)\%$ (ALBRECHT 92O) and $(6.4 \pm 0.8 \pm 0.8)\%$ (CRAWFORD 92). Combining these results, we get $B(\Lambda_c^+ \to pK^-\pi^+) = (4.14 \pm 0.91)\%$. However, the assumption that $\overline{B}$ decay modes to baryons other than $\Lambda_c^+ \overline{N} X$ are negligible is not on solid ground experimentally or theoretically [1]. Therefore, the branching fraction for $\Lambda_c^+ \to pK^-\pi^+$ given above may be low by some undetermined amount.

The second type of model-dependent determination of $B(\Lambda_c^+ \to pK^-\pi^+)$ is based on measurements by ARGUS (ALBRECHT 91G) and CLEO (BERGFELD 94) of $\sigma(e^+e^- \to \Lambda_c^+ X) \cdot B(\Lambda_c^+ \to \Lambda\ell^+\nu_\ell) = (4.15 \pm 1.03 \pm 1.18)$ pb and $(4.77 \pm 0.25 \pm 0.66)$ pb. ARGUS (ALBRECHT 96E) and CLEO (AVERY 91) have also measured $\sigma(e^+e^- \to \Lambda_c^+ X) \cdot B(\Lambda_c^+ \to pK^-\pi^+)$. The weighted average is (11.2 ± 1.3) pb.

From these measurements, we extract $R \equiv B(\Lambda_c^+ \to pK^-\pi^+)/B(\Lambda_c^+ \to \Lambda\ell^+\nu_\ell) = 2.40 \pm 0.43$. We estimate the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction from the equation

$$B(\Lambda_c^+ \to pK^-\pi^+) = R\, f\, F\, \frac{\Gamma(D \to X\ell^+\nu_\ell)}{1+|V_{cd}/V_{cs}|^2} \cdot \tau(\Lambda_c^+) \; , \quad (1)$$

where $f = B(\Lambda_c^+ \to \Lambda\ell^+\nu_\ell)/B(\Lambda_c^+ \to X_s\ell^+\nu_\ell)$ and $F = \Gamma(\Lambda_c^+ \to X_s\ell^+\nu_\ell)/\Gamma(D^0 \to X_s\ell^+\nu_\ell)$. When we use $1+|V_{cd}/V_{cs}|^2 = 1.05$ and the world averages $\Gamma(D \to X\ell^+\nu_\ell) = (0.163\pm0.006)\times10^{-12}\ \mathrm{s}^{-1}$ and $\tau(\Lambda_c^+) = (0.206\pm0.012)\times10^{-12}$ s, we calculate $B(\Lambda_c^+ \to pK^-\pi^+) = (7.7\pm1.5)\%\cdot f\, F$. Theoretical estimates for f and F are near 1.0 with significant uncertainties.

So, we have two results with significant model-dependence: $B(\Lambda_c^+ \to pK^-\pi^+) = (4.14\pm0.91)\%$ from $\overline{B}$ decays, and $B(\Lambda_c^+ \to pK^-\pi^+) = (7.7\pm1.5)\%\cdot f\, F$ from semileptonic Λ_c^+ decays. If we set $f\,F = 1.0$ in the second result, and assign an uncertainty of 30% to each result to account for the unknown model-dependence, we get the consistent results $B(\Lambda_c^+ \to pK^-\pi^+) = (4.14\pm0.91\pm1.24)\%$ and $B(\Lambda_c^+ \to pK^-\pi^+) = (7.7\pm1.5\pm2.3)\%$. The weighted average of these two results is $B(\Lambda_c^+ \to pK^-\pi^+) = (5.0\pm1.3)\%$, where the uncertainty contains both the experimental uncertainty and the 30% estimate of model dependence in each result.

This procedure is clearly rather arbitrary, but so is any other procedure until good measurements of the absolute branching fraction are made. Therefore, we have assigned the value $(5.0\pm1.3)\%$ to the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction (given as PDG 00 below). As was noted earlier, most of the other modes are measured relative to this mode.

New methods for measuring the Λ_c^+ absolute branching fractions have been proposed [1,2].

Λ_c^+ DECAY PARAMETERS

See the "Note on Baryon Decay Parameters" in the neutron Listings.

α FOR $\Lambda_c^+ \to \Lambda\pi^+$

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
−0.98±0.19 OUR AVERAGE					
−0.94±0.21±0.12	414	[19] BISHAI	95	CLE2	$e^+e^- \approx \Upsilon(4S)$
−0.96±0.42		ALBRECHT	92	ARG	$e^+e^- \approx 10.4$ GeV
−1.1 ±0.4	86	AVERY	90B	CLEO	$e^+e^- \approx 10.6$ GeV

[19] BISHAI 95 actually gives $\alpha = -0.94^{+0.21}_{-0.06}{}^{+0.12}_{-0.06}$, chopping the errors at the physical limit −1.0. However, for $\alpha \approx -1.0$, some experiments should *get* unphysical values ($\alpha < -1.0$), and for averaging with other measurements such values (or errors that extend below −1.0) should *not* be chopped.

α FOR $\Lambda_c^+ \to \Sigma^+\pi^0$

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT

$\Lambda_c(2593)^+$

$I(J^P) = 0(\frac{1}{2}^-)$ Status: ∗∗∗

Seen in $\Lambda_c^+\pi^+\pi^-$ but not in $\Lambda_c^+\pi^0$, so this is indeed an excited Λ_c^+ rather than a Σ_c^+. The $\Lambda_c^+\pi^+\pi^-$ mode is largely, and perhaps entirely, $\Sigma_c\pi$, which is just at threshold; thus (assuming, as has not yet been proven, that the Σ_c has $J^P = 1/2^+$) the J^P here is almost certainly $1/2^-$. This result is in accord with the theoretical expectation that this is the charm counterpart of the strange $\Lambda(1405)$.

$\Lambda_c(2593)^+$ MASS

The mass is obtained from the $\Lambda_c(2593)^+ - \Lambda_c^+$ mass-difference measurements below.

$\Lambda_c(2593)^+$ DECAY MODES

$\Lambda_c^+\pi\pi$ and its submode $\Sigma_c(2455)\pi$ — the latter just barely — are the only strong decays allowed to an excited Λ_c^+ having this mass; and the submode seems to dominate.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$\Lambda_c^+\pi^+\pi^-$	[a] ≈ 67 %
Γ_2	$\Sigma_c(2455)^{++}\pi^-$	24 ± 7 %
Γ_3	$\Sigma_c(2455)^0\pi^+$	24 ± 7 %
Γ_4	$\Lambda_c^+\pi^+\pi^-$ 3-body	18 ± 10 %
Γ_5	$\Lambda_c^+\pi^0$	not seen
Γ_6	$\Lambda_c^+\gamma$	not seen

[a] Assuming isospin conservation, so that the other third is $\Lambda_c^+\pi^0\pi^0$.

$\Lambda_c(2625)^+$

$I(J^P) = 0(\frac{3}{2}^-)$ Status: ∗∗∗

Seen in $\Lambda_c^+\pi^+\pi^-$ but not in $\Lambda_c^+\pi^0$ so this is indeed an excited Λ_c^+ rather than a Σ_c^+. The spin-parity has not been measured but is expected to be $3/2^-$: this is presumably the charm counterpart of the strange $\Lambda(1520)$.

$\Lambda_c(2625)^+$ MASS

The mass is obtained from the $\Lambda_c(2625)^+ - \Lambda_c^+$ mass-difference measurements below.

Ξ_c^+

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ∗∗∗

According to the quark model, the Ξ_c^+ (quark content usc) and Ξ_c^0 form an isospin doublet, and the spin-parity ought to be $J^P = 1/2^+$. None of I, J, or P has actually been measured.

Ξ_c^+ MASS

The fit uses the Ξ_c^+ and Ξ_c^0 mass and mass-difference measurements.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT

2460 ±25	82	BIAGI	83	SPEC	Σ^- Be 135 GeV

[1] Although COTEUS 87 claims to agree well with BIAGI 83 on the mass and width, there appears to be a discrepancy between the two experiments. BIAGI 83 sees a single peak (stated significance about 6 standard deviations) in the $\Lambda K^-\pi^+\pi^+$ mass spectrum. COTEUS 87 sees *two* peaks in the same spectrum, one at the Ξ_c^+ mass, the other 75 MeV lower. The latter is attributed to $\Xi_c^+ \rightarrow \Sigma^0 K^-\pi^+\pi^+ \rightarrow (\Lambda\gamma)K^-\pi^+\pi^+$, with the γ unseen. The *combined* significance of the double peak is stated to be 5.5 standard deviations. But the absence of any trace of a lower peak in BIAGI 83 seems to us to throw into question the interpretation of the lower peak of COTEUS 87.

Ξ_c^0

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

According to the quark model, the Ξ_c^0 (quark content dsc) and Ξ_c^+ form an isospin doublet, and the spin-parity ought to be $J^P = 1/2^+$. None of I, J, or P has actually been measured.

Ξ_c^0 MASS

The fit uses the Ξ_c^0 and Ξ_c^+ mass and mass-difference measurements.

$\Xi_c'^+$

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

The $\Xi_c'^+$ and $\Xi_c'^0$ presumably complete the SU(3) sextet whose other members are the Σ_c^{++}, Σ_c^+, Σ_c^0, and Ω_c^0: see Fig. 3 in the Note on Charmed Baryons just before the the Λ_c^+ Listings. The quantum numbers given above come from this presumption but have not been measured.

$\Xi_c'^+$ MASS

The mass is obtained from the mass-difference measurement that follows.

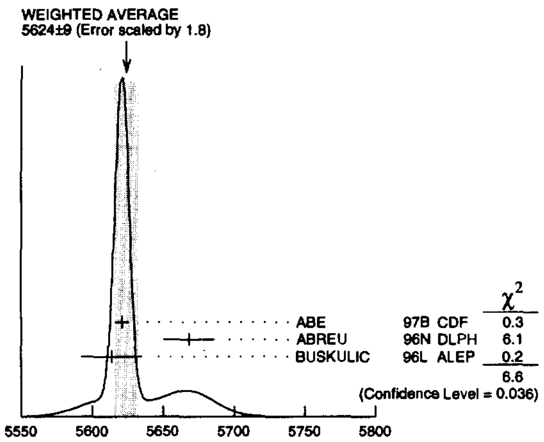
5650^{+150}_{-200}	90	BARI	91 SFM	$\Lambda_b^0 \to \Lambda_c^+\pi^+\pi^-\pi^-$

[1] ABE 97B observed 38 events above a background 18 ± 1.6 events in the mass range 5.60–5.65 GeV/c^2, a significance of > 3.4 standard deviations.
[2] Uses 4 fully reconstructed Λ_b events.
[3] ABE 93B states that, based on the signal claimed by ALBAJAR 91E, CDF should have found 30 ± 23 $\Lambda_b^0 \to J/\psi(1S)\Lambda$ events. Instead, CDF found not more than 2 events.
[4] ALBAJAR 91E claims 16 ± 5 events above a background of 9 ± 1 events, a significance of about 5 standard deviations.



Λ_b^0 mass (MeV)

Λ_b^0 MEAN LIFE

These are actually measurements of the average lifetime of weakly decaying b baryons weighted by generally unknown production rates, branching fractions, and detection efficiencies. Presumably, the mix is mainly Λ_b^0, with some Ξ_b^0 and Ξ_b^-.

See b-baryon Admixture section for data on b-baryon mean life average over species of b-baryon particles.

"OUR EVALUATION" is an average of the data listed below performed by the LEP B Lifetimes Working Group as described in our review "Production and Decay of b-flavored Hadrons" in the $B^\pm$ Section of the Listings. The averaging procedure takes into account correlations between the measurements and asymmetric lifetime errors.

[5] Measured using $\Lambda_c \ell^-$ and $\Lambda \ell^+ \ell^-$.

Λ_b^0 DECAY MODES

These branching fractions are actually an average over weakly decaying b-baryons weighted by their production rates in Z decay (or high-energy $p\overline{p}$), branching ratios, and detection efficiencies. They scale with the LEP b-baryon production fraction B($b \to$ b-baryon) and are evaluated for our value B($b \to$ b-baryon) = (11.6 ± 2.0)%.

The branching fractions B(b-baryon $\to \Lambda \ell^- \overline{\nu}_\ell$anything) and B($\Lambda_b^0 \to \Lambda_c^+ \ell^- \overline{\nu}_\ell$anything) are not pure measurements because the underlying measured products of these with B($b \to$ b-baryon) were used to determine B($b \to$ b-baryon), as described in the note "Production and Decay of b-Flavored Hadrons."

	Mode	Fraction (Γ_i/Γ)	Confidence level
Γ_1	$J/\psi(1S)\Lambda$	$(4.7\pm2.8)\times10^{-4}$

Ξ_b^0, Ξ_b^-

$I(J^P) = 0(\frac{1}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

ABREU 95V observe an excess of same-sign $\Xi^\mp \ell^\mp$ events in jets, which they interpret as $\Xi_b \to \Xi^- \ell^- \overline{\nu}_\ell X$. They find that the probability for these events to come from non-b-baryon decays is less than 5×10^{-4} and that Λ_b decays can account for less than 10% of these events.

In the quark model, Ξ_b^0 and Ξ_b^- are an isodoublet (usb, dsb) state; the lowest Ξ_b^0 and Ξ_b^- ought to have $J^P = 1/2^+$. None of I, J, or P have actually been measured.

Ξ_b MEAN LIFE

This is actually a measurement of the average lifetime of b-baryons that decay to a jet containing a same-sign $\Xi^\mp \ell^\mp$ pair. Presumably the mix is mainly Ξ_b, with some Λ_b.

"OUR EVALUATION" is an average of the data listed below performed by the LEP B Lifetimes Working Group as described in our review "Production and Decay of b-flavored Hadrons" in the $B^\pm$ Section of the Listings. The averaging procedure takes into account correlations between the measurements and asymmetric lifetime errors.

b-baryon ADMIXTURE (Λ_b, Ξ_b, Σ_b, Ω_b)

b-baryon ADMIXTURE MEAN LIFE

Each measurement of the b-baryon mean life is an average over an admixture of various b baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different b-baryon mean life. More b-baryon flavor specific channels are not included in the measurement.

"OUR EVALUATION" is an average of the data listed below performed by the LEP B Lifetimes Working Group as described in our review "Production and Decay of b-flavored Hadrons" in the $B^\pm$ Section of these Listings. The averaging procedure takes into account correlations between the measurements and asymmetric lifetime errors.

SEARCHES FOR MONOPOLES, SUPERSYMMETRY, TECHNICOLOR, COMPOSITENESS, etc.

Magnetic Monopole Searches

MAGNETIC MONOPOLE SEARCHES

Revised December 1997 by D.E. Groom (LBNL).

"At the present time (1975) there is no experimental evidence for the existence of magnetic charges or monopoles, but chiefly because of an early, brilliant theoretical argument by Dirac, the search for monopoles is renewed whenever a new energy region is opened up in high energy physics or a new source of matter, such as rocks from the moon, becomes available [1]." Dirac argued that a monopole anywhere in the universe results in electric charge quantization everywhere, and leads to the prediction of a least magnetic charge $g = e/2\alpha$, the Dirac charge [2]. Recently monopoles have become indispensable in many gauge theories, which endow them with a variety of extraordinarily large masses. The discovery by a candidate event in a single superconducting loop in 1982 [6] stimulated an enormous experimental effort to search for supermassive magnetic monopoles [3,4,5].

Monopole detectors have predominantly used either induction or ionization. Induction experiments measure the monopole magnetic charge and are independent of monopole electric charge, mass, and velocity. Monopole candidate events in single semiconductor loops [6,7] have been detected by this method, but no two-loop coincidence has been observed. Ionization experiments rely on a magnetic charge producing more ionization than an electrical charge with the same velocity. In the case of supermassive monopoles, time-of-flight measurements indicating $v \ll c$ has also been a frequently sought signature.

Cosmic rays are the most likely source of massive monopoles, since accelerator energies are insufficient to produce them. Evidence for such monopoles may also be obtained from astrophysical observations.

Jackson's 1975 assessment remains true. The search is somewhat abated by the lack of success in the 1980's and the decrease of interest in grand unified gauge theories.

[7] AMBROSIO 97 global MACRO 90%CL is 0.78×10^{-15} at $\beta=1.1 \times 10^{-4}$, goes through a minimum at 0.61×10^{-15} near $\beta=(1.1\text{–}2.7) \times 10^{-3}$, then rises to 0.84×10^{-15} at $\beta=0.1$. The global limit in this region is below the Parker bound at 10^{-15}. Less stringent limits are established for $4 \times 10^{-5} < \beta < 1$. Limits set by various triggers in the detector are listed below. All limits assume a catalysis cross section smaller than 10 mb.

[8] AMBROSIO 97 "Scintillator D" (low velocity) 90%CL increases from 4.1×10^{-15} at $\beta=2.7 \times 10^{-3}$ to 14.6×10^{-15} at $\beta=0.006$.

[9] AMBROSIO 97 "Scintillator B" 90%CL (single medium-velocity trigger with two analysis criteria).

[10] AMBROSIO 97 streamer tube 90%CL. Tubes contain helium, and hence trigger is sensitive via the atomic induction mechanism.

[11] AMBROSIO 97 CR39 90%CL improves to 4.3×10^{-15} at $\beta=1.0 \times 10^{-4}$. CR39 is sensitive for $4 \times 10^{-5} < \beta < 1$ except for a window at $0.25 \times 10^{-3} < \beta < 2.1 \times 10^{-3}$. In the middle region other triggers set better limits.

[12] AMBROSIO 97 CR39 90%CL falls to 2.7×10^{-15} at $\beta=1$ and increases at lower velocities. Provides better limit than "Scintillator C" for $0.1 < \beta < 1.0$.

[13] AMBROSIO 97 "Scintillator C" 90%CL, based on high absolute energy loss in two scintillator layers.

[14] AHLEN 94 limit for dyons extends down to β=0.9E−4 and a limit of 1.3E−14 extends to β = 0.8E−4. Also see comment by PRICE 94 and reply of BARISH 94. One loophole in the AHLEN 94 result is that in the case of monopoles catalyzing nucleon decay, relativisitic particles could veto the events. See AMBROSIO 97 for additional results.

[15] Catalysis of nucleon decay; sensitive to assumed catalysis cross section.

[16] ORITO 91 limits are functions of velocity. Lowest limits are given here.

[17] Used DKMPR mechanism and Penning effect.

[18] Assumes monopole attaches fermion nucleus.

[19] Limit from combining data of CAPLIN 86, BERMON 85, INCANDELA 84, and CABRERA 83. For a discussion of controversy about CAPLIN 86 observed event, see GUY 87. Also see SCHOUTEN 87.

[20] Based on lack of high- energy solar neutrinos from catalysis in the sun.

[21] Anomalous long-range α (^{4}He) tracks.

[22] CABRERA 82 candidate event has single Dirac charge within ±5%.

[23] ALVAREZ 75, FLEISCHER 75, and FRIEDLANDER 75 explain as fragmenting nucleus. EBERHARD 75 and ROSS 76 discuss conflict with other experiments. HAGSTROM 77 reinterprets as antinucleus. PRICE 78 reassesses.

[24] Catalysis of nucleon decay.

[25] ADAMS 93 limit based on "survival and growth of a small galactic seed field" is 10^{-16} ($m/10^{17}$ GeV) $cm^{-2}s^{-1}sr^{-1}$. Above 10^{17} GeV, limit 10^{-16} (10^{17} GeV/m) $cm^{-2}s^{-1}sr^{-1}$ (from requirement that monopole density does not overclose the universe) is more stringent.

[26] Re-evaluates PARKER 70 limit for GUT monopoles.

Review

Supersymmetric Particle Searches

SUPERSYMMETRY

Revised October 1999 by Howard E. Haber (Univ. of California, Santa Cruz) Part I, and by M. Schmitt (Harvard Univ.) Part II

This review is divided into two parts:

Supersymmetry, Part I (Theory)

Supersymmetry, Part II (Experiment)

SUPERSYMMETRY, PART I (THEORY)

(by H.E. Haber)

I.1. Introduction: Supersymmetry (SUSY) is a generalization of the space-time symmetries of quantum field theory that transforms fermions into bosons and vice versa. It also provides a framework for the unification of particle physics and gravity [1–3], which is governed by the Planck scale, $M_{\rm P} \approx 10^{19}$ GeV (defined to be the energy scale where the gravitational interactions of elementary particles become comparable to their gauge interactions). If supersymmetry were an exact symmetry of nature, then particles and their superpartners (which differ in spin by half a unit) would be degenerate in mass. Thus, supersymmetry cannot be an exact symmetry of nature, and must be broken. In theories of "low-energy" supersymmetry, the effective scale of supersymmetry breaking is tied to the electroweak scale [4–6], which is characterized by the Standard Model Higgs vacuum expectation value $v = 246$ GeV. It is thus possible that supersymmetry will ultimately explain the origin of the large hierarchy of energy scales from the W and Z masses to the Planck scale.

At present, there are no unambiguous experimental results that require the existence of low-energy supersymmetry. However, if experimentation at future colliders uncovers evidence for supersymmetry, this would have a profound effect on the study of TeV-scale physics and the development of a more fundamental theory of mass and symmetry-breaking phenomena in particle physics.

*I.2. **Structure of the MSSM:*** The minimal supersymmetric extension of the Standard Model (MSSM) consists of taking the Standard Model and adding the corresponding supersymmetric partners [2,7]. In addition, the MSSM contains two hypercharge $Y = \pm 1$ Higgs doublets, which is the minimal structure for the Higgs sector of an anomaly-free supersymmetric extension of the Standard Model. The supersymmetric structure of the theory also requires (at least) two Higgs doublets to generate mass for both "up"-type and "down"-type quarks (and charged leptons) [8,9]. All renormalizable supersymmetric interactions consistent with (global) B–L conservation (B =baryon number and L =lepton number) are included. Finally, the most general soft-supersymmetry-breaking terms are added [10].

If supersymmetry is associated with the origin of the scale of electroweak interactions, then the mass parameters introduced by the soft-supersymmetry-breaking terms must in general be of order 1 TeV or below [11] (although models have been proposed in which some supersymmetric particle masses can be larger, in the range of 1–10 TeV [12]). Some lower bounds on these parameters exist due to the absence of supersymmetric-particle production at current accelerators [13]. Additional constraints arise from limits on the contributions of virtual supersymmetric particle exchange to a variety of Standard Model processes [14,15]. In particular, the Standard Model fit (without supersymmetry) to precision electroweak data is quite good [16]. If all supersymmetric particle masses are significantly heavier than m_Z (in practice, masses greater than 300 GeV are sufficient [17]), then the effects of the supersymmetric particles decouple in loop-corrections to electroweak observables [18]. In this case the Standard Model global fit to precision data and the corresponding MSSM fit yield similar results. On the other hand, regions of parameter space with light supersymmetric particle masses can generate significant one-loop corrections, resulting in a poorer overall fit to the data [19]. Thus, the precision electroweak data provide some constraints on the magnitude of the soft-supersymmetry-breaking terms.

As a consequence of B–L invariance, the MSSM possesses a multiplicative R-parity invariance, where $R = (-1)^{3(B-L)+2S}$ for a particle of spin S [20]. Note that this formula implies that all the ordinary Standard Model particles have even R-parity, whereas the corresponding supersymmetric partners have odd R-parity. The conservation of R-parity in scattering and decay processes has a crucial impact on supersymmetric phenomenology. For example, starting from an initial state involving ordinary (R-even) particles, it follows that supersymmetric particles must be produced in pairs. In general, these particles are highly unstable and decay quickly into lighter states. However, R-parity invariance also implies that the lightest supersymmetric particle (LSP) is absolutely stable, and must eventually be produced at the end of a decay chain initiated by the decay of a heavy unstable supersymmetric particle.

In order to be consistent with cosmological constraints, a stable LSP is almost certainly electrically and color neutral [21]. Consequently, the LSP in a R-parity-conserving theory is weakly-interacting in ordinary matter, *i.e.* it behaves like a stable heavy neutrino and will escape detectors without being directly observed. Thus, the canonical signature for conventional R-parity-conserving supersymmetric theories is missing (transverse) energy, due to the escape of the LSP. Moreover, the LSP is a prime candidate for "cold dark matter" [22], a potentially important component of the non-baryonic dark matter that is required in many models of cosmology and galaxy formation [23].

In the MSSM, supersymmetry breaking is accomplished by including the most general renormalizable soft-supersymmetry-breaking terms consistent with the SU(3)×SU(2)×U(1) gauge symmetry and R-parity invariance. These terms parameterize our ignorance of the fundamental mechanism of supersymmetry breaking. If supersymmetry breaking occurs spontaneously, then a massless Goldstone fermion called the *goldstino* ($\widetilde{G}$) must exist. The goldstino would then be the LSP and could play an important role in supersymmetric phenomenology [24]. However, the goldstino is a physical degree of freedom only in models of spontaneously broken global supersymmetry. If the supersymmetry is a local symmetry, then the theory must incorporate gravity; the resulting theory is called supergravity. In models of spontaneously broken supergravity, the goldstino is "absorbed" by the *gravitino* ($\widetilde{g}_{3/2}$), the spin-3/2 partner of the graviton [25]. By this super-Higgs mechanism, the goldstino is removed from the physical spectrum and the gravitino acquires a mass ($m_{3/2}$).

It is very difficult (perhaps impossible) to construct a model of spontaneously-broken low-energy supersymmetry where the supersymmetry breaking arises solely as a consequence of the interactions of the particles of the MSSM. A more viable scheme posits a theory consisting of at least two distinct sectors: a "hidden" sector consisting of particles that are completely neutral with respect to the Standard Model gauge group, and a "visible" sector consisting of the particles of the MSSM. There are no renormalizable tree-level interactions between particles of the visible and hidden sectors. Supersymmetry breaking is assumed to occur in the hidden sector, and then transmitted to the MSSM by some mechanism. Two theoretical scenarios have been examined in detail: gravity-mediated and gauge-mediated supersymmetry breaking.

Supergravity models provide a natural mechanism for transmitting the supersymmetry breaking of the hidden sector to the particle spectrum of the MSSM. In models of *gravity-mediated* supersymmetry breaking, gravity is the messenger of supersymmetry breaking [26,27]. More precisely, supersymmetry breaking is mediated by effects of gravitational strength (suppressed by an inverse power of the Planck mass). In this scenario, the gravitino mass is of order the electroweak-symmetry-breaking scale, while its couplings are roughly gravitational in strength [1,28]. Such a gravitino would play no role in supersymmetric phenomenology at colliders.

In *gauge-mediated* supersymmetry breaking, supersymmetry breaking is transmitted to the MSSM via gauge forces. A typical structure of such models involves a hidden sector where supersymmetry is broken, a "messenger sector" consisting of particles (messengers) with SU(3)×SU(2)×U(1) quantum numbers, and the visible sector consisting of the fields of the MSSM [29,30]. The direct coupling of the messengers to the hidden sector generates a supersymmetry breaking spectrum in the messenger sector. Finally, supersymmetry breaking is transmitted to the MSSM via the virtual exchange of the messengers. If this approach is extended to incorporate gravitational phenomena, then supergravity effects will also contribute to supersymmetry breaking. However, in models of gauge-mediated supersymmetry breaking, one usually chooses the model parameters in such a way that the virtual exchange of the messengers dominates the effects of the direct gravitational interactions between the hidden and visible sectors. In this scenario, the gravitino mass is typically in the eV to keV range, and is therefore the LSP. The helicity $\pm\frac{1}{2}$ components of $\widetilde{g}_{3/2}$ behave approximately like the goldstino; its coupling to the particles of the MSSM is significantly stronger than a coupling of gravitational strength.

I.3. Parameters of the MSSM: The parameters of the MSSM are conveniently described by considering separately the supersymmetry-conserving sector and the supersymmetry-breaking sector. A careful discussion of the conventions used in defining the MSSM parameters can be found in Ref. 31. For simplicity, consider the case of one generation of quarks, leptons, and their scalar superpartners. The parameters of the supersymmetry-conserving sector consist of: (i) gauge couplings: g_s, g, and g', corresponding to the Standard Model gauge group SU(3)×SU(2)×U(1) respectively; (ii) a supersymmetry-conserving Higgs mass parameter μ; and (iii) Higgs-fermion Yukawa coupling constants: λ_u, λ_d, and λ_e (corresponding to the coupling of one generation of quarks, leptons, and their superpartners to the Higgs bosons and higgsinos).

The supersymmetry-breaking sector contains the following set of parameters: (i) gaugino Majorana masses M_3, M_2 and M_1 associated with the SU(3), SU(2), and U(1) subgroups of the Standard Model; (ii) five scalar squared-mass parameters for the squarks and sleptons, $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, $M^2_{\widetilde{L}}$, and $M^2_{\widetilde{E}}$ [corresponding to the five electroweak gauge multiplets, *i.e.*, superpartners of $(u,d)_L$, u^c_L, d^c_L, $(\nu, e^-)_L$, and e^c_L]; (iii) Higgs-squark-squark and Higgs-slepton-slepton trilinear interaction terms, with coefficients A_u, A_d, and A_e (these are the so-called "A-parameters"); and (iv) three scalar Higgs squared-mass parameters—two of which contribute to the diagonal Higgs squared-masses, given by $m_1^2 + |\mu|^2$ and $m_2^2 + |\mu|^2$, and one off-diagonal Higgs squared-mass term, $m_{12}^2 \equiv B\mu$ (which defines the "B-parameter"). These three squared-mass parameters can be re-expressed in terms of the two Higgs vacuum expectation values, v_d and v_u, and one physical Higgs mass. Here, v_d (v_u) is the vacuum expectation value of the Higgs field which couples exclusively to down-type (up-type) quarks and leptons. (Another notation often employed in the literature is $v_1 \equiv v_d$ and $v_2 \equiv v_u$.) Note that $v_d^2 + v_u^2 = (246\ \mathrm{GeV})^2$ is fixed by the W mass, while the ratio

$$\tan\beta = v_u/v_d \tag{1}$$

is a free parameter of the model.

The total number of degrees of freedom of the MSSM is quite large, primarily due to the parameters of the soft-supersymmetry-breaking sector. In particular, in the case of three generations of quarks, leptons, and their superpartners, $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, $M^2_{\widetilde{L}}$, and $M^2_{\widetilde{E}}$ are hermitian 3×3 matrices, and the A-parameters are complex 3×3 matrices. In addition, M_1, M_2, M_3, B and μ are in general complex. Finally, as in the Standard Model, the Higgs-fermion Yukawa couplings, λ_f ($f = u$, d, and e), are complex 3×3 matrices which are related to the quark and lepton mass matrices via: $M_f = \lambda_f v_f/\sqrt{2}$, where $v_e \equiv v_d$ (with v_u and v_d as defined above). However, not all these parameters are physical. Some of the MSSM parameters can be eliminated by expressing interaction eigenstates in terms of the mass eigenstates, with an appropriate redefinition of the MSSM fields to remove unphysical degrees of freedom. The analysis of Ref. 32 shows that the MSSM possesses 124 truly independent parameters. Of these, 18 parameters correspond to Standard Model parameters (including the QCD vacuum angle θ_{QCD}), one corresponds to a Higgs sector parameter (the analogue of the Standard Model Higgs mass), and 105 are genuinely new parameters of the model. The latter include: five real parameters and three CP-violating phases in the gaugino/higgsino sector, 21 squark and slepton masses, 36 new real mixing angles to define the squark and slepton mass eigenstates and 40 new CP-violating phases that can appear in squark and slepton interactions. The most general R-parity-conserving minimal supersymmetric extension of the Standard Model (without additional theoretical assumptions) will be denoted henceforth as MSSM-124 [33].

I.4. The supersymmetric-particle sector: Consider the sector of supersymmetric particles (*sparticles*) in the MSSM. The supersymmetric partners of the gauge and Higgs bosons are fermions, whose names are obtained by appending "ino" at the end of the corresponding Standard Model particle name. The *gluino* is the color octet Majorana fermion partner of the gluon with mass $M_{\widetilde{g}} = |M_3|$. The supersymmetric partners of the electroweak gauge and Higgs bosons (the *gauginos* and *higgsinos*) can mix. As a result, the physical mass eigenstates are model-dependent linear combinations of these states, called *charginos* and *neutralinos*, which are obtained by diagonalizing the corresponding mass matrices. The chargino-mass matrix depends on M_2, μ, $\tan\beta$ and m_W [34].

The corresponding chargino-mass eigenstates are denoted by $\widetilde{\chi}_1^+$ and $\widetilde{\chi}_2^+$, with masses

$$M^2_{\widetilde{\chi}_1^+,\widetilde{\chi}_2^+} = \tfrac{1}{2}\Bigg\{|\mu|^2 + |M_2|^2 + 2m_W^2 \mp \Big[\left(|\mu|^2 + |M_2|^2 + 2m_W^2\right)^2 - 4|\mu|^2|M_2|^2 - 4m_W^4 \sin^2 2\beta + 8m_W^2 \sin 2\beta \,\mathrm{Re}(\mu M_2)\Big]^{1/2}\Bigg\}, \quad (2)$$

where the states are ordered such that $M_{\widetilde{\chi}_1^+} \leq M_{\widetilde{\chi}_2^+}$. If CP-violating effects are neglected (in which case, M_2 and μ are real parameters), then one can choose a convention where $\tan\beta$ and M_2 are positive. (Note that the relative sign of M_2 and μ is meaningful. The sign of μ is convention-dependent; the reader is warned that both sign conventions appear in the literature.) The sign convention for μ implicit in Eq. (2) is used by the LEP collaborations [13] in their plots of exclusion contours in the M_2 *vs.* μ plane derived from the non-observation of $e^+e^- \to \widetilde{\chi}_1^+\widetilde{\chi}_1^-$.

The neutralino mass matrix depends on M_1, M_2, μ, $\tan\beta$, m_Z, and the weak mixing angle θ_W [34]. The corresponding neutralino eigenstates are usually denoted by $\widetilde{\chi}_i^0$ ($i = 1,\ldots 4$), according to the convention that $M_{\widetilde{\chi}_1^0} \leq M_{\widetilde{\chi}_2^0} \leq M_{\widetilde{\chi}_3^0} \leq M_{\widetilde{\chi}_4^0}$. If a chargino or neutralino eigenstate approximates a particular gaugino or higgsino state, it is convenient to employ the corresponding nomenclature. Specifically, if M_1 and M_2 are small compared to m_Z and $|\mu|$, then the lightest neutralino $\widetilde{\chi}_1^0$ would be nearly a pure *photino*, $\widetilde{\gamma}$, the supersymmetric partner of the photon. If M_1 and m_Z are small compared to M_2 and $|\mu|$, then the lightest neutralino would be nearly a pure *bino*, $\widetilde{B}$, the supersymmetric partner of the weak hypercharge gauge boson. If M_2 and m_Z are small compared to M_1 and $|\mu|$, then the lightest chargino pair and neutralino would constitute a triplet of roughly mass-degenerate pure *winos*, $\widetilde{W}^\pm$ and $\widetilde{W}_3^0$, the supersymmetric partners of the weak SU(2) gauge bosons. Finally, if $|\mu|$ and m_Z are small compared to M_1 and M_2, then the lightest neutralino would be nearly a pure *higgsino*. Each of the above cases leads to a strikingly different phenomenology.

The supersymmetric partners of the quarks and leptons are spin-zero bosons: the *squarks*, charged *sleptons*, and *sneutrinos*. For simplicity, only the one-generation case is illustrated below (using first-generation notation). For a given fermion f, there are two supersymmetric partners $\widetilde{f}_L$ and $\widetilde{f}_R$ which are scalar partners of the corresponding left and right-handed fermion. (There is no $\widetilde{\nu}_R$ in the MSSM.) However, in general, $\widetilde{f}_L$ and $\widetilde{f}_R$ are not mass-eigenstates since there is $\widetilde{f}_L$-$\widetilde{f}_R$ mixing which is proportional in strength to the corresponding element of the scalar squared-mass matrix [35]

$$M_{LR}^2 = \begin{cases} m_d(A_d - \mu\tan\beta), & \text{for "down"-type } f \\ m_u(A_u - \mu\cot\beta), & \text{for "up"-type } f, \end{cases} \quad (3)$$

where m_d (m_u) is the mass of the appropriate "down" ("up") type quark or lepton. The signs of the A-parameters are also convention-dependent; see Ref. 31. Due to the appearance of the *fermion* mass in Eq. (3), one expects M_{LR} to be small compared to the diagonal squark and slepton masses, with the possible exception of the top-squark, since m_t is large, and the bottom-squark and tau-slepton if $\tan\beta \gg 1$.

The (diagonal) L- and R-type squark and slepton squared-masses are given by

$$M^2_{\widetilde{f}_L} = M^2_{\widetilde{F}} + m_f^2 + (T_{3f} - e_f \sin^2\theta_W) m_Z^2 \cos 2\beta\,,$$
$$M^2_{\widetilde{f}_R} = M^2_{\widetilde{R}} + m_f^2 + e_f \sin^2\theta_W m_Z^2 \cos 2\beta\,, \quad (4)$$

where $M^2_{\widetilde{F}} \equiv M^2_{\widetilde{Q}}$ [$M^2_{\widetilde{L}}$] for $\widetilde{u}_L$ and $\widetilde{d}_L$ [$\widetilde{\nu}_L$ and $\widetilde{e}_L$], and $M^2_{\widetilde{R}} \equiv M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$ and $M^2_{\widetilde{E}}$ for $\widetilde{u}_R$, $\widetilde{d}_R$, and $\widetilde{e}_R$, respectively. In addition, $e_f = \frac{2}{3}, -\frac{1}{3}, 0, -1$ for $f = u$, d, ν, and e, respectively, $T_{3f} = \frac{1}{2}$ [$-\frac{1}{2}$] for up-type [down-type] squarks and sleptons, and m_f is the corresponding quark or lepton mass. Squark and slepton mass eigenstates, generically called $\widetilde{f}_1$ and $\widetilde{f}_2$ (these are linear combinations of $\widetilde{f}_L$ and $\widetilde{f}_R$), are obtained by diagonalizing the corresponding 2×2 squared-mass matrices.

In the case of three generations, the general analysis is more complicated. The scalar squared-masses [$M^2_{\widetilde{F}}$ and $M^2_{\widetilde{R}}$ in Eq. (4)], the fermion masses m_f and the A-parameters are now 3×3 matrices as noted in Section I.3. Thus, to obtain the squark and slepton mass eigenstates, one must diagonalize 6×6 mass matrices. As a result, intergenerational mixing is possible, although there are some constraints from the nonobservation of FCNC's [14,15]. In practice, because off-diagonal scalar mixing is appreciable only for the third generation, this additional complication can usually be neglected.

It should be noted that all mass formulae quoted in this section are tree-level results. One-loop corrections will modify all these results, and eventually must be included in any precision study of supersymmetric phenomenology [36].

I.5. The Higgs sector of the MSSM: Next, consider the Higgs sector of the MSSM [8,9,37]. Despite the large number of potential CP-violating phases among the MSSM-124 parameters, one can show that the tree-level MSSM Higgs sector is automatically CP-conserving. That is, unphysical phases can be absorbed into the definition of the Higgs fields such that $\tan\beta$ is a real parameter (conventionally chosen to be positive). Moreover, the physical neutral Higgs scalars are CP eigenstates. There are five physical Higgs particles in this model: a charged Higgs boson pair ($H^\pm$), two CP-even neutral Higgs bosons (denoted by H_1^0 and H_2^0 where $m_{H_1^0} \leq m_{H_2^0}$) and one CP-odd neutral Higgs boson (A^0).

The properties of the Higgs sector are determined by the Higgs potential, which is made up of quadratic terms [whose squared-mass coefficients were mentioned above Eq. (1)] and quartic interaction terms. The strengths of the interaction terms are directly related to the gauge couplings by supersymmetry (and are not affected at tree-level by supersymmetry breaking). As a result, $\tan\beta$ [defined in Eq. (1)] and one Higgs mass determine the tree-level Higgs-sector parameters. These include the Higgs masses, an angle α [which measures the component of the original $Y = \pm 1$ Higgs doublet states in the physical CP-even neutral scalars], and the Higgs boson couplings.

When one-loop radiative corrections are incorporated, additional parameters of the supersymmetric model enter via virtual loops. The impact of these corrections can be significant [38]. For example, at tree-level, MSSM-124 predicts $m_{H_1^0} \leq m_Z|\cos 2\beta| \leq m_Z$ [8,9]. If this prediction were unmodified, it would imply that H_1^0 must be discovered at the LEP collider (running at its maximum energy and luminosity); otherwise MSSM-124 would be ruled out. However, when radiative corrections are included, the light Higgs-mass upper bound may be significantly increased. The qualitative behavior of the radiative corrections can be most easily seen in the large top-squark mass limit, where in addition, both the splitting of the two diagonal entries [Eq. (4)] and the two off-diagonal entries [Eq. (3)] of the top-squark squared-mass matrix are small in comparison to the average of the two top-squark squared-masses, $M_S^2 \equiv \frac{1}{2}(M_{\tilde{t}_1}^2 + M_{\tilde{t}_2}^2)$. In this case (assuming $m_{A^0} > m_Z$), the upper bound on the lightest CP-even Higgs mass at one-loop is approximately given by

$$m_{H_1^0}^2 \lesssim m_Z^2 + \frac{3g^2 m_t^4}{8\pi^2 m_W^2}\left\{\ln\left(M_S^2/m_t^2\right) + \frac{X_t^2}{M_S^2}\left(1 - \frac{X_t^2}{12M_S^2}\right)\right\}, \quad (5)$$

where $X_t \equiv A_t - \mu\cot\beta$ is the top-squark mixing factor [see Eq. (3)]. A more complete treatment of the radiative corrections [39] shows that Eq. (5) somewhat overestimates the true upper bound of $m_{H_1^0}$. These more refined computations, which incorporate renormalization group improvement and the leading two-loop contributions, yield $m_{H_1^0} \lesssim 130$ GeV (with an accuracy of a few GeV) for $m_t = 175$ GeV and $M_S \lesssim 1$ TeV [39].

In addition, one-loop radiative corrections can also introduce CP-violating effects in the Higgs sector, which depend on some of the CP-violating phases among the MSSM-124 parameters [40]. Although these effects are more model-dependent, they can have a non-trivial impact on the Higgs searches at LEP and future colliders.

I.6. Reducing the MSSM parameter freedom: Even in the absence of a fundamental theory of supersymmetry breaking, one is hard-pressed to regard MSSM-124 as a fundamental theory. For example, no fundamental explanation is provided for the origin of electroweak symmetry breaking. Moreover, MSSM-124 is not a phenomenologically viable theory over most of its parameter space. Among the phenomenologically deficiencies are: (i) no conservation of the separate lepton numbers L_e, L_μ, and L_τ; (ii) unsuppressed FCNC's; and (iii) new sources of CP-violation that are inconsistent with the experimental bounds. As a result, almost the entire MSSM-124 parameter space is ruled out! This theory is viable only at very special "exceptional" points of the full parameter space.

MSSM-124 is also theoretically deficient since it provides no explanation for the origin of the supersymmetry-breaking parameters (and in particular, why these parameters should conform to the exceptional points of the parameter space mentioned above). Moreover, the MSSM contains many new sources of CP violation. For example, some combination of the complex phases of the gaugino-mass parameters, the A-parameters, and μ must be less than of order 10^{-2}–10^{-3} (for a supersymmetry-breaking scale of 100 GeV) to avoid generating electric dipole moments for the neutron, electron, and atoms in conflict with observed data [41,42].

There are two general approaches for reducing the parameter freedom of MSSM-124. In the low-energy approach, an attempt is made to elucidate the nature of the exceptional points in the MSSM-124 parameter space that are phenomenologically viable. Consider the following two possible choices. First, one can assume that $M_{\tilde{Q}}^2$, $M_{\tilde{U}}^2$, $M_{\tilde{D}}^2$, $M_{\tilde{L}}^2$, $M_{\tilde{E}}^2$ and the matrix A-parameters are generation-independent (horizontal universality [5,32,43]). Alternatively, one can simply require that all the aforementioned matrices are flavor diagonal in a basis where the quark and lepton mass matrices are diagonal (flavor alignment [44]). In either case, L_e, L_μ, and L_τ are separately conserved, while tree-level FCNC's are automatically absent. In both cases, the number of free parameters characterizing the MSSM is substantially less than 124. Both scenarios are phenomenologically viable, although there is no strong theoretical basis for either scenario.

In the high-energy approach, one treats the parameters of the MSSM as running parameters and imposes a particular structure on the soft-supersymmetry-breaking terms at a common high-energy scale [such as the Planck scale ($M_{\rm P}$)]. Using the renormalization group equations, one can then derive the low-energy MSSM parameters. The initial conditions (at the appropriate high-energy scale) for the renormalization group equations depend on the mechanism by which supersymmetry breaking is communicated to the effective low energy theory. Examples of this scenario are provided by models of gravity-mediated and gauge-mediated supersymmetry breaking (see Section I.2). One bonus of such an approach is that one of the diagonal Higgs squared-mass parameters is typically driven negative by renormalization group evolution. Thus, electroweak symmetry breaking is generated radiatively, and the resulting electroweak symmetry-breaking scale is intimately tied to the scale of low-energy supersymmetry breaking.

One prediction of the high-energy approach that arises in most grand unified supergravity models and gauge-mediated supersymmetry-breaking models is the unification of gaugino mass parameters at some high-energy scale $M_{\rm X}$, *i.e.*,

$$M_1(M_X) = M_2(M_X) = M_3(M_X) = m_{1/2}\,. \quad (6)$$

Consequently, the effective low-energy gaugino mass parameters (at the electroweak scale) are related:

$$M_3 = (g_s^2/g^2)M_2\,, \qquad M_1 = (5g'^2/3g^2)M_2 \simeq 0.5M_2\,. \quad (7)$$

In this case, the chargino and neutralino masses and mixing angles depend only on three unknown parameters: the gluino mass, μ, and $\tan\beta$. If in addition $|\mu| \gg M_1$, m_Z, then the lightest neutralino is nearly a pure bino, an assumption often made in supersymmetric particle searches at colliders.

Recently, attention has been given to a class of supergravity models in which Eq. (7) does not hold. In models where no tree-level gaugino masses are generated, one finds a model-independent contribution to the gaugino mass whose origin can be traced to the super-conformal (super-Weyl) anomaly which is common to all supergravity models [45]. This approach has been called *anomaly-mediated* supersymmetry breaking. Eq. (7) is then replaced (in the one-loop approximation) by:

$$M_i \simeq \frac{b_i g_i^2}{16\pi^2} m_{3/2}\,, \qquad (8)$$

where $m_{3/2}$ is the gravitino mass (assumed to be of order 1 TeV), and b_i are the coefficients of the MSSM gauge beta-functions corresponding to the corresponding U(1), SU(2) and SU(3) gauge groups: $(b_1, b_2, b_3) = (\frac{33}{5}, 1, -3)$. Eq. (8) yields $M_1 \simeq 2.8 M_2$ and $M_3 \simeq -8.3 M_2$, which implies that the lightest chargino pair and neutralino make up a nearly-mass degenerate triplet of winos. The corresponding supersymmetric phenomenology differs significantly from the standard phenomenology based on Eq. (7), and is explored in detail in Ref. [46]. Anomaly-mediated supersymmetry breaking also generates (approximate) flavor-diagonal squark and slepton mass matrices. However, in the MSSM this cannot be the sole source of supersymmetry-breaking in the slepton sector (which yields negative squared-mass contributions for the sleptons).

I.7. The constrained MSSMs: mSUGRA, GMSB, and SGUTs: One way to guarantee the absence of significant FCNC's mediated by virtual supersymmetric-particle exchange is to posit that the diagonal soft-supersymmetry-breaking scalar squared-masses are universal at some energy scale. In models of gauge-mediated supersymmetry breaking, scalar squared-masses are expected to be flavor independent since gauge forces are flavor-blind. In the *minimal* supergravity (mSUGRA) framework [1–3], the soft-supersymmetry-breaking parameters at the Planck scale take a particularly simple form in which the scalar squared-masses and the A-parameters are flavor diagonal and universal [26]:

$$\begin{aligned}
&M^2_{\widetilde{Q}}(M_{\rm P}) = M^2_{\widetilde{U}}(M_{\rm P}) = M^2_{\widetilde{D}}(M_{\rm P}) = m_0^2 \mathbf{1}\,,\\
&M^2_{\widetilde{L}}(M_{\rm P}) = M^2_{\widetilde{E}}(M_{\rm P}) = m_0^2 \mathbf{1}\,,\\
&m_1^2(M_{\rm P}) = m_2^2(M_{\rm P}) = m_0^2\,,\\
&A_U(M_{\rm P}) = A_D(M_{\rm P}) = A_L(M_{\rm P}) = A_0 \mathbf{1}\,,
\end{aligned} \qquad (9)$$

where $\mathbf{1}$ is a 3×3 identity matrix in generation space. Renormalization group evolution is then used to derive the values of the supersymmetric parameters at the low-energy (electroweak) scale. For example, to compute squark and slepton masses, one must use the *low-energy* values for $M^2_{\widetilde{F}}$ and $M^2_{\widetilde{R}}$ in Eq. (4). Through the renormalization group running with boundary conditions specified in Eq. (7) and Eq. (9), one can show that the low-energy values of $M^2_{\widetilde{F}}$ and $M^2_{\widetilde{R}}$ depend primarily on m_0^2 and $m_{1/2}^2$. A number of useful approximate analytic expressions for superpartner masses in terms of the mSUGRA parameters can be found in Ref. 47.

Clearly, in the mSUGRA approach, the MSSM-124 parameter freedom has been sharply reduced. For example, typical mSUGRA models give low-energy values for the scalar mass parameters that satisfy $M_{\widetilde{L}} \approx M_{\widetilde{E}} < M_{\widetilde{Q}} \approx M_{\widetilde{U}} \approx M_{\widetilde{D}}$ with the squark mass parameters somewhere between a factor of 1–3 larger than the slepton mass parameters (*e.g.*, see Ref. 47). More precisely, the low-energy values of the squark mass parameters of the first two generations are roughly degenerate, while $M_{\widetilde{Q}_3}$ and $M_{\widetilde{U}_3}$ are typically reduced by a factor of 1–3 from the values of the first and second generation squark mass parameters because of renormalization effects due to the heavy top quark mass.

As a result, one typically finds that four flavors of squarks (with two squark eigenstates per flavor) and $\widetilde{b}_R$ are nearly mass-degenerate. The $\widetilde{b}_L$ mass and the diagonal $\widetilde{t}_L$ and $\widetilde{t}_R$ masses are reduced compared to the common squark mass of the first two generations. (If $\tan\beta \gg 1$, then the pattern of third generation squark masses is somewhat altered; *e.g.*, see Ref. 48.) In addition, there are six flavors of nearly mass-degenerate sleptons (with two slepton eigenstates per flavor for the charged sleptons and one per flavor for the sneutrinos); the sleptons are expected to be somewhat lighter than the mass-degenerate squarks. Finally, third generation squark masses and tau-slepton masses are sensitive to the strength of the respective $\widetilde{f}_L$–$\widetilde{f}_R$ mixing as discussed below Eq. (3).

Due to the implicit $m_{1/2}$ dependence in the low-energy values of $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$ and $M^2_{\widetilde{D}}$, there is a tendency for the gluino in mSUGRA models to be lighter than the first and second generation squarks. Moreover, the LSP is typically the lightest neutralino, $\widetilde{\chi}_1^0$, which is dominated by its bino component. However, there are some regions of mSUGRA parameter space where the above conclusions do not hold. For example, one can reject those mSUGRA parameter regimes in which the LSP is a chargino.

One can count the number of independent parameters in the mSUGRA framework. In addition to 18 Standard Model parameters (excluding the Higgs mass), one must specify m_0, $m_{1/2}$, A_0, and Planck-scale values for μ and B-parameters (denoted by μ_0 and B_0). In principle, A_0, B_0 and μ_0 can be complex, although in the mSUGRA approach, these parameters are taken (arbitrarily) to be real. As previously noted, renormalization group evolution is used to compute the low-energy values of the mSUGRA parameters, which then fixes all the parameters of the low-energy MSSM. In particular, the two Higgs vacuum expectation values (or equivalently, m_Z and $\tan\beta$) can be expressed as a function of the Planck-scale supergravity parameters. The simplest procedure is to remove μ_0 and B_0 in favor of m_Z and $\tan\beta$ (the sign of μ_0 is not fixed in this process). In this case, the MSSM spectrum and its interaction strengths are determined by five parameters: m_0, A_0, $m_{1/2}$, $\tan\beta$, and the sign of μ_0, in addition to the 18 parameters of the Standard Model. However, the mSUGRA approach is probably too simplistic. Theoretical considerations suggest that the universality of Planck-scale soft-supersymmetry-breaking parameters is not generic [49].

In the minimal gauge-mediated supersymmetry-breaking (GMSB) approach, there is one effective mass scale, Λ, that determines all low-energy scalar and gaugino mass parameters through loop-effects (while the resulting A-parameters are suppressed). In order that the resulting superpartner masses be of order 1 TeV or less, one must have $\Lambda \sim 100$ TeV. The origin of the μ and B-parameters is quite model dependent and lies somewhat outside the ansatz of gauge-mediated supersymmetry breaking. The simplest models of this type are even more restrictive than mSUGRA, with two fewer degrees of freedom. However, minimal GMSB is not a fully realized model. The sector of supersymmetry-breaking dynamics can be very complex, and no complete model of gauge-mediated supersymmetry yet exists that is both simple and compelling.

It was noted in Section I.2 that the gravitino is the LSP in GMSB models. Thus, in such models, the next-to-lightest supersymmetric particle (NLSP) plays a crucial role in the phenomenology of supersymmetric particle production and decay. Note that unlike the LSP, the NLSP can be charged. In GMSB models, the most likely candidates for the NLSP are $\widetilde{\chi}_1^0$ and $\widetilde{\tau}_R^\pm$. The NLSP will decay into its superpartner plus a gravitino (*e.g.*, $\widetilde{\chi}_1^0 \to \gamma\widetilde{g}_{3/2}$, $\widetilde{\chi}_1^0 \to Z\widetilde{g}_{3/2}$ or $\widetilde{\tau}_R^\pm \to \tau^\pm\widetilde{g}_{3/2}$), with lifetimes and branching ratios that depend on the model parameters.

Different choices for the identity of the NLSP and its decay rate lead to a variety of distinctive supersymmetric phenomenologies [30,50]. For example, a long-lived $\widetilde{\chi}_1^0$-NLSP that decays outside collider detectors leads to supersymmetric decay chains with missing energy in association with leptons and/or hadronic jets (this case is indistinguishable from the canonical phenomenology of the $\widetilde{\chi}_1^0$-LSP). On the other hand, if $\widetilde{\chi}_1^0 \to \gamma\widetilde{g}_{3/2}$ is the dominant decay mode, and the decay occurs inside the detector, then nearly *all* supersymmetric particle decay chains would contain a photon. In contrast, the case of a $\widetilde{\tau}_R^\pm$-NLSP would lead either to a new long-lived charged particle (*i.e.*, the $\widetilde{\tau}_R^\pm$) or to supersymmetric particle decay chains with τ-leptons.

Finally, grand unification can impose additional constraints on the MSSM parameters. Perhaps one of the most compelling hints for low-energy supersymmetry is the unification of SU(3)×SU(2)×U(1) gauge couplings predicted by models of supersymmetric grand unified theories (SGUTs) [5,51] (with the supersymmetry-breaking scale of order 1 TeV or below). Gauge coupling unification, which takes place at an energy scale of order 10^{16} GeV, is quite robust (*i.e.*, the unification depends weakly on the details of the theory at the unification scale). In particular, given the low-energy values of the electroweak couplings $g(m_Z)$ and $g'(m_Z)$, one can predict $\alpha_s(m_Z)$ by using the MSSM renormalization group equations to extrapolate to higher energies and imposing the unification condition on the three gauge couplings at some high-energy scale, M_X. This procedure (which fixes M_X) can be successful (*i.e.*, three running couplings will meet at a single point) only for a unique value of $\alpha_s(m_Z)$. The extrapolation depends somewhat on the low-energy supersymmetric spectrum (so-called low-energy "threshold effects") and on the SGUT spectrum (high-energy threshold effects), which can somewhat alter the evolution of couplings. Ref. [52] summarizes the comparison of present data with the expectations of SGUTs, and shows that the measured value of $\alpha_s(m_Z)$ is in good agreement with the predictions of supersymmetric grand unification for a reasonable choice of supersymmetric threshold corrections.

Additional SGUT predictions arise through the unification of the Higgs-fermion Yukawa couplings (λ_f). There is some evidence that $\lambda_b = \lambda_\tau$ leads to good low-energy phenomenology [53], and an intriguing possibility that $\lambda_b = \lambda_\tau = \lambda_t$ may be phenomenologically viable [54,48] in the parameter regime where $\tan\beta \simeq m_t/m_b$. Finally, grand unification imposes constraints on the soft-supersymmetry-breaking parameters. For example, gaugino-mass unification leads to the relations given in Eq. (7). Diagonal squark and slepton soft-supersymmetry-breaking scalar masses may also be unified, which is analogous to the unification of Higgs-fermion Yukawa couplings.

In the absence of a fundamental theory of supersymmetry breaking, further progress will require a detailed knowledge of the supersymmetric-particle spectrum in order to determine the nature of the high-energy parameters. Of course, any of the theoretical assumptions described in this section could be wrong and must eventually be tested experimentally.

I.8. Beyond the MSSM: Non-minimal models of low-energy supersymmetry can also be constructed. One approach is to add new structure beyond the Standard Model at the TeV scale or below. The supersymmetric extension of such a theory would be a non-minimal extension of the MSSM. Possible new structures include: (i) the supersymmetric generalization of the see-saw model of neutrino masses [55,56]; (ii) an enlarged electroweak gauge group beyond SU(2)×U(1) [57]; (iii) the addition of new, possibly exotic, matter multiplets [*e.g.*, a vector-like color triplet with electric charge $\frac{1}{3}e$; such states sometimes occur as low-energy remnants in E_6 grand unification models]; and/or (iv) the addition of low-energy SU(3)×SU(2)×U(1) singlets [58]. A possible theoretical motivation for such new structure arises from the study of phenomenologically viable string theory ground states [59].

A second approach is to retain the minimal particle content of the MSSM but remove the assumption of R-parity invariance. The most general R-parity-violating (RPV) theory involving the MSSM spectrum introduces many new parameters to both the supersymmetry-conserving and the supersymmetry-breaking sectors. Each new interaction term violates either B or L conservation. For example, consider new scalar-fermion Yukawa couplings derived from the following interactions:

$$(\lambda_L)_{pmn}\widehat{L}_p\widehat{L}_m\widehat{E}^c_n+(\lambda'_L)_{pmn}\widehat{L}_p\widehat{Q}_m\widehat{D}^c_n+(\lambda_B)_{pmn}\widehat{U}^c_p\widehat{D}^c_m\widehat{D}^c_n\,, \quad (10)$$

where p, m, and n are generation indices, and gauge group indices are suppressed. In the notation above, $\widehat{Q}$, $\widehat{U}^c$, $\widehat{D}^c$, $\widehat{L}$, and $\widehat{E}^c$ respectively represent $(u,d)_L$, u_L^c, d_L^c, $(\nu, e^-)_L$, and e_L^c and the corresponding superpartners. The Yukawa interactions are obtained from Eq. (10) by taking all possible combinations involving two fermions and one scalar superpartner. Note that the term in Eq. (10) proportional to λ_B violates B, while the other two terms violate L.

Phenomenological constraints on various low-energy B- and L-violating processes yield limits on each of the coefficients $(\lambda_L)_{pmn}$, $(\lambda'_L)_{pmn}$ and $(\lambda_B)_{pmn}$ taken one at a time [60]. If more than one coefficient is simultaneously non-zero, then the limits are in general more complicated. All possible RPV terms cannot be simultaneously present and unsuppressed; otherwise the proton decay rate would be many orders of magnitude larger than the present experimental bound. One way to avoid proton decay is to impose B- or L-invariance (either one alone would suffice). Otherwise, one must accept the requirement that certain RPV coefficients must be extremely suppressed.

If R-parity is not conserved, supersymmetric phenomenology exhibits features that are quite distinct from that of the MSSM. The LSP is no longer stable, which implies that not all supersymmetric decay chains must yield missing-energy events at colliders. Both $\Delta L = 1$ and $\Delta L = 2$ phenomena are allowed (if L is violated), leading to neutrino masses and mixing [61], neutrinoless double beta decay [62], sneutrino-antisneutrino mixing [56,63,64], and s-channel resonant production of the sneutrino in e^+e^- collisions [65]. Since the distinction between the Higgs and matter multiplets is lost, R-parity violation permits the mixing of sleptons and Higgs bosons, the mixing of neutrinos and neutralinos, and the mixing of charged leptons and charginos, leading to more complicated mass matrices and mass eigenstates than in the MSSM. Note that if $\lambda'_L \neq 0$, then squarks can behave as leptoquarks since the following processes are allowed: $e^+\overline{u}_m \to \overline{\widetilde{d}}_n \to e^+\overline{u}_m$, $\overline{\nu}\overline{d}_m$ and $e^+d_m \to \widetilde{u}_n \to e^+d_m$. (As above, m and n are generation labels, so that $d_2 = s$, $d_3 = b$, *etc.*)

The theory and phenomenology of alternative low-energy supersymmetric models and its consequences for collider physics have recently begun to attract significant attention. In particular, experimental and theoretical constraints place some non-trivial restrictions on R-parity-violating alternatives to the MSSM (see, e.g., Refs. [60,66] for further details).

SUPERSYMMETRY, PART II (EXPERIMENT)

Revised October 1999 by M. Schmitt (Harvard University)

II.1. Introduction: The theoretical strong points of supersymmetry (SUSY) have motivated many searches for supersymmetric particles. Most of these have been guided by the MSSM and are based on the canonical missing-energy signature caused by the escape of the LSP's ('lightest supersymmetric particles'). More recently, other scenarios have received considerable attention from experimenters, widening the range of topologies in which new physics might be found.

Unfortunately, no convincing evidence for the production of supersymmetric particles has been found. The most far reaching laboratory searches have been performed at the Tevatron and at LEP, and these are the main topic of this review. In addition, there are a few special opportunities exploited by HERA and certain fixed-target experiments.

Theoretical aspects of supersymmetry have been covered in Part I of this review by H.E. Haber (see also Ref. 1, 2); we use his notations and terminology.

II.2. Common supersymmetry scenarios: In the 'canonical' scenario [1], supersymmetric particles are pair-produced and decay directly or via cascades to the LSP. For most typical choices of model parameters, the lightest neutralino is the LSP. If R-parity is conserved, the LSP is stable. Since the neutralino is neutral and colorless, interacting only weakly with matter, it can be a candidate for cold dark matter, and in fact for a wide range of theoretical parameters, an appropriate density of relic neutralinos is expected. (See the Listings for current limits and constraints.) Assuming the conservation of R-parity, the LSP's will escape detection, giving signal events the appearance of "missing energy." In proton colliders, the momentum component along the beam direction is not useful, so one works with the so-called "missing transverse energy" ($\not{E}_T$), which is the vector sum of the transverse components of all visible momenta. In e^+e^- machines, both the missing transverse momentum, $p_T^{\rm miss}$ (essentially the same quantity as $\not{E}_T$), and the missing energy, $E^{\rm miss}$, which is the difference between twice the beam energy and the total visible energy, are utilized. There are always at least two LSP's per event. Collimated jets, isolated leptons or photons, and appropriate kinematic cuts provide additional handles to reduce backgrounds.

The conservation of R-parity is not required in supersymmetry, however, and in some searches it is assumed that supersymmetric particles decay via interactions which violate R-parity (RPV), and hence, lepton and/or baryon number. For the most part the production of superpartners is unchanged, but in general the missing-energy signature is lost. Depending on the choice of the R-parity–breaking interaction, SUSY events are characterized by an excess of leptons or hadronic jets, and in many cases it is relatively easy to suppress SM backgrounds [3]. A distinction is made between "indirect" RPV, in which the LSP decays close to the interaction point but no other decays are modified, and "direct" RPV, in which the supersymmetric particles decay to SM particles, producing no LSP's. In either case the pair-production of LSP's, which need not be $\widetilde{\chi}_1^0$'s or $\widetilde{\nu}$'s, is a significant SUSY signal.

In models assuming gauge-mediated supersymmetry breaking (GMSB) [4], the gravitino $\widetilde{g}_{3/2}$ is a weakly-interacting fermion with a mass so small that it can be neglected when considering the event kinematics. It is the LSP, and the lightest neutralino decays to it radiatively, possibly with a very long lifetime. With few exceptions the decays and production of other superpartners are the same as in the canonical scenario, so when the $\widetilde{\chi}_1^0$ lifetime is not too long, the event topologies are augmented by the presence of photons which can be energetic and isolated. If the $\widetilde{\chi}_1^0$ lifetime is so long that it decays outside of the detector, the event topologies are the same as in the canonical scenario. In some variants of this theory the right-sleptons are lighter than the lightest neutralino, and they decay to a lepton and a gravitino. This decay might occur after the slepton exits the apparatus, depending on model parameters.

Finally, in another scenario the gluino $\widetilde{g}$ is assumed to be light ($M_{\widetilde{g}} < 5$ GeV/c^2) [5]. Its decay to the lightest neutralino is kinematically suppressed, so long-lived supersymmetric hadrons ($\widetilde{g} + g$ bound states called R^0's) are formed [6]. While the sensitivity of most searches at LEP and the Tevatron would be lost, specific searches at fixed target experiments seem to have closed this gap definitively. (See the review article by H. Murayama.)

II.3. Experimental issues: Before describing the results of the searches, a few words about experimental isues are in order.

Given no signal for supersymmetric particles, experimenters are forced to derive limits on their production. The most general formulation of supersymmetry is so flexible that few universal bounds can be obtained. Often more restricted forms of the theory are evoked for which predictions are more definite—and exclusions more constraining. The most popular of these is minimal supergravity ('mSUGRA'). As explained in the Part I of this review, parameter freedom is drastically reduced by requiring related parameters to be equal at the unification scale. Thus, the gaugino masses are equal with value $m_{1/2}$, and the slepton, squark, and Higgs masses depend on a *common* scalar mass parameter, m_0. In the individual experimental analyses, only some of these assumptions are necessary. For example, the gluon and squark searches at proton machines constrain mainly M_3 and a scalar mass parameter m_0 for the squark masses, while the chargino, neutralino, and slepton searches at e^+e^- colliders constrain M_2 and a scalar mass parameter m_0 for the slepton masses. In addition, results from the Higgs searches can be used to constrain $m_{1/2}$ and m_0 as a function of $\tan\beta$. (The full analysis involves large radiative corrections coming from squark mixing, which is where the dependence on $m_{1/2}$ and m_0 enter.) In the mSUGRA framework, all the scalar mass parameters m_0 are the same and the three gaugino mass parameters are proportional to $m_{1/2}$, so limits from squarks, sleptons, charginos, gluinos, and Higgs all can be used to constrain the parameter space.

While the mSUGRA framework is convenient, it is based on several highly specific theoretical assumptions, so limits presented in this framework cannot easily be applied to other supersymmetric models. Serious attempts to reduce the model dependence of experimental exclusions have been made. When model-independent results are impossible, the underlying assumptions and their consequences are carefully delineated. This is easier to achieve at e^+e^- colliders than at proton machines.

The least model-dependent result from any experiment is the upper limit on the cross section. It requires only the number N of candidate events, the integrated luminosity $\mathcal{L}$, the total expected background b, and the acceptance ϵ for a given signal. The upper limit on the number of signal events for a given confidence level $N^{\rm upper}$ is computed from N and b (see review of Statistics). The experimental bound is simply

$$\epsilon \cdot \sigma < N^{\rm upper}/\mathcal{L}. \qquad (1)$$

This information is nearly always reported, but some care is needed to understand how the acceptance was estimated, since it can be quite sensitive to assumptions about masses and branching ratios. Also, in the more complicated analyses, $N^{\rm upper}$ also changes as a result of the optimization for a variety of possible signals.

The theoretical parameter space is constrained by computing $\epsilon \cdot \sigma$ of Eq. (1) in terms of the relevant parameters while $N^{\rm upper}/\mathcal{L}$ is fixed by experiment. Even after the theoretical scenario and assumptions have been specified, some choice remains about how to present the constraints. The quantity $\epsilon \cdot \sigma$ may depend on three or more parameters, yet in a printed page one usually can display limits only in a two-dimensional space. Three rather different tactics are employed by experimenters:

- Select "typical" values for the parameters not shown. These may be suggested by theory, or values giving more conservative—or more powerful—results may be selected. Although the values are usually specified, one sometimes has to work to understand the possible 'loopholes.'
- Scan the parameters not shown. The lowest value for $\epsilon \cdot \sigma$ is used in Eq. (1), thereby giving the weakest limit for the parameters shown. As a consequence, the limit applies for all values of the parameters *not* shown.
- Scan parameters to find the lowest acceptance ϵ and use it as a constant in Eq. (1). The limits are then safe from theoretical uncertainties but may be over-conservative, hiding powerful constraints existing in more typical cases.

Judgment is exercised: the second option is the most correct but may be impractical or uninteresting; most often representative cases are presented. These latter become standard, allowing a direct comparison of experiments, and also the opportunity to combine results.

Limits reported here are derived for 95% C.L. unless noted otherwise.

II.4. Supersymmetry searches in e^+e^- colliders: The large electron-positron collider (LEP) at CERN has been running at center-of-mass energies more than twice the mass of the Z boson. After collecting approximately 150 pb^{-1} at LEP 1 (collider energy at the Z peak), each experiment (ALEPH, DELPHI, L3, OPAL) has accumulated large data sets at LEP 2: about 5.7 pb^{-1} at $\sqrt{s} \sim 133$ GeV (1995), 10 pb^{-1} at 161 GeV and 11 pb^{-1} at 172 GeV (1996), 57 pb^{-1} near 183 GeV (1997), and most recently, 180 pb^{-1} at 189 GeV (1998). This review emphasizes the most recent LEP 2 results.

The LEP experiments and SLD at SLAC excluded essentially all visible supersymmetric particles up to about half the Z mass (see the Listings for details). These limits come mainly from the comparison of the measured Z widths to SM expectations, and are relatively insensitive to the details of SUSY particle decays [7]. The data taken at higher energies allow much stronger limits to be set, although the complex interplay of masses, cross sections, and branching ratios makes simple general limits impossible to specify.

The main signals come from SUSY particles with charge, weak isospin, or large Yukawa couplings. The gauge fermions (charginos and neutralinos) generally are produced with large cross sections, while the scalar particles (sleptons and squarks) are suppressed near threshold by kinematic factors.

Charginos are produced via γ^*, Z^*, and $\widetilde{\nu}_e$ exchange. Cross sections are in the 1–10 pb range, but can be an order of magnitude smaller when $M_{\widetilde{\nu}_e}$ is less than 100 GeV/c^2 due to the destructive interference between s- and t-channel amplitudes. Under the same circumstances, neutralino production is enhanced, as the t-channel $\widetilde{e}$ exchange completely dominates the

s-channel Z^* exchange. When Higgsino components dominate the field content of charginos and neutralinos, cross sections are large and insensitive to slepton masses.

Sleptons and squarks are produced via γ^* and Z^* exchange; for selectrons there is an important additional contribution from t-channel neutralino exchange which generally increases the cross section substantially. Although the Tevatron experiments have placed general limits on squark masses far beyond the reach of LEP, a light top squark (stop) could still be found since the flavor eigenstates can mix to give a large splitting between the mass eigenstates. The coupling of the lightest stop to the Z^* will vary with the mixing angle, however, and for certain values, even vanish, so the limits on squarks from LEP depend on the mixing angle assumed.

The various SUSY particles considered at LEP typically would decay directly to SM particles and LSP's, so signatures consist of some combination of jets, leptons, possibly photons, and missing energy. Consequently the search criteria are geared toward a few distinct topologies. Although they may be optimized for one specific signal, they are often efficient for others. For example, acoplanar jets are expected in both $\widetilde{t}_1\overline{\widetilde{t}}_1$ and $\widetilde{\chi}^0_1\widetilde{\chi}^0_2$ production, and acoplanar leptons for both $\widetilde{\ell}^+\widetilde{\ell}^-$ and $\widetilde{\chi}^+\widetilde{\chi}^-$.

The major backgrounds come from three sources. First, there are the so-called 'two-photon interactions,' in which the beam electrons emit photons which combine to produce a low mass hadronic or leptonic system leaving little visible energy in the detector. Since the electrons are seldom deflected through large angles, $p_T^{\rm miss}$ is low. Second, there is difermion production, usually accompanied by large initial-state radiation induced by the Z pole, which gives events that are well balanced with respect to the beam direction. Finally, there is four-fermion production through states with one or two resonating bosons (W^+W^-, ZZ, $We\nu$, Ze^+e^-, etc.) which can give events with large $E^{\rm miss}$ and $p_T^{\rm miss}$ due to neutrinos and electrons lost down the beam pipe.

In the canonical case, $E^{\rm miss}$ and $p_T^{\rm miss}$ are large enough to eliminate most of these backgrounds. The e^+e^- initial state is well defined so searches utilize both transverse and longitudinal momentum components. It is possible to measure the missing mass ($M_{\rm miss} = \{(\sqrt{s} - E_{\rm vis})^2 - \vec{p}^{\,2}_{\rm vis}\}^{1/2}$) which is small if $p_T^{\rm miss}$ is caused by a single neutrino or undetected electron or photon, and can be large when there are two massive LSP's. The four-fermion processes cannot be entirely eliminated, however, and a non-negligible irreducible background is expected. Fortunately, the uncertainties for these backgrounds are not large.

High efficiencies are easily achieved when the mass of the LSP is lighter than the parent particle by at least 10 GeV/c^2 and greater than about 10 GeV/c^2. Difficulties arise when the mass difference ΔM between the produced particle and the LSP is smaller than 10 GeV/c^2 as the signal resembles background from two-photon interactions. A very light LSP is challenging also since, kinematically speaking, it plays a role similar to a neutrino, so that, for example, a signal for charginos of mass 85 GeV/c^2 is difficult to distinguish from the production of W^+W^- pairs. The lower signal efficiency obtained in these two extreme cases has been offset by the large integrated luminosities delivered over the last two years, so mass limits are not degraded very much.

Since the start of LEP 2, experimenters have made special efforts to cover a wide range of mass differences. Also, since virtual superpartners exchanged in decays can heavily influence branching ratios to SM particles, care has been taken to ensure that the search efficiencies are not strongly dependent on the final state. This ability to cover a wide range of topologies has driven the push for bounds with a minimum of model dependence.

Charginos have been excluded up to 94 GeV/c^2 [8,9] except in cases of very low acceptance ($\Delta M = M_{\widetilde{\chi}^\pm} - M_{\widetilde{\chi}^0_1} \lesssim 3$ GeV/c^2) or low cross section ($M_{\widetilde{\nu}_e} \lesssim 120$ GeV/c^2). When $|\mu| \ll M_2$, the Higgsino components are large for charginos and neutralinos. In this case the associated production of neutralino pairs $\widetilde{\chi}^0_1\widetilde{\chi}^0_2$ is large and the problem of small mass differences ($M_{\widetilde{\chi}^0_2} - M_{\widetilde{\chi}^0_1}$) less severe. Experimental sensitivity now extends down to mass differences of 3 GeV/c^2, corresponding to M_2 above 2 TeV/c^2.

The possibility of extremely small mass differences has been raised in several theoretical papers, and the DELPHI Collaboration has engineered several searches to cover this scenario [10]. For $\Delta M \sim 1$ GeV/c^2, they distinguish signal from two-photon background on the basis of photons radiated in the initial state, which have different kinematic characteristics. For $\Delta M \sim 0.4$ GeV/c^2, the chargino acquires a non-negligible lifetime, so they look for displaced vertices and tracks which do not originate from the interaction point. The modeling of lifetime and chargino decays required special care. When $\Delta M < m_\pi$, the lifetime is so long that the chargino appears as a heavily ionizing particle which exits the apparatus before decaying. The bounds on the chargino mass are weaker than in the canonical case with larger ΔM, but still are well above the bounds from LEP 1 (Fig. 1).

The limits from chargino and neutralino production are most often used to constrain M_2 and μ for fixed $\tan\beta$. For large $|\mu|$ (the gaugino case), chargino bounds limit M_2, and vice versa (the Higgsino case). When $\tan\beta$ is not large, the region of parameter space with $\mu < 0$ and $|\mu| \sim M_2$ corresponds to 'mixed' field content, and the limits on M_2 and $|\mu|$ are relatively modest, numerically. This is especially true when electron sneutrinos are light, leading to a degradation of the indirect limits on the LSP mass, as discussed below.

When the sleptons are light, two important effects must be considered for charginos: the cross section is significantly reduced and the branching ratio to leptons is enhanced, especially to τ's via $\widetilde{\tau}$'s which can have non-negligible mixing. These effects are greatest when the chargino has a large gaugino component. The weakest bounds are found for small negative μ and small $\tan\beta$, as the cross section is reduced with respect to larger $|\mu|$, the impact of $\widetilde{\tau}$ mixing can be large, and the efficiency is not optimal because ΔM is large.

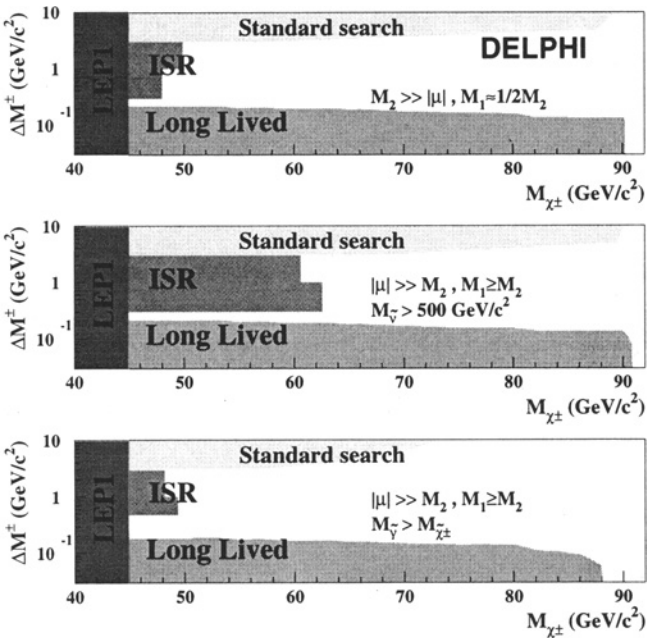

Figure 1: Ranges of excluded chargino and neutralino masses, for very small ΔM , from DELPHI [10].

If the sneutrino is lighter than the chargino, then two-body decays $\tilde{\chi}^+ \rightarrow \ell^+\tilde{\nu}$ dominate, and in the 'corridor' $0 < M_{\tilde{\chi}^\pm} - M_{\tilde{\nu}} \lesssim 3$ GeV/c^2 the acceptance is so low that no exclusion is possible [11,9].

The limits on slepton masses [12] fall a bit below the kinematic limit due to a phase space suppression near threshold. The simplest topology results from $\tilde{\ell} \rightarrow \ell\tilde{\chi}_1^0$. Considering the production of $\tilde{\ell}_R$ only, the 189 GeV data from OPAL gives 89 GeV/c^2 for $\tilde{e}_R$, 82 GeV/c^2 for $\tilde{\mu}_R$, and 81 GeV/c^2 for $\tilde{\tau}_1$. For selectrons and smuons there is a small improvement from the preliminary combination of the four LEP experiments [13], and one sees that the dependence on $\Delta M = M_{\tilde{\ell}} - M_{\tilde{\chi}_1^0}$ is weak for $\Delta M \gtrsim 5$ GeV/c^2. Assuming a common scalar mass term m_0, the masses of the left- and right-sleptons can be related as a function of $\tan\beta$, and one finds $m_{\tilde{\ell}_L} > m_{\tilde{\ell}_R}$ by a few GeV/c^2. Consequently, in associated $\tilde{e}_L\tilde{e}_R$ production, the special case $M_{\tilde{\chi}} \lesssim M_{\tilde{e}_R}$ still results in a viable signature: a single energetic electron. ALEPH have used this to close the gap $M_{\tilde{e}_R} - M_{\tilde{\chi}} \rightarrow 0$. In this same framework, bounds on the parameters $m_{1/2}$ and m_0 have been derived.

In some GMSB models, photons from the decay $\tilde{\chi}_1^0 \rightarrow \gamma\,\tilde{g}_{3/2}$ accompany the leptons. The resulting limits are similar to the canonical case. In other GMSB models, sleptons may decay to $\ell^\pm\,\tilde{g}_{3/2}$ outside the detector, so the experimental signature is a pair of collinear, heavily ionizing tracks [14]. Combined search limits are 86 GeV/c^2 for $\tilde{\mu}_R$ and $\tilde{\tau}_R$ [15]. Shorter lifetimes are possible, however, so searches have been performed for displaced vertices, tracks with kinks, and tracks with large impact parameters. Combining these together, slepton mass limits independent of lifetime have been derived. The result from ALEPH for $\tilde{\tau}_R$ is shown in Fig. 2 [12].

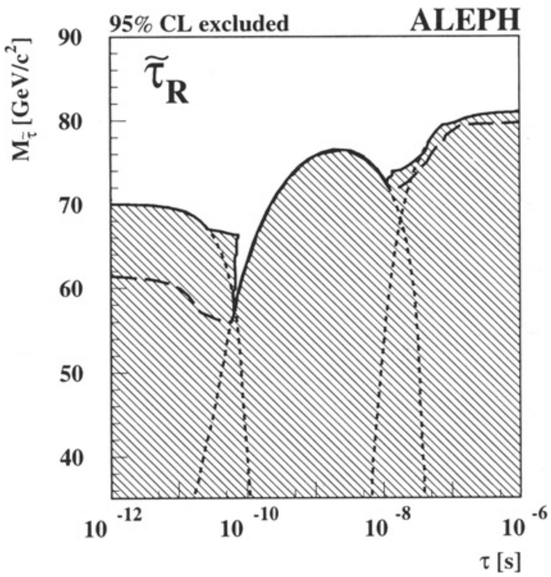

Figure 2: Lower limit on the mass of $\tilde{\tau}_R$ as a function of its lifetime, from the ALEPH 183 GeV data [12]. The full line shows the actual mass limit obtained, while the long dashed line shows the limit expected from Monte Carlo studies. The short dashed lines indicate the limits from the three types of searches: acoplanar leptons ($\tau < 10^{-9}s$), tracks with large impact parameters and kinks ($10^{-11}s < \tau < 10^{-7}s$); and, heavily ionizing tracks ($\tau > 10^{-8}s$).

For these same GMSB models, it is possible that the lightest stau is significantly lighter than the other sleptons. If so, then special topologies may result, such as 4τ final states from neutralino pair production. DELPHI has searched in this and related channels, finding no evidence for a signal [16].

Limits on stop and sbottom masses [17,18], vary with the mixing angle because the cross section does: for $\theta_{\tilde{t}} = 56°$ and $\theta_{\tilde{b}} = 67°$ the contribution from Z exchange is "turned off." The stop decay $\tilde{t}_1 \rightarrow c\tilde{\chi}_1^0$ proceeds through loops, giving a lifetime long enough to allow the top squark to form supersymmetric hadrons which provide a pair of jets and missing energy. If sneutrinos are light, the decay $\tilde{t}_1 \rightarrow b\ell\tilde{\nu}$ dominates, giving two leptons in addition to the jets. Access to small ΔM is possible due to the visibility of the decay products of the c and b quarks. Limits vary from 91 GeV/c^2 for an unrealistic pure $\tilde{t}_L$ state to 89 GeV/c^2 if the coupling of $\tilde{t}_1$ to the Z vanishes. The electric charge of the sbottoms is smaller than that of stops, leading to weaker limits, but the use of b-jet tagging helps retain sensitivity: the bounds range between 75 and 90 GeV/c^2 depending on $\theta_{\tilde{b}}$. Limits from the Tevatron reach much higher masses, but only when the neutralino is much lighter than the stop or sbottom. ALEPH has interpreted the results of their search in terms of generic squarks, excluding a rather small region not covered at the Tevatron [17].

In canonical SUSY scenarios the lightest neutralino leaves no signal in the detector. Nonetheless, the tight correspondences among the neutralino and chargino masses allow an indirect limit on $M_{\widetilde{\chi}_1^0}$ to be derived [9,11]. The key assumption is that the gaugino mass parameters M_1 and M_2 unify at the GUT scale, which leads to a definite relation between them at the electroweak scale: $M_1 = \frac{5}{3}\tan^2\theta_W M_2$. Assuming slepton masses to be at least 200 GeV/c^2, the bound on $M_{\widetilde{\chi}_1^0}$ is derived from the results of chargino and neutralino searches and certain bounds from LEP 1.

When sleptons are lighter than 120 GeV/c^2, all the effects of light sneutrinos on both the production and decay of charginos and heavier neutralinos must be taken into account. Although the bounds from charginos are weakened, useful additional constraints from slepton and higher-mass neutralino searches rule out the possibility of a massless neutralino. The current OPAL limit [8], shown in Fig. 3, is $M_{\widetilde{\chi}_1^0} > 32.8$ GeV/c^2 for $\tan\beta > 1$ and $m_0 \gtrsim 500$ GeV/c^2 (effectively, $M_{\widetilde{\nu}} > 500$ GeV/c^2). Allowing the universal scalar mass parameter m_0 to have any value, the limit is $M_{\widetilde{\chi}_1^0} > 31.6$ GeV/c^2.

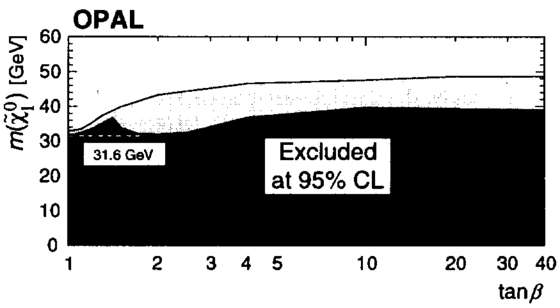

Figure 3: Lower limit on the mass of the lightest neutralino, derived by the OPAL Collaboration using constraints from chargino, neutralino, and slepton searches [8]. The light shaded region is obtained assuming $m_0 \gtrsim 500$ GeV/c^2; the dark region, for any m_0.

The ALEPH Collaboration has explored the constraints coming from the negative results of Higgs searches [9]. These are depicted as excluded regions in the $(m_0, m_{1/2})$ plane and can be translated into bounds on $M_{\widetilde{\chi}_1^0}$; they do not, however, substantially strengthen bounds coming from less complicated analyses. This work has also been performed by the LEP SUSY Working Group [19].

If R-parity is not conserved, searches based on missing energy are not viable. The three possible RPV interaction terms ($LL\overline{E}$, $LQ\overline{D}$, $\overline{U}\,\overline{D}\,\overline{D}$) violate lepton or baryon number, consequently precisely measured SM processes constrain products of dissimilar terms. Collider searches assume only one of the many possible terms dominates; given this assumption, searches for charginos and neutralinos, sleptons and squarks have been performed. All sets of generational indices (λ_{ijk}, λ'_{ijk}, λ''_{ijk}) have been considered, allowing for both *direct* and *indirect* RPV processes. Rather exotic topologies can occur, such as six-lepton final states in slepton production with $LL\overline{E}$ dominating, or ten-jet final states in chargino production with $\overline{U}\,\overline{D}\,\overline{D}$ dominating; entirely new search criteria keyed to an excess of leptons and/or jets have been devised [20]. Searches with a wide scope have found no evidence for supersymmetry with R-parity violation, and limits are as constraining as in the canonical scenario. In fact, the direct exclusion of pair-produced $\widetilde{\chi}_1^0$'s rules out some parameter space not accessible in the canonical case.

Visible signals from the lightest neutralino are also realized in special cases of GMSB which predict $\widetilde{\chi}_1^0 \to \gamma\,\widetilde{g}_{3/2}$ with a lifetime short enough for the decay to occur inside the detector [21]. The most promising topology consists of two energetic photons and missing energy resulting from $e^+e^- \to \widetilde{\chi}_1^0\widetilde{\chi}_1^0$. For the DELPHI search, a technique was developed to identify photons which do not originate from the primary vertex. No excess was observed over the expected number of background events [21], leading to a bound on the neutralino mass of about 84 GeV/c^2. When the results are combined [22], the limit is $M_{\widetilde{\chi}_1^0} > 89$ GeV/c^2. Single-photon production has been used to constrain the process $e^+e^- \to \widetilde{g}_{3/2}\widetilde{\chi}_1^0$.

II.5. Supersymmetry searches at proton machines: Although the LEP experiments can investigate a wide range of scenarios and cover obscure corners of parameter space, they cannot match the mass reach of the Tevatron experiments (CDF and DØ). Each experiment has logged approximately 110 pb^{-1} of data at $\sqrt{s} = 1.8$ TeV. Although the full energy is never available for annihilation, the cross sections for supersymmetric particle production are large due to color factors and the strong coupling.

The main source of signals for supersymmetry are squarks (scalar partners of quarks) and gluinos (fermionic partners of gluons), in contradistinction to LEP. Pairs of squarks or gluinos are produced in s, t and u-channel processes, which decay directly or via cascades to at least two LSP's. The number of jets depends on whether the gluino or the squark is heavier, with the latter occurring naturally in mSUGRA models. The possibility of cascade decays through charginos or heavier neutralinos also complicates the search. The u, d, s, c, and b squarks are assumed to have similar masses; the search results are reported in terms of their average mass $M_{\widetilde{q}}$ and the gluino mass $M_{\widetilde{g}}$.

The classic searches [23] rely on large missing transverse energy $\not{E}_T$ caused by the escaping neutralinos. Jets with high transverse energy are also required as evidence of a hard interaction; care is taken to distinguish genuine $\not{E}_T$ from fluctuations in the jet energy measurement. Backgrounds from W, Z and top production are reduced by rejecting events with identified leptons. Uncertainties in the rates of these processes are minimized by normalizing related samples, such as events with two jets and one or more leptons. The tails of more ordinary hard-scattering processes accompanied by multiple gluon emission are estimated directly from the data.

The bounds are derived for the $(M_{\widetilde{g}}, M_{\widetilde{q}})$ plane and have steadily improved with the integrated luminosity. If the squarks are heavier than the gluino, then $M_{\widetilde{g}} \gtrsim 180$ GeV/c^2. If they all have the same mass, then that mass is at least 260 GeV/c^2, according to the DØ analysis. If the squarks are much lighter than the gluino (in which case they decay via $\widetilde{q} \to q\widetilde{\chi}_1^0$), the bounds from UA1 and UA2 [24] play a role giving $M_{\widetilde{g}} \gtrsim 300$ GeV/c^2. All of these bounds assume there is no gluino lighter than 5 GeV/c^2.

Since these results are expressed in terms of the physical masses relevant to the production process and experimental signature, the excluded region depends primarily on the assumption of nearly equal squark masses with only a small dependence on other parameters such as μ and $\tan\beta$. Direct constraints on the theoretical parameters m_0 and $m_{1/2} \approx 0.34\, M_3$ have been obtained by the DØ Collaboration assuming the mass relations of the mSUGRA model [23]. In particular, m_0 is keyed to the squark mass and $m_{1/2}$ to the gluino mass, while for the LEP results these parameters usually relate to slepton and chargino masses.

Charginos and neutralinos may be produced directly by annihilation ($q\overline{q} \to \widetilde{\chi}_i^{\pm}\widetilde{\chi}_j^0$) or in the decays of heavier squarks ($\widetilde{q} \to q'\widetilde{\chi}_i^{\pm}, q\widetilde{\chi}_j^0$). They decay to energetic leptons (for example, $\widetilde{\chi}^{\pm} \to \ell\nu\widetilde{\chi}_1^0$ and $\widetilde{\chi}_2^0 \to \ell^+\ell^-\widetilde{\chi}_1^0$) and the branching ratio can be high for some parameter choices. The presence of energetic leptons has been exploited in two ways: the 'trilepton' signature and the 'dilepton' signature.

The search for trileptons is most effective for the associated production of $\widetilde{\chi}_1^{\pm}\widetilde{\chi}_2^0$ [25]. The requirement of three energetic leptons reduces backgrounds to a very small level, but is efficient for the signal only in special cases. The results reported to date are not competitive with the LEP bounds.

The dilepton signal is geared more for the production of charginos in gluino and squark cascades [26]. Jets are required as expected from the rest of the decay chain; the leptons should be well separated from the jets in order to avoid backgrounds from heavy quark decays. Drell-Yan events are rejected with simple cuts on the relative azimuthal angles of the leptons and their transverse momentum. In some analyses the Majorana nature of the gluino is exploited by requiring two leptons with the same charge, thereby greatly reducing the background. In this scenario limits on squarks and gluinos are almost as stringent as in the classic jets+ $\not\!\!E_T$ case.

It should be noted that the dilepton search complements the multijet+ $\not\!\!E_T$ search in that the acceptance for the latter is reduced when charginos and neutralinos are produced in the decay cascades—exactly the situation in which the dilepton signature is most effective.

The top squark is different from the other squarks because its SM partner is so massive: large off-diagonal terms in the squared-mass matrix lead to large mixing effects and a possible light mass eigenstate, $M_{\widetilde{t}_1} \ll M_{\widetilde{q}}$. When the parameters A, μ and $\tan\beta$ are suitably tuned, light bottom squarks can also be expected. Analyses designed to find light stops and sbottoms have been performed [27]. The first of these was based on the jets+ $\not\!\!E_T$ signature expected when the the stop is lighter than the chargino. The search was improved by employing heavy-flavor tagging, which made the selection effective for sbottoms, too. A powerful limit $M_{\widetilde{t}} \gtrsim 115$ GeV/c^2 was obtained for a neutralino mass around 40 GeV/c^2, shown in Fig. 4.

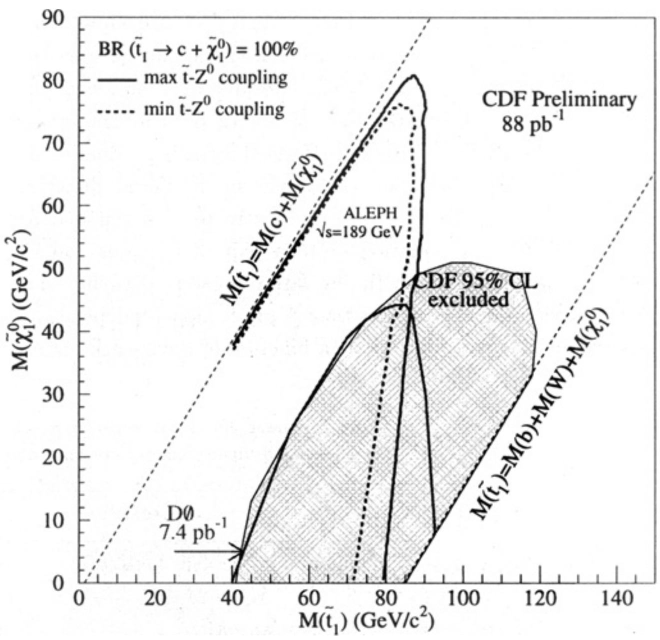

Figure 4: Excluded stop and sneutrino masses, for the $c\widetilde{\chi}_1^0$ decay mode, from the CDF Collaboration [27].

A search for the pair-production of light stops decaying to $b\widetilde{\chi}_1^{\pm}$ has been performed by DØ [27]. The presence of two energetic electrons was required; backgrounds from W's were greatly reduced. Regrettably this experimental bound does not yet improve existing bounds on stop masses.

The CDF and DØ collaborations have searched for supersymmetry in certain RPV scenarios [28]. DØ employs their search for events with two energetic electrons and jets, which is appropriate to decays $\widetilde{\chi}_1^0 \to eq\overline{q}$. Within the mSUGRA framework they sum contributions from all processes predicted as a function of m_0, $m_{1/2}$ and $\tan\beta$, thereby obtaining exclusions in parameter space. CDF uses the same-sign dielectron and jets topology to look for gluino and squark production and obtain general upper limits on cross sections. They also consider a special case of $\widetilde{g} \to c\,\widetilde{c}_L$ followed by $\widetilde{c}_L \to e\,d$, motivated by an excess of rare events reported by the HERA collaborations.

Interest in GMSB models was generated by an anomalous event observed by the CDF Collaboration [29]. These models predict large inclusive signals for $p\overline{p} \to \gamma\gamma + X$ given kinematic constraints derived from the properties of the CDF event.

DØ reported a result from events with two energetic photons and large $\not{E}_T$ resulting in the limit $M_{\widetilde{\chi}_1^0} > 75$ GeV/c^2 [30]. DØ also looked specifically for squarks and gluinos in the scenario, which would give two photons and two or more jets, and obtained squark and gluino mass limits of 320 GeV/c^2. An analysis reported by CDF looks for virtually all thinkable topologies involving two energetic photons [30]. The neutralino mass limit is the same.

II.6. Supersymmetry searches at HERA and fixed-target experiments: The electron-proton collider (HERA) at DESY runs at a center-of-mass energy of 310 GeV and, due to its unique combination of beam types, can be used to probe certain channels effectively. Results were obtained on associated selectron-squark production with R-parity conservation [31]. An RPV search was performed assuming a dominant $LQ\overline{D}$ interaction [32]. Squarks would be produced directly in the s-channel, decaying either directly to a lepton and a quark via R-parity violation or to a pair of fermions and a chargino or neutralino, with the latter possibly decaying via R-parity violation. From less than 3 pb^{-1}, model-independent bounds on λ'_{111} were derived as a function of the squark mass. The special case of a light $\widetilde{t}_1$ was also considered, and limits derived on λ'_{131} as a function of $M_{\widetilde{t}}$.

It is difficult to conduct direct searches for light gluinos ($M_{\widetilde{g}} \lesssim 5$ GeV/c^2) at colliders because they would form light, long-lived hadrons (R^0's, a $g\widetilde{g}$ bound state) which would be difficult to identify. Certain fixed-target experiments, however, are well suited to the task. The most sensitive searches have been conducted by KTeV at Fermilab and NA48 at CERN, both designed to study very large samples of neutral kaons. KTeV looked for $R^0 \to \rho^0\widetilde{\gamma}$ with $\rho^0 \to \pi^+\pi^-$ and also $R^0 \to \pi^0\widetilde{\gamma}$, important below the 2π threshold [33]. NA48 searched for $R^0 \to \eta\widetilde{\gamma}$ with $\eta \to 3\pi^0$ [34]. The searches required decay vertices far downstream of the target and enough missing transverse momentum to eliminate K^0_L decays. Backgrounds were estimated directly from data and fluxes measured using known K^0_L decay modes; the R^0 flux is related to the K^0_L flux theoretically. No evidence for R^0's was found, and a wide range of R^0 lifetimes was ruled out for 0.9 GeV/$c^2 < M_{R^0} \lesssim 5$ GeV/c^2. These results definitively excludes the possibility of light gluinos with very light photinos (from light gluino decay) solving the cold dark matter problem.

Table 1: Lower limits on supersymmetric particle masses. 'GMSB' refers to models with gauge-mediated supersymmetry breaking, and 'RPV' refers to models allowing R-parity violation.

particle		Condition	Lower limit (GeV/c^2)	Source
$\widetilde{\chi}_1^\pm$	gaugino	$M_{\widetilde{\nu}} > 500$ GeV/c^2	94	LEP 2
		$M_{\widetilde{\nu}} > M_{\widetilde{\chi}^\pm}$	75	LEP 2
		any $M_{\widetilde{\nu}}$	45	Z width
	Higgsino	$M_2 < 1$ TeV/c^2	89	LEP 2
	GMSB		150	DØ isolated photons
	RPV	$LL\overline{E}$ worst case	87	LEP 2
		$LQ\overline{D}$ $m_0 > 500$ GeV/c^2	88	LEP 2
$\widetilde{\chi}_1^0$	indirect	any $\tan\beta$, $M_{\widetilde{\nu}} > 500$ GeV/c^2	33	LEP 2
		any $\tan\beta$, any m_0	32	LEP 2
	GMSB		83	DØ and LEP 2
	RPV	$LL\overline{E}$ worst case	23	LEP 2
$\widetilde{e}_R$	$e\widetilde{\chi}_1^0$	$\Delta M > 10$ GeV/c^2	89	LEP 2 combined
$\widetilde{\mu}_R$	$\mu\widetilde{\chi}_1^0$	$\Delta M > 10$ GeV/c^2	84	LEP 2 combined
$\widetilde{\tau}_R$	$\tau\widetilde{\chi}_1^0$	$M_{\widetilde{\chi}_1^0} < 20$ GeV/c^2	71	LEP 2
$\widetilde{\nu}$			43	Z width
$\widetilde{\mu}_R$, $\widetilde{\tau}_R$		stable	71	LEP 2 combined
$\widetilde{t}_1$	$c\widetilde{\chi}_1^0$	any $\theta_{\rm mix}$, $\Delta M > 10$ GeV/c^2	87	LEP 2 combined
		any $\theta_{\rm mix}$, $M_{\widetilde{\chi}_1^0} < \frac{1}{2}M_{\widetilde{t}}$	88	DØ
	$b\ell\widetilde{\nu}$	any $\theta_{\rm mix}$, $\Delta M > 7$ GeV/c^2	90	LEP 2 combined
$\widetilde{g}$	any $M_{\widetilde{q}}$		190	DØ jets+$\not{E}_T$
			180	CDF dileptons
$\widetilde{q}$	$M_{\widetilde{q}} = M_{\widetilde{g}}$		260	DØ jets+$\not{E}_T$
			230	CDF dileptons

II.7. Conclusions: A huge variety of searches for supersymmetry have been carried out at LEP, the Tevatron, and in fixed-target experiments. Despite all the effort, no signal has been found, forcing the experimenters to derive limits. We have tried to summarize the interesting cases in Table 1. At the present time there is little room for SUSY particles lighter than M_Z. The LEP collaborations will analyze more data taken at a center-of-mass energy of 200 GeV, and the Tevatron collaborations will begin a high luminosity run towards the end of the year 2000. If still no sign of supersymmetry appears, definitive tests will be made at the LHC.

SUPERSYMMETRIC MODEL ASSUMPTIONS

Most of the results shown below, unless stated otherwise, are based on the Minimal Supersymmetric Standard Model (MSSM), as described in the Note on Supersymmetry. Unless otherwise indicated, this includes the assumption of common gaugino and scalar masses at the scale of Grand Unification (GUT), and use of the resulting relations in the spectrum and decay branching ratios. It is also assumed that R-parity (R) is conserved. Unless otherwise indicated, the results also assume that:

1) The $\widetilde{\chi}^0_1$ is the lighest supersymmetric particle (LSP)
2) $m_{\widetilde{f}_L} = m_{\widetilde{f}_R}$, where $\widetilde{f}_{L,R}$ refer to the scalar partners of left- and right-handed fermions.

Limits involving different assumptions are identified in the Comments or in the Footnotes. We summarize here the notations used in this Chapter to characterize some of the most common deviations from the MSSM (for further details, see the Note on Supersymmetry).

Theories with R-parity violation ($\not{R}$) are characterised by a superpotential of the form: $\lambda_{ijk}L_iL_je^c_k + \lambda'_{ijk}L_iQ_jd^c_k + \lambda''_{ijk}u^c_id^c_jd^c_k$, where i,j,k are generation indices. The presence of any of these couplings is often identified in the following by the symbols $LL\overline{E}$, $LQ\overline{D}$, and $\overline{UDD}$. Mass limits in the presence of $\not{R}$ will often refer to "direct" and "indirect" decays. Direct refers to $\not{R}$ decays of the particle in consideration. Indirect refers to cases where $\not{R}$ appears in the decays of the LSP.

In several models, most notably in theories with so-called Gauge Mediated Supersymmetry Breaking (GMSB), the gravitino ($\widetilde{G}$) is the LSP. It is usually much lighter than any other massive marticle in the spectrum, and $m_{\widetilde{G}}$ is then neglected in all decay processes involving gravitinos. In these scenarios, particles other than the neutralino are sometimes considered as the next-to-lighest supersymmetric particle (NLSP), and are assumed to decay to their even-R partner plus $\widetilde{G}$. If the lifetime is short enough for the decay to take place within the detector, $\widetilde{G}$ is assumed to be undetected and to give rise to missing energy ($\not{E}$) or missing transverse energy ($\not{E}_T$) signatures.

When needed, specific assumptions on the eigenstate content of $\widetilde{\chi}^0$ and $\widetilde{\chi}^\pm$ states are indicated, using the notation $\widetilde{\gamma}$ (photino), $\widetilde{H}$ (higgsino), $\widetilde{W}$ (wino), and $\widetilde{Z}$ (zino) to signal that the limit of pure states was used. The terms gaugino is also used, to generically indicate wino-like charginos and zino-like neutralinos.

$\widetilde{\chi}^0_1$ (Lightest Neutralino) MASS LIMIT

$\widetilde{\chi}^0_1$ is often assumed to be the lightest supersymmetric particle (LSP). See also the $\widetilde{\chi}^0_2$, $\widetilde{\chi}^0_3$, $\widetilde{\chi}^0_4$ section below.

We have divided the $\widetilde{\chi}^0_1$ listings below into four sections:

1) Accelerator limits for stable $\widetilde{\chi}^0_1$,
2) Bounds on $\widetilde{\chi}^0_1$ from dark matter searches,
3) Other bounds on $\widetilde{\chi}^0_1$ from astrophysics and cosmology, and
4) Bounds on unstable $\widetilde{\chi}^0_1$.

Accelerator limits for stable $\widetilde{\chi}^0_1$

Unless otherwise stated, results in this section assume spectra, production rates, decay modes, and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers generally study production of $\widetilde{\chi}^0_i\widetilde{\chi}^0_j$ ($i \geq 1$, $j \geq 2$), $\widetilde{\chi}^+_1\widetilde{\chi}^-_1$, and (in the case of hadronic collisions) $\widetilde{\chi}^+_1\widetilde{\chi}^0_2$ pairs. The mass limits on $\widetilde{\chi}^0_1$ are either direct, or follow indirectly from the constraints set by the non-observation of $\widetilde{\chi}^\pm_1$ and $\widetilde{\chi}^0_2$ states on the gaugino and higgsino MSSM parameters M_2 and μ.

Obsolete limits obtained from e^+e^- collisions up to $\sqrt{s}$=136 GeV have been removed from this compilation and can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review. $\Delta m_0 = m_{\widetilde{\chi}^0_2} - m_{\widetilde{\chi}^0_1}$.

[1] ABBIENDI 00H data collected at $\sqrt{s}$=189 GeV. The results hold over the full parameter space defined by $0 \leq M_2 \leq 2$ TeV, $|\mu| \leq 500$ GeV, $m_0 \leq 500$ GeV, $A=\pm M_2$, $\pm m_0$, and 0. The minimum mass limit is reached for $\tan\beta$=1. The results of ABBIENDI 99F are used to constrain regions of parameter space dominated by radiative $\widetilde{\chi}^0_2 \to \widetilde{\chi}^0_1\gamma$ decays. The limit improves to 48.5 GeV for m_0=500 GeV and $\tan\beta$=35. See their Table and Figs 4–5 for the $\tan\beta$ and m_0 dependence of the limits.

[2] ABREU 00J data collected at $\sqrt{s}$=189 GeV. The parameter space is scanned in the domain $0<M_2 < 3000$ GeV, $|\mu| < 200$ GeV, $1<\tan\beta < 35$. The analysis includes the effects of gaugino cascade decays. In the case of radiative neutralino decays, the limits from $Z \to \widetilde{\chi}^0_1\widetilde{\chi}^0_2$ decays in ABREU 97J are assumed.

[3] ACCIARRI 00D data collected at $\sqrt{s}$=189 GeV. The results hold over the full parameter space defined by $0.7 \leq \tan\beta \leq 60$, $0 \leq M_2 \leq 2$ TeV, $m_0 \leq 500$ GeV, $|\mu| \leq 2$ TeV The minimum mass limit is reached for $\tan\beta$=1 and large m_0. The results of slepton searches from ACCIARRI 99W are used to help set constraints in the region of small m_0. The limit improves to 48 GeV for $m_0 \gtrsim 200$ GeV and $\tan\beta \gtrsim 10$. See their Figs. 6–8 for the $\tan\beta$ and m_0 dependence of the limits.

[4] BARATE 99P data collected at $\sqrt{s}$=183 GeV. The limit is also based on the constraints from the total and invisible Z^0 width from ABBANEO 97, on direct searches for neutralinos at LEP1 from DECAMP 92 and on the slepton limits from BARATE 98K. The limit improves to 29 GeV if the unification of Higgs and sfermion masses is also assumed, and direct constraints on the Higgs mass are used.

[5] ABBIENDI 99G data collected at $\sqrt{s} \leq 184$ GeV. The parameter space is scanned in the domain $0 <M_2 < 2000$ GeV, $|\mu| < 500$ GeV, and for various values of A. No dependence of the limits on A is found. The analysis includes the effects of gaugino cascade decays. In the case of radiative neutralino decays, the limits from ACKERSTAFF 98J are assumed. The limit for all values of m_0 assumes $m_{\widetilde{\nu}_e} > 43$ GeV and direct limits on charged sleptons. See Table 5 for limits under different assumptions on Δm_0 and $\tan\beta$.

[6] ABREU 99E data collected at $\sqrt{s}$=183 GeV. These results include and update the limits from ABREU 98. The parameter space is scanned in the domain $0 <M_2 < 3000$ GeV, $|\mu| < 400$ GeV, $1 <\tan\beta < 35$. The analysis includes the effects of gaugino cascade decays. In the case of radiative neutralino decays, the limits from ABREU 97J are assumed.

[7] ABE 98J searches for trilepton final states ($\ell=e,\mu$). See footnote to ABE 98J in the Chargino Section for details on the assumptions. The quoted result corresponds to the best limit within the selected range of parameters, obtained for $m_{\widetilde{q}} > m_{\widetilde{g}}$, $\tan\beta$=2, and $\mu=-600$ GeV.

[8] ABREU 98 bound combines the chargino and neutralino searches at $\sqrt{s}$=161, 172 GeV with single-photon-production results at LEP-1 from ABREU 97J.

[9] ACCIARRI 98F limit is obtained for $0 < M_2 < 2000$, $|\mu| < 500$, and $1 < \tan\beta < 40$, but remains valid outside this domain. No dependence on the trilinear-coupling parameter A is found. The limit holds for all values of m_0 consistent with scalar lepton contraints. It improves to 24.6 GeV for $m_{\tilde\nu} > 200$ GeV. Data taken at $\sqrt{s} = 130$–172 GeV.

[10] ACKERSTAFF 98L limit is obtained for $0 < M_2 < 1500$, $|\mu| < 500$ and $\tan\beta > 1$, but remains valid outside this domain. The limit holds for the smallest value of m_0 consistent with scalar lepton constraints (ACKERSTAFF 97H). It improves to 24.7 GeV for m_0=1 TeV. Data taken at $\sqrt{s}$=130–172 GeV.

[11] ELLIS 97C uses constraints on $\chi^\pm$, χ^0, and $\tilde\ell$ production obtained by the LEP experiments from e^+e^- collisions at $\sqrt{s}$ = 130–172 GeV. It assumes a universal mass m_0 for scalar leptons at the grand unification scale.

Bounds on $\tilde\chi_1^0$ from dark matter searches

These papers generally exclude regions in the $M_2 - \mu$ parameter plane assuming that $\tilde\chi_1^0$ is the dominant form of dark matter in the galactic halo. These limits are based on the lack of detection in laboratory experiments or by the absence of a signal in underground neturino detectors. The latter signal is expected if $\tilde\chi_1^0$ accumlates in the Sun or the Earth and annihilates into high-energy ν's.

VALUE	DOCUMENT ID		TECN

	[20] MORI	91B	KAMI
none 4–15 GeV	[21] OLIVE	88	COSM

[12] AMBROSIO 99 set new neutrino flux limits which can be used to limit the parameter space in supersymmteric models based on neutralino annihilation in the Sun and the Earth.

[13] BOTTINO 97 points out that the current data from the dark-matter detection experiment DAMA are sensitive to neutralinos in domains of parameter space not excluded by terrestrial laboratory searches.

[14] LOSECCO 95 reanalyzed the IMB data and places lower limit on $m_{\tilde\chi_1^0}$ of 18 GeV if the LSP is a photino and 10 GeV if the LSP is a higgsino based on LSP annihilation in the sun producing high-enery neutrinos and the limits on neutrino fluxes from the IMB detector.

[15] MORI 93 excludes some region in M_2–μ parameter space depending on $\tan\beta$ and lightest scalar Higgs mass for neutralino dark matter $m_{\tilde\chi^0} > m_W$, using limits on upgoing muons produced by energetic neutrinos from neutralino annihilation in the Sun and the Earth.

[16] BOTTINO 92 excludes some region M_2-μ parameter space assuming that the lightest neutralino is the dark matter, using upgoing muons at Kamiokande, direct searches by Ge detectors, and by LEP experiments. The analysis includes top radiative corrections on Higgs parameters and employs two different hypotheses for nucleon-Higgs coupling. Effects of rescaling in the local neutralino density according to the neutralino relic abundance are taken into account.

[17] BOTTINO 91 excluded a region in $M_2 - \mu$ plane using upgoing muon data from Kamioka experiment, assuming that the dark matter surrounding us is composed of neutralinos and that the Higgs boson is not too heavy.

[18] GELMINI 91 exclude a region in $M_2 - \mu$ plane using dark matter searches.

[19] KAMIONKOWSKI 91 excludes a region in the M_2-μ plane using IMB limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the sun, assuming that the dark matter is composed of neutralinos and that $m_{H_1^0} \lesssim$ 50 GeV. See Fig. 8 in the paper.

[20] MORI 91B exclude a part of the region in the M_2-μ plane with $m_{\tilde\chi_1^0} \lesssim$ 80 GeV using a limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the earth, assuming that the dark matter surrounding us is composed of neutralinos and that $m_{H_1^0} \lesssim$ 80 GeV.

[21] OLIVE 88 result assumes that photinos make up the dark matter in the galactic halo. Limit is based on annihilations in the sun and is due to an absence of high energy neutrinos detected in underground experiments. The limit is model dependent.

Other bounds on $\tilde\chi_1^0$ from astrophysics and cosmology

Most of these papers generally exclude regions in the $M_2 - \mu$ parameter plane by requiring that the $\tilde\chi_1^0$ contribution to the overall cosmological density is less than some maximal value to avoid overclosure of the Universe. Those not based on the cosmological density are indicated. Many of these papers also include LEP and/or other bounds.

[22] ELLIS 98 updates ELLIS 97C (see relative footnote). Use is made of one-loop mass and coupling relations, as well as of chargino limits from e^+e^- data at $\sqrt{s}$=183 GeV. The limits on $\tan\beta$ from ELLIS 97C improve to: $\tan\beta > 2$ ($\mu < 0$) and $\tan\beta > 1.65$ ($\mu > 0$).

[23] ELLIS 98B assumes a universal scalar mass and radiative supersymmetry breaking with universal gaugino masses. The upper limit to the LSP mass is increaded due to the inclusion of $\chi - \tilde\tau_R$ coannihilations.

[24] ELLIS 97C uses in addition to cosmological constraints, data from e^+e^- collisions at 170–172 GeV. It assumes a universal scalar mass for both the Higgs and scalar leptons, as well as radiative supersymmetry breaking with universal gaugino masses. ELLIS 97C also uses the absence of Higgs detection (with the assumptions listed above) to set a limit on $\tan\beta > 1.7$ for $\mu < 0$ and $\tan\beta > 1.4$ for $\mu > 0$. This paper updates ELLIS 96B.

[25] ELLIS 96B uses, in addition to cosmological constraints, data from BUSKULIC 96K and SUGIMOTO 96. It assumes a universal scalar mass m_0 and radiative Supersymmetry breaking, with universal gaugino masses.

[26] Mass of the bino (=LSP) is limited to $m_{\tilde B} \lesssim$ 350 GeV for m_t = 174 GeV.

[27] Mass of the bino (=LSP) is limited to $m_{\tilde B} \lesssim$ 350 GeV for $m_t \leq$ 200 GeV. Mass of the higgsino (=LSP) is limited to $m_{\tilde H} \lesssim$ 1 TeV for $m_t \leq$ 200 GeV.

[28] Mass of the bino (=LSP) is limited to $m_{\tilde B} \lesssim$ 550 GeV. Mass of the higgsino (=LSP) is limited to $m_{\tilde H} \lesssim$ 3.2 TeV.

[29] GRIFOLS 90 argues that SN1987A data exclude a light photino ($\lesssim$ 1 MeV) if $m_{\tilde q} <$ 1.1 TeV, $m_{\tilde e} <$ 0.83 TeV.

[30] ELLIS 88B argues that the observed neutrino flux from SN 1987A is inconsistent with a light photino if 60 GeV $\lesssim m_{\tilde q} \lesssim$ 2.5 TeV. If m(higgsino) is O(100 eV) the same argument leads to limits on the ratio of the two Higgs v.e.v.'s. LAU 93 discusses possible relations of ELLIS 88B bounds.

[31] KRAUSS 83 finds $m_{\tilde\gamma}$ not 30 eV to 2.5 GeV. KRAUSS 83 takes into account the gravitino decay. Find that limits depend strongly on reheated temperature. For example a new allowed region $m_{\tilde\gamma}$ = 4–20 MeV exists if $m_{\text{gravitino}}$ <40 TeV. See figure 2.

Unstable $\tilde\chi_1^0$ (Lightest Neutralino) MASS LIMIT

Unless otherwise stated, results in this section assume spectra and production rates as evaluated in the MSSM. Unless otherwise stated, the goldstino or gravitino mass $m_{\tilde G}$ is assumed to be negligible relative to all other masses. In the following, $\tilde G$ is assumed to be undetected and to give rise to a missing energy ($\not\!\!E$) signature.

[32] ABREU 00I searches for the production of charginos and neutralinos in the case of R-parity violation with $LL\overline{E}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. Limits are obtained in the M_2 versus μ plane and a limit on the neutralino mass is derived from a scan over the parameters m_0 and tanβ.

[33] BARATE 00G search for diphoton + $\not{E}$ topologies using data collected at $\sqrt{s}$=189 GeV. Limits are obtained from a scan of GMSB parameters space, under the assumption of a short-lived $\tilde{\chi}^0_1$ NLSP. The limit is reduced to 45 GeV for long-lived neutralinos.

[34] ABBIENDI 99F obtained an upper bound on the cross section for the process $e^+e^- \rightarrow \tilde{G}\tilde{\chi}^0_1$ followed by the prompt decay $\tilde{\chi}^0_1 \rightarrow \tilde{G}\gamma$ of 0.46–0.075 pb for $m_{\tilde{\chi}^0_1}$=91–183 GeV. See Fig. 8 for the detailed dependence of $m_{\tilde{\chi}^0_1}$. Data taken at $\sqrt{s}$=183 GeV.

[35] ABBIENDI 99F looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$=183 GeV. The limit is for pure bino $\tilde{B}$ and assumes $m_{\tilde{e}_R}$=1.35$m_{\tilde{B}}$ and $m_{\tilde{e}_L}$=2$m_{\tilde{e}_R}$. See Fig. 13 for the cross-section limits as a function of $m_{\tilde{\chi}^0_1}$.

[36] ABBIENDI 99T searches for the production of neutralinos in the case of R-parity violation with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings using data from $\sqrt{s}$=183 GeV. They investigate topologies with mulitiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. Mixed decays (where one particle has a direct, the other an indirect decay) are also considered for the $\overline{UDD}$ couplings. Upper limits on the cross section are derived which, combined with the constraint from the Z^0 width, allow to exclude regions in the M_2 versus μ plane for any coupling. Limits on the neutralino mass are obtained for non-zero $LL\overline{E}$ couplings $> 10^{-5}$. The limit disappears for tanβ < 1.2 and it improves to 50 GeV for tanβ > 20.

[37] ABE 99I looked for chargino and neutralino production, where the lightest neutralino in their decay products further decays into $\gamma\tilde{G}$. The limit assumes the gaugino mass unification, and holds for 1 <tanβ < 25, M_2 < 200 GeV, and all μ. ABE 99I is an expanded version of ABE 98L.

[38] ABREU 99D looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$=130–183 GeV. The limit is for prompt decay of pure bino $\tilde{B}$ and assumes $m_{\tilde{e}_R}$=1.1$m_{\tilde{B}}$ GeV. The limit reduces to 76 GeV for $m_{\tilde{e}_R}$=150 GeV. See Fig. 14 for the limits as a function of $m_{\tilde{e}_R}$. Model-independent cross-section limits in the range 0.10–0.13 pb are shown in Fig. 9, for neutralino masses in the range 45–81.5 GeV. Cross section limits were also derived, see Fig. 13, as function of the decay length, including non-pointing single photon final states.

[39] ABREU 99F looked for acoplanar ditaus, taus with large impact parameters, kinks, and stable heavy-charged tracks at $\sqrt{s}$=130–183 GeV. See Table 5 for explicit $m_{\tilde{\chi}^0_1}$ limits under different model assumptions.

[40] ACCIARRI 99I looked for multi-lepton and/or multi-jet final states from $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=130–183 GeV. The situations where the $\tilde{\chi}^0_1$ is the LSP (indirect decays) and where a $\tilde{\ell}$ is the LSP (direct decays) were both considered and both yield the same mass limit.

[41] ACCIARRI 99R searches for $\gamma\not{E}$ final states using data from $\sqrt{s}$=189 GeV. From limits on cross section times branching ratio, mass limits are derived in a no-scale SUGRA model, see their Fig. 5. Supersedes the results of ACCIARRI 98V.

[42] ACCIARRI 99R searches for $\gamma\not{E}$ final states using data from $\sqrt{s}$=189 GeV. From a scan over the GMSB parameter space, a limit on the mass is derived under the assumption that the neutralino is the NLSP. Supersedes the results of ACCIARRI 98V.

[43] BARATE 99E looked for the decay of gauginos via R-violating couplings $LQ\overline{D}$. The bound is significantly reduced for smaller values of m_0. Data collected at $\sqrt{s}$=130–172 GeV.

[44] ABBOTT 98 studied the chargino and neutralino production, where the lightest neutralino in their decay products further decays into $\gamma\tilde{G}$. The limit assumes the gaugino mass unification.

[45] ABREU 98 uses data at $\sqrt{s}$=161 and 172 GeV. Upper bounds on $\gamma\gamma\not{E}$ cross section are obtained. Similar limits on $\gamma\not{E}$ are also given, relevant for $e^+e^- \rightarrow \tilde{\chi}^0_1\tilde{G}$ production.

[46] ACCIARRI 98V obtained an upper bound on the cross section for the process $e^+e^- \rightarrow \tilde{G}\tilde{\chi}^0_1$ followed by the prompt decay $\tilde{\chi}^0_1 \rightarrow \tilde{G}\gamma$ of 0.28–0.07 pb $m_{\tilde{\chi}^0_1}$=0–183 GeV. See Fig. 4b for the detailed dependence on $m_{\tilde{\chi}^0_1}$. Data taken at $\sqrt{s}$=183 GeV.

[47] ACCIARRI 98V looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$=183 GeV. The limit is for pure bino $\tilde{B}$ and assumes $m_{\tilde{e}_{R,L}}$=150 GeV. The limit improves to 84 GeV for $m_{\tilde{e}_{R,L}}$=100 GeV. See Fig. 7 for the cross-section limits as a function of $m_{\tilde{\chi}^0_1}$, for different cases of neutralino composition.

[48] ACKERSTAFF 98J looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$=161–172 GeV. They set limits on $\sigma(e^+e^- \rightarrow \tilde{\chi}^0_1\tilde{\chi}^0_1)$ in the range 0.22–0.50 pb for $m_{\tilde{\chi}^0_1}$ in the range 45–86 GeV. Mass limits for explicit models from the literature are given in Fig. 19 of their paper. Similar limits on γ+missing energy are also given, relevant for $\tilde{\chi}^0_1\tilde{G}$ production.

[49] BARATE 98H obtained an upper bound on the cross section for the process $e^+e^- \rightarrow \tilde{G}\tilde{\chi}^0_1$ followed by the prompt decay $\tilde{\chi}^0_1 \rightarrow \tilde{G}\gamma$ of 0.4–0.75 pb for $m_{\tilde{\chi}^0_1}$ = 40–170 GeV. Data taken at $\sqrt{s}$ = 161,172 GeV.

[50] BARATE 98H looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$ = 161,172 GeV. The limit is for pure bino $\tilde{B}$ with $\tau(\tilde{B})$< 3 ns and assumes $m_{\tilde{e}_R}$ = 1.5$m_{\tilde{B}}$. See Fig. 5 for the dependence of the limit on $m_{\tilde{e}_R}$.

[51] BARATE 98J looked for $\gamma\not{E}$ final states at $\sqrt{s}$ = 161–183 GeV. They obtained an upper bound on the cross section of about 0.2 pb for the process $e^+e^- \rightarrow XY$ followed by the prompt decay $X \rightarrow Y\gamma$ ($\tau(X)$< 0.1 ns) if m_Y = 0. The bound applies for $\tilde{G}\tilde{\chi}^0_1$.

[52] BARATE 98J looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$ = 161–183 GeV. The limit is for pure bino $\tilde{B}$ with $\tau(\tilde{B})$< 3 ns and assumes $m_{\tilde{e}_R}$ = 1.1$m_{\tilde{B}}$. See Fig. 5 for the dependence of the limit on $m_{\tilde{e}_R}$.

[53] BARATE 98S looked for the decay of gauginos via R-violating coupling $LL\overline{E}$. The bound improves to 25 GeV if the chargino decays into neutralino which further decays into lepton pairs. Data collected at $\sqrt{s}$=130–172 GeV.

[54] ACCIARRI 97V looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$=161 and 172 GeV. They set limits on $\sigma(e^+e^- \rightarrow \tilde{\chi}^0_1\tilde{\chi}^0_1)$ in the range 0.25–0.50 pb for masses in the range 45–85 GeV. The lower limits on $m_{\tilde{\chi}^0_1}$ vary in the range of 64.8 GeV (pure bino with 90 GeV slepton) to 75.3 GeV (pure higgsino). There is no limit for pure zino case.

[55] ELLIS 97 reanalyzed the LEP2 ($\sqrt{s}$=161 GeV) limits of $\sigma(\gamma\gamma+E_{\rm miss})$< 0.2 pb to exclude $m_{\tilde{\chi}^0_1}$ < 63 GeV if $m_{\tilde{e}_L}$=$m_{\tilde{e}_R}$ < 150 GeV and $\tilde{\chi}^0_1$ decays to $\gamma\tilde{G}$ inside detector.

[56] CABIBBO 81 consider $\tilde{\gamma} \rightarrow \gamma+$ goldstino. Photino must be either light enough (<30 eV) to satisfy cosmology bound, or heavy enough (>0.3 MeV) to have disappeared at early universe.

$\tilde{\chi}^0_2$, $\tilde{\chi}^0_3$, $\tilde{\chi}^0_4$ (Neutralinos) MASS LIMITS

Neutralinos are unknown mixtures of photinos, z-inos, and neutral higgsinos (the supersymmetric partners of photons and of Z and Higgs bosons). The limits here apply only to $\tilde{\chi}^0_2$, $\tilde{\chi}^0_3$, and $\tilde{\chi}^0_4$. $\tilde{\chi}^0_1$ is the lightest supersymmetric particle (LSP); see $\tilde{\chi}^0_1$ Mass Limits. It is not possible to quote rigorous mass limits because they are extremely model dependent; i.e. they depend on branching ratios of various $\tilde{\chi}^0$ decay modes, on the masses of decay products ($\tilde{e}$, $\tilde{\gamma}$, $\tilde{q}$, $\tilde{g}$), and on the $\tilde{e}$ mass exchanged in $e^+e^- \rightarrow \tilde{\chi}^0_i\tilde{\chi}^0_j$. Limits arise either from direct searches, or from the MSSM constraints set on the gaugino and higgsino mass parameters M_2 and μ through searches for lighter charginos and neutralinos. Often limits are given as contour plots in the $m_{\tilde{\chi}^0} - m_{\tilde{e}}$ plane vs other parameters. When specific assumptions are made, e.g, the neutralino is a pure photino ($\tilde{\gamma}$), pure z-ino ($\tilde{Z}$), or pure neutral higgsino ($\tilde{H}^0$), the neutralinos will be labelled as such.

Limits obtained from e^+e^- collisions at energies up to 136 GeV, as well as other limits from different techniques, are now superseded and have not been included in this compilation. They can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

[57] ABBIENDI 00H used the results of direct searches in the $e^+e^- \rightarrow \tilde{\chi}^0_1\tilde{\chi}^0_{2,3}$ channels, as well as the indirect limits from $\tilde{\chi}^0_1$ and $\tilde{\chi}^\pm_1$ searches, in the framework of the MSSM with gaugino and sfermion mass unification at the GUT scale. See the footnote to ABBIENDI 00H in the chargino Section for further details on the assumptions. Data collected at $\sqrt{s}$=189 GeV. The limits improve to 86.2 GeV ($\tilde{\chi}^0_2$) and 124 GeV ($\tilde{\chi}^0_3$) for tanβ=35. See their Table 6 for more details on the tanβ and m_0 dependence of the limits.

[58] ABBIENDI 99F looked for $\gamma\not{E}$ final states at $\sqrt{s}$=183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \rightarrow \tilde{\chi}^0_2\tilde{\chi}^0_1$ followed by the prompt decay $\tilde{\chi}^0_2 \rightarrow \gamma\tilde{\chi}^0_1$ of 0.075–0.80 pb in the region $m_{\tilde{\chi}^0_2}$+$m_{\tilde{\chi}^0_1}$ >m_Z, $m_{\tilde{\chi}^0_2}$=91–183 GeV, and Δm_0 > 5 GeV. See Fig. 7 for explicit limits in the ($m_{\tilde{\chi}^0_2}$,$m_{\tilde{\chi}^0_1}$) plane.

[59] ABBIENDI 99F looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$=183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \rightarrow \tilde{\chi}^0_2\tilde{\chi}^0_2$ followed by the prompt decay $\tilde{\chi}^0_2 \rightarrow \gamma\tilde{\chi}^0_1$ of 0.08–0.37 pb for $m_{\tilde{\chi}^0_2}$=45–81.5 GeV, and Δm_0 > 5 GeV. See Fig. 11 for explicit limits in the ($m_{\tilde{\chi}^0_2}$,$m_{\tilde{\chi}^0_1}$) plane.

[60] ABBIENDI 99G uses the results of direct searches in the $e^+e^- \rightarrow \tilde{\chi}^0_1\tilde{\chi}^0_{2,3}$ channels, as well as the indirect limits from $\tilde{\chi}^0_1$,$\tilde{\chi}^\pm_1$ searches within the MSSM. See the footnote to ABBIENDI 99G in the Chargino Section for further details on the assumptions. Data collected at $\sqrt{s}$=181–184 GeV.

[61] ABREU 99D looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$=183 GeV. They obtained upper bounds in the range 0.10–0.25 pb on the cross section for the production $e^+e^- \rightarrow \tilde{\chi}^0_2\tilde{\chi}^0_2$ followed by the prompt decay $\tilde{\chi}^0_2 \rightarrow \gamma\tilde{\chi}^0_1$ with Δm_0 > 6 GeV. See Fig. 12 for explicit limits in the ($m_{\tilde{\chi}^0_2}$,$m_{\tilde{\chi}^0_1}$) plane.

[62] ACCIARRI 99I looked for multi-lepton and/or multi-jet final states from $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=130–183 GeV. The situations where the $\tilde{\chi}^0_1$ is the LSP (indirect decays) and where a $\tilde{\ell}$ is the LSP (direct decays) were both considered. The weakest limit, quoted above, comes from direct decays with $\overline{UDD}$ couplings; indirect decays lead to a limit of 44.3 GeV.

[63] ACCIARRI 99R searches for $\gamma\not{E}$ and $\gamma\gamma\not{E}$ final states using data from $\sqrt{s}$=189 GeV. Limits on the cross section for the processes $e^+e^- \to \tilde{\chi}^0_2\tilde{\chi}^0_{2,1}$ with the decay $\tilde{\chi}^0_2 \to \tilde{\chi}^0_1\gamma$ are derived, as shown in their Figs. 4 and 7. Supersedes the results of ACCIARRI 98V.

[64] ABBOTT 98C searches for trilepton final states (ℓ=e,μ). See footnote to ABBOTT 98C in the Chargino Section for details on the assumptions. Assuming a negligible decay rate of $\tilde{\chi}^\pm_1$ and $\tilde{\chi}^0_2$ to quarks, they obtain $m_{\tilde{\chi}^0_2} \gtrsim 103$ GeV.

[65] ABE 98J searches for trilepton final states (ℓ=e,μ). See footnote to ABE 98J in the Chargino Section for details on the assumptions. The quoted result for $m_{\tilde{\chi}^0_2}$ corresponds to the best limit within the selected range of parameters, obtained for $m_{\tilde{q}} > m_{\tilde{g}}$, tan$\beta$=2, and μ=−600 GeV.

[66] ACCIARRI 98F is obtained from direct searches in the $e^+e^- \to \tilde{\chi}^0_{1,2}\tilde{\chi}^0_2$ production channels, and indirectly from $\tilde{\chi}^\pm_1$ and $\tilde{\chi}^0_1$ searches within the MSSM. See footone to ACCIARRI 98F in the chargino Section for futher details on the assumptions. Data taken at $\sqrt{s}$ = 130–172 GeV.

[67] ACCIARRI 98V looked for $\gamma(\gamma)\not{E}$ final states at $\sqrt{s}$=183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}^0_2\tilde{\chi}^0_{1,2}$ followed by the prompt decay $\tilde{\chi}^0_2 \to \gamma\tilde{\chi}^0_1$. See Figs. 4a and 6a for explicit limits in the $(m_{\tilde{\chi}^0_2}, m_{\tilde{\chi}^0_1})$ plane.

[68] ACKERSTAFF 98L is obtained from direct searches in the $e^+e^- \to \tilde{\chi}^0_1\tilde{\chi}^0_{2,3}$ production channels, and indirectly from $\tilde{\chi}^\pm_1$ and $\tilde{\chi}^0_1$ searches within the MSSM. See footnote to ACKERSTAFF 98L in the chargino Section for further details on the assumptions. Data taken at $\sqrt{s}$=130–172 GeV.

[69] BARATE 98H looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$ = 161,172 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}^0_2\tilde{\chi}^0_2$ followed by the prompt decay $\tilde{\chi}^0_2 \to \gamma\tilde{\chi}^0_1$ of 0.4–0.8 pb for $m_{\tilde{\chi}^0_2}$ = 10–80 GeV. The bound above is for the specific case of $\tilde{\chi}^0_1 = \tilde{H}^0$ and $\tilde{\chi}^0_2 = \tilde{\gamma}$ and $m_{\tilde{e}_R}$ = 100 GeV. See Fig. 6 and 7 for explicit limits in the $(\tilde{\chi}^0_2,\tilde{\chi}^0_1)$ plane and in the $(\tilde{\chi}^0_2,\tilde{e}_R)$ plane.

[70] BARATE 98J looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$ = 161–183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}^0_2\tilde{\chi}^0_2$ followed by the prompt decay $\tilde{\chi}^0_2 \to \gamma\tilde{\chi}^0_1$ of 0.08–0.24 pb for $m_{\tilde{\chi}^0_2} < 91$ GeV. The bound above is for the specific case of $\tilde{\chi}^0_1 = \tilde{H}^0$ and $\tilde{\chi}^0_2 = \tilde{\gamma}$ and $m_{\tilde{e}_R}$ = 100 GeV.

[71] ABACHI 96 searches for 3-lepton final states. Efficiencies are calculated using mass relations and branching ratios in the Minimal Supergravity scenario. Results are presented as lower bounds on $\sigma(\tilde{\chi}^\pm_1\tilde{\chi}^0_2) \times B(\tilde{\chi}^\pm_1 \to \ell\nu_\ell\tilde{\chi}^0_1) \times B(\tilde{\chi}^0_2 \to \ell^+\ell^-\tilde{\chi}^0_1)$ as a function of $m_{\tilde{\chi}^0_1}$. Limits range from 3.1 pb ($m_{\tilde{\chi}^0_1}$ = 45 GeV) to 0.6 pb ($m_{\tilde{\chi}^0_1}$ = 100 GeV).

[72] ABE 96K looked for tripleton events from chargino-neutralino production. They obtained lower bounds on $m_{\tilde{\chi}^0_2}$ as a function of μ. The lower bounds are in the 45–50 GeV range for gaugino-dominant $\tilde{\chi}^0_2$ with negative μ, if tanβ <10. See paper for more details of the assumptions.

[73] ACKERSTAFF 96C is obtained from direct searches in the $e^+e^- \to \tilde{\chi}^0_1\tilde{\chi}^0_{2,3}$ production channel, and indirectly from $\tilde{\chi}^\pm_1$ searches within MSSM. Data from $\sqrt{s}$ = 130, 136, and 161 GeV are combined. The same assumptions and constraints of ALEXANDER 96J apply. The limit improves to 94.3 GeV for m_0 = 1 TeV.

$\tilde{\chi}^\pm_1$, $\tilde{\chi}^\pm_2$ (Charginos) MASS LIMITS

Charginos are unknown mixtures of w-inos and charged higgsinos (the supersymmetric partners of W and Higgs bosons). A lower mass limit for the lightest chargino ($\tilde{\chi}^\pm_1$) of approximately 45 GeV, independent of the field composition and of the decay mode, has been obtained by the LEP experiments from the analysis of the Z width and decays. These results, as well as other now superseded limits from e^+e^- collisions at energies below 136 GeV, and from hadronic collisions, can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

Unless otherwise stated, results in this section assume spectra, production rates, decay modes and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers generally study production of $\tilde{\chi}^0_1\tilde{\chi}^0_2$, $\tilde{\chi}^+_1\tilde{\chi}^-_1$ and (in the case of hadronic collisions) $\tilde{\chi}^+_1\tilde{\chi}^0_2$ pairs, including the effects of cascade decays. The mass limits on $\tilde{\chi}^\pm_1$ are either direct, or follow indirectly from the constraints set by the non-observation of $\tilde{\chi}^0_2$ states on the gaugino and higgsino MSSM parameters M_2 and μ. For generic values of the MSSM parameters, limits from high-energy e^+e^- collisions coincide with the highest value of the mass allowed by phase-space, namely $m_{\tilde{\chi}^\pm_1} \lesssim \sqrt{s}/2$. At the time of this writing, preliminary and unpublished results from the 1999 run of LEP2 at $\sqrt{s}$ up to 202 GeV give therefore a lower mass limit of approximately 101 GeV valid for general MSSM models. The limits become however weaker in special regions of the MSSM parameter space where the detection efficiencies or production cross sections are suppressed. For example, this may happen when: (i) the mass differences $\Delta m_+ = m_{\tilde{\chi}^\pm_1} - m_{\tilde{\chi}^0_1}$ or $\Delta m_\nu = m_{\tilde{\chi}^\pm_1} - m_{\tilde{\nu}}$ are very small, and the detection efficiency is reduced; (ii) the electron sneutrino mass is small, and the $\tilde{\chi}^\pm_1$ production rate is suppressed due to a destructive interference between s and t channel exchange diagrams. The regions of MSSM parameter space where the following limits are valid are indicated in the comment lines or in the footnotes.

[74] ABBIENDI 00H data collected at $\sqrt{s}$=189 GeV. The results hold over the full parameter space defined by $0 \leq M_2 \leq 2$ TeV, $|\mu| \leq 500$ GeV, $m_0 \leq 500$ GeV, $A=\pm M_2$, $\pm m_0$, and 0. The results of slepton searches from ABBIENDI 00G were used to help set constraints in the region of small m_0. The limit improves to 78 GeV for tanβ=1.5. See their Table 5 and Fig. 4 for the tanβ and M_2 dependence of the limits.

[75] ABREU 00J data collected at $\sqrt{s}$=189 GeV. They investigate topologies with multiple leptons, jets plus leptons, multi-jets, or isolated photons. The parameter space is scanned in the domain $0 < M_2 < 3000$ GeV, $|\mu| < 200$ GeV, 1<tanβ < 35. The analysis includes the effects of gaugino cascade decays.

[76] ACCIARRI 00D data collected at $\sqrt{s}$=189 GeV. The results hold over the full parameter space defined by 0.7 ≤ tanβ ≤ 60, $0 \leq M_2 \leq 2$ TeV, $|\mu| \leq 2$ TeV $m_0 \leq 500$ GeV. The results of slepton searches from ACCIARRI 99W are used to help set constraints in the region of small m_0. See their Figs. 5 for the tanβ and M_2 dependence on the limits. See the text for the impact of a large $B(\tilde{\chi}^\pm \to \tau\tilde{\nu}_\tau)$ on the result.

[77] BARATE 98X limit holds for all values of m_0 consistent with the slepton mass limits of BARATE 97N. The limit improves to 79 GeV for a mostly higgsino $\tilde{\chi}^\pm_1$ (with Δm > 5 GeV) and to 85.5 GeV for a mostly gaugino $\tilde{\chi}^\pm_1$ (μ=−500 GeV and $m_{\tilde{\nu}}$ > 200 GeV). The cases of $m_{\tilde{\chi}^\pm_1} > m_{\tilde{\nu}}$ or nonuniversal scalar mass or nonuniversal gaugino mass are also studied in the paper. Data collected at $\sqrt{s}$=161–172 GeV.

[78] ABREU 00I searches for the production of charginos and neutralinos in the case of R-parity violation with $LL\overline{E}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. Limits are obtained in the M_2 versus μ plane and a limit on the neutralino mass is derived from a scan over the parameters m_0 and tanβ.

[79] This ABREU 00J limit holds for Δm_+ > 10 GeV and $m_{\tilde{\nu}}$ > 300 GeV. For the other assumptions, see previous footnote to ABREU 00J in this Section. A limit of 94.2 GeV is obtained for Δm_+=1 GeV and $m_{\tilde{\nu}} > m_{\tilde{\chi}^\pm}$.

[80] BARATE 00H data collected at $\sqrt{s}$=183 GeV. The limit holds for any possible R-parity violating coupling.

[81] ABBIENDI 99G data collected at $\sqrt{s} \leq 184$ GeV. The parameter space is scanned in the domain $0 < M_2 < 2000$ GeV, $|\mu| < 500$ GeV, and for various values of A. No dependence of the limits on A is found. The analysis includes the effects of gaugino cascade decays. In the case of radiative neutralino decays, the limits from ACKERSTAFF 98J are assumed. The limit for all values of m_0 assumes $m_{\tilde{\nu}_e}$ > 43 GeV and direct limits on charged sleptons. See Table 5 for limits under different assumptions on Δm_+ and tanβ.

[82] ABBIENDI 99T searches for the production of neutralinos in the case of R-parity violation with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. Mixed decays (where one particle has a direct, the other an indirect decay) are also considered for the $\overline{UDD}$ couplings. Upper limits on the cross section are derived which, combined with the

constraint from the Z^0 width, allow to exclude regions in the M_2 versus μ plane for any coupling. Limits on the chargino mass are obtained for non-zero $LL\overline{E}$ couplings $> 10^{-5}$ and assuming decays via a W^*.

[83] ABE 99I looked for chargino and neutralino production, where the lightest neutralino in their decay products further decays into $\gamma\tilde{G}$. The limit assumes the gaugino mass unification, and holds for $1 < \tan\beta < 25$, $M_2 < 200$ GeV, and all μ. ABE 99I is an expanded version of ABE 98L.

[84] ABREU 99E data collected at $\sqrt{s} \leq 183$ GeV. These results include and update the limits from ABREU 98. The parameter space is scanned in the domain $0 < M_2 < 3000$ GeV, $|\mu| < 400$ GeV, $1 < \tan\beta < 35$. The analysis includes the effects of gaugino cascade decays. In the case of radiative neutralino decays, the limits from ABREU 97J are assumed.

[85] This ABREU 99E limit holds for $\Delta m_0 > 10$ GeV and $m_{\tilde{\nu}} > 300$ GeV. For the other assumptions, see previous footnote to ABREU 99E in this Section. A limit of 90.6 GeV is obtained for $\Delta m_+ = 1$ GeV and $m_{\tilde{\nu}} > 41$ GeV.

[86] ABREU 99V reinterprets search results at 183 GeV on $\tilde{\tau}$ decays at the interaction vertex (ABREU 99E), visible decay vertices in the tracking devices or large impact parameters (ABREU 99F) and stable charged heavy particles (ABREU 98P). Limits are computed by scanning the GMSB parameter space where $\tilde{\tau}_1$ is the NLSP, with the constraints that electroweak symmetry is broken radiatively and that trilinear couplings are zero at the messenger scale. All branching ratios in the above decay chain are taken equal to 1. The limit holds for $m_{\tilde{\chi}_1} - m_{\tilde{\tau}_1} > 0.3$ GeV, and any gravitino mass, in the domain $m_{\tilde{\tau}_1} > 68$ GeV, not excluded by the direct $\tilde{\tau}$ production searches of ABREU 99F. The limit is reached for $m_{\tilde{G}} \leq 1$ eV and improves to 89 GeV for $m_{\tilde{G}} > 100$ eV. See Fig. 4 for the dependence of the limit on $m_{\tilde{\tau}_1}$.

[87] ABREU 99Z searches for the production of charginos degenerate with $\tilde{\chi}_1^0$, using data from $\sqrt{s}$= 130 to 183 GeV. The range $\Delta m_+ < 200$ MeV is covered by a search for decays visible in the detector or for heavy stable particles identified by their ionization or Cherenkov radiation. The region 300 MeV$< \Delta m_+ < 3$ GeV is explored by searching events with initial state radiation and few low energy particles. For 200 MeV$< \Delta m_+ <$ 300 MeV, no limits are obtained. For limits in various scenarios, see Fig. 12 and Table 3.

[88] ACCIARRI 99I looked for multi-lepton and/or multi-jet final states from $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=130–183 GeV. The situations where the $\tilde{\chi}_1^0$ is the LSP (indirect decays) and where a $\tilde{\ell}$ is the LSP (direct decays) were both considered. The weakest limit, quoted above, comes from direct decays with $\overline{UDD}$ couplings; indirect decays lead to a limit of 91.1 GeV for $LL\overline{E}$ and 90.9 GeV for $\overline{UDD}$ couplings.

[89] BARATE 99E looked for the decay of charginos via R-violating couplings $LQ\overline{D}$. The bound is reduced to 56 GeV for m_0=80 GeV (in the case of decays via a neutralino), and to 51 GeV for m_0=70 GeV (in the case of direct R-violating decays). Data collected at $\sqrt{s}$=130–172 GeV.

[90] MALTONI 99B studied the effect of light chargino-neutralino to the electroweak precision data with a particular focus on the case where they are nearly degenerate ($\Delta m_+ \sim 1$ GeV) which is difficult to exclude from direct collider searches. The quoted limit is for higgsino-like case while the bound improves to 56 GeV for wino-like case. The values of the limits presented here are obtained in an update to MALTONI 99B, as described in MALTONI 00.

[91] ABBOTT 98 studied the chargino and neutralino production, where the lightest neutralino in their decay products further decays into $\gamma\tilde{G}$. The limit assumes the gaugino mass unification.

[92] ABBOTT 98C searches for trilepton final states (ℓ=e,μ). Efficiencies are calculated using mass relations in the Minimal Supergravity scenario, exploring the domain of parameter space defined by $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$ and $m_{\tilde{\chi}_1^\pm} = 2m_{\tilde{\chi}_1^0}$. Results are presented in Fig. 1 as upper bounds on $\sigma(p\overline{p} \rightarrow \tilde{\chi}_1^\pm \tilde{\chi}_2^0) \times B(3\ell)$. Assuming equal branching ratio for all possible leptonic decays, limits range from 2.6 pb ($m_{\tilde{\chi}_1^\pm}$=45 GeV) to 0.4 pb ($m_{\tilde{\chi}_1^\pm}$=124 GeV) at 95%CL. Assuming a negligible decay rate of $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ to quarks, this corresponds to $m_{\tilde{\chi}_1^\pm} > 103$ GeV.

[93] ABE 98J searches for trilepton final states (ℓ=e,μ). Efficiencies are calculated using mass relations in the Minimal Supergravity scenario, exploring the domain of parameter space defined by $1.1 < \tan\beta < 8$, $-1000 < \mu$(GeV)< -200, and $m_{\tilde{q}}/m_{\tilde{g}}$=1–2. In this region $m_{\tilde{\chi}_1^\pm} \sim m_{\tilde{\chi}_2^0}$ and $m_{\tilde{\chi}_1^\pm} \sim 2m_{\tilde{\chi}_1^0}$. Results are presented in Fig. 1 as upper bounds on $\sigma(p\overline{p} \rightarrow \tilde{\chi}_1^\pm \tilde{\chi}_2^0) \times B(3\ell)$. Limits range from 0.8 pb ($m_{\tilde{\chi}_1^\pm}$=50 GeV) to 0.23 pb ($m_{\tilde{\chi}_1^\pm}$=100 GeV) at 95%CL. The gaugino mass unification hypothesis and the assumed mass relation between squarks and gluinos define the value of the leptonic branching ratios. The quoted result corresponds to the best limit within the selected range of parameters, obtained for $m_{\tilde{q}} > m_{\tilde{g}}$, $\tan\beta$=2, and μ=$-$600 GeV. Mass limits for different values of $\tan\beta$ and μ are given in Fig. 2.

[94] ABREU 98 uses data at $\sqrt{s}$=161 and 172 GeV. The limit is for $41 < m_{\tilde{\nu}} < 100$ GeV, and $\tan\beta$=1–35. The limit improves to 84.3 GeV for $m_{\tilde{\nu}} > 300$ GeV. For Δm_+ below 10 GeV, the limit is independent of $m_{\tilde{\nu}}$, and is given by 80.3 GeV for $\Delta m_+ = 5$ GeV, and by 52.4 GeV for $\Delta m_+ = 3$ GeV.

[95] ABREU 98 uses data at $\sqrt{s}$=161 and 172 GeV. The radiative decay of the lightest neutralino into gravitino is assumed. The limit is for $\Delta m > 10$ GeV, $41 < m_{\tilde{\nu}} < 100$ GeV, and $\tan\beta$=1–35. The limit improves to 84.5 GeV if either $m_{\tilde{\nu}} > 300$ GeV, or Δm_+=1 GeV independently of $m_{\tilde{\nu}}$.

[96] ACCIARRI 98F limit is obtained for $0 < M_2 < 2000$, $\tan\beta < 1.41$, and $\mu = -200$ GeV, and holds for all values of m_0. No dependence on the trilinear-coupling parameter A is found. It improves to 84 GeV for large sneutrino mass, at μ=$-$200 GeV. See the paper for limits obtained with specific assumptions on the gaugino/higgsino composition of the state. Data taken at $\sqrt{s}$ = 130–172 GeV.

[97] ACKERSTAFF 98K looked for dilepton+$\not{E}_T$ final states at $\sqrt{s}$=130–172 GeV. Limits on $\sigma(e^+e^- \rightarrow \tilde{\chi}_1^+\tilde{\chi}_1^-) \times B^2(\ell)$, with $B(\ell)$=$B(\chi^+ \rightarrow \ell^+\nu_\ell\chi_1^0)$ ($B(\ell)$=$B(\chi^+ \rightarrow \ell^+\tilde{\nu}_\ell)$), are given in Fig. 16 (Fig. 17).

[98] ACKERSTAFF 98L limit is obtained for $0 < M_2 < 1500$, $|\mu| < 500$ and $\tan\beta > 1$, but remains valid outside this domain. The dependence on the trilinear-coupling parameter A is studied, and found neglibible. The limit holds for the smallest value of m_0 consistent with scalar lepton constraints (ACKERSTAFF 97H) and for all values of m_0 where the condition $\Delta m_{\tilde{\nu}} > 2.0$ GeV is satisfied. $\Delta m_\nu > 10$ GeV if $\tilde{\chi}^\pm \rightarrow \ell\tilde{\nu}_\ell$. The limit improves to 84.5 GeV for m_0=1 TeV. Data taken at $\sqrt{s}$=130–172 GeV.

[99] ACKERSTAFF 98V excludes the light gluino with universal gaugino mass where charginos, neutralinos decay as $\tilde{\chi}_1^\pm, \tilde{\chi}_2^0 \rightarrow q\overline{q}\tilde{g}$ from total hadronic cross sections at $\sqrt{s}$=130–172 GeV. See paper for the case of nonuniversal gaugino mass.

[100] BARATE 98S looked for the decay of charginos via R-violating coupling $LL\overline{E}$. The bound improves to 78 GeV if the chargino decays into neutralino which further decays into lepton pairs. Data collected at $\sqrt{s}$=130–172 GeV.

[101] CARENA 97 studied the constraints on chargino and sneutrino masses from muon $g-2$. The bound can be important for large $\tan\beta$.

[102] KALINOWSKI 97 studies the constraints on the chargino-neutralino parameter space from limits on $\Gamma(W \rightarrow \tilde{\chi}_1^\pm \tilde{\chi}_1^0)$ achievable at LEP2. This is relevant when $\tilde{\chi}_1^\pm$ is "invisible," i.e., if $\tilde{\chi}_1^\pm$ dominantly decays into $\tilde{\nu}_\ell \ell^\pm$ with little energy for the lepton. Small otherwise allowed regions could be excluded.

[103] ABE 96K looked for tripleton events from chargino-neutralino production. The bound on $m_{\tilde{\chi}_1^\pm}$ can reach up to 47 GeV for specific choices of parameters. The limits on the combined production cross section times 3-lepton branching ratios range between 1.4 and 0.4 pb, for $45 < m_{\tilde{\chi}_1^\pm}(GeV)<100$. See the paper for more details on the parameter dependence of the results.

[104] ACKERSTAFF 96C assumes the dominance of off-shell W-exchange in the chargino decay and applies for $\Delta m > 10$ GeV in the region of parameter space defined by: $M_2 < 1500$ GeV, $|\mu| < 500$ GeV and $\tan\beta > 1.5$. The bound is for the smallest $\tilde{\ell}$,$\tilde{\nu}$ mass allowed by LEP, with the efficiency for $\tilde{\chi}^\pm \rightarrow \tilde{\nu}\nu$ decays set to zero. The limit improves to 78.5 GeV for m_0 = 1 TeV. Data taken at $\sqrt{s}$ = 130,136, and 161 GeV.

Long-lived $\tilde{\chi}^\pm$ (Chargino) MASS LIMITS

Limits on charginos which leave the detector before decaying.

[105] ABREU 98P searches for production of pairs of heavy, charged particles in e^+e^- annihilation at $\sqrt{s}$=130–183 GeV. The upper bound improves to 89.5 GeV for $m_{\tilde{\nu}} > 200$ GeV. These limits include and update the results of ABREU 97D.

[106] ACKERSTAFF 98P bound assumes a heavy sneutrino $m_{\tilde{\nu}} > 500$ GeV. Data collected at $\sqrt{s}$ = 130–183 GeV.

[107] ABREU 97D bound applies only to masses above 45 GeV. Data collected in e^+e^- collisions at $\sqrt{s}$=130–172 GeV. The limit improves to 84 GeV for $m_{\tilde{\nu}} > 200$ GeV.

[108] BARATE 97K uses e^+e^- data collected at $\sqrt{s}$ = 130–172 GeV. Limit valid for $\tan\beta = \sqrt{2}$ and $m_{\tilde{\nu}} > 100$ GeV. The limit improves to 86 GeV for $m_{\tilde{\nu}} > 250$ GeV.

$\tilde{\nu}$ (Sneutrino) MASS LIMIT

The limit depends on the number, $N(\tilde{\nu})$, of sneutrinos assumed to be degenerate in mass. Only $\tilde{\nu}_L$ (not $\tilde{\nu}_R$) is assumed to exist. It is possible that $\tilde{\nu}$ could be the lightest supersymmetric particle (LSP).

We report here, but do not include in the Listings, the limits obtained from preliminary, unpublished constraints by the LEP Collaborations on the invisible width of the Z boson ($\Delta\Gamma_{inv.} < 2.0$ MeV, LEP 00): $m_{\tilde{\nu}} > 43.7$ GeV ($N(\tilde{\nu})$=1) and $m_{\tilde{\nu}} > 44.7$ GeV ($N(\tilde{\nu})$=3) .

[109] ADRIANI 93M limit from $\Delta\Gamma(Z)$(invisible)< 16.2 MeV.

[110] DECAMP 92 limit is from Γ(invisible)/$\Gamma(\ell\ell) = 5.91 \pm 0.15$ ($N_\nu = 2.97 \pm 0.07$).

[111] ALEXANDER 91F limit is for one species of $\tilde{\nu}$ and is derived from Γ(invisible, new)/$\Gamma(\ell\ell)$ < 0.38.

[112] ABBIENDI 00 searches for the production of sneutrinos in the case of R-parity violation with $LL\overline{E}$ or $LQ\overline{D}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. For non-zero $LL\overline{E}$ couplings, they obtain limits on the electron sneutrino mass of 88 GeV for direct decays and of 87 GeV for indirect decays with a low mass χ^0_1. For non-zero $LQ\overline{D}$ couplings, the limits are 86 GeV for indirect decays of $\tilde{\nu}_e$ with a low mass χ^0_1 and 80 GeV for direct decays of $\tilde{\nu}_e$. There exists a region of small Δm, of varying size, for which no limit is obtained, see Fig. 20. It is assumed that tanβ=1.5 and μ=−200 GeV. For muon sneutrinos, direct decays via $LL\overline{E}$ couplings lead to a 66 GeV mass limit and via $LQ\overline{D}$ couplings to a 58 GeV limit.

[113] ABREU 00I studies decays induced by R-parity-violating $LL\overline{E}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. The limits, valid for each individual flavor, are determined by the indirect decays and assume a neutralino mass limit of 27 GeV, also derived in ABREU 00I. Better limits for specific flavors and for specific $\not{R}$ couplings can be obtained and are discussed in the paper.

[114] BARATE 00H data collected at $\sqrt{s}$=183 GeV. The limit holds for indirect $\tilde{\nu}$ decays mediated by $\not{R}$ $LL\overline{E}$ couplings, and improves to 66 GeV for direct decays. Better limits are obtained for specific flavors, or couplings. Limits are also given for direct decays via $LQ\overline{D}$ couplings ($m_{\nu_{\mu,\tau}}$ > 59GeV) and for indirect decays via $\overline{UDD}$ couplings (m_{ν_e} > 70GeV with μ=−200 GeV and tanβ=2). For $LL\overline{E}$ indirect decays, use is made of neutralino mass limits from BARATE 98S.

[115] ABBIENDI 99 studied the effect of s- and t-channel τ or μ sneutrino exchange in $e^+e^- \rightarrow e^+e^-$ at $\sqrt{s}$=130–183 GeV, via the R-parity violatin coupling $\lambda_{1i1}L_1L_ie^c_1$ (i=2 or 3). The limits quoted here hold for λ_{1i1} > 0.13. The effect of t-channel electron-sneutrino exchange on rate and asymmetries of $e^+e^- \rightarrow \tau^+\tau^-$ leads to weaker limits on the electron sneutrino mass.

[116] ABBIENDI 99 studied the effect of s-channel τ sneutrino exchange in $e^+e^- \rightarrow \mu^+\mu^-$ at $\sqrt{s}$=130–183 GeV, in presence of the R-parity violating couplings $\lambda_{i3i}L_iL_3e^c_i$ (i=1 and 2), with λ_{131}=λ_{232}. The limits quoted here hold for λ_{131} > 0.09.

[117] ABBIENDI 99 studied the effect of t-channel electron sneutrino exchange in $e^+e^- \rightarrow \tau^+\tau^-$ at $\sqrt{s}$=130–183 GeV, in presence of the R-parity violating couplings $\lambda_{131}L_1L_3e^c_1$. The limits quoted here hold for λ_{131} > 0.6.

[118] ABREU 99A searches for anomalies in the production cross sections and forward-backward asymmetries of the $\ell^+\ell^-(\gamma)$ final states (ℓ=e,μ,τ) from e^+e^- collisions at $\sqrt{s}$=130–172 GeV. Limits are set on the s- and t-channel exchange of sneutrinos in the presence of $\not{R}$ with λLLe^c couplings. For points between the energies at which data were taken, information is obtained from events in which a photon was radiated. Exclusion limits in the (λ,$m_{\tilde{\nu}}$) plane are given in Fig. 13.

[119] BARATE 99E looked for $\tilde{\nu}_\mu$ pairs with decay $\tilde{\nu}_\mu \rightarrow jj$ via R-violating coupling $LQ\overline{D}$. Data collected at $\sqrt{s}$=130–172 GeV.

[120] BARATE 98S looked for $\tilde{\nu}_\ell$ pairs with decay $\tilde{\nu}_\ell \rightarrow \ell\tilde{\chi}^0_1$, where $\tilde{\chi}^0_1$ further decays to $\ell^+\ell^-\nu$ via R-violating coupling $LL\overline{E}$. The limit assumes tanβ=2, The bound on $\tilde{\nu}_e$ is for the higgsino region. It improves to 72 GeV for the gaugino region. Data collected at $\sqrt{s}$=130–172 GeV.

[121] ACCIARRI 97U studied the effect of the s-channel tau-sneutrino exchange in $e^+e^- \rightarrow e^+e^-$ at $\sqrt{s}$=m_Z and $\sqrt{s}$=130–172 GeV, via the R-parity violating coupling $\lambda_{131}L_1L_je^c_1$. The limits quoted here hold for λ_{131} > 0.05. Similar limits were studied in $e^+e^- \rightarrow \mu^+\mu^-$ together with $\lambda_{232}L_2L_3e^c_2$ coupling.

[122] CARENA 97 studied the constraints on chargino and sneutrino masses from muon $g-2$. The bound can be important for large tanβ.

[123] BUSKULIC 95E looked for $Z \rightarrow \tilde{\nu}\bar{\tilde{\nu}}$, where $\tilde{\nu} \rightarrow \nu\chi^0_1$ and χ^0_1 decays via R-parity violating interactions into two leptons and a neutrino.

[124] BECK 94 limit can be inferred from limit on Dirac neutrino using $\sigma(\tilde{\nu}) = 4\sigma(\nu)$. Also private communication with H.V. Klapdor-Kleingrothaus.

[125] FALK 94 puts an upper bound on $m_{\tilde{\nu}}$ when $\tilde{\nu}$ is LSP by requiring its relic density does not overclose the Universe.

[126] SATO 91 search for high-energy neutrinos from the sun produced by annihilation of sneutrinos in the sun. Sneutrinos are assumed to be stable and to constitute dark matter in our galaxy. SATO 91 follow the analysis of NG 87, OLIVE 88, and GAISSER 86.

CHARGED SLEPTONS

This section contains limits on charged scalar leptons ($\tilde{\ell}$, with ℓ=e,μ,τ). Studies of width and decays of the Z boson (use is made here of $\Delta\Gamma_{\rm inv}$ < 2.0 MeV, LEP 00) conclusively rule out $m_{\tilde{\ell}_R}$ < 40 GeV (41 GeV for $\tilde{\ell}_L$), independently of decay modes, for each individual slepton. The limits improve to 43 GeV (43.5 GeV for $\tilde{\ell}_L$) assuming all 3 flavors to be degenerate. Limits on higher mass sleptons depend on model assumptions and on the mass splitting Δm= $m_{\tilde{\ell}} - m_{\tilde{\chi}^0_1}$. The mass and composition of $\tilde{\chi}^0_1$ may affect the selectron production rate in e^+e^- collisions through t-channel exchange diagrams. Production rates are also affected by the potentially large mixing angle of the lightest mass eigenstate $\tilde{\ell}_1$=$\tilde{\ell}_R$ sinθ_ℓ + $\tilde{\ell}_L$ cosθ_ℓ. It is generally assumed that only $\tilde{\tau}$ may have significant mixing. The coupling to the Z vanishes for θ_ℓ=0.82. In the high-energy limit of e^+e collisions the interference between γ and Z exchange leads to a minimal cross section for θ_ℓ=0.91, a value which is sometimes used in the following entries relative to data taken at LEP2. When limits on $m_{\tilde{\ell}_R}$ are quoted, it is understood that limits on $m_{\tilde{\ell}_L}$ are usually at least as strong.

Possibly open decays involving gauginos other than $\tilde{\chi}^0_1$ will affect the detection efficiencies. Unless otherwise stated, the limits presented here result from the study of $\tilde{\ell}^+\tilde{\ell}^-$ production, with production rates and decay properties derived from the MSSM. Limits made obsolete by the recent analyses of e^+e^- collisions at energies above 161 GeV have been removed from this compilation, and can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

For decays with final state gravitinos ($\tilde{G}$), $m_{\tilde{G}}$ is assumed to be negligible relative to all other masses.

[127] ABBIENDI 00G looked for acoplanar dielectron + $\not{E}_T$ final states at $\sqrt{s}$=183–189 GeV. The limit assumes $\mu < -100$ GeV and tanβ=1.5 for the production cross section and decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than $\tilde{e} \rightarrow e\tilde{\chi}^0_1$. See their Fig. 14 for the dependence of the limit on Δm and tanβ.

[128] ABREU 99C looked for acoplanar dielectron +$\not{E}$ final states at $\sqrt{s}$= 130–172 GeV. The limit assumes μ=−200 GeV and tanβ=1.5 in the calculation of the production cross section, and B($\tilde{e} \rightarrow e\tilde{\chi}^0_1$)=100%. See Fig. 8a for limits on the ($m_{\tilde{e}_R}$,$m_{\tilde{\chi}^0_1}$) plane and for different tanβ values. These results include and update limits from ABREU 96O.

[129] ACCIARRI 99W looked for acoplanar dielectron $\not{E}_T$ final states at $\sqrt{s}$=130–189 GeV. The limit assumes μ=−200 GeV and tanβ=$\sqrt{2}$ for the production cross section and decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than $\tilde{e} \rightarrow e\tilde{\chi}^0_1$. The scan of parameter space, covering the region 1<tanβ < 60, M_2 < 2 TeV, $|\mu|$ < 2 TeV, m_0 < 500 GeV, leads to an absolute lower limit of 65.5 GeV. See their Figs. 5–6 for the dependence of the limit on Δm and tanβ.

[130] BARATE 99Q looked for acoplanar dielectron + $\not{E}_T$ final states at $\sqrt{s}$=189 GeV. The limit assumes μ=−200 GeV and tanβ=2 for the production cross section and decay branching ratios, and zero efficiency for decays other than $\tilde{e} \rightarrow e\tilde{\chi}^0_1$. Assuming a common scalar mass at the GUT scale, and extending the search to $\tilde{e}^\pm_R\tilde{e}^\mp_L$ final states, a Δm independent limit of 68 GeV is obtained. See their Fig. 3 for the dependence of the limit on Δm. The limits presented here make use of, and supersede, the results of BARATE 98K.

[131] ABBIENDI 00 searches for the production of selectrons in the case of R-parity violation with $LL\overline{E}$ or $LQ\overline{D}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. For non-zero $LL\overline{E}$ couplings, they obtain limits on the selectron mass of 84 GeV both for direct decays and for indirect decays with a low mass $\tilde{\chi}^0_1$. For non-zero $LQ\overline{D}$ couplings, the limits are 72 GeV for indirect decays of $\tilde{e}_R$ with a low mass $\tilde{\chi}^0_1$ and 76 GeV for direct decays of $\tilde{e}_L$. It is assumed that tanβ=1.5 and μ=−200 GeV.

[132] ABREU 00I studies decays induced by R-parity-violating $LL\overline{E}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. The limits, valid for each individual flavor, are determined by the indirect decays and assume a neutralino mass limit of 27 GeV, also derived in ABREU 00I. Better limits for specific flavors and for specific $\not{R}$ couplings can be obtained and are discussed in the paper.

[133] BARATE 00G combines the search for acoplanar dileptons, leptons with large impact parameters, kinks, and stable heavy-charged tracks, assuming 3 flavors of degenerate sleptons, produced in the s channel. Data colleced at $\sqrt{s}$=189 GeV.

[134] BARATE 00H data collected at $\sqrt{s}$=183 GeV. The limit holds for indirect decays mediated by $\not{R}$ $LL\overline{E}$ couplings, and improves to 82 GeV for direct decays with μ=−200 GeV and tanβ=2. Limits are also given for indirect decays via $\overline{UDD}$ couplings ($m_{\tilde{e}_R}$ > 81 and $m_{\tilde{e}_L}$ >70 GeV, with Δm > 10 GeV). For $LL\overline{E}$ indirect decays, use is made of neutralino mass limits from BARATE 98S.

[135] ACCIARRI 99H looked for acoplanar dielectron + $\not{E}_T$ final states at $\sqrt{s}$=130–183 GeV. The limit assumes μ=−200 GeV and tanβ=$\sqrt{2}$ for the production cross section and zero efficiency for decays other than $\tilde{e} \rightarrow e\tilde{\chi}^0_1$. See Fig. 6 for the dependence of the limit on Δm.

[136] ACCIARRI 99I establish indirect limits on $m_{\tilde{e}_R}$ from the regions excluded in the M_2 versus m_0 plane by their chargino and neutralino searches at $\sqrt{s}$=130–183 GeV. The situations where the $\tilde{\chi}^0_1$ is the LSP (indirect decays) and where a $\tilde{\ell}$ is the LSP (direct

decays) were both considered. The weakest limit, quoted above, comes from direct decays with $\overline{UDD}$ couplings; $LL\overline{E}$ couplings or indirect decays lead to a stronger limit.

[137] BARATE 99E looked for $\tilde{e}_R$ pairs with decay $\tilde{e}_R \rightarrow e\tilde{\chi}_1^0$, where $\tilde{\chi}_1^0$ further decays via R-violating coupling $LQ\overline{D}$. The limit assumes gaugino-like $\tilde{\chi}_1^0$. The limit is 52 GeV for the case of $\tilde{e}_L$ pair production with $\tilde{e}_L \rightarrow jj$ decay. Data collected at $\sqrt{s}$=130–172 GeV.

[138] ACCIARRI 98F looked for acoplanar dielectron+$\not{E}_T$ final states at $\sqrt{s}$=130–172 GeV. The limit assumes μ=−200 GeV, and zero efficiecny for decays other than $\tilde{e}_R \rightarrow e\tilde{\chi}_1^0$. See their Fig. 6 for the dependence of the limit on Δm.

[139] ACKERSTAFF 98K looked for dielectron+$\not{E}$ final states at $\sqrt{s}$=130–172 GeV. The limit assumes $\mu < -100$ GeV, tanβ=35, and zero efficiency for decays other than $\tilde{e}_R \rightarrow e\tilde{\chi}_1^0$. The limit improves to 66.5 GeV for tanβ=1.5.

[140] BARATE 98K looked for acoplanar dielectron + $\not{E}$ final states at $\sqrt{s}$= 161–184 GeV. The limit assumes μ=−200 GeV and tanβ=2 in the calculation of the production cross section, and B($\tilde{e} \rightarrow e\tilde{\chi}_1^0$)=100%. See Fig. 3 for limits on the ($m_{\tilde{e}_R}$,$m_{\tilde{\chi}_1^0}$) plane and for the effect of cascade decays.

[141] BARATE 98K looked for $e^+e^-\gamma\gamma + \not{E}$ final states at $\sqrt{s}$= 161–184 GeV. The limit assumes μ=−200 GeV and tanβ=2 for the evaluation of the production cross section. See Fig. 4 for limits on the ($m_{\tilde{e}_R}$,$m_{\tilde{\chi}_1^0}$) plane and for the effect of cascade decays.

[142] BARATE 98K combines the search for acoplanar dielectrons, electrons with large impact parameters, kinks, and stable heavy charged tracks at $\sqrt{s}$= 161–184 GeV. The limit assumes no t-channel neutralino exchange diagram which can make the bound weaker. See Fig. 5 for limits as a function of the lifetime $\tau(\tilde{e}_R)$.

[143] BARATE 98K combines the search for acoplanar dileptons and single electrons with universal scalar mass assumption at the GUT scale. The limit holds for all Δm, and assumes μ=−200 GeV and tanβ=2 for the evaluation of the $\tilde{e}$ production cross section.

[144] BARATE 98S looked for $\tilde{e}_R$ pairs with decay $\tilde{e}_R \rightarrow e\tilde{\chi}_1^0$, where $\tilde{\chi}_1^0$ further decays to $\ell^+\ell^-\nu$ via R-violating coupling $LL\overline{E}$. The limit assumes tanβ=2 and gaugino-like $\tilde{\chi}_1^0$. Data collected at $\sqrt{s}$=130–172 GeV.

[145] BREITWEG 98 used positron+jet events with missing energy and momentum to look for $e^+q \rightarrow \tilde{e}\tilde{q}$ via gaugino-like neutralino exchange with decays into ($e\tilde{\chi}_1^0$)($q\tilde{\chi}_1^0$). See paper for dependences in $m(\tilde{q})$, $m(\tilde{\chi}_1^0)$.

[146] BARATE 97N uses e^+e^- data collected at $\sqrt{s}$=161 and 172 GeV. The limit is for tanβ=2. It improves to 75 GeV if Δm >35 GeV.

[147] AID 96C used positron+jet events with missing energy and momentum to look for $e^+q \rightarrow \tilde{e}\tilde{q}$ via neutralino exchange with decays into ($e\tilde{\chi}_1^0$)($q\tilde{\chi}_1^0$). See the paper for dependences on $m_{\tilde{q}}$, $m_{\tilde{\chi}_1^0}$.

[148] BUSKULIC 95E looked for $Z \rightarrow \tilde{e}_R^+\tilde{e}_R^-$ where $\tilde{e}_R \rightarrow e\chi_1^0$ and χ_1^0 decays via R-parity violating interactions into two leptons and a neutrino.

[149] ABBIENDI 00G looked for acoplanar dimuon + $\not{E}_T$ final states at $\sqrt{s}$=183–189 GeV. The limit assumes B($\tilde{\mu} \rightarrow \mu\tilde{\chi}_1^0$)=1. Using decay branching ratios derived from the MSSM, a lower limit of 81.7 GeV is obtained for $\mu < -100$ GeV and tanβ=1.5. See their Figs. 12 and 15 for the dependence of the limits on the branching ratio and on Δm.

[150] ABREU 99C looked for acoplanar dimuon +$\not{E}$ final states at $\sqrt{s}$= 130–172 GeV. The limit assumes B($\tilde{\mu} \rightarrow \mu\tilde{\chi}_1^0$)=100%. See Fig. 8b for limits on the ($m_{\tilde{\mu}_R}$,$m_{\tilde{\chi}_1^0}$) plane. These results include and update limits from ABREU 96O.

[151] ACCIARRI 99W looked for acoplanar dimuon + $\not{E}_T$ final states at $\sqrt{s}$=189 GeV. The limit assumes μ=−200 GeV and tanβ=$\sqrt{2}$ and zero efficiency for decays other than $\tilde{\mu} \rightarrow \mu\tilde{\chi}_1^0$. See their Fig. 5 for the dependence of the limit on Δm and tanβ.

[152] BARATE 99Q looked for acoplanar dimuon + $\not{E}_T$ final states at $\sqrt{s}$=189 GeV. The limit assumes μ=−200 GeV and tanβ=2 for the decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than $\tilde{\mu} \rightarrow \mu\tilde{\chi}_1^0$. See their Fig. 3 for the dependence of the limit on Δm. The limits presented here make use of, and supersede, the results of BARATE 98K.

[153] ABBIENDI 00 searches for the production of smuons in the case of R-parity violation with $LL\overline{E}$ or $LQ\overline{D}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. For non-zero $LL\overline{E}$ couplings, they obtain limits on the smuon mass of 66 GeV for direct decays and of 74 GeV for indirect decays with a low mass $\tilde{\chi}_1^0$. For non-zero $LQ\overline{D}$ couplings, the limits are 50 GeV for indirect decays of $\tilde{\mu}_R$ with a low mass $\tilde{\chi}_1^0$ and 64 GeV for direct decays of $\tilde{\mu}_L$. It is assumed that tanβ=1.5 and μ=−200 GeV.

[154] ABREU 00I studies decays induced by R-parity-violating $LL\overline{E}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. The limits, valid for each individual flavor, are determined by the indirect decays and assume a neutralino mass limit of 27 GeV, also derived in ABREU 00I. Better limits for specific flavors and for specific $\not{R}$ couplings can be obtained and are discussed in the paper.

[155] BARATE 00G combines the search for acoplanar dileptons, leptons with large impact parameters, kinks, and stable heavy-charged tracks, assuming 3 flavors of degenerate sleptons, produced in the $s$channel. Data collected at $\sqrt{s}$=189 GeV.

[156] BARATE 00H data collected at $\sqrt{s}$=183 GeV. The limit holds for direct decays mediated by $\not{R}$ $LL\overline{E}^c$ couplings, and improves to 74 GeV for indirect decays. Limits are also given for direct decays via $LQ\overline{D}$ couplings ($m_{\tilde{\mu}_L}$ > 61 GeV) for indirect decays via $\overline{UDD}$ couplings ($m_{\tilde{\mu}_R}$ > 67 GeV and $m_{\tilde{\mu}_L}$ > 70 GeV, with $\Delta m > 10$ GeV). For $LL\overline{E}$ indirect decays, use is made of neutralino mass limits from BARATE 98S.

[157] ACCIARRI 99H looked for acoplanar dimuon + $\not{E}_T$ final states at $\sqrt{s}$=130–183 GeV. The limit assumes μ=−200 GeV and tanβ=$\sqrt{2}$ and zero efficiency for decays other than $\tilde{\mu} \rightarrow \mu\tilde{\chi}_1^0$. See Fig. 6 for the dependence of the limit on Δm.

[158] BARATE 99E looked for $\tilde{\mu}_R$ pairs with decay $\tilde{\mu}_R \rightarrow \mu\tilde{\chi}_1^0$, where $\tilde{\chi}_1^0$ further decays via R-violating coupling $LQ\overline{D}$. The limit is 52 GeV for the case of $\tilde{\mu}_L$ pair production with $\tilde{\mu}_L \rightarrow jj$ decay. Data collected at $\sqrt{s}$=130–172 GeV.

[159] ACCIARRI 98F looked for dimuon+$\not{E}_T$ final states at $\sqrt{s}$=130–172 GeV. The limit assumes μ=−200 GeV, and zero efficiecny for decays other than $\tilde{\mu}_R \rightarrow \mu\tilde{\chi}_1^0$. See their Fig. 6 for the dependence of the limit on Δm.

[160] ACKERSTAFF 98K looked for dimuon+$\not{E}_T$ final states at $\sqrt{s}$=130–172 GeV. The limit assumes $\mu < -100$ GeV, tanβ=1.5, and zero efficiency for decays other than $\tilde{\mu}_R \rightarrow \mu\tilde{\chi}_1^0$. The limit improves to 62.7 GeV for B($\tilde{\mu}_R \rightarrow \mu\tilde{\chi}_1^0$)=1.

[161] BARATE 98K looked for acoplanar dimuon + $\not{E}$ final states at $\sqrt{s}$= 161–184 GeV. The limit assumes B($\tilde{\mu}_R \rightarrow \mu\tilde{\chi}_1^0$)=1. See Fig. 3 for limits on the ($m_{\tilde{\mu}_R}$,$m_{\tilde{\chi}_1^0}$) plane and for the effect of cascade decays.

[162] BARATE 98K looked for $\mu^+\mu^-\gamma\gamma + \not{E}$ final states at $\sqrt{s}$= 161–184 GeV. See Fig. 4 for limits on the ($m_{\tilde{\mu}_R}$,$m_{\tilde{\chi}_1^0}$) plane and for the effect of cascade decays.

[163] BARATE 98K combines the search for acoplanar dimuons, muons with large impact parameters, kinks, and stable heavy charged tracks at $\sqrt{s}$= 161–184 GeV. See Fig. 5 for limits as a function of the lifetime $\tau(\tilde{\mu}_R)$.

[164] BARATE 98S looked for $\tilde{\mu}_R$ pairs with decay $\tilde{\mu}_R \rightarrow \mu\tilde{\chi}_1^0$, where $\tilde{\chi}_1^0$ further decays to $\ell^+\ell^-\nu$ via R-violating coupling $LL\overline{E}$. The limit assumes tanβ=2, Data collected at $\sqrt{s}$=130–172 GeV.

[165] ACKERSTAFF 97H limit is for $m_{\tilde{\chi}_1^0}$ >12 GeV allowed by their chargino, neutralino search, and for tan$\beta \geq 1.5$ and $|\mu| > 200$ GeV. The study includes data from e^+e^- collisions at $\sqrt{s}$=161 GeV, as well as at 130–136 GeV (ALEXANDER 97B).

[166] BARATE 97N uses e^+e^- data collected at $\sqrt{s}$=161 and 172 GeV. The limit assumes B($\tilde{\mu} \rightarrow \mu\tilde{\chi}_1^0$) = 1.

[167] BUSKULIC 95E looked for $Z \rightarrow \tilde{\mu}_R^+\tilde{\mu}_R^-$, where $\tilde{\mu}_R \rightarrow \mu\chi_1^0$ and χ_1^0 decays via R-parity violating interactions into two leptons and a neutrino.

[168] ABBIENDI 00G looked for acoplanar ditau + $\not{E}_T$ final states at $\sqrt{s}$=183–189 GeV. The limit assumes B($\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0$)=1. Using decay branching ratios derived from the MSSM, a lower limit of 75.9 at $\Delta m > 7$ GeV is obtained for $\mu < -100$ GeV and tanβ=1.5. See their Figs. 13 and 16 for the dependence of the limits on the branching ratio and on Δm.

[169] ABREU 99C looked for acoplanar ditaus $+\not{E}$ final states at $\sqrt{s}$= 130–172 GeV. The limit assumes B($\tilde{\tau}_R \to \tau\tilde{\chi}_1^0$)=1. See Figs. 4c and 4d for limits on the ($m_{\tilde{\tau}_R}$,$m_{\tilde{\chi}_1^0}$) plane and and as a function of the mixing angle.

[170] ACCIARRI 99W looked for acoplanar ditau + $\not{E}_T$ final states at $\sqrt{s}$=189 GeV. See their Fig. 5 for the dependence of the limit on Δm and tanβ.

[171] BARATE 99Q looked for acoplanar ditau + $\not{E}_T$ final states at $\sqrt{s}$=189 GeV. The limit assumes B($\tilde{\tau} \to \tau\tilde{\chi}_1^0$)=1. See their Fig. 3 for the dependence of the limit on Δm. The limits presented here make use of, and supersede, the results of BARATE 98K.

[172] ABBIENDI 00 searches for the production of staus in the case of R-parity violation with $LL\overline{E}$ or $LQ\overline{D}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. For non-zero $LL\overline{E}$ couplings, they obtain limits on the stau mass of 66 GeV both for direct decays and for indirect decays with a low mass χ_1^0. For non-zero $LQ\overline{D}$ couplings, the limits are 66 GeV for indirect decays of $\tilde{\tau}_R$ with a low mass χ_1^0 and 63 GeV for direct decays of $\tilde{\tau}_L$. It is assumed that tanβ=1.5 and μ=−200 GeV.

[173] ABREU 00I studies decays induced by R-parity-violating $LL\overline{E}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. The limits, valid for each individual flavor, are determined by the indirect decays and assume a neutralino mass limit of 27 GeV, also derived in ABREU 00I. Better limits for specific flavors and for specific $\not{R}$ couplings can be obtained and are discussed in the paper.

[174] BARATE 00G combines the search for acoplanar dileptons, leptons with large impact parameters, kinks, and stable heavy-charged tracks, assuming 3 flavors of degenerate sleptons, produced in the s channel. Data collected at $\sqrt{s}$=189 GeV.

[175] BARATE 00G combines the search for acoplanar ditaus, taus with large impact parameters, kinks, and stable heavy-charged tracks. Staus are also looked for in the decay chain $\tilde{\chi}_1^0 \to \tilde{\tau}\tau \to \tau\tau\tilde{G}$; see paper for results. Data colleced at $\sqrt{s}$=189 GeV.

[176] BARATE 00H data collected at $\sqrt{s}$=183 GeV. The limit holds for direct decays mediated by $\not{R}$ $LL\overline{E}$ couplings, and improves up to 70 GeV for indirect decays, using the neutralino mass limits from BARATE 98S.

[177] ABREU 99C combines the search for acoplanar ditaus, taus with large impact parameters, kinks, and stable heavy-charged tracks at $\sqrt{s}$= 130–172 GeV. See Fig. 11 for limits under different lifetime hypothesis.

[178] ABREU 99F combines the search for acoplanar ditaus, taus with large impact parameters, kinks, and stable heavy-charged tracks at $\sqrt{s}$=130–183 GeV. See Fig. 13 for limits under various lifetime scenarios.

[179] ACCIARRI 99H looked for acoplanar ditau + $\not{E}_T$ final states at $\sqrt{s}$=130–183 GeV. The limit assumes μ=−200 GeV and tanβ=$\sqrt{2}$ and zero efficiency for decays other than $\tilde{\tau} \to \tau\tilde{\chi}_1^0$. See Fig. 6 for the dependence on the limit on Δm.

[180] BARATE 99E looked for $\tilde{\tau}_R$ pairs with decay $\tilde{\tau}_R \to \tau\tilde{\chi}_1^0$, where $\tilde{\chi}_1^0$ further decays via R-violating coupling $LQ\overline{D}$. Data collected at $\sqrt{s}$=130–172 GeV.

[181] BARATE 98K looked for acoplanar ditaus + $\not{E}$ at $\sqrt{s}$= 161–184 GeV. The limit assumes zero efficiency for decays other than $\tilde{\tau}_R \to \tau\tilde{\chi}_1^0$. See Fig. 3 for limits on the ($m_{\tilde{\tau}}$,$m_{\tilde{\chi}_1^0}$) plane and for the effect of cascade decays.

[182] BARATE 98K looked for $\tau^+\tau^-\gamma\gamma + \not{E}$ final states at $\sqrt{s}$= 161–184 GeV. See Fig. 4 for limits on the ($m_{\tilde{\tau}_R}$,$m_{\tilde{\chi}_1^0}$) plane and for the effect of cascade decays.

[183] This limit also uses BARATE 97N to extend limit to low $m_{\tilde{\tau}}$.

[184] BARATE 98S looked for $\tilde{\tau}_R$ pairs with decay $\tilde{\tau}_R \to \tau\tilde{\chi}_1^0$, where $\tilde{\chi}_1^0$ further decays to $\ell^+\ell^-\nu$ via R-violating coupling $LL\overline{E}$. The limit assumes tanβ=2, Data collected at $\sqrt{s}$=130–172 GeV.

Long-lived $\tilde{\ell}$ (Slepton) MASS LIMIT

Limits on scalar leptons which leave detector before decaying. Limits from Z decays are independent of lepton flavor. Limits from continuum e^+e^- annihilation are also independent of flavor for smuons and staus. However, selectron limits from continuum e^+e^- annihilation depend on flavor because there is an additional contribution from neutralino exchange that in general yields stronger limits.

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>81.2	95	[185] ACCIARRI	99H	L3	$\tilde{\mu}_R$, $\tilde{\tau}_R$

>82.5	95	[187] ACKERSTAFF	98P	OPAL	$\tilde{\mu}_R$, $\tilde{\tau}_R$
>81	95	[188] BARATE	98K	ALEP	$\tilde{\mu}_R$, $\tilde{\tau}_R$

[185] ACCIARRI 99H searched for production of pairs of back-to-back heavy charged particles at $\sqrt{s}$=130–183 GeV. The upper bound improves to 82.2 GeV for $\tilde{\mu}_L$, $\tilde{\tau}_L$.

[186] ABREU 98P searches for production of pairs of heavy, charged particles in e^+e^- annihilation at $\sqrt{s}$=130–183 GeV. The upper bound improves to 81 GeV for $\tilde{\mu}_L$,$\tilde{\tau}_L$. These limits include and update the results of ABREU 97D.

[187] ACKERSTAFF 98P bound improves to 83.5 GeV for $\tilde{\mu}_L$, $\tilde{\tau}_L$. Data collected at $\sqrt{s}$ = 130–183 GeV.

[188] The BARATE 98K mass limit improves to 82 GeV for $\tilde{\mu}_L$,$\tilde{\tau}_L$. Data collected at $\sqrt{s}$=161–184 GeV.

$\tilde{q}$ (Squark) MASS LIMIT

For $m_{\tilde{q}}$ > 60–70 GeV, it is expected that squarks would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included.

Limits from e^+e^- collisions depend on the mixing angle of the lightest mass eigenstate $\tilde{q}_1$=$\tilde{q}_R$sinθ_q+$\tilde{q}_L$cosθ_q. It is usually assumed that only the sbottom and stop squarks have non-trivial mixing angles (see the stop and sbottom sections). Here, unless otherwise noted, squarks are always taken to be either left/right degenerate, or purely of left or right type. Data from Z decays have set squark mass limits above 40 GeV, in the case of $\tilde{q} \to q\tilde{\chi}_1$ decays if Δm=$m_{\tilde{q}} - m_{\tilde{\chi}_1^0} \gtrsim$5 GeV. For smaller values of Δm, current constraints on the invisible width of the Z ($\Delta\Gamma_{inv}$ < 2.0 MeV, LEP 00) exclude $m_{\tilde{u}_{L,R}}$ <44 GeV, $m_{\tilde{d}_R}$ <33 GeV, $m_{\tilde{d}_L}$ <44 GeV and, assuming all squarks degenerate, $m_{\tilde{q}}$ <45 GeV.

Limits which are obsolete relative to the current results are not included in this compilation, and can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this *Review*.

[189] ABBOTT 99L consider events with three or more jets and large $\not{E}_T$. Spectra and decay rates are evaluated in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and scanning the space of the universal gaugino ($m_{1/2}$) and scalar (m_0) masses. See their Figs. 2–3 for the dependence of the limit on the relative value of $m_{\tilde{q}}$ and $m_{\tilde{g}}$.

[190] ACCIARRI 99V assumes four degenerate flavors and B($\tilde{q} \to q\tilde{\chi}_1^0$)=1, with Δm=$m_{\tilde{q}} - m_{\tilde{\chi}_1^0}$. The bound is reduced to 90 GeV if production of only $\tilde{q}_R$ states is considered. See their Fig. 7 for limits in the ($m_{\tilde{q}}$,$m_{\tilde{\chi}_1^0}$) plane. Data collected at $\sqrt{s}$=189 GeV.

[191] BARATE 99Q assumes five degenerate flavors and B($\tilde{q} \to q\tilde{\chi}_1^0$)=1, with Δm= $m_{\tilde{q}} - m_{\tilde{\chi}_1^0}$. Data collected at $\sqrt{s}$=189 GeV. The limits presented here make use of, and update, the results of BARATE 98N.

[192] ABE 96D searched for production of gluinos and five degenerate squarks in final states containing a pair of leptons, two jets, and missing E_T. The two leptons arise from the semileptonic decays of charginos produced in the cascade decays. The limit is derived for fixed tanβ = 4.0, μ = −400 GeV, and m_{H^+} = 500 GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario.

[193] BARATE 00H data collected at $\sqrt{s}$=183 GeV. The limits hold for direct decays of u-type and d-type squarks, mediated by $\not{R}$ $\overline{UDD}$ couplings.

[194] ABBOTT 99 searched for $\gamma\not{E}_T$ + $\ge$ 2 jet final states, and set limits on $\sigma(p\bar{p} \to \tilde{q}+X)\cdot$B($\tilde{q} \to \gamma\not{E}_T X$). The quoted limits correspond to $m_{\tilde{g}} \ge m_{\tilde{q}}$, with B($\tilde{\chi}_2^0 \to \tilde{\chi}_1^0\gamma$)=1 and B($\tilde{\chi}_1^0 \to \tilde{G}\gamma$)=1, respectively. They improve to 310 GeV (360 GeV in the case of $\gamma\tilde{G}$ decay) for $m_{\tilde{g}}$=$m_{\tilde{q}}$.

[195] ABBOTT 99K uses events with an electron pair and four jets to search for the decay of the $\tilde{\chi}_1^0$ LSP via $\not{R}$ $LQ\overline{D}$ couplings. The particle specrum and decay branching ratios are taken in the framework of minimal supergravity. An excluded region at 95% CL is obtained in the (m_0,$m_{1/2}$) plane under the assumption that A_0=0, μ < 0, tanβ=2 and any one of the couplings λ'_{1jk} > 10^{-3} (j=1,2 and k=1,2,3) and from which the above limit is computed. For equal mass squarks and gluinos, the corresponding limit is 277 GeV. The results are essentially independent of A_0, but the limit deteriorates rapidly with increasing tanβ or μ >0.

[196] ABE 99M looked in 107 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with like sign dielectrons and two or more jets from the sequential decays $\tilde{q} \to q\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0 \to eq\bar{q}'$, assuming $\not{R}$ coupling $L_1Q_jD_k^c$, with j=2,3 and k=1,2,3. They assume five degenerate squark flavors, B($\tilde{q} \to q\tilde{\chi}_1^0$)=1, B($\tilde{\chi}_1^0 \to eq\bar{q}'$)=0.25 for both e^+ and e^-, and $m_{\tilde{g}} \ge$ 200 GeV. The limit is obtained for $m_{\tilde{\chi}_1^0} \ge m_{\tilde{q}}/2$ and improves for heavier gluinos or heavier χ_1^0.

[197] ACKERSTAFF 98V and ACCIARRI 98J studied the interference of t-channel squark ($\tilde{d}_R$) exchange via R-parity violating $\lambda'_{1jk} L_1 Q_j d^c_k$ coupling in $e^+e^- \rightarrow q\overline{q}$. The limit is for λ'_{1jk}=0.3. See paper for related limits on $\tilde{u}_L$ exchange. Data collected at $\sqrt{s}$=130–172 GeV.

[198] BARATE 98N assumes five degenerate flavors $\tilde{u}_{L,R}$, $\tilde{d}_{L,R}$, $\tilde{c}_{L,R}$, $\tilde{s}_{L,R}$, $\tilde{b}_{L,R}$, and their direct decay $\tilde{q} \rightarrow q\tilde{\chi}^0_1$. The bound applies for $\Delta m > 5$ GeV. See Fig. 5 for limits in the ($m_{\tilde{q}}$,$m_{\tilde{\chi}^0}$) plane. Data collected at $\sqrt{s}$=181–184 GeV.

[199] BREITWEG 98 used positron+jet events with missing energy and momentum to look for $e^+ q \rightarrow \tilde{e}\tilde{q}$ via gaugino-like neutralino exchange with decays into $(e\tilde{\chi}^0_1)(q\tilde{\chi}^0_1)$. See paper for dependences in $m_{\tilde{e}}$, $m_{\tilde{\chi}^0_1}$.

[200] DATTA 97 argues that the squark mass bound by ABACHI 95C can be weakened by 10–20 GeV if one relaxes the assumption of the universal scalar mass at the GUT-scale so that the $\tilde{\chi}^{\pm}_1$,$\tilde{\chi}^0_2$ in the squark cascade decays have dominant and invisible decays to $\tilde{\nu}$.

[201] DERRICK 97 looked for lepton-number violating final states via R-parity violating couplings $\lambda'_{ijk} L_i Q_j d_k$. When $\lambda'_{11k}\lambda'_{ijk} \neq 0$, the process $eu \rightarrow \tilde{d}^*_k \rightarrow \ell_i u_j$ is possible. When $\lambda'_{1j1}\lambda'_{ijk} \neq 0$, the process $e\overline{d} \rightarrow \tilde{u}^*_j \rightarrow \ell_i \overline{d}_k$ is possible. 100% branching fraction $\tilde{q} \rightarrow \ell j$ is assumed. The limit quoted here corresponds to $\tilde{t} \rightarrow \tau q$ decay, with λ'=0.3. For different channels, limits are slightly better. See Table 6 in their paper.

[202] HEWETT 97 reanalyzed the limits on possilbe resonances in di-jet mode ($\tilde{q} \rightarrow q\tilde{g}$) from ALITTI 93 quoted in "Limits for Excited q (q^*) from Single Production," ABE 96 in "SCALE LIMITS for Contact Interactions: $\Lambda(qqqq)$," and unpublished CDF, DØ bounds. The bound applies to the gluino mass of 5 GeV, and improves for lighter gluino. The analysis has gluinos in parton distribution function.

[203] TEREKHOV 97 improved the analysis of TEREKHOV 96 by including di-jet angular distributions in the analysis.

[204] AID 96 looked for first-generation squarks as s-channel resonances singly produced in $e^+ p$ collision via the R-parity violating coupling in the superpotential $W=\lambda' L_1 Q_1 d^c_1$. The degeneracy of squarks $\tilde{Q}_1$ and $\tilde{d}_1$ is assumed. Eight different channels of possible squark decays are considered.

[205] AID 96C used positron+jet events with missing energy and momentum to look for $e^+ q \rightarrow \tilde{e}\tilde{q}$ via neutralino exchange with decays into $(e\tilde{\chi}^0_1)(q\tilde{\chi}^0_1)$. See the paper for dependences on $m_{\tilde{e}}$, $m_{\tilde{\chi}^0_1}$.

[206] TEREKHOV 96 reanalyzed the limits on possible resonances in di-jet mode ($\tilde{u} \rightarrow u\tilde{g}$) from ABE 95N quoted in "MASS LIMITS for g_A (axigluon)." The bound applies only to the case with a light gluino.

[207] ABACHI 95C assume five degenerate squark flavors with $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. Sleptons are assumed to be heavier than squarks. The limits are derived for fixed $\tan\beta = 2.0$ $\mu = -250$ GeV, and m_{H^+}=500 GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space. No limit is given for $m_{\text{gluino}} > 547$ GeV.

[208] ABE 95T looked for a cascade decay of five degenerate squarks into $\tilde{\chi}^0_2$ which further decays into $\tilde{\chi}^0_1$ and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For $\mu = -40$ GeV, $\tan\beta = 1.5$, and heavy gluinos, the range $50 < m_{\tilde{q}}$ (GeV)<110 is excluded at 90% CL. See the paper for details.

[209] BUSKULIC 95E looked for $Z \rightarrow \tilde{q}\overline{\tilde{q}}$, where $\tilde{q} \rightarrow q\chi^0_1$ and χ^0_1 decays via R-parity violating interactions into two leptons and a neutrino.

[210] ABE 92L assume five degenerate squark flavors and $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. ABE 92L includes the effect of cascade decay, for a particular choice of parameters, $\mu = -250$ GeV, $\tan\beta = 2$. Results are weakly sensitive to these parameters over much of parameter space. No limit for $m_{\tilde{q}} \leq 50$ GeV (but other experiments rule out that region). Limits are 10–20 GeV higher if B($\tilde{q} \rightarrow q\tilde{\gamma}$) = 1. Limit assumes GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\tilde{\chi}^0_1} \approx m_{\tilde{g}}/6$. This last relation implies that as $m_{\tilde{g}}$ increases, the mass of $\tilde{\chi}^0_1$ will eventually exceed $m_{\tilde{q}}$ so that no decay is possible. Even before that occurs, the signal will disappear; in particular no bounds can be obtained for $m_{\tilde{g}} > 410$ GeV. m_{H^+}=500 GeV.

[211] ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on squark production in R-parity violating models. The 100% decay $\tilde{q} \rightarrow q\tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $\ell q\overline{d}$ or $\ell\ell\overline{e}$ is assumed.

[212] NOJIRI 91 argues that a heavy squark should be nearly degenerate with the gluino in minimal supergravity not to overclose the universe.

Long-lived $\tilde{q}$ (Squark) MASS LIMIT

The following are bounds on long-lived scalar quarks, assumed to hadronise into hadrons with lifetime long enough to escape the detector prior to a possible decay. Limits may depend on the mixing angle of mass eigenstates: $\tilde{q}_1 = \tilde{q}_L\cos\theta_q + \tilde{q}_R\sin\theta_q$. The coupling to the Z^0 boson vanishes for up-type squarks when θ_u=0.98, and for down type squarks when θ_d=1.17.

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
none 2–85	95	[213] ABREU	98P DLPH	$\tilde{u}_L$

[213] ABREU 98P assumes that 40% of the squarks will hadronise into a charged hadron, and 60% into a neutral hadron which deposits most of its energy in hadron calorimeter. Data collected at $\sqrt{s}$=130–183 GeV.

$\tilde{b}$ (Sbottom) MASS LIMIT

Limits in e^+e^- depend on the mixing angle of the mass eigenstate $\tilde{b}_1 = \tilde{b}_L\cos\theta_b + \tilde{b}_R\sin\theta_b$. Coupling to the Z vanishes for $\theta_b \sim 1.17$. As a consequence, no absolute constraint in the mass region $\lesssim 40$ GeV is available in the literature at this time from e^+e^- collisions. In the Listings below, we use $\Delta m = m_{\tilde{b}_1} - m_{\tilde{\chi}^0_1}$.

[214] AFFOLDER 00D search for final states with 2 or 3 jets and $\not{E}_T$, one jet with a b tag. See their Fig. 3 for the mass exclusion in the $m_{\tilde{t}}$, $m_{\tilde{\chi}^0_1}$ plane.

[215] ABBIENDI 99M looked for events with two acoplanar jets and $\not{p}_T$. See Fig. 4 and Table 5 for the dependence on the limit on Δm and θ_b. Data taken at $\sqrt{s}$=161–189 GeV. These results supersede ACKERSTAFF 99.

[216] ACCIARRI 99V looked for events with two acoplanar b-tagged jets and $\not{p}_T$, at $\sqrt{s}$=189 GeV. See their Figs. 4 and 6 for the more general dependence of the limits on Δm and θ_b.

[217] BARATE 99Q looked for events with two acoplanar b-tagged jets and $\not{p}_T$. The limit assumes B($\tilde{b} \rightarrow b\tilde{\chi}^0_1$)=1. See their Fig. 2 for the dependence of the limit on Δm and θ_b. Data taken at $\sqrt{s}$=189 GeV.

[218] ABBOTT 99F looked for events with two jets, with or without an associated muon from b decay, and $\not{E}_T$. See Fig. 2 for the dependence of the limit on $m_{\tilde{\chi}^0_1}$. No limit for $m_{\tilde{\chi}^0_1} > 47$ GeV.

[219] ABREU 99C looked for $\tilde{b}$ pair production at $\sqrt{s}$= 130–172 GeV. See Fig. 4 for other choices of Δm. These results include and update limits from ABREU 96O.

[220] ACCIARRI 99C looked for $\tilde{b}$ pair production at $\sqrt{s}$=161–183 GeV. See Figs. 4–5 for other choices of θ_b and Δm.

[221] ACKERSTAFF 99 looked for $\tilde{b}$ pair production at $\sqrt{s}$=130–183 GeV. The analysis includes and updates the results of ACKERSTAFF 97Q. See Table 11 and Fig. 12 for other choices of θ_b and Δm.

[222] BARATE 99E looked for $\tilde{b}_L$ pairs with decay $\tilde{b}_L \rightarrow b\tilde{\chi}^0_1$, where $\tilde{\chi}^0_1$ further decays via R-violating coupling $LQ\overline{D}$. $m_{\tilde{\chi}^0_1} > 30$ GeV. The limit is 73 GeV for the case of $\tilde{b}_L$ pair production with $\tilde{b}_L \rightarrow j\nu$ decay. The limits for $\tilde{b}_R$ pairs with $\tilde{b}_R \rightarrow b\nu, j\tau$ are much weaker. Data collected at $\sqrt{s}$=130–172 GeV.

[223] BARATE 98N data taken at $\sqrt{s}$=181–184 GeV. The limit is significantly reduced for $\theta_b \approx 1.17$.

[224] BARATE 98S looked for $\tilde{b}_L$ pairs with decay $\tilde{b}_L \rightarrow b\tilde{\chi}^0_1$, where $\tilde{\chi}^0_1$ further decays to $\ell^+\ell^-\nu$ via R-violating coupling $LL\overline{E}$. The limit assumes $\tan\beta$=2, Data collected at $\sqrt{s}$=130–172 GeV.

$\tilde{t}$ (Stop) MASS LIMIT

Limits depend on the decay mode. In e^+e^- collisions they also depend on the mixing angle of the mass eigenstate $\tilde{t}_1 = \tilde{t}_L\cos\theta_t + \tilde{t}_R\sin\theta_t$. The coupling to the Z vanishes when θ_t = 0.98. In the Listings below, we use $\Delta m \equiv m_{\tilde{t}_1} - m_{\tilde{\chi}^0_1}$ or $\Delta m \equiv m_{\tilde{t}_1} - m_{\tilde{\nu}}$, depending on relevant decay mode. See also bounds in "$\tilde{q}$ (Squark) MASS LIMIT." Previous obsolete limits are not included in this compilation, and can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this *Review*.

[225] ABBIENDI 99M looked for events with two acoplanar jets, $\not p_T$, and, in the case of $b\ell\tilde{\nu}$ $(b\tau\tilde{\nu})$ final states, two leptons (taus). Limits for θ_t are ~ 2.5 GeV stronger. In the case of $c\tilde{\chi}^0_1$ decays, the limits with Δm > 10 GeV improve to 90.3 for θ_t=0 and 87.2 for θ_t=0.98. See Figs. 2–3 and Table 4 for the more general dependence of the limits on Δm. Data taken at $\sqrt{s}$=161–189 GeV. All limits assume 100% branching ratio for the respective decay modes. These results supersede ACKERSTAFF 99.

[226] ABREU 99C looked for $\tilde{t}$ pair production at $\sqrt{s}$= 130–172 GeV. The limit for θ_t is 72 GeV. See Fig. 4 for other choices of Δm. These results include and update limits from ABREU 96O.

[227] ACCIARRI 99V looked for events with two acoplanar jets, $\not p_T$ and, in the case of $b\ell\tilde{\nu}$ $(b\tau\tilde{\nu})$ final states, two leptons (taus). The limits for θ_t=0 improve to 88, 89, and 88 GeV, respectively. See their Figs. 4–6 for the more general dependence of the limits on Δm and θ_t. Data taken at $\sqrt{s}$=189 GeV. All limits assume 100% branching ratio for the respective decay modes.

[228] BARATE 99Q looked for events with two acoplanar jets, $\not p_T$ and, in the case of $b\ell\tilde{\nu}$ final states, two leptons. All limits assume 100% branching ratio for the respective decay modes, with flavor-independent rates in the case of semileptonic decays. See their Fig. 1 for the dependence of the limit on Δm and θ_t. Data taken at $\sqrt{s}$=189 GeV. The limits presented here make use of, and supersede, the results of BARATE 98N.

[229] ABBIENDI 00 searches for the production of stop in the case of R-parity violation with $\overline{UDD}$ or $LQ\overline{D}$ couplings, using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero. For mass exclusion limits relative to $LQ\overline{D}$-induced decays, see their Table 5.

[230] ABREU 00I searches for the production of stop in the case of R-parity violation wiht $LL\overline{E}$ couplings, for which only indirect decays are allowed. They investigate topologies with jets plus leptons in data from $\sqrt{s}$=183 GeV. The lower bound on the stop mass assumes a neutralino mass limit of 27 GeV, also derived in ABREU 00I.

[231] AFFOLDER 00D search for final states with 2 or 3 jets and $\not E_T$, one jet with a c tag. See their Fig. 2 for the mass exclusion in the $(m_{\tilde{t}}, m_{\tilde{\chi}^0_1})$ plane. The maximum excluded $m_{\tilde{t}}$ value is 119 GeV, for $m_{\tilde{\chi}^0_1}$= 40 GeV.

[232] BARATE 00H data collected at $\sqrt{s}$=183 GeV. The limit holds for indirect decays mediated by $\not R$ $\overline{UDD}$ couplings, and $m_{\tilde{\chi}^0_1}$ > 20 GeV. It improves to 61 GeV for indirect decays mediated by $\not R$ $LL\overline{E}$ couplings, with neutralino mass limits from BARATE 98S. For direct decays, the limits from BARATE 00H in the squark section apply.

[233] ABE 99M looked in 107 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with like sign dielectrons and two or more jets from the sequential decays $\tilde{q} \rightarrow q\tilde{\chi}^0_1$ and $\tilde{\chi}^0_1 \rightarrow eq\overline{q}'$, assuming $\not R$ coupling $L_1 Q_j D^c_k$, with j=2,3 and k=1,2,3. They assume B($\tilde{t}_1 \rightarrow c\tilde{\chi}^0_1$)=1, B($\tilde{\chi}^0_1 \rightarrow eq\overline{q}'$)=0.25 for both e^+ and e^-, and $m_{\tilde{\chi}^0_1} \geq m_{\tilde{t}_1}/2$. The limit improves for heavier $\tilde{\chi}^0_1$.

[234] ACCIARRI 99C looked for $\tilde{t}$ pair production at $\sqrt{s}$=161–183 GeV. See Figs. 4–5 for other choices of θ_t and Δm. These results update ACCIARRI 96F.

[235] ACKERSTAFF 99 looked for $\tilde{t}$ pair production. The analysis considers data taken at $\sqrt{s}$=130–183 GeV, and includes the results of ACKERSTAFF 97Q. Unless the ℓ=τ decay mode is explicitly indicated, the same branching fractions to ℓ=e, μ, and τ are assumed for $b\ell\tilde{\nu}$ modes. See Table 10 and Figs. 9–11 for other choices of θ_t and Δm.

[236] BARATE 99E looked for $\tilde{t}_L$ pairs with decay $\tilde{t}_L \rightarrow c\tilde{\chi}^0_1$, where $\tilde{\chi}^0_1$ further decays via R-violating coupling $LQ\overline{D}$. $m_{\tilde{\chi}^0_1}$ > 30 GeV. The limit is 62 GeV for the case of $\tilde{t}_L$ pair production with $\tilde{t}_L \rightarrow q\tau$ decays. Data collected at $\sqrt{s}$=130–172 GeV.

[237] BARATE 98N assumes the lepton universality for the case of $\tilde{t} \rightarrow b\ell\tilde{\nu}$ and the lower bound on $m_{\tilde{\nu}}$ from Z decay is used. See Figs. 2 and 3 for limits as a function of Δm. Data collected at $\sqrt{s}$=181–184 GeV.

[238] BARATE 98S looked for $\tilde{t}$ pairs with decay $\tilde{t} \rightarrow c\tilde{\chi}^0_1$, where $\tilde{\chi}^0_1$ further decays to $\ell^+\ell^-\nu$ via R-violating coupling $LL\overline{E}$. The limit assumes $\tan\beta$=2, Data collected at $\sqrt{s}$=130–172 GeV.

[239] ABACHI 96B searches for final states with 2 jets and missing E_T. Limits on $m_{\tilde{t}}$ are given as a function of $m_{\tilde{\chi}^0_1}$. See Fig. 4 for details.

[240] AID 96 considers photoproduction of $\tilde{t}\tilde{t}$ pairs, with 100% R-parity violating decays of $\tilde{t}$ to eq, with q=d, s, or b quarks.

[241] AID 96 considers production and decay of $\tilde{t}$ via the R-parity violating coupling $\lambda' L_1 Q_3 d^c_1$.

[242] CHO 96 studied the consistency among the B^0-$\overline{B}^0$ mixing, ϵ in K^0-$\overline{K}^0$ mixing, and the measurements of V_{cb}, V_{ub}/V_{cb}. For the range 25.5 GeV<$m_{\tilde{t}_1}$ <$m_Z/2$ left by AKERS 94K for θ_t = 0.98, and within the allowed range in M_2-μ parameter space from chargino, neutralino searches by ACCIARRI 95E, they found the scalar top contribution to B^0-$\overline{B}^0$ mixing and ϵ to be too large if $\tan\beta$ <2. For more on their assumptions, see the paper and their reference 10.

[243] BUSKULIC 95E looked for $Z \rightarrow \tilde{t}\overline{\tilde{t}}$, where $\tilde{t} \rightarrow c\chi^0_1$ and χ^0_1 decays via R-parity violating interactions into two leptons and a neutrino.

[244] SHIRAI 94 bound assumes the cross section without the s-channel Z-exchange and the QCD correction, underestimating the cross section up to 20% and 30%, respectively. They assume m_c=1.5 GeV.

Heavy $\tilde{g}$ (Gluino) MASS LIMIT

For $m_{\tilde{g}}$ > 60–70 GeV, it is expected that gluinos would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included.

[245] ABBOTT 99L consider events with three or more jets and large $\not E_T$. Spectra and decay rates are evaluated in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and scanning the space of the universal gaugino $(m_{1/2})$ and scalar (m_0) masses See their Figs. 2–3 for the dependence of the limit on the relative value of $m_{\tilde{q}}$ and $m_{\tilde{g}}$.

[246] ABE 97K searched for production of gluinos and five degenerate squarks in events with three or more jets but no electrons or muons and missing transverse energy $\not E_T$ > 60 GeV. The limit for any $m_{\tilde{q}}$ is for μ=−200 GeV and $\tan\beta$=2, and that for $m_{\tilde{q}}$=$m_{\tilde{g}}$ is for μ=−400 GeV and $\tan\beta$=4. Different choices for $\tan\beta$ and μ lead to changes of the order of ±10 GeV in the limits. See Footnote [16] of the paper for more details on the assumptions.

[247] ABE 96D searched for production of gluinos and five degenerate squarks in final states containing a pair of leptons, two jets, and missing E_T. The two leptons arise from the semileptonic decays of charginos produced in the cascade decays. The limits are derived for fixed $\tan\beta$ = 4.0, μ = −400 GeV, and m_{H^+} = 500 GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the values of the three fixed parameters for a large fraction of parameter space. See Fig. 2 for the limits corresponding to different parameter choices.

[248] ABBOTT 99 searched for $\gamma\not E_T$ + ≥ 2 jet final states, and set limits on $\sigma(p\overline{p} \rightarrow \tilde{g}+X)\cdot B(\tilde{g} \rightarrow \gamma\not E_T X)$. The quoted limits correspond to $m_{\tilde{q}} \geq m_{\tilde{g}}$, with B($\tilde{\chi}^0_2 \rightarrow \tilde{\chi}^0_1\gamma$)=1 and B($\tilde{\chi}^0_1 \rightarrow \tilde{G}\gamma$)=1, respectively. They improve to 310 GeV (360 GeV in the case of $\gamma\tilde{G}$ decay) for $m_{\tilde{g}}$=$m_{\tilde{q}}$.

[249] ABBOTT 99K uses events with an electron pair and four jets to search for the decay of the $\tilde{\chi}^0_1$ LSP via $\not R$ $LQ\overline{D}$ couplings. The particle specrum and decay branching ratios are taken in the framework of minimal supergravity. An excluded region at 95% CL is obtained in the $(m_0, m_{1/2})$ plane under the assumption that A_0=0, μ < 0, $\tan\beta$=2 and any one of the couplings λ'_{1jk} > 10^{-3} (j=1,2 and k=1,2,3) and from which the above limit is computed. For equal mass squarks and gluinos, the corresponding limit is 277 GeV. The results are essentially independent of A_0, but the limit deteriorates rapidly with increasing $\tan\beta$ or μ >0.

[250] ABACHI 95C assume five degenerate squark flavors with with $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. Sleptons are assumed to be heavier than squarks. The limits are derived for fixed $\tan\beta = 2.0$ $\mu = -250$ GeV, and m_{H^+}=500 GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space.

[251] ABE 95T looked for a cascade decay of gluino into $\tilde{\chi}_2^0$ which further decays into $\tilde{\chi}_1^0$ and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For $\mu = -40$ GeV, $\tan\beta = 1.5$, and heavy squarks, the range $50 < m_{\tilde{g}}$ (GeV)<140 is excluded at 90% CL. See the paper for details.

[252] HEBBEKER 93 combined jet analyses at various e^+e^- colliders. The 4-jet analyses at TRISTAN/LEP and the measured α_s at PEP/PETRA/TRISTAN/LEP are used. A constraint on effective number of quarks N=6.3 ± 1.1 is obtained, which is compared to that with a light gluino, N=8.

[253] ABE 92L bounds are based on similar assumptions as ABACHI 95C. Not sensitive to $m_{\rm gluino}$ <40 GeV (but other experiments rule out that region).

[254] ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on gluino production in R-parity violating models. The 100% decay $\tilde{g} \rightarrow q\overline{q}\tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $\ell q\overline{d}$ or $\ell\ell\overline{e}$ is assumed.

[255] NOJIRI 91 argues that a heavy gluino should be nearly degenerate with squarks in minimal supergravity not to overclose the universe.

[256] The limits of ALBAJAR 87D are from $p\overline{p} \rightarrow \tilde{g}\tilde{g}X$ ($\tilde{g} \rightarrow q\overline{q}\tilde{\gamma}$) and assume $m_{\tilde{q}} > m_{\tilde{g}}$. These limits apply for $m_{\tilde{\gamma}} \lesssim 20$ GeV and $\tau(\tilde{g}) < 10^{-10}$ s.

[257] The limit of ANSARI 87D assumes $m_{\tilde{q}} > m_{\tilde{g}}$ and $m_{\tilde{\gamma}} \approx 0$.

LIGHT GLUINO

Written March 1998 by H. Murayama (UC Berkeley).

It is controversial if a light gluino of mass below 5 GeV is phenomenologically allowed. Below we list some of the most important and least controversial constraints which need to be met for a light gluino to be viable. For reviews on the subject, see, *e.g.*, Ref. 1.

1. Either $m_{\tilde{g}} \lesssim 1.5$ GeV or $m_{\tilde{g}} \gtrsim 3.5$ GeV to avoid the CAKIR 94 limit. See also Ref. 2 for similar quarkonium constraints on lighter masses.
2. The lifetime of the gluino or the ground state gluino-containing hadron (typically, $g\tilde{g}$) must be $\gtrsim 10^{-10}$ s in order to evade beam-dump and missing energy limits [1,2].
3. Charged gluino-containing hadrons (*e.g.* $\tilde{g}u\bar{d}$) must decay into neutral ones (*e.g.* $R^0(\tilde{g}g)\pi^+$ or $(\tilde{g}u\bar{u})e^-\bar{\nu}_e$) with a lifetime shorter than about 10^{-7} s to avoid the AKERS 95R limit. Older limits for lower masses and shorter lifetimes are summarized in Ref. 1.
4. The lifetime of R^0 should be outside the ranges excluded by ALAVI-HARATI 99E ($R^0 \rightarrow \pi^+\pi^0\tilde{\gamma}$, $\pi^0\tilde{\gamma}$) and FANTI 99 ($\eta\tilde{\gamma}$). The $R_p^+(\tilde{g}uud)$ state, which is believed to decay weakly into $S^0(\tilde{g}uds)\pi^\pm$ (FARRAR 96), must be heavier than 2 GeV or have lifetime $\tau_{R_p} \gtrsim 1$ ns or $\tau_{R_p} \lesssim 50$ ps (*e.g.* if the strong decay into $S^0K^\pm$ is allowed), or its production cross sections must be at least a factor of 5 smaller than those of hyperons, to avoid ALBUQUERQUE 97 limit.
5. $m_{\tilde{g}} \geq 6.8$ GeV (95% CL) if the "experimental optimization" method of fixing the renormalization scale is valid and if the hadronization and resummation uncertainties are as estimated in BARATE 97L, from the D_2 event shape observable in Z^0 decay. The 4-jet angular distribution is less sensitive to renormalization scale ambiguities and yields a 90%CL exclusion of a light gluino (DEGOUVEA 97). A combined LEP analysis based on all the Z^0 data and using the recent NLO calculations [3] is warranted.
6. Constraints from the effect of light gluinos on the running of α_s apply independently of the gluino lifetime and are insensitive to renormalization scale. They disfavor a light gluino at 70% CL (CSIKOR 97), which improves to more than 99% with jet analysis.

[250] ABACHI 95C assume five degenerate squark flavors with with $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. Sleptons are assumed to be heavier than squarks. The limits are derived for fixed $\tan\beta = 2.0$ $\mu = -250$ GeV, and m_{H^+}=500 GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space.

[251] ABE 95T looked for a cascade decay of gluino into $\tilde{\chi}_2^0$ which further decays into $\tilde{\chi}_1^0$ and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For $\mu = -40$ GeV, $\tan\beta = 1.5$, and heavy squarks, the range $50 < m_{\tilde{g}}$ (GeV)<140 is excluded at 90% CL. See the paper for details.

[252] HEBBEKER 93 combined jet analyses at various e^+e^- colliders. The 4-jet analyses at TRISTAN/LEP and the measured α_s at PEP/PETRA/TRISTAN/LEP are used. A constraint on effective number of quarks $N=6.3 \pm 1.1$ is obtained, which is compared to that with a light gluino, $N=8$.

[253] ABE 92L bounds are based on similar assumptions as ABACHI 95C. Not sensitive to m_{gluino} <40 GeV (but other experiments rule out that region).

[254] ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on gluino production in R-parity violating models. The 100% decay $\tilde{g} \to q\overline{q}\tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $\ell q\overline{d}$ or $\ell\ell\overline{e}$ is assumed.

[255] NOJIRI 91 argues that a heavy gluino should be nearly degenerate with squarks in minimal supergravity not to overclose the universe.

[256] The limits of ALBAJAR 87D are from $p\overline{p} \to \tilde{g}\tilde{g}X$ ($\tilde{g} \to q\overline{q}\tilde{\gamma}$) and assume $m_{\tilde{q}} > m_{\tilde{g}}$. These limits apply for $m_{\tilde{\gamma}} \lesssim 20$ GeV and $\tau(\tilde{g}) < 10^{-10}$ s.

[257] The limit of ANSARI 87D assumes $m_{\tilde{q}} > m_{\tilde{g}}$ and $m_{\tilde{\gamma}} \approx 0$.

LIGHT GLUINO

Written March 1998 by H. Murayama (UC Berkeley).

It is controversial if a light gluino of mass below 5 GeV is phenomenologically allowed. Below we list some of the most important and least controversial constraints which need to be met for a light gluino to be viable. For reviews on the subject, see, *e.g.*, Ref. 1.

1. Either $m_{\tilde{g}} \lesssim 1.5$ GeV or $m_{\tilde{g}} \gtrsim 3.5$ GeV to avoid the CAKIR 94 limit. See also Ref. 2 for similar quarkonium constraints on lighter masses.
2. The lifetime of the gluino or the ground state gluino-containing hadron (typically, $g\tilde{g}$) must be $\gtrsim 10^{-10}$ s in order to evade beam-dump and missing energy limits [1,2].
3. Charged gluino-containing hadrons (*e.g.* $\tilde{g}u\bar{d}$) must decay into neutral ones (*e.g.* $R^0(\tilde{g}g)\pi^+$ or $(\tilde{g}u\bar{u})e^-\bar{\nu}_e$) with a lifetime shorter than about 10^{-7} s to avoid the AKERS 95R limit. Older limits for lower masses and shorter lifetimes are summarized in Ref. 1.
4. The lifetime of R^0 should be outside the ranges excluded by ALAVI-HARATI 99E ($R^0 \to \pi^+\pi^0\tilde{\gamma}$, $\pi^0\tilde{\gamma}$) and FANTI 99 ($\eta\tilde{\gamma}$). The $R_p^+(\tilde{g}uud)$ state, which is believed to decay weakly into $S^0(\tilde{g}uds)\pi^\pm$ (FARRAR 96), must be heavier than 2 GeV or have lifetime $\tau_{R_p} \gtrsim 1$ ns or $\tau_{R_p} \lesssim 50$ ps (*e.g.* if the strong decay into $S^0K^\pm$ is allowed), or its production cross sections must be at least a factor of 5 smaller than those of hyperons, to avoid ALBUQUERQUE 97 limit.
5. $m_{\tilde{g}} \geq 6.8$ GeV (95% CL) if the "experimental optimization" method of fixing the renormalization scale is valid and if the hadronization and resummation uncertainties are as estimated in BARATE 97L, from the D_2 event shape observable in Z^0 decay. The 4-jet angular distribution is less sensitive to renormalization scale ambiguities and yields a 90%CL exclusion of a light gluino (DEGOUVEA 97). A combined LEP analysis based on all the Z^0 data and using the recent NLO calculations [3] is warranted.
6. Constraints from the effect of light gluinos on the running of α_s apply independently of the gluino lifetime and are insensitive to renormalization scale. They disfavor a light gluino at 70% CL (CSIKOR 97), which improves to more than 99% with jet analysis.

Technicolor

DYNAMICAL ELECTROWEAK SYMMETRY BREAKING

Written October 1999 by R.S. Chivukula (Boston Univ.) and J. Womersley (Fermilab).

In theories of dynamical electroweak symmetry breaking, the electroweak interactions are broken to electromagnetism by the vacuum expectation value of a fermion bilinear. These theories may thereby avoid the introduction of fundamental scalar particles, of which we have no examples in nature. In this note, we review the status of experimental searches for the particles predicted in technicolor, topcolor, and related models.

I. Technicolor

The earliest models [1,2] of dynamical electroweak symmetry breaking [3] include a new non-abelian gauge theory ("technicolor") and additional massless fermions ("technifermions") which feel this new force. The global chiral symmetry of the fermions is spontaneously broken by the formation of a technifermion condensate, just as the chiral symmetries in QCD are broken to isospin by the formation of a quark condensate. If the quantum numbers of the technifermions are chosen correctly (*e.g.* by choosing technifermions in the fundamental representation of an SU(N) technicolor gauge group, with the left-handed technifermions being weak doublets and the right-handed ones weak singlets) this condensate can break the electroweak interactions down to electromagnetism.

The breaking of the global chiral symmetries implies the existence of Goldstone bosons, the "technipions" (π_T). Through the Higgs mechanism, three of the Goldstone bosons become the longitudinal components of the W and Z, and the weak gauge bosons acquire a mass proportional to the technipion decay constant (the analog of f_π in QCD). The quantum numbers and masses of any remaining technipions are model dependent. There may be technipions which are colored (octets and triplets) as well as those carrying electroweak quantum numbers, and some technipions could be dangerously light [4,5]. The lightest technicolor resonances are expected to be the analogs of the vector mesons in QCD. The technivector mesons can also have color and electroweak quantum numbers and, for a theory with a small number of technifermions, are expected to have a mass in the TeV range [6].

While technicolor chiral symmetry breaking can give mass to the W and Z particles, additional interactions must be introduced to produce the masses of the standard model fermions. The most thoroughly studied mechanism for this invokes "extended technicolor" (ETC) gauge interactions [4,7]. In ETC, technicolor, color and flavor are embedded into a larger gauge group which is broken to technicolor and color at an energy scale of 100–500 TeV. The massive gauge bosons associated with this breaking mediate transitions between quarks/leptons and technifermions, giving rise to the couplings necessary to produce fermion masses. The ETC gauge bosons also mediate transitions among technifermions themselves, leading to interactions which can explicitly break unwanted chiral symmetries and raise the masses of any light technipions. The ETC interactions connecting technifermions to quarks/leptons also mediate technipion decays to ordinary fermion pairs. Since these interactions are responsible for fermion masses, one generally expects technipions to decay to the heaviest fermions kinematically allowed (though this need not hold in all models).

In addition to quark masses, ETC interactions must also give rise to quark mixing. One expects, therefore, that there are ETC interactions coupling quarks of the same charge from different generations. A stringent limit on these flavor-changing neutral current interactions comes from K^0–$\overline{K}^0$ mixing [4]. These force the scale of ETC breaking and the corresponding ETC gauge boson masses to be in the multi-hundred TeV range (at least insofar as ETC interactions of first two generations are concerned). To obtain quark and technipion masses that are large enough then requires an enhancement of the technifermion condensate over that expected naively by scaling from QCD. Such an enhancement can occur if the technicolor gauge coupling runs very slowly, or "walks" [8]. Many technifermions typically are needed to make the TC coupling walk, implying that the technicolor scale and, in particular, the technivector mesons may be much lighter than 1 TeV [3,9]. It should also be noted that there is no reliable calculation of electroweak parameters in a walking technicolor theory, and the values of precisely measured electroweak quantities [10] cannot directly be used to constrain the models.

In existing colliders, technivector mesons are dominantly produced when an off-shell standard model gauge-boson "resonates" into a technivector meson with the same quantum numbers [11]. The technivector mesons may then decay, in analogy with $\rho \rightarrow \pi\pi$, to pairs of technipions. However, in walking technicolor the technipion masses may be increased to the point that the decay of a technirho to pairs of technipions is kinematically forbidden [9]. In this case the decay to a technipion and a longitudinally polarized weak boson (an "eaten" Goldstone boson) may be preferred, and the technivector meson would be very narrow. Alternatively, the technivector may also decay, in analogy with the decay $\rho \rightarrow \pi\gamma$, to a technipion plus a photon, gluon, or transversely polarized weak gauge boson. Finally, in analogy with the decay $\rho \rightarrow e^+e^-$, the technivector meson may resonate back to an off-shell gluon or electroweak gauge boson, leading to a decay into a pair of leptons, quarks, or gluons.

If the dominant decay mode of the technirho is $W_L\pi_T$, promising signal channels [12] are $\rho_T^\pm \rightarrow W^\pm\pi_T^0$ and $\rho_T^0 \rightarrow W^\pm\pi_T^\mp$. Both channels yield a signal of $W(\ell\nu)$ + 2jets, with one or more heavy flavor tags. Recently, the CDF collaboration has carried out a search in this final state [13] based on Run I data and using PYTHIA [14] version 6.1 for the signal simulation. The results are shown in Fig. 1. We see that the search is sensitive to $\sigma \cdot B \gtrsim 10$ pb and that roughly $170 < m_{\rho_T} < 190$ GeV is excluded at the 95% confidence level, for $m_{\pi_T} \approx m_{\rho_T}/2$.

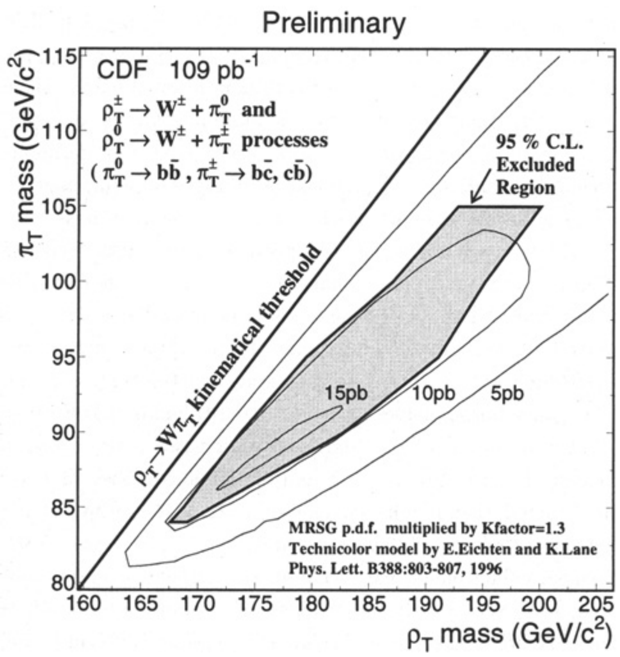

Figure 1: 95% CL exclusion region [13] for light technirho's decaying to $W^{\pm}$ and a π_T, and in which the π_T decays to two jets including at least one b quark.

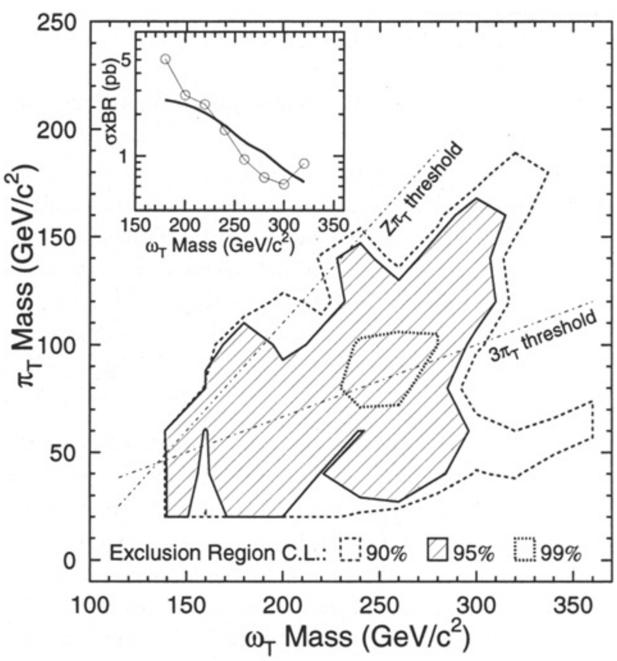

Figure 2: 95% CL exclusion region [15] for light techniomega's decaying to γ and a π_T, and in which the π_T decays to two jets including at least one b quark. (Inset: cross section limit for $m_{\pi_T} = 120$ GeV.)

CDF has also searched [15] for the process $\omega_T^0 \to \gamma\pi_T^0$, yielding a signal of a hard photon plus two jets, with one or more heavy flavor tags. The sensitivity to $\sigma \cdot B$ is of order 1 pb. The excluded region is shown in Fig. 2 and is roughly $140 < m_{\omega_T} < 290$ GeV at the 95% level, for $m_{\pi_T} \approx m_{\omega_T}/3$. The analysis assumes four technicolors, $Q_D = Q_U - 1 = \frac{1}{3}$ and $M_T = 100$ GeV/c^2. Here Q_U and Q_D are the charges of the lightest technifermion doublet and M_T is a dimensionful parameter, of order 100 GeV/c^2, which controls the rate of $\rho_T, \omega_T \to \gamma\pi_T$.

Both DØ [16] and CDF [17] have searched for low-scale technicolor resonances ρ_T and ω_T decaying to dileptons, using inclusive e^+e^- (both experiments) and $\mu^+\mu^-$ (CDF) samples from Run I. In the search, the ρ_T and ω_T are assumed to be degenerate in mass. The absence of structure in the dilepton invariant mass distribution is then used to set limits. Those from DØ are slightly more restrictive. Masses $m_{\rho_T} = m_{\omega_T} <$ 250 GeV are excluded, provided $m_{\rho_T} < m_{\pi_T} + m_W$, or provided $M_T > 300$ GeV. The latter case is shown in Fig. 3. With 2 fb^{-1} of data in Run II, the sensitivity will extend to $m_{\rho_T} = m_{\omega_T} \approx$ 500 GeV.

L3 [18] has reported a search for four topologies: $e^+e^- \to W^+W^-$; $e^+e^- \to W^{\pm}\pi_T^{\mp} \to \ell\nu bc$; $e^+e^- \to \pi_T\pi_T \to b\bar{c}\bar{b}c$; $e^+e^- \to \gamma\pi_T \to \gamma b\bar{b}$. All processes proceed through an intermediate ρ_T or ω_T resonance, which are assumed to be degenerate in mass. No excess is seen in any channel, based on 176 pb^{-1} of data taken at an average center of mass energy of 189 GeV. The excluded region in m_{ρ_T}, m_{π_T} parameter space is shown in Fig. 4 and rules out $m_{\rho_T} < 190$ GeV, for all values of m_{π_T}, for the range of parameters considered. This L3 analysis is the only one so far to make use of the latest calculations [19] of technihadron production and decay, as implemented in PYTHIA version 6.126 and higher [20]. All the other analyses described in this review used older versions of PYTHIA and the limits are not directly comparable.

Searches have also been carried out at the Tevatron for colored technihadron resonances [21,22]. CDF has used a search for structure in the dijet invariant mass spectrum to set limits on a color-octet technirho ρ_{T8} produced by an off-shell gluon and decaying to two real quarks or gluons. As shown in Fig. 5 masses $260 < m_{\rho_{T8}} < 480$ GeV are excluded; in Run II the limits will improve to cover the whole mass range up to about 0.8 TeV [23].

The CDF third-generation leptoquark search [24] has also been interpreted in terms of the complementary ρ_{T8} decay mode: $p\bar{p} \to \rho_{T8} \to \pi_{LQ}\pi_{LQ} \to \tau q\tau q$. Here π_{LQ} denotes a color-triplet technipion carrying both color and lepton number, assumed to decay to τ plus quark. Fig. 6 shows that technirho masses $m_{\rho_{T8}} < 465$ GeV and technipion masses up to $m_{\rho_{T8}}/2$ are excluded in this picture ($m_{\pi_{LQ}} < 99$ GeV already having been ruled out by the standard continuum-production leptoquark searches).

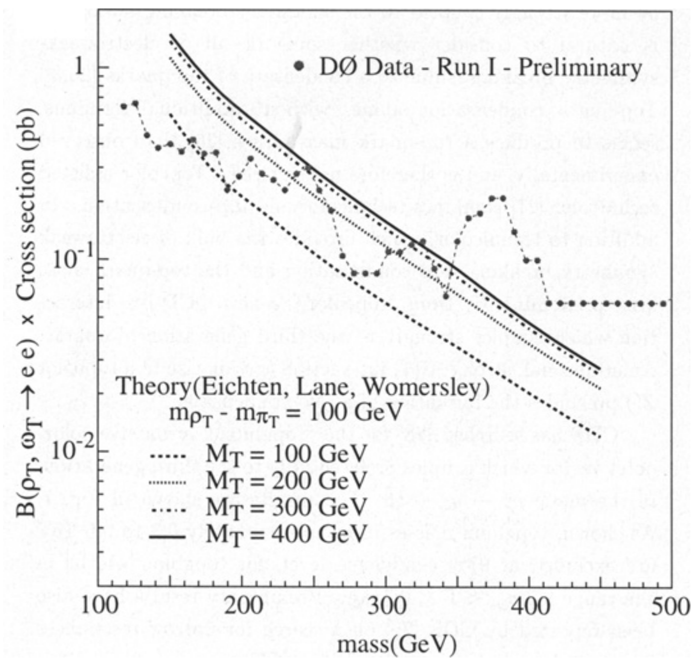

Figure 3: 95% CL cross section limit [16] for light techniomega's and technirho's decaying to $\ell^+\ell^-$.

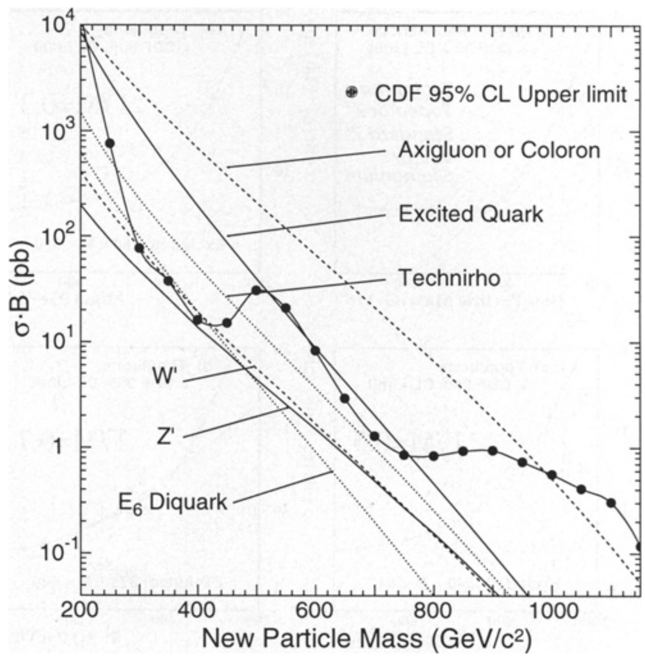

Figure 5: 95% CL cross section limits [22] for technirho's decaying to two jets at the Tevatron.

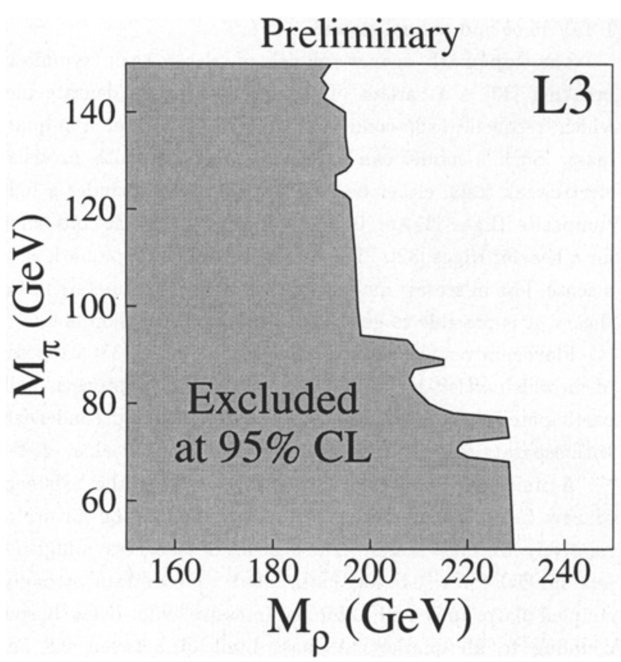

Figure 4: 95% CL exclusion region [18] in the technirho-technipion mass plane obtained from searches by the L3 collaboration at LEP 2.

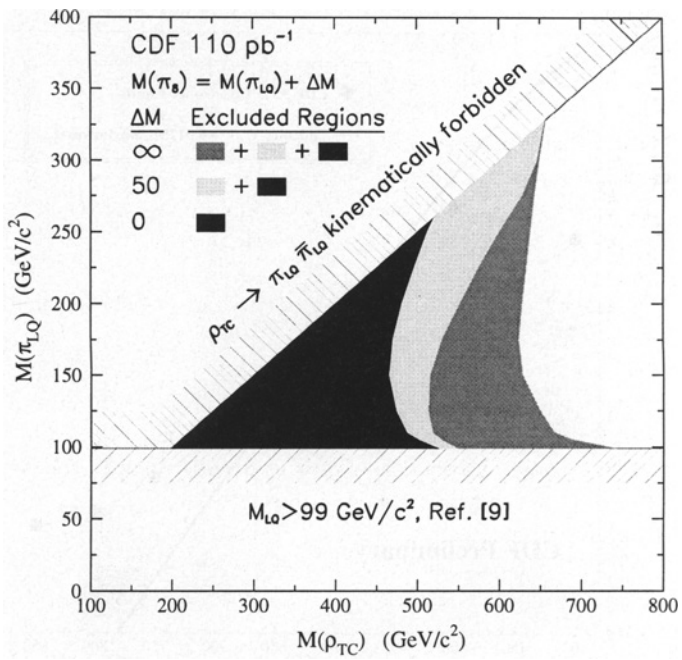

Figure 6: 95% CL exclusion region [24] in the technirho-technipion mass plane for pair produced technipions, with leptoquark couplings, decaying to τq.

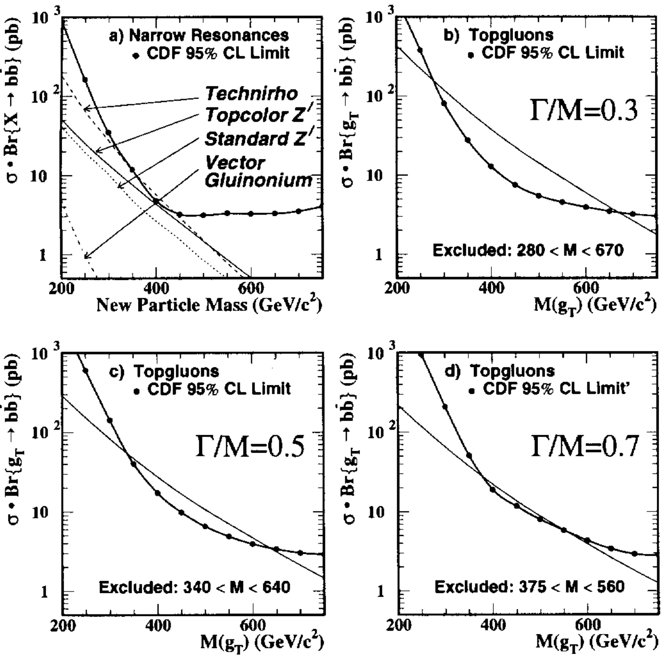

Figure 7: Tevatron limits [28] on new particles decaying to $b\bar{b}$: narrow resonances and topgluons for various widths.

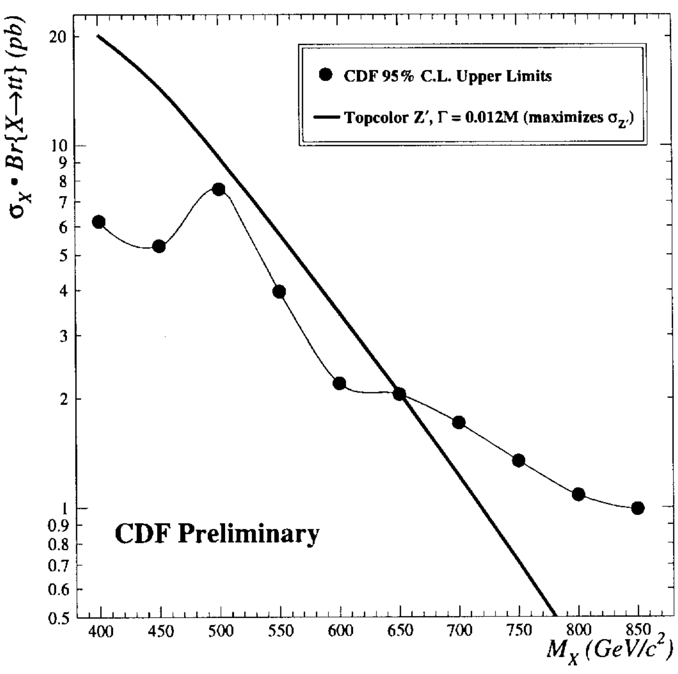

Figure 8: Cross section limits for a narrow resonance decaying to $t\bar{t}$ [29] and expected cross section for a topcolor Z' boson.

II. Top Condensate and Related Models

The top quark is much heavier than other fermions and must be more strongly coupled to the symmetry-breaking sector. It is natural to consider whether some or all of electroweak-symmetry breaking is due to a condensate of top quarks [25,3]. Top-quark condensation alone, without additional fermions, seems to produce a top-quark mass larger [26] than observed experimentally, and is therefore not favored. Topcolor assisted technicolor [27] combines technicolor and top-condensation. In addition to technicolor, which provides the bulk of electroweak symmetry breaking, top condensation and the top-quark mass arise predominantly from "topcolor," a new QCD-like interaction which couples strongly to the third generation of quarks. An additional, strong, U(1) interaction (giving rise to a topcolor Z') precludes the formation of a $\langle \bar{b}b \rangle$ condensate.

CDF has searched [28] for the "topgluon," a massive color-octet vector which couples preferentially to the third generation, in the mode $p\bar{p} \to g_t \to b\bar{b}$. The results are shown in Fig. 7. As shown, topgluon masses from approximately 0.3 to 0.6 TeV are excluded at 95% confidence level, for topgluon widths in the range $0.3 m_{g_t} < \Gamma < 0.7 m_{g_t}$. Preliminary results have also been reported by CDF [29] on a search for narrow resonances in the $t\bar{t}$ invariant mass distribution. The cross section limit is shown in Fig. 8 and excludes a topcolor Z' with masses less than 650 GeV/c^2, for the case where its width $\Gamma = 0.012\, m_{Z'}$. This choice of width maximizes the cross section. A broad topgluon could also be detected in the same final state, though no results are yet available. In Run II, the Tevatron [23] should be sensitive to topgluon and topcolor Z' masses up to of order 1 TeV in $b\bar{b}$ and $t\bar{t}$ final states.

The top-quark seesaw model of electroweak symmetry breaking [30] is a variant of the original top-condensate idea which reconciles top-condensation with a lighter top-quark mass. Such a model can easily be consistent with precision electroweak tests, either because the spectrum includes a light composite Higgs [31] or because additional interactions allow for a heavier Higgs [32]. The unique role of the top quark is, in a sense, lost in seesaw models. By adjusting parameters in the theory, it is possible to generate *any* required fermion mass.

Flavor-universal versions of the seesaw model [33] are possible in which *all* left-handed quarks (and possibly leptons as well) participate in the electroweak symmetry-breaking condensate with separate (one for each flavor) right-handed weak singlets.

A universal prediction of these models, is the existence of new heavy gauge bosons, coupling to color or flavor, at relatively low mass scales. The absence of an excess of high-E_T jets in DØ data [34] has been used to constrain strongly-coupled flavor-universal colorons (massive color-octet bosons coupling to all quarks). A mass limit of between 0.8 and 3.5 TeV is set [35] depending on the coloron-gluon mixing angle. Precision electroweak measurements constrain [36] the masses of these new gauge bosons to be greater than 1–3 TeV in a variety of models, for strong couplings. These limits are all summarized in Table 1.

Table 1: Summary of the mass limits. Symbols are defined in the text.

Process	Excluded mass range	Decay channels	Ref.
$p\bar{p} \to \rho_T \to W\pi_T$	$170 < m_{\rho_T} < 190$ GeV for $m_{\pi_T} \approx m_{\rho_T}/2$	$\rho_T \to W\pi_T$ $\pi_T^0 \to b\bar{b}$ $\pi_T^\pm \to b\bar{c}$	[13]*
$p\bar{p} \to \omega_T \to \gamma\pi_T$	$140 < m_{\omega_T} < 290$ GeV for $m_{\pi_T} \approx m_{\omega_T}/3$ and $M_T = 100$ GeV	$\omega_T \to \gamma\pi_T$ $\pi_T^0 \to b\bar{b}$ $\pi_T^\pm \to b\bar{c}$	[15]
$p\bar{p} \to \omega_T/\rho_T$	$m_{\omega_T} = m_{\rho_T} < 250$ GeV for $m_{\omega_T} < m_{\pi_T} + m_W$ or $M_T > 300$ GeV	$\omega_T/\rho_T \to \ell^+\ell^-$	[16]*
$e^+e^- \to \omega_T/\rho_T$	$m_{\omega_T} = m_{\rho_T} < 190$ GeV	$\rho_T \to WW$, $W\pi_T$, $\pi_T\pi_T$ $\omega_T \to \gamma\pi_T$ $\pi_T^0 \to b\bar{b}$ $\pi_T^\pm \to b\bar{c}$	[18]*
$p\bar{p} \to \rho_{T8}$	$260 < m_{\rho_{T8}} < 480$ GeV	$\rho_{T8} \to q\bar{q}$, gg	[22]
$p\bar{p} \to \rho_{T8}$	$m_{\rho_{T8}} < 465$ GeV	$\rho_{T8} \to \pi_{LQ}\pi_{LQ}$ $\pi_{LQ} \to \tau q$	[24]
$p\bar{p} \to g_t$	$0.3 < m_{g_t} < 0.6$ TeV for $0.3m_{g_t} < \Gamma < 0.7m_{g_t}$	$g_t \to b\bar{b}$	[28]
$p\bar{p} \to Z'$	$m_{Z'} < 650$ GeV for $\Gamma = 0.012m_{Z'}$	$Z' \to t\bar{t}$	[29]*

*Preliminary, not yet published.

none 260–480	95	[4] ABE 97G	CDF	color-octet techni-ρ, $\rho_T \to$ 2 jets
none 320–480	95	[5] ABE 95N	CDF	color-octet techni-ρ, $\rho_T \to$ 2 jets

[1] ABE 99F search for a new particle X decaying into $b\overline{b}$ in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV. See Fig. 7 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\overline{p} \to X)\times B(X \to b\overline{b})$. ABE 99F also exclude top gluons of width $\Gamma=0.3M$ in the mass interval 280 $<M<$ 670 GeV, of width $\Gamma=0.5M$ in the mass interval 340 $<M<$ 640 GeV, and of width $\Gamma=0.7M$ in the mass interval 375 $<M<$ 560 GeV.

[2] ABE 99H search for the color-octet techni-ρ decaying into a pair of color-triplet technipions which subsequently decay into $\tau+$ jet. See Fig. 6 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the $M_{\rho_T}-M_{\pi_T}$ plane.

[3] ABE 99H search for the techni-ω decaying into $\gamma\pi_T$. The technipion is assumed to decay $\pi_T \to b\overline{b}$. See Fig. 2 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the $M_{\omega_T}-M_{\pi_T}$ plane.

[4] ABE 97G search for a new particle X decaying into dijets in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV. See Fig. 5 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\overline{p} \to X)\times B(X \to 2j)$.

[5] ABE 95N search for a new particle decaying into dijets in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV.

Quark and Lepton Compositeness, Searches for

SEARCHES FOR QUARK AND LEPTON COMPOSITENESS

Revised 1999 by K. Hagiwara (KEK) and K. Hikasa (Tohoku Univ.).

If quarks and leptons are made of constituents, then at the scale of constituent binding energies, there should appear new interactions among quarks and leptons. At energies much below the compositeness scale (Λ), these interactions are suppressed by inverse powers of Λ. The dominant effect should come from the lowest dimensional interactions with four fermions (contact terms), whose most general chirally invariant form reads [1]

$$L = \frac{g^2}{2\Lambda^2}\Big[\eta_{LL}\,\overline{\psi}_L\gamma_\mu\psi_L\,\overline{\psi}_L\gamma^\mu\psi_L + \eta_{RR}\,\overline{\psi}_R\gamma_\mu\psi_R\,\overline{\psi}_R\gamma^\mu\psi_R + 2\eta_{LR}\,\overline{\psi}_L\gamma_\mu\psi_L\,\overline{\psi}_R\gamma^\mu\psi_R\Big]\ . \qquad (1)$$

Chiral invariance provides a natural explanation why quark and lepton masses are much smaller than their inverse size Λ. We may determine the scale Λ unambiguously by using the above form of the effective interactions; the conventional method [1] is to fix its scale by setting $g^2/4\pi = g^2(\Lambda)/4\pi = 1$ for the new strong interaction coupling and by setting the largest magnitude of the coefficients $\eta_{\alpha\beta}$ to be unity. In the following, we denote

$$\begin{aligned}
\Lambda &= \Lambda^{\pm}_{LL} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1,\, 0,\, 0)\ ,\\
\Lambda &= \Lambda^{\pm}_{RR} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0,\, \pm1,\, 0)\ ,\\
\Lambda &= \Lambda^{\pm}_{VV} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1,\, \pm1,\, \pm1)\ ,\\
\Lambda &= \Lambda^{\pm}_{AA} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1,\, \pm1,\, \mp1)\ , \qquad (2)
\end{aligned}$$

as typical examples. Such interactions can arise by constituent interchange (when the fermions have common constituents, e.g., for $ee \to ee$) and/or by exchange of the binding quanta (whenever binding quanta couple to constituents of both particles).

Another typical consequence of compositeness is the appearance of excited leptons and quarks (ℓ^* and q^*). Phenomenologically, an excited lepton is defined to be a heavy lepton which shares leptonic quantum number with one of the existing leptons (an excited quark is defined similarly). For example, an excited electron e^* is characterized by a nonzero transition-magnetic coupling with electrons. Smallness of the lepton mass and the success of QED prediction for g–2 suggest chirality conservation, *i.e.*, an excited lepton should not couple to both left- and right-handed components of the corresponding lepton.

Excited leptons may be classified by SU(2)×U(1) quantum numbers. Typical examples are:

1. Sequential type

$$\begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_L\ , \qquad [\nu^*_R]\ , \qquad \ell^*_R\ .$$

ν^*_R is necessary unless ν^* has a Majorana mass.

2. Mirror type

$$[\nu^*_L]\ , \qquad \ell^*_L\ , \qquad \begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_R\ .$$

3. Homodoublet type

$$\begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_L\ , \qquad \begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_R\ .$$

Similar classification can be made for excited quarks.

Excited fermions can be pair produced via their gauge couplings. The couplings of excited leptons with Z are listed in the following table (for notation see Eq. (1) in "Standard Model of Electroweak Interactions"):

	Sequential type	Mirror type	Homodoublet type
V^{ℓ^*}	$-\frac{1}{2}+2\sin^2\theta_W$	$-\frac{1}{2}+2\sin^2\theta_W$	$-1+2\sin^2\theta_W$
A^{ℓ^*}	$-\frac{1}{2}$	$+\frac{1}{2}$	0
$V^{\nu^*_D}$	$+\frac{1}{2}$	$+\frac{1}{2}$	$+1$
$A^{\nu^*_D}$	$+\frac{1}{2}$	$-\frac{1}{2}$	0
$V^{\nu^*_M}$	0	0	—
$A^{\nu^*_M}$	$+1$	-1	—

Here ν^*_D (ν^*_M) stands for Dirac (Majorana) excited neutrino. The corresponding couplings of excited quarks can be easily obtained. Although form factor effects can be present for the gauge couplings at $q^2 \neq 0$, they are usually neglected.

In addition, transition magnetic type couplings with a gauge boson are expected. These couplings can be generally parametrized as follows:

$$\begin{aligned}\mathcal{L} = &\frac{\lambda_\gamma^{(f^*)} e}{2m_{f^*}} \overline{f}^* \sigma^{\mu\nu}(\eta_L \tfrac{1-\gamma_5}{2} + \eta_R \tfrac{1+\gamma_5}{2}) f F_{\mu\nu} \\ &+ \frac{\lambda_Z^{(f^*)} e}{2m_{f^*}} \overline{f}^* \sigma^{\mu\nu}(\eta_L \tfrac{1-\gamma_5}{2} + \eta_R \tfrac{1+\gamma_5}{2}) f Z_{\mu\nu} \\ &+ \frac{\lambda_W^{(\ell^*)} g}{2m_{\ell^*}} \overline{\ell}^* \sigma^{\mu\nu} \tfrac{1-\gamma_5}{2} \nu W_{\mu\nu} \\ &+ \frac{\lambda_W^{(\nu^*)} g}{2m_{\nu^*}} \overline{\nu}^* \sigma^{\mu\nu}(\eta_L \tfrac{1-\gamma_5}{2} + \eta_R \tfrac{1+\gamma_5}{2}) \ell W_{\mu\nu}^\dagger \\ &+ \text{h.c.} \,, \end{aligned} \tag{3}$$

where $g = e/\sin\theta_W$, $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ is the photon field strength, $Z_{\mu\nu} = \partial_\mu Z_\nu - \partial_\nu Z_\mu$, *etc.* The normalization of the coupling is chosen such that

$$\max(|\eta_L|, |\eta_R|) = 1 \,.$$

Chirality conservation requires

$$\eta_L \eta_R = 0 \,. \tag{4}$$

These couplings can arise from SU(2)×U(1)-invariant higher-dimensional interactions. A well-studied model is the interaction of homodoublet type ℓ^* with the Lagrangian [2,3]

$$\mathcal{L} = \frac{1}{2\Lambda} \overline{L}^* \sigma^{\mu\nu}(g f \tfrac{\tau^a}{2} W_{\mu\nu}^a + g' f' Y B_{\mu\nu}) \tfrac{1-\gamma_5}{2} L + \text{h.c.} \,, \tag{5}$$

where L denotes the lepton doublet (ν, ℓ), Λ is the compositeness scale, g, g' are SU(2) and U(1)$_Y$ gauge couplings, and $W_{\mu\nu}^a$ and $B_{\mu\nu}$ are the field strengths for SU(2) and U(1)$_Y$ gauge fields. The same interaction occurs for mirror-type excited leptons. For sequential-type excited leptons, the ℓ^* and ν^* couplings become unrelated, and the couplings receive the extra suppression of (250 GeV)/Λ or m_{L^*}/Λ. In any case, these couplings satisfy the relation

$$\lambda_W = -\sqrt{2} \sin^2\theta_W (\lambda_Z \cot\theta_W + \lambda_\gamma) \,. \tag{6}$$

Additional coupling with gluons is possible for excited quarks:

$$\begin{aligned}\mathcal{L} = &\frac{1}{2\Lambda} \overline{Q}^* \sigma^{\mu\nu} \left(g_s f_s \tfrac{\lambda^a}{2} G_{\mu\nu}^a + g f \tfrac{\tau^a}{2} W_{\mu\nu}^a + g' f' Y B_{\mu\nu} \right) \\ &\times \tfrac{1-\gamma_5}{2} Q + \text{h.c.} \,, \end{aligned} \tag{7}$$

where Q denotes a quark doublet, g_s is the QCD gauge coupling, and $G_{\mu\nu}^a$ the gluon field strength.

Some experimental analyses assume the relation $\eta_L = \eta_R = 1$, which violates chiral symmetry. We encode the results of such analyses if the crucial part of the cross section is proportional to the factor $\eta_L^2 + \eta_R^2$ and the limits can be reinterpreted as those for chirality conserving cases $(\eta_L, \eta_R) = (1,0)$ or $(0,1)$ after rescaling λ.

Several different conventions are used by LEP experiments to express the transition magnetic couplings. To facilitate comparison, we reexpress these in terms of λ_Z and λ_γ using the following relations and taking $\sin^2\theta_W = 0.23$. We assume chiral couplings, *i.e.*, $|c| = |d|$ in the notation of Ref. 2.

1. ALEPH (charged lepton and neutrino)

$$\lambda_Z^{\text{ALEPH}} = \frac{1}{2}\lambda_Z \quad \text{(1990 papers)} \tag{8a}$$

$$\frac{2c}{\Lambda} = \frac{\lambda_Z}{m_{\ell^*}\,[\text{or } m_{\nu^*}]} \quad (\text{for } |c| = |d|) \tag{8b}$$

2. ALEPH (quark)

$$\lambda_u^{\text{ALEPH}} = \frac{\sin\theta_W \cos\theta_W}{\sqrt{\frac{1}{4} - \frac{2}{3}\sin^2\theta_W + \frac{8}{9}\sin^4\theta_W}} \lambda_Z = 1.11\lambda_Z \tag{9}$$

3. L3 and DELPHI (charged lepton)

$$\lambda^{\text{L3}} = \lambda_Z^{\text{DELPHI}} = -\frac{\sqrt{2}}{\cot\theta_W - \tan\theta_W} \lambda_Z = -1.10\lambda_Z \tag{10}$$

4. L3 (neutrino)

$$f_Z^{\text{L3}} = \sqrt{2}\lambda_Z \tag{11}$$

5. OPAL (charged lepton)

$$\frac{f^{\text{OPAL}}}{\Lambda} = -\frac{2}{\cot\theta_W - \tan\theta_W} \frac{\lambda_Z}{m_{\ell^*}} = -1.56 \frac{\lambda_Z}{m_{\ell^*}} \tag{12}$$

6. OPAL (quark)

$$\frac{f^{\text{OPAL}} c}{\Lambda} = \frac{\lambda_Z}{2m_{q^*}} \quad (\text{for } |c| = |d|) \tag{13}$$

7. DELPHI (charged lepton)

$$\lambda_\gamma^{\text{DELPHI}} = -\frac{1}{\sqrt{2}} \lambda_\gamma \tag{14}$$

If leptons are made of color triplet and antitriplet constituents, we may expect their color-octet partners. Transitions between the octet leptons (ℓ_8) and the ordinary lepton (ℓ) may take place via the dimension-five interactions

$$\mathcal{L} = \frac{1}{2\Lambda} \sum_\ell \left\{ \overline{\ell}_8^\alpha \, g_S \, F_{\mu\nu}^\alpha \sigma^{\mu\nu} \left(\eta_L \, \ell_L + \eta_R \, \ell_R \right) + h.c. \right\} \tag{15}$$

where the summation is over charged leptons and neutrinos. The leptonic chiral invariance implies $\eta_L \, \eta_R = 0$ as before.

[24] BARATE 00I limits are from $e^+e^- \rightarrow q\bar{q}$ cross section and jet-charge asymmetry at 130–183 GeV.
[25] From $e^+e^- \rightarrow e^+e^-$, $\mu^+\mu^-$, and $\tau^+\tau^-$.
[26] BUSKULIC 93Q uses the following prescription to obtain the limit: when the naive 95%CL limit is better than the statistically expected sensitivity for the limit, the latter is adopted for the limit.
[27] This BUSKULIC 93Q value is from ALEPH data plus PEP/PETRA/TRISTAN data reanalyzed by KROHA 92.
[28] HOWELL 92 limit is from $e^+e^- \rightarrow \mu^+\mu^-$ and $\tau^+\tau^-$.
[29] KROHA 92 limit is from fit to most PEP/PETRA/TRISTAN data. The fit gives η/Λ^2_{LL} = −0.0200 ± 0.0666 TeV^{-2}.

SCALE LIMITS for Contact Interactions: $\Lambda(eeqq)$

Limits are for $\Lambda^{\pm}_{LL}$ only. For other cases, see each reference.

>6.5		[54] DIAZCRUZ	94	RVUE	$\Lambda^-_{LL}(\tau\nu_\tau\mu\nu_\mu)$

[52] JODIDIO 86 limit is from $\mu^+ \to \bar{\nu}_\mu e^+\nu_e$. Chirality invariant interactions $L = (g^2/\Lambda^2)$ $[\eta_{LL}\ (\bar{\nu}_{\mu L}\gamma^\alpha\mu_L)\ (\bar{e}_L\gamma_\alpha\nu_{eL}) + \eta_{LR}\ (\bar{\nu}_{\mu L}\gamma^\alpha\nu_{eL}\ (\bar{e}_R\gamma_\alpha\mu_R)]$ with $g^2/4\pi = 1$ and $(\eta_{LL},\eta_{LR}) = (0,\pm1)$ are taken. No limits are given for $\Lambda^{\pm}_{LL}$ with $(\eta_{LL},\eta_{LR}) = (\pm1,0)$. For more general constraints with right-handed neutrinos and chirality nonconserving contact interactions, see their text.
[53] DIAZCRUZ 94 limits are from $\Gamma(\tau \to e\nu\nu)$ and assume flavor-dependent contact interactions with $\Lambda(\tau\nu_\tau e\nu_e) \ll \Lambda(\mu\nu_\mu e\nu_e)$.
[54] DIAZCRUZ 94 limits are from $\Gamma(\tau \to \mu\nu\nu)$ and assume flavor-dependent contact interactions with $\Lambda(\tau\nu_\tau\mu\nu_\mu) \ll \Lambda(\mu\nu_\mu e\nu_e)$.

SCALE LIMITS for Contact Interactions: $\Lambda(qqqq)$

Limits are for $\Lambda^{\pm}_{LL}$ with color-singlet isoscalar exchanges among u_L's and d_L's only, unless otherwise noted. See EICHTEN 84 for details.

>0.370	95	[67] APPEL	85	UA2	$p\bar{p} \to$ jets inclusive
>0.275	95	[68] BAGNAIA	84C	UA2	Repl. by APPEL 85

[55] The quoted limit is from inclusive dijet mass spectrum in $p\bar{p}$ collisions at E_{cm}=1.8 TeV. ABBOTT 99C also obtain Λ^-_{LL} > 2.4 TeV. All quarks are assumed composite.
[56] ABBOTT 98G limit is from dijet angular distribution in $p\bar{p}$ collisions at E_{cm}= 1.8 TeV. All quarks are assumed composite.
[57] BERTRAM 98 obtain limit on the scale of color-octet axial-vector flavor-universal contact interactions: Λ_{A8} > 2.1 TeV. They also obtain a limit Λ_{V8} > 2.4 TeV on a color-octet flavor-universal vectorial contact interaction.
[58] ABE 96 finds that the inclusive jet cross section for E_T >200 GeV is significantly higher than the $O(\alpha_s^3)$ perturbative QCD prediction. This could be interpreted as the effect of a contact interaction with Λ_{LL} ~ 1.6 TeV. However, ABE 96 state that uncertainty in the parton distribution functions, higher-order QCD corrections, and the detector calibration may possibly account for the effect.
[59] ABE 96S limit is from dijet angular distribution in $p\bar{p}$ collisions at E_{cm} = 1.8 TeV. The limit for Λ^-_{LL} is > 1.4 TeV. ABE 96S also obtain limits for flavor symmetric contact interactions among all quark flavors: Λ^+_{LL} > 1.8 TeV and Λ^-_{LL} > 1.6 TeV.
[60] ABE 93G limit is from dijet mass distribution in $p\bar{p}$ collisions at E_{cm} = 1.8 TeV. The limit is the weakest from several choices of structure functions and renormalization scale.
[61] Limit is from inclusive jet cross-section data in $p\bar{p}$ collisions at E_{cm} = 1.8 TeV. The limit takes into account uncertainties in choice of structure functions and in choice of process scale.
[62] ABE 92M limit is from dijet angular distribution for m_{dijet} >550 GeV in $p\bar{p}$ collisions at E_{cm}=1.8 TeV.
[63] ALITTI 91B limit is from inclusive jet cross section in $p\bar{p}$ collisions at E_{cm} = 630 GeV. The limit takes into account uncertainties in choice of structure functions and in choice of process scale.
[64] ABE 89H limit is from dijet angular distribution for m_{dijet} > 200 GeV at the Fermilab Tevatron Collider with E_{cm} = 1.8 TeV. The QCD prediction is quite insensitive to choice of structure functions and choice of process scale.
[65] ARNISON 86C limit is from the study of inclusive high-p_T jet distributions at the CERN $\bar{p}p$ collider (E_{cm} = 546 and 630 GeV). The QCD prediction renormalized to the low-p_T region gives a good fit to the data.
[66] ARNISON 86D limit is from the study of dijet angular distribution in the range 240 < m(dijet) < 300 GeV at the CERN $\bar{p}p$ collider (E_{cm} = 630 GeV). QCD prediction using EHLQ structure function (EICHTEN 84) with Λ_{QCD} = 0.2 GeV for the choice of Q^2 = $p_T{}^2$ gives the best fit to the data.
[67] APPEL 85 limit is from the study of inclusive high-p_T jet distributions at the CERN $\bar{p}p$ collider (E_{cm} = 630 GeV). The QCD prediction renormalized to the low-p_T region gives a good description of the data.
[68] BAGNAIA 84C limit is from the study of jet p_T and dijet mass distributions at the CERN $\bar{p}p$ collider (E_{cm} = 540 GeV). The limit suffers from the uncertainties in comparing the data with the QCD prediction.

SCALE LIMITS for Contact Interactions: $\Lambda(\nu\nu qq)$

Limits are for $\Lambda^{\pm}_{LL}$ only. FOr other cases, see each reference.

Λ^+_{LL}(TeV)	Λ^-_{LL}(TeV)	CL%	DOCUMENT ID		TECN	COMMENT
>5.0	**>5.4**	95	[69] MCFARLAND	98	CCFR	νN scattering

[69] MCFARLAND 98 assumed a flavor universal interaction. Neutrinos were mostly of muon type.

MASS LIMITS for Excited e (e^*)

Most e^+e^- experiments assume one-photon or Z exchange. The limits from some e^+e^- experiments which depend on λ have assumed transition couplings which are chirality violating ($\eta_L = \eta_R$). However they can be interpreted as limits for chirality-conserving interactions after multiplying the coupling value λ by $\sqrt{2}$; see Note.

Excited leptons have the same quantum numbers as other ortholeptons. See also the searches for ortholeptons in the "Searches for Heavy Leptons" section.

Limits for Excited e (e^*) from Pair Production

These limits are obtained from $e^+e^- \to e^{*+}e^{*-}$ and thus rely only on the (electroweak) charge of e^*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the e^* coupling is assumed to be of sequential type. Possible t channel contribution from transition magnetic coupling is neglected. All limits assume $e^* \to e\gamma$ decay except the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45**, 1 June, Part II (1992)).

[70] From $e^+ e^-$ collisions at $\sqrt{s}$= 183 GeV. $f=f'$ is assumed. ABREU 99O also obtain limit for $f=-f'$ ($e^* \to \nu W$): $m_{e^*} > 81.3$ GeV.

[71] From $e^+ e^-$ collisions at $\sqrt{s}$=170–172 GeV. ACKERSTAFF 98C also obtain limit from $e^* \to \nu W$ decay mode: $m_{e^*} > 81.3$ GeV.

[72] BARATE 98U obtain limits on the form factor. See their Fig. 14 for limits in mass-form factor plane.

[73] From $e^+ e^-$ collisions at $\sqrt{s}$= 161 GeV.

[74] ABREU 97B also obtain limit from charged current decay mode $e^* \to \nu W$, $m_{e^*} > 70.9$ GeV.

[75] ABREU 97B also obtain limit from charged current decay mode $e^* \to \nu W$, $m_{e^*} > 44.6$ GeV.

[76] ACKERSTAFF 97 also obtain limit from charged current decay mode $e^* \to \nu W$, $m_{\nu^*_e} > 77.1$ GeV.

[77] From $e^+ e^-$ collisions at $\sqrt{s}$= 130–136 GeV.

[78] From $e^+ e^-$ collisions at $\sqrt{s}$= 130–140 GeV.

[79] BARDADIN-OTWINOWSKA 92 limit is independent of decay modes. Based on $\Delta\Gamma(Z)$<36 MeV.

[80] Limit is independent of e^* decay mode.

[81] ADEVA 90F is superseded by ADRIANI 93M.

[82] Superseded by DECAMP 92.

[83] ABE 88B limits assume $e^+ e^- \to e^{*+} e^{*-}$ with one photon exchange only and $e^* \to e\gamma$ giving $ee\gamma\gamma$.

Limits for Excited e (e^*) from Single Production

These limits are from $e^+ e^- \to e^* e$, $W \to e^* \nu$, or $ep \to e^* X$ and depend on transition magnetic coupling between e and e^*. All limits assume $e^* \to e\gamma$ decay except as noted. Limits from LEP, UA2, and H1 are for chiral coupling, whereas all other limits are for nonchiral coupling, $\eta_L = \eta_R = 1$. In most papers, the limit is expressed in the form of an excluded region in the $\lambda - m_{e^*}$ plane. See the original papers.

For limits prior to 1987, see our 1992 edition (Physical Review **D45**, 1 June, Part II (1992)).

[91] See Fig. 2 and Fig. 3 of ACCIARRI 97G for the exclusion limit in the mass-coupling plane.

[92] ACKERSTAFF 97 result is from $e^+ e^-$ collisions at $\sqrt{s}$= 161 GeV. See their Fig. 3 for the exclusion limit in the mass-coupling plane.

[93] ADLOFF 97 search for single e^* production in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. See their Fig. 4 for the rejection limits on the product of the production cross section and the branching ratio into a specific decay channel.

[94] ABREU 96K result is from $e^+ e^-$ collisions at $\sqrt{s}$= 130–136 GeV. See their Fig. 4 for the exclusion limit in the mass-coupling plane.

[95] ACCIARRI 96D result is from $e^+ e^-$ collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 2 for the exclusion limit in the mass-coupling plane.

[96] ALEXANDER 96Q result is from $e^+ e^-$ collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 3a for the exclusion limit in the mass-coupling plane.

[97] BUSKULIC 96W result is from $e^+ e^-$ collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 3 for the exclusion limit in the mass-coupling plane.

[98] DERRICK 95B search for single e^* production via $e^* e\gamma$ coupling in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. See their Fig. 13 for the exclusion plot in the $m_{e^*}-\lambda\gamma$ plane.

[99] ABT 93 search for single e^* production via $e^* e\gamma$ coupling in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. See their Fig. 4 for exclusion plot in the $m_{e^*}-\lambda_\gamma$ plane.

[100] DERRICK 93B search for single e^* production via $e^* e\gamma$ coupling in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. See their Fig. 3 for exclusion plot in the $m_{e^*}-\lambda_\gamma$ plane.

[101] Superseded by ADRIANI 93M.

[102] Superseded by DECAMP 92.

[103] ABE 88B limits use $e^+ e^- \to ee^*$ where t-channel photon exchange dominates giving $e\gamma(e)$ (quasi-real compton scattering).

[104] ANSARI 87D is at E_{cm} = 546–630 GeV.

Limits for Excited e (e^*) from $e^+ e^- \to \gamma\gamma$

These limits are derived from indirect effects due to e^* exchange in the t channel and depend on transition magnetic coupling between e and e^*. All limits are for $\lambda_\gamma = 1$. All limits except ABE 89J are for nonchiral coupling with $\eta_L = \eta_R = 1$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45**, 1 June, Part II (1992)).

[105] BARATE 98U is from $e^+ e^-$ collision at $\sqrt{s}=M_Z$. See their Fig. 5 for limits in mass-coupling plane

[106] ACCIARRI 97W also obtain a limit on e^* with chiral coupling, $m_{e^*} > 157$ GeV (95%CL).

[107] BUSKULIC 93Q obtain Λ^+ >121 GeV (95%CL) from ALEPH experiment and Λ^+ >135 GeV from combined TRISTAN and ALEPH data. These limits roughly correspond to limits on m_{e^*}.

[108] ADRIANI 92B superseded by ACCIARRI 95G.

[109] BARDADIN-OTWINOWSKA 92 limit from fit to the combined data of DECAMP 92, ABREU 91E, ADEVA 90K, AKRAWY 91F.

[110] SHIMOZAWA 92 fit the data to the limiting form of the cross section with $m_{e^*} \gg E_{cm}$ and obtain m_{e^*} >168 GeV at 95%CL. Use of the full form would reduce this limit by a few GeV. The statistically unexpected large value is due to fluctuation in the data.

[111] The ABE 89J limit assumes chiral coupling. This corresponds to $\lambda_\gamma = 0.7$ for nonchiral coupling.

Indirect Limits for Excited e (e^*)

These limits make use of loop effects involving e^* and are therefore subject to theoretical uncertainty.

VALUE (GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[112] DORENBOS...	89	CHRM	$\overline{\nu}_\mu e \to \overline{\nu}_\mu e$ and $\nu_\mu e \to \nu_\mu e$
	[113] GRIFOLS	86	THEO	$\nu_\mu e \to \nu_\mu e$
	[114] RENARD	82	THEO	$g-2$ of electron

[112] DORENBOSCH 89 obtain the limit $\lambda^2_\gamma \Lambda^2_{cut}/m^2_{e^*} < 2.6$ (95% CL), where Λ_{cut} is the cutoff scale, based on the one-loop calculation by GRIFOLS 86. If one assumes that Λ_{cut} = 1 TeV and $\lambda_\gamma = 1$, one obtains $m_{e^*} > 620$ GeV. However, one generally expects $\lambda_\gamma \approx m_{e^*}/\Lambda_{cut}$ in composite models.

[113] GRIFOLS 86 uses $\nu_\mu e \to \nu_\mu e$ and $\overline{\nu}_\mu e \to \overline{\nu}_\mu e$ data from CHARM Collaboration to derive mass limits which depend on the scale of compositeness.

[114] RENARD 82 derived from $g-2$ data limits on mass and couplings of e^* and μ^*. See figures 2 and 3 of the paper.

MASS LIMITS for Excited μ (μ^*)

Limits for Excited μ (μ^*) from Pair Production

These limits are obtained from $e^+e^- \to \mu^{*+}\mu^{*-}$ and thus rely only on the (electroweak) charge of μ^*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the μ^* coupling is assumed to be of sequential type. All limits assume $\mu^* \to \mu\gamma$ decay except for the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45**, 1 June, Part II (1992)).

[165] BUSKULIC 96W result is from e^+e^- collisions at $\sqrt{s}$= 130–140 GeV. See their Fig. 3 for the exclusion limit in the mass-coupling plane.
[166] Superseded by ADRIANI 93M.
[167] Superseded by DECAMP 92.
[168] BARTEL 86 is at E_{cm} = 30–46.78 GeV.
[169] BEHREND 86 limit is at E_{cm} = 33–46.8 GeV.

MASS LIMITS for Excited Neutrino (ν^*)

Limits for Excited ν (ν^*) from Pair Production

These limits are obtained from $e^+e^- \to \nu^*\nu^*$ and thus rely only on the (electroweak) charge of ν^*. Form factor effects are ignored unless noted. The ν^* coupling is assumed to be of sequential type unless otherwise noted. Limits assume $\nu^* \to \nu\gamma$ decay except for the $\Gamma(Z)$ measurement which makes no assumption about decay mode.

[170] From e^+e^- collisions at $\sqrt{s}$= 183 GeV. $f=f'$ is assumed. ABREU 99O also obtain limit for $f=-f'$: $m_{\nu^*_e} > 87.3$ GeV, $m_{\nu^*_\mu} > 88.0$ GeV, $m_{\nu^*_\tau} > 81.0$ GeV.
[171] From e^+e^- collisions at $\sqrt{s}$= 130–183 GeV, ABBIENDI 99F obtain limit on $\sigma(e^+e^- \to \nu^*\nu^*)$ B$(\nu^* \to \nu\gamma)^2$. See their Fig. 13. The limit ranges from 0.094 to 0.14 pb for $\sqrt{s}/2 > m_{\nu^*} > 45$ GeV.
[172] From e^+e^- collisions at $\sqrt{s}$=170–172 GeV. ACKERSTAFF 98C also obtain limit from charged decay modes: $m_{\nu^*_e} > 84.1$ GeV, $m_{\nu^*_\mu} > 83.9$ GeV, and $m_{\nu^*_\tau} > 79.4$ GeV.
[173] BARATE 98U obtain limits on the form factor. See their Fig. 14 for limits in mass-form factor plane.
[174] From e^+e^- collisions at $\sqrt{s}$= 161 GeV.
[175] ABREU 97B also obtain limits from charged current decay modes, $m_{\nu^*} > 56.4$ GeV.
[176] ABREU 97B also obtain limits from charged current decay modes, $m_{\nu^*} > 44.9$ GeV.
[177] ACCIARRI 97G also obtain limits from charged current decay mode $\nu^*_e \to eW$, $m_{\nu^*} > 64.5$ GeV.
[178] ACKERSTAFF 97 also obtain limits from charged current decay modes $m_{\nu^*_e} > 78.3$ GeV, $m_{\nu^*_\mu} > 78.9$ GeV, $m_{\nu^*_\tau} > 76.2$ GeV.
[179] From e^+e^- collisions at $\sqrt{s}$= 130–140 GeV.
[180] ACCIARRI 96D also obtain limit from $\nu^* \to eW$ decay mode: $m_{\nu^*} > 57.3$ GeV.
[181] From e^+e^- collisions at $\sqrt{s}$= 130–136 GeV.
[182] ALEXANDER 96Q also obtain limits from charged current decay modes: $m_{\nu^*_e} > 66.2$ GeV, $m_{\nu^*_\mu} > 66.5$ GeV, $m_{\nu^*_\tau} > 64.7$ GeV.
[183] BARDADIN-OTWINOWSKA 92 limit is for Dirac ν^*. Based on $\Delta\Gamma(Z)$<36 MeV. The limit is 36.4 GeV for Majorana ν^*, 45.4 GeV for homodoublet ν^*.
[184] Limit is based on B$(Z \to \nu^*\overline{\nu}^*)\times$B$(\nu^* \to \nu\gamma)^2 < 5 \times 10^{-5}$ (95%CL) assuming Dirac ν^*, B$(\nu^* \to \nu\gamma) = 1$.
[185] Limit is for Dirac ν^*. The limit is 34.6 GeV for Majorana ν^*, 45.4 GeV for homodoublet ν^*.
[186] DECAMP 90O limit is from excess $\Delta\Gamma(Z) < 89$ MeV. The above value is for Dirac ν^*; 26.6 GeV for Majorana ν^*; 44.8 GeV for homodoublet ν^*.
[187] Superseded by DECAMP 92.
[188] DECAMP 90O limit based on B$(Z \to \nu^*\nu^*)\cdot$B$(\nu^* \to \nu\gamma)^2 < 7 \times 10^{-5}$ (95%CL), assuming Dirac ν^*, B$(\nu^* \to \nu\gamma) = 1$.

Limits for Excited ν (ν^*) from Single Production

These limits are from $Z \to \nu\nu^*$ or $ep \to \nu^*X$ and depend on transition magnetic coupling between ν/e and ν^*. Assumptions about ν^* decay mode are given in footnotes.

[219] ABE 97G search for new particle decaying to dijets.

[220] BREITWEG 97C search for single q^* production in ep collisions with the decays $q^* \to q\gamma$, qW. f_s=0, and $f=-f'=2\Lambda/m_{q^*}$ is assumed for the q^* coupling. See their Fig. 11 for the exclusion plot in the mass-coupling plane.

[221] ABE 95N assume a degenerate u^* and d^* with $f_s = f = f' = \Lambda/m_{q^*}$. See their Fig. 4 for the excluded region in $m_{q^*} - f$ plane.

[222] ALITTI 93 search for resonances in the two-jet invariant mass. The limit is for $f_s = f = f' = \Lambda/m_{q^*}$. u^* and d^* are assumed to be degenerate. If not, the limit for u^* (d^*) is 277 (247) GeV if $m_{d^*} \gg m_{u^*}$ ($m_{u^*} \gg m_{d^*}$).

[223] Assumes $B(q^* \to q\gamma) = 0.1$.

[224] ABREU 99O result is from e^+e^- collisions at $\sqrt{s}$= 183 GeV. See their Fig. 6 for the exclusion limit in the mass-coupling plane.

[225] BARATE 98U obtain limits on the Zqq^* coupling. See their Fig. 16 for limits in mass-coupling plane

[226] ADLOFF 97 search for single q^* production in ep collisions with the decay $q^* \to q\gamma$. See their Fig. 6 for the rejection limits on the product of the production cross section and the branching ratio.

[227] DERRICK 95B search for single q^* production via $q^* q\gamma$ coupling in ep collisions with the decays $q^* \to qW$, qZ, qg, $q\gamma$. See their Fig. 15 for the exclusion plot in the m_{q^*}–$\lambda\gamma$ plane.

[228] ABE 94 search for resonances in jet-γ and jet-W invariant mass in $p\overline{p}$ collisions at E_{cm} = 1.8 TeV. The limit is for $f_s = f = f' = \Lambda/m_{q^*}$ and u^* and d^* are assumed to be degenerate. See their Fig. 4 for the excluded region in m_{q^*}-f plane.

[229] Assumes $B(q^* \to qg) = 1$.

[230] ABREU 92D give $\sigma(e^+e^- \to Z \to q^*\overline{q}$ or $q\overline{q}^*) \times B(q^* \to q\gamma) <$ 15 pb (95% CL) for $m_{q^*} <$ 80 GeV.

[231] ADRIANI 92F search for $Z \to qq^*$ with $q^* \to q\gamma$ and give the limit $\sigma_Z \cdot B(Z \to qq^*) \cdot B(q^* \to q\gamma) <$ (2–10) pb (95%CL) for m_{q^*} = (46–82) GeV.

[232] ALBAJAR 89 give $\sigma(q^* \to W + \text{jet})/\sigma(W) < 0.019$ (90% CL) for $m_{q^*} >$ 220 GeV.

[233] BEHREND 86C has E_{cm} = 42.5–46.8 GeV. See their Fig. 3 for excluded region in the m_{q^*}–$(\lambda_\gamma/m_{q^*})^2$ plane. The limit is for $\lambda_\gamma = 1$ with $\eta_L = \eta_R = 1$.

MASS LIMITS for Color Sextet Quarks (q_6)

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
>84	95	[234] ABE	89D CDF	$p\overline{p} \to q_6\overline{q}_6$

[234] ABE 89D look for pair production of unit-charged particles which leave the detector before decaying. In the above limit the color sextet quark is assumed to fragment into a unit-charged or neutral hadron with equal probability and to have long enough lifetime not to decay within the detector. A limit of 121 GeV is obtained for a color decuplet.

MASS LIMITS for Color Octet Charged Leptons (ℓ_8)

$\lambda \equiv m_{\ell_8}/\Lambda$

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT

>19.8	95	[239] BARTEL	87B	JADE	e_8, μ_8, τ_8: e^+e^-; R
none 5–23.2	95	[239] BARTEL	87B	JADE	μ_8: $e^+e^- \rightarrow \mu\mu$ + jets
		[240] BARTEL	85K	JADE	e_8: $e^+e^- \rightarrow gg$; R

[235] ABE 89D look for pair production of unit-charged particles which leave the detector before decaying. In the above limit the color octet lepton is assumed to fragment into a unit-charged or neutral hadron with equal probability and to have long enough lifetime not to decay within the detector. The limit improves to 99 GeV if it always fragments into a unit-charged hadron.

[236] ABT 93 search for e_8 production via e-gluon fusion in ep collisions with $e_8 \rightarrow eg$. See their Fig. 3 for exclusion plot in the m_{e_8}–Λ plane for m_{e_8} = 35–220 GeV.

[237] KIM 90 is at E_{cm} = 50–60.8 GeV. The same assumptions as in BARTEL 87B are used.

[238] KIM 90 result $(m_{e_8}\Lambda_M)^{1/2} > 178.4$ GeV (95%CL, $\alpha_s = 0.16$ used) is subject to the same restriction as for BARTEL 85K.

[239] BARTEL 87B is at E_{cm} = 46.3–46.78 GeV. The limits assume ℓ_8 pair production cross sections to be eight times larger than those of the corresponding heavy lepton pair production.

[240] In BARTEL 85K, R can be affected by $e^+e^- \rightarrow gg$ via e_q exchange. Their limit m_{e_8} >173 GeV (CL=95%) at $\lambda = m_{e_8}/\Lambda_M = 1$ ($\eta_L = \eta_R = 1$) is not listed above because the cross section is sensitive to the product $\eta_L \eta_R$, which should be absent in ordinary theory with electronic chiral invariance.

• • • We do not use the following data for averages, fits, limits, etc. • • •					
none 3.8–29.8	95	[242] KIM	90	AMY	ν_8: $e^+e^- \rightarrow$ acoplanar jets
none 9–21.9	95	[243] BARTEL	87B	JADE	ν_8: $e^+e^- \rightarrow$ acoplanar jets

[241] BARGER 89 used ABE 89B limit for events with large missing transverse momentum. Two-body decay $\nu_8 \rightarrow \nu g$ is assumed.

[242] KIM 90 is at E_{cm} = 50–60.8 GeV. The same assumptions as in BARTEL 87B are used.

[243] BARTEL 87B is at E_{cm} = 46.3–46.78 GeV. The limit assumes the ν_8 pair production cross section to be eight times larger than that of the corresponding heavy neutrino pair production. This assumption is not valid in general for the weak couplings, and the limit can be sensitive to its $SU(2)_L \times U(1)_Y$ quantum numbers.

MASS LIMITS for W_8 (Color Octet W Boson)

VALUE (GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[244] ALBAJAR	89	UA1	$p\overline{p} \rightarrow W_8 X$, $W_8 \rightarrow Wg$

[244] ALBAJAR 89 give $\sigma(W_8 \rightarrow W + \text{jet})/\sigma(W) < 0.019$ (90% CL) for $m_{W_8} > 220$ GeV.

Limits on $ZZ\gamma$ Coupling

Limits are for the electric dipole transition form factor for $Z \rightarrow \gamma Z^*$ parametrized as $f(s') = \beta(s'/m_Z^2 - 1)$, where s' is the virtual Z mass. In the Standard Model $\beta \sim 10^{-5}$.

WIMPs and Other Particle Searches

OMITTED FROM SUMMARY TABLE

WIMPS AND OTHER PARTICLE SEARCHES

Revised March 2000 by K. Hikasa (Tohoku University).

We collect here those searches which do not appear in any of the above search categories. These are listed in the following order:

1. Galactic WIMP (weakly-interacting massive particle) searches
2. Concentration of stable particles in matter
3. Limits on neutral particle production at accelerators
4. Limits on jet-jet resonance in hadron collisions
5. Limits on charged particles in e^+e^- collisions
6. Limits on charged particles in hadron reactions
7. Limits on charged particles in cosmic rays
8. Search for low-scale gravity effects

Note that searches appear in separate sections elsewhere for Higgs bosons (and technipions), other heavy bosons (including W_R, W', Z', leptoquarks, axigluons), axions (including pseudo-Goldstone bosons, Majorons, familons), heavy leptons, heavy neutrinos, free quarks, monopoles, supersymmetric particles, and compositeness. We include specific WIMP searches in the appropriate sections when they yield limits on hypothetical particles such as supersymmetric particles, axions, massive neutrinos, monopoles, *etc.*

We omit papers on CHAMP's, millicharged particles, and other exotic particles. We no longer list for limits on tachyons and centauros. See our 1994 edition for these limits.

GALACTIC WIMP SEARCHES

Cross-Section Limits for Dark Matter Particles (X^0) on Nuclei

These limits are for weakly-interacting stable particles that may constitute the invisible mass in the galaxy. Unless otherwise noted, a local mass density of 0.3 GeV/cm^3 is assumed; see each paper for velocity distribution assumptions. In the papers the limit is given as a function of the X^0 mass. Here we list limits only for typical mass values of 20 GeV, 100 GeV, and 1 TeV. Specific limits on supersymmetric dark matter particles may be found in the Supersymmetry section.

For m_{X^0} = 20 GeV

[1] BAUDIS 99 give the limit $\sigma < 1 \times 10^{-4}$ pb for scalar X^0-nucleon cross section.

[2] BELLI 99C give $\sigma < 10$ pb for the spin-dependent X^0-proton cross section.

[3] See the following subsection for claim of a possible signal.

[4] OOTANI 99 give $\sigma < 40$ pb for the spin-dependent neutralino-proton cross section. The cross-section limit extends to lower masses compared to other experiments.

[5] BERNABEI 98C use pulse shape discrimination to enhance a possible signal. The limits $\sigma < 3 \times 10^{-4}$ pb (90%CL) for spin-independent X^0-nucleon cross section (assuming isoscalar), and $\sigma < 20$ pb (90%CL) for spin-dependent (assuming Z^0 exchange) are given.

[6] KLIMENKO 98 limit is for inelastic scattering $X^0\ {}^{73}\text{Ge} \to X^0\ {}^{73}\text{Ge}^*$ (13.26 keV).

[7] BERNABEI 97 give $\sigma < 12$ pb (90%CL) for the spin-dependent X^0-proton cross section.

[8] BELLI 96 limit for inelastic scattering $X^0\ {}^{129}\text{Xe} \to X^0\ {}^{129}\text{Xe}^*$(39.58 keV).

[9] BELLI 96C use background subtraction and obtain $\sigma < 150$ pb (< 1.5 fb) (90%CL) for spin-dependent (independent) X^0-proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.

[10] BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.

[11] SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.

[12] SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.

[13] GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.

[14] SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.

[15] REUSSER 91 limit here is changed from published (0.04) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For m_{X^0} = 100 GeV

[16] BELLI 00 discuss the effect of astrophysical uncertainties on the WIMP interpretation of the BERNABEI 99 signal.

[17] AMBROSIO 99 search for upgoing muon events induced by neutrinos originating from WIMP annihilations in the Sun and Earth.

[18] BAUDIS 99 give the limit $\sigma < 7 \times 10^{-6}$ pb for scalar X^0-nucleon cross section.

[19] BELLI 99C give $\sigma < 4.8$ pb for the spin-dependent X^0-proton cross section.

[20] BERNABEI 99 search for annual modulation of the WIMP signal. The data favor the hypothesis of annual modulation at 99.6%CL and are consistent with $m_{X^0}=59^{+17}_{-14}$ GeV and spin-independent X^0-proton cross section of $(7.0^{+0.4}_{-1.2}) \times 10^{-6}$ pb (1 σ errors).

[21] BRHLIK 99 discuss the effect of astrophysical uncertainties on the WIMP interpretation of the BERNABEI 99 signal.

[22] OOTANI 99 give $\sigma < 0.1$ nb for the spin-dependent neutralino-proton cross section.

[23] BERNABEI 98 search for annual modulation of the WIMP signal. The data is consistent with $m_{X^0}=59^{+36}_{-19}$ GeV and spin-independent X^0-proton cross section of $(1.0^{+0.1}_{-0.4}) \times 10^{-5}$ pb (1 σ errors).

[24] BERNABEI 98C use pulse shape discrimination to enhance a possible signal. The limits $\sigma < 7 \times 10^{-6}$ pb (90%CL) for spin-independent X^0-nucleon cross section (assuming isoscalar), and $\sigma < 0.6$ pb (90%CL) for spin-dependent (assuming Z^0 exchange) are given.

[25] KLIMENKO 98 limit is for inelastic scattering $X^0\ {}^{73}\text{Ge} \to X^0\ {}^{73}\text{Ge}^*$ (13.26 keV).

[26] KLIMENKO 98 limit is for inelastic scattering $X^0\ {}^{73}\text{Ge} \to X^0\ {}^{73}\text{Ge}^*$ (66.73 keV).

[27] BERNABEI 97 give $\sigma < 5$ pb (90%CL) for the spin-dependent X^0-proton cross section.

[28] BELLI 96 limit for inelastic scattering $X^0\ {}^{129}\text{Xe} \to X^0\ {}^{129}\text{Xe}^*$(39.58 keV).

[29] BELLI 96C use background subtraction and obtain $\sigma < 0.35$ pb (< 0.15 fb) (90%CL) for spin-dependent (independent) X^0-proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
[30] BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
[31] SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
[32] SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.
[33] GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
[34] SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
[35] BECK 94 uses enriched ^{76}Ge (86% purity).
[36] REUSSER 91 limit here is changed from published (0.3) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For $m_{\chi^0} = 1$ TeV

[56] YAMAGATA 93 used deep sea water at 4000 m since the concentration is enhanced in deep sea due to gravity.
[57] VERKERK 92 looked for heavy isotopes in sea water and put a bound on concentration of stable charged massive particle in sea water. The above bound can be translated into into a bound on charged dark matter particle (5×10^6 GeV), assuming the local density, ρ=0.3 GeV/cm^3, and the mean velocity $\langle v \rangle$=300 km/s.
[58] See HEMMICK 90 Fig. 7 for other masses 100–10000 m_p.

$<2.5 \times 10^{-35}$		0	[67] GUSTAFSON	76	CNTR	τ > 10^{-7} s

[63] ADAMS 97B search for a hadron-like neutral particle produced in pN interactions, which decays into a ρ^0 and a weakly interacting massive particle. Upper limits are given for the ratio to K_L production for the mass range 1.2–5 GeV and lifetime 10^{-9}–10^{-4} s. See also our Light Gluino Section.
[64] GALLAS 95 limit is for a weakly interacting neutral particle produced in 800 GeV/c pN interactions decaying with a lifetime of 10^{-4}–10^{-8} s. See their Figs. 8 and 9. Similar limits are obtained for a stable particle with interaction cross section 10^{-29}–10^{-33} cm^2. See Fig. 10.
[65] AKESSON 91 limit is from weakly interacting neutral long-lived particles produced in pN reaction at 450 GeV/c performed at CERN SPS. Bourquin-Gaillard formula is used as the production model. The above limit is for $\tau > 10^{-7}$ s. For $\tau > 10^{-9}$ s, $\sigma < 10^{-30}$ cm^{-2}/nucleon is obtained.
[66] BADIER 86 looked for long-lived particles at 300 GeV π^- beam dump. The limit applies for nonstrongly interacting neutral or charged particles with mass >2 GeV. The limit applies for particle modes, $\mu^+\pi^-$, $\mu^+\mu^-$, $\pi^+\pi^-$X, $\pi^+\pi^-\pi^\pm$ etc. See their figure 5 for the contours of limits in the mass-τ plane for each mode.
[67] GUSTAFSON 76 is a 300 GeV FNAL experiment looking for heavy (m >2 GeV) long-lived neutral hadrons in the M4 neutral beam. The above typical value is for m = 3 GeV and assumes an interaction cross section of 1 mb. Values as a function of mass and interaction cross section are given in figure 2.

Production of New Penetrating Non-ν Like States in Beam Dump

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[68] LOSECCO	81	CALO	28 GeV protons

[68] No excess neutral-current events leads to σ(production) $\times$ σ(interaction)$\times$acceptance $< 2.26 \times 10^{-71}$ cm^4/nucleon^2 (CL = 90%) for light neutrals. Acceptance depends on models (0.1 to 4. $\times 10^{-4}$).

LIMITS ON JET-JET RESONANCES

Heavy Particle Production Cross Section in $p\overline{p}$

Limits are for a particle decaying to two hadronic jets.

Units(pb)	CL%	Mass(GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •						
			[69] ABE	99F	CDF	1.8 TeV $p\overline{p} \rightarrow b\overline{b}+$ anything
			[70] ABE	97G	CDF	1.8 TeV $p\overline{p} \rightarrow$ 2 jets

< 7	95	600	[71] ABE	93G	CDF	1.8 TeV $p\overline{p} \rightarrow$ 2jets

[69] ABE 99F search for narrow $b\overline{b}$ resonances in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. Limits on $\sigma(p\overline{p} \rightarrow X+$ anything)$\times$B$(X \rightarrow b\overline{b})$ in the range 3–10^3 pb (95%CL) are given for m_X=200–750 GeV. See their Table I.

[70] ABE 97G search for narrow dijet resonances in $p\overline{p}$ collisions with 106 pb^{-1} of data at E_{cm} = 1.8 TeV. Limits on $\sigma(p\overline{p} \rightarrow X+\text{anything})\cdot B(X \rightarrow jj)$ in the range 10^4–10^{-1} pb (95%CL) are given for dijet mass m=200–1150 GeV with both jets having $|\eta| < 2.0$ and the dijet system having $|\cos\theta^*| < 0.67$. See their Table I for the list of limits. Supersedes ABE 93G.

[71] ABE 93G gives cross section times branching ratio into light (d, u, s, c, b) quarks for $\Gamma = 0.02\,M$. Their Table II gives limits for M = 200–900 GeV and Γ = (0.02–0.2) M.

LIMITS ON CHARGED PARTICLES IN e^+e^-

Heavy Particle Production Cross Section in e^+e^-

Ratio to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$ unless noted. See also entries in Free Quark Search and Magnetic Monopole Searches.

[72] ACKERSTAFF 98P search for pair production of long-lived charged particles at $\sqrt{s}$ between 130 and 183 GeV and give limits σ <(0.05–0.2) pb (95%CL) for spin-0 and spin-1/2 particles with m=45–89.5 GeV, charge 1 and 2/3. The limit is translated to the cross section at $\sqrt{s}$=183 GeV with the s dependence described in the paper. See their Figs. 2–4.

[73] ABREU 97D search for pair production of long-lived particles and give limits σ <(0.4–2.3) pb (95%CL) for various center-of-mass energies $\sqrt{s}$=130–136, 161, and 172 GeV, assuming an almost flat production distribution in $\cos\theta$.

[74] BARATE 97K search for pair production of long-lived charged particles at $\sqrt{s}$ = 130, 136, 161, and 172 GeV and give limits σ <(0.2–0.4) pb (95%CL) for spin-0 and spin-1/2 particles with m=45–85 GeV. The limit is translated to the cross section at $\sqrt{s}$=172 GeV with the $\sqrt{s}$ dependence described in the paper. See their Figs. 2 and 3 for limits on J = 1/2 and J = 0 cases.

[75] AKERS 95R is a CERN-LEP experiment with $W_{cm} \sim m_Z$. The limit is for the production of a stable particle in multihadron events normalized to $\sigma(e^+e^- \rightarrow$ hadrons). Constant phase space distribution is assumed. See their Fig. 3 for bounds for $Q = \pm 2/3$, $\pm 4/3$.

[76] BUSKULIC 93C is a CERN-LEP experiment with $W_{cm} = m_Z$. The limit is for a pair or single production of heavy particles with unusual ionization loss in TPC. See their Fig. 5 and Table 1.

[77] ADACHI 90C is a KEK-TRISTAN experiment with W_{cm} = 52–60 GeV. The limit is for pair production of a scalar or spin-1/2 particle. See Figs. 3 and 4.

[78] ADACHI 90E is KEK-TRISTAN experiment with W_{cm} = 52–61.4 GeV. The above limit is for inclusive production cross section normalized to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)\cdot\beta(3-\beta^2)/2$, where $\beta = (1 - 4m^2/W^2_{cm})^{1/2}$. See the paper for the assumption about the production mechanism.

[79] KINOSHITA 82 is SLAC PEP experiment at W_{cm} = 29 GeV using lexan and ^{39}Cr plastic sheets sensitive to highly ionizing particles.

[80] BARTEL 80 is DESY-PETRA experiment with W_{cm} = 27–35 GeV. Above limit is for inclusive pair production and ranges between $1. \times 10^{-1}$ and $1. \times 10^{-2}$ depending on mass and production momentum distributions. (See their figures 9, 10, 11).

[85] BALDIN 76 is a 70 GeV Serpukhov experiment. Value is per Al nucleus at θ = 0. For other charges in range −0.5 to −3.0, CL = 90% limit is $(2.6 \times 10^{-36})/|(\text{charge})|$ for mass range (2.1–9.4 GeV) $\times$ |(charge)|. Assumes stable particle interacting with matter as do antiprotons.

[86] ALBROW 75 is a CERN ISR experiment with E_{cm} = 53 GeV. θ = 40 mr. See figure 5 for mass ranges up to 35 GeV.

[87] JOVANOVICH 75 is a CERN ISR 26+26 and 15+15 GeV pp experiment. Figure 4 covers ranges Q = 1/3 to 2 and m = 3 to 26 GeV. Value is per GeV momentum.

[88] APPEL 74 is NAL 300 GeV pW experiment. Studies forward production of heavy (up to 24 GeV) charged particles with momenta 24–200 GeV (−charge) and 40–150 GeV (+charge). Above typical value is for 75 GeV and is per GeV momentum per nucleon.

[89] ALPER 73 is CERN ISR 26+26 GeV pp experiment. p >0.9 GeV, 0.2 < β <0.65.

[90] ANTIPOV 71B is from same 70 GeV p experiment as ANTIPOV 71C and BINON 69.

[91] ANTIPOV 71C limit inferred from flux ratio. 70 GeV p experiment.

[92] DORFAN 65 is a 30 GeV/c p experiment at BNL. Units are per GeV momentum per nucleus.

Long-Lived Heavy Particle Invariant Cross Section

$<3.0 \times 10^{-37}$	90	0	[98] VIDAL	78	CNTR		m=4.5–6 GeV

[93] BERNSTEIN 88 limits apply at x = 0.2 and p_T = 0. Mass and lifetime dependence of limits are shown in the regions: m = 1.5–7.5 GeV and $\tau = 10^{-8}$–2×10^{-6} s. First number is for hadrons; second is for weakly interacting particles.

[94] THRON 85 is FNAL 400 GeV proton experiment. Mass determined from measured velocity and momentum. Limits are for $\tau > 3 \times 10^{-9}$ s.
[95] ARMITAGE 79 is CERN-ISR experiment at $E_{cm} = 53$ GeV. Value is for $x = 0.1$ and $p_T = 0.15$. Observed particles at $m = 1.87$ GeV are found all consistent with being antideuterons.
[96] BOZZOLI 79 is CERN-SPS 200 GeV pN experiment. Looks for particle with τ larger than 10^{-8} s. See their figure 11–18 for production cross-section upper limits vs mass.
[97] CUTTS 78 is pBe experiment at FNAL sensitive to particles of $\tau > 5 \times 10^{-8}$ s. Value is for $-0.3 < x < 0$ and $p_T = 0.175$.
[98] VIDAL 78 is FNAL 400 GeV proton experiment. Value is for $x = 0$ and $p_T = 0$. Puts lifetime limit of $< 5 \times 10^{-8}$ s on particle in this mass range.

$< 7. \times 10^{-10}$	90	0	YOCK	75	ELEC	±	Q >7e or < −7e
$> 6. \times 10^{-9}$		5	[114] YOCK	74	CNTR		m >6 GeV
$< 3.0 \times 10^{-8}$		0	DARDO	72	CNTR		
$< 1.5 \times 10^{-9}$		0	TONWAR	72	CNTR		m >10 GeV
$< 3.0 \times 10^{-10}$		0	BJORNBOE	68	CNTR		m >5 GeV
$< 5.0 \times 10^{-11}$	90	0	JONES	67	ELEC		m=5–15 GeV

[106] SAITO 90 candidates carry about 450 MeV/nucleon. Cannot be accounted for by conventional backgrounds. Consistent with strange quark matter hypothesis.
[107] MINCER 85 is high statistics study of calorimeter signals delayed by 20–200 ns. Calibration with AGS beam shows they can be accounted for by rare fluctuations in signals from low-energy hadrons in the shower. Claim that previous delayed signals including BJORNBOE 68, DARDO 72, BHAT 82, SAKUYAMA 83B below may be due to this fake effect.
[108] SAKUYAMA 83B analyzed 6000 extended air shower events. Increase of delayed particles and change of lateral distribution above 10^{17} eV may indicate production of very heavy parent at top of atmosphere.
[109] BHAT 82 observed 12 events with delay $> 2. \times 10^{-8}$ s and with more than 40 particles. 1 eV has good hadron shower. However all events are delayed in only one of two detectors in cloud chamber, and could not be due to strongly interacting massive particle.
[110] MARINI 82 applied PEP-counter for TOF. Above limit is for velocity = 0.54 of light. Limit is inconsistent with YOCK 80 YOCK 81 events if isotropic dependence on zenith angle is assumed.
[111] YOCK 81 saw another 3 events with $Q = \pm 1$ and m about $4.5 m_p$ as well as 2 events with $m > 5.3 m_p$, $Q = \pm 0.75 \pm 0.05$ and $m > 2.8 m_p$, $Q = \pm 0.70 \pm 0.05$ and 1 event with $m = (9.3 \pm 3.) m_p$, $Q = \pm 0.89 \pm 0.06$ as possible heavy candidates.
[112] YOCK 80 events are with charge exactly or approximately equal to unity.
[113] BHAT 78 is at Kolar gold fields. Limit is for $\tau > 10^{-6}$ s.
[114] YOCK 74 events could be tritons.

Superheavy Particle (Quark Matter) Flux in Cosmic Rays

VALUE (cm^{-2}sr^{-1}s^{-1})	CL%	EVTS	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •						
$<1.8 \times 10^{-12}$	90		[115] ASTONE	93	CNTR	$m \geq 1.5 \times 10^{-13}$gram
$<1.1 \times 10^{-14}$	90		[116] AHLEN	92	MCRO	$10^{-10} < m < 0.1$ gram
$<3.2 \times 10^{-11}$	90	0	[117] NAKAMURA	85	CNTR	$m > 1.5 \times 10^{-13}$gram
$<3.5 \times 10^{-11}$	90	0	[118] ULLMAN	81	CNTR	Planck-mass 10^{19}GeV
$<7. \times 10^{-11}$	90	0	[118] ULLMAN	81	CNTR	$m \leq 10^{16}$ GeV

[115] ASTONE 93 searched for quark matter ("nuclearites") in the velocity/c range = 10^{-3}–1. Their Table 1 gives a compilation of searches for nuclearites.
[116] AHLEN 92 searched for quark matter ("nuclearites"). The bound applies to velocity/c $< 2.5 \times 10^{-3}$. See their Fig. 3 for other velocity/c and heavier mass range.
[117] NAKAMURA 85 at KEK searched for quark-matter. These might be lumps of strange quark matter with roughly equal numbers of u, d, s quarks. These lumps or nuclearites were assumed to have velocity/c of 10^{-4}–10^{-3}.
[118] ULLMAN 81 is sensitive for heavy slow singly charge particle reaching earth with vertical velocity 100–350 km/s.

SEARCH FOR LOW-SCALE GRAVITY EFFECTS

This section contains experimental papers searching for effects of real or virtual gravitons (massless and massive, denoted by G) with observable coupling strength. This is expected if there are extra spacetime dimensions with a size larger than the electroweak scale, in which case the fundamental gravity scale can be around TeV, not 10^{19} GeV.

VALUE	DOCUMENT ID		TECN
• • • We do not use the following data for averages, fits, limits, etc. • • •
